Received January 7, 2003

Several new arene–phosphine ligands were synthesized and used to prepare the following series of tethered dialkylruthenium(II) complexes: $(\eta^6:\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)_2$, where R = Cy (**1**), Ph (**2**), Et (**3**). The structures of complexes **1** and **2** were determined by X-ray diffraction. While complexes **1** and **2** were found to be more thermally stable than analogous nontethered analogues, complex **3** was found to decompose at room temperature. In preliminary studies, the use of complexes **1** and **2** as catalyst precursors for the polymerization of ethylene was examined.

Introduction

Early-transition-metal alkyl complexes have been widely studied, at least in part, because they serve as important catalyst precursors for the polymerization of olefins.^{1,2} Recent research, however, has focused on the development of new types of Ziegler–Natta catalysts based on late transition metals because of the anticipated tolerance of these metals toward polar functional groups.^{3–18} In particular, several new catalysts that

oligomerize and/or polymerize olefins have been recently developed based on group VIII–X metals such as Fe,^{3–9} Co,^{3–5,8} Rh,¹⁰ Ni,^{11–18} and Pd.^{12–14} Despite these advances, there are relatively few examples of ruthenium-based Ziegler–Natta catalysts.^{19–22}

Because ruthenium complexes have been shown to exhibit a high tolerance toward polar functional groups in the ring-opening metathesis polymerization (ROMP) of cyclic olefins,^{23–28} we have been exploring the development of ruthenium-based Ziegler–Natta polymerization catalysts.^{29,30} In particular, our research has found that the abstraction of one of the *cis* methyl groups of *cis*-(DMPE)₂RuMe₂ in the presence of ethylene affords the cation *trans*-[(DMPE)₂RuMe(CH₂=CH₂)]⁺, which fails to insert ethylene into the remaining Ru–methyl bond.³⁰ One of the major drawbacks of this system apparently derives from the rapid isomerization of the bidentate phosphine ligand during cation formation, which gives rise to an inaccessible *trans* location of the Ru–methyl bond relative to the coordinated ethylene group.

From these observations, we concluded that it should be possible to lock the vacant orbital *cis* to an alkyl group by employing a rigid ligand system incapable of isomerization. To this end, we have designed a family

of dimethylruthenium(II) complexes containing the unique arene–phosphine ligand, $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2$, where R = Cy, Ph, Et. We specifically targeted the study of $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)_2$ complexes because the abstraction of a single methyl group from these substrates would necessarily afford a vacant site cis to the residual methyl group. Moreover, the resultant cationic intermediates would be isolobal with those postulated in the catalytically active $[\text{CpCoH}(\text{C}_2\text{H}_4)\text{-PR}_3]^+$ olefin polymerization systems.³¹ Furthermore, we believed that it might be possible to achieve stereo-specific catalysis arising from the C_1 symmetry of the metal center in specially designed analogues.³²

In this paper, we describe the synthesis and characterization of a new family of complexes, $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{-CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)_2$, where R = Cy (1), Ph (2), Et (3). Through a series of thermal decomposition studies, we then compare the thermal stabilities of these complexes to each other and to those of known nontethered analogues such as $(\eta^6\text{-C}_6\text{H}_6)\text{RuMe}_2(\text{PPh}_3)$ and $(\eta^6\text{-1,3,5-C}_6\text{H}_3\text{Me}_3)\text{RuMe}_2(\text{PMe}_2\text{Ph})$.³³ Furthermore, we conduct preliminary experiments in which complexes 1 and 2 are examined for use as Ziegler–Natta catalyst precursors for the polymerization of ethylene.

Results and Discussion

Synthesis of Complexes 1–3. Scheme 1 illustrates the strategy used to synthesize complexes 1–3. In the first step, a series of new arene–phosphine ligands were prepared by the reaction of (2-phenylethyl)magnesium bromide with the appropriate dialkylchlorophosphines in diethyl ether. These ligands were subsequently treated with $[(p\text{-cymene})\text{RuCl}_2]_2$ in refluxing benzene to give the orange-red nontethered complexes $(p\text{-cymene})\text{-RuCl}_2(\text{PR}_2\text{CH}_2\text{CH}_2\text{C}_6\text{H}_5)$ (R = Cy, Ph, Et) in greater than 90% yield. Subsequent heating of the nontethered

