**Abstract**—New compounds of composition  $\text{NaM}'\text{M}''\text{P}_3\text{O}_{12}$  ( $\text{M}' = \text{Nb, Sb}; \text{M}'' = \text{Al, Ga, In, Fe}$ ) with structures related to that of the fast ion conductor called “NASICON” have been prepared. The X-ray powder diffraction data are presented and the variation in the lattice parameters as aluminium in  $\text{NaNbAlP}_3\text{O}_{12}$  is replaced by larger gallium, indium and iron ions is discussed. The lattice parameters and the resistivities of the compounds are indicative of the occupation by  $\text{Na}^+$  of only the Type I sites.

Compounds of composition  $\text{AM}'\text{P}_3\text{O}_{12}$  have structures which involve the corner sharing of  $\text{PO}_4$  tetrahedra with  $\text{MO}_6$  octahedra thereby producing a three-dimensional linked channel network in which the A ions can be located.<sup>1–4</sup> The A ions can occupy two different types of sites within the channels.<sup>3</sup> The Type I sites have a distorted octahedral coordination and are situated between two  $\text{MO}_6$  octahedra along the *c* axis to produce ribbons of  $\text{O}_3\text{MO}_3\text{AO}_3\text{MO}_3$ . The Type II sites are larger with eight to ten co-ordinating oxygen ions and are located between the ribbons. The structure is amenable to substitution on the A, M or phosphorus sites and a wide range of isostructural materials can be formed. The occupancy of the Type I and II sites can also be varied from four to zero. For example, the compound  $\text{Na}_3\text{Zr}_2\text{Si}_2\text{PO}_{12}$  which is called NASICON has sodium ions in both Type I and II sites and has attracted considerable interest because of its high sodium-ion mobility.<sup>1,2</sup>

We report here on the preparation and char-

acterisation of new compounds of the type  $\text{AM}'\text{M}''\text{P}_3\text{O}_{12}$ .

## EXPERIMENTAL

Compounds of composition  $\text{NaM}'\text{M}''\text{P}_3\text{O}_{12}$  ( $\text{M}' = \text{Nb, Sb}; \text{M}'' = \text{Al, Ga, In, Fe}$ ) were prepared by sequential heating of well ground appropriate stoichiometric mixtures of  $\text{NaNO}_3$ ;  $\text{Nb}_2\text{O}_5$  or  $\text{Sb}_2\text{O}_5$ ;  $\text{Al}_2\text{O}_3$ ,  $\text{Ga}_2\text{O}_3$ ,  $\text{In}_2\text{O}_3$  or  $\text{Fe}_2\text{O}_3$ ; and  $\text{NH}_4\text{H}_2\text{PO}_4$  at 500 °C (6 h), 800 °C (14 h), and at 1000 °C (5 h). Compounds where  $\text{M}'' = \text{Ga}$  and  $\text{In}$  required treatment at 1000 °C for 16 h to achieve monophasic composition.

X-ray powder diffraction data were recorded with a Siemens D5000 diffractometer using  $\text{Cu-K}_\alpha$  radiation.  $^{57}\text{Fe}$  Mössbauer spectra were recorded with a microprocessor-controlled Mössbauer spectrometer using a  $^{57}\text{Co}$ —Rh source. The drive velocity was calibrated with a  $^{57}\text{Co}$ —Rh source and a natural iron foil. All the spectra were computer fitted. The  $^{57}\text{Fe}$  Mössbauer chemical isomer shift data are quoted relative to metallic iron. Resistivity measurements were recorded with an EG and G

Princeton Potentiostat Model 273A. Pellets of 2 mm thickness were prepared in a KBr press and the conductivity measured using platinum wire electrodes.

## RESULTS AND DISCUSSION

The formation of monophasic compounds of composition  $\text{NaM}^{\text{M}''}\text{P}_3\text{O}_{12}$  ( $\text{M}' = \text{Nb, Sb}; \text{M}'' = \text{Al, Ga, In, Fe}$ ) was confirmed by X-ray powder diffraction. The X-ray powder diffraction data for  $\text{NaNbAlP}_3\text{O}_{12}$  are contained in Table 1. The  $^{57}\text{Fe}$  Mössbauer spectrum recorded from  $\text{NaNbFeP}_3\text{O}_{12}$  ( $\delta$  0.35  $\text{mm s}^{-1}$ ,  $\Delta$  0.96  $\text{mm s}^{-1}$ ) confirmed the occupation by  $\text{Fe}^{3+}$  of the octahedral structural site in  $\text{NaNbFeP}_3\text{O}_{12}$ . The lattice parameters for compounds of the type  $\text{NaNbM}^{\text{M}''}\text{P}_3\text{O}_{12}$  ( $\text{M} = \text{Al, Ga, In, Fe}$ ) are shown in Table 2. The systematic increase in lattice parameters is a reflection of the increasing size<sup>5</sup> of the  $\text{M}''$  ion as  $\text{Al}^{3+}$  ( $r = 0.51 \text{ \AA}$ ) is replaced by  $\text{Ga}^{3+}$  ( $r = 0.62 \text{ \AA}$ ),  $\text{Fe}^{3+}$

In	8.34	23.08
Fe	8.38	22.22

( $r = 0.64 \text{ \AA}$ ) and  $\text{In}^{3+}$  ( $r = 0.81 \text{ \AA}$ ). This is depicted in Fig. 1 which shows the increase in the  $c$  lattice parameter to exceed that of the  $a$  and  $b$  lattice parameters. The trend is similar to that recently observed<sup>6,7</sup> when the structurally related  $\text{Nb}^{\text{V}}\text{Ti}^{1\text{V}}\text{P}_3\text{O}_{12}$  phases, which contain empty Type I and Type II sites, were reacted with iron and tin. The results were interpreted in terms of the incor-

Fig. 1. Variation in lattice parameters for compounds of the type  $\text{NaNbM}^{\text{M}''}\text{P}_3\text{O}_{12}$  ( $\text{M}'' = \text{Al, Ga, In, Fe}$ ).

poration of the large  $\text{Fe}^{2+}$  and  $\text{Sn}^{2+}$  ions in the Type I sites with concomitant reduction of niobium in the host structure. We envisage that in materials of the type  $\text{NaNb}^{\text{V}}\text{M}^{\text{III}}\text{P}_3\text{O}_{12}$  the small sodium ions, which maintain electrical neutrality in the phases, are also located in the octahedral Type I sites as opposed to being distributed over both the Type I and Type II sites as in NASICON. The preliminary measurement of the resistivities of compounds of the type  $\text{NaNbM}^{\text{V}}\text{P}_3\text{O}_{12}$  recorded from pelleted samples were found to be  $>10^8$  ohms at 298 K which contrasts with the fast sodium ion conduction properties of NASICON. We also associate this with the structural evidence for the occupation by sodium of only the Type I sites in  $\text{NaNbM}^{\text{V}}\text{P}_3\text{O}_{12}$ .

Compounds of the type  $\text{NaSbM}^{\text{V}}\text{P}_3\text{O}_{12}$  were similar. The lattice parameters (Table 2) showed similar variations according to the size of the  $\text{M}^{\text{V}}$  ion.

Hence new compounds of the type  $\text{NaM}'\text{M}^{\text{V}}\text{P}_3\text{O}_{12}$  ( $\text{M}' = \text{Nb, Sb}$ ;  $\text{M}^{\text{V}} = \text{Al, Ga, In, Fe}$ ) with NASICON type structures have been prepared. It appears however that, in contrast with NASICON, the small sodium ions are incorporated

only within the octahedral Type I sites and that this influences the ionic conduction properties of the materials.
