Combining (3.6) and (3.7), we can assert the existence of $(\vec{p}^*, \vec{\lambda}^*) \in H_0(\mathrm{div}) \times \mathbb{H}_0^1(\Omega)^*$ such that for a subsequence denoted by the same symbol

$$(\vec{p}_c, \vec{\lambda}_c) \rightharpoonup (\vec{p}^*, \vec{\lambda}^*) \qquad \text{weakly in } H_0(\mathrm{div}) \times \mathbb{H}_0^1(\Omega)^*. \tag{3.8}$$

We recall the variational form of (3.2), i.e.,

$$\begin{aligned} \frac{1}{c}(\nabla \vec{p}_c, \nabla \vec{v}\,) + (\operatorname{div} \vec{p}_c, \operatorname{div} \vec{v}\,)_B + (\mathrm{K}^* f, \operatorname{div} \vec{v}\,)_B + \gamma (\mathrm{P}_{\mathrm{div}} \vec{p}_c, \mathrm{P}_{\mathrm{div}} \vec{v}\,) \\ + (\vec{\lambda}_c, \vec{v}\,) = 0 \quad \text{for all } \vec{v} \in \mathbb{H}_0^1(\Omega). \end{aligned}$$

Passing to the limit $c \to \infty$, using (3.6) and (3.8) we have

$$\begin{aligned} (\operatorname{div} \vec{p}^*, \operatorname{div} \vec{v}\,)_B + (\mathrm{K}^* f, \operatorname{div} \vec{v}\,)_B + \gamma (\mathrm{P}_{\mathrm{div}} \vec{p}^*, \mathrm{P}_{\mathrm{div}} \vec{v}\,) \\ + \langle \vec{\lambda}^*, \vec{v}\,\rangle_{\mathbb{H}_0^1(\Omega)^*, \mathbb{H}_0^1(\Omega)} = 0 \quad \text{for all } \vec{v} \in \mathbb{H}_0^1(\Omega). \end{aligned} \tag{3.9}$$

Since $\mathbb{H}_0^1(\Omega)$ is dense in $H_0(\mathrm{div})$ and $\vec{p}^* \in H_0(\mathrm{div})$, we have that (3.9) holds for all $\vec{v} \in H_0(\mathrm{div})$. Consequently $\vec{\lambda}^*$ can be identified with an element in $H_0(\mathrm{div})^*$, and $\langle \cdot, \cdot \rangle_{\mathbb{H}_0^1(\Omega)^*, \mathbb{H}_0^1(\Omega)}$ in (3.9) can be replaced by $\langle \cdot, \cdot \rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})}$. We next verify that $\vec{p}^*$ is feasible. For this purpose note that

$$(\vec{\lambda}_c, \vec{p} - \vec{p}_c) = \big(\max(0, c(\vec{p}_c - \beta \vec{1})) + \min(0, c(\vec{p}_c + \beta \vec{1}), \vec{p} - \vec{p}_c \big) \le 0 \tag{3.10}$$

for all $-\beta \vec{1} \le \vec{p} \le \beta \vec{1}$. From (3.1) we have

$$\frac{1}{c}|\nabla \vec{p}_c|^2 + |\operatorname{div} \vec{p}_c + \mathrm{K}^* f|_B^2 + \gamma |\mathrm{P}_{\mathrm{div}} \vec{p}_c|^2 + \frac{1}{c}|\vec{\lambda}_c|^2 \le |\mathrm{K}^* f|_B^2. \tag{3.11}$$

Consequently, $\frac{1}{c}|\vec{\lambda}_c|^2 \le |\mathrm{K}^* f|_B^2$ for all $c > 0$. Note that

$$\frac{1}{c}|\vec{\lambda}_c|_{\mathbb{L}^2(\Omega)}^2 = c|\max(0, \vec{p}_c - \beta \vec{1})|_{\mathbb{L}^2(\Omega)}^2 + c|\min(0, \vec{p}_c + \beta \vec{1})|_{\mathbb{L}^2(\Omega)}^2$$

and thus

$$\begin{aligned} |\max(0, (\vec{p}_c - \beta \vec{1}))|_{\mathbb{L}^2(\Omega)}^2 &\overset{c \to \infty}{\to} 0, \\ |\min(0, (\vec{p}_c + \beta \vec{1}))|_{\mathbb{L}^2(\Omega)}^2 &\overset{c \to \infty}{\to} 0. \end{aligned} \tag{3.12}$$

Recall that $\vec{p}_c \rightharpoonup \vec{p}^*$ weakly in $\mathbb{L}^2(\Omega)$. Weak lower semicontinuity of the convex functional $\vec{p} \mapsto |\max(0, \vec{p} - \beta\vec{1})|_{\mathbb{L}^2(\Omega)}$ and (3.12) imply that

$$\int_\Omega |\max(0, \vec{p}^* - \beta\vec{1})|^2 dx \le \liminf_{c\to\infty} \int_\Omega |\max(0, \vec{p}_c - \beta\vec{1})|^2 dx = 0.$$

Consequently, $\vec{p}^* \le \beta\vec{1}$, and analogously one verifies that $-\beta\vec{1} \le \vec{p}^*$. In particular, $\vec{p}^*$ is feasible, and from (3.10) we conclude that

$$\langle \vec{\lambda}_c, \vec{p}^* - \vec{p}_c \rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})} \le 0 \quad \text{for all } c > 0. \tag{3.13}$$

By optimality of $\vec{p}_c$ for (3.1) we have

$$\limsup_{c\to\infty} \left(\frac{1}{2} |\operatorname{div} \vec{p}_c + \mathrm{K}^* f|_B^2 + \frac{\gamma}{2} |\mathrm{P}_{\mathrm{div}} \vec{p}_c|^2 \right) \le \frac{1}{2} |\operatorname{div} \vec{p} + \mathrm{K}^* f|_B^2 + \frac{\gamma}{2} |\mathrm{P}_{\mathrm{div}} \vec{p}\,|^2 \tag{3.14}$$

for all $\vec{p} \in S_2 = \{\vec{p} \in (C_0^1(\Omega))^2 : -\beta\vec{1} \le \vec{p} \le \beta\vec{1}\}$. Density of S_2 in $S_1 = \{\vec{p} \in H_0(\mathrm{div}) : -\beta\vec{1} \le \vec{p} \le \beta\vec{1}\}$ in the norm of $H_0(\mathrm{div})$ implies that (3.14) holds for all $\vec{p} \in S_1$ and consequently

$$\begin{aligned} \limsup_{c\to\infty} \left(\frac{1}{2} |\operatorname{div} \vec{p}_c + \mathrm{K}^* f|_B^2 + \frac{\gamma}{2} |\mathrm{P}_{\mathrm{div}} \vec{p}_c|^2 \right) &\le \frac{1}{2} |\operatorname{div} \vec{p}^* + \mathrm{K}^* f|_B^2 + \frac{\gamma}{2} |\mathrm{P}_{\mathrm{div}} \vec{p}^*|^2 \\ &\le \liminf_{c\to\infty} \left(\frac{1}{2} |\operatorname{div} \vec{p}_c + \mathrm{K}^* f|_B^2 + \frac{\gamma}{2} |\mathrm{P}_{\mathrm{div}} \vec{p}_c|^2 \right), \end{aligned}$$

where for the last inequality weak lower semicontinuity of norms is used. The above inequalities together with weak convergence of $\vec{p}_c$ to $\vec{p}^*$ in $H_0(\mathrm{div})$ imply strong convergence of $\vec{p}_c$ to $\vec{p}^*$ in $H_0(\mathrm{div})$. Finally we aim at passing to the limit in (3.13). This is impeded by the fact that we only established $\vec{\lambda}_c \rightharpoonup \vec{\lambda}^*$ in $\mathbb{H}_0^1(\Omega)^*$. Note from (3.2) that $\{-\frac{1}{c}\Delta\vec{p}_c + \vec{\lambda}_c\}_{c\ge 1}$ is bounded in $H_0(\mathrm{div})$. Hence there exists $\vec{\mu}^* \in H_0(\mathrm{div})^*$ such that

$$-\frac{1}{c}\Delta\vec{p}_c + \vec{\lambda}_c \rightharpoonup \vec{\mu}^* \quad \text{weakly in } H_0(\mathrm{div})^*,$$

and consequently also in $\mathbb{H}_0^1(\Omega)^*$. Moreover, $\{\frac{1}{\sqrt{c}}|\nabla\vec{p}_c|\}_{c\ge 1}$ is bounded and hence

$$-\frac{1}{c}\Delta\vec{p}_c \rightharpoonup 0 \quad \text{weakly in } \mathbb{H}_0^1(\Omega)^*$$

as $c \to \infty$. Since $\vec{\lambda}_c \rightharpoonup \vec{\lambda}^*$ weakly in $\mathbb{H}_0^1(\Omega)^*$, it follows that

$$\langle \vec{\lambda}^* - \vec{\mu}^*, \vec{v} \rangle_{\mathbb{H}_0^1(\Omega)^*, \mathbb{H}_0^1(\Omega)} = 0 \quad \text{for all } \vec{v} \in \mathbb{H}_0^1(\Omega).$$

Since both $\vec{\lambda}^*$ and $\vec{\mu}^*$ are elements of $H_0(\mathrm{div})^*$ and since $\mathbb{H}_0^1(\Omega)$ is dense in $H_0(\mathrm{div})$, it follows that $\vec{\lambda}^* = \vec{\mu}^*$ in $H_0(\mathrm{div})^*$. For $\vec{p} \in S_2$ we have

$$\begin{aligned} \langle \vec{\lambda}^*, \vec{p} - \vec{p}^* \rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})} &= \langle \mu^*, \vec{p} - \vec{p}^* \rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})} \\ &= \lim_{c\to\infty} \left\langle -\frac{1}{c}\Delta\vec{p}_c + \vec{\lambda}_c, \vec{p} - \vec{p}_c \right\rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})} \\ &= \lim_{c\to\infty} \left(\frac{1}{c}(\nabla\vec{p}_c, \nabla(\vec{p} - \vec{p}_c)) + (\vec{\lambda}_c, \vec{p} - \vec{p}_c) \right) \\ &\le \lim_{c\to\infty} \left(\frac{1}{c}(\nabla\vec{p}_c, \nabla\vec{p}) + (\vec{\lambda}_c, \vec{p} - \vec{p}_c) \right) \le 0 \end{aligned}$$

by (3.10) and (3.11). Since S_2 is dense in S_1, we find

$$\langle \vec{\lambda}^*, \vec{p} - \vec{p}^* \rangle_{H_0(\mathrm{div})^*, H_0(\mathrm{div})} \leq 0 \quad \text{for all } \vec{p} \in S_1. \qquad \square$$

The problem formulation (3.1) contains two limiting processes: the $\mathbb{H}_0^1(\Omega)$ smoothing, which will be used to guarantee superlinear convergence of semismooth Newton methods applied to the first order optimality conditions (3.2) of (3.1) in function spaces (see section 4), and a penalization of the constraints $-\beta\vec{1} \leq \vec{p} \leq \beta\vec{1}$ resulting in the max- and min-terms. There is no need to utilize the same parameter c for both limiting processes. Rather, if $\frac{1}{2c}|\nabla\vec{p}|^2$ is replaced by $\frac{1}{2\bar{c}}|\nabla\vec{p}|^2$, then $(\vec{p}_{\bar{c},c}, \vec{\lambda}_{\bar{c},c})$ converges to $(\vec{p}^*, \vec{\lambda}^*)$ weakly in $H_0(\mathrm{div}) \times \mathbb{H}_0^1(\Omega)^*$, where $(\vec{p}_{\bar{c},c}, \vec{\lambda}_{\bar{c},c})$ denotes the solution of (3.2) with $\frac{1}{c}\Delta\vec{p}_c$ replaced by $\frac{1}{\bar{c}}\Delta\vec{p}_{\bar{c},c}$, as $c \to \infty$ and $\bar{c} \to \infty$.

4. Semismooth Newton methods. Here we shall describe two algorithms, one for a discretized form of (2.2) and another one for (3.1). Both algorithms are locally superlinearly convergent.

First we consider the unregularized problem (2.2). After discretization it is of the form

$$\begin{cases} \min \quad \dfrac{1}{2}|A_1 p + \tilde{f}|^2 + \dfrac{\gamma}{2}|A_2 p|^2 \\ \text{s.t.} \quad -\beta\mathbf{1} \leq p \leq \beta\mathbf{1}, \end{cases} \tag{4.1}$$

where $p \in \mathbb{R}^m$, for some $m \in \mathbb{N}$ with coordinates p_i. Further, A_1, A_2 are $m \times m$-matrices, $\tilde{f} \in \mathbb{R}^m$, and $\mathbf{1} \in \mathbb{R}^m$ denotes the vector with all entries equal to 1. We assume that $\ker A_1 \cap \ker A_2 = 0$. The optimality condition for (4.1) is given by

$$\begin{aligned} &A_1^T A_1 p + \gamma A_2^T A_2 p + A_1^T \tilde{f} + \lambda = 0, \\ &\lambda = \max(0, \lambda + c(p - \beta\mathbf{1})) + \min(0, \lambda + c(p + \beta\mathbf{1})), \end{aligned} \tag{4.2}$$

where $c > 0$ is arbitrary and fixed. The primal-dual active set strategy, or equivalently the semismooth Newton algorithm applied to (4.2), is specified next.

ALGORITHM A.

(1) *Choose* $p_0, \lambda_0 \in \mathbb{R}^m$ *and set* $k = 0$.

(2) *Define*

$$\begin{aligned} \mathcal{A}_{k+1}^+ &= \{i : (\lambda_k + c(p_k - \beta\mathbf{1}))_i > 0\}, \\ \mathcal{A}_{k+1}^- &= \{i : (\lambda_k + c(p_k + \beta\mathbf{1}))_i < 0\}, \\ \mathcal{I}_{k+1}^i &= \{i : i \notin \mathcal{A}_{k+1}^\pm\}. \end{aligned}$$

(3) *Solve for* p_{k+1}, λ_{k+1}

$$\begin{aligned} &A_1^T A_1 p_{k+1} + \gamma A_2^T A_2 p_{k+1} + A_1^T \tilde{f} + \lambda_{k+1} = 0, \\ &(\lambda_{k+1})_i = 0 \text{ for } i \in \mathcal{I}_{k+1}, \\ &(p_{k+1})_i = \beta \text{ for } i \in \mathcal{A}_{k+1}^+, \quad (p_{k+1})_i = -\beta \text{ for } i \in \mathcal{A}_{k+1}^-. \end{aligned}$$

(4) *Stop, or set* $k = k + 1$ *and go to* (2).

This algorithm can be obtained by applying a formal Newton step to (4.2), choosing as generalized derivative for the function $s \mapsto \max(0, s)$ the value 1 if $s \geq 0$ and 0 if $s < 0$, and making an analogous choice for $s \mapsto \min(0, s)$.

For the following result we suppose that, given p_0, the first equation in (4.2) is used to compute λ_0. Then we have the following result.

THEOREM 4.1. *If $|p_0 - p^*|_{\mathbb{R}^m}$ is sufficiently small, then the iterates $\{(p_k, \lambda_k)\}_{k=1}^{\infty}$ of Algorithm A converge superlinearly to the solution (p^*, λ^*) of* (4.2).

The result can be verified by standard techniques from semismooth Newton methods; see, e.g., [17]. We do not enter into the details here but rather for Algorithm B below, where they are more involved.

We turn to the algorithmic treatment of the infinite-dimensional problem (3.1), for which we propose the following algorithm.

ALGORITHM B.

(1) *Choose $\vec{p}_0 \in \mathbb{H}_0^1(\Omega)$ and set $k = 0$.*

(2) *Set, for $i = 1, 2$,*

$$\begin{aligned} \mathcal{A}_{k+1}^{+,i} &= \{x : (\vec{p}_k^{\,i} - \beta\vec{1})(x) > 0\}, \\ \mathcal{A}_{k+1}^{-,i} &= \{x : (\vec{p}_k^{\,i} + \beta\vec{1})(x) < 0\}, \\ \mathcal{I}_{k+1}^{i} &= \Omega \setminus (\mathcal{A}_{k+1}^{+,i} \cup \mathcal{A}_{k+1}^{-,i}). \end{aligned}$$

(3) *Solve for $\vec{p} \in \mathbb{H}_0^1(\Omega)$ and set $\vec{p}_{k+1} = \vec{p}$, where*

$$\begin{aligned} \frac{1}{c}(\nabla\vec{p}, \nabla\vec{v}\,) + (\operatorname{div}\vec{p}, \operatorname{div}\vec{v}\,)_B + (\mathrm{K}^* f, \operatorname{div}\vec{v}\,)_B + \gamma(\mathrm{P}_{\mathrm{div}}\vec{p}, \mathrm{P}_{\mathrm{div}}\vec{v}\,) \\ + (c(\vec{p} - \beta\vec{1}\,)\chi_{\mathcal{A}_{k+1}^{+}}, \vec{v}\,) + (c(\vec{p} + \beta\vec{1}\,)\chi_{\mathcal{A}_{k+1}^{-}}, \vec{v}\,) = 0 \end{aligned} \tag{4.3}$$

for all $\vec{v} \in \mathbb{H}_0^1(\Omega)$.

(4) *Set*

$$\vec{\lambda}_{k+1}^{i} = \begin{cases} 0 & \text{on } \mathcal{I}_{k+1}^{i}, \\ c(\vec{p}_{k+1}^{\,i} - \beta\vec{1}) & \text{on } \mathcal{A}_{k+1}^{+,i}, \\ c(\vec{p}_{k+1}^{\,i} + \beta\vec{1}) & \text{on } \mathcal{A}_{k+1}^{-,i}, \end{cases}$$

for $i = 1, 2$.

(5) *Stop, or set $k = k + 1$ and go to* (2).

In the above, $\chi_{\mathcal{A}_{k+1}^{+}}$ stands for

$$\chi_{\mathcal{A}_{k+1}^{+}}^{i} = \begin{cases} 1 & \text{if } x \in \mathcal{A}_{k+1}^{+,i}, \\ 0 & \text{if } x \notin \mathcal{A}_{k+1}^{+,i}, \end{cases}$$

and analogously for $\mathcal{A}_{k+1}^{-}$. The superscript i, $i = 1, 2$, refers to the respective component. We note that (4.3) admits a solution $\vec{p}_{k+1} \in \mathbb{H}_0^1(\Omega)$. Step (4) is included for the sake of the analysis of the algorithm. Let $C : \mathbb{H}_0^1(\Omega) \to H^{-1}(\Omega) \times H^{-1}(\Omega)$ stand for the operator

$$C = -\frac{1}{c}\Delta - \nabla B^{-1} \operatorname{div} + \gamma \mathrm{P}_{\mathrm{div}}.$$

It is a homeomorphism for every $c > 0$ and allows us to express (3.2) as

$$C\vec{p} - \nabla B^{-1}\mathrm{K}^* f + c\max(0, \vec{p} - \beta\vec{1}) + c\min(0, \vec{p} + \beta\vec{1}) = 0, \tag{4.4}$$

where we drop the index in the notation for $\vec{p}_c$. For $\varphi \in \mathrm{L}^2(\Omega)$ we define

$$\mathrm{Dmax}(0,\varphi)(x) = \begin{cases} 1 & \text{if } \varphi(x) > 0, \\ 0 & \text{if } \varphi(x) \le 0, \end{cases} \tag{4.5}$$

and

$$\mathrm{Dmin}(0,\varphi)(x) = \begin{cases} 1 & \text{if } \varphi(x) < 0, \\ 0 & \text{if } \varphi(x) \ge 0. \end{cases} \tag{4.6}$$

These operators define semismooth derivatives; see, e.g., [22] for the finite-dimensional case and [17, 24] for the infinite dimensions. Using (4.5), (4.6) as generalized derivatives for the max and the min operations in (4.4), the semismooth Newton step can be expressed as

$$C\vec{p}_{k+1} + c(\vec{p}_{k+1} - \beta\vec{1})\chi_{\mathcal{A}^+_{k+1}} + c(\vec{p}_{k+1} + \beta\vec{1})\chi_{\mathcal{A}^-_{k+1}} - \nabla B^{-1}\mathrm{K}^* f = 0, \tag{4.7}$$

and $\vec{\lambda}_{k+1}$ from step (4) of Algorithm B is given by

$$\vec{\lambda}_{k+1} = c(\vec{p}_{k+1} - \beta\vec{1})\chi_{\mathcal{A}^+_{k+1}} + c(\vec{p}_{k+1} + \beta\vec{1})\chi_{\mathcal{A}^-_{k+1}}. \tag{4.8}$$

The iteration of Algorithm B can also be expressed with respect to the variable $\vec{\lambda}$ rather than $\vec{p}$. For this purpose we define

$$F(\vec{\lambda}) = \vec{\lambda} - c\max(0, C^{-1}(\nabla\hat{f} - \vec{\lambda}) - \beta\vec{1}) - c\min(0, C^{-1}(\nabla\hat{f} - \vec{\lambda}) + \beta\vec{1}), \tag{4.9}$$

where we put $\hat{f} = B^{-1}\mathrm{K}^* f$. Setting $\vec{p}_k = C^{-1}(\nabla\hat{f} - \vec{\lambda}_k)$, the semismooth Newton step applied to $F(\vec{\lambda}) = 0$ at $\vec{\lambda} = \vec{\lambda}_k$ results in

$$\vec{\lambda}_{k+1} = c(C^{-1}(\nabla\hat{f} - \vec{\lambda}_{k+1}) - \beta\vec{1})\chi_{\mathcal{A}^+_{k+1}} + c(C^{-1}(\nabla\hat{f} - \vec{\lambda}_{k+1}) + \beta\vec{1})\chi_{\mathcal{A}^-_{k+1}},$$

which coincides with (4.8). Therefore the semismooth Newton iterations according to Algorithm B and for $F(\vec{\lambda}) = 0$ coincide, provided that the initializations are related by $C\vec{p}_0 - \nabla\hat{f} + \vec{\lambda}_0 = 0$. The mapping F is slantly differentiable; i.e., for every $\vec{\lambda} \in \mathbb{L}^2(\Omega)$

$$|F(\vec{\lambda} + \vec{h}) - F(\vec{\lambda}) - DF(\vec{\lambda} + \vec{h})h|_{\mathbb{L}^2(\Omega)} = o(|\vec{h}|_{\mathbb{L}^2(\Omega)}) \tag{4.10}$$

for $|\vec{h}|_{\mathbb{L}^2(\Omega)} \to 0$ (see [17]). Here D denotes the derivative of F defined by means of (4.5) and (4.6). For (4.10) to hold the smoothing property of C^{-1} in the sense of an embedding from $\mathbb{L}^2(\Omega)$ into $\mathbb{L}^p(\Omega)$ for some $p > 2$ is essential. The following result now follows from standard arguments.

THEOREM 4.2. *If $|\vec{\lambda}_c - \vec{\lambda}_0|_{\mathbb{L}^2(\Omega)}$ is sufficiently small, then the iterates $\{(\vec{p}_k, \vec{\lambda}_k)\}_{k=1}^{\infty}$ of Algorithm B converge superlinearly in $\mathbb{H}^1_0(\Omega) \times \mathbb{L}^2(\Omega)$ to the solution $(\vec{p}_c, \vec{\lambda}_c)$ of* (3.1).

5. Discretization and numerical examples. We report now on numerical results attained by Algorithms A and B. In the examples below we choose $K = \mathrm{I}$ and $\alpha = 0$ for image denoising. We also include results for image zooming; see, e.g., [20] for a general description. In this case, we use given data f which correspond to a coarse (low-pixel–based) approximation of a given image. Then the aim is to

reconstruct the original image at the original pixel-scale. As a consequence, $K \neq \mathrm{I}$ with $\ker(K)$ typically nontrivial, which requires us to choose $\alpha > 0$.

In our tests, for the div-operator we use backward differences with quadratic extrapolation on the left boundary for Algorithm B. For Algorithm A we use symmetric differences with quadratic extrapolation on the boundary, where A_1 denotes the discretized divergence operator. The discrete grad $-$ div-operator is taken as $A_1^T A_1$. For Algorithm B we need the discrete Laplacian with homogeneous Dirichlet boundary conditions. We use the standard five-point stencil for its discretization. The projection $P_{\mathrm{div}}\vec{p}$ is obtained by solving a Neumann problem as stated at the end of section 1. Again we use the five-point stencil for discretizing the Laplace operator with symmetric differences for the discretization of the Neumann boundary condition.

To investigate possible ill-conditioning due to the parameter c appearing in Algorithm B we also tested a first order augmented Lagrangian variant of Algorithm B. To specify the algorithm we define

$$L(\vec{p},\vec{\lambda}) = \frac{1}{2\bar{c}}|\nabla\vec{p}\,|^2 + \frac{1}{2}|\operatorname{div}\vec{p} + \mathrm{K}^* f|_B^2 + \tfrac{\gamma}{2}|\mathrm{P}_{\mathrm{div}}\vec{p}\,|^2 + \phi_c(\vec{p},\vec{\lambda}),$$

where ϕ_c is the generalized Moreau–Yosida regularization of the indicator function ϕ of the set $\{\vec{p} \in \mathbb{L}^2(\Omega) : -\beta\vec{1} \le \vec{p} \le \beta\vec{1}\}$. We have

$$\phi_c(\vec{p},\vec{\lambda}) = \inf_{\vec{q}\in\mathbb{L}^2(\Omega)} \phi(\vec{p}-\vec{q}\,) + (\vec{\lambda},\vec{q}\,)_{\mathbb{L}^2(\Omega)} + \frac{c}{2}|\vec{q}\,|^2_{\mathbb{L}^2(\Omega)}$$

for $c > 0$ and $\vec{\lambda} \in \mathbb{L}^2(\Omega)$. Some simple manipulations result in

$$\begin{aligned}\phi_c(\vec{p},\vec{\lambda}) = \frac{1}{2c}\big|\max\big(0,\vec{\lambda}+c(\vec{p}-\beta\vec{1})\big)\big|^2_{\mathbb{L}^2(\Omega)} \\ + \frac{1}{2c}\big|\min\big(0,\vec{\lambda}+c(\vec{p}+\beta\vec{1})\big)\big|^2_{\mathbb{L}^2(\Omega)} - \frac{1}{2c}|\vec{\lambda}|^2_{\mathbb{L}^2(\Omega)}.\end{aligned}$$

Augmented Lagrangian Method (ALM).

(1) *Choose* $\vec{\lambda}_0 \in \mathbb{L}^2(\Omega)$, $c > 0$, *and* $n = 0$.

(2) *Given* $\vec{\lambda}_n \in \mathbb{L}^2(\Omega)$, *determine*

$$\vec{p}_n = \operatorname{argmin}\{L(\vec{p},\vec{\lambda}_n) : \vec{p} \in \mathbb{L}^2(\Omega)\}.$$

(3) *Update* $\vec{\lambda}_n$ *by* $\vec{\lambda}_{n+1} = \phi_c'(\vec{p}_n,\vec{\lambda}_n)$.

(4) *If convergence is not achieved, set* $n = n+1$ *and go to step* (2).

In step (3) we have

$$\phi_c'(\vec{p},\vec{\lambda}) = \max\big(0,\vec{\lambda}+c(\vec{p}-\beta\vec{1})\big) + \min\big(0,\vec{\lambda}+c(\vec{p}+\beta\vec{1})\big).$$

Note that the auxiliary problems in step (2) of ALM coincide with (3.1) except for the shift by $\vec{\lambda}_n$ in the max/min operations. In our numerical tests below we typically choose $\bar{c} = c$.

The algorithms in sections 3 and 4 are stated in terms of exact system solutions. Our numerical implementation utilizes inexact Newton techniques to underscore the feasibility of the proposed methods for large scale problems. In order to describe our approach let r_k denote the residual of the respective system, i.e., (4.2) for Algorithm A and (4.3) for Algorithm B. We resolve the respective system with the preconditioned conjugate gradient method (CG-method). The preconditioner involves the (vector)

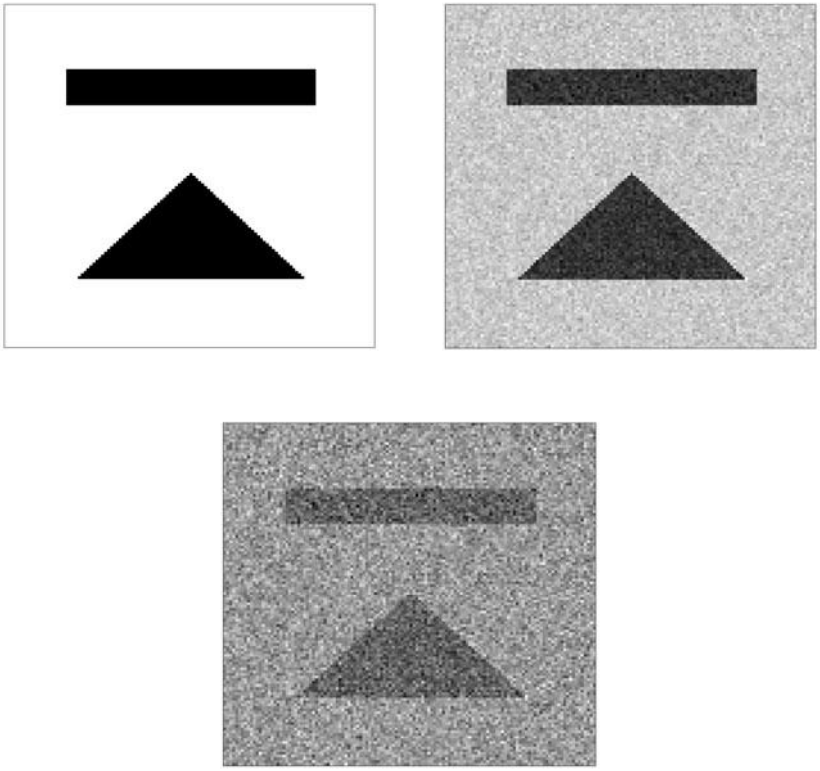

FIG. 1. *Upper left: original image (*128×128 *pixel). Upper right: noisy image with* 10% *noise. Lower: noisy image with* 50% *noise.*

Laplacian and, for Algorithm B, the terms involving the indicator functions of $\mathcal{A}^{\pm}_{k+1}$. The stopping tolerance for the CG-method in iteration $k+1$ is given by

$$\text{tol}_{k+1} = 0.1 \min(r_k^{1.25}, r_k).$$

This choice is motivated by the locally superlinear convergence rate of our algorithms.

Example 1. The test images for our first image denoising example are displayed in Figure 1. The upper left image is the original image, which is similar to the one in [8]. It has a dynamic range of $[0, 255]$. The other two images contain Gaussian white noise. The upper right one has 10% noise, and the remaining image contains 50% noise; i.e., we add Gaussian noise with standard deviation of 25.5 and 127.5, respectively. In the subsequent tables we denote by #as the total number of active set iterations, by #cg the total number of CG-iterations, and by #alm the total number of iterations updating $\vec{\lambda}_n$ for ALM. We stopped each algorithm as soon as the discrete L_2-norm of the residual dropped below `tol`$= \sqrt{\epsilon_M}$, with ϵ_M the machine precision, or when the difference between two successive residuals was smaller than `tol`, i.e., no further progress was observed.

Let us first report on the results obtained for denoising the image with 10% noise. For all algorithms we choose $c = 1E4$. However, let us note that Algorithm A does not require large c since c is not linked to a regularization term. Rather it is a parameter associated with the reformulation of the complementarity system induced by the box

TABLE 5.1

constraints. Further, for all three algorithms we chose $\beta = 0.2$, $\gamma = 0$ for ALM and Algorithm B, and $\gamma = 1E\text{-}3$ for Algorithm A. In general, for ALM and Algorithm B, γ had no noticeable effect on the results attained. However, Algorithm A is more sensitive to γ. This can be attributed to the fact that the system matrix in Algorithm A is singular for $\gamma = 0$. In Table 5.1 we report on the iteration numbers for the respective algorithms.

We note that Algorithm B requires the least number of AS-iterations. For ALM we point out that we initialized it with $\vec{\lambda}_0 \equiv 0$; then, typically, 8–10 AS-iterations were required in the first ALM-iteration. The subsequent ALM-iterations needed 2–3 AS-iterations.

In Figure 2 we display the reconstructions. The upper left and right correspond to Algorithms A and B. The lower image is the result obtained by Algorithm ALM. The quality of the reconstructions is equally good for all algorithms.

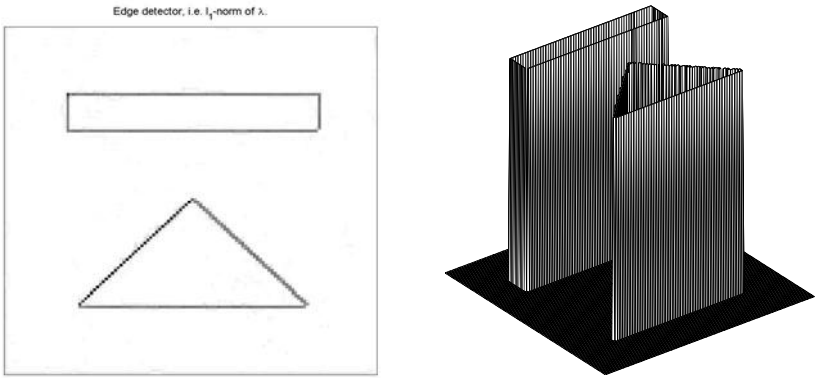

FIG. 3. *Left: Lagrange multiplier of Algorithm B. Right: corresponding edge detector.*

Results for 50% *noise.*

Algorithm	#as	#cg	#alm
Algorithm A	15	59	-
Algorithm B	7	18	-
ALM	13	33	3

In the introduction we mentioned that the Lagrange multiplier associated with the box constraints serves as an edge detector. Figure 3 shows the ℓ_1-norm of the multiplier attained by Algorithm B and a resulting edge detector. The edge detector is obtained from a simple thresholding technique. In fact, as a threshold we took c and computed the edge detector λ_e as

$$\lambda_e(x_i) = \begin{cases} 1 & \text{if } |\vec{\lambda}^*(x_i)|_{\ell_1} \geq c, \\ 0 & \text{otherwise.} \end{cases}$$

In the above, x_i denotes the ith pixel of the image, and $\vec{\lambda}^*$ the multiplier upon termination of B. For the multipliers resulting from Algorithms A and ALM a similar observation holds true.

Now we turn to the results for the image containing 50% noise. The parameters had the values $c = 1E4$, $\beta = 0.9$, and $\gamma = 0$ for ALM and Algorithm B, and $c = 1E4$, $\beta = 0.75$, $\gamma = 1E$-3 for Algorithm A. Figure 4 shows the reconstructions obtained from our algorithms. As in the previous test case, the quality of the results for Algorithms B and ALM is comparable. Algorithm A appears to be slightly more sensitive to noise. This behavior could not be ruled out by tuning the parameters c, γ, and β. The iteration numbers are reported on in Table 5.2. As can be seen from these results, the number of iterations of the respective algorithm is rather stable with respect to the noise level.

In Figure 5 we display the ℓ_1-norm of the multiplier $\vec{\lambda}^*$ upon termination of Algorithm B. The related edge detector, which is obtained in the same way as explained previously, is given in the right image of Figure 5. We conclude that—without any thresholding—the Lagrange multiplier may act as an edge detector.

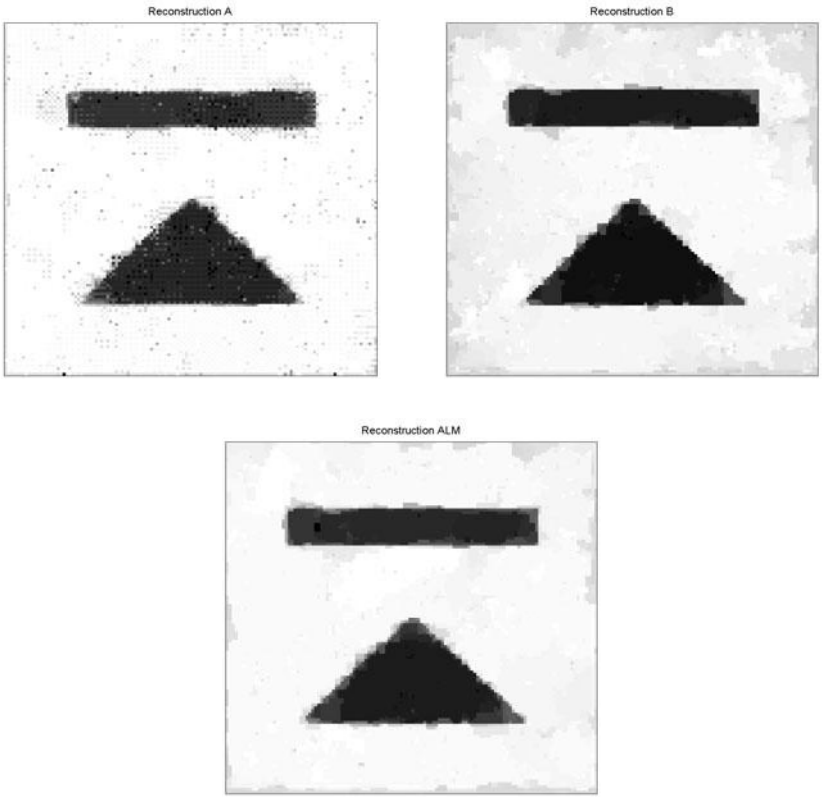

FIG. 4. *Upper left: result of Algorithm A. Upper right: result of Algorithm B. Lower: result of ALM.*

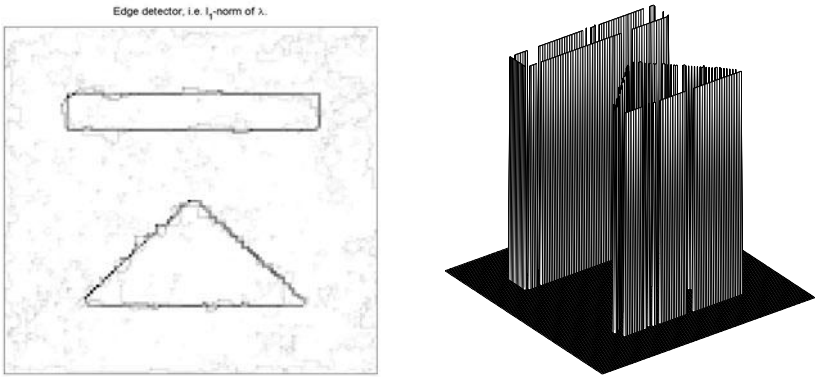

FIG. 5. *Left: Lagrange multiplier of Algorithm B. Right: corresponding edge detector.*

Let us briefly comment on the difference of stability with respect to β of Algorithms A and B compared to ALM. In general the choice of β influences the quality of the reconstruction. A large value for β decreases the number of active pixels, i.e., pixels at which $\vec{p}^*$ hits either the upper or the lower bound. As a consequence, details of the image are missed in the reconstruction. The right image in Figure 6 corresponds to the result attained by Algorithm B with $\beta = 1.5$ (compared to $\beta = 1.25$ in the

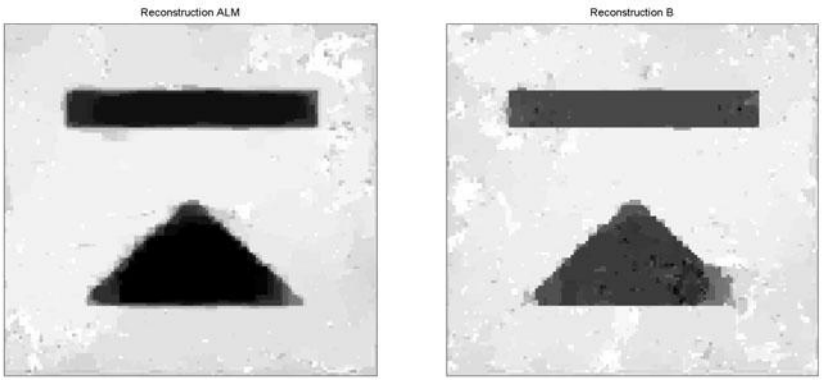

FIG. 6. *Reconstruction for $\beta = 1.5$. Left: ALM. Right: Algorithm B.*

TABLE 5.3
Convergence behavior of the residual.

#as	4.67E6	1.5E-1	9.6E-4	6.2E-7	1.8E-8	9.15E-9

previous run). Due to the larger β-value, the quality of the reconstruction degrades in the sense that details are missed, e.g., at the corners of the triangle. On the other hand, the left image in Figure 6 shows the result for ALM with $\beta = 1.5$.

Obviously the reconstruction is superior to the one obtained from Algorithm B. This reflects a general observation from our test runs, i.e., ALM is more stable with respect to the choice of β. The behavior of Algorithm A with respect to changes in β is comparable to that of Algorithm B.

Let us discuss the convergence behavior of our algorithms in terms of reductions of the residuals. From the results reported in Tables 5.1 and 5.2 we find that our algorithms require a rather small number of iterations which are even stable with respect to different noise levels. In Table 5.3 we show the behavior of the residual for Algorithm B for 50% noise, indicating a fast convergence. This fast convergence is also true for the numerical resolution of the auxiliary problem of ALM. A similar convergence behavior is obtained for Algorithm A. For smaller values of β the iterates converge superlinearly. Small values of β, however, imply a deterioration of the reconstruction. Here the ill-posedness in the problem becomes evident.

In [8] an inexact Newton method for solving a primal-dual formulation of the Euler–Lagrange equations associated with a regularized TV-based image reconstruction problem is proposed. The test problem in [8] involves the same geometry as in our test example. In Figure 7 (upper left plot) we show the noisy image containing Gaussian white noise with variance $\sigma^2 \approx 1200$, which gives a signal-to-noise ratio of approximately 1. This parallels the test setting in [8]. We also made an effort to adjust the stopping rule of Algorithm B for the comparison with the algorithm in [8]. Algorithm B requires nine iterations for obtaining the denoised image in the upper right plot of Figure 7. The algorithm in [8] with a line search and a continuation strategy with respect to δ in the regularization of the TV-seminorm of the type (1.2) is reported to need 12 iterations. The size of the systems which have to be solved per iteration in both algorithms is comparable. The edged detector, based on the ℓ_1-norm of $\vec{\lambda}$ upon termination of Algorithm B, is given in the last subplot of Figure 7.

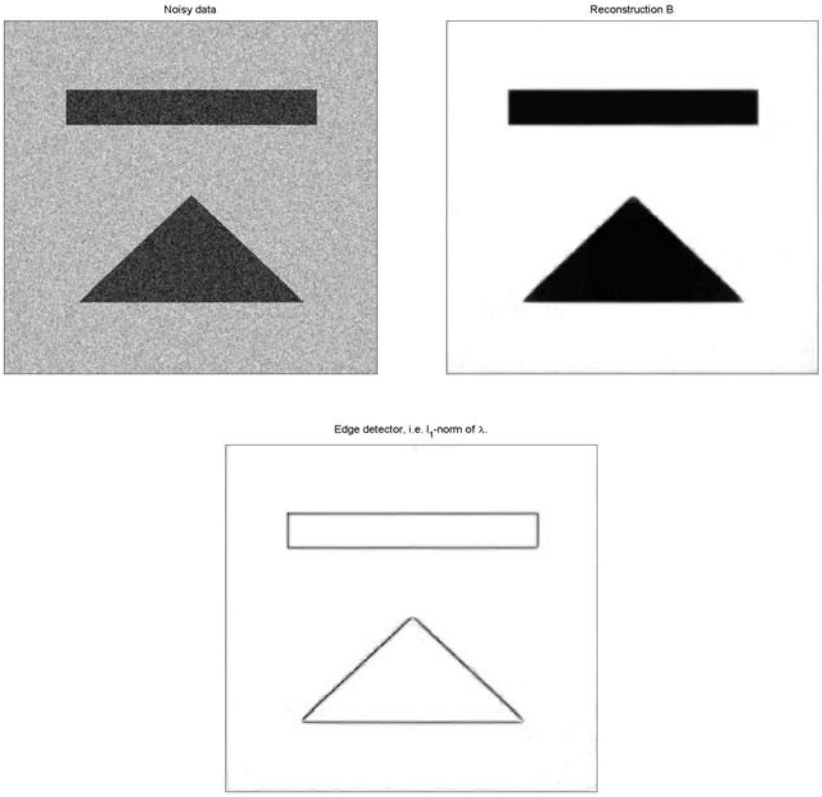

FIG. 7. *Upper left: noisy image (*256×256 *pixel). Upper right: result of Algorithm B. Lower:* ℓ_1*-norm of* $\vec{\lambda}$.

Example 2. Now we report on the behavior of Algorithm B for the benchmark problem in Figure 8. The upper left plot shows the original image. The upper right image contains 7.5% Gaussian white noise. The parameters had the values $c = 1E4$, $\gamma = 0$, and $\beta = 0.15$. The algorithm stopped after nine AS-iterations (31 CG-iterations total) with a residual of 6.2E-9. The corresponding reconstruction is given in the lower left plot of Figure 8. The lower right plot displays the ℓ_1-norm of the Lagrange multiplier associated with the box constraints. As in the previous examples, it behaves like an edge detector.

Example 3. We conclude our numerical section with the results obtained by Algorithm B for an image zooming/resizing problem. In this case, we have $K \neq \mathrm{I}$. The data f correspond to a *coarse* version of the original image satisfying $f_{2i-1,2j-1} = f_{2i,2j-1} = f_{2i-1,2j} = f_{2i,2j}$. For an arbitrary 256×256-pixel image u the application $v = Ku$ is related to a 128×128-pixel version $\tilde{v}$ of the image with $\tilde{v}_{i,j} = u_{2i-1,2j-1}$ and $v_{2i-1,2j-1} = v_{2i,2j-1} = v_{2i-1,2j} = v_{2i,2j} = \tilde{v}_{i,j}$. For more details on image zooming involving more advance operators K, we refer to [20]. Our aim is to use Algorithm B for reconstructing the fine image u from the given coarse image f. Since K has a nontrivial kernel, we choose $\alpha = 1\text{E-}10$. Further, we pick the parameter values $c = 1\text{E}5$, $\beta = 0.35$, and $\gamma = 0$. In Figure 9 we display the original image in the upper left plot. The result after 16 iterations of Algorithm B is shown in the upper right plot. The lower left plot shows the 128×128-pixel version expanded by a factor of 2, and

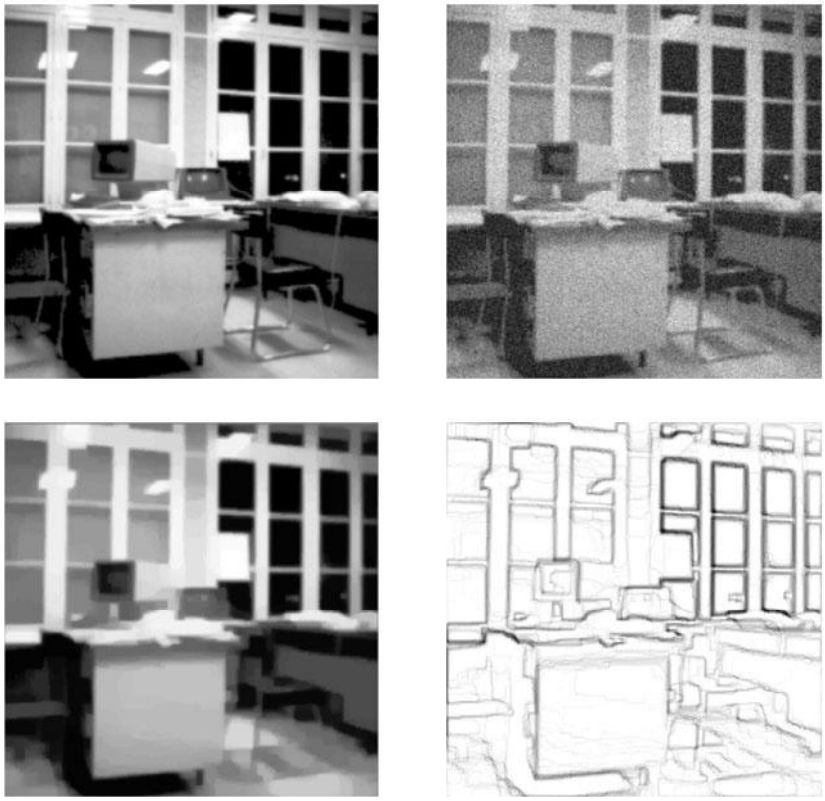

FIG. 8. *Upper left: exact data (*256×256 *pixel). Upper right: noisy data. Lower left: reconstruction obtained by Algorithm B. Lower right:* ℓ_1*-norm of the Lagrange multiplier.*

the lower right plot provides the result obtained by a nearest neighbor interpolation. Observe that the reconstructions differ quite noticeably along the boundaries of the person's left arm, for example.

6. Conclusions. The efficient numerical treatment of BV-regularization–based image restoration poses many challenges in theory as well as in the design of algorithms. In this paper we first establish the relationship between the primal problem in the nonreflexive Banach space BV and its predual which is posed in the Hilbert space $H_0(\mathrm{div})$. This analytical result appears to be of interest in its own right. We then introduce and study two semismooth Newton methods for solving the Fenchel predual problem of the underlying BV-regularized minimization problem. By predualization we obtain a box constrained minimization problem which—from the numerical optimization point of view—has the advantage that we can rely on sophisticated minimization algorithms. The convergence analysis of our semismooth Newton methods in function spaces relies on a smoothing procedure. The regularizing effect of our smoothing results in a two-norm property which is required for arguing locally superlinear convergence of our semismooth Newton method in an L^2-setting. Without smoothing we obtain a locally superlinearly convergent method on the discrete level.

Acknowledgment. We would like to thank Prof. O. Scherzer, University of Innsbruck, Austria, for making us aware of the taut string algorithm discussed in Remark 1.

CONSTRUCTING MULTIPLY CONNECTED QUADRATURE DOMAINS*

DARREN CROWDY† AND JONATHAN MARSHALL†

Abstract. Multiply connected bounded quadrature domains, with finite connectivity, are reconstructed from their quadrature data using conformal mappings that are ratios of products of Schottky–Klein prime functions. This method provides the natural generalization of the conformal maps to simply and doubly connected quadrature domains constructed by the first author in a number of physical applications. The efficacy of the method is demonstrated by the explicit construction of a range of examples as well as by comparison with alternative constructive methods recently introduced by Crowdy [*R. Soc. Lond. Proc. Ser. A Math. Phys. Eng. Sci.*, 457 (2001), pp. 2337–2359] and Richardson [*European J. Appl. Math.*, 12 (2001), pp. 571–599].

Key words. quadrature domains, multiply connected, conformal mapping

1. Introduction.

The mathematical theory of quadrature domains is well developed (e.g., [1], [2], [3], [4], [5], [6]). The simplest example of a quadrature domain is a circular disc. Let $z = x + iy$ and suppose that the disc is centered at the origin $z = 0$ with radius r. The well-known "mean value theorem" says that, if $h(z)$ is any function analytic in the disc D and integrable over it, then

$$\int\int_D h(z)dxdy = \pi r^2 h(0). \tag{1}$$

Equation (1) is a simple example of a *quadrature identity*. The idea of quadrature domain theory is to consider more complicated domains satisfying more complicated quadrature identities. Consider a planar domain D and let $h(z)$ be any function that is analytic in D and integrable over it. Suppose that

$$\int\int_D h(z)dxdy = \sum_{k=1}^{N}\sum_{j=0}^{n_k-1} c_{jk}h^{(j)}(z_k), \tag{2}$$

where $\{z_k \in \mathbb{C}\}$ is a set of points strictly inside D, $\{c_{jk} \in \mathbb{C}\}$, and $h^{(j)}(z)$ denotes the jth derivative of h. Here, N and $\{n_k \geq 1\}$ are integers. Then D is known as a *quadrature domain*. The quadrature identity (2) generalizes (1).

While quadrature domains are mathematically interesting in their own right, perhaps more remarkable is the fact that they are relevant to the mathematical study of a wide range of physical problems. An important early paper of Richardson [7] was the first to illustrate the connection with the study of the free boundary problem involving singularity-driven flows in a Hele–Shaw cell. Richardson's paper involved

†Department of Mathematics, Imperial College, 180 Queen's Gate, London, SW7 2AZ United Kingdom (d.crowdy@imperial.ac.uk, jonathan.marshall@imperial.ac.uk).

simply connected fluid domains. The essential result is that quadrature domains are preserved by the dynamics of the physical problem. Since then, quadrature domains have been found to be useful in a variety of different problems. For example, Entov, Etingof, and Kleinbock [8] have discussed a number of generalizations of the singularity-driven Hele–Shaw problem, including the dynamics of flows in a rotating Hele–Shaw cell and the problem of "squeeze flow" in a Hele–Shaw cell. Both problems also preserve quadrature domains [9], [10]. Crowdy [11] has pointed out the relevance of quadrature domains to a biharmonic-governed (as opposed to the harmonic-governed Hele–Shaw model) free boundary problem involving slow viscous flows driven by surface tension. Here, in certain circumstances, the dynamics is also such as to preserve quadrature domains. Outside the realm of free boundary problems, it has also been shown [12], [13] that quadrature domains have relevance to the study of multipolar vortical equilibria of the two-dimensional Euler equations governing the inviscid flow of an ideal fluid. The problem of finding equilibrium shapes of free boundaries involving irrotational Euler flows with surface tension (see, e.g., [14]) can also be interpreted in terms of quadrature domain theory.

This compendium of different physical applications suggests a need to be able to construct quadrature domains of various finite connectivities. Gustafsson [5] has shown that construction of an N-connected quadrature domain is equivalent to the construction of a conformal mapping, which is a meromorphic function on a Riemann surface of genus $N-1$. For $N=1$ and $N=2$, this is possible using the theory of rational functions and elliptic functions (or, equivalently, loxodromic functions, which are naturally related to elliptic functions [15]). Indeed, these two cases constitute most of the existing literature. Richardson used rational function conformal mappings in his original paper [7] and, more recently, elliptic function conformal mappings for singularity-driven Hele–Shaw flows of doubly connected fluid regions [16]. Crowdy [9] has used loxodromic functions to derive exact solutions for the evolution of doubly connected domains in a rotating Hele–Shaw cell, providing a mathematical model for some recent experimental results involving a fluid annulus [17]. Elliptic/loxodromic function theory has also been used to construct exact solutions to the problem of the surface tension–driven Stokes flow of doubly connected fluid regions [18], [19], [20].

For higher connectivities, the situation is much more challenging. The subject of constructing multiply connected quadrature domains (of connectivity greater than 2) has been the focus of much recent activity. Two new methods of construction have recently been proposed in the context of specific applications. The first author [13] has implemented a construction based on the fact that the boundaries of quadrature domains are algebraic curves. This method has been successfully applied, for example, to the construction of vortical equilibria of the Euler equations [13] and to the squeeze flow problem in a Hele–Shaw cell [10]. Meanwhile, in considering the related problem of singularity-driven flow of multiply connected fluid domains (with zero surface tension) in a Hele–Shaw cell, Richardson [23] has proposed a different method based on conformal mapping. In this paper we present a new method which, like Richardson's, is based on conformal maps. However, our approach is different. In light of all the recent work on this problem, we also discuss in detail how the new construction differs from other methods, and how it compares to them in terms of practical application.

To motivate the present work, we recall that it is a standard result [1] that simply connected quadrature domains can be constructed by rational function mappings from a unit ζ-disc to the domain. Any rational function with given zeros and poles can be written as a ratio of products of the fundamental function $P(\zeta)=1-\zeta$. For example,

if the conformal map has poles $\{\alpha_k | k = 1, \ldots, N\}$ and zeros $\{\beta_k | k = 1, \ldots, N\}$, it can be written

$$z(\zeta) = R \frac{\prod_{k=1}^{N} P(\zeta \beta_k^{-1})}{\prod_{k=1}^{N} P(\zeta \alpha_k^{-1})}, \tag{3}$$

where R is a constant. Furthermore, it is also known that a representation of a general conformal mapping (again with poles $\{\alpha_k | k = 1, \ldots, N\}$ and zeros $\{\beta_k | k = 1, \ldots, N\}$) from the annulus $\rho < |\zeta| < 1$ to a doubly connected quadrature domain can be written exactly as in (3) but with the fundamental function $P(\zeta, \rho)$ defined differently as

$$P(\zeta, \rho) = (1 - \zeta) \prod_{k=1}^{\infty} (1 - \rho^{2k} \zeta)(1 - \rho^{2k} \zeta^{-1}). \tag{4}$$

Note that when $\rho = 0$, (4) reduces to the function $P(\zeta) = (1 - \zeta)$ relevant for the construction of the rational functions in the simply connected case. In light of this, it is natural to ask whether the representation (3) can *also* be used for quadrature domains with connectivity greater than two but with suitably generalized "fundamental functions." This is the question addressed in this paper. The generalized "fundamental functions" needed are known as the Schottky–Klein prime functions [21].

The treatment in this paper is based on the presentation in Chapter 12 of a monograph by Baker [21]. Our aim here is to show how to apply these general results for the specific purpose of constructing multiply connected quadrature domains. For clarity, any general results needed are stated without proof and in modified form suited to present purposes. The interested reader is referred to [21] for more details.

Richardson's constructive method also employs the Schottky model and mappings from the circular domains used here, but his representation of the conformal maps is different. Richardson does not use, or define, the Schottky–Klein prime function. Instead, his conformal maps are constructed as ratios of Poincaré series—a method of constructing meromorphic functions on compact Riemann surfaces described, for example, by Beardon [22]. The present authors believe the new construction based on the Schottky–Klein prime function presented herein to be an important alternative to Richardson's method for two reasons. First, it is the natural generalization of the representation (4) used by Crowdy [20] and, moreover, it is closely related to a representation in terms of ratios of products of generalized theta functions defined on Riemann surfaces [21], [25]. Note that (4) *is* the Schottky–Klein prime function in the genus-1 case. Second, we have found the present method to be easier to implement than Richardson's method both conceptually and practically. The majority of the example domains in this paper have been constructed using both methods. In all cases considered, the boundaries of the domains are indistinguishable even at very low orders of truncation.

2. Quadrature domains. Let D denote a bounded $g+1$-connected quadrature domain. It is known [5] that the conformal mapping from a conformally equivalent region (in, say, a parametric ζ-plane) to D is given by a meromorphic function on a Riemann surface of genus g. This Riemann surface can be identified with the *Schottky double* of the region D [5]. These conformal mapping functions will be explicitly constructed here as ratios of products of Schottky–Klein prime functions [21]. Such functions are defined in section 4. In order to define them, it is necessary to introduce Schottky groups [22], [24]; these are discussed in section 3. In what follows, we first show how Schottky groups are relevant to multiply connected quadrature domains.

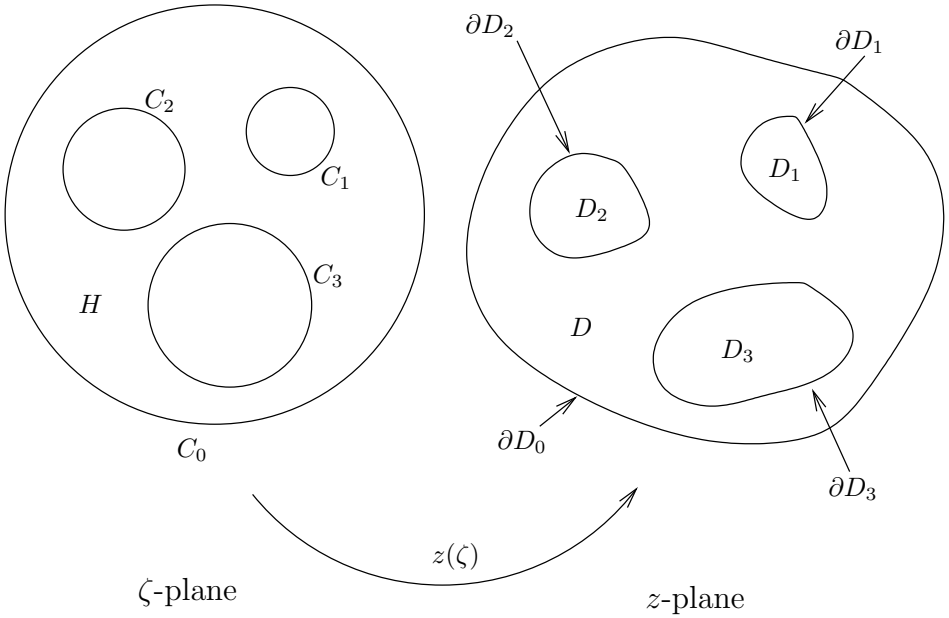

FIG. 1. *Schematic of conformal mapping from region H in the ζ-plane to region D in the physical z-plane.*

Consider the integral

$$\int\int_D h(z)d\bar{z}\wedge dz, \tag{5}$$

where $h(z)$ is analytic in D and $d\bar{z}\wedge dz = 2idxdy$ if $z = x + iy$. If D is a quadrature domain, then

$$\int\int_D h(z)d\bar{z}\wedge dz = \sum_{k=1}^{N}\sum_{j=0}^{N_k-1} c_{jk}h^{(j)}(z_k) \tag{6}$$

for some set of complex numbers $\{c_{jk}, z_k\}$, where the points $\{z_k\}$ are strictly inside D. $\{N_k \geq 1 | k = 1,\ldots,N\}$ are a set of integers, and $\sum_{k=1}^{N} N_k$ is known as the *order* of the quadrature identity. Using Green's theorem,

$$\int\int_D h(z)d\bar{z}\wedge dz = \oint_{\partial D_0} h(z)\bar{z}dz - \sum_{j=1}^{g}\oint_{\partial D_j} h(z)\bar{z}dz, \tag{7}$$

where ∂D_0 denotes the outer boundary of the bounded quadrature domain and $\partial D_i,\ i = 1,\ldots,g$, denotes the boundaries of the g enclosed holes.

Now let us introduce a conformal mapping $z(\zeta)$ to the domain D from a region H in a parametric ζ-plane bounded by the unit ζ-circle and a set of g smaller nonoverlapping circles totally contained inside $|\zeta| = 1$. Such a region shall be referred to as a *circular region*. Let the unit circle be denoted C_0, and let the g enclosed circles be labeled $C_i,\ i = 1,\ldots,g$, with centers δ_i and radii ρ_i. The circle C_0 will map to the outer boundary ∂D_0, while the circle C_i maps to the boundary ∂D_i. A schematic is shown in Figure 1. Note that, by the assumed reflectional symmetry about the

real axis of the domains considered here, the conjugate conformal map, defined by $\bar{z}(\zeta) \equiv \overline{z(\bar{\zeta})}$, satisfies

$$\bar{z}(\zeta) = z(\zeta). \tag{8}$$

Using this conformal mapping function, the integral in (7) becomes

$$\int\int_D h(z)d\bar{z} \wedge dz = \oint_{C_0} h(z(\zeta))\bar{z}(\bar{\zeta})z_\zeta(\zeta)d\zeta - \sum_{j=1}^{g} \oint_{C_j} h(z(\zeta))\bar{z}(\bar{\zeta})z_\zeta(\zeta)d\zeta. \tag{9}$$

On C_0,

$$\bar{\zeta} = \zeta^{-1}, \tag{10}$$

so that, written as a function of ζ, the first integrand on the right-hand side of (9) is

$$h(z(\zeta))\bar{z}(\zeta^{-1})z_\zeta(\zeta). \tag{11}$$

Let us now consider what is necessary in order that the sum of *all* the integrals on the right-hand side of (9) reduces to a *single* integral of the *same* integrand (11) around the entire boundary of H. For this to happen, it is necessary that

$$\bar{z}(\phi_j(\zeta)) = \bar{z}(\zeta^{-1}), \qquad j = 1, \ldots, g, \tag{12}$$

where, on C_j,

$$\bar{\zeta} = \phi_j(\zeta) \equiv \bar{\delta}_j + \frac{\rho_j^2}{\zeta - \delta_j}. \tag{13}$$

Therefore, defining

$$\theta_j(\zeta) \equiv \overline{\phi}_j(\zeta^{-1}) = \delta_j + \frac{\rho_j^2 \zeta}{1 - \bar{\delta}_j \zeta}, \tag{14}$$

we require that the conformal mapping $z(\zeta)$ satisfy

$$z(\zeta) = z(\theta_j(\zeta)), \qquad j = 1, \ldots, g. \tag{15}$$

The g maps $\{\theta_j\}$ are Mobius maps and generate a free group of transformations known as a Schottky group [21], [24]. See section 3 to follow. The mapping $z(\zeta)$ must be invariant with respect to the substitutions of this group.

For $j = 1, 2, \ldots, g$, let C_j' be the circle obtained by reflection of the circle C_j in the unit circle $|\zeta| = 1$ (i.e., the circle obtained by the transformation $\zeta \mapsto 1/\bar{\zeta}$). C_j' lies in the region exterior to the unit ζ-circle. The image of the circle C_j' under the transformation θ_j is the circle C_j. Since the g circles $\{C_j\}$ are nonoverlapping, so are the g circles $\{C_j'\}$. Consider the region of the plane exterior to the $2g$ circles $\{C_j\}$ and $\{C_j'\}$; a schematic is shown in Figure 2. This region turns out to have a special significance. (It is known as the *fundamental region* associated with the Schottky group generated by the Mobius maps $\{\theta_j | j = 1, \ldots, g\}$ and their inverses—see the next section.) This is because the functional relations (15) allow the function $z(\zeta)$ to be analytically continued outside this fundamental region to any point of the plane which can be reached by a finite number of applications of the transformations $\{\theta_j\}$

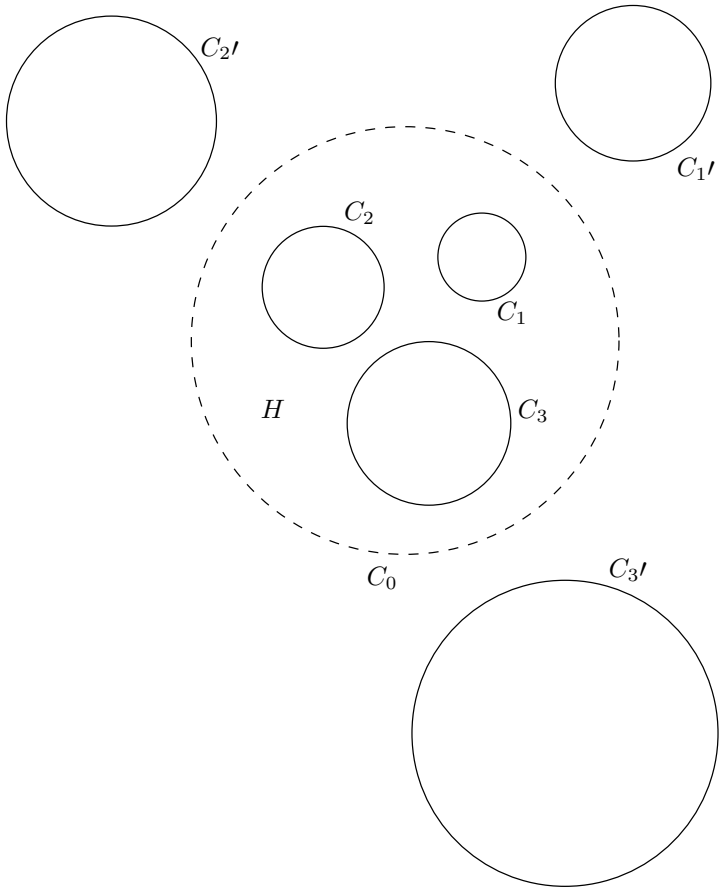

FIG. 2. *The fundamental region is the unbounded region exterior to all six Schottky circles* $C_1, C_1', C_2, C_2', C_3, C_3'$.

and their inverses to a point in this fundamental region. It is therefore enough to establish the singularity structure of $z(\zeta)$ within just this fundamental region.

Now, if the functional relations (15) hold, we have

$$\int\int_D h(z)d\bar{z}\wedge dz = \oint_{\partial H} h(z(\zeta))\bar{z}(\zeta^{-1})z_\zeta(\zeta)d\zeta, \tag{16}$$

where ∂H denotes the whole boundary of H. Now let

$$z_k = z(\bar{\alpha}_k^{-1}), \qquad k = 1,\ldots,N, \tag{17}$$

for some points $\{\bar{\alpha}_k^{-1} | k = 1,\ldots,N\}$ contained in H. Now if $\bar{z}(\zeta^{-1})$ has poles in H only at the points $\{\bar{\alpha}_k^{-1}\}$, then the integral on the right-hand side of (16) produces the pure sum of residues (6). This means that $z(\zeta)$ will have poles in the fundamental region only at the points $\{\alpha_k\}$. That is, $z(\zeta)$ is meromorphic in the fundamental region.

3. Schottky groups. Consider the $2g$ Mobius maps given by

$$\theta_1, \theta_1^{-1}, \theta_2, \theta_2^{-1}, \ldots, \theta_g, \theta_g^{-1}. \tag{18}$$

The Schottky group of transformations will be denoted Θ and is the infinite free group formed by all possible compositions of the Mobius maps (18). These maps are also referred to as the primary substitutions. Associated with this group is a fundamental region mentioned in the previous section. Sometimes we shall refer to the *ordinary* and *singular* points of the group [22], [24]. If a point in the plane can be reached by a finite number of applications of any of the $2g$ primary substitutions to a point in the fundamental region, then it is called an ordinary point of the group. If it can be reached only by an infinite number of applications, then it is called a singular point. A very accessible discussion of Schottky groups and their applications can be found in a recent monograph by Mumford, Series, and Wright [24].

Some special infinite subsets of transformations in a given Schottky group will be needed in the construction of the conformal mapping functions taking the circular regions in the ζ-plane to the multiply connected quadrature domains. A special notation is now introduced. This notation is not standard but is introduced here to clarify the presentation.

Notation. The full Schottky group is denoted Θ. The notation ${}_i\Theta_j$ is used to denote all transformations of the full group which do not have a power of θ_i or θ_i^{-1} on the left-hand end or a power of θ_j or θ_j^{-1} on the right-hand end. As a special case of this, the notation Θ_j simply means all substitutions of the group which do not have any positive or negative power of θ_j at the right-hand end (but with no stipulation about what appears on the left-hand end). Similarly, ${}_j\Theta$ means all substitutions which do not have any positive or negative power of θ_j at the left-hand end (but with no stipulation about what appears on the right-hand end). In addition, the single prime notation will be used to denote a subset where the identity is excluded from the set; thus Θ_1' denotes all substitutions, excluding the identity, and all transformations with a positive or negative power of θ_1 at the right-hand end. The double prime notation will be used to denote a subset where the identity *and* all inverse substitutions are excluded from the set. This means, for example, that if $\theta_1\theta_2$ is included in the set, the transformation $\theta_2^{-1}\theta_1^{-1}$ must be excluded. Thus, Θ'' means all substitutions of the group excluding the identity and all inverses. Similarly, the notation ${}_1\Theta_2''$ denotes all substitutions of the group, excluding inverses and the identity, which do not have any power of θ_1 or θ_1^{-1} on the left-hand end or any power of θ_2 or θ_2^{-1} on the right-hand end. In the same way, Θ_j'' denotes all substitutions of the group, excluding the identity and all inverses, which do not have any positive or negative power of θ_j at the right-hand end.

3.1. The loxodromic group. Consider a mapping to a doubly connected quadrature domain from an annular region $\rho_1 < |\zeta| < 1$ in the ζ-plane. In this case, the mapping must satisfy

$$z(\zeta) = z(\rho_1^2\zeta). \tag{19}$$

Meromorphic functions satisfying (19) are known as loxodromic functions [15]. They are automorphic with respect to the transformations of the *loxodromic group* generated by a single map of the form $\theta_1(\zeta) = \rho_1^2\zeta$. It should be noted that the fundamental region in this case can be taken to be the annulus $\rho_1 < |\zeta| < \rho_1^{-1}$, which does not include the point at infinity. The usual definition of the fundamental region associated with a classical Schottky group [22] *does* include the point at infinity. However, we adopt the convention of considering the loxodromic group to be a special case of a general Schottky group. Richardson [23] adopts the same convention.

4. The Schottky–Klein prime function. Following Baker [21], if the ith substitution of the group Θ acts on some point ζ, then the image point will be denoted ζ_i for brevity. Using this notation, the Schottky–Klein prime function is defined as

$$\omega(\zeta,\gamma) = (\zeta-\gamma)\prod_{i\in\Theta''}\left\{\zeta,\frac{\gamma}{\gamma_i},\zeta_i\right\}, \tag{20}$$

where the product is over all substitutions in the set Θ''. The curly bracket notation denotes the cross-ratio defined in the standard way as

$$\left\{\zeta,\frac{\gamma}{\gamma_i},\zeta_i\right\} \equiv \frac{(\zeta_i-\gamma)(\gamma_i-\zeta)}{(\zeta_i-\zeta)(\gamma_i-\gamma)}. \tag{21}$$

The function $\omega(\zeta,\gamma)$ is single-valued on the whole ζ-plane, has a zero at γ and all points equivalent to γ under the substitutions of the group Θ, and, excepting the singular points of the group, is infinite only at $\zeta=\infty$.

The Schottky–Klein prime function can be regarded as fundamental and is the generalization to Riemann surfaces of genus g of the irreducible factor $(\zeta-\gamma)$ used in the construction of meromorphic functions on a genus-0 Riemann surface (i.e., the rational functions) and the function $P(\zeta/\gamma,\rho)$ (see (4)) used in the construction of meromorphic functions on a genus-1 Riemann surface (i.e., the loxodromic functions).

4.1. Trivial group. When the Schottky group is just the trivial group, the definition (20) reduces to $\omega(\zeta,\gamma)=(\zeta-\gamma)$. It is well known that any rational function with poles at the N points $\{\alpha_k|k=1,\dots,N\}$ and zeros at $\{\beta_k|k=1,\dots,N\}$ admits the representation

$$R\frac{(\zeta-\beta_1)(\zeta-\beta_2)\cdots(\zeta-\beta_N)}{(\zeta-\alpha_1)(\zeta-\alpha_2)\cdots(\zeta-\alpha_N)}, \tag{22}$$

where R is a multiplicative constant. Note that in this case there is no restriction on the locations of the poles and zeros of the function.

4.2. Loxodromic group. When the relevant Schottky group is the loxodromic group generated by the single substitution $\theta_1(\zeta)=\rho_1^2\zeta$, the definition (20) reduces to

$$\begin{aligned}\omega(\zeta,\gamma) &= (\zeta-\gamma)\prod_{k=1}^{\infty}\frac{(\rho_1^{2k}\zeta-\gamma)(\rho_1^{2k}\gamma-\zeta)}{(\rho_1^{2k}\zeta-\zeta)(\rho_1^{2k}\gamma-\gamma)}\\ &= (\zeta-\gamma)\prod_{k=1}^{\infty}\frac{(\rho_1^{2k}\zeta/\gamma-1)(\rho_1^{2k}\gamma/\zeta-1)}{(\rho_1^{2k}-1)(\rho_1^{2k}-1)}\\ &= \left(\frac{-\gamma}{\prod_{k=1}^{\infty}(\rho_1^{2k}-1)^2}\right)P(\zeta/\gamma,\rho_1),\end{aligned}$$

so that the relevant Schottky–Klein prime function $\omega(\zeta,\gamma)$ in this case is simply proportional to the function $P(\zeta/\gamma,\rho_1)$ given in the introduction. It is well known [15] that one representation for a loxodromic function with poles at $\{\alpha_k|k=1,\dots,N\}$ and zeros at $\{\beta_k|k=1,\dots,N\}$ is

$$R\frac{P(\zeta/\beta_1,\rho_1)P(\zeta/\beta_2,\rho_1)\cdots P(\zeta/\beta_N,\rho_1)}{P(\zeta/\alpha_1,\rho_1)P(\zeta/\alpha_2,\rho_1)\cdots P(\zeta/\alpha_N,\rho_1)}, \tag{23}$$

provided the poles and zeros satisfy the condition

$$\prod_{k=1}^{N} \alpha_k = \prod_{k=1}^{N} \beta_k, \tag{24}$$

i.e., there is a single condition on the poles and zeros of the function. It is important to point out that another representation of a loxodromic function with the same poles and zeros is given by

$$R\zeta \frac{P(\zeta/\beta_1,\rho_1)P(\zeta/\beta_2,\rho_1)\cdots P(\zeta/\beta_N,\rho_1)}{P(\zeta/\alpha_1,\rho_1)P(\zeta/\alpha_2,\rho_1)\cdots P(\zeta/\alpha_N,\rho_1)}, \tag{25}$$

where we emphasize the appearance of an additional prefactor of ζ in front of the ratio of products of the $P(\zeta,\rho)$-functions. In this case, the poles and zeros must satisfy the modified condition

$$\prod_{k=1}^{N} \alpha_k = \rho_1^2 \prod_{k=1}^{N} \beta_k. \tag{26}$$

Crowdy [20] has explicitly constructed quadrature domains corresponding to annular arrays of near-touching cylindrical particles using the second representation (25).

4.3. More general Schottky groups. By a natural extension of the familiar special cases of sections 4.1 and 4.2, it can be shown [21] that one representation of a meromorphic function on a Riemann surface of genus g with the poles $\{\alpha_k | k = 1,\ldots,N\}$ and zeros $\{\beta_k | k = 1,\ldots,N\}$ is

$$R\frac{\omega(\zeta,\beta_1)\omega(\zeta,\beta_2)\cdots\omega(\zeta,\beta_N)}{\omega(\zeta,\alpha_1)\omega(\zeta,\alpha_2)\cdots\omega(\zeta,\alpha_N)}. \tag{27}$$

It is natural that in the genus-g case there exist g conditions on the poles and zeros. These are the generalizations of the single condition (24) or (26) in the $g = 1$ case. To ascertain these conditions, introduce A_k and B_k as the two fixed points of the generating substitution θ_k defined as

$$A_k = \theta_k^{-\infty}\zeta, \quad B_k = \theta_k^{\infty}\zeta, \tag{28}$$

where ζ is any given point. Note that A_k and B_k are simply the roots of $\zeta = \theta_k(\zeta)$, which is just a quadratic because $\theta_k(\zeta)$ is a Mobius transformation. Letting $\theta_k = \zeta'$, it is possible to write

$$\frac{\zeta' - B_k}{\zeta' - A_k} = \mu_k e^{i\kappa_k}\frac{\zeta - B_k}{\zeta - A_k}, \tag{29}$$

where $\mu_k, \kappa_k \in \mathbb{R}$. The two roots A_k and B_k are then distinguished by the fact that $|\mu_k| < 1$ in (29). Now the function (27) is the required meromorphic function, provided the following g conditions hold:

$$\prod_{j=1}^{N}\prod_{\theta_i\in\Theta_k}\frac{(\alpha_j - \theta_i(B_k))}{(\alpha_j - \theta_i(A_k))}\Big/\frac{(\beta_j - \theta_i(B_k))}{(\beta_j - \theta_i(A_k))} = 1, \quad k = 1,\ldots,g. \tag{30}$$

Note that the substitutions in the second product are taken from the subset Θ_k. The g conditions (30) will be referred to henceforth as the *automorphicity conditions*.

In the same way that both (23) and (25) are two different representations of a loxodromic function with the same distribution of poles and zeros, there are a number of distinct representations of meromorphic functions on a Riemann surface of genus $g > 1$ as shown in Baker [21]. In constructing a particular quadrature domain, it is necessary to ascertain which representation is the appropriate one needed to construct the required conformal mapping. One alternative representation (used later in the case studies) is

$$\left(R\zeta \prod_{i\in\Theta_1'} \frac{\zeta-\theta_i(B_1)}{\zeta-\theta_i(A_1)} \right) \frac{\omega(\zeta,\beta_1)\omega(\zeta,\beta_2)\cdots\omega(\zeta,\beta_N)}{\omega(\zeta,\alpha_1)\omega(\zeta,\alpha_2)\cdots\omega(\zeta,\alpha_N)}, \tag{31}$$

where θ_1 denotes the loxodromic transformation given as

$$\theta_1(\zeta) = \rho_1^2\zeta. \tag{32}$$

The poles and zeros also satisfy g automorphicity conditions, one of which is given by

$$\prod_{i=1}^{N}\prod_{j\in\Theta_1}\left(\frac{\beta_i-\theta_j(B_1)}{\beta_i-\theta_j(A_1)}\Big/\frac{\alpha_i-\theta_j(B_1)}{\alpha_i-\theta_j(A_1)}\right) = \frac{1}{\mu_1 e^{i\kappa_1}}\prod_{s\in_1\Theta_1''}\left(\frac{B_1-\theta_s(A_1)}{A_1-\theta_s(A_1)}\Big/\frac{B_1-\theta_s(B_1)}{A_1-\theta_s(B_1)}\right)^2, \tag{33}$$

while the remaining $g-1$ conditions are given by

$$\prod_{i=1}^{N}\prod_{j\in\Theta_b}\left(\frac{\beta_i-\theta_j(B_b)}{\beta_i-\theta_j(A_b)}\Big/\frac{\alpha_i-\theta_j(B_b)}{\alpha_i-\theta_j(A_b)}\right) = \prod_{s\in_1\Theta_b}\left(\frac{\theta_s^{-1}(B_1)-A_b}{\theta_s^{-1}(A_1)-A_b}\Big/\frac{\theta_s^{-1}(B_1)-B_b}{\theta_s^{-1}(A_1)-B_b}\right) \tag{34}$$

for $b = 2,\ldots,g$, where A_b and B_b denote the fixed points of the mapping θ_b.

Finally, it is instructive to see how the general condition (30) reduces to (24) in the $g = 1$ case, where the Schottky group is the loxodromic group. In this case the group is generated by the single substitution,

$$\theta_1(\zeta) = \rho_1^2\zeta. \tag{35}$$

The subset Θ_1 then contains only the identity. It is also clear that

$$A_1 = \infty, \quad B_1 = 0. \tag{36}$$

With these identifications, it is easy to show that (30) is precisely equivalent to (24). Indeed, it is also straightforward to show that the factor

$$\zeta\prod_{i\in\Theta_1'}\frac{\zeta-\theta_i(B_1)}{\zeta-\theta_i(A_1)} \tag{37}$$

in (31) reduces simply to ζ in the case where the Schottky group is precisely the loxodromic group, so that (31) reduces to (25). At the same time, the automorphicity condition (33) reduces to (26).

5. Equations for the mapping parameters. Only quadrature domains satisfying quadrature identities of the form

$$\int\int_D h(z)d\bar{z}\wedge dz = 2i\sum_{k=1}^{N} a_k h(z_k) \tag{38}$$

will be considered here. The equations to be satisfied by the conformal mapping parameters come from the specified quadrature identity together with any assumptions made regarding the areas of the enclosed holes. Intuitively, it is useful to think of specifying the real parameter ρ_i as equivalent to specifying the area of the ith hole.

From (17) recall that we require

$$z(\bar{\alpha}_k^{-1}) = z_k, \quad k = 1, \ldots, N. \tag{39}$$

Also, recall that we require $\bar{z}(\zeta^{-1})$ to have poles in H only at the points $\bar{\alpha}_k^{-1}$. In this case, where the quadrature identity is of the form (38), these poles are simple. Thus near $\zeta = \bar{\alpha}_k^{-1}$, $\bar{z}(\zeta^{-1})$ has the form

$$\bar{z}(\zeta^{-1}) = \frac{P_k}{\zeta - \bar{\alpha}_k^{-1}} + \text{regular}, \tag{40}$$

where $P_k \in \mathbb{C}$. We therefore require that

$$a_k = \pi P_k z_\zeta(\bar{\alpha}_k^{-1}), \quad k = 1, \ldots, N. \tag{41}$$

It is useful to think of the N conditions (39) as being equations for the N poles $\{\alpha_k | k = 1, \ldots, N\}$, while (41) provides equations for the N zeros $\{\beta_k | k = 1, \ldots, N\}$.

This leaves only the set $\{\delta_k | k = 1, \ldots, g\}$ to be determined. However, equations for these can be understood as being given by the g automorphicity conditions (30). The equation count is therefore very natural, as indicated by the following schematic encapsulating the correspondence between parameters:

$$\begin{aligned} \{z_k \in \mathbb{C} | k = 1, \ldots, N\} &\to \{\alpha_k \in \mathbb{C} | k = 1, \ldots, N\}, \\ \{a_k \in \mathbb{C} | k = 1, \ldots, N\} &\to \{\beta_k \in \mathbb{C} | k = 1, \ldots, N\}, \\ \{\text{specifying the area of g holes}\} &\to \{\rho_k \in \mathbb{R} | k = 1, \ldots, g\}, \\ \{\text{g automorphicity conditions}\} &\to \{\delta_k \in \mathbb{C} | k = 1, \ldots, g\}. \end{aligned} \tag{42}$$

A minor modification of the prime function (20) is needed when the mapping is required to have a zero or pole at the point at infinity. In this case formula (20) must be replaced by

$$\omega(\zeta, \infty) = \prod_{i \in \Theta''} \frac{(\infty_i - \zeta)}{(\zeta_i - \zeta)}, \tag{43}$$

where ∞_i denotes the images of the point at infinity under the ith substitution of the set Θ''.

Many of the examples to follow possess various rotational symmetries in the distribution of the poles and zeros of the relevant conformal mapping function. It is therefore convenient to define $\omega_n(\zeta, \gamma)$ as

$$\omega_n(\zeta, \gamma) \equiv \prod_{k=0}^{n-1} \omega(\zeta, e^{2\pi i k/n}\gamma). \tag{44}$$

It should be noted that the Schottky–Klein prime function depends implicitly on the parameters $\{\delta_k, \rho_k | k = 1, \ldots, g\}$ from which the primary substitutions are constructed; however, the notation $\omega(\zeta, \gamma)$ suppresses this dependence.

6. Examples. In computing explicit cases it is necessary to truncate the number of maps used from any of the relevant infinite sets. This is done in a natural way by picking a *level* of composition of the primary substitutions up to which all composed substitutions are included. (Mumford, Series, and Wright [24] discuss various other methods of truncation.) For example, if a Schottky group has two primary substitutions θ_1 and θ_2 and all maps up to and including level 2 are used, the following maps would be included in the definition of $\omega(\zeta,\gamma)$:

$$\text{level } 1: \ \theta_1,\theta_2; \quad \text{level } 2: \ \theta_1^2,\theta_2^2,\theta_1\theta_2,\theta_2\theta_1,\theta_1^{-1}\theta_2,\theta_1\theta_2^{-1}. \tag{45}$$

Note that the identity is the only map at level 0, and this is excluded in defining the Schottky–Klein prime function.

Since the zeros and poles in the Schottky–Klein prime function representation are explicit, construction of a given quadrature domain requires only consideration of the distribution of the poles and zeros of the conformal mapping in the ζ preimage plane. Often, the quadrature identity combined with symmetry considerations can be used to deduce the positions of these poles and zeros. The functional form of the relevant conformal mapping can then be written down immediately.

6.1. A triply connected quadrature domain. Consider four circular discs of equal radius r initially less than 1, with centers at $\pm\sqrt{3}$ and $\pm i$. For $r<1$ the circular discs are disconnected. If we increase r to 1, then the discs touch. If $r\le 1$, such a configuration is a disconnected quadrature domain satisfying the quadrature identity (38) with $N=4$, $a_1=a_2=a_3=a_4=\pi r^2$, and $z_1=\sqrt{3}=-z_3$, $z_2=i=-z_4$. When r increases above 1, the domain satisfying the quadrature identity (38) with quadrature data given by $a_1=a_2=a_3=a_4=\pi r^2$ and $z_1=\sqrt{3}=-z_3, z_2=i=-z_4$ can be expected to form a triply connected quadrature domain.

We shall construct a triply connected domain which is close to the case of touching circular discs. In particular, we take $a_1=a_2=a_3=a_4=1.0010\pi$ and $z_1=1.6966, z_2=0.9969i$.

Note that the quadrature domain is symmetric with respect to reflection in both the real and imaginary axes, and its two holes have their centers on the real axis. It is natural to expect the same structure in the associated circular region H in the ζ-plane. If C_1 and C_2 are the circles mapping to the boundaries of these two holes, we expect them to have equal radii with centers at $\delta_1,\delta_2\in\mathbb{R}$, where $\delta_1=-\delta_2$. The conformal mapping will have four poles corresponding to each of the z_k for $k=1,2,3,4$. We label these α_k for $k=1,2,3,4$. It will also have four zeros, which we label β_k $(k=1,2,3,4)$. Again, it is natural to expect the distribution of the poles of the conformal map in the ζ-plane to mirror the distribution of the points z_k $(k=1,2,3,4)$ in the physical plane. We therefore expect $\alpha_1=-\alpha_3$ purely real and $\alpha_2=-\alpha_4$ purely imaginary. Thus, the combination $\omega_2(\zeta,\alpha_1)\omega_2(\zeta,\alpha_2)$ will appear in the denominator of the conformal map. Note that the compact notation $\omega_2(\zeta,\alpha_1)$ (defined in (44)) automatically captures both the pole at α_1 and that at $-\alpha_1$. As for the zeros, because we choose $\zeta=0$ to map to $z=0$, one of the zeros (say β_3) is at the origin. Thus $\omega(\zeta,0)$ appears in the numerator of the conformal map. By symmetry, one of the remaining three zeros (say β_4) must be at ∞, while the other two, β_1 and β_2, should be either purely real or purely imaginary with $\beta_1=-\beta_2$. Thus, the combination $\omega(\zeta,\infty)\omega_2(\zeta,\beta_1)$ also appears in the numerator. In fact, it is found that β_1 is purely real. Figure 3 shows a schematic illustrating the ζ preimage plane and the distribution of poles and zeros in the fundamental region.

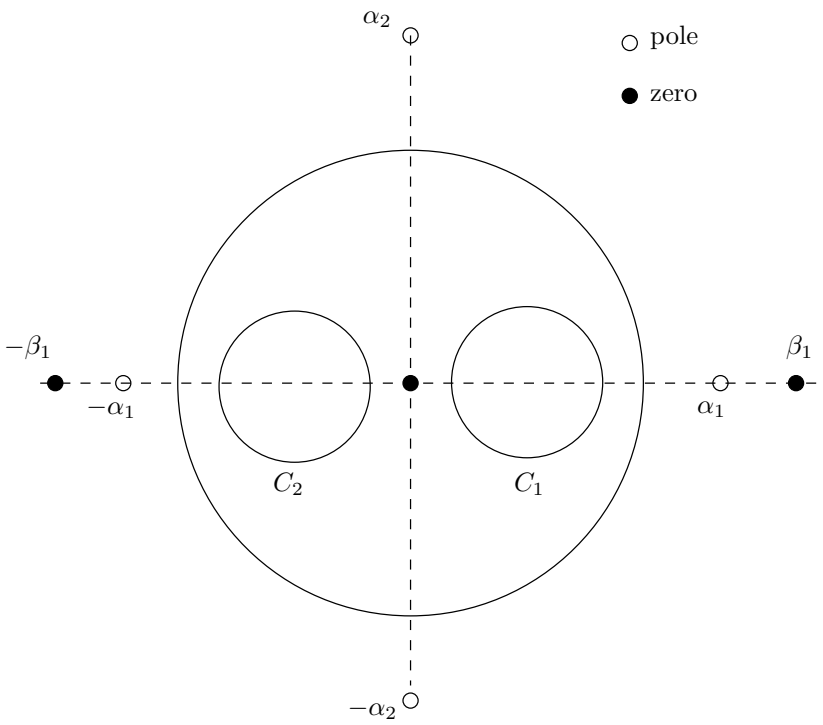

FIG. 3. *Schematic illustrating the ζ preimage plane with distribution of poles and zeros of the conformal mapping to the triply connected quadrature domain in Figure* 4.

Combining the above considerations, the form of the conformal map is deduced to be

$$z(\zeta) = R\frac{\omega(\zeta,0)\omega(\zeta,\infty)\omega_2(\zeta,\beta_1)}{\omega_2(\zeta,\alpha_1)\omega_2(\zeta,\alpha_2)}. \tag{46}$$

The map contains six parameters: $R, \beta_1, \alpha_1, \alpha_2, \delta_1, \rho_1$. We can specify ρ_1, which corresponds to fixing the area of each of the two holes. Then the equations to solve for the remaining five unknowns come from (30), (39), (41). Note that, due to symmetry, the two equations given by (30) are actually the same, and (39), (41) each give only two independent equations. Thus we have five equations for five unknowns. Explicitly, these are

$$\prod_{j=1}^{4}\prod_{\theta_i\in\Theta_1}\frac{(\alpha_j-\theta_i(B_1))}{(\alpha_j-\theta_i(A_1))}\Big/\frac{(\beta_j-\theta_i(B_1))}{(\beta_j-\theta_i(A_1))} = 1, \tag{47}$$

$$z_1 = z(\bar{\alpha}_1^{-1}), \tag{48}$$

$$z_2 = z(\bar{\alpha}_2^{-1}), \tag{49}$$

$$a_1 = \pi P_1 z_\zeta(\bar{\alpha}_1^{-1}), \tag{50}$$

$$a_2 = \pi P_2 z_\zeta(\bar{\alpha}_2^{-1}), \tag{51}$$

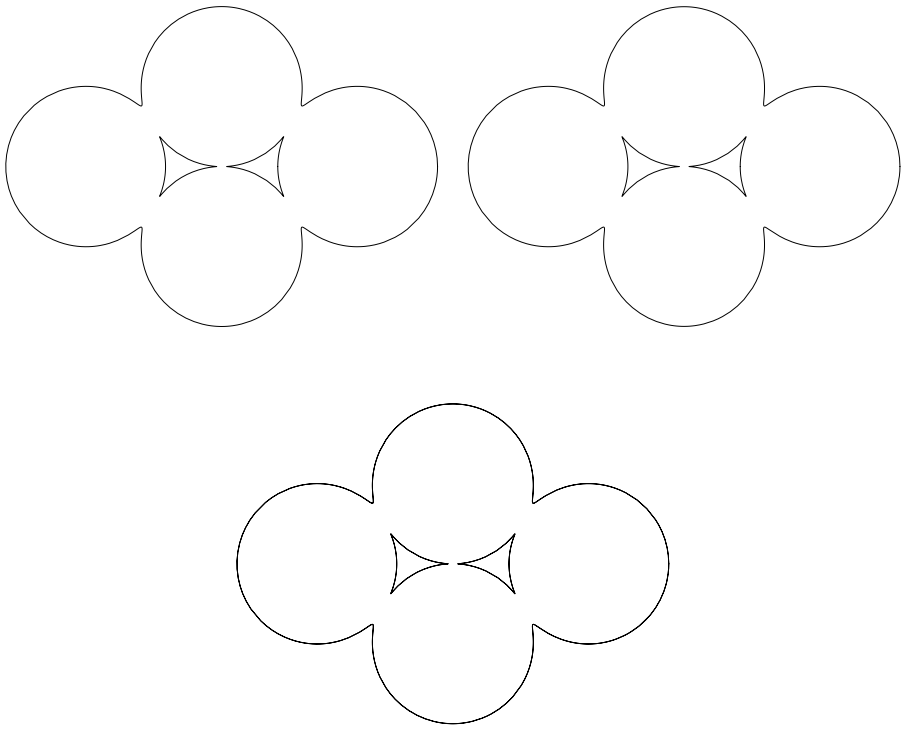

FIG. 4. *Triply connected domain constructed using the Schottky–Klein prime function (top left) and Poincaré series (top right) both at level* 3. *Here* $R = 2.5215,\ \beta_1 = 1.4776,\ \alpha_1 = 1.1520,\ \alpha_2 = 1.5969i,\ \delta_1 = 0.3160,\ \rho_1 = 0.2000$. *For comparison, the lower diagram shows a superposition of the upper two diagrams.*

where analytical formulae for P_1 and P_2 can easily be deduced. For example,

$$P_1 = -\frac{R}{\alpha_1^2}\left(\frac{\omega(\alpha_1,0)\omega(\alpha_1,\infty)\omega_2(\alpha_1,\beta_1)}{\hat{\omega}(\alpha_1,\alpha_1)\omega(\alpha_1,-\alpha_1)\omega_2(\alpha_1,\alpha_2)}\right), \tag{52}$$

where $\hat{\omega}(\zeta,\gamma)$ is defined as

$$\hat{\omega}(\zeta,\gamma) \equiv \prod_{i\in\Theta''}\left\{\zeta, \frac{\gamma}{\gamma_i}, \zeta_i\right\}. \tag{53}$$

These five equations are solved for the unknown parameters using Newton's method. The image of the conformal map is shown in the left-most diagram in Figure 4.

For purposes of comparison with the approach to constructing quadrature domains expounded recently by Richardson [23] we constructed the *same* quadrature domain using a conformal map based on the use of Poincaré series as opposed to the Schottky–Klein prime function. The image of this map is shown in the right-most diagram in Figure 4. The images of the respective conformal maps are indistinguishable, as can be seen from their superposition in the lower diagram in Figure 4. A brief overview of Richardson's general method, and details of how it was used to construct the above triply connected domain, are given in the appendix.

6.2. A quadruply connected quadrature domain. A second example is to consider three circular discs in an annular array surrounding a smaller circular disc.

The quadrature identity associated with such a domain is of the form (38) with $N = 4$ and z_1 purely real, $z_2 = z_1 e^{2\pi i/3}, z_3 = z_1 e^{4\pi i/3}$, and $z_4 = 0$. In the case where the circular discs are touching, we have $a_1 = a_2 = a_3 = \pi$, $a_4 = \pi(2/\sqrt{3} - 1)^2$ and $z_1 = 2/\sqrt{3}, z_4 = 0$. We shall construct a quadruply connected domain which is close to the case of touching discs. In particular, we have taken the quadrature data to be $a_1 = a_2 = a_3 = 1.0010\pi, a_4 = 0.0250\pi$ and $z_1 = 1.1488, z_4 = 0$.

The domain has three holes. Since the holes in the physical plane are rotations of each other through $\frac{2\pi}{3}$, we expect the circles in the preimage plane to share these symmetries. Let C_1, C_2, and C_3 be the circles inside the unit ζ-circle mapping to the boundaries of the holes. Then C_1 will be centered on the ray $\arg[\zeta] = \frac{\pi}{3}$, and C_2 and C_3 will be rotations of this circle through $\frac{2\pi}{3}$.

If we fix the physical origin to be the image of $\zeta = 0$, then we require the factor $\omega(\zeta, 0)$ to appear in the numerator of the conformal map. Note that one of the z_k is zero, namely z_4. Thus from (17), we see that we require the pole α_4 (corresponding to the point z_4) to be at ∞. Thus we must include the factor $\omega(\zeta, \infty)$ in the denominator of the map. There will also be three other poles, symmetrically disposed about $\zeta = 0$, corresponding to the symmetrically disposed points z_1, z_2, and z_3. One of these, denoted α_1, is on the real ζ-axis. There will also be three additional zeros of the conformal map in the fundamental region, which are also expected to be symmetrically disposed about $\zeta = 0$. One of these, β_1 say, is found to be real.

Using these considerations, the conformal map is deduced to have the form

$$z(\zeta) = R\frac{\omega(\zeta, 0)\omega_3(\zeta, \beta_1)}{\omega(\zeta, \infty)\omega_3(\zeta, \alpha_1)}. \tag{54}$$

The image of this map, constructed to level-3 accuracy, is shown in the left-most diagram in Figure 5 along with the image of the conformal map constructed using the Poincaré series method of Richardson [23] to its right (again, to level-3 accuracy). Their superposition is also shown in Figure 5. The boundaries are indistinguishable.

6.3. A quintuply connected quadrature domain. It is straightforward to generalize the previous example to a quadrature domain which is close to the case of four circular discs in an annular array surrounding a smaller circular disc. The quadrature identity associated with such a domain is of the form (38) with $N = 5$ and z_1 purely real, $z_k = z_1 e^{(k-1)\pi i/2}, k = 2, 3, 4$, and $z_5 = 0$. In the case where the discs are touching, we have $a_1 = a_2 = a_3 = a_4 = \pi$, $a_5 = \pi(\sqrt{2} - 1)^2$ and $z_1 = \sqrt{2}, z_5 = 0$. We shall construct a quintuply connected domain which is close to the case of touching circular discs. In particular, we choose quadrature data given by $a_1 = a_2 = a_3 = a_4 = 0.9980\pi, a_5 = 0.1716\pi$ and $z_1 = 1.4029, z_5 = 0$.

Considerations similar to the previous example can be used to deduce that the associated map has the form

$$z(\zeta) = R\frac{\omega(\zeta, 0)\omega_4(\zeta, \beta_1)}{\omega(\zeta, \infty)\omega_4(\zeta, \alpha_1)}. \tag{55}$$

The image of the conformal map is shown in the left-most diagram in Figure 6 along with the image of the conformal map constructed using Poincaré series. Both are constructed to level-3 accuracy. Their superposition is also shown in Figure 6 and, again, the quadrature domain boundaries are indistinguishable. Crowdy [13] has considered this class of domains from the point of view of algebraic curves in the context of constructing multipolar equilibria of the Euler equations, and this will be considered again later in section 8.

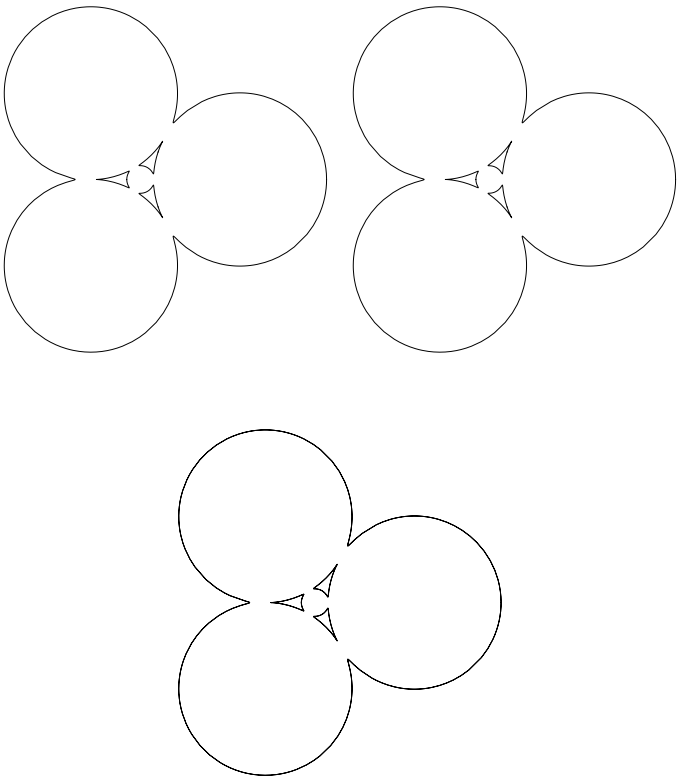

FIG. 5. *Quadruply connected domain constructed using the Schottky–Klein prime function (top left) and Poincaré series (top right) at level* 3*, with superposition (lower). Here* $R = 0.0536,\ \beta_1 = 3.4038,\ \alpha_1 = 1.2500,\ \delta_1 = 0.2608e^{i\pi/3},\ \rho_1 = 0.1275.$

6.4. A septuply connected quadrature domain. Richardson [23] has considered the case of *six* circular discs in an annular array containing a disc of equal radius in the center. Such a case is a trivial extension of the examples in sections 6.2 and 6.3. The preceding two examples have conformal mappings of the general functional form

$$z(\zeta) = R\frac{\omega(\zeta,0)\omega_n(\zeta,\beta_1)}{\omega(\zeta,\infty)\omega_n(\zeta,\alpha_1)}, \tag{56}$$

where section 6.2 deals with $n = 3$ while section 6.3 treats the case $n = 4$. The case of six circular discs surrounding a central one will have a conformal map of the form

$$z(\zeta) = R\frac{\omega(\zeta,0)\omega_6(\zeta,\beta_1)}{\omega(\zeta,\infty)\omega_6(\zeta,\alpha_1)}, \tag{57}$$

i.e., it is given by a mapping of the form (56) with $n = 6$. The associated quadrature identity is of the form (38) with $N = 7$ and z_1 purely real, $z_k = z_1 e^{(k-1)\pi i/3}, k = 2,\ldots,6$, and $z_7 = 0$. In the case of touching circular discs, we have $a_1 = \cdots = a_7 = \pi$ and $z_1 = 2, z_7 = 0$. For illustration, we construct a septuply connected domain which is close to the case of touching circular discs with $a_1 = \cdots = a_6 = 1.0266\pi, a_7 = 1.0010\pi$ and $z_1 = 2.0002, z_7 = 0$. Figure 7 shows the results constructed using both methods to level-2 accuracy.

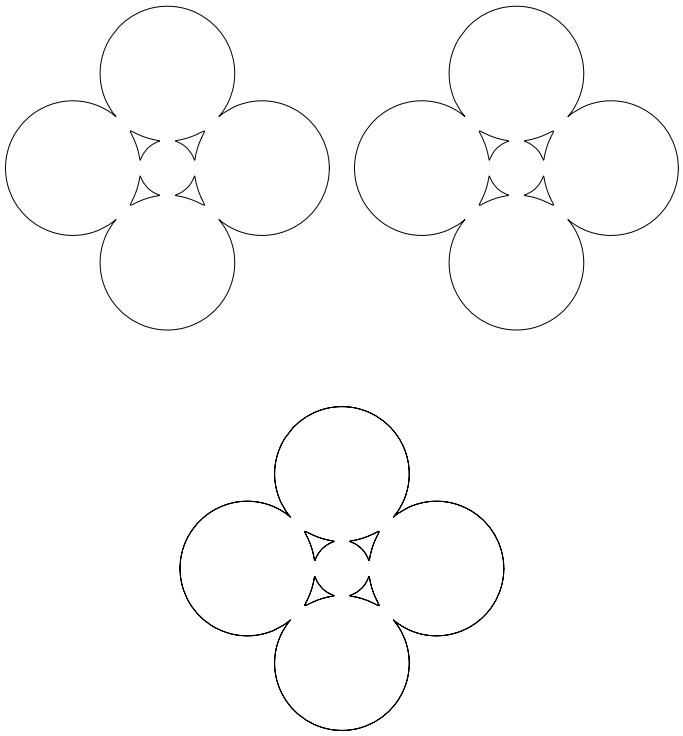

FIG. 6. *Quintuply connected domain constructed using the Schottky–Klein prime function (top left) and Poincaré series (top right) at level* 3, *with superposition (lower). Here* $R = 0.1849,\ \beta_1 = 2.0789,\ \alpha_1 = 1.2329,\ \delta_1 = 0.3591e^{i\pi/4},\ \rho_1 = 0.1290.$

6.5. 3-by-3 square array. More complicated domains are also easy to construct using the Schottky–Klein prime function representation. Consider, for example, nine circles in a 3-by-3 square array. The associated quadrature domain is of the form (38) with $N = 9$ and z_1 real, $z_2 = z_1 i, z_3 = -z_1, z_4 = -z_1 i$, and z_5 on the $\pi/4$ ray, with $z_6 = z_5 i, z_7 = -z_5, z_8 = -z_5 i$, and $z_9 = 0$. In the case where the circular discs are touching, we have $z_1 = 2, z_5 = 2\sqrt{2}e^{\pi i/4}$, and $a_1 = \cdots = a_9 = \pi$. We shall construct a quintuply connected domain which is close to the case of touching circular discs with $a_1 = \cdots = a_9 = 1.0010\pi$ and $z_1 = 1.9533, z_5 = 2.7696e^{\pi i/4}, z_9 = 0$.

There will be four circles $C_1, \ldots, C_4$ inside the unit circle in the preimage ζ-plane. Since the holes in the physical plane are centered on the rays $\arg[z] = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4}$, we also expect the centers of the circles $C_1, \ldots, C_4$ to be on these rays in the ζ-plane. Let $\zeta = 0$ map to $z = 0$. This means that $\omega(\zeta, 0)$ must appear in the numerator of the conformal map. Furthermore, because $z_9 = 0$, there must be a corresponding pole of the conformal map at infinity in the ζ-plane. Therefore, $\omega(\zeta, \infty)$ must appear in the denominator. We expect four symmetrically disposed poles in the ζ-plane corresponding to $z_1, \ldots, z_4$. Let one of these be α_1 on the real axis. Similarly, let α_2 (taken on the ray $\arg[\zeta] = \frac{\pi}{4}$) and its rotations through $\frac{\pi}{2}$ correspond to $z_5, \ldots, z_8$. Thus, the combination $\omega_4(\zeta, \alpha_1)\omega_4(\zeta, \alpha_2)$ will also appear in the denominator. The zeros are expected to be similarly distributed in the ζ-plane. Therefore we include the combination $\omega_4(\zeta, \beta_1)\omega_4(\zeta, \beta_2)$ in the numerator so that the zeros of the map are β_1 (and its three rotations through $\frac{\pi}{2}$) and β_2 (along with its three rotations through $\frac{\pi}{2}$). It is found that β_1 is real while β_2 is on the ray $\arg[\zeta] = \frac{\pi}{4}$.

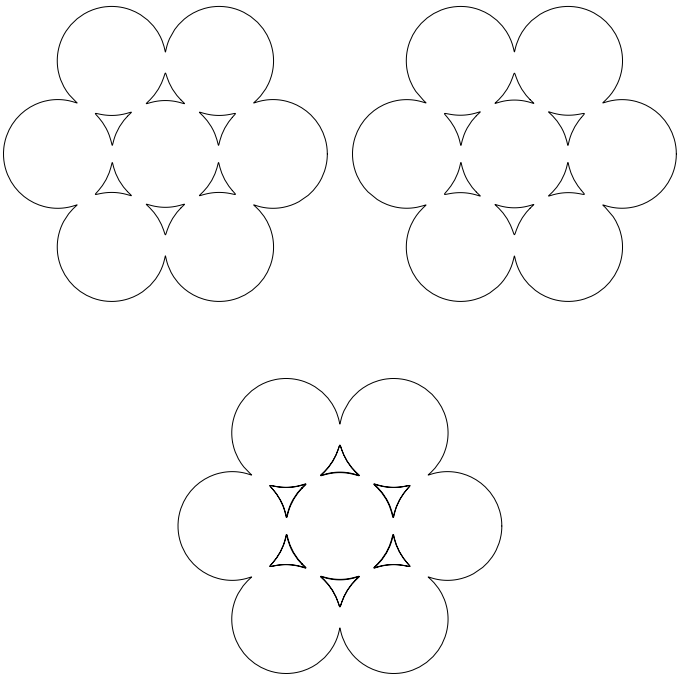

FIG. 7. *Septuply connected domain constructed using the Schottky–Klein prime function (top left) and Poincaré series (top right) at level* 2, *with superposition (lower). Here* $R = 0.6089,\ \beta_1 = 1.5358,\ \alpha_1 = 1.2195,\ \delta_1 = 0.4900e^{i\pi/6},\ \rho_1 = 0.1260.$

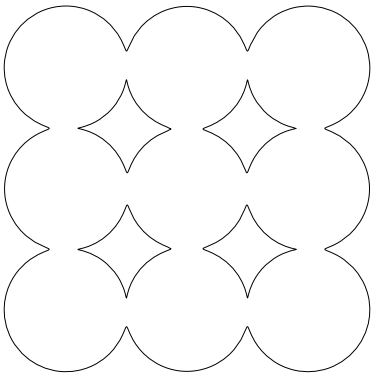

FIG. 8. *3-by-3 square array constructed using the Schottky–Klein prime function at level* 2. *Here* $R = 0.7887,\ \beta_1 = 1.8298,\ \beta_2 = 1.1828e^{i\pi/4},\ \alpha_1 = 1.3899,\ \alpha_2 = 1.0989e^{i\pi/4},\ \delta_1 = 0.5093e^{i\pi/4},\ \rho_1 = 0.2100.$

The conformal map therefore has the form

$$z(\zeta) = R\frac{\omega(\zeta,0)\omega_4(\zeta,\beta_1)\omega_4(\zeta,\beta_2)}{\omega(\zeta,\infty)\omega_4(\zeta,\alpha_1)\omega_4(\zeta,\alpha_2)}. \tag{58}$$

The image of the conformal map is shown in Figure 8.

6.6. Examples with a loxodromic subgroup. If we map H onto a multiply connected quadrature domain which is rotationally symmetric about the origin and which has the origin inside one of its holes, then the boundary ∂D_1 of this hole will be centered at the origin, and thus the circle C_1 in the associated circular region in the ζ-plane will be centered at $\zeta = 0$. So, referring to (14), we see that the associated Schottky group will contain a loxodromic subgroup.

If the quadrature domain is in fact just doubly connected and ∂D_1 is its only inner boundary, then the associated Schottky group will be precisely the loxodromic group. In this case, the form (23) does not map the circular region to the required image. However, Crowdy [20] has shown that the appropriate loxodromic function is given by (25) where the poles and zeros satisfy (26). It is similarly found that if a more general Schottky group contains the loxodromic group as a subgroup, it is necessary to use a suitably generalized representation of the required conformal mapping.

We now present an example where the Schottky group has a loxodromic subgroup. The example chosen is one suggested by Richardson [23]. Consider six circular discs arranged in a triangular array. The quadrature identity associated with such a domain is of the form (38) with $N = 6$ and z_1 purely real, $z_2 = z_1 e^{2\pi i/3}$, $z_3 = z_1 e^{4\pi i/3}$, and z_4 on the $\pi/3$ ray, $z_5 = z_4 e^{2\pi i/3}$, $z_6 = z_4 e^{4\pi i/3}$. In the case where the circular discs are touching we have $a_1 = \cdots = a_6 = \pi$ and $z_1 = \frac{2}{\sqrt{3}}$, $z_4 = \frac{4}{\sqrt{3}} e^{\pi i/3}$. We shall construct a quintuply connected domain which is close to the case of touching circular discs with $a_1 = \cdots = a_6 = 1.0500\pi$ and $z_1 = 1.1737$, $z_4 = 2.3536 e^{\pi i/3}$.

In this case, there will be a total of four enclosed holes: one centered at the origin and three others at symmetrically disposed positions about the origin. Let C_1 be the circle in the ζ-plane mapping to the central hole, and let C_2, C_3, C_4 map to the other three holes. C_2 is a circle centered at some point δ_2 on the ray $\arg[\zeta] = \frac{\pi}{3}$, while C_3 and C_4 are the rotations of this circle through $\frac{2\pi}{3}$ and $\frac{4\pi}{3}$, respectively. Corresponding to z_1, z_2, and z_3 we expect three symmetrically disposed poles in the ζ-plane. Let one of these be α_1 on the real axis. Similarly, let α_2 (on the ray $\arg[\zeta] = \frac{\pi}{3}$) and its two rotations through $\frac{2\pi}{3}$ correspond to z_4, z_5, and z_6. The combination $\omega_3(\zeta, \alpha_1)\omega_3(\zeta, \alpha_2)$ will therefore appear in the denominator of the conformal map. Again, the distribution of zeros is expected to be similar. Thus, we put $\omega_3(\zeta, \beta_1)\omega_3(\zeta, \beta_2)$ in the numerator so that β_1 and β_2 (along with their respective rotations through $\frac{2\pi}{3}$) will be the zeros of the conformal map in the fundamental region. It is found that β_1 is real while β_2 is on the ray $\arg[\zeta] = \frac{\pi}{3}$.

A natural choice to make for the mapping is therefore

$$z(\zeta) = R \frac{\omega_3(\zeta, \beta_1)\omega_3(\zeta, \beta_2)}{\omega_3(\zeta, \alpha_1)\omega_3(\zeta, \alpha_2)}. \tag{59}$$

However, no univalent conformal maps to a quadrature domain with the given quadrature data could be found for a map of this form. Therefore, a modified representation of a meromorphic function on the same Riemann surface (and with the same poles and zeros) is required. Such a representation is given by (31). Thus, it is natural to propose that the conformal mapping has the generalized form

$$z(\zeta) = \left(R\zeta \prod_{i \in \Theta_1'} \frac{\zeta - \theta_i(B_1)}{\zeta - \theta_i(A_1)} \right) \frac{\omega_3(\zeta, \beta_1)\omega_3(\zeta, \beta_2)}{\omega_3(\zeta, \alpha_1)\omega_3(\zeta, \alpha_2)}, \tag{60}$$

where θ_1 denotes the loxodromic transformation

$$\theta_1(\zeta) = \rho_1^2 \zeta \tag{61}$$

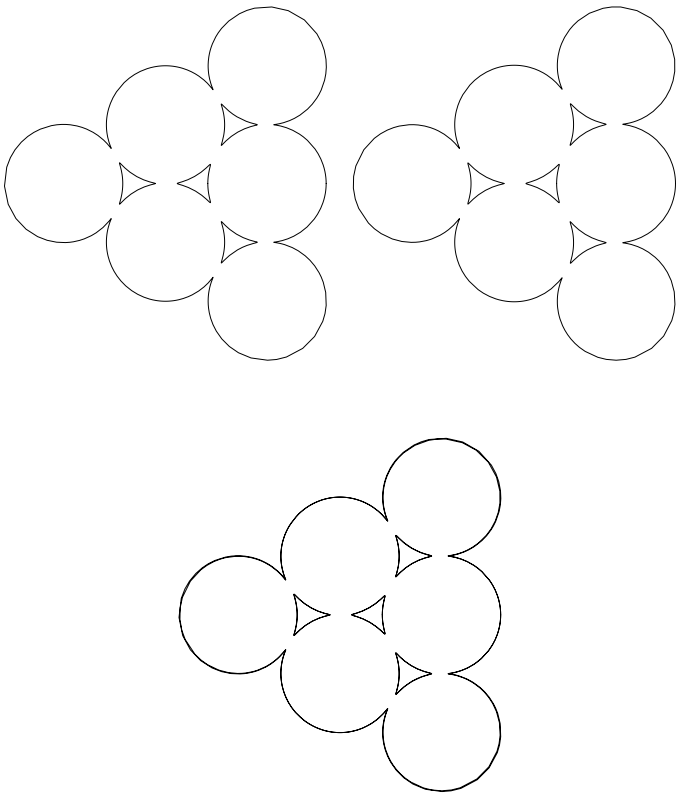

FIG. 9. *Quintuply connected domain constructed using the Schottky–Klein prime function (top left) and Poincaré series (top right) at level* 2, *with superposition (lower). Here* $R = 0.0302$, $\beta_1 = 5.3203$, $\beta_2 = 1.1228e^{i\pi/3}$, $\alpha_1 = 1.6393$, $\alpha_2 = 1.0526e^{i\pi/3}$, $\delta_1 = 0$, $\delta_2 = 0.6054e^{i\pi/3}$, $\rho_1 = 0.1450$, $\rho_2 = 0.1450$.

associated with the circle $C_1 = \{|\zeta| = \rho_1\}$. Note that, accordingly, the poles and zeros must now satisfy g modified automorphicity conditions given (in the general case) by (33) and (34). The map (60) is indeed found to provide the required univalent map to a quadrature domain satisfying the given quadrature identity. It is emphasized that the additional prefactor in (60) relative to (59) is precisely the generalization of the additional ζ-prefactor in (25) relative to (23).

The image of the conformal map constructed using both conformal mapping methods is shown in Figure 9 along with their superposition. Although this complicated domain is only constructed to level-2 accuracy (in both methods), the plots are again virtually indistinguishable.

7. Nonsymmetric domains. All the examples considered so far have certain degrees of spatial symmetry. However, the general method also applies to domains devoid of any such symmetry. Figure 10 shows two typical quadrature domains, plotted using conformal maps based on Schottky–Klein prime functions, possessing less symmetry than those in Figure 4. The constructive method is essentially the same, with only minor differences. For example, with no symmetry, there are now *two* independent automorphicity conditions, whereas in the symmetric case there was just one.

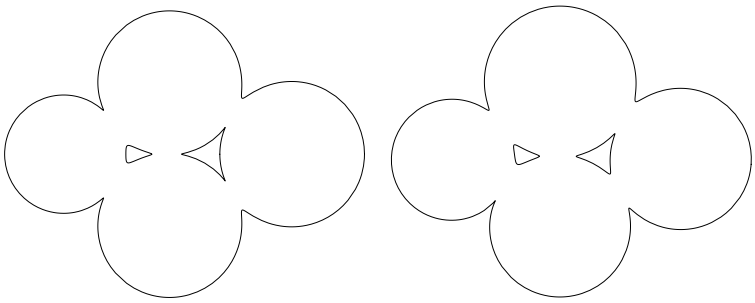

FIG. 10. *More general triply connected quadrature domains.*

8. Algebraic curves and uniformization. In the context of steady vortical equilibria of the Euler equation, Crowdy [13] has recently presented an alternative construction of multiply connected quadrature domains from their quadrature data. The method makes use of the result that the boundaries of quadrature domains are algebraic curves [2]. For completeness, and purposes of comparison, we now use conformal maps to reconstruct one of the domains of [13].

The quintuply connected quadrature domains constructed in [13] satisfy the identity

$$\int\int_D h(z)dxdy = \pi r^2 h(z_1) + \pi r^2 h(z_2) + \pi r^2 h(z_3) + \pi r^2 h(z_4) + \pi p^2 h(0). \tag{62}$$

To within a finite set of *special points* [6] (which turn out to be useful in the construction; see [13]), the boundaries of the domains corresponding to (62) are given by the algebraic curve

$$\mathcal{P}(z, \bar{z}) = 0, \tag{63}$$

where

$$\mathcal{P}(z, w) = \sum_{k,j=0}^{5} a_{kj} z^k w^j. \tag{64}$$

The set of coefficients $\{a_{kj}\}$ form a Hermitian matrix $\mathbf{A}$, where $\mathbf{A}_{kj} = a_{kj}$ and

$$\mathbf{A} = \begin{pmatrix} k & 0 & 0 & 0 & 4p^2 & 0 \\ 0 & g & 0 & 0 & 0 & -4 \\ 0 & 0 & f & 0 & 0 & 0 \\ 0 & 0 & 0 & e & 0 & 0 \\ 4p^2 & 0 & 0 & 0 & -(4r^2+p^2) & 0 \\ 0 & -4 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{65}$$

The top-left diagram of Figure 11 features a reproduction of the quadrature domain in Figure 8 of Crowdy [13] (this reference contains all the information required to derive the matrix $\mathbf{A}$).

