Received October 30, 2006

Tungsten alkylidene complexes that contain the 2,6-dichlorophenylimido ligand (NAr_{Cl}), W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) (OR_{F6} = OCMe(CF₃)₂; Biphen²⁻ = 3,3'-dit-Bu-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diolate; THP = tetrahydropyran), have been prepared from W(NAr_{Cl})(CHCMe₃)(OSO₂CF₃)₂(dme). Reaction of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ with excess ethylene gave the tungstacyclobutane complex W(NAr_{Cl})(OR_{F6})₂(C₃H₆), while reaction of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ with internal olefins gave the dimer, [W(μ -NAr_{Cl})(OR_{F6})₂]₂. W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) reacted with excess ethylene to give W(NAr_{Cl})(Biphen)(C₃H₆), which yielded W(NAr_{Cl})(Biphen)(C₂H₄)(THF) upon addition of THF. The tungstacyclopentane complex, W(NAr_{Cl})(Biphen)(C₄H₈), was formed upon treatment of W(NAr_{Cl})(Biphen)(C₂H₄)(THF) with ethylene. W(NAr_{Cl})(Biphen)(C₃H₆) decomposed to yield (*inter alia*) the dimeric, heterochiral methylidene complex, [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂, which decomposed further to yield homochiral [W(NAr_{Cl})(Biphen)]₂(μ -CH₂CH₂). Finally, [W(NAr_{Cl})(Biphen)]₂-(μ -CH₂CH₂) loses ethylene reversibly to yield [W(NAr_{Cl})(Biphen)]₂, which could not be isolated in pure form. {W(μ -NAr_{Cl})[OC(CF₃)₂Me]₂}₂, W(NAr_{Cl})(Biphen)(C₃H₆), W(NAr_{Cl})(Biphen)(C₂H₄)(THF), W(NAr_{Cl})(Biphen)(C₄H₆), [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂, and [W(NAr_{Cl})(Biphen)]₂(μ -CH₂CH₂) were characterized through X-ray studies.

Introduction

Imido alkylidene bisalkoxide complexes of molybdenum or tungsten of the type M(NR)(CHR')(OR")₂ are now established as well-defined high oxidation state olefin metathesis catalysts.¹ The overall efficiencies shown by such catalysts are controlled to a dramatic degree by the electronic and steric characteristics of the NR and OR" groups. Since the rate of decomposition is part of overall efficiency, the stability of the alkylidenes that are accessible during the catalytic reaction is an issue; for example, methylene species are likely to be formed in the presence of ethylene or terminal olefins, and they are especially susceptible to bimolecular decomposition to yield "reduced" metal species. In order to understand and predict the reactivity of M(NR)(CHR')(OR")₂ species, catalysts that contain new imido and alkoxide (or diolate) groups are continually being synthesized and evaluated. Recently many catalysts for asymmetric metathesis reactions that contain an enantiomerically pure diolate ligand have been prepared and employed in a variety of asymmetric metathesis reactions.^{1a}

The most common imido ligands that have been employed in M(NR)(CHR')(OR'')₂ catalysts are N-2,6-i-Pr₂C₆H₃, N-2,6-Me₂C₆H₃, N-2-t-BuC₆H₄, N-2-CF₃C₆H₄, N-2,6-Cl₂C₆H₃, and N-1-adamantyl. ^{1a} Molybdenum catalysts that contain the 2,6-dichlorophenylimido (NAr_{Cl}) ligand² and an enantiomerically pure biphenolate or binaphtholate ligand have shown reactivities with some substrates that are not duplicated in terms of conversion and % ee by other imido/diolate combinations that have been tried. The NAr_{Cl} ligand is one of the smallest aryl

substituents and is relatively electron withdrawing. The NAr_{Cl} ligand also is likely to be a relatively robust ligand, since there is no opportunity for CH activation in substituents in the 2 or 6 positions of the aryl ring, a complicating feature of some recent chemistry involving 2,6-dimethylimido complexes.³ Finally, the only crystallographically characterized example of a M(NR)-(OR'')₂(olefin) complex is a molybdenum complex that contains the NAr_{Cl} ligand, namely, Mo(NAr_{Cl})(Biphen)(C₂H₄)(Et₂O) (Biphen²⁻ = 3,3'-di-t-Bu-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diolate).⁴

W(NR)(CHR')(OR")₂ catalysts were discovered and developed before Mo(NR)(CHR')(OR")₂ catalysts.⁵ However, tungsten forms relatively stable tungstacyclobutane species, especially unsubstituted tungstacyclobutanes, a circumstance that has been proposed to limit alkylidenes that are available for metathesis at temperatures where the WC₃ ring does not lose olefin readily. Molybdenum catalysts have gained favor over tungsten catalysts since molybdacyclobutane species appear to lose an olefin more readily. However, that is not to say that tungsten catalysts would not be preferred in certain circumstances.

Reactions of W(NAr)(CHR')(Biphen) (Ar = 2,6-i-Pr₂C₆H₃) species with ¹³C-labeled ethylene revealed a relatively complete picture of the initiation, propagation, and decomposition reactions under ethylene.⁶ Unfortunately, several of the interesting species that were observed (ethylene, tungstacyclobutane, and tungstacyclopentane complexes) could not be isolated. The most

interesting of the unisolated species observed in this study was a dimeric complex, $[W(NAr)(Biphen)(\mu-CH_2)]_2$, in which an unsymmetrically bridging methylene ligand bound to one tungsten was proposed to behave as a "donor" toward the second tungsten. This species was proposed to be heterochiral, i.e., $\{W-(NAr)[(S)-Biphen](\mu-CH_2)\}\{W(NAr)[(R)-Biphen](\mu-CH_2)\}$. $[W(NAr)(Biphen)(\mu-CH_2)]_2$ was not observed in a system in which the Biphen²⁻ ligand was enantiomerically pure.

We decided to attempt to synthesize tungsten species that contain the 2,6-dichlorophenylimido ligand in order to compare them with molybdenum species. Our goal was to prepare two prototypical tungsten alkylidene complexes of the type W(NAr_{Cl})-(CHCMe₃)(OR")₂, one in which $OR'' = OC(CF_3)_2Me$ (OR_{F6}) and the other in which $(OR")_2 = (Biphen)$, and to explore their reactions with selected olefins. These experiments are the subject of this paper.

Results

Syntheses of W(NAr_{Cl})(CHCMe₃)[OC(CF₃)₂Me]₂ and W-(NAr_{Cl})(CHCMe₃)(Biphen)(THP) (THP = tetrahydropyran). The synthesis of W(NAr_{Cl}) complexes follows the traditional route. W(NAr_{Cl})₂Cl₂(DME) (DME = 1,2-dimethoxyethane) is first prepared in a reaction between Me₃SiCl, 2,6-lutidine, and WO₂Cl₂ in dimethoxyethane. Alkylation of W(NAr_{Cl})₂-Cl₂(DME) with Me₃CCH₂MgCl to give W(NAr_{Cl})₂(CH₂CMe₃)₂ proceeded without complication. W(NAr_{Cl})₂Cl₂(DME) and W(NAr_{Cl})₂(CH₂CMe₃)₂ have been reported in a recent Ph.D. thesis. Experimental details are reported in this paper for convenience.

Addition of 3 equiv of triflic acid to W(NAr_{Cl})₂(CH₂CMe₃)₂ in DME produced W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME) as bright yellow microcrystals in 57% yield. NMR data are consistent with W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME) being a 1:1 mixture of two isomers in C₆D₆ (δ H_{α} = 11.80 and 10.96 ppm) and a 5:1 mixture of two isomers in CD₂Cl₂ (δ H_{α} = 11.52 and 10.83 ppm). The isomer in which the alkylidene proton resonance has the smaller chemical shift has mirror symmetry and is proposed to be that in which the triflate ligands are *trans* to one another. (The molybdenum analogue, Mo(N-2,6-i-Pr₂C₆H₃)(CHCMe₃)-(OTf)₂(DME), has this geometry.⁹) The isomer in which the alkylidene proton resonance has the larger chemical shift has no symmetry and is believed to be one of the possible species in which the triflate ligands are *cis* to one another; its precise structure is not known.

Bright yellow crystals of $W(NAr_{Cl})(CHCMe_3)(OR_{F6})_2$ (OR_{F6} = $OC(CF_3)_2Me$) could be isolated from the reaction between $W(NAr_{Cl})(CHCMe_3)(OTf)_2(DME)$ (as the mixture of isomers described above) and 2 equiv of $LiOR_{F6}$ in toluene (6 mmol scale, 80% yield). Alternatively, $W(NAr_{Cl})(CHCMe_3)(OR_{F6})_2$ can be prepared in a reaction between $W(NAr_{Cl})(CHCMe_3)(OTf)_2(DME)$ and 2 equiv of $(CF_3)_2MeCOH$ in the presence of 2,6-lutidine, as shown in eq 1. The method shown in eq 1 avoids the alkoxide anion, which in some circumstances leads to deprotonation of an alkylidene to give an alkylidyne species. 10 Only the syn isomer of $W(NAr_{Cl})(CHCMe_3)(OR_{F6})_2$ is observed

$$W(NAr_{Cl})(CHCMe_3)(OTf)_2(DME) \xrightarrow{\begin{array}{c} 2 \text{ } 2,6\text{-lutidine} \\ \text{benzene} \\ -2 [2,6\text{-lutidineH}]OTf \end{array}} R_{F6}O \xrightarrow{H} CMe_3$$

$$(1)$$

in C_6D_6 at 25 °C. The neopentylidene α proton resonance was found at 8.91 ppm ($^2J_{WH}=14.1$ Hz, $^1J_{CH}=115.2$ Hz) in the 1H NMR spectrum, and the α carbon resonance was found at 257.3 ppm ($^1J_{WC}=195.9$ Hz) in the ^{13}C NMR spectrum.

The Biphen²⁻ complex, W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) (THP = tetrahydropyran), was prepared in a reaction between W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and Li₂Biphen in toluene in the presence of THP on a 2.6 mmol scale and isolated as a benzene-soluble pale yellow powder in 82% yield (eq 2). (It should be

$$R_{F6}O$$

$$R_{F$$

assumed that all Biphen^{2–} complexes in this paper contain rac-Biphen^{2–}, unless otherwise noted.) Attempts to prepare W(NAr_{Cl})-(CHCMe₃)(Biphen)(THF) by adding K₂Biphen to W(NAr_{Cl})-(CHCMe₃)(OTf)₂(DME) or W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ in the presence of THF failed. It appears that polyTHF is formed in either reaction, which compromises the yield and the ease of product isolation. In W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) the alkylidene H_{α} resonance in C₆D₆ at 25 °C is observed at 9.19 ppm (² J_{WH} = 8.3 Hz, ¹ J_{CH} = 109.4 Hz) in the ¹H NMR spectrum. This resonance is assigned to a syn isomer on the basis of the low value for ¹ J_{CH} . The alkylidene α carbon atom resonance is found at 266.5 ppm in the ¹³C NMR spectrum. The structure is likely to be one in which the imido and alkylidene ligands occupy equatorial positions in a trigonal bipyramid, a common structure for simple adducts.

