### SUMMARY

Hexafluoropropene (HFP) - 1,1-difluoroethene (VDF) copolymers have been synthesized in the 0-16 mole % HFP range and the results of a physico-chemical characterization by means of XRD (crystallinity index) and DSC techniques are related to the microstructure of the polymers, as determined by <sup>19</sup>F NMR. The addition of a small percentage of the HFP comonomer does not affect the polymorphism of poly(vinylidene fluoride).

### INTRODUCTION

As important properties of vinylic copolymers are greatly dependent upon their composition and microstructure, we have modified the polymeric chain of highly crystalline poly(1,1-difluoroethene) (PVDF) by introducing variable amounts of hexafluoropropene (HFP). The composition of the copolymer and the mean length of the monomer sequences, as determined by NMR spectroscopy, are correlated to crystallinity and thermoanalytical data. In view of the poor crystallinity of the products in the compositional range of high HFP values we have limited ourselves to the study of the 0-16 mole % HFP range. The residual crystallinity of the commercial fluororubbers, such as Tecnoflon, Viton, Fluorel (HFP > 17 mole %) may be investigated by means of other physico-chemical techniques, such as SAXS.

EXPERIMENTALSynthesis

Aqueous emulsion copolymerizations were carried out in batch in a stainless steel autoclave (5 l) at 85°C under continuous stirring. The autoclave was charged with 850 ml of demineralized water and a mixture of the monomers, up to attaining a pressure of 14 atm at 85°C. After injection of an aqueous solution (150 ml) of 2 g (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, the reaction was blocked by interruption of stirring and cooling to room temperature, when a pressure drop of 2 atm was observed. As previously reported (ARNOLD et al.), surfactants are not required in this process. After venting the gases, the latexes were cooled to room temperature without stirring. The polymers were coagulated by pouring the emulsion in 500 ml 37% HCl under stirring, washed with demineralized water and dried at 45°C under vacuum for 7 h. The number average molecular weight of the copolymers was of the order of 10<sup>5</sup>. It was calculated according to relations between intrinsic viscosity and molecular weight developed for a copolymer of VDF and HFP (FOGIEL) and for PVDF homopolymer (STALLINGS and HOWELL).

### Physico-chemical characterization

$^{19}\text{F}$  NMR spectra, recorded at 56.4 MHz using a Varian EM 360 L spectrometer, were interpreted on the basis of the chemical shifts (Table 1) according to literature (FERGUSON; SCHMIEGEL; MOGGI et al.) data.

The experimental parameters derived from these spectra are reported in Table 2. Elementary chemical analysis was carried out to verify the copolymer composition. Glass transition temperatures ( $T_g$ ) and endothermal effects were determined by means of DSC, using a Du Pont 900 Thermal Analyzer; their dependency upon the composition is given in Table 2.

Wide angle x-ray patterns of unoriented samples were recorded on a Philips powder diffractometer using  $\text{Cu K}\alpha$  radiation. Relative crystallinities (Table 3) were determined with respect to reference specimens of PVDF homopolymers which exhibit the highest degree of observed crystallinity and of high HFP containing copolymers which approach most closely to the completely amorphous state.

RESULTS AND DISCUSSION

The polymers were synthesized in conditions in which as well known, homopolymerization of HFP is impossible. Therefore also the formation of HFP sequences in the copolymer is avoided (SCHMIEGEL).

Consequently, only VDF sequences were examined. The mean sequence lengths  $\bar{L}_n$  (VDF) were derived from NMR data following previous works (FERGUSON; SCHMIEGEL; MOGGI et al.). The values of  $\bar{L}_n$  were found to be in good accordance with those obtained theoretically according to RIOS and GUILLOT, by means of the relationship :

$$\bar{L}_n (A) - 1 = r_{AB} \frac{[A]}{[B]}$$

where [A] and [B] are the concentrations of the comonomers during polymerization and  $r_{AB}$  is the reactivity ratio. A reactivity ratio  $r_{VDF/HFP} = 3.0 \pm 0.5$  was assumed, which was deduced from our experimental data according to the procedures of FINEMAN and ROSS.