The relevant conformal map will have the form (55). In addition to the quadrature data, to determine this map we also need to specify the area of the holes. This can be computed using the algebraic curve, but we employ an alternative (equivalent)

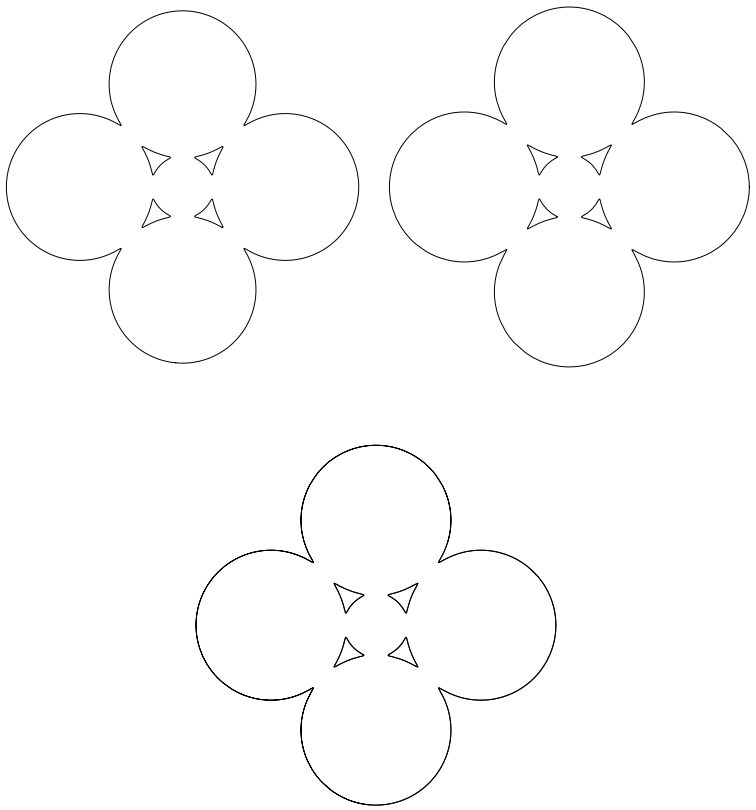

FIG. 11. *A quintuply connected quadrature domain from Crowdy (see Figure* 8 *of* [13]*) constructed using algebraic curves (top left); the same domain constructed using conformal maps based on the Schottky–Klein prime function (top right). The superposition is shown in the lower diagram.*

method. Following Crowdy [13], it is known that there exists a so-called special point at some point $z_s = se^{i\pi/4}$. At such a point it is known [13] that

$$\bar{z}_s = S(z_s), \tag{66}$$

where $S(z)$ is known as the Schwarz function of the quadrature domain boundary [13]. It is related to the conformal mapping function by the relation

$$S(z(\zeta)) = \bar{z}(\zeta^{-1}). \tag{67}$$

Crowdy [13] gives the explicit value $s = 1.008$ for the domain shown in Figure 11 (on the left). In terms of the conformal map, this point must correspond to the image of some point $\hat{\delta}e^{i\pi/4}$ in the ζ preimage plane, i.e.,

$$z_s = se^{i\pi/4} = z(\hat{\delta}e^{i\pi/4}). \tag{68}$$

At the same time, by the property (66), we must have

$$\bar{z}_s = se^{-i\pi/4} = \bar{z}(\hat{\delta}^{-1}e^{-i\pi/4}). \tag{69}$$

Therefore, instead of considering the area of the holes, (68) and (69) provide two equations relating the conformal mapping parameters, one determining the newly

introduced $\hat{\delta}$ and the other effectively specifying the area of the hole. The top-right diagram in Figure 11 shows the domain constructed using the conformal map. The lower figure shows a superposition with the domain constructed using algebraic curves. Again, the boundaries are indistinguishable.

From a theoretical viewpoint, the conformal map just constructed essentially provides the *uniformization* of the algebraic curve (63). That is, given the matrix $\mathbf{A}$, the conformal map is such that

$$\mathcal{P}(z(\zeta), \bar{z}(\zeta^{-1})) = 0. \tag{70}$$

This relation holds everywhere on the boundary of the quadrature domain, but it also holds globally by analytic continuation. In this sense, the conformal map has uniformized the algebraic curve.

9. Discussion. There are a variety of ways in which multiply connected quadrature domains can be constructed from their quadrature data (and information regarding the area of any holes). The algebraic curve method of Crowdy [13] has many conceptual advantages and requires the least analytical overhead. Using this method, an implicit description of the boundary is obtained. The idea is to iterate on the algebraic curve coefficients until equations deriving from the quadrature identity are satisfied. When the domains have symmetry, the consideration of the special points of the domain can greatly facilitate the construction by providing explicit sets of equations to be satisfied by the coefficients of the curve. The special points can also have physical significance; in Crowdy [13] they corresponded to stagnation points of the vortical flow.

In this paper, a conceptually different method has been used based on conformal mapping from a canonical region in a parametric plane. This leads to an explicit representation of the boundary curve. The Schottky model has been employed and the mappings written as ratios of products of Schottky–Klein prime functions. These functions are the natural generalizations of the well-known prime functions in a simply and doubly connected case, as discussed in the introduction. The conformal mappings are essentially "uniformizing functions" of the algebraic curves considered in [13]. Richardson [23] has presented an alternative conformal mapping method based on the use of Poincaré series to represent the mapping functions.

From a mathematical point of view, it is natural to ask questions about the convergence properties of the infinite products used in defining the Schottky–Klein prime functions. We have not studied such questions in detail. However, the boundaries of the quadrature domains obtained in the explicit examples of this paper have been found to be indistinguishable from those obtained using either the algebraic curve method of Crowdy [13] or the conformal mapping method based on Poincaré series introduced by Richardson [23]. We consider this to be direct evidence that convergence issues do not necessarily constitute an impediment to the practical use of the Schottky–Klein prime function in the reconstruction of quadrature domains from their quadrature data.

Appendix. The method of Richardson [23]. We shall now briefly describe an alternative construction of the quadrature domains via an approach using Poincaré series as expounded recently by Richardson [23]. This method also produces maps from circular regions of a parametric ζ-plane and requires the machinery of the Schottky groups associated with these circular regions. The method differs in the functional form, and representation, of the conformal mapping functions; Richardson constructs his maps as a ratio of two automorphic forms which are each constructed as Poincaré series.

DEFINITION A.1. *A Poincaré series associated with a given Schottky group is of the form*

$$T(\zeta) = \sum_{i=0}^{\infty} \frac{H(\theta_i(\zeta))}{(c_i\zeta + d_i)^{2m}}, \tag{71}$$

where

$$\theta_i(\zeta) \equiv \frac{a_i\zeta + b_i}{c_i\zeta + d_i}, \quad a_i d_i - b_i c_i = 1 \tag{72}$$

denotes the ith Mobius map of the Schottky group, $H(\zeta)$ is some rational function of which none of the poles is at a singular point of the Schottky group, and m is an integer. Provided $\zeta = \infty$ is not a singular point of the Schottky group, this series converges for all $m \geq 2$.

DEFINITION A.2. *A form $\phi(\zeta)$ is called an automorphic form with respect to the Schottky group if it has the property*

$$\phi(\theta_i(\zeta)) = (c_i\zeta + d_i)^{2m}\phi(\zeta) \tag{73}$$

for all maps θ_i of the Schottky group, where m is some integer.

If the Schottky group Θ is generated by g basic maps, and $\phi(\zeta)$ is an automorphic form with Z zeros and P poles in the fundamental region, then it is known that

$$Z - P = 2mg. \tag{74}$$

If $\phi(\zeta)$ is in fact an automorphic function, then we see $Z = P$.

Richardson's construction is to use two different choices of the rational functions $H_n(\zeta), H_d(\zeta)$ to form the respective Poincaré series for two automorphic forms $T_n(\zeta), T_d(\zeta)$ corresponding to the same value of $m \geq 2$. Then the ratio

$$\frac{T_n(\zeta)}{T_d(\zeta)} \tag{75}$$

and any constant multiple of this give the required automorphic function. Richardson's strategy is precisely the one described by Beardon [22] for the construction of meromorphic functions on compact Riemann surfaces.

Given a quadrature domain, there are a number of constraints on the relevant choices for $H_n(\zeta)$ and $H_d(\zeta)$. These are discussed in the context of a number of specific examples in Richardson [23]. Here we give very brief details of the construction for the triply connected example of section 6.1. Following Richardson, we choose $m = 2$. Recall that, in this example, there are poles at α_1 and α_3, where $\alpha_1 = -\alpha_3$ (purely real), and two at α_2 and α_4, where $\alpha_2 = -\alpha_4$ (purely imaginary). Also, $g = 2$. Following Richardson [23], we take $H_d(\zeta)$ to be 1. From (74) it follows that $T_d(\zeta)$ has eight zeros in the fundamental region. Due to the symmetry of the quadrature domain, we expect these zeros to be arranged in a pattern that is symmetric with respect to reflection in both axes. Thus we include in $H_n(\zeta)$ the polynomial factor $(\zeta^8 + a\zeta^6 + b\zeta^4 + c\zeta^2 + d)$, where the four real parameters a, b, c, d are to be chosen so that $T_n(\zeta)$ has the same zeros as $T_d(\zeta)$ in the fundamental region. Also due to the symmetry of the quadrature domain, we include a factor of ζ in the numerator of $H_n(\zeta)$. Finally, because none of the z_k in the associated quadrature identity are zero,

the map must be bounded as $\zeta \to \infty$; in fact, we require it to behave like $1/\zeta$ at ∞. So the denominator of $H_n(\zeta)$ must be of degree 10. Since we require simple poles at $\alpha_1, \alpha_2, \alpha_3$, and α_4, we include the factors $(\zeta - \alpha_j)$ for $j = 1, \ldots, 4$ in the denominator of $H_n(\zeta)$. We must then choose the remaining factors such that $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ are still the only poles of the map in the fundamental region. This can be done by choosing to include $(\zeta - \theta_i(\alpha_j))$ for $i = 1, 2$ and $j = 1, 2, 3$ as the extra factors. Finally, the form for the map is the ratio (75) multiplied by some constant R to be determined.

In this representation there are *nine* unknowns, namely $R, \alpha_1, \alpha_2, \delta_1, \rho_1$ as well as a, b, c, d. We can specify a value for ρ_1, thus leaving eight unknowns. The eight equations for the remaining eight unknowns are (39) and (41) plus the four from the requirement that $T_n(\zeta)$ be zero at the zeros of $T_d(\zeta)$ in the fundamental region. Note that these zeros are not known explicitly and must therefore be found (numerically) as part of the solution.

There are a number of comments to be made concerning the two methods:

(i) The zeros of the map are not explicit in the Poincaré series representation, but are explicit in the Schottky–Klein prime function representation. The explicitness of the poles and zeros means that the general form of the required mapping can be written down immediately.

(ii) Once ρ is specified, the Poincaré series representation depends on *eight* parameters compared to only *five* parameters when the Schottky–Klein prime function representation is used. Moreover, the determination of the eight parameters in the Poincaré series representation in fact requires the solution of *twelve* nonlinear equations, owing to the fact that the four (distinct) zeros of $T_d(\zeta)$ (in the fundamental region) must be found numerically during the solution process. In the prime function representation, exactly five equations are solved for exactly five unknowns.

(iii) Two of the equations to be solved in either method are the residue equations (41). With the prime function representation, explicit formulae for the residues P_1, P_2 are straightforward to compute (cf. the formula for P_1 in (52)). However, care has to be taken when finding the analogous equations with the Poincaré series representation because the inclusion of factors such as $(\zeta - \theta_i(\alpha_j))$ in the denominator of $H_n(\zeta)$ can mean that more than one term in the sum $T_n(\zeta)$ contributes to the residue at each of the poles.

(iv) As discussed in detail by Richardson [23], the most convenient choice is $H_d(\zeta) = 1$. However, if the Schottky group has a loxodromic subgroup, then the Poincaré series $T_d(\zeta)$ with $H_d(\zeta) = 1$ does not converge. Richardson therefore proposes three possible remedial measures in this case, two of which are not implemented for various reasons. Such complications do not arise when using the Schottky–Klein prime function representation. In the latter case, it is simply necessary to pick the appropriate representation for the mapping, which can involve additional prefactors of the ratio of products of prime functions, as illustrated explicitly in the context of the example in section 6.6.

(v) A particular advantage of using the Schottky–Klein prime function representations concerns changes of topology, particularly in cases where the connectivity of the domain decreases. In the conformal mappings constructed in this paper, the functional form of the mappings as ratios of products of prime functions is the same; the only change is the definition of the relevant Schottky group.

PARAMETRIC RESONANCE AND RADIATIVE DECAY OF DISPERSION-MANAGED SOLITONS*

DMITRY E. PELINOVSKY† AND JIANKE YANG‡

Abstract. We study propagation of dispersion-managed solitons in optical fibers which are modeled by the nonlinear Schrödinger equation with a periodic dispersion coefficient. When the dispersion variations are weak compared to the average dispersion, we develop perturbation series expansions and construct asymptotic solutions at the first and second orders of approximation. Due to a parametric resonance between the dispersion map and the dispersion-managed soliton, the soliton generates continuous-wave radiation leading to its radiative decay. The nonlinear Fermi golden rule for radiative decay of dispersion-managed solitons is derived from the solvability condition for the perturbation series expansions. Analytical results are compared to direct numerical simulations, and good agreement is obtained.

Key words. dispersion management, optical solitons, perturbation series, parametric resonance, radiative decay, Fermi golden rule

1. Introduction.

This paper addresses the dispersion-periodic nonlinear Schrödinger (NLS) equation,

$$i\frac{\partial u}{\partial z} + \frac{m}{2\epsilon} D_\epsilon(z) \frac{\partial^2 u}{\partial t^2} + \frac{1}{2} D_0 \frac{\partial^2 u}{\partial t^2} + |u|^2 u = 0, \tag{1.1}$$

which models optical pulse propagation in dispersion-managed communication systems. Here $u \in \mathbb{C}$ is the wave envelope of the electromagnetic field, z (≥ 0) is the distance along the optical fiber, $t \in \mathbb{R}$ is the retarded time of the optical pulse, D_0 is the average dispersion, $D_\epsilon(z)$ is an ϵ-periodic mean-zero dispersion map, and m is the strength of the map variations. Lump amplification and losses are not included in the model (1.1) for the sake of simplicity.

Special solutions of the dispersion-periodic NLS equation (1.1) are called dispersion-managed (DM) solitons. They have been the subject of growing interest in recent literature [1, 2, 3]. DM solitons are periodic solutions of (1.1) in the form

$$u(z,t) = \Phi(z,t)\, e^{i\mu z}, \tag{1.2}$$

where $\Phi(z+\epsilon,t) = \Phi(z,t)$ and $\mu \in \mathbb{R}$. Existence of periodic solutions of (1.1) is studied with the normal-form transformations in the limit $\epsilon \to 0$ [4]. The normal-form transformations average the fast periodic variations of $\frac{1}{\epsilon} D_\epsilon(z)$ and reduce the dispersion-periodic NLS equation (1.1) to an integral NLS equation [5, 6]. Bound states of the integral NLS equation exist in the case of $D_0 > 0$ [7] and in the case

$D_0 = 0$ [8]. Numerical results indicate nonexistence of bound states of the integral NLS equation in the case $D_0 < 0$ [9].

In what follows we consider the case $D_0 > 0$ only. Early papers by Nijhof et al. [11] reported numerically the existence of "exactly" periodic bound states in the dispersion-periodic NLS equation (1.1), which do not radiate any energy. Later, more careful numerics [3] showed that such bound states actually had nonvanishing radiation tails. Recent results of Yang and Kath [10] showed that exactly-periodic DM solitons do not exist in the dispersion-periodic NLS equation (1.1) because resonances in the perturbation series generate nonvanishing radiation tails. These tails can be extremely small in certain parameter regimes [10], but they do not vanish when $D_0 > 0$.

Radiation tails of DM solitons occur due to parametric resonance between the DM soliton and the periodic variation of the dispersion. This parametric resonance drains energy out of the DM soliton and leads to its radiative damping. Parametric resonances can be predicted by viewing the periodic term of (1.1) as an external forcing term:

$$i\frac{\partial u}{\partial z} + \frac{1}{2}D_0\frac{\partial^2 u}{\partial t^2} + |u|^2 u = -\frac{m}{2\epsilon}D_\epsilon(z)\frac{\partial^2 u}{\partial t^2}. \tag{1.3}$$

We expand $D_\epsilon(z)$ into a Fourier series,

$$D_\epsilon(z) = \sum_{n=-\infty}^{\infty} d_n\, e^{\frac{2\pi i n z}{\epsilon}}, \quad d_0 = 0, \quad d_{-n} = \bar{d}_n, \tag{1.4}$$

where $\bar{d}_n$ is the complex conjugate of d_n. When the nonlinear term in (1.3) is neglected and the averaged DM soliton $u(z,t) = \Phi(t)\, e^{i\mu z}$ is substituted into the right-hand side of (1.3), we find a solution of the linear inhomogeneous problem in the form of the Fourier series in z,

$$u(z,t) = \left(\sum_{n=-\infty}^{\infty} u_n(t)\, e^{\frac{2\pi i n z}{\epsilon}}\right)\, e^{i\mu z}. \tag{1.5}$$

The correction terms $u_n(t)$ take the form of Fourier integrals in t,

$$u_n(t) = -\frac{m d_n}{4\pi\epsilon}\int_{-\infty}^{\infty} \frac{\omega^2 \hat{\Phi}(\omega) e^{i\omega t} d\omega}{\frac{1}{2}D_0\omega^2 + \frac{2\pi n}{\epsilon} + \mu}, \tag{1.6}$$

where $\hat{\Phi}(\omega)$ is the Fourier transform of $\Phi(t)$. The inhomogeneous solution has resonant denominators at

$$\omega^2 = \omega_n^2 = -\frac{2}{D_0}\left(\mu + \frac{2\pi n}{\epsilon}\right) > 0. \tag{1.7}$$

Resonances are absent if $D_0 = 0$ and $\mu \neq -2\pi n/\epsilon$ for any integer n. This is the only case when DM soliton solutions (1.2) may exist in the dispersion-periodic NLS equation (1.1). In this case, the asymptotic representation of $\Phi(z,t)$ in (1.2) was found recently in [12] in the limit $\epsilon = \mathrm{O}(m) \gg 1$ with the use of the inverse scattering transform methods.

If $D_0 > 0$, sufficiently large negative terms of the Fourier series (1.5)–(1.6) are in resonance (1.7) for $n \leq -N_\mu$, where $N_\mu = \left\lceil \frac{\epsilon\mu}{2\pi} \right\rceil$ is the integer ceiling of $\frac{\epsilon\mu}{2\pi} > 0$. The periodic variations of the dispersion map $D_\epsilon(z)$ lead to a coupling of a bound state

and linear waves of the averaged dispersion map and to the energy transfer from the bound state to radiative waves. As a result, the pulse solution has resonant peaks in the spectrum $\hat{u}(z,\omega)$ at $\omega = \pm\omega_n$, and nonzero values of $u(z,t)$ in the far-field $|t| \gg 1$, as reported numerically in [3, 10].

Radiation damping of solitons in the presence of a weak sinusoidal dispersion variation was considered analytically in [13]. The radiative wave amplitudes and decay rates of solitons were computed by means of the soliton perturbation theory for the standard NLS equation. Dynamics of DM solitons was studied in [14, 15, 16] by variational and numerical methods. Recently, analytical and numerical studies of the same problem were undertaken in [10] by asymptotic beyond-all-orders methods in the limit $\epsilon = \mathrm{O}(m) \ll 1$. Radiation-tail amplitudes and decay rates of DM solitons were found to be exponentially small in this limit. It was also shown in [10] that radiation-tail amplitudes drop to near-zero values in certain windows on the m-axis.

We study here nonlinear parametric resonance of DM solitons for average-anomalous dispersion ($D_0 > 0$) in the limit $m \ll 1$, while we keep $\epsilon = \mathrm{O}(1)$. This is a different limit from the one studied in [10]. In this limit, the DM soliton decays much faster because radiation-tail amplitudes are only algebraically small in terms of $\mathrm{O}(m)$. The new feature of our analysis is that the periodic dispersion map $D_\epsilon(z)$ is allowed to be arbitrary in (1.4) as compared to a single sine function in [13]. Thus, our dispersion maps include the piecewise-constant dispersion map which is widely used in fiber communication systems.

Our analysis starts with the standard NLS equation (1.3) for $m = 0$, such that the right-hand side of (1.3) is treated as a small perturbation. The first-order perturbation theory describes generation of linear waves due to parametric resonances (1.7), and the second-order perturbation theory leads to the decay rate of DM solitons. Methods of our analysis are similar to the soliton perturbation theory in [13], but our calculations are more systematic. We find that the DM soliton decays according to a nonlinear Fermi golden rule, which generalizes the Fermi golden rule for radiative decay of bound states in the linear Schrödinger equation with a time-periodic potential. Rigorous analysis of decay rates in the linear Schrödinger equation was recently considered in [17, 18], where the bound states were supported by a time-dependent periodic potential in [17] and by a time-independent potential in [18].

This paper is structured as follows. Section 2 contains perturbation series expansions and derivations of the Fermi golden rule for DM solitons. Section 3 is devoted to analytical approximations of radiative decay of DM solitons. Section 4 describes a comparison between the analytical and numerical results. Section 5 concludes the paper. Appendices A and B describe technical details of the first-order solution in the perturbation series expansions.

2. Perturbation series expansions. We start with the dispersion-periodic NLS equation in the form (1.3), where ϵ is finite and m is small. If $D_0 > 0$, we employ the following rescaling of variables:

$$z = \epsilon\hat{z}, \quad u = \frac{\hat{u}}{\sqrt{\epsilon}}, \quad t = \sqrt{\epsilon D_0}\,\hat{t}, \quad m = \epsilon D_0 \hat{m}. \tag{2.1}$$

When the hats are dropped, (1.3) becomes

$$iu_z + \frac{1}{2}u_{tt} + |u|^2 u = -\frac{m}{2}D_1(z)u_{tt}, \tag{2.2}$$

where the dispersion map $D_1(z)$ has unit period. In other words, we have normalized ϵ and D_0 in (1.3) so that $\epsilon = 1$ and $D_0 = 1$.

When $m = 0$, the standard NLS equation (2.2) has a bound state:

$$u(z,t) = \Phi(t;\mu)e^{i\mu z}, \tag{2.3}$$

where $\mu > 0$ and $\Phi(t;\mu) = \sqrt{2\mu}\ \mathrm{sech}\left(\sqrt{2\mu}\, t\right)$. When $m \neq 0$, the NLS soliton (2.3) would generate radiative tails and decay accordingly. Parameter μ of the NLS soliton (2.3) changes in z, such that the z-dependence of $\mu(z)$ serves as a condition for Poincaré continuation of the perturbation series for $u(z,t)$ in powers of m. The Fermi golden rule of radiative decay of NLS solitons follows from the dynamical equation for $\mu = \mu(z)$. In order to formalize this qualitative picture, we employ the transformation

$$u(z,t) = U(z,t;\mu(z))e^{i\int_0^z \mu(z')dz'}, \tag{2.4}$$

where $U(z,t;\mu)$ solves the problem

$$i\frac{\partial U}{\partial z} + i\dot{\mu}\frac{\partial U}{\partial \mu} - \mu U + \frac{1}{2}\frac{\partial^2 U}{\partial t^2} + |U|^2 U = -\frac{m}{2}D_1(z)\frac{\partial^2 U}{\partial t^2} \tag{2.5}$$

with the initial data $U(0,t;\mu_0) = \Phi(t;\mu_0)$ and $\mu(0) = \mu_0$. The transformation (2.4) describes the adiabatically varying orbit of the NLS soliton (2.3). We present the asymptotic solution of (2.5) as a perturbation series for $U(z,t;\mu)$ and $\mu(z)$ in powers of m:

$$U(z,t;\mu) = \sum_{k=0}^{\infty} m^k U^{(k)}(z,t;\mu) \tag{2.6}$$

and

$$\dot{\mu} = \sum_{k=1}^{\infty} m^{2k}\Gamma^{(2k)}(\mu), \tag{2.7}$$

where $\Gamma^{(2k)}(\mu)$ are corrections of the Fermi golden rule for radiative decay of NLS solitons. Substitution of (2.6)–(2.7) into (2.5) produces a chain of equations for corrections of the perturbation series. At the leading, first and second orders, the chain of perturbative equations takes the form

$$i\frac{\partial U^{(0)}}{\partial z} - \mu U^{(0)} + \frac{1}{2}\frac{\partial^2 U^{(0)}}{\partial t^2} + |U^{(0)}|^2 U^{(0)} = 0, \tag{2.8}$$

$$i\frac{\partial U^{(1)}}{\partial z} - \mu U^{(1)} + \frac{1}{2}\frac{\partial^2 U^{(1)}}{\partial t^2} + 2|U^{(0)}|^2 U^{(1)} + U^{(0)2}\bar{U}^{(1)} = -\frac{1}{2}D_1(z)\frac{\partial^2 U^{(0)}}{\partial t^2}, \tag{2.9}$$

and

$$\begin{aligned} i\frac{\partial U^{(2)}}{\partial z} - \mu U^{(2)} + \frac{1}{2}\frac{\partial^2 U^{(2)}}{\partial t^2} + 2|U^{(0)}|^2 U^{(2)} + U^{(0)2}\bar{U}^{(2)} \\ = -i\Gamma^{(2)}(\mu)\frac{\partial U^{(0)}}{\partial \mu} - \frac{1}{2}D_1(z)\frac{\partial^2 U^{(1)}}{\partial t^2} - 2|U^{(1)}|^2 U^{(0)} - U^{(1)2}\bar{U}^{(0)}. \end{aligned} \tag{2.10}$$

Initial conditions for these equations are

$$U^{(0)}(0,t;\mu_0) = \Phi(t;\mu_0), \qquad \mu(0) = \mu_0, \tag{2.11}$$

and

$$U^{(k)}(0,t;\mu_0) = 0, \quad k \geq 1. \tag{2.12}$$

Order O(1). The nonlinear equation (2.8) at order O(1) with initial data (2.11) has a unique solution, $U^{(0)}(z,t;\mu) = \Phi(t;\mu)$, which is the NLS soliton with the adiabatic change of $\mu = \mu(z)$.

Order O(m). The linear inhomogeneous equation (2.9) at order O(m) has the Fourier series solution

$$U^{(1)}(z,t;\mu) = \sum_{n=-\infty}^{\infty} U_n^{(1)}(z,t;\mu)\, e^{2\pi i n z}, \tag{2.13}$$

where $U_0^{(1)} = 0$ and $(U_n^{(1)}, \bar{U}_{-n}^{(1)})$ at $n \geq 1$ solve the coupled equations

$$\begin{aligned} & i\frac{\partial U_n^{(1)}}{\partial z} - (\mu + 2\pi n)\, U_n^{(1)} + \frac{1}{2}\frac{\partial^2 U_n^{(1)}}{\partial t^2} + \Phi^2(t;\mu)\, \left(2U_n^{(1)} + \bar{U}_{-n}^{(1)}\right) \\ & \quad = -\frac{d_n}{2}\Phi''(t;\mu), \end{aligned} \tag{2.14}$$

$$\begin{aligned} & -i\frac{\partial \bar{U}_{-n}^{(1)}}{\partial z} - (\mu - 2\pi n)\, \bar{U}_{-n}^{(1)} + \frac{1}{2}\frac{\partial^2 \bar{U}_{-n}^{(1)}}{\partial t^2} + \Phi^2(t;\mu)\, \left(2\bar{U}_{-n}^{(1)} + U_n^{(1)}\right) \\ & \quad = -\frac{d_n}{2}\Phi''(t;\mu). \end{aligned} \tag{2.15}$$

It follows from (2.12) that the system (2.14)–(2.15) is supplemented with zero initial conditions: $U_n^{(1)}(0,t;\mu_0) = 0$ for any $|n| \geq 1$. Solutions of the system (2.14)–(2.15) are constructed in Appendix A with the use of the spectral decomposition for a linearized NLS operator [19, 20]. Asymptotic limits of the correction terms $U_n^{(1)}(z,t;\mu)$ are obtained in Appendix B with the use of generalized functions. These calculations show that the continuous-wave radiation in the solution $U_n^{(1)}(z,t;\mu)$ at large distance z and time t is given by the following expression [see (A.1) and (B.9)]:

$$\lim_{|t|\to\infty, z\to\infty} U_{-n}^{(1)} = -\frac{\pi i\sqrt{2\mu}\, d_{-n}(k_n+i)^2}{4k_n}\, \operatorname{sech}\frac{\pi k_n}{2}\, e^{i\sqrt{2\mu}\, k_n |t|}, \quad n \geq N_\mu, \tag{2.16}$$

and

$$\lim_{|t|\to\infty, z\to\infty} U_{-n}^{(1)} = 0, \quad n < N_\mu, \tag{2.17}$$

where

$$k_n = \sqrt{\frac{2\pi n}{\mu} - 1} > 0, \qquad N_\mu = \left[\frac{\mu}{2\pi}\right]. \tag{2.18}$$

This result will be used at order O(m^2) to calculate the decay rate $\Gamma^{(2)}(\mu)$ of DM solitons.

Order O(m^2). Solution of the linear inhomogeneous equation (2.11) at order O(m^2) can also be represented by the Fourier series:

$$U^{(2)}(z,t;\mu) = \sum_{n=-\infty}^{\infty} U_n^{(2)}(z,t;\mu)\, e^{2\pi i n z}. \tag{2.19}$$

Since the right-hand side of (2.11) has a nonzero mean term in z, the nonzero mean term $U_0^{(2)}(z,t;\mu)$ satisfies the inhomogeneous equation

$$i\frac{\partial U_0^{(2)}}{\partial z} - \mu U_0^{(2)} + \frac{1}{2}\frac{\partial^2 U_0^{(2)}}{\partial t^2} + \Phi^2(t;\mu)\left(2U_0^{(2)} + \bar{U}_0^{(2)}\right) = -i\Gamma^{(2)}(\mu)\frac{\partial \Phi(t;\mu)}{\partial \mu}$$
$$- \sum_{n=-\infty}^{\infty}\left(\frac{1}{2}d_{-n}\frac{\partial^2 U_n^{(1)}}{\partial t^2} + 2\Phi(t;\mu)U_n^{(1)}\bar{U}_n^{(1)} + \Phi(t;\mu)U_n^{(1)}U_{-n}^{(1)}\right). \tag{2.20}$$

The mean term in the right-hand side of (2.20) leads to a secular growth of $U_0^{(2)}(z,t;\mu)$ in z unless the right-hand side of (2.11) is orthogonalized with respect to eigenfunctions of the kernel of the linearized operator (the Fredholm alternative theorem). The correction $\Gamma^{(2)}(\mu)$ is found from the orthogonalization constraint as follows. Projecting (2.20) onto $\Phi(t;\mu)$ and subtracting a complex conjugate equation, we obtain a single equation under the condition that $U_0^{(2)}(z,t;\mu)$ is bounded in t:

$$i\frac{\partial}{\partial z}\langle \Phi, U_0^{(2)} + \bar{U}_0^{(2)}\rangle = -i\Gamma^{(2)}(\mu)\frac{\partial}{\partial \mu}\langle \Phi, \Phi\rangle - \frac{1}{2}\sum_{n=-\infty}^{\infty}\langle \Phi'', d_{-n}U_n^{(1)} - \bar{d}_{-n}\bar{U}_n^{(1)}\rangle$$
$$- \sum_{n=-\infty}^{\infty}\langle \Phi^2, U_n^{(1)}U_{-n}^{(1)} - \bar{U}_n^{(1)}\bar{U}_{-n}^{(1)}\rangle, \tag{2.21}$$

where $\langle f, g\rangle$ is the standard inner product in $L^2(\mathbb{R})$:

$$\langle f, g\rangle = \int_{-\infty}^{\infty}\bar{f}(t)g(t)dt.$$

The right-hand side of (2.21) can be simplified with the use of the system (2.14)–(2.15) as follows:

$$i\frac{\partial}{\partial z}|U_n^{(1)}|^2 + \frac{1}{2}\frac{\partial}{\partial t}\left(\bar{U}_n^{(1)}\frac{\partial U_n^{(1)}}{\partial t} - U_n^{(1)}\frac{\partial \bar{U}_n^{(1)}}{\partial t}\right) = -\frac{1}{2}\Phi''(t;\mu)\left(\bar{d}_{-n}\bar{U}_n^{(1)} - d_{-n}U_n^{(1)}\right)$$
$$-\Phi^2(t;\mu)\left(\bar{U}_n^{(1)}\bar{U}_{-n}^{(1)} - U_n^{(1)}U_{-n}^{(1)}\right). \tag{2.22}$$

As a result, the projection formula (2.21) takes the form

$$i\frac{\partial}{\partial z}\left[\langle \Phi, U_0^{(2)} + \bar{U}_0^{(2)}\rangle + \sum_{n=-\infty}^{\infty}\langle U_n^{(1)}, U_n^{(1)}\rangle\right]$$
$$= -i\Gamma^{(2)}(\mu)\frac{\partial}{\partial \mu}\langle \Phi, \Phi\rangle - \frac{1}{2}\sum_{n=-\infty}^{\infty}\left(\bar{U}_n^{(1)}\frac{\partial U_n^{(1)}}{\partial t} - U_n^{(1)}\frac{\partial \bar{U}_n^{(1)}}{\partial t}\right)\Bigg|_{t=-\infty}^{t=\infty}. \tag{2.23}$$

It follows from (B.1) and (B.5) of Appendix B for finite t that $\langle U_n^{(1)}, U_n^{(1)}\rangle$ becomes z-independent in the limit $z \to \infty$. It also follows from (2.16) that the limiting values of $U_n^{(1)}$ at $|t| \gg 1$ are nonzero and constant in the limit $z \to \infty$ for large negative $n \le -N_\mu$, where $N_\mu = [\frac{\mu}{2\pi}]$ is the integer ceiling of $\frac{\mu}{2\pi} > 0$. Therefore, we conclude that the correction term $U_0^{(2)}(z,t;\mu)$ is free of secular terms in z in the limit $z \to \infty$ only if $\Gamma^{(2)}(\mu)$ is defined by the nonlinear Fermi golden rule,

$$\Gamma^{(2)}(\mu) = -\frac{\sqrt{2\mu}}{4i}\sum_{n=-\infty}^{-N_\mu}\lim_{z\to\infty}\left(\bar{U}_n^{(1)}\frac{\partial U_n^{(1)}}{\partial t} - U_n^{(1)}\frac{\partial \bar{U}_n^{(1)}}{\partial t}\right)\Bigg|_{t=-\infty}^{t=\infty}, \tag{2.24}$$

where we use the formula

$$\frac{\partial}{\partial \mu}\langle \Phi, \Phi \rangle = \frac{\sqrt{2}}{\sqrt{\mu}}. \tag{2.25}$$

Using (2.16), we transform (2.24) to the explicit form

$$\Gamma^{(2)}(\mu) = -\frac{\pi^2 \mu^2}{4} \sum_{n=N_\mu}^{\infty} \frac{|d_n|^2 (1+k_n^2)^2}{k_n} \operatorname{sech}^2\left(\frac{\pi k_n}{2}\right). \tag{2.26}$$

Assuming $\lim_{n\to\infty} |d_n|^2 = 0$, the infinite series in (2.26) converges when $\mu \neq \mu_n \equiv 2\pi n$, where n is any positive integer. Critical resonances occur at $\mu = \mu_n$, when $k_n = 0$. This case will be studied in more detail in section 3.

The correction term $U_0^{(2)}(z,t;\mu)$ solves the linear inhomogeneous equation (2.20) under the constraint (2.26). The right-hand side of (2.20) is bounded but nondecaying in the limits $|t| \to \infty$ and $z \to \infty$ because of the asymptotic limit (2.16). The nondecaying terms in (2.16) are not in resonance with the left-hand side of (2.20) since $k_n^2 + 1 = \frac{2\pi n}{\mu} \neq 0$ for $n \neq 0$. As a result, we conclude from (2.20) that a solution $U_0^{(2)}(z,t;\mu)$ exists and is bounded in the limit $z \to \infty$ under the condition (2.26). Similarly, one can show that a bounded solution exists for any $U_n^{(2)}(z,t;\mu)$ where n is an integer; i.e., the bounded right-hand side term $D_1(z)U_{tt}^{(1)}$ in (2.11) is not in resonance with the left-hand side of (2.11). This completes consideration of the order $\mathrm{O}(m^2)$ of the perturbation series expansions.

3. Decay rates of DM solitons. Formula (2.26) generalizes the Fermi golden rule for radiative decay of bound states in a linear Schrödinger equation with time-periodic potentials [17, 18]. The correction term $\Gamma^{(2)}(\mu)$ is always negative, such that the dynamical system (2.7) exhibits a simple behavior of a monotonic decay of $\mu(z)$ to zero, starting with any initial value $\mu(0) = \mu_0 > 0$. Therefore, the DM soliton decays due to parametric resonances and radiative losses. The decay rate of $\mu(z)$ depends on the nonlinear function $\Gamma^{(2)}(\mu)$ in (2.26). Here we study solutions of the truncated equations (2.7) and (2.26) at the order of $\mathrm{O}(m^2)$:

$$\frac{d\mu}{dz} = -m^2 \pi^4 \sum_{n=N_\mu}^{\infty} \frac{|d_n|^2 n^2}{k_n} \operatorname{sech}^2\left(\frac{\pi k_n}{2}\right). \tag{3.1}$$

We choose the dispersion coefficient $D_1(z)$ as a two-step symmetric function,

$$D_1(z) = \begin{cases} 1, & \mathrm{mod}(z,1) \in \left(0, \frac{1}{4}\right) \cup \left(\frac{3}{4}, 1\right), \\ -1, & \mathrm{mod}(z,1) \in \left(\frac{1}{4}, \frac{3}{4}\right). \end{cases} \tag{3.2}$$

For this dispersion map, the DM soliton is chirp-free at $\mathrm{mod}(z,1) = 0$ and $\mathrm{mod}(z,1) = \frac{1}{2}$ (see [21], for instance). The Fourier coefficients d_n for this dispersion map are

$$d_n = \frac{2(-1)^{n+1}}{\pi n} \sin\left(\frac{\pi n}{2}\right). \tag{3.3}$$

As a result, the dynamical system (3.1) takes an explicit form,

$$\frac{d\mu}{dz} = -4\pi^2 m^2 \sum_{\substack{n=N_\mu \\ n \text{ odd}}}^{\infty} \frac{1}{k_n} \operatorname{sech}^2\left(\frac{\pi k_n}{2}\right), \qquad k_n = \sqrt{\frac{2\pi n}{\mu} - 1}. \tag{3.4}$$

This equation is the main result of this paper. It describes the radiation damping of DM solitons in the normalized dispersion-periodic NLS equation (2.2) with piecewise-constant dispersion maps. It is asymptotically accurate when $m \ll 1$ and μ is not close to critical values $\mu_n = 2\pi n$, where n is a positive odd integer. If $\mu \approx \mu_n$, critical resonances occur and radiation tails become large, such that the perturbation series breaks down in a strict mathematical sense. The decay-rate function $\Gamma^{(2)}(\mu)$ in the right-hand side of (3.4) for $m = 1$ is plotted in Figure 1.

A similar equation for the radiative decay of DM solitons in the presence of weak sinusoidal dispersion variation has been derived in [13]. In that paper, only one term appears in the right-hand side of (3.1) since the Fourier series for $D_\epsilon(z)$ in (1.4) contains only a single term in that case.

Below, we analyze the dynamical equation (3.4) under three different limits: (i) $\mu \ll 1$; (ii) $\mu = \mathrm{O}(1)$; (iii) $\mu \gg 1$.

1. *Limit of small values of* μ. When $\mu \ll 1$, all terms in the series in (3.4) are present since $N_\mu = 1$. But only the first term with $n = 1$ dominates, since the higher terms are exponentially smaller in μ compared to the (exponentially small) first term. Therefore, the dynamical equation (3.4) can be truncated at the first term and simplified as

$$\frac{d\mu}{dz} = -\frac{16\pi^2 m^2 e^{-\pi k_1}}{k_1}, \qquad k_1 = \sqrt{\frac{2\pi}{\mu} - 1}. \tag{3.5}$$

Comparison between numerical solutions of the simplified equation (3.5) and the original equation (3.4) indicates that the simplified equation (3.5) gives a very good approximation to the original equation (3.4) not only for $\mu \ll 1$, but also for $\mu < 2\pi$ (see Figures 2 and 3).

In the limit $\mu \to 0$, methods of exponential asymptotics can be developed after further simplification of the dynamical equation (3.5):

$$\frac{d\mu}{dz} = -\alpha m^2 \mu^{1/2} \exp\left(-\frac{\beta}{\mu^{1/2}}\right), \tag{3.6}$$

where $\alpha = 4(2\pi)^{3/2}$ and $\beta = \pi(2\pi)^{1/2}$. In this limit, the radiation damping of DM solitons and the continuous-tail radiation emitted by the DM soliton are exponentially weak. This agrees with the asymptotic beyond-all-orders calculations by Yang and Kath [10]. A similar situation occurs in the dynamics of embedded solitons in the perturbed integrable fifth-order KdV equation in the small velocity limit [22].

Results of [10] are valid when $\mu \ll 1$ and m is arbitrary, while our results are valid when $m \ll 1$ and μ arbitrary. In the regime of common validity, i.e., $m \ll 1$ and $\mu \ll 1$, the two results match each other, as shown next. When $\mu \ll 1$, the radiation field is dominated by the $n = -1$ term in the Fourier-series solution (2.13) for $U^{(1)}(z, t; \mu)$. The amplitude of this radiation field is thus given asymptotically from (2.16) as

$$u_{\mathrm{rad}} = 2m\pi^{\frac{1}{2}} \exp\left(-\frac{\pi^{3/2}}{\sqrt{2\mu}}\right). \tag{3.7}$$

Due to the rescaling of variables (2.1) and different notations, results of [10] need to be reformulated. In the present notations, the amplitude of the radiation field obtained in [10] is in the form

$$u_{\mathrm{rad}} = \frac{1}{2} C\pi^{\frac{1}{2}} \exp\left(-\frac{\pi^{3/2}}{\sqrt{2\mu}}\right), \tag{3.8}$$

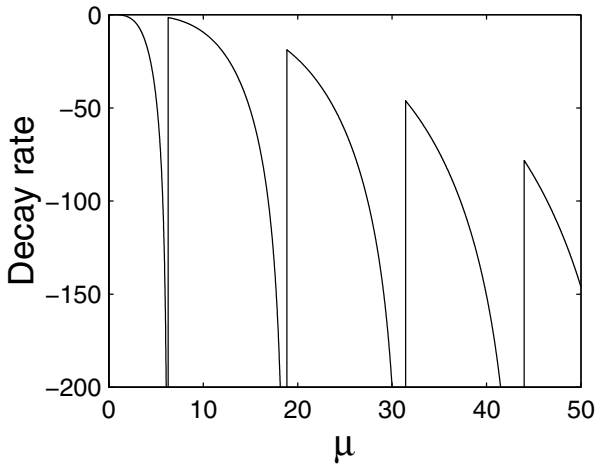

FIG. 1. *Decay rate* $\Gamma^{(2)}(\mu)$ *of DM solitons versus the parameter* μ *as in* (3.4) *for* $m = 1$.

where C is a dispersion map-dependent constant given in Figure 1 of [10]. Our parameter m is equal to $\frac{1}{2}(\sigma_2 - \sigma_1)$ of [10]. When $m \ll 1$, inspection of Figure 1 in [10] shows that $C \approx 2(\sigma_2 - \sigma_1) = 4m$. Thus, in the limits $m, \mu \ll 1$, the radiation field (3.7) from our analysis agrees perfectly with (3.8) from [10]. We note that Yang and Kath [10] also found windows of low radiation field at large values of m. Since our results are valid only in the limit $m \ll 1$ and up to the order of $\mathrm{O}(m^2)$, the low-radiation windows cannot be recovered in our analysis unless the perturbation series (2.6) and (2.7) are extended to at least $\mathrm{O}(m^4)$.

The dynamical equation (3.6) can be integrated with the help of the Laplace method as follows:

$$\frac{1}{2}\alpha m^2(z + z_0) = \exp\left(\frac{\beta}{\mu^{1/2}}\right)\left[\frac{\mu}{\beta} + \mathrm{O}(\mu^{3/2})\right], \tag{3.9}$$

where z_0 is a constant of integration. The leading-order asymptotic solution for $\mu(z)$ in the limit $\mu \to 0$ is derived from (3.9) in the form

$$\mu(z) = \left[\frac{\beta}{\log\left[\frac{\alpha m^2}{2\beta}(z + z_0)\log^2(z + z_0)\right] + \mathrm{O}\left(\frac{1}{\log(z+z_0)}\right)}\right]^2. \tag{3.10}$$

As $z \to \infty$, the parameter $\mu(z)$ decays logarithmically as

$$\mu(z) \sim \frac{\beta^2}{\log^2 z}\left[1 - 4\frac{\log\log z}{\log z}\right]. \tag{3.11}$$

This logarithmic decay of bound states has been reported previously for internal modes of envelope solitons in [23]. Logarithmic decay is associated with an exponentially small Fermi golden rule for exponentially small radiative waves.

2. *Solutions near critical values* μ_n. If $\mu(0) > 2\pi$, the decay of DM solitons always leads to the point where the parameter μ has to pass through a critical value $\mu_n = 2\pi n$, where n is a positive odd integer. When this happens, the radiation field becomes large, and the perturbation-series solution formally breaks down. Consequently, the

solution of the dynamical equation (3.4) may no longer give a good approximation to the true solution. However, numerical results indicate that the solution of (3.4) still agrees qualitatively with the solution of the full equation (2.2) (see Figure 4). Here we derive the solution of the dynamical equation (3.4) when it passes through a single critical value $\mu = \mu_N$ at $z = z_N$.

Since N_μ is an integer ceiling of $\frac{\mu}{2\pi}$, and N_μ is odd, the one-sided limit $z \to z_N^-$ is nonsingular, and the parameter $\mu(z)$ approaches μ_N with a linear slope:

$$\mu(z) = \mu_N - \mu_N'(z - z_N) + \mathrm{O}(z - z_N)^2, \qquad z < z_N, \tag{3.12}$$

where

$$\mu_N' = 4m^2\pi^2 \sum_{\substack{n=N_\mu \\ n \text{ odd}}}^{\infty} \frac{1}{k_n} \mathrm{sech}^2\left(\frac{\pi k_n}{2}\right), \tag{3.13}$$

and k_n are all computed at $\mu = \mu_N$. Once the parameter $\mu(z)$ passes below μ_N, a singular term with $n = N$ appears in the dynamical equation (3.4) because $k_N = 0$ at $\mu = \mu_N$. The leading-order asymptotic approximation for the solution $\mu(z)$ for $z > z_N$ takes the form

$$\mu(z) = \mu_N - [\alpha(z - z_N)]^{2/3} + \mathrm{O}(z - z_N), \qquad z > z_N, \tag{3.14}$$

where $\alpha = 6m^2\pi^2\sqrt{\mu_N}$. The slope of $\mu(z)$ is infinite in the limit $z \to z_N^+$, but the solution $\mu(z)$ is still continuous at $z = z_N$. The asymptotic solution (3.14) describes a sharp drop in the amplitude of the DM soliton after it passes through a critical resonance value μ_N.

3. *Limit of large values of* μ. When $\mu \gg 1$, the dynamical equation (3.4) can also be simplified. Using the formula

$$k_{n+2}^2 - k_n^2 = \frac{4\pi}{\mu} \tag{3.15}$$

and the Riemann sum approximation for the integral with areas of rectangles, we approximate the sum as

$$\begin{aligned} \frac{1}{\mu} \sum_{\substack{n=N_\mu \\ n \text{ odd}}}^{\infty} \frac{1}{k_n} \mathrm{sech}^2\left(\frac{\pi k_n}{2}\right) &= \frac{1}{2\pi} \sum_{\substack{n=N_\mu \\ n \text{ odd}}}^{\infty} \mathrm{sech}^2\left(\frac{\pi k_n}{2}\right) \frac{(k_{n+2} + k_n)}{2k_n}(k_{n+2} - k_n) \\ &\approx \frac{1}{2\pi} \int_{k_0(\mu)}^{\infty} \mathrm{sech}^2\left(\frac{\pi k}{2}\right) dk, \end{aligned} \tag{3.16}$$

where $k_0(\mu) = k_{N_\mu}$ such that $0 < k_0(\mu) < 1$. In this approximation, the dynamical system (3.4) simplifies to the form

$$\frac{d\mu}{dz} = -4m^2\mu\left[1 - \tanh(k_0(\mu))\right]. \tag{3.17}$$

Using the comparison principle for (3.17), we conclude that DM solitons decay with a linear decay rate when $\mu(z) \gg 1$:

$$\mu(0)\, \exp\left(-4m^2 z\right) \le \mu(z) \le \mu(0)\, \exp\left(-4m^2\alpha_0 z\right), \tag{3.18}$$

where $\alpha_0 = 1 - \tanh 1 > 0$.

We note that when $\mu(0) \gg 1$, the monotonic decay of $\mu(z)$ passes through many critical values, where radiation amplitudes are large. As a result, the asymptotic solution (3.18) may not give a good quantitative approximation to the true solution. Nevertheless, the solution (3.18) still describes qualitatively the decay of DM solitons for $\mu(0) \gg 1$ (see Figure 5).

4. Numerical simulations of DM solitons. Here we directly simulate the normalized dispersion-periodic NLS equation (2.2) and compare numerical solutions with the above analytical solutions. Our numerical method uses the fast Fourier transform (FFT) to compute the derivatives in t, and the fourth-order Runge–Kutta scheme to advance in z. At the values of z where the dispersion has a discontinuity (i.e., $\mathrm{mod}(z,1) = \frac{1}{4}$ and $\mathrm{mod}(z,1) = \frac{3}{4}$), the stepsize Δz is reduced so that the overall fourth-order accuracy in z is assured. To eliminate radiation reflection at the boundaries of the t-interval, damping boundary conditions are used. Our results are checked with longer t-intervals, more grid points in t, and smaller stepsize Δz, and the results are found to remain the same.

Our numerical simulation starts with the initial condition of a standard (unchirped) NLS soliton:

$$u(0,t) = \sqrt{2\mu_0}\,\mathrm{sech}\sqrt{2\mu_0}\,t. \tag{4.1}$$

It is known that DM solitons are unchirped in the middle point of each constant-dispersion segment, i.e., at $\mathrm{mod}(z,1) = 0$ and $\mathrm{mod}(z,1) = 1/2$ in the present case. Thus, when the unchirped NLS soliton (4.1) is launched at $z = 0$, the radiation emission is minimal compared to that of chirped solitons.

Below, we describe numerical computations with $m = 0.1$ and four different values of $\mu(0)$.

1. *Figure 2:* $\mu(0) = 1$. Figure 2(a) shows the soliton amplitude versus distance z. We see that this soliton's amplitude is oscillating (breathing) with unit period, which is the period of the dispersion map $D_1(z)$. This behavior is a signature of DM solitons. The evolution of the average soliton amplitude in z is plotted in Figure 2(b). This average amplitude is numerically calculated for each unit distance z as the average between the maximum and minimum amplitudes. It is clear from Figure 2(b) that the DM soliton slowly decays due to the parametric resonance between the soliton and the dispersion map, in accordance with the analytical prediction above. Also in Figure 2(b), the analytical values of the average soliton amplitude $\sqrt{2\mu}$ obtained from the dynamical equation (3.4) and its simplified version (3.5) are plotted as circles "o" and crosses "x," respectively. We see that both analytical equations (3.4) and (3.5) agree with numerical values and with each other extremely well. This comparison confirms that the dynamical equation (3.4) for radiation damping of DM solitons is asymptotically accurate in the case $m \ll 1$ and $\mu(0) < \mu_1 = 2\pi$, and that the simplified equation (3.5) is a very good approximation to (3.4) not only for $\mu \ll 1$, but also for $\mu = \mathrm{O}(1)$. The soliton profile at $z = 2000$ is shown in Figure 2(c) in a logarithmic scale. We clearly see the central DM-pulse is flanked by continuous-wave radiation. The radiation amplitude is nearly constant. This is because the radiation is excited mainly by the lowest-order resonance with $n = 1$ in (3.4), and the radiation field is dominated by the lowest-order radiative waves with $n = 1$ in (2.16). At $z = 2000$, the parameter μ can be inferred from Figure 2(b) as roughly 0.6731, and the radiation field should be dominated by waves

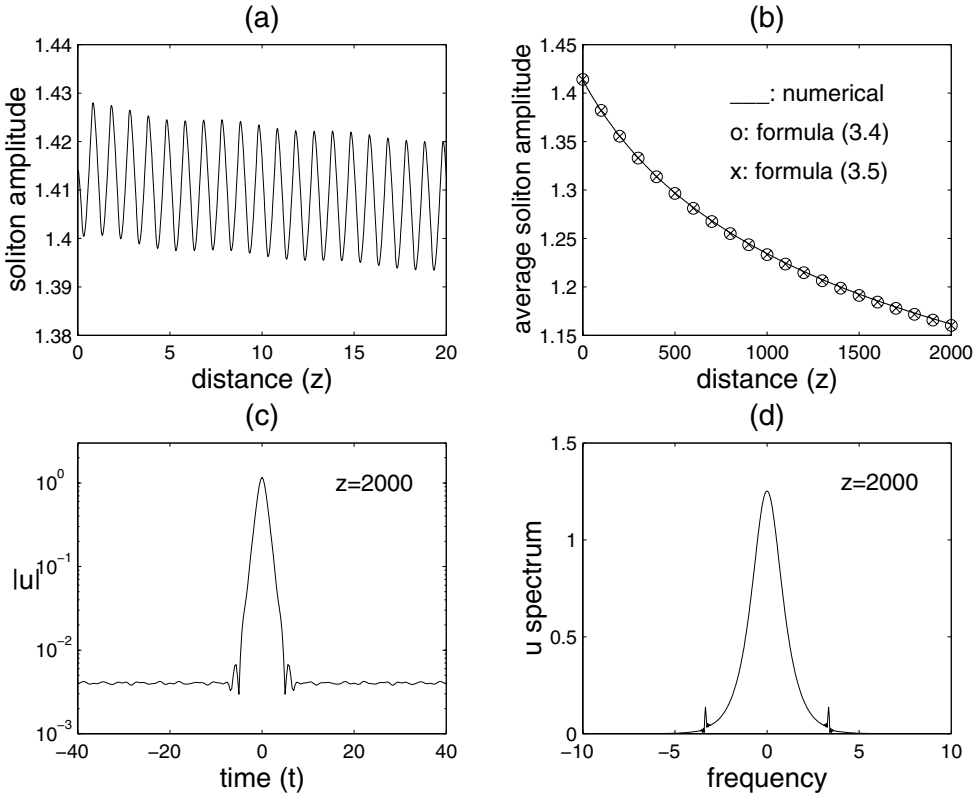

FIG. 2. *Numerical evolution of the DM soliton with* $m = 0.1$ *and* $\mu(0) = 1$. (a) *Soliton amplitude versus distance* z. (b) *Average soliton amplitude versus* z*: numerical results (solid curve); analytical average soliton amplitude* $\sqrt{2\mu}$ *from* (3.4) *(circles); analytical average soliton amplitude* $\sqrt{2\mu}$ *from* (3.5) *(crosses).* (c) *Solution profile at* $z = 2000$. (d) *Fourier spectrum of the solution at* $z = 2000$.

with frequencies $\pm\sqrt{2\mu}\, k_1 \approx \pm 3.35$, according to (2.16). This is confirmed in Figure 2(d), where the solution spectrum at $z = 2000$ is shown. This spectrum has two spikes at frequencies ± 3.33, which are due to the radiation field. The locations of these frequency spikes are in excellent agreement with the theoretical values ± 3.35.

2. *Figure* 3*:* $\mu(0) = 6$. In this case, the initial value of μ is close to but still below the lowest critical resonance value $\mu_1 = 2\pi$. Therefore, we expect that the radiation field would be larger, and the theoretical approximation (3.4) for the DM soliton less accurate. This is indeed the case. In Figure 3(a), the soliton amplitude versus distance z is plotted. We see that the amplitude oscillates irregularly, and the period of oscillations is not equal to the unit dispersion map period any-more. This is an indication that the central pulse has deviated from the DM soliton. However, our analytical solution for the average soliton amplitude $\sqrt{2\mu}$, which is calculated from the dynamical equation (3.4), still gives a very reasonable approximation to the true solution (see the dashed line in Figure 3(a)). We have also compared solutions from the dynamical equation (3.4) and its simplified form (3.5) for the present set of parameters, and found that the two solutions differ by only less than 6%. Thus, over a wide range of μ values below the critical resonance $\mu_1 = 2\pi$, the simplified equation (3.5) gives a very good approximation to the original dynamical equation

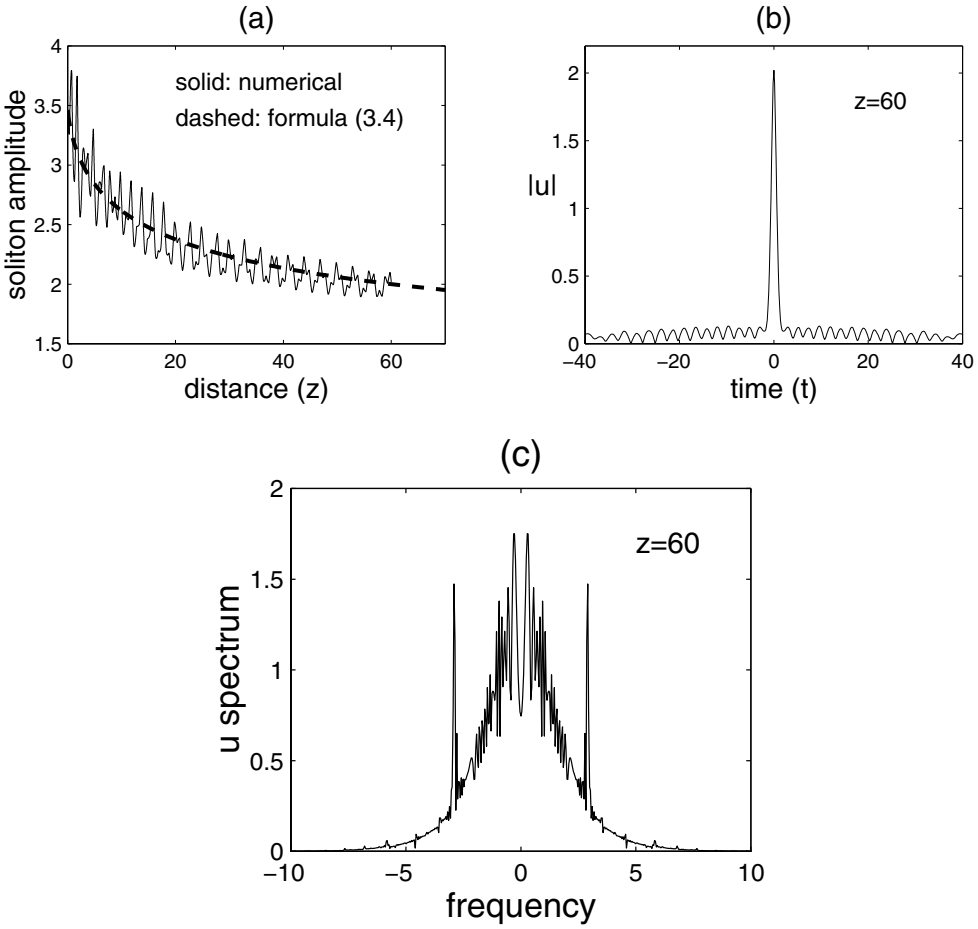

FIG. 3. *Numerical evolution of the DM soliton with* $m = 0.1$ *and* $\mu(0) = 6$. (a) *Soliton amplitude versus* z*: numerical results (solid curve); analytical average soliton amplitude* $\sqrt{2\mu}$ *from* (3.4) *(dashed curve).* (b) *Solution profile at* $z = 60$. (c) *Spectrum of the solution at* $z = 60$.

(3.4). In Figures 3(b) and (c), the numerically obtained field profile and its Fourier spectrum at distance $z = 60$ are plotted. Due to the quasi-critical resonance, the radiation field in Figure 3(b) is much larger than that in Figure 2(c). In addition, the Fourier spectrum in Figure 3(c) indicates that the solution can no longer be called a DM soliton. Nevertheless, the main resonant spikes on the two sides of Figure 3(c) are still well predicted by the resonance conditions at $k = \pm\sqrt{2\mu}\, k_1$.

3. *Figure* 4*:* $\mu(0) = 12$. In this case, the initial value of μ is above the lowest critical resonance value $\mu_1 = 2\pi$, and the monotonic decay of the DM soliton passes through this critical resonance. Here we focus on how this transition occurs. In Figure 4(a), the soliton amplitude versus distance z is plotted as the solid curve. We see that radiation damping is initially slow, as the average soliton amplitude decreases toward the critical value at $\sqrt{2\mu_1} \approx 3.54$. In this process, the DM soliton oscillates with the unit period of the dispersion map. A solution profile plotted in Figure 4(b) at $z = 50$ shows a weak radiation field, which is the reason for the slow decay of the DM soliton. The corresponding Fourier spectrum in Figure 4(d) shows that the radiation field consists of a discrete set of frequencies which are precisely the resonant frequencies.

When the average soliton amplitude passes through $\sqrt{2\mu_1}$, a critical resonance occurs. Consequently, the soliton decays much faster (see Figure 4(a)). Strong continuous-wave radiation is emitted in this process, and the DM soliton is strongly modified. After the average soliton amplitude passes below $\sqrt{2\mu_1}$, the pulse oscillates irregularly, and its oscillation period is no longer equal to the unit period of the dispersion map. A solution profile shown in Figure 4(c) at $z = 100$ confirms that the radiation field becomes much stronger past the critical-resonance stage. The Fourier spectrum in Figure 4(e) shows that the radiation field is no longer dominated by a discrete set of resonant frequencies. In addition, the Fourier spectrum appears to be quite noisy.

When a critical resonance is reached, the perturbation-series solution (2.6) and (2.7) formally breaks down, and the analytical results are not expected to provide quantitatively accurate approximations to the numerical solution. This is indeed the case. In Figure 4(a), the analytical average soliton amplitude $\sqrt{2\mu}$ obtained from (3.4) is also plotted (dashed line). We see that prior to the critical resonance, the analytical curve closely follows the numerical average soliton amplitude (not shown). However, when the numerical solution gets close to the critical resonance, it starts to deviate from the analytical curve considerably. In fact, the numerical solution passes through the critical resonance much earlier than what the theory predicts (see Figure 4(a)). Nevertheless, the analytical solution still agrees qualitatively with the numerical solution. For instance, the sharp (infinite-slope) drop of the soliton amplitude as predicted in (3.14) does occur past the critical value of the soliton amplitude at $\sqrt{2\mu_1} \approx 3.54$ (see Figure 4(a)).

4. *Figure* 5*:* $\mu(0) = 100$. When the initial value of μ is large, the asymptotic analysis predicts that the soliton decays exponentially according to the bounds in (3.18). However, the monotonic soliton-decay passes through many critical resonances in this case. Thus, the accuracy of the analytical prediction needs to be examined. To address this issue, the results from numerical simulations at $m = 0.1$ and $\mu(0) = 100$ are shown in Figures 5(a)–(e). When $\mu \gg 1$, the DM soliton spends most of the time inside individual constant-dispersion segments, where the DM soliton is governed by the standard NLS equation. This is reflected by the fast amplitude oscillations inside each constant-dispersion segment in Figure 5(a). Due to the radiative damping, the DM soliton passes through critical resonances at $n = 15, 13, 11, 9, 7, \ldots, 1$, when the average soliton amplitude matches the critical values at $\sqrt{4\pi n} = 13.73, 12.78, 11.76, 10.63, 9.38, \ldots, 3.54$, respectively. It follows from Figure 5(a) that, even though the DM soliton passes through a number of critical resonances here, it still holds up and maintains its DM soliton character and the unit periodicity up to the first four critical resonances. The solution profile and the Fourier spectrum of the DM soliton at $z = 15$ are shown in Figures 5(b) and (d). Further evolution of the DM soliton shows that the DM soliton character is lost after the fifth critical resonance at the average amplitude about 9.38. The solution profile and its Fourier spectrum at $z = 24$ are shown in Figures 5(c) and (e). A noisy spectrum past the critical resonances similar to that of Figure 4(e) is observed.

It follows from Figure 5(a) that higher-order critical resonances have a much weaker effect on the dynamics of the DM soliton than do lower-order resonances. As a result, the analytical dashed curve in Figure 5(a) for the average soliton amplitude agrees well with the numerical results until the fifth critical resonance is reached. We have also checked that the analytical curve in Figure 5(a) is indeed bounded between the two exponentially decaying functions in (3.18).

In the end of this section, we discuss how the solution changes when the perturbation strength m gets larger. For this purpose, we choose $m = 0.2$, compared to $m = 0.1$ in Figures 2–5. The soliton amplitudes versus distance z for $\mu(0) = 1, 6, 12$ are shown in Figures 6(a), (b), and (c), respectively. The average soliton amplitudes predicted from (3.4) are also plotted for comparison. Figure 6(a) shows that in the case of small and moderate values of $\mu(0)$, the soliton still decays according to the analytical equation (3.4). Figures 6(b) and (c) indicate that when $\mu(0)$ is close to or above the lowest critical resonance value $\mu_1 = 2\pi$, the pulse deviates further from the DM soliton than in the case of $m = 0.1$, and the pulse amplitude oscillates with a period further away from the unit period of the dispersion map. When m increases, the distance scale for soliton evolution shrinks by a factor of m^2, as formula (3.4) predicts. For instance, when $m = 0.1$ and $\mu(0) = 12$, the lowest critical resonance is reached in the numerical solution at $z \approx 76$ (see Figure 4(a)), while when $m = 0.2$, the critical resonance in the numerical solution is reached at $z \approx 18$, i.e., four times faster.

5. Summary and discussion. In this paper, we have studied the nonlinear parametric resonance of DM solitons for average-anomalous dispersion ($D_0 > 0$) in the limit $m \to 0$ by both analytical and numerical methods. We have found that due to a resonance between the DM soliton and the dispersion map, the soliton

keeps shedding continuous-wave radiation and consequently decays. The radiation amplitude is on the order of m, while the decay rate of DM solitons is on the order of m^2. We have calculated the analytical approximations for the decay rate of DM solitons in the limits of small, intermediate, and large initial soliton amplitudes. We have shown that when the soliton passes through a critical resonance, it decays much faster. All these analytical results are found to be in excellent agreement with direct numerical simulations.

Resonances in the dispersion-periodic NLS equation (1.1) resemble a nonlinear generalization of parametric resonances in a linear Schrödinger equation studied recently in [17, 18]. The perturbation term in [17, 18] satisfies the assumption of being periodic in time and decaying fast in space. The nonlinear problem (1.1) does not satisfy this localization assumption. In addition, the periodic variations of $D_\epsilon(z)$ are not generally small perturbations of the mean term D_0 in real communication systems. Thus, rigorous analysis of the parametric resonance of DM solitons in dispersion-periodic NLS equation (1.1) with nonsmall dispersion variations needs further investigation.

Appendix A: Solutions of the first-order problem (2.14)–(2.15). We use Kaup's method [19] to solve the inhomogeneous problem (2.14)–(2.15) with the spectral decomposition for a linearized NLS operator. Since the potential of the problem can be rescaled as $\Phi(t;\mu) = \sqrt{2\mu}\,\Phi(T)$, where $\Phi(T) = \mathrm{sech} T$ and $T = \sqrt{2\mu}t$, we transform the variables as follows:

$$U_n^{(1)}(z,t;\mu) = 2d_n\sqrt{2\mu}\,V_n(Z,T), \quad Z = \mu z, \quad T = \sqrt{2\mu}t. \tag{A.1}$$

The system (2.14)–(2.15) in new variables transforms to the following:

$$i\frac{\partial V_n}{\partial Z} - (1+\lambda_n)\,V_n + \frac{\partial^2 V_n}{\partial T^2} + 2\,\mathrm{sech}^2 T\,\left(2V_n + \bar{V}_{-n}\right) = -\frac{1}{2}\Phi''(T), \tag{A.2}$$

$$-i\frac{\partial \bar{V}_{-n}}{\partial Z} - (1-\lambda_n)\,\bar{V}_{-n} + \frac{\partial^2 \bar{V}_{-n}}{\partial T^2} + 2\,\mathrm{sech}^2 T\,\left(2\bar{V}_{-n} + V_n\right) = -\frac{1}{2}\Phi''(T), \tag{A.3}$$

where

$$\lambda_n = \frac{2\pi n}{\mu}.$$

The system is written in matrix notations as

$$\mathcal{L}\begin{bmatrix} V_n \\ \bar{V}_{-n} \end{bmatrix} = \left(i\frac{\partial}{\partial Z} - \lambda_n\right)\begin{bmatrix} V_n \\ \bar{V}_{-n} \end{bmatrix} + \frac{1}{2}\begin{bmatrix} 1 \\ -1 \end{bmatrix}\Phi''(T), \tag{A.4}$$

where the linearized NLS operator is

$$\mathcal{L} = \begin{bmatrix} -\frac{\partial^2}{\partial T^2} + 1 - 4\,\mathrm{sech}^2 T & -2\,\mathrm{sech}^2 T \\ 2\,\mathrm{sech}^2 T & \frac{\partial^2}{\partial T^2} - 1 + 4\,\mathrm{sech}^2 T \end{bmatrix}. \tag{A.5}$$

The linearized NLS operator $\mathcal{L}$ possesses a complete set of eigenfunctions [19] that consists of eigenfunctions associated with two branches of the continuous spectrum and eigenfunctions associated with the zero eigenvalue of the discrete spectrum. The continuous spectrum eigenfunctions are

$$\boldsymbol{\psi}_1(T;k) = e^{ikT}\left[\left(1 - \frac{2ike^{-T}}{(k+i)^2\cosh T}\right)\begin{pmatrix} 0 \\ 1 \end{pmatrix} + \frac{1}{(k+i)^2\cosh^2 T}\begin{pmatrix} 1 \\ 1 \end{pmatrix}\right] \tag{A.6}$$

and

$$\boldsymbol{\psi}_2(T;k) = e^{-ikT}\left[\left(1+\frac{2ike^{-T}}{(k-i)^2\cosh T}\right)\begin{pmatrix}1\\0\end{pmatrix}+\frac{1}{(k-i)^2\cosh^2 T}\begin{pmatrix}1\\1\end{pmatrix}\right], \tag{A.7}$$

such that $\mathcal{L}\boldsymbol{\psi}_1(T;k) = -(1+k^2)\boldsymbol{\psi}_1(T;k)$ and $\mathcal{L}\boldsymbol{\psi}_2(T;k) = (1+k^2)\boldsymbol{\psi}_2(T;k)$. The zero eigenvalue has algebraic multiplicity four and geometric multiplicity two. The eigenfunctions of the zero eigenvalue are

$$\boldsymbol{\phi}_1(T) = \begin{pmatrix}1\\-1\end{pmatrix}\operatorname{sech}T, \quad \boldsymbol{\phi}_2(T) = \begin{pmatrix}1\\1\end{pmatrix}\operatorname{sech}T\tanh T, \tag{A.8}$$

such that $\mathcal{L}\boldsymbol{\phi}_{1,2}(T) = 0$. The generalized eigenfunctions of the zero eigenvalue are

$$\boldsymbol{\phi}_1^d(T) = \begin{pmatrix}1\\1\end{pmatrix}(T\tanh T - 1)\operatorname{sech}T, \quad \boldsymbol{\phi}_2^d(T) = \begin{pmatrix}1\\-1\end{pmatrix}T\operatorname{sech}T, \tag{A.9}$$

such that $\mathcal{L}\boldsymbol{\phi}_{1,2}^d(T) = 2\boldsymbol{\phi}_{1,2}(T)$. Eigenfunctions of the linearized NLS operator $\mathcal{L}$ satisfy the orthogonality conditions

$$\langle\boldsymbol{\psi}_1(k')|\sigma_3|\boldsymbol{\psi}_1(k)\rangle = -2\pi\delta(k'-k), \quad \langle\boldsymbol{\psi}_2(k')|\sigma_3|\boldsymbol{\psi}_2(k)\rangle = 2\pi\delta(k'-k), \tag{A.10}$$

$$\langle\boldsymbol{\phi}_1|\sigma_3|\boldsymbol{\phi}_1^d\rangle = -2, \quad \langle\boldsymbol{\phi}_2|\sigma_3|\boldsymbol{\phi}_2^d\rangle = 2, \tag{A.11}$$

with respect to the inner product

$$\langle\mathbf{f}|\sigma_3|\mathbf{g}\rangle = \int_{-\infty}^{\infty}\left[\bar{f}_1(T)g_1(T) - \bar{f}_2(T)g_2(T)\right]dT. \tag{A.12}$$

All other inner products computed with eigenfunctions (A.6)–(A.9) are identically zero. The orthogonality conditions (A.10)–(A.11) are modified compared with the original definition in [19]. Orthogonality conditions similar to (A.10)–(A.11) were used by Kaup and Lakoba [20].

The right-hand side term of (A.4) can be decomposed through a complete set of eigenfunctions (A.6)–(A.9) as follows:

$$\begin{aligned}\mathbf{F} = \frac{1}{2}\begin{bmatrix}1\\-1\end{bmatrix}\Phi''(T) = &\int_{-\infty}^{\infty}\left[\alpha(k)\boldsymbol{\psi}_1(T;k) + \beta(k)\boldsymbol{\psi}_2(T;k)\right]dk\\ &+a\boldsymbol{\phi}_1(T) + b\boldsymbol{\phi}_2(T) + c\boldsymbol{\phi}_1^d(T) + d\boldsymbol{\phi}_2^d(T),\end{aligned} \tag{A.13}$$

where the expansion coefficients can be explicitly computed as

$$\alpha(k) = -\frac{1}{2\pi}\langle\boldsymbol{\psi}_1(k)|\sigma_3|\mathbf{F}\rangle = \frac{(k+i)^2}{8}\operatorname{sech}\frac{\pi k}{2}, \tag{A.14}$$

$$\beta(k) = \frac{1}{2\pi}\langle\boldsymbol{\psi}_2(k)|\sigma_3|\mathbf{F}\rangle = -\frac{(k-i)^2}{8}\operatorname{sech}\frac{\pi k}{2}, \tag{A.15}$$

$$a = -\frac{1}{2}\langle\boldsymbol{\phi}_1^d|\sigma_3|\mathbf{F}\rangle = -\frac{1}{2}, \quad b = \frac{1}{2}\langle\boldsymbol{\phi}_2^d|\sigma_3|\mathbf{F}\rangle = 0, \tag{A.16}$$

$$c = -\frac{1}{2}\langle \boldsymbol{\phi}_1 | \sigma_3 | \mathbf{F} \rangle = 0, \quad d = \frac{1}{2}\langle \boldsymbol{\phi}_2 | \sigma_3 | \mathbf{F} \rangle = 0. \tag{A.17}$$

Here we have used the exact value,

$$\frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\cos kT}{\cosh T} dT = \operatorname{sech}\left(\frac{\pi k}{2}\right).$$

The solution of (A.2)–(A.3) can be found by using the spectral decomposition:

$$\begin{aligned}\begin{bmatrix} V_n \\ \bar{V}_{-n} \end{bmatrix}(Z,T) &= \int_{-\infty}^{\infty} \left[\alpha_n(k,Z)\boldsymbol{\psi}_1(T;k) + \beta_n(k,Z)\boldsymbol{\psi}_2(T;k)\right] dk \\ &+ a_n(Z)\boldsymbol{\phi}_1(T) + b_n(Z)\boldsymbol{\phi}_2(T) + c_n(Z)\boldsymbol{\phi}_1^d(T) + d_n(Z)\boldsymbol{\phi}_2^d(T).\end{aligned} \tag{A.18}$$

Coefficients of the expansion satisfy a simple Z-evolution problem with zero initial conditions:

$$i\frac{\partial \alpha_n}{\partial Z} = (\lambda_n - 1 - k^2)\alpha_n - \alpha(k), \quad i\frac{\partial \beta_n}{\partial Z} = (\lambda_n + 1 + k^2)\beta_n - \beta(k), \tag{A.19}$$

$$i\frac{\partial a_n}{\partial Z} = \lambda_n a_n + 2c_n - a, \quad i\frac{\partial b_n}{\partial Z} = \lambda_n b_n + 2d_n - b, \tag{A.20}$$

and

$$i\frac{\partial c_n}{\partial Z} = \lambda_n c_n - c, \quad i\frac{\partial d_n}{\partial Z} = \lambda_n d_n - d. \tag{A.21}$$

The unique solution of the Z-evolution problem (A.19)–(A.21) is

$$\alpha_n(k,Z) = \frac{\alpha(k)}{\lambda_n - 1 - k^2}\left[1 - e^{-i(\lambda_n - 1 - k^2)Z}\right], \tag{A.22}$$

$$\beta_n(k,Z) = \frac{\beta(k)}{\lambda_n + 1 + k^2}\left[1 - e^{-i(\lambda_n + 1 + k^2)Z}\right], \tag{A.23}$$

$$a_n(Z) = -\frac{1}{2\lambda_n}\left[1 - e^{-i\lambda_n Z}\right], \quad b_n(Z) = 0, \tag{A.24}$$

and

$$c_n(Z) = 0, \quad d_n(Z) = 0. \tag{A.25}$$

Equations (A.24)–(A.25) are obtained with the use of (A.16)–(A.17).

Appendix B: Asymptotic limits for the first-order solution. We analyze the first-order solution $(V_n, \bar{V}_{-n})(Z,T)$ defined in the spectral representation form (A.18) of Appendix A with explicit spectral coefficients in (A.14)–(A.15) and (A.22)–(A.25). The asymptotic limit $Z \to \infty$ depends on a range of values of T.

(i) $|T| < \infty$ and $Z \to \infty$. The first-order solution is a sum of two terms, $V_n(Z,T) = W_n(T) + Q_n(Z,T)$, where $W_n(T)$ is generated by the inhomogeneous part of the system (A.2)–(A.3) and $Q_n(Z,T)$ is generated by the homogeneous part of the

system (A.2)–(A.3) in the initial-value problem. Using the spectral decomposition (A.18), we express $W_n(T)$ and $Q_n(Z,T)$ explicitly as

$$\left[\begin{array}{c} W_n \\ \bar{W}_{-n} \end{array} \right](T) = \int_{-\infty}^{\infty} \left[\frac{\alpha(k)}{\lambda_n - 1 - k^2} \boldsymbol{\psi}_1(T;k) + \frac{\beta(k)}{\lambda_n + 1 + k^2} \boldsymbol{\psi}_2(T;k) \right] dk - \frac{1}{2\lambda_n} \boldsymbol{\phi}_1(T) \tag{B.1}$$

and

$$\begin{aligned} \left[\begin{array}{c} Q_n \\ \bar{Q}_{-n} \end{array} \right](Z,T) = - \int_{-\infty}^{\infty} \left[\frac{\alpha(k) e^{-i(\lambda_n - 1 - k^2)Z}}{\lambda_n - 1 - k^2} \boldsymbol{\psi}_1(T;k) \right. \\ \left. + \frac{\beta(k) e^{-i(\lambda_n + 1 + k^2)Z}}{\lambda_n + 1 + k^2} \boldsymbol{\psi}_2(T;k) \right] dk + \frac{e^{-i\lambda_n Z}}{2\lambda_n} \boldsymbol{\phi}_1(T). \end{aligned} \tag{B.2}$$

We use formulas of generalized functions,

$$\lim_{Z \to \infty} \frac{e^{\pm iKZ}}{K} = \pm \pi i \delta(K) \tag{B.3}$$

and

$$\delta(k^2 + k_n^2) = 0, \quad \delta(k^2 - k_n^2) = \frac{1}{2k_n} \left[\delta(k - k_n) + \delta(k + k_n) \right], \tag{B.4}$$

and notice that the limit $Z \to \infty$ in (B.2) is nonzero only if the resonance equation $1 + k^2 \pm \lambda_n = 0$ has a solution for real k. We consider $n > 0$ such that $\lambda_n > 0$ and denote $k_n = \sqrt{\lambda_n - 1} \geq 0$ for $\lambda_n \geq 1$. The resonance condition $\lambda_n \geq 1$ is satisfied for $n \geq N_\mu$, where $N_\mu = [\frac{\mu}{2\pi}]$ is the integer ceiling of $\frac{\mu}{2\pi} > 0$. With the use of (B.3)–(B.4), we compute the limit $Z \to \infty$ for $Q_n(Z,T)$ at $n \geq N_\mu$ and finite T:

$$\lim_{Z \to \infty} \left[\begin{array}{c} Q_n \\ \bar{Q}_{-n} \end{array} \right](Z,T) = \frac{\pi i}{2k_n} \left[\alpha(k_n) \boldsymbol{\psi}_1(T;k_n) + \alpha(-k_n) \boldsymbol{\psi}_1(T;-k_n) \right]. \tag{B.5}$$

The first-order solution $V_n(Z,T) = W_n(T) + Q_n(Z,T)$ is bounded in T and Z in the limit $Z \to \infty$.

(ii) $|T| \to \infty$ and $Z \to \infty$. It follows from (B.3)–(B.4) that

$$\lim_{T \to \pm\infty} \frac{e^{ikT}}{(k - k_n)(k + k_n)} = \pm \frac{\pi i}{2k_n} \left[\delta(k - k_n) e^{ik_n T} - \delta(k + k_n) e^{-ik_n T} \right]. \tag{B.6}$$

Using this formula for $n \geq N_\mu$, we find from (B.1) and (B.5) that

$$\lim_{T \to \pm\infty} \left[\begin{array}{c} W_n \\ \bar{W}_{-n} \end{array} \right](T) = \mp \frac{\pi i}{16 k_n} \operatorname{sech} \frac{\pi k_n}{2} \left[e^{ik_n T} (k_n \pm i)^2 - e^{-ik_n T} (k_n \mp i)^2 \right] \left(\begin{array}{c} 0 \\ 1 \end{array} \right) \tag{B.7}$$

and

$$\lim_{T \to \pm\infty, Z \to \infty} \left[\begin{array}{c} Q_n \\ \bar{Q}_{-n} \end{array} \right](Z,T) = \frac{\pi i}{16 k_n} \operatorname{sech} \frac{\pi k_n}{2} \left[e^{ik_n T} (k_n \pm i)^2 + e^{-ik_n T} (k_n \mp i)^2 \right] \left(\begin{array}{c} 0 \\ 1 \end{array} \right). \tag{B.8}$$

As a result, the boundary values of the first-order solution $V_n(Z,T)$ satisfy the Sommerfeld radiation boundary conditions:

$$\lim_{|T|\to\infty, Z\to\infty} V_{-n}(Z,T) = -\frac{\pi i(k_n+i)^2}{8k_n}\operatorname{sech}\frac{\pi k_n}{2}e^{ik_n|T|}, \quad n \geq N_\mu. \tag{B.9}$$

(iii) $|T| \to \infty$ and $Z < \infty$. Using formula (B.6) in (B.1)–(B.2), we find that both terms cancel out since

$$\lim_{k\to\pm k_n}\left(1 - e^{-i(\lambda_n - 1 - k^2)Z}\right) = 0.$$

As a result, we have zero boundary values for $V_n(Z,T)$ in the limit $|T| \to \infty$ for finite Z:

$$\lim_{|T|\to\infty} V_n(Z,T) = 0. \tag{B.10}$$

The first-order solution represents radiative waves diverging from the NLS soliton. In the limit $Z \to \infty$, the radiative waves approach the Z-independent boundary values given by (B.9). In the intermediate region, where $|T| \to \infty$, $Z \to \infty$, and $\lim_{Z\to\infty} T/Z = C$, where $0 < C < \infty$, the radiative waves move with the group velocity $2k_n$, according to the intermediate asymptotic expression

$$\lim_{|T|\to\infty, Z\to\infty} V_{-n}(Z,T) = -\frac{\pi i(k_n+i)^2}{8k_n}\operatorname{sech}\frac{\pi k_n}{2}\; e^{ik_n|T|}\; H\left(2k_n - \frac{|T|}{Z}\right), \quad n \geq N_\mu, \tag{B.11}$$

where $H(z) = 1$ for $z > 0$ and $H(z) = 0$ for $z < 0$. The intermediate asymptotic expression includes (B.9) and (B.10) as particular cases.

Acknowledgments. The authors thank W. Kath, E. Kirr, B. Malomed, M. Weinstein, and V. Zharnitsky for useful discussions.

COLLAPSE OF THE KELDYSH CHAINS AND STABILITY OF CONTINUOUS NONCONSERVATIVE SYSTEMS*

OLEG N. KIRILLOV† AND ALEXANDER P. SEYRANIAN†

Abstract. In the present paper, eigenvalue problems for non-self-adjoint linear differential operators smoothly dependent on a vector of real parameters are considered. Bifurcation of eigenvalues along smooth curves in the parameter space is studied. The case of a multiple eigenvalue with the Keldysh chain of arbitrary length is investigated. Explicit expressions describing bifurcation of eigenvalues are found. The obtained formulas use eigenfunctions and associated functions of the adjoint eigenvalue problems as well as the derivatives of the differential operator taken at the initial point of the parameter space. These results are important for the stability problems and sensitivity analysis of nonconservative systems. As a mechanical application, the extended Beck problem of stability of an elastic column subjected to a partially tangential follower force is considered and discussed in detail.

Key words. nonconservative system, non-self-adjoint differential operator, Keldysh chain, multiple eigenvalue, bifurcation, stability boundary

1. Introduction.

In nonconservative dynamic stability problems arising in mechanics and physics, energy is not conserved; it can be pumped into the system or taken out depending on problem parameters. Increase of energy leads to growth of vibrational amplitudes, i.e., to instability of vibrations. If energy is lost the amplitudes decay in time, which implies stability for the system. Unlike buckling problems of conservative systems for nonconservative ones, the dynamic method of stability study must be applied. Two types of instability in nonconservative systems are distinguished: static (divergence) and dynamic (flutter). Important examples of nonconservative systems are aircraft wings and panels vibrating in a flow, elastic missiles subjected to a jet thrust, which is a nonpotential follower force, and tubes conveying fluid; see Bolotin [1], Ziegler [2], Leipholz [3], and Paidoussis [4]. Sensitivity analysis of critical stability parameters for nonconservative systems was developed by Pedersen and Seyranian in [5]. A comprehensive review of nonconservative stability problems was given by Langthjem and Sugiyama in [6].

Non-self-adjoint operators naturally appear in nonconservative problems. In discrete problems such an operator is just a nonsymmetrical matrix. The general theory of non-self-adjoint operators going back to the works by Birkhoff was then developed by many mathematicians; see the review by Davies [7]. Keldysh [8] was the first to generalize the notion of the Jordan chain of vectors to a wide class of non-self-adjoint operators. For that reason it was called the Keldysh chain; see Gohberg and Krein [9] and Gohberg, Lancaster, and Rodman [10]. In the work by Vishik and Lyusternik [11], the perturbation theory for nonsymmetrical matrices and non-self-adjoint differential

operators, $L = L_0 + \epsilon L_1$ with ϵ as a small parameter, was developed. This practical and constructive theory allows one to find the perturbation coefficients of eigenvalues and eigenvectors in an explicit form. The paper by Vishik and Lyusternik [11] was not widely known in the Western (and even Russian) literature on the subject for a long time. However, its importance was highly appreciated in the paper by Moro, Burke, and Overton [12]. We extend this perturbation theory to multiparameter bifurcation analysis of eigenvalues of non-self-adjoint differential operators.

It is known that in the generic case the spectrum of a multiparameter family of nonsymmetrical matrices contains multiple eigenvalues with the Jordan chains; see Arnold [13]. In many important cases multiple eigenvalues define geometrical properties of the stability boundary of a corresponding system. At the same time, multiple eigenvalues create considerable mathematical difficulties due to their nondifferentiability with respect to parameters. An effective tool for analysis of stability boundary is the study of bifurcations of multiple eigenvalues due to change of parameters. For the discrete case, this method based on the perturbation theory [11] was developed in the works by Seyranian [14], Mailybaev and Seyranian [15], and Seyranian and Kirillov [16]. To perform the stability analysis in the continuous case, we need to consider bifurcations of eigenvalues in multiparameter families of non-self-adjoint differential operators. The study of generic properties of the spectrum of the multiparameter family of non-self-adjoint differential operators remains a difficult problem. It seems that in the infinite-dimensional case there is still no analogue to the Arnold theory of versal deformations of matrices, allowing us to classify the generic singularities of the bifurcation and stability diagrams: even in the self-adjoint case the progress is quite slow; see Teytel [17].

In our paper we combine the ideas of [8], [11], and [14]. This allows us to find explicit formulas describing bifurcation of multiple eigenvalues with the Keldysh chain of any length. These formulas suit for a wide class of non-self-adjoint eigenvalue problems arising in applications and take into account parameters both in the differential expression and in the boundary conditions. Besides, our approach allows one to study bifurcations of multiple eigenvalues both in regular and degenerate cases. An analogous approach was applied by Seyranian and Kliem to the investigation of stability problems for continuous conservative systems with gyroscopic forces [18].

The paper is organized in the following way. In section 2 basic relations for eigenvalue problems with general linear differential operators and boundary conditions are introduced.

In section 3 it is supposed that the differential expression and boundary conditions smoothly depend on a vector of real parameters. A formula describing splitting of a multiple eigenvalue with the Keldysh chain of arbitrary length depending on a change of the parameters is derived. Both regular and degenerate cases are studied. Finally, a formula for bifurcation of a semisimple multiple eigenvalue is obtained. These formulas generalize the results for splitting of eigenvalues obtained earlier for the finite-dimensional case in [14], [15], and [16]. The obtained formulas take into account both variations of the differential expression and boundary conditions due to change of the parameters and can be applied to a wide class of nonconservative problems.

In section 4 we apply the results of previous sections to stability problems of general nonconservative (circulatory) systems. General solutions in an explicit form via eigenvalues and eigenvectors are obtained. Then stability boundaries in the parameter space are investigated. It is shown that the smooth parts of the boundaries correspond to either simple zero (stability-divergence boundary) or double positive

eigenvalues with the Keldysh chain of length 2 (stability-flutter boundary). Normal vectors to the boundaries between stability, flutter, and divergence domains are found. It is remarkable that only information at a point of the stability boundary is needed for the calculation of the vectors.

Section 5 treats a mechanical example—an elastic column loaded by the partially tangential follower force. This problem is referred to as the extended Beck column. The stability boundaries of this two-parameter continuous system are carefully investigated and analyzed. Explicit expressions for eigenfunctions and associated functions are derived. With the use of these expressions, the linear and quadratic approximations of the stability boundary at its regular and singular points are constructed. The behavior of eigenvalues in the vicinity of the stability boundaries is studied by the perturbation approach, showing a good agreement with the numerical results.

2. Basic relations. Using the notation of Naimark [19] we consider an eigenvalue problem for a linear differential operator L defined by

$$l(u) = \lambda u, \quad U^s(u) = 0, \quad s = 1, \dots, m, \tag{2.1}$$

$$l(u) \equiv \sum_{i=0}^{m} a_i \frac{d^{m-i}u}{dx^{m-i}}, \quad U^s(u) \equiv \sum_{i=0}^{m-1} \left(\alpha_i^s \frac{d^i u}{dx^i}\bigg|_{x=0} + \beta_i^s \frac{d^i u}{dx^i}\bigg|_{x=1} \right).$$

The operators $U^s(u)$ are linear forms with respect to the variables $u(0)$, $u'(0), \dots,$ $u^{(m-1)}(0)$; $u(1)$, $u'(1), \dots,$ $u^{(m-1)}(1)$. These variables are values of the function $u \in C^{(m)}[0,1]$ and its derivatives up to $(m-1)$th order evaluated at the points $x = 0$ and $x = 1$. It is assumed that the forms U^s, $s = 1, 2, \dots, m$, are linearly independent.

The differential expression

$$l^*(v) \equiv \sum_{i=0}^{m} (-1)^{m-i} \, \overline{a_i} \, \frac{d^{m-i}v}{dx^{m-i}},$$

where the overbar denotes complex conjugation, is called *adjoint* to the differential expression $l(u)$ [19]. With the use of integration by parts it can be shown that

$$\int_0^1 l(u)\bar{v}dx = P(\alpha, \beta) + \int_0^1 u\overline{l^*(v)}dx, \tag{2.2}$$

where $P(\alpha, \beta)$ is a bilinear form of the variables

$$\alpha = (u(0), u'(0), \dots, u^{(m-1)}(0), u(1), u'(1), \dots, u^{(m-1)}(1)), \tag{2.3}$$

$$\beta = (v(0), v'(0), \dots, v^{(m-1)}(0), v(1), v'(1), \dots, v^{(m-1)}(1)). \tag{2.4}$$

Let us choose the forms $U^{m+1}, U^{m+2}, \dots, U^{2m}$ so that $U^1, U^2, \dots, U^{2m}$ are linearly independent. Then variables (2.3) can be expressed as linear combinations of the forms $U^1, U^2, \dots, U^{2m}$. Substituting these linear combinations into (2.2), we get the Lagrange identity [19]

$$(l(u), v) - (u, l^*(v)) = U^1 V^{2m} + \dots + U^{2m} V^1, \tag{2.5}$$

where $(u, v) = \int_0^1 u(x)\overline{v}(x)dx$ is the inner product of the functions $u, v \in C^m[0,1]$.

The coefficients at $U^1, U^2, \dots, U^{2m}$ are linear forms with respect to variables (2.4) and are denoted by $V^{2m}, \dots, V^2, V^1$, respectively. The forms $V^1, V^2, \dots, V^{2m}$ are linearly independent [19]. The boundary conditions

$$V^s(v) = 0, \quad s = 1, \dots, m,$$

are called *adjoint* to boundary conditions (2.1). The differential operator L^*, corresponding to the differential expression $l^*(v)$ and to the adjoint boundary conditions, is referred to as adjoint to the operator L, and we say that the eigenvalue problem

$$l^*(v) = \overline{\lambda} v, \quad V^s(v) = 0, \quad s = 1, \dots, m, \tag{2.6}$$

is adjoint to eigenvalue problem (2.1).

Due to the boundary conditions in (2.1) and (2.6), identity (2.5) for the adjoint operators L and L^* takes a simple form: $(l(u), v) = (u, l^*(v))$. If we consider differential expression $l(u)$ and assume that the function u satisfies the nonhomogeneous boundary conditions

$$U^s(u) = G^s, \quad s = 1, \dots, m, \tag{2.7}$$

then the Lagrange identity (2.5) yields

$$(l(u), v) - (u, l^*(v)) = G^1 V^{2m} + \cdots + G^m V^{m+1}. \tag{2.8}$$

This is valid since v satisfies the boundary conditions in (2.6).

3. Collapse of the Keldysh chain. Suppose that in eigenvalue problem (2.1) the coefficients of the differential expression $l(u)$ and the coefficients of the forms $U^s(u)$ are real functions, *smoothly* dependent on a vector of real parameters $\mathbf{p} = (p_1, p_2, \dots, p_n)$ on an open set $\Omega \subset R^n$. Let λ_0 be an eigenvalue of the operator L at the point $\mathbf{p} = \mathbf{p}_0$. We are interested in bifurcation of eigenvalues along the curves $\mathbf{p}(\epsilon) = \mathbf{p}_0 + \epsilon \mathbf{e} + \epsilon^2 \mathbf{d} + o(\epsilon^2)$, emitted from the initial point $\mathbf{p}_0$ in the parameter space. The vector $\mathbf{e} = (e_1, e_2, \dots, e_n)$ defines a direction of the curve, and $\epsilon \geq 0$ is a small parameter.

Due to variation of parameters the differential expression $l(u)$ and the forms $U^s(u)$ are expanded as

$$l(u) = l_0(u) + \epsilon l_1(u) + \epsilon^2 l_2(u) + \cdots, \quad U^s(u) = U_0^s(u) + \epsilon U_1^s(u) + \epsilon^2 U_2^s(u) + \cdots, \tag{3.1}$$

where $l_0 = l(u)|_{\mathbf{p}=\mathbf{p}_0}$, $U_0^s = U^s(u)|_{\mathbf{p}=\mathbf{p}_0}$, the differential expressions $l_1(u)$, $l_2(u)$ look like

$$l_1(u) = \sum_{i=1}^n e_i \frac{\partial l}{\partial p_i}(u), \quad l_2(u) = \sum_{i=1}^n d_i \frac{\partial l}{\partial p_i}(u) + \frac{1}{2} \sum_{i,j=1}^n e_i e_j \frac{\partial^2 l}{\partial p_i \partial p_j}(u), \tag{3.2}$$

and for the forms $U_1^s(u)$, $U_2^s(u)$ we have

$$U_1^s(u) = \sum_{i=1}^n e_i \frac{\partial U^s}{\partial p_i}(u), \quad U_2^s(u) = \sum_{i=1}^n d_i \frac{\partial U^s}{\partial p_i}(u) + \frac{1}{2} \sum_{i,j=1}^n e_i e_j \frac{\partial^2 U^s}{\partial p_i \partial p_j}(u). \tag{3.3}$$

All the derivatives in formulas (3.2) and (3.3) are evaluated at the point $\mathbf{p} = \mathbf{p}_0$. Thus, we deal with the *regular* perturbations which do not increase the order of the nonperturbed operator $L_0 = L(\mathbf{p}_0)$ [11].

Consider an eigenvalue λ_0 with *the Keldysh chain of length* $k > 0$. This means that at $\mathbf{p} = \mathbf{p}_0$ there exist an eigenfunction $u_0(x)$ and *associated* functions $u_1(x)$, $u_2(x), \dots, u_{k-1}(x)$, corresponding to the λ_0 and satisfying the equations and the boundary conditions

$$\begin{array}{cc} l_0(u_0) = \lambda_0 u_0, & U_0^s(u_0) = 0; \\ l_0(u_i) = \lambda_0 u_i + u_{i-1}, & U_0^s(u_i) = 0; \\ i = 1, \dots, k-1; \quad s = 1, \dots, m. & \end{array} \tag{3.4}$$

For the adjoint operator L^* we have

$$\begin{array}{cc} l_0^*(v_0) = \overline{\lambda_0} v_0, & V_0^s(v_0) = 0; \\ l_0^*(v_i) = \overline{\lambda_0} v_i + v_{i-1}, & V_0^s(v_i) = 0; \\ i = 1, \dots, k-1; \quad s = 1, \dots, m. & \end{array} \tag{3.5}$$

The notion of the Keldysh chain is an analogue of the Jordan chain of vectors when we consider eigenvalue problems for differential operators [8], [9], [19]. Eigenfunctions and associated functions of adjoint operators L and L^* are related by the following conditions:

$$(u_j, v_0) = 0, \quad j = 0, \dots, k-2, \quad (u_{k-1}, v_0) \equiv (u_0, v_{k-1}) \neq 0; \tag{3.6}$$

$$(u_{j-1}, v_i) \equiv (u_j, v_{i-1}), \quad i, j = 1, \dots, k-1. \tag{3.7}$$

This naturally follows from (3.4) and (3.5) with the relation $(l(u), v) = (u, l^*(v))$ stated for the adjoint operators.

A variation of the vector of parameters $\mathbf{p} = \mathbf{p}_0 + \epsilon \mathbf{e} + o(\epsilon)$ causes perturbation of eigenvalues and eigenfunctions. In the case of a multiple eigenvalue with the Keldysh chain of length k, the expansions for eigenvalues and eigenfunctions contain terms with fractional powers of the small parameter $\epsilon^{j/k}$, $j = 0, 1, 2, \dots$ [11]:

$$\lambda = \lambda_0 + \epsilon^{1/k} \lambda_1 + \epsilon^{2/k} \lambda_2 + \cdots, \quad u = u_0 + \epsilon^{1/k} w_1 + \epsilon^{2/k} w_2 + \cdots. \tag{3.8}$$

Substituting expansions (3.1) and (3.8) into eigenvalue problem (2.1), we get expressions that determine the first order perturbations of the eigenvalue λ_0 and eigenfunction u_0,

$$l_0(w_j) - \lambda_0 w_j = \lambda_j u_0 + \sum_{i=1}^{j-1>0} \lambda_{j-i} w_i, \quad U_0^s(w_j) = 0, \quad j = 1 \dots k-1, \tag{3.9}$$

$$l_0(w_k) - \lambda_0 w_k = \lambda_k u_0 - l_1(u_0) + \sum_{i=1}^{k-1>0} \lambda_{k-i} w_i, \quad U_0^s(w_k) = -U_1^s(u_0). \tag{3.10}$$

The functions w_j can be found from (3.4) and (3.9) in the form

$$w_j = \lambda_1^j u_j + \sum_{p=0}^{j-1} \gamma_{jp} u_p, \quad j = 1, \dots, k-1, \tag{3.11}$$

where γ_{jp} are arbitrary constants.

Consider the inner product of the function v_0 with the left- and right-hand sides of (3.10). Using then expression (3.11) for w_j, equations (3.6) and (3.7), and the Lagrange identity (2.8), which in this case has the form

$$(l_0(w_k) - \lambda_0 w_k, v_0) - (w_k, l_0^*(v_0) - \overline{\lambda_0} v_0) = -\sum_{s=1}^{m} U_1^s(u_0) V_0^{2m-s+1}(v_0),$$

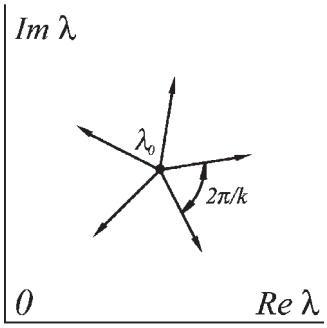

FIG. 3.1. *Splitting of the multiple eigenvalue λ_0 with the Keldysh chain of length $k = 5$.*

we get the coefficient λ_1 in the expansion of the eigenvalue λ,

$$\lambda_1^k = \frac{(l_1(u_0), v_0) - \sum_{s=1}^{m} U_1^s(u_0) V_0^{2m-s+1}(v_0)}{(u_{k-1}, v_0)}. \tag{3.12}$$

Introducing scalar product $\langle \mathbf{a}, \mathbf{b} \rangle$ of the vectors $\mathbf{a}, \mathbf{b} \in R^n$ and taking into account expressions (3.2) and (3.3) we can rewrite (3.12) in the form [14]

$$\lambda_1 = \sqrt[k]{\langle \mathbf{f}_k, \mathbf{e} \rangle + i \langle \mathbf{g}_k, \mathbf{e} \rangle}, \tag{3.13}$$

where the real vectors $\mathbf{f}_k$ and $\mathbf{g}_k$ correspond to the k-fold eigenvalue λ_0 at the point $\mathbf{p} = \mathbf{p}_0$ and their components are

$$f_k^j + i g_k^j = \frac{(\frac{\partial l}{\partial p_j}(u_0), v_0) - \sum_{s=1}^{m} \frac{\partial U^s}{\partial p_j}(u_0) V_0^{2m-s+1}(v_0)}{(u_{k-1}, v_0)}, \quad j = 1, \ldots, n. \tag{3.14}$$

The right-hand side of (3.13) takes k complex values. If the radicand in (3.13) is not zero, the expression $\lambda = \lambda_0 + \epsilon^{1/k} \lambda_1 + o(\epsilon^{1/k})$ describes the splitting of the k-fold eigenvalue with a change of parameters along a curve emitted in the direction $\mathbf{e}$, as shown in Figure 3.1.

We emphasize that for real eigenvalue λ_0 the vector $\mathbf{g}_k$=0 since the eigenfunctions and associated functions can be chosen real, and the coefficient λ_1 does not depend on normalization conditions.

After splitting, the length of the Keldysh chain decreases from k to 1, and we say that *collapse of the Keldysh chain* occurs.

In particular, (3.8) and (3.13) describe the behavior of a simple eigenvalue for $k = 1$, and for $k = 2$-splitting of a double eigenvalue λ_0 with the Keldysh chain of length 2, which are the most important cases in applications.

Consider now for a double eigenvalue the *degenerate* case

$$\langle \mathbf{f}_2, \mathbf{e}_* \rangle + i \langle \mathbf{g}_2, \mathbf{e}_* \rangle = 0. \tag{3.15}$$

It follows from condition (3.15) that the coefficient λ_1 in expansions (3.8) becomes zero. Substitution of expansions (3.8) into eigenvalue problem (2.1) gives equations determining second order terms λ_2 and w_2,

$$l_0(w_2) - \lambda_0 w_2 = \lambda_2 u_0 - l_1(u_0), \quad U_0^s(w_2) = -U_1^s(u_0), \tag{3.16}$$

$$l_0(w_4)-\lambda_0 w_4 = \lambda_4 u_0 - l_2(u_0)+\lambda_2 w_2 - l_1(w_2), \quad U_0^s(w_4) = -U_1^s(w_2)-U_2^s(u_0). \tag{3.17}$$

Multiplying both parts of (3.17) by v_0 and using the Lagrange identity (2.8), we get

$$\lambda_2(w_2,v_0)-(l_1(w_2),v_0)-(l_2(u_0),v_0)+\sum_{s=1}^{m}(U_1^s(w_2)+U_2^s(u_0))V_0^{2m-s+1}(v_0)=0. \tag{3.18}$$

Multiplication of (3.16) by v_1 with the use of (2.8) and (3.5) gives the term (w_2, v_0),

$$(w_2,v_0) = \lambda_2(u_0,v_1) - (l_1(u_0),v_1) + \sum_{s=1}^{m} U_1^s(u_0)V_0^{2m-s+1}(v_1). \tag{3.19}$$

The solution of (3.16) has the form $w_2 = \lambda_2 u_1 + \hat{w}_2 + \gamma u_0$, where γ is an arbitrary constant and $\hat{w}_2$ is a particular solution of the boundary value problem

$$l_0(\hat{w}_2) - \lambda_0 \hat{w}_2 = -l_1(u_0), \quad U_0^s(\hat{w}_2) = -U_1^s(u_0). \tag{3.20}$$

The solution of boundary value problem (3.20) exists due to degeneration condition (3.15), playing here the role of the solvability condition. Substituting (3.19) and the expression for w_2 into (3.18) we get the quadratic equation in λ_2,

$$\lambda_2^2 + \lambda_2 a_1 + a_2 = 0. \tag{3.21}$$

The coefficients a_1 and a_2 are determined by the expressions

$$a_1 = \frac{\sum_{s=1}^{m}[U_1^s(u_0)V_0^{2m-s+1}(v_1) + U_1^s(u_1)V_0^{2m-s+1}(v_0)]}{(u_0,v_1)} - \frac{(l_1(u_0),v_1)+(l_1(u_1),v_0)}{(u_0,v_1)}, \tag{3.22}$$

$$a_2 = \frac{-(l_1(\hat{w}_2),v_0) - (l_2(u_0),v_0) + \sum_{s=1}^{m}(U_1^s(\hat{w}_2)+U_2^s(u_0))V_0^{2m-s+1}(v_0)}{(u_0,v_1)}. \tag{3.23}$$

These coefficients can be written in the form

$$a_1 = \langle \mathbf{h}, \mathbf{e}_* \rangle + i\langle \mathbf{k}, \mathbf{e}_* \rangle, \quad a_2 = \langle \mathbf{H}\mathbf{e}_*, \mathbf{e}_* \rangle + i\langle \mathbf{K}\mathbf{e}_*, \mathbf{e}_* \rangle - \langle \mathbf{f}_2, \mathbf{d} \rangle - i\langle \mathbf{g}_2, \mathbf{d} \rangle, \tag{3.24}$$

where components of the real vectors $\mathbf{h}$, $\mathbf{k}$ are defined by the relationship

$$h^j + ik^j = \frac{\sum_{s=1}^{m}[\frac{\partial U^s}{\partial p_j}(u_0)V_0^{2m-s+1}(v_1) + \frac{\partial U^s}{\partial p_j}(u_1)V_0^{2m-s+1}(v_0)]}{(u_0,v_1)} - \frac{(\frac{\partial l}{\partial p_j}(u_0),v_1)+(\frac{\partial l}{\partial p_j}(u_1),v_0)}{(u_0,v_1)}, \tag{3.25}$$

and the real symmetric matrices $\mathbf{H}$ and $\mathbf{K}$ can be found according to (3.23) and (3.24). Thus, bifurcation of the double eigenvalue λ_0 in degenerate case (3.15) is described by the formula $\lambda = \lambda_0 + \epsilon\lambda_2 + o(\epsilon)$, where λ_2 are the two roots of (3.21).

Finally, we consider at $\mathbf{p} = \mathbf{p}_0$ a so-called [18] semisimple eigenvalue λ_0 of multiplicity k with k linearly independent eigenfunctions $u_0^1, u_0^2, \ldots, u_0^k$ satisfying eigenvalue problem (2.1). The complex-conjugate $\overline{\lambda}_0$ is the semisimple eigenvalue of adjoint eigenvalue problem (2.6) with the eigenfunctions $v_0^1, v_0^2, \ldots, v_0^k$.

Expansion of the parameters $\mathbf{p} = \mathbf{p}_0 + \epsilon\mathbf{e} + o(\epsilon)$ causes perturbations of the eigenvalue and eigenfunctions, which can be expressed as Taylor series with respect to the small parameter ϵ [11],

$$\lambda = \lambda_0 + \epsilon\lambda_1 + o(\epsilon), \quad u = w_0 + \epsilon w_1 + o(\epsilon). \tag{3.26}$$

Substituting these expansions as well as expansions (3.1) into eigenvalue problem (2.1) we get equations determining the functions w_0, w_1:

$$l_0(w_0) - \lambda_0 w_0 = 0, \quad U_0^s(w_0) = 0; \tag{3.27}$$

$$l_0(w_1) - \lambda_0 w_1 = -l_1(w_0) + \lambda_1 w_0, \quad U_0^s = -U_1^s(w_0). \tag{3.28}$$

A general solution of eigenvalue problem (3.27) has the form

$$w_0 = \sum_{i=1}^{k} \gamma_i u_0^i$$

with unknown coefficients γ_i. Taking the inner product of (3.28) and the functions v_0^1, $v_0^2, \ldots, v_0^k$ and using the Lagrange identity

$$(l_0(w_0) - \lambda_0 w_0, v_0^j) - (w_0, l_0^*(v_0^j) - \overline{\lambda_0} v_0^j) = -\sum_{s=1}^{m} U_1^s(w_0) V_0^{2m-s+1}(v_0^j),$$

we come to the system of equations on the coefficients $\gamma_1, \gamma_2, \ldots, \gamma_k$,

$$\sum_{i=1}^{k} \left((l_1(u_0^i), v_0^j) - \sum_{s=1}^{m} U_1^s(u_0^i) V_0^{2m-s+1}(v_0^j) - \lambda_1(u_0^i, v_0^j) \right) \gamma_i = 0, \quad j = 1, \ldots, k.$$

This system has a nontrivial solution if and only if

$$\det \left[(l_1(u_0^i), v_0^j) - \sum_{s=1}^{m} U_1^s(u_0^i) V_0^{2m-s+1}(v_0^j) - \lambda_1(u_0^i, v_0^j) \right] = 0. \tag{3.29}$$

The coefficients of (3.29) can also be expressed in terms of the vector of variation $\mathbf{e}$. For the sake of convenience we suppose that the eigenfunctions satisfy the orthonormality conditions

$$(u_0^\sigma, v_0^j) = \delta_{\sigma j}, \quad \sigma, j = 1, \ldots, k, \tag{3.30}$$

where $\delta_{\sigma j}$ is the Kronecker symbol. Introducing the real vectors $\mathbf{f}^{\sigma j}$ and $\mathbf{g}^{\sigma j}$ of dimension n with the components defined by the equation

$$f_r^{\sigma j} + i g_r^{\sigma j} = \left(\frac{\partial l}{\partial p_r}(u_0^\sigma), v_0^j \right) - \sum_{s=1}^{m} \frac{\partial U^s}{\partial p_r}(u_0^\sigma) V_0^{2m-s+1}(v_0^j), \quad r = 1, \ldots, n, \tag{3.31}$$

we can write (3.29) in the following form:

$$\det[\langle \mathbf{f}^{\sigma j} + i\mathbf{g}^{\sigma j}, \mathbf{e} \rangle - \lambda_1 \delta_{\sigma j}] = 0, \quad \sigma, j = 1, \ldots, k. \tag{3.32}$$

Equation (3.32) is a polynomial of kth order for the coefficients λ_1 in expansions (3.26), which describe splitting of a multiple eigenvalue λ_0.

4. Application to nonconservative stability problems. Let us consider nonconservative systems, described by a partial differential equation with the boundary conditions

$$\ddot{y} + l(y) = 0, \quad U^s(y) = 0, \quad s = 1, \ldots, m, \tag{4.1}$$

where $y = y(x,t)$, dots mean differentiation with respect to time t, while $l(y)$ and $U^s(y)$ are, respectively, the linear differential expression in terms of $x \in [0,1]$ and the boundary forms defined in section 2. Such systems are usually called *circulatory systems* [1], [2], [3]. Note that damping and gyroscopic forces are not involved in such systems. However, circulatory forces play an important role in aeroelasticity, plasma physics, gyrodynamics, and other fields.

Looking up the solution of (4.1) in the form

$$y(x,t) = u(x)e^{\pm it\sqrt{\lambda}}$$

we come to the eigenvalue problem (2.1). Recall that the coefficients of the differential expression $l(u)$ and the coefficients of the forms $U^s(u)$ are real functions, smoothly dependent on a vector of real parameters $\mathbf{p} = (p_1, p_2, \dots, p_n)$. It follows from the basic theorems of the theory of ordinary differential equations [20] that solutions $z_1, \dots, z_m$ of (2.1) with the initial conditions (δ_{ij} is the Kronecker symbol)

$$z_i^{(j-1)}(0) = \delta_{ij}, \quad i,j = 1, \dots, m,$$

forming the fundamental system of solutions of (2.1), smoothly depend on λ and $\mathbf{p}$. The characteristic determinant $\Delta \equiv \det \left\| U^i(z_j) \right\|$ is thus a smooth function of the spectral parameter λ and the vector $\mathbf{p}$: $\Delta = \Delta(\lambda, \mathbf{p})$.

We assume that at some fixed value $\mathbf{p}_0$ of the vector $\mathbf{p}$ the spectrum of the operator L formed by the differential expression $l(u)$ and boundary conditions $U^s(u) = 0$ is discrete. The eigenvalues λ can be simple or multiple roots of the characteristic equation $\Delta(\lambda, \mathbf{p}_0) = 0$.

If all eigenvalues λ_j are simple, then a general solution of (4.1) has the form

$$y(x,t) = \sum_{j=1}^{\infty} u_0^j(x)(\alpha_j e^{it\sqrt{\lambda_j}} + \beta_j e^{-it\sqrt{\lambda_j}}) \tag{4.2}$$

with arbitrary constants α_j, β_j. This form is also valid for semisimple eigenvalues λ_0 of algebraic multiplicity k ($\lambda_j = \lambda_{j+1} = \dots = \lambda_{j+k-1} = \lambda_0$), which means that the number of linearly independent eigenfunctions μ corresponding to λ_0 is equal to k. However, when $\mu < k$ in the general solution of (4.1), the *secular* terms proportional to $t^\sigma e^{\pm it\sqrt{\lambda_0}}$ with $\sigma < k$ appear.

Let $\lambda = \lambda_0$ be the k-fold root of the characteristic equation $\Delta(\lambda, \mathbf{p}_0) = 0$, and let the functions $u_0(x)$, $u_1(x), \dots, u_{k-1}(x)$ satisfying (3.4) be the Keldysh chain of length k corresponding to λ_0. In this case $\mu = 1$, and the partial solution of the boundary value problem (4.1) has the form

$$y(x,t) = (\alpha e^{it\sqrt{\lambda_0}} + \beta e^{-it\sqrt{\lambda_0}}) \sum_{r=0}^{k-1} y_r(x) \frac{t^{k-r-1}}{(k-r-1)!}, \tag{4.3}$$

$$y_r(x) = \sum_{j=0}^{r} (-1)^{r-j} (2i\sqrt{\lambda_0})^{r-2j} C_{r-j}^{r-2j} u_{r-j}(x), \quad C_{r-j}^{r-2j} = \begin{cases} 0, & 2j > r, \\ \frac{(r-j)!}{j!(r-2j)!}, & 2j \le r, \end{cases}$$

which can be verified by direct substitution to (4.1).

In the more complicated case of the multiple eigenvalue λ_0 of multiplicity $\sum_{s=1}^{\mu} k_s$ with μ Keldysh chains of lengths $k_1, k_2, \dots, k_\mu$, respectively, the solution corresponding to λ_0 is a sum of functions (4.3) over all μ Keldysh chains,

$$y(x,t) = \sum_{s=1}^{\mu} (\alpha_s e^{it\sqrt{\lambda_0}} + \beta_s e^{-it\sqrt{\lambda_0}}) \sum_{r=0}^{k_s-1} y_r^s(x) \frac{t^{k_s-r-1}}{(k_s-r-1)!}, \tag{4.4}$$

where the functions $y_r^s(x)$ are related to the functions $u_r^s(x)$ by the second of equations (4.3).

From (4.2)–(4.4) it is obvious that the linear system described by (4.1) is stable if and only if all the eigenvalues λ are nonnegative and semisimple. If all λ are real and some of them negative, then the circulatory system is statically unstable (divergence). Existence of at least one complex eigenvalue or a multiple real positive eigenvalue with the Keldysh chain of length $k > 1$ means flutter instability. Multiple zero eigenvalue with the Keldysh chain of length $k > 1$ causes divergence.

Let us now study the stability boundaries of circulatory systems in the parameter space. If at the point $\mathbf{p} = \mathbf{p}_0$ the characteristic equation has the k-fold real root $\lambda = \lambda_0$, i.e., $\Delta(\lambda_0, \mathbf{p}_0) = \partial\Delta/\partial\lambda = \cdots = \partial^{k-1}\Delta/\partial\lambda^{k-1} = 0$, $\partial^k\Delta/\partial\lambda^k \neq 0$, then according to Malgrange's preparation theorem [21] there exists a neighborhood $U_0 \subset R \times R^n$ of the point $(\lambda_0, \mathbf{p}_0)$, where $\Delta(\lambda, \mathbf{p})$ has the form

$$\Delta(\lambda, \mathbf{p}) = \left[(\lambda - \lambda_0)^k + \sum_{i=0}^{k-1}(\lambda - \lambda_0)^i a_i(\mathbf{p})\right] b(\lambda, \mathbf{p}). \tag{4.5}$$

The functions $a_0(\mathbf{p}), \ldots, a_{k-1}(\mathbf{p})$ and $b(\lambda, \mathbf{p})$ are real and smooth, $a_i(\mathbf{p}_0) = 0$, and $b(\lambda_0, \mathbf{p}_0) \neq 0$.

Let, for example, λ_0 be a simple real root of the equation $\Delta(\lambda, \mathbf{p}_0) = 0$. Then due to (4.5) we can write $\lambda = \lambda_0 - a_0(\mathbf{p})$, and λ remains real and simple in some neighborhood of the point $\mathbf{p}_0$. We can conclude from this fact that if at $\mathbf{p} = \mathbf{p}_0$ all the eigenvalues of eigenvalue problem (2.1) are positive and simple, then $\mathbf{p}_0$ is the inner point of the stability domain of circulatory system (4.1).

Similarly, the points of the parameter space, corresponding to either simple zero eigenvalue or real double eigenvalue with the Keldysh chain of length 2, form smooth surfaces of dimension $n-1$. Indeed, if $\lambda_0 = 0$ at $\mathbf{p} = \mathbf{p}_0$, then in the vicinity of $\mathbf{p}_0$ we have $\lambda = -a_0(\mathbf{p})$. The equation $a_0(\mathbf{p}) = 0$ defines a hypersurface in the parameter space.

If λ_0 is a double eigenvalue, then according to (4.1) its behavior near the point $\mathbf{p}_0$ is described by the quadratic equation

$$(\lambda - \lambda_0)^2 + a_1(\mathbf{p})(\lambda - \lambda_0) + a_0(\mathbf{p}) = 0. \tag{4.6}$$

It follows from (4.6) that the eigenvalue $\lambda(\mathbf{p})$ remains double in the neighborhood of the point $\mathbf{p}_0$ if $\mathbf{p}$ belongs to the hypersurface $a_1^2(\mathbf{p}) - 4a_0(\mathbf{p}) = 0$.

It is clear that the stability of the system in a neighborhood of the point $\mathbf{p}_0$ belonging to these hypersurfaces depends on the behavior of the zero or the double eigenvalues due to change of parameters if all other eigenvalues at the point $\mathbf{p}_0$ are positive and semisimple. According to (3.8) and (3.13), where we should put $k = 1$ or $k = 2$, the behavior of the simple zero eigenvalue is described by the formula

$$\lambda = \epsilon\langle \mathbf{f}_1, \mathbf{e}\rangle + o(\epsilon), \tag{4.7}$$

and the splitting of the real double λ_0 is governed by the expression

$$\lambda = \lambda_0 \pm \sqrt{\epsilon\langle \mathbf{f}_2, \mathbf{e}\rangle} + o(\epsilon^{1/2}). \tag{4.8}$$

The inequality $\langle \mathbf{f}_1, \mathbf{e}\rangle > 0$ defines a set of directions $\mathbf{e}$ such that the curves $\mathbf{p} = \mathbf{p}(\epsilon)$ emitted along these vectors lie in the stability domain, i.e., *a tangent cone* to the stability domain. The eigenvalue λ becomes negative for $\langle \mathbf{f}_1, \mathbf{e}\rangle < 0$. Consequently,

this inequality gives a tangent cone to the static instability (divergence) domain. The eigenvalue remains zero up to the terms of order ϵ^2 on the curves, emitted in the directions $\mathbf{e}$, such that $\langle \mathbf{f}_1, \mathbf{e} \rangle = 0$. Thus, the equation $\langle \mathbf{f}_1, \mathbf{p} - \mathbf{p}_0 \rangle = 0$ defines a tangent plane to the surface, where the operator L has a simple zero eigenvalue. If other eigenvalues remain simple and positive on this surface, then it forms a boundary between stability and divergence domains. The vector $\mathbf{f}_1$ is the normal vector to the boundary and is directed to the stability domain.