complexes in refluxing chlorobenzene led to the replacement of the cymene ligand with the phenyl moiety of the phosphine ligand to give the tethered dichloro complexes $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{RuCl}_2$ (R = Cy, Ph, Et) in 60–95% yield. Alkylation of these complexes with excess methyl lithium in diethyl ether gave the targeted dialkyl complexes $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)_2$ (R = Cy, Ph, Et) in ~35% yield. We found that the use of less than 5 equiv of methyl lithium led to incomplete alkylation (e.g., monomethylated Ru side products). We isolated pure samples of $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PCy}_2)\text{Ru}(\text{CH}_3)_2$ (1) and $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PPh}_2)\text{Ru}(\text{CH}_3)_2$ (2) by use of flash chromatography through particulate Al_2O_3 . We were, however, unable to isolate pure samples of $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PEt}_2)\text{Ru}(\text{CH}_3)_2$ (3) due to its rapid decomposition during flash chromatography. Complexes 1–3 were soluble in CH_2Cl_2 , benzene, and toluene and slightly soluble in diethyl ether.

Characterization of Complexes 1–3. Analysis by ^1H NMR spectroscopy of 1–3 in CD_2Cl_2 showed that the coordinated arene exhibits three well-separated resonances in the region δ 4.5–5.5 (for 1, δ 5.13 (t), 4.97 (d), 4.53 (t); for 2, δ 5.42 (t), 5.10 (d), 4.88 (t); for 3, δ 5.04 (t), 4.65 (t), 4.53 (d)). The doublets at δ –0.02 for 1, δ –0.20 for 2, and δ 0.50 for 3 correspond to the Ru– CH_3 protons coupled to the phosphine nucleus. The coupling constants (J_{HP}) of these doublets were 4.8, 6.0, and 5.7 Hz for 1–3, respectively, which is consistent with values reported for related compounds such as $(\eta^6\text{-C}_6\text{H}_6)\text{RuMe}_2(\text{PPh}_3)$,³³ $(\eta^6\text{-1,3,5-C}_6\text{H}_3\text{Me}_3)\text{RuMe}_2(\text{PMe}_2\text{-Ph})$,³³ $(\eta^6\text{-C}_6\text{Me}_6)\text{RuMe}_2(\text{L})$ (where L = PMe_3 , PMePh_2 , PPh_3),³⁴ and $[(\eta^6\text{-C}_6\text{Me}_6)\text{RuMe}(\text{PMe}_3)(\text{CO})]^+$.³⁵

We performed X-ray structural analyses of crystals of 1 and 2 generated by the slow evaporation of CH_2Cl_2 from concentrated solutions containing the respective complexes. We were, however, unable to obtain crystals of 3, despite using a variety of solvent and mixed-solvent systems during crystallization trials. Thermal ellipsoid plots and views perpendicular to the η^6 -phenyl ring for compounds 1 and 2 are shown in Figures 1 and 2, respectively. Selected bond distances and angles are provided in Tables 1 and 2, respectively. The phenyl ring and ethylene bridge of compound 1 were disordered 60:40 over two positions approximately related by a mirror plane. In contrast, the structure of compound 2 was well ordered.

The Ru–C(1) and Ru–C(2) bond distances were similar in both compounds (2.136(4) and 2.129(4) Å for 1; 2.142(4) and 2.143(4) Å for 2). These values are comparable to those reported in the literature for ruthenium alkyls.^{33,34} The bond distances from Ru to each carbon of the coordinated arene were as follows for 1: 2.210(8) Å, Ru–C(5); 2.240(9) Å, Ru–C(6); 2.27(1) Å, Ru–C(7); 2.268(8) Å, Ru–C(8); 2.238(6) Å, Ru–C(9); 2.209(7) Å, Ru–C(10). The analogous distances were as follows for 2: 2.181(3) Å, Ru–C(13); 2.250(4) Å, Ru–C(14); 2.215(4) Å, Ru–C(15); 2.237(4) Å, Ru–C(16); 2.239(3) Å, Ru–C(17); 2.262(4) Å, Ru–C(18). In both complexes, the ruthenium metal lies beneath the center of the coordinated arene. The elongated Ru–carbon bonds trans to the bridge and the

induced by the presence of the two-carbon bridge. Similar distortion was observed in the related dichloro complexes $(\eta^6:\eta^1\text{-C}_6\text{H}_5(\text{CH}_2)_3\text{PPh}_2)\text{RuCl}_2$ ³⁶ and $(o\text{-HOCH}_2\text{-}\eta^6:\eta^1\text{-C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{PPh}_2)\text{RuCl}_2$.³⁷ While the three ligands (CH₃, CH₃, P) of compound **2** lie in an eclipsed conformation relative to the coordinated arene, those of compound **1** are either eclipsed or slightly staggered relative to the coordinated arene, depending on the nature of the disordered structure.

