The Chloromethylgermyl Complexes $(\eta^5-C_5H_5)M(CO)_nGeR_2CH_2Cl$ [M = Fe (n = 2), Mo, W (n = 3)]: Rearrangements, Transformations to 1-Germa-3-metallacyclobutanes

$(\eta^5 - C_5 H_4)M(CO)_n CH_2 GeR_2$, and their Ring-Opening Polymerizations

The reactions between the transition metal-carbonylate salts $[(\eta^5-C_5H_5)M(CO)_n]^-Na^+$ (M = Fe (n = 2), Mo, W (n = 3)) and ClCH₂GeR₂Cl result in the high-yield formation of $(\eta^5-C_5H_5)M(CO)_n$ GeR₂CH₂Cl (M = Fe, R = Me (1), n-Bu (2); M = Mo, R = Me (3), R = n-Bu (4); M = W, R = Me (5), R = n-Bu (6)). Complexes 1, 2, 5, and 6 are transformed into the isomers $(\eta^5-C_5H_5)M(CO)_n$ CH₂GeR₂Cl (1a, 2a, 5a, and 6a) thermally and/or photochemically. Treatment of either type of complex and the Mo complexes 3 and 4 with lithium diisopropylamide results in the formation of the metallacycles $(\eta^5-C_5H_4)M(CO)_n$ CH₂GeR₂ (7-12). The metallacycles of Mo and W (9 and 11) are crystalline complexes, and single-crystal X-ray analysis reveals a degree of ring strain. However, these complexes cannot be ring-opened, in contrast to the corresponding Fe complexes (7 and 8), which readily form new polymeric

materials $[(\eta^5 - C_5H_4)Fe(CO)_2CH_2GeR_2]_n$.

Introduction

Ring-opening of well-defined metallacycles can lead to attractive materials with potential applications as catalysts,¹ ion-exchange resins,² polymeric support materials,³ precursors for ceramic materials,⁴ conducting polymers,^{5,6} and chemical sensors.⁶ There are limited reports on the synthesis and reactivity of germametallacyclobutanes.⁷ ansa-Dimethylgermyldicyclopentadienyl ligands of Zr, Hf, and Ti yield tetrahedral complexes with little ring strain in the metallacycle portion of the structure, and no specific metallacyclobutane chemistry has been reported.⁷ However, they are useful catalysts for the polymerization of olefins.⁸ Although, 1-sila-3-metallacyclobutanes, Cp₂MCH₂SiMe₂CH₂, (M = Ti, Zr, Hf)^{1a} are known for their ring expansion chemistry, such chemistry is not reported for the related germa^{7a} and stanna^{7b} derivatives. On the other hand, 1-germa- and stannaferrocenophanes have been studied and shown to readily ring open to form interesting high molecular weight polymers.⁹

We recently reported a series of 1-sila-3-ferracycles (η^{5} -C₅H₄)Fe(CO)₂ER₂SiR₂' (ER₂ = CH₂, SiR₂; R' = Me, *n*-Bu) that under certain conditions ring-opened to organometallic polymers.¹⁰ We now report the synthesis, characterization, rearrangements, and ring-opening polymerization of 1-germa-3-metallacyclobutanes, (η^{5} -C₅H₄)M(CO)_nCH₂GeR₂ [M = Mo, W (*n* = 3); Fe (*n* = 2) and R = Me, Bu].

Results and Discussion

Using standard salt-elimination chemistry the synthesis of a series of dialkyl(chloromethyl)germyl metal complexes, MpGeR₂CH₂Cl, was accomplished in moderate yields as outlined in eq 1, Mp = $(\eta^5-C_5H_5)$ Fe(CO)₂ [R = Me (1), *n*-Bu (2)]; $(\eta^5-C_5H_5)$ Mo(CO)₃ [R = Me (3), *n*-Bu (4)]; $(\eta^5-C_5H_5)$ W(CO)₃ [R = Me (5), Bu (6)].

$$[Mp]^{-}Na^{+} + ClGeR_{2}CH_{2}Cl \rightarrow MpGeR_{2}CH_{2}Cl + NaCl$$
(1)