Analyzing splitting of the double eigenvalue with the formula (4.8) we see that the points of the parameter space, corresponding to the real double eigenvalue with the Keldysh chain of length 2, belong to the smooth parts of the boundary between the flutter domain and the stability domain if $\lambda_0 > 0$ or the divergence domain if $\lambda_0 < 0$. In this case the vector $\mathbf{f}_2$ is the normal vector to the flutter boundary looking at the stability or divergence domains, respectively.

Finally, we assume that at the point $\mathbf{p}_0$ there exists a double positive semisimple eigenvalue λ_0 with the two linearly independent eigenfunctions u_0^1 and u_0^2. We choose them, satisfying orthonormality condition (3.30). The splitting of this eigenvalue with a change of parameters is governed by (3.32), which for $k = 2$ takes the form

$$\lambda_1^2 - \lambda_1 \langle \mathbf{f}^{11} + \mathbf{f}^{22}, \mathbf{e} \rangle + \langle \mathbf{f}^{11}, \mathbf{e} \rangle \langle \mathbf{f}^{22}, \mathbf{e} \rangle - \langle \mathbf{f}^{12}, \mathbf{e} \rangle \langle \mathbf{f}^{21}, \mathbf{e} \rangle = 0, \tag{4.9}$$

where the real vectors $\mathbf{f}^{11}$, $\mathbf{f}^{12}$, $\mathbf{f}^{21}$, and $\mathbf{f}^{22}$ are defined in (3.31). The stability of the circulatory system near the point $\mathbf{p}_0$ depends on the sign of the discriminant D of quadratic equation (4.9), which can be written as

$$D = \langle \mathbf{f}^{11} - \mathbf{f}^{22}, \mathbf{e} \rangle^2 + \langle \mathbf{f}^{12} + \mathbf{f}^{21}, \mathbf{e} \rangle^2 - \langle \mathbf{f}^{12} - \mathbf{f}^{21}, \mathbf{e} \rangle^2. \tag{4.10}$$

The stability condition implies $D > 0$, while the flutter condition yields $D < 0$. The boundary between the flutter and stability domains in the parameter space is defined by the equality $D = 0$. It is easy to see from (4.10) that the equality $D = 0$ describes a circular cone $z^2 = x^2 + y^2$ in the space of three coordinates $x = \langle \mathbf{f}^{11} - \mathbf{f}^{22}, \mathbf{e} \rangle$, $y = \langle \mathbf{f}^{12} + \mathbf{f}^{21}, \mathbf{e} \rangle$, $z = \langle \mathbf{f}^{12} - \mathbf{f}^{21}, \mathbf{e} \rangle$, the flutter domain $z^2 > x^2 + y^2$ being inside the cone and the stability domain $z^2 < x^2 + y^2$ outside. The apex of the cone $(x = 0, y = 0, z = 0)$ corresponds to the double semisimple positive eigenvalue, while the skirts of the cone correspond to the double positive eigenvalues with the Keldysh chain.

Therefore, a double eigenvalue λ_0 defines a smooth surface of codimension 1 or the singularity of codimension 3 in the space of parameters $(p_1, \ldots, p_n)$ depending on the number of linearly independent eigenfunctions at λ_0. This result for matrices was established in [13]. Note that eigenvalue problems with the self-adjoint operators which are widely known in physics may have only semisimple multiple eigenvalues.

Eigenvalues of multiplicity higher than 2 are also responsible for the appearance of singularities on the stability boundaries, as is seen directly from (3.13) and Figure 3.1. Indeed, the eigenvalue with multiplicity $k > 1$ splits in the nondegenerate case into k distinct complex eigenvalues implying flutter instability of the system as it was discussed in the beginning of this section. This was also shown for the discrete circulatory systems in [16].

In aeroelasticity a condition of onset of flutter, which can be easily verified, is of major importance. For circulatory systems such a condition was derived by Plaut [22] in a form $(u_0, v_0) = 0$, where u_0 and v_0 are eigenfunctions of the adjoint problems. His derivation was based on the idea that the first derivative of the nonconservative load with respect to the spectral parameter λ becomes zero at the onset of flutter. This

question attracts current interest; see [23] and comments in [24]. However, Plaut's derivation is restricted by the assumptions that the flutter instability takes place due to interaction of only two eigenvalues in a one-parameter system and the nonconservative load parameter is a smooth function of λ. In our approach the "flutter condition" $(u_0, v_0) = 0$ is just a simple consequence of existence at a multiple eigenvalue λ_0 the Keldysh chain of length $k \geq 2$. Thus, this condition is satisfied at the flutter boundary of a multiparameter circulatory system.

5. Stability boundaries of the extended Beck problem. As an example of a continuous nonconservative mechanical system we consider stability of a uniform elastic cantilevered column of length L_c, loaded by a nonconservative force P; see Figure 5.1. It is assumed that the force P, which can be represented as the sum of a tangential follower force and a potential load, is acting at the free end of the column. The parameter $\eta \in [0, 1]$ measures the nonconservativity of the force P. The case $\eta = 1$ means that the column is loaded by purely tangential follower force (Beck's problem [25]). If $\eta = 0$, then the force P is potential (conservative). This problem was first considered by Dzhanelidze [26] and Kordas and Zyczkowski [27]. Note that the force P models the jet thrust acting on the free end of the column. Recent experiments on stability of such a column were carried out by Sugiyama; see [6]. We will investigate properties of the stability boundary in this problem.

Consider the transverse vibrations of the column in the plane OXY as in Figure 5.1. In the nondimensional variables

$$x = X/L_c, \quad y = Y/L_c, \quad \tau = t/\sqrt{\rho A L_c^4/EI}, \quad q = PL_c^2/EI,$$

the differential equation describing small in-plane vibrations of the column and the appropriate boundary conditions have the form

$$y''''(x,\tau) + qy''(x,\tau) + \ddot{y}(x,\tau) = 0,$$

$$y(0,\tau) = y'(0,\tau) = y''(1,\tau) = y'''(1,\tau) + (1-\eta)qy'(1,\tau) = 0.$$

Dots mean differentiation with respect to time τ, and primes denote differentiation with respect to coordinate x.

Separating time by $y(x,\tau) = u(x)\exp(i\sqrt{\lambda}\tau)$, we get the eigenvalue problem [27]

$$l(u) \equiv u'''' + qu'' = \lambda u, \tag{5.1}$$

$$\begin{aligned} U^1(u) &\equiv u(0) = 0, & U^3(u) &\equiv u''(1) = 0, \\ U^2(u) &\equiv u'(0) = 0, & U^4(u) &\equiv u'''(1) + (1-\eta)qu'(1) = 0. \end{aligned} \tag{5.2}$$

The corresponding adjoint eigenvalue problem looks like

$$l^*(v) \equiv v'''' + qv'' = \lambda v, \tag{5.3}$$

$$\begin{aligned} V^1(v) &\equiv -v(0) = 0, & V^3(v) &\equiv v''(1) + \eta q v(1) = 0, \\ V^2(v) &\equiv v'(0) = 0, & V^4(v) &\equiv -v'''(1) - qv'(1) = 0, \end{aligned} \tag{5.4}$$

and for the forms $V^5, \ldots, V^8$ we have

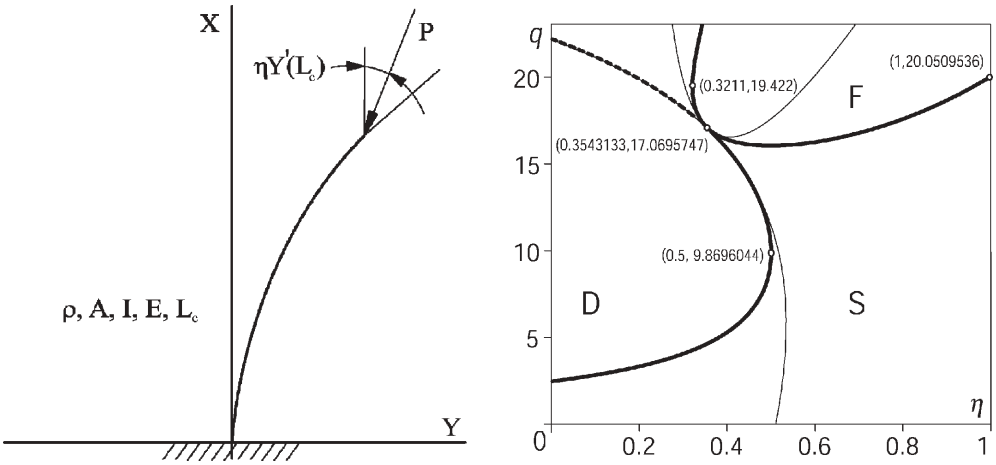

FIG. 5.1. *The extended Beck's problem and its stability diagram.*

$$V^5 \equiv v(1), \quad V^6 \equiv -v'(1), \quad V^7 \equiv -v''(0) - qv(0), \quad V^8 \equiv v'''(0) + qv'(0). \tag{5.5}$$

Substituting the general solution of differential equation (5.1)

$$u(x) = C_1 \cosh(ax) + C_2 \sinh(ax) + C_3 \cos(bx) + C_4 \sin(bx),$$

$$a = \sqrt{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \lambda}}, \quad b = \sqrt{\frac{q}{2} + \sqrt{\frac{q^2}{4} + \lambda}}, \quad \lambda \neq -\frac{q^2}{4},$$

into boundary conditions (5.2) we obtain the condition of the existence of a nontrivial solution $u(x)$ to eigenvalue problem (5.1), (5.2) in the form [27]

$$\Delta(\lambda, \eta, q) = 0, \tag{5.6}$$

$$\Delta \equiv (2\lambda + (1-\eta)q^2)(1 + \cosh(a)\cos(b)) + q(2\eta - 1)(q + ab\sinh(a)\sin(b)).$$

Equation (5.6) gives eigenvalues λ, depending on the parameters η and q.

The vertical equilibrium of the column is stable if all the eigenvalues λ are positive and semisimple; i.e., each eigenvalue has the same number of eigenfunctions as its algebraic multiplicity. After substitution $\lambda = 0$ in (5.6), it gives possible values of the parameters η and q at which the system loses stability statically [26], [27],

$$\eta(q) = \frac{\cos(\sqrt{q})}{\cos(\sqrt{q}) - 1}. \tag{5.7}$$

Equation (5.7) defines the curve of simple zero eigenvalues, the part of which forms the boundary between stability and divergence domains on the plane of parameters (η, q). The smooth parts of the flutter boundary consist of such points (η, q) that $\lambda(\eta, q)$ is a double real eigenvalue with the Keldysh chain. Calculation of the roots of characteristic equation (5.6) for different values of the load parameter q (at a fixed value of the parameter η) gives approximately the point where two simple eigenvalues form a double. Finding such points for different values of the parameter η we get the curve of double real eigenvalues.

The curves found subdivide the plane of the parameters (η, q) into stability (S), flutter (F), and divergence (D) domains; see Figure 5.1. The boundaries between these domains are shown in Figure 5.1 by the firm thick lines, while the dashed thick line shows the part of the curve of zero eigenvalues, which belongs to the divergence domain. Note that the boundary of stability domain has a singular point where the smoothness of the boundary is broken. The divergence boundary has two points with the vertical tangents. One can see that when the influence of the nonconservative part of the load q is small ($\eta < 0.5$), the column loses stability by divergence. Mainly nonconservative loads ($\eta > 0.5$) cause dynamical instability.

Our goal here is to demonstrate the advantages of the theory developed in the previous sections on the example of this stability problem. It will be applied for finding linear and quadratic approximations of the stability and instability domains both at singular and regular points of their boundaries. The explicit expression describing the overlapping of the frequency curves near the flutter boundary will be obtained and compared with the numerical results, given in [28]. Finally, we will obtain the exact coordinates of the singular point of the stability boundary, show that this point corresponds to the double zero eigenvalue with the Keldysh chain of length 2, and investigate the splitting of this eigenvalue in the vicinity of the singularity.

5.1. Bifurcation of eigenvalues in the vicinity of the flutter boundary. Consider a point $\mathbf{p}_0 = (\eta_0, q_0)$ of the flutter boundary, where the spectrum of the operator L contains double eigenvalue λ_0 with the Keldysh chain of length 2. Bifurcation of this eigenvalue is described by (4.8). Substituting the differential expression $l(u)$ from (5.1), the forms $U^1, \dots, U^4$ and $V^5, \dots, V^8$ from (5.2) and (5.5) into formula (3.14), we get the normal vector to the boundary,

$$\mathbf{f}_2 = \left(\frac{q_0 u_0'(1) v_0(1)}{\int_0^1 u_0 v_1 dx}, \frac{\int_0^1 u_0'' v_0 dx - (1-\eta_0) u_0'(1) v_0(1)}{\int_0^1 u_0 v_1 dx} \right). \tag{5.8}$$

For evaluation of the vector $\mathbf{f}_2$ it is essential to know the eigenfunctions u_0, v_0 as well as the associated functions u_1, v_1 at the double eigenvalue λ_0. The solution of eigenvalue problems (5.1), (5.2) and (5.3), (5.4) yields [5]

$$u_0(x) = \cosh(ax) - \cos(bx) + F(a\sin(bx) - b\sinh(ax)), \tag{5.9}$$

$$v_0(x) = \cosh(ax) - \cos(bx) + G(a\sin(bx) - b\sinh(ax)), \tag{5.10}$$

where the coefficients F and G depend on the parameters η and q:

$$F = \frac{a^2\cosh(a) + b^2\cos(b)}{ab(a\sinh(a) + b\sin(b))}, \quad G = \frac{(a^2+\eta q)\cosh(a) + (b^2 - \eta q)\cos(b)}{b(a^2+\eta q)\sinh(a) + a(b^2-\eta q)\sin(b)}. \tag{5.11}$$

Associated function u_1 is a solution of the boundary value problem (3.4), where we should put $k = 2$ and take the differential expression and the boundary forms from (5.1) and (5.2). A particular solution of the ordinary linear differential equation with constant coefficients

$$u_1'''' + q u_1'' - \lambda_0 u_1 = u_0,$$

whose right-hand side is the linear combination of trigonometric and hyperbolic functions (5.9), has the form

$$\hat{u}_1 = x(C_1\sin(bx) + C_2\cos(bx) + C_3\sinh(ax) + C_4\cosh(ax)).$$

Substitution of $\hat{u}_1$ into the second of equations (3.4) allows one to determine the coefficients $C_1, \dots, C_4$. After these coefficients are found one tries the solution of boundary value problem (3.4) in the form

$$u_1 = \hat{u}_1 + D_1 \sin(bx) + D_2 \cos(bx) + D_3 \sinh(ax) + D_4 \cosh(ax).$$

The unknown constants $D_1, \dots, D_4$ can be found from the boundary conditions (3.4). After all necessary manipulations we arrive at the associated function u_1,

$$u_1(x) = \frac{a\sin(bx) + b\sinh(ax) + F(a^2\cos(bx) - b^2\cosh(ax))}{2ab(a^2+b^2)}x + \frac{A_1\sinh(ax) - B_1\sin(bx)}{2ab(a^2+b^2)(a\sinh(a) + b\sin(b))^2}, \tag{5.12}$$

where the coefficient F is taken from (5.11), while for the coefficients A_1, B_1 we have the expressions

$$A_1 = \frac{\sin(b)(b^2\cos(b) - a^2\cosh(a)) + 2ab\cos(b)\sinh(a)}{a^2} q + b(a^2+b^2)(1+\cosh(a)\cos(b)),$$

$$B_1 = \frac{\sinh(a)(b^2\cos(b) - a^2\cosh(a)) - 2ab\cosh(a)\sin(b)}{b^2} q + a(a^2+b^2)(1+\cosh(a)\cos(b)).$$

Similarly, solving boundary value problem (3.5) with the differential expression and boundary forms from (5.1) and (5.2) we get the associated function v_1,

$$v_1(x) = \frac{a\sin(bx) + b\sinh(ax) + G(a^2\cos(bx) - b^2\cosh(ax))}{2ab(a^2+b^2)}x + \frac{A_2\sinh(ax) - B_2\sin(bx)}{2ab(a^2+b^2)(b(a^2+\eta q)\sinh(a) + a(b^2-\eta q)\sin(b))^2}, \tag{5.13}$$

where the coefficient G is defined in (5.11) and the coefficients A_2, B_2 are

$$A_2 = q\sin(b)[[-a^2b^2 + \eta((a^2+b^2)^2 - \eta q^2)]\cosh(a) + \cos(b)(b^2-\eta q)^2] + 2qab^3(1-2\eta)\sinh(a)\cos(b) + b(a^2+b^2)[a^2b^2 + \eta^2q^2 + (a^2b^2 + \eta(1-\eta)q^2)\cos(b)\cosh(a)];$$

$$B_2 = q\sinh(a)[[a^2b^2 - \eta((a^2+b^2)^2 - \eta q^2)]\cos(b) - \cosh(a)(a^2+\eta q)^2] - 2qba^3(1-2\eta)\sin(b)\cosh(a) + a(a^2+b^2)[a^2b^2 + \eta^2q^2 + (a^2b^2 + \eta(1-\eta)q^2)\cos(b)\cosh(a)].$$

A possibility of appearance of associated functions at the critical values of the nonconservative load in Beck's problem was noticed earlier in [29]. Nevertheless, the explicit expressions for the associated functions seem to be obtained first in the present paper. Note that although the eigenfunctions u_0, v_0 are defined up to arbitrary multipliers and associated functions u_1, v_1 are defined up to the addends C_1u_0 and C_2v_0, respectively, the vector $\mathbf{f}_2$ does not depend on these uncertainties.

Consider now the point $\mathbf{p}_0 = (1, 20.0509536)$, corresponding to the double eigenvalue $\lambda_0 = 121.347049$. This point is known as critical for the column subjected to a purely tangential follower force [25]. Substituting the values of λ_0 and $\mathbf{p}_0$ into (5.9)–(5.13) we obtain the functions u_0, v_0, u_1, v_1; see Figure 5.2.

Notice that for the case of tangential force ($\eta = 1$), the eigenfunction v_0 of the adjoint eigenvalue problem has a physical meaning. It is the vibrational mode for the loss of stability of a column loaded by a force with a fixed line of action; see [1] for the theory and [6] for the experiments.

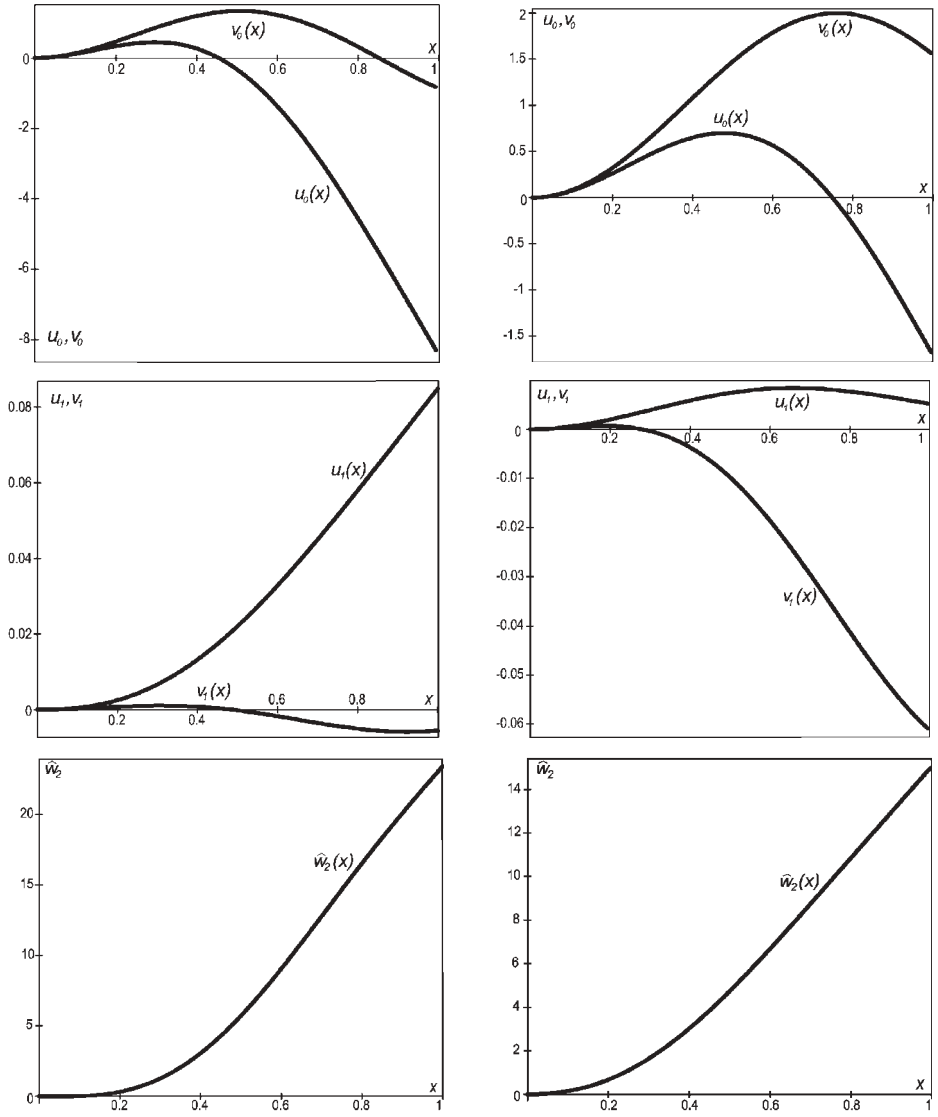

FIG. 5.2. *The eigenfunctions, associated functions, and functions* $\hat{w}_2(x)$ *at the points* $(1, 20.0509536)$ *and* $(0.35431330, 17.0695748)$*, the left and right columns, respectively.*

With the use of these functions, (5.8) gives the normal vector to the flutter boundary at the point $\mathbf{p}_0 = (1, 20.0509536)$,

$$\mathbf{f}_2 = (35458.3181, -2296.10536).$$

Let us look at the splitting of the double eigenvalue λ_0 due to change of parameters in different directions $\mathbf{e}$ on the parameter plane. Consider, for example, the vertical direction $\mathbf{e} = (0, 1)$. Taking into account that $\Delta\mathbf{p}$=$(0, q - q_0)$ we get from (4.8)

$$\lambda = 121.347049 \pm 47.9176936\sqrt{q_0 - q}. \tag{5.14}$$

For the horizontal variation $\Delta\mathbf{p} = (\eta - \eta_0, 0)$ corresponding to the vector $\mathbf{e} = (1, 0)$

TABLE 5.1
Splitting of the double eigenvalue near the point $\mathbf{p}_0 = (1, 20.0509536)$.

$(\Delta\eta, \Delta q)$	λ : Eqs. (5.14), (5.15), (5.19).	λ : Eq. (5.6)
$(0, \ 2{\cdot}10^{-5})$	$121.347049 \pm i0.21429444$	$121.342379 \pm i0.21422599$
$(0, -2{\cdot}10^{-5})$	121.132755 121.561343	121.128319 121.556963
$(\ 2{\cdot}10^{-5}, 0)$	122.189169 120.504929	122.188528 120.504432
$(-2{\cdot}10^{-5}, 0)$	$121.347049 \pm i0.84212016$	$121.338540 \pm i0.84201129$
$2{\cdot}10^{-3}\mathbf{e}_*$	120.762103 121.542851	120.755389 121.540824

we have

$$\lambda = 121.347049 \pm 188.303792\sqrt{\eta - \eta_0}. \tag{5.15}$$

The results of probing of a small neighborhood of the point $\mathbf{p}_0$ in different directions are summarized in Table 5.1. Thus, for example, for $q = q_0 + 0.00002$, i.e., when the new point is situated above the initial point $\mathbf{p}_0$, splitting yields $\lambda = 121.347049 \pm i0.21429444$, and thus the point $\mathbf{p}_0 + \Delta\mathbf{p}$ belongs to the flutter domain; see Figure 5.1. Characteristic equation (5.6) gives for the same values of parameters two complex conjugate eigenvalues, which differ from those found with the use of (5.14) only in a sixth digit; see Table 5.1.

Degeneration condition (3.15) defines the vector $\mathbf{e}_* = (-1, -15.4428097)$ tangent to the flutter boundary at the point $\mathbf{p}_0 = (1, 20.0509536)$. The double eigenvalue λ_0 splits in the tangent direction in accordance with (3.21),

$$\lambda = \lambda_0 - \frac{a_1}{2}\epsilon \pm \frac{\epsilon}{2}\sqrt{a_1^2 - 4a_2} + o(\epsilon). \tag{5.16}$$

Substitution of the differential expression $l(u)$ from (5.1) and the forms $U^1, \dots, U^4$, $V^5, \dots, V^8$ from (5.2) and (5.5) into (3.22) and (3.23) gives the coefficients a_1 and a_2 in the form

$$a_1 = \frac{e_2^* \int_0^1 (u_0'v_1' + v_0'u_1')dx - (e_2^*\eta_0 + e_1^*q_0)(v_1(1)u_0'(1) + v_0(1)u_1'(1))}{\int_0^1 u_0v_1dx}, \tag{5.17}$$

$$a_2 = \frac{e_2^* \int_0^1 v_0'\hat{w}_2'dx - (e_2^*\eta_0 + e_1^*q_0)v_0(1)\hat{w}_2'(1) - e_1^*e_2^*v_0(1)u_0'(1)}{\int_0^1 u_0v_1dx}.$$

The functions u_0, v_0, u_1, v_1 are presented by (5.9), (5.10), (5.12), and (5.13). The function $\hat{w}_2(x)$ (Figure 5.2) is a solution of boundary value problem (3.20), where the differential expressions l_0, l_1 and forms U_0^s, U_1^s are derived from differential expression (5.1) and boundary forms (5.2) according to (3.2) and (3.3):

$$\hat{w}_2(x) = \frac{b\sin(bx) - a\sinh(ax) + Fab(\cos(bx) + \cosh(ax))}{2(a^2 + b^2)}e_2^*x + \frac{A_3\sin(bx) - B_3\sinh(ax)}{2ab(a^2 + b^2)(b\sin(b) + a\sinh(a))^2}e_2^*. \tag{5.18}$$

The coefficient F in (5.18) is defined in (5.11), and for the coefficients A_3 and B_3 we have

$$\begin{aligned} A_3 =& -a(a^2+b^2)(q+ab\sin(b)\sinh(a)) + 2a^2b(b\sinh(a)\cos(b) - a\cosh(a)\sin(b)) \\ & - 2a^3\cosh(a)(a\sinh(a)+b\sin(b)), \\ B_3 =& -b(a^2+b^2)(q+ab\sin(b)\sinh(a)) + 2b^2a(b\sinh(a)\cos(b) - a\cosh(a)\sin(b)) \\ & + 2b^3\cos(b)(a\sinh(a)+b\sin(b)). \end{aligned}$$

With the use of the eigenfunctions, associated functions, and the function $\hat{w}_2$ we find from (5.17) the coefficients $a_1 = 194.571965$, $a_2 = -28633.4466$. Substitution of these coefficients into (5.16) gives approximate expressions for two simple eigenvalues which result from the splitting of the double λ_0 in the tangent direction to the stability boundary

$$\lambda_1 = 121.347049 - 292.473089\epsilon, \quad \lambda_2 = 121.347049 + 97.9011324\epsilon. \tag{5.19}$$

For example, take $\epsilon = 0.002$; then the double eigenvalue λ_0 splits into two positive eigenvalues (Table 5.1). This means that the tangent vector $\mathbf{e}_* = (-1, -15.4428097)$ lies in the stability domain, whence it follows that the flutter domain is convex at the point $\mathbf{p}_0$; see Figure 5.1. At the same values of the parameters, the characteristic equation has very close solutions (Table 5.1), showing thereby that formulas (5.19) give a good approximation to the directly computed eigenvalues.

Consider now the point $\mathbf{p}_0 = (0.32112653, 19.4220703)$ on the boundary between the flutter and divergence domains; see Figure 5.1. In this point there exists the negative double eigenvalue $\lambda_0 = -46.4046486$ with Keldysh chain of length 2. The normal vector to the flutter boundary evaluated at this point by formula (5.8) is

$$\mathbf{f}_2 = (-53123.691, 0).$$

The corresponding tangent vector to the boundary follows from degeneration condition (3.15),

$$\mathbf{e}_* = (0, 1).$$

One can see that the normal vector is parallel to the η-axis and is situated in the divergence domain, so the flutter boundary has a vertical tangent at the point $\mathbf{p}_0 = (0.32112653, 19.4220703)$; see Figure 5.1.

We are interested now in behavior of the frequency curves $\omega(q)$, where $\omega{=}\sqrt{\lambda}$ is a frequency of oscillations, in the vicinity of the point $\mathbf{p}_0$ of the boundary between the flutter and divergence domains. From the formula (3.21) it follows that along the curves $\mathbf{p} = \mathbf{p}_0 + \epsilon\mathbf{e}_* + \epsilon^2\mathbf{d} + o(\epsilon^2)$ the double eigenvalue splits according to

$$(\lambda - \lambda_0)^2 + \langle \mathbf{h}, \mathbf{e}_* \rangle (\lambda - \lambda_0)\epsilon + \langle \mathbf{H}\mathbf{e}_*, \mathbf{e}_* \rangle \epsilon^2 = \epsilon^2 \langle \mathbf{f}_2, \mathbf{d} \rangle + o(\epsilon^2); \tag{5.20}$$

see [30]. Taking into account that along the curve $\mathbf{p}(\epsilon)$ tangent to the flutter boundary at the point $\mathbf{p}_0$,

$$q - q_0 = \epsilon e_*^q + o(\epsilon), \quad \eta - \eta_0 = \epsilon e_*^\eta + \epsilon^2 d^\eta + o(\epsilon^2),$$

we convert expression (5.20) into

$$\left(\lambda - \lambda_0 + \frac{h^q}{2}(q - q_0)\right)^2 - \left(\frac{(h^q)^2}{4} - H^{qq}\right)(q - q_0)^2 = f_2^1(\eta - \eta_0). \tag{5.21}$$

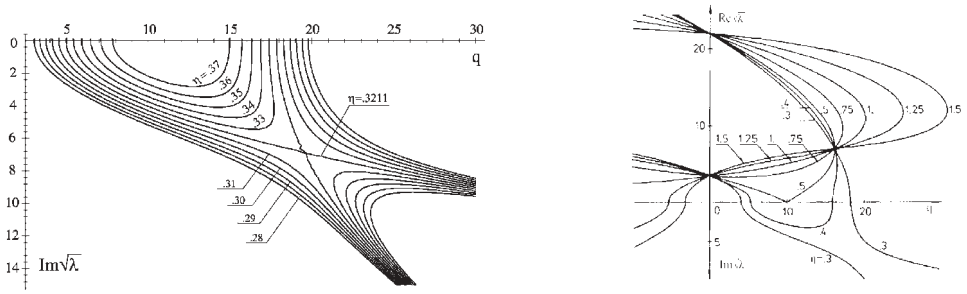

FIG. 5.3. *The frequency curves (from left to right) by* (5.21) *and by the work of* [28].

Formulas (3.22)–(3.25) give the components of the vector $\mathbf{h}$ and matrix $\mathbf{H}$,

$$h^\eta = 686267882692882, \quad h^q = 32.1039479,$$

$$H^{\eta\eta} = 0, \quad H^{\eta q} = 1917.18297, \quad H^{qq} = 93.4817323.$$

The double eigenvalue λ_0 does not split in the first approximation if the discriminant of (5.21) is zero. This condition gives us the quadratic approximation of the flutter boundary near the point $\mathbf{p}_0 = (0.32112653, 19.4220703)$,

$$\eta = 0.32112653 + 0.0030906(q - 19.4220703)^2. \tag{5.22}$$

Equation (5.22) shows that the flutter domain is convex at the point $\mathbf{p}_0$; see Figure 5.1. Formula (5.21) approximates in the vicinity of the point q_0, λ_0 the family of frequency curves $\omega(q) = \sqrt{\lambda(q)}$, parameterized by η. At $\eta = \eta_0$, (5.21) disintegrates into two parts:

$$q = 0.30878129(Im\sqrt{\lambda})^2 + 5.09318321, \quad q = 0.03464354(Im\sqrt{\lambda})^2 + 17.814449. \tag{5.23}$$

Parabolas (5.23) are symmetrical with respect to the axis q and are situated on the plane $(q, Im\sqrt{\lambda})$. At the points $(19.4220703, \pm 6.81209576)$ corresponding to two purely imaginary eigenfrequencies $\omega = \pm i 6.81209576$ these parabolas intersect.

In the left picture of Figure 5.3, the behavior of frequency curves described by (5.21) near one of the intersecting points is shown. One can see that at $\eta < \eta_0$ there exist two purely imaginary frequencies, meaning static instability. With the increase of η, frequency curves come closer together, overlap, and at $\eta > \eta_0$ move apart, forming a zone of complex eigenvalues (flutter). In the right picture of Figure 5.3, the dependence of the two lowest eigenfrequencies $\omega = \sqrt{\lambda}$ on the load q at the different values of the parameter $\eta \in [0.3, 1.5]$, obtained earlier in [28] by numerical solution of characteristic equation (5.6), is shown. Comparing the two pictures of Figure 5.3 we note a good qualitative and quantitative agreement in behavior of frequency curves calculated by two different methods in the range $\eta \in [0.3, 0.4]$.

5.2. Behavior of eigenvalues near the stability-divergence boundary. Consider a point $\mathbf{p}_0 = (\eta_0, q_0)$ on the boundary between the stability and divergence domains, where the spectrum of the eigenvalue problem (5.1), (5.2) contains a simple eigenvalue $\lambda_0 = 0$. Due to variation of parameters, a simple eigenvalue changes according to formula (4.7). Substituting the differential expression $l(u)$ from (5.1)

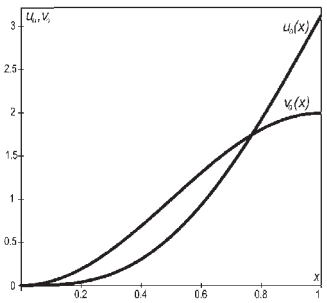

FIG. 5.4. *The eigenfunctions of the zero eigenvalue at the point* $\mathbf{p}_0 = (0.5, 9.86960440)$.

TABLE 5.2
Changing of zero eigenvalue near the point $\mathbf{p}_0 = (0.5, 9.86960440)$.

$(\Delta\eta, \Delta q)$	λ : Eq. (5.27)	λ : Eq. (5.6)
$(\ \ 10^{-4}, 0)$	0.00789568	0.00789498
$(-10^{-4}, 0)$	−0.00789568	−0.00789639

and the forms $U^1, \dots, U^4$ and $V^5, \dots, V^8$ from (5.2) and (5.5) into (3.14), we get the normal vector $\mathbf{f}_1$,

$$\mathbf{f}_1 = \left(\frac{q_0 u_0'(1) v_0(1)}{\int_0^1 u_0 v_0 dx}, \frac{\int_0^1 u_0'' v_0 dx - (1-\eta_0) u_0'(1) v_0(1)}{\int_0^1 u_0 v_0 dx} \right). \tag{5.24}$$

The eigenfunctions u_0 and v_0 at the simple zero eigenvalue have the form

$$u_0 = \sin(b) - xb\cos(b) - \sin(b)\cos(bx) + \cos(b)\sin(bx), \tag{5.25}$$

$$v_0 = 1 - \cos(bx), \quad b = \sqrt{q_0}. \tag{5.26}$$

These eigenfunctions are solutions of eigenvalue problems (5.1)–(5.4) at $\lambda_0 = 0$ and are presented in Figure 5.4.

Consider the point $\mathbf{p}_0 = (0.5, 9.86960440)$ on the divergence boundary described by (5.7). Substituting eigenfunctions (5.25) and (5.26) evaluated at this point into (5.24), we get the normal vector to the divergence boundary,

$$\mathbf{f}_1 = (78.9568352, 0).$$

Hence, the divergence boundary has the vertical tangent at the point $\mathbf{p}_0$; see Figure 5.1. Variation of the parameters $\Delta\mathbf{p} = (\eta - \eta_0, 0)$ changes the zero eigenvalue. According to (4.7) we have

$$\lambda = 78.956835(\eta - \eta_0). \tag{5.27}$$

One can see that for $\eta - \eta_0 < 0$ the eigenvalue $\lambda_0 = 0$ becomes negative. Therefore, the point $\mathbf{p}_0 + \Delta\mathbf{p}$ is inside the divergence domain; see Figure 5.1. If $\eta - \eta_0 > 0$, we come to the stability domain; see Table 5.2.

5.3. The singularity 0^2 of the stability boundary. Figure 5.1 clearly shows that the flutter domain has a common boundary with the domains of stability and divergence. Recall that at the points of the boundary between flutter and stability domains, the spectrum of the differential operator contains positive double eigenvalues, while at the points of the boundary between the flutter and divergence domains, double eigenvalues are negative.

Thus, the double eigenvalue becomes double zero at such point of the flutter boundary that separates stability and divergence domains. At the same time the point with double zero eigenvalue should belong to the curve of zero eigenvalues (5.7). Besides, due to (3.6) the orthogonality condition $\int_0^1 u_0 v_0 dx = 0$ must be true at the points of the flutter boundary. It is clear that this integral evaluated at the points of curve (5.7) becomes zero only at the point corresponding to the double zero eigenvalue.

Integrating the product of the eigenfunctions $u_0(x)$ and $v_0(x)$ from (5.25) and (5.26) over the range $[0, 1]$, we come to the transcendental equation for the ordinate of the desired point,

$$q_0 = (\sqrt{q_0} - 2\sin(\sqrt{q_0}))(\sqrt{q_0}(1 + 2\cos(\sqrt{q_0})) - 4\sin(\sqrt{q_0})). \tag{5.28}$$

The minimal element of the set of solutions of (5.28) at $q_0 > 0$ is $q_0 = 17.0695748$. Substituting this solution into (5.7), we find the corresponding value of the second parameter $\eta_0 = 0.35431330$.

Note that an equation similar to (5.28) was derived first in [27] from the analysis of characteristic equation (5.6) and without use of the eigenfunctions. However, formula (3.23) of [27] contains a misprint: the first term $k_2^2 l^2 \cos^2 k_2 l$ should be read as $k_2^2 l^2 \cos k_2 l$. Nevertheless, the coordinates of the singular point found in [27] are correct and coincide with those obtained from (5.28).

Thus, at the point $\mathbf{p}_0 = (0.35431330, 17.0695748)$ there exists the double eigenvalue $\lambda_0 = 0$ with the Keldysh chain of length 2. Following Arnold [13] we denote this point by the symbol 0^2, where the upper index means the length of the Keldysh chain corresponding to the double zero eigenvalue.

The bifurcation of a double eigenvalue is described by formula (4.8). To evaluate the normal vector $\mathbf{f}_2$ at this point, one needs to know the associated functions u_1, v_1 at the double zero eigenvalue along with the eigenfunctions u_0, v_0. Solving at $k = 2$ and $\lambda = 0$ boundary value problems (3.4) and (3.5) with the differential expressions and boundary forms from (5.1)–(5.4) we get

$$u_1 = -\frac{\cot(b)}{6b}x^3 + \frac{1}{2b^2}x^2 + \frac{\cot(b)(\cos(bx) - 1) + \sin(bx)}{2b^3}x + \frac{(bx - \sin(bx))(b + 2b\cos(b) - 2\sin(b))}{2b^4 \sin^2(b)}, \tag{5.29}$$

$$v_1 = \frac{x + x^2}{2b^2} + \frac{x - 1}{2b^3}\sin(bx) + \frac{b^2\cos(b) - \sin^2(b)}{b^4(b\cos(b) - \sin(b))}(\sin(bx) - bx), \tag{5.30}$$

where $b = \sqrt{q_0}$.

Substituting eigenfunctions (5.25) and (5.26) and associated function (5.30) into expression (5.8), we find the normal vector to the flutter boundary at the point $\mathbf{p}_0 = (0.35431330, 17.0695748)$,

$$\mathbf{f}_2 = (-24288.8139, -1024.49949). \tag{5.31}$$

TABLE 5.3
Splitting of the double zero near the singular point $\mathbf{p}_0 = (0.35431330, 17.0695748)$.

$(\Delta\eta, \Delta q)$	λ : Eqs. (5.32), (5.33)	λ : Eq. (5.6)
$(0, \ 10^{-4})$	$\pm i0.32007804$	$-0.00151188 \pm i0.32007586$
$(0, -10^{-4})$	0.32007804	0.32159210
	-0.32007804	-0.31856833
$(\ 10^{-4}, 0)$	$\pm i1.55848689$	$0.02668744 \pm i1.55823291$
$(-10^{-4}, 0)$	1.55848689	1.53205170
	-1.55848689	-1.58543004
$-10^{-5}\mathbf{e}_*$	-0.01207531	-0.01207543
	-0.00043108	-0.00043108
$10^{-5}\mathbf{e}_*$	0.01207531	0.01207520
	0.00043108	0.00043108

Knowing the normal vector allows us to study the neighborhood of the point of the flutter boundary in any direction $\mathbf{e}$ such that $\langle \mathbf{f}_2, \mathbf{e}\rangle \neq 0$. In particular, for two orthogonal directions $\mathbf{e} = (1, 0)$ and $\mathbf{e} = (0, 1)$, we get

$$\lambda = \pm 155.848689\sqrt{\eta_0 - \eta}, \quad \lambda = \pm 32.0078037\sqrt{q_0 - q}, \tag{5.32}$$

appropriately. It is easy to see that in the typical situation the double zero eigenvalue splits either into a complex conjugate pair or into two real eigenvalues, one of which is negative; see Table 5.3. Thus, the normal vector $\mathbf{f}_2$ at the point $\mathbf{p}_0$ is directed into the divergence domain. The inequality $\langle \mathbf{f}_2, \mathbf{e}\rangle > 0$ defines the tangent cone to this domain, and $\langle \mathbf{f}_2, \mathbf{e}\rangle < 0$ defines the tangent cone to the flutter domain; see Figure 5.1. Only curves, emitted in the tangent direction to the boundary, can reach the stability domain from the singular point.

Using the degeneration condition $\langle \mathbf{f}_2, \mathbf{e}_*\rangle = 0$, we find the tangent vector $\mathbf{e}_* = (1, -23.7079804)$. To examine whether this vector points to the stability domain, we should consider bifurcation of a double zero eigenvalue in the degenerate case. Substituting eigenfunctions (5.25) and (5.26), associated functions (5.29) and (5.30), and the function $\hat{w}_2$, which according to (5.18) takes the form

$$\hat{w}_2 = e_2^* x \frac{\cot(b)(\cos(bx) - 1) + \sin(bx)}{2b} + e_2^* \frac{bx - \sin(bx)}{2b\sin^2(b)}, \quad b = \sqrt{q_0},$$

into expressions (5.17) we find the coefficients of (5.16),

$$a_1 = 1250.63981, \quad a_2 = 52054.6889.$$

In accordance with (5.16) in the first approximation we have

$$\lambda_1 = 1207.53146\epsilon, \quad \lambda_2 = 43.1083501\epsilon. \tag{5.33}$$

It follows from (5.33) that the double zero eigenvalue splits into two positive simple eigenvalues (stability) only if the parameters change in the direction specified by the vector $\mathbf{e}_* = (1, -23.7079804)$; see Table 5.3. Changing the parameters in the opposite direction results in the splitting of the double $\lambda_0 = 0$ into two negative simple eigenvalues, which means static instability (divergence). Note that the approximate expressions for the eigenvalues are in a good agreement with the solutions of characteristic equation (5.6); see Table 5.3.

One can see that the tangent cone to the stability domain at the singular point is a ray on the plane of parameters. Stability domain in the vicinity of this point is a long narrow tongue (Figure 5.1). Our technique allows us to find the quadratic approximation of the flutter and divergence domains and therefore the stability domain near the singular point.

It is easy to see that (5.20), describing splitting of the double eigenvalue $\lambda_0 = 0$ along smooth curves tangent to the flutter boundary at the point $\mathbf{p} = \mathbf{p}_0$, can be rewritten as follows [30]:

$$\lambda^2 + \langle \mathbf{h}, \Delta\mathbf{p}\rangle\lambda + \langle \mathbf{H}\Delta\mathbf{p}, \Delta\mathbf{p}\rangle = \langle \mathbf{f}_2, \Delta\mathbf{p}\rangle + o(||\Delta\mathbf{p}||^2). \tag{5.34}$$

Components of the real vector $\mathbf{h}$ and real symmetrical matrix $\mathbf{H}$ are determined by formulas (3.22)–(3.25). Their evaluation at the singular point gives

$$\begin{gathered} h^\eta = -917.197355, \quad h^q = 14.0645660, \\ H^{\eta\eta} = 0, \quad H^{\eta q} = -690.854898, \quad H^{qq} = 34.3323737. \end{gathered} \tag{5.35}$$

Equation (5.34) provided that $\lambda = 0$ gives the quadratic approximation of the divergence boundary near the singular point,

$$f_2^\eta(\eta - \eta_0) + f_2^q(q - q_0) = 2H^{\eta q}(\eta - \eta_0)(q - q_0) + H^{qq}(q - q_0)^2. \tag{5.36}$$

The equality of the discriminant of (5.34) to zero guarantees the nonsplitting of the double zero eigenvalue and therefore defines the approximation of the flutter boundary

$$\begin{gathered} f_2^\eta(\eta - \eta_0) + f_2^q(q - q_0) \\ = (h^\eta(\eta - \eta_0) + h^q(q - q_0))^2/4 - (2H^{\eta q}(\eta - \eta_0)(q - q_0) + H^{qq}(q - q_0)^2). \end{gathered} \tag{5.37}$$

Substitution of the components of the normal vector $\mathbf{f}_2$ from (5.31) and the vector $\mathbf{h}$ and matrix $\mathbf{H}$ from (5.35) into (5.36) and (5.37) gives the quadratic approximations of the flutter and divergence domains in the vicinity of the point $\mathbf{p}_0 = (0.35431330, 17.0695748)$. These approximations are shown in Figure 5.1 by the thin solid lines. One can see that the approximation of the divergence domain is very good at far distances from the singular point while the approximation of the flutter domain is good only in the neighborhood of the point $\mathbf{p}_0$.

6. Conclusion. A new approach to obtain explicit formulas for the bifurcation of multiple eigenvalues of non-self-adjoint differential operators smoothly dependent on a vector of real parameters is presented. The formulas found use the derivatives of the differential expression and the boundary forms with respect to parameters as well as the functions of the Keldysh chain evaluated at the point of the parameter space corresponding to a multiple eigenvalue.

The results obtained let us study the splitting of the multiple eigenvalues in both regular and degenerate cases and serve as a basis for the sensitivity analysis of continuous nonconservative systems. This allows one to avoid the variational calculus in every specific problem to find sensitivities of eigenvalues or critical values of parameters.

Then the multiparameter stability problems of continuous circulatory systems are studied. It is found that the stability boundaries of these systems are smooth surfaces in the parameter space corresponding to simple zero (divergence) or double

real eigenvalues with Keldysh chain of length 2 (flutter). It is shown that the flutter condition for the circulatory systems is a simple consequence of the existence of the Keldysh chain of length $k \geq 2$.

The advantages of the proposed approach are illustrated by the mechanical example known as the extended Beck problem. With the use of the bifurcation analysis of eigenvalues, stability boundaries in this problem are investigated. Linear and quadratic approximations to the stability and instability domains at both regular and singular points of their boundaries are found and compared with the exact numerical values.

DISCRETIZATION OF CONTINUOUS SPECTRA BASED ON PERFECTLY MATCHED LAYERS*

FRANK OLYSLAGER†

Abstract. As a tool of analysis in physics, wavefields are often expanded in a set of eigensolutions obtained from a Sturm–Liouville problem. For singular Sturm–Liouville problems subject to radiation boundary conditions, i.e., problems defined on an infinite domain, this set of eigensolutions has continuous parts. In this paper we will show that it is possible to approximate this continuous set of eigensolutions by a discrete set of eigensolutions of the same Sturm–Liouville operator but subject to Dirichlet boundary conditions in complex space. The idea of Dirichlet boundary conditions in complex space stems from the perfectly matched layer (PML) absorbing boundary condition. The PML was introduced in 1994 [J. P. Bérenger, *J. Comput. Phys.*, 114 (1994), pp. 185–200] as an absorbing termination of a finite difference time domain grid. These complex space Dirichlet boundary conditions have been used recently to close open electromagnetic waveguide structures. In the present paper we aim at developing a mathematical basis for the wavefields existing in such structures. On the one hand, this yields a better understanding of the properties of such waveguides and their applications in electromagnetic field problems. On the other hand, this opens the road for applications in other wavefields such as elastodynamics and quantum mechanics.

Key words. eigenfunction expansion, Green functions, waveguides, boundary value problems on infinite intervals, absorbing boundary conditions

DOI. 10.1137/S0036139903430197

1. Introduction.

In 1994, Bérenger published [1] a new absorbing boundary condition for the finite difference time domain (FDTD) technique to solve electromagnetic field problems. That absorbing boundary condition, also called the perfectly matched layer (PML), has shown to be extremely useful in FDTD and finite element techniques. A PML is capable of absorbing without reflection the incident waves arriving from almost any direction and for all frequencies; i.e., it mimics infinite space. Originally Bérenger presented the PML in FDTD as a split field formalism. Later other formulations for a PML were given by interpreting a PML as an artificial uniaxial anisotropic medium [2] or as a layer with a complex thickness backed by a perfect electric conductor [3].

Originally, PMLs were used only in numerical, finite difference, or finite element–based techniques. Later it turned out that PMLs are also useful in semianalytical techniques. The first such application of PMLs aimed at the study of open waveguide discontinuities with the mode matching technique [4], [5]. An open waveguide is not bounded in the transverse plane orthogonal to the propagation direction. This means that the eigenmodes are solutions of a singular Sturm–Liouville problem over an infinite domain, subject to radiation boundary conditions. Hence, the modal spectrum of an open waveguide contains continuous parts corresponding to so-called radiation modes. These continuous parts impede the application of the mode matching technique. With the addition of a PML around the waveguide, the waveguide becomes a closed waveguide described by a Sturm–Liouville problem over a finite domain, having

*Received by the editors June 13, 2003; accepted for publication (in revised form) October 28, 2003; published electronically May 20, 2004.

†Electromagnetics Group, Department of Information Technology, Ghent University, Sint-Pietersnieuwstraat 41, B-9000 Ghent, Belgium (olyslag@intec.ugent.be).

only a discrete spectrum. Since the PML absorbs all incident waves without reflections, it is to be expected that this discrete spectrum is a good representation of the continuous spectrum of the open waveguide. In the subsequent years the usage of PMLs for mode matching techniques has shown to be very successful, especially in the study of optics; see, e.g., [6], [7].

Another semianalytical application of PMLs is intended for the determination of Green functions for electromagnetic fields in two and three dimensions in open layered media [8], [9]. To determine the Green function of a layered structure one usually first solves for the spectral Green function in the spatial Fourier domain with respect to the coordinates parallel to the layers. This spectral Green function is usually easily obtained in closed form. Its inverse Fourier transform cannot, in general, be evaluated in closed form and often relies on quite delicate numerical techniques. For the three-dimensional case these inverse Fourier transforms are known as Sommerfeld integrals. An expansion of the Green function in the eigenmodes of the waveguide consisting of the layered medium does not allow us to escape the numerical evaluation of an integral because the spectrum is again continuous due to the open nature of the structure. The spectral Green function has branch-cuts, corresponding to the continuous spectrum, apart from some discrete poles. With the addition of a PML, the layered medium again becomes closed, and the Green function can be expanded in a series of the discrete eigenmodes of the closed layered waveguide. The spectral Green function now has only discrete poles. By invoking Cauchy's residue theorem, this allows an expansion of the inverse Fourier transform in a series of residues in the discrete poles. This yields the modal expansion of the Green function.

In both these applications one could say that the addition of PMLs results in a discretization of continuous spectra.

All studies so far on semianalytical techniques mainly focussed on numerical accuracy and did not particularly explore the underlying mathematics. In the present paper we want to fill this gap and prove that field solutions in structures with PMLs converge to the field solutions in the original structures without a PML. At the same time, we will investigate the convergence properties of the discrete eigenmode series.

The usage of the PML technique to discretize continuous spectra is not restricted to electromagnetic field problems but can be applied to other and more general wave problems in physics and elsewhere. Our feeling is that this technique has advantageous applications in other branches of physics and especially in quantum physics, where one is often confronted with unbounded spaces, i.e., open structures, yielding continuous spectra of states. In order to avoid these continuous spectra, one often adds a box which again yields discrete spectra. The PML technique provides an alternative by adding a box with PML walls. We remark that this is easily implemented because the PML can be formulated as a Dirichlet boundary condition in complex rather than real space. By providing more mathematical rigor, it is hoped that the present paper will pave the way for the application of PMLs in semianalytical techniques outside the electromagnetic community. Noteworthy is a recent application of PMLs in economics for the prediction of the evolution of stock options [10].

In this paper we will treat the PML as a Dirichlet boundary condition placed at complex space coordinates. We will focus on the Green function problem; i.e., we will consider linear wave equations with Dirac distributions at the right-hand side. This poses no restriction, since arbitrary right-hand sides can be dealt with by considering convolutions with the Green functions. Our aim is to investigate when the Green function of a wave equation subject to radiation boundary conditions converges to the Green function of the same wave equation subject to Dirichlet boundary

conditions at points in complex space. First we will consider the Green function of a two-dimensional Helmholtz wave equation. This allows a simple treatment, and a closed form expression of the Green function is available, i.e., the Hankel function. By adding the Dirichlet boundary conditions, we obtain a new series representation for the Hankel function. It is shown that this series can be made as accurate as required by adjusting the position in complex space of the Dirichlet boundary conditions. Some of the results concerning this new series for the Hankel function were announced in [11]. We also investigate the conditions under which the series converges. In a second step this is generalized to the Green function of an inhomogeneous two-dimensional Helmholtz equation. In this case the Green function subject to radiation conditions is not expressible in closed form. However, the Green function subject to Dirichlet boundary conditions in complex space can be expanded in a series. For one particular case the convergence properties of the series are investigated. Last, some further generalizations are treated, such as Green functions of the homogeneous and inhomogeneous three-dimensional Helmholtz operator and of some vectorial Helmholtz wave equations. In all these cases the Green function is expanded in the discrete eigenfunctions of a wave operator, i.e., of a Sturm–Liouville problem, bounded by the Dirichlet boundary conditions. This wave operator is the spatial Fourier transform in one or more directions of the original wave equation. Along these directions the radiation condition is still imposed. In the last section we consider the situation in which the domain of the wave operator is subject to a Dirichlet boundary condition in all directions. The proofs of the various theorems are concentrated in Appendix A, and in Appendix B the asymptotic solutions of a transcendental equation are derived. A few numerical experiments illustrate some of our findings.

2. The basic problem. Consider the Green function that satisfies the two-dimensional Helmholtz equation

$$\nabla_{xy}^2 g(x,y) + g(x,y) = \delta(x)\delta(y) \tag{1}$$

over the entire xy-plane, i.e., $x, y \in \mathbf{R}$. To obtain a unique solution we demand that $g(x,y)$ represent outgoing waves when a $e^{j\omega t}$ time-dependence is assumed. This can be translated in the radiation condition [12]

$$\lim_{\rho\to+\infty}\left[\frac{\partial}{\partial\rho}g(x,y) + jg(x,y)\right] = 0, \tag{2}$$

with $\rho = \sqrt{x^2+y^2}$, which automatically selects the correct solution. It is well known that this solution is given by

$$g(x,y) = g(\rho) = \frac{j}{4}H_0^{(2)}(\rho), \tag{3}$$

with $H_0^{(2)}(\rho)$ the Hankel function of zeroth order and second kind.

Consider the spatial Fourier transform $G(\lambda, y)$ with respect to x of $g(\rho)$

$$G(\lambda,y) = \int_{-\infty}^{+\infty} g(\rho)e^{j\lambda x}dx. \tag{4}$$

The spectral Green function $G(\lambda, y)$ is a solution of

$$\frac{\mathrm{d}^2}{\mathrm{d}y^2}G(\lambda,y) + (1-\lambda^2)G(\lambda,y) = \delta(y) \tag{5}$$

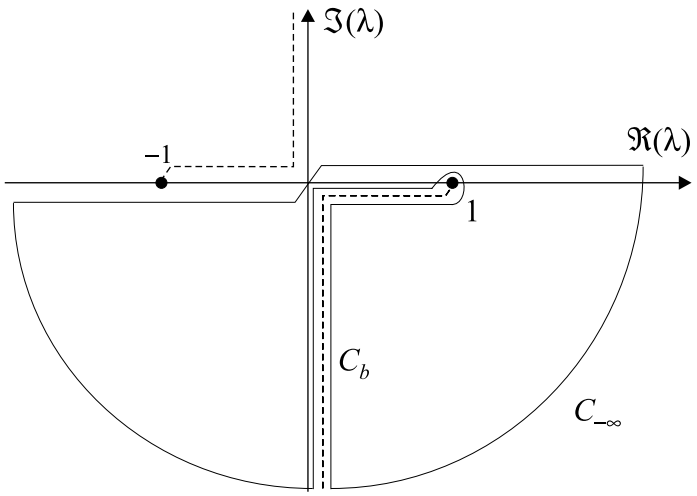

FIG. 1. *The complex λ-plane.*

and is given by

$$G(\lambda, y) = \frac{je^{-j\sqrt{1-\lambda^2}|y|}}{2\sqrt{1-\lambda^2}}. \tag{6}$$

Writing the inverse transform yields

$$\frac{j}{4}H_0^{(2)}(\rho) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{je^{-j\sqrt{1-\lambda^2}|y|}}{2\sqrt{1-\lambda^2}} e^{-j\lambda x} d\lambda. \tag{7}$$

If we choose the branch-cut of $\sqrt{\zeta}$ along $\arg(\zeta) = 0^+$, then the integrand has branch-cuts, emanating from $\lambda = \pm 1$, as indicated in the complex λ-plane in Figure 1. For $x > 0$ ($x < 0$) the integral along the real λ-axis can be replaced by an integral along the branch-cut in the lower (upper) half-plane, since the semicircle at infinity will not contribute. So far, this is a well known trivial matter.

Consider another Green function $\tilde{g}(x, y)$, a solution of (1) but subject to the boundary condition

$$\tilde{g}(x, y = \pm d) = 0, \tag{8}$$

$d \in \mathbf{R}$ that represents outgoing waves for $x \to \pm\infty$. The spectral Green function $\tilde{G}(\lambda, y)$ is readily found,

$$\tilde{G}(\lambda, y) = \frac{\sin[\sqrt{1-\lambda^2}(|y| - d)]}{2\sqrt{1-\lambda^2}\cos[\sqrt{1-\lambda^2}d]}, \tag{9}$$

and hence

$$\tilde{g}(x, y) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{\sin[\sqrt{1-\lambda^2}(|y| - d)]}{2\sqrt{1-\lambda^2}\cos[\sqrt{1-\lambda^2}d]} e^{-j\lambda x} d\lambda. \tag{10}$$

Let us extend d in (10) to the complex plane; i.e., assume that $d = \gamma e^{-j\alpha}$. Now we conjecture for all $x, y \in \mathbf{R}$ that

$$\forall \epsilon > 0, \qquad \exists \delta(\epsilon) > 0 : \gamma > \delta(\epsilon) > 0 \Rightarrow |g(x, y) - \tilde{g}(x, y)| < \epsilon \tag{11}$$

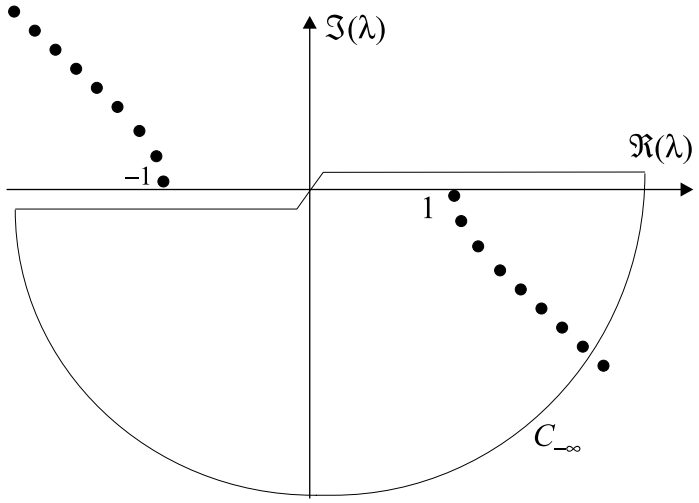

FIG. 2. *Complex λ-plane.*

when $0 < \alpha < \frac{\pi}{2}$. This can be seen from

$$g(x,y) - \tilde{g}(x,y) = -\frac{1}{\pi}\int_0^{+\infty}\left[\frac{\sinh[\sqrt{\lambda^2-1}(|y|-d)]}{\sqrt{\lambda^2-1}\cosh[\sqrt{\lambda^2-1}d]} + \frac{e^{-\sqrt{\lambda^2-1}|y|}}{\sqrt{\lambda^2-1}}\right]\cos(\lambda x)d\lambda$$

$$= \frac{1}{\pi}\int_0^{+\infty}\frac{\tanh(\sqrt{\lambda^2-1}\gamma e^{-j\alpha})-1}{\sqrt{\lambda^2-1}}\cosh(\sqrt{\lambda^2-1}|y|)\cos(\lambda x)d\lambda, \tag{12}$$

where the branch-cut of $\sqrt{\zeta}$ now is along $\arg(\zeta) = \pi^+$. The proof of (11) is an immediate consequence of Theorem A.4 in Appendix A. This means that we can use $\tilde{g}(x,y)$ as an approximation for $g(x,y)$, provided that γ is chosen large enough and that $0 < \alpha < \frac{\pi}{2}$.

Now consider the integral (10). The integrand has no branch-cuts but simple poles at

$$\lambda_n^{\pm} = \pm\sqrt{1 - \frac{(2n+1)^2\pi^2}{4d^2}}, \tag{13}$$

$n = 0, 1, 2, \ldots$. Figure 2 shows a typical distribution of these poles in the complex λ-plane. Let us assume that $x > 0$. Using Cauchy's theorem, the integral along the real axis can be replaced by a sum of the residues at the poles in the lower half-plane and an integral along the semicircle $C_{-\infty}$ at infinity in the lower half-plane. If the contribution of $C_{-\infty}$ vanishes, then (10) allows the following series representation:

$$\tilde{g}(x,y) = -\frac{j}{2d}\sum_{n=0}^{+\infty}\cos\frac{(2n+1)\pi y}{2d}\frac{e^{-j\sqrt{1-\frac{(2n+1)^2\pi^2}{4d^2}}x}}{\sqrt{1-\frac{(2n+1)^2\pi^2}{4d^2}}}. \tag{14}$$

Let us investigate when the contribution from $C_{-\infty}$ vanishes. At a semicircle with radius R in the lower half-plane, the spectral Green function $\tilde{G}(\lambda, y)$, with $\lambda = Re^{j\phi}$,

$-\pi \le \phi \le 0$, can be written as

$$\tilde{G}(\lambda, y) \approx -\frac{e^{-j\phi}}{2R} \frac{e^{Re^{j\phi}(|y|-\gamma e^{-j\alpha})} - e^{-Re^{j\phi}(|y|-\gamma e^{-j\alpha})}}{e^{Re^{j\phi}\gamma e^{-j\alpha}} + e^{-Re^{j\phi}\gamma e^{-j\alpha}}} e^{-j\lambda x}, \tag{15}$$

where we have assumed that R is large enough such that $\sqrt{1-\lambda^2} \approx jRe^{j\phi}$.

We distinguish two cases as follows.

1. Assume first that $\cos(\phi - \alpha) > 0$; this will be the case if $-\frac{\pi}{2} + \alpha \le \phi \le 0$. In this case we can write (15) as

$$\tilde{G}(\lambda, y) \approx -\frac{e^{-j\phi}}{2R} \frac{e^{R|y|e^{j\phi}} e^{-2R\gamma e^{j(\phi-\alpha)}} - e^{-Re^{j\phi}|y|}}{1 + e^{-2R\gamma e^{j(\phi-\alpha)}}} e^{-jRxe^{j\phi}}. \tag{16}$$

This function decays exponentially for increasing R if

$$|y| \cos\phi - 2\gamma \cos(\phi - \alpha) + x \sin\phi \le 0, \tag{17}$$

$$|y| \cos\phi + x \sin\phi \le 0. \tag{18}$$

Writing $x = \rho \cos\tau$ and $|y| = \rho \sin\tau$, with $0 \le \tau \le \frac{\pi}{2}$, this becomes

$$\rho \sin(\phi + \tau) - 2\gamma \cos(\phi - \alpha) \le 0, \tag{19}$$

$$\rho \sin(\phi - \tau) \le 0. \tag{20}$$

For the considered ranges of ϕ and τ the condition (20) is always satisfied. For the condition (19) it is easily checked that it is satisfied for $-\frac{\pi}{2} + \alpha \le \phi \le 0$ if it is satisfied for $\phi = 0$, i.e., if $\rho \sin\tau - 2\gamma \cos\alpha \le 0$. This can always be assured by taking γ large enough.

2. Now assume that $\cos(\phi - \alpha) < 0$, i.e., that $-\pi \le \phi \le -\frac{\pi}{2} + \alpha$. We can cast (15) as

$$\tilde{G}(\lambda, y) = -\frac{e^{-j\phi}}{2R} \frac{e^{R|y|e^{j\phi}} - e^{-Re^{j\phi}|y|} e^{2R\gamma e^{j(\phi-\alpha)}}}{e^{2R\gamma e^{j(\phi-\alpha)}} + 1} e^{-jRxe^{j\phi}}. \tag{21}$$

Exponential decay now demands that

$$\rho \sin(\phi + \tau) \le 0, \tag{22}$$

$$\rho \sin(\phi - \tau) + 2\gamma \cos(\phi - \alpha) \le 0. \tag{23}$$

The condition (23) can be assured by taking γ large enough. Indeed, one again checks that (23) is satisfied for all ϕ when it is satisfied for $\phi = -\pi$, i.e., when $\rho \sin\tau - 2\gamma \cos\alpha \le 0$. Condition (22) is a different matter. That condition is only satisfied for $-\pi \le \phi \le -\frac{\pi}{2} + \alpha$ when $\tau \le \frac{\pi}{2} - \alpha$.

By taking the limit for $R \to +\infty$, we have shown that the contribution of $C_{-\infty}$ will not vanish for x and y values for which $\tau > \frac{\pi}{2} - \alpha$. One could imagine closing the contour by a semicircle $C_{+\infty}$ at infinity in the upper half-plane to resolve this problem, but also the contribution of $C_{+\infty}$ will not vanish.

The previous steps can be repeated for $x < 0$ by closing the contour in the upper half-plane with $C_{+\infty}$ and considering the residues of the poles in the upper half-plane. The result is that a series representation of the integral (10) is possible in the nonhatched region of the xy-plane indicated in Figure 3. As a confirmation of this result one can check that the terms in the series (14) diverge exponentially in

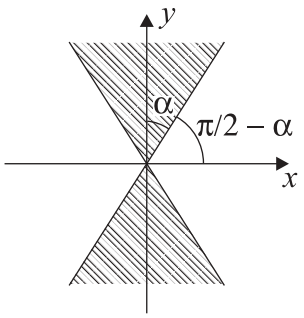

FIG. 3. *Region of convergence of the series* (14).

the hatched region of Figure 3. Outside the hatched region we have found a series approximation for the Green function (3), i.e., the Hankel function, that becomes more accurate if γ increases. In particular, we have that

$$H_0^{(2)}(x) \approx -\frac{2}{d}\sum_{n=0}^{+\infty} \frac{e^{-j\sqrt{1-\frac{(2n+1)^2\pi^2}{4d^2}}x}}{\sqrt{1-\frac{(2n+1)^2\pi^2}{4d^2}}} \tag{24}$$

for $x > 0$.

It is unnecessary to keep y real. One could as well analytically extend (14) to the complex plane with respect to y. Let us consider one particular example where we take $y = \tilde{y}e^{-j\alpha}$ with $\tilde{y} \in \mathbf{R}$. With this choice it is obvious that the series (14) is convergent for all $x > 0$ and for all $\tilde{y}$. It is then verified that $\tilde{g}(x, y = \pm d) = 0$ with d complex. Hence, we could say that $\tilde{g}(x, y)$ is the solution of (1) subject to Dirichlet boundary conditions in the complex y-plane. As was already the case on the real axis, the series (14) will not converge in the entire complex y-plane.

Applying Cauchy's theorem on the right-hand side of (7) allows us to write $g(x, y)$ for $x > 0$ as

$$\begin{aligned} g(x,y) &= \frac{1}{2\pi}\int_{C_b} \frac{je^{-j\sqrt{1-\lambda^2}|y|}}{2\sqrt{1-\lambda^2}} e^{-j\lambda x} d\lambda \\ &= -\frac{1}{2\pi}\int_0^1 \frac{e^{-j\lambda x}\cos(|\sqrt{1-\lambda^2}||y|)}{|\sqrt{1-\lambda^2}|} d\lambda + \frac{1}{2\pi}\int_0^{+\infty} \frac{e^{-\kappa x}\cos(|\sqrt{1+\kappa^2}||y|)}{|\sqrt{1+\kappa^2}|} d\kappa, \end{aligned} \tag{25}$$

where we have closed the contour with $C_{-\infty}$ and an integration along the branch-cut C_b as indicated on Figure 1. The right-hand side is nothing but an expansion of the Green function $g(x, y)$ in the continuous spectrum of eigenfunctions of the operator

$$\frac{\mathrm{d}^2}{\mathrm{d}y^2} + 1 \tag{26}$$

along the entire y-axis. The spectrum is continuous because the domain of the operator is infinite in the y-direction. The first term on the right-hand side represents propagating plane waves, and the second term on the right-hand side represents evanescent or inhomogeneous plane waves. The series (14) is also an expansion in eigenfunctions of the operator (26) but now subject to the Dirichlet boundary conditions at $y = \pm d$. These eigenfunctions constitute a discrete set. Physically we can thus say that we

have constructed a discrete spectrum representation of the continuous spectrum. In the analysis we considered the Green function problem, but it is clear that one could as well consider the field due to a general source (i.e., an arbitrary function $s(x, y)$ on the right-hand side in (1)) by taking the convolution with the Green function.

The expression (14) for the Green function $\tilde{g}(x, y)$ can also be obtained by a different route. Let us, for the moment, assume that the resolution

$$\delta(y) = \frac{1}{d} \sum_{n=0}^{+\infty} \cos \frac{(2n+1)\pi y}{2d} \tag{27}$$

of the $\delta(y)$ distribution remains valid for complex d. It then follows that the solution of (5) for $\tilde{G}(\lambda, y)$ can be written as

$$\tilde{G}(\lambda, y) = \frac{1}{d} \sum_{n=0}^{+\infty} \frac{\cos \frac{(2n+1)\pi y}{2d}}{1 - \lambda^2 - \frac{(2n+1)^2\pi^2}{4d^2}}, \tag{28}$$

and its inverse Fourier transform as

$$\tilde{g}(x, y) = \frac{1}{2\pi d} \sum_{n=0}^{+\infty} \cos \frac{(2n+1)\pi y}{2d} \int_{-\infty}^{+\infty} \frac{e^{-j\lambda x}}{1 - \lambda^2 - \frac{(2n+1)^2\pi^2}{4d^2}} d\lambda. \tag{29}$$

The integral is easily evaluated in closed form by again invoking Cauchy's theorem and closing, for $x > 0$, the contour along $C_{-\infty}$, the contribution of which always vanishes. The result is again (14). Since we know that (14) is invalid in the hatched region of Figure 3, we find that the resolution (27) of the Dirac distribution is invalid for real y. This is in agreement with [13]. However, for $y = \tilde{y}e^{-j\alpha}$ with $\tilde{y} \in \mathbf{R}$, (27) is a good resolution of the Dirac distribution in $-\gamma < \tilde{y} < \gamma$ since (14) is then valid for all x. This means that

$$\int_{-d}^{+d} h(y) \frac{1}{d} \sum_{n=0}^{+\infty} \cos \frac{(2n+1)\pi y}{2d} dy = h(0), \tag{30}$$

where $h(y)$ is holomorphic and where the path connecting $-d$ and d in the complex y-plane is arbitrary.

In Figure 4 the number of digits of accuracy of the series (24) is shown for three different distances x as a function of the parameter $q = \log_{10}(\gamma)$. It is seen that the accuracy increases with γ and that γ has to increase for a given accuracy when x increases in agreement with the aforementioned conclusion. In Figure 5 the number of terms needed in the series is shown to approximate the series sum with an accuracy of 10^{-7}. The results are plotted for the same distances x as a function of the parameter q.

3. A more general problem. Consider the Green function satisfying the inhomogeneous two-dimensional Helmholtz equation

$$\nabla_{xy}^2 g(x, y) + k^2(y) g(x, y) = \delta(x)\delta(y - y'), \tag{31}$$

where we assume that $y' \leq 0$, that $k^2(y) \in \mathbf{R}^+$, and that $k^2(y) = 1$ for $y > 0$. We also assume that $g(x, y)$ satisfies the radiation condition (2) in the half-plane $y > 0$. The spectral Green function $G(\lambda, y)$ satisfies

$$\frac{\mathrm{d}^2}{\mathrm{d}y^2} G(\lambda, y) + [k^2(y) - \lambda^2] G(\lambda, y) = \delta(y - y'). \tag{32}$$

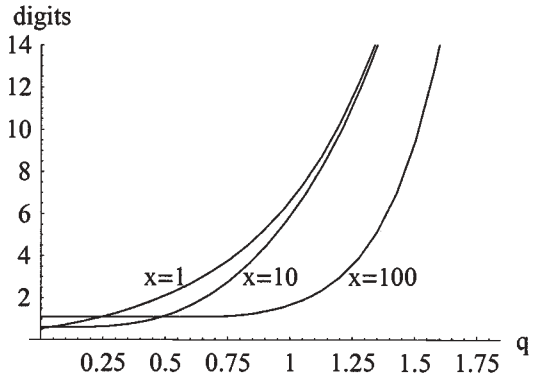

FIG. 4. *Number of digits of accuracy of* (24) *as a function of* $q = \log_{10}(\gamma)$ *for* $x = 1, 10, 100$.

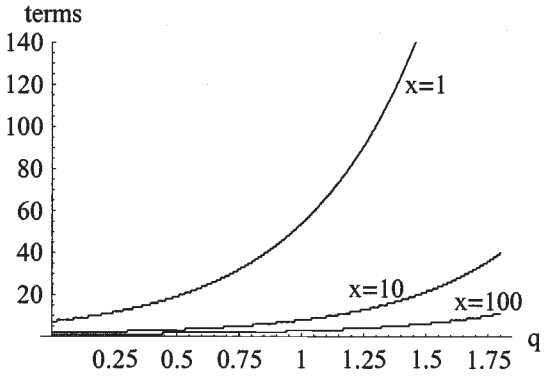

FIG. 5. *Number of terms needed in* (24) *as a function of* $q = \log_{10}(\gamma)$ *for an accuracy of* 10^{-7} *for* $x = 1, 10, 100$.

Note that $G(\lambda, y)$ is an even function of λ since $g(x, y)$ is an even function of x. In the region $y > 0$ we can write

$$G(\lambda, y) = G(\lambda, 0)e^{-j\sqrt{1-\lambda^2}y}. \tag{33}$$

Consider another Green function $\tilde{g}(x, y)$ that also satisfies (31) but subject to the boundary condition $\tilde{g}(x, y = d) = 0$. If $R(\lambda)$ is the reflection coefficient for an incident wave $e^{j\sqrt{1-\lambda^2}y}$ on the structure at $y = 0$, then we can expand $\tilde{G}(\lambda, y)$ in the region $y > 0$ as a series of waves

$$\begin{aligned}\tilde{G}(\lambda, y) &= G(\lambda, 0)\sum_{n=0}^{+\infty}[-R(\lambda)e^{-2jd\sqrt{1-\lambda^2}}]^n(e^{-j\sqrt{1-\lambda^2}y} - e^{j\sqrt{1-\lambda^2}(y-2d)}) \\ &= G(\lambda, 0)\frac{e^{-j\sqrt{1-\lambda^2}y} - e^{j\sqrt{1-\lambda^2}(y-2d)}}{1 + R(\lambda)e^{-2jd\sqrt{1-\lambda^2}}}. \end{aligned} \tag{34}$$

The term $n = 0$ corresponds to the wave $G(\lambda, y)$ and the down-propagating reflected

wave at $y = d$,

$$G_1(\lambda, y) = -G(\lambda, 0)e^{j\sqrt{1-\lambda^2}(y-2d)}, \tag{35}$$

with inverse Fourier transform

$$g_1(x, y) = -\frac{1}{\pi}\int_0^{+\infty} G(\lambda, 0)e^{-\sqrt{\lambda^2-1}(2d-y)}\cos(\lambda x)d\lambda. \tag{36}$$

From Theorem A.5 in Appendix A it follows, with $d = \gamma e^{-j\alpha}$ for all x, that

$$\forall \epsilon > 0, \qquad \exists \delta(\epsilon) > 0 : \gamma > \delta(\epsilon) > 0 \Rightarrow |g_1(x, 0)| < \epsilon. \tag{37}$$

This means that γ can be chosen such that $g_1(x, 0)$ becomes negligibly small. This in turn means that the waves generated by the incidence of $g_1(x, y)$ on the region $y < 0$ will be negligible compared to $g(x, y)$. In other words, for all x,

$$\forall \epsilon > 0, \qquad \exists \delta(\epsilon) > 0 : \gamma > \delta(\epsilon) > 0 \Rightarrow |g(x, y) - \tilde{g}(x, y)| < \epsilon \tag{38}$$

for $y < 0$.

Return to problem (31) and assume that $k^2(y)$ takes constant values $(k^+)^2$ for $y > a^+$ and $(k^-)^2$ for $y < a^-$, and assume that $g(x, y)$ represents outgoing waves in the regions $y > a^+$ and $y < a^-$; then this Green function can be approximated by another Green function $\tilde{g}(x, y)$ that satisfies (31) with $a^- \leq y' \leq a^+$ but subject to the boundary conditions $\tilde{g}(x, a^+ + d^+) = \tilde{g}(x, a^- - d^-) = 0$ with $d^\pm = \gamma^\pm e^{-j\alpha^\pm}$. If $0 < \alpha^\pm < \pi/2$, then the difference $|g(x, y) - \tilde{g}(x, y)|$ can be made as small as required by taking $\gamma^\pm$ sufficiently large.

The spectral Green function $G(\lambda, y)$ will have branch-cuts emanating from $\pm k^+$ and $\pm k^-$, together with some discrete poles [14], [15]. The discrete poles and the branch-cuts constitute the spectrum of the operator

$$\frac{\mathrm{d}^2}{\mathrm{d}y^2} + k^2(y), \tag{39}$$

where the continuous part, i.e., the branch-cuts, are again due to the infinite domain. Due to the Dirichlet boundary conditions in the y-direction, the spectral Green function $\tilde{G}(\lambda, y)$ will have only discrete poles and no branch-cuts; i.e., the operator (39) has a discrete spectrum. This means that $\tilde{g}(x, y)$ can be written as a sum of residues of a number of these discrete poles if the contributions from semicircles at infinity vanish. This series will approximate $g(x, y)$.

Let us consider one particular example where we look for solutions of (31) with $k^2(y) = 1$ for $y > y' > 0$ and $k^2(y) = k^2$ for $y < y'$. We bound the domain at $y = 0$ by imposing $g(x, y = 0) = 0$. The spectral Green function $G(\lambda, y)$ is readily given by

$$G(\lambda, y) = -\frac{\sin[\kappa_1(\lambda)y]}{j\kappa_2(\lambda)\sin[\kappa_1(\lambda)y'] + \kappa_1(\lambda)\cos[\kappa_1(\lambda)y']} \tag{40}$$

for $0 < y < y'$ and by

$$G(\lambda, y) = -\frac{e^{j\kappa_2(\lambda)y'}e^{-j\kappa_2(\lambda)y}\sin[\kappa_1(\lambda)y']}{j\kappa_2(\lambda)\sin[\kappa_1(\lambda)y'] + \kappa_1(\lambda)\cos[\kappa_1(\lambda)y']} \tag{41}$$

for $y > y'$ with $\kappa_1(\lambda) = \sqrt{k^2 - \lambda^2}$ and $\kappa_2(\lambda) = \sqrt{1 - \lambda^2}$. These functions clearly have branch-cuts emanating from $\lambda = \pm 1$, and their inverse Fourier transforms are not available in closed form. The spectral Green function $\tilde{G}(\lambda, y)$, on the other hand, is given by

$$\tilde{G}(\lambda, y) = -\frac{\sin[\kappa_2(\lambda)d]\sin[\kappa_1(\lambda)y]}{N(\lambda)} \tag{42}$$

for $0 < y < y'$ and by

$$\tilde{G}(\lambda, y) = -\frac{\sin[\kappa_1(\lambda)y']\sin[\kappa_2(\lambda)(y' + d - y)]}{N(\lambda)} \tag{43}$$

for $y > y'$ with $N(\lambda) = \kappa_2(\lambda)\sin[\kappa_1(\lambda)y']\cos[\kappa_2(\lambda)d] + \kappa_1(\lambda)\cos[\kappa_1(\lambda)y']\sin[\kappa_2(\lambda)d]$. This spectral Green function has no branch cuts but only poles at the zeroes of $N(\lambda)$.

Let us examine the case $y > y'$. The space domain Green function $\tilde{g}(x, y)$ can be calculated using Cauchy's theorem by closing the contour with $C_{-\infty}$ for $x > 0$. The result is

$$\begin{aligned} \tilde{g}(x, y) &= -\frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{\sin[\kappa_2(\lambda)(y' + d - y)]\sin[\kappa_1(\lambda)y']e^{-j\lambda x}}{N(\lambda)} d\lambda \\ &= j\sum_{i=0}^{+\infty} \frac{\sin[\kappa_2(\lambda_i)(y' + d - y)]\sin[\kappa_1(\lambda_i)y']e^{-j\lambda_i x}}{N'(\lambda_i)}, \end{aligned} \tag{44}$$

with $N(\lambda_i) = 0$ and $N'(\lambda) = \frac{d}{d\lambda}N(\lambda)$. In (44) it is assumed that the contribution of $C_{-\infty}$ vanishes. Let us prove that this assumption is correct by showing that the series in (44) converges for $x > 0$. To do so we look at the asymptotic form of the terms in the series (44). For this we need the asymptotic roots of the equation $N(\lambda_i) = 0$. This is discussed in Appendix B. It turns out that there are two branches of solutions.

The asymptotic solutions corresponding to the first branch can be approximated by the solutions of the equation

$$\kappa_2(\lambda)\cosh(\lambda d) + \kappa_1(\lambda)\sinh(\lambda d) = 0; \tag{45}$$

i.e., these solutions are independent of the value of y'. According to Appendix B, an asymptotic expression for the solutions of this equation is given by

$$\lambda_i \approx -\frac{1}{d}\log\left[\frac{2(i\pi + \alpha)}{\sqrt{k^2 - 1}\gamma}\right] - \frac{i\pi + \alpha}{d}j. \tag{46}$$

These values of λ_i allow us to approximate the terms in the series (44) for large values of i as

$$j\frac{\sin[\kappa_2(\lambda_i)(y' + d - y)]\sin[\kappa_1(\lambda_i)y']e^{-j\lambda_i x}}{N'(\lambda_i)} \approx a_i e^{-\frac{i\pi x}{d}} e^{-j\frac{i\pi\Delta y}{d}}, \tag{47}$$

with $\Delta y = y - y'$ and a_i such that $\lim_{i\to+\infty} a_i e^{-\epsilon i} = 0$ for all $\epsilon > 0$. For real values of y these terms are exponentially decaying if $x > \Delta y \tan\alpha$, which gives us the convergence region of the part of the series corresponding to the first branch. This region corresponds again to the nonhatched region of Figure 3 when we replace the y-parameter by Δy. In [9] the solutions corresponding to this first branch are called PML surface waves.

The solutions of the second branch asymptotically satisfy the equation

$$\kappa_2(\lambda)\sinh(\lambda y') - \kappa_1(\lambda)\cosh(\lambda y') = 0, \tag{48}$$

which shows that these solutions are independent of d. An asymptotic expression for the solutions of (48) is given by

$$\lambda_i \approx \frac{1}{y'}\log\left[\frac{(2i+1)\pi}{y'\sqrt{k^2-1}}\right] - \frac{(2i+1)\pi}{2y'}j. \tag{49}$$

For these values of λ_i the terms in the series (44) asymptotically behave as

$$j\frac{\sin[\kappa_2(\lambda_i)(y'+d-y)]\sin[\kappa_1(\lambda_i)y']e^{-j\lambda_i x}}{N'(\lambda_i)} \approx b_i e^{-\frac{(2i+1)\pi x}{2y'}} e^{-j\frac{(2i+1)\pi\Delta y}{2y'}}, \tag{50}$$

with $\lim_{i\to+\infty} b_i e^{-\epsilon i} = 0$ for all $\epsilon > 0$. For real values of y these terms are always decaying exponentially for $x > 0$, proving the convergence of the part of the series corresponding to the second branch. In [9] the solutions corresponding to the second branch are called pseudoleaky surface waves.

It can be shown that the corresponding series for $0 < y < y'$,

$$\tilde{g}(x,y) = j\sum_{i=0}^{+\infty}\frac{\sin[\kappa_2(\lambda_i)d]\sin[\kappa_1(\lambda_i)y]e^{-j\lambda_i x}}{N'(\lambda_i)}, \tag{51}$$

is convergent for all $x > 0$. Note also that for $\Delta y = \Delta\tilde{y}e^{-j\alpha}$ and $0 < \Delta\tilde{y} < \gamma$ both terms (47) and (50) decay exponentially for all $x > 0$.

Remarkable is that previous convergence analysis breaks down when $k = 1$. For $k = 1$ the conclusions regarding the convergence of (44) and (51) are invalid. This finds its origin in the fact that the asymptotic solutions do not separate anymore into two independent parts where one part depends only on d and the other only on y'. We will not pursue the case $k = 1$.

We can also construct a resolution of the $\delta(y-y')$ distribution in the eigenfunctions of the operator (39). Let us write for $0 < y < y'$

$$\delta(y-y') = \sum_{i=0}^{+\infty}\alpha_i\sin[\kappa_1(\lambda_i)y], \tag{52}$$

with yet unknown expansion coefficients α_i. From (32) it then follows that

$$\tilde{G}(\lambda,y) = \sum_{i=0}^{+\infty}\frac{\alpha_i}{\lambda_i^2-\lambda^2}\sin[\kappa_1(\lambda_i)y]. \tag{53}$$

Inverse Fourier transformation and identification with the series expansion (51) yields that

$$\alpha_i = -\frac{\lambda_i\sin[\kappa_2(\lambda_i)d]}{\pi N'(\lambda_i)}. \tag{54}$$

As a numerical example, assume that $k = 1.75$, that $y' = 2$, and that $d = \gamma e^{-j\pi/8}$, i.e., that $\alpha = \pi/8$. Figure 6 shows the solutions of $N(\lambda) = 0$ by large dots when $\gamma = 10$. There is a solution that is almost located on the real axis; its value is given

TABLE 1
Shift of the pole on the real axis to the complex plane as a function of γ.

γ	λ
10	$1.34274364519737586140 - 9.16986697792\,10^{-9}j$
20	$1.34274365934371669251 - 9.9180\,10^{-16}j$
∞	1.34274365934371713609

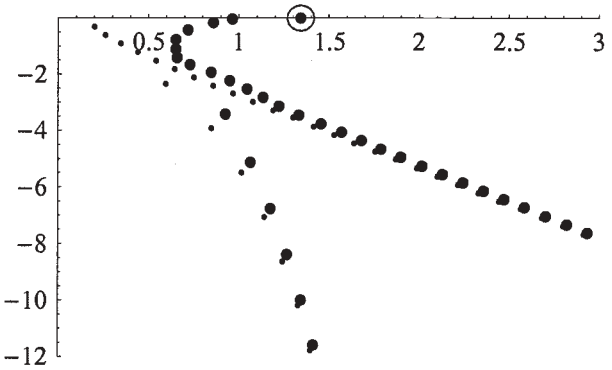

FIG. 6. *Solutions of $N(\lambda) = 0$ when $d = 10e^{-j\pi/8}$, $k = 1.75$, $y' = 2$.*

in Table 1. For $\gamma = 20$ this solution slightly shifts, as is also shown in Table 1. This solution corresponds to a zero of the denominator of (40) or (41) shown on the last row of Table 1 and indicated on Figure 6 by a circle. This is the only pole of the spectral Green function $G(\lambda, y)$. The asymptotic solutions (46) and (49) are also indicated on Figure 6 by small dots. For higher order solutions these asymptotic solutions better approximate the exact solutions. These asymptotic solutions allow for a very efficient determination of the exact solutions. One first calculates the asymptotic solutions (46) for $i = n$, $i = n + 1$, and $i = n + 2$, with n sufficiently large. Then one uses a Newton iteration technique starting from these asymptotic solutions to find the exact solutions. A quadratic extrapolation from these three exact solutions yields an approximate solution with index $n - 1$. The Newton technique is then used again to polish this solution to the exact solution. This process of quadratic extrapolation is repeated for decreasing index solutions. The same can be done starting from (49). The process breaks down at the very low index solutions. These low index solutions can be found by using a combined contour integration [9] and Newton technique. The solution that is located almost on the real axis can be found by first determining the real zero of the denominator of (40) and then polishing this solution to the corresponding solution of $N(\lambda) = 0$.

Assume that $y = y' = 2$ and $\gamma = 10$. Figure 7 shows the number of terms needed in the series (51) to approximate the series with a relative accuracy of 0.01, 0.0001, and 0.000001 as a function of the distance $s = \log_{10}(x)$. We have ordered the poles λ_i by decreasing imaginary part. Evidently, when x becomes larger, fewer terms are needed. When γ increases, the spacing between the poles decreases (cf. (46)), and hence more poles are needed to approximate the series to a given accuracy.

Finally, Figure 8 shows the absolute accuracy $a = |g(x, y') - \tilde{g}(x, y')|$ as a function of $s = \log_{10}(x)$ for $\gamma = 10$ and 20. In the series (51) we limited the sum to poles with

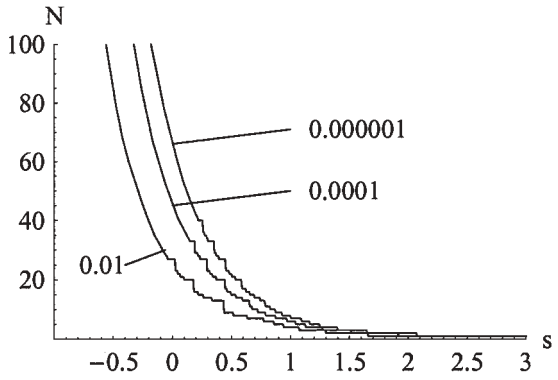

FIG. 7. *Number of terms in* (51) *as a function of* $s = \log_{10}(x)$ *for a relative accuracy of* $10^{-2}, 10^{-4}, 10^{-6}$.

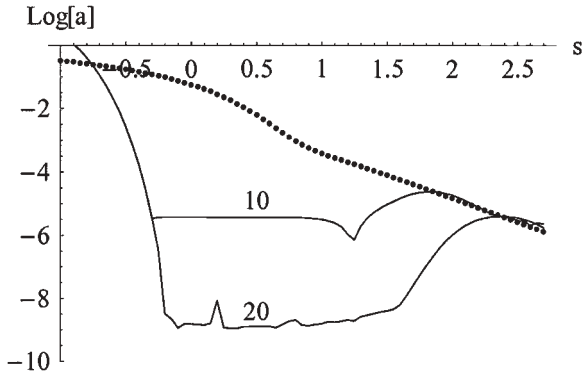

FIG. 8. *Absolute accuracy* $a = |g(x,y) - \tilde{g}(x,y)|$ *as a function of* $s = \log_{10}(x)$ *for* $\gamma = 10, 20$.

an imaginary part larger than -30. This explains the loss of accuracy for small x. As expected, when γ increases, the accuracy increases. The small ripple on the curve for $\gamma = 20$ is due to numerical noise in the evaluation of $g(x, y')$. The Green function $g(x, y')$ has been evaluated by a careful numerical integration of the inverse Fourier transformation of (40). For larger values of x we note a decrease in the accuracy. This is consistent with the results in section 2. However, for even larger values of x the accuracy increases again. In this regime it is only the pole of Table 1 that contributes to the series. In this regime, $g(x, y')$ is also approximated by the residue of (40) or (41) in this pole for $y = y'$. This residue is shown by a dotted line on the figure. For even larger values of x, not shown on Figure 8, the accuracy will decrease again because the small imaginary part of the pole close to the real axis will start to create significant exponential decay. Indeed, $\lim_{x\to+\infty} \tilde{g}(x, y') = 0$!

4. Further generalizations. The Green function of the three-dimensional Helmholtz-equation

$$\nabla^2_{xyz} g(x,y,z) + g(x,y,z) = \delta(x)\delta(y)\delta(z) \tag{55}$$

satisfying the Sommerfeld radiation condition is obviously

$$g(x,y,z) = g(r) = -\frac{e^{-jr}}{4\pi r}, \tag{56}$$

with $r = \sqrt{x^2+y^2+z^2}$. Expressing this as an inverse Fourier transform in the x- and y-direction of the spectral Green function yields

$$\begin{aligned} g(x,y,z) &= \frac{1}{2\pi}\int_0^{+\infty} \frac{je^{-j\sqrt{1-\lambda^2}|z|}}{2\sqrt{1-\lambda^2}} J_0(\lambda\sqrt{x^2+y^2})\lambda d\lambda \\ &= \frac{1}{4\pi}\int_{+\infty e^{-j\pi}}^{+\infty} \frac{je^{-j\sqrt{1-\lambda^2}|z|}}{2\sqrt{1-\lambda^2}} H_0^{(2)}(\lambda\sqrt{x^2+y^2})\lambda d\lambda, \end{aligned} \tag{57}$$

where $\lambda = \sqrt{\lambda_x^2+\lambda_y^2}$, with λ_x and λ_y the spectral variables in the x- and y-direction. This inverse Fourier transform is a Sommerfeld type of integral, which for this simple case can be evaluated in closed form. The spectral Green function has branch-cuts corresponding to the continuous set of eigenfunctions of $\nabla_{xy}+1$ consisting of propagating and evanescent cylindrical waves. For this simple case only the angular independent cylindrical waves are involved.

Consider another Green function $\tilde{g}(x,y,z)$ satisfying (55) but subject to the condition $\tilde{g}(x,y,z=\pm d)=0$. The corresponding spectral Green function is

$$\tilde{G}(\lambda,z) = \frac{\sin[\sqrt{1-\lambda^2}(|z|-d)]}{2\sqrt{1-\lambda^2}\cos[\sqrt{1-\lambda^2}d]}, \tag{58}$$

which obviously only has poles. Using Cauchy's theorem it is possible to expand $\tilde{g}(x,y,z)$ as the following series:

$$\tilde{g}(x,y,z) = -\frac{j}{4d}\sum_{n=0}^{+\infty}\cos\left[\frac{(2n+1)\pi z}{2d}\right] H_0^{(2)}\left[\sqrt{1-\frac{(2n+1)^2\pi^2}{4d^2}}\sqrt{x^2+y^2}\right]. \tag{59}$$

Since for large arguments the function $H_0^{(2)}(\zeta)$ behaves as $\sqrt{\frac{2j}{\pi\zeta}}e^{-j\zeta}$, it follows, by comparison with (14), that the series is convergent in the nonhatched region of Figure 3 if we replace y by z and x by ρ. From Theorem A.7 in Appendix A it follows again for a complex $d=\gamma e^{-j\alpha}$ and for all $x,y,z\in\mathbf{R}$ that

$$\forall\epsilon>0, \qquad \exists\delta(\epsilon)>0 : \gamma>\delta(\epsilon)>0 \Rightarrow |g(x,y,z)-\tilde{g}(x,y,z)|<\epsilon, \tag{60}$$

with $0<\alpha<\frac{\pi}{2}$. This can obviously be generalized to Green functions satisfying equations of the form

$$\nabla_{xyz}^2 g(x,y,z) + k^2(z)g(x,y,z) = \delta(x)\delta(y)\delta(z-z'). \tag{61}$$

In this case the Sommerfeld integrals cannot be evaluated in closed form. Numerical evaluation of Sommerfeld integrals is not always easy because the integrands are often highly oscillatory and have poles and branch-cuts. With the technique outlined here, a series representation is obtained for these Sommerfeld integrals. There are other discrete representations for Sommerfeld integrals, but those rely on rational approximations, i.e., Padé approximations [16]. To obtain these rational approximations Prony's techniques, or equivalents, are needed. Here, the series representation

follows in a natural way and requires only the determination of the complex zeroes of a transcendental function. In our series the x, y, z, and z'-dependence is available in explicit form, making this series representation especially attractive if the Green function is needed for many values of x, y, z, or z' and for further analytic manipulations. Other series representations [17] for Sommerfeld integrals can be obtained by transforming the integral to its steepest descent path and adding integral contributions from the branch-cuts and discrete contributions from the residues in the poles. The steepest descent integral and branch-cut integrals can then be approximated by Gaussian quadrature sums yielding a series representation. This technique is based on a pure numerical evaluation of the integrals and becomes complicated when poles, branch-cuts, and/or the steepest descent path come into each other's neighborhood. More on the evaluation of Sommerfeld integrals can be found in [18].

We can also derive another approximate series representation for the Green function $g(x, y, z)$ by considering a Green function $\hat{g}(x, y, z)$ that also satisfies (55) but now subject to the condition $\hat{g}(\rho = \sqrt{x^2 + y^2} = d, z) = 0$. By using a Fourier transform along the z-axis, we can express $\hat{g}(x, y, z)$ as

$$\hat{g}(x, y, z) = \frac{j}{4d} \sum_{n=1}^{+\infty} \frac{\sqrt{1-\lambda_n^2} J_0(\sqrt{1-\lambda_n^2}\rho) Y_0(\sqrt{1-\lambda_n^2} d)}{\lambda_n J_1(\sqrt{1-\lambda_n^2} d)} e^{-j\lambda_n z} \tag{62}$$

with $\lambda_n = \sqrt{1-\frac{\alpha_n^2}{d^2}}$, $n = 1, 2, \ldots$, where $\alpha_n \in \mathbf{R}$ are the zeroes of J_0. With $d = \gamma e^{-j\alpha}$, $0 < \alpha < \frac{\pi}{2}$, and γ sufficiently large, the function $\hat{g}(x, y, z)$ will again approximate $g(x, y, z)$. The condition $\hat{g}(\rho = d, z) = 0$ is equivalent to adding a curvilinear PML [19].

Still another approximation $\check{g}(x, y, z)$ can be obtained by imposing that $\check{g}(x = \pm d, y = \pm d, z) = 0$. The result is

$$\check{g}(x, y, z) = -\frac{j}{2d^2} \sum_{n,m=0}^{+\infty} \cos\frac{(2n+1)\pi x}{2d} \cos\frac{(2m+1)\pi y}{2d} \frac{e^{-j\kappa_{nm}|z|}}{\kappa_{nm}}, \tag{63}$$

with

$$\kappa_{nm} = \sqrt{1 - \frac{(2n+1)^2\pi^2}{4d^2} - \frac{(2m+1)^2\pi^2}{4d^2}}. \tag{64}$$

In analogy with section 2, this series will converge when $|z| \leq |x| \tan\alpha$ and $|z| \leq |y| \tan\alpha$.

Also Green functions satisfying equations of the form

$$\nabla_{xyz}^2 g(x, y, z) + k^2(x, y) g(x, y, z) = \delta(x - x')\delta(y - y')\delta(z) \tag{65}$$

can be treated in the same way as $\hat{g}(x, y, z)$ or $\check{g}(x, y, z)$.

Further generalizations include Green functions of other more complex wave operators such as

$$\nabla_{xyz} \cdot \overline{\overline{A}}(z) \cdot \nabla_{xyz} g(x, y, z) + \mathbf{b}(z) \cdot \nabla_{xyz} g(x, y, z) + k^2(z) g(x, y, z)$$

$$= \delta(x)\delta(y)\delta(z - z'), \tag{66}$$

or higher order operators. Equations of this form are obtained when considering electromagnetic field problems in anisotropic media (see [20] and references therein).

However, for that type of problems the present analysis needs to be adapted and further investigated; it will not just suffice to place a Dirichlet boundary condition in complex space. Indeed, adding PMLs to anisotropic media can cause problems, as has been reported in [21]. For an overview of some closed form Green functions of wave equations in infinite homogeneous space, i.e., of wave equations with constant coefficients, we refer the reader to [22].

In [9] series representations were derived for the Green tensor $\overline{\overline{g}}(x,y,z)$ of a vectorial wave equation of the form

$$\nabla_{xyz} \times [\alpha(z) \nabla_{xyz} \times \overline{\overline{g}}(x,y,z)] - k^2(z) \overline{\overline{g}}(x,y,z) = \delta(x)\delta(y)\delta(z-z')\overline{\overline{I}}, \tag{67}$$

with $\overline{\overline{I}}$ the unit tensor. The study in [9] focussed on a numerical investigation of the accuracy of the series.

5. Further remarks. In the previous sections we considered Green functions of wave equations with coefficients that were independent of at least one coordinate along which the outgoing wave condition was imposed. Along this direction we could apply a spatial Fourier transformation and write the result as a series of eigenfunctions.

Let us now consider cases where there is no such direction. As a simplest possible case consider

$$\frac{\mathrm{d}^2}{\mathrm{d}x^2} g(x) + g(x) = \delta(x), \tag{68}$$

where $g(x)$ represents outgoing waves. The solution obviously is

$$g(x) = -\frac{e^{-j|x|}}{2j}. \tag{69}$$

If we consider another Green function $\tilde{g}(x)$ satisfying (68) but subject to $\tilde{g}(x = \pm d) = 0$, then there is no invariant direction. Obviously $\tilde{g}(x)$ is given by

$$\tilde{g}(x) = \frac{1}{2} \frac{\sin(|x| - d)}{\cos d} = -\frac{1}{2j} \frac{e^{-j|x|} - e^{j|x|-2jd}}{1 + e^{-2jd}}. \tag{70}$$

If $d = \gamma e^{-j\alpha}$ with $0 < \alpha < \pi/2$, then one easily verifies for all $x \in \mathbf{R}$ that

$$|\tilde{g}(x) - g(x)| \leq e^{-2\gamma \sin \alpha}, \tag{71}$$

proving the convergence of $\tilde{g}(x)$ to $g(x)$ when γ increases. Using the result (28) for $\lambda = 0$, we can formally write

$$\tilde{g}(x) = \frac{1}{d} \sum_{n=0}^{+\infty} \frac{\cos \frac{(2n+1)\pi x}{2d}}{1 - \frac{(2n+1)^2 \pi^2}{4d^2}}. \tag{72}$$

For $x \neq 0$ this series diverges again, illustrating that the resolution (27) is invalid on the real axis.

Another case is the Green function (56) of the three-dimensional Helmholtz equation (55). We approximate this Green function by another Green function $\tilde{g}(x,y,z)$ that satisfies $\tilde{g}(x = \pm d, y = \pm d, z = \pm d) = 0$. Using the result (63), one can show that this Green function can be written as

$$\tilde{g}(x,y,z) = \frac{1}{2d^2} \sum_{n=0}^{+\infty} \sum_{m=0}^{+\infty} \cos \frac{(2n+1)\pi x}{2d} \cos \frac{(2m+1)\pi y}{2d} \frac{\sin[\kappa_{nm}(|z| - d)]}{\kappa_{nm} \cos[\kappa_{nm} d]}, \tag{73}$$

with κ_{nm} defined in (64). This series is still another approximation for the Green function (56) which converges if $|z| \leq |x| \tan\alpha$ and $|z| \leq |y| \tan\alpha$. Evidently more approximations for that Green function can be found by, e.g., imposing Dirichlet boundary conditions on a spherical or a finite cylindrical surface in complex space.

6. Conclusions. We have shown that the continuous spectrum of a singular Sturm–Liouville eigenvalue problem subject to radiation boundary conditions can be approximated by the discrete spectrum of the same Sturm–Liouville problem but now subject to Dirichlet boundary conditions at points in complex space. This allows new approximate series expansions for Green functions. The conditions under which these series converge were investigated.

Appendix A. Theorems and lemmas.

LEMMA A.1.

$$\forall \zeta \in \mathbf{C}, \qquad \xi = \Re(\zeta) > 1 \Rightarrow |\tanh\zeta - 1| < 4e^{-2\xi}. \tag{74}$$

Proof. From

$$|\tanh\zeta - 1| = \left|\frac{2e^{-2\zeta}}{1+e^{-2\zeta}}\right| = \frac{2e^{-2\xi}}{|1+e^{-2\zeta}|}, \tag{75}$$

it follows that

$$|\tanh\zeta - 1| < \frac{2e^{-2\xi}}{1-e^{-2\xi}} = \frac{2}{e^{2\xi}-1} < \frac{2}{\frac{e^{2\xi}}{2}} = 4e^{-2\xi} \tag{76}$$

if $\xi > 1$, since $e^{2\xi} - 1 > e^{2\xi}/2$ when $\xi > 1$. □

THEOREM A.2. *If* $0 < \alpha < \pi/2$ *and* $x \in \mathbf{R}$*, then*

$$\forall \epsilon > 0, \quad \exists \delta(\epsilon) > 0 : \gamma > \delta(\epsilon) \Rightarrow \left| \int_0^{+\infty} \frac{\tanh(\sqrt{\lambda^2-1}\gamma e^{-j\alpha}) - 1}{\sqrt{\lambda^2-1}} \cos(\lambda x) d\lambda \right| < \epsilon, \tag{77}$$

where the branch-cut of $\sqrt{\zeta}$ *is along* $\arg(\zeta) = \pi^+$.

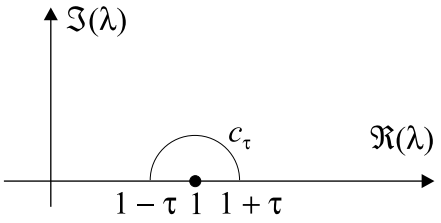

FIG. 9. *Deformed contour in the complex λ-plane.*

Proof. With the choice of the branch-cut the integrand in (77) is holomorphic in the first quadrant of the complex λ-plane. This means that we can deform the integration path as indicated in Figure 9. The part of the integration on the real λ axis from $\lambda = 1 - \tau$ to $\lambda = 1 + \tau$, with $0 < \tau < 1$, is replaced by a semicircle c_τ, as shown in Figure 9. Hence we have

$$\left|\int_0^{+\infty} \ldots d\lambda\right| \leq \left|\int_0^{1-\tau} \ldots d\lambda\right| + \left|\int_{c_\tau} \ldots d\lambda\right| + \left|\int_{1+\tau}^{+\infty} \ldots d\lambda\right|. \tag{78}$$

Using Lemma A.1, $|\cos\lambda x| \le 1$, and $|\lambda^2 - 1| \ge -\tau^2 + 2\tau$, we find for the first term on the right-hand side that

$$\left|\int_0^{1-\tau} \dots d\lambda\right| < \int_0^{1-\tau} \frac{4e^{-2\sqrt{1-\lambda^2}\gamma\sin\alpha}}{\sqrt{-\tau^2+2\tau}} d\lambda < \frac{4(1-\tau)}{\sqrt{-\tau^2+2\tau}} e^{-2\sqrt{-\tau^2+2\tau}\gamma\sin\alpha} \tag{79}$$

if

$$\gamma > \frac{1}{\sqrt{-\tau^2+2\tau}\sin\alpha}. \tag{80}$$

The second term on the right-hand side of (78) can be written as

$$\left|\int_{c_\tau} \dots d\lambda\right| = \left|\int_0^{\pi} \frac{\tanh(\sqrt{\tau^2 e^{-2j\phi} - 2\tau e^{-j\phi}}\gamma e^{-j\alpha}) - 1}{\sqrt{\tau^2 e^{-2j\phi} - 2\tau e^{-j\phi}}} \cos[(1-\tau e^{-j\phi})x]\tau e^{-j\phi} d\phi\right|. \tag{81}$$

For $0 \le \phi \le \pi$ we have that

$$|\sqrt{\tau^2 e^{-2j\phi} - 2\tau e^{-j\phi}}| > \sqrt{-\tau^2+2\tau}, \tag{82}$$

that

$$\Re(\sqrt{\tau^2 e^{-2j\phi} - 2\tau e^{-j\phi}} e^{-j\alpha}) > \sigma = \min[\sqrt{-2\tau+\tau^2}\sin\alpha, \sqrt{\tau^2+2\tau}\cos\alpha] > 0, \tag{83}$$

and also that

$$|\cos[(1-\tau e^{-j\phi})x]| < 2e^{\tau|x|}. \tag{84}$$

Using Lemma A.1, this all allows us to write for the second term on the right-hand side of (78) that

$$\left|\int_{c_\tau} \dots d\lambda\right| < \frac{8\pi\tau}{\sqrt{-\tau^2+2\tau}} e^{-2\sigma\gamma+\tau|x|} \tag{85}$$

if

$$\gamma > \frac{1}{\sigma}. \tag{86}$$

Using Lemma A.1, $|\cos\lambda x| \le 1$, and $|\lambda^2 - 1| \ge \tau^2 + 2\tau$, we find for the third term on the right-hand side of (78) that

$$\left|\int_{1+\tau}^{+\infty} \dots d\lambda\right| < \int_{1+\tau}^{+\infty} \frac{4e^{-2\sqrt{\lambda^2-1}\gamma\cos\alpha}}{\sqrt{\tau^2+2\tau}} d\lambda \tag{87}$$

if

$$\gamma > \frac{1}{\sqrt{\tau^2+2\tau}\cos\alpha}. \tag{88}$$

If we now restrict τ further such that $(2-\sqrt{3})/\sqrt{3} < \tau < 1$, then $\lambda/2 < \sqrt{\lambda^2-1}$ for $\lambda > 1+\tau$. Now we find

$$\int_{1+\tau}^{+\infty} \frac{4e^{-2\sqrt{\lambda^2-1}\gamma\cos\alpha}}{\sqrt{\tau^2+2\tau}} d\lambda < \frac{4}{\sqrt{\tau^2+2\tau}} \int_{1+\tau}^{+\infty} e^{-\lambda\gamma\cos\alpha} d\lambda = \frac{4e^{-(1+\tau)\gamma\cos\alpha}}{\sqrt{\tau^2+2\tau}\gamma\cos\alpha}. \tag{89}$$

Taking (79), (85), and (89) together allows us to write that

$$\left|\int_0^{+\infty} \dots d\lambda\right| < f(\gamma), \tag{90}$$

with

$$f(\gamma)=\frac{4(1-\tau)}{\sqrt{-\tau^2+2\tau}}e^{-2\sqrt{-\tau^2+2\tau}\gamma\sin\alpha}+\frac{8\pi\tau}{\sqrt{-\tau^2+2\tau}}e^{-2\sigma\gamma+\tau|x|}+\frac{4e^{-(1+\tau)\gamma\cos\alpha}}{\sqrt{\tau^2+2\tau}\gamma\cos\alpha} \tag{91}$$

if

$$\gamma > \max\left[\frac{1}{\sqrt{-\tau^2+2\tau}\sin\alpha}, \frac{1}{\sqrt{\tau^2+2\tau}\cos\alpha}\right]. \tag{92}$$

Note that the condition (92) also implies that $\gamma > 1/\sigma$. Since $f(\gamma)$ is a monotonic decreasing function of γ, we have shown that

$$\left|\int_0^{+\infty} \dots d\lambda\right| < \epsilon \tag{93}$$

if

$$\gamma > \max\left[f^{-1}(\epsilon), \frac{1}{\sin\alpha\sqrt{-\tau^2+2\tau}}, \frac{1}{\cos\alpha\sqrt{\tau^2+2\tau}}\right]. \tag{94}$$

□

From the proof it follows that, for a given ϵ, γ needs to be taken larger when $|x|$ increases. γ also needs to be taken large when α comes close to 0 or $\pi/2$.

LEMMA A.3.

$$\forall\zeta\in\mathbf{C}, \qquad \xi=\Re(\zeta)>0 \Rightarrow |\cosh\zeta| < e^{\xi}. \tag{95}$$

Proof. The proof is trivial. □

THEOREM A.4. *If* $0<\alpha<\pi/2$ *and* $x,y\in\mathbf{R}$, *then*

$$\forall\epsilon>0, \quad \exists\delta(\epsilon)>0:$$

$$\gamma>\delta(\epsilon)\Rightarrow\left|\int_0^{+\infty}\frac{\tanh(\sqrt{\lambda^2-1}\gamma e^{-j\alpha})-1}{\sqrt{\lambda^2-1}}\cosh(\sqrt{\lambda^2-1}|y|)\cos(\lambda x)d\lambda\right|<\epsilon, \tag{96}$$

where the branch-cut of $\sqrt{\zeta}$ *is along* $\arg(\zeta)=\pi^+$.

Proof. This can be proven in the same manner as Theorem A.2. Let us settle for mentioning the differences.

From Lemma A.3 it follows for the first term on the right-hand side of (78) that

$$|\cosh(\sqrt{\lambda^2-1}|y|)| < e^{\sqrt{-\tau^2+2\tau}|y|}, \tag{97}$$

for the second term on the right-hand side of (78) that

$$|\cosh(\sqrt{\lambda^2-1}|y|)| < e^{\sqrt{\tau^2+2\tau}|y|}, \tag{98}$$

and for the third term on the right-hand side of (78) that

$$|\cosh(\sqrt{\lambda^2-1}|y|)| < e^{\sqrt{\lambda^2-1}|y|}, \tag{99}$$

which means that in (89) we have to replace $\gamma\cos\alpha$ by $\gamma\cos\alpha - |y|/2$. We also have to impose that

$$\gamma > \frac{|y|}{2\cos\alpha}, \tag{100}$$

in order to assure that the integrals in (89) remain convergent.

Taking all this together, the function $f(\gamma)$ now becomes

$$f(\gamma) = \frac{4(1-\tau)}{\sqrt{-\tau^2+2\tau}} e^{-\sqrt{-\tau^2+2\tau}(2\gamma\sin\alpha - |y|)} + \frac{8\pi\tau}{\sqrt{-\tau^2+2\tau}} e^{-2\sigma\gamma+\tau|x|+\sqrt{\tau^2+2\tau}|y|}$$

$$+ \frac{4e^{-(1+\tau)(\gamma\cos\alpha-|y|/2)}}{\sqrt{\tau^2+2\tau}(\gamma\cos\alpha - |y|/2)}, \tag{101}$$

which still is a monotonic decreasing function of γ. Hence, the proof is complete by adding the condition (100) to (94). □

From the proof it now also follows that, for a given ϵ, γ needs to be taken larger when $|y|$ increases.

THEOREM A.5. *If $0 < \alpha < \pi/2$, if $F(\lambda)$ is holomorphic along the contour of Figure 9, and if $\int_0^{+\infty} F(\lambda)\cos(\lambda x)d\lambda$ exists for all $x > 0$, then*

$$\forall\epsilon > 0, \qquad \exists\delta(\epsilon) > 0 : \gamma > \delta(\epsilon) \Rightarrow \left| \int_0^{+\infty} F(\lambda) e^{-\sqrt{\lambda^2-1}2d} \cos(\lambda x) d\lambda \right| < \epsilon, \tag{102}$$

where the branch-cut of $\sqrt{\zeta}$ is along $\arg(\zeta) = \pi^+$.

Proof. Let us deform the integration path and split the integration as in Theorem A.2. The first contribution is

$$\left| \int_0^{1-\tau} \ldots d\lambda \right| = \left| \int_0^{1-\tau} F(\lambda) e^{j\sqrt{1-\lambda^2}2\gamma\cos\alpha} e^{-\sqrt{1-\lambda^2}2\gamma\sin\alpha} \cos(\lambda x) d\lambda \right|$$

$$< e^{-\sqrt{2\tau-\tau^2}2\gamma\sin\alpha} \int_0^{1-\tau} |F(\lambda)\cos(\lambda x)|\, d\lambda. \tag{103}$$

Using the definition of σ from Theorem A.2, the second contribution obeys

$$\left| \int_{c_\tau} \ldots d\lambda \right| < \int_{c_\tau} |F(\lambda)\cos(\lambda x)|\, e^{-\sigma\gamma} d\lambda$$

$$< e^{-\sigma\gamma} \int_{c_\tau} |F(\lambda)\cos(\lambda x)|\, d\lambda. \tag{104}$$

For the third term we have

$$\left| \int_{1+\tau}^{+\infty} \ldots d\lambda \right| < \int_{1+\tau}^{+\infty} |F(\lambda)| e^{-\sqrt{\lambda^2-1}2\gamma\cos\alpha} d\lambda. \tag{105}$$

Since $\int_0^{+\infty} F(\lambda)\cos(\lambda x)d\lambda$ exists for all $x > 0$, the limit $\lim_{\lambda\to+\infty} F(\lambda)$ exists. Because $F(\lambda)$ is holomorphic, there exists a number M such that $|F(\lambda)| < M$ for $\lambda \geq 1 + \tau$. Hence, we can proceed as in (89) and write

$$\left|\int_{1+\tau}^{+\infty} \dots d\lambda\right| < \int_{1+\tau}^{+\infty} |F(\lambda)| e^{-\sqrt{\lambda^2-1}2\gamma\cos\alpha} d\lambda = \frac{M e^{-(1+\tau)\gamma\cos\alpha}}{\gamma\cos\alpha} \tag{106}$$

when $(2-\sqrt{3})/\sqrt{3} < \tau < 1$.

The three parts of the integration are, as in previous theorems, again bounded by an exponential decreasing function of γ. This completes the proof. Note that the proof remains valid if $F(\lambda)$ has simple poles along the real axis. These poles can be avoided in a similar way as the branch-point. □

LEMMA A.6.

$$\forall\zeta \in \mathbf{C}, \qquad |J_0(\zeta)| \leq e^{|\zeta|}. \tag{107}$$

Proof. Because

$$e^{|\zeta|} = \left[e^{|\zeta|/2}\right]^2 = \left[\sum_{n=0}^{+\infty} \frac{|\zeta|^n}{n!2^n}\right]^2 \geq \sum_{n=0}^{+\infty} \frac{|\zeta|^{2n}}{(n!)^2 2^{2n}}, \tag{108}$$

we prove that

$$|J_0(\zeta)| = \left|\sum_{n=0}^{+\infty} \frac{(-1)^n\zeta^{2n}}{(n!)^2 2^{2n}}\right| \leq \sum_{n=0}^{+\infty} \frac{|\zeta|^{2n}}{(n!)^2 2^{2n}} \leq e^{|\zeta|}. \tag{109}$$ □

THEOREM A.7. *If* $0 < \alpha < \pi/2$, $z \in \mathbf{R}$, *and* $\rho > 0$, *then*

$$\forall\epsilon > 0, \qquad \exists\delta(\epsilon) > 0 :$$

$$\gamma > \delta(\epsilon) \Rightarrow \left|\int_0^{+\infty} \frac{\tanh(\sqrt{\lambda^2-1}\gamma e^{-j\alpha}) - 1}{\sqrt{\lambda^2-1}} \cosh(\sqrt{\lambda^2-1}|z|) J_0(\lambda\rho)\lambda d\lambda\right| < \epsilon, \tag{110}$$

where the branch-cut of $\sqrt{\zeta}$ *is along* $\arg(\zeta) = \pi^+$.

Proof. This can be proven in the same manner as Theorems A.2 and A.4 by replacing $\cos(\lambda x)$ by $\lambda J_0(\lambda\rho)$ and y by z. Let us simply mention the changes.

