The activity of the ICHG on a variety of glycoside substrates is summarized in Table 3. This enzyme is able to hydrolyze a range of synthetic glucosides, but generally only with relatively low specificity constant (k_{cat}/K_m). Although the enzyme has moderate affinity with several other natural glucosides, the specificity constant for those tested is far lower than that of the isoflavone conjugates (Table 3). Interestingly, the enzyme showed no measurable activity with several flavonol glycosides, although we did not test the 7-*O*-substituted flavones or flavonols. In contrast, commercial almond emulsin β-glucosidase has much higher specificity toward the synthetic substrate, *p*-nitrophenyl β-glucoside than toward the isoflavone conjugates (Table 3). While almond emulsin β-glucosidase does not hydrolyze the malonylglucosyl isoflavone conjugates, consistent with the fact that most β-glucosidases only cleave non-modified terminal glucose residues, the partially purified ICHG apparently hydrolyzes malonyl isoflavone glucosides as well as isoflavone glucosides with similar kinetics (Table 3). The breakdown of isoflavone conjugates is mediated by two distinct enzymes in chickpea, a malonylesterase and a β-glucosidase, which successively

Table 2
The effect of inorganic and organic chemicals on the activity of the isoflavone-conjugate hydrolyzing β-glucosidase

remove the malonyl and glucose moieties, respectively (Fig. 1). By using the isoflavone conjugate mixture coupled with the HPLC assay, we are able to examine these two enzyme activities simultaneously. However, a separate malonylesterase activity was never observed in any soybean tissue extract or at any stage of purification. Moreover, the lack of esterase activity in the partially purified IGHG preparation was also demonstrated when malonylated isoflavone glucosides were the sole substrates in the assay system with an excess of the glucosidase inhibitor, glucono-δ-lactone, over its IC_{50} value (data not shown). While the current data certainly do not preclude the existence of a separate isoflavone malonyl esterase in soybean and do not unequivocally support the existence of both activities in ICHG, it is possible that the soybean system may differ in this regard from the chickpea system. In the literature, only one other β-glucosidase, the flavone 7-*O*-glucoside-specific β-glucosidase from ligulate florets of *Chamomilla recutita*, can also use apigenin 7-*O*-acetylglucoside as a substrate, but the V_{max} was reduced dramatically when the glucose is esterified (Maier et al., 1993). Ultimately, more detailed characterization of the various enzymes will be needed to resolve these issues.

3. Conclusions

The hydrolysis of glucosyl and malonylglucosyl isoflavone conjugates is biologically relevant. A relatively high percentage of the total malonylated isoflavone glucosides is found in the apoplast in soybean (T. L. Graham, unpublished observation) and in chickpea. The genistein aglycone is toxic to fungal pathogens, such as *Phytophthora sojae* (Rivera-Vargas et al., 1993), and genistein also may function to activate an extracellular NADH oxidase that functions in defense potentiation (Graham and Graham, 1999). The quick release of genistein during pathogen attack by the apoplastic isoflavone conjugate-hydrolyzing β-glucosidase may thus be critically important for several aspects of disease resistance.

Although previous non-specific β-glucosidases were reported to hydrolyze isoflavone glucosides in soybean (Matsuura and Obata, 1993; Matsuura et al., 1995), the currently purified soybean ICHG has higher specific activity towards isoflavone conjugates with substrate specificity constants 160-fold to 1000-fold over *p*-nitrophenyl β-glucoside (Table 3). The β-glucosidase B and C isolated from soybean cotyledons had a relatively low

reaction rates (79 and 38%, respectively) with isoflavone glucosides compared to *p*-nitrophenyl β-glucoside (100%) (Matsuura and Obata, 1993; Matsuura et al., 1995). The substrate binding affinities of ICGH towards isoflavone conjugates are comparable to the chickpea isoflavone-specific β-glucosidase and flavone-glucoside-cleaving β-glucosidase from *Charmomilla recutita* (in the submillimolar range), suggesting favored binding to their natural substrates (Hösel and Barz, 1975; Maier et al., 1993). However, chickpea isoflavone-specific β-glucosidase has apparently higher specificity constants toward formononetin and biochanin A glucosides ($\sim 10^6$ M^{-1} s^{-1}) than that of ICHG. Furthermore, Hg^+, Ag^+ and glucono-δ-lactone are all inhibitory to ICGH, consistent with other plant β-glucosidases, although ICGH is less sensitive to Hg^+ and glucono-δ-lactone compared to the chickpea enzyme. Although further characterization will be required to firmly determine this, the ICHG may hydrolyze isoflavone malonylglucosides directly. This may distinguish it from the chickpea β-glucosidase. Taken together, we conclude that the β-glucosidase purified from soybean roots is a novel β-glucosidase with high specificity toward isoflavone conjugates.

4. Experimental

4.1. Plant material

Soybean (*Glycine max* L.) cv. Williams was obtained from Dr. A. F. Schmitthnner (Department of Plant Pathology, The Ohio State University and the Ohio Agricultural Research and Development Center, Wooster, OH). Seedlings were grown as described previously (Graham, 1991a). Soybean roots from 7–9 day-old seedlings were washed with tap water to remove planting media and blotted with paper towels. The roots were frozen at −20 °C until used.

4.2. Isolation and purification of isoflavone conjugates

Isoflavone conjugate substrates were prepared as follows. Soybean cv. Williams seeds (50 g) were ground to a fine powder with a coffee grinder and the powder was extracted with 100 ml chloroform for 30 min with stirring. The slurry was filtered through Whatman No. 1 filter paper with suction and washed two more times with chloroform. The defatted soybean flour was extracted twice with 50 ml distilled water. The aqueous extract (100 ml) was clarified by low speed centrifugation (International Equipment Co., Needham, MA). The isoflavone conjugates of genistein and daidzein were partially purified using a C18 PrepSep column (Fisher Scientific, Springfield, NJ). The crude aqueous substrate preparation was passed through the column, and the column was washed successively with water and 1 ml of 10% acetonitrile (HPLC grade, Sigma Chemical Co., MO). The 10% eluent was discarded. Washing with 1 ml of 20% acetonitrile released bound daidzin, genistin, MGD and MGG. This provided a preparation of the isoflavone conjugates free of aglycones (which remained bound to the column and are eluted only at higher acetonitrile concentrations). For measurement of enzyme activity in initial protein fractionations, this isoflavone conjugate fraction was brought to dryness and dissolved in an appropriate amount of 100 mM phosphate–50 mM citrate buffer, pH 5.0 to make the concentrations of each isoflavone conjugate greater than 2.5 mM as judged by HPLC (Graham, 1991a). For final purification and characterization of the glucosidase, individual isoflavone conjugates were isolated by semi-preparative HPLC using a Merck Lichrosorb RP-18 10 mm C18 column (Alltech Associates, Deerfield, IL) with non-acidic water and acetonitrile as described by Graham (1991a).

4.3. Buffers

Buffer A, 200 mM sodium phosphate buffer, pH 6.0; buffer B, 200 mM sodium phosphate buffer, pH 6.0, containing 0.5 M NaCl; buffer C, 20 mM sodium phosphate buffer, pH 6.0, containing 3 mM DTT and 10% glycerol; buffer D, buffer C containing 1 M NaCl; buffer E, buffer C containing 5 mM sodium ascorbate; and buffer F, buffer D containing 5 mM sodium ascorbate.

4.4. Enzyme extraction and purification

Frozen roots were ground almost to a powder in a mortar and pestle pre-chilled to 0 °C and extracted three times with cold buffer A (1 ml buffer/ 1 g tissue). The combined extracts were centrifuged at 10,000×*g* for 10 min. The pellet was extracted with buffer B (1 ml buffer/ g tissue) overnight at 4 °C. The root residue was further extracted one more time with an equal volume of buffer B for another 3 h. The crude extracts were pooled and 1% (w/v) insoluble polyvinylpolypyrolidone (PVPP) was added to remove phenolics. This mixture was stirred for 3 h on ice. The extract was then filtered through four-layers of cheesecloth, and clarified by centrifugation at 10,000×*g* for 20 min. The resulting solution was slowly brought to 40–60% saturation with solid ammonium sulfate at 4 °C followed by gentle stirring overnight. The pellet was collected by centrifugation at 10,000×*g* for 20 min, and then dissolved in a minimum volume of buffer C. The protein solution was clarified by centrifugation and desalted using a Sephadex G-25 column (1.7×20 cm) equilibrated with buffer C. The desalted protein solution was applied to a DEAE-Sephadex A-50 column (2.8×35 cm) equilibrated with the same buffer system and washed with buffer C. The enzyme was found in the unbound fractions. Sodium

ascorbate was added to the protein solution to a final concentration of 5 mM, and the solution was then loaded onto a column of CM-Sephadex C-50 (2.8×19 cm), equilibrated with buffer E. The elution was carried out with a 400 ml linear gradient of buffer F in buffer E. Chromatographic fractions having ICHG activity were pooled and lyophilized. The concentrated enzyme was stored at −20 °C for further study.

4.5. Enzyme and protein assays

Protein concentration was determined by the Bradford (1976) method with BSA as standard. During purification and unless otherwise noted, ICHG activity was determined in 0.2 M phosphate–0.1 M citrate buffer, pH 5.0 at 40 °C in a total reaction volume of 10 μl containing 5 μl of isoflavone conjugate mixture. The reaction was stopped at 30 min by adding 90 μl of methanol and activity was measured by quantifying the release of aglycones by HPLC (Graham, 1991a). This enzyme assay allowed us to simultaneously examine the relative release of aglycones from both daidzein and genistein conjugates, and also allowed us to measure the possible esterase activities in fractions leading to the formation of daidzin and genistin from MGD and MGG, respectively. During the course of the fractionation, the glucosidic activities towards daidzein and genistein conjugates were always comparable and thus results are expressed in terms of total aglycone release. One unit of enzyme activity was defined as the amount of enzyme that produced 1 mmol of product per minute. Specific activity was expressed as enzyme units per mg protein. No apparent conversion of MGD or MGG to daidzin or genistin was observed in any extract or during any fractionation step; that is, we never observed an isoflavone-specific malonylesterase activity as reported in chickpea (Hösel and Barz, 1975).

In the study of substrate specificity, the concentration of substrate was 2 mM unless otherwise noted. Daidzein 7-*O*-glucoside, daidzein 7-*O*-glucoside-6″-*O*-malate, genistein 7-*O*-glucoside, and genistein 7-*O*-glucoside-6″-*O*-malate were assayed at 0.2, 0.18, 0.79 and 1.15 mM, respectively. The appropriate concentration of the ICHG used for each substrate was determined graphically from the linear portions of initial reaction velocity. All substrates were dissolved in 0.2 M phosphate–0.1 M citrate buffer, pH 5.0, except that *p*-nitrophenyl α-glucoside, 4-methylumbelliferyl β-glucoside, and genistein 7-*O*-glucoside were dissolved in ethylene glycol monoethyl ether at 50 mM and then diluted to final concentration in the same buffer.

Depending on the substrate, activity was measured either spectrophotometrically or by HPLC. For those substrates releasing an aglycone with known molar coefficient (ϵ), the assay solution containing the enzyme (10 μl) and substrate (90 μl) in 0.2 M phosphate–0.1 M citrate buffer, pH 5.0, was incubated at 40 °C for various time courses. The reaction was stopped by alkalization of the assay mixture with 100 μl of sodium carbonate, and the mix was then diluted to 1 ml with distilled water for measurement of absorbance. For quantitative calculations, the following wavelengths and ε values (mM^{-1} cm^{-1}) were used: *p*-nitrophenol, 400 nm, $\varepsilon = 19.3$; *o*-nitrophenol, 420 nm, $\varepsilon = 4.55$; 4-methylumbelliferone, 360 nm, $\varepsilon = 18.25$; and salicyl alcohol, 295 nm, $\varepsilon = 3.3$. For the substrates, esculin and arbutin, without known ε values, the following method was developed. The UV spectrum of esculin showed a peak at 374 nm and the absorbance intensity decreased over time with enzymatic activity. The activity assay was conducted as described above, and the absorbance change was converted to concentration by a linear standard curve made from various concentrations of esculin in 100 μl Na_2CO_3 and 900 μl water. The enzyme activity against arbutin was determined similarly at 267 nm.

Activity against several natural substrates was assayed by the HPLC method for isoflavone conjugates as described above for enzyme purification, except that the total reaction volume was 15 μl and the reaction was stopped at various times by adding 85 μl of methanol. The substrates assayed by HPLC included the four isoflavone conjugates, two flavonol glycosides (rutin and isoquercitrin), phloridzin (a chalcone glucoside), and amygdalin (a cyanogenic di-glucoside). Commercial almond emulsin β-glucosidase, a classic non-specific β-glucosidase, was also examined to compare substrate specificity. All K_m and V_{max} values were calculated based on Lineweaver-Burk plots, and the k_{cat} value is equal to V_{max} divided by the total enzyme concentration (in molarity) which was calculated using M_r of 165 kDa for ICHG and 135 kDa for almond emulsin β-glucosidase. The kinetic parameters reported are the mean values of two or three independent determinations.

The temperature optimum of the ICHG was resolved by incubating the enzyme solution with isoflavone conjugates over a temperature range from 0 to 90 °C for 30 min. Enzyme activity was monitored by the standard HPLC method. To determine the pH optimum, 4-methylumbelliferyl β-glucoside was used in various buffers varying in pH values from 2.6 to 10.6. Enzyme activity was determined spectrophotometrically as described above.

4.6. SDS-polyacrylamide gel electrophoresis (PAGE)

SDS-PAGE was performed as described by Laemmli (1970) using a Mini-Protein II electrophoresis system (Bio-Rad). Analyses were carried out under non-reducing or reducing (mercaptoethanol) conditions as specified. The molecular markers used were bovine serum albumin (66 kD), ovalbumin (45 kD), and carbonic

anhydrase (29 kD) all from Sigma Chemical Co. Protein gels were stained with silver stain (Bio-Rad).

4.7. Inhibition assays

Several inorganic and organic compounds and solvents were examined for their inhibitory effects. The reaction mixture was in 0.2 M phosphate–0.1 M citrate buffer, pH 5.0 using a total reaction volume of 15 μl incubated at 40 °C for 30 min; the reaction was stopped by adding 85 μl of methanol. The enzyme activity was measured by HPLC and designated as 100% in the absence of added chemicals. The activity reported is the average from two independent measurements. A series of concentrations of Ag^+, β-mercaptoethanol and glucono-δ-lactone, respectively, were further inspected to determine the concentration for 50% inhibition (IC_{50}). For prevention of inhibition of activity by silver ions, 250 mM of β-mercaptoethanol was incubated with 5 μl of isoflavone-conjugate substrate and 5 μl of various concentrations of Ag^+ for 20 min before the enzyme was introduced. IC_{50} values are obtained from the least square fit to the Langmuir isotherm equation, $v_i/v_0 = 1/(1 + [I]/IC_{50})$, using Igor Pro software (WaveMetrics, Inc., OR), where v_i is the velocity in the presence of inhibitor at concentration [I] and v_0 is the velocity in the absence of inhibitor.

Acknowledgements

We would like to acknowledge frequent stimulating conversations with and useful suggestions for the work from Dr. Madge Graham. Funding for this project was provided by grants from the USDA-NRI and the North Central Biotechnical Consortium. Salaries and research support were also provided by State and Federal Funds appropriated to the Ohio Agricultural Research and Development Center, the Ohio State University.

Phospho*enol*pyruvate carboxylase from cherimoya fruit: properties, kinetics and effects of high CO_2

Teresa Muñoz, María Isabel Escribano, Carmen Merodio*

Departamento de Ciencia y Tecnología de Productos Vegetales, Instituto del Frío, Consejo Superior de Investigaciones Científicas, Ciudad Universitaria, 28040-Madrid, Spain

Received 23 February 2001; received in revised form 30 July 2001

Abstract

Phospho*enol*pyruvate carboxylase (PEPC, EC 4.1.1.31) regulatory properties were studied in non-photosynthetic (mesocarp) and photosynthetic (peel) tissues from cherimoya (*Annona cherimola* Mill.) fruit stored in air, in order to gain a better understanding of in vivo enzyme regulation. Analyses were also performed with fruit treated with 20% CO_2–20% O_2 to define the role of PEPC as part of an adaptive mechanism to high external carbon dioxide levels. The results revealed that the special kinetic characteristics of the enzyme from mesocarp—high V_{max} and low sensibility to L-malate inhibition - are related to the active acid metabolism of these fruits and point to a high rate of reassimilation of respired CO_2 into keto-acids. With respect to fruit stored in air, PEPC in crude extracts from CO_2-treated cherimoyas gave a similar V_{max} (1.12 ± 0.03 μkat·mg^{-1} protein), a lower apparent K_m (68 ± 9 μM for PEP) and a higher I_{50} of L-malate (5.95 ± 0.3 mM). These kinetic values showed the increase in the affinity of this enzyme toward one of its substrate, PEP, by elevated external CO_2 concentrations. The lower K_m value and lower sensitivity to L-malate are consistent with higher in vivo carboxylation reaction efficiency in CO_2-treated cherimoyas, while pointing to an additional enzyme regulation system via CO_2. © 2001 Elsevier Science Ltd. 1. Introduction

Phospho*enol*pyruvate carboxylase (PEPC, EC 4.1.1.31) catalyses irreversible carboxylation of phosphoenolpyruvate (PEP) in the presence of Mg^{2+} and/or Mn^{2+} and bicarbonate to yield oxaloacetate and Pi under physiological conditions. PEPC, with a relatively low K_m for the bicarbonate substrate, plays a general role in the carbon economy of fruits by recapturing atmospheric or respiratory CO_2 in C_4-dicarboxylic acid metabolism (Blanke, 1991). Several functions have been described for the PEPC enzyme in non-photosynthetic tissues: replenishment of tricarboxylic acid cycle intermediates, NADPH generation, recapture of respired CO_2, malate fermentation, pH stability and maintenance of electroneutrality (Andreo et al., 1987).

PEPC enzyme is present in all fruits so far examined (Blanke et al., 1986; Blanke and Notton, 1991) and has been characterised in several kinds of fruit (Lakso and Kliewer, 1975; Blanke et al., 1988; Notton and Blanke, 1993; Law and Plaxton, 1995). PEPC has been reported to refix some of the CO_2 produced during respiration in climacteric fruit (Blanke et al., 1987). With respect to the effect of high external CO_2 concentrations on PEPC activity, Blanke and Notton (1991) observed no inhibition of this activity in vitro up to 125 mM CO_2 (equivalent to 87% CO_2) in avocado fruit. Thus, there was no inhibition of enzyme activity at the intercellular CO_2 concentration of 2–3% at harvest, which rose to 20% CO_2 during the respiratory climacteric in this fruit.

Ripening cherimoya fruit have been found to exhibit a high respiration rate (with two maxima of up to 200 mg CO_2 kg^{-1} h^{-1}) and high acidity (Merodio and De La Plaza, 1997). Also, we have observed that pretreatments with high concentrations of CO_2 (20%) improved fruit chilling tolerance during storage at low temperatures (Merodio et al., 1998) and delayed the ripening process during storage at ambient temperature (Muñoz et al., 1999). Bearing in mind these specific characteristics of cherimoya fruit, the aims of the present study were 1) to

examine the activity and kinetic properties of crude PEPC extracts from cherimoya fruit extracted from mesocarp, a non-photosynthetic tissue, and from green photosynthetic peel tissues, as a first step towards the formulation of a model for *in vivo* regulation of PEPC in *Annonas*; and 2) to analyse the effect of treatment with 20% CO_2 on properties of PEPC and its metabolic implications in ripening cherimoya fruit.

2. Results and discussion

2.1. Kinetic characterisation of PEPC in crude extracts from cherimoya fruit mesocarp and peel

PEPC activity (0.39 ± 0.02 μkat mg^{-1} protein) in cherimoya fruit was extremely high (two or three orders higher) as compared to those described for kiwi, avocado and grape (Lakso and Kliewer, 1975; Blanke et al., 1988; Blanke and Notton, 1991) and similar to the values of 0.54 μkat mg^{-1} protein obtained from purified enzyme of banana (Law and Plaxon, 1995). The PEPC was extracted from cherimoya fruit as a soluble enzyme. Enzyme extraction was aided by the inclusion of DTT and PVPP in the extraction medium. When the crude extract was filtered through a deslating column (Econo-Pac 10DG, 10×30 cm, Sigma, 1 ml/min) the PEPC activity decreased more than six-fold. The enzyme required a divalent cation (Mg^{2+} or Mn^{2+}) for its activity, but the addition of 10 units of malate dehydrogenase (MDH) to the standard assay medium did not change the rate of NADH oxidation of the crude cherimoya enzyme extract. Moreover, because in crude cherimoya fruit extracts the MDH activity is one order of magnitude higher than PEPC activity (data not shown), the former was not a limiting factor in the assay of PEPC activity following the method previously described by Blanke et al. (1986). Thus, the assay of PEPC activity in crude cherimoya fruit extract was carried out without the addition of exogenous MDH enzyme. This result is consistent with the notion that both PEPC and MDH enzymes could be physiologically bound.

The properties and kinetic data for cherimoya fruit PEPCs were evaluated after 4 days of storage at 20 °C, when maximum PEPC activity was reached. An optimum pH of 7.8 was found for PEPC extracted from mesocarp in the pH range 6–9 (Fig. 1), determined in the presence of either 50 mM Tris–HCl or 50 mM MOPS–KOH and using saturating substrate concentrations (4 mM PEP and 12 mM bicarbonate) with 460–480 ppm CO_2 present in the laboratory. This optimum pH value was similar to those reported for PEPC in avocado (Blanke and Notton, 1991), apple (Blanke et al., 1986) and banana (Law and Plaxton, 1995).

The PEPC crude extract extracted from mesocarp and peel was used to compare kinetic properties for the substrate PEP, in the presence of saturating bicarbonate

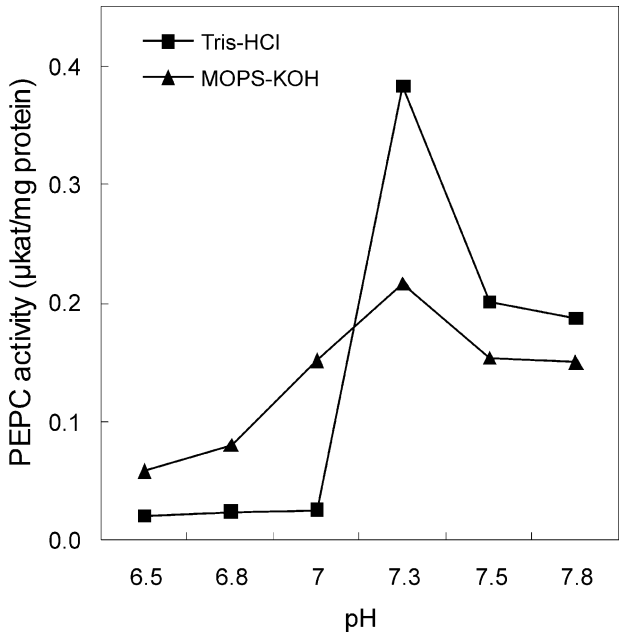

Fig. 1. Effect of pH on cherimoya PEPC activity measured in the presence of specified buffers (50 mM) and using a saturating PEP and bicarbonate concentrations.

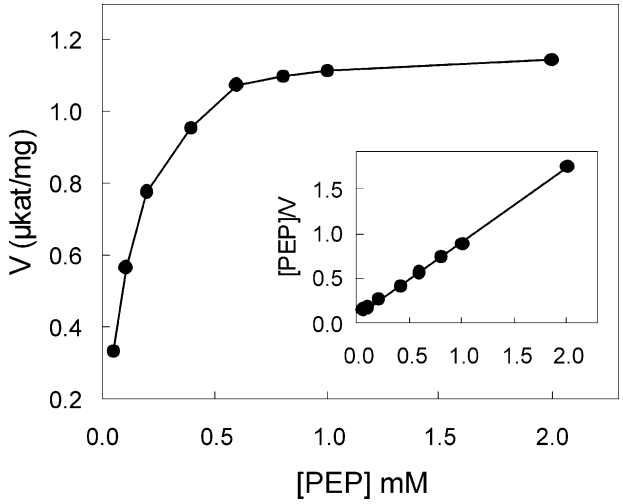

Fig. 2. Dependence on PEP concentration of the PEPC activity extracted from mesocarp tissues. The insert shows the Hanes–Woolf plot.

concentration. As Fig. 2 shows, PEPC from mesocarp followed a hyperbolic Michaelis–Menten kinetics in a substrate (PEP) concentration ranging from 0.05 to 2 mM, being saturated from 1 mM. Estimation of the kinetics parameters by different fitting approaches (Table 1) yielded similar apparent K_m (120 ± 8 μM for PEP) and V_{max} values (1.26 ± 0.02 μ kat mg^{-1} protein).

The enzyme extracted from cherimoya peel had a similar apparent K_m value (140 ± 6 μM) to PEPC from mesocarp, but the V_{max} was 0.57 ± 0.01μ kat·mg^{-1} protein (Fig. 3 and Table 1), that is 2.2 times lower than

Table 1
Kinetics parameters (PEP) for PEPC extracted from different tissues of cherimoyas stored in air or in 20% CO_2 at pH 7.8, estimated by different fitting approaches. Data are means of V_{max} (μKat/mg protein) and K_m (μM) values ± S.E.

Treatment	Tissue	Michaelis–Menten	Hanes–Woolf	Lineweaver–Burk
Air	Mesocarp	$V_{max}=1.26\pm0.02$ $K_m=120\pm8$	$V_{max}=1.24\pm0.01$ $K_m=110\pm5$	$V_{max}=1.32\pm0.05$ $K_m=150\pm5$
20% CO_2	Mesocarp	$V_{max}=1.12\pm0.03$ $K_m=68\pm9$	$V_{max}=1.12\pm0.03$ $K_m=70\pm6$	$V_{max}=1.13\pm0.05$ $K_m=70\pm5$
Air	Peel	$V_{max}=0.57\pm0.01$ $K_m=140\pm6$	$V_{max}=0.56\pm0.01$ $K_m=134\pm6$	$V_{max}=0.56\pm0.03$ $K_m=134\pm5$

the value obtained for non-photosynthetic tissues (Fig. 2 and Table 1).

PEPCs extracted from cherimoya fruit yielded higher V_{max} values for PEP than those previously reported in other fruits and plant sources and a K_m value which was comparable to those described in apple fruit, higher than in other fruits like avocado or banana, and lower than in maize leaf (a C_4-species) (Blanke et al., 1986 and references therein; Blanke and Notton, 1991; Law and Plaxton, 1995).

2.2. Effect of inhibitors on PEPC activity

Malate and pyruvate are known inhibitors of PEPC. Fig. 4 shows a semi-logarithmic representation of the dose-response curve of mesocarp PEPC activity in the presence of L-malate in a concentration range 1–12 mM. Malate inhibited enzyme activity, and the concentration required to produce 50% inhibition (I_{50} value) at pH 7.8 was 3.84±0.2 mM. PEPC from cherimoya mesocarp was more resistant to the inhibition of pyruvate, the I_{50} value being 9.5±0.5 mM, (Table 2). The L-malate and pyruvate I_{50} values for PEPC from peel were 2.01±0.1 and 8.15±0.3 mM respectively (Table 2). PEPC enzyme extracted from photosynthetic

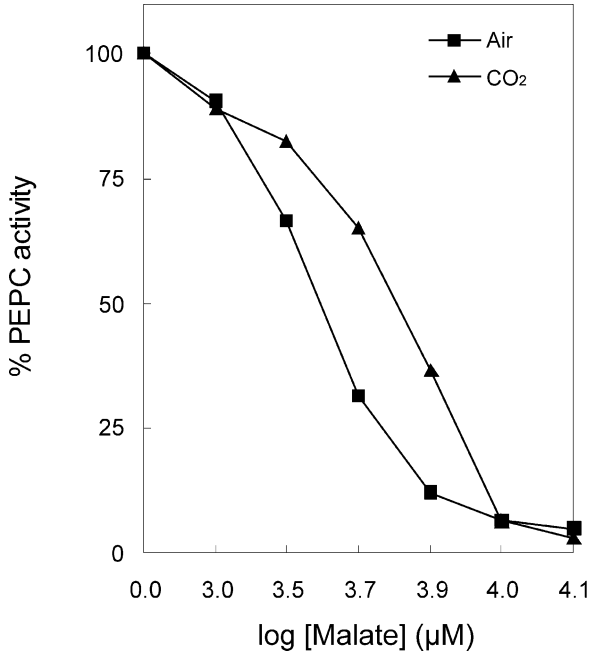

Fig. 4. Semilogarithmic plots of the dose-response curves used to determine I_{50} value for L-malate on PEPC activity extracted from mesocarp of air and 20% CO_2-treated fruit.

Table 2
I_{50} values for PEPC activity extracted from different tissues of cherimoyas stored in air or in 20% CO_2 at pH 7.8. Data are means ±S.E.

Treatment	Tissue	L-Malate (mM)	Pyruvate (mM)
Air	Mesocarp	3.84±0.2 a[a]	9.50±0.5 a
20% CO_2	Mesocarp	5.95±0.3 b	9.70±0.6 a
Air	Peel	2.01±0.1 c	8.15±0.3 b

[a] Mean separation within columns (by LSD test) at $P\leqslant 0.05$.

cherimoya tissues showed higher sensitivity to L-malate and pyruvate inhibition than enzyme from non-photosynthetic tissues.

For avocado, the inhibitory effect of malate on PEPC was pH dependent; the value of I_{50} was 150 μM at pH 7.0 and 46 mM at pH 8.0 (Blanke and Notton, 1991). The latter concentration was comparable to that reported

for the I_{50} of grape berry (35 mM) at pH 7.4 (Lakso and Kliewer, 1975). For cherimoya fruit PEPC, a value of I_{50} 3.84 mM at pH 7.8 was found, that is comparable to the concentrations reported for maize leaf PEPC (10 mM at pH 8.0, Gonzalez et al., 1984) or banana fruit PEPC (8 mM at pH 8.0, Law and Plaxton, 1995).

2.3. Changes in the regulatory and kinetic properties of PEPC enzyme from CO_2-treated cherimoyas

Calculation of the endogenous bicarbonate in the bulter using Henderson-Hasselbach equatation yielded 0.41 mM HCO_3 at pH 7.8 and 470 ppm CO_2 at room temperature. The effect of L-malate and pyruvate inhibitors was studied in PEPC extracted from mesocarp tissues of cherimoyas treated with 20% CO_2 (Fig. 4 and Table 2). As regards malate inhibition, the I_{50} value of CO_2-treated cherimoyas was 5.95 ± 0.3 mM, that is 1.5-time higher than in air-treated ones. Although significant differences were achieved in susceptibility to L-malate inhibition, the value of I_{50} for pyruvate was similar in air and CO_2-treated fruit (9.5 ± 0.5 mM and 9.7 ± 0.6 mM, respectively).

PEPC from CO_2-treated fruit exhibited a hyperbolic Michaelis–Menten curve with substrate (PEP) concentration ranging from 0.05 to 2 mM. The estimation of kinetic parameters yielded a similar V_{max} (1.12 ± 0.03 μkat mg^{-1} protein) but a lower apparent K_m value (68 ± 9 μM) for PEP (Fig. 5 and Table 1) than air-treated fruits. These kinetic values revealed increased affinity of this enzyme toward its substrate, PEP, caused by high external CO_2 concentrations. The lower K_m value, together with lower sensitivity to L-malate supports the notion of higher *in vivo* carboxylation reaction efficiency in CO_2-treated cherimoyas, while revealing an additional enzyme regulation system via CO_2.

2.4. Physiological implications of PEPC activity and effect of high levels of external CO_2

PEPC in cherimoya fruit has some of the kinetic properties (high V_{max} and intermediate K_m values) and the degree of L-malate and pyruvate inhibitions characteristic of the PEPC from C_4 and CAM species (Huber and Edwards, 1975; Osmond, 1978). The differences in the regulatory properties of PEPC from mesocarp and peel tissues (similar K_m, higher V_{max} and I_{50} values) may be related to different physiological functions. In non-photosynthetic tissues, due to its high respiration rate and where it has been previously confirmed by inmunodetection assays the absence of RuBPCase (Del Cura et al., 1996), PEPC could be involved in the re-assimilation of the CO_2 released during the climacteric respiration, as has been proposed in the case of other climacteric fruits (Blanke et al., 1986; Law and Plaxton, 1995). The high value of V_{max} and low sensitivity towards L-malate inhibition are consistent with the high concentrations of

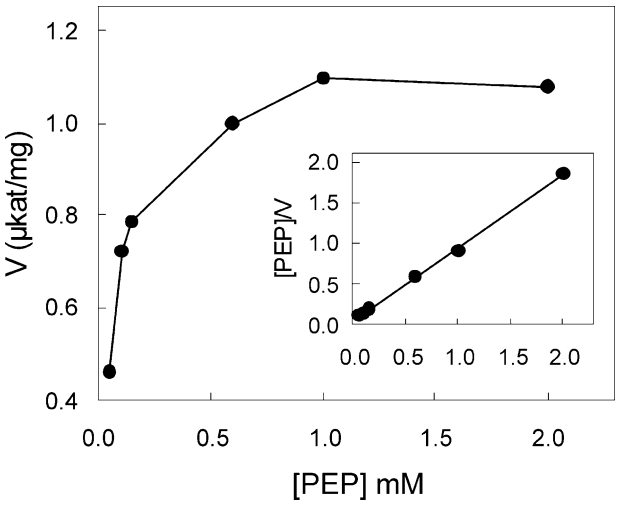

Fig. 5. Dependence on PEP concentration of the PEPC activity extracted from mesocarp of 20% CO_2-treated cherimoyas. The insert shows the Hanes–Woolf plot.

organic acids, mainly malate, in cherimoya fruit (Merodio and De La Plaza, 1997). Moreover, in the large vacuoles present in these non-photosynthetic tissues, PEPC-derived keto-acids (or malate) may be accumulated for osmoregulation and/or as storage molecules for carbon and reducing power to be used later for the metabolism of cherimoya fruits, or may have a more general role in furnishing substrate to the mitochondria, functioning anaplerotically (Bihzad and El-Shora, 1996). The consumption of these TCA-intermediates during ripening in different biosynthetic reactions, serving particularly in this fruit for massive accumulation of nitrogenous compounds (Escribano and Merodio, 1994; Escribano et al., 1996), supports the necessity of an active PEPC for the synthesis of carbon skeletons.

Moreover, the differences found in PEPC kinetical properties (similar K_m, higher V_{max} and lower L-malate sensitivity), suggest that in non-photosynthetic tissues PEPC may be subject to a different regulatory mechanism in vivo. This regulation is in good agreement with the requirement of an active PEPC in cherimoya fruit. Although changes in the cytosolic levels of opposing allosteric effectors and H^+ probably contribute to the overall regulation of PEPC activity in vivo, research over the past decade has focused primarily on the reversible phosphorylation of the enzyme (Wedding et al., 1989; Jiao and Chollet, 1991; Echevarria et al., 1994). It was recently proposed that a protein phosphorylation cycle imposes an additional but related level of regulation on different PEPC isoforms and is a general regulatory mechanism affecting higher plant PEPC in vivo (Chollet et al., 1996 and references therein; Law and Plaxton, 1997). Enzyme phosphorylation results in an increase of catalytic activity (an approximately twofold increase in the V_{max} or decrease in the K_m for PEP) and more notably, a

two- to threefold decrease in L-malate sensitivity (Osuna et al., 1996; Law and Plaxton, 1997; Vidal and Chollet, 1997). Moreover, some evidences suggest that the activation of PEPC kinase activity/PEPC phosphorylation state depends on the prior alkalinisation of the cytosol (Pierre et al., 1992). Time-course kinetic studies suggest that PEPC in banana fruit exists mainly in the dephosphorylated form, but its kinase is expressed throughout ripening (Law and Plaxton, 1997).

The fine tuning of carboxylating activity may be the result of a delicate balance between positive and negative effectors whose influence would be further modulated by the regulatory phosphorylation process and cytoplasmic pH. These regulatory process may prove essential for the functioning of PEPC (and to continue to fix respiratory carbon dioxide) in the highly acidic environment in cherimoya cell metabolism as measured by ^{31}P MNR experiments (Muñoz et al., 2001).

Analysing the overall effect of CO_2 treatment on PEPC, we observed that while the V_{max} value did not change, the enzyme was less sensitive to feedback inhibition by L-malate and showed a higher affinity (lower K_m) for PEP. These results suggest higher in vivo PEPC efficiency under increasing external CO_2 levels where substrate (PEP) availability is low due to utilisation by nonimpaired aerobic respiration, phenylpropanoid and CO_2-activated fermentative pathways (Muñoz et al., 1997; Assis et al., 2001). These results further indicate that another level of enzyme regulation takes place under the CO_2 treatment. It has been reported that positive effectors (e.g., hexose–phosphates) increase the apparent affinity of PEPC for PEP, so that by lowering the K_m value for this substrate, the positive effector enhances the enzyme's ability to compete with L-malate (Raghavendra et al., 1993; Moraes and Plaxton, 2000). Moreover, the putative positive effectors could act directly on in vivo PEPC activity while also modulating the degree of enzyme phosphorylation (Jiao and Chollet, 1992; Echevarria et al., 1994; Zhang et al., 1995). This particular PEPC regulation, which increases enzyme affinity for PEP and reduces its sensitivity to inhibition by L-malate, will allow the PEPC to continue carboxylating PEP at high rates under low substrate availability and to cope with the high malate concentration in CO_2-treated mesocarp cells. These regulatory properties are consistent with increased synthesis of nitrogen-derived compounds such as polyamines (mainly spermidine and spermine) in cherimoya fruit treated with high CO_2 levels (Muñoz et al., 1999). As in other systems, in cherimoya fruit this enzyme may discharge an additional vital function in co-ordinating carbon and nitrogen metabolisms by replenishing the dicarboxylic acids consumed (Huppe and Turpin, 1994), regulated by the increase of some metabolic positive effector(s) such as sugar-P, ammonium or glutamine (Vanlerberghe et al., 1990; Thi Manh et al., 1993).

It has been reported that PEPC in ripening bananas is regulated by metabolites involved in carbohydrate and nitrogen metabolism in a pH-dependent fashion (Law and Plaxton, 1995, 1997). The enzyme activation in CO_2-treated fruit may not only protect cherimoya PEPC against L-malate, but may also adjust its catalytic activity to the demand of carbon skeletons (e.g. oxaloacetate and 2-oxoglutarate) required for ammonium assimilation and transamination reactions in tissues active in the synthesis of nitrogen compounds, to replenish TCA cycle intermediates consumed in biosynthesis (unpublished results).

3. Concluding remarks

Our results demonstrate that PEPC of cherimoya fruit is highly regulated in order to adapt its activity to the demand of C_4-carbon skeletons deriving from the cellular metabolic changes imposed by different postharvest conditions. Through changes in the kinetic constant (K_m for PEP) and sensitivity to malate, the PEPC regulatory mechanism may play a fundamental role in adapting cherimoya tissues to high CO_2 levels. In this mechanism, pH may play a fundamental role in vivo, as an overall regulator of kinetic properties, covalent modifications and allosteric effects of this enzyme in cherimoyas. The pH as an environmental signal is of particular relevance in these fruits, which store parts of their carbon reserves as organic acids. Further study is now in progress on the in vivo relationship between cytoplasmic and vacuolar pH, the levels of related metabolites and the activity of PEPC-kinase, during cherimoya ripening at atmospheric and 20% CO_2.

4. Experimental

4.1. Plant material

Cherimoya (*Annona cherimola* Mill., cv. 'Fino de Jete') fruits harvested in Almuñecar (Granada, Spain) were selected for freedom of physical and pathological defects. At the Instituto del Frío (Madrid), fruits classified uniformly by colour, size and weight were randomly divided into two groups of 20 cherimoyas each and stored in the dark at 20 °C. Each group was placed in separate respiration chambers (20 l) in a continuous flow (100 ml min^{-1}) of air or a gas mixture containing 20% CO_2 + 20% O_2 + 60% N_2. After three days under CO_2 treatment, the fruits were transferred to air for two additional days. To detemine the maximum PEPC activity, for futher characterization studies, fruit were sampled after 1, 2, 3, 4 and 5 days of storage at 20 °C. Peel and mesocarp tissues from three cherimoyas were frozen in liquid nitrogen and stored at −80 °C.

4.2. Enzyme extraction

Frozen tissue (2.5 g) was ground in a precooled pestle and mortar with clean sand (0.5 g) and was homogenised using a buffer:tissue ratio of 3:1. Extraction buffer was 50 mM Tris–HCl (pH 7.8), 10 mM $MgCl_2$, 5 mM $NaHCO_3$, 2 mM DTT, 0.25 mM EDTA and 2% (w/v) PVPP. The homogenate was filtered through two layers of muslin and centrifuged at 20,000 *g* for 30 min. All steps were carried out at 4 °C. The clear supernatant was used for enzyme assay.

4.3. Assay of PEPC activity

Activity of PEPC was determined spectrophotometrically as described by Blanke et al. (1986) at 340 nm by coupling the reaction to the oxidation of NADH in the presence of malate dehydrogenase (MDH). Enzyme activity was expressed as μkat of PEP consumed per mg of protein. The rate of PEP carboxylation declined during the course of the reaction. An approximation to linearity was obtained over the initial period of about 10 min. The standard assay medium contained 0.2 ml of crude enzyme extract (which contained endogenous MDH activity), 0.14 mM NADH, 10 mM $MgCl_2$, 12 mM $NaHCO_3$, 10 mM DTT, 0.25 mM EDTA and 50 mM Tris–HCl buffer (pH 7.8). The reaction was started by the addition of PEP at 4 mM final concentration in the spectrophotometer cuvette containing the assay mixture at 27 °C. The rate of oxidation of NADH was measured in the linear range (1 min).

4.4. Kinetics studies

For the determination of pH optimun and buffer dependence of PEPC activity, 50 mM of Tris–HCl or MOPS–KOH was used in the pH range 6.5–9.

Kinetic parameters and their standard errors were calculated using the curve-fitting facilities of the software package SigmaPlot 6.0 (SPSS Inc., Chicago, IL). V_{max} and apparent K_m values were determined from the plot of initial velocities vs. substrate concentration fitted by non-linear regression to the standard Michaelis–Menten equation, and from linear regression equations using the Hanes–Woolf and Lineweaver–Burk models (all the r^2 values were higher than 0.98).

The L-malate and pyruvate concentrations required for 50% inhibition of PEPC activity under the above assay conditions were determined graphically from semilogarithmic plots of the dose–response curves and defined as malate or pyruvate I_{50} values.

4.5. Protein estimation

Protein concentration was measured by the Bradford (1976) method using a protein-dye reagent (Bio-Rad) and BSA as a standard.

4.6. Statistical analyses

Data from at least three replicates per sample were subjected to analysis of variance (Statgraphics program, STSC, Rockville, Md.). Multiple variance analysis was employed to determine the significance of the data at $P \leqslant 0.05$. The results presented here represent data from three or more experiments performed in succession.

Isolation and properties of arginase from a shade plant, ginseng (*Panax ginseng* C.A. Meyer) roots

Hye Jin Hwang, Eun Hee Kim, Young Dong Cho*

Department of Biochemistry, College of Science, Yonsei University, Seoul 120-749, South Korea

Received 15 February 2001; received in revised form 2 August 2001

Abstract

Arginase (EC 3.5.3.1) was purified to homogeneity from root tissues of three-year-old ginseng (*Panax ginseng* C.A. Meyer), shade plant, and was found to be an extraordinarily large molecule relatively stable to heat. The enzyme was decameric having a molecular mass of 352,000 Da, with an optimal temperature and pH of 60 °C and 9.5, respectively. Analogues of arginine could not replace it as substrate, and a cysteine residue is at or near the active site. Maximum activity was obtained with Mn^{2+} and Co^{2+} also activated the proteins, whereas, both agmatine and 5′-deoxy-methylthioadenosine were inhibitors. Specific activities of the enzyme in sliced ginseng roots were increased by plant hormones such as GA_3, IAA, kinetin and putrescine, whereas the activities of the purified enzyme were unaffected by putrescine. Increases in arginase activities by these plant hormones could affect metabolism of polyamine intracellularly. © 2001 Elsevier Science Ltd. All rights reserved.

1. Introduction

An important feature of arginine metabolism is the degradation of arginine to ornithine and urea by arginase (EC 3.5.3.1) since both free arginine and bound protein arginine constitute a large part of the nitrogen reserves in storage organs in many plant species (Polacco and Holland, 1993; Nordin and Naesholm, 1997). Ornithine is a precursor of proline and/or polyamines and arginine nitrogen in urea is recycled by urease-catalyzed hydrolysis to ammonia (Polacco and Holland, 1993). For utilization of arginine, arginase activity increases sharply during germination in several species such as pumpkin (Splittstoesser, 1969), broad bean (Kollöffel and Van Dijke, 1975), soybean (Kang and Cho, 1990), *Arabidopsis thaliana* (Zonia et al., 1995), and loblolly pine (King and Gifford, 1997).

There are several reports of plant arginase cDNAs from *Arabidopsis thaliana* (Krumpelman et al., 1995) and soybean (Goldraij et al., 1998), as well as hormonal effects in tomato ovaries (Alabadí et al., 1996), and arginase purification and characterization from soybean axes (Kang and Cho, 1990), iris bulbs (Boutin, 1982), *Arachis hypogea* L. seedlings (Desai, 1983), and the lichen, *Evernia prunastri* (Martín-Falquina and Legaz, 1984). However, little is yet understood about properties of plant arginases versus those of animals and bacteria, in part because the plant enzymes have not been extensively purified to provide information on their properties. Although information on plant arginases is available, it is almost always obtained from annual plant sources; little has been published on perennial plant arginases.

Ginseng (*Panax ginseng* C.A. Meyer), a perennial shade plant, has been used as herbal medicine in the Orient, especially in China, Japan and Korea for thousands of years. However, 10 years ago, arginine was reported to be a major nitrogenous compound, representing approximately 60.6% of the free amino acid

nitrogen and 13.6% of the total nitrogen in three-year-old ginseng roots (Park et al., 1990). Since there have been no reports on properties of arginase in a shade plant being rich in arginine, we have chosen ginseng as a representative shade plant for the present study. Here we describe the first purification of arginase from ginseng roots to apparent homogeneity and properties of the purified enzyme.

2. Results and discussion

Although arginases have been purified and characterized from such non-shade plants as soybean (Kang and Cho, 1990), iris bulbs (Boutin, 1982), *Arachis hypogea* L. seedlings (Desai, 1983), and *Evernia prunastri* (Martín-Falquina and Legaz, 1984), there are no descriptions of the properties of shade plant arginases. Hence, we focused upon the shade plant, ginseng, where it was found that the specific activity of its ginseng arginase increased steadily after germination and reached its highest level in 3-year-old roots (data not included). Beyond 3 years growth, the specific activity of the arginase gradually decreased. Additionally, very low activities were detected in leaves from 1 to 5-year-old ginsengs as compared to that of roots. Accordingly, 3-year-old ginseng roots were used in the present studies.

2.1. Arginase purification and heat stability

The purification of arginase to apparent homogeneity is summarized in Table 1, whose final specific activity was 18,090 units/mg, i.e. with a 1055 fold enrichment and a 0.5% recovery with respect to the total activity of the crude extract toward L-arginine. Since the method employed for iris bulb enzyme (Boutin, 1982) was not suitable, we used two different columns such as phenyl sepharose and arginine sepharose 4B. Heat treatment was also conducted since heat application removed large amounts of unwanted proteins which were not removed or fractionated using various column chromatographic procedures. To ensure the conditions used in heat treatment were innocuous for arginase, experiments were carried out at various temperatures and pH 7.5 (Fig. 1a). Even for longer incubation times from 15 min to 1 h, there was no decrease in enzyme activity at 50 °C. Therefore, heat treatment was effective in removing non-arginase proteins with no effect on arginase activity.

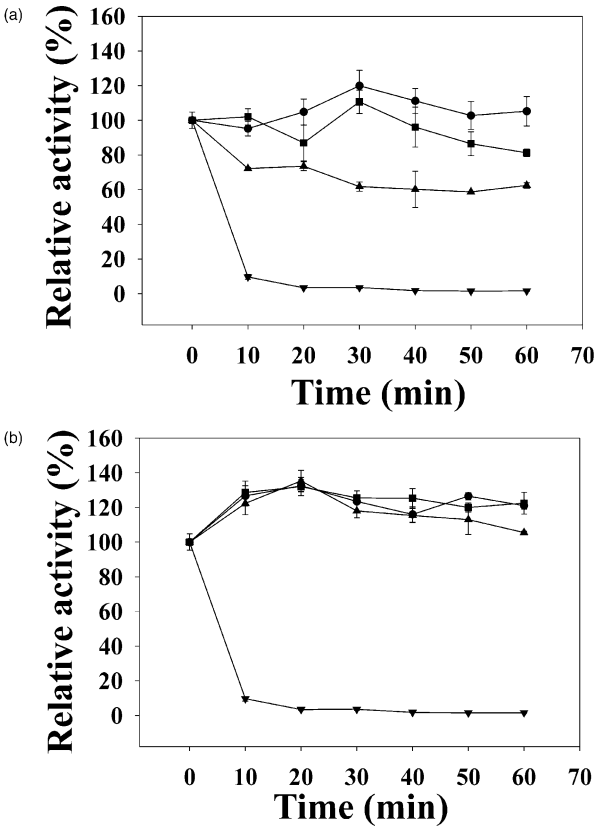

Fig. 1. Heat stability of arginase activities. The enzyme was incubated in 10 mM Tris–HCl [pH 7.5 (a) and pH 9.5 (b)] buffer containing 1 mM $MnCl_2$ and 400 mM L-arginine at 40 °C (●), 50 °C (■), 60 °C (▲), and 70 °C (▼) for various time intervals. After the indicated time, residual activities of the enzyme were determined as described in Experimantal. Arginase activity is presented as a percentage of initial activity. Each value represents the mean ±S.D. of three replicates.

2.2. Molecular weight determination

Coomassie blue staining following SDS–PAGE revealed that there was only one polypeptide (Fig. 2a), and silver staining gave comparable results as well (data not included). To our knowledge, however, this is the

Table 1
Purification table of arginase from ginseng (*Panax ginseng* C.A. Meyer) roots

Step	Total protein (mg)	Total activity (units)	Specific activity (units/mg)	Purification fold (fold)	Yield (%)
Crude extract	3151	54040	17.15	–	100
45–60% $(NH_4)_2SO_4$	360.9	27850	77.18	4.500	51.54

Prepared from 300 g of fresh ginseng roots.

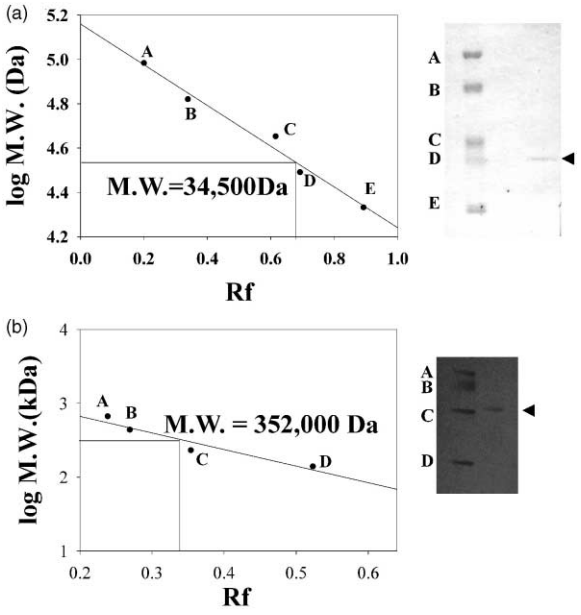

Fig. 2. Molecular weight of purified ginseng arginase as estimated by SDS–PAGE (a) and 4–20% gradient gel electrophoresis (b). (a) Molecular standard markers and an aliquot of purified arginase were electro-phoresed on 10% SDS-polyacrylamide gel and stained by Coomassie brilliant blue. The protein markers used were: A, phosphorylase *b* (96,400 Da); B, serum albumin (66,200 Da); C, ovalbumin (45,000 Da); D, carbonic anhydrase (31,000 Da) and E, trypsin inhibitor (21,500 Da). The subunit of arginase is indicated in the symbol (◀) (b) 4–20% polyacrylamide gel was used and the protein markers are: A, thyroglo-bulin (669,000 Da); B, ferritin (440,000 Da); C, catalase (232,000 Da) and D, lactate dehydrogenase (140,000 Da). The native arginase is indicated in the symbol (◀).

first reported homogeneity of arginase from a shade plant, whose analysis by SDS–PAGE showed one band with a molecular mass of approximately 34,500 Da (Fig. 2a). On the other hand, results of gradient gel electrophoresis gave a single band corresponding to a molecular mass of 352,000 Da (Fig. 2b). We did not, however, observe any dissociation of the enzyme into subunits or oligomers during electrophoresis and other manipulations. Analysis of the UV spectra of the ginseng enzyme revealed that there was identical conformation before and after heat treatment (data not included), and such results suggest that there is no dissociation of the decameric enzyme into subunits or oligomers and no effect on the subunit itself. The gel-based subunit and native sizes indicate that ginseng root arginase is decameric. With respect to molecular mass and number of subunits, ginseng arginase differs markedly from other arginases reported thus far, since the molecular masses of those from animals and micro-organisms are in the range of 98,000 (Brusdeilins et al., 1983) to 278,000 (Reddy and Campbell, 1968). Additionally, the number of subunits reported ranges from three to six i.e. a trimer from *Saccharomyces cerevisiae* (Green et al., 1990), a tetramer from mouse liver (Spolarics and Bond, 1988), and hexamers from iris bulbs (Boutin, 1982) and *Bacillus brevis* Nagano (Kanda et al., 1997). There have been reports on the presence of decameric enzymes, such as carbonic anhydrase from *Vicia canencens* leaves (Demir et al., 1999) and arginine decarboxylase form *E. coli* B (Boecker, 1978), but, no decameric arginase has been reported from a plant source.

2.3. Substrate specificity

Substrate specificity studies (Table 2) showed that purified arginase is highly specific for L-arginine since analogs such as L-homoarginine, agmatine, and canavanine did not replace it as a substrate. However, other arginases differ in their substrate specifities: arginase from rat liver (Reczkowski and Ash, 1994) can use argininamide, L-canavanine, and homoarginine as substrates, in addition to L-arginine. Whereas, the arginases from *Helicobacter pylori* (Mendz et al, 1998), rat small intestine (Fujimoto et al., 1976), and iris bulb (Boutin, 1982) are specific for only *L*-arginine.

2.4. Chemical modifications

Chemical modifications were carried out for the purpose of identifying amino acids located in the binding/catalytic site of ginseng arginase. Among the chemical modification reagents employed, treatment of the enzyme with sulfhydryl-specific reagents, DTNB and PCMB, resulted in loss of activity (Table 3), these following pseudo first order kinetics (data not included). DTNB-treated enzyme activity was restored to more than 96% of the control after 10 min treatment with 0.1 mM DTT, indicating that its inactivation is due, not to a change in conformation of the enzyme, but to modification of a cysteine residue in the active center. Furthermore, the presence of the substrate, arginine, reduced the rate of modification (Table 3), which also suggested that the cysteine residue is directly involved in enzyme activity. This finding thus explains the difference between mammalian and plant arginases, since treatment of rat liver arginase with *N*-bromosuccinimide demonstrated that a histidine residue is catalytically essential (Daghigh et al.,

Table 2
Substrate specificity of ginseng arginase

Substrate (100 mM)	Relative activity (%)
L-Arginine	100±3.8
Agmatine	N.D.
Canavanine	N.D.
γ-Guanidinobutyrate	N.D.
L-Homoarginine	5.57 ±0.031
MGBG	N.D.

Enzyme (5 μg) was incubated with analogues of arginine and then activities were assayed as described in Experimental. Arginase activity is presented as a percentage of control activity with L-arginine. MGBG and N.D. stand for 'methyl glyoxal bis-(guanylhydrazone)' and 'not detected', repectively.

Table 3
Inhibitory effects of chemical modification reagents on purified ginseng arginase activity

Reagents	Concentration (mM)	Relative activity (%)	Substrate protection
None	–	100±0.03	–[a]
DTNB	0.1	98.3±0.045	100±0.016
	1	74.6±0.056	96.4±0.038
EDAC	0.1	95.0±0.13	–
	1	100±0.25	–
Hydroxylamine	0.1	88.7±0.35	–
	1	96.3±0.57	–

	1	133±1.25	–
Succinyl anhydride	0.1	88.5±0.24	–
	1	101±1.25	–

Enzyme (5 μg) was incubated with the chemical reagents (0.1 and 1 mM, respectively), with activities assayed as described in Experimental. Arginase activity is presented as a percentage of control activity without any chemical reagents. When sulfhydryl group inhibitors were tested, β-mercaptoethanol was removed from the enzyme solution before incubation. DTNB, 5,5-dithiobis-2-nitrobenzoic acid; EDAC, 1-ethyl-3-(3-dimethyl) aminopropylcarbodiimide; PCMB, ρ-chloromercuribenzoate; PLP, pyridoxal-5-phosphate. Arginine was used as a substrate in substrate protection experiments.

[a] Substrate protection experiments were not carried out.

1996) and the X-ray diffraction study of rat liver arginase provided the result that His, Asp, Glu, and Arg residues are related to arginine binding and catalysis (Kanyo et al., 1996). Thus, our results are in accordance with reports of Ber et al. (1978) and Muszyńska et al. (1972) that the SH group of cysteine is essential for the catalytic activity of arginases from non-shade plants. It is thus tentatively proposed that either arginases from a non-shade plant or a shade plant need the SH group of cysteine for catalytic activity.

2.5. Effects of metal ions on arginase

A common feature of all arginases so far studied is a requirement for divalent cation activators although metal activation seems to be species dependent. That is, while Co^{2+}, Ni^{2+}, Cd^{2+}, and Zn^{2+} activate arginase from some sources (Hellerman and Perkins, 1935; Harrell and Sokolovsky, 1972; Green et al., 1991), one general property is the requirement for metal ions, especially Mn^{2+}, for full catalytic activity (Carvajal et al., 1971; Hirsch-Kolb et al., 1971; Green et al., 1991; Kuhn et al., 1995; Kanyo et al., 1996). Among the cations examined, Mn^{2+} was the most effective as expected and Co^{2+} could replace Mn^{2+} as a metal activator, especially at 1 mM (Table 4). The arginase from *Helicobacter pylori* (Mendz et al., 1998) is activated fourfold by cobalt and twofold by nickel rather than manganese. Activity of arginase with Co^{2+} is an important observation since we could not exclude the possibility that the enzyme with Co^{2+} might maintain activity to some extent in case of deficiency in Mn^{2+} in vivo.

Table 4
Effects of metal ions on purified ginseng arginase activity

Metal ion added	Concentration (mM)	Relative activity (%)
$CaCl_2$	0.01	N.D.
	0.1	N.D.
	1	N.D.
$CoCl_2$	0.01	2.412±0.02
	0.1	44.08±1.5
	1	67.54±2.1
$FeCl_2$	0.01	2.851±0.01
	0.1	N.D.
	1	N.D.
$FeCl_3$	0.01	2.851±0.03
	0.1	4.605±0.02
	1	6.798±0.15
$MgCl_2$	0.01	1.316±0.02
	0.1	N.D.
	1	N.D.
$MnCl_2$	0.01	87.6±0.15
	0.1	100±0.058
	1	63.4±0.85

Arginase (5 μg) was incubated with L-arginine and several metal ions and then activities were assayed as described in Experimental. Arginase activity is summarized as a percentage of control activity in the presence of 0.1 mM $MnCl_2$. N.D. stands for 'not detected'.

2.6. Effects of polyamines, agmatine and MTA on arginase

We have previously shown that agmatine produced by arginase from arginine and MTA formed by spermine synthase from dcSAM inhibited soybean arginase and spermine synthase, respectively (Park and Cho, 1992; Kim and Cho, 2000). To determine if polyamines and

their intermediates affect purified ginseng arginase, we assayed its activity after incubation of arginase with them. Among those examined, agmatine and MTA were found to have inhibitory effects (Table 5), suggesting that they could reduce levels of putrescine through reducing ornithine. However, the amounts of these compounds in a shade plant are not known even though physiological and biochemical roles of ingredients such as saponin have been extensively studied. Therefore, the in vivo physiological and biochemical role of agmatine and MTA in ginseng roots are as yet unclear.

2.7. Kinetic properties

The K_m of the purified ginseng arginase was determined by a Lineweaver–Burk plot to be 82.7 mM (Fig. 3). To further confirm this value, Hanes–Woolf and Eadie–Hofstee plots were also employed giving the same value. The ginseng arginase K_m for arginine is similar to that reported for soybean (83 mM) (Kang and Cho, 1990), but differs somewhat from those reported for the embryo axis of *Arachis hypogea* L. seedlings (5.6 mM) (Desai, 1983), *Bacillus brevis* Nagano (12.8 mM) (Kanda et al., 1997), *Saccharomyces cerevisiae* (15.7 mM) (Green et al., 1990), and rat small intestine (19 mM) (Fujimoto et al., 1976). To determine the optimum pH for arginase, we assayed its activity in buffers from pH 6.0 to 10.5, using each buffer in its effective range. The activity was highest at pH 9.5 (Fig. 4a), this being similar to that of arginases from iris bulbs (pH 9.0) (Boutin, 1982), *Bacillus brevis* Nagano (pH 9.0) (Kanda et al., 1997), soybean (pH 9.5) (Kang and Cho, 1990) and rat small intestine (pH 9.5) (Fujimoto et al., 1976), but this was

Arginase (5 μg) was incubated at 37 °C for 20 min in 10 mM Tris–HCl (pH 7.5) buffer in the presence of the indicated concentrations of these compounds and then assayed for enzyme activity. Arginase activity is presented as a percentage of that of enzyme incubated in the absence of any compound.

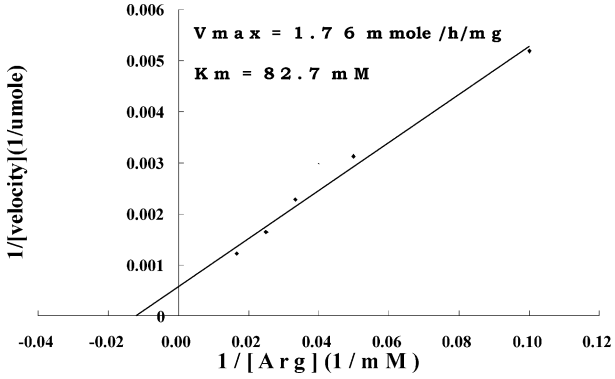

Fig. 3. Lineweaver–Burk plot of initial reaction velocities (mmole urea formed per 1 h) for arginase measured at various concentrations of L-arginine.

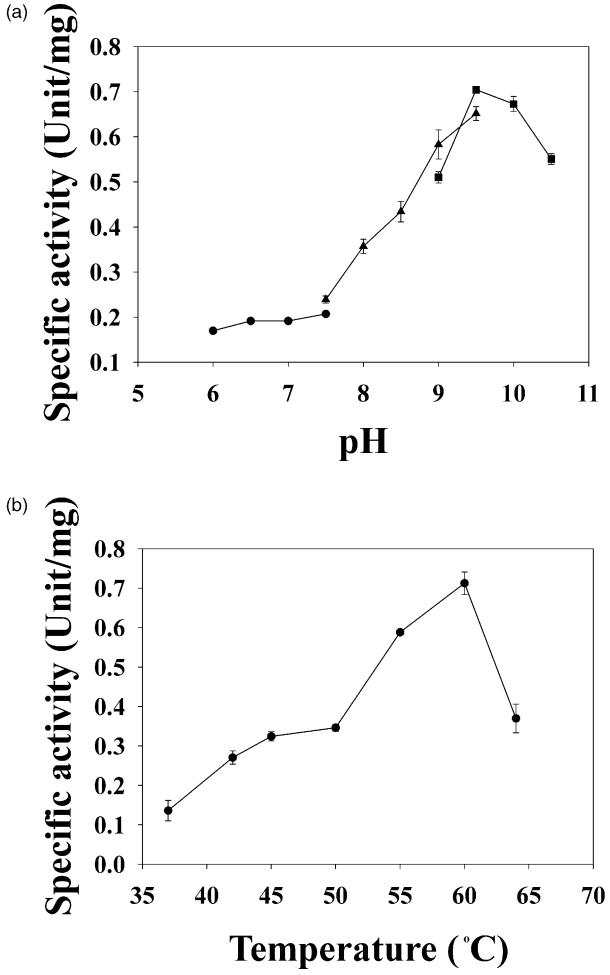

Fig. 4. Determination of optimum pH (a) and optimum temperature (b) for purified ginseng arginase. (a) The reaction buffers used were potassium phosphate for pH 6.0–7.5 (●), Tris–HCl for pH 7.5–9.5 (▲), and glycine/NaOH for pH 9.0–10.5 (■). (b) The reaction temperature was 37, 42, 45, 50, 55, 60 and 65 °C. Each value represents the mean ±s.d. of the results from three replicates.

dissimilar to that of mouse liver arginase (pH 7.4) (Spolarics and Bond, 1998). An optimum temperature for arginase from soybean (Kang and Cho, 1990), iris bulbs (Boutin, 1982), *Bacillus brevis* Nagano (Kanda et al., 1997), rat small intestine (Fujimoto et al., 1976), *Saccharomyces cerevisiae* (Green et al., 1990), and human liver (Kuhn et al., 1995) is in the range of 30 to 37 °C. However, the optimum temperature for ginseng arginase was 60 °C (Fig. 4b), which is high compared to those reported so far. Although there is no report on arginase having such a high optimum temperature, that of a decameric carbonic anhydrase from *Vicia canencens* leaves is 70 °C (Demir et al., 1999). Since both optimum pH and temperature were relatively high, we carried out enzymatic kinetic analyses at 60 °C and pH 9.5 for 1 h (enzyme assay conditions) to determine if any decrease in enzymatic activity occurs during the incubation period (Fig. 1b), but none was observed. Since freezing and thawing caused about 15% loss in enzyme activity in buffer B, we did not freeze the enzyme solution and it was routinely stored at temperatures ranging from 0 to 4 °C in this buffer. Under these conditions, the enzyme activity was reduced by about ca. 8% of the original activity one day after storage. Further, since glycerol, dimethyl sulfoxide, and dimethylformamide in buffer were not effective in preventing this loss of activity, the enzyme should be used immediately after purification.

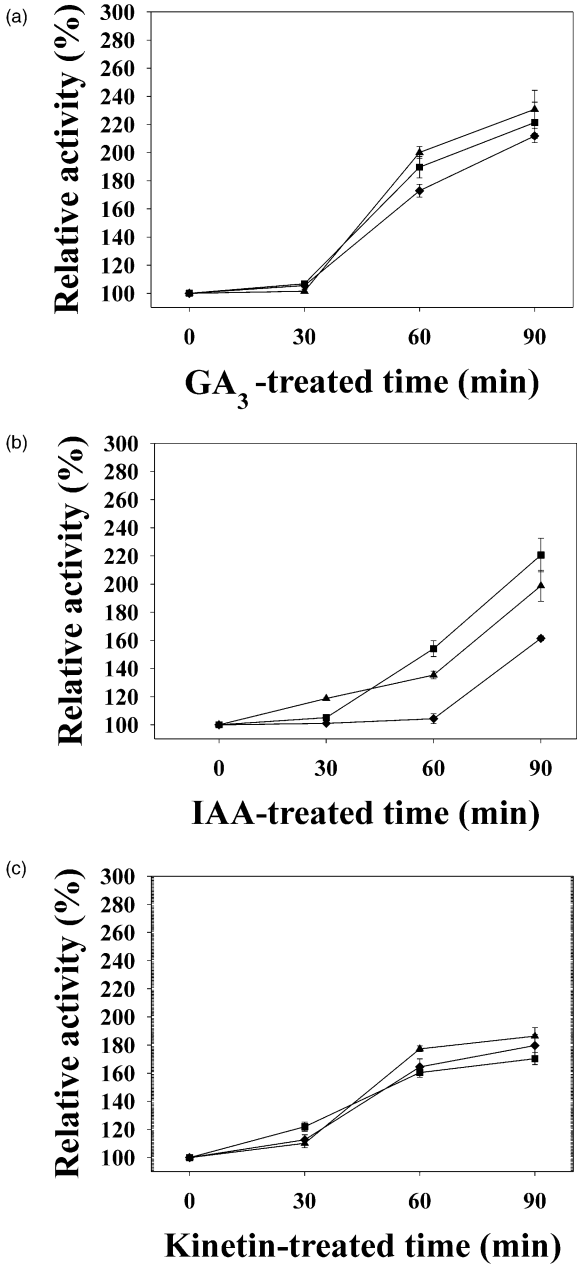

Fig. 5. Time course of arginase activities in GA_3-treated (a), IAA-treated (b), and kinetin-treated (c) slices. Sliced ginseng roots were cultured in Petri dishes containing each plant hormone at the concentrations of 1 nM (■), 10 nM (▲), and 100 nM (◆) at 25 °C for indicated time intervals. For details, see Experimental. Arginase activity is presented as a percentage of each control activity in the absence of each hormone. Each value represents the mean ±S.D. of the results from three replicates.

2.8. Effects of various compounds on arginase activity in sliced ginseng roots

Little has been published on an increase in specific activity of a shade plant arginase in the presence of plant hormones, substrate and polyamines. Indeed, while attempts to induce arginase activity by arginine in soybean (Yu and Cho, 1998) were unsuccessful, other attempts to increase the specific activity by addition GA_3 and IAA in tomato ovaries (Alabadí et al., 1996) were successful (Fig. 5). That is, 30 min after addition of GA_3, arginase specific activity started to increase steadily up to about 230% until 90 min, compared to the control specific activity. Similar results were observed for IAA (about 220% increase) and kinetin (about 180% increase) (Fig. 5). Putrescine at 100 μM increased arginase specific activity up to about 180% after 120 min incubation, compared to that of the control specific activity (Fig. 6). However, the other polyamines seemed to have no effect on arginase specific activity. Further work is thus necessary to verify how they increase the specific activity of a shade plant arginase, since they appear to effect polyamine metabolism.

3. Experimental

3.1. Plant materials and chemicals

Three-year-old ginseng (*Panax ginseng* C.A. Meyer) roots were purchased from a ginseng farm. Trizma base, GA_3, IAA, kinetin, agmatine, ornithine, putrescine, spermidine, spermine, canavanine, cadaverine, L-homoarginine, MGBG, MTA, EDAC, DTNB, PCMB, PLP, agar and Coomassie brilliant blue R-250 were purchased from Sigma (USA). DEAE-sepharose fast flow

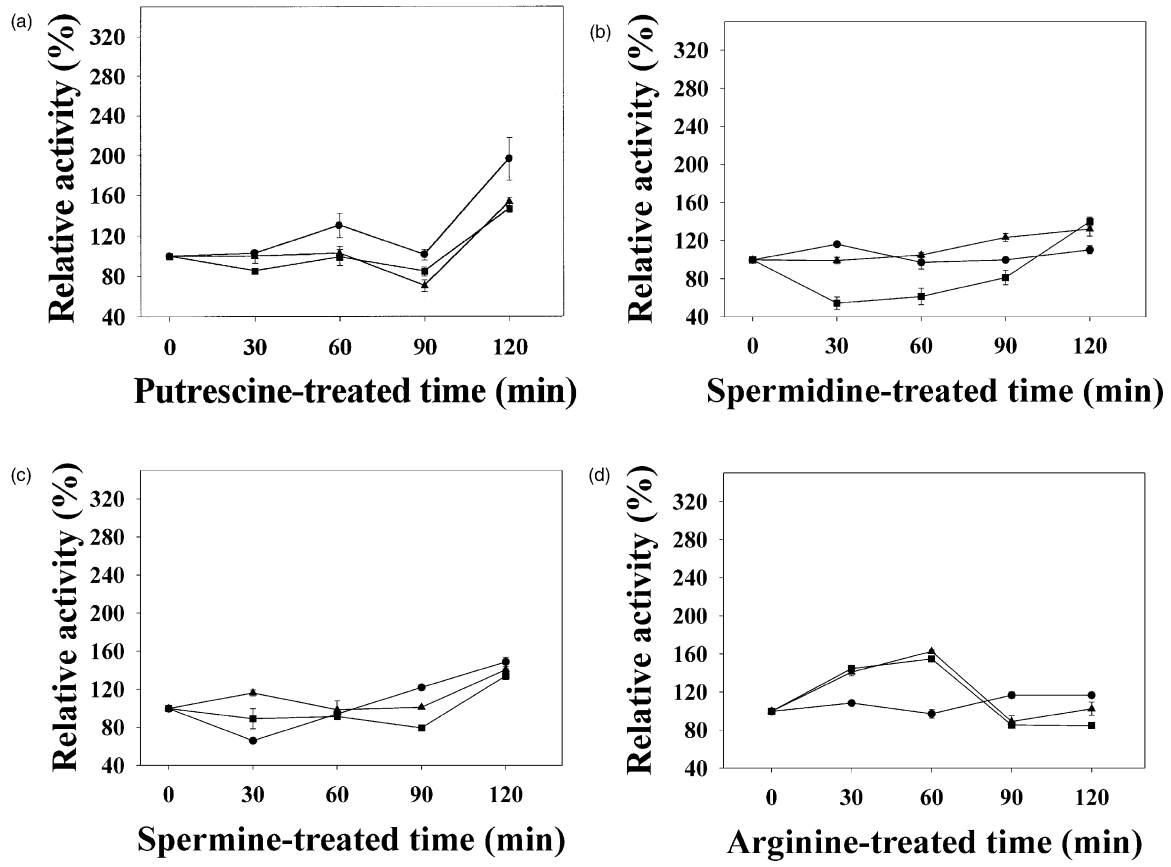

Fig. 6. Time course of arginase activities in putrescine-treated (a), spermidine-treated (b), spermine-treated (c), and arginine-treated (d) slices. Sliced ginseng roots were cultured in Petri dishes containing each compound at the concentrations of 1 μM (▲), 10 μM (■), and 100 μM (●) at 25 °C for indicated time intervals. For details, see Experimental. Arginase activity is presented as a percentage of the control activity in the absence of any substance. Each value represents the mean ±S.D. of the results from three replicates.

resin, Phenyl-sepharose 6B fast flow resin, arginine-sepharose 4B resin, high molecular weight calibration kit, acrylamide, *N*,*N*-methylene-bisacrylamide, *L*-arginine, bovine serum albumin, and ammonium sulfate were purchased from Amersham-Pharmacia Biotech (UK). Other chemicals used were of the highest quality commercially available.

3.2. Arginase assay

The reaction mixture contained 25 mM Tris–HCl (pH 9.5), 1 mM $MnCl_2$, 100 mM L-arginine and enzyme solution in a total volume of 200 μl. The reaction was conducted at 60 °C for 1 h and was terminated by addition of 20 μl of 70% a perchloric acid. Precipitated proteins were removed by centrifugation at 12,000×*g* for 10 min and urea in the supernatant was spectrophotometrically measured by the modified method of Archibald (Archibald, 1945). One unit is defined as the amount of enzyme producing 1 μmol per 1 h. The arginase activity was a linear function of both enzyme concentration and incubation time up to at least 1 h under these conditions. All enzyme assays were made in triplicate, and generally reproduced within ±5%.

3.3. Protein determination

Protein concentration was determined by the method of Bradford (Walker, 1996) with bovine serum albumin as the standard protein.

3.4. Arginase purification

All purification procedures were performed at 0–4 °C, unless otherwise stated. Fresh ginseng roots (300 g) were homogenized in a chilled electric mixer with two volumes of buffer A [50 mM Tris–HCl (pH 7.5) buffer containing 1 mM $MnCl_2$, 0.1% β-mercaptoethanol, and 10% glycerol]. The homogenate was filtered through four layers of gauze and clarified by centrifugation at 14,000×*g* for 20 min. The supernatant was pooled as a crude extract, which was adjusted to 45% (w/v) saturation with solid $(NH_4)_2SO_4$ and stirred at 4 °C for 1 h. The resulting solution was centrifuged at 13,000×*g* for 20 min and the pellet was discarded. The supernatant was brought to 60% (w/v) saturation with solid $(NH_4)_2SO_4$ and treated as above, except that the pellet was retained. The pellet was dissolved in a minimal volume of buffer B [10 mM Tris–HCl (pH 7.5) buffer containing 0.1% β-

mercaptoethanol] and then dialyzed with the same buffer overnight. The dialyzed solution with 400 mM L-arginine (pH 7.5) and 1 mM $MnCl_2$ was rapidly brought to 50 °C in a hot-water bath, maintained at this temperature by swirling for 15 min, and then cooled in an ice bath. After the precipitate was removed by centrifugation at 12,000×*g* for 20 min, the supernatant was dialyzed with buffer B overnight. The dialysate was applied to a DEAE-sepharose fast flow anion exchange column previously equilibrated with buffer B. The column was washed with 600 ml of the same buffer and an equal volume of buffer containing 0.1 M NaCl. The arginase was eluted with a 300 ml linear gradient of 0.1–0.3 M NaCl in buffer B at a flow rate of 46 ml/h. Active fractions were collected and dialyzed with 10 mM Tris–HCl (pH 7.5) buffer. This protein solution was applied to a phenyl-sepharose 6B fast flow hydrophobic column previously equilibrated with 10 mM Tris–HCl (pH 7.5) buffer containing 30 mM $(NH_4)_2SO_4$. The column was washed with a 50 ml of the same buffer. The arginase was eluted with 40 ml of 10 mM Tris–HCl (pH 7.5) buffer at a flow rate of 30 ml/h. Active fractions were collected and concentrated. This protein solution was applied to an arginine-sepharose 4B affinity column previously equilibrated with 10 mM Tris–HCl (pH 7.5) buffer. The column was washed with 20 ml of the same buffer and eluted with a 10 ml linear gradient of 0–0.4 M arginine in 10 mM Tris–HCl (pH 7.5) buffer at a flow rate 5 ml/h. Active fractions were collected and dialyzed with buffer B.

3.5. Molecular weight determination

The molecular weight of the native purified enzyme was estimated by 4–20% native pore gradient gel electrophoresis by the method of Davis (Walker, 1996); thyroglobulin (669,000 Da), ferritin (440,000 Da), catalase (232,000 Da), and lactate dehydrogenase (140,000 Da) served as molecular standard markers. The molecular weight of subunits was obtained by SDS–PAGE. SDS–PAGE was performed by the method of Laemmli (Walker, 1996) using a 10% separating gel and phosphorylase B (96,400 Da), serum albumin (66,200 Da), ovalbumin (45,000 Da), carbonic anhydrase (31,000 Da), and trypsin inhibitor (21,500 Da) served as molecular markers. The gels were stained with Coomassie brilliant blue R-250.

3.6. Heat stability

The enzyme solution containing 1 mM $MnCl_2$ and 400 mM L-arginine was incubated at various temperature and pH for various time intervals to find the temperature at which heat treatment could be carried out and to find stability of enzyme during incubation time. After incubation, the enzyme solution was centrifuged at 12,000×*g* for 20 min to remove denatured proteins and the supernatant was dialyzed with buffer B for 2 h to remove remaining arginine and urea formed. The remaining arginase activity was assayed as described elsewhere. The enzyme solution not treated with heat was used as the control and the enzyme activities were expressed as a percentage of the control activity.

3.7. Substrate specificity

Several compounds with a guanidino group were used to determine the substrate specificity for the arginase of ginseng roots. Each compound was added to a reaction mixture instead of arginine and the enzyme assay was performed as described before. The reaction mixture containing arginine used as the control and the enzyme activities were expressed as a percentage of the control activity.

3.8. Chemical modification

The enzyme solution was incubated with modification reagents such as EDAC, DTNB, hydroxylamine, PCMB, phenylglyoxal, PLP, and succinyl anhydride under appropriately different conditions (Walker, 1996). After incubation, the enzyme activity was assayed as described. The reaction mixture containing the enzyme solution not treated was used as the control and the enzyme activities are expressed as a percentage of the control activity.

3.9. Effects of metal ions on arginase

The chloride salts of divalent cations (Ca^{2+}, Co^{2+}, Fe^{2+}, Mg^{2+} and Mn^{2+}) were used. The concentrations of ions were varied in the reaction mixture over a range from 0.01 to 1 mM, with the enzyme activity assayed as before. The reaction mixture containing 0.1 mM $MnCl_2$ was used as the control and the enzyme activities were expressed as a percentage of the control activity.

3.10. Effects of polyamines, agmatine and MTA on arginase

Various concentrations of cadaverine, agmatine, MTA, putrescine, spermidine and spermine were added to the enzyme solution and the mixtures were incubated at 37 °C for 20 min, with the enzyme assay being performed as described aforehand. The enzyme solution not treated with any compounds was used as the control and the enzyme activities were expressed as a percentage of the control activity.

3.11. Effects of plant hormones on arginase activity in sliced ginseng roots

Three-year-old ginseng roots were treated with various concentrations of GA_3, IAA and kinetin. Ginseng roots were sterilized in 95% ethanol for 5 s and rinsed with autoclaved distilled water. These roots were re-sterilized

in 3% sodium hyperchlorite for 10 min and rinsed with autoclaved distilled water. Sterilized roots were sliced to 0.7–1.0 mm thick, 1 g of sliced ginseng roots was incubated with Murashige and Skoog salt medium (pH 5.0) containing 3% sucrose (w/v) and various concentrations of plant hormones in Petri dishes at 25 °C. After incubation for a given time (0, 30, 60 and 90 min), sliced ginseng roots were transferred on new Murashige and Skoog salt medium (pH 5.7) containing 8 g/l of agar and cultured at 25 °C for 40 h. After that, samples were immediately frozen in liquid nitrogen and stored at −70 °C. Samples were homogenized with 2 ml of buffer A. The homogenate was centrifuged at 14,000×*g* for 20 min and the supernatant was used as enzyme solution. The enzyme assay was performed as described in Experimental. Solutions of plant hormones were prepared as 1000-fold stock solutions. Stock solutions of IAA and GA_3 were dissolved in 100% ethanol and that of kinetin was dissolved in 1 N NaOH.

3.12. Effects of polyamines and arginine on arginase activity in sliced ginseng roots

Three-year-old ginseng roots were treated with various concentrations of polyamines and arginine. Sliced ginseng roots were prepared and used as described above, except that polyamines and arginine were used instead of plant hormones.

3.13. General methods

Optimum pH, optimum temperature, K_m and V_{max} of purified enzyme were determined as described previously (Kamio and Terawa, 1983).

Failed expression of an *endo*-β-1,4-glucanhydrolase (cellulase) in a non-abscinding mutant of *Lupinus angustifolius* cv Danja

Janice Henderson, Linden Lyne, Daphne J. Osborne*

Oxford Research Unit, Open University, Foxcombe Hall, Boars Hill, Oxford, OX1 5HR, UK

Received 17 May 2001; received in revised form 24 August 2001

Abstract

Cellulase expressions in a normal shedding wild-type and a non-abscinding single gene mutant of *Lupinus angustifolius* have been studied during ethylene treatments of leaf abscission zone explants. Of the range of different glycohydrolases investigated only the abscission cell-specific β-1,4-glucanhydrolase (cellulase) was not produced in the non-abscinding mutant. An *endo*-polygalacturonase was induced equally in both wild-type and mutant and other glycohydrolases were equally up-regulated. The abscission cell-specific cellulase induced at shedding of wild-type is antigenically similar to the *Phaseolus vulgaris* induced leaf abscission pI 9.5 cellulase but with a higher molecular mass (50 kD compared with 48 kD) and like the bean abscission-specific cellulase that of lupin is not glycosylated. Causes of the loss of function of cellulase expression in the non-shedding mutant are discussed. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Cellulase; β-1,4-Glucanhydrolase; Abscission; Mutant gene; *Lupinus angustifolius*; Glycohydrolases, Polygalacturonase

1. Introduction

Modification of abscission zone formation or suppression of abscission cell separation has long been a goal in agronomics because of the potential this offers for improving yield or facilitating harvesting. Mutants with reduced flower bud abscission can provide advantages for beans, tomatoes and cotton where early pod or fruit shedding is common during transient stress conditions. Reduced abscission of all parts is valuable for fodder crops where total vegetative yield is the objective. For certain special crops, such as the plantation oil palm, the absence of abscission in ripe fruit can abolish shedding losses before and during bunch harvesting and hence permit extended lipid synthesis (Henderson and Osborne, 1999).

In Australia, a spontaneous single gene mutant was discovered in the early 1990s amongst plants of *Lupinus angustifolius* cv Danja. This mutant does not shed any organ despite an apparently normal pattern of growth and senescence (Atkins and Pigeaire, 1993). The wild-type of this cultivar is a narrow-leafed variety grown commercially for compound animal feed. The seeds of other white lupins are important sources of protein for livestock (Edwards and van Barneveld, 1998). Since abscission normally occurs primarily among fertilised flowers and small pods (Pigeaire et al., 1992) a non-abscinding mutant offers benefits with respect to yield from assimilates filling pods that might otherwise abscind prematurely. Also, the absence of abscission of leaves under stress conditions permits the retention of all nutrients taken up and the continued mobilisation of metabolites to the reproductive structures. It is to the biochemistry of organ shedding in the wild-type and the single gene non-abscinding mutant (*Abs*$^{-}$) of this lupin that the current paper is directed.

A common feature of the biochemistry of abscission is the synthesis of tissue-specific ethylene-induced hydrolases which degrade the polysaccharide and protein complex of the middle lamella and loosen the primary walls of cells in the separation layer (Osborne, 1989). In the leaf pulvinus-petiolar or pulvinus-stem abscission zones of bean (*Phaseolus vulgaris*) a specific cell wall loosening pI 9.5 cellulase is induced (Horton and Osborne, 1967; Reid et al., 1974) and in tomato flower abscission, multiple cellulase mRNAs are newly expressed at the separating zone in the pedicel (Lashbrook et

PII: S0031-9422(01)00384-3

al., 1994; del Campillo and Bennett, 1996). In addition to cellulase, a polygalacturonase increases during cell separation in tomato leaf and flower abscission zones (Kalaitzis et al., 1997) and is induced with very high levels of activity in oil palm fruit abscission zones (Henderson et al., 2001). Activities of β-galactosidase and other glycosidases can also rise during abscission but these are generally up-regulated rather than induced (Henderson and Osborne, 1999). Although polygalacturonase and other cell wall hydrolase activities in the leaves of lupin change during abscission in the wild-type zone and in the zone of the non-abscinding mutant, we report here that a specific difference in the abscission-linked cellulase expression alone could account for the loss of shedding competence in the *Abs*$^-$ mutant.

2. Results

2.1. Cellulase

After 72 h in ethylene leaflet abscission of the wild-type explants is complete. Enzyme assays for total *exo*- and *endo*-β-1,4-glucanhydrolase in wild-type and the non-abscinding *Abs*$^-$ mutant showed an increase in cellulase activity at abscission only in the zone tissue of the wild-type. Cellulase activity remains low in the adjacent non-zone tissue of both wild-type and *Abs*$^-$ (Table 1).

The cellulase present in intact 0 h zones of both wild-type and *Abs*$^-$ has an optimal activity between pH 4.3 to 5.8 (Fig. 1A) and this, we believe, represents the consititutive cellulase present both in zone and non-zone cells of both genetic lines (compare Figs. 1A and 2A). In wild-type 72 h ethylene-treated tissue (100% abscission) cellulase activity occurs over a wide range of pHs including pH 6.3–7.8 (Fig. 1B) indicating that, in addition to a constitutive cellulase, a new isoenzyme activity is induced at abscission that extends to a higher pH range. Whereas, in the 72 h ethylene-treated *Abs*$^-$ tissue in which no abscission occurs (0%) the pH dependency and optimum for this cellulase remains at pH 4.3–5.8 with a similar pH profile to that of the 0 h intact zones. Final viscosity readings even after 24 h incubations showed no decrease at higher pH (pH 7.3 and 7.8) in extracts from *Abs*$^-$ material.

Table 1
Comparison of cellulase activity at pH 7.8 in extracts of wild-type (WT) and *Abs*$^-$ lupin explants at 0 h and after incubation in ethylene (2.5 μl l^{-1}) for 72 h[a]

	Cellulase activity (% decrease in viscosity)			
	WT		*Abs*$^-$	
	0 h	72 h	0 h	72 h
Zone	4.0±5.6	41.4±5.5	9.0±2.5	3.8±1.3
Non-zone	14.7±2.5	9.0±0.3	9.9±3.2	7.4±4.8
Abscission	0%	100%	0%	0%

[a] Change in viscosity was measured over 3 h ($n=3\pm$s.d.)

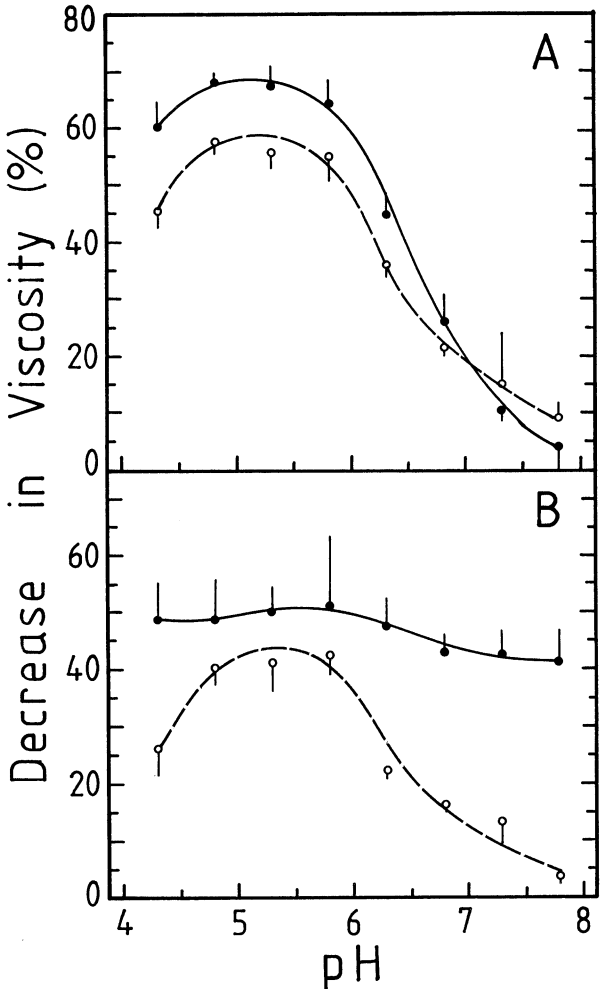

Fig. 1. pH activity profiles of cellulase from extracts of freshly cut (0 h) intact abscission zone cells (A) and after 72 h in ethylene, 2.5 μl l^{-1} (B). Change in viscosity was measured over 3 h ($n=3\pm s.d.$). Wild-type (100% abscission) ●; *Abs*$^-$ (0% abscission) ○ (See Section 4.4.1.).

Coomassie staining of IEF gels (Fig. 3) shows inducible or up-regulated protein bands in 72 h zones of both wild-type and *Abs*$^-$ at pIs 8.4–8.6 and 9.3 (calibrated using the IEF standard protein mix (Sigma, Novex) and from the known pI of tomato PG1). Viscometric assays of gel segments containing these bands excised from IEF gels run in parallel with those for protein staining confirm the presence of an *endo*-cellulase activity induced at pI 8.4–8.5 in the wild-type but no activity above background in this induced band in *Abs*$^-$ (Table 2). Another cellulase activity present in both wild-type and *Abs*$^-$ includes pIs 4.6–5.1, and is detectable at 0 and 72 h but with slightly higher activity in wild-type.

Activity gels (IEF) to visualise enzymic production of reducing groups at 72 h after coating the gel with CMC solution, incubation and development with TTC/NaOH show an *endo*-cellulase activity present at the point of

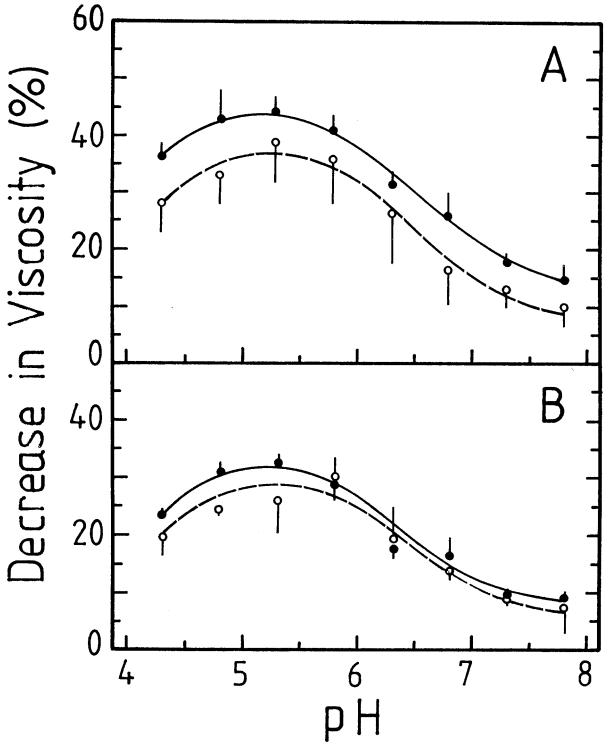

Fig. 2. pH activity profiles of cellulase from extracts of freshly cut (0 h) petiole (non-zone) tissue (A) and after 72 h in ethylene, 2.5 μl l^{-1} (B). Change in viscosity was measured over 3 h ($n=2\pm s.d.$). Wild-type ●; *Abs*$^-$ ○ (See Section 4.4.1.).

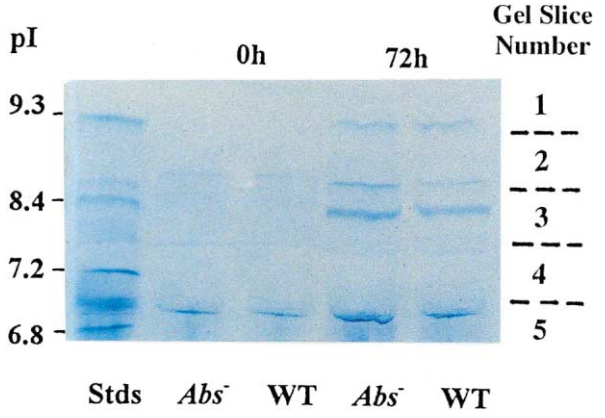

Fig. 3. Isoelectrophoretic fractionation of protein extracts from 0 and 72 h ethylene-treated explants (2.5 μl l^{-1}). Wild-type, WT (100% abscission at 72 h) and *Abs*$^-$ (0% abscission). Stained with Coomassie Blue to show inducible or up-regulated protein bands at pI 8.4–8.6 and 9.3.

application (ca pI 7.0, gel slice 5, Table 2) and at ca pI 5.1 (gel slice 8, Table 2) in both wild-type and *Abs*$^-$. Only in wild-type were reducing groups detectable at pI 8.4–8.5 (corresponding to gel slice 3, Table 2) indicating an increase in the presence of reducing end groups resulting from an *endo*-cellulase activity at this pI (activity gel not shown).

Abscission cellulase in extracts of the abscinded wild-type lupin at 72 h is recognised in Western blotting by

Table 2
Cellulase activity in 1 cm slices cut from IEF gels of wild-type (WT) and *Abs*$^-$ lupin abscission zone extracts fractionated at 0 h and after 72 h in ethylene (2.5 μl l^{-1})[a]

[a] Sample application was at ca. pI 7.0; the pI of each slice was determined by calibration against an IEF standard protein mix (gel slices 1–5 shown in Fig. 3). Each slice was added to a 2% solution of CMC and incubated as described in Section 4.4.1. Final measurements of viscosity were made at 24 h. Representative set of experiments repeated 3 times.

two cellulase pI 9.5 antisera (LL and MM) raised against bean (Fig. 4). Immunorecognition of the bean abscission cellulase on SDS–PAGE gels indicated a molecular mass ca 48 kD which is in agreement with the data of others (Brummell et al., 1994). Run on the same gels as bean, the lupin abscission cellulase of wild-type has a molecular mass that is slightly higher than bean at about 50 kD. No abscission cellulase can be recognised in Western blots of extracts of *Abs*$^-$ at 72 h.

In immunoprecipitation experiments the addition of the pI 9.5 antisera solution (MT) to bean or lupin cellulase extracts reduced activity of the cellulase in viscosity assays by ca 92% (bean) or ca 88% (lupin). Addition of PG antisera or of the YZ 2.23 monoclonal antibody had no inhibitory effects upon cellulase activity measured by CMC loss in viscosity. This lack of reduction in enzyme activity following the addition of YZ 2.23 confirms also that neither bean nor lupin cellulases possess the *N*-linked xylose-fucose heptasaccharide sequence common to many plant proteins (McManus et al., 1988).

Further evidence for the absence of glycosylation comes from experiments in which lupin extracts of 72 h wild-type fractionated by SDS–PAGE directly or were first fractionated on IEF gels and the IEF gel slices at pI 8.4 to 8.5 then re-fractionated on SDS–PAGE gels before staining for glycoprotein. No glycosylated bands were evident above 42 kD. Western blots of SDS–PAGE gels of proteins extracted from abscinded bean domes, or from 72 h wild-type and *Abs*$^-$ abscission zones probed with the monoclonal YZ 2.23 also showed no recognition between 42 kD and 58 kD, again indicating the absence

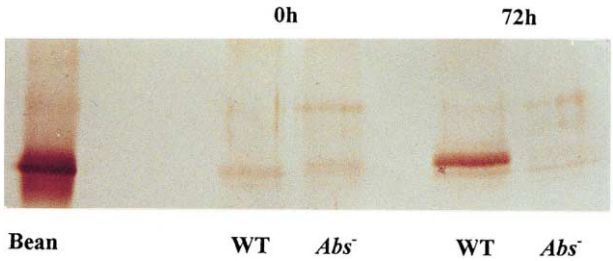

Fig. 4. Western blot of SDS–PAGE fractionation of lupin abscission zone proteins at 0 h and after 72 h in ethylene (2.5 μl l^{-1}); wild-type (WT, 100% abscission) and *Abs*$^{-}$ (0% abscission) together with bean (100% abscission) as control. All probed with the pI 9.5 antiserum (LL) to abscission zone-specific cellulase of bean (48 kD). Each lane 4 μg protein.

of glycosylation of a cellulase protein in either bean or lupin between these kD values.

In a direct comparison of the extent of cellulase induction in bean and wild-type lupin, under similar conditions of ethylene treatment, the activity of *endo*-cellulase in abscinded lupin was always approximately half that extractable from the same fresh weight of abscinded bean abscission zones.

2.2. β-Glucosidase

There is a low level of constitutive activity in both lupin lines at 0 h and an up-regulation (ca 5×) in both after 72 h in ethylene (Table 3A). Non-zone tissue shows a similar low level of activity at 0 h with a 3–4 times increase at 72 h (Table 3A).

Although total enzyme assays for β-glucosidase indicate similar levels of increased activity after 72 h in ethylene in both wild-type and mutant, when extracts of zone tissue of both are fractionated on IEF gels and the gel slices assayed with *p*-nitrophenyl-β-glucopyranoside, three β-glucosidase isoenzymes are detected at pIs ca 8.5, 7.0 and 5.5 (Fig. 5). Of particular interest is the isoform at pI ca 8.5 which is not present at 0 h and is induced in 72 h zone tissue of both wild-type and *Abs*$^{-}$. The large increase in the activity of the pI 7.0 isoform and the smaller contribution of the induced pI ca 8.5 isoform probably together represent the induction of the total glucosidase activity observed by Osborne and Thompson (1992). As in their experiments, there is no quantitative difference between the two genetic lines (wild-type and *Abs*$^{-}$).

The induced pI ca 8.5 glucosidase isoform has a similar pI to that of cellulase but the two activities have been separated by re-fractionation on SDS–PAGE. For this the location of the active β-glucosidase in 72 h zone tissue at pI 8.4 to 8.5 in both wild-type and *Abs*$^{-}$ was first confirmed by assay of gel slices following electrofocussing. The wild-type and *Abs*$^{-}$ 0 h and 72 h IEF gel slices from pI 8.4–8.5 and control IEF gel slices were then re-fractionated, together with protein standards, by SDS–PAGE. After silver-staining, a protein band, not present in either 0h tissue or in the control IEF gel slices, was observed at ca 63 kD (Fig. 6). Since Western blots confirm the induced lupin abscission cellulase to be antigenically similar to bean but with a slightly higher molecular mass (ca 50 kD compared with 48 kD), the 63 kD band may well correspond with the induced pI ca 8.5 β-glucosidase.

2.3. Other glycosidases

β-Galactosidase is also up-regulated to a very high level of activity after 72 h incubation in ethylene but,

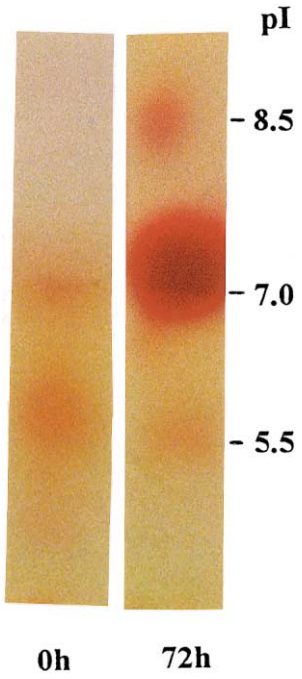

Fig. 5. β-Glucosidase activity in gel slices (IEF) of wild-type zones at 0 and 72 h of ethylene treatment (2.5 μl l^{-1}). At 72 h a new β-glucosidase activity is induced at pI ca 8.5 with up-regulation of activity at pI ca 7.0. A third activity resides at pI ca 5.5. Each gel slice assayed with *p*-nitrophenyl-β-glucopyranoside as substrate.

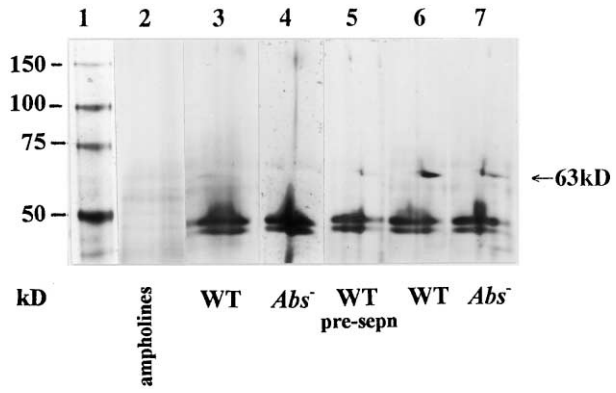

Fig. 6. Location of the pI 8.5 induced β-glucosidase activity excised from an IEF gel and re-fractionated on SDS-PAGE show the induced protein at 63 kD with the progression of abscission in wild-type (WT) and similar protein at 72 h in the non-abscinded *Abs*$^{-}$. (1) MW markers; (2) IEF control gel slice; (3 and 4) WT and *Abs*$^{-}$ at 0 h; (5) WT, 72 h pre-separation; (6) WT (100% abscission) at 72 h; (7) *Abs*$^{-}$ (0% abscission) at 72 h.

again, no differences were detected in either the intact or abscinded abscission zones or in the non-zone tissues between the two genetic lines.

Five other *exo*-cleaving enzymes that could play a minor, though possibly still critical, role in lupin leaf abscission, either show low levels of up-regulation at 72 h in both wild-type and mutant (β-cellobioside, β-xylosidase and α-arabinofuranosidase) or remain essentially unchanged in both (α-glucosidase, α-galactosidase) (Table 4).

2.4. Polygalacturonase

In tomato fruit ripening both *exo*- and *endo*- isoforms are induced (Pressey and Avants, 1973; Pressey, 1987). When lupin abscission zone extracts were fractionated on IEF gels in parallel with tomato fruit extracts, Western blots showed recognition with tomato *endo*-PG antiserum for both wild-type and *Abs*$^{-}$ zones at both 0 h and 72 h (Fig. 7A) with a greater intensity in both at 72 h. The pI of lupin PG is ca 9.0, higher than that for tomato *endo*-PG1 (pI 8.6) (Ali and Brady, 1982). Western blots of SDS–PAGE gels (Fig 7B) run in parallel with an extract of ripe tomato fruit give a molecular mass for the lupin PG of 40 to 44 kD, slightly lower than that for tomato *endo*-PG (43 to 46 kD) reported by Tucker et al. (1980) and Ali and Brady (1982).

Direct assays for PG activity in extracts of abscission zone and non-zone tissue at 0 h show no differences

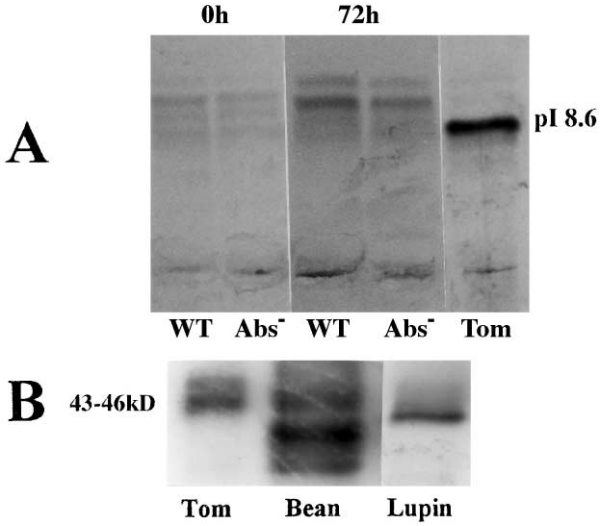

Fig. 7. Western blots probed with tomato fruit *endo*-PG antiserum: A. IEF fractionation of proteins from abscission zones at 0 h and after 72 h in ethylene (2.5 μl l^{-1}). Wild-type (WT, 100% abscission) and *Abs*$^{-}$ (0% abscission) compared with an extract of ripe tomato fruit expressing tomato *endo*-PG1 (pI 8.6). Both wild-type and *Abs*$^{-}$ are equally induced but have a higher pI than tomato PG. Each lane 27 μg protein. B. SDS-PAGE fractionation of proteins from lupin abscission zones of wild-type (100% abscission) after 72 h ethylene treatment (2.5 μl l^{-1}) in comparison with protein extracts of tomato fruit (43–46 kD) and abscinded bean abscission zones. Each lane 9 μg protein.

between the two lupin lines, and by 72 h in ethylene that in wild-type and *Abs*$^{-}$ is up-regulated to the same extent, abscission zone tissue (ca ×4) and non-zone tissue (ca ×2) (Table 3B).

2.5. Laminarinase (β-1,3-glucanhydrolase)

Of potential interest in abscission is β-1,3-glucanhydrolase. Both Abeles and Forrence (1970) and Felix and Meins (1985) have recorded large increases in this enzyme in plants and in excised leaf sections of bean and tobacco respectively, in response to ethylene. In the lupin, using reducing group assays with laminarin as substrate, β-1,3-glucanhydrolase activity rose four-fold in zone tissue after 72 h in ethylene, but no differences were found between the extracts of the abscinded tissue of wild-type and those of *Abs*$^{-}$ (data not shown).

3. Discussion

Whilst the mutant non-abscinding *Abs*$^{-}$ plants develop normally in every respect and initially are indistinguishable from wild-type, no abscission of the leaflets (nor of any other organ) occurs. Furthermore, the leaflets are not induced to abscind by incubation under ethylene at levels as high as 100 μl l^{-1} for 120 h (Clements and Atkins, 2001). However, the leaflet explants do release ethylene, and they do show a normal level of ACC-enhanced ethylene production (Thompson, unpublished data). Ethylene applied to etiolated wild-type and mutant lupin seedlings inhibits shoot elongation in both, causes lateral swelling of the shoots and the typical 'triple response' (Osborne and Thompson, 1992). The *Abs*$^{-}$ mutant, therefore, can perceive and respond to ethylene so a general insensitivity to ethylene (as in an ETR mutant) is not the reason for the absence of abscission. Also, at 0 h there are no obvious anatomical differences between the abscission zone regions of wild-type and the *Abs*$^{-}$ mutant (Clements and Atkins, 2001)

The pH profiles for cellulases (including the abscission pI 9.5 cellulase) reported for the petiole-leaf abscission zone of the bean, by del Campillo et al. (1988) show that they are very similar to those we find induced in the abscinded zone of the wild-type lupin.

Fractionation of extracts of the lupin abscission-site proteins at 0 and 72 h run in parallel with similar extracts from bean have shown that on IEF gels, there is an induced protein band in wild-type with cellulase activity at a lower pI than that induced at bean abscission (pI 8.4–8.5 compared with pI 9.5). In addition, in the *Abs*$^{-}$ mutant, a protein band that also fractionates at pI 8.4–8.5 is induced at 72 h, but this has no *endo*-cellulase activity; nor does this fraction liberate reducing sugars when incubated with CMC—unlike the corresponding fraction from wild-type. When fractionated on SDS-gels and silver-stained, a protein band is seen to be induced by 72 h in ethylene in both wild-type and *Abs*$^{-}$ with a molecular mass (calculated from marker standards) of ca 50 kD compared with ca 48 kD for the bean abscission cellulase. Western blots (using both the original L.Lewis bean pI 9.5 and a new antibody raised against a bean cellulase protein amplified from a bean abscission cellulase cDNA transformed into *E. coli*) both confirmed similar antigenic recognition at ca 48 and 50 kD for the bean and wild-type lupin cellulase, respectively. This is not unexpected since lupin and bean are both members of the Leguminosae. However, there was no recognition by pI 9.5 cellulase antiserum of any protein band (including that at 50 kD) in *Abs*$^{-}$ blots.

The cellulases as a group of enzymes show a high level of heterogeneity between species (Brummell et al., 1994) and between different tissues in the same plant, as in peach (Bonghi et al, 1992). Some isoforms are glycosylated as in ripening avocado (Bennett and Christoffersen, 1986) and in leaves and fruits of pepper plants (Ferrarese et al., 1995), whilst the basic form of cellulase in the bean leaf, the pI 9.5 abscission-induced cellulase, is reported as not glycosylated (Bennett and Christoffersen, 1986). The difference in mobility that we find between lupin and bean abscission cellulase appears not to be the result of differential addition of sugar residues as neither lupin nor bean abscission cellulase is positive in our glycosylation tests. Also, neither bean nor lupin

cellulase bands are recognised on Western blots by the monoclonal YZ 2.23 indicating an absence of the abscission cell-linked, but common *N*-xylose-fucose oligosaccharide protein terminus (McManus et al., 1988).

Polygalacturonase is another much studied and important enzyme in fruit ripening and in some species also in abscission (Roberts et al., 1997; Henderson and Osborne, 1999). The increase in PG activity observed in lupin in both the abscinding and non-abscinding genetic lines appears not to be directly linked to abscission but rather to a response to ethylene. Although PG has been reported as an *exo*-acting enzyme in bean abscission zones (Berger and Reid, 1979) in our experiments, the recognition by the tomato *endo*-PG antiserum of a protein in the abscinded bean dome shows it to possess *endo*-PG activity (Fig. 7B). This *endo*-PG activity is induced to the same extent in both wild-type and *Abs*$^-$ lupin even though *Abs*$^-$ does not shed, so failure of *Abs*$^-$ to abscind is unlikely to be due to failures in PG.

β-Glucosidase is of special interest as this enzyme was considered to be equally induced by ethylene in both wild-type and *Abs*$^-$ abscission zones by Osborne and Thompson (1992) using a less sensitive assay procedure. They found that ethylene led to a similar rise in the level of expressed activity by wild-type and *Abs*$^-$ at 72 h despite the lack of abscission in *Abs*$^-$. Present results indicate that the rise includes the expression of a new β-glucosidase isoenzyme and the up-regulation of at least one other isoform as part of the ethylene-inducible response.

Another enzyme, β-1,3-glucanhydrolase, is also equally enhanced in the abscinding zone cells of wild-type and the non-abscinding zone cells of *Abs*$^-$ when the tissues are exposed to ethylene. One may conclude that even if β-glucosidase and β-1,3-glucanhydrolase are important components of the enzyme cohort that is responsible for abscission cell separation, neither determines the difference in shedding between wild-type and *Abs*$^-$. Although it seems evident that a critical threshold level of ethylene is an essential requirement for triggering abscission, ethylene induces in both abscission cells and in neighbour non-abscission cells an array of different new or up-regulated gene expressions and suppressions that are not directly related to the shedding response, but instead are linked to an accumulation of pathogenesis-related proteins or stress-related proteins (del Campillo and Lewis, 1992). A comparison of such accelerations or repressions between an abscinding wild-type and a non-abscinding mutant provides the opportunity to discriminate between those expressions directly essential to abscission and those that are "fellow travellers" of a wider array of ethylene controlled responses.

Although not all potential wall-modifying glyco- and glucan-hydrolases were investigated in relation to the non-abscission of *Abs*$^-$ only the absence of an inducible abscission-specific cellulase is recognisable as the enzymic expression lacking in the non-separating *Abs*$^-$. As a single gene mutant (Atkins and Pigeaire, 1993) this could be the only gene activity that has been lost or suppressed in *Abs*$^-$.

Taken together, the results suggest that there could be the production, in the *Abs*$^-$ mutant, of a protein with a disabled cellulase function. This situation could arise from a mutant cellulase gene or alternatively from failures in the subsequent transcription, translational or post-translational events of a normal gene.

4. Experimental

4.1. Plant material

Seeds of *L. angustifolius* cv Danja and *Abs*$^-$ were sown in 30 cm diameter pots in multipurpose compost in an unheated greenhouse under natural light conditions during the months of May–November. Plants were harvested at an average of 44 days (39 days min, 50 days max) when they were about 8–10 inches tall and when each plant had 6–8 fully expanded leaves.

For the bean (*Phasolus vulgaris* L. var. Masterpiece) plants were grown in seed boxes under the same conditions as for lupin and the primary leaves harvested when plants were ca 21 days old (20 days min; 30 days max).

4.2. Preparation of explants

For the lupin, the compound leaves, including the petiole, were first cut from the plant. Explants containing the leaflet abscission zones were prepared by removing the lower part of the petiole to leave a length ca 2 cm and shortening the blades of the leaflets so that only a 1 to 2 mm base of each leaflet and its pulvinule remained where each leaflet abscission zone joined the petiole. Explants were placed on glass in a glass dish over 2% (w/v) agar. Each dish (ca 1 l) was sealed with a glass lid fitted with a Suba-Seal. Ethylene was injected to give a concentration of 2.5 μl l^{-1}, and the dishes were held in an unlit incubator at 25 °C for 72 h with daily aeration. For the wild-type material a thin slice of tissue was removed from the petiole surface of the abscission zone after the zone cells had separated (72 h). For the *Abs*$^-$ material an equivalent amount of tissue was excised to include the whole of the region of the non-separated zone. For 0 h samples, the unseparated abscission zones were excised directly from the freshly collected leaves. For non-zone material, 5 mm segments of petiole tissue were cut from 3 to 4 mm below the attachment of the pinnules.

For the bean, the pulvinus-petiole abscission zone of the primary leaf was excised as a 1.5 cm segment to include the whole of the pulvinus, the abscission zone and ca. 1 cm of the subtending petiole. The explants

were held in glass containers on perspex racks over 2% agar and, as for the lupin explants, ethylene was injected to give a final concentration of 2.5 μl l^{-1}. All explants had completed abscission by 48 h and a narrow slice of tissue (< 1 mm) was removed from the exposed surface of the petiole dome at the pulvinar/petiolar junction. For 0 h samples, a thin slice (to include all the abscission zone cells) was excised directly from the leaf pulvinus-petiole junction.

4.3. Extraction of tissue

The amount of zone tissue obtained from ca 30 lupin plants was 200–300 mg. Freshly collected tissue (200 mg) was ground in a cooled mortar with 200 μl 50 mM sodium acetate pH 5.5 containing protease inhibitors leupeptin (1μg ml^{-1}), amidinophenylmethane sulfonyl fluoride (APMSF, 40 μg ml^{-1}), 200 mM NaCl and a little acid-washed sand. After centrifugation in a benchtop microfuge (Beckman) at 9000 g_{max} for 1 min, the pellet was re-extracted in de-ionised (MilliQ) water (200 μl) and centrifuged. The two supernatants were combined and assayed directly. Extracts of non-zone tissue were prepared in the same way. Extraction procedures for the bean were similar to those for lupin and experiments were carried out in parallel.

The presence of NaCl did not interfere with any of the enzyme assays (viscosity, reducing sugar, *p*-nitrophenol release). Partial purification of enzyme extracts (gel filtration/ultrafiltration) always resulted in some loss of each enzyme activity. Heterologous mixtures of wild-type and *Abs*$^-$ extracts indicated no inhibition or activation of any enzyme assayed. Protein determinations were made by the method of Bradford (1976) with BSA as the standard.

4.4. Enzyme assays

4.4.1. Viscosity measurements

Cellulase (EC 3.2.1.4) activity was measured by a decrease in viscosity of a solution of carboxymethyl cellulose (CMC, Hercules, USA, Type 7HF). Enzyme extract (50 μl) was added to 400 μl of a 2% (w/v) aqueous solution of CMC with 50 μl 1 M buffer (acetate or phosphate) at the appropriate pH. Viscosity readings were started after a 5 min equilibration period in the water bath (30 °C) and taken thereafter at regular intervals. The pH-dependent activity was determined for cellulase with acetate (pH 3.8–5.8) and phosphate (pH 6.3–7.8) buffers.

4.4.2. Reducing sugar assays

Polygalacturonase (PG, EC 3.2.1.15) and β-1,3-glucanhydrolase (laminarinase, EC 3.2.1.39) activities were measured by the cyanoacetamide method for reducing sugars (Gross, 1982). Enzyme extract (20 μl) was added to each substrate (50 μl) in 50 mM acetate buffer (130 μl); for PG activity, polygalacturonic acid (10 mg ml^{-1}, Sigma) at pH 5.5; for laminarinase activity, laminarin (30 mg ml^{-1}, Sigma) at pH 4.7, and cellulase, CMC (10 mg ml^{-1}) at pH 5.5 and 7.8. Galacturonic acid was used as the standard for PG and glucose for laminarinase and cellulase.

4.4.3. p-Nitrophenol release

Exo-glycosidase activities were determined with *p*-nitrophenylglycoside substrates (Sigma). Enzyme extract (20 μl) was added to substrate (200 μl, 2 mg ml^{-1}) in 50 mM acetate buffer (30 μl). Activities of α- and β-glucosidase, β-cellobiosidase and α-galactosidase were measured at pH 5.3; β-galactosidase, α-arabinofuranosidase and β-xylosidase at pH 4.3. Assays were terminated with 1.25 ml 200 mM sodium carbonate and the release of *p*-nitrophenol assessed at 400 nm. Activity was calculated by reference to standard curves of *p*-nitrophenol.

4.5. Electrophoresis

4.5.1. Isoelectricfocusing

Zone tissue was extracted in 50 mM sodium acetate pH 5.5 (without NaCl) for isoelectric focusing. Pre-cast IEF gels on a plastic backing (pI 3.5–9.5, Pharmacia Ampholine PAGplates) were used with an Ultrophor Electrofocusing Unit (LKB 2217) and electrofocusing constant power supply (LKB 2197). The Ultrophor unit was connected to a MultiTemp II thermostatic circulator (LKB) with the temperature set at 5 °C and pre-cooled 1 h before electrophoresis. Gels (7–14 cm wide) were run at 5 to 7.5 W power with starting voltage of ~250 V for 1.5 h. The voltage at the end of the gel run never exceeded 1500 V. Each sample was loaded onto a 1×0.5 cm applicator strip (2 application pieces were placed on top of each other for 30–50 μl samples). A standard IEF protein mix (Sigma, Novex) with pIs between 3.6 and 9.3 and a tomato PG1 (pI 8.6) enzyme preparation were used to calibrate the pI of the cellulase isoenzyme induced at lupin abscission.

After electrophoresis, the cellulase protein activity at each pI was confirmed by direct enzyme assay. For this, each sample lane of the gel (10 cm in length) was cut into 1 cm horizontal slices and each slice was added to 700 μl 1.5% CMC in 50 mM sodium acetate pH 5.8 and viscosity changes measured over time. The tubes were covered in parafilm and a final viscosity reading was taken after 24 h.

4.5.2. Activity gels

In parallel with viscosity assays for cellulase activity, the formation of reducing sugars from CMC was located visually on other similar sample gels by the addition of triphenyltetrazolium chloride (TTC) in 1 N NaOH

which, on heating, forms a pink precipitate with reducing groups. For this, it was necessary first to remove all the ampholytes from the IEF gels by thorough washing (3×5 min in 50 ml 100 mM acetate pH 5.8) with gentle rotation. Each gel was then blotted and overlaid with ca 1 ml substrate solution (1% CMC in 50 mM sodium acetate pH 5.8), covered with transparent film, placed in a sealed plastic box and incubated at 30 °C (18 h). Gels were then rinsed briefly in distilled water, placed in a hot TTC/NaOH solution [0.15% (w/v) TCC in 1 N NaOH] and heated in a microwave oven, 20 s full power, once or twice until pink bands representing reducing sugars appeared, and the gel background was not too dark (Pan et al., 1989). The activity of β-glucosidase was located also on IEF gels by the liberation of reducing sugar from a 0.002% solution of *p*-nitrophenyl-β-glucopyranoside in 50 mM sodium acetate pH 5.3 for 3 h (with development as for cellulase location). A control IEF gel of the fractionated sample was routinely overlaid with deionised water alone; on development with TTC/NaOH, this consistently showed a pink spot of activity only at pI 3.5 which represented negatively-charged reducing sugars present in the original extracts.

4.5.3. SDS–PAGE

For these gels, the discontinuous SDS–PAGE method of Laemmli (1970) was used. Enzyme extracts (100 mg fresh weight) were extracted in the presence of NaCl (0.5 M) and concentrated to 100 μl under nitrogen gas by ultrafiltration (Flowgen, 3 K) to remove buffer salts and NaCl. Aliquots (30 μl) were denatured in sample buffer (60 mM 2-amino-2-(hydroxymethyl)-1,3-propanediol (Tris)–HCl, pH 6.8 containing 10% (v/v) glycerol, 2.5% (w/v) 2-mercaptoethanol, 2% (w/v) SDS and 0.005% (w/v) bromophenol blue) by heating at 100 °C for 3 min. Samples were fractionated by electrophoresis through 10% (v/v) acrylamide gel (Pro-Sieve, Flowgen) at constant voltage (130 V) at room temperature.

4.5.4. Western blotting

Proteins fractionated by SDS–PAGE were electroblotted (Multiphor, Pharmacia) onto nitrocellulose membrane (Schleicher and Schull, 0.45 μm) using the semi-dry method (Bjerrum and Schafer-Nielson, 1986). After transfer, membranes were first blocked with a solution containing BSA (2%, Sigma) and dried milk powder (2%, Marvel). Blots were then exposed to solutions of antisera of primary antigens: (i) bean pI 9.5 cellulase antiserum (Koehler et al., 1981) from Dr. L. Lewis (LL) via Dr. R. Sexton, University of Stirling; (ii) a new pI 9.5 bean cellulase antiserum from Dr. M.T. McManus (MM) (Massey University, New Zealand) produced from the full-length pBAC10 cDNA (Tucker and Milligan, 1991) cloned into expression vector pPROEX-1 (Life Technologies Inc. Gathersbury, MD, USA) and transformed into *E. coli* strain DH5α. Induction and purification of the expressed protein and production of antibodies in laboratory rabbits was as described in Hunter et al. (1999); (iii) tomato *endo*-polygalacturonase antiserum (Tucker and Grierson, 1982) from Dr. G. Tucker, University of Nottingham, Sutton Bonington; (iv) the monoclonal YZ2.23 raised against an abscission zone-specific protein of *Sambucus nigra* that recognises a xylose-fucose heptasaccharide antigenic glyco-grouping of sequence Manα3(Manα6)(Xylβ2)Manβ4GlcNAcβ4(Fucα3)GlcNAc (McManus et al., 1988).

The washed blots were exposed to either a solution of HRP-conjugated rabbit (cellulase, polygalacturonase) or rat (YZ 2.23) second antibody (Sigma, 1:1000) in PBS/1% blocking buffer and developed with 2 mM 3,3′-diaminobenzidine (Sigma) in 50 mM Tris/HCl pH 7.4 and 2% H_2O_2.

4.5.5. Immunoprecipitation

For these experiments another Dr. L. Lewis pI 9.5 antiserum sample was used from Dr. M. Tucker, USDA, Maryland, USA. Extracts of abscinded wild-type lupin (72 h) and bean (48 h) abscission zones were incubated with either 20 μl of the pI 9.5 abscission cellulase antiserum to a final dilution of 1:3 at pH 8.5 or pH 5.5; or 20 μl of distilled water. The mixtures were first held on ice for 15 min, then centrifuged (16,900 g_{max}, 10 min, 4 °C). Each sample was adjusted to pH 5.8 with 1M sodium acetate (50 μl) and finally incubated with similarly buffered CMC. Viscosity was measured over time as described for cellulase.