The photolysis of benzene solutions of complexes MpGeR₂CH₂Cl (1, 2, and 6) in sealed Pyrex NMR tubes for 14-24 h resulted in quantitative rearrangement to the isomeric complexes MpCH₂GeR₂Cl [M = Fe, R = Me (1a), n-Bu (2a)]and M = W, R = n-Bu (6a)] containing a direct M-C bond. Benzene solutions of the iron complexes 1 and 2 also rearranged thermally to 1a and 2a, reminiscent of the thermal rearrangement of $(\eta^5-C_5H_5)Fe(CO)_2SiMe_2CH_2Cl$ to $(\eta^5-C_5H_5)Fe(CO)_2CH_2$ SiMe₂Cl.^{10,11} The iron isomers **1a** and **2a** were easily distinguished by the 13 C resonances of the methylene group, -16.8ppm (1a, Fe- CH_2Ge), -20.6 ppm (2a, Fe- CH_2Ge) versus those of their parent complexes, 37.6 ppm (1, Fe-GeCH₂), 35.2 ppm (2, Fe-GeCH₂). Infrared spectroscopy was also useful to distinguish the two sets of isomers, and the carbonyl stretching frequencies for the Fp-Ge complex 1 are $\sim 10 \text{ cm}^{-1}$ lower than the carbonyl stretching frequencies of Fp-C complex **1a**.¹² It is possible that the mechanism of the photochemical rearrangement may involve the initial decarbonylation to generate a 16e⁻ coordinatively unsaturated complex followed by β -elimination of chlorine to the metal center to generate a transient germene complex. The recoordination of CO drives the migration of chlorine to the germanium, Scheme 1, to effect the rearrangement process. Presumably the initial formation of the M-Ge complexes is associated with the greater kinetic lability of the Ge-Cl bond versus the C-Cl bond. However, the greater bond energy of the Ge–Cl versus C–Cl ($E_{Ge-Cl} = 83.1$ kcal/mol;¹³ $E_{\rm C-Cl} = 68.3 \text{ kcal/mol}^{14}$) is in large measure the driving force for the formation of the thermodynamically stable product. The $E_{\text{Fe-Ge}}$ and $E_{\text{W-Ge}}$ data are not available to complete this

(14) Kumaran, S. S.; Su, M.-C.; Lim, K. P.; Michael, J. V.; Wagner, A. F.; Harding, L. B.; Dixon, D. A. J. Phys. Chem. **1996**, 100, 7541.

analysis, but they cannot be more stable by ~14.8 kcal/mol than the respective Fe–C and W–C bond energies ($E_{\text{Fe-C}} = 68.0$ kcal/mol,¹⁵ $E_{\text{W-C}} = 60.8$ kcal/mol).¹⁶ However, it is of interest that the Mo derivative, (η^{5} -C₅H₅)Mo(CO)₃GeMe₂CH₂Cl, did not rearrange either thermally or photochemically, presumably due to the higher Mo–Ge bond energy as compared to the Mo–C bond, as indicated by available data ($E_{\text{Mo–Ge}} = 51.5$ kcal/mol, $E_{\text{Mo-C}} = 33.2$ kcal/mol,^{14,17} $\Delta E = 18.3$ kcal/mol).

Treatment of complexes 1–6, 1a, 2a, and 6a containing M–Ge or M–C bonds with 1 equiv of lithium diisopropylamide, LDA, resulted in the initial formation of the corresponding 1-alkylgerma-3-metallacyclobutanes in high yield (\sim 80%), Scheme 2, pathway A. In all cases the initial proof for the formation of the metallacyclobutanes was the observation of the ring methylene resonance in the ¹³C NMR spectra at between ca. –50 and –65 ppm.

Isolation of the cyclobutanes was dependent upon the metal involved. In the case of the Mo and W complexes, **9–12**, these metallacyclobutanes were isolated as stable crystalline materials. The dimethylgerma iron complex **7** was short-lived and transformed to a polymer **7a**, $M_w = 2.5 \times 10^3$, $M_n = 2.2 \times 10^3$, $(M_w/M_n) = 1.13$ (Scheme 2, B).

The corresponding butylgermyl iron complex **8** was stable enough for isolation and purification by column chromatography; however, it also undergoes a ring-opening polymerization if it is kept for a prolonged time (~ a month) even at low temperature (0 °C), resulting in the formation of polymer **8a**, $M_w = 5.4 \times 10^3$, $M_n = 2.5 \times 10^3$, PDI (M_w/M_n) = 2.1. This differs from our results with the silicon analogue di-*n*-butylsilaferracyclobutane, (η^5 -C₅H₄)Fe(CO)₂CH₂SiBu₂, which was found to be very stable.^{10a} TGA analysis of the polymers **7a** and **8a** showed an onset of weight loss between 200 and 300 °C, resulting in ~45% residual mass at 650 °C.

