Summary: $[Me_2AIN(i-Pr)CH_2Ph]_2$ (1) and the related dimer series $[RAIN(i-Pr)-\mu-(CH_2C_6H_4)]_2$, R = Me(2), n-Pr (3), n-Bu (4), and i-Bu (5), were synthesized by thermolysis of 1:1 mixtures of R₃Al and HN(i-Pr)CH₂Ph. The reaction times and temperatures required and the molecular structure and NMR data for 1-5 are compared with reported data for [Me₂AlN(CH₂Ph)₂]₂ and the series $[RAIN(CH_2Ph)-\mu-(CH_2C_6H_4)]_2$ and $[RAIN(t-Bu)-\mu (CH_2C_6H_4)]_2.$

Introduction

Recently, there have been several reports discussing the influence that bulky substituents have on the formation of orthometalated palladium complexes.¹ Also, we have reported the synthesis and characterization of two series of orthometalated aluminum-nitrogen dimers from the thermolysis of R_3Al (R = Me, Et, *n*-Pr, *n*-Bu, i-Bu) with dibenzylamine and with tert-butylbenzylamine.^{1–3} Therein, the effects of the steric bulk of the organic substituents on the nitrogen and aluminum atoms were investigated in terms of the ease of the formation of the orthometalated dimers and their spectral and structural properties. The reactions of R₃-Al and $HN(CH_2Ph)_2$ lead to the formation of $[R_2AIN-$ (CH₂Ph)₂]₂ at 120 °C,³⁻⁶ but the orthometalated dimers are obtained only after heating at 150 °C for three weeks. The thermolysis reactions of mixtures of R₃Al and $HN(t-Bu)CH_2Ph$ proceed more readily,¹ and the orthometalated dimers $[RAIN(t-Bu)-\mu-(CH_2C_6H_4)]_2$ are obtained at lower temperatures, with much shorter reaction times, and in higher yields. In fact, the orthometalation reactions are so facile that they proceed before the initial reactants are consumed and dimer formation, $[R_2AIN(t-Bu)CH_2Ph]_2$, is complete; as a consequence, no dimers were isolated for the tert-butylbenzylamine reaction system. To our knowledge, the synthesis and characterization of only two similar aluminum-nitrogen orthometalated dimers have been reported.^{7,8} Therefore, to understand more fully the requirements for orthometalation in these systems, we have chosen the amine HN(*i*-Pr)CH₂Ph, with the less bulky isopropyl group, for reaction with R₃Al in an attempt to optimize both dimer and orthometalated dimer formation and to investigate in more detail the influence of the groups attached to the aluminum and nitrogen atoms. In this paper, we report the study of the thermolysis reactions of HN(*i*-Pr)CH₂Ph with R₃Al. The ease of synthesis and spectral and molecular structure properties of the three orthometalated dimer series $[RAIN(R')-\mu-(CH_2C_6H_4)]_2$ (R' = benzyl, *i*-Pr, *t*-Bu) are compared in terms of R and R'.

Results and Discussion

Synthesis. Equimolar mixtures of R₃Al and HN- $(i-Pr)CH_2Ph$ in toluene (R = Me, Et, *n*-Pr, *n*-Bu, *i*-Bu) were heated from 80 to 120 °C and monitored by ¹H NMR to establish experimental conditions for dimer formation. The aminoalane dimers, [R₂AlN(*i*-Pr)CH₂- Ph_{2} (R = Me, Et, *n*-Pr, *n*-Bu), were formed under moderate conditions (80-100 °C, 12-36 h) and isolated in almost quantitative yields (90-98%),⁹ but crystals suitable for X-ray diffraction studies were obtained only

⁽⁹⁾ The synthesis and characterization of [R₂AlN(*i*-Pr)CH₂Ph]₂, where R = Et, *n*-Pr, *n*-Bu, is given in the Supporting Information.