Reactivity of W(NAr_{Cl})(CHCMe₃)[OC(CF₃)₂Me]₂ toward Olefins. W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ reacts readily with ethylene (1 atm) in benzene to yield the metallacyclobutane complex W(NAr_{Cl})(C₃H₆)(OR_{F6})₂ (eq 3); on a 0.3 mmol scale the product was isolated in 90% yield. A color change is observed immediately. NMR data suggest that the reaction is complete in less than 15 min with the only organic product being *tert*-butylethylene. NMR data are consistent with the product having a trigonal bipyramidal structure in solution with the alkoxides occupying equatorial and apical positions, as shown.¹¹

A species of this type has been crystallographically characterized where the alkoxide is $OC(CF_3)_2(CF_2CF_2CF_3)$ and the imido ligand is 2,6-diisopropylphenyl. ^{5a} Tungstacyclobutane species that contain the Biphen²⁻ ligand have also been crystallographically characterized. ⁶ The α methylene resonances in the WC_3 ring in $W(NAr_{Cl})(OR_{F6})_2(C_3H_6)$ are found at 4.91 and 4.77 ppm in the proton NMR spectrum in C_6D_6 , while the β methylene resonances are found at -0.87 and -1.46 ppm. The ¹³C NMR spectrum exhibits characteristic resonances at 103.4 ppm for the α carbon atoms in the WC_3 ring (with ¹ J_{CH} values of 160.6

and 165.2 Hz) and at -4.7 ppm for the β carbon atom in the WC_3 ring (with ${}^1J_{CH}$ values of 162.0 and 166.2 Hz). The reaction between W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and ethylene is proposed to yield an initial α -t-Bu-substituted tungstacyclobutane complex that loses tert-butylethylene to yield intermediate W(NArCI)-(CH₂)(OR_{F6})₂. This methylene species is then trapped with ethylene to give the observed product. W(NAr_{Cl})(C₃H₆)(OR_{F6})₂ does not lose ethylene readily in the absence of excess ethylene at room temperature, since the resulting methylene species almost certainly would decompose readily in a bimolecular fashion and thereby provide a facile decomposition pathway for $W(NAr_{Cl})(C_3H_6)(OR_{F6})_2$ overall.

We were somewhat surprised to find that W(NAr_{Cl})(CHCMe₃)-(OR_{F6})₂ reacts relatively readily with 1 equiv of 2-methyl-2butene in benzene. After 15 min the bright yellow solution turned orange and purple microcrystals were deposited. After 7 days at 25 °C the purple product was isolated in 75% yield on a 0.3 mmol scale. According to ¹H and ¹⁹F NMR spectra W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ was the only fluorine-containing species observable in solution at any point during the reaction. The purple microcrystals are insoluble in pentane, benzene, and dichloromethane and are only sparingly soluble in THF. On the basis of an X-ray structure (vide infra) the purple product was shown to be a dimeric species that contains bridging imido ligands, $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$, in which one of the ortho chlorides in each bridging imido group is bonded weakly to one of the tungsten centers, as shown schematically in eq 4.

$$\begin{array}{c} Ar_{Cl} \\ R_{F6}O \\ \end{array} \begin{array}{c} Ar_{Cl} \\ R_{F6}O \\ \end{array} \begin{array}{c} Cl \\$$

The presence of only one ¹⁹F resonance in the room-temperature ¹⁹F NMR spectrum of $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ at -79.0 ppm in THF- d_8 suggests that this structure is not maintained in solution on the NMR time scale. Recently, we have shown that [W(NR)-(OR")₂]₂ species are formed upon decomposition of W(NR)-(CHR')(OR")₂ species when the CHR' ligand is relatively small (e.g., ethylidene or propylidene). 12 We propose that ethylidene complexes formed in the reaction shown in eq 4 decompose most readily and lead to the observed dimeric species, although precise details are uncertain.

The structure of [W(NAr_{Cl})(OR_{F6})₂]₂ (Table 1) is shown in Figure 1. All non-hydrogen atoms of the imido group lie approximately in a plane that is orthogonal to the plane that contains both tungsten atoms and the four oxygen atoms. The geometry around each tungsten atom is approximately a trigonal bipyramid with one bridging chloride and one nitrogen atom in the apical position; the equatorial positions are occupied by the other bridging nitrogen and two alkoxide oxygens. The bridging imido ligands are asymmetrically disposed with the "equatorial" W(1)-N(1) distance being shorter (1.897(17) Å) than the "axial" W(1)'-N(1) distance (2.0265(17) Å). A greater degree of π bonding to the nitrogen in an "equatorial" position around W(1) is believed to be the reason for the shorter W(1)-N(1) bond. The short W-Cl distance (W(1)-Cl(1) = 2.6136(5) Å) should be compared with the distance between the other tungsten center and the other ortho chloride in one aryl ring (W(1)'-Cl(2))3.5845(6) Å), which is clearly nonbonding. The W(1)-Cl(1) distance is similar to the Mo-Cl bond length (2.624(1) Å) in the Schiff base complex $Mo(C_{13}H_8Cl_2N)Cl(CO)_3$ that contains

^{(12) (}a) Lopez, L. P. H.; Schrock, R. R. J. Am. Chem. Soc. 2004, 126, 9526. (b) Lopez, L. P. H.; Schrock, R. R.; Müller, P. Organometallics 2006, 25, 1978.

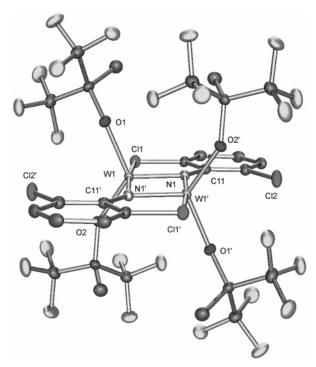

Figure 1. Molecular structure of $\{W(\mu\text{-NAr}_{Cl})[OC(CF_3)_2Me]_2\}_{2-(C_6H_6)}$. Hydrogen and solvate atoms are omitted for clarity; thermal ellipsoids are drawn at 50% probability level. Selected bond lengths [Å] and angles [deg]: W-N(1)=1.8965(17), W-N(1)'=2.0265-(17), W-O(1)=1.9511(14), W-O(2)=1.9214(14), W-Cl(1)=2.6136(5), W-W'=2.5297(3), Cl(1)-W-N(1)'=173.31(5), O(1)-W-N(1)=115.22(7), O(1)-W-O(2)=122.36(6).

a dative aryl Cl to Mo interaction.¹³ The chlorides (Cl(1) and Cl(1')) are bound in approximately axial positions *trans* to the imido nitrogens. [W(μ -NAr_{Cl})(OR_{F6})₂]₂ is the only complex in the category of [W(NR)(OR")₂]₂ complexes¹² that does not contain an unsupported double bond. Formation of a species that contains a bridging NAr_{Cl} group might be encouraged through binding of a chlorine. The interatomic W1–W1' distance in [W(NAr_{Cl})(OR_{F6})₂]₂ (2.5297(3) Å) is slightly longer than in related tungsten complexes that contain unsupported double bonds (2.4445(3)–2.4925(3) Å).¹² It is interesting to note that [Mo(μ -NAr)(OCMe₃)₂]₂ (Ar = 2,6-diisopropylphenyl) is a purple dimer that contains bridging imido ligands and that the Mo–Mo distance in this species is 2.654(1) Å.¹⁴

When a benzene solution of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ is treated with an excess of propylene, the color of the solution changes rapidly from bright yellow to pale yellow. NMR spectra showed that the parent alkylidene complex had been converted into the unsubstituted tungstacyclobutane complex, W(NAr_{Cl})-(C₃H₆)(OR_{F6})₂. No intermediate tungsten species were observed under these conditions. We presume that W(NAr_{Cl})(CH₂)(OR_{F6})₂ is formed and trapped with ethylene (that is generated through metathesis of propylene) to yield the observed product.

In a reaction between $W(NAr_{Cl})(CHCMe_3)(OR_{F6})_2$ and 1 equiv of styrene the color of the solution changed from bright yellow to dark brown within 45 min. At this time 90% of the $W(NAr_{Cl})(CHCMe_3)(OR_{F6})_2$ had been converted into a mixture of $W(NAr_{Cl})(C_3H_6)(OR_{F6})_2$ and $(Me_3C)CH=CHPh$ and minor unidentified products. After 16 h at 25 °C, the yellow solution

contained W(NAr_{Cl})(C₃H₆)(OR_{F6})₂ as the only tungsten species along with a minor amount of $[W(\mu\text{-NAr}_{Cl})(OR_{F6})_2]_2$ as a purple deposit.

The reaction between W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and 1 equiv of *trans*-3-hexene after 40 min at 0 °C yielded a 2:1:1 mixture of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂, W(NAr_{Cl})(CHEt)-(OR_{F6})₂, and what appears to be a mixture of various tungstacyclobutanes. The alkylidene resonance for W(NAr_{Cl})(CHEt)-(OR_{F6})₂ is found at 9.27 ppm in toluene- d_8 at 0 °C. Proton resonances at -0.31, -0.41, -0.51, and -0.80 ppm are typical for β protons in TBP metallacyclobutanes of this type.¹¹ After 24 h at 0 °C, the reaction solution contained a 1:1 mixture of unreacted W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and various tungstacyclobutanes along with a purple deposit of [W(μ -NAr_{Cl})(OR_{F6})₂]₂. After 3 days at 25 °C, only [W(μ -NAr_{Cl})(OR_{F6})₂]₂ was present.

The amount of $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ formed in reactions between W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ and trans-3-hexene at 22 °C depends to a significant degree on the ratio of starting materials. A maximum amount of $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ is produced under approximately stoichiometric conditions. Only a trace of $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ was formed when 10 equiv of trans-3-hexene was added to W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂, and $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ did not form when $W(NAr_{Cl})(CHCMe_3)$ -(OR_{F6})₂ was treated with neat trans-3-hexene. GC/MS analysis and ¹H NMR spectroscopy of the orange solution that was obtained in this last experiment after 72 h at 25 °C indicated that \sim 25% of the *trans*-3-hexene had been converted into approximately a 1:1 mixture of C₅H₁₀ and C₇H₁₄ (4:1 ratio of trans and cis olefins). No further attempt was made to identify the hydrocarbon products. Clearly the presence of a high concentration of 3-hexene slows formation of the dimer dramatically, most likely because 3-hexene must be lost from some intermediate to yield $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$.