X-ray Crystal Structures of 9 and 11. The molecular structures of **9** and **11** are shown in Figure 1. The two metallacycles are isostructural and crystallize in the triclinic space group $P\overline{1}$, and the asymmetric unit contains two molecules for each of the metallacycles with little variations in the bond lengths and angles. They exhibit almost planar cyclobutane rings, and the ligands are disposed in a distorted four-legged

M = Fe, R = Me (7a), n-Bu (8a), n = 2

piano stool fashion as observed for analogous tricarbonyl cyclopentadienyl group 6 metal complexes.¹⁸ The angles between adjacent atoms in the ring vary from 74.3° to 94.3 (4)° in **9** and 74.1° to 96.3 (4)° in **11** and are also typical for these types of structures (Table 2).¹⁸ The internal angles of the fourmembered ring differ significantly from the values of normal tetrahedral angles, indicating that the cyclic portion of the molecules composed of M–C–Ge–C possesses a significant strain and causes the cyclobutane ring to be puckered with folding angles of 15.5° (**9**, molecule 1), 9.8° (**9**, molecule 2) and 9.9° (**11**, molecule 1), 16° (**11**, molecule 2). Despite the ring strain, to date these metallacycles have not exhibited a propensity for ring-opening polymerization.

Metallacycle Reactivity. The Mo metallacycle (9) was treated with a range of reagents including a radical initiator (AIBN), anionic and base species (n-BuLi, LDA, Et₃N), and transition metal complexes such as (PPh₃)₄Pd in attempts to observe ring-opened polymerization. None of these experiments were successful.

The thermal reaction of **9** and **11** with Ph₃P in THF resulted in the formation of the simple phosphine-substituted products $(\eta^5-C_5H_4)Mo(CO)_2(Ph_3P)CH_2GeMe_2$ (**9a**) and $(\eta^5-C_5H_4)W(CO)_2(Ph_3P)CH_2GeMe_2$ (**11a**) (eq 2).

Infrared and ¹³C NMR spectral values indicated that **9a** [1920 (vs), 1843 cm⁻¹ (s); -47.2 (d, CH₂, ${}^{2}J_{P-C} = 7.6$ Hz); 228.6 (d, CO, ${}^{2}J_{P-C} = 16.5$ Hz)] and **11a** [1918 (vs), 1847 cm⁻¹ (s); -57.6 (d, CH₂, ${}^{2}J_{P-C} = 7.3$ Hz); 228.6 (d, CO, ${}^{2}J_{P-C} = 16.0$ Hz)] adopt the trans-isomeric form. The ¹³C NMR spectral data of compound **9a** are similar to those of *trans-*(η^{5} -

 \dot{C}_5H_4)Mo(CO)₂{(PhO)₃P}CH₂ $\dot{G}eMe_2$ [233.9 (d, CO, ${}^2J_{P-C} =$ 33.8 Hz); -47.2 (d, CH₂, ${}^2J_{P-C} =$ 8.4 Hz)].¹⁹ In addition to that, other molybdenum complexes, (η^5 -C₅H₅)Mo(CO)₂(L)R (L = P(OR₃), PR₃; R = H, Hal, Me, PhCH₂, etc.),²⁰ revealed the increase of trans-isomer percentage on increasing the steric bulk around the metal atom; for example, L = Ph₃P, R = Me, PhCH₂ forms >99% trans-isomer. Similarly, W complexes (η^5 -C₅H₅)W(CO)₂(Ph₃P)X (X = alkyl)²¹ are reported to adopt a trans-isomeric form on increasing the steric bulk around the metal atom.

No fluxional behavior for these compounds in solution state has been seen in the NMR spectroscopy, which is authenticated by the presence of only one doublet in the methylene and carbonyl region.

Experimental Procedures

All syntheses were performed using standard Schlenk techniques under nitrogen atmospheres. The required glassware was oven-dried at 100 °C for a period of 12 h, assembled hot and cooled under vacuum, and purged with nitrogen. Reagent grade tetrahydrofuran (THF) was dried and distilled from sodium-benzophenone. Benzene, hexanes, and toluene were dried and distilled from Na wire. The following reagents were purchased from Aldrich and used as received: bromobenzene, bromochloromethane, diisopropylamine, and *n*-BuLi (as a 1.6 M solution in hexanes). Dimethyldichlorogermane and di-*n*-butyldichlorogermane were purchased from Gelest and used as received. The dimers $[(\eta^5-C_5H_5)(CO)_2Fe]_2$ and $[(\eta^5-C_5H_5)(CO)_3Mo]_2$ were purchased from Strem Chemical; $[(\eta^5-C_5H_5)(CO)_3W]_2$ was purchased from Acros Organics. Lithium diisopropylamide (LDA) was freshly prepared from (1.6 M) *n*-BuLi and diisopropyl amine. Solution NMR spectra were recorded on a

Figure 1. ORTEP diagram of the molecular structures of $(\eta^5 - C_5H_5)Mo(CO)_3CH_2GeMe_2$ (9) and $(\eta^5 - C_5H_5)W(CO)_3CH_2GeMe_2$ (11). Thermal ellipsoids are drawn at the 50% probability level (only one molecule of each compound is shown).