Using the fact that $|J_0(\lambda\rho)| \leq 1$, we now find that first term on the right-hand side of (78) as

$$\left|\int_0^{1-\tau} \dots d\lambda\right| < \frac{4(1-\tau)^2}{\sqrt{-\tau^2+2\tau}} e^{-\sqrt{-\tau^2+2\tau}(2\gamma\sin\alpha - |\rho|)}. \tag{111}$$

Along the second part of the integration c_τ it follows from Lemma A.6 that

$$|J_0[(1-\tau e^{j\phi})\rho]| < e^{|1-\tau e^{j\phi}||\rho|} \leq e^{(1+\tau)|\rho|}. \tag{112}$$

This allows us to bound the second term in (78) as

$$\left|\int_{c_\tau} \dots d\lambda\right| < \frac{4\pi\tau^2}{\sqrt{-\tau^2+2\tau}} e^{-2\sigma\gamma + (1+\tau)|\rho| + \sqrt{\tau^2+2\tau}|z|}. \tag{113}$$

For the third term in (78) we can again use the fact that $|J_0(\lambda\rho)| \leq 1$, resulting in

$$\left|\int_{1+\tau}^{+\infty} \dots d\lambda\right| < \frac{4}{\sqrt{\tau^2+2\tau}} \int_{1+\tau}^{+\infty} e^{-\lambda(\gamma\cos\alpha - |z|/2)} \lambda d\lambda$$

$$= \frac{4[(\gamma\cos\alpha - |z|/2)(1+\tau)+1]e^{-(1+\tau)(\gamma\cos\alpha-|z|/2)}}{\sqrt{\tau^2+2\tau}(\gamma\cos\alpha - |z|/2)^2}. \tag{114}$$

Summing the results (111), (113), and (114) results in a new function $f(\gamma)$ that is still monotonic decreasing. This completes the proof. □

Appendix B. Asymptotic expressions. In this appendix we derive asymptotic expressions for the solutions of the equation

$$\kappa_2(\lambda)\sin[\kappa_1(\lambda)d_1]\cos[\kappa_2(\lambda)d_2] + \kappa_1(\lambda)\cos[\kappa_1(\lambda)d_1]\sin[\kappa_2(\lambda)d_2] = 0 \tag{115}$$

for large values of $|\lambda|$. In (115), $\kappa_i = \sqrt{k_i^2 - \lambda^2}$, $i = 1, 2$, and we assume that $k_1 > k_2$. Here also d_1 and d_2 can be complex and satisfy $0 \geq \arg(d_1) > \arg(d_2) > -\pi/2$. In this appendix the argument function arg has its branch-cut along the negative real axis. Since (115) is a quadratic equation in λ, we restrict the analysis to $\Im(\lambda) < 0$. For large values of $|\lambda|$ one can approximate

$$\kappa_i \approx j\lambda. \tag{116}$$

This allows us to write (115) as

$$\kappa_2(\lambda)\sinh(\lambda d_1)\cosh(\lambda d_2) + \kappa_1(\lambda)\cosh(\lambda d_1)\sinh(\lambda d_2) = 0 \tag{117}$$

for large values of $|\lambda|$. It will become clear further on why we did not approximate κ_i in front of the hyperbolic functions. If $\lim_{|\lambda|\to+\infty} \arg(\lambda d_i) \neq -\pi/2$, then

$$|\sinh(\lambda d_i)| \approx |\cosh(\lambda d_i)| \approx \frac{e^{|\Re(\lambda d_i)|}}{2}. \tag{118}$$

If $\lim_{|\lambda|\to+\infty} \arg(\lambda d_i) = -\pi/2$, then

$$\lim_{|\lambda|\to+\infty} \frac{\Re(\lambda d_i)}{\Im(\lambda d_i)} = 0, \tag{119}$$

but not necessarily $\lim_{|\lambda|\to+\infty} \Re(\lambda d_i) = 0$. Note that $\lim_{|\lambda|\to+\infty} \arg(\lambda d_i) = \pi/2$ is impossible with the argument constraints on d_i and λ. We have to distinguish three different cases.

In the first case we assume that

$$\lim_{|\lambda|\to+\infty} \arg(\lambda d_1) = -\frac{\pi}{2}. \tag{120}$$

This means that

$$\lim_{|\lambda|\to+\infty} \Re(\lambda d_2) = -\infty. \tag{121}$$

Hence, for large $|\lambda|$ we can approximate

$$-\sinh(\lambda d_2) \approx \cosh(\lambda d_2) \approx \frac{e^{-\lambda d_2}}{2} \tag{122}$$

and reduce (117) to

$$\kappa_2(\lambda)\sinh(\lambda d_1) - \kappa_1(\lambda)\cosh(\lambda d_1) = 0 \tag{123}$$

or

$$e^{2\lambda d_1} = \frac{\kappa_2(\lambda) + \kappa_1(\lambda)}{\kappa_2(\lambda) - \kappa_1(\lambda)}. \tag{124}$$

In the denominator on the right-hand side we cannot use the approximation (116), but we have to take an extra term into account, i.e.,

$$\kappa_i(\lambda) \approx j\lambda\left(1 - \frac{k_i^2}{2\lambda^2}\right). \tag{125}$$

This allows us to recast (124) as

$$e^{p_1} = \pm\frac{p_1}{\sqrt{k_1^2 - k_2^2 d_1}}, \tag{126}$$

with $p_1 = \lambda d_1$. From (126) it follows that

$$e^{\Re(p_1)} = \frac{2|p_1|}{\sqrt{k_1^2 - k_2^2|d_1|}}. \tag{127}$$

In view of (119) we can approximate $|p_1| \approx |\Im(p_1)|$ such that

$$\Re(p_1) = \log\left[\frac{2|\Im(p_1)|}{\sqrt{k_1^2 - k_2^2|d_1|}}\right], \tag{128}$$

and also

$$e^{j\Im(p_1)} = \pm\frac{p_1|d_1|}{d_1|\Im(p_1)|} \approx \pm\frac{\Im(p_1)|d_1|}{d_1|\Im(p_1)|}, \tag{129}$$

which gives

$$\Im(p_{1,i}) = -\arg(d_1) - (2i+1)\frac{\pi}{2}. \tag{130}$$

Hence, asymptotically the equation has a first infinite set of solutions of the form

$$\lambda_i = \frac{1}{d_1}\log\frac{2[\arg d_1 + (2i+1)\frac{\pi}{2}]}{\sqrt{k_1^2 - k_2^2|d_1|}} - \frac{j[\arg d_1 + (2i+1)\frac{\pi}{2}]}{d_1}. \tag{131}$$

In the second case we assume that

$$\lim_{|\lambda|\to+\infty}\arg(\lambda d_2) = -\frac{\pi}{2}. \tag{132}$$

This means that

$$\lim_{|\lambda|\to+\infty}\Re(\lambda d_1) = +\infty, \tag{133}$$

resulting in the approximate equation

$$\kappa_2(\lambda)\cosh(\lambda d_2) + \kappa_1(\lambda)\cosh(\lambda d_2) = 0, \tag{134}$$

or, proceeding as above,

$$e^{p_2} = \pm j\frac{\sqrt{k_1^2 - k_2^2}d_2}{p_2}, \tag{135}$$

with $p_2 = \lambda d_2$. This equation can be solved in the same way as (127). The result is

$$\lambda_i = -\frac{1}{d_2}\log\left[\frac{2(i\pi - \arg d_2)}{\sqrt{k_1^2 - k_2^2}|d_2|}\right] - \frac{j(i\pi - \arg d_2)}{d_2}. \tag{136}$$

In the remaining case neither (120) nor (132) is valid. In this case (117) reduces to

$$[\kappa_1(\lambda) \pm \kappa_2(\lambda)]e^{2[|\Re(\lambda d_1)|+|\Re(\lambda d_2)|]} = 0, \tag{137}$$

which has no solutions.

In [23] a similar analysis was given. However, (123) and (134) were derived on physical grounds without proof of the nonexistence of other possible solutions. The solutions (131) and (136) were also derived indirectly as asymptotic approximations of a special function, and the initial conditions were not taken as general as considered here.

A DIFFUSIONAL-THERMAL THEORY OF NEAR-STOICHIOMETRIC PREMIXED FLAMES*

ELIANA S. ANTONIOU†, JOHN K. BECHTOLD‡, AND MOSHE MATALON§

Abstract. In this paper we present a diffusional-thermal theory of premixed flames for near-stoichiometric conditions. Our theory exhibits an explicit dependence on the equivalence ratio as well as on two distinct Lewis numbers which correspond to the fuel and the oxidizer. Normally, the deficient component in the mixture is totally depleted in the reaction zone. However, for curved or strained flames, it is possible for the initially excess reactant to be consumed at the reaction zone if it is the less mobile of the two species, while the initially deficient species leaks through. The form of the derived jump conditions for temperature and enthalpy gradients across the reaction sheet depends on which of the two species is consumed. This can have important implications on predicted flame dynamics. For example, we show that, as a result of preferential diffusion, portions of a corrugated flame may burn rich while neighboring regions burn lean. This results in leakage of fuel and oxidizer through the premixed flame which are then consumed downstream by trailing diffusion flame tongues. Furthermore, the extinction characteristics of strained flames are found to depend on whether fuel or oxidizer is ultimately depleted.

1. Introduction.

Many technologies employ combustion as a source of energy, for example, engines, furnaces, and jets, and important issues regarding efficiency and pollutants depend significantly on the mixture composition. The mixture composition is known to have a significant effect on flame shape and dynamics. For example, flames in light hydrocarbon mixtures are observed to propagate with a smooth surface when the mixture is rich, while the flame surface can take on a cellular appearance when the mixture is lean [1]. Similarly, a great deal of soot formation typically occurs in rich mixtures, while substantially less is produced when the mixture is lean [2].

Despite the recognized importance of mixture strength in practical combustion applications, most theoretical studies are based on single reactant models in which the chemistry is represented by a one-step overall irreversible reaction and proceeds at a rate that depends on the concentration of the deficient component in the mixture. All other reactants appear in relatively large amounts, so only a minimal amount is consumed. These models are therefore valid only when the mixture is far from stoichiometry, i.e., very lean or very rich. They don't exhibit any dependence on the mixture strength, usually measured in terms of the equivalence ratio, which is the ratio of the mass of fuel to oxidizer in the fresh mixture. Many practical combustion systems operate in a regime closer to stoichiometry, and, as noted above, this is a

transition regime where the composition may have an effect on flame dynamics. The objective of this paper is to examine these effects within the context of a diffusional-thermal model accounting for the entire spectrum of mixture compositions, from lean to rich, including the near-stoichiometric regime.

As noted, most earlier theories considered the mixture to be far removed from stoichiometry. As such, all results depend on a single Lewis number, the ratio of thermal diffusivity of the mixture to mass diffusivity of the deficient reactant. It has been shown, for example, that an initially smooth flame will lose stability to a cellular surface when this Lewis number is less than a critical value, slightly less than unity [3]. It has also been observed that a flame in a nonuniform flow can be extinguished by stretch when the Lewis number is greater than one but not otherwise [4, 5]. Therefore, predicted behavior in a given mixture can be quite different depending on whether conditions are lean or rich, but single-reactant models cannot describe the transition from one burning regime to another as stoichiometry is crossed. For conditions close to stoichiometry, both fuel and oxidizer can be expected to play a role in flame characteristics, and a scheme that depends on both reactants must be used. In this case, two Lewis numbers, one associated with the fuel and the other with the oxidizer, as well as the equivalence ratio are all important parameters affecting flame response.

Theoretical investigations of stoichiometric, or near-stoichiometric, flames have mostly been limited to planar or perturbed planar flames. Expressions for the flame speed and temperature, illustrating their dependence on the equivalence ratio, were given by Sen and Ludford [6] and by Mitani [7]. In the context of a diffusional-thermal model, Joulin and Mitani [8] showed that conclusions from the stability analyses of off-stoichiometric flames remain valid under near-stoichiometric conditions, with an average Lewis number replacing the one based on the deficient reactant. In that study, the initially deficient reactant is always consumed by the flame, while a small amount of the abundant species leaks through. Similar conclusions were reached by Jackson [9], who included the effect of thermal expansion in the linear stability analysis, and by Sivashinsky [10], who presented a weakly nonlinear analysis of the problem at exact stoichiometric conditions. Matalon, Cui, and Bechtold [11] have recently shown that hydrodynamic models of flames of arbitrary shape in general flows are modified in a similar way. Although their model can be used to treat nonplanar flames, the flame structure remains quasi–one-dimensional. Since these theories all consider the flame structure to be planar or nearly planar, with the Lewis numbers close to unity, the initially deficient reactant is nearly always consumed at the reaction front, and since temperature perturbations behind the flame are generally weak, the burning characteristics are only slightly modified. However, when the two species diffuse at unequal rates, that is, when the associated Lewis numbers are distinct, and when the flame structure is nonplanar, flame behavior is expected to be quite different. Recently, Bechtold and Matalon [12] derived a slowly-varying-flame model for two-reactant flames in near-stoichiometric mixtures and found that, for strained or curved flames, it is possible for a less mobile reactant that is initially in excess in the mixture to be locally deficient, and hence consumed, at the reaction zone. This can have important consequences on the flame temperature, and hence the burning characteristics. The asymptotic structure of premixed flames has also been analyzed for moderately rich methane-air flames using a four-step kinetic scheme [13]; these authors also find that the response of strained flames depends on the Lewis numbers of both fuel and oxygen.

Still lacking is a diffusional-thermal model of near-stoichiometric flames; the main goal of this paper is to fill that void. The model is derived in a formal asymptotic

way from the full system of equations governing premixed flames in a two-reactant mixture. The analysis is carried out considering the limit of large activation energy, which enables an analytical resolution of the nonlinear reaction rate terms, and the assumption of near-unity Lewis numbers, which is required to obtain a consistent closed model. The model differs from the corresponding single-reactant model in two significant ways. First, it consists of two equations governing the transport of the two reactants, and second, the form of the derived jump conditions for the gradients across the reaction sheet depends on which of the two species is ultimately consumed by the reaction. This can lead to quantitative and qualitative differences in flame structure and in predicted dynamic behaviors. We show that it is possible along a corrugated flame to have regions burning fuel-lean while neighboring regions burn fuel-rich. The excess oxidizer leaking through the first region and fuel leaking through the other both burn along diffusion flame tongues that trail behind the premixed flame. For strained flames we provide a description of the extinction characteristics, showing that the flame response depends significantly on which of the two species is ultimately consumed at the reaction zone.

2. Formulation. Consider a premixed combustible mixture, consisting of an excess (E) and deficient (D) reactant, in which reaction proceeds according to

$$\nu_E \mathcal{M}_E + \nu_D \mathcal{M}_D \rightarrow \text{Products},$$

where $\mathcal{M}_i$ are the chemical symbols for species i, and ν_i are the stoichiometric coefficients. An important parameter in this analysis is the equivalence ratio

$$\phi = \frac{Y_F/\nu_F W_F}{Y_O/\nu_O W_O},$$

which is the ratio of the mass fraction of the fuel to oxidizer in the fresh mixture to their stoichiometric ratio. Here Y_i denote the mass fractions of species i and W_i their molecular weights. Values of ϕ larger than unity correspond to fuel-rich mixtures, and values of ϕ less than one correspond to lean mixtures. To avoid discussing lean and rich mixtures separately it is convenient to introduce the parameter

$$\Phi = \frac{Y_E/\nu_E W_E}{Y_D/\nu_D W_D},$$

based on the ratio of the mass fractions of excess to deficient reactants. As defined, Φ is always greater than one; it is equal to ϕ for rich mixtures and $1/\phi$ for lean mixtures.

The governing equations are made dimensionless by using the adiabatic flame speed, S_f^0, and thermal thickness, $l_D = \lambda/\hat{\rho} c_p S_f^0$, as the characteristic velocity and length, respectively, where λ is the thermal conductivity, c_p the specific heat, and $\hat{\rho}$ the density of the fresh mixture. The time scale is chosen to be l_D/S_f^0. All other variables are made dimensionless by their values in the fresh mixture, which are denoted by the subscript u. The governing equations for temperature and species mass fractions are

$$\frac{DT}{Dt} - \nabla^2 T = \frac{q}{Y_{D,u}}\Omega, \tag{2.1}$$

$$\frac{DY_D}{Dt} - Le_D^{-1}\nabla^2 Y_D = -\Omega, \tag{2.2}$$

$$\frac{DY_E}{Dt} - Le_E^{-1}\nabla^2 Y_E = -\nu\Omega. \tag{2.3}$$

These are coupled to the equations of hydrodynamics, which we avoid writing here since our objective is a diffusional-thermal model. The two sets of equations decouple by considering weak thermal expansion. Here $D/Dt = \partial/\partial t + \mathbf{V}\cdot\nabla$ is the convective derivative with $\mathbf{V}$ the prescribed velocity field. The parameters appearing in these equations include the Lewis numbers $Le_i = \lambda/\hat{\rho}c_p\mathcal{D}_i$, the heat release $q = QY_{D,u}/c_p\hat{T}_u\nu_D W_D$, and the mass-weighted stoichiometric coefficient ratio $\nu = \nu_E W_E/\nu_D W_D$. The reaction rate term on the right-hand side of (2.1)–(2.3) has the form

$$\Omega = DY_E Y_D \exp\left\{\frac{\beta T_a^2}{q}\left(\frac{1}{T_a} - \frac{1}{T}\right)\right\}, \tag{2.4}$$

where D is the Damköhler number, a ratio of the flow time to the chemical time, given by

$$D = \frac{\lambda}{c_p(S_f^0)^2}\frac{\nu_D B}{W_E}e^{-\frac{\beta T_a}{q}}. \tag{2.5}$$

Here $\beta = E(\hat{T}_a - \hat{T}_u)/R\hat{T}_a^2$ is the Zeldovich number, and $\hat{T}_a$ is the adiabatic flame temperature, which in dimensionless form is expressed as $T_a = 1 + q$. In the limit of large activation energy and considering near unity Lewis numbers and near-stoichiometric conditions,

$$Le_i^{-1} = 1 - \beta^{-1}l_i, \qquad \Phi = 1 + \beta^{-1}\varphi, \tag{2.6}$$

the flame speed is given by

$$S_f^0 = \left[\frac{2\lambda\nu_D B}{c_p W_E}\beta^{-3}(\varphi+2)\nu Y_{D,u}\right]^{1/2} e^{-\beta T_a/2q}, \tag{2.7}$$

and thus the Damköhler number can be written $D = \beta^3/[2(\varphi+2)\nu Y_{D,u}]$.

It is convenient in our formulation to introduce the enthalpy functions

$$H_D = T + q\frac{Y_D}{Y_{D,u}}, \qquad H_E = T + \frac{q}{\nu}\frac{Y_E}{Y_{D,u}}. \tag{2.8}$$

Temperature gradients behind the flame are assumed small, i.e., $O(\beta^{-1})$, and correspondingly only an $O(\beta^{-1})$ amount of reactants can leak through. Thus, the enthalpy variables can be expanded as

$$H_D = 1 + q + \beta^{-1}qh_D + \cdots, \qquad H_E = 1 + q\Phi + \beta^{-1}qh_E + \cdots, \tag{2.9}$$

and equations for the enthalpy perturbations, h_i, which follow from (2.1)–(2.3), are given by

$$\frac{Dh_D}{Dt} - \nabla^2 h_D = \frac{l_D}{q}\nabla^2 T, \tag{2.10}$$

$$\frac{Dh_E}{Dt} - \nabla^2 h_E = \frac{l_E}{q}\nabla^2 T. \tag{2.11}$$

2.1. Reaction zone analysis. In the asymptotic limit $\beta \to \infty$, the reaction rate is negligible everywhere except where $T \sim T_a$, i.e., along the reaction sheet given by $x = f(y,z,t)$ (to fix ideas, we will let $x > f(y,z,t)$ correspond to the burned region). We expand all variables, on either side of the sheet, in the form

$$T = T^{(0)} + \beta^{-1} T^{(1)} + \cdots.$$

To leading order, the temperature is continuous across the sheet, while its gradient suffers a jump which is determined from the internal structure of the reaction zone. Integration of (2.10) and (2.11) determines that, to leading order, the two enthalpy variables are also continuous across the flame sheet, and that

$$h_D^* = \frac{1}{q} T^{(1)} + \frac{Y_D^{(1)}}{Y_{D,u}}, \tag{2.12}$$

$$h_E^* = \frac{1}{q} T^{(1)} + \frac{Y_E^{(1)}}{\nu Y_{D,u}} - \varphi. \tag{2.13}$$

Here the right-hand side is to be evaluated at $n = 0^+$ or $n = 0^-$, where n denotes the distance normal to the sheet. In the following, we will evaluate these quantities at $n = 0^+$ unless otherwise noted. Stretching the normal coordinate, integrating the temperature equation, and then matching with the solution outside the sheet yields

$$\left.\frac{\partial T^{(0)}}{\partial n}\right|_{n=0^-} = \frac{q}{\sqrt{2+\varphi}} \sqrt{2 + \left(Y_D^{(1)} + \frac{1}{\nu} Y_E^{(1)}\right)/Y_{D,u}}\ e^{T_b^{(1)}/2q}, \tag{2.14}$$

where $T_b^{(1)} = T^{(1)}$ evaluated at $n = 0^+$. This condition can also be written as

$$\left.\frac{\partial T^{(0)}}{\partial n}\right|_{n=0^-} = \frac{q}{\sqrt{2+\varphi}} \sqrt{2 + Y_{LE}/Y_{D,u}}\ e^{T_b^{(1)}/2q}, \tag{2.15}$$

where Y_{LE} denotes the reactant which is locally in excess. For a planar flame, the initially deficient reactant is always consumed at the reaction sheet, i.e., $Y_D^{(1)} = 0$, and thus $Y_{LE} = Y_E^{(1)}/\nu$. In general, however, it is possible, due to disparate diffusivities, for the initially excess species to be locally deficient, and hence, totally consumed by the reaction. In this case, a small amount of the initially deficient reactant leaks through and $Y_{LE} = Y_D^{(1)}$. The condition (2.15) on the temperature gradient depends on the temperature perturbation behind the flame and the amount of reactant that leaks through the sheet. Both of these quantities can be expressed in terms of the enthalpy perturbations.

To determine which species is consumed and which leaks through, we subtract (2.12) from (2.13), which gives

$$\left(\frac{1}{\nu} Y_E^{(1)} - Y_D^{(1)}\right)/Y_{D,u} = \varphi + h_E^* - h_D^*. \tag{2.16}$$

Recognizing that the mass fractions cannot be negative, the sign of the right-hand side of (2.16) provides the necessary information. If the right-hand side is positive, then $Y_D^{(1)} = 0$, $T_b^{(1)}/q = h_D^*$, and (2.16) determines the amount of initially excess

reactant that leaks through. On the other hand, if the right-hand side of (2.16) is negative, then $Y_E^{(1)} = 0$, $T_b^{(1)}/q = h_E^* + \varphi$, and (2.16) determines the amount of initially deficient reactant that leaks through. When these are inserted into (2.15), we obtain

$$\left.\frac{\partial T^{(0)}}{\partial n}\right|_{n=0^-} = q\sqrt{\frac{2+|\varphi+h_E^*-h_D^*|}{2+\varphi}} \times \exp\left\{\frac{\varphi+h_E^*+h_D^*-|\varphi+h_E^*-h_D^*|}{4}\right\}. \tag{2.17}$$

To summarize, in the limit $\beta \to \infty$, the problem reduces to solving the reaction-free equation for the leading order temperature, $T^{(0)}$, together with the equations for the enthalpies, h_E and h_D, on either side of the reaction sheet. Solutions must satisfy the derived jump conditions as well as appropriate initial and boundary conditions. Our objective is a diffusional-thermal model, accounting for the entire spectrum of mixture composition, that is free of hydrodynamic disturbances. It is therefore commonplace to consider weak thermal expansion ($q \ll 1$), formally done by expanding the temperature as $T^{(0)} = 1 + q\tau + \cdots$, to obtain

$$\frac{D\tau}{Dt} - \nabla^2\tau = 0, \quad x < f(y,z,t), \tag{2.18}$$

$$\tau = 1, \quad x > f(y,z,t), \tag{2.19}$$

$$\frac{Dh_i}{Dt} - \nabla^2 h_i = l_i\nabla^2\tau, \quad x \neq f(y,x,t). \tag{2.20}$$

The jump conditions at the reaction sheet $x = f(y,x,t)$ are

$$[\tau] = 0, \quad [h_i] = 0, \tag{2.21}$$

$$\left[\frac{\partial h_i}{\partial n}\right] + l_i\left[\frac{\partial \tau}{\partial n}\right] = 0, \tag{2.22}$$

$$\left[\frac{\partial \tau}{\partial n}\right] = -\sqrt{\frac{2+|\varphi+h_E^*-h_D^*|}{2+\varphi}}\ \exp\left\{\frac{\varphi+h_E^*+h_D^*-|\varphi+h_E^*-h_D^*|}{4}\right\}, \tag{2.23}$$

where we have used the notation $[\tau] = \tau(\text{burned}) - \tau(\text{unburned})$.

The above system is seen to differ from the single-reactant theory [14] in several ways. First, two species are accounted for, and thus the model has an explicit dependence on both Lewis numbers as well as the equivalence ratio. Second, the jump in the temperature gradient is sensitive not only to the temperature perturbation behind the flame but also to the local species concentrations. Note that for off-stoichiometric mixtures, $\varphi \to \infty$, the inequality $\varphi + h_E^* - h_D^* > 0$ is always satisfied, and the right-hand side of (2.23) reduces to $-e^{h_D^*/2}$, in agreement with single-reactant theory. Our model appropriately describes the flame behavior for conditions far removed from stoichiometry as well, and thus spans the whole range from lean to rich conditions.

3. Weakly corrugated flames. In this section we examine the spontaneous self-corrugation of a planar near-stoichiometric flame using linear and weakly nonlinear stability results. Although in general the flame behaves similarly to that in a mixture far from stoichiometry, there are some differences in the details, as we shall see.

The stability of a planar flame in a near-stoichiometric mixture has been studied previously by Joulin and Mitani [8] and Sivashinsky [10], and their results are readily obtained from our model. When small disturbances are introduced and the linearized equations are solved for the perturbed variables, the following dispersion relation is found for the growth rate ω:

$$64\omega^3 + \omega^2(192k^2 + 32 + 8l - l^2) + 2\omega(12k^2 + 1)(8k^2 + l + 2) + k^2(8k^2 + l + 2)^2 = 0, \tag{3.1}$$

where k is the wavenumber and l is an effective (reduced) Lewis number defined by

$$l = \frac{l_E + l_D + l_D\varphi}{2 + \varphi}. \tag{3.2}$$

This is identical to the result of the single-reactant theory with l appearing in the place of l_D, and, in fact, $l \to l_D$ as $\varphi \to \infty$.

When conditions are stoichiometric or very close to stoichiometric, the perturbed flame may burn rich along some portions and lean along others, depending on the relative magnitudes of the enthalpy perturbations. From the linear theory, the difference in the enthalpy perturbations on the burned side of the flame is found to be

$$h_E^* - h_D^* = -\frac{A(l_E - l_D)}{2(1 + 4k^2)}[1 - \sqrt{1 + 4(\omega + k^2)}]e^{iky+\omega t}, \tag{3.3}$$

where A is the amplitude of the disturbance. Because of the sinusoidal nature of the perturbations, the difference in enthalpy variables, $h_E^* - h_D^*$, changes sign along the front provided there exists preferential diffusion ($l_E \neq l_D$). Thus both forms of the jump relation for the temperature gradient (2.23) are applied along different segments of the corrugated flame. The two conditions, when linearized, are equivalent, and therefore the stability characteristics are not modified despite the local differences in mixture composition along the front. However, the structure of the resulting corrugated front beyond the instability threshold may be affected by these differences.

A weakly nonlinear analysis can be performed for $l + 2 \ll 1$. Upon introducing the appropriate scalings, we find that the species that leaks through is determined by the sign of the quantity

$$\mathcal{E} = \varphi + (l_D - l_E)\frac{\partial^2 f}{\partial y^2}, \tag{3.4}$$

where y is the transverse coordinate. Although the concentrations along the corrugated front vary in concave/convex segments, the overall flame dynamics remain governed by the Kuramoto–Sivashinsky equation as envisaged by Sivashinsky [10] under exact stoichiometric conditions. Thus, the curvature of the front plays a role in determining which species leaks through. However, the jump conditions remain identical to all orders considered, and the Kuramoto–Sivashinsky equation is found to govern the flame dynamics regardless of whether a particular region burns rich or lean.

3.1. Trailing diffusion flames. The excess of fuel and oxidizer leaking along neighboring regions of the premixed flame front burns in trailing diffusion flame tongues attached at the stoichiometric points. Here we analyze the diffusion flame structure. The system we investigate is reminiscent of the classical Burke–Schumann flame [15], but with several important differences. First, the inlet boundary is a *corrugated* premixed flame as opposed to a burner rim. Second, the distribution of species on either side of the diffusion flame is not uniform. Third, the temperature is everywhere within $O(\beta^{-1})$ of its adiabatic value and species concentrations are small $(O(\beta^{-1}))$. Finally, the Damköhler number is not a free controlled parameter; its value is fixed by the presence of the premixed flame.

To analyze the region behind the premixed flame, we introduce the expansions

$$T = T_a + \beta^{-1} q\theta, \qquad Y_i = \beta^{-1} Z_i,$$

which are inserted into the governing equations (2.1)–(2.3) to yield the system

$$\frac{\partial \theta}{\partial x} - \frac{\partial^2 \theta}{\partial x^2} - \frac{\partial^2 \theta}{\partial y^2} = \frac{\beta^2}{2(\varphi+2)\nu Y_{D,u}^2} Z_D Z_E \, e^{\theta}, \tag{3.5}$$

$$\frac{\partial Z_D}{\partial x} - \frac{\partial^2 Z_D}{\partial x^2} - \frac{\partial^2 Z_D}{\partial y^2} = -\frac{\beta^2}{2(\varphi+2)\nu Y_{D,u}} Z_D Z_E \, e^{\theta}, \tag{3.6}$$

$$\frac{\partial Z_E}{\partial x} - \frac{\partial^2 Z_E}{\partial x^2} - \frac{\partial^2 Z_E}{\partial y^2} = -\frac{\beta^2 \nu}{2(\varphi+2)\nu Y_{D,u}} Z_D Z_E \, e^{\theta}. \tag{3.7}$$

We assume a steady corrugated premixed flame front at $x = A\cos(ky)$, where A, k are the amplitude and wavenumber, respectively. From the linear analysis the temperature and concentration perturbations along the premixed flame front are given by

$$\begin{aligned} &\theta = l_D B \cos(ky), \quad Z_D = 0, \\ &Z_E = \nu Y_{D,u}[(l_E - l_D) B \cos(ky) + \varphi] \qquad \text{for } \mathcal{E} > 0, \end{aligned} \tag{3.8}$$

and

$$\begin{aligned} &\theta = l_E B \cos(ky) + \varphi, \quad Z_E = 0, \\ &Z_D = -Y_{D,u}[(l_E - l_D) B \cos(ky) + \varphi] \qquad \text{for } \mathcal{E} < 0, \end{aligned} \tag{3.9}$$

where $B = A[\sqrt{1+4k^2}-1]/2(1+4k^2)$. These are the appropriate boundary conditions to be applied for the determination of the solution in the burned region.

We rescale $y \to y\pi/k$ and introduce the variable $W = \frac{1}{\nu} Z_E - Z_D$, which satisfies the system

$$\frac{dW}{dx} - \frac{d^2 W}{dx^2} - \frac{k^2}{\pi^2} \frac{d^2 W}{dy^2} = 0, \tag{3.10}$$

$$W = Y_{D,u}[(l_E - l_D) B \cos(\pi y) + \varphi] \quad \text{at } x = A\cos(\pi y). \tag{3.11}$$

Recall that the amplitude of the perturbation, A, has been assumed small, and thus we seek solutions in the form of a power series in A. We rescale $B \to AB$, $\varphi \to A\varphi$, $W \to AW$ and at leading order we find

$$W = Y_{D,u}\varphi + Y_{D,u}(l_E - l_D)Be^{-rx}\cos\pi y, \tag{3.12}$$

where $r = \frac{1}{2}[\sqrt{1+4k^2}-1]$. We now restrict our attention to $0 < y < 1$ and determine the diffusion flame sheet location by setting $W = 0$, which yields the expression

$$y = \frac{1}{\pi}\arccos\left(-\frac{a_0}{a_1}e^{rx}\right),$$

where

$$a_0 = Y_{D,u}\varphi, \quad a_1 = Y_{D,u}(l_E - l_D)B.$$

Under exact stoichiometric conditions, $\varphi = 0$ $(a_0 = 0)$, the diffusion flame location is $y = 1/2$ and extends to infinity, parallel to the x-axis. When conditions are not exactly stoichiometric, the location of attachment depends on the relative magnitude of the two Lewis numbers. When $l_E > l_D$, the flame is attached to the premixed flame on the interval $y = [1/2, 1]$ and extends downstream to a length $x^* = \frac{1}{r}\ln(a_1/a_0)$. Alternatively, when $l_E < l_D$, the diffusion flame is attached to the premixed flame on the interval $y = [0, 1/2]$ and its length is $x^* = \frac{1}{r}\ln(-a_1/a_0)$. By increasing φ, the diffusion flames shorten and disappear when φ is sufficiently large. The entire structure is shown schematically in Figure 3.1.

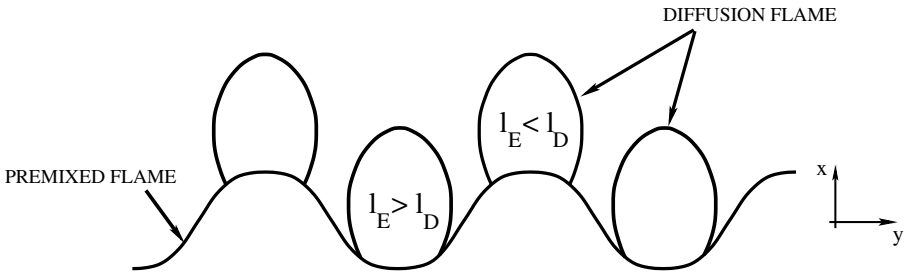

FIG. 3.1. *Schematic of diffusion flames trailing a segment of the perturbed premixed flame.*

Solutions for the temperature and species distribution on either side of the diffusion flame sheet are now found to be

$$\theta = l_D Be^{-rx}\cos(\pi y), \quad z_D = 0, \quad z_E = \nu W \quad \text{for} \quad W > 0, \tag{3.13}$$

and

$$\theta = l_E Be^{-rx}\cos(ky) + \varphi, \quad z_D = -W, \quad z_E = 0 \quad \text{for} \quad W < 0. \tag{3.14}$$

The temperature is continuous across the flame sheet, where it assumes the value

$$\theta^* = -\frac{l_D\varphi}{l_E - l_D}.$$

Note that in the absence of preferential diffusion, $l_E = l_D$, there are no trailing diffusion flames, since the deficient reactant is always depleted at the premixed reaction zone and only the initially excess species leaks through.

To investigate the structure of the diffusion flame, we must perform a local analysis of the reaction zone. Thus we introduce the local coordinate

$$y = F(x) + \beta^{-2/3}\zeta, \qquad F(x) = \frac{1}{\pi}\arccos\left(-\frac{a_0}{a_1}e^{rx}\right).$$

Note that this scaling suggests that the diffusion flame zone is broader than the premixed flame zone. We now introduce the expansions

$$\theta = \theta^* + \beta^{-2/3}\theta_1, \qquad Z_i = \beta^{-2/3}z_i,$$

and insert these into (3.5)–(3.7) to obtain

$$-\frac{\partial^2\theta_1}{\partial\zeta^2} = \frac{G(x)}{\nu Y_{D,u}}z_D z_E, \tag{3.15}$$

$$\frac{\partial^2 z_D}{\partial\zeta^2} = \frac{G(x)}{\nu}z_D z_E, \tag{3.16}$$

$$\frac{\partial^2 z_E}{\partial\zeta^2} = G(x)z_D z_E, \tag{3.17}$$

where

$$G(x) = \frac{e^{\theta^*}}{2(\varphi+2)Y_{D,u}(1+F_x^2)}.$$

Solutions to this system must match the outer solutions (3.13)–(3.14) which provide the conditions

$$z_E \sim \begin{cases} 0, & a_1\zeta > 0, \\ -\nu a_1\zeta\pi\sin(\pi F)e^{-rx}, & a_1\zeta < 0, \end{cases} \tag{3.18}$$

$$z_D \sim \begin{cases} a_1\zeta\pi\sin(\pi F)e^{-rx}, & a_1\zeta > 0, \\ 0, & a_1\zeta < 0. \end{cases} \tag{3.19}$$

To solve the above system, we first sum (3.16) and (3.17) to determine z_D in terms of z_E, i.e.,

$$z_D = \frac{1}{\nu}z_E + \zeta\alpha,$$

where $\alpha = a_1\pi\sin(\pi F(x))e^{-rx}$. Inserting this into (3.17) now results in a single boundary value problem for z_E. It is convenient to introduce the new variable U as $z_E = \nu\alpha U$, which satisfies

$$\frac{\partial^2 U}{\partial\zeta^2} = G(x)\alpha U(U+\zeta), \tag{3.20}$$

$$U \sim \begin{cases} -\zeta, & a_1\zeta \to -\infty, \\ 0, & a_1\zeta \to \infty. \end{cases} \tag{3.21}$$

The transformation

$$U \to (4G\alpha)^{-1/3}V, \quad \zeta = (2/G\alpha)^{1/3}\xi$$

now converts this system to the form

$$\frac{\partial^2 V}{\partial \xi^2} = (V+\xi)(V-\xi), \tag{3.22}$$

$$V \sim \begin{cases} -\xi, & \xi \to -\infty, \\ \xi, & \xi \to \infty. \end{cases} \tag{3.23}$$

This is identical to the diffusion flame structure for the infinite Damköhler number [16, 17], i.e., the Burke–Schumann flame sheets. Solutions of this system indicate that no reactants leak through the flame, and consequently no extinction is possible. We note that these structures resemble tribrachial (triple) flames, which consist of both lean and rich premixed flame segments with a diffusion flame attached to the stoichiometric point and trailing downstream. The present analysis suggests that such structures may form as a result of self-wrinkling of premixed flames when conditions are close to stoichiometric.

4. Flames in counterflow. We now examine the response of a positively stretched flame in a counterflow under near-stoichiometric conditions. As shown in Figure 4.1, consider a flow originating at $x = -\infty$ and impinging against an adiabatic wall located at $x = 0$. This configuration supports a planar flame situated at $x = -d$. Note that this geometry also corresponds to a twin flame configuration with a symmetric flame located in the right half-plane at $x = d$. The flow remains potential flow in the absence of density variations and is given by $\mathbf{V} = K(-x, y)$, where K is the strain rate. This problem was considered previously by Buckmaster [4] using a single-reactant model.

If the flame is planar, the solution is independent of y, and thus we seek steady solutions to the governing equations

$$-Kx\frac{d\tau}{dx} = \frac{d^2\tau}{dx^2}, \quad x < -d, \tag{4.1}$$

$$\tau = 1, \quad x > -d, \tag{4.2}$$

$$-Kx\frac{dh_i}{dx} = \frac{d^2h_i}{dx^2} + l_i\frac{d^2\tau}{dx^2}, \quad x \neq -d. \tag{4.3}$$

These equations are to be solved subject to the following jump conditions evaluated at $x = -d$:

$$[\tau] = 0, \quad [h_i] = 0, \tag{4.4}$$

$$\left[\frac{dh_i}{dx}\right] + l_i\left[\frac{d\tau}{dx}\right] = 0, \tag{4.5}$$

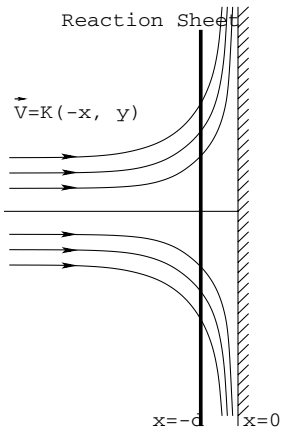

FIG. 4.1. *Schematic of a premixed flame in stagnation point flow against an adiabatic wall. The flame is situated at* $x = -d$.

$$\left[\frac{d\tau}{dx}\right] = \begin{cases} -\sqrt{\frac{2+\varphi+h_E^*-h_D^*}{2+\varphi}}\, e^{h_D^*/2} & \text{if } \varphi + h_E^* - h_D^* > 0, \\ -\sqrt{\frac{2-\varphi+h_D^*-h_E^*}{2+\varphi}}\, e^{(h_E^*+\varphi)/2} & \text{if } \varphi + h_E^* - h_D^* < 0, \end{cases} \tag{4.6}$$

where the boundary conditions are

$$\tau \to 0, \quad h_D \to 0, \quad h_E \to 0, \quad \text{as} \quad x \to -\infty, \tag{4.7}$$

$$\frac{dh_D}{dx}(0-) = 0, \qquad \frac{dh_E}{dx}(0-) = 0. \tag{4.8}$$

The solution to this system is

$$\tau = \begin{cases} \operatorname{erfc}\left(-\sqrt{\frac{K}{2}}x\right) / \operatorname{erfc}\left(\sqrt{\frac{K}{2}}d\right), & x < -d, \\ 1, & x > -d, \end{cases} \tag{4.9}$$

$$h_i = \begin{cases} -l_i \frac{(1+Kd^2)\operatorname{erfc}\left(-x\sqrt{\frac{K}{2}}\right)}{2\operatorname{erfc}\left(d\sqrt{\frac{K}{2}}\right)} - \frac{l_i\sqrt{\frac{K}{2\pi}}}{\operatorname{erfc}\left(d\sqrt{\frac{K}{2}}\right)}\, x\, e^{\frac{-Kx^2}{2}}, & x < -d, \\ -\frac{l_i}{2}(1+Kd^2) + \frac{l_i\sqrt{\frac{K}{2\pi}}}{\operatorname{erfc}\left(d\sqrt{\frac{K}{2}}\right)}\, d\, e^{\frac{-Kd^2}{2}}, & -d < x < 0. \end{cases} \tag{4.10}$$

We note the nonzero enthalpy perturbations behind the flame, and, in particular, the sign of the quantity

$$\varphi + (l_D - l_E)\left(\frac{1}{2}(1+Kd^2) - \sqrt{\frac{K}{2\pi}}\frac{de^{-Kd^2/2}}{\operatorname{erfc}\left(d\sqrt{K/2}\right)}\right)$$

determines which of the two conditions (4.6) is to be used to determine the location of the flame, d. In particular, we find the following.

$\varphi + (l_D - l_E)\Gamma > 0$:

$$\sqrt{K} = \sqrt{\frac{\pi}{2}}\ \mathrm{erfc}(\gamma)\ e^{\gamma^2}\ (1+\mu\Gamma)^{\frac{1}{2}}\ e^{\frac{-l_D}{2}\Gamma}, \tag{4.11}$$

$\varphi + (l_D - l_E)\Gamma < 0$:

$$\sqrt{K} = \sqrt{\frac{\pi}{2}}\ \mathrm{erfc}(\gamma)\ e^{\gamma^2}\left(\frac{2-\varphi}{2+\varphi} - \mu\Gamma\right)^{\frac{1}{2}}\ e^{\frac{-l_E}{2}\Gamma + \frac{\varphi}{2}}, \tag{4.12}$$

where

$$\Gamma = \frac{1}{2} + \gamma^2 - \frac{\gamma e^{-\gamma^2}}{\sqrt{\pi}\ \mathrm{erfc}(\gamma)}, \qquad \gamma = \sqrt{\frac{K}{2}}\ d, \tag{4.13}$$

and

$$\mu = \frac{l_D - l_E}{2+\varphi}. \tag{4.14}$$

For a given mixture, μ and φ are specified, and these expressions determine the flame standoff distance, d, as a function of strain rate, K. Since $\gamma > 0$, the response curve can be constructed by incrementing from $\gamma = 0$ and calculating K from either (4.11) or (4.12), depending on the appropriate inequality that characterizes the mixture. The standoff distance, d, is then found from the second equation in (4.13). As is the case in the single-reactant theory, the dependence of d on K is found to either be a monotonically decreasing function, reaching $d = 0$ at a sufficiently large value of K, or to have a backward C-shape with a turning point at a critical value of K. In the former case, the flame can be pushed all the way to the wall. In the latter case, the turning point corresponds to an extinction point, a maximum strain rate beyond which no steady solution exists.

While constructing the response curves, one must continually monitor the sign of the inequality in (4.11) and (4.12) to decide which condition is the appropriate one to apply. For the uniformly stretched flame considered here, i.e., for K constant, the same equation determines the response along the entire flame surface. In other words, for a given set of parameters, the same species leaks through along the entire flame surface. This is in contrast to the corrugated flame discussed earlier, where it was shown that some portions of the surface burn lean while neighboring regions burn rich.

4.1. Flame response. To discuss the general features of the response curves, we first consider the quantity $\varphi + (l_D - l_E)\Gamma$, whose sign determines whether (4.11) or (4.12) is to be used. A plot of Γ as a function of γ is shown in Figure 4.2. Clearly, Γ is always positive, it assumes its largest value of $1/2$ at $\gamma = 0$, and then decreases monotonically to zero as $\gamma \to \infty$. Since φ, as defined, is also positive, we can conclude that (4.11) determines the response in the following cases, for which, clearly, $\varphi + (l_D - l_E)\Gamma > 0$.

$\varphi \gg \mathbf{1}$:
When conditions are far removed from stoichiometry, the single-reactant theory is recovered. In this limit, $\mu \to 0$ and (4.11) reduces to Buckmaster's result [4] in which the flame response depends only on l_D.

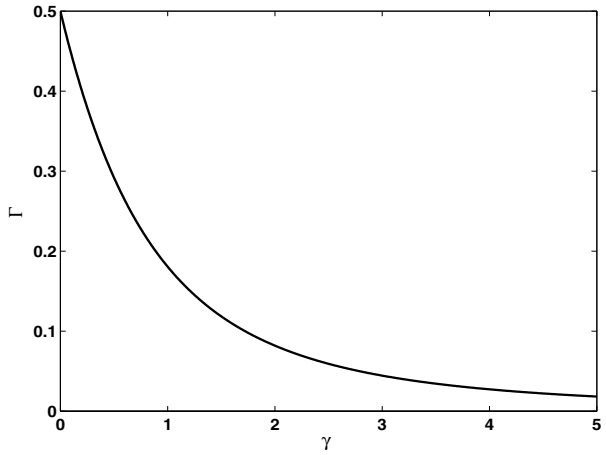

FIG. 4.2. *The quantity* Γ *as a function of* γ*, as determined by* (4.13).

$K \ll 1$:
When the flame is weakly strained, such that $\gamma \gg 1$, the flame retreats and stands far from the stagnation plane, i.e., $d \to \infty$. The structure of these flames is essentially that of a planar flame in a uniform flow field.
$l_D > l_E$:
When the initially deficient reactant is the less mobile of the two, for example, propane in a lean propane/air mixture, it will always be consumed at the reaction sheet.

Equation (4.12) determines the response only when $\varphi + (l_D - l_E)\Gamma < 0$. This occurs for moderately strained flames, in mixtures with $l_E > l_D$, and when conditions are sufficiently close to stoichiometry. In such cases, the initially excess reactant is the less mobile of the two, and its concentration in the reaction zone is consequently low. It is ultimately consumed at the reaction sheet, with the initially deficient species leaking through.

Typical response curves are shown in Figures 4.3–4.6. Figures 4.3 and 4.4 show the standoff distance and flame speed, respectively, as a function of strain rate for several different values of the Lewis number and conditions far removed from stoichiometry, $\varphi \to \infty$. This limit corresponds to the single-reactant theory of Buckmaster [4]. As shown in Figure 4.3, when $l_D < l_D^* = 4$ the response is monotonic, suggesting that the flame can be pushed all the way down to the wall before it is extinguished. When $l_D > l_D^*$, the response curve becomes double-valued. The turning point observed in the corresponding curves is regarded as the extinction point. When the strain rate exceeds the critical value at the turning point, the system can no longer support a planar flame and extinction occurs. The lower portion of the curve, below the extinction point, is presumed to be unstable.

The flame speed, S_f, defined to be the speed of the flame relative to the underlying flow field, is the normal velocity of the incoming flow evaluated at the reaction sheet, i.e., $S_f = Kd$. Curves illustrating the dependence of S_f on K are shown in Figure 4.4. Again we observe that for $\varphi \to \infty$, $l_D^* = 4$ is the critical condition determining the form of the response. We also note that the flame speed of a weakly strained flame can exceed the adiabatic flame speed, $S_f = 1$, when l_D is sufficiently small. This is consistent with previous studies of flame response to straining, cf. [18]. When the flame is weakly strained, the flame retreats far from the stagnation plane and $d \to \infty$.

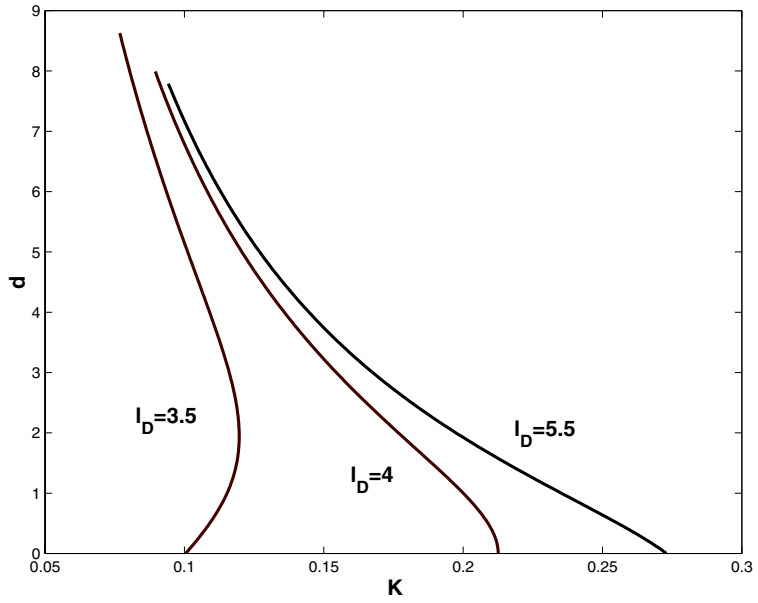

FIG. 4.3. *Standoff distance vs. strain rate for conditions far removed from stoichiometry.*

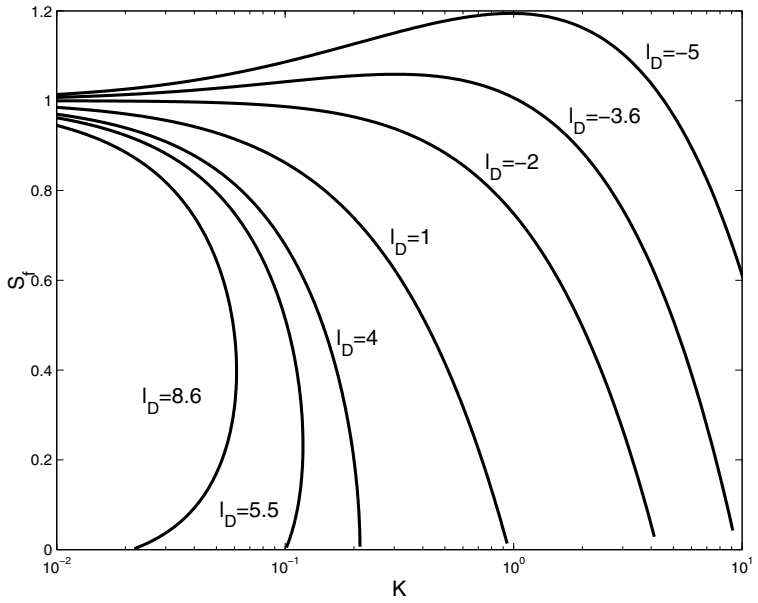

FIG. 4.4. *Standoff distance vs. strain rate for conditions far removed from stoichiometry.*

In this case $\gamma \to \infty$, and thus, again, the inequality $\varphi + (l_D - l_E)\Gamma > 0$ holds for any nonzero φ. Therefore (4.11) is always the appropriate condition to determine flame behavior. For the weak strain rate, this condition determines the flame position to be

$$d = \frac{1}{K} + \left(\frac{\mu - l_D}{2} - 1\right) + o(1),$$

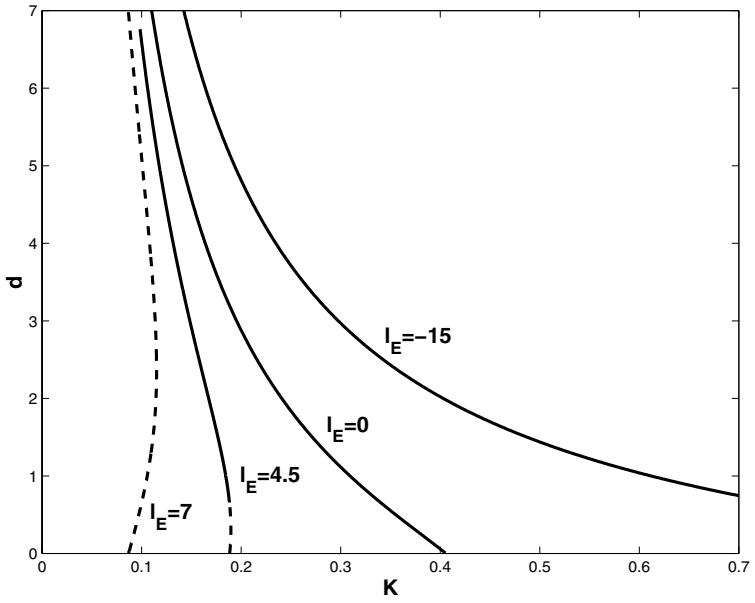

FIG. 4.5. *Standoff distance vs. strain rate for several values of* l_E *with* $l_D = 4.0$ *and* $\varphi = 0.2$. *The solid portions of the curves are determined by* (4.11)*, and the dashed portions by* (4.12).

and the flame speed takes the form

$$S_f = 1 - \left(1 + \frac{l_D - \mu}{2}\right) K + o(K).$$

We conclude that the flame speed will exceed its adiabatic value when $l_D - \mu < -2$, which reduces to the single-reactant theory result, $l_D < -2$, when conditions are far removed from stoichiometry ($\mu \to 0$).

The curves in Figures 4.5 and 4.6 are drawn for selected values of l_E and conditions close to stoichiometry, with $\varphi = 0.2$ and $l_D = 4.0$. The solid portion of each curve represents the segment determined by (4.11), while the dashed portions show where (4.12) is valid.

Since smaller values of d result from larger values of Γ, (4.12) always becomes relevant on the lower portion of the curves when l_E sufficiently exceeds l_D. When the flame is near the wall, the low mobility of the initially excess reactant prevents it from diffusing quickly enough across the strained flow field and it becomes locally deficient, and hence consumed, at the reaction sheet. As the flame moves further away from the wall and the strain weakens, (4.11) will eventually take over.

We note that in situations where the curve becomes double-valued, the transition from a lean to a rich flame may occur either before or after the turning point, and thus extinction conditions may be determined by either (4.11) or (4.12). When (4.11) is valid, the strain rate at which the reaction sheet reaches the wall is given by

$$K = \frac{\pi}{2}(1 + \mu/2)e^{-l_D/2}. \tag{4.15}$$

When a turning point first develops, the slope at this point of intersection will be

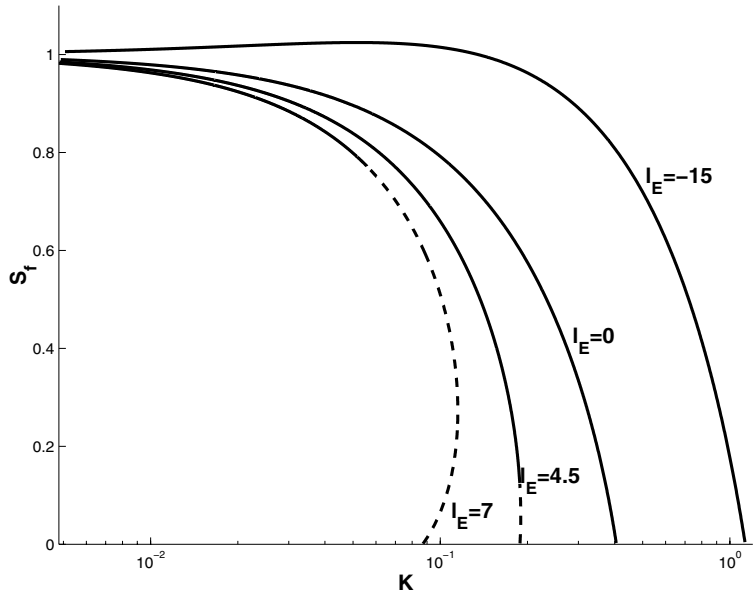

FIG. 4.6. *Flame speed vs. strain rate for several values of* l_E *with* $l_D = 4.0$ *and* $\varphi = 0.2$.

infinite, and upon differentiating (4.11) we find that this occurs at

$$l_D + \frac{2\mu}{2+\mu} = 4.$$

The response is single-valued when $l_D + \frac{2\mu}{2+\mu} < 4$ and double-valued when $l_D + \frac{2\mu}{2+\mu} > 4$. When (4.12) is valid, the value of the strain rate when $d = 0$ is found to be

$$K = \frac{\pi}{2}(p - \mu/2)e^{-l_E/2+\varphi}, \tag{4.16}$$

and the response is single-valued when $l_E + \frac{2\mu}{2p-\mu} < 4$ and double-valued when $l_E + \frac{2\mu}{2p-\mu} > 4$, where $p = (2-\varphi)/(2+\varphi)$.

Comparing Figures 4.3 and 4.5, we observe that the response curves showing d vs. K with $l_D = 4$ and $\varphi = 0.2$ may be either monotonic or double-valued, depending on the values of l_E. The single-reactant model predicts only a monotonic response; see Figure 4.3. Similarly, the flame speed can be significantly modified when conditions are close to stoichiometry, as shown in Figure 4.6. Whereas the single-reactant theory predicts a monotonically decreasing response when $l_D = 4$, the present theory demonstrates that the response may be either single- or double-valued. Furthermore, the flame speed can exceed its adiabatic value for sufficiently small l_E, as can be seen for the curve with $l_E = -15$.

4.2. Effect of the equivalence ratio. Recall that the effects of stoichiometry are measured in terms of φ, which is the deviation from unity of the ratio of the mass fractions of the excess-to-deficient reactants. Also, as defined in (2.6), $\varphi = \beta(\Phi - 1)$ is always positive. Note that the deviation from unity of the equivalence ratio, $\phi_1 = \beta(\phi - 1)$, is related to φ in the following way:

$$\varphi = \begin{cases} \phi_1, & \text{rich mixtures,} \\ -\phi_1, & \text{lean mixtures.} \end{cases}$$

For a given fuel mixture, the roles of l_D and l_E are reversed as stoichiometry is crossed. That is, for lean mixtures l_D and l_E assume the values of l_F and l_O, respectively. However, when the mixture composition is altered to become fuel-rich, $l_D = l_O$ and $l_E = l_F$. It follows from our discussion above that (4.11) will always be valid on one side of stoichiometry while (4.12) will be valid on the other, at least in the immediate vicinity of $\phi_1 \approx 0$. This implies, for example, that a slightly rich mixture can burn lean, with the fuel totally consumed at the reaction sheet, when the Lewis number of the fuel exceeds that of the oxidizer. Of course, as conditions move sufficiently far away from stoichiometry, (4.11) always takes over, indicating that a sufficiently rich mixture will always burn rich. As discussed, Γ assumes its largest value of $1/2$ when $d = 0$, so that in order for (4.12) to play a role along some portion of the response curve, the following inequality must be satisfied:

$$\varphi + (l_D - l_E)/2 < 0.$$

4.2.1. Heavy fuels. To illustrate typical response curves over a range of equivalence ratios, we will first consider a mixture with $l_F = 6.0$, $l_O = 0.0$. These are representative values for mixtures of heavy hydrocarbons in air, for example. For lean mixtures, $l_D = 6.0$, $l_E = 0.0$, and it follows that $\varphi + (l_D - l_E)/2 > 0$. Therefore the entire flame response is determined by (4.11), and the fuel is always consumed. Furthermore, for these parameter values, $l_D + \frac{2\mu}{2+\mu} > 4$ so the response is always double-valued. For rich mixtures, on the other hand, $l_D = 0.0$, $l_E = 6.0$, and we find that (4.12) will determine the lower portion of the response curve when $0 < \phi_1 < 3.0$; (4.11) is valid otherwise. That is, up to $\phi_1 = 3.0$, the flame burns lean when the flame is near the wall and rich when the flame is sufficiently far from the wall. Beyond $\phi_1 = 3.0$ the flame always burns rich. The above inequalities also determine that the response is double-valued when $0 < \phi_1 < 2.0$. Beyond $\phi_1 = 2.0$ the response is single-valued.

In Figure 4.7 we show the standoff distance, strain rate, and flame temperature at extinction as a function of the deviation from unity of the equivalence ratio. The dashed lines on the rich side of stoichiometry indicate that the flame is actually burning lean when it extinguishes. Beyond $\phi_1 = 2.0$ there is no turning point. In this region K_{ext} is taken to be the value of K at which the flame first touches the wall, or when twin flames merge in counterflow. Analysis of the system when $d \approx 0$, presented below, reveals that the flame is indeed extinguished at precisely this value of K, given explicitly by (4.15) and (4.16).

4.2.2. Light fuels. Now we consider a mixture for which the fuel is the lighter species, such as methane/air or hydrogen/air. In Figure 4.8 we show extinction conditions as a function of the equivalence ratio for $l_F = -2.0$, $l_O = 6.0$. The dashed lines on the lean side, but close to stoichiometry, indicate that the flame burns rich at extinction. Note that the trends are opposite of those for heavy fuels, as shown in Figure 4.7.

Similar curves can be readily constructed for various parameter values. In general when the Lewis number of the fuel sufficiently exceeds that of the oxidizer, the response is monotonic when the mixture is sufficiently rich and double-valued otherwise. The response is typical of heavy hydrocarbons such as propane and butane. On the other hand, when the fuel Lewis number is less than that of the oxidizer, the response is monotonic only if the mixture is sufficiently lean. The curves in Figure 4.8 showing d_{ext} as a function of the equivalence ratio are consistent with the theory presented in [12], as well as with the experimental results of Yamaoka and Tsuji [19],

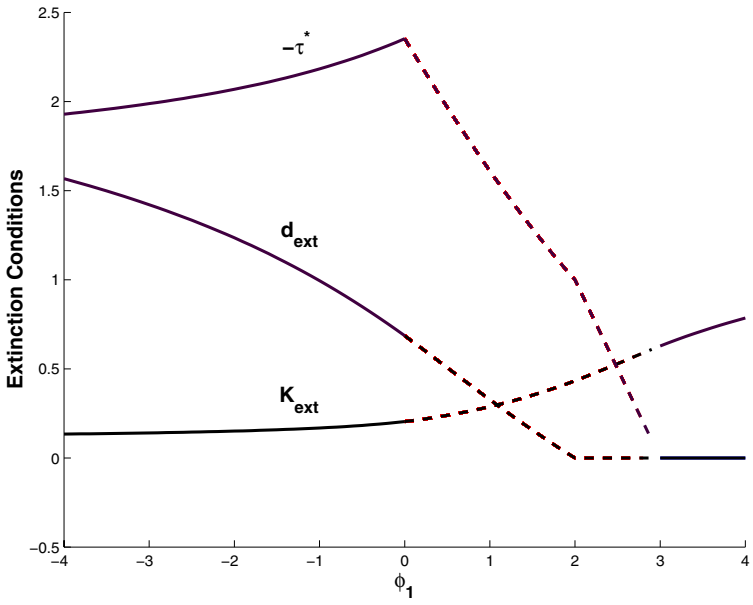

FIG. 4.7. *Standoff distance, strain rate, and (negative) flame temperature perturbation at extinction as a function of mixture strength for* $l_F = 6.0$ *and* $l_O = 0.0$. *The solid portions of the curves indicate extinction is determined by* (4.11) *and dashed portions by* (4.12).

where they measured the standoff distance as a function of the equivalence ratio for methane/air flames. We also note that the flame temperature perturbation levels off on the lean side for lighter fuels and on the rich side for heavier fuels. These regimes correspond to smaller effective Lewis numbers and thus these trends are consistent with the computations of Sato and Tsuji [20], who found that the flame temperature at extinction remains essentially a constant for Lewis numbers below unity.

4.3. The merged flame. In this section, we consider the structure of the flame for the case $d \approx 0$, in order to determine more accurately the extinction criteria after the flames have merged. An analysis of merged flames has been performed previously by Vedarajan, Buckmaster, and Ronney [21] for a single-reactant mixture with unity Lewis number. Here we consider a generalized two-reactant mixture with nonunity Lewis number.

The governing equations are

$$-Kx\frac{d\tau}{dx} = \frac{d^2\tau}{dx^2} + \frac{\beta^2}{2(\varphi+2)\nu Y_{D,u}^2} Y_D Y_E e^{\beta(\tau-1)}, \quad x \le 0, \tag{4.17}$$

$$-Kx\frac{dh_i}{dx} = \frac{d^2h_i}{dx^2} + l_i\frac{d^2\tau}{dx^2}, \quad x \le 0, \tag{4.18}$$

and the mass fractions are given by

$$Y_D/Y_{D,u} = 1 - \tau + \beta^{-1}h_D, \tag{4.19}$$

$$Y_E/\nu Y_{D,u} = 1 - \tau + \beta^{-1}(\varphi + h_E). \tag{4.20}$$

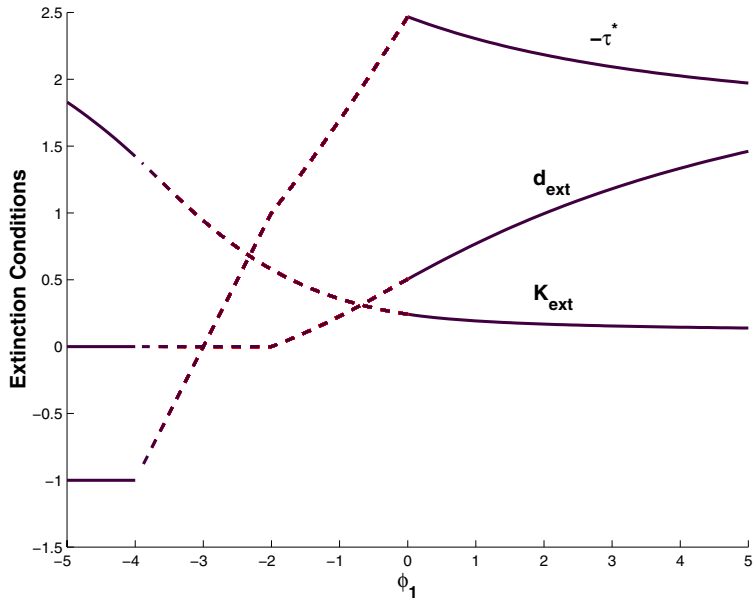

FIG. 4.8. *Standoff distance, strain rate, and (negative) flame temperature perturbation at extinction as a function of mixture strength for* $l_F = -2.0$ *and* $l_O = 6.0$. *The solid portions of the curves indicate extinction is determined by* (4.11) *and dashed portions by* (4.12).

Ahead of the flame, $x < 0$, the solutions are

$$\tau = \operatorname{erfc}(-\sqrt{K/2}x), \tag{4.21}$$

$$h_i = c_i \operatorname{erfc}(-\sqrt{K/2}x) - l_i\sqrt{K/2\pi}\,x e^{-Kx^2/2}, \tag{4.22}$$

where the constants, c_i, are determined by matching to the reaction zone near $x = 0$. The appropriate variables to analyze the reaction zone are

$$x = \beta^{-1}\xi, \quad \tau = 1 + \beta^{-1}\theta, \quad h_i = S_{i,0} + \beta^{-1}S_{i,1}. \tag{4.23}$$

To leading order, $S_{i,0}$ are found to remain constant throughout the reaction zone, and θ satisfies the equation

$$\frac{d^2\theta}{d\xi^2} = -\frac{1}{2(\varphi+2)}(S_{D,0} - \theta)(\varphi + S_{E,0} - \theta)e^{\theta}. \tag{4.24}$$

At the next order, matching the solution of the local enthalpy equation to the outer solution determines a condition for the leading order outer gradients, namely,

$$\frac{dh_i}{dx}(0^-) + l_i\frac{d\tau}{dx}(0^-) = 0.$$

This determines the constant c_i to be $c_i = -l_i/2$, and thus $S_{i,0} = -l_i/2$ throughout the reaction zone. Equation (4.24) can now be integrated once, and matching to the solution upstream yields the following formula for the temperature at the stagnation point θ^*:

$$\frac{K}{\pi} = \left\{\frac{l_D}{2}\left(\frac{l_E}{2} - \varphi\right) + \left(\frac{l_D}{2} + \frac{l_E}{2} - \varphi\right)(\theta^* - 1) + (\theta^* - 1)^2 + 1\right\}\frac{e^{\theta^*}}{2(\varphi+2)}. \tag{4.25}$$

The requirement of nonnegative mass fractions provides the following restriction on θ^*:

$$\theta^* \leq \min[-l_D/2;\ \varphi - l_E/2].$$

A typical plot of θ^* vs. K is shown in Figure 4.9 for the parameter values $\varphi = 1.0$, $l_D = l_E = 2.0$. Only the solid portion of the curve, below $\theta^* = -1$, is valid, to ensure nonnegative mass fractions. Extinction is seen to occur at the lower turning point, where $\theta^* = -1$.

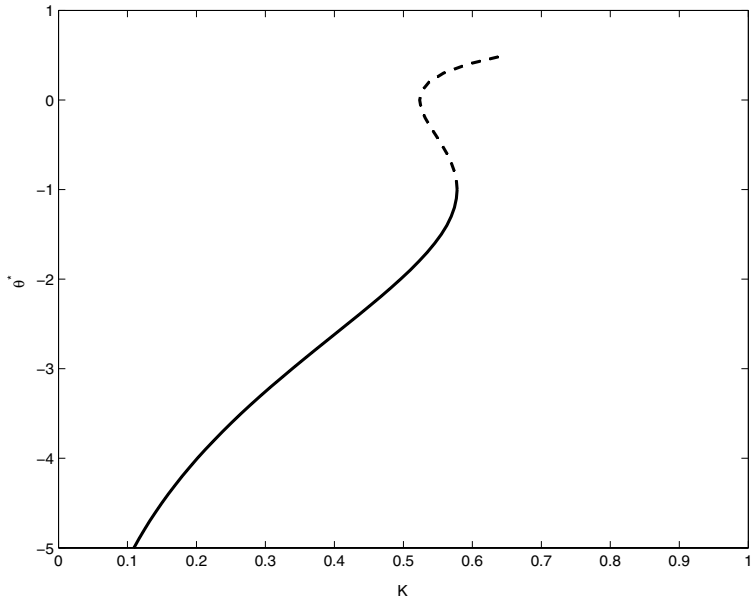

FIG. 4.9. *Flame temperature perturbation vs. strain rate for the merged flame, as determined by* (4.25). *Parameter values are* $l_D = l_E = 2.0$, $\varphi = 1.0$. *Only the solid portion of the curve is relevant, as the dotted portion corresponds to negative mass fractions.*

In general, the resulting curves from (4.25) have turning points at $\theta^* = -l_D/2$ and $\varphi - l_E/2$. However, as we have just discussed, physically relevant solutions exist only for θ^* less than the smaller of these values. Inserting these into (4.25) determines the strain rate at extinction to be

$$K_{\text{ext}} = \frac{\pi}{2}(1 + \mu/2)e^{-l_D/2} \quad \text{when } \theta^* = -l_D/2$$

and

$$K_{\text{ext}} = \frac{\pi}{2}(p - \mu/2)e^{-l_E/2+\varphi} \quad \text{when } \theta^* = \varphi - l_E/2.$$

These are precisely the values of the strain rate at which the flame first touches the stagnation plane, as predicted by the analysis of the separated flames; see (4.15) and (4.16). The present analysis therefore shows that when flames merge, extinction will occur immediately after the flames come into contact with one another (or with an adiabatic wall in the case of stagnation point flow).

5. Conclusions. We have derived a diffusional-thermal model of premixed flames under near-stoichiometric conditions. Our model, (2.18)–(2.23), differs from the single-reactant theory in several ways. First, it consists of an additional coupled equation for the second species, and, consequently, it has an explicit dependence on two Lewis numbers as well as the equivalence ratio. Second, the jump in temperature gradient across the reaction sheet is sensitive not only to the temperature perturbation but also to the local species concentrations. Finally, the derived jump conditions for the gradients across the flame sheet can take one of two forms, depending on which of the two species is ultimately consumed by the reaction. Although the derivation of our model assumes conditions close to stoichiometry, the single-reactant theory is recovered in the appropriate limit, indicating the validity of our model over the complete range of mixture strengths.

In general, the form of the final jump condition (2.23) depends on the sign of the quantity

$$\varphi + h_E^* - h_D^*.$$

This is directly proportional to the difference between the mass fractions of the initially deficient and excess reactants. We have determined that when this quantity is negative, the initially excess reactant is ultimately consumed by the reaction, while a small amount of the initially deficient reactant leaks through. For a weakly strained or curved flame, this quantity takes the form

$$\varphi + (l_D - l_E)(\kappa + K),$$

where κ is the curvature and K the strain rate. Thus, when the two species diffuse at unequal rates, which of the two is ultimately consumed depends on the magnitude and sign of the flame stretch, i.e., the combined effects of curvature and strain. This can have important implications on flame dynamics.

We employed our model to examine the behavior of corrugated flames using a sinusoidal disturbance imposed on a planar flame. Although the stability characteristics were found to be the same as those predicted by the single-reactant theory, albeit with an effective Lewis number properly defined, the overall flame structure is different. Under conditions sufficiently close to stoichiometry, the perturbed flame was found to burn rich along some portions and lean along others. The leakage of fuel and oxidizer along neighboring segments of the premixed flame front resulted in trailing diffusion flame tongues. Analysis of these flames showed them to be Burke–Schumann flame sheets, characterized by complete combustion, that were broader than the premixed reaction zone. Despite these differences, the dynamics of the premixed flame were shown to be unaffected by the local differences in mixture composition along the front.

Our model was also used to investigate the extinction of premixed flames in counterflow. We used our formulas to calculate critical values of strain rate and standoff distance at extinction over a range of equivalence ratios for parameter values typical of both heavy and light fuels. Our theory predicts that rich mixtures of heavy fuels, say, rich propane, are more resistant to strain than lean mixtures; they can withstand larger strain rates and can be pushed closer to the stagnation plane. The opposite trends are predicted for light fuels such as methane or hydrogen. Indeed, our results are consistent with the methane/air experiments reported by Yamaoka and Tsuji [19].

A SEMICONTINUOUS FORMULATION OF THE BLOCH–BOLTZMANN–PEIERLS EQUATIONS*

CH. AUER†, F. SCHÜRRER†, AND W. KOLLER‡

Abstract. This paper presents new transport equations to describe the kinetics of coupled electron-phonon systems in semiconductors. The model is based on a semicontinuous version of the Bloch–Boltzmann–Peierls equations for electrons interacting with acoustic and optical phonons. Major aspects of the resulting kinetic equations, such as conservation laws and stability, are investigated. Numerical results of the model applied to a system of phonons and photo-excited electrons in gallium arsenide (GaAs) are compared with data obtained by an ensemble Monte Carlo technique.

Key words. electron-phonon kinetics, Bloch–Boltzmann–Peierls equations, semicontinuous model, far-from-equilibrium systems, laser photo-excitation

1. Introduction.

Among various classical and quantum mechanical models [7], quasi-hydrodynamic transport equations are today's standard method for simulating the electrical behavior of semiconductor devices. This semiclassical and macroscopic description is based on the semiconductor Boltzmann equation [4]. One of the main requirements for the derivation of hydrodynamic equations, however, is the assumption that the distribution functions are well approximated by equilibrium distributions with time dependent parameters [13]. Since this condition is rarely met in ultra-integrated devices, i.e., the system is far from equilibrium, the focus of modeling the carrier transport must be shifted to directly solving the Boltzmann equation.

We consider a coupled system of semiclassical Boltzmann equations, the so-called Bloch–Boltzmann–Peierls (BBP) equations, for the interacting system of electrons and phonons. These transport equations have mainly been solved by means of ensemble Monte Carlo simulations [6] to investigate the kinetics of far-from-equilibrium systems [11, 18, 20]. Apart from the popular Monte Carlo technique, the discrete kinetic theory offers an alternative way of treating such problems. For elastically and inelastically interacting classical gases, the semicontinuous version of the Boltzmann equation is a well-established method [2, 8, 9, 10, 15, 16, 17].

Here, we derive a conservative formulation of the BBP equations in the framework of a semicontinuous kinetic theory. This formulation is based on a discretization of the energy variables and a continuum of momentum directions. Since a general class of dispersion relations of carriers and phonons is considered, some assumptions, which are discussed in section 3.1, are made for the aim of a concise treatment. As an application, we study numerically the relaxation of photo-excited electrons interacting with the phonon system in the Γ-valley of gallium arsenide (GaAs). The relaxation process is found to be significantly influenced by reabsorption processes of polar

optical phonons.

Our approach (combined with a P_N-expansion) offers the possibility of solving the BBP equations for general dispersion relations of electrons, holes, and phonons with much less consumption of CPU-time than with Monte Carlo methods. It has the advantage of providing a posteriori error estimates. Moreover, the results are independent of random number generators. The derived model equations reflect all major aspects of the continuous description, such as conservation laws, equilibrium states, and stability theorems. A detailed mathematical proof of these properties is deferred to a subsequent publication.

The derived semicontinuous equations are generally applicable to problems without external fields. Such problems are of great interest in semiconductor device modeling. The relaxation after laser photo-excitation, recombination, and the effect of far-from-equilibrium phonon distributions on the electronic system can be studied and provide important insight into the dynamical behavior of electron-phonon systems.

This paper is organized as follows. In section 2 we review the continuous transport equations and discuss their interesting mathematical and physical features. The semicontinuous formulation of the BBP equations for a general class of dispersion relations for electrons and phonons is developed in section 3. In section 4 we summarize the conservation laws and provide an H-theorem concerning the stability of the equilibrium solution. Finally, we present some numerical results concerning hot electrons in GaAs in section 5.

2. Kinetic model. We set up our kinetic model with the standard BBP equations [21],

$$\frac{\partial f}{\partial t} + \boldsymbol{v}(\boldsymbol{k}) \cdot \nabla_r f = \sum_{i=1}^{n_{ph}} C_i^{el}(f, g_i), \tag{2.1}$$

$$\frac{\partial g_i}{\partial t} + \boldsymbol{c}_i(\boldsymbol{q}) \cdot \nabla_r g_i = C_i^{ph}(f, g_i), \tag{2.2}$$

with the phase space distribution functions $f(\boldsymbol{k}, \boldsymbol{r}, t)$ for electrons and $g_i(\boldsymbol{q}, \boldsymbol{r}, t)$ for different types $i = 1, \dots, n_{ph}$ of phonons. The wave vectors $\boldsymbol{k} \in \mathcal{B}, \boldsymbol{q} \in \mathcal{B}$ are elements of the first Brillouin zone $\mathcal{B}$, while $\boldsymbol{r} \in V \subset \mathbb{R}^3$ indicates the position and $t \in \mathbb{R}^+$ denotes the time. Further, we introduce the mean velocity of electrons $\boldsymbol{v}(\boldsymbol{k})$ and $\boldsymbol{c}_i(\boldsymbol{q})$ for the phonon type i by

$$\boldsymbol{v}(\boldsymbol{k}) = \frac{1}{\hbar} \nabla_k E(\boldsymbol{k}), \qquad \boldsymbol{c}_i(\boldsymbol{q}) = \nabla_q \omega_i(\boldsymbol{q}), \tag{2.3}$$

with $\hbar = h/2\pi$, the reduced Planck constant, the electron energy $E(\boldsymbol{k})$ in the considered band, and the dispersion relation $\omega_i(\boldsymbol{q})$ of the ith phonon branch. The collision operators

$$C_i^{el}(f, g_i) = \frac{V}{8\pi^3} \int_{\mathcal{B}} d\boldsymbol{k}' \Big[w_i^+(\boldsymbol{k}, \boldsymbol{k}', \boldsymbol{q}^+) \kappa_1(g_i^+, f, f') + w_i^-(\boldsymbol{k}, \boldsymbol{k}', \boldsymbol{q}^-) \kappa_2(g_i^-, f, f') \Big], \tag{2.4}$$

$$C_i^{ph}(f, g_i) = \frac{V}{4\pi^3} \int_{\mathcal{B}} d\boldsymbol{k}' \, w_i^+(\boldsymbol{k}^-, \boldsymbol{k}', \boldsymbol{q}) \kappa_1(g_i, f^-, f') \tag{2.5}$$

with the transition rates

$$w_i^{\pm}(\boldsymbol{k}, \boldsymbol{k}', \boldsymbol{q}) = s_i(\boldsymbol{q}) \, \delta[E(\boldsymbol{k}) - E(\boldsymbol{k}') \pm \hbar \omega_i(\boldsymbol{q})] \tag{2.6}$$

and the functions

$$\kappa_1(g,f,f') = (g+1)f'(1-f) - gf(1-f') = g(f'-f) + f'(1-f), \tag{2.7}$$

$$\kappa_2(g,f,f') = gf'(1-f) - (g+1)f(1-f') = g(f'-f) - f(1-f') \tag{2.8}$$

couple the electron equation with the phonon equations. We have omitted the arguments $\boldsymbol{r}, t$ of the distribution functions and have used the abbreviations $\boldsymbol{q}^{\pm} = \pm(\boldsymbol{k}'-\boldsymbol{k})$, $\boldsymbol{k}^{-} = \boldsymbol{k}' - \boldsymbol{q}$, $f = f(\boldsymbol{k})$, $f' = f(\boldsymbol{k}')$, $f^{-} = f(\boldsymbol{k}^{-})$, $g_i = g_i(\boldsymbol{q})$, $g_i^{\pm} = g_i(\boldsymbol{q}^{\pm})$ in (2.4) and (2.5) for brevity. The collision operators (2.4) and (2.5) with the transition rates (2.6) take into account only normal processes due to the electron-phonon interaction. The function $s_i(\boldsymbol{q})$ introduced in (2.6) is determined by the absolute value of the matrix element of the electron-phonon interaction Hamilton operator in the states $|\boldsymbol{k}\rangle$, $|\boldsymbol{k}'\rangle$ and, therefore, depends on the type of interaction. The delta distribution in the transition rates ensures conservation of the total energy of the affected electron and phonon in every scattering event. It should be noted that the wave vectors $\boldsymbol{k}, \boldsymbol{k}', \boldsymbol{q}$ do not appear independently from each other in the operators (2.4) and (2.5). If we consider an electron that is scattered from the initial state $\boldsymbol{k}$ to the final state $\boldsymbol{k}'$ involving a phonon of the branch i with wave vector $\boldsymbol{q}$, then the plus sign of $w_i^{\pm}$ represents an absorption process and the minus sign represents an emission process of the phonon.

The major aspects of the transport equations (2.1) and (2.2) with the collision operators (2.4) and (2.5), such as conservation laws, equilibrium solutions and their stability, as well as the initial value problem for the space homogeneous problem, have been analyzed by Majorana [12] in the case of a constant phonon frequency, i.e., $\omega_i(\boldsymbol{q}) = \omega_0$. A generalized kinetic theory for electrons and phonons, based on the BBP equations, is presented in [19].

3. Semicontinuous model. In this section, we derive a semicontinuous version of the kinetic equations (2.1) and (2.2) with the collision operators (2.4) and (2.5). For this purpose, it is necessary to distinguish between two different types of phonons: acoustic phonons, labeled with index $i = 1$, obeying the dispersion relation $e_1(\boldsymbol{q}) = \hbar\omega(\boldsymbol{q})$, and optical phonons, $i = 2$, with constant energy $e_2(\boldsymbol{q}) = e_0 = \hbar\omega_0$ (Einstein model).

In the case of electrons interacting with acoustic phonons, we first introduce the electron and phonon energy, E, $e = \hbar\omega$, as relevant variables of the distribution functions f, g_1 and reformulate the collision operators. This reformulation is possible under mild assumptions on the dispersion relations. The energy variables are then discretized in a second step.

Since optical phonons in the Einstein model cannot be characterized by their energy, we split up the wave vector into its modulus and direction, i.e., $\boldsymbol{q} = q\boldsymbol{\Omega}_{\boldsymbol{q}}$, and discretize the modulus q. After applying a special approximation procedure to functions of the discretized variables, we obtain the semicontinuous BBP equations.

3.1. Interaction geometry and assumptions on the dispersion relations. The semicontinuous model is based on an energy dependent formulation of the kinetic equations. To introduce the electron and phonon energies as relevant variables, we assume that the unique functions

$$|\boldsymbol{k}| = k(E, \boldsymbol{\Omega}_k), \qquad |\boldsymbol{q}| = q(\hbar\omega, \boldsymbol{\Omega}_q) \tag{3.1}$$

exist for the given dispersion relations $E(\boldsymbol{k}), \omega(\boldsymbol{k})$ if $\boldsymbol{\Omega}_k = \boldsymbol{k}/|\boldsymbol{k}| \in \mathbb{S}^2$, $\boldsymbol{\Omega}_q = \boldsymbol{q}/|\boldsymbol{q}| \in \mathbb{S}^2$ and $E \in I^1 \subset \mathbb{R}^+$, $\hbar\omega \in I^2 \subset \mathbb{R}^+$, respectively. The energy intervals I^1 and I^2 are

chosen in such a way that the distribution functions $f(\boldsymbol{k})$ and $g_1(\boldsymbol{k})$ vanish for energies $E(\boldsymbol{k}), \hbar\omega(\boldsymbol{k})$ outside I^1 and I^2, respectively. It should be mentioned that for common semiconductors the functions (3.1) usually exist in that region of the $\boldsymbol{k}$-space, which is relevant for the transport properties. In some cases, however, this region consists of several isolated parts located around band extrema. Such situations can be treated with multivalley models, where different species, one for each part of the Brillouin zone, are introduced and described separately by appropriate distribution functions. In the following we consider only one kind of electron.

In order to derive the semicontinuous BBP equations, we introduce suitable coordinate systems. This often turns out to be very useful when approximating Boltzmann collision operators [14]. We consider the orthonormal transformation matrix

$$\mathrm{T}(\boldsymbol{\Omega}) = \begin{pmatrix} \cos\vartheta\cos\varphi & -\sin\varphi & \sin\vartheta\cos\varphi \\ \cos\vartheta\sin\varphi & \cos\varphi & \sin\vartheta\sin\varphi \\ -\sin\vartheta & 0 & \cos\vartheta \end{pmatrix}, \quad \boldsymbol{\Omega} = \begin{pmatrix} \sin\vartheta\cos\varphi \\ \sin\vartheta\sin\varphi \\ \cos\vartheta \end{pmatrix} \tag{3.2}$$

with $\vartheta \in [0,\pi]$, $\varphi \in [0,2\pi]$, and two coordinate systems $\mathcal{S}_j$, $j = 1,2$, whose basis vectors $\boldsymbol{a}_i^{(j)} \in \mathbb{R}^3, i = 1,2,3$, should be given by

$$\boldsymbol{a}_i = \mathrm{T}^{-1}(\boldsymbol{\Omega}_k)\boldsymbol{a}_i^{(1)} = \mathrm{T}^{-1}(\boldsymbol{\Omega}_q)\boldsymbol{a}_i^{(2)}, \quad i = 1,2,3, \tag{3.3}$$

where $\boldsymbol{a}_i$ are the basis vectors of an arbitrary but fixed basic coordinate system. It should be pointed out that the third axis of the system $\mathcal{S}_1$ ($\mathcal{S}_2$) is aligned with the vector $\boldsymbol{k}$ ($\boldsymbol{q}$). If we represent the unit vector $\boldsymbol{\Omega}_{k'} = \boldsymbol{k}'/|\boldsymbol{k}'|$ by

$$\boldsymbol{\Omega}_{k'}^{(j)} = \begin{pmatrix} \sin\vartheta_j\cos\varphi_j \\ \sin\vartheta_j\sin\varphi_j \\ \cos\vartheta_j \end{pmatrix}, \qquad j = 1,2, \tag{3.4}$$

the quantity ϑ_j is the angle between $\boldsymbol{k}'$ and $\boldsymbol{k}$ for $j = 1$ and between $\boldsymbol{k}'$ and $\boldsymbol{q}$ for $j = 2$, which is advantageous for the integration of the collision operators (2.4) and (2.5).

The electron-phonon interaction processes considered in our kinetic model are governed by the energy and momentum relations

$$\boldsymbol{k}' = \boldsymbol{k} \pm \boldsymbol{q}, \qquad E(\boldsymbol{k}') = E(\boldsymbol{k}) \pm e_i(\boldsymbol{q}) \tag{3.5}$$

of the affected electron and phonon of type $i = 1,2$. Due to (3.4) the direction $\boldsymbol{\Omega}_{k'}$ of $\boldsymbol{k}'$ is parameterized by the angular variables ϑ_1 and φ_1. Now, we concentrate on interaction processes between electrons and acoustic phonons. We consider fixed values for the initial quasi momentum $\boldsymbol{k} = k(E,\boldsymbol{\Omega}_k)\boldsymbol{\Omega}_k$, the electron energy after the interaction E', and the polar angle φ_1. The solutions of (3.5), for the fixed parameters E, $\boldsymbol{\Omega}_k$, E', and φ_1, determine the scattering angle ϑ_1 as well as the phonon wave vector $\boldsymbol{q}$ for allowed scattering events. For the following treatment, we assume that such solutions, if they exist, are unique. In the case of optical phonons, we impose the uniqueness of solutions to (3.5) for fixed parameters E, $\boldsymbol{\Omega}_k$, q, and φ_1. Concerning the phonon collision operators, we additionally require that solutions to (3.5) with respect to ϑ_2 are unique for a fixed phonon wave vector $\boldsymbol{q}$ and fixed parameters E' and φ_2. These conditions are satisfied by dispersion relations which depend weakly on the direction of the wave vector. It should be pointed out that the above mentioned assumptions are made in order to ensure a clear formalism and notation.

3.2. Integration of the collision operators. We reformulate the collision operators by carrying out the variable transformation $(k'_1, k'_2, k'_3) \to (E', \vartheta_1, \varphi_1)$ in the integral of the electron collision operator (2.4) with the relation

$$\boldsymbol{k}'(E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = k[E', \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k)]\, \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k), \tag{3.6}$$

$$\boldsymbol{u}(\xi_j, \varphi_j, \boldsymbol{\Omega}_k) = \mathrm{T}(\boldsymbol{\Omega}_k)\, \boldsymbol{\Omega}_{k'}^{(j)}, \quad j = 1, 2, \tag{3.7}$$

where we split up the vector $\boldsymbol{k}'$ into its modulus and direction unit vector. The latter is expressed as a function of ϑ_1, φ_1 through the transformation (3.2) and we introduce the abbreviation $\xi_1 = \cos\vartheta_1$. The absolute value of the Jacobi determinant results in

$$|J(E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k)| = \left|\det\left[\frac{\partial(k'_1, k'_2, k'_3)}{\partial(E', \xi_1, \varphi_1)}\right]\right| = k'^2 \left|\frac{\partial k'}{\partial E'}\right| \tag{3.8}$$

with $k' = k[E', \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k)]$. Concerning the integration limits, we can assume that the relevant $\boldsymbol{k}$-region, i.e., in which $E(\boldsymbol{k}) \in I^1$, is a subset of the first Brillouin zone $\mathcal{B}$ and we obtain

$$\boldsymbol{k}' \in \mathcal{B} \longrightarrow E' \in I^1, \quad \xi_1 \in [-1, 1], \quad \varphi_1 \in [0, 2\pi]. \tag{3.9}$$

Taking into account (2.6), the electron collision operators (2.4) can then be written as

$$C_i^{el}(f, g_i) = \frac{V}{8\pi^3} \int_{I^1} dE' \int_0^{2\pi} d\varphi_1 \int_{-1}^{1} d\xi_1\, |J| \left\{ s_i^+ \kappa_1(g_i^+, f, f') \delta(F_i^+) + s_i^- \kappa_2(g_i^-, f, f') \delta(F_i^-) \right\} \tag{3.10}$$

for $i = 1, 2$ with the functions

$$F_i^{\pm}(E, E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = E - E' \pm e_i[\boldsymbol{q}^{\pm}(E, E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k)], \tag{3.11}$$

$$\boldsymbol{q}^{\pm}(E, E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = \pm\{k[E', \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k)]\, \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k) - k(E, \boldsymbol{\Omega}_k)\, \boldsymbol{\Omega}_k\} \tag{3.12}$$

and the abbreviation $s_i^{\pm} = s_i(\boldsymbol{q}^{\pm})$. At first sight the representation (3.6) seems to result in needlessly complicated expressions for the integrand of the collision operator (3.10). However, it has the advantage that we obtain convenient functions $q^{\pm}(E, E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k)$, representing the modulus of the phonon wave vector. For example, if we consider dispersion relations, which depend on only the wave vector moduli, then $q^{\pm}$ depends on only ξ_1, i.e., the cosine of the angle between $\boldsymbol{k}$ and $\boldsymbol{k}'$ for given energies E, E'.

An analogous treatment of the phonon collision operators (2.5) leads to

$$C_i^{ph}(f, g_i) = \frac{V}{4\pi^3} s_i \int_{I^1} dE' \int_0^{2\pi} d\varphi_2 \int_{-1}^{1} d\xi_2\, |J| \kappa_1(g_i, f^-, f') \delta(G_i) \tag{3.13}$$

for $i = 1, 2$, where we have introduced the functions

$$G_i(E', \xi_2, \varphi_2, \boldsymbol{q}) = E[\boldsymbol{k}^-(E', \xi_2, \varphi_2, \boldsymbol{q})] - E' + e_i(\boldsymbol{q}), \tag{3.14}$$

$$\boldsymbol{k}^-(E', \xi_2, \varphi_2, \boldsymbol{q}) = k[E', \boldsymbol{u}(\xi_2, \varphi_2, \boldsymbol{\Omega}_q)]\, \boldsymbol{u}(\xi_2, \varphi_2, \boldsymbol{\Omega}_q) - \boldsymbol{q}. \tag{3.15}$$

We continue with the investigation of the poles $\xi_1^{\pm}$ of the delta distribution $\delta(F_1^{\pm})$ defined by

$$F_1^{\pm}(E, E', \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = 0. \tag{3.16}$$

We consider solutions to (3.16) with respect to ξ_1 for arbitrary, but fixed, parameters E, E', φ_1, and $\mathbf{\Omega}_k$. According to section 3.1 there exist unique solutions, and we denote them with

$$\xi_1^{\pm} = \zeta_1^{\pm}(E, E', \varphi_1, \mathbf{\Omega}_k). \tag{3.17}$$

It must be remembered that the functions (3.17) are subject to the condition

$$|\zeta_1^{\pm}(E, E', \varphi_1, \mathbf{\Omega}_k)| \leq 1 \tag{3.18}$$

because of $\xi_1 = \cos\vartheta_1$. The arguments of the functions (3.17) will be omitted in the following for brevity. If the solutions to (3.16) do not exist for the given parameters E, E', φ_1, $\mathbf{\Omega}_k$ or if the solutions do not satisfy the condition (3.18), the collision term (3.10) vanishes. Hence, the energies E' can be restricted to the range

$$\mathcal{D}^{a\pm}(E, \varphi_1, \mathbf{\Omega}_k) = \left\{ E' \in I^1 \middle| \, \exists \zeta_1^{\pm} \wedge |\zeta_1^{\pm}| \leq 1 \right\}, \tag{3.19}$$

which can be seen as a selection rule for the scattering processes. Now, we carry out the integration with respect to ξ_1 in the operator (3.10) to obtain

$$C_1^{el}(f, g_1) = \int_0^{2\pi} d\varphi_1 \int_{I^1} dE' \left[\sigma_1^{+} \kappa_1(g_1^{+}, f, f'^{+}) + \sigma_1^{-} \kappa_2(g_1{}^{-}, f, f'^{-}) \right], \tag{3.20}$$

where we use $f'^{\pm} = f[k(E', \boldsymbol{u}_1^{\pm})\boldsymbol{u}_1^{\pm}]$ and the functions $\boldsymbol{u}_1^{\pm} = \boldsymbol{u}(\zeta_1^{\pm}, \varphi_1, \mathbf{\Omega}_k)$, $g_1^{\pm} = g_1[\boldsymbol{q}^{\pm}(E, E', \zeta_1^{\pm}, \varphi_1, \mathbf{\Omega}_k)]$ are evaluated at $\xi_1 = \zeta_1^{\pm}$. The scattering rate is given by

$$\sigma_1^{\pm}(E, E', \varphi_1, \mathbf{\Omega}_k) = \frac{V}{8\pi^3} \left[|J| s_1^{\pm} \left(\left| \frac{\partial F_1^{\pm}}{\partial \xi_1} \right| \right)^{-1} \right]_{\xi_1 = \zeta_1^{\pm}} \chi_{\mathcal{D}^{a\pm}}(E'), \tag{3.21}$$

with the characteristic function $\chi_{\mathcal{M}}$ of the set $\mathcal{M}$. Further, we use (3.8), (3.11), (3.19), and $s_1^{\pm} = s_1(\boldsymbol{q}^{\pm})$, where $\boldsymbol{q}^{\pm}$ is given in (3.12). It should be mentioned that $e[\boldsymbol{q}^{\pm}(\xi_1 = \zeta_1^{\pm})] = \pm(E' - E)$ and, therefore, we can write

$$\boldsymbol{q}^{\pm} = q[\pm(E' - E), \hat{\boldsymbol{u}}^{\pm}(E, E', \zeta_1^{\pm}, \varphi_1, \mathbf{\Omega}_k)] \hat{\boldsymbol{u}}^{\pm}(E, E', \zeta_1^{\pm}, \varphi_1, \mathbf{\Omega}_k), \tag{3.22}$$

$$\hat{\boldsymbol{u}}^{\pm}(E, E', \xi_j, \varphi_j, \mathbf{\Omega}_k) = \frac{\boldsymbol{q}^{\pm}(E, E', \xi_j, \varphi_j, \mathbf{\Omega}_k)}{|\boldsymbol{q}^{\pm}(E, E', \xi_j, \varphi_j, \mathbf{\Omega}_k)|}, \quad j = 1, 2. \tag{3.23}$$

Concerning the integration of the phonon collision operator (3.13) with respect to ξ_2, the pole ξ_2^{+} is defined by

$$G_1[e, E', \xi_2^{+}, \varphi_2, \mathbf{\Omega}_q] = E[\boldsymbol{k}^{-}(E', \xi_2^{+}, \varphi_2, q(e, \mathbf{\Omega}_q)\mathbf{\Omega}_q)] - E' + e = 0, \tag{3.24}$$

where we have introduced the phonon energy $e = e_1(\boldsymbol{q})$. The uniqueness of an existing solution to (3.24) with respect to ξ_2 for fixed e, E', φ_2, $\mathbf{\Omega}_q$ as postulated in section 3.1, i.e.,

$$\xi_2^{+} = \zeta_2(e, E', \varphi_2, \mathbf{\Omega}_q), \tag{3.25}$$

leads us to the relevant energy ranges

$$\mathcal{D}^{a}(e, \varphi_2, \mathbf{\Omega}_q) = \left\{ E' \in I^1 \middle| \, \exists \zeta_2 \wedge |\zeta_2| \leq 1 \right\} \tag{3.26}$$

by additionally exploiting the relation $\xi_2 = \cos\vartheta_2$. Hence, the phonon collision operator can be written as

$$C_1^{ph}(f, g_1) = \int_0^{2\pi} d\varphi_2 \int_{I^1} dE' \sigma_1 \kappa_1(g_1, f^-, f'), \tag{3.27}$$

with $f' = f[k(E', \boldsymbol{u}_2)\boldsymbol{u}_2]$ and $f^- = f(\boldsymbol{k}_2^-)$. The functions $\boldsymbol{u}_2 = \boldsymbol{u}[\zeta_2, \varphi_2, q(e, \boldsymbol{\Omega}_q)\boldsymbol{\Omega}_q]$ and $\boldsymbol{k}_2^- = \boldsymbol{k}^-(E', \zeta_2, \varphi_2, \boldsymbol{\Omega}_q)$ are defined by (3.7), (3.15) and evaluated at $\xi_2 = \zeta_2$. The new scattering rate is given by

$$\sigma_1(e, E', \varphi_2, \boldsymbol{\Omega}_q) = \frac{V}{4\pi^3} s_1 \left[|J| \left(\left| \frac{\partial G_1}{\partial \xi_2} \right| \right)^{-1} \right]_{\xi_2 = \zeta_2} \chi_{\mathcal{D}^a}(E') \tag{3.28}$$

with the relations (3.8), (3.24), and (3.26).

Next, we treat the collision operators in the case of optical phonons. This means that we assume a constant phonon energy $e_2(\boldsymbol{q}) = e_0 = \hbar\omega_0$, which simplifies the argument $F_2^{\pm}$ of the delta distribution (3.11) in the collision operator (3.10). Performing the integration with respect to the electron energy E' leads to

$$\begin{aligned} C_2^{el}(f, g_2) = \frac{V}{8\pi^3} \int_0^{2\pi} d\varphi_1 \int_{-1}^{1} d\xi_1 \Big[& |J|^+ s_2^+ \kappa_1(g_2^+, f, f'^+_*)\, \chi_{\mathcal{D}^{o+}}(E) \\ & + |J|^- s_2^- \kappa_2(g_2^-, f, f'^-_*)\, \chi_{\mathcal{D}^{o-}}(E) \Big]. \end{aligned} \tag{3.29}$$

The functions $|J|^{\pm}, s_2^{\pm}, g_2^{\pm}, f'^{\pm}_*$ are evaluated at $E' = E \pm e_0$. The insertion of the characteristic functions $\chi_{\mathcal{D}^{o\pm}}(E)$ of the sets

$$\mathcal{D}^{o+} = [\min(I^1), \max(I^1) - e_0], \quad \mathcal{D}^{o-} = [\min(I^1) + e_0, \max(I^1)] \tag{3.30}$$

ensures that $E \pm e_0 = E' \in I^1$. We introduce the modulus of the phonon wave vector $q^{o\pm} = |\boldsymbol{q}^{\pm}|$ as the relevant variable instead of ξ_1 with the relations

$$q^{o\pm}(E, \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = \left[k^2 + (k'^{\pm})^2 - 2kk'^{\pm}\xi_1 \right]^{\frac{1}{2}} \tag{3.31}$$

for the triangle formed by $\boldsymbol{k}, \boldsymbol{k'}^{\pm}, \boldsymbol{q}^{\pm}$. The vector

$$\boldsymbol{k'}^{\pm}(E, \xi_1, \varphi_1, \boldsymbol{\Omega}_k) = k[E \pm e_0, \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k)]\, \boldsymbol{u}(\xi_1, \varphi_1, \boldsymbol{\Omega}_k) \tag{3.32}$$

corresponds to energies $E' = E \pm e_0$. In section 3.1 we have imposed unique solutions to the energy and momentum relations (3.5) for given parameters E, q, φ_1, and $\boldsymbol{\Omega}_k$. In this case the inverse functions of $q = q^{o\pm}$ with respect to ξ_1 exist, and we denote them with

$$\xi_1 = \zeta_1^{o\pm}(E, q, \varphi_1, \boldsymbol{\Omega}_k). \tag{3.33}$$

If we substitute q for ξ_1 in the integral of (3.29), the collision operator results in

$$C_2^{el}(f, g_2) = \int_0^{2\pi} d\varphi_1 \int_{I^3} dq \left[\sigma_2^+ \kappa_1(g_2^+, f, \hat{f}'^+) + \sigma_2^- \kappa_2(g_2^-, f, \hat{f}'^-) \right]. \tag{3.34}$$

Here $g_2^{\pm} = g_2[q\hat{\boldsymbol{u}}^{\pm}(E, E \pm e_0, \zeta_1^{o\pm}, \varphi_1, \boldsymbol{\Omega}_k)]$ and $\hat{f}'^{\pm} = f(\boldsymbol{k'}^{\pm})$ with the vectors $\hat{\boldsymbol{u}}$ introduced in (3.23) and $\boldsymbol{k'}^{\pm}$ given in (3.32), which are computed at $\xi_1 = \zeta_1^{o\pm}$. The

interval I^3 is defined in such a way that the phonon distribution function $g(\boldsymbol{q})$ vanishes for q-values outside I^3. The equations (3.31), (3.33) and the sets

$$\mathcal{D}^{\pm}(E,\varphi_1,\boldsymbol{\Omega}_k)=\left\{q\in I^3\middle|\,|k-k'^{\pm}(\xi_1=1)|\le q\le k+k'^{\pm}(\xi_1=-1)\right\} \tag{3.35}$$

together with $|J|^{\pm}=|J(E'=E\pm e_0)|$, where (3.8) is used, yield the transition rates

$$\sigma_2^{\pm}(E,q,\varphi_1,\boldsymbol{\Omega}_k)=\frac{V}{8\pi^3}\left[|J|^{\pm}s_2^{\pm}\left(\frac{\partial q^{o\pm}}{\partial\xi_1}\right)^{-1}\right]_{\xi_1=\zeta_1^{o\pm}}\chi_{\mathcal{D}^{\pm}}(q)\chi_{\mathcal{D}^{o\pm}}(E). \tag{3.36}$$

The phonon collision operator for optical phonons can be obtained from the acoustic phonon operator (3.27) by setting $e=e_0$, i.e.,

$$C_2^{ph}(f,g_2)=\int_0^{2\pi}d\varphi_2\int_{I^1}dE'\sigma_2\kappa_1(g_2,\hat{f}^-,\hat{f}') \tag{3.37}$$

with $\hat{f}'=f[k(E',\boldsymbol{u}_2^o)\boldsymbol{u}_2^o]$ and $\hat{f}^-=f(\boldsymbol{k}_2^{o-})$. The functions $\boldsymbol{u}_2^o=\boldsymbol{u}(\zeta_2^o,\varphi_2,\boldsymbol{\Omega}_q)$ and $\boldsymbol{k}_2^{o-}=\boldsymbol{k}^-(E',\zeta_2^o,\varphi_2,\boldsymbol{\Omega}_q)$ are defined by (3.7), (3.15) and evaluated at $\xi_2=\zeta_2^o$, which is determined by

$$G_2(E',\xi_2^+,\varphi_2,q\boldsymbol{\Omega}_q)=0\Rightarrow\xi_2^+=\zeta_2^o(q,E',\varphi_2,\boldsymbol{\Omega}_q). \tag{3.38}$$

The scattering rate results in

$$\sigma_2(q,E',\varphi_2,\boldsymbol{\Omega}_{\boldsymbol{q}})=\frac{V}{4\pi^3}s_2\left[|J|\left(\left|\frac{\partial G_2}{\partial\xi_2}\right|\right)^{-1}\right]_{\xi_2=\zeta_2^o}\chi_{\mathcal{D}^o}(E'), \tag{3.39}$$

with (3.8), (3.24), and the energy ranges

$$\mathcal{D}^o(q,\varphi_2,\boldsymbol{\Omega}_q)=\left\{E'\in I^1\middle|\,\exists\zeta_2^o\wedge|\zeta_2^o|\le 1\right\}. \tag{3.40}$$

It should be pointed out that at this stage we have performed only a reformulation of the collision operators and therefore no approximations have been made.

3.3. Discretization. The following discretization and approximation procedure is similar to the discretizations presented in [17]. Here, we introduce discretizations of the electron energy, the phonon energy, and the modulus of the optical phonon wave vector. Starting with the electron energy variable, we choose $n+1$ values $E_i\in I^1$, which form an arithmetic series $E_i=E_0+i\Delta^1$, $i\in S_1=[0,n]\subset\mathbb{N}$, with the energy distance $\Delta^1>0$. Furthermore, we introduce a partition I_i^1, $i\in S_1$, of the interval I^1, so that E_i belongs to the interior of I_i^1. It is convenient to use equidistant intervals I_i^1 with length Δ^1. Due to the energy conserving transition rates (2.6), the acoustic phonon energy can always be expressed as electron energy difference, $e=E'-E$, in the collision operators (3.20) and (3.27). Thus, the discretization of the electron energy determines the set of phonon energies $e_i=i\Delta^2$, with $\Delta^2=\Delta^1=\Delta$ and $i\in S_2=[1,n]\subset\mathbb{N}$, if we assume that $e>0$. As in the case of electrons, we define a partition I_i^2, $i\in S_2$, of the interval I^2, where e_i is an element of the interior of I_i^2. Again, it is reasonable to assume equidistant intervals I_i^2 with length Δ. This fragmentation of I^1, I^2 is possible if the basic phonon energy range is defined by $I^2=[E_0-\min(I^1),E_n-\min(I^1)]$.

The state of the particles is characterized by a discrete set of energies E_i, e_i and arbitrary unit vectors $\mathbf{\Omega}$. The discretization has been constructed to ensure that $E_i \pm e_j = E_k$ with $k = i \pm j$ if $k = (i \pm j) \in S_1$. Hence, the relevant energy and momentum relations are exactly fulfilled on the level of individual microscopic collision processes. This is the main feature of a conservative semicontinuous model.

In the case of optical phonons, we discretize the modulus q of the wave vector $\boldsymbol{q}$. Since the phonon energy does not depend on the wave vector, the energy momentum relations decouple and we can freely choose discrete values for q. To satisfy the relation $E_i \pm e_0 = E_j$ with discrete energy values E_i, E_j, the phonon energy must be an integer multiple of the discretization length, i.e., $e_0 = \alpha\Delta$, $\alpha \in S_1$. We introduce a partition of I^3 with m subintervals I_i^3, $i \in S_3 = [1, m] \subset \mathbb{N}$, and a set of m values q_i, $i \in S_3$, in such a way that q_i is an element of I_i^3. The length of the interval I_i^3 is denoted with Δ_i^3.

Next, we approximate functions $\Phi(x^j)$, $j = 1, 2, 3$, of the discretized variables $x^1 = E$, $x^2 = e$, $x^3 = q$ by

$$\Phi(x^j) \approx \sum_{i \in S_j} \Theta_{ij}(x^j)\Phi_i^j, \qquad \Phi_i^j = \Phi(x_i^j), \quad j = 1, 2, 3, \tag{3.41}$$

with the shape function $\Theta_{ij}(x^j)$, which is equal to 1 for $x^j \in I_i^j$ and zero otherwise for $j = 1, 2, 3$. The approximation method applied to integrals of functions $\Phi(x^j)$ yields

$$\int_{I^j} \Phi(x^j)dx^j \approx \sum_{i \in S_j} \Delta_i^j \Phi_i^j, \quad j = 1, 2, 3. \tag{3.42}$$

The approximation of functions of electron energy differences, e.g.,

$$\Phi(E - E') = \sum_{i,j \in S_1,\, i>j} \Theta_{i1}(E)\Theta_{j1}(E')\Phi(E_i - E_j) = \sum_{i \in S_1} \sum_{k \in S_2} \Theta_{i1}(E)\Theta_{k2}(e)\Phi(e_k) \tag{3.43}$$

with $e = (E - E') \in I^2$ and $k = (i - j) \in S_2$, constitutes a special case.

3.4. Semicontinuous kinetic equations. We start to discretize the electron equation (2.1) by integrating the equation over the interval I_i^1 with respect to the variable E. The left-hand side can then be approximated by

$$\int_{I_i^1} \left[\frac{\partial f}{\partial t} + \boldsymbol{v}(\boldsymbol{k}) \cdot \nabla_r f\right] dE \approx \Delta \left[\frac{\partial f_i}{\partial t} + \boldsymbol{v}_i \cdot \nabla_r f_i\right] \tag{3.44}$$

with the abbreviations $f_i = f[k(E_i, \mathbf{\Omega}_k)\mathbf{\Omega}_k, \boldsymbol{r}, t]$ and $\boldsymbol{v}_i = \boldsymbol{v}[k(E_i, \mathbf{\Omega}_k)\mathbf{\Omega}_k]$. The application of the approximation procedure (3.41) to the integral of C_1^{el}, (3.20), yields

$$\int_{I_i^1} C_1^{el}(f, g_1)dE \approx \Delta C_{1i}^{el} = \Delta \int_0^{2\pi} d\varphi_1 \sum_{j \in S_1} \left[A_{1ij}^{+} \kappa_1(g_{1ij}^{+}, f_i, f'^{+}_{ij}) + A_{1ij}^{-} \kappa_2(g_{1ij}^{-}, f_i, f'^{-}_{ij})\right] \tag{3.45}$$

for $i \in S_1$ with the abbreviations

$$f'^{\pm}_{ij} = f[k(E_j, \boldsymbol{u}^{\pm}_{1ij})\boldsymbol{u}^{\pm}_{1ij}, \boldsymbol{r}, t], \tag{3.46}$$

$$g^{\pm}_{1ij} = g^{\pm}_1[\boldsymbol{q}^{\pm}(E_i, E_j, \zeta^{\pm}_{1ij}, \varphi_1, \boldsymbol{\Omega}_k), \boldsymbol{r}, t], \tag{3.47}$$

$$A^{\pm}_{1ij} = \Delta\sigma^{\pm}_1(E_i, E_j, \varphi_1, \boldsymbol{\Omega}_k), \tag{3.48}$$

$$\boldsymbol{u}^{\pm}_{1ij} = \boldsymbol{u}(\zeta^{\pm}_{1ij}, \varphi_1, \boldsymbol{\Omega}_k), \quad \zeta^{\pm}_{1ij} = \zeta^{\pm}_1(E_i, E_j, \varphi_1, \boldsymbol{\Omega}_k). \tag{3.49}$$

We use the unit vector $\boldsymbol{u}^{\pm}$ introduced in (3.7), and the function $\zeta^{\pm}_1$ defined in (3.17) is evaluated at E_i, E_j.

Now, we treat the second part of the electron collision operator involving the optical phonons. We integrate the operator (3.34) over I^1_i with respect to the electron energy variable E. The approximation (3.41) of functions of E and q results in

$$\int_{I^1_i} C^{el}_2(f, g_2)dE \approx \Delta C^{el}_{2i} = \Delta \int_0^{2\pi} d\varphi_1 \sum_{j\in S_3} \left[A^{+}_{2ij}\kappa_1(g^{+}_{2ij}, f_i, \hat{f}'^{+}_{ij}) + A^{-}_{2ij}\kappa_2(g^{-}_{2ij}, f_i, \hat{f}'^{-}_{ij})\right] \tag{3.50}$$

for $i \in S_1$ with

$$\hat{f}'^{\pm}_{ij} = f[k(E_{i\pm\alpha}, \boldsymbol{u}^{o\pm}_{1ij})\boldsymbol{u}^{o\pm}_{1ij}, \boldsymbol{r}, t], \tag{3.51}$$

$$g^{\pm}_{2ij} = g^{\pm}_2[q_j\hat{\boldsymbol{u}}^{\pm}(E_i, E_{i\pm\alpha}, \zeta^{o\pm}_{1ij}, \varphi_1, \boldsymbol{\Omega}_k), \boldsymbol{r}, t], \tag{3.52}$$

$$A^{\pm}_{2ij} = \Delta^3_j\sigma^{\pm}_2(E_i, q_j, \varphi_1, \boldsymbol{\Omega}_k), \tag{3.53}$$

$$\boldsymbol{u}^{o\pm}_{1ij} = \boldsymbol{u}(\zeta^{o\pm}_{1ij}, \varphi_1, \boldsymbol{\Omega}_k), \quad \zeta^{o\pm}_{1ij} = \zeta^{o\pm}_1(E_i, q_j, \varphi_1, \boldsymbol{\Omega}_k). \tag{3.54}$$

We point out that $e_0 = \alpha\Delta$ holds as imposed in section 3.3. The function $\zeta^{o\pm}_{1ij}$ has been introduced in (3.33), and concerning the vectors $\boldsymbol{u}$ and $\hat{\boldsymbol{u}}^{\pm}$ we refer to (3.7) and (3.23). Adding up the two scattering operators (3.45), (3.50) and equating this sum with the approximation of the streaming part (3.44) gives a discretized version of the electron Boltzmann equation (2.1).

In the next step, we approximate the integral of the left-hand sides of the phonon equations (2.2). Starting with acoustic phonons, we obtain

$$\int_{I^2_i} \left[\frac{\partial g_1}{\partial t} + \boldsymbol{c}_1(\boldsymbol{q}) \cdot \nabla_r g_1\right] de \approx \Delta \left[\frac{\partial g_{1i}}{\partial t} + \boldsymbol{c}_{1i} \cdot \nabla_r g_{1i}\right] \tag{3.55}$$

for $i \in S_2$ and with $g_{1i} = g[q(e_i, \boldsymbol{\Omega}_q)\boldsymbol{\Omega}_q, \boldsymbol{r}, t]$, $\boldsymbol{c}_{1i} = \boldsymbol{c}_1[q(e_i, \boldsymbol{\Omega}_q)\boldsymbol{\Omega}_q]$. The approximation of the integrated optical phonon streaming operator yields

$$\int_{I^3_i} \frac{\partial g_2}{\partial t} dq \approx \Delta^3_i \frac{\partial g_{2i}}{\partial t} \tag{3.56}$$

for $i \in S_3$ if we use the abbreviation $g_{2i} = g(q_i\boldsymbol{\Omega}_q, \boldsymbol{r}, t)$ and take into account that the mean velocity $\boldsymbol{c}_2(\boldsymbol{q})$ defined in (2.3) vanishes for the Einstein dispersion relation $e_2(\boldsymbol{q}) = e_0$. The collision operators (3.27) and (3.37) are discretized in the same way as the streaming operators above. In the case of acoustic phonons, the approximation (3.41) results in

$$\int_{I^2_i} C^{ph}_1(f, g_1)de \approx \Delta C^{ph}_{1i} = \Delta \int_0^{2\pi} d\varphi_2 \sum_{j\in S_1} B_{1ij}\kappa_1(g_{1i}, f^{-}_{ij}, f'_{ij}) \tag{3.57}$$

for $i \in S_2$ with

$$f'_{ij} = f[k(E_j, \boldsymbol{u}_{2ij})\boldsymbol{u}_{2ij}, \boldsymbol{r}, t], \tag{3.58}$$

$$f^-_{ij} = f[\boldsymbol{k}^-(E_j, \zeta_{2ij}, \varphi_2, q(e_i, \boldsymbol{\Omega}_q)\,\boldsymbol{\Omega}_q), \boldsymbol{r}, t], \tag{3.59}$$

$$B_{1ij} = \Delta\sigma_1(e_i, E_j, \varphi_2, \boldsymbol{\Omega}_q). \tag{3.60}$$

The vectors $\boldsymbol{u}_{2ij} = \boldsymbol{u}(\zeta_{2ij}, \varphi_2, \boldsymbol{\Omega}_q)$, $\boldsymbol{k}^-$ are defined in (3.7), (3.15), and the function $\zeta_{2ij} = \zeta_2(e_i, E_j, \varphi_2, \boldsymbol{\Omega}_q)$ is introduced in (3.25). The discretization of the modulus of the phonon wave vector and the approximation of the optical phonon collision operator yield

$$\int_{I_i^3} C_2^{ph}(f, g_2)dq \approx \Delta_i^3 C_{2i}^{ph} = \Delta_i^3 \int_0^{2\pi} d\varphi_2 \sum_{j\in S_1} B_{2ij}\kappa_1(g_{2i}, \hat{f}^-_{ij}, \hat{f}'_{ij}) \tag{3.61}$$

for $i \in S_3$ with

$$\hat{f}'_{ij} = f[k(E_j, \boldsymbol{u}^o_{2ij})\boldsymbol{u}^o_{2ij}, \boldsymbol{r}, t], \tag{3.62}$$

$$\hat{f}^-_{ij} = f[\boldsymbol{k}^-(E_j, \zeta^o_{2ij}, \varphi_2, q_i\,\boldsymbol{\Omega}_q), \boldsymbol{r}, t], \tag{3.63}$$

$$B_{2ij} = \Delta\sigma_2(q_i, E_j, \varphi_2, \boldsymbol{\Omega}_q). \tag{3.64}$$

We define the unit vector $\boldsymbol{u}^o_{2ij} = \boldsymbol{u}(\zeta^o_{2ij}, \varphi_2, \boldsymbol{\Omega}_q)$ by using (3.7) and the function $\zeta^o_{2ij} = \zeta^o_2(q_i, E_j, \varphi_2, \boldsymbol{\Omega_q})$, where we evaluate (3.38) at $q = q_i$, $E' = E_j$. The phonon energy is given by $e_0 = \alpha\Delta$.

Equating the approximations (3.55) and (3.56) of the left-hand side of (2.2) to the collision operators (3.57) and (3.61) yields discretized phonon Boltzmann equations. Together with the streaming operator (3.44) and the collision operators of the electron equation, (3.45) and (3.50), we obtain the semicontinuous BBP equations

$$\frac{\partial f_i}{\partial t} + \boldsymbol{v}_i \cdot \nabla_r f_i = C_{1i}^{el} + C_{2i}^{el}, \quad i \in S_1, \tag{3.65}$$

$$\frac{\partial g_{1i}}{\partial t} + \boldsymbol{c}_{1i} \cdot \nabla_r g_{1i} = C_{1i}^{ph}, \quad i \in S_2, \tag{3.66}$$

$$\frac{\partial g_{2i}}{\partial t} = C_{2i}^{ph}, \quad i \in S_3. \tag{3.67}$$

3.5. Macroscopic quantities. For the introduction of macroscopic quantities in the semicontinuous model, it is useful to define the vector function

$$\boldsymbol{\Phi} = [\phi_0^1(\boldsymbol{\Omega}), \dots, \phi_n^1(\boldsymbol{\Omega}), \phi_1^2(\boldsymbol{\Omega}), \dots, \phi_n^2(\boldsymbol{\Omega}), \phi_1^3(\boldsymbol{\Omega}), \dots, \phi_m^3(\boldsymbol{\Omega})] \tag{3.68}$$

for $\boldsymbol{\Omega} \in \mathbb{S}^2$. Its components are $\phi_i^1(\boldsymbol{\Omega}) = \Phi^1[k(E_i, \boldsymbol{\Omega})\boldsymbol{\Omega}]$, $\phi_i^2(\boldsymbol{\Omega}) = \Phi^2[q(e_i, \boldsymbol{\Omega})\boldsymbol{\Omega}]$, and $\phi_i^3(\boldsymbol{\Omega}) = \Phi^3(q_i\boldsymbol{\Omega})$, where $\Phi^1(\boldsymbol{k})$, $\Phi^2(\boldsymbol{q})$, and $\Phi^3(\boldsymbol{q})$ are arbitrary functions of $\boldsymbol{k}$, $\boldsymbol{q} \in \mathcal{B}$. In addition, we introduce the vector

$$\boldsymbol{f} = (f_0^1, \dots, f_n^1, f_1^2, \dots, f_n^2, f_1^3, \dots, f_m^3) = (f_0, \dots, f_n, g_{11}, \dots, g_{1n}, g_{21}, \dots, g_{2m}), \tag{3.69}$$

consisting of the discretized distribution functions. Then, we consider the functional

$$\langle \boldsymbol{\Phi}, \boldsymbol{f} \rangle = \sum_{i=1}^{3} \sum_{j\in S_i} \Delta_j^i \int_{\mathbb{S}^2} d\boldsymbol{\Omega} D_j^i(\boldsymbol{\Omega})\phi_j^i(\boldsymbol{\Omega})f_j^i(\boldsymbol{\Omega}), \tag{3.70}$$

where $\Delta_j^i = \Delta$ for $i = 1, 2$, $j \in S_i$, holds, and we use

$$D_i^1(\mathbf{\Omega}_k) = D^1(E_i, \mathbf{\Omega}_k) = \frac{1}{4\pi^3} \left| \det \left[\frac{\partial(k_1, k_2, k_3)}{\partial(E, \xi_k, \varphi_k)} \right] \right|_{E=E_i}, \quad i \in S_1, \tag{3.71}$$

$$D_i^2(\mathbf{\Omega}_q) = D^2(e_i, \mathbf{\Omega}_q) = \frac{1}{8\pi^3} \left| \det \left[\frac{\partial(q_1, q_2, q_3)}{\partial(e, \xi_q, \varphi_q)} \right] \right|_{e=e_i}, \quad i \in S_2, \tag{3.72}$$

$$D_i^3(\mathbf{\Omega}_q) = D^3(q_i, \mathbf{\Omega}_q) = \frac{1}{8\pi^3} q_i^2, \quad i \in S_3. \tag{3.73}$$

The angular variables $\xi_k = \cos\vartheta_k, \varphi_k$ and $\xi_q = \cos\vartheta_q, \varphi_q$ represent the unit vectors $\mathbf{\Omega}_k$ and $\mathbf{\Omega}_q$ as defined in (3.2). With the latter functional we can express the macroscopic quantities in the semicontinuous formalism. The densities of the electron particle number, the total quasi momentum, and the total energy are given by

$$n^{el}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_n, \boldsymbol{f} \rangle, \quad \Phi_n^1 = 1, \Phi_n^2 = \Phi_n^3 = 0, \tag{3.74}$$

$$k_l^{tot}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_{k_l}, \boldsymbol{f} \rangle, \quad \Phi_{k_l}^1 = k_l, \Phi_{k_l}^2 = \Phi_{k_l}^3 = q_l, \ l = 1, 2, 3, \tag{3.75}$$

$$e^{tot}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_e, \boldsymbol{f} \rangle, \quad \Phi_e^1 = E(\boldsymbol{k}), \Phi_e^2 = e(\boldsymbol{q}), \Phi_e^3 = e_0. \tag{3.76}$$

By defining the vectors

$$\boldsymbol{\nu}_\beta = (v_{0\beta} f_0, \dots, v_{n\beta} f_n, c_{11\beta} g_{11}, \dots, c_{1n\beta} g_{1n}, c_{21\beta} g_{21}, \dots, c_{2m\beta} g_{2m}) \tag{3.77}$$

for $\beta = 1, 2, 3$, we obtain the corresponding current densities of the particle number, the total quasi momentum, and the total energy, $u_\beta^{el}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_n, \boldsymbol{\nu}_\beta \rangle$, $K_{\beta\gamma}^{tot}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_{k_\beta}, \boldsymbol{\nu}_\gamma \rangle$, $Q_\beta^{tot}(\boldsymbol{r}, t) = \langle \mathbf{\Phi}_e, \boldsymbol{\nu}_\beta \rangle$ with $\beta = 1, 2, 3$ and $\gamma = 1, 2, 3$.

