Pressure Coefficient and Compressibility of Liquid He⁴ Very Close to the λ Curve*

O. V. LOUNASMAA[†] Argonne National Laboratory, Argonne, Illinois and Wihuri Physical Laboratory, University of Turku, Turku, Finland

(Received 21 December 1962)

Measurements of the pressure coefficient $\beta_V = (\partial p / \partial T)_V$ and the compressibility $\kappa_T = -(1/V)(\partial V / \partial p)_T$ in the immediate vicinity of the point $p_{\lambda} = 13.04$ atm, $V_{\lambda} = 24.20$ cm³/mole, $T_{\lambda} = 2.023$ °K are described. For β_V the smallest increments were $\Delta T \simeq 2 \times 10^{-5}$ °K and for κ_T they were $\Delta p \simeq 1 \times 10^{-3}$ atm corresponding to $\Delta V / V \simeq 8 \times 10^{-6}$. From about 2×10^{-2} °K to within 10^{-5} °K of T_{λ} , β_V is given by relations

$$\begin{split} \beta_{V=V\lambda} &= 3.5 + 3.4 \log_{10} |T-T_{\lambda}| \quad \text{(He I),} \\ \beta_{V=V\lambda} &= -6.0 + 2.3 \log_{10} |T-T_{\lambda}| \quad \text{(He II).} \end{split}$$

 κ_T , from 10⁻² to 10⁻³ atm of p_{λ} , may be represented by equations

 $\kappa_T = 0.0079 - 0.02(p - p_{\lambda}) - 1.5(T - T_{\lambda})$ (He I), $\kappa_T = 0.0089 + 0.11(p - p_{\lambda}) + 8.4(T - T_{\lambda})$ (He II).

In these relations T is expressed in °K, p in atm, β_V in atm/°K, and κ_T in atm⁻¹. Close to the λ curve β_V is thus a linear function of $\log |T-T_{\lambda}|$ and κ_T has a discontinuity at the transition point amounting to about 10% of its value. The results are discussed on the basis of thermodynamic equations derived recently by Buckingham and Fairbank.

I. INTRODUCTION

N EAR the λ curve the properties of liquid He⁴ change rapidly. Consequently, for studying the thermodynamics of the transition He I \rightleftharpoons He II measurements have to be made very close to the λ curve with exceedingly small increments of the variables. Only thus can useful information be obtained about the λ transition itself. In this paper, measurements of the pressure coefficient $\beta_V = (\partial p/\partial T)_V$ and the compressibility $\kappa_T = -(1/V)(\partial V/\partial p)_T$ in the immediate vicinity of the point $p_{\lambda} = 13.04$ atm, $V_{\lambda} = 24.20$ cm³/mole, $T_{\lambda} = 2.023^{\circ}$ K (p_{λ} , V_{λ} , and T_{λ} always refer to these values of p, V, and T) are described. The point ($p_{\lambda}, V_{\lambda}, T_{\lambda}$) is on the λ curve.¹ For β_V the smallest increments were $\Delta T \simeq 2$ $\times 10^{-5^{\circ}}$ K and for κ_T they were $\Delta p \simeq 1 \times 10^{-3}$ atm corresponding to $\Delta V/V \simeq 8 \times 10^{-6}$. Measurements of the pressure coefficient were thus done with almost two orders of magnitude smaller temperature increments and two orders of magnitude closer to the λ curve than in the previous work of Lounasmaa and Kaunisto.¹ A similar improvement was obtained for κ_T as compared with the experiments of Grilly and Mills.² The present results indicate that close to the λ curve β_V is a linear function of $\log |T-T_{\lambda}|$ and that κ_T has a discontinuity at the transition point.

II. EXPERIMENTAL

The apparatus is schematically shown in Fig. 1. Parts not drawn include a vacuum case insulating the piezometer (G) from the main helium bath, and a helium and a nitrogen Dewar. (G) was first cooled down to 4.2°K with the help of exchange gas which was then removed. Next, the temperature of the bath was lowered to 2.2°K by pumping and (G) filled approximately to the desired pressure. Simultaneously, liquid helium at 2.2°K was condensed to the upper compartment (E).