Reactions of W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) with Ethylene. Exposure of a degassed solution of W(NAr_{Cl})-(CHCMe₃)(Biphen)(THP) in C_6D_6 (40 μ mol/mL) to 1 atm of ethylene for 25 min led to consumption of 30% of the starting material and formation of W(NAr_{Cl})(C₃H₆)(Biphen), according to ¹H NMR spectra (eq 5). After 24 h at 25 °C, only W(NAr_{Cl})-

 (C_3H_6) (Biphen), excess ethylene, *tert*-butylethylene, and free tetrahydropyran could be detected in the proton NMR spectrum. W(NAr_{Cl})(C_3H_6)(Biphen) could be isolated as a pale yellow powder upon lyophilization of the above NMR sample. Analytically pure W(NAr_{Cl})(C_3H_6)(Biphen) could be prepared from W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) and ethylene on a 0.8 mmol scale in virtually quantitative yield in a similar manner. The ¹H NMR spectrum of W(NAr_{Cl})(C_3H_6)(Biphen) shows six multiplets at 4.71, 4.42, 4.35, 3.41, -0.03, and -0.27 ppm at 25 °C in C_6D_6 that can be ascribed to the six protons of the unsubstituted tungstacyclobutane ring in a TBP complex. Coupling constants for the methylene units of the tungstacyclobutane moiety ($^1J_{CH}$ values between 148.9 and 161.3 Hz) are typical of metallacyclobutane complexes of this general type.¹¹

Single crystals of W(NAr_{Cl})(C₃H₆)(Biphen) (containing 0.25 equiv of CH₂Cl₂ of crystallization) suitable for X-ray structure

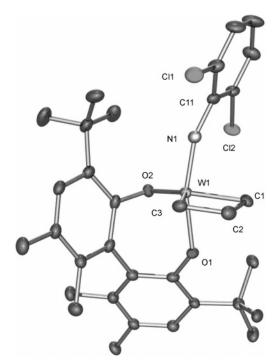

Figure 2. Molecular structure of W(NAr_{Cl})(Biphen)(CH₂CH₂-CH₂)(CH₂Cl₂)_{0.25}. Hydrogen and solvate atoms are omitted for clarity; thermal ellipsoids are drawn at 50% probability level. Selected bond lengths [Å] and angles [deg]: W-O(1) = 1.983(3), W-O(2) = 1.967(3), W-N(1) = 1.766(4), W-C(1) = 2.078(4),W-C(2) = 2.398(4), W-C(3) = 2.016(4), N(1)-W-O(1) =161.75(14), C(1)-W-O(2) = 143.49(16), C(1)-W-C(3) = 81.54-(17), W-C(3)-C(2) = 82.6(2), C(1)-C(2)-C(3) = 115.0(3), C(2)-C(1)-W = 80.5(2), W-N(1)-Cl(11) = 158.9(3).

analysis were grown from a saturated CH₂Cl₂/Et₂O solution at -30 °C. The complex was found to be a distorted trigonal bipyramid with the imido nitrogen and one oxygen of the Biphen ligand adopting axial positions (Table 1, Figure 2). The WC₃H₆ ring is analogous to other known TBP metallacyclobutane species of this type, i.e., essentially planar with a short $W-C_{\beta}$ distance (2.398(4) Å) and a C_{α} – C_{β} – C_{α} angle of 115.0(3)°. The bending of the NAr_{Cl} ligand probably can be attributed largely to steric interactions between the CMe₃ group attached to C(42) of the Biphen ligand and the NAr_{Cl} ligand; Cl(2) is not within bonding distance of the metal (W(1)-Cl(2) = 3.5730(11) Å). The larger C(1)-W(1)-O(2) angle $(143.49(16)^{\circ})$ relative to the C(3)-W(1)-O2 angle $(132.75(16)^{\circ})$ is consistent with Cl(2)being forced between O(2) and C(1) when the imido group bends. The W-N(1)-C(11) angle $(158.9(3)^{\circ})$ is within the expected range. For example in Mo(NAr_{Cl})(Biphen)(C₂H₄)- $(Et_2O)^4$ Mo-N-C = 169.4(7)°, while in Mo(NAr_{Cl})(CHCMe₃)- $((S)-Biphen)(THF) Mo-N-C = 149.8(8)^{\circ}.^{2}$

Comparison of the structure of TBP W(NAr_{Cl})(C₃H₆)(Biphen) with that of SP W(NAr)[CH₂CH(CMe₂Ph)CH₂](Biphen)⁶ reveals differences in the tungstacyclobutane rings that are analogous to those found in other TPB versus SP metallacycles in this family of bisalkoxide complexes. The W-C $_{\alpha}$ distances in the TBP WC₃ ring (2.078(4) and 2.016(4) Å) are approximately 0.1 Å shorter than the W–C $_{\alpha}$ distances in the SP WC₃ ring (2.157(14) and 2.173(15) Å), while the W-C $_{\alpha}$ -C $_{\beta}$ angles are smaller (81.54(17)° and 82.6(2)° versus 95.7(9)° and 94.8(9)°) and the $C_{\alpha}-C_{\beta}-C_{\alpha}$ angle is larger (115.0(3)° versus 97.2(11)°). In short, the WC₃ ring in the TBP species is more diamond shaped with a shorter W-C_{β} distance (2.398(4) Å), while the WC₃ ring in the SP species is more square with a W-C_{\beta} distance = 2.762 Å. What this means in terms of olefin loss from the WC₃ ring versus β hydride rearrangement of the WC₃ ring is a fundamental question that is still not known for any metallacyclobutane species in the general category of bisalkoxide species.

Decomposition of W(NAr_{Cl})(Biphen)(C₃H₆) and Other W(Biphen) Species. When W(NAr_{Cl})(Biphen)(C₃H₆) is dissolved in THF- d_8 (200 μ mol/mL), the ethylene complex, $W(NAr_{Cl})(Biphen)(C_2H_4)(THF-d_8)$, and approximately a 2:1 mixture of propylene and ethylene are formed after 90 min. The formation of both propylene and ethylene from $W(NAr_{Cl})$ - (C_3H_6) (Biphen) suggests that both β hydride rearrangement of the tungstacyclobutane ring as well as formation and bimolecular decomposition of a transient methylidene complex are pathways for the generation of $W(NAr_{Cl})(Biphen)(C_2H_4)(THF-d_8)$ from W(NAr_{Cl})(Biphen)(C₃H₆). If we assume that the ratio of propylene to ethylene in solution is a good estimate of the relative amounts of each formed as decomposition products, then we can conclude that only $\sim 25\%$ of the W(NAr_{Cl})(Biphen)- (C_3H_6) decomposes via β hydride rearrangement, as shown in eq 6. The major pathway of decomposition under these conditions is loss of ethylene to give transient W(NAr_{Cl})(CH₂)-(Biphen) and ethylene, which evolve into a mixture of W(NAr_{Cl})-(Biphen)(C_2H_4)(THF- d_8) and ethylene (eq 6).

$$W \longrightarrow 0.75 \text{ W}=\text{CH}_2 + 0.75 \text{ C}_2\text{H}_4 + 0.25 \text{ W}(\text{MeCH}=\text{CH}_2)$$

$$W(\text{CH}_2\text{CH}_2) + 0.125 \text{ C}_2\text{H}_4 + 0.25 \text{ MeCH}=\text{CH}_7, \qquad (6)$$

In the ¹H NMR spectrum of W(NAr_{Cl})(Biphen)(C₂H₄)(THF d_8) in THF- d_8 at 25 °C, the four ethylene protons appear as multiplets at 3.31, 3.01, 2.13, and 2.06 ppm. The ¹³C NMR spectrum of W(NAr_{Cl})(Biphen)(C₂H₄)(THF-d₈) exhibits two resonances at 55.8 and 52.6 ppm that are assigned (through an HMQC study) to the ethylene carbons. The CH coupling constants (${}^{1}J_{\text{CH}} = 152 - 158 \text{ Hz}$) are what one would expect.

Yellow crystals of W(NAr_{Cl})(Biphen)(C₂H₄)(THF-d₈) suitable for an X-ray structure were isolated in 55% yield from an NMR sample of W(NAr_{Cl})(C₃H₆)(Biphen) in THF-d₈ that was allowed to stand for 48 h at 22 °C. The molecular structure of W(NAr_{Cl})-(Biphen)(C_2H_4)(THF- d_8) shown in Figure 3 closely resembles that of Mo(NAr_{Cl})(Biphen)(C₂H₄)(Et₂O),⁴ hitherto the only crystallographically characterized ethylene adduct of a group 6 metal imido bis(alkoxide) complex. The coordination geometry around tungsten is best described as square pyramidal with the ethylene ligand in the apical position. The ethylene is symmetrically bound to tungsten (W-C(1) = 2.121(2) Å, W-C(2) = 2.143(2) Å) with the C(1)-C(2) distance (1.452(3) Å) similar to what it is in the related complexes W(NPh) $\{\kappa^2-C_6H_4 (NSiMe_3)_2$ $\{(C_2H_4)(PMe_3)_2 (1.434(6) \text{ Å}) \text{ and } Mo(NAr_{Cl})(Biphen) (C_2H_4)(Et_2O) (1.400(13) \text{ Å}).^{4,15}$ Bending of the NAr_{Cl} ligand in $W(NAr_{Cl})(Biphen)(C_2H_4)(THF-d_8) (W-N(1)-C(11) = 170.27-$ (14)°) is less pronounced than in W(NAr_{Cl})(C₃H₆)(Biphen) (158.9(3)°; vide supra), since there is no significant steric interaction of the NAr_{Cl} ligand with a tert-butyl group in the Biphen²⁻ ligand, as there is in $W(NAr_{Cl})(C_3H_6)(Biphen)$. The W=N−C angle is similar to what it is in Mo(NAr_{Cl})(Biphen)- $(C_2H_4)(Et_2O) (169.4(7)^\circ).^4$

When W(NAr_{Cl})(Biphen)(C_2H_4)(THF- d_8) in CD₂Cl₂ is treated with ${}^{13}\text{CH}_2 = {}^{13}\text{CH}_2$ (14 equiv), the color of the solution immediately changes from yellow to orange. Proton and carbon NMR spectra indicate that the tungstacyclopentane complex, $W(NAr_{Cl})(^{13}CH_2^{13}CH_2^{13}CH_2^{13}CH_2)(Biphen)$ (eq 7), is formed.

⁽¹⁵⁾ Wang, S. Y. S.; van der Lende, D. D.; Abboud, K. A.; Boncella, J. M. Organometallics 1998, 17, 2628.

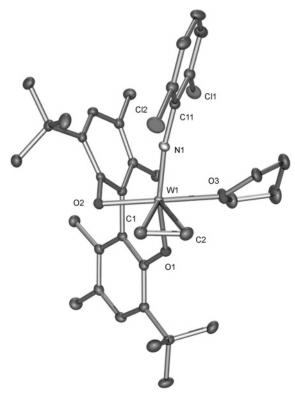

Figure 3. Molecular structure of W(NAr_{Cl})(Biphen)(C_2H_4)(THF). Hydrogen and solvate atoms are omitted for clarity; thermal ellipsoids are drawn at 50% probability level. Selected bond lengths [Å] and angles [deg]: W-C(1) = 2.121(2), W-C(2) = 2.143(2), W-O(1) = 1.9684(13), W-O(2) = 2.0239(13), W-O3 = 2.2462-(14), W-N(1) = 1.7742(16), C(1)-C(2) = 1.452(3), N(1)-W-O(1) = 161.44(6), O(2)-W-O(3) = 152.52(5), W-C(1)-C(2) = 70.91(11), C(1)-C(2)-W = 69.28(11), C(2)-W-C(1) = 39.81-(8), W-N(1)-C(11) = 170.27(14).

As found in the case of W(NAr)(Biphen)(13CH₂13CH₂13CH₂13- CH_2)6 and $W(NPh){\kappa^2-C_6H_4(NSiMe_3)_2}(C_4H_8)$, 15 the 13C NMR spectrum of W(NAr_{Cl})(¹³CH₂¹³CH₂¹³CH₂)(Biphen) exhibits two doublets at 86.4 ppm (${}^{1}J_{CC} = 35.4 \text{ Hz}, \alpha\text{-CH}_{2}$) and 75.3 ppm (${}^{1}J_{CC} = 34.5 \text{ Hz}, \alpha\text{-CH}_{2}$) as well as one higher order multiplet at 37.6 ppm for the two β -CH₂ groups. In the ¹H NMR spectrum, the methylene protons of the WC₄H₈ moiety appear as broad multiplets in the region 2.56 to 3.33 ppm. Although formation of the tungstacyclopentane complex from W(NAr_{Cl})-(Biphen)(C₂H₄)(THF-d₈) and ethylene is reversible in the presence of THF, it was possible to isolate W(NAr_{Cl})(C₄H₈)-(Biphen) on a 1 mmol scale as an orange powder through lyophilization of a benzene solution of W(NAr_{Cl})(Biphen)-(C₂H₄)(THF) that had been treated with excess ethylene. Isolated W(NAr_{Cl})(C₄H₈)(Biphen) showed no signs of decomposition in benzene (90 µmol/mL) at 60 °C over a period of 12 h. This result suggests that solvent-free "W(NAr_{Cl})(C₂H₄)(Biphen)" is highly reactive, and in the absence of THF the equilibrium between W(NAr_{Cl})(CH₂CH₂CH₂CH₂)(Biphen) and "W(NAr_{Cl})-(CH₂=CH₂)(Biphen)" must lie far toward W(NAr_{Cl})(CH₂CH₂-CH₂CH₂)(Biphen) (eq 7). Heating a sample of W(NAr_{Cl})(C₄H₈)-(Biphen) to 100 °C for 90 h in benzene leads to ~20% decomposition to yield ethylene and a mixture of unidentified tungsten compounds.

