One of the activation procedures most frequently used in late transition metal chemistry consists in generating cationic metal complexes by halide abstraction from the metal center in the presence of a weakly coordinating anion. We report here on the major effect of replacing Ag(I) with Tl(I) salts, although they are often used indiscriminately as halide abstractors. The Pt(II) complex [Pt(CH₂Ph)Cl(PCH₂-ox)] (**1**) (PCH₂-ox = κ^2 -*P,N*-(oxazolinylmethyl)-diphenylphosphine) yielded the expected metathesis product [Pt(CH₂Ph)(OTf)(PCH₂-ox)] (**2**) when treated with 1 equiv of AgOTf (OTf = SO₃CF₃) in CH₂Cl₂. In a coordinating solvent such as acetonitrile, chloride displacement readily afforded [Pt(CH₂Ph)(NCCH₃)(PCH₂-ox)]X (**3**), irrespective of the nature of the halide abstractor (M⁺ = Ag⁺ or Tl⁺) and counterion (X⁻ = OTf⁻, BF₄⁻, PF₆⁻) used. Reaction of **1** in CH₂Cl₂ with only half an equivalent of AgBF₄ afforded the new, chloride-bridged dinuclear complex [{Pt(CH₂Ph)(PCH₂-ox)}₂(μ -Cl)]BF₄ (**5**·BF₄), which results from trapping of the cation [Pt(η^3 -CH₂Ph)(PCH₂-ox)]⁺ (**4**) by unreacted **1**. Similarly, the Pt/Pd heterometallic, single-chloride bridged complex [{Pt(CH₂Ph)(PCH₂-ox)}(μ -Cl){PdMe(PCH₂-ox)}]BF₄ (**6**·BF₄) was obtained by reaction of **4** with [PdClMe(PCH₂-ox)] in a 1:1 ratio. When **1** was reacted in CH₂Cl₂ with Tl⁺ instead of Ag⁺, formation of **4** was not observed and the main product was an unexpected adduct of Tl⁺ to **1** whose X-ray analysis established the formation of both a Pt–Tl bond and a η^6 -benzyl–Tl interaction. This bimetallic complex, [(PCH₂-ox)ClPtTl{ μ -(η^1 -CH₂; η^6 -C₆H₅)CH₂Ph}(Pt–Tl)]PF₆ (**7**·PF₆), is to our knowledge the first metal–metal bonded Tl–Pt–Cl complex to be fully characterized. The coordination geometry around Pt(II) is square-pyramidal, with Tl(I) in the apical position. The Pt–Tl distance of 3.0942(9) Å corresponds to a metal–metal bond that results mainly from donation of electron density from the Pt(II) 5d_{z²} orbital to the vacant Tl(I) 6p_z orbital. The Pt–Tl bond is not exactly orthogonal to the Pt(II) square-plane (angle of 70(3)°), but parallel to the C(1)–C(2) bond, thus allowing better π -donation from the benzyl ligand to Tl⁺. When the corresponding benzoyl complex [Pt{C(O)Ph}Cl(PCH₂-ox)] (**9**) was reacted with MX (M⁺ = Ag⁺, Tl⁺) in CH₂Cl₂, only chloride abstraction and CO deinsertion occurred. Our findings explain why halide abstraction to generate a cationic metal complex with enhanced (catalytic) reactivity may not come to full completion or fail owing to trapping of the cationic complex or “capture” of Tl⁺ by the neutral precursor acting, in our case, as an unprecedented chelate through metal–metal bond formation and benzyl coordination. The crystal structures of **1**, **5**·BF₄·0.5CH₂Cl₂, **7**·PF₆, **9**·0.5CH₂Cl₂, and **10**·PF₆·0.75C₄H₈O have been determined by X-ray diffraction.

Introduction

Generating cationic metal complexes represents a general strategy to enhance stoichiometric and catalytic reactivity toward unactivated¹ or electron-rich substrates, which is very often performed *in situ*.² A potentially vacant or lightly stabilized coordination site

at the metal center facilitates substrate binding and activation. One of the activation procedures most frequently used in late transition metal chemistry consists in halide abstraction from the metal center in the presence of a weakly coordinating anion (WCA).³ If the

influence of the anion on the nature and catalytic activity of the resulting cationic complex has been clearly evidenced,^{3c,4} that of the halide-abstracting Lewis acid (e.g., Ag^+ , Tl^+ , Na^+ , NR_4^+ , or ZnCl_2) should also be carefully considered because of its possible relevance to the activation procedure, as demonstrated here.