Other immunoprecipitations with the antisera to tomato PG or with the monoclonal YZ 2.23 to the *Sambucus nigra* abscission-cell derived *N*-linked xylose-fucose heptasaccharide were carried out as controls.

4.5.6. Direct staining for glycoprotein

Enzyme extracts of wild-type 72 h abscinded abscission zones of lupin were first fractionated by isoelectric focusing and the protein band containing cellulase activity (pI 8.4–8.5) excised from the IEF gel. Duplicate gel pieces were then inserted into wells of SDS–PAGE gels and the pI 8.4–8.5 proteins were re-fractionated together with lanes containing purified tomato polygalacturonase (43–46 kD) and horseradish peroxidase (40 kD) which are both glycosylated. Soybean trypsin inhibitor was run as the unglycosylated protein control lane. The SDS gels were then either silver-stained for protein (GelCode SilverSNAP stain kit) or stained with a GelCode glycoprotein staining kit (both from Pierce and Warriner, UK). Gels were also transferred to membranes and the blots probed with the monoclonal YZ 2.23 for recognition of *N*-acetyl xylose-fucose heptasaccharide glycosylation.

Chemical syntheses of caffeoyl and 5-OH coniferyl aldehydes and alcohols and determination of lignin *O*-methyltransferase activities in dicot and monocot species

Fang Chen, Parvathi Kota, Jack W. Blount, Richard A. Dixon*

Plant Biology Division, Samuel Roberts Noble Foundation, 2510 Sam Noble Parkway, Ardmore, OK 73401, USA

Received 3 July 2001; accepted 27 July 2001

Abstract

To investigate the substrate preferences of *O*-methyltransferases in the monolignol biosynthetic pathways, caffeoyl and 5-hydroxy coniferyl aldehydes were synthesized by a new procedure involving a Wittig reaction with the corresponding hydroxybenzaldehydes. The same procedure can also be used to synthesize caffeoyl and 5-hydroxyconiferyl alcohols. Relative *O*-methyltransferase activities against these substrates were determined using crude extracts and recombinant caffeic acid *O*-methyltransferase from alfalfa (*Medicago sativa*), and crude extracts from the model legume *Medicago truncatula*, tobacco, wheat and tall fescue. Extracts from all these species catalyzed methylation of the various monolignol aldehydes and alcohols more effectively than the corresponding hydroxycinnamic acids. © 2001 Elsevier Science Ltd. 1. Introduction

The current concept of monolignol biosynthesis is a metabolic grid, through which side chain reduction and ring hydroxylation/methylation can occur at several different levels (reviewed in Lewis and Yamamoto 1990, Whetten and Sederoff 1995, Dixon et al., 2001). This concept was first proposed following the discovery of apparently independent pathways for monolignol *O*-methylation at the levels of hydroxycinnamic acids and their coenzyme A esters, catalyzed by caffeic acid *O*-methyltransferase (COMT) and caffeoyl CoA *O*-methyltransferase (CCoAOMT), respectively (Ye et al., 1994; Higuchi 1996). However, in recent years, increasing evidence has pointed to the hydroxylation/methylation of cinnamyl aldehydes or cinnamyl alcohols in lignin biosynthesis (Chen et al., 1999; Osakabe et al., 1999; Li et al., 2000).

Our recent studies (Guo et al., 2001) have centered on genetic manipulation of the *O*-methylation reactions of guaiacyl (G) and syringyl (S) lignin biosynthesis in alfalfa (*Medicago sativa*). Alfalfa is the world's major forage legume and a species in which lignification has important implications for forage digestibility and therefore utilization efficiency (Jung et al., 1997). To fully understand the opportunities for, and consequences of, genetically modifying lignin *O*-methyltransferases (OMTs), it is important to determine relative OMT activities against all potential substrates in the monolignol pathway. Unfortunately, caffeoyl- and 5-hydroxyconiferyl aldehydes and alcohols are not commercially available, and present some challenges in synthesis due to their *o*-dihydroxy ring substitution. In the past, 4-hydroxycinnamyl alcohol was synthesized by reducing 4-hydroxycinnamic acid esters with lithium aluminum hydride or diisobutylaluminum hydride (DIBALH) (Quideau and Ralph, 1992; Terashima et al., 1995). 4-Hydroxycinnamaldehyde was obtained by reduction of cinnamic acid ester or chloride followed by oxidation of the alcohol by manganese dioxide. These protocols involve many reaction steps and separations, leading to poor yields and difficulties with purification. Daubresse et al. (1994) developed a mild protocol to synthesize coumaryl, coniferyl, and sinapyl aldehydes and alcohols, performed under phase-transfer conditions.

We tried to use this procedure for synthesis of caffeoyl aldehyde and 5-hydroxyconiferaldehyde but without success. Nevertheless, the idea of using a Wittig reaction (McMurry, 2000) with (1,3 - dioxolan - 2 - yl) - methyltriphenylphosphonium bromide inspired us to develop a new procedure for synthesis of these compounds. We have found that 18-crown-6 can effectively catalyze the Wittig reaction and give good yields for synthesis of monolignol precursors. We here describe the synthetic procedures, and the use of caffeoyl and 5-hydroxyconiferyl aldehydes and alcohols to determine substrate preferences for OMTs in extracts from several plant species.

2. Results and discussion

2.1. New synthetic approaches for hydroxycinnamyl aldehydes and alcohols

To investigate fully the monolignol biosynthetic pathway, it is a prerequisite to obtain all potential substrates in the pathway. Caffeoyl aldehyde, caffeoyl alcohol, 5-hydroxyconiferaldehyde and 5-hydroxyconiferyl alcohol are all potential substrates for monolignol *O*-methyltransferase but are not commercially available at this time. In recent reports, 5-hydroxyconiferaldehyde was prepared from 5-hydroxyvanillin (Osakabe et al., 1999). This protocol demands several steps of reaction and purification (Fig. 1), and gives only moderate overall yield (reported to be around 25%). Daubresse et al. (1994) have described mild syntheses of cinnamyl aldehydes and alcohols from 4-acetoxybenzaldehyde. The key step for this procedure is a Wittig reaction with (1,3-dioxolan-2-yl-methyl)-triphenylphosphonium bromide catalyzed by tris-[2-(2-methoxyethoxy)-ethyl]amine (TDA-1). We therefore attempted to prepare caffeoyl aldehyde and 5-hydroxyconiferaldehyde using this procedure. However, in our hands, the yields of dioxolanes obtained from 3,4-diacetoxybenzaldehyde and 3,4-diacetoxy-5 methoxybenzaldehyde were too low and the predominant products of the reaction were the corresponding piperonals even if the phenolic groups were already acetylated. To exploit the convenience of synthesis of cinnamyl aldehydes and alcohols with (1,3-dioxolan-2-yl-methyl)-triphenylphosphonium bromide, we tried two alternative catalysts for Wittig reactions, 18-crown-6 (1,4,7,10,13,16-hexaoxacyclooctadecane) and tetrabutylammonium bromide, and found that 18-crown-6 most efficiently catalyzed the reactions with 3,4-diacetoxy-5-methoxybenzaldehyde and 3,4-diacetoxybenzaldehyde. The new procedure (Fig. 2) described here requires fewer steps than previous methods, can be

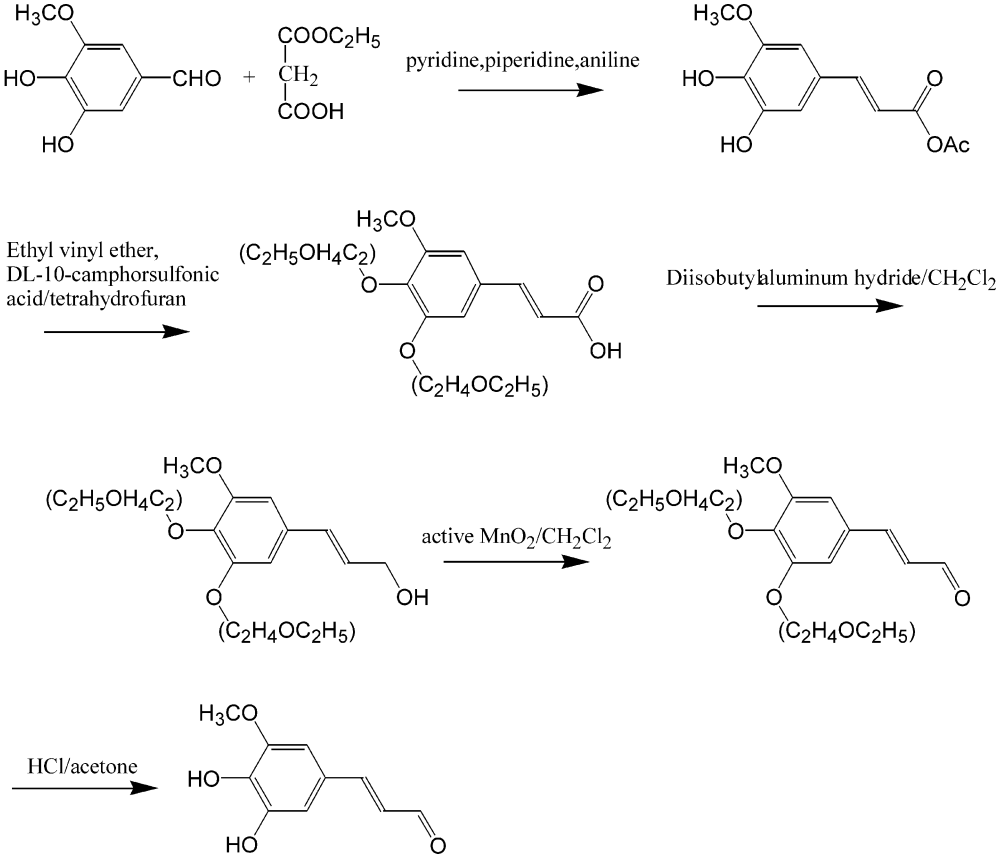

Fig. 1. Synthesis of 5-hydroxyconiferaldehyde from 5-hydroxyvanillin and monoethyl malonate.

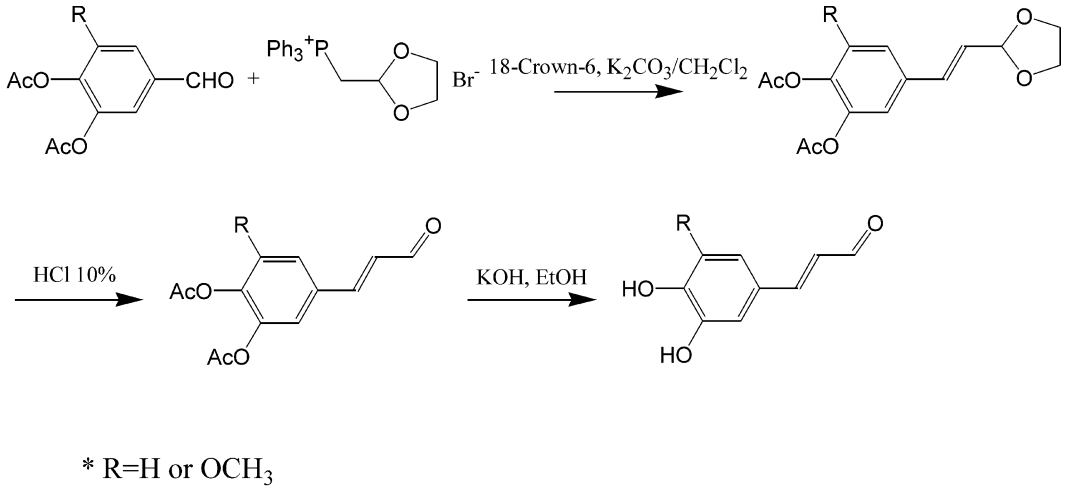

Fig. 2. Synthesis of caffeoyl and 5-hydroxyconiferyl aldehydes by a Wittig reaction with the corresponding hydroxybenzaldehydes and (1,3-dioxolan-2-yl-methyl)- triphenylphosphonium bromide.

performed in ambient atmosphere, and gives higher yields than previous methods (50–60% being routine in our hands).

3,4 - Dihydroxybenzaldehyde and 3,4 - dihydroxy - 5 - methoxybenzaldehyde can be acetylated at both phenolic hydroxyls using acetic anhydride under alkaline conditions. The acetylated products were then mixed with (1,3-dioxolan-2-yl-methyl)- triphenylphosphonium bromide, 18-crown-6 and solid K_2CO_3 in dry dichloromethane to produce the corresponding dioxolanes. The process can easily be monitored by GC/MS in one-hour intervals to ensure the maximum yield. Dioxolanes are obtained as isomers with a Z/E ratio of about 60/40, as described by Daubresse et al. (1994). After removal of the solid phase by filtration, the mixture can be hydrolyzed without further purification. Acid hydrolysis of the dioxolanes leads to nearly pure (E)-acetylated aldehydes as revealed by GC/MS. After purification of the 3,4-diacetoxyconiferyl aldehyde by column chromatography, the acetyl groups can be removed by transesterification in absolute EtOH. Fig. 3 shows the mass spectra of the resulting caffeoyl aldehyde and 5-hydroxyconiferaldehyde after trimethylsilylation. Methoxime derivatization of the products was also conducted to confirm the presence of the aldehyde groups. Fig. 4 shows the mass spectra of caffeoyl aldehyde and 5-hydroxyconiferaldehyde after methoximation and trimethylsilylation.

Caffeoyl alcohol and 5-hydroxyconiferyl alcohol can be obtained by condensation of 3,4-dihydroxybenzaldehyde or 5-hydroxyvanillin, respectively, with monoethyl malonate according to the method of Umezawa et al. (1991). However, the yield for these compounds (around 20%) is much lower than that reported for the synthesis of coniferyl alcohol (around 50%). With the procedure described by Daubresse et al. (1994), we were able to synthesize caffeoyl alcohol and 5-hydroxyconiferyl alcohol from 3,4-diacetoxycaffeoyl aldehyde and 3,4-diacetoxyconiferaldehyde with a yield of approximately 70%. Fig. 5 shows the mass spectra of the obtained products. The results reported here show that a Wittig reaction with (1,3-dioxolan-2-yl-methyl)-triphenylphosphonium bromide is a relatively straightforward method for synthesis of caffeoyl and 5-hydroxyconiferyl aldehydes and alcohols in good yield. The method can be performed with limited demands on synthetic expertise.

2.2. Substrate preferences of O-methyltransferases in dicots and monocots

To determine if the various hydroxycinnamyl aldehydes and alcohols were effective substrates for alfalfa COMT, the alfalfa COMT cDNA (Inoue et al., 1998) was cloned into the pET15b vector and expressed in *E. coli*. The His-tagged recombinant COMT enzyme was purified to homogeneity from the soluble protein using nickel affinity chromatography. Enzyme assays were conducted with the usual substrates, caffeic acid, 5-hydroxyferulic acid, and caffeoyl and 5-hydroxy-coniferyl aldehydes and alcohols. HPLC/diode-array analyses with parallel radio-detection showed that all these compounds acted as substrates for recombinant alfalfa COMT and gave the predicted products (Parvathi et al., 2001). The relative activites are summarized in Table 1. These results provide in vitro evidence for a potential alternative pathway to monolignols involving methylation of hydroxycinnamyl aldehydes and alcohols.

To determine whether OMT activity against all the hydroxycinnamyl aldehydes and alcohols was also found in other plant species, we assayed crude extracts from alfalfa, *Medicago truncatula* (a close relative of alfalfa), tobacco, wheat and tall fescue. The results (Table 1) indicate that, in each case, all substrates were effectively methylated, and, in each case, caffeic acid was

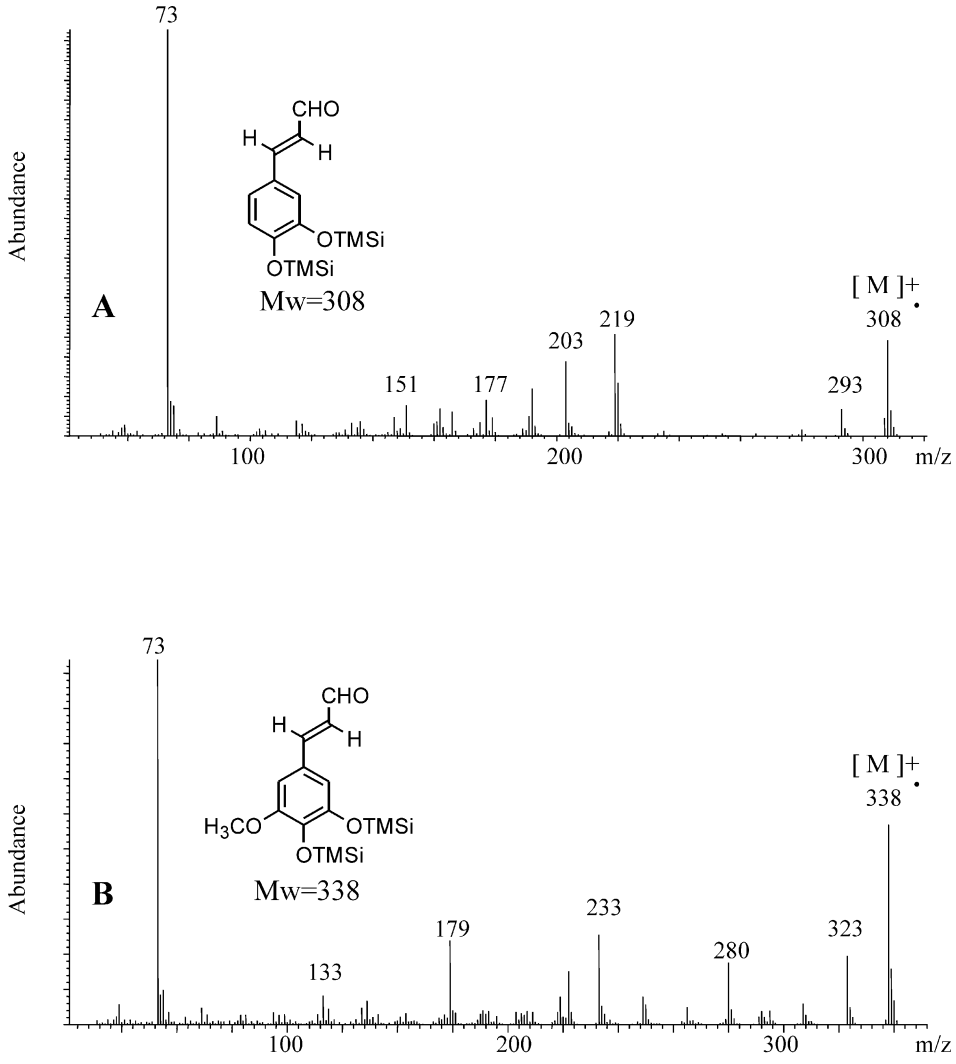

Fig. 3. Mass spectra of caffeoyl aldehyde (**A**) and 5-hydroxyconiferaldehyde (**B**) after TMSi derivatization.

the poorest substrate. In alfalfa, *M. truncatula*, tobacco and fescue, 5-hydroxyferulic acid, caffeoyl aldehyde, caffeoyl alcohol and 5-hydroxyconiferyl alcohol were methylated much more effectively than caffeic acid. In contrast, 5-hydroxyconiferaldehyde was methylated with about the same efficiency as caffeic acid in extracts from alfalfa and *M. truncatula*, whereas this compound was as good a substrate as the other aldehydes and alcohols in extracts from wheat. There were no obvious differences in substrate preferences between monocots and dicots in this experiment (compare alfalfa and tall fescue).

Recently, some OMTs have been found to have an unexpectedly broad range of substrates and even to exhibit functional overlap between different biosynthetic pathways. For example, a series of 38 potential substrates have been tested with four recombinant OMTs of *Thalictrum tuberosum* (Frick and Kutchan, 1999; Frick et al., 2001). Some of the enzymes showed similar catalytic activity with catechol, caffeic acid and the alkaloid norcoclaurine. It is not clear whether these enzymes are also active with caffeoyl aldehyde or 5-hydroxyconiferaldehyde, although this would not appear unlikely. To fully address OMT substrate preferences in vivo, or the potential activities of the large number of OMTs now appearing in plant gene EST databases or being identified from proteomic analyses (Van der Mijnsbrugge et al., 2000; Bell et al., 2001), even broader ranges of substrates will be needed. The relatively facile synthetic procedure reported here will make such substrates more widely available.

3. Experimental

3.1. Plant material, enzymes and chemicals

All plants used in this study were grown under standard greenhouse conditions. Stem tissues were collected and ground under liquid N_2. The powdered tissues were

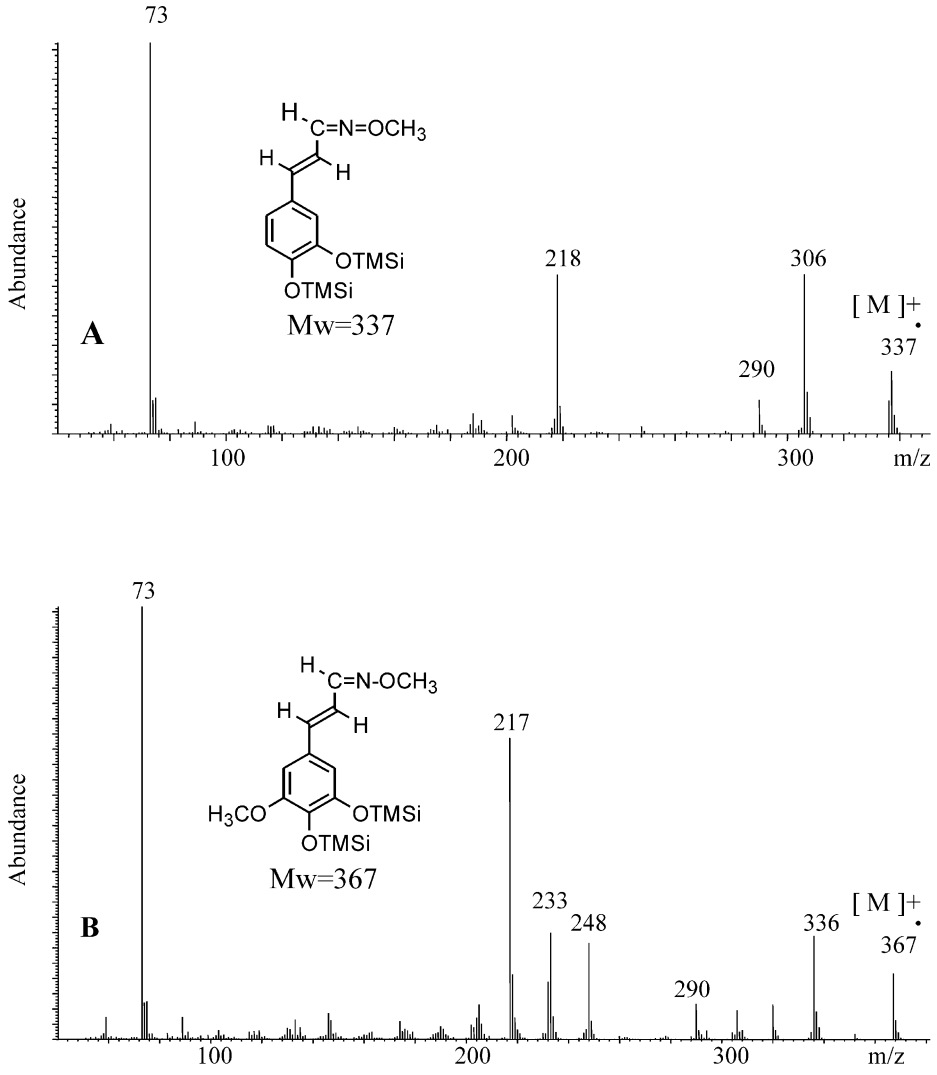

Fig. 4. Mass spectra of caffeoyl aldehyde (**A**) and 5-hydroxyconiferaldehyde (**B**) after methoxime derivatization and TMSi derivatization.

extracted and the soluble proteins were used for enzyme assay (Parvathi et al., 2001). Expression of alfalfa COMT in *E. coli* was performed as described previously (Parvathi et al., 2001). The enzyme was extracted from the *E. coli* cells by sonication and purified from the soluble fraction using His.bind resin (Novagen, Madison, WI, USA) according to the manufacturer's protocol. 3,4-Dihydroxybenzaldehyde, 5-hydroxy vanillin, (1,3-dixoxolan-2-yl-methyl)-triphenylphosphosphonium bromide, 18-crown-6, acetic anhydride, and ethyl acetate were purchased from Aldrich-Sigma Co (St. Louis, MO, USA) and used without further purification.

3.2. Synthesis procedures

3,4-Diacetoxy-3-methoxybenzaldehyde (5 mmol) and (1,3-dioxolan-2-yl-methyl)-triphenylphosphosphonium bromide (5 mmol) were dissolved in CH_2Cl_2 (80 ml) with vigorous stirring. Solid K_2CO_3 (5 mmol) and 18-crown-6 (0.05 mmol) were added. The reaction mixture was kept at room temperature for 8 h. The organic phase was separated from the solid phase by filtration. Aqueous HCl (10%, 50 ml) was added to the organic portion and the mixture stirred at room temperature for a further 6 h. During this period, a small amount of organic phase was taken and subjected to GC/MS analysis. After 2 h, 3,4-diacetoxyconiferaldehyde could be detected (MS *m*/*z*: 278, 236, 194, 177, 166, 151). At the end of the reaction, the mixture was diluted with 50 ml H_2O and extracted three times with 100 ml CH_2Cl_2. The combined organic layers were washed with saturated $NaHCO_3$ and saturated aqueous NaCl solution successively, dried over $MgSO_4$ and evaporated under vacuum. The residue was dissolved in a small amount of CH_2Cl_2 and passed through a silica gel column (eluted with CH_2Cl_2: EtOAc, 90:10, v/v). The eluate was monitored by TLC and the portions containing 3,4-diacetoxyconiferaldehyde were pooled. After evaporation of

Data represent the mean and spread of values for two replicate assays.

[a] Crude enzyme extracts from alfalfa, *M. truncatula* and tobacco were prepared from the 6–9th internodes, the extract from wheat was from the pseudo stem and leaf sheath, and the extract from tall fescue was from the 1st–4th stem internodes.

the solvent, 3,4-diacetoxyconiferaldehyde was obtained as a white solid (1.05 g, 72% yield). The 3,4-diacetoxyconiferaldehyde (0.56 g) was dissolved in 100 ml of 0.2 M KOH in 95% EtOH, and stirred for 8 h under N_2. The solvent was removed under vacuum, and the mixture diluted with 50 ml H_2O and extracted with ethyl

acetate (50 ml ×3). The combined organic layers were dried over Na_2SO_4 and evaporated to give 5-OH coniferaldehyde (0.29 g).

5-Hydroxyconiferyl alcohol was synthesized from 3,4-diacetoxyconiferaldehyde (70% yield) according to the procedure described by Daubresse et al. (1994). Caffeoyl aldehyde and alcohol were synthesized using the same procedure starting from 3,4-diacetoxybenzaldehyde with overall yield of 49–53%.

3.3. Derivatization for GC/MS analysis

Methoxime derivatization of the carbonyl groups of caffeoyl aldehyde and 5-hydroxyconiferaldehyde was performed using 0.5 ml MOX reagent (Pierce, Rockford, IL, USA) at 60 °C for 3 h, followed by evaporation to dryness with N_2. TMSi derivatization of the synthesized products and methoxime derivatives was performed using 250 μl MSTFA reagent (Pierce, Rockford, IL, USA) at 30 °C for 2 h.

3.4. Gas chromatography/ mass spectrometry

The synthesized products were identified by GC/MS. The GC/MS was performed on a Hewlett Packard 5890 series II gas chromatograph with a 5971 series mass selective detector (column: HP-1, 60 m×0.25 mm×0.25 μm film thickness). The mass spectra were obtained using electron ionization (70 eV) with a 60 to 650 m/z scanning range.

3.5. Enzyme extraction and assay

Stem internodes from alfalfa were collected and ground under liquid N_2. The powdered tissue was extracted for 1 h at 4 °C in extraction buffer (100 mM Tris–HCl, pH 7.5, 0.2 mM $MgCl_2$, 2mM DTT and 10% glycerol). The samples were then centrifuged at 12,000 g for 10 min at 4 °C and the extracts desalted on PD-10 columns (Pharmacia). The soluble protein fractions were used for COMT enzyme assay. The protein concentration was measured using Bradford's reagent (Bio-Rad) with BSA as standard (Bradford, 1976). COMT activity was assayed as described previously (Gowri et al., 1991, Inoue et al., 1998).

Abstract

The bioactivity of 25-hydroxybrassinolide, (25*S*)- and (25*R*)-26-hydroxybrassinolide, (25*S*)- and (25*R*)-25,26-dihydroxybrassinolide, and of (25*R*)-25,26-epoxybrassinolide was tested in the rice leaf lamina inclination assay. The 25- and (25*S*)-26-hydroxy derivatives are known metabolites of the naturally-occurring phytohormone brassinolide, whereas the other compounds are novel, but closely related, congeners. When tested alone, all showed either no activity or only weak activity at relatively high doses. When coapplied with indole-3-acetic acid (IAA), an auxin that synergizes the effects of brassinosteroids, enhanced bioactivity was observed for each compound. However, even when applied together with IAA, none of the compounds proved more bioactive than brassinolide with or without IAA. We conclude from these results that enzymatic hydroxylation of endogenous brassinolide at C-25 and/or C-26 does not enhance brassinosteroid activity, and so does not comprise an activation pathway in brassinolide biosynthesis. Instead, these hydroxylations result in modest to appreciable metabolic deactivation. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Rice leaf lamina inclination assay; Brassinolide; Metabolites; 25- and 26-hydroxylated brassinolide derivatives

1. Introduction

Brassinolide (**1**) is a powerful steroidal phytohormone whose structure was first determined by Grove et al. (1979). The chemistry and biology of **1** and of related brassinosteroids such as 24-epibrassinolide (**2**) and castasterone (**3**) has recently been reviewed (Cutler et al., 1991; Khripach et al., 1999; Sakurai et al., 1999). Structures **1**–**3** are shown in Fig. 1. The metabolism of brassinosteroids such as **1**–**3** is of considerable current interest and has been studied both in cell cultures and intact plants (Adam et al., 1996; Adam and Schneider, 1999; Khripach et al., 1999). For example, the metabolism of exogenously applied 24-epibrassinolide (**2**) in cell cultures of *Lycopersicon esculentum* resulted in enzymatic hydroxylation at C-25 and C-26, followed by glucosylation of these sites (Schneider et al., 1994; Hai et al., 1995) (Fig. 2). The glucosylated conjugates have low activity in bioassays and thus appear to constitute metabolic deactivation products. However, the hydroxylated aglycones **4** and **5** were described as having varying degrees of bioactivity (Hai et al., 1995; Adam et al., 1996; Voigt et al., 1996). Thus, the role of the hydroxylated aglycones, as either activation or deactivation products, is currently less clear. The question of metabolic activation vs. deactivation of exogenously applied brassinosteroids is also of practical importance for commercial applications, since it affects both their efficacy and persistence.

The metabolism of brassinolide (**1**), which is generally recognized as the most active of the naturally-occurring brassinosteroids, has also been studied. Voigt et al. (1996) reported that 25-hydroxybrassinolide (**6**) displays comparable bioactivity to **1** in the rice leaf lamina inclination bioassay. In contrast, Seto et al. (1999) found relatively low activity for **6** and for (25*S*)-26-hydroxybrassinolide (**7**). Moreover, we recently reported that 25-fluorobrassinolide (**8**) and 25-azabrassinolide (**9**), where enzymatic hydroxylation at C-25 is expected to be

blocked, show no bioactivity in the rice leaf lamina inclination bioassay (Back et al., 1999). This suggested the possibility that enzymatic hydroxylation at this position is required for biological activity of brassinosteroids such as **1**, and that the hydroxylated metabolites are the true phytohormone 'effectors'. The latter hypothesis is also consistent with an earlier report that hydroxylation at C-25 is an activating step in the 24-epibrassinolide series, since 25-hydroxy-24-epibrassinolide (**4**) was found to be ca. ten times more active than **2** in the rice leaf lamina inclination test (Hai et al., 1995; Adam et al., 1996). On the other hand, strong activity was found for the 25-methoxy (Back et al., 1999) and 25-methyl (Mori and Takeuchi, 1988; Back et al., 2000a) analogues **10** and **11**, respectively, indicating that strong bioactivity is possible even in the absence of a 25-hydroxyl group. Neff et al. (1999) reported an *Arabidopsis bas1-D* mutant that accumulates 26-hydroxybrassinolide, but has reduced levels of **1** and other endogenous brassinosteroids. This was attributed to enhanced expression of a cytochrome P450 that results in the hydroxylation of brassinosteroids at C-26. The authors concluded that *BAS1* is a key control point in the brassinolide signal transduction process. A precise measurement of the relative biological activities of brassinosteroids and their hydroxylated metabolites is therefore of importance in attempts to better understand and control brassinosteroid-regulated effects. While it is generally agreed that metabolic glucosylation of brassinosteroids results in deactivation, there have been conflicting reports regarding whether enzymatic hydroxylation at C-25 and C-26 represents an activation or deactivation step. Moreover, the effect of the C-25 configuration of 26-hydroxylated brassinosteroids (where C-25 is a stereocenter) upon their biological activity has not yet been studied.

In order to shed further light on the bioactivity of C-25 and C-26-hydroxylated derivatives of **1**, we recently developed new synthetic routes to the known compounds **6** and **7**, as well as to a series of novel but related analogues. The latter include (*25R*)-26-hydroxybrassinolide (**12**), both C-25 epimers **13** and **14** of 25-26-dihydroxybrassinolide and the 25,26-epoxide **15** (Back et al., 2000b). The structures of compounds **6**–**15** are shown in Fig. 3. We now report the biological activity of the known metabolites **6** and **7** and of the novel congeners **12**–**15**, as determined in the rice leaf lamina inclination bioassay (Takeno and Pharis, 1982).

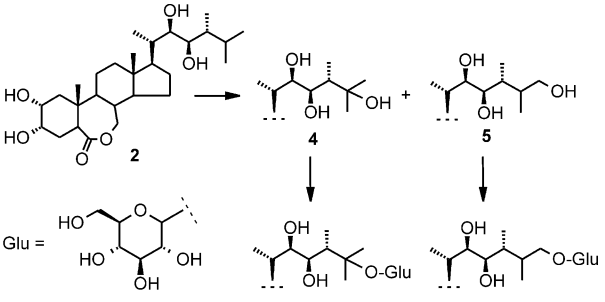

Fig. 2. Hydroxylation and glucosylation of 24-epibrassinolide.

2. Results and discussion

The biological activity of compounds **6**, **7** and **12**–**15** is shown in Figs. 4–9, respectively, with **1** included as a standard for comparison. Since it is known that the effects of brassinosteroids are synergized by auxins such as indole-3-acetic acid (IAA) (Takeno and Pharis, 1982;

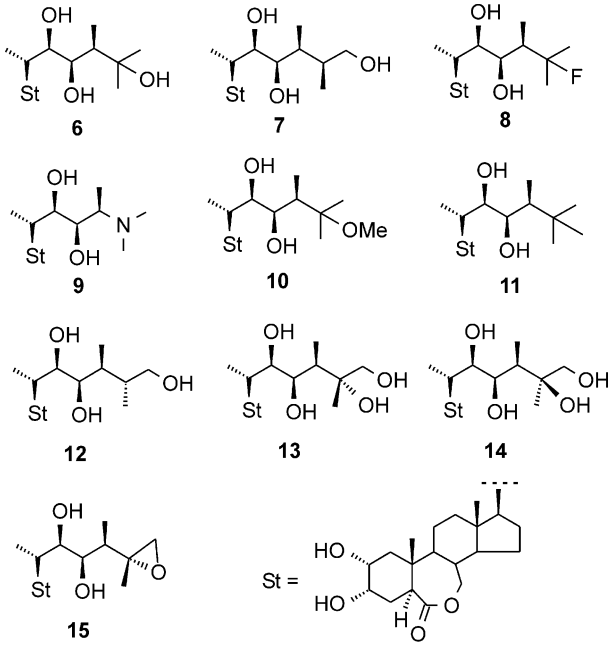

Fig. 3. Structures of side-chain metabolites and congeners of brassinolide.

Mandava, 1988; Sasse, 1991), the bioassays were also repeated in the presence of 1000 ng of IAA. The coapplication of IAA has been observed to enhance the activity of **1** by a factor of 10–100, thus dropping the threshold activity from ca. 1 ng to ca. 0.1 ng–0.01 ng (Baron et al., 1998 and Figs. 4–9).

Of the known brassinolide metabolites **6** and **7**, when assayed alone, the 25-hydroxy analogue **6** showed stronger bioactivity than the (25*S*)-26-hydroxy derivative **7** (Figs. 4 and 5, respectively), but this activity was only observed at relatively high doses ($\geqslant$100 ng). However, when **6** and **7** were coapplied with IAA, the bioactivity of both metabolites was appreciably and comparably enhanced (Figs. 4 and 5), but in neither case did it approach that of brassinolide with IAA. The (25*R*)-26-hydroxy epimer **12** was similar to **7** in the absence of IAA, but showed a slightly greater enhancement of bioactivity than **7** when each was coapplied with IAA (Fig. 6). The low activity of both epimers **7** and **12**, when applied alone, contrasts sharply with their relatively high bioactivity when coapplied with IAA. As such, they may prove useful tools in studying the mechanism of auxin synergism in brassinosteroid induced cell expansion. The diminished bioactivity seen

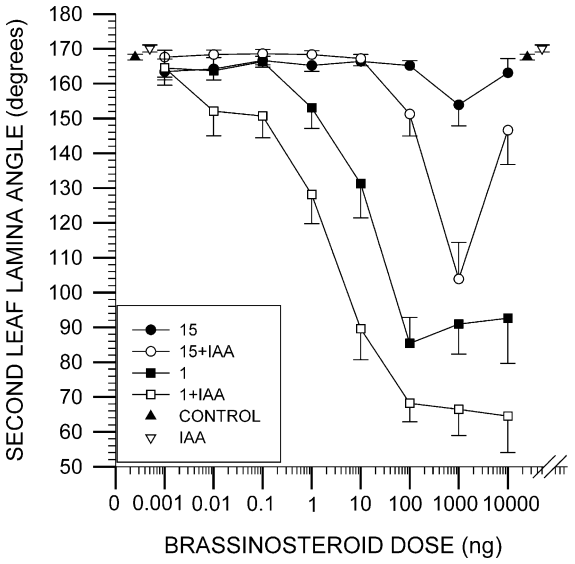

Fig. 9. Rice leaf lamina inclination bioassay of **15**, compared to brassinolide (**1**), with and without coapplication of 1000 ng of IAA. Error bars represent 95% confidence limits.

at the highest doses (10,000 ng) of brassinolide (**1**) or derivatives **6**, **7** and **12**, particularly in the presence of IAA, is not clearly understood. We tentatively attribute it to saturation and/or toxicity effects.

The bioactivity of the two 25,26-dihydroxy analogues **13** and **14** is shown in Figs. 7 and 8, respectively. Both epimers displayed only weak activity, and only at the highest doses of 1000 and 10,000 ng when applied on their own. However, when coapplied with IAA, the activity of **13** showed only slight enhancement (Fig. 7), while the 25-*S* epimer **14** gave a much stronger response when coapplied with IAA (Fig. 8). In this respect, the dihydroxylated epimers **13** and **14** differ from the monohydroxylated epimeric pair **7** and **12**, in which **12** was enhanced only slightly more than **7** by coapplied IAA. Thus, 25,26-dihydroxylation results in greater epimeric discrimination with respect to the C-25 stereocentre than does 26-monohydroxylation in the expression of IAA synergy. Epoxide **15** showed similar behaviour to **14** when coapplied with IAA, but displayed only weak activity at the 1000 ng dose on its own (Fig. 9). The loss of biological activity at the 10,000 ng dose was especially noticeable for **14** and **15**, but not **13**, when they were coapplied with IAA (Figs. 7–9). It is possible that the activity of epoxide **15** stems from its hydrolysis to **13** and/or **14** in vivo.

Our results indicate that neither the known brassinolide metabolites **6** and **7**, nor the novel, but structurally related analogues **12**–**15**, approach the bioactivity of brassinolide in the rice leaf lamination inclination assay. All of compounds **6**, **7** and **12**–**15**, when assayed alone, proved only weakly active, and only at the highest doses. While the activity of all of these compounds was appreciably and significantly increased by the coapplication of IAA, even then bioactivity did not exceed that of brassinolide (**1**) without coapplied auxin, and was substantially lower than that of **1** plus IAA. The considerably lower bioactivity of the hydroxylated and epoxy derivatives **6**, **7** and **12**–**15**, compared to **1** itself, thus indicates that hydroxylation at C-25 and/or C-26 does not comprise an activation pathway in brassinolide biosynthesis in rice, regardless of the configuration at C-25 stereocenters. Instead, it strongly suggests that enzymatic hydroxylation at these positions is part of an overall metabolic deactivation process.

3. Experimental

3.1. Preparation

The known hydroxylated metabolites **6** and **7**, the novel hydroxylated analogues **12**–**14**, and the epoxide **15** were prepared as reported earlier (Back et al., 2000b).

3.2. Bioassays

Compounds **6**, **7** and **12**–**15** were tested for biological activity by means of the rice leaf lamina assay, using a dwarf cv., Tan-ginbozu, as described by Takeno and Pharis (1982). Brassinolide (**1**) was included in the bioassays as a standard. The compounds were dissolved in 95% ethanol and applied as 0.5 μl microdrops to the rice plants 48 h after planting the germinated seeds on 0.8% water agar. At high doses, several rounds of application of the 0.5 μl microdrops were required to attain the desired dose per plant. Where IAA was a co-treatment, 1,000 ng of IAA was similarly applied per plant ca. 2 h prior to the application of the brassinosteroids.

The resultant leaf lamina angle was measured 60–65 h later. For an individual bioassay, each data point is the mean of the leaf angles from ca. 36 plants for doses up to 100 ng and from ca. 24 plants for the 1000 and 10,000 ng doses. Parallel applications of ethanol alone (control) and IAA alone (1000 ng) were carried out for each bioassay (see Figs. 4–9). In each of Figs. 4–9, error bars represent 95% confidence limits.

Abstract

The biosynthesis of the triterpene 22-(30)-hopene-29-acid and the diterpenes 7,17-sacculatadiene-11,12-dial (sacculatal), *trans*-phytol and a new neoverrucosane-type diterpenoid (5-oxo-neoverrucos-(13)-ene) was studied by incorporation of [1-^{13}C]-labelled glucose into axenic cultures of the artic liverwort *Fossombronia alaskana*. Quantitative ^{13}C NMR spectroscopic analysis of the resulting labelling patterns showed that the isoprene units of the triterpene are derived from the mevalonic acid pathway, whereas the isoprene units of the diterpenes are built up via the methylerythritol phosphate pathway. © 2001 Elsevier Science Ltd. Keywords: *Fossombronia alaskana*; Isopentenyl diphosphate; Mevalonic acid pathway; Methylerythritol phosphate pathway; Isoprenoids; Triterpene; Diterpene; ^{13}C labelling; Liverwort; Quantitative ^{13}C NMR spectroscopy; Neoverrucosane

1. Introduction

Isoprenoids are the largest group of secondary metabolites with over 30,000 known compounds, including the steroids (Dictonary of Natural Products, 2000). Their common building block, the isoprene unit, is derived from isopentenyl diphosphate (IPP). Whereas in the past, the mevalonic acid (MVA) pathway has been accepted as the only biosynthetic route leading to IPP, the existence of the methylerythritol phosphate (MEP) pathway as an alternative route for IPP has only been known for a few years (Rohmer et al., 1993; Schwarz, 1994). The reaction sequence of this alternative pathway is established up to the formation of the cyclic diphosphate intermediate 2-C-methylerythritol-2,4-cyclodiphosphate (Rohmer et al., 1993; Sprenger et al., 1997; Lois et al., 1998; Takahashi et al., 1998; Rohdich et al., 1999; Herz et al., 2000; Lüttgen et al., 2000); several subsequent so far unknown steps finally lead to IPP.

This methylerythritol phosphate pathway can be distinguished from the mevalonic acid pathway on the basis of different labelling patterns of the isoprene units resulting after incorporation of [1-^{13}C]glucose into isoprenoids (Rohmer et al., 1993; Schwarz, 1994; Schwender et al., 1996).

The general understanding of isoprenoid biosynthesis has extensively changed by the discovery of the methylerythritol phosphate (MEP) pathway. Whereas vertebrates and archaebacteria appear to use only the mevalonate pathway for the biosynthesis of isoprenoids, different eubacteria have been found to use either the mevalonate or the MEP pathway.

Several algae (with the exception of chlorophytes), bryophytes and higher plants have been found to use the MVA pathway for the biosynthesis of steroids, and the MEP pathway for the biosynthesis of hemiterpenoids, monoterpenoids, carotenoids, phytol and other diterpenes (for review, see Lichtenthaler et al., 1997a; Eisenreich et al., 1998, Lichtenthaler, 1999; Rohmer, 1999). Whereas the deoxyxylulose pathway seems to be limited to the plastid compartment, the mevalonate pathway appears to be operative in the cytoplasm of plant cells. However, segregation of the two pathways is not necessarily complete, and exchange of metabolites between the two pools has been observed in plants and plant cell cultures (Schwarz, 1994; Nabeta et al., 1995; Arigoni et al., 1997; Adam and Zapp, 1998; Piel et al., 1998; Adam et al., 1999).

In continuation of our previous work on IPP biosynthesis in liverworts (Thiel et al., 1997; Adam et al., 1998; Eisenreich et al., 1999; Barlow et al., 2001) that covered hemi-, mono- sesqui- and diterpene formation in this plant taxon, this study was initiated to elucidate triterpene biosynthesis in liverworts. Until now, no information on the IPP biosynthesis of triterpenes in liverworts has been available. For this study we have chosen axenic cultures of the arctic liverwort *Fossombronia alaskana* as an experimental system. This liverwort appeared to be a useful candidate since we demonstrated previously that this plant forms larger amounts of triterpenes of the hopane series (Grammes et al., 1994).

In this paper, we describe the incorporation of [1-^{13}C]glucose into the triterpene 22-(30)-hopene-29-acid as well as three structurally different diterpenes (**1**–**3**) in *F. alaskana*. The biosynthesis of their isoprene units has been studied based on the NMR spectroscopic analysis of their ^{13}C labelling patterns.

2. Results and discussion

The triterpene 22-(30)-hopene-29-acid (**4**) and the diterpenes 7,17-sacculatadiene-11,12-dial (**1**), 5-oxo-neoverrucos-(13)-ene (**2**) and *trans*-phytol (**3**) were isolated with standard chromatographic procedures. Assignments of the ^{13}C NMR spectroscopic signals of the purified compounds were obtained from the literature (Grammes et al., 1994, (**4**); Asakawa et al., 1980 (**1**); Adam et al., 1998 (**3**) and by 2D NMR spectroscopic experiments (**2**). Labelling patterns and absolute ^{13}C enrichments of the compounds were individually determined by quantitative ^{13}C NMR spectroscopy using Cr(III)-acetylacetonate as a relaxation reagent for the carbon nuclei (Braun et al., 1996). The absolute enrichment has been calculated from the integrals of ^{13}C NMR signals on the basis of ^{13}C satellite analysis of the well separated proton signals in the respective ^{1}H NMR spectra.

22-(30)-Hopene-29-acid (**4**) shows three labelled carbons per isoprene unit with an average ^{13}C abundance of 6.68±0.45 (Table 1). The labelling positions correspond to the MVA pathway (Fig. 1). The remaining carbon atoms also display an increased ^{13}C abundance (3.61–4.45%), compared to the expected natural abundance of 1.11%. This general background labelling might be explained by complex metabolic turnover of [1-^{13}C]glucose during the growth period with subsequent statistical distribution of the labelled carbon atoms in various positions of intermediates of carbohydrate metabolism (e.g. metabolism of glucose to carbon dioxide and subsequent assimilation via the Calvin cycle).

7,17-Sacculatadiene-11,12-dial (**1**) and 5-oxo-neoverrucos-(13)-ene (**2**) both showed an enrichment pattern typical for the alternative MEP pathway, with an average ^{13}C abundance of 8.16±0.62% and 8.04±0.29%, respectively (Table 2). The isolated compounds also show a ^{13}C enrichment (3.15±0.26% and 2.98±0.20%, respectively) of the unlabelled positions as already discussed above. The rearrangement reaction during formation of the *neoverrucosane* skeleton has been demonstrated in an earlier study on the biosynthesis of 8α-acetoxy-13α-hydroxy-5-oxo-13-*epi*-neoverrucosane biosynthesis in *F. alaskana* (Eisenreich et al., 1999).

The labelling pattern of *trans*-phytol (**3**) from *F. alaskana* proves the formation of the isoprene units via the MEP pathway (average abundance of enriched ^{13}C: 8.21±0.21%, Table 2). Again, an increased ^{13}C background labelling could be observed (4.23±0.15%, Table 2).

The analysis of the labelling patterns demonstrates that both pathways of IPP biosynthesis operate in *F. alaskana*. The investigated compounds could be assigned to two groups formed independently from each other: firstly the triterpene, biosynthesised via the MVA pathway, and secondly the diterpenes, derived from the MEP pathway. In all compounds we observed a strict separa-

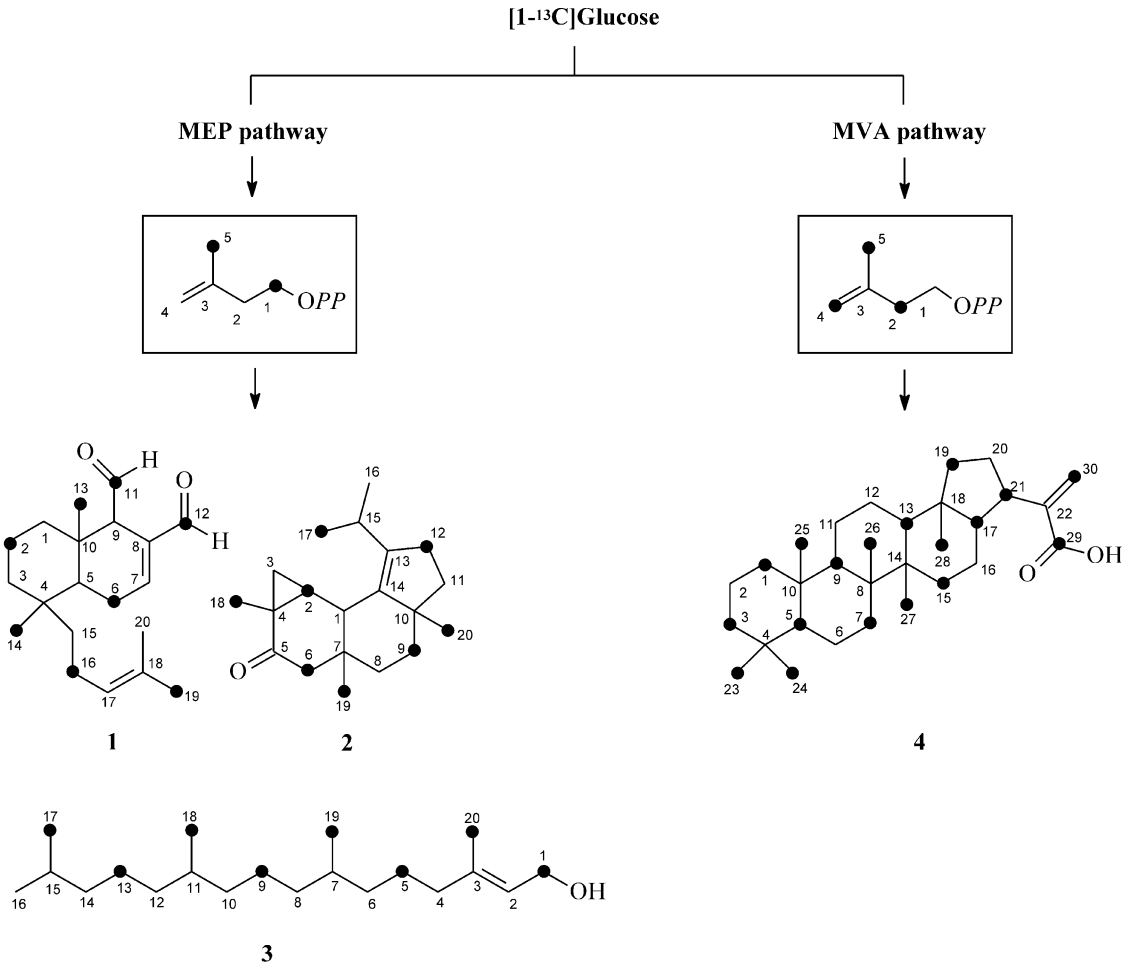

Fig. 1. Incorporation of [1-^{13}C]glucose into IPP via MVA pathway and MEP pathway and the resulting labelling patterns of compounds **1**, **2**, **3** and **4**. *PP* = diphosphate residue, ● = ^{13}C labelled position.

tion of the two pathway specific labelling patterns. A significant mixing of both IPP biosynthesis pathways in any of the isoprene units could not be deduced from the data. However, a minor incorporation of both IPP species in an isoprene unit could not be excluded, since the respective labelling could have been masked by the variation of the ^{13}C abundance data.

These results are in agreement with our earlier findings from the liverworts *R. natans*, *C. conicum* and *Trichocolea tomentella* (Adam et al., 1998; Barlow et al., 2001). They confirm the assumption that at least two well separated types of cellular compartments exist in liverworts, with different IPP biosynthesis machineries creating either C_5-units, mono- and diterpenes (MEP pathway) or sesquiterpenes and sterols and—as demonstrated in this study—also triterpenes (MVA pathway).

The results also support the current hypothesis of localization of the biosynthesis of the different isoprenoid classes assuming that the MEP pathway is located in the cytoplasm while the MEP pathway is segregated in plastids (Lichtenthaler et al., 1997b; Rohdich et al., 1999).

The quantitative analysis of the labelling patterns (Table 3) leads to an even more detailed view of the biosynthesis of the diterpenes. The average ^{13}C abundances of the background-labelled carbons of the sacculatane (**1**) (3.15±0.26% ^{13}C) and the neoverrucosane (**2**) (2.98±0.20% ^{13}C) are similar but much lower than the corresponding data of phytol (**4**) (4.23±0.15% ^{13}C). These differences possibly indicate the presence of two independent compartments in *F. alaskana* that both synthesize diterpenes via the MEP pathway. Since phytol is part of the chlorophyll molecule it could be assumed that its biosynthesis is localized in the chloroplasts whereas the diterpenes **1** and **2** are formed in a different plastidial compartment.

5-Oxo-neoverrucos-(13)-ene (**2**) is a previously unreported neoverrucosane type diterpenoid. Both the ^{1}H and ^{13}C NMR spectra were very similar to the related compound 13-hydroxy-5-oxo-*epi*-neoverrucosane (Grammes et al., 1997). In contrast to 13-hydroxy-5-oxo-*epi*-neoverrucosane, the ^{13}C NMR spectrum showed the presence of one double bond instead of the hydroxy group in position 13 (δ_C 136.1 and 139.1, both *s*). The structure

of compound **2** was established from analysing DEPT, COSY, HSQC and HMBC NMR spectral data.

3. Experimental

3.1. Spectroscopy and spectrometry

NMR spectra were recorded in $CDCl_3$ [^1H NMR (500 MHz), ^{13}C NMR (125 MHz)] relative to $CDCl_3$ at δ_H 7.24, δ_C 77.0. ^{13}C multiplicities were determined using the DEPT pulse sequence. 2D spectra were recorded as COSY, HSQC and HMBC experiments. Quantitative ^{13}C NMR measurements were recorded with the inverse gated decoupling pulse sequence in the presence of 0.1 M $Cr(acac)_3$ (Braun et al., 1996). For integration, the signal-to-noise ratio of the ^{13}C-signals was at least 40:1. In case of overlapping signals, ^{13}C abundance data were either obtained by doubling the integral of the non-overlapped half of the signal or by averaging integrals.

3.2. Plant material and labelling procedure

The axenic culture of *F. alaskana* Steere & Inoue was provided by Professor Basile, New York Botanical Garden. The liverwort was grown in 200 ml Erlenmeyer flasks under continuous incandescent light (60 μmol photons m^{-2} s^{-1} photosynthetically active radiation) at 22 °C on 75 ml of Gamborg B5 medium (Gamborg et al., 1968) solidified with 0.9% agar and supplemented with 1% glucose. For labelling 20% of the glucose was substituted by [1-^{13}C]glucose. Cultures were grown for 12 weeks.

3.3. Extraction and isolation

The extraction and isolation scheme followed standard procedures of our group (Adam et al., 1998). Dried ^{13}C labelled plant material (25 g) was ground and extracted in a Soxhlet apparatus using diethyl ether. After removal of the solvent, the crude extract was subjected to silica gel chromatography (vacuum liquid chromatography, VLC) employing a *n*-hexane–EtOAc gradient. The VLC fraction containing crude 7,17- sacculatadiene-11,12-dial and 22-(30)-hopene-29-acid (9–10% EtOAc) was further purified via HPLC (250 × 4 mm, Si 60 Lichrospher Merck, 5 μm, *n*-hexane–EtOAc, 91:9), yielding 7 mg of (**1**) and 15 mg of (**4**). VLC fractions (15–20% EtOAc) were purified by HPLC (250×4 mm, Si 60 Lichrospher, Merck, *n*-hexane-TBME 93:7) yielding 4 mg of (**2**) as a colourless oil.

The chlorophyll-containing fractions were combined and saponified by reaction overnight at room temperature with 6% (w/v) KOH in methanol. Following hydrolysis, the mixture was extracted 5×with CH_2Cl_2. After removal of the solvent, the mixture was separated by VLC on silica gel with *n*-hexane–EtOAc (3.8% EtOAc) yielding 20 mg of *trans*-phytol (**3**).

Received 24 April 2001; received in revised form 14 August 2001

Abstract

Trichloroethylene (TCE) is a widespread and persistent environmental contaminant. Recently, plants, poplar trees in particular, have been investigated as a tool to remove TCE from soil and groundwater. The metabolism of TCE in plants is being investigated for two reasons: one, plant uptake and metabolism represent an important aspect of the environmental fate of the contaminant; two, metabolism pattern and metabolite identification will help assess the applicability of phytoremediation. It was previously shown that TCE metabolites in plants are similar to ones that result from cytochrome P450-mediated oxidation in mammals: trichloroethanol, trichloroacetate and dichloroacetate. Our measurements indicate that one of these metabolites, trichloroethanol, is further glycosylated in tobacco and poplar. The glycoside was detected in all tissues (roots, stems and leaves) in comparable levels, and was at least 10 fold more abundant than free trichloroethanol. The glycoside in tobacco was identified as the ß-D-glucoside of trichloroethanol by comparison of the mass spectra and the chromatographic retention time of its acetylation product to that of the synthesized standard. Trichloroethanol and its glucoside did not persist in plant tissue once plants are removed from TCE contaminated water, indicating further metabolism. © 2001 Elsevier Science Ltd. 1. Introduction

Trichloroethylene (TCE) is one of the most common environmental pollutants in the industrialized world. It has been used for decades in military, industrial, medical and household settings (Ensley, 1991), in a wide range of applications including as a metal degreaser, dry cleaning agent, and anaesthetic. TCE is relatively stable in the environment, and has persisted in some aquifers for decades. Trichloroethylene is a hepatotoxin, mutagen and suspected carcinogen (Lash et al., 2000; Moore and Harrington-Brock, 2000). The prevalence of this contaminant, coupled with the limited biodegradability, presents a difficult and expensive remediation problem.

Recently, phytoremediation, or the use of plants for environmental cleanup, has been studied as a potential tool for the inexpensive and efficient removal of TCE from the environment. Laboratory studies showed that a number of plant species are capable of taking up and metabolizing TCE (Anderson and Walton, 1995; Narayanan et al., 1995; Newman et al., 1997; Orchard et al., 2000), and a controlled field study showed that poplar trees in an artificially constructed aquifer contributed to the removal of 99% of TCE injected to simulated ground water (Newman et al., 1999).

Though phytoremediation has shown initial promise, further research needs to be undertaken to gain a better understanding of its biochemical and ecological implications. One of the most important areas that requires more research is the fate of TCE in plants.

In mammals, TCE is metabolized via two pathways: the oxidative pathway mediated by cytochrome P450 monooxygenases (primarily 2E1), and the glutathione conjugation pathway catalyzed by glutathione-*S*-transferase. The oxidative pathway is the predominant one, resulting in

metabolites such as trichloroethanol (TCOH), trichloroacetate (TCAA), and dichloroacetate (DCAA). These metabolites can be dechlorinated to oxalic acid. Trichloroethanol is conjugated to glucuronic acid (for review of mammalian metabolism of TCE see Lash et al., 2000).

In previous studies, TCOH, TCAA and DCAA were found in plants exposed to TCE, both in controlled exposures and in field conditions (Newman et al., 1997, 1999; Doucette et al., 1998; Orchard et al., 2000). The concentrations of these metabolites are low, the highest level reported being 40 ppm (fresh weight basis) for TCAA in poplar trees exposed to TCE in a controlled field situation for 3 seasons (Newman et al., 1999). Experiments utilizing [^{14}C] TCE to trace the fate of TCE carbon in plants showed that most of the radioactivity incorporated in plant tissue can not be extracted by organic solvents (Schroll et al., 1994; Schnabel et al., 1997; Orchard et al., 2000). Since TCE and the aforementioned metabolites are analyzed by solvent extraction, the majority of plant TCE metabolites have not been identified.

Miller (1941a,b) found that tomato and gourd plants take up TCOH and metabolize it to its corresponding glycoside. Being very polar, TCOH glycosides would not be extractable by organic solvents, and are, therefore, good candidates for the unidentified TCE metabolites.

This study investigates the metabolism of TCOH as a part of the overall TCE metabolism in plants. In particular, the identification and characterization of the TCOH glycoside as a TCE metabolite is reported.

2. Results and discussion

Among the previously identified TCE plant metabolites, TCOH is the primary metabolite in tobacco (Doty et al., 2000). Although other TCE metabolites, such as TCAA and DCAA, have been reported (Newman et al., 1997; Orchard et al., 2000), the concentrations of these metabolites were often below the level of detection in our experiments. Since TCOH was the most prevalent metabolite in several plant species, we chose to study the fate of this metabolite. The release of free TCOH upon-glucosidase hydrolysis was used as an assay for the existence of TCOH glycosides.

2.1. TCOH is conjugated to sugars in tobacco plants exposed to TCE or TCOH

Tobacco plants were treated with TCE, and the tissues (leaf, stem and root) were harvested and extracted for free and glycosylated TCOH. Fig. 1 is a typical pair of GC chromatographs from the glycoside assay. Upon hydrolysis with ß-glucosidase, a much higher level of trichloroethanol was released, in comparison to the free trichloroethanol in the BSA (bovine serum albumin) control.

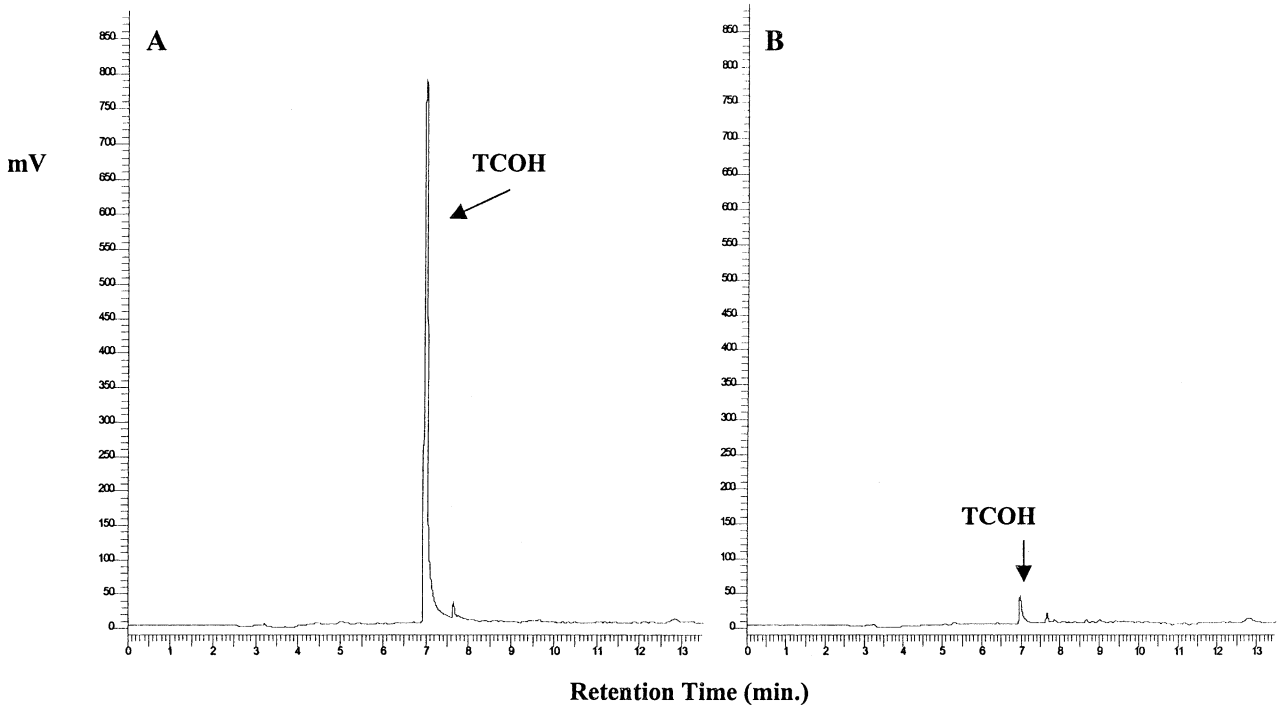

Fig. 1. A sample gas chromatograph (GC–ECD) of the trichloroethanol glycoside assay. Tobacco leaves dose with TCE were extracted. A, extract incubated with β-glucosidase. B, extract incubated with BSA.

When exposed to TCOH, tobacco plants took up TCOH and transported it to the shoots (discussed in Section 2.3.). Similar to TCE treated plants, ß-glucosidase hydrolysis released a high level of TCOH in these plant tissues.

Table 1 lists the percentage of trichloroethanol that is glycosylated in tobacco under various treatments. In all tissues tested, most of the TCOH exists in some kind of glycoside form. The percentage of glycosylation was not influenced by whether the plant was dosed with TCE or TCOH, nor was it influenced by the expression of a TCE-metabolizing transgene, the human P450 2E1.

2.2. Identity of the TCOH-glycoside in tobacco

The identity of the glycoside was investigated with GC–MS. Hydroponic tobacco plants (both transgenic and wild-type) were treated with trichloroethanol, and the leaves were extracted and acetylated. The acetylated extract was subjected to GC using electron capture negative chemical ionization (ECNCI) and electron ionization (EI) mass spectrometry (MS) in comparison to the synthesized TCOH-ß-glucoside tetra-acetate standard (Fig. 2). In both ionization modes, the spectra of the acetylated tobacco glycoside were identical to those of the standard (Figs. 3 and 4, respectively). In addition, when the standard and the acetylated tobacco extracts were mixed and subjected to chromatography as before, the synthesized glucoside and the tobacco glycoside co-eluted as one peak (not shown). The ECNCI mass spectrum of the acetylated glucoside

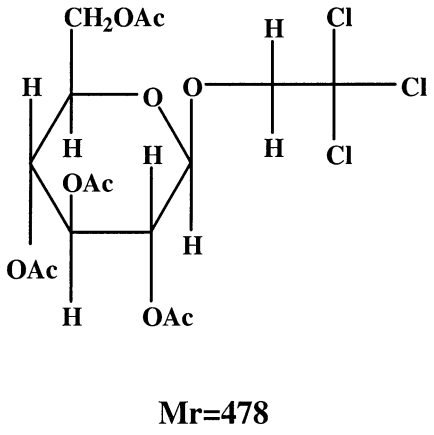

Fig. 2. The structure of the acetylated TCOH β-glucoside. The molecular formula is $C_{16}H_{21}Cl_3O_{10}$.

(Fig. 3) yielded the molecular ion (M^-) at m/z 478 as well as its chloride adduct $[M+l]^-$ at m/z 513 exhibiting isotopic envelopes characteristic for three and four chlorine atoms, respectively. The molecular ion of the glucoside was not observed in the EI spectra (Fig. 4). While mass spectra do not establish whether the acetylated glucoside was in the α- or β-conformation, the glucoside only releases significant amounts of trichloroethanol upon β-glucosidase hydrolysis, but not α-glucosidase (data not shown).

Miller (1941a,b) found that chloral hydrate and trichloroethanol were both converted to β-glycosides in plants. The sugar component, however, varied with species. In *Lagenaria leucantha* Rusby (gourd), a β-glucoside

		Root	20–35	88±7 ($n=3$)
Tobacco hairy roots (wild-type)[e]	TCE		1.7–6.4	82±3 ($n=3$)
	TCOH		140–188	96±0 ($n=3$)
Tobacco leaf suspensions (wild-type)	TCE		0–0.01	0% ($n=3$)
	TCOH		6.5–9	41±34 ($n=3$)

[a] All plants were hydroponic and were dosed with 10g/ml TCE or TCOH in root solutions for 5 days. TCOH concentrations listed were combined values of free and glycosylated TCOH.

[b] Transgenic tobacco plants express human cytochrome P450 2E1 as described in Doty et al., 2000.

[c] In TCE dosed wild-type tobacco, TCOH was detected in leaves only.

[d] n, Number of replicates.

[e] Hairy roots were generated from wild-type tobacco transformed by wild-type *Agrobacterium rhizogenes* as described in Experimental.

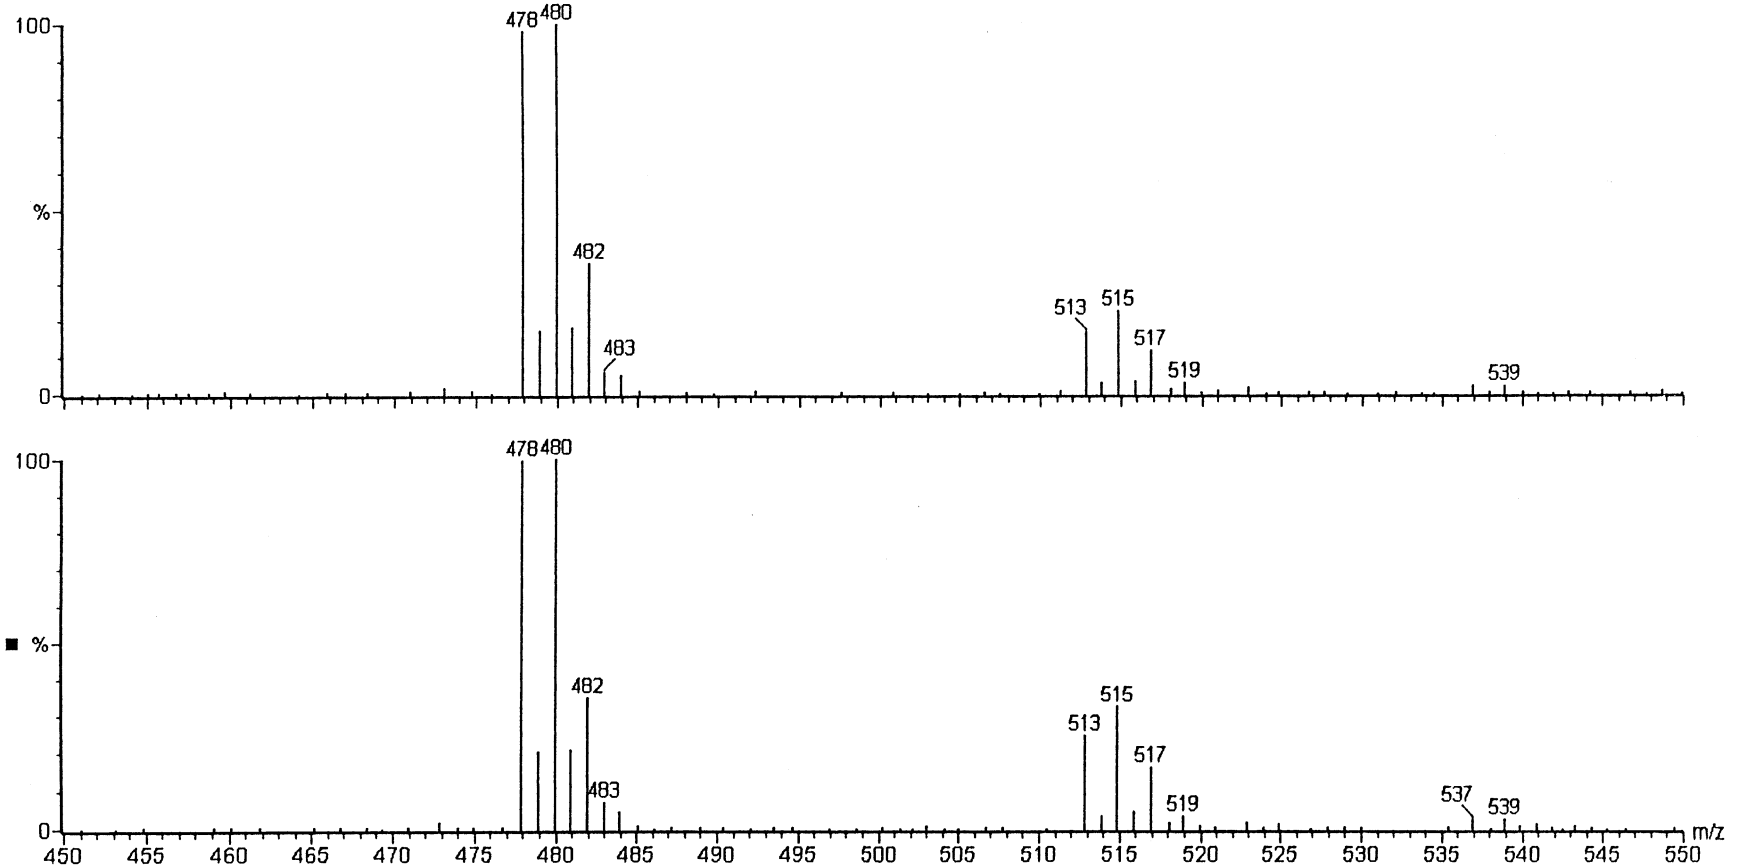

Fig. 3. Elcetron capture negative chemical ionization mass spectra of synthesized tricholoroethyl-β-D-glucopyranose tetra-acetate standard (top) and the acetylated glycoside extracted from tobacco leaves (bottom).

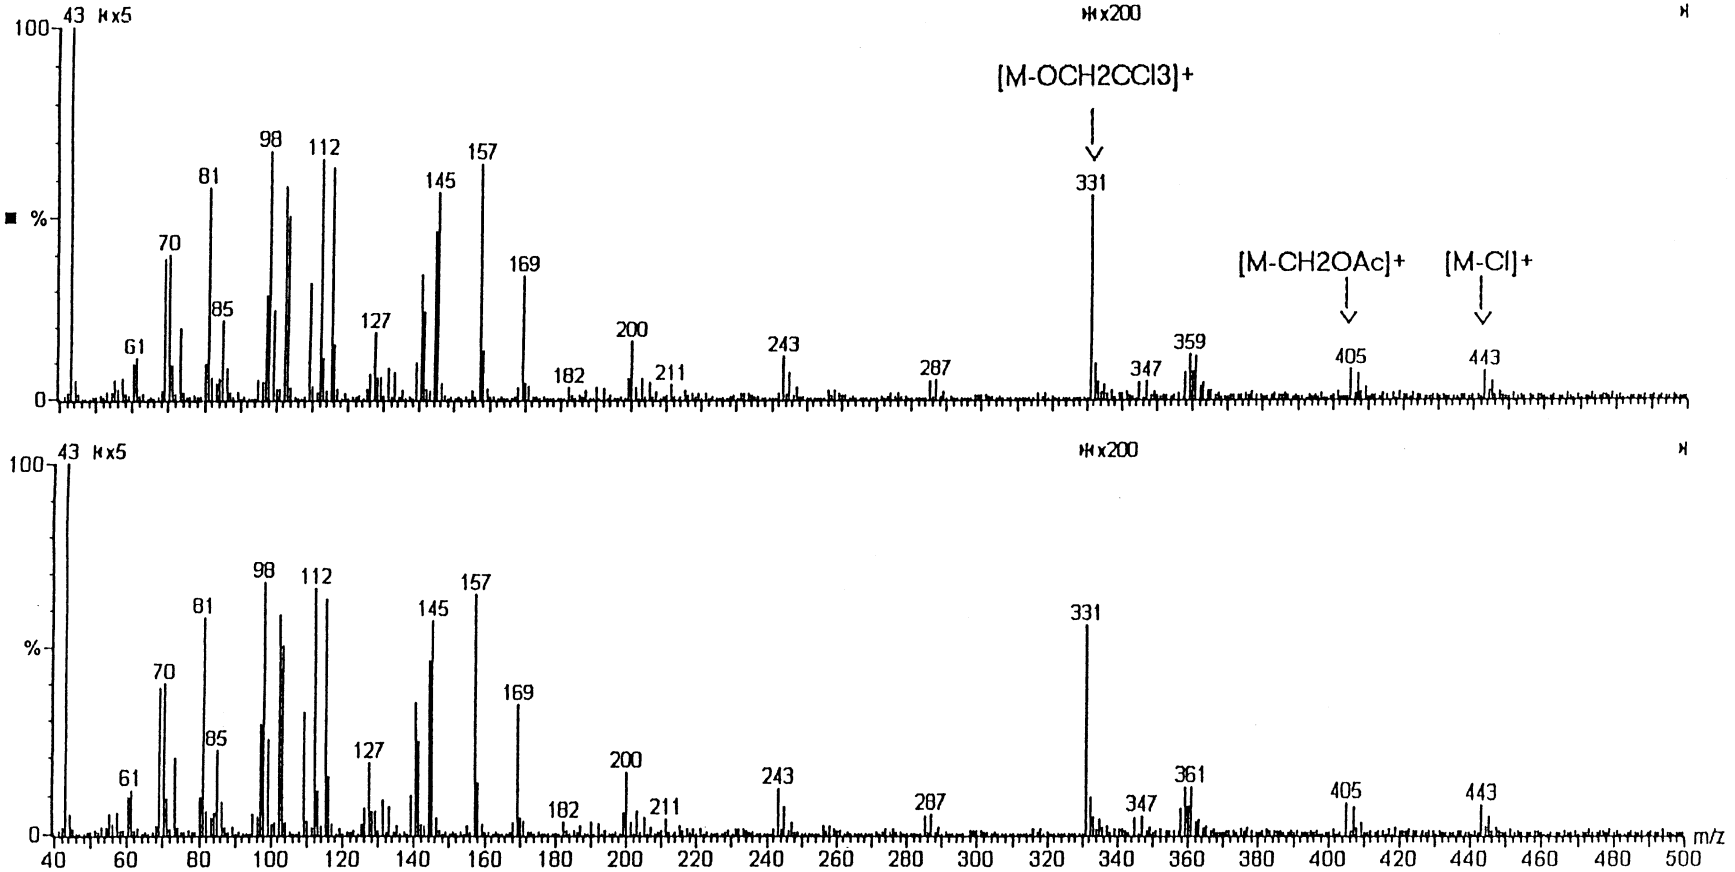

Fig. 4. Electron impact mass spectra of synthesized trichloroethyl-β-D-glucopyranose tetra-acetate standard (top) and the acetylated glycoside extracted from tobacco leaves (bottom).

was formed, while in tomato it was a β-gentiobioside. We propose that in tobacco, glucose is the sugar moiety, given the identical behavior of the glycoside and the synthesized glucoside both in terms of mass spectra and chromatographic retention time, as described above. However, we can not rule out the possibility of another hexose, such as galactose or mannose, as the conjugant, since such glycosides would produce similar mass spectra as a glucoside would. It is not known whether the GC system used in this study can distinguish between various monosaccharide conjugates, but the alditol acetates of the free monosaccharides, including glucose, fructose, and galactose, have been separated by Dormaar and Willms (1990) using the same typeof GC column. Therefore, the co-elution of the acetylation products of the glycoside and the authentic glucoside strongly supports the identification assignment.

Though only the monosaccharide conjugate was detected in TCE treated tobacco plants, conjugates with oligosaccharides can not be ruled out, since the acetylation products of such conjugates can not be detected with the instrumentation used in this study.

2.3. The fate of trichloroethanol in tobacco

Tobacco plants (both transgenic and wild-type) were treated with 10 mg l^{-1} trichloroethanol for 5 days. At the end of 5 days, 94±11% of total TCOH was recovered as either unaltered or glycosylated (including in growth media or in tissue). Twenty-two ±7% of the TCOH dose was recovered in plant tissue, mostly in glycosylated form (85–96% glycosylated, depending on tissue type). Table 2 shows that a significant amount of trichloroethanol can be taken up from roots and transported to leaves.

In plants dosed with TCE, leaves usually accumulate higher concentrations of oxidative metabolites such as TCOH than do roots (Newman et al., 1997, 1999). It was previously postulated that oxidation of TCE occurs primarily in leaves after TCE is transported from the roots (Newman et al., 1997). The results here showed that this is not necessarily the case, since plants can transport trichloroethanol into leaves, sometimes resulting in concentrations higher than those in roots.

There is additional evidence suggesting that TCE oxidation can occur in roots, and the resulting TCOH is glycosylated in the roots and transported to the shoots. When tobacco hairy root culture (see experimental) was treated with TCE or trichloroethanol, TCOH-glycoside was produced in both treatments (Table 1), showing that roots are capable of both TCE oxidation and TCOH glycosylation in the absence of the rest of the plant. Therefore, at least some of the TCOH and its glycoside are formed prior to transport to leaves. In addition, hairy roots accumulate much higher concentrations of total TCOH than do roots of whole plants (Table 1), whether upon TCE or TCOH treatment. In contrast, when tobacco leaves were excised and suspended in

Table 2
Trichloroethanol concentration (μg/g) taken up in hydroponic tobacco plants exposed to trichloroethanol in root solutions after 5 days

Plant number	Leaf	Stem	Root

2	27	13	30
3	21	10	49
4	18	12	36
5	22	13	32

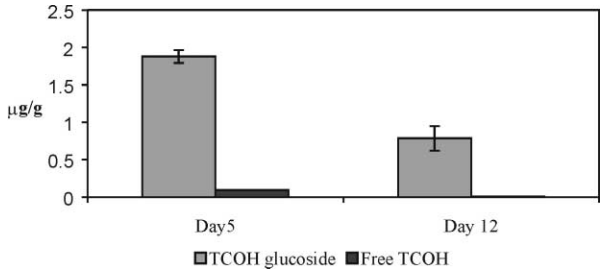

Fig. 5. Disappearance of trichloroethanol and its glucoside in hydroponic tobacco plants (average of two experiments). Plants were treated with TCE in the root solution for 5 days, then moved to uncontaminated media for 7 more days.

Table 3
Formation and glycosylation of trichloroethanol in various plants and cultures treated with TCE [a]

Plant	Tissue	Range of TCOH concentration (μg/g)	% Glycosylation of total TCOH
Poplar H11-11 [b]	Leaf	0.06–0.4	96±6 (n=3)[c]
	Stem	0.05–0.06	
Leuceana leucocephala	Leaf	0.6–5.8	88±14 (n=10)
	Stem	0.2–13	92±9 (n=8)
	Root	0.1–6	91±10 (n=5)
Belladonna hairy roots		0.7–1.2	85±1 (n=3)

[a] All plants were hydroponic and were dosed with 10 g /mL TCE or TCOH in root solutions for 5 days. TCOH concentrations listed were combined values of free and glycosylated TCOH.

[b] In hydroponic poplar dosed with TCE, free TCOH was detected in leaves only, and no TCOH, free or glycosylated, was detected in roots.

[c] n = number of replicates.

media containing TCE or TCOH, the concentrations of trichloroethanol accumulation in leaf tissue were much lower than in hairy roots, with no or low glycosylation (Table 1).

We propose, therefore, that glycosylation occurs in the roots, and the glycoside is transported to the shoots. On the other hand, the transport of the glycoside does not preclude the possibility that some glycosylation also occurs to free TCOH after it moves up to the shoots.

2.4. Trichloroethanol and its glucoside do not persist in tobacco

Fig. 5 shows that neither trichloroethanol nor its glucoside accumulates in tobacco plants after the plants are removed from TCE. The glucoside disappears at a slower rate (58% reduction over 5 days) than the free trichloroethanol (86%).

The decline of TCOH and TCOH-glycoside after removal of TCE source indicates further metabolism of TCOH, which is slower than the rate of TCE oxidation, since TCOH accumulates in the presence of a continuous supply of TCE. As discussed earlier, TCOH may oxidize to TCAA, which may be dechlorinated to such products as oxalic acid. The glycosides can be hydrolyzed when plants become injured or undergo other physiological changes (Lamoureux and Rusness, 1986). The glycosides may also become incorporated into polymers such as polysaccharides, and eventually be incorporated as cell wall components (for review see Colemann et al. 1997). All these pathways may contribute to the disappearance of TCOH in tobacco, and further research is needed to ascertain the final fate of TCOH and its glycoside.

The toxicity of trichloroethanol has not been clearly established, though other metabolites of TCE, such as TCAA and DCAA, are considered toxic (Lash et al., 2000). This study shows that in plants, trichloroethanol is stabilized by glycosylation. The toxicity of the glycoside is not known, but it is likely that once ingested, the glycoside will be hydrolyzed to release free trichloroethanol. The concentrations of trichloroethanol and its glycoside in all plants tested have been low (Tables 1 and 3). Nevertheless, it is a factor to be considered where phytoremediation is used.

2.5. Trichloroethanol and the glycoside as TCE metabolites in other plant species

In addition to tobacco, the oxidation of TCE to trichloroethanol and its corresponding glycosides also occurs in poplar, *L. leucocephala* (a tropical legume) and *Atropa belladonna* hairy roots (Table 3). Poplar and *leucocephala* are both candidates for phytoremediation of halogenated hydrocarbons. *A. Belladonna* is a medicinal plant used as a model system for *Agrobacterium rhizogenes*-mediated transformation of plants with mammalian genes of xenobiotic detoxification properties (Banerjee et al., unpublished). In all tissues tested, at least 85% of total TCOH was sugar conjugated. The only exception is suspension callus cells of poplar (Fig. 6). Though TCOH is readily taken up by the cells, only about $22 \pm 7\%$ was in the glycoside form. This suggests that full glycosylation of TCOH may be tissue dependent, as the callus cell culture is undifferentiated.

Doucette et al. (1997) found TCOH in saw palmetto, oak and castor bean plants on TCE contaminated sites, at up to 0.3 g/g dry weight basis. Assuming approximately 50–90% water content, this corresponds to about 0.03–0.15 μg/g fresh weight. Newman et al. (1999) found up to 0.56 μg/g free TCOH in poplar leaves in a controlled field study where poplar trees were treated with TCE in simulated groundwater. The concentrations reported here are

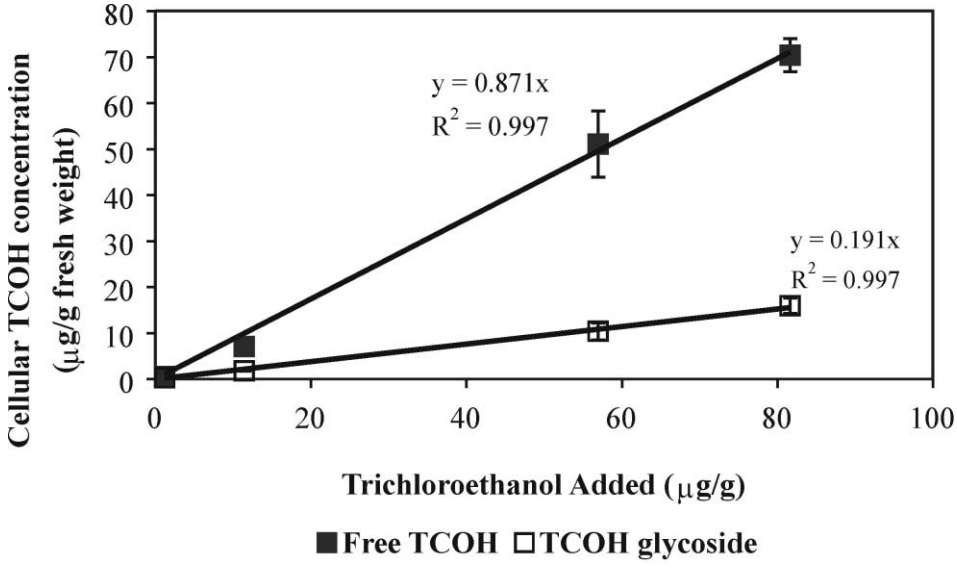

Fig. 6. Trichloroethanol uptake and glycoslation in poplar suspension cell culture. Every datum point is the average of triplicates.

in agreement with the overall range of concentrations reported elsewhere.

3. Concluding remarks

Fig. 7 shows an integrated scheme of the proposed TCE metabolism pathway in plants.

In mammals, detoxification of a xenobiotic substance is described as a three-phase process: oxidation (phase I), conjugation (phase II) and excretion (phase III) (Sandermann, 1994). Sandermann proposed the "green liver" concept to describe the similarity between plant and mammalian detoxification of xenobiotics. Previously, it has been shown that oxidation of TCE leads to similar metabolites in plants to those in mammals. This study

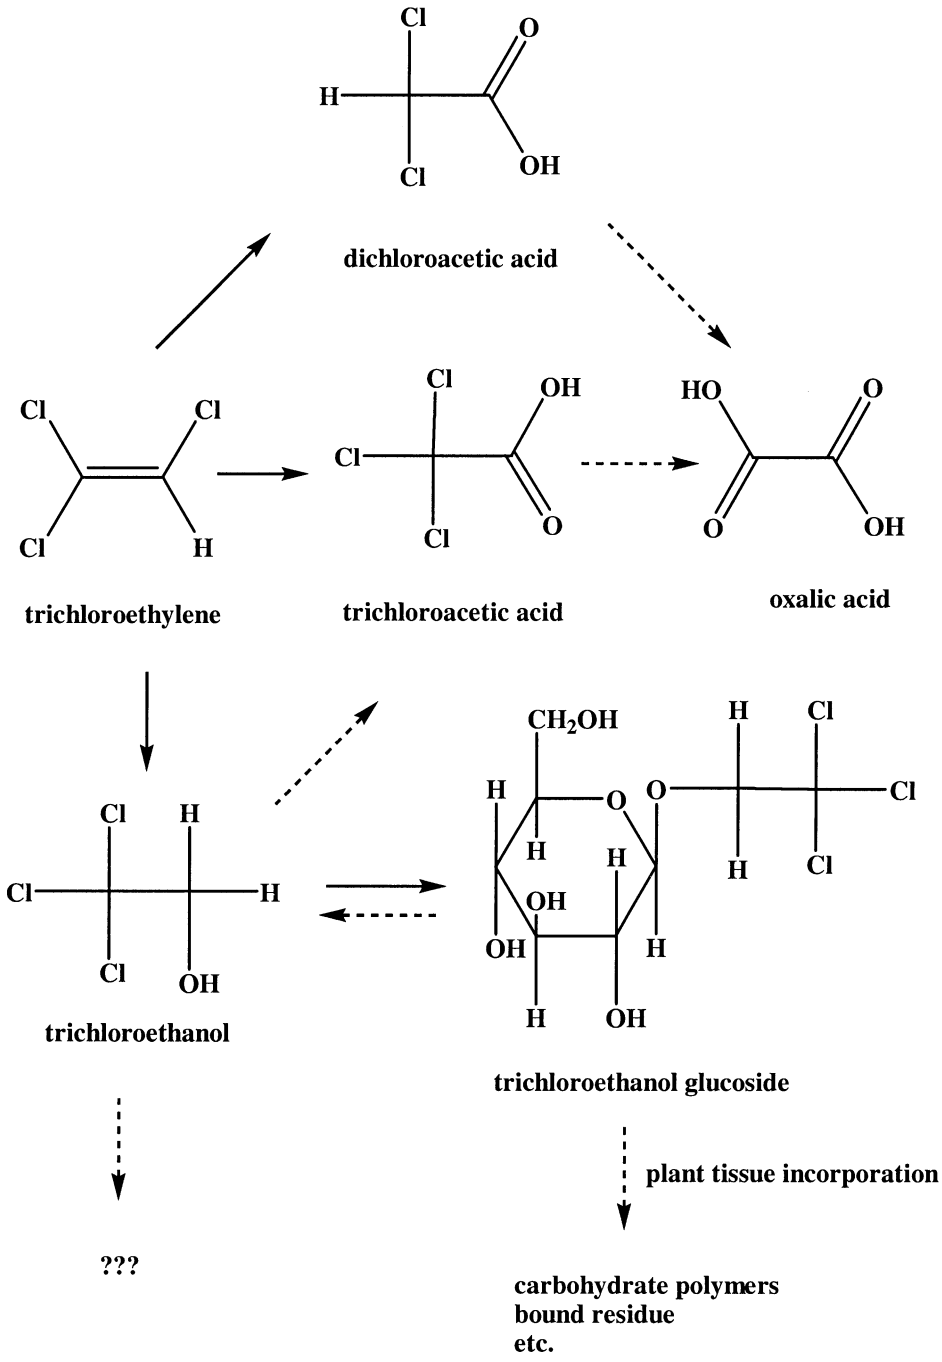

Fig. 7. Proposed scheme of TCE metabolism in higher plants. Solid arrows represent pathways that have been experimentally observed, and dotted arrows represent pathways that are speculated.

shows that one of the oxidation products, trichloroethanol, is conjugated to glucose, a process paralleled in mammals by conjugation to glucuronic acid (Lash et al., 2000). Radiolabel tracer studies showed that some of the radiolabels are transformed to bound residue, possibly incorporated to structural components of the plant. Thus, mammalian metabolism of TCE is closely mirrored in higher plants, adding to a growing body of evidence that support the green liver concept.

4. Experimental

Chemicals and enzymes were purchased from Sigma, St. Louis, MO, unless otherwise noted.

4.1. Plants, cell and tissue culture

Plant species used in this study were tobacco (*Nicotiana tabacum* cv. Xanthii), poplar (*Populus trichocarpa* x *Populus deltoides*), *Atropa belladonna* and *Leuceana leucocephala*.

Poplar suspension cells were prepared by transformation of H11-11 hybrid poplar (P. *trichocarpa* x P. *deltoides*) with *Agrobacterium tumefacien*s strain A281. The resulting callus cells were grown on hormone-free media, and the Agrobacteria were eliminated with antibiotics. Suspension cells were prepared from the callus, and maintained in media containing Murashige and Skoog (MS) basal salts, MS vitamins and 3% sucrose, pH 5.7–5.9. Cells were shaken on an orbital shaker at room temperature at 100 rpm, and were diluted weekly with fresh media.

Tobacco hairy root culture was prepared by inoculating surface sterilized tobacco leaves with 2-day culture of *Agrobacterium rhizogenes* strain R1000. The resulting hairy roots were excised and grown in liquid MS media containing 500 μg/ml cefotaxime to eliminate the Agrobacteria. One root tip was used to establish a clone of hairy root culture, which was maintained in MS media with 3% sucrose without hormones and antibiotics.

4.2. Assay for TCE metabolism

Hydroponic plants were generated by surface-sterilizing the stems in 10% bleach for 12 min and 10% iodophore for 2 min, and rinsing several times in sterile water. Plants were grown in sterile hydroponic solution and treated with TCE. as described in Doty et al. (2000).

Poplar suspension cell cultures were axenic as verified by microscopy and by plating samples of the cells periodically on non-selective media. The cells were grown to at least 0.2 g/ml, and diluted with fresh MS media to approximately 0.06 g/ml. Aliquots of the diluted cells (50 ml) were distributed into 125-ml glass 2-armed Erlenmeyer flasks. The two arms of each flask were sealed with a screw cap with Teflon-lined septum and a screw cap with Teflon mini-nert valve (Pierce, Rockford, IL), respectively. TCE saturated water (~1000 ppm) was chilled on ice to minimize evaporation, and injected with a glass gastight syringe (Hamilton, Reno, NV) through the mini-nert valve. The flasks were shaken at 100 rpm at room temperature for 5 days. Cell suspensions were vacuum filtered, and the cells collected on filter paper were weighed and flash frozen in liquid nitrogen, and stored at −80 °C until analysis.

Hairy roots were grown to a dense stage and transferred to 2-armed Erlenmeyer flasks. TCE treatment was carried out as described above in the case of cell culture. At the end of the 5-day incubation, roots were removed from media and briefly blotted dry on filter paper, weighed and flash frozen in liquid nitrogen, and stored at −80 °C until analysis.

4.3. Assay for TCOH uptake and metabolism

Hydroponic plants, cells and hairy roots were treated with TCOH the same way as in the case of TCE, except the flasks were not air-tight. Loosely fitted screw caps or aluminum foil-covered cotton plugs were used to keep the solutions sterile.

4.4. Determination of TCOH and TCOH-glycoside in plant tissue

The procedures described below were modified from Miller (1941a,b) and Mortimer and Shields (1995). Plant tissue or filtered suspension cells were ground to a powder in liquid nitrogen, then extracted twice with five to ten volumes of acetone. The mixture of plant tissue and acetone was vacuum filtered with a Büchner funnel and Whatman No. 1 filters. The filtrate was reduced in a rotary evaporator at room temperature. After all the acetone was removed, the aqueous extract was clarified by centrifugation at 12,000 rpm for 5 min. The supernatant was divided into two equal aliquots. One aliquot was hydrolyzed with an equal volume of almond ß-glucosidase (1 mg/ml in potassium phosphate buffer at pH 5.0). The other aliquot received an equal volume of the same concentration of BSA as control. The reactions were carried out at 37 °C for 2 h. The reaction mixtures were then transferred to glass centrifuge tubes, and a half volume of 1 N H_2SO_4/10% NaCl solution was added to each tube. The mixture was vortexed for 1 min, and 10 ml methyl-*tert*-butyl ether (MTBE) was added, followed by vortexing (1 min) and centrifugation (6000 rpm, 5 min). The MTBE layer was transferred to a glass vial containing 2 g Na_2SO_4 and dried for 1 h. The MTBE extract was transferred to an autosampler vial and analyzed on GC–ECD. BSA treatments give free TCOH concentrations, and glucosidase treatments lead to total TCOH concentrations (free plus sugar conjugated). Percentage glycosylation values were calculated

as follows: % glycosylation = ([TCOH]$_{total}$–[TCOH]$_{free}$)/([TCOH]$_{total}$)*100.

4.5. Isolation and acetylation of trichloroethanol-glycoside from plant tissue

Plant tissue was ground to a powder in liquid nitrogen, then extracted as described above. After rotary evaporation and centrifugation, the aqueous extract was transferred to a glass flask and washed with MTBE and hexane in a separatory funnel. The washed extract was purged with a gentle stream of nitrogen to remove traces of organic solvents, and lyophilized to a powder. Approximately 50 mg of the powder was weighed into a 10-ml glass vial with a conical bottom and a magnetic stirrer (Reacti-vial, Pierce). Pyridine (1 ml) was added to dissolve the powder, followed with the addition of 0.5 ml acetic anhydride (Fisher Scientific, Houston, TX). The mixture was stirred at room temperature for 2 h. The acetylated glycoside was precipitated by addition of 10 ml ice cold water and centrifugation (8000 rpm, 10 min). After removal of the supernatant, the pellet was dissolved in 1 ml acetone, dried with anhydrous Na_2SO_4, and analyzed with GC-MS.

4.6. Synthesis of trichloroethanol-glucoside tetra-acetate

The synthesis was modified from Miller (1941b). In a 125-ml glass flask, 6.4 ml 2,2,2-trichloroethanol was dissolved in 30 ml benzene and cooled on ice. 5 g 2,3,4,6-Tetra-*O*-acetyl-D-glucopyranosyl bromide (Arcos, Fisher Scientific) and 4.5 g silver carbonate was added, and the mixture was allowed to stand on ice for 3 h, and was shaken frequently. The mixture was then allowed to stand at room temperature overnight. The remaining solids were removed by filtration, and washed with benzene. The filtrate was evaporated in vacuo. After the removal of benzene, the resulting syrup was washed with water, and dissolved in absolute ethanol for GC–MS analysis.

4.7. Gas chromatography–mass spectrometry (GC-MS)

ECNCI–MS and EI–MS were performed on Finnigan Trio 1000 (ThermoQuest Corp., San Jose, CA) and Micromass Trio 2000 (Micromass Ltd, Manchester, UK) quadrupole mass spectrometers, respectively. Each instrument was directly interfaced to an Hewlett-Packard 5890 gas chromatograph (Agilent Technologies, Palo Alto, CA) fitted with a J&W DB-5 (J&W Scientific, Rancho Cordova, CA) fused-silica capillary gas chromatographic column (30 m×0.32 mm I.D., 0.25 m film thickness) and operated with helium as carrier gas (head pressure, 5 psi).

The ionization conditions for the respective instruments were as follows: ECNCI using methane as a moderating gas (~1 mbar), with a filament emission current and electron energy of 100 μA and 75 eV respectively; and EI with an emission and energy of 200 μA and 70 eV, respectively. The ion source temperatures in both cases were 200 °C with the GC/MS interfaces held at 250 °C.

4.8. Gas chromatography–electron capture detection (GC–ECD)

Routine GC–ECD analysis of trichloroethanol and other chlorinated metabolites was performed with a Perkin Elmer autosystem gas chromatograph (Perkin Elmer, Norwalk, CT) with a Restek (Restek Corp., Bellefonte, PA) XTI-5 column (30 m×0.25 mm I.D.,1 m film thickness).

Institute of Marine Biology, Far East Branch, Russian Academy of Sciences, 690041 Vladivostok, Russia

Received 9 April 2001; received in revised form 13 July 2001

Abstract

The influence of solar irradiance and seasons on prostaglandin (PG) and arachidonic acid (AA) content in the marine red alga *Gracilaria verrucosa* (Huds.) Papenf. (unattached form) was investigated. PGA_2, PGE_2, PGF_2, and 15-keto-PGE_2 were isolated from the alga, quantitatively analyzed as 4-methyl-7-methoxycoumarin esters by high-performance liquid chromatography, and their chemical structures were confirmed by ^1H NMR. In June–September, the PG content in the alga was relatively stable (420 μg/g of dry wt. of $PGE_2 + PGF_2$; 40 μg/g of PGA_2) and it increased 1.5 times in October. The highest level of PGs was detected in November (2500 μg/g of $PGE_2 + PGF_2$; 74 μg/g of PGA_2) when water temperature was fairly low (5–10 °C). Algae grown for five months at 50% of incident photosynthetic active radiation (PAR_0) contained two times less PGE_2 and PGF_2 than algae grown under natural conditions, but the amount of these PG in algae grown at 5% of PAR_0 was close to the normal level. On the contrary, when algae were grown at 5% of PAR_0 the content of PGA_2 increased up to 4 times compared to algae cultivated at 100% PAR_0. In June–November, the amount of AA in total algal lipids slightly varied from 48.9 to 56.7% and did not virtually depend on the light intensity. The probable reasons of the PG content variation in response to environmental factors are discussed. © 2001 Elsevier Science Ltd. All rights reserved.

1. Introduction

Red algae are rich in polyunsaturated fatty acids (PUFA) with 20 carbon atoms, mainly arachidonic (AA) and eicosapentaenoic acids, which are precursors of prostaglandins (PG). It has been demonstrated that marine plants are capable of metabolizing C_{20} PUFA to eicosanoids via various oxidative pathways. Oxidized fatty acid derivatives were isolated from fairly many species of Rhodophyta (Gerwick and Bernart, 1993). Algae of the genus *Gracilaria*, as well as *Gracilariopsis*, are of particular interest because they contain eicosanoids characteristic of the higher plants and human. Acyclic eicosanoids such as 12-HETE and 12-HEPE were found in *Gracilariopsis lemeneiformis* (Jiang and Gerwick, 1991). Two isomers of LTB_4 (6-*trans*-LTB_4 and 6-*trans*-12-*epi*-LTB_4,) as well as 8-HETE were detected in *Gracilaria asiatica* (Sajiki and Kakimi, 1998; Sajiki, 1999). However, members of the genus *Gracilaria* are distinguished from other red algae by that they contain PG. Thus, PGE_2 and PGF_2 were isolated from *Gracilaria lichenoids* (Gregson et al., 1979); PGE_2 and 15-keto-PGE_2 were found in *G. asiatica* (Sajiki, 1999). *Gracilaria verrucosa* was found to contain PGA_2 in addition to PGE_2; however, its presence in the alga may be a consequence of partial non-enzymatic dehydration of PGE_2 (Fusetani and Hashimoto, 1984). These PG from Japanese *G. verrucosa* appear to be responsible for a gastro-intestinal disorder, known as ''ogonori'' poisoning, which is associated with ingestion of the popular edible seaweeds in Japan (Fusetani and Hashimoto, 1984).

The most widespread *G. verrucosa* in the Sea of Japan is the attached form of alga growing on a rocky substrate. However, there is an unattached form of the same species found in lagoons, which differs from the

PII: S0031-9422(01)00321-1

attached form by that it reproduces asexually, by fragmentation (Tityanova et al., 1990). The unattached form contains much more agar and twice as much lipids as the attached one (Lapshina et al., 1993; Khotimchenko and Levchenko, 1997).

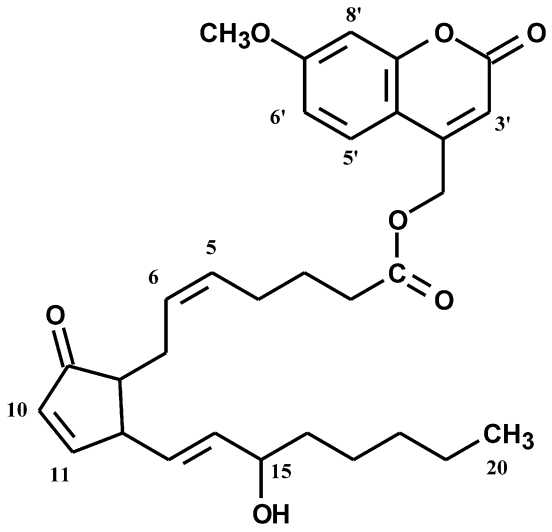
The aim of the present study was to determine the PG composition and the influence of environmental factors such as season and solar irradiance on the PG content in the unattached form of *G. verrucosa*. In addition, we have investigated the relation between contents of AA and PG in this alga.

2. Results and discussion

2.1. Identification of PG in the alga and optimization of HPLC analytical method

We identified prostaglandins PGA_2, PGE_2, PGF_2, and 15-keto-PGE_2 as major eicosanoids in the unattached form of red alga *G. verrucosa*. The presence of these compounds in the form of methyl esters was confirmed by co-chromatography with the authentic PG standards using TLC and HPLC. It was shown that at least 25 mg PGE_2 methyl ester, 8 mg 15-keto-PGE_2 methyl ester, and 20 mg PGF_2 methyl ester can be isolated from 1 kg of fresh *G. verrucosa* using a combination of chromatographic methods (Nevshupova and Imbs, 1999). The structure of PGE_2, PGF_2, and 15-keto-PGE_2 was unequivocally proved by analysis of their ^{1}H NMR spectra which were identical to those of authentic PG methyl esters and the spectra reported previously (Schneider et al., 1977; Fusetani and Hashimoto, 1984). Unfortunately, the quantity of obtained PGA_2 methyl ester was not sufficient for correct NMR analysis. The presence of PGF_2 in the attached form of *G. verrucosa* has not been reported in recent works (Sajiki and Kakimi, 1998; Sajiki, 1999).

To determine the quantity of PG in *G. verrucosa* samples, we applied the HPLC analysis of their 4-bromomethyl-7-methoxycoumarin (BrMMC) derivatives. Firstly, a semi-preparative amount of BrMMC derivatives of individual PGB_2, PGD_2, PGA_2, PGE_2, and $PGF_{2\alpha}$ was synthesized with a yield more than 80%. We applied the reaction between organic acid salt and BrMMC in the presence of a phase-transfer catalyst in non-aquiver solvent as described earlier (Tsuchiya et al., 1982; Berger and Petz, 1991) with some variances. Acetonitrile usually used as the solvent was partly replaced with chloroform to increase the solubility of BrMMC and the lipid extract of *G. verrucosa*. The optimum temperature was 50–55 °C and time 50–60 min. The structure of the synthesized compounds was confirmed by the ^{1}H NMR analysis. As an example, the structure of (4′-methylene-7′-methoxycoumarin)-PGA_2 ester (**1**) and selected ^{1}H NMR signal assignments (Table 1) are presented. The spectrum showed a terminal methyl signal at δ 0.89 (*t*), one carbinol methine at δ 4.09 (*m*), three sets of double bound at δ 5.40, 5.43, 5.61, 5.70, and a methylene adjacent to a carboxyl group at δ 2.32. The values of 5, 6, and 16 Hz coupling constants are typical of the $\Delta5(Z)$ and $\Delta13(E)$ olefin functionalities. A set of double bound at δ 6.18, 7.50 suggested the presence of α,β-unsaturated cyclopentenone. These features were quite similar to those of PGA_2 ester. The spectrum also showed signals of four coumarin protons at δ 6.33, 6.84, 6.99, 7.42 and a methoxy group at δ 3.66 (*s*) (Table 1). The ^{1}H NMR spectra of other synthesized compounds contained the described signals of the methylmethoxycoumarin group and signals similar to ^{1}H NMR shifts of PG esters published elsewhere (Schneider et al., 1977; Chen and Janda, 1997, 1998; Mikolajczyk et al., 2000).



1

An isocratic reversed-phase HPLC separation of the BrMMC derivatives of the five synthesized PG was achieved within 30 min in a single run. The peaks of esters were completely resolved when a 25-cm column was used. With a 15-cm column, the resolution of PGE_2 and PGF_2 was poorer, but the analysis time was reduced to 16 min. As a rule, we determined the sum of PGE_2 and PGF_2 because many tests on a 25-cm column showed that the amount of PGE_2 related to that of PGF_2 as 25:10 and this value was quite stable in all experiments.

Fusetani and Hashimoto (1984) successfully used hot methanol to extract PG from *G. verrucosa*. Our experiments showed that the heating time strongly influences the content of PG in the prepared extract. The maximum content of PG was isolated from alga after 5 min heating, but the PG level fell drastically after 1 h heating (Table 2). A temporary increase in the amount of PGA_2 in 30 min was most likely caused by non-enzymatic

dehydratation of PGE_2. A long-period soaking of *G. verrucosa* (up to 48 h) in methanol at room temperature recovered PG with a very low yield. The classic method of total lipids extraction with chloroform–methanol was not suitable because of chromatographic difficulties in detecting extremely low levels of PG in algal total lipid extract.

It should be noted that our attempts at the direct HPLC analysis of crude reaction mixture after derivatization with BrMMC were unsuccessful. To remove an excess of BrMMC and non-polar substances, we purified BrMMC derivatives on a solid-phase extraction tube with silica gel. All PG esters were quantitatively recovered from the tube without appreciable losses.

Thus, high-performance liquid chromatography of the BrMMC derivatives of PG has proven to be a powerful method for the analysis of eicosanoids in marine algae. Using this method, we obtained new data on the variation of *G. verrucosa* PG content in relation to season and light intensity.

2.2. Changes of PG and AA content related with seasons and solar irradiance

In the lagoons of southern Primorye, the unattached form of *G. verrucosa* begins to grow in May. Growth is highest in July–August; in September–October it is markedly retarded, and fragmentation of the thalli commences. In December–March, alive alga winters frozen into the ice (Tityanova et al., 1990).

In June–September 1999, the unattached form of *G. verrucosa* did not show significant differences in the levels of 15-keto-PGE_2, PGE_2, and PGF_2 but there were higher levels of the PG in algae collected in October (Table 3). The highest level of the above PG was detected in November when water temperature is relatively low (5–10 °C). In contrast, no significant difference ($P > 0.05$) in the PGA_2 content of *G. verrucosa* was found in June-November (Table 3). Measurements of the levels of PG in *G. verrucosa* were repeated at the next year (2000) and the results did not differ significantly ($P < 0.05$, data not shown). Recently, an appreciable increase in the PGF_2 level in February compared to July was described for the attached form of *G. asiatica* growing in the Bay of Tokyo, Sea of Japan (Sajiki, 1997).

A variety of factors can be responsible for the accumulation of PG in the cold season: environmental conditions (solar irradiance, seawater temperature, contents of dissolved components, etc.), level of the PG biosynthesis substrate (arachidonic acid) in algal tissues, activity of enzymes of eicosanoid synthesis, stage of life cycle, and others.

We found that the level of PG in the unattached form of *G. verrucosa* depends on solar irradiation. The content of PG in algae cultivated during 5 months under

Table 3
Changes in the content of prostaglandins (μg/g dry wt.) in *G. verrucosa* (unattached form) during June–November

Prostaglandin	Collection time				
	June	July	September	October	November
15-keto-PGE_2	90 ± 6^a	86 ± 18^a	120 ± 42^a	$231 \pm ^b$	306 ± 18^c
$PGE_2 + PGF_2$	398 ± 21^a	413 ± 45^a	429 ± 64^a	640 ± 43^b	2468 ± 112^c
PGA_2	40 ± 4^a	47 ± 14^a	46 ± 12^a	67 ± 17^a	74 ± 4^a

Data are mean ± S.D. of triplicates. Different superscript letters in the same measurements are significantly different ($P < 0.01$) among the same prostaglandin.

Table 4
Changes in the content of prostaglandins (μg/g dry wt.) in *G. verrucosa* (unattached form) grown during June-October at various levels of photosynthetic active radiation (PAR_0)

Prostaglandin	PAR_0		
	95%	50%	5%
15-keto-PGE_2	231 ± 3^a	113 ± 12^b	213 ± 15^a
PGE_2+PGF_2	640 ± 43^a	332 ± 52^b	496 ± 1^c
PGA_2	67 ± 17^a	122 ± 20^b	226 ± 27^c

Data are mean ± S.D. of triplicates. Different superscript letters in the same measurements are significantly different ($P<0.05$) among the same prostaglandin.

different light intensity are shown in Table 4. The amount of 15-keto-PGE_2, PGE_2, and PGF_2 in algae exposed to 50% of incident photosynthetic active radiation (PAR_0) was about half that of the control sample ($P<0.01$), but the quantity of 15-keto-PGE_2 was relatively stable and the level of PGE_2 and PGF_2 were slightly lower ($P<0.05$) in algae grown under extremely low illumination conditions (5% PAR_0). On the contrary, the decreasing light intensity led to a consistent increase in PGA_2 in the algae ($P<0.05$). Hence, it is highly improbable that the reduced solar irradiance in October-November can cause the observed high level of main PG (except for PGA_2) in *G. verrucosa* in the cold period. Conceivably, the mechanism of formation of PGA_2 in *G. verrucosa* differs from that of the other PG, and part of PGA_2 originated from PGE_2 by a non-enzymatic process which intensified under adverse environmental conditions.

The changes in the fatty acid composition of a number of *Gracilaria* species cultivated under different environmental conditions were previously investigated, and it was shown that the arachidonic acid is the dominant fatty acid (Khotimchenko and Levchenko, 1997). Our data on *G. verrucosa* are indicative only of a slight increase in AA content (Table 5) in total algal lipids in the cold period, as well as under reduced solar irradiance (data not shown), and confirm the conclusion that the increase in AA content due to low temperature and low light intensity, which has been demonstrated in higher plants, is not consistent in *G. verrucosa* (Dawes et al., 1993).

Table 5
Content of arachidonic and eicosapentaenoic acids (% of total fatty acids) in *G. verrucosa* (unattached form) in June–November

Collection time	Content of fatty acids (%)		Seawater temperature (°C)
	Arachidonic	Eicosapentaenoic	
June	48.9	0.9	17
July	49.2	1.1	20
August	46.6	0.5	22
September	49.6	0.5	18
October	45.9	5.5	10
November	56.7	1.6	5

There was only a slight increase in AA content in November which did not correlate with a 6-fold rise in PG amount in the alga. On the other hand, the inhibition of PG synthesis in *G. verrucosa* by a high level of AA was postulated earlier (Sajiki, 1997). Thus, it is improbable that the seasonal changes in PG content in the unattached form of *G. verrucosa* were regulated by the AA level in algae lipids.

It is also unlikely that the total level of PG in *G. verrucosa* is dependent on the mode of reproduction because both the attached form, which reproduces sexually, and the unattached form, which reproduces vegetatively way, have markedly higher PG content in the summer than in the winter.

It should be noted that the PG content in the attached form of *G. verrucosa* collected at the same site was twice lower (207 ± 14 μg/g dry wt. of PGE_2+PGF_2, July sample) compared to the unattached one. This difference in PG content can be attributed to that the unattached form of the alga synthesized and accumulated twice as much lipids as the attached one, 5.6 and 2.8 mg/g, respectively (Khotimchenko and Levchenko, 1997).

The major lipid classes of *Gracilaria* that contain AA are monogalactosyldiacylglycerol (75% of AA), and phosphatidylcholine (73% of AA) (Araki et al., 1990). Since neither phospholipase A_1 nor A_2 activity was detected in raw alga (Sajiki, 1997), the splitting-off of arachidonic acid by acylhydrolases from monogalactosyldiacyl glycerol can be considered as a probable source of the substrate for PG synthesis in *G. verrucosa*. In this event, the PG level in *G. verrucosa* can be modulated through regulation of the activity of acylhydrolases or enzymes of the AA oxidation cascade.

It is most likely that the increased PG level in *G. verrucosa* is a response to decreased water temperature in the fall-winter period and it is not related to reduced solar irradiance. *G. verrucosa* is the rare algal species that contains PG and the level of PUFA in this alga is little dependent on water temperature, so we can postulate that PG may be involved in processes allow the algal tissue to survive in cold water and ice.

3. Experimental

3.1. Study site and sampling

Samples of *G. verrucosa* (unattached form) were collected during June–November 1999 in lagoons of southern Primorye (Peter the Great Bay, the Sea of Japan). Algae were grown in lagoons by the method of "rope culture" (Titlyanov et al., 1995) from June through October under natural light at 95% of incident

photosynthetic active radiation (PAR_0). Irradiance level was maintained using neutral density filters (50 and 5% PAR_0) and determined with an LI-190SA flat quantum sensor (LI-Cor, Lincoln, Nebraska). All samples were immediately frozen and stored at −20 °C not more than 1 week before analysis.

3.2. Isolation of PG methyl esters from G. verrucosa

Frozen alga (347 g) was extracted with $CHCl_3$–MeOH (1:2), the total lipid extract (730 mg) was redissolved in 10 ml of Et_2O, and 20 ml of saturated solution of diazamethane in Et_2O at 0 °C was added to obtain carboxylic acid methyl esters. After 1 h, the solution was evaporated and the residue was separated by low pressure silica gel column chromatography with gradient from $CHCl_3$ to MeOH. Fractions containing total PG methyl esters were additionally separated using a gradient of C_6H_6–EtOAc. Finally, pure PGE_2 methyl ester (9 mg), 15-keto-PGE_2 methyl ester (3 mg) and PGF_2 methyl ester (7 mg) were isolated by preparative HPLC with MeOH–H_2O (4.5 ml min^{-1}) on a Zorbax ODS column (25 cm×9.4 mm i.d.) with a refractive index detector. TLC of the obtained PG methyl esters was carried out on silica gel plates with C_6H_6–EtOAc (1:1); analytical HPLC was performed on a Zorbax ODS column (25 cm×4.6 mm i.d.) with UV detectors (200 nm) in MeOH–H_2O (65:35) at a flow rate of 1 ml min^{-1}. ^1H NMR spectra of PG esters were recorded at 250 MHz in $CDCl_3$.

3.3. Synthesis of 4′-methylen-7′-methoxycoumarin esters of PG

The work solutions of 21 mg dicyclohexyl-18-crown-6 (DCHC) in 0.2 ml CH_3CN and 15 mg 4-bromomethyl-7-methoxycumarin (BrMMC) in a mixture of 0.1 ml CH_3CN and 0.9 ml $CHCl_3$ were prepared. 1 mg PG was transferred with 0.1 ml $CHCl_3$ into a 1 ml reaction vial with a screw cap. After adding 0.05 ml of the DCHC solution, 0.2 ml of the BrMMC solution, and 0.1 g K_2CO_3, the PG reacted for 1 h at 55 °C. The reaction mixture was filtered, evaporated, and the PG ester was purified by TLC in $CHCl_3$–MeOH (9:1). BrMMC derivatives of PGB_2, PGD_2, PGA_2, PGE_2, and $PGF_{2\alpha}$ were synthesized. ^1H NMR spectra of PG derivatives were recorded at 250 MHz in $CDCl_3$.

3.4. Analysis of the PG content in G. verrucosa

About 120 g of freshly frozen alga were homogenized with 200 ml of MeOH, heated to 60C, and after 5 min filtered under vacuum. The solution was evaporated to a volume of 50 ml, acidified to pH 2, and extracted twice with 50 ml of EtOAc. Evaporation to dryness of combined extracts resulted in 97 mg of polar lipids. About 30 mg of the polar lipids were transferred with 0.2 ml $CHCl_3$ into a 1 ml reaction vial with a screw cap. After adding 0.1 ml CH_3CN, 0.05 ml of the DCHC solution, 0.2 ml of the BrMMC solution, and 0.2 g of K_2CO_3, the mixture was heated at 55 °C for 1 h. The reaction mixture was filtered, dried, dissolved in C_6H_6–EtOAc (85:15), and placed on a 3 ml solid-phase extraction tube with silica gel. The tube was washed with 2 ml of the same system, then the crude PG esters were eluted with 3 ml $CHCl_3$–MeOH (1:1). The last fraction was evaporated, solved in 0.2 ml MeOH and a 10 μl portion was analyzed by HPLC on a Zorbax ODS column (15 cm×4.6 mm i.d.) with a UV detector at 313 nm. An isocratic system of MeOH–H_2O (70:30) at a flow rate of 1.5 ml min^{-1} was used. The quantity of PG esters was calculated using calibration graphs of peak areas of PG esters standards synthesized previously.

3.5. Fatty acid (FA) analysis

Lipids were extracted according to Bligh and Dyer (1959). Fatty acid methyl esters (FAME) of total lipids were prepared according to Carreau and Dubacq (1979) and purified by TLC in C_6H_6. Analysis of FAME was carried out on a GC equipped with a flame-ionization detector, a fused quartz capillary column (30 m×0.25 mm i.d.) with Supelcowax 10M; split ratio 1:30, carrier gas He (1 ml min^{-1}). The column and detector temp was 210°, the injector temp was 240°. Identification of FAME was confirmed by chromatographic comparison with authentic standards and calculation of ECL (Christie, 1988).

3.6. Statistical analysis

Statistical analysis of the data was carried out as described elsewhere (Friedlander et al., 1993). Significant differences were located using Duncan's new multiple range test (one-way ANOVA's) and Student's *t*-test.

Abstract

Twenty-four aromatic metabolites belonging to cyanogenins, lignans, flavonoids, and phenolic glycosides were obtained from *Sambucus nigra*. Structures were determined on the basis of their spectroscopic features. Two compounds have been isolated and identified as (2*S*)-2-*O*-β-D-glucopyranosyl-2-hydroxyphenylacetic acid and benzyl 2-*O*-β-D-glucopyranosyl-2,6-dihydroxybenzoate. All the compounds have been assayed on dicotyledons *Lactuca sativa* (lettuce) and *Raphanus sativus* (radish) and monocotyledon *Allium cepa* (onion) to test their stimulatory or inhibitory effects on seed germination and radicle elongation. Cyanogenins have a mainly inhibiting effect while lignans stimulate the growth. Some compounds show different effects on dicotyledons and monocotyledons.

