VI. *Periodicities in European Weather.*

By D. BRUNT, M.A., B.Sc.

Communicated by Dr. G. C. SIMPSON, F.R.S.

(Received June 9.—Read June 25, 1925.)

1. The present investigation was undertaken with a view to determining to what extent the variations of meteorological factors might be ascribed to periodicities, and to what extent it might be possible to forecast the general nature of the weather for long distances ahead. It was considered also that any evidence of the existence of periodicities of the same length and phase, in observations made at stations situated at wide distances apart, would afford some clue to the nature of the large scale movements of the atmosphere.

2. *The Observations Used.*

A search was made for all the series of observations which extended over a minimum of 100 years. It was found that a number of records of temperature, rainfall and pressure were started about 1764, and eventually 12 sets of observations were selected. Monthly means or totals for 100 years were used in the investigation of periods up to 10 years, and for periods greater than 10 years all the annual values which were readily available were used. The data employed are given in the Tables in the Appendix. These tables give all the data used, and only those data. The sources from which the data were taken are shown below.

- I. Milan Rainfall—‘Annali dell’ Ufficio Centrale di Meteorologia Italiana,’ vol. 3, Part I, p. 20.
 - Monthly totals 1764–1863
 - Annual totals 1764–1900
- II. Padua Rainfall—‘Sitzungsberichte der k.k. Akad. Wiss. Wien.,’ vol. 111, Part II, A, p. 78.
 - Monthly totals 1764–1863
 - Annual totals 1725–1900
- III. London Rainfall—‘Records of Rain measured at Camden Square from 1858 onwards.’ Earlier figures taken from G. DINES’s diagrams.
 - Monthly totals 1813–1912
 - Annual totals 1782–1922

These data were supplied to me by the late Mr. Carle Salter.
- IV. Edinburgh Rainfall—‘Transactions Royal Society Edinburgh,’ vol. 39, p. 143.
 - Monthly totals 1785–1884
 - Annual totals 1785–1896

- V. Edinburgh Pressure—‘Transactions Royal Society Edinburgh,’ vol. 39, p. 109.
 Monthly means 1770–1869
 Annual means 1770–1896

 vol. 76, p. 714.
 Monthly and annual means 1775–1874

The first step in the treatment of the observations was to form 5-yearly totals of rainfall
 and 5-yearly means of temperature and pressure, with a view to forming a general
 idea of the nature of the variation during the intervals considered. These figures
 are represented graphically in Appendix figs. IA–XIIA. The most striking feature of
 these diagrams is the variability which they display. Figs. IA and IIa, representing

rainfall at Milan and Padua respectively, show little resemblance to one another. Figs. IIIA and IV_A, representing rainfall at Edinburgh and London, show some similarity in their main outlines. Fig. VI_A shows a remarkable decrease in mean pressure at Paris from about 1760 onwards for 50 years. Temperatures at London, Paris and Berlin show a striking decrease of temperature at the end of the 18th century, followed by a gradual recovery. The details of the other diagrams only bear slight resemblance to each other.

3. Treatment of the Monthly Means.

In the case of temperature measured in degrees Centigrade, a constant, 20°, was added to all the monthly figures, in order to get rid of all negative values. The 12 sets of data for each of 1,200 months, were punched on cards, each card representing a single month. The cards in question are ruled into 45 parallel columns, so that three columns could be given to each set of data. Two sets of cards were prepared and checked by superposition in order to see that the punch holes coincided in each case. The cards were then used for the evaluation of the totals to be analysed harmonically for different trial periods. For example, in order to evaluate the amplitude of a trial period of 42 months, the cards were dealt out into 42 packs, in which the first pack contained the cards for the 1st, 43rd, 85th, etc., months. The packs were separated by blank cards, and the 42 packs put into the Hollerith adding machine. This machine will add up any column, or combination of columns, and in three or four complete operations it gave the totals of each set of data in each pack of cards. This gave the numbers to be analysed harmonically for the trial period of 42 months. The operation was repeated for each of the trial periods representing integral numbers of months, shown in the Tables I to XII.