With the hope of isolating and fully characterizing reaction intermediates that would be too reactive with the catalytically most relevant metals, such as Pd(II), we focused on Pt(II) systems and report here on the major effect of replacing Ag(I) with Tl(I) salts, although they are often used indiscriminately as halide abstractors. The Pt(II) complex $[\text{Pt}(\text{CH}_2\text{Ph})\text{Cl}(\text{PCH}_2\text{-ox})]$ (**1**) ($\text{PCH}_2\text{-ox} = \kappa^2\text{-}P,N\text{-}(\text{oxazolinylmethyl})\text{diphenylphosphine}$) (see Figure 1a) was chosen as a model system and is related to Ni(II) and Pd(II) complexes recently used in ethylene oligomerization,⁵ CO/olefin copolymerization,⁶ or allylic alkylation.⁷ Whereas **1** did not react with NH_4PF_6 or NaBPh_4 in THF, it quantitatively yielded the expected metathesis product $[\text{Pt}(\text{CH}_2\text{Ph})(\text{OTf})(\text{PCH}_2\text{-ox})]$ (**2**) when treated with 1 equiv of AgOTf (OTf = SO_3CF_3) in CH_2Cl_2 . In a coordinating solvent like acetonitrile, chloride displacement readily afforded $[\text{Pt}(\text{CH}_2\text{Ph})(\text{NCCH}_3)(\text{PCH}_2\text{-ox})]^+\text{X}^-$ (**3**), irrespective of the nature of the halide abstractor ($\text{M}^+ = \text{Ag}^+$ or Tl^+) and counterion ($\text{X}^- = \text{OTf}^-$, BF_4^- , PF_6^-) used.

In the absence of relatively good donor ligands, such as OTf^- or acetonitrile, abstraction of the halide from **1** by 1 equiv of AgBF_4 or AgPF_6 in CH_2Cl_2 resulted in the formation of a dynamic, cationic complex. It was formulated as $[\text{Pt}(\text{CH}_2\text{Ph})(\text{PCH}_2\text{-ox})]^+$ (**4**) on the basis of its ES mass spectrum, which shows only one peak at m/z 555 with the correct isotopic distribution. This complex is likely to contain an η^3 -benzyl ligand,⁸ as supported by its quantitative conversion to **3** upon

dissolution in CDCl_3 containing a drop of acetonitrile ($^{31}\text{P}\{^1\text{H}\}$ NMR monitoring).

Reaction of **1** in CH_2Cl_2 with only half an equivalent of AgBF_4 afforded the new, chloride-bridged dinuclear complex **5** (Scheme 2). It clearly results from trapping of the cation **4** by unreacted **1**, and accordingly, **5** was also obtained by reaction of **4** with 1 equiv of **1** in CH_2Cl_2 . Such complexes with a single halide bridge⁹ are attracting renewed interest because they illustrate a possible deactivation route of cationic catalytic intermediates.¹⁰ Only four dinuclear, single-bridged Pt(II) chloro complexes appear to have been structurally characterized (CSD version 5.25).¹¹ The Pt1–Cl–Pt2 angle in **5** is $119.1(3)^\circ$, and the Pt–Cl distances of

Scheme 3

2.401(2) and 2.390(2) Å are, as expected, slightly longer than that in **1** (2.359(1) Å) (Figure 1b). The two metal coordination planes are almost orthogonal to each other (87(1)°).

Reaction pathway I in Scheme 2 suggests a possible extension to the synthesis of heterometallic single-chloride-bridged complexes. Reaction between **4** and [PdClMe(PCH₂-ox)]⁶ in a 1:1 ratio indeed yielded [(Pt-(CH₂Ph)(PCH₂-ox))(μ-Cl)(PdMe(PCH₂-ox))]BF₄ (**6**·BF₄). Both, the Pt/Pt (**5**·BF₄) and Pt/Pd (**6**·BF₄) complexes react irreversibly with acetonitrile by splitting of the bridge to afford [Pt(CH₂Ph)Cl(PCH₂-ox)] (**1**) and the solvento species [Pt(CH₂Ph)(NCMe)(PCH₂-ox)]BF₄ (**3**·BF₄), and **1** and the known [PdMe(NCMe)(PCH₂-ox)]BF₄,⁶ respectively,¹² consistent in the latter case with a stronger Pt–Cl than Pd–Cl bond in **6**·BF₄.