4. Conservation laws, stability, and equilibrium of the discretized model. Here, we briefly summarize the interesting mathematical aspects of the semicontinuous BBP equations and sketch their derivation, while the rigorous proofs are deferred to a subsequent paper. To this end, we introduce the vector $\boldsymbol{J}$ formed by the semicontinuous collision operators (3.45), (3.50), (3.57), and (3.61), i.e., $J_i^1 = C_{1i}^{el} + C_{2i}^{el}$ for $i \in S_1$, $J_i^2 = C_{1i}^{ph}$ for $i \in S_2$, and $J_i^3 = C_{2i}^{ph}$ for $i \in S_3$, and define the functional

$$\langle \mathbf{\Phi}, \boldsymbol{J} \rangle = \sum_{i=1}^{3} \sum_{j \in S_i} \Delta_j^i \int_{\mathbb{S}^2} d\mathbf{\Omega} D_j^i(\mathbf{\Omega}) \phi_j^i(\mathbf{\Omega}) J_j^i(\mathbf{\Omega}). \tag{4.1}$$

In addition, we consider the space of collisional invariants $\mathcal{C}$, which contains all triples $[\Phi^1(\boldsymbol{k}), \Phi^2(\boldsymbol{q}), \Phi^3(\boldsymbol{q})]$ satisfying $\langle \mathbf{\Phi}, \boldsymbol{J} \rangle = 0$. Moreover, we introduce the functions

$$\Phi_H^1(\boldsymbol{k}) = \log\left[\frac{f(\boldsymbol{k})}{1 - f(\boldsymbol{k})}\right], \ \Phi_H^2(\boldsymbol{q}) = \log\left[\frac{g_1(\boldsymbol{q})}{1 + g_1(\boldsymbol{q})}\right], \ \Phi_H^3(\boldsymbol{q}) = \log\left[\frac{g_2(\boldsymbol{q})}{1 + g_2(\boldsymbol{q})}\right]. \tag{4.2}$$

With the definitions above and the sets

$$S_i^+(\varphi, \mathbf{\Omega}) = \left\{ j \in S_1 \middle| E_j \in \mathcal{D}^{a+}(E_i, \varphi, \mathbf{\Omega}) \right\}, \tag{4.3}$$

$$S_i^q(\varphi, \mathbf{\Omega}) = \left\{ j \in S_3 \middle| q_j \in \mathcal{D}^{+}(E_i, \varphi, \mathbf{\Omega}) \right\}, \tag{4.4}$$

we can state the basic theorem.

THEOREM 4.1. *The presented semicontinuous BBP equations* (3.65)–(3.67) *have the following properties.*

1. *They provide the continuity equations*

$$\begin{aligned}
&\frac{\partial n^{el}(\boldsymbol{r},t)}{\partial t} + \nabla_r \cdot \boldsymbol{u}^{el}(\boldsymbol{r},t) = 0,\\
&\frac{\partial \boldsymbol{k}^{tot}(\boldsymbol{r},t)}{\partial t} + \nabla_r \cdot \mathrm{K}^{tot}(\boldsymbol{r},t) = \boldsymbol{0},\\
&\frac{\partial e^{tot}(\boldsymbol{r},t)}{\partial t} + \nabla_r \cdot \boldsymbol{Q}^{tot}(\boldsymbol{r},t) = 0
\end{aligned} \tag{4.5}$$

for the macroscopic quantities defined in section (3.5).

2. *In the equilibrium state, the relation*

$$\boldsymbol{J} = 0 \Leftrightarrow [\Phi_H^1(\boldsymbol{k}), \Phi_H^2(\boldsymbol{q}), \Phi_H^3(\boldsymbol{q})] \in \mathcal{C} \tag{4.6}$$

holds, and these conditions are equivalent to

$$\begin{aligned}
f_i(\boldsymbol{\Omega}) &= \left[\exp\left(\frac{E_i - \mu}{k_B T}\right) + 1\right]^{-1},\\
g_{1ij}^{+}(\varphi_1, \boldsymbol{\Omega}) &= \left[\exp\left(\frac{e_{j-i}}{k_B T}\right) - 1\right]^{-1},\\
g_{2ik}^{+}(\varphi_1, \boldsymbol{\Omega}) &= \left[\exp\left(\frac{e_0}{k_B T}\right) - 1\right]^{-1}
\end{aligned} \tag{4.7}$$

with $i \in S_1$, $j \in S_i^+(\varphi_1, \boldsymbol{\Omega})$, $k \in S_i^q(\varphi_1, \boldsymbol{\Omega})$, $\varphi_1 \in [0, 2\pi]$, $\boldsymbol{\Omega} \in \mathbb{S}^2$, *if the total quasi momentum* $\boldsymbol{k}^{tot}(\boldsymbol{r},t)$ *vanishes identically.*

3. *A Lyapunov functional for the considered kinetic equations is given by*

$$\begin{aligned}
H &= \sum_{i=1}^{3} \sum_{j \in S_i} \Delta_j^i \int_{\mathbb{S}^2} d\boldsymbol{\Omega}\, D_j^i(\boldsymbol{\Omega}) h_j^i(\boldsymbol{\Omega}),\\
h_i^1 &= f_i \log(f_i) + (1 - f_i)\log(1 - f_i),\\
h_i^{j+1} &= g_{ji}\log(g_{ji}) - (1 + g_{ji})\log(1 + g_{ji}), \quad j = 1, 2,
\end{aligned} \tag{4.8}$$

with the distribution functions $f_i = f[k(E_i, \boldsymbol{\Omega})\boldsymbol{\Omega}]$, $g_{1i} = g_1[q(e_i, \boldsymbol{\Omega})\boldsymbol{\Omega}]$, $g_{2i} = g_2(q_i\boldsymbol{\Omega})$, *and* $D_j^i(\boldsymbol{\Omega})$ *defined in* (3.71)–(3.73).

The integration of the continuity equations (4.5) over the crystal volume V with respect to the local variable $\boldsymbol{r}$ shows that the electron particle number, the total quasi momentum, and the total energy are preserved. It should be mentioned that the conservation of the total quasi momentum is a consequence of neglecting umklapp processes in the scattering operators.

From (4.7), we infer that the equilibrium solutions of the model equations are discretized versions of the Fermi–Dirac distribution concerning the electrons and Bose–Einstein distribution for the phonons. The restriction of the indices j, k of the equilibrium phonon distributions results from the fact that the scattering rates A_{1ij}^{+}, A_{2ik}^{+} appearing in the electron collision operators (3.45) and (3.50) vanish for $j \notin S_i^+(\varphi_1, \boldsymbol{\Omega})$ and $k \notin S_i^q(\varphi_1, \boldsymbol{\Omega})$.

The Boltzmann H-functional presented in Theorem 4.1 satisfies the relations

$$\frac{dH}{dt} \le 0, \qquad H - H_* \ge 0, \tag{4.9}$$

where H_* denotes the functional (4.8) evaluated with the equilibrium distributions (4.7) and the equality signs hold if and only if the system is in the equilibrium state.

4.1. Sketch of the proof. In order to derive the mathematical properties presented in Theorem 4.1, we reformulate the functional (4.1) by exploiting symmetries of the integrated semicontinuous collision operators (3.45), (3.50), (3.57), and (3.61). By introducing the abbreviations $\Phi_i^1 = \Phi^1[k(E_i, \boldsymbol{\Omega}_k)\boldsymbol{\Omega}_k]$, $\Phi'^1_{ij} = \Phi^1[k(E_j, \boldsymbol{u}^+_{1ij})\boldsymbol{u}^+_{1ij}]$, and $\hat{\Phi}'^1_{ij} = \Phi^1[k(E_{i+\alpha}, \boldsymbol{u}^{o+}_{1ij})\boldsymbol{u}^{o+}_{1ij}]$, as well as $\Phi^2_{ij} = \Phi^2[\boldsymbol{q}^+(E_i, E_j, \zeta^+_{1ij}, \varphi_1, \boldsymbol{\Omega}_k)]$ and $\Phi^3_{ij} = \Phi^3[q_j\hat{\boldsymbol{u}}^+(E_i, E_{i+\alpha}, \zeta^{o+}_{1ij}, \varphi_1, \boldsymbol{\Omega}_k)]$, this reformulation results in

$$\begin{aligned}\langle \boldsymbol{\Phi}, \boldsymbol{J}\rangle = \Delta \int_{\mathbb{S}^2} d\boldsymbol{\Omega}_k \int_0^{2\pi} d\varphi_1 \sum_{i\in S_1}\sum_{j\in S_1} \left[\Phi_i^1 - \Phi'^1_{ij} + \Phi^2_{ij}\right] D_i^1 A^+_{1ij}\kappa_1(g^+_{1ij}, f_i, f'^+_{ij}) \\ + \Delta \int_{\mathbb{S}^2} d\boldsymbol{\Omega}_k \int_0^{2\pi} d\varphi_1 \sum_{i\in S_1}\sum_{j\in S_3} \left[\Phi_i^1 - \hat{\Phi}'^1_{ij} + \Phi^3_{ij}\right] D_i^1 A^+_{2ij}\kappa_1(g^+_{2ij}, f_i, \hat{f}'^+_{ij}).\end{aligned} \tag{4.10}$$

Starting from this expression, we can show that the macroscopic quantities (3.74)–(3.76) are collisional invariants, and therefore, we can state the continuity equations (4.5). The derivation of (4.10) also allows us to prove the equivalence (4.6). Expanding the triple (4.2) evaluated at equilibrium $[\Phi_H^{1*}, \Phi_H^{2*}, \Phi_H^{3*}]$ in terms of the natural basis $\{\Phi^i_n, \Phi^i_{k_1}, \Phi^i_{k_2}, \Phi^i_{k_3}, \Phi^i_e\}$, $i = 1, 2, 3$, of the space of collisional invariants $\mathcal{C}$, leads us to the equilibrium distribution functions (4.7). Moreover, we find the relations (4.9) by inserting (4.2) into (4.10) and by considering the statement (4.6).

5. Numerical results. In this section, we present numerical results concerning the relaxation of an interacting hot-electron hot-phonon system in GaAs. More precisely, we investigate the temporal evolution of the distribution functions of conduction band electrons, longitudinal acoustic phonons, and polar optical phonons during and after a photo-excitation with a laser pulse [5, 11].

We consider spherically symmetric dispersion relations and scattering probabilities, i.e., $E(\boldsymbol{k}) = E(|\boldsymbol{k}|)$, $e_1(\boldsymbol{q}) = e_1(|\boldsymbol{q}|)$, and $s_i(\boldsymbol{q}) = s_i(|\boldsymbol{q}|)$. This implies that the distribution functions $f_i(\boldsymbol{\Omega}_k, \boldsymbol{r}, t)$, $i \in S_1$, and $g_{ij}(\boldsymbol{\Omega}_q, \boldsymbol{r}, t)$, $i = 1, 2$, $j \in S_{i+1}$, do not depend on the angular variables $\boldsymbol{\Omega}_k$, $\boldsymbol{\Omega}_q$ during the time evolution determined by the semicontinuous BBP equations (3.65)–(3.67) if the initial distributions $f_i^I(\boldsymbol{\Omega}_k, \boldsymbol{r})$, $g^I_{ij}(\boldsymbol{\Omega}_q, \boldsymbol{r})$ are independent of $\boldsymbol{\Omega}_k$ and $\boldsymbol{\Omega}_q$. Consequently, the integrations with respect to φ_1 and φ_2 in the scattering operators (3.45), (3.50) and (3.57), (3.61) contribute only the trivial factor 2π to the corresponding scattering rates. When we further restrict our attention to space-homogeneous problems, the derived model equations (3.65)–(3.67) simplify to a coupled system of first order ordinary differential equations, which can be solved with standard numerical methods.

Since we choose excitation energies that are not too high, the relevant $\boldsymbol{k}$-region of the first Brillouin zone can be restricted to a small area near the Γ-point where the conduction band shows an absolute minimum. Hence, we use a parabolic electron dispersion relation $E(\boldsymbol{k}) = \hbar^2|\boldsymbol{k}|^2/2m^*$ with the effective mass m^* and apply the Debey model to the acoustic phonons, i.e., $e_1(\boldsymbol{q}) = c|\boldsymbol{q}|$, where c denotes the sound velocity (see [1]). The polar optical phonons are treated in the Einstein approximation, i.e., $\hbar\omega(\boldsymbol{q}) = e_0$ as introduced in section 3. The scattering rate corresponding to the electron-phonon interaction is given by (2.6) with

$$s_1(\boldsymbol{q}) = \frac{2\pi}{\hbar}\frac{\hbar^2\Xi_1^2 q^2}{2V\rho e_1(\boldsymbol{q})}, \tag{5.1}$$

$$s_2(\boldsymbol{q}) = \frac{2\pi}{\hbar}\frac{\hbar^2\varepsilon_0^2}{2V\gamma e_0}\frac{1}{q^2}, \qquad \frac{1}{\gamma} = \frac{e_0^2}{\hbar^2}\left(\frac{1}{\epsilon_\infty} - \frac{1}{\epsilon_0}\right) \tag{5.2}$$

for acoustic and optical phonons. Here, ρ denotes the mass density, ε_0 denotes the elementary charge, and the quantities ϵ_∞, ϵ_0 represent the high-frequency and electrostatic dielectric functions. The interaction with acoustic phonons is modeled as first order scattering [4] with the deformation potential Ξ_1. Concerning the interaction with the polar optical phonons, screening effects [4] are not taken into account. The values of all relevant parameters are taken from [11] and summarized in Table 5.1.

TABLE 5.1
Material parameters of GaAs used in the calculations.

Effective electron mass:	m^*/m_0	0.063
Mass density:	ρ_m (g/cm^3)	5.32
Sound velocity:	c (km/s)	5.12
Optical phonon energy:	e_0 (meV)	35.5
Static dielectric constant:	ϵ_0	12.9
High-frequency dielectric constant:	ϵ_∞	10.9
Acoustic deformation potential:	Ξ_1 (eV)	7.0

As an initial condition we consider a thermal equilibrium at 77 K. Therefore, the phonons are governed by Bose–Einstein distributions with the same temperature, and we assume that the conduction band is empty at the beginning. As soon as the laser pulse sets in, electrons from the valence bands are transferred to the conduction band. We suppose that the transfer rate of electrons with energy E_i is given by

$$\frac{dn_i^{el}(t)}{dt} = \alpha_n \left\{ \left[1 + \left(\frac{E_i - E_*}{\alpha_E} \right)^2 \right] \cosh\left(\frac{t - t_0}{\alpha_t} \right) \right\}^{-1}, \tag{5.3}$$

where $n_i^{el}(t)\Delta^1$ represents the particle density of electrons with energies in the interval I_i^1, E_* denotes the averaged injection energy, and at $t = t_0$, the maximum of the transfer rate is reached. Furthermore, the parameter α_E characterizes the energetic and α_t the temporal width of the laser pulse, while α_n determines the total number of excited electrons n^{el} or, equivalently, the intensity of the laser. We use $E_* = 250$ meV, $\alpha_E = 10$ meV, $\alpha_t = 0.305$ ps, where the energy scale is fixed in such a way that $E = 0$ at the conduction band minimum. The parameter t_0 is chosen high enough so that we can neglect the contributions of (5.3) for negative times t, and α_n is determined by fixing the total electron density to $n^{el} = 5 \times 10^{15}\text{cm}^{-3}$. The increase of the electron density through the photo-excitation is modeled by an appropriate source term on the right-hand side of (3.65) according to the rate (5.3).

It should be pointed out that the collision operators (3.45), (3.50), (3.57), and (3.61) take into account only normal processes caused by the electron-phonon interaction. Since the electron density is very small, the electron-electron interaction plays a minor role and is neglected. Due to the selection rules of the phonon-phonon interaction, the only important interaction process for the present problem is the decay of optical phonons into two acoustic phonons and vice versa (see [21]). The energy of the optical phonons is very high compared to the electronically active acoustic phonons. Hence, the acoustic phonons resulting from a decay of an optical phonon do not contribute to the electron-phonon interaction for the considered electron energy range. The collision operator for the phonon-phonon interaction can then be treated in the relaxation time approximation (see [11]), i.e.,

$$\left[\frac{\partial g_{2i}}{\partial t} \right]_{pp} = C_2^{pp} = -\frac{g_{2i} - g_{*2}(e_0, T_0)}{\tau_0} \tag{5.4}$$

with the relaxation time τ_0 and the Bose–Einstein distribution $g_{*2}(e_0, T_0)$. If the temperature T_0 is fixed, we realize the coupling of the optical phonon system to a heat bath, represented by acoustic phonons in equilibrium at T_0, which do not affect the electrons. The operator (5.4) is added to the right-hand side of (3.61), and we set $\tau = 3.5$ ps, $T_0 = 77$ K.

Regarding the discretization parameters, we choose 800 discrete electron energy values between $E_0 = 0.1$ meV and $E_{799} = 400.1$ meV with the constant stepsize $\Delta = 0.5$ meV. Since the optical phonon energy is given by $e_0 = 35$ meV, we take $\alpha = 71$. According to the choice of the electron energies, we obtain 11 relevant values for the acoustic phonon energies in the range from $e_1 = 0.5$ meV to $e_{11} = 5.5$ meV. Furthermore, we use an equidistant discretization for the modulus of the optical phonon wave vector q with a discretization length $\Delta^3 = 0.2 \times 10^5$ cm^{-1}. The 800 discrete q-values belong to the interval $[1.1, 160.9] \times 10^5$ cm^{-1}.

The integration of the model equations (3.65)–(3.67) supplemented by the terms for the laser excitation and the phonon-phonon interaction is performed with a standard solver based on an explicit Runge–Kutta scheme [3]. The results of the calculations are discussed in the following.

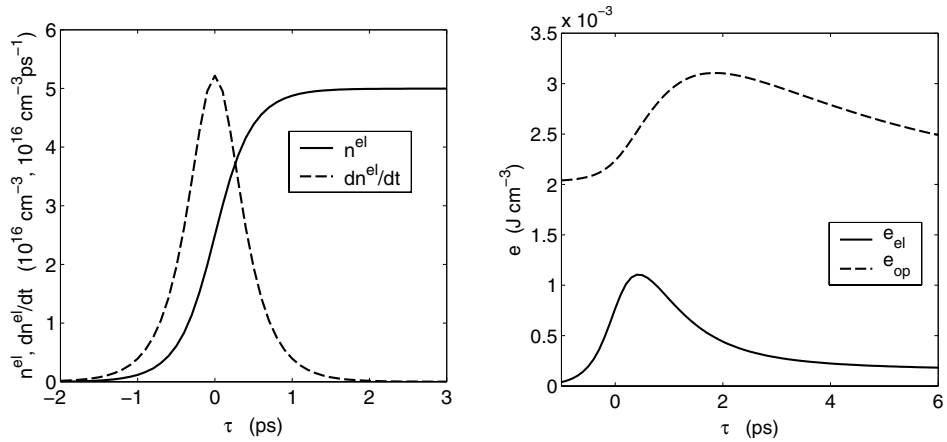

FIG. 5.1. *Electron density and its time derivative as a function of time on the left-hand side. Time evolution of the electron energy and the optical phonon energy in the right-hand plot.*

The left-hand plot of Figure 5.1 depicts the time dependence of the electron particle number and the transfer rate due to the laser photo-excitation. We observe that the electron density in the conduction band tends to the constant value $n^{el} = 5 \times 10^{15}$cm^{-3}, as soon as the laser intensity vanishes. Obviously, the electron density is conserved during the subsequent relaxation process. The time evolution of the energy densities of electrons and optical phonons is shown in the right-hand plot of Figure 5.1. For $t < 0$, the electron energy rises in concert with the laser intensity while the energy of the optical phonons remains largely unaffected. Although the laser pulse then fades away, the electron energy continues to increase. At the same time the emission of optical phonons transfers energy to the phonon system. For times $t \gtrsim 3$, both electrons and optical phonons lose energy to the heat bath of acoustic phonons.

Our semicontinuous model provides further insight into the details of the relaxation process. The left-hand plot of Figure 5.2 shows n_i^{el}, the electron particle density per energy interval Δ according to the energies E_i for different times $\tau = t - t_0$. The mean energy E_* of the photo-excited electrons is bigger than that of the equilib-

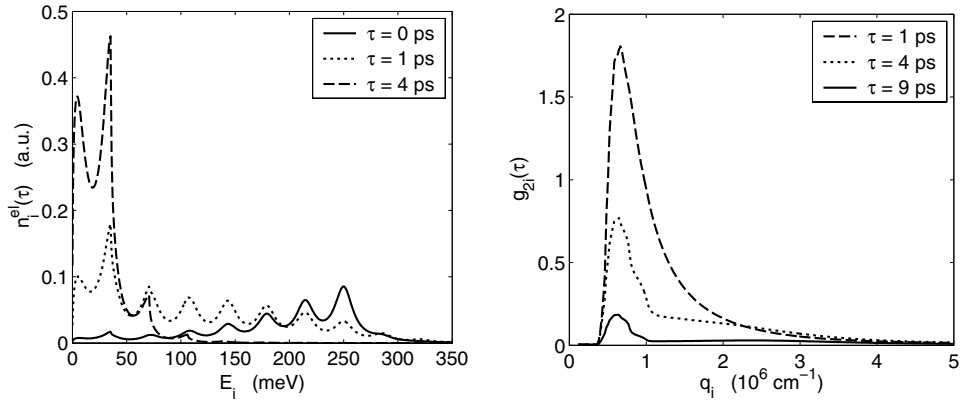

FIG. 5.2. *Particle density of electrons with energies E_i (left-hand plot) and phonon distribution function (right-hand plot) for different times during and after the laser excitation.*

rium distribution with the temperature of the phonon system. Therefore, we observe a relaxation of the hot electron gas accompanied by the emission of mainly optical phonons in accord with the much stronger interaction of electrons with polar optical phonons compared to that with acoustic phonons. Since the emission of an optical phonon always reduces the electron energy by the same constant phonon energy e_0, the electron density as a function of E_i shows a quasi-periodic structure with period e_0. The increase of optical phonons strongly depends on the modulus of the wave vector and leads to far-from-equilibrium distributions as can be seen in the right-hand plot of Figure 5.2. The dependence of $g_{2i}(\tau)$ on q_i is mainly determined by the function $s_2(q)$ and the sets $D_q^{\pm}(E, \varphi_1, \mathbf{\Omega}_k)$ defined in (3.35), which reflect the conservation laws for the involved collision processes.

Figure 5.3 displays the optical phonon distribution function for fixed values q_i and presents a comparison with data obtained from a Monte Carlo simulation [11]. Initially, the distribution functions increase due to the emission of phonons. Af-

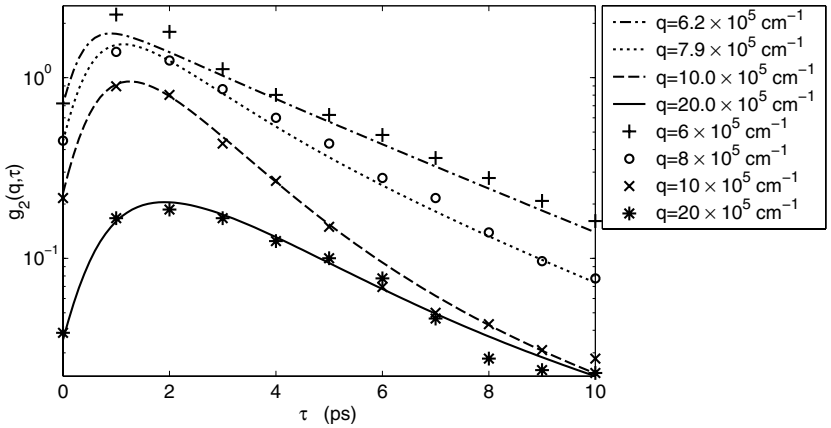

FIG. 5.3. *Distribution functions of the polar optical phonons as a function of time for different moduli of the wave vector q. The lines represent the results from the semicontinuous model equations, and the markers $+, \circ, \times, *$ display the Monte Carlo data taken from* [11].

terward, they decrease due to the phonon-phonon interaction and the reabsorption of polar optical phonons. The distribution functions for $q_i \approx 6 \times 10^5 \mathrm{cm}^{-1}$, $q_i \approx 20 \times 10^5 \mathrm{cm}^{-1}$ show an exponential decay with the time constant τ_0 as a result of the relaxation time approximation of the phonon-phonon interaction. In the case of $q_i \approx 10 \times 10^5 \mathrm{cm}^{-1}$ the reabsorption is very efficient and gives rise to a reinforced decrease of $g_{2i}(\tau)$ as compared to that for smaller and higher q-values. A more detailed discussion of the Monte Carlo results can be found in [11]. The results of our calculation are in good agreement with the Monte Carlo data. The dominant kinetic effect, i.e., the strong reabsorption of polar optical phonons, shows up in both treatments.

As a consequence of the weak interaction of electrons with acoustic phonons, the influence of such phonons on the electrons is negligible in the considered time interval. Taking into account the acoustic phonons, however, prevents the occurrence of decoupling effects of the kinetic equations (2.1) and (2.2) as treated in [12].

To summarize, we find that the semicontinuous model equations are able to accurately describe the kinetics of far-from-equilibrium systems. Numerical results on relaxation processes are obtained by standard methods. The calculations can be performed on a PC with a small consumption of CPU-time. We find that the physical conservation laws are satisfied within numerical roundoff errors. Our formulation is quite general regarding dispersion relations and flexible concerning the modeling of collision processes. It can be extended, e.g., by taking into account electron-electron interaction, phonon-phonon interaction, or impurity scattering.

STEREOGRAPHIC COMBING A PORCUPINE OR STUDIES ON DIRECTION DIFFUSION IN IMAGE PROCESSING*

NIR A. SOCHEN†, CHEN SAGIV†, AND RON KIMMEL‡

Abstract. This paper addresses the problem of feature enhancement in noisy images when the feature is known to be constrained to a manifold. As an example, we approach the direction denoising problem in a general dimension via the geometric Beltrami framework for image processing. The spatial-direction space is a fiber bundle in which the spatial part is the base manifold and the direction space is the fiber. The feature (direction) field is represented accordingly as a section of the spatial-feature fiber bundle. The resulting Beltrami flow is a selective smoothing process that respects the bundle's structure, i.e., the feature constraint. Direction diffusion is treated as a canonical example of a non-Euclidean feature space. The structures of the fiber spaces of interest in this paper are the unit circle S^1, the unit sphere S^2, and the unit hypersphere S^n. Applications to color analysis are discussed, and numerical experiments demonstrate again the benefits of the Beltrami framework in comparison to other feature enhancement schemes for nontrivial geometries in image processing.

1. Introduction.

Many objects of low-level vision are vector fields of various types. This is the case for gray-value images, color images, movies, 3D (three-dimensional) volumetric images, and disparity in stereo vision, to name just a few examples. These vector fields are traditionally considered as taking values in $\mathbb{R}^n$. Operations on these fields such as denoising, enhancement, sharpening, and segmentation are done using a variety of algorithms. Several types of vector fields are constrained in a nontrivial way. When the constraint can be expressed via the vanishing of a smooth function, e.g., a polynomial, the vector fields take their values in a non-Euclidean space. One notable example is the direction vector field which assigns a local direction to each pixel in the image. These directions are unit length vectors that span the unit n-dimensional sphere S^n. Other classes of non-Euclidean vector fields are perceptually treated color images [20] and the regularization of frames [23]. We study in this paper the n-dimensional direction vector fields and spherically constrained color models via the Beltrami framework [19].

The basic objects in the Beltrami framework are embedding maps of Riemannian manifolds. These maps embed the image manifold (a surface for a 2D image) in a fiber bundle whose base is the spatial manifold, e.g., $\mathbb{R}^2$, and the fiber is the feature manifold, e.g., $\mathbb{R}^1$, for the intensity feature alone. If we denote by F the feature manifold and assume that the image is given on a flat surface, then the spatial-feature manifold M is given locally as $M = \mathbb{R}^2 \otimes F$. In all the examples below, the

fiber bundle is trivial, yet our local treatment extends to nontrivial bundles as well. Global issues of nontrivial fiber bundles are beyond the scope of this paper.

Another important ingredient of the Beltrami framework is a geometrical functional, known as the Polyakov action (or harmonic energy [1]), which is defined over the space of embedding maps. The minimization of the Polyakov action is done by an Euler–Lagrange operator that drives, through a gradient descent equation, the initial noisy feature vector fields towards a minimum of the Polyakov action. The special form of this functional favors piecewise smooth images. Jumps in the feature space (feature edges) are consequently preserved [4, 5].

Almost all works that try to minimize a functional with respect to a constraint quantity embed the constrained feature in a higher-dimensional Euclidean space and perform the minimization for the coordinates of this unconstrained space. The common wisdom is to combine a minimization of an unconstrained function and a projection on the constraint variety/manifold. The treatment of direction diffusion was recently addressed along these lines in the low-level vision community. These studies follow the well established literature in the liquid crystal community [3]. The harmonic energy functional and its minimization are subjects to intensive mathematical study as well [6, 7]. Two approaches for this problem are known: in a paper that first directly addresses this issue, Perona [13] uses a single parameter θ as an internal coordinate in S^1. The second approach [21, 22, 2] embeds the unit circle S^1 in $\mathbb{R}^2$ (the sphere S^2 in $\mathbb{R}^3$) and works with the external coordinates; see also [24] for a related effort. The first approach is problematic because of the periodicity of S^1. Averaging small angles around zero such as $\theta = \epsilon$ and $\theta = 2\pi - \epsilon$ leads to the erroneous conclusion that the average angle is $\theta = \pi$. Perona solved this problem by exponentiating the angle so that $V = e^{i\theta}$. This is actually the embedding of S^1 in $\mathbb{C}$ which is isometric to $\mathbb{R}^2$. This method is specific to a 2D embedding space where complex numbers can be used. The problem in using only one internal coordinate manifests itself in the numerical implementation of the PDE through the breaking of rotation invariance. In the second approach we have to make sure that we always stay on S^1 along the flow. This problem is known as the projection problem. It is solved in the continuum by adding a projection term. Tang, Sapiro, and Caselles [21, 22] propose the formalism of p-harmonic maps applied to the case of direction and color diffusion, and present experiments in the case $p = 2$, which corresponds to the Dirichlet integral. Moreover, they also present experiments for the case $p = 1$ as the immediate extension of the Rudin–Osher–Fatemi total variation (TV) denoising algorithm [14] to the case of general maps with values on manifolds. Nevertheless, they did not study in detail the algorithm for the $p = 1$ case. The algorithmic study for the case $p = 1$ was done by Chan and Shen [2], who also use external coordinates with a projection term and a TV measure in order to better preserve discontinuities in the vector field. This works well for the case where the codimension is one, like a circle. Yet it is difficult to generalize this approach to higher codimensions like the sphere. Moreover, the flow of the external coordinates is difficult to control numerically since numerical errors should be projected onto S^1 and since no well-defined projection exists. Recently an implicit way to define manifolds has been used in this context [1]. We concentrate in this paper on the explicit methods. A comparison between the implicit harmonic energy method and the implicit Beltrami framework can be found in [16].

We propose to work directly on the constrained manifold and to avoid the projection problem altogether. Our solution produces an adaptive smoothing process, which preserves direction discontinuities. The proposed solution works for all dimensions and codimensions, and overcomes possible parameterization singularities by introducing

several internal coordinates on different patches (charts) such that the union of the patches is the feature manifold, i.e., S^n. Adaptive smoothness is achieved by the description of the vector field as a 2D section of the $(n+2)$-dimensional spatial-feature fiber bundle manifold with S^n fibers.

The problem is formulated, in the Beltrami framework [19, 9], in terms of the embedding map

$$Y : (\Sigma, g) \to (M, h),$$

where Σ is the 2D image manifold and M, in this case, is $\mathbb{R}^n \otimes S^1$ with $n = 2$ ($n = 4$) for gray-level (color) images. The key point is the choice of *local coordinate systems* for *both* manifolds,[1] the image manifold Σ (with metric g) and the embedding manifold M (with metric h). At the same time we should verify that the geometric filter (i.e., the denoising PDE) does not depend on the specific choice of coordinates we make.

Once a local coordinate system is chosen for the embedding space and the optimization is done directly in this local coordinate system, we can never leave M and avoid the problem of projection. The difficulty represented in the problem of projection is transformed into the problem of the choice of a local coordinate system, as we describe below. Other examples of enhancement by the Beltrami framework of nonflat feature spaces, like the color perceptual space and the derivatives vector field, can be found in [20, 17].

An important issue in this approach is the numerical consideration in the choice of local coordinates. While all coordinates are equally good from analytic and geometric points of view, they are different from a numeric standpoint. A comparative study on the numerical and algorithmic accuracies of different schemes is presented here and shows that, for a range of parameters, one can get a better numerical accuracy while maintaining the edge preserving quality of the anisotropic diffusions.

This paper is organized as follows. We review the Beltrami framework and point to the relation with harmonic maps in section 2. We analyze the case of the general n-dimensional direction diffusion with hemispheric coordinate system in section 3. A stereographic coordinate system is introduced in section 4, and the appropriate equations are derived. Section 5 deals with the numerical implementation of the ideas presented in the previous sections for color image processing. Section 6 presents results on various vector fields and color images. We compare in section 7 different direction diffusion schemes from numerical and algorithmic points of view. We summarize and conclude in section 8.

2. The Beltrami framework. Let us briefly review the Beltrami geometric framework for nonlinear diffusion in computer vision [19].

2.1. Representation and Riemannian structure. An image, and many other quantities of interest in computer vision, are naturally represented via the concept of a fiber bundle. The image domain is the base manifold. In the present study it is taken as a subset of $\mathbb{R}^2$ with the canonical Cartesian coordinate system (Y^1, Y^2). It is denoted by Ω. At each point in the base manifold we attach a feature space—the fiber. The fibers at different points of the base manifold are isomorphic. The fiber space is denoted by F. The feature space, or fiber, may be a linear vector space or more interestingly a Riemannian manifold. An image (or other quantity of interest)

[1] Note the difference between this approach and the one presented in [21, 22, 2], where the image metric is flat.

is a choice of a particular point in the fiber for every point in the base manifold. Such a particular choice is called *a section* of the (trivial) fiber bundle $\Omega \otimes F$.

In general an n-dimensional (Riemannian) manifold is defined by a collection of maps from charts of the manifold to $\mathbb{R}^n$. Each chart covers part of the manifold. Their union covers the whole manifold, and the transformation of the coordinates on the intersection between any two charts is smooth. The Riemannian structure transforms in a proper way (as a tensor) under any change of the coordinate system. We denote the coordinates on the 2D section by (x^1, x^2), the coordinates on a chart of the embedding space (the fiber bundle) by $(Y^1, \ldots, Y^n)$. The embedding space is a hybrid spatial-feature space. The first two coordinates (Y^1, Y^2) are the spatial coordinates on Ω (the base manifold), and the rest $(Y^3, \ldots, Y^n)$ are the feature coordinates (the fiber's coordinates). The simplest example is a gray-value image which is represented as a 2D surface embedded in $\mathbb{R}^3$. We denote the map by $Y : \Sigma \to \mathbb{R}^3$, where Σ is a 2D section. The map Y is given in our example by $(Y^1 = x^1,\ Y^2 = x^2,\ Y^3 = I(x^1, x^2))$. We choose on this surface a Riemannian structure, namely a metric. Note that this differs from the harmonic energy functional, where the metric is taken from the base manifold and not from the section. The metric is a positive definite and a symmetric 2-tensor that may be defined through the local distance measurements

$$ds^2 = g_{11}(dx^1)^2 + 2g_{12}dx^1dx^2 + g_{22}(dx^2)^2. \tag{2.1}$$

We use the Einstein summation convention in which the above equation reads as $ds^2 = g_{\mu\nu}dx^\mu dx^\nu$, where repeated indices are summed over. We denote the inverse of the metric by $g^{\mu\nu}$.

2.2. Image metric selection: The induced metric. A reasonable assumption is that distances measured in the embedding spatial-feature fiber bundle, such as distances between pixels and differences between gray-levels, correspond directly to distances measured on the image manifold, i.e., the section. This is the assumption of isometric embedding under which we can calculate the image metric in terms of the embedding maps Y^i and the embedding space metric h_{ij}. This follows directly from the fact that the length of infinitesimal distances on the manifold can be calculated on the manifold and on the embedding space with the same result. Formally, $ds^2 = g_{\mu\nu}dx^\mu dx^\nu = h_{ij}dY^i dY^j$. By the chain rule, $dY^i = \partial_\mu Y^i dx^\mu$, we get $ds^2 = g_{\mu\nu}dx^\mu dx^\nu = h_{ij}\partial_\mu Y^i \partial_\nu Y^i dx^\mu dx^\nu$, from which we have

$$g_{\mu\nu} = h_{ij}\partial_\mu Y^i \partial_\nu Y^j. \tag{2.2}$$

As an example we take the gray-level image as a 2D image manifold embedded in the 3D Euclidean space $\mathbb{R}^3$. The embedding maps are

$$(Y^1(x^1, x^2) = x^1,\ Y^2(x^1, x^2) = x^2,\ Y^3(x^1, x^2) = \beta I(x^1, x^2)). \tag{2.3}$$

The scaling factor β defines the ratio between distances in gray-values and distances in the spatial space. It is a free parameter of the framework that interpolates between the Euclidean L_2 and L_1 types of flows, as we will see below. We choose to parameterize the image manifold by the canonical coordinate system $x^1 = x$ and $x^2 = y$. The embedding, by abuse of notation, is $(x, y, \beta I(x, y))$. The induced metric element g_{11} is calculated as follows:

$$g_{11} = h_{ij}\partial_{x^1} Y^i \partial_{x^1} Y^j = \delta_{ij}\partial_x Y^i \partial_x Y^j = \partial_x x \partial_x x + \partial_x y \partial_x y + \partial_x \beta I \partial_x \beta I = 1 + \beta^2 I_x^2. \tag{2.4}$$

Other elements are calculated in the same manner. The result is

$$G = (g_{\mu\nu}) = \begin{pmatrix} 1+\beta^2 I_x^2 & \beta^2 I_x I_y \\ \beta^2 I_x I_y & 1+\beta^2 I_y^2 \end{pmatrix}. \tag{2.5}$$

2.3. Polyakov action: A measure on the space of embedding maps. Denote by (Σ, g) the image manifold and its metric, and by (M, h) the space-feature manifold and its metric. Then the functional $S[\cdot,\cdot,\cdot]$ attaches a real number to a map $Y : \Sigma \to M$,

$$S[Y^i, g_{\mu\nu}, h_{ij}] = \int dV ||\nabla \vec{Y}||^2_{h,g}, \tag{2.6}$$

where dV is a volume element and the integration is over the Riemannian Frobenius norm[2] of the tangent map dY. In a local coordinate system the volume element is expressed by $dV = dx^1 dx^2 \sqrt{g}$ and $||\nabla \vec{Y}||^2_{h,g} = \langle \nabla Y^i, \nabla Y^j \rangle_g h_{ij} = g^{\mu\nu} \partial_\mu Y^i \partial_\nu Y^j h_{ij}$. The Polyakov action is expressed in this local system of coordinates as

$$S[Y^i, g_{\mu\nu}, h_{ij}] = \int dx^1 dx^2 \sqrt{g} g^{\mu\nu} \partial_\mu Y^i \partial_\nu Y^j h_{ij}. \tag{2.7}$$

This functional, for $m = 2$ (a 2D image manifold) and $h_{ij} = \delta_{ij}$, was proposed by Polyakov [12] in the context of high energy physics and the theory known as *string theory*. It is important to note that the image metric and the feature coordinates—i.e., intensity, color, direction, etc.—are independent variables. This functional is the natural generalization of the L_2 norm from Euclidean domains to Riemannian manifolds. The minimization of the functional with respect to the image metric can be solved analytically in the 2D case (see, for example, [18]). The minimizer is the induced metric. If we choose, a priori, the image metric induced from the metric of the embedding spatial-feature space M, then the Polyakov action is reduced to the area (volume) of the image manifold:

$$S[Y^i, h_{ij}] = 2\int dV = 2\int dx^1 dx^2 \sqrt{g} = 2\int dx^1 dx^2 \sqrt{\det(\partial_\mu Y^i \partial_\nu Y^j h_{ij})}. \tag{2.8}$$

This follows from the form of the induced metric,

$$\langle \nabla Y^i, \nabla Y^j \rangle_g h_{ij} = g^{\mu\nu} \partial_\mu Y^i \partial_\nu Y^j h_{ij} = g^{\mu\nu} g_{\mu\nu}$$

and the identity

$$g^{\mu\nu} g_{\mu\nu} = \mathrm{Tr}(G^{-1} G^T) = \mathrm{Tr}(G^{-1} G) = \mathrm{Tr}(\mathrm{Id}) = 2, \tag{2.9}$$

where $\mathrm{Tr}(X)$ denotes the trace of the matrix X.

Using standard methods in the calculus of variations (see [18]), the Euler–Lagrange equations with respect to the embedding are

$$-\frac{1}{2\sqrt{g}} h^{il} \frac{\delta S}{\delta Y^l} = \frac{1}{\sqrt{g}} \partial_\mu (\sqrt{g} g^{\mu\nu} \partial_\nu Y^i) + \Gamma^i_{jk} \langle \nabla Y^j, \nabla Y^k \rangle_g. \tag{2.10}$$

Since $(g_{\mu\nu})$ is positive definite, $g \equiv \det(g_{\mu\nu}) > 0$ for all x^μ. This factor is the simplest one that does not change the minimization solution while giving a reparameterization

[2]By Riemannian Frobenius norm we mean that the square of the elements is with respect to the Riemannian structures of the corresponding Riemannian manifolds.

invariant expression. The operator that is acting on Y^i in the first term is the natural generalization of the Laplacian from flat spaces to manifolds and is called *the second order differential operator of Beltrami* [10], or the *Beltrami operator*, and is denoted by Δ_g. The second term involves the Levi–Civita connection whose coefficients are the Christoffel symbols. The coefficients are given in terms of the metric of the embedding space

$$\Gamma^i_{jk} = \frac{1}{2} h^{il} \left(\partial_j h_{lk} + \partial_k h_{jl} - \partial_l h_{jk} \right). \tag{2.11}$$

This is the term that takes into account the fact that the image surface flows in a non-Euclidean manifold and not in $\mathbb{R}^n$.

A map that satisfies the Euler–Lagrange equations $-\frac{1}{2\sqrt{g}} h^{il} \frac{\delta S}{\delta Y^l} = 0$ is a *harmonic map*. The 1D and 2D examples are a geodesic curve on a manifold and a minimal surface.

The nonlinear diffusion or scale-space equation emerges as the gradient descent minimization flow

$$Y^i_t = \frac{\partial}{\partial t} Y^i = -\frac{1}{2\sqrt{g}} h^{il} \frac{\delta S}{\delta Y^l} = \Delta_g Y^i + \Gamma^i_{jk} \langle \nabla Y^j, \nabla Y^k \rangle_g. \tag{2.12}$$

This flow evolves a given surface towards a minimal surface, and in general it continuously changes a map towards a harmonic map.

Before closing this review of the Beltrami framework, we would like to point out a few similarities and differences between this flow and those suggested in [14, 13, 21, 2]:

1. For flat fibers:
   - We use the induced metric, while in other flows the image metric is flat. The difference comes from the fact that in our framework the image manifold is a *section* of the fiber bundle, while in the harmonic map formulation it is the *base* manifold.
   - In the case of flat and 1D fibers we get the "regularized total variation" functional. In the limit of large β the evolution equation is identical (up to $\sqrt{g}$) to the TV one. In the limit $\beta \to 0$ we get the linear diffusion case. In intermediate values we find a good compromise such that over-smoothing, on the one hand, and stair-casing, on the other hand, can be avoided. The Beltrami framework, in this case, is a one-parameter generalization of the TV scheme.
   - The multichannel functional, in the Beltrami framework, is another generalization of the TV functional. A term that depends on the direction of the gradients is added to the term that depends on their magnitude only. This provides a better adaptation of the process to the image features.
   - The Beltrami flow is degenerate (at $\nabla I \to \infty$). One can prove that discontinuities are preserved for a finite time [5].
2. For nonflat fibers:
   - The coordinates Y^i are the local coordinates of the feature space, while in the above-mentioned flows they are coordinates of a *third* manifold, i.e., $\mathbb{R}^{n+1}$, in which the feature space S^n is embedded. In other words, the fiber in the harmonic map approach is embedded in $\mathbb{R}^{n+1}$. This is not possible in general (see the Nash embedding theorem [11]).
   - The Polyakov functional is different in this case from the TV functional due to the different weighting of the magnitude of the gradients.

- The flow equation (2.12) has a clear geometric meaning. It is a mean curvature flow projected (analytically) on the fiber. This projection is an edge preserving operation [19]. It depends on ∇I in the general multichannel case and not on $|\nabla I|$ as in the harmonic map approach.

3. Hemispheric direction diffusion.

3.1. Fiber geometry. We are interested in the case where the fiber feature space is the hypersurface S^n. We choose to represent the hypersphere S^n as an n-dimensional manifold embedded in $\mathbb{R}^{n+1}$, with Cartesian coordinate system $\{U^i\}_{i=3}^{n+3}$, as the constrained hypersurface

$$\sum_{i=3}^{n+3}(U^i)^2 = 1. \tag{3.1}$$

We work in the chart, where $\{Y^i\}_{i=3}^{n+2}$ are local coordinates. On this chart, $U^i = Y^i$, $i = 3, \ldots, n+2$, and

$$U^{n+3} = \sqrt{1 - \sum_{i=3}^{n+2}(Y^i)^2}.$$

Denote the metric elements for the feature space only by $\tilde{h}_{ij}$. The metric elements and the inverse metric elements are given by

$$\tilde{h}_{ij} = \delta^{ij} + \frac{Y^i Y^j}{1 - \sum_{k=3}^{n+2}(Y^k)^2},$$

$$(\tilde{h}^{-1})_{ij} = \delta^{ij} - Y^i Y^j. \tag{3.2}$$

3.2. The induced metric. The induced metric and its inverse are accordingly

$$\begin{aligned} g_{\mu\nu} &= \delta_{\mu\nu} + \sum_{i,j=3}^{n+2} \tilde{h}_{ij}\partial_\mu Y^i \partial_\nu Y^j, \\ g^{\mu\nu} &= \frac{1}{g}\left(\delta^{\mu\nu} + \epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j=3}^{n+3}\tilde{h}_{ij}\partial_\sigma Y^i \partial_\rho Y^j\right), \\ g &= \det(g_{\mu\nu}), \\ &= 1 + \sum_{i,j=3}^{n+3}\tilde{h}_{ij}(Y_x^i Y_x^j + Y_y^i Y_y^j), \\ &\quad + \frac{1}{2}\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j,k,l=3}^{n+3}\tilde{h}_{ij}\tilde{h}_{kl}\partial_\mu Y^i \partial_\rho Y^j \partial_\nu Y^k \partial_\sigma Y^l, \end{aligned} \tag{3.3}$$

where $(g^{\mu\nu})$ is the inverse of $(g_{\mu\nu})$, g is the determinant, and $\epsilon^{\mu\nu}$ is the 2D antisymmetric tensor

$$(\epsilon^{\mu\nu}) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

An implicit summation on all repeated Greek indices is assumed.

3.3. The flow equations. The Levi–Civita coefficients are calculated in Appendix B with the simple result

$$\Gamma^i_{jk} = Y^i \tilde{h}_{jk}. \tag{3.4}$$

The minimization of the Polyakov action leads to the following evolution equations:

$$Y^i_t = \Delta_g Y^i + 2Y^i - Y^i \mathrm{Tr}(g^{\mu\nu}), \qquad i = 1, \ldots, n. \tag{3.5}$$

3.4. The 1D hemispheric direction diffusion.

3.4.1. The S^1 Beltrami operator. The S^1 manifold can be described as the solution to $U^2 + V^2 = 1$. We will work with two charts. One is ($Y^1 = x$, $Y^2 = y$, $Y^3 = \beta U$), and the other is ($Y^1 = x$, $Y^2 = y$, $Y^3 = \beta V$). By abuse of notation we denote the map by $(x, y, \beta Y)$. The parameter β is a scaling factor. Each one of the charts will be used in the range $Y^2 \leq 1/2$. The line element on each of the charts of the image manifold is

$$ds^2 = ds^2_{\mathbb{R}^2} + ds^2_{S^1} = dx^2 + dy^2 + \frac{\beta^2}{1 - Y^2} dY^2. \tag{3.6}$$

By using the chain rule we find

$$ds^2 = (1 + A(Y)Y_x^2)dx^2 + 2A(Y)Y_x Y_y dxdy + (1 + A(Y)Y_y^2)dy^2, \tag{3.7}$$

where $A(Y) = \frac{\beta^2}{1-Y^2}$.

The induced metric is therefore

$$(g_{\mu\nu}) = \begin{pmatrix} 1 + A(Y)Y_x^2 & A(Y)Y_x Y_y \\ A(Y)Y_x Y_y & 1 + A(Y)Y_y^2 \end{pmatrix}, \tag{3.8}$$

and the Beltrami operator acting on Y is $\Delta_g Y = \frac{1}{\sqrt{g}} \partial_\mu (\sqrt{g} g^{\mu\nu} \partial_\nu Y)$, where $g = 1 + A(Y)(Y_x^2 + Y_y^2)$ is the determinant of $(g_{\mu\nu})$, and $(g^{\mu\nu})$ is the inverse matrix of $(g_{\mu\nu})$.

3.4.2. The Levi–Civita connection. Since the embedding space is non-Euclidean, we have to calculate the Levi–Civita connection. Remember that the metric of the embedding space is

$$(h_{ij}) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & A(Y) \end{pmatrix}. \tag{3.9}$$

The Levi–Civita connection coefficients are given by the fundamental theorem of Riemannian geometry in the following formula: $\Gamma^i_{jk} = \frac{1}{2} h^{il} (\partial_j h_{lk} + \partial_k h_{jl} - \partial_l h_{jk})$, where the derivatives are taken with respect to Y^i for $i = 1, 2, 3$.

The only nonvanishing term is Γ^3_{33}, which reads

$$\Gamma^3_{33} = \frac{1}{2A(Y)} \partial_Y (A(Y)) = \frac{Y}{1 - Y^2} = Y h_{33}. \tag{3.10}$$

The second term in the Euler–Lagrange equations in this case reads $Y h_{33} ||\nabla Y||^2_g$. We can rewrite this expression using the following identities:

$$\begin{aligned} h_{33}||\nabla Y||^2_g &= (h_{11}g^{11} + h_{22}g^{22} + h_{33}\partial_\mu Y \partial_\nu Y g^{\mu\nu}) - (h_{11}g^{11} + h_{22}g^{22}) \\ &= g_{\mu\nu}g^{\mu\nu} - (g^{11} + g^{22}) = 2 - \frac{1}{g}(g_{11} + g_{22}) = 2 - \frac{1}{g}(1 + g), \end{aligned} \tag{3.11}$$

where we used the induced metric identity (2.2), and the identity (2.9), in order to rewrite

$$2 = \mathrm{Tr}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = g_{\mu\nu}g^{\mu\nu} = h_{11}g^{11} + h_{22}g^{22} + h_{33}\partial_\mu Y \partial_\nu Y g^{\mu\nu}. \tag{3.12}$$

3.4.3. The flow and the switches. The Beltrami flow is

$$Y^i_t = \Delta_g Y^i + \Gamma^i_{jk}(Y^1, Y^2, Y^3)\langle \nabla Y^j, \nabla Y^k \rangle_g \tag{3.13}$$

for $i = 3$. Only modifying the fiber values while keeping the case manifold constant is a *projection* in the direction of the fiber. This projection slows the diffusion around edges. The Beltrami flow on the two charts reads finally as

$$U_t = \Delta_g U + U\frac{g-1}{g},$$

$$V_t = \Delta_g V + V\frac{g-1}{g}. \tag{3.14}$$

In the implementation we compute the diffusion for U and V simultaneously and take the values $(U, \mathrm{sign}(V)\sqrt{1-U^2})$ for the range $U^2 \le V^2$, and $(\mathrm{sign}(U)\sqrt{1-V^2}, V)$ for the range $V^2 \le U^2$.

4. Stereographic direction diffusion.

4.1. Fiber geometry. The hemispheric parameterization requires more charts as n increases. As a result we have to work closer and closer to the singularity. As a cure for that we switch to stereographic parameterization, which demands only two charts independent of the dimension of the sphere. Moreover, we always work on the furthest point from the singularity, that is, on the equator.

Every hypersphere S^n can be isometrically embedded in $\mathbb{R}^{n+1}$. The hypersphere is realized as the place of all the points in $\mathbb{R}^{n+1}$ that satisfy the constraint $\sum_{i=1}^{n+1} U^i U^i = 1$. We denote by Y^i for $i = 1, \ldots, n$ the Cartesian coordinate system on the subspace $\mathbb{R}^n$ that passes through the equator of S^n, i.e., $\{\vec{U} \in \mathbb{R}^{n+1} | U^{n+1} = 0\}$. The stereographic transformation gives the values of Y^i as functions of the points on the north (south) hemispheres of the hypersphere. Explicitly it is given (after shifting the indices by two for notation consistent with the next sections) as

$$Y^i = \frac{U^i}{1 - U^{n+3}}, \quad i = 3, \ldots, n+2.$$

Inverting these relations, we find

$$U^i = \frac{2Y^i}{1 + \sum_{i=1}^n Y^i}, \quad i = 3, \ldots, n+2,$$

$$U^{n+3} = \frac{-1 + \sum_{i=3}^{n+2} Y^i}{1 + \sum_{i=3}^{n+2} Y^i}. \tag{4.1}$$

4.2. The induced metric. Now we can compute the induced metric of our feature space

$$h_{ij} = \sum_{k=3}^{n+3} \frac{\partial U^k \partial U^k}{\partial Y^i \partial Y^j} = \frac{4}{(1+A)^2}\delta_{ij}, \quad i, j = 3, \ldots, n+2, \tag{4.2}$$

where $A = \sum_{k=3}^{n+2} (Y^k)^2$.

4.3. The flow equations. The Levi–Civita connection can be obtained using (2.11) and (4.2). The result is

$$\Gamma^i_{jk} = \frac{4}{1+A}\left(Y^i\delta_{jk} - Y^k\delta_{ij} - Y^j\delta_{ki}\right).$$

The resulting diffusion equations are

$$Y^i_t = \Delta_g Y^i + \sum_{jk} \frac{4}{1+A}\left(Y^i\delta_{jk} - Y^k\delta_{ij} - Y^j\delta_{ki}\right)\partial_\mu Y^j \partial_\nu Y^k g^{\mu\nu}, \tag{4.3}$$

where $i = 3, \ldots, n+2$. This can be rearranged to

$$Y^i_t = \Delta_g Y^i - 4g^{\mu\nu}(\partial_\mu \log(1+A))(\partial_\nu Y^i) + (1+A)(2 - g^{11} - g^{22})Y^i. \tag{4.4}$$

4.4. 1D and 2D directions. We denote our coordinate system by the subscripts s (for south) and n (for north). The equations for the 1D case read

$$(Y_s)_t = \Delta_g Y_s - 4g^{\mu\nu}(\partial_\mu \log(1+A))(\partial_\nu Y_s) + (1+A)(2 - g^{11} - g^{22})Y_s, \tag{4.5}$$

where $A = Y_s^2$ and the induced metric is a function of Y_s. A parallel equation is written for Y_n. We solve the north and south equations simultaneously for values *smaller* than 1. At each iteration we update the values which are greater than 1 by the simple relation $Y_s = 1/Y_n$. Note that the problematic zone(s), i.e., ± 1, are as far as possible from the singularities, i.e., the poles.

The 2D case is managed similarly via

$$\begin{aligned}(Y^1_s)_t &= \Delta_g Y^1_s - 4g^{\mu\nu}(\partial_\mu \log(1+A_s))(\partial_\nu Y^1_s) + (1+A_s)(2 - g^{11} - g^{22})Y^1_s,\\ (Y^2_s)_t &= \Delta_g Y^2_s - 4g^{\mu\nu}(\partial_\mu \log(1+A_s))(\partial_\nu Y^2_s) + (1+A_s)(2 - g^{11} - g^{22})Y^2_s,\end{aligned} \tag{4.6}$$

where $A_s = (Y^1_s)^2 + (Y^2_s)^2$ and the induced metric depends on Y^1_s and Y^2_s. As in the 1D case, we solve simultaneously for the south and north patches and work with Y^i's which are smaller than 1. The update for values that are greater than 1 after the diffusion (in each iteration) is done by $Y^i_s = A_s Y^i_n$. Again the decision zone, i.e., the equator, is the most numerically stable region since it is the furthest from the poles, where singularities may appear.

5. Color diffusion. There are many coordinate systems and models of color space which try to be as close as possible to human color perception. One of the popular coordinate systems is the HSV system [15]. In this system, color is characterized by hue, saturation, and value. The saturation and value take their values in $\mathbb{R}^+$, while the hue is an angle that parameterizes S^1.

In order to denoise and enhance color images by a nonlinear diffusion process which is more adapted to human perception, we use here the HSV system. We need a special treatment of the hue coordinate in section 3.

Let us represent the image as a mapping $\mathbf{Y} : \Sigma \to \mathbb{R}^4 \times S^1$, where Σ is the 2D image surface and $\mathbb{R}^4 \times S^1$ is parameterized by the coordinates (x, y, H, S, V). As mentioned above, a diffusion process in this coordinate system is problematic. We define therefore two coordinates,

$$U = \cos H \qquad \text{and} \qquad W = \sin H,$$

and continue in a way similar to section 3. The metric of $\mathbb{R}^4 \times S^1$ on the patch where U parameterizes S^1 and $W(U)$ is nonsingular is

$$h_{ij} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & A(U) & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \tag{5.1}$$

where $A(U) = 1/(1 - U^2)$.

The induced metric is therefore

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + A(U)dU^2 + dS^2 + dV^2 \\ &= dx^2 + dy^2 + A(U)(U_x dx + U_y dy)^2 + (S_x dx + S_y dy)^2 + (V_x dx + V_y dy)^2 \\ &= (1 + A(U)U_x^2 + S_x^2 + V_x^2)dx^2 \\ &\quad + 2(A(U)U_x U_y + S_x S_y + V_x V_y)dxdy + (1 + A(U)U_y^2 + S_y^2 + V_y^2)dy^2. \end{aligned} \tag{5.2}$$

Similar expressions are obtained on the other dual patch.

The only nonvanishing Levi–Civita connection coefficient is $\Gamma^3_{33} = U h_{33}$. The resulting flow is

$$\begin{aligned} U_t &= \Delta_g U + 2U - U(g^{11} + g^{22}), \\ W_t &= \Delta_g W + 2W - W(g^{11} + g^{22}), \\ S_t &= \Delta_g S, \\ V_t &= \Delta_g V. \end{aligned} \tag{5.3}$$

Note that the switch between U and W should be applied not only to the U and W equations but also to the S and V evolution equations where, at each point, one needs to work with the metric that is defined on one of the patches.

6. Experimental results. Our first example deals with the gradient direction flow via the Beltrami framework. Figure 6.1 shows a vector field before and after the application of the flow for a given evolution time. The normalized gradient vector field extracted from the image is presented before and after the flow and shows the way the field flows into a new smooth direction transactions field.

Our second example deals with color diffusion using different color spaces. We use machine color space as our spectral model, where we first restrict the colors to one quarter of the upper hemisphere defined around the black point in the RGB space, as shown in Figure 6.2. In this example we use the hemispheric direction diffusion. The intensity, or more accurately the magnitude, is handled separately. This is a simple example since a single chart can be used as a parameterization, and indeed this simplified version was often used by others as an example.

Next, we explore a popular model that captures some of our color perception. The HSV (hue, saturation, value) model proposed in [15] is often used as a "user-oriented" color model, rather than the RGB "machine-oriented" model.

Figure 6.3 shows the classical representation of the HSV color space, in which the hue is measured as an angle, while the value (sometimes referred to as brightness) and the color saturation are mapped onto finite nonperiodic intervals. This model lands itself into a filter that operates on the spatial x, y coordinates, the value and saturation coordinates, and the hue periodic variable. Our image is now embedded in $\mathbb{R}^4 \times S^1$.

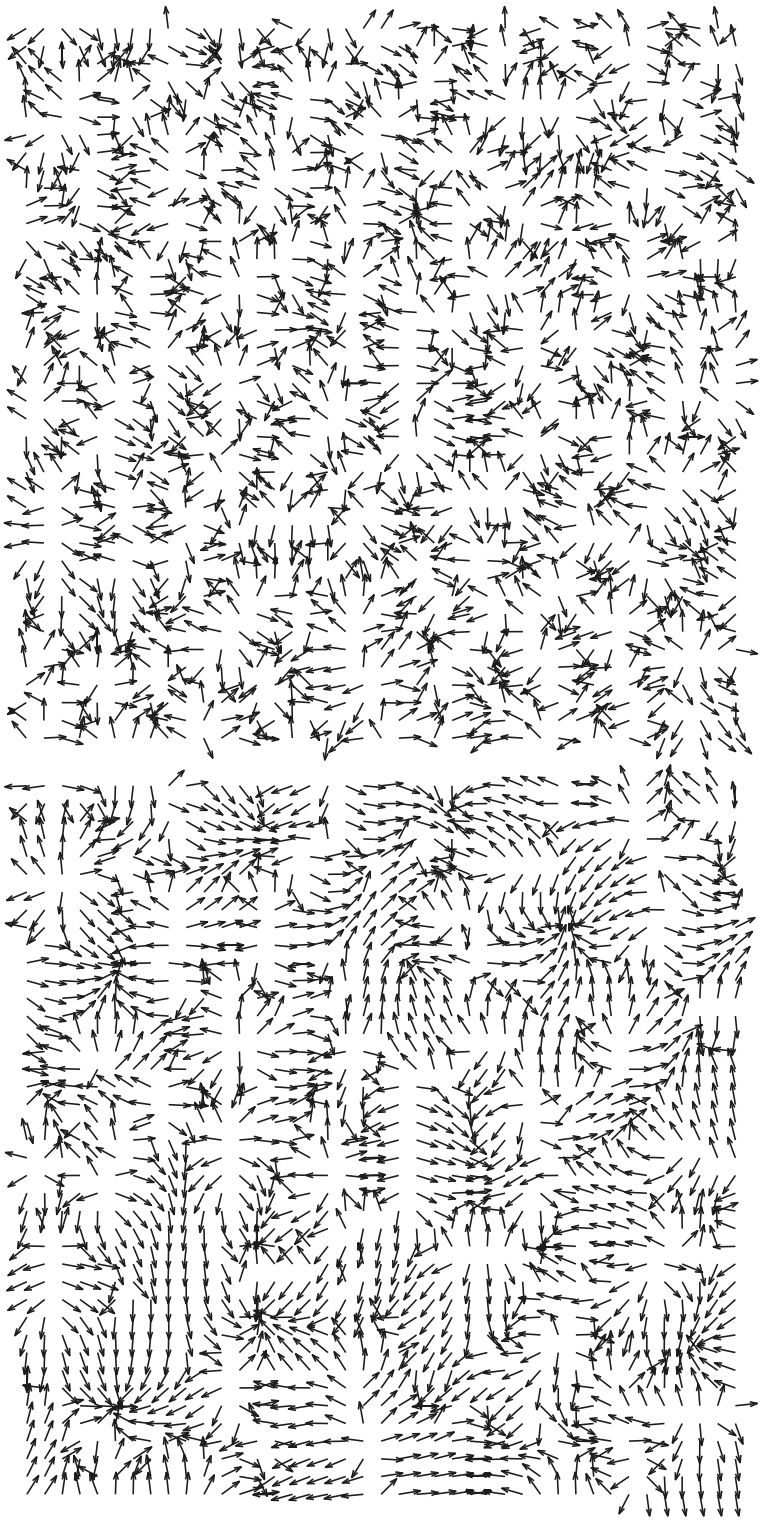

FIG. 6.1. *Two vector fields before (upper) and after (lower) the flow on* S^1.

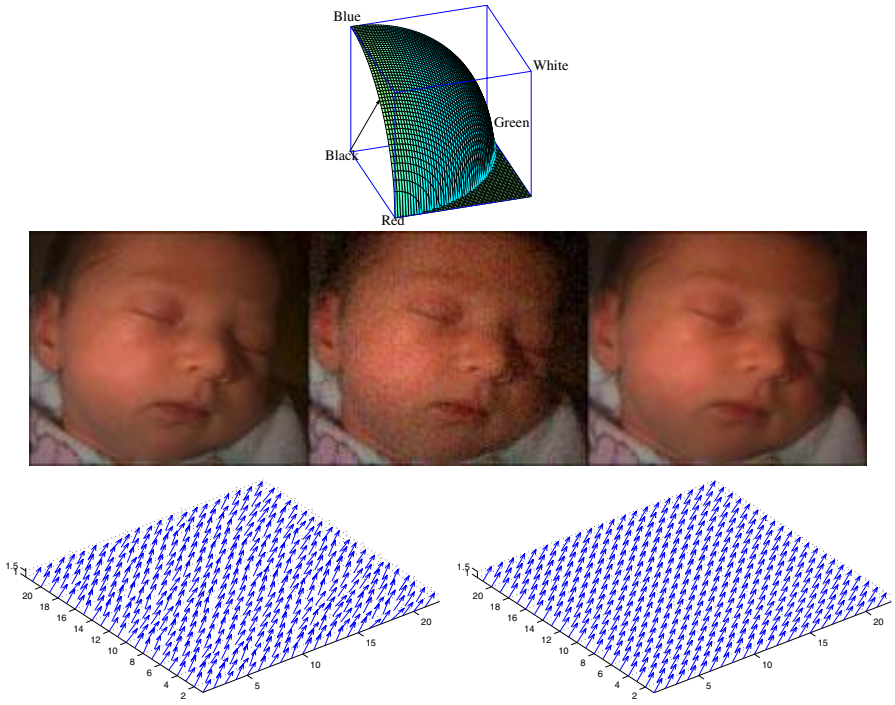

FIG. 6.2. *The colors are restricted to one quarter of the upper hemisphere defined around the black point in the RGB space.*

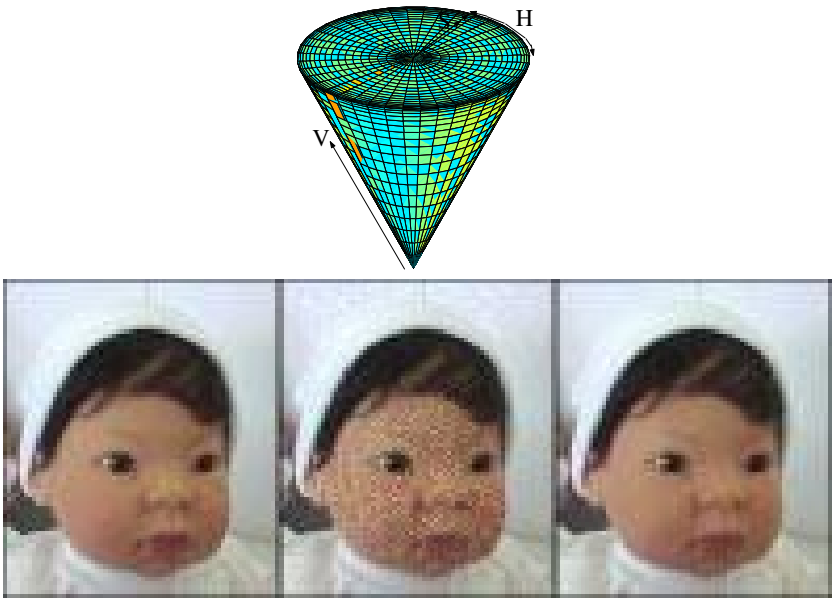

FIG. 6.3. *The HSV color model captures human color perception better than the RGB model which is the common way our machines represent colors. The original image (left), the noisy image (middle), and the filtered image (right) demonstrate the effect of the flow as a denoising filter in the HSV color space when using hemispheric coordinates.*

FIG. 6.4. *An example of stereographic direction diffusion used in the HSV color space. The original image (left), the noisy image (middle), and the filtered image (right) demonstrate the effect of the flow as a denoising filter in the HSV color space when using stereographic coordinates.*

We use the hemispheric direction diffusion for the results shown in Figure 6.3 and the stereographic direction diffusion for the results shown in Figure 6.4. For the complete set of full-size color images see http://www.math.tau.ac.il/∼sochen/Porcupine/porcupine.html.

7. Comparison to other schemes. Several schemes have been suggested to handle direction diffusion. The first to directly address this issue was Perona [13], who uses a single parameter θ as an internal coordinate. However, the periodicity of S^1 leads to erroneous values of θ. Another approach, the linear approach, was offered by Tang, Sapiro, and Caselles [21], in which the unit circle S^1 is embedded in R^2 and external coordinates are used. However, in this flow we have to actively keep our coordinates on S^1, which means that we have to project the results on the unit circle. Chan and Shen [2] studied in detail another scheme in which the evolution equation is derived according to the TV measure.

Kimmel and Sochen [8] have proposed an adaptive hemispheric smoothing scheme, which is edge preserving, based on the Beltrami framework [19]. Throughout this section this scheme is referred to as HP (hemispheric porcupine). The direction vector field is described as a 2D manifold embedded in a higher-dimensional space $M = R^2 \times S^1$. The key point in the HP scheme is the selection of local coordinate systems on the manifold, so that their union is S^1. On the other hand, the local coordinates selection is done so that the numerical error is minimized. The advantage of this scheme is that throughout the flow the coordinates are constrained to S^1. Thus, there is no need for a supplementary projection stage. We address in this work the issue of selecting the right charts to cover S^1, and an alternative stereographic coordinate system is proposed. In this paper we refer to this scheme as SP (stereographic porcupine).

In this study we compare the numerical behavior of the above-mentioned schemes, evaluate their algorithmic performance, and examine their edge preserving quality.

7.1. The evolution equations. In this subsection we mention the evolution equations for each scheme. The interested reader is referred to the original articles.

As a first step, the direction θ is embedded in R^2 via the map $\theta \to \omega = [\cos(\theta), \sin(\theta)]$. The plane is then diffused for some time t, and the result is projected back to the unit circle via the map $\omega_t = [x, y] \to \arctan(\frac{y}{x})$. This is if (x, y) is still a one unit vector. If not, then the phase of the vector is used to determine the appropriate projection; see Figure 7.1.

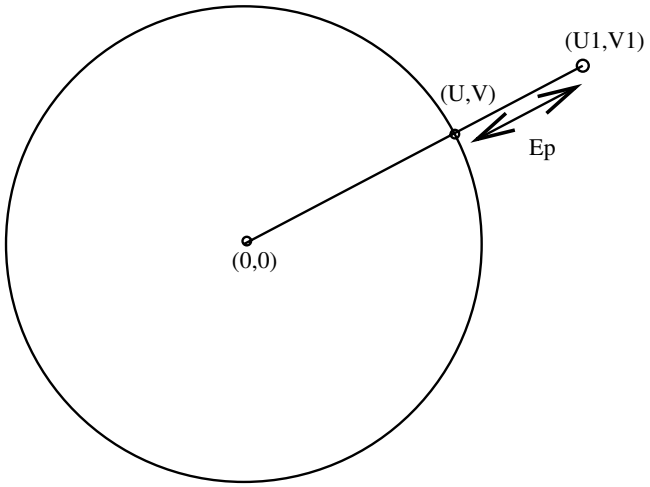

FIG. 7.1. *The projection error in the linear and TV schemes.*

Tang, Sapiro, and Caselles [21] use the following flow for an L_2 energy (which results in a linear scheme),

$$f_t = \Delta f + \| \bigtriangledown f \|^2 f, \tag{7.1}$$

where f stands for the pair (U, V).

Chan and Shen [2] use the following flow for the TV energy:

$$f_t = \text{div}\left(\frac{\bigtriangledown f}{\|f\|}\right) + \| \bigtriangledown f \| f, \tag{7.2}$$

where f stands for the pair (U, V).

Kimmel and Sochen [8] use the following equation for the HP scheme:

$$u_t = \Delta_g U + U \cdot \frac{g-1}{g}, \tag{7.3}$$

$$v_t = \Delta_g V + V \cdot \frac{g-1}{g}, \tag{7.4}$$

where $g = 1 + A(U)((U_x)^2 + (U_y)^2)$ and $A(U) = \frac{1}{1-U^2}$. The SP scheme is given by the following equation:

$$Z_t = \Delta_g Z - 4g^{\mu\nu}(\partial_\mu log(1+A))(\partial_\nu Z) + (1+A)(2 - g^{11} - g^{22})Z, \tag{7.5}$$

where a stereographic coordinate system is used. Here $A = Z^2$, and Z stands for both north and south coordinates.

We remark that in the HP and SP schemes, according to the Beltrami framework, images are considered as surfaces rather than functions. The related diffusion scheme minimizes the area of the image surface. Thus, a basic concept in the Beltrami framework is the manifold's metric. In order to construct a valuable geometric measure for a direction image we have to combine the spatial coordinates with the direction

information. The simplest combination is done by introducing a scaling parameter β, so that

$$ds^2 = dx^2 + dy^2 + \beta^2 \frac{1}{1-U^2} dU^2.$$

The parameter β has dimensions $[\frac{distance}{direction}]$, and it fixes the relative scale between the size of direction information and spatial distances. The parameter β plays an important role in this study. It is a measure of the degree of coupling between the different channels in the diffusion flow. Higher values of β draw the scheme to a behavior similar to that of the TV scheme [2], and smaller values of β cause a behavior similar to that of the linear scheme [21].

Therefore, we expect both HP and SP schemes to have a numerical error and an edge preserving quality which depend on this parameter β.

7.2. Evaluation of the direction diffusion schemes. The evaluation of the different schemes offered for direction diffusion is based on two main attributes of these schemes. The first is their numerical and algorithmic accuracy, which is presented by their degree of error. The second is the edge preserving quality of the scheme. We use direction information which is synthetic. Then, random noise chosen from a uniform distribution on a predefined interval is added to the direction data, and each scheme is used to denoise the image. The numerical error of each scheme is calculated. The algorithmic error is also defined, as the deviation of the resultant direction from the original noise-free direction data. The edge preserving quality of each algorithm is examined on an artificial image which is composed of two different directions, and also on an image which combines a slowly varying direction and a large direction edge.

7.3. Definition of the numerical error. The numerical error is differently defined and calculated for each scheme. In the linear and TV schemes, the numerical error is defined as the amount of the projection needed, so that the direction information is on the unit circle. Thus, if the flow has resulted in some coordinates $(U1, V1)$ which are not necessarily on the unit circle, we take as the projected coordinates the intersection of the unit circle with the line connecting $(U1, V1)$ to the origin of axes; see Figure 7.1. The point (U, V) is given by

$$U = \frac{U1}{\sqrt{U1^2 + V1^2}}, \quad V = \frac{V1}{\sqrt{U1^2 + V1^2}}. \tag{7.6}$$

Thus, the error is clearly

$$error = \sqrt{(U1 - U)^2 + (V1 - V)^2}. \tag{7.7}$$

In the HP and SP schemes, the evaluation of the error is not straightforward, as there is no projection error; the evolving coordinates never leave the unit circle. The numerical error is therefore defined relative to the results of a similar flow in which there is no selection of a local coordinate system; thus, the coordinates (u, v) are not coupled and are not constrained to the unit circle. For the HP we denote this error by $HE_{U1,V1}$ and expect it to obtain a sharp maximum at $(-\pi, \frac{-\pi}{2}, 0, \frac{\pi}{2}, \pi)$ because one of the internal coordinates approaches 1 there and the denominator approaches infinity (see Figure 7.2). It is important to notice that *it is not an error of the hemispheric scheme*. In its minimum value, obtained between the sharp maximum points, it provides a maximum bound on the error in the HP scheme.

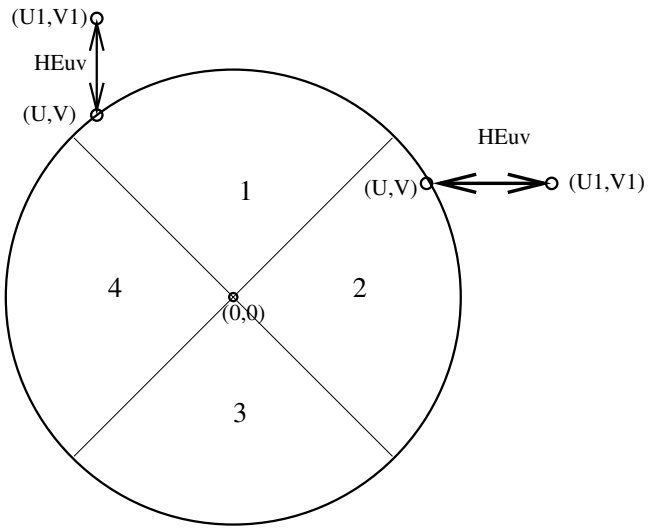

FIG. 7.2. *Artificial error in the HP scheme. In regions* 1 *and* 3 *the* U *coordinate is selected, and therefore the numerical error results from the difference between* $V1$*, which is independently calculated, and* V*, which is derived from the coordinate* U*. In regions* 2 *and* 4 *the* V *coordinate is selected, and therefore the numerical error results from the difference between* $U1$*, which is independently calculated, and* U*, which is derived from the coordinate* V*.*

For SP the definition of an error is even more complicated. Not only is there no projection error, but there are more variables for which an error term may be defined. First, u and v are obtained using the embedding $\theta \to (u, v) = [\cos(\theta), \sin(\theta)]$. Next, the stereographic coordinates Z_n and Z_s are derived, as the intersection of the line between the north (south) pole and the south (north) hemisphere. Thus, we may look at the error in Z_s and Z_n as well as in u and v. Following are the error terms used:

- $\boldsymbol{SE_{zn}}$ **and** $\boldsymbol{SE_{zs}}$**—Error terms for the stereographic coordinates.** We let Z_n and Z_s evolve independently. Then, we compare the stand-alone Z_n to the one calculated using the coupled Z_n and Z_s (where we select the local appropriate chart according to the direction). We do the same for Z_s (see Figure 7.3). We expect the error for Z_n to have a singularity at $\frac{\pi}{2}$ and the error for Z_s to have a singularity at $\frac{-\pi}{2}$. Note that SE_{zn} as defined is expected to be zero in the range $[-\pi, 0]$, and SE_{zs} as defined is expected to be zero in the range $[0, \pi]$. Since this is an error for the values of Z_n and Z_s, we need another error definition which measures the degree of error in the (u, v) coordinates.
- $\boldsymbol{SE_{UV}}$**—Error terms for** $\boldsymbol{U}$ **and** $\boldsymbol{V}$**.** It is important to evaluate the error for the (U, V) variables. We define the error term as the distance between the vector (U, V) when evaluated using the coupled Z_n and Z_s, and the vector (U, V) when using the independently calculated Z_n and Z_s (see Figure 7.4).

It is important to note that SE_z and SE_{UV} *are not errors* of the Beltrami porcupine methods. They give an indication of the actual error by noticing that *the minimum* of SE_z and SE_{UV} is *the upper bound for the Beltrami porcupine algorithm*. This is so since the most unreliable numeric regions are exactly the regions where the minimum in the $SE_{Z,UV}$ is obtained. The actual error in other areas is smaller since we do not trust one of the components that leads to a greater error. Thus, a small value of an error may indicate that using the appropriate local chart

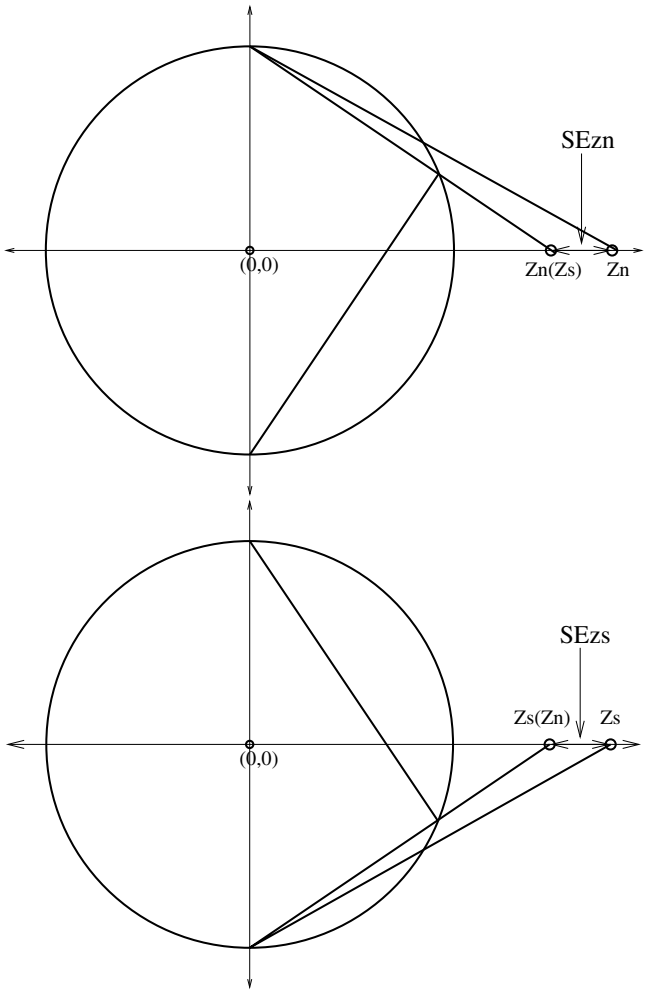

FIG. 7.3. *Artificial error in the Z_n (upper) and Z_s (lower) variables in the SP scheme.*

is not as important as it is when the error is larger. The higher the error, the more important it is to use the right local chart.

7.3.1. Definition of the algorithmic error. The definition of the algorithmic error is the same for all schemes. It is simply the deviation of the direction following diffusion from the noise-free direction, which is originally given. While the numerical error gives an indication of the stability of the method, the algorithmic error deals with performance: how close the resultant direction is to the actual one. The algorithmic error is defined as follows:

$$E = \sqrt{(\cos(\theta) - \cos(\theta_1))^2 + (\sin(\theta) - \sin(\theta_1))^2},$$

where θ is the original noise-free angle and θ_1 is the resultant angle following the diffusion scheme.

7.3.2. Definition of an edge preservation quality. An important quality of any diffusion scheme is its edge preserving ability. The first test image used to examine

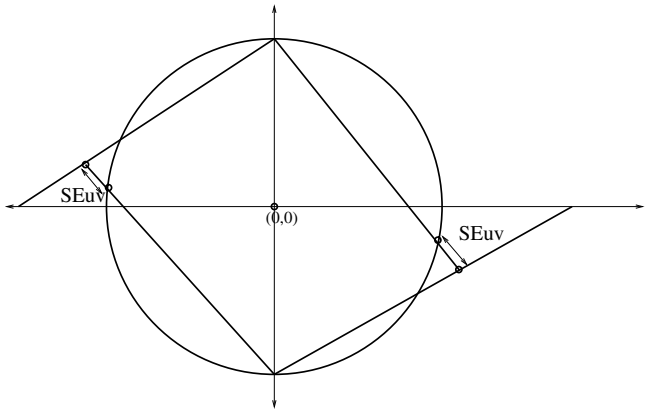

FIG. 7.4. *Artificial error in the* (U, V) *coordinates in the SP scheme.*

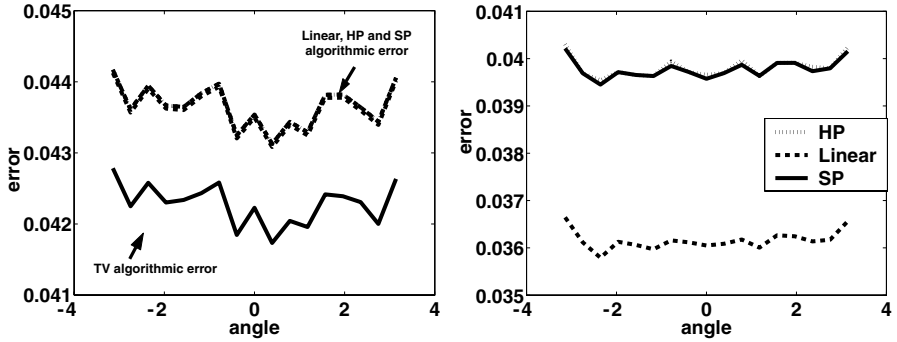

FIG. 7.5. *Algorithmic error for the linear, TV, HP, and SP schemes. Left: the four schemes together, using a small time step,* $dt = 0.00001$. *Right: the HP, SP, and linear schemes, using a larger time step,* $dt = 0.001$.

edge preservation is composed of two different directions. We apply each tested scheme to this image. We expect that the TV-based method will preserve edges better than the linear-based approach. As for the porcupine methods, we expect edge preservation quality to depend on the parameter β. The second test image is composed of two significantly different directions, where each direction is slowly varying. Using this test image, we may compare the edge preserving quality with the handling of the slowly varying data.

7.4. Comparison results and discussion. In this section we present the results of the numerical errors, algorithmic errors, and edge preserving performance.

In the test we go over S^1 from $-\pi$ to π using an equal step size. For each angle, random noise entries, chosen from a uniform distribution, are added to the vector field.

In Figure 7.5(left) we present the algorithmic error for the four schemes using a time step $dt = 0.00001$. All errors lie within the same range. However, the best performance is presented by the TV scheme, while the linear, HP, and SP approaches seem to have the same performance. In Figure 7.5(right) we used a larger time step, $dt = 0.001$, to observe the different behavior of the linear, HP, and SP schemes. The linear scheme has the smallest algorithmic error among the three schemes, and the HP and SP schemes seem to have the same algorithmic performance.

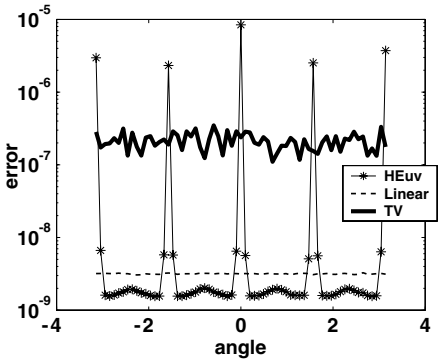

FIG. 7.6. *Numerical error for the TV, linear, and HP schemes. In this test we go over* S^1 *from* $-\pi$ *to* π *using an equal step size of* $\frac{\pi}{32}$.

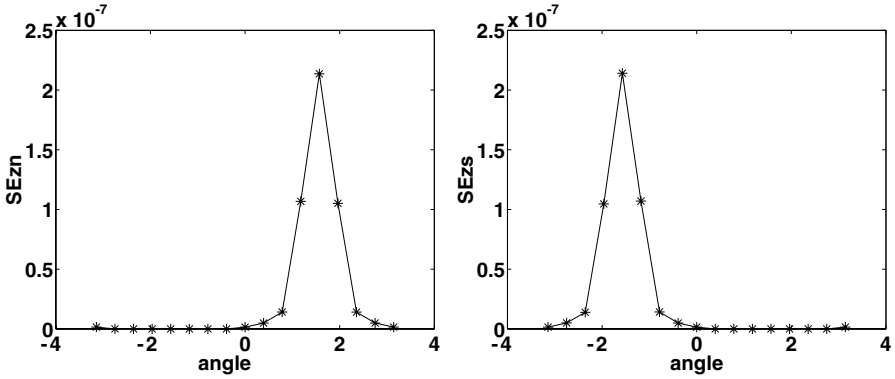

FIG. 7.7. *Left: numerical error for* Z_n. *Here we go over* S^1 *from* $-\pi$ *to* π *using an equal step size of* $\frac{\pi}{8}$. *As expected, it has a singular point at* $\frac{\pi}{2}$. *Right: numerical error for* Z_s. *As expected, it has a singular point at* $\frac{-\pi}{2}$.

Figure 7.6 compares the numerical errors of the HP, TV, and linear schemes. A logarithmic scale is used, as the error of the TV scheme is two orders of magnitude higher than the error of the linear and HP schemes! The HP error term has a periodic behavior, and it is very large at the singular points, $(-\pi, \frac{-\pi}{2}, 0, \frac{\pi}{2}, \pi)$. Away from the singular points, the HP error is slightly smaller than the linear scheme error, and the TV error is significantly higher than the HP error. However, as we approach the singularities, the HP error increases, and there the linear scheme's error is smaller.

In Figure 7.7 we show the numerical errors of Z_n and Z_s in the SP scheme. As expected, the errors have sharp maxima at $\frac{\pi}{2}$ and $\frac{-\pi}{2}$, respectively.

Another definition for the numerical error of the SP scheme was given, SE_{UV}, in which we refer to the (U, V) variables rather than the (Z_n, Z_s) variables. In Figure 7.8 this error is presented: the differences between the values of (U, V) when calculated using a coupled scheme for (Z_n, Z_s) and when calculated using an independent scheme for (Z_n, Z_s) are shown. It is interesting to note that this error has a periodic behavior, with maximum values at $(\frac{-\pi}{2}, \frac{\pi}{2})$, as can be expected.

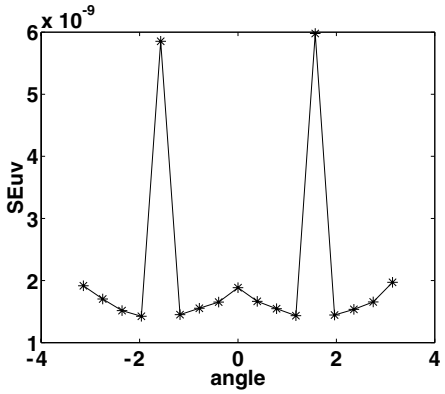

FIG. 7.8. *The differences between the values of* (u, v) *when calculated using the* (Z_n, Z_s) *coupled scheme and when independently calculated using* (Z_n, Z_s). *Here we go over* S^1 *from* $-\pi$ *to* π *using an equal step size of* $\frac{\pi}{8}$.

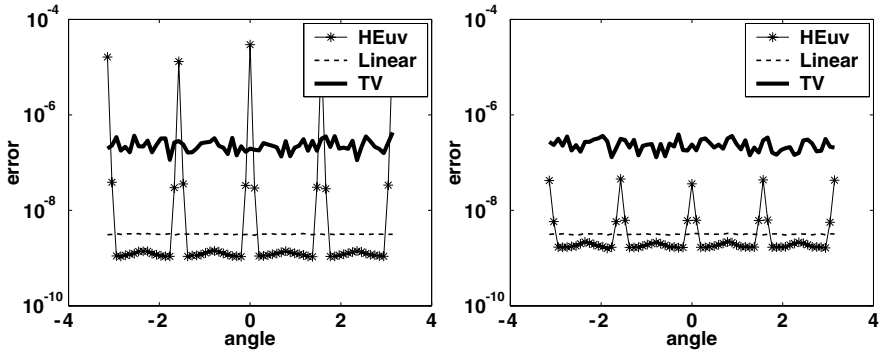

FIG. 7.9. *Numerical error for HP for* $\beta = 10$ *(left) and for* $\beta = 0$ *(right). Here we go over* S^1 *from* $-\pi$ *to* π *using an equal step size of* $\frac{\pi}{32}$.

The next step is to examine the dependence of the numerical error in the HP and SP schemes on the scaling parameter β. Figure 7.9 shows the numerical error for the HP scheme for a larger value of β (left) and for a smaller value of β (right). The scale used for presenting these results is again logarithmic. Away from the singular points, larger values of β produce smaller errors. In the vicinity of the singular points, the error increases when β increases.

The same goes for the SP scheme. In Figures 7.10 and 7.11 we present the results with respect to the three error measures we have defined for the SP scheme. The scale used for presenting the results is logarithmic. In Figure 7.10 the results for a larger value of β are presented, and in Figure 7.11 the results for a smaller value of β are presented.

When $\beta = 100$, the values of SE_{zn} in the range $[0, \pi]$ and away from the singularity at $\frac{\pi}{2}$ lie between the numerical errors of the linear and TV schemes. The error decreases as we move away from $\frac{\pi}{2}$ and is even smaller than the linear scheme error as we move closer to 0 and π. In the range $[-\pi, 0]$, SE_{zn} is equal to zero. SE_{zs} presents a mirror behavior. SE_{UV} is smaller than the numerical errors of the TV and linear schemes. It obtains maximum values at $\pm\frac{\pi}{2}$. When $\beta = 0$, the values of SE_{zn} in the

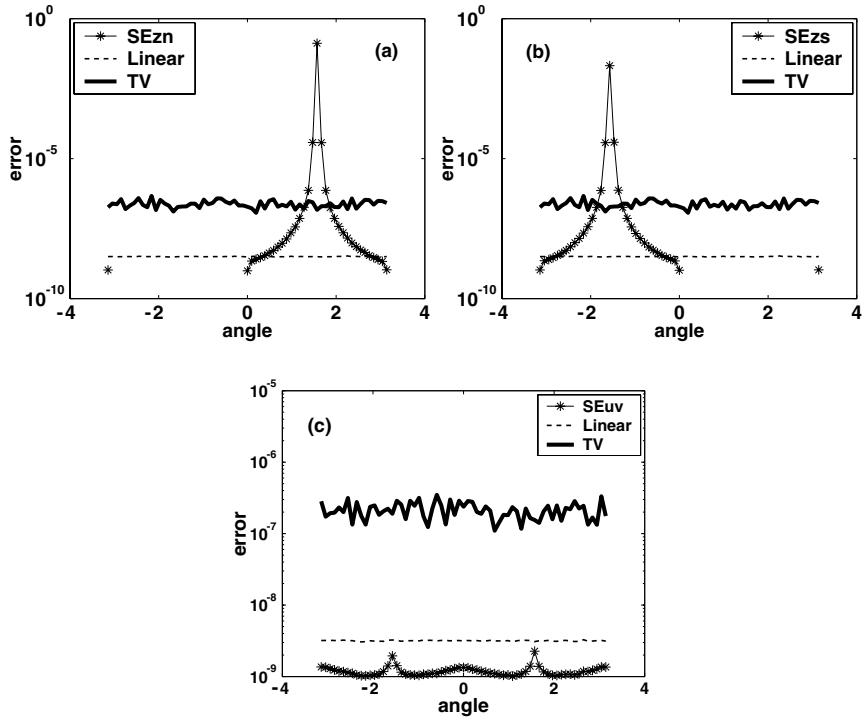

FIG. 7.10. *Numerical errors of the SP scheme for a large value of* $\beta = 100$. (a) *The numerical error of* Z_n. (b) *The numerical error of* Z_s. (c) *The numerical error of the* (U, V) *variables.*

range $[0, \pi]$ and away from the singularity at $\frac{\pi}{2}$ are a little bigger than those obtained for $\beta = 100$. Again, SE_{zs} presents a mirror behavior. In this case, SE_{UV}, away from the singular points $\pm\frac{\pi}{2}$, is higher than the one obtained for $\beta = 100$. Note that the error values in the vicinity of the singularities are much higher for the lower value of β.

Next, we examine the edge preserving quality of each direction diffusion scheme. The following synthetic data was generated so that there is a difference of $\frac{\pi}{2}$ radians between the left and right sides of the noise-free image. Random noise entries, chosen from a uniform distribution in the range $[\frac{-\pi}{9}, \frac{\pi}{9}]$, are added to the noise-free data, and each scheme is applied to the image. The noise-free and noisy initial images are shown in Figure 7.12. The diffusion results are presented for all schemes, while for the HP and SP approaches we show the results for both smaller and higher values of the parameter β. In Figure 7.13 the results for the linear and the TV schemes are presented. It is interesting to note that the linear scheme is less edge preserving than the TV scheme, as can be expected. In Figures 7.14 and 7.15 the results for the HP and SP schemes are also presented. Here, we note the dependence of the results on the value of the parameter β. We can go from linear to TV behavior simply by adjusting the value of β. If we examine the relationship between the numerical errors of the TV and linear schemes (see Figure 7.6), and their edge preserving quality, we note that while the linear scheme offers a low numerical error, it is less edge preserving, and while the TV scheme better preserves edges, it has a significantly higher numerical error. For the HP and SP schemes, both the numerical errors (see Figures 7.9, 7.10, 7.11) and the edge preserving quality depend on the parameter β. We may find a

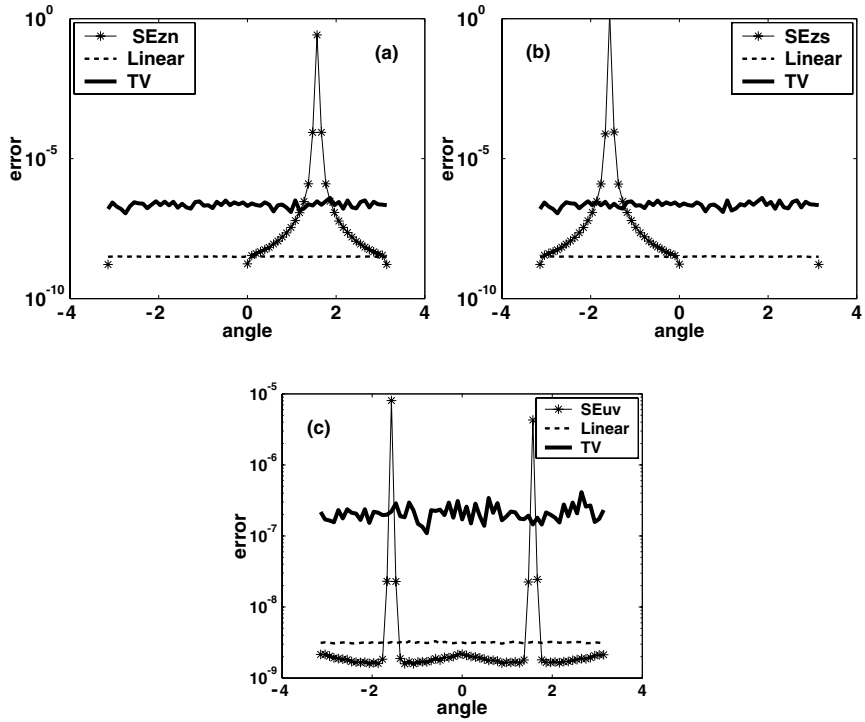

FIG. 7.11. *Numerical errors for the SP scheme for a small value of* $\beta = 0$. (a) *The numerical error of* Z_n. (b) *The numerical error of* Z_s. (c) *The numerical error of the* (U, V) *variables.*

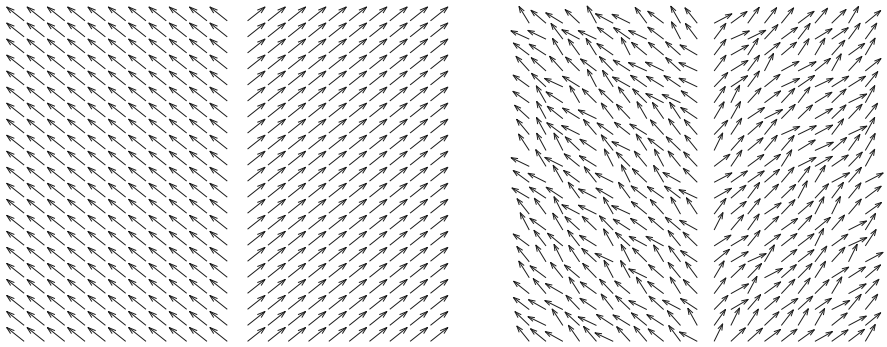

FIG. 7.12. *The original noise-free image (left) and the image after random noise was added (right).*

value of β in the HP and SP schemes so that we obtain a numerical error which is in the order of the linear scheme's error and an edge preserving quality which is comparable to that of the TV scheme.

Another example for exploring the edge preserving quality of each scheme is the direction fan example. The test image (Figure 7.15) is composed of a major gradient in directions in the image's center and a slowly varying angle as we move away from the center. The direction information is presented both by arrows (Figure 7.16 (left)) and by a color image, representing the angles (Figure 7.16 (right)). Random noise

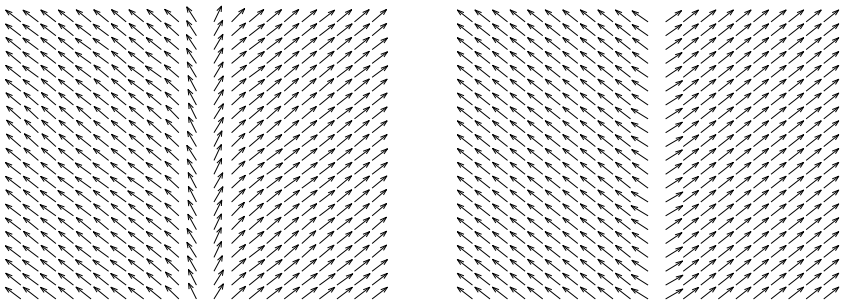

FIG. 7.13. *Left: the result of linear diffusion, with* 10,000 *iterations and a time step equal to* 0.0001. *Right: the result of TV diffusion, with* 100,000 *iterations and a time step equal to* 0.00001.

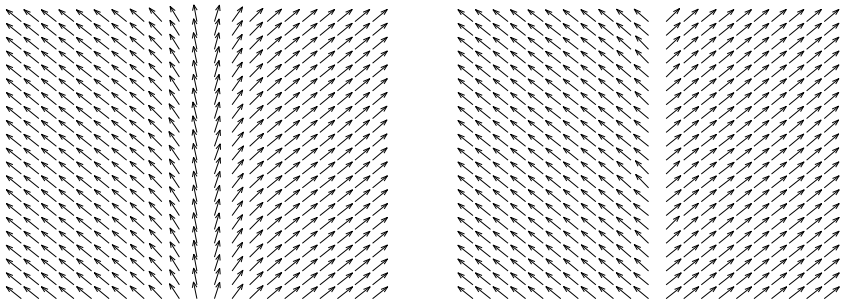

FIG. 7.14. *Left: the result of HP diffusion for* $\beta = 0$. *Right: the result of HP diffusion for* $\beta = 10$. *These results were obtained following* 10,000 *iterations with time step equal to* 0.001.

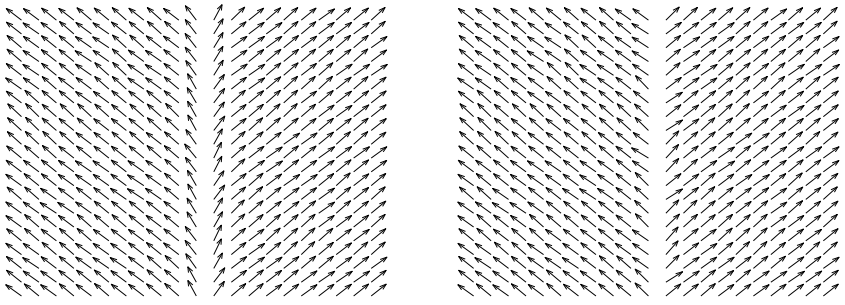

FIG. 7.15. *Left: the result of SP diffusion for* $\beta = 0$. *Right: the result of SP diffusion for* $\beta = 100$. *These results were obtained following* 10,000 *iterations with time step equal to* 0.0001.

entries, chosen from a uniform distribution in the range $[\frac{-\pi}{9}, \frac{\pi}{9}]$, are added to the noise-free data, and a noisy direction image is obtained (Figure 7.17). Next, each scheme is applied to the image with the time step, number of iterations, and value of β (for the HP and SP schemes) that produce the best results. When applying the linear scheme, the edge is blurred while the amount of noise is still significant (Figure 7.18). The TV approach results in a sharper boundary relative to the linear

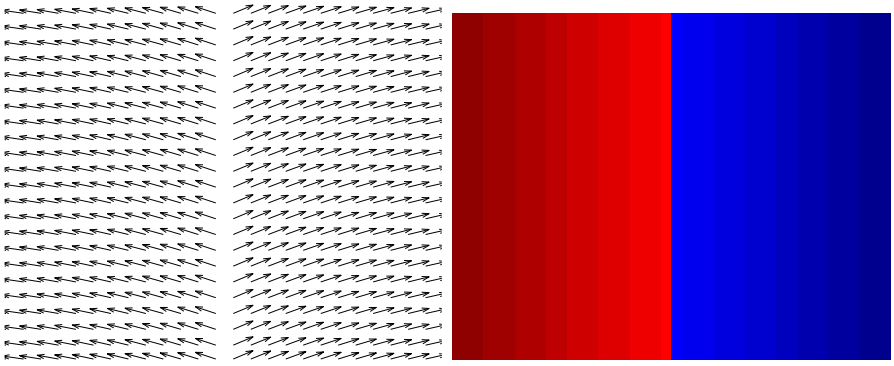

FIG. 7.16. *The noise-free direction fan image, represented by arrows (left) and as a color image (right).*

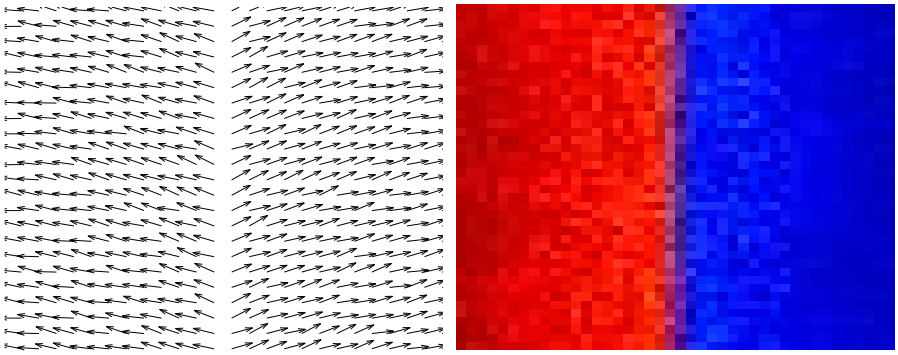

FIG. 7.17. *The noisy direction fan image, represented by arrows (left) and as a color image (right).*

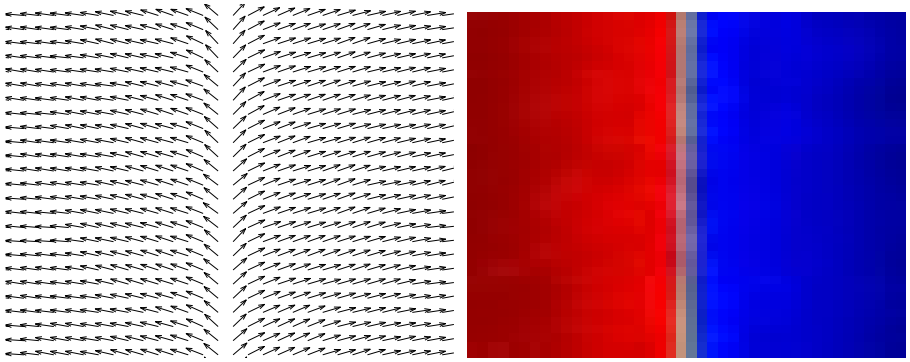

FIG. 7.18. *The result of linear diffusion following* 10,000 *iterations with time step* 0.0001*, represented by arrows (left) and as a color image (right).*

scheme, but if we examine the smoothed direction, we note a stair-casing effect; thus the smaller changes in direction are ignored (Figure 7.19).

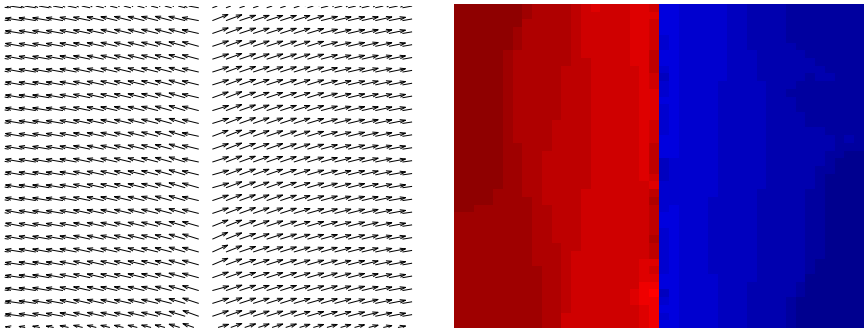

FIG. 7.19. *The result of TV diffusion following* 100,000 *iterations with time step* 0.00001*, represented by arrows (left) and as a color image (right).*

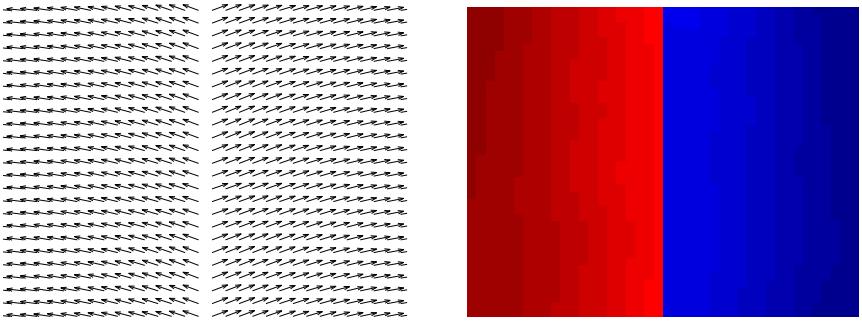

FIG. 7.20. *The result of HP diffusion following* 1,000 *iterations with time step* 0.01*. The value of* β *is* 1.5*. Representation by arrows (left) and as a color image (right).*

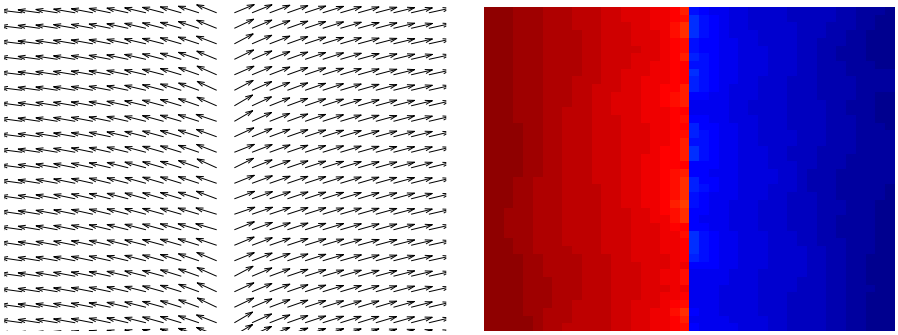

FIG. 7.21. *The result of SP diffusion following* 1,000 *iterations with time step* 0.01*. The value of* β *is* 10*. Representation by arrows (left) and as a color image (right).*

The HP scheme produces good results, as it keeps a sharp boundary and restores the original slowly changing behavior of the original direction data (Figure 7.20). The SP scheme produces similar results to those for the HP scheme, but as can be seen, some noise is still present (Figure 7.21).

8. Concluding remarks. There are some important issues in the process of denoising a constrained feature field. The first is to make the process compatible with the constraint in such a way that the latter is never violated along the flow. The second is the type of regularization which is applied in order to preserve significant discontinuities of the feature field while removing noise. The third is the numeric and algorithmic accuracy of the algorithms.

These issues are treated in this paper via the Beltrami framework. First a Riemannian structure, i.e., a metric, is introduced on the feature manifold, and several local coordinate systems are chosen to *intrinsically* describe the constrained feature manifold. The diffusion process acts on these coordinates, and the compatibility with the constraint is achieved through the intrinsic nature of the coordinate system. The difficulty in working on a non-Euclidean space transforms itself to the need to locally choose the best coordinate system to work with.

The preservation of significant discontinuities is dealt with by using the induced metric and the corresponding Laplace–Beltrami operator acting on feature coordinates only. This operation is in fact a projection of the mean curvature, in the normal(s) direction(s) to the surface, to the feature direction(s). This projection slows the diffusion process along significant (supported) discontinuities while letting the process proceed in the homogeneous regions at a normal speed.

The result of this algorithm is an adaptive smoothing process for a constrained feature space in every dimension and codimension. As an example we have shown how our geometric model coupled with a proper choice of charts handles the direction diffusion problem. This is a new application of the Beltrami framework, proposed in [18]. We tested the new model on vector fields restricted to the unit circle S^1, and hybrid spaces like the HSV color space. The integration of the spatial coordinates with the color coordinates yields a selective smoothing filter for images in which some of the coordinates are restricted to a circle.

Moreover, it is shown that even when algorithms are analytically equivalent, they may differ in their accuracy (numerical and algorithmic). It is shown that the hemispheric and stereographic coordinate systems present an advantage in the sense that a parameter β can be found, i.e., $\beta = 10$, or 100, respectively, such that the edge preserving quality is as good as that for the TV algorithm, while the numerical error is two orders of magnitude smaller!

Appendix A. The Levi–Civita method for S^2. Using (3.9) and the general formula

$$\Gamma^i_{jk} = \frac{1}{2} h^{il} \left(\partial_j h_{lk} + \partial_k h_{jl} - \partial_l h_{jk} \right), \tag{A.1}$$

we get, for example,

$$\begin{aligned}
\Gamma^3_{33} &= \frac{1}{2} h^{3l} \left(2\partial_3 h_{l3} - \partial_l h_{33} \right) = \frac{1}{2} \left(h^{33} \partial_3 h_{33} + 2h^{34} \partial_3 h_{34} - h^{34} \partial_4 h_{33} \right) \\
&= \frac{1}{2} \Bigg[(1-U^2) \frac{\partial}{\partial U} \left(\frac{1-V^2}{1-U^2-V^2} \right) - 2UV \frac{\partial}{\partial U} \left(\frac{UV}{1-U^2-V^2} \right) \\
&\qquad + UV \frac{\partial}{\partial V} \left(\frac{1-V^2}{1-U^2-V^2} \right) \Bigg],
\end{aligned}$$

and a straightforward calculation gives

$$\Gamma^3_{33} = \frac{U(1-V^2)}{1-U^2-V^2} = Uh_{33}. \tag{A.2}$$

Appendix B. The S^n diffusion flow. The hypersphere S^n is presented as an n-dimensional manifold embedded in $\mathbb{R}^{n+1}$ as the constrained hypersurface

$$\sum_{i=1}^{n+1}(U^i)^2 = 1.$$

We work in the chart where $\{U^i\}_{i=1}^n$ are local coordinates. On this chart, $U^{n+1} = \sqrt{1-\sum_{i=1}^n (U^i)^2}$.

THEOREM B.1. *The local S^n metric elements are*

$$\tilde{h}_{ij} = \delta^{ij} + \frac{U^i U^j}{1-\sum_{s=1}^n (U^s)^2}.$$

Proof. The hypersphere is embedded isometrically in $\mathbb{R}^{n+1}$. We use the induced metric technique as follows:

$$ds^2 = \sum_{i=1}^n (dU^i)^2 + (dU^{n+1})^2. \tag{B.1}$$

The U^{n+1} coordinate is a function of all the others, and as such we can apply the chain rule to get

$$dU^{n+1} = \sum_{i=1}^n \frac{\partial U^{n+1}}{\partial U^i} dU^i = -\sum_{i=1}^n \frac{U^i}{\sqrt{1-\sum_{s=1}^n (U^s)^2}} dU^i.$$

Using this expression in (B.1), we get

$$\begin{aligned} ds^2 &= \sum_{i,j=1}^n \tilde{h}_{ij} dU^i dU^j \\ &= \sum_{i=1}^n (dU^i)^2 + \left(-\sum_{i=1}^n \frac{U^i}{\sqrt{1-\sum_{s=1}^n (U^s)^2}} dU^i\right)\left(-\sum_{j=1}^n \frac{U^j}{\sqrt{1-\sum_{s=1}^n (U^s)^2}} dU^j\right) \\ &= \sum_{i,j=1}^n \delta_{ij} dU^i dU^j + \sum_{i,j=1}^n \frac{U^i U^j}{1-\sum_{s=1}^n (U^s)^2} dU^i dU^j \\ &= \sum_{i,j=1}^n \left(\delta_{ij} + \frac{U^i U^j}{1-\sum_{s=1}^n (U^s)^2}\right) dU^i dU^j, \end{aligned} \tag{B.2}$$

from which the assertion follows. ∎

THEOREM B.2. *The local S^n inverse metric elements are*

$$\tilde{h}^{-1}_{ij} = \delta^{ij} - U^i U^j.$$

Proof. By direct calculation,

$$\begin{aligned}\sum_{j=1}^{n}\tilde{h}_{ij}\tilde{h}^{-1}_{jk} &= \sum_{j=1}^{n}\left(\delta^{ij}+\frac{U^iU^j}{1-\sum_{s=1}^{n}(U^s)^2}\right)\left(\delta^{jk}-U^jU^k\right)\\ &= \delta^{ik}-U^iU^k+\frac{U^iU^k}{1-\sum_{s=1}^{n}(U^s)^2}-\sum_{j=1}^{n}\frac{U^i(U^j)^2U^k}{1-\sum_{s=1}^{n}(U^s)^2}\\ &= \delta^{ik}. \qquad \text{(B.3)}\end{aligned}$$

One can check similarly that

$$\sum_{j=1}^{n}\tilde{h}^{-1}_{ij}\tilde{h}_{jk}=\delta^{ik}. \qquad \square$$

THEOREM B.3. *The induced metric, and its inverse, are accordingly*

$$\begin{aligned}g_{\mu\nu} &= \delta_{\mu\nu}+\sum_{i,j=1}^{n}\tilde{h}_{ij}U^i_\mu U^j_\nu,\\ g^{\mu\nu} &= \frac{1}{g}\left(\delta^{\mu\nu}+\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j=1}^{n}\tilde{h}_{ij}U^i_\sigma U^j_\rho\right),\\ g &= \det(g_{\mu\nu})\\ &= 1+\sum_{i,j=1}^{n}\tilde{h}_{ij}(U^i_xU^j_x+U^i_yU^j_y)+\frac{1}{2}\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j,k,l=1}^{n}\tilde{h}_{ij}\tilde{h}_{kl}U^i_\mu U^j_\nu U^k_\rho U^l_\sigma, \qquad \text{(B.4)}\end{aligned}$$

where $(g^{\mu\nu})$ is the inverse of $(g_{\mu\nu})$, g is the determinant, and $\epsilon^{\mu\nu}$ is the 2D antisymmetric tensor

$$(\epsilon^{\mu\nu})=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}.$$

An implicit summation on all repeated Greek indices is assumed.