Thermal Stability of Complexes 1 and 2. We examined the thermal stability of complexes **1** and **2** both in solution and in the solid state. Due to our inability to purify complex **3** (vide supra) and the unknown manner by which the impurities might influence its apparent thermal stability, we chose to exclude complex **3** from these studies. Crystals of complex **1** were found to be stable over several months at room temperature under an inert atmosphere. Crystals of complex **2**, however, gradually decomposed over a period of 1 month under the same conditions. The stability of the compounds in solution was monitored by ¹H NMR spectroscopy. Compounds **1** and **2** were dissolved in dry, oxygen-free *o*-xylene-*d*₁₀ in an NMR tube. The NMR tube was then sealed under vacuum and gradually heated to 130 °C. The concentrations of **1** and **2** were measured by integration of the peaks due to the $\eta^6\text{-C}_6\text{H}_5$ moiety at δ 5.12 for **1** and at δ 5.32 for **2** using C₆Me₆ (0.001 M) as an internal standard. When the solution was heated for several hours, its color gradually changed from light yellow to orange and eventually to black.

Figure 3. Thermal decomposition profiles of $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{-CH}_2\text{CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)_2$, where R = Cy (●), Ph (■).

The intensities of all ^1H NMR resonances attributed to **1** and **2** were observed to gradually decrease with heating over time. New resonances at δ 0.43 (s) and 7.5 (broad m) appeared after 22 h for **1** and 5 h for **2**. Line broadening over the range δ 0–3.5 was observed for both species, perhaps suggesting the formation of paramagnetic decomposition products. Figure 3 shows that the decomposition of **1** and **2** exhibited first-order kinetics, as measured quantitatively by ^1H NMR spectroscopy. The rate constants at 130 °C were calculated to be $2.21 \times 10^{-2} \text{ min}^{-1}$ with $t_{1/2} = 31 \text{ min}$ for compound **1** and $5.75 \times 10^{-2} \text{ min}^{-1}$ with $t_{1/2} = 12 \text{ min}$ for compound **2**. While we were unable to characterize fully the decomposition reactions, we believe that the decomposition reactions proceed via the formation of methane and displacement of the coordinated arene, because of the appearance of the singlet at δ 0.43 (corresponding to free methane)³⁸ and the broad multiplet at δ 7.5 (uncoordinated aromatic) as described above. It is possible that the methane is generated via α -hydride transfer from one methyl group to another and a radical reaction—a process similar to that observed in studies of the thermal decomposition of diethylruthenium(IV) porphyrin complexes.³⁹ Although we attempted to further characterize the decomposition reactions by UV spectroscopy, the stronger absorption band of the decomposed products (λ_{max} 267) overlapped that of the starting materials (λ_{max} ~270) and thus prevented a detailed analysis.

Although the complexes $(\eta^6\text{-C}_6\text{Me}_6)\text{RuMe}_2(\text{L})$, where L = PMe₃, PMePh₂, PPh₃, were reportedly isolable at room temperature,³⁴ separate studies showed that the related nontethered complexes $(\eta^6\text{-C}_6\text{H}_6)\text{RuMe}_2(\text{PPh}_3)$ and $(\eta^6\text{-1,3,5-C}_6\text{H}_3\text{Me}_3)\text{RuMe}_2(\text{PMe}_2\text{Ph})$ could not be isolated at room temperature due to their facile decomposition.³³ Given that the structures of the last two complexes more closely resemble the structures of **1–3**, the results presented here provide strong evidence that

the new tethered arene–phosphine dialkylruthenium complexes are more thermally stable than analogous nontethered systems.

Attempted Polymerization of Ethylene Using Complexes 1 and 2 as Catalyst Precursors. We briefly examined the use of complexes **1** and **2** as catalyst precursors for the Ziegler–Natta polymerization of ethylene. Due to our inability to purify complex **3** (vide supra), we chose to exclude it from these polymerization trials. A Fisher–Porter bottle was charged with a solution of methylalumoxane (MAO) in toluene under ethylene. Separately, the complexes were dissolved in toluene and then added to the reactor, which led to an immediate color change in the solutions from light yellow to slightly orange and then to yellow within a few minutes. For both complexes, the following polymerization conditions were employed: (a) pressure of ethylene, 8.5 atm; (b) temperature, 25 and 50 °C; (c) quantity of Ru complex, 10 and 20 μmol ; (d) Ru/MAO ratio, 1/1000 and 1/3000. Even at the highest temperature and concentration of reactants, only trace amounts of polymer were produced upon reaction for 1–2 h.