When Ag⁺ was replaced with Tl⁺ as chloride abstractor, **4** was not observed. TlCl appeared only in traces, and the main product (**7**) turned out to be an unexpected adduct of Tl⁺ to **1**, which readily crystallized (Scheme 3). Its X-ray analysis established the formation of both a Pt–Tl bond and a η⁶-benzyl–Tl interaction (Figure 2). This bimetallic complex, [(PCH₂-ox)ClPtTl{μ-(η¹-

CH₂;η⁶-C₆H₅)/CH₂Ph}(Pt–Tl)]PF₆ (**7**·PF₆), was also formed when only half an equivalent of TlPF₆ was used, illustrating that Tl⁺ is less reactive than Ag⁺ toward the Pt–Cl bond, although the bond formation enthalpies for TlCl and AgCl are ΔH_f = –204 and –127 kJ/mol, respectively.¹³ Solutions of **7**·PF₆ in CH₂Cl₂ are stable for weeks, but in coordinating solvents, like acetone and acetonitrile, elimination of TlCl occurs immediately with formation of the corresponding solvento species [Pt(CH₂-Ph)(PCH₂-ox)(solvent)]⁺.

To our knowledge, **7**·PF₆ is the first metal–metal bonded Tl–Pt–Cl complex to be fully characterized.¹⁴ The coordination geometry around Pt(II) is square-pyramidal, with Tl(I) in the apical position (Figure 2). The Pt–Tl distance of 3.0942(9) Å is in the range found for the few other d⁸–s² Pt(II)–Tl(I) bonds reported in the literature: 2.79–3.14 Å (CSD version 5.25).¹⁵ The metal–metal bond in **7**·PF₆ is best described as resulting mainly from donation of electron density from the Pt(II) 5d_{z²} orbital to the vacant Tl(I) 6p_z orbital.¹⁶ The Pt–Tl bond is not exactly orthogonal to the Pt(II) square-plane (angle of 70(3)°), but parallel to the C(1)–C(2) bond (Figure 2b). This deviation is likely to allow better π-donation from the benzyl ligand to Tl⁺. The distances between the benzyl carbon atoms C(2)–C(7) and Tl⁺ are in the range 3.015(5)–3.620(5) Å, so that Tl⁺ is not perfectly above the centroid of the aromatic ring. The occurrence of both metal–metal and benzyl–Tl⁺ bonding results in an unprecedented “chelating” behavior for a Pt–benzyl complex. We believe that these interactions are, at least in part, retained in CH₂Cl₂ solution since no precipitation of TlCl (or TlPF₆) was observed. The ³¹P{¹H} NMR spectrum shows no resolved ²J(P–Tl) coupling and only a minor change in the ¹J(Pt–P) coupling.^{15f} No ¹J(Pt–Tl) coupling was detected in the ¹⁹⁵Pt{¹H} NMR spectrum in CD₂Cl₂ or CDCl₃ solution, and only a broadening of the signal was observed (Δν_{1/2} ca. 500 Hz). This is consistent with a weak s-character¹⁷ and an important ionic contribution to the Pt–Tl bond and/or a longer Pt–Tl distance in solution, probably for the benefit of a stronger Tl–η⁶-benzyl interaction no longer limited by geometrical constraints. The weak intermolecular Tl–F interactions of 2.91(1) and 3.09(1) Å are similar to those in Pt(II)–Tl(I) complexes with C₆F₅ substituents at the Pt center.^{15e} Because no Tl–F coupling was detected in the ¹⁹F{¹H} NMR at room temperature, it is likely that the ion pair **7**·PF₆ is more separate in solution. No significant change in the NMR spectrum was observed down to –80 °C; in particular no diagnostic coupling to Tl was detected. The structural features of **7**·PF₆ are different

Moreover, dissolving equivalent amounts of **1** and **3**·BF₄ in CDCl₃, in place of CD₃CN, did not lead to the formation of **5**·BF₄.