An X-ray study of W(NAr_{Cl})(Biphen)(C_4H_8) (Table 2, Figure 4) showed it to have structural parameters reminiscent of W(NPh){ κ^2 - C_6H_4 (NSiMe₃)₂}(C_4H_8),¹⁵ i.e., a slightly distorted square pyramid geometry around W with the imido ligand in the axial position. The W–C(1) and W–C(4) bond lengths

$$\begin{array}{c} Ar_{CI} \\ CMe_3 \\ N \\ O-W \\ O \\ CMe_3 \\ N \\ CH_2 \\ + CH_2 = CH_2 \end{array}$$

$$\begin{array}{c} Ar_{CI} \\ CMe_3 \\ N \\ CH_2 \\ + CH_2 = CH_2 \end{array}$$

$$\begin{array}{c} CMe_3 \\ N \\ CH_2 \\ - CMe_3 \\ \end{array}$$

(2.129(8) and 2.112(8) Å) are marginally shorter than those found in other crystallographically characterized tungstacyclopentane complexes (2.173(6)–2.191(12) Å). The C–C distances (1.504(12)–1.535(11) Å) in the WC₄ ring suggest that they are essentially single bonds, as expected for complexes of this type. The NAr_{Cl} ligand is only slightly bent (W–N(1)–C(11) = 175.5(6)°).

When generated in C₆D₆ from W(NAr_{Cl})(CHCMe₃)(Biphen)-(THP) and ethylene, W(NAr_{Cl})(C₃H₆)(Biphen) was found to be stable for at least 24 h at 22 °C in the presence of excess ethylene. However, in the absence of ethylene W(NAr_{Cl})(C₃H₆)-(Biphen) decomposes within 36 h in C_6D_6 (90 μ mol/mL) at 22 °C. Decomposition of W(NAr_{Cl})(¹³C₃H₆)(Biphen) led to formation of W(NAr_{Cl})(¹³C₄H₈)(Biphen). The second tungsten species formed as a product of decomposition of W(NAr_{Cl})(13C₃H₆)-(Biphen) gave rise to a singlet resonance at 187.8 ppm that has two sets of tungsten satellites (${}^{1}J_{WC} = 52.6 \text{ Hz}$, 84.5 Hz), which is indicative of formation of a dimeric methylidene complex, $[W(NAr_{Cl})(Biphen)(\mu^{-13}CH_2)]_2$, analogous to [W(NAr)(Biphen)- $(\mu$ - 13 CH₂)]₂.⁶ In the 1 H NMR spectrum, two resonances at 8.14 ppm (${}^{1}J_{CH} = 146.7 \text{ Hz}, {}^{2}J_{HH} = 6.1 \text{ Hz}$) and 7.62 ppm (${}^{2}J_{HH} =$ 6.3 Hz) are ascribed to the diastereotopic protons of two equivalent methylidene groups.

Decomposition of W(NAr_{Cl})(C₃H₆)(Biphen) at 40 °C in C₆D₆ (90 μmol/mL) was followed by ¹H NMR spectroscopy. During the first 3 h, $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ and $W(NAr_{Cl})(C_4H_8)$ -(Biphen) formed at the expense of W(NAr_{Cl})(C₃H₆)(Biphen). The ratio of propylene to ethylene in solution during the first 2 h of this reaction was found to be approximately 1.7-2.0, similar to what was found in THF (eq 6). The amount of propylene in solution never exceeded 2 equiv per W. All propylene was consumed over a period of 8 h. After 3 h, a maximum amount of $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ was formed with the species in solution being $W(NAr_{Cl})(C_3H_6)(Biphen)$ $(\sim 30\%)$, [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂ ($\sim 20\%$), and W(NAr_{Cl})- (C_4H_8) (Biphen) (\sim 30%). At this point, no more ethylene could be detected in solution. It is clear that decomposition of W(NAr_{Cl})(C₃H₆)(Biphen) is accelerated in the absence of ethylene, the concentration of W(NAr_{Cl})(C₄H₈)(Biphen) reaches a steady state, and the $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ that is formed decomposes with time under the reaction conditions. In spite of the complexity of the decomposition reaction $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ could be isolated as purple microcrystals in 29% yield upon decomposition of a sample of W(NAr_{Cl})(C₃H₆)(Biphen) in benzene at 25 °C on a 0.5 mmol

An X-ray study of $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ (Table 2) showed it to have the centrosymmetric (heterochiral) structure shown in Figure 5. The coordination geometry around each W is a distorted trigonal bipyramid with the equatorial position occupied by one biphenoxide oxygen, a methylidene ligand, and an imido ligand. The $W_2(CH_2)_2$ core exhibits two short (1.982-(6) Å) and two long (2.277(6) Å) interatomic W-C distances.

The first is characteristic of a W=C bond in bisalkoxide imido alkylidene species, while the latter is typical of a 2e donor ligand bound in the axial position. In short, [W(NAr_{Cl})(Biphen)(µ- CH_2)₂ is essentially a dimer containing $W(NAr_{Cl})(CH_2)[(R)-$ Biphen] and $W(NAr_{Cl})(CH_2)[(S)$ -Biphen] in which each of the methylidene groups behaves as a donor toward the second tungsten in an apical position. The interatomic W(1)-W(1')distance (3.1211(6) Å) suggests that no W-W bond is present, while the C(1)-C(1)' distance (2.913(12) Å) suggests that no C-C bond is present. The W-C-H_a-H_b dihedral angle was found to be 131(7)°, while the W-C-H_b-H_a dihedral angle was found to be 136(6)°. These dihedral angles for a sp³hybridized carbon atom are expected to be 120° and for a sp²hybridized carbon atom are expected to be 180°. Therefore these methylene ligands are slightly distorted from a planar structure, as one would expect as a consequence of their behavior as donors to another tungsten, but they retain many of the structural and spectroscopic characteristics we would expect of the methylene ligand in the unobservable monomeric species, W(NAr_{Cl})(CH₂)(Biphen). The W₂(CH₂)₂ core in [W(NAr_{Cl})-(Biphen) $(\mu$ -CH₂)]₂ contrasts with that in the centrosymmetric W(V) complex, $[W(O)(\eta^5-C_5Me_5)(\mu-CH_2)]_2$, in which the two W-C bond lengths (2.076(4) and 2.078(4) Å) are essentially identical. 17 The centrosymmetric titanium(IV) methylene derivative, $[Ti\{N(C_6H_{11})_2\}_2(\mu-CH_2)]_2$, also contains symmetrically bridging methylidene groups (Ti-C = 2.020(5) and 2.016(5)Å). 18 To our knowledge [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂ is the only crystallographically characterized W(VI) methylene species.

Decomposition of W(NAr_{Cl})(C_3H_6)(Biphen) at 100 °C for 90 min in C_6D_6 under argon produces a new compound in 70%

yield whose proton NMR spectrum contains resonances at 3.71 and 2.06 ppm, each with an area of one proton per Biphen ligand. A trace of W(NAr_{Cl})(C₄H₈)(Biphen) is also present. A ¹³C NMR spectrum reveals an ethylene resonance at 70.6 ppm for a carbon with two protons attached (${}^{1}J_{CH} = 140.8$ and 151.4 Hz). An X-ray structure (Table 2, Figure 6) shows the product to be a homochiral "1,2-ditungstacyclobutane" dimer that contains a bridging ethylene and two bridging imido groups, i.e., $W_2(Biphen)_2(\mu-NAr_{Cl})_2(\mu-CH_2CH_2)$. The W-C distance in the W_2C_2 ring is 2.152(5) Å, and the ethylene is slightly twisted. The C-C bond length of the ethylene is 1.556(10) Å, consistent with it being a long single bond. Since a C_2 axis passes through the middle of the ethylene C-C bond, two different sets of ethylene protons are present. It should be noted that neither chloride in the bridging imido ligands is coordinated to the metal, as found in [W(NAr_{Cl})(OR_{F6})₂]₂ (Figure 1), and that the W_2N_2 unit is puckered, not planar (Figure 7). The two W-N bond distances are essentially the same (W(1)-N(1) = 1.974(4) Å, W(1)-N(1)' 1.926(4) Å). A W-W single bond must be present on the basis of the W-W bond length (W(1)-W(1)' =2.5782(6) Å). W₂(Biphen)₂(μ -NAr_{Cl})₂(μ -CH₂CH₂) is similar to the "1,2-ditungstacyclobutane" species with the formula W₂- $(N-2,3-Me_2C_6H_3)_2(OCMe_2CF_3)_3(\mu-OCMe_2CF_3)(\mu-CH_2CH_2)$ prepared by adding ethylene to the W=W bond in [W(N-2,3- $Me_2C_6H_3)(OCMe_2CF_3)_2]_2$. The fact that $W_2(Biphen)_2(\mu-$ NAr_{Cl})₂(*u*-CH₂CH₂) is homochiral constitutes proof that it cannot form directly from heterochiral [W(NAr_{Cl})(Biphen)(µ- CH_2)]₂ without $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ breaking into monomeric units. Monomeric units with the same chirality then recombine to give homochiral W₂(Biphen)₂(μ -NAr_{Cl})₂(μ -CH₂CH₂).

A 27 μ mol/mL suspension of [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂ in C₆D₆ decomposes after 50 min at 100 °C to yield a mixture of decomposition products, \sim 25% of which consist of W₂-

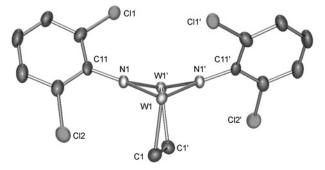

Figure 7. View of the structure of $[W(NAr_{Cl})(Biphen)]_2(\mu-CH_2-$ CH₂) down the W-W axis with the Biphen²⁻ ligands removed. resonances that are consistent with $[W(Biphen)(\mu-NAr_{Cl})]_2$, formed through loss of ethylene from W₂(Biphen)₂(μ-NAr_{CI})₂(μ-CH₂CH₂). These resonances disappear upon addition of ethylene, while the intensities of the resonances for $W_2(Biphen)_2(\mu$ NAr_{Cl})₂(μ -CH₂CH₂) correspondingly increase. Although we cannot eliminate the possibility that the Biphen²⁻ ligand is not intact in some of the unidentified decomposition products, a significant fraction of the product appears to be [W(Biphen)-(NAr_{Cl})₂, although we cannot confirm that it has a structure analogous to the species shown in Figure 1. The main points are that homochiral W₂(Biphen)₂(μ -NAr_{Cl})₂(μ -CH₂CH₂) can form from heterochiral [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂, that the process must involve scission of [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂ into monomeric units and recombination of homochiral monomers, and that $W_2(Biphen)_2(\mu-NAr_{Cl})_2(\mu-CH_2CH_2)$ appears to lose ethylene reversibly to yield a [W(Biphen)(NAr_{Cl})]₂ species whose structure has not been confirmed.