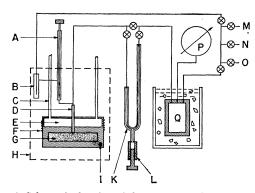

FIG. 1. Schematic drawing of the apparatus. (A) needle valve; (B) charcoal purifier at 4.2° K; (C) pumping and vapor pressure tubes (2) for (E); (D) tube connecting (G) with (A) and (K); (F) heater; (G) piezometer packed with thin copper wire for rapid equilibrium (volume 38.77 cm³ at 4°K, height 10 mm to keep hydrostatic pressure differences small); (H) dashed lines enclose space at 4.2° K or below; (I) germanium thermometer; (K) differential oil manometer (left-hand tube: length 40 cm, bore 1.89 mm²; right-hand tube: length 90 cm, bore 1.99 mm²); (L) oil reservoir filled with Apiezon B oil; (M) to He⁴ supply tank; (N) to pump; (O) to atmosphere; (P) 25-cm dial test gauge calibrated against a dead weight tester; (Q) ballast volume (1461 cm³) for balancing the right-hand side of (K); \otimes needle valves.

The bath was then allowed to warm up to 4.2° K and helium in (G) brought to the point $(p_{\lambda}, V_{\lambda}, T_{\lambda})$. The temperature in (G) was controlled by the heater (F) and by pumping on liquid helium in (E). Since the temperature could thus be kept constant when desired, the measurements of β_V and κ_T were done under equilibrium conditions.

For differential measurements of the present type it is very important that the amount of He⁴ in the dead volumes outside (G) remains the same as accurately as possible. The dead volume thus had to be made small and its temperature kept constant. Accordingly, the tube (D) connecting (G) with the oil manometer (K)was a german-silver capillary of 0.1 mm i.d. from (G) to the top of the cryostat and then increased to 0.5 mm i.d. Further, this tube was isolated from the helium bath by vacuum and it was kept warm down almost to the top of the vacuum case by soldering it inside a 1-mm copper tube extending to room temperature. (G)could not be filled through the long 0.1-mm tube owing to the possibility of blocks caused by tiny amounts of impurities in the He⁴ gas. A needle value (A), closing in the immediate vicinity of (G), was, therefore, constructed for admitting He^4 to (G). After these precautions, no spurious effects were observed during pressure measurements.

The method of measuring β_V was essentially similar to that commonly employed in constant volume gas thermometry. The pressure change produced in (G) by a small, known, temperature change was determined with the differential oil manometer (K). During these measurements the oil level in the left-hand manometer tube was kept constant within 0.01 mm and pressure changes were read from the right-hand tube with a cathetometer. At each point the temperature was stabilized for about 5 min before a measurement was taken. To the observed pressure differences 21.6% had to be added because of compression of He⁴ gas in (Q) due to movements of oil in the right-hand manometer tube.³ Including this correction, 1 cm of oil corresponded to 1.008×10^{-3} atm. The temperature of the ice bath around (Q) had to remain constant to about 0.001° C during the measurement of one pressure change. This was achieved by using distilled ice and water and by an effective stirring arrangement.

In measuring κ_T the molar volume of He⁴ in (G) was changed by raising the oil level gradually in the lefthand manometer tube and thereby pushing more He⁴ into (G). A 1-cm rise corresponded to $\Delta V/V=6.32$ $\times 10^{-6}$. The pressure changes in (G) were calculated as for β_V except that movements of oil in both manometer tubes had to be taken into account. During the measurements of κ_T the temperature was kept constant within 0.5×10^{-6} K.

