Pharmazie 59: 753–755 (2004)

A series of 2-methyl-3-(substituted methylamino)-(3*H*)-quinazolin-4-ones were synthesized from 3-amino-2-methyl-(3*H*)-quinazolin-4-one. Their structures were confirmed by spectral data (IR, NMR and MS) and the purity was ascertained by microanalysis. When tested for H₁-receptor blocking activity on isolated guinea pig ileum all the test compounds inhibited histamine induced contraction whereas compound **5** (IC₅₀ 0.22 · 10³ ng/ml) was found to be four times more potent than chlorpheniramine maleate (IC₅₀ 1 · 10³ ng/ml) and it showed lesser sedation (8%) than the standard (32%).

1. Introduction

The first generation anti-histamines penetrate the blood brain barrier and also possess anticholinergic properties and this has led to the development of a second generation (Simons and Simons 1994) of H₁-antagonists such as terfenadine, cetirizine and astemizole, known as “non sedative antihistamines”. These may also bind more selectively to the H₁-receptor and do not bind to serotonin, muscarinic or alpha adrenergic receptors (Snyder and Snowman 1987). A common feature of first generation compounds includes two aryl or heteroaryl rings linked to an aliphatic tertiary amine via the side chain (Ellis et al. 1985) (e.g. diphenhydramine, pheniramine), the second generation compounds (terfenadine and cetirizine) also contain many of the structural features of first generation compounds. A literature survey reveals excellent antihistaminic activity (Kottke et al. 1978; Wade 1984; West and July 1981) in 2,3-disubstituted quinazolones. It has been proposed that for H₁-antihistaminic activity, a compound should have the above mentioned pharma-

cophore (two aryl (or) hetero aryl rings linked to an aliphatic tertiary amine via the side chain). From these studies and to develop earlier reported 2-substituted-3-(substituted methylamino)-(3*H*)-quinazolin-4-ones (Alagarsamy et al. 2000, 2002), which exhibited good antihistaminic activity, in the present study a series of 2-methyl-3-(substituted methylamino)-(3*H*)-quinazolin-4-ones were prepared.

2. Investigations, results and discussion

The title compounds were prepared by condensing the active hydrogen atom of the 3-amino group of 3-amino-2-methyl-(3*H*)-quinazolin-4-one with formaldehyde and appropriate amines. The starting material was synthesized as presented in the Scheme. The chemical structures of the synthesized compounds (Table 1) were confirmed by ¹H NMR, IR and MS data, the purity was ascertained by elemental analysis. The synthesized compounds were tested for their antihistaminic activity on isolated guinea pig ileum.

The data presented in Table 2 revealed that all the test compounds show H₁-receptor blocking activity. Compound **1** with dimethyl substitution shows good antihistaminic activity (IC₅₀ 0.42 · 10³ ng/ml); with increased lipophilicity (i.e. diethyl compound **2** and pyrrolidine compound **3**) activity was retained (IC₅₀ 0.46, 0.48 · 10³ ng/ml respectively), introduction of an oxygen atom (compound **4**) leads to a decrease in activity (IC₅₀ 0.62 · 10³ ng/ml) whereas introduction of an additional nitrogen atom gave better activity (compound **5** IC₅₀ 0.22 · 10³ ng/ml). Aryl or heteroaryl substitution decreases activity. A small alkyl side chain (methyl and ethyl) and alicyclic groups with an additional nitrogen atom (piperazine) seem to provide optimum activity. When the title compounds were evaluated for their sedative-hypnotic activity all compounds were found to exhibit only weak sedation.