The next step was to graph the figures obtained from the Hollerith machine. The harmonic analysis was carried out by means of a Mader harmonic analyser combined with an Amsler planimeter. The first, second and third harmonics were obtained for all the trial periods, and in addition the fourth harmonic was obtained for periods up to 40 months.

The procedure was, up to this point, relatively simple, except for the errors introduced by the wearing of a commutator bearing in the Hollerith machine, leading to a very considerable waste of time.

4. Checking the Results derived from the Harmonic Analyser.

It was found that the harmonic analyser was capable of giving very accurate results for the shorter periods. But for periods up to 120 months, which gave 120 points in the diagram, the cumulative effect of slight inaccuracy in tracing out the complex curve led in some cases to quite considerable errors. It was therefore necessary to check the general nature of the results, and also to check the amplitudes and phases of the peaks in the periodogram. In certain cases a period was evaluated independently from two or three different sets of figures, e.g., 22 months were evaluated as a first harmonic, as the second harmonic of 44, and as the third harmonic of 66, and thus could readily be checked. A further useful check was yielded by drawing difference-periodograms

for one year, two years, and four years, by the method of C. E. P. BROOKS, described in the 'Proceedings Royal Society,' A, vol. 105, pp. 346-359.

Usually the difference periodogram gave indications of periods at peaks in the periodogram representing the results derived from the Mader analyser, but when these indicated periods at other points, the results were checked by arithmetical analysis. In addition to this, the phase and amplitude for each trial period which gave a peak in the diagram, were checked arithmetically, on account of the importance of obtaining accurate estimates of the epoch of maximum of each true periodicity. A further check was sometimes used for longer periods, by using Schuster's method of Secondary Analysis for such periods as 8, 9, 10 years, etc. A very considerable amount of arithmetic was involved, but the results, shown in Tables I to XII, may be regarded as complete, in that no important trial period has been missed. The amplitudes of Tables I to XII are shown graphically in figs. I to XII.

5. *The Treatment of the Annual Means.*

For each separate series of data, all the annual means available were analysed for trial periods varying from 11 years up to 35 years. This analysis was carried out arithmetically and checked at each stage of the computation. The results obtained are shown in Tables I to XII, and in figs. I to XII.

