### Summary

A group of new polyimides has been prepared by solution condensation of 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl]pyridine containing pendant NMe<sub>2</sub> units and various dianhydrides in N-methylpyrrolidone (NMP). The tridentate (N-N'-N) pyridine ligands were prepared by Schiff-base condensation of 2,6-diacetylpyridine and 4-dimethylaminoaniline in the presence of formic acid as catalyst. These polymers were investigated for their extraction capabilities for Zn(II), Mn(II), Cu(II), Cd(II) and Ni(II) and at different pH. Under different conditions enhanced selectivity was observed. Up to 98% quantitative recoveries were observed for all metals.

### 1. Introduction

The selective extraction of noble metals such as Zn, Cd, Mn, Hg, Au, Pd, Ag, Pt, Ir and Co is still an intensively investigated area of research. Noble metal purification is still accomplished by traditional precipitation and complexation procedures that require the large amount of highly toxic mineral acids and complexation agents such sodium or potassium cyanide which have negative impact on environment. In order to circumvent the used of such chemicals liquid-liquid extraction, as well as solid-phase extraction (SPE) techniques applying numerous sorbents, have already been developed. Polymer supported extractants, usually based on PS-DVB or some methacrylates suffer from insufficient selectivity and reduced chemical stability in the extraction media [1-7]. Alternatively, crown ethers on silica [8-11] possessed high selectivity for the metal ions of interest, the use of PS-DVB sorbents impregnated with guanidines [12], poly(amide-ester) based pyridine-2,6-dicarboxylic acids [13], poly(glycidyl methacrylate) supported oligoamines [14] etc have been described.

Since there is a great interest in pyridine based ligand which is primarily due to their stability under a variety of oxidative and reductive conditions and the fact that pyridine ligands are mild lewis bases and capable of bonding abilities toward metals. Several complexes containing pyridine ligands have appeared in the literature [15].

To the best of our knowledge, however, no paper has dealt with the preparation of polyimide from 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl]pyridine by one-stage polycondensation for solid-phase extraction. We have therefore developed synthetic

procedures based on diimines derived from 2,6-diacetylpyridine. This paper reports on the synthesis of 2,6-*bis*(imino)pyridyl with pendant NMe<sub>2</sub> groups at the *p*-position of the phenyl ring that acts as tridentate ligand that could be used to built supromolecular architectures by the self assembling of pydim component with metal ions. The most prominent examples are Cu(II), Cd (II), Mn (II), Zn(II) and Ni(II) complexes due to their ability to form defined supromolecular architectures. The synthesis of polyimides [16-20] starting from these new monomer is reported and the influence of the incorporation of this moiety into the polymer backbone on the sorption capacity of metals has been evaluated.

## 2. Experimental Section

### 2.1. Materials.

Reagent grade aromatic dianhydrides such as pyromellitic dianhydride (PMDA), 3,3',4,4'-benzophenonetetracarboxylic dianhydride (BPDA), 4,4'-oxydiphthalic anhydride (ODPA) that was sublimed at 250°C under reduced pressure, 3,3',4,4'-biphenyltetracarboxylic dianhydride (BTDA) was used after crystallization in proper solvents (all Aldrich Co.), dimethylaminoaniline and 2,6-diacetylpyridine (Merck). Aqueous standard solutions of Zn(NO<sub>3</sub>)<sub>2</sub>, Ni(NO<sub>3</sub>)<sub>2</sub>, Mn(NO<sub>3</sub>)<sub>2</sub>, Cu(NO<sub>3</sub>)<sub>2</sub>, Cr(NO<sub>3</sub>)<sub>3</sub> (in 0.5 M HNO<sub>3</sub>), (all Merck, Germany) were used.

### 2.2. Instrumentation.

Infrared spectra were recorded as KBr pellets in the range 4000 - 400 cm<sup>-1</sup> on an Ati Unicam Mattson 1000 Fourier Transform Infrared Spectrometer. <sup>1</sup>H NMR spectra (300.133 MHz) and <sup>13</sup>C NMR on a Bruker AM 300 WB with δ referenced to residual solvent CDCl<sub>3</sub>. Microanalyses were performed by the TUBITAK (Ankara). Differential scanning calorimeter (DSC), differential thermal analysis (DTA) and thermogravimetry (TG) were performed with Shimadzu DSC-60, DTA-50 and TGA-50 thermal analyzers respectively.

Inherent viscosities ( $\eta_{inh} = \ln \eta_r / c$  at polymer concentration of 0.5 g/dL) were measured with an Ubbelohde suspended-level viscometer at 30 °C using NMP as the solvent.