from the methyl derivative, 1. Reaction of (*i*-Bu)₃Al with HN(*i*-Pr)CH₂Ph leads initially to dimer formation, [(*i*-Bu)₂AlN(*i*-Pr)CH₂Ph]₂, but its decomposition occurs before the reactants are consumed. The reaction conditions for formation of [R₂AlN(*i*-Pr)CH₂Ph]₂ are similar to those for the series [R₂AlN(CH₂Ph)₂]₂, but for the latter all five dimers were isolated and characterized.³⁻⁶ However, the thermolysis reactions of 1:1 mixtures of R_3Al with HN(*t*-Bu)CH₂Ph at 100 °C are similar to the reaction of (*i*-Bu)₃Al with HN(*i*-Pr)CH₂Ph in that the reactions are facile and the dimers formed are subject to further alkane elimination.¹ The role of R and R' in influencing the reaction sequence $2R_3Al + HNR'_2 \rightarrow 2R_3$ -Al·HNR'₂ \rightarrow [R₂AlNR'₂]₂ + 2RH has been discussed in terms of the steric and electronic effects of the R and R' groups.¹⁰ Our results are in agreement with those of Bradley¹⁰ in that the influence of R' is more important than that of R and that the effect is primarily steric in nature. Mass spectral studies on the related series [Me2-InNR'2]2¹¹ and on [Me2AlN(CH2Ph)2]2 and [Me2AlN(H)-CH₂Ph]₂^{12,13} suggest that the dimers become less stable in the vapor phase with increasing steric bulk of the R' group.

Thermolysis of the R₃Al/HN(*i*-Pr)CH₂Ph mixtures at higher temperatures results in additional alkane elimination. Orthometalated dimer formation is complete for 2 after heating for 6 days at 150 °C followed by 4 days at 175 °C, whereas compounds 3-5 require less heating (6 days at 155 °C).¹⁴ The synthesis of [RAlN(CH₂Ph)- μ -(CH₂C₆H₄)]₂ requires heating of the R₃Al/HN(CH₂Ph)₂ mixtures at 150–155 °C for three weeks, independent of R; however, the reaction conditions for the formation of $[RAIN(t-Bu)-\mu-(CH_2C_6H_4)]_2$ from thermolysis of $R_3Al/$ HN(*t*-Bu)CH₂Ph are more moderate (120 °C, 1–4 days, with R = Me requiring heating for the longest time).¹ Substitution of an isopropyl or *tert*-butyl group for a benzyl group in the secondary amine facilitates the orthometalation reaction, and as the steric bulk of the R' group increases, the reaction conditions depend more on the nature of the R alkyl group. Also, [R₂AlN(Me)-CH₂Ph]₂ is readily formed from the thermolysis of R₃-Al/HN(Me)CH₂Ph mixtures, but the corresponding orthometalated dimers are obtained from these reaction mixtures only at high temperatures and very long heating times.¹⁵ The thermolysis reaction of Me₃Al with the primary amine H_2NCH_2Ph , where R' = H instead of benzyl, at 135 °C results in the formation of the hexameric cage compound [MeAlNCH₂Ph]₆,¹² rather than the orthometalated dimer.

Therefore, our systematic study of the formation of the aluminum-nitrogen dimers [R₂AlN(R')CH₂Ph]₂ (where R' = Me; benzyl, isopropyl, *tert*-butyl) and the requirements for formation of their respective ortho-

Figure 1. ORTEP diagram of [Me₂AlN(*i*-Pr)CH₂Ph]₂ (1a). Hydrogen atoms omitted for clarity and thermal ellipsoids at 30% probability.

metalated dimers [RAIN(R')-µ-(CH₂C₆H₄)]₂ have established that aluminum-nitrogen dimer stability and the subsequent ease of orthometalation depend to a significant degree on the steric nature of the group on the nitrogen atom of the amine, R', and are affected only slightly by the alkyl group R. These findings are in agreement with reactivity studies involving the formation of orthometalated palladium complexes from dibenzylamine or similar aromatic amines.¹