Discussion

We have shown in this work that tungsten 2,6-dichlorophenylimido complexes are accessible and that the chemistry of tungsten 2,6-dichlorophenylimido (NAr_{Cl}) alkylidene bisalkoxide complexes does not differ dramatically from that of NAr (N-2,6-diisopropylphenyl) complexes.⁶ However, since the NAr_{Cl}

ligand is more electron withdrawing and sterically less bulky than the NAr ligand, it renders the metal more electrophilic as well as more accessible. It is perhaps for these reasons that NAr_{Cl} complexes appear to decompose bimolecularly more readily than complexes that contain the NAr ligand. Bimolecular reactions also may be encouraged as a consequence of intermolecular coordination of an ortho chloride, a circumstance that appears in the structure of $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$ described in this work. In any case, we can now add tungsten 2,6dichlorophenylimido complexes to the lengthening list of available variations of M(NR)(CHR')(OR")₂ complexes. There does not appear to be any special feature of the 2,6-dichlorophenylimido species, aside from interaction of one of the chlorides with the metal in certain situations, that would differentiate the chemistry of 2,6-dichlorophenylimido species strongly from that of other imido complexes such as 2,6diisopropylphenylimido. 2,6-Dichlorophenylimido species appear to be less soluble than 2,6-diisopropylphenylimido species (inter alia), a property that probably has assisted in the isolation of the six species that have been crystallographically characterized here.

The work described here presents the most complete picture of how W(VI) imido methylene complexes decompose. It also serves as a model study for decomposition of other (e.g., monosubstituted) alkylidenes. Several of the intermediates on the decomposition pathway of monosubstituted alkylidenes for steric reasons either will not be formed or will lose a disubstituted olefin readily to yield (ultimately) a dimeric species that contains only imido and alkoxide groups.

Perhaps the most striking compound prepared and characterized in this work is $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$. The analogous $[W(NAr)(Biphen)(\mu-CH_2)]_2$ species was observed in solution,⁶ but since it was not isolated and crystallographically characterized, the proposal that it was indeed a relatively stable dimeric form of a methylene complex remained unconfirmed. Since it has long been known that methylene complexes decompose more readily in a bimolecular manner than any other alkylidene to give ethylene or ethylene complexes, we were astonished that an apparent intermediate in this process would actually be stable. We now know that heterochiral $[W(NAr_{Cl})(Biphen)(\mu -$ CH₂)]₂ is *not* an intermediate along a pathway to homochiral W₂(Biphen)₂(μ-NAr_{Cl})₂(μ-CH₂CH₂). Instead, it breaks up to yield monomeric W(NAr_{Cl})(Biphen)(μ-CH₂) species, and homochiral monomers then combine to yield homochiral W₂- $(Biphen)_2(\mu-NAr_{Cl})_2(\mu-CH_2CH_2)$, either directly or via homochiral $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ that is unstable with respect to rearrangement to yield W₂(Biphen)₂(μ -NAr_{Cl})₂(μ -CH₂CH₂). Likewise, either heterochiral $[W(NAr_{Cl})(Biphen)(\mu-CH_2)]_2$ cannot rearrange intramolecularly in order to bring the methylenes close enough to form a "1,2-ditungstacyclobutane" species or else a C-C bond is formed in a more direct manner when homochiral W(NAr_{Cl})(Biphen)(μ -CH₂) complexes combine.

Although we have not yet confirmed that ethylene is lost from $W_2(Biphen)_2(\mu\text{-NAr}_{Cl})_2(\mu\text{-CH}_2CH_2)$ to form [W(Biphen)($\mu\text{-NAr}_{Cl}$)]2, the structure of $W_2(Biphen)_2(\mu\text{-NAr}_{Cl})_2(\mu\text{-CH}_2CH_2)$ suggests that it is poised to lose ethylene as an ortho chloride coordinates to the metal, as shown in Figure 1 for the OR_{F6} analogue. We have observed that ethylene is lost reversibly from the 1,2-ditungstacyclobutane species with the formula $W_2(N-2,3\text{-Me}_2C_6H_3)_2(OCMe_2CF_3)_3(\mu\text{-OCMe}_2CF_3)(\mu\text{-CH}_2CH_2)$ to yield $[W(N-2,3\text{-Me}_2C_6H_3)(OCMe_2CF_3)_2]_2$, which contains an unbridged W=W bond.³ Does the chirality at each metal play an important role in decompositions of alkylidene complexes? Nothing is known, but it would be difficult to justify any

sweeping statement at this juncture. Nevertheless, it would seem that chirality at least *could* be a determinant of an enantiomerically pure catalyst's longevity or lack thereof.

We have obtained some evidence that alkylidenes can be regenerated from reduced metal species.^{3,19} We have been entertaining the possibility of regenerating alkylidene species from decomposition products, a circumstance that could lead to long-lived catalysts, possibly through reactions with main group alkylidene sources. However, the possibility of regenerating catalysts in this manner would seem to be most favorable if a single product of alkylidene decomposition were present. Unfortunately a single decomposition product is far from reality in the system that we have examined here and perhaps also in many other systems. Therefore regeneration of a catalyst employing a main group alkylidene may be possible only rarely, if ever. It remains to be seen whether that circumstance will change if a catalyst is attached to a silica surface where bimetallic species cannot form readily.²⁰

Experimental Section

General Procedures. All operations were performed under a nitrogen atmosphere in the absence of oxygen and moisture in a glovebox or using standard Schlenk procedures. The glassware and NMR tubes were flame-dried or oven-dried prior to use. Benzene, ether, dichloromethane, pentane, and toluene were degassed with dinitrogen and passed through activated alumina columns. Dimethoxyethane (DME) was distilled from a dark purple solution of sodium benzophenone ketyl and degassed three times by freeze-pumpthaw techniques. 1H, 13C, and 19F NMR spectra were acquired at room temperature (unless otherwise noted) using a Bruker Avance 400 spectrometer (1H 400 MHz, 13C 100 MHz, 19F 376 MHz) and referenced to the residual protio solvent peaks or external C₆F₆ (-163.0 ppm). HMQC spectra were recorded on a Bruker Avance 600 spectrometer. Elemental analyses were performed by H. Kolbe Mikroanalytisches Laboratorium, Mülheim an der Ruhr, Germany. Neopentylmagnesium chloride was titrated against propanol in a THF solution using 1,10-phenanthroline as an indicator immediately prior to use. WO2Cl2 was prepared from WCl6 and 2 equiv of hexamethyldisiloxane in dichloromethane. All other chemicals were purchased from commercial sources and used as received.

Xray Crystallography. Low-temperature diffraction data were collected on a Siemens Platform three-circle diffractometer coupled to a Bruker-AXS Smart Apex CCD detector with graphitemonochromated Mo K α radiation ($\lambda = 0.71073$ Å), performing ϕ and ω -scans. The structures were solved by direct methods using SHELXS²¹ and refined against F^2 on all data by full-matrix leastsquares with SHELXL-97.22 All non-hydrogen atoms were refined anisotropically. All hydrogen atoms (except the hydrogen atoms on carbon that binds directly to tungsten, which have been taken from the difference Fourier synthesis and refined semifreely with the help of distance restraints) were included in the model at geometrically calculated positions and refined using a riding model. The isotropic displacement parameters of all hydrogen atoms were fixed to 1.2 times the U value of the atoms they are linked to (1.5 times for methyl groups). Details of the data quality and a summary of the residual values of the refinements are listed in Tables 1 and 2.

The shape of the anisotropic displacement ellipsoids in W(NAr_{Cl})- $(C_3H_6)(Biphen)(CH_2Cl_2)_{0.25}$ for atoms C(12) to C(16), Cl(1), and Cl(2) suggest some disorder for the dichlorinated aryl ring. A refinement of this disorder was attempted but was not stable. The solvent molecule was refined with 1/4 occupancy, leading to noninteger values for the elements C, H, and Cl in the empirical formula. The THF molecule in [W(NAr_{Cl})(Biphen)(CH₂)₂(THF d_8)] is deuterated. The deuteria were refined as hydrogens (same scattering factor). The highest two residual density maxima are much higher than the others. Taking into account the symmetry equivalents of those maxima, two possible additional components can be hypothesized (the distance between Q(1) and Q(2A) is about the same as the distance between the two W atoms of the main component). Refinement as a three-component whole molecule disorder is surprisingly stable as long as only the W positions are split. Even though this interpretation gives an explanation for the two highest residual electron density maxima, it was abandoned, as no general improvement of the model was gained. The structure of [W(NArCl)(Biphen)]₂(-CH₂-CH₂-) shows whole molecule disorder, which refines relatively well. The occupancies of the two components were refined freely, while constraining the sum of the occupancies of the components to unity. The ratio converged at a value of 0.895(2). The disorder was refined with the help of similarity restraints on 1-2 and 1-3 distances and displacement parameters as well as rigid bond restraints for anisotropic displacement parameters, but no ADP restraints were used for the main component. All bond distances and angles of this structure as given in this publication refer to the main component of the whole molecule disorder.

W(NAr_{Cl})₂Cl₂(DME). This synthesis was adapted from that reported by P. Tsang.⁸ A mixture of SiMe₃Cl (96 mL, 750 mmol) and 2,6-lutidine (58 mL, 500 mmol) was added dropwise to a stirred suspension of WO₂Cl₂ (40.45 g, 125 mmol) and 2,6-dichloroaniline (40.50 g, 250 mmol) in DME (120 mL). The yellow suspension was stirred for 48 h at 60 °C, and an orange powder was filtered off from a red solution. The solvent was removed from the red solution in vacuo, and the orange residue was extracted with DME $(4 \times 500 \text{ mL})$. The volume of the combined solutions was reduced in vacuo to approximately 50 mL. The supernatant was decanted, and the orange crystalline mass of W(NAr_{Cl})₂Cl₂(DME) was washed with pentane (100 mL); yield 62.78 g (76%): ¹H NMR (CD₂Cl₂) δ 7.29 (d, ${}^{3}J_{\text{HH}} = 8.1 \text{ Hz}, 2 \times 2 \text{ H}, \text{NAr}_{\text{Cl}}$ -3 and NAr}_{cl}-5), 6.79 (t, ${}^{3}J_{\text{HH}} = 8.1 \text{ Hz}, 2 \times 1 \text{H}, \text{NAr}_{\text{Cl}}\text{-}4), 4.11, 4.07 \text{ (br s, 10 H, DME)};$ ¹³C NMR (C_6D_6) δ 150.7, 133.1, 127.9, 126.1 (NAr_{Cl}), 71.7, 65.2 (DME). Anal. Calcd for C₁₆H₁₆Cl₆N₂O₂W: C, 28.90; H, 2.43; N, 4.21. Found: C, 28.86; H, 2.52; N, 4.20.