of [PtClPh(PCH₂-ox)] (**8**) afforded [Pt{C(O)Ph}Cl(PCH₂-ox)] (**9**) (Figure 3a), which was reacted with MX ($M^+ = \text{Ag}^+, \text{Tl}^+$) in CH_2Cl_2 . This resulted exclusively in chloride abstraction and CO deinsertion (Scheme 4). That the phenyl ligand in **10** is *trans* to P, in contrast to *trans* to N in **8**, was established by X-ray diffraction (Figure 3b) and results from the respective *trans* influences of the ligands. A comparison of the molecular structures of the benzyl complex **1** and the benzoyl complex **9** shows that although the Pt–C1–C2 angles are similar in both cases (115.9(4)° (**1**), 121(1)° (**9**)), coordination of the aromatic moiety of **9** to a Pt-bound Tl⁺ would not be possible due to an unfavorable Pt–C–aryl torsion angle (Pt–C1–C2–C3): 64.7(6)° (**1**), 87.1(5)° (**7**), 164(1)° (**9**). The orientation of the aryl ring in **9** is due to the π -interaction with the carbonyl group.

Conclusion

Our findings explain why a procedure widely used to abstract a halide ligand in order to generate a positively charged metal complex with enhanced (catalytic) reactivity may not come to full completion or fail owing to either trapping of the cationic complex by the neutral precursor molecule or unexpected "capture" of the Tl(I) cation by the neutral complex acting, in our case, as an unprecedented chelate through metal–metal bond formation and η^6 -benzyl coordination. The bonding interaction between the d^8 Pt(II) and s^2 Tl(I) center is assisted by π -donation from the benzyl ligand to the Tl⁺ ion. That such interactions were not evidenced in the case of the benzoyl ligand emphasizes the importance of relatively small structural differences (CO vs CH₂) on the reactivity of typical organometallic chloride complexes toward usual halide abstractors. Similar ligand-assisted metallophilic interactions may have a broader scope in reactivity studies and catalysis than previously thought. In this context, it is interesting to note that related alkali metal cation– π interactions involving unsaturated organic moieties continue to attract considerable interest owing to their intrinsic nature and their potential importance in biological systems and for the synthesis of novel molecular devices.¹⁹

Experimental Section

General Procedures. All manipulations were carried out under inert dinitrogen atmosphere, using standard Schlenk-line conditions and dried and freshly distilled solvents. The ¹H, ¹H{³¹P}, ¹³C{¹H}, ¹⁹F{¹H}, and ³¹P{¹H} NMR spectra were recorded on a Bruker Avance 300 instrument at 300.13, 75.47, 282.40, and 121.49 MHz, respectively, using TMS, CFCl₃, or H₃PO₄ (85% in D₂O) as external standards. The ¹⁹⁵Pt{¹H} NMR spectra were recorded on a Bruker Avance 400 at 86.02 MHz using H₆PtCl₆ in D₂O as external standard. The irradiation experiments on **5**·BF₄ were carried out on a Bruker Avance 500 at 500.13 MHz. All NMR spectra were measured at 298 K, unless otherwise specified. The assignment of the signals was made by ¹H, ¹H-COSY and ¹H, ¹³C-HMQC experiments. IR spectra were recorded as KBr pellets on a FT-IR IFS66 Bruker spectrometer. Elemental C, H, and N analyses were performed by the "Service de Microanalyses", Université Louis Pasteur, Strasbourg. ES mass spectra were recorded on a Bruker Daltonics microTOF mass spectrometer.

The ¹H NMR spectra of oxazoline systems *N*-coordinated to Pt always show the typical AA'BB' system for the two methylene groups; the NCH₂ group can additionally show a ⁵J_{H-H} to the PCH₂ group. When BF₄⁻ was used as counterion, the ¹⁹F{¹H} spectra provided the appropriate signal with the pattern typical for ¹⁰B–¹⁹F and ¹¹B–¹⁹F.²⁰

The following compounds were synthesized according to literature procedures: [Pt(CH₂Ph)Cl(cod)],²¹ [PtClPh(cod)],²¹

PCH₂-ox,⁶ [Au(PPh₃)Cl],²² [Cu(NCMe)₄]BF₄,²³ Other chemicals were commercially available and used as received. All yields given are based on Pt.

