cùm ferè in ea fuerim opinione, illam vel nunquam, ut plernmque factum fuit, vel tam cito non redituram, ad locum illum haud sepius oculos direxi; nec fieri id quidem poterat, cùm hac hyeme, nocturno tempore, circa sinfra Horizontem Caput Cygni perpetuo haserit. Certus interim sum, ad mensem Decemb. Januar. imo Februarii haud conspicuam fuisse. Etenim post 14. Octobris, quo videri desiit, memini me eam sapius quasivisse eo in loco, sed nusquam apparuisse. Idcirco quantum colligere datur, vix ante initium Martis, quin, sine dubio, adhuc tardius iterum prodiit. Pridie eam à reliquis quibustam Fixis sum dimensus. Distat à Cauda Cygni, 20 gr. 55'. 20"; ab ancone Ala superioris Cygni, 17 gr. 47'. 50'; à Capite vero Serpentarii, 34 gr. 19'. 40"; sic ut eodem planè loco adhuc per-sistat, ubi antea suerat.

De reliquo, mihi persuadeo, cùm semel, & quidem intra adeo breve temporis spatium redierit, illam sepius fore invisibilem rursusque conspicuam, cum incremento & decremento illius, que in Collo Ceti est, adinstar. Proinde opera pretium suerit, cùm Philosophia plurimum intersit scire, Andentur evidentes ejusmodi alterationes in Calo plures, ub diligentius imposterum ad eam attendamus; possitue certa quadam Hypothesis de ejus occasu & ortu, decremento item & incremento, à nobis excogitari? Et an singulis annis, ut Stella in Collo Ceti, sub aspectum veniat? An certo anni & omni tempore sub aspectum veniat, pari ratione; an vero cum retardatione vel anticipatione aliqua certa? Et denique, an semper aquali magnitudine, simili colore & lumine prodeat, permaneat que? Ego, dante Deo, meam operam hac in parte polliceer; reliqui Vrania cultores quin idem facturi sint, nullus dubito.

Another Accompt of the same Subject, Englished out of the French Journal des Scavans, printed at Paris the 22th of June 1671.

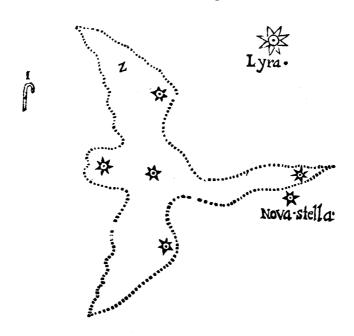

He New Star, which Don Anthelme, a Carthusian of Dyon, hath lately discover'd *, is one of the rarest Appearances

> See Numb. 65.p. 2092. Where the time mentioned of the first discovery of this Star, differs from that of the relation of this lournal, and is doubtless hence to be corrected.

observed this good while. As this person contemplated the Heavens at night, June 20th of the last year, desirous to discover that admirable Star, which hath appear'd and disappear'd twice since the beginning of this Century in the Constellation of the

the Swan*; he perceived near the same Constellation which is that in a Star of the Third Magnitude, which he had never yet Pectore Cygni. observed. He presently signified it to the Company which assembleth in the Library of the King: And divers of that Assembly having beheld the Heavens about the end of June and the beginning of July, took notice, that there was indeed about the Beak of the Swan a New Star of the third magnitude, not to be met with in any Catalogue of Astronomers, although many other neighbouring Stars, that are much smaller, be exactly marked by them. It was scituate as appears in the following figure*.

But that which is further remarkable, is, that in the beginning of fuly * this Star was observed to decrease. In the night of fuly 3d, it appear'd yet of the Third magnitude, but her Light was sensibly fainter. In the night of the same month, she scarce appear'd of the Fourth magnitude. In the night of August 10th, she was but of the Fifth. And she hath ever since decreased still, so that at last she became so small that she was seen no more.

And so she hath remained for six months without shewing her self, and we could not discover her again till the night of March 17th last, when Don Anthelme spied her in the very same place, where she was the year before, and sound, that she was of the Fourth.

magnitude.

The Assembly that meets in the Kings Library, having notice thereof, several of them did observe this Star in the night of the 2d of
April last, sinding her in the self same place where they had seen her
the precedent year. The 3d of the same month M. Cassini found her
greater than the two Stars of the Third magnitude that are below in the
Constellation of Lyra, but a little smaller than that in the Beak of
Cygnus.

The 4th of the same month, she appear'd to him almost as great and much more radiant than that of the Beak of the

Swan.

The 9th of the same, he found her a little diminish't; and almost equal to the greatest of the two Stars that are below in Lyra.

The 12th, she was equal to the least of these two Stars.

The 15th, he perceived that she encreased, and he found her equal, the fecond time, to the greatest of these two Stars.

From the 16th unto the 27th, she appear'd of different magnitudes, being sometimes equal to the biggest of these two Stars, sometimes equal to the least, and now and then between both.

But the 27th and 28th, she was become as big as the Star in the Swan's beak: The 30th, she appear'd a little clearer. And the first six days in

May, she was greater.

The 15th of May she was seen smaller than the same Star. The 16th, she was in bigness between the two Stars that are below in Lyra: And ever since she hath still diminished.

Thus this Star hath been twice in her greatest splendour, first on the 2th of April; and the second time, in the beginning of May: Which

we read not to have ever happen'd to any other Star.

As far as can be judged from the few Observations made of this Star, 'tis likely she is returning about Tenmonths unto the same appearance; whereas that in the Whale's Neck maketh its revolution in Eleven months. As for the Star in the Smans Breast, we have as yet no certain knowledge of the period of her revolution;

yet one may affure, that she taketh no less than Fourteen years to finish it.