Keywords: *Sambucus nigra*; Adoxaceae; Cyanogenins; Lignans; Flavonoids; Phenolic glycosides; Allelopathic activity

1. Introduction

Weed interference, which consists of the effects of competition and/or allelopathy, represents a serious threat to several crops. *Sambucus nigra* L., a shrub widely found throughout Italy, causes large crops losses, and, in a previous study Jensen and Nielsen (1973) reported the presence of cyanogenic glycosides. These compounds are considered highly phytotoxic since the action of microbes in the rhizosphere produces HCN and benzaldehydes (Conn, 1981). In a study of the detrimental effects of weeds on crops, we have reinvestigated *S. nigra* and, together with the cyanogenic glycosides **1**–**5** (Della Greca et al., 2000a) and three related compounds **6**–**8** (Della Greca et al., 2000b), we have isolated the phenolic glycosides **9**–**13** besides the lignans **14**–**19** and the flavonoids **20**–**24**. All the compounds have been tested for their effects on the seed germination and growth of *Lactuca sativa* L., *Raphanus sativus* L., and *Allium cepa* L.

2. Results and discussion

The air dried leaves of *S. nigra* were sequentially extracted with petrol, EtOAc, and MeOH. A preliminary seed germination test on *R. sativus* evidenced a strong inhibitory activity only of the MeOH extract, which was distributed between water and EtOAc (Scheme 1). The organic fraction was chromatographed on silica gel column to give fractions A–C. Chromatography on Sephadex LH-20 of fraction A, eluted with $CHCl_3$, gave the degraded cyanogenins **6**–**8** (Della Greca et al., 2000b) along with the neolignan (2*R-trans*) 2,3-dihydro-2-(4-hydroxy-3-methoxyphenyl)-3-(hydroxymethyl)-7-methoxy-5-benzofuranpropanol acetate (**14**) (Popoff and Theander, 1975) and the lignans (+) pinoresinol (**17**) (Pelter et al., 1982), (+) medioresinol (**18**) (Zhuang et al., 1982) and (+) lariciresinol (**19**) (Katayama et al., 1992). Fraction B, eluted with EtOAc, was re-chromatographed on Sephadex LH-20 to give the glucoside **13**, besides a further two neolignans, identified as (2*R-trans*)-2,3-dihydro-2-(4-hydroxy-3-methoxyphenyl)-3-(hydroxymethyl)-7-methoxy-5-benzofuran-propanol (**15**) (Toshio et al., 1989) and (2*R-trans*)-2,3-dihydro-2-(4-hydroxy-3-methoxyphenyl)-3-(hydroxymethyl)-7-

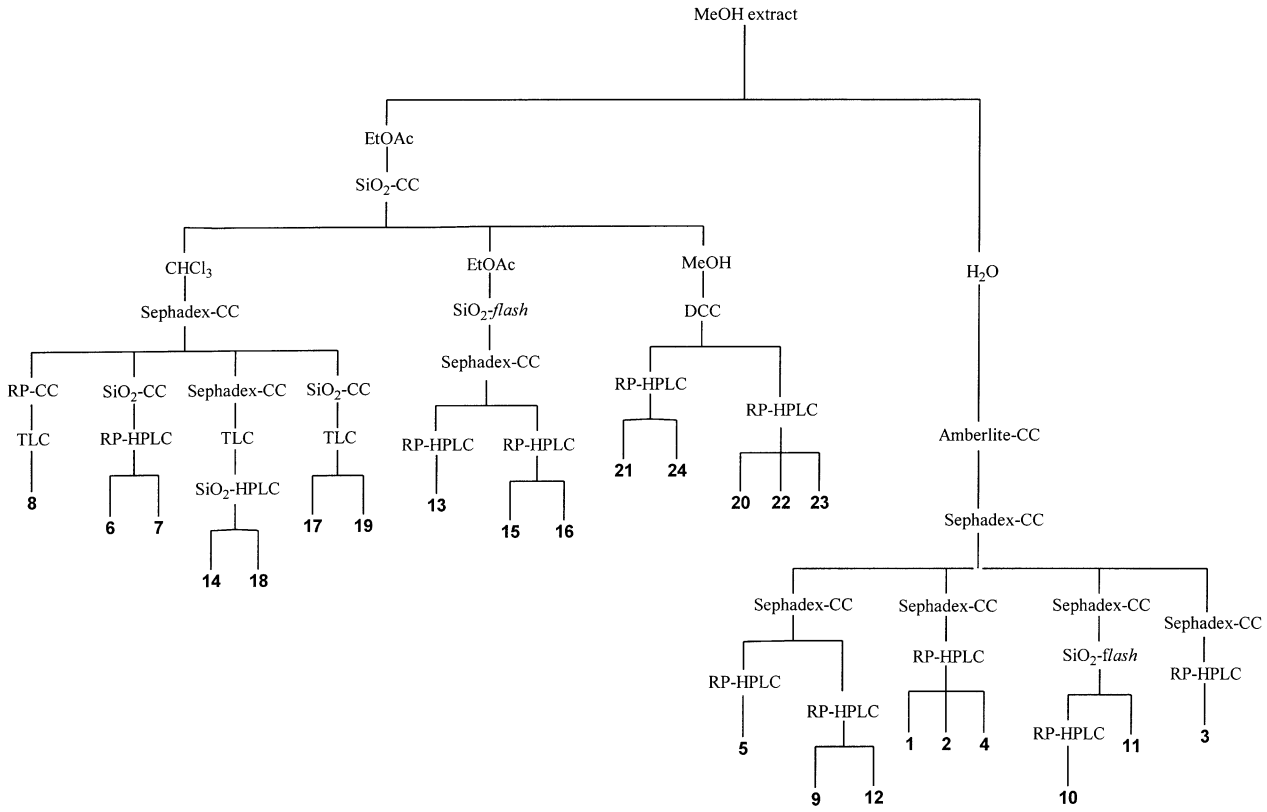


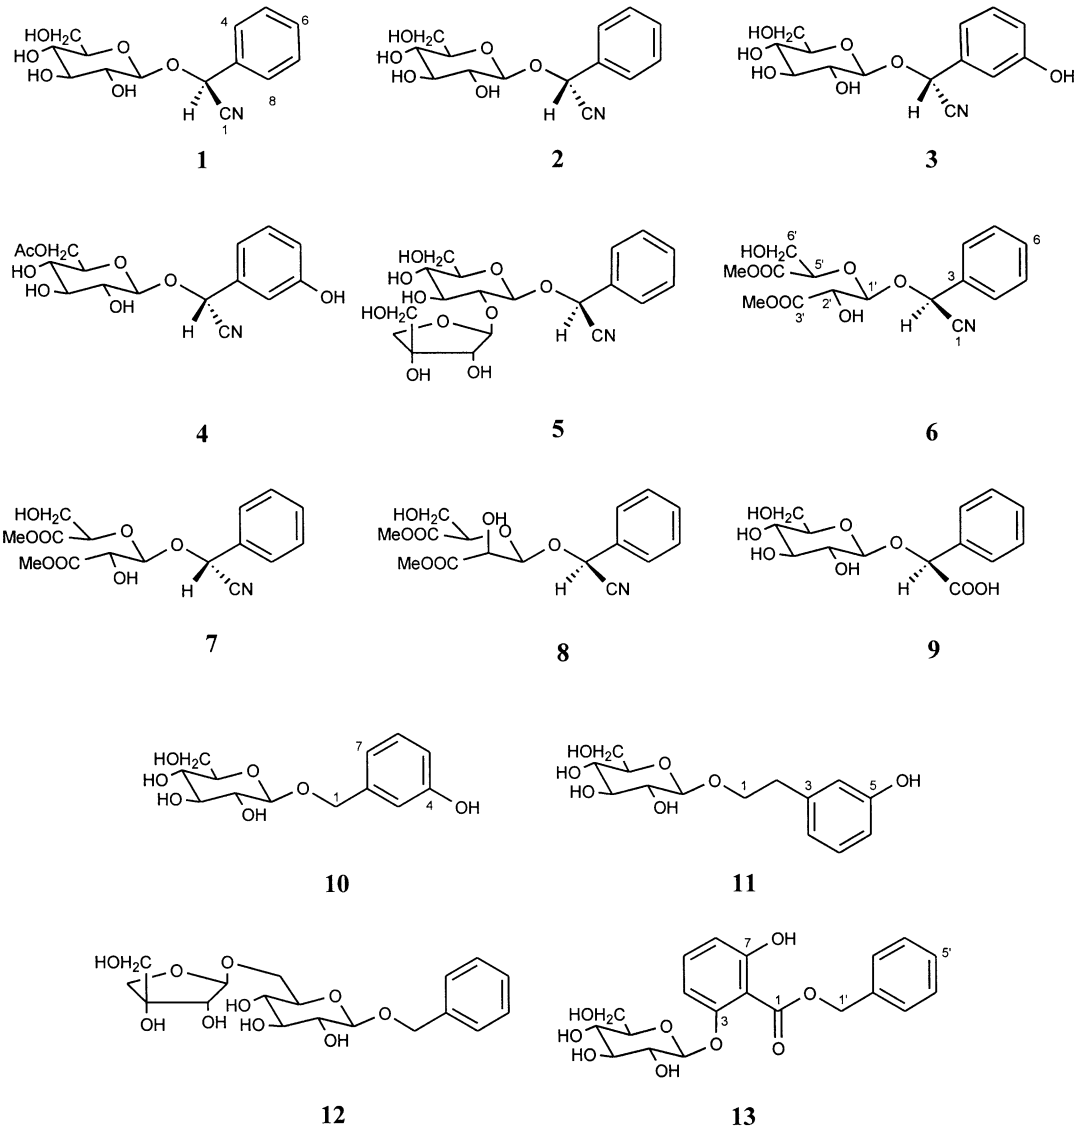
Scheme 1.

hydroxy-5-benzofuran-propanol (**16**) (Popoff and Theander, 1975).

The new compound **13** had the molecular formula $C_{20}H_{22}O_9$ according to the elemental analysis and the ^{13}C NMR data. The EIMS spectrum showed a peak at *m/z* 244 due to the loss of the glucose, besides other peaks at *m/z* 137, 107, 91 and 77. The ^1H NMR spectrum showed three aromatic protons as two double doublets at δ 6.73 and 6.59 and a triplet at δ 7.26, besides five further aromatic protons in the 7.55–7.32 ppm range. A singlet at δ 5.37, two double doublets at δ 3.86 and 3.65, and four overlapping protons in the 3.45–3.35 ppm range were also present in the spectrum. Also on the basis of HMQC and HMBC experiments structure of benzyl 2-*O*-β-D-glucopyranosyl-2,6-dihydroxybenzoate structure. Accordingly enzymatic hydrolysis with β-glucosidase gave verimol K (Sy and Brown, 1998). Fraction C, eluted with MeOH, was chromatographed by DCCC to give the flavone glycosides quercitin 3-glucoside (**20**) and quercitin 3-*O*-neohesperidoside (**24**) (Markham et al., 1978), kampferol 3-*O*-neohesperidoside (**21**) and kampferol 3-glucoside (**22**) (Harborne and Williams, 1988) and rhamnetin 3-glucoside (**23**).

The aqueous fraction was chromatographed on Amberlite XAD-4 and the fraction eluted with MeOH was partitioned on Sephadex LH-20 into fractions A–D. Fraction A, eluted with water, gave the cyanogenin (2*S*)-[β-D-apiofuranosyl-(1→2)]-β-D-glucopyranosyl-mandelonitrile (**5**) (Della Greca et al., 2000a) and the glycosides **9** and **12**. The first, $[\alpha]_D$ +6°, has been isolated for the first time and identified as (2*S*)-2-*O*-β-D-glucopyranosyl-2-hydroxy-phenylacetic acid. It had the molecular peak at *m/z* 314 in the EIMS spectrum and showed 14 carbon signals in the ^{13}C NMR spectrum in accordance to the molecular formula $C_{14}H_{18}O_8$. All its physical data were identical to those reported by Kitajima and Tanaka (1993) for (2*R*)-2-*O*-β-D-glucopyranosyl-2-hydroxy-phenylacetic acid, isolated from *Prunus zippeliana*, except for its rotation, thus justifying the *S* configuration at C-2. Accordingly, acid hydrolysis of **9** gave *l*-mandelic acid. We have identified compound **12** as icariside F_2 [benzyl alcohol β-D-apiofuranosyl-(1→6)-β-D-glucopyranoside] by comparison with the NMR data given by Miyase et al. (1989). Fraction B, eluted with MeOH–H_2O (1:3), consisted of the cyanogenins sambunigrin (**1**), prunasin (**2**) and 6-acetyl holocalin (**4**) (Della Greca et al., 2000a). Fraction C, eluted with MeOH–H_2O (1:2), afforded the glucosides **10** and **11**. The first glucoside was obtained by enzymatic synthesis by Trincone et al. (1994) while the latter was reported as a tobacco fragrance-improving agent by Keniji et al. (2000). Fraction D, eluted with MeOH–H_2O (1:1), afforded the cyanogenin holocalin (**3**) (Della Greca et al., 2000a).

All the compounds have been tested on *L. sativa* (lettuce), *R. sativus* (radish), and *A. cepa* (onion) to evalu-



ate their influence on the seed germination and the radicle elongation. The assays have been run according to the procedures optimised by Macías et al. (2000). Flavonoids **20**–**24** show no significant activity, while the effects of the active compounds, presented as percentage differences from the control, are reported in Tables 1 and 2 and in Figs. 1 and 2.

Cyanogenins **1**–**3** inhibit the germination of the test species at the highest concentration. The effects are stronger on dicotyledons *R. sativus* and *L. sativa* than on monocotyledon *A. cepa*. The inhibition decreases with dilution and at 10^{-5} M concentration only the most active holocalin (**3**) conserves its activity while sambunigrin (**1**), and prunasin (**2**) have a slight stimulant effect. A chemical comparison between sambunigrin (**1**) and prunasin (**2**) shows that the different configuration at the C-2 stereocentre is non-influent, while the introduction of the hydroxyl group at the *meta* position of prunasin (**2**) to give holocalin (**3**) enhances the activity. All the modifications of cyanogenins, such as acetylation of holocalin (**3**) to **4**, glycosylation of sambunigrin (**1**) to **5** as well as glucose oxidation, which transforms **1** and **2** into **6** and **7**, reduce the inhibitory activity, and the overall germination effects of the compounds show less than 10% difference from the control. The effects on the radicle elongation of the three species are rather similar to those observed for germination. Cyanogenins **1**–**3** have strong activity at the highest concentrations and an almost total inhibition is observed at 10^{-3} M concentration on *R. sativus*. At the lowest concentrations sambunigrin (**1**) and prunasin (**2**) stimulate the radicle growth of *R. sativus* slightly. The effect of the modification of cyanogenins is less strong on the radicle length. Only acetyl-holocalin (**4**) is practically inactive, while the other cyanohydrins are moderately inhibiting.

Among glycosides **9**–**13**, **9** and **10** may be considered to derive respectively from sambunigrin (**1**) and holocalin (**3**) by hydrolysis of nitrile or from hydrolysis and subsequent decarboxylation. Both of them affect the

germination of the three species slightly. It is worth noting that the effect is inhibiting on dicotyledons and stimulating on monocotyledon. Further effects are observed on the radicle elongation and a reduction of the length occurs in the test species. The other glycosides **11**–**13** have an analogous behaviour.

The neolignans **14**–**16** have little effect on the germination of the three species, while they stimulate the radicle elongation of lettuce and radish quite well. *A. cepa* is inhibited at its highest concentration. Furofuran lignans **17** and **18** have no effect on the germination of dicotyledons, whereas they do influence onion. It is interesting that compound **17** is stimulating but **18** is inhibiting. The chemical difference between the compounds is the presence of a further methoxyl group in **18**. The radicle elongation test shows that the compounds have strong effects on dicotyledons, while they influence monocotyledon only slightly. The effect is that of a strong increase of the radicle length which is higher with compound **17**. Lignan **19** has little effect on the germination but a good stimulating effect on the radicle elongation.

In conclusion, *S. nigra* produces phytostimulating and phytoinhibiting metabolites. Lignans belong to the first group, while the cyanogenins and their derivatives belong to the latter.

3. Experimental

3.1. General experimental procedures

NMR spectra were recorded at 400 MHz for ^{1}H and 100 MHz for ^{13}C on a Bruker AC400 spectrometer with 0.05 solns. in $CDCl_3$ or CD_3OD at 37 °C. Proton-detected heteronuclear correlations were measured using HMQC (optimised for $^1J_{HC} = 145$ Hz) and HMBC (optimised for $^1J_{HC} = 7$ Hz). Optical rotations were measured on a Perkin–Elmer 343 polarimeter. IR spectra were determined in $CHCl_3$ solns on a FT–IR Perkin–Elmer 1740 spectrometer. UV spectra were obtained on a Perkin–Elmer Lambda 7 spectrophotometer in EtOH solns. EI mass spectra were obtained with a Kratos MS 80 apparatus. FAB mass spectra were recorded on a VG ZAB 2SE apparatus. HPLC UV apparatus consisted of a Beckman pump—System Gold 127, a Beckman System Gold 166 UV detector, and a Shimadzu Chromatopac C-R6A recorder. Preparative HPLC were performed using SiO_2 (Maxsil Silica 10 μm, 250×10 mm i.d., Phenomenex), RP-18 (Luna 10 μm, 250×10 mm i.d., Phenomenex), or RP-8 (Luna 10 μm, 250×10 mm i.d., Phenomenex) columns. Analytical TLC was performed on Merck Kieselgel 60 F_{254} or RP-18 F_{254} plates with 0.2 mm film thickness. Spots were visualised by UV light or by spraying with H_2SO_4–AcOH–H_2O (1:20:4) followed by heating for 5 min at 110 °C. Preparative TLC was performed on Merck Kieselgel 60 F_{254} plates, with 0.5 or 1 mm film thickness. Flash column chromatography was performed on Merck Kieselgel 60 (230–400 mesh) at a medium pressure. Column chromatography (CC) was performed on Merck Kieselgel 60 (70–240 mesh), on Sephadex LH-20® (Pharmacia) or on Amberlite XAD-4 (20-60 mesh, Fluka). DCCC was performed on a D.C.C.-A Tokyo Rikakikai LTD (300 columns, 400×2 mm).

3.2. Plant material

Plants of *S. nigra* L. were collected in Agerola (Naples) in July and identified by professor G. Aliotta. A voucher specimen (HERBNAPG074) was deposited at the Dipartimento di Biologia Vegetale of University Federico II of Naples.

3.3. Extraction and isolation

The air-dried and powdered plant material (4.1 kg) was sequentially and exhaustively extracted with petrol, EtOAc and MeOH. The MeOH extract (370 g) was partitioned between H_2O (2 l) and EtOAc (1 l).

The organic fraction (92.9 g) was chromatographed on SiO_2 to give fractions A–C. Fraction A (57 g), eluted with $CHCl_3$, was chromatographed on Sephadex LH-20 eluting with hexane –$CHCl_3$–MeOH (3:1:1) and collecting volumes of 10 ml. Fractions 15-19 were chromatographed on TLC [$CHCl_3$–AcOEt (4:1)] and purified on RP-8 eluting with MeOH–MeCN–H_2O (3:2:5) to give compound **8** (18 mg). Silica gel chromatography of fractions 20–23 gave the epimeric mixture of **6** and **7** that was resolved on RP-18 HPLC by eluting with MeOH–MeCN–H_2O (1:1:3) (5 and 3 mg, respectively). Fractions 24–30 were re-chromatographed on TLC [$CHCl_3$–MeOH (99:1)] and SiO_2 HPLC [hexane–acetone (13:7)] to give the lignans **14** (15 mg) and **18** (8 mg). Finally, fractions 31–37 were purified first by flash chromatography [$CHCl_3$–MeOH (49:1)] and then by TLC [benzene–MeOH (9:1)], to give the compounds **17** (21 mg) and **19** (19 mg). Fraction B (11 g), eluted with EtOAc, was chromatographed on SiO_2. The fractions so

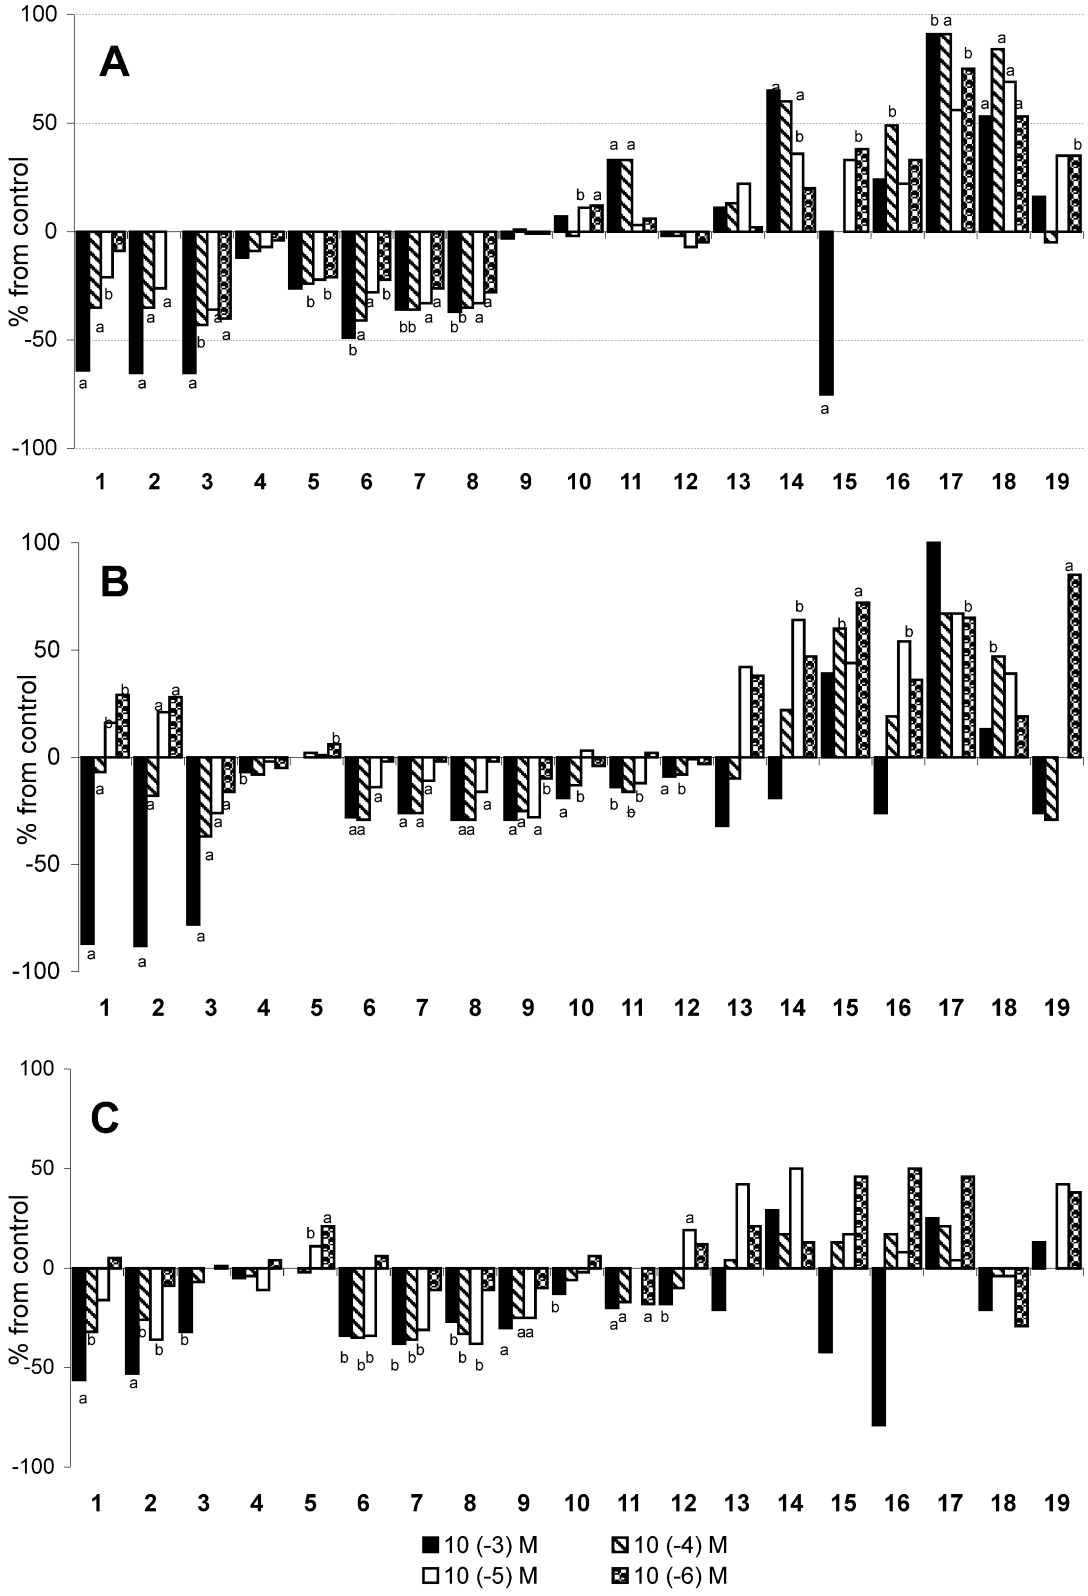

Fig. 1. Effect of compounds **1**–**19** on radical length of *Lactuca sativa* (A), *Raphanus sativus* (B) and *Allium cepa* (C). Values presented as percentage differences from control; $P > 0.05$ for the Welch's test. A, $P < 0.01$; B, $0.01 < P < 0.05$.

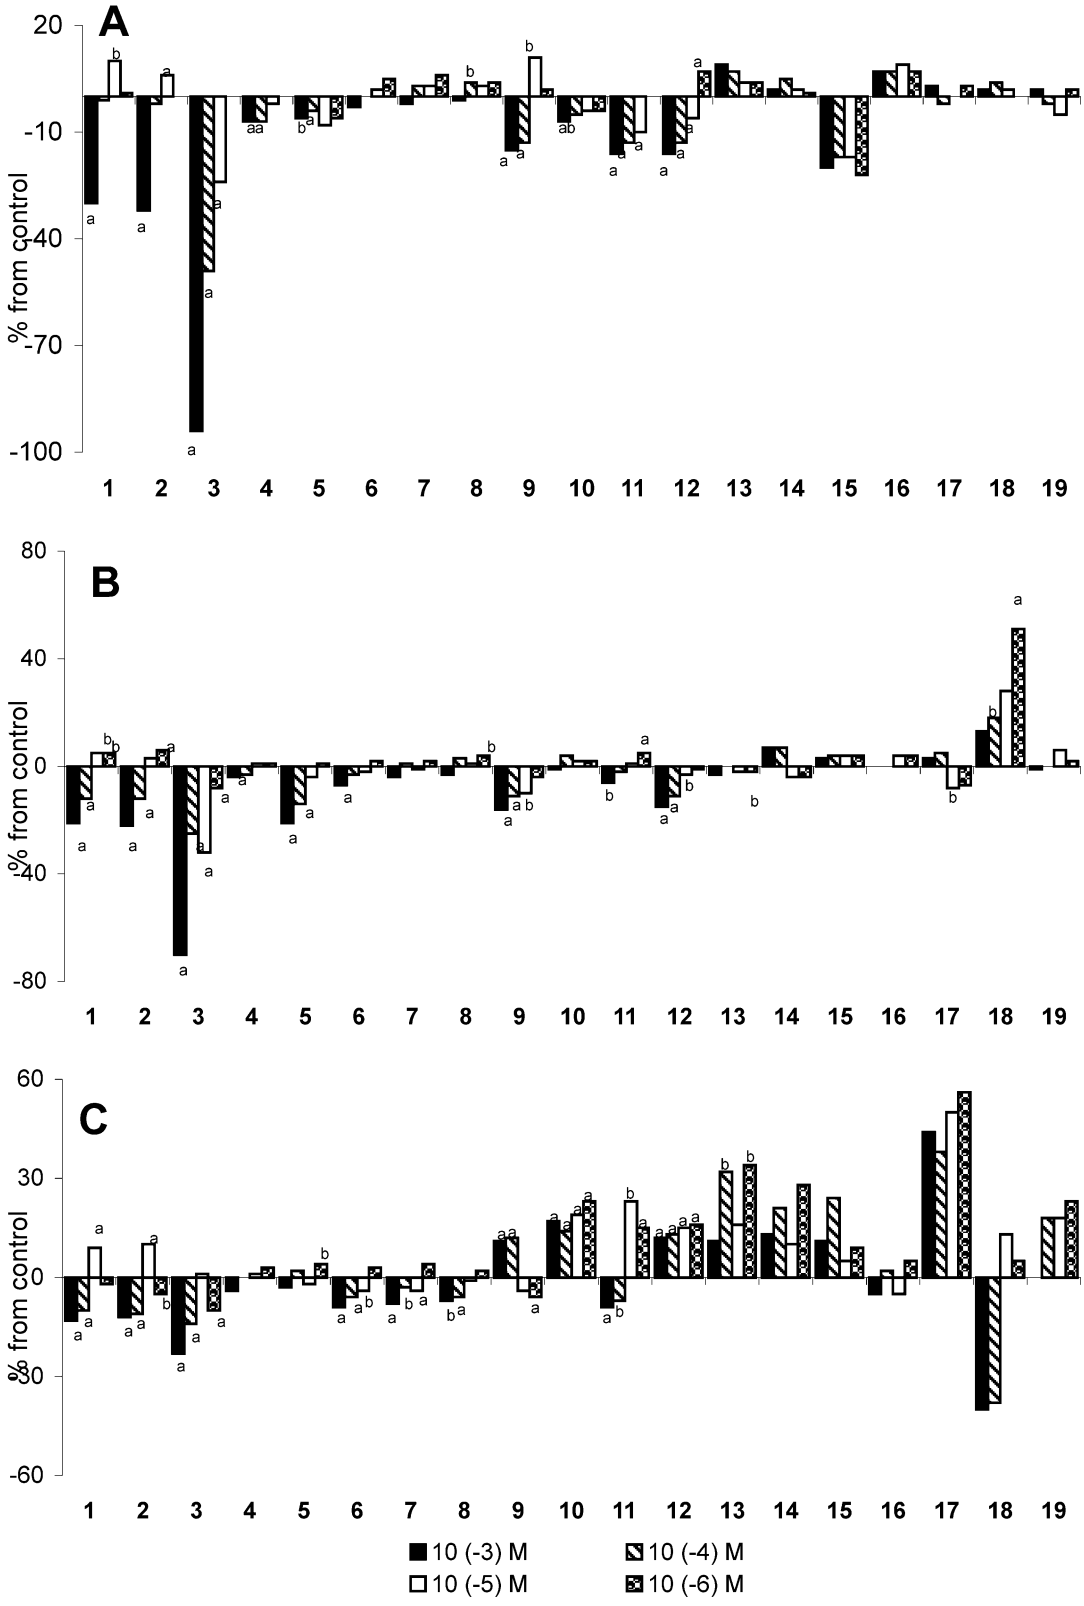

Fig. 2. Effect of compounds **1**–**19** on seed germination of *Lactuca sativa* (A), *Raphanus sativus* (B) and *Allium cepa* (C). Values presented as percentage differences from control; $P > 0.05$ for the Welch's test. A, $P < 0.01$; B, $0.01 < P < 0.05$.

obtained, eluted with $CHCl_3$–MeOH–H_2O (14:5:1), were re-chromatographed by Sephadex LH-20 with MeOH-H_2O (7:3) as eluent; fractions 43–48 were purified by RP-18 HPLC [MeOH–MeCN–H_2O (37:2:11)] to give glucoside **13** (21 mg), while fractions 51-58 were purified by RP-18 HPLC [MeOH–MeCN–H_2O (9:2:9)] to give compounds **15** (11 mg) and **16** (7 mg). Fraction C (10.2 g), eluted with MeOH, was chromatographed on a DCCC apparatus with $CHCl_3$–MeOH–H_2O (13:7:5) in ascending mode, using the upper layer as mobile phase. RP-18 HPLC of the fractions 17–22 [A: 2% AcOH, B: MeOH-2% AcOH (8:2); gradient A:B from 19:1 to 3:2 in 30 min] gave the disaccharide flavonoids **21** (25 mg) and **24** (19 mg); RP-18 HPLC purification of the fractions 75–96 [A: 2% AcOH, B: MeOH-2% AcOH (8:2); gradient A:B from 3:1 to 9:11 in 30 min] gave the flavone glucosides **20** (18 mg), **22** (14 mg) and **23** (6 mg).

The aqueous layer, conc. at 500 ml, was chromatographed on Amberlite XAD-4 and, using chromatography on Sephadex LH-20, the MeOH elute (5.9 g) was partitioned into the fractions A–D. Fraction A (1.9 g), eluted with H_2O, was re-chromatographed on Sephadex LH-20 using MeOH-$CHCl_3$–hexane (4:2:1) as eluent to give crude **5**, which was purified by RP-18 HPLC [MeOH–MeCN–H_2O (17:3:30), 6 mg)] and a mixture of glycosides **9** and **12** that was resolved by RP-18 HPLC (13 and 11 mg, respectively). Fraction B (345 mg), eluted with H_2O–MeOH (3:1) was re-chromatographed on Sephadex LH-20, using MeOH–$CHCl_3$–hexane (4:2:1) as eluent to give a mixture of cyanogenic glycosides **1**, **2** and **4** which was resolved by RP-18 HPLC [A: 2% AcOH, B: MeOH-2% AcOH (8:2); gradient A:B from 17:3 to 7:3 in 25 min; **1**, **2** and **4**: 45, 68 and 8 mg, respectively]. Subsequent purification of fraction C (684 mg), eluted with MeOH–H_2O (2:1), on Sephadex LH-20 and then by flash chromatography [$CHCl_3$–MeOH–H_2O (13:7:3), lower layer] gave the compound **11** (9 mg) and a fraction that, purified by RP-18 HPLC [MeOH–MeCN–H_2O (7:2:4)], gave the glucoside **10** (13 mg). Fraction D (2.0 g), eluted with H_2O–MeOH (1:1) was chromatographed on Sephadex LH-20, using MeOH–$CHCl_3$–hexane (4:2:1) as eluent to give crude **3** (220 mg). An aliquot of the crude product was purified by RP-18 HPLC [A: 2% AcOH, B: MeOH-2% AcOH (8:2); gradient A:B from 4:1 to 3:1 in 10 min].

3.4. Compound characterisation

3.4.1. (2S)-2-O-β-D-Glucopyranosyl-2-hydroxyphenylacetic acid (9)

Colorless oil; $[\alpha]_D$ +6°; UV (EtOH) λ_{max} nm: 279; ^{1}H NMR (CD_3OD) δ 7.50 (2H, *m*, H-4 and H-8), 7.32 (3H, *m*, H-5–H-7), 5.27 (1H, *s*, H-2), 4.51 (1H, *d*, J = 8.0 Hz, glc-1), 3.86 (1H, *dd*, J = 11.8 and 1.1 Hz, glc-6), 3.68 (1H, *dd*, J = 11.8 and 5.6 Hz, glc-6), 3.50–3.30 (4H, *m*, glc-2–glc-5). EIMS *m*/*z*: 314 $[M]^+$, 152 $[M-glucose]^+$. (Found: C, 53.3; H, 5.9. $C_{14}H_{18}O_8$ requires: C, 53.5; H, 5.8%.)

3.4.2. 3-Hydroxybenzyl 1-O-β-D-glucopyranoside (10)

Colorless oil; UV λ_{max} (EtOH) nm 280; ^{1}H NMR (CD_3OD) δ 7.14 (1H, *dt*, J = 7.7 and 1.0 Hz, H-6), 6.87 (1H, *dd*, J = 7.7 and 1.9 Hz, H-7), 6.86 (1H, *d*, J = 1.8 Hz, H-3), 6.71 (1H, *ddd*, J = 7.7, 1.9 and 1.0 Hz, H-5), 4.85 (1H, *d*, J = 11.8 Hz, H-1), 4.59 (1H, *d*, J = 11.8 Hz, H-1), 4.35 (1H, *d*, J = 7.7 Hz, glc-1), 3.89 (1H, *dd*, J = 12.0 and 2.2 Hz, glc-6), 3.69 (1H, *dd*, J = 12.0 and 5.5 Hz, glc-6), 3.35–3.20 (4H, H-2′–H5′). EIMS *m*/*z*: 286 $[M]^+$, 124 $[M-glucose]^+$, 107 $[M-OH-glucose]^+$. (Found: C, 54.4; H, 6.5. $C_{13}H_{18}O_7$ requires: C, 54.5; H, 6.3%.)

3.4.3. 1-O-β-D-Glucopyranosyl-2-(3-hydroxyphenyl)-ethanol (11)

Colorless oil; UV λ_{max} (EtOH) nm: 280; ^{1}H NMR (CD_3OD) δ 7.09–6.78 (4H, *m*, H-4, H-6–H-8), 4.75 (1H, *d*, J = 8.0 Hz, glc-1), 3.92 (1H, *dd*, J = 11.8 and 1.1 Hz, glc-6), 3.73 (1H, overlapped, glc-6), 3.72 (2H, *t*, J = 7.0 Hz, H-1), 3.50–3.30 (4H, *m*, glc-2–glc-5), 2.71 (2H, *t*, J = 7.0 Hz, H-2). EIMS *m*/*z*: 300 $[M]^+$, 138 $[M-glucose]^+$. (Found: C, 59.9; H, 6.8. $C_{14}H_{20}O_7$ requires: C, 56.0, H, 6.7%.)

3.4.4. Benzyl alcohol β-D-apiofuranosyl-(1→6)-β-D-glucopyranoside (12)

Colorless oil; UV λ_{max} (EtOH) nm: 280. ^{1}H NMR (CD_3OD) δ 7.42–7.25 (5H, *m*, H-3–H-7), 5.07 (1H, *d*, J = 2.0 Hz, api-1), 4.91 (1H, *d*, J = 11.9 Hz, H-1), 4.66 (1H, *d*, J = 11.9 Hz, H-1), 4.33 (1H, *d*, J = 7.8 Hz, glc-1), 4.05–3.30 (11H, glc-2–glc-6 and api-2–api-5). FABMS (negative) *m*/*z*: 401 $[M-H]^-$, 269 $[M-api-H]^-$, 107 $[M-api-glc-H]^-$. (Found: C, 53.8; H, 6.4. $C_{18}H_{26}O_{10}$ requires: C, 53.7, H, 6.5%.)

3.4.5. Benzyl 2-O-β-D-glucopyranosyl-2,6-dihydroxybenzoate (13)

Colorless oil; IR ν_{max} ($CHCl_3$) cm^{-1}: 1715, 1605. ^{1}H NMR (CD_3OD) δ 7.55–7.32 (5H, *m*, H-3′–H-7′), 7.26 (1H, *t*, J = 8.4 Hz, H-5), 6.73 (1H, *dd*, J = 8.4 and 1.0 Hz, H-4), 6.59 (1H, *dd*, J = 8.4 and 1.0 Hz, H-6), 5.37 (2H, *s*, H-1), 4.93 (1H, *d*, J = 7.2 Hz, glc-1), 3.86 (1H, *dd*, J = 12.0 and 1.2 Hz, glc-6), 3.65 (1H, *dd*, J = 12.0 and 5.9 Hz, glc-6), 3.45–3.35 (4H, *m*, glc-2–glc-5); ^{13}C NMR (CD_3OD) δ 170.3 (C-1), 160.1 (C-3), 158.5 (C-7), 137.6 (C-2′), 134.3 (C-5), 129.8 (C-4′, C-6′), 129.5 (C-3′, C-5′, C-7′), 111.9 (C-6), 108.1 (C-2), 108.0 (C-4), 103.0 (glc-1), 78.6 (glc-5), 78.2 (glc-3), 75.2 (glc-2), 71.5 (glc-4), 68.4 (C-1′), 62.8 (glc-6). EIMS *m*/*z*: 244, 137, 107, 91, 77. (Found: C, 59.0; H, 5.4. $C_{20}H_{22}O_9$ requires C, 59.1, H, 5.5%.)

3.5. Bioassays

Seeds of *R. sativus* L. "Saxa", collected during 2000, were purchased from Improta Co., Naples. Seeds of *L. sativa* and *A. cepa,* collected during 2000, were obtained from Blumen® (Milan, Italy). All undersized or damaged

seeds were discarded and the assay seeds were selected for uniformity.

For the bioassays we used Petri dishes in two sizes (90 and 50 mm diameter) with one sheet of Whatman No. 1 filter paper as support. In three replicate experiments, germination and growth were conducted in aqueous solutions at controlled pH. Test solns. (10^{-3} M) were prepared using MES (2-[*N*-morpholino]ethanesulfonic acid, 10 mM, pH 6) and the rest (10^{-4} –10^{-6} M) were obtained by dilution. Parallel controls were performed. After adding 30 seeds and aqueous solns., Petri dishes were sealed with Parafilm® to ensure closed-system models. Seeds were placed in a growth chamber KBW Binder 240 at 25 °C, with 60% relative humidity, and a 12 h photoperiod, 10,000 lux. Germination percentage was determined daily for four days for radish and five days for onion and lettuce (no more germination occurred after this time). After growth, plants were frozen at −20 °C to avoid subsequent growth until the measurement process.

Data are reported as percentage differences from control in the graphics and tables. Thus, zero represents the control; positive values represent stimulation of the control; positive values represent stimulation of the parameter studied and negative values represent inhibition.

3.5.1. Statistical treatment

Comparison was made between the two blocks assayed by applying Welch's test, a variant of Student's *t* test (Zar, 1984; Martin and Luna, 1990), calculating mean values for every parameter (germination average, and radicle elongation) and their population variance within a Petri dish.

Coefficient of variation (CV) was used to compare dispersion from different populations. This parameter is expressed as a percentage and represents the ratio between the standard deviation and the sample mean.

Acknowledgements

The authors thank one of the referees for the helpful discussion for the compound **13** identification.

Abstract

From the aerial parts of *Artemisia dracunculus*, one known alkamide, pellitorine, two new alkamides neopellitorine A and neopellitorine B, and one known coumarin herniarine were isolated. Structures were elucidated by means of UV, IR, MS, ^{1}H and ^{13}C NMR. These compounds showed insecticidal activity against *Sitophilus oryzae* and *Rhyzopertha dominica* at 200 μg/ml concentrations. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Artemisia dracunculus*; Asteraceae; Anthemideae; *N*-Isobutyl amides; Insecticidal activity; *Sitophilus oryzae*; *Rhyzopertha dominica*

1. Introduction

The large genus *Artemisia*, from the tribe Anthemideae, has been the subject of numerous chemical and biological studies (Tan et al., 1998). The species give sesquiterpene lactones, coumarins and acetylenes as the main metabolites (Marco and Barbera, 1990). Preparations from *Artemisia* plants have a long tradition in adjuvant therapy. In previous papers we reported eudesmanolides from the aerial parts of *Artemisia herba alba* (Boriky et al., 1996). This paper describes the isolation and structural elucidation of three alkamides and one know coumarin from the aerial parts of *A. dracunculus*, and their insecticidal effect against the rice wevil (*Sitophilus oryzae*) and grain borer (*Rhyzopertha dominica*). These stored products pests are characterized by their bioecology and the nature of their damage. In fact, these two harmful insects cause the most damage in stocks of corn and barley in Morocco and through out the world.

2. Results and discussion

The petroleum ether extract of aerial parts afforded, after silica gel chromatography pure amide compounds **1**–**3**. Pellitorine **1** is reported for the first time in an *Anacyclus* species (Dunstan and Garnett, 1895). The IR spectrum of these compounds indicated the presence of amide group (bands at 3300, 3070, 1650 and 1540 cm^{-1}) as well as olefinic double bands (1630 and 950 cm^{-1}). This together with the absorption maximum at 257 nm suggested a chromophore of conjugated dienoic acid amides for **1**–**3**. The amide moiety was established by the mass spectrum. The peaks matching $[M-15]^{+}$, $[M-43]^{+}$, $[M-57]^{+}$, $[M-72]^{+}$ and $[M-100]^{+}$ were assigned to a piperidide moiety for **3**.

The ^{1}H NMR spectra of compounds **1**–**2** showed characteristic signals at δ 3.18 (H-1′), δ 1.80 (H-2′), and δ 0.92 (H-3′,4′) indicating the isobutylamide moiety (Su and Horvart, 1981; Greger and Hofer, 1987; Bauer et al., 1988, 1989). In addition, the signals of a conjugated diene moiety were apparent (δ 5.82 (H-2), δ 7.21 (H-3), δ 6.24 (H-4) and δ 6.12 (H-5)) in a *trans–cis* configuration as indicated by the coupling constants of 15 and 11 Hz for each pair of olefinic protons (Greger and Hofer, 1987; Bauer et al., 1988, 1989). The structure of **2** differed from the **1** in the hydrocarbon chain attached to a carbon bearing the conjugated diene moiety, which could be observed from the ^{1}H and ^{13}C NMR spectra (Tables 1 and 2). Compound **3** showed different signals in ^{1}H NMR spectrum caused by the amine part, three multiplets at δ 1.57, δ 1.64 and δ 1.62 that were characteristic to the cyclic methylenes and two typical multiplets at δ 3.49 and δ 3.61 attached to protons in α

PII: S0031-9422(01)00347-8

position of nitrogen (Greger et al., 1982). Also the presence of an piperidide moiety was supported by the ^{13}C NMR signals at δ 25.6 (C-2′), δ 24.7 (C-3′), δ 26.7 (C-4′), δ 46.9 (C-1′) and δ 43.2 (C-5′). The structure of **3** differed from the **1** in the amine moiety, which could be deduced from the MS-fragmentation pattern $[M-84]^+$ instead of $[M-72]^+$ and the ^1H, ^{13}C NMR spectra (Tables 1 and 2).

Compounds **1**–**3** have never been identified as constituents of *Artemisia*. Compounds **2** and **3** have been isolated for the first time, while compound **1** has previously been found in *Anacyclus pyrethrum* (Dunstan and Garnett, 1895). According to previous reports (Jacobson, 1954; Bohlmann and Hoffmann, 1983) unsaturated isobutylamides are well-known from the Asteraceae and for their insecticidal activities (Greger, 1984). They have also been reported from other genera such as *Spilanthes* (Ramscwak et al., 1999), *Echinacea* (Bauer et al., 1989), Achillea (Greger et al., 1982; Greger and Hofer, 1989) and *Acmella* (Martin and Becker, 1985).

Insecticidal tests on *Sitophilus oryzae* and *Rhyzopertha dominica* revealed that compounds **1**–**3** were very active, as shown in Fig. 1. Indeed compound **2** showed 100% mortality at a concentration of 200 μg/ml after 3 days on the two insects tested, however, compounds **1** and **3** showed a mortality of about 50 and 80%, respectively, toward *R. dominica* and *S. oryzae* at the same concentration after 3 days.

This investigation yielded two purely olefinic alkamides and an acetylenic alkamide. Two of the three compounds possessed an isobutyl side chain. The difference in insecticidal activity of these compounds could be attributed to their structural difference, especially the acetylenic group contained in compound **2** which showed the best insecticidal activity.

3. Experimental

3.1. General

^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ on Varian Unity 600 instrument at 600 and 150 MHz, respectively; the chemical shifts are reported in δ units (ppm) values relative to TMS. IR spectra were recorded as films on a Nicolet 205-FTIR spectrometer. UV spectra were determined in MeOH with Shimadzu 265FS spectrophotometer. HR-EI-MS and ES-MS measurements were carried out on a Fisons VG Autospec. TLC were carried out on Silica gel F_{254} precoated plates (0.25

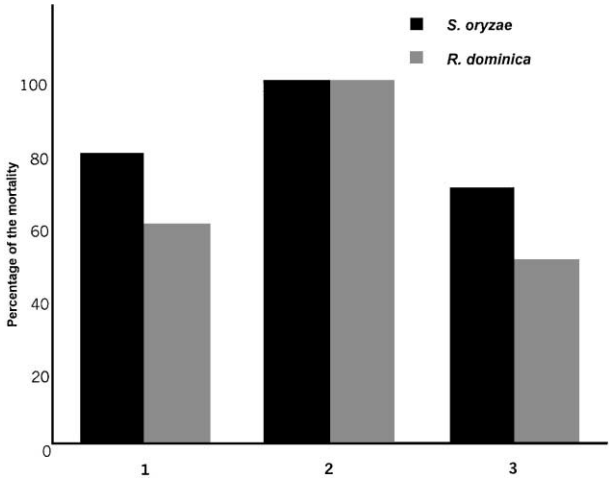

Fig. 1. Toxicity of compounds **1**–**3** on *S. oryzae* and *R. dominica* at 200 μg/ml concentration after 3 days. Statistical analysis was done using ANOVA ($P < 10^{-3}$).

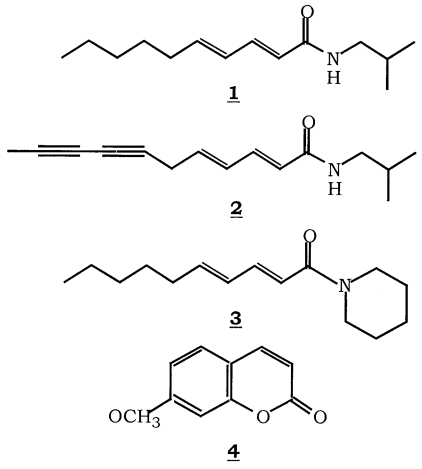
mm). C.C were also performed on Silica gel (Merck Silica gel 60, 70–230 mesh).

3.2. Plant material

Aerial parts of plants *A. dracunculus* were collected at Salé, Morocco, in September 1997. Identification of the plant was confirmed by Dr. A. Ouyahya. A voucher specimen is deposited in the herbarium of the DBEV (Département de Botanique et Ecologie Végétal, Institut Scientifique) in Rabat (Morocco).

3.3. Extraction and isolation

The plant material was air-dried at room temp., finely ground and extracted (100 g), successively with petroleum ether (pb 40–60°) and CH_2Cl_2. The extracts were filtered, and the solvent was concentrated under reduced pressure. One portion (6 g) of the crude petroleum ether extract was fractionated by column chromatography on silica gel [A: hexane–EtOAc (9:1), B: hexane–EtOAc (7:3) and C: hexane–EtOAc (4:6)]. Fraction A (1.06 g) was fractionated by column chromatography on silica gel (hexane–EtOAc, 2:3) to give **1** (36 mg), **2** (17 mg) and **3** (9 mg). Crystallization of the fraction B from CH_2Cl_2 afforded 476 mg of herniarine **4**. This compound was isolated from *A. dracunculus* and identified as described previously (Ahmad and Misra., 1997).



3.4. Deca-2E, 4Z-diynoic acid isobutylamide *1*

Yellow oil; UV λ_{max} nm: 257; IR $\surd_{max}$ cm^{-1}: 3300, 3070, 1650, 1540 (–CO–NH–); 2950 (CH–); 1650, 950 (–C=C–); HR-EI-MS: *m/z* (%, rel. int.) $[M]^+$ 223.1939 (26.5) (calc. for 223.1936), 208.1706 (5.8), 180.1391 (5.7), 166.1236 (6), 151.1123 (100), 124.0763 (2.1), 100.0402 (4.3); ES-MS: *m/z* (%) $[2M]^+$ 447.65 (14), 226.42 (4), 225.37 (13), $[M+1]^+$ 224.36 (100), 196.18 (4), 177.09 (11), 156.16 (11).

3.5. Undeca-2E, 4Z-dien-7,9-diynoic acid isobutylamide *2*

Yellow oil; UV λ_{max} nm: 257; IR $\surd_{max}$ cm^{-1}: 3300, 3070, 1660, 1520 (–CO–NH–); 2960 (CH–); 1620, 990 (–C=C–); EI-MS: *m/z* (%, rel. int.) $[M]^+$ 229 (33), 214 (10), 186 (7), 172 (12), 157 (100), 129 (31), 127 (38), 57 (43.5); ES-MS: *m/z* (%) $[M]^+$ 459.56 (5), $[M+2]^+$ 231.36 (18), $[M+1]^+$ 230.31 (100), 226.30 (5), 196.25 (24), 158.18 (12), 156.17 (41); ^1H and ^{13}C NMR data are presented in Tables 1 and 2.

3.6. Deca-2E, 4Z-dienoic acid piperidide *3*

Yellow oil; UV λ_{max} nm: 257; IR $\surd_{max}$ cm^{-1}: 3280, 3080, 1670, 1638 (–CO–N<); 2940 (CH–); 1630, 970 (–C=C–); EI-MS: *m/z* (%, re. int.) $[M+1]^+$ 236 (4.5), $[M]^+$ 235 (17.5), 192 (25.5), 178 (12), 164 (31), 151 (24), 138 (25), 127 (34), 112 (46), 84 (100), 57 (38.5); ^1H and ^{13}C NMR data are presented in Tables 1 and 2.

3.7. Insecticidal test

The procedure was similar to the one described by Regnaut–Roger (Hamraoui and Regnault, 1997).

The isolated compounds (each sample at a concentration 5 mg/ml) were tested for their insecticidal activity, using paper discs (Whatman, Ø = 9 mm) impregnated with 30, 40 and 50 µl of the samples from which the solvent was allowed to evaporate at room temperature. Then, the paper disc was introduced into the experimental chamber containing 10 g of wheat and 20 adults insects (each species was tested separately). The tests were conducted in semi-aerated medium at 25 °C and a relative humidity of 70%.

Three replicates were employed for each sample and the mortality was recorded at 24 h, 2, 3 and 4 days.

Received 15 May 2001; received in revised form 3 September 2001

Abstract

Two novel cyclic depsipeptides were isolated from axenic cultures of the terrestrial cyanobacterium *Scytonema hofmanni* PCC 7110 and designated scyptolin A and B. Amino acid analyses in context with mass and $^{1}H/^{13}C$ NMR spectroscopies revealed a composition typical for heterologous cyanopeptolins but containing the uncommon residue 3′-chloro-*N*-methyl-Tyr (cmTyr) and a unique sidechain. Scyptolin A and B both consist of the *N*-acylated peptide But[1]-Ala[2]-Thr[3]-Thr[4]-Leu[5]-Ahp[6] (3-amino-6-hydroxy-2-oxo-1-piperidine)-Thr[7]-cmTyr[8]-Val[9], which forms a 19-membered ring by esterification of the carboxyl of Val[9] with the hydroxyl of Thr[4]. In scyptolin B, the hydroxyl of the Thr[3] residue is additionally esterified with *N*-butyroyl-Ala. Both scyptolin A and B exhibit selective inhibition of porcine pancreatic elastase *in vitro* with IC_{50} values of 3.1 μg/ml. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Scytonema hofmanni*; Cyanobacteria; Cyanopeptolins; Cyclic depsipeptides; Scyptolin

1. Introduction

Cyanobacteria are a rich source of secondary metabolites, such as alkaloids, phenolic dilactones, polyketides and macrolides or peptides, which biosynthetically originate from widely different pathways and show a broad spectrum of biological activities (Namikoshi and Rinehart, 1996). Some of these metabolites are potent toxins (Beasley et al., 2000), a phenomenon which initially caught the attention of the food and health industries (Humpage et al., 2000). Selective pharmacological activities have also been observed, e. g. antiviral (Mundt et al., 1997), antitumor (Trimurtulu et al., 1994), or immunosuppressive (Zhang et al., 1997) effects were reported for various of these compounds, and some cyanobacterial metabolites were even introduced as molecular tools in protein phosphatase research (Toivola, 1998).

Whereas the toxic cyclic heptapeptides (microcystins) were studied intensively and more than 60 structural variations have been reported so far, much less is known about the related non-toxic metabolites produced by different strains of cyanobacteria. As a consequence, the attention has recently shifted to these unusual cyanobacterial secondary metabolites, and especially to the cyanopeptolins (Martin et al., 1993), e.g. microcystilid A (Tsukamoto et al., 1993), the aeruginopeptins (Harada et al., 1993), the micropeptins (Banker and Carmeli, 1999), or the cyanopeptolins A–B (Martin et al., 1993), S (Jakobi et al., 1995) and SS (Jakobi et al., 1996).

Some cyanopeptolins are known as specific inhibitors of serine proteases including elastase. This protease appears to be a rewarding object of research, since its activity is of critical importance in a number of human diseases, e.g. lung emphysema which is mediated by the excessive action of elastase (Mal et al., 1999). Furthermore, it has been proposed that unphysiologically high levels of elastase activity are involved in myocardial damage (Zaidi et al., 1999) and may cause a particular

PII: S0031-9422(01)00400-9

form of psoriasis (Orem et al., 1997). Thus, natural elastase inhibitors might serve as valuable lead structures in pharmaceutical research dedicated to the development of new and more effective drugs.

We describe here the isolation and structural elucidation of two novel compounds, scyptolin A and B from axenic cultured cells of *Scytonema hofmanni* PCC 7110. These metabolites significantly inhibited porcin pancreatic elastase in in vitro assays. Since the human elastase sequence is highly homologous to the elastase from other vertebrates (Bode et al., 1989), commercial porcine pancreatic elastase can be conveniently used for the inhibition assays.

2. Results

2.1. Isolation of scyptolin A and B

Scytonema hofmanni PCC 7110, was grown axenically for four weeks in stationary culture under continuous irradiation. The cells were collected by filtration, deep-frozen and lyophilized. The lyophilized cell mass was extracted with aq. MeOH, and the extract was fractionated by stepwise adsorption and desorption of the amphiphilic, charged components to reversed phase chromatographic materials and ion exchange matrices. Two compounds, A and B, were eventually isolated from the partially purified extract by reversed phase HPLC in acidic aq. acetonitrile. Starting from 7 to 9 g of dry cell mass in different rounds of purification, 5 and 25 mg, respectively, of pure compounds A and B, were recovered on average. Ultraviolet and NMR spectroscopies (Reshef and Carmeli, 2001) suggested that both compounds belonged to the class of depsipeptides containing aromatic residues, and, with reference to the taxonomic source, the compounds were designated scyptolin A and scyptolin B.

2.2. Structural composition of scyptolin A and B

The amino acid analyses revealed an identical qualitative pattern for both scyptolin A and B and indicated a core composition of Thr, Ala, Val and Leu. However, distinct quantitative differences were recorded with stoichiometries of 3:1:1:1 for scyptolin A vs. 3:2:1:1 for scyptolin B. While these data would be compatible with the scyptolins being regular oligopeptides, their hydrophobicity upon chromatography pointed to more uncommon features, such as a blocked *N*-terminus and/or a cyclic structure. The chirality of the amino acids was determined by GC of their trifluoroacetylated methyl esters on a chiral stationary phase (König et al., 1989) and revealed the L-configuration for all amino acids employed, as described for other cyanopeptolins (Jakobi et al., 1995).

Three prominent ions were observed on LC–MS analysis in the positive-ion mode of scyptolin A at m/z 963.3 (base peak), 1003.5 (45% rel. intensity) and 981.1 Da (15% rel. intensity). Similarly, scyptolin B yielded ions at m/z 1104.4 (base peak), 1144.5 (85% rel. intensity) and 1121.3 Da (12% rel. intensity). In both instances, the isotopic distribution of the ions indicated the presence of chlorine in the molecules. The HR–MS of scyptolin A revealed a monoisotopic mass [M + Na] of 1003.4512 corresponding to the molecular composition of $C_{45}H_{69}N_8O_{14}Cl$, and the mass of scyptolin B [M + Na] was determined at 1144.5297 revealing the composition of $C_{52}H_{80}N_9O_{16}Cl$. Furthermore, the absorption in the ultraviolet range (λ_{max} 281.54 and 281.98 nm, respectively) and the banding pattern on IR spectroscopy (identical for both compounds) with prominent signals also in the range from 660 to 720 cm^{-1} supported the identification of chlorinated, aromatic peptides.

The ^1H NMR of scyptolin A revealed at least 69 protons resonating in the range from 10.5 and 0 ppm (Table 1). HSQC correlations and integration indicated 10 methyl, six methylene and 17 methine groups, leaving 10 protons unattached to carbon. The latter protons were assigned to six NH groups (doublets in the range 8.5–7.2 ppm), one phenolic OH (10 ppm) and three alcoholic OH groups (6.04, 4.91 and 4.47 ppm). Among the methyl groups, one primary (triplet), eight secondary (doublets) and one *N*-methyl group (singlet at 2.7 ppm, resonating at 30.4 ppm on ^{13}C NMR) were distinguished. All six methylene groups are attached to carbons as indicated by their ^1H and ^{13}C shifts (Table 1). The ^{13}C correlation of the methine groups revealed that four are attached to oxygen and eight to nitrogen, three represent aromatic and two aliphatic groups. The three aromatic protons belong to a 1,3,4-trisubstituted aromatic ring with the substituents CH_2 (no. 1), chlorine (no. 3) and OH (no. 4), which is part of the amino acid 3′-chloro-*N*-methyl-Tyr present in both scyptolin A and B. The structure of this amino acid was deduced from coupling constants, ^1H and ^{13}C shifts, COSY, ROESY and HMBC correlations of scyptolin B and with reference to the literature (Ishida et al., 1997).

The following *N*-acylated amino acids were identified from the spinsystems in the TOCSY and COSY and in accordance with their H–C correlations in the HSQC spectra: Ala, Leu, Val, Thr, *O*-acylated Thr, *N*-alkylated Thr, *N*-alkylated (3′-substituted) Tyr, and the Ahp (Radau, 2000) ring system. The configuration of the Ahp residue was inferred from NOEs and corresponded to the configuration observed in other cyanopeptolins (Martin et al., 1993). The *N*-alkylation of the Thr residue was supported further by the NOE correlation (double-headed arrow in Fig. 1, Table 1). The spinsystem of a propyl chain indicated an additional butyryl group. The amino acid sequence could be deduced from sequential proton NOE's like $\alpha-N_{i,\,i+1}$, $\beta-N_{i,\,i+1}$,

[a] HMBC and NOE correlations within the spin system of an amino acid are not listed.

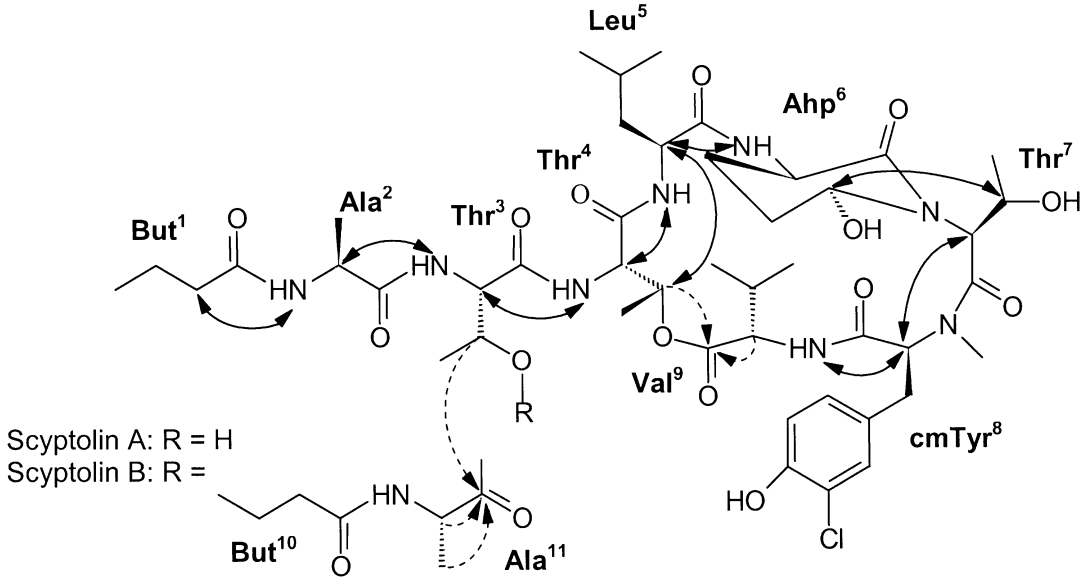

Fig. 1. Chemical composition of scyptolin A and B. Dotted arrows indicate the HMBC correlations of carbonyl groups, and double-headed arrows designate the NOE correlations. **But,** butyric acid; **Ahp,** 3-amino-6-hydroxy-2-oxo-1-piperidine; **cmTyr,** 3′-chloro-*N*-methyl-Tyr.

$\delta-\beta_{\ i,\ i+1}$ or $\alpha-\alpha_{,\ i,\ i+1}$ (Table 1). The α–α NOE between Thr^{7} and cmTyr^{8} indicate a *cis*-amide bond between these two amino acids. All other amide bonds show *trans* configuration, and the sequential NOE's (Table 1) are pointed out by double-headed arrows in Fig. 1. No NOE correlation is observed across the ester bridge between Val^{9} and Thr^{4} of scyptolin A and scyptolin B, and across the ester bridge between Ala^{11} and Thr^{3} of scyptolin B, while the HMBC correlations (dotted arrows, Fig. 1) supported the Thr^{4}-Val^{9} and Thr^{3}-Ala^{11} ester linkages.

The NMR data of scyptolin A is fully compatible with the composition of $C_{45}H_{69}ClN_8O_{14}$ derived from HR–MS and amounting to a nominal M_r of 980. Furthermore, the prominent ions observed on positive mode ESI–MS at m/z 981.2, 1003.5 and 963.3 (base peak) can be assigned to the pseudomolecular ion [MH$^+$] and the ions resulting from sodium addition [M + Na] and loss of water [MH–H_2O], respectively. Taken together, the structure of scyptolin A can be assigned as in Fig. 1.

The ^{1}H NMR of scyptolin B showed the presence of at least 80 protons resonating in the range 10.5 and 0.2 ppm and due to 12 methyl, eight methylene and 18 methine groups in addition to 10 exchangeable protons (Table 1). TOCSY and COSY spectra revealed the same amino acid composition as in scyptolin A, but indicated in addition the presence of one Ala and one butyryl residue as well as the *O*-acylation of a Thr residue (Table 1).

The ^{13}C shifts and the HMBC data (dotted arrows in Fig. 1) of the carbonyl groups are summarized in Table 1. An additional butyryl-Ala group is responsible for the elemental composition of $C_{52}H_{80}ClN_9O_{16}$ and a nominal M_r of 1121 of scyptolin B, which is again fully supported by the fragmentation pattern recorded on ESI–MS with the molecular ion [MH$^+$] at m/z 1121.4 accompanied by the signals for [M + Na] (m/z 1144.5 Da) and [MH−H_2O] forming the base peak (m/z 1104.4 Da).

2.3. Enzyme inhibition

Since some cyanopeptolins are known to inhibit protease activities, scyptolin A and B were subjected to inhibition assays with commercial proteases which are of medicinal relevance, e.g. trypsin, thrombin, plasmin,

papain and elastase. Among these proteases only elastase was inhibited to a significant extent at low concentrations, and an IC_{50} of 3.1 μg/ml was determined for both scyptolin A and B. Trypsin and papain were hardly affected ($IC_{50} > 500$ μg/ml), no inhibition at all was determined with plasmin and thrombin under the conditions employed. This result is puzzling in a sense, since the active site of serine-type proteases is proposed to be highly homologous.

3. Discussion

Terrestrial *Scytonema hofmanni*, in contrast to various related cyanobacteria, has hardly been investigated for its spectrum of secondary metabolites, and only a few compounds, e.g. the herbicidal cyanobacterin and hydroxycyanobacterin (Lee and Gleason, 1994) or the mirabimides (Carmeli et al., 1991) were characterized, none of which being a cyclic depsipeptide. This report, therefore, presents the first depsipeptide metabolites from *Scytonema* species. The core structure of scyptolin A an B is very similar to that of cyanopeptolins from other cyanobacteria (Weckesser et al., 1996), but two peculiar features distinguish these metabolites from most heterologous depsipeptides. The fifth position which is commonly held by a basic amino acid (Arg, Lys, *N*-Me-Lys, *N,N*-Di-Me-Lys) or Tyr and tetrahydrotyrosine (ThTyr), respectively, is replaced by Leu in the scyptolins, as had been reported also for nostopeptins (Okino et al., 1997). Furthermore, the *N*-methyl-Tyr residue in eighth position is 3-chlorinated in the scyptolins. This unusual amino acid has been detected before in only few heterologous cyanopeptolins (Ishida et al., 1997; Rouhiainen et al., 2000). A blocked *N*-terminus is typical for the cyanopeptolins, while the kind of acyl residue is variable ranging from aromatic (4-hydroxyphenyllactic acid) or medium chain-length aliphatic acids (hexanoic, octanoic acids) to mono and disulfated glyceric acid and even include hydrophilic amino acids (Gln, Thr, Asp; Weckesser et al., 1996). However, the *N*-terminal butyroylation detected in the scyptolins has not yet been observed in other cyanopeptolins.

Scyptolin A and B are homologous cyanopeptolins with scyptolin B representing the *N*-butyroyl-Ala-ester of scyptolin A. Thus, scyptolin A might be considered as a biogenetic precursor or as a breakdown product of scyptolin B, which even could have resulted as an artefact of purification. One step of the purification was carried out at pH 2.8, a condition that might partially hydrolyze scyptolin B. This concern was settled, however, by HPLC separation of crude *Scytonema* cell extracts which also detected scyptolin A, and the quantitative ratio of scyptolin A to B was repoduced in several runs. Moreover, incubations at pH 2.8 for up to 4 h of crude extracts did not release scyptolin A. Taking into account that *Scytonema* produces scyptolin B far in excess of scyptolin A, we propose that scyptolin A is the precursor of scyptolin B. This assumption requires further experimental support.

It is conceivable that cyanobacteria produce the unusual peptide metabolites to defend their ecological niche and to regulate their life cycle, respectively. For example, the heptapeptide microcystins were supposed to be harmful to competitors (Carmichael, 1992) and to chelate those metal ions (Humble et al., 1997) which are known to be toxic at high concentrations. Microcystins and other cyanopeptolins have also been described as more or less potent protein phosphatase inhibitors (Boland et al., 1993; Rapala, 1998), and cycles of protein phosphorylation and dephosphorylation are an integral part of metabolic regulation. Furthermore, energy-dependent proteases were proposed to play an important role in regulating cyanobacterial adaptive responses (for review see Mann, 2000), and a particular serine protease was cloned from *Anabaena* that is thought to be induced during nitrogen deficiency (Maldner et al., 1991). Signalling processes via proteases are supposedly as difficult to control as the kinase/phosphatase cycle and accordingly appear to require selective inhibitors.

The protease inhibitory capacities of depsipeptide metabolites have been tested occasionally, i.e. the nostopeptins A and B were found to be potent inhibitors of elastase and chymotrypsin (Okino et al., 1997). The scyptolins A and B also blocked elastase activity at low concentration but failed to inhibit any of the other serine-type proteases in the in vitro assays. An eventual effect on chymotrypsin activity remains to be tested, however, since the scyptolins and nostopeptins share the Leu-Ahp motif (Okino et al., 1997). Just like in other studies (Nakanishi et al., 2000), porcine pancreatic elastase was chosen for the assays, which is most similar to human leukocyte elastase (Bode et al., 1989) and allows to extrapolate the results to the human enzyme. The molecular basis for this kind of selectivity is unclear and the spatial structure of the enzyme-inhibitor complexes needs to be investigated. It appears possible that the mode of action reflects the physiological function of the scyptolins, but this aspect still remains a matter of speculation.

4. Experimental

4.1. Organism and culture conditions

Scytonema hofmanni PCC 7110 was obtained from the Pasteur Culture Collection (Institut Pasteur, Paris, France). Cells were grown photoautotrophically at 28 °C in 10-l flasks (Schott, Mainz, Germany) filled with 7 l of BG-11 growth medium (Rippka et al., 1979). These flasks were aerated at 0.5 bar and irradiated continuously with fluorescent white light (1000 Lux). After

4 weeks of culture, the cells were harvested by filtration through a net (pore size 55 μm), lyophilyzed and stored at −20 °C.

4.2. Extraction and purification

The cells (ca. 8 g dry wt.) were extracted three times with 75% (v/v) aq. MeOH. The cell debris was removed by centrifugation (Sorvall SLA-3000, 10,000 rpm, 20 min), the supernatant was diluted with water to adjust the concentration of MeOH to 10%, and Sephadex LH20 (Amersham Pharmacia Biotech, Freiburg, Germany), which had been pre-equilibrated in 50% aq. MeOH, was added. The solid material was removed by suction through a syringe equipped with a filter plate. Subsequently, Chromabond C_{18} (Macherey and Nagel, Düren, Germany), which had been pre-equilibrated in 90% aq. MeOH, was added to the filtrate and the particulate material was collected again by suction through a filter syringe. The amphiphilic components were eluted from the Chromabond C_{18} particles in 90% aq. MeOH, and the eluate was adjusted to 30% aq. MeOH, at pH 7.5. This solution was partially purified by filtration through anion exchange catridges (QMA, Waters, Eschborn, Germany). The pH was adjusted to 2.8, and the solution was applied subsequently to cation exchange catridges (SA, Waters, Eschborn, Germany), which partially resolved the depsipeptides. Elution was carried out using 0.25 mM ammonium hydrogencarbonate in 30% aq. MeOH. The fractions containing scyptolin A or B were diluted with water to 10% MeOH, and the peptide components were adsorbed to a C_{18}-cartridge. Elution was carried out with a small volume of 90% MeOH, and the solution was applied to a SP 250/21 Nucleosil 100-7 C_{18}-HPLC-column (Macherey and Nagel, Düren, Germany) using a Waters 600 multisolvent delivery system in line with a model 991 photodiode array detector (Waters, Eschborn, Germany) for final separation in acidic aq. acetonitrile under isocratic conditions at 40 °C. The depsipeptide A was separated in water/acetonitrile/0.5% TFA-acetonitrile 69/21/10, while the depsipeptide B was purified in water/acetonitrile/0.5% TFA-acetonitrile 60/30/10 at a flow rate of 10 ml/min. The fractions containing the depsipeptides were pooled and dried in a speed vac (maxi dry lyo, Heto-Holten GmbH, Wettenberg, Germany) at 35 °C for 12 h.

4.3. Amino acid analysis

The amino acid analysis was performed using a Waters kit (AccQ Tag, Waters, Eschborn, Germany). The pure depsipeptides (0.5 μg) were hydrolysed in a hydrolysis vial containing 2 mg PhOH in 200 μl 6 M HCl. The vial was sealed and heated under nitrogen to 115 °C for 22 h. The mixture was dried subsequently in a speed vac and the sample was redissolved in 20 μl 0.02 M HCl for derivatization with a fluorescence label. Reference amino acids were treated the same way, for comparison, the derivatives were separated on a Waters AccQ Tag column in Waters AccQ Tag eluent A (acetate-phosphate buffer), and the fluorescence was recorded at 250 and 395 nm exication and emission wavelength, respectively.

For the determination of absolute configuration of the amino acids, approximately 1 mg of the scyptolin sample was taken up in 1 ml of 6 N HCl and heated at 110 °C for 18 h in a screw cap glass vial with teflon liner in the cap. The hydrolyzate was then taken to dryness by a stream of nitrogen, and the residue was treated with a 2.5 molar solution of HCl gas in MeOH for esterification of the amino acids for 30 min at 100 °C. After removal of the excess of MeOH and HCl the sample was taken up in 0.2 ml of dichloromethane and 0.05 ml of trifluoroacetic anhydride and kept at room temp. for 30 min. Excess of the reagent was removed in a gentle stream of dry nitrogen and the residue was dissolved in 0.2 ml of dichloromethane for gas chromatographic analysis. The sample was injected onto a 25 m capillary column with octakis(3-*O*-butyryl-2,6-di-*O*-pentyl)-γ-cyclodextrin (60% in polysiloxane OV 1701, w/w) at 80 °C. A temp. program of 1 °C/min was used. The peak assignment was achieved by comparison and co-injection with samples of racemic amino acid derivatives which were prepared in the same way. On the chiral stationary phase used in this experiment except for proline the D-enantiomers are eluted before the L-enantiomers (König et al., 1989).

4.4. Spectrometry

For mass spectral analysis, the samples were loaded onto an Inertsil ODS-3, C18, 5 μm, 50×0.8 mm column equipped with a C18, 2×0.8 mm μ-guard column (LC Packings) using a FAMOS μ-sampling workstation (LC Packings, Amsterdam, The Netherlands). Chromatography was carried out using an HP1100 HPLC system (Hewlett-Packard, Waldbronn, Germany) running at 100 μl/min. The flow was split by an Acurate μ-flow processor (LC Packings) installed between the HPLC pump and the injector of the FAMOS workstation to yield a flow of 25 μl/min on the reversed-phase column. The HPLC solvents were: A, 0.05% TFA/water; B, 96% acetonitrile/0.05% TFA/water. Linear gradients from 10% to 80% B were run over 12 min, with an isocratic step of 3 min at 95% at the end of the gradient. The column effluent passed through a U-Z view 30 nl flow cell (LC Packings) with the detector set at 214 nm, and from there was then directed through a fused silica capillary (340 μm o.d.×50 μm i.d.) into the electrospray source of an LCQ ion trap mass spectrometer (Finnigan Corp., San Jose, CA, USA) run in the full scan mode for mass determination with the scan range set between

200 and 2000 amu. The source was operated at 4.5 kV with the heated capillary set at 220 °C and sheath nitrogen gas flow rate at 80. The ion time was set at 500 ms and the target number of ions at 5×10^7. Three microscans/spectrum were performed. The electron multiplier was set at −1000 V and spectra were collected in the positive-ion mode.

The ultraviolet absorption was measured on a Perkin Elmer Lambda 19 spectrometer (Perkin Elmer GmbH, Überlingen, Germany) employing 0.1 g/l of the sample in MeOH. The IR transmission spectra were recorded on a Perkin Elmer FT–IR Microscope i-Series coupled with a Spectrum 2000 FT–IR Spectrometer (Perkin Elmer GmbH, Überlingen, Germany).

NMR spectra were recorded on a BRUKER DMX 500 (Faellanden, Switzerland) spectrometer using a selective probe for the 1D–^{13}C spectrum and a triple inverse probe for the 1D–^{1}H and 2D spectra. The sample concentration was <2 mg/0.5 ml DMSO-d_6. ^{1}H and ^{13}C shifts are referenced to DMSO-d_6 = 2.49 ppm and 39.9 ppm respectively. The following NMR experiments were carried out: 1D–^{1}H, 1D–^{13}C, ^{1}H–^{1}H–COSY, ^{1}H–^{1}H–ROESY, ^{1}H–^{1}H–TOCSY, ^{1}H–^{13}C–COSY (HSQC), and the amino acid sequence was deduced primarily by HMBC correlations.

4.5. Enzyme inhibition

The isolated depsipeptides were dissolved in 50% aq. MeOH at 500 μg/ml, and a series of dilutions was preincubated with either one of the proteases trypsin, plasmin, thrombin, elastase and papain. Then, a *p*-nitrophenyl-labeled substrate peptide was added and the proteolytic release of *p*-nitrophenol was recorded spectrophotometrically at 405 nm (ELISA reader Dynatech MR 5000, Dynatech, Chantilly, Virginia, USA). All assays were carried out in microtiter plates and repeated in triplicate.

The following buffers were used: (A) 0.1 M Tris–HCl, pH 8.2, containing 23 mM $CaCl_2$, for trypsin (Elfant et al., 1985); (B) 0.05 M Tris–HCl, pH 8.9 for plasmin (Lottenberg et al., 1981, with modifications); (C) 0.2 M Tris–HCl, pH 8.0, for elastase (Bieth et al., 1974); (D) 0.2 M Tris–HCl, pH 8.0 for thrombin (adapted according to Lottenberg et al., 1981); (E) 0.1 M sodium phosphate, pH 6.5, containing 1 mM EDTA for papain (Barrett, 1981).

Trypsin *EC 3.4.21.4* (Sigma T 8802) was dissolved in 1 mM HCl containing 20 mM $CaCl_2$ (pH 3.1; 0.1 mg/ml). 10 μl of this solution were preincubated with the depsipeptide (10 μl) and 130 μl buffer A for 10 min at 25 °C. Subsequently, 150 μl of the substrate BAPNA (Sigma B 3133, 0.45 mg/ml in water) were added, and the incubation was continued for an additional 3 min.

Plasmin *EC 3.4.21.7* (Sigma P 8644) was dissolved in buffer B (0.5 mg/ml). 10 μl of this solution were preincubated with the depsipeptide (10 μl) and 170 μl buffer B for 10 min at 25 °C before 10 μl of the substrate *N*-*p*-tosyl-Gly-Pro-Lys-*p*-nitroanilide (Sigma T 6140, 1.1 mg/ml in water) were added and the incubation continued for 3 min.

Elastase Type IV *EC 3.4.21.36* (Sigma E 0258) was dissolved in buffer C (0.075 mg/ml). 10 μl of this solution were preincubated with the depsipeptide (10 μl) and 150 μl buffer C for 20 min at 30 °C. Then, 30 μl of the substrate *N*-succinyl-Ala-Ala-Ala-*p*-nitroanilide (Sigma S 4760, 18 mg/20 ml buffer C) were added, and the incubation was continued for an additional 3 min.

Thrombin *EC 3.4.21.5* (Sigma T 4648) was dissolved in buffer D (0.5 mg/ml). 10 μl of this solution were preincubated with the depsipeptide (10 μl) and 170 μl buffer D for 10 min at 25 °C. Thereafter, 10 μl of the substrate *N*-*p*-tosyl-Gly-Pro-Lys-*p*-nitroanilide (Sigma T 6140, 0.5 mg/ml water) were added, and the incubation was continued for an additional 3 min.

Papain *EC 3.4.22.2* (Sigma P3125) was dissolved in buffer E (100 μl in 1 ml). 10 μl of this solution were preincubated with the depsipeptide (10 μl) and 170 μl buffer E, containing additionally 2 mM cysteine (Sigma C 7755), for 10 min at 40 °C. Subsequently, 10 μl of the substrate BAPNA (Sigma B 3133, 4.2 mg/ml DMSO) were added and the incubation was continued for an additional 3 min.

4.6. Compound characterization

Scyptolin A: Colourless amorphous powder. Optical rotation $[\alpha]_D^{20}$ −66,0° (MeOH). Ultraviolet absorption λ_{max}^{MeOH} nm (log ε): 281.54 (3.29). Infrared spectrum ν_{max}^{film} cm^{-1}: 3364, 3310 (NH and OH stretching), 3063 (aromatic CH stretching), 2967, 2938, 2877 (aliphatic CH stretching), 1737 (ester C=O stretching), 1675 (amide C=O), 1530 (amide II).

Scyptolin B: Colourless amorphous powder. Optical rotation $[\alpha]_D^{20}$ −58.1° (MeOH). Ultraviolet absorption λ_{max}^{MeOH} nm (log ε): 281.98 (3.35). Infrared spectrum ν_{max}^{film} cm^{-1}: 3364, 3286 (NH and OH stretching), 3058 (aromatic CH stretching), 2965, 2938, 2876 (aliphatic CH stretching), 1738 (ester C=O stretching), 1666 (amide C=O stretching), 1534 (amide II).

Acknowledgements

We thank U. Neumann (University of Freiburg) for his introductory advice and S. Moss (Novartis, Basel) for infrared and ultraviolet analyses. The work was supported by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie.

Abstract

Soybean cotyledons directly exposed to UV-C (190–280 nm) contained a colored pigment in those areas of the epidermis directly exposed to UV-C. Ethanolic extracts from UV-C irradiated cotyledons showed a significant peak at 532 nm at pH = 10, but not seen at pH = 6, successive changes in pH were accompanied by reversible changes in the spectra. The identity of the pigment isolated from soybean cotyledons was established as apigeninidin by comparing the features of standard of a apigeninidin (from sorghum) previously characterized by FAB–MS, UV, HPLC, ^{1}H NMR, and IR spectroscopy. To characterize antioxidant activity of this compound, its ability to scavenge radical species in vitro was tested. In the concentration range tested (up to 200 μg ml $^{-1}$), apigeninidin did not show any scavenger activity towards hydroxyl radical, quinones or NO. However, ascorbyl radical and lipid radicals were effectively quenched in a dose-dependent manner. Overall, UV-C radiation triggers molecular signals that lead in soybean cotyledons to the synthesis and accumulation of an antioxidant pigment, apigeninidin, that shows scavenger activity against ascorbyl and lipid radicals in in vitro studies. © 2001 Elsevier Science Ltd. Keywords: *Glycine max*; Fabaceae antioxidant capacity; 3-Deoxyanthocyanidin; Apigeninidin

1. Introduction

Flavonoid glycosides constitute an important group of plant secondary metabolites. Various soybean flavonoids have been identified, including coumestrol, biochanin A, genistein, naringenin, isorhamnetin, quercetin, isoquercetin, daidzein, formononetin, kaempferol, apigenin, and chrysin (Rivera-Vargas et al., 1993). An aurone (hispidol-6-glucoside) that in solution showed color changes in response to high pH reaching a peak at 478 nm, has been described in soybean cotyledons (Wong, 1966). Flavonoids play a significant role in many physiological processes. Flavonoids and other phenylpropanoids have long been thought to participate in protecting against UV radiation, because they accumulate primarily in the epidermal and hypodermal layers of leaves and stems (the most illuminated layers) (Dixon and Paiva, 1995). Recently, Kozak et al. (1999) reported that UV-B + UV-C radiation seems to be responsible for the appearance in soybean cotyledons, of a colored pigment with a strong absorption in the UV region. The increase in flavonoid accumulation occurred specifically in areas that had been exposed to UV-C radiation, in agreement with previous data from Lois (1994) on leaves of *Arabidopsis* exposed to UV radiation. Kozak et al. (1999), suggested by comparison with literature values, as the identity of observed pigment an uncommon 3-deoxyanthocyanidin, probably apigeninidin or a related compound. This finding was potentially very interesting since this compound has not been identified in legumes previously, and anthocyanidins are usually present as glycosides and not as free aglycones. In fact, soybean anthocyanidins previously identified in hypocotyls are malvidin glycosides and related compounds like delphinidin (Peters et al., 1984). Apigeninidin (3-deoxypelargonidin) was the first 3-deoxyanthocyanidin to be isolated; it was found by Robinson and Robinson (1932) in the bright scarlet corollas of *Rechsteineria cardinalis* (formerly *Gesneria cardinalis*). It occurs widely in the Gesneriaceae as a petal pigment and it is

present in the fronds of several ferns (Harborne, 1967), in the leaf of *Sorghum vulgare*, (Stafford, 1965), and in the stems of *Sorghum bicolor* (Rey et al., 1993).

Regarding its physiological function, apigeninidin showed a high fungicidal activity in sorghum (Aida et al., 1996). Ratty and Das (1988) reported the effect of several flavonoids on nonenzymatic lipid peroxidation and showed that flavonoid aglycones were more potent in their antiperoxidative action than their corresponding glycosides. Moreover, the flavonoid aglycones (apigenin, luteolin, chrysoeriol, kaempferol, quercetin and isorhamnetin) from an illuminated parsley cell suspension culture change the antioxidative capacity of plasma in rats (Hempel et al., 1999).

The aim of this work was to study the nature of the colored pigment that appeared after UV irradiation in superficial layers of soybean cotyledons. Soybean plants were exposed in vivo to UV-C and the pigment was characterized by FAB–MS, UV and HPLC, and its properties were compared with the features of an standard of apigeninidin (from sorghum). The antioxidant capacity of this pigment against hydroxyl, semiquinone, nitric oxide (NO), ascorbyl and lipid radicals was also assessed by in vitro studies employing electron paramagnetic resonance (EPR) methods.

2. Results

Soybean cotyledons exposed to UV-C radiation (190–280 nm) accumulated a colored pigment in the epidermis as early as 15 h after receiving the UV irradiation, with a maximum after 24 h of irradiation. Pigmentation was observed in areas of the epidermis directly exposed to the UV-C source (Fig. 1); cotyledons from control and UV-B (280–320 nm) exposed plants did not show any change in pigmentation over the studied time period, in agreement with previous data from Kozak et al. (1999).

The spectra of ethanolic extracts of soybean cotyledons from control and UV-C irradiated plants after 24 h of a single exposure showed that absorbance in the region between 250 and 340 nm increased after irradiation (data not shown). Extraction with 0.01% (v/v) HCl in methanol gave an orange solution. This solution turned yellow after fuming with HCl, and changed back to red after exposure to ammonia. As previously reported with soybean cotyledons exposed to UV-B + UV-C, ethanolic extracts from UV-C irradiated cotyledons showed a significant peak at 532 nm at pH = 10, but not seen at pH = 6, and successive changes in pH were accompanied by reversible changes in the spectra (Kozak et al., 1999).

Kozak et al. (1999) suggested, by comparison with literature values (Harborne, 1967), that the above spectral data were consistent with the features of an uncommon 3-deoxyanthocyanidin, probably apigeninidin or a related compound. Further studies were therefore performed to establish the identity of the pigment. Apigeninidin is a natural component in sorghum (Rey et al., 1993). Apigeninidin from sorghum was purchased, characterized by FAB–MS, UV, HPLC, ^{1}H NMR and IR spectroscopy, to be employed as standard. Although apigeninidin has been prepared through total synthesis (Harborne, 1967; Sweeny, 1977, 1981) NMR spectroscopic data was not reported. The extremely low solubility of apigeninidin in different deuterated solvents made it difficult to reach an appropriate concentration to acquire NMR spectra. However, the data reported here were obtained using an acid medium, such as the mixture TFA_d–$DMSO_{d6}$–CD_3OD, 1:3:1, to acquire a ^{1}H NMR spectrum of the standard apigeninidin from sorghum. The ^{1}H NMR of sorghum apigeninidin showed the profile expected for this type of compound (3-deoxyanthocyanidin) (Mitchell et al., 1998): ^{1}H NMR δ: 9.05 (*d*, 1H, H4, $J = 8.8$ Hz), 8.34 (*d*, 2H, H2′ and H6′, $J = 9.1$ Hz), 8.15 (*d*, 1H, H3, $J = 8.8$ Hz), 7.06 (*d*, 2H, H3′ and H5′, $J = 9.1$ Hz), 6.97 (*d*, 1H, H6, $J = 1.7$ Hz), 6.70 (*d*, 1H, H8, $J = 1.7$ Hz). The ^{1}H NMR spectrum of the pigment isolated from soybean cotyledons was not of the quality of that obtained with the standard, since due to the experimental isolation procedure, a low amount of sample was obtained. However, FAB-MS studies were useful to characterize the pigment isolated from soybean. FAB-MS data shows a m/z at 255 (rel. int. 15) corresponding to $[M]^+$, and a m/z signal at 162 (rel. int. 100) corresponding to $[M]^+$–C_6H_5O. The FAB-MS of the standard (from sorghum) showed the same pattern with signals at 255 (*rel. int*. 100), and 162 (rel. int. 12). No other significant signals were found neither in experiments employing standard pigment nor in soybean samples. The standard of apigeninidin (from sorghum), was characterized by IR and UV, and the data obtained were consistent with data from the literature: IR KBr cm^{-1}: 3400, 3049, 1640, 1536, 1510, 1338, 1234, 1175, 1150, 838; and UV spectroscopy of apigeninidin in 0.01% (v/v) HCl–methanol, showed λ_{max} at 240, 276, 324 and 476 nm.

Aglycones are not usually found in living tissues. Since acid-containing solvents were used during extraction and isolation, under the experimental conditions employed in this study hydrolysis was minimized. Chromatograms were obtained on extracts within minutes of extracting the tissue with ice-cold methanol containing 0.1% (v/v) HCl to prevent hydrolysis (Harborne, 1967).

TLC studies of the extract obtained from irradiated cotyledons of soybean indicated that R_f values for the single pigment band were 0.75 and 0.63 in Forestal: HOAc:HCl:H_2O (30:3:10) and HCO_2H:HCl:H_2O (9:2:3) solvents, respectively. The UV–visible spectrum of the isolated pigment in 0.01% (v/v) HCl in methanol

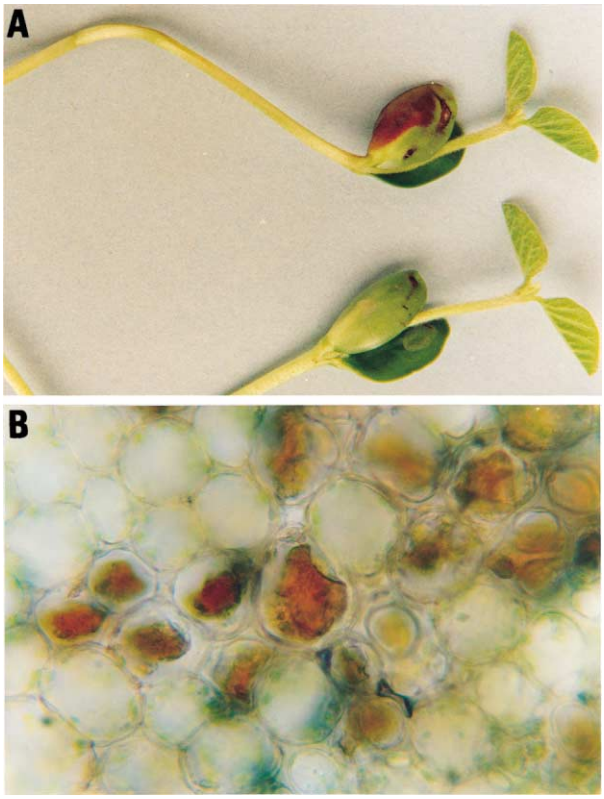

Fig. 1. Effect of UV-C (190–280 nm) on soybean cotyledons. A, UV-C irradiated seedling (top) and control seedling (bottom); B, longitudinal sections of epidermis of fresh cotyledons photographed at ×400, 24 h after UV-C exposure. A Leitz–Wetzler microscope equipped with a Canon A1 camera and regular 135-mm 100 ASA color film was used for the photograph.

showed a clearly defined maximum at 476 nm and another maximum at 276 nm (Fig. 2). The ratio $E_{440nm/474nm}$ was 0.55. No changes were detected after treatment of the pigment isolated from soybean cotyledons in 0.01% (v/v) HCl in methanol, with drops of 5% (w/v) $AlCl_3$ in methanol, suggesting that the molecule had no free *o*-dihydroxyl groups.

HPLC chromatograms of the standard of apigeninidin from sorghum and the pigment isolated from soybean were compared. Data shown in Fig. 3A using the standard apigeninidin (from sorghum) and in Fig. 3B employing the pigment extracted from soybean cotyledons, are in agreement in terms of R_t (2.85 min).

To assess the ability of apigeninidin to function as an antioxidant, in vitro studies were performed. Ascorbyl radical was generated by ascorbic acid in potassium phosphate buffer pH = 7.4. The EPR signal obtained under these conditions showed hyperfine splittings that are characteristic for ascorbyl radicals ($a^H = 1.88$ G, $g = 2.0054$) (Buettner and Jurkiewicz, 1993). The supplementation of the reaction medium with 200 μg ml^{-1} of apigeninidin significantly decreased the area of the recorded signal (Fig. 4A). The content of lipid radicals in rat liver microsomes, were detected by EPR using α-(4-pyridyl 1-oxide)-*N*-*t*-butyl nitrone (POBN) as spin trap. The characteristic signal of the POBN-lipid radical

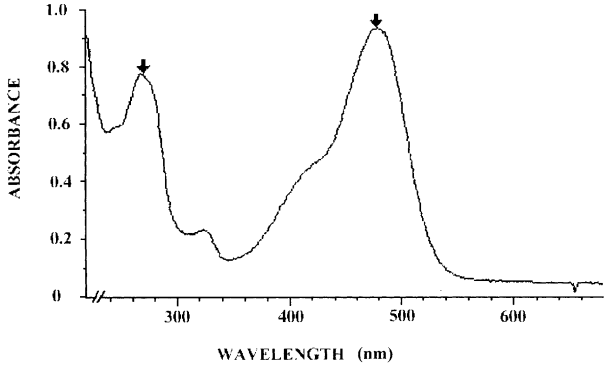

Fig. 2. UV-visible spectrum of the isolated pigment in 0.01% (v/v) HCl in methanol. Arrows indicate λ 276 and 476 nm, respectively.

adduct ($a^N = 15.8$ G, $a^H = 2.6$ G), (Jurkiewicz and Buettner, 1994) was significantly decreased in the presence of 200 μg ml^{-1} of apigeninidin (Fig. 4B). The content of thiobarbituric acid reactive substances (TBARS) is currently used as an index of lipid peroxidation (Slater, 1984). TBARS content in rat liver microsomes was significantly decreased by the addition of apigeninidin as shown in Fig. 5. The dose-dependent effect of apigeninidin on ascorbyl radical, lipid radical and TBARS content was studied (Fig. 5). Comparable

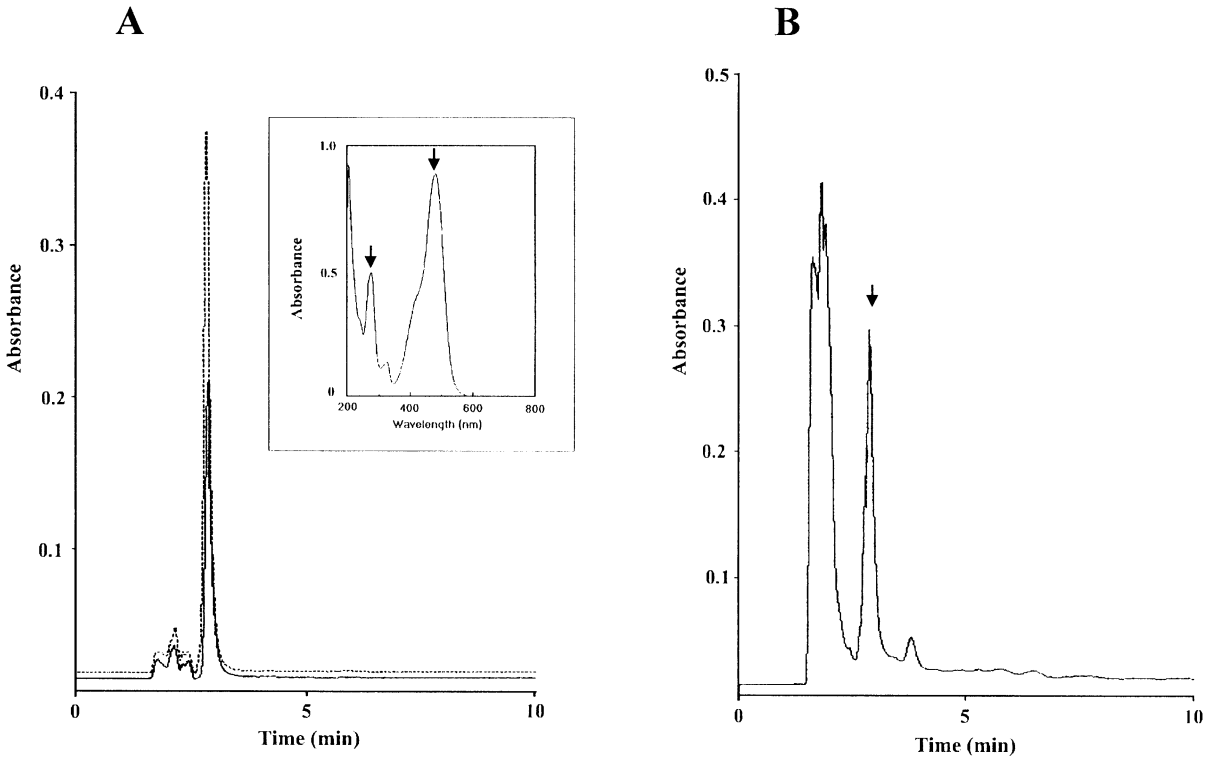

Fig. 3. Identification of apigeninidin by high performance liquid chromatography (HPLC). A, chromatogram of standard apigeninidin (from sorghum) in mobile phase (H_2O–THF–H_3PO_4 85% (v/v)-iso-PrOH (58:40:1:1) monitored to 270 (—) and 482 nm (·····) (Rt: 2.85 min). Inset, absorption spectra of the natural standard apigeninidin (from sorghum) in the same mobile phase. Arrows indicate the peaks at 270 and 482 nm; B, chromatograms obtained with the pigment isolated from soybean cotyledons exposed to UV-C (—) monitored to 270 nm. Arrow indicates R_f: 2.85 min.

results were obtained employing apigeninidin partially purified from soybean cotyledons exposed to UV-C (data not shown).

Hydroxyl radicals, semiquinone radicals and nitric oxide were generated in vitro as indicated in the Experimental section. The addition of apigeninidin (up to a concentration of 160, 200 and 200 μg ml^{-1} respectively), did not significantly affect the amount of each of the mentioned radicals detected by EPR.

3. Discussion

During the Precambrian, ultraviolet radiation reaching the Earth's surface, including UV-C wavelengths (190–280 nm), was considerably higher than at present because of the lack of absorbing gases (e.g. O_2 and O_3) in the atmosphere (Kastin et al., 1989). Although protection from UV-C radiation is not currently biologically important, high UV-C flux would have been damaging to photosynthetic organisms exposed to solar radiation in the past. Dillon and Castenholz (1999) postulated that a cyanobacterial extracellular sheath pigment may have been an important ecophysiological protective factor in cyanobacterial evolutionary history. The results presented here suggest that in soybean cotyledons, there are metabolic pathways that could be triggered by UV-C radiation. No UV-B exposure was required for the appearance of the pigment in soybean cotyledons since UV-C by itself could lead to apigeninidin accumulation. Adaptation to photooxidative stress is multifactorial, it may be also possible that UV-C irradiation activates molecular signals in common with more than one metabolic pathway. It has been shown that light-mediated responses affect the activity of the enzymes involved in flavonoid and anthocyanin biosynthesis (Lewis et al., 1998). The presence of apigeninidin in soybean has not been previously fully verified and the results presented here employing TLC, FAB-MS, and HPLC confirmed the identity of the observed pigment in soybean cotyledons exposed to UV-C as apigeninidin. The presence of this compound in soybean is an interesting finding since as it was previously indicated, aglycones are not normally found in living tissues and soybean anthocyanins previously identified in hypocotyls are malvidin glycosides and related pigments like delphinidin (Peters et al., 1984). On the other hand, since the experimental procedure employed is used to isolate glycosides, it should be discarded that the presence of the pigment could be an artifact generated by experimental isolation (Peters et al., 1984).

Flavonoids in general attract wide attention as possible useful agents for combating the pathological states

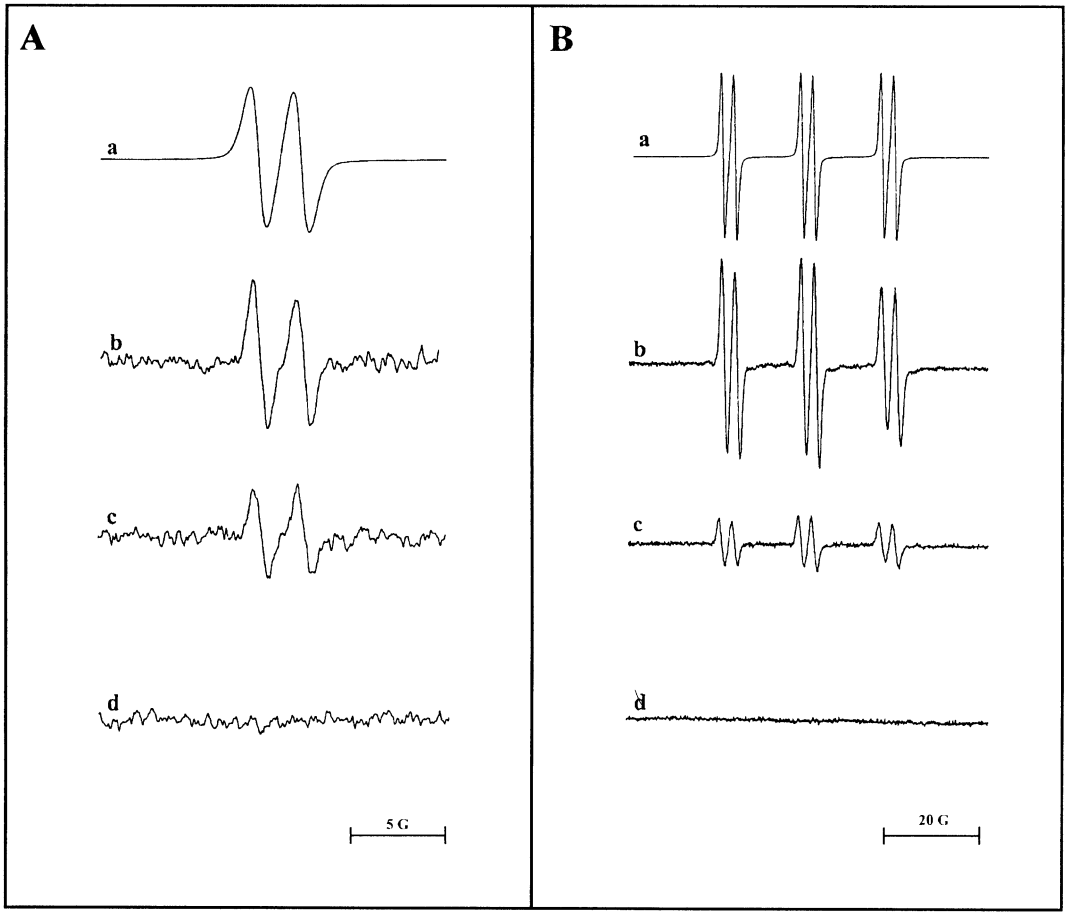

Fig. 4. Apigeninidin scavenging activity against ascorbyl radical and lipid radicals. A, electron paramagnetic resonance (EPR) spectra from ascorbyl radical generated by ascorbic acid in potassium phosphate buffer pH = 7.4. Computer simulated spectrum employing as spectral parameters $a^H = 1.88$ G and g = 2.0054 (a); ascorbic acid in 100 mM potassium phosphate buffer pH = 7.4 (b); ascorbic acid in 100 mM potassium phosphate buffer pH = 7.4 and 200 μg ml^{-1} apigeninidin (c); and basal system (in the absence of ascorbic acid)(d). B, EPR spectra of the lipid radicals-POBN (α-(4-pyridyl 1-oxide)-*N*-*t*-butyl nitrone) spin adduct. Computer simulated spectrum employing as spectral parameters $a^N = 15.8$ G and $a^H = 2.6$ G and g = 2.005 (a); lipid radicals-POBN spin adduct generated in rat liver microsomes (b); as (a), but in the presence of 200 μg ml^{-1} apigeninidin (c); and basal system (in the absence of microsomes) (d).

associated with free radical overproduction. To characterize the antioxidant activity of apigeninidin, its ability to scavenge radical species in vitro was tested. In the concentration range studied (up to 200 μg ml^{-1}), apigeninidin did not show any scavenger activity towards hydroxyl radical, semiquinones or NO. However ascorbyl radical and lipid radicals were effectively quenched.

Ascorbyl radical may be considered as a terminal product of free radical transformations in the biological antioxidant defense system. In living photosynthetic tissues both the enzymatic and non-enzymatic generation of ascorbyl radicals occur and could be substantially increased under oxidative stress conditions. For example, after exposure to UV-B the ascorbyl radical-dependent EPR signal was enhanced by 76 and 46% in algal cultures and soybean leaves, respectively (Malanga et al., 1999). The ability of apigeninidin to act as an scavenger of ascorbyl radical could have positive applications in terms of preventing the development of oxidative stress in those situations where ascorbyl radical content is increased.

In previous reports on structure-activity analysis of several flavonoids on non-enzymatic lipid peroxidation in rat brain mitochondria, it was concluded that flavonoid molecules with polyhydroxylated substitutions on rings A and B, a 2,3-double bond, a free 3-hydroxyl substitution and a 4-keto moiety, would confer upon the compound potent antioxidant properties (Ratty and Das, 1988). In that study, the flavonoid aglycones were more potent in their antiperoxidative action than their corresponding glycosides. According to the structure of apigeninidin, the lack of the ketone group (different that of the flavone), and the 3′ and 4′ hydroxy groups (different that of the catechin) that contribute to stabilize the radical formed, strong antioxidative effect was not expected, at least studying in vitro systems. It was also reported that flavonoids having fewer than four

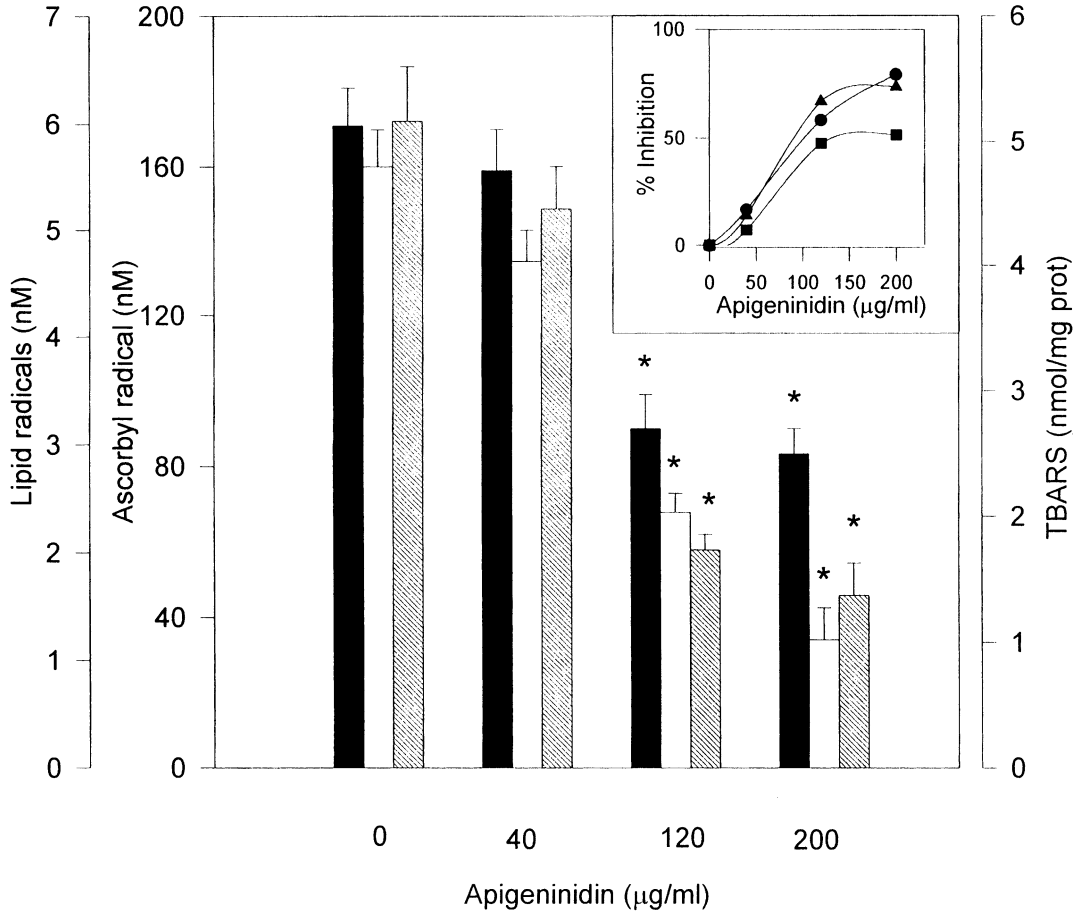

Fig. 5. Dose-dependent effect of apigeninidin on ascorbyl radical (■), thiobarbituric acid reactive substances (TBARS) (□) and lipid radical (▨) content. Lipid radical content and TBARS were assessed after 20 min incubation at 37° and ascorbyl radical was measured immediately as described in Experimental. Inset: percentages of inhibition by apigeninidin supplementation on ascorbyl radicals (■), TBARS (●) and lipid radicals (▲). * Significantly different ($P<0.05$, ANOVA) from control (without addition of apigeninidin).

hydroxyl groups show very little antioxidant efficiency (Larson, 1988). The effect of apigeninidin on lipid peroxidation was tested by measuring its quenching ability on TBARS and lipid radical content in microsomal membranes. Under the experimental conditions used here, a significant capacity of the pigment to limit lipid peroxidation was measured. It can be concluded that the antioxidant activity of the pigment depends on its posibility of accessing the membrane location where radicals are generated. Thus, the antioxidant capacity of apigininidin could be related not only to the pigment structural features but to the membrane characteristics as well.

The results presented here suggest that UV-C radiation triggers molecular signals that lead to the production of the pigment apigeninidin that exhibits antioxidant capacity. Further studies are required to assess the potential cellular function of the compound described here beside its ability of acting as scavenger of ascorbyl radical or as an inhibitor of lipid peroxidation. Moreover, since it was reported that flavonoid aglycones increased antioxidant capacity of blood plasma (Hempel et al., 1999) and soybean products are widely consumed in Western and Asian diets for health benefits, it could be of potential interest to use this cellular response to develop strategies to improve antioxidant capacity of soybean before the utilization of this products in the food and cosmetic industries.

4. Experimental

4.1. Plant material

Soybean seeds (*Glycine max* var Hood) were grown in controlled environmental conditions for 7 days at 26°, under hydroponic culture in modified Steinberg nutrient solution (Tiffin, 1966). Fe was supplemented as an Fe–EDTA (1:2) complex to a final concentration of 50 μM. The buffers and the water used to prepare all solutions were passed through columns containing Chelex 100 resin (Sigma Chemical Co.) to remove metal con-

taminants. The photo-period was approximately 12:12 h light:dark. Relative irradiance was measured using a Jarrell-Ash monochromator and an EMI 9634q5 photomultiplier for UV detection. The fluence rate at the surface was approximately 38 W m^{-2} of photosynthetically active radiation (Philips 40-W day-light-fluorescent light). A germicidal UV-C lamp (190–280 nm) with a band intensity centered at 254 nm (TUV 30 W/630 TB, Philips, The Netherlands) was used for UV-C treatments. Plants were situated 15 cm below the lamp and exposed to UV-C for 60 min. Cotyledons were excised 24 h after UV exposure.

4.2. Extraction and isolation procedures

The epidermical pigment was obtained by scraping the superficial layers of the cotyledons with ice-cold methanol containing 0.1% v/v conc. HCl to avoid hydrolysis (Harborne, 1967). Immediately after extraction, the colored solution was analyzed by TLC performed on Sigma Cell Type 100 cellulose, using HCO_2H:HCl:H_2O (9:2:3) and Forestal:HOAc:HCl:H_2O (30:3:10) as the mobile phases. A mixture of apigeninidin, pelargonidin and cyanidin was used as reference. After drying thoroughly the chromatograms under nitrogen flow, they were observed under daylight. An orange-yellow band, which turned to red after fuming with ammonia was observed. This band showed identical R_f, original color and reaction with ammonia than the standard apigeninidin. The original acid extract was employed for chromatographic assays using Forestal. Bands with the same R_f of apigeninidin from several chromatograms were eluted with ice-cold methanol containing 0.01% v/v conc. HCl, pooled and purified by chromatography using formic acid–HCl–H_2O (9:2:3). Bands were finally eluted with ice-cold methanol containing 0.01% v/v conc. HCl to perform characterization analysis.

4.3. Characterization analysis

FAB–MS studies were collected on a VG-ZAB-SEQ4F Spectrometer. Nuclear Magnetic Resonance (^{1}H NMR) was obtained on a Bruker MSL 300 spectrometer with a mixture of TFA d-DMSO d_6–CD_3OD 1:3:1 as solvent and TMS as internal standard. IR was recorded on a Bruker IFS 25 FT IR in KBr. The UV-visible spectrum of the isolated pigment in 0.01% (v/v) HCl in methanol was recorded in a Hewlett Packard 8452 A diode array spectrophotometer. HPLC analysis were performed with a reverse-phase column (Lichosorbs RP 18). The mobile phase was H_2O-THF-H_3PO_4 85% (v/v)-*iso*-PrOH (58:40:l:l) at a flow rate of 1 ml min^{-1} (Rey et al., 1993). UV detection was monitored at 270 or 482 nm with Waters 486 absorbance detector. Apigeninidin (from sorghum) was used as standard.

4.4. Electron paramagnetic resonance (EPR) measurements

The antioxidant capacity of apigeninidin was assessed studying its scavenger capacity on in vitro systems, by measuring free radical generation before and after pigment addition. Free radical measurements were performed at room temperature in a Bruker (Karlsruhe, Germany) ECS 106 EPR spectrometer with a ER 4102ST cavity.

4.4.1. Scavenging of hydroxyl radicals

Prior to use, the spin trap DMPO (5,5′-dimethyl-pyroline-*N*-oxide), was purified following the method of Green and Hill (1984), to remove contaminants that contribute to EPR background signal. In this procedure, 10 ml of 1 M DMPO in doubly distilled water were mixed with 1.25 g activated charcoal for 1 min, allowed to stand for 1 h, and then filtered. This purification procedure was repeated twice. Hydroxyl radicals were generated by a basic system consisting of 100 mM DMPO, rat liver microsomes (0.4 mg prot ml^{-1}), 0.2 mM sodium azide, 0.3 mM DTPA (diethylene-triaminepentaacetic acid), and 100 mM potassium phosphate buffer pH = 7.4, in the presence or absence of apigeninidin. Reactions were started by addition of 0.5 mM NADPH. The microsomal reaction system was incubated at 37° for 20 min and immediately transferred to a Pasteur pipette for recording. The EPR settings were: microwave power 20 mW, time constant 655.36 ms, modulation amplitude 0.490 G; field scan 100 G, sweep time 168 s, and modulation frequency 50 kHz (McCay et al., 1992). Quantification of the spin adduct was performed using an aqueous solution of 2,2,5,5-tetramethyl piperidine 1-oxyl (TEMPO) introduced into the same sample cell used for spin trapping. EPR spectra for both sample and TEMPO solutions were recorded at exactly the same spectrometer settings and the first derivative EPR spectra were double integrated to obtain the area intensity, then the concentration of spin adduct was calculated according to Kotake et al. (1996).

4.4.2. Scavenging of semiquinone radicals

The reaction system for semiquinone radical generation was: 1 mM Q_0 (2,3-dimethoxy-5-methyl-1,4-benzoquinone), 1 mM Q_0H_2, 100 mM potassium phosphate buffer pH = 7.4, and aliquots of apigeninidin. The setting of the Bruker Espectrometer ECS 106 were: microwave power 20 mW; center field 3490 G; time constant 1310.72 ms, modulation amplitude 0.979 G, sweep time 168 s, modulation frecuency 50 kHz, and sweep width 50 G. Quantification of the spin adduct was performed using an aqueous solution of TEMPO as previously indicated.

4.4.3. Scavenging of nitric oxide

NO was generated using *S*-nitroso-*N*-acetyl-penicillamine (SNAP) as NO donor. The reaction mixture

consisted of: 50 μM SNAP, *N*-methyl-D-glucamine dithiocarbamate iron (MGD:Fe (20:2 mM)) as spin trap, 100 mM potassium phosphate buffer pH = 7.4, and aliquots of apigeninidin. The EPR spectrometer settings were: microwave power 20 mW, center field 3450 G, time constant 164 ms, modulation amplitude 6.2 G, sweep time 168 s, modulation frequency 50 kHz, and sweep width 150 G (Komarov and Lai, 1995). Quantification of the spin adduct was performed using an aqueous solution of TEMPO as previously indicated.

4.4.4. Scavenging of ascorbyl radicals

The reaction mixture was: 62.5 μM ascorbic acid in 100 mM potassium phosphate buffer pH = 7.4 and aliquots of apigeninidin. The EPR spectrometer settings were: microwave power 1 mW, microwave frequency 9.75 GHz, center field 3487 G, time constant 327.68 ms, modulation amplitude 1 G and sweep width 15 G (Buettner and Jurkiewicz, 1993). Quantification of the spin adduct was performed using an aqueous solution of TEMPO as previously indicated.

4.4.5. Scavenging of lipid radicals

Rat liver microsomes prepared by differential centrifugation (0.4 mg prot ml^{-1}) were supplemented with 100 mM α-(4-pyridyl 1-oxide)-*N*-*t*-butyl nitrone (POBN), 5.5 mM ADP, 0.1 mM $FeCl_3$, 1 mM NADPH, 100 mM potassium phosphate buffer pH = 7.4, and incubated for 20 min at 37° in the presence or absence of aliquots of apigeninidin. The EPR spectrometer settings for the spin trapping experiments were: microwave power 20 mW, microwave frequency 9.75 GHz, center field 3480 G, time constant 82 ms, modulation amplitude 1.2 G and sweep width 100 G (Jurkiewicz and Buettner, 1994). Quantification of the spin adduct was performed using an aqueous solution of TEMPO as previously indicated.

4.4.6. Scavenging of thiobarbituric acid reactive substances (TBARS)

Microsomal TBARS content was measured using a modified fluorescence method (Fraga et al., 1987). Rat liver microsomes prepared by differential centrifugation (0.4 mg prot ml^{-1}) were supplemented with 5.5 mM ADP, 0.1 mM $FeCl_3$, 1 mM NADPH, 100 mM potassium phosphate buffer pH = 7.4, and incubated for 20 min at 37° in the presence or absence of aliquots of apigeninidin. To 0.5 ml of suspension, 0.05 ml of 4% (w/v) BHT and 0.5 ml of 3% (w/v) sodium dodecyl sulfate were added. After mixing, 2 ml of 0.1 N HCl, 0.3 ml 10% (w/v) phosphotungstic acid, and 1 ml of 0.7% (w/v) 2-thiobarbituric acid were added. The mixture was heated for 45 min in boiling water, and TBARS were extracted into 5 ml of *n*-butanol. After a brief centrifugation, the fluorescence of the *n*-butanol layer was measured at 515 nm excitation and 555 nm emission. The values were expressed as nmol TBARS (malondialdehyde equivalents) per mg protein. Malondialdehyde standards were prepared from 1,1,3,3-tetramethoxypropane.

4.4.7. Statistical analyses

Data are expressed as mean ± S.E. from 4 to 6 independent experiments. Statistical tests were carried out using Statview S.E.±, v 1.03 (Abacus Concepts Inc, Berkeley, CA, USA).

Received 8 May 2001; received in revised form 16 August 2001

Abstract

Two taraxastane triterpenoids, i.e. taraxast-20-ene-3β,30-diol (**1**) and 20α,21α-epoxy-taraxastane-3β,22α-diol (**2**), as well as four known triterpenes taraxast-20(30)ene-3β,21α-diol (**3**), taraxast-20(30)-ene-3β-ol (**4**), taraxast-20-ene-3β-ol (**5**) and taraxastane-3β,20α-diol (**6**) were isolated from the Chinese medicinal plant *Saussurea petrovii*. Their structures were elucidated by spectroscopic methods. These compounds, especially **1** and **2**, exhibit significant antitumor and antibacterial activity.

Keywords: Saussurea petrovii Compositae; Taraxastane; Triterpenoids, Cytotoxicity; Antibiosis

1. Introduction

Saussurea petrovii (Compositae) is a perennial herbaceous plant growing mainly in North China. Its rhizome has been used as a traditional Chinese medicine for treatment of rheumatism and bleeding since ancient times (Ma et al., 1982). Its phytochemical or pharmacological properties have not been reported to date. In our effort to find biologically active components from Chinese medicinal plants (Zhu et al., 1999; Su et al., 2000; Wang et al., 2000; Zhang et al., 2000) we found two new triterpenoids, i.e. taraxast-20-ene-3β,30-diol (**1**) and 20α,21α-epoxy-taraxastane- 3β,22α-diol (**2**), as well as four known triterpenes taraxast-20(30)ene-3β,21α-diol (**3**), taraxast-20-ene-3β-ol (**4**), taraxast-20-ene-3β-ol (**5**) and taraxastane-3β,20α-diol (**6**) in the acetone extract of *Saussurea petrovii*. Compound **1** was previously reported as an oxidation product of taraxasterol (Pai and Kulkarni, 1977), but it has not been reported as a natural product. We report herein the isolation, structural elucidation and antitumor and antibacterial activities of these compounds. It was found that **1** and **2** possess strong cytotoxicity against mouse melanoma (B16) cells.

2. Results and discussion

From the acetone extract of the rhizome of *S. petrovii,* six taraxastane-type triterpenoids (**1**–**6**) were obtained and purified by repeated chromatography on silica gel. Each of the isolates was subjected to detailed spectroscopic analyses to establish their chemical structures.