Synthesis and Spectroscopic Data for [Pt(CH₂Ph)Cl(PCH₂-ox)] (1). Solid [Pt(CH₂Ph)Cl(cod)] (0.39 g, 0.91 mmol) and PCH₂-ox (0.25 g, 0.93 mmol) were dissolved in CH₂Cl₂ (20 mL), and the resulting solution was stirred for 3 h at room temperature. Removing all volatiles yielded an off-white residue, which was washed with diethyl ether (2 × 15 mL) and pentane (20 mL) and dried in vacuo to afford the product as a white powder (0.49 g, 0.83 mmol, 91%). Synthesis and Spectroscopic Data for [Pt(CH₂Ph)(NCMe)(PCH₂-ox)]BF₄ (3·BF₄). Solid [Pt(CH₂Ph)Cl(PCH₂-ox)] (1) (0.21 g, 0.36 mmol) was dissolved in CH₃CN (25 mL), and AgBF₄ (0.07 g, 0.36 mmol) was added in one portion. A white precipitate was formed immediately, and the mixture was stirred at room temperature for 1.5 h. The solvent was removed in vacuo and the residue extracted with CH₂Cl₂ (2 × 20 mL). After reducing the volume in vacuo, the product was obtained as an off-white powder by addition of diethyl ether. The elemental analysis proved the formation of a diethyl ether adduct (0.24 g, 0.32 mmol, 89%). Anal. Calcd for C₂₅H₂₆BF₄N₂·OPPt·C₄H₁₀O (757.48): C 45.98, H 4.79, N 3.70. NMR spectra showed the existence of mixture of $[\text{Au}(\text{PPh}_3)_2]\text{BF}_4$ and $[\{\text{Pt}(\text{CH}_2\text{Ph})(\text{PCH}_2\text{-ox})\}_2(\mu\text{-Cl})]\text{BF}_4$ (**5**· BF_4).

Procedure D. A mixture of equimolar amounts of **1** and **4**· BF_4 in CDCl_3 also led to the formation of **5**· BF_4 ; the reaction was monitored by $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy.

Synthesis and Spectroscopic Data for $[\{\text{Pt}(\text{CH}_2\text{Ph})(\text{PCH}_2\text{-ox})\}(\mu\text{-Cl})\{\text{PdMe}(\text{PCH}_2\text{-ox})\}]\text{BF}_4$ (6**· BF_4).** To a solution of $[\text{Pt}(\text{CH}_2\text{Ph})\text{Cl}(\text{PCH}_2\text{-ox})]$ (**1**) (0.16 g, 0.27 mmol) in CH_2Cl_2 or THF (15 mL) at $-60\text{ }^{\circ}\text{C}$ was added AgBF_4 (0.06 g, 0.31 mmol) in one portion. The mixture was stirred for 1.5 h at room temperature, some Celite was added, and the mixture was stirred for an additional 30 min. The solution was then filtered into a solution of $[\text{PdMeCl}(\text{PCH}_2\text{-ox})]$ (0.12 g, 0.27 mol) in CH_2Cl_2 or THF (15 mL) at $-60\text{ }^{\circ}\text{C}$, and stirring was continued for an additional 2 h. After removing the solvent in vacuo, the residue was extracted with THF (20 mL) and the volume of the solution was reduced again. Addition of diethyl ether afforded a beige powder of the product as a THF adduct (0.26 g, 0.23 mmol, 85%). Anal. The diffraction data were collected on a Nonius Kappa-CCD area detector diffractometer (Mo K α , $\lambda = 0.71070$ Å; ϕ scan) at $T = 173(2)$ K. The complete conditions of the data collection (Denzo software) and structural refinements are given below. The cell parameters were determined from reflections taken from one set of 10 frames (1.0° steps in ϕ angle), each at 20 s exposure. The structures were solved using direct methods (SHELXS97) and refined against F^2 using the SHELXL97 software. The absorption was corrected empirically (with Sortav)^{26a} for compounds **1**, **5**·BF₄·0.5CH₂Cl₂, **7**·PF₆, and **9**·0.5-CH₂Cl₂. Largest peaks are near the Pt atoms (at 0.88 and 0.92 Å). All non-hydrogen atoms were refined anisotropically unless otherwise specified. Hydrogen atoms were generated according to stereochemistry and refined using a riding model in SHELXL97.^{26b}

Complex 1: C₂₃H₂₃ClNO₂Pt; $M = 590.93$; monoclinic, $P2_1$ / a ; $a = 16.103(2)$ Å, $b = 8.642(1)$ Å, $c = 17.032(2)$ Å, $\beta = 114.11(5)^\circ$; $V = 2163.4(4)$ Å³, $Z = 4$, $D_c = 1.814$ g cm⁻³, $\mu = 6.697$ mm⁻¹, $F(000) = 1144$; $T_{\text{min/max}} = 0.318/0.408$. Colorless prisms, dimensions $0.14 \times 0.13 \times 0.11$ mm³; total number of collected reflections 9400 (independent 9399), with 6804 having $I > 2\sigma$

(I); $2.62^\circ < \theta < 34.96^\circ$; 253 parameters. Final results: $R1 = 0.0511$; $wR2 = 0.1392$, $\text{Gof} = 1.001$, max./min. residual electronic density = $4.548/-3.877$ e Å⁻³.