The principle aim of the present study was to modify and optimize the structural features of our earlier reported series of 2-mercapto-3-(substituted methylamino)-(3*H*)-quinazo-

Scheme

Table 1: Physical and preparative data for 2-methyl-3-(substituted methylamino)-3H-quinazolin-4-ones

| Code | R | Molecular formula | Molecular weight* | M.p. (°C) | Yield (%) |
|------|---|---|-------------------|-----------|-----------|
| | | | | | |
| 1 | —N(CH ₃) ₂ | C ₁₂ H ₁₆ N ₄ O | 232 | 116 | 71 |
| 2 | —N(C ₂ H ₅) ₂ | C ₁₄ H ₂₀ N ₄ O | 260 | 159 | 70 |
| 3 | | C ₁₄ H ₁₈ N ₄ O | 258 | 215 | 71 |
| 4 | | C ₁₄ H ₁₈ N ₄ O ₂ | 274 | 116 | 73 |
| 5 | | C ₁₄ H ₁₉ N ₅ O | 273 | 139 | 65 |
| 6 | | C ₁₆ H ₁₆ N ₄ O | 280 | 107 | 69 |
| 7 | | C ₁₇ H ₁₈ N ₄ O ₂ | 310 | 115 | 60 |
| 8 | | C ₁₇ H ₁₈ N ₄ O ₂ | 310 | 136 | 63 |
| 9 | | C ₁₇ H ₁₅ N ₅ O | 305 | 101 | 59 |
| 10 | | C ₁₆ H ₁₄ N ₆ O | 306 | 128 | 67 |

Table 2: Antihistaminic and sedative-hypnotic activities of compounds 1–10

| Compound | IC ₅₀ (ng/ml) | Percent CNS depression | | |
|--------------------------|----------------------------------|------------------------|-------------|--------------|
| | | 30 min | 1 h | 2 h |
| 1 | 0.42 · 10 ³ ± 1.12* | 6 ± 5.76* | 7 ± 3.81* | 8 ± 3.86** |
| 2 | 0.46 · 10 ³ ± 3.46* | 8 ± 6.17** | 13 ± 5.13* | 14 ± 3.38*** |
| 3 | 0.48 · 10 ³ ± 2.41** | 5 ± 3.63* | 10 ± 6.18** | 14 ± 3.19* |
| 4 | 0.62 · 10 ³ ± 1.17** | 5 ± 5.13** | 7 ± 4.33*** | 10 ± 6.39** |
| 5 | 0.22 · 10 ³ ± 2.67*** | 5 ± 4.43** | 9 ± 3.18** | 10 ± 2.16* |
| 6 | 1.24 · 10 ³ ± 4.26* | 7 ± 1.44** | 12 ± 2.36** | 11 ± 1.18*** |
| 7 | 1.12 · 10 ³ ± 2.39** | 5 ± 3.92*** | 11 ± 4.14** | 12 ± 4.12** |
| 8 | 1.64 · 10 ³ ± 1.19* | 10 ± 1.36** | 13 ± 3.24** | 14 ± 3.17* |
| 9 | 1.46 · 10 ³ ± 4.17** | 9 ± 4.14* | 11 ± 1.15** | 12 ± 3.95** |
| 10 | 1.22 · 10 ³ ± 6.13* | 6 ± 4.14** | 10 ± 3.41** | 12 ± 4.5* |
| Chlorpheniramine maleate | 1 · 10 ³ ± 3.16* | 25 ± 1.19*** | 33 ± 5.36* | 39 ± 2.19* |

Each value represents the mean \pm SEM (n = 6). Significance levels * p < 0.5, ** p < 0.01 and *** p < 0.001 as compared with the respective control

lin-4-ones (Alagarsamy et al. 2000), which has shown good antihistaminic activity and is associated with CNS depression (15–20%). When the mercapto group (which may be principally responsible for sedation) in the C-2 was substituted by phenyl, an increase in antihistaminic activity with negligible sedation was observed (Alagarsamy et al. 2002). In order to further increase the antihistaminic activity the C-2 phenyl group was substituted by methyl which led to a two-fold increase in activity. Compound **5** (IC₅₀ 0.22 · 10³ ng/ml) was the most active (with lowest IC₅₀ and sedation) and it is two-fold as potent as our earlier reported phenyl series lead molecule (IC₅₀ 0.49 · 10³ ng/ml).

3. Experimental

3.1. Chemistry

Melting points were determined in open capillary tubes on a Thomas Hoover apparatus and are uncorrected. IR spectra were recorded in KBr on a Perkin Elmer-841 grating spectrometer (cm⁻¹), mass spectra on a Varian Atlas CH-7 mass spectrometer at 70 eV and NMR spectra on a Varian A-60 or EM-360 spectrometer, using TMS as internal standard. Elemental analysis was performed on Carlo Erba 1108.