Compound **1** was obtained as colorless crystals. The EIMS revealed a molecular ion peak at *m*/*z* 442. The ^{13}C NMR and DEPT spectra of **1** exhibited 30 carbon signals ($7\times CH_3$, $10\times CH_2$, $7\times CH$, $6\times C$), and the molecular composition of **1** was deduced to be $C_{30}H_{50}O_2$, which was confirmed by HR–EIMS (*m*/*z* 442.3811, calc. 442.3811). Its IR spectrum showed strong absorptions for hydroxyl groups and double bonds (3234 and 1656 cm^{-1}, respectively). The ^1H NMR spectrum demonstrated the presence of seven methyl groups, of which six were singlets (δ 0.75, 0.76, 0.85, 0.95, 0.96, 1.04) and one was a doublet (δ 1.00, *d*, *J* = 6.4 Hz), and an olefinic proton (δ 5.51, *dd*, *J* = 6.6, 1.8 Hz), two hydroxymethylene protons (δ 4.13, *d*, *J* = 12.3 Hz; δ 4.02, *d*, *J* = 12.3 Hz) and a hydroxymethine proton (δ 3.21, 1H, *dd*, *J* = 11.2, 4.9 Hz). These spectral data suggested that **1** was a pentacyclic triterpene with two hydroxyl groups and a trisubstituted double bond (Table 1). Comparison of the ^{13}C NMR spectroscopic data with those of pseudotaraxasterol (Reynolds et al., 1986) and its 22α-hydroxy derivative (Chiang and Kuo, 2000) showed that, except for the ring E carbons and C-28, the chemical shifts are almost identical. This suggested that the second

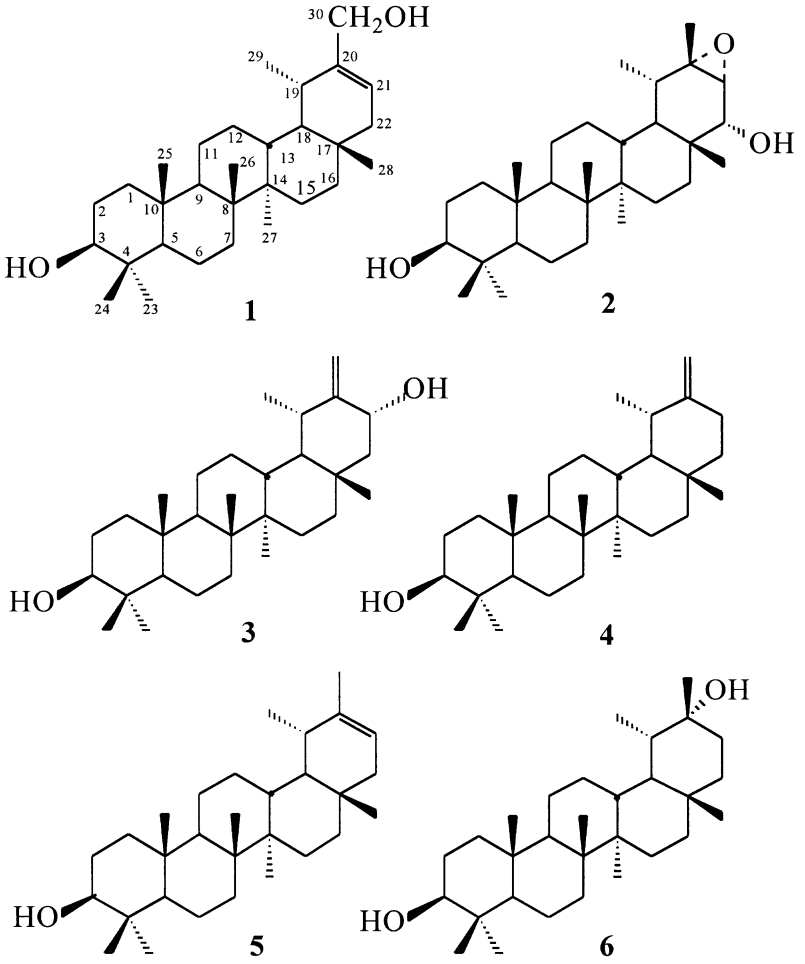
PII: S0031-9422(01)00397-1



hydroxyl group must be located on ring E. Its definitive location was established by 2D NMR spectroscopic experiments. The ^{1}H–^{1}H COSY spectrum of **1** showed that the olefinic proton (δ 5.51) correlated only with H-22α (δ 1.55). In the HMBC spectrum H-16, H-18, H-22 and Me-28 correlated with C-17 (δ 34.5); H-19, H-21 and H-30 (hydroxymethyl group) correlated with C-20 (δ 143.7), indicating that the double bond is located at the C-20 (21) positions and C-30 is hydroxylated (Fig. 1). Therefore, compound **1** is deduced to be taraxast-20-ene-3β,30-diol.

Compound **2** was assigned the molecular formula $C_{30}H_{50}O_3$ by HR–EIMS (m/z 458.3746, calc. 458.3759). The IR absorption bands at 3240 cm^{-1} indicated the presence of hydroxyl groups. Comparison of the 1D (^{1}H, ^{13}C / DEPT) and 2D (^{1}H–^{1}H COSY, HMQC, HMBC) NMR spectra of **2** with those of **1** (Table 1) revealed that **2** possessed a similar structure except in ring E. Compound **2** has two more protons on oxygenated carbons at δ 3.12 (d, J=4.1 Hz) and δ 2.93 (d, J=4.1 Hz) and three oxygenated carbons at 65.7 (correlated to the ^{1}H signal at δ 2.93), 60.8 (correlated to the ^{1}H signal at δ 3.12) and δ 70.5 (a quaternary carbon), but no double bond was observed. Taking into account of the 6 double bond equivalent, compound **2** was deduced to be a taraxastane triterpenoid with an epoxy

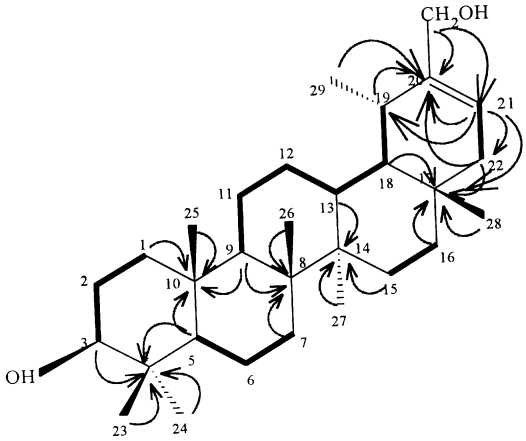


Fig. 1. ^{1}H–^{1}H COSY (—) and HMBC (H→C) correlations of compound

moiety and a hydroxyl group. ^{1}H–^{1}H COSY and HMQC (Fig. 2) showed the presence of a −CH−CH− fragment bearing an epoxide oxygen (δ 60.8) and one hydroxyl group (δ 65.7), suggesting that they are located at C-21 and C-22 respectively. This was confirmed by HMBC spectrum which showed clear correlations of H-21 with C-20, C-19 and C-30, and correlations of H-22 with C-17 and C-28 (Fig. 2). The magnitude of the coupling constant (4.1 Hz) between H-21 and H-22 suggested that

they are located at the same face of the molecule. The NOESY spectrum showed clear cross peaks between H-19β, H-21, H-22 and H-30, indicating the α-configuration of the epoxide. The COSY correlation between H-21β and H-22β and the J coupling of 4.1 Hz confirmed that H-22 must be an equatorial hydrogen, hence the 22-hydroxyl must be axial (α-configuration). In addition, the significant upfield shift of the C-18 and H-18 chemical shifts (δ 37.0 and 1.10 respectively) relative to those of **1** and related compounds without epoxy functionality (Reynolds et al., 1986; Mahato and Kundu, 1994) indicates that C-18 and H-18 are shielded by the α-epoxide. Therefore, **2** was deduced as 20α,21α-epoxy-taraxastane-3β,22α-diol which has not been reported in the literature.

[a] Some ^{1}H peaks overlapped in the range of δ 1.2–1.9, hence the coupling constants could not be measured. Chemical shift assignments of those peaks were based on their ^{1}H–^{1}H COSY and HMQC spectra.

The structures of **3**, **4**, **5** and **6** were identified as taraxast-20(30)ene-3β,21α-diol, taraxast-20(30)ene-3β-ol, taraxast-20-ene-3β-ol and taraxastane-3β,20α-diol, respectively, by comparing their NMR spectral data with those reported in the literature (Anjaneyulu et al., 1985; Reynolds et al., 1986; Mahato and Kundu, 1994; Petrovic et al., 1999). Recently **3** was first isolated and identified from *Hieracium gymnocephalum* (Petrovic et al., 1999), but only 1 mg of **3** was obtained from 1.15 kg of the plant, and no melting point and optical rotation data were reported.

The cytotoxicity and antibacterial activity of compounds **1**–**6** have not been reported previously. Therefore, the antitumour activity of **1**–**6** was determined using the [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] (MTT) assay (Price and McMillan, 1990) with three tumor cell lines, i.e. human hepatoma cells, (SMMC-7721), human uterine cervix carcinoma cells (Hela) and mouse melanotic carcinoma cells (B16) with vincristine as a positive control (Table 2). It is seen from the table that all of these compounds exhibit moderate in vitro cytotoxic activity against these tumor cells, especially for Hela and B16 cells. The 50% inhibitory concentration (IC_{50}) values of the new compounds **1** and **2** are comparable to vincristine in the case of Hela and much smaller than vincristine in the case of B16.

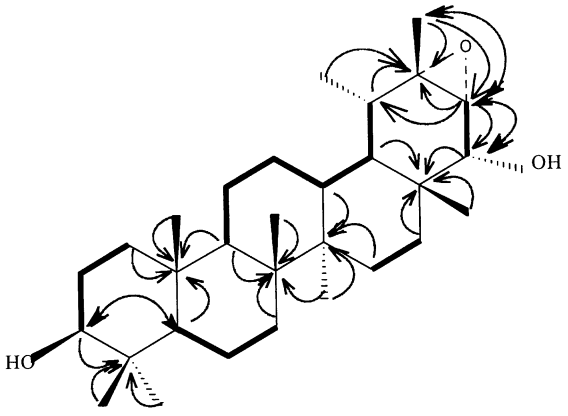

Fig. 2. ^{1}H–^{1}H COSY (—), HMBC (H→C) and NOESY (H←→H) correlations of compound **2**.

Table 2
Antitumor activity for compounds **1**–**6**[a]

Compound	SMMC-7721	B16	Hela

5	131.8±1.9	86.4±4.5	123.6±2.2
6	104.1±4.3	79.7±5.6	71.8±4.4
Vincristine	63.2±1.8	70.7±2.8	67.2±2.2

[a] Activities are expressed as IC_{50} (50% inhibitory concentration) in μg ml^{-1}. Data are expressed as mean±standard deviations of triplicate determinations.

The IC_{50} of 20 μg/ml demonstrates **1** as being an effective inhibitor of B16.

The antibacterial activity of **1**–**6** was determined against *Bacillus subtilis, Escherichia coli* and *Staphylococcus aureus* and compared with that of chloramphenicol (Table 3). It is seen that these triterpenoids, especially **1** and **6**, possess antibacterial activity close to that of the positive control, chloramphenicol.

Table 3
Antibacterial activity of compounds **1**–**6**[a]

Compound	*Bacillus subtilis*	*Escherichia coli*	*Staphylococcus aureus*
1	14.0±1.0	13.7±1.4	14.7±1.5

4	11.1±1.2	12.8±1.3	8.3±0.5
5	12.0±0.6	13.6±0.6	9.1±1.4
6	13.7 ±0.7	14.8±0.8	14.5±1.6
Chloramphenicol	14.5±1.1	14.9±1.3	15.1±1.2

[a] Activities are expressed as the diameter of the inhibitory zone in mm. Data are expressed as mean±standard deviations of triplicate determinations.

3. Experimental

3.1. General

Melting points were determined on a Yanagimoto melting point apparatus and were uncorrected. Optical rotations were measured on a Perkin-Elmer 241 polarimeter. The IR spectra were taken on a Nicolet 170SX FT-IR spectrometer. ^1H, ^{13}C NMR and 2D NMR spectra were recorded using a Bruker AM 400 NMR spectrometer at 400 and 100.58 MHz respectively with TMS as internal standard. HR–EIMS and EIMS data were obtained using a Bruker APEX II FT–MS and HP-5988 MS spectrometers respectively. Silica gel (200–300 and 300–400 mesh) was used for CC and silica GF_{254} for TLC. Spots were detected on TLC under UV or by heating after spraying with 5% H_2SO_4 in C_2H_5OH.

3.2. Plant material

The whole plants of *Saussurea petrovii* were collected in the suburb of Lanzhou city, Gansu province, China, in August 1999. A voucher specimen (No. 9901) was deposited at the National Laboratory of Applied Organic Chemistry, Lanzhou University, Lanzhou, China, and identified by Professor Yong-Hong Zhang at the Department of Chemistry, Lanzhou University.

3.3. Extraction and isolation

The chopped whole plant material (3.0 kg) was extracted repeatedly (3 times, 7 days each time) with acetone at room temperature to give a residue (80 g) after evaporation. This residue was separated by CC over 800 g silica gel (200–300 mesh) with a gradient (2000 ml each eluant) of petroleum ether-acetone (30:1, 20:1, 15:1, 10:1, 5:1, 3:1, 1:1, 0:1). From the fraction of petroleum ether-acetone (15:1), crude crystals of **4** and **5** were obtained successively. Recrystallization from AcOEt gave **4** (60 mg) and **5** (45 mg). The fraction of petroleum ether-acetone (5:1, 10 g) was separated on CC over 200 g silica gel (200–300 mesh) with $CHCl_3$-MeOH (25:1, 1000 ml, 20:1, 1000 ml) to give two subfractions A and B. Fraction A (6.0 g) was separated on CC over 60 g silica gel (200–300 mesh) with petroleum ether–AcOEt (4:1, 350 ml) to give crude **1** and **2**. Fraction B (3.5 g) was separated on CC over 40 g silica gel (200–300 mesh) with petroleum ether–EtOAc (4:1, 250 ml) to give crude **3** and **6.** Subsequently, each of them was purified by rechromatography on a silica gel column (300-400 mesh) with petroleum ether–Me_2CO (6:1) to give pure compounds **1** (35 mg), **2** (17 mg), **3** (30 mg) and **6** (15 mg).

3.4. Taraxast-20-ene-3β,30-diol (*1*)

Colorless crystals, mp 198–200 °C ($CHCl_3$–MeOH); $[\alpha]_D^{25}$ +116 (*c* 0.35, $CHCl_3$); HR–EIMS: $m/z = 442.3811$ [$C_{30}H_{50}O_2$, requires 442.3811]; IR (KBr): $\nu_{max} = 3420$ (OH), 1656 (C=C) cm^{-1}. EI–MS: m/z (rel. int.) = 442 (5) $[M]^+$, 424 (6), 391 (3), 273 (5), 229 (7), 207 (86), 189 (100), 135 (49), 121 (44), 81 (36). For ^1H and ^{13}C NMR spectral data see Table 1. For 2D NMR specral correlations see Fig. 1.

3.5. 20α,21α-Epoxy-taraxastane-3β,22α-diol (*2*)

Colorless crystals, mp 223–224 °C ($CHCl_3$–MeOH); $[\alpha]_D^{25}$ +121° (*c* 0.56, $CHCl_3$); HR–EIMS: $m/z = 458.3746$ [$C_{30}H_{50}O_3$, requires 458.3759]; IR (KBr): $\nu_{max} = 3240$ (OH) cm^{-1}. EIMS: m/z (rel. int.) = 458 (3) $[M]^+$, 440 (5), 397 (3), 247 (4), 243 (11), 207 (73), 189 (100), 175 (26), 149 (23), 95 (52). For ^1H and ^{13}C NMR spectral data see Table 1. For 2D NMR correlations see Fig. 2.

3.6. Taraxast-20(30)ene-3β,21α-diol (*3*)

Colorless crystals, mp 256–258 °C ($CHCl_3$–MeOH); $[\alpha]_D^{25}$ +225 (*c* 0.09, $CHCl_3$); HR–EIMS: $m/z = 442.3819$ [$C_{30}H_{50}O_2$, requires 442.3811]; IR (KBr): $\nu_{max} = 3234$ (OH), 1637 (C=C) cm^{-1}. The ^1H and ^{13}C NMR data are identical with those reported recently (Petrovic et al., 1999).

3.7. Cytotoxicity assay

The cytotoxicity of compounds **1**–**6** was tested in three cell lines: human hepatoma (SMMC-7721), mouse melanoma (B16) and human carcinoma of uterine cervix

(Hela). Cells were cultured at 37 °C under a humidified atmosphere of 5% CO_2 in RPMI 1640 medium supplemented with 10% fetal calf serum and dispersed in replicate 96-well plates with 1×10^4 cells/well for 24 h. Compounds **1**–**6** (10–400 μM) or vincristine (used as a positive control) were then added. After 48-h exposure to the toxins, cell viability was determined by the [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] (MTT) colorimetric assay (Price and McMillan, 1990) by measuring the absorbance at 595 nm with an ELISA reader. Each test was performed in triplicate.

3.8. Antibacterial assay

The paper-disk method (Xu and Bian, 1982) was used for antibacterial tests. A 10 μg portion of comounds **1**–**6** or chloramphenicol (used as a positive control) was applied onto a paper disk, and the paper disk was air-dried. Then the disks were placed on agar plates that had been seeded with *B. subtilis*, *E. coli* or *S. aureus*, respectively, and incubated at 37 °C for 24 h. The antibacterial activity was determined by measuring the diameter of the inhibitory circles. Each test was performed in triplicate.

Acknowledgements

The authors are grateful to Professor Yong-Hong Zhang, Department of Chemistry, Lanzhou University, for her help in identifying the plant material. They also thank the Department of Science and Technology of China for financial support (Grant No. G1998051113).

Abstract

Bioassay-directed fractionation of the CH_2Cl_2–MeOH (1:1) extract of the stem bark of *Erythrina indica,* has resulted in the isolation of two new isoflavone derivatives named indicanines D and E together with 11 known compounds including: six isoflavones (genistein, wighteone, alpinumisoflavone, dimethylalpinumisoflavone, 8-prenyl erythrinin C, and erysenegalensein E), one cinnamate (erythrinassinate B), two pentacyclic triterpenes (oleanolic acid and erythrodiol), and two phytosterols (stigmasterol and its 3-*O*-β-D-glucopyranoside). The structures of the new compounds were elucidated by means of spectroscopic analysis. The in vitro cytocidal activity against KB cells of some of the isolated compounds is also reported. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Erythrina indica; Leguminosae; Papilionaceae; Indicanines D and E, Isoflavones; Ferulic acid ester; Pentacyclic triterpenes; Phytosterols; Cytotoxic activity

1. Introduction

The genus *Erythrina* (Leguminosae) occurs in the tropical and subtropical regions over the world and comprises about 110 species (Dyke and Quessy, 1981). Some of these species have been used in traditional medicine for the treatment of several diseases (Dalziel, 1937). *Erythrina,* species are also a rich source of bioactive alkaloids (Ghosal et al., 1971; Furukawa et al., 1976; Barakat et al., 1977; Cordell, 1981) and of many flavonoid compounds (Nakanishi et al., 1981; Fomum et al., 1986; Mitscher et al., 1988; Nkengfack et al., 1997). Recently, investigations on the root bark constituents of *Erythrina indica,* a plant used in cameroonian folk medicine for the treatment of trachoma, elephantiasis, and microbial infections (Ayensu, 1978), have resulted in the isolation and identification of eight phenolic metabolites among which there were two 3-phenyl coumarin derivatives, indicanines A and B, and one new isoflavone derivative, indicanine C, along with five known compounds including, robustic acid, 8-prenyldaidzein, daidzein, cajanin, and dimethyl alpinumisoflavone (Azebaze et al., 2000; Nkengfack et al., 2000). As part of our continuing search for biological active principles related to non-alkaloidal compounds in *Erythrina* species, now we wish to report the phytochemical analysis of the stem bark of *Erythrina indica* as well as the in vitro cytotoxic activity and potency of some of the isolated compounds.

2. Results and discussion

Dried and ground stem bark of *Erythrina indica* was extracted with a dichloromethane–methanol (1:1) and methanol, successively. These extracts were concentrated to dryness under vacuum and their cytocidal activities against KB cells were evaluated in vitro. As a result, ED_{50} values of the CH_2Cl_2–MeOH (1:1) and MeOH extracts were l0 and 36 μg/ml respectively. Since the first extract showed strong cytocidal activity, we decided to elucidate its active principle (s). Extensive column chromatography on silica gel of this residue yielded pure indicanines D (**1**) and E (**2**) together with eleven known compounds. Compounds (**3**–**8**) were characterized as isoflavones from their spectral data and identified as

genistein (**3**) (Imamura et al., 1981) wighteone (**4**) (Min et al., 1991), alpinumisoflavone (**5**) (Khalid and Waterman, 1983) dimethylalpinumisoflavone (**6**) (Khalid and Waterman, 1983), 8-prenylerythrinin C (**7**) (Fomum et al., 1990), and erysenegalensein E (**8**) (Wandji et al., 1994), whereas compounds (**9**–**13**) were identified by comparison of their spectral data with literature values as erythrinassinate B (**9**) (Fomum et al., 1990), oleanolic acid (**10**) (Mahato and Kundu, 1994), erythrodiol (**11**) (David et al., 1981), stigmasterol (**12**) (Alam et al., 1996), and stigmasteiol 3-*O*-β-D glucopyranoside (**13**) (Alam et al., 1996).

Compound (**1**), obtained as yellow needles. mp 212–214 °C, reacted positively to $FeCl_3$ reagent suggesting the presence of phenolic hydroxyl group(s). Its high resolution FAB-mass spectrum gave an $[MH]^+$ ion at *m*/*z* 803.5826 (calc. 803.5825) consistent with a molecular formula $C_{51}H_{75}O_7$ corresponding to 13° of unsaturation. The IR spectrum exhibited vibration bands for free hydroxyl (3420) chelated hydroxyl (3227) conjugated carbonyl (1647), olefine (1631, 1516). and ether (1285, 1142) cm^{-1} functionalities. The ^1H NMR signal at δ 7.80 (H-2), ^{13}C NMR signal at δ 153.9, and UV absorption band at λ_{max}^{MeOH} 270 nm (log ε 4.46) were all typical of an isoflavone skeleton (Agrawal and Bansal, 1989; Mabry et al., 1970). The small bathochromic shift (Δλ = 3 and 4 nm) observed in the UV spectrum of (**1**) by adding the $AlCl_3$ and NaOAc reagents, respectively, suggested that (**1**) has chelated and free hydroxyl groups at C-5 and C-7 positions, respectively (Mabry et al., 1970). This was confirmed by the presence, in the ^1H NMR spectrum of the downfield signals at δ 13.04 and 8.89 due to intramolecular hydrogen bonded group and free hydroxyl phenolic group at C-5 and C-7 positions, respectively. Compound (**1**) has also one γ, γ-dimethylallyl group which was confirmed in the ^1H NMR spectrum by one 2H doublet at δ 3.43 (2H, *J* = 7.0 Hz, H-1″), one 1H triplet at δ 5.25 (1H, *J* = 7.0 Hz, H-2″), two 3H singlets at 1.68 (Me, *trans*) and 1.79 (Me, *cis*). The presence of an hydroxyprenylated unit linked to an aromatic ring was also indicated by two diastereotopic benzylic proton signals appearing as two double doublets at δ 2.94 (1H, *J* = 8.0, 15.0 Hz, H-1‴ and 3.19 (1H, *J* = 8.0, 15.0 Hz, H-1‴), one methine proton signal as a doublet of doublet at δ 4.36 (1H, *dd*, *J* = 2.0. 8.0 Hz, H-2‴), two olefinic *gem*-proton signals as two doublets at δ 4.88 (1H, *d*, *J* = 1.0 Hz) and 4.98 (1H, *d*, *J* = 1.0 Hz, H-4‴) and one methyl proton signal as singlet at δ 1.84 (3H, *s*). In the aromatic region, a typical AA′BB′ spin system of four aromatic protons at δ 7.37 (2H, *J* = 9.0 Hz, H-2′ and H-6′) and 6.88 (2H, *J* = 9.0 Hz, H-3′ and H-5′) was also shown suggesting the presence of a *para*-substituted ring B. Furthermore, the set of signals consisting 1H singlet at δ 5.25 due to an hydroxyl group, one methine multiplet at δ 4.20 (1H, *m*, H-1⁗), two 1H double doublets at 3.70 (1H *dd*, *J* = 12.0. 9.0 Hz) and 3.60 (1H, *dd*, *J* = 12.0. 9.0 Hz) due to diastereostopic hydroxyl methyl protons, a 46 H broad band signal at δ 1.39 corresponding to $(CH_2)_{23}$ and one 3H triplet at δ 0.85 (3H, *J* = 6.8 Hz) due to a terminal methyl group established the presence of an hydroxylmethylpentacosanyl long chain moiety.

It remained for us to establish unambiguously the positions of the long chain moiety, the free and hydroxylated prenyl groups on the isoflavone skeleton.

The presence of the two five-carbon units (prenyl and hydroxylated) in compound (**1**) was confirmed by the E1-mass spectrum which showed the highest ion peak at *m*/*z* 422 (A_1) due probably to the loss of the hydroxylhexacosanyl moiety from the molecular ion and important ion fragments at *m*/*z* 351 $[A_1–C_4H_7O]^+$ and 295 $[A_1–C_4H_7O–C_4H_8]^+$. Other important ion fragments such as ion fragments at *m*/*z* 177 and 118 were also observed. Both resulted from the Retro Diels–Alder (RDA) cleavage of the most stable ion at *m*/*z* 295 (see Scheme 1) and suggested that the two five carbon units were linked to ring A (*m*/*z* 177), notably at the C-6 and C-8 positions since the ^1H NMR did not show any signal between δ 5.90–6.10 characteristic of the protons of these positions (Agrawal and Bansal, 1989). The relative positions of these groups were determined on the basis of the long-range proton heteronuclear correlations experiment. Thus, the HMBC spectrum of compound (**1**) (Fig. 1) showed through ^2J and ^3J interactions that a ^1H signal at δ 3.19 (H-1‴) was correlated to ^{13}C signals at δ 162.1 (C-7), 154.3 (C-9), 104.6 (C-8), 77.1 (C-2′) and ^1H signal at δ 7.80 showed correlations with ^{13}C signals at δ 154.3 (C-9), indicating that the hydroxyprenylated group was located at C-8 position. Furthermore, the observed correlations between the chelated hydroxyl proton at δ 13.04 and C-5 (δ 158.9), C-6 (δ 113.1), and C-10 (105.9) and between the H-1′ protons at δ 3.43 and C-5 (δ 158.9), C-6 (δ 113.1), and C-7 (δ 162.1) indicated that the free prenyl group was linked to the C-6 position. On the other hand, the three bond correlations of the methine proton at δ 4.20 (H-1⁗) to C-4′ (δ 158.4) and hydroxymethylene carbon (δ 65.2) established that the hydroxymethylpentacosanyl long chain moiety was

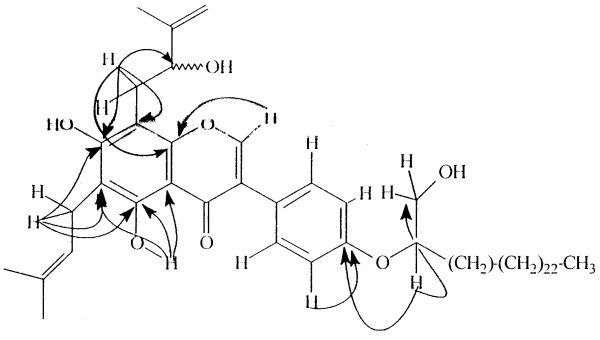

Fig. 1. Significant long-range correlations observed in $^{13}C–^1H$ HMBC spectrum of indicanine D (**1**) in $CDCl_3$.

linked to oxygen atom at C-4′ position. Further evidence of the structure of indicanine D (**1**) was given by the analysis of the ^1H–^1H NOESY spectrum as shown in Fig. 2.

From the above spectroscopic evidence, compound (**1**) was deduced to be 5,7-dihydroxy-6-(γ, γ-dimethylallyl)-8-(2‴-hydroxy-3‴-methylbut-3‴-enyl)-4′-(1‴′-hydroxymethylpentacosanyl)isoflavone.

Compound (**2**), to which we have assigned trivial name indicanine E, was obtained as brown crystals, mp 138–139 °C, and reacted positively to the $FeCl_3$ reagent. Its high-resolution EI mass spectrum displayed a molecular ion $[M^+]$ at m/z 380.1257 in agreement with the empirical formula $C_{22}H_{70}O_6$, (380.1259) corresponding to 13° of unsaturation. Its IR spectrum showed absorption bands for free hydroxyl (3485), conjugated carbonyl (1660), olefin (1630) and ether (1275, 1178) cm^{-1} functionalities.

The broad band decoupled ^{13}C NMR spectrum of compound (**2**) showed 22 carbon signals. The analysis of this spectrum with the Jmod and DEPT techniques unequivocally indicated that four of these were methyls, seven were methines and eleven quaternary carbons (among which one carbonyl, 9 sp^2carbons, and one sp^3 carbon). The UV spectrum [λ_{max}^{MeOH} 286 nm (log ε 4.62)] of indicanine E was typical of compounds having an isoflavone skeleton (Mabry et al., l970). This was supported by the ^1H and ^{13}C NMR spectra which showed resonance signals at δ 7.98 for H-2 and δ 151.3 (C-2) characteristic of isoflavone (Agrawal and Bansal, 1989; Mabry et al., 1970).

Also, the ^1H NMR spectrum of compound (**2**) showed an AB spin system consisting of two doublets at δ 5.85 and 6.70 (J=10.0 Hz) which, together with the 6H singlet at δ 1.45, suggested the presence of 2″,2″-dimethylpyrano substituent. The base ion peak at m/z 365 $[M–Me]^+$ in the EIMS and the set of signals at δ 28.3, 78.4, 131.1, and 116.4 in the ^{13}C NMR spectrum provided further support for the presence of a *gem*-dimethyl chromene system (Mabry et al., 1970). The ^1H NMR spectrum further revealed the presence of 1H singlet at δ 6.59 which could he assigned either to a H-6 or a H-8 proton of ring A, two methoxyl groups signals at δ 3.85 (3H, *s*) and δ 3.84 (3H, *s*) and one broad hydroxyl signal at δ 3.00. In the aromatic region, the appearance of an ABX spin system at δ 7.40 (1H, *d*, J=6.6 Hz), 6.80 (1H, *d*, J=2.1 Hz), and 6.95 (1H, *dd*, J=6.6. 2.1 Hz) established the presence of three aromatic protons on ring B. The location of one methoxyl group and a *gem*-dimethylpyran moiety on ring A was determined from the mass spectral fragmentation pattern which exhibited fragment ions at m/z 217 and 148 caused by a usual (RDA) cleavage from ion $[M–Me]^+$ at m/z 365. The absence of the C-5 chelated hydroxyl signal between δ 11–13 permitted us to locate one of the methoxyl groups at C-5 position. It remained to establish whether the fusion of the γ, γ dimethylpyran moiety on ring A was linear or angular. This was deduced from 2D NOESY spectrum (Fig. 3) which shows no correlation between the single aromatic ring A proton at δ 6.59 (H-6 or H-8) and methoxyl protons at δ 3.85, but correlation contours between methoxyl protons at δ 3.85 and one (δ 6.71) of the AB spin system. This finding indicated clearly that the *gem*-dimethylpyran moiety was fused in a linear manner on ring A. On the other hand, the ion peak at m/z 148 is due to ring B carrying one hydroxyl and the second methoxyl substituent. The *meta* position of these two moieties was determined by the ^{13}C NMR spectrum which shows diagnostic signals at δ 157.4 and 156.4 due to *meta* aromatic carbons bearing an oxygen atom (Agrawal and Bansal, 1989). The 2′(OH)/4′(OMe) substitution pattern was readily deduced, once more, on the basis of the phase sensitive NOESY experiment which showed interactions between methoxyl protons at δ 3.84 and H-3 (δ 6.80) and H-5′(δ 6.95). On these grounds, compound (**2**) was characterized as 2′-hydroxyl-5, 4′-dimethoxyl-2‴, 2‴-dimethylpyran-[5‴, 6‴: 6,7]isoflavone.

Compounds (**1**), (**4**), (**5**) and (**8**) were evaluated for their cytotoxic activity and potency against KB cells using established methods (Monks et al., 1988; Boyd, 1989). As shown in Table 2, wighteone (**4**) appeared to be the most potent compound.

Alpinumisoflavone (**5**) is as potent or slightly more potent than erysenegalensein E (**8**) whereas 8-prenylerythrinin C (7) and indicanine D (**1**) displayed weak cytotoxic activity.

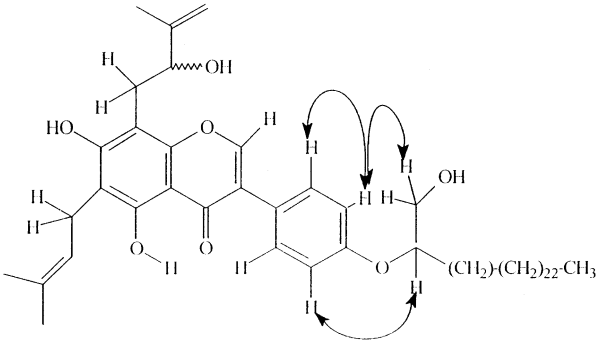

Fig. 2. Selected NOESY correlations for indicanine D (**1**).

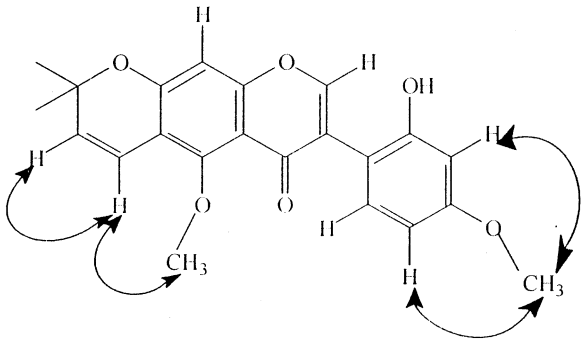

Fig. 3. Selected NOESY correlations for indicanine E (**2**).

3. Experimental

3.1. General experimental procedures

Melting points were determined on a Kofler hot-stage apparatus and are uncorrected. Silica gel, 60 GF 254, was used for TLC with the mixture of *n*-hexane-ethyl acetate as eluent system. The $[\alpha]_D$ value was measured with a Perkin-Elmer 141 polarimeter. IR spectra were recorded on a SHIMADZU 408 Spectrophotomcter in KBr disks. UV spectra were obtained on a Beckman Model 25 Spectrophotometer. EIMS (ionization voltage 70 eV) were measured with LKB9000S and Nermag/Sidar U 3:1 Spectrometers. ^1H and ^{13}C NMR spectra were recorded on a Varian Gemini 2000 and Bruker spectrometers equipped with a 5 mm ^1H and ^{13}C probe operating at 300 and 75 MHz, respectively with TMS as internal standard. DEPT, Jmod, amid 2D NMR spectra were measured with the usual pulse sequence and data processing were obtained with standard software.

3.2. Plant material

Stem bark of *Erythrina indica* was collected in June 1998 at Ibadan (Nigeria). A voucher specimen (No. 49028 HNC) documenting the collection was identified

at the National Herbarium, Yaounde, Cameroon and is on deposit there.

3.3. Extraction and isolation

Air dried powdered stem bark of *E. indica* (6 kg) was extracted successively with CH_2Cl_2–MeOH (1:1) and MeOH at room temp. during 24 h. Both extracts were concentrated under vacuum to afford a viscous mass of CH_2Cl_2–MeOH (1:1) extract (150 g) and a sticky residue of methanol extract (100 g). These two extracts were assayed for their cytotoxicity against KB cell line. As a result, ED_{50} values of the CH_2Cl_2–MeOH (1:1) and MeOH extracts were l0 and 36 μg/ml, respectively. Since the first extract showed strong cytocidal activity, we decided to elucidate the active principle(s) of this extract. The crude extract was then subjected to flash column chromatography over Si gel 60 (70–230 mesh, ASTM; Merck) eluting with a *n*-hexane–EtOAc mixture with increasing polarity. A total of 30 fractions of ca. 300 ml each were collected and combined on the basis of TLC analysis leading to three main series A–C. Fractions 1–15, eluted with the mixture of *n*-hexane–EtOAc (17:3) gave series A (76 g); series B (10 g) was constituted of fractions 16–23 eluted with a mixture of *n*-hexane–EtOAc (3:2) while serie C (25 g) resulted from fractions 24–30 eluted with *n*-hexane–EtOAc (1:1).

Series A was column chromatographed over Si gel packed in *n*-hexane. Gradient elution was effected with *n*-hexane–EtOAc mixture. A total of 80 fractions of ca 300 ml each were collected and combined on the basis of TLC. The pure compounds were obtained either by direct crystallization or after further purifications by column chromatography. Crystallization of the combined fractions 1–10, eluted with *n*-hexane–EtOAc (19:1), gave erythrinassinate B (**9**) (2 g), and dimethylalpinumisofiavone (**6**) (1.5 g). The combined fractions 11–40, eluted with *n*-hexane–EtOAc (9:1), afforded stigmasterol (**12**) (300 mg), indicanine D (**1**) (25 mg), and indicanine E (**2**) (35 mg), respectively. The combined fractions 41–80, eluted with *n*-hexane–EtOAc (17:3), yielded erythrodiol (**11**) (200 mg), erysenegalesein E (**8**) (15 mg) alpinumisoflavone (**5**) (400 mg), and oleanolic acid (**10**) (50 mg).

Series B, treated in the same manner as A, yielded wighteone (**4**) (20 mg), 8-prenylerythrinin C (**7**) (20 mg), and genistein (**3**) (30 mg).

From series C, very rich in tannins, only 3-*O*-β-D glucopyranosyl stigmasterol (**13**) (150 mg) was obtained.

3.4. 5,7- Dihydroxy-6 (γ,γ-dimethylallyl)-8-(2‴-hydroxy-3‴-methylbut-3‴–enyl)-4′-(1″-hydroxymethylpenta cosanyl) isoflavone (indicanine D) (*1*)

Yellow needles, mp 212–214 °C, $[\alpha]_D^{20} + 8.5$ ° (MeOH; *c* 0.045) UV λ_{max}^{MeOh} nm (log ε): 270 (4.46), + [$AlCl_3$] 273 (4.43), + [NaOAc] 274 (4.40); IR ν_{max}^{KBr} cm^{-1}: 3420, 3227, 1647, 1631, 1516, 1285, and 1142; ^1H NMR ($CDCl_3$) see Table 1, ^{13}C NMR ($CDCl_3$) see Table 1; FABMS: *m/z* 803.5826 $[M+H]^+$ (Calc. for $C_{51}H_{79}O_7$, 803.5825); EIMS *m/z* (rel int): 422 $[M–C_{26}H_{51}O]^+$ (9), 351 $[M–C_{26}11_{51}O–C_4H_7O]^+$ (18), 295 $[M–C_{26}H_{51}O–C_4H_7O–C_3H_7]^+$ (45), 260 (33), 177 (39), 118(27), 83 (56), 69(57), 55 (35), 43 (75).

3.5. 2′-Hydroxy-5,4′-dimethoxy-2″-2″-dimethylpyran-[5″- 6″:6,7] isoflavone (Indicanine E) (*2*)

Brown crystals, mp 138–139 °C; UV λ_{max}^{MeOH} nm (log ε) 286 (4.62); IR ν_{max}^{KBr} cm^{-1}: 3485, 1660, 1630, 1275 and 1178; ^1H NMR (acetone-d_6), see Table 1; ^{13}C NMR (acetone d_6), see Table 1; HREIMS *m/z* 380.1257 (Calc. for $C_{22}H_{20}O_6$, 380.1259); EIMS *m/z* (rel. int): 380 $[M]^+$ (15), 365 (100), 336 (83), 307 (15), 217 $[M–CH_3\text{-}148]^+$ (15), 202 (22), 183 (24), 148 $[M–CH_3\text{-}217]^+$ (15), 105 (20), 55 (25), 43 (45), 28 (50).

3.6. Cytotoxicity assay

Cytotoxicity to human solid tumor cells was evaluated at Cell Culture Laboratory of "Museum National d′Histoire Naturelle", Paris, France. Each test material was added to cultivated KB cell after 24 h and the cells were further cultivated for 72 h. The ratio of the living cells was evaluated according to literature (Monks et al., 1988; Boyd, 1989) and cytocidal activity was indicated as ED_{50} values.

Acknowledgements

This investigation was supported by grant No. F/1392-3F from the International Foundation for Science (IFS), Stockholm (Sweden) and 3 months visiting fellowship from "Museum National d′Histoire Naturelle", Paris, France.

Received in revised form 3 July 2001

Abstract

Macrophyllidimer C, a novel bis-sesquiterpene, in which the two sesquiterpene units are directly connected by a C–C bond, and eight other sesquiterpenolides were obtained from the bark of *Inula macrophylla*. Seven of these, macrophyllilactones A–G, are new eudesmanolide- and elemanolide-type sesquiterpenes. Their structures were determined on the basis of spectroscopic evidence and chemical reaction. © 2001 Published by Elsevier Science Ltd.

Keywords: *Inula macrophylla*; Compositae; Macrophyllidimer C; bis-Sesquiterpene; Macrophyllilactones A–G; Eudesmanolide and elemanolide sesquiterpenes

1. Introduction

The traditional Uzbekistan herb *Inula macrophylla* Kar. et Kir. (Compositae) has been used to treat many diseases, including bronchitis, diabetes, and intestinal ulcers. The characteristic components of the genus *Inula* are sesquiterpenes, especially eudesmanolides (Oksuz and Topcu, 1992; Oksuz et al., 1997), guaianolides (Topcu and Oksuz, 1990; Tan et al., 1998), and monoterpenes (Bokadia et al., 1986; Marco et al., 1993). However, the phytochemistry of *Inula macrophylla* has not yet been studied. Recently, Topcu et al. (1993) and Cantrell et al. (1999) reported on the cytotoxic and antibacterial activities of sesquiterpenoids from the genus *Inula*. These findings inspired us to investigate the chemical constituents of *I. macrophylla*. We have previously reported the structural determination of monoterpene and bis-sesquiterpenes (Su et al., 2000a,b), and rearranged eudesmane sesquiterpene acids (Su et al., 2000c) from this plant. As part of our continuing study of Uzbekistan plants, this paper reports a novel bis-sesquiterpene, macrophyllidimer C (**1**) and seven new eudesmane and elemane sesquiterpenolides, macrophyllilactones A–G (**2**–**8**), together with one known eudesmanolide **9**, which were isolated from the bark of *I. macrophylla*.

2. Results and discussion

Macrophyllidimer C (**1**) was obtained as a colorless oil. Its IR spectrum showed absorption bands of a hydroxyl (3511 cm^{-1}), the carbonyl of a γ-lactone (174 6 cm^{-1}), an α β-unsaturated lactone (1717 and 1638 cm^{-1}), and terminal olefinic bonds (919 and 868 cm^{-1}). The ^{13}C NMR and DEPT spectra (Table 1) exhibited 30 carbon signals including nine quaternary carbons, seven methines, 10 methylenes, and four methyls. FABMS showed molecular ion peaks at m/z 537 $[M+Na]^+$ and 515 $[M+H]^+$. These findings suggested that this compound was a bis-sesquiterpene similar to those isolated previously (Su et al., 2000b). Its molecular formula was established to be $C_{30}H_{42}O_7$ based on the above information, which was supported by HRFABMS of its acetylated product (**1a**), which gave molecular ion peaks at m/z 663.3151 $[M+Na]^+$ and 641.3421 $[M+H]^+$ for $C_{36}H_{48}O_{10}$ Na and $C_{36}H_{49}O_{10}$, respectively (calc. 663.3145 and 641.3326). The ^1H NMR spectrum (Table 1) of compound **1** exhibited five olefinic proton

signals at δ_H 5.73 (1-H) , 5.02 (2a-H), 4.96 (2b-H), 5.00 (3a-H) and 4.73 (3b-H), which showed the presence of an elemanolide-type sesquiterpene unit in the structure of **1** (unit A, Fig. 1). The ^{13}C NMR spectrum also showed the corresponding carbon signals at δ_C 146.4 (C-1), 112.2 (C-2), 114.3 (C-3) and 144.7 (C-4). In the ^1H–^1H COSY spectrum, four fragments were defined through the correlations of 1-H with 2a-H and 2b-H, 3a-H with 3b-H, 8-H with 9-H, and 5-H with 6-H were observed. In the HMBC spectrum, these fragments were connected by the correlations from 8-H to C-11, C-12, C-6, C-7 and C-10, 5-H to C-1, C-3, C-14, C-15, C-9 and C-7, 14-H to C-1, C-5, C-9 and C-10, and 15-H to C-3, C-4 and C-5, which confirmed the partial structure. Apart from those signals of unit A, the remaining signals in the ^1H and ^{13}C NMR spectra were consistent with another elemanolide sesquiterpene moiety (unit B, Fig. 1). On the basis of 2D NMR spectroscopic technique,

[a] 400 MHz for ^{1}H NMR, 100 MHz for ^{13}C NMR and DEPT. Coupling constants are in parentheses in Hz.

the structure of unit B was also elucidated, especially by the correlations of 1′-H with 2′-H, and 4′-H with 3′-H, 15′-H and 6′-H (long-range coupling) in the ^{1}H–^{1}H COSY spectrum, as well as by the correlations of 3′-H to C-5′ and C-15′, 15′-H to C-5′ and C-3′, 6′-H to C-4′, C-8′, C-10′ and C-11′, 1′-H to C-5′, C-9′ and C-14′, and 2′-H to C-10′ in the HMBC spectrum. Based on a comparison of the ^{1}H and ^{13}C NMR spectral data of unit B with those of unit A, the two olefinic methylenes of unit A were replaced by two methyls at δ_H 1.22 (2′-H) and 1.12 (3′-H) in the structure of unit B. Thus, unit B possesed two single bonds instead of the two double bonds at C-1, C-2, C-3 and C-4 in unit A.

Considering the position through which the two sesquiterpene units are reportedly connected (Su et al., 2000b), the connection in compound **1** was at first thought to be between C-13 and C-13′. However, based on a careful study of the HMBC spectrum of **1**, correlations of an oxygenated methylene proton at δ_H 4.39 (13-H) with C-7 and C-12, which indicated the presence of a hydroxyl group at C-13, were observed. Acetylation of **1** gave an acetylated product **1a**. In the ^{1}H NMR spectrum of **1a**, the signals of 13-H and 13′-H were shifted downfield (Table 1) supported the above conclusion and effectively eliminated the possibility of the connection through either an ether or ester group between C-13 and C-13′. In the ^{1}H–^{1}H COSY spectra of **1a** and **1**, 15-H was correlated to 15′-H, and in the HMBC spectrum of **1**, 15-H correlated to C-15′ and C-4′; while 15′-H correlated to C-15 and C-4. Thus, the two

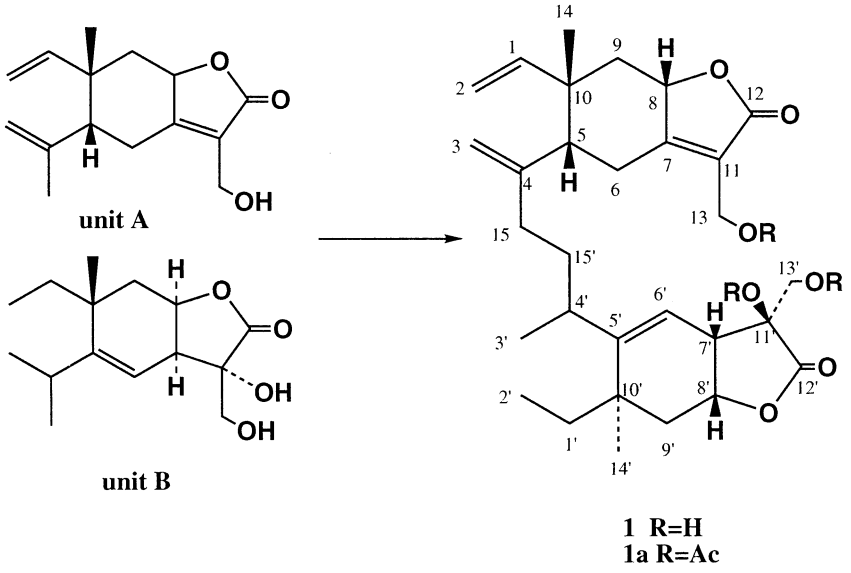

Fig. 1. Two sesquiterpene units of **1**.

units were concluded to be connected by a direct C–C bond between C-15 and C-15′.

The NOESY spectrum exhibited the correlations of 8-H with 9β-H (δ_H 2.25, *dd*, J = 12.4, 6.2 Hz) and 14-H, 5-H with 6β-H and 14-H, 3-H with 6α-H (δ_H 2.63, *dd*, J = 14.4, 13.8 Hz), 7′-H with 8′-H and 11′-OH (δ_H 3.81, *brs*), and 9′α-H (δ_H 2.15, *dd*, J = 14.3, 12.8 Hz) with 14′-H. According to these correlations and coupling constants, the relative configuration of **1** was determined to be as shown.

HRFABMS of macrophyllilactone A (**2**) gave a molecular ion peak at m/z 249.1484 $[M+H]^+$ for $C_{15}H_{21}O_3$ (calc. 249.1491), and based on a strong fragment peak at m/z 230 for the loss of water seen in the ElMS of **2**, the molecular formula of compound **2** was established to be $C_{15}H_{20}O_3$. Its ^{1}H NMR, ^{13}C NMR and DEPT spectra (Table 2) were very similar to those of unit A of **1**, and also displayed the typical double bond signals of 1-H, 2-H and 3-H of an elemanolide-type sesquiterpene. Based on the correlations in the 2D NMR spectra of **2**, its structure was confirmed to be the same as that shown for unit A of **1**.

On the basis of the FABMS of macrophyllilactone B (**3**) and the HRFABMS of its acetylated product (**3a**), the molecular formula of **3** was determined to be $C_{15}H_{22}O_4$. The ^{1}H and ^{13}C NMR spectra (Table 2) of compound **3** were similar to those of **2**, apart from a methine carbon (δ_C 44.9) and an oxygenated quaternary carbon (δ_C 78.0) instead of the double bond at C-7 and C-11 in **2**. Thus, the difference in the molecular formula of **2** and **3** was H_2O, which indicated the presence of another hydroxyl group in addition to the one at C-13. In the HMBC spectrum, the clear correlations of the corresponding methine proton at δ_H 2.34 with C-12, C-13, C-5, and C-9 confirmed that this methine proton was

[a] 100 MHz for ^{13}C NMR and DEPT.

7-H. In addition, the oxygenated quaternary carbon at δ_C 78.0 correlated with 6-H and 8-H, which indicated that the quaternary carbon was C-11. The coupling constant of 8-H (δ_H 5.02, *ddd*, J = 12.8, 12.0, 1.9) implied the presence of a 7,8-*trans*-lactone in the structure of **3**. The NOESY correlations of 8-H with 6β-H and 14-H, 5-H with 7-H and 9α-H, and 6β-H with 9β-H, 3b-H, 14-H and 13b-H also supported the relative configuration of **3** as shown.

Compounds **4** and **5** were an inseparable mixture, even through attempted HPLC separation of their acetates. The ^{1}H and ^{13}C NMR spectra (Table 3) of the mixture were very similar to those of **3**. FABMS of them showed the same molecular ion peaks at m/z 289 $[M+Na]$ and 267 $[M+H]$ as for **3**. Their ^{1}H–^{1}H COSY

[a] 100 MHz for ^{13}C NMR and DEPT.

and HMBC spectra indicated that **4** and **5** were also 11,13-dihydroxy-1,3-elemadien-12, 8-olides like **3**. However, in the NOESY spectrum of the mixture, the 5-H of **4** correlated with 9α-H, and 9β-H correlated with 7-H, 8-H and 14-H, which clearly confirmed that compound **4** had a 5αH, 10βMe-*trans*-7βH, 8βH-*cis*-configuration. The NOESY spectrum also showed the correlations of 14-H of **5** with 5-H, 9β-H and 8-H, 7-H with 9α-H, and 13-H with 6β-H and 8-H. Consequently, it can be deduced that compound **5** had a 5βH,10βMe-*cis*-7αH, 8βH-*trans*-configuration. Hence, compounds **3**, **4** and **5** were stereoisomers.

Compound **6**, macrophyllilactone E, showed strong IR bands for a hydroxyl (3512 cm^{-1}) and an γ-unsaturated lactone (1737 and 1658 cm^{-1}). Its EIMS spectrum showed a molecular ion peak at *m*/*z* 248 and a strong fragment peak at *m*/*z* 230 due to the loss of water. HRFABMS gave a molecular ion peak at *m*/*z* 249.1502 (calc. for $C_{15}H_{21}O_3$, 249.1491), which supported a molecular formula of $C_{15}H_{20}O_3$. An eudesmanolide skeleton was deduced from the methyl signals at δ_H 1.27 (*s*) and 1.29 (*d*, $J=7.6$ Hz) in its ^1H NMR spectrum, which were similar to those of neoalantolactone from *Inula racemosa* (Ravindranath et al., 1978). The obvious difference is that another methyl signal in the structure of neoalantolactone was replaced by a hydroxymethyl at δ_H 4.45 (13-H_2) in that of **6**. The hydroxymethyl was confirmed to be 13-H_2 due to the correlations of the hydroxymethyl protons with the carbon at δ_C 163.7 (C-7) and 175.1 (C-12) in the HMBC spectrum. The stereochemistries of 8β-H and 4β-H were derived from the NOESY correlations of 8-H with 9β-H and 14-H, 4-H with 9β-H and 2β-H. Therefore, the compound **6** was determined to have the structure as shown.

The EIMS of macrophyllilactone F (**7**) gave a molecular ion peak at *m*/*z* 266 and a strong fragment peak at *m*/*z* 235 due to the loss of a hydroxymethyl group. Its ^1H NMR and ^{13}C NMR spectra were almost the same as those of 11,13-dihydroxyalantolactone, which is an oxidation product of alantolactone with OsO_4 (Cantrell et al., 1999). The NOESY spectrum and the coupling constants revealed that **7** was a stereoisomer of 11,13-dihydroxyalantolactone, showing the correlations of 9β-H with 14-H and 8-H, of 7-H with 6-H and 8-H, and of 15-H with 2β-H and 3β-H, of 14-H with 2β-H. Thus, **7** had a 7βH, 8βH-*cis*-lactone configuration. In the ^1H NMR spectrum of the acetate **7a** of **7**, 8β-H was shifted downfield to δ_H 5.25 due to the effect of the 13-acetoxy group. This supported the notion that 13-H and 8β-H were close to each other in space. Therefore, the relative configuration of the 11α-hydroxyl was determined.

The ^1H NMR spectrum of macrophyllilactone G (**8**) displayed a typical 12, 8-lactone signal like **7**. Its EIMS showed a molecular ion peak at *m*/*z* 294 and fragment peaks at *m*/*z* 263 $[M–CH_2OH]^+$, 258 $[M–2H_2O]^+$, and 245 $[M–CH_2OH–H_2O]^+$, which implied the presence of hydroxyl and hydroxylmethyl groups. The molecular formula of **8** was suggested to be $C_{15}H_{18}O_6$ by consideration of the ^{13}C NMR spectral data (Table 2). The UV spectrum of **8** showed a presence of conjugated diene unit (274 nm). The ^1H NMR spectrum of **8** was compared to that of **7**: a pair of doublets at δ_H 6.92 and 6.66 was observed in that of **8**, and the ^1H NMR spectrum of **8** also showed signals of a hydroxymethyl group at δ_H 4.56 and 4.44 and a 13-hydroxylmethyl instead of the signal of the methyl group (14-H_3) of **7**. The corresponding carbon signals were also to be found in the ^{13}C NMR spectrum, and the ^{13}C NMR spectral data revealed that the pair of doublets was attributed to two double bonds. Based on the coupling constant (8.0 Hz) between the pair of doublets, the conjugated diene was deduced to be at C-1 and C-2, as well as C-3 and C-4. In the HMBC spectrum, the key correlations of one olefinic proton (2-H) of the conjugated diene with C-4 and C-10, and the other proton (3-H) with C-1, C-5 and C-15 further confirmed the conclusion. Since the methyl group signal was shifted downfield to δ_H 2.28, it should be attached to a double bond and is attributed to 15-H. This indicated that another hydroxymethyl group was located at C-14. In addition, a sharp singlet at δ_H 8.84 inferred the presence of a hydroxyl group attached to a ring similar to an aromatic ring. Consistent with this notion, a hydroxyl group was likely at C-1. In the HMBC spectrum of **8**, the downfield olefinic quaternary carbon at δ_C 156.8 correlated with 3-H and 14-H, which supported the location of 1-hydroxyl group in the structure of **8**. In the NOESY spectrum of **8**, the correlations of 9β-H with 8-H, 14-H and 13-H as well as of 7-H with 9α-H permitted assignment of the stereochemistry.

Compound **9**, reynosin, was identified by comparison of its physical and spectral data with those in the literature (Ando and Takase, 1977).

3. Experimental

3.1. General

^{1}H NMR (400 MHz), ^{13}C NMR (100 MHz with TMS as internal standard; MS: Jeol JMS-DX-303 and JMS SX-102 A; CC: silica gel 60 (Merck), Sephadex LH-20 (Pharmacia); HPLC: GPC (general permeation chromatography, Asahipark GS-310 2G, MeOH), silica gel (Si60, HIbar, TR250-25, Merck) IR: 1720 infrared Fourier-transform spectrometer (Perkin-Elmer); UV: UV2100 UV-vis recording spectrometer (Shimadzu); Optical rotation: JASCO DIP-370 digital polarimeter.

3.2. Plant material

The bark of *Inula macrophylla* (1.6 kg) was purchased at a medicinal plant market in Uzbekistan, in August 1997, and identified by Dr. Olimjon K. Kodzhimatov. A voucher specimen (ESM4141) is preserved at the herbarium of the Academy of Sciences, Institute of Botany, and Botanical Garden Uzbekistan.

3.3. Extraction and isolation

The MeOH extract (228 g) of the powdered air-dried bark (1.6 kg,) obtained with MeOH at 60 °C three times, 6 h each) of *I. macrophylla* were partitioned between H_2O and $CHCl_3$. The $CHCl_3$-soluble fraction (115 g) was subjected to a silica gel column chromatograph (eluted with *n*-hexane–EtOAc, from 10:1 to 1:1 then with pure EtOAc) to give 11 fractions. Fraction 9 (7.5 g) was applied to a silica gel column (eluted with *n*-hexane–EtOAc, from 2:1 to 1:6, then with pure EtOAc) to give 12 fractions (9.01–9.12). Fr. 9.01 (2.7 g) was applied to a Sephadex LH-20 column (eluted with MeOH), and 8 fractions (9.01.1–9.01.8) were obtained. Fr. 9.01.4 was further separated by HPLC (silica gel, *n*-hexane–EtOAc, 2.5:1) to give compounds **8** (6.6 mg), **6** (15 mg), **2** (6.5 mg) and **9** (18 mg). Fr. 9.01.5 was purified by GPC (eluted with MeOH) to give 9 fractions (9.01.5.1–9.01.5.9). Fr. 9.01.5.4 was separated by HPLC (silica gel, *n*-hexane–EtOAc, 2:1) to give a mixture of **4** and **5** (16.3 mg) as well as **3** (4.7 mg), **7** (16.7 mg) and **1** (36.5 mg). Compounds **1** (20.6 mg), **3** (4.2 mg), **7** (12 mg), and the mixture of **4** and **5** (15 mg) were respectively acetylated by Ac_2O–pyridine and DMAP, and purified by preparative TLC (developed with *n*-hexane–EtOAc, 2:1) to give a mixture of **4a** and **5a** (12.9 mg), **7a** (10.9 mg), **1a** (15.2 mg) and **3a** (3.5 mg), respectively.

3.4. Macrophyllidimer C (*1*) and *1a*

Macrophyllidimer C (**1**): colorless oil, $[\alpha]_D^{25}$ −87.2° ($CHCl_3$; *c* 0.83); UV (MeOH) λ_{max} (log ε) nm: 219 (*br*, 4.29), 203 (4.35); IR (KBr) ν_{max} cm^{-1}: 3836, 3511, 3089, 3026., 2933, 2869, 2360, 2339, 1746, 1717, 1684, 1638, 1457, 1378, 1337, 1223, 1209, 1070, 1021, 972, 919, 903, 868; EI–MS *m*/*z* (rel. int.): 230 [M–H_2O-266]$^+$ (21), 162 [230–C_5H_7]$^+$ (61), 147 (31), 133 (22), 105 (81), 91 (100), 77 (47), 55 (52), 41 (70); FABMS (rel. int.) *m*/*z* (**1**): 537 [M + Na]$^+$ (9) 519 [M + Na–H_2O]$^+$(19), 289 [M + Na-249]$^+$ (38), 271 [266 + Na–H_2O]$^+$(100), 249 [M + H-266]$^+$(93), 231 [249-H_2O]$^+$(7); (**1a**): 663 [M + Na]$^+$(7) 641 [M + H]$^+$ (3) 603 [M + H-HOAc]$^+$ (3), 581 [M + Na]$^+$, 373 [350 + Na]$^+$(59), 313 [290 + Na]$^+$(100); HRFABMS *m*/*z* (**1a**) 663.3145 (calc. for $C_{36}H_{48}O_{10}Na$, 663.3151), 641.3326 (calc. for $C_{36}H_{49}O_{10}$, 641.3421), 603.2934 (calc. for $C_{34}H_{44}$,O_8Na, 603.2890); ^{1}H NMR, ^{13}C NMR and DEPT data of **1** and **1a**, see Table 1.

3.5. Macrophyllilactone A (*2*)

Colorless oil, $[\alpha]_D^{25}$ −60.9° ($CHCl_3$; *c* 0.97); UV (MeOH) λ_{max} (log ε) nm: 218 (*br*, 4.04), 191 (3.29); IR (KBr) ν_{max} cm^{-1}: 3650, 3391, 3020, 2928, 2331, 1718, 1678, 1629, 1462, 1385, 1331, 1220, 1201, 1021, 975, 923, 903, 859; EI–MS *m*/*z* (rel. int.): 230 [M–H_2O]$^+$(100), 217 [M–CH_2OH]$^+$ (7) 215 [M–H_2O–CH_3]$^+$ (81), 201 (37), 188 (40), 174 (29), 133 (62), 121 (99), 105 (95), 91 (90), 77 (88), 55 (46), 41 (83), 39 (72), 31(14); FABMS (rel. int.) *m*/*z* :249 [M + H]$^+$(100) 231 [M + H–H_2O]$^+$ (9), 214 (17), 152 (29), 135 (29), 91(20); HRFABMS *m*/*z* 249.1484 (calc. for $C_{15}H_{21}O_3$, 249.1491); ^{1}H NMR data δ_H ($CDCl_3$): 1.18 (3H, *s*, 14-Hβ), 1.76 (3H, *s*, 15-H), 1.42 (1H, *dd*, *J* = 12.4, 11.7, 9-Hα), 2.26 (1H, *dd*, *J* = 12.4, 6.1, 9-Hβ), 2.12 (1H, *dd*, *J* = 13.6, 4.0, 5-Hβ), 2.59 (1H, *dd*, *J* = 14.4, 13.6, 6-Hα), 2.83 (1H, *dd*, *J* = 14.4, 4.0, 6-Hβ), 4.40 (2H, *brs*, 13-H), 4.73 (1H, *brs*, 3a-H), 5.00 (1H, *brs*, 3b-H), 4.89 (1H, *dd*, *J* = 11.7, 6.1, 8-Hβ), 4.96 (1H, *d*, *J* = 10.8, 2a-H), 5.02 (1H, *d*, *J* = 17.2, 2b-H), 5.74 (1H, *dd*, *J* = 17.2, 10.8, 1-H); ^{13}C NMR and DEPT data, see Table 2.

Received 7 June 2001; received in revised form 23 August 2001

Abstract

From the cultures of the spore-derived mycobionts of the lichen *Lecanora cinereocarnea*, five dibenzofurans, 3,7-dihydroxy-1,9-dimethyldibenzofuran, 2-chloro-3,7-dihydroxy-1,9-dimethyldibenzofuran, 2,8-dichloro-3,7-dihydroxy-1,9-dimethyldibenzofuran, 3-hydroxy-7-methoxy-1,9-dimethyldibenzofuran, and 2-chloro-7-hydroxy-3-methoxy-1,9-dimethyldibenzofuran, were isolated. Their structures were determined by spectroscopic methods. © 2001 Elsevier Science Ltd. All rights reserved.

1. Introduction

Lichens, a symbiotic association of mycobiont and photobiont partners, produce diverse secondary metabolites, some of which show a wide range of potentially useful biological activities (Yamamoto, 1991). One of the intriguing questions in lichenology is the role of mycobiont and photobiont partners in the biosynthesis of such substances. Our recent studies demonstrated that cultures of spore-derived lichen mycobionts have an ability to produce certain lichen substances or novel metabolites in large amounts under osmotically stressed conditions (Tanahashi et al., 1997, 1999, 2000; Takenaka et al., 2000). It was also pointed out that cultures of lichen mycobionts could be good systems for investigating secondary metabolism in lichens. In the course of our studies on cultured lichen mycobionts, we cultivated mycobionts of the lichen *Lecanora cinereocarnea* and isolated from their cultures five dibenzofurans, four of which are new. The isolation and structural determination of these compounds are reported.

2. Results and discussion

The polyspore-derived mycobionts of *Lecanora cinereocarnea* collected in Japan were cultured on conventional malt-yeast extract medium supplemented with 10% sucrose at 18 °C in the dark. After cultivation over 11–12 months, the colonies and agar medium were harvested and extracted with cold Et_2O and Me_2CO. The extract was separated by a combination of preparative TLC and preparative HPLC to afford five compounds, **1**–**5**.

Compound **1** was isolated as colorless needles, mp. 242 °C. Its HR–EIMS spectrum indicated a molecular formula of $C_{14}H_{12}O_3$. Its ^{1}H NMR spectrum (Table 1) exhibited a broad singlet for a methyl group and a pair of *meta*-coupled doublets. The ^{13}C NMR spectrum of **1** showed a methyl carbon, two aromatic CH carbons and four quaternary carbons, two of which were oxygenated (Table 2). These NMR spectral features together with its structural formula suggested a symmetrical dibenzofuran structure for **1**. The presence of two phenolic hydroxyl groups in **1** was indicated by its acetylation to a diacetate **1a**. The substitution pattern on the aromatic rings was demonstrated by the HMBC spectrum of **1** where an aromatic proton at δ 6.70 was coupled with two oxygenated carbons at δ 156.9 and 159.2, a methine carbon at δ 114.8 and a quaternary carbon at δ 117.6, the latter two carbons were correlated with the methyl

PII: S0031-9422(01)00394-6

protons at δ 2.76. Final confirmation was obtained by direct comparison with an authentic sample prepared from 3,5-dimethoxytoluene (Asahina and Aoki, 1941). Although this compound has already been known as a synthetic product, this constitutes the first instance of it's isolation and characterization as a natural product.

The HR–EIMS spectrum of compound **2** established the composition $C_{14}H_{11}ClO_3$. Conventional acetylation of **2** gave a diacetate **2a**, $C_{18}H_{15}ClO_5$. The ^1H NMR spectrum of **2** exhibited signals for two methyl groups atδ 2.76 and 2.86, a pair of *meta*-coupled aromatic protons at δ 6.57 and 6.70 and an aromatic proton at δ 6.86. These findings suggested the isolated compound to be a chlorinated derivative of **1**. Significant HMBC correlations between the aromatic proton at δ 6.86 and two oxygenated carbons at δ 152.5 and 156.3 showed that the chlorine atom was substituted at C-2 rather than C-4. This was further confirmed by HMBC experiments with **2a**. Thus, the structure of **2** was determined as 2-chloro-3,7-dihydroxy-1,9-dimethyldibenzofuran.

Compound **3**, $C_{14}H_{10}Cl_2O_3$, also showed NMR spectral features suggesting a symmetrical structure. The ^{13}C NMR spectral data of **3** and its acetate **3a** were in good agreement with those of chlorinated aromatic ring of **2** and **2a**, respectively, suggesting chlorination at C-2 and C-8 in **3** and **3a**. This proposal was further supported by

[c] Measured in $CDCl_3$.

significant correlations between the aromatic proton signal and two oxygenated carbon signals in the HMBC spectra of **3** and **3a**. Accordingly, the isolated compound was characterized as 2,8-dichloro-3,7-dihydroxy-1,9-dimethyldibenzofuran.

A comparison of the ^1H and ^{13}C NMR spectra of the new compound **4** with those of **1** suggested a close relationship between their structures. The NMR spectral features of **4** resembled those of **1** except for the presence of an aromatic methoxyl signal [δ_H 3.83, δ_C 56.0]. The HR–EIMS of **4**, showed a molecular ion peak at *m/z* 242.0961, indicating a molecular formula of $C_{15}H_{14}O_3$, an increase of CH_2 when comparing with **1**. Conventional acetylation of **4** yielded the monoacetate **4a**. These findings suggested that a hydroxyl group of **1** was methylated in **4**, and this received further support from methylation of **1** with dimethylsulfate, which afforded **4** and the dimethyl ether **6**. Thus, **4** was also elucidated.

Compound **5** was isolated in minute amount. Its HR–EIMS spectrum indicated a molecular formula of $C_{15}H_{13}ClO_3$. Its ^1H NMR spectrum exhibited signals for two methyl groups at δ 2.81 and 2.93, a methoxyl group at δ 3.93, a pair of *meta*-coupled aromatic protons at δ 6.61 and 6.75, and an aromatic proton at δ 7.08 (s). Acetylation of **5** yielded an acetate **5a**, indicating the presence of a phenolic hydroxyl group in **5**. These findings suggested that **5** is a chlorinated derivative of **4**. The detailed 2D-NMR studies confirmed that the substitution of chlorine atom was at C-2, and not at C-4, C-5, nor C-7. The NOESY spectrum showed a through-space connectivity between the methoxyl group and a

singlet for a aromatic proton. In the HMBC spectrum of **5**, the aromatic proton signal was coupled with two oxygenated carbons at δ 155.0 and 156.4, and two quaternary carbons at δ 119.4 and 119.5; the latter two carbon resonances were correlated with the methyl singlet at δ 2.92, implying that a methoxyl group and a chlorine atom were located at C-3 and C-2, respectively, on the same benzene ring of the dibenzofuran. Further, HMBC correlations among the signals due to another benzene ring, as well as comparison of the ^1H and ^{13}C NMR spectral data of **5** and **5a** with those of **1** and **1a** suggested the same substitution pattern on a benzene ring of **1** and **5**. These observations thus allowed us to formulate the structure **5** for the isolated compound. The location of the chlorine atom at C-2 in **5** was further supported by comparative studies of the ^{13}C NMR spectral data of **1**, **2**, **4**, **5**, **1a**, **2a**, **4a** and **5a**. When a chlorine atom was introduced at C-2 in **1** and **1a**, C-2 was shifted downfield whereas C-1, C-3, C-4a and 1-Me were shifted upfield. Similar trends were observed with **4**, **5**, **4a** and **5a**. Accordingly the structure of **5** was elucidated as 2-chloro-7-hydroxy-3-methoxy-1,9-dimethyldibenzofuran.

It is noteworthy that the isolated dibenzofurans from the cultured mycobionts have no carboxyl group in the structure by contrast with dibenzofurans from natural lichens such as pannaric acid (Huneck and Yoshimura, 1996). According to Culberson and Ahamdjian, most lichen substances arise from phenolic acid precursors such as orsellinic acid. In non-lichen fungi these precursors lead to phycotoxic compounds, the biosynthesis of which includes a phenolic acid decarboxylation involving fungal decarboxylases. In lichens the algal partner may inhibit such decarboxylases to divert the phenolic acid precursors into secondary metabolites that are nontoxic to photobionts and accumulate in large quantities in the thallus (Culberson and Ahmajian, 1980). This hypothesis was consistent with our results that dibenzofurans with no carboxyl group were obtained from the cultured mycobionts. These results indicated that dormant fungal metabolism was induced in the cultures of the isolated mycobiont.

3. Experimental

3.1. General

Melting points were measured on a Yanaco micro melting point apparatus and are uncorr. The UV spectra were recorded on a Shimadzu UV-240 spectrophotometer and the IR spectra on a Shimadzu FTIR-8200 infrared spectrophotometer. HR–EIMS were obtained with a Hitachi M-4100 mass spectrometer. The NMR spectroscopic experiments were performed with Varian VXR-500, Varian Gemini-300 and Varian Gemini-200 spectrometers, with tetramethylsilane as internal standard. HPLC was performed using a Waters system (600E Multisolvent Delivery System, 486 Tunable Absorbance Detector). Thin-layer chromatography was performed on precoated Kieselgel $60F_{254}$ plates (Merck) and spots were visualized under UV light.

3.2. Plant material

Specimens of *Lecanora cinereocarnea* (Eschw.) Vain. were collected from the bark of trees in Okinawa Prefecture, Japan (27 N, ca. 100 m alt.) in 1996. The voucher specimen was identified by Dr. H. Miyawaki, Saga University, Japan and was deposited at Osaka City Institute of Public Health and Environmental Sciences with the registration No. NH96112944. Mycobionts of *L. cinereocarenea* were obtained from the spores discharged from apothecia of a thallus, and were cultivated in test tubes containing modified MY10 medium (malt extract 10 g, yeast extract 4 g, sucrose 100 g, agar 15 g, H_2O 1 l, pH 7) at 18 °C in the dark. After cultivation for 11–12 months, the colonies and slants with crystals were harvested.

3.3. Extraction and isolation

(1) The harvested colonies (101 test tubes, fresh cell weight 12.3 g) were extracted continuously with Et_2O and then with Me_2CO. The slants were collected and extracted in the same way. The Et_2O extracts were concentrated under reduced pressure to give a residue (550 mg). The extracts were repeatedly subjected to preparative TLC (toluene–acetone 9:1) and preparative HPLC (μBondasphere 5 μC18-100 Å, MeCN–H_2O, 7:13), giving **1** (1.2 mg), **2** (14.7 mg), **3** (20.3 mg), **4** (4.9 mg) and **5** (1.6 mg). The Me_2CO extracts (898 mg) were also repeatedly purified by preparative TLC and preparative HPLC to afford **2** (5.0 mg), **3** (7.5 mg), **4** (2.5 mg) and **5** (1.4 mg).

(2) The harvested colonies (37 test tubes, dry cell weight 6.86 g) and slants were extracted continuously with Et_2O and then with Me_2CO. The Et_2O extracts (380 mg from the colonies and 1.02 g from the slants) were repeatedly subjected to preparative TLC with (toluene–acetone, 19:1, Me_2CO–$CHCl_3$, 3:1), giving **1** (3.3 mg), **2** (7.9 mg) and **3** (11.4 mg). The Me_2CO extracts (898 mg from the colonies and 3.72 g from the slants) were also repeatedly purified by preparative TLC with (toluene–acetone, 19:1) to afford **1** (5.0 mg), **2** (11.6 mg) and **3** (24.5 mg).

3.3.1. 3,7-Dihydroxy-1,9-dimethyldibenzofuran (*1*)

Colorless crystalline solid, mp 242 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 219 (4.51), 226 (4.52), 239.5 (4.35), 257 *sh* (4.09), 263 (4.12), 302 (4.23), 310 (4.23); IR ν_{max}^{KBr} cm^{-1}: 3275, 1616, 1585, 824; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; HMBC correlations: 1-CH_3/9-CH_3→C-1/C-9, C-2/C-8, C-9a/C-9b; H-2/H-8→C-3/C-7, C-4/C-6, C-9a/C-9b; H-4/H-6→C-2/C-8, C-3/C-7, C-4a/C-5a, C-9a/C-9b; HR-EIMS *m/z*: calc. for $C_{14}H_{12}O_3$ $[M]^+$: 228.0787. Found: 228.0781.

3.3.2. 2-Chloro-3,7-dihydroxy-1,9-dimethyldibenzofuran (*2*)

Colorless crystalline solid, mp 193–194 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 205 (4.37), 223 (4.55), 228 (4.57), 243 *sh* (4.35), 263 (4.09), 306.5 (4.25), 314.5 (4.25); IR ν_{max}^{KBr} cm^{-1}: 3324, 1611, 1576, 830; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; NOESY correlation: H-8↔9-CH_3; HMBC correlations: 1-CH_3→C-1, C-2, C-9b; H-4→C-2, C-3, C-4a, C-9b; H-6→ C-5a, C-7, C-8, C-9a; H-8→C-6, C-7, C-9a; 9-CH_3→C-8, C-9, C-9a; HR-EIMS *m/z*: calcd. for $C_{14}H_{11}{}^{35}ClO_3$ $[M]^+$: 262.0397. Found: 262.0374; calc. for $C_{14}H_{11}{}^{37}ClO_3$ $[M]^+$: 264.0368. Found: 264.0357.

3.3.3. 2,8-Dichloro-3,7-dihydroxy-1,9-dimethyldibenzofuran (*3*)

Colorless crystalline solid, mp 217.5–218.5 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 231 (4.60), 245 (4.35), 262.5 (4.02), 309 *sh* (4.27), 317.5 (4.32); IR ν_{max}^{KBr} cm^{-1}: 3422, 1607, 1583, 812; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; HMBC correlations: 1-CH_3/9-CH_3→C-1/C-9, C-2/C-8, C-9a/C-9b; H-4/H-6→C-2/C-8, C-3/C-7, C-4a/C-5a, C-9a/C-9b; HR–EIMS *m/z*: calc. for $C_{14}H_{10}{}^{35}Cl_2O_3$ $[M]^+$: 296.0007. Found: 296.0016; calc. for $C_{14}H_{10}{}^{35}Cl^{37}ClO_3$ $[M]^+$: 297.9978. Found: 297.9962; calc. for $C_{14}H_{10}{}^{37}Cl_2O_3$ $[M]^+$: 299.9948. Found: 299.9936.

3.3.4. 3-Hydroxy-7-methoxy-1,9-dimethyldibenzofuran (*4*)

Colorless crystalline solid, mp 139–139.5 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 219 (4.45), 225.5 (4.46), 239 *sh* (4.30), 257 *sh* (4.04), 263 (4.07), 300.5 (4.19), 308.5 (4.23); IR ν_{max}^{KBr} cm^{-1}: 3368, 1612, 1582, 808; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; NOESY correlations: 1-CH_3↔H-2; OCH_3↔H-4; H-8↔9-CH_3; HMBC correlations: 1-CH_3→C-1, C-2, C-9b; H-4→C-4a; H-6→C-5a, C-6; H-8→C-7; 9-CH_3→C-8, C-9, C-9a; HR–EIMS *m/z*: calc. for $C_{15}H_{13}O_3$ $[M]^+$: 242.0944. Found: 242.0961.

3.3.5. 2-Chloro-7-hydroxy-3-methoxy-1,9-dimethyldibenzofuran (*5*)

Colorless crystalline solid, mp 198–199 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 227 (4.26), 241 *sh* (4.18), 255 (3.88), 263 (3.91), 305 (4.07), 312.5 (4.06); IR ν_{max}^{KBr} cm^{-1}: 3110, 1638, 1609, 1589, 814; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; NOESY correlations: H-4↔OCH_3, H-8↔9-CH_3; HMBC correlations: 1-CH_3→C-1, C-2, C-9b; OCH_3→C-3; H-4→C-2, C-3, C-4a, C-9b; H-6→C-5a, C-8, C-9a; H-8→C-6, C-9a; 9-CH_3→C-8, C-9, C-9a. HR–EIMS *m/z*: calc. for $C_{15}H_{14}{}^{35}ClO_3$ $[M]^+$: 276.0554. Found: 276.0577; calc. for $C_{15}H_{14}{}^{37}ClO_3$ $[M]^+$: 278.0524. Found: 278.0503.

3.4. Acetylation of *1*–*5*

Compound **1** (3.4 mg) was acetylated with Ac_2O-pyridine (each 0.1 ml) and the crude acetate was purified by preparative TLC ($CHCl_3$) to yield **1a** (3.9 mg). Com-

pound **2** (7.7 mg) and **3** (7.8 mg) were acetylated and purified in the same as for **1** to give **2a** (8.0 mg) and **3a** (7.6 mg), respectively. A mixture (19.1 mg) of **4** and **5** was acetylated and purified by preparative HPLC (μBondasphere 5 μC18–100 Å, MeCN–H_2O, 5:3) to give **4a** (2.9 mg) and **5a** (4.6 mg).

3.4.1. 3,7-Diacetoxy-1,9-dimethyldibenzofuran (*1a*)

Colorless crystalline solid, mp. 162–162.3°C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 213 (4.66), 227 (4.73), 252 (4.21), 260 (4.30), 287 (4.46), 296 *sh* (4.34); IR ν_{max}^{KBr} cm^{-1}: 1753, 1609, 1585, 1499; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; HMBC correlations: 1-CH_3/9-CH_3→C-1/C-9, C-2/C-8, C-9a/C-9b; H-2/H-8→C-1/C-9, C-3/C-7, C-4/C-6, C-9a/C-9b; H-4/H-6→C-2/C-8. EIMS *m/z* (rel. int.%): 312 (21.6) $[M]^+$, 270 (17.8), 228 (100); HR–EIMS *m/z*: calc. for $C_{18}H_{16}O_5$ $[M]^+$: 312.0998. Found: 312.1015.

3.4.2. 3,7-Diacetoxy-2-chloro-1,9-dimethyldibenzofuran (*2a*)

Colorless crystalline solid, mp 171.5–172.0 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 216 (4.51), 230 (4.61), 253 (4.02), 261 (4.12), 289 (4.29), 299 *sh* (4.11), 312 (3.74); IR ν_{max}^{KBr} cm^{-1}: 1765, 1601, 1587; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; HMBC correlations: 1-CH_3→C-1, C-2, C-9b; H-4→C-2, C-3, C-4a, C-9b; H-6→C-7, C-8; H-8→C-6, C-7, C-9a; 9-CH_3→C-8, C-9, C-9a; EIMS *m/z*: (rel. int.%): 348 (3.5), 346 (9.8) $[M]^+$, 306 (5.5), 304 (15.4), 264 (37), 262 (100); HR-EIMS *m/z* calc. for $C_{18}H_{15}{}^{35}ClO_5$ $[M]^+$: 346.0609. Found: 346.0602; calc. for $C_{18}H_{15}{}^{37}ClO_5$ $[M]^+$: 348.0579. Found: 348.0583.

3.4.3. 3,7-Diacetoxy-2,8-dichloro-1,9-dimethyldibenzofuran (*3a*)

Colorless crystalline solid, mp 192–193 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 218 (4.52), 233 (4.66), 253 (4.03), 261 (4.12), 293 (4.29), 304 *sh* (4.00); IR ν_{max}^{KBr} cm^{-1}: 1771, 1593; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; HMBC correlations: 1-CH_3/9-CH_3→C-1/C-9, C-2/C-8, C-9a/C-9b; H-4/H-6→C-2/C-8, C-3/C-7, C-4a/C-5a, C-9a/C-9b; EIMS *m/z*: (rel. int.%): 384 (1.1), 382 (4.9), 380 (7.9) $[M]^+$, 342 (1.4), 340 (4.9), 338 (9.3), 300 (12), 298 (67), 296 (100); HR–EIMS *m/z* calc. for $C_{18}H_{14}{}^{35}Cl_2O_5$ $[M]^+$: 380.0219. Found: 380.0203; calc. for $C_{18}H_{14}{}^{35}Cl^{37}ClO_5$ $[M]^+$: 382.0189. Found: 382.0143; calc. for $C_{18}H_{14}{}^{37}Cl_2O_5$ $[M]^+$: 384.0160. Found: 384.0108.

3.4.4. 3-Acetoxy-7-methoxy-1,9-dimethyldibenzofuran (*4a*)

Colorless crystalline solid, mp 116–117 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 215.5 (4.35), 226 (4.49), 237 *sh* (4.35), 256 *sh* (4.01), 262 (4.09), 295 (4.26), 301 (4.26), 305.5 (4.26); IR ν_{max}^{KBr} cm^{-1}: 1759, 1607, 1578, 829; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; EIMS *m/z*: (rel. int.%): 284 (37) $[M]^+$, 242 (100). HR–EIMS *m/z*: calc. for $C_{17}H_{16}O_4$ $[M]^+$: 284.1049. Found: 284.1060.

3.4.5. 7-Acetoxy-2-chloro-3-methoxy-1,9-dimethyldibenzofuran (*5a*)

Colorless crystalline solid, mp 169 °C (MeOH). UV λ_{max}^{MeOH} nm (log ε): 229.5 (4.41), 254.5 (3.88), 262 (3.95), 291 *sh* (4.04), 301 (4.10), 313.5 (3.95); IR ν_{max}^{KBr} cm^{-1}: 1747, 1607, 1541, 810; ^1H NMR: see Table 1; ^{13}C NMR: see Table 2; EIMS *m/z*: (rel. int.%): 320 (11), 318 (30) $[M]^+$, 278 (36), 276 (100), 262 (12), 260 (35); HR–EIMS *m/z*: calc. for $C_{17}H_{15}{}^{35}ClO_4$ $[M]^+$: 318.0659. Found: 318.0675; calc. for $C_{17}H_{15}{}^{37}ClO_4$ $[M]^+$: 320.0630. Found: 320.0637.

3.5. Synthesis of *1* and *4*

Compound **1** was prepared from 3,5-dimethoxytoluene according to Asahina. (Asahina and Aoki, 1941). The physical and spectral data of the product were identical to those of the isolated compound. To a solution of **1** (19.8 mg) in acetone (20 ml) were added K_2CO_3 (600 mg) and Me_2SO_4 (20 μl), and the whole was heated under reflux for 4 h. The reaction mixture was diluted with 5% $NaHCO_3$ and extracted with $CHCl_3$. The washed and dried $CHCl_3$ layers were concentrated in vacuo and the residue was subjected to prep. TLC with (toluene–acetone 19:1) to afford a monomethyl ether (3.3 mg) and a dimethyl ether (**6**) (17.9 mg). The monomethyl ether was identified with **4**. **6**: needles, mp. 153.7–154 °C (MeOH). ^1H NMR ($CDCl_3$): δ 2.83 (6H, *s*, 1-CH_3 and 9-CH_3), 3.84 (6H, *s*, 3-OCH_3 and 7-OCH_3), 6.69 (2H, *m*, H-2 and H-8), 6.92 (2H, *m*, H-4 and H-6). EIMS *m/z* (%): 330 $[M]^+$ (35), 315 (100), 300 (7.3), 285 (28). HR–EIMS *m/z*: calc. for $C_{16}H_{16}O_3$ $[M]^+$: 256.1100. Found: 256.1095.

Abstract

Two segatane diterpenoids containing a bicyclic [4,3,1] ring system were isolated, together with 11 known diterpenoids, four segetanes, five jatrophanes and two paralianes, from the aerial parts of *Euphorbia paralias*. The structures of the new compounds were established by spectroscopic means, including by 2D NMR and CD spectroscopic analyses. The antifeedant and antiviral activities of the isolated compounds are also described. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Euphorbia paralias*; Euphorbiaceae; Diterpenoids; Segetanes A and B; Segetanes; Paralinones; Jatrophenes; Paralianes; Antifeeding activity; Antiviral activity

1. Introduction

Euphorbiaceae plants are well known to contain irritant and tumor-promoting constituents (Hecker, 1977). In particular, diterpenoids from the Euphorbiaceae have been found to possess interesting biological activities (Evans and Soper, 1978). *Euphorbia paralias* L. (Sea Spurge) is a hardy perennial which inhabits sandy coasts and shingle beaches and is native to the entire Mediterranean region. It is also one of the most common *Euphorbia* species growing in Egypt (Tackholm, 1974). Chemical constituents of this species have been investigated previously and the presence of irritant and cytotoxic ingenanes (Sayed et al., 1980), paralinones (Öksüz et al., 1997), segetanes, jatrophanes, paralianes and another tetracyclic diterpenoids (Jakupovic et al., 1998a,b), as well as triterpenoids and flavonoids (Rizk et al., 1974, 1976; Khafagy et al., 1976), have been reported.

In this paper, we report the isolation and structure elucidation of two new segetane diterpenoids, containing a conjugated enone system, together with 11 known diterpenoids, four segatanes, five jatrophanes and two paralianes, from the aerial parts of *Euphorbia paralias*. The antifeeding and antiviral activities of the isolated compounds against the larvae of the Japanese insect pest *Spodoptera littoralis* and HIV-1 replication are also described.

2. Results and discussion

The CH_2Cl_2 soluble part of the methanol extract of the dried aerial parts of *Euphorbia paralias* was fractionated by column chromatography on silica gel and purified by HPLC to afford two new segetane diterpenoids possessing a conjugated enone, named segetenes A (**1**) and B (**2**), and eleven known diterpenoids in the segetanes (**3–6**), jatrophanes (**7–11**) and paralianes (**12** and **13**), which had previously been isolated from the same plant collected in Turkey (Öksüz et al., 1997) and Spain (Jakupovic et al., 1998b), and from *Euphorbia segetalis* (Jakupovic et al., 1998a). The known compounds were identified by comparison of their NMR spectral data with those reported previously.

Segetene A (**1**) was obtained as a white amorphous powder of $[\alpha]_D$ −4° (*c* 0.17, MeOH). Its molecular formula $C_{37}H_{44}O_{14}$ (16 unsaturations) was determined by accurate HR–FAB–MS (*m*/*z*: 713.2802 $[M+H]^+$, Δ −0.8 mmu.). In the FAB–MS, the presence of the prominent peak at *m*/*z* 105 [C_6H_5–CO] implied the presence of a benzoyl moiety in the molecule. The UV spectrum also showed the presence of the benzoyl group together with

a conjugated enone group at 231 nm (ε 25,000). The IR spectrum exhibited characteristic absorption bands for hydroxyl (3600–3400 cm^{-1}) and carbonyl (1751 and 1701 cm^{-1}) groups. From the ^1H and ^{13}C NMR spectroscopic analyses (Table 1), 11 of the unsaturation elements were present as double bonds: four carbon-carbon (one benzene ring and one tetra-substituted) and seven carbonyls (one keto and six ester). Therefore, the molecule is pentacyclic. The NMR spectra also revealed that **1** contained nine methyl groups (three tertiary, one secondary and five acetyl), two methylenes, twelve methines (5 olefinic), fourteen quaternary carbons (three olefinic and one keto and six ester carbonyls) and one tertiary hydroxyl group.

All of the proton-bearing carbons were assigned by the HMQC experiment. Extensive studies using spin decoupling and the COSY and HMBC revealed **1** to be a segetane type diterpenoid. The ^1H and ^{13}C NMR spectra resembled those of segetane **3**, isolated from the same plant collected in Spain (Jakupovic et al., 1998a,b), except for the presence of an additional tetra-substituted double bond in **1**. The conjugated enone system in **1** was apparent from the presence of a downfield shifted olefinic carbon (C-12) at δ 164.2 and a carbonyl carbon (C-9) at δ 208.4 compared with δ 214.2 in **3**. Irradiation of the H-11 triplet at δ 6.13 coalesced a pair of methylene signals at δ 2.47 (*dd*, $J = 17.0$ and 2.0 Hz, H-7α) and 2.90 (*br d*, $J = 17.0$ Hz, H-7β) to a pair of doublets. This homoallylic coupling clarified the partial structure of C_7–C_{11}.

Further information by HMBC spectrum elucidated the presence of the bicyclo[4.3.1^{6,13}]decane ring system and the location of acetoxy and benzoyloxy groups in the skeleton at the positions, 5, 6, 11, 14 and 17, and at C-3, respectively, similarly to **3** (Fig. 1).

The relative stereochemisrty of **1** was established by NOE studies (Fig. 2). The NOE correlations of H-4

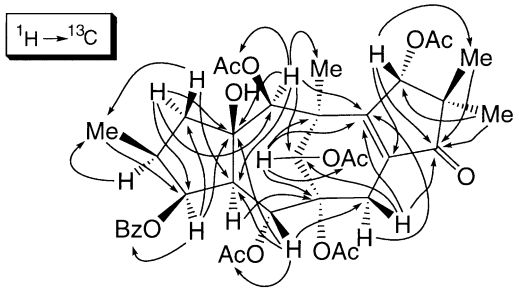

Fig. 1. Selected HMBC correlations in **1**.

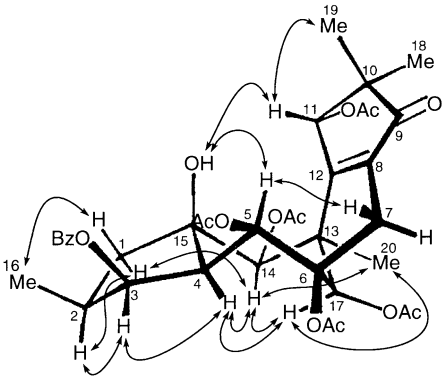

Fig. 2. Significant NOE correlations in **1**.

with H-1α, H-3 and H-17 established that the stereochemistry of **1** was virtually the same as that of the segatanes, **3**–**6** (Öksüz et al., 1997; Jakupovic et al., 1998a,b). On the other hand, the H-14 signal in **1** showed NOEs with the H-1α, H-4 and H-17 signals and the 13-Me (20) indicating it to possess an α configulation, different from that of the previously reported segatanes. Finally, the absolute stereochemistry of **1** was determined from the CD spectrum (Fig. 2), which showed a split CD curve at 242 ($\Delta\varepsilon+0.7$) and 224 nm ($\Delta\varepsilon-0.3$) due to a coupling of the π–π^* transitions of the benzoate and enone chromophores. The positive splitting suggested a positive twisting of the two chromophores to reveal the absolute stereochemistry at C-3 to be *S*. This is the first report of the occurrence of this type of segatane diterpenoid.

The segetene structure of compound **2**, having the same molecular formula $C_{37}H_{44}O_{14}$ as **1**, was readily suggested from the spectral data. Compound **2** showed similar IR and UV spectra to those of **1**. The ^1H and ^{13}C NMR spectra of **2** (Table 1) displayed the presence of eight methyls, four methylenes, eleven methines, and fourteen quaternary carbons, including one conjugated enone structure, five acetyl and one benzoyl groups. Thus, the molecule is also pentacyclic.

The spectra were similar to those of **1**, except for the lack of the isolated oxymethine signal coupling with allylic H_2-7 signals in **1**, and the presence of two addi-

tional methylene signals in **2**. One of these methylenes showed a characteristic AB signal at δ 4.44 (*d*, $J = 15.9$ Hz) and 4.48 (δ, $J = 15.8$ Hz) assigned to acetoxyacetate methylene protons, $CH_3CO_2\underline{CH_2}COO$–, which were confirmed from the HMBC correlations with two ester carbonyl carbons at δ 166.8 and 169.8. These carbonyl carbons were correlated to an oxymethine proton at δ 5.43 attached to C-5 at δ 69.3 and acetyl methyl protons at δ 2.02, respectively. This acetoxyacetate group has been observed in the segatanes, **4** and **5**, from *E. paralias* (Öksüz et al., 1997; Jakupovic et al., 1998a,b). The other methylene protons at δ 2.32 (*br d*, $J = 16.7$ Hz) and 2.73 (*br dt*, $J = 16.7$ and 2.9 Hz) were assigned to H_2-11 from their homoallylic couplings with the 7-methylene protons at δ 2.38 (*br dt*, $J = 16.8$ and 2.9 Hz) and 2.83 (*br d*, $J = 16.8$ Hz). Other protons in **2**, including the acetyl and benzoyl groups, were assigned to the same positions in **1** by HMQC and HMBC studies to clarify a similar structure for **2**, except for the stereochemistry.

The stereochemistry of **2** was also determined by NOE experiments (Fig. 3), which revealed that it differed from **1** only at C-14. Thus, the H-14 singlet at δ 5.31 showed NOEs only with H-11β at δ 2.73 and the 13α-Me (20) at δ 1.03, not with the H-4 and H-7 signals. This NOE observation strongly suggested H-14 to be in a β configulation. The CD spectrum showed a similar positive split absorption at 245 nm ($\Delta\varepsilon + 0.3$) and 226 nm ($\Delta\varepsilon - 1.9$) with **1** to elucidate the absolute structure of **2**.

Insect antifeeding and antiviral activities of the isolated compounds were examined (Table 2). Antifeedant activity was tested by the conventional leaf disk method (Wada and Munakata, 1968) against the third instar larvae of *Spodoptera littoralis*. The tests were performed at 500 and 1000 ppm, with 50 ppm corresponding to a concentration of ca. 1 μg/leaf-cm^2. The most potent compounds were **5** and **8**, which were moderately active at 500 ppm. This activity was comparable to those of many limonoid antifeedants from the Meliaceae (Huang et al., 1995; Mootoo et al., 1996; Nakatani, 1999). Although compounds **3**, **4**, **7**, **9**, **12** and **13** also showed moderate activities at 500–1000 ppm, the new compounds **1** and **2** were not active at 1000 ppm. Antiviral activity against HIV-1 replication was tested on the inhibition of virus-induced cytopathicity in MT-4 cells (Pauwels et al., 1988). In the tested compounds, only one compound **13** showed a moderate activity ($EC_{50} = 14$ μg/ml). Although compounds **5**, **7**, **10**, **11** and **12** also showed the activities in the range 40–79 μg/ml, their activities were concluded to be due to their cytotoxicity.

3. Experimental

3.1. General

^{1}H and ^{13}C NMR spectra were measured at 600 and 125 MHz in $CDCl_3$ on a Jeol FX-600 spectrophotometer. IR (KBr) and UV (MeOH) spectra were recorded on JASCO FT/IR 5300 and Shimadzu UV-210A spectrophotometers. Optical rotation and CD spectra were measured at 22° on JASCO DIP-370S and JASCO J-720 spectrophotometers. HPLC were performed on a Waters μBondapak C_{18} column by using 20–45% H_2O/MeOH as solvent.

3.2. Plant material

The aerial parts of *Euphorbia paralias* were collected in January 1999 from Marsa-Matrouh, Egypt, and identified by Dr. Khaleil Darweish of Alexandria University. A voucher specimen is deposited in the Faculty of Agriculture, Alexandria University.

3.3. Extraction and isolation of compounds *1–13*

The dried and powdered aerial parts (1.2 kg) of *Euphorbia paralias* were extracted with MeOH (8 l) at room temperature for 4 weeks. The extract was concentrated under reduced pressure to give a crude extract (137 g). The MeOH extract (30 g) was dissolved in a small amount of H_2O–MeOH (1:1) and extracted with hexane and CH_2Cl_2 (500 ml×3). The CH_2Cl_2 extract (8.6 g) was applied to a silica gel column (320 g) using a

gradient hexane–EtOAc (20–100%) as eluant. Fourteen fractions (each 100 ml) were collected and monitored by TLC. Fractions 8–11 were purified through HPLC with a reversed phase μBondapak C_{18} column using 20–45% H_2O/MeOH as solvent to give **1** (9.2 mg), **2** (8.2 mg), **3** (9.2 mg), **4** (5.8 mg), **5** (35.2 mg), **6** (1.8 mg), **7** (24.9 mg), **8** (4.5 mg), **9** (3.4 mg), **10** (1.8 mg), **11** (1.6 mg), **12** (15.1 mg), and **13** (5.4 mg).

3.4. Segetene A (1); 5α,6,11α,14β,17(R)-pentaacetoxy-3β-benzoyloxy-15β-hydroxyseget-8(12)-en-9-one

A white amorphous powder, $C_{37}H_{44}O_{14}$; HRFAB–MS *m/z*: 713.2802 $[M+H]^+$, Δ −0.8 mmu.; $[\alpha]_D$ −4° (*c* 0.17); IR ν_{max} cm^{-1}: 3600–3400, 2974, 1751, 1701, 1647, 1373, 1224, 1030 and 715 ; UV λ_{max} nm (ε): 204 (8000), 231 (25,000) and 273 (2000); CD: $\Delta\varepsilon_{224}$ −0.3 and $\Delta\varepsilon_{242}$ +0.7. NMR spectral data, see Table 1.

3.5. Segetene B (2); 6,14α,17(R)-triacetoxy-5α-(2-acetoxyacetoxy)-3β-benzoyloxy-15β-hydroxyseget-8(12)-en-9-one

A white amorphous powder, $C_{37}H_{44}O_{14}$; HR–FAB–MS *m/z*: 713.3 $[M+H]^+$; $[\alpha]_D$ −51° (*c* 0.13); IR ν_{max} cm^{-1}: 3600–3300, 2966, 1751, 1726, 1373, 1244, 1033 and 715 ; UV λ_{max} nm (ε): 205 (4000) and 232 (11000); CD: $\Delta\varepsilon_{226}$ −1.9 and $\Delta\varepsilon_{242+}$0.3. NMR data, see Table 1.

3.6. Antifeedant test

The antifeedant potential of the isolated compounds was tested by a conventional leaf disk method against third-instar larvae of *Spodopetra littoralis*. Five leaf disks (diameter 1.2 cm) of Chinese cabbage (*Brassica campestris* var. *chinensis*) were immersed in an acetone solution of the sample for 2 s. The treated disks were arranged alternatively with another five control disks (immersed only in acetone) close to the wall of a Petri dish. Ten larvae were placed in the center of each Petri dish. The eaten areas of treated and untreated leaf disks were evaluated at appropriate intervals for 2–12 h. The experiment was terminated after the larvae had eaten approximately 50% of one of the disks. This choice test was done at concentrations 500 and 1000 ppm to determine the minimum antifeedant inhibitory concentration of the isolated compounds.

3.7. Antiviral assays

The activity of the compounds against HIV-1 replication was based on the inhibition of virus-induced cytopathicity in MT-4 cells. MT-4 cells (100,000 cells/ml) were infected with HIV-1 (IIIB strain) at a multiplicity of infection of 0.02 and were cultured in the presence of various concentrations of the test compounds. After a 4-day incubation at 37 °C, the number of viable MT-4 cells was measured by the MTT method (Pauwels et al., 1988). Cytotoxicity of the compounds was evaluated in parallel with their anti-HIV-1 activity. It was based on the viability of mock-infected MT-4 cells as determined by the MTT method.

Acknowledgements

We would like to thank Mr. K. Takezaki, Kagoshima Prefectural Agricultural Experiment Station, for the supply of the insects.

[c]*Department of Chemistry, Nanjing University, Nanjing 210093, PR China*

Received 24 April 2001; received in revised form 17 August 2001

Abstract

Three highly oxygenated guaianolides were isolated from the aerial parts of *Ajania fruticulosa* along with 17 known phytochemicals including a triterpene (α-amyrin), two plant sterols (β-sitosterol, daucosterol), four flavonoids (axillarin, centaureidin, santin and 5,7,4′-trihydroxy-3,3′-dimethoxyflavone), and ten sesquiterpenes [1α-hydroperoxy-4β,8α,10α,13-tetrahydroxyguaia-2-en-12,6α-olide, 1α-hydroperoxy-4α,10α-dihydroxyguaia-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide, 3β,4α-dihydroxyguaia-11(13),10(14)-dien-12,6α-olide, 1α,4α,10α-trihydroxy-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide, 1β,2β-epoxy-3β,4α,10α-trihydroxy-guaia-11(13)-en-12,6α-olide and 2-oxo-8α-hydroxyguaia-1(10),3,11(13)-trien-12,6α-olide, ketoplenolide B, alantolactone, 9β-hydroxyeudesma-4,11(13)-dien-12-oic acid and 9β-acetoxyeudesma-4,11(13)-dien-12-oic acid]. The structures of the three guaianolides were elucidated by a combination of spectroscopic methods (EIMS, HREIMS, COSY, HMQC, HMBC and NOESY) as 1β,2β-epoxy-3β,4α,8β,10α-tetrahydroxyguaia-11(13)-en-12,6α-olide (**1**), 1β,2β-epoxy-3β,4α,9α,10α-tetrahydroxyguaia-11(13)-en-12,6α-olide (**2**) and 1β,2β-epoxy-10α-hydroperoxy-3β,4α,8β-trihydroxyguaia-11(13)-en-12,6α-olide (**3**), respectively. Antifungal bioassay of all isolates showed that guaianolides **1**, **2**, **3**, and 1β,2β-epoxy-3β,4α,10α-trihydroxyguaia-11(13)-en-12,6α-olide were inhibitory to the growth of *Candida albicans* with MICs being 20, 20, 20, and 40 μg/ml, respectively. © 2001 Published by Elsevier Science Ltd.

Keywords: *Ajania fruticulosa*; Asteraceae; Guaianolides; Flavonoids; Sesquiterpenes

1. Introduction

Ajania fruticulosa (Ledeb.) Poljak (Asteraceae), distributed mainly in the northwestern part of China, has long been used as traditional Chinese medicine in the treatment of appendicitis, tuberculosis and emphysema. Sesquiterpenes and phenolic constituents were isolated from this species in a previous phytochemical investigation (Li et al., 1999). In our continued investigation of structurally novel and/or biologically active constituents of medicinal plants (Meng et al., 2000), we reexamined the title plant phytochemically to characterize further three new highly oxygenated guaianolides (**1**–**3**) in addition to 17 known constituents, four of which were also active.

2. Results and discussion

Repeated silica gel chromatography of the crude extract of *Ajania fruticulosa* afforded a triterpene, two plant sterols, four flavonoids, three new and six known guaianolides, and other four sesquiterpene lactones. The triterpene (α-amyrin) and two plant sterols (β-sitosterol and daucosterol) were identified by direct comparisons (TLC, IR, ^{1}H NMR) with the authentic samples available in our laboratory. The ^{1}H and ^{13}C NMR data of four flavonoids revealed that they were axillarin (Al-Yahya et al., 1988), centaureidin (Martinez et al., 1997), santin (Rashid et al., 1992), and 5,7,4′-trihydroxy-3,3′-dimethoxyflavone (Dong et al., 1987). The ten known sesquiterpene lactones were shown by extensive spectroscopic analyses to be 1α-hydroperoxy-4β,8α,10α,13-tetrahydroxyguaia-2-en-12,6α-olide (Li et al., 1999), 1α-hydroperoxy-4α,10α-dihydroxyguaia-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide (Li et al., 1999), 3β,4α-dihydroxyguaia-11(13),10(14)-dien-12,6α-olide (Sigstad

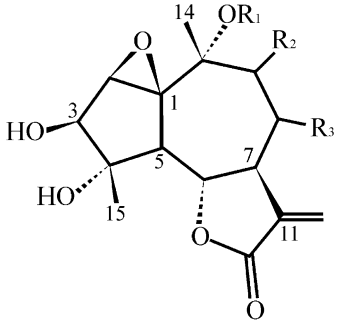
et al., 1991), 1α,4α,10α-trihydroxy-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide (Wang et al., 1994), 1β,2β-epoxy-3β,4α,10α-trihydroxyguaia-11(13)-en-12,6α-olide (Jakupovic et al., 1988), 2-oxo-8α-hydroxyguaia-1(10),3,11(13)-trien-12,6α-olide (Daniewskii et al., 1988), ketoplenolide B (Wang et al., 1994), alantolactone (Tsuda et al., 1957), 9β-hydroxyeudesma-4,11(13)-dien-12-oic acid (Tan et al., 1995a), and 9β-acetoxyeudesma-4,11(13)-dien-12-oic acid (Tan et al., 1995b), respectively.

Compound **1** was obtained as a colorless gum. The EIMS spectrum of **1** gave a molecular ion at *m*/*z* 312 $[M]^+$ accompanied by an intense fragment peak at *m*/*z* 294 produced by an elimination of H_2O from parent molecule. Its molecular formula $C_{15}H_{20}O_7$ was indicated by the exact weight (*m*/*z* 312.1217) of the molecular ion given by the HREIMS spectrum of **1**. In the ^1H NMR spectrum of **1**, it showed two methyl singlets at *δ* 1.12 (3H, *s*, H-14) and 1.31 (3H, *s*, H-15), and two exomethylene proton signals at *δ* 5.56 (1H, *br s*, H-13a) and 5.98 (1H, *d*, *J* = 3.3 Hz, H-13b). The ^{13}C NMR spectrum of **1** displayed 15 carbon resonances including two methyl, two methylene, six methine, and five quaternary carbons. In addition, the chemical shifts and coupling pattern of two oxygenated methine singlets at *δ* 3.60 and 4.04 in the ^1H NMR spectrum, along with the carbon resonance lines at *δ* 72.3 (C), 62.9 (CH), and 66.1 (CH) in the ^{13}C NMR spectrum, demonstrated the presence of an 1β,2β-epoxy-3β-hydroxyl moiety on a five-member ring (Jakupovic et al., 1988). All these observations suggested that compound **1** was a highly oxygenated guaianolide (Jakupovic et al., 1988). This hypothesis was confirmed by 2D NMR spectroscopic analyses (HMQC, HMBC and NOESY) which allowed as well the unequivocal assignment of all ^1H and ^{13}C NMR spectral data. Moreover, the 8-hydroxyl group had a broad singlet at *δ* 3.86 (H-8) which showed typically long-range correlations with C-6 and C-10 in the HMBC spectrum. Furthermore, the signals due to H-14 and H-15 were exhibited as a pair of three-proton singlets at *δ* 1.12 and 1.32 indicating the presence of 4- and 10-dihydroxyls. Relative to the biogenetically rationalized α-configuration for H-7 (Huneck et al., 1991), the stereochemistry of compound **1** was readily established by a NOESY experiment. The clear NOE correlations between any pair of H-5, H-7 and H-8 suggested that 8-OH was in a *β*-configuration. Similarly, the formulated configurations of C-1–C-4 and C-10 were deduced from the NOE correlations of H-5 with H-2 and H-3, and of H-6 with H-14 and H-15. In conclusion, the structure of compound **1** was determined to be 1β,2β-epoxy-3β,4α,8β,10α-tetrahydroxyguaia-11(13)-en-12,6α-olide.

The molecular ion at *m*/*z* 312.1215 in its HREIMS spectrum of compound **2** indicated that its molecular formula was also $C_{15}H_{20}O_7$. The ^1H and ^{13}C NMR spectra of **2** were similar to those of compound **1**. All proton and carbon data of compound **2** were assigned exactly by extensive 2D NMR spectroscopic analyses (COSY, HMQC, HMBC and NOESY). However, the 9-hydroxyl group was required by the H-9 singlet at *δ* 5.25 which, as anticipated, exhibited long-range correlations with C-7 and C-14 in the HMBC spectrum. As in the case of compound **1**, the stereochemistry of compound **2** was established by NOE correlations in its NOESY spectrum where strong cross peaks between any pair of H-14, H-6 and H-9 substantiated the *α*-orientation of the 9-hydroxyl group. In conclusion, the structure of compound **2** was determined to be 1β,2β-epoxy-3β,4α,9α,10α-tetrahydroxyguaia-11(13)-en-12,6α-olide.



1 $R_1 = R_2 = H$, $R_3 = \beta$-OH
2 $R_1 = R_3 = H$, $R_2 = \alpha$-OH
3 $R_1 = OH$, $R_2 = H$, $R_3 = \beta$-OH

Compound **3** was obtained as a colorless gum. The molecular formula $C_{15}H_{20}O_8$, indicates an oxygen atom more than that of guaianolide **1**, could be readily deduced from the molecular ion at *m*/*z* 328.1164 in the HREIMS spectrometry. The ^1H and ^{13}C NMR spectra of compound **3** were similar to those in compound **1** in the splitting pattern and the chemical shifts suggested that it was also a highly oxygenated guaianolide with its structure very similar to that of **1**. The 2D NMR spectra (COSY, HMQC, HMBC and NOESY) confirmed this assumption with all ^1H and ^{13}C NMR spectroscopic data assigned unambiguously. The C-10 resonance of **3** at *δ* 95, shifted downfield by 24.4 ppm from that of **1**, along with a broadened singlet at *δ* 7.70 in the ^1H NMR spectrum, demonstrated the presence of a 10-hydroperoxyl group. Again, the stereochemistry of compound **3** was unequivocally assigned on the basis of NOE correlations exhibited in its NOESY spectrum. Thus, the *α*-orientation of hydroperoxyl group was required by the NOE correlations between H-14 and H-6. And the strong cross peak between any pair of H-5, H-7 and H-8 indicated the β-configuration of the 8-hydroxyl group. Accordingly, compound **3** was 1β,2β-epoxy-10α-hydroperoxy-3β,4α,8β-trihydroxyguaia-11(13)-en-12,6α-olide.

All isolates were tested for their antifungal activity against *Candida albicans*. The new guaianolides **1**, **2**, and **3** were inhibitory to the growth of *Candida albicans* with the same MIC values of 20 μg/ml, while 1β,2β-

epoxy-3β,4α,10α-trihydroxyguaia-11(13)-en-12,6α-olide was also active with a MIC of ~40 μg/ml.

3. Experimental

3.1. General

Optical rotations were measured on a DXP-118 apparatus. EIMS and HREIMS experiments were run on VG-ZAB-HS and Jeol JMX-HX110 mass spectrometers, respectively. All NMR experiments were performed on a Jeol JNM-A 500 FT–NMR spectrometer using TMS as the internal standard. Silica gel (200–300 mesh) for column chromatography and GF_{254} (30–40 μ) for TLC were produced by Qingdao Marine Chemical Factory, Qingdao, People's Republic of China. Sephadex LH-20 was from Pharmacia Biotech., Sweden. All other chemicals used in this study were of analytical grade.

3.2. Plant material

The aerial parts of *Ajania fruticulosa* was recollected in July, 1998 from Gaolan Mountain near Lanzhou Railway Station, Lanzhou, China, and identified by Professor G. L. Zhang. A voucher specimen (GLZ-92721) has been deposited in the herbarium of Lanzhou University, Lanzhou 730070, China.

3.3. Extraction and isolation

The air-dried plant material (3.2 kg) was pulverized, and then extracted three times with petroleum ether–Et_2O–MeOH (1:1:1) at room temperature. The extract was concentrated under reduced pressure to give a residue (102 g) which was dissolved completely at 50 °C in a minimum amount of MeOH. The solution was kept at −20 °C overnight to precipitate waxy substances, then filtered while chilled. In vacuo removal of the solvent from the filtrate afforded a black gum (50 g) which was applied to a silica gel column (1.2 kg) using petroleum ether with gradually increasing amounts of acetone to give α-amyrin (24 mg), β-sitosterol (102 mg), and daucosterol (88 mg) together with other five fractions (F-1, 2 g; F-2, 9 g; F-3, 15 g; F-4, 18 g; and F-5, 2 g). Column chromatography of F-2 over silica gel (240 g, 200–300 mesh) with a chloroform–acetone gradient (15:1–10:1, each 200 ml) followed by gel filtration over Sephadex LH-20 with $CHCl_3$–MeOH (1:1) afforded centaureidin (17 mg) and 5,7,4′-trihydroxy-3,3′-dimethoxyflavone (21 mg). F-3 was subjected to silica gel chromatography (500 g, 200–300 mesh) eluting with a $CHCl_3$–MeOH gradient (15:1, 13:1, 11:1, 9:1, each 300 ml) to give santin (17 mg), axillarin (21 mg), ketoplenolide B (18 mg) and alantolactone (23 mg), respectively. Column chromatography of F-4 with a $CHCl_3$–MeOH gradient gave three fractions (F-4-1, 4.5 g; F-4-2, 5.3 g; F-4-3, 7.1 g). CC of F-4-1 with $CHCl_3$ containing gradually increasing amounts of MeOH (15:1–10:1) afforded 2-oxo-8α-hydroxyguaia-1(10),3,11(13)-trien-12,6α-olide (15 mg; 15:1, 300 ml), 9β-acetoxyeudesma-4,11(13)-dien-12-oic acid (21 mg; 15:1, 500 ml), 9β-hydroxyeudesma-4,11(13)-dien-12-oic acid (18 mg; 13:1, 350 ml), and 3β,4α-dihydroxyguaia-11(13),10(14)-dien-12,6α-olide (24 mg; 11:1, 500 ml). Also by a combination of silica gel column chromatography (300 g, 200–300 mesh) eluting with a CH_2Cl_2–MeOH gradient (15:1, 13:1, 10:1, each 500 ml), F-4-2 finally yielded 1α-hydroperoxy-4β,8α,10α,13-tetrahydroxyguaia-2-en-12,6α-olide (13 mg), 1α-hydroperoxy-4α,10α-dihydroxyguaia-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide (11 mg), and 1α,4α,10α-trihydroxy-9α-angeloyloxyguaia-2,11(13)-dien-12,6α-olide (26 mg), respectively. Repetitive gel filtrations [Sephadex LH-20, $CHCl_3$–MeOH (1:1)] of F-4-3 afforded the interesting fractions F-4-3-1 (210 mg) and F-4-3-2 (150 mg). F-4-3-1 was then subjected to silica gel column chromatography (20 g, 200–300 mesh) eluting with CH_2Cl_2–MeOH (10:1, each 200 ml) and finally gave 1β,2β-epoxy-3β,4α,10α-trihydroxyguaia-11(13)-en-12,6α-olide (20 mg), and **3** (15 mg). Preparative TLC of F-4-3-2 (CH_2Cl_2-MeOH, 9:1) yielded **1** (12 mg, R_f = 0.40), and **2** (17 mg, R_f = 0.54).

3.4. 1β,2β-Epoxy-3β,4α,8β,10α-tetrahydroxyguaia-11(13)-en-12,6α-olide (1)

Colorless gum; $[\alpha]_D^{20}$ +31 ° (MeOH; *c* 0.12); EIMS *m*/*z* (rel. int.): 312 $[M]^+$ (5), 297 $[M^+–Me]$ (12), 294 $[M^+–H_2O]$ (48), 57 (100); HREIMS *m*/*z*: 312.1217 (calc. for $C_{15}H_{20}O_7$: 312.1209); ^1H and ^{13}C NMR spectral data are given in Table 1.

3.7. Antifungal assays

All isolates were dissolved in DMF at concentrations of 10, 20, and 40 μg/ml, respectively. The concentration of DMF in the broth media was maintained at 1%, which did not affect the growth of the test microorganism. The minimal inhibitory concentrations (MIC) against *Candida albicans* were measured by the serial 2-fold dilution method as reported in the literature (Kubo et al., 1991). Ketoconazole was used as a positive control at concentrations of 1, 2, and 4 μg/ml, respectively.

Book reviews

Chemotaxonomie der Pflanzen, Volume XIb—2: Leguminosae, Part 3
R. Hegnauer and M. Hegnauer, Birkhäuser-Verlag, Basel, 1494 pp., 2001. SFR 998. ISBN 3-7643-6269-3.

During the 1950′s Robert Hegnauer of Leiden University made the decision to devote a major part of his working life to the writing of a complete review of known phytochemistry, setting the data in a taxonomic context but not neglecting ethnobotanical, ecological, physiological and medicinal aspects. The first volume of this masterwork appeared in 1962 and dealt with the chemotaxonomy of thallophytes, bryophytes, pteridophytes and gymnosperms. Subsequent volumes, appearing every two or three years, covered the consierable richness in chemistry of angiosperms, family by family. The present volume under review is the 13th and final book in the series. It is devoted to the phytochemistry of a single subfamily, the Papilionoideae, of the Leguminosae.

What we have here is a masterly review of the chemistry of these plants, species by species, genus by genus and tribe by tribe. There are many tables and many figures with structural formulae. The work is completely up-to-date, with an Appendix recording the primary literature up to December 2000. Nothing of importance is omitted. Take the Vicieae, for example, a tribe which includes *Lathyrus*, *Lens*, *Pisum* and *Vicia*. There are 65 pages of text on the Vicieae, followed by 322 refences, and the results of surveys for 10 classes of chemical are described. The book concludes with an Appendix on recent ethnobotany and there are complete indexes to both taxonomy and chemistry.

In writing this volume, Robert Hegnauer has been joined by his wife Minie, not surprisingly considering the vast amount of data contained herein. It is undoubtedly a masterwork. The Hegnauers are to be congratulated on completing this mammoth task, particularly in the face of battle with ill-health in recent years. Legume phytochemists will rejoice greatly at this appearance of this splendid account of papilionoid phytochemistry.

PII: S0031-9422(01)00367-3

Natural Terpenoids as Messengers
P. Harrawijn, A.M. van Oosten and P.G.M. Piron, Kluwer Academic, Dordrecht, The Netherlands, 2001. 440 pp. £100. ISBN 0792368916.

The contents of this novel and instructive book on terpenoids can be appreciated better from the subtitle "a multi-disciplinary study of terpenoid production, biological functions and practical applications". Some terpenoids—especially mono- and sesquiterpenoids—are indeed important messenger signals in nature, but as a class, they have many other roles as well. Many of their biological properties are discussed here with regard to their roles as messengers at the cellular level as well as acting as semiochemicals. A significant chapter in the book describes terpenoids as being beneficial to human health and the applications of terpenoids in medicine are particularly well covered.

As one might expect in a book on terpenoids, there is much information given on their biosynthesis in different organisms, from bacteria to vertebrates. Some of the key enzymes of isoprenoid biosynthesis are considered, as well as the regulation of biosynthesis via feedback mechanisms.

This attractive textbook is well illustrated with descriptive figures portraying the various interactions that are possible between insects and plants, fungi and plants, and so on. The text is clear and fully referenced. My only regret is that the authors, who are perfectly fluent in English, did not consult an Englishman to read

the text before typesetting. Nevertheless, this is a highly readable volume and the authors should be congratulated in producing this lively account of terpenoids in their natural environments.

There are 65 pages of text on the Vicieae, followed by 322 refences, and the results of surveys for 10 classes of chemical are described. The book concludes with an Appendix on recent ethnobotany and there are complete indexes to both taxonomy and chemistry.

In writing this volume, Robert Hegnauer has been joined by his wife Minie, not surprisingly considering the vast amount of data contained herein. It is undoubtedly a masterwork. The Hegnauers are to be congratulated on completing this mammoth task, particularly in the face of battle with ill-health in recent years. Legume phytochemists will rejoice greatly at this appearance of this splendid account of papilionoid phytochemistry.

Natural Terpenoids as Messengers
P. Harrawijn, A.M. van Oosten and P.G.M. Piron, Kluwer Academic, Dordrecht, The Netherlands, 2001. 440 pp. £100. ISBN 0792368916.

The contents of this novel and instructive book on terpenoids can be appreciated better from the subtitle "a multi-disciplinary study of terpenoid production, biological functions and practical applications". Some terpenoids—especially mono- and sesquiterpenoids—are indeed important messenger signals in nature, but as a class, they have many other roles as well. Many of their biological properties are discussed here with regard to their roles as messengers at the cellular level as well as acting as semiochemicals. A significant chapter in the book describes terpenoids as being beneficial to human health and the applications of terpenoids in medicine are particularly well covered.

As one might expect in a book on terpenoids, there is much information given on their biosynthesis in different organisms, from bacteria to vertebrates. Some of the key enzymes of isoprenoid biosynthesis are considered, as well as the regulation of biosynthesis via feedback mechanisms.

This attractive textbook is well illustrated with descriptive figures portraying the various interactions that are possible between insects and plants, fungi and plants, and so on. The text is clear and fully referenced. My only regret is that the authors, who are perfectly fluent in English, did not consult an Englishman to read

Received 19 June 2001; received in revised form 14 August 2001

Abstract

From the aerial parts of *Origanum syriacum*, three new monoterpene glucosides thymoquinol 2,5-*O*-β-diglucopyranoside (**3**), carvacrol 2-*O*-β-glucopyranosyl-(1→2)-β-glucopyranoside (**4**) and *p*-menth-1-ene-3,4-diol 4-*O*-β-glucopyranoside (**5**) together with two known monoterpene glucosides thymoquinol 2-*O*-β-glucopyranoside (**1**), thymoquinol 5-*O*-β-glucopyranoside (**2**) have been isolated. The structures of the isolated compounds were verified by means of MS and NMR spectral analyses. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Origanum syriacum*; Lamiaceae; Thymoquinol glucosides; Carvacrol glucoside

1. Introduction

Origanum syriacum L. (Lamiaceae) is an aromatic, herbaceous and perennial plant growing wild in the Sinai Desert of Egypt (Tackholm, 1974). The essential oils and the constituents of many *Origanum* species have been intensively studied (Sendra et al., 1980; Ravid et al., 1983; Akgul et al., 1987; Harvala et al., 1987; Halim et al., 1991; Afsharypuor et al., 1997). In folk medicine, *Origanum* species are used as powerful disinfectants, flavouring agents, in perfumes and in scenting soaps (Gunther, 1949; Chiej, 1984; Kotb, 1985). It was reported that thymol and carvacrol represent the major constituents of the essential oils of *Origanum* species (Sarer et al., 1982). From Egyptian majorana (*Origanum vulgare*), arbutin and methyl arbutin have been already isolated and quantitatively estimated (Assaf et al., 1987). The present study deals with isolation and assignment of three new and two known monoterpene glucosides from the aerial parts of *Origanum syriacum* L.

2. Results and discussion

The ethanolic extract of the aerial parts of *O. syriacum* was deffated with CH_2Cl_2 and the aqueous layer was subjected to a column chromatography of Diaion HP-20. The methanol eluate was repeatedly chromatographed on columns of silica gel and then by MPLC and HPLC to afford 5 glycosides.