Complex 7·PF₆: C₂₃H₂₃ClF₆NOP₂PtTl; $M = 940.27$; triclinic, $P\bar{1}$; $a = 8.864(1)$ Å, $b = 11.287(1)$ Å, $c = 13.984(1)$ Å, $\alpha = 80.83(3)^\circ$, $\beta = 72.74(3)^\circ$, $\gamma = 84.38(3)^\circ$; $V = 1317.1(2)$ Å³, $Z = 2$, $D_c = 2.371$ g cm⁻³, $\mu = 11.698$ mm⁻¹, $F(000) = 872$; $T_{\text{min/max}} = 0.214/0.339$. Colorless needles, dimensions $0.12 \times 0.10 \times 0.11$ mm³; total number of collected reflections 9064 (independent 6017), with 5346 having $I > 2\sigma(I)$; $1.54^\circ < \theta < 27.46^\circ$; 325 parameters. Final results: $R1 = 0.0284$; $wR2 = 0.0920$, $\text{Gof} = 1.209$, max./min. residual electronic density = $0.901/-2.403$ e Å⁻³.

Complex 9·0.5CH₂Cl₂: C₂₃H₂₁ClNO₂PtP₂·0.5CH₂Cl₂; $M = 647.38$; monoclinic, $P2_1/a$; $a = 11.094(1)$ Å, $b = 12.717(1)$ Å, $c = 16.605(1)$ Å, $\beta = 104.04(5)^\circ$; $V = 2272.7(3)$ Å³, $Z = 4$, $D_c = 1.892$ g cm⁻³, $\mu = 6.501$ mm⁻¹, $F(000) = 1252$, $T_{\text{min,max}} = 0.574/0.602$. Pale yellow prisms, dimensions $0.08 \times 0.07 \times 0.07$ mm³; total number of collected reflections 11 590 (independent 6631), with 3687 having $I > 2\sigma(I)$; $1.26^\circ < \theta < 30.02^\circ$; 270 parameters. Final results: $R1 = 0.1201$; $wR2 = 0.1404$, $\text{Gof} = 1.119$, max./min. residual electronic density = $2.43/-1.86$ e Å⁻³. The heavy atoms of the solvent molecules have only been refined isotropically. A disordered CH₂Cl₂ molecule (occupancy factor = 0.5) was found near to the -1 symmetry center (0,0,0.5), which could account for the relatively large $wR2$ value.

Complex 10·PF₆·0.75C₄H₈O: C₂₃H₂₁F₆NO₂P₂Pt·0.75C₄H₈O; $M = 768.52$; orthorhombic, $P2_12_12_1$; $a = 9.849(1)$ Å, $b = 12.830(3)$ Å, $c = 22.661(5)$ Å; $V = 2864(1)$ Å³, $Z = 4$, $D_c = 1.783$ g cm⁻³, $\mu = 5.078$ mm⁻¹, $F(000) = 1496$. Off-white prisms, dimensions $0.08 \times 0.07 \times 0.07$ mm³; total number of collected reflections 25 904 (independent 6565), with 5301 having $I > 2\sigma(I)$; $1.59^\circ < \theta < 27.47^\circ$; 334 parameters. Final results: $R1 = 0.0550$; $wR2 = 0.1311$, $\text{Gof} = 1.033$, max./min. residual electronic density = $1.712/-1.912$ e Å⁻³; Flack parameter 0.004(13). The heavy atoms of the solvent molecules have only been refined isotropically, leading to one residue corresponding to a THF molecule with occupancy factor 0.5 and another THF molecule with occupancy factor 0.25.

Crystallographic data for these structures have been deposited with the Cambridge Crystallographic Data Centre as Supplementary Publication nos. CCDC 241929–241933. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: (44) 1223-336-033; e-mail: deposit@ccdc.cam.ac.uk).
