XXX. Astronomical Observations made in the Austrian Netherlands in the Years 1773, 1774, and 1775. By Nathaniel Pigott, Esq. F. R. S. Foreign Member of the Academies of Brussels and Caen, and Correspondent of the Royal Academy of Sciences at Paris.

TO THE REV. DR. MASKELYNE.

REV. SIR,

Read May 7, THE inclosed observations are a sequel to those I communicated to you in 1775, and which are printed in the LXVIth vol. of Phil. Trans. for the year 1776.

Louvain being a very confiderable and the only university in the Austrian Netherlands, and upon that account a town of very great note, I was particularly desirous of settling its longitude and latitude with all the accuracy my situation and time would admit of; and the more so, that I believe myself to be the first person who ever made any astronomical observations in that place, and

and the first, of course, who has determined its position with any degree of certainty: there is, however, reason to think, that the government there will, in a short time, provide an observatory, and supply the same with proper instruments; the first use of which will, no doubt, be to verify the inclosed observations. I spared no pains to render their refults as accurate as possible. With this view I collected, by the help of my friends, all the obfervations of Jupiter's fatellites I could, corresponding to each of ours; convinced by a mature confideration of this matter, that the most effectual method of obviating the unavoidable errors which arise from the different goodness and power of instruments from the different conformation of eyes, different states of the atmosphere and other circumstances, is to compare each observation to as great a number corresponding as possible, made in different places by known observers, whose longitudes from a given meridian are well determined, and then taking a mean arifing from each fuch comparison. The amazing differences which not unfrequently are found in observations of this kind, even among astronomers of high note, confirm me still more in this opinion; and I own, I should prefer, in order to settle the longitude of any place by Jupiter's fatellites, three or four immersions and as many emersions, made in favourable circumstances,

and compared with a great number of corresponding ones, made in different places, to a far greater number, which could but be compared with those of one or two astronomers only. If this consideration be of the weight it appears to me, it has not been sufficiently attended to, and I mention it as it may be of use, particularly to young astronomers.

The meridian zenith diffances of the Sun and flars were taken with a quadrant one foot and a half radius made by BIRD, exactly and very steadily fixed in the plane of the meridian. The declinations of the fixed flars, with the equations for aberration and nutation, were taken from the Connoissance des Tems; the Sun's declination from the Nautical Almanac; its parallax and refractions, with the corrections for the barometer and thermometer, were computed from MAYER's tables published by the Board of Longitude. It may not be improper to add, that, when I observed both the upper and lower limbs of the Sun upon the meridian, I made the horizontal wire of the quadrant merely a tangent to the Sun's limb; for which reason its diameter will come out by fuch observations confiderably greater than it really was.

For the observations of Jupiter's satellites we used a reflector two feet and a half focal length, a telescope by short.

SHORT, 18 inches focus, and fometimes an achromatic treble-object glass of the same length, and not much inferior to it, made by Mr. RAMSDEN; the times were got by a quadrant and a grid-iron pendulum.

It is necessary to mention the difference of meridians between Paris and the places where the observations were made to which we compared our own; the more so, as some are not generally known, and others differ a small matter, from what is commonly supposed and printed in the Connoissance des Tems.

M. MESSIER, in communicating a confiderable number of observations, informed me in a letter of the longitudes of the following places:

Corbeil East of		•	•	-	0	0	38
Nolon, Mein.		•	, ,,	-	0	_	45

						Tl	ne

The longitudes of the other observatories are assumed, as set down in the *Connoissance des Tems*, 1777, as being well settled.

Twenty feconds were added to, or fubtracted from, the observations of the fatellites made at Greenwich, with the fix-feet reflector, on account of the great and superior power of that instrument.

Although Jupiter's fatellites observed at Brussels be emersions only, nevertheless, as they agree with what the astronomers of the Academy of Sciences at Paris have done, as appears by the *Connoissance des Tems*, the result is well established.

Being defirous of affording every means of examining and forming a right judgement of these observations, I could not avoid saying thus much concerning them. It now remains for me to return you my thanks for the obliging communication of your observations.

I am, &c.

NATH. PIGOTT.

Latitude of the Refuge de Vrowperg, Rue des Dominiquaines, at Louvain.

Having on the 21st, 23d, 24th, 25th of April 1775, observed the zenith distances of ε and ζ ursæ majoris with the face of the quadrant to the East and West, in order to determine the error of the line of collimation, which I found to be 25,2, to be subtracted from the observed zenith distances, I computed the latitude likewise from the same stars, and can depend the more upon the result from them, as, being so near the zenith, they were little affected by refraction, and not at all by the error of the line of collimation, because observed both on the quadrantal arc and arc of excess.

```
By a ursæ majoris the latitude was found,

By & ursæ majoris the latitude was,

By a mean of the Sun and stars as above,

Now, if a mean of the whole be taken, the latitude North of my observatory at Louvain will be
```

Longitude of the Refuge de Vrowperg, Rue des Dominiquaines, at Louvain, deduced from observations of Jupiter's fatellites.

Corresponding altitudes of Sun and stars.

At Louvain,				****	8	8	43

On a mean, Louvain East of Paris 9' 39"

RESULT.

If the observations made at Louvain, excepting that of the second satellite of August 31, 1773, in which I suspect an error of a minute, be compared to those made at Greenwich alone, with which there is a singular agreement, they stand as follows:

If a mean be taken between 9' 30", the refult of the whole of the compared observations as above, and 9' 43" the mean of the Louvain observations, compared with those made at Greenwich only, the mean of these means will probably be very near the truth, and give the Refuge de Vrowperg, Rue des Dominiquaines, at Louvain, 9' 37"—in time, or 2° 24' 15" of a great circle, East of the Royal Observatory at Paris.

Farther observations of Louvain.

1775, February 18.

Occultation of Saturn by the Moon.

Contact of Saturn's West and D's	East limb,		9 25 15
Total immersion of Saturn's body,	-		9 25 39
Total immersion of the ring,		,	9 26 5

made in the Austrian Netherlands.

By my fon, with the fame reflector as above, magnifying 95 times on Saturn's emerging from a cloud, he appeared in contact with the limb of the Moon at 9h 25' 15". The fuddenness of this observation may possibly make it uncertain for a few seconds. At the total immersion of Saturn's body, the Eastern part of the ring became very faint by the brightness of the Moon. Vapours affected pretty strongly both Saturn and the Moon. Clouds hindered from seeing the emersion.

RESULT.

The mean of these emersions give Brussels East of Paris 8' in time; but if the observation of January 11, 1774, be rejected, as it ought, because differing considerably from the rest, the mean of the others will give the Court at Brussels 8' 7" in time, or 2° 1' 45" in parts of a great circle, East of the Royal Observatory at Paris.

Farther observations at Brussels.

1773, October 27.

At 3½ h. P.M. height of quickfilver in a SW. room, out of the Sun,	in FAHR	enheit's	thermomete	70