The Discoveries, that have been made in the Heavens this last age, do evince, that Changes are not fo rare there, as formerly was believed. If that was true, what Pliny faith, that Hipparchus, on the occasion of a New Star he perceived, made an Enumeration of all those which appear'd at that time, there would not be any one Constellation, in which some change were not found since that time, in regard there are few, wherein there be not found more Stars now than that Astronomer hath noted in them.

But as the little assurance we have of the exactness of Hipparchus his Catalogue giveth us cause to believe, that many Stars, which were not in that Catalogue, were yet in the Heavens; so we may well grant, that some of those, that have been observed since, have not appear'd always. For not to speak of the Stars, that have been seen in the Constellation of Cassiopea, in the Neck of the Whale, in the Breast of the Sman, and in Serpentarius; Monsieur Cassini hath discover'd many other little ones *, which may very well be presumed * Compare those, difto be New. For example, he hath observ'd one of the cover'd by M. He. Fourth magnitude, and two of the Fifth in Cassiopea, velius, in Numb. 65.p.2091. where tis certain they were not feen before, many

Astronomers having exactly reckon'd up the very smallest Stars of that Constellation, and yet not one of them mention'd those three. He hath discover'd Two others, towards the Beginning of the Constellation of Eridanus, where we were fure they were not yet about the end of the Year 1664, considering that this place of the Heavens, where passed the then appearing Comet, was diligently beheld by many, who perceived divers other small Stars, without observing those two. The same hath also observed, towards the Arctick Pole Four of the Fifth or Sixth magnitude, which Astronomers, that always have their Eyes upon that place, would not have failed to note, if they had there appear'd before.

Nor are we to wonder at it, that we see now more Stars in the Heavens than there appear'd formerly, seeing there appear'd those formerly, vyhich are feen no more novy. For M. Cassini hath obferv'd, that the Star, which Bayerus puts near that which he marketh in the Figure of Orsa minor, appears no more; that that, which is marked A in the Figure of Andromeda, is also disappear'd; that in lieu of that, which is marked u, at the knee of the same figure, there are two others more Nordward; and that that, which is noted &, is very much diminisht, The Star, which Tycho placeth at the extremity of Andromeda's Chain, and calls it of the Fourth magnitude, is novv so small that one can scarce see it: And that which is in his Catalogue the 20th of the Constellation of Pisces, is novy no more feen; unless you will say, that it is gone down lower than four Hhh 2

degrees.

degrees, to the place marked o in the Figure of Bayerus *.

* We cannot omit taking notice here of fently to fay, that the Stars, that what was communicated to the R. Society, about the same subject, in a Letter of April 30. 1670. by Signor Montanari, the Learn'd Professor of the Mathematicks in Bonovia, in these words: Multa possem certè nova de Calo Vobis tradere, qua à multis annis observo, atque Firmamento meo Instabili excrnando as propediem evulgando (nppeditavero; fed unum, quod cateris admirabilius est, proferam. De sunt in Calo dua Stella Secundæ Magnitudinis in Puppi Navis ejuf ue Transtru, Bayero & & Y, prope Canem majorem, à me & aliis, occasione præsertim Cometa A. 1664. observata & recognita. Earum D: sparitionem cui Anno debeam, non movi; boc indubium, quod à die 10. April. 1668. ne vest gium quidem illarum adesse amplius observo; cateris circa eas, etiam quarta & quinta magnitudin's, immotis Plura de aliarum stellarum matationibus, pla squam centenis, at non tanti ponderis annotavi,&c.

But wve are not therefore prehave been lately discover'd, were not in the Heavens before, although they vvere not seen there. For, as vve now knovy, that there are Stars, vwhich appear and difappear from time to time, so we have cause to suspect, that most of the Stars, that were not seen formerly, or that are feen no more novv, or are found diminish't. are of the same nature with the Star in the Whal's Neck, and do not cease to be in the Heavens, though they there appear not.

It is also possible, that these New Stars not only vvere in the Heavens, but even appear'd there before they were taken notice of as

Nevv ones: And it is very probable, that 'tis also with most Stars, as vvith that in the Neck of the Whale, vvhich vvas not observed at first, but when it was already of the third magnitude; although it hath been since found, that it is not really so great when it begins to appear, but that, being very small in the beginning, it encreaseth infensibly untill it come to that greatness.

However, these Phenomena deserve always to be carefully observed by all Astronomers.

An Answer of Dr. Wallis to Mr. Hobbes's Rosetum Geometricum in a Letter to a friend in London, dated July 16. 1671.

Clarissime vir,

DErlegi Hobbij sive Rosetum, sive Fimetum, (nam utrumque olet;) in quo antiquum obtinet : Mirumque est ,ut nec sibi in animum inducere possit nec ab amicis sunderi, ne sic delirando persistat se contemptui exponere. Notata quadam hic tibi mitto: non quasi metuerim, te talibus ratiociniis seauci posse, sed ut tu, alique, quibuscum hac forte communicaveris, sine anxia consideratione denuò instituendà, statim videatis ubi potissimum peccatur.

Primæ Propositionis, sive Problematis, constructio (ut ut in re facili) Rectam extremâ & media ratione secare; docuerat Euclides. & demonstraverat, prop 30. El.6. (cui & alii haetenus consenserunt.) Secundum quem, posità rella seconnda 1R, erit majus segmentum : R; adeoque