¹H and ¹³C NMR Data. The ¹H and ¹³C NMR chemical shift assignments for 1-5 were made using a combination of 1D and 2D NMR techniques and the procedures established for the NMR chemical shift assignments of [Me₂AlN(H)CH₂Ph]₂,¹² [R₂AlN(CH₂- $Ph_{2}_{2}_{2}^{3,6}$ [RAIN($CH_{2}Ph$)- μ -($CH_{2}C_{6}H_{4}$)]₂,² and [RAIN-(t-Bu)-µ-(CH₂C₆H₄)]₂.¹ The ¹H and ¹³C NMR spectra of $[Me_2AlN(i-Pr)CH_2Ph]_2$ (1) indicate the presence of both cis (1a) and trans (1b) isomers with respect to the Al_2N_2 ring in benzene- d_6 solution at RT in a 60:40 cis/trans isomer ratio. The ¹H NMR chemical shift assignments for the individual isomers were made from the 1D and the 2D ¹H{¹H} COSY and NOESY NMR spectra. The two ¹H NMR cis isomer methyl chemical shifts H(1) and H(2) (Figure 1), were assigned from the NOESY NMR spectra. Substitution of the more sterically demanding isopropyl group for a benzyl group in [Me₂AlN(CH₂- $Ph_{2}_{2}^{3}$ causes significant downfield NMR chemical shifts for the ortho protons (H(12), H(16); $\Delta \delta_{\rm H} = 0.41$ ppm) and the ipso (C(11); $\Delta \delta_{\rm C} = 3.4$ ppm), ortho (C(12), C(16); $\Delta \delta_{\rm C} = 0.94$), and methyl (C(1), $\Delta \delta_{\rm C} = 1.2$; C(2), $\Delta \delta_{\rm C} = 3.1$; trans-CH₃, $\Delta \delta_{\rm C} = 2.6$ ppm) carbons. ¹³C NMR chemical shifts are known to be sensitive to steric effects in related aluminum-nitrogen^{4-6,10,16} and aluminumphosphorus¹⁷ systems.

Restricted conformational averaging is observed in portions of the ¹H NMR spectra for compounds 2-5 (Figure 2). There is chemical shift nonequivalence for the C(1) methylene group protons in 3-5, the C(10) methylene group protons, the C(21) and C(22) methyl group protons in the isopropyl group, and the methyl group protons for the isobutyl group in 5. The C(21) and C(22) methyl group protons were assigned from the 2D NOESY spectra, where the C(22) methyl group protons correlate with one of the C(10) methylene protons and the C(21) methyl group protons correlate with the C(13)aromatic ring proton. Interestingly, the C(22) methyl group protons are, on average, 0.30 ppm to higher field and the C(21) methyl group protons are 0.14 ppm to

lower field in 2-5, compared to 1a and 1b. In contrast, the ¹H NMR spectra show that the C(21) and C(22)methyl group protons are chemically equivalent in 1a and in 1b, as are the C(10) methylene group protons; also, the tert-butyl methyl group protons are equivalent in [RAlN(t-Bu)-µ-(CH₂C₆H₄)]₂.¹ The NOESY data suggest a trans conformation for 2-5 in solution with respect to the Al₂N₂ ring, consistent with the X-ray data, and the ¹H NMR solution and X-ray data for [RAIN-(t-Bu)-µ-(CH₂C₆H₄)]₂.¹ Substitution of a *tert*-butyl for a benzyl group in the othometalated dimer series [RAIN- $(CH_2Ph)-\mu-(CH_2C_6H_4)]_2^2$ results in significant ¹³C NMR chemical shift changes at the C(1) ($\Delta \delta_{\rm C}(av) = 5.9$ ppm), C(10) (-4.8 ppm), and C(12) (4.8 ppm) carbons. Substitution of an isopropyl group for a benzyl group leads to a large ¹³C chemical shift change only at the C(10) carbon ($\Delta \delta_{\rm C}(av) = -9.1$ ppm). This ¹³C NMR chemical shift change, larger than any observed for the substitution of a tert-butyl group for a benzyl group, may arise due to a significant interaction with the C(22) methyl group, as evidenced by the restricted rotation of isopropyl group in 2-5.

X-ray Crystallography Data. The ORTEP drawing of the molecular structure and the atom labeling scheme for *cis*- $[Me_2AIN(i-Pr)CH_2Ph]_2$ (**1a**) are shown in Figure 1, with selected bond lengths (Å) and angles (deg) summarized in Table 1. The molecular structure of **1a** has a nonplanar Al₂N₂ core with a fold angle about the Al···Al axis of 26.9°. These data are consistent with those reported for *cis*- $[Me_2AIN(H)i-Pr]_2$,¹⁸ *cis*- $[Me_2AIN-(Me)CH_2Ph]_2$,¹⁵ and $[Me_2AIN(C_6H_{11})_2]_2$,¹⁹ with fold angles of 15.5°, 20.4°, and 27.4°, respectively. The molecular

structure data for **1a** are in agreement with published data and correlations of the steric properties of functional groups attached to the amine nitrogen with the corresponding dimer geometries.^{3,6,10-12,18-22}