Bruker 300 MHz spectrometer using CDCl₃ or C₆D₆ as solvent and reported as ppm; infrared spectra were recorded on an ATI Mattson Infinity Series FTIR; elemental analyses were performed by Galbraith Laboratories. Gel permeation chromatography (GPC) analysis of the molecular weight distribution of the polymers was performed on a high-performance liquid chromatography (HPLC) instrument comprised of a Spectra-Physics Spectra System P1500 gradient pump, UV2000 detector, and Winner for Windows software. A Waters 7.8 × 300 mm Styragel column packed with 5 μ m particles of mixed pore size and highly cross-linked styrenedivinylbenzene copolymer particles maintained at 24 °C was used for the analysis. The eluting solvent was HPLC grade THF at a flow rate of 1.0 mL/min. The retention times were calibrated against known polystyrene standards at molecular weights of 4000, 18 700, 44 000, 97 000, and 212 400.

Synthesis of (η^{5} -C₅H₅)Fe(CO)₂GeMe₂CH₂Cl (1). To 60 mL of a THF solution of [(η^{5} -C₅H₅)Fe(CO)₂]⁻Na⁺ (prepared from 1.40 g (4.0 mmol) of [(η^{5} -C₅H₅)Fe(CO)₂]₂) was added, via syringe, 1.5 g (8.0 mmol) of ClCH₂GeMe₂Cl²² in 10 mL of THF at -78 °C. The solution was initially stirred at low temperature, warmed to room temperature, and further stirred overnight. The solvent was removed under vacuum, the residue was extracted with 40 mL of hexane and filtered through Celite, and the solvent was removed under vacuum. The residue was redissolved in 30 mL of hexane and again filtered through Celite. Removal of the solvent afforded (2.0 g, 6.0 mmol, 77% yield) (η^{5} -C₅H₅)Fe(CO)₂GeMe₂CH₂Cl (1)

(η^{5} -C₅H₅)Fe(CO)₂GeBu₂CH₂Cl (2). As above FpGeBu₂CH₂Cl (2) was obtained as a red viscous material from the reaction of $[(\eta^{5}-C_{5}H_{5})Fe(CO)_{2}]^{-}Na^{+}$ (prepared from 2.0 g (5.6 mmol) of $[\eta^{5}-C_{5}H_{5})Fe(CO)_{2}]_{2}$) and 2.9 g (11.0 mmol) of ClCH₂GeBu₂Cl;¹⁷ yield 3.8 g, 9.2 mmol, 84%. Anal. Calcd for C₁₆H₂₅FeO₂GeCl (mol wt 413.28): C, 46.50; H, 6.10. Found: C, 47.05; H, 6.25. ¹H NMR (C₆D₆): 0.96 (m, 6H, Bu), 1.21–1.50 (m, 12H, Bu), 3.20 (s, 2H, CH₂), 4.14 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): 13.9, 20.4, 26.8, 28.7 (Bu), 35.2 (CH₂), 82.5 (C₅H₅), 215.7 (CO). IR (ν CO, cm⁻¹, THF): 1999, 1951.

 $(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}GeMe_{2}CH_{2}CI$ (3). In a manner similar to that described above $(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}GeMe_{2}CH_{2}CI$ (3) was obtained as a pale pink solid from the reaction between $[(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}]^{-}Na^{+}$ (prepared from 0.88 g (1.80 mmol) of $[(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}]_{2}$) and 0.70 g (3.60 mmol) of ClCH₂GeMe₂Cl; yield (1.2 g, 3.0 mmol, 90%), mp 78 °C. Anal. Calcd for C₁₁H₁₃MoO_{3}GeCl: C, 33.26; H, 3.30. Found: C, 33.22; H, 3.42. ¹H NMR (C₆D₆): 0.69 (s, 6H, Me), 3.17 (s, 2H, CH₂), 4.47 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): 3.18 (Me), 36.8 (CH₂), 89.9 (C₅H₅), 225.8, 231.0 (CO). IR (ν CO, cm⁻¹, THF): 1999, 1926, 1901.