In these polymerization trials, the use of large excesses of MAO prevented a detailed analysis of the products formed when complexes **1** and **2** were treated with MAO. We were thus unable to determine whether any cationic alkyl complexes were formed as intermediates. In separate studies,⁴⁰ however, we have examined the reactivity of complexes **1** and **2** with $[\text{H}(\text{Et}_2\text{O})_2]\text{[B(3,5-C}_6\text{H}_3(\text{CF}_3)_2)_4]$.⁴¹ In the presence of CO, we were able to isolate the cationic alkyl complexes, $[(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{Ru}(\text{CH}_3)(\text{CO})][\text{B(3,5-C}_6\text{H}_3(\text{CF}_3)_2)_4]$ (R = Cy, Ph).^{40,42} The details of these synthetic studies and an exploration of the use of the resultant cationic alkyl complexes as olefin polymerization catalysts are reported separately.

Regarding the inactivity of the cis-constrained complexes toward the polymerization of olefins, Werner has observed in similar systems ortho metalation of the phenyl moiety attached to phosphorus,³⁵ which would lead in our case to a Ru benzyl product that might fail to insert ethylene. Another possibility is that a stable Ru alkyl olefin complex having a high energy of insertion is formed in the reaction. The latter can plausibly occur if the olefin orients in a manner that precludes insertion (e.g., perpendicular to the alkyl group).

Conclusions

We have synthesized a new family of arene–phosphine ligands, $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2$ (R = Cy, Ph, Et), and used them to prepare the corresponding ruthenium(II) dichloride complexes, $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{PR}_2)\text{RuCl}_2$. Alkylation of these complexes with methyllithium afforded the novel dialkyl complexes $(\eta^6\text{-}\eta^1\text{-C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{-PR}_2)\text{Ru}(\text{CH}_3)_2$, where R = Cy (**1**), Ph (**2**), Et (**3**). Complexes **1** and **2** were thoroughly characterized by NMR spectroscopy, X-ray crystallography, and thermal

(38) We measured the ^1H NMR spectrum of methane in *o*-xylene- d_{10} and observed a single resonance at δ 0.43. In ^1H NMR spectroscopy, the singlet for ethane typically appears downfield of that for methane by ~0.6 ppm. See, for example: Friebolin, H. *Basic One- and Two-Dimensional NMR Spectroscopy*; VCH: New York, 1993; p 52.

(42) In contrast to ref 30, where the boron activator abstracts a methide moiety, ref 35 reports that Ph_3CX (X = PF_6^- , BF_4^-) abstracts a hydride moiety from related late-transition-metal dimethyl complexes.

stability. Due to our inability to completely purify complex **3**, we were unable to characterize it fully, nor were we able to evaluate its thermal stability. Analysis of the thermal stabilities of complexes **1** and **2** revealed that complex **1** is more stable than complex **2**; furthermore, both complexes appear to be more thermally stable than analogous nontethered systems described in the literature. Preliminary studies of the use of complexes **1** and **2** as catalyst precursors in the Ziegler–Natta polymerization of ethylene revealed that neither complex exhibited significant catalytic activity under the limited polymerization conditions examined.

Experimental Section

Materials and Methods. All solvents were dried by passage through alumina and degassed by freeze–pump–thaw methods prior to use. The compounds methyllithium and 2-(bromoethyl)benzene were purchased from Aldrich Chemical Co. and used as received. Similarly, the compounds bis(μ -chloro)bis(p -cymene)chlororuthenium(II), dicyclohexylchlorophosphine (CIPCy₂), diphenylchlorophosphine (CIPPh₂), and diethylchlorophosphine (CIPeT₂) were purchased from Strem Chemical Co. and used as received. All deuterated solvents were purchased from Cambridge Isotope Laboratories. Nuclear magnetic resonance (NMR) spectra were recorded on a General Electric QE-300 spectrometer operating at 300 MHz (for ¹H), 75.5 MHz (for ¹³C), and 121 MHz (for ³¹P). Elemental analyses were performed by National Chemical Consulting.

Synthesis of C₆H₅CH₂CH₂PCy₂. To a cooled (0 °C) solution of dry diethyl ether (60 mL) charged with dicyclohexylchlorophosphine (5.0 g, 2.1 × 10⁻² mol) was added 1.1 equiv (9.0 mL of a 2.6 M solution; 2.4 × 10⁻² mol) of C₆H₅CH₂CH₂MgBr prepared by the reaction of magnesium and (2-bromoethyl)benzene in dry diethyl ether. The solution was warmed slowly to room temperature and refluxed overnight under argon. The excess Grignard reagent was destroyed by the addition of degassed methanol, and the solution was concentrated under vacuum. Due to apparent decomposition of the product during attempted purification by column chromatography on silica gel, the crude product was used in subsequent synthetic steps (vide infra). ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 7.26 (m, 5 H, C₆H₅), 2.73 (m, 2 H, C₆H₅CH₂CH₂P), 1.2–2.2 (m, 24 H, C₆H₅CH₂CH₂P, Cy₂).

