(Revised Received 1 August 1974)

**Key Word Index**—*Swertia lawii*; Gentianaceae; 1,3,7,8-, 1,3,5,8-tetraoxygenated xanthenes; 1-hydroxy-3,4,7,8-tetramethoxyxanthone; chemotaxonomy.

**Abstract**—1,3,7,8-Tetrahydroxyxanthone, 1,7,8-trihydroxy-3-methoxyxanthone, 1,8-dihydroxy-3,7-dimethoxyxanthone, 1-hydroxy-3,7,8-trimethoxyxanthone, and 1-hydroxy-3,4,7,8-tetramethoxyxanthone have been identified in *Swertia lawii*. In addition, 1,3,5,8-tetrahydroxy- and 1-hydroxy-3,5,8-trimethoxyxanthone has been detected by analytical TLC. Chemotaxonomic significance of the polyoxygenated xanthenes occurring in the *Swertia* is appraised.

### INTRODUCTION

In connection with our work on xanthenes of Gentianaceae, we undertook investigation of *Swertia lawii*, which is distributed in the mountains of the Western Peninsula and in the Nilgiris and is used as a substitute for *S. chirata* in the Indian system of medicine [1]. Previously, the isolation of erythrocentaurin from the whole plant was reported from this laboratory [2]. The isolation and identification of the polyoxygenated xanthenes from the whole plant of *S. lawii* constitute the subject of this paper.

### RESULTS AND DISCUSSION

The entire plants were milled and extracted for xanthenes. The isolation and purification of the individual compounds were accomplished by solvent extraction, column chromatography, preparative layer chromatography and derivatization. The identity of the known compounds was established by spectral (UV, PMR, MS) evidence and by direct comparison with reference samples [3, 4]. The characterization of only the new naturally occurring xanthone, viz. 1-hydroxy-3,4,7,8-tetramethoxyxanthone, is described here.

**1-Hydroxy-3,4,7,8-tetramethoxyxanthone (3).** The compound, m.p. 192–194°,  $C_{17}H_{16}O_7$  ( $M^+$ , 332), is a monohydroxytetramethoxyxanthone in which the hydroxyl group is strongly chelated, since it remained unaffected with ethereal diazomethane, but formed the permethyl ether with dimethyl sulphate and alkali. Its UV spectrum is characteristic of 1,3,4,7,8-pentaoxygenated xanthenes [5, 6]. The 60 MHz PMR spectrum of the compound, in  $CDCl_3$ , showed one strongly chelated proton at  $\delta$  3.04 ( $C_1$ -OH), four methoxyl groups at  $\delta$  3.94–4.02, and three aromatic protons at  $\delta$  6.40 (1H, s,  $C_2$ -H), 7.05 (1H, d,  $J$  9 Hz,  $C_5$ -H), 7.28 (1H, d,  $J$  9 Hz,  $C_6$ -H). In the MS of the xanthone, aside from the molecular ion peak which is the base peak, significant fragment ion peaks appeared at  $m/e$  317 (35%), 302 (48), 289 (20), 259 (10), associated with the loss of Me,  $CH_2O$ ,  $C_2H_3O$  complex, and  $CH_2O + C_2H_3O$  fragments, respectively. There were significant abundances of metastable ions to support the postulated rationalizations [3, 4; 6–8]. On the basis of the above observations, the pentaoxygenated xanthone is assigned 1-hydroxy-3,4,7,8-tetramethoxyxanthone structure (3), which was confirmed by direct comparison with an authentic synthetic sample.

\* Part 15 in the series "Chemical Constituents of Gentianaceae". For Part 14 see Ref. [28].