Proof. The calculation of the metric element is done directly by the induced metric identity

$$\begin{aligned}ds^2 &= g_{\mu\nu}dx^\mu dx^\nu = dx^2+dy^2+\sum_{i,j=1}^{n}\tilde{h}_{ij}dU^idU^j\\ &= \delta_{\mu\nu}dx^\mu dx^\nu+\sum_{ij}\tilde{h}_{ij}U^i_\mu U^j_\nu dx^\mu dx^\nu, \qquad \text{(B.5)}\end{aligned}$$

from which we extract the metric coefficients. The metric is a 2×2 matrix whose determinant is $g=g_{11}g_{22}-g_{12}^2=\epsilon^{\mu\nu}g_{1\mu}g_{2\nu}$. Using the explicit form of the metric, we get

$$
\begin{aligned}
g &= \left(1+\sum_{ij}\tilde{h}_{ij}U_x^iU_x^j\right)\left(1+\sum_{kl}\tilde{h}_{kl}U_y^kU_y^l\right)-\left(\sum_{ij}\tilde{h}_{ij}U_x^iU_y^j\right)\left(\sum_{kl}\tilde{h}_{kl}U_x^kU_y^l\right)\\
&= 1+\sum_{ij}\tilde{h}_{ij}(U_x^iU_x^j+U_y^iU_y^j)+\sum_{ijkl}\tilde{h}_{ij}\tilde{h}_{kl}U_x^i(U_x^jU_y^k-U_y^jU_x^k)U_y^l\\
&= 1+\sum_{ij}\tilde{h}_{ij}(U_x^iU_x^j+U_y^iU_y^j)+\epsilon^{\mu\nu}\sum_{ijkl}\tilde{h}_{ij}\tilde{h}_{kl}U_x^iU_\mu^jU_\nu^kU_y^l\\
&= 1+\sum_{ij}\tilde{h}_{ij}(U_x^iU_x^j+U_y^iU_y^j)\\
&\quad+\frac{1}{2}\epsilon^{\mu\nu}\sum_{ijkl}\tilde{h}_{ij}\tilde{h}_{kl}U_x^iU_\mu^jU_\nu^kU_y^l-\frac{1}{2}\epsilon^{\mu\nu}\sum_{ijkl}\tilde{h}_{ij}\tilde{h}_{kl}U_y^iU_\mu^jU_\nu^kU_x^l \qquad \text{(B.6)}\\
&= 1+\sum_{ij}\tilde{h}_{ij}(U_x^iU_x^j+U_y^iU_y^j)+\frac{1}{2}\epsilon^{\mu\nu}\epsilon^{\sigma\rho}\sum_{ijkl}\tilde{h}_{ij}\tilde{h}_{kl}U_\sigma^iU_\mu^jU_\nu^kU_\rho^l.
\end{aligned}
$$

Finally, we prove the formula for the inverse metric

$$
\begin{aligned}
g^{\mu\nu}g_{\nu\lambda} &= \frac{1}{g}\left(\delta^{\mu\nu}+\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j=1}^{n}\tilde{h}_{ij}U_\sigma^iU_\rho^j\right)\left(\delta_{\nu\lambda}+\sum_{i,j=1}^{n}\tilde{h}_{ij}U_\nu^iU_\lambda^j\right)\\
&= \frac{1}{g}\left(\delta_\lambda^\mu+\epsilon^{\mu\sigma}\epsilon^{\lambda\rho}\sum_{i,j=1}^{n}\tilde{h}_{ij}U_\sigma^iU_\rho^j+\sum_{k,l=1}^{n}\tilde{h}_{kl}U_\mu^kU_\lambda^l\right.\\
&\qquad\left.+\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j,k,l=1}^{n}\tilde{h}_{ij}\tilde{h}_{kl}U_\sigma^iU_\rho^jU_\nu^kU_\lambda^l\right) \qquad \text{(B.7)}\\
&= \frac{1}{g}\left(\delta_\lambda^\mu+\sum_{i,j=1}^{n}\tilde{h}_{ij}(U_x^iU_x^j+U_y^iU_y^j)\delta_\lambda^\mu+\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j,k,l=1}^{n}\tilde{h}_{ij}\tilde{h}_{kl}U_\sigma^iU_\rho^jU_\nu^kU_\lambda^l\right),
\end{aligned}
$$

where the last equality comes from a case-by-case analysis. Remember that $\lambda,\nu\in\{1,2\}$, and take, for example, $\mu=\lambda-1=1$. In this case we get

$$
\begin{aligned}
\sum_{\sigma,\rho=1}^{2}\epsilon^{1\sigma}\epsilon^{2\rho}\sum_{i,j=1}^{n}\tilde{h}_{ij}U_\sigma^iU_\rho^j+\sum_{k,l=1}^{n}\tilde{h}_{kl}U_x^kU_y^l &= \epsilon^{12}\epsilon^{21}\sum_{i,j=1}^{n}\tilde{h}_{ij}U_y^iU_x^j+\sum_{i,j=1}^{n}\tilde{h}_{ij}U_x^iU_y^a\\
&= -\sum_{i,j=1}^{n}\tilde{h}_{ij}U_y^iU_x^j+\sum_{i,j=1}^{n}\tilde{h}_{ij}U_x^jU_y^i=0, \qquad \text{(B.8)}
\end{aligned}
$$

where we have used the fact that the metric is a symmetric tensor. Other cases are analyzed in a similar manner. The third term is also analyzed on a case-by-case basis, and the result, as the reader can verify, is

$$
\epsilon^{\mu\sigma}\epsilon^{\nu\rho}\sum_{i,j,k,l=1}^{n}\tilde{h}_{ij}\tilde{h}_{kl}U_\sigma^iU_\rho^jU_\nu^kU_\lambda^l=\frac{1}{2}\delta_\lambda^\mu\epsilon^{\alpha\beta}\epsilon^{\nu\rho}\sum_{i,j,k,l=1}^{n}\tilde{h}_{ij}\tilde{h}_{kl}U_\alpha^iU_\nu^jU_\rho^kU_\beta^l.
$$

The whole expression in the parentheses in B.7 is, therefore, $\delta_\lambda^\mu g$, which completes our proof. ∎

The last piece of information needed for our machinery is the explicit form of the Levi–Civita coefficients.

THEOREM B.4. *The Levi–Civita coefficients are*

$$\Gamma^i_{jk} = U^i \tilde{h}_{jk}. \tag{B.9}$$

Proof. From the formula (2.11) we get

$$\begin{aligned}\Gamma^i_{jk} &= \frac{1}{2}\sum_l h^{-1}_{il}\left(\partial_j h_{lk} + \partial_k h_{jl} - \partial_l h_{jk}\right)\\ &= \frac{1}{2}\sum_l (\delta^{il} - U^i U^l)\left(\partial_j\left(\frac{U^l U^k}{1-\sum_s (U^s)^2}\right) + \partial_k\left(\frac{U^j U^l}{1-\sum_s (U^s)^2}\right) - \partial_l\left(\frac{U^j U^k}{1-\sum_s (U^s)^2}\right)\right).\end{aligned}$$

Let us compute the first term, for example,

$$\partial_j\left(\frac{U^l U^k}{1-\sum_s (U^s)^2}\right) = \frac{\delta^{jl}U^k}{1-\sum_s (U^s)^2} + \frac{\delta^{jk}U^l}{1-\sum_s (U^s)^2} + \frac{2U^j U^l U^k}{(1-\sum_s (U^s)^2)^2}. \tag{B.10}$$

Summing up the three terms, we get

$$\begin{aligned}\Gamma^i_{jk} = \frac{1}{2}\sum_l (\delta^{il} - U^i U^l)\Bigg(&\frac{\delta^{jl}U^k}{1-\sum_s (U^s)^2} + \frac{\delta^{kj}U^l}{1-\sum_s (U^s)^2} + \frac{2U^j U^l U^k}{(1-\sum_s (U^s)^2)^2}\\ &+ \frac{\delta^{kj}U^l}{1-\sum_s (U^s)^2} + \frac{\delta^{lk}U^j}{1-\sum_s (U^s)^2} + \frac{2U^j U^l U^k}{(1-\sum_s (U^s)^2)^2}\\ &- \frac{\delta^{lk}U^j}{1-\sum_s (U^s)^2} - \frac{\delta^{jl}U^k}{1-\sum_s (U^s)^2} - \frac{2U^j U^l U^k}{(1-\sum_s (U^s)^2)^2}\Bigg).\end{aligned}$$

Now simple algebra gives

$$\begin{aligned}\Gamma^i_{jk} &= \frac{1}{1-\sum_s (U^s)^2}\sum_l (\delta^{il} - U^i U^l)\left(\delta^{kj}U^l + \frac{U^j U^l U^k}{1-\sum_s (U^s)^2}\right)\\ &= \frac{1}{1-\sum_s (U^s)^2}\left(U^i - U^i\sum_l (U^l U^l)\right)\left(\delta^{kj} + \frac{U^j U^k}{1-\sum_s (U^s)^2}\right) = U^i \tilde{h}_{jk}. \qquad \square\end{aligned}$$

Acknowledgments. We thank Alfred Bruckstein from the Technion Israel for stimulating discussions on diffusion and averaging, and on color analysis. We also thank Guillermo Sapiro from the University of Minnesota for sharing with us his ideas and results on direction diffusion.

BURGERS–POISSON: A NONLINEAR DISPERSIVE MODEL EQUATION*

KLEMENS FELLNER† AND CHRISTIAN SCHMEISER†‡

Abstract. A dispersive model equation is considered, which has been proposed by Whitham [*Linear and Nonlinear Waves*, John Wiley & Sons, New York, 1974] as a shallow water model, and which can also be seen as a caricature of two-species Euler–Poisson problems. A number of formal properties as well as similarities to other dispersive equations are derived. A travelling wave analysis and some numerical tests are carried out. The equation features wave breaking in finite time. A local existence result for smooth solutions and a global existence result for weak entropy solutions are proved. Finally, a small dispersion limit is carried out for situations where the solution of the limiting equation is smooth.

Key words. dispersive models, entropy solutions, small dispersion limit

1. Introduction and motivation.

In this paper, a nonlinear dispersive model problem is proposed, the Burgers–Poisson (BP)-system:

$$u_t + uu_x = \varphi_x, \tag{1.1}$$

$$\varphi_{xx} = \varphi + u, \tag{1.2}$$

where u and φ depend on $(t,x) \in (0,\infty)\times\mathbb{R}$, and subscripts denote partial derivatives. The Burgers equation (1.1) is driven by the right-hand side φ_x, which is determined by solving the Poisson equation (1.2).

Using the Green's function $G(x) = -\frac{1}{2}e^{-|x|}$ (of $\partial_x^2 - 1$) to define the convolution operator

$$\varphi[u](x) = (G * u)(x) = \int_{\mathbb{R}} G(x-y)u(y)\,dy, \tag{1.3}$$

the BP-system reduces to the single BP-equation

$$u_t + uu_x = \varphi_x[u], \tag{1.4}$$

with the obvious notation $\varphi_x[u] := (\varphi[u])_x$.

A rescaled version of (1.4) was considered by Whitham in [30, section 13.14] as a shallow water equation modelling unidirectional water waves subject to weaker

dispersive effects than the Korteweg–de Vries (KdV)-equation. More precisely, the rescaled kernel $\widetilde{G}(x) = \frac{\pi}{4} e^{-\frac{\pi}{2}|x|}$ was used as an approximation for the kernel

$$G_g(x) = \frac{1}{2\pi} \int_{\mathbb{R}} \Big(\frac{g}{\kappa} \tanh(\kappa h_0) \Big)^{\frac{1}{2}} e^{i\kappa x} \, d\kappa \tag{1.5}$$

when g and h_0 are normalized to 1. Equation (1.5) is the Fourier transform of the dispersion relation of linearized (small amplitude, velocity potential) gravity (g is the gravitational acceleration) water waves in an inviscid, incompressible, and irrotational fluid of constant depth h_0 [30]. In contrast to the KdV-equation, where the dispersion kernel is singular, the above smooth kernels feature weaker dispersive effects and allow, in particular, peaking and breaking of waves.

The present study of (1.1), (1.2) has been motivated by earlier work [10], [11] on two-species-Euler–Poisson (2SEP)-systems modelling the dynamics of two oppositely charged species of particles subject to Coulomb interaction. A simple version in dimensionless form is given by

$$\rho_t + (\rho u)_x = 0, \tag{1.6}$$

$$u_t + u u_x + \frac{\rho_x}{\rho} = \varphi_x, \tag{1.7}$$

$$\varepsilon \varphi_{xx} = \rho - e^{-\varphi}. \tag{1.8}$$

Here, the unknowns ρ, u, and φ depend on position $x \in \mathbb{R}$ and time $t > 0$. The system (1.6), (1.7) comprises the isothermal Euler equations for the first species of particle with density ρ and velocity u. In the Poisson equation (1.8) for the electrostatic potential φ, the density of the second species is modelled by the equilibrium approximation $e^{-\varphi}$, resulting from an equation like (1.7) with the first two terms neglected and the opposite sign on the right-hand side. The dimensionless parameter ε denotes the scaled Debye length.

In view of the formal similarities between the BP- and the 2SEP-system, we shall use the terms position, time, velocity, and potential for the variables x, t, u, and φ, respectively. Note that the velocity (instead of the density) appears on the right-hand side of the Poisson equation. Nevertheless one can consider the BP-system as a caricature of the 2SEP-system with the Burgers equation replacing the Euler equations, and the potential terms in (1.2) coming from a linearization of the two-species Poisson equation (1.8).

The BP-system has a number of interesting formal properties, collected in section 2. In particular, we mention its relation to the Camassa–Holm equation [4], [5] and the Benjamin–Ono equation [2], [26], its Galilean invariance, and its Hamiltonian structure, as well as the existence of an entropy.

In section 3, a general travelling wave analysis of the BP-system is performed, recovering the result of Fornberg and Whitham [17] in the particular case of solitary waves. It turns out that the travelling wave structure of the BP-system and several versions of the 2SEP-system (see [10], [11]) are qualitatively equivalent. The section is completed with some numerical experiments.

In section 4, existence and uniqueness of smooth solutions locally in time for smooth initial data are proved. Recently, for three related problems—the Euler–Poisson system [13], the Camassa–Holm equation [9], [27], and the Rosenau regularization of viscous conservation laws [23], [28]—global existence of smooth solutions has been shown under certain conditions on the initial data. The methods employed there

do not apply to the BP-system. Also our numerical experiments with the BP-system indicate that comparable results are not true.

A global existence and uniqueness result for weak entropy solutions with initial data in $BV(\mathbb{R})$ is also derived. Comparable results have been shown for Rosenau regularized conservation laws [28], [21]. The Rosenau regularization is formally closely related to the right-hand side of (1.4). It is obtained from the BP-system, replacing u by $-u_x$ in the right-hand side of (1.2). As opposed to the dispersive nature of the BP-system, it is dissipative.

The Rosenau regularization has several favorable properties (similar to hyperbolic or viscous conservation laws, but different from the BP-system): It is L^1-contracting, TVD, and has a comparison principle [28]. For the BP-system we do not have uniform (in time) L^∞-bounds, and the total variation may grow with time.

Finally, the rescaling $x \to x/\varepsilon$, $t \to t/\varepsilon$, $0 < \varepsilon \ll 1$, is introduced in (1.1), (1.2), leading to

$$u_t^\varepsilon + u^\varepsilon u_x^\varepsilon = \varphi_x^\varepsilon, \tag{1.9}$$

$$\varepsilon^2 \varphi_{xx}^\varepsilon = \varphi^\varepsilon + u^\varepsilon. \tag{1.10}$$

A Chapman–Enskog expansion of (1.9), (1.10) recovers the Burgers equation with flux $(u^\varepsilon + 1)^2/2$ and the leading order perturbation $\varepsilon^2 u_{xxx}^\varepsilon$. For a rescaled system, the KdV-equation is formally obtained in the limit $\varepsilon \to 0$.

The travelling wave analysis and numerical simulations suggest that the quasi-neutral limit $\varepsilon \to 0$ in general is a weak limit, both for the 2SEP- and the BP-systems. Here, a result is shown for the BP-system which has been proved for a 2SEP-system in [12] and for the Rosenau regularization in [21]: convergence to smooth solutions of the formal limit problem. In general this is only a local-in-time result since the limiting inviscid Burgers equation can develop singularities in finite time. The situation is the same for a 2SEP-system, but not for the Rosenau regularization, where the limiting equation is the viscous Burgers equation with global smooth solutions.

2. Formal properties. First, we rewrite the BP-system as a single differential equation for u. By applying $1 - \partial_x^2$ to (1.1) and using (1.2) on the resulting right-hand side, we calculate

$$u_t - u_{xxt} + u_x + uu_x = 3u_x u_{xx} + uu_{xxx}. \tag{2.1}$$

The terms in (2.1) correspond to those in the Camassa–Holm equation [4]:

$$u_t - u_{xxt} + 2\kappa u_x + 3uu_x = 2u_x u_{xx} + uu_{xxx}, \tag{2.2}$$

where the constant $\kappa \geq 0$ is related to the critical shallow water wave speed. Conversely, the Camassa–Holm equation (2.2) can be written in "BP form":

$$u_t + uu_x = \varphi_x\,, \tag{2.3}$$

$$\varphi_{xx} = \varphi + 2\kappa u + u^2 + \frac{1}{2}u_x^2\,. \tag{2.4}$$

Note that for $\kappa = 1/2$ the BP-system is recovered by neglecting the two quadratic terms in (2.4).

The Camassa–Holm equation was introduced by Fokas and Fuchssteiner [15] as a formally integrable bi-Hamiltonian generalization of the KdV-equation. Camassa and Holm [4] rediscovered it as a shallow water equation by approximating the Hamiltonian

for the vertically averaged incompressible Euler equations. By the bi-Hamiltonian property, they derived an infinite sequence of conservation laws and showed that the associated flows of this hierarchy are isospectral and, thus, completely integrable.

Most commonly (cf. [5], [9], [8], [27]), the Camassa–Holm equation (2.2) is considered with $\kappa = 0$. Then the Camassa-Holm equation possesses peaked soliton solutions (called peakons), attractive travelling waves of the form $u(x,t) = c\exp(-|x-ct|)$, and other breaking phenomena, which is desirable for a shallow water equation and in contrast to the KdV-behavior.

For some initial data (e.g., with sufficiently large negative slope [8], [27]) the solution develops verticality within finite time. On the other hand, global well-posedness was proved (see [9], [27]) for initial data $u_0 \in H^s(\mathbb{R})$ with $s > 3/2$, provided that $\int |u_0|\,dx < \infty$ and $(1-\partial_x^2)u_0$ does not change sign. The Camassa–Holm equation is remarkable since it combines complete integrability with the formation of singularities.

In the existence analysis of section 4, (1.4) will be considered, subject to the initial conditions

$$u(x,0) = u_0(x), \qquad x \in \mathbb{R}. \tag{2.5}$$

Note that (1.4) contains additional information compared to (1.1), (1.2), since for bounded u, (1.3) is the unique bounded solution of the Poisson equation (1.2). The properties of the solution operator of the Poisson equation in a L^2-setting will be used, in particular the smoothing

$$\|\varphi[u]\|_{H^{k+2}(\mathbb{R})} \le \|u\|_{H^k(\mathbb{R})}, \qquad u \in H^k(\mathbb{R}),\ k \ge 0, \tag{2.6}$$

and the symmetry

$$\int_{\mathbb{R}} \varphi[u]v\,dx = \int_{\mathbb{R}} \varphi[v]u\,dx, \qquad u, v \in L^2(\mathbb{R}), \tag{2.7}$$

following from the evenness of the Green's function G.

The BP-equation (1.4) becomes the Benjamin–Ono equation when $\varphi[u]$ is replaced by $-2H[u_x]$, where H is the Hilbert transform

$$H[u] = \text{p.v.}\frac{1}{\pi}\int_{-\infty}^{\infty} \frac{u(y)}{y-x}\,dy,$$

with p.v. denoting the Cauchy principle value. The Benjamin–Ono equation arises in the study of long internal gravity waves in stratified fluids of great depth [2], [26]. It is a completely integrable Hamiltonian system [19] possessing multisoliton solutions [3], [6]. There exists also the analogue of the inverse scattering method [1] and Bäcklund transformations [24]. Although the dispersive regularization by the Hilbert transform is weak compared to KdV (cf. [20]), the dispersion is strong enough that the Benjamin–Ono equation has globally smooth solutions for initial data $u_0 \in H^k(\mathbb{R})$, $k \ge 3/2$ (see [18], [25]), and even for sublinearly growing initial data [16].

The BP-system (1.1), (1.2) is *Galilean invariant*, i.e., invariant under changes of the reference frame of the form

$$x \to x + x_0 + u_0 t, \qquad u \to u + u_0, \qquad \varphi \to \varphi - u_0.$$

Note that the potential transforms like a velocity. The Galilean invariance will simplify the travelling wave analysis in section 3.

The *dispersion relation* of the BP-equation (1.4) linearized at $u = c$ is given by

$$\frac{\omega}{k} = c + \frac{1}{1+k^2}, \tag{2.8}$$

with the frequency ω and the wave number k. The group velocities lie between c and $c+1$, the limits for large and small wave numbers, respectively. The existence of a finite limit for large wave numbers indicates that (1.4) does not have smoothing properties.

Finally, we look for *conservation laws*. Obviously, (1.4) can be written in conservation form:

$$u_t + \left(\frac{u^2}{2} - \varphi[u]\right)_x = 0. \tag{2.9}$$

As a consequence, $\int_{\mathbb{R}} u\,dx$ is conserved for weak solutions with sufficiently strong decay for $x \to \pm\infty$. Moreover, for smooth convex functions Φ, multiplication of (1.4) with Φ' yields for smooth solutions

$$\Phi(u)_t + \Psi(u)_x = \varphi_x[u]\Phi'(u), \tag{2.10}$$

where Ψ is such that $\Psi'(u) = u\Phi'(u)$. In section 4, we prove that weak solutions constructed via a vanishing viscosity approach satisfy, instead of (2.10), entropy inequalities with the equality sign replaced by $\leq$.

We remark that only the choice $\Phi'(u) = u = \varphi_{xx} - \varphi$ allows us to write the right-hand side of (2.10) in conservation form. It leads, for smooth solutions, to the second conservation law

$$(u^2)_t + \left(\frac{2}{3}u^3 + \varphi^2 - \varphi_x^2\right)_x = 0, \tag{2.11}$$

while for weak solutions, the entropy $\int_{\mathbb{R}} u^2\,dx$ is nonincreasing.

The *jump conditions* for entropic shocks with velocity s are those of the Burgers equation:

$$s = \frac{1}{2}(u_l + u_r), \qquad u_l > u_r, \tag{2.12}$$

where u_l and u_r denote the left-sided and, respectively, right-sided limit of u at the shock.

The BP-equation has a *Hamiltonian structure* similar to the Benjamin–Ono equation. The bi-Hamiltonian structure of the Camassa–Holm equation is completely destroyed by dropping the quadratic terms in (2.4). With the Hamiltonian

$$H(u) = \frac{1}{2}\int_{\mathbb{R}} \left(-\varphi[u]u + \frac{u^3}{3}\right) dx,$$

equation (1.4) can be written as

$$u_t + \left(\frac{\delta H}{\delta u}\right)_x = 0,$$

where $\frac{\delta H}{\delta u} = -\varphi[u] + \frac{u^2}{2}$ is the L^2-representation of the Frechet-derivative of H. Note that this relies on the symmetry property (2.7) of $\varphi[\cdot]$. Conservation of the quantity $\int_{\mathbb{R}} H(u)\,dx$ corresponds to the third local conservation law

$$\left(-\varphi u + \frac{u^3}{3}\right)_t + \left(\varphi_x\varphi_t - \varphi\varphi_{xt} - \left(-\varphi + \frac{u^2}{2}\right)^2\right)_x = 0,$$

which (as (2.11)) can be expected to hold only for smooth solutions.

3. Travelling wave analysis. The results of this section should be compared to those of [10], [11] for different versions of the Euler–Poisson system. The qualitative similarities of the results have been one of the main motivations for this work.

By the Galilean invariance it suffices to consider only travelling waves with velocity 0, i.e., steady states. Travelling waves with velocity c are then found by adding the constant c to the velocity u (and $-c$ to the potential φ). After integration of the steady state version of (1.1) and using the result in (1.2), the steady state equations can be written as

$$uu_x = E, \tag{3.1}$$

$$E_x = \frac{u^2}{2} + u - d, \tag{3.2}$$

where we have used the notation $\varphi_x = E$ and d is the constant of integration. The system (3.1), (3.2) will be studied in the (u, E)-phase-plane. We shall also allow shocks (of course with velocity $s = 0$) satisfying the jump conditions (2.12):

$$-u_r = u_l > 0.$$

By (3.2), E is continuous across shocks.

Also worth mentioning is the line of singularities $u = 0$. In general, trajectories end (or begin) there with square root behavior. By (3.1), smooth trajectories can cross $u = 0$ only through the origin of the (u, E)-plane. Our analysis will be restricted to $d > -1/2$, whence there are two stationary points

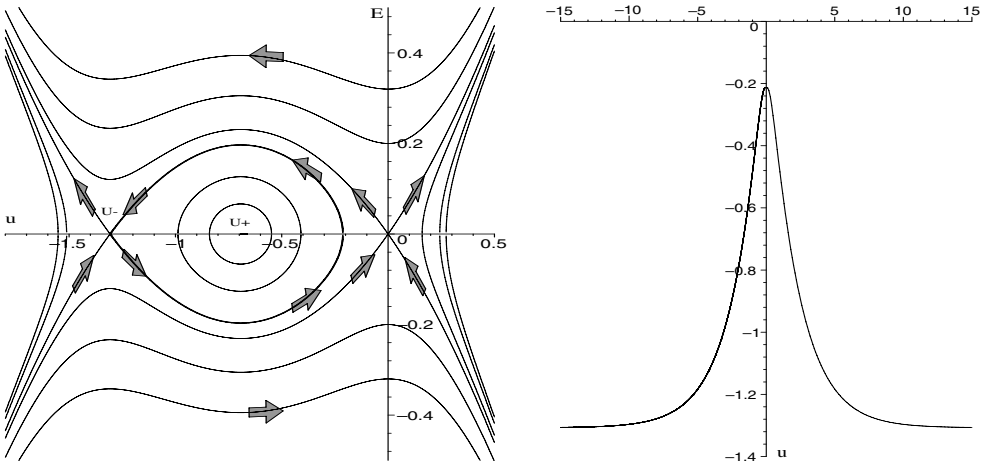
$$P_\pm = \begin{pmatrix} E_\pm \\ u_\pm \end{pmatrix} = \begin{pmatrix} 0 \\ -1 \pm \sqrt{1+2d} \end{pmatrix}.$$

It is easily seen that u_- is always negative and a saddle. The second stationary point u_+ is negative and a center for $-1/2 < d < 0$. It becomes positive and a saddle for $d > 0$. By separation of variables, a first integral of (3.1), (3.2) can be found:

$$A = \frac{E^2}{2} - \frac{u^4}{8} - \frac{u^3}{3} + \frac{du^2}{2}. \tag{3.3}$$

Besides the stationary points, this family of curves (parametrized by A) has the origin as a critical point. Only away from the line $u = 0$ can these curves be seen as trajectories (with opposite orientation on opposite sides of $u = 0$).

Depending on the value of d, three generic cases of phase portraits occur as follows.



(a) Phase portrait for $-\frac{1}{2} < d \leq -\frac{4}{9}$.

(b) Solitary wave.

FIG. 1. *Solitary waves for* $-\frac{1}{2} < d \leq -\frac{4}{9}$.

Solitary waves for $-1/2 < d \leq -4/9$. The phase portraits for $-1/2 < d < -4/9$ are characterized by a homoclinic orbit (pulse, solitary wave) connecting P_- to itself (see Figure 1(a), (b)). Its interior is filled with periodic solutions around P_+. These features are reminiscent of the KdV-equation. By the singularity, the origin is a point of nonuniqueness for the initial value problem. Taylor expansion shows a pair of smooth trajectories passing through the origin. An implicit formula for the solitary waves has already been calculated in [17], together with a numerical simulation of the soliton-like interaction of two solitary waves.

In the critical case $d = -4/9$, the trajectories through the origin coincide with the stable and unstable manifolds of P_-. As a consequence of the nonuniqueness, we can switch from the unstable to the stable manifold at the origin, producing a nonsmooth solitary wave, reminiscent of the peakon solutions of the Camassa–Holm equation. It can be computed explicitly:

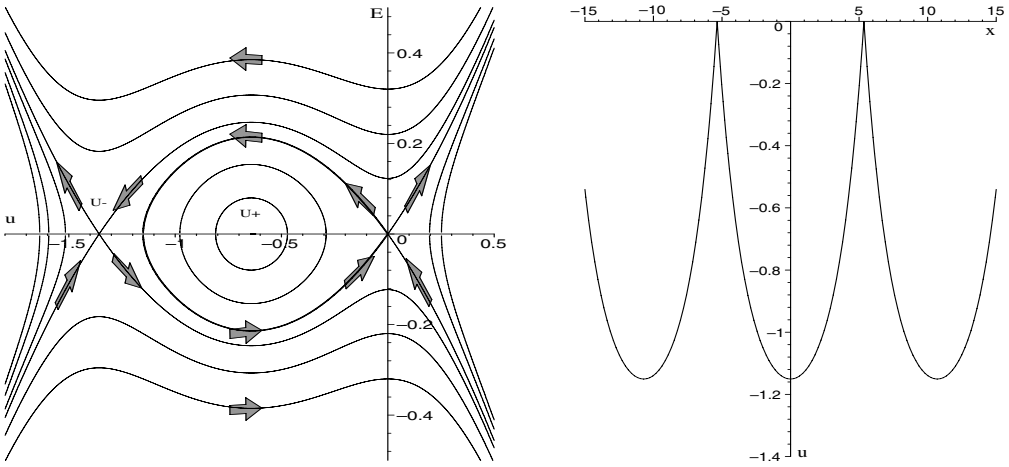
$$u(x) = \frac{4}{3}\left(e^{-|x|/2} - 1\right).$$

Peaked periodic solutions for $-4/9 < d < 0$. In this case the solitary wave disappears, and the trajectories passing through the origin connect to themselves (see Figure 2(a)). This closed curve in the left half plane corresponds to a peaked periodic solution (see Figure 2(b)). Again, these solutions can be computed explicitly. Taking the derivative of (3.1) and using (3.3) for the evaluation of u_x^2, we obtain (with $A = 0$)

$$u_{xx} = \frac{u}{4} + \frac{1}{3}.$$

The peaked periodic solution is given by

$$u(x) = \frac{4}{3}\left(\frac{\cosh(x/2)}{\cosh(p/2)} - 1\right)$$



(a) Phase portrait for $-\frac{4}{9} < d < 0$.

(b) Peaked periodic solution.

FIG. 2. *Periodic solutions for* $-\frac{4}{9} < d < 0$.

for $-p < x < p$ and by periodic continuation with period $2p$. The length of the period is connected to the parameter d by

$$\cosh\left(\frac{p}{2}\right) = \left(1 + \frac{9}{4}d\right)^{-1/2}.$$

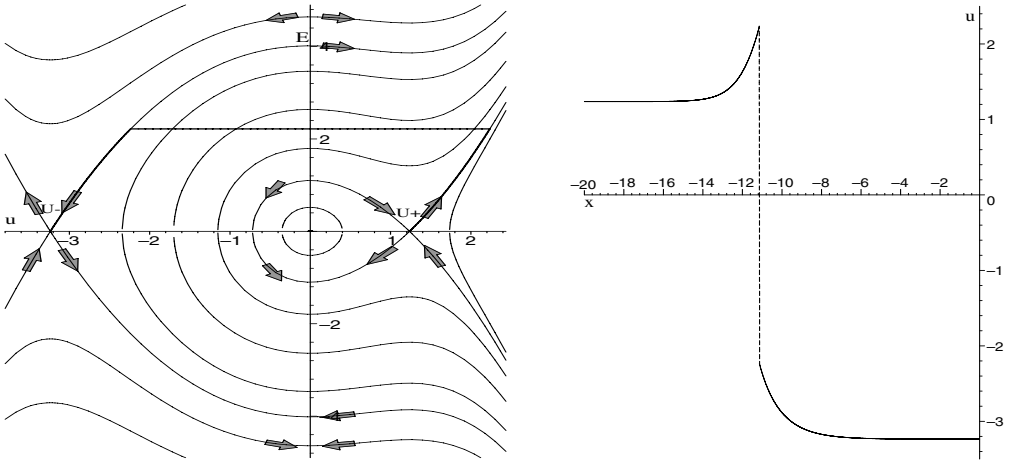
As d tends to zero, p tends to zero and the peaked periodic orbit shrinks to the origin in the phase portrait.

Heteroclinic connections for $d \geq 0$. For $d > 0$, the stationary points are saddles and lie on opposite sides of the line $u = 0$ (see Figure 3(a)). A heteroclinic connection (front wave) between them can be constructed using an entropic shock. There is a unique pair of points $P_l = (u_l, E_l) = (\sqrt{1+2d}, \sqrt{11/12+2d})$, $P_r = (-u_l, E_l)$, satisfying the jump conditions, with P_l lying on the unstable manifold of P_+, and P_r on the stable manifold of P_-. The u-component of the heteroclinic solution is depicted in Figure 3(b). Note that a solution with this qualitative behavior also exists for $d = 0$. In this case, however, the convergence towards P_+ is not exponential, since for $d = 0$, P_+ is a degenerate stationary point.

Remark 3.1. The question arises whether two arbitrary constant states $u_{-\infty}$, u_∞ can be connected by a front wave. The answer is negative. The set of admissible pairs $(u_{-\infty}, u_\infty)$ is constructed by shifting pairs $(u_+(d), u_-(d))$, $d \geq 0$ (exploiting the Galilean invariance). This leads to the requirement $u_\infty - u_{-\infty} \geq 2$.

Transient behavior, numerical experiments. We have studied the transient behavior of solutions of the BP-equation (1.4) numerically. A MATLAB program was written employing a straightforward explicit discretization: In a first step, the Poisson equation is solved for given u at the old time step. A centered difference scheme is used on a bounded interval with boundary conditions $\varphi + u = 0$ at both ends.

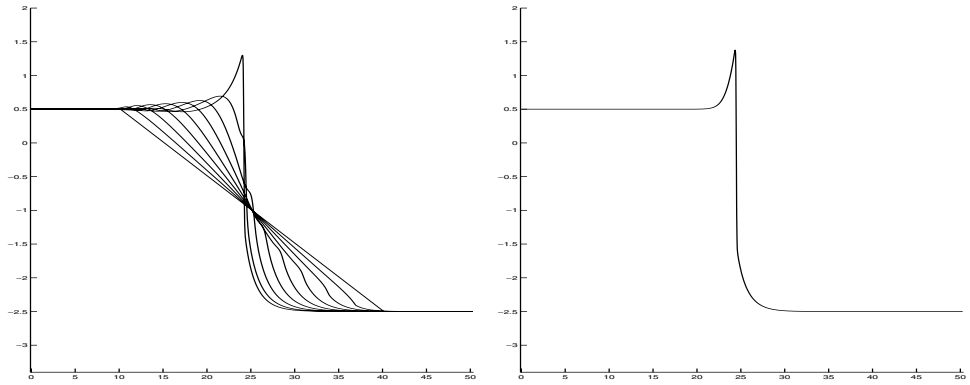
The result is used for the evaluation of the right-hand side of (1.4). Alternatively, we used an implicit spectral method (cf. [7, Part II, Chapter 8]) and obtained very



(a) Phase portrait for $d > 0$.

(b) Shock solution.

FIG. 3. *Shock solutions for* $d \geq 0$.



(a) Shock formation.

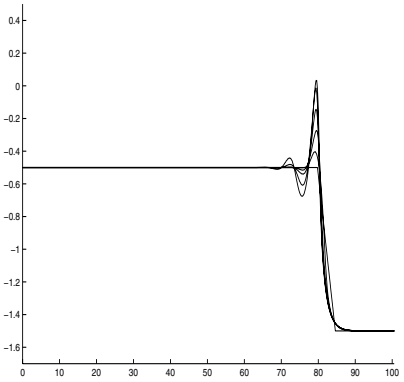
(b) Numerical stationary solution.

FIG. 4. *Initial ramp of height* $3 : 0.5 \searrow -2.5$.

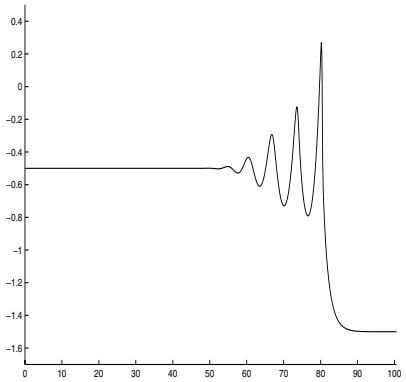
similar results. This spectral method is between three and four times faster due to the use of FFT, but it applies only for spatially periodic situations.

The Burgers flux term is discretized by the Lax–Friedrichs method. Time steps are chosen according to the CFL-condition. As initial data, linear ramps connecting two constant states are prescribed. Recalling Remark 3.1, we are interested in the behavior depending on the difference between the asymptotic states at $x = \pm\infty$.

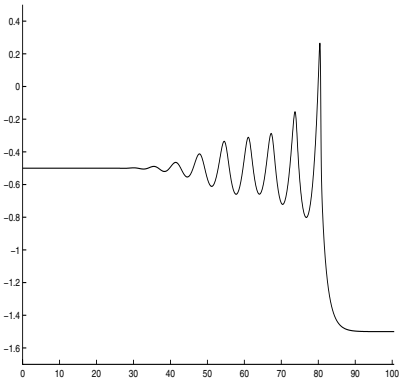
Our results for downward ramps of height larger than 2 suggest the conjecture that the heteroclinic waves constructed above are attractive. For a typical example, see Figure 4(a) and (b). For a ramp with height 3 and the constant states lying symmetric with respect to $u = -1$, we observe numerical convergence to the stationary solution



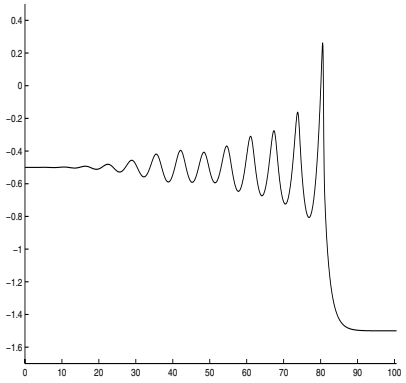
(a) Formation of first oscillations ($t = 0, 2, 4, 6, 10, 15$).



(c) Numerical solution at $t = 40$.



(b) Numerical solution at $t = 80$.



(d) Numerical solution at $t = 120$.

FIG. 5. *Initial ramp of height* $1 : -0.5 \searrow -1.5$.

of the type of Figure 3(b). The development of shocks seems not to depend on the steepness of the ramp.

A completely different behavior is observed for initial ramps with a height less than 2: In this case, there exists no stationary solution connecting the asymptotic states. For a typical example, Figure 5, the observed behavior is reminiscent of the KdV-equation and shows typical dispersive effects with oscillations at the left side of a smoothed ramp. This is in accordance with the dispersion relation (2.8) showing that high frequency components travel with lower velocities.

4. Existence. In this section, the initial value problem

$$u_t + uu_x = \varphi_x[u], \qquad u(x,0) = u_0(x) \tag{4.1}$$

is considered, where the operator $\varphi[\cdot]$ is defined in (1.3).

THEOREM 4.1 (local strong solution). *Assume $u_0 \in H^k(\mathbb{R})$ with $k > \frac{3}{2}$. Then there exists a time $T(\|u_0\|_{H^k(\mathbb{R})}) > 0$ and a unique solution*

$$u \in L^\infty\big((0,T); H^k(\mathbb{R})\big) \cap C\big([0,T]; H^{k-1}(\mathbb{R})\big)$$

of (4.1) *such that $T(\|u_0\|_{H^k(\mathbb{R})})$ depends only on $\|u_0\|_{H^k(\mathbb{R})}$.*

Proof. The proof is based on a contraction argument similar to that of [29, section 16.1]. We define the iteration map S_T as follows: For any function $v \in B_T$ with

$$B_T := \Big\{ w \in L^\infty((0,T), H^k(\mathbb{R})) \cap C([0,T]; H^{k-1}(\mathbb{R})) : \sup_{t\in[0,T]} \|w(\cdot,t)\|_{H^k(\mathbb{R})} \le 2\|u_0\|_{H^k(\mathbb{R})} \Big\}$$

the image $S_T(v)$ is the unique solution u of

$$u_t + uu_x = \varphi_x[v], \qquad u(t=0) = u_0. \tag{4.2}$$

First, we show that S_T maps B_T into itself for T small enough. We apply ∂_x^α to (4.2) for $\alpha \le k$ and take the L^2-scalar product with $\partial_x^\alpha u$:

$$\frac{1}{2}\frac{d}{dt}\big\|\partial_x^\alpha u\big\|^2_{L^2(\mathbb{R})} \quad + \quad \underbrace{\int_{\mathbb{R}} \partial_x^\alpha (uu_x)\, \partial_x^\alpha u \, dx}_{A} \quad = \quad \underbrace{\int_{\mathbb{R}} \varphi_x[\partial_x^\alpha v]\, \partial_x^\alpha u \, dx}_{B}. \tag{4.3}$$

The first factor in the integrand of A is differentiated by the product rule:

$$\partial_x^\alpha (uu_x) = u\, \partial_x^{\alpha+1} u + \sum_{l=1}^{\alpha} \binom{\alpha}{l} \partial_x^l u\, \partial_x^{\alpha+1-l} u.$$

Accordingly, A is split into two parts which are estimated separately:

$$\left| \int_{\mathbb{R}} u\, (\partial_x^{\alpha+1} u)(\partial_x^\alpha u)\, dx \right| = \frac{1}{2} \left| \int_{\mathbb{R}} u\, \partial_x (\partial_x^\alpha u)^2 \, dx \right| \le \frac{1}{2} \|u_x\|_{L^\infty(\mathbb{R})} \|u\|^2_{H^k(\mathbb{R})}. \tag{4.4}$$

For the second part of A, we use the Cauchy–Schwarz inequality and the interpolation estimate

$$\big\| \big(\partial_x^{l-1} f_x\big)\, \big(\partial_x^{\alpha-l} g_x\big) \big\|_{L^2(\mathbb{R})} \le c\, \big(\|f_x\|_{L^\infty(\mathbb{R})} \|g\|_{H^\alpha(\mathbb{R})} + \|f\|_{H^\alpha(\mathbb{R})} \|g_x\|_{L^\infty(\mathbb{R})} \big)$$

(see [29, Chapter 13, Proposition 3.6]) to obtain

$$\left| \int_{\mathbb{R}} \partial_x^\alpha u \sum_{l=1}^{\alpha} \binom{\alpha}{l} \partial_x^{l-1} u_x\, \partial_x^{\alpha-l} u_x \, dx \right| \le c \|u\|^2_{H^k(\mathbb{R})} \|u_x\|_{L^\infty(\mathbb{R})}\,,$$

with some constant c depending only on k. By the Sobolev imbedding $W^{1,\infty}(\mathbb{R}) \hookrightarrow H^k(\mathbb{R})$ for $k > 3/2$, we calculate

$$|A| \le c \|u\|^3_{H^k(\mathbb{R})}. \tag{4.5}$$

For B, we apply the Cauchy–Schwarz inequality and (2.6):

$$|B| \le \|\varphi_x[\partial_x^\alpha v]\|_{L^2(\mathbb{R})} \|\partial_x^\alpha u\|_{L^2(\mathbb{R})} \le c \|v\|_{H^k(\mathbb{R})} \|u\|_{H^k(\mathbb{R})}. \tag{4.6}$$

Using (4.5) and (4.6) in (4.3) gives

$$\frac{d}{dt}\|u\|_{H^k(\mathbb{R})} \le c\left(\|u\|^2_{H^k(\mathbb{R})} + \|v\|_{H^k(\mathbb{R})}\right).$$

For T small enough, a comparison principle shows $\|u(\cdot,t)\|_{H^k(\mathbb{R})} \le 2\|u_0\|_{H^k(\mathbb{R})}$ for $0 \le t \le T$. Since $u \in C([0,T];H^{k-1}(\mathbb{R}))$ is an obvious consequence of (4.2), we conclude that $S_T : B_T \to B_T$. In a second step, we prove S_T to be a strict contraction. Therefore, we consider two functions v_1 and v_2 in B_T and set $u_1 = S_T(v_1)$, $u_2 = S_T(v_2)$, and $u = u_1 - u_2$, $v = v_1 - v_2$. The difference of the equations for u_1, u_2 reads as

$$u_t + u(u_1)_x + u_2 u_x = \varphi_x[v], \qquad u(t=0) = 0.$$

We proceed similarly to (4.2), using B from (4.3):

$$\frac{1}{2}\frac{d}{dt}\|\partial_x^\alpha u\|^2_{L^2(\mathbb{R})} + \underbrace{\int_{\mathbb{R}} \partial_x^\alpha(u\partial_x u_1)\,\partial_x^\alpha u\,dx}_{A_1} + \underbrace{\int_{\mathbb{R}} \partial_x^\alpha(u_2 u_x)\,\partial_x^\alpha u\,dx}_{A_2} = B.$$

In contrast to (4.4), the highest order term of A_1 is not bounded in terms of the $H^\alpha(\mathbb{R})$-norm. Therefore, we are obliged to reduce the order of differentiation to $\alpha \le k-1$ and estimate as above for the second part of A:

$$\begin{aligned}|A_1| &\le c\|u\|_{H^{k-1}(\mathbb{R})}\left(\|\partial_x u_1\|_{L^\infty(\mathbb{R})}\|u\|_{H^{k-1}(\mathbb{R})} + \|u\|_{L^\infty(\mathbb{R})}\|u_1\|_{H^k(\mathbb{R})}\right)\\ &\le c\|u\|^2_{H^{k-1}(\mathbb{R})}\|u_1\|_{H^k(\mathbb{R})}.\end{aligned}$$

For A_2, we proceed as in (4.4)–(4.5):

$$\begin{aligned}|A_2| &= \left|\int_{\mathbb{R}}\left(\frac{u_2\,\partial_x(\partial_x^\alpha u)^2}{2} + \partial_x^\alpha u\sum_{l=1}^{\alpha}\binom{\alpha}{l}\partial_x^l u_2\,\partial_x^{\alpha-l}u_x\right)dx\right|\\ &\le c\|u\|^2_{H^{k-1}(\mathbb{R})}\|u_2\|_{H^k(\mathbb{R})}.\end{aligned}$$

Since $\|u_{1,2}\|_{H^k(\mathbb{R})} \le 2\|u_0\|_{H^k(\mathbb{R})}$, this leads to

$$\frac{d}{dt}\|u\|_{H^{k-1}(\mathbb{R})} \le c\left(\|u\|_{H^{k-1}(\mathbb{R})} + \|v\|_{H^{k-1}(\mathbb{R})}\right),$$

and the Gronwall lemma implies that for T small enough, S_T is a strict contraction with respect to the topology in $C([0,T];H^{k-1}(\mathbb{R}))$. ∎

THEOREM 4.2 (global weak solution). *Assume $u_0 \in BV(\mathbb{R})$. Then there exists a unique global weak solution*

$$u \in L^\infty_{loc}([0,\infty);BV(\mathbb{R})) \tag{4.7}$$

of (4.1)*, satisfying (in the distributional sense) the entropy inequalities*

$$\Phi(u)_t + \Psi(u)_x \le \varphi_x[u]\Phi'(u) \tag{4.8}$$

for convex entropy densities $\Phi \in C^1(\mathbb{R})$ and for Ψ such that $\Psi'(u) = u\Phi'(u)$.

Remark 4.1. For convex functions $\Phi \in W^{1,\infty}(\mathbb{R})$, it is possible to establish generalizations of (4.8) in the sense that the right-hand side of (4.8) has to be interpreted

as the limit of an approximating procedure. More precisely, considering a smoothing $\Phi_\delta \to \Phi$ in $W^{1,\infty}(\mathbb{R})$, the dominated convergence theorem and the upper bound $\varphi_x[u]\|\Phi'\|_{L^\infty}$ imply that the limit $\delta \to 0$ of the right-hand side of (4.8) exists, although it depends on the pointwise limit $\lim_{\delta\to 0} \Phi'_\delta$ since the level sets $\{u = \alpha\}$ may have nonzero measure.

Such problems do not occur in the theory of scalar conservation laws with local flux terms [29] where Kruzhkov's entropy densities $\Phi = |u - \alpha| \in W^{1,\infty}(\mathbb{R})$ for all $\alpha \in \mathbb{R}$ are well defined and allow us, for instance, to show L^1-contractivity (and therefore uniqueness) of the entropy solutions. For the BP-equation (4.1), only L^1-stability can be shown using the above generalizations of (4.8), which is nevertheless sufficient to show the uniqueness.

Proof. The proof is based on a viscosity method similar to that of [29, Chapter 16.6]. Instead of (4.1), we consider the regularized equation

$$u_t + uu_x = \varphi_x[u] + \nu u_{xx} \tag{4.9}$$

with $\nu > 0$. Local existence of a unique smooth solution of the initial value problem for (4.9) with $u(t = 0) = u_0 \in BV(\mathbb{R})$ can be shown by standard arguments. The next step is an L^1-stability result for (4.9). Let u_1, u_2 denote solutions of (4.9) with initial data $f_1, f_2 \in L^1(\mathbb{R})$. Then the difference $v = u_1 - u_2$ satisfies

$$v_t + (wv)_x = \varphi_x[v] + \nu v_{xx}, \qquad v(t = 0) = f_1 - f_2, \tag{4.10}$$

with $w = (u_1 + u_2)/2$. Let $\mathrm{abs}_\delta(\cdot)$ be a convex regularization of the modulus, uniformly converging to $|\cdot|$ as $\delta \to 0$, and satisfying $|\mathrm{abs}'_\delta(v)| \le 1$. Multiplication of (4.10) with $\mathrm{abs}'_\delta(v)$ and integration with respect to x leads to

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}} \mathrm{abs}_\delta(v)\,dx = &\int_{\mathbb{R}} wv\,\mathrm{abs}''_\delta(v)v_x\,dx - \int_{\mathbb{R}} \mathrm{abs}'_\delta(v)\varphi_x[v]\,dx \\ &- \nu\int_{\mathbb{R}} \mathrm{abs}''_\delta(v)\,(v_x)^2\,dx.\end{aligned} \tag{4.11}$$

Since the function $\int_0^v s\,\mathrm{abs}''_\delta(s)\,ds$ converges to zero uniformly as $\delta \to 0$, we have for the first term on the right-hand side of (4.11)

$$\int_{\mathbb{R}} wv\,\mathrm{abs}''_\delta(v)v_x\,dx = -\int_{\mathbb{R}} w_x \int_0^v s\,\mathrm{abs}''_\delta(s)\,ds\,dx \to 0 \qquad \text{as } \delta \to 0.$$

Boundedness of the operator $\varphi_x[\cdot] : L^1(\mathbb{R}) \to L^1(\mathbb{R})$ can be shown easily. With the properties of abs_δ, we obtain from (4.11) in the limit $\delta \to 0$

$$\frac{d}{dt}\|v\|_{L^1(\mathbb{R})} \le c\|v\|_{L^1(\mathbb{R})}. \tag{4.12}$$

Analogously to [29, Lemma 6.1], it can be shown that

$$\frac{d}{dt}\|v\|_{BV(\mathbb{R})} \le c\|v\|_{BV(\mathbb{R})}$$

holds for the solution of (4.9) as a consequence of (4.12). This is sufficient for proving that the solution of (4.9) is global and bounded in $L^\infty_{loc}([0,\infty); BV(\mathbb{R}))$ uniformly in ν. This again is sufficient to show that the solution converges pointwise a.e. on $(0,\infty)\times\mathbb{R}$ as $\nu \to 0$. For the details of the vanishing viscosity limit we refer to [29].

To show that the constructed solutions satisfy the entropy inequalities (4.8) we first consider smooth convex entropy densities Φ and multiply (4.9) with $\Phi'(u(t,x))$. In the weak formulation with nonnegative testfunctions $\theta \in C_0^\infty((0,\infty)\times\mathbb{R})$, integration by parts yields

$$-\int\limits_{(0,\infty)\times\mathbb{R}}\int (\Phi\,\theta_t + \Psi\,\theta_x)\,dtdx = \int\limits_{(0,\infty)\times\mathbb{R}}\int \left(\varphi_x[u]\Phi'(u) - \nu\Phi'' u_x^2 + \nu\Phi_{xx}\right)\theta\,dtdx,$$

where Ψ is as smooth as Φ and satisfies $\Psi' = u\Phi'$. Now, in the vanishing viscosity limit like above, $\Phi(u), \Psi(u)$, and $\varphi_x[u]\Phi'(u)$ converge pointwise a.e. on $(0,\infty)\times\mathbb{R}$ as $\nu \to 0$ by the smoothness of Φ and Ψ. Moreover (see [29]), $\nu\Phi_{xx} \to 0$ weakly, while $-\nu\Phi'' u_x^2 \le 0$ by the convexity of Φ, which implies the inequality sign (4.8). By an approximation argument, (4.8) holds clearly for $\Phi \in C^1(\mathbb{R})$.

For convex $\Phi \in W^{1,\infty}(\mathbb{R})$, Φ' is defined a.e. and monotonically increasing and has therefore at most a countable number of jumps. Hence, after defining Φ' pointwise everywhere in some way such that $|\Phi'|(x) \le \|\Phi'\|_{L^\infty}$, there exist smooth approximations $\Phi_\delta \to \Phi$ in $W^{1,\infty}(\mathbb{R})$ such that $|\Phi_\delta'|(x) \le |\Phi'|(x)$ and $\Phi_\delta' \to \Phi'$ pointwise everywhere. Therefore, considering a particular smoothing Φ_δ, the limit $\delta \to 0$ in the right-hand side of (4.8) is well defined by the dominated convergence theorem using the common upper bound $\varphi_x[u]\|\Phi'\|_{L_\infty}$.

To shown uniqueness of the entropy solution, we choose a particular smoothing Φ_δ of Kruzhkov's entropy densities $\Phi(u) = |u-\alpha|$ for $\alpha \in \mathbb{R}$ such that the limit $\lim_{\delta\to 0}\Phi_\delta'(0) = \operatorname{sign}(0) = 0$. Moreover, we consider two solutions $u(t,x)$ and $\widetilde{u}(s,y)$ and sum, respectively, two generalizations of (4.8), where we set $\alpha = \widetilde{u}(s,y)$ in the first and $\widetilde{\alpha} = u(t,x)$ in the latter. Hence, after estimating $|\operatorname{sign}(u-\alpha)| \le 1$ on the right-hand side, we obtain

$$\begin{aligned}-\iiiint |u-\widetilde{u}|\,(\theta_t+\theta_s)\,dtdxdsdy - \iiiint \Psi(u,\widetilde{u})(\theta_x+\theta_y)\,dtdxdsdy \\ \le \iiiint |\varphi_x[u]-\varphi_y[\widetilde{u}]|\,\theta\,dtdxdsdy,\end{aligned}$$

where $\Psi(u,\widetilde{u}) = \frac{1}{2}(u+\widetilde{u})|u-\widetilde{u}|$ and $\theta = \theta(t,x,s,y)$, a nonnegative testfunction, which we choose especially as

$$\theta(t,x,s,y) = f(t)\,\delta_\varepsilon\left(\frac{t-s}{2}\right)\,g(x)\,\delta_\varepsilon\left(\frac{x-y}{2}\right),$$

where $f, \delta_\varepsilon, g_\varepsilon$ are nonnegative in $C_0^\infty(\mathbb{R})$ and $\delta_\varepsilon(\cdot)$ approximates the delta distribution as $\varepsilon \to 0$, while g_ε is a plateau-function with $0 \le g_\varepsilon \le 1$ and $g_\varepsilon \equiv 1$ on $(-\varepsilon^{-1},\varepsilon^{-1})$. Since

$$\theta_t+\theta_s = f'\,\delta_\varepsilon\left(\frac{t-s}{2}\right)\,g\,\delta_\varepsilon\left(\frac{x-y}{2}\right), \qquad \theta_x+\theta_y = f\,\delta_\varepsilon\left(\frac{t-s}{2}\right)\,g'\,\delta_\varepsilon\left(\frac{x-y}{2}\right),$$

we obtain in the limit $\varepsilon \to 0$

$$-\int\limits_{(0,\infty)\times\mathbb{R}}\int |u(t,x)-\widetilde{u}(t,x)|f'\,dtdx \le \int\limits_{(0,\infty)\times\mathbb{R}}\int |\varphi_x[u]-\varphi_x[\widetilde{u}]|\,f\,dtdx.$$

Since obviously $\int_{\mathbb{R}} |\varphi_x[u-\widetilde{u}]|\,dx \le \|G_x\|_\infty \int_{\mathbb{R}} |u-\widetilde{u}|\,dx$ with $\|G_x\|_\infty = \frac{1}{2}$, we conclude (after integration by parts and by the arbitrariness of f) that

$$\frac{d}{dt}\int_{\mathbb{R}} |u-\widetilde{u}|\,dx \le \frac{1}{2}\int_{\mathbb{R}} |u-\widetilde{u}|\,dx,$$

and the Gronwall lemma implies the uniqueness. □

5. Asymptotics and the quasineutral limit. In this section, we investigate the rescaled $(x \to x/\varepsilon, t \to t/\varepsilon)$ BP-system

$$u_t^\varepsilon + u^\varepsilon u_x^\varepsilon = \varphi_x^\varepsilon, \tag{5.1}$$

$$\varepsilon^2 \varphi_{xx}^\varepsilon = \varphi^\varepsilon + u^\varepsilon, \tag{5.2}$$

with $\varepsilon \ll 1$. In accordance with the terminology taken from the Euler–Poisson system, the limit $\varepsilon \to 0$ will be called the quasi-neutral limit. With the rescaled potential operator

$$\varphi^\varepsilon[u](x) = -\frac{1}{2\varepsilon} \int_{\mathbb{R}} \exp\left(-\frac{|x-y|}{2\varepsilon}\right) u(y)dy,$$

the initial value problem

$$u_t^\varepsilon + u^\varepsilon u_x^\varepsilon = \varphi_x^\varepsilon[u^\varepsilon], \qquad u^\varepsilon(t=0) = u_0, \tag{5.3}$$

will be compared to its formal limit

$$u_t^0 + (u^0+1)u_x^0 = 0, \qquad u^0(t=0) = u_0. \tag{5.4}$$

The limit is the inviscid Burgers equation for the unknown $u^0 + 1$. Even for smooth initial data its solution can develop shocks in finite time. The travelling wave analysis of section 3 can be seen as an attempt to approximate solution profiles in the neighborhood of shocks of (5.4). The heteroclinic connections computed in section 3 are such profiles connecting two states u_l and u_r satisfying the jump conditions

$$s = \frac{1}{2}(u_l + u_r + 2), \qquad u_l > u_r.$$

However, these connections exist only for $u_l - u_r > 2$. For a better understanding of the situation, we expand the potential operator

$$\varphi^\varepsilon[u] = -u - \varepsilon^2 u_{xx} + O(\varepsilon^4).$$

Thus, an $O(\varepsilon^4)$-approximation of (5.3) is given by the KdV equation (for the unknown $u+1$)

$$u_t + (u+1)u_x + \varepsilon^2 u_{xxx} = 0. \tag{5.5}$$

Actually, the KdV equation can be obtained as a formal limit of (5.3). If (5.3) is rescaled by

$$t \to \frac{t}{\varepsilon^2}, \qquad u^\varepsilon \to -1 + \varepsilon^2 U,$$

then the formal limit of the resulting equation for U is

$$U_t + UU_x + U_{xxx} = 0.$$

In analogy to the well known results concerning the limit as $\varepsilon \to 0$ of (5.5) (e.g., [22], [14]), we expect that in general the limits of solutions of (5.3) are weak limits, which do not satisfy the formal limiting equation (5.4). In our last result, however,

we prove that—as long as the solution of the limiting equation remains smooth—it is the strong limit of the solution of (5.3). For $u_0 \in C^{0,1}(\mathbb{R})$, the space of all Lipschitz continuous function on $\mathbb{R}$, there exists a $T > 0$ such that the Burgers equation (5.4) has a solution $u^0 \in C([0,T];\, C^{0,1}(\mathbb{R}))$. Also, if $u_0 \in H^s(\mathbb{R})$, then $u^0 \in L^\infty((0,T);\, H^s(\mathbb{R}))$.

THEOREM 5.1. *Assume $u_0 \in C^{0,1}(\mathbb{R}) \cap H^s(\mathbb{R})$ with $s > 1$. Then, for a time interval $(0,T)$ as mentioned above, the solutions of* (5.3) *and* (5.4) *satisfy*

$$\|u^\varepsilon - u^0\|_{L^\infty((0,T);L^2(\mathbb{R}))} = O\left(\varepsilon^r\right), \qquad r = \min\{2, s-1\}.$$

Proof. Let $v = u^\varepsilon - u^0$ with initial data $v(t=0) = 0$. We subtract (5.4) from (5.3) to obtain an equation for v:

$$v_t + \left(\frac{v^2}{2} + u^0 v\right)_x = u^0_x + \varphi^\varepsilon[u^0_x] = \varepsilon^2 \varphi^\varepsilon_{xx}[u^0_x].$$

By taking the L^2-scalar product with v and by integration by parts, we calculate

$$\frac{1}{2}\frac{d}{dt}\|v\|^2_{L^2(\mathbb{R})} + \int_{\mathbb{R}} \frac{v^2}{2}\, u^0_x\, dx = \varepsilon^2 \int_{\mathbb{R}} v\, \varphi^\varepsilon_{xx}[u^0_x]\, dx,$$

which implies

$$\frac{d}{dt}\|v\|_{L^2(\mathbb{R})} \le \frac{1}{2}\|u^0_x\|_{L^\infty(\mathbb{R})}\|v\|_{L^2(\mathbb{R})} + \|\varepsilon^2 \varphi^\varepsilon_{xx}[u^0_x]\|_{L^2(\mathbb{R})}. \tag{5.6}$$

With the Fourier transform $\widehat{u^0}(k,t)$ of $u^0(x,t)$, the last term can be estimated by

$$\|\varepsilon^2 \varphi^\varepsilon_{xx}[u^0_x]\|_{L^2(\mathbb{R})} = \left\| \frac{\varepsilon^2 |k|^3 |\widehat{u^0}|}{1+\varepsilon^2 k^2} \right\|_{L^2(\mathbb{R})} \le \sup_{k\in\mathbb{R}} \frac{\varepsilon^2 |k|^3}{(1+\varepsilon^2 k^2)(1+k^2)^{s/2}} \|u^0\|_{H^s(\mathbb{R})}.$$

The factor on the right-hand side is obviously $O(\varepsilon^2)$ for $s \ge 3$. For $s < 3$, it can be estimated by

$$\frac{\varepsilon^2 |k|^3}{(1+\varepsilon^2 k^2)|k|^s} = \varepsilon^{s-1} \frac{|\varepsilon k|^{3-s}}{1+|\varepsilon k|^2} = O(\varepsilon^{s-1}),$$

and thus

$$\|\varepsilon^2 \varphi^\varepsilon_{xx}[u^0_x]\|_{L^2(\mathbb{R})} \le c\varepsilon^r \|u^0\|_{H^s(\mathbb{R})}.$$

The statement of the theorem is now a direct consequence of the Gronwall lemma applied to (5.6). ∎

LOW-FIELD LIMIT FOR A NONLINEAR DISCRETE DRIFT-DIFFUSION MODEL ARISING IN SEMICONDUCTOR SUPERLATTICES THEORY*

THIERRY GOUDON†, OSCAR SÁNCHEZ‡, JUAN SOLER‡, AND LUIS L. BONILLA§

Abstract. Charge transport in semiconductor superlattices can be described through a discrete drift-diffusion model. In this model, we identify some small parameter $h > 0$, related to the ratio between the length of a superlattice period and the observation length scale. Specifically, we investigate a regime where the length of the superlattice period is small while the doping profile is low. In the limit $h \to 0$, we are led to a nonlinear drift-diffusion model, coupled to the Poisson equation.

Key words. semiconductor supperlattices, drift-diffusion models

1. Introduction.

A semiconductor superlattice (SL) is a periodic array of layers of two different semiconductors whose lateral dimension is much larger than the length of one period. These devices exhibit nonlinear charge transport phenomena due to the existence of electric field domains. Depending on the charge density (produced by doping or irradiating the SL) and on the applied voltage, different qualitative responses of the current can be obtained, as shown, e.g., by Bonilla [6]. In experiments at intermediate values of the charge density, stationary responses and self-sustained oscillations are observed depending on the values of the voltage. There exist solutions corresponding to low voltages which are stationary and typically develop low electric fields. It is very important to understand the time evolution of the solutions toward these stationary profiles (see [5] where relocation experiments are studied).

Electronic transport in such semiconductor devices can be described by a discrete drift-diffusion model. Details on the modeling will be given in section 2, following the works by Aguado, Platero, Moscoso, and Bonilla [1] and Bonilla, Platero, and Sánchez [4] and review papers by Bonilla [6] and Wacker [15]. The model consists of the Poisson equation coupled to charge continuity equations for the electron density n and average electric field F at each SL period. Tunneling currents across barriers are approximated by a discrete drift-diffusion (DDD) law, whose coefficients are themselves field dependent. We aim at investigating asymptotics regimes for this model. To this end, we shall write the equations in dimensionless form. Hence, we are able to identify some small parameter—denoted $h > 0$ in what follows—by means of physically relevant dimensionless parameters of the DDD system. Having set up this DDD system, we prove that the solutions converge, in an appropriate weak setting, to solutions of a continuous drift-diffusion-Poisson problem with field-dependent mobilities,

as the parameter h tends to 0. The limit equation reads

$$\text{(1.1)}\qquad \begin{cases} \partial_t n + \partial_x J(F,n) = 0 & \text{in } (0,T)\times[-X,X], \\ J(F,n) = v(F)n - D(F)\partial_x n\,, & \\ \partial_x F = n - N_D & \text{in } (0,T)\times[-X,X]. \end{cases}$$

These equations are completed by bias, boundary, and initial conditions

$$\begin{cases} \displaystyle\int_{-X}^{X} F\,dx = V & \text{on } (0,T), \\ J(F,n)(X) = W^{(f)}(F)n(X) & \text{on } (0,T), \\ J(F,n)(-X) = (j^{(e)}(F) - W^{(b)}(F)n)(-X) & \text{on } (0,T), \\ n(t=0,x) = n^0(x) & \text{on } [-X,X]. \end{cases}$$

The techniques employed to prove the convergence are based on a priori estimates and compactness properties. At this point, we have to remark that the solutions to the DDD model are stepwise constant functions, which forces us to consider the solutions in the framework of the bounded variation (BV) spaces.

Our main result admits a reversal lecture. Since the dimensionless system of the DDD model coincides with a finite difference discretization of (1.1), the analysis proposed can be read as a convergence analysis for numerical approximations of that drift-diffusion continuous equation. In this direction our problem is related with other works on approximation of field-dependent mobilities. System (1.1) is a monopolar one-dimensional version of the drift-diffusion system analyzed by Gajewski and Gröger [8] and Jerome [10]. Our DDD system is simpler than the general version studied in those works, where different boundary conditions are considered. Here, we deal with the time-dependent problem, while, to the best of our knowledge, the previous analyses are devoted to approximate steady state solutions.

This paper is organized as follows. In section 2 we present in detail the DDD model, recalling some aspects of its derivation. We also justify its well-posedness. In section 3 we perform the dimension analysis of the system. Then, we derive the dimensionless equations for which the analysis is actually performed and we state precisely our main convergence result for the DDD model. Actually, our analysis applies either when considering a Dirichlet boundary condition for the electric field or with the bias condition. Section 4 is devoted to the crucial a priori estimates satisfied by the solution. For the sake of simplicity, we start with the Dirichlet boundary condition. Then, in section 5 we use these estimates to show the convergence to the continuous model, through compactness arguments. Finally, section 6 sketches the slight adaptation of the proof to treat the DDD system endowed with the bias condition. The paper ends with two appendices: in the first one we deal with a technical auxiliary result, and the latter investigates uniqueness of the limit system.

2. Discrete drift-diffusion model. Since the two semiconductors constituting the SL have different energy gaps, the conduction band of an SL can be viewed as a periodic array of potential wells and barriers, of widths w and d, respectively, with $\ell = d + w$ the length of one period. We assume that scattering times are shorter than escape times from quantum wells, the latter being shorter than dielectric relaxation times. In such a weakly coupled semiconductor SL, the dominant mechanism of charge transport is sequential resonant tunneling. In the simplest situation, the center of each quantum well is n-doped and the thermal energy is large compared to the energy of the lowest miniband. Then, a description of charge transport in such devices has been

proposed through a DDD model; see [1, 4, 6, 15]. This model has been extended by taking into account stochastic effects by Bonilla, Sánchez, and Soler [5], in comparison with the experimental results of Rogozia et al. [12].

In such a modeling, we consider an array of $2N+1$ consecutive cells, which are well-barrier pairs, labeled by the index $i \in \{-N, \dots, +N\}$. The barrier separating the injecting contact from the first well of the SL is considered as the $(-N-1)$th barrier, while the barrier of the Nth SL period separates the Nth well from the collector. The model assumes that the electrons are singularly concentrated on a two-dimensional region located in the center of the quantum well. The unknowns are the two-dimensional electron density n_i (number of electrons per unit area of the SL cross section at the center of the ith well) and the average electric field F_i in each cell. These quantities are related through the following discrete Poisson equation:

$$F_i - F_{i-1} = \frac{e}{\overline{\varepsilon}}(n_i - N_D^w), \quad i \in \{-N, \dots, N\}. \tag{2.1}$$

In (2.1), N_D^w stands for the two-dimensional doping in the wells, assumed to be constant, while $\overline{\varepsilon}$ is the average permittivity in the SL and $(-e)$ stands for the electron charge. Notice that the set of relations (2.1) involves as an additional unknown the electric field F_{-N-1} at the injecting contact. On the other hand, denoting by $eJ_{i\to i+1}$ the tunneling current density through the barrier separating the cells $\#i$ and $\#(i+1)$, the density in the ith cell satisfies the following charge continuity equation:

$$\frac{dn_i}{dt} = J_{i-1\to i} - J_{i\to i+1}, \quad i \in \{-N, \dots, N\}. \tag{2.2}$$

Consequently, differentiating (2.1) and using (2.2), we notice that the quantity

$$\frac{\overline{\varepsilon}}{e}\frac{dF_i}{dt} + J_{i\to i+1} = J(t), \quad i \in \{-N-1, \dots, N\} \tag{2.3}$$

does not depend on the considered cell. This is the so-called Ampère's law, where $eJ(t)$ stands for the total current density through the SL which does not depend on the index i.

Then, the model is completed by a constitutive law which defines the current density $eJ_{i\to i+1}$ by means of the (n_k, F_k)'s. The tunneling current density depends on the electrochemical potentials at cells $\#i$ and $\#(i+1)$ and on the average electric field F_i; see [6, 15]. The electrochemical potentials that "drive" the tunneling current (a nonzero current is a consequence of unequal electrochemical potentials at cells $\#i$ and $\#(i+1)$) are functions of the electron densities and therefore, according to [6, 15], we may consider that the tunneling current $eJ_{i\to i+1}$ depends on n_i, n_{i+1} and F_i. First-principles calculations of $eJ_{i\to i+1}$ are at best sketchy. In the literature, formulas have been derived from quantum kinetic equations for Green's functions (see [15], assuming constant electric field across the SL, simplified hopping Hamiltonians, and scattering) and from the transfer Hamiltonian formalism as in [1, 4, 6] (a many-body version of the WKB method originally proposed by Bardeen [3]). At high (room) temperature, all these formulas imply that the tunneling current is given by the difference of a drift term and a diffusion term as follows:

$$J_{i\to i+1} = \frac{n_i v(F_i)}{\ell} - \frac{D(F_i)(n_{i+1} - n_i)}{\ell^2}, \quad i \in \{-N, \dots, N-1\}. \tag{2.4}$$

The drift velocity and the diffusion coefficient are defined through functions v and D of the electric field, which depend on the physical properties of the material used in the SL; see [6] for more details. The special nature of the three-dimensional emitter and collector layers (different from the essentially two-dimensional quantum wells that form the SL) is considered in the calculation of the boundary tunneling current. By using the transfer Hamiltonian formalism, the following approximate formulas can be derived [4]:

$$J_{-N-1\to -N} = j^{(e)}(F_{-N-1}) - \frac{n_{-N} W^{(b)}(F_{-N-1})}{\ell}, \tag{2.5}$$

$$J_{N\to N+1} = \frac{n_N W^{(f)}(F_N)}{\ell}. \tag{2.6}$$

These equations involve the emitter current density $ej^{(e)}$, the emitter backward velocity $W^{(b)}$, and the collector forward velocity $W^{(f)}$, which are given functions of the electric field. All the coefficients $v, D, W^{(b)}, W^{(f)}, j^{(e)}$ are supposed to be nonnegative and satisfy some regularity properties. Typical graphs for these functions can be found in [5].

We remark that one equation is still missing since we have one more unknown than we have equations. There are several ways to close the system. The simplest way is to assume that the electric field at the emitter is prescribed as

$$F_{-N-1}(t) = F_-(t), \tag{2.7}$$

the right-hand side being a given function $F_- : \mathbb{R}^+ \to \mathbb{R}$. This Dirichlet boundary condition has been proposed when the number of periods considered in the SL is high enough (infinite supperlattice). Therefore, this condition is well adapted to our work since we shall deal with an asympotic problem where the number of cells goes to infinity.

However, from a physical viewpoint, it is certainly more realistic to complete the system by using the so-called voltage bias condition: the total voltage across the SL,

$$\ell \sum_{i=-N}^{N} F_i = V, \tag{2.8}$$

remains equal to a given quantity V. In what follows we essentially deal with the Dirichlet-like boundary condition (2.7) for the electric field. We will come back to the voltage bias condition (2.8) at the end of the paper.

Relations (2.1), (2.2), and (2.7) form a closed system of equations for n_i and F_i with $i \in \{-N, \dots, N\}$, referred to in what follows as the DDD model. We remark that the electric field in the cell $\#i$ can be expressed as a function of the incoming field F_- and the density in the previous cells as follows:

$$F_i(t) = F_-(t) + \frac{e}{\bar{\varepsilon}} \sum_{j=-N}^{i} (n_j(t) - N_D^w), \quad i \in \{-N, \dots, N\} \quad \forall t \in [0, T]. \tag{2.9}$$

Consequently, we can rewrite the initial value problem associated to the DDD model in terms of the densities

$$\frac{d\vec{n}}{dt} = g(t, \vec{n}(t)), \qquad \vec{n}(0) = \vec{n}^0, \tag{2.10}$$

where $\vec{n}(t) = (n_{-N}, \dots, n_N)^T \in \mathbb{R}^{2N+1}$, $g : \mathbb{R}^{2N+1} \to \mathbb{R}^{2N+1}$ is a smooth function, and $\vec{n}^0 \in \mathbb{R}^{2N+1}$ is the initial condition.

THEOREM 2.1. *Let $n_i^0 \geq 0$ for $i \in \{-N, \dots, N\}$ be the initial data for the DDD system. Let F_- be a C^1 function of time. Also let $v, D, W^{(b,f)}, j^{(e)}$ be C^1 nonnegative functions. Then, there exists a unique global solution associated with the initial value problem* (2.10). *The solution verifies $n_i(t) \geq 0$ for all $i \in \{-N, \dots, N\}$, $t \geq 0$.*

Proof. Local existence and uniqueness follow by a direct application of the Cauchy–Lipschitz theorem for ODE, since the function g inherits the regularity properties of the coefficients. The estimates proved in section 4, especially in Lemma 4.1, also provide a uniform bound on the solution which prevents a finite time blowup. Consequently, the solution is globally defined. There remains only to justify the nonnegativeness of the solution. To this end, it is convenient to rewrite (2.2) as a difference between a gain term and a loss term as follows:

$$\frac{dn_i}{dt} = \begin{cases} \frac{v(F_{i-1})}{\ell} n_{i-1} + \frac{D(F_i)}{\ell^2} n_{i+1} + \frac{D(F_{i-1})}{\ell^2} n_{i-1} - \Big(\frac{v(F_i)}{\ell} + \frac{D(F_i)}{\ell^2} + \frac{D(F_{i-1})}{\ell^2} \Big) n_i \\ \qquad\qquad \text{for } i \in \{-N+1, \dots, N-1\}, \\ \frac{D(F_{-N})}{\ell^2} n_{-N+1} + j^{(e)}(F_{-N-1}) - \Big(\frac{v(F_{-N})}{\ell} + \frac{D(F_{-N})}{\ell^2} + \frac{W^{(b)}(F_{-N-1})}{\ell} \Big) n_{-N} \\ \qquad\qquad \text{for } i = -N, \\ \frac{v(F_{N-1})}{\ell} n_{N-1} + \frac{D(F_{N-1})}{\ell^2} n_{N-1} - \Big(\frac{D(F_{N-1})}{\ell^2} + \frac{W^{(f)}(F_N)}{\ell} \Big) n_N \\ \qquad\qquad \text{for } i = N. \end{cases}$$

Let $t \geq 0$ such that $n_i(t) \geq 0$ for any $i \in \{-N, \dots, N\}$. Suppose $n_j(t) = 0$ for some $j \in \{-N, \dots, N\}$. Thus, we notice that its time derivative $\frac{dn_j}{dt}(t)$ is nonnegative and, hence, we deduce the nonnegative character of the solution along the time evolution. ∎

3. Dimensionless equations. The aim of this section is to write the system in dimensionless form. Hence, we will identify some dimensionless physical parameters. Next, we appropriately order these parameters in terms of a quantity $h > 0$ intended to tend to 0. Studying the limit $h \to 0$ we obtain a nonlinear continuous drift-diffusion model, as described in the introduction. This approach relating discrete to continuous models is reminiscent of hydrodynamic limits in kinetic theory (see [9]). Actually, it has been used for models of phase transition, for example, in [7].

Let us introduce time and length units, respectively, denoted by $\mathcal{T}$ and $\mathcal{L}$. They correspond to observation scales. We also need characteristic values for the electron density and for the electric field, respectively, denoted by $\mathcal{N}$ and $\mathcal{F}$. For instance, it is quite natural to define $\mathcal{N}$ from the doping profile N_D^w and $\mathcal{F}$ from the emitter field F_-. Then, using the convention that overlined quantities are dimensionless, we set

$$\begin{cases} \mathcal{N}\, \overline{n_i}(\bar{t}) = n_i(\mathcal{T}\bar{t}), & \mathcal{N}\, \overline{N_D} = N_D^w, \\ \mathcal{F}\, \overline{F_i}(\bar{t}) = F_i(\mathcal{T}\bar{t}), & \mathcal{F}\, \overline{F_-}(\bar{t}) = F_-(\mathcal{T}\bar{t}), \\ \dfrac{\mathcal{L}}{\mathcal{T}}\, \overline{v}(\overline{F}) = v(\mathcal{F}\overline{F}), & \dfrac{\mathcal{L}}{\mathcal{T}}\, \overline{W^{(b,f)}}(\overline{F}) = W^{(b,f)}(\mathcal{F}\overline{F}), \\ \dfrac{\mathcal{L}^2}{\mathcal{T}}\, \overline{D}(\overline{F}) = D(\mathcal{F}\overline{F}), & \dfrac{\overline{\varepsilon}\mathcal{F}}{e}\, \dfrac{1}{\mathcal{T}}\, \overline{j^{(e)}}(\overline{F}) = j^{(e)}(\mathcal{F}\overline{F}). \end{cases}$$

Note that the emitter current density has been scaled with respect to the density $\frac{\overline{\varepsilon}}{e}\mathcal{F}$ instead of with respect to $\mathcal{N}$ (the other choice is also possible; the proof adapts immediately and the emitter current density disappears as $h \to 0$ in that case).

Therefore, we are led to the continuity equations in the following dimensionless form:

$$\frac{d\overline{n}_i}{d\bar{t}} = \frac{\mathcal{L}}{\ell}\Big(\overline{v}(\overline{F}_{i-1})\overline{n}_{i-1} - \overline{v}(\overline{F}_i)\overline{n}_i - \frac{\mathcal{L}}{\ell}\overline{D}(\overline{F}_{i-1})(\overline{n}_{i-1} - \overline{n}_i) + \frac{\mathcal{L}}{\ell}\overline{D}(\overline{F}_i)(\overline{n}_i - \overline{n}_{i+1})\Big)$$

for $i \in \{-N+1, \dots, N-1\}$ and

$$\begin{aligned}
\frac{d\overline{n}_{-N}}{d\bar{t}} &= \frac{\mathcal{L}}{\ell}\Big(\frac{\ell}{\mathcal{L}}\frac{\overline{\varepsilon}\mathcal{F}}{\epsilon\mathcal{N}}\bar{j}^{(e)}(\overline{F}_{-N-1}) - \overline{n}_{-N}\overline{W}^{(b)}(\overline{F}_{-N-1}) \\
&\qquad -\overline{v}(\overline{F}_{-N})\overline{n}_{-N} - \frac{\mathcal{L}}{\ell}\overline{D}(\overline{F}_{-N})(\overline{n}_{-N} - \overline{n}_{-N+1})\Big), \\
\frac{d\overline{n}_N}{d\bar{t}} &= \frac{\mathcal{L}}{\ell}\Big(\overline{v}(\overline{F}_{N-1})\overline{n}_{N-1} + \frac{\mathcal{L}}{\ell}\overline{D}(\overline{F}_{N-1})(\overline{n}_{N-1} - \overline{n}_N) - \overline{n}_{-N}\overline{W}^{(f)}(\overline{F}_N)\Big).
\end{aligned}$$

On the other hand, the Poisson equation reads

$$\frac{\overline{\varepsilon}\mathcal{F}}{e\mathcal{N}}\,(\overline{F}_i - \overline{F}_{i-1}) = (\overline{n}_i - \overline{N}_D)$$

for $i \in \{-N, \dots, N\}$.

In these expressions, we identify two dimensionless parameters

$$\alpha = \frac{\overline{\varepsilon}\mathcal{F}}{e\mathcal{N}}, \quad \beta = \frac{\mathcal{L}}{\ell}.$$

Roughly speaking, we go from the discrete equations to a continuous description by interpreting the difference between consecutive cells as differential quotients. It means that we shall consider the situation

$$\alpha = \beta = \frac{1}{h} \gg 1,$$

where h is a positive quantity intended to tend to 0. (Actually, we might suppose, with some obvious adaptations in the proofs, that $\alpha = \frac{1}{h} \gg 1$, and $\frac{\alpha}{\beta}$ has a finite positive limit.) Coming back to the physical meaning, the ordering for β means that the size of the cells is small compared to the observation length scale $\ell \ll \mathcal{L}$, while the ordering for α is an assumption about the data; the doping profile N_D^w is small compared to the density $\frac{\overline{\varepsilon}}{e}F_-$ associated with the electric field at the injecting contact ($\mathcal{N} \ll \frac{\overline{\varepsilon}}{e}\mathcal{F}$). Furthermore, we shall assume that the total length of the SL is given and is equal to $2X$, so that the number of cells in the SL also should be appropriately rescaled. Namely, the number of cells is defined in terms of the parameter $h > 0$ by

$$N^h = X/h.$$

The limit performed in this paper is motivated by the comparison between the profiles of the drift velocity and of the diffusion coefficient. Figure 3.1 shows these profiles for a 9nm/4nm GaAs/AlAs SL at $5K$, while the inset picture enlarges these coefficients in the low-field range. In this region the diffusion coefficient is larger than the drift velocity, which is close to zero; i.e., $v(F) \ll D(F)/\ell$ holds. This implies that the diffusion coefficient is large (order h^{-2}) in comparison to the drift velocity (order h^{-1}). Accordingly, we call this asymptotic approach low-field limit. A continuum limit also can be performed in a regime in which $v(F) \approx D(F)/\ell$; this high-field regime will be investigated in a forthcoming work. A complementary interpretation of our asymptotic analysis can be given in terms of a parameter (the so-called Lorentzian half-width) defining the Lorentzian functions involved in the expression of the coefficients of the DDD model; see [4]. The smaller the Lorentzian half-width, the lower the field.

A stationary solution for the DDD model can be obtained in the low-field range as shown by the dotted line in Figure 3.1 (right). In this experiment, we have applied

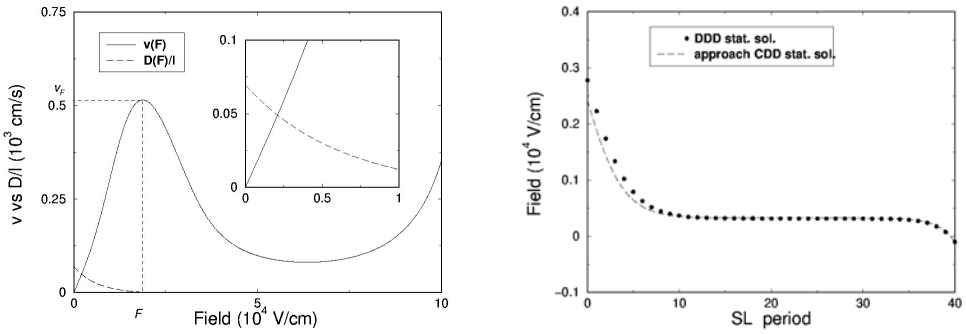

FIG. 3.1. *Left: Drift velocity versus diffusion coefficient for a 9nm/4nm GaAs/AlAs SL. Inset: Detailed low-field range. Right: Electric field distribution for a stationary solution of 40 periods 9nm/4nm GaAs/AlAs SL (dots) and numerical approach to the continuum drift-diffusion model (dashed line) with bias constraint $V = 0.52$ V.*

voltage 0.52 V, $N_D^w = 0.05 \times 10^{11}$ cm^{-2} and contact doping $N_D = 0.2 \times 10^{18}$ cm^{-3}. The Lorentzian half-width involved in the computation of the coefficients of the DDD model is 1 eV and the other parameters are equal to those used in [5]. Thus, $\mathcal{N} = N_D^w$, $\mathcal{F} \approx 0.3\,10^4$ V/cm, $v \approx 0.001\,10^3$ cm/s, and $D/\ell \approx 0.076\,10^3$ cm/s. This leads to the values $\alpha = 3.29$ and $\beta = 7.67$; a sequence of values of the same order can be obtained (low-field limit) by modifying V.

Let us summarize the low-field problem we are interested in as follows. We drop the overlines and emphasize the dependence of the solution (n, F) with respect to the parameter h by a superscript. Hence, we consider the system

$$\frac{dn_i^h}{dt} = \frac{1}{h}(J_{i-1\to i}^h - J_{i\to i+1}^h), \quad i \in \{-N^h, \dots, N^h\}, \tag{3.1}$$

coupled to

$$F_i^h - F_{i-1}^h = h(n_i^h - N_D), \quad i \in \{-N^h, \dots, N^h\}, \tag{3.2}$$

with $F_{-N^h-1}^h = F_-$ given. Note that, coming back to (2.9), we also have

$$F_i^h(t) = F_-(t) + h \sum_{j=-N^h}^{i} (n_j^h(t) - N_D), \quad i \in \{-N^h, \dots, N^h\}. \tag{3.3}$$

Here, we used the following definition for the tunneling currents:

$$\begin{cases} J_{i\to i+1}^h = n_i^h v_i^h - \dfrac{1}{h} D(F_i^h)(n_{i+1}^h - n_i^h), \quad i \in \{-N^h, \dots, N^h - 1\}, \\ J_{-N^h-1\to -N^h}^h = j^{(e)}(F_-) - n_{-N^h}^h W^{(b)}(F_-), \\ J_{N^h\to N^h+1}^h = n_{N^h} W^{(f)}(F_{N^h}^h). \end{cases}$$

The idea is to investigate the limit as $h \to 0$.

To this end, we set $I = (-X, +X) = (-N^h h, N^h h)$ and we associate to the unknowns $(n_{-N^h}^h, \dots, n_{N^h-1}^h) \in \mathbb{R}^{2N^h}$ and $(F_{-N^h}^h, \dots, F_{N^h-1}^h) \in \mathbb{R}^{2N^h}$, the stepwise

constant functions $n^h(t,x)$ and $F^h(t,x)$ defined almost everywhere on $[0,\infty)\times I$ by saying

$$n^h(t,x)=n_i^h(t),\quad F^h(t,x)=F_i^h(t),\quad ih<x<(i+1)h,\quad i\in\{-N^h,\dots,N^h-1\}.$$

Note that it is not relevant to define these functions on the negligible set of points $\{ih,\, i\in\{-N^h,\dots,N^h\}\}$; note also that $F_-, n^h_{N^h}, F^h_{N_h}$ seem to play no role in these definitions. However, they will be used in the definition of traces in the limit $h\to 0$. As a consequence of these definitions, we shall use that sums of n_i^h or F_i^h can be considered as integrals: for example, for any function $\psi:\mathbb{R}\to\mathbb{R}$ we have

$$\int_{-X}^{+X}\psi(n^h)\,dx=h\sum_{i=-N^h}^{N^h-1}\psi(n_i^h)\,,$$

because n_i^h is constant on $ih<x<(i+1)h$. Then, passing to a continuous variable, it is tempting to interpret finite differences as differential quotients. Following this rough idea, we formally guess that the limiting problem corresponding to $h\to 0$ consists of the following nonlinear drift-diffusion equation:

$$\left\{\begin{array}{ll}
\partial_t n+\partial_x J(F,n)=0 & \text{in } (0,T)\times I,\\
J(F,n)=v(F)n-D(F)\partial_x n, & \\
\partial_x F=n-N_D & \text{in } (0,T)\times I,\\
F(-X)=F_- & \text{on } (0,T),\\
J(F,n)(X)=W^{(f)}(F)n(X) & \text{on } (0,T),\\
J(F,n)(-X)=(j^{(e)}(F)-W^{(b)}(F)n)(-X) & \text{on } (0,T),\\
n(t=0,x)=n^0(x) & \text{on } I.
\end{array}\right.\tag{3.4}$$

Thus, the main result of the paper is the following.

THEOREM 3.1. *Let $v,D,W^{(b,f)},j^{(e)}:\mathbb{R}\to\mathbb{R}$ be continuous and nonnegative functions. Suppose that $D(F)>0$ and $W^{(b,f)}(F)>0$ for any $F\in\mathbb{R}$. Let $F_-\in \mathrm{C}^1(\mathbb{R}^+)$. Let $n^{h,0}=(n^{h,0}_{-N^h},\dots,n^{h,0}_{N^h})\in\mathbb{R}^{2N^h+1}$ be the initial data for the rescaled problem. We suppose that $n_i^{h,0}\ge 0$ satisfy*

$$\sup_{h>0}\left(h\sum_{i=-N^h}^{N^h}|n_i^{h,0}|^2\right)\le C_0<\infty.\tag{3.5}$$

Let (n^h,F^h) be the associated solution of (3.1), (3.2). *Then, up to a subsequence, we have*

$$\left\{\begin{array}{ll} n^h\to n & \text{strongly in } \mathrm{L}^2((0,T)\times I) \text{ and in } \mathrm{C}^0([0,T];\mathrm{L}^2(I)-\text{weak}),\\ F^h\to F & \text{uniformly in } [0,T]\times\overline{I}.\end{array}\right.$$

Furthermore, the limits satisfy $n\in\mathrm{L}^2(0,T;\mathrm{H}^1(I))$, $F\in\mathrm{C}^0([0,T]\times\overline{I})$ and solve the nonlinear problem (3.4) *in the sense that*

$$\frac{d}{dt}\int_{-X}^{X}n\phi\,dx=\int_{-X}^{X}J(F,n)\phi'\,dx+W^{(f)}(F)n\phi(X)+(j^{(e)}(F)-W^{(b)}(F)n)\phi(-X)$$

holds in $\mathcal{D}'(0,T)$ for any test function $\phi\in\mathrm{C}^\infty(\overline{I})$, coupled to the Poisson equation

$$\partial_x F=n-N_D,\quad F(-X)=F_-$$

also considered in the sense of the distributions.

This kind of nonlinear parabolic equation, coupled to the Poisson equation, has been investigated by Liang [11]. Actually, in [11] the diffusion coefficient is constant and the boundary conditions are slightly different. In the convergence proof, we need only to assume the continuity of the coefficients; however, using locally Lipschitz properties of the coefficients, we can prove the uniqueness of solution for (3.4); see Appendix B. Consequently, assuming the convergence of the initial data, in Theorem 3.1 the entire sequence converges.

A stationary solution (continuous line) for the continuous drift-diffusion model (CDD) has been obtained in Figure 3.1 (right). The corresponding stationary solution for the DDD model, with the same voltage, can be seen now as a numerical approach to that of the CDD model with $h \in [\frac{1}{7.67}, \frac{1}{3.29}]$. We can observe that the agreement between the solutions to the discrete model and the continuous one is better at the inner periods, where the low-field hypothesis plays a determinant role. The difference between both profiles in the emitter region comes from the fact that the simulations have been done under bias constraint.

4. A priori estimates. This section is devoted to the derivation of the crucial estimates on the solutions (n^h, F^h) that will lead us to rigorously perform the limit $h \to 0$. We assume that the initial data $n_i^{h,0} \geq 0$ satisfies (3.5). This implies that the $\mathrm{L}^1[-X, X]$-norm is bounded as follows:

$$h \sum_{i=-N^h}^{N^h} n_i^{h,0} \leq \left(h \sum_{i=-N^h}^{N^h} |n_i^{h,0}|^2 \right)^{1/2} \sqrt{(2N^h + 1)h}$$

is bounded independently of $h \in (0, 1)$. We recall that

$$\left\{ \begin{array}{l} D, W^{(b,f)}, j^{(e)}, v \in \mathrm{C}^0(\mathbb{R}), \\ v(F) \geq 0, \quad j^{(e)} \geq 0, \\ W^{(b,f)}(F) > 0, \quad D(F) > 0. \end{array} \right. \tag{4.1}$$

We split our argument into several steps. We shall use the convention that C_T stands for a constant possibly depending on T and on the data $F_-, j^{(e)}, W^{(b,f)}$, or on the estimates (3.5), but not on h. Also, we denote as usual by $\mathcal{M}(I)$ the set of Radon measures on the open interval I. Elements of $\mathcal{M}(I)$ identify with distributions Φ on I satisfying $|\langle \Phi, \varphi \rangle| \leq C \|\varphi\|_{L^\infty(I)}$ for all $\varphi \in C_c^\infty(I)$ for some $C > 0$ being independent of the support of the test function (see, e.g., [13]). As usual we denote by $\mathrm{BV}(I)$ the set of bounded variation functions, i.e., functions which are in $\mathrm{L}^1(I)$ and such that their distributional derivative belongs to $\mathcal{M}(I)$.

LEMMA 4.1 (L^1 estimate on the density). *The sequence n^h is bounded in* $\mathrm{L}^\infty(0, T; \mathrm{L}^1(I))$.

Proof. Summing up the equations in (3.1), we obtain

$$\begin{aligned} h \frac{d}{dt} \sum_{i=-N^h}^{N^h} n_i^h &= \sum_{i=-N^h}^{N^h} (J_{i-1\to i}^h - J_{i\to i+1}^h) = J_{-N^h-1\to -N^h}^h - J_{N^h\to N^h+1}^h \\ &= j^{(e)}(F_-) - n_{-N^h}^h W^{(b)}(F_-) - n_{N^h}^h W^{(f)}(F_{N^h}^h). \end{aligned}$$

Therefore, integrating with respect to time and using $n_i^h \geq 0$ and $W^{(b,f)} \geq 0$, we find

$$
\begin{aligned}
& h \sum_{i=-N^h}^{N^h} n_i^h(t) + \int_0^t n_{-N^h}^h W^{(b)}(F_-(s))\,ds + \int_0^t n_{N^h}^h W^{(f)}(F_{N^h}^h)(s)\,ds \\
& = h \sum_{i=-N^h}^{N^h} n_i^{h,0} + \int_0^t j^{(e)}(F_-(s))\,ds \leq C_0 + \|j^{(e)}(F_-)\|_{L^1(0,T)} \leq C_T\,,
\end{aligned} \tag{4.2}
$$

which concludes the proof. □

LEMMA 4.2 (estimates on the electric field). *The sequence F^h is bounded in $\mathrm{L}^\infty((0,T)\times I)$ and in $\mathrm{L}^\infty(0,T;\mathrm{BV}(I))$, while $F_{N_h}^h$ is bounded in $\mathrm{L}^\infty(0,T)$.*

Proof. We combine the estimate in Lemma 4.1 with the identity (3.3) to yield

$$
\begin{aligned}
|F_i^h(t)| &= \left| F_-(t) + h \sum_{j=-N^h}^{i} (n_j^h(t) - N_D) \right| \\
&\leq |F_-(t)| + h \sum_{j=-N^h}^{i} n_j^h(t) + h(i + N^h + 1)N_D \\
&\leq |F_-(t)| + h \sum_{j=-N^h}^{N^h} n_j^h(t) + (2X + h)N_D \leq C_T\,,
\end{aligned}
$$

which proves that F^h is bounded in $L^\infty((0,T)\times I)$ and implies the estimate on $F_{N^h}^h$.

Next, let $\phi \in \mathrm{C}_0^\infty(I)$ be a test function. We have

$$
\begin{aligned}
\langle \partial_x F^h, \phi \rangle &= -\int_{-X}^{X} F^h(t,x)\phi'(x)\,dx = -\sum_{i=-N^h}^{N^h-1} F_i^h \int_{ih}^{(i+1)h} \phi'(x)\,dx \\
&= \sum_{i=-N^h}^{N^h-1} F_i^h(\phi(ih) - \phi((i+1)h)) \\
&= \sum_{i=-N^h}^{N^h} \Big((F_i^h - F_{i-1}^h)\ \phi(ih) \Big) + F_{-N^h-1}^h \phi(-N^h h) - F_{N^h}^h \phi(N^h h) \\
&= h \sum_{i=-N^h}^{N^h} \Big((n_i^h - N_D)\ \phi(ih) \Big) + F_-\phi(-X) - F_{N^h}^h \phi(X),
\end{aligned}
$$

where we have used (3.2). Hence, by using the above bounds we deduce that the following estimate,

$$
|\langle \partial_x F^h, \phi \rangle| \leq \|\phi\|_{\mathrm{L}^\infty(I)} \left(h \sum_{i=-N^h}^{N^h} n_i^h + (2X + h)N_D \right) \leq \|\phi\|_{\mathrm{L}^\infty(I)}\ C_T\,,
$$

holds. This proves that $\partial_x F^h$ is bounded in $\mathrm{L}^\infty(0,T;\mathcal{M}(I))$. □

Remark 4.3. Since the functions $W^{(b,f)}$ and D are continuous and positive in $\mathbb{R}$, the uniform bound on F_i^h guarantees that

$$\begin{cases} \inf\limits_{h>0, i\in\{-N^h,\dots,N^h\}, 0\le t\le T} D(F_i^h(t)) \ge \delta > 0, \\ \inf\limits_{h>0, 0\le t\le T} W^{(f)}(F_{N^h}^h(t)) \ge \delta > 0, \\ \inf\limits_{0\le t\le T} W^{(b)}(F_-(t)) \ge \delta > 0 \end{cases}$$

for some $\delta > 0$. Coming back to (4.2), we deduce that the boundary terms $n_{\pm N^h}$ are bounded in $\mathrm{L}^1(0,T)$. Similarly, there exists $0 < M < \infty$ such that

$$\begin{cases} \sup\limits_{h>0, i\in\{-N^h,\dots,N^h\}, 0\le t\le T} |D(F_i^h)| \le M, \\ \sup\limits_{h>0, i\in\{-N^h,\dots,N^h\}, 0\le t\le T} |v(F_i^h)| \le M, \\ \sup\limits_{h>0, 0\le t\le T} |W^{(f)}(F_{N_h}^h)| \le M, \\ \sup\limits_{h>0, 0\le t\le T} |W^{(b)}(F_-^h)| \le M, \\ \sup\limits_{0\le t\le T} |j^{(e)}(F_-)| \le M. \end{cases}$$

LEMMA 4.4 (L^2 estimate on the density). *The sequence n^h is bounded in $\mathrm{L}^\infty(0,T;\mathrm{L}^2(I))$. The "boundary terms" $n^h_{\pm N^h}$ are bounded in $\mathrm{L}^2(0,T)$. Moreover, we have*

$$\int_0^T \sum_{i=-N^h}^{N^h-1} \frac{|n_{i+1}^h - n_i^h|^2}{h}\, ds \le C_T\,.$$

Proof. Multiplying (3.1) by n_i^h and summing over i, we obtain

$$\begin{aligned} \frac{h}{2}\frac{d}{dt}\sum_{i=-N^h}^{N^h} |n_i^h|^2 &= \sum_{i=-N^h}^{N^h} (J^h_{i-1\to i} - J^h_{i\to i+1}) n_i^h \\ &= \sum_{i=-N^h}^{N^h-1} J^h_{i\to i+1}(n_{i+1}^h - n_i^h) + J^h_{-N^h-1\to -N^h} n^h_{-N^h} - J^h_{N^h\to N^h+1} n^h_{N^h} \\ &= \sum_{i=-N^h}^{N^h-1} \left(n_i^h v(F_i^h) - \frac{1}{h} D(F_i^h)(n_{i+1}^h - n_i^h) \right) (n_{i+1}^h - n_i^h) \\ &\qquad + j^{(e)}(F_-) n^h_{-N^h} - |n^h_{-N^h}|^2 W^{(b)}(F_-) - |n_{N^h}|^2 W^{(f)}(F^h_{N^h}). \end{aligned}$$

By using Remark 4.3, we deduce the inequality

$$\frac{h}{2}\sum_{i=-N^h}^{N^h}|n_i^h(t)|^2+\delta\int_0^t\left(\sum_{i=-N^h}^{N^h-1}\frac{|n_{i+1}^h-n_i^h|^2}{h}+|n_{-N^h}^h|^2+|n_{N^h}|^2\right)ds$$
$$\leq\frac{h}{2}\sum_{i=-N^h}^{N^h}|n_i^h(0)|^2+M\int_0^t\left(\sum_{i=-N^h}^{N^h-1}n_i^h|n_{i+1}^h-n_i^h|+n_{-N^h}^h\right)ds\,.$$

Now, by using the Young inequality we estimate

$$\int_0^t\sum_{i=-N^h}^{N^h-1}n_i^h|n_{i+1}^h-n_i^h|\,ds\leq\frac{2Mh}{\delta}\int_0^t\sum_{i=-N^h}^{N^h}|n_i^h|^2\,ds+\frac{\delta}{2M}\int_0^t\sum_{i=-N^h}^{N^h-1}\frac{|n_{i+1}^h-n_i^h|^2}{h}\,ds.$$

It follows that

$$\frac{h}{2}\sum_{i=-N^h}^{N^h}|n_i^h(t)|^2+\frac{\delta}{2}\int_0^t\sum_{i=-N^h}^{N^h-1}\frac{|n_{i+1}^h-n_i^h|^2}{h}\,ds+\delta\int_0^t(|n_{-N^h}^h|^2+|n_{N^h}|^2)\,ds$$
$$\leq\frac{h}{2}\sum_{i=-N^h}^{N^h}|n_i^h(0)|^2+\frac{2M^2}{\delta}\int_0^t\left(h\sum_{i=-N^h}^{N^h}|n_i^h|^2\right)ds+M\int_0^t n_{-N^h}^h\,ds.$$

We conclude the proof by applying the Gronwall inequality and by taking into account that $n_{-N^h}^h$ is bounded in $\mathrm{L}^1(0,T)$ (see Remark 4.3). ∎

In order to study the limit in boundary terms we consider the next statement.

LEMMA 4.5 (H^1 estimate of the electric field at the boundary). *The sequence $F_{N^h}^h$ is bounded in $\mathrm{H}^1(0,T)$.*

Proof. We have proved that $F_{N^h}^h$ is bounded in $\mathrm{L}^\infty(0,T)$. There remains to bound its time derivative in $\mathrm{L}^2(0,T)$. This is a consequence of (3.3) together with the estimates in Lemma 4.2 and 4.4. Indeed, we get (see the argument given in Lemma 4.1)

$$\begin{aligned}\left|\frac{d}{dt}F_{N^h}^h(t)\right| &= \left|\frac{d}{dt}F_-+\frac{d}{dt}\left(h\sum_{i=-N^h}^{N^h}(n_i^h-N_D)\right)\right|\\ &= \left|\frac{d}{dt}F_-+j^{(e)}(F_-)-n_{-N^h}^hW^{(b)}(F_-)-n_{N^h}^hW^{(f)}(F_{N^h}^h)\right|\\ &\leq \left\|\frac{d}{dt}F_-\right\|_{\mathrm{L}^\infty(0,T)}+M(1+n_{-N^h}^h+n_{N^h}^h).\end{aligned}$$

By Lemma 4.4 the right-hand side is bounded in $\mathrm{L}^2(0,T)$, which ends the proof. ∎

LEMMA 4.6 (BV estimate on the density). *The sequence n^h is bounded in $\mathrm{L}^2(0,T;\mathrm{BV}(I))$.*

Proof. Once the L^2 estimate on n^h is known, we derive some bounds for $\partial_x n^h$.

Consider $\phi \in \mathrm{C}_0^\infty(I)$. We have

$$
\begin{aligned}
|\langle \partial_x n^h, \phi\rangle| &= \left| -\int_{-X}^{X} n^h \phi'\, dx \right| = \left| -\sum_{i=-N^h}^{N^h-1} n_i^h \int_{ih}^{(i+1)h} \phi'\, dx \right| \\
&= \left| -\sum_{i=-N^h}^{N^h-1} n_i^h \ (\phi((i+1)h) - \phi(ih)) \right| \\
&= \left| \sum_{i=-N^h+1}^{N^h} (n_i^h - n_{i-1}^h)\ \phi(ih) + n_{-N^h}^h \phi(-N^h h) - n^h N^h \phi(N^h h) \right| \\
&\le \left(h \sum_{i=-N^h+1}^{N^h} |\phi(ih)|^2 \right)^{1/2} \left(\frac{1}{h} \sum_{i=-N^h+1}^{N^h} |n_i^h - n_{i-1}^h|^2 \right)^{1/2} \\
&\le \|\phi\|_{\mathrm{L}^\infty(I)}\ (2X)^{1/2} \left(\sum_{i=-N^h}^{N^h-1} \frac{|n_{i+1}^h - n_i^h|^2}{h} \right)^{1/2}. \qquad (4.3)
\end{aligned}
$$

Lemma 4.4 implies that the $\mathrm{L}^2(0,T)$-norm of the right-hand side of (4.3) is bounded uniformly with respect to h. Hence, we conclude that $\partial_x n^h$ is in $\mathrm{L}^2(0,T;\mathcal{M}(I))$. ∎

LEMMA 4.7 (estimate on the time derivative). *The sequences $\partial_t n^h$ and $\partial_t F^h$ are bounded in $\mathrm{L}^2(0,T;\mathcal{M}(I)) + \mathrm{L}^2(0,T;\mathrm{W}^{-1,1}(I))$ and in $\mathrm{L}^2(0,T;\mathcal{M}(I))$, respectively.*

Proof. Let $\phi \in \mathrm{C}_0^\infty(I)$ and denote

$$\Gamma_i^h = \int_{ih}^{(i+1)h} \phi(x)\, dx$$

for $i \in \{-N^h, \dots, N^h - 1\}$. Since the support of ϕ is included in I, we can extend Γ_i^h by 0 for $i \ge N^h$. We shall use the following basic estimates:

$$
\begin{cases}
|\Gamma_i^h| \le h\ \|\phi\|_{\mathrm{L}^\infty(I)}, \\
|\Gamma_{i+1}^h - \Gamma_i^h| \le h^2\ C\|\phi'\|_{\mathrm{L}^\infty(I)}.
\end{cases}
$$

Now we estimate the time derivative of the electric field by using the Ampère equations (2.3). We have

$$
\begin{aligned}
\langle \partial_t F^h, \phi\rangle &= \sum_{i=-N^h}^{N^h-1} \frac{d}{dt} F_i^h \int_{ih}^{(i+1)h} \phi(x)\, dx \\
&= J^h \sum_{i=-N^h}^{N^h-1} \Gamma_i^h - \sum_{i=-N^h}^{N^h-1} J_{i\to i+1}^h \Gamma_i^h = I_1 + I_2, \qquad (4.4)
\end{aligned}
$$

where $J^h(t)$ stands for the total current density, which is defined by the $(-N^h-1)$th Ampère equation,

$$J^h(t) = \frac{d}{dt} F_- + J_{-N^h-1\to -N^h}^h = \frac{d}{dt} F_- + j^{(e)}(F_-) - W^{(b)}(F_-) n_{-N^h}^h.$$

By Lemma 4.4, this quantity is bounded in $\mathrm{L}^2(0,T)$. Therefore, the first term of the right-hand side of (4.4) is bounded by

$$|I_1| \le \|\varphi\|_{\mathrm{L}^\infty(I)}\ 2hN^h\ |J^h| = \|\varphi\|_{\mathrm{L}^\infty(I)}\ 2X\ |J^h|,$$

which belongs to a bounded set in $\mathrm{L}^2(0,T)$. Next, I_2 is estimated as follows:

$$\begin{aligned}
|I_2| &\le \left| \sum_{i=-N^h}^{N^h-1} n_i^h v(F_i^h)\ \Gamma_i^h \right| + \left| \sum_{i=-N^h}^{N^h-1} \frac{1}{h} D(F_i^h)(n_i^h - n_{i+1}^h)\ \Gamma_i^h \right| \\
&\le M\ \|\phi\|_{\mathrm{L}^\infty(I)}\ h \left(\sum_{i=-N^h}^{N^h-1} n_i^h + \sum_{i=-N^h}^{N^h-1} \frac{|n_i^h - n_{i+1}^h|}{h} \right) \\
&\le M\ \|\phi\|_{\mathrm{L}^\infty(I)} \left(h \sum_{i=-N^h}^{N^h-1} n_i^h + \sqrt{2hN^h \sum_{i=-N^h}^{N^h-1} \frac{|n_i^h - n_{i+1}^h|^2}{h}} \right).
\end{aligned}$$

We conclude that $\partial_t F^h$ is bounded in $\mathrm{L}^2(0,T;\mathcal{M}^1(I))$.

Similarly, we deal with the time derivative of n^h. We have

$$\begin{aligned}
|\langle \partial_t n^h, \varphi \rangle| &= \left| \sum_{i=-N^h}^{N^h-1} \frac{dn_i^h}{dt} \int_{ih}^{(i+1)h} \phi(x)\,dx \right| = \left| \frac{1}{h} \sum_{i=-N^h}^{N^h-1} (J_{i-1\to i}^h - J_{i\to i+1}^h)\ \Gamma_i^h \right| \\
&= \frac{1}{h} \left| \sum_{i=-N^h}^{N^h-1} J_{i\to i+1}^h\ (\Gamma_{i+1}^h - \Gamma_i^h) + J_{-N^h-1\to -N^h}^h \Gamma_{-N^h}^h - J_{N^h-1\to N^h}^h \Gamma_{N^h}^h \right| \\
&\le \frac{1}{h} \left| \sum_{i=-N^h}^{N^h-1} v(F_i^h) n_i^h\ (\Gamma_{i+1}^h - \Gamma_i^h) \right| + \frac{1}{h^2} \left| \sum_{i=-N^h}^{N^h-1} D(F_i^h)(n_i^h - n_{i+1}^h)(\Gamma_{i+1}^h - \Gamma_i^h) \right| \\
&\quad + \frac{1}{h} |j^{(e)}(F_-) - n_{-N^h}^h W^{(b)}(F_-)|\ |\Gamma_{-N^h}^h| \\
&\le C\ h^2\ \|\phi'\|_{\mathrm{L}^\infty(I)} \left(\frac{M}{h} \sum_{i=-N^h}^{N^h-1} n_i^h + \frac{M}{h^2} \sum_{i=-N^h}^{N^h-1} |n_i^h - n_{i+1}^h| \right) \\
&\quad + h\ \|\phi\|_{\mathrm{L}^\infty(I)}\ \frac{M}{h}(1 + n_{-N^h}^h) \\
&\le C\ \|\phi'\|_{\mathrm{L}^\infty(I)} \left(h \sum_{i=-N^h}^{N^h-1} n_i^h + \sqrt{2hN^h \sum_{i=-N^h}^{N^h-1} \frac{|n_i^h - n_{i+1}^h|^2}{h}} \right) \\
&\quad + \|\phi\|_{\mathrm{L}^\infty(I)}\ M(1 + n_{-N^h}^h),
\end{aligned}$$

which proves the estimate on $\partial_t n^h$. ∎

5. Continuous model. Let us combine the estimates discussed in the previous section with the following classical compactness result (see, e.g., [2], [14]).

PROPOSITION 5.1. *Consider Banach spaces B, X, and Y. We suppose that $X \subset B \subset Y$, the first embedding being compact. Let $\mathcal{C}$ be a bounded set in $\mathrm{L}^p(0,T;X)$, $1 \le p \le \infty$. Assume that $\partial_t \mathcal{C} = \{\partial_t f,\ f \in \mathcal{C}\}$ is a bounded set in $\mathrm{L}^r(0,T;Y)$. Then, $\mathcal{C}$ is relatively compact in $\mathrm{L}^p(0,T;B)$ if $1 \le p < \infty$ and $r \ge 1$, or in $\mathrm{C}^0([0,T];B)$ if $p = \infty$ and $r > 1$.*

Hence, from the previous estimates we have, possibly at the cost of extracting subsequences, that

$$\left\{\begin{array}{ll} n^h \to n & \text{strongly in } \mathrm{L}^2((0,T)\times I) \text{ and in } \mathrm{C}^0([0,T];L^2(I)-\textit{weak}),\\ \partial_x n^h \rightharpoonup \partial_x n & \text{weakly}-* \text{ in } \mathrm{L}^2(0,T;\mathcal{M}(I)),\\ F^h \to F & \text{strongly in } \mathrm{C}^0([0,T];L^p(I)) \text{ for any } 1 \le p < \infty, \end{array}\right. \tag{5.1}$$

as h goes to 0. Notice in particular that the convergence of traces in time makes sense and

$$n^h(t,x)_{|t=0} = n^{h,0}(x) \rightharpoonup n^0(x) = n(t,x)_{|t=0} \text{ weakly in } \mathrm{L}^2(I)$$

holds, with $n^{h,0}(x) = n_i^h$ for $ih < x < (i+1)h$, $i \in \{-N^h, \dots, N^h - 1\}$. In other words, we recover the initial condition in the limit $h \to 0$. Finally, we can also guarantee from Lemmas 4.4 and 4.5 the following properties:

$$\left\{\begin{array}{ll} n^h_{\pm N^h} \rightharpoonup n_\pm & \text{weakly in } \mathrm{L}^2(0,T),\\ F^h_{N^h} \to F_+ & \text{uniformly in } \mathrm{C}^0([0,T]). \end{array}\right. \tag{5.2}$$

We first get the continuous Poisson equation.

PROPOSITION 5.2. *The electric field limit F and the density limit n satisfy the continuous Poisson equation*

$$\partial_x F = n - N_D, \quad F_{|x=-X} = F_-$$

in a weak sense.

Remark 5.3. The Poisson relation with $n \in \mathrm{L}^2((0,T)\times I)$ implies, by the Sobolev embedding, that F is in $\mathrm{L}^2(0,T;\mathrm{C}^0(\bar I))$ so that the traces of F are well defined.

Proof. Let $\phi \in C^\infty(\bar I)$ and $\phi_i^h = \phi(ih)$ for $i \in \{-N^h, \dots, N^h\}$. We denote by ϕ^h the associated stepwise constant function. For the sake of simplicity it will be convenient to also introduce the stepwise constant function $\nabla^h(\phi)(x) = \frac{\phi^h_{i+1} - \phi^h_i}{h}$ for $x \in (ih, (i+1)h)$. Multiplying (3.2) by ϕ_i^h, we get

$$\begin{aligned} h \sum_{i=-N^h}^{N^h} \frac{F_i^h - F_{i-1}^h}{h}\, \phi_i^h &= h \sum_{i=-N^h}^{N^h} (n_i^h - N_D)\, \phi_i^h \\ &= \int_{-X}^{X} (n^h - N_D)\, \phi^h\, dx + h\, (n^h_{N^h} - N_D)\, \phi(X) \\ &= h \sum_{i=-N^h}^{N^h-1} F_i^h\, \frac{\phi_i^h - \phi_{i+1}^h}{h} + F^h_{N^h}\phi(X) - F_-\phi(-X) \\ &= -\int_{-X}^{X} F^h\, \nabla^h(\phi)\, dx + F^h_{N^h}\phi(X) - F_-\phi(-X). \end{aligned}$$

Since $\nabla^h(\phi)$ converges uniformly to $\phi'(x)$ on $\overline{I}$, we have

$$\int_{-X}^{X} (n^h - N_D)\ \phi^h\, dx \to -\int_{-X}^{X} F\ \phi'(x)\, dx + F_+\phi(X) - F_-\phi(-X)$$

as $h \to 0$.

We conclude that $\partial_x F = n - N_D \in \mathrm{L}^2((0,T)\times I)$ and, by the Sobolev embedding, F lies in $\mathrm{L}^2(0,T;\mathrm{C}^0(\overline{I}))$ and the traces of F are well defined and are given by $F(t,\pm X) = F_\pm(t)$. ∎

Let us now show that the limit n is more regular than n^h is. In fact, we will prove that $n \in \mathrm{L}^2(0,T;\mathrm{H}^1(I))$, which guarantees that $n \in \mathrm{L}^2(0,T;\mathrm{C}^0(\overline{I}))$ due to the Sobolev embedding, so that the traces of the limit n with respect to the space variable are also well defined.

PROPOSITION 5.4. *The density limit n of n^h belongs to* $\mathrm{L}^2(0,T;\mathrm{H}^1(I))$.

Proof. Let $\phi \in \mathrm{C}_c^\infty(I)$. We have seen in the proof of Lemma 4.6 that the estimate

$$\|\langle \partial_x n^h, \phi\rangle\|_{\mathrm{L}^2(0,T)} \le C_T \left(h \sum_{i=-N^h+1}^{N^h} |\phi(ih)|^2 \right)^{1/2} = C_T\ \|\phi^h\|_{\mathrm{L}^2(I)}$$

holds. We also readily check that ϕ^h tends to ϕ in $\mathrm{L}^2(I)$. Hence, letting $h \to 0$ leads to

$$\|\langle \partial_x n, \phi\rangle\|_{\mathrm{L}^2(0,T)} \le C_T\ \|\phi\|_{\mathrm{L}^2(I)}.$$

By a density argument the estimate can be extended for any function $\phi \in \mathrm{L}^2(I)$. We conclude that $\partial_x n \in L^2((0,T)\times I)$. ∎

Convergence properties stronger than (5.1) will be necessary due to the nonlinear term. The idea is that the estimate in Lemma 4.4 is close to an $\mathrm{L}^2(0,T;\mathrm{H}^1(I))$ estimate on n^h. To this end we introduce the following $\mathbb{P}_1$ approximation: for $x \in (ih,(i+1)h)$, $i \in \{-N^h,\dots,N^h-1\}$, we set

$$\text{(5.3)} \qquad \begin{cases} m^h(t,x) = \dfrac{n^h_{i+1} - n^h_i}{h}\ (x - ih) + n^h_i, \\ G^h(t,x) = \dfrac{F^h_{i+1} - F^h_i}{h}\ (x - ih) + F^h_i. \end{cases}$$

Then, the sequences (m^h, G^h) are close to the original quantities (n^h, F^h) and enjoy better compactness properties as shown in the following lemma.

LEMMA 5.5. *The following estimates are verified:*

$$\begin{cases} \|n^h - m^h\|_{\mathrm{L}^2((0,T)\times I)} \le C_T\ h, \\ \|F^h - G^h\|_{\mathrm{L}^\infty((0,T)\times I)} \le C_T\ \sqrt{h}. \end{cases}$$

Furthermore, $\left(m^h\right)_{h>0}$ is relatively compact in $\mathrm{L}^2(0,T;\mathrm{C}^0(\overline{I}))$ and $\left(G^h\right)_{h>0}$ is relatively compact in $\mathrm{C}^0([0,T]\times\overline{I})$.

Proof. By taking into account the definition of the $\mathbb{P}_1$ approximations, we have

$$m^h(t,x) - n^h(t,x) = \frac{n^h_{i+1} - n^h_i}{h}\ (x - ih)$$

in the interval $(ih,(i+1)h)$, $i\in\{-N^h,\dots,N^h-1\}$. Hence, by using Lemma 4.4 we get

$$\begin{aligned}\|m^h-n^h\|^2_{\mathrm{L}^2((0,T)\times I)} &= \int_0^T\sum_{i=-N^h}^{N^h-1}\Big|\frac{n^h_{i+1}-n^h_i}{h}\Big|^2\int_{ih}^{(i+1)h}(x-ih)^2\,dx\,ds\\ &= \frac{h^2}{3}\int_0^T\sum_{i=-N^h}^{N^h-1}\frac{|n^h_{i+1}-n^h_i|^2}{h}\,ds\le C_T\ h^2\,.\end{aligned}$$

On the other hand, (3.2) yields

$$\begin{aligned}|G^h(t,x)-F^h(t,x)| &= \left|\frac{F^h_{i+1}-F^h_i}{h}\ (x-ih)\right|\\ &= |n^h_{i+1}-N_D|\ (x-ih)\le |n^h_{i+1}-N_D|\ h\end{aligned}$$

for $x\in(ih,(i+1)h)$, $i\in\{-N^h,\dots,N^h-1\}$. Therefore, Lemma 4.4 allows us to control this quantity as follows:

$$\begin{aligned}|G^h(t,x)-F^h(t,x)| &\le \sqrt{h}\ \sqrt{h}\ (n^h_{i+1}+N_D)\\ &\le \sqrt{h}\left(\Big(h|n^h_{i+1}|^2\Big)^{1/2}+\sqrt{h}N_D\right)\\ &\le \sqrt{h}\left(\left(h\sum_{j=-N^h}^{N^h}|n^h_j|^2\right)^{1/2}+\sqrt{h}N_D\right)\le C_T\ \sqrt{h}.\end{aligned}$$

This proves the first part of the result.