 $(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}GeBu_{2}CH_{2}CI (4)$. The reaction between $[(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}]^{-}Na^{+}$ (prepared from 2.0 g (4.10 mmol) of $[(\eta^{5}-C_{5}H_{5})Mo(CO)_{3}]_{2}$) and 2.90 g (10.0 mmol) of ClCH₂GeBu₂Cl afforded (4.0 g, 8.30 mmol, 83%) ($\eta^{5}-C_{5}H_{5}$)Mo(CO)₃GeBu₂CH₂Cl (5) as a pale pink oil. Anal. Calcd for C₁₇H₂₅MoO₃GeCl: C, 42.42; H, 5.23. Found: C, 42.26; H, 5.19. ¹H NMR (C₆D₆): 0.93 (m, 6H, Bu), 1.45 (m, 12H, Bu), 3.36 (s, 2H, CH₂), 4.66 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): 13.4, 20.4, 26.3, 28.5 (Bu), 35.0 (CH₂), 89.3 (C₅H₅), 225.7, 230.9 (CO). IR (ν CO, cm⁻¹, hexanes): 2005, 1936, 1913.

 $(\eta^{5}-C_{5}H_{5})W(CO)_{3}GeMe_{2}CH_{2}Cl$ (5). As above, the reaction between $[(\eta^{5}-C_{5}H_{5})W(CO)_{3}]^{-}Na^{+}$ (prepared from 1.0 g (1.50 mmol) of $[(\eta^{5}-C_{5}H_{5})W(CO)_{3}]_{2})$ and 0.56 g (3.0 mmol) of ClCH₂GeMe₂Cl afforded (1.2 g, 2.47 mmol, 82.7%) of $(\eta^{5}-C_{5}H_{5})W(CO)_{3}GeMe_{2}CH_{2}Cl$ (3) as a yellow solid, mp 86 °C. Anal. Calcd for C₁₁H₁₃WO₃GeCl: C, 27.23; H, 2.70. Found: C, 27.01; H, 2.65. ¹H NMR (C₆D₆): 0.72 (s, 6 H, Me), 3.20 (s, 2H, CH₂), 4.47 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): 2.36 (Me), 36.1 (CH₂), 82.6 (C₅H₅), 215.6, 219.3 (CO). IR (ν CO, cm⁻¹, hexanes): 2005, 1930, 1909.

 $(\eta^{5}-C_{5}H_{5})W(CO)_{3}GeBu_{2}CH_{2}Cl$ (6). The reaction between $[(\eta^{5}-C_{5}H_{5})W(CO)_{3}]^{-}Na^{+}$ (prepared from 1.0 g (1.50 mmol) of $[(\eta^{5}-C_{5}H_{5})W(CO)_{3}]_{2}$) and 0.81 g (3.0 mmol) of ClCH₂GeBu₂Cl afforded

(1.44 g, 2.50 mmol, 85.0%) of (η^{5} -C₅H₅)W(CO)₃GeBu₂CH₂Cl (**6**) as a yellow oil. Anal. Calcd for C₁₇H₂₅WO₃GeCl: C, 35.87; H, 4.43. Found: C, 36.21; H, 4.32. ¹H NMR (C₆D₆): 0.94 (m, 6H, Bu), 1.44 (m, 12H, Bu), 3.40 (s, 2H, CH₂), 4.66 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): 13.9, 19.9, 26.8, 29.1 (Bu), 34.8 (CH₂), 88.5 (C₅H₅), 216.1, 219.7 (CO). IR (ν CO, cm⁻¹, hexanes): 2003, 1928, 1907.

Synthesis of (η^5 -C₅H₅)Fe(CO)₂CH₂GeMe₂Cl (1a). A solution of 100 mg of (η^5 -C₅H₅)Fe(CO)₂GeMe₂CH₂Cl in 1 mL of C₆D₆ was degassed and sealed in an NMR tube. The NMR tube was placed in an oil bath at a temperature of 90–100 °C, and the progress of the reaction was followed by ¹³C NMR. After 16 h the reaction was completed and the spectroscopic data indicated the quantitative formation of the rearranged product, 91% yield (0.9 g, 2.7 mmol). The photolysis of FpGeMe₂CH₂Cl in a sealed NMR tube for 48 h also afforded the rearranged compound in an 80% yield along with some decomposition. Anal. Calcd for C₁₀H₁₃FeO₂GeCl: C, 36.49; H, 3.98. Found: C, 36.81; H, 3.84. ¹H NMR (C₆D₆): 0.65 (s, 6H, Me), 0.23 (s, 2H, CH₂), 4.04 (s, 5H, C₅H₅). ¹³CNMR (C₆D₆): -16.8 (CH₂), 6.6 (Me), 84.9 (C₅H₅), 216.7 (CO). IR (ν CO, cm⁻¹, hexanes): 2017, 1965.