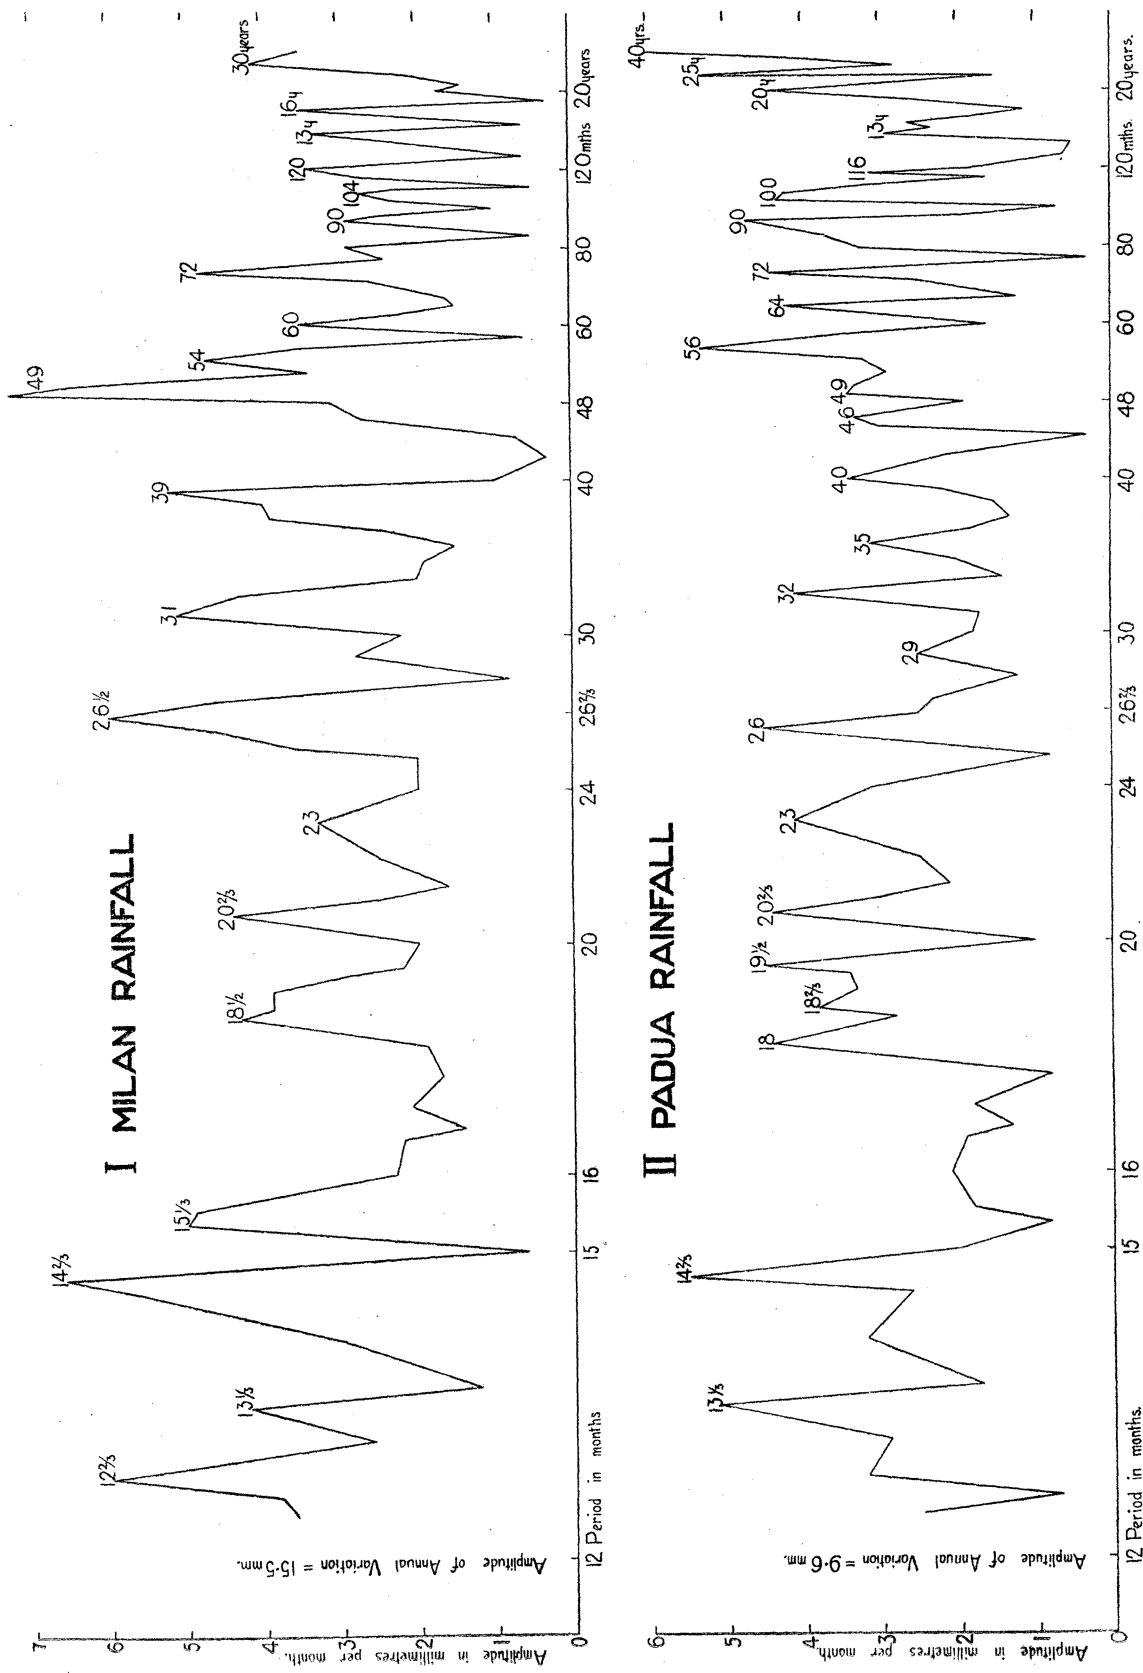

6. *The Results Derived.*

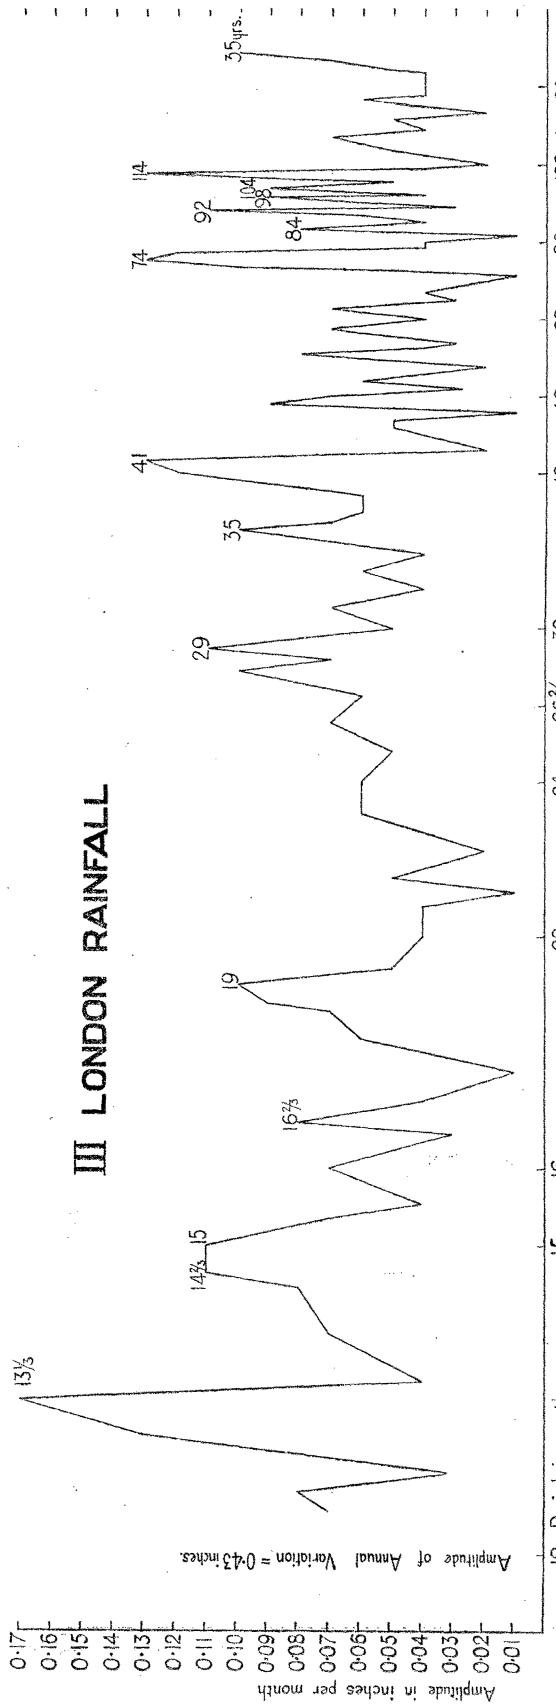

All the figures derived are shown in the Tables I to XII. The amplitude R is measured in the same unit as the original observations. The phase of maximum ϕ is measured from the middle or the first month covered by the monthly observations, except for periods greater than 10 years, for which ϕ is measured from the middle of the first year for which the annual mean or total was used. Unfortunately all 12 series of observations do not commence at the same year 1764, so that ϕ is not measured from the same zero for all 12 series. This disadvantage is, however, of little importance.