Note that m^h and G^h are bounded in $\mathrm{L}^2(0,T;\mathrm{H}^1(I))$ and $\mathrm{L}^\infty(0,T;\mathrm{H}^1(I))$, respectively. Indeed, we have $\partial_x m^h=(n^h_{i+1}-n^h_i)/h$ on $(ih,(i+1)h)$, and the bound for $\partial_x m^h$ in L^2 follows directly from Lemma 4.4. For the approximate electric field we have $\partial_x G^h=(F^h_{i+1}-F^h_i)/h=n^h_{i+1}-N_D$, so that

$$\begin{aligned}\|\partial_x G^h\|^2_{\mathrm{L}^2(I)} &= \sum_{i=-N^h}^{N^h}|n^h_{i+1}-N_D|^2\int_{ih}^{(i+1)h}dx\le 2\sum_{i=-N^h}^{N^h}\Big(|n^h_{i+1}|^2+N_D^2\Big)\ h\\ &\le 2\left(h\sum_{i=-N^h}^{N^h}|n^h_{i+1}|^2+(2X+h)N_D^2\right)\le C_T.\end{aligned}$$

Hence, to justify the compactness properties there remains to obtain some estimates on the time derivatives. We check that (see Appendix A)

$$\begin{aligned}&\partial_t(G^h-F^h)\quad\text{is bounded in } \mathrm{L}^2(0,T;\mathcal{M}(I)),\\ &\partial_t(m^h-n^h)\quad\text{is bounded in } \mathrm{L}^2(0,T;\mathcal{M}(I))+\mathrm{L}^2(0,T;\mathrm{W}^{-1,1}(I)).\end{aligned}\tag{5.4}$$

Then, combining this information with Lemma 4.7, we deduce the asserted compactness by application of Proposition 5.1. ∎

As a consequence of the compactness property, and by identifying limits, we can assure that

$$\begin{cases}G^h\to F & \text{uniformly on } [0,T]\times\overline{I},\\ m^h\to n & \text{strongly in } \mathrm{L}^2(0,T;C^0(\overline{I})),\\ \partial_x m^h\rightharpoonup\partial_x n & \text{weakly in } \mathrm{L}^2((0,T)\times I).\end{cases}\tag{5.5}$$

Since G^h is $\sqrt{h}$-close to F^h in the L^∞-norm, we can improve the convergence in (5.1). Actually, we have

$$F^h \to F \text{ uniformly on } [0,T]\times\overline{I}. \tag{5.6}$$

Notice also in (5.5) that the traces are well defined and the following convergences

$$\begin{cases} m^h(\pm X) = n^h_{\pm N^h} \to n(\pm X) = n_\pm & \text{strongly in } \mathrm{L}^2(0,T),\\ G^h(\pm X) = F^h_{\pm N^h} \to F(\pm X) = F_\pm & \text{strongly in } \mathrm{L}^2(0,T), \end{cases}$$

hold. In particular, the traces of n at $\pm X$ can be identified with the limits $n_\pm$, respectively, which were defined in (5.2).

In order to pass to the limit in the equation, we write a discrete weak formulation. Let $\phi \in \mathrm{C}^\infty(\overline{I})$. We denote $\phi^h_i = \phi(ih)$, and ϕ^h stands for the associated piecewise constant approximation. Then, we get

(5.7)
$$\begin{aligned} h\sum_{i=-N^h}^{N^h} \frac{d}{dt} n^h_i\ \phi^h_i &= \sum_{i=-N^h}^{N^h} \left(J^h_{i-1\to i} - J^h_{i\to i+1}\right)\ \phi^h_i \\ &= \sum_{i=-N^h}^{N^h-1} J^h_{i\to i+1}\ (\phi^h_{i+1}-\phi^h_i) - J^h_{N^h\to N^h+1}\phi^h_{N^h} + J^h_{-N^h-1\to -N^h}\phi^h_{-N^h} \\ &= \sum_{i=-N^h}^{N^h-1} v(F^h_i) n^h_i\ (\phi^h_{i+1}-\phi^h_i) - \sum_{i=-N^h}^{N^h-1} D(F^h_i)\frac{1}{h}\ (n^h_{i+1}-n^h_i)\ (\phi^h_{i+1}-\phi^h_i) \\ &\quad -W^{(f)}(F^h_{N^h}) n^h_{N^h}\phi^h_{N^h} + (j^{(e)}(F_-) - W^{(b)}(F_-) n^h_{-N^h})\phi^h_{-N^h}. \end{aligned}$$

Let us rewrite the discrete sums as integrals as follows:

$$\begin{aligned} &\frac{d}{dt}\int_{-X}^{X} n^h\ \phi^h\,dx + h\frac{d}{dt} n^h_{N^h}\ \phi(X) \\ &\quad = \int_{-X}^{X} v(F^h) n^h\ \nabla^h\phi\,dx - \int_{-X}^{X} D(F^h)\partial_x m^h\ \nabla^h\phi\,dx \\ &\qquad -W^{(f)}(F^h_{N^h}) n^h_{N^h}\phi(X) + (j^{(e)}(F_-) - W^{(b)}(F_-) n^h_{-N^h})\phi(-X), \end{aligned} \tag{5.8}$$

following the notation $\nabla^h\phi(x) = (\phi^h_{i+1}-\phi^h_i)/h$, for $x \in (ih,(i+1)h)$. We can now pass to the limit $h\to 0$.

We check that $\phi^h \to \phi$ and $\nabla^h\phi \to \phi'$ uniformly on $\overline{I}$. Let us pass to the limit in each term of (5.8). Taking into account that $n^h \to n$ in $\mathrm{C}^0([0,T];\mathrm{L}^2(I)-weak)$, we have $\int_{-X}^X n^h\phi^h\,dx \to \int_{-X}^X n\phi\,dx$ in $\mathrm{C}^0([0,T])$. Since $n^h_{N^h}$ is bounded in $\mathrm{L}^2(0,T)$, the second term in the left-hand side of (5.8) vanishes as $h\to 0$ in $\mathcal{D}'(0,T)$. Next, by using (5.6), $v(F^h)\nabla^h\phi \to v(F)\phi'$ and $D(F^h)\nabla^h\phi \to D(F)\phi'$ uniformly on $[0,T]\times\overline{I}$. To do that we combine the strong convergence $n^h \to n$ and the weak convergence $\partial_x m^h \to \partial_x n$ in $\mathrm{L}^2((0,T)\times I)$ so that the integrals in the right-hand side of (5.8) tend to

$$\int_X^X v(F) n\ \phi',dx - \int_X^X D(F)\partial_x n\ \phi'\,dx$$

as $h\to 0$ in $\mathcal{D}'(0,T)$. Finally, for the boundary terms we combine the convergence properties in (5.2) to find as the limit as $h\to 0$ the expression

$$-W^{(f)}(F) n\phi(X) + \left(j^{(e)}(F) - W^{(b)}(F) n\right)\phi(-X)\,.$$

Therefore, letting $h \to 0$ in (5.8), we have

$$\frac{d}{dt}\int_X^X n\ \phi, dx = \int_X^X v(F)n\ \phi', dx - \int_X^X D(F)\partial_x n\phi'\, dx + W^{(f)}(F)n\phi(X) + \left(j^{(e)}(F) - W^{(b)}(F)n\right)\phi(-X)$$

in $\mathcal{D}'(0,T)$. This ends the proof of Theorem 3.1.

Remark 5.6. The proof adapts readily if instead of assuming a constant doping density N_D, we deal with a sequence $\{N^h_{D,i},\ i \in \{-N^h, \dots, N^h\}\}$ verifying

$$h \sum_{i=-N^h}^{N^h} |N^h_{D,i}|^2 < \infty.$$

Accordingly, we obtain in the continuous limit a (possibly nonconstant) $\mathrm{L}^2(-X,X)$ doping density.

6. The bias constraint. In this section we reconsider the bias condition (2.8) as an alternative to the prescription of the emitter electric field (2.7). The arguments are exactly those of the previous section and we point out only the main differences in the proof. In rescaled form the condition is

$$h \sum_{i=-N^h}^{N^h} F^h_i = V, \tag{6.1}$$

which is added to the system (3.1), (3.2). This scaling means that the ratio $\frac{\mathcal{LF}}{\mathcal{V}}$ has order 1, $\mathcal{V}$ being a characteristic value for the total voltage. Of course, the L^1 estimate in Lemma 4.1 still holds, provided that $j^{(e)}$ is a bounded function. Then, the key point in the previous analysis is to establish a uniform estimate (with respect to h) on the electric field $F^h_{-N^h-1}$.

LEMMA 6.1. *The quantity $F^h_{-N^h-1}$ is bounded in $\mathrm{L}^\infty((0,T))$.*

Proof. Let us sum the relations (3.3). We get

$$\begin{aligned} h \sum_{i=-N^h}^{N^h} F^h_i &= V = h \sum_{i=-N^h}^{N^h} \left(F^h_{-N^h-1} + h \sum_{j=-N^h}^{i} (n^h_j - N_D) \right) \\ &= (2N^h+1)h\ F^h_{-N^h-1} + h^2 \sum_{j=-N^h}^{N^h} \left((n^h_j - N_D) \sum_{i=j}^{N^h} 1 \right) \\ &= (2N^h+1)h\ F^h_{-N^h-1} + h^2 \sum_{j=-N^h}^{N^h} (n^h_j - N_D)(N^h - j + 1). \end{aligned}$$

Consequently, the electric field at the emitter is given by

$$F^h_{-N^h-1} = \frac{V}{(2N^h+1)h} - \frac{h}{2N^h+1} \sum_{j=-N^h}^{N^h} (n^h_j - N_D)(N^h - j + 1). \tag{6.2}$$

It follows that

$$\begin{aligned}
|F^h_{-N^h-1}| &\leq \frac{|V|}{(2N^h+1)h} + \frac{h^2}{(2N^h+1)h}\sum_{j=-N^h}^{N^h} |n^h_j - N_D|\,|N^h - j + 1| \\
&\leq \frac{|V|}{2X} + \frac{h}{(2N^h+1)h}\left(h\sum_{j=-N^h}^{N^h} n^h_j + (2N^h+1)hN_D\right)(2N^h+1) \\
&\leq \frac{|V|}{2X} + h\sum_{j=-N^h}^{N^h} n^h_j + (2X+h)N_D.
\end{aligned}$$

This leads to the estimate of $F^h_{-N^h-1}$ in $\mathrm{L}^\infty((0,T))$. □

Once we have this estimate, we can justify the bounds in Lemmas 4.2 and 4.4. We also need some control on the time derivative of $F^h_{-N^h-1}$.

LEMMA 6.2. *The quantity $F^h_{-N^h-1}$ is bounded in $\mathrm{H}^1((0,T))$.*

Proof. Differentiating (6.2), we find

$$\begin{aligned}
\frac{d}{dt}F^h_{-N^h-1} &= \frac{h}{2N^h+1}\sum_{i=-N^h}^{N^h}\left(\sum_{j=-N^h}^{i}\frac{d}{dt}n^h_j\right) \\
&= \frac{1}{2N^h+1}\sum_{i=-N^h}^{N^h}\left(\sum_{j=-N^h}^{i}(J^h_{j-1\to j} - J^h_{j\to j+1})\right) \\
&= \frac{1}{2N^h+1}\sum_{i=-N^h}^{N^h}(J^h_{-N^h-1\to -N^h} - J^h_{i\to i+1}) \\
&= J^h_{-N^h-1\to -N^h} - \frac{1}{2N^h+1}\,J_{N^h\to N^h+1} \\
&\quad + \frac{1}{2N^h+1}\sum_{i=-N^h}^{N^h-1}\left(v(F^h_i)n^h_i - D(F^h_i)\frac{n^h_{i+1}-n^h_i}{h}\right).
\end{aligned}$$

Using the bounds of Lemmas 6.1 and 4.2, we can bound $v(F^h_i)$, $D(F^h_i)$, $j^{(e)}(F^h_{-N^h-1})$, $W^{(b)}(F^h_{-N^h-1})$, and $W^{(f)}(F^h_{N^h})$ by some constant $0 < M < \infty$. Hence, we deduce that

$$\begin{aligned}
\left|\frac{d}{dt}F^h_{-N^h-1}\right| &\leq M(1 + n^h_{-N^h} + n^h_{N^h}) \\
&\quad + \frac{M}{(2N^h+1)h}\left(h\sum_{i=-N^h}^{N^h} n^h_i + \sum_{i=-N^h}^{N^h}|n^h_{i+1} - n^h_i|\right) \\
&\leq M(1 + n^h_{-N^h} + n^h_{N^h}) + \frac{M}{2X}\,h\sum_{i=-N^h}^{N^h} n^h_i \\
&\quad + \frac{M}{\sqrt{2X}}\left(\sum_{i=-N^h}^{N^h}\frac{|n^h_{i+1} - n^h_i|^2}{h}\right)^{1/2}.
\end{aligned}$$

We conclude by applying the estimates of Lemma 4.4. □

By using these estimates, we can reproduce mutatis mutandis the arguments of the previous section. We conclude with the following result.

THEOREM 6.3. *Assume that $j^{(e)}$ is a bounded function. Then, the conclusions of Theorem* 3.1 *are still valid by replacing the condition* (2.7) *by* (6.1). *Accordingly, in the limit problem the electric field satisfies the Poisson equation $\partial_x F = n - N_D$ coupled to the constraint $\int_{-X}^{X} F\,dx = V$.*

Appendix A. Proof of (5.4). We write $m^h = \nu^h + n^h$, $G^h = \Phi^h + F^h$. Recall that ν^h, Φ^h are defined on $(0,T)\times(ih,(i+1)h)$, $i \in \{-N^h, \dots, N^h - 1\}$, by

$$\nu^h(t,x) = \frac{1}{h}\,(n^h_{i+1} - n^h_i), \qquad \Phi^h(t,x) = \frac{1}{h}\,(F^h_{i+1} - F^h_i) = n^h_{i+1} - N_D\,,$$

where we have used (3.2) in the second relation. As in the proof of Lemma 4.7, we consider a test function $\phi \in \mathrm{C}^\infty_0(I)$ and set $\Gamma^h_i = \int_{ih}^{(i+1)h}(x-ih)\phi(x)\,dx$, which verifies $|\Gamma^h_i| \le \|\phi\|_{\mathrm{L}^\infty(I)} h^2/2$. We have

$$\begin{aligned}
\langle \partial_t \Phi^h, \phi\rangle &= \sum_{i=-N^h}^{N^h-1} \frac{dn^h_{i+1}}{dt} \int_{ih} (i+1)h(x-ih)\phi(x)\,dx \\
&= \sum_{i=-N^h}^{N^h-1} \frac{1}{h}\,(J^h_{i\to i+1} - J^h_{i+1\to i+2})\,\Gamma^h_i \\
&= \sum_{i=-N^h}^{N^h-1} J^h_{i\to i+1}\,\frac{1}{h}\,(\Gamma^h_i - \Gamma^h_{i-1}) - \frac{1}{h} J^h_{N^h\to N^h+1}\Gamma^h_{N^h-1}\,.
\end{aligned}$$

We can bound this expression as follows:

$$\begin{aligned}
|\langle \partial_t \Phi^h, \phi\rangle| &\le \|\phi\|_{\mathrm{L}^\infty(I)} h \left(\sum_{i=-N^h}^{N^h-1} \left| v(F^h_i) n^h_i + \frac{1}{h} D(F^h_i)(n^h_{i+1} - n^h_i) \right| \right) \\
&\quad + \|\phi\|_{\mathrm{L}^\infty(I)} h\,|W^{(f)}(F^h_{N^h}) n^h_{N^h}| \\
&\le \|\phi\|_{\mathrm{L}^\infty(I)}\; M \left(h \sum_{i=-N^h}^{N^h-1} n^h_i + \left(\sum_{i=-N^h}^{N^h-1} \frac{|n^h_{i+1} - n^h_i|^2}{h} \right)^{1/2} \sqrt{2X} + n^h_{N^h} \right).
\end{aligned}$$

Thus, from Lemma 4.4 we deduce that $\partial_t \Phi^h$ is bounded in $\mathrm{L}^2(0,T;\mathcal{M}(I))$.

We proceed with ν^h in a similar way. Indeed, we can write

$$\begin{aligned}
\langle \partial_t \nu^h, \phi\rangle &= \frac{1}{h} \sum_{i=-N^h}^{N^h-1} \left(\frac{dn^h_{i+1}}{dt} - \frac{dn^h_i}{dt} \right) \int_{ih} (i+1)h(x-ih)\phi(x)\,dx \\
&= \frac{1}{h^2} \sum_{i=-N^h}^{N^h-1} (-J^h_{i+1\to i+2} + 2J^h_{i\to i+1} - J^h_{i-1\to i})\,\Gamma^h_i \\
&= \frac{1}{h^2} \sum_{i=-N^h}^{N^h-1} J^h_{i\to i+1}\,(-\Gamma^h_{i+1} + 2\Gamma^h_i - \Gamma^h_{i-1}) \\
&\quad - \frac{1}{h^2} J^h_{N^h\to N^h+1}\Gamma^h_{N^h-1} - \frac{1}{h^2} J^h_{-N^h-1\to -N^h}\Gamma^h_{-N^h}.
\end{aligned} \tag{A.1}$$

The boundary terms in (A.1) are bounded by

$$M(1+n^h_{-N^h}+n^h_{N^h})\|\phi\|_{\mathrm{L}^\infty(I)},$$

which belongs to a bounded set of $\mathrm{L}^2(0,T)$. Next, we have the bound

$$\frac{1}{h^2}|-\Gamma^h_{i+1}+2\Gamma^h_i-\Gamma^h_{i-1}|\le C\|\phi'\|_{\mathrm{L}^\infty(I)}\ h.$$

Therefore, the sum in the right-hand side of (A.1) can be estimated by

$$\begin{aligned}C\|\phi'\|_{\mathrm{L}^\infty(I)}\ h\sum_{i=-N^h}^{N^h-1}|J^h_{i\to i+1}| \ &\le\ CM\|\phi'\|_{\mathrm{L}^\infty(I)}\left(h\sum_{i=-N^h}^{N^h-1}n^h_i\right.\\ &\quad\left.+\left(\sum_{i=-N^h}^{N^h-1}\frac{|n^h_{i+1}-n^h_i|^2}{h}\right)^{1/2}\sqrt{2X}\right),\end{aligned}$$

as we did in the previous proof for Φ^h. We conclude that $\partial_t\nu^h$ is bounded in $\mathrm{L}^2(0,T;\mathcal{M}(I))+\mathrm{L}^2(0,T;\mathrm{W}^{-1,1}(I))$. This ends the proof of (5.4). ∎

Appendix B. Uniqueness for the limit problem. In this section, we show the uniqueness of the solution of (3.4). Let us consider two solutions (n_1,F_1) and (n_2,F_2) of (3.4) with $n_i\in\mathrm{C}^0([0,T];\mathrm{L}^2(I))\cap\mathrm{L}^2(0,T;\mathrm{H}^1(I))$. For the difference, we have

$$\partial_t(n_1-n_2)+\partial_x J(F_1,n_1-n_2)+\partial_x\Big((v(F_1)-v(F_2))n_2-(D(F_1)-D(F_2))\partial_x n_2\Big)=0,$$

where $J(F,n)=v(F)n-D(F)\partial_x n$. The boundary conditions read

$$\begin{cases}J(F_1,n_1-n_2)(X)=W^{(f)}(F_1)(n_1-n_2)+(W^{(f)}(F_1)-W^{(f)}(F_2))n_2,\\ J(F_1,n_1-n_2)(X)=j^{(e)}(F_1)-j^{(e)}(F_2)-W^{(b)}(F_1)(n_1-n_2)\\ \qquad\qquad\qquad\qquad -(W^{(b)}(F_1)-W^{(b)}(F_2))n_2.\end{cases}$$

Thus, we are left with only the task of evaluating

$$\begin{aligned}&\frac{d}{dt}\int_{-X}^X\frac{|n_1-n_2|^2}{2}\,dx+\int_{-X}^X D(F_1)|\partial_x(n_1-n_2)|^2\,dx\\ &=\int_{-X}^X v(F_1)(n_1-n_2)\partial_x(n_1-n_2)\,dx+\int_{-X}^X(v(F_1)-v(F_2))n_2\partial_x(n_1-n_2)\,dx\\ &\quad-\int_{-X}^X(D(F_1)-D(F_2))\partial_x n_2\partial_x(n_1-n_2)\,dx\\ &\quad+J(F_1,n_1-n_2)(n_1-n_2)(-X)-J(F_1,n_1-n_2)(n_1-n_2)(X).\end{aligned}\tag{B.1}$$

Denote by A,B,C,D, and E the five terms in the right-hand side of (B.1). Recall that F_i belongs to L^∞, so that the coefficients are lying in a bounded set. Also denote by Λ a Lipschitz constant for the functions $v,D,j^{(e)}$ and $W^{(b,f)}$ in the range of values of F_1 and F_2. Let $\nu>0$ be a parameter to be specified later on. By using the Cauchy–Schwarz and Young inequalities, we can estimate

$$|A|\le C_\nu\int_{-X}^X|n_1-n_2|^2\,dx+\nu\int_{-X}^X|\partial_x(n_1-n_2)|^2\,dx.$$

Next, we have

$$\begin{aligned} |B| &\leq \Lambda \|F_1 - F_2\|_{\mathrm{L}^\infty(I)} \int_{-X}^{X} |n_2| \, |\partial_x (n_1 - n_2)| \, dx \\ &\leq C_\nu \Lambda^2 \int_{-X}^{X} |n_2|^2 \, dx \, \|F_1 - F_2\|^2_{\mathrm{L}^\infty(I)} + \nu \int_{-X}^{X} |\partial_x (n_1 - n_2)|^2 \, dx. \end{aligned}$$

The Poisson equations yield to

$$(F_1 - F_2)(t,x) = F_{-,1} - F_{-,2} + \int_{-X}^{x} (n_1 - n_2)(t,y) \, dy,$$

which provides the bound

$$\|F_1 - F_2\|^2_{\mathrm{L}^\infty(I)} \leq 2|F_{-,1} - F_{-,2}|^2 + 4X \int_{-X}^{X} |n_1 - n_2|^2 \, dx.$$

Hence, we get (changing the value of C_ν)

$$|B| \leq C_\nu \int_{-X}^{X} |n_2|^2 \, dx \left(|F_{-,1} - F_{-,2}|^2 + \int_{-X}^{X} |n_1 - n_2|^2 \, dx \right) + \nu \int_{-X}^{X} |\partial_x (n_1 - n_2)|^2 \, dx.$$

A similar reasoning for C leads to

$$|C| \leq C_\nu \int_{-X}^{X} |\partial_x n_2|^2 dx \left(|F_{-,1} - F_{-,2}|^2 + \int_{-X}^{X} |n_1 - n_2|^2 dx \right) + \nu \int_{-X}^{X} |\partial_x (n_1 - n_2)|^2 dx.$$

For the boundary terms, we get rid of the terms $-W^{(b,f)}(F_1)|n_1 - n_2|^2$ which are nonnegative and get

$$D + E \leq \Lambda \Big((1 + n_2) \, |F_1 - F_2| \, |n_1 - n_2|(-X) + n_2 \, |F_1 - F_2| \, |n_1 - n_2|(+X) \Big).$$

Then, we use the Sobolev embedding to control the traces of $n_1 - n_2$ with the H^1-norm. Finally, we obtain

$$\begin{aligned} D + E &\leq C_\nu (1 + |n_2(-X)|^2 + |n_2(X)|^2) \left(|F_{-,1} - F_{-,2}|^2 + \int_{-X}^{X} |n_1 - n_2|^2 \right) \\ &\quad + \nu \left(\int_{-X}^{X} |n_1 - n_2|^2 \, dx + \int_{-X}^{X} |\partial_x (n_1 - n_2)|^2 \, dx \right). \end{aligned}$$

Having disposed of these preliminaries, we recall that $D(F_1)$ is bounded from below by some $\delta > 0$. Then, we put all the pieces together and choose $\nu = \nu(\delta)$ appropriately so that we finally find

$$\begin{aligned} &\frac{d}{dt} \int_{-X}^{X} |n_1 - n_2|^2 \, dx + \frac{\delta}{2} \int_{-X}^{X} |\partial_x (n_1 - n_2)|^2 \, dx \\ &\qquad \leq f(t) \int_{-X}^{X} |n_1 - n_2|^2 \, dx + g(t) |F_{-,1} - F_{-,2}|^2, \end{aligned}$$

where the nonnegative functions $f, g \in \mathrm{L}^1(0,T)$ depend on Λ, δ and $\int_{-X}^{X}(n_2^2 + |\partial_x n_2|^2)\,dx$. The Gronwall lemma provides the inequality

$$\int_{-X}^{X}|n_1 - n_2|^2(t,x)\,dx \leq e^{\int_0^t f(s)\,ds}\left(\int_{-X}^{X}|n_1 - n_2|^2(0,x)\,dx + \int_0^t g(s)|F_{-,1} - F_{-,2}|^2(s)\,ds\right).$$

This proves the continuity of the solution with respect to the data and, consequently, the uniqueness of the solution. We skip the adaptation of the proof to the bias condition.

WELL-POSEDNESS OF TWO NONRIGID MULTIMODAL IMAGE REGISTRATION METHODS*

OLIVIER FAUGERAS† AND GERARDO HERMOSILLO†

Abstract. Image registration methods may be designed as solutions of minimization problems on a set of geometric deformations. In the nonrigid case, solving these problems often means computing the steady state of a system of evolution equations involving the "gradient" of the error criterion, defined from the Euler–Lagrange equations of the corresponding minimization problem. The well-posedness of the registration method requires showing the existence of a solution to the minimization problem, as well as that of a stable solution of the evolution equations derived from it. We provide such proofs in the case where the error criterion is derived from two different statistical similarity measures: global mutual information and local cross-covariance. We also describe our numerical implementation for solving the corresponding evolution equations and show examples of registrations of real 2D and 3D images achieved with these algorithms. The proofs are quite general and can be applied to most of the known nonrigid image registration methods.

Key words. multimodal image matching, variational methods, image registration, mutual information, cross-covariance, Euler–Lagrange equations, initial-value problems, analytical semigroups of linear operators

1. Introduction.

The problem of estimating the geometric deformation between two images has a long history. Most of the existing methods have been developed for images acquired with the same sensor or at least the same modality (e.g., in the visible spectrum). They often rely on the minimization of an error criterion which takes into account two sources of a priori knowledge: (a) the properties of the images' intensities that characterize their similarity and (b) the constraints on the possible geometric deformations.

For the first point, the basic idea is that the intensities at corresponding points should be "similar," i.e., equal as in the case of the optical flow problem [28]. This is, of course, too strict a requirement in many cases, and it has been relaxed to an average intensity similarity in the neighborhoods of the corresponding points, as in the case of local image differences [29] or more general block matching strategies [51, 41]. One more step and one can characterize similarity as a large score of a nonlocal similarity measure such as the cross-correlation [20, 21, 11, 39], the correlation ratio [49], or mutual information [55, 58, 56, 32], among several others [59, 26, 45, 31].

As for the second point, the possible geometric deformations, a first idea is to restrict the search to sets of low-dimensional parametric transformations (e.g., Euclidean, affine, quadratic, or spline-interpolation between a set of control points [36, 50]). Another example of a constrained deformation is the stereo case, in which knowledge of the fundamental matrix allows one to restrict the search for the matching point along the epipolar line [1, 60]. If the deformation is not defined parametrically,

the constraint may consist of requiring some smoothness of the displacement field, possibly preserving discontinuities [53, 1, 47, 2, 34, 35, 4, 3, 18]. Concerning this regularization, we can distinguish the approaches based on explicit smoothing of the field, as in Thirion's deamons algorithm [53] (we refer to [44] for a variational interpretation of this algorithm), from those considering an additive term in the error criterion, yielding (possibly anisotropic) diffusion terms [5, 57]. For a comparison of these two approaches, we refer to the work of Cachier and Ayache [9, 10]. Approaches relying on a regularization functional induce a certain amount of competition between the similarity of the images and the smoothness of the deformation. Fluid methods do not impose this competition, although they still require a parameter that fixes the amount of desired smoothness or fluidness of the result [13, 54, 12].

Many of the previous methods are "differential" and are mostly valid for small displacements. Special techniques are required in order to recover large deformations. For instance, Alvarez, Weickert, and Sánchez [2] use a scale-space focusing strategy. Christensen, Miller, and Vannier [13] adopt a different approach. They look for a continuously invertible mapping which is obtained by the composition of small displacements. Each small displacement is calculated as the solution of an elliptic partial differential equation describing the nonlinear kinematics of fluid-elastic materials under deforming forces given by the matching term (in their case the image differences). Trouvé [54] has generalized this approach using Lie group ideas on sets of diffeomorphisms. Under a similar formalism, a very general framework which also allows for changes in the intensity values is proposed by Miller and Younes [37].

In the case of multimodal image registration (e.g., visible and infrared, anatomical and functional magnetic resonance images, etc.) the similarity in the intensities is "weak" and one has to rely on statistical definitions. Such definitions have been widely used in the case of low-dimensional parametric transformations. Mutual information was introduced by Viola and colleagues [55, 58, 56] and independently by Maes et al. [32]. The correlation ratio was first proposed as a similarity measure for image matching by Roche et al. [49]. Other statistical approaches rely on learning the joint distribution of intensities, as done, for instance, by Leventon and Grimson [31]. Extensions to more complex (nonrigid) transformations using statistical similarity measures include approaches relying on more complex parametric transformations [36, 50], block matching strategies [33, 24, 22], and parametric intensity corrections [48]. Some recent approaches rely on the computation of the gradient of the local cross correlation [11, 39].

Several papers have discussed the theoretical well-posedness of similar registration problems in the monomodal case as, for instance, [27, 14]. However, none of those treating the multimodal case has dealt significantly with the problem of the existence and uniqueness of a solution of the registration problem. Our work is an attempt to improve this situation. We consider the problem of multimodal image registration and use statistical considerations to define similarity. In order to be able to deal with strongly nonstationary variations in the intensity we extend the usual statistical framework to act locally instead of globally in the images. Since most of the geometric deformations that occur in practice are nonparametric, we model them as dense deformation fields that are constrained to belong to some reasonable functional spaces, e.g., Sobolev spaces. We then classically define the problem as a variational one and show that it is well posed.

In detail, we consider the problem of dense matching between two images using statistical dissimilarity criteria, which are well adapted to the case of multimodal im-

age data often encountered, e.g., in medical imaging. The minimization of the sum of the dissimilarity term and the regularization term defines, through the associated Euler–Lagrange equations, a set of coupled functional evolution equations. The conditions under which this type of evolution equation is well posed are known. We show that the matching functions that we obtain satisfy these conditions in the case where the error functional is derived from two different statistical similarity measures: global mutual information and local cross-covariance.

1.1. A generic registration problem. At a conceptual level, images are integrable real bounded functions defined on $\mathbb{R}^n$ (we restrict ourselves to $n = 2, 3$). These abstract images are not directly observable because of the physics of acquisition. What we call an *image* is the convolution of such a function with a C^∞ mollifier. We therefore view the *images* as belonging to the space of infinitely differentiable functions, $C^\infty(\mathbb{R}^n)$. They are bounded and Lipschitz continuous, as well as all their derivatives. These assumptions are not central to this article and can be greatly weakened. The reader will verify that the first image is required only to be C^2 while the second is required to be C^1 with a Lipschitz continuous first order derivative. This asymmetry is due to the fact that the two images do not play the same role in the registration problem. Weaker conditions may be possible but we have not investigated this specific problem. The range of the values of an image is the interval $[0, \mathcal{A}]$, $\mathcal{A} > 0$.

Let I_1 and I_2 be two images. Let $\mathbf{Id}$ be the identity mapping of $\mathbb{R}^n$ and $\mathbf{h} : \Omega \to \mathbb{R}^n$ a given vector field defined on a bounded and regular region of interest $\Omega \subset \mathbb{R}^n$. By regular we mean C^2. This technical assumption is required in the proofs of Lemma 2.3 and Proposition 2.4. Images are usually defined on a product of intervals. Ω is in practice chosen as a C^2 superset of this set (e.g., a disk). The image values are smoothly extended outside the product of intervals to reach the value of 0 on the boundary $\partial\Omega$ of Ω. The registration or matching problem may be defined as that of finding a vector field $\mathbf{h}^*$ minimizing an error criterion between I_1 and the warped image $I_2 \circ (\mathbf{Id} + \mathbf{h})$.

The search for this function is done within a set $\mathcal{F}$ of admissible functions such that it minimizes an energy functional $\mathcal{I} : \mathcal{F} \to \mathbb{R}$ of the form

$$\mathcal{I}(\mathbf{h}) = \mathcal{J}(\mathbf{h}) + \mathcal{R}(\mathbf{h}).$$

The term $\mathcal{J}(\mathbf{h})$ is designed to measure the "dissimilarity" between the reference image (I_1) and the $\mathbf{h}$-warped second image $(I_2(\mathbf{Id} + \mathbf{h}))$. The term $\mathcal{R}(\mathbf{h})$ is designed to penalize fast variations of the function $\mathbf{h}$. It is a regularization term introducing an a priori preference for smoothly varying functions.

Generally speaking, the set $\mathcal{F}$ is a dense linear subspace of a Hilbert space H, the scalar product of which is denoted by $(\cdot, \cdot)_H$. If $\mathcal{I}$ is sufficiently regular, its first variation[1] at $\mathbf{h} \in \mathcal{F}$ in the direction of $\mathbf{k} \in H$ is defined by (see, e.g., [15])

$$\delta_{\mathbf{k}}\mathcal{I}(\mathbf{h}) = \lim_{\varepsilon \to 0} \frac{\mathcal{I}(\mathbf{h} + \varepsilon\mathbf{k}) - \mathcal{I}(\mathbf{h})}{\varepsilon}. \tag{1.1}$$

If the mapping $\mathbf{k} \to \delta_{\mathbf{k}}\mathcal{I}(\mathbf{h})$ is linear and continuous, the Riesz representation theorem [19] guarantees the existence of a unique vector, denoted by $\nabla_H\mathcal{I}(\mathbf{h})$, and called the gradient of $\mathcal{I}$, which satisfies the equality

$$\delta_{\mathbf{k}}\mathcal{I}(\mathbf{h}) = (\nabla_H\mathcal{I}(\mathbf{h}), \mathbf{k})_H$$

[1] Also called the Gâteaux derivative.

for every $\mathbf{k} \in H$. The gradient depends on the choice of the scalar product $(\cdot,\cdot)_H$ though, a fact which explains our notation. If a minimizer $\mathbf{h}^*$ of $\mathcal{I}$ exists, then the set of equations $\delta_{\mathbf{k}}\mathcal{I}(\mathbf{h}^*) = 0$ must hold for every $\mathbf{k} \in H$, which is equivalent to $\nabla_H \mathcal{I}(\mathbf{h}^*) = 0$. These equations are called the Euler–Lagrange equations associated with the energy functional $\mathcal{I}$. They give necessary conditions for the existence of a minimizer, but they are not sufficient since they guarantee only the existence of a critical point of the functional $\mathcal{I}$. These critical points can be found in many ways, including methods for nonlinear equations. Rather than solving them directly, the search for a minimizer of $\mathcal{I}$ is done using a "gradient descent" strategy. Given an initial estimate $\mathbf{h}_0 \in \mathcal{F}$, a time-dependent differentiable function (also denoted by $\mathbf{h}$) from the interval $[0, +\infty[$ into H is computed as the solution of the following initial value problem:

$$\begin{cases} \dfrac{d\mathbf{h}}{dt} = -\Big(\nabla_H \mathcal{J}(\mathbf{h}) + \nabla_H \mathcal{R}(\mathbf{h})\Big), \\ \mathbf{h}(0)(\cdot) = \mathbf{h}_0(\cdot). \end{cases} \tag{1.2}$$

The asymptotic state (i.e., when $t \to \infty$) of $\mathbf{h}(t)$ is then chosen as the solution of the matching problem, provided that $\mathbf{h}(t) \in \mathcal{F}\ \forall t > 0$. We shall restrict ourselves to the case when $\nabla_H \mathcal{R}$ is an unbounded *linear* operator from its domain into H, whereas $\nabla_H \mathcal{J}$ may be a nonlinear function mapping H into H.

There are two (mostly theoretical) advantages in introducing the artificial time variable. The first is that, as shown in Theorem 1.2, we are able to prove the well-posedness of the initial value problem (1.2). The second is that, as shown in Proposition 2.5, we are able to prove that the asymptotic state of the solution of (1.2) is indeed a zero of the Euler–Lagrange equations and, in effect, a local minimum of $\mathcal{I}$. The third advantage is practical: our experiments (see section 6) have shown that when we discretize (1.2) we converge toward a local minimum at a reasonable speed.

1.2. Existence of a classical solution of (1.2). Equation (1.2) may be viewed as a first order ordinary differential equation with values in H. By borrowing tools from functional analysis and the theory of semigroups generated by unbounded linear operators on Hilbert spaces, we can prove the existence of a unique classical solution of (1.2) under fairly general hypotheses. We refer to the books of Brezis [7], Pazy [43], and Tanabe [52] for an in-depth study of these subjects. Because of our choice of the regularization term $\mathcal{R}$ (described in section 2), it turns out that the mapping $A : \mathbf{h} \to -\nabla_H \mathcal{R}(\mathbf{h})$ is linear from its domain, a subset $\mathcal{D}(A)$ of H, into H. Similarly, we denote by F the (nonlinear) mapping defined by $\mathbf{h} \to -\nabla_H \mathcal{J}$. F is called the *matching* function of the registration problem. The unknown of the initial-value problem (1.2) is an H-valued function $\mathbf{h} : [0, +\infty[\to H$ defined on $\mathbb{R}^+$. We now establish the properties required for A and F in order for (1.2), which is now written as a semilinear abstract initial value problem of the form

$$\begin{cases} \dfrac{d\mathbf{h}}{dt} - A\mathbf{h}(t) = F(\mathbf{h}(t)), \qquad t > 0, \\ \mathbf{h}(0) = \mathbf{h}_0 \in H, \end{cases} \tag{1.3}$$

to have a unique solution.

We first recall the following definition.

DEFINITION 1.1. *A function* $\mathbf{h} : [0, +\infty[\to H$ *is a classical solution of* (1.3) *if*

$$\mathbf{h} \in C([0, +\infty[; H) \cap C^1(]0, +\infty[; H) \cap C(]0, +\infty[; \mathcal{D}(A))$$

and (1.3) *is satisfied for* $t > 0$.

As a consequence of known results we have the following.

THEOREM 1.2. *If in* (1.3) *the linear operator* $-A$ *is strongly elliptic, invertible*[2] *and the nonlinear function* F *is bounded and Lipschitz continuous, then there exists a unique classical solution of* (1.3). *Moreover, the function* $t \to d\mathbf{h}/dt$ *from* $]0, +\infty[$ *into* H_α *(defined in the proof) is Hölder continuous.*

Proof. We use the notion of an analytical semigroup of operators on H defined, e.g., in [52, 43]. Theorem 3.6.1 in [52] or Theorem 2.7 in Chapter 7 of [43] show that if the operator $-A$ is strongly elliptic, then A generates an analytical semigroup $S_A(t)$, $t \geq 0$, on H. It follows from [43, Chapter 2, section 2.6], that $(-A)^\alpha$ can be defined for $0 < \alpha \leq 1$ and that $(-A)^\alpha$ is a closed linear invertible operator with domain $\mathcal{D}((-A)^\alpha)$ dense in H. It is invertible because $-A$ is. The closedness of $(-A)^\alpha$ implies that $\mathcal{D}((-A)^\alpha)$ endowed with the graph norm of $(-A)^\alpha$, i.e., the norm $|||\mathbf{h}||| = \|\mathbf{h}\|_H + \|(-A)^\alpha \mathbf{h}\|_H$, is a Banach space. Since $(-A)^\alpha$ is invertible, its graph norm is equivalent to the norm $\|\mathbf{h}\|_\alpha = \|(-A)^\alpha \mathbf{h}\|_H$. Thus, $\mathcal{D}((-A)^\alpha)$ equipped with the norm $\|\cdot\|_\alpha$ is a Banach space, which we denote by H_α. The space H_α is continuously embedded in H for all α's, which implies

$$\|\mathbf{h}\|_H \leq k_\alpha \|\mathbf{h}\|_{H_\alpha} \quad \forall \mathbf{h} \in H_\alpha,$$

for some $k_\alpha > 0$. Theorems 3.1 and 3.3 of [43] allow us to conclude. ∎

The remainder of the paper is divided into five additional sections. Section 2 discusses the regularization part of the initial-value problem (1.3). Section 3 is devoted to the definition of the two statistical dissimilarity measures we have considered and to the computations of the associated Euler–Lagrange equations. Section 4 contains the proofs of the Lipschitz continuity of the corresponding matching functions. Finally, sections 5 and 6 describe the implementation of the matching algorithms and present experimental results with real two- and three-dimensional (2D and 3D) images, respectively.

2. Regularization term. This section studies the regularization part of the initial-value problem (1.2), i.e., the term $\nabla_H \mathcal{R}(\mathbf{h})$. A one-parameter family of regularization operators is considered which encourages the preservation of edges of the displacement field along the edges of the reference image. In view of the results of the previous section, we choose concrete functional spaces $\mathcal{F}$ and H and specify the domain of the regularization operators. We then show that these operators satisfy the properties of A which are sufficient to assert the existence of a classical solution of (1.2) according to the main result of the previous section.

2.1. Function spaces and boundary conditions. We begin with a brief description of the functional spaces that will be appropriate for our purposes. In doing this, we will make reference to Sobolev spaces, denoted by $W^{k,p}(\Omega)$. We refer to the books of Evans [19] and Brezis [7] for formal definitions and in-depth studies of the properties of these functional spaces.

For the definition of $\nabla_H \mathcal{I}$, we use the Hilbert space

$$H = \mathbf{L}^2(\Omega) = \underbrace{L^2(\Omega) \times \cdots \times L^2(\Omega)}_{n \text{ terms}} = \left(W^{0,2}(\Omega)\right)^n.$$

[2]The invertibility of A is not required, as discussed in, e.g., [43, p. 195], but it makes the proofs simpler.

The regularization functionals that we consider are of the form

$$\mathcal{R}(\mathbf{h}) = \kappa \int_\Omega \varphi(D\mathbf{h}(\mathbf{x}))\, d\mathbf{x}, \tag{2.1}$$

where $D\mathbf{h}(\mathbf{x})$ is the Jacobian of $\mathbf{h}$ at $\mathbf{x}$, φ is a quadratic form of the elements of the matrix $D\mathbf{h}(\mathbf{x})$, and $\kappa > 0$. Therefore the set of admissible functions $\mathcal{F}$ will be contained in the space

$$\mathbf{H}^1(\Omega) = (W^{1,2}(\Omega))^n.$$

Additionally, the boundary conditions for $\mathbf{h}$ will be specified in $\mathcal{F}$. We consider Dirichlet conditions of the form $\mathbf{h} = 0$ almost everywhere on $\partial\Omega$ (in fact, because of the regularity of $\mathbf{h}$, proved in Proposition 2.4, this condition holds everywhere on $\partial\Omega$), and set

$$\mathcal{F} = \mathbf{H}_0^1(\Omega) = (W_0^{1,2}(\Omega))^n.$$

Because of the special form of $\mathcal{R}(\mathbf{h})$, the corresponding regularization operator is a second order differential one, and we therefore will need the space

$$\mathbf{H}^2(\Omega) = (W^{2,2}(\Omega))^n$$

for the definition of its domain.

2.2. Image-driven anisotropic diffusion. The family that we consider is obtained by defining φ in (2.1) by

$$\varphi(D\mathbf{h}) = \frac{1}{2}\mathrm{Tr}\big(D\mathbf{h}\ \mathbf{T}_{I_1}\ D\mathbf{h}^T\big), \tag{2.2}$$

where $\mathbf{T}_{I_1}$ is an $n \times n$ symmetric matrix defined at every point of Ω by the following expression:

$$\mathbf{T}_f = \frac{(\lambda + |\nabla f|^2)\mathbf{Id} - \nabla f \nabla f^T}{(n-1)|\nabla f|^2 + n\lambda} \quad \text{for} \quad f : \mathbb{R}^n \to \mathbb{R},\ \text{regular.}$$

This matrix is a regularized projector in the plane perpendicular to ∇f. It was first proposed by Nagel and Enkelmann [38] for computing optical flow while preserving the discontinuities of the deforming template. As pointed out by Alvarez, Weickert, and Sánchez [2], applying the smoothness constraint to the reference image (here I_1) instead of the deforming one (here I_2) allows us to avoid artifacts which appear when recovering large displacements. The matrix $\mathbf{T}_f$ has one eigenvector equal to ∇f, while the remaining eigenvectors span the plane perpendicular to ∇f. The eigenvalues λ_i of this matrix are all positive and verify $\sum_i \lambda_i = 1$, independently of ∇f.

It is straightforward to verify that the Euler–Lagrange equation corresponding to (2.1) in this case is

$$\mathbf{div}(D\varphi(D\mathbf{h})) = \begin{pmatrix} \mathrm{div}(\mathbf{T}_{I_1}\nabla h_1) \\ \vdots \\ \mathrm{div}(\mathbf{T}_{I_1}\nabla h_n) \end{pmatrix} = 0.$$

Thus, the regularization operator $\nabla_H \mathcal{R}(\mathbf{h})$ yields a linear diffusion term with $\mathbf{T}_{I_1}$ as diffusion tensor. In regions where $\nabla \mathbf{h}_i$ is small compared to the parameter λ in $\mathbf{T}_{I_1}$,

the diffusion tensor is almost isotropic and so is the regularization. At the edges of f, where $|\nabla I_1| \gg \lambda$, the diffusion takes place mainly along these edges. This operator is thus well suited for encouraging large variations of $\mathbf{h}$ along the edges of the reference image I_1.

We define the corresponding regularization operator as follows.

DEFINITION 2.1. *The linear operator $A : \mathcal{D}(A) \to H$ is defined as*

$$\begin{cases} \mathcal{D}(A) = \mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega), \\ \\ A\mathbf{h} = \begin{pmatrix} \operatorname{div}(\mathbf{T}_{I_1} \nabla h_1) \\ \vdots \\ \operatorname{div}(\mathbf{T}_{I_1} \nabla h_n) \end{pmatrix}. \end{cases}$$

We now check that $-A$ is strongly elliptic (or, in functional analytic language, is variational) by applying the standard variational approach [19].

PROPOSITION 2.2. *The operator $-A$ defines a bilinear form B on the space $\mathbf{H}_0^1(\Omega)$ which is continuous and coercive (strongly elliptic).*

Proof. The proof is quite standard, and we only sketch it here.

Because of the form of the operator A, it is sufficient to work on one of the coordinates, to consider the operator $a : \mathcal{D}(a) \to L^2(\Omega)$ defined by

$$a\, u = \operatorname{div}(\mathbf{T}_{I_1} \nabla u),$$

and to show that the operator $u \to -au$ defines a bilinear form b on the space $H_0^1(\Omega)$ which is continuous and coercive. Continuity is obtained from the fact that the coefficients of $\mathbf{T}_{I_1}$ are bounded by integrating by parts the expression of $b(u, v)$ and applying the Cauchy–Schwarz inequality. Coercivity is obtained from the fact that the eigenvalues of $\mathbf{T}_{I_1}$ are strictly positive and by using Poincaré's inequality. ∎

LEMMA 2.3. *The linear operator $-\kappa A$ is invertible for all $\kappa > 0$.*

Proof. It is sufficient to show that the equation $-\kappa A\mathbf{h} = \mathbf{f}$ has a unique solution for all $\mathbf{f} \in \mathbf{L}^2(\Omega)$. The proof of Proposition 2.2 shows that the bilinear form associated with the operator $-\kappa A$ is continuous and coercive in $\mathbf{H}^1(\Omega)$; hence the Lax–Milgram theorem tells us that the equation $-\kappa A\mathbf{h} = \mathbf{f}$ has a unique weak solution in $\mathbf{H}_0^1(\Omega)$ for all $\mathbf{f} \in \mathbf{L}^2(\Omega)$. Since Ω is regular (i.e., C^2), the weak solution is in $\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)$ and is a strong solution. ∎

2.3. Existence of a regular solution of (1.2). Now that the domain of the regularization operator is defined, we give a stronger result concerning the existence of a solution of (1.2): because the domain of A is defined in terms of Sobolev spaces, a classical solution of the abstract problem corresponds in fact to the notion of *weak* solution in PDE theory. The existence of a *regular* solution in this context may be shown, assuming regularity of the boundary $\partial\Omega$ of Ω. In effect we have the following result.

PROPOSITION 2.4. *The functions $(t, \mathbf{x}) \to \mathbf{h}(t, \mathbf{x})$ and $(t, \mathbf{x}) \to (\partial/\partial t)\mathbf{h}(t, \mathbf{x})$ are continuous on $]0, +\infty[\times\overline{\Omega}$, and for each $t > 0$ the function $\mathbf{x} \to \mathbf{h}(t, \mathbf{x})$ is in $\mathbf{C}^2(\Omega)$.*

Proof. It follows from a theorem due to Sobolev that $\mathbf{H}^2(\Omega) \subset \mathbf{C}(\overline{\Omega})$ for $n = 2, 3$; hence $\mathcal{D}(A) \subset \mathbf{H}^2(\Omega) \subset \mathbf{C}(\overline{\Omega})$ and, since $\mathbf{h}(t) \in \mathcal{D}(A)$ for $t > 0$, this proves the continuity of $\mathbf{h}$ on $]0, +\infty[\times\overline{\Omega}$. Next, because of Theorem 1.2, $t \to d\mathbf{h}/dt \in H_\alpha$ is Hölder continuous for $t > 0$. Moreover, a theorem due to Sobolev, which can be found, e.g., in Theorem 8.4.3 of [43], shows that if $\alpha > 3/4$ ($n = 3$) and $\alpha > 1/2$

$(n = 2)$, H_α is a set of Hölder continuous functions, and we have the continuity of $d\mathbf{h}/dt$ on $]0, +\infty[\times\overline{\Omega}$.

It remains to show that $\mathbf{h}(t,\cdot) \in \mathbf{C}^2(\Omega)$. First the function $\mathbf{x} \to F(\mathbf{h}(\mathbf{x}))$ from $\Omega \to \mathbb{R}^n$ is Hölder continuous if $\mathbf{h}$ is (this is proved in Propositions 4.12 and 4.22). Since $\mathbf{h}(t) \in \mathbf{H}^2(\Omega)$ for $t > 0$ and (Sobolev) $\mathbf{H}^2(\Omega) \subset \mathbf{C}^\gamma(\overline{\Omega})$ $(0 \le \gamma < 0.5$ for $n = 3$ and $0 \le \gamma < 1$ for $n = 2)$, $\mathbf{x} \to \mathbf{h}(t,\mathbf{x})$ is Hölder continuous for $t > 0$. Finally, since $(\partial/\partial t)\mathbf{h}(t,.)$ is Hölder continuous in Ω, it follows that $-A\mathbf{h} = F(\mathbf{h}) - d\mathbf{h}/dt$ is Hölder continuous in Ω, and by a classical regularity theorem for elliptic equations [16, 23], it follows that $\mathbf{h}(t,\cdot) \in \mathbf{C}^{2+\delta}(\Omega)$ for some $\delta > 0$, i.e., has second order Hölder continuous derivatives in the space variable and is thus a regular solution. ∎

2.4. Existence of minimizers. Having defined the regularization functional, we discuss in this section the existence of minimizers of the global energy functional

$$\mathcal{I}(\mathbf{h}) = \mathcal{J}(\mathbf{h}) + \kappa \int_\Omega \varphi(D\mathbf{h}(\mathbf{x}))\, d\mathbf{x}. \tag{2.3}$$

We assume that $\mathcal{J}(\mathbf{h})$ is continuous in $\mathbf{h}$ and bounded below. These properties are shown for the statistical dissimilarity functionals $\mathcal{J}(\mathbf{h})$ that we study in Proposition 3.1 and Theorem 4.18. In this case, a classical result (see, e.g., Chapter 8, Theorem 2, in [19]) shows that a minimizer exists if φ is convex and coercive. We readily check that φ given in (2.2) satisfies these hypotheses. As pointed out in [2], because of the smoothness of $\partial_i I_1$, $\mathbf{T}_{I_1}$ has strictly positive eigenvalues and therefore, clearly, the mapping $\varphi : \mathbf{X} \in \mathbb{R}^n \mapsto \mathbf{X}\mathbf{T}_{I_1}\mathbf{X}^T \in \mathbb{R}^+$ is convex. Then the functional $\mathcal{R}(\mathbf{h}) = \int_\Omega \varphi(D\mathbf{h}(\mathbf{x}))\, d\mathbf{x}$ satisfies the coercivity inequality, i.e., there exist $c_1 > 0$, $c_2 \ge 0$ such that $\varphi(D\mathbf{h}(\mathbf{x})) \ge c_1|D\mathbf{h}|^2 - c_2$, since we have $\nabla u^T \mathbf{T}_{I_1} \nabla u \ge \theta|\nabla u|^2$ for all $\mathbf{x} \in \Omega$, where $\theta > 0$ is the smallest eigenvalue of $\mathbf{T}_{I_1}$ in Ω.

2.5. Existence of a limiting steady state solution. Theorem 1.2 proves the existence of a solution of the initial-value problem (1.2) or (1.3). Proposition 2.4 gives some regularity properties of this solution. We also have to show that it satisfies the Euler–Lagrange equation in the limit. In order to see this, we introduce the function $L : \mathbb{R}^+ \to \mathbb{R}$ defined by

$$L(t) = \mathcal{I}(\mathbf{h}(t)). \tag{2.4}$$

The properties of L relevant to our goal are stated in the following.

PROPOSITION 2.5. *The function L is bounded below and differentiable. Its derivative is given by*

$$\frac{dL}{dt} = -\left\| \frac{d\mathbf{h}(t)}{dt} \right\|_H^2$$

and hence is continuous.

Proof. The boundedness of L follows from Proposition 3.1 in the mutual information case and from Theorem 4.18 in the local cross-covariance case. In order to prove differentiability we consider

$$\frac{L(t+\varepsilon) - L(t)}{\varepsilon} = \frac{\mathcal{I}(\mathbf{h}(t+\varepsilon)) - \mathcal{I}(\mathbf{h}(t))}{\varepsilon}. \tag{2.5}$$

We then use the first order Taylor expansion with integral remainder of the C^1 function $\mathbf{h}$,

$$\mathbf{h}(t+\varepsilon) = \mathbf{h}(t) + \varepsilon \int_0^1 \frac{d\mathbf{h}}{dt}(t + \zeta\varepsilon) d\zeta, \tag{2.6}$$

and replace $\mathbf{h}(t+\varepsilon)$ by the right-hand side of the previous equation on the right-hand side of (2.5). We denote by $\mathbf{k}(t,\varepsilon)$ the integral on the right-hand side of (2.6) and obtain

$$\frac{L(t+\varepsilon)-L(t)}{\varepsilon} = \frac{\mathcal{I}(\mathbf{h}(t)+\varepsilon\mathbf{k}(t,\varepsilon))-\mathcal{I}(\mathbf{h}(t))}{\varepsilon}. \tag{2.7}$$

In the proof of Proposition 2.4 we have shown the continuity of $d\mathbf{h}/dt$ on $]0,+\infty[\times\overline{\Omega}$; hence on $[t,t+\varepsilon]\times\overline{\Omega}$, $t>0$. This shows that $\mathbf{k}(t,\varepsilon)\in\mathbf{C}(\overline{\Omega})$, $t>0$. In fact, (2.5), Theorem 1.2, and Proposition 2.4 show that $\mathbf{k}(t,\varepsilon)\in\mathbf{C}^2(\Omega)\cap\mathcal{D}(A)$.

We would now like to take the limit of both sides when $\varepsilon\to 0$. Because of the similarity of the right-hand side of (2.7) with (1.1), we define

$$\tilde{\delta}_{\mathbf{k}}\mathcal{I}(\mathbf{h}(t)) = \lim_{\varepsilon\to 0}\frac{\mathcal{I}(\mathbf{h}(t)+\varepsilon\mathbf{k}(t,\varepsilon))-\mathcal{I}(\mathbf{h}(t))}{\varepsilon}. \tag{2.8}$$

The difference is that the function $\mathbf{k}$ here also depends upon ε, unlike in (1.1). We prove that this limit is well defined and equal to $\delta_{\mathbf{k}(t,0)}\mathcal{I}(\mathbf{h}(t))$.

First we show that $\lim_{\varepsilon\to 0}\mathbf{k}(t,\varepsilon)=\mathbf{k}(t,0)$ almost everywhere in Ω. Indeed,

$$\begin{aligned}\|\mathbf{k}(t,\varepsilon)-\mathbf{k}(t,0)\|_H &\le \int_0^1 \left\|\frac{d\mathbf{h}}{dt}(t+\zeta\varepsilon)-\frac{d\mathbf{h}}{dt}(t)\right\|_H d\zeta\\ &\le k_\alpha\int_0^1 \left\|\frac{d\mathbf{h}}{dt}(t+\zeta\varepsilon)-\frac{d\mathbf{h}}{dt}(t)\right\|_{H_\alpha} d\zeta\end{aligned}$$

for some α, $0<\alpha\le 1$ (Theorem 1.2); k_α is defined in the proof of the same theorem. Because of the same theorem, the function $t\to d\mathbf{h}/dt$ from $]0,+\infty[$ into H_α is Hölder continuous, say with exponent $\gamma>0$. This proves that

$$\int_0^1 \left\|\frac{d\mathbf{h}}{dt}(t+\zeta\varepsilon)-\frac{d\mathbf{h}}{dt}(t)\right\|_{H_\alpha} d\zeta \le C\varepsilon^\gamma,$$

where C is independent of ε and the convergence in H follows. Since $H=\mathbf{L}^2(\Omega)$ and $\mathbf{k}(t,\varepsilon)$ is continuous in $\overline{\Omega}$, the L^2 convergence implies the convergence almost everywhere.

The proof that $\tilde{\delta}_{\mathbf{k}}\mathcal{I}(\mathbf{h}(t))=\delta_{\mathbf{k}(t,0)}\mathcal{I}(\mathbf{h}(t))$ follows from this result, the computations done in sections 3.1.2 and 3.2, the fact that $\mathbf{k}(t,\varepsilon)$ converges almost everywhere toward $\mathbf{k}(t,0)$, and the fact that each coordinate of $\mathbf{k}(t,\varepsilon)$ is bounded and hence integrable. The last two points guarantee that such integrals as $\int_\Omega \mathbf{k}(t,\varepsilon)(x)\cdot\nabla I_2(x+\mathbf{h}(t,x))\,dx$ converge toward $\int_\Omega \mathbf{k}(t,0)(x)\cdot\nabla I_2(x+\mathbf{h}(t,x))\,dx$ by applying the dominated convergence theorem.

The boundedness of $\mathbf{k}(t,\varepsilon)$ follows from its continuity on the compact set $\overline{\Omega}$.

The continuity of dL/dt follows from the continuity of $d\mathbf{h}/dt$ (Theorem 1.2) and the continuity of the norm in H. □

We have therefore proved that our criterion $\mathcal{I}$ decreases along the "trajectory" $\mathbf{h}(t)$, solution of the initial-value problem (1.3). In order to prove that the solution asymptotically satisfies the Euler–Lagrange equations, we prove the following claim.

PROPOSITION 2.6. *If $\|d\mathbf{h}(t)/dt\|_H$ is bounded on $]0,+\infty[$, the limit when $t\to+\infty$ of the derivative dL/dt of the function $L(t)$ defined by (2.4) is equal to 0.*

Proof. We assume the converse and prove a contradiction. We assume that dL/dt does not go to zero when t goes to infinity. Therefore there exists $\varepsilon>0$ such that for

all $T > 0$ there exists $t > T$ such that $dL(t)/dt < -\varepsilon$. We can therefore construct an infinite, strictly increasing, sequence $\{t_n\}$, $n \geq 0$, $t_n > 0$, such that $dL(t_n)/dt < -\varepsilon$. Let us assume that there exists $\eta(t_n) > 0$ such that $dL(t_n + \eta(t_n))/dt = -\varepsilon/2$ and $dL(t)/dt < -\varepsilon/2$ for all $t_n \leq t < t_n + \eta(t_n)$. If there is no such t_n, we are done; otherwise we choose $t_{n+1} > t_n + \eta(t_n)$. We prove that $\eta(t_n)$ is bounded below. Indeed we write

$$\begin{aligned}\varepsilon/2 &\leq \left|\frac{dL(t_n+\eta(t_n))}{dt} - \frac{dL(t_n)}{dt}\right| = \left|\left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n))\right\|_H^2 - \left\|\frac{d\mathbf{h}}{dt}(t_n)\right\|_H^2\right| \\ &= \left(\left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n))\right\|_H + \left\|\frac{d\mathbf{h}}{dt}(t_n)\right\|_H\right)\left|\left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n))\right\|_H - \left\|\frac{d\mathbf{h}}{dt}(t_n)\right\|_H\right|.\end{aligned}$$

Let A be an upper bound on $\|d\mathbf{h}(t)/dt\|_H$; then the rightmost term in the above equation is less than or equal to

$$2A\left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n)) - \frac{d\mathbf{h}}{dt}(t_n))\right\|_H.$$

According to Theorem 1.2,

$$\left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n)) - \frac{d\mathbf{h}}{dt}(t_n))\right\|_H \leq k_\alpha \left\|\frac{d\mathbf{h}}{dt}(t_n+\eta(t_n)) - \frac{d\mathbf{h}}{dt}(t_n))\right\|_{H_\alpha} \leq k_\alpha(\eta(t_n))^\gamma,$$

and therefore

$$\eta(t_n) \geq \left(\frac{\varepsilon}{4Ak_\alpha}\right)^{1/\gamma}.$$

Consider now the sequence of intervals $[t_n, t_n + \eta(t_n)]$. On each such interval we have $dL/dt \leq -\varepsilon/2$, and therefore

$$L(t_n+\eta(t_n)) \leq L(t_n) - \eta(t_n)\frac{\varepsilon}{2} \leq L(t_n) - \frac{\varepsilon}{2}\left(\frac{\varepsilon}{4Ak_\alpha}\right)^{1/\gamma}.$$

This contradicts the fact that $L(t)$ is bounded below; hence we have

$$\lim_{t\to+\infty}\frac{dL}{dt} = 0. \qquad \square$$

This result shows that, asymptotically, $dL/dt = 0$, therefore $d\mathbf{h}(t)/dt = 0$, and hence the solution of the initial-value problem (1.2) satisfies the Euler–Lagrange equations associated with the energy functional $\mathcal{I}$.

3. Statistical similarity measures and their Euler–Lagrange equations. Our approach to matching multimodal images relies on regarding the intensity values of two different modalities as samples of two random processes. Within this probabilistic framework, the link between the two modalities is characterized by their joint probability density function (pdf). In this section, we compute the variational gradient of two statistical dissimilarity functionals. Among many possible criteria, the cross-covariance and the mutual information provide us with a convenient trade-off between robustness and generality. To be able to evaluate these criteria for a given field $\mathbf{h}$, we consider a nonparametric Parzen estimator [42] for the joint pdf as described

below. This estimator can be either *global*, assuming that the unknown relationship between the intensity values does not vary spatially, or *local*. We give only one example of each case because they are the ones we found to work best in our applications. However, the method and the proofs are quite generic. More examples can be found in [25]. We denote by X the random variable associated with the intensity values of I_1 and by $Y_{\mathbf{h}}$ that associated with the values of $I_2(\mathbf{Id}+\mathbf{h})$. For conciseness, we will use the notation $\mathbf{i}=(i_1,i_2)$ and $\mathbf{I_h}(\mathbf{x})=(I_1(\mathbf{x}),I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})))$.

3.1. Global mutual information. Our estimator is based on a one-dimensional (1D) normalized Gaussian kernel of variance β,

$$g_\beta(i)=\frac{1}{\sqrt{2\pi\beta}}\exp\left(\frac{-i^2}{2\beta}\right),$$

from which we construct $G_\beta(\mathbf{i})=g_\beta(i_1)\,g_\beta(i_2)$:

$$P(\mathbf{i},\mathbf{h})=\frac{1}{|\Omega|}\int_\Omega G_\beta(\mathbf{I_h}(\mathbf{x})-\mathbf{i})\,d\mathbf{x}.$$

Note that for each pair of intensities $\mathbf{i}\in\mathbb{R}^2$ the value of the estimated joint pdf is a nonlinear functional of $\mathbf{h}$. Also note that it is strictly positive. Its first variation is obtained by applying (1.1):

$$\frac{P(\mathbf{i},\mathbf{h}+\varepsilon\mathbf{k})-P(\mathbf{i},\mathbf{h})}{\varepsilon}$$
$$=\frac{1}{\varepsilon|\Omega|}\int_\Omega g_\beta(I_1(\mathbf{x})-i_1)\left(g_\beta(I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})+\varepsilon\mathbf{k}(\mathbf{x}))-i_2)-g_\beta(I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))-i_2)\right)d\mathbf{x}.$$

We use the first order Taylor expansion with integral remainder of the C^1 function g_β for the second factor within the integral:

$$\frac{P(\mathbf{i},\mathbf{h}+\varepsilon\mathbf{k})-P(\mathbf{i},\mathbf{h})}{\varepsilon}$$
$$=\frac{1}{|\Omega|}\int_\Omega\left[g_\beta(I_1(\mathbf{x})-i_1)\frac{I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})+\varepsilon\mathbf{k}(\mathbf{x}))-I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))}{\varepsilon}\right.$$
$$\left.\times\int_0^1 g'_\beta(I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))-i_2+\zeta(I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})+\varepsilon\mathbf{k}(\mathbf{x}))-I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))))\,d\zeta\right]d\mathbf{x}.$$

Taking the limit when $\varepsilon\to 0$, we obtain

$$\delta_{\mathbf{k}}P(\mathbf{i},\mathbf{h})=\frac{1}{|\Omega|}\int_\Omega \partial_2\,G_\beta(\mathbf{I_h}(\mathbf{x})-\mathbf{i})\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))\cdot\mathbf{k}(\mathbf{x})\,d\mathbf{x}, \tag{3.1}$$

where ∂_2 indicates the first order partial derivative with respect to the second variable.

Using this estimate, we first consider the maximization of mutual information, a concept which is borrowed from information theory. Given two random variables X and Y, their mutual information is defined as

$$\mathbf{MI}(X,Y)=\mathcal{H}(X)+\mathcal{H}(Y)-\mathcal{H}(X,Y),$$

where $\mathcal{H}$ stands for the differential entropy. The mutual information is positive and symmetric and measures how the intensity distributions of two images fail to be

independent. It can be defined in terms of the joint pdf P and its marginals $p(i_1) = \int_{\mathbb{R}} P(\mathbf{i},\mathbf{h})\, di_2$ and $p(i_2,\mathbf{h}) = \int_{\mathbb{R}} P(\mathbf{i},\mathbf{h})\, di_1$. These last two functions are also strictly positive. The following short notation will be useful:

$$E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) = -\log \frac{P(\mathbf{i},\mathbf{h})}{p(i_1)\, p(i_2,\mathbf{h})}. \tag{3.2}$$

The dissimilarity functional based on mutual information is then defined as the expected value of the function E^{MI}:

$$\mathcal{J}_{\mathrm{MI}}(\mathbf{h}) = -\mathbf{MI}(X, Y_{\mathbf{h}}) = \int_{\mathbb{R}^2} P(\mathbf{i},\mathbf{h})\, E^{\mathrm{MI}}(\mathbf{i},\mathbf{h})\, d\mathbf{i}.$$

3.1.1. Continuity of $\mathcal{J}_{\mathbf{MI}}(\mathbf{h})$. Recall that the existence of minimizers for $\mathcal{I}(\mathbf{h})$ was discussed by assuming the continuity and boundedness of $\mathcal{J}(\mathbf{h})$.

PROPOSITION 3.1. *Let $\mathbf{h}_n, n = 1,\dots,\infty$, be a sequence of functions of H such that $\mathbf{h}_n \to \mathbf{h}$ almost everywhere in Ω. Then $\mathcal{J}_{\mathrm{MI}}(\mathbf{h}_n) \to \mathcal{J}_{\mathrm{MI}}(\mathbf{h})$. Moreover, $|\mathcal{J}_{\mathrm{MI}}(\mathbf{h})|$ is bounded.*

Proof. Because I_2 and g_β are continuous, $G_\beta(\mathbf{I}_{\mathbf{h}_n}(\mathbf{x}) - \mathbf{i}) \to G_\beta(\mathbf{I}_{\mathbf{h}}(\mathbf{x}) - \mathbf{i})$ almost everyone in Ω for all $\mathbf{i}$. Since $G_\beta(\mathbf{I}_{\mathbf{h}_n}(\mathbf{x}) - \mathbf{i}) \le g_\beta(0)^2$, the dominated convergence theorem implies that $P(\mathbf{i},\mathbf{h}_n) \to P(\mathbf{i},\mathbf{h})$ for all $\mathbf{i} \in \mathbb{R}^2$. A similar reasoning shows that $p(i_2,\mathbf{h}_n) \to p(i_2,\mathbf{h})$ for all $i_2 \in \mathbb{R}$. Hence, the logarithm being continuous, and $p(i_1)$, $P(\mathbf{i},\mathbf{h}_n)$, $P(\mathbf{i},\mathbf{h})$, $p(i_2,\mathbf{h}_n)$, and $p(i_2,\mathbf{h})$ being > 0,

$$P(\mathbf{i},\mathbf{h}_n) \log \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)} \to P(\mathbf{i},\mathbf{h}) \log \frac{P(\mathbf{i},\mathbf{h})}{p(i_1)p(i_2,\mathbf{h})} \quad \forall \mathbf{i} \in \mathbb{R}^2.$$

We next consider three cases to find an upper bound for $P(\mathbf{i},\mathbf{h}_n)\big|\log \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)}\big|$.

We detail only the first one: $i_2 \le 0$ This is the case where

$$0 \le |i_2| \le |i_2 - I_2(\mathbf{x} + \mathbf{h}_n(\mathbf{x}))| \ \le |i_2 - \mathcal{A}| \ \ n \ge 1.$$

Hence

$$g_\beta(i_2 - \mathcal{A}) \le g_\beta(i_2 - I_2(\mathbf{x} + \mathbf{h}_n(\mathbf{x}))) \ \le g_\beta(i_2) \ \ n \ge 1.$$

This yields

$$\frac{g_\beta(i_2 - \mathcal{A})}{g_\beta(i_2)} \le \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)} \le \frac{g_\beta(i_2)}{g_\beta(i_2 - \mathcal{A})}$$

and

$$\left|\log \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)}\right| \le \log \frac{g_\beta(i_2)}{g_\beta(i_2 - \mathcal{A})},$$

and therefore

$$P(\mathbf{i},\mathbf{h}_n)\left|\log \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)}\right| \le g_\beta(i_2)p(i_1) \log \frac{g_\beta(i_2)}{g_\beta(i_2 - \mathcal{A})}.$$

The function on the right-hand side is continuous and integrable in $\mathbb{R}\times]-\infty,\mathcal{A}]$.

The next two cases, $0 \le i_2 \le \mathcal{A}$ and $i_2 \ge \mathcal{A}$, are left to the reader. Combining the three cases, the dominated convergence theorem implies that

$$\mathcal{J}_{\mathrm{MI}}(\mathbf{h}_n) = -\int_{\mathbb{R}^2} P(\mathbf{i},\mathbf{h}_n) \log \frac{P(\mathbf{i},\mathbf{h}_n)}{p(i_1)p(i_2,\mathbf{h}_n)}\, d\mathbf{i} \to \mathcal{J}_{\mathrm{MI}}(\mathbf{h}) = -\int_{\mathbb{R}^2} P_{\mathbf{h}}(\mathbf{i}) \log \frac{P_{\mathbf{h}}(\mathbf{i})}{p(i_1)p_{\mathbf{h}}(i_2)}\, d\mathbf{i}.$$

The proof also shows that $|\mathcal{J}_{\mathrm{MI}}(\mathbf{h})|$ is bounded. ∎

3.1.2. Euler–Lagrange equation. We do an explicit computation of the first variation of $\mathcal{J}_{\mathrm{MI}}$ by applying (1.1). First we obtain

$$\delta_{\mathbf{k}} E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) = -\frac{\delta_{\mathbf{k}} P(\mathbf{i},\mathbf{h})}{P(\mathbf{i},\mathbf{h})} + \frac{\delta_{\mathbf{k}} p(i_2,\mathbf{h})}{p(i_2,\mathbf{h})}.$$

We then write

$$\begin{aligned}\delta_{\mathbf{k}} \mathcal{J}_{\mathrm{MI}}(\mathbf{h}) &= \int_{\mathbb{R}^2} \left[\delta_{\mathbf{k}} P(\mathbf{i},\mathbf{h})\ E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) + P(\mathbf{i},\mathbf{h})\ \delta_{\mathbf{k}}\ E^{\mathrm{MI}}(\mathbf{i},\mathbf{h})\right] d\mathbf{i} \\ &= \int_{\mathbb{R}^2} \left[(E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) - 1)\,\delta_{\mathbf{k}} P(\mathbf{i},\mathbf{h})\ + \frac{P(\mathbf{i},\mathbf{h})}{p(i_2,\mathbf{h})}\delta_{\mathbf{k}} p(i_2,\mathbf{h})\right] d\mathbf{i}.\end{aligned}$$

Using the fact that

$$\int_{\mathbb{R}^2} \frac{P(\mathbf{i},\mathbf{h})}{p(i_2,\mathbf{h})}\delta_{\mathbf{k}} p(i_2,\mathbf{h})\, d\mathbf{i} = \int_{\mathbb{R}} \delta_{\mathbf{k}} p(i_2,\mathbf{h})\, di_2 = 0,$$

this yields

$$\delta_{\mathbf{k}} \mathcal{J}_{\mathrm{MI}}(\mathbf{h}) = \int_{\mathbb{R}^2} (E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) - 1)\,\delta_{\mathbf{k}} P(\mathbf{i},\mathbf{h})\, d\mathbf{i}.$$

We then apply (3.1) to obtain

$$\delta_{\mathbf{k}} \mathcal{J}_{\mathrm{MI}}(\mathbf{h}) = \frac{1}{|\Omega|}\int_{\mathbb{R}^2}\int_{\Omega} (E^{\mathrm{MI}}(\mathbf{i},\mathbf{h}) - 1)\,\partial_2 G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))\cdot\mathbf{k}(\mathbf{x})\ d\mathbf{x}\, d\mathbf{i}.$$

A convolution with respect to the intensity variable $\mathbf{i}$ appears in this expression. It commutes with the derivative ∂_2 with respect to the second intensity variable i_2, and therefore

$$\delta_{\mathbf{k}} \mathcal{J}_{\mathrm{MI}}(\mathbf{h}) = \frac{1}{|\Omega|}\int_{\Omega} (G_\beta \star \partial_2\, E^{\mathrm{MI}})\big(\mathbf{I_h}(\mathbf{x}),\mathbf{h}\big)\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))\cdot\mathbf{k}(\mathbf{x})\ d\mathbf{x}.$$

To simplify notation, we denote by L_{MI} the function $\frac{1}{|\Omega|}\partial_2\, E^{\mathrm{MI}}$. We then define the function $f_{\mathrm{MI}} : \mathbb{R}^2 \times H \to \mathbb{R}$:

$$f_{\mathrm{MI}}(\mathbf{i},\mathbf{h}) = G_\beta \star L_{\mathrm{MI}}(\mathbf{i},\mathbf{h}). \tag{3.3}$$

It is easily verified that

$$L_{\mathrm{MI}}(\mathbf{i},\mathbf{h}) = -\frac{1}{|\Omega|}\ \left(\frac{\partial_2 P}{P}(\mathbf{i},\mathbf{h}) - \frac{p'}{p}(i_2,\mathbf{h})\right) = \frac{1}{\beta}\ (r(i_2,\mathbf{h}) - R(\mathbf{i},\mathbf{h})), \tag{3.4}$$

where

$$r(i_2,\mathbf{h}) = \frac{1}{p(i_2,\mathbf{h})}\frac{1}{\beta|\Omega|}\int_{\Omega} I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))\ g_\beta(I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})) - i_2)\ d\mathbf{x}, \tag{3.5}$$

$$R(\mathbf{i},\mathbf{h}) = \frac{1}{P(\mathbf{i},\mathbf{h})}\frac{1}{\beta|\Omega|}\int_{\Omega} I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))\ G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\ d\mathbf{x}. \tag{3.6}$$

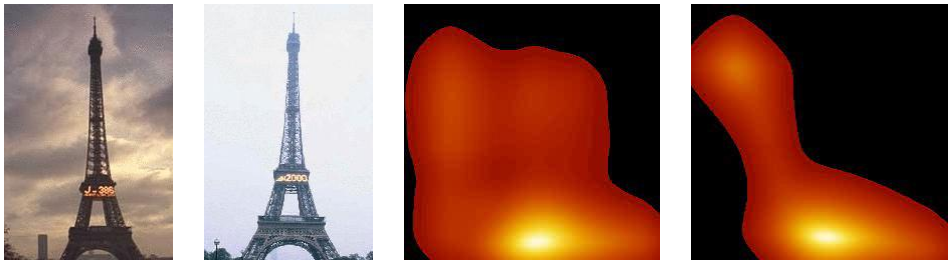

FIG. 1. *Effect on $P(\mathbf{i},\mathbf{h})$ of minimizing $\mathcal{J}_{MI}(\mathbf{h})$ with respect to $\mathbf{h}$: the two images on the right show the estimated joint pdf between the two images on the left before and after optimization. Notice that the joint pdf has been clustered, but the final shape of its support remains nonfunctional.*

Since $I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})) \in [0,\, \mathcal{A}]$ for all $\mathbf{h} \in H$ and for all $\mathbf{x} \in \Omega$, we have

$$0 \leq r(i_2,\mathbf{h}),\ R(\mathbf{i},\mathbf{h}) \leq \frac{\mathcal{A}}{\beta} \quad \forall \mathbf{h} \in H. \tag{3.7}$$

For each $\mathbf{h} \in H$, the mapping $\mathbf{k} \to \delta_{\mathbf{k}}\mathcal{J}_{\mathrm{MI}}(\mathbf{h})$ is clearly linear. To show that it is continuous it is sufficient, according to Schwarz inequality, to show that the function $x \to f_{\mathrm{MI}}(\mathbf{I_h}(\mathbf{x}),\mathbf{h})\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))$ is bounded, and this is a consequence of Theorem 4.11. The variational gradient $\nabla_H \mathcal{J}_{\mathrm{MI}}(\mathbf{h})$ of $\mathcal{J}_{\mathrm{MI}}$ can therefore be defined, and its expression is given by

$$\nabla_H \mathcal{J}_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) = f_{\mathrm{MI}}\big(\mathbf{I_h}(\mathbf{x}),\mathbf{h}\big)\ \nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})).$$

The function L_{MI} plays the role of an intensity comparison function. Its first term $\partial_2 P(\mathbf{i},\mathbf{h})/P(\mathbf{i},\mathbf{h})$ tends to cluster the joint pdf, while the term $-p'(i_2,\mathbf{h})/p(i_2,\mathbf{h})$ tries to prevent the marginal law $p(i_2,\mathbf{h})$ from becoming too clustered; i.e., it keeps the intensities of $I_2(\mathbf{Id}+\mathbf{h})$ as unpredictable as possible. For an example of the effect on $P(\mathbf{i},\mathbf{h})$ of minimizing $\mathcal{J}_{\mathrm{MI}}(\mathbf{h})$ with respect to $\mathbf{h}$, see Figure 1. The reader will notice that the resulting joint pdf is more localized than the original one but that the minimization has not imposed a strong functional relation of the type $i_1 = f(i_2)$, unlike the method described in the next section.

According to the notation introduced in section 1.2, we define $F_{\mathrm{MI}} : H \to H$ by

$$F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) = -f_{\mathrm{MI}}\big(\mathbf{I_h}(\mathbf{x}),\mathbf{h}\big)\ \nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})). \tag{3.8}$$

3.2. Local cross-covariance. An interesting generalization is to make the probability density estimator local, since it allows one to take into account nonstationarities in the relation between intensities. To do this, we build an estimate in the neighborhood of each point $\mathbf{x}_0$ in Ω. This is achieved by weighting our previous estimate with a normalized spatial Gaussian of variance γ:

$$G_\gamma(\mathbf{x}) = \frac{1}{2\pi\gamma} e^{-\frac{|\mathbf{x}|^2}{2\gamma}}.$$

This means that to each point $\mathbf{x}_0$ of Ω we associate a joint pdf defined by

$$P(\mathbf{i},\mathbf{h},\mathbf{x}_0) = \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i}) G_\gamma(\mathbf{x}-\mathbf{x}_0)\, d\mathbf{x},$$

where $\mathcal{G}_\gamma(\mathbf{x}_0) = \int_\Omega G_\gamma(\mathbf{x}-\mathbf{x}_0)\ d\mathbf{x}$. This new pdf is along the line of the ideas discussed in [30], except that we consider a bidimensional local histogram at each

TABLE 3.1

Definitions of the local mean μ_1 and variance v_1 of X, the local mean μ_2 and variance v_2 of $Y_{\mathbf{h}}$, and the local correlation $v_{1,2}$ of X and $Y_{\mathbf{h}}$.

$\mu_1(\mathbf{x}) = \int_{\mathbb{R}} i_1\, p(i_1, \mathbf{x})\, di_1$	$v_1(\mathbf{x}) = \int_{\mathbb{R}} i_1^2\, p(i_1, \mathbf{x})\, di_1 - \mu_1^2(\mathbf{x})$
$\mu_2(\mathbf{h}, \mathbf{x}) = \int_{\mathbb{R}} i_2\, p(i_2, \mathbf{h}, \mathbf{x})\, di_2$	$v_2(\mathbf{h}, \mathbf{x}) = \int_{\mathbb{R}} i_2^2\, p(i_2, \mathbf{h}, \mathbf{x})\, di_2 - \mu_2(\mathbf{h}, \mathbf{x})^2$
$v_{1,2}(\mathbf{h}, \mathbf{x}) = \int_{\mathbb{R}^2} i_1\, i_2\, P(\mathbf{i}, \mathbf{h}, \mathbf{x})\, d\mathbf{i} - \mu_1(\mathbf{x})\, \mu_2(\mathbf{h}, \mathbf{x})$	

point. Its marginals are now given by $p(i_1, \mathbf{x}) = \int_{\mathbb{R}} P(\mathbf{i}, \mathbf{h}, \mathbf{x})\ di_2$ and $p(i_2, \mathbf{h}, \mathbf{x}) = \int_{\mathbb{R}} P(\mathbf{i}, \mathbf{h}, \mathbf{x})\ di_1$. Using these local estimates, we consider the case of the cross-covariance, which has been widely used as a robust comparison function for image matching. Within recent energy-minimization approaches relying on the computation of its gradient, we can mention, for instance, the works of Faugeras and Keriven [21], Cachier and Pennec [11], and Netsch et al. [39]. The cross-covariance, being a measure of the *affine* dependency between the intensities, is more constraining than the mutual information. A dissimilarity functional is obtained as a function of the quantities defined in Table 3.1 by averaging the local cross-covariance

$$\mathcal{J}_{\mathrm{CC}}(\mathbf{h}) = \int_\Omega \mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x})\ d\mathbf{x} = -\int_\Omega \frac{v_{1,2}(\mathbf{h}, \mathbf{x})^2}{v_1(\mathbf{x})\, v_2(\mathbf{h}, \mathbf{x})}\ d\mathbf{x}.$$

The minus sign simply reflects the fact that we want to minimize the dissimilarity. The continuity and boundedness of this criterion (needed for proving the existence of a minimizer) are a consequence of Theorem 4.18. In a way similar to the case of the mutual information, its first order variation is well defined and defines a gradient given by

$$\nabla_{\!H} \mathcal{J}_{\mathbf{CC}}(\mathbf{h})(\mathbf{x}) = f_{\mathrm{CC}}\big(\mathbf{I}_{\mathbf{h}}(\mathbf{x}), \mathbf{h}, \mathbf{x}\big)\ \nabla I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})),$$

where

$$f_{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}) = G_\gamma \star G_\beta \star L_{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}),$$

$$L_{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}) = \frac{1}{\mathcal{G}_\gamma(\mathbf{x})} \partial_2\, E^{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}),$$

and

$$E^{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}) = -\frac{1}{v_1(\mathbf{x})\ v_2(\mathbf{h}, \mathbf{x})} \Big(2\ v_{\ 1,2}(\mathbf{h}, \mathbf{x})\, i_2\, (i_1 - \mu_1(\mathbf{x})) + \ \mathcal{J}_{\mathbf{CC}}(\mathbf{h}, \mathbf{x})\, v_1(\mathbf{x})\, i_2\, (i_2 - 2\, \mu_2(\mathbf{h}, \mathbf{x})) \Big).$$

Hence

(3.9)

$$L_{\mathrm{CC}}(\mathbf{i}, \mathbf{h}, \mathbf{x}) = -\frac{2}{\mathcal{G}_\gamma(\mathbf{x})} \left(\frac{v_{1,2}(\mathbf{h}, \mathbf{x})}{v_2(\mathbf{h}, \mathbf{x})} \left(\frac{i_1 - \mu_1(\mathbf{x})}{v_1(\mathbf{x})} \right) + \mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x}) \left(\frac{i_2 - \mu_2(\mathbf{h}, \mathbf{x})}{v_2(\mathbf{h}, \mathbf{x})} \right) \right).$$

Notice that L_{CC} is an affine function of $\mathbf{i}$, and therefore

$$G_\beta \star L_{\mathrm{CC}}(\mathbf{i},\mathbf{h},\mathbf{x}) = L_{\mathrm{CC}}(\mathbf{i},\mathbf{h},\mathbf{x}).$$

Thus

$$\begin{aligned} f_{\mathrm{CC}}(\mathbf{i},\mathbf{h},\mathbf{x}) &= G_\gamma \star L_{\mathrm{CC}}(\mathbf{i},\mathbf{h},\mathbf{x}) \\ &= -G_\gamma \star \frac{2}{\mathcal{G}_\gamma(\mathbf{x})} \left(\frac{v_{1,2}(\mathbf{h},\mathbf{x})}{v_2(\mathbf{h},\mathbf{x})} \left(\frac{i_1 - \mu_1(\mathbf{x})}{v_1(\mathbf{x})} \right) + \mathcal{J}_{\mathrm{CC}}(\mathbf{h},\mathbf{x}) \left(\frac{i_2 - \mu_2(\mathbf{h},\mathbf{x})}{v_2(\mathbf{h},\mathbf{x})} \right) \right). \end{aligned}$$

As in the mutual information case, the function L_{CC} compares intensities in the two images. It shows that minimizing $\mathcal{J}_{\mathbf{CC}}$ with respect to the field $\mathbf{h}$ amounts to attempting to make the pair of intensities at corresponding pixels lie on a straight line in $\mathbb{R}^2$.

According to the notation introduced in section 1.1, we define $F_{\mathrm{CC}} : H \to H$ by

$$F_{\mathrm{CC}}(\mathbf{h})(\mathbf{x}) = -f_{\mathrm{CC}}(\mathbf{I}_{\mathbf{h}}(\mathbf{x}),\mathbf{h},\mathbf{x}) \nabla I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})). \tag{3.10}$$

For an example of the effect of minimizing $\mathcal{J}_{\mathrm{CC}}(\mathbf{h})$ with respect to $\mathbf{h}$ on $P(\mathbf{i},\mathbf{h})$, see Figure 2. The reader will notice that the resulting joint pdf is more localized than the original one and that the minimization has imposed an affine relation between the intensities i_1 and i_2, unlike the method described in the previous section.

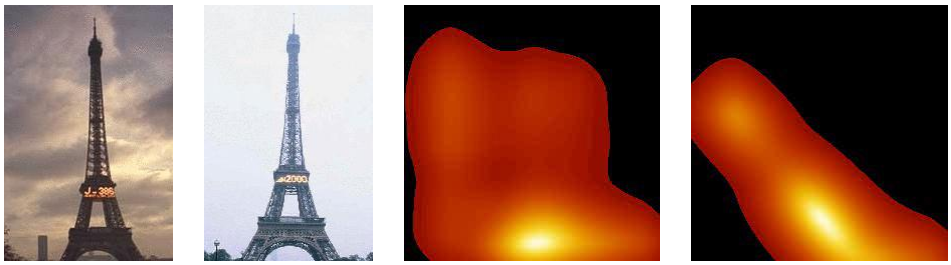

FIG. 2. *Effect on $P(\mathbf{i},\mathbf{h})$ of minimizing $\mathcal{J}_{\mathrm{CC}}(\mathbf{h})$ with respect to $\mathbf{h}$: the two images on the right show the estimated joint pdf between the two images on the left before and after optimization. Notice that the joint pdf has been clustered, and the final shape of its support approaches an affine function. The global estimation of the cross-covariance has been used to illustrate this effect. In the local case, each locally estimated pdf would undergo this effect.*

4. Lipschitz continuity of the matching functions. This section is devoted to proving that the functions F_{MI} and F_{CC} are Lipschitz continuous. We begin with some elementary results on Lipschitz continuous functions that will be used very often in what follows. We state them here without proof.

PROPOSITION 4.1. *Let $\mathcal{H}$ be a Banach space, and let us denote its norm by $\|.\|_{\mathcal{H}}$. Let f_i, $i = 1,2 : \mathcal{H} \to \mathbb{R}$, be two Lipschitz continuous functions. We have the following:*

1. *$f_1 + f_2$ is Lipschitz continuous.*
2. *If f_1 and f_2 are bounded, then the product $f_1 f_2$ is Lipschitz continuous.*
3. *If $f_2 > 0$ and if f_1 and f_2 are bounded, then the ratio $\frac{f_1}{f_2}$ is Lipschitz continuous.*

In what follows, we will need the following definitions and notations.

DEFINITION 4.2. *We denote by* $\mathcal{H}_1 = [0, \mathcal{A}] \times H$ *and* $\mathcal{H}_2 = [0, \mathcal{A}]^2 \times H$ *the Banach spaces equipped with the norms* $\|(z, \mathbf{h})\|_{\mathcal{H}_1} = z + \|\mathbf{h}\|_H$ *and* $\|(z_1, z_2, \mathbf{h})\|_{\mathcal{H}_2} = z_1 + z_2 + \|\mathbf{h}\|_H$*, respectively.*

We will use several times the following (obvious) result.

LEMMA 4.3. *Let* $f : \mathcal{H}_2 \to \mathbb{R}$ *be such that* $(z_1, z_2) \to f(z_1, z_2, \mathbf{h})$ *is Lipschitz continuous for all* $\mathbf{h}$ *with a Lipschitz constant* l_f *independent of* $\mathbf{h}$ *and such that* $\mathbf{h} \to f(z_1, z_2, \mathbf{h})$ *is Lipschitz continuous for all* (z_1, z_2) *with a Lipschitz constant* L_f *independent of* (z_1, z_2)*. Then* f *is Lipschitz continuous.*

4.1. Global mutual information. In the following, we will use the function $L_{\mathrm{MI}} : [0, \mathcal{A}]^2 \times H \to \mathbb{R}$ defined in (3.4)–(3.6) We then consider the result f_{MI} of convolving L_{MI} with G_β, i.e., the two functions $s : \mathcal{H}_1 \to \mathbb{R}$, defined as

$$s(z_2, \mathbf{h}) = (g_\beta \star r)(z_2, \mathbf{h}) = \int_{\mathbb{R}} g_\beta(z_2 - i_2) r(i_2, \mathbf{h})\, di_2, \tag{4.1}$$

and $S : \mathcal{H}_2 \to \mathbb{R}$, defined as

$$S(z_1, z_2, \mathbf{h}) = (G_\beta \star R)(\mathbf{z}, \mathbf{h}) = \int_{\mathbb{R}^2} G_\beta(\mathbf{z} - \mathbf{i}) R(\mathbf{i}, \mathbf{h})\, d\mathbf{i}. \tag{4.2}$$

We prove a series of propositions.

PROPOSITION 4.4. *For each* $\mathbf{h} \in H$*, the function* $[0, \mathcal{A}] \to \mathbb{R}^+$ *defined by* $z_2 \to s(z_2, \mathbf{h})$ *is Lipschitz continuous with a Lipschitz constant* l_s*, which is independent of* $\mathbf{h}$*. Moreover, it is bounded by* $\frac{\mathcal{A}}{\beta}$*.*

Proof. The second part follows from (3.7). We then prove that the magnitude of the derivative of the function is bounded independently of $\mathbf{h}$. Indeed

$$\begin{aligned} |s'(z_2, \mathbf{h})| &= \frac{1}{\beta} \left| \int_{-\infty}^{+\infty} (z_2 - i_2) g_\beta(z_2 - i_2) r(i_2, \mathbf{h}) di_2 \right| \\ &\leq \frac{\mathcal{A}}{\beta} \int_{-\infty}^{+\infty} |z_2 - i_2| g_\beta(z_2 - i_2) di_2 = 2\frac{\mathcal{A}}{\beta^2}. \end{aligned}$$

∎

PROPOSITION 4.5. *For each* $z_2 \in [0, \mathcal{A}]$*, the function* $\mathbf{h} \to s(z_2, \mathbf{h}) : H \to \mathbb{R}$ *is Lipschitz continuous on* H *with Lipschitz constant* L_s*, which is independent of* $z_2 \in [0, \mathcal{A}]$*.*

Proof. We consider

$$s(z_2, \mathbf{h}_1) - s(z_2, \mathbf{h}_2) = \int_{\mathbb{R}} g_\beta(z_2 - i_2) \left(r(i_2, \mathbf{h}_1) - r(i_2, \mathbf{h}_2) \right) di_2. \tag{4.3}$$

According to (3.5), $r(i_2, \mathbf{h})$ is proportional to the ratio $N(i_2, \mathbf{h})/p(i_2, \mathbf{h})$ of the two functions

$$N(i_2, \mathbf{h}) = \int_\Omega I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) g_\beta(I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) - i_2)\, d\mathbf{x}$$

and

$$p(i_2, \mathbf{h}) = \int_\Omega g_\beta(I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) - i_2)\, d\mathbf{x}.$$

We write

$$|s(z_2,\mathbf{h}_1)-s(z_2,\mathbf{h}_2)| \le \int_{\mathbb{R}} g_\beta(z_2-i_2)\frac{N(i_2,\mathbf{h}_2)\,|p(i_2,\mathbf{h}_2)-p(i_2,\mathbf{h}_1)|}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\,di_2 + \int_{\mathbb{R}} g_\beta(z_2-i_2)\frac{p(i_2,\mathbf{h}_2)\,|N(i_2,\mathbf{h}_2)-N(i_2,\mathbf{h}_1)|}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\,di_2, \tag{4.4}$$

and consider the first term on the right-hand side:

$$p(i_2,\mathbf{h}_2)-p(i_2,\mathbf{h}_1)=\int_\Omega \left(g_\beta(i_2-\ I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\,)-g_\beta(i_2-\ I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\,)\right)\,d\mathbf{x}.$$

We use the first order Taylor expansion with integral remainder of the C^1 function g_β:

$$g_\beta(i+t)=g_\beta(i)+t\int_0^1 g'_\beta(i+t\alpha)\,d\alpha.$$

We can therefore write

$$\begin{aligned} &g_\beta(i_2-\ I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})))-g_\beta(i_2-\ I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x})))\\ &=(I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\ -\ I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})))\int_0^1 g'_\beta\Big(i_2-\big(\alpha\,I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\\ &\qquad\qquad +(1-\alpha)\,I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\big)\Big)\,d\alpha. \end{aligned}$$

We use the fact that I_2 is Lipschitz continuous and write

$$\begin{aligned} &|p(i_2,\mathbf{h}_2)-p(i_2,\mathbf{h}_1)|\\ &\le Lip(I_2)\int_\Omega\Bigg(|\mathbf{h}_1(\mathbf{x})-\mathbf{h}_2(\mathbf{x})|\\ &\qquad\qquad\times\left|\int_0^1 g'_\beta(i_2-(\alpha\,I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\ +(1-\alpha)\,I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\,)\,d\alpha\right|\Bigg)\,d\mathbf{x}. \end{aligned}$$

The Schwarz inequality implies

$$\begin{aligned} &|p(i_2,\mathbf{h}_2)-p(i_2,\mathbf{h}_1)|\\ &\le Lip(I_2)\|\mathbf{h}_1-\mathbf{h}_2\|_H\Bigg(\int_\Omega\Bigg(\int_0^1 g'_\beta(i_2-(\alpha\,I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\\ &\qquad\qquad+\ (1-\alpha)\,I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\,)\,d\alpha\Bigg)^2\,d\mathbf{x}\Bigg)^{\frac12}. \end{aligned}$$

We introduce the function

$$\begin{aligned} c(i_2,\mathbf{h}_1,\mathbf{h}_2)=\Bigg(\int_\Omega\Bigg(\int_0^1\Big|i_2-\Big(\alpha\,I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\ +(1-\alpha)\,I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\Big)\Big|\\ \cdot\ g_\beta\Big(i_2-\big(\alpha\,I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))\ +(1-\alpha)\,I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))\,\big)\Big)\,d\alpha\Bigg)^2\,d\mathbf{x}\Bigg)^{\frac12} \end{aligned}$$

and notice that

$$\left(\int_\Omega \left(\int_0^1 g'_\beta(i_2 - (\alpha\, I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})) + (1-\alpha)\, I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))))\, d\alpha\right)^2 d\mathbf{x}\right)^{\frac{1}{2}} \leq \frac{1}{\beta} c(i_2, \mathbf{h}_1, \mathbf{h}_2).$$

So far we have

$$\int_{\mathbb{R}} g_\beta(z_2 - i_2) \frac{N(i_2,\mathbf{h}_2)\,|p(i_2,\mathbf{h}_2) - p(i_2,\mathbf{h}_1)|}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\, di_2 \leq \frac{Lip(I_2)}{\beta}\|\mathbf{h}_1 - \mathbf{h}_2\|_H \left(\int_{\mathbb{R}} g_\beta(z_2 - i_2) \frac{N(i_2,\mathbf{h}_2)\; c(i_2,\mathbf{h}_1,\mathbf{h}_2)}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\, di_2\right). \tag{4.5}$$

We study the function of z_2 that is on the right-hand side of this inequality. First we note that the function is well defined since no problems occur when i_2 goes to infinity because "there are three Gaussians in the numerator and two in the denominator." We then show that this function is bounded independently of $\mathbf{h}_1$ and $\mathbf{h}_2$ for all $z_2 \in [0, \mathcal{A}]$.

As in the proof of Proposition 3.1, we consider three cases and detail only the first one: $i_2 \leq 0$. This is the case where

$$\begin{aligned} 0 \leq |i_2| &\leq |i_2 - I_2(\mathbf{x}+\mathbf{h}_j(\mathbf{x}))| \leq |i_2 - \mathcal{A}|, \quad j = 1,2, \\ 0 \leq |i_2| &\leq |i_2 - (\alpha I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})) + (1-\alpha) I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x})))| \leq |i_2 - \mathcal{A}|, \quad 0 \leq \alpha \leq 1. \end{aligned}$$

Hence

$$\begin{aligned} g_\beta(i_2 - \mathcal{A}) &\leq g_\beta(i_2 - I_2(\mathbf{x}+\mathbf{h}_j(\mathbf{x}))) \leq g_\beta(i_2), \quad j = 1,2, \\ g_\beta(i_2 - \mathcal{A}) &\leq g_\beta(i_2 - (\alpha I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})) + (1-\alpha) I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x})))) \leq g_\beta(i_2), \; 0 \leq \alpha \leq 1. \end{aligned}$$

This yields

$$\begin{aligned} &\int_{-\infty}^0 g_\beta(z_2 - i_2) \frac{N(i_2,\mathbf{h}_2)\; c(i_2,\mathbf{h}_1,\mathbf{h}_2)}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\, di_2 \\ &\leq |\Omega|^{1/2}\mathcal{A} \int_{-\infty}^0 g_\beta(z_2 - i_2)|i_2 - \mathcal{A}| \left(\frac{g_\beta(i_2)}{g_\beta(i_2 - \mathcal{A})}\right)^2 di_2. \end{aligned}$$

The integral on the right-hand side is well defined and defines a continuous function of z_2.

The remaining two cases, $0 \leq i_2 \leq \mathcal{A}$ and $i_2 \geq \mathcal{A}$, are left to the reader. In all three cases, the functions of z_2 appearing on the right-hand side are continuous, independent of $\mathbf{h}_1$ and $\mathbf{h}_2$, and therefore upperbounded on $[0, \mathcal{A}]$ by a constant independent of $\mathbf{h}_1$ and $\mathbf{h}_2$. Returning to inequality (4.5), we have proved that there existed a positive constant C independent of z_2 such that

$$\int_{\mathbb{R}} g_\beta(z_2 - i_2) \frac{N(i_2,\mathbf{h}_2)\,|p(i_2,\mathbf{h}_2) - p(i_2,\mathbf{h}_1)|}{p(i_2,\mathbf{h}_1)p(i_2,\mathbf{h}_2)}\, di_2 \leq C\|\mathbf{h}_1 - \mathbf{h}_2\|_H \quad \forall z_2 \in [0,\mathcal{A}], \quad \forall \mathbf{h}_1,\, \mathbf{h}_2 \in H.$$

A similar proof can be developed for the second term on the right-hand side of inequality (4.4). In conclusion, we have proved that there exists a constant L_s, independent of z_2, such that

$$|s(z_2,\mathbf{h}_1) - s(z_2,\mathbf{h}_2)| \leq L_s\|\mathbf{h}_1 - \mathbf{h}_2\|_H \quad \forall z_2 \in [0,\mathcal{A}], \quad \forall \mathbf{h}_1,\, \mathbf{h}_2 \in H. \qquad \square$$

Thus, we can state the following.

PROPOSITION 4.6. *The function $s : \mathcal{H}_1 \to \mathbb{R}$ is Lipschitz continuous.*

Proof. The proof follows from Propositions 4.4 and 4.5 and Lemma 4.3. ∎

We now proceed with showing the same kind of properties for the function S.

PROPOSITION 4.7. *For all $\mathbf{h} \in H$, the function $[0, \mathcal{A}]^2 \to \mathbb{R}^+$ defined by $(z_1, z_2) \to S(z_1, z_2, \mathbf{h})$ is Lipschitz continuous with a Lipschitz constant l_S, which is independent of $\mathbf{h}$. Moreover, it is bounded by $\frac{\mathcal{A}}{\beta}$.*

Proof. The proof follows the same pattern as the proof of Proposition 4.4. ∎

PROPOSITION 4.8. *For all $(z_1, z_2) \in [0, \mathcal{A}]^2$, the function $\mathbf{h} \to S(z_1, z_2, \mathbf{h})$, $H \to \mathbb{R}$ is Lipschitz continuous with a Lipschitz constant L_S, which is independent of $(z_1, z_2) \in [0, \mathcal{A}]^2$.*

Proof. The proof follows the same pattern as that of Proposition 4.5. ∎

Therefore we can state the following result.

PROPOSITION 4.9. *The function $S : \mathcal{H}_2 \to \mathbb{R}$ is Lipschitz continuous.*

Proof. The proof follows those of Propositions 4.7 and 4.8 and Lemma 4.3. ∎

From Propositions 4.6, 4.9, and 4.1 we obtain the following.

COROLLARY 4.10. *The function $f_{\mathrm{MI}} : \mathcal{H}_2 \to \mathbb{R}$ defined by $(z_1, z_2, \mathbf{h}) \to s(z_2, \mathbf{h}) - S(z_1, z_2, \mathbf{h})$ is Lipschitz continuous and bounded by $2\frac{\mathcal{A}}{\beta}$. We denote by $Lip(f_{\mathrm{MI}})$ the corresponding Lipschitz constant.*

We can now state the main result of this section, as follows.

THEOREM 4.11. *The function $F_{\mathrm{MI}} : H \to H$, defined by*

$$\begin{aligned} F_{\mathrm{MI}}(\mathbf{h}) &= -f_{\mathrm{MI}}(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}), \mathbf{h})\nabla I_2(\mathbf{Id}+\mathbf{h}) \\ &= (S(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}), \mathbf{h}) - s(I_2(\mathbf{Id}+\mathbf{h}), \mathbf{h}))\nabla I_2(\mathbf{Id}+\mathbf{h}), \end{aligned}$$

is Lipschitz continuous and bounded.

Proof. Boundedness comes from Corollary 4.10 and the fact that $|\nabla I_2|$ is bounded. This implies that $F_{\mathrm{MI}}(\mathbf{h}) \in H = \mathbf{L}^2(\Omega)$ for all $\mathbf{h} \in H$.

We consider the ith component F^i_{MI} of F_{MI}:

$$F^i_{\mathrm{MI}}(\mathbf{h}_1)(\mathbf{x}) - F^i_{\mathrm{MI}}(\mathbf{h}_2)(\mathbf{x}) = U_1 T^i_1 - U_2 T^i_2, \qquad i = 1, \ldots, n,$$

with

$$\begin{aligned} U_j &= S(I_1(\mathbf{x}), I_2(\mathbf{x}+\mathbf{h}_j(\mathbf{x})), \mathbf{h}_j) - s(I_2(\mathbf{x}+\mathbf{h}_j(\mathbf{x})), \mathbf{h}_j), \\ T^i_j &= \partial_i I_2(\mathbf{x}+\mathbf{h}_j(\mathbf{x})), \quad i = 1, \ldots, n, \end{aligned}$$

and $j = 1, 2$. We continue with

$$|F^i_{\mathrm{MI}}(\mathbf{h}_1)(\mathbf{x}) - F^i_{\mathrm{MI}}(\mathbf{h}_2)(\mathbf{x})| \le |U_1 - U_2||T_1| + |U_2||T_1 - T_2|.$$

Because $\partial_i I_2$ is bounded, $|T^i_j| \le \|\partial_i I_2\|_\infty$. Because of Corollary 4.10, $|U_2| \le 2\frac{\mathcal{A}}{\beta}$. Because $\partial_i I_2$ is Lipschitz continuous, $|T_1 - T_2| \le Lip(\partial_i I_2)|\mathbf{h}_1(\mathbf{x}) - \mathbf{h}_2(\mathbf{x})|$.

Finally, because of Corollary 4.10 and the fact that I_2 is Lipschitz continuous,

$$|U_1 - U_2| \le Lip(f_{\mathrm{MI}})\left(Lip(I_2)|\mathbf{h}_1(\mathbf{x}) - \mathbf{h}_2(\mathbf{x})| + \|\mathbf{h}_1 - \mathbf{h}_2\|_H\right).$$

Collecting all terms, we obtain

$$|F^i_{\mathrm{MI}}(\mathbf{h}_1)(\mathbf{x}) - F^i_{\mathrm{MI}}(\mathbf{h}_2)(\mathbf{x})| \le C^i(|\mathbf{h}_1(\mathbf{x}) - \mathbf{h}_2(\mathbf{x})| + \|\mathbf{h}_1 - \mathbf{h}_2\|_H)$$

for some positive constant C^i, $i = 1, \ldots, n$. The last inequality yields, through the application of the Cauchy–Schwarz method,

$$\|F_{\mathrm{MI}}(\mathbf{h}_1) - F_{\mathrm{MI}}(\mathbf{h}_2)\|_H \leq L_F \|\mathbf{h}_1 - \mathbf{h}_2\|_H$$

for some positive constant L_F, and this completes the proof. □

The following proposition is needed in the proof of Proposition 2.4.

PROPOSITION 4.12. *The function* $\Omega \to \mathbb{R}^n$ *such that* $\mathbf{x} \to F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x})$ *satisfies*

$$|F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) - F_{\mathrm{MI}}(\mathbf{h})(\mathbf{y})| \leq K(|\mathbf{x} - \mathbf{y}| + |\mathbf{h}(\mathbf{x}) - \mathbf{h}(\mathbf{y})|)$$

for some constant $K > 0$.

Proof. We write

$$\begin{aligned} F_{\mathrm{MI}}(\mathbf{h})(\mathbf{y}) - F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) = {} & f_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) \nabla I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) - f_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) \nabla I_2(\mathbf{y} + \mathbf{h}(\mathbf{y})) \\ & + f_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) \nabla I_2(\mathbf{y} + \mathbf{h}(\mathbf{y})) - f_{\mathrm{MI}}(\mathbf{h})(\mathbf{y}) \nabla I_2(\mathbf{y} + \mathbf{h}(\mathbf{y})). \end{aligned}$$

Hence

$$\begin{aligned} |F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) - F_{\mathrm{MI}}(\mathbf{h})(\mathbf{y})| \leq {} & + |f_{\mathrm{MI}}(\mathbf{h})(\mathbf{x})| \, |\nabla I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) - \nabla I_2(\mathbf{y} + \mathbf{h}(\mathbf{y}))| \\ & |\nabla I_2(\mathbf{y} + \mathbf{h}(\mathbf{y}))| \, |f_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) - f_{\mathrm{MI}}(\mathbf{h})(\mathbf{y})|. \end{aligned}$$

Corollary 4.10 and the fact that the functions I_1, I_2, and its first order derivative are Lipschitz continuous imply

$$\begin{aligned} & |F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) - F_{\mathrm{MI}}(\mathbf{h})(\mathbf{y})| \\ & \leq 2 \frac{\mathcal{A}}{\beta} Lip(\nabla I_2)(|\mathbf{x} - \mathbf{y}| + |\mathbf{h}(\mathbf{x}) - \mathbf{h}(\mathbf{y})|) + \| |\nabla I_2| \|_\infty Lip(f_{\mathrm{MI}}) |\mathbf{h}(\mathbf{x}) - \mathbf{h}(\mathbf{y})|, \end{aligned}$$

and hence the result. □

4.2. Local cross-covariance. In this section we prove the Lipschitz-continuity of the mapping $H \to H$ defined by $F_{\mathrm{CC}}(\mathbf{h})$ (see (3.10)). The reasoning is analogous to that for the global case. We start with some estimates of the bounds of the means and variances of the relevant random variables.

LEMMA 4.13. *Let* $\mathrm{diam}(\Omega)$ *be the diameter of the open bounded set* Ω*:*$\mathrm{diam}(\Omega) = \sup_{\mathbf{x},\mathbf{y} \in \Omega} \|\mathbf{x} - \mathbf{y}\|$. *We denote by* $G_\gamma(\mathrm{diam}(\Omega))$ *the value* $\inf_{\mathbf{x},\mathbf{y} \in \Omega} G_\gamma(\mathbf{x} - \mathbf{y})$ *and define*

$$K_\Omega = \frac{G_\gamma(\mathbf{0})}{G_\gamma(\mathrm{diam}(\Omega))}. \tag{4.6}$$

We have $\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \geq |\Omega| G_\gamma(\mathrm{diam}(\Omega)) > 0$ *and* $\int_\Omega G_\gamma(\mathbf{x} - \mathbf{x}_0) \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \, d\mathbf{x}_0 \leq K_\Omega$ *for all* $\mathbf{x} \in \Omega$.

Proof. Since $\mathcal{G}_\gamma(\mathbf{x}_0) = \int_\Omega G_\gamma(\mathbf{y} - \mathbf{x}_0) \, d\mathbf{y}$, we have $\mathcal{G}_\gamma(\mathbf{x}_0) \geq |\Omega| G_\gamma(\mathrm{diam}(\Omega))$. Therefore

$$\begin{aligned} \int_\Omega G_\gamma(\mathbf{x} - \mathbf{x}_0) \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \, d\mathbf{x}_0 & \leq \frac{1}{|\Omega| G_\gamma(\mathrm{diam}(\Omega))} \int_\Omega G_\gamma(\mathbf{x} - \mathbf{x}_0) d\mathbf{x}_0 \\ & \leq \frac{1}{|\Omega| G_\gamma(\mathrm{diam}(\Omega))} \times |\Omega| G_\gamma(\mathbf{0}) = K_\Omega. \end{aligned}$$

□

LEMMA 4.14. *For all* $\mathbf{x}_0 \in \Omega$, *the following inequalities are verified:*

$$0 \leq \mu_1(\mathbf{x}_0) \leq \mathcal{A} \quad \textit{and} \quad \beta \leq v_1(\mathbf{x}_0) \leq \beta + \mathcal{A}^2.$$

Proof. We have

$$\mu_1(\mathbf{x}_0) = \int_{\mathbb{R}^2} i_1 \left(\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} \right) di_1\, di_2 \tag{4.7}$$
$$= \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_1(\mathbf{x})\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x},$$

and the first inequalities follow from the fact that $I_1(\mathbf{x}) \in [0, \mathcal{A}]$. Similarly, for $v_1(\mathbf{x}_0)$, we have

$$v_1(\mathbf{x}_0) = \int_{\mathbb{R}^2} i_1^2 \left(\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} \right) di_1\, di_2 - \mu_1^2(\mathbf{x}_0) \tag{4.8}$$
$$= \beta + \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_1(\mathbf{x})^2\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} - \left(\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_1(\mathbf{x})\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} \right)^2,$$

from which the right-hand side of the second inequality follows. The application of the Cauchy–Schwarz inequality to

$$\int_\Omega I_1(\mathbf{x})\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} = \int_\Omega \left(I_1(\mathbf{x}) \sqrt{G_\gamma(\mathbf{x} - \mathbf{x}_0)} \right) \sqrt{G_\gamma(\mathbf{x} - \mathbf{x}_0)}\, d\mathbf{x}$$

yields the left-hand side. ∎

We then characterize the mean $\mu_2(\mathbf{x}_0, \mathbf{h})$; see Table 3.1.

LEMMA 4.15. *The function $\Omega \times H \longrightarrow \mathbb{R}$ defined by $(\mathbf{x}_0, \mathbf{h}) \longrightarrow \mu_2(\mathbf{x}_0, \mathbf{h})$ is bounded and Lipschitz continuous in H uniformly in Ω.*

Proof. According to the definition of μ_2 in Table 3.1 we have

$$\mu_2(\mathbf{x}_0, \mathbf{h}) = \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x}.$$

We have immediately

$$\mu_2(\mathbf{x}_0, \mathbf{h}) \leq \mathcal{A}.$$

Moreover,

$$|\mu_2(\mathbf{x}_0, \mathbf{h}_1) - \mu_2(\mathbf{x}_0, \mathbf{h}_2)| \leq \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega |I_2(\mathbf{x} + \mathbf{h}_1(\mathbf{x})) - I_2(\mathbf{x} + \mathbf{h}_2(\mathbf{x}))| G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x}.$$

Since I_2 is Lipschitz, a combination of Lemma 4.13 and the Cauchy–Schwarz inequality yields

$$|\mu_2(\mathbf{x}_0, \mathbf{h}_1) - \mu_2(\mathbf{x}_0, \mathbf{h}_2)| \leq Lip(I_2) K_\Omega \|\mathbf{h}_1 - \mathbf{h}_2\|_H. \qquad \blacksquare$$

We have similar properties for the variance $v_2(\mathbf{x}_0, \mathbf{h})$; see Table 3.1.

LEMMA 4.16. *The function $\Omega \times H \longrightarrow \mathbb{R}$ defined by $(\mathbf{x}_0, \mathbf{h}) \longrightarrow v_2(\mathbf{x}_0, \mathbf{h})$ is strictly positive, bounded, and Lipschitz continuous in H uniformly in Ω.*

Proof. According to the definition of v_2 in Table 3.1 we have

$$v_2(\mathbf{h}, \mathbf{x}_0) = \int_{\mathbb{R}^2} i_2^2 \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \left(\int_\Omega g_\beta(I_2(\mathbf{x} + \mathbf{h}(\mathbf{x})) - i_2)\, G_\gamma(\mathbf{x} - \mathbf{x}_0)\, d\mathbf{x} \right) di_2 - \mu_2(\mathbf{x}_0, \mathbf{h})^2.$$

Hence

$$v_2(\mathbf{h},\mathbf{x}_0) = \beta + \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))^2 \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} - \mu_2(\mathbf{h},\mathbf{x}_0)^2.$$

Therefore $v_2(\mathbf{h},\mathbf{x}_0) \leq \beta + \mathcal{A}^2$. To prove that it is strictly positive, we write

$$\begin{aligned} v_2(\mathbf{h},\mathbf{x}_0) = \beta &+ \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))^2 \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \\ &- \left(\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})) G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \right)^2, \end{aligned}$$

and the same reasoning as in Lemma 4.14 shows that $\beta \leq v_2(\mathbf{h},\mathbf{x}_0)$. For the second part, since $\mu_2(\mathbf{h},\mathbf{x}_0)$ is bounded and Lipschitz continuous uniformly in Ω (Lemma 4.15), it suffices to show the Lipschitz continuity of the first term on the right-hand side. For this term we have, using again a combination of Lemma 4.13 and the Cauchy–Schwarz inequality,

$$\begin{aligned} &\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \left| \int_\Omega I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))^2 \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} - \int_\Omega I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))^2 \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \right| \\ &\leq \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega (I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))+I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))) \, |I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x}))-I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))| \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \\ &\leq 2\mathcal{A} \, Lip(I_2) \, K_\Omega \|\mathbf{h}_1 - \mathbf{h}_2\|_H. \qquad \square \end{aligned}$$

We now show the boundedness and Lipschitz continuity of the correlation $v_{1,2}(\mathbf{x}_0,\mathbf{h})$; see Table 3.1.

PROPOSITION 4.17. *The function $H \times \Omega \to \mathbb{R}$ defined by $(\mathbf{h},\mathbf{x}_0) \mapsto v_{1,2}(\mathbf{h},\mathbf{x}_0)$ is bounded and Lipschitz continuous in H, uniformly in Ω.*

Proof. According to the definition of $v_{1,2}$ in Table 3.1 we have

$$\begin{aligned} v_{1,2}(\mathbf{h},\mathbf{x}_0) = \int_{\mathbb{R}^2} i_1 \, i_2 \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \left(\int_\Omega G_\beta(\mathbf{I}_\mathbf{h}(\mathbf{x}) - \mathbf{i}) \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \right) \, di_1 \, di_2 \\ - \mu_1(\mathbf{x}_0)\mu_2(\mathbf{x}_0,\mathbf{h}). \end{aligned}$$

Hence

$$v_{1,2}(\mathbf{h},\mathbf{x}_0) = \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega I_1(\mathbf{x}) \, I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})) \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} - \mu_1(\mathbf{x}_0) \, \mu_2(\mathbf{h},\mathbf{x}_0).$$

Thus we have, for all $\mathbf{x}_0 \in \Omega$, $|v_{1,2}(\mathbf{h},\mathbf{x}_0)| \leq 2\mathcal{A}^2$, which proves the first part of the proposition. For the second part, since $\mu_2(\mathbf{h},\mathbf{x}_0)$ is Lipschitz continuous uniformly in Ω (Lemma 4.15) and μ_1 is bounded, it suffices to show the Lipschitz continuity of the first term on the right-hand side. For this term we have, using again a combination of Lemma 4.13 and the Cauchy–Schwarz inequality,

$$\begin{aligned} &\frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \left| \int_\Omega I_1(\mathbf{x}) I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x})) \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} - \int_\Omega I_1(\mathbf{x}) \, I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x})) \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \right| \\ &\leq \frac{1}{\mathcal{G}_\gamma(\mathbf{x}_0)} \int_\Omega |I_1(\mathbf{x})| \, |I_2(\mathbf{x}+\mathbf{h}_1(\mathbf{x})) - I_2(\mathbf{x}+\mathbf{h}_2(\mathbf{x}))| \, G_\gamma(\mathbf{x}-\mathbf{x}_0) \, d\mathbf{x} \\ &\leq \mathcal{A} \, Lip(I_2) \, K_\Omega \|\mathbf{h}_1 - \mathbf{h}_2\|_H. \qquad \square \end{aligned}$$

THEOREM 4.18. *The function $H \times \Omega \to \mathbb{R}$ defined by $(\mathbf{h}, \mathbf{x}) \mapsto \mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x})$ is bounded and Lipschitz continuous in H, uniformly in Ω.*

Proof. Indeed, by definition we have $-1 \leq \mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x}) \leq 0$ for all $\mathbf{h} \in H$. Moreover, we have

$$\mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x}) = -\frac{v_{1,2}(\mathbf{h}, \mathbf{x})^2}{v_1(\mathbf{x})\, v_2(\mathbf{h}, \mathbf{x})}, \tag{4.9}$$

and the following properties hold true:

- $v_{1,2}(\mathbf{h}, \mathbf{x})$ is bounded and Lipschitz-continuous in H uniformly in Ω (Proposition 4.17).
- $v_2(\mathbf{h}, \mathbf{x})$ is strictly positive, bounded, and Lipschitz-continuous in H, uniformly in Ω (Lemma 4.16).
- $v_1(\mathbf{x})$ is bounded and > 0 (Lemma 4.14).

We may therefore apply Proposition 4.1. ∎

THEOREM 4.19. *The function $\mathcal{H}_2 \times \Omega \to \mathbb{R}$ defined by*

$$(\mathbf{z}, \mathbf{h}, \mathbf{x}) \mapsto L_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x})$$

is bounded and Lipschitz continuous in $\mathcal{H}_2$, uniformly in Ω.

Proof. We have

$$L_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}) = -\frac{2}{\mathcal{G}_\gamma(\mathbf{x})} \left[\frac{v_{1,2}(\mathbf{h}, \mathbf{x})}{v_2(\mathbf{h}, \mathbf{x})} \left(\frac{z_1 - \mu_1(\mathbf{x})}{v_1(\mathbf{x})} \right) + \mathcal{J}_{\mathrm{CC}}(\mathbf{h}, \mathbf{x}) \left(\frac{z_2 - \mu_2(\mathbf{h}, \mathbf{x})}{v_2(\mathbf{h}, \mathbf{x})} \right) \right].$$

This can be rewritten as

$$L_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}) = f_1(\mathbf{h}, \mathbf{x})\, z_1 + f_2(\mathbf{h}, \mathbf{x})\, z_2 + f_3(\mathbf{h}, \mathbf{x}).$$

The functions $H \times \Omega \to \mathbb{R}$, f_1, f_2, and f_3, are bounded and Lipschitz continuous in H uniformly in Ω because of Lemmas 4.13, 4.14, 4.15, 4.16, Proposition 4.17, and Theorem 4.18. The result readily follows. ∎

THEOREM 4.20. *The function $f_{\mathrm{CC}} : \mathcal{H}_2 \times \Omega \to \mathbb{R}$, defined by*

$$f_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}) = G_\gamma \star L_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}),$$

is bounded and Lipschitz continuous in $\mathcal{H}_2$ uniformly in Ω.