Synthesis of C₆H₅CH₂CH₂PPh₂. An aliquot (25 mL, 6.8 × 10⁻² mol) of a 2.7 M solution of C₆H₅CH₂CH₂MgBr in diethyl ether was slowly added to a cooled (0 °C) solution of diphenylchlorophosphine (10 g, 4.5 × 10⁻² mol) in 100 mL of dry diethyl ether. The solution was slowly warmed to room temperature and refluxed overnight under argon. The excess Grignard reagent was destroyed by the dropwise addition of 1 N HCl solution. The solution was then adjusted to basic pH by the careful addition of a saturated solution of NaHCO₃. The organic phase was separated, and the aqueous phase was extracted with diethyl ether (3 × 60 mL). The combined organic phases were dried over MgSO₄ and filtered. The volatiles were removed under vacuum, and the product was purified by column chromatography on silica gel using 40/1 hexanes/diethyl ether (*R_f* = 0.46, 10/1 hexanes/diethyl ether). Yield of white solid: 7.4 g, 56%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 7.15–7.69 (m, 15 H, Ar), 2.96 (m, 2 H, C₆H₅CH₂CH₂P), 2.59 (m, 2 H, C₆H₅CH₂CH₂P). ³¹P{¹H} NMR (CDCl₃; 121 MHz; 293 K): δ -15.3 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 142.68 (d, *J_{CP}* = 13.14 Hz, C₆H₅CH₂CH₂P), 138.72 (d, *J_{CP}* = 13.36 Hz, Ar), 132.91 (d, *J_{CP}* = 16.23 Hz, Ar), 132.70 (d, *J_{CP}* = 16.99 Hz, Ar), 128.56 (m, C₆H₅CH₂CH₂P, Ar), 126.08 (s, C₆H₅CH₂CH₂P), 32.25 (d, *J_{CP}* = 17.74 Hz), 30.30 (d, *J_{CP}* = 13.14 Hz).

Synthesis of C₆H₅CH₂CH₂PEt₂. This ligand was prepared using a procedure analogous to that used to prepare C₆H₅CH₂–

CH₂PPh₂, except for the use of 1.98 M C₆H₅CH₂CH₂MgBr (12.16 mL, 2.4 × 10⁻² mol) and diethylchlorophosphine (2.0 g, 1.6 × 10⁻² mol) in dry diethyl ether (20 mL). The crude oily residue was purified by vacuum distillation. Yield: 1.00 g, 32%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 7.28 (m, 5 H, C₆H₅), 2.77 (m, 2 H, C₆H₅CH₂CH₂P), 1.73 (m, 2 H, C₆H₅CH₂CH₂P), 1.48 (q, *J_{HH}* = 7.8 Hz, 4 H, P(CH₂CH₃)₂), 1.12 (m, 6 H, P(CH₂CH₃)₂). ³¹P{¹H} NMR (CDCl₃; 121 MHz; 293 K): δ -21.3 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 143.06, 128.34, 128.03, 125.81, 32.28 (d, *J_{CP}* = 14.57 Hz), 28.20 (d, *J_{CP}* = 15.55 Hz), 18.64 (d, *J_{CP}* = 11.33 Hz), 9.50 (d, *J_{CP}* = 11.78 Hz).

