DOUBLE ASYMMETRIC INDUCTION AS METHOD FOR THE SYNTHESIS OF CHIRAL ORGANOPHOSPHORUS COMPOUNDS

Oleg I. Kolodiazhnyi

National Academy of Sciences of Ukraine, Ukraine

(Received July 29, 2001; accepted December 25, 2001)

New examples of multistereoselective syntheses of organophosphorus compounds are described.

Keywords: Asymmetric Michael addition; chiral aminophosphonic acids; chiral phosphoric acid esters; double asymmetric synthesis; multistereoselectivity

Multistereoselectivity is the reaction process proceeding under the control of several chiral auxiliaries effecting the asymmetric induction. Stereoselectivity of reagents can be estimated as a difference of reaction rates or activation energies leading to two opposite stereoisomers.^{1,2}

The individual diastereofacial preferences of the two chiral reactants may reinforce one another (matched asymmetric synthesis (AS)), or, on the contrary, oppose one another (mismatched AS).

In the present work the following versions of multistereoselective syntheses have been studied:

- a chiral reagent reacts with a chiral substratum;
- a chiral reagent containing two chiral auxiliaries reacts with an achiral substratum; and
- AS of a chiral reagent in the presence of asymmetric catalyst.

Thus, the addition of chiral di- and trialkylphosphites ($R^*O = \text{Menthyl, Bornyl, Gluco-}D\text{-furanosyl}$) to chiral $C=N$ compounds is accompanied by double asymmetric induction at the α -carbon atom,

This work is supported by the State Foundation of Basic Research of Ukraine (DFFD).

with formation of optically active aminophosphonic acid ethers of $\sim 100\%$ de in case of reagents having matched asymmetric induction and of 80% de in case of reagents possessing mismatched asymmetric induction. The reaction of di- and trimethylphosphites gives aminophosphonic acids of opposite configuration, that allows to prepare all four possible diastereomers. The menthyl esters by acidic hydrolysis were converted to N-substituted aminophosphonic acids and then by catalytic hydrogenation under Pd/C to 1-aminobenzylphosphonic acids.^{3,4}

Addition of chiral esters of trivalent phosphorus acids to chiral esters of crotonic or cinnamic acids proceeds more stereoselectively than in the case when only one of these reagents is chiral.⁵ The reaction of dimethyl phosphite with menthyl crotonoate proceeds with $\sim 96\text{--}98\%$ stereoselectivity.^{2,5}

FIGURE 2

FIGURE 3

The addition of nitrostyrene to trimenthylphosphite leads to the formation of optically active β -nitroalkylphosphonates and β -aminophosphonic acids 3,5.²

Reduction of dimethyl acylphosphonate with LiAlH_4 or NaBH_4 affords a mixture of chiral (*R*)- and (*S*)-diastereomers in the ratio of $\sim 3:1$.⁵ Meantime catalytic hydrogenation of the acylphosphonate by complex of lithium alumohydride with chiral ligand (*A* = cinchonin or cyclohexylidene 1,2-glucosylidene-*D*-furanose) furnishes predominantly one diastereomer of dimethyl 1-oxybenzylphosphonic acid.⁵

This diastereoface selectivity is explained by effect of menthyl group of the compounds which closes one of the sides of carbonyl group in such a manner that *Si*-side of ketone is shielded more than *Re*-party and lithium alumohydride attacks preferentially this side.

Chiral reagents containing two asymmetric auxiliaries in one molecule, increasing asymmetric induction, are especially interesting.⁶ Thus, the lithium derivative of Schiff base, formed from (*R*)-camphor and diethyl aminomethanephosphonate, was allowed to react with alkyl and benzyl halides to yield the corresponding esters of (*S*)- α -aminoalkanephosphonic acids.

Acidolysis of the chiral di-alkylaminophosphines by formic acid leads in good yield to the formation of optically pure phosphonic acid amides.⁷⁻⁹

So multistereoselectivity represents effective methodology to increase the asymmetric synthesis of chiral organophosphorus compounds using in one reaction two or three asymmetric auxiliaries

reinforcing one another. In some cases this methodology allows to increase the stereoselectivity of reactions up to 100% de.