In Tables I to XII, the columns headed C and S give, in the same units as R, the cosine and sine components, so that $C = R \cos \phi$, and $S = R \sin \phi$.

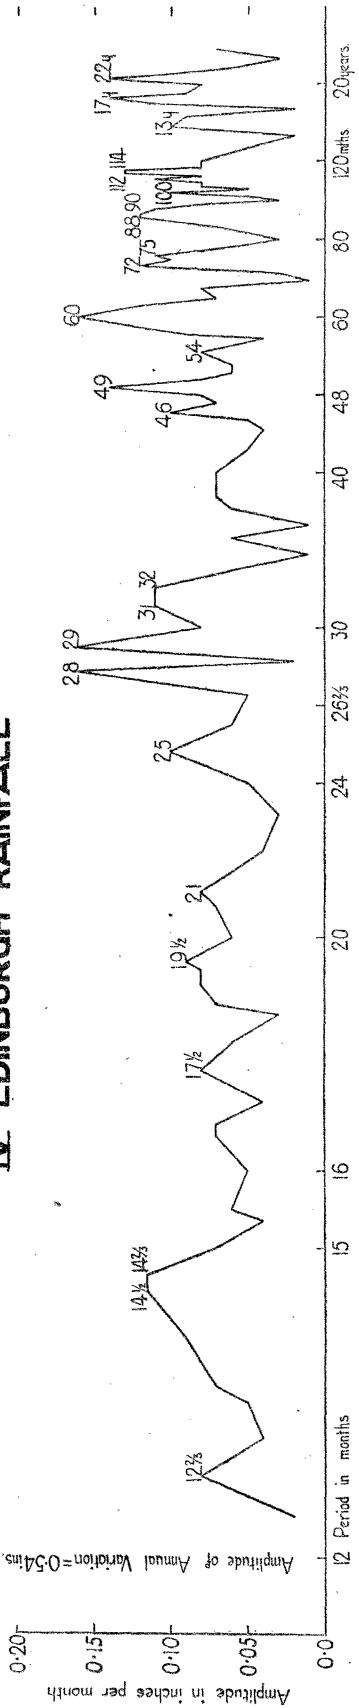

The amplitudes R given in Tables I to XII are shown graphically in figs. I to XII. The horizontal scale represents frequency, or the reciprocal of the period. A few points are marked on the horizontal scale, but for facility of reference the length of the period in months is shown at each peak in the diagram. It is thus relatively easy to interpolate the length of period corresponding to any other point in the diagram. The longer periods appear crowded in the diagram only because it is readily possible to evaluate trial periods differing by one year in length whose difference of frequency is slight.

In the course of the work the amplitudes of a number of periods shorter than 12 months were evaluated, but these were omitted from the tables and diagrams, as they are separated by wide intervals of frequency.

7. *Brief Discussion of the Results.*(a) *Periods longer than 10 years.*

Only a brief discussion of the results will be entered into at this stage, as it is desired to restrict the present communication to entirely non-speculative matter.

It is perhaps easier to commence with the periods longer than 10 years. The peaks in the periodograms occur at the following periods :—