As well known, polymerization with chemical initiation leads to  $\beta$ -PVDF (GALPERIN et al.), even though the planar zigzag (or TT) conformation of the chain in this

crystalline form is less stable than the 2/1 helical (or TGT $\bar{G}$ ) conformation (HASEGAWA et al.). Accordingly, our homopolymer sample assumes the  $\beta$  form, as shown in Table 3. Addition of small percentages of HFP comonomer does not affect the polymorphism of PVDF. As a matter of fact, it is well known (DOLL and LANDO) that introduction of perfluorinated units in the PVDF chain favours crystallization in phase  $\beta$  for steric and electronic reasons. This tendency is more pronounced in case of introduction of tetrafluoroethylene units in PVDF (DOLL and LANDO) and apparently also holds for hexafluoropropene units. It further appears that the PVDF orthorhombic cell is not appreciably deformed by the introduction of HFP units. Only small amounts of the random  $\alpha$  form ( $\alpha_r$ ) (GAL' PERIN et al.) are present in most samples. By annealing at 145°C the crystallites take on the highly ordered  $\alpha$ -form ( $\alpha_h$ ). The crystallinity of the copolymers decreases with an increase of the HFP fraction, according to the linear relationship of Fig. 1.

Figure 1. Crystallinity index of VDF-HFP copolymers

This is expected on the basis of the perturbation of the constitutional regularity due to the trifluoromethyl groups.

The effect is accompanied by a gradual shift in position of the maximum of the amorphous fraction (from  $18.5^\circ$  to  $17.0^\circ$ ,  $2\theta$  Cu K $\alpha$ ), which is readily interpreted on the basis of the substituent effect of the HFP units. This trend sets through also for higher HFP percentages (max. at  $16.3^\circ$  for a 41 mole %  $C_3F_6$  content). As shown in Table 2, the glass transition temperature varies regularly with the mean sequence length of VDF units. In terms of the composition of the copolymers,  $T_g$  increases linearly with the HFP content (Table 2, Fig. 2). This trend fits in with a report about a linear growth of  $T_g$  with the increasing  $C_3F_5H$  fraction in VDF-1,2,3,3,3-pentafluoropropene copolymers (MIGLIERINA and CECCATO) and is also in line with the fact that  $T_g$  increases if the hydrogen atoms of the main chain are substituted by groups of atoms, especially if these substituents have a polar character (JANACEK). Nevertheless, the observed trend does not agree with the reported non-linear relationships between  $T_g$  and composition, such as the FOX equation :

Figure 2. Glass transition temperatures of VDF-HFP copolymers : experimental  $T_g$  (●) and those according to the Fox equation (○)

$$(1/Tg) = (W_1/Tg_1) + (W_2/Tg_2)$$

where :

- $W_1, W_2$  = weight fractions of monomers in the copolymer  
 $Tg_1, Tg_2$  = glass transition temperatures ( $^{\circ}K$ ) of the homopolymers  
 $Tg$  = glass transition temperature ( $^{\circ}K$ ) of the copolymer.

Table 2 and Fig. 2 compare the results of calculations according to the FOX equation with experimental values of  $Tg$ .

As shown in Fig. 2 the linear growth of  $Tg$  with the increasing  $C_3F_6$  fraction fits well also with the  $Tg$  values of two high HFP containing copolymers we have prepared as reference compounds (HFP = 22 mole %,  $Tg = -22^{\circ}C$ ; HFP = 38 mole %,  $Tg = -6^{\circ}C$ ).

However, extrapolation to PHFP leads to a  $Tg$  value of  $59^{\circ}C$ , which is in complete disagreement with the reported experimental values of  $152^{\circ}C$  (BROWN and WALL) and  $167^{\circ}C$  (ARNOLD et al.; ELEUTERIO and MOORE).

Various endothermal transitions have been observed in PVDF and VDF-HFP copolymers. The homopolymer (PVDF) exhibits a m.p. at  $167^{\circ}C$ , which is lowered by introduction of a very small fraction of the HFP comonomer into the polymeric chain. Namely, in a low HFP content polymer (2.9 mole %) two transitions are observed at  $143$  and  $153^{\circ}C$ , where the latter value can be considered as the melting temperature. Various other endothermal effects have been observed, but could not be interpreted. We intend to gain better understanding of these features by studying the behaviour of other VDF copolymers.