The ORTEP drawing of the molecular structure of the orthometalated dimer $[n-BuAlN(i-Pr)-\mu-(CH_2C_6H_4)]_2$ (5) is shown in Figure 2, and representative bond lengths and bond angles for 2-5 are listed in Tables 2 and 3. The molecular structures of $[RAlN(i-Pr)-\mu-(CH_2C_6H_4)]_2$ each exhibit a planar Al₂N₂ core that possesses inversion symmetry. The Al₂N₂ ring is flanked on both sides by bridging CH₂C₆H₄ groups in a trans orientation relative to the core ring. The Al₂N₂ ring geometry is almost square planar; the N-Al-N angle varies from 90.80(14)° to 91.03(10)° and the Al-N-Al angle from 88.97(10)° to 89.20(13)° with R. The two Al-N distances are very similar, with the Al-N bond included in the five-membered orthometalated ring being slightly shorter (1.9629(15)-1.977(3) Å) than the other Al-N bond (1.9707(16)-1.986(3) Å). There are only minor variations in the Al_2N_2 ring geometry with R.

The Al_2N_2 ring geometries for the $[RAIN(i-Pr)-\mu-(CH_2C_6H_4)]_2$ and $[RAIN(CH_2Ph)-\mu-(CH_2C_6H_4)]_2$ dimers are very similar. Substitution of the isopropyl for a benzyl group results in small increases in the nonorthometalated Al–N bond distances (average, 0.027 Å) and slight changes in the N–Al–N and Al–N–Al bond angles, with the Al_2N_2 rings becoming more square. Modest changes occur in certain angles external to the ring, with the greatest change being 6.8° for the C(1)–

Al(1)–N(1) angle. Substitution of the more sterically demanding *tert*-butyl group for a benzyl group causes a reversal in the relative magnitudes of the N–Al–N and Al–N–Al angles¹ with elongation of the Al₂N₂ ring now along the Al···Al line. For the dibenzylamine and isopropylbenzylamine orthometalated dimers, the N···N distances are longer. Also, four angles external to the Al₂N₂ ring change more than 10° upon *t*-Bu group substitution.

Experimental Section

Standard inert atmosphere and vacuum line techniques were employed for the synthesis and purification of the compounds. All solvents were dried by refluxing over sodium and were distilled under nitrogen. The trialkylaluminum compounds (Texas Alkyls) were used as received. Isopropylbenzylamine (Aldrich) was stored over molecular sieves. ¹H and ¹³C NMR spectra were obtained on a Bruker DRX-400 FT-NMR spectrometer, operating at 400.132 and 100.625 MHz, respectively. Solutions for NMR analysis were prepared using benzene-d₆ with (CH₃)₄Si as internal reference. Complete ¹H and ¹³C NMR chemical shift assignments were made on the basis of both coupled and decoupled 1D NMR, ¹³DEPT, and ¹H{¹H} COSY, ¹³C{¹H} HETCOR, and ¹H{¹H} NOESY 2D NMR experiments. The FT-IR spectra were obtained using split mull samples in Nujol and Kel-F (halocarbon emulsions) on KBr disks. Elemental analyses were carried out by E & R Microanalytical Laboratory, Inc. Parsippany, NJ. All melting points reported are uncorrected and were obtained in sealed capillaries under nitrogen.

General Synthesis of [Me2AlN(i-Pr)CH2Ph]2 and [RAIN- $(i-Pr)-\mu-(CH_2C_6H_4)]_2$. [Me₂AlN(*i*-Pr)CH₂Ph]₂ (1) and [RAlN- $(i-\Pr)-\mu-(CH_2C_6H_4)]_2$, R = Me (2), n-Pr (3), n-Bu (4), i-Bu (5), were synthesized by mixing in the drybox at room temperature in a high-pressure thick-walled glass tube R₃Al (10 mmol) diluted in 5 mL of dry toluene with HN(*i*-Pr)CH₂Ph (1.486 g, 10 mmol) also diluted in 5 mL of dry toluene. The total volume of the solution was then brought up to 15 mL with toluene. Each tube was then heated in an oil bath to the desired temperature. The progress of each reaction was monitored by ¹H NMR After the reaction was complete, the toluene was removed under reduced pressure, and the products were isolated as white solids. The products were purified by crystallization from pentane. X-ray grade crystals were obtained either by slowly cooling the toluene solution or from a saturated pentane solution of the isolated product. The reaction times for the completion of each reaction were as follows: 1, 36 h at 80 °C; 2, 6 days at 150 °C followed by 4 days at 175 °C; 3, 4, and 5, 6 days at 155 °C