Members of the genus *Swertia* are known to make 1,3,5,8- and 1,3,7,8-tetraoxygenated xanthenes [3,6,9] but the occurrence of penta-oxygenated xanthenes (1,3,4,5,8 and 1,3,4,7,8) in this genus was reported only once before (in *S. purpurascens*) [6]. The tetra and penta oxygenated xanthenes occurring in *Swertia* were also encountered in *Gentiana* [5]. The close similarity between the polyoxygenated xanthenes of the *Swertia* and those of the *Gentiana* seems to indicate a close relationship between the two genera. Members of the genus *Swertia* were initially identified with those of *Frasera* and *Halenia*. Subsequently, however, on the basis of elaboration of oxygenation patterns of the xanthonic constituents of a number of *Frasera* and *Halenia* species, a closer phytochemical relationship between the latter two than between

either and *Swertia* was proposed [10]. Phytochemical examination of a number of *Swertia* species in the authors' laboratory, however, indicated that the above categorization is rather premature. Thus, *S. himaculata* has been recently found [11] to contain polyoxygenated xanthenes whose oxygenation and methylation patterns are closely similar to those of *Frasera albicaulis* [12] and *F. caroliensis* [13]. It is also interesting to note in this connection that marked variation in the relative abundance of 1,3,5,8- and 1,3,7,8-tetraoxygenated xanthenes was observed in the members of the *Swertia* and *Gentiana*. The content of the two types of xanthenes in several members of these two genera was found to be inversely proportional. In the present investigation of *S. lawii* also, the presence of the 1,3,5,8-tetraoxygenated xanthenes

\* The distribution of glycoxanthenes, glycoflavones and xanthone-*O*-glycosides in Gentianaceae has recently been reported [6]; † identified as the permethyl ether; ‡ denotes 1,3,5,8-tetraoxygenated xanthenes occurring as the major constituents; § denotes 1,3,7,8-tetraoxygenated xanthenes occurring as the major constituents.

could only be detected by TLC while the 1,3,7,8 and 1,3,4,7,8 patterns were obtained in high yields. This observation has a direct bearing on the biogenesis of polyoxygenated xanthenes. Table 1 lists all the polyoxygenated xanthenes that have been isolated so far from Gentianaceae (Table 1).

#### EXPERIMENTAL

The general procedures used are the same as reported in a recent paper [3].

*Isolation of xanthenes from S. lawii.* Dried and milled whole plants (1.2 kg) were continuously extracted (24 hr) in a Soxhlet with light petrol. (60–80°) and the defatted plant material was then extracted with alcohol (24 hr). The two extracts were separately processed.

*Treatment of petrol. extract.* The petrol. extract was conc. (ca 500 ml) and the concentrate was kept overnight at ordinary temp. when a yellow amorphous solid (Fraction A, 4.3 g) separated. The solid was collected by filtration and the mother liquor was evaporated (Fraction B).

*Separation of xanthenes present in Fraction A.* The solid (2.4 g), from Fraction A, was mixed with equal amount of silica gel and packed over a column (20 × 3 cm) of silica gel. C<sub>6</sub>H<sub>6</sub> (8 l.) and CHCl<sub>3</sub> (4 l.) were used as the eluents. Earlier C<sub>6</sub>H<sub>6</sub> fractions gave a solid, m.p. 218–220° (0.47 g) which showed one major and one minor spots on TLC.

*1,7,8-Trihydroxy-3-methoxyxanthone (1).* A portion of the above solid on repeated crystallizations from MeOH afforded yellow needles, m.p. 220°. The m.p., UV, PMR and MS of the compound were identical with those of 1,7,8-trihydroxy-3-methoxyxanthone [27]. The dimethyl ether, prepared with ethereal diazomethane, was identical with decussatin [4] in all respects.

*Separation of xanthenes present in Fraction B.* The solid (12.8 g), from Fraction B, was dissolved in Et<sub>2</sub>O (1 l.) and the

phenolic and neutral components were separated in the usual way [3]. The mixture of phenolic constituents (1.2 g) was chromatographed over silica gel column ( $18 \times 3$  cm) using light petrol. (1 litre), petrol.- $C_6H_6$  (1:1, 3 l.),  $C_6H_6$  (2 l.), and  $CHCl_3$  (3 l.). The light petrol. eluates gave only a small amount of an amorphous solid which was not processed further.