The structure of compound **1** was determined as thymoquinol 2-*O*-β-glucopyranoside while that of **2** was identified as thymoquinol 5-*O*-β-glucopyranoside previously isolated from *Schisandrae chinensis* (Yahara et al., 1993). The enzymatic hydrolysis of compounds **1** and **2** produced thymoquinol as aglycone (**1a**). In general, this is the first report for isolation of compounds **1** and **2** from family lamiaceae. The molecular formula of compound **3** was deduced as $C_{22}H_{34}O_{12}$ from HR FAB-MS spectrometry (see Experimental). The enzymatic hydrolysis of **3** gave also the aglycone **1a**. ^{13}C NMR spectrum (Table 1) and DEPT experiment of **3** displayed the presence of two unsubstituted β-glucopyranosyl units from the signals at δ 104.0 (C-1, 1′); 75.1, 75.0 (C-2, 2′); 78.6 (C-3, 3′); 71.3, 71.4 (C-4, 4′); 78.7 (C-5, 5′) and 62.4 (C-6, 6′) (Bradbury et al., 1984) together with 10 carbon signals for the aglycone as follows: 3 methyl groups (δ 16.4, 23.3 and 23.2), 3 methines (δ 119.1, 114.9 and 26.8) and 4 quaternary carbons (δ 152.3, 150.9, 137.0 and 126.2). Comparison of the ^{13}C NMR data of **3** with those of **1**, **2** and **1a** (Table 1) revealed that compound **3** is a bisdesmoside and its aglycone is 2,5-disubstituted thymoquinol. From ^{1}H NMR spectrum of **3**, the two singlets at δ 7.60 and 7.50 were assigned for H-3 and H-6, respectively (Metwally et al., 1986). The one proton

multiplet at δ 3.80 together with two methyl doublets at δ 1.26 and 1.21 were obvious for H-8, 9 and 10, respectively and the methyl singlet at δ 2.40 was assigned for H-7 (Laswell et al., 1977). The β-configuration of the glucopyranosyl units was deduced from the coupling constants (6.8, 7.3 Hz) of the anomeric proton doublets at δ 5.46 and 5.47, respectively in the ^{1}H NMR spectrum of **3**. The negative FAB-MS spectrum of 3 exhibited M^+ at m/z 489 $[M–H]^-$ as well as significant peaks at m/z 327 [M–H-glucose]$^-$ and 165 [glucose]$^-$. Consequently the structure of compound 3 was assigned as thymoquinol 2,5-*O*-β-diglucopyranoside.

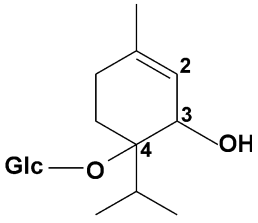
(4)



(5)

The molecular formula of compound **4** was deduced as $C_{22}H_{34}O_{11}$ from HR FAB–MS spectrometry (see Experimental). ^{13}C NMR spectrum (Table 1) and DEPT experiment of **4** displayed the presence of one unsubstituted β-glucopyranosyl unit from the signals at δ 106.5 (C-1′), 76.8 (C-2′), 78.6 (C-3′), 71.3 (C-4′) 78.7 (C-5′) and 62.4 (C-6′), one substituted β-glucopyranosyl unit from the signals at δ 100.1 (C-1), 83.4 (C-2), 78.1 (C-3), 71.1 (C-4), 78.3 (C-5) and 62.2 (C-6) (Bradbury et al., 1984) together with 10 carbon signals for the aglycone as follows: 3 methyl groups (δ 16.3, 24.3 and 24.0), 4 methines (δ 130.7, 119.8, 112.8 and 34.2) and 3 quaternary carbons (δ 156.4, 147.9 and 124.9). ^{1}H NMR spectrum of **4** revealed the presence of one methyl singlet (δ 2.5) and two methyl doublets (δ 1.15 and 1.16) assignable for Me-7, 9 and 10, respectively. Moreover, the two doublet signals at δ 5.5 and 5.6 ($J = 7.6$ and 7.2 Hz, respectively) deduced the β-configuration of the glucopyranosyl units. ^{13}C NMR signals of the aglycone were similar to those reported for carvacrol (Zechmeister, 1979). The downfield shift of C-2 (δ 83.4) of the inner glucopyranosyl residue indicated its substitution with the terminal glucopyranosyl unit at this position (Bradbury et al., 1984). The negative FAB–MS spectrum of **4** exhibited M^+ at m/z 473 $[M–H]^-$ as well as significant peaks at m/z 311 [M–H-glucose]$^-$ and 149 [M–H–2 glucose]$^-$. Consequently the structure of compound **4** was assigned as carvacrol 2-*O*-β-glucopyranosyl-(1→2)-β-glucopyranoside.

[e] Data published for the first time for thymoquinol.

The molecular formula of compound **5** was deduced as $C_{16}H_{28}O_7$ from HR FAB-MS spectrometry (see Experimental). ^{13}C NMR spectrum (Table 1) and DEPT experiment of **5** displayed the presence of one β-glucopyranosyl unit from the signals at δ 97.9 (C-1), 75.3 (C-2), 78.1 (C-3), 71.9 (C-4) 78.5 (5) and 62.7 (C-6) (Bradbury et al., 1984) together with 10 carbon signals for the aglycone as follows: 3 methyl groups (δ 16.9, 21.4 and 21.2), 2 methylene groups (δ 33.1 and 25.2), 3 methines (δ 123.4, 72.8 and 34.1) and 2 quaternary carbons (δ 143.4 and 79.8). The carbon signals at δ 72.8 and 79.8 indicated the attachment of two hydroxyl groups to these carbons (Breitmaier et al., 1987). On the other hand, ^{1}H NMR spectrum of **5** revealed the presence of one methyl singlet (δ 1.5) and two methyl doublets (δ 0.87) assignable for Me-7, 9 and 10 respectively. The broad singlets at δ 5.5 and 4.7 were assigned for H-2 and 3 respectively proving the attachment of the hydroxyl

groups to C-3 and C-4 of the aglycone together with the location of the double bond between C-1 and 2. Furthermore, comparison of ^{13}C NMR spectrum of **5** with *p*-menth-1-ene-4-ol confirmed the location of the hydroxyl group at C-3 of **5** from its downfield shift to δ 72.8 (Zechmeister, 1979). Moreover, the one proton multiplet signal at δ 3.9 in the ^1H NMR spectrum of **5** was interpreted for H-8 while the four protons multiplet at δ 1.8 – 2.2 was assigned for two methylene groups (H-5 and 6). The doublet signal at δ 5.16 ($J=8$ Hz) deduced the β-configuration of the glucopyranosyl unit. The attachment of the β-glucosyl moiety to C-4 of the aglycone was based on the downfield shift of this carbon (δ 79.8) in addition to the upfield shift of the anomeric carbon of the glucosyl unit (δ 97.9) that is characteristic for the attachment of the glucosyl moiety to a tertiary alcohol (Zhou et al., 1981; Mohamed et al., 1994). In general, the absolute configuration of the chiral center C-3 could not be determined because of the location of both a double bond and a quaternary chiral center (C-4) vicinal to it. The negative FAB-MS spectrum of **5** exhibited M^+ at *m/z* 331 $[M–H]^-$ as well as a significant peak at *m/z* 169 $[M–H\text{-glucose}]^-$. Consequently the structure of compound **5** was assigned as *p*-menth-1-ene-3, 4-diol 4-*O*-β-glucopyranoside.

3. Experimental

^1H and ^{13}C NMR (TMS as int. standard): 400 MHz and 100 MHz respectively were recorded on a Jeol JNM α-400 spectrometer. FAB MS spectra were taken on a Jeol JMS-SX 102 spectrometer by direct inlet method at an ionizing voltage of 70 eV MPLC: RP-18 column (20 mm i.d. ×40 cm); flow rate of mobile phase 3 ml/min. HPLC: D-ODS-5 and polyamine columns (each 20 mm i.d. ×25 cm, YMC) with a Toyo Soda high speed chromatograph HLC-803 D pump and a Tosoh refraction index (RI-8) detector; flow rate of mobile phase 6 ml/min, injection vol. 0.8–1.0 ml. On the ODS column, 60% MeOH (I) and 55% MeOH (II) were used while 90% MeCN (III) was used on the polyamine column. CC: Kieselgel 60 (70–230 mesh, Merck) and Diaion HP 20 (Mitsubishi). TLC: silica gel 60 precoated plates F-254 and HPTLC using RP-18 precoated plates, F-254 s (Merck).

3.1. Plant material

The aerial parts (stems and leaves) of *O. syriacum* L. (Lamiaceae) were collected from Saint Kathrine, Sinai desert, Egypt in May 1997. The plant was identified by Dr. Salah El-Naggar, Department of Botany, Faculty of Science, Assiut University, Assiut, Egypt. A voucher specimen is deposited at the Herbarium of Department of Pharmacognosy, Faculty of Pharmacy, Assiut University, Assiut, Egypt.

3.2. Extraction and isolation of compounds (*1–5*)

The air-dried powdered aerial parts of *O. syriacum* (2 kg) were extracted with 70% EtOH. The dried ethanolic extract (450 g) was suspended in H_2O and deffated with CH_2Cl_2. The aq. fr. was applied to a column of Diaion HP-20 and eluted with H_2O, MeOH and acetone successively. The MeOH eluate (30 g) was chromatographed by silica gel CC using CH_2Cl_2–MeOH–H_2O (85:15:1) and finally with (70:30:3) to give 5 fractions. Fraction 2 (500 mg) was separated by MPLC on RP-18 using 65% MeOH and HPLC using ODS column and solvent I to afford compounds **1** (white powder, 90 mg), **2** (white powder, 40 mg) and **5** (white powder, 15 mg). Fraction 3 (350 mg) was subjected to HPLC using first ODS column with solvent II and then Polyamine column with solvent III to give compounds **3 (**white powder, 60 mg) and **4** (white powder, 40 mg).

3.2.1. Compound (*1*)

Thymoquinol 2-*O*-β-glucopyranoside, HR FAB-MS (negative) *m/z*: 327.1469 $[M–H]^-$ $C_{16}H_{23}O_7$ (req. 327.1444). ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR (C_5D_5N): δ 7.50 (1H, *s,* H-3), 7.10 (1H, *s*, H-6), 5.40 (1H, *d*, $J=6.8$ Hz, H-1 Glc), 3.82 (1H, *m*, H-8), 2.40 (3H, *s*, Me-7), 1.21 and 1.20 (each 3H, *d*, $J=6.1$ and 6.6 Hz, respectively, Me-9 and 10).

3.2.2. Compound (*1a*)

Thymoquinol, ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR (C_5D_5N): δ 7.20 (1H, *s,* H-3), 7.10 (1H, *s*, H-6), 3.70 (1H, *m*, H-8), 2.40 (3H, *s*, Me-7), 1.30 (6H, *d*, $J=7.1$ Hz, Me-9 and 10).

3.2.3. Compound (*2*)

Thymoquinol 5-*O*-β-glucopyranoside, HR FAB-MS (negative) *m/z*: 327.1419 $[M–H]^-$ $C_{16}H_{23}O_7$ (req. 327.1444). ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR (C_5D_5N): δ 7.60 (1H, *s,* H-3), 7.0 (1H, *s*, H-6), 5.40 (1H, *d*, $J=6.4$ Hz, H-1 Glc), 3.60 (1H, *m*, H-8), 2.40 (3H, *s*, Me-7), 1.32 (6H, *d*, $J=6.8$ Hz, Me-9 and 10).

3.2.4. Compound (*3*)

Thymoquinol 2,5-*O*-β-diglucopyranoside, $[\alpha]_D^{25}$ −12.5° (MeOH; c 1.20). HR FAB–MS (negative) *m/z*: 489.1955 $[M–H]^-$ $C_{22}H_{33}O_{12}$ (req. 489.1972). ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR (C_5D_5N): δ 7.60 (1H, *s,* H-3), 7.50 (1H, *s*, H-6), 5.47 (1H, *d*, $J=7.3$ Hz, H-1 Glc), 5.46 (1H, *d*, $J=6.8$ Hz, H-1′ Glc), 3.80 (1H, *m*, H-8), 2.40 (3H, *s*, Me-7), 1.26 and 1.21 (each 3H, *d*, $J=7.1$ Hz, Me-9 and 10).

3.2.5. Compound (*4*)

Carvacrol 2-*O*-β-glucopyranosyl-(1→2)-β-glucopyranoside, $[\alpha]_D^{25}$ −25.1° (MeOH; c 1.60). HR FAB–MS (negative) *m/z*: 473.2058 $[M–H]^-$ $C_{22}H_{33}O_{11}$ (req. 473.2023). ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR

(C_5D_5N): δ 7.40 (1H, *bs,* H-3), 7.04 (1H, *d*, $J=8$ Hz, H-6), 6.76 (1H, *bd*, $J=7.6$ Hz, H-5), 5.60 (1H, *d*, $J=7.2$ Hz, H-1 Glc), 5.50 (1H, *d*, $J=7.6$ Hz, H-1′ Glc), 2.80 (1H, *m*, H-8), 2.50 (3H, *s*, Me-7), 1.16 and 1.15 (each 3H, *d*, $J=6.8$ Hz, Me-9 and 10).

3.2.6. Compound (*5*)

p-Menth-1-ene-3,4-diol 4-*O*-β-glucopyranoside, $[\alpha]_D^{25}$ −18.9° (MeOH; *c* 1.50). HR FAB–MS (negative) *m*/*z*: 331.1758 $[M-H]^-$ $C_{16}H_{27}O_7$ (req. 331.1757). ^{13}C NMR (C_5D_5N, Table 1). ^1H NMR (C_5D_5N): δ 5.50 (1H, *bs,* H-2), 5.16 (1H, *d*, $J=8.0$ Hz, H-1 Glc), 4.70 (1H, *bs*, H-3), 3.90 (1H, *m*, H-8), 1.80–2.20 (4H, *m*, H-5 and 6), 1.50 (3H, s, H-7), 0.87 (6H, *d*, $J=6.8$ Hz, Me-9 and 10).

3.2.7. Enzymatic hydrolysis of compound *1*

Compound **1** (20 mg) was dissolved in 0.5 ml MeOH and a solution of β-glucosidase (100 mg) in 20 ml water was added. The mixture was extracted with diethyl ether (3 times ×20 ml) after stirring at 37 °C for 2 days. The combined ethereal extracts were evaporated and the residue was purified by HPLC using 95% MeCN on polyamine column to afford the aglycone **1a** (6 mg). Compounds **2** and **3** have been subjected to same procedure as **1** to afford the aglycone **1a**.

Received in revised form 6 June 2001

Abstract

Three known and two new diterpenes were isolated from the ethyl acetate extract of *Hymenaea courbaril* var. *stilbocarpa* seed pods. One of the compounds was elucidated as (5*R**,8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oic acid and the other was elucidated, after treatment with diazomethane, as methyl (5*S**,8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oate. The known diterpenes were identified as (−)-ozic acid, (−)-isoozic acid and (−)-kovalenic acid which were characterized as their methyl ester derivatives. © 2001 Elsevier Science Ltd. Keywords: *Hymenaea courbaril* var. *stilbocarpa*; Clerodane; Diterpenes

1. Introduction

Hymenaea (*Caesalpinoideae*, Ditareae) is a genus widely distributed from Central to South America, mainly in the Amazon basin (Lee and Langenheim, 1975). The trunk exudes a resin, which is locally used in folk medicine for treatment of wounds, bronchitis and stomach disorders (Marsaioli et al., 1975; Corrêa, 1984). Analgesic and anti-inflammatory activities were also reported for the hydroalcoholic extract of the bark (Neves et al., 1993). The "jatoba" fruits, a commonly used name, provides a large quantities of proteic flour containing soluble and insoluble fibers; it was recently used in the preparation of high-fiber content snacks (Chang et al., 1998). *Hymenaea* species are known to mainly contain diterpenes of the *enantio*-labdanoic type in the trunk resin and bark extract (Nakano and Djerassi, 1961; Cunningham et al., 1973,1974; Marsaioli et al., 1975; Imamura et al., 1977), and *ent*-halimane diterpenes in the seed pod resin (Khoo et al., 1973). Searching for new source of diterpenes to be used as starting material in organic synthesis (Costa et al., 1999), we have investigated the composition of the seed pod resin of *H. courbaril* var. *stilbocarpa* Hayne and have succeed in isolating three of the known diterpenes and two new clerodanes, (−)-(5*R**, 8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oic acid (**4**) and (−)-(5*S**,8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oic acid, the latter being characterized as a methyl ester derivative **5b**.

2. Results and discussion

The ethyl acetate extract of *H. courbaril* var. *stilbocarpa* seed pods was submitted to a combination of column chromatography (silica gel), preparative TLC on $SiO_2/AgNO_3$ (5%) and RP-HPLC to afford three known and two new diterpenoid acids **4** and **5a**. The three known diterpenes were characterized as methyl ester derivatives: methyl (−)-ozate (**1**) {$[\alpha]_D^{20}$ −39.5° (*c* 7.0, $CHCl_3$)}, (Stipanovic et al., 1979); methyl (−)-isoozate (**2**) {$[\alpha]_D^{20}$ −23.0° (*c* 1.2, $CHCl_3$)}, (Khoo et al 1973) and methyl (−)-kovalenate (**3**) {$[\alpha]_D^{20}$ −58.0° (*c* 0.7, $CHCl_3$)}, (Hara et al., 1995). (Fig. 1).

Compound **4** was obtained as a colorless oil, $[\alpha]_D^{20}$ −61.0° (*c* 0.4, $CHCl_3$) and the HREIMS gave a $[M]^+$ at *m*/*z* 304.23205 corresponding to a molecular formula $C_{20}H_{30}O_3$ (calc. 304.24023). The ^1H NMR spectra of **4** and **3** showed similar features except for the presence of a singlet at δ 3.70 assigned to the methoxyl group of **3**

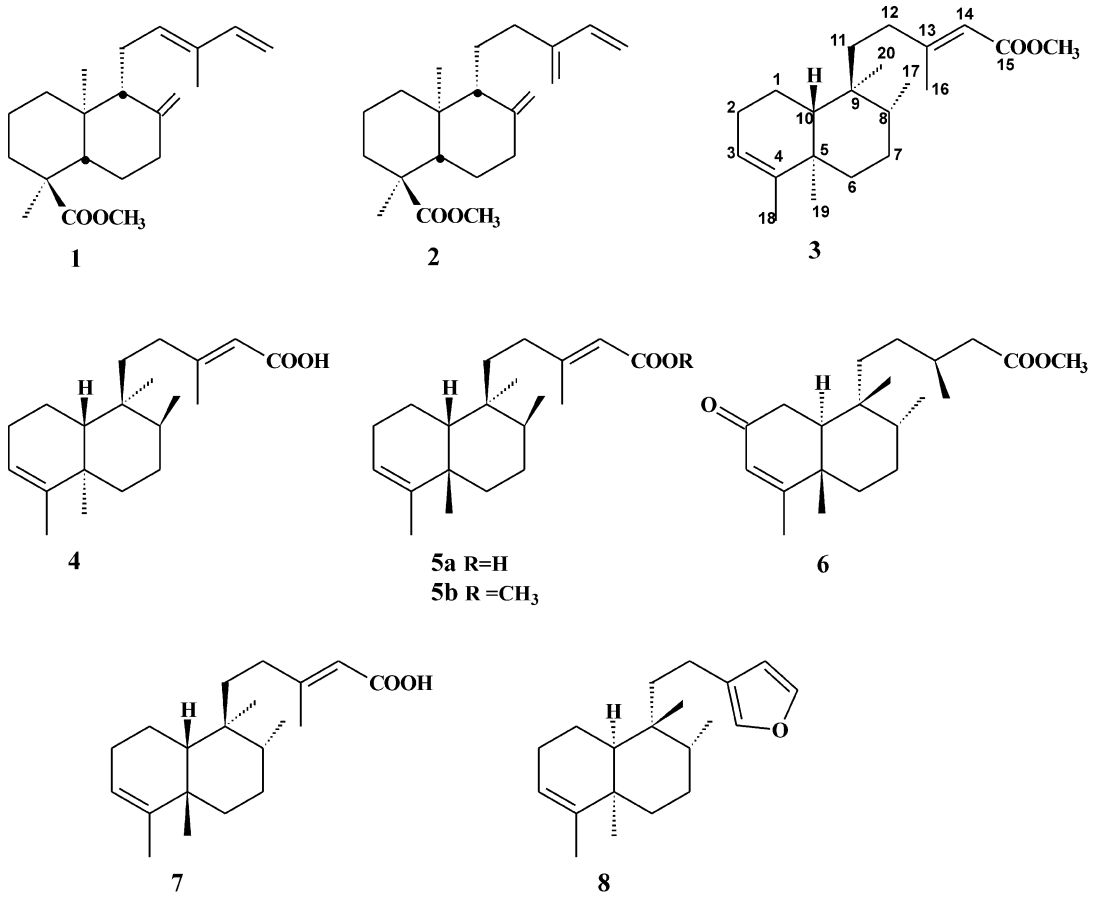

Fig. 1.

and a slight deshielding of the signals at δ 0.94 (*s*, H-20) and 0.95 (*d*, $J=6.0$ Hz, H-17) of **4** when compared with those of **3** [δ 0.73 (*s*, H-20) and δ 0.82 (*d*, $J=6.0$ Hz), H-17]. The remaining characteristic signals of **4** at δ 1.05 (*s*, H-19), 1.59 (*bd*, $J=1.5$ Hz, H-18) and 2.19 (*d*, $J=1.2$ Hz, H-16), δ 5.20 (*bs*, H-3) and 5.71 (*bd*, $J=0.9$ Hz, H-14) had similar chemical shift with those of **3**. From this first analysis we concluded that both compounds shared equal diterpene skeletons with different ring B relative configurations.

The full ^{1}H and ^{13}C NMR signal assignments were based on homonuclear and heteronuclear 2D NMR experiments (COSY-90, HETCOR, COLOC) (Table 1). The COSY-90 contour plot displayed cross peaks between H-14 at δ 5.71 and H-16 at δ 2.19 and H-12 at δ 2.13. The latter also correlates with the diastereotopic methylene hydrogens of C-11 at δ 1.16 and δ 1.55. Thus with all side chain hydrogens fully assigned, the corresponding carbon chemical shifts were easily obtained by one bond $^{1}H/^{13}C$ chemical shift correlations. (Table 1). To establish ring A ^{1}H and ^{13}C connectivities we have taken H-3 (δ 5.20) as safe entry point. The cross peaks in the COSY spectrum confirmed that hydrogen H-3 is coupled to hydrogens at δ 1.59 and δ 2.04 and according to the HETCOR spectrum, they correspond to C-18 methyl group (δ 18.0) and H-2 (δ 26.8). The COLOC plot proves the existence of a long range $^{1}H,^{13}C$ coupling between the quaternary C-4 (δ 144.4) and H-18 (δ 1.59) and H-19 (δ 1.05) which correspond to C-18 (δ 18.0) and C-19 (δ 20.6), respectively. All other signals not yet assigned were identified analogously (Table 1). The *trans* relationship at the AB ring juncture was first inferred from the chemical shift of C-19 at δ 20.6 (δ 33.2 for *cis* fusion) (Lopes et al., 1987) and the spatial proximity between H-19 and H-20 was inferred from the cross peak in the phase sensitive NOESY spectrum (Fig. 2).

A γ-gauche interaction between C-17 (axial, δ 14.8) and C-6 (δ 30.1) was invoked to explain the C-6 shielding ($\Delta\delta=-6.7$) of **4** in comparison with the corresponding carbon of **3** (δ 36.8, C-17 equatorial). There is also a good agreement between the C-6 chemical shifts of **4** (δ 30.1) and 2-oxo-3-cleroden-15-oic acid **(6)** (δ 29.1) (Urones et al., 1991), which has the same relative stereochemistry at C-5, C-8, C-9 and C-10. Therefore, the suggested structure for **4** is (5*R**,8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oic acid.

Compound **5a** was obtained as colorless crystals, mp 175–178 °C, and its decomposition was prevented by methylation with diazomethane. It was therefore characterized as the methyl ester **5b**, an oil $[\alpha]_{D}^{20}$ −65.0° (*c* 1.1,

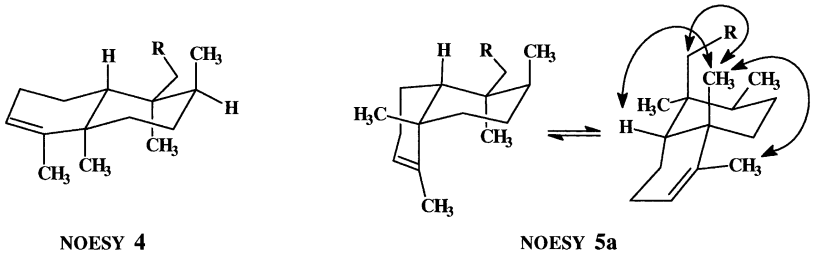

Fig. 2. Significant correlation in the NOESY spectrum of **4** and **5a**.

$CHCl_3$). The HREIMS gave a $[M]^+$ at m/z 318.25581 corresponding to a molecular formula $C_{21}H_{32}O_3$ (calc. 318.25588). The ^1H NMR spectrum of **5b** was very similar to those of **3** and **4**, except for the deshielding of H-18 (δ 1.64), H-19 (δ 1.15), H-20 (δ 1.03) and shielding of H-17 (δ 0.86) when compared with those of **4**. (Table 1).

The complete assignments of the ^1H and ^{13}C signals of **5b** were based on homonuclear and heteronuclear 2D experiments (COSY-90, HETCOR, COLOC) (Table 1), and by comparison with the ^{13}C NMR spectra of **4** which depicted major differences in the chemical shift of the carbons belonging to the decalin moiety.

Owing to the C-20 and C-17 methyl resonance differences in **5a** ($\Delta\delta_C = 11.0$) and **4** ($\Delta\delta_C = 5.6$), *cis*-decalin and *trans* decalin, respectively, we proposed that both compounds share the same *trans* methyl relationship. Moreover a literature survey revealed that compounds **3** (*trans* decalin) and **7** (*cis* decalin) possessing a *cis* relationship between C-20 and C-17 displayed a $\Delta\delta \sim 2$, therefore, corroborating the proposed C-20/C-17 *trans* relationship in compound **5b**. The *cis* relationship at the AB ring juncture was first inferred from the C-19 chemical shift (δ 27.7). The relative configuration at C-5 and C-10 was confirmed by nOe enhancements arising from the dipolar interaction between H-19 (δ 1.15) and H-10 (δ 1.42). The spatial proximity between H-19 (δ 1.15), H-10 (δ 1.42), H-11 (δ 1.88, 1.25) was confirmed by cross peaks between these signals in the NOESY experiment of the underivatized acid. The proximity of H-19 and H-11 is due to the flexibility of *cis*-decalin system for A/B rings of **5** as shown in Fig. 2. Finally, the structure of **5b** was established as methyl (−)-(5*S**,8*S**,9*S**,10*R**)-cleroda-3,13*E*-dien-15-oate. This conclusion was corroborated by comparison of ^1H NMR spectroscopic data of **5b** with those reported for **8**, a solidagoic acid derivative (Anthonsen et al., 1973) that has the same relative stereochemistry at C-5, C-8, C-9 and C-10. The chemical shifts of the methyl groups at δ 1.17 for C-19, 1.08 for C-20 and 0.92 for C-17, are in good agreement with those

observed for **5b**, which appeared, respectively, at δ 1.15, 1.03 and 0.86. As far as we know, this is the first report of clerodane diterpenes in *Hymenaea*, the co-occurrence of *cis*- and *trans*-clerodanes is also noteworthy.

Taking into consideration that the absolute configuration of **3** has already been established (Caputo and Mangoni, 1974), and that **3, 4** and **5b** have been isolated from the same extract, we tentatively propose that the absolute configuration of **4** is (−)-(5*R*,8*S*,9*S*,10*R*)-cleroda-3,13*E*-dien-15-oic acid and that of **5b** is (−)-(5S,8S,9S,10R)-cleroda-3,13*E*-dien-15-oic acid with both acids belonging to the same enantiomeric series as depicted in Fig. 1.

3. Experimental

3.1. General

^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ solution at 300 MHz and 75.5 MHz, respectively, with a Bruker AC 300/P spectrometer (internal standard TMS). IR spectra of neat samples were measured with a Perkin-Elmer 1600 series FTIR. Mass spectra of purified compounds were recorded with a Hewlett-Packard 5890 GC equipped with a Model 5970 mass-selective detector. Elemental analyses were performed with a Perkin-Elmer 2400 CHN analyzer. Optical rotations were measured with a Carl Zeiss photoelectric polarimeter.

3.2. Isolation

The seed pods of *H. courbaril* var. *stilbocarpa* were collected in August 1993 at Fazenda Santa Elisa (IAC—Campinas). A voucher specimen was deposited in the Herbarium of IB-UEC (No. GS 01/02). Dry seed pods (668.4 g) were pulverized and soaked in EtOAc (31) for 5 days at room temperature, with occasional shaking. Filtration and solvent evaporation at reduced pressure produced a crude extract (60.0 g) as a viscous oily resin. Acid and base extraction furnished the acidic (41.0 g) and the neutral fraction (17.0 g). A sample of the acidic fraction (712 mg) was submitted to preparative TLC on SiO_2/5% $AgNO_3$ eluting four times with benzene: EtOAc (9:1; v/v) to afford two fractions which were immediately esterified with CH_2N_2 to furnish the corresponding methyl esters **1** (10 mg) and **2** (17 mg), respectively. A third fraction containing a mixture of, at least 4 compounds was also obtained. This fraction was submitted to further purification on a HPLC semi-preparative μ-Bondpack C-18 column (250 mm×10 mm×5 μm, Waters) and eluted with MeOH–H_2O (85:15) containing 1% of formic acid to furnish four fractions. The first fraction containing an oil, was esterified with diazomethane to furnish compound **3** (22 mg). Two other fractions containing compound **4** (6 mg) and **5a** (14 mg) were obtained. Due to instability observed for the latter, this acid was esterified with excess of diazomethane and characterized as a methyl ester **5b**.

3.3. (−)-(5R,8S,9S,10R)-Cleroda-3,13E-dien-15 oic acid (*4*)

$[\alpha]_D^{20}$ −61.0° (*c* 0.4, $CHCl_3$); HREIMS *m*/*z*: 304.23205 $[M]^+$ (calc. 304.24023 for $C_{20}H_{32}O_2$); IR ν_{max}^{film} cm^{-1}: 3600–3200, 1690, 1638; ^{1}H NMR: Table 1; ^{13}C NMR: Table 1.

3.4. Methyl (−)-(5S,8S,9S,10R)-cleroda-3,13E-dien-15 oate (*5b*)

$[\alpha]_D^{20}$ −65.0 (*c* 1.1, $CHCl_3$); HREIMS *m*/*z*: 318.25581 $[M]^+$ (calc. 318.25588 for $C_{21}H_{34}O_2$); IR ν_{max}^{film} cm^{-1}: 1721, 1648, 1150; ^{1}H NMR: Table 1; ^{13}C NMR: Table 1.

Deoxyarteannuin B, dihydro-deoxyarteannuin B and *trans*-5-hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol from *Artemisia anuua*

Lai-King Sy, Geoffrey D. Brown*

Chemistry Department, The University of Hong Kong, Pokfulam Rd., Hong Kong

Received 4 May 2001; received in revised form 16 July 2001

Abstract

The amorphane sesquiterpenes, deoxyarteannuin B and dihydro-deoxyarteannuin B, were isolated from *Artemisia annua* and their structures mainly determined by two-dimensional NMR spectoscopic analyses. The irregular monoterpene, *trans*-5-hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol, was also characterized in the same way, and its structure was confirmed by synthesis from lavandulol. All of these natural products are suggested to be formed by autoxidation reactions. Full assignments of the ^{1}H and ^{13}C resonances for the known natural products *epi*-deoxyarteannuin B and isoannulide, determined by the same methodology, are also reported. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Artemisia annua* L.; Compositae; Sesquiterpene; Monoterpene; Deoxyarteannuin B; Dihydro-deoxyarteannuin B; *Epi*-deoxyarteannuin B; Isoannulide; *trans*-5-Hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol; 2D-NMR

1. Introduction

Artemisia annua L. (Compositae) is the source of the important anti-malarial drug artemisinin (Haynes and Vonwiller, 1997). Extensive phytochemical investigation of this species has resulted in the isolation of a large number of cadinane and amorphane sesquiterpenes over the past two decades (Sy et al., 1998), in addition to artemisinin itself. Most of the natural products reported from this species have been characterized by NMR spectroscopic analyses (Agrawal et al., 1991; Marsaioli et al., 1994; Karle and Lin, 1995; Agrawal and Bishnoi, 1996). We now report the isolation and structure determination, by 2D-NMR, of three new constituents from *A. annua*, deoxyarteannuin B (**1**), dihydro-deoxyarteannuin B (**2**) and *trans*-5-hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol (**11**).

2. Results and discussion

Extensive HPLC separation of a relatively non-polar fraction from the CH_2Cl_2 extract of *A. annua* yielded the new sesquiterpene **1**. The base peak in the mass spectrum of **1** occurred at m/z 232, corresponding to the molecular formula $C_{15}H_{20}O_2$ as evidenced by high-resolution mass spectrometry. The IR spectroscopic analysis was consistent with the presence of a five-membered lactone ring (ν 1751 cm^{-1}), while ^{13}C/DEPT NMR spectra confirmed the presence of fifteen carbon atoms with twenty protons directly attached (Table 1). The structure of **1**, therefore, contains six double bond equivalents, of which two are already accounted for by the lactone ring. A further two equivalents were identified as being due to carbon-carbon double bonds as indicated by the characteristic resonances observed in the ^{13}C and ^{1}H NMR spectra (δ_C 142.5, 139.9, 118.8 and 116.8 ppm and δ_H 6.10, 5.36 and 5.13 ppm). One of these double bonds in compound **1** was shown to be a γ-substitutent on the butyrolactone ring by HSQC (Tables 1 and 2), HMBC (Fig. 2) and ^{1}H–^{1}H COSY experiments (in particular by correlations observed from C-7 to H-13a/b, C-11 to H-13a and C-12 to H-13a in HMBC and by a weak correlation seen in ^{1}H–^{1}H

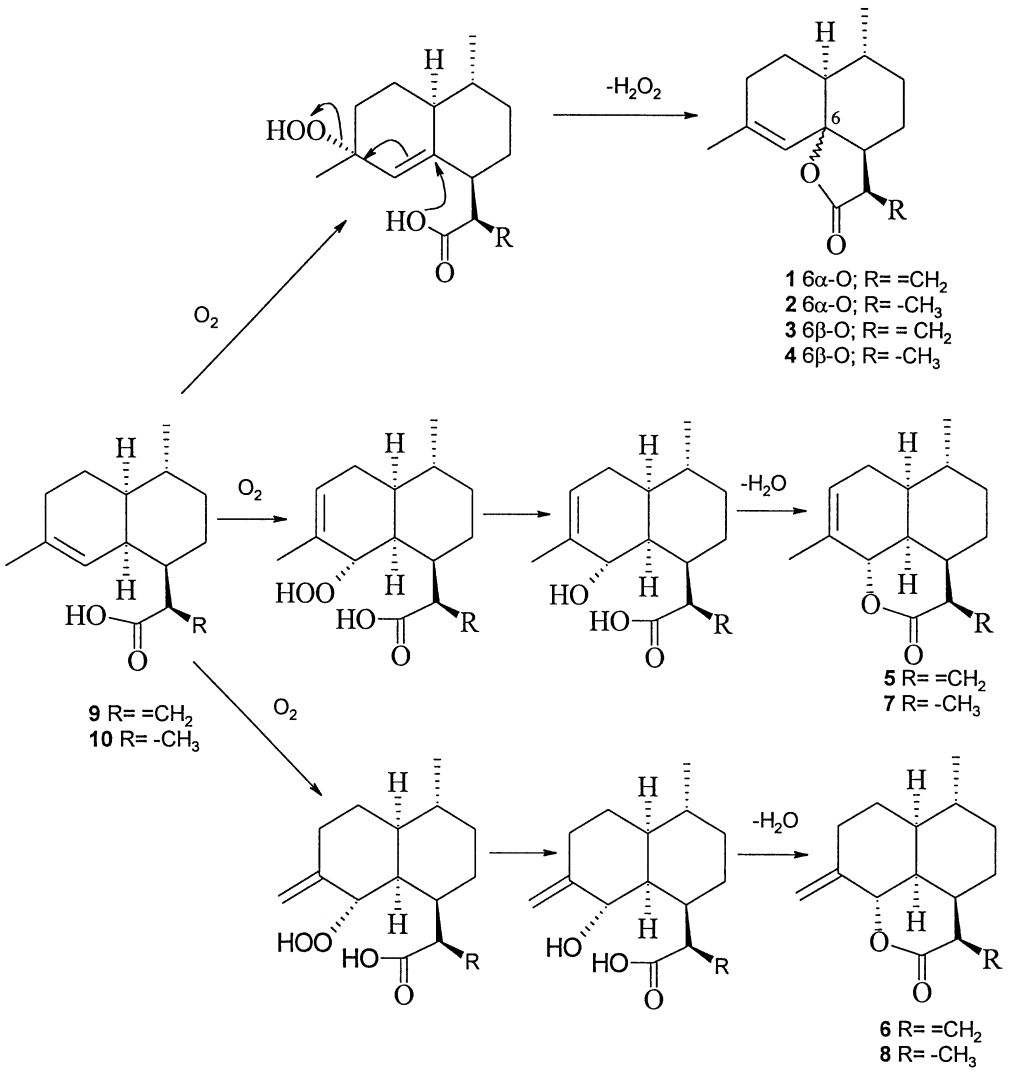

Scheme 1. Proposed biogenesis of sesquiterpenes **1–8** from autoxidation reactions of arteannuic acid (artemisinic acid) (**9**) and dihydroartemisinic acid (**10**) in *A. annua*.

COSY from H-7 to H-13a/b, which corresponds to a small allylic coupling). The second double bond was shown to be substituted by a methyl group by HMBC correlations from C-3, C-4 and C-5 to H-15, and the tri-substituted nature of this double bond was confirmed by a weak correlation observed in ^{1}H–^{1}H COSY from H-5 to H-3. The remaining two double bond equivalents required in the structure of **1** were then identified as being due to two fused six-membered rings by strong correlations observed in the ^{1}H-^{1}H COSY spectrum between successive pairs of vicinal protons around the amorphane skeleton of **1** (from H-3 "clockwise" as far as H-7). Following complete assignment of all the ^{1}H resonances for **1**, the relative stereochemistry was determined by NOESY correlations, which showed the decalin ring to be *cis*-fused.

In addition, the 11,13-dihydro analog of **1**, dihydrodeoxyarteannuin B (**2**), was isolated from the same extract, and was fully characterized by 2D-NMR spectroscopic analysis in the same way as **1**. The known compounds, *epi*-deoxyarteannuin B (**3**) and dihydro-*epi*-deoxyarteannuin B (**4**), were also obtained and are epimeric with **1** and **2** at the 6-position. Although compound **3** was reported on several occasions, both as a natural product from *A. annua* (Roth and Acton, 1987; El-Feraly et al., 1989; Brown, 1992) and through synthesis (Jung et al., 1987), full NMR spectral assignments for compound **3** are reported for the first time in Tables 1 and 2. These data support the structure proposed for **1**. Previously published 2D-NMR assignments for **4** (Brown, 1992; Sy et al., 1998) are reproduced for completeness and to allow comparison with the assignments of **2**.

Through repeated HPLC, isoannulide (**5**) was also isolated from this extract of *A. annua*. This natural product was described previously only as a mixture with annulide (**6**) (Brown, 1993), and there was some uncertainty regarding the ^{13}C and ^{1}H NMR spectral assignments for **5** as a result. Complete and unambiguous NMR spectral assignments for **5** are presented for the

first time in Tables 1 and 2. A minor revision to the previous ^{13}C assignments for the alkene carbons of annulide (**4**) is reported, based on 2D-NMR analysis. The assignments established for annulide and isoannulide (Tables 1 and 2) are consistent with those recently reported for their 11,13-dihydro analogues, arteannuins J (**7**) and I (**8**) (Sy et al., 1998).

Although deoxyarteannuin B (**1**) was not reported previously as a secondary metabolite, it is known as a synthetic product. Thus, Acton and Roth (1989) obtained **1** together with its 6-epimer, *epi*-deoxyarteannuin B (**3**), as products from the photo-oxygenation of arteannuic acid (**9**). However, Jung et al. (1987) isolated only *epi*-deoxyarteannuin B (together with

arteannuin B) from this reaction, and El-Feraly et al. (1989) found that oxidation of arteannuic acid, using a variety of chemical reagents, yielded only *epi*-deoxyarteannuin B. We speculate that **1–8** may be biogenetically derived from the ene-type reactions of molecular oxygen with the tri-substituted double bond in **9/10** as shown in Scheme 1 (Roth and Acton, 1989). This hypothesis is based on our general ideas concerning the autoxidation chemistry of terpenes (Sy and Brown, 1999). More specifically, we have previously presented results regarding the biogenetic origins of several sesquiterpene metabolites of *A. annua* from hydroperoxides which are derived from autoxidation of the $\Delta^{4,5}$-double bond of dihydroartemisinic acid (**10**) (Sy et al., 1998, 1999).

In addition to the amorphane sesquiterpenes **1–6**, the irregular monoterpene **11** was also isolated from more polar fractions. *trans*-5-Hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol (**11**) is apparently a new natural product, although its 1-acetate was reported previously from a *Lavandula* oil (Belsten et al., 1972). The structure of this irregular monoterpene was determined by 2D-NMR (Fig. 2; Tables 3 and 4). Thus, correlations between vicinal protons in the ^{1}H–^{1}H COSY spectrum

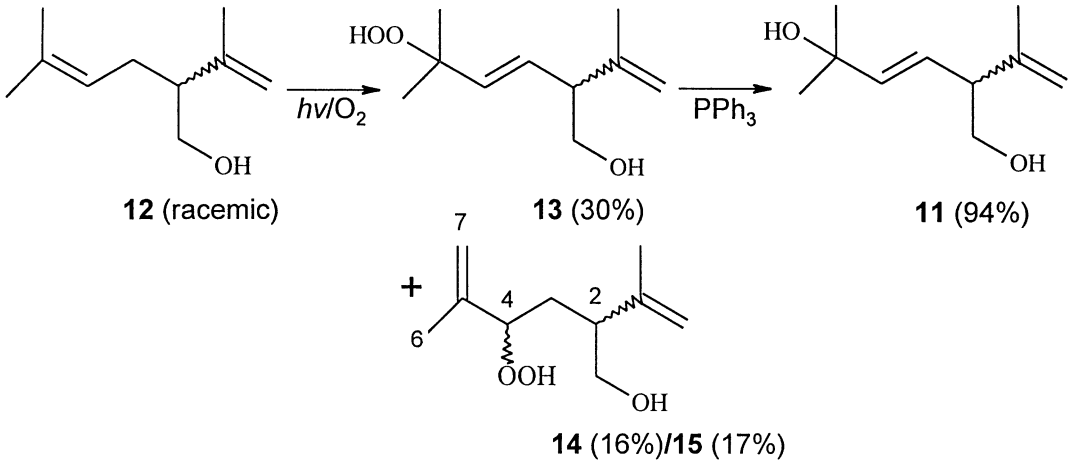
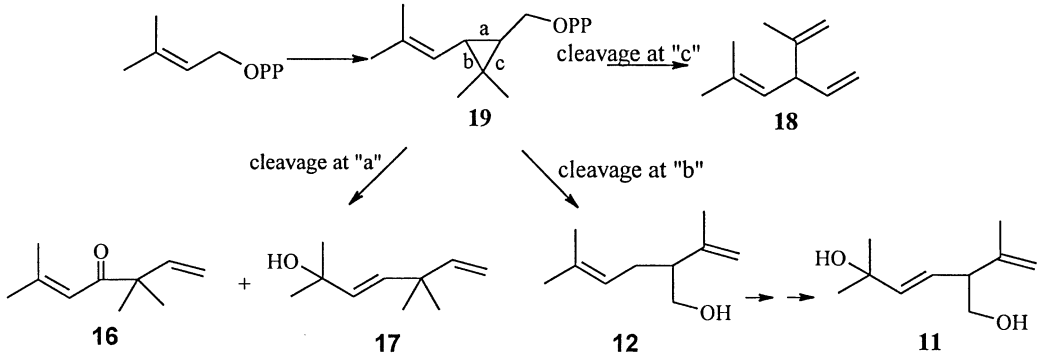


Scheme 2. Biomimetic synthesis of **11** from racemic **12** via the tertiary allylic hydroperoxide **13**.



Scheme 3. Proposed biogenesis of three classes of irregular monoterpenoids from the genus *Artemisia*.

of **11** indicated that the molecule contained a "core" consisting of a (HO)CH_2–CH–CH=CH spin system, while correlations observed in the HMBC spectrum indicated the location of 2-isopropylidene and 2-isopropanol "substituents" at C-2 and C-4 respectively. It was thought that **11** was derived from the monoterpene lavandulol (**12**) (Banthorpe et al., 1977) by spontaneous autoxidation reactions occurring in the plant. In order to confirm the structure proposed for compound **11** from 2D-NMR spectral analysis, a "biomimetic synthesis", in which racemic lavandulol was first subjected to photo-oxygenation was performed. This resulted in the three allylic hydroperoxides (**13–15**) which are expected from the ene-type reaction of singlet oxygen with the trisubstituted double bond in lavandulol. Reduction of the tertiary allylic hydroperoxide **13** by triphenylphosphine (Scheme 2) afforded an allylic alcohol with identical NMR spectra to the natural product **11**.

Several other irregular monoterpenes were reported previously from the genus *Artemisia* including the artemisinanes, artemisia ketone (**16**) and yomogi alcohol (**17**), and the santolinane, santolinatriene (**18**). The occurrence of the lavandulane skeleton in *A. annua*, as exemplified by **11**, is consistent with previous proposals that all three irregular monoterpene skeletons may be derived from the common precursor, chrysanthemyl pyrophosphate (**19**) (Scheme 3), by cleavage reactions associated with each of the three carbon-carbon bonds of a cyclopropyl ring (Banthorpe et al., 1977; Charlwood and Charlwood, 1991).

3. Experimental

Chemical shifts are expressed in ppm (δ) relative to TMS as internal standard. Proton chemical shifts, multiplicities, coupling constants, and integrals reported in this section are those which are clearly resolved in one-dimensional ^{1}HNMR without recourse to 2D-NMR analysis (see Tables 1 and 2 for 2D-NMR results). All NMR experiments were run on a Bruker DRX 500 instrument. HSQC and HMBC spectra were recorded with 1024 data points in F_2 and 256 data points in F_1. High-resolution MS were recorded in EI mode at 70 e.v. on a Finnigan-MAT 95 MS spectrometer. IR spectra were recorded in $CHCl_3$ on a Shimadzu FTIR-8201 PC instrument. Column chromatography was performed using silica gel 60–200 μm (Merck). HPLC separations were performed using a Varian chromatograph equipped with RI star 9040 and UV 9050 detectors and a YMC diol column, 20 mm×25 cm column, flow rate 8 ml/minute.

3.1. Plant material

A. annua plants were grown outdoors from seeds supplied by the NCCPG *Artemisia* collection (31 Smith Street, Elsworth, Cambridge, CB3 8HY, UK). Taxonomically verified specimens are held by the collection. Mature plants were harvested in April, 3–4 months after sowing, when they were just beginning to come into flower.

3.2. Extraction and isolation

The fresh aerial parts of *A. annua* (266 g) were ground to a fine powder under liquid nitrogen and then extracted with CH_2Cl_2. The organic extract was dried ($MgSO_4$) and solvent removed on a rotary evaporator to yield an aromatic dark green gum (1.77 g, 0.67% w/w) which was subjected to repeated HPLC separation. Compound **1** (1 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane (R_t 12.5 min), then from

HPLC in 7% EtOAc/*n*-hexane (R_t 18.1 min); compound **2** (0.5 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane (R_t 13.8 min), then from 5% EtOAc/*n*-hexane (R_t 26.6 min); compound **3** (2 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane (R_t 12.5 min), then from 7% EtOAc/*n*-hexane (R_t 17.6 min); compound **4** (15 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane (R_t 12.5 min), then from 7% EtOAc/*n*-hexane (R_t 18.4 min); compound **5** (1 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane; (R_t 13.1 min), then from 7% EtOAc/*n*-hexane (R_t 26.6 min); compound **6** (4 mg) was obtained from HPLC in 18% EtOAc/*n*-hexane (R_t 13.1 min), then from 7% EtOAc/*n*-hexane (R_t 27.3 min); compound **11** (1 mg) was obtained from HPLC in 50% EtOAC/*n*-hexane/1%CH_3COOH (R_t 17.0 min), then from 26% EtOAc/*n*-hexane/0.7%CH_3COOH (R_t 42.0 min).

3.3. Deoxyarteannuin B (*1*)

Oil. IR ν_{max} ($CHCl_3$) cm^{-1}: 3020, 2930, 2855, 1751, 1456; ^1H NMR: see Table 2; ^{13}C NMR: see Table 1; HREIMS: *m/z* (rel. int.) 232.1466 [M^+, $C_{15}H_{20}O_2$, requires 232.1463] (100), 217 (25), 187 (70), 173 (33).

3.4. Dihydro-deoxyarteannuin B (*2*)

Oil. IR ν_{max} ($CHCl_3$) 3026, 2934, 2874, 1761, 1456 cm^{-1}; ^1H NMR: see Table 2; ^{13}C NMR: see Table 1; HREIMS: *m/z* (rel. int.) 234.1613 [M^+, $C_{15}H_{22}O_2$, requires 234.1620] (19), 219 (4), 190 (91), 161 (100).

3.5. Epi-deoxyarteannuin B (*3*)

See Brown (1992) and Roth and Acton (1987) for physical properties other than NMR spectral analyses. Full ^1H and ^{13}C NMR assignments are given in Tables 1 and 2.

3.6. Dihydro-epi-deoxyarteannuin B (*4*)

See Sy et al., 1998 for physical properties; NMR assignments in Tables 1 and 2 reproduced from this reference.

3.7. Isoannulide (*5*)

See Brown (1993) for physical properties other than NMR spectral analyses. Full ^1H and ^{13}C NMR assignments are given in Tables 1 and 2.

3.8. Annulide (*6*)

See Brown (1993) for physical properties other than NMR spectral analyses. Full ^1H and ^{13}C NMR assignments are given in Tables 1 and 2.

3.9. Trans-5-hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol (*11*)

Oil. IR ν_{max} ($CHCl_3$) cm^{-1}: 3591, 3406 (*br*), 3011, 2976, 2936, 2882, 1645, 1454, 1375; ^1H NMR: see Table 4; ^{13}C NMR: see Table 3; HREIMS: *m/z* (rel. int.) 152.1173 [M^+-H_2O, $C_{10}H_{16}O$, requires 152.1201] (17), 134.1083 [M^+–$2H_2O$, $C_{10}H_{14}$ requires 134.1096] (25), 122 (70), 119 (35), 107 (100).

3.10. Photo-oxygenation of lavandulol

To a solution of (±)-lavandulol (2-isopropenyl-5-methyl-hex-4-en-1-ol, *ex*. Fluka, Cat. No. 61735) in acetone (310 mg/30 ml) was added methylene blue (5 mg) and the mixture was irradiated by a strong light source (500 W tungsten bulb) for 2 h in an ice bath. The solvent was removed on a rotary evaporator, and the residue was taken up into Et_2O, filtered to remove the photosensitizer, and solvent removed to yield a crude product (300 mg; 97% w/w) which was separated by HPLC (35% EtOAc/*n*-hexane) into compound **13** (114 mg, 30%; R_t 58.0 min); compound **14** (58 mg, 16%; R_t 41.3 min); and compound **15** (62 mg, 17%; R_t 46.7 min).

3.11. trans-5-hydroperoxy-2ξ-isopropenyl-5-methylhex-3-en-1-ol (*13*)

Oil. IR ν_{max} ($CHCl_3$) cm^{-1} 3530, 3350 (*br*), 3011, 2982, 1645, 1456, 1379; ^1H NMR: see Table 4; ^{13}C NMR: see Table 3; HREIMS: *m/z* (rel. int.) 168.1147 [M^+–H_2O, $C_{10}H_{16}O_2$, requires 168.1150] (3), 153 (12), 150 (11), 137 (54), 122 (75), 107 (100).

3.12. 4ξ-Hydroperoxy-2ξ-isopropenyl-5-methylene-hexan-1-ol (*14*)

Oil. IR ν_{max} ($CHCl_3$) cm^{-1}: 3528, 3329 (*br*), 3013, 2943, 1645, 1447, 1377; ^1H NMR: see Table 4; ^{13}C NMR: see Table 3; HREIMS: *m/z* (rel. int.) 168.1152 [M^+-H_2O, $C_{10}H_{16}O_2$ requires 168.1150] (13), 153 (30), 151 (36), 150 (100), 148 (28), 135 (35), 107 (65).

3.13. 4ξ-Hydroperoxy-2ξ-isopropenyl-5-methylene-hexan-1-ol (*15*)

Oil. IR ν_{max} ($CHCl_3$) cm^{-1}: 3524, 3310 (*br*), 3012, 2945, 1645, 1447, 1377; ^1H NMR: see Table 4; ^{13}C NMR: see Table 3; HREIMS: *m/z* (rel. int.) 186.1258 [M^+, $C_{10}H_{18}O_3$, requires 186.1256] (0.5), 150 (12), 137 (12), 122 (20), 121 (28), 107 (100).

3.14. Reduction of allylic hydroperoxide *13*

To a solution of compound **13** in MeOH (46.4 mg/10 ml) was added PPh_3 (65 mg) and the reaction mixture

was stirred for 3 h at room temperature. Solvent was removed under reduced pressure, and the crude residue subjected to CC (45% EtOAC, *n*-hexane) to yield compound **11** (40 mg, 94%), with identical spectroscopic properties to the natural product *trans*-5-hydroxy-2-isopropenyl-5-methylhex-3-en-1-ol isolated from *A. annua*.

Abstract

A taxine, 5α*O*-(3′-dimethylamino-3′-phenylpropionyl) taxinine M (**1**) together with two known compounds 7-*O*-acetyltaxine A (**2**) and 2α-acetoxy-2′β-deacetylaustrospicatine (**3**) were isolated from the needles of the Himalayan yew, *Taxus wallichiana* Zucc. Their structures were elucidated on the basis of the NMR spectral data, ESI–MS/MS analysis and chemical methods. Compounds **1** and **3** showed moderate cytotoxic activity against the lung cancer cell line A549 in vitro. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Taxus wallichiana*; Taxaceae; Taxine; Cytotoxic

1. Introduction

The emergence of paclitaxel (taxol) as one of the most useful anticancer natural products has stimulated great interest in analysis of *Taxus* species with a view to finding alternative sources of this compound. As a result, numerous taxoids have been reported from various *Taxus* species (Wani et al., 1971; Chen and Kingston, 1994; Zhang et al., 2000). The needles of the Himalayan yew (*Taxus wallichiana* Zucc., Taxaceae) is one of the valuable source of taxoids (Appendino et al., 1992; Chattopadhyay et al., 1999). Recently, a new taxane IDN5109, derived from 14β-hydroxy-10-deacetylbaccatin III, is reported to have a potent antitumor activity in ovarian carcinoma (Nicoletti et al., 2000). In course of our program to isolate bio-active taxoids from the needles of *Taxus wallichiana*, we isolated a new taxine 5α-*O*-(3′-dimethylamino-3′-phenylpropionyl) taxinine M (**1**). To the best of our knowledge, this is the first benzoate containing cytotoxic taxine belonging to taxagifine type. We report herein the structure elucidation of this minor compound together with its cytotoxic activity against the lung tumor cell line A549.

2. Results and discussion

The air-dried needles (1 kg) of *T. wallichiana* were extracted with EtOH, and the EtOH extract was dissolved in EtOAc and extracted with 10% HCl. Following an acid-base partition scheme, we isolated **1** (0.5 mg) along with two other known taxines, 7-*O*-acetyltaxine A (**2**) and 2α-acetoxy-2β-deacetylaustrospicatine (**3**). Purification of these compounds was performed by semi-preparative reversed phase HPLC.

Compound **1** was obtained as a colorless solid having $[\theta]_{308}^{25}$ 2500 (0.001 M, MeOH). The HR–FAB–MS showed an intense $[M+H]^+$ ion at *m*/*z* 862.36481 which corresponded to a molecular formula of $C_{46}H_{55}NO_{15}$. Low collision energy electrospray tandem mass spectrometric (ESI–MS/MS) analysis of this compound provided a series of product ions representing diterpene ring fragments and side chains. The product ion at *m*/*z* 194.1 corresponds to a loss of 193.1 Da from the *m*/*z* 861.8 to a product ion at *m*/*z* 668.7.

Further loss of three acetic acid molecules (3×60 Da), an acetyl group (42 Da), and a benzoic acid molecule (122 Da) produced an ion at *m*/*z* 324.9. There is an another series of product ions due the loss three molecules of acetic acid, an acetyl, and a benzoic acid molecule originating from the ion at *m*/*z* 668.7. From these fragmentation patterns, it was deduced that compound **1** has at least four acetyl groups, one benzoate, and a nitrogen containing side chain (193.2 Da).

The product ion at *m*/*z* 194.1 was further characterized by the MS/MS/MS experiment. Four product ions were observed at *m*/*z* 46, 79, 107 and 149 corresponding to $(CH_3)_2NH_2^+$, $[C_6H_7]^+$, $C_7H_6OH^+$ and $C_6H_5C_2H_2COOH_2^+$, respectively. Thus these data indicated the presence of an *N*-dimethyl phenyl propionate side chain in the molecule. Furthermore, the side chain was considered to be 3-(dimethylamino)-3-phenylpropionate

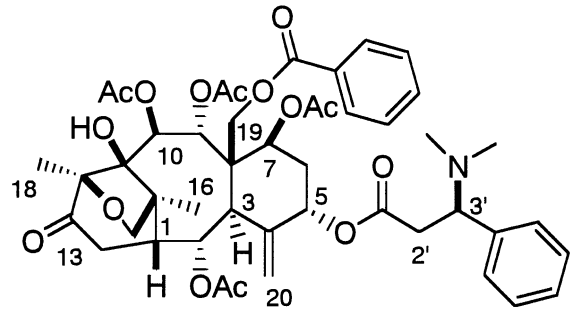
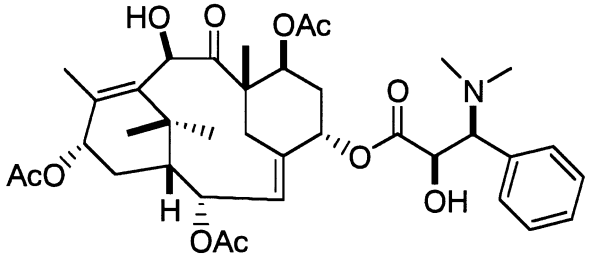
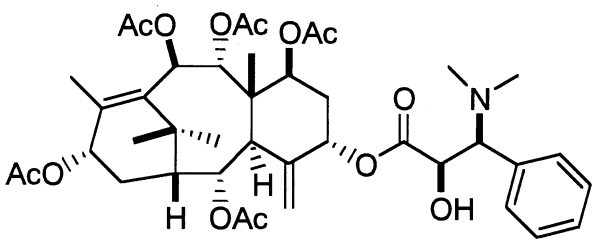
(Winterstein ester) in view of the biosynthesis of taxoid phenylisoserine side chain (Leete and Badem, 1966).



1



2



3

In order to confirm the structure of this side chain, 3-dimethylamino-3-phenylpropionic acid was synthesized by reacting 3-amino-3-phenylpropionic acid with formaldehyde and sodium borohydride. The MS/MS analysis of which produced product ions identical to those of the ion 194. Thus the presence of a Winterstein ester in **1** was concluded and remaining structure elucidation was performed by its NMR spectral analysis.

A part of the ^{1}H NMR spectrum of **1** in MeOH was similar to that of taxinine M (Beutler et al., 1991), indicating the presence of a tetracyclic structure with one isolated double bond, four acetates and one benzoate group (Table 1). The connectivities of the protons in the taxane skeleton of **1** were determined by its ^{1}H–^{1}H COSY spectrum. The ^{1}H NMR spectrum of **1** showed the presence of only two methyl groups (δ 1.15 *s* and 1.26 *s*) instead of four, which is common in many taxoids, and two oxymethylenes (δ 4.10, *d*, 7.9 Hz, 3.65, *d*, 8.0 Hz, and δ 5.19, *d*, 12.2 Hz, 4.37, *d*, 12.2 Hz).

The HMQC and HMBC spectra of **1** indicated the oxygenation at C-17, with the oxygen present as an oxido bridge to C-12. The carbonyl carbon (δ 205.7) showed a long range correlation with the methyl group (δ 1.15) which showed correlations with both C-12 and C-11 in the HMBC spectrum. Thus the carbonyl carbon was assigned at C-13. The long range correlation observed in the HMBC spectrum of **1** between H-19 and the benzoate carbonyl clearly indicated the position of benzoate group at C-19. Likewise, the H_2-20 showed correlations with both C-3 and C-5, indicating an exocyclic double bond at C-4. The presence of a Winterstein ester in **1** was supported by the signals at 2.88 (3H, *s*), 2.76 (3H, *s*), 3.78 (2H, *m*), 4.95 (1H, *m*), and 7.48 (5H, *m*) in the ^{1}H NMR spectrum. Since the compound was purified

[a] The ^{13}C NMR data were deduced from the HMQC and HMBC spectra. Direct measurement of ^{13}C NMR was not possible due to the meager quantity of the sample. δ in ppm and *J* in Hz. Ob = obscure. 1D and 2D NMR experiments (500 MHz in $CDCl_3$).

by HPLC using acetonitrile/water/TFA system, the dimethylamino group was protonated and the ^{1}H NMR signals were found to be shifted more downfield than those of similar basic taxoids.

The stereochemistry of **1** around the diterpene skeleton was deduced by comparison with taxinine M, in view the similarity in splitting pattern (coupling constants) in the ^{1}H NMR, and NOESY correlations. As in the case of taxinine M, NOESY correlations were observed between the proton pairs H-3/H-10, H-9/Me-17, H-2/Me-17, OH-11/H*b*-16, and H*a*-16/Me-17. Moreover, transannular interactions between the pairs H-3/H-10, H-9/Me-17, H-2/Me-17 may occur because the internal space may be inadequate for all the quasi-axial hydrogen atoms to fit without interacting. In this situation, some of the carbon bonds adopt eclipsed or partially eclipsed conformations (March, 1992).

The small value (ca. 3 Hz) of $J_{9,10}$ is due to an eclipsed conformation around the C-9, C-10 bond causing H-9 and H-10 to adopt an anticlinal position (Barboni et al., 1995a,b). The conformation of ring B is in the taxagifine-type owing to the presence of the C-12, C-17 oxygen bridge and the large coupling constant between H-2 and H-3 (Table 1). The signal at δ 5.23 (1H, *br s*) was characteristic of H-5α (Shi et al., 1999). The coupling constant of H-7 (δ 5.34, *br d*, 6.2 Hz) was similar to that of taxinine M. The stereochemistry at the chiral centre C-3′ was assigned as *R* from the biosynthesis of Winterstein's acid (Leete and Badem, 1966). Based on these evidences, the sterochemistry of **1** was elucidated, and the isolate was determined to be 5α- *O*-(3′-dimethylamino-3′-phenylpropionyl) taxinine M.

Compounds **2** and **3** were identified as 7-*O*-acetyltaxine A and 2α-acetoxy-2′β-deacetylaustrospicatine, respectively by comparison of their spectral data with published ones (Ettouati et al., 1988; Barboni et al., 1995a,b). Compound **1** is a minor constituent of the needles of the Himalayan yew in which taxine's concentration might be much lower than in the European or the Japanese yew (Barboni et al., 1995a,b).

We, for the first time, have attempted to elucidate the structure of a taxine through MS/MS analyses. The MS/MS analyses revealed that compound **1** is composed of four major segments, i.e. a core diterpene ring, one benzoate, four acetate, and one Winterstein ester side chain. It is interesting to note that no taxines are reported to be of the taxagifine type and compound **1** represents the first example of the taxine with a taxagifine core structure and is the second example of a taxoid involving both a benzoate and the Winterstein ester (Kobayashi et al., 1996). This type of compound possesses a different diterpene ring conformation than those of the taxol type. The unusual conformation may be responsible for diminution in biological activity compared to taxol (Chauviére et al., 1982).

Compounds **1**–**3** were evaluated for their cytotoxicity against A549 cell line and **1** and **3** showed a cytotoxicity with ED_{50} 10.1±2.4 and 28.3±3.8 μM, respectively, while **2** was inactive.

Cytotoxicity of many taxines against cancer cells has not been fully investigated. Taxinine M is reported to show a weak toxicity in the brine shrimp assay (Beutler et al., 1991). The co-occurrence of an aromatic group and an alkaloid side chain in **1** may be responsible for its cytotoxicity against A549 cells by the fact that similar activity was observed with taxuspine N (Kobayashi et al., 1996). Further elaboration on structure–activity relationships of **1** is underway.

3. Experimental

3.1. General

CD spectra were recorded with a JASCO J-710 spectropolarimeter. Mass spectrometry measurements were performed by using a Sciex API III tandem quadrupole mass spectrometer. Full-scan mass spectra were obtained while continuously scanning from *m*/*z* 300 to 1000 with a step size of 0.1 *m*/*z* and with a dwell time of 2.0 ms. MS/MS spectrum of 3-dimethylamino-3-phenylpropionic acid was obtained by selecting the protonated ion at *m*/*z* 194 at the first quadrupole (Q1), followed by collision-induced dissociation (cid) with argon gas at the second quadrupole (Q2). The resulting fragments were analyzed by the third quadrupole (Q3).

MS/MS/MS experiment of compound **1** was performed by accelerating **1** at the orifice with a high orifice potential of 150 V and by fragmenting it at Q0. The fragment with *m*/*z* 194 was selected at Q1 and was further fragmented at Q2 with argon collision gas. The fragments were analyzed by Q3. The parent scan of compound **1** in MS/MS/MS was carried out under the same condition. After fragmenting compound **1** at Q0 using orifice potential 150, the parent fragment for the ion at *m*/*z* 445 was found in the parent scan experiment. A high resolution FAB mass spectrometry was VG Micromass ZAB 2F HS. ^{1}H and 2D NMR spectra were recorded on a Bruker AMX2 500 NMR spectrometer. HPLC was performed using a Waters Delta Prep 4000 with a semi preparative RP-Vydac C-8. The eluant was monitored by the absorbance at 254 nm. Chemicals used for the synthesis of 3-dimethylamino-3-phenylpropionic acid were purchased from Aldrich.

3.2. Plant material

The needles of *T. wallichiana* were obtained from plants grown in the garden of Trichandra college, Tribhuvan University, Nepal.

3.3. Extraction and isolation

Air-dried needles (1 kg) were extracted with EtOH (4 lit ×3) at room temperature. The EtOH solvent was

evaporated under reduced pressure to obtain a semi-solid EtOH extract (110 g). A fraction of EtOH extract (50 g) was dissolved in EtOAc and extracted with 10% HCl. The acidic phase was washed with EtOAc (2 × 200 ml) and neutralized with Na_2CO_3, followed by extraction with EtOAc. After drying (Na_2SO_4), a semi-solid residue (0.5 g) was obtained which was further fractionated by the reversed-phase HPLC [a linear gradient of acetonitrile from 0 to 40% (0.6%/min) in 0.1% TFA; flow rate, 13 ml/min)]. Compounds **1**, **2** and **3** were eluted at the 40, 36 and 29% CH_3CN in the gradient system, respectively. All collected fractions were lyophilized immediately, and tested for cytotoxic activity. Those found inactive and complicated mixture were discarded. After lyophilization, 0.9 mg of **1**, 1.0 mg of **2** and 1.5 mg of **3** were obtained.

3.4. 5α-O-(3′-Dimethylamino-3′-phenylpropionyl) taxinine M (*1*)

Colorless solid, $[\theta]_{308}^{25}$ 2500 (0.001 M, MeOH). ^1H and ^{13}C NMR data, see Table 1; HR–FAB–MS *m*/*z* 862.36481 $[M+H]^+$ (required for $C_{46}H_{55}NO_{15}$ 862.36500).

3.5. Preparation of 3-dimethylamino-3-phenylpropionic acid

To a stirred solution of *dl*-3-phenyl-3-amino-phenyl propionic acid (500 mg) in H_2O/MeOH (10 ml, v/v 1:1) and formaldehyde (1 ml, 37%), $NaBH_4$ (0.7 g) was added and the mixture was stirred at 0° C for 30 min. The reaction mixture was further incubated for 5 h to give 3-dimethylamino-3-phenylpropoinic acid that was dissolved in AcOH, lyophilized and purified by reversed-phase semi-prep (yield 30%). HPLC [linear gradient (0.5%/min) of CH_3CN from 0 to 30% in 0.1% TFA with a flow rate of 13 ml/min] was used for purification. ESI–MS *m*/*z* $[M+H]^+$ 194; ^1H NMR (500 MHz, MeOH-d_4) δ 7.51 (5H, m, H-Ph), 4.79 (1H, *t*, $J=7.0$ Hz, H-3), 3.34 (1H, *dd*, $J=17.0$, 6.0 Hz, H-2a), 3.19 (1H, *dd*, $J=17.0$, 7.0 Hz, H-2b), 2.79 (6H, *s*, NMe_2).

3.6. Cytotoxic activity

A549 cells were cultivated in Dulbecco's Eagle Modified medium supplemented with 5% bovine calf serum (Hyclin). Cellular viability in the presence and absence of test samples was determined using the standard MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide; Sigma) method (Mosmann, 1983). Briefly, 0.2 ml cell suspension containing 2000 cells was seeded to each well of a 96-well microtitre plate (Costar, Corning Inc., NY), and incubated in a CO_2 incubator at 37 ^{0}C for 24 h before test compounds were added.

New medium with or without test compound was added to each well ($n=3$). The cells were further incubated at the same condition for 48 h. The medium was removed by aspiration, and crystals of viable cells were dissolved in DMSO (100 μl/well) and the plate was read immediately on a microtitrer plate reader (SOFTmax, Molecular Device) at the wavelength of 540 nm. Absorbance taken from cell grown in the absence of test compound was considered as a negative control.

Apianane terpenoids from *Salvia officinalis*

Kayoko Miura, Hiroe Kikuzaki, Nobuji Nakatani*

Division of Food and Health Science, Graduate School of Human Life Science, Osaka City University, 3-3-138 Sugimoto, Sumiyoshi, Osaka, 558-8585, Japan

Received 9 March 2001; received in revised form 16 July 2001

Abstract

Three apianane terpenoids, *rel*-(5*S*, 6*S*, 7*S*, 10*R*, 12*S*, 13*R*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide, *rel*-(5*S*, 6*S*, 7*R*, 10*R*, 12*S*, 13*R*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide and *rel*-(5*S*, 6*S*, 7*S*, 10*R*, 12*R*, 13*S*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide were isolated from the leaves of *Salvia officinalis*, together with 15 known compounds, salvigenin, lupeol, β-sitosterol, stigmasterol, physcion, carnosol, rosmadial, rosmanol, epirosmanol, isorosmanol, columbaridione, atuntzensin A, miltirone, carnosic acid and 12-*O*-methyl carnosic acid. Their structures were established on the basis of spectral evidence.

Keywords: *Salvia officinalis*; Labiatae; Apianane; Abietane; Diterpenoid; Sage

1. Introduction

Sage, *Salvia officinalis*, has been most commonly known not only as a culinary herb for flavoring and seasoning, but it has been also of great medicinal importance. Many components have been isolated from *S. officinalis* such as diterpenoids (Brieskorn and Fuchs, 1962; Djarmati et al. 1992; Cuvelier and Berset, 1994; Tada et al., 1994, 1997), triterpenoids (Brieskorn and Kapadia, 1980), flavonoids, (Brieskorn and Biechele, 1971; Brieskorn and Kapadia, 1979), phenolic glycosides (Wang et al., 1998a,b, 1999) and phenolic acid derivatives (Lu and Foo, 1999; Lu et al., 1999). In continuation of our chemical investigation of *S. officinalis*, we reported the isolation of antioxidative diterpenoids, flavonoids (Nakatani et al., 1989) and glycosides (Wang et al., 2000). In this paper, we describe the isolation and structural determination of C_{23} terpenoids, named apianane (Luis et al., 1996) from the methylene chloride extract of *S. officinalis*.

2. Results and discussion

Repeated chromatography of the methylene chloride extract of the leaves of *S. officinalis* afforded new compounds **1**, **2** and **3** (Fig. 1), together with 16 known compounds. The known compounds were identified with salvigenin, lupeol, β-sitosterol, stigmasterol, physcion, carnosol, rosmadial, rosmanol, epirosmanol, isorosmanol, columbaridione, atuntzensin A, miltirone, carnosic acid and 12-*O*-methyl carnosic acid by comparing with spectral data of authentic samples and the previous reports (Inatani et al., 1982; Nakatani and Inatani, 1983, 1984; Houlihan et al., 1985; Al-Hazimi et al., 1987; Wu et al., 1993; Luis et al., 1994, Richheimer et al., 1996). Lupeol, physion, columbaridione, atuntzensin A and miltirone were isolated from sage for the first time.

Compound **1** was obtained as colorless needles from benzene/ acetone, mp 245 °C, with positive optical rotation ($[\alpha]_D^{27}$ +131.3° *c* 0.420, $CHCl_3$). The molecular formula of **1** was assigned as $C_{23}H_{28}O_5$ based on HR–MS analysis. The ^{13}C NMR spectrum (Table 1) of **1** also revealed the presence of 23 carbon atoms, including three carbonyl carbons (δ 176.7, 198.2 and 200.5). The IR spectrum of **1** showed the presence of a hydroxyl group at 3465 cm^{-1}, a γ-lactone at 1774 cm^{-1}, and α,β-unsaturated ketone functions at 1718 and 1672 cm^{-1}. The ^1H NMR spectrum of **1** (Table 2) showed signals for an isopropyl group (δ 0.65 and 0.75, each 3H, *d*, *J* = 6.8 Hz and δ 2.53, *sept*, *J* = 6.8 Hz), geminal dimethyl groups (δ 0.83 and 1.00, *s*), three methylene groups (δ 1.2∼1.6 and δ 2.86), a methine proton (δ 2.14, *s*),

two methine protons bearing oxygen functions (δ 4.57 and δ 4.69) and a hydroxyl group (δ 5.56). Analysis the ^{1}H–^{1}H COSY spectrum revealed that the methine proton at δ 4.57 was coupled with the protons at δ 4.69 and δ 2.86, respectively. These signals suggested that the partial structure of **1** was an abietane skeleton possessing a γ-lactone (Nakatani and Inatani, 1984). Signals of a methine proton (δ 3.89), a methyl protons (δ 2.49), an olefinic proton (δ 5.76), and olefinic carbons (δ 130.9, 144.1, 168.8 and 178.5) were observed in the ^{1}H and ^{13}C NMR spectra. Based on these data, it was deduced that this compound (**1**) was a rare C_{23} terpenoid which was proposed as apianane (Luis et al., 1996). The assignment of all signals was made by ^{1}H–^{1}H COSY, HMQC and HMBC (Table 3) experiments and by comparison of the spectral data of apiananes. All signals obtained for **1** were in good agreement with those of 7α-methoxyapiana-8,14-diene-11,16-dion-(22,6)-olide, reported by Luis et al. (1996), except for the signal of a methoxyl group. The downfield shift of signals at C-6, C-8, H-7 and H-13, and the upfield shift of a signal at C-7 in the ^{1}H and ^{13}C NMR spectra of **1** showed the presence of a hydroxyl group at C-7 in **1** instead of a methoxyl group. Furthermore its relative configuration was confirmed by a NOESY experiment (Fig. 2). That is, the absence of the NOESY correlation between H-5 and H-7 suggested that H-7 had a β-configuration and the hydroxyl group at C-7 was in the α-configuration. In addition, the strong NOESY correlation between the signals of the proton pairs (H-7 and H-13, H-13 and H_3-18, 19) confirmed that the stereochemical relationship between H-13 and 12-isopropyl group was *cis* with β-configuration. Thus **1** was determined to be *rel*-(5*S*, 6*S*, 7*S*, 10*R*, 12*S*, 13*R*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide.

Compound **2** had a molecular formula of $C_{23}H_{28}O_5$ by HR–MS, which is the same as that of **1**. The IR, UV, ^{1}H and ^{13}C NMR spectral data of **2** were very similar to those of **1**, except for the optical rotation ($[\alpha]_D^{27}$ +89.2° *c* 0.251, $CHCl_3$), suggesting that **2** had a different stereostructure from **1**. Comparing the ^{1}H and ^{13}C NMR spectra of **2** with those of **1**, some differences were observed. The signals of H-6 (δ 4.83) and H-7 (δ 4.98) were paramagnetically shifted ($\Delta\delta$+0.26 and $\Delta\delta$+0.29 ppm, respectively) in comparison with those of **1**. Moreover, the signals of C-5 (δ 55.8), C-9 (δ 140.8) and C-13 (δ 51.8) were shifted. The observed differences suggested **2** to be an isomer of **1** at C-7. A NOESY experiment of **2** (Fig. 2) showed a strong cross peak between H-5 and H-7, indicating that H-7 had an α-configuration. In addition, the absence of the NOESY correlation between the signals of H-13 and H-7 suggested H-13 had a β-configuration as for **1**. Moreover, H-13 was also correlated with the isopropyl methyl groups, which suggested the stereostructure between H-13 and the 12-isopropyl group of **2** to be in the *cis*-configuration as for **1**. Thus compound **2** was determined to be *rel*-(5*S*, 6*S*, 7*R*, 10*R*, 12*S*, 13*R*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide.

Compound **3** had a molecular formula of $C_{23}H_{28}O_5$ by HR–MS, and was very similar to **1** and **2** in the IR,

UV, ^{1}H NMR and ^{13}C NMR spectral data. However, **3** also exhibited a different optical rotation ($[\alpha]_D^{27}$ +18.8° *c* 0.136, $CHCl_3$) from those of **1** and **2**. This fact indicated **3** to have the different stereostructure. As shown in Fig. 2, the absence of the correlation between H-5 and H-7 in a NOESY experiment suggested a β-configuration of H-7 as for **1**. The strong cross peak between H-13 and H_3-18, 19 observed in a NOESY experiment as well as the presence of the NOESY correlation between H-5 and H_3-18, and H-1α and H_3-18 indicated an α-configuration for both H-13 and the 12-isopropyl group. Thus **3** was *rel*- (5*S*, 6*S*, 7*S*, 10*R*, 12*R*, 13*S*)-7-hydroxyapiana-8,14-diene-11,16-dion-(22,6)-olide.

3. Experimental

3.1. General

Mps were measured with a Yanagimoto micro-melting point apparatus and are uncorrected. Optical rotations were measured using a JASCO P-1030 polarimeter. UV spectra were recorded on a Shimadzu UV-2500PC spectrophotometer. IR spectra were run on a Perkin-Elmer FT–IR 1720X spectrometer. The ^{1}H, ^{13}C and 2D NMR spectra (^{1}H–^{1}H COSY, HMQC, HMBC and NOESY) were obtained on a Varian Unity plus 500 (500 MHz) spectrometer. The chemical shifts were

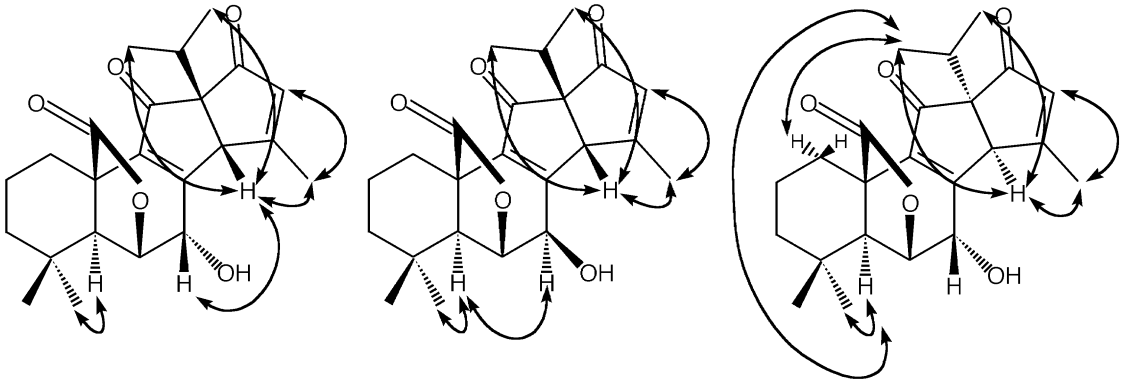

Fig. 2. Significant NOESY correlations of **1**–**3**.

relative to the TMS or solvent peak. EIMS and HR–MS (70 eV) were measured on a Hitachi M-2000 mass spectrometer. Column chromatography was performed using silica gel 60 (70–230 mesh, Merck), Sephadex LH-20 (Pharmacia) and Chromatorex ODS DM1020T (100–200 mesh, Fuji Silysia Chemical). TLC was performed on silica gel 60 F_{254} plates (Merck) and ODS plates (Merck).

3.2. Plant material

S. officinalis was kindly provided by Takasago Perfumery Co., Ltd.

3.3. Extraction and isolation

Air dried and ground leaves of *S. officinalis* (1.0 kg) were extracted 3 times with CH_2Cl_2 (4000 ml) at room temperature. Evaporation of solvent under reduced pressure gave the CH_2Cl_2 extract (129.7 g). The CH_2Cl_2 extract (22.2 g) was dissolved in *n*-hexane and the hexane soluble part (21.8 g) was subjected to column chromatography on silica gel (500 g) using *n*-hexane with increasing amounts of Me_2CO as eluent to afford 15 fractions by monitoring with TLC. (Fr. 1∼5 (eluted with *n*-hexane, 5000 ml), Fr. 6 (eluted with *n*-hexane–Me_2CO (95:5), 2600 ml), Fr. 7 (eluted with *n*-hexane–Me_2CO (90:10), 3000 ml), Fr. 8–10 (eluted with *n*-hexane-Me_2CO (85:15), 4000 ml), Fr. 11 (eluted with *n*-hexane-Me_2CO (80:20), 1600 ml), Fr. 12 (eluted with *n*-hexane-Me_2CO (75:15), 2000 ml), Fr. 13 (eluted with *n*-hexane-Me_2CO (50:50), 2800 ml), Fr.14 (eluted with Me_2CO, 2000 ml) and Fr. 15 (eluted with MeOH, 2000 ml)). Repeated chromatography of the less polar fraction (Fr. 6, 1.23 g) and recrystallization afforded known compounds, lupeol (colorless crystals, 4.7 mg), physcion (orange solid, 2.6 mg), β-sitosterol (50 mg) and stigmasterol (5 mg). Fr. 8 (0.9 g) was successively subjected to a Sephadex LH-20 column chromatography eluted with Me_2CO and a silica gel column eluted with C_6H_6–Me_2CO to give rosmadial (colourless crystals, 4.4 mg), columbaridione (orange solid, 2 mg) and miltirone (orange solid, 1.4 mg). The mixture (4.6 g) of Fr. 11 and Fr. 12 was applied to a Sephadex LH-20 column with Me_2CO to separate 9 fractions (Fr. A–I). Furthermore, Fr. C was subjected to column chromatography on silica gel eluted with C_6H_6–Me_2CO (97:3) to afford crude solid of **1**, which was triturated with C_6H_6 to separate crystals. These colorless crystals were recrystallized from a mixture of C_6H_6 and Me_2CO to afford **1** (10.1 mg). The C_6H_6 soluble part was applied to a silica gel column eluted with CH_2Cl_2–Me_2CO (97:3) to afford amorphous solids, **2** (2.5 mg) and **3** (1.5 mg). Fr. D was triturated with Me_2CO to separate the insoluble solid, which was recrystallized from Me_2CO to afford salvigenin (yellow crystals, 23 mg). Rechromatography of Me_2CO soluble part of Fr. D on Sephadex LH-20 eluting with Me_2CO and on silica gel eluting with C_6H_6–Me_2CO gave atuntzensin A (yellow solid, 3.8 mg) and 12-*O*-methyl carnosic acid (off-white solid, 400 mg). Fr. E was also triturated with Me_2CO to separate insoluble solid, which was recrystallized from Me_2CO to afford rosmanol (colorless prisms, 475 mg). The acetone soluble part of Fr. E was applied to a silica gel column with a solution of C_6H_6–Me_2CO (95:5) as an eluting solvent to afford epirosmanol (5 mg). The *n*-hexane insoluble part (0.4 g) of the CH_2Cl_2 extract was subjected to on Sephadex LH-20 chromatography with Me_2CO as an eluent to afford carnosic acid (9 mg), carnosol (40 mg) and isorosmanol (11 mg).

Received 1 March 2001; received in revised form 4 July 2001

Abstract

Two novel triterpenoid saponins belonging to a modified hopane group, spergulin A {3-*O*-(β-D-xylopyranosyl 4-sulphate)-spergulagenin A} (**1**) and spergulin B {3-*O*-[α-rhamnopyranosyl (1→2)-β-D-xylopyranosyl]-spergulatriol} (**4**) were isolated from the aerial part of *Mollugo spergula* along with spergulacin (**2**) and spergulacin A (**3**). Their structures and relative stereochemistry were determined by a combination of 2D–NMR (COSY, TOCSY, HETCOR, NOESY and HMBC) and HR-FAB–MS analysis coupled with strategic chemical and enzymatic transformations. © 2001 Elsevier Science Ltd. Keywords: *Mollugo spergula*; Molluginaceae; Triterpene saponins; Triterpene; Spergulin A; Spergulin B; 2D NMR; Rearranged hopane; Bis-nor hopane

1. Introduction

Mollugo spergula Linn. (Syn. *Glinus oppositifolia*) (Family: Molluginaceae) is an annual herb which finds application for the treatment of skin diseases in the indigenous system of medicine (Sastri, 1962). Previous chemical investigations of the plant had led to the isolation of a number of genuine and rearranged triterpenes of hopane series (Chakrabarti et al., 1966, 1968; Kitagawa et al., 1974, 1977) and two triterpenoid saponins (Barua et al., 1986a,b). In continuation of our work on chemical studies on naturally occurring saponins (Sahu and Achari, 2001) we decided to reinvestigate the saponin constituents of the plant. The present paper describes the isolation and characterization of two new triterpenoid saponins including a sulfated derivative saponin. As detailed spectral data for the two saponins reported by Barua et al. (1986a,b) are not available, those have also been presented here.

2. Results and discussion

Spergulin A (**1**) was assigned the molecular formula $C_{35}H_{58}O_{11}S$ from the negative high resolution FAB–MS, supported by elemental analysis. The presence of a sulfur atom as part of a sulfate group was also evident from the fragment ions at m/z 97 $[SO_4H]^-$ and 80 $[SO_3]^-$ in the negative low resolution FAB–MS and from the peak at 1383 cm^{-1} for a sulfate group in the IR spectrum. The compound displayed 35 signals in its ^{13}C NMR spectrum of which five could be assigned to a pentose unit. Structure elucidation for spergulin A was mainly accomplished by critical analysis of the 1D and 2D NMR results. HMBC measurement proved to be the method of choice; beginning with assignments for the methyl groups, two and three bond correlations permitted the assignment of most of the signals. The determination of atom connectivities was straightforward and unambiguous. Thus the HMBC correlation involving signals of H-3 with C-23 and C-24; H-3 and H-5 with C-4 and C-25; and 3H-25 with C-1, C-9 and C-10 identified most of the structural elements of rings A and B. This was gradually extended to cover the other rings. Thus the C-9 signal showed cross peaks with 3H-26 and H(β)-11; C-11 with H-13; and C-14 with H-13, 3H-26, 3H-27 and 3H-28. Further observation of HMBC involving C-15 and C-13 with 17-H provided a clear picture of the six membered rings A–D. The cyclopentanyl nature of ring E was ascertained from the following HMBC correlations: H-17/C-21 and C-22, H(β)-19/C-21, H-17/C-18, H(β)-19/C-18, H(α)-20/C-29, H(β)-20/C-18, 3H-29/C-20. That the ketomethyl group is attached to C-21 was established from the observed HMBC between C-22 and 3H-29, H-17, H(α)-20 as also between C-21 and 3H-30.

Regarding the substitution pattern, the downfield chemical shifts attributed to 16-H (δ 3.59) and 12-H (δ 3.67) as well as to the corresponding carbon signals suggested the presence of –OH groups at C-16 and C-12. The signals of 2H-11 and H-13 showed HMBC cross peaks with δ 67.3 (C-12) whereas the δ 64.1 (C-16) signal displayed correlations with H-17 and H-15α signals confirming the placement of hydroxy groups. The relative orientations of the aglycone hydrogens and the stereochemistry of the ring system of spergulin A (**1**) were established from identified ^{1}H–^{1}H coupling patterns and cross peaks generated from phase-sensitive NOESY. The β-orientation of the hydroxy groups was evident from the NOESY cross peaks between H(α)-12 and 3H-27, 28 as also between H(α)-16 and 3H-27, 28, 29.

From ^{1}H and ^{13}C chemical shifts, ^{1}H–^{1}H coupling constants and a close examination of TOCSY spectrum, it was obvious that the sugar constituent is D-xylose (The absolute configuration of the monosaccharides were chosen in keeping with those commonly encountered among plant glycosides). Acid hydrolysis of **1** followed by GLC analysis of the hydrolysate after derivatisation gave only one peak corresponding to xylose. The anomeric proton signal appeared as a doublet at δ 4.23 ($J = 7.4$ Hz) confirming its β-configuration ($^4C_1$ conformation). That the sugar constituent was attached to C-3 (δ 87.8) of the aglycone moiety was evident from HMBC and NOESY cross peaks. Thus C-3 showed HMBC with H-1 of xylose, which in turn showed NOE correlation with that of H-3 of the aglycone. Interestingly, the C-3 chemical shift of xylose appeared significantly downfield (δ 82.6) in comparison with that (δ 77.7) of standard methyl β-D-5-xylose, indicating the presence of a substituent. Absence of any NMR signal attributable to a substituent and the IR and mass spectral evidence for a sulfate group as discussed earlier helped to identify the substituent. This was confirmed by solvolysis of the compound to yield sulfuric acid and compound (**5**), characterized mainly by 2D NMR techniques. Acid hydrolysis of **5** furnished the sapogenin spergulagenin A (**6**). Thus the structure of spergulin A is established as 3-*O*-(β-D-xylopyranosyl 4-sulphate)-spergulagenin A (**1**). The same sapogenin had been isolated earlier by Barua et al. (1986 a, b) and Chakrabarti et al. (1966), but only the melting point and some ^{1}H NMR data were reported.

Spergulacin (**2**) and spergulacin A (**3**) proved to be saponins of the same sapogenin **6** and their structures were elucidated following the same method as used for **1**. The monosaccharides for both **2** and **3** were shown to be D-xylose and L-rhamnose, present in 1:1 ratio based on GLC analysis of the acid hydrolysate. β-Configuration ($^4C_1$ conformation) for the xylopyranosyl unit and α-configuration for the rhamnopyranosyl unit were inferred from the large $J_{H1,H2}$ for the xylopyranosyl unit and the singlet like appearance of the H-1 signal for the rhamnopyranosyl unit respectively. The observed HMBC between the H-1 signals of xylose and C-3 signal of the aglycone suggested that in both the saponins xylose was linked directly to the aglycone at C-3. Interglycosidic linkages in **2** and **3** were derived from the observed HMBC of H-1 of rhamnose with C-3 of xylose in **2** and C-2 of xylose in **3**. Compounds **2** and **3** were found to be identical with spergulacin and spergulacin A respectively reported earlier by Barua et al. (1986a,b).

Spergulin B (**4**) was concluded to be a new saponin of another sapogenin spergulatriol (**8**) reported previously by Kitagawa et al. (1977). The structure elucidation was principally based on 2D NMR analysis of the genin (**8**) and the prosapogenin (**7**) obtained by enzymatic hydrolysis of **4.** The monosaccharides were identified as xylose and rhamnose by co-GLC with authentic specimens (vide experimental). Interglycosidic and sugar-aglycone linkages were deduced on the basis of the arguments as described for **2** and **3**. Further, the prosapogenin (**7**) liberated by the enzymatic hydrolysis contained only xylose, linked to C-3 of the aglycone. Thus the structure of spergulin B was established as 3-*O*-[α-rhamnopyranosyl (1→2)-β-D-xylopyranosyl]-spergulatriol (**4**).

It is noteworthy that saponins based on hopane or rearranged hopane skeletons are very few while none have been reported for nor hopane sapogenins (Mahato et al., 1988; Mahato and Nandy, 1991; Mahato and Garai, 1998).

3. Experimental

3.1. General procedures

All melting points were measured on a Yanagimoto micromelting point apparatus and are uncorrected. ^{1}H and ^{13}C NMR were recorded using a Jeol ECP-500 spectrometer (^{1}H at 500 MHz and ^{13}C at 125 MHz) in DMSO-d_6 or C_5D_5N with TMS as internal standard. LR and HR FAB–MS (negative) were done using KRATOS CONCEPT mass spectrometer with a mixture of glycerol and *m*-nitrobenzyl alcohol for LR–FAB–MS and PEG-600 for HR–FAB–MS as matrices. MALDI–TOF–MS (positive) were performed on a Perspective Biosystems Voyager DE-STR spectrometer with 2,5-dihydroxybenzoic acid as matrix. TLC was carried out on silica gel 60 F_{254} (Merck) [$CHCl_3$:MeOH:H_2O; 30:13:2] and spots were visualized by spraying with 10% H_2SO_4.

3.2. Plant material

The plant material was collected from the suburbs of Calcutta, India and identified at Indian Botanic Garden, Howrah. A voucher specimen was deposited at the Steroids and Terpenoids Chemistry Department.

3.3. Extraction and isolation

The air-dried powdered plant (1 kg) (aerial part of *Mollugo spergula*) was successively extracted with light petrol (60–80 °C), $CHCl_3$ and MeOH under reflux conditions. The residue (15 g) obtained after evaporation of the MeOH under reduced pressure was applied to a column of Diaion HP 20 (500 g) and the column washed with water followed by 30, 40, 60, 80 and 100% of MeOH. Fractions eluted with 60% MeOH showed single spot on TLC over silica gel and the residue was crystallized from methanol-water to furnish 150 mg of spergulin A (**1**) (R_f 0.41). The residue from fractions eluted with 80% methanol was rechromatographed over silica gel. Fractions eluted with $CHCl_3$–MeOH (17:3) showed three spots on TLC and the residue was subjected to fractional crystallization to obtain spergulacin (**2**) (R_f 0.59) (135 mg). The mother liquor was chromatographed repeatedly over silica gel and eluted with various mixtures of chlorform and methanol. Later fractions eluted with $CHCl_3$–MeOH (17: 3) furnished 95 mg of spergulacin A (**3**) (R_f 0.55), while fractions eluted with $CHCl_3$–MeOH (4:1) gave 65 mg of spergulin B (**4**) (R_f 0.49).

3.4. Spergulin A (*1*)

Colorless needles, mp 220–221 °C (dec.); $[\alpha]_D^{25}$ +19.1° (*c* 0.66, DMSO); IR: ν_{max} cm^{-1} (KBr): 3550, 3468, 1698, 1637, 1460, 1383, 1062, 1021, 972, 824; HR FAB–MS (negative): *m*/*z* 685.36164 [M–H]$^-$, (calc. for $C_{35}H_{57}O_{11}S$, *m*/*z* 685.36216); LR–FAB–MS (negative): *m*/*z* 685.4 [M–H]$^-$, 641.3, 459.1, 352.1, 227.0, 199.0, 97.0 [SO_4H]$^-$ and 80.0 [SO_3]$^-$; MALDI–TOF–MS (positive): 747.03 [M + Na + K–1]$^+$, 731.11 [M + 2Na–1]$^+$, 687.07 [M + H]$^+$. ^{1}H NMR (DMSO-d_6). Sugar moiety: 4.23 (*d*, *J* = 7.4 Hz, H′-1), 3.13 (*m*, H′-2), 3.91 (*t*, *J* = 9 Hz, H′-3), 3.43 (*m*, H′-4), 3.09 (*m*, H′$_a$-5), 3.71 (*dd*, *J* = 5.5, 11.4 Hz, H′$_b$-5); ^{13}C NMR (DMSO-d_6) data: Table 2. (Found: C, 57.91; H, 8.28; S, 4.26. $C_{35}H_{57}O_{11}NaS.H_2O$ requires: C, 57.83; H, 8.18; S, 4.41%.).

3.5. Solvolysis of spergulin A (*1*)

Spergulin A (18 mg) was refluxed with a mixture of pyridine and dioxane (4:1, 5 ml) for 6 h. The reaction mixture was passed through a Sep-pak cartridge (Waters), and eluted successively with water (15 ml) and MeOH (15 ml). The MeOH eluted fraction was chromatographed on silica gel using chloroform–methanol–water (50:10:1) to yield **5** (14.5 mg), crystallized from methanol–acetonitrile to furnish fine needles, mp 238–240 °C (dec.); $[\alpha]_D^{20}$ +16.30° (*c* 0.92, pyridine); IR: ν_{max} cm^{-1} (KBr): 3433, 1696, 1651, 1642, 1097, 1043 and 972; LR–FAB–MS (positive): *m*/*z* 645 [M + K]$^+$, 629 [M + Na]$^+$; ^{1}H NMR (DMSO-d_6): δ 0.74, 0.79, 0.90, 0.91, 0.95, 0.96, 1.25, 2.10 (each 3H *s*, H_3 of C-24, 25, 27, 28, 26, 23, 29, 30), 0.67 (1H, *d*, *J* = 10.7 Hz, H-5), 1.30 (1H, *d*, *J* = 10.5 Hz, H-13), 1.62 (1H, *d*, *J* = 11.4 Hz, H-17), 1.75 (1H, *dd*, *J* = 8.7, 14.0 Hz, H-20β), 2.01 (1H, *dd*, *J* = 7.1, 12.4 Hz, H-19β), 2.96 (*m*, H-3α), 3.58 (*m*, H-16α), 3.67 (*m*, H-12α), Sugar moiety: 4.11 (*d*, *J* = 7.5 Hz, H′-1), 2.95 (*m*, H′-2), 3.07 (*m*, H′-3), 3.26 (*m*, H′-4), 2.96 (*m*, H′$_a$-5), 3.64 (*dd*, *J* = 5.2, 11.2 Hz, H′$_b$-5).; ^{13}C NMR (DMSO-d_6): Table 2. (Found: C, 69.19; H, 9.51; $C_{35}H_{58}O_8$ requires: C, 69.27; H, 9.63%).

The aqueous part was examined by paper chromatography (Advantee, No. 50) employing methanol–water (1:1). Sulfuric acid was detected as a light yellow spot (R_f 0.71) after spraying the paper with a solution of potassium rhodizonate (10 mg in 50 ml of 50% methanol).

3.6. Acid hydrolysis of *5*

Compound **5** (5 mg) was heated in 1 ml of 1 M HCl (dioxane–H_2O, 1:1) at 80 °C for 2 h on a water bath. Dioxane was distilled off under reduced pressure and the solution was extracted with EtOAc (1 ml ×3). The organic layer was washed with water, dried, and the residue was crystallized from EtOAc to give fine needles (3 mg) of spergulagenin A (**6**), mp 276–277 °C; [lit. (Kitagawa

et al., 1975), mp 278–279.5 °C; $[\alpha]_D^{20}$ +35.3° (*c* 0.68, pyridine); LR–FAB–MS (positive): *m/z* 497 $[M+Na]^+$, 513 $[M+K]^+$; ^{1}H NMR (DMSO-d_6): δ 0.67, 0.78, 0.89, 0.91, 0.92, 0.96, 1.25, 2.10 (each 3H *s*, H_3 of C-24, 25, 23, 27, 28, 26, 29, 30), 0.63 (1H, *d*, *J* = 9.4 Hz, H-5), 1.30 (1H, *d*, *J* = 11 Hz, H-13), 1.62 (1H, *d*, *J* = 11.5 Hz, H-17), 1.75 (1H, *dd*, *J* = 8.5, 14 Hz, H-20β), 2.01 (1H, *dd*, *J* = 7.5, 12.5 Hz, H-19β), 2.98 (1H, *m*, H-3α), 3.68 (1H, *m*, H-12α), 3.58 (1H, *m*, H-16α); ^{13}C NMR: Table 2. (Found: C, 75.86; H, 10.65; Calc. for $C_{30}H_{50}O_4$: C, 75.90; H.10.62%).

The aqueous part was neutralized by passing through an ion-exchange resin (Amberlite MB-3) column, then dried under vacuum, and treated with 1-(trimethylsilyl) imidazole at room temperature for 2 h. Excess reagent was decomposed with water and the mixture extracted with *n*-hexane (1 ml ×2). The monosaccharide was identified as xylose (R_t 20.26) by co-GLC analysis of the TMSi derivative with standard sample (R_t 20.56).

3.7. Spergulacin (**2**)

The compound was crystallized from MeOH to yield microneedles, mp 280–282 °C (dec.); $[\alpha]_D^{20}$ −13.7° (*c* 0.76, pyridine) [lit. (Barua et al., 1986b)]; HR–FAB–MS (negative): *m/z* 751.46564 $[M-H]^-$ (calc. for $C_{41}H_{67}O_{12}$: *m/z* 751.46325); LR–FAB–MS (positive): *m/z* 753.4 $[M+H]^+$; ^{1}H NMR (DMSO-d_6): δ 0.75, 0.80, 0.91, 0.92, 0.95, 0.96, 1.26, 2.10 (each 3H, *s*, H_3 of C-24, 25, 27, 28, 23, 26, 29, 30), 0.67 (1H, *d*, *J* = 10.8 Hz, H-5), 1.30 (1H, *d*, *J* = 10.8 Hz, H-13), 1.62 (1H, *d*, *J* = 11.5 Hz, H-17), 1.76 (1H, *dd*, *J* = 9, 13.8 Hz, H-20β), 2.01 (1H, *dd*, *J* = 7.3, 12.4 Hz, H-19β), 3.02 (1H, *dd*, *J* = 4.5, 11.5 Hz, H-3α), 3.60 (*m*, H-16α), 3.67 (*m*, H-12α), Sugar moiety: 4.17 (*d*, *J* = 7.5 Hz, H′-1), 3.10 (*m*, H′-2), 3.30 (*m*, H′-3), 3.31 (*m*, H′-4), 3.10 (*m*, H′$_a$-5), 3.70 (*m*, H′$_b$-5); 5.0 (s, H″-1), 3.71 (m, H″-2), 3.48 (m, H″-3), 3.19 (m, H″-4), 3.86 (m, H″-5) and 1.10 (*d*, *J* = 6.2 Hz, CH_3); ^{13}C NMR: Table 2. (Found: C, 65.38; H, 9.15; calc. for $C_{41}H_{68}O_{12}$: C, 65.40, H, 9.10%).

3.8. Spergulacin A (**3**)

Crystallized from methanol as colorless needles, mp 260–262 °C (dec.); $[\alpha]_D^{20}$ −16.1° (*c* 0.77, pyridine); [lit., (Barua et al., 1986a)]; HR–FAB–MS (negative): *m/z* 751.46515 $[M-H]^-$ (calc. for $C_{41}H_{68}O_{12}$: *m/z* 751.46325); LR–FAB–MS (positive): 753.5 $[M+H]^+$; ^{1}H NMR (DMSO-d_6): δ 0.74, 0.79, 0.905, 0.910, 0.94, 0.95, 1.25, 2.10 (each 3H, *s*, H_3 of C-24, 25, 27, 28, 23, 26, 29, 30), 0.67 (1H, *d*, *J* = 10.8 Hz, H-5), 1.30 (1H, *d*, *J* = 10.8 Hz, H-13), 1.61 (1H, *d*, *J* = 11.5 Hz, H-17), 1.73 (1H, *dd*, *J* = 8.5, 14 Hz, H-20β), 2.01 (1H, *dd*, *J* = 7.3, 12.4 Hz, H-19β), 3.02 (*m*, H-3α), 3.59 (*m*, H-16α), 3.71 (*m*, H-12α).

[a] Assignments based upon COSY, TOCSY, HETCOR, HSQC, HMBC and NOESY experiments.
[b] In DMSO-d_6 (30 °C).
[c] In C_5D_5N (30 °C).

Sugar moiety: 4.23 (*d*, $J=7.0$ Hz, H′-1), 3.23 (*m*, H′-2), 3.19 (*m*, H′-3), 3.27 (*m*, H′-4), 3.02 (*m*, H′$_a$-5), 3.68 (*dd*, $J=5$, 11.3 Hz, H′$_b$-5), 5.22 (*s*, H″-1), 3.71 (*m*, H″-2), 3.48 (*m*, H″-3), 3.14 (*m*, H″-4), 3.78 (*dd*, $J=6.2$, 9.2 Hz, H″-5) and 1.06 (*d*, $J=6.2$ Hz, CH_3); ^{13}C NMR: Table 2. (Found: C, 65.36; H, 9.14; calc. for $C_{41}H_{68}O_{12}$: C, 65.40; H, 9.10%).

3.9. Acid hydrolysis of *2* and *3*

Both of **2** and **3** (5 mg each) was hydrolyzed separately with 1 M HCl in a manner similar to that described for **5**. In both the cases, the genin was identified as spergulagenin A (mp, PMR, CMR and MS) and the monosaccharides were found to be xylose (R_t 13.55) and rhamnose (R_t 20.20) (co-GLC of the TMSi derivatives with standard samples).

3.10. Spergulin B (*4*)

Colorless powder, mp 271–273 °C (dec.); $[\alpha]_D^{20}$ −20.0° (*c* 0.85, pyridine); IR: ν_{max} cm^{-1} (KBr): 3414, 1654, 1454, 1040, 985, 839; HR–FAB–MS (negative): *m*/*z*

707.43757 $[M–H]^-$ (calc. for $C_{39}H_{63}O_{11}$: *m/z* 707.43734); LR–FAB–MS (positive): *m/z* 709.4 $[M+H]^+$; MALDI–TOF–MS (positive): 747.03 $[M+K]^+$, 731.11 $[M+Na]^+$; ^1H NMR (C_5D_5N): δ 0.84, 1.04, 1.07, 1.17, 1.18, 1.25 (each 3H *s*, H_3 of C-25, 26, 28, 27, 24, 23), 0.74 (1H, *d*, $J=11.5$ Hz, H-5), 1.77 (1H, *d*, $J=10.8$ Hz, H-13), 2.12 (1H, *m*, H-17), 3.30 (1H, *dd*, $J=4.1$, 11.7 Hz, H-3α), 4.18 (1H, *t*, $J=8.5$ Hz, H-12α), 4.30 (*m*, H-16α), Sugar moiety: 4.84 (*d*, $J=6.2$ Hz, H′-1), 4.23 (*m*, H′-2), 4.16 (*m*, H′-3), 4.14 (*m*, H′-4), 4.33 (*m*, H'_a-5), 3.71 (*dd*, $J=9.6$, 11.0 Hz, H'_b-5), 6.52 (*brs*, H″-1), 4.86 (*dd*, $J=1.4$, 3.2 Hz, H″-2), 4.67 (*dd*, $J=3.4$, 9.4 Hz, H″-3), 4.33 (*m*, H″-4), 4.76 (*m,* H″-5) and 1.71(*d,* $J=6.2$ Hz, CH_3); ^{13}C NMR (C_5D_5N): Table 2. (Found: C, 66.10; H, 9.05; $C_{39}H_{64}O_{11}$ requires: C, 66.07; H, 9.10%).

3.11. Enzymatic hydrolysis of spergulin B (**4**)

A solution of **4** (9 mg) in acetate buffer (pH 5.0, 1 ml) was treated with naringinase (ca 100 mg) at 37 °C for 6 days to obtain a precipitate which showed two spots on TLC. The mixture was chromatographed on a silica gel column using $CHCl_3$–MeOH–H_2O (5:1:0.1) to yield the prosapogenin **7** (3.1 mg) and the genin **8** (2.2 mg). The aqueous part was worked up as described earlier and the monosaccharides were identified to be xylose and rhamnose by co-GLC analysis of the TMS derivatives with authentic samples.

3.12. Prosapogenin (7)

Amorphous powder, $[\alpha]_D^{20}+34.8°$ (*c* 0.10, MeOH); IR ν_{max} cm^{-1} (KBr): 3428, 1657, 1461, 1042, 971, 890; MALDI–TOF–MS (positive): *m/z* 585 $[M+Na]^+$; ^1H NMR (C_5D_5N): δ 0.83, 1.00, 1.04, 1.08, 1.18, 1.31 (each 3H *s*, 6 x-CH_3), 0.78 (1H, *d*, $J=11.5$ Hz, H-5), 1.79 (1H, *d*, $J=10.8$ Hz, H-13), 2.12 (*m*, H-17), 3.36 (1H, *dd*, $J=4.3$, 11.6 Hz, H-3), 5.15 (1H, *brs*, H_a-22) and 6.07 (1H, *brs*, H_b-22), Sugar moiety: 4.85(*d*, $J=7.6$ Hz, H′-1), 4.03 (*t*, 8 Hz, H′-2), 4.17 (*t*, 9 Hz, H′-3), 4.23 (*dd*, $J=5$, 10 Hz, H′-4), 3.78 (*t*, $J=11.2$ Hz, H'_a-5), 4.39 (*dd*, $J=5.3$, 11.3 Hz, H'_b-5); ^{13}C NMR (C_5D_5N): Table 2. (Found: C, 70.38; H, 9.69; $C_{33}H_{54}O_7$ requires: C, 70.40; H, 9.67%).

3.13. Spergulatriol (**8**)

Crystallized from methanol as fine needles, mp 221–222 °C (dec.), $[\alpha]_D^{20}$ +54.8° (*c* 0.28, $CHCl_3$) [lit. (Kitagawa et al., 1977) mp 224–226 °C (dec.), $[\alpha]_D^{28}$ +60.90° (*c* 0.29, $CHCl_3$)]; IR ν_{max} cm^{-1} (KBr): 3432, 1660, 1081, 1029, 970; MALDI–TOF–MS (positive): *m/z* 453 $[M+Na]^+$, 469 $[M+K]^+$; LR FAB–MS (positive): *m/z* 431 $[M+H]^+$, 429 $[M–H]^+$, 413 $[M–H_2O+H]^+$, 395 $[M–2H_2O+H]^+$, 377 $[M–3H_2O+H]^+$; ^1H and ^{13}C NMR (C_5D_5N): Tables 1 and 2. (Found: C, 78.14; H, 10.70; calc. for $C_{28}H_{46}O_3$: C, 78.09; H, 10.77%).

Received 27 February 2001; received in revised form 23 May 2001

Abstract

Three insecticidal sesquiterpene polyol esters were isolated from the root bark of *Celastrus angulatus* by bioassay-guided fractionation. Their chemical structures were elucidated as 1α,2α-diacetoxy-8β-isobutanoyloxy- 9α-benzoyloxy-13-(α-methyl)butanoyloxy-4β, 6β-dihydroxy-β-dihydroagarofuran (**1**), 1α,2α-diacetoxy-8β-(β- furancarbonyloxy)-9α-benzoyloxy-13-isobutanoyloxy-4β, 6β-dihydroxy-β-dihydroagarofuran (**2**) and 1α, 6β, 8α,13-tetraacetoxy-9α-benzoyloxy-2 α-hydroxy-β-dihydroagarofuran (**3**) mainly by analyses NMR and MS spectral data. © 2001 Published by Elsevier Science Ltd.

Keywords: *Celastrus angulatus*; Celastraceae; Insecticide; β-Dihydroagarofuran sesquiterpene

1. Introduction

The plants of the Celastraceae family produce various β-dihydroagarofuran sesquiterpene polyol esters and alkaloids, some of which exhibit insect antifeedant, insecticidal and antitumor activity (Bruning and Wagner, 1978; Tu, 1991; Takaishi et al., 1993). Many species of the Celastraceae family such as the Chinese bittersweet, *Celastrus angulatus* Max., are widely distributed and used as traditional insecticides in China (Jacobson, 1958). Results of bioactivity tests showed the plant extract exhibited antifeedant, narcotic and insecticidal activity against several insects (Wu, 1991). In our previous study, some antifeedant and insecticidal components were isolated from *C. angulatus*, *C. flagellris* and *C. orbiculatus* (Wakabayashi et al., 1988; Wu et al., 1992, 2001; Wang and Chen, 1995; 1997). Continued activity-guided fractionation has led to isolation of three new sesquiterpene polyol esters (**1**, **2** and **3**) with the β-dihydroagarofuran skeleton from the root bark of *C. angulatus*. In this paper, we present the isolation and structure elucidation of compounds **1**–**3**.

2. Results and discussion

Compound **1** was analyzed for $C_{35}H_{48}O_{13}$ by HR–FAB–MS. Its IR spectrum revealed a characteristic ester absorption at 1748 cm^{-1} and free hydroxyl absorption at 3419 cm^{-1}. The NMR spectra suggested the presence of two acetate esters [^{1}H NMR δ 1.59 *s* and 2.15 *s* (2×3H); ^{13}C NMR δ 20.5, 21.1, 169.4, 169.5 (2×Ac)], one isobutanoate ester [^{1}H NMR δ 0.95 *d*, 0.98 *d* (2×3H, J=7.0 Hz), 2.45 *m* (1H); ^{13}C NMR δ 18.5, 18.7, 34.1, 175.7], one (α-methyl) butanoate ester [^{1}H NMR δ 1.06 *t* (3H, J=7.0 Hz), 1.37 *d* (3H, J=7.2 Hz), 2.72 *m*, 1.90 *m*, 1.65 *m* (3×1H); ^{13}C NMR δ 11.7, 16.9, 26.6, 41.6, 176.2] and one benzoate ester [^{1}H NMR δ 7.90 *d* (2H, J=7.2 Hz), 7.60 *t* (1H, J=7.5 Hz), and 7.40 *dd* (2H, J=7.2, 7.5 Hz); ^{13}C NMR δ 128.2, 128.6,129.5.133.4, 165.7] and two free hydroxyl groups [^{1}H NMR δ 3.20 *s*, 5.25 *s* (2×1H, disappeared when exchange with D_2O)], which were confirmed by fragmentation ions at m/z 661 $[M–CH_3]^+$, 643 $[661–H_2O]^+$, 633 $[M–Ac]^+$, 616 $[M–HOAc]^+$, 600 $[M+H–HOAc–OH]^+$, 85 $[CH_3CH_2CHMeCO]^+$, 105 $[C_6H_5CO]^+$, 71 $[Me_2CHCO]^+$, 43 $[Ac]^+$ in the EI mass spectrum and m/z 659 $[M+H–H_2O]^+$, 641 $[M+H-2H_2O]^+$, 599 [659-HOAc]$^+$, 469 [659-2HOAc–Me_2CH CO]$^+$ and 409 in the FAB mass spectrum.

The ^{1}H NMR spectrum of compound **1** showed the presence of three tertiary methyl groups at δ 1.65 *s*, 1.76

s and 1.80 *s*. The signals observed at δ 5.52 *d* (J = 3.1 Hz), 5.43 *m*, 5.63 *dd* (J = 10.0, 3.0 Hz) and 6.11 *d* (J = 10.0 Hz) were assigned to the four protons attached to carbon atoms bearing secondary ester groups, and signals at δ 4.63 *d*, 4.97 *d* (J = 13.4 Hz) were assigned to the two protons attached to carbon atoms bearing primary ester group. The signal observed at δ 5.25 *s* was the proton attached to carbon atom bearing hydroxy group. The ^{13}C NMR DEPT spectrum of the parent skeleton of 1 showed three methyls, two methylenes, six methines, and four quaternary carbons. Their chemical shifts were very similar to those of other 1,2,4,6,8,9,13-heptasubstituded β-dihydroagarofuran (Liu et al., 1991, 1995; Wang et al., 1991: Tu et al., 1992).

From the COSY spectrum of compound 1, the doublets at δ 4.63 and 4.97, the doublet at δ 5.52, the multiplet at δ 5.43, the double doublet at δ 5.63 and the doublet at δ 6.11 were assigned to H-13, H-1, H-2, H-8 and H-9. The singlet at δ 5.25 was assigned to H-6 because the dihedral angles of H-6 and H-7 were near 90°in similar compounds containing an ester or hydroxy group at C-6 (Liu et al., 1991; 1995; Wang et al., 1991; Tu et al., 1992). The remaining ^{1}H signals were assigned as shown in Table 1. The ^{13}C NMR signals were assigned on the basis of ^{13}C–^{1}H COSY and are given in Table 1. Generally, H-1, H-2, and H-6 in this class of compounds have axial, equatorial, and axial stereochemistry, respectively. The large coupling constant ($J_{8,9}$ = 10.0 Hz) between H-8 and H-9 suggested that both had axial stereochemistry which was confirmed by the cross peaks between H-1 and H-9, H-6 and H-8 in the NOESY spectrum of **1**.

One of the two free hydroxy groups was situated at C-4, the second at C-6 as shown by the ^{1}H NMR chemical shift, because the normal value of H-6 is generally greater than or near to δ 6.00 when OH-6 is esterified (Liu et al., 1991, 1995; Wang et al., 1991; Tu et al., 1992). Comparing the ^{1}H NMR chemical shift of **1** with known compounds **4** (Wang et al., 1991) and **5** (Liu et al., 1995) isolated from *C. angulatus*, we found only the chemical shift of one of the H-13 protons shifted downfield by 0.12 or 0.21, the other signals were very similar. This result suggested that only the ester group at C-13 was changed into an (α-methyl)butanoate ester in **1** from the isobutanoate ester in **4** or acetate ester in **5**, the other ester groups are the same as in **4** and **5**, which were confirmed by the cross peaks between H-1 and the carbonyl at δ 169.4, H-2 and the carbonyl at δ 169.5, H-8 and the carbonyl at δ 175.7, H-9 and the carbonyl at δ 165.7, H-13 and the carbonyl at δ 176.2 in COLOC spectrum (Sang et al., 1991), respectively. Therefore, the structure of **1** was elucidated to be 1α,2α-diacetoxy-8β-isobutanoyloxy-9α-benzoyloxy-13-(α-methyl)butanoyl-oxy-4β,6β-dihydroxy-β-dihydroagarofuran.

Compound **2** was analyzed for $C_{35}H_{42}O_{14}$ by HR–FAB–MS. Its ^{1}H NMR and ^{13}C NMR spectral data suggested the presence of two acetate esters, one isobutanoate ester, one benzoate ester, one β-furancarboxylate ester and two free hydroxyl groups. The ^{1}H NMR and ^{13}C NMR spectroscopic data for **2** were very similar to those of **1** and **4**, which suggested that **2** also contained the 1,2,4,6,8,9,13-heptasubstituted-β-dihydroagarofuran skeleton. Compound **2** was found to have the same stereochemistry for H-1, H-2, H-6, H-8 and H-9 as **1** and **4** because of the similar coupling patterns, coupling constants and the cross peaks in the NOESY spectrum. As with **1** and **4**, the two free hydroxyl groups were at C-4 and C-6. Comparing the ^{1}H NMR spectrum of **2** with **1** and **4**, we found only the chemical shifts of H-7, H-8 and H-9 were downfield, the other signals were very similar. These results suggested that only the ester group at C-8 should be changed into the β-furancarboxylate ester in **2** from the isobutanoate ester in **1** and **4**, the other ester groups are the same as in **4**. The ester group distributions were confirmed by the COLOC spectrum, which

showed cross peaks between H-1 and the carbonyl at δ 169.4, H-2 and the carbonyl at δ 169.5, H-8 and the carbonyl at δ 161.8, H-9 at δ 6.18 and the carbonyl at δ 165.7, respectively. The ester group at C-13 would be an isobutanoate. Thus, the structure of 2 was 1α,2α-diacetoxy-8β - (β - furancarbonyloxy) - 9α - benzoyloxy - 13 - isobutanoyloxy-4β,6β-dihydroxy-β-dihydroagarofuran.

Compound **3** was analyzed for $C_{30}H_{38}O_{12}$ by HR–FAB–MS. Its ^1H NMR and ^{13}C NMR spectral data suggested the presence of four acetate esters, one benzoate ester, one free hydroxyl group, and the 1,2,6,8,9,13-hexasubstituted β-dihydroagarofuran skeleton (Rozsa and Pekzer, 1989; Rozsa et al., 1989). Based on the COSY spectrum, H-1, H-2, H-6, H-8, H-9 and the other protons were assigned and are shown in Table 1. The signals at δ 5.02 *d*, 5.06 *d* ($J = 12.5$ Hz) were assigned to H-13. The H-2 proton also showed one cross peak with free hydroxy proton at δ 2.89 (disappeared when exchanged with D_2O) in the COSY spectrum, which indicated that the substituent group at C-2 was hydroxy group. The ester group distributions were determined from the COLOC spectrum, which showed clearly cross peaks between H-9 and the carbonyl carbon at δ 165.2, H-8 and the carbonyl carbon at δ 169.6. This observation indicated one acetate ester was at C-8, the benzoate ester at C-9, and the other three acetate esters were at C-1, C-6 and C-13. As with **1** and **2**, the H-1, H-2 and H-6 had axial, equatorial and axial orientations. The coupling constant ($J_{8,9} = 6.0$ Hz) between H-8 and H-9 indicated that they had different stereochemistry. The cross peaks between H-8 and H-9, H-8 and H-14, H-9 and H-14, H-7 and H-8, H-1 and H-9 in the NOESY spectrum showed that H-8 and H-9 had the equatorial and axial orientation, respectively. Thus, the structure of **3** was 1α,6β,8α,13-tetraacetoxy-9α-benzoyloxy-2α-hydroxy-β-dihydroagarofuran.

The preliminary bioassay results (methodology described in Wu et al., 1992) showed that the KD_{50} values (the dose required to knock down 50% of the population of *Mythimna separate*) for compounds **1**–**3** were 135.3, 73.3, 388.0 μg/g, respectively. Compounds **1** and **2** exhibited stronger activity than celangulin IV (KD_{50} 260.0 μg/g), but were weaker than celangulin II (KD_{50} 46.0 μg/g); on the other hand, compound **3** was much weaker than both celangulin II and IV. These data suggest that the number and orientation of the ester groups have characteristic influence on active strength of β-dihydroagarofuran sesquiterpene polyol esters.

3. Experimental

3.1. General experimental procedures

Melting points were measured on a X_4 apparatus and are uncorrected. Optical rotations were measured on a JASCO 500C polarimeter. UV spectra were obtained on a 756MC spectrophotometer. IR spectra were determined on Equinox 55 instrument (KBr plate). ^1H NMR, ^{13}C NMR, COSY, ^{13}C–^1H COSY, NOESY and COLOC

spectra were recorded on a Bruker DPX 300 NMR spectrometer with $CDCl_3$ as solvent and TMS as internal standard. EIMS were obtained on VG ZAB–HS mass spectrometer operating at 70 eV with a direct insert system, whereas FAB–MS and HR–FAB–MS employed a Brüker Apex II mass spectrometer using nitrobenzoyl alcohol and sodium chloride as matrixes.

3.2. Plant material

The root bark of *C. angulatus* was collected in Mazhao villiage, Zhouzhi county, Shanxi Province, China, (1995) and authenticated by Professor Yang Jianqiang of the Department of Plant Protection, Northwestern Agricultural University. A voucher specimen (sample No. NWAU95-C06) was deposited at the Department of Plant Protection, Northwestern Agricultural University.

3.3. Extraction and isolation

The dried and pulverized root bark (6.6 kg) of *C. angulatus* was extracted with petroleum ether under reflux for 3 h. The extracted material was re-extracted with petroleum ether two times. The extracts obtained were combined and concentrated to give a yellow semi-solid residue (260 g). This crude extract was applied to a silica gel (200–300 mesh) column using EtOAc–petroleum ether (2:8–8:2) as eluent to give 180 fractions (each 500 ml). Fractions 116–176 were combined (40 g) and applied to a silica gel (200–300 mesh) coloumn using EtOAc–petroleum ether (4:6) to give 29 fractions (each 500 ml). Fractions 21–28 (9 g) were subjected to low-pressure LC (RP-18, MeOH–H_2O 65:35) to give 140 fractions (each 100 ml). Fractions 7–9, 98–112, 113–122 were combined respectively, and subjected to HPLC (RP-18, MeOH-H_2O 60:40) to afford compound **1** (23 mg), 2 (74 mg) and 3 (65 mg).