For these experiments it is of utmost importance to determine the point $(p_{\lambda}, V_{\lambda}, T_{\lambda})$ accurately. Starting slightly below T_{λ} and by allowing the temperature in (G) to increase slowly the λ point could be located within 0.5×10^{-6} K from a change in the slope of the warming-up curve. The position of oil level in the lefthand manometer tube at the transition could be determined with a precision of 0.3 mm, corresponding to a relative accuracy of 3×10^{-5} atm in the pressure. For temperature measurements an ordinary carbon thermometer was employed at first, but this proved unsuitable owing to an apparent drift of about 5×10^{-5} K/h after cooling down. This drift rate became smaller with time but was still easily detectable after 24 h from the beginning of an experiment. The required stability of 0.5×10^{-6} °K was achieved with a Radiation Research Company germanium thermometer (Model CG-1). Its sensitivity was 670 $\Omega/^{\circ}$ K at T_{λ} and its resistance was measured to 0.0003 Ω in a potentiometer circuit (Rubicon No. 2773 double potentiometer). The thermometer was calibrated against the vapor pressure of He⁴, measured from (E), on the T_{58} scale.⁴

All the final measurements (3 runs for β_V and 4 runs for κ_T) were made during a single 9-day experiment. This insured that the bulk quantity of He⁴ in (G) remained constant.

Originally, it was planned to measure also C_V , the specific heat at constant volume, very close to $(p_{\lambda}, V_{\lambda}, T_{\lambda})$. The present apparatus, however, proved somewhat unsuitable for this purpose and the experiments were abandoned.

III. RESULTS

The experimental results on β_V are shown in Fig. 2; they cover the temperature range from $10^{-3^{\circ}}$ K to within $10^{-5^{\circ}}$ K of T_{λ} . Lounasmaa and Kaunisto¹ have measured β_V from $10^{-1^{\circ}}$ K to within $10^{-3^{\circ}}$ K of the transition temperature. One of their experimental runs was made in the vicinity of the point $p_{\lambda}'=13.02$ atm, $V_{\lambda}'=24.21$ cm³/mole, $T_{\lambda}'=2.0214^{\circ}$ K, which is so close to the point $(p_{\lambda}, V_{\lambda}, T_{\lambda})$ that their results are directly comparable with the present ones. As may be seen from Fig. 2, the agreement is very satisfactory. Together the two sets of data cover a range of about 4 orders of magnitude in $|T-T_{\lambda}|$ on both sides of T_{λ} .

Points in the He I and He II regions separate clearly and, furthermore, on a β_V vs $\log|T-T_{\lambda}|$ plot, from about $2 \times 10^{-2^{\circ}}$ K to the smallest experimental values of $|T-T_{\lambda}|$, they fall on two straight lines with equations (along the isochore $V = V_{\lambda}$)

$$\beta_{V=V_{\lambda}} = 3.5 + 3.4 \log_{10} |T - T_{\lambda}|, \quad (\text{He I})$$
 (1a)

$$\beta_{V=V_{\lambda}} = -6.0 + 2.3 \log_{10} |T - T_{\lambda}|$$
, (He II), (1b)

where T is expressed in °K and β_V in atm/°K. These expressions are similar to those used previously for C_p and $\alpha_p = (\partial V/\partial T)_p$ along the saturation vapor pressure curve of He^{4,5–8} except that the two lines are not

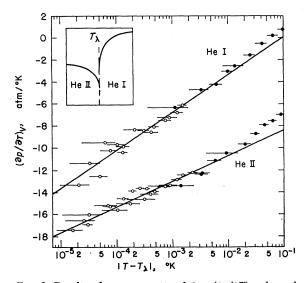

FIG. 2. Results of measurements of $\beta_V = (\partial p/\partial T)_V$ along the isochore $V = V_{\lambda}(p \simeq 13 \text{ atm}, T_{\lambda} = 2.023^{\circ}\text{K})$: \bigcirc present measurements, \bullet Lounasmaa and Kaunisto.¹ Equations of the straight lines: $\beta_{V=V_{\lambda}} = 3.5 + 3.4 \log_{10} |T - T_{\lambda}|$ (He I), $\beta_{V=V_{\lambda}} = -6.0 + 2.3 \log_{10} |T - T_{\lambda}|$ (He II). Horizontal lines extending through each point give the temperature increment used in determining β_V . The behavior of the pressure coefficient near T_{λ} is shown on a linear plot in the upper left corner,