- I. Milan rainfall 13 (1801·0), 16 (1812·5), 30 (1818·0).
- II. Padua rainfall 13 (1810·0), 20 (1810·1), 25 (1801·2), 35 (1804·8).
- III. London rainfall 12 (1806·5), 35 (1809·7).
- IV. Edinburgh rainfall 13 (1800·4), 17 (1810·3), 22 (1812·1).
- V. Edinburgh pressure 14½ (1810·9), 22 (1806·5), 25 (1811·1).
- VI. Paris pressure 14½ (1807·5), 22 (1807·0), 35 (1832·8).
- VII. Edinburgh temperature . 11 (1801·0), 13 (1805·3), 17 (1812·1), 23 (1803·3).
- VIII. Stockholm temperature . 15 (1804·0), 25 (1810·0), 35 (1830·6).
- IX. London temperature 15 (1810·0), 17½ (1811·5), 23 (1803·2).
- X. Berlin temperature 14 (1807·0), 15 (1809·6), 35 (1831·8).
- XI. Paris temperature 15 (1806·5), 30 (1800·7), 35 (1811·7).
- XII. Vienna temperature 14 (1808·3).

In this list the first figure gives the period in years, and the figures in brackets give the date of the first maximum after 1800.

In the case of the rainfall data, there is no striking resemblance between the results derived for four sets of data, except for a period of 13 years which occurs in Milan, Padua and Edinburgh, having the same date of maximum at Milan and Edinburgh, the maximum at Padua occurring some four years earlier than at the other two stations.

The pressures at Edinburgh and Paris show very close coincidence of epoch of maximum for the period of 22 years, but a difference of roughly a quarter of the period in the incidence of maximum of the 14½-year period.

The temperature records, series VII to XII, show curious divergencies. In series VII, Edinburgh temperature, the maximum amplitude discovered throughout the whole range from one year to 35 years occurs at 11 years, suggesting an effect due to sun-spots, but no one of the other series yields an appreciable amplitude for 11 years. The Edinburgh temperatures also yield a peak in the periodogram at 13 years, whose minimum coincides approximately with the maximum of the 13-year period in rainfall at Edinburgh. A period of 14 years is shown by Berlin and Vienna with fairly close agreement of the epoch of maximum ; while the 15-year period, which occurs in four series of temperatures—Stockholm, London, Paris and Berlin—only give coincidence of dates

of maxima for London and Berlin. The period of 23 years, shown by Edinburgh and London, gives remarkably close agreement of the dates of maxima, and the amplitudes of this period for these two stations are both very high. In the case of the other series, the secondary analysis of the 22-year period, or the difference-periodogram, did not indicate a period at 23 years, and the amplitude of the trial period of 23 years was consequently not evaluated. In any case it is not possible to fix accurately a period of about 23 years with observations of a little more than a century.

A period of about 35 years, probably the Brückner cycle, is shown by temperature at Stockholm, Berlin and Paris, with agreement of phase for the first two of these stations, and approximately a reversal of phase at the third.

(b) *Periods shorter than 10 years.*

1. *Rainfall.*—On account of the complexity of the periodograms, it is not possible to discuss all twelve together. A comparison of figs. I and II shows a remarkably large number of peaks at corresponding points in the two diagrams. The peaks at $12\frac{2}{3}$, $14\frac{1}{2}$ or $14\frac{2}{3}$, 18 or $18\frac{1}{2}$, 23, 26 or $26\frac{1}{2}$, 31 or 32, and 54 or 56 months, show differences of phase of only 10° to 24° , while the peaks at $13\frac{1}{3}$, $20\frac{2}{3}$, 49 and 72 months correspond to differences of phase varying from 40° to 75° . In view of the striking differences between figs. IA and IIA, it is remarkable that the periodograms of figs. I and II should show such a considerable degree of resemblance.

The periodograms for London and Edinburgh rainfall bear little resemblance to one another, the only peak common to both being at $14\frac{2}{3}$ months, unless we include the peak which appears at 19 months in London and $19\frac{1}{2}$ months at Edinburgh, which may be due to the same cause as the peaks which appear in the Milan diagram at $18\frac{1}{2}$ months, and in the Padua diagram at $19\frac{1}{2}$ months. Edinburgh rainfall also shows peaks at $12\frac{2}{3}$, 49, and 72 months, which are common to Milan and Padua.