Gel Permeation Chromatography GPC, size exclusion chromatography (SEC) analyses were performed at 30°C using NMP as eluant at a flow rate of 0.5 mL/min. A differential refractometer was used as a detector. The instrument (Agilent 1100 series GPC-SEC system) was calibrated with a mixture of polystyrene standards (polysciences; molecular masses between 200-1200000 Da) using GPC software for the determination of the average molecular masses and the polydispersity of the polymer samples.

SPE experiments were carried out using 1.5 mL PP-Isolute SPE cartridges equipped with PP frits as given in literature [6].

### 2.3. Procedures.

#### *Synthesis of 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl] pyridine (1):*

As shown in Scheme 1, the tridentate ligand used in this study is pyridine diimine ligand prepared by the Schiff-base condensation of 2 equiv. of the 4-dimethylaminoaniline with 2,6-diacetylpyridine in the presence of catalytic amount

of formic acid. The mixture was stirred under nitrogen atmosphere with reflux and the precipitate formed was collected by filtration and washed with ethyl alcohol and dried in air (m.p.197°C). The compound gave satisfactory microanalysis; displaced the expected  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra.  $\delta_{\text{H}}$  (300 MHz,  $\text{CDCl}_3$ ) 2.45 (6H,s,H-*d*), 2.94 (12H,s, H-5), 6.76 (4H,d,*J* 9.0, H-3), 6.85 (4H,d,*J* 8.9, H-2), 7.80 (1H,t,*J* 8.0, H-*a*), 8.29 (2H,d, *J*7.7, H-*b*);  $\delta_{\text{C}}$  (75.4 MHz,  $\text{CDCl}_3$ ) 16.2 (C-*d*), 41.0 (C-5), 113.2 (C-3), 121.4, 121.8 (C-*b*, C-2), 136.6 (C-*a*), 141.0 (C-4), 147.7 (C-1), 156.0 (C-*c*), 166.5 (C-*e*). Analytically calculated for  $\text{C}_{25}\text{H}_{29}\text{N}_5$ , (399.54) C: 75.15; H: 7.32; N: 17.53, Found: C: 75.37; H: 7.95; N: 16.99.

#### Synthesis of polyimides:

A typical polyimide (**P1a-d**) synthesis was performed as follows: Monomer 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl] pyridine (1.66g, 4.15 mmol) was dissolved in NMP (15 mL) in a 50 mL Schlenk tube equipped with a nitrogen line, overhead stirrer, a xylene filled Dean-Stark trap, and a condenser. PMDA (0.9 g, 4.15 mmol) was added to the amine solution and stirred overnight to give a viscous solution. The mixture was heated to 70°C, xylene (5 mL) was added, and the mixture was refluxed for 3-h. Following the removal of xylene by distillation, the reaction mixture was cooled at room temperature and the product was precipitated by addition of a large excess of methanol. The dark yellow product was isolated and dried at 100°C under vacuum and then at 200-250°C under nitrogen for 2h; Yield, 89%.  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra.  $\delta_{\text{H}}$  (300 MHz, $d^6$  DMSO) 2.38 (s,H-*d*), 6.82 (d,*J* 9.0, H-3), 6.78 (d,*J* 8.9, H-2), 7.85 (t,*J* 8.0, H-*a*), 8.32 (d, *J*7.7, H-*b*), 9.01 (s, pyromellitic); Analytically calculated for  $\text{C}_{25}\text{H}_{29}\text{N}_5$ , (399.54) C: 75.15; H: 7.32; N: 17.53, Found: C: 75.37; H: 7.95; N: 16.99.

#### SPE Experiments

For all experiments the SPE material was first stirred in methanol-water (20:80) for 1h. Columns were slurry packed and conditioned by passing 100 mL of methanol-water solution through the column, followed by 100 mL water flow rate of 3mL/min. For SPE, solutions containing 100 ppm single element standards, respectively, were passed through a slurry-packed filtration column (Isolute<sup>TM</sup> accessories, 200 mg sorbent). Recoveries were determined under non-competitive conditions by AAS.

### 3. Results and Discussion

The starting monomer 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl]pyridine, (**1**) used in the synthesis of polyimides was prepared by the Schiff-base condensation of two equiv. of the desired aniline with 2,6-diacetylpyridine as shown in Scheme 1. In this work, the synthesis of tridentate ligand with promising properties was achieved.

Scheme 1: Synthesis of 2,6-bis[1-(*p*-dimethylaminophenylimino) ethyl] pyridine, (**1**)

Incorporating  $\text{NMe}_2$  groups at the *p*-position of the phenyl ring facilitated not only polyimide synthesis, but also a potent to prepare metal coordinated polymers. FT-IR,  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra and elemental analysis were used to confirm the structures of the monomer, 2,6-*bis*[1-(*p*-dimethylamino phenylimino) ethyl] pyridine. The NMR spectra of the monomer was diagnostic. Only a single set of signals were observed for two pendant groups of pydim complexes in both  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra that indicate the two arms of the ligands are magnetically equivalent in solution and the ligands are tridentate. Polyimides **P1a-d** were synthesized by one-stage polycondensation of dianhydrides with 2,6-*bis*[1-(*p*-dimethylaminophenylimino)ethyl] pyridine.