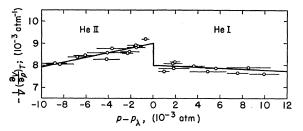

FIG. 3. Results of measurements of $\kappa_T = -(1/V)(\partial V/\partial p)_T$ along the isotherm $T = T_{\lambda}$ ($p \simeq 13$ atm, $T_{\lambda} = 2.023$ °K). Equations of straight lines: $\kappa_{T=T_{\lambda}} = 0.0079 - 0.02(p - p_{\lambda})$ (He I), $\kappa_{T=T_{\lambda}} = 0.0089$ $+0.11(p - p_{\lambda})$ (He II). Horizontal lines extending through each point give the pressure increment used in determining κ_T .

parallel to each other. In fact, if Eqs. (1) are extrapolated towards T_{λ} , the lines cross at 2×10^{-9} °K, where $\beta_V = -26$ atm/°K. Further, at $T = T_{\lambda}$ the relations give $\beta_V = -\infty$. This, however, is impossible since the pressure coefficient cannot have a larger absolute value than the slope of the λ curve,^{1,9} which at $(p_{\lambda}, V_{\lambda}, T_{\lambda})$ is $(dp/dT)_{\lambda} = -76$ atm/°K.¹ Equations (1) thus have to break down very close to T_{λ} . [According to (1a), $\beta_V = -76$ atm/°K at $|T - T_{\lambda}| = 10^{-23}$ °K.]

The scatter of points in Fig. 2 gives a good idea of the relative accuracy of these measurements. Their absolute precision, particularly in view of the good agreement between the present results and the earlier work of Lounasmaa and Kaunisto,¹ is estimated as 2% at $T-T_{\lambda}=\pm 10^{-3}$ °K.

Results of measurements of κ_T , covering a range from 10^{-2} to within 10^{-3} atm of p_{λ} , are shown in Fig. 3. Unfortunately, it was impossible to investigate a wider pressure range in our apparatus. The results show that κ_T has a discontinuity at the λ point amounting to about 10% of its magnitude. Closer than 10^{-2} atm to p_{λ} and along the isotherm $T=T_{\lambda}$, κ_T is, within the experimental accuracy, a linear function of p; thus

$$\kappa_{T=T_{\lambda}} = 0.0079 - 0.02(p - p_{\lambda}), \quad (\text{He I})$$
 (2a)

$$\kappa_{T=T_{\lambda}} = 0.0089 + 0.11(p - p_{\lambda}), \quad (\text{He II}).$$
 (2b)

In the immediate vicinity of the point $(p_{\lambda}, V_{\lambda}, T_{\lambda}) \kappa_T$ only depends on the distance from the λ curve and we may thus write $p - p_{\lambda} = -(dp/dT)_{\lambda}(T - T_{\lambda})$. By combining this result with Eqs. (2), we get for κ_T as a function of p and T

$$\kappa_T = 0.0079 - 0.02(p - p_{\lambda}) - 1.5(T - T_{\lambda}), \quad (\text{He I}) \quad (3a)$$

$$\kappa_T = 0.0089 + 0.11(p - p_{\lambda}) + 8.4(T - T_{\lambda}), \text{ (He II)} (3b)$$

where T is in °K, p in atm, and κ_T in atm⁻¹.

The experimental measurements of κ_T along the isotherm $T = T_{\lambda}$ can also be expressed as a function of V. One may further write, with the same justification as above, $V - V_{\lambda} = -(dV/dT)_{\lambda} \cdot (T - T_{\lambda})$, where $(dV/dT)_{\lambda}$ = 12.9 cm³/mole °K is the slope of the λ curve in the

⁸ L. Goldstein, Phys. Rev. 122, 726 (1961).