W(NAr_{Cl})₂(CH₂CMe₃)₂. This synthesis was adapted from that reported by P. Tsang. A solution of ClMg(CH₂CMe₃) (51.3 mL of a 1.76 M ether solution, 90 mmol) was added dropwise to a stirred ether solution (300 mL) of W(NAr_{Cl})₂Cl₂(DME) (30.0 g, 45 mmol). After the reaction mixture was stirred for 16 h, an off-white solid was filtered off and extracted with ether (3 × 100 mL). The volatiles were removed under reduced pressure from the combined solutions to give a yellow foam. Trituration with pentane gave a bright yellow powder of W(NAr_{Cl})₂(CH₂CMe₃)₂ (24.46 g, 91%): ¹H NMR (C₆D₆) δ 6.94 (d, ³J_{HH} = 8.1 Hz, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.23 (t, ³J_{HH} = 8.1 Hz, 1 H, NAr_{Cl}-4), 2.27 (s, 2 × 2 H, WCH₂), 1.20 (s, 2 × 9 H, CH₂CCH₃); ¹³C NMR (C₆D₆) δ 151.4, 131.7, 128.7, 125.2 (NAr_{Cl}), 95.4 (WCH₂), 35.6, 34.5 (CMe₃). Anal. Calcd for C₂₂H₂₈Cl₄N₂W: C, 40.90; H, 4.37; N, 4.34. Found: C, 41.11; H, 4.32; N, 4.28.

W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME). A suspension of triflic acid (17.42 g, 116.1 mmol) in pentane (10 mL) was added dropwise at -78 °C to a stirred solution of W(NAr_{Cl})₂(CH₂CMe₃)₂ (25.00 g, 38.7 mmol) in DME (300 mL). The stirred reaction mixture was allowed to warm to 25 °C to give a dark yellow solution after 16 h at this temperature. Activated charcoal was added and the reaction

mixture stirred at 25 °C for 1 h. The charcoal was filtered off, and the volatiles were removed under reduced pressure to give an oil that solidified upon trituration with toluene. The suspension was kept under dynamic vacuum at 60 °C until the pressure reached 15 \times 10⁻³ Torr (\sim 6 h). Toluene (200 mL) was added to the yellow solid and the suspension stirred for 1 h at 25 °C. The reaction mixture was filtered over Celite and the deposit extracted with toluene (2 × 100 mL) to give a dark yellow filtrate. The volatiles were removed under reduced pressure to give the crude product as a yellow foam. Recrystallization from ether (400 mL, -78 °C) gave analytically pure W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME) (17.65 g, 57%) as bright yellow microcrystals. The NMR spectroscopic data are consistent with approximately a 1:1 mixture of two isomers in C₆D₆ and a 5:1 mixture of two isomers in CD₂Cl₂, respectively: ¹H NMR (C_6D_6) δ 11.80, 10.96 (s, 1 H, WCH), 6.80 (br m, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.25 (br m, 1 H, NAr_{Cl}-4); 3.95, 3.84, 3.23, 3.18, 2.86, 2.78, 2.34 (br, 10 H, DME), 1.52, 1.29 (s, 9 H, CHCCH₃); ¹H NMR (CD₂Cl₂) major isomer, OTf⁻ ligands in *cisoid* arrangement δ 11.52 (s, ${}^{1}J_{CH} = 121.0 \text{ Hz}$, 1 H, WCH), 7.45 (d, ${}^{3}J_{HH} = 8.3$ Hz, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 7.16 (t, ${}^{3}J_{HH} = 8.3$ Hz, 1 H, NAr_{Cl}-4), 4.58 (s, 3 H, DME), 4.38 (m, 2 H, DME), 4.15 (m, 1 H, DME), 3.76 (m, 1 H, DME), 3.72 (s, 3 H, DME), 1.22 (s, 9 H, CHCCH₃); minor isomer, OTf⁻ ligands in transoid arrangement δ 10.83 (s, ${}^{1}J_{\text{CH}} = 115.7 \text{ Hz}, 1 \text{ H, WCH}, 7.39 (d, {}^{3}J_{\text{HH}} = 8.1 \text{ Hz}, 2 \text{ H, NAr}_{\text{Cl}}$ -3 and NAr_{Cl}-5), 4.35 (s, 3 H, DME), 4.09 (m, 2 H, DME), 3.87 (m, 2 H, DME), 3.67 (s, 3 H, DME), 1.25 (s, 9 H, CHCCH₃). The NAr_{Cl}-4 resonance of the minor isomer was obscured by the major isomer; ¹³C{¹H} NMR (CD₂Cl₂) major isomer, OTf⁻ ligands in *cisoid* arrangement δ 302.5 (WCH), 148.8, 135.2, 129.2, 128.9, (NAr_{Cl}), 120.2 (quart, ${}^{1}J_{FC} = 317.3 \text{ Hz}$, CF₃), 119.3 (quart, ${}^{1}J_{FC} =$ 318.7 Hz, CF₃), 82.3, 79.5, 71.9, 62.3 (DME), 48.5 (CMe₃), 33.2 (CMe₃); minor isomer, OTf⁻ ligands in transoid arrangement δ 294.7 (WCH); ¹⁹F NMR (CD₂Cl₂) major isomer, OTf⁻ ligands in cisoid arrangement δ -76.2 (m), 77.1 (m); minor isomer, OTf ligands in transoid arrangement δ -76.4 (s). Anal. Calcd for C₁₇H₂₃-Cl₂F₆NO₈S₂W: C, 25.45; H, 2.89; N, 1.75. Found: C, 25.38; H, 2.95; N, 1.77.

W(NAr_{Cl})(CHCMe₃)[OC(CF₃)₂Me]₂. Method A: A suspension of W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME) (5.00 g, 6.23 mmol) in toluene (200 mL) was warmed until the compound completely dissolved. A solution of LiOC(CF₃)₂Me (2.34 g, 12.47 mmol) in Et₂O (50 mL) was added dropwise to the chilled (−30 °C) toluene solution while it was stirred. The clear yellow-orange solution was stirred for 12 h at 25 °C, then the volatiles were removed under reduced pressure (10^{-2} Torr for 12 h to remove all DME). The yellow powder was suspended in pentane (200 mL), and after stirring it for 30 min at 25 °C the mixture was filtered through Celite and the solid was washed with pentane (3 × 50 mL). The yellow filtrate was reduced in volume and stored at −30 °C to give yellow crystals of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂. The pure product was obtained by washing powdered W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ with chilled (−30 °C) pentane; yield of bright yellow powder (3 crops) 3.80 g (80%).

Method B: Neat HOC(CF₃)₂Me (4.09 g, 22.44 mmol) was added dropwise to a stirred solution of W(NAr_{Cl})(CHCMe₃)(OTf)₂(DME) (9.00 g, 11.22 mmol) and 2,6-lutidine (2.41 g, 22.50 mmol) in benzene (200 mL). After the yellow suspension was stirred for 12 h at 25 °C, the volatiles were removed by lyophilization to yield a yellow powder. Pentane (150 mL) was added, and the yellow suspension was stirred at 25 °C for 30 min. The colorless deposit was filtered off and washed with pentane (3 × 50 mL). The volatiles were removed under reduced pressure, and the crude product was recrystallized from pentane to give bright yellow crystals; yield 6.41 g (74%) in 3 crops: ¹H NMR (C₆D₆) δ 8.91 (s, ² J_{WH} = 14.1 Hz, ¹ J_{CH} = 115.2 Hz, 1 H, WCH), 6.82 (d, ³ J_{HH} = 8.1 Hz, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.25 (t, ³ J_{HH} = 8.1 Hz, 1 H, NAr_{Cl}-4), 1.37 (s, 2 × 3 H, OCCH₃), 1.06 (s, 9 H, CHCCH₃); ¹³C{¹H} NMR (C₆D₆) δ 257.3 (¹ J_{WC} = 195.9 Hz, WCH), 150.5, 133.7, 127.4

(NAr_{Cl}), 124.2 (quart, ${}^{1}J_{FC} = 287.5$ Hz, CF₃), 82.4 (sept, ${}^{2}J_{FC} = 30.5$ Hz, OCCH₃), 46.0 (CMe₃), 33.6 (CMe₃), 19.3 (OCCH₃); one carbon resonance of the NAr_{Cl} ligand was obscured by C₆D₆; ${}^{19}F$ NMR (C₆D₆) δ -76.8 (br m), -76.9 (br m). Anal. Calcd for C₁₉H₁₉-Cl₂F₁₂NO₂W: C, 29.40; H, 2.47; N, 1.80. Found: C, 29.21; H, 2.43; N, 1.79.

W(NAr_{Cl})(CH₂CH₂CH₂)[OC(CF₃)₂Me]₂. A stirred solution of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ (250 mg, 322 μ mol) in benzene (5 mL) was exposed to 1 atm of ethylene for 2 min. The resulting pale yellow solution was stirred for 30 min at 25 °C. The reaction mixture was frozen, and the volatiles were removed by lyophilization to give a pale brown powder (213 mg, 90%): ¹H NMR (C₆D₆) δ 6.70 (d, ${}^{3}J_{HH} = 8.1 \text{ Hz}$, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.01 (t, ${}^{3}J_{HH}$ = 8.1 Hz, 1 H, NAr_{Cl}-4), 4.91, 4.77 (m, ${}^{1}J_{CH}$ = 165.2 Hz, 160.6 Hz, 2×2 H, α -CH₂), 1.59, 1.55 (br s, 2×3 H, OCCH₃), -0.87, -1.46 (m, ${}^{1}J_{CH} = 166.2$ Hz, 162.0 Hz, 2×1 H, β -CH₂); ${}^{13}C\{{}^{1}H\}$ NMR (C_6D_6) δ 147.1, 134.2, 128.9, 127.3 (NAr_{Cl}), 124.7 (quart, ${}^{1}J_{FC} = 287.9 \text{ Hz}, \text{ CF}_{3}$), 103.4 (${}^{1}J_{CH} = 160.6 \text{ Hz}, 165.2 \text{ Hz}, {}^{1}J_{WC} =$ 64.7 Hz, α-CH₂), 84.5, 81.7 (OCCH₃), 17.8, 17.6 (OCCH₃), -4.7 $(^{1}J_{\text{CH}} = 162.0 \text{ Hz}, 166.2 \text{ Hz}, \beta\text{-CH}_{2}); ^{1}J_{\text{CH}} \text{ values were determined}$ in an HMQC experiment; 19 F NMR (C_6D_6) δ -77.4 (s), -77.5 (s). Anal. Calcd for C₁₇H₁₅Cl₂F₁₂NO₂W: C, 27.30; H, 2.02; N, N, 1.87. Found: C, 27.08; H, 1.89; N, 1.81.

 $\{W(\mu\text{-NAr}_{\text{Cl}})[OC(\text{CF}_3)_2\text{Me}]_2\}_2$. Amylene (40 μL , 376 μmol) was added to a stirred solution of W(NAr}_{\text{Cl}})(CHCMe_3)(OR_{F6})_2 (250 mg, 322 μmol) in benzene (5 mL). After 15 min the bright yellow solution turned orange, and purple microcrystals started to be deposited. After the reaction mixture was stirred for 7 days at 25 °C, the purple product was filtered off and washed with pentane (3 × 2 mL); yield 170 mg (75%): ^1H NMR (THF- d_8) δ 7.96 (d, $^3J_{\text{HH}} = 8.1$ Hz, 2 × 2 H, NAr}_{\text{Cl}}_3 and NAr}_{\text{Cl}}_5), 7.18 (t, $^3J_{\text{HH}} = 8.1$ Hz, 2 × 1 H, NAr}_{\text{Cl}}_4), 0.88 (s, 4 × 3 H, OCCH}_3); the ^{13}C NMR spectrum could not be obtained due to the limited stability and solubility of [W(μ -NAr}_{\text{Cl}})(OR_{F6})_2]2 in common NMR solvents; ^{19}F NMR (THF- d_8) δ -79.0 (s). Anal. Calcd for C₂₈H₁₈-Cl₄F₂₄N₂O₄W₂: C, 23.82; H, 1.28; N, 1.98. Found: C, 24.03; H, 1.22; N, 2.01.

