*(Received September 5, 1988)*

Interaction of hexachlorocyclodiphosphazanes (**Ia-h**) with ethyl-acetoacetate, sodium ethylacetoacetate and benzyl chloride are described. The structure of the obtained cyclodiphosphazane derivatives (**II-IV**) were proposed on the basis of microanalytical data, ir, uv,  $^1\text{H}$  n.m.r and mass spectra. The mechanism of the reaction is also discussed.

**Key words:** hexachlorocyclodiphosphazanes; Cyclodiphosphazanes; Phosponitrilic derivatives; Chlorophosphinimine dimers.

### INTRODUCTION

The reaction of hexachlorocyclodiphosphazanes (**I**) with amino compounds has been investigated in great detail.<sup>1-7</sup> Recently, the authors showed that the reaction of hexachlorocyclodiphosphazanes (**I**) with bifunctional reagents (such as urea, thiourea and amino acids) furnished geminal and nongeminal aminocyclodiphosphazanes).<sup>8,9,10</sup>

### RESULTS AND CONCLUSIONS

In the present investigation, ethylacetoacetate (or its sodium salt), and benzyl chloride were allowed to react with halophosph(V)azanes (**Ia-h**) in inert solvents such as benzene to give a substitution product at the phosphorus atoms. The analytical data suggest structure (**IIa-c**), (**IIIa-i**) and (**IVa-e**) for these materials.

The assignment of the proposed structures (**IIa-c**), (**IIIa-i**) and (**IVa-e**) was based on elemental analysis. Infrared spectra of these compounds showed characteristic  $\nu_{\text{P}=\text{C}}$ ,  $\nu_{\text{P}=\text{O}}$ ,  $\nu_{\text{P}-\text{N}}$ ,  $\nu_{\text{C}=\text{O}}$  and  $\nu_{\text{P}-\text{Cl}}$  absorption bands which are summarized in Table I, the  $^1\text{H}$  n.m.r. spectra of (**IIa, c**), (**IIIa, c-f, i**) and (**IVa-d**) showed the characteristic proton signals, which are listed in Table II, the uv spectra showed the characteristic band at 270 nm for the phosphazane four-membered ring<sup>11</sup> (Figures 1 & 2).

| <b>IIb</b>      | 2-pyridyl                           | "  |
| <b>IIc</b>      | 4-pyridyl                           | "  |

Further insight concerning the structure of these products was gleaned from a consideration of their mass spectra. Thus, the mass spectrum of compound (**IIIa**), (**IIIc**) and (**IIIf**) showed the following masses at 422 m/e, 491 m/e and 482 m/e respectively as the highest mass in the spectrum corresponding to M<sup>+</sup>—2 Cl<sub>2</sub>.

It should be noted that the parent peak of all these compounds does not appear in the spectra, presumably owing to the fact that these ions are meta stable and hence do not appear.

### *Mechanistic Proposal*

We proposed that the direct interaction between a halophosphazane (**I**) and an active methylene group containing compounds or its sodium salt was found to be rapid. The degree of substitution and the pattern of halogen replacement was found to be sensitive to the steric characteristic of the reactants. Thus, the reaction between chlorocyclodiphosphazanes (**I**) and the active methylene group

containing compounds or its sodium salt led to the formation of cyclodiphosphazane derivatives (II-IV), through the elimination of HCl gas or NaCl:

The direction and rate of the reaction depend on the nature of the active methylene group compound (R' or R'') and also on the type of substituents present (R). It is evident that direct elimination of HCl or NaCl leads eventually to the proposed cyclodiphosphazane derivatives (II) and (III) and the oxycyclic structure (IV). When R' and R'' groups are electron-withdrawing groups, this makes the CH proton in compound (II) more acidic and facilitates the removal of the methine proton in compounds (II) as HCl to give eventually compounds of the type (III).

<sup>a</sup> Sodium ethylacetoacetate was prepared from ethylacetoacetate (2.5 ml, 0.02 mole) and 0.46 g sodium metal in 30 ml benzene. The solution was heated under reflux for half hour.

FIGURE 2 uv spectra of compds IV.

The formation of the terminal  $\text{P}=\text{O}$  group in some products demonstrates that the reaction in these products go according to the following reaction scheme to give the partially substituted products as follows:

The possibility, also exists that the nongeminal replacement pattern observed with compound (IV) may results from electron supply from substituent to

phosphorus, which lowers the reactivity of Cl—P—C-unit below that of a Cl—P—Cl unit, or also due to steric factors in which little difficulty is encountered in effecting complete replacement of halogens in spite of the steric retardation which must be involved and only a so called intermediate as the above compounds would be possible.

## EXPERIMENTAL

Microanalytical determinations were carried out by the microanalytical laboratory, Cairo University. Infrared spectra were recorded on a Unicam SP 1200 spectrophotometer (KBr technique). Ultraviolet spectra were recorded on a Unicam SP 8000 ultraviolet recording spectrophotometer.  $^1\text{H}$  n.m.r. spectra were measured on a Varian EM-360L, 60  $\text{MHz}$  spectrometer and mass spectrometric measurements were carried out using a Finnigan MAT 1125 mass spectrometer by the direct inlet system.

### Preparation of compounds

The preparation and purification of hexachlorocyclodiphosphazanes (**Ia-h**) has been described previously.<sup>12,13</sup> All compounds used were B.D.H. reagent grade products.

### Synthesis of cyclodiphosphazane derivatives (II-IV):

#### preparation of ethylacetoacetate derivatives:

A solution of ethylacetoacetate (or a suspension of sodium ethylacetoacetate) (0.02 mole) was added dropwise to a cold well-stirred solution of hexachlorocyclodiphosphazane (**I**) (0.01 mole) in 100 ml benzene during 1/2 hour. After the addition was completed, the reaction mixture was heated under reflux for three hours. After the completion of the reaction (HCl gas ceased to evolve or NaCl precipitated), the reaction mixture was filtered while hot. The solid obtained after cooling was filtered, washed several times with benzene, diethylether and dried in vacuo to give the corresponding cyclodiphosphazane derivatives (**IIa-c**, **IIIg-i** and **IVa-e**) (Table III).

#### Preparation of benzyl chloride derivatives

The hexachlorocyclodiphosphazane (**I**) (0.02 mole) was added to excess benzyl chloride (50 ml) in a round-bottom flask fitted with a condenser. The reaction mixture was heated under reflux for ten hours. During this time, the hexachlorocyclodiphosphazane (**I**) was dissolved with the evolution of HCl gas. After completion of the reaction (HCl gas ceased to evolve), the reaction mixture was cooled to room temperature and the formed solid was filtered, washed several times with diethyl ether, then dried in vacuo to give the corresponding cyclodiphosphazane derivatives (**IIIa-f**) (Table III).