TABLE]	[. Coi	mpari	son o	of β_V	in	atm/	°K)	as

V, T plane.¹ We thus obtain for κ_T as a function of V and T

 $\kappa_T = 0.0079 + 0.10(V - V_{\lambda}) - 1.3(T - T_{\lambda}), \quad (\text{He I}) \quad (4a)$

$$\kappa_T = 0.0089 - 0.51(V - V_{\lambda}) + 6.6(T - T_{\lambda}), \quad (\text{He II}) \quad (4b)$$

where T is in °K, V in cm³/mole, and κ_T in atm⁻¹.

The absolute accuracy of κ_T is estimated as 3% at $p-p_{\lambda}=\pm 10^{-2}$ atm; the relative accuracy may be seen from the scatter of points in Fig. 3.

IV. DISCUSSION

By employing a method due to Buckingham and Fairbank¹⁰ the following relation, valid in the immediate vicinity of the λ curve, can be derived for the pressure coefficient:

$$\beta_V = (dp/dT)_{\lambda} + (dV/dT)_{\lambda}/\kappa_T V.$$
(5)

A few values calculated for β_V by using this equation and relations (4) (by putting $V = V_{\lambda}$) for κ_T are compared with directly measured data (1) in Table I. At 10^{-5°}K the agreement is quite good for He II but less satisfactory for He I. However, not a very close agreement can be expected since β_V from (5) is obtained as the difference of two large quantities and thus an error of 3% in $(dp/dT)_{\lambda}$, $(dV/dT)_{\lambda}$, or κ_T would change the calculated value of β_V by about 20%. At distances greater than $10^{-4}{}^{\circ}\mathrm{K}$ from the λ curve the agreement rapidly becomes poorer presumably for two reasons. Firstly, (5) is no longer valid to sufficient accuracy. By employing the relation^{10,11}

$$\alpha_{p} = (dV/dT)_{\lambda} + \kappa_{T} V (dp/dT)_{\lambda}$$
(6)

to measurements of α_p and κ_T along the saturation vapor pressure curve Chase, Maxwell, and Millett⁸ found that (6) is valid only at temperatures closer than 10^{-4} °K to the λ point. A similar range of validity may be expected for (5) also. Chase *et al.* further observed that the agreement is better in He II than in He I region. Secondly, the present measurements of κ_T cover only 1 order of magnitude in $p-p_{\lambda}$, and one would thus expect that relations (2-4) might rapidly lose their usefulness at pressures outside 10^{-2} atm (corresponding to 10^{-4} °K) of the transition point. The true temperature dependence of κ_T

might be rather different from that given in Eqs. (2)-(4)and this would also explain the discrepancies. As an example, in He I region, according to (5), $\beta_V = 0$ at $T - T_{\lambda} = 7 \times 10^{-4^{\circ}}$ K, whereas in reality this only happens at $6 \times 10^{-2^{\circ}}$ K (Fig. 2). Equation (1a) gives for this temperature $9 \times 10^{-2^{\circ}}$ K.

Several other relations, suitable for comparing different thermodynamic quantities of He⁴ near the λ curve have been derived by Buckingham and Fairbank.¹⁰ Unfortunately, due to considerable difficulties in making precise measurements close to the transition temperature, very few experimental data are available for such a comparison. Furthermore, most of these investigations have been done under saturation vapor pressure even though measurements in the pure liquid phase are more fundamental. Besides the experiments on β_V by Lounasmaa and Kaunisto¹ the present results may only be compared with the C_V data of Lounasmaa and Kojo.¹² This can be done by employing the following relation,¹⁰ valid at the λ curve:

$$C_{V,\lambda} = T_{\lambda} (dS/dT)_{\lambda} - T_{\lambda} (dV/dT)_{\lambda} (dp/dT)_{\lambda}.$$
 (7)

The values of T_{λ} , $(dV/dT)_{\lambda}$, and $(dp/dT)_{\lambda}$ have already been given; $(dS/dT)_{\lambda} = 3.9$ J/mole °K^{2.13} We thus get $C_{V,\lambda} = 208$ J/mole °K. Experimental data by Lounasmaa and Kojo¹² are about 40 J/mole °K. The smallest temperature increments used in the C_V experiments were about 7×10^{-3} °K which explains the discrepancies. For a more meaningful comparison, measurements with at least 2 orders of magnitude smaller temperature increments would be most desirable.