 $(\eta^{5}-C_{5}H_{5})Fe(CO)_{2}CH_{2}GeBu_{2}Cl$ (2a). Compound 2a was obtained in the same manner as 1a as a red oil in a 95% yield. ¹H NMR (C₆D₆): 0.26 (s, 2H, CH₂), 0.92 (t, 6H, Bu), 1.16–1.60 (m, 12H, Bu), 4.19 (s, 5H, C₅H₅). ¹³C NMR (C₆D₆): -20.6 (CH₂), 13.9, 21.7, 26.3, 26.9 (Bu), 85.2 (C₅H₅), 215.0 (CO). IR (ν CO, cm⁻¹, THF): 2015, 1963. Elemental analysis could not be performed due to continuous decomposition of the compound, which was used immediately upon formation.

Synthesis of (η^5 -C₅H₅)W(CO)₃CH₂GeBu₂Cl (6a). A solution of 100 mg of (η^5 -C₅H₅)W(CO)₃GeBu₂CH₂Cl (6) in 1 mL of C₆D₆ was degassed and sealed in an NMR tube. The photochemical (350 nm) treatment of this solution resulted in the quantitative formation of the rearranged product (6a). ¹H NMR (C₆D₆): 0.57 (s, 2H, CH₂), 0.95 (m, 6H, Bu), 1.44 (m, 12H, Bu), 4.57(s, 5H, C₅H₅). ¹³C NMR (C₆D₆): -34.8 (CH₂), 13.9, 22.5, 26.3, 26.9 (Bu), 88.5 (C₅H₅), 218.1, 229.4 (CO). IR (ν CO, cm⁻¹, hexanes): 2021, 1937, 1926. As with **2a**, elemental analysis was unsuccessful, and the material was used immediately upon formation.

Synthesis of $(\eta^5 - C_5H_4)Fe(CO)_2CH_2GeMe_2$ (7). In a 50 mL round-bottomed Schlenk flask was placed 0.6 g (1.8 mmol) of either $(\eta^{5}-C_{5}H_{5})Fe(CO)_{2}GeMe_{2}CH_{2}Cl$ (1) or $(\eta^{5}-C_{5}H_{5})Fe(CO)_{2}CH_{2}$ GeMe₂Cl (1a) in 10 mL of THF. To this solution at -25 °C was added 1.5 mL (1.9 mmol) of freshly prepared LDA in the same solvent via cannula. The color of the reaction solution immediately changed from red to dark brown. The solution was stirred for 30 min at low temperature and for 2 h at room temperature, and the formation of 7 was monitored by ¹³C NMR spectroscopy. After that, the solvent was removed from the reaction mixture under vacuum and the product was extracted with hexanes. The NMR spectral data indicated the formation of the metallacycle 7. ¹H NMR $(CDCl_3)$: -1.53 (2H, s, CH₂), 0.41 (3H, s, Me), 4.86 (t, J = 1.5Hz, 2H, C₅H₄), 5.13 (t, J = 1.5 Hz, 2H, C₅H₄). ¹³C NMR (CDCl₃): -52.6 (CH₂), -1.14, (Me), 82.7 (ipso), 85.6, 92.5 (C₅H₄), 217.9 (CO). IR (ν CO, cm⁻¹, hexanes): 1957, 2009. Purification and elemental analysis of 7 could not be done due to continuous ringopening behavior, which eventually led to the formation of **7a** in quantitative yield. The solution of **7** in THF transformed into **7a** at low temperature (0 °C) after ~24–48 h. The purification of the polymer **7a** was done by repeated precipitation of a THF solution into hexanes. The spectroscopic data indicated the formation of polymer **7a** in 70% yield. ¹H NMR (CDCl₃): 0.11 (2H, CH₂), 0.36 (6H, GeMe₂), 4.3–4.8 (4H, C₅H₄). ¹³C NMR (CDCl₃): -22.1 (CH₂), 84.7 (ipso, C₃H₄), 87.8, 91.2 (C₅H₄), 217.7 (CO). IR (ν CO, cm⁻¹, THF): 1999, 1943. GPC in THF: $M_w = 2563$, $M_n = 2263$, PDI (M_w/M_p) = 1.13.