Scheme 2: Polyimide synthesis (**P1a-d**)

Figure 1. FT-IR Spectrum of polyimides prepared from 2,6-*bis*[1-(*p*-dimethylaminophenylimino)ethyl] pyridine (**P1a-d**) and the monomer

All the polymerizations proceeded in homogeneous solution and the precipitation was prevented in all cases by adjusting the solvent to the monomer ratio. The FT-IR spectra (Figure 1) showed that aliphatic C-H stretching frequencies were appeared between  $2850\text{--}2890\text{ cm}^{-1}$ ,  $1720\text{--}1730\text{ cm}^{-1}$  sym. imide  $\nu(\text{C}=\text{O})$ ,  $1765\text{--}1790\text{ cm}^{-1}$  asym. imide  $\nu(\text{C}=\text{O})$  stretching, C-N imide ring stretching  $1360\text{ cm}^{-1}$ , whereas imide ring deformation was appeared at near  $1070\text{ cm}^{-1}$  and C-N bending at  $730\text{--}760\text{ cm}^{-1}$  and the C=N peak in the monomers gave two peaks at  $1440\text{--}1660\text{ cm}^{-1}$  respectively [21-22].

Polyimides were synthesized in NMP solvent in a one-stage solution polycondensation in which the dimethylamino groups were reacted with a stoichiometric amount of the dianhydride (Scheme 2). The polymers were isolated in almost quantitative yield by precipitation from methanol. The formation of the imide ring was confirmed by FTIR, that was discussed in our previous papers [23-24].

Figure 2. DTA curves of polyimides prepared from 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl] pyridine (P1a-d)

The thermal properties of the polyimides were evaluated by differential scanning calorimetry (DSC), differential thermal analysis (DTA) (Figure 2) and thermogravimetry (TG) (Figure 3). The thermal behavior data of all the polymers are presented in Table 1. DSC experiments were conducted at a heating rate of 10 °C/min in nitrogen. Rapid cooling from 400 °C to room temperature produced predominantly amorphous samples, so  $T_g$ 's of all the polyimides could easily be read in the subsequent heating DSC traces. The  $T_g$  values of polyimides P1a-d were in the 245-391 °C range depending on the structure of the dianhydride component and decreasing with increasing flexibility of the polymer backbones. As expected, the polyimide P1a derived from PMDA exhibited the highest  $T_g$  because of the rigid pyromellitimide unit. The thermal stability of the polymers was evaluated by TGA conducted at a heating rate of 10 °C/min. in nitrogen atmosphere. The temperatures of 10% weight loss in nitrogen stayed within 415-524 °C range. P1-d having oxygen group in dianhydride exhibited the lowest  $T_{10}$  values than the other polyimides.

The solubility of the polyimides was tested in various organic solvents, and the results are summarized in Table 2. Polymers had excellent solubilities in aprotic polar solvents such as NMP, DMAc, DMF and DMSO. This high solubility might be attributed to the formation of some intermolecular spacing due to the tridentate ligand.

#### SPE Experiments

The polymer supported organic reactions in which the structure of the ligand was not changed during polymerization was directly used for preliminary investigations concerning the complex formation capabilities with various metals.

For this purpose, solutions of metals summarized in Table 4, in the presence of interfering ions, were extracted under different conditions. The loadings that reach the theoretical amount were indicative for the complex formations which explain for the selectivity of the sorbent for certain metal ions. Metals sorbed onto the material (>90%) desorbed by nitric acid (5M). In case loading was stopped before reaching the corresponding point of breakthrough. The data in Table 4 and 5 illustrate the potential of polyimide based sorbent for the extraction of metals which may be used to substitute traditional purification techniques. From the entire set of data, the following extraction order was deduced at given pH: Cr  $\approx$  Mn  $\approx$  Cd  $\approx$  Zn  $\approx$  Ni. This clearly indicates that new sorbents allows the adsorption of metals onto the material under competitive or non-competitive conditions.

#### 4. Conclusions

Novel monomers, 2,6-bis[1-(*p*-dimethylaminophenylimino)ethyl] pyridine, 1, was prepared in high purity. Since the tridentate ligands not only offers suitable sites for metal coordination, but also stable under oxidative conditions and there is a great interest in these type of ligands due to their mild basicity, a series of polyimides was prepared and tested. All polyimides not only showed good thermal properties and high glass-transition temperatures but also the introduction of tridentate units in polyimides backbone results in potent polyimides that could be used further complexation with various metals.