3.3.1. Compound *1*

Amorphous white powder; mp 95–96 °C. $[\alpha]_D^{24}$ −12.8°($CHCl_3$; *c* 0.60). UV λ_{max}^{MeOH} nm (log ε): 244 (3.4530). IR υ_{max} cm^{-1}: 3416 (OH), 2974, 1741 (C=O), 1370, 1235, 1148, 1095, 1033, 952, 712. ^1H NMR (300 MHz, $CDCl_3$): δ 1.59 and 2.15 (each 3H, *s*, 2×Ac), 0.95 and 0.98 (each 3H, *d*, *J* = 7.0 Hz), 2.45 (1H, *m*, Me_2CHCO), 1.06 (3H, *t*, *J* = 7.0 Hz), 1.37 (3H, *d*, *J* = 7.0 Hz), 2.72, 1.90, 1.65 (each 1H, *m*, $CH_3CH_2CHMeCO$), 7.90 (2H, *d*, *J* = 7.2 Hz), 7.60 (1H, *t*, *J* = 7.5 Hz), 7.40 (2H, *dd*, *J* = 7.2, 7.5 Hz, C_6H_5CO); ^{13}C NMR (75 MHz, $CDCl_3$): δ 20.5, 21.1, 169.4, 169.5 (2×Ac), 18.5, 18.7, 34.1, 175.7 (Me_2CHCO), 11.7, 16.9, 26.6, 41.6, 176.2 ($CH_3CH_2CHMeCO$), 128.2, 128.6, 129.5, 133.4, 165.7 (C_6H_5CO). ^1H NMR and ^{13}C NMR data for sesquiterpenoid portion see Table 1. FAB–MS *m/z*: 699 $[M+Na]^+$, 659 $[M+H-H_2O]^+$, 641 $[M+H-2H_2O]^+$, 599 [659-HOAc]$^+$, 469 [659-2×HOAc–Me_2CHCO]$^+$, 409; EIMS 70 eV *m/z*: 661 $[M-CH_3]^+$, 643 [661-H_2O]$^+$, 633 $[M-Ac]^+$, 616 [M–HOAc]$^+$, 600 [661 + H–HOAc]$^+$, 244, 202, 105 [C_6H_5CO]$^+$, 85 [$CH_3CH_2CHMeCO$]$^+$, 71 [Me_2CHCO]$^+$, 43 $[Ac]^+$; HR–FAB–MS *m/z*: 699.2980 $[M+Na]^+$ (calc. for $C_{35}H_{48}O_{13}Na$, 699.2987).

3.3.2. Compound *2*

Amorphous white powder, mp 248–249°C. $[\alpha]_D^{24}$ +7.6° ($CHCl_3$; *c* 0.66). UV λ_{max}^{MeOH} nm (log ε): 247 (3.3481). IR υ_{max} cm^{-1}: 3383 (OH), 2979, 1727 (C=O), 1443, 1269, 1149, 1105, 1031, 955, 756, 714. ^1H NMR (300 MHz, $CDCl_3$): δ 1.53 and 2.16 (each 3H, *s*, 2×Ac), 1.35 and 1.37 (each 3H, *d*, *J* = 7.1 Hz), 2.86 (1H, *m*, Me_2CHCO), 7.83 (2H, *d*, *J* = 7.2 Hz), 7.54 (1H, *t*, *J* = 7.5 Hz), 7.39 (2H, *dd*, *J* = 7.2, 7.5 Hz, C_6H_5CO), 6.63 (1H, *d*, *J* = 1.8 Hz), 7.35 (1H, *d*, *J* = 1.8 Hz), 7.91 (1H, *d*, *J* = 0.5 Hz, β-furancarbonyl); ^{13}C NMR (75 MHz, $CDCl_3$): δ 20.3, 21.1, 169.4, 169.5 (2×Ac), 19.0, 19.1, 34.3, 176.6 (Me_2CHCO), 128.5, 129.3, 129.4, 133.3, 165.7 (C_6H_5CO), 109.5, 118.6, 143.8, 148.2, 161.8 (β-furancarbonyl). ^1H NMR and ^{13}C NMR data for sesquiterpenoid portion see Table 1. FAB–MS *m/z*: 709 $[M+Na]^+$, 687 $[M+H]^+$, 669 $[M-OH]^+$, 577 $[M+H-CH_3-Fu]^+$; EIMS 70 eV *m/z*: 671 [M-CH_3]$^+$, 626 [M–HOAc]$^+$, 608 [626-H_2O]$^+$, 593 [608-CH_3]$^+$, 574 [M–FuOH]$^+$, 566 [M–2HOAc]$^+$, 551 [M–CH_3–2HOAc]$^+$, 514 [574–HOAc]$^+$, 244, 229, 202, 105 [C_6H_5CO]$^+$, 95 [Fu]$^+$, 71 [Me_2CHCO]$^+$, 43 $[Ac]^+$; HR–FAB–MS *m/z*: 709.2467 $[M+Na]^+$ (calc for $C_{35}H_{42}O_{14}Na$, 709.2466).

3.3.3. Compound *3*

Amorphous white powder, mp 99–100°C. $[\alpha]_D^{24}$ −19.9°($CHCl_3$, C 0.66). UV λ nm (log ε) 243 (3.4676), 274 (2.9809). IR υ_{max} cm^{-1}: 3472 (OH), 2976, 1743 (C=O), 1374, 1237, 1106, 1039, 872, 714. ^1H NMR (300 MHz, $CDCl_3$): δ 2.04, 2.13, 2.15 and 2.24 (each 3H, s, 4×Ac), 7.98 (2H, *d*, *J* = 7.2 Hz), 7.55 (1H, *t*, *J* = 7.5 Hz), 7.44 (2H, *dd*, *J* = 7.2, 7.5 Hz, C_6H_5CO); ^{13}C NMR (75 MHz, $CDCl_3$): δ 20.9, 21.2, 21.3, 21.4, 169.6, 169.8, 169.9, 170.6 (4×Ac), 128.4, 129.5, 129.9, 133.1, 165.2 (C_6H_5CO). ^1H NMR and ^{13}C NMR data for sesquiterpenoid portion see Table 1. FA–BMS *m/z*: 613 $[M+Na]^+$, 591 $[M+H]^+$, 573 $[M-OH]^+$, 531 [M + H–HOAc]$^+$, 471 [M + H–2HOAc]$^+$; EIMS 70 eV *m/z*: 548 [M + H–Ac]$^+$, 530 [M + H–HOAc]$^+$, 515 [M–CH_3–HOAc]$^+$, 505 [548–Ac]$^+$, 244, 218, 105 [C_6H_5CO]$^+$, 43 $[Ac]^+$; HR–FAB–MS *m/z*: 613.2552 $[M+Na]^+$ (calc. for $C_{30}H_{38}O_{12}Na$, 613.2555).

Dedicated to Univ. Prof. Dr. W. Fleischhacker, Vienna on the occasion of his 70th birthday

Abstract

From flower heads of *Achillea asiatica* (L.) Serg., three new guaianolides were isolated by repeated column chromatography and HPLC. The constitution and the stereochemistry of these new, labile compounds were determined by MS, one (^{1}H, ^{13}C, selective ^{1}H-TOCSY and ^{1}H-NOESY) and two-dimensional NMR experiments (^{1}H, ^{1}H-COSY, ^{1}H, ^{13}C-HSQC, ^{1}H, ^{13}C-HMBC). The substances were identified as 8α-angeloxy-2α, 4α,10β-trihydroxy-6βH,7αH, 11βH-1(5)-guaien-12,6α-olide (**1**), 8α-angeloxy-1β,2β:4β,5β-diepoxy-10β-hydroxy-6βH, 7αH, 11βH-12,6α-guaianolide (**2**) and 8α-angeloxy-4α,10β-dihydroxy-2-oxo-6βH,7αH, 11βH-1(5)-guaien-12,6α-olide (**3**). They were also detected in Middle European species (*Achillea collina, Achillea ceretanica* (2× and 4×), *Achillea roseoalba, Achillea asplenifolia*) by HPLC, TLC and off line MS and have not been described before. The possibility that these compounds might be products of an oxidation process is discussed. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Achillea asiatica*; *Achillea collina*; *Achillea ceretanica*; *Achillea roseoalba*; *Achillea asplenifolia*; Compositae; Guaianolides; Sesquiterpene lactones; Proazulenes

1. Introduction

The isolation and characterization of some flavonoids and sesquiterpenes of Mongolian *Achillea asiatica* have recently been reported for the first time (Narantuya et al., 1999). The sesquiterpene pattern on TLC corresponded to proazulene containing species such as *Achillea collina*. The apolar and medium polar sesquiterpenes 8α-angeloxy-artabsin, 8α-tigloxy-artabsin, achillicin, 8α-angeloxy-3-oxa-artabsin, 8α-tigloxy-3-oxa-artabsin and 3-oxa-achillicin were identified by their chromatographical (TLC, HPLC) and spectral (UV, MS) behaviour (Narantuya et al., 1999). As the drug contained considerable amounts of polar proazulenes, the isolation and structure elucidation of the respective compounds (**1–3**) was carried out. In addition their presence in Middle European *Achillea* species was shown by combination of HPLC, TLC and off line MS after extraction with dichloromethane and purification on silica gel.

2. Results and discussion

Compounds **1–3** were isolated from polar fractions and are characterized by lability under the influence of light, oxygen and room temperature. **1** and **2** are proazulenes, giving a blue colour by spraying with acetic acid–phosphoric acid reagent, whereas **3** showed brown spots with anisaldehyde reagent on TLC. Molecular weights were determined by combination of EI- and CI-MS. The fragmentation pattern of all three compounds on electron impact ionization suggested the presence of several OH– and CH_3– groups but did not clearly show the molecular weights. Therefore the more soft chemical ionization was employed using either isobutane (positive mode, protonation of the molecule by H^+ ions) or the mixture CH_4–N_2O (77 + 23, negative mode, abstraction of one proton by OH^- ions) as reactant gas. The fragment $m/z = 83$ of high intensity as well as the occurrence

3

of another fragment resulting from a loss of 100 mass units indicated an unsaturated C-5 carboxylic acid ($M^+ - 82–18$). This was confirmed by ^{1}H-NMR spectrometry which showed the signals of an angelate for each compound. NMR spectra of **1**–**3** were recorded in deuterated acetone as in this solvent possible hydroxyl protons appear as sharp signals (see Table 1). That of **1** was additionally measured in chloroform-d, showing shifted proton signals but no deviations of the carbons compared to the spectra obtained with acetone-d_6 as solvent. The combination of the mass spectra with the information from the NMR experiments indicated the following for **1**–**3**: **1** (molecular mass $m/z = 380$, $C_{20}H_{28}O_7$, 7 double bond equivalents), **2** and **3** (molecular mass $m/z = 378$, $C_{20}H_{26}O_7$, eight double bond equivalents). The difference of one double bond equivalent must be related to a modified oxygen function as **1** showed three clearly visible OH signals (singlets at $\delta = 3.40$ and 4.04 ppm, doublet at $\delta = 3.72$ ppm) in contrast to **2** and **3**. They both exhibited a smaller number of hydroxyl groups, thus correlating well with the different chromatographical behaviour (Glasl et al., 2001).

In **1,** four spin systems were determined with the help of ^{1}H,^{1}H COSY, ^{1}H,^{13}C HSQC and selective ^{1}H-TOCSY (irradiation of H-2, H-3, H-8) experiments which could be connected with the aid of the ^{1}H,^{13}C-HMBC spectrum in addition to the carbon shifts. The largest spin system from C-6 to C-9 including the saturated lactone ring was connected via a quaternary carbon with a free hydroxyl group (C-10, $\delta = 71$ ppm) to a sp^2 carbon (C-1, $\delta = 147$ ppm). The corresponding sp^2 carbon of this double bond was represented by C-5 ($\delta = 143$ ppm) which showed cross peaks to CH_3-15, H-2β and H-2α in the ^{1}H,^{13}C HMBC. These correlations finally led to a 1(5)-guaien-12,6-olide substituted by three hydroxyl groups (positions 1, 4 and 10) and an angelate in position 8. Compound **1** as well as **2** and **3** showed substitution with angelic acid in position 8, indicated by a cross peak of H-8 to the carboxylic carbon of the acid ($\delta = 166–168$ ppm) in the ^{1}H,^{13}C HMBC on the one hand and the shift of H-8 at high frequency ($\delta = 5.60–5.66$ ppm) on the other hand. From the literature, is known that the substitution of the OH-group in position 8 with acetic acid causes reduction of the shielding (Martinez and Munoz-Zamora, 1988) and shifts the geminal proton for more than 1 ppm to deeper field, which confirms the described conditions in the present substances.

The more apolar compounds **2** and **3** had the same molecular formula but differed in the number of hydroxyl functions. Compared with **1** compound **3** had only two hydroxyl groups (singlets at $\delta = 3.94$ and 4.58 ppm) and lacked the doublet corresponding to OH-2 as well as H-2. An additional quaternary carbon at $\delta = 206$ ppm as well as a high frequency shift of H-6 ($\delta = 5.78$ ppm, $\Delta\delta = 0.3$ ppm) suggested that C-2 carried a carbonyl. Conjugation with the 1(5) double bond resulted in a shift of λ_{max} to 230 nm in contrast to **1** which had only a slight shoulder at 220 nm. Signals of H-7, H-11 and CH_3-15 were shifted to higher frequency and those of H-3β and H-3α appeared as a two proton singlet at $\delta = 2.58$ ppm. The latter seems to be typical for five-membered rings with one carbonyl function, as the same phenomenon has been described for a similar compound oxygenated in position 3 (Bordoloi et al., 1989).

The chemical shifts in the ^{1}H,^{13}C-HMBC of compound **2** suggested the presence of three additional carbons with an oxygen function besides C-4 and C-10 instead of one carbonyl and two sp^2 carbons. The one hydroxyl visible in the ^{1}H NMR as a singlet ($\delta = 4.61$ ppm) was related to position 10 due to a long range coupling with C-9. Consequently five of the seven oxygens were thus accounted for by this OH group, the lactone ring and the angelate. Thus the four remaining C–O functions formed two epoxides in positions 1, 2 and 4, 5.

Selective NOE experiments were necessary to determine the stereochemistry of **1–3**. Irradiation of the protons H-6,

Multiplicities and coupling constants of overlapping signals were estimated from selective 1D-TOCSY- and NOESY experiments; *J* (Hz): compound **1**: 2α,2β = 7.6; 2β,3β = 3.5; 3α,3β = 13.8; 6,7 = 10.4; 6,8 = 1.8; 7,8 = 10.7; 8,9β = 4.8; 9α,9β = 14.2; 11,13 = 6.9; 3′,4′ = 7.2; 3′,5′ = 1.5; compound **2**: 2α,3α = 2.6; 3α,3β = 15.9; 6,7 = 10.2; 7,8 = 10.6; 8,9β = 3.8; 9α,9β = 13.9; 11,13 = 7.1; 3′,4′ = 7.2; 3′,5′ = 1.5; compound **3**: 3α,3β = 18.5; 6,7 = 10.7; 7,8 = 10.1; 8,9β = 4.9; 9α,9β = 15.3; 11,13 = 6.9; 3′,4′ = 7.2; 3′,5′ = 1.5.

[a] n.d., not detectable.

[b] Signals interchangeable.

H-7, H-8, H-11, CH_3-13 and CH_3-14 suggested a similar stereochemistry of the seven-membered ring in all three compounds. The values of the coupling constants with respect to the Dieder dihedral angles indicated axial orientation for H-6β, H-7α, H-8β and H-9α. Positive NOEs between H-6β and CH_3-15 as well as from H-2β to H-3β and OH-10β led to the relative configurations of **1** and **3**. The orientation of H-2 in compound **2** as alpha was shown by positive NOEs with H-3α (strong) and H-9α (weak). Also that H-2α showed only one cross peak with H-3α can be explained if it is α orientated, implying dihedral angles of 90° with H-3β (therefore no coupling) and of 45° with H-3α leading to a coupling constant of 3–4 Hz. If H-2 was β orientated only coupling with H-3β would be expected. Positive NOEs between CH_3-15α and H-7α, H-3α (both strong) and CH_3-13α (weak) led to the relative configuration shown.

Similar substances lacking the oxygen in position 8 have been reported from *Artemisia absinthium*: artabsinolide A (8-deangeloxy-derivative of **3**) and the 8-deangeloxy-derivative of **2** with both epoxides α-orientated (Kelsey and Shafizadeh, 1979; Beauhaire and Fourrey, 1982). Beauhaire and Fourrey (1982) showed that artabsin dissolved in methanol together with Rose Bengal was converted via an unstable 1,4-endoperoxide to several intermediates in the presence of oxygen. Similarly the compounds **1**–**3** might be formed from 8α-angeloxyartabsin, one of the main compounds in *Achillea asiatica* (Narantuya et al., 1999), by a ''photo-oxygenation'' process. This might take place during the vegetation period in the living plant or could be triggered artificially during the isolation procedure by careless handling. To minimize the latter, fractions were not heated beyond 40 °C, protected from daylight by tin foil and dried before storage over night at + 4 °C maximum. **1**–**3** were also detected in the proazulene containing Middle European species *A. collina, Achillea ceretanica* (2× and 4×), *Achillea roseoalba* and *Achillea asplenifolia*. After a drying period of three weeks at room temperature these species were extracted and analyzed within 1 day, which indicates the oxidation to take place already in the living plant.

The occurrence of guaianolides without exocyclic methylengroup in the lactone ring corresponds with the literature describing this carbon skeleton as characteristic for diploid and tetraploid taxa of the *Achillea millefolim* group (Kubelka et al., 1999). They show antiphlogistic activity in the croton oil ear test (Kastner et al., 1993) lacking any allergenic potential due to the saturated methyl group in the lactone ring, which could also be expected for the compounds presented in this paper. Considering the increased polarity of **1**–**3** compared to 8α-angeloxy- and 8α-tigloxyartabsin a higher rate of transfer into aqueous preparations might occur. Taking these facts into account, a contribution of **1–3** to the efficacy of remedies prepared from *Achillea* can be expected. Quantification analyses and pharmacological investigations are in process.

3. Experimental

3.1. Plant material, extraction, isolation

Aerial parts of *A. asiatica* (L.) Serg. were collected in Central Mongolia (Töv aimag) near the River Shavart, at the time of full flowering. The plants were identified by Dr. Ganbold (Institute of Biology and Biotechnology, Mongolian Academy of Sciences), voucher specimens were deposited at the same Institute, Ulaanbaatar, Mongolia.

One thousand grams dried above ground parts (chopped) of *A. asiatica* were extracted three times in portions with dichloromethane by ultrasonification for 10 min. The oily green residue (29.0 g) was solved again in dichloromethane and purified by addition of the same volume of methanol–water (1 + 1). Evaporation of the dichloromethane at 40 °C maximum yield an oily sticky residue which was filtered and extracted again. After extraction of the unified methanol–water (1 + 1) fractions with dichloromethane 3.9 g of a yellow oily residue resulted. Separation into eleven fractions was performed by VLC using silica gel as stationary phase and dichloromethane, dichloromethane–acetone and dichloromethane–methanol with increasing polarity as mobile phase. Repeated HPLC (RP-8) and CC (silica gel) yielded 16.0 mg of **1**, 1.6 mg of **2** and 3.0 mg of **3** (colourless oils; Glasl et al., 2001). Due to the lability of the compounds this amount does not represent the real concentrations in the plant.

For the identification of **1**–**3** in the Middleeuropean taxa dried flowerheads (2 g) of the respective drug were extracted and purified as described above. The yellow oily residue (0.1 g) was fractionated by CC on silica gel using dichloromethane and dichloromethane-acetone with increasing polarity. The polar proazulene fractions containing **1** eluted with the mixture dichloromethane-acetone (7 + 3) and were analyzed by TLC and HPLC with the pure compound as reference (Glasl et al., 2001).

3.2. Thin layer chromatography

Silica gel 60 Merck plates (0.25 mm) were used with dichloromethane–acetone (9 + 1, v/v; **1**: $R_f = 0.1$; **2**: $R_f = 0.18$; **3**: $R_f = 0.25$; matricin: $R_f = 0.4$) and dichloromethane–methanol (9 + 1, V/V; **1**: $R_f = 0.5$; matricin: $R_f = 0.8$) as mobile phase. As reference a dichloromethane extract of chamomile was prepared. After detection with acetic acid–phosphoric acid reagent (Stahl, 1967) under heat (140 °C) proazulenes **1** and **2** gave blue coloured spots, **3** was characterized by quenching of fluorescence and brown colour after spraying with anisaldehyde sulfuric acid reagent (Dequeker, 1964).

3.3. HPLC

The HPLC system consisted of a Perkin-Elmer Series 200 pump and a LC235C diode array detector (detection at 220 and 255 nm). All computations were performed using the Perkin-Elmer software Turbochrom®. Separations were carried out using a Hewlett Packard LiChrospher®100 RP-8 5 μm column (250×4.0 mm) guarded by a Hewlett Packard LiChrospher®100 RP-8 5 μm guard column (4×4 mm). The binary system employed the eluents methanol and water according to a gradient. The elution started from 20% methanol to 80% methanol in 90 min (linear; rate = 0.67%/min) with a flow-rate of 1.0 ml/min at room temperature. The identification of **1-3** in the Middle European taxa was achieved by retention times and the UV-vis spectra (DAD detection), additionally off-line TLC-MS was performed by sampling the corresponding HPLC fractions. The fractions were extracted with dichloromethane, the organic layer was removed under reduced pressure, the residue was redissolved in ≈50 μl dichloromethane and used for TLC confirmation and off-line MS (Glasl et al., 2001).

3.4. Structure elucidation

3.4.1. MS

A Shimadzu QP-1000 EX MSPAC 200 with direct inlet and two possible ionisation modi (EI-MS, CI-MS) was used. EI-mode: ion source: 250 °C, 70 eV; vacuum: 4×10^{-6} torr; scan: 40–500/2s; heating rate of sample vial: 80 °C/min; CI-mode: ion source: 180 °C, 200 eV; reactant gas: CH_4–N_2O (77 + 23) 4.8 and isobutane 4.0, pre-pressure: 1 bar; vacuum: 5×10^{-5} torr; scan: 60–400/2s; heating rate of sample vial: 80 °C/min. HRMS spectra were measured with a Finnigan MAT 8230 instrument at the Institute of Organic Chemistry, University of Vienna (70 eV, resolution 1000).

3.4.2. IR

A solution of the respective compound in dichloromethane was dropped on a silicium plate (13×1 mm, polished optically, Korth Kristalle GmbH) leaving a slight oily film. Spectra were recorded with a Perkin-Elmer System 2000GC IR (software Spectrum for Windows 1.30); resolution: 4 cm^{-1}; J-stop resolution: 7.77 cm^{-1}; apodization: strong; gain: 1; OPD velocity: 2 cm/s; interferogramm: bi-directional double sided; phase correction: self 64; number of scans: 1; scan range: 5200–370 cm^{-1}; interval: 1.0 cm^{-1}.

3.4.3. UV

The UV spectra were recorded on line in methanol–water by DAD detection during an HPLC run.

3.4.4. NMR

^1H, ^{13}C, ^1H, ^1H-COSY, ^1H, ^{13}C-HSQC, ^1H, ^{13}C-HMBC, selective ^1H-TOCSY and ^1H-NOE experiments were recorded with a Varian Unity Inova 400 NMR spectrometer at 297 K. Tubes: 5 mm diameter (Kontes). Dual probe head with shielded *z*-gradients or broadband

probe (400 MHz). Solvents: acetone-d_6, chloroform-*d*. TMS was used as internal standard. Chemical shifts were given in ppm. The HMBC experiment was optimized for a long-range coupling constant of 8 Hz. Before NOE experiments were performed, dissolved oxygen was removed by bubbling Ar through the solution.

3.4.5. 8α-Angeloxy-2α,4α,10β-trihydroxy-6βH,7αH, 11βH-1(5)-guaien-12,6α-olide (**1**)

Triterpenoids from *Lawsonia alba*

Bina. S. Siddiqui*, Muhammad Nadeem Kardar

H.E.J. Research Institute of Chemistry, University of Karachi, Pakistan

Received 11 January 2001; received in revised form 5 July 2001

Abstract

Two pentacyclic triterpenoids have been isolated from the aerial parts of *Lawsonia alba*. The structures of the new constituents, named as lawsonic acid and lawsonin have been elucidated as 3α-*E*-ferulyloxy-lup-20(29)-en-28-oic acid and 3α-*E*-ferulyloxy-urs-11-en-13β-ol respectively through spectroscopic studies. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Lawsonia alba*; Lythraceae; Aerial parts; Triterpenoids; 3α-*E*-Ferulyloxy-lup-20 (29)-en-28-oic acid and 3α; -*E*-Ferulyloxy-urs-11-en-13β-ol; Lawsonic acid and Lawsonin

1. Introduction

Lawsonia is a monotypic genus represented by *Lawsonia inermis* Linn (syn. *Lawsonia alba* Lam, Lythraceae), a native of North Africa and south-west Asia, widely cultivated as an ornamental hedge and dye-plant. The leaves of *L. inermis* have long been used in India and Middle East countries as a cosmetic for colouring palms of hands and dyeing of hair for personal adornment (Manjunath, 1962). The leaves also used as a prophylactic in the form of paste or decoction for the skin inflammation (Chopra et al., 1956). The essential oil obtained from the flowers finds use in perfumery due to its β-ionone content. The leaves have been reported to contain various compounds like coumarins, flavonoids, gallic acid, naphthoquinones, naphthalene derivatives, lupane type triterpenoids (Handa et al., 1997; Mebe et al., 1998), aliphatic constituents, phenolic glycosides and xanthones (Gupta et al., 1992). Recently, reports have appeared on the chemical constituents of the roots (Gupta et al., 1992) and bark (Gupta et al., 1992). However, studies on the chemical constituents of the seeds are lacking and only analysis of fatty acids, waxes and colouring matter is reported (Manjunath, 1962). In the present work, studies on the chemical constituents of the aerial parts of *Lawsonia alba,* collected from Karachi university campus were undertaken which resulted in the isolation and structure elucidation of two new triterpenoids of lupane and α-amyrin skeleton, named as lawsonic acid and lawsonin along with three known constituents, β-sitosterol, oleanaldehyde and betulinaldehyde. The structures of these constituents have been elucidated through spectral studies including 1D ^{1}H and ^{13}C NMR (broad band and DEPT) and 2D NMR (COSY-45, NOESY, *J*-resolved, HMQC and HMBC) analysis. These studies form the basis of present communication.

2. Results and discussion

The HR–EIMS of lawsonic acid (**1**) showed molecular ion peak at *m/z* 632.4076 corresponding to the formula $C_{40}H_{56}O_6$. Five methyl singlets at δ 0.86, 1.01, 0.85, 0.87 and 0.97 in the ^{1}H NMR spectrum and the molecular formula were indicative of a triterpenoidal skeleton. The ^{1}H NMR spectrum further displayed an isopropenyl side chain by signals at *δ* 1.63 (3H, *s*, H-30), 4.57 and 4.67 (each 1H, *d*, H-29a and H-29b) manifesting its relation with lupane type of triterpenoids. These protons had their connectivities with carbons at *δ* 147.8 and 110.6 respectively in the HMBC spectrum. Besides these, a quaternary carbon at *δ* 179.2 in the BB spectrum was assigned to C-28 from its connectivity with H-29 a/b and H-30 in the HMBC spectrum. The molecular formula indicated that apart from a C-30 skeleton 1 had a side chain of C-10 units. This could be decided as 6′-methoxy-7′-hydroxy-*trans*-cinnamoyloxy (*E*-ferulyloxy) group on the basis of spectral data (vide experimental).

Important MS fragments of **1** and **2**

The ^{1}H NMR spectrum showed two doublets at δ 7.59 and 6.30 each with a coupling constant of 15.9 Hz (H-3′ and H-2′ respectively); two one-proton doublets at δ 7.03 (J = 1.6 Hz, H-5′) and 6.91 (J = 8.1 Hz, H-8′) and a one-proton double doublet at δ 7.06 (J = 8.1, 1.6 Hz, H-9′). The carbons connected to these protons were identified at δ 145.6 (C-3′), 115.0 (C-2′), 109.5 (C-5′), 114.6 (C-8′) and 123.0 (C-9′) respectively in the HMQC spectrum. The UV maxima at 325.2 and 299.4 nm further support this moiety. Furthermore, four downfield quaternary carbons were noted in the BB spectrum at δ 167.5, 127.0, 146.0 and 147.2 which were ascribable to C-1′, C-4′, C-6′ and C-7′ respectively through comparison of their shifts with the reported values (Kuo, et al., 1997) and interaction observed for these carbons and aromatic protons in the HMBC spectrum. A three-proton downfield signal was present at 3.90 (δ_c, 55.5) which could be placed at C-6′ as these protons had interaction

with H-5′ in the NOESY spectrum. This ester group was placed at C-3 on biogentic consideration since there was only one downfield double doublet at δ 4.89 ($J=11.6$, 4.7 Hz). These features justified 12 out of 13 unsaturations hence the remaining double bond equivalence was justified by a carboxyl group at C-17 which was supported by a significant mass fragment at m/z 248 (B.P) due to cleavage of ring C. Thus the structure of lawsonic acid was elucidated as 3α-*E*-ferulyloxy-lup-20 (29)-en-28-oic acid and substantiated by various mass fragments at m/z 438 (fragment **a**), 385 (fragment **b**), 248 (fragment **c**), 203 (fragment **d**), 194 (fragment **e**), 189 (fragment **f**) (vide structure). The skeleton was finally confirmed through hydrolysis of 1 with 2% methanolic KOH which yielded betulinic acid (vide experimental).

The HR–EIMS of lawsonin (**2**) showed a molecular ion peak at m/z 600.4178 corresponding to the formula $C_{40}H_{56}O_4$ [M^+–H_2O]. The presence of six methyl singlets at δ 0.87,0.88, 0.89, 0.99, 1.05, and 1.14 and two doublets of three-proton each at δ 0.95 ($J=6.2$ Hz) and 0.94 ($J=5.4$ Hz) in the ^{1}H-NMR spectrum were indicative of its triterpenoidal skeleton. The two doublets of methyl protons and a doublet of H-18 at δ 2.01 ($J=12.3$ Hz) manifested that it belongs to ursane series. The molecular formula, number of unsaturation, UV absorption at 323.6 nm, and the NMR data (vide infra) further suggested its relation with an α-amyrin group with a *E*-ferulyloxy substituent. Thus, the ^{1}H NMR spectrum displayed two AB doublets at δ 7.59 and 6.30 with a coupling constant of 15.9 Hz which were attributable to H-3′ and H-2′ respectively. These had connectivity with C-3′ (δ 144.4) and C-2′ (δ 116.2) respectively in the HMQC spectrum. The ^{1}H NMR spectrum further showed three downfield protons at δ 7.06 (*dd*, $J=8.1$, 1.6 Hz), 7.03 (*d*, $J=1.6$ Hz) and 6.91 (*d*, $J=8.1$ Hz) due to ortho-meta (H-9′), meta (H-5′) and ortho (H-8′) coupled protons. These protons had cross peaks at δ 123.0 (C-9′), 109.2 (C-5′) and 114.6 (C-8′) respectively in the HMQC spectrum. One of the substituents in the aromatic ring was decided as a methoxy group considering a three-proton singlet at δ 3.90 (δ_c 55.5.), while the other could be a hydroxyl group as all the carbons of the molecule were justified. Their respective positions could be decided on the basis of interactions in the NOESY spectrum which showed connectivity between H-5′ and-OCH_3 and hence the hydroxyl group was placed at C-7′ and the methoxy group at C-'6.

The ester group was placed at C-3 of the terpenoidal skeleton on biogenetic grounds and was supported by the characteristic double doublet of H-3 now present at δ 4.65 ($J=11.5$, 5.2 Hz) instead of its normal value (*ca.* δ 3.11). These features justified eleven unsaturations, five by the skeletal rings and six by the ester group and left one double bond equivalent to be decided. This could be accounted for by a double bond at C-11 due to two one-proton signals at δ 5.57 (*br. d*, $J=5.8$ Hz) and 5.50 (*dd*, $J=5.8$, 3.0 Hz). That H-12 has a larger coupling constant with H-9 as compared to that of H-11 was established on the basis of 2D NMR data including ^{1}H–^{1}H-COSY and HMBC interactions. This observation has been recorded earlier also based on 2D NMR experiments (Siddiqui et al., 1999). This left only one oxygen to be accounted for which was decided to be a hydroxyl group (δ 1.6 *br. s*, exchangeable with D_2O) located on a non-protonated carbon as no other carbinylic proton was present and the ^{13}C NMR had a non-protonated downfield carbon at δ 80.7. It was placed at C-13 as H-12 showed only one coupling with H-9. An interaction of the hydroxyl proton with H-29 (δ 0.95) and H-18β (δ 2.01, *d*, $J=12.3$ Hz) displayed the β disposition of the hydroxyl group at C-13. In the light of these considerations, the structure of lawsonin was elucidated as 3α-*E*-ferulyloxy-13β-hydroxy-urs-11-ene. Substantial evidence was also provided by the mass fragments at m/z 442 (fragment **a**), 424 (fragment **b**), 234 (fragment **c**), 193 (fragment **d**) (vide structure).

3. Experimental

3.1. General

The NMR spectra were recorded on Bruker AMX-500 instrument with TMS as int. standard. MS were obtained on Finnigan MAT 311A instrument. IR spectra were recorded on JASCO IR A-1 spectrophotometer, whereas UV spectra were recorded on Hitachi U-3200 spectrophotometer. Optical rotations were measured on JASCO DIP-360 digital polarimeter. The petrol used was of the boiling range 60–80 °C.

3.2. Plant material

The aerial parts (40 kg) of *Lawsonia alba* were collected from the region of University of Karachi, Pakistan in October 1998. The plant was identified by Dr. Surayya Khatoon, University of Karachi, and a voucher (specimen No. 67503) has been deposited at the Herbarium of the same University.

3.3. Extraction and isolation

The aerial parts of *Lawsonia alba* (40 kg) was extracted with dichloromethane (×5) and the marc left was repeatedly extracted with methanol (×5) at room temperature. The solvent from both these extracts was removed separately under reduced pressure. The gummy residue from dichloromethane extract was treated with petrol to give petrol soluble and insoluble fractions. The latter was treated with Et_2O to yield Et_2O soluble and Et_2O insoluble fractions. The Et_2O insoluble fraction was divided into EtOAc soluble and EtOAc insoluble fractions. The EtOAc soluble fraction was concentrated and poured into an excess of petrol and was kept in cold over night. A brownish residue (4 g) which settled down was filtered and subjected to column chromatography over silica gel GF_{254}. The column was eluted with $CHCl_3$, $CHCl_3$–MeOH and MeOH in order of increasing polarity. The fractions were combined on the basis of TLC to give 29 fractions. Out of these, fractions No 5 (15 mg), and No 9 (18 mg), were pure showing single spots on TLC. Their spectral studies revealed them to be new constituents and they were named as lawsonic acid (**1**) and lawsonin (**2**). Fraction No. 8 showed three main spots, which were separated through thick layer chromatography on silica gel (GF_{254}, E-Merck; ($CHCl_3$–MeOH, 9.8:0.2). Three pure compounds were thus obtained which were identified as β-sitosterol (9.1 mg), oleanaldehyde (6.0 mg) and betulinaldehyde (4 mg) through comparison of their spectral data, with those reported in literature (Budzikiewicz et al., 1963).

3.3.1. Lawsonic acid (*1*)

Amorphous powder (15 mg); $[\alpha]_D^{26}$ +7.8 (MeOH, *c*, 0.76); UV λ_{max} MeOH nm: 325.2, 299.4; IR ν_{max} $CHCl_3$ cm^{-1}: 3650 (OH), 2900 (C–H), 1700 (C=O), 1600–1450 (aromatic), 1350 (C–O); ^1H NMR spectral data ($CDCl_3$) δ: 0.85, 0.86, 0.87, 0.97, 1.01 (each 3H, *s*, 5×CH_3), 4.57 (1H, br.*s*, H-29a), 4.67 (1H, br.*s*, H-29b), 4.89 (1H, *dd*, *J* = 11.6, 4.7 Hz, H-3), 6.30 (1H, *d*, *J* = 15.9 Hz, H-2′), 6.91 (1H, *d*, *J* = 8.1 Hz, H-8′), 7.03 (1H, *d*, *J* = 1.6 Hz, H-5′), 7.06 (1H, *dd*, *J* = 8.1, 1.6 Hz, H-9′), 7.59 (1H, *d*, *J* = 15.9 Hz, H-3′); HR–EIMS *m*/*z*: 632.4073 (calc. $C_{40}H_{56}O_6$ 632.4076); EIMS *m*/*z* (rel. int.): 632 [M^+] (16), 438 (13), 248 (100), 233 (14), 207 (19.3), 203 (98), 194 (3.27), 189 (75), 177 (21.7), 163 (94.3), 133 (50); ^{13}C NMR: Table 1.

3.3.1.1. Hydrolysis of (1). To lawsonic acid (5 mg) 2% methanolic KOH (1 ml) was added and the reaction mixture was kept overnight at room temperature. On usual work up a whitish solid was obtained showing a single spot on TLC. It formed fine needles in MeOH. m.p. 282-285 °C (betulinic acid m.p. 282-285 °C, Ikuta et al., 1988). M^+ 456.

3.3.2. Lawsonin (*2*)

Amorphous powder (18 mg); $[\alpha]_D^{25}$ + 36.4 (MeOH, *c*, 0.245); UV λ_{max} MeOH nm: 323.6, 294.0; IR ν_{max}: $CHCl_3$ cm^{-1}: 3500 (OH), 2800 (C–H), 1700 (C=O), 1600–1450 (aromatic), 1300 (C–O); ^1H NMR spectral data ($CDCl_3$) δ: 0.87, 0.88, 0.89, 0.99, 1.05, 1.14 (each 3H, *s*, 6×CH_3), 0.94 (3H, *d*, *J* = 5.48, H-29/H-30), 0.95 (3H, *d*, *J* = 6.2, H-29/H-30), 4.65 (1H, *dd*, *J* = 11.5, 5.2 Hz, H-3), 5.50 (1H, *dd*, *J* = 5.8, 3.1 Hz, H-12), 5.57 (1H, *br*. *d*, *J* = 5.8 Hz, H-11), 6.30 (1H, *dd*, *J* = 15.9, H-2′), 6.91 (1H, *d*, *J* = 81.Hz, H-8′), 7.03 (1H, *d*, *J* = 1.6 Hz, H-5′), 7.06 (1H, *dd*, *J* = 8.1, 1.6 Hz, H-9′), 7.59 (1H, *J* = 15.9 Hz, H-3′); HR–EIMS *m*/*z*: 600.4176 (calc. $C_{40}H_{56}O_4$ 600.4178); EIMS *m*/*z* (rel. int.); 600 [M^+] (63.4), 442 (23.8), 424 (10.10), 414 (15.26), 234 (30.53), 232 (19.30), 207 (54.34), 203 (100), 193 (5.47), 189 (59.6), 177(21.7), 163 (94.6), 123 (79.3); ^{13}C NMR: Table 1.

Abstract

Three compounds, pubadysone [11α-hydroxy-18,20-oxido-3-oxo-pregna-1,4,17(20)-triene] (**1**), puboestrene [3-acetoxy-17-oxo-1,3,5(10)-estratriene] (**2**) and pubamide [3,18-dioxo-11α-hydroxycona-1,4-diene] (**3**), have been isolated from the bark of *Holarrhena pubescens*. Their structures have been established through spectroscopic studies. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Holarrhena pubescens; Apocynaceae; Bark; Steroids; Alkaloids

1. Introduction

Holarrhena pubescens (Buch. Ham) [synonym: *H. antidysenterica* L. Apocynaceae] is an Indian medicinal tree. The tree is common in the forests of India and Pakistan indigenous to tropical Himalaya and Assam (Bhutani et al., 1984). The stem bark of this plant, commercially known as kurchi, has astringent, antidysenteric, anthelmintic, stomachic, febrifugal and tonic properties. It is used in the treatment of amoebic dysentery and diarrhoea (Sastri, 1957), usually administered as an extract or decoction. A hot decoction of bark is used as a gargle in toothache (Dymock et al., 1980). Chemical studies on *H. pubescens* were undertaken as far back as 1858 when the alkaloid conessine was first isolated from the bark of the plant (Dymock et al., 1980). Since then this plant has been extensively studied for its alkaloids (Atta-ur-Rahman, 1990) due to their pharmacological significance. Studies undertaken by our group on the bark of the plant led to the isolation of several new compounds (Begum et al., 1993, 1994; Siddiqui et al., 1993, 1994, 1995). In continuation of these investigations three new compounds pubadysone, a steroid in the pregnane series, puboestrene, a steroid in the oestrone series and pubamide an alkaloid in the conanine series have now been obtained. The isolation and structure elucidation of these constituents form the basis of this report. The structural studies are based on 1D and 2D NMR experiments (COSY 45, HMQC and HMBC) and other spectral evidences.

2. Results and discussion

Pubadysone (**1**) showed a molecular ion peak in the HRMS at *m*/*z* 326.1857, corresponding to the molecular formula $C_{21}H_{26}O_3$ (calc. 326.1881). The molecular formula showed nine double bond equivalents in the molecule. Compound **1** showed one three-proton singlet for a tertiary methyl at δ 1.34 and an olefinic methyl singlet at δ 2.07 in the ^{1}H NMR spectrum (Table 1). It exhibited strong absorptions in the IR spectrum at 1650 cm^{-1} and the UV spectrum at 247 nm indicating the presence of a conjugated carbonyl moiety. The ^{1}H NMR spectrum showed three deshielded olefinic protons at *δ* 7.81 (1H, *d*, *J* = 10.3 Hz, H-1), 6.15 (1H, *dd*, *J* = 10.3, 2.0 Hz, H-2) and 6.09 (1H, *t*, *J* = 2.0 Hz, H-4), accounting for three double-bond equivalents (2 C=C and 1 C=O). The chemical shifts and coupling constants of the olefinic signals, along with a peak at *m*/*z* 121.0679, permitted the location of a 1,4-dien-3-one moiety in ring A of the molecule (Davis et al., 1970). This was further confirmed by ^{13}C NMR showing a signal at *δ*, 186.7 characteristic of an α,β-unsaturated ketone, and other peaks at δ, 158.8, 125.3, 124.7 and 167.8 for olefinic carbons (Table 1). A one-proton

doublet of triplets at δ, 3.69 ($J=11.0$, 11.0, 4.7 Hz) indicated an axial proton geminal to an OH group followed by a peak at δ, 70.1 in the ^{13}C NMR spectrum. The multiplicities and coupling constants of this signal suggested the location of the OH group at either C-7 or C-11. The downfield chemical shift (δ, 7.81) of H-1 which is comparable with other 11α-OH compounds (Bhutani et al., 1988) located this group at position 11. Further support was obtained from the interactions in the HMBC spectrum. Two mutually coupled doublets at δ, 3.68 and 3.51 ($J=9.2$), a vinylic three-proton singlet at δ, 2.07 and the remaining six degrees of unsaturation indicated that a five-membered unsaturated ring with oxygen as a hetero atom is present in a pregnane-type skeleton. These observations were further confirmed by ^{13}C NMR signals at δ, 72.7, 110.1 and 158.6 assigned to C-18, C-17 and C-20, respectively. These observations led to the assignment of structure **1** to pubadysone. The structure was substantiated by various connectivities observed in COSY 45°, NOESY, HMQC and HMBC spectra and mass fragments (vide structure).

The molecular formula of **2**, $C_{20}H_{24}O_3$, was obtained through accurate mass measurement (found 312.1702, calcd. for $C_{20}H_{24}O_3$: 312.1725) of the molecular ion and showed nine double-bond equivalents. Its IR (1720, 1600, 1590, 1480 and 1450 cm^{-1}) and UV (267 nm) absorptions and the signals in the ^1H NMR spectrum at δ, 7.26 (1H, *d*, $J=8.5$ Hz, H-1), 6.84 (1H, *dd*, $J=8.5$, 2.6 Hz, H-2), 6.98 (1H, *d*, $J=2.6$ Hz, H-4) and 2.27 (3H, *s*, $COCH_3$) (Table 1) were suggestive of an aromatic ring A carrying an acetoxy function. In the HMQC spectrum, cross peaks for hydrogen and carbon connectivities were noted for C-1/H-1 (δ, 126.4/7.26), C-2/H-2 (δ, 118.8/6.84), C-4/H-4 (δ, 121.6/6.98) and $CO\underline{C}H_3/COC\underline{H}_3$ (21.1/2.27). Besides these, in the Broad Band spectrum signals were present at δ, 169.9 ($\underline{C}OCH_3$), 148.7 (C-3), 138.0 (C-5) and 137.4 (C-10). The mass fragments at *m/z* 134.0347 and 178.1397 (vide structure) confirmed this ring. The placement of the acetoxy group at C-3 was fully supported by the multiplicities of H-1, H-2 and H-3, and HMBC correlations.

The presence of a tertiary methyl signal at δ, 0.90 (3H, *s*, H-18) and absence of H-19 signal in both ^1H and ^{13}C NMR showed that **2** belongs to the estrane series of steroids. The IR spectrum further showed an absorption at 1745 cm^{-1}, characteristic of a five- membered ketone which was placed at C-17 on the basis of the connectivities of H-16a, H-16b (δ, 2.36, 2.10) and H-18 (δ, 0.90) with the carbonyl carbon (δ, 220.5) observed in the HMBC spectrum. This was further confirmed by comparison to data for other 17-keto steroids (Breitmaier and Voelter, 1978; Johnson and Jankowski, 1978). On the basis of these observations, structure **2** has been assigned to puboestrene.

The molecular formula ($C_{21}H_{27}NO_3$) of **3**, obtained through accurate mass measurement (found 341.1989, calc. for $C_{21}H_{27}NO_3$: 341.1990) of the molecular ion showed nine double-bond equivalents. Its IR (1660 cm^{-1}) and UV (245 nm) absorptions indicated the presence of 1,4-dien-3-one system in ring A. The dienone system was supported by the ^1H NMR signals at δ, 7.77 (1H, *d*, $J=10.5$ Hz), 6.10 (1H, *dd*, $J=10.5$, 2.0 Hz) and 6.09 (1H, *t*, $J=2.0$ Hz) (Table 1); the corresponding carbon signals were observed in the HMQC plot at δ, 159.1, 126.6 and 124.8, and quaternary carbons at δ, 186.9 (C-3) and 168.7 (C-5) in the broad band spectrum. This ring was substantiated by a strong peak at *m/z* 121.0727 (C_8H_9O) in the HRMS (Budzikiewicz et al., 1964). The IR spectrum also showed the presence of an OH group (3400 cm^{-1}) which was placed at C-11 with α-disposition on the basis of the evidence discussed for compound **1**. The IR spectrum (1690 cm^{-1}) and remaining degree of unsaturation revealed the presence of another carbonyl group in the molecule. The absence of a carbon-18 signal, and downfield chemical shifts of C-14 and C-20 (i.e. δ, 59.4 and 67.8) were suggestive of a carbonyl group at position 18, making a five-membered lactam ring. This was supported by a mass fragment at *m/z* 71.0371 (C_3H_5NO) in the HRMS spectrum (vide structure) and a signal at δ, 183.8 for amido carbonyl carbon in the ^{13}C NMR spectrum. Thus, pubamide has been assigned structure **3**, which was further supported by significant mass fragments (vide structure).

3. Experimental

3.1. General

Mps are uncorrected. Mass spectra were recorded on a Finnigan MAT 112 and 312 double-focusing mass spectrometer connected to a PDP 11/34 computer system; NMR spectra ($CDCl_3$ 400 MHz for ^1H and 75 MHz for ^{13}C) were recorded on a Bruker AM 400 and an AM 300 FT NMR, respectively. The chemical shifts are reported in δ, (ppm) and the coupling constants are in Hz. The ^{13}C NMR spectral assignments (Table 1) have been made partly through a comparison of the chemical shifts with the published data for similar compounds (Atta-ur-Rahman, 1990) and partly through the appearance of signals in DEPT, HMQC (Table 1) and HMBC spectra. Precoated thin-layer cards (DC-karten SiF) were used for TLC. The petroleum ether used was of the boiling range 60–70 °C. Flash column chromatography was performed on model Eyela EF-10. Si gel used was from Merck 9385 and Al_2O_3 was from Merck 90.

Ltd. It was identified by Miss. Ashreen Jahan, a botanist at Hamdard Foundation Pakistan Ltd.

3.3. Extraction and isolation

Uncrushed bark (10 kg) was macerated with 10% methanolic NaOH (10 l) for 48 h at 28 °C, and repeatedly percolated with MeOH for 48 h (five times) at the same temperature following the reported procedure (Siddiqui and Pillay, 1932) in order to hydrolyze the tannates. Each extract was neutralized with 30% aqueous HOAc. The syrupy concentrate (2 l) obtained on removal of the solvent from the combined extracts under reduced pressure was acidified by adding 10% aqueous HOAc at 28 °C and the solution was extracted with EtOAc. The aqueous phase was basified with 20% NH_3 and again shaken out with EtOAc. The EtOAc phase was treated with vigorous stream of CO_2. The precipitate containing the carbonate bases was filtered and the filtrate was dried over anhydrous Na_2SO_4 and freed of the solvent under reduced pressure. The residue (20 g) from the filtrate was divided into petroleum ether soluble and petroleum ether insoluble fractions. The petroleum ether soluble fraction yielded conessine (9 g) according to the reported isolation procedure (Siddiqui and Pillay, 1932). The petroleum ether insoluble portion (11 g), when dissolved in 10% aqueous AcOH and treated with $(NH_4)_2SO_4$, furnished a colourless precipitate of sulfates which was filtered. The sulfate mother liquor was made alkaline with 10% aqueous NaOH and extracted with EtOAc. The EtOAc phase was washed with H_2O to neutral pH, dried (Na_2SO_4) and evaporated under reduced pressure to give a colourless residue (9.5 g). This residue was subjected to flash column chromatography (Al_2O_3, Merck 90; petroleum ether, petroleum ether–EtOAc; $CHCl_3$, in order of increasing polarity). Nine fractions were ultimately obtained on combining the eluates on the basis of TLC. The major fraction eluted with $CHCl_3$ was re-chromatographed on flash column (Si gel; petroleum ether, petroleum ether–EtOAc, in order of increasing polarity). The petroleum ether–EtOAc (4:6) eluate furnished a crude fraction A (52 mg). The petro-

Received 20 December 2000; received in revised form 14 May 2001

Abstract

An investigation of the methanol and ethyl acetate extracts from the roots of *Peritassa campestris* (Hippocrateaceae) afforded the sesquiterpene pyridine alkaloid, 4-hydroxy-7-epi-chuchuhuanine E-V, and nine known alkaloids, forrestine, euonimine, ebenifoline E-I, wilforine, euojaponine F, euonine, wilforjine, neowilforine, and wilforzine. The structures of the isolates were elucidated on the basis of spectral data, particularly HMQC and HMBC experiments. © 2001 Published by Elsevier Science Ltd.

Keywords: *Peritassa campestris*; Hippocrateaceae; Sesquiterpene pyridine alkaloids; 4-Hydroxy-7-epi-chuchuhuanine E-V

1. Introduction

Sesquiterpene pyridine alkaloids, based on a highly oxygenated dihydro-β-agarofuran core on a sesquiterpene moiety, and evoninoate or wilfordate esters on their alkaloid moiety, constitute a relatively small group of natural products frequently found in plants of the Celastraceae family (Brüning and Wagner, 1978). Recently, these alkaloids have also been described in plants of the Hippocrateaceae (Mata et al., 1990; Lião et al., 1997). This chemical aspect reinforces the recent botanical classification in which the two families, Celastraceae and Hippocrateaceae, appear to be grouped in the Celastraceae (Brüning and Wagner, 1978; Heywood, 1993). These alkaloids have also been of interest due to their cytotoxicity against several human tumour cell lines (Kuo et al., 1994), and their insect antifeedant, and insecticidal activities (Shirota et al., 1994). Sesquiterpene pyridine alkaloids isolated from *Tripterygium* species have also shown immunosuppressive activity (Zheng et al., 1989).

As part of our continuing search for bioactive compounds from plants, especially from the savanna, we investigated the MeOH and EtOAc soluble portions of the crude extract of the roots of *Peritassa campestris* Cambess. (Hippocrateaceae), a plant that occurs in the Brazilian savanna (Cerrado), popularly known as "bacupari do campo", and which is used in folk medicine for wound healing in the form of a decoction (Septímio, 1994). In this paper we report the isolation and structure elucidation of a new sesquiterpene pyridine alkaloid, 4-hydroxy-7-epi-chuchuhuanine E-V (**1**), and the isolation of nine known alkaloids forrestine (Chunquan et al., 1992), euonimine, ebenifoline E-I, euojaponine F, euonine (Itokawa et al., 1993), wilforine (Beroza, 1951), wilforjine (Deng et al., 1992), neowilforine (He et al., 1989), and wilforzine (He et al., 1987).

2. Results and discussion

4-Hydroxy-7-epi-chuchuhuanine E-V (**1**) was isolated as a colorless amorphous solid, in low yield, and its IR spectrum displayed absorptions at 3614, 1740, and 1583 cm^{-1}. The ^1H and ^{13}C NMR spectra suggested a dihydro-β-agarofuran sesquiterpene skeleton with an evoninic diester bridge. The sesquiterpene moiety was characterised in the ^1H NMR spectrum by tertiary methyl groups at δ 1.67 (3H, *s*, Me-14) and δ 1.58 (3H, *d*, $J=1.2$ Hz, Me-12), coupling with one hydrogen-bonded hydroxyl group at δ 4.50 (*q*, $J=1.2$ Hz, OH-4), two sets of methylene protons at δ 4.62 (*d*, $J=13.6$ Hz, H-11a), δ 5.28 (*d*, $J=13.6$ Hz, H-11b), δ 3.67 (*d*, $J=11.6$ Hz, H-15a) and δ 5.98 (*d*, $J=11.6$ Hz, H-15b), seven methine protons at δ 5.43 (*d*, $J=4.0$ Hz, H-1), 4.07 (*dd*, $J=4.0$

PII: S0031-9422(01)00315-6

and 2.4 Hz, H-2), 4.76 (*d*, $J=2.4$ Hz, H-3), 7.03 (*s*, H-5), 2.33 (*d*, $J=4.0$ Hz, H-6), 5.53 (*dd*, $J=6.0$ and 4.0 Hz, H-7) and 5.35 (*d*, $J=6.0$ Hz, H-8), and five acetyl groups at δ 2.31, 2.21, 2.15, 2.01 and 1.95. A further oxygenated functional group was assumed to be a hydroxyl group, based on a broad singlet at δ 3.65 (exchanged with D_2O). The evoninic acid fragment in **1** was assigned by the signals at δ 8.05 (*dd*, $J=8.0$ and 2.0 Hz, H-4′), 7.26 (*dd*, $J=8.0$ and 4.8 Hz, H-5′) and 8.69 (*dd*, $J=4.8$ and 2.0 Hz, H-6′), corresponding to a 2,3-disubstituted pyridine unit. It also contains two secondary methyl groups at δ 1.38 (*d*, $J=6.8$ Hz, Me-9′) and 1.15 (*d*, $J=7.2$ Hz, Me-10′), coupled with two methine protons at δ 4.66 (*dq*, $J=6.8$ and 1.0 Hz, H-7′) and 2.53 (*dq*, $J=7.2$ and 1.0 Hz, H-8′). This sesquiterpene pyridine alkaloid includes one macrocyclic structure formed by two ester linkages between one sesquiterpene molecule and one evoninic acid, at positions 3 and 15. In order to determine the positions of the acetate groups and consequently the hydroxyl group position, ^1H–^1H COSY, HMQC and HMBC spectra were recorded. In the former the cross-peak of H-2 (δ 4.07) with H-1 (δ 5.43) and H-3 (δ 4.76), suggested the position of the hydroxyl group at C-2, which reinforced by the observation that H-2 was at higher field than the corresponding proton in alkaloids containing a benzoyl or acetyl group, attached to this position. This proposal was confirmed by the HMBC spectrum which located the acetate groups by cross-peaks between these groups and H-1, H-5, H-7, H-8, and H-11. The ^{13}C NMR spectrum showed 36 signals, characteristic of evoninoate sesquiterpene pyridine alkaloids and showing five acetate groups. The carbon attached to the hydroxyl group appeared at δ 69.65, approximately δ 1.0 deshielded when compared with alkaloids with an acetate group at carbon 2. Additional support was obtained by a full scan ESI mass spectrum, where the molecular ion peak for this compound was detected at m/z 764 ($[M+H]^+$), reinforcing this structural proposal.

The relative stereochemistry around the dihydroagarofuran nucleus was determined from the coupling constants to be the same as other alkaloids isolated, including wilforine, wherein the stereochemistry was determined by X-ray analysis (Lião et al., 1997). The C-7 epimeric relationship between this compound and chuchuhuanine E-V (**1a**), was defined by the coupling constant between H-7 and H-8. While in **1** this coupling constant was 6.0 Hz, in **1a** it was 9.4 Hz (Shirota et al., 1994), indicating a *cis* and *trans* H-7/H-8 relationship for **1** and **1a**, respectively.

Alkaloid **1** was assayed for lethality in the brine shrimp toxicity (BST) test, and showed LC_{50} 99.0 μg/ml. This test is proposed as a simple bioassay for natural product research, which active compounds could then be subjected to more elaborate bioassays for specific pharmacological activities. Sesquiterpene pyridine alkaloids was assayed against several tumor cell lines, and emarginatine F turned out to be active against some cell lines (Kuo et al., 1994).

3. Experimental

3.1. General experimental procedures

NMR: Bruker DRX 400, in $CDCl_3$ and TMS as int. standard; ESI-MSMS: low resolution on a triple quadrupole Micromass Quattro LC instrument, equipped with a "Z-spray" ion source; HRMS were obtained on a Fisons VG Autospec; $[\alpha]_D$: Perkin-Elmer 241 instrument; DCCC: Tokyo Rikakikai Co. with 300 columns of 40 cm×2 mm i.d.

3.2. Plant material

Roots of *P. campestris* were collected in a Savanna Reserve at Universidade Federal de São Carlos, in October 1992 and identified by Dr. Maria Helena de O. Antunes, Departamento de Botânica, Universidade Federal de São Carlos, São Paulo, Brazil, wherein a voucher specimen (no. 2845) is deposited.

3.3. Extraction and isolation

The roots were dried, powdered (2.8 kg) and successively extracted with hexane, CH_2Cl_2 and MeOH at room temperature. The combined extracts were submitted to liquid-liquid partition, resulting in hexane (5.1 g), methanol (35.84 g), ethyl acetate (5.87 g), *n*-butanol (5.21 g), and aqueous (23.80 g) extracts. The methanolic extract (3.5 g) was submitted to droplet countercurrent chromatography (DCCC), using the aqueous layer of hexane:MeOH:H_2O:EtOAc (5:4:1:2) as the stationary and the organic layer as the mobile phase, in a flow rate of 0.6 ml/min. The collected fractions were monitored by TLC and grouped in 22 fractions. Fractions 20–22 were separately filtered on Florisil (70–230 mesh) using hexane:CH_2Cl_2:MeOH (8:2:0.5). Fraction 20 was flash chromatographed on silica gel (230–400 mesh), eluting with hexane: CH_2Cl_2:MeOH (8:2:0.5), affording wilforine

(330.0 mg, 9.428%) and a mixture of sesquiterpene pyridine alkaloids. Fraction 22 was submitted to recycling HPLC using a GS-310P column (MeOH; 50.0× 2.15; 3 ml/min; UV 254 nm), affording euojaponine F (15.7 mg, 0.448%), wilforjine (5.9 mg, 0.168%), wilforzine (3.5 mg, 0.100%), and another mixture of alkaloids. The ethyl acetate extract (3.0 g) was also submitted to DCCC, using the aqueous layer of $CHCl_3$:MeOH:*n*-BuOH:H_2O (10:10:1:6) as the stationary and the organic layer as the mobile phase, in a flow rate of 0.6 ml/min, and after TLC was grouped in 12 fractions. Fractions 3, 4 and 5, after Florisil filtration, were individually submitted to recycling HPLC under the same conditions as the methanol extract, affording forrestine (186.8 mg, 6.226%), wilforine (50.1 mg, 1.670%), euojaponine F (0.4 mg, 0.013%), euonine (4.2 mg, 0.140%), neowilforine (4.3 mg, 0.143%), euonimine (6.1 mg, 0.203%), and a mixture of sesquiterpene pyridine alkaloids. The mixtures of alkaloids obtained were monitored by TLC using the Dragendorff reagent and grouped into two sets. The second set was rechromatographed on recycling HPLC using a Shim-pack column (silica 5 μ; 2.0×25 cm; hexane: CH_2Cl_2:MeOH− (8:2:0.5); 3 ml/min; UV 254 nm), affording the alkaloid **1** (1.5 mg, 0.023%) and ebenifoline E-I (2.0 mg, 0.038%).

3.4. Biological assays

The in vitro lethality assay against *Artemia salina* (BST) was carried out according to procedures described in Alkofahi et al. (1989).

3.4.1. 4-Hydroxy-7-epi-chuchuhuanine E-V (*1*)

This was obtained as a colorless amorphous solid: $[\alpha]_D^{20}$ −37.4° ($CHCl_3$; 0.002,); UV λ_{max}^{MeOH} nm (log ε): 201 (3.92), 223 (3.61), 265 (3.24) nm; IR $\nu_{max}^{CHCl_3}$ cm^{-1}: 3614, 1740, 1583, 1566, 1231 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$): see text; ^{13}C NMR (100 MHz, $CDCl_3$): δ 9.3 (*q*, C-10′), 11.8 (*q*, C-9′), 18.5 (*q*, C-14), 20.5 (*q*, $OCO\underline{C}H_3$), 20.8 (*q*, $OCO\underline{C}H_3$), 21.0 (*q*, $OCO\underline{C}H_3$), 21.4 (*q*, $OCO\underline{C}H_3$), 21.6 (*q*, $OCO\underline{C}H_3$), 22.7 (*q*, C-12), 36.3 (*d*, C-7′), 44.9 (*d*, C-8′), 50.4 (*d*, C-6), 52.5 (*s*, C-9), 60.3 (*t*, C-11), 68.9 (*d*, C-7), 69.6 (*d*, C-2), 69.9 (*t*, C-15), 70.4 (*s*, C-4), 70.9 (*d*, C-8), 73.8 (*d*, C-5), 75.3 (*d*, C-1), 77.9 (*d*, C-3), 83.9 (*s*, C-13), 94.4 (*s*, C-10), 121.1 (*d*, C-5′), 125.3 (*s*, C-3′), 137.6 (*d*, C-4′), 151.4 (*d*, C-6′), 165.1 (*s*, C-2′), 165.1 (*s*, $O\underline{C}OCH_3$), 168.5 (*s*, C-12′), 169.1 (*s*, $O\underline{C}OCH_3$), 169.3 (*s*, $O\underline{C}OCH_3$), 169.9 (*s*, $O\underline{C}OCH_3$), 170.1 (*s*, $O\underline{C}OCH_3$), 174.4 (*s*, C-11′); ESI-MSMS (probe) 30 eV, *m*/*z* (rel. int.): 764 $[M+H]^+$ (5), 746 (21), 728 92), 686 (9), 206 (100), 188 (9), 178 (33), 160 (6); HR-MS *m*/*z*: 763.2672 (calcd for $C_{36}H_{45}NO_{17}$, 763.2687).

Received 13 June 2001; received in revised form 18 July 2001

Abstract

The presence of betacyanin pigments and their isoforms has been detected in the fruit of *Hylocereus polyrhizus*, a vine cactus native to South America. Along with the known betanin and phyllocactin (6′-*O*-malonylbetanin), a new betacyanin was structurally elucidated as betanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methyl-glutaryl)-β-D-glucopyranoside] (proposed trivial name hylocerenin) by means of electrospray MS/MS, HPLC, and NMR techniques. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Vine cactus; *Hylocereus polyrhizus*; Cactaceae; Betacyanins; Betalains; Betanin; Phyllocactin

1. Introduction

Hylocereus polyrhizus [(F. A. C. Weber) Britton and Rose] and its related species belong to the vine cacti from the subfamily Cactoideae of the tribe Cacteae (Raveh et al., 1993). This tribe contains many species with edible fruits mostly known as pitaya, or pitahaya. The common name of these fruits is pitaya since they contain scales on the fruit skin and hence the name pitaya "the scaly fruit" (Canto, 2000).

In the last two decades efforts have been made to develop the cultivation of pitayas, vine species of the genus *Hylocereus*. Some of them contained pulp of red and/or purple colors of various hues (Mizrahi et al. 1997; Mizrahi and Nerd, 1999; Canto, 2000). In Israel, some of these cacti are already produced commercially, among them *Hylocereus polyrhizus* with glowing deep red-purple fruit flesh (Fig. 1) (Mizrahi and Nerd, 1999). The pulp of *H. polyrhizus* is already used in Israel for the production of red-violet colored ice cream. They have also the potential to be used in low temperature dairy drinks and in light drinks with or without other fruit juices. In cacti the most important fruit pigments are the betacyanins and betaxanthins (Gibson and Nobel, 1986), the betalains.

The pigments in these newly domesticated species are unknown, therefore, their structure elucidation is reported here.

2. Results and discussion

The presence of the betacyanins (**1**–**3**) and their *15R*-isoforms (**1′**–**3′**) has been detected by HPLC of fruit pulp extracts from *H. polyrhizus* by their characteristic spectral properties (Fig. 2). From the ratio of the absorbances at 540 and 320 nm (1:0.14) the presence of hydroxycinnamoyl residues as acylating moieties in **1**–**3** can be excluded (Heuer et al., 1994).

Compounds **1/1′** were assigned as betanin and isobetanin, by UV-vis spectroscopy and co-chromatography with authentic betanin from red beet. The assignment was confirmed by ESI–MS/MS giving the expected protonated molecular ion $[M+H]^+$ (m/z 551) and the prominent daughter ion at m/z 389 [betanidin + H]$^+$. Subsequent NMR analysis confirmed undoubtedly the aglycones (betanidin, isobetanidin) in the compounds **1** and **1′**, respectively. The only significant differences in

Fig. 1. Fruits of *Hylocereus polyrhizus*.

chemical shifts are a small (0.03 ppm) shielding of H-15. The suggestion is that the pairs of compounds are *11Z* or *E* isomers. The small chemical shift difference between H-4 and H-7 of 0.12 ppm is characteristic of a substitution of the hydroxyl group at C-5 (Heuer et al., 1992, 1994). The signals of the ^{1}H NMR were comparable to those published recently (Strack et al., 1993).

Compounds **2** and **2′** were identified as already known phyllocactin and isophyllocactin, respectively (Fig. 3) (Minale et al., 1966). The MS and NMR data of phyllocactin has been recently discussed (Kobayashi et al., 2000). The protonated parent ion ($[M+H]^+$) for compound 2 was found at *m/z* 637 [550 (betanin) + 86 (malonyl) + H]$^+$ and the daughter ions at *m/z* 551 [betanin + H]$^+$ and 389 [betanidin + H]$^+$. Additional ions at *m/z* 619 and 593 were assigned to losses of H_2O and CO_2 (Table 1). The 1D and 2D ^{1}H NMR data of **2** and **2′** were virtually the same as published recently (Kobayashi et al., 2000). The presence of the aglycone, glucose and malonyl moieties was confirmed and the small chemical shift of 0.14 ppm

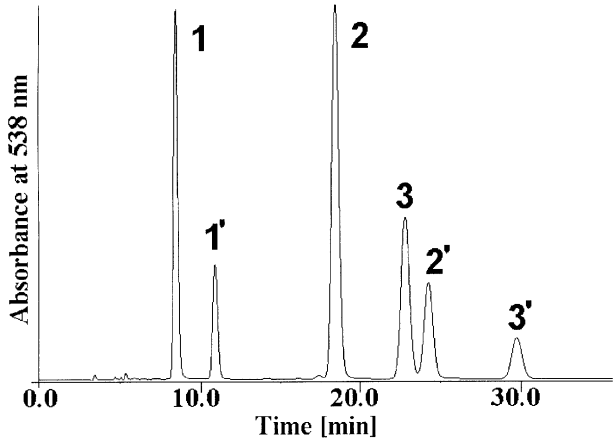

Fig. 2. HPLC pattern of betacyanins from fruit pulp of *Hylocereus polyrhizus*. For peak identification see Table 1. Peak numbers refer to Fig. 3.

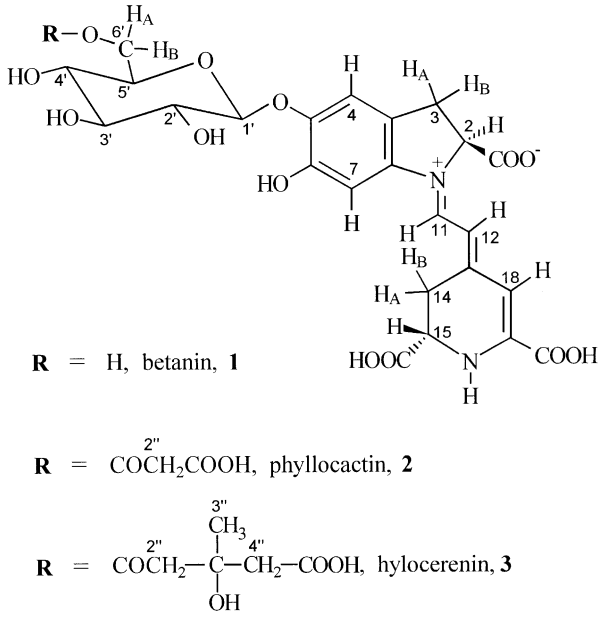

Fig. 3. Chemical structures of analyzed betacyanins in *Hylocereus polyrhizus*. Compound numbers refer to Fig. 2 and Table 1.

between H-4 and H-7 indicated the substitution at the hydroxyl group at C-5 of betanidin. Additionally the AB quartet of H-2″A/H-2″B at $\delta = 3.46$ ppm suggested a malonate moiety. The low field chemical shift of H-6′A/H-6′B (4.59 and 4.35) provides definitive evidence that the malonate moiety is bound to C-6′.

The protonated parent ion ($[M+H]^+$) for compound **3** was found at *m/z* 695 (Table 1). Characteristic ions at *m/z* 551 and 389 indicated that compound **3** is a derivative of betanin and betanidin. The mass difference (*m/z* 695–551) of 144 suggested the presence of aliphatic acyl moiety connected to the glucose of **1**. The additional ions found after fragmentation of $[M+H]^+$ for **3** and **3′** at *m/z* 677, 651 and 633 were assigned to losses of H_2O and CO_2. Compounds **3** and **3′** had ^{1}H NMR spectra which were virtually identical to those of **2** and **2′**, respectively, except of the absence of the malonate protons H_2-2″ at $\delta = 3.46$ ppm. Instead, an extra singlet of H_3-3″ (methyl group) at $\delta = 1.57$ ppm and two new methylene groups at $\delta = 2.89$ ppm (singlet of H-4″) and 2.71 ppm (AB quartet of H-2″A/H-2″B) were seen. These data are in accordance with the MS data and are indicative for the presence of a 3-hydroxy-3-methylglutaryl moiety (HMG) at C-6′ of betanin.

Hence, the combination of ESI–MS and ^{1}H NMR data identified **3** as betanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methylglutaryl)-β-D-glucopyranoside], a new betacyanin pigment (Fig. 3). A similar compound, amaranthin acylated with 3-hydroxy-3-methyl-glutaric acid (iresinin-I) has been isolated from *Iresine herbstii* (Amaranthaceae) (Minale et al., 1966). Upon β-glucuronidase treatment iresinin-I yielded glucuronic acid and degradation products (Minale et al., 1966) containing most probably 6′-HMG-betanin, an

Table 1

[a] Compound numbers correspond to peak numbers in Fig. 2.
[b] New compound: betanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methyl-glutaryl)-β-D-glucopyranoside].
[c] New compound: isobetanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methyl-glutaryl)-β-D-glucopyranoside].

artificially formed compound, which is now shown to be an endogenously occurring pigment in *H. polyrhizus*.

The *15S*-forms are eluted in HPLC (ODS-type columns with acidic eluents) earlier than the *15R*-forms (the isoforms) (Bokern et al., 1991; Schliemann et al., 1996). Therefore, peaks **1**, **2** and **3** can be attributed to betanidin based forms, whereas peaks **1′**, **2′** and **3′** to isobetanidin based forms.

The contents of all pigments in purified extracts before HPLC fractionation ranged between 30 and 80 mg betanin equivalents/100 g of fresh fruit pulp, taking E_{538} (1%) = 1120 (Forni et al., 1992) for spectrophotometric calculations of betacyanins concentration in purified extracts. Fruit pulp of *H. polyrhizus* is characterized by the glowing purple-red colour, which can be attributed to the presence of **3** in the fruit. Assuming that the E_{538}(1%) of the all pigments are similar, the relative concentrations of *H. polyrhizus* pigments were calculated from the chromatogram (Fig. 2) and showed in Table 1.

In summary, the betacyanins of fruits of *H. polyrhizus* were identified as the known betanin, phyllocactin and their *iso*-forms. Additionally, a new betacyanin was identified as betanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methyl-glutaryl)-β-D-glucopyranoside] and its isoform. The formation of the *15R*-isoforms (**1′–3′**) may occur during fruit maturation, but they could be also artefacts of isolation.

3. Experimental

3.1. Plant material

Seven-year-old plants of *Hylocereus polyrhizus* grown on trellis system under greenhouse conditions in Beer-Sheva, Israel, were used (Mizrahi and Nerd, 1999). All flowers were hand-crossed pollinated with other compatible clones and tagged (Weiss et al., 1994). Fruits were harvested for analysis when reaching full ripening stage, 35 days after pollination for *H. polyrhizus* (Nerd et al., 1999). The edible pulp was taken for analysis.

3.2. Pigment extraction

One hundred grams of the peeled fruit (of watery consistency) were shaken with 200 ml 80% aq. EtOH for few minutes, followed by fast filtration and centrifugation at 18 000 rpm and −4 °C for 20 min. After careful decantation, the extract was concentrated in vacuo at 25 °C to 3–4 ml and stored in a dark vessel at −18 °C. The roots from red beet (*Beta vulgaris*) was processed by the same procedure.

3.3. Extract purification

The concentrated betacyanin extracts were purified prior to prep. HPLC by column chromatography (40×1.2 cm, i.d.) on Sephadex G-25 (Sigma Steinheim, Germany) according to Adams and von Elbe (1977) and subsequently on LH-20-100 (Sigma Steinheim, Germany) (Schliemann et al., 1996). The betacyanin fractions were lyophilized.

3.4. HPLC

Preparative HPLC was carried out with a Waters Delta Prep 4000 prep. chromatography system (Waters, Milford MA, USA) equipped with a LiChroCART® 250-10, LiChrospher® 60 RP-select B, (10 μm) column protected by a guard column. The separation was performed isocratically using a mixture of 90% solvent A (0.5% aq. TFA) with 10% solvent B (acetonitrile) for 35 min, at a flow rate of 3.1 ml min^{-1} (injection volume: 1 ml; detection at 538 nm). **1**: R_t 14–17 min; **2**: R_t 25–29 min; **3**: R_t 41–45 min. To remove the solvent, the pooled fractions were concentrated in vacuo and subsequently lyophilised. The yields were: **2**—3.3 mg; **3**—2.1 mg. After checking the purity of the fractions by analytical HPLC the compounds were dissolved in appropriate solvents prior to analysis by UV/vis, electrospray MS/MS or ^{1}H NMR. Analytical HPLC was carried out on LC-10AT-VP chromatograph with photodiode-array SPD-M10A VP detector (Shimadzu Corp., Kyoto, Japan) equipped

with a LiChroCART® 250-4, LiChrospher® 60 RP-select B, (5 μm) column. The elution system was the same as for the prep. HPLC at a flow rate of 0.5 ml/min (injection volume: 10 μl; detection at 538 nm).

3.5. UV/vis

UV/vis absorption spectra in the range of 200–800 nm were recorded with a Jasco U-530 UV/vis spectrophotometer (JASCO Corp., Tokyo, Japan). On-line spectra in the range of 200–700 nm were obtained by HPLC-photodiode array detection.

3.6. Electrospray MS/MS and NMR

Electrospray mass spectra were obtained with LCQ Deca FINNIGAN-MAT mass spectrometer (subsidiary of ThermoQuest Corp., USA), operating in the positive ion, full scan MS/MS mode. The spectra were taken in the presence of minute quantities of formic acid promoting $[M+H]^+$ ion production (electrospray voltage 4.5 kV, heated capillary temperature 210 °C; sheath gas: nitrogen; injection: 80 μl min^{-1}).

Compound **1** (betanin), (positive ion mode) (*m*/*z*, rel. int.): 551 $[M+H]^+$ (100). Compound **2** (phyllocactin), (positive ion mode) (*m*/*z*, rel. int.): 637 $[M+H]^+$ (100); daughter ion scan mode of *m*/*z* 637: 619 $[M+H-H_2O]^+$ (20); 593 $[M+H-CO_2]^+$ (100); 551 [betanin + H]$^+$ (65); 389 [betanidin + H]$^+$ (18). Compound **3** (hylocerenin), (positive ion mode) (*m*/*z*, rel. int.): 695 $[M+H]^+$ (100); daughter ion scan mode of *m*/*z* 695: 677 $[M+H-H_2O]^+$ (5); 651 $[M+H-CO_2]^+$ (3); 633 $[M+H-CO_2-H_2O]^+$ (7); 551 [betanin + H]$^+$ (3); 389 [betanidin + H]$^+$ (100).

1D and 2D ^{1}H (COSY) NMR spectra were recorded at 300 K on a Bruker DMX-600 instrument locked to the major deuterium resonance of the solvent, CD_3OD containing traces of DCl. Chemical shifts are given in ppm relative to TMS and coupling constants in Hz.

Compound **3** {betanidin 5-*O*-[6′-*O*-(3″-hydroxy-3″-methyl-glutaryl)-β-D-glucopyranoside]} ^{1}H NMR (600.1 MHz, CD_3OD/DCl) $\delta = 8.69$ (1H, *d*, $J_{11-12} = 12.3$ Hz, H-11), 7.34 (1H, *s*, H-7), 7.22 (1H, *s*, H-4), 6.46 (1H, *s*, H-18), 6.24 (1H, *d*, H-12), 5.47 (1H, *dd*, $J_{2-3A} = 9.9$ Hz, H-2), 4.87 (1H, *d*, $J_{1'-2'} = 7.8$ Hz, H-1′), 4.64 (1H, *dd*, $J_{15-14A} = 5.3$ Hz, $J_{15-14B} = 7.3$ Hz, H-15), 4.56 (1H, *dd*, $J_{6'A-6'B} = 12.1$ Hz, H-6′A), 4.37 (1H, *dd*, H-6′B), 3.74 (1H, *m*, $J_{5'-6'A} = 2.1$ Hz, $J_{5'-6'B} = 6.5$ Hz, H-5′), 3.73 (1H, *dd*, $J_{3A-3B} = 16.4$ Hz, H-3A), 3.72 (1H, *dd*, $J_{14A-14B} = 17.4$ Hz, H-14A), 3.57 (1H, *m*, H-2′), 3.53 (1H, *m*, H-3′), 3.50 (1H, *dd*, H-3B), 3.43 (1H, *m*, H-4′), 3.31 (1H, *dd*, H-14B), 2.89 (2H, *s*, H-4″), 2.71 (2H, AB*q*, H-2″A, H-2″B), 1.57 (3H, s, H-3″).

Received 28 May 2001; received in revised form 23 July 2001; accepted 23 July 2001

Abstract

A new anthraquinone glycoside, emodin-6-*O*-β-D-glucopyranoside, and a new simple halogenated flavan-3-ol, 6-chlorocatechin, have been isolated from the roots of *Rumex patientia* L. together with seven known phenolic compounds. Their structures were elucidated on the basis of spectroscopic methods. Cytotoxic effects and radical scavenging properties of the isolated compounds have been demonstrated. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Rumex patientia*; Polygonaceae, Anthraquinones; Emodin-6-*O*-β-D-glucopyranoside; Tannins; 6-Chlorocatechin

1. Introduction

The dried roots of *Rumex patientia* L. (Polygonaceae) have been used as purgative, constipate, depurative and tonic in Turkish traditional medicine (Baytop, 1984). It was reported that *R. patientia* contains anthraquinone, tannin, naphthalene and naphthoquinone derivatives (Sharma et al., 1977; Demirezer and Kuruüzüm, 1997b; Suri et al., 1978). A literature search revealed only few information on the characterization of tannins and anthraquinone glycosides from *Rumex* species. Previously we reported that the aqueous extract of the roots of *R. patientia* exhibited a highly antiinflammatory activity (Süleyman et al., 1999). Several novel naphthalenes from this material have been also reported by our group (Kuruüzüm et al., 2001). In the course of continuous studies on this plant a new anthraquinone glycoside, emodin-6-*O*-β-D-glucopyranoside (**6**), a new simple halogenated flavan-3-ol, 6-chlorocatechin (**7**) and seven known compounds, chrysophanol (**1**), physcion (**2**), emodin (**3**), chrysophanol-8-*O*-β-D-glucopyranoside (**4**), emodin-8-*O*-β-D-glucopyranoside (**5**), catechin (**8**) and orcinol (**9**) were isolated. Cytotoxic effects and radical scavenging properties of this compounds have been investigated.

2. Results and discussion

The aqueous and methanolic extract of the roots of *R. patientia* were subjected to repeated different column chromatographies to yield compounds **1**–**9**. Known compounds were shown to be chrysophanol (1), physcion (**2**), emodin (**3**), chrysophanol-8-*O*-β-D-glucopyranoside (**4**, emodin-8-*O*-β-D-glucopyranoside (**5**), catechin (**8**) and orcinol (**9**) by comparison with authentic samples and their spectral data with those previously reported (Cohen and Towers, 1995; Coskun et al., 1990; Demirezer, 1991; Foo and Karchesy, 1989; Lin et al., 1990; Lin and Wei, 1993; Markham and Geiger, 1993; Pascual Teresa et al., 1986; Sakar et al., 1993; Van Der Nat et al., 1991).

The presence of the anthraquinone derivatives and flavan-3-ols were detected by TLC on Si gel with spraying a 5% KOH solution and 1% vanillin-H_2SO_4, respectively, according to their red spots. Colour reactions and the UV and IR spectra of the compounds (**1**–**6**) indicated that they contain a hydroxy anthraquinone chromophor. The infrared spectrum of **6** showed the presence of free hydroxyl groups (3432 cm^{-1}), non-chelated (1670 cm^{-1})

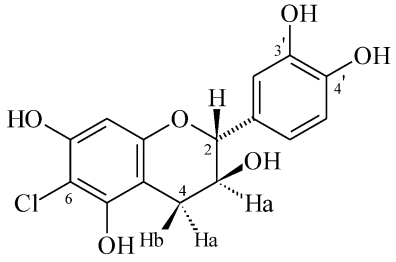
Compound 6



Compound 7

and chelated carbonyl groups (1633 cm^{-1}) and aromatic ring moieties (1060 cm^{-1}). In the UV spectrum of 6, absorption maxima were exhibited at 223, 264, 293 sh and 411 nm.

The structure of compound **6**, $C_{21}H_{20}O_{10}$, in DMSO-d_6 was determined from the one-dimensional ^1H and ^{13}C NMR spectra and by using 2D sequences. The ^1H NMR spectrum of compound **6** (see Table 1) exhibited two doublet signals at δ 7.33 and 7.87 (each 1H, *d*, $J = 2.1$ Hz) due to meta coupled aromatic protons at H-5 and H-7, respectively; two broad singlet signals at δ 7.17 and 7.50 (each 1H) assigned to H-2 and H-4, respectively; aromatic methyl proton signal at δ 2.42 (3H, s), a glucosyl anomeric proton at δ 5.07 (*d*, $J = 7.4$ Hz) and the other proton signals of the sugar moiety, indicating the presence of a β-glucosidic moiety attached to one of the hydroxyl groups of emodin. In the COSY experiment, cross peaks were revealed between the methyl proton signal and aromatic protons (H-2, H-4) indicating that the methyl group was next to them on the same aromatic ring.

Furthermore, in the ^{13}C NMR spectrum (see Table 1), the characteristic signals of emodin were observed. The proton bearing carbon atoms were assigned with a HMQC experiment. A HMBC experiment was used to determine the position of different carbon atoms of 6. However, the assigment of positions **6** and **8** for compounds **5** and **6** was not possible by means of HMBC experiments as the proton H-7 (δ_H 7.33) correlated with both neighboured carbon atoms (**5**: δ_C 173.9, 163.3 and **6**: δ_C 159.9, 159.7) and proton 5 (δ_H 7.87) with none of them.

Other spectroscopic experiments such NOESY delay or relay COSY have been carried out but none of them allowed an exact assigment of these two carbon atoms. For **5** and **6**, a HMBC correlation between 1′-H (**5**: δ_H 4.95 and **6**: δ_H 5.07) of the glucose unit and the aglycone (**5**: δ_C 163.3 and **6**: δ_C 159.9) can be observed. In both cases, the considered carbon atom is not at position 1. Based on a comparison with literature data (Demirezer, 1991) compound **5** was assumed to be emodin-8-glucoside and compound **6**, which exhibited remarkable differences to **5** in ^{13}C data especially at position 6 (**5**: δ_C 173.9 and 6: δ_C 159.9) and its physical data (R_f ($CHCl_3$/CH_3OH/H_2O, 80:20:2) *5*: 0.36, *6*: 0.08) was deduced to be emodin-6-*O*-β-D-glucoside.

Colour reaction and the UV and IR spectra of compound **7** suggested the presence of a flavan-3-ol skele-

ton. Its ESI MS gave ion double peaks for $[M–H]^+$ at m/z 325/323 and $[2M–H]^+$ at *m/z* 649/647 with the isotope pattern of a chloro derivative, indicating the compound **7** to be a chloro flavan-3-ol. This conclusion was supported by the 1D and 2D NMR spectral data. Based on this results, the molecular formula of **6** was determined as $C_{15}H_{13}O_6Cl$.

The ^{1}H NMR spectrum of **7** (see Table 2) in CD_3OD exhibited a singlet at δ 6.07 of an aromatic proton; two doublets at δ 6.81 ($J=1.8$ Hz) and 6.75 ($J=8.1$ Hz) and a doublet of doublet at δ 6.69 ($J=8.1/1.8$ Hz) which were assigned to H-8, H-2, H-5 and H-6, respectively. However, the proton resonances observed at δ 4.75 (H-2, *d*, $J=6.7$ Hz), δ 4.02 (H-3, dd*d*, $J=$ 7.2/6.7/5.2 Hz), δ 2.76 (H-4α, d*d*, $J=16.3/5.2$ Hz) and δ 2.55 (H-4β, d*d*, $J=16.3/7.2$ Hz). The large coupling constant ($J=6.7$ Hz) of H-2 with H-3 indicated that this unit had the 2, 3 *trans* configuration. The ^{1}H NMR data of **7** were similar to those of catechin except for the presence of signal due to H-6.

The assigments for all carbons and protons of **7** (see Table 2) were determined from 1D (^{1}H, ^{13}C) NMR and 2D (COSY, HMQC, HMBC) NMR spectra. In comparison to the ^{13}C NMR spectrum of catechin, the C-6 resonance of compound **7** was shifted almost 5 ppm downfield to δ 100.18. Therefore, the chloro group was considered to be located at position C-6. ^{1}H, ^{1}H-homonuclear COSY spectrum showed the aromatic protons in the same spin system.

Considering the coupling constant of H-2 and H-3 and the sign and the value of the optical rotation of 7 ($[\alpha]_D^{20}=+50^\circ$, c = 0.16, DMSO), it can be deduced that the absolute stereochemistry of **7** is (2*R*,3*S*)-6-chloro-5,7,3′,4′- tetrahydroxylflavan-3-ol [= 6-chlorocatechin]. This is the first report of the occurrence of a halogenated flavan-3-ol in nature.

In the present study, compounds **7** and **8** exhibited a potent DPPH radical scavenging activity while compounds **1**–**6** and **9** did not show any activity.

Cytotoxicity tests were done with MCF (human breast carcinoma), HM02 (human melanoma) and HEPG2 (Human epidermoid carcinoma) cells. Compounds **1**–**9** did not inhibit the growth of the cell lines. In our previous study, *R. patientia* was examined against brine shrimp and was found to possess potent cytotoxic activity ($LC_{50}=1.30$ μg/ml) Nevertheless purified anthraquinone aglycons from *Rumex scutatus* possesses strong cytotoxic activity but anthraquinone glycosides and catechin are inactive (Demirezer and Kuruüzüm, 1997a).

In conclusion, using either varying cell lines or cytotoxic methods may bring forth differences.

3. Experimental

UV: Shimadzu UV-160A Spectrophotometer; IR: Perkin-Elmer FTIR 1720X Infrared Spectrometer; ^{1}H NMR and ^{13}C NMR spectra: Bruker AMX-300 at 300 MHz (for proton) and 75.5 MHz (for carbon) ; EI MS: Finnigan MAT 311A (70 eV); DCI MS: Varian MAT

731; TLC: normal phase Si gel 60 F_{254} (Merck 5554, 0.2 mm) and reversed phase Si gel, RP18 F_{254} (Merck 5559,0.2 mm); CC: normal phase Si gel 60 (Merck, 0.063 - 0.200 mm), reversed phase Si gel (LiChroprep RP-18, Merck 25–40 μm), sephadex LH-20 (Fluka), polyamide (Polyamid-MN-polyamid SC 6, Macherey-Nagel, Düren). In CC, fractions were selected on the basis of TLC and pooled.

3.1. Plant material

Roots of *Rumex patientia* L. were collected from Bor/Nigde, Turkey in September 1996 at an altitude of 1050 m. A voucher specimen (no: HUEF 96003) has been deposited in the Herbarium of the Faculty of Pharmacy, Hacettepe University, Ankara, Turkey.

3.2. Extraction and isolation

As a preliminary step, dried and powdered roots of *Rumex patientia* L. (500 g) were extracted with water (2×3.5 l) at 40–60 °C. The aqueous extracts were combined and concentrated. The suspended residue was partitioned with *n*-hexane, EtOAc and *n*-BuOH, respectively. Each extract was concentrated and lyophilized in vacuo.

The *n*-hexane fraction (370 mg) was chromatographed on Si gel column with a gradient of petroleum ether and EtOAc to yield compound **1** (15 mg) and compound **2** (20 mg).

The *n*-BuOH fraction (4.6 g) was subjected to Si gel column chromatography eluted with $CHCl_3$–MeOH (90:10→20:80) to give compound **3** (14 mg).

The EtOAc fraction (1.7 g) was applied to a polyamide column using increasing amounts of MeOH in H_2O. The fractions eluted with 40 and 50% MeOH were subjected to MPLC using RP-18 material as stationary phase and a H_2O-MeOH gradient solvent system and purified by repeated sephadex LH-20 column chromatographies eluted with MeOH to afford compound **4** (23 mg), compound **7** (7 mg), compound **8** (17 mg) and compound **9** (17 mg).

As the second step, dried and powdered roots of *R. patientia* (500 g) were extracted with MeOH (3×2.5 l) at 40–60 °C and evaporated to dryness (99 g). Aqueous extract, isolated compounds and methanolic extract were compared by TLC. In addition to the presence of the isolated compounds, several non-isolated anthraquinone derivatives were found in the methanolic extract.

Forty grams of methanolic extract were fractionated on a polyamide column by a gradient elution with H_2O–MeOH mixtures. The fractions eluted with 60 and 70% MeOH were rechromatographed over Si gel (EtOAc–MeOH–H_2O, 100:17:13) and Sephadex LH-20 (MeOH) to yield compound **5** (18 mg) and compound **6** (6.4 mg).

3.3. Emodin-6-O-β-D-glucopyranoside (6)

Amorphous; ESI MS *m/z*: 453 (23) $[M+Na]^+$, 413 (29), 365 (5); UV λ_{max} (MeOH) nm: 223, 264, 293 *sh*, 411; IR ν_{max} (KBr) cm^{-1}: 3432 (OH), 2921, 2850, 1670 (free C=O), 1633 (chelated C=O), 1060 (C–O); ^1H (300 MHz; DMSO-d_6) and ^{13}C NMR (75.5 MHz; DMSO-d_6): Table 1; R_f: 0.08 ($CHCl_3$/CH_3OH/H_2O, 80:20:2).

3.4. 6-Chlorocatechin (7)

Amorphous; ESIMS *m/z*: 649 (35), 647 (100) $[2M–H]^+$, 325 (24), 323 (70) $[M–H]^+$, 287 (5) $[M–H–Cl]^+$; UV λ_{max} (MeOH) nm: 208, 233 *sh*, 281; IR ν_{max} (KBr) cm^{-1}: 3381 (OH), 2922 (CH), 1623 (C=C, arom); ^1H (300 MHz; CD_3OD) and ^{13}C NMR (75.5 MHz; CD_3OD): Table 2; $[\alpha]_D^{20} = +50°$ ($c = 0.16$, DMSO); r_f: 0.36 ($CHCl_3$/CH_3OH/H_2O, 80:20:2).

3.5. Assay for antioxidative activity (Cuendet et al., 1997)

After developing and drying, TLC plates were sprayed with a 0.2% DPPH (1,1-diphenyl-2-picrylhydrazyl) solution in MeOH. The plates were examined 30 min after spraying. Active compounds appeared as yellow spots against a purple background. Quercetin was used as reference compound.

3.6. Assay for cytotoxic activity

Cytotoxic effect of pure compounds were tested against different cell lines, i.e. MCF (human breast carcinoma), HM02 (human melanoma) and HEPG2 (human epidermoid carcinoma). This study was carried out by Professor Dr. W. Beil (Faculty of Medicine, Institute of Pharmacology, MHH-Hannover).

Acknowledgements

We thank Professor Dr. W. Beil (Medizinische Hochschule Hannover) for performing the cytotoxic activity tests.

Abstract

Two new acyclic phenylpropane lignanamides, grossamide K and *erythro*-canabisine H, and the naphthol glucoside 2,5-dimethyl-3-*O*-β-D-glucopyranosylnaphthol, along with six known compounds were isolated from the acetone extract of bark of *Hibiscus cannabinus*. All structures were established by spectroscopic methods including 2D NMR techniques, which allowed the correction of certain previously reported ^{13}C NMR assignments of grossamide. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Kenaf (*Hibiscus cannabinus*); Malvaceae; Lignanamides; Grossamide K; *erythro*-Canabisine H; Naphthol glucoside

1. Introduction

Kenaf (*Hibiscus cannabinus*) is an annual dicotyledonous herbaceous plant, well known in Asia and Africa, which has been recently cultivated in some Mediterranean areas. This plant was used in traditional medicine (Chifundera et al., 1994) and also by pulp and paper industries since its core and bark are sources of fibres with different lengths (Pande and Roy, 1996). In previous phytochemical investigations on kenaf, we have reported the aliphatic composition of the bark and core (Seca et al., 2000) and also the identification of new lignans isolated from the core (Seca et al., 2001). In the present study we report the isolation and structural characterisation of new lignanamides, named grossamide K **1** and *erythro*-canabisine H **2**, and of the 2,5-dimethyl-3-*O*-β-D-glucopyranosylnaphthol **3**, as well as six other compounds from the acetone extract of bark of *Hibiscus cannabinus*.

2. Results and discussion

The bark of *Hibiscus cannabinus* was finely ground and extracted, successively, with light petroleum and acetone. The acetone extract was partitioned with dichloromethane, chloroform and acetone, giving three fractions. Each one of these fractions was subjected to column and preparative thin layer chromatography leading to the isolation of three new compounds **1**–**3** (two lignanamides and a naphthol glucoside) (Fig. 1) and six other compounds.

Spectral data of compounds **1** and **4** have some similarities. The NMR spectra of both compounds displayed resonances corresponding of two methine groups, which correlate each other in the COSY spectra. The connectivities found in the HMBC spectra suggest that these two methine groups belong to a furan ring of a benzodihydrofuran structure (Fig. 1). The coupling constant of these protons ($J = 6.4$ Hz) indicates that these protons have *trans* configuration. The aromatic region of the ^1H NMR spectra of both **1** and **4** shows an AB set of signals; the coupling constant ($J = 15.6/15.8$ Hz) of these vinylic systems indicates that they have a *trans* configuration. The long-range connectivities of these protons, found in the HMBC spectra, with those of the carbons at δ 166.7/167.4 and the IR absorption bands at 3301–3355 (N–H) and 1650–1652 cm^{-1} (C=O), suggest the presence of an α,β-unsaturated amide moiety in both structures.

Analysis of the ^1H, ^{13}C and COSY NMR spectra of **1** and **4** also shows the proton and carbon resonances corresponding to two vicinal methylene groups. In the HMBC spectra these proton resonances correlates with those of the amide carbons (δ 166.7/167.4) and of a *p*-substituted

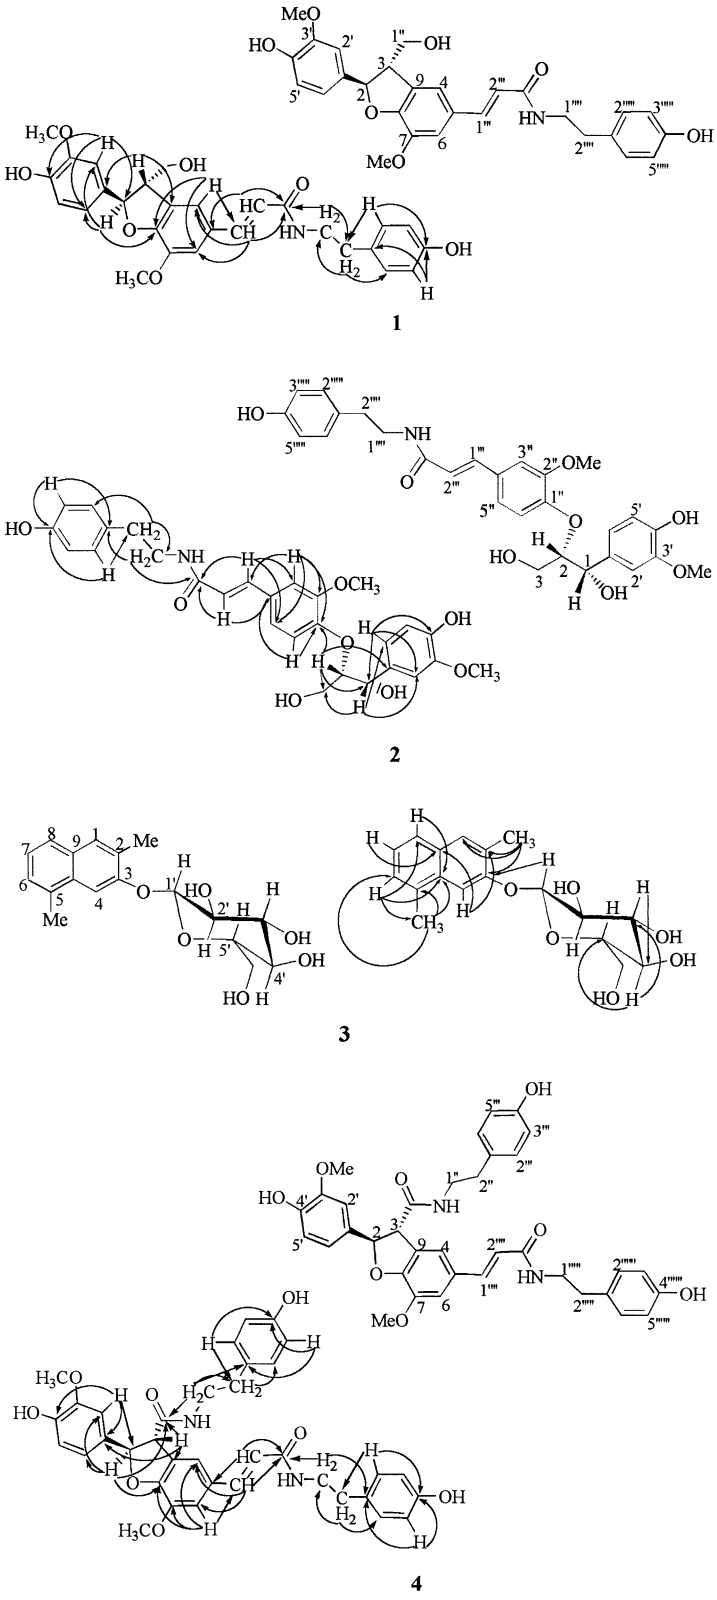

Fig. 1. Structure of compounds **1**–**4** from bark of *Hibiscus cannabinus* and major HMBC connectivities.

aromatic ring. These data, together with the presence of fragments $[M\text{-}136]^+$ and $[HOC_6H_4CH_2CH_2NH_2]^+$ (m/z 137) in the mass spectra, indicate the presence of at least one tyramine moiety in these structures.

The ^1H and ^{13}C NMR spectra of compound **1** indicate the presence of another methylene group, which are coupled with H-3 and other proton at δ_H 4.40 (1H, *s br*, which disappears after shaking its $CDCl_3$ solution with

D_2O). These data indicated the presence of a hydroxymethyl group attached to the position 3 of the benzodihydrofuran nuclei.

The spectral data of **1** are compatible with the structure of a lignanamide like grossamide K (Fig. 1), which was confirmed by the HR–FABMS spectrum, which shows a $[M+H]^+$ ion at m/z 492.2019 being consistent with the molecular formula $C_{28}H_{29}NO_7$ (calculated mass: 492.2022). The assignment of all carbon resonances supporting the assignment of the grossamide K **1** structure was done from the connectivities found in its HMBC spectrum (Fig. 1).

The presence of another tyramine moiety on structure **4** was deduced from its ^1H and ^{13}C NMR, where two additional methylene groups and another amide group were observed. These methylene proton present connectivities with the carbons of the amide group and of the *ortho* position of a *p*-substituted aromatic ring. This data was also confirmed by the molecular ion at m/z 625 $[C_{36}H_{36}N_2O_8+H]^+$ and the fragment at m/z 351 [M-2×tyr]. The discussed spectroscopic data and the analysis of the HMBC spectra (Fig. 1) support the assignment of its structure to grossamide (Lajide et al., 1995; Santos et al., 1996) and allowed the correction of the literature assignment of C-4, C-2′, C-4′, C-5′ and C-8.

The ^1H NMR spectrum of **2** showed basically the same resonances and coupling constants of grossamide K **1** (see experimental), but with a few differences. The absence of the dihydrofuran ring was suggested by the presence of a protonated aromatic carbon resonance (C-6″), instead the signal of the quaternary carbon C-9 of grossamide K **1**, and some important connectivities found in the HMBC spectrum (Fig. 3). The HR–FABMS of **2** showed a $[M+Na]^+$ ion at m/z 532.1971, consistent with the molecular formula of $C_{28}H_{31}O_8$ (calculated mass: 532.1947). Due to the skeleton similarities to canabisine E (Sakakibara et al., 1995) compound **2** was called canabisine H.

Due to the presence of two chiral carbons in the 1,2,3-trioxygenated propane moiety of canabisine H **2**, two possible diastereomers (*erythro* and *threo*) might be present. In their ^1H NMR spectrum H-1 appears as a slightly broad singlet, suggesting a small coupling constant with H-2, which indicates the presence of the *erythro* diastereomer (Shimomura et al., 1987; Abraham et al., 1991).

The FAB–HRMS spectrum of **3** exhibits the molecular ion peak at m/z 335.1490 corresponding to a molecular formula $C_{18}H_{23}O_6$ $[(M+H)^+$; calculated mass: 335.1495]. In the EI–MS spectrum the molecular ion at m/z 334 and the main fragment at m/z 172, corresponding to loss of $C_6H_{12}O_5$, have been observed. These data and analysis of the NMR spectra of **3** let us to conclude on the presence of a six-membered monosaccharide unity. Acid hydrolysis of **3** afforded only one sugar, which was identified by gas chromatography as glucose by comparison with authentic sugar sample (see Experimental). The anomeric proton of the glucose moiety appears as a doublet (δ_H 5.15, $J_{H1\text{-}H2}=7.5$ Hz), indicating the presence of this sugar in the β configuration. The spectroscopic data of **3** and the analysis of its HMBC spectrum (Fig. 1) allowed to conclude that the glucose moiety is attached to the 3 position of the naphthol unit and to fully assign this structure as 2,5-dimethyl-3-*O*-β-D-glucopyranosylnaphthol.

Additional isolated compounds were identified by comparing available literature data with their spectral features as kaempherol-3,7-rhamnoside (Mulinacci et al., 1995; Grasza et al., 1993), lariciresinol (Badawi et al., 1983; Katayama et al., 1993), pinoresinol (Tsukamoto et al., 1984; Deyama et al., 1987), syringaresinol (Ratnayake et al., 1992; Changzeng and Zhongjian, 1997) and of the most abundant compound (3.7% of extract), *N-trans*-feruloyl tyramine (Fukuda et al., 1983; Lajide et al., 1995).

3. Experimental

3.1. General

^1H and ^{13}C NMR spectra were recorded in acetone-d_6 on a Bruker AMX 300 spectrometer operating at 300.13 and 75.47 MHz, respectively; chemical shifts are expressed in δ (ppm) values relative to TMS as internal reference and the coupling constants J are expressed in Hz. ^1H Assignments were made using 2D COSY and NOESY (mixing time of 800 ms) experiments, while ^{13}C assignments were made using 2D HETCOR and HMBC experiments (long range C/H coupling constants were optimised to 4 and 7 Hz). MS were obtained at 70 eV electron impact and positive FAB (nitrobenzyl alcohol as matrix) ionisation using a VG Autospect Q mass spectrometer. IR spectra were obtained with a MATTSON 7000 FTIR spectrometer. GC analysis was performed using a Carlo Erba GC 6000 Vega Series 2 chromathograph equipped with a FID detector. Injector and detector temperatures were 220 and 250 °C respectively. Initial oven temperature was 220 °C (5 min), then 10 °C/min up to 230 °C (6 min), carrier gas hydrogen (55 cm/s), split ratio, 1:100, injections 2 μl. Fused silica capillary column DB-225 (30 m×0.25 mm×0.15 m) was used. Prep. TLC was carried out on silica gel plates (Merck silica gel 60 F_{254}); spots were detected under UV (λ 254 and/or 366 nm). Phenolic compounds were detected by the appearance of a brown colour when the TLC plates were sprayed with a (3:2) $CHCl_3$:pyridine solution of $FeCl_3$ (1%) (Browning, 1967). Column chromatography was also performed on silica gel (Merck silica gel 60, 70–230 mesh).

3.2. Plant material

Hibiscus cannabinus, variety Salvador, was harvested in Figueira da Foz, Portugal in September 1995.

3.3. Extraction and isolation

Stems of *H. cannabinus* were separated from foliage and air-dried at room temperature. The bark of *H. cannabinus* was separated from core and then finely ground (1503 g) and extracted successively with light petroleum and Me_2CO. The Me_2CO extract (12.9 g) was defatted with hexane and then fractionated by its solubility in CH_2Cl_2, $CHCl_3$ and Me_2CO. The residue obtained from the CH_2Cl_2 soluble fraction was subjected to silica gel CC. The column was eluted with $CHCl_3$–EtOAc (10:1) (fr I), $CHCl_3$–EtOAc (2:1) (fr II), and $CHCl_3$–EtOAc (1:1) (fr III). Fr I was chromatographed on prep. TLC, eluted with Et_2O-light petroleum (6:1), to give **7** (58.9 mg). Fr II on prep. TLC, eluted with CH_2Cl_2–EtOAc (2:1) yielded **8** (15.9 mg) and **9** (133.3 mg). Fr III on prep. TLC, eluted with $CHCl_3$–EtOAc (1:2) gave **2** (12.1 mg). The residue obtained from the $CHCl_3$ fraction was then subjected to prep. TLC, eluted with different mixtures of $CHCl_3$–EtOAc, to give **6** (11.8 mg), **7** (5.1 mg) and **9** (31.0 mg). The residue obtained from the fraction taken in acetone was subjected to silica gel CC. The column was eluted with $CHCl_3$–Me_2CO (1:2) (fr I), $CHCl_3$–Me_2CO (1:4) (fr II), and Me_2CO (fr III). Fr I was chromatographed by prep. TLC, eluting with $CHCl_3$–Me_2CO (2:1), to give **1** (24.3 mg), **2** (28.0 mg), **4** (11.6 mg) and **9** (315.2 mg). Fr II by prep. TLC, eluted with EtOAc yielded **2** (13.7 mg) and **3** (12.8 mg). Fr III by ppt. on Me_2CO gave **5** (31.6 mg).

3.3.1. 2-(4-Hydroxy-3-methoxyphenyl)-3-hydroxymethyl-5-[N-2-(4-hydroxyphenyl)ethyl]carbamoylethenyl-7-methoxybenzodihydrofuran (grossamide K) 1

FABMS *m*/*z* (rel. int.): 625 $M+H^+$ (20), 488 $[(M+H)\text{-tyr}]^+$ (5), 451 $[(M+H)\text{-}2\times\text{tyr}]^+$ (10).

3.4. Hydrolysis of 2,5-dimethyl-3-O-β-D-glucopyranosylnaphthol **3**

The hydrolysis of compound **3** (2–3 mg) was carried out with 72% H_2SO_4 (0.1 ml) at room temperature during 3 h, followed by 3% H_2SO_4 at 100 °C during 2.5 h. One ml of the reaction mixture was neutralised with 200 μl of 25% NH_3 aqueous solution and then the monosaccharide(s) were reduced by the addition of 100 μl of 3 M NH_3 solution containing $NaBH_4$ 150 mg/ml, during 1 h at 30 °C. Excess $NaBH_4$ was decomposed by addition of HOAc (100 μl). Acetylation of alditol(s) was carried out with Ac_2O (3 ml) in the presence of 1-methylimidazole (0.45 μl), according to Blakeney et al. (1983). The obtained acetates were extracted with CH_2Cl_2; the organic layer was washed three times with water, evaporated to dryness at 30 °C under nitrogen atmosphere. The dry residue was diluted with CH_2Cl_2 and analysed by GC. The presence of glucose was identified by comparison with the sample obtained when this pure monosaccharide was submitted to the same procedure.

Hydroxysesamone and 2,3-epoxysesamone from roots of *Sesamum indicum*

A.F.M. Feroj Hasan, Toshio Furumoto, Setara Begum, Hiroshi Fukui*

Department of Biochemistry and Food Science, Faculty of Agriculture, Kagawa University, Kagawa 761-0795, Japan

Received 12 April 2001; received in revised form 17 July 2001

Abstract

A red naphthoquinone, named hydroxysesamone, was isolated from the roots of *Sesamum indicum* together with a known yellow naphthoxirene derivative, 2,3-epoxy-2,3-dihydro-5,8-dihydroxy-2-(3-methyl-2-butenyl)-1,4-naphthoquinone, named 2,3-epoxysesamone. The structure of the naphthoquinone was characterized as 2,5,8-trihydroxy-3-(3-methyl-2-butenyl)-1,4-naphthoquinone on the basis of spectral evidence. Full assignments of NMR resonances of 2,3-epoxysesamone were also confirmed by two-dimensional NMR spectroscopic experiments. Chlorosesamone, hydroxysesamone and 2,3-epoxysesamone all showed antifungal activities toward *Cladosporium fulvum*. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Sesamum indicum*; Pedaliaceae; Sesame root; Naphthoquinones; Hydroxysesamone; Chlorosesamone; 2,3-Epoxysesamone; Antifungal activity

1. Introduction

Sesamum indicum L. (Pedaliaceae) is one of the most important crops throughout the world, and its seeds have been utilized for a long time as edible oilseeds and food materials. There are many phytochemical studies on the genus *Sesamum* which have been concerned with lignans (Bedigian et al., 1985; Osawa et al., 1985), phenolic acids (Das et al., 1966; Dabrowski and Sosulski, 1984), flavonoids (Krishnaswamy et al., 1970; Sinha and Dogra, 1985), saponins (Fenwick and Oakenfull, 1983; Sinha and Dogra, 1985), alkaloids (Sinha and Dogra, 1985). However, little research has been reported on the constituents of the roots, an unutilized part of sesame. In our search for antifungal compounds among the metabolites of sesame roots, chlorosesamone (**1**) was isolated from the roots of *S. indicum* and characterized (Hasan et al., 2000).

Chlorosesamone (**1**) is a chlorinated antifungal naphthoquinone. Natural chlorine-containing compounds occurring in higher plants are of increasing interest due to their frequent occurrence and various biological activities (Engvild, 1986), but only has a limited knowledge of their biosynthetic pathways. During our further research, we found that sesame roots contain two additional antifungal metabolites. In this paper, we report the isolation and structural elucidation of a new red naphthoquinone, named hydroxysesamone (**2**), and full assignments of NMR resonances of a known yellow naphthoxirene derivative (Potterat et al., 1987; Ogasawara et al., 1993), named 2,3-epoxysesamone (**3**), which seem to be biogenetically related to chlorosesamone (**1**).

2. Results and discussion

Hydroxysesamone (**2**) was isolated as red needles from fresh roots of *S. indicum* after purification as described in the Experimental. The HR–EIMS and ^{13}C NMR spectral data (Table 1) for **2** revealed the molecular formula $C_{15}H_{14}O_5$, which corresponds to the substitution of a hydroxyl group for a chlorine atom in chlorosesamone (**1**, $C_{15}H_{13}O_4Cl$) (Hasan et al., 2000). The ^{13}C NMR spectrum of **2** showed 15 resonances, two due to methyl groups, one to methylene, three to methines and nine to quaternary carbons from its DEPT data, confirming that three of the protons in the

PII: S0031-9422(01)00357-0

molecule are bound to oxygen atoms. The ^1H and ^{13}C NMR spectral data for **2** (Table 1), as well as its UV-vis and IR bands, were similar to those of **1**. These findings suggested that **2** is a trihydroxylated naphthoquinone analogue. The structure of hydroxysesamone (**2**) was unambiguously substantiated by analysis of ^1H–^1H COSY, HMQC, LR-HETCOR (HMBC and COLOC) and DIFNOE data.

A 3-substituted 2,5,8-trihydroxy-1,4-naphthoquinone ring was deduced from the ten carbon (C-1–C-8a), two aromatic methine protons (δ_H 7.26, *d*, $J=9.4$ Hz, H-6 and 7.14, *d*, $J=9.4$ Hz, H-7), one hydroxyl proton (δ_H 7.37, *br.s*, 2-OH), and two chelated hydroxyl protons (δ_H 12.82, *s*, 5-OH and 11.46, *s*, 8-OH) signals. Moreover, the chemical shifts of C-2 (δ_C 153.3), C-5 (δ_C 157.1) and C-8 (δ_C 157.5) suggested bonds between these carbon atoms and the hydroxyl groups. The HMQC and LR-HETCOR experiments supported this deduction. The 2-OH signal was correlated with the C-2 and C-3 resonances, and 5-OH and 8-OH signals respectively correlated with the C-4a, C-5 and C-6 signals and with C-7, C-8 and C-8a signals, providing further evidence for the 2,5,8-trihydroxy-3-substituted, not a 5,6,8-trihydroxy-7-substituted, ring. The NMR spectroscopic assignments of two C_3 units (C-4a–C-6 and C-7–C-8a) including two chelated hydroxyl group (5-OH and 8-OH) were presumed by comparison to the chemical shifts of chelated hydroxyl group for 5- (2,5-hydroxyl isomer, δ_H 12.45) and 8-hydroxylapachol (2,8-hydroxyl isomer, δ_H 11.00) (Khan and Mlungwana, 1999). However, these assignments in **2** may be interchanged because of no availability of LR-HETCOR correlations.

The ^1H NMR spectrum of **2** (Table 1) exhibited two methyl broad singlets at δ_H 1.67 and 1.76, one methylene broad doublet at δ_H 3.28 ($J=7.3$ Hz) and one vinylic methine signal (δ_H 5.16, *tqq*, $J=7.3$, 1.4 and 1.4 Hz). These signals closely resembled those of the side chain of **1** (Hasan et al., 2000) and lapachol derivatives (Khan and Mlungwana, 1999), suggesting the presence of a 3-methyl-2-butenyl group in **2**. The structure of the side chain was confirmed by the ^1H–^1H COSY and LR-HETCOR experiments. Furthermore, the NMR spectroscopic assignments of the two methyl groups (C-4′ and C-5′) were established by the DIFNOE data. Irradiation of the H-4′ methyl signal (δ_H 1.67) caused NOE enhancement of the H-2′ vinylic methine signal (δ_H 5.16), indicating that the C-4′ methyl group and H-2′ proton lie on the same side of the double bond. The attachment of the side chain to the naphthoquinone ring was demonstrated by the correlation of the H-1′ signal with the C-2, C-3 and C-4 observed in the LR-HETCOR experiments. Therefore, the structure for hydroxysesamone (**2**) was unambiguously established as 2,5,8-trihydroxy-3-(3-methyl-2-butenyl)-1,4-naphthoquinone.

Compound **3** was isolated as pale yellow crystals, and had the same molecular formula $C_{15}H_{14}O_5$ (HR–EIMS and ^{13}C NMR spectral data) as **2**. The ^1H and ^{13}C NMR spectra of **3** (Table 1) showed the presence of two carbonyl groups, three olefinic methines and five olefinic quaternary carbons, indicating that **3** contains three

rings in its structure. Furthermore, one methine singlet at δ_H 3.48 and two oxygen-bearing carbon signals (δ_C 59.3 and 63.4), respectively, were present instead of one hydroxyl proton (δ_H 7.37) and two olefinic carbon (δ_C 153.3 and 124.6) signals observed in **2**. These facts suggested that **3** is a 2,3-epoxy analogue of **2**. The MS and NMR spectral data for **3** were identical with those for a naphthoxirene derivative previously isolated from the root bark of *S. angolense* (Potterat et al., 1987) and from the hairy roots of *S. indicum* (Ogasawara et al., 1993). Thus, compound **3** was identified as 2,3-epoxy-2,3-dihydro-5,8-dihydroxy-2-(3-methyl-2-butenyl)-1,4-naphthoquinone, and was named 2,3-epoxysesamone.

Assignments of ^1H and ^{13}C NMR spectroscopic signals of **3**, some of which were ambiguous previously, were also confirmed on the basis of DEPT, ^1H–^1H COSY, HSQC, LR-HETCOR and DIFNOE data in the same manner as in the structural elucidation of **2**, since its structure was determined mainly by X-ray diffraction analysis (Potterat et al., 1987). The LR-HETCOR experiments of **3** revealed significant long-range ^{13}C–^1H correlations as follows: H-2/C-1, C-1′ and C-8a; 5-OH/C-4a, C-5 and C-6; 8-OH/C-7, C-8 and C-8a; H-1′/C-2, C-3 and C-4. Consequently, full assignments of the NMR resonances of 2,3-epoxysesamone (**3**) were unambiguously accomplished.

The carbon skeletons of hydroxysesamone (**2**) and 2,3-epoxysesamone (**3**), a naphthoquinone ring plus a prenyl side chain, are identical with that of chlorosesamone (**1**), suggesting that these metabolites have the same biosynthetic origin. In addition, the naphthoquinone moiety of these metabolites would be biosynthesized from shikimate and 2-ketoglutarate (Inoue et al., 1984; Herbert, 1989; Haslam, 1993; Thomson, 1997). The biogenetic origin of the prenyl side chain and relationship of **1**, **2** and **3**, especially the mechanism and precursor for chlorination, are interesting topics now under investigation.

The antifungal activities toward *Cladosporium fulvum* of **1**, **2** and **3** were tested using a bioautographical assay (Fukui et al., 1999). In this assay, chlorosesamone (**1**), hydroxysesamone (**2**) and 2,3-epoxysesamone (**3**) inhibited the spore germination of the fungus at respective amounts of 0.1, 1 and 10 μg per spot, indicating that **1** having chlorine atom in the molecule is the strongest fungicide among three naphthoquinones **1**–**3**.

3

3. Experimental

3.1. General experimental procedures

Mps are uncorr. NMR spectra were recorded with a Jeol JNM-A400 FT NMR spectrometer at 400 MHz for ^1H and 100.4 MHz for ^{13}C. All NMR chemical shifts were referenced to the signal of the deuterated solvent used ($CDCl_3$, δ_H 7.24, δ_C 77.0; benzene-d_6, δ_H 7.15, δ_C 128.0). Mass spectra were measured with a Jeol JMS-SX102AQQ hybrid mass spectrometer. UV spectra were obtained with a HITACHI 340 recording spectrophotometer, and IR spectra with a JASCO A-302 spectrometer. Silica gel 60 (70–230 mesh, Nacalai Tesque) and Sephadex LH-20 (Amersham Pharmacia Biotech) were used for CC. TLC were done on silica gel 60 F_{254} (Merck).

3.2. Plant material

Seeds of *Sesamum inducum* L. were purchased from the seed and seedling supplier (Hashimoto Seed) in Kagawa, Japan. Sesame plants were cultivated in the field of Kagawa University in 1999, and the roots were harvested ca. three months after sowing the seeds.

3.3. Extraction and isolation of 2 and 3

Fresh roots of *S. indicum* (5 kg) were treated with MeOH, then were filtered from MeOH through filter paper. This treatment was repeated twice. The MeOH soln. obtained was evaporated in vacuo, and the aq. residue was partitioned with EtOAc (×3) to give the EtOAc-soluble fraction (10 g). This fraction was separated by silica gel CC eluted stepwise with mixtures of *n*-hexane and EtOAc. A fraction eluted with 20% EtOAc in *n*-hexane was purified by Sephadex LH-20 CC with MeOH–$CHCl_3$ (1:1) as eluent to afford compound **2** (45 mg). A fraction eluted with 15% EtOAc in *n*-hexane was subjected to a combination of silica gel CC (1% Me_2CO in $CHCl_3$), Sephadex LH-20 CC (EtOH–C_6H_6,

1:2) and prep. TLC (EtOAc–*n*-hexane–HOAc, 2:98: 0.2, triple development). A R_f 0.53 band was further purified by Sephadex LH-20 CC with EtOH–C_6H_6 (3:2) as eluent to give compound **3** (49 mg).

3.4. Hydroxysesamone (**2**)

Red needles from *n*-hexane–$CHCl_3$, mp 145–146 °C. UV-vis λ_{max} (MeOH) nm (log ϵ): 242 (4.05), 270 (3.81), 287 (3.76), 484 (3.64), 538 (3.64). IR ν_{max} ($CHCl_3$) cm^{-1}: 3415, 1605, 1570, 1455. ^1H and ^{13}C NMR spectral data ($CDCl_3$): Table 1. EIMS (probe) 70 eV, *m*/*z* (rel. int.): 274 $[M]^+$ (95), 259 (100). HR-EIMS *m*/*z*: 274.0838; $C_{15}H_{14}O_5$ requires 274.0841.

3.5. 2,3-Epoxysesamone (**3**)

Pale yellow crystals from MeOH, mp 85–86 °C. $[\alpha]_D^{25}$ −43° ($CHCl_3$; *c* 0.34). HR-EIMS *m*/*z*: 274.0845; $C_{15}H_{14}O_5$ requires 274.0841. The EIMS, UV and IR spectral data matched the lit. values (Potterat et al., 1987). ^1H and ^{13}C NMR spectral data (benzene-d_6): Table 1.

A flavonoid sulphate and other compounds from the roots of *Centaurea bracteata*

Guido Flamini*, Maria Pardini, Ivano Morelli

Dipartimento di Chimica Bioorganica e Biofarmacia,Universita di Pisa, Via Bonanno 33, 56126 Pisa, Italy

Received 6 April 2001; received in revised form 26 July 2001

Abstract

The roots of *Centaurea bracteata* Scop. (Asteraceae) have been studied for the first time. Twenty-three compounds were isolated and identified, namely a sterol glucoside, two quinic acid derivatives, one sugar, and 19 flavonoids (five sulphates), one of which, centaradixin, resulted in a new natural product. Structural elucidation was performed mainly by means of FABMS, 1D and 2D NMR spectroscopy. NMR data of some sulphate flavonoids are reported for the first time. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Centaurea bracteata*; Asteraceae; Flavonoids; Axillarin 7-sulphate; Centaradixin

1. Introduction

Centaurea bracteata Scop. (Asteraceae), known in Italy as "fiordaliso bratteato" is a herbaceous plant placed by Pignatti (1982) in the *C. jacea* group, together with 10 other species. The plant is not used in Italian folk medicine, although other species of the same genus (i.e. *Centaurea cyanus* and *Centaurea scabiosa*) are used against coughs and as ophthalmic drugs (Poletti, 1978) or vulneraries (Mazza, 2000). The studies on this genus deal mainly with sesquiterpene lactones, while flavonoids are less investigated; only our previous study about its aerial parts is reported in literature (Flamini et al., 2001); the roots have never been studied at all.

This paper deals with the isolation and characterisation of 23 substances belonging to various classes of compounds, in particular two quinic acid derivatives, a sterol glucoside, a monosaccharide, and 19 flavonoids, one of which is a new natural products. Moreover, NMR data of some known flavonoid sulphates are reported for the first time.