Synthesis of $(\eta^5 - C_5H_4)Fe(CO)_2CH_2GeBu_2$ (8). Complex 8 was synthesized as described above by treatment of either (η^{5} - C_5H_5)Fe(CO)₂GeBu₂CH₂Cl or (η^5 -C₅H₅)Fe(CO)₂CH₂GeBu₂Cl with freshly prepared LDA. After removal of the solvent the red-brown residue was extracted with hexanes and filtered on Celite. Evaporation of the solvent yielded the pure stable germametallacycle (8) as a red oil (70% yield). Anal. Calcd for C₁₆H₂₄FeO₂Ge: C, 42.44; H, 6.63. Found: C, 42.10; H, 6.55. ¹H NMR (CDCl₃): -1.21 (s, 2H, CH₂), 0.97-1.4 (m, 18H, Bu), 4.56, 4.64 (m, 4H, C₅H₄). ¹³C NMR (C₆D₆): -54.4 (CH₂), 13.9, 15.1, 26.5, 27.1 (Bu), 75.4, 86.4, 92.6 (C₅H₄), 218.5 (CO). IR (ν CO, cm⁻¹, hexanes): 1999, 1947. The germametallacycle was stored at low temperature (0 °C) for 30 days, and after this time the spectroscopic data indicated the transformation of the metallacycle into the corresponding polymer (8a). ¹H NMR (CDCl₃): 0.11 (s, 2H, CH₂), 0.95-1.40 (m, 18H, Bu), 4.67-4.81 (m, 4H, C₅H₄). ¹³C NMR (CDCl₃): -26.1 (CH₂), 13.7, 16.3, 26.6, 27.5 (Bu), 83.0 (ipso), 88.7, 91.2 (C5H4), 217.8 (CO). IR (ν CO, cm⁻¹, THF): 1997, 1943. GPC in THF: $M_{\rm w} =$ 5452, $M_{\rm n} = 2526$, PDI $(M_{\rm w}/M_{\rm n}) = 2.1$.

Synthesis of $(\eta^5 - C_5H_4)M_0(CO)_3CH_2GeR_2$ [R = Me (9), *n*-Bu (10)] and $(\eta^5 \cdot C_5 H_4)W(CO)_3 CH_2 GeR_2$ [R = Me (11), n-Bu (12)]. The above compounds were synthesized in the same manner, and the preparation of $(\eta^5 - C_5H_4)M_0(CO)_3CH_2GeMe_2$ (9) is described as a representative example. In a 50 mL roundbottomed Schlenk flask was placed 1.0 g (2.52 mmol) of (η^{5} -C5H5)Mo(CO)3GeMe2CH2Cl in 20 mL of THF. To this solution at -25 °C was added 1.5 mL (2.6 mmol) of freshly prepared LDA in the same solvent via cannula. The color of the reaction solution immediately changed from a light yellow to dark red. The solution was stirred for 30 min at low temperature and overnight at room temperature. After removal of the solvent, the brown residue was extracted with hexanes and filtered on Celite. Evaporation of the hexanes yielded a pink solid material along with some decomposed material. After recrystallization from hexanes, 0.72 g (80%) of light pink crystals were obtained. Spectroscopic data indicated the

formation of (η^{5} -C₅H₄)Mo(CO)₃CH₂GeMe₂ with no evidence of a ring-opening polymerization. This metallacyle was stored under nitrogen for several days, and no decomposition was observed. Mp: 66 °C. Anal. Calcd for C₁₁H₁₂MoO₃Ge: C, 36.62; H, 3.35. Found: C, 36.45; H, 3.50. ¹H NMR (C₆D₆): -1.21 (s, 2H, CH₂), 0.16 (s, 6H, Me), 4.71-5.00 (m, 4H, C₅H₄). ¹³C NMR (C₆D₆): -51.9 (CH₂), -1.20 (Me), 80.5, 94.3, 95.9 (C₅H₄), 228.2, 239.5 (CO). IR (ν CO, cm⁻¹, hexanes): 2018, 1945, 1934.

 $(\eta^{5}-\dot{C}_{5}H_{4})Mo(CO)_{3}CH_{2}GeBu_{2}$ (10): yellow oil, 0.7g (87%). Anal. Calcd for C₁₇H₂₄MoO₃Ge: C, 45.89; H, 5.44. Found: C, 45.78; H, 5.40. ¹H NMR (C₆D₆): δ -1.19 (s, 2H, CH₂), 0.84-0.91 (m, 12H, Bu), 1.31-1.36 (m, 6H, Bu), 4.77 (t, *J* = 1.8 Hz, 2H, C₅H₄), 5.11 (t, *J* = 1.8 Hz, 2H, C₅H₄). ¹³C NMR (C₆D₆): -54.2 (CH₂), 13.9, 15.1, 26.4, 26.8 (Bu), 79.5, 94.5, 96.5 (C₅H₄), 228.3, 239.5 (CO). IR (ν CO, cm⁻¹, hexanes): 2017, 1943, 1932.