3.1.1. 2-Methyl-3,1-benzoxazin-4-one

A mixture of anthranilic acid (0.01 mol) and acetic anhydride (0.1 mol) was refluxed on gentle flame for 1 h. The excess acetic anhydride was distilled off under reduced pressure and the residue was dissolved in petroleum ether and kept aside for 1 h, m.p. 182 °C; IR (KBr): 3350 (NH), 1700 (C=O) and 1640 cm⁻¹ (C=N); NMR (CDCl₃) (δ ppm): 2.5 (s, 3 H, CH₃), 6.9–7.4 (m, 4H, ArH); MS (m/z) 161 (M⁺); Anal. (C₉H₇NO₂) C, H, N.

3.1.2. 3-Amino-2-methyl-(3H)-quinazolin-4-one

A mixture of 2-methyl-3,1-benzoxazin-4-one (0.01 mol) and hydrazine hydrate (0.03 mol) in ethanol was refluxed for 3 h and cooled. The separated solid was recrystallized from ethanol, m.p. 140–142 °C; IR (KBr): 3300–3260 (NH₂), 1680 (C=O), 1640 (C=N) and 1600 cm⁻¹ (C=C); NMR (CDCl₃) (δ ppm): 2.6 (s, 3H, CH₃), 4.6 (s, 2H, NH₂), 6.6–7.2 (m, 4H, ArH); MS (m/z) 175 (M⁺); Anal. (C₉H₉N₃O) C, H, N.

3.1.3. 2-Methyl-3-(dimethylamino)methylamino-(3H)-quinazolin-4-one (1)

To a slurry of 3-amino-2-methyl-(3H)-quinazolin-4-one (0.005 mol) in dimethylformamide (15 ml), a mixture of formalin (37–41%; 1 ml) and dimethylamine (0.005 mol) was added drop by drop with stirring. The reaction mixture was heated on a water bath for about 25 min. After cooling it was poured into ice-water, the solid obtained was filtered, washed with water, dried and recrystallized from ethanol, m.p. 116 °C; IR (KBr): 3280 (NH), 2860 (—CH₂), 1700 cm⁻¹ (C=O); NMR (CDCl₃) (δ ppm): 2.3 (s, 6H, N(CH₃)₂), 2.6 (s, 3H, CH₃), 5.1 (s, 2H, CH₂) 7.2–7.7 (m, 4H, Ar-H), 9.0 (t, 1H, NH); MS (m/z) 232 (M⁺); Anal. (C₁₂H₁₆N₄O) C, H, N.

Compounds **2–10** were prepared similarly.

3.2. Antihistaminic activity

Antihistaminic activity of compounds **1–10** was determined on isolated guinea pig ileum (Mehta and Kulkarni 1983). The segments (1 cm) of ileum containing tyrode solution were suspended in an organ bath. The contractile response to histamine (5.4 · 10⁻⁷ mol/L) was measured with an isotonic transducer. Each test compound was added in the organ bath 5 min before the addition of histamine. Concentration dependent response due to histamine was recorded. After washing thoroughly with tyrode solution, concentration response curve of histamine in presence of standard, test compounds and vehicle were recorded, 6 such determinations were made for each compound. The IC₅₀ of test compounds and the standard required to block the histamine induced contraction were determined (Table 2).

3.3. Sedative-hypnotic activity

Sedative-hypnotic activity was determined by measuring the reduction in motor activity, using an actophotometer (Dews 1953; Kuhn and Van Manen 1961). Mice were chosen as test animals in a group of 6. Basal activity score was taken and then compounds **1–10** and standard chlorpheniramine maleate were administered intraperitoneally at a dose of 5 mg/kg. Scores were recorded at 0.5, 1 and 2 h after the drug administration. The

percent reduction in motor activity was calculated by the following formula and shown in Table 2.

$$\% \text{ Reduction in motor activity} = [(A-B)/A] \times 100$$

Where A-basal score, B-score after drug treatment.