2. Results and discussion

From the *n*-hexane residue (R_H), by repeated flash and p-TLC chromatographies, four compounds were isolated, namely jaceidin, jacein, 6-hydroxyluteolin-6,4′-dimethylether and centaureidin, which were identified by comparison of their physical and spectroscopic properties with literature reports (Roitman and James, 1985; Agrawal et al., 1989). Similarly, from the chloroform extract (R_C), hispidulin, 6-hydroxykaempferol 3,6-dimethylether and β-sitosterol 3-*O*-glucoside were obtained (Agrawal et al., 1989; Reher and Budensisky, 1992).

Fractionation of the $CHCl_3$–MeOH (9:1) extract (R_{CM}) by size-exclusion chromatography, column chromatography, and preparative TLC, led to the isolation of further eight pure compounds. These were axillarin, nepetin, 6-hydroxyluteolin-6,4′-dimethylether-7-*O*-glucoside, jacesiolin, centaurein, nepetin 7-glucoside, 5-caffeoylquinic acid and fructose (Collado et al., 1985; Iwahashi et al., 1985; Barbera et al., 1986; Berghöfer and Hölzl, 1987; Wada et al., 1987; Agrawal et al., 1989), all identified by ^1H and ^{13}C NMR spectroscopy.

The R_{MAc} and R_{MBu} residues, after size-exclusion chromatography and repeated Lobar RP-8, RP-18, flash and preparative TLC chromatographies, gave 3-caffeoylquinic acid methyl ester, axillarin 7-glucoside, isokaempferide, nepetin 7-sulphate, patuletin 7-sulphate, hispidulin 7-sulphate, quercetin 3,3′-disulphate and the new flavonoid sulphate, which we named centaradixin (**1**) Table 1. Known isolates were identified by comparison with literature data (Saleh et al., 1971; Redaelli et al., 1980; Iwahashi et al., 1985; Kubo et al., 1986; Ahmed and Mabry, 1987; Barron and Ibrahim,

[d] Signals may be exchanged.

1987a; Nishizawa et al., 1988; Tomas-Barberan et al., 1987; Agrawal et al., 1989).

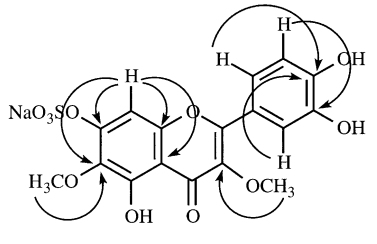
Centaradixin (**1**) was obtained as a yellowish amorphous powder that appears on TLC as a yellow-orange arrow-shaped spot after treatment with Naturstoffereagenz A-PEG. The negative FABMS spectrum gave a quasimolecular peak $[M-H]^-$ at 425 *m/z*, corresponding to the molecular formula $C_{17}H_{14}O_{11}S$, supported also by elemental analysis (see Experimental); another significant ion at *m/z* 448 ($[M+Na-H]^-$) showed the presence of sodium in the sample. The ^{13}C NMR spectrum showed 17 resonances, sorted by DEPT experiments into 4 CH, 2 CH_3 and 11 quaternary C. In the ^{1}H NMR spectrum obtained in DMSO-d_6 a three-proton ABM system was present (δ 7.56, *d*, $J=2.0$ Hz; 7.50, *dd*, $J=8.3$, 2.0 Hz; 6.90, *d*, $J=8.3$ Hz), typical of the 3′,4′-disubstituted ring B of a flavonoid unit. Ring A showed only a resonance as one-proton singlet at δ 7.28. Moreover, two three-proton singlets were present at δ 3.73 and 3.78. The situation was very close to that of axillarin, apart from the signal of ring A that resulted deshielded. This circumstance was more evident in the ^{1}H NMR spectrum recorded in CD_3OD, where the resonance of the ring A proton appeared at very low fields (δ 7.36). Analysis of the ^{13}C NMR spectrum confirmed the 'strange' situation of ring A with respect to axillarin. Resonances of ring A carbons showed the typical shifts due to the presence of a sulphate group linked to the C-7 hydroxy group (Barron and Ibrahim, 1987b; Barron et al., 1988): 4.6 ppm upfield for the *ipso* carbon (C-7), 4.3 and 6.6 ppm downfield for the *ortho* carbons (C-6 and C-8, respectively), and 3.1 ppm downfield for the *para* carbon (C-10), in DMSO-d_6; in CD_3OD the results are very similar (−4.9, +3.1, +5.6 and +3.0 ppm, respectively). This situation is confirmed also by the large downfield shift (0.80 ppm) experienced by the proton attached to the *alpha* carbon (H-8).

The high resonance value of the two methoxyl groups (δ 59.6 and 60.3) suggested that both the *ortho* positions should be substituted, so they must be placed only at the 3 and 6 position (Agrawal et al., 1989). This situation is corroborated by the characteristic downfield shifts observed for C-2, C-3 and C-4 (ca. 10.5, 4.0 and 2.5 ppm, respectively) because the 3-OCH_3, and the shifts experienced by C-5, C-6, C-7 and C-9 (ca. −9, +31, −10, −5 ppm, respectively) due to the 6-OCH_3 with respect to quercetin (Agrawal et al., 1989) and by comparison with similar methoxy-substituted flavonoids (Barbera et al., 1986; Agrawal et al., 1989) (Fig. 1). Moreover, a cross peak was evidenced in the NOESY spectrum between the 3-OCH_3 and the H-2′ and H-6′ resonances.

Therefore, **1** is axillarin 7-sulphate sodium salt, which we named centaradixin. This structure is supported by its negative FABMS spectrum where, besides the quasimolecular peak at *m/z* 425, $[M-H]^-$, and at *m/z* 448, $[M+Na-H]^-$, there was a peak due to loss of a sulphate group at *m/z* 345, $[M-H-80]^-$. Finally, the presence of sodium was confirmed by the yellow colour obtained by the flame assay; acid hydrolysis of **1** liberated axillarin and sulphate, identified by TLC with authentic samples and precipitation with barium chloride, respectively.

Most of the known flavonoid sulphates have been characterized only by UV and MS measurements, so we report their NMR data for the first time.

Summarising, the roots of *C. bracteata* yielded 23 compounds, among which 19 were flavonoids, two caffeoylquinic derivatives, one sugar and one sterol glucoside. Most of the flavonoids, according to the pattern of this genus, were polymethoxylated and three compounds have been obtained in great amounts (centaureidin 7800 mg, nepetin-7-glucoside 455 mg, and 6-hydroxyluteolin-6,4′-dimethylether-7-glucoside 335 mg; 0.51, 0.03 and 0.02% with respect to the dry plant material). It is quite interesting to note that the main constituent of the roots was centaureidin (7800 mg),



1

Fig. 1. Significant CH long range correlations observed in COLOC of compound **1**.

while in the aerial parts was its isomer jaceidin (3650 mg) (Flamini et al., 2001). Five of the flavonoids, were sulphate conjugate; these compounds are relatively rare in nature (Williams and Harborne, 1994) and, among the Asteraceae, they are produced only by four tribes: Inuleae, Eupatorieae, Senecioneae and Heliantheae (Barron et al., 1988). We have reported the identification of another flavonoid sulphate from the aerial parts of *C. bracteata* (Flamini et al., 2001). This study definitively confirms the presence of flavonoid sulphate esters in the genus *Centaurea* and that now there are five producing tribes among the Asteraceae, comprising also the Centaureinae.

Flavonoid sulphates, generally, are obtained as potassium salts, while our isolates are all the less common sodium salts. Till now only the genus *Lippia* (Verbenaceae) seems to produce sodium salts, among which nepetin and hispidulin 7-sulphates (Tomas-Barberan et al., 1987); our study is the first report, besides the new compound centaradixin (**1**), of patuletin 7-sulphate and quercetin 3,3′-disulphate sodium salts.

Normally, these compounds have been obtained from the aerial parts; Varin et al. (1986) went into detail about *Flaveria bidentis* affirming the presence of the highest amounts of flavonoids sulphates in the buds, followed by the leaves, while in the roots they were completely absent. Therefore, the presence of five flavonoid sulphates in the roots of *C. bracteata*, besides the further one isolated from the aerial parts (Flamini et al., 2001), seems to be noteworthy. Really, on the contrary with respect to *F. bidentis, C. bracteata* prefers to synthetize/store these substances in the roots.

Our findings seem to confirm the previous observations on *Brickellia* spp. and *Flaveria chloraefolia* (Barron et al., 1988) about the competition between the glucosilation and sulphation reactions for the same aglycones. In fact we have observed the concomitant presence of the 7-glucosides and 7-sulphates, of axillarin and nepetin; moreover the aerial parts (Flamini et al., 2001) contained quercetin 3-glucoside-3′-sulphate and the roots quercetin 3,3′-disulphate.

The large diffusion of flavonoid sulphates in water or hydrophyte plants (Tomas-Barberan et al., 1987; Barron et al., 1988; De Beck et al., 1998; Seabra and Correia Alves, 1988) seems to support the view that this conjugation could represent an ecological adaptation to the aquatic habitat. However our findings, both on the aerial parts (Flamini et al., 2001) and the roots, seems to contradict this hypotesis, in fact *C. bracteata* has been collected in a very arid environment, the normal habitat according to Pignatti (1982), that describes this species as a xerophytic one.

Flavonoids sulphates showed many biological activities, useful both to human health and plant physiology. They are enzymes inhibitors (Haraguchi et al., 1996), allergens (Sallusto et al., 2000), antioxidants (Yagi et al., 1994), regulators of auxin transport (Faulkner and Rubery, 1992). Moreover, rutine sulfate was demonstrated to be not carcinogenic (Habs et al., 1984).

The group of *C. jacea* to which *C. bracteata* belongs together with other ten species, was also considered as constituted by polymorphic forms of one (*C. jacea*) or two (*C. jacea* and *C. nigrescens*) species (Pignatti, 1982). Comparing the chemicals isolated from the other studied species of this group [*C. jacea*, *C. nigrescens* and *C. pannonica* (Bowie and Cameron, 1965; Bohlmann and Zdero, 1967; Wagner et al., 1969; Rosler et al., 1970; Monya, 1971; Kaïj-a-Kamb et al., 1992)], we can see some convergences but also many differences. Consequently, the separation of the species as suggested by Pignatti (1982) could be correct hypothesis.

Sesquiterpene lactones, typical compounds of this genus, are not produced at all by *C. bracteata*. The same is true for the other studied species of this group. If this finding will be confirmed for the remaining species of the group, it could be of chemotaxonomical interest.

3. Experimental

3.1. General

Melting points (uncorrected) were determined with a Kofler apparatus; optical rotations were measured on a Perkin-Elmer 241 polarimeter; FABMS were recorded, in the negative mode, with a VG ZAB instrument; ^{1}H and ^{13}C NMR spectra were obtained with a Bruker AC200 spectrometer in CD_3OD, DMSO-d_6, and $CDCl_3$, using TMS as internal standard. All 1D and 2D NMR experiments were performed using the standard Bruker library of microprograms.

The following adsorbents were used for purification: flash chromatography, Merck Kieselgel 60 (230–410 mesh); low-pressure chromatography, Merck Lobar Lichroprep RP-8 (31 × 2.5 cm); size-exclusion chromatography, Pharmacia Fine Chemicals Sephadex LH-20; analytical TLC, Merck Kieselgel 60 F_{254} precoated plates; chromatograms were visualised under UV light at 254 and 366 nm and/or sprayed with Komarowsky or Cerium Sulphate or Naturstoffereagenz A-PEG reagents.

3.2. Plant material

The roots were collected during full bloom at Montelaterone, Amiata Mount, South Tuscany, Italy, at 600 m above the sea level, in July 1999. A voucher specimen is deposited in PI (Herbarium of the University of Pisa).

3.3. Extraction and isolation

The dried and ground roots (1540 g) were extracted, successively, in a Soxhlet apparatus with *n*-hexane,

$CHCl_3$, $CHCl_3$–MeOH (9:1) (6.0 l × 35 h) and, at room temperature, with MeOH (7.0 l × 7 days × 3 times). After removal of solvents, in vacuo at up to 40 °C, the following residues were obtained: R_H (14.1 g), R_C (14.7 g), R_{CM} (67.1 g), and R_M (18.4 g).

R_M was suspended in MeOH–H_2O (7:3) and extracted, in turn, with EtOAc and *n*-BuOH obtaining, after removal of the solvents, the residues R_{MAc} and R_{MBu}.

The R_H residue, after repeated SiO_2 flash chromatographies and preparative TLCs, gave jaceidin (6 mg; yield 0.0004%), jacein (6 mg; yield 0.0004%), 6-hydroxyluteolin-6,4′-dimethylether (3 mg; yield 0.0002%) and centaureidin (7800 mg; yield 0.51%). In a similar fashion, from the R_C residue, hispidulin (18 mg; yield 0.001%), 6-hydroxykaempferol 3,6-dimethylether (8 mg; yield 0.0005%) and β-sitosterol-3-*O*-β-D-glucoside (29 mg; yield 0.02%) were obtained.

The R_{CM} residue was submitted to Sephadex LH-20 size-exclusion chromatography with MeOH–$CHCl_3$ (9:1) as eluent and the fractions were submitted to SiO_2 column chromatographies and p-TLC, obtaining eight pure compounds: axillarin (48 mg; yield 0.02%), nepetin (20 mg; yield 0.0002%), 6-hydroxyluteolin-6,4′-dimethylether-7-*O*-β-D-glucopyranoside (335 mg; yield 0.03%), jacesiolin (13 mg; yield 0.0008%), centaurein (24 mg; yield 0.0002%), nepetin-7-*O*-β-D-glucopyranoside (455 mg; yield 0.03%), 5-caffeoylquinic acid (11 mg; yield 0.0008%), and fructopyranose (18 mg; yield 0.001%).

The R_{MAc} residue was submitted to a Sephadex LH-20 column with MeOH as eluent, obtaining 18 main fractions (A–R). From these fractions, after repeated Lobar RP-8 and RP-18 chromatography, 3-caffeoylquinic acid methyl ester (6 mg; yield 0.0004%), axillarin 7-*O*-β-D-glucopyranoside (7 mg; yield 0.0005%), isokaempferide (6 mg; yield 0.0004%), nepetin 7-sulphate (15 mg; yield 0.001%) and patuletin 7-sulphate (12 mg; yield 0.0008%) were isolated.

R_{MBu} was chromatographed over Sephadex LH-20 column with MeOH as eluent, obtaining 26 main fractions (A–Z). Fraction H gave a precipitate constituted by pure quercetin 3,3′-disulphate (12 mg; yield 0.0008%). From fractions L–M, by flash chromatography and SiO_2 p-TLC, hispidulin 7-sulphate (6 mg; yield 0.0004%) was purified. Fraction K was submitted to p-TLC obtaining pure compound **1** (18 mg; yield 0.001%).

Received 22 March 2001; received in revised form 3 July 2001

Abstract

Bioassay-guided fractionation of a $CHCl_3$ extract from the leaves of *Ardisia teysmanniana* Scheff. (Myrsinaceae) has led to the isolation of three new alkyldibenzoquinone derivatives that showed inhibitory activity in an in vitro assay for UDP-MurNac synthesis. The structures of ardisiaquinone G, H and I were established using MS and NMR spectroscopic methods. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Ardisia teysmanniana*; Myrsinaceae; Leaves; 1,4-Benzoquinone; Ardisiaquinone

1. Introduction

The first committed step in bacterial peptidoglycan synthesis involves the conversion of UDP-N-acetylglucos amine (UDP-GlcNac) to UDP-N-acetylmuramic acid (UDP-MurNac) with the concomitant utilisation of NADPH, catalysed by the two enzymes UDP-GlcNAc transferase (MurA) and UDP-GlcNAc enolpyruvyl reductase (MurZ) (Benson et al., 1993). In the course of our search for new antimicrobials from natural resources, an enzymatic assay that coupled the reactions of the two enzymes to generate UDP-MurNac was designed to identify potential lead compounds that interfere with bacterial cell wall synthesis.

The family of Myrsinaceae consists of about 1250 plants which are classified into 37 genera (Raffauf, 1996). A $CHCl_3$ extract from the leaves of *A. teysmanniana* Scheff. (Myrsinaceae), one of 10 species of *Ardisia* found in Singapore (Keng, 1990), was found to inhibit the enzymatic assay. Bioassay-directed fractionation led to the isolation of three new alkyldibenzoquinones, ardisiaquinone G (**1**), H (**2**) and I (**3**). Ardisiaquinones A (**4**), B (**5**) and C (**6**) were first isolated from the root bark of *A. sieboldii* Miguel (Ogawa and Natori, 1968a,b; Ogawa et al., 1968) and total synthesis of ardisiaquinone A had also been reported (Fukuyama et al., 1994). In 1995, Fukuyama et al. reported the isolation of ardisiaquinone D (**7**), E (**8**) and F (**9**) from the same species and later published the total syntheses of these compounds (Fukuyama et al., 1998).

2. Results and discussion

Ardisiaquinone G (**1**) was isolated as amorphous powder. Positive ESIMS of **1** showed an $[M+H]^+$ at m/z 573 and a $[M+NH_4]^+$ ion peak at m/z 590.5. A HR–ESIMS measurement of the $[M+H]^+$ ion peak suggested a molecular formula of $C_{31}H_{40}O_{10}$. MS fragmentation at m/z 531.0 $[M-Ac]^+$ and m/z 489.5 $[M-2\times Ac]^+$ indicated the presence of two acetyl units. The ^1H NMR spectrum of **1** (Table 1) contained signals for an aliphatic chain (δ 2.38–2.44, 4 H and δ 1.20–1.50, ca. 20 H), two tertiary methyl groups (δ 1.94 and 1.96), two acetyl groups (δ 2.35 and 2.36) and two OH signals (δ 7.02 and 7.05) that disappeared upon addition of D_2O. The ^{13}C NMR spectrum revealed the presence of two methyl groups (δ 7.9 and 8.8), two acetyl groups (δ 20.3), at least 12 methylenes (δ 20–30), two carbonyl groups (δ 167.8 and 168.1) and 12 quaternary signals belonging to two benzoquinone rings. The substitution pattern of the two acetyl, two hydroxy and two methyl subunits on the benzoquinone rings was further

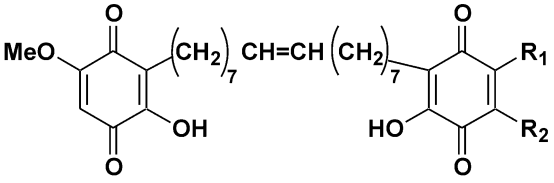
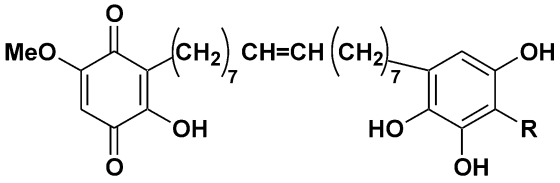
ardisiaquinone G (**1**) n = 11
ardisiaquinone H (**2**) n = 12
ardisiaquinone I (**3**) n = 13



ardisiaquinone A (**4**) R_1=OMe, R_2=H
ardisiaquinone B (**5**) R_1=OH, R_2=Me
ardisiaquinone C (**6**) R_1=OAc, R_2=Me
ardisiaquinone D (**7**) R_1=OMe, R_2=OMe



ardisiaquinone E (**8**) R = H
ardisiaquinone F (**9**) R = Me

revealed by the HMBC correlations as shown in Fig. 1. The absence of two olefinic protons at δ 5.33 and four allylic protons at δ 1.90 – 2.10 in **1** compared to other ardisiaquinones indicated that **1** contained a fully saturated aliphatic chain between the two benzoquinone rings. Further support for the structure was obtained from the MS data where the two fully substituted benzoquinone rings accounted for mass of 390, which implied that the remaining mass of 182 corresponded to 13 methylene units between the quinone moieties. The spectroscopic data of **1** were also in excellent agreement with that of the dihydro derivative of ardisiaquinone A, **10**, prepared by catalytic hydrogenation (Table 1) (Ogawa and Natori, 1968b; Ogawa et al., 1968).

The molecular formula of ardisiaquinone H (**2**) was determined to be $C_{32}H_{42}O_{10}$ on the basis of HR–ESIMS data (*m*/*z* 587.2856, calc. 587.2857). The ESIMS showed an $[M+NH_4]^+$ ion peak at *m*/*z* 604.5 and an $[M+H]^+$ at *m*/*z* 587.5, as well as two fragments at *m*/*z* 545.5 and 503.5, corresponding to a loss of one and two Ac units, respectively. The ^1H and ^{13}C NMR spectra of compound **2** matched nearly identical to that of ardisiaquinone G (**1**) (Table 1), which indicated that the extra 14 mass units were accounted for by an extra CH_2 unit in the alkyl chain.

Table 1

[a] Assignments based on COSY, HMQC and HMBC.

The ESIMS of ardisiaquinone I (**3**) showed an $[M+H]^+$ ion peak at *m*/*z* 601.5 and an $[M+NH_4]^+$ ion peak at *m*/*z* 618.5 that suggested that **3** contained one extra CH_2 unit compared to **2** and two CH_2 units compared to **1**. The spectral data for **3** closely paralleled those of **1** and **2** (Table 1) which indicated that **3** contained an alkyl bridge with 15 methylene units.

When tested in the UDP-MurNac synthesis assay, ardisiaquinone G (**1**), H (**2**) and I (**3**) gave IC_{50} values of 35, 26 and 26 μM respectively. However, the same compounds failed to show any whole cell activity in the disk diffusion assay against *Staphylococcus aureus*, *S. sangui*, *Escherichia coli* and *P. aeruginosa*.

3. Experimental

3.1. General

Column chromatography was performed using Sephadex LH-20 (Pharmacia). TLC analyses was done using plates of silica gel 60 F_{254} (0.2 mm, Merck), solvent system of EtOAc–$CHCl_3$ (1:1) and visualized under UV light (254 and 366 nm). HPLC analyses and isolations were carried out on Waters LC systems, including

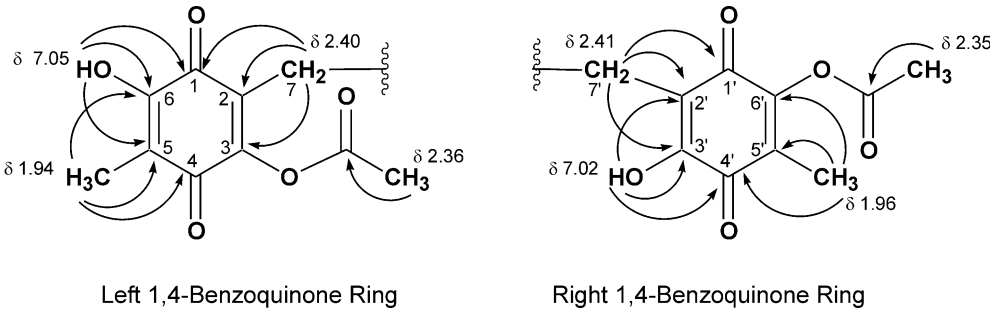

Fig. 1. HMBC correlations for the left and right 1,4-benzoquinone rings of **1**.

a 600E pump, a 490 programmable multiwavelength detector and NovaPak C_{18} column (5 μm, 40×100 mm). ^1H (500 MHz) and ^{13}C (125 MHz) NMR, ^1H–^1H COSY, HMQC and HMBC spectra were recorded on a Bruker AVANCE-500 digital NMR spectrometer, using solvent peaks as reference standard. LC–MS and MS/MS spectra were obtained on a Perkin-Elmer API 300 spectrometer operating with ESI and heated nebulizer ion sources in positive mode (CAD, 2 V; OR, +30 V; RO_3, 35 V; CEM, 3000 V), linked to a Hewlett-Packard 1100 HPLC system using a Novapak C_{18} column (3.9×50 mm). HR-MS spectra were obtained on a PerSeptive Biosystems Mariner TOF spectrometer operating with an ESI ion source in positive mode (spray tip potential, 3300 V; nozzle potential, 100 V; resolution, 5219). UV spectra were measured on an Ultraspec 2000 UV/vis spectrophotometer.

3.2. Plant material

The leaves of *A. teysmanniana* Scheff. (Myrsinaceae) were collected from Bukit Timah Nature Reserve in Singapore in October 1995. A herbarium voucher (No. 1026) was deposited in the Singapore Botanic Garden.

3.3. Extraction and separation

Dried and ground leaves (25 g) were extracted three times with $CHCl_3$ (500 ml) at room temperature with sonication for 30 min. After filtration, the $CHCl_3$ was evaporated under reduced pressure to leave an extract (2 g) that was chromatographed on Sephadex LH-20, using an EtOAc/$CHCl_3$ to MeOH/$CHCl_3$ gradient. The active fraction (0.3 g) was pooled according to TLC and separated by reversed-phase preparative HPLC using H_2O–MeCN gradient (20:80→10:90 in 15 mins, 20 ml/min) to give ardisiaquinone G (**1**) (69.4 mg, 0.3%), H (**2**) (32.7 mg, 0.1%) and I (**3**) (13.4 mg, 0.05%).

3.3.1. Ardisiaquinone G (*7*)

Yellow amorphous powder; UV (MeOH) λ_{max} nm (log ε) 209 (4.49), 295 (4.45), 535 (3.02); IR ν_{max} (KBr) 3330, 1777, 1618 cm^{-1}; (+)-ESIMS (rel. int.) *m/z*: 590.5 (35%), 573.0 (59%), 531.0 (41%), 489.5 (100%); (−)-ESIMS (rel. int.) *m/z*: 571.5 (23%), 529.5 (44%), 487.5 (100%); (+)-ESI MS/MS for *m/z* 573: 531.0, 489.0; HR–ESIMS $[M+H]^+$ 573.2700 (calc. for $C_{31}H_{41}O_{10}$ 573.2700); ^1H and ^{13}C NMR: Table 1.

3.4. UDP-MurNac synthesis assay

Assays were performed in 96-well microtitre plates in a 100 μl reaction volume. Extracts, fractions and compounds were dissolved in 12.5% DMSO with 10 μl of solutions delivered to the wells. Typically, 40 μl of enzyme solution containing purified MurA and MurZ (260 and 425 ng/well, respectively) in 50 mM Tris–HCl (pH 8.0) and 2.5 mM DTT were added to the wells. Reaction was initiated by adding 50 μl of substrate solution containing 7.6 mM UDP-GlcNAc, 1 mM PEP, 5 mg NADPH, 40 mM KCl, 0.4 mM EDTA (pH 8.0), 100 mM Tris–HCl (pH 8.0) and 0.2 mg/ml of BSA. After 1 h incubation at 37 °C, progress of the reaction was assessed by monitoring the decrease in absorbance at 340 nm. The standard inhibitor used for the assay was the specific inhibitor of MurA, fosfomycin, which gave an average IC_{50} of 25 μM.

Acknowledgements

The authors wish to thank Mr. Haji Sidek bin Kiah and Mr. Eugene Tang for collection and identification of the plant material. We are grateful to the staff who provided the NMR spectra in the Department of Chemistry, National University of Singapore. We also express our gratitude to GlaxoSmithKline, the Economic Development Board of Singapore, the Institute of Molecular and Cell Biology, and National University of Singapore for financial support.

Received 22 March 2001; received in revised form 28 July 2001

Abstract

Two acylated flavonol glycosides and 15 known polyphenols have been isolated and identified from the leaves of *Eugenca jambolana* Lam. The structures of the new compounds were identified as 3-*O*-(4″-*O*-acetyl)-α-L-rhamnopyranoside of mearnsetin (myricetin 4′-methyl ether) and myricetin 3-*O*-(4″-*O*-acetyl-2″-*O*-galloyl)-α-L-rhamnopyranoside. The complete structure elucidation of all isolated metabolites based on chemical and spectroscopic methods of analysis (UV, 1D and 2D NMR) as well as negative ESI–MS with and without CID in-source fragmentation. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Eugenia jambolana*; Myrtaceae; Leaves; Acylated flavonol glycosides; ID and 2D NMR; ESI–MS

1. Introduction

The genus *Eugenia* is one of 75 genera (~3000 species) belonging to the family Myrtaceae which are native in the tropics, particularly in tropical America and Australia (Hutchinson, 1960). Plants of this family are known to be rich in volatile oils which are reported for their uses in medicine. Genus *Eugenia* was reported to be used as an anti-inflammatory, analgesic, antipyretic (Karla et al., 1994a,b), antifungal (Rahhal, 1997) and peptic ulcer treatment (Tu, 1979). Fruits and seeds of *E. jambolana* used as an antidiabetic (Kelkar and Kaklij, 1997; Dhaliwal, 1999). Also anti-inflammatory compounds were characterized from *E. jambos* (Karla et al., 1996). Moreover, many *Eugenia* species were reported as very rich plants in polyphenols gallic and ellagic acid derivatives (Park et al., 1997; Son et al., 1998), tannins (Tanaka et al., 1996; Lee et al., 1997) and flavonol glycosides (Karla et al., 1994a,b; Schmeda-Hirschmann, 1995; Lee et al., 1997; Nair et al., 1999). Three flavonol glycosides were isolated from *E. jambolana* roots (Vaishnava and Gupta, 1990; Vaishnava et al., 1992). This report deals with a phytochemical study of the constitutive polyphenolic metabolites of *E. jambolana* leaves grown in Egypt.

2. Results and discussion

Using 2D-PC and different spray reagents of polyphenols, ethyl acetate extract of *E. jambolana* leaves was found to contain a complicated mixture of polyphenols, specially flavonol glycosides and some of phenolic acids together with minor ellagitannins. Fractionation of this extract on a silica gel column followed by successive separation on Sephadex LH-20 and cellulose columns afforded 17 polyphenolic metabolites. Depending on chromatographic and spectroscopic analyses, the isolated compounds were identified as gallic acid **3**, methylgallate **4**, kaempferol **5**, myricetin **6**, ellagic acid **7**, 3-*O*-methylellagic acid **8**, myricetin 3-*O*-(4″-*O*-acetyl)-α-L-rhamnopyranoside i.e (myricetrin 4″-*O*-acetate) **9**, myricetin 4′-methyl ether 3-*O*-α-L-rhamnopyranoside **10**, myricetrin **11**, chlorogenic acid **12**, quercetrin 4″-*O*-acetate **13**, quercetin 3-*O*-α-L-rhamnopyronside (quercet) **14**, kaempferol 3-*O*-β-D-glucuronopyranoside **15**, myricetin 3-*O*-β-D-glcuronopyranoside **16** and an ellagitannin, nilocitin **17**. The two new compounds were identified as mearnsetin 3-*O*-(4″-*O*-acetyl)-α-L-rhamnopyranoside **1** and myricetrin 4″-*O*-acetyl-2″-*O*-gallate **2**.

Structurally related compounds **1** and **9**–**11** were tentatively identified as myrincetin 3-*O*-glycosides according to their chromatographic properties [R_f-values, fluorescence under UV light, UV/NH_3, responses towards $FeCl_3$ and naturstoff (NA/PE) reagents] and UV spectral analyses

(Table 1). UV spectra in MeOH of these compounds gave absorption maxima bands I and II at $\geqslant$350 and $\geqslant$257 nm which are characteristic for flavonols (Mabry et al., 1970). A bathochromic shift with NaOMe without decrease in intensity of band I, was diagnostic for the presence of free 4′-OH group in **9** and **11** while decrease in intensity in the case of both **1** and **10** revealed the 4′-*O*-substituted structures. The bathochromic shift in band II with NaOAc was indicative of free 7-OH groups in their structures. On the other hand, the strong bathochromic shift in band I (>60 nm) remaining after addition of HCl to $AlCl_3$ indicated the presence of free 5-OH group and suggested the absence of free 3-OH group. On account of these data, compounds **9** and **11** are expected to be myricetin 3-*O*-glycosides while **1** and **10** 4′-*O*-substituted myricetin 3-*O*-glycosides. On complete acid hydrolysis, **9** and **11** gave L-rhamnose and myricetin (CoPC), while mearnsetin (Sakushima et al., 1983) in the case of **1** and **10** (UV data) was obtained. The identity of the aglycone was more evidenced as myricetin in **9** and **11** on the basis of direct infusion −ve ESI–MS spectrometric data which showed a fragment ion peak at *m*/*z* 316, while ion peak at 331 were observed in the case of **1** and **10** indicative to myricetin 4′-methyl ether aglycone. The evidence that **10** is a methyl ether derivative of **11**, whereas **9** is its acetyl derivative was concluded from their molecular ion peaks (**11**: 463, **10**: 477, **9**: 505). Also, **1** was expected to be a methyl ether derivative of **9** due to the difference in the molecular ion peak by 14 mu (**1**: 519.3), indicative to MF of $C_{24}H_{24}O_{13}$. The complete structure elucidation was based on the comparison of ^1H and ^{13}C NMR data. The sugar moiety of all four compounds was identified as $^1C_4$-α-L-rhamnopyranoside on the basis of δ ppm and *J*-values (Table 2). The presence of an *O*-acetyl group in both **1** and **9** structures (*s*, δ 2.0 and 1.99) on C-4″ was confirmed by downfield shift of H-4′ at δ 4.69, *t* and 4.71, respectively relative to H-4″ at 3.15, *m* in free rhamnoside moiety of **10** and **11**. Presence of a singlet signal integrated to 3 protons at 6 3.74 in each of the two ^1H NMR spectra of **1** and **10**, referred to a methoxy group at 4′-position. These evidences were supported from ^{13}C NMR data (Table 3). The two carbon resonances at δ 170.0 and 21.0 were assigned to C=O and CH_3 carbons of an acetyl group in the structures of both **1** and **9**. The attachment of these groups at C-4″ was confirmed by the downfield shift of C-4″ signals (73.3 and 73.19) and upfield shift of both C-3″ and C-5″ signals (67.9, 68.03) relative to the corresponding resonances of **10** and **11** (Table 3). The presence of a methoxy group (δ 59.8 and 59.75), at 4′-position in each of **1** and **10** deduced from the downfield shifts of C-3′ and C-5′ resonances (150.8 and 150.6) comparing to

[a] Exchangeable carbon resonances.
[b] Carbon resonances which were affected by substitution of OMe or *O*-acetyl at C-4′ and C-4″, respectively.

those of **9** and **11** (Markham et al., 1978). The remaining carbon resonances of all structures were confirmed and completely assigned according to the ^{1}H ^{1}H– and ^{1}H ^{13}C COSY correlation spectroscopy of **9** and **11**, in addition to comparison study with the published data of related structures (Karin et al., 1989; Toshiya et al., 1991; Karla et al., 1994a,b; Hiroyuki et al., 1996). Accordingly, the structures of **9**, **10** and **11** were identified as the known compounds myricetin 3-*O*-(4″-*O*-acetyl)-α-L-$^1C_4$-rhamnopyranoside, mearnsetin 3-*O*-α-L-$^1C_4$-rhamnopyranoside and myricetin 3-*O*-α-L-$^1C_4$-rhamnopyranoside, respectively. Whereas **1** was identified as the new mearnsetin 3-*O*-(4″-*O*-acetyl)-α-L-$^1C_4$-rhamnopyranside.

Compound **2**, on the basis of chromatographic properties (R_f values, fluorescences under UV and UV/NH_3, responses towards NP/PE-UV and $FeCl_3$) was expected to be myricetin 3-*O*-glycoside. Band I (351 nm) and Band II (264 nm) in UV/MeOH spectrum together with the different bathochromic and hypsochromic shifts on addition of all diagnostic shift reagents supported the previous evidence (Mabry et al., 1970). On complete acid hydrolysis, it gave gallic acid and myricetin in the organic phase in addition to L-rhamnose in the aqueous phase (CoPC) to suggest myricetin 3-*O*-galloylrhamnoside structure. Partial hydrolysis with boiling H_2O, **2** gave **9** as an intermediate together with gallic acid indicative of a diacylated rhamnose with both gallic and acetic acids. Negative ESI–MS spectrum of **2** showed $[M–H]^-$ ion peak at *m*/*z* 657.2 as base peak corresponding to a *Mr* of 658 and MF of $C_{30}H_{26}O_{17}$. Additionally, using in-source (CID) fragmentation potential, led to observation of very significant three fragment ions at *m*/*z* 505 [M-galloyl]$^-$, 317 [myricetin-H]$^-$ and 316 [myricetin-2H]$^-$. These results suggested that the structure of **2** contains not only a galloyl moiety but also an acetyl group located on the rhamnoside moiety at C-4″. Positions of substitution of the galloyl and acetyl moieties as well as the complete structure of **2** were determined by ^{1}H and ^{13}C NMR analyses. The aglycone moiety was simply identified as myricetin through its three proton resonances of H-2′/6′, H-8 and H-6. The presence of gallic acid moiety as well as acetyl moiety was concluded through the two resonances at δ 6.96 (2H, *s*) and 2.03 (3H, *s*), assignable to H-2‴/6‴ and –CO–CH_3, respectively. Also locations of the gallic acid moiety at C-2″ and acetyl moiety at C-4″ of rhamnosyl moiety were detected through the downfield shifts of both H-2″ (5.53 ppm) and H-4″ (4.78) relative to those of corresponding resonances at δ 3.96 and 3.2 in the structure of myricetrin (**11**). The configuration and conformation of the sugar moiety were identified as

2″,4″-diacylated α-L-$^1C_4$-rhamnopyranosyl according to the δ- and J-values of all other signals of H-1″, H-3″, H-5″ and CH_3-6″. Accordingly, **2** was identified as myricetin 3-*O*-(4″-*O*-acetyl-2″-*O*-galloyl)-α-L-rhamnopyranoside. This structure was finally confirmed by the complete assignment of all C-resonances in its ^{13}C NMR spectrum by comparison with the corresponding resonances of both **11** and **9** (Table 4).

According to the downfield/upfield shift rule for the resonance of substitution position and the two adjacent carbons, acylation at C-2″ (72.5) of **2** led to downfield shift of +2.5 ppm relative to those of **11** and **9** (~70.0) together with upfield shift of both C-1″ (100.1) by −1.8 and C-3″ (67.0) by −1.0 in the case of **9** and −3.4 in the case of **11** due to the acylation also at C-4″. The acylation at C-4″ resulted in downfield shift from 71.2 (**11**) to 73.3 in **9** and 74.5 in **2**, but it led to upfield shift of C-5″ (68.5) by −2.0 relative to that of **11** (70.5). The two resonances at δ 171.26 and 22.3 were assigned to CO and CH_3 of the acetyl moiety whereas resonance at δ 166.2 was assigned to C=O of galloyl moiety. Additionally, the complete assignment of all other resonances was based on the comparison study with those of **11** and **9** as well as the published data of structurally related compounds (Hyoung et al., 1998; Yonungsoo et al., 2000). This complete assignment confirmed the configuration and conformation of the rhaninosyl moiety, as well as the complete structure of **2** as myricetin 3-*O*-(4″-*O*-acetyl-2″-*O*-galloyl)-α-L-$^1C_4$-rhamnopyranoside which was identified here as a new natural product.

This study revealed that leaves of *E. jambolana* are rich in flavonol glycosides and some of their acylated rhamnosides, which based on the myricetin or mearnsetin as aglycones in most of them. All the identified compounds were isolated for the first time from this species and both **9** and **10** were isolated in nature once before (Harborne, 1994; Ossipov et al., 1995). Also two new acylated flavonol rhamnosides were identified as two new natural products (**1** and **2**).

3. Experimental

3.1. Plant material

Leaves of *E. jambolana* Lam. were collected from the plant grown in the Zoological Garden, Giza, in July 1999. Identification of the plant was confirmed by Dr. Mohamed El-Gebaly, Lecturer of Plant Flora Taxonomy NRC, Giza, Egypt and comparison with reference herbarium specimens. Voucher specimens are kept in the herbarium, Pharmacognosy Department, Faculty of Pharmacy, Helwan University, Egypt.

Table 4
Comparison of C-resonances of rhamnoside moieties in the structures of **2**, **9** and **11**

Compound	C-1″	C-2″	C-3″	C-4″	C-5″
2	100.1	72.5	67.0	74.5	68.5
9	101.8	70.02	68.0	73.3	68.0
11	101.9	70.0	70.4	71.2	70.5

3.2. Isolation and identification

Dry powder of *E. jambolana* leaves (2 kg) was defatted with pet. ether (60–80), then extracted with hot 70% MeOH under reflux. After evaporation of the solvent, dry residue was extracted with EtOAc to give 45 g dry extract. EtOAc extract was fractionated on silica gel G column and starting the elution with pet. ether (60–80), then gradually addition of EtOAc affording collective six frs (1–6). The obtained frs were subjected separately to consecutive combination of column chromatography on microcrystalline cellulose for CC (E. Merck, Darmstadt, Germany) and sephadex LH-20 (Pharmacia, Uppsala, Sweden) with aq. EtOH and/or *n*-BuOH saturated with H_2O solvent systems to afford chromatographically pure samples of compounds **1**–**17**. All separation processes were followed up by 2D-PC and CoPC using Whatmann No. 1 paper with (S_1) *n*-BuOH–AcOH– H_2O (4:1:5, top layer) and (S_2) 15% AcOH as solvent systems. The isolated quantities were 18, 15, 20, 15, 20, 30, 12, 18, 67, 23, 53, 7, 10, 17, 21, 28 and 70 mg of compounds **1**–**17**, respectively.

3.3. UV analysis

Pure samples were measured separately as MeOH solns and with different diagnostic shift reagents (Mabry et al., 1970) on a UV IKON 940 spectrophotometer.

3.4. NMR analyses

NMR analyses were run on Brucker 300, Jeol EX-270 and 400 MHz spectrometers relative to TMS in different deuterated solvents.

3.5. Negative ESI–MS

The diluted soln of each sample, in 1:1 MeOH–H_2O was directly infused using a syringe Harvard infusion pump to a double focusing sector field mass spectrometer Finnigan MAT 95 according to the previously published conditions (Nawwar et al., 1997) as well as to LC–MS LCQ deca spectrometer (Finnigan, Bremen, Germany).

3.6. Mearnsetin 3-O-(4″-O-acetyl)-α-L-$^1C_4$-rhamnopyranoside *1*

Yellow amorphous powder; its chromatographic properties and UV spectral data (Table 1). Acid hydrolysis; a

small amount of **1** (8 mg) was hydrolysed with 2 N HCl in MeOH–H_2O (1:1), under reflux at 100 °C for 2 h to yield L-rhamnose and mearnsetin (CoPC and spray reagents). -ve ESI–MS: *m/z* 519 $[M–H]^-$, 463 [M–acetyl]$^-$, 331 [Mearnsetin–H]$^-$. ^{1}H NMR data (300 MHz, DMSO-d_6): Table 2. ^{13}C NMR (75 MHz, DMSO-d_6): Table 3.

3.7. Myricetin 3-O-(4″-O-acctyl-2″-O-galloyl)-α-L-$^1C_4$-rhamnopyranoside 2

Yellow amorphous powder; d.pr. fluorescence under UV, changed to yellow with NH_3 vapour. Org-red with NP/PE and bl-gr. with $FeCl_3$ spray reagents. R_f values: 0.64 and 0.10 in S_1 and S_2, respectively. UV spectral data λ_{max}, nm; (MeOH): 222, 264, 284, 300 (*sh*), 351; (+NaOMe): 275, 322, 395; (+NaOAc): 273, 310 (*sh*), 365; (+NaOAc/H_3BO_3): 230, 263, 369; (+$AlCl_3$): 231, 268, 331, 418; (+$AlCl_3$/HCI): 220, 270, 404. Acid hydrolysis; 7 mg of **2** were hydrolysed under the same conditions in the case of **1** to yield L-rhamnose, gallic and myricetin (CoPC and spray reagents). Partial hydrolysis; 6 mg from **2** were dissolved in H_2O and boiled under reflux for about 18 h; the reaction mix was examined by CoPC against authentic samples of gallic acid and **9**. −ve ESI–MS: *m/z* 657 $[M–H]^-$, 505 [M–gallyl]$^-$, 317 [myricetin–H]$^-$, 316 [myricetin–2H]$^-$. ^{1}H NMR data (300 MHz, DMSO-d_6): δ ppm 6.96 (2H, *s,* H-2‴/6‴), 6.9 (2H, *s,* H-2′/6′), 6.39 (1H, *d,* J=1.9 Hz, H-8), 6.21 (1H, *d,* J=1.9 Hz, H-6), 5.53 (1H, *brd,* H-2″), 5.48 (1H, *d*, J=1.5 Hz, H-1″), 4.78 (1H, *t,* J=9.8 Hz, H-4″), 4.06 (1H, *dd,* J=9.8, 3.3 Hz, H-3″), 3.4 (1H, *m* hidden by H_2O-signal, H-5″), 2.03 (3H, *s,* CO-Me) and 0.82 (3H, *d,* J=6.1 Hz, CH_3-6″). ^{13}C NMR (75 MHz, DMSO-d_6): δ ppm 178.6 (C-4), 171.3 (CO-acetyl), 166.2 (C-7‴), 165.6 (C-7), 162.6 (C-5), 159.9 (C-2), 157.8 (C-9), 147.3 (C-3‴/5‴), 146.9 (C-3′/C-5′), 139.9 (C-4‴), 138.0 (C-4′), 135.5 (C-3), 120.6 (C-1‴), 120.3 (C-1′), 110.2 (C-2‴/6‴), 109.0 (C-2′/6′), 105.36 (C-10), 100.1 (C-1″), 99.3 (C-6), 93.6 (C-8), 74.5 (C-4″), 72.5 (C-2″), 68.5 (C-5″), 67.0 (C-3″), 22.3 (Me-acetyl), 18.6 (C-6″).

Acknowledgements

We thank Professor Dr. M. Linscheid, Dr. J. Mügge and their co-workers (Institute of Chemistry, Humboldt University, Berlin, Germany) for their efforts and helpful cooperation in the MS and NMR measurements.

Xanthones from the stems of *Securidaca inappendiculata*

Xue-Dong Yang*, Li-Zhen Xu, Shi-Lin Yang

Institute of Medicinal Plant Development, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing 100094, PR China

Received 9 March 2001; received in revised form 17 July 2001

Abstract

From the stems of *Securidaca inappendiculata*, securixanthones A (1,3,7-trihydroxy-2,8-dimethoxyxanthone) and B (3,7-dimethoxy-4-hydroxyxanthone) along with ten known xanthones were isolated. Their structures were elucidated by analysis chemical and spectroscopic evidence, and the chemotaxonomic significance of these findings are also discussed. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Securidaca inappendiculata*; Polygalaceae; Xanthones; Securixanthone A; Securixanthone B

1. Introduction

The roots and stems of *Securidaca inappendiculata* Hassk. (Polygalaceae) are used as anti-inflammatory, anti-bacterial and anti-rheumatoid agents under the names "Chan yi teng", "Wu wei teng" or "Diu le bang" in the south of China (Jiangsu Institute of Botany, 1988). According to available literature, no phytochemical research work has been carried out on this plant. The genus *Securidaca* accumulates flavonoids (Hamburger et al., 1985; Galeffi et al., 1990), alkaloids (Costa et al., 1992; Scandola et al., 1994), saponins (Davreux and Delaude, 1971), organic acids (Mahmood et al., 1993) and sucrose derivatives (Tommasi et al., 1993).

In our search for anti-HIV active principles in *Securidaca* plants, the xanthone constituents of *S. inappendiculata* Hassk. were examined. This paper describes the structural elucidation of xanthones isolated from this plant and discusses the chemotaxonomic significance of these findings.

2. Results and discussion

The stems of *S. inappendiculata* were collected, dried, ground, and extracted with ethanol. Column chromatography combined with medium pressure liquid chromatography (MPLC) of the chloroform-soluble part yielded two new xanthones along with ten known xanthones.

Xanthone **1**, obtained as yellow needles, mp 218 °C, had a molecular formula of $C_{15}H_{12}O_7$ as established by HR–EI mass spectrometry (m/z 304.0584 $[M]^+$). The UV spectrum of **1** exhibited characteristic absorption bands of a xanthone (λ_{max}^{MeOH}, 238, 261, 312, 381 nm), and a bathochromic shift induced by addition of NaOAc suggested the presence of a free hydroxyl group at either C-6 or C-3 (Harborne, 1973). The lack of a di-ortho-hydroxyl group was evident by the absence of a shift after the addition of NaOAc and H_3BO_3. The ^1H NMR spectrum showed a chelated OH (δ 13.38), an AB system (δ 7.36 H-6 and 7.20 H-5) of two *ortho*-coupled protons ($J = 9.12$ Hz), a singlet (δ 6.37) and two methoxyl groups (δ 3.80 and 3.73). In the ^{13}C NMR spectrum, signals at δ 59.83 and δ 60.91 were indicative of two di-*ortho*-substituted methoxyl groups (Frahm and Hambloch, 1982). The positions of the substituents were confirmed unambiguously through a NOESY experiment. The NOESY spectrum of **1** (in DMSO-d_6) showed four significant cross peaks, namely) the peaks between: (1) the single aromatic proton (H-4) signal at δ 6.38 and the hydroxyl signal at δ 10.88 (OH-3); (2) the hydroxyl signal (OH-1) at δ 13.38 and the methoxyl signal at δ 3.73 (OMe-2); (3) the methoxyl signal (OMe-8) at δ 3.80 and the hydroxyl signal (OH-7) at δ 9.57 and (4) the hydroxyl signal (OH-7) at δ 9.57 and the downfield aromatic proton (H-6) at δ 7.36. This indicated that hydroxyl groups were at the C-1, C-3 and C-7 positions,

PII: S0031-9422(01)00356-9

and the two methoxyl groups were at the C-2 and C-8 positions. Furthermore, the presence of a 1,3-dihydroxy- 2-methoxyl moiety and a 7-hydroxy-8-methoxyl moiety in **1** was supported by analysis of the ^{13}C NMR spectrum. The C-8b, C-1, C-2, C-3, C-4 and C-4a shifts in the ^{13}C NMR spectrum of **1** were comparable to those of 1,3,6-trihydroxy-2,5-dimethoxyxanthone (**13**) (Pinto et al., 1994). The C-4b, C-5, C-6, C-7, C-8 and C-8a shifts in the ^{13}C NMR spectrum of **1** were essentially the same as those of (C-4a, C-4, C-3, C-2, C-1 and C-8b) in 2,5-dihydroxy-1-methoxyxanthone (**14**) (Minami et al., 1996). From the above data, **1** was determined to be 1,3,7-trihydroxy-2,8-dimethoxyxanthone, and was named securixanthone A.

Xanthone **2** was obtained as fine yellow needles, mp 178 °C. The molecular formula was assigned as $C_{15}H_{12}O_5$ on the basis of HR–EI mass spectrometry (*m*/*z* 272.0686 $[M]^+$). The UV spectrum (in MeOH) of **2** showed absorptions at 237, 262, 318 and 384 nm. The presence of a free hydroxyl group at either C-6 or C-3 was excluded based on the lack of any change in the UV spectrum upon addition of NaOAc. In the IR spectrum, characteristic absorptions of a xanthone were observed at 3500 and 3420 cm^{-1} (OH), 1640 cm^{-1} (conjugated carbonyl), 1620 and 1565 cm^{-1} (aromatic moieties). The ^1H NMR spectrum displayed resonances for two aromatic methoxyls (δ 3.81 and 3.86), a hydroxyl (δ 9.42), a three-proton spin system (δ 7.51, 7.40 and 7.52; $J=9.18$ and 2.98 Hz) and an AB system (δ 7.37 and 7.26) of two ortho-coupled protons ($J=9.15$ Hz). The ^{13}C NMR spectrum indicated that the aromatic methoxyl at δ 61.04 was di-*ortho*-substituted and that there were no substituted groups at either a C-1 or C-8 position according to the carbonyl carbon shift (δ 174.98) (Philip et al., 1977). Furthermore, the presence of MeO-7 rather than MeO-6 in **2** was supported by analysis of the ^{13}C NMR spectrum. The C-4b, C-5, C-6, C-7, C-8 and C-8a shifts in the ^{13}C NMR spectrum of **2** are essentially the same as those (C-4a, C-4, C-3, C-2, C-1 and C-8b) of 2-methoxyxanthone (Fernandes et al., 1998). The positions of the substituents were confirmed through a NOESY experiment. The NOESY spectrum of **2** (in DMSO-d_6) showed two significant cross peaks between the methoxyl signal (OMe-7) at δ 3.86 and the aromatic proton signals (H-8, H-6) at δ 7.52 and 7.40. Acetylation of **2** with Ac_2O in pyridine gave the acetate **2a**. In the ^1H NMR spectrum of **2a**, signals due to the protons were not shifted markedly compared to that of **2**. On the basis of this evidence, the structure of **2** was concluded to be 3,7-dimethoxy-4-hydroxyxanthone, named securixanthone B.

In addition to the two new xanthones described above, ten known xanthones, 1,6-dihydroxyxanthone (**3**) (Lin et al., 1996), 1,7-dihydroxyxanthone (**4**) (Tosa et al., 1997), 2-hydroxy-1,7-dimethoxyxanthone (**5**) (Galeffi et al., 1990), 1,7-dihydroxy-4-methoxyxanthone (**6**) (Galeffi et al., 1990), 1,7-dihydroxy-3,4-dimethoxyxanthone (**7**) (Bashir et al., 1992), 1,3,8-tri-hydroxy-2-methoxyxanthone (**8**) (Gil et al., 1990), 1,3,6-trihydroxy-2,7-dimethoxyxanthone (**9**) (Silveria et al., 1995), 1,3,7-trihydroxyxanthone (**10**) (Stout et al., 1969), 2,7-dihydroxy-1-methoxyxanthone (**11**) (Nagem et al., 1992) and 1,3,7-trihydroxy-2-methoxyxanthone (**12**) (Pinheriro et al., 1998) were isolated from the same extract. They were identified by spectral (include NOESY) and chemical data and by comparison with literature data.

2.1. Chemotaxonomic significance

The genus *Securidaca* comprises about 80 species, and are mainly distributed in the tropical regions of America. Only two species, *S. yaoshanennsis* Hao and *S. inappendiculata* Hassk, occur in China (Delectis Florae Republicae Popularis Sinicae Agendae Academiae Sinicae Edita, 1997). To our knowledge, only a few phytochemical studies of this genus have been made (Yang et al., 2000a). So, after we finished our investigation, we compared the xanthone components of this genus with those found in *Polygala* L. The two genera belong to the same tribe, Polygaleae Chodat of Polygalaceae.

More than 60 kinds of xanthones have been obtained from *Polygala* L. so far (Yang et al., 2000b). In their structures, there are three types of substituents, namely hydroxyl, methoxyl and methylenedioxyl groups and the highest number of oxygenated substituents is 6 (only 1 case). In the 13 xanthones isolated from *Securidaca* L.

[a] Assignments confirmed by NOESY; *J* (Hz) in parentheses.

[one (2-hydroxy-1,7-dimethoxyxanthone) from *S. longipedunculata* (Galeffi et al., 1990) and twelve from *S. inappendiculata* (this paper)], only have hydroxyl and methoxyl groups and the highest number of oxygenated groups are 5. In xanthones of the genus *Polygala* L., all eight possible substituted positions can be then subsituted oxygenated, but the substitution probabilities are quite different: 5 position is the least subsituted, 4 and 8 position take the second place and the 1, 2, 3 and 7 positions are most commonly. The oxygenation pattern of xanthones obtained from *Securidaca* L. has similar characteristics. The probability number of xanthones in which an oxygenated group appears at a certain position/in either *Polygala* or *Securidaca* in (Yang et al., 2000b) is illustrated in Table 3. These results strongly suggest that both genera have a chemotaxonomic relationship.

3. Experimental

3.1. General

Mps: uncorr. ^{1}H NMR: 400 MHz. ^{13}C NMR: 125 MHz (for xanthon **1** and **8**) and 100 MHz (for other xanthones), TMS as int. standard. 2D-NOE data were obtained from a NOESY experiment using the standard DISNMR software package (Bruker). IR: KBr discs. CC: silica gel and polyamide. TLC: silica gel G with visualization by UV (254 and 365 nm) and exposure to iodine vapor. TLC was used to analyze the frs. collected from CC.

3.2. Plant material

The stems of *Securidaca inappendiculata* Hassk. were collected in Yunnan province of China and identified by Professor Wen-Yan Lian (our institute) and Professor Hong Wang (Menglun Botanical Garden). Voucher specimens are deposited in the Phytochemistry Department of our institute.

3.3. Extraction and isolation

The dried and ground stems (10 kg) were extracted with 95% EtOH (30 l×3, 2 h each) under condition of reflux. The EtOH extract (750 g) was evaporated to dryness under reduced pressure then fractionated by solvent reflux in a Soxhlet apparatus (silica gel as absorbent) into $CHCl_3$, EtOAc, Me_2CO and MeOH solubles, respectively. The $CHCl_3$ soluble (10.5 g) were subjected to MPLC (silica gel, 200–300 mesh) luted with a gradient of Me_2CO in petroleum ether (95:5–50:50) to give 18 main fractions. Each fraction was purified by polyamide CC eluted with $CHCl_3$–MeOH (1:0–0:1, gradient) and Sephadex LH-20 to give xanthones **1** (8 mg) from fraction sixteen (65:35), **2** (10 mg) from fraction eight (85:15), **3** (5 mg) and **4** (13 mg) from fraction five (90:10), **5** (6 mg) from fraction ten (80:20), **6** (12 mg) and **7** (10 mg) from fraction eleven (75:25), **8** (4 mg) from fraction four (94:6), and **9** (5 mg) from fraction fourteen (70:30). The EtOAc soluble (31 g) were subjected to MPLC (silica gel, 200–300 mesh) eluted with a gradient of Me_2CO in $CHCl_3$ (100:0–40:60) to give thirty-six main fractions. Fractions 1–3 (100:0–96:4) were purified by polyamide CC eluted with $CHCl_3$–MeOH (1:0–0:1, gradient) and Sephadex LH-20 to give xanthones **10** (12 mg), **11** (20 mg) and **12** (10 mg).

3.4. 1,3,7-Trihydroxy-2,8-dimethoxyxanthone (*1*)

Fine yellow needles (from MeOH), mp 218 °C; HR–EIMS *m/z:* 304.0584, calc. for $[M]^+$, $C_{15}H_{12}O_7$: 304.0583; dark purple fluorescence under UV light (on polyamide sheet) and dark green color with $FeCl_3$; UV λ_{max}^{nm} MeOH: 238, 261, 312, 381; +NaOAc: 220, 259 sh, 315 sh, 359; +NaOAc+H_3BO_3: 222, 259 sh, 318; IR (cm^{-1}, KBr): 3400, 2940, 1650, 1610, 1580, 1479, 1400, 1300; EIMS *m/z* (rel. int.): 304 (100), 289 (52), 286 (24), 271 (20), 261 (60), 246 (30), 218 (60); ^{1}H and ^{13}C NMR spectral data: see Tables 1 and 2, respectively.

3.5. 1,3,7-Triacetoxy-2,8-dimethoxyxanthone (*1a*)

Xanthone **1** (3 mg) was treated with Ac_2O and pyridine (1:1) at room temp. overnight, dil. with H_2O and extracted with Et_2O. The dried Et_2O extract was purified by Sephadex LH-20 ($CHCl_3$: MeOH, 1:1) to give **1a** (2 mg) as white needles (from MeOH), mp 188 °C. UV λ_{max}^{nm} MeOH: 236, 277, 304, 342; +NaOAc: 212, 348; +NaOAc+H_3BO_3: 212, 348; ^{1}H NMR spectral data: see Table 1.

Received 2 March 2001; received in revised form 24 May 2001

Abstract

Two coumaroyl flavonol glycosides, isorhamnetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside], and kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside, were isolated from the *n*-BuOH extract of *Ginkgo biloba* leaves. These two, together with six other flavonol glycosides, kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside], quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside], quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside, quercetin 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside, quercetin 3-*O*-β-rutinoside, and quercetin 3-*O*-β-D-glucopyranoside, showed profound antioxidant activities in DPPH and cytochrome-*c* reduction assays using the HL-60 cell culture system. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Ginkgo biloba* L.; Ginkgoaceae; Flavonol glycoside; Antioxidant activity

1. Introduction

Extracts from *Ginkgo biloba* L. (maidenhair tree) have been used therapeutically for centuries. Ginkgo, like ginseng, is mentioned in the traditional Chinese pharmacopoeia and the Chinese made tea from parts of the ginkgo tree for treatment of asthma and bronchitis. The *n*-BuOH extract of *G. biloba* leaves showed antioxidant activity in preliminary DPPH assays. This prompted us to search for antioxidant compounds from this plant. Bioassay-guided fractionation of the *n*-BuOH extract led to the isolation of antioxidant flavonol glycosides **1**–**13**, including two new compounds isorhamnetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] (**1**) and kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside (**2**). Kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] (**3**), quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] (**4**), quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside (**5**), kaempferol 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside (**6**), isorhamnetin 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside (**7**), quercetin 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside (**8**), isorhamnetin 3-*O*-β-rutinoside (**9**), quercetin 3-*O*-*β*-rutinoside (**10**), kaempferol 3-*O*-*β*-rutinoside (**11**), quercetin 3-*O*-β-D-glucopyranoside (**12**) and kaempferol 3-*O*-β-D-glucopyranoside (**13**) were also isolated from *G. biloba* leaves.

2. Results and discussion

The *n*-BuOH extract of *G. biloba* was applied to a Si gel column using $CHCl_3$–MeOH (25:1) as eluant, followed by stepwise addition of MeOH to afford 12 fractions. Each fraction was further subjected to Si gel, and Sephadex LH-20 column chromatography, as well as reversed-phase HPLC to afford 13 flavonol glycosides **1**–**13**.

Compound **1** was obtained as a pale yellow amorphous powder. Upon acid hydrolysis of **1**, isorhamnetin, *p*-coumaric acid, glucose and rhamnose were identified

by TLC. Isorhamnetin and *p*-coumaric acid were also identified by UV and ^{1}H NMR spectroscopy. Under UV light, compound **1** appeared as a dull brown flavonol-like fluorescent spot on silica gel and polyamide plates, indicating the substitution of the C-3 hydroxyl group. This spot changed to yellow with ammonia and to yellowish-green with Naturstoffreagenz A indicating respectively the presence of free 5- and 4′-hydroxyl groups and absence of an *ortho*-dihydroxyl group in the B-ring. The UV shift on addition of diagnostic reagents confirmed the presence of free hydroxyl groups at positions C-5, C-7 and C-4′ (Markham, 1982). Therefore, the position of the linkage between isorhamnetin and the other moiety, occurs at C-3. Its IR spectrum indicated the presence of two carbonyl groups (1656 and 1680 cm^{-1}) indicating the flavonol carbonyl and ester carbonyl groups. The positive-ion FABMS spectrum exhibited a quasi-molecular ion peak at *m*/*z* 771 $[M+H]^+$ in accordance with a *p*-coumaroyl ester of a isorhamnetin bioside. Other prominent peaks were observed at *m*/*z* 463 $[M\text{-}308+H]^+$ and *m*/*z* 317 $[aglycone+H]^+$, which showed that glucose was located between rhamnose and *p*-coumaric acid.

The ^{1}H NMR spectrum exhibited two doublets at δ 6.24 and 7.46 with large coupling constants (15.9 Hz) which identified *trans* olefinic double bond protons, and the other caused by the four aromatic ring proton signals at δ 6.72 and 7.46 (AA′BB′), which confirmed the presence of the *p*-coumaroyl subunit. The ^{1}H NMR spectrum also indicated the presence of a methoxyl signal at δ 3.84 (3H, *s*, 3′-OMe), and five aromatic proton signals at δ 6.18 (1H, *d*, H-6, $J=1.9$ Hz), 6.33 (1H, *d*, H-8, $J=1.9$ Hz), 6.90 (1H, *d*, H-5′, $J=8.4$ Hz), 7.53 (1H, *dd*, H-6′, $J=2.1$ and 8.4 Hz) and 7.86 (1H, *d*, H-2′, $J=2.1$ Hz), which confirmed the isorhamnetin 3-*O*-glycoside structure. The ^{1}H NMR spectrum also supported the presence of one rhamnose and one glucose with the rhamnose anomeric proton at δ 5.54 (H-1, brs) and the glucose H-1 at δ 4.31 (d, 7.8 Hz). The ^{1}H–^{1}H COSY and TOCSY experiments permitted the full assignment of the sugar protons (Table 1). In the ^{13}C NMR spectral data, the C-2 (rha) was shifted downfield at δ 81.7, indicating that glycosylation of the rhamnose unit by the glucopyranosyl was on in 2-hydroxyl. In the HMBC spectrum, a crosspeak between C-2 (rha) and H-1 (glc), and a crosspeak between C-2 (rha) and H-1 (rha) established the linkage point between the two sugar moieties (Table 1). In addition to this, downfield shielding of C-2 indicated that position 3 was substituted by a glycosyl moiety. This was confirmed by a crosspeak between H-1 (rha) and C-3 of the aglycone in the HMBC spectrum. The ^{13}C NMR spectrum of the sugar moiety of **1** also showed a downfield shift of C-6 glc ($\Delta+1.9$) from the chemical shift values reported for the corresponding carbon resonances of unlinked C-6 glucose such as flavonol 3-*O*-glucopyranoside (Markham et al., 1978). This shift was expected from the substituent effect of C-6 glucose acylation. This was also confirmed by a crosspeak between H-6 (glc) and C-1 (Coum) in the HMBC spectrum. Therefore, compound **1** was characterized as isorhamnetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside].

Compound **2** was a yellow amorphous powder. Upon acid hydrolysis of **2**, kaempferol, *p*-coumaric acid, glucose and rhamnose were identified by TLC. Kaempferol and *p*-coumaric acid were also identified by UV and ^{1}H NMR spectroscopy. The UV and IR spectra of **2** were similar to those of **1**. The molecular formula, $C_{42}H_{46}O_{22}$, was inferred from the $[M+H]^+$ peak at *m*/*z* 903 in the FABMS, and it was supported by ^{13}C NMR and DEPT spectroscopic analyses. The ^{1}H NMR and ^{13}C NMR spectra of **2** showed the presence of a kaempferol moiety, three sugar residues and a *p*-coumaric acid moiety. Its ^{1}H NMR, ^{13}C NMR and 2D NMR spectra showed the presence of a 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] as for **1** (Table 2). A ^{13}C NMR signal at δ 162.8

was assigned to C-7, based on its long-range ^{13}C-^{1}H correlation observed in the HMBC experiment with the two ^{1}H NMR signals at δ 6.40 (H-6) and δ 6.60 (H-8). C-7 showed a three-bond correlation with an anomeric proton at δ 5.05. The 2D NMR spectra allowed the assignment of all ^{1}H and ^{13}C NMR signals of the 7-glucosyl residue, which could be identified as a glucopyranoside (Markham et al., 1982). The β-configuration of the anomeric carbon was evident from the coupling constant of H-1⁗′ (J = 7.5 Hz) observed in the ^{1}H NMR spectrum (Markham and Geiger, 1994). The structure of compound 2 is therefore kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside.

Compounds **3**–**8** were identified by comparing their physical and spectral data with the literature values: kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] (**3**) (Markham et al., 1992), quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside] (**4**) (Nasr et al., 1987; Markham et al., 1992), quercetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-*O*-β-D-glucopyranoside (**5**) (Hasler, et al. 1992), kaempferol 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamno-

pyranoside (**6**) (Hasler et al., 1992), isorhamnetin 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside (**7**) (Tang et al., 2000), quercetin 3-*O*-β-D-glucopyranosyl-(1-2)-α-L-rhamnopyranoside (**8**) (Hasler et al. 1992). Compounds **9**–**13** were identified by comparison of their spectral data with those of authentic samples: isorhamnetin 3-*O*-β-rutinoside (**9**), quercetin 3-*O*-β-rutinoside (**10**), kaempferol 3-*O*-*β*-rutinoside (**11**), quercetin 3-*O*-β-D-glucopyranoside (**12**), and kaempferol 3-*O*-β-D-glucopyranoside (**13**).

For the screening and evaluation of antioxidant activity of pure compounds and/or plant extracts, DPPH and cytochrome-*c* reduction assays were adopted. Compounds **1**–**5**, **8**, **10** and **12** exhibited inhibitory activity as strong as the positive control against TPA-induced free radical formation in a HL-60 cell culture system and showed free radical scavenging activity in the DPPH assay (Table 3). Five coumaroyl flavonol glycosides (IC_{50} of **1**–**5**, 17.5, 17.9, 17.7, 13.2, 13.5 μg/ml, respectively) showed profound activity. Generally, the presence of hydroxyl substituents on the flavonoid nucleus enhanced activity, whereas substitution by methoxyl groups diminished antioxidant activity. Substitution patterns on the B-ring especially affected antioxidant potencies of the flavonoids (Arora et al., 1998). The di-OH substitution at 3′ and 4′ of the B-ring is

particularly important to the oxygen radical absorbing activity of a flavonoid (Cao et al., 1997). These trends are consistent with less active flavonoids (**6**, **7**, **9**, **11** and **13**) that possess monohydroxyl substitution in the B-ring.

3. Experimental

3.1. General experimental procedures

UV spectra were recorded in MeOH using a Perkin-Elmer Lambda 2 spectrophotometer. IR spectra were recorded in KBr using a Nicolet Impact 410 spectrometer. ^1H and ^{13}C NMR spectra were recorded on a Bruker AM-400 spectrometer. FAB-MS spectra were recorded in NAB matrix in the positive ion mode on a Finnigan MAT TSQ 7000 spectrometer. Column chromatography was performed over Si gel (200–400 mesh, Marine Chemical Factory in Qingdao, China), or Sephadex LH-20 (25–100 μm, Pharmacia).

3.2. Plant material

The leaves of *G. biloba* were collected from mature trees, growing in Nanjing, China, in November 1998, and identified by Professor Luoshan Xu in Division of Pharmacognosy and deposited in the Department of Natural Medicinal Chemistry, China Pharmaceutical University.

3.3. Extraction and isolation

The dried leaves of *G. biloba* (10.0 kg) were extracted three times with MeOH–H_2O (85:15) using an ultrasonic apparatus for 3 h. The MeOH extract (1585.6 g) was suspended in H_2O and partitioned with petroleum ether, $CHCl_3$, and *n*-BuOH, successively. The *n*-BuOH extract (520.6 g) was subjected to Si gel column chromatography eluting with $CHCl_3$–MeOH (25:1) followed by stepwise addition of MeOH to yield 12 fractions. Fraction 7 (23.2 g) was subjected to Si gel ($CHCl_3$–MeOH, 10:1), and Sephadex LH-20 (MeOH) chromatographic steps purified by HPLC (RP_{18}, 4 μm, 260 nm, MeOH-1% acetic acid, 20:80; **1**: $t_R = 30.03$ min; **2**: $t_R = 16.54$ min; **3**: $t_R = 26.03$ min; **4**: $t_R = 20.26$ min; **5**: $t_R = 13.58$ min) to give compounds **1** (8 mg), **2** (6 mg), **3** (20 mg) **4** (25 mg), and **5** (13 mg). Fraction 8 (28.6 g) was subjected to Si gel ($CHCl_3$–MeOH, 9:1), and Sephadex LH-20 (MeOH) chromatographies to give compounds **6** (22 mg), **7** (6 mg), and **8** (28 mg). Fraction 6 (36.7 g) was subjected to Si gel ($CHCl_3$-MeOH, 12:1), and Sephadex LH-20 (MeOH) chromatographies to give compounds **9** (20 mg), **10** (186 mg), and **11** (80 mg). Fraction 5 (36.7 g) was subjected to Si gel ($CHCl_3$–MeOH, 15:1), and Sephadex LH-20 (MeOH) chromatographic steps to give compounds **12** (90 mg), and **13** (76 mg).

3.4. Acidic hydrolysis of *1* and *2*

A solution of each compound (**1** and **2**) in 5 ml 6% HCl and heated for 3 h. The reaction mixture was extracted with EtOAc. The EtOAc fraction (aglycone) and the aqueous fraction (sugars) were concentrated until dryness for identification.

3.5. Identification

3.5.1. Compound *1*

Isorhamnetin 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]. Pale yellow amorphous powder; UV λ_{max} (nm): MeOH: 365, 315, 265sh, 253, NaOMe: 407, 323, 270, NaOAc: 378, 330, 272, $NaOAc/H_3BO_3$: 368, 314, 267sh, 253, $AlCl_3$: 404, 313sh, 308, 283, 230, $AlCl_3$/HCl: 405, 313sh, 309, 283, 231; IR (KBr) ν_{max} 3537, 3500 (OH), 3258, 2984, 2920, 2850, 1680 (ester C=O), 1656 (α,β-unsaturated C=O), 1605, 1573, 1513, 1450, 1349, 1303, 1263, 1198, 1171, 1142, 1114, 1082, 1065, 1048, 995, 950, 820, 810, 595; ^1H NMR (400 MHz, DMSO-d_6), see Table 1; ^{13}C NMR (100 MHz, DMSO-d_6), see Table 1; FAB-MS *m*/*z* 771 $[M+H]^+$, 463 [aglycone + rha + H]$^+$, 317 [aglycone + H]$^+$.

3.5.2. Compound *2*

Kaempferol 3-*O*-α-L-[6‴-*p*-coumaroyl-(β-D)-glucopyranosyl-(1,2)-rhamnopyranoside]-7-O-β-D-glucopyranoside. Yellow amorphous powder; UV λ_{max} (nm): MeOH: 316, 268, NaOMe: 368, 278sh, NaOAc: 373, 324, 266, $NaOAc/H_3BO_3$: 321, 267, $AlCl_3$: 397, 320, 303, 277, $AlCl_3$/HCl: 396, 320, 302, 277; IR (KBr) ν_{max} 3530, 3345 (OH), 3285, 2981, 2955, 1680 (ester C=O),

1655 (α,β-unsaturated C=O), 1604, 1572, 1510, 1449, 1352, 1300, 1288, 1263, 1249, 1198, 1174, 1137, 1114, 1088, 1063, 1048, 1014, 1005, 996, 950, 820, 594; ^{1}H NMR (400 MHz, DMSO-d_6), see Table 2; ^{13}C NMR (100 MHz, DMSO-d_6), see Table 2; FABMS m/z 903 $[M+H]^+$.

3.6. Antioxidant assay

DPPH assay was performed essentially according to the modified method of Kirby and Schmidt (1997): 95 μl of 3.2×10^{-4} M of DPPH solution in absolute EtOH and 5 μl of sample solution in DMSO were mixed in a 96-well plate. The optical density was measured at 515 nm after incubation of the plate for 1 h at 37 °C. The DPPH control contained no sample but was otherwise identical. The cytochrome-*c* reduction assay was performed according to Sharma et al. (1994). HL-60 cells were maitained in RPMI 1640 medium supplemented with 5% heat-inactivated fetal calf serum, 1% penicillin-streptomycin at 37 °C in humidified atmosphere at 5% CO_2 in air. Differentiation was induced by 7-day treatment with 1.3% DMSO, and the cells were cultured in a 96-well plate (1×10^6 cells per well) in HBSS. After the addition of TPA (8 μM) to induce free radical formation, cytochrome-*c* (160 μM) and samples were added. The cells were incubated for 1 h at 37 °C, and antioxidant activity was determined by monitoring absorbance at 550 nm. The same reaction mixture, without the HL-60 cells, was used as a blank control.

Two diacylated malvidin glycosides from *Petunia hybrida* flowers

Emmanuel Gonzalez, André Fougerousse, Raymond Brouillard*

Laboratoire de Chimie des Polyphénols, UMR 7509 du CNRS, Université Louis Pasteur, 4, rue Blaise Pascal, 67008 Strasbourg, France

Received 25 January 2001; received in revised form 5 June 2001

Abstract

Two novel diacylated and two known anthocyanins were isolated from violet flowers of *Petunia hybrida* cv Festival. The new anthocyanins are malvidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-feruloyl-β-D-glucopyranosyl)-*E*-*p*-coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-β-D-glucopyranoside and malvidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-*E*-*p*-coumaroyl-β-D-glucopyranosyl)-*E*-*p*-coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-β-D-glucopyranoside. The two known pigments are the 3-caffeoylglucosyl-*p*-coumaroylrutinoside-5-glucosides of malvidin and petunidin. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Petunia hybrida*; Solanaceae; Diacylated anthocyanins; Ferulic acid; Malvidin; ^{1}H and ^{13}C NMR spectroscopies

1. Introduction

Petunia hybrida (Solanaceae), the cultivated garden petunia, is not a true species but an artificial hybridisation between *Petunia axillaris* and *Petunia integrifolia* (Sink, 1984). Many studies concerning phytochemistry and genetic of petunia have been completed, in particular on *P. hybrida* for the establishment of the anthocyanin biosynthetic pathway (Dooner et al., 1991; Katz and Weiss, 1999; Quattrocchio et al., 1999). The inheritance of anthocyanin pigmentation is found to be controlled by multiple independent genes. At least 35 genes are known to affect flower colour in petunia (Wiering and de Vlaming, 1984). Some genes in *Petunia*, playing a role in determining pH and vacuolar pH values, are closely correlated with flower colour. In 1999, the latest reports of anthocyanin structures in that plant included the following: the 3-glucosides of the six common anthocyanidins; the 3-rutinosides of delphinidin, cyanidin, petunidin and pelargonidin; the 3-sophorosides of cyanidin and peonidin; the 3-gentiobioside and the 3,7-diglucoside of cyanidin; the 3-rutinoside-5-glucosides and the 3-(*E* or *Z*)-*p*-coumaroylrutinoside-5-glucosides of cyanidin, peonidin, petunidin, delphinidin and malvidin; the 3-caffeoylrutinoside-5-glucosides of malvidin, petunidin and peonidin; the 3-glucosyl-*p*-coumaroylrutinoside-5-glucosides of malvidin, petunidin and delphinidin; the 3-glucosyl-caffeoylrutinoside-5-glucosides of malvidin and petunidin (Wiering and de Vlaming, 1984; Griesbach et al., 1991; Ando et al., 1999; Tatsuzawa et al., 2000). Recently, six diacylated malvidin, petunidin and delphinidin derivatives have been fully characterized as the 3-caffeoylglucosyl-caffeoylrutinoside-5-glucosides of malvidin and petunidin, the 3-caffeoylglucosyl-*p*-coumaroylrutinoside-5-glucosides of malvidin, petunidin and delphinidin, and the 3-caffeoylglucosyl-*p*-coumaroylrutinoside of malvidin (Tatsuzawa et al., 1997, 1999, 2000; Fukui et al., 1998; Ando et al., 1999). In this paper, we report the isolation and the structural elucidation of two new diacylated malvidins in the violet flowers of *Petunia hybrida* cv Festival.

2. Results and discussion

Violet flower petals were extracted with methanol containing HCl (0.2%). Four major anthocyanins were isolated from the crude extract by preparative HPLC and identified as **1** (relative abundance 16%), **2** (69%), **3** (10%) and **4** (5%). The structure determination of these anthocyanins was performed by UV-visible, mass and NMR spectroscopies. **1** and **2** were identified, respectively, as petunidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-caffeoyl-β-D-glucopyranosyl)-E-*p*-coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-*O*-β-D-glucopyranoside and malvidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-caffeoyl-β-D-glucopyranosyl)-E-*p*-

coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-*O*-β-D-glucopyranoside by multiple spectral analysis (NMR, UV, MS and HPLC) but have been previously reported (Table 1) (Fukui et al., 1998; Ando et al., 1999). Two new structures, pigments **3** and **4**, were elucidated by comparison of their characteristic spectral features with those of **2**.

2.1. Pigment *3*

The UV-visible spectrum of **3** features a maximum at 543 nm and a UV-band at 285 nm. A ratio A_{440}/A_{543} of 12% indicates the presence of an anthocyanin 3,5-diglucoside and a ratio A_{UV}/A_{543} of 108% provides evidence that **3** has two acyl groups per molecule (Harborne, 1967). The FAB mass spectrum shows a molecular ion peak $[M]^+$ at 1285 *m*/*z*, corresponding to the molecular formula $C_{60}H_{69}O_{31}$ (Table 1).

Full assignment of the ^1H NMR and the ^{13}C NMR signals of **3** using H,H-COSY, H,H-ROESY, 2D-HMQC and 2D-HMBC has been carried out (Table 2). The downfield part of the ^1H NMR spectrum showed a 1H singlet at 8.92 ppm (*s*, H-4), a 2H singlet at 7.85 ppm (*s*, H-2′/H-6′) a 1H doublet at 7.02 ppm (*d*, $J=2$ Hz, H-6) and a 1H doublet at 6.98 ppm (*d*, $J=2$ Hz, H-8). An additional 6H singlet at 3.94 ppm was attributed to C-3′ and C-5′ methoxyl protons. These findings correspond to the malvidin aglycone. The observation of two sets of olefinic proton signals at 5.85 and 7.33 ppm (*d*, $J=16$ Hz) and at 6.21 and 7.48 ppm (*d*, $J=16$ Hz) indicated the presence of two cinnamic acid residues both in the *E* configuration. The first set was assigned to the *p*-coumaric acyl group. The second set was assigned, by analysis of its H,H-COSY, H,H-ROESY and HMBC spectra, to ferulic acid: a 3H singlet at 3.69 ppm was attributed to the methoxyl protons of the ferulic acyl group. These protons correlated in the H,H-ROESY spectrum with the proton H-2 of the ferulic acid moiety, and in the 2D-HMBC spectrum with the C-3 carbon of the ferulic acid moiety (Figure 1). The signal of four anomeric protons of **3**, corresponding to three glucosyl groups and one rhamnosyl group, appeared at 5.57 ppm (*d*, $J=7.7$ Hz, Glc-A), 5.21 ppm (*d*, $J=7.7$ Hz, Glc-B), 4.92 ppm (*d*, $J=7.5$ Hz, Glc-C) and 4.79 (*d*, $J=1.4$ Hz, Rha) (Table 2). The assigned glucose protons had coupling constants between 7.5 and 12.2 Hz suggesting that these glucose moieties were in the β-D-glucopyranose form. In the rhamnose moiety, the coupling constant of the anomeric proton (*d*, $J=1.4$ Hz) and the 3H doublet at 0.98 ppm (*d*, $J=6.2$ Hz, Rha–CH_3) indicated the existence of the α-rhamnopyranose form. H,H-ROESY and 2D-HMBC spectra were used to distinguish the connection sites of the cinnamic acid moieties, of the sugars and of the malvidin aglycone (Fig. 1). The signal of the anomeric proton of Glc-A correlates to the signal of the C-3 carbon, in the HMBC spectra, and to the signal of the H-4 proton in the ROESY spectrum of malvidin. The signal of the anomeric proton of Glc-B was correlated to the signal of the C-5 carbon in the HMBC spectra, and to the different signals of the protons H-6/H-8, in the ROESY spectrum of malvidin. These characteristic features revealed that malvidin 3- and 5- positions are both connected to a glucose. A cross-peak between the anomeric proton of the rhamnose at 4.79 ppm and the C-6 carbon of the Glc-A at 66.7 ppm in the HMBC spectra, revealed the linkage between these two groups. A downfield shift of proton H-4 of the rhamnose and a correlation in the HMBC spectra between this signal and the carbonyl carbon of the *p*-coumaric acid moiety revealed their connection site. A NOE effect was observed between the anomeric proton of Glc-C and the protons H-3/H-5 of the *p*-coumaric acid moiety, and a cross-peak in the HMBC spectra between this same anomeric proton and the carbon C-4 of the *p*-coumaric acid moiety, indicating that Glc-C was glycosylated on OH-4 of the *p*-coumaric acid. A downfield shift of the protons H-6 of Glc-C and a correlation in the HMBC spectra between these signals and the carbonyl carbon of the ferulic acid moiety, revealed the linkage between these two groups.

The structure of **3** was therefore determined as malvidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-feruloyl-β-D-glucopyranosyl)-*E*-*p*-coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-*O*-β-D-glucopyranoside, which is a new anthocyanin.

Table 1
Spectral properties of anthocyanins extracted from violet petals of *Petunia hybrida* cv Festival

Anthocyanin	Spectral data in 0.1% HCl–MeOH				Rt[a] (min)	FAB–MS $[M]^+$
	λ_{max} (nm)	A_{UV}/A_{max} (%)	A_{440}/A_{max} (%)	$AlCl_3$

[a] Column: Merck LiChrospher C_{18} (125×4 mm, 5 μm); for more details, see Experimental.

2.2. Pigment *4*

The UV-visible spectrum of **4** appeared to be very similar to that of **3**, showing a visible maximum at 543 nm and a UV band at 288 nm. A ratio A_{440}/A_{543} of 13% indicates the presence of an anthocyanin 3,5-diglycoside and the ratio A_{UV}/A_{543} of 106% provides evidence that **4** has two acyl groups per molecule. The FAB mass spectrum of **4** features a molecular ion peak $[M]^+$ at 1255 corresponding to the molecular formula $C_{59}H_{67}O_{30}$, 30 mass units lower than that of **3** (Table 1).

The different NMR spectral data of **4** are similar to those of **3**, except for the terminal moiety that was

demonstrated not to be a ferulic residue (Table 2). A 2H doublet at 6.64 ppm (*d*, $J = 8.6$ Hz) and a 2H doublet at 7.19 ppm (*d*, $J = 8.6$ Hz) were assigned, respectively, to the protons H-3/H-5 and H-2/H-6 of a *p*-coumaric acid moiety. The set of olefinic proton signals at 6.17 and 7.44 ppm (*d*, $J = 16$ Hz) determines the *E* configuration of the *p*-coumaric acid moiety. The connecting sites were confirmed by different NMR methods. These findings indicate that the ferulic acid moiety in **3** is replaced by the *E*-*p*-coumaric acid moiety in **4** (Fig. 2).

The structure of **4** was therefore deduced to correspond to malvidin 3-*O*-(6-*O*-(4-*O*-(4-*O*-(6-*O*-*E*-*p*-coumaroyl-β-D-glucopyranosyl)-*E*-*p*-coumaroyl)-α-rhamnosyl)-β-D-glucopyranoside)-5-*O*-β-D-glucopyranoside, which is a new anthocyanin.

The four anthocyanins extracted from petals of the violet flower of *Petunia hybrida* cv Festival are very similar and only differ by one or two atoms (Fig. 2). Two novel structures of diacylated anthocyanins, together with two already known diacylated anthocyanins, were elucidated in this work.

3. Experimental

3.1. Plant material

Plant pots of *Petunia hybrida* cv Festival were grown in window boxes on the balcony of one of the authors (E.G.). Fresh violet petals were collected during the July–September 1999 period and stored at −18 °C in a plastic bag.

3.2. Isolation

Thirty grams of violet flower petals were extracted with 200 ml of 0.2% (v/v) HCl–MeOH for 4 h at +4 °C (three times). After removal of methanol under reduced

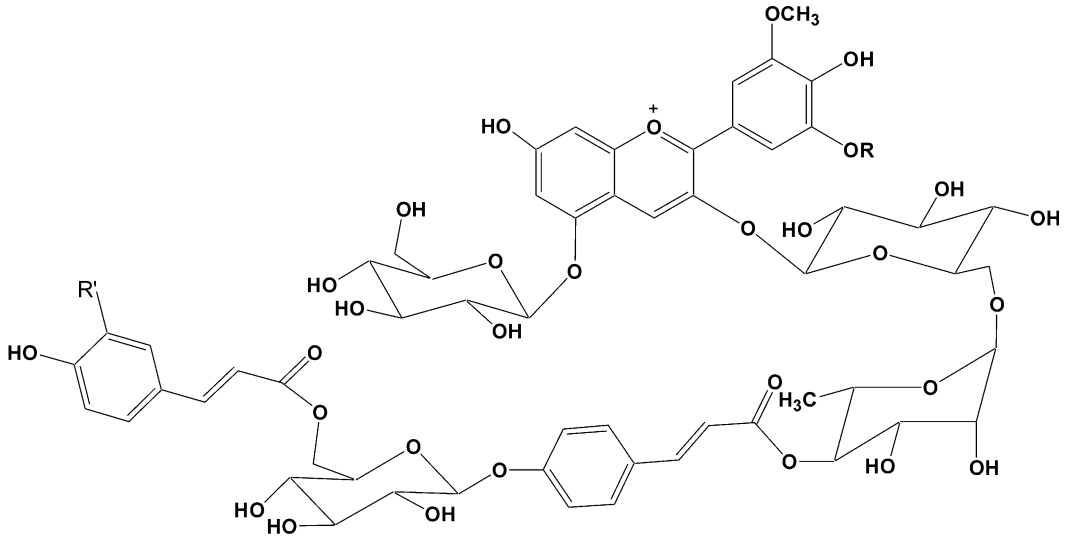

Fig. 2. Anthocyanins from violet petals of *Petunia hybrida* cv Festival. Pigments **1** R = H, R′ = OH; **2** R = CH_3, R′ = OH; **3** R = CH_3, R′ = OCH_3; **4** R = CH_3, R′ = H.

pressure, the water enriched extract was partitioned against ethyl acetate and 1.04 g of crude extract was obtained. The different pigments were purified by preparative HPLC on a Waters SymetryPrep C_{18} column (300×19 mm, 7 μm) connected to a Gilson 305/306 apparatus equipped with a UV detector monitoring at 280 nm. The solvent systems used were as follows: a linear gradient elution for 25 min from 20 to 40% solvent B (95% H_2O, 5% HCOOH) in solvent A (47.5% CH_3CN, 47.5% H_2O, 5% HCOOH). The flow rate was 10 ml/min. 125 mg of the filtered extract were dissolved in 500 μl of solvent B then were injected through a Rheodyne injector. The pigment fractions were evaporated in vacuum to dryness. **1** (6.1 mg), **2** (26.4 mg), **3** (3.8 mg) and **4** (2.0 mg) were isolated from the crude extract.

3.3. HPLC analysis

Anthocyanins were analysed by HPLC on a Merck LiChrospher C_{18} column (125×4 mm, 5 μm) connected to a LC Spectra Physics apparatus equipped with a 1040M Hewlett Packard diode array detector. Solvents and gradient elution profiles were the same as for preparative HPLC. The flow rate was 0.5 ml/min.

3.4. Spectral analysis

NMR spectra were run at 298 K on a Bruker AM-500 spectrometer at 500 and 125 MHz for ^1H and ^{13}C, respectively, in a 2.5 mm diam. tube using 10% (v/v) TFA-d/CD_3OD as solvent. Chemical shifts were reported relative to a TMS internal standard. Mass spectra were recorded in the positive mode from an AutoSpec E Micromass spectrometer using a NBA matrix.

Received in revised form 3 July 2001

Abstract

An immunosuppressive, tryptophan-derived alkaloid cristatin A (**1**), and two known compounds, cycloartenol and stigmasta-5,11(12)-diene-3β-ol, were isolated from the whole plant *Lepidagathis cristata* Willd. The structures of the isolates were established by interpretation of their spectral data. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Lepidagathis cristata*; Acanthaceae; Cristatin A; Cycloartenol; Stigmasta 5,11(12)-dien-3β-ol; Immunosuppressive activity

1. Introduction

In the Indian system of medicine, the whole plant *Lepidagathis cristata* Willd. (Acanthaceae) is used as a remedy for skin infections and fever (Ambasta, 1992; Nadakarni and Chopra, 1996). It is a perennial, procumbent herb common in the dry places on rocks and wastelands in most districts of Andhra Pradesh, India. A literature survey has revealed that this plant afforded 6-hydroxyluteolin and 6-hydroxyluteolin-7-*O*-D apioside (Ranganathan et al., 1980). In continuation of our search for new, biologically active compounds from natural sources (Reddy et al., 1999), we have re-examined the whole plant *Lepidagathis cristata*, which afforded a new tryptophan-derived alkaloid cristatin A (**1**) and two known compounds cycloartenol (Radics et al., 1975) and Stigmasta-5,11(12)-dien-3β-ol (Alam et al., 1994). We have also examined the immunosuppressive activity of the new alkaloid **1**.

2. Results and discussion

2.1. Isolation and characterization of cristatin A (*1*)

The freshly collected, shade-dried and powdered whole plant of *L. crisata* was extracted separately with hexane and ethyl acetate. These extracts were subjected to silica gel column chromatography to afford a new tryptophan-derived alkaloid cristatin A (**1**) and two known compounds cycloartenol (Radics et al., 1975) and stigmasta-5,11(12)-dien-3β-ol (Alam et al., 1994). These two known compound structures were deduced by comparison of the obtained NMR and mass spectra with those reported in the literature.

Alkaloid **1** was obtained as a pale yellow solid, mp 260 °C, $[\alpha]_D^{25}$ +1.2° (c 0.25, $CHCl_3$) analyzing for $C_{29}H_{37}N_3O_2$ by HREIMS which indicated 13° of unsaturation. Its ^{13}C NMR spectrum (Table 1) displayed 29 carbons, of which sixteen sp^2 carbons appeared between δ 102 and 145, in addition to two amide carbonyl signals at δ 160.00 and 165.70. Thus the molecule is tricyclic.

The ^1H NMR spectrum of alkaloid **1** showed signals (Table 1) for a trisubstituted double bond proton at δ 7.18 (1H, s), two *ortho*-coupled aromatic protons at δ 7.05 (1H, d, $J=8.2$ Hz) and δ 6.98 (1H, *d*, $J=8.2$ Hz), a 1′,1′ dimethyl allyl group, two isopentenyl groups, a secondary

1

methyl group at δ 4.28 (1H, *q*, $J = 7.0$ Hz), and 1.59 (3H, *d*, $J = 7.0$ Hz), and three protons at δ 8.37 (1H, *s*), 7.48 (1H, *s*) and 6.88 (1H, *s*). Among these, the protons at δ 7.48 and 6.88 were exchanged with D_2O. A survey of the literature revealed that alkaloid **1** belongs to the echinulin class [*cyclo*-L-alanyl-5,7-diisopentenyl-2-(1′,1′-dimethyl allyl)-L-tryptophan] (Takamatsu, 1971) isolated from the fungus *Aspergilus echinulatus*, and to a related alkaloid tardioxopiperazine A [*cyclo*-L-alanyl-5-isopentenyl-2-(1′,1′-dimethyl allyl)-L-tryptophan] isolated from the ascomycete, *Microascus tardifaciens* (Fujimoto et al., 1999).

The structure **1** was established through the application of spectroscopic techniques, including ^1H and ^{13}C-NMR analysis. With the aid of DEPT, COSY, HMQC, HMBC, and NOE pulse sequences, the multiplicity of the proton peaks, their inter relationship and the identity of each carbon and hydrogen could be established (Fujimoto et al., 1999).

The spectral data revealed that the alkaloid **1** must have a partial structure containing a 2,3,4,5 or a 2,3,6,7-tetra substituted indole. In HMBC correlations the C-8 vinylic proton at δ 7.18 showed correlations with C-2 (142.8), C-9 (124.1), and C-14 (160.0). Thus, the signal at δ 7.18 (1H, *s*) could be due to the presence of a double bond between C-8 and C-9 carbons in alkaloid 1 as observed in dopadazine, a diketopiperazine from *Penicillium dipodomyis* and the stereochemistry at C-8, 9

Table 1
^1H and ^{13}C NMR spectral data for alkaloid **1**

C28	–	132.6	
C29	1.89 (*s*)	25.7	C27, C26

Values are recorded at 500 MHz (in $CDCl_3$ in the δ scale, with *J* values in Hz in parentheses). HMBC ($J = 7$ Hz).

indicates Z-configuration (Sorensen et al., 1999). The disposition of the two-isopentenyl groups was determined by NOED experiments. Irradiation of the C-25 methylene protons at δ 3.43 (2H, *d*, $J=7.1$ Hz) caused an enhancement of the indole NH signal at δ 8.37 (1H, *s*) and the C-26 vinylic proton at δ 5.31 (1H, *m*). Irradiation of the C-20 methylene protons at δ 3.57 (2H, *d*, $J=7.1$ Hz) caused an enhancement of the signal at δ 6.98 (1H, *d*, $J=8.2$ Hz, 5-H) and the C-21 vinylic proton at δ 5.22 (1H, *m*), indicating that the two isopentenyl groups are situated at the C-6 and C-7 positions. In the HMBC spectrum, the secondary methyl at δ 1.56 (3H, *d*, $J=7$ Hz) showed correlations with C-11 (165.7 *s*) and C-12 (51.6, *d*). The ^{1}H NMR and ^{13}C chemical shifts of the C-12 methyl of alkaloid **1** are comparable with those of reported data for echinulin isolated from an ascomycete, *Microascus tardifaciens* (Fujimoto et al., 1999) for which the stereochemistry was not assigned. From the fore-going spectral data the structure of cristatin A (**1**) was established as (*cyclo*-alanyl-6,7-disiopentenyl-2-(1′,1′-dimethylallyl-8-(*Z*)-ene-tryptophan).

2.2. Immunosuppressive activity

Fujimoto et al., recently reported that echinulin type alkaloids exhibit immunosuppressive activity (Fujimoto et al., 1999) using mouse splenic lymphocytes. The immunosuppressive activity (IC_{50}) of alkaloid **1** was assayed against Con A- (T-cells) and LPS-induced (B-cells) proliferation of mouse splenic lymphocytes, here Con A and LPS were used as controls and cyclosporin A was used as standard drug. The immunosuppressive activity of alkaloid **1** (IC_{50}) against Con A and LPS induced proliferation is higher (1 μg/ml) than the immunosuppressive activity of tardioxopiperzine A against Con A LPS induced proliferation (IC_{50} 4.5 and 0.7 μg/ml) (Fujimoto et al., 1999) and lower than that of cyclosporin A (IC_{50} 0.06 and 0.10 μg/ml). To our knowledge this is the first report of isolation of this class of alkaloid with immunosuppressive activity from plant sources.

3. Experimental

3.1. General

The ^{1}H NMR and ^{13}C NMR spectra were recorded on a Varian Unity INOVA 500 MHz spectrometer with standard pulse sequences, operating at 500 and 125 MHz, respectively and all 1D and 2D spectra (^{1}H–^{1}H COSY, NOED, HMQC and HMBC) were recorded using tetramethylsilane (TMS) as an internal standard. Chemical shifts are reported in parts per million, and coupling constants (*J*) are expressed in Hz. UV and IR spectra were recorded on Shimadzu 240 and Perkin–Elmer RXI FT-IR spectrophotometers, respectively. Mass spectra were recorded on a Finnigan-MAT 1020 instrument. Optical rotations were measured on a JASCO DIP-370 polarimeter.

3.2. Plant material

The plant material *Lepidagathis cristata* (Acanthaceae) was collected from, Bhadrachalam forest, Andhra Pradesh, India in December, 1998, and identified by Professor M. Prabhakar Rao, Department of Botany, Osmania University, Hyderabad, India. The voucher specimen (No. 002319) is kept in the herbarium of department of Botany, Osmania University.

3.3. Extraction and isolation

The shade-dried and powdered plant (750 g) *Lepidagathis cristata* was successively refluxed with hexane and ethyl acetate (3×1.5 l). The hexane extract (8 g) was subjected to silica gel chromatography eluting with hexane through hexane-ethyl acetate mixtures to ethyl acetate afforded stigmasta-5,11(12)-dien-3β-ol (100 mg). The ethyl acetate extract (17 g) was subjected to silica gel chromatography eluting with hexane through hexane-ethyl acetate mixtures to ethyl acetate to give two fractions. Fr-1 (hexane/EtOAc, 8:2) was futher CC on silica gel to afford cycloartenol (110 mg) and fr-2 (hexane/EtOAc, 6:4) was further CC on silica gel to afford alkaloid **1** (40 mg).

3.4. Cristatin A (*1*)

Obtained as a yellow solid (40 mg), mp 260 °C; $[\alpha]_D^{25}+1.2°$ (c 0.25, $CHCl_3$); UV ($CHCl_3$) λ_{max} (log ϵ) 208 (4.37), 222 (4.39), 290 (3.866), 330 (3.808); IR (KBr) ν_{max} 3367, 2967, 2926, 2361, 1685, 1636, 1438, 1380, 1326, 1039, 901, 766, 667, 492 cm^{-1}; ^{1}H and ^{13}C NMR spectral data, see Table 1; EIMS *m*/*z* (%) 459 (M^+ 66), 390 (11), 334 (8); HREIMS *m*/*z* 459.2872 [M^+] (calcd. for $C_{29}H_{37}N_3O_2$, 459.2885).

3.5. Immunosuppressive activity

Mouse splenic lymphocytes were prepared on a Ficoll–Hypaque gradient and plated in DMEM-FCS (1×10^5 cells/well). The cells were grown for 24 h with Con A (2 μg/ml) and LPS (100 ng/ml). After 24 h, the cells were treated with different concentrations of cristatin A (**1**) (0.1–5 μg/ml) and cyclosporin A (0.06–0.5 μg/ml) for 24 h. Subsequently, the cells were treated with ^{3}[H]-thymidine (10 μci/well) and incubated further for 24 h in a CO_2 incubator. The cells were harvested on GF filters, washed with 5% TCA and methanol, and counted for radioactivity.

Acknowledgements

We are thankful to Professor M. Prabhakar Rao, Department of Botany, Osmania University, Hyderabad, India, for identifying the plant; the Director, IICT and Dr. J. S. Yadav for their constant encouragement. VR and VLNR are thankful to CSIR, New Delhi and Ministry of Health, New Delhi for providing fellowships, respectively.

Received 20 April 2001; received in revised form 6 August 2001

Abstract

A pyrroloisoquinoline alkaloid, 2,3-dimethoxy-6-(3-oxo-butyl)-7,9,10,11,11a,12-hexahydrobenzo[*f*]pyrrolo[*1,2-b*]isoquinoline (**1**), whose structure was determined by spectroscopic methods, was isolated from the aerial parts of *Cynanchum komarovii*, together with two known alkaloids, 7-demethoxytylophorine (**2**) and 7-demethoxytylophorine *N*-oxide (**3**). Alkaloids **2** and **3** had antiviral activities against tobacco mosaic virus. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Pyrroloisoquinoline; Phenanthroindolizidines; Tobacco mosaic virus; *Cynanchum komarovii*; Asclepiadaceae

1. Introduction

Cynanchum komarovii Al Iljinski (Asclepiadaceae) is a wild shrub, widely distributed in the northwest part of the People's Republic of China, and is used as a Chinese herbal medicine to cure fever, diarrhea, and cholecystitis (Jiangsu New Medical College 1977). Several phenanthroindolizidine alkaloids were reported previously to occur in this species (Fang et al., 1989; Zhang et al., 1991). In the present study, an alcohol extract of *C. komarovi* was found to show moderate antiviral activity against the tobacco mosaic virus. Using a bioassay-directed fractionation approach, a new alkaloid **1** was obtained, together with two known alkaloids, 7-demethoxytylophorine **2** and 7-demethoxytylophorine *N*-oxide **3**. Alkaloid **2** was the major active substance and was more potent against TMV than **3**, whereas alkaloid **1** had no significant activity. The structures of **2** and **3** were determined by comparison with reference spectra and physical properties. (Xi et al., 1989, Zhang et al., 1991, Lavault et al.,1994). Herein we report the isolation and structure elucidation of **1**, and the activity of **1**, **2** and **3** against TMV.

2. Results and discussion

Alkaloid **1** was isolated as colorless needles from the aerial parts of *C. komarovii*. The HREIMS of **1** showed a molecular ion at *m/z* 353.1984, corresponding to the molecular formula $C_{22}H_{27}NO_3$ (calcd. as 353.1990). The presence of a naphthalene ring was suggested by the observed UV (235, 254, 315, 330 nm) (Budzikiewicz et al., 1979) and IR (1612, 1510, 1475 cm^{-1}) absorptions. A strong absorption at 1716 cm^{-1} in the IR spectrum indicated that the compound must contain a ketone carbonyl group. The ^{13}C NMR spectrum of **1** (Table 1) showed the presence of 22 carbon signals, including one carbonyl carbon (δ 208.1), three methyl carbons [of which two were oxygenated methyls (both at δ 55.8)], seven methylenes [among which two were *N*-methylenes (δ 55.0, δ 53.7)], one aliphatic methine bearing a nitrogen atom (δ 60.2), and ten aromatic carbons, including two carbons that were connected to methoxy groups (δ 149.2 and δ 149.0). The ten aromatic carbons were assigned to a naphthalene ring system. The ^1H NMR and ^1H–^1H COSY spectra of **1** showed three isolated aromatic protons at δ 7.34, δ 7.14, and δ 7.06, and three pairs of geminal protons at H_2-7 (δ 4.29 and δ 3.45), H_2-11 (δ 2.22 and δ 1.25), and H_2-12 (δ 3.30 and δ 2.86).

The ^1H NMR, ^1H–^1H COSY, ^{13}C NMR, and HMBC data of **1** (see Table 1) demonstrated the

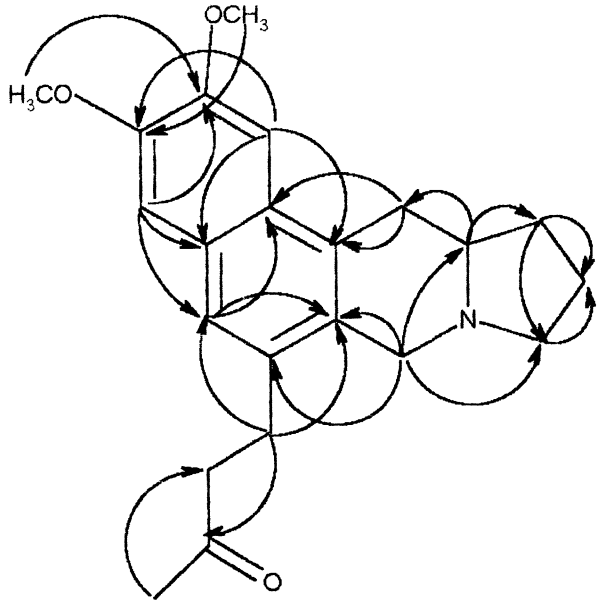

Fig. 1. Important-HMBC interactions in alkaloid **1**.

presence of a 3-oxobutyl side chain. The HMBC spectrum (Fig. 1) showed long-range correlations between H_2-7 and the carbons at δ 60.2 (C-11a), δ 55.0 (C-9), δ 133.9 (C-6), and δ 129.0 (C-6a), and correlations between H_2-12 and the carbons at δ 60.2 (C-11a), δ 31.4 (C-11), δ 129.0 (C-12a), and δ 128.0 (C-12b). In this manner, the connectivities from C-6a to C-12b could be established. The location of the 3-oxobutyl side chain at C-6 was established by analysis of the correlations between the methylene protons H_2-13 (δ 2.91) and C-5 (δ 124.0), C-6 (δ 133.9), and C-6a (δ 129.0). Accordingly, the structure of **1** was established as 2,3-dimethoxy-6-[3-oxobutyl]-7,9,10,11,11a,12- hexahydrobenzo [*f*]pyrrolo[*1,2-b*]isoquinoline. Since the NOESY spectrum did not give much information about the stereochemistry of C-11a due to overlapping of the key signal (H-11a), the stereochemistry of C-11a was not established.

Alkaloid **2** and **3** were characterized as 7-demethoxytylophorine and 7-demethoxytylophorine *N*-oxide respectively by comparing their spectral data and physical properties with that of references (Xi et al., 1989; Zhang et al., 1991; Lavault et al.,1994).

The major active alkaloid **2** exhibited 65% inhibition against the TMV at a concentration of 1.0 μg/ml. Alkaloid **3** showed 60% inhibition at 500 μg/ml and alkaloid **1** showed 15% inhibition at 500 μg/ml. A commercial antiviral agent, 2,4-dioxo-hexahydro-1,3,5-triazine, showed 50% inhibition at 500 μg/ml under the same conditions.

3. Experimental section

3.1. General experimental procedures

The melting points were determined on a Yanaco melting point apparatus and are uncorrected. Optical rotations were recorded on a Perkin-Elmer 241 MC. UV spectra were measured on a Shimadzu UV-250 spectrophotometer, and IR spectra were recorded on a Perkin-Elmer 599B spectrophotometer. NMR spectra were acquired on Bruker AC-P200, AM-400 and DRX-400 NMR spectrometers with $CDCl_3$ as solvent. Mass spectra (EIMS and HREIMS) were obtained on a MAT-7070 instrument.

3.2. Plant material

The aerial parts of *C. komarovii* were collected from the Autonomous Region of Inner Mongolia of the People's Republic of China, in August, 1996. The plant was identified by Prof. Qingru Wu (Department of Biology, Inner Mongolia Polytechnic University, Huhehaote). A voucher specimen (No: 96007) is maintained in the laboratory at the Inner Mongolia Polytechnic University.

3.3. Extraction and isolation

The air-dried aerial parts of *C. komarovii* (30 kg) were extracted with hot ethyl alcohol three times. After evaporating the alcohol in vacuo, the residue was stirred with $CHCl_3$ and extracted three times with a 5% aqueous solution of citric acid. The aqueous phase was

made alkaline (pH 9) with ammonium hydroxide (30% v/v) and extracted with $CHCl_3$. The $CHCl_3$ extract was dried (anhydr Na_2SO_4) and evaporated in vacuo to yield a crude alkaloid extract (3.5 g) which was subjected to column chromatography on Si gel eluting with various proportions of $CHCl_3$–CH_3OH–H_2O (10:1:1, 5:1:1, 5:2:1, lower layer). Each fraction was further purified sequentially using a Sephadex LH-20 column ($CHCl_3$–CH_3OH, 1:1) and a Si gel column ($CHCl_3$–CH_3OH–H_2O, lower layer). The first fraction that was eluted with $CHCl_3$–CH_3OH–H_2O (10:1:1, lower layer) afforded alkaloid **1** (11 mg) and alkaloid **2** (320 mg). Alkaloid **3** (35 mg) was obtained from the fraction that was eluted with $CHCl_3$–CH_3OH–H_2O (5:2:1, lower layer) on Si gel.

3.4. 2,3-Dimethoxy-6-(3-oxobutyl)-7,9,10,11,11a,12-hexahydrobenzo[f]pyrrolo[1,2-b]isoquinoline (*1*)

Colorless needles (0.012 g); mp 164–166 °C; $[\alpha]_D^{25}$ −71.0° (c 0.0011, $CHCl_3$); UV (CH_3OH) λ_{max} (log ϵ) 235 (3.93), 315 (3.50), 330 (3.54) nm; IR (film) ν_{max} 2961, 1716, 1612, 1510, 1476 cm^{-1}; ^1H NMR and ^{13}C NMR spectroscopic data, see Table 1; EIMS *m/z* (%) 353 $[M]^+$ (11), 295 (100), 282 (31), 247 (23); HREIMS *m/z* 353.1984 (calcd. for $C_{22}H_{27}NO_3$, 353.1990).

3.5. Antiviral activity

Activity against tobacco mosaic virus was performed by the conventional half-leaf method (Chen, 1990). A fresh leaf of *Nicotiana chinensis* Fisch. ex Lehm that had been inoculated by the juice-leaf rubbing method was cut into two halves along the main vein. Both were immersed into the solution of alkaloid **1**, **2**, and **3** (each at the concentrations of 1.0, 50, and 500 μg/ml) and distilled water for 2 s each, respectively, and then cultured at 25 °C for 72 h. Distilled water and a commercial antiviral agent, 2,4-dioxo-hexahydro-1,3,5-triazine, were used as control. The inhibition ratio was calculated by comparing the numbers of the viral inflammations on the two half leaves.

Cyclopeptide alkaloids from stems of *Paliurus ramossisimus*

Shoei-Sheng Lee*, Whei-Chuan Su, Karin C.S. Chen Liu

School of Pharmacy, College of Medicine, National Taiwan University, Taipei 100, Taiwan, Republic of China

Received 7 November 2000; received in revised form 30 April 2001

Abstract

Three 13-membered cyclopeptide alkaloids, paliurines G, H and I, together with six known alkaloids, nummularine H, daechuine-S3, paliurines A–C and F, were isolated from the stem of *Paliurus ramossisimus* by a combination of centrifugal partition chromatography and preparative TLC. Their structures were characterized and established on the basis of spectral analysis. A preliminary study indicated that nummularine H could shorten the methohexital induced sleeping time. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Paliurus ramossisimus*; Rhamnaceae; Stem; Cyclopeptide alkaloid; Paliurines G–I; Sedative effect

1. Introduction

Recently, we reported the isolation and structural characterization of seven zizyphine A-type cyclopeptide alkaloids from the root of *Paliurus ramossisimus* (Lour.) Poir (Rhamnaceae) (Lin et al., 2000), a plant growing in the wild along the west coast of Taiwan island. Six of them, i.e. paliurines A–F, were new compounds. Being interested in their potential biological activities, we need more of each as well as any other structural analogues. Thus we continued the phytochemical study of the aerial part of this plant. In the present paper we report the isolation and structural characterization of nine cyclopeptide alkaloids present in the stem of this plant. The sedative effect of some isolated compounds is also reported here.

2. Results and discussion

The ethanolic extract of the stem was processed in a manner to facilitate the separation of cyclopeptide alkaloids. After focusing on the weakly basic and less polar alkaloids by fractionation through a Si gel column, the cyclopeptide alkaloids were separated by a combination of centrifugal partition chromatography and preparative thin layer chromatography. Nine compounds were isolated and characterized. Four were found to be zizyphine A-type cyclopeptide paliurines A–C and F, having been isolated from the roots (Lin et al., 2000). The remainder (**1**–**5**) were also found to belong to the same type of 13-membered cyclopeptide alkaloids, as exemplified by their UV absorptions maxima at 265 and 317 nm (Tschesche and Kaußmann, 1975), CD spectra exhibiting two negative Cotton effects around 264 and 324 nm (Tschesche and Kaußmann, 1975), ^{1}H NMR spectra showing common signals for the 14-OMe (ca. δ 3.77), the protons H-1 (ca. δ 5.90, *d*), H-2 (ca. δ 6.93, *dd*) and H-3 (ca. δ 8.40, *d*), appearing as an AMX system (Marchand et al., 1969), and H-12 (ca. δ 6.65, *d*), H-12′ (ca. δ 6.77, *dd*) and H-13′ (ca. δ 6.86, *d*), appearing as an ABX system (Lin et al, 2000). The CD data also suggested 5*S*,8*S*,9*S* configuration for these five compounds (Schmidt et al., 1983). The coupling pattern of H-8 (ca. δ 4.39, *d*) and H-9 (ca. δ 5.40, ddd or dt) was also characteristic for a 3*S*-β-hydroxyproline unit (Tschesche and Kaußmann, 1975, Lin et al., 2000). Besides these data, the ^{1}H NMR spectra of compounds **1**–**4** had common signals at ca. δ 4.25 (*dd*, H-5), 0.86 (Me-17) and 0.95 (Me-18), assignable for a ring bond isoleucine residue (Lin et al., 2000). Their FAB mass spectra revealed two characteristic fragment ions at *m*/*z* 374 (**a**) and 216 (**b**) (Tschesche and Kaußmann, 1975). These data established compounds **1**–**4** to be zizyphine A type cyclopeptide containing isoleucine as the ring bonded amino acid. The followings describe the respective structural characterization of compounds **1**–**5**.

Compound **1**, an amorphous solid, had a molecular formula $C_{36}H_{49}N_5O_6$, as deduced from its FAB mass spectrum, $[M+H]^+$ at *m/z* 648, and analysis of its ^{13}C NMR spectral data. Its mass spectrum had a base peak at *m/z* 148, corresponding to the fragment ion **c** obtained from β-cleavage of the terminal *N*-monomethylated phenylalanine unit. Subtracting the ring nucleus moiety and terminal basic amino acid residue from the formula left a C_5 intermediate amino acid. Since the high resolution ^1H NMR spectrum of **1** ($CDCl_3$) (Table 1) revealed two additional methyl doublets at δ 0.83 ($J=6.7$ Hz) and 0.86 ($J=6.7$ Hz) besides those mentioned above, the intermediate amino acid was determined to be valine. Constructing these moieties together established the structure of compound **1** as shown in the figure.

Compound **2**, an amorphous solid, had a molecular formula $C_{39}H_{47}N_5O_6$, as deduced from its FAB mass spectrum, $[M+H]^+$ at *m/z* 682, and analysis of its ^{13}C NMR spectral data. Its mass spectrum had a base peak at *m/z* 134, for which fragment ion **d** was accounted. Subtracting the ring nucleus moiety and terminal basic amino acid residue, *N*-monomethylphenylalanine, from the formula left phenylalanine as an intermediate amino acid. Composing these structural moieties established **2** to be nummularine H, having been isolated from*Zizyphus nummularia* (Tschesche et al., 1977).

Compound **3**, an amorphous solid, had a molecular formula $C_{33}H_{51}N_5O_6$, as deduced from its FAB mass spectrum, $[M+H]^+$ at *m/z* 614, and analysis of its ^{13}C NMR spectral data. The high resolution ^1H NMR spectrum of **3** ($CDCl_3$) (Table 1) revealed signals for an NHMe (δ 2.34) and four additional methyl groups, including three doublets (δ 0.82, 0.91 and 0.94) and one triplet (δ 0.83), besides those mentioned above. This would suggest the intermediate and terminal amino acid residues to be isoleucine and leucine, one of which contained an

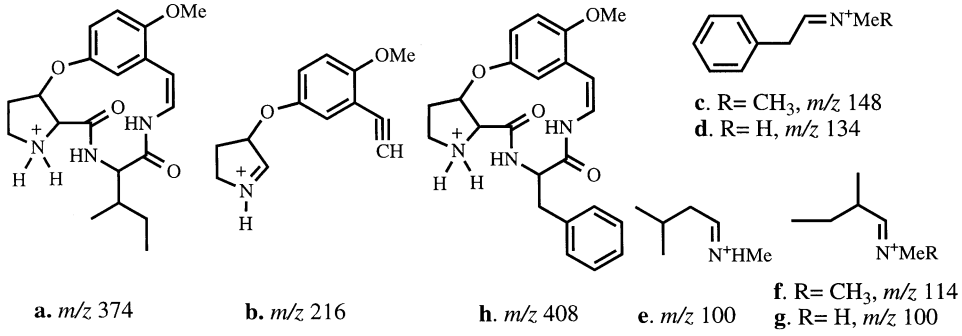
5	Phe	Leu	Ile(NHMe)



a. *m/z* 374 **b.** *m/z* 216 **h.** *m/z* 408 **e.** *m/z* 100

NHMe group. That the characteristic α-H of the terminal amino acid was located at δ 2.98 (*dd*, $J = 8.9, 4.8$ Hz) and the base peak in its mass spectrum appeared at *m/z* 100 (**e**) established *N*-monomethylleucine as the terminal amino acid residue. By elimination, the intermediate amino acid was isoleucine. Consequently, compound **3** had a structure as shown in the figure. That is **3** is mono-*N*-norpaliurine F.

Compound **4** had a molecular formula $C_{34}H_{53}N_5O_6$ as deduced from its FAB mass spectrum, $[M+H]^+$ at *m/z* 628, and analysis of its ^{13}C NMR spectral data. The high resolution ^1H NMR spectrum of **4** ($CDCl_3$) (Table 1) revealed signals of an NMe_2 (δ 2.21) and four additional methyl groups including two doublets (δ 0.82, 0.87) and two triplets (δ 0.86, 0.92) besides those signals mentioned above. This would suggest both intermediate and terminal amino acid residues to be isoleucine and *N*,*N*-dimethylisoleucine, respectively. This proposal was supported by its mass spectrum, which had a base peak at *m/z* 114, for which fragment ion **f** was accounted. These data established **4** to be daechuine-S3 (Han et al., 1989).

Compound **5** had a molecular formula $C_{36}H_{49}N_5O_6$ as deduced from its FAB mass spectrum, $[M+H]^+$ at *m/z* 648, and analysis of its ^{13}C NMR spectral data. Its ^1H NMR spectrum displayed signals for a monosubstituted phenyl group (ca. δ 7.25), four additional methyl groups including three doublets and one triplet, and an NHMe (δ 2.43). These data suggested that **5** contained three amino acid residues, i.e. Phe, Ile, and Leu. Its ^1H NMR spectrum revealed the α-H signals of these amino acid residues at δ 4.56 (*dt*), 4.70 (*dt*, $J = 8.5$, 7.0 Hz) and 2.85 (*d*). Since the latter was assignable to α-H of the terminal basic residue, this amino acid was *N*-monomethylisoleucine, as supported by its mass spectrum which had a base peak at *m/z* 100, for which fragment ion **g** was accounted. The chemical shift at δ 4.56 (*dt*, $J = 10.0$, 5.0, 5.0 Hz) was assignable to the signal of H-5, as compared to the corresponding signals of paliurines A–F (Lin et al., 2000). Upon irradiation of H-5 signals in a double resonance experiment collapsed a doublet at δ 7.38 ($J = 5.0$ Hz, H-6) to a singlet, and two double doublets at δ 3.28 ($J = 14.3$ and 5.0 Hz) and 2.82 ($J = 14.3$ and 10.0 Hz) to an AX system. This result suggested phenylalanine to be the ring bound amino acid residue. This suggestion was supported by the mass spectrum which showed a characteristic fragment ion at *m/z* 408 (**h**), accountable for the ring nucleus moiety. By elimination, the intermediate amino acid was leucine. Constructing these moieties together established the structure of **5** as shown in the figure.

The key ^1H NMR spectral data of **5** (Table 1) were assigned by three additional selected double resonance experiments, i.e. irradiation at the frequency of H-2′ (δ 4.70) and H-2 and H-20α (δ 4.05). Other proton assignments were made by analyzing their coupling patterns and comparison with the data of related cyclopeptide alkaloids such as paliurine B (Lin et al., 2000). Although **2** and **4** were known compounds, some of

their spectral data including CD, ^{13}C NMR spectral data and part of their ^{1}H NMR data remained to be assigned. Thus, following a similar approach to that of **5** allowed the assignment of the ^{1}H NMR spectral data of compounds **1**–**4** (Table 1). The ^{13}C NMR spectral data of **1**–**5** were assigned by correlation with those of paliurines A–F (Lin et al., 2000). These correlations were very consistent except the ambiguous assignment for C-15 and C-3′ in **5**. This problem was settled by using L-Leu(OMe)-L-Phe(NMe_2) as a model compound, whose ^{13}C NMR spectral data (Table 2) had been unambiguously assigned by analysis of the

Table 3
Effect of paliurines A, F and nummularine H (**2**) on methohexital induced sleeping time in mice

Sample	Sleeping time (min, mean±S.E.) (*n*)		Effect in sleeping time (%)
	Control[a]	Experiment[b]	
Paliurine A	5.95±1.72 (4)	8.30±1.50 (4)	+39.5
Paliurine F	7.67±4.06 (4)	11.17±5.06 (4)	+45.6
Nummularine H (**2**)	8.10±2.81 (7)	6.45±1.15 (7)	-20.4

[a] Control: i.p. injection of methohexital in a dose of 50 mg/kg to mice (weight, 27–33 g).
[b] Experimental group: oral administration of tested samples was given 1 h before i.p. injection of methohexital (50 mg/kg) to mice. Dose: paliurine A 14.4 mg/kg, paliurine F 10 mg/kg, and nummularine H 10 mg/kg.

COLOC spectrum (Lin et al., 2000). Since C-3 of Leu(OMe) was assigned at δ 41.5 (*t*), the corresponding C-3′ in the intermediate amino acid (Leu) in **5** was assignable at δ 41.4 (*t*). By elimination, C-15 in the ring bond amino acid (Phe) in **5** was assigned at δ 36.5 (*t*).

The stereochemistry in the ring nucleus of these compounds was deduced by the CD method as indicated above, which established both ring bond amino acids and proline to be L-form. Those of intermediate and terminal amino acids in **4** were determined by the consistency of the ^{13}C NMR spectral data of the terminal Leu(NMe_2) with the corresponding signals of a model dipeptide, L-Ile(OMe)-L-Ile(NMe_2) (Lin et al., 2000). Based on this, the terminal dipeptides in compounds **1**–**3** and **5** are assumed all L-form.

To our knowledge, compounds **1**, **3** and **5** represent the first natural occurrence of such compounds and were named paliurines G, H and I, respectively, after their plant origin.

The sedative effect of cyclopeptide alkaloids such as sanjoinine A had been reported (Han et al., 1989). In a preliminary study, we found that, in mice, nummularine H (**2**) could shorten the mexthohexital-induced sleeping time instead of prolonging as shown for the paliurines A and F (Table 3). Further studies on structure and activity relationship on such effects are needed to disclose their mechanism of action and potential use.