 $(\eta^{5}-C_{5}H_{4})W(CO)_{3}CH_{2}GeMe_{2}$ (11): yellow solid, mp 98 °C (82%). Anal. Calcd for $C_{11}H_{12}WO_{3}Ge: C, 29.45$; H, 2.70. Found: C, 29.32, 2.63. ¹H NMR ($C_{6}D_{6}$): 0.99 (s, 2H, CH₂), 0.12 (s, 6H, Me), 4.63, 5.07 (m, 4H, $C_{5}H_{4}$). ¹³C NMR ($C_{6}D_{6}$): -64.2 (CH₂), -1.20 (Me), 83.9, 92.1, 94.3 ($C_{5}H_{4}$), 217.6, 222.2 (CO). IR (ν CO, cm⁻¹, hexanes): 2015, 1936, 1926.

 $(\eta^{5}-C_{5}H_{4})W(CO)_{3}CH_{2}GeBu_{2}$ (12): yellow oil (77%). Anal. Calcd for C₁₇H₂₄WO₃Ge: C, 38.32; H, 4.54. Found: C, 38.29; H, 4.30. ¹H NMR (CDCl₃): -0.93 (s, 2H, CH₂), 0.74-0.93 (m, 12H, Bu), 1.25-1.39 (m, 6H, Bu), 4.67 (t, *J*= 1.5 Hz, 2H, C₅H₄), 5.17 (t, *J* = 1.8 Hz, 2H, C₅H₄). ¹³C NMR (C₆D₆): -66.7 (CH₂), 12.5, 15.1, 26.3, 26.6 (Bu), 82.9, 92.3, 94.9 (C₅H₄), 217.7, 229.3 (CO). IR (ν CO, cm⁻¹, hexanes): 2014, 1935, 1924.

Synthesis of $(\eta^5 - C_5H_4)M_0(CO)_2(Ph_3P)CH_2Ge^{\dagger}Me_2$ (9a) and

 $(\eta^5 - C_5 H_4)W(CO)_2(Ph_3P)CH_2GeMe_2$ (11a). To 0.5 mL of a THF solution of 9 or 11 (1.0 mmol) in a NMR tube was added (1.10 mmol) PPh₃, and the contents were degassed twice by freeze—thaw cycles. The solution was then heated at 100 °C for ~48 h. After completion of the reaction the solvent was removed under vacuum. The solid material obtained was extracted with hexanes and

recrystallized from a benzene/hexanes mixture to yield **9a** or **11a** as an orange solid compound in 70% yield.

(η^{5} -C₅H₄)Mo(CO)₂(Ph₃P)CH₂GeMe₂ (9a): orange solid, mp 131–132 °C (72%). Anal. Calcd for C₂₈H₂₇MoO₂GeP: C, 56.45; H, 4.70. Found: C, 56.52; H, 4.57. ¹H NMR (C₆D₆): -0.30 (s, 2H, CH₂), 0.42 (s, 6H, Me), 4.40, 5.55 (m, 4H, C₅H₄), 7.10–7.90 (15H, Ph). ¹³C NMR (C₆D₆): -47.2 (d, CH₂, ²J_{P-C} = 7.6 Hz), 0.81 (Me), 89.6, 93.4, 94.9 (C₅H₄), 128.1, 130.9, 131.9, 132.8 (Ph), 228.6 (d, CO, ²J_{P-C} = 16.5 Hz). ³¹P NMR (C₆D₆): 42.7. IR (ν CO, cm⁻¹, THF): 1920(vs), 1843(s).

($η^{5}$ -C₅H₄)W(CO)₂(Ph₃P)CH₂GeMe₂ (11a): orange solid, mp 145–148 °C (70%). Anal. Calcd for C₂₈H₂₇WO₂GeP: C, 49.20; H, 4.10. Found: C, 49.24; H, 3.98. ¹H NMR (C₆D₆): -0.26 (s, 2H, CH₂), 0.49 (s, 6H, Me), 4.43, 5.58 (m, 4H, C₃H₄) 7.12–7.87 (15H, Ph). ¹³C NMR (C₆D₆): -57.6 (d, CH₂, ²J_{P-C} = 7.3 Hz), -1.10 (Me), 81.6, 92.2, 94.2 (C₅H₄), 128.7, 132.3, 133.9, 138.2 (Ph), 228.6 (d, CO, ²J_{P-C} = 16.0 Hz). ³¹P NMR (C₆D₆): 42.7 (¹J_{W-P} = 262.0 Hz).