Characterization of [Me₂AlN(*i***-Pr)CH₂Ph]₂ (1). Mp: 141– 145 °C. Yield: 1.84 g, 90%. 1 exists as a cis–trans (1a, 1b) mixture in solution in a 60:40 ratio. 1a: ¹H NMR: \delta_{\rm H} –0.19 (s, 6H, H1), –0.11 (s, 6H, H2), 0.91 (d, 12H, H21, H22), 3.57 (m, 2H, H20), 4.03 (s, 4H, H10), 7.05 (2H, H14), 7.10 (4H, H13, H15), 7.39 (4H, H12, H16). ¹³C NMR: \delta_{\rm C} –6.41 (C1), –4.49 (C2), 23.01 (C21, C22), 50.01 (C20), 52.48 (C10), 127.58 (C14), 128.30 (C13, C15), 130.43 (C12, C16), 140.12 (C11). 1b: ¹H NMR: \delta_{\rm H} –0.13 (s, 12H, H1, H2), 0.94 (d, 12H, H21, H22), 3.46 (m, 2H, H20), 4.16 (s, 4H, H10), 7.06 (2H, H14), 7.10 (4H, H13, H15), 7.39 (4H, H12, H16). ¹³C NMR: \delta_{\rm C} –5.0 (C1, C2), 23.15 (C21, C22), 48.39 (C20), 51.85 (C10), 127.33 (C14), 128.45 (C13, C15), 130.08 (C12, C16), 139.98 (C11). Anal. Calcd (found) for C₂₄H₄₀Al₂N₂: C, 70.21(70.17); H, 9.82 (9.75); N, 6.82 (6.76).**

Characterization of [MeAlN(*i*-**Pr**)- μ -(**CH**₂**C**₆**H**₄)]₂ (2). Mp: 186–190 °C. Yield: 1.02 g, 54%. ¹H NMR: $\delta_{\rm H}$ –0.41 (s, 6H, H1), 0.59 (d, 6H, H22), 1.03 (d, 6H, H21), 3.10 (m, 2H, H20), 3.95, 4.13 (dd, 4H, H10), 7.14 (2H, H16), 7.26 (2H, H14), 7.28 (2H, H15), 7.80 (2H, H13). ¹³C NMR: $\delta_{\rm C}$ –12.1 (C1), 19.88 (C22), 22.57 (C21), 48.85 (C20), 49.59 (C10), 123.86 (C16), 126.37 (C14), 128.68 (C15), 136.11 (C13), 145.2 (C12), 150.86 (C11). Anal. Calcd (found) for $C_{22}H_{32}Al_2N_2$: C, 69.82 (69.77); H, 8.52 (8.49); N, 7.40 (7.38).

Characterization of [*n*-**PrAlN**(*i*-**Pr**)- μ -(**CH**₂**C**₆**H**₄)]₂ (3). Mp: 156–160 °C. Yield: 1.20 g, 55%. ¹H NMR: $\delta_{\rm H}$ 0.14, 0.29 (m, 4H, H1), 0.63 (d, 6H, H22), 1.07 (d, 6H, H21), 1.15 (t, 6H, H3), 1.64 (m, 4H, H2), 3.07 (m, 2H, H20), 3.96, 4.16 (dd, 4H, H10), 7.15 (2H, H16), 7.27 (2H, H14), 7.29 (2H, H15), 7.84 (2H, H13). ¹³C NMR: $\delta_{\rm C}$ 10.9 (C1), 19.39 (C2), 20.91 (C3), 20.11 (C22), 22.94 (C21), 48.86 (C20), 49.75 (C10), 123.83 (C16), 126.35 (C14), 128.64 (C15), 136.38 (C13), 145.1 (C12), 150.98 (C11). Anal. Calcd (found) for C₂₆H₄₀Al₂N₂: C, 71.86 (70.96); H, 9.28 (9.27); N, 6.45 (6.79).