3. Experimental

3.1. General

Perkin Elmer 1760-X Infrared FT spectrometer (KBr); Hitachi 2000 UV (MeOH); Jasco J-710 spectropolarimeter (MeOH); Jeol JMX-HX110 Mass Spectrometer; Bruker AM-300 and AMX-400 NMR spectrometer in $CDCl_3$ (δ_H 7.24, δ_C 77.0) using Bruker standard pulse programs: in the HETCOR, HMQC, COLOC and HMBC experiments, Δ = 1 s and J = 140, 140, 8 and 8 Hz, respectively, the correlation maps consisted of 512×1 K data points per spectrum, each composed of 16–64 transients; Sanki CPC-B92-N with 6 30E cartridges (90 ml), using the upper and lower layer of the solvent system $CHCl_3$–MeOH–6% HOAc (5: 5: 3) as mobile and stationary phases, respectively, 2.0 ml/min flow rate, 700 rpm rotation speed, about 40 kg/cm^2 pressure; Si gel TLC analysis [Me_2CO–toluene–25%NH_4OH (30:70:1)].

3.2. Plant material

The stem of *Paliurus ramossisimus* for this study was collected in August 1985, along the west coast of Ho-Long village, Miao-Li county, Taiwan. A voucher specimen (no. NTUPH-19850801) has been deposited in the School of Pharmacy, National Taiwan University.

3.3. Extraction and isolation

The ground dry powders of the stem (12.00 kg) were percolated with 95%EtOH (60 l × 3). The EtOH extract was triturated with H_2O and *n*-hexane to give residue (ca 80 g) which was fractionated on a Si gel column (ca 400 g, 70–230 mesh) eluted with 5–20% MeOH in $CHCl_3$ stepwise. The components eluted with 5% MeOH elution were applied to a Si gel column (230–400 mesh, second column) eluted with $CHCl_3$ to give four fractions. Fr. 4 (0.64 g ×3) containing cyclopeptide alkaloids was fractionated via a Sanki CPC as above to give nine subfractions. Subfr. 1 (107 mg) was separated on Si gel preparative TLC plates (1 mm × 3) developed twice by toluene–Me_2CO–25%NH_4OH (70:30:1) to give **3** (21 mg, R_f 0.32). Under similar process, subfr. 4 (47.8 mg) yielded **2** (18.6 mg, R_f 0.34) and a mixture (11.7 mg) of **4** and paliurine A; subfr. 5 (22 mg) yielded paliurine F (8.6 mg, R_f 0.45), **1** (3.9 mg, R_f 0.34) and a mixture (5.6 mg) of **4** and paliurine A; subfr. 6 (105 mg) yielded paliurine F (80 mg), and **1** (16.4 mg). The mixture of **4** and paliurine A (17.3 mg) obtained above was separated on a Si gel preparative TLC (1 mm) developed five times by cyclohexane-Me_2CO (3: 1) to give **4** (6 mg) and paliurine A (7 mg), each having R_f value of 0.327 and 0.274, respectively, under the identical PTLC. Subfr. 9 (34.4 mg) was paliurine C (R_f 0.50, developed twice). Fraction 3 (0.78 g×2) from the second Si gel column was fractionated via a CPC column using similar delivery system except for the replacement of 6%HOAc by 5%HOAc to give five subfrs. These subfrs. were separated by Si gel preparative TLC using similar conditions as mentioned above to give **5** (16.9 mg, R_f 0.36) and paliurine B (20.9 mg, R_f 0.30) (from subfr. 1), **2** (32 mg), a mixture of **4** and paliurine A (31 mg) (from subfr. 3), paliurine F (42 mg) (from subfr. 4). Further separation of the mixture yielded **4** (13 mg) and paliurine A (16 mg).

3.4. Paliurine G (*1*)

Amorphous powder; $[\alpha]_D^{30}$ −335.0° (c = 0.33, MeOH). IR ν_{max} cm^{-1}: 3324, 3120, 2960, 2924, 2878, 1680, 1640, 1600 (*sh*), 1502, 1450, 1438, 1220, 1180, 1088, 1040, 796, 770, 700. Abstract

The 18-(13→12β)-*abeo*-lanostene triterpenoid acid, ananosic acid A (**1**), and the dibenzocyclooctadiene lignan, ananosin A (**2**), were isolated from the stem bark of *Kadsura ananosma*. Their structures were elucidated by extensive spectral studies and the structure of **1** was confirmed by single crystal X-ray diffraction analysis. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Kadsura ananosma*; Schisandraceae; Ananosic acid A; Ananosin A

1. Introduction

Plants of the Schisandraceae family are rich sources of dibenzocyclooctadiene lignans, and lanostane triterpenoid acids and lactones, which have been found to possess some beneficial pharmacological effects, including antihepatitis, antitumor, and anti-HIV activities (Liu, 1983; Liu and Li, 1995; Chen et al., 1996, 1999; Kuo et al., 1997, 1999). Previously, we have reported on the isolation and structural determination of eight lignans from *Kadsura angustifolia* (Chen et al., 1998a,b). A literature survey showed that only four sesquiterpenoids had been isolated from the plant *K. ananosma* (Zou et al., 1993). In continuing studies of Schisandraceae plants, we isolated a new 18-(13→12β)-*abeo*-lanostene triterpenoid acid, ananosic acid A (**1**), and a new dibenzocyclooctadiene lignan, ananosin A (**2**) from the stem bark of *K. ananosma*. This paper describes the isolation and structural elucidation of these two compounds.

2. Results and discussion

Repeated column chromatography of the CH_2Cl_2 extracts of the stem bark of *K. ananosma* yielded two new compounds (**1**–**2**). Ananosic acid A (**1**), colorless crystals (m.p. 164–166 °C), has the molecular formula $C_{30}H_{46}O_3$ by HREIMS. The IR spectrum displayed the absorption for an α,β-unsaturated acid (1693, 2500–3200 cm^{-1}) and hydroxyl groups (3423 cm^{-1}). The ^1H NMR spectrum revealed an angelic acid unit [δ_H 6.14 (1H, *tq*, $J=7.3$, 1.4 Hz) and 1.92 (3H, *d*, $J=1.3$ Hz)], two secondary methyl [δ_H 0.94 (3H, *d*, $J=6.8$ Hz) and 1.23 (3H, *d*, $J=7.0$ Hz)], and four tertiary methyl groups [δ_H 0.87, 0.91, 0.98, and 1.03 (each 3H, *s*)]. These features closely resembled those of lanost-24(*Z*)-en-26-oic acids isolated from Schisandraceae plants (Liu et al., 1988; Sun et al., 1996), suggesting that **1** was a lanostane triterpenoid acid. The signal at δ_H 3.54 (1H, *dd*, $J=3.7$, 2.0 Hz) indicated that a hydroxyl group was attached to C-3 with an α-orientation, the same as that of isoanwuweizic acid (**3**), which was previously isolated from *K. heteroclita* (Dai et al., 1990). The signal at δ_H 5.46 (1H, *dd*, $J=5.3$, 2.0 Hz) showed there was a tri-substituted double bond located at C-7 (8), C-9 (11), or C-5 (6). In the HMBC spectrum, the olefinic proton at δ 5.46 was correlated with the carbon resonance at δ 54.4 (C-14), suggesting that the tri-substituted double bond was at C-7 (8). Comparison of the ^1H NMR spectrum of **1** (Table 1) with that of **3** revealed that the C-13 tertiary methyl signal present in **3** (at δ_H 0.65) disappeared in **1**, instead appearing as a secondary methyl signal at δ_H 1.23 (3H, *d*, $J=7.0$ Hz), leading to the formation of a tetra-substituted double bond at C-13 (17) in **1**. In the HMBC spectrum, the ^1H signal at δ_H 0.94 (H-21) was correlated with the ^{13}C signal at δ_C 136.0 (C-17), and the ^1H signal at δ_H 1.23 (H-18) correlated with the ^{13}C sig-

nal at δ_C 145.8 (C-13), which supported the presence of a C-13(17) double bond.

An X-ray crystallographic study was performed to confirm the structure and determine the absolute configuration of **1** (Fig. 1). Thus, **1** was unambiguously elucidated as 3α-hydroxy-18(13→12β)*abeo* lanostan-7(8), 13(17), 24(*Z*)-trien-26-oic acid. The ^1H and ^{13}C NMR spectral data were fully assigned by various NMR techniques including DEPT, ^1H–^1H COSY, HSQC, and HMBC. The 18(13→12β)*abeo* lanostene triterpenoid skeleton was previously obtained by rearrangement of 3β-acetoxy-9α,11α-epoxylanostan-7-one treated with boron trifluoride-diethyl ether (Baddeley et al., 1979). To our knowledge, **1** is the first example of a 18(13→12β)*abeo* lanostene triterpenoid found in nature.

Ananosin A (**2**), colorless crystals (mp 132–134 °C), was assigned the molecular formula $C_{28}H_{34}O_9$ by HREIMS. The UV spectrum showed absorption maxima at 225 nm (log ε, 4.78) and 288 nm (log ε, 3.43), indicating that **2** was a dibenzocyclooctadiene lignan (Ikeya et al., 1979). The CD curve of **2** showed a negative Cotton effect around 241 nm and a positive one around 220 nm, suggesting that **2** possesses an *S*-biphenyl configuration (Ikeya et al., 1979). The ^1H NMR spectrum of **2** revealed signals for two aromatic protons at δ_H 6.71 and 6.34 each 1H, s), a methylenedioxy moiety [δ_H 5.98 and 5.95 (each 1H, *d*, *J* = 1.4 Hz)], and four methoxyl groups [δ_H 3.90 (6H, *s*), 3.76 and 3.64 (each 3H, *s*)] on two aromatic rings. In the cyclooctadiene ring, two secondary methyl groups at δ_H 0.95 and 1.14 (each 3H, *d*, *J* = 7.1 Hz) can be assigned to CH_3-7 and CH_3-8, respectively, suggesting no substituent at C-7 and C-8, with the two methyls in *cis*-orientation (Chen et al., 1976). The signals at δ_H 5.81 (1H, *d*, *J* = 7.0 H) and 4.66 (1H, *br s*) were assigned to two oxygen-bearing benzylic methines, indicating an ester group and a hydroxyl group substituted at C-6 and C-9, respectively, similar to the previously reported angustifolin C (**4**) (Chen et al., 1998a). In the HMBC spectrum, correlations between the aromatic proton at δ_H 6.34 (H-11) and the carbon signal at δ_C 82.2 (C-9), and the aromatic proton at δ_H 6.71 (H-4) and the carbon signal at δ_C 80.8 (C-6) supported the above assignments. IR (3473 cm^{-1}) and MS (*m*/*z* 496 [M^+-H_2O]) confirmed the presence of a hydroxyl group. The presence of a tigloyl group was deduced from the IR (1705 cm^{-1}), MS (414 [$M^+-C_4H_7COOH$], 83 [$C_4H_7CO^+$] and 55 [$C_4H_7]^+$) and ^1H NMR (Table 2) data, and further confirmed by a correlation between the proton signal at δ_H 6.21 (1H, *m*) and alkenyl methyl group at 1.67 (3H, *d*, *J* = 7.1 Hz) in the NOESY spectrum.

An aromatic proton appeared at higher field at δ_H 6.34 and the lack of correlation between this proton signal and any methoxyl signal suggested that it was adjacent to the methylenedioxy moiety (Mervic and Ghera, 1977). The correlation between the proton signal at δ_H 6.34 and benzylic methine at δ_H 4.66, and the proton signal at δ_H 6.71 and the benzylic methine at δ_H 5.81 in the NOESY spectrum, indicated that the tigloyl and hydroxyl groups were located in the 6β and 9α positions, respectively. The NOESY spectrum also showed correlations between Me-7 (δ_H 0.95) and H-4 (δ_H 6.71), and between Me-8 (δ_H 1.14) and H-9 (δ_H 4.66), suggesting that both Me-7 and Me-8 are α-oriented. On basis of the results mentioned above, the structure of ananosin A was thus determined as **2**. No coupling was showed between H-8β and H-9β, but the NOE correlation between H-4 and Me-7, H-4 and H-6α, Me-8 and H-9, and H-9 and H-11 indicated a twist-boat-chair conformation for the cyclooctadiene ring (Fig. 2).

3. Experimental

3.1. General

IR spectra were recorded as KBr pellets on a Perkin-Elmer 599B spectrophotometer. UV spectra were measured on a Shimadzu UV-3000 spectrophotometer in absolute MeOH. MS were determined on a Varian Mat-711 mass

spectrometer. NMR spectra were measured on a Brüker AM-400 spectrometer with TMS as int. standard and $CDCl_3$ as solvent. 2D-NMR spectra were performed on a Brüker DRX 500 spectrometer. Optical rotations were recorded with a JASCO Dip-181 spectropolarimeter. Silica gel (200–300 mesh) was used for column chromatography and silica gel GF_{254} for TLC (Qingdao Marine Chemical Co.)

3.2. Plant materials

The stem bark of *K. ananosma* Kerr was collected from Men-Na County of Yunnan Province, China in February 1998, and identified by Mr. Hong Wang, a botanist of Xi-Shuang-Bang-Na Botanical Garden, Chinese Academy of Sciences, where a voucher specimen (No. 9802015) is deposited.

3.3. Extraction and isolation

The dried powdered stem bark of *K. ananosma* (6.0 kg) was extracted with CH_2Cl_2 exhaustively. The CH_2Cl_2 extract was concentrated in vacuo to give a residue (500 g), which (100 g) was applied to a silica gel column, eluted with petroleum ether containing increasing amounts of Me_2CO to afford seven fractions

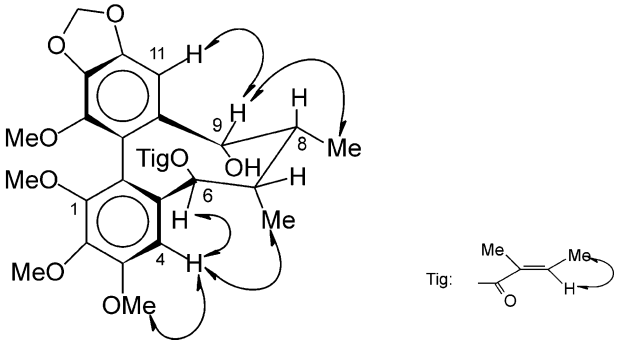

Fig. 2. NOE correlations of compound **2**.

(A–G). Fraction B was subjected to repeated column chromatography to yield ananosic acid A (**1**, 475 mg). Fraction C was treated in a similar manner as fraction B to yield ananosin A (**2**, 146 mg).

3.3.3. *X-ray analysis of **1***

Crystal data: $C_{30}H_{46}O_3$, MW = 454.34, monoclinic, space group *C*2 (No. 5), *a* = 34.852 (3) Å, *b* = 9.412 (2) Å, *c* = 8.527 (2) Å, β = 90.11 (2)°, *V* = 2797.1 (7) $Å^3$, *Z* = 4, *D*c = 1.080 g cm^{-3}, μ (M_0-K_α) = 0.67 cm^{-1}, *F* (000) = 1000, *T* = 301 K. Crystal dimensions: 0.4×0.2×0.1 mm. The intensity was recorded with a MAR diffractometer. From a total of 11646 measurements, those 1824 reflections with $1 > 3\sigma$ (I) were retained for the analysis. The crystal structure was solved by direct methods (SIR 92[2]) and expanded by Fourier method and refinement by full-matrix least-squares using the software package TeXsan[3] on a Silicon Graphics Indy computer. The all non-H atoms were refined anisotropically. The positional parameters of the H atoms bonded to O (1) and O (3) and located in the difference Fourier synthesis were refined and 44 other H atoms at calculated positions with thermal parameters equal to 1.3 times that of the attached C atoms, were not refined.

Received 29 March 2001; received in revised form 13 August 2001

Abstract

The compounds isolated from the extract of Central Asian lichen (*Acarospora gobiensis* H. Magn.) comprised three new glycosides having 18-hydroxy-dihydroalloprotolichesterinic, 18-hydroxy-neodihydroprotolichesterinic and 18-hydroxy-dihydroprotolichesterinic acids as aglycones and a di- or trisaccharide moiety linked at C-18 and at the carboxylic group. These compounds, called gobienines A–C, were found to be di- or trisacharides forming a macrolactone with the aglycone. The structures were elucidated by using extensive spectroscopic analysis (1D and 2D NMR, MS, IR and ORD) and chemical and enzymatic methods. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: Macrolactone glycoside esters; Lichens of Central Asia; *Acarospora gobiensis*; Acarosporaceae; NMR; MS; IR spectra

1. Introduction

Macrolactone glycosides containing an aglycone and di- or trisaccharides are found very rarely in nature (Ikan, 1999). At present only a few examples of these unusual compounds are known to come from living organisms. The best known are compounds isolated from tropical and subtropical plants, mainly of the genus *Ipomaea* and/or family Convolvulaceae (Noda et al., 1988; Hernandez-Carlos et al., 1999; Lehmann et al., 2000). Further examples of macrocyclic lactones were isolated from a Japanese mountain shrub (*Polygala*) or roots of the genera *Sonchus*; all are glycosides that have a terpenic aglycone and two sugars (Iwagawa and Hase, 1983; Helal et al., 2000; Kobayashi et al., 2000).

Similar compounds have also been reported in *Candida bogoriensis* and *Torulopsis* (*Candida*) *bombicola* (Spencer et al., 1970). The glycolipids produced by these yeast strains contain the disaccharide sophorose (β-D-Glc-(1-2)-D-Glc) linked to a lipid moiety containing a 17-hydroxyoctadecanoic acid.

As a continuation of our search for unusual bioactive compounds from Central Asian lichens (Řezanka and Dembitsky, 1998, 1999; Řezanka and Guschina, 1999, 2000, 2001a,b), we examined the lichen *Acarospora gobiensis* H. Magn.

2. Results and discussion

Detailed investigation of fractions of oligosaccharide mixtures from *A. gobiensis* led to the isolation of three additional glycosides. These compounds were purified to homogeneity by HPLC using an amino bonded silica gel column. Structural investigation of these three new macrolactone di- and trisaccharides of lichen acids, gobienine A (**1**), gobienine B (**2**) and gobienine C (**3**) was performed by NMR and FAB–MS. Their aglycones are the following lichen acids: 18-hydroxy-dihydroalloprotolichesterinic, 18 - hydroxy - neodihydroprotolichesterinic and 18-hydroxy-dihydroprotolichesterinic acid. All were present in the relatively small amounts ($<0.01\%$ of dry mass).

Compound **1** gave either positive or negative-ion FAB–MS. The positive ion in the mass spectrum of gobienine A (**1**) was a pseudo-molecular ion at m/z 677.3751 $(M+H)^+$ which indicates the molecular formula $C_{33}H_{56}O_{14}$.

In addition to the common fragment peaks produced by a glycosidic cleavage of the sugar moieties in each of the oligosaccharide cores (Fig. 1), i.e. m/z 513 $(M–H-162)^-$, m/z 351 (513–162 (hexose); (aglycone))$^-$, the negative ions of compound **1** determined by FAB–MS were observed at m/z 675 $(M–H)^-$.

Treatment of **1** with esterase (EC 3.1.1.1 from porcine liver) gave compound **1a** (37.1%) together with unreacted **1**. The positive ion FAB mass spectrum of **1a** exhibited a $[M+H]^+$ ion peak at m/z 695. The negative FAB–MS of **1a** showed an $(M–H)^-$ peak at m/z 693 along with the fragment peak at m/z 369 (M–H-324 (2× hexose units))$^-$ and a peak at m/z 531 (M–H-162 (hexose unit))$^-$ in place of that detected at m/z 513 in the spectrum of **1**. The difference of 18 mass units indicated (see above) that the ester linkage of the lichen acid is placed at C-2 of second glucose (Glu″).

The use of various one- and two-dimensional NMR spectroscopic methods provided information about the interglycosidic linkage, the sequence of monosaccharide residues and the site of esterification in all these complex oligosaccharides. The ^{1}H NMR spectrum of **1a**, when compared with that of **1**, showed an upfield shift (δ 1.52 ppm) of H-2″ of the second glucose (Glc″) and a disappearance of the signal at δ 5.73 indicating a loss of lactonization. The ester linkage of the aglycone is therefore located at 2-OH of Glc″.

The acid-catalyzed hydrolysis of **1a** gave a mixture of degradation products from the aglycone and the monosaccharide. The two saccharide units were identified as D-glucose by using the acetylated-2-butyl derivatives prepared from glycosides and analyzed by gas chromatography using a capillary column (Supelco SPB-1) (Gerwig et al., 1978).

The ^{1}H NMR spectrum of **1a** showed the signal of H-18 at δ 3.76. The proton and carbon signals arising from the sugar moiety were assigned with the aid of ^{1}H–^{1}H and ^{1}H–^{13}C two-dimensional shift-correlated NMR (COSY) analyses (Tables 2 and 4).

The ^{13}C NMR spectrum of **1a** showed glycosylation shifts only at C-2′ (Δ 5.7 ppm) of the first glucose relative to those of corresponding methyl pyranoside (δ_{C-2} = 74.8) (Seo et al., 1978).

The enzymatic hydrolysis of **1a** by β-glucosidase (EC 3.2.1.21) gave **1b** (EI–MS, m/z 370 $(M)^+$). The ^{1}H NMR, ^{13}C NMR and also ORD spectra of **1b** revealed it to the 18-hydroxydihydroallo-protolichesterinic acid, previously described by Řezanka and Guschina (2001b). The coupling constants of both anomeric proton signals of the sugar moiety indicated that the mode of glycosidic linkage of the two glucopyranose units is β (Kasai et al., 1977; Tori et al., 1977). The above data indicated that **1a** is (18*R*)-18-hydroxydihydroalloprotolichesterinic acid 18-*O*-β-D-glucopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside.

To complete the determination of the primary structure of compound **1**, ^{1}H and ^{13}C NMR spectra of this compound were recorded. Gobienine A (**1**) showed a well resolved ^{1}H NMR spectrum (no-overlap in the proton region between δ 3.8 and 4.4). No derivatization was needed to achieve the total structural assignment of gobienine A (**1**) which was readily made through an extensive investigation using NMR spectroscopy. A combination of ^{1}H NMR spectra with 2-D homonuclear techniques including DQF-COSY and TOCSY allowed all C-bonded protons to be sequentially assigned within

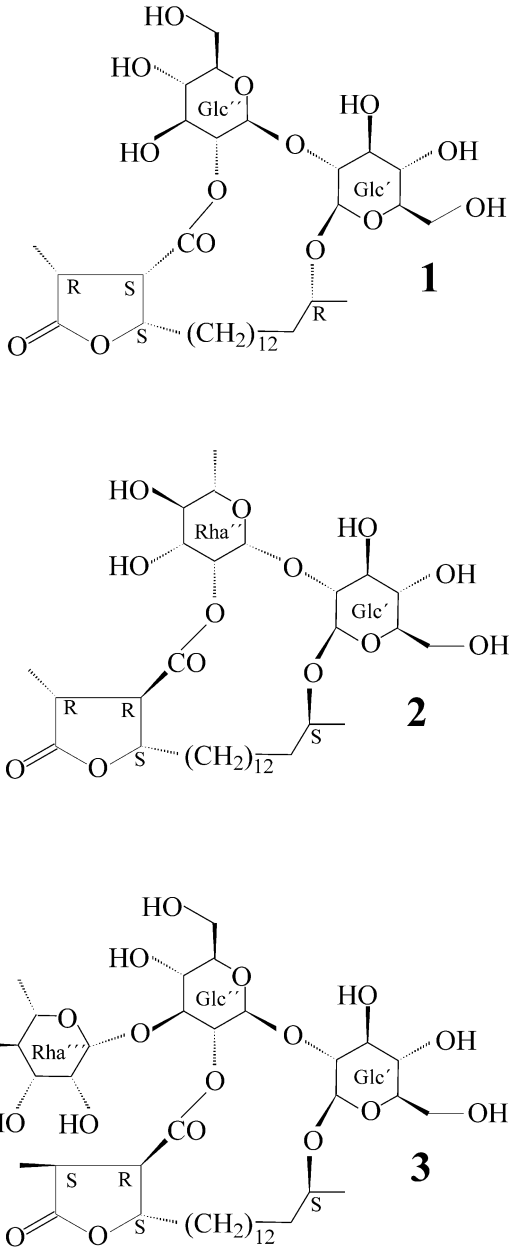

Fig. 1. The structures of gobienines A–C: (**1**) (18*R*)-18-hydroxydihydroalloprotolichesterinic acid 18-*O*-β-D-glucopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone), (**2**) (18*S*)-hydroxyneodihydroprotolichesterinic acid 18-*O*-α-L-rhamnopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone), (**3**) (18*S*)-hydroxydihydroprotolichesterinic acid 18-*O*-α-L-rhamnopyranosyl-(1‴-3″)-*O*-β-D-glucopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone).

each ring system (Table 2) and all the resonances in the ^{13}C NMR spectra were assigned by using a ^{1}H-detected (^{1}H–^{13}C) one-bond correlation experiment (HMQC) (Table 4). The interglycosidic connectivities, as well as the site of lactonization, were established entirely on the basis of the observed ^{13}C–^{1}H long-range cross peaks ($^2J_{CH}$ and $^3J_{CH}$) in HMBC experiments. For example, ^{13}C–^{1}H long-range cross peaks (^3J) were observed in the spectrum of gobienine A (**1**) between C-1′ (δ 103.4) of the first glucose and H-18 of the aglycone and C-1″ of the second glucose (δ_C 103.8) and H-2′ of the first glucose (δ_H 4.18). A series of gated decoupling experiments was performed for further determination of the anomeric configuration of the glycosyl linkages, from the completely resolved multiplets for the two anomeric ^{13}C atoms of compounds **1** (Table 4), all $^1J_{CH}$ values of the glucoses were found to be <165 Hz. Such coupling constants established the mode of glycosidic linkage to be β (Collins and Ferrier, 1995) type for each of the monosaccharide units.

From the ^{1}H NMR spectra (Table 2), the esterified positions on the disaccharide cores were easily identified through strong deshielding effects relative to the non-esterified equivalents on **1a**. In this way, the primary structure of gobienine A (**1**) was established as (18*R*)-18-hydroxydihydroalloprotolichesterinic acid 18-*O*-β-D-

glucopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone).

In **2**, both positive and negative FAB–MS were obtained (*m/z* 661.3801, $(M+H)^+$, i.e. $C_{33}H_{56}O_{13}$,). For compound **3**, the positive ion mode revealed a quasi-molecular ion peak $(M+H)^+$ at *m/z* 823.4331 indicating a molecular formula of $C_{39}H_{66}O_{18}$. The negative ion FAB–MS of compounds **2** and **3** showed the same fragmentation pathways that resulted from the cleavage of glucoside-ester bonds that yields high-mass fragment ions representing each monosaccharide and aglycone. Compounds **2** and **3** showed also the pseudomolecular peaks at *m/z* 659 $(M–H)^-$ and *m/z* 821 $(M–H)^-$, respectively. In **2** the appropriate cleavages resulted in the presence of the ions at *m/z* 497 $(M–H\text{-}162)^-$, 351 [$(M–H\text{-}162–146)^-$; (aglycone)] while **3** yielded ions at *m/z* 821 $(M–H)^-$, 675 $(M–H\text{-}146)^-$, 513 $(M–H\text{-}146–162)^-$, 351 [$(M–H\text{-}146\text{-}2\times162)^-$; (aglycone)].

The site of lactonization of **2** was placed at C-2″ of rhamnose based on the observed ^3J-coupling between the carbonyl carbon of the aglycone (δ 162.7) and its geminal proton (δ ca. 6.4) in the pyranose unit. For **3**, the position of lactonization was verified by the observed connectivities between the carbonyl group of the aglycone (δ 163.1) and H-2″ of the second glucose.

The position of lactonization was also verified by the $^3J_{CH}$ connectivities between the carbonyl group of the aglycone and proton H-2 of the monosaccharide unit in both natural disaccharides as in compound **1**.

A series of gated decoupling experiments was performed for further determination of the anomeric configuration of the glycosyl linkages and the completely resolved multiplets for the two anomeric ^{13}C atoms of compounds **2** (Table 4) showed that all $^1J_{CH}$ values of the glucoses were <165 Hz. Such coupling constants established the mode of glycosidic linkage as β of the pyranose (Collins and Ferrier, 1995) type for each of the monosaccharide units. A different diglycoside was identified as the oligosaccharide core of gobienine B (**2**) and the structure of this natural product was determined to be (18*S*)-hydroxyneodihydroprotolichesterinic acid 18-*O*-α-L-rhamnopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone).

The ^1H and ^{13}C signals arising from the sugar moieties in the spectra of compound **3** were assigned by ^1H–^1H DQ-COSY and ^1H–^{13}C HETCOR analyses (Tables 2 and 4). The ^{13}C NMR spectrum of **3** showed the glycosylation shifts at C-3″ (Δδ 6.3) of the second glucose relative to those of corresponding methyl pyranosides (Seo et al., 1978). The selective INEPT technique (Cordell and Kinghorn, 1991), applied to gobienine C (**3**), confirmed the nature of the saccharide substitution. Thus, irradiation of the anomeric proton H-1′ of the first glucose at δ 5.65 ($^3J_{CH}=6$ Hz) selectively enhanced C-18 of the aglycone. When H-2′ of the first glucose (δ 4.20) was irradiated ($^3J_{CH}=6$ Hz), a clear enhancement of the anomeric carbon C-1″ of the second glucose resulted (δ 103.1). Irradiation of the inner glucose H-3″ at δ 4.16 ($^3J_{CH}=6$ Hz) resulted in the polarization transfer to the anomeric carbon C-1‴ (δ 102.1) of the terminal rhamnose. The application of a COLOC NMR experiment in **3** further confirmed the sequence of the sugar moiety. ^{13}C-^1H long-range cross peaks were observed and unambiguously assigned as those between C-1′ of glucose and H-18 of the aglycone and C-1‴ of the terminal rhamnose and H-3″ of inner glucose.

4‴				73.9
5‴				69.6
6‴				18.7

In compound **3**, the $^1J_{CH}$ showed the following coupling value: 163.1 Hz for the first glucose, 164.7 Hz for the second glucose and 172.5 Hz for the rhamnose. The latter value is typical for the equatorial configuration of the anomeric proton, confirming the α-L-rhamnose residue (Etse et al., 1991).

Long-range heteronuclear coupling correlations were used to determine the linkages within the trisaccharide core of gobienine C (**3**). For instance a connectivity was observed between H-2″ of the second glucose at δ 5.81 and the anomeric carbon of the first glucose at δ 103.7, and between H-3‴ of rhamnose (δ 4.65) and C-1″ of the second glucose (δ 103.1).

The signals for the sugar moiety in the ^{1}H NMR spectra of **3** and **1a** were compared in order to establish the site of lactone linkage at the oligosaccharide core. Significant downfield shifts owing to acylation were observed for the inner glucose proton H-2″ (Δ 1.60 ppm).

The above mentioned spectral evidence indicated that compound **3** is a glycoside similar to those isolated from this source, having the carbonyl group of the aglycone linked to an oligosaccharide core to form a macrocyclic lactone. Its correct structure is (18*S*)-hydroxydihydroprotolichesterinic acid 18-*O*-α-L-rhamnopyranosyl-(1‴-3″)-*O*-β-D-glucopyranosyl-(1″-2′)-*O*-β-D-glucopyranoside-(21,2″-lactone).

3. Experimental

3.1. General experimental procedures

UV spectra were measured in heptane in the range of 200–350 nm by a Cary 118 (Varian) apparatus. Optical rotatory dispersion (ORD) measurement was carried out under dry N_2 on a Jasco-500A spectropolarimeter at 24 °C. A Perkin-Elmer Model 1310 (Perkin-Elmer, Norwalk, CT, USA) IR spectrophotometer was used for scanning IR spectroscopy of acids and glycosides as neat films. NMR spectra were recorded on a Bruker AMX 500 spectrometer (Bruker Analytik, Karlsruhe, Germany) at 500.1 MHz (^{1}H), 125.7 MHz (^{13}C). High- and also low-resolution MS were recorded using a VG 7070E-HF spectrometer (70 eV). HR–FAB–MS (positive and/or negative ion mode) were obtained with a PEG-400 matrix. HPLC was carried out using Shimadzu gradient LC system (Shimadzu, Kyoto, Japan). Gas chromatographic analysis was done on a Hewlett Packard HP 5980 gas chromatograph (Hewlett Packard Ltd., Czech Republic).

3.2. Plant material

The specimen of *Acarospora gobiensis* H. Magn., (Acarosporaceae, Lecanorales, Ascolichenes) was collected in July 1996 along the shore of Lake Issyk Kul, Tian-Shan mountains. The voucher specimens are deposited in the collection of the second author (I.A. Guschina).

3.3. Extraction and isolation

The lichen specimen [100 g of air-dried lichen, see Řezanka and Guschina, (2000)] was extracted by the Blight and Dyer (1959) method and the extract was chromatographed on a column of Sephadex LH-20 eluted with EtOH–i–PrOH (fraction 1), EtOH (fraction 2) and then MeOH (fraction 3). Fraction 3 was further fractionated by HPLC on a NH_2-Bondapak (Waters Ltd., Czech Republic) column (30 cm×7.8 mm, flow rate 1.8 ml/min) with ACN–H_2O (2:5) to yield compounds **1** (2.1 mg), **2** (1.4 mg) and **3** (0.6 mg).

The identification and the D or L configuration of sugars was determined using gas chromatography according to the method of Gerwig et al. (1978), with some modifications as previously described (Řezanka and Guschina, 2000).

3.4. Acid hydrolysis of *1a*

The glycoside (~0.1 mg) was refluxed in 2 N HCl (0.5 ml) for 2 h. The degradation products of the aglycone were extracted three times with EtOAc (10 ml). After separating the organic layer, the aqueous phase was neutralized with $NaHCO_3$ and lyophilized.

3.5. Enzymatic hydrolysis

A solution of glycoside (~0.1 mg) in acetate buffer (pH 4.4, 10 ml) was treated with β-glucosidase (EC 3.2.1.21) for 48 h at 37 °C. The reaction solution was evaporated to dryness, and the residue was chromatographed on a column of silica gel (10 g), using CH_2Cl_2–MeOH–H_2O (90:10:1) to provide lichen acids for ^{1}H NMR and ORD analysis.

Glycosides (~ 0.1 mg) were suspended in $(NH_4)_2SO_4$ solution of esterase (EC 3.1.1.1, from porcine liver) at pH ~8 and incubated 15 min at 25 °C. The aglycone was extracted three times with EtOAc (10 ml). After separating the organic layer, the aqueous phase was neutralized with 0.5 N HCl and lyophilized.

3.6. (S)-MTPA and (R)-MTPA esters

Treatment of each hydroxy acid (**1b**, **2b** and **3b**) with (*R*)-(−)-MTPACl or (*S*)-(+)-MTPACl converted them into the (*S*)- and (*R*)-2-methoxy-2-trifluoromethylphenylacetic acid (MTPA) esters (**1s**, **2s**, and **3s** and **1r**, **2r** and **3r**, respectively). The values of $\Delta\delta = [\delta(S\text{-MTPA ester}) - \delta(R\text{-MTPA ester})]$ in the ^{1}H NMR spectra suggested that the absolute configuration at C-18 of compound **1** was (*R*) while that of **2** and **3** were (*S*) (Ohtani et al., 1991b). The data are shown in Table 5.

Table 5
Stereochemical analysis of compounds **1b**, **2b** and **3b** with (*R*)- and (*S*)-MTPA (Mosher) derivatives[a]

MTPA esters of compound No.	$\Delta\delta = \delta_{S\text{-ester}} - \delta_{R\text{-ester}}$ (Hz)		
	H-19	H-17	Carbinol configuration
1b	+12.8	−30.1	*R*
2b	−16.9	+26.7	*S*
3b	−15.8	+34.2	*S*

[a] The aglycones from glycosides **1**–**3** are identical from one from **1b** or **2b** or **3b**.

(*S*)-MTPA esters of free acids (**1**–**3**) (Ohtani et al., 1991a, b). To a CH_2Cl_2 solution (100 μl) of aglycone (0.3 mg), DMAP (1.0 mg), and Et_3N (2 μl) was added (*R*)-(−)-MTPACl (2.0 mg) at room temperature, and stirring was continued for 3 h. After the evaporation of the solvent, the residue was purified by Silica gel TLC (hexane–AcOEt, 2:1) to provide the (*S*)-MTPA ester as colorless oil.

(*R*)-MTPA Esters of free acids (**1**–**3**). Each aglycone (0.3 mg) was treated with (*S*)-(+)-MTPACl (2.0 mg) by the same procedure as described above to provide the (*R*)-MTPA ester as colorless oil. The data are given in Table 5.

18*R*-Hydroxydihydroalloprotolichesterinic acid **1b**, white crystals, mp 143 °C, $[\alpha]_D^{24}$ −48° (*c* 0.19, $CHCl_3$), UV λ_{max} (EtOH, nm) 218 (log ε 2.28); ORD: $[\alpha]_{222}^{24}$ nm (−790), ^{1}H NMR, ^{13}C NMR and MS spectra, see (Řezanka and Guschina, 2001b).

Received 27 February 2001; received in revised form 13 June 2001

Abstract

From the chloroform extract of the roots of *Ferula assa-foetida*, two sesquiterpene coumarins designated assafoetidnol A and assafoetidnol B were isolated, in addition to six known compounds, gummosin, polyanthin, badrakemin, neveskone, samarcandin and galbanic acid. The structures of the sesquiterpenes new compounds were established by spectroscopic methods. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Ferula assa-foetida*; Umbelliferae; Resins; Sesquiterpene coumarins

1. Introduction

The genus *Ferula* presents interesting phytochemical features, such as the occurrence of sesquiterpenes (Gonzalez and Barrera, 1995; Appendino et al., 1997; Kojima et al., 1999, 2000; Chen et al., 2000; Su et al., 2000a,b) and sesquiterpene coumarins (Murray, 1989; Ahmed, 1999; Su et al., 2000a,b). *Ferula assa-foetida* grows in Kashmir, Iran and Afghanistan. It is herbaceous and perennial and grows up to 2 m high (Kapoor, 1990). One part used is an oleogum resin, obtained by incision from the roots, and this is called asa-foetida (Kapoor, 1990). The resin of *F. assa-foetida* enjoys a reputation as a folklore medicine (Boulus, 1983). In Nepal asa-foetida is considered to be a sedative, carminative, antispasmodic and a diuretic in its properties. It is also believed is have aphrodisiac properties and increases the sexual appetite (Eigner and Scholz, 1990). Indeed, asa-foetida is consumed regularly in the daily Nepali diet. It is popular household remedies and its components are used for many prescriptions in traditional healing (Eigner and Scholz, 1999). The characteristic features of this plant include the presence of glucuronic acid, galactose, arabinose and rhamnose which have been isolated from the gum (Kapoor, 1990), whereas the taste and smells are due to sulfur containing compounds. Asadisulphide (Kajimoto et al., 1989), disulfides, as well as symmetric tri- and tetrasulfides have been isolated (Rajanikanth et al., 1984). Also, umbelliferone, farnesiferol A, B and C, and ferulic acid (Caglioti et al., 1958, 1959), kamolonol (Hofer et al., 1984), assafoetidin and ferocolicin (Banerji, 1988), assacoumarin A and B (Kajimoto et al., 1989), foetidin (Buddrus et al., 1985), episamarcandin, umbelliprenin and conferol (Nassar et al., 1995), 5-hydroxyumbelliprenin, 8-hydroxyumbelliprenin and 8-acetoxyumbelliprenin (Appendino et al., 1994), and episamarcandin acetate (Nassar and Mohamed, 1998) have been isolated. Until 1994 the stereochemistry of assacoumarin B had not been elucidated, when a detailed spectroscopic investigation was carried out with the aid of 1D and 2D NMR spectroscopic techniques. This study showed that assacoumarin B has a constitution different from the originally reported and this compound was actually galbanic acid (Appendino et al., 1994), a known constituents of galbanum (Bagirov et al., 1980). We wish to report the isolation and structure elucidation of two new sesquiterpene coumarins from the resins of *Ferula assa-foetida*.

2. Results and discussion

The resins of *F. assa-foetida* were extracted with chloroform. Successive chromatographic separation led

PII: S0031-9422(01)00324-7

to the isolation of two new sesquiterpene coumarins, designated assafoetidnol A (**1**) and assafoetidnol B (**2**).

Assafoetidnol A (**1**) had a molecular formula $C_{24}H_{30}O_5$ as established by HREIMS (*m/z* 398.2106 $[M]^+$, Δ +1.3 mmu). The IR spectrum indicated the presence of hydroxyl and carbonyl groups. The structure of **1** was established from analysis of the ^1H NMR and ^{13}C NMR spectra, as shown in Table 1. Compound **1** displayed 24 carbon signals, nine being typical for an umbelliferone skeleton and the other 15 signals were ascribable to a sesquiterpene moiety. This suggested that **1** was derived from sesquiterpene and umbelliferone components. The downfield signal at δ_C 161.3 was assigned to the carbonyl carbon of the coumarin moiety. DEPT experiments classified the carbon signals to three methyls at δ_C 15.9, 31.2, and 23.2 which were attributed to C-13′, C-14′, and C-15′, respectively, three aliphatic methylenes at δ_C 27.1, 35.3 and 43.5, an olefinic carbon at δ_C 112.5 and a primary alcoholic carbon at δ_C 67.5 characteristic for C-11′, and nine methines, five of them for umbelliferone moiety at δ_C 112.8 (C-3), 143.5 (C-4), 128.7 (C-5), 113.2 (C-6) and 101.4 (C-8). Assignments of all protonated carbons were made by the analysis of the HMQC spectrum. The ^1H–^1H COSY spectrum showed that the methine proton at δ_H 1.39 (H-5′) is coupled to the downfield secondary alcoholic at δ_H 3.98 (H-6′), which in turn is coupled to the methylene protons at δ_H 2.21 (H-7′$_{ax}$) and 2.62 (H-7′$_{eq}$). The other secondary alcoholic at δ_H 3.21 (H-3′) coupled to the methylene protons at δ_H 1.66 (H-2′$_{ax}$) and 1.35 (H-2′$_{eq}$).

The location of two hydroxyl groups at C-3′ and C-6′ was proven by HMBC. The stereochemistry of **1** was deduced from the comparison of coupling constants with those of cauferin (Kuliev and Khasanov, 1978), previously isolated from *F. conocaula*. Acetylation of **1** afforded a diacetyl derivative **1a**, which showed two oxygenated carbon signals at δ_C 80.2 and 71.6, these being ascribed to the secondary alcoholic carbons. Also these facts were supported by the downfield shifts of H-3′ to δ_H 4.45 and H-6′ to δ_H 5.16. Esterfication of **1** with *p*-bromobenzoyl chloride gave assafoetidnol A di-*p*-bromobenzoate (**1b**),

which showed a good separation of proton signals and allows a clear NOE. In NOE experiments, irradiation of H-3′ resulted in enhancements of H-13′ and H-5′ signal, as shown in Fig. 1, whereas irradiation of H-6′ resulted in enhancement of H-7′$_{eq}$, H-14′ and H-15′. Additionally, irradiation of H-9′ resulted in enhancement of Me-15′ and irradiation of Me-15′ showed a clear enhancements of H-1′$_{eq}$, H-2′$_{ax}$, H-6′ and H-9′, indicating the α-orientation of H-1′$_{eq}$, H-2′$_{ax}$, H-6′, H-9′ and Me-15′. Irradiation of H-11′ resulted in enhancements of H-1′$_{ax}$, H-5′ and H-7′$_{ax}$ signals, thereby indicating the β-orientation of H-1′$_{ax}$, H-5′, H-7′$_{ax}$ and H-11′. The NOE experiments supported the relative stereochemistry of the chiral centers. The absolute configuration of **1** was determined by the application of dibenzoate rule (Gonnella et al., 1982). The CD spectrum of the dibenzoyl derivative **1b** in MeOH exhibited a negative Cotton effect at 253 nm and a positive one at 234 nm, as shown in Fig. 2. This indicates that the absolute configuration of **1** was 3′R,6′R. Thus the complete structure of **1** was determined to be as shown in Fig. 1.

Assafoetidnol B (**2**) was estimated by the molecular formula $C_{26}H_{32}O_7$ by HRFABMS (*m*/*z* 457.2205, $[M+H]^+$, Δ −4.7 mmu). The NMR spectral data of **2** were similar to those of **1**, the main differences between both compounds being the signals assigned to the sesquiterpene unit. In the ^{1}H NMR spectrum of **2**, the presence of an additional oxygen functionality at C-7′ was determined by ^{1}H–^{1}H COSY, HMQC and HMBC. Furthermore, the downfield shift of H-3′ to δ_H 4.63 suggested that C-3′ should be acetylated. In the ^{1}H–^{1}H COSY spectrum, the H-5′ proton at δ_H 2.01 was coupled to the oxygenated methine proton at δ_H 3.67 (H-6′) which in turn was coupled to the oxygenated methine proton at δ_H 4.08 (H-7′). In the HMBC spectrum, the secondary alcoholic H-6′ (δ_H 3.67) showed HMBC correlations to C-7′ (δ_C 77.3) and C-5′ (δ_C 45.3), and the other secondary alcoholic H-7′ also showed HMBC correlations to C-6′ (δ_C 75.2), C-12′ (δ_C 110.0), and C-8′ (δ_C 145.6). Moreover, the HMBC correlations of the broad singlet at δ_H 4.63 (H-3′) with C-1′ (δ_C 30.3), C-5′ (δ_C 45.3), and the acetyl function at δ_C 170.3, proved that C-3′ should be acetylated. NOE experiments suggested the stereochemistry at C-6′ and C-7′. Irradiation of H-6′ at δ_H 3.67 resulted in enhancements of H-14′ (δ_H 1.11, 7%) and H-15′ (δ_H 1.06, 18%), whereas irradiation

of H-7′$_{ax}$ at δ_H 4.08 resulted in an enhancement H-5′$_{ax}$ (δ_H 2.01, 13%). Additionally, irradiation of H-9′$_{eq}$ at δ_H 2.35 resulted in an enhancement H-15′ (δ_H 1.06, 6%). Acetylation of **2** yielded a diacetyl derivative **2a**, which showed a downfield shift of H-6′ to δ_H 5.36 and H-7′ to δ_H 5.50 in the ^{1}H NMR spectrum. Esterification of **2** with *p*-bromobenzoyl chloride gave assafoetidnol B di-*p*-bromobenzoate (**2b**). The CD spectrum of **2b** showed a positive Cotton effect at 254 nm and a negative one at 236 nm (Fig. 3), indicating that the absolute configuration of **2** was 6′S,7′S.

Six known sesquiterpene coumarins gummosin (**3**) (Kir'yalov and Movchan, 1966; Perel'son et al., 1975), polyanthin (**4**) (Khasanov et al., 1974), badrakemin (**5**) (Kir'yalov, 1967; Perel'son et al., 1975), neveskone (**6**) (Bagirov, 1978), samarcandin (**7**) (Kir'yalov and Movchan, 1968; Nasirov et al., 1985), and galbanic acid (**8**) (Bagirov et al., 1980) were isolated and identified by the comparison of their spectral data with those published in the literature. The structures of these known compounds were also confirmed by 2D NMR (^{1}H–^{1}H COSY, HMQC and HMBC). The structure of **3** was confirmed by the X-ray crystallographic analysis, as shown in Fig. 4.

3. Experimental

3.1. Plant material

Resins of *F. assa-foetida* were obtained from a local market in Cairo in April 1999.

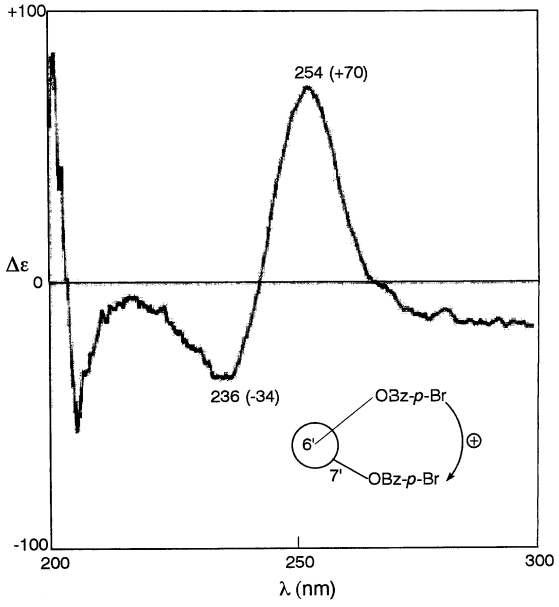

Fig. 3. CD spectrum of **2b**.

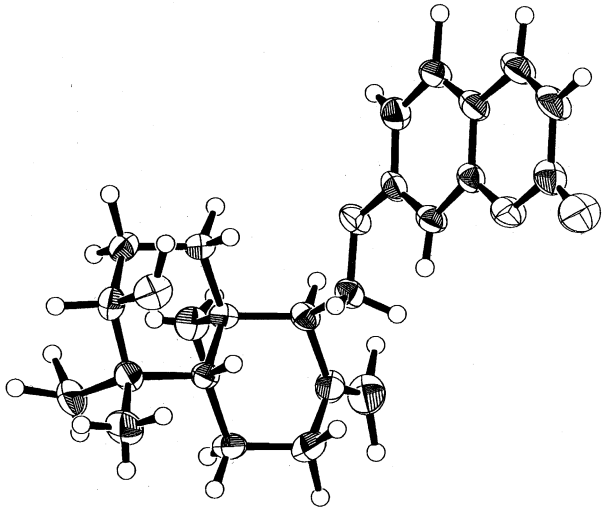

Fig. 4. ORTEP drawing of **3**.

3.2. Isolation and purification

Dried and coarsely powdered resins (250 g) were extracted with $CHCl_3$ at room temp. for 24 h. The extract (60 g) was subjected to flash chromatography over silica gel, this being eluted with hexane with an increasing amount of $CHCl_3$. Fr. A (hexane–$CHCl_3$, 1:1) was further applied to a Sephadex LH-20 column, eluted with hexane–EtOAc, 1:1 to give galbanic acid (**8**; 30 mg) and gummosin (**3**; 100 mg). Fr. B (hexane–$CHCl_3$, 1:2) was also subjected to Sephadex LH-20 chromatography (hexane–$CHCl_3$–MeOH, 5:3:0.5) to afford polyathin (**4**; 40 mg), and badrakemine (**5**; 27 mg). Fr. C ($CHCl_3$) was separated by TLC (silica gel, $CHCl_3$–MeOH, 7.0:0.5) to give neveskone (**6**; 37 mg). Fr. D ($CHCl_3$–MeOH, 85:15) was subjected to silica gel chromatography ($CHCl_3$–MeOH, 7.5:0.5), then over Sephadex LH-20 (hexane–$CHCl_3$–MeOH, 5:3:1.5) to give samarcandin (**7**; 70 mg), assafoetidnol A (**1**; 50 mg), and assfoetidnol B (**2**; 33 mg). Known compounds were identified by the comparison of their IR, MS, and ^1H NMR data with those reported in the literature.

3.3. Assafoetidnol A (*1*)

Amorphous solid; $[\alpha]_D$ −80.0° (*c* 0.2, MeOH); UV (MeOH) λ_{max} (log ε) : 322 (4.69), 258 nm (3.44); IR (film) ν_{max} 3408, 1707 cm^{-1}; HREIMS *m/z* 398.2106 $[M]^+$ (calcd. for $C_{24}H_{30}O_5$, 398.2093); EIMS *m/z* (rel. int.) 398 $[M]^+$ (3), 380 $[M–H_2O]^+$ (5), 362 $[M–2H_2O]^+$ (2), 237 [M-coumarin]$^+$ (50), 161 [M-sesquiterpene]$^+$ (100); ^1H and ^{13}C NMR spectral data see Table 1.

3.3.1. Acetylation of *1*

Compound **1** (10 mg) was refluxed in 1 ml of Ac_2O–C_5H_5N (1:1) for 2 h. The mixture was worked up by standard methods to give the diacetate **1a** (10 mg).

Colourless oil; IR (film) ν_{max} 1690, 1722 cm^{-1}; HREIMS *m/z* 482.2272 $[M]^+$ (calc. for $C_{28}H_{34}O_7$, 482.2305); EIMS *m/z* (rel. int.) 482 $[M]^+$ (4), 321 [M-coumarin]$^+$ (20), 161 [M-sesquiterpene]$^+$ (100); ^1H NMR (500 MHz, $CDCl_3$): δ 0.94 (3H, *s*, H-15′), 1.02 (3H, *s*, H-13′), 1.04 (3H, *s*, H-14′), 1.37 (1H, *dd*, *J* = 14.4, 4.9 Hz, H-2′$_{eq}$), 1.70 (3H, *m*, H-2′$_{ax}$ and H-1′), 1.79 (1H, *d*, *J* = 10.7 Hz H-5′), 1.99, 2.00 ($\underline{CH_3}CO\times2$), 2.16 (2H, *m*, H-7′$_{ax}$ and H-9′), 2.67 (1H, *dd*, *J* = 13.8, 5.5 Hz, H-7′$_{eq}$), 4.09 (1H, *dd*, *J* = 10.1, 5.5 Hz, H-11′$_a$), 4.28 (1H, *dd*, *J* = 10.1, 6.7 Hz, H-11′$_b$), 4.45 (1H, *dd*, *J* = 11.3, 4.9 Hz, H-3′), 4.81 (1H, *br s*, H-12′$_a$), 4.89 (1H, *br s*, H-12′$_b$), 5.16 (1H, *ddd*, *J* = 13.3, 10.7, 5.5 Hz, H-6′), 6.23 (1H, *d*, *J* = 9.5 Hz, H-3), 6.78 (2H, *m*, H-6 and H-8), 7.34 (1H, *d*, *J* = 8.5 Hz, H-5), 7.62 (1H, *d*, *J* = 9.5 Hz, H-4); ^{13}C NMR (125 MHz, $CDCl_3$): δ 170.9, 169.9 ($CH_3\underline{CO}$ ×2), 161.7 (C-7), 161.1 (C-2), 155.8 (C-9), 143.3 (C-8′), 142.6 (C-4), 128.8 (C-5), 113.9 (C-12′), 113.2 (C-6), 112.8 (C-3), 112.7 (C-10), 101.7 (C-8), 80.2 (C-3′), 71.6 (C-6′), 67.5 (C-11′), 55.9 (C-9′), 49.2 (C-5′), 38.7 (C-7′), 38.4 (C-4′), 37.8 (C-10′), 34.8 (C-2′), 30.5 (C-14′), 23.6 (C-1′), 23.3 (C-15′), 21.8, 21.2 ($\underline{CH_3}CO\times2$), 17.2 (C-13′).

3.3.2. p-Bromobenzoylation of *1*

To a stirred solution of **1** (8 mg) in C_5H_5N (1.5 ml) was added *p*-bromobenzoyl chloride (80 mg). After being stirred at room temp. for overnight, the mixture was worked up by standard methods to give the di-*p*-bromobenzoate **1b** (8 mg).

Colourless oil; IR (film) ν_{max} 1786, 1720, 1690, 800 cm^{-1}; CD (MeOH) see Fig. 2; HREIMS *m/z* 762.0823 $[M]^+$ (calc. for $C_{38}H_{36}O_7Br_2$, 762.0828); EIMS *m/z* (rel. int.) 762, 764, 766 $[M]^+$ (2, 4, 2), 601 [M-coumarin]$^+$ (30), 161 [M-sesquiterpene]$^+$ (100); ^1H NMR (500 MHz, $CDCl_3$): δ 1.12 (3H, *s*, H-15′), 1.14 (3H, *s*, H-13′), 1.18 (3H, *s*, H-14′), 1.50 (1H, *dd*, *J* = 14.4, 4.9 Hz, H-2′$_{eq}$), 1.90 (3H, *m*, H-2′$_{ax}$ and H-1′), 2.06 (1H, *d*, *J* = 10.7 Hz, H-5′), 2.29 (1H, *dd*, *J* = 6.7, 5.5 Hz, H-9′), 2.35 (1H, *m*, H-7′$_{ax}$), 2.81 (1H, *dd*, *J* = 13.8, 5.5 Hz, H-7′$_{eq}$), 4.19 (1H, *dd*, *J* = 10.1, 5.5 Hz, H-11′a), 4.39 (1H, *dd*, *J* = 10.1, 6.7 Hz, H-11′b), 4.76 (1H, *dd*, *J* = 11.3, 4.9 Hz, H-3′), 4.90 (1H, *br s*, H-12′$_a$), 4.94 (1H, *br s*, H-12′$_b$), 5.54 (1H, *ddd*, *J* = 13.3, 10.7, 5.5 Hz, H-6′), 6.27 (1H, *d*, *J* = 9.5 Hz, H-3), 6.85 (2H, *m*, H-6 and H-8), 7.39 (1H, *d*, *J* = 8.5 Hz, H-5), 7.55 (2H, *d*, *J* = 10 Hz, H-3″ and H-7″), 7.57 (2H, *d*, *J* = 10 Hz, H-3‴ and H-7‴), 7.68 (2H, *d*, *J* = 10 Hz, H-4″ and H-6″), 7.83 (1H, *d*, *J* = 9.5 Hz, H-4), 8.08 (2H, *d*, *J* = 10 Hz, H-4‴ and H-6‴); ^{13}C NMR (125 MHz, $CDCl_3$): δ 165.0, 164.7 (C-1″, C-1‴), 161.7 (C-7), 161.1 (C-2), 155.9 (C-9), 143.3 (C-8′), 142.4 (C-4), 132.4, 132.2, 131.9, 131.8 (C-3″, C-3‴, C-7″, C-7‴), 131.7 131.6 131.2, 131.0 (C-4″, C-4‴, C-6″, C-6‴), 130.9, 130.2 (C-2″, C-2‴), 129.6, 129.4 (C-5″, C-5‴), 128.9 (C-5), 114.2 (C-12′), 113.3 (C-6), 112.9 (C-3), 112.8 (C-10), 101.7 (C-8), 81.0 (C-3′), 72.4 (C-6′), 67.6 (C-11′), 55.9 (C-9′), 49.6 (C-5′), 38.7 (C-7′), 38.5 (C-4′), 38.3 (C-10′), 34.9 (C-2′), 31.1 (C-14′), 23.6 (C-1′), 23.4 (C-15′), 17.5 (C-13′).

3.4. Assafoetidnol B (*2*)

Amorphous solid; $[\alpha]_D$ +29.4° (*c* 0.2, MeOH); UV (MeOH) λ_{max} (log ε) :320 (4.90), 258 nm (4.20); IR (film) ν_{max} 3999, 2900, 1690 cm^{-1}; HRFABMS *m/z* 457.2205 $[M+H]^+$ (calc. for $C_{26}H_{33}O_7$, 457.2252); ^1H and ^{13}C NMR spectral data see Table 1.

3.4.1. Acetylation of *2*

As described above for **1a**, compound **2** (10 mg) was converted into the diacetate **2a** (10 mg).

Colourless oil; IR (film) ν_{max} 1690, 1720, 1733 cm^{-1}; EIMS *m/z* (rel. int.) 456 $[M]^+$ (4), 295 [M-coumarin]$^+$ (30), 161 [M-sesquiterpene]$^+$ (100); ^1H NMR (500 MHz, $CDCl_3$): δ 0.96 (3H, *s*, H-15′), 1.04 (3H, *s*, H-14′), 1.12 (3H, *s*, H-13′), 1.33 (1H, *m*, H-2′$_{eq}$), 1.71 (3H, *m*,

H-2′$_{ax}$, H-1′), 1.95 (1H, *d*, *J* = 12.0 Hz, H-5′), 1.97, 2.01, 2.10 ($\underline{CH_3}CO$ ×3), 2.28 (1H, *dd*, J = 6.7, 5.5 Hz, H-9′), 4.24 (1H, *dd*, *J* = 10.1, 5.5 Hz, H-11′$_a$), 4.39 (1H, *dd*, *J* = 10.1, 6.7 Hz, H-11′$_b$), 4.60 (1H, *br s*, H-3′), 4.96 (1H, *br s*, H-12′$_a$), 5.00 (1H, *br s*, H-12′$_b$), 5.36 (1H, *dd*, *J* = 12.0, 9.5 Hz, H-6′), 5.50 (1H, *d*, *J* = 9.5 Hz, H-7′), 6.26 (1H, *d*, *J* = 9.5 Hz, H-3), 6.83 (1H, *d*, *J* = 2.5 Hz, H-8), 6.87 (1H, *dd*, *J* = 8.5, 2.5 Hz, H-6), 7.38 (1H, *d*, *J* = 8.5 Hz, H-5), 7.64 (1H, *d*, *J* = 9.5 Hz, H-4); ^{13}C NMR (125 MHz, $CDCl_3$): δ 170.3, 170.0×2 ($CH_3\underline{CO}$× 3), 161.6 (C-7), 161.0 (C-2), 155.9 (C-9), 143.3 (C-4), 141.1 (C-8′), 129.0 (C-5), 113.4 (C-6), 113.1 (C-3), 112.8 (C-10), 111.2 (C-12′), 101.7 (C-8), 79.6 (C-3′), 75.6 (C-7′), 73.3 (C-6′), 68.5 (C-11′), 56.7 (C-9′), 44.4 (C-5′), 38.0 (C-4′), 37.0 (C-10′), 31.0 (C-13′), 30.0 (C-1′), 23.5 (C-15′), 22.5 (C-2′), 22.2 (C-14′), 21.6, 21.1, 20.6 ($\underline{CH_3}CO$×3).

3.4.2. *p*-Bromobenzoylation of **2**

As described above for **1b**, compound **2** (12 mg) was converted into the di-*p*-bromobenzoate **2b** (12 mg).

Colourless oil; IR (film) ν_{max} 1777, 1727, 1699, 799 cm^{-1}; CD (MeOH) see Fig. 3; EIMS *m*/*z* (rel. int.) 720, 722, 724 [M]$^+$ (2, 4, 2), 661 [M-coumarin]$^+$ (40), 161 [M-sesquiterpene]$^+$ (100); ^{1}H NMR (500 MHz, $CDCl_3$): δ 1.02 (3H, *s*, H-15′), 1.13 (3H, *s*, H-14′), 1.27 (3H, *s*, H-13′), 1.44 (1H, *m*, H-2′$_{eq}$), 1.80 (3H, *m*, H-2′$_{ax}$, H-1′), 2.00 (CH_3CO), 2.48 (1H, *dd*, *J* = 6.7, 5.5 Hz, H-9′), 2.61 (1H, *d*, *J* = 12.0 Hz, H-5′), 4.37 (1H, *dd*, *J* = 10.1, 5.5 Hz, H-11′$_a$), 4.47 (1H, *dd*, *J* = 10.1, 6.7 Hz, H-11′$_b$), 4.61 (1H, *br s*, H-3′), 5.02 (2H, *br s*, H-12′), 5.80 (1H, *dd*, *J* = 12.0, 9.5 Hz, H-6′), 5.87 (1H, *d*, *J* = 9.5 Hz, H-7′), 6.29 (1H, *d*, *J* = 9.5 Hz, H-3), 6.91 (2H, *m*, H-6 and H-8), 7.45 (1H, *d*, *J* = 8.5 Hz, H-5), 7.63 (4H, *m*, H-4″, H-4‴, H-6″, and H-6‴), 7.64 (1H, *d*, *J* = 9.5 Hz, H-4), 7.82 (4H, *m*, H-3″, H-3‴, H-7″, and H-7‴); ^{13}C NMR (125 MHz, $CDCl_3$): δ 170.1 ($CH_3\underline{CO}$), 165.2, 164.8 (C-1″, C-1‴), 161.5 (C-7), 161.0 (C-2), 155.7 (C-9), 143.3 (C-4), 140.9 (C-8′), 131.8×4 (C-3″, C-3‴,C-7″,C-7‴), 131.7×4 (C-4″, C-4‴, C-6″, C-6‴), 131.1×2 (C-2″, C-2‴), 128.9 (C-5), 128.5×2 (C-5″, C-5‴), 113.4 (C-6), 113.1 (C-3), 112.8 (C-10), 111.4 (C-12′), 101.7 (C-8), 79.5 (C-3′), 76.8 (C-7′), 74.0 (C-6′), 68.0 (C-11′), 56.8 (C-9′), 45.0 (C-5′), 38.3 (C-4′), 37.1 (C-10′), 31.4 (C-13′), 30.3 (C-1′), 23.6 (C-15′), 22.4 (C-2′), 22.2 (C-14′), 21.1 ($\underline{CH_3}CO$).

3.5. X-ray structure analysis of **3**

The reflection data were collected on a Mac Science DIP 2030 imaging plate area detector with monochromated Mo-K_α radiation (λ = 0.71069 Å) with ω-techniques to a maximum 2θ value of 55.7° at room temp. (22±1 °C). Of the 4605 reflections which were collected, 2625 were unique. The structure was solved by direct methods SIR 92 (Altomare et al., 1994) and expanded using Fourier techniques (Beurskens et al., 1994). The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. The final cycle of the full-matrix least squares refinement was based on 4191 observed reflections ($I > 3.00\sigma$ (I)). The structure was finally refined to $R = 0.049$ ($R_w = 0.091$). The crystal data are: $a = 13.474$ (5) Å, $b = 7.151$ (5) Å, $c = 21.386$ (7) Å, $V = 2060.6$ (1) Å^3, space group $P2_12_12_1$, $Z = 4$, $Dc = 1.23$ g/cm^3. Atomic coordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre, UK.

Received 23 February 2001; received in revised form 31 July 2001

Abstract

Pseudomonas fluorescens strain G308 isolated from barley leaves produces a novel antibiotic substance that was purified by preparative TLC and HPLC and identified as *N*-mercapto-4-formylcarbostyril (Cbs) by LC/DAD, IR, LC–ES$^+$/MS, LC–ES$^-$/MS, GC–EI/MS, LC–HRES$^+$/MS, mass isotope ratios analysis, ^{1}H NMR and ^{13}C NMR analysis. The purified new antibiotic compound is effective against many phytopathogenic fungi in vitro. The compound inhibited at 25 ppm spore germination and germ tube growth of the following fungi; *Fusarium oxysporum* f. sp. *lycopersici*, *Fusarium culmorum*, *Cladosporium cucumerinum* and *Colletotrichum lagenarium*. At concentrations up to 125 ppm, the compound did not interfere with release of zoospores from sporangia and germination of encysted zoospores of *Phytophthora infestans*. © 2001 Elsevier Science Ltd. Keywords: *Pseudomonas fluorescens*; Antibiotic; Spore germination; Germ tube growth

1. Introduction

Secondary metabolites produced by microorganisms provide a rich source of novel biological active compounds. However, only a small percentage of the microorganisms has been investigated worldwide phytochemically until now. Therefore, searching for natural antimicrobial substances especially with new mode of actions is still one of the very important aspects with a big potential in the field of phytomedicine (Berdy, 1982; Hostettman and Wolfender, 1997). Fluorescent pseudomonads are among the important bioagents that have been intensively studied with regard to the production of antibiotics. An important role of antibiotics with antifungal activities in suppression of several diseases has been demonstrated, such as take-all of wheat, damping-off in cotton and black root-rot in tobacco (Howell and Stipanovic, 1980; Keel et al., 1990). Substances produced by fluorescent pseudomonads that are involved in control of diseases include for instance pyoluteorin, phenazine derivatives, hydrogen cyanide and 2,4-diacetylphloroglucinol (Howell and Stipanovic, 1980; Thomashow and Weller, 1988; Voisard et al., 1989; Keel et al., 1990). Pyrrolnitrin and oomycin A are further metabolites of fluorescent pseudomonads which are involved in biological control of damping-off in cotton and other plant pathogens (Howie and Suslow, 1991; McLoughlin et al., 1992; Burkhead et al., 1994). Pseudobactin B10, rhamnolipid, agrocin 84, 2-hexyl-5-resorcinol, 2,3-deepoxy-2,3-didehydro-rhizoxin and aeruginoic acid are also biocontrol factors produced by fluorescent pseudomonads and involved in disease suppression (Leisinger and Margraff, 1979; Kloepper et al., 1980; Kerr and Tate, 1984; Carmi and Carmeli, 1994; Wright et al., 1999; Ligon et al., 2000).

Pyrrolnitrin, produced as a secondary metabolite from *Pseudomonas pyrroconia*, represents the lead structure of the synthetically produced fungicides fenpiclonil and fludioxonil. The two synthetic derivatives have an improved photostability compared to the natural product and possess a broad disease control spectrum and low toxicity to mammals, birds and honeybees and low mobility in the soil (Nevill et al., 1988; Gehmann et al., 1990).

The characteristics of *Pseudomonas fluorescens* strain G308, representing a potential biocontrol agent, encouraged us to examine its production of antibiotics in vitro. Thus, the aim of the present work is to isolate and identify antibiotic compounds produced by this strain.

2. Results

2.1. The biochemical and physiological characteristics of the strain G308

Pseudomonas fluorescens strain G308 biotype V isolated from the surface of barley leaves was also able to colonize tomato roots sufficiently under greenhouse conditions (data not shown). It produces beside the siderophore pyochelin, also cyanide and exoenzymes such as arginine dihydrolase, proteinase and protease.

2.2. Extraction and purification of the antibiotics

The TLC bioassay showed that the ethylacetate extract of the culture filtrate of the bacterial strain G308 in KB liquid medium exhibited two inhibition zones on the TLC when *Cladosporium cucumerinum* (3×10^7 spores/ml) and *Colletotrichum lagenarium* (2×10^6 spores/ml) were used as test organisms. The two antifungal substances had R_f values of 0.66 and 0.70. Furthermore, the purity of two compounds eluted from the silica gel was tested by HPLC-DAD (Merck-Hitachi®) with a corresponding retention times (*RT*) of 15.5 and 19.8 min, respectively. The production of the two antifungal substances by the isolate G308 in sucrose-asparagin (SuA) liquid medium was less pronounced and no antifungal compounds were detected in biomalt (BM) liquid medium.

2.3. Spectroscopic analysis and structure identification

The new antibiotic substance *N*-mercapto-4-formylcarbostyril with the R_f value of 0.70 and *RT* 19.8 min has been identified according to IR analysis, mass spectroscopy by LC–MS (ES^+/ES^-) and GC–EI/MS, high resolution mass spectroscopy (LC–$HRES^+$/MS) also ^1H, ^{13}C NMR, H–H-COSY, HSQC and HMQCSS spectra. The following data have been obtained: UV λ_{max} nm (ratio%): 222 (100%), 280 (65%) and 318 (50%); IR ν_{max} cm^{-1}: 3349, 3124, 2933, 2853, 2568, 1651, 1435, 1120, 750 and 685. The isotopic pattern of the protonated molecular ion peak in LC–$HRES^+$/MS showed the masses 206.0293 $[M+H]^+$, 207.0377 and 208.0327 with the corresponding ratios 100, 15 and 7%, respectively. LC–$HRES^+$/MS of the new compound *m/z*: $[M+H]^+$ 206.0293 ($C_{10}H_7NO_2S$, calc. mass 206.0276, mDa error 1.7). The mass fragmentation of the compound in the GC–EI/MS showed that the molecular ion peak at *m/z* 205.0 $[M]^+$ lost one carbon monoxide molecule to give peak at *m/z* 177.0 $[M–CO]^+$ and one thiol group to give peak at *m/z* 144.0 [*m/z*: 177-SH]$^+$. The ^1H NMR chemical shifts (300 MHz, $(CD_3)_2CO$) were: δ ppm 7.95 (1H, *dd*, $J=$ 8.35 and 1.16 Hz, H-7), 7.48 (1H, pseudotriplet, $J=$ 8.43, 7.14 and 1.29 Hz, H-8), 7.05 (1H, *t*, $J=$ 7.33 and 8.15 Hz, H-9), 7.12 (1H, *d*, $J=$8.36 Hz, H-10), 11.55 (1H, *br s*, H-11a, N-S-H), 8.65 (1H, *s*, H-3a), 10.1 (1H, *s*, H-13a) (Fig. 1). The ^{13}C NMR spectrum (300 MHz, $(CD_3)_2CO$) exposed: δ (multiplicity, carbon position, proton HSQC) 170.17 (*s*, C-2), 129.69 (*s*, C-3, H3a), 154.69 (*s*, C-4), 117.54 (*s*, C-5), 157.51 (*s*, C-6), 128.8 (*s*, C-7, H7a), 120.72 (*s*, C-8, H8a), 133.46 (*s*, C-9, H9a), 118.36 (*s*, C-10, H10a), 184.22 (*s*, C-13, H13a) (Fig. 2).

In addition, the new antibiotic substance after acetylation increased by 43 mass units (dalton) to be 248.0 M^+ (Fig. 3). The ^1H NMR chemical shifts (LC–NMR 500 MHz, $(CD_3)_2CO$) of the acetylated derivative compound showed all proton signals of the original antibiotic substance except the signal of the proton coupled to the nitrogen atom in the heteroaromatic ring: δ ppm 11.55 (1H, *br s*, H-11a, N-S-H), where the acetylation process at that position could be assumed (Fig. 4).

On the other hand, the antifungal substance of R_f value 0.66 and *RT* 15.5 min produced by the bacterial strain G308 was identified as pyoluteorin according to LC–ES^+/MS, isotopic pattern of the signal cluster of the mole peak, ^1H NMR and H–H-COSY spectra. Pyoluteorin is a well known antibiotic, which is produced by several *Pseudomonas fluorescens* strains (Howell and Stipanovic, 1980). The following data have been obtained: UV λ_{max} nm (ratio%): 310 (100%) and 230 (40%), GC–EI/MS *m/z* 271.0 dalton $[M]^+$, $C_{11}H_7O_3NCl_2$); isotopic patterns 271.14 (100%), 273.17 (70%) and 275.13 (10%); ^1H NMR chemical shifts (300 MHz, $(CD_3)_2CO$): δ ppm 3.8 (1H, *br s*, H-1, N-H), 6.88 (1H, *s*, H-4), 6.34 (2H, *d*, $J=$ 8.16 Hz, H-14 and H-12), 7.1 (1H, *t*, $J=$ 8.15 Hz, H-13). These data obtained were in complete agreement with the data of the standard pyoluteorin.

2.4. Antifungal bioassay in vitro

This new substance with R_f value of 0.70 and *RT* of 19.8 min showed antifungal effects in vitro against several plant pathogenic fungi. Twenty five ppm of the compound inhibited the spore germination and germ tube growth of the following fungi: *Fusarium oxysporum* f. sp. *lycopersici* (5×10^6 spores/ml), *Fusarium culmorum* (3.1×10^6 spores/ml), *Cladosporium cucumerinum* (3×10^7 spores/ml), *Colletotrichum lagenarium* (2×10^6 spores/ml).

At 100 ppm, the substance inhibited the germination of teliospores of *Ustilago maydis* und *U. nuda* (8×10^6 spores/ml). The compound did not interfere in release of zoospores from zoosporangia and germination of encysted zoospores of *Phytophthora infestans* at concentrations up to 150 ppm.

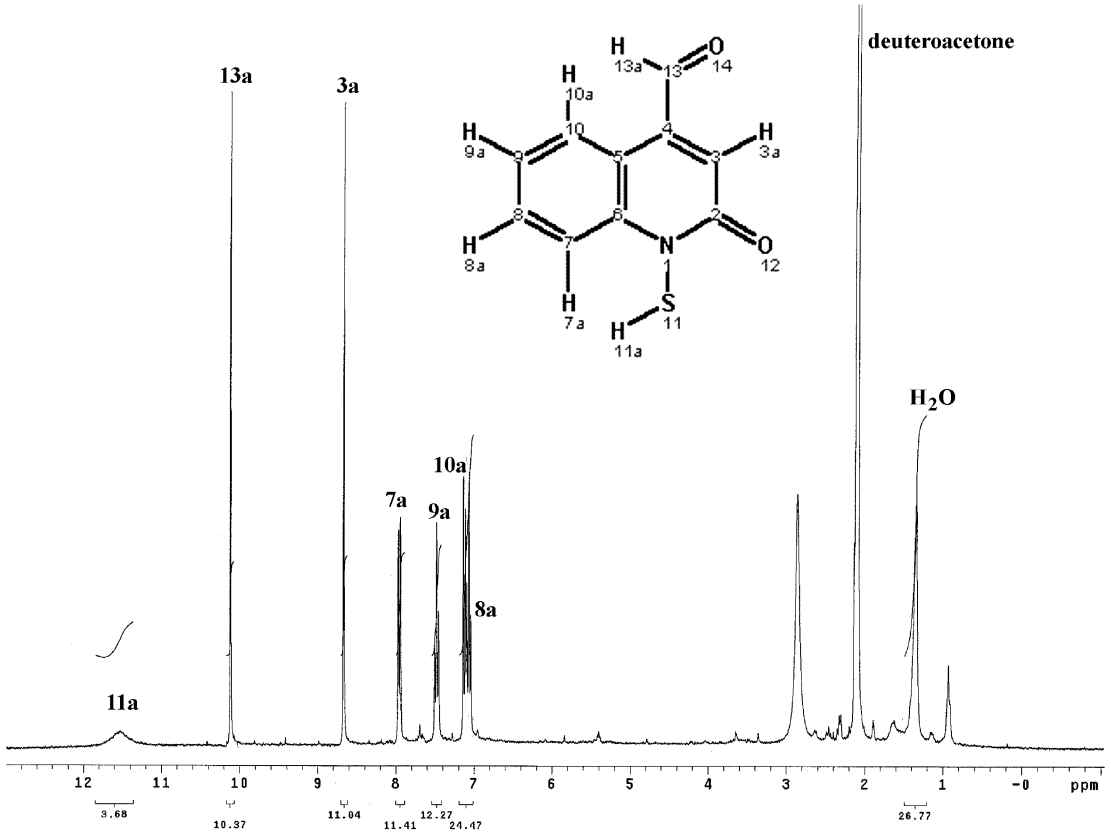

Fig. 1. ^{1}H NMR spectrum of numerated *N*-mercapto-4-formyl-carbostyril (Cbs) shows the position of proton signals and the proton integration in $[(CD_3)_2CO]$.

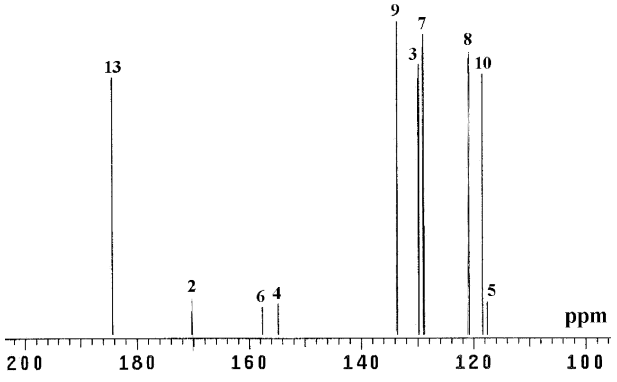

Fig. 2. ^{13}C NMR spectrum of *N*-mercapto-4-formyl-carbostyril (Cbs) shows carbon atom signals and its position.

3. Discussion

The structure of the new antibiotic compound *N*-mercapto-4-formylcarbostyril has been identified according to all data and analysis which are mentioned before. Depending on the LC/DAD absorption spectrum, the substance has three UV λ_{max} nm (ratio%): 222 (100%), 280 (65%) and 318 (50%) which could indicate the presence of the aromatic ring moiety and heteroaromatic moiety with substitution effect. The IR data showed the presence of following functional groups: carbo-amide group (3349 cm^{-1}), mercapto group (2568 cm^{-1}) and the carbonyl group (1651 cm^{-1}). The isotopic pattern of the protonated molecular ion peak at 206.0293 $[M+H]^+$ indicated the presence of one sulfur moiety. High resolution LC–ES^+/MS experiments revealed that the protonated molecular ion peak $[M+H]^+$ of the new compound is 206.0293, corresponding nearest to $C_{10}H_7NO_2S$ (calc. mass: 206.0276). GC–EI/MS spectrum confirmed that the molecular weight of the substance is 205.0 and this was proved by GC–CI^+/MS, LC–$APCI^{-1}$/MS and LC–$APCI^+$/MS in the negative and positive modes which showed a quasi-molecular ion at *m*/*z* 204.0 $[M–H^+]$ and 206 $[M+H]^+$, respectively. Furthermore, GC/MS/MS fragmentation of the new antibiotic compound revealed the presence of carbonyl group bind to the heteroaromatic ring through appearance of the corresponding molecular ion at *m*/*z*: 177.0 $[M–CO]^+$ by eliminating of the carbon monoxide group (CO) and one thiol group to give peak at *m*/*z* 144.0 [*m*/*z:* 177S-H]$^+$.

The ^{1}H and ^{13}C NMR spectra enabled us to interpret and to determine the configuration of the new antibiotic substance. The integration of the whole ^{1}H NMR signals showed the presence of 7 protons. Among these protons, 4 protons coupled to an aromatic ring, one proton coupled to the pyridine ring, one aldehyde proton and

one proton linked to S with a broad signal. The diagonal two dimensional H–H-COSY showed the coupling between the 4 aromatic protons. Integration of the whole ^{13}C NMR signals revealed the presence of 10 carbon atoms. The six signals between 120 and 160 ppm correspond to the aromatic ring, while the two signals at 170.17 and 184.22 ppm correspond to carbon coupled to the oxy and aldehyde group, respectively (Günther, 1992; Hesse et al., 1995).

The HSQC experiments showed the six proton-bearing signals in the ^{13}C NMR spectrum. Six of the seven signals in the ^{1}HNMR spectrum exhibited correlations (HMQCSS) with the carbon atoms in ^{13}C NMR spectrum. These long-range correlations (^{1}J, ^{2}J, ^{3}J and ^{4}J) allowed us to confirm the arrangement of the protons with the carbon atoms.

Furthermore, the antibiotic substance increased by 43 mass units (dalton) after acetylation by addition dryness acetic anhydride and using pyridine as a catalysator. Thus, the molecular weight of the acetylated derivative antibiotic increased to 248.0 $[M]^+$. The ^{1}H NMR spectrum of the derivative antibiotic showed the absence of the broad signal of the proton (δ ppm 11.55) link to the S atom where the acetylation happened (Fig. 4).

The nomenclature of the ground structure of our new antibiotically active carbostyril substance was already documented by Eistert et al. (1969) through synthesis of *N*-hydroxycarbostyril from expansion of *N*-hydroxyisatin. In addition, Cornforth and James (1956) proposed the biosynthesis pathway of pyo compound (pseudanes) from anthranilic acid and a β-keto acid intermediate in *Pseudomonas aeruginosa* by using the isotopes ^{14}C and ^{15}N atoms (Fig. 5). Our antibiotic compound seems to be synthesized through this pathway because it has the same ground structure with different substitution on the pyridine ring. The antifungal effect of carbostyril group as fungicide has been demonstrated in the patent of Sumitomo Chemical Company by Uematsu et al. (1979). Moreover, synthetic carbostyril derivatives were applied for patents in many pharmaceutical products with inotropic cardiotonic activity (Uchida et al., 1984; Tanaka et al., 1989).

The data of UV, LC–ES$^+$/MS ($m/z = 271.0$), isotopic pattern of the signal cluster with the distinct peak $[M–H]^+$ (270.0) indicated chlorine substituents, ^{1}H NMR and H–H-COSY spectra confirmed that the purified antibiotic compound with R_f value 0.66 and *RT* 15.5 min was indeed pyoluteorin. These data obtained are consistent with the spectra of the authentic pyoluteorin compound.

4. Experimental

4.1. Bacterial strain, characteristics and cultural media

The bacterial strain *Pseudomonas fluorescens* G308 was isolated from barley leaves (Kremer, 1994). Some of the biochemical and physiological characteristics of the strain G308 were studied according to the methods described by Mauerhofer et al. (1994), Press et al. (1997), and Voisard et al. (1989) with some modifications. For antibiotic production, three types of broth media containing different nutrient sources were used in order to encourage the production of a wide range of secondary metabolites. These media are King's B (KB),

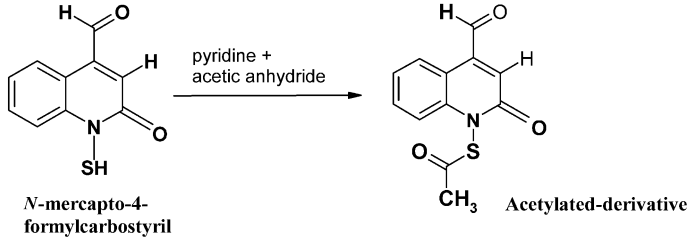

Fig. 4. The chemical structure of *N*-mercapto-4-formyl-carbostyril and its acetyl-derivative.

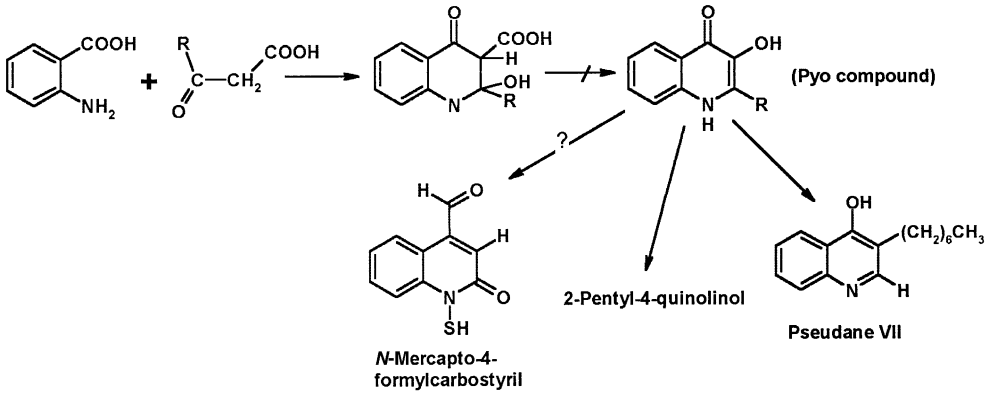

Fig. 5. Biosynthesis of pyo compound (pseudanes) from anthranilic acid and a β-keto acid intermediate as proposed by Cornforth and James (1956). Our antibiotic compound (Cbs) seems to be synthesized through this pathway.

biomalt (BM) and sucrose-asparagin (SuA) (Schaad, 1980; Shanahan et al., 1992).

4.2. Extraction and purification of the antibiotics

With regard to the antibiotic production, the isolate G308 was cultivated in 500 ml of three different media KB, BM and SuA on a shaker at 100 rpm and 28 °C for 3 days. After incubation, the pH value of the bacterial suspensions was adjusted to 2.0 with 2 N HCl. Ethylacetate (EtOAc) was added to the suspensions in a ratio of 1:1 (1/2 : 1/2 l; v/v). Then, the ethylacetate-bacterial suspensions were placed on a shaker at 200 rpm for 4 h and then centrifuged at 10,000 *g* and 4 °C for 30 min. After that, the centrifugation cups were placed in the refrigerator at −20 °C for 3 h to solidify the aqueous phase. The EtOAc phase was filtered through filter paper to remove the non dissolved compounds. The organic phase was preconcentrated in a rotary evaporator and the residue was reconstituted with 100% methanol (MeOH). Then, the volume of the methanolic extract was reduced to 1 ml by using nitrogen gas flow. Ten microliters of the MeOH extract was applied to thin layer chromatography plates (ALUGRAM-SIL-G/UV_{254}, Macherey–Nagel) and the substances in the extract developed in *tert*-butyl-methyl-ether: hexane: methanol (50: 40: 3.5; v/v/v). The antifungal properties of the bands were detected by the bioautographic method using *Cladosporium cucumerinum* (3×10^7 spores/ml) and *Colletotrichum lagenarium* (2×10^6 spores/ml) as test organisms. The procedure for locating bands and detecting zones with antibiotic activity was repeated. The bands that showed antifungal activities were scratched off from the preparative thick layer chromatography plates (Kieselgel 60 F254/Merck) and developed in *tert*-butyl-methyl-ether : hexane : methanol (50: 40: 3.5; v/v/v). The separated substances were eluted from the silica gel with acetone by using filter discs with pore diameter of 0.45 μm. The isolated substances were further purified by using preparative HPLC (a gradient pump; Kronlab HD2-200) coupled with UV/vis detector (Spectraflow 500) at wavelength of 250 nm. The MeOH extract of each sample (2 ml) was directly injected in the preparative HPLC column Kieselgel 60 (Merck 107734, 270 × 22 mm and pore diameter 0.063–0.2 mm). Separation of the compounds was done at room temperature with flow rate of 0.10 ml/min using gradient TBME : MeOH. Finally, the purity and spectrum analysis were determined by using HPLC (Merck-Hitachi®), coupled to a Waters 991 photodiode array detector (DAD) and a Merck-Hitachi (4000A) autosampler. Separation was done with a RP18 column (5 μm) at 35 °C with a flow rate of 0.5 ml/min using gradient elute phosphate buffer/ACN, maximum pressure 250 (bar) and oven temperature 25 °C.

4.3. Spectroscopy analysis and identification

4.3.1. Gradient HPLC-system with MS-detection (LC–MS)

Gradient HPLC-system series 1100 (Hewlett-Packard®) combined with an autosampler ALS G1313A, a gradient pump G1311A, a degasser G1322A were used. The mass spectrometric detector was a Micromass Platform-II (Mass Lynx® 4.0, UK) equipped with a cross flow interface. The tuning parameters for positive ion spray (ES^+) were 3.5 kV for capillary and 40 V for cone at a source temperature of 120 °C. Positive ion characterization was performed in the *m*/*e* range of 200–600 at a scan rate of 1.49 scans/s and a multiplier voltage of 650 V. Separation was carried out with a Luna® ODS column (250 × 3 mm i.d.; 5 μm, Phenomenex®) at 25 °C with a flow rate of 0.5 ml/min using H_2O/ACN in a ratio of 80:20%, maximum pressure 250 (bar) and oven temperature 25 °C. For the LC–$HRES^+$/MS analysis, the tuning parameters were 24V for cone, 23.5 LM resolution and 13.2 for HM resolution. Polyethyleneglycol 200 was used as reference substance.

4.3.2. IR, GC–EI–MS, GC–EI–MS/MS and GC–CIMS spectra

The FTIR spectra were recorded on a Nicolet Avatar 320 F.S.P. instrument (Single bounce ATR). Electron impact (EI) and chemical ionisation (CI)/mass spectra were recorded by a Varian® 3800 Gas Chromatograph coupled to an ion trap mass spectrometer operating in EI and CI modes (Varian®, Saturn 2000). An extract of the antibiotic substance in hexane was injected at a continuous flow of 1.4 ml/min on a Chrompack SIL-24 CP column. Column temperature ranged from 80 to 270 °C, while the injector and detector (trap) temperatures were 250 and 230 °C, respectively. Full-scan EI-mass spectra (m/z: 100–600) were recorded for peak identification. In addition, GC–CI/MS data were obtained using the same setup conditions of GC–EI/MS, but methanol was used as a reagent medium.

4.3.3. ^{1}H NMR and ^{13}C NMR spectra

^{1}H, ^{13}C NMR (nuclear magnetic resonance), HH-COSY (correlation spectroscopy), HSQC (hetero-single quantum correlation) and HMQCSS (hetero-multi-quantum correlation solvent substraction) spectra were recorded using Varian® (NMR-INOVA- 300 MHz and Varian® LC–NMR; stopflow INOVA-500 MHz) instruments as a gated spin echo in deuteroacetone. Shifts were reported in parts per million (ppm) downfield from TMS using the central resonance of deuteroacetone as an internal standard.

4.4. Antifungal bioassay in vitro

The antifungal activity of the purified antibiotic with the R_f value 0.7 was tested in vitro against several plant fungal pathogens. Four different concentrations of the antibiotic were used 25, 50, 100 and 150 ppm. The plant pathogens which were included in the antifungal bioassay were spore suspensions of *Fusarium oxysporum* f. sp. *lycopersici* (5×10^6 spores/ml), *Fusarium culmorum* (3.1×10^6 spores/ml), *Cladosporium cucumerinum* (3×10^7 spores/ml), *Colletotrichum lagenarium* (2×10^6 spores/ml), *Ustilago maydis* and *U. nuda* (8×10^6 spores/ml), *Phytophthora infestans* (4×10^4 sporangia/ml). The bioassay test was conducted in Eppis cups and placed in an incubator according to the optimal temperature of each fungus. Spore germination and germ tube growth were recorded 12 and 24 h after incubation by means of light microscopy. The chemically synthesized antimicrobial compound 2,4-diacetylphloroglucinol at a concentration of 25–125 ppm was included as a reference.

4.5. Acetylation of the antibiotic substance

The purified antibiotic with R_f value of 0.70 was transformed to the acetyl-derivative by addition of dry pyridine (C_5H_5N) (0.5 ml) and dry acetic anhydride (Ac_2O) (0.5 ml) to the dried antibiotic substance (2 mg) under room temperature conditions. Also, this derivatization was repeated under different temperatures ranging from 50 to 70 °C and with different time intervals (6–42 h).

Acknowledgements

The authors thank Mrs. S. Reeb and Mrs. B. Meier for the technical help and Dr. M. Mauerhofer (ETH-Zürich) for supplying the authentic pyoluteorin compound. Also, we thank so much Dr. J. Conrad, Mrs. I. Klaiber and Dr. M Lederer for the technical assistance. The financial support of the German Academic Exchange Service (DAAD, Bonn) for the first author is gratefully acknowledged.

Received 30 November 2000; received in revised form 17 May 2001

Abstract

The rhizomes of *Serratula strangulata* yielded three glyceroglycolipids, i.e. 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-amine-6-deoxy-α-D-glucosyl)-glycerol, 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-*p*-hydroxy-phenyl-propionamido-6-deoxy-α-D-glucosyl)-glycerol and 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-[α-D-glucose(1-6)-β-D-allose]-glycerol, as well as a known sesquiterpene lactone and three known phytoecdysones. Their structures were elucidated on the basis of spectral data, especially by 2D NMR spectroscopic methods and chemical conversion. These compounds exhibited significant antibacterial and antitumor activities.

Keywords: *Serratula strangulata*; Compositae; Glyceroglycolipids; Cytotoxicity; Antimicrobial

1. Introduction

Serratula strangulata (Compositae) is a perennial herbaceous plant growing mainly in North China. Its rhizomes have been used as a traditional chinese medicine for treatment of chickenpox, toxicosis, and high cholesterol levels since ancient times (Liu, 1987). Its phytochemical or pharmacological properties have not been reported to date. In our effort to find active components from this plant, we found three new glyceroglycolipids, i.e. 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-amine-6-deoxy-α-D-glucosyl)-glycerol (**1**), 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-*p*-hydroxy-phenyl-propionamido-6-deoxy-α-D-glucosyl)-glycerol (**2**) and 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-[α-D-glucose(1-6)-β-D-allose]-glycerol (**3**), as well as four known compounds, centaurepensin (**4**), 20-hydroxyecdysone (**5**), 25-deoxy-11,20-dihydroxyecdysone (**6**) and 20-hydroxyecdysone-20,22-monoacetonide (**7**) from the alcohol extract of the whole plant. We report herein the isolation, structural elucidation and antibacterial and antitumor activities of the above three new glyceroglycolipids. It was found that these compounds exhibited significant antibacterial and antitumor activities, especially **2** possess strong cytotoxicity for B 16 (mouse melanoma).

2. Results and discussion

From the EtOAc- and BuOH-soluble fraction of an EtOH extract of the rhizome of *S. strangulata*, seven compounds (**1**–**7**) were purified by repeated chromatography on silica gel. Each of the isolates was subjected to detailed spectroscopic analyses in order to establish their chemical structures.

Compound **1** was isolated as a colorless gum. FAB–MS which gave a quasi-molecular ion peak at *m*/*z* 796 $(M+Na)^+$, 780 $(M+Li)^+$, as well as its elemental analysis (found: C 69.85%, H 9.70%, N 1.80%; required: C 69.86%, H 9.70%, N 1.81%) indicated that the molecular formula should be $C_{45}H_{75}NO_9$, which was proved by HR–FAB–MS (*m*/*z* 773.5422, calc. 773.5441). Its IR spectrum showed strong absorptions for hydroxyl and ester groups (3464 cm^{-1}, 1729 cm^{-1}), while the ^1H NMR spectrum exhibited two terminal methyl signals (δ 0.90, 6H, *t*), a broad methylene signal at 1.23 ppm which the integration showed 20 protons, and the signal (δ 2.30, 4H, *m*) due to two methylene protons linked to a carbonyl function. The ^1H NMR spectrum of **1** further revealed olefinic proton (δ 5.30, 12H, *m*) and methylene protons linked to double bonds (δ 1.69, 4H; δ 2.01, 4H; δ 2.75, 8H). These were consistent with the proton signals of two linolenic acid moieties (Pchelkin and Vereshchagin, 1980). In addition, coupling constant analysis of the homonuclear decoupling spectrum defined the

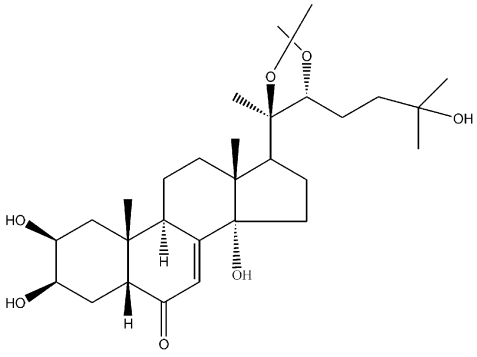
5 $R_1 = H$ $R_2 = H$ $R_3 = OH$
6 $R_1 = OH$ $R_2 = H$ $R_3 = H$



sugar component as glucose; this being consistent with the ^{13}C spectrum (Table 1). The configuration at C-1′ of the glucose was determined to be α by the coupling constant of the anomeric proton ($J = 3.5$ Hz). Treatment of **1** with NaOMe–MeOH gave mono-glucosyl-glycerol and linolenic acid. The ^{13}C NMR and DEPT spectrum of **1** confirmed the presence of linolenic acid (Frangulyan, 1987) and an α-aminoglucose moieties. Simultaneously, they also revealed three carbon signals connected to oxygen atoms: δ_C 62.62 (CH_2), 69.73 (CH) and 64.63 (CH_2), which pointed to the presence of a glyceryl moiety. The sites of attachment of the two linolenic acids and aminoglucose moiety of **1** were determined to be at C-1, C-2, C-3 respectively, by means of the HMBC, ^1H-^1HCOSY and HMQC spectrum. Because the upfield shift of C-6′ in the aminoglucose observed of ^1H NMR and ^{13}C NMR spectral analysis, the amine group should be attached to C-6′. Thus, **1** was assigned as 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-amine-6-deoxy-α-D-glucosyl)-glycerol. This appears to be the first reported occurrence of glucosaminediacylglycerol in the genus *Serratula*.

Compound **2** was isolated as a colorless gum. FAB–MS showed $[M + Na]^+$ at *m*/*z* 944 and $[M + Li]^+$ at 928. Its ^1H, ^{13}C and DEPT spectrum were similar to those of **1**. In the ^1H, ^{13}C NMR spectral analyses of **2**, the extra

[a] Assignment from ^1H–^1H COSY, HMQC and HMBC.

signals at δ_H 7.02 (dd, $J=7.2$, 2.1 Hz), 6.69 (dd, $J=7.2$, 2.1 Hz) and δ_C 40.12 (CH_2), 32.22 (CH_2), 172.48 (ester C=O) revealed the presence of a *p*-substituted benzene ring and the partial structure –CH_2–CH_2– and carbonyl group. ^1H–^1H COSY and HMQC spectrum confirmed above assignments. According to the results of HMBC spectrum: C-1″/H-6′, H-2″, H-3″; C-4″/H-3″, H-5″ (9″); C-7″/H-6″ (8″) (Fig. 1), the structure of **2** was deduced as 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-(6-*p*-hydroxyphenyl-propionamido-6-deoxy-α-D-glucosyl)-glycerol.

Compound **3** was obtained as a colorless gum. The IR spectrum showed absorption bands due to hydroxyl and ester carbonyl at 3460, 1729 cm^{-1}. The molecular formula $C_{51}H_{84}O_{15}$ was established on the basis of the strong quasi-molecular ion peak at *m*/*z* 959 $[M+Na]^+$ and 943 $[M+Li]^+$ in the FAB–MS, together with the support of combined spectroscopic methods (^1H NMR, ^{13}C NMR and DEPT). The ^1H and ^{13}C NMR spectrum showed that **3** had the same skeleton and type as **1** and **2**. Detailed analysis of the remaining signals in the ^1H and ^{13}C NMR spectrum of **3** suggested that it possessed an allose moiety attached to the inner glucose unit. On acid hydrolysis with 2 mol/l HCl, **3** gave glucose and allose, and on acid hydrolysis with 0.5 mol/l HCl, **3** afforded only allose (identified by ^{13}C NMR and TLC), confirming the above deduction. The β-configuration of the glucosidic bond between the glucose and allose residue was determined on the basis of anomeric carbon signal at 103.2 ppm. The observation of the downfield shift of the C-6′ carbon confirmed α1-6 linkage of the two glucide units (Gong, 1983). Thus, the structure of **3** was assigned as 1,2-di-*O*-(9*Z*,12*Z*,15*Z*-octadecatrienoyl)-3-*O*-[α-D-glucose (1-6)-β-D-allose]-glycerol, which was further supported by HMBC and HMQC analysis.

During the course of the isolation of the plant extract, a sesquiterpene lactone and three phytoecdysones were also obtained in pure form. This appears to be the first reported occurrence of sesquiterpenes in the genus *Serratula*. Each of these isolates was characterized by its spectral properties and subsequently identified as centaurepensin (Harley-Mason et al., 1972), 20-hydroxyecdysone (Nishimoto et al., 1987), 25-deoxy-11,20-dihydroxyecdysone (Zhang et al., 1992) and 20-hydroxyecdysone-20, 22-monoacetonide (Zhang et al., 1992) by comparison with published spectral data and/or reference samples.

Previous studies have reported the cytotoxicity of centaurepensin against SMMC-7721 cells (Syrov et al., 1991), and interesting pharmacological effects of ecdysteroids on mammals including a stimulation of protein synthesis, and a reduction of blood glucose and cholesterol levels (Camps, 1991; Simon and Koolman, 1989). Murakami et al. (1990) also reported anti algal activity of unsaturated fatty acids. In our study, compound **1**–**3** exhibited antibacterial activity against *Bacillus. subtilis, Escherichia. coli* and *Staphylococcus. aureus*. The results were compared with chloramphenicol and are summarized in Table 2. Meanwhile, the inhibitory effects of compounds **1**–**3** on the survival of three tumor cell lines, human hepatoma cells (SMMC-7721), human uterine cervix carcinoma cells (HeLa) and mouse melanotic carcinoma cells (B16), were studied (Table 3). The survival rates of cells were determined by MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] method. **2** exhibited the most effective antitumor activity, especially on B16, and **3** had no effect on survival of the three tested tumor cells even when its concentrations was as high as 455 μg /ml.

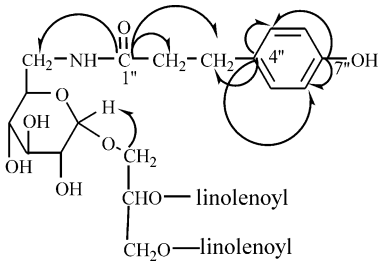

Fig. 1. The key correlations of **2** in HMBC (C⇀H).

Table 2
Antibacterial activity of compound **1**, **2**, **3**[a]

	B. subtilis	*E. coli*	*S. aureus*
Compound **1**	+	+ + +	+
Compound **2**	+ +	+ + +	+
Compound **3**	+ +	+ +	+
Chloramphenicol	+ + +	+ + +	+ + +

[a] Antimicrobial activity is defined as follows: + + + = the diameter is equal to 16–20 mm; + + = 13–15 mm; + = 10–12 mm.

Table 3
Antitumour activity of compound **1** and **2**[a]

	SMMC-7721	B16	Hela
Compound **1**	351.4±6.1	157.3±2.5	168.2±1.9
Compound **2**	151.6±6.3	70.3±2.2	121.9±3.1
Vincristine	63.2±1.8	70.7±2.8	67.2±2.2

[a] Activities are expressed as IC_{50} (50% inhibitory concentration) in μg ml^{-1}.

3. Experimental

3.1. General

FAB–MS were determined on a MS 50 (A.E.I. Brunner) and a ZAB–HS mass spectrometer. ^1H, ^{13}C and 2D NMR spectra were recorded on Bruker AM-400 MHz spectrometer using TMS as internal standard. Deuterated solvents (DMSO-d_6 for **1**–**3** and CD_3COCD_3 for **4**–**7**) were used. IR spectra were obtained as KBr pellets on Nicolet-5DX. IR spectrometer.

3.2. Plant material

The whole plants of *S. strangulata* were collected in Zhuanglang county, Gansu Province of China in August 1996 and were identified by Professor Yong-hong Zhang of Lanzhou University. A voucher specimen (No. 9602) has been deposited at the Lab. of Natural Products, Department of Chemistry, Lanzhou University, Lanzhou, PR China.

3.3. Extraction and isolation

Air-dried and powdered whole plants of *S. strangulata* (3 kg) were exhaustively extracted with 95%EtOH at room temperature. The extract was concentrated under reduced pressure. The residue (120 g) was suspended in H_2O, extracted with petroleum ether, EtOAC and BuOH, respectively. The EtOAC extract (40 g) was subjected to column chromatography on silica gel eluting with petrol and Me_2CO mixtures to afford **4** (50 mg), **5** (45 mg), **6** (28 mg), **7** (16 mg). From the BuOH extract (60 g), three glyceroglycolipids **1** (40 mg), **2** (20 mg), **3** (48 mg) were purified by silica gel chromatography using $CHCl_3$–MeOH mixtures as solvent.

3.6. 1,2-Di-O-(9Z,12Z,15Z-octadecatrienoyl)-3-O-[α-D-glucose(1-6)-β-D-allose]-glycerol (*3*)

Colorless gum. $[\alpha]_D^{24}$ +25.3 (*c* 6.01, MeOH). IR ν_{max}^{KBr} cm^{-1}: 3460, 1720, 1651; FAB–MS *m/z*: 959 $(M+Na)^+$, 937 $(M+Li)^+$. HR–FAB–MS *m/z* 936.5811, calc. for $C_{51}H_{84}O_{15}$ 936.5810. ^1H NMR (DMSO-d_6) δ 0.89 (6H, *t*, *J*=7.3 Hz), 1.20 (20H, *m*), 1.46 (4H, *m*), 1.97 (4H, *m*), 2.22 (4H, *m*), 2.72 (8H, *m*), 3.78 (1H, *dd*, *J*=11.0, 5.3 Hz, *sn*-3-H_a), 3.60 (1H, *dd*, *J*=11.0, 4.5 Hz, *sn*-3-H_b), 4.22 (1H, *dd*, *J*=12.1, 7.0 Hz, *sn*-1-H_a), 4.43 (1H, *dd*, *J*=12.1, 2.9 Hz, *sn*-1-H_b), 4.66 (1H, *dd*, J=3.5 Hz, H-1″), 5.08 (1H, *m*, *sn*-2-H), 5.26 (12H, *m*). For ^{13}C NMR spectral data, see Table 1.

3.7. Alkaline treatment of *1*

A solution of **1** (5.0 mg) in dry MeOH (1.0 ml) was treated with 5% NaOMe–MeOH (0.2 ml) at room temperature for 10 min. The reaction mixture was neutralized by using ion exchange resin (Dowex 50 W×8)

and the resin was removed by filtration. The filtrate was extracted with hexane and the hexane layer was concentrated under reduced pressure to yield methyl linolenate (3.5 mg). The methyl ester was identified by GLC comparison with authentic samples. Removal of the solvent from the MeOH layer under reduced pressure gave a residue, which was purified by SiO_2 column chromatography ($CHCl_3$–MeOH–H_2O = 6:4:1) to furnish monoglucosyl-glycerol (1.8 mg).

3.8. Acid hydrolysis of 3

A solution of **3** (15 mg) in 0.5 M HCl (5 ml) was heated at 70 °C for 3 h. After cooling, the reaction mixture was neutralized with 1% NaOH, and extracted with $CHCl_3$ (5 ml). In the aqueous layer, allose was detected with PC by direct comparison with the authentic sample of D-allose, and ^{13}C NMR of the product was consistent with those of authentic sample.

3.9. Antimicrobial assays

Three strains of bacteria, *B. subtilis*, *E. coli* and *S. aureus*, were cultured under agar. The paper-disk method (Xu and Bian, 1982) was used as an antimicrobial test, 0.1 ml of 100 μg/ml of compounds **1**, **2**, **3** or chloramphenicol (used as positive control) was added to each piece of paper. After 1 h, the disks were dried and placed on to a culture dish at 37 °C for 24 h. The antimicrobial activity was calculated by the diameter (in millimeters) of the antibacterial circle. Each test was performed in duplicate.

3.10. Cytotoxicity assays

The cytotoxicity of compounds **1–3** was tested in three cell lines: SMMC-7721 (human hepatoma), B16 (mouse melanoma) and HeLa (human carcinoma of uterine cervix). Cells were cultured at 37 °C under a humidified atmosphere of 5% CO_2 in RPMI 1640 medium supplemented with 10% fetal calf serum and dispersed in replicate 96-well plates with 1×10^4 cells/well for 24 h. Compounds **1**–**3** (10–400 μM) or vincristine (used as a positive control) were then added. After 48 h exposure to the toxins, cell viability was determined by the [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] (MTT) colorimetric assay (Price and McMillan, 1990) by measuring the absorbance at 595 nm with an ESILA reader. Each test was performed in triplicate.

Abstract

Three oxidized heptenes, 7-benzoyloxy-6-oxo-2,4*Z*-heptadiene-1,4-olide, [7-benzoyloxy-4-hydroxy-1-methoxy-2*E*,4*Z*-heptadiene-1,6-dione] and 7-benzoyloxy-6-oxo-2,4*E*-heptadiene-1,4-olide, were isolated from flowers of *Melodorum fruticosum*. Their structures were determined by spectral data analysis. The first two compounds exhibited moderate cytotoxicity against a panel of human tumor cell lines, whereas the third was inactive. © 2001 Elsevier Science Ltd. All rights reserved.

Keywords: *Melodorum fruticosum*; Annonaceae; Heptene, Cytotoxic activity

1. Introduction

In previous work on potential antitumor compounds from *Melodorum fruticosum* Lour. (Annonaceae), we isolated melodorinol (**4**) and acetylmelodorinol (**5**) as well as several open-chain analogues (Jung et al., 1990, 1991). Additional heptenes from the same plant and their cytotoxicity were also reported by another group (Tuchinda et al., 1991). In this work our continuing study on the flowers of this plant has yielded three heptenes, compounds **1**, **2** and **3**. In this paper we describe both the structural elucidation of compounds **1**–**3** as well as their cytotoxicity against a small panel of human tumor cell lines.

2. Results and discussion

Compound **1** was obtained from an EtOAc extract of the flowers of *M. fruticosum*, by precipitation, followed by re-crystallization from EtOAc. The methane CIMS of compound **1** exhibited a MH^+ at *m*/*z* 259, indicating a M^+ of *m*/*z* 258. The molecular formula, $C_{14}H_{10}O_5$, was established from the elemental analysis, CIMS, and ^1H and ^{13}C NMR spectroscopic data (Table 1). The IR spectrum showed three carbonyl absorption bands at 1790, 1731, and 1704 cm^{-1} consistent with a carbonyl ester of an α,β-unsaturated-γ-lactone ring, a carbonyl ester of benzoate, and α,β-unsaturated ketone, respectively.

The ^1H and ^{13}C NMR spectra together with 2D NMR experiments permitted the complete structure of compound **1** to be established. The ^1H NMR spectrum indicated that compound **1** possesses two methylene protons (δ 5.38), three olefinic protons (δ 5.69, 6.49, and 7.54), and five aromatic protons (δ 7.44, 7.57, and 8.09). The ^{13}C NMR spectrum revealed one methylene carbon (δ 69.3), eight sp^2 carbons (δ 107.3, 124.2, 128.4, 129.9, 133.3, and 145.0), two quaternary carbons (δ 129.3, 155.9), two carboxyl carbons (δ 165.8, 166.9) and a conjugated carbonyl carbon (δ 190.8). The presence of a benzoyl moiety was confirmed by comparison of the ^1H and ^{13}C NMR spectral data of **1** with those of melodorinol (**4**) (Jung et al., 1991). Two olefinic protons were coupled to each other with $J = 5.4$ Hz indicating that this double bond is part of the α,β-unsaturated-γ-lactone ring. The methylene carbon showed a chemical shift further downfield than typical methylene carbons, and the COLOC experiment exhibited long range coupling from the methylene protons to the carbonyl carbon of the benzoyl moiety; thus, the benzoyl moiety was determined to be part of the methylene

[a] Chemical shifts are relative to the solvent signal ($CDCl_3$).
[b] Multiplicities were established from DEPT spectra (s = singlet, d = doublet, and t = triplet).

benzoyloxy moiety. One olefinic proton (δ 5.69) showed long-range coupling to the β-carbon of the α,β-unsaturated-γ-lactone ring. Thus, the presence of an sp^2 carbon at the γ-carbon of the lactone moiety was indicated. The carbonyl carbon at δ 190.8 was consistent with an α,β-unsaturated ketone. This carbon showed long-range coupling from the methylene protons, so the methylene benzoyloxy moiety and the exocyclic sp^2 carbon of the γ-lactone ring were connected via this carbonyl. However, the structure of compound **1** could be in either a cisoid or transoid configuration. Irradiation of the H-3 signal (δ 7.54) enhanced the H-5 signal (δ 5.69) (8.2%) and confirmed the cisoid configuration. Thus, compound **1** was assigned as 7-benzoyloxy-6-oxo-2,4*Z*-heptadiene-1,4-olide, a new benzoylated heptene presumably representing an oxidized form of melodorinol.

Compound **2**, $C_{14}H_{10}O_5$, was isolated as colorless bulky crystals from the 70% aqueous acetone extract of *M. fruticosum* by crystallization and then re-crystallization from EtOAc. The molecular formula was established from the elemental analysis, CIMS, and NMR data (Table 1). Using the same approach as in compound **1**, in terms of ^{1}H and ^{13}C NMR analysis including 2D NMR experiments, it was found that **2** was identical to 1 except that the chemical shifts of H-3 (δ 8.32) and C-4 (δ 160.5) were further downfield than in compound **1**, indicating that compound **2** could be in the transoid configuration. Irradiation of the H-3 signal

(δ 8.32) enhanced the H-2 signal (δ 6.51) (5.6%) but not the H-5 signal (δ 6.33). Hence, the transoid configuration was proposed; therefore compound **2** was assigned as 7-benzoyloxy-6-oxo-2,4*E*-heptadiene-1,4-olide.

Compound **3**, $C_{15}H_{14}O_6$, was isolated as a white crystalline solid from EtOAc extract by Sephadex LH-20 chromatography eluting with EtOAc followed by silica gel chromatography eluting with EtOAc in hexane and then re-crystallization from EtOAc. The EIMS of this compound exhibited MH^+ at m/z 291, indicating a M^+ of m/z 290. The molecular formula was established from the elemental analysis, EIMS, and ^1H and ^{13}C NMR data (Table 1). IR spectrum showed two strong carbonyl absorption bands at 1724 and 1587 cm^{-1} consistent with a carbonyl ester and carbonyl group with tautomeric keto-enol forms, respectively. The OH stretching appeared as a broad peak between 2800 and 3500 cm^{-1} suggesting strong hydrogen bonding nature of the hydroxyl group. The mass spectrum showed a typical benzoyl moiety at m/z 105 (base peak) and a methyl ester moiety at m/z 259 (M^+–OCH_3) and m/z 231 (M^+–$COOCH_3$). Thus, compound **3** consisted of methyl ester and tautomeric keto-enol moiety in addition to the benzoate ester as in **1** and **2**.

The ^1H NMR spectrum of **3** displayed a methoxyl proton singlet (δ 3.77), a methylene proton singlet (δ 4.93), three olefinic proton signals (δ 5.86, 6.75 and 6.92), five aromatic protons belonging to the benzoyl group (δ 7.47, 7.60 and 8.09), and the downfield signal belonging to a tautomeric proton with strong hydrogen bond (δ 13.84). The ^{13}C NMR spectrum revealed one methoxyl carbon (δ 52.2), one methylene carbon (δ 66.6), and eight sp^2 carbons (δ 100.2, 128.1, 128.6, 128.9, 129.9, 133.6, 137.4 and 165.7), two carboxyl carbons (δ 165.8, and 170.6), and one unsaturated carbonyl carbon (δ 198.2). Comparison of ^1H and ^{13}C NMR spectral data of **3** with those of melodienone and 7-hydroxy-6-hydromelodienone (Jung et al., 1990; Tuchinda et al., 1991) suggested the structure of **3** as the oxidized form of 7-hydroxy-6-hydromelodienone. Two olefinic protons at δ 6.75 and 6.91 coupled to each other with the coupling constant of 15.6 Hz indicating the *trans* configuration at C-2/C-3 of **3**. Moreover, a strong hydrogen bonding at δ 13.84 suggested the cyclic structure of the intramolecular hydrogen bonding. Therefore, compound **3** was 7-benzoyloxy-4-hydroxy-1-methoxy-2*E*,4*Z*-heptadien-1,6-dione.

In addition to **1**, **2** and **3**, the known acetylmelodorinol (**5**) (Jung et al., 1990) together with 5,7-dihydroxyflavone (Markham and Chari, 1982) and 5,7-dimethoxyflavone (Jaipetch et al., 1983) were also isolated. Their spectroscopic data were in agreement with those reported in the literature.

Compounds **1**–**3** and **5** were tested for their cytotoxicity against human tumor cell lines. Doxorubicin hydrochloride was used as a positive control. Compound **1** showed moderate activities against human breast ductol carcinoma (BT474), liver hepatocarcinoma (HEP-G2), gastric carcinoma (KATO3), and colon adenocarcinoma (SW620) with IC_{50} values of 3.0, 3.7, 3.3, and 2.6 μg/ml, respectively, but was inactive against human undifferentiated lung carcinoma (CHAGO, $IC_{50} > 10$ μg/ml) (Table 2). A similar trend was observed for compound **3** (Table 2). Compound **2** was inactive against all cell lines ($IC_{50} > 10$ μg/ml). This was perhaps due to the solubility problem of compound **2** in the test media. It was also found that compound **5** was the most active of all four heptenes tested and its cytotoxic activity was in agreement to those previously reported (Jung et al., 1990).

3. Experimental

All commercial grade solvents were distilled prior to use. Uncorr. mps were determined using a Gallenkamp melting point apparatus. UV spectra were recorded on a Shimadzu UV-160A UV/VIS spectrophotometer, whereas IR spectra were obtained on a Perkin-Elmer Spectrum 2000 FT–IR spectrophotometer. EIMS and CIMS were obtained on a Micromass Platform II mass spectrometer at 70 and 30 eV, respectively, with methane. The ^1H and ^{13}C NMR spectra were recorded at 300 and 75 MHz, respectively, on a Bruker Avance DPX-300 NMR spectrometer.

Table 2
Cytotoxicity data of compounds **1**–**3** and **5**[a]

	Cell lines[b]				
Compound	BT 474	CHAGO	HEP-G2	KATO 3	SW 620
1	3.0	> 10	3.7	3.3	2.6
2	> 10	> 10	> 10	> 10	> 10
3	5.6	> 10	5.3	3.9	4.9
5	0.2	3.1	2.1	0.4	0.3
Doxorubicin hydrochloride	0.1	2.3	0.9	1.7	1.1

[a] Results are expressed as IC_{50} values (μg/ml).

[b] BT 474, Human breast ductol carcinoma ATCC No. HTB 20; CHAGO, Human undifferentiated lung carcinoma; HEP-G2, Human liver hepatoblastoma ATCC No. HB8065; KATO 3, Human gastric carcinoma ATCC No. HTB 103; SW 620, Human colon adenocarcinoma ATCC No. CCL 227.

Microanalyses were performed on a Perkin-Elmer PE2400 Series II CHNS/O analyzer.

3.1. Plant material

Flowers of *M. fruticosum* were collected in Amphur Muang, Srisaket Province, Thailand, in March 1998. Voucher herbarium specimens (BKF No.13900) of the plant were identified and deposited at the Forest Herbarium, Royal Forest Department, Ministry of Agriculture and Cooperatives, Bangken, Bangkok, Thailand.

3.2. Extraction and isolation

The powdered, dried flowers of *M. fruticosum* (2.3 kg) were extracted successively with petroleum ether (3×3 l), EtOAc (3×3 l), and 70% aqueous acetone (3×3 l). Each extract was evaporated under reduced pressure to yield a petroleum ether (58.44 g), an EtOAc (58.04 g), and a 70% aqueous acetone extract (24.78 g), respectively. Upon standing overnight, compound **1** precipitated out from the EtOAc extract and it was re-crystallized from EtOAc to give pure colorless bulky crystals (5.89 g, 0.26%). The EtOAc mother liquor was fractionated by a Sephadex LH-20 column eluting with EtOAc to obtain 7 fractions. The fractions with similar TLC pattern were combined and subjected to Si gel column chromatography, eluting with a hexane-EtOAc gradient in a stepwise fashion. Compound **3** was obtained as a white crystalline solid (602 mg, 2.62×10^{-2}%). In addition, 5,7-dihydroxyflavone was obtained as a yellow powder (1.57 g, 0.07%) and 5,7-dimethoxyflavone was obtained as colorless crystal (31 mg, 1.3×10^{-2}%). The 70% aqueous acetone extract, after removal of solvents under reduced pressure gave 140 mg of precipitate. This precipitate was re-crystallized from EtOAc to yield colorless bulky crystals of compound **2** (60 mg, 2.6×10^{-3}%). Compound **5** (150 mg, 6.5×10^{-3}%) was isolated as colorless crystals from successive silica gel column chromatography of the petroleum ether extract.

3.3. Biological evaluation

Bioassay of cytotoxic activity against human tumor cell cultures in vitro was performed by the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) colorimetic method (Carmichael et al., 1987; Twentyman and Luscombe 1987).

3.4. 7-Benzoyloxy-6-oxo-2,4Z-heptadiene-1,4-olide (*1*)

Colorless bulky crystals; mp 136–138 °C; (Found C, 65.15; H, 3.87 $C_{14}H_{10}O_5$ requires: C 65.12; H, 3.90%) UV λ_{max} $CHCl_3$ nm (log ε): 283 (4.52), 243 (4.14); FTIR ν_{max}^{KBr} cm^{-1}:1790 (C=O), 1731 (C=O), 1704 (C=O), 1649 (C=C); ^1H and ^{13}C NMR: Table 1. CIMS *m/z* (rel.int.): 259 [MH^+] (0.9); EIMS *m/z* (rel. int.): 258 [M^+] (0.3), 228 (5), 136 (23), 123 (31), 105 (100), 95 (13), 77 (63), 69 (16), 51 (35).

3.5. 7-Benzoyloxy-6-oxo-2,4E-heptadiene-1,4-olide (*2*)

Colorless bulky crystals; mp 139–140 °C; (Found C, 65.11; H, 3.87 $C_{14}H_{10}O_5$ requires: C 65.12; H, 3.90%) UV λ_{max} $CHCl_3$ nm (log ε): 292 (4.17), 243 (3.89); FTIR ν_{max}^{KBr} cm^{-1} :1785 (C=O), 1731 (C=O), 1703 (C=O), 1628 (C=C); ^1H and ^{13}C NMR: Table 1. CIMS m/z (rel. int.): 287 [$M+C_2H_5^+$] (0.7) 259 [MH^+] (11); EIMS m/z (rel. int.): 258 [M^+] (0.1), 228 (3), 136 (9), 123 (20), 105 (100), 95 (8), 77 (37), 69 (9), 51 (14).

3.6. 7-Benzoyloxy-4-hydroxy-1-methoxy-2E,4Z-heptadiene-1,6-dione (*3*)

White crystalline solid; mp 116–118 °C; (Found C, 62.06; H, 4.85 $C_{15}H_{14}O_6$ requires: C 62.07; H, 4.86%) UV λ_{max} $CHCl_3$ nm (log ϵ): 317 (4.40); FTIR ν_{max}^{KBr} cm^{-1} : 3500–2700 (OH), 1724 (C=O), 1658 (C=C), 1628 (C=C), 1587 (C=O),); ^1H and ^{13}C NMR: Table 1. EIMS m/z (rel. int.): 291 [MH^+] (8), 290 [M^+] (2), 273 (3), 259 (1), 231 (30), 168 (37), 155 (64), 136 (7), 123 (52), 113 (53), 106 (14), 105 (100), 95 (20), 85 (8), 77 (82), 69 (17), 59 (15), 55 (20), 51 (59).

Acknowledgements

We thank the Graduate School and the Department of Pharmacognosy, Faculty of Pharmaceutical Sciences, Chulalongkorn University, for financial support. We are grateful to Dr. Tirayut Vilaivan, Department of Chemistry, Faculty of Science, and Dr. Khanit Suwanborirux, Department of Pharmacognosy, Faculty of Pharmaceutical Sciences, Chulalongkorn University, for helpful discussions on the NMR data.