The thermal expansion coefficient α_p can be calculated from (6) or from the general thermodynamic relation $\alpha_p = V \kappa_T \beta_V$. Results by the latter method are probably valid over a wider temperature range than those obtained by using Eq. (6).

Buckingham and Fairbank¹⁰ have derived equations [relations (5)-(7)] are examples for a transition characterized by the absence of a latent heat but at which C_p becomes infinite. Their results show that at such a transition α_p and κ_T both become infinite and that $\beta_V = (dp/dT)_{\lambda}$. C_V will have the finite value given by (7). The present measurements seem to contradict some of these conclusions. Firstly, it seems doubtful (cf. Fig. 2) whether β_V can reach the value -76 atm/°K at $T = T_{\lambda}$ when this point is approached from either side. Secondly, there are no indications at all (cf. Fig. 3) that κ_T would be tending towards infinity at the λ point. However, according to Chase, Maxwell, and Millett⁸ one would have to come exceedingly close to the transition curve (10^{-68°}K for a 100% increase in κ_T) before this trend becomes apparent.

Previous measurements of C_p by Fairbank, Buckingham, and Kellers⁵ and of α_p by several groups of inves-

¹² O. V. Lounasmaa and E. Kojo, Ann. Acad. Sci. Fennicae Ser. AVI, No. 36 (1959). ¹³ O. V. Lounasmaa, Cryogenics 1, 212 (1961).

¹⁰ M. J. Buckingham and W. M. Fairbank, *Progress in Low-Temperature Physics*, edited by J. C. Gorter (North-Holland Publishing Company, Amsterdam, 1961), Vol. 3, p. 80. ¹¹ A. B. Pippard, Phil. Mag. 1, 473 (1956).

tigators^{6-8,14} along the saturation vapor pressure curve indicate that both these quantities have logarithmictype singularities at the λ point and that they may be represented by equations similar to (1), with the important difference that the two lines corresponding to He I and He II are parallel to each other. Experimental evidence for parallelism is strong in the case of C_p but much less so for α_p . It is quite possible, on the basis of results by Chase et al.,⁸ that the line corresponding to α_p in He II region has a smaller slope than that in He I region, as in the case of β_V (cf. Fig. 2). However, there is a basic difference between C_p and α_p on one side and β_V on the other: β_V has a finite value at the transition point and thus a logarithmic equation (1) cannot be valid right up to $T = T_{\lambda}$, whereas for C_p and α_p there is no reason, in principle, why this could not be so. When the present measurements are taken into account, the difference in the slopes of the straight lines in Fig. 2 becomes more pronounced than it was according to the observations of Lounasmaa and Kaunisto.¹

Direct measurements of C_V and α_p with very small increments of temperature would provide valuable information about the λ transition and such data could be used, together with the present results, for checking the relations of Buckingham and Fairbank¹⁰ if the experiments were made close to the point $(p_{\lambda}, V_{\lambda}, T_{\lambda})$. Measurements of κ_T should also be extended over a wider pressure range.

When experiments with smaller and smaller temperature increments have been made, the apparent character of the λ transition in liquid He⁴ has been shifting from one with sharp discontinuities in C_p and β_V to one at which these quantities change less drastically, showing that the transition is of milder character than was originally assumed.

ACKNOWLEDGMENTS

The author wishes to express his gratitude to Pat Roach for effective help in the earlier stages of these experiments and to Conrad Littig for assistance during the final measurements. He is also indebted to the Osk. Huttunen Foundation for a research grant.