2. *Pressures.*—Pressures at Edinburgh and Paris show corresponding peaks at 13, $14\frac{2}{3}$, $15\frac{1}{3}$, 16, $18\frac{1}{2}$, 29, 35 months, all of which, except $18\frac{1}{2}$ months, show close agreement of the phase of maximum. Each of these two also shows a number of peaks not occurring in the other. In the case of Edinburgh, peaks occur at 13, $14\frac{2}{3}$, 19, 29, 60 and 72 months in the periodograms of both rainfall and pressure, and the differences of phase (ϕ converted to the same zero) were 100, 184, 181, 193, 180 and 135 respectively, showing a strongly marked tendency for maximum rainfall at minimum pressure, similar to that already noted for the period of 13 years.

3. *Temperatures.*—Except for Vienna, the temperature records used in the first analysis of 100 years all commenced in 1764, so that the zero of ϕ is the same for five temperature records. The periodograms in figs VII to XII show several very striking features, peaks occurring in all six cases at 13 months ($13\frac{1}{3}$ for Vienna), $14\frac{2}{3}$ (possibly $14\frac{1}{2}$ for London, Paris and Vienna), about 19 months, about 25 or 26 months, and 42 months. In the table below are shown for each of the periods giving peaks in three or more of these six periodograms, the deviation of the phase from the mean value of the

phase for all the series for which that particular period gives a peak in the periodogram. When the figure is bracketed, it indicates that for the series concerned, that particular period is not at the peak, though near it. When no value is given in a particular compartment it conveys the information that in the series of observations to which it refers, that particular period is not at or near a peak :—

8. General Conclusions.

No attempt will be made in this paper to discuss the reality of periods on the basis of the theory of probability. Nor will any comparison with the results of other workers be attempted.* The results are put forward in the present form in the belief that physical results of consequence can be derived by the comparison of periodograms based on observations at widely separated stations.

Considering each periodogram separately, we find so great a number of peaks in each diagram that it can safely be concluded that these results cannot be profitably utilised for forecasting the general nature of next year's weather. Each meteorological element considered is highly variable, the variations being partly periodic and partly casual in their incidence. On account of the casual variations, it is never possible to fix with certainty the length, amplitude or phase of the periodic variations, and so it is not possible to calculate with any degree of confidence the value of the periodic variations for any future epoch.

A number of probably real periodic variations represented by peaks in the periodograms are found to be common to all six-temperature records, with approximately the same phase of maximum, and hence we conclude that some physical cause of variation of temperature is common to all six phases. It is admittedly possible that casual

* The reader may, however, be referred to a paper by Prof. H. H. Turner in the 'Quarterly Journal of the Royal Meteorological Society,' p. 315 (1915), which takes up the problem of weather periodicities from a somewhat different standpoint.

variations extending over a wide area might simulate a periodic variation, but the area which will include Edinburgh, London, Paris, Berlin, Vienna and Stockholm is so great that it is, to say the least, improbable that casual variations should give the remarkable coincidence of periods and phases noted. The resemblances found for the shorter periods make it appear all the more curious that the long-period variations should differ so widely.

The discussion of the details of the results described above is reserved for a future occasion.

Finally, I have to acknowledge my indebtedness to the Director of the Meteorological Office for placing at my disposal the facilities for obtaining the data and carrying out the work involved in this investigation, which was done partly as official duty and partly as a private investigation. I am also much indebted to Mr. C. E. BRITTON, Meteorological Office, Shoeburyness, under whose supervision a considerable portion of the computations was carried out.

In the Tables I to XII, which follow, there are given for a number of trial periods shown the amplitude R , the phase of maximum ϕ , and the sine and cosine components of each harmonic term are given. Thus $C = R \cos \phi$, $S = R \sin \phi_0$.

The unit of R is 1 mm. of rainfall per month. For periods up to 10 years ϕ is measured from mid-January, 1764, and for periods longer than 10 years from the middle of the year 1764.

TABLE II.—Padua Rainfall.