Synthesis of (p -cymene)Ru(PCy₂CH₂CH₂C₆H₅)Cl₂. The synthesis was performed using an adaptation of a related literature procedure.³³ An aliquot of [(p -cymene)RuCl₂]₂ (3.14 g, 5.13 × 10⁻³ mol) was dissolved in 80 mL of benzene. To this solution was added 2.5 equiv of crude C₆H₅CH₂CH₂PCy₂ prepared as described above (*note*: the amount of C₆H₅CH₂CH₂PCy₂ was estimated by integration using ¹H NMR spectroscopy). The solvent was evaporated, and the resultant red residue was extracted into CH₂Cl₂ and the extract filtered. The solution was evaporated to dryness, and the resultant red solid was washed with hexanes and diethyl ether and then dried under vacuum. Yield: 4.63 g, 75%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 5.55 (s, 4 H, η^6 -CH₃C₆H₄CH(CH₃)₂), 2.82 (m, 2 H, C₆H₅CH₂CH₂P), 2.29 (m, 2 H, C₆H₅CH₂CH₂P), 2.10 (s, 3 H, Ar-CH₃), 1.40–2.03 (m, 23 H, Cy₂, CH(CH₃)₂), 1.28 (d, *J_{HH}* = 6.9 Hz, 6 H, CH(CH₃)₂). ³¹P{¹H} NMR (CD₂Cl₂; 121 MHz; 293 K): δ 25.5 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 141.65 (Ar), 128.56 (m, Ar), 126.10 (Ar), 108.69 (η^6 -CH₃C₆H₄CH(CH₃)₂), 94.11 (η^6 -CH₃C₆H₄CH(CH₃)₂), 88.94 (η^6 -CH₃C₆H₄CH(CH₃)₂), 83.66 (η^6 -CH₃C₆H₄CH(CH₃)₂), 37.88 (d, *J_{CP}* = 20.5 Hz), 31.10 (d, *J_{CP}* = 5.1 Hz), 30.89, 29.45, 29.07, 27.74, 26.72, 22.55, 18.21. A satisfactory analysis could not be obtained. Anal. Calcd for C₃₀H₄₅RuP₂Cl₂: C, 59.20; H, 7.40. Found: C, 58.43; H, 7.28.

Synthesis of (p -cymene)Ru(PPh₂CH₂CH₂C₆H₅)Cl₂. An aliquot of [(p -cymene)RuCl₂]₂ (1.00 g, 1.63 × 10⁻³ mol) was dissolved in 50 mL of benzene. To this solution was added 2.1 equiv of C₆H₅CH₂CH₂PPh₂ (0.99 g, 3.4 × 10⁻³ mol). The solution was heated at 45 °C for 3 h, and then the solvent was removed by evaporation. The resultant red residue was extracted into CH₂Cl₂, and the extract was filtered and evaporated to dryness. The resultant red solid was washed with hexanes and diethyl ether, and then dried under vacuum. Yield: 1.85 g, 95%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 7.94 (m, 4 H, PPh₂), 7.53 (m, 6 H, PPh₂), 7.13 (m, 3 H, C₆H₅), 6.93 (m, 2 H, C₆H₅), 5.26 (d, *J_{HH}* = 6.3 Hz, 2 H, η^6 -CH₃C₆H₄CH(CH₃)₂), 5.09 (d, *J_{HH}* = 6.3 Hz, 2 H, η^6 -CH₃C₆H₄CH(CH₃)₂), 2.85 (m, 2 H, C₆H₅CH₂CH₂P), 2.55 (m, 1 H, CH(CH₃)₂), 2.32 (m, 2 H, C₆H₅CH₂CH₂P), 1.90 (s, 3 H, Ar-CH₃), 0.83 (d, *J_{HH}* = 6.9 Hz, 6 H, CH(CH₃)₂). ³¹P{¹H} NMR (CDCl₃; 121 MHz; 293 K): δ 23.4 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 141.65 (d, *J_{CP}* = 12.16 Hz, Ar), 133.40 (d, *J_{CP}* = 8.23 Hz, Ph₂), 133.28 (m, Ph₂), 130.83 (Ph₂), 128.35 (m, Ar), 126.02 (Ar), 108.39 (η^6 -CH₃C₆H₄CH(CH₃)₂), 93.94 (η^6 -CH₃C₆H₄CH(CH₃)₂), 90.65 (η^6 -CH₃C₆H₄CH(CH₃)₂), 85.80 (η^6 -CH₃C₆H₄CH(CH₃)₂), 30.15, 29.68, 25.19 (d, *J_{CP}* = 26.27 Hz), 21.48, 17.53. Anal. Calcd for C₃₀H₃₃RuP₂Cl₂: C, 60.40; H, 5.54. Found: C, 60.65; H, 5.40.

Synthesis of (p -cymene)Ru(PeT₂CH₂CH₂C₆H₅)Cl₂. An aliquot of [(p -cymene)RuCl₂]₂ (0.50 g, 8.2 × 10⁻⁴ mol) was dissolved in 50 mL of benzene. To this solution was added 2.3 equiv of C₆H₅CH₂CH₂PEt₂ (0.36 g, 1.9 × 10⁻³). The solution was refluxed for 30 min, and the solvent was evaporated to afford a red residue, which was extracted into CH₂Cl₂, filtered, and evaporated to dryness. The resultant red solid was washed with hexanes and diethyl ether and then dried under vacuum. Yield: 0.78 g, 95%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 7.27 (m, 5 H, C₆H₅), 5.45 (m, 4 H, η^6 -CH₃C₆H₄CH(CH₃)₂), 2.85 (m, 3 H, CH(CH₃)₂, C₆H₅CH₂CH₂P), 2.26 (m, 2 H, C₆H₅CH₂CH₂P), 2.17 (m, 4 H, P(CH₂CH₃)₂), 2.11 (s, 3 H, Ar-CH₃), 1.26 (d, *J_{HH}* = 6.9 Hz, 6 H, CH(CH₃)₂), 1.17 (m, 6 H, P(CH₂CH₃)₂). ³¹P{¹H}