W(NAr_{Cl})(CHCMe₃)(Biphen)(THP). A solution of Biphen(Li₂)-(Et₂O) (1.14 g mg, 2.58 mmol) in toluene (20 mL) was added dropwise to a stirred solution of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ (2.00 g, 2.58 mmol) in toluene (50 mL) at -30 °C. The orange solution was stirred at 25 °C for 12 h and then stored at -30 °C for 3 h. The colorless deposit was filtered off and washed with chilled toluene (10 mL, -30 °C) to give an orange solution, to which THP (4 mL) was added. After all volatiles were removed under reduced pressure, the yellow-brownish residue was suspended in pentane (40 mL) to precipitate W(NAr_{Cl})(CHCMe₃)(Biphen)(THP) as a pale yellow powder, which was washed with pentane (10 mL) and dried under reduced pressure (1.80 g, 82%): ¹H NMR (C_6D_6) δ 9.19 (s, $^{2}J_{WH} = 8.3 \text{ Hz}, \, ^{1}J_{CH} = 109.4 \text{ Hz}, \, 1 \text{ H}, \, WCH), \, 7.28, \, 7.12 \, (s, \, 2 \times 10^{-3})$ 1 H, Biphen), 7.03, 6.87 (d, ${}^{3}J_{HH} = 8.1 \text{ Hz}$, 2 × 1 H, NAr_{Cl}-3 and NAr_{Cl} -5), 6.15 (t, ${}^{3}J_{HH}$ = 8.1 Hz, 1 H, NAr_{Cl} -4), 3.24 (br, 2 × 2 H, α -CH₂, THP), 2.33, 2.03, 1.90, 1.76 (s, 4 × 3 H, Biphen-CH₃), 1.72, 1.55, 1.49 (s, 3 \times 9 H, CMe₃), 1.04 (s, 3 \times 2 H, β - and γ -CH₂, THP); ¹³C{¹H} NMR (C₆D₆) δ 266.5 (WCH), 160.5 (aryl), 158.1 (aryl), 151.2 (aryl), 136.7 (aryl), 136.5 (aryl), 136.0 (aryl), 135.4 (aryl), 132.0 (aryl), 131.6 (aryl), 130.1 (aryl), 129.2 (aryl), 128.3 (aryl), 126.9 (aryl), 126.8 (aryl), 123.9 (aryl), 69.8, 46.4, 36.2, 35.3, 34.2, 33.1, 32.8, 26.1, 22.8, 20.9, 20.6, 20.0, 17.6, 17.3. Fifteen out of 18 carbon resonances were observed. Anal. Calcd for C₄₀H₅₅-Cl₂NO₃W: C, 56.35; H, 6.50; N, 1.64. Found: C, 56.22; H, 6.37; N, 1.57.

 $W(NAr_{Cl})(C_3H_6)(Biphen).$ A yellow solution of W(NAr_{Cl})-(CHCMe_3)(Biphen)(THP) (672 mg, 788 $\mu mol)$ in benzene (20 mL) was stirred under ethylene (1 atm) at 25 °C for 16 h. The reaction mixture was frozen, and the volatiles were removed by lyophilization. The analytically pure product was obtained as a pale yellow

powder (553 mg, 95%): ¹H NMR (C_6D_6) δ 7.31 (s, 2 × 1 H, Biphen), 6.82 (d, $^3J_{\rm HH}=8.1$ Hz, 2 × 1 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.09 (t, $^3J_{\rm HH}=8.1$ Hz, 1 H, NAr_{Cl}-4), 4.71, 4.42, 4.35, 3.41 (m, $^1J_{\rm CH}=148.9$ Hz, 161.3 Hz, 153.8 Hz, 151.4 Hz, 4 × 1 H, α-CH₂), 2.16, 1.79 (s, 4 × 3 H, Biphen-CH₃), 1.57 (s, 2 × 9 H, Biphen-CMe₃), -0.03, -0.27 (m, $^1J_{\rm CH}=151.4$ Hz, 153.8 Hz, 2 × 1 H, β-CH₂); 13 C{ 1 H} NMR (toluene- 1 ₈) δ 149.0, 134.2, 129.2, 128.1, 125.9, 96.6 ($^1J_{\rm CH}=148.9$ Hz, 153.8 Hz, α-CH₂), 86.5 ($^1J_{\rm CH}=151.4$ Hz, 161.3 Hz, α-CH₂), 31.4, 20.7, 17.1, -0.1 ($^1J_{\rm CH}=151.4$ Hz, 153.8 Hz, β-CH₂). The resonances of the quarternary carbons of the Biphen ligand could not be assigned unambiguously. The coupling constants $^1J_{\rm CH}$ were determined in an HMQC experiment. Anal. Calcd for C₃₃H₄₁Cl₂NO₂W: C, 53.68; H, 5.60; N, 1.90. Found: C, 53.52; H, 5.54; N, 1.82.

W(NAr_{Cl})(13 CH₂ 13 CH₂(Biphen) was observed when 13 CH₂= 13 CH₂ was employed: 13 C{ 1 H} NMR (C₆D₆) δ 97.7 (br d, α-CH₂), 87.5 (br d, α-CH₂), -0.5 (br t, β-CH₂).

W(NAr_{Cl})(C₂H₄)(Biphen)(THF). Complex W(NAr_{Cl})(C₃H₆)-(Biphen) (1.00 g, 1.35 mmol) was suspended in THF (4 mL), and the mixture was stirred at 25 °C. The yellow suspended powder dissolved to yield an orange-red solution within 2 min. After the reaction mixture was stirred for 16 h, the product precipitated as yellow microcrystals, which were isolated by filtration and washed with pentane (5 mL); yield 700 mg (65%): ¹H NMR (CD₂Cl₂) δ 7.15–7.05 (br, 1 H, Biphen and, 2 × 1 H, NAr_{Cl}-3 and NAr_{Cl}-5), δ 7.00 (s, 1 H, Biphen), 6.72 (t, ³ $J_{\rm HH}$ = 8.1 Hz, 1 H, NAr_{Cl}-4), 3.99 (br, 2 × 2 H, α-CH₂, THF), 3.34, 3.13 (m, 2 × 1 H, WC₂H₄), 2.27, 2.15, 1.86 (s, 3 × 3 H, Biphen-CH₃), 1.83 (br, 2 × 2 H, β-CH₂, THF), 1.42 (s, 3 H, Biphen-CH₃), 1.28, 1.17 (s, 2 × 9 H, Biphen-CMe₃). Two protons in the ethylene group were obscured by other resonances.

 $W(NAr_{CI})(C_2H_4)(Biphen)(THF-d_8)$. An orange solution of W(NAr_{Cl})(C₃H₆)(Biphen) (150 mg, 203 μ mol) in THF- d_8 was kept for 90 min at 25 °C before the NMR spectra were recorded. After 48 h the solvent was decanted to leave behind vellow crystals of W(NAr_{Cl})(C₂H₄)(Biphen)(THF-d₈) (90 mg, 55%): ¹H NMR (THF d_8) δ 7.08 (s, 1 H, Biphen and d, ${}^3J_{\rm HH} = 8.1$ Hz, 2 × 1 H, NAr_{Cl}-3 and NAr_{Cl}-5), δ 6.94 (s, 1 H, Biphen), 6.72 (t, ${}^{3}J_{\rm HH} = 8.1$ Hz, 1 H, NAr_{Cl}-4), 3.31, 3.01 (m, ${}^{1}J_{CH} = 154.4$ Hz, 157.9 Hz, 2 × 1 H, WC_2H_4), 2.27, 2.21, (s, 2 × 3 H, Biphen-CH₃), 2.13, 2.06 (m, $^1J_{CH}$ = 151.7 Hz, 152.6 Hz, 2×1 H, WC₂H₄), 1.87, 1.43 (s, 2×3 H, Biphen-CH₃), 1.29, 1.17 (s, 2×9 H, Biphen-CMe₃); ${}^{13}C\{{}^{1}H\}$ NMR (THF- d_8) δ 160.5 (aryl), 155.7 (aryl), 151.3 (aryl), 140.3 (aryl), 135.8 (aryl), 134.4 (aryl), 134.2 (aryl), 132.1 (aryl), 131.5 (aryl), 131.4 (aryl), 130.6 (aryl), 128.7 (aryl), 128.4 (aryl), 127.2 (aryl), 127.0 (aryl), 123.9 (aryl), 55.8 (${}^{1}J_{CH} = 152.6 \text{ Hz}$, 151.7 Hz, ${}^{1}J_{WC}$ = 37.9 Hz, WC₂H₄), 52.6 (${}^{1}J_{CH}$ = 157.9 Hz, 154.4 Hz, ${}^{1}J_{WC}$ = 34.5 Hz, WC₂H₄), 36.0, 34.7, 31.3, 30.7, 20.5, 20.2, 17.0, 16.9. The coupling constants ${}^{1}J_{CH}$ were determined in an HMQC experiment. Anal. Calcd for C₃₆H₃₉D₈Cl₂NO₃W: C, 53.74; H, 6.89; N, 1.74. Found: C, 53.68; H, 6.95; N, 1.68.

 $W(NAr_{Cl})(C_4H_8)(Biphen)$. $W(NAr_{Cl})(Biphen)(C_2H_4)(THF)$ (600 mg, 813 μ mol) was suspended in benzene (50 mL), and the degassed reaction mixture was stirred under ethylene (1 atm) at 25 °C for 15 min. Upon addition of ethylene, the yellow suspension immediately dissolved to yield an orange-red solution. The reaction mixture was frozen, and the volatiles were removed by lyophilization to give an approximate 6:1 mixture of W(NAr_{Cl})(C₄H₈)(Biphen) and unreacted W(NAr_{Cl})(Biphen)(C₂H₄)(THF). This material was redissolved in benzene (50 mL), and the above procedure was repeated (addition of ethylene, lyophilization) to yield W(NAr_{Cl})-(C₄H₈)(Biphen) as an orange powder (500 mg, 82%): ¹H NMR $(C_6D_6) \delta 7.32, 7.13 (s, 2 \times 1 H, Biphen), 6.78 (d, {}^3J_{HH} = 8.1 Hz,$ 2×1 H, N NAr_{Cl}-3, N NAr_{Cl}-5), 6.09 (t, ${}^{3}J_{HH} = 8.1$ Hz, 1 H, N NAr_{Cl}-4), 3.75 (m, ${}^{1}J_{CH} = 124.4$ Hz, 1 H, α -CH₂, WC₄H₈), 3.46 $(m, {}^{1}J_{CH} = 123.3 \text{ Hz}, 1 \text{ H}, \alpha\text{-CH}_{2}, WC_{4}H_{8}), 3.41 \text{ (m, } {}^{1}J_{CH} = 136.7 \text{ m}$ Hz, 1 H, β-CH₂, WC₄H₈), 3.37 (m, ${}^{1}J_{CH} = 128.5$ Hz, 1 H, α-CH₂,