**1,8-Dihydroxy-3,7-dimethoxyxanthone (2).** The petrol.- $C_6H_6$  eluates, on conc. furnished a yellow solid (72 mg) which crystallized from EtOH as yellow needles, m.p. and mixed m.p. 185–186°. The co-TLC, UV and MS of the compound were also identical with those of 1,8-dihydroxy-3,7-dimethoxyxanthone [3]. Treatment of the compound with ethereal diazomethane gave decussatin (m.p., m. m.p., co-TLC). The middle benzene eluates showed one major and one minor spots on TLC. The two components were separated by preparative TLC using  $CHCl_3$ .

**1-Hydroxy-3,4,7,8-tetramethoxyxanthone (3).** The major component (preparative layer zone,  $R_f \sim 0.2$ ) was eluted with  $CHCl_3$  from one chromatoplate. The residue, obtained from the  $CHCl_3$  soln, crystallized from EtOH as yellow needles (12 mg), m.p. 192–194° (Ref. 5, m.p. 192–193°); UV:  $\lambda_{max}$  (EtOH) 240 (0.63), 262 (0.78), 270–275 sh (0.44), 312 (0.305), 380 nm (0.09). It was found to be identical with a synthetic sample of 1-hydroxy-3,4,7,8-tetramethoxyxanthone, prepared from decussatin by persulphate oxidation followed by methylation with ethereal diazomethane. The minor component (from the upper preparative layer zone,  $R_f \sim 0.5$ ), obtained in a similar way as above, was shown to be identical with 1-hydroxy-3,5,8-trimethoxyxanthone [3] by direct comparison (co-TLC, UV). The  $CHCl_3$  eluates of Fraction B showed several spots on TLC and could not be disentangled due to their close  $R_f$  values and small quantity.

**1-Hydroxy-3,7,8-trimethoxyxanthone (4).** The solid (0.43 g) appeared at the  $Et_2O$ - $H_2O$  interface, during separation of the phenolic constituents of Fraction B, was washed with dil. HCl and then with  $H_2O$ , and then dried. It crystallized from EtOH as yellow needles (112 mg), m.p. 148–149°. The m.p., m.m.p.  $R_f$ , and UV spectrum were identical with those of an authentic sample of decussatin.

**Treatment of EtOH extract.** The EtOH extract was conc. to a syrupy liquid. It was poured into aq. HOAc (4%, 400 ml.) and the mixture was kept at ordinary temp. overnight. The solid was collected by filtration and was kept for further processing for more polar compounds. The clarified acidic soln was extracted with  $Et_2O$  (10–200 ml portions) and the combined extracts was worked up for xanthenes to give a yellow solid (3–4 g).

**1,3,7,8-Tetrahydroxyxanthone (5).** The above solid was repeatedly extracted with hot  $CHCl_3$  (5–100 ml portions). The combined  $CHCl_3$  extracts was conc. when a  $CHCl_3$ -sparingly soluble solid separated. The mother liquor was marked Fraction C. The solid crystallized from MeOH as light yellow micro needles (0.32 g), m.p. 328–339° (Ref. 27, m.p. 335°). The corresponding tri- and tetramethyl ethers, prepared in the usual way, were found to be identical, respectively, with decussatin [3] and 1,3,7,8-tetramethoxyxanthone [3]. The MeOH mother liquor, after separation of 1,3,7,8-tetrahydroxyxanthone, showed the presence of 1,3,5,8-tetrahydroxyxanthone (co-TLC, UV).

**Separation of xanthenes present in Fraction C.** The  $CHCl_3$  concentrate was chromatographed over silica gel ( $24 \times 3$  cm). Elution was carried out with  $C_6H_6$  (3 l.),  $CHCl_3$  (4 l.) and MeOH (4 l.). Fractions (500 ml) were collected. The  $C_6H_6$ ,  $CHCl_3$  and MeOH eluates on concn gave further crops of xanthenes 4 (380 mg), 1 (222 mg), and 5 (178 mg), respectively.

**Acknowledgements.**—The authors are grateful to Professor G. B. Singh, Department of Chemistry, Banaras Hindu University and to Dr. B. C. Das, CNRS, Institut de Chemie des Substances Naturelles, Gif-Sur-Yvette, France, for the spectral data. The generous gift of the plant material by Dr. P. K. Thomas, Soil Conservation Research, Demonstration and Training Centre, Ootacamund, is acknowledged with thanks.