NMR (CDCl₃; 121 MHz; 293 K): δ 21.2 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 142.12 (d, J_{CP} = 12.30 Hz, Ar), 128.74 (Ar), 128.17 (Ar), 126.36 (Ar), 107.54 (η^6 -CH₃C₆H₄CH(CH₃)₂), 94.59 (η^6 -CH₃C₆H₄CH(CH₃)₂), 88.99 (η^6 -CH₃C₆H₄CH(CH₃)₂), 84.86 (η^6 -CH₃C₆H₄CH(CH₃)₂), 30.75, 29.93, 26.98 (d, J_{CP} = 24.23 Hz), 22.40, 18.38, 18.21 (d, J_{CP} = 25.82 Hz), 7.99 (d, J_{CP} = 6.88 Hz). Synthesis of (η^6 : η^1 -C₆H₅CH₂CH₂PCy₂)RuCl₂. A sample of 4.63 g (7.61×10^{-3} mol) of (*p*-cymene)Ru(PCy₂CH₂CH₂C₆H₅)Cl₂ was refluxed in 80 mL of degassed chlorobenzene for 6 h under argon. Fine orange crystals, which formed during the reaction, were isolated by filtration and washed with hexanes and diethyl ether. The remaining solution was again refluxed, and the crystals were collected. This process was repeated three times until crystal formation was observed to cease. The crystals were washed with hexanes and diethyl ether and dried under vacuum. Yield: 3.40 g, 94%. ¹H NMR (CDCl₃; 300 MHz; 293 K): δ 6.22 (td, J_{HH} = 5.7 Hz, J_{HH} = 2.4 Hz, 1 H, η^6 -C₆H₅), 5.84 (t, J_{HH} = 5.7 Hz, 2 H, η^6 -C₆H₅), 5.01 (d, J_{HH} = 5.7 Hz, 2 H, η^6 -C₆H₅), 2.92 (m, 2 H, C₆H₅CH₂CH₂P), 2.63 (dt, J_{HH} = 7.5 Hz, J_{gem} = 18.6 Hz, 2 H, C₆H₅CH₂CH₂P), 2.27 (m, 2 H, Cy₂), 1.28–1.83 (m, 20 H, Cy₂). ³¹P{¹H} NMR (CDCl₃; 121 MHz; 293 K): δ 70.2 (s). ¹³C NMR (CDCl₃; 75.5 MHz; 293 K): δ 112.00 (η^6 -C₆H₅), 97.66 (η^6 -C₆H₅), 90.88 (η^6 -C₆H₅), 75.25 (η^6 -C₆H₅), 34.67 (d, J_{CP} = 26.7 Hz), 34.15 (d, J_{CP} = 21.3 Hz), 32.07, 26.06–27.53 (m). Synthesis of (η^6 : η^1 -C₆H₅CH₂CH₂PPh₂)Ru(CH₃)₂ (2). The synthesis of compound **2** was performed using a procedure analogous to that used to prepare compound **1**. Yellow crystals of **2** were obtained by the slow evaporation of CH₂Cl₂. Yield: 48%. ¹H NMR (CD₂Cl₂; 300 MHz; 293 K): δ 7.36 (m, 10 H, PPh₂), 5.42 (t, J_{HH} = 5.7 Hz, 2 H, η^6 -C₆H₅), 5.10 (d, J_{HH} = 5.7 Hz, 2 H, η^6 -C₆H₅), 4.87 (t, J_{HH} = 5.7 Hz, 1 H, η^6 -C₆H₅), 2.96 (m, 2 H, C₆H₅CH₂CH₂P), 2.11 (dt, J_{HH} = 7.2 Hz, J_{gem} = 21.9 Hz, 2 H, C₆H₅CH₂CH₂P), -0.19 (d, J_{HP} = 6.0 Hz, 6 H, Ru(CH₃)₂). ³¹P{¹H} NMR (CD₂Cl₂; 121 MHz; 293 K): δ 63.7 (s). ¹³C NMR (CD₂Cl₂; 75.5 MHz; 293 K): δ 135.24 (d, J_{CP} = 34.88 Hz, Ph₂), 133.36 (d, J_{CP} = 9.66 Hz, Ph₂), 129.67, 128.38 (d, J_{CP} = 9.21 Hz, Ph₂), 108.46 (η^6 -C₆H₅), 98.97 (η^6 -C₆H₅), 84.87 (η^6 -C₆H₅), 76.68 (d, J_{CP} = 15.2 Hz, η^6 -C₆H₅), 47.48 (d, J_{CP} = 30.9 Hz), 28.64 (d, J_{CP} = 7.5 Hz), -10.82 (d, J_{CP} = 16 Hz). Anal. Calcd for C₂₂H₂₅RuP: C, 62.71; H, 5.94. Found: C, 62.87; H, 5.98.