WC₄H₈), 3.37 (m, ${}^{1}J_{\text{CH}} = 132.1$ Hz, 1 H, β -CH₂, WC₄H₈), 3.34 (m, ${}^{1}J_{\text{CH}} = 137.9$ Hz, 1 H, β -CH₂, WC₄H₈), 3.32 (m, ${}^{1}J_{\text{CH}} = 126.8$ Hz, 1 H, α -CH₂, WC₄H₈), 3.07 (m, ${}^{1}J_{\text{CH}} = 135.6$ Hz, 1 H, β -CH₂, WC₄H₈), 2.09, 2.05, 1.73, 1.61 (s, 4 × 3 H, Biphen-CH₃), 1.60 (s, 9 H, CMe₃), 1.49 (s, 9 H, CMe₃); ${}^{13}\text{C}\{{}^{1}\text{H}\}$ NMR (C₆D₆) δ 160.4, 150.8, 150.3, 140.9, 136.5, 136.4, 134.6, 133.6, 133.2, 132.6, 131.2, 130.9, 129.6, 128.9, 127.8, 126.7, 126.1, 85.3 (${}^{1}J_{\text{WC}} = 79.3$ Hz, ${}^{1}J_{\text{CH}} = 123.3$ Hz, 128.5 Hz, α -CH₂), 77.5 (${}^{1}J_{\text{WC}} = 79.3$ Hz, ${}^{1}J_{\text{CH}} = 124.4$ Hz, 126.8 Hz, α -CH₂), 38.3 (${}^{1}J_{\text{CH}} = 132.1$ Hz, 135.6 Hz, β -CH₂), 37.8 (${}^{1}J_{\text{CH}} = 136.7$ Hz, 137.9 Hz, β -CH₂), 35.6, 35.5, 32.0, 31.0, 20.7, 20.5, 17.4, 17.2. One aromatic carbon resonance could not be located. The coupling constants ${}^{1}J_{\text{CH}}$ were determined in an HMQC experiment. Anal. Calcd for C₃₄H₄₃Cl₂NO₂W: C, 54.27; H, 5.76; N, 1.86. Found: C, 54.18; H, 5.71; N, 1.84.

W(NAr_{Cl})(13 CH₂)₄(Biphen) was observed when 13 CH₂= 13 CH₂ was employed; 13 C{ 1 H} NMR (C₆D₆) δ 85.4 (d, 1 J_{CC} = 33.6 Hz, α-CH₂), 77.4 (d, 1 J_{CC} = 32.8 Hz, α-CH₂), 38.3, 37.7 (dt, 1 J_{CC} = 33.6 and 32.8 Hz, β-CH₂).

[W(NAr_{Cl})(Biphen)(μ -CH₂)]₂. A solution of W(NAr_{Cl})(C₃H₆)-(Biphen) (400 mg, 542 μ mol) in benzene (2 mL) was stirred for 24 h at 25 °C, and pentane (8 mL) was added. Purple microcrystals of [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂ were isolated by filtration and washed with pentane (2 mL); yield 112 mg (29%). Due to the insolubility of isolated [W(NAr_{Cl})(Biphen)(μ -CH₂)]₂, a complete set of NMR spectroscopic data could not be obtained.

 $[W(NAr_{Cl})(Biphen)]_2(\mu-CH_2CH_2)]_2$. A degassed solution of $W(NAr_{Cl})(C_3H_6)(Biphen)$ (500 mg, 677 μ mol) in benzene (10 mL) was stirred in a sealed thick-walled glass vessel for 90 min at 100 °C to give a dark orange solution, which was filtered through Celite. The volatiles were removed by lyophilization to leave behind a brown powder that was approximately a 5:1 mixture of [W(NArCl)-(Biphen)]₂(μ -CH₂CH₂) and [W(NArCl)(Biphen)]₂, along with a trace of W(NAr_{Cl})(C₄H₈)(Biphen). The product mixture was washed with pentane (50 mL) to extract all W(NAr_{Cl})(C₄H₈)(Biphen). After all volatiles were removed under reduced pressure, the brown powder was suspended in benzene (~2 mL) and exposed to ethylene (1 atm) for 2 h. The supernatant was decanted from the orange microcrystalline product, which was then washed with pentane (5 mL); yield 140 mg (29%): 1 H NMR (C₆D₆) δ 7.28 (s, 4 × 1 H, Biphen), 7.02 (d, ${}^{3}J_{HH} = 8.1 \text{ Hz}$, 2 × 1 H, NAr_{Cl}-3), 6.47 (d, ${}^{3}J_{HH}$ = 8.1 Hz, 2 × 1 H, NAr_{Cl}-5), 6.14 (t, ${}^{3}J_{HH}$ = 8.1 Hz, 2 × 1 H, NAr_{Cl}-4), 3.71 (m, ${}^{1}J_{CH} = 151.4 \text{ Hz}$, 2 × 1 H, WCH₂), 2.21, 2.11 (s, 4 × 3 H, Biphen-CH₃), 2.06 (m, ${}^{1}J_{CH} = 140.8$ Hz, 2 × 1 H, WCH₂), 1.95, 1.61 (s, 4×3 H, Biphen-CH₃), 1.34, 1.21 (s, 4×9 H, Biphen-CMe₃); ${}^{13}C\{{}^{1}H\}$ NMR (C₆D₆) δ 162.6, 161.6, 161.5, $136.3 (2 \times s), 136.1, 134.3, 131.8, 130.7, 130.6, 130.5, 129.9, 128.7,$ 127.9, 126.9, 70.6 (${}^{1}J_{CH} = 140.8 \text{ Hz}$, 151.4 Hz, WCH₂), 36.6, 35.7, 33.3, 31.9, 23.8, 21.2, 18.0 (2 \times s). The WCH₂ coupling constants ${}^{1}J_{\text{CH}}$ were determined in an HMQC experiment. Anal. Calcd for C₃₁H₃₇Cl₂NO₂W: C, 52.41; H, 5.25; N, 1.97. Found: C, 52.35; H, 5.31; N, 1.85.

Reaction of W(NAr_{Cl})(CHCMe₃)[OC(CF₃)₂Me]₂ with *trans*-3-Hexene. A bright yellow solution of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂ (25 mg, 32 μ mol) in toluene- d_8 was treated with *trans*-3-hexene (4 μ L, 32 μ mol), and the sample was kept at -78 °C until the NMR spectra were recorded. After 40 min at 0 °C, the yellow solution

contained a 2:1:1 mixture of W(NAr_{Cl})(CHCMe₃)(OR_{F6})₂, W(NAr_{Cl})(CHEt)(OR_{F6})₂, and W(NAr_{Cl})(OR_{F6})₂(CHEt)₃. W(NAr_{Cl})(CHEt)-(OR_{F6})₂ resonances were observed in the ¹H NMR spectrum (toluene- d_8 , 0 °C) at 9.27 (br, 1 H, WCH), 6.69 (d, ³ $J_{\rm HH}$ = 8.1 Hz, 2 H, NAr_{Cl}-3 and NAr_{Cl}-5), 6.00 (t, ³ $J_{\rm HH}$ = 8.1 Hz, 1 H, NAr_{Cl}-4), 3.56 (m, 2 H, WCHC H_2), 1.81 (s, 2 × 3 H, OCCH₃), and 0.75 (t, ³ $J_{\rm HH}$ = 7.2 Hz, 3 H, WCHCH₂C H_3) ppm. The tungstacyclobutane resonances were observed in the ¹H NMR spectrum (toluene- d_8 , 0 °C) at -0.31, -0.41, -0.51, and -0.80 ppm (m, 5:1:3:1 mixture of 4 isomers, 1 H, β -CH). Other resonances could not be assigned unambiguously.

After 24 h at 0 °C, the above solution contained a 1:1 mixture of unreacted starting material and tungstacyclobutanes, along with insoluble $[W(\mu-NAr_{Cl})(OR_{F6})_2]_2$.

Reaction of W(NAr_{Cl})(Biphen)(CH₂CH₂)(THF-d₈) with Excess $^{13}CH_2$ = $^{13}CH_2$: Observation of W(NAr_{Cl})(Biphen)($^{13}C_4H_8$). At -196 °C, ${}^{13}\text{CH}_2 = {}^{13}\text{CH}_2$ (600 μ mol) was condensed into an NMR tube that was charged with a yellow solution of W(NAr_{Cl})-(Biphen)(CH₂)₂(THF-d₈) (35 mg, 44 μmol) in CD₂Cl₂ (0.7 mL). After the sealed NMR tube was allowed to warm to 25 °C, the color of the solution rapidly changed to orange. NMR spectra recorded after the sample was kept for 30 min at 25 °C indicated that W(NAr_{Cl})(Biphen)(CH₂)₂(THF-d₈) had been completely converted into W(NAr_{Cl})(Biphen)(¹³CH₂)₄: ¹H NMR (CD₂Cl₂) δ 7.07 $(d, s, 3 \times 1 \text{ H}, NAr_{Cl}-3, NAr_{Cl}-5 \text{ and Biphen}) 6.94 (s, 1 H, Biphen),$ 6.70 (t, ${}^{3}J_{HH} = 8.1 \text{ Hz}$, 1 H, NAr_{Cl}-4), 5.23 (m, 40 H, ${}^{13}\text{CH}_{2}$ = 13 -CH₂), 3.33-2.56 (m, 8 H, W¹³C₄H₈), 2.07, 1.98, 1.52 (s, 3×3 H, Biphen-CH₃), 1.32 (s, 3 + 9 H, Biphen-CH₃ and CMe₃), 1.15 (s, 9 H, CMe₃); ${}^{13}C\{{}^{1}H\}$ NMR (CD₂Cl₂) δ 123.4 (s, ${}^{13}CH_2={}^{13}CH_2$), 86.4 (d, ${}^{1}J_{CC} = 35.4 \text{ Hz}$, α -CH₂), 75.3 (d, ${}^{1}J_{CC} = 34.5 \text{ Hz}$, α -CH₂), 37.6 (m, β -CH₂). Coupling constants ${}^{2}J_{HH}$ and chemical shifts of the methylidene resonances in the ¹H NMR spectrum were determined in an experiment employing unlabeled ethylene instead of ¹³CH₂=¹³CH₂. Since the methylidene resonance at 7.61 ppm in the ¹H NMR spectrum of W(NAr_{Cl})(Biphen)(μ -¹³CH₂)₂ was obscured, ${}^{1}J_{\text{CH}}$ could not be determined.

Acknowledgment. R.R.S. thanks the National Science Foundation (CHE-0138495) for supporting this research and W. C. P. Tsang for initial investigations during his Ph.D. studies. S.A. thanks the Alexander von Humboldt Foundation for partial support through a Feodor Lynen Research Fellowship.

Supporting Information Available: Labeled thermal ellipsoid drawings, crystal data and structure refinement, atomic coordinates and equivalent isotropic displacement parameters, bond lengths and angles, and anisotropic displacement parameters for all crystallographically characterized compounds. This material is available free of charge via the Internet at http://pubs.acs.org. Data for $\{W(\mu-NAr_{Cl})[OC(CF_3)_2Me]_2\}_2(C_6H_6)$ (06034), $W(NAr_{Cl})(Biphen)-(C_3H_6)(CH_2Cl_2)_{0.25}$ (06135), $W(NAr_{Cl})(Biphen)(C_2H_4)(THF-d_8)$ (06140), $W(NAr_{Cl})(Biphen)(C_4H_6)$ (06179), $[W(NAr_{Cl})(Biphen)-(\mu-CH_2)]_2$ (06185), and $W_2(Biphen)_2(\mu-NAr_{Cl})_2(\mu-CH_2CH_2)$ (06208) are also available to the public at http://www.reciprocalnet.org/.