Characterization of [*n*-BuAlN(*i*·Pr)- μ -(CH₂C₆H₄)]₂ (4). Mp: 153–155 °C. Yield: 1.15. g, 50%. ¹H NMR: $\delta_{\rm H}$ 0.14, 0.30 (m, 4H, H1), 0.66 (d, 6H, H22), 1.08 (d, 6H, H21), 0.99 (t, 6H, H4), 1.49 (m, 4H, H3), 1.60 (m, 4H, H2), 3.09 (m, 2H, H20), 3.98, 4.18 (dd, 4H, H10), 7.16 (2H, H16), 7.26 (2H, H14), 7.28 (2H, H15), 7.85 (2H, H13). ¹³C NMR: $\delta_{\rm C}$ 7.6 (C1), 14.08 (C4), 28.18 (C2), 29.21 (C3), 20.14 (C22), 22.96 (C21), 48.86 (C20), 49.75 (C10), 123.84 (C16), 126.36 (C14), 128.65 (C15), 136.36 (C13), 145.1 (C12), 151.00 (C11). Anal. Calcd (found) for C₂₈H₄₄-Al₂N₂: C, 72.69 (72.19); H, 9.59 (9.74); N, 6.06 (6.16).

Characterization of [*i*-BuAlN(*i*-Pr)- μ -(CH₂C₆H₄)]₂ (5). Mp: 159–162 °C. Yield: 1.37 g, 59%. ¹H NMR: $\delta_{\rm H}$ 0.12, 0.27 (m, 4H, H1), 0.66 (d, 6H, H22), 1.10 (d, 6H, H21), 1.13 (d, 6H, H3 or H4), 1.16 (d, 6H, H3 or H4), 2.01 (m, 2H, H2), 3.07 (m, 2H, H20), 3.98, 4.16 (dd, 4H, H10), 7.14 (2H, H16), 7.26 (2H, H14), 7.27 (2H, H15), 7.89 (2H, H13). ¹³C NMR: $\delta_{\rm C}$ 20.1 (C1), 26.40 (C2), 28.43 (C3 or C4), 28.55 (C3 or C4), 20.18 (C22), 22.91 (C21), 48.85 (C20), 49.85 (C10), 123.83 (C16), 126.39 (C14), 128.62 (C15), 136.50 (C13), 145.3 (C12), 150.99 (C11). Anal. Calcd (found) for C₂₈H₄₄Al₂N₂: C, 72.69 (72.64); H, 9.59 (9.56); N, 6.06 (5.99).

X-ray Crystallography. Crystals suitable for single-crystal X-ray diffraction were selected and mounted in nitrogenflushed capillaries. The data were collected on a Siemens P4 diffractometer equipped with a SMART/CCD detector. The systematic absences and diffraction symmetry are consistent for the space groups C2/c and Cc for **1a** and P1 and P1 for **2** and 4 and were uniquely consistent with the assigned space group options for 3 and 5. The E-statistics suggested the centrosymmetric options for 1a, 2, and 4, which yielded chemically reasonable and computationally stable results of refinement. Compound 1a exists as 0.5 molecule per asymmetric unit lying on a 2-fold rotation axis, while compound 2 has 1.5 molecules per asymmetric unit with one molecule lying on a general position and 0.5 molecule lying on an inversion center. Compounds 3, 4, and 5 exist as 0.5 molecule per asymmetric unit lying on an inversion center. The structures were solved by direct methods, completed by subsequent difference Fourier syntheses, and refined by full-matrix, leastsquares procedures. All non-hydrogen atoms were refined with anisotropic displacement coefficients, and all hydrogen atoms were treated as idealized contributions. All software and sources of the scattering factors are contained in the SHELXTL (5.10) program library (G. Sheldrick, Siemens XRD, Madison, WI). X-ray crystal data collection and refinement parameters and structural data for 1a-5 are included in the Supporting Information. Selected bond distances and angles are given in Tables 1-3.

Supporting Information Available: Tables of X-ray crystallographic data, crystal data and structure refinement, atomic coordinates, interatomic distances and angles, and hydrogen atom coordinates for compounds **1a**–**5**. Synthesis and characterization data for $[R_2AIN(i-Pr)CH_2Ph]_2$, where R = Et (**6**), *n*-Pr (**7**), *n*-Bu (**8**), and $[EtAIN(i-Pr)-\mu-CH_2C_6H_4]_2$ (**9**). IR data for compounds **1**–**9**. This material is available free of charge via the Internet at http://pubs.acs.org.