Synthesis of (η^6 : η^1 -C₆H₅CH₂CH₂PET₂)Ru(CH₃)₂ (3). The corresponding dichloride, (η^6 : η^1 -C₆H₅CH₂CH₂PET₂)RuCl₂ (0.123 g, 3.34×10^{-4} mol), was suspended in 20 mL of diethyl ether. To the above solution was added 5 equiv of methyl-lithium (1.69×10^{-3} mol) at -78°C . The solution was gradually warmed to

room temperature and stirred for 1 h. The solvent was evaporated, and the residue was extracted with benzene. The brown solid obtained after evaporation of benzene was subjected to column chromatography on particulate Al_2O_3 using diethyl ether as the eluant. A yellow solution was collected, which turned brown during evaporation of the diethyl ether. The apparent decomposition precluded the isolation of the pure samples of **3**. ¹H NMR (C_6D_6 ; 300 MHz; 293 K): δ 5.04 (t, $J_{\text{HH}} = 5.7$ Hz, 2 H, $\eta^6\text{-C}_6\text{H}_5$), 4.65 (t, $J_{\text{HH}} = 5.7$ Hz, 1 H, $\eta^6\text{-C}_6\text{H}_5$), 4.53 (d, $J_{\text{HH}} = 5.7$ Hz, 2 H, $\eta^6\text{-C}_6\text{H}_5$), 1.87 (m, 2 H, $\text{C}_6\text{H}_5\text{-CH}_2\text{CH}_2\text{P}$), 1.60 (dt, $J_{\text{HH}} = 7.5$ Hz, $J_{\text{gem}} = 18.0$ Hz, 2 H, $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{P}$), 1.34 (m, 4 H, $\text{P}(\text{CH}_2\text{CH}_3)_2$), 0.81 (m, 6 H, $\text{P}(\text{CH}_2\text{CH}_3)_2$), 0.50 (d, $J_{\text{HP}} = 5.7$ Hz, 6 H, $\text{Ru}(\text{CH}_3)_2$).

X-ray Crystal Structure Determinations. The data were collected using the TEXSAN⁴³ automatic data collection series on a Rigaku AFC5S diffractometer. The crystallographic data

collection parameters for compounds **1** and **2** are summarized in Tables 3 and 4, respectively. The data were corrected for Lorentz and polarization effects and for absorption correction using ψ scans. Crystal and instrument stability were checked by measuring 3 standard reflections every 150 observations. Structures were solved using SHELXS-97⁴⁴ on a PC. Weighted *R* factors (R_w) and all goodness of fit values (*S*) were based on F^2 ; conventional *R* factors (*R*) were based on *F*. The H atom positions were refined using a riding model.

Trial Polymerizations of Ethylene Using MAO-Activated 1 and 2.⁴⁵ These experiments were performed in a Fisher–Porter bottle equipped with a pressure release valve, a sample injection inlet, an ethylene and argon inlet, and a pressure gauge. In a typical polymerization trial, a mixture of MAO (1000–3000 equiv based on Ru) and toluene (30 mL) were placed in the Fisher–Porter bottle, which was then pressurized with ethylene at 40 psi for 5 min. The pressure of ethylene was slowly reduced to 25 psi, and a solution containing the ruthenium complexes (10 or 20 μmol) was injected by syringe under a flow of ethylene. The reactor was pressurized with ethylene (8.5 atm), and the reaction mixture was stirred for 1–2 h at temperatures adjusted to either 25 or 50 °C over several independent runs. The reaction mixture was then slowly poured into a methanolic solution containing 5% HCl to precipitate any polyethylene formed in the reaction.

Acknowledgment. The Robert A. Welch Foundation (Grants C-0976 and E-1320) and the National Science Foundation (Grant CHE-9983352 and CAREER Award to T.R.L., Grant CHE-9625003) provided generous support for this research. We thank Dr. James Korp for technical assistance with the X-ray crystallographic analyses.