Proof. The fact that it is bounded follows from Theorem 4.19. To obtain the Lipschitz continuity, we write

$$\begin{aligned} &|f_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}) - f_{\mathrm{CC}}(\mathbf{z}', \mathbf{h}', \mathbf{x})| \\ &= \left| \int_\Omega G_\gamma(\mathbf{x} - \mathbf{x}_0) \left(L_{\mathrm{CC}}(\mathbf{z}, \mathbf{h}, \mathbf{x}_0) - L_{\mathrm{CC}}(\mathbf{z}', \mathbf{h}', \mathbf{x}_0) \right) d\mathbf{x}_0 \right| \\ &\leq G_\gamma(0)\, |\Omega|\, Lip(L_{\mathrm{CC}}) \left(|\mathbf{z} - \mathbf{z}'| + \|\mathbf{h} - \mathbf{h}'\|_H \right) \end{aligned}$$

and

$$\begin{aligned} &|G_\gamma \star f(\mathbf{z}, \mathbf{h}, \mathbf{x}) - G_\gamma \star f(\mathbf{z}, \mathbf{h}, \mathbf{y})| \\ &\qquad \leq \int_\Omega |G_\gamma(\mathbf{x} - \mathbf{x}_0) - G_\gamma(\mathbf{y} - \mathbf{x}_0)||f(\mathbf{z}, \mathbf{h}, \mathbf{x}_0)|\, d\mathbf{x}_0 \leq B_f\, Lip(G_\gamma) |\Omega|\, |\mathbf{x} - \mathbf{y}|, \end{aligned}$$

and hence obtain the result. ∎

THEOREM 4.21. *The function* $F_{\mathrm{CC}} : H \to H$ *defined by*

$$F_{\mathrm{CC}}(\mathbf{h}) = -f_{\mathrm{CC}}(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}), \mathbf{h}, \mathbf{Id})\nabla I_2(\mathbf{Id}+\mathbf{h})$$

is Lipschitz continuous and bounded.

Proof. Since f_{CC} is bounded (Theorem 4.20) as well as ∇I_2, so is F_{CC}, which therefore belongs to H. For the Lipschitz continuity, we write

$$\begin{aligned} F_{\mathrm{CC}}(\mathbf{h}_1) - F_{\mathrm{CC}}(\mathbf{h}_2) &= f_{\mathrm{CC}}(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}_1), \mathbf{h}_1, \mathbf{Id})\,(\nabla I_2(\mathbf{Id}+\mathbf{h}_2) - \nabla I_2(\mathbf{Id}+\mathbf{h}_1)) \\ &+ \nabla I_2(\mathbf{Id}+\mathbf{h}_2)\,(f_{\mathrm{CC}}(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}_2), \mathbf{h}_2, \mathbf{Id}) - f_{\mathrm{CC}}(I_1(\mathbf{Id}), I_2(\mathbf{Id}+\mathbf{h}_1), \mathbf{h}_1, \mathbf{Id}))\,. \end{aligned}$$

The Lipschitz continuity follows from that of ∇I_2, of L_{CC} (Theorem 4.20), and the use of the Cauchy–Schwarz inequality as in the proof of Theorem 4.11. □

PROPOSITION 4.22. *The function* $\Omega \to \mathbb{R}^n$ *such that* $\mathbf{x} \to F_{\mathrm{CC}}(\mathbf{h})(\mathbf{x})$ *satisfies*

$$|F_{\mathrm{CC}}(\mathbf{h})(\mathbf{x}) - F_{\mathrm{CC}}(\mathbf{h})(\mathbf{y})| \leq K(|\mathbf{x}-\mathbf{y}| + |\mathbf{h}(\mathbf{x}) - \mathbf{h}(\mathbf{y})|),$$

for some constant $K > 0$.

Proof. The proof is similar to that of Proposition 4.12; it follows from Theorem 4.20 and the fact that the functions I_1, I_2 and all the derivatives of I_2 are Lipschitz continuous. □

5. Numerical implementation. The numerical implementation of the previously described continuous matching flows involves estimating the matching term, which depends on one of the two intensity-comparison functions F_{MI} and F_{CC} and the regularization operator, which is $\mathbf{div}(\mathbf{T}_{I_1} D\mathbf{h})$. For the discretization in time, we adopt an explicit forward scheme. Implicit schemes are difficult to devise due to the high nonlinearity of the matching functions. The way in which the time step is chosen is discussed in the following section. Alvarez, Weickert, and Sánchez [2] propose a very efficient scheme for discretizing the Nagel–Enkelmann divergence operator which we adopt in our experiments. We use a schematic notation for the description of the finite-difference schemes. For instance, let us denote by $h_p^{i,j}$ and $L_p^{i,j}$ the components $(p = 1, 2)$ of $\mathbf{h}$ and its Laplacian $\Delta\mathbf{h}$ at the grid point (i, j) in the discrete image domain. The voxel size in all directions is assumed to be equal to one. A possible scheme for $\alpha\Delta\mathbf{h}$ is

$$L_p^{i,j} = \alpha\Big(h_p^{i+1,j} + h_p^{i-1,j} + h_p^{i,j-1} + h_p^{i,j+1} - 4\,h_p^{i,j}\Big), \tag{5.1}$$

which we write schematically as

$$L_p^{i,j} = \alpha * \begin{array}{|c|c|c|} \hline & 1 & \\ \hline 1 & -4 & 1 \\ \hline & 1 & \\ \hline \end{array}\ h_p.$$

In this notation, the tables represent the discrete grid and contain the weights associated with each pixel (zero if none). The function to which the grid corresponds is written at the bottom. The scheme proposed in [2] is the following. Let $A = \mathbf{div}(\mathbf{T}_{I_1} D\mathbf{h})$, where

$$\mathbf{T}_{I_1} = \begin{pmatrix} a & b \\ b & c \end{pmatrix}.$$

Then, for $p = 1, 2$,

$$A_p^{i,j} = \tfrac{1}{2} * \underset{a}{\begin{array}{|c|c|c|}\hline & & \\ \hline & 1 & 1 \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline & -1 & 1 \\ \hline & & \\ \hline\end{array}} + \tfrac{1}{2} * \underset{a}{\begin{array}{|c|c|c|}\hline & & \\ \hline 1 & 1 & \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline 1 & -1 & \\ \hline & & \\ \hline\end{array}}$$

$$+ \tfrac{1}{2} * \underset{c}{\begin{array}{|c|c|c|}\hline & 1 & \\ \hline & 1 & \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & 1 & \\ \hline & -1 & \\ \hline & & \\ \hline\end{array}} + \tfrac{1}{2} * \underset{c}{\begin{array}{|c|c|c|}\hline & & \\ \hline & 1 & \\ \hline & 1 & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline & -1 & \\ \hline & 1 & \\ \hline\end{array}}$$

$$+ \tfrac{1}{4} * \underset{b}{\begin{array}{|c|c|c|}\hline & & \\ \hline & 1 & \\ \hline & & 1 \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline & -1 & \\ \hline & & 1 \\ \hline\end{array}} + \tfrac{1}{4} * \underset{b}{\begin{array}{|c|c|c|}\hline 1 & & \\ \hline & 1 & \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline 1 & & \\ \hline & -1 & \\ \hline & & \\ \hline\end{array}}$$

$$- \tfrac{1}{4} * \underset{b}{\begin{array}{|c|c|c|}\hline & & 1 \\ \hline & 1 & \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & 1 \\ \hline & -1 & \\ \hline & & \\ \hline\end{array}} - \tfrac{1}{4} * \underset{b}{\begin{array}{|c|c|c|}\hline & & \\ \hline & 1 & \\ \hline 1 & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline & -1 & \\ \hline 1 & & \\ \hline\end{array}} .$$

The 3*D case.* This scheme generalizes readily to the 3D case. In order to write the 3D scheme explicitly in a compact way, we take advantage of its very simple form and introduce a more compact notation. We write

$$S_{\frac{1}{2}}(a, x^+) \equiv \frac{1}{2} * \underset{a}{\begin{array}{|c|c|c|}\hline & & \\ \hline & 1 & 1 \\ \hline & & \\ \hline\end{array}} * \underset{h_p}{\begin{array}{|c|c|c|}\hline & & \\ \hline & -1 & 1 \\ \hline & & \\ \hline\end{array}},$$

where x^+ indicates the direction defined by the voxels with non-null weights, starting at the center. With this notation, we write the 2D Nagel–Enkelmann operator above as

$$\begin{aligned} A_p^{i,j} = {} & S_{\frac{1}{2}}(a, x^+) + S_{\frac{1}{2}}(a, x^-) + S_{\frac{1}{2}}(c, y^+) + S_{\frac{1}{2}}(c, y^-) \\ & + S_{\frac{1}{4}}(b, x^+y^+) + S_{\frac{1}{4}}(b, x^-y^-) - S_{\frac{1}{4}}(b, x^+y^-) - S_{\frac{1}{4}}(b, x^-y^+). \end{aligned}$$

In the 3D case, we have

$$\mathbf{T}_{I_1} = \begin{pmatrix} a & b & c \\ b & d & e \\ c & e & f \end{pmatrix},$$

and the corresponding scheme is, for $p = 1, 2, 3$,

$$\begin{aligned} A_p^{i,j,k} = {} & S_{\frac{1}{2}}(a, x^+) + S_{\frac{1}{2}}(a, x^-) + S_{\frac{1}{2}}(d, y^+) + S_{\frac{1}{2}}(d, y^-) + S_{\frac{1}{2}}(f, z^+) \\ & + S_{\frac{1}{2}}(f, z^-) + S_{\frac{1}{4}}(b, x^+y^+) + S_{\frac{1}{4}}(b, x^-y^-) - S_{\frac{1}{4}}(b, x^+y^-) - S_{\frac{1}{4}}(b, x^-y^+) \\ & + S_{\frac{1}{4}}(c, x^+z^+) + S_{\frac{1}{4}}(c, x^-z^-) - S_{\frac{1}{4}}(c, x^+z^-) - S_{\frac{1}{4}}(c, x^-z^+) \\ & + S_{\frac{1}{4}}(e, y^+z^+) + S_{\frac{1}{4}}(e, y^-z^-) - S_{\frac{1}{4}}(e, y^+z^-) - S_{\frac{1}{4}}(e, y^-z^+). \end{aligned}$$

5.1. Intensity comparison functions. Concerning the intensity comparison functions, we approximate convolutions with a Gaussian kernel by recursive filtering using the smoothing operator introduced in [17]. Terms of the form $\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))$ and $I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))$ are calculated by trilinear interpolation. The global function F_{MI} is estimated by explicitly computing the global density estimate $P(\mathbf{i},\mathbf{h})$ through recursive smoothing of the discrete joint histogram of intensities, as detailed in section 5.1.2. For the local function F_{CC}, a special implementation has been developed, as detailed in section 5.1.4.

5.1.1. Convolutions. The convolutions by a Gaussian kernel are approximated by recursive filtering using the smoothing operator introduced by Deriche [17]. Given a discrete 1D input sequence $x(n), n = 1,\dots,M$, its convolution by the smoothing operator $S_\alpha(n) = k\,(\alpha|n|+1)\,e^{-\alpha|n|}$ is calculated efficiently as (see [17])

$$y(n) = (S_\alpha \star x)(n) = y_1(n) + y_2(n),$$

where

$$\begin{cases} y_1(n) \;=\; k\big(x(n) \;+\; e^{-\alpha}\,(\alpha-1)\,x(n-1)\big) \\ \qquad\qquad\qquad\qquad + 2\,e^{-\alpha}\,y_1(n-1) \;-\; e^{-2\alpha}\,y_1(n-2), \\ \\ y_2(n) \;=\; k\big(e^{-\alpha}\,(\alpha+1)\,x(n+1) \;-\; e^{-2\alpha}\,x(n+2)\big) \\ \qquad\qquad\qquad\qquad + 2\,e^{-\alpha}\,y_2(n+1) \;-\; e^{-2\alpha}\,y_2(n+2). \end{cases}$$

The normalization constant k is chosen by requiring that $\int_{\mathbb{R}} S_\alpha(t)\;dt = 1$, which yields $k = \alpha/4$. This scheme is very efficient since the number of operations required is independent of the smoothing parameter α. The smoothing filter can be readily generalized to n dimensions by defining the separable filter $T_\alpha(\mathbf{x}) = \prod_{i=1}^{n} S_\alpha(x_i)$.

5.1.2. Density estimation. Parzen density estimates are obtained by smoothing the discrete joint histogram of intensities. We define the piecewise constant function $\mathbf{v} : \Omega \to [0,N]^2 \subset \mathbb{N}^2$ by quantification of $\mathbf{I_h}(\mathbf{x})$ into $N+1$ intensity levels (bins):

$$\mathbf{v}(\mathbf{x}) = \begin{pmatrix} \lfloor \zeta I_1(\mathbf{x}) \rfloor \\ \\ \lfloor \zeta I_2(\mathbf{x}+\mathbf{h}(\mathbf{x})) \rfloor \end{pmatrix} = \begin{cases} (0,0)^T & \text{on} \quad \Omega_{0,0}, \\ \vdots & \\ (N,N)^T & \text{on} \quad \Omega_{N,N}, \end{cases}$$

where $\zeta = N/\mathcal{A}$, $\lfloor\cdot\rfloor$ denotes the floor operator in $\mathbb{R}^+$, i.e., the function $\mathbb{R}^+ \to \mathbb{N}$ such that $\lfloor x \rfloor = \max\{n \in \mathbb{N} : n \le x\}$ and $\{\Omega_{k,l}\}_{(k,l)\in[0,N]^2}$ is a partition of Ω. We then compute, setting $\beta' = \zeta^2\beta$,

$$\begin{aligned} P(\mathbf{i},\mathbf{h}) &= \frac{1}{|\Omega|}\int_\Omega G_\beta(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\;d\mathbf{x} = \frac{\zeta}{|\Omega|}\int_\Omega G_{\beta'}\big(\zeta\;(\mathbf{I_h}(\mathbf{x}) - \mathbf{i})\big)\;d\mathbf{x} \\ &\simeq \frac{\zeta}{|\Omega|}\int_\Omega G_{\beta'}\big(\mathbf{v}(\mathbf{x}) - \zeta\mathbf{i}\big)\;d\mathbf{x} = \frac{\zeta}{|\Omega|}\;\sum_{k=0}^{N}\sum_{l=0}^{N}\;\int_{\Omega_{k,l}} G_{\beta'}(k-\zeta i_1, l-\zeta i_2)\;d\mathbf{x} \\ &= \zeta\sum_{k=0}^{N}\sum_{l=0}^{N}\;\underbrace{|\Omega_{k,l}|/|\Omega|}_{H(k,l)}\;G_{\beta'}(k-\zeta i_1, l-\zeta i_2) = \zeta\;\big(H \star G_{\beta'}\big)(\zeta\mathbf{i}), \end{aligned}$$

H being the discrete joint histogram. The convolution is performed by recursive filtering, as described in the previous section. Note that this way of computing P is quite efficient since only one pass on the images is required, followed by the convolution.

5.1.3. Implementation of the computation of $\boldsymbol{F}_{\mathrm{MI}}$. The global mutual information function is then estimated as follows:

- Estimate $P(\mathbf{i},\mathbf{h})$ and its marginals.
- Estimate $L_{\mathrm{MI}}(\mathbf{i},\mathbf{h})$ (equation (3.4)) using centered finite-differences for the derivatives.
- Estimate $f_{\mathrm{MI}}(\mathbf{i},\mathbf{h}) = G_\beta \star L_{\mathrm{MI}}(\mathbf{i},\mathbf{h})$ (equation (3.3)) by recursive smoothing.
- Estimate $F_{\mathrm{MI}}(\mathbf{h})(\mathbf{x}) = -f_{\mathrm{MI}}(\mathbf{I}_{\mathbf{h}}(\mathbf{x}),\mathbf{h})\,\nabla I_2(\mathbf{x}+\mathbf{h}(\mathbf{x}))$ (equation (3.8)).

5.1.4. Implementation of the computation of $\boldsymbol{F}_{\mathrm{CC}}$. The function f_{CC} is estimated as

$$L_{\mathrm{CC}}(\mathbf{i},\mathbf{x}) = (G_\gamma \star f_1)(\mathbf{x})\; i_1 + (G_\gamma \star f_2)(\mathbf{x})\; i_2 + (G_\gamma \star f_3)(\mathbf{x}),$$

where

$$f_1(\mathbf{x}) = -2\; v_{1,2}(\mathbf{h},\mathbf{x})/(\mathcal{G}_\gamma(\mathbf{x})\; v_1(\mathbf{x})\; v_2(\mathbf{h},\mathbf{x})),$$

$$f_2(\mathbf{x}) = -2\; \mathcal{J}_{\mathrm{CC}}(\mathbf{h},\mathbf{x})/(\mathcal{G}_\gamma(\mathbf{x})\; v_2(\mathbf{h},\mathbf{x})),$$

and

$$f_3(\mathbf{x}) = -\big(f_1(\mathbf{x})\; \mu_1(\mathbf{x}) + f_2(\mathbf{x})\; \mu_2(\mathbf{h},\mathbf{x})\big).$$

All the required space dependent quantities like $\mu_1(\mathbf{x})$ are computed through recursive spatial smoothing. This algorithm is similar to the one proposed in [11].

5.2. Parameters. We now discuss the way in which the different parameters of the algorithms are determined.

- γ: This is the variance of the spatial Gaussian for local density estimates. Its value does not affect the computation time since the local statistics are calculated using the recursive smoothing filter. Thanks to this, we have conducted some experiments with different values of this parameter, which have shown that the algorithms are not very sensitive to it. Qualitatively speaking, the local window has to be large enough for the statistics to be significant and small enough to account for nonstationarities of the density. We set γ to 5 in all our experiments.
- β: This is the variance of the Gaussian for the Parzen estimates. Unlike γ, determining a good value for β is important for obtaining good results. In our case, it is determined automatically as follows (we refer to [6] for a recent comprehensive study on nonparametric density estimation). We adopt a cross-validation technique based on an empirical maximum likelihood method. We denote by $\{\mathbf{i}_k\}$ a set of m intensity pair samples ($k = 1,\ldots,m$) and take the value of β which maximizes the empirical likelihood:

$$L(\beta) = \prod_{k=1}^{m} \hat{P}_{\beta,k}(\mathbf{i}_k),$$

where

$$\hat{P}_{\beta,k}(\mathbf{i}_k) = \frac{1}{m-n_k} \sum_{\{s:\ \mathbf{i}_s \neq \mathbf{i}_k\}} G_\beta(\mathbf{i}_k - \mathbf{i}_s)$$

and n_k is the number of data samples for which $\mathbf{i}_s = \mathbf{i}_k$.
For the experiments shown in this paper, the optimal value of β varies in the range 15–20.

- κ: This parameter determines the coefficient of the regularization term in the energy functional. Since the range of the different matching functions F varies considerably, we normalize it by dividing by the maximum value $\kappa_0 = \|F(\mathbf{h}_0)\|_\infty$, $\mathbf{h}_0$ being the initial field. This is equivalent to replacing κ by C such that

$$C = \kappa\,\kappa_0.$$

  The behavior of the algorithms is much more stable with respect to C than to κ. κ has been kept to the fixed value of 10 in all our experiments except the one with the Eiffel tower, where the expected displacement is close to a translation, a very smooth transformation indeed. In this experiment the value of κ has been fixed to 100.
- Δt: The time step is chosen such that the coefficient of the regularization term (i.e., $C\Delta t$) is less than a specified value. It is known, for instance, that the scheme (5.1) is stable for values of $C\Delta t$ no larger than 0.25. In our experiments, we fix $C\Delta t$ to a value of 0.1. The resulting Δt is different at each resolution due to the fact that C is recomputed at the beginning of each level. In some of the examples, we have computed the value of Δt by doing a line-search in the gradient direction, looking for the minimum of the criterion. At each resolution, the line-search consistently produces values which are asymptotically (a) almost constant for that particular resolution and (b) close to a value such that $C\Delta t$ is approximately 0.15–0.2. This is true only asymptotically for each resolution. The first optimal steps are much larger, and this has suggested to us to use the line-search in conjunction with more sophisticated minimization algorithms such as the conjugate gradient. We discuss this point in one of the examples of section 6.
- σ: This is the scale parameter. We adopt a multiresolution approach (see the next section), smoothing the images at each stage by a small amount. Within each stage of the multiresolution pyramid, the parameter σ is fixed to a small value, typically 0.5 voxels/pixels.

One extra parameter is needed for the regularization operator.

- λ: This is the parameter controlling the anisotropic behavior of the Nagel–Enkelmann tensor. We adopt the method proposed by Alvarez, Weickert, and Sánchez [2]. Given q, which in practice is fixed to 0.1, we take the value of λ such that

$$q = \int_0^\lambda \mathcal{H}_{|\nabla I_1|}(z)\,dz,$$

  where $\mathcal{H}_{|\nabla I_1|}(z)$ is the normalized histogram of $|\nabla I_1|$.

6. Experimental results. We present results of experiments using the previously described algorithms. To recover large deformations, we use a multiresolution approach by applying the gradient descent to a set of smoothed and subsampled images. Since the functionals considered are not convex, this coarse-to-fine strategy helps avoid irrelevant extrema while reducing the computational cost of the algorithms. The first stage of the multiresolution pyramid is initialized with $\mathbf{h}_0 = 0$. The field resulting from the computation at a coarse level is multiplied by two and resampled at the

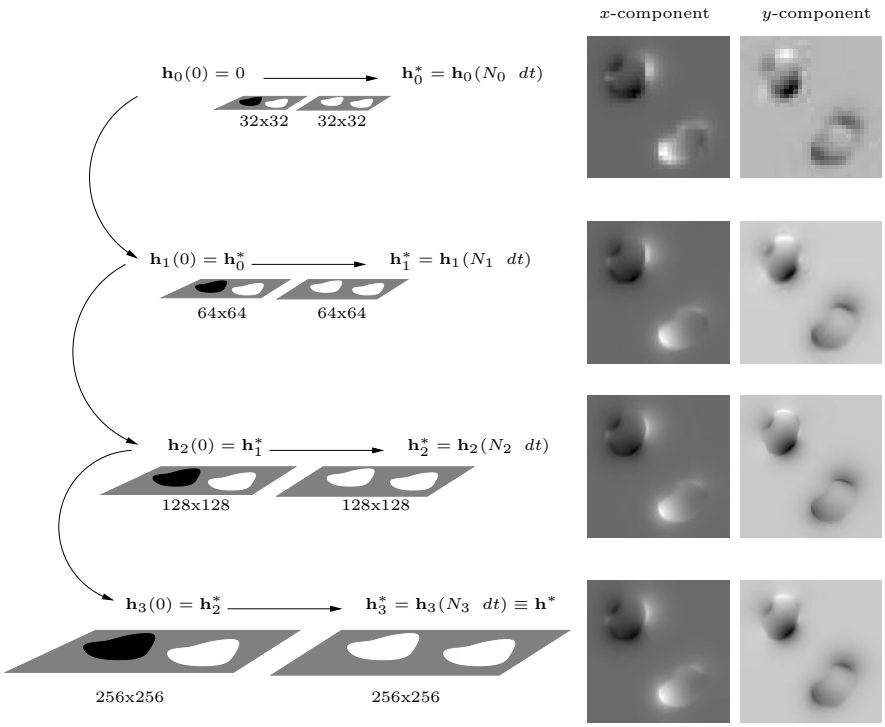

FIG. 3. *Multiresolution strategy: the first stage of the multiresolution pyramid is initialized with* $\mathbf{h}_0 = 0$*, and the resulting field from a coarse level is scaled by two and resampled at the next finer scale (by (tri)-linear interpolation) at each step of the pyramid descent where it is used as the initial value of the corresponding evolution equation. The left column shows the pyramid; the right shows the computed deformation field at each level. This example illustrates the result of the experiment in Figure* 4.

finer scale (by (tri)-linear interpolation) at each step of the pyramid descent, where it is used as the initial value of the corresponding evolution equation. The number of iterations at each level is automatically determined based on the reduction of the criterion. Iterations at each level are stopped when the criterion changes by an amount less than a specified threshold. The number of resolution levels in the pyramid is chosen so that at the coarsest level the image has approximately n pixels (voxels) in its smallest dimension, n being manually fixed to a small value such as 8, 16, or 32. (see Figure 3).

Experiment with synthetic data (Figure 4). In this example, we use the mutual information criterion to compute the displacement field between two synthetic images. Despite its simplicity, this example illustrates the main difficulties of the problem we consider: the distortion is nonrigid, and we are unable to directly compare intensities. Besides, this particular example is especially difficult since the discrete histogram (i.e., before Gaussian smoothing) contains only six nonzero entries, which underlines the importance of the Parzen-window regularization.

T2-PD registration (Figure 5). We use the mutual information criterion to realign two slices from a proton density (PD) and a T2-weighted magnetic resonance image (MRI) volume (same patient). A good introduction to medical image acquisition can be found in [8, 40]. An artificial geometric distortion has been applied to the

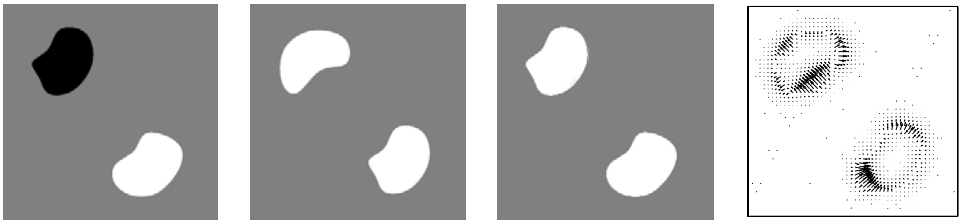

FIG. 4. *Mutual information criterion with a synthetic example. From left to right:* I_1 *(*256×256*),* I_2*,* $I_2(\mathbf{Id} + \mathbf{h}^*)$*, and a plot of the estimated optimal displacement field* $\mathbf{h}^*$*.*

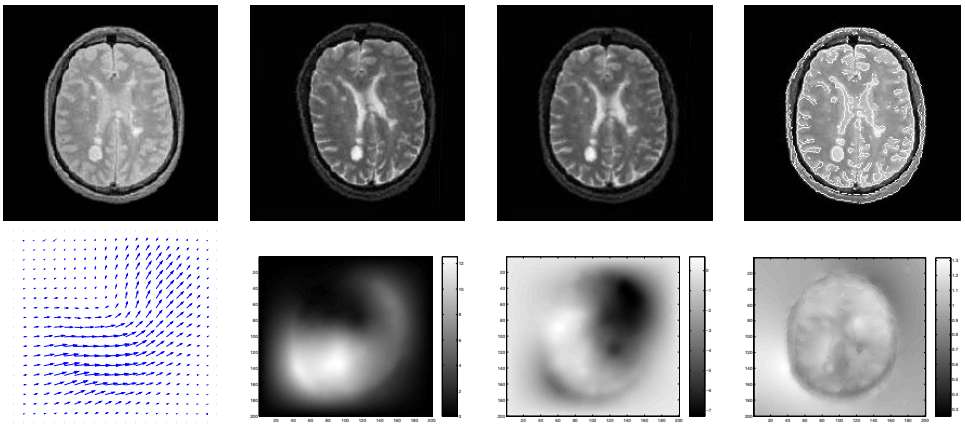

FIG. 5. *PD/T2 MRI registration using mutual information. First row, from left to right:* I_1*,* I_2*,* $I_2(\mathbf{Id} + \mathbf{h}^*)$*, and the contours of* $I_2(\mathbf{Id} + \mathbf{h}^*)$ *superimposed on* I_1*. The second row shows, from left to right: an arrow-plot of* $\mathbf{h}^*$ *(one every three pixels shown), the dense* x *and* y *components of* $\mathbf{h}^*$*, and the determinant of the Jacobian of the transformation* $\mathbf{Id} + \mathbf{h}^*$*.*

original preregistered dataset. In order to evaluate the accuracy of the realignment, we superimposed some contours of the T2 image (initial and recovered pose) over the reference image (PD). It gives a good qualitative indication of the quality of the registration. Most of the anatomical structures seem correctly realigned.

MRI-fMRI registration (Figure 6). This example shows an experiment with MR data of the brain of a macaque monkey. The reference image is a T1-weighted anatomical volume, and the image to register is a functional, mion (monocrystalline iron oxide nanoparticle) contrast, MRI (fMRI). The contrast in this modality is related to blood oxygenation level. This registration was obtained using mutual information. Each image in this figure shows the intersection of the image volume with three orthogonal planes. The crosses in each plane image show a point of interest. The observation of these points shows that the correspondence has been improved by the registration process.

Matching of anatomical versus diffusion-tensor–related MRI (Figure 7). Our next experiment shows the results of an experiment with real 3D MR data of a human brain. This registration was also obtained using mutual information. The reference image is a T1-weighted anatomical MRI of a human brain. The target image is a T2-weighted anatomical MRI from the same patient, which was acquired as part of the process of obtaining an image of the water diffusion tensor at each voxel (dif-

fusion MR). Notice that the intensities in this modality are related in a noninvertible way, i.e., the correspondence $i_1 \to i_2$ is not a monotonous function, thereby justifying the use of mutual information. The estimated deformation field has a dominant y component, a property which is physically coherent with the applied gradient. The observation of the points pointed at by the crosses shows that the correspondence has been improved by the registration process.

Face template matching (Figure 8). This experiment shows template matching of human faces. The different albedos (fractions of incident light reflected by the surfaces) of the two skins create a "multimodal" situation, and the transformation is truly nonrigid due to the different shapes of the noses and mouths. Notice the excellent matching of the different features. This result was obtained using local cross-covariance. The running time was approximately five minutes on a PC at 900MHz. With the correspondences, one can interpolate the displacement field and the texture to perform fully automatic morphing.

The Eiffel tower example (Figure 9). This last experiment shows matching under varying illumination conditions. The Eiffel tower is taken at nearly one year distance under very different weather conditions. The result was obtained using local cross-covariance.

Conjugate gradient minimization. The explicit time discretization using a fixed time step corresponds to a steepest descent method without line-search, which is generally quite inefficient. In this section, we present results obtained with a modified version of the algorithm, which performs line-searching and uses a Fletcher–Reeves conjugate gradient minimization routine as described in [46]. Figure 10 shows plots of the decrease of the functional for the face template matching experiment of Figure 8

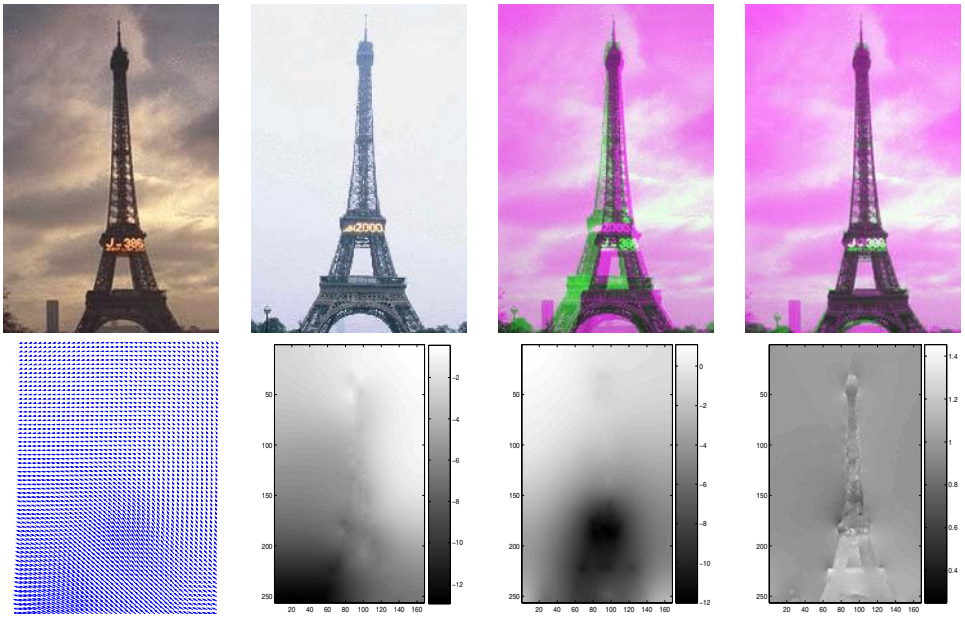

FIG. 9. *Matching under varying illumination conditions. First row from left to right:* I_1, I_2, I_2 *superimposed to* I_1, *and* $I_2(\mathbf{Id}+\mathbf{h}^*)$ *superimposed to* I_1. *The second row shows, from left to right: an arrow-plot of* $\mathbf{h}^*$ *(one every three pixels shown), its dense* x *and* y *components, and the determinant of the Jacobian of the transformation* $\mathbf{Id}+\mathbf{h}^*$. *The local cross-covariance was used as similarity criterion.*

using both the standard steepest descent and the modified conjugate gradient version. Plots (b) and (c) show the advantage of the multiresolution approach over the single resolution plot in (a), as a local minimum is avoided using a five-level multiresolution pyramid (the three coarsest levels are shown in (b), the finest two in (c)). Plots (d) and (e) show that the conjugate gradient method allows about one order of magnitude reduction in the total number of iterations required. In this example the gain in speed is much higher since the number of iterations at the finest level in (e) is very small, despite the fact that each iteration is slightly more costly. The result of Figure 8 is obtained in less than two seconds on a PC at 2.4GHz using the conjugate gradient version, instead of four minutes using the multiresolution approach. The same criterion was used to stop iterations in every case.

7. Conclusion. Image registration is best posed as an optimization problem defined over some functional space. The optimization functional is in general the sum of two terms, a data term and a regularization term. When one deals with different image modalities, the data term has to rely on image statistics rather than directly on the image intensities. This has the effect of making the data term a bit complicated. We have considered two such terms, a global and a local one. We have considered only one regularization term, but it is in effect quite representative. In order to prove that the registration problem is well posed, we have shown the existence of minimizers, computed the Euler–Lagrange equations induced by our functionals, and shown that the corresponding evolution functional equations had a unique and regular solution for a given initial condition.

In order to prove this last point we have used well-known theorems in functional

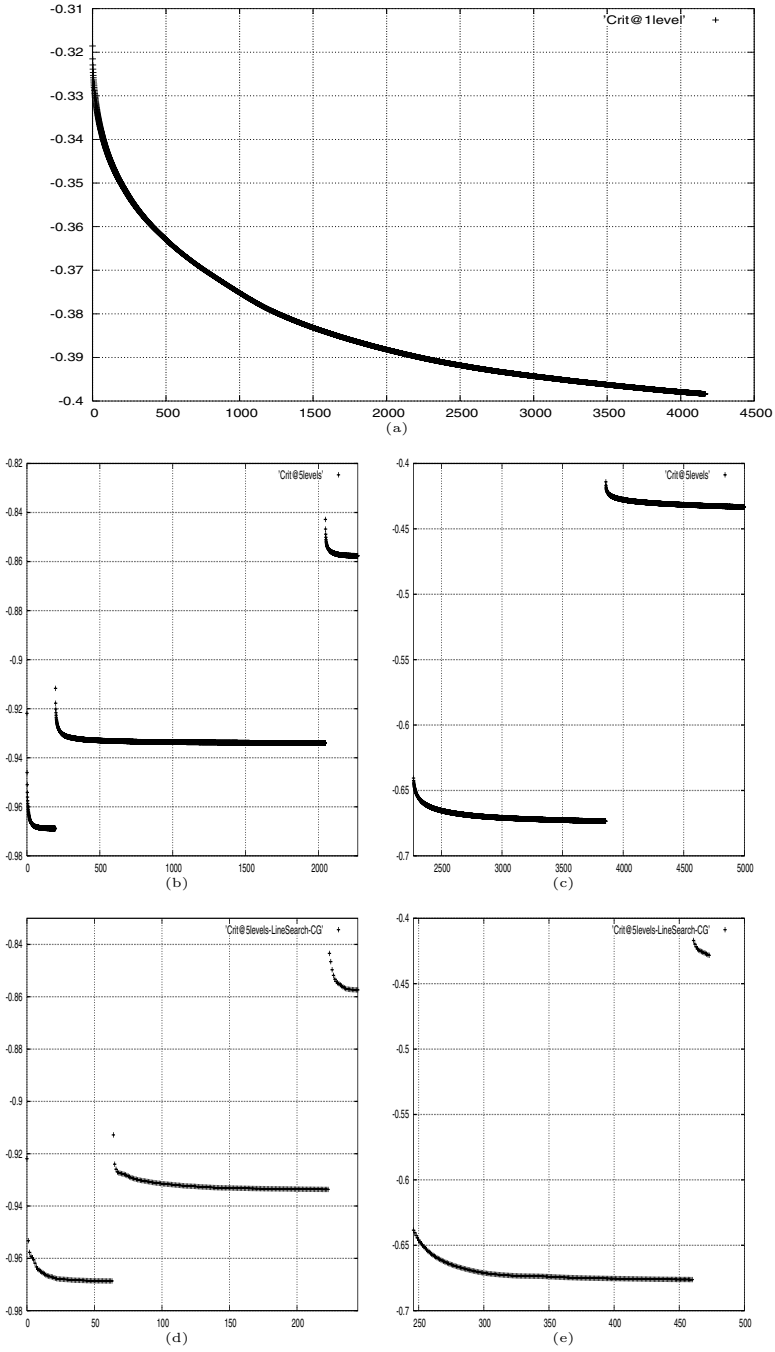

FIG. 10. *Plots of the decrease of the functional for the face template matching experiment of Figure* 8 *as a function of the number of iterations using both the standard steepest descent and the modified conjugate gradient version. Plots* (b) *and* (c) *show the advantage of the multiresolution approach over the single resolution plot in* (a)*, as a local minimum is avoided by using a five-level multiresolution pyramid (the three coarsest levels are shown in* (b)*). Plots* (d) *and* (e) *show that the conjugate gradient method allows about one order of magnitude reduction in the total number of iterations required. In this example the gain in speed is much higher since the number of iterations at the finest level in* (e) *is very small. The same criterion was used to stop iterations in every case.*

analysis. These theorems say that if the differential operator defined by the regularization term is strictly elliptic and the gradient of the data term is Lipschitz continuous, then the functional evolution equation has a unique classical solution. We have proved that these hypotheses are satisfied in our two examples. Since they are "generic" in image registration, this suggests that most of these problems are well posed. Our numerical implementation for computing the solutions of the Euler–Lagrange equations has allowed us to demonstrate the power and the flexibility of the approach for solving a wide range of difficult image registration problems.

A RADIAL BIPHASIC MODEL FOR LOCAL CELL-MATRIX MECHANICS IN ARTICULAR CARTILAGE*

MANSOOR A. HAIDER†

Abstract. Analytical and numerical solutions are presented for an interface problem that models deformation in the local cell-matrix unit (chondron) of articular cartilage. The cell and its protective pericellular matrix layer are modeled as isotropic biphasic continua deforming in small strain. A spherical geometry with purely radial deformation is assumed. Enforcement of the boundary and interface conditions results in an eigenvalue problem that is self-adjoint when the permeabilities of the cell and the layer are the same. In this case, a series solution of the interface problem is presented for a time-varying displacement prescribed at the boundary of the pericellular layer. The case of nonuniform permeability is considered via a numerical finite difference solution. The analytical and numerical solutions are used to conduct a parametric analysis of mechanical signal transmission due to an applied sinusoidal displacement. The dual role of the pericellular matrix as a mechanical signal transmitter and a protective layer is analyzed. For frequencies in the range 0-3Hz, transmission of transient-free radial displacement, solid stress, and strain are evaluated with varying pericellular stiffness and permeability in biphasic models of normal and osteoarthritic chondrons.

1. Introduction.

Articular cartilage is a hydrated biological soft tissue that lines the surfaces of diarthroidal joints such as the knee, shoulder, and hip. The primary function of cartilage is to distribute stresses in load-bearing and to provide a low friction surface for joint motion [15]. While cartilage can perform these functions over a lifetime, the degeneration of cartilage, called osteoarthritis (OA), is a common condition that progresses with age. The structure of cartilage arises from an *extracellular matrix (ECM)* that consists predominantly of cross-linked type-II collagen fibers and entrapped proteoglycan macromolecules. Embedded in the ECM are specialized cells called *chondrocytes* (Figure 1.1). The metabolic activity of the chondrocytes dictates maintenance and turnover of the ECM constituents and hence the structural integrity of the tissue [22]. Within the ECM, the chondrocytes are locally isolated and make up less than 10% of the tissue volume in adult cartilage [21]. Articular cartilage is an avascular and aneural biological soft tissue. Consequently, chondrocyte metabolism depends not only on inherent genetic and biochemical factors but also on mechanical and physicochemical factors in the local environment of a single cell. Such factors include matrix stress, fluid pressurization, fixed-charge density of the ECM, and ionic composition of the interstitial fluid [8]. Describing the complex relationships between components of the local cell environment and external loading of a joint requires the formulation and solution of biomechanical models at several scales. Knowledge of these relationships is an important step in describing the sequence of events that cause changes in the local cellular environment to alter the biochemical response of a chondrocyte.

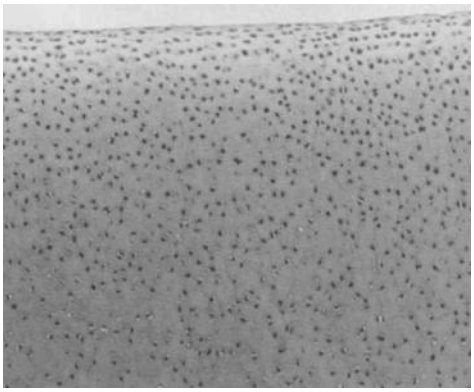

FIG. 1.1. *A photomicrograph of articular cartilage. The chondrocytes (black) are cellular inclusions that populate the extracellular matrix (grey).* Reprinted from F. Guilak, A. Ratcliffe, and V. C. Mow, *Chondrocyte deformation and local tissue strain in articular cartilage: A confocal microscopy study,* J. Orthop. Res., 13 (1995), pp. 410–421, with permission from Orthopaedic Research Society[7].

The local mechanical environment of a single cell is strongly influenced by its *pericellular matrix (PCM)*. The PCM is a protective layer that encapsulates the chondrocyte and is believed to play a significant role in regulating transmission of mechanical signals to the cell. Together, the cell and its PCM are termed a *chondron*. As a joint undergoes loading, mechanical signals are transmitted via the ECM to each chondron and, via the PCM, to each cell which, in response, can alter its metabolic activity. The composition of the PCM differs from that of the ECM in that the PCM is dominated by type-VI collagen and has a higher proteoglycan density. To quantify the effect of the PCM on mechanical signal transmission using biomechanical models, material parameter values are required for the chondrocyte and the PCM.

Using video microscopy, elastic parameter values for the chondrocyte are typically obtained by employing solutions of static contact problems for an elastic half-space [23] or sphere [9] that model micropipette aspiration testing of isolated cells. In a study of human chondrocytes [12], cells extracted via enzymatic digestion were found to be nearly incompressible, with a mean modulus on the order of 1kPa. No significant difference was observed between cells in the healthy and osteoarthritic sample groups. Recently, the solution of a layered elastic contact problem was used to determine elastic properties of the PCM via micropipette aspiration tests performed on intact chondrons that were mechanically extracted from human articular cartilage [1]. The mean Young's modulus of chondron PCM from healthy human articular cartilage was found to be 66.5kPa, whereas a 38% decrease in the mean modulus to 41.2kPa was observed in the osteoarthritic group [1]. In a multiscale finite element analysis [6], the macroscopic solution for transient deformation of a cartilage layer under a step load was computed and used to solve a separate microscale problem to determine the mechanical environment of a single chondrocyte. In this study, the inclusion of a PCM layer in the microscale model significantly altered the mechanical environment of a single cell. Together, these findings support the hypotheses that the PCM acts as a stiff protective layer that strongly influences the local environment of a chondrocyte, and that the mechanical properties of the PCM can be altered significantly with OA.

In the current study, analytical and numerical solutions are presented for an

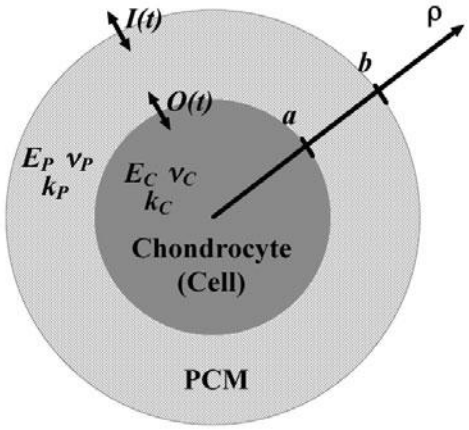

FIG. 1.2. *Spherical model of a chondron. The chondrocyte is modeled as a biphasic sphere with an attached biphasic layer that represents the pericellular matrix. Of primary interest is the effect of the PCM layer on transmission of a mechanical signal $I(t)$ from the chondron boundary to the cell-PCM interface.*

interface problem that models local transmission of mechanical signals in a single chondron. The chondron is idealized to consist of a spherical chondrocyte with an attached spherical layer that represents the PCM (Figure 1.2). Both regions are assumed to be biphasic continua that are isotropic and deforming in small strain. At present, experimental values are available for only the "drained" elastic moduli associated with equilibrated deformation states (where fluid motion has ceased) of isolated chondrocytes [12] and chondrons [1]. Hence, the primary focus of the current study is the effect of the large PCM stiffness, relative to the cell, on mechanical signal transmission through the PCM layer. Given the lack of direct measurements of permeability in the chondron, ranges of permeability in the cell and PCM are estimated (see section 4.2). Enforcement of the boundary and interface conditions results in an eigenvalue problem that is self-adjoint when the permeability of the chondron is assumed to be uniform (i.e., $k_C = k_P$). The resulting characteristic equation is analyzed in the limit of a very stiff PCM layer. Via Duhamel's principle, a series solution is obtained for a time-varying displacement prescribed at the boundary of the chondron. The case $k_C \neq k_P$ is considered using a numerical finite difference solution. These solutions are evaluated for the case of an applied sinusoidal displacement and used to assess the dual role of the PCM as a mechanical signal transmitter and a protective layer via a parametric analysis of radial displacement, solid stress, and strain. Since dissipation time scales are rapid, the transient-free oscillatory response is evaluated as a function of forcing frequency in a range that is representative of dynamic human motion (0–3Hz). Scaled amplitudes of the transient-free displacement and stress signals at the cell-PCM interface are computed as functions of frequency for several values of the material and geometric parameters. The analytical biphasic solution developed herein can also be used to verify the accuracy of biphasic finite element methods that model deformation of soft tissues with material interfaces via penalty methods (e.g., joint contact problems [5]).

2. Reduction of biphasic theory for the case of radial deformation.

2.1. Biphasic governing equations. The modern mixture theories [3], [25] provide a foundation for modeling the mechanics of articular cartilage and other biological soft tissues. In these mixture models, variations in structure and composition within a tissue are quantified via material parameters. The biphasic model [18], [16], based on Bowen's theory of incompressible mixtures [3], has been widely employed in modeling the mechanics of articular cartilage and other orthopedic tissues (e.g., intervertebral disc [11], bone [14], meniscus [20]).

In biphasic models of articular cartilage, the ECM is idealized as a solid phase that is saturated by a second phase of interstitial fluid. This continuum model is valid on scales for which the two phases can be treated as superimposed continua with an interphase drag mechanism [13]. Since the diameter of a chondrocyte is several orders of magnitude larger than the characteristic length scale of the ECM constituents and the cell cytoskeleton, this continuum approach is appropriate for modeling local biphasic cell-matrix mechanics. While biphasic models of cartilage ignore physicochemical effects, they capture essential load-bearing mechanisms including deformation of the tissue matrix, pressurization of the interstitial fluid, and dissipation due to interphase drag.

In this study, flow and deformation in the chondron are modeled using linear biphasic theory [18]. The momentum balance laws for the solid and fluid phases are, respectively,

$$\nabla \cdot \sigma^s + \Pi = \mathbf{0}, \qquad \nabla \cdot \sigma^f - \Pi = \mathbf{0}, \tag{2.1}$$

where σ^s and σ^f are partial Cauchy stress tensors that measure the force per unit mixture area on each phase. The symbol Π denotes a momentum exchange vector that accounts for the interphase drag force as fluid flows past solid in the mixture. Note that, in biphasic models of cartilage, the contribution of inertial terms to the momentum balance equations is negligible as the motion is dominated by elastic deformation and diffusive drag, and occurs at relatively low frequencies. The mixture is assumed to be intrinsically incompressible and saturated, so that

$$\phi \nabla \cdot (\partial_t \mathbf{u}) + (1-\phi)(\nabla \cdot \mathbf{v}) = 0, \tag{2.2}$$

where $\mathbf{u}$ is the solid displacement, $\mathbf{v}$ is the fluid velocity, and ϕ is the solid volume fraction, which is constant in the linear model and typically less than 20%. The solid phase is assumed to be linear elastic and isotropic, the fluid phase is assumed to be inviscid, and the momentum exchange is assumed to be due to Darcy's Law. The resulting constitutive laws are

$$\sigma^s = -\phi p \mathbf{I} + \lambda \mathrm{tr}(\mathbf{e})\mathbf{I} + 2\mu \mathbf{e}, \qquad \sigma^f = -(1-\phi)p\mathbf{I}, \qquad \Pi = K(\mathbf{v} - \partial_t \mathbf{u}), \tag{2.3}$$

where $\mathbf{I}$ is the identity tensor, p is a pore pressure used to enforce the incompressibility constraint (2.2), $\mathbf{e}(= 1/2(\nabla \mathbf{u} + \nabla \mathbf{u}^T))$ is the infinitesimal strain tensor, λ, μ are Lamé coefficients for the solid phase, and K is a diffusive drag coefficient. The Lamé coefficients λ, μ are associated with drained elastic equilibrium states that occur under static loading when all fluid flow has ceased in the mixture. An alternate set of elastic moduli are the Young's modulus E and Poisson ratio ν $(0 \le \nu < 0.5)$, where $\mu = \frac{E}{2(1+\nu)}$ and $\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)}$.

By substituting (2.3) into (2.1), the governing equations (2.1) and (2.2) constitute a system of seven equations in the seven unknowns $\mathbf{u}, \mathbf{v}, p$. The fluid velocity $\mathbf{v}$ is

eliminated to yield the reduced system of four equations in the four unknowns $\mathbf{u}, p$:

$$\partial_t(\nabla\cdot\mathbf{u}) = k\nabla^2 p, \qquad \mu\left[\frac{1}{1-2\nu}\nabla(\nabla\cdot\mathbf{u}) + \nabla^2\mathbf{u}\right] = \nabla p, \tag{2.4}$$

where $k = \frac{(1-\phi)^2}{K}$ is the *permeability*. The fluid velocity is then given by

$$\mathbf{v} = \partial_t\mathbf{u} - \frac{1-\phi}{K}\nabla p. \tag{2.5}$$

Based on in situ testing of intact cartilage from knee joints, typical mean values for the ECM material parameters in the linear biphasic model are known to vary with both site and species. In [2], mean parameter values in normal human knees were found to lie in the ranges $H^A \equiv \lambda + 2\mu = 0.53$-$0.70$MPa, $\nu = 0.00$-0.10 and $k = 1.18$-$2.17 \times 10^{-15}\mathrm{m}^4/\mathrm{N}\cdot\mathrm{s}$.

2.2. Boundary and interface conditions. On a bounded biphasic domain Ω, a boundary value problem is obtained by solving (2.4) subject to boundary conditions that prescribe values of the pore pressure p, and solid displacement $\mathbf{u}$ or mixture traction vector $\mathbf{t} = (\sigma^s + \sigma^f)\cdot\mathbf{n}$ on the boundary $\partial\Omega$ with unit outward normal $\mathbf{n}$. When Ω contains an internal interface Γ with unit outward normal $\mathbf{n}$, the following biphasic interface conditions are enforced on Γ [10]:

$$[[\mathbf{u}]] = \mathbf{0}, \qquad [[p]] = 0, \qquad [[\lambda\mathrm{tr}(\mathbf{e})\mathbf{I} + 2\mu\mathbf{e}]]\cdot\mathbf{n} = \mathbf{0}, \qquad [[k\nabla p]]\cdot\mathbf{n} = 0, \tag{2.6}$$

where $[[\bullet]] \equiv (\bullet)_+ - (\bullet)_-$. Since the first two relations in (2.6) require continuous displacement and pressure, respectively, the last two relations provide four equations for the four unknown quantities on the interface Γ.

2.3. Reduced equations for the case of radial deformation. Let $\mathbf{r} = (\rho, \theta, \phi)$ denote a spherical coordinate system. A radial biphasic model for chondron deformation is developed by assuming that the displacement $\mathbf{u}(\mathbf{r}, t)$ has only a radial component and that the displacement and pressure $p(\mathbf{r}, t)$ vary only in the radial direction ρ. Hence,

$$\mathbf{u}(\mathbf{r}, t) = (u(\rho, t), 0, 0), \qquad p(\mathbf{r}, t) = p(\rho, t). \tag{2.7}$$

Substituting into the first relation of (2.4) and integrating, we arrive at

$$\partial_\rho p = k^{-1}\partial_t u - \rho^{-2}c(t), \tag{2.8}$$

where $c(t)$ is an arbitrary function of time. Substituting (2.7) into the second relation of (2.4) and using (2.8) yield

$$\partial_t u = kH^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho u) - 2\rho^{-2}u\right) + k\rho^{-2}c(t), \tag{2.9}$$

where $H^A = \lambda + 2\mu$ is called the *aggregate modulus*. For the radial chondron model, equations (2.8)–(2.9) are the reduced governing equations for the unknown displacement $u(\rho, t)$ and pore pressure $p(\rho, t)$.

In order to integrate (2.8), first take the divergence of the second relation in (2.4) to obtain

$$\nabla^2 p = H^A\nabla^2(\nabla\cdot\mathbf{u}). \tag{2.10}$$

It then follows that $p = H^A(\nabla\cdot\mathbf{u})+\psi$, where ψ is harmonic. Substituting this relation for p into (2.8) and using (2.9), one obtains

$$H^A\partial_\rho(\rho^{-2}\partial_\rho(\rho^2 u)) + \partial_\rho\psi = H^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho u) - 2\rho^{-2}u\right)$$

which simplifies to $\partial_\rho\psi = 0$. Hence the pore pressure is given by

$$p = H^A(2\rho^{-1}u + \partial_\rho u) + f(t), \tag{2.11}$$

where $f(t)$ is an arbitrary function of time.

3. Radial biphasic model of a chondron. A chondron consists of a single cell (chondrocyte) that is encapsulated by a PCM layer. For this initial model of chondron mechanics, a spherical geometry is assumed in which a biphasic cell is surrounded by an attached biphasic layer that represents the PCM (Figure 1.2). The displacement $\mathbf{u}$ and velocity $\mathbf{v}$ are assumed to be nonzero in only the radial direction and depend only on the radial coordinate ρ and time t. Consequently, the reduced biphasic equations of section 2.3 apply.

This study focuses on the use of biphasic solutions to model the effect of the large PCM-to-cell modulus ratio on signal transmission from the ECM to the cell via the PCM layer. Recent micropipette experiments on isolated chondrons indicated that the PCM was much stiffer than the chondrocyte in healthy human cartilage (mean $H_C^A/H_P^A = 0.044$), but that the PCM stiffness decreased significantly in the osteoarthritic group (mean $H_C^A/H_P^A = 0.071$) [1]. The biphasic solutions considered herein enable a parametric analysis that can provide insight into the effect of tissue degradation, and subsequent loss of PCM stiffness, on mechanical signal transmission in the chondron. A secondary benefit is that the analytical solution in the case $k_C = k_P$ can be used to verify the accuracy of biphasic finite element codes that employ penalty methods (e.g., [5]) to enforce the interface conditions (2.6).

3.1. Governing equations. The radial biphasic interface problem for mechanical signal transmission in a chondron is now formulated. In the cell ($0 \le \rho \le a$), the requirement that the solid velocity $\partial_t u$ is bounded at $\rho = 0$ implies that $c(t) \equiv 0$ in (2.9). In addition, the first relation in (2.6) implies that $\partial_t u$ is continuous at $\rho = a$. By (2.8), the last relation in (2.6) will then be satisfied provided that $c(t) \equiv 0$ for $a < \rho \le b$. Hence the reduced governing equations (2.9) and (2.11) are, respectively,

$$\partial_t u = \begin{cases} k_C H_C^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho u) - 2\rho^{-2}u\right), & 0 \le \rho \le a, \\ k_P H_P^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho u) - 2\rho^{-2}u\right), & a < \rho \le b, \end{cases} \quad t > 0, \tag{3.1}$$

$$p = \begin{cases} H_C^A(2\rho^{-1}u + \partial_\rho u) + f_C(t), & 0 \le \rho \le a, \\ H_P^A(2\rho^{-1}u + \partial_\rho u) + f_P(t), & a < \rho \le b, \end{cases} \quad t > 0. \tag{3.2}$$

The subscripts C and P denote quantities associated with the chondrocyte and PCM, respectively.

At this point, it is observed that the pressure $p(\rho, t)$ and displacement $u(\rho, t)$ are uncoupled in the reduced governing equations (3.1)–(3.2). The diffusion equation (3.1) can be solved on $0 \le \rho \le b$ subject to the first and third jump conditions of (2.6) at $\rho = a$, and a time-varying displacement boundary condition at $\rho = b$. The pressure is then obtained from (3.2), where $f_C(t)$ and $f_P(t)$ are used to satisfy the second jump condition of (2.6) at $\rho = a$, and to satisfy a pressure boundary condition at $\rho = b$. Note that satisfaction of the fourth jump condition in (2.6) follows from (2.8) by displacement continuity at $\rho = a$ and the fact that $c(t) = 0$ for $0 \le \rho \le b$.

3.2. Reduction to an eigenvalue problem in the case $k_C = k_P$. Consider separable solutions $u(\rho,t) = e^{-\gamma t}\phi(\rho)$ of (3.1). Substitution and separation of variables leads to the following eigenvalue problem for the eigenvalue-eigenfunction pair (γ,ϕ):

$$L\phi = \gamma\phi, \quad \text{where} \quad L \equiv \begin{cases} k_C H_C^A \rho^{-2}\left[\partial_\rho(\rho^2\partial_\rho) - 2\right], & 0 \le \rho \le a, \\ k_P H_P^A \rho^{-2}\left[\partial_\rho(\rho^2\partial_\rho) - 2\right], & a < \rho \le b. \end{cases} \tag{3.3}$$

In this study, the signal transmission problem is considered for a time-varying displacement $u(b,t)$ prescribed at the outer PCM boundary. The prescribed displacement models the arrival of a mechanical signal from the ECM at the boundary of the chondron. Since displacement is prescribed, a homogeneous boundary condition is employed for the eigenfunction ϕ at $\rho = b$ (time-dependence is incorporated via Duhamel's principle in section 3.3.1). Along with the homogeneous boundary condition, the first and third jump conditions in (2.6) give

$$\phi(b) = 0, \qquad \phi(a^+) = \phi(a^-), \qquad H_P^A \phi'(a^+) - H_C^A \phi'(a^-) = \frac{2(\lambda_C - \lambda_P)}{a}\phi(a). \tag{3.4}$$

Note that the third relation in (3.4) has been obtained from the third condition in (2.6) by employing the second relation in (3.4), where $\phi(a) \equiv \phi(a^+) = \phi(a^-)$.

It is straightforward to show that the operator L in (3.3) is self-adjoint in the special case where the permeability of the cell k_C is equal to the permeability of the PCM k_P (see Appendix A). In this case, all eigenvalues $\gamma_j (j = 1, 2, \dots)$ of the eigenvalue problem (3.3)–(3.4) are real and distinct, the corresponding eigenfunctions $\phi_j (j = 1, 2, \dots)$ are orthogonal, and the common value of the permeability is denoted by k.

Eigenfunctions for the eigenvalue problem (3.3)–(3.4) are constructed via the following representation based on spherical Bessel functions that satisfy (3.3):

$$\phi_j = \begin{cases} \frac{kH_C^A}{\gamma_j \rho^2}\left[\sin\left(\sqrt{\frac{\gamma_j}{kH_C^A}}\rho\right) - \sqrt{\frac{\gamma_j}{kH_C^A}}\rho\cos\left(\sqrt{\frac{\gamma_j}{kH_C^A}}\rho\right)\right], & 0 \le \rho \le a, \\ \frac{\delta_j kH_P^A}{\gamma_j \rho^2}\left[\sin\left(\sqrt{\frac{\gamma_j}{kH_P^A}}(\rho+\kappa_j)\right) - \sqrt{\frac{\gamma_j}{kH_P^A}}\rho\cos\left(\sqrt{\frac{\gamma_j}{kH_P^A}}(\rho+\kappa_j)\right)\right], & a < \rho \le b. \end{cases} \tag{3.5}$$

In (3.5), κ_j and δ_j are constants that are used to satisfy the interface conditions (3.4). Using (3.5) in the first condition of (3.4) gives

$$\kappa_j = \sqrt{\frac{kH_P^A}{\gamma_j}}\tan^{-1}\left(\sqrt{\frac{\gamma_j}{kH_P^A}}b\right) - b. \tag{3.6}$$

The second condition in (3.4) gives

$$\delta_j = \frac{H_C^A}{H_P^A}\frac{\sin\left(\sqrt{\frac{\gamma_j}{kH_C^A}}a\right) - \sqrt{\frac{\gamma_j}{kH_C^A}}a\cos\left(\sqrt{\frac{\gamma_j}{kH_C^A}}a\right)}{\sin\left(\sqrt{\frac{\gamma_j}{kH_P^A}}(a+\kappa_j)\right) - \sqrt{\frac{\gamma_j}{kH_P^A}}a\cos\left(\sqrt{\frac{\gamma_j}{kH_P^A}}(a+\kappa_j)\right)}. \tag{3.7}$$

Lastly, (3.5) is substituted into the last condition of (3.4). Using (3.6) and (3.7), the constants κ_j and δ_j are eliminated and, after some manipulation, the following nondimensional characteristic equation for the scaled eigenvalues $\bar{\gamma}_j = \frac{\gamma_j a^2}{kH_C^A}$ is obtained:

$$\begin{aligned}&\left[\bar{F}_1(\bar{\gamma})\sin\left(\sqrt{\bar{\gamma}}\right) + \bar{F}_3(\bar{\gamma})\cos\left(\sqrt{\bar{\gamma}}\right)\right]\sin\left(\frac{b-a}{a}\sqrt{\epsilon_1\bar{\gamma}}\right)\\ &\quad + \left[\bar{F}_2(\bar{\gamma})\cos\left(\sqrt{\bar{\gamma}}\right) + \bar{F}_4(\bar{\gamma})\sin\left(\sqrt{\bar{\gamma}}\right)\right]\cos\left(\frac{b-a}{a}\sqrt{\epsilon_1\bar{\gamma}}\right) = 0,\end{aligned} \tag{3.8}$$

where

$$\begin{aligned}\bar{F}_1(\bar{\gamma}) &= -4\epsilon_1(\beta_P - \epsilon_2) - \frac{4b}{a}\bar{\gamma}\epsilon_1^2(\beta_P - \epsilon_2) - \frac{b}{a}\bar{\gamma}^2\epsilon_1^3,\\ \bar{F}_2(\bar{\gamma}) &= -\frac{4(b-a)}{a}\bar{\gamma}\epsilon_1^{3/2}(\beta_P - \epsilon_2) + \frac{b}{a}\bar{\gamma}^2\epsilon_1^{5/2},\\ \bar{F}_3(\bar{\gamma}) &= 4\bar{\gamma}^{1/2}\epsilon_1(\beta_P - \epsilon_2) + \left(\frac{4b}{a}\beta_P - 1\right)\bar{\gamma}^{3/2}\epsilon_1^2 - \frac{4b}{a}\bar{\gamma}^{3/2}\epsilon_1^2\epsilon_2,\\ \bar{F}_4(\bar{\gamma}) &= \frac{4(b-a)}{a}\bar{\gamma}^{1/2}\epsilon_1^{3/2}(\beta_P - \epsilon_2) - \bar{\gamma}^{3/2}\epsilon_1^{5/2},\end{aligned}$$

$\beta_P = \frac{\mu_P}{H_P^A}$, $\epsilon_1 = \frac{H_C^A}{H_P^A}$, and $\epsilon_2 = \frac{\mu_C}{H_P^A}$.

Note that the eigenvalues have been scaled by the quantity $t_C \equiv a^2/(kH_C^A)$, which is the gel relaxation time [17] for the chondrocyte.

Given that the PCM is much stiffer than the chondrocyte, the characteristic equation (3.8) is analyzed in the regime where $\epsilon_1 \ll 1$. Using (3.8), it is straightforward to show that, to leading-order, the eigenvalues $\bar{\gamma}^{(0)}$ satisfy $\sin(\sqrt{\bar{\gamma}^{(0)}}) - \sqrt{\bar{\gamma}^{(0)}}\cos(\sqrt{\bar{\gamma}^{(0)}}) = 0$. The eigenvalues $\bar{\gamma}_j^{(0)}$ are well separated (e.g., $\bar{\gamma}_1^{(0)} \approx 20.19$, $\bar{\gamma}_2^{(0)} \approx 59.68$, $\bar{\gamma}_3^{(0)} \approx 118.90$) and, as $j \to \infty$, $\bar{\gamma}_j \sim (j + 1/2)^2\pi^2$ with separation $\Delta\bar{\gamma}_j = \bar{\gamma}_j - \bar{\gamma}_{j-1} \sim 2j\pi^2$. As the ratio ϵ_1 increases up to 0.1, the separation of the eigenvalues does not deviate far away from this asymptotic behavior. Hence, the first N roots of the characteristic equation (3.8) are readily obtained in MAPLE using the fsolve routine.

It is noted that the smallest leading-order eigenvalue $\bar{\gamma}_1^{(0)}$ represents a characteristic diffusion time t_P for stress relaxation in the chondron. Comparison to the biphasic gel relaxation time for the cell t_C indicates that

$$t_P = \frac{1}{\gamma_1} \sim \frac{1}{\bar{\gamma}_1}\frac{a^2}{kH_C^A} \approx 0.04953\frac{a^2}{kH_C^A} = (0.04953)t_C. \tag{3.9}$$

Hence, the radial chondron model indicates that the presence of a stiff PCM layer encapsulating the chondrocyte reduces the biphasic gel relaxation time by a factor of 20. This result is consistent with the functional role of the PCM as a mechanical signal transmitter. Components of the transient deformation are dissipated on time scales that are much faster than the typically lengthy relaxation times associated with stress diffusion in the ECM of articular cartilage. Hence, in the context of forced dynamic loading of a cartilage layer, it is likely that the transient-free oscillatory response is the dominant component of the mechanical signal that is transmitted to the chondrocyte.

3.3. Signal transmission model. The solution of (3.1)–(3.2) subject to a time-dependent displacement boundary condition at $\rho = b$ is now considered. At the cell-PCM interface ($\rho = a$) the first and third jump conditions in (2.6) reduce to

(3.10)
$$u(a^+,t) = u(a^-,t), \;\; H_P^A \partial_\rho u(a^+,t) - H_C^A \partial_\rho u(a^-,t) = \frac{2}{a}(\lambda_C - \lambda_P)u(a,t), \;\; t > 0,$$

respectively. The displacement must be zero at $\rho = 0$, and a time-dependent displacement signal is prescribed at the outer cell boundary:

$$u(0,t) = 0, \qquad u(b,t) = I(t), \qquad t > 0. \tag{3.11}$$

The chondron is also assumed to be free of displacement at $t = 0$ so that $u(\rho,0) = 0$ ($0 \le \rho \le b$). The second boundary condition in (3.11) models the arrival of a mechanical signal at the interface between the chondron and ECM. Clearly, the assumption of purely radial deformation is a simplification that facilitates a parametric analysis of signal transmission in the chondron. In reality, the relationship between local mechanics at the cellular scale and external loading of a cartilage layer is highly complex, requiring the solution of the three-dimensional biphasic equations at multiple length scales. As such, the applied displacement signal $I(t)$ is interpreted as a radial displacement averaged over the surface of the interface between the chondron and the extracellular matrix.

3.3.1. Series solution in the case $k_C = k_P$. The homogeneous differential equation (3.1), subject to the time-dependent boundary condition in (3.11), is transformed to a nonhomogeneous equation with a homogeneous boundary condition by writing $u(\rho,t) = v(\rho,t) + w(\rho,t)$, where

$$w(\rho,t) = I(t) \begin{cases} \alpha_3 \rho^2, & 0 \le \rho \le a, \\ \alpha_1 \rho^2 + \alpha_2 \rho, & a < \rho \le b. \end{cases} \tag{3.12}$$

The coefficients $\alpha_1, \alpha_2, \alpha_3$ are chosen such that $w(\rho,t)$ satisfies the interface conditions (3.10) and boundary conditions (3.11). They are

$$\alpha_1 = \frac{H_P^A - 2H_C^A - 2\lambda_C + 2\lambda_P}{b\chi}, \quad \alpha_2 = \frac{2a(H_C^A - H_P^A + \lambda_C - \lambda_P)}{b\chi}, \quad \alpha_3 = \frac{-H_P^A}{b\chi},$$

where $\chi = (b-2a)H_P^A + 2(b-a)(-H_C^A + \lambda_P - \lambda_C)$. The function $v(\rho,t)$ then satisfies the nonhomogeneous equation

$$\partial_t v = \begin{cases} kH_C^A \left(\rho^{-2}\partial_\rho(\rho^2 \partial_\rho v) - 2\rho^{-2} v\right) + h_C(\rho,t), & 0 \le \rho \le a, \\ kH_P^A \left(\rho^{-2}\partial_\rho(\rho^2 \partial_\rho v) - 2\rho^{-2} v\right) + h_P(\rho,t), & a < \rho \le b, \end{cases} \quad t > 0, \tag{3.13}$$

where the functions $h_C(\rho,t), h_P(\rho,t)$ are given by

$$h_C(\rho,t) = 4kH_C^A \alpha_3 I(t) - \alpha_3 \rho^2 I'(t), \qquad h_P(\rho,t) = 4kH_P^A \alpha_1 I(t) - (\alpha_1 \rho^2 + \alpha_2 \rho) I'(t).$$

Equation (3.13) is solved subject to the interface conditions

(3.14)
$$v(a^+,t) = v(a^-,t), \;\; H_P^A \partial_\rho v(a^+,t) - H_C^A \partial_\rho v(a^-,t) = \frac{2}{a}(\lambda_C - \lambda_P)v(a,t), \;\; t > 0,$$

the homogeneous boundary conditions

$$v(0,t)=0, \qquad v(b,t)=0, \qquad t>0, \tag{3.15}$$

and the modified initial condition

$$v(\rho,0)=-w(\rho,0), \qquad 0\le\rho\le b. \tag{3.16}$$

The solution of (3.13)–(3.16) is then obtained via Duhamel's principle [4]. Let

$$v(\rho,t)=\int_0^t \tilde{v}(\rho,t-s;s)ds, \tag{3.17}$$

where the new function $\tilde{v}(\rho,t;s)$ satisfies the homogeneous equation

$$\partial_t\tilde{v}=\begin{cases} kH_C^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho\tilde{v})-2\rho^{-2}\tilde{v}\right), & 0\le\rho\le a,\\ kH_P^A\left(\rho^{-2}\partial_\rho(\rho^2\partial_\rho\tilde{v})-2\rho^{-2}\tilde{v}\right), & a<\rho\le b, \end{cases} \qquad t>0 \tag{3.18}$$

subject to the interface conditions

$$\tilde{v}(a^+,t)=\tilde{v}(a^-,t),\ H_P^A\partial_\rho\tilde{v}(a^+,t)-H_C^A\partial_\rho\tilde{v}(a^-,t)=\frac{2}{a}(\lambda_C-\lambda_P)\tilde{v}(a,t),\ t>0, \tag{3.19}$$

the homogeneous boundary conditions

$$\tilde{v}(0,t)=0, \qquad \tilde{v}(b,t)=0, \qquad t>0, \tag{3.20}$$

and the initial condition

$$\tilde{v}(\rho,0;s)=-w(\rho,0)+\begin{cases} h_C(\rho,s), & 0\le\rho\le a,\\ h_P(\rho,s), & a<\rho\le b. \end{cases} \tag{3.21}$$

Assuming separable solutions, $\tilde{v}(\rho,t;s)=e^{-\gamma t}\phi(\rho)$, the eigenfunctions $\phi_j(j=1,2,\dots)$ and the eigenvalues $\gamma_j(j=1,2,\dots)$ are those of section 3.2. Hence, the solution of the time-dependent mechanical signal transmission model (3.1), (3.11) is given by

$$u(\rho,t)=w(\rho,t)+\sum_{j=1}^{\infty}\left[\int_0^t c_j(s)e^{\gamma_j s}ds\right]e^{-\gamma_j t}\phi_j(\rho), \tag{3.22}$$

where $w(\rho,t)$ is given by (3.12) and

$$c_j(s)=\frac{\langle h(\rho,s),\phi_j(\rho)\rangle}{\langle\phi_j(\rho),\phi_j(\rho)\rangle}, \quad h(\rho,s)=-w(\rho,0)+\begin{cases} h_C(\rho,s), & 0\le\rho\le a,\\ h_P(\rho,s), & a<\rho\le b. \end{cases} \tag{3.23}$$

Recall that the inner product in (3.23) is defined as $\langle f,g\rangle=\int_0^b f(s)g(s)s^2ds$. Once the displacement solution is known, a series solution for the pore pressure $p(\rho,t)$ (see (2.11)) is obtained by substitution of (3.22) into

$$p(\rho,t)=\begin{cases} H_C^A\left[2\rho^{-1}u(\rho,t)+\partial_\rho u(\rho,t)\right]+f_C(t), & 0\le\rho\le a,\\ H_P^A\left[2\rho^{-1}u(\rho,t)+\partial_\rho u(\rho,t)\right]+f_P(t), & a<\rho\le b. \end{cases} \tag{3.24}$$

The function $f_P(t)$ is used to match the pore pressure to a prescribed function $p_0(t)$ at $\rho = b$, so that

$$f_P(t) = p_0(t) - H_P^A \left[2b^{-1} I(t) + \partial_\rho u(b,t)\right]. \tag{3.25}$$

The function $f_C(t)$ is used to satisfy the second condition in (2.6) and is given by

$$f_C(t) = f_P(t) + 2a^{-1}(H_P^A - H_C^A)u(a,t) + H_P^A \partial_\rho u(a^+,t) - H_C^A \partial_\rho u(a^-,t). \tag{3.26}$$

From (3.22) and (3.24), series solutions for the partial stress components σ^s and σ^f in (2.3) and the fluid-phase velocity, $\mathbf{v}$, in (2.5) can also be obtained by substitution.

3.3.2. Finite difference solution in the case $k_C \neq k_P$. The governing displacement equation (3.1) is rewritten as

$$\partial_t u = r\left(\partial_\rho^2 u + 2\rho^{-1}\partial_\rho u - 2\rho^{-2}u\right), \qquad 0 < \rho < b, \quad \text{where } r = \begin{cases} k_C H_C^A & 0 < \rho < a, \\ k_P H_P^A & a < \rho < b. \end{cases} \tag{3.27}$$

Equation (3.27) was solved numerically using a finite difference method on a regular spatial mesh subject to the boundary conditions (3.11) and the interface conditions (3.10). In the discretization, backward and centered finite difference approximations were employed in time and space, respectively, at all interior mesh points except those immediately to the left and right of the interface at $\rho = a$, where the interface conditions (3.10) were enforced. The details of the numerical scheme employed to obtain the displacement solution are presented in Appendix B. Via first-order finite difference approximations of the spatial derivative of displacement, the radial strain $\partial_\rho u$, pore pressure (3.24), and solid stress (2.3) were evaluated once the displacement solution was obtained. The accuracy of the finite difference scheme was verified in the case $k_C = k_P$ by comparison to the analytical solution presented in section 3.3.1.

4. Application: Parametric analysis for a sinusoidal displacement.

4.1. Transient-free displacement solution. Deformation of the chondron was simulated for a prescribed sinusoidal displacement with amplitude u_0 and frequency ω at the outer PCM boundary:

$$u(b,t) = I(t) = u_0 \sin(\omega t), \quad t > 0. \tag{4.1}$$

This boundary condition models the arrival of a mechanical signal at the PCM-ECM interface under conditions of dynamic external loading of a joint.

In the case $k_C = k_P = k$, the function $h(\rho, s)$ in (3.23) reduces to

$$h(\rho, s) = u_0 \left[h_1(\rho)\sin(\omega s) + h_2(\rho)\cos(\omega s)\right],$$

where

$$h_1(\rho) = \begin{cases} 4kH_C^A\alpha_3, & 0 \le \rho \le a, \\ 4kH_P^A\alpha_1, & a < \rho \le b, \end{cases} \qquad h_2(\rho) = \begin{cases} -\alpha_3\omega\rho^2, & 0 \le \rho \le a, \\ -\omega(\alpha_1\rho^2 + \alpha_2\rho), & a < \rho \le b. \end{cases}$$

Hence, the coefficients $c_j(s)$ in (3.22)–(3.23) are given by

$$c_j(s) = \frac{u_0}{A_j}\left[A_j^{(1)}\sin(\omega s) + A_j^{(2)}\cos(\omega s)\right], \tag{4.2}$$

where

$$A_j^{(1)} = \langle h_1(\rho), \phi_j(\rho)\rangle,\ A_j^{(2)} = \langle h_2(\rho), \phi_j(\rho)\rangle,\ A_j = \langle \phi_j(\rho), \phi_j(\rho)\rangle. \tag{4.3}$$

Substituting these relations into (3.22), the following series solution is obtained for the case of a prescribed sinusoidal displacement:

$$\frac{u(\rho,t)}{u_0} = v_{tr}(\rho,t) + v_\infty(\rho,t) + \sin(\omega t)\begin{cases} \alpha_3\rho^2, & 0 \le \rho \le a, \\ \alpha_1\rho^2 + \alpha_2\rho, & a < \rho \le b, \end{cases} \tag{4.4}$$

where

$$v_{tr}(\rho,t) = \sum_{j=1}^{\infty} \frac{\omega A_j^{(1)} - \gamma_j A_j^{(2)}}{A_j(\gamma_j^2+\omega^2)} e^{-\gamma_j t}\phi_j(\rho), \tag{4.5}$$

$$v_\infty(\rho,t) = \sum_{j=1}^{\infty} \left[\frac{\gamma_j A_j^{(1)} + \omega A_j^{(2)}}{A_j(\gamma_j^2+\omega^2)} \sin(\omega t) + \frac{-\omega A_j^{(1)} + \gamma_j A_j^{(2)}}{A_j(\gamma_j^2+\omega^2)} \cos(\omega t) \right] \phi_j(\rho). \tag{4.6}$$

In (4.4), $v_{tr}(\rho,t)$ is the scaled transient displacement that, for a stiff PCM layer, tends to zero rapidly as $t \to \infty$. Consequently, the parametric analysis was based on evaluation of the steady displacement in a range of frequencies (0–3Hz) that is typical of human joint motion.

In the case $k_C \neq k_P$, the finite difference solution of section 3.3.2 was employed to evaluate transient-free deformation in the chondron. The time-marching method was allowed to run until a steady state deformation signal was obtained with amplitude that changed by less than 1%. Via a mesh refinement analysis in the case $k_C = k_P$, it was established that a spatial mesh resolution of $M = 300$ and a time step of $\Delta t = 1/300$ were sufficient for obtaining graphs in the parametric analysis that were indistinguishable in the two cases.

4.2. Parametric analysis. We employed the analytical and finite difference solutions in a parametric analysis of mechanical signal transmission through the PCM layer. Transient-free radial displacement, solid stress, and radial strain were used to assess the functional role of the PCM as a layer that facilitates transmission of mechanical signals to the chondrocyte and, simultaneously, protects the cell from excessive forces. In the parametric analysis, the PCM Young's modulus was varied in the range E_P = 10–100kPa, with particular attention to the mean measured values for normal (E_P = 66.5kPa) and OA (E_P = 41.3kPa) human chondrons obtained in a recent micropipette aspiration study [1]. Values of the Young's modulus for the cell, and the Poisson ratio for the cell and PCM were taken as E_C = 1kPa, $\nu_C = 0.43$ and $\nu_P = 0.04$, respectively [1]. Reference values for the radii of the chondrocyte and chondron were taken as $a = 10\mu$m and $b = 12.5\mu$m, respectively, and the solid volume fraction was $\phi_C = \phi_P = 0.17$ [6]. The amplitude of the prescribed displacement signal was chosen as $u_0 = (b-a)/10$.

To date, only limited estimates of permeability in the chondrocyte and PCM are available. In a micropipette analysis of creep deformation of isolated normal and OA human chondrocytes using a viscoelastic half-space model [24], a rough estimate of chondrocyte permeability on the order of 10^{-15}m^4/N·s was obtained using a characteristic creep time based on the biphasic gel relaxation time [18]. A more direct measurement of cellular permeability for osteoblast-like cells, via cytoindentation, found a much larger permeability on the order of 10^{-10}m^4/N·s [19]. While no direct

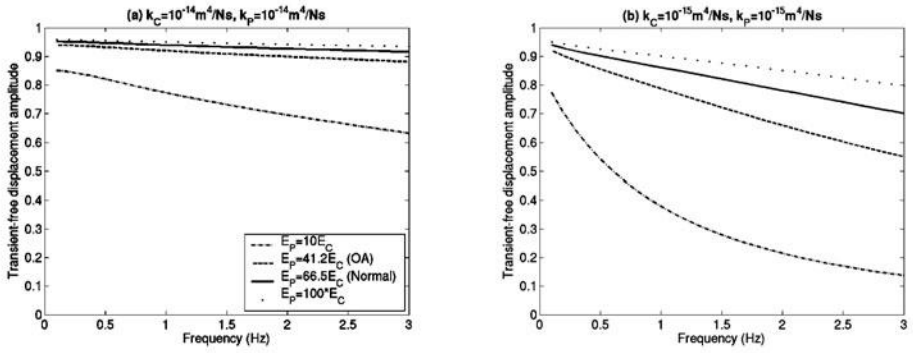

FIG. 4.1. *Scaled amplitude, $A(\omega)$, of the transient-free displacement at the cell-PCM interface* (4.7) *for frequencies in the range* 0–3*Hz in the case* $k_C = k_P$. (a) $k_C = k_P = 10^{-14} m^4/N{\cdot}s$; (b) $k_C = k_P = 10^{-15} m^4/N{\cdot}s$.

measurements of PCM permeability are currently available, given its composition, it is reasonable to assume that k_P should not deviate by more than a few orders of magnitude from the permeability of cartilage ECM (i.e., $\sim 10^{-15}\mathrm{m}^4/\mathrm{N}{\cdot}\mathrm{s}$). Based on these observations, the range of permeability for the parametric analysis was chosen as $(k_C, k_P) = (10^{-15}\text{–}10^{-12}, 10^{-16}\text{–}10^{-14})\mathrm{m}^4/\mathrm{N}{\cdot}\mathrm{s}$.

4.2.1. Transmission of displacement. To assess the role of the PCM as a transmissive layer that encapsulates the chondrocyte, the scaled amplitude of the transient-free displacement at the cell-PCM interface

$$A(\omega) = \frac{\mathrm{Amp}(u_\infty(a,t))}{u_0} \tag{4.7}$$

was evaluated. In the case $k_C = k_P$, $A(\omega)$ is given by the following series obtained from (4.4):

$$A(\omega) \approx \sqrt{\left(\alpha_3 a^2 + \sum_{j=1}^{N} \frac{\gamma_j A_j^{(1)} + \omega A_j^{(2)}}{A_j(\gamma_j^2+\omega^2)}\phi_j(a)\right)^2 + \left(\sum_{j=1}^{N} \frac{-\omega A_j^{(1)} + \gamma_j A_j^{(2)}}{A_j(\gamma_j^2+\omega^2)}\phi_j(a)\right)^2},$$

where the infinite series was truncated at N terms. The decay in series coefficients is governed by the magnitude of the eigenvalues γ_j with increasing j. Given that the eigenfunctions $\phi_j(\rho)$ are $O(\gamma_j^{-1/2})$ as $j \to \infty$, it is straightforward to show that terms in the sums of $A(\omega)$ are $O(\gamma_j^{-1})$ as $j \to \infty$. The scaled amplitude $A(\omega)$ was evaluated in MAPLE for 30 frequencies in the range 0–3Hz, which is typical of human joint motion. Numerical convergence of $A(\omega)$ to a tolerance of 10^{-3} was achieved with $N = 100$ terms of the series. In the case $k_C \neq k_P$, $A(\omega)$ was computed by allowing the finite difference method to proceed until the amplitude of the displacement changed by less than 1% between successive periods of the oscillation.

In the case $k_C = k_P$, plots of scaled amplitude $A(\omega)$ versus forcing frequency $f = \omega/(2\pi)$, for the range of parameters considered, are shown in Figure 4.1. When plotted on the same graph, curves obtained using the numerical solution were indistinguishable from those obtained using the analytical series solution. It is observed that a highly stiff PCM layer preserves transmission of a transient-free time-varying

TABLE 4.1

mechanical signal to the chondrocyte. Transmission is excellent for a permeability of 10^{-14}m^4/N·s in that over 90% signal amplitude is retained in the normal model (Figure 4.1(a)), with a slight decrease in transmission for the OA model and little sensitivity to frequency. As the permeability is decreased by one order of magnitude, transmission is moderately reduced, decreases with increasing frequency, and is more sensitive to the reduction in E_P observed for OA human chondrons (Figure 4.1(b)). An analysis of $A(\omega)$, over the full range of permeabilities under consideration, was conducted and is summarized via range intervals for $A(\omega)$ in Table 4.1. In the normal chondron model, it is observed that $A(\omega)$ is in excess of 75% in the range $(k_C, k_P) = (10^{-14}$–$10^{-12}, 10^{-15}$–$10^{-14})$m^4/N·s, and drops significantly as k_P is reduced to 10^{-16}m^4/N·s. In this regime, ranges of $A(\omega)$ are more sensitive to k_P than to k_C. In the range $(k_C, k_P) = (10^{-13}$–$10^{-12}, 10^{-14})$m^4/N·s, the displacement is almost fully transmitted through the PCM and there are no differences in $A(\omega)$ for the OA model. By contrast, when k_P is reduced to 10^{-15}m^4/N·s, a significant drop in $A(\omega)$ is observed for the OA model. These simulations suggest that a PCM permeability that is 1–10 times the permeability of cartilage ECM is consistent with excellent displacement signal transmission through the PCM for normal human chondrons.

4.2.2. Transmission of solid stress. In regimes where displacement signals are well transmitted through the PCM, it is important to evaluate the magnitude of forces on the chondrocyte. A parametric analysis of stress amplitude can indicate the extent to which the PCM serves as a protective layer for the cell. To this end, the displacement solution and resulting pore pressure (3.24) were substituted into the first relation of (2.3) to evaluate the solid stress at the chondron boundary and at the cell-PCM interface. These stress values were used to compute the transient-free solid stress amplitude ratio

$$S(\omega) = \frac{\mathrm{Amp}(\sigma^s_\infty(a,t))}{\mathrm{Amp}(\sigma^s_\infty(b,t))}. \tag{4.8}$$

The independently prescribed part of the pore pressure at the chondron boundary, which would result from transmission of mechanical signals via the ECM to the chondron, was taken to be zero (i.e., $p_0(t) \equiv 0$) in both the numerator and denominator of (4.8). The ratio $S(\omega)$ provides a measure of the extent to which a stress signal that arrives at the chondron is dissipated as it is transmitted through the PCM. The solid stress was chosen as the measure since it is an indicator of forces that are transmitted to intracellular components (e.g., cytoskeleton, nucleus, organelles), which could be adversely affected by excessive forces.

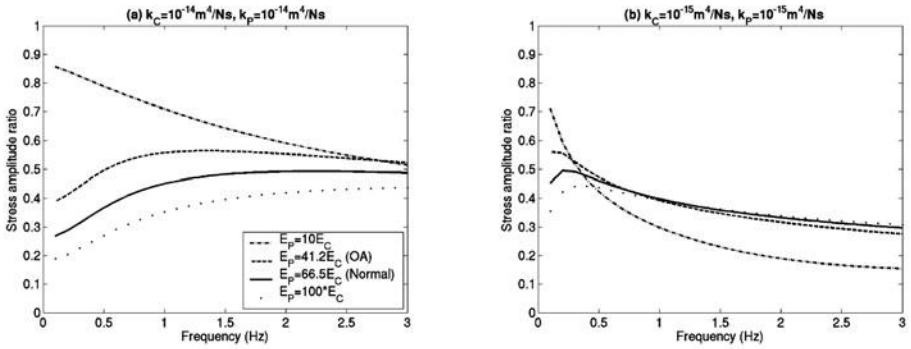

FIG. 4.2. *The solid stress amplitude ratio, $S(\omega)$, for frequencies in the range 0–3Hz in the case $k_C = k_P$:* (a) $k_C = k_P = 10^{-14}, m^4/N{\cdot}s$; (b) $k_C = k_P = 10^{-15} m^4/N{\cdot}s$.

TABLE 4.2
Intervals of the stress amplitude ratio $S(\omega)$ for frequencies in the range 0–3Hz with varying permeability in normal and OA chondron models.

[k in m^4/N·s]		$k_C = 10^{-12}$	$k_C = 10^{-13}$	$k_C = 10^{-14}$	$k_C = 10^{-15}$
$k_P = 10^{-14}$	Normal	(0.23, 0.26)	(0.26, 0.28)	(0.27, 0.49)	(0.47, 0.84)
	OA	(0.25, 0.38)	(0.30, 0.38)	(0.39, 0.56)	(0.64, 0.92)
$k_P = 10^{-15}$	Normal	(0.20, 0.25)	(0.21, 0.25)	(0.23, 0.28)	(0.30, 0.50)
	OA	(0.20, 0.33)	(0.21, 0.33)	(0.22, 0.35)	(0.28, 0.56)
$k_P = 10^{-16}$	Normal	(0.18, 0.21)	(0.18, 0.21)	(0.18, 0.21)	(0.18, 0.26)
	OA	(0.18, 0.21)	(0.18, 0.21)	(0.18, 0.21)	(0.18, 0.26)

In the case $k_C = k_P$, evaluation of $S(\omega)$ involves first-order derivatives of the displacement, and it can be shown that the terms in the sums of $S(\omega)$ are $O(\gamma_j^{-1/2})$ as $j \to \infty$. In contrast to the computation of $A(\omega)$, evaluation of $S(\omega)$ required a larger number of terms ($N = 1000$) to guarantee numerical convergence to a tolerance of 10^{-3}. Plots of the stress amplitude ratio $S(\omega)$ versus forcing frequency, corresponding to those of Figure 4.1, are shown in Figure 4.2. When plotted on the same graph, curves obtained using the analytical and numerical solutions were indistinguishable.

When the chondron permeability is equal to that of cartilage ECM, it is observed that the stress amplitude in the normal chondron model has been reduced to less than 50% of its prescribed value at $\rho = b$ (Figure 4.2(b)). In this case, $S(\omega)$ exhibits only a slight change in the OA chondron model and is rather insensitive to E_P. As the chondron permeability is increased by an order of magnitude, $S(\omega)$ remains less than 0.5 in the normal model but increases significantly in the OA model (Figure 4.2(a)). In this case of higher permeability, further increases in PCM stiffness reduce the stress amplitude ratio. An analysis of $S(\omega)$ corresponding to Table 4.1 was conducted and is summarized in Table 4.2. Our attention is focused on the range $(k_C, k_P) = (10^{-14}$–$10^{-12}, 10^{-15}$–$10^{-14})\mathrm{m}^4/\mathrm{N{\cdot}s}$, where $A(\omega)$ was in excess of 0.75 in the normal chondron model. In this regime, it is observed that, if the case $(k_C, k_P) = (10^{-14}, 10^{-14})\mathrm{m}^4/\mathrm{N{\cdot}s}$ is excluded, then $S(\omega)$ is less than 0.30 for all frequencies, with increases up to 0.38 in the corresponding OA models. As k_P is decreased to $10^{-16}\mathrm{m}^4/\mathrm{N{\cdot}s}$, $S(\omega)$ exhibits

almost no sensitivity to varying k_C. In the range of permeabilities considered, intervals of $S(\omega)$ are more sensitive to k_P than to k_C, though this is less pronounced than was the case for $A(\omega)$.

The transient-free analyses using $A(\omega)$ and $S(\omega)$ indicate that retention of the displacement amplitude at a level of at least 75% occurs in conjunction with transmission of the solid stress amplitude at a level of at most 30% in the ranges of chondron permeability given by $(k_C, k_P) = (10^{-14}\text{–}10^{-12}, 10^{-15})\text{m}^4/\text{N·s}$ and $(k_C, k_P) = (10^{-13}\text{–}10^{-12}, 10^{-14})\text{m}^4/\text{N·s}$. In the range $(k_C, k_P) = (10^{-13}\text{–}10^{-12}, 10^{-14})\text{m}^4/\text{N·s}$, there are only slight differences in the normal and OA models, whereas these differences are more significant in the range $(k_C, k_P) = (10^{-14}\text{–}10^{-12}, 10^{-15})\text{m}^4/\text{N·s}$, particularly for displacement transmission. Overall, the chondron model suggests that the functional role of the PCM as both a transmissive and a protective layer is enhanced in cases where k_C is at least one order of magnitude larger than k_P.

4.2.3. Strain in the chondron. It is known that mechanical loading of a cartilage layer strongly influences the metabolic activity of the chondrocytes [8]. However, little is known regarding the specific components of the local cellular environment that correlate with observed alterations in cell metabolic activity. Based on the hypothesis that strain may play a significant role in this process, the radial strain distribution in the chondron was evaluated. PCM permeability was taken on the order of cartilage ECM permeability (i.e., $k_P = 10^{-15}\text{m}^4/\text{N·s}$) and, based on the analyses of sections 4.2.1 and 4.2.2, two values of chondrocyte permeability, $k_C = 10^{-13}\text{m}^4/\text{N·s}$ and $k_C = 10^{-14}\text{m}^4/\text{N·s}$, were considered.

The amplitude of the transient-free radial strain in the chondron is shown in Figure 4.3 for both the normal and OA models. The case $k_C = k_P = 10^{-15}\text{m}^4/\text{N·s}$ was also included for comparison. In the regime where k_C is at least one order of magnitude greater than k_P (Figures 4.3(a)–4.3(d)), strain amplitudes are consistent with the small strain assumption of linear biphasic theory. As k_C is increased to $10^{-15}\text{m}^4/\text{N·s}$, large strains are present in the cell, near the cell-PCM interface, and the linear biphasic model may be inaccurate. In the normal chondron model, when k_C is at least one order of magnitude larger than k_P (Figures 4.3(a) and 4.3(c)), peak strain amplitudes in the chondrocyte increase with frequency and occur near the interface with the PCM. Strain amplitudes decrease rapidly towards the center of the cell to less than 0.02 and reduce further with increasing frequency. As k_C is increased to $10^{-13}\text{m}^4/\text{N·s}$, strain amplitudes in the entire cell are less than 0.04 and there is less sensitivity to frequency (Figure 4.3(a)), although predictions inside the cell do not accurately reflect the nonhomogeneous nature of the chondrocyte. Strain amplitudes in the PCM are insensitive to k_C, decrease linearly in the direction of the cell, and increase significantly with frequency. In the case $k_C = 10^{-14}\text{m}^4/\text{N·s}$ (Figure 4.3(c)), there is peak-to-peak amplification of the strain amplitude from the PCM boundary to the cell-PCM interface, indicating excellent transmission of radial strain and potential significance as a signalling mechanism. In contrast, for $k_C = 10^{-13}\text{m}^4/\text{N·s}$ (Figure 4.3(a)), the strain amplitude is significantly diminished, particularly at higher frequencies. In the OA chondron model (Figures 4.3(b) and 4.3(d)), where E_P is roughly 38% lower, strain amplitudes are increased in the PCM. In the case $k_C = 10^{-14}\text{m}^4/\text{N·s}$, the peak-to-peak strain amplitude in the OA model drops significantly for higher frequencies, indicating alteration of strain signal transmission with the decreased PCM stiffness associated with OA chondrons (Figure 4.3(d)). As k_C is increased to $10^{-13}\text{m}^4/\text{N·s}$, strain amplitudes in the cell are greatly diminshed and there is little difference between the normal and OA models (Figures 4.3(a) and 4.3(b)).

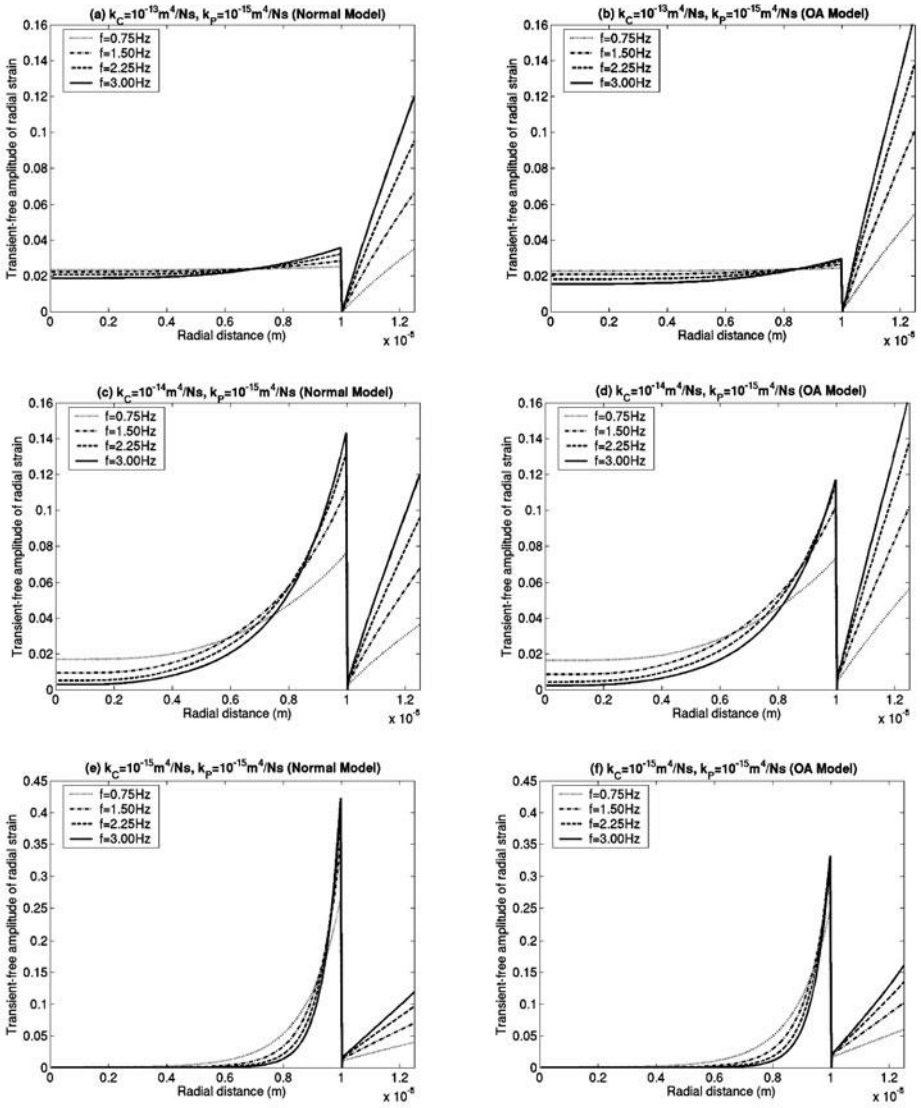

FIG. 4.3. *Amplitude of the transient-free radial strain component in the normal* (a), (c), (e) *and OA* (b), (d), (f) *chondron models. Strain amplitudes, as distributed in the chondron, are shown at four frequencies in the range* 0–3*Hz in the cases* (a) $(k_C, k_P) = (10^{-13}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 66.5kPa$, (b) $(k_C, k_P) = (10^{-13}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 41.2kPa$, (c) $(k_C, k_P) = (10^{-14}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 66.5kPa$, (d) $(k_C, k_P) = (10^{-14}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 41.2kPa$, (e) $(k_C, k_P) = (10^{-15}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 66.5kPa$, (f) $(k_C, k_P) = (10^{-15}, 10^{-15}) m^4/N{\cdot}s$, $E_P = 41.2kPa$. *The cell and chondron radii are* $a = 10\mu m$ *and* $b = 12.5\mu m$, *respectively.*

This analysis of strain amplitude in the chondron suggests that while the PCM serves to significantly reduce transmission of solid stress to the cell, transmission of radial strain is excellent in normal chondrons when k_C is one order of magnitude larger than a value of k_P similar to that of cartilage ECM. For these values of permeability, the analysis also suggests that transmission of radial strain decreases in the presence of the lower PCM stiffness associated with OA, particularly at higher frequencies.

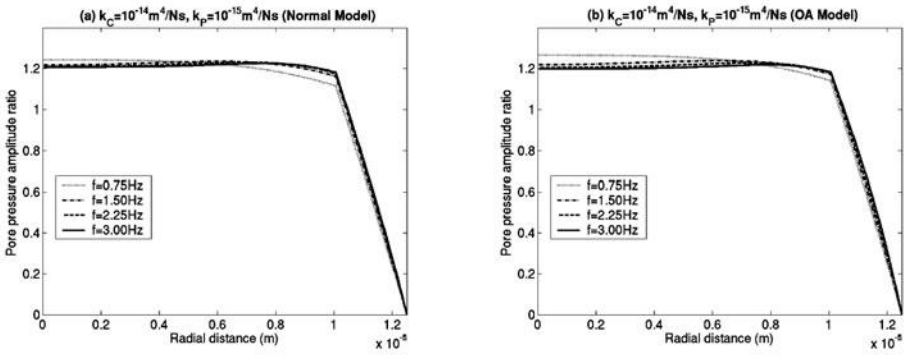

FIG. 4.4. *Pore pressure amplitude ratio for the normal* (a) *and OA* (b) *chondron models in the case* $(k_C, k_P) = (10^{-14}, 10^{-15})m^4/N{\cdot}s$ *for frequencies in the range* $0 - 3Hz$. *The cell and chondron radii are* $a = 10\mu m$ *and* $b = 12.5\mu m$, *respectively.*

Fluid stress in the chondron was evaluated for $(k_C, k_P) = (10^{-14}, 10^{-15})\mathrm{m}^4/\mathrm{N{\cdot}s}$, via the pore pressure amplitude ratio $\mathrm{Amp}(p_\infty(a,t))/\mathrm{Amp}(\sigma^s_\infty(b,t))$ (Figure 4.4). It is observed that this ratio is nearly uniform inside the cell, as was the pore pressure itself (not shown), and does not change significantly in the OA model, or with increasing frequency. The pore pressure amplitude ratio indicates that the transient-free fluid stress $\sigma^f_\infty = -(1-\phi)p$ inside the cell is roughly on the same scale as the solid stress at the outer PCM boundary. The large difference in spatial gradients of the pore pressure amplitude ratio between the cell and PCM has a less pronounced effect on fluid flow in the chondron since k_C is one order of magnitude larger than k_P (see (2.5)). The isolated effects of fluid stress on chondrocyte metabolic activity are not known. However, given that forces and deformation of the intracellular organelles are determined by the solid stress and strain in the biphasic model, these solid phase variables are more likely to serve as predictors of mechanical effects on chondrocyte metabolism.

5. Summary. The presence of a thin, highly stiff and less permeable PCM layer surrounding an articular chondrocyte enhances the transmission of displacement and strain signals from the ECM to the cell while simultaneously protecting the cell from excessive solid stress. The amplitude of these mechanical signals is rather sensitive to decreasing stiffness of the PCM, indicating that mechanical signal transmission may be significantly altered in the presence of OA. The optimal mechanical environment of a healthy chondrocyte is a complex function of the geometric and material properties of the cell, the PCM, and the biomechanical interface between these two regions. A more realistic chondron model would incorporate effects of the lipid bilayer and mechanical connections between the cell and PCM. Such a model would require measurements of material parameters for these subcomponents of the cell and its interface, and once such measurements are available, model predictions could provide a more precise picture of mechanical signal transduction to the cell. A triphasic model of chondron mechanics, incorporating physicochemical effects such as the fixed-charge density in the PCM, can also be considered. Ultimately, chondron mechanics should be coupled to multiphasic macroscopic models for deformation of the ECM. Such models will enable a description of relationships between external dynamic loading of a tissue layer and mechanical signals at the cellular scale. This modeling will be facilitated by further experimental studies that aim to determine geometric and material properties of the chondron, and variations in these properties with site, species, and disease.

Appendix A. Demonstration that L is self-adjoint in the case $k_C = k_P$. Define the inner product $\langle F, G\rangle \equiv \int_0^b F(\rho)\overline{G(\rho)}\rho^2 d\rho$. It is shown that when $k_C = k_P$ and the interface conditions (3.4) are satisfied, then $\langle L\phi, \phi\rangle = \langle \phi, L\phi\rangle$ (i.e., the operator L is self-adjoint).

Consider

$$\langle L\phi, \phi\rangle = \int_0^a \left[k_C H_C^A(\partial_\rho(\rho^2\partial_\rho\phi) - 2\phi)\right]\overline{\phi}d\rho + \int_a^b \left[k_P H_P^A(\partial_\rho(\rho^2\partial_\rho\phi) - 2\phi)\right]\overline{\phi}d\rho.$$

Integrating once by parts,

$$\langle L\phi, \phi\rangle = a^2\overline{\phi}(a)(k_C H_C^A\phi^{'}(a^-) - k_P H_P^A\phi^{'}(a^+)) - k_C H_C^A\int_0^a \rho^2\partial_\rho\phi\partial_\rho\overline{\phi}d\rho$$
$$-k_P H_P^A\int_a^b \rho^2\partial_\rho\phi\partial_\rho\overline{\phi}d\rho - 2k_C H_C^A\int_0^a \phi\overline{\phi}d\rho - 2k_P H_P^A\int_a^b \phi\overline{\phi}d\rho,$$

where the first relation in (3.4) has been employed along with the assumptions that ϕ and $\phi^{'}$ are bounded at $\rho = 0$. A second integration-by-parts yields

$$\langle L\phi, \phi\rangle =$$
$$a^2\overline{\phi}(a)(k_C H_C^A\phi^{'}(a^-) - k_P H_P^A\phi^{'}(a^+)) + a^2\phi(a)(k_P H_P^A\overline{\phi}^{'}(a^+) - k_C H_C^A\overline{\phi}^{'}(a^-))$$
$$+k_C H_C^A\int_0^a \phi(\rho)(\partial_\rho(\rho^2\partial_\rho\overline{\phi}) - 2\overline{\phi})d\rho + k_P H_P^A\int_a^b \phi(\rho)(\partial_\rho(\rho^2\partial_\rho\overline{\phi}) - 2\overline{\phi})d\rho,$$

which simplifies to

$$\langle L\phi, \phi\rangle = \langle \phi, L\phi\rangle + a^2\overline{\phi}(a)(k_C H_C^A\overline{\phi}^{'}(a^-) - k_P H_P^A\phi^{'}(a^+))$$
$$+a^2\phi(a)(k_P H_P^A\overline{\phi}^{'}(a^+) - k_C H_C^A\overline{\phi}^{'}(a^-)).$$

Using the last relation of (3.4), $\phi^{'}(a^+)$ can be eliminated and the expression reduces to

$$\langle L\phi, \phi\rangle = \langle \phi, L\phi\rangle + a^2 H_C^A(k_C - k_P)(\overline{\phi}(a)\phi^{'}(a^-) - \phi(a)\overline{\phi}^{'}(a^-)).$$

Since $k_C = k_P$, $\langle L\phi, \phi\rangle = \langle \phi, L\phi\rangle$ and the operator L is self-adjoint.

Appendix B. Finite difference scheme. Let $u_i^j = u(\rho_i, t_j)$, where $\rho_i = i\Delta\rho$, $t_j = j\Delta t$, and $\Delta\rho = b/M$. Let K denote the index of the mesh point to the immediate left of the cell-PCM interface at $\rho = a$. Equation (3.27) was discretized using a first-order finite difference in time and second-order finite differences in space to obtain the following implicit scheme at time step j. For $i = 1, \ldots, K-1, K+2, \ldots, M-1$,

$$\text{(B.1)}\qquad \frac{u_i^{j+1} - u_i^j}{\Delta t} = r\left(\frac{u_{i+1}^{j+1} - 2u_i^{j+1} + u_{i-1}^{j+1}}{(\Delta\rho)^2} + \frac{2}{\rho_i}\frac{u_{i+1}^{j+1} - u_{i-1}^{j+1}}{2\Delta\rho} - \frac{2}{\rho_i^2}u_i^{j+1}\right).$$

For $i = K$, the first condition in (3.10) was enforced via $u_{K+1}^{j+1} = u_K^{j+1}$. For $i = K+1$, the second condition in (3.10) was discretized using first-order finite difference approximations in space to obtain

$$\text{(B.2)}\qquad H_P^A\left(\frac{u_{K+2}^{j+1} - u_{K+1}^{j+1}}{\Delta\rho}\right) - H_C^A\left(\frac{u_K^{j+1} - u_{K-1}^{j+1}}{\Delta\rho}\right) = \frac{2}{a}\left(\lambda_C u_K^{j+1} - \lambda_P u_{K+1}^{j+1}\right).$$

At $i = 0$ and $i = M$ the boundary conditions at (3.11) were enforced. Marching in time via j, the finite difference equations were assembled at each time step into a linear algebraic system that was solved for each set of parameters using MATLAB 6.5.

Acknowledgments. The author would like to thank F. Guilak and M. Shearer for helpful discussions.

SUSTAINED SPATIAL PATTERNS OF ACTIVITY IN NEURONAL POPULATIONS WITHOUT RECURRENT EXCITATION*

JONATHAN E. RUBIN† AND WILLIAM C. TROY†

Abstract. Spatial patterns of neuronal activity arise in a variety of experimental studies. Previous theoretical work has demonstrated that a synaptic architecture featuring recurrent excitation and long-range inhibition can support sustained, spatially patterned solutions in integrodifferential equation models for activity in neuronal populations. However, this architecture is absent in some areas of the brain where persistent activity patterns are observed. Here we show that sustained, spatially localized activity patterns, or bumps, can exist and be linearly stable in neuronal population models without recurrent excitation. These models support at most one bump for each background input level, in contrast to the pairs of bumps found with recurrent excitation. We explore the shape of this bump as well as the mechanisms by which this bump is born and destroyed as background input level changes. Further, we introduce spatial inhomogeneity in coupling and show that this induces bump pinning: for a given starting position, bumps can exist only for a small, discrete set of background input levels, each with a unique corresponding bump width.

Key words. neuronal population, spatial pattern, localized activity bump, off-center coupling, bifurcation, spatial inhomogeneity

1. Introduction.

Evidence suggests that sustained, spatially patterned neuronal activity may play a role in short-term encoding of information. For example, localized persistent activity, or bumps, may provide the basis for a working memory of external stimulus features [14, 7, 18] or a representation of internal states such as head direction (reviewed in [25, 21]). Previous theoretical works have explored the ways in which a network of spiking neurons with short-range recurrent excitation (i.e., positive local coupling) and long-range inhibition can support sustained, spatially organized activity [28, 1, 15, 13, 8, 17, 16, 4, 5]. These studies focus on various forms of rate or activity models, in which a single equation encapsulates the temporal evolution of some measure of the activity level of an entire population of spiking neurons (i.e., neurons firing regularly with some average spike rate). A related result shows that when timescales of synaptic dynamics are taken into account in a conductance-based network model, sustained, localized activity can arise in a two-layer network of *bursting* thalamic cells that lacks recurrent excitation [20]. This leads naturally to the fundamental question of just how crucial the presence of recurrent excitation is for the existence of sustained spatial patterns of activity in rate or activity models of populations of *spiking* neurons. This paper shows that spatially localized activity can be sustained in a neuronal network without recurrent excitation or bursting mechanisms.

We consider a rate model of the form

$$\frac{\partial u(x,t)}{\partial t} = -\sigma u(x,t) + \int_{-\infty}^{\infty} w(x-y) f(u(y,t))\, dy + h. \tag{1.1}$$

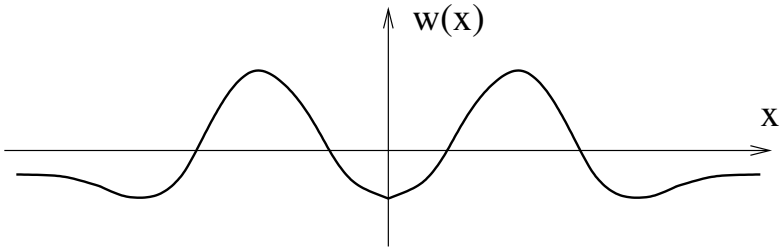

FIG. 1. *Off-center coupling function for an excitatory population. Cells at any position x with $w(x) > 0$ receive excitatory input from cells at position $x = 0$, while cells at x with $w(x) < 0$ receive inhibitory input.*

Equation (1.1) models a single population of spiking neurons. The function $u(x,t)$ encodes the activity level, or average voltage, of a neuronal subgroup at position $x \in (-\infty, \infty)$ and time $t \geq 0$. The connection function $w(x)$ determines the coupling between subgroups, and the nonnegative, nondecreasing function $f(u)$ denotes the neuronal firing rate, or average rate at which spikes are generated, corresponding to an activity level u. Neurons at a point x are said to be active if $f(u(x,t)) > 0$. Finally, the parameter h encodes a constant external stimulus applied uniformly to the entire neural field [1], such as an average background input level received from other areas of the brain, and the parameter σ denotes a positive rate constant; the ratio h/σ represents the baseline level of activity in the population without coupling. Without loss of generality, we set $\sigma = 1$.

In this paper, we take $f(u(x,t)) = H(u(x,t))$, the Heaviside step function, which gives

$$\frac{\partial u(x,t)}{\partial t} = -u(x,t) + \int_{-\infty}^{\infty} w(x-y)H(u(y,t))\,dy + h. \tag{1.2}$$

For the Heaviside form of firing rate function, the activity level $u = 0$ represents an absolute threshold for synaptic input required to drive spiking activity. This form of (1.1) was considered in [1] and by many subsequent authors. Further, it was shown in [15] that results for (1.2) are crucial in determining solution structure for (1.1) with more general nondecreasing f.

After we detail additional assumptions on the model, we prove that recurrent excitation is not necessary for the existence of stable stationary, spatially localized solutions (i.e., bumps) in populations of spiking cells. The synaptic architecture that we consider, as an alternative to recurrent excitation, takes the form shown in Figure 1. Such an *off-center architecture* may be relevant in several different contexts. For example, consider a network featuring interconnected excitatory (E) and inhibitory (I) populations of cells, in which E-cells are intrinsically capable of spiking and I-cells inhibit both E-cells and other I-cells. In such a network, activity of E-cells leads to activity of corresponding I-cells. This may lead to feedback inhibition onto the active E-cells as well as inhibition of nearby I-cells. This I-I inhibition can in turn disinhibit nearby E-cells, effectively acting as an off-center form of excitation onto E-cells, as portrayed in Figure 1. This form of architecture may arise in interactions of the subthalamic nucleus (E) and external segment of the globus pallidus (I) in the primate basal ganglia [22, 26]. It also may occur in interactions of thalamocortical

relay cells (E) and thalamic reticular cells (I) in the thalamus in awake states, where activity bumps in certain subpopulations of cells can encode head direction [23, 24]. Long-range inhibitory connections have been found in the thalamus [9, 10], but no thalamic recurrent excitatory connections are known to exist. In the first subsection of the appendix, we discuss the derivation of the effective coupling shown in Figure 1 from coupled E and I populations modelled by a pair of equations of the form (1.1), as in [28, 1, 19] but without recurrent excitation, although a rigorous mathematical derivation, or a complete mathematical treatment of the coupled equations, remains for future research. Alternatively, this form of suppression of recurrent excitation by localized inhibitory feedback may be generated by inhibitory interneurons in a variety of cortical areas, or in the CA1 region of the hippocampus, which features at most sparse recurrent excitatory connections [6, 27].

We consider this coupling architecture in section 2. Under certain assumptions, we prove the existence of a bump solution $u(x)$ to (1.2) such that $u(x) > 0$ if and only if $x \in (0, a)$ for a fixed constant a. We also show that this bump solution is linearly stable when it exists. Our proof method for existence generalizes that given by Amari [1] for bumps in (1.2) with lateral inhibition. However, details become much more subtle due to the more complicated synaptic architecture that we consider.

Unlike the case with recurrent excitation, where two bump solutions exist [1], the bump of localized positive activity that we find is unique for each fixed h in some finite interval. We show how the shape of a bump depends on its size, which in turn depends on h, relative to certain features of the coupling function $w(x)$. Further, as h varies, bump solutions (parametrized by h) are created and destroyed by atypical mechanisms that do not involve saddle-node bifurcations (since only a single solution exists for each h) or the entire bump collapsing to 0, and we explain the possible mechanisms and how they are selected.

For consideration of stability, we deviate from [1] to give a rigorous linear stability calculation. A simplified version of the calculation shows that a spatially uniform state can also be stable, such that the system exhibits bistability, consistent with [20, 24].

It has been argued that coupling strengths between neurons should not be purely distance dependent but rather should allow for spatial variation [2, 3]. In section 3, we introduce spatial inhomogeneity in coupling, replacing $w(x-y)$ by $w(x-y)p(y)$ under the integral in equation (1.2). We set up equations relevant to bump existence in this case, which we treat through a combination of analysis and numerics. The presence of spatial inhomogeneity naturally destroys the translation invariance of bumps. In fact, we find that it induces a form of bump pinning, such that for a given starting position, bumps exist for only a small, discrete set of background input levels, each with a unique corresponding bump width. Interestingly, in our primary numerical example, we find that there is a special bump width which is possible for any starting position. We comment on possible functional implications of these results in the discussion in section 4.

2. Spatially homogeneous coupling.

2.1. Assumptions.

In this section, we consider (1.2)

$$\frac{\partial u(x,t)}{\partial t} = -u(x,t) + \int_{-\infty}^{\infty} w(x-y)H(u(y,t))\,dy + h$$

with a coupling function $w(x)$ satisfying the hypothesis

($H1$) $w(x)$ is continuous and integrable on $\mathbb{R}$ and is symmetric; i.e., $w(-x) = w(x)$ for all $x \in \mathbb{R}$.

Moreover, we assume that there exist constants $x_* > x_1 > x^* > x_0 > 0$ such that

($H2$) $w(x) < 0$ on $(-x_0, x_0)$ and on (x_1, ∞), with $w(x_0) = w(x_1) = 0$;

($H3$) $w(x)$ is increasing on $(0, x^*)$ and on (x_*, ∞);

($H4$) $w(x) > 0$ on (x_0, x_1);

($H5$) $w(x)$ is decreasing on (x^*, x_*).

Coupling functions that satisfy ($H2$) and ($H4$) are sometimes called off-center coupling functions.

To simplify notation, we will also assume the following symmetry hypothesis in certain cases noted below

($H6$) there exists $\delta > 0$ such that $x_1 = x^* + \delta$ and $x_0 = x^* - \delta$, and $w(x^* + \eta) = w(x^* - \eta)$ for all $\eta \in [0, \delta]$.

We will comment further on the role of this hypothesis in Remark 2.8 after the proof of Theorem 2.5. A coupling function $w(x)$ satisfying ($H1$)–($H6$) appears in Figure 2.

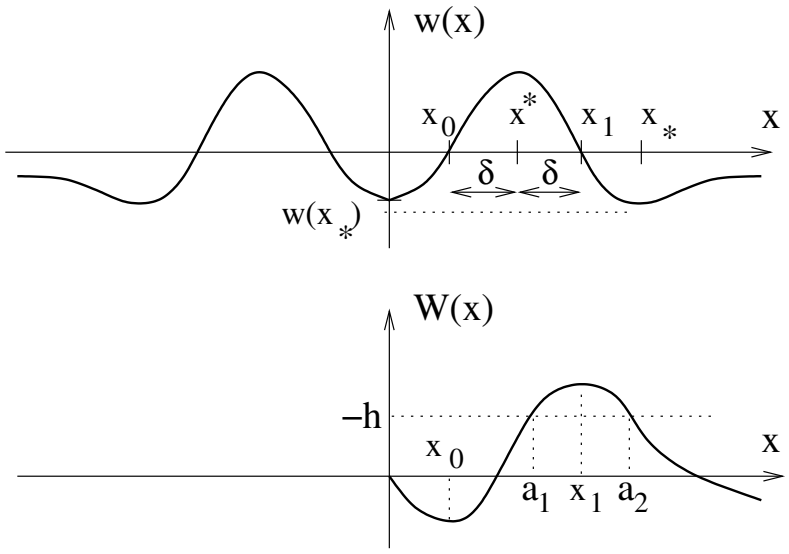

FIG. 2. *Off-center coupling function $w(x)$, together with antiderivative $W(x)$. From the plot of $W(x)$, we can visualize the necessary condition* (2.3)*, $W(a) + h = 0$, for bump existence.*

2.2. Existence of a unique bump. Following Amari [1], we seek stationary bump solutions $u(x)$ to (1.2), for which $u(x) > 0$ if and only if $x \in (0, a)$ for some constant a. Note that this is equivalent to the existence of a bump on any other interval of length a; that is, the system is translation invariant. Such solutions satisfy the condition

$$u(x) = \int_0^a w(x - y)\, dy + h\,. \tag{2.1}$$

Since $\lim_{x\to\infty} w(x) = 0$, the fact that $\lim_{x\to\infty} u(x) \le 0$ for such a solution requires that $h \le 0$. Thus, we impose the existence condition that

($E1$) the constant $h \le 0$.

Let $W(x) = \int_0^x w(t)\,dt$, which is an odd function. Then (2.1) becomes

$$u(x) = W(x) - W(x-a) + h. \tag{2.2}$$

From (2.2), the conditions $u(0) = 0$ and $u(a) = 0$ both give

$$W(a) + h = 0. \tag{2.3}$$

Figure 2 displays a graphical representation of equation (2.3). Note that for fixed $h < 0$, there exist either zero or two solutions of (2.1), unless $-h = W(x_1)$.

We will require a second existence condition, namely, that

($E2$) $W(x) + h > 0$ for some $x \in \mathbb{R}^+$ and $\lim_{x\to\infty} W(x) < -h$.

For fixed h such that conditions ($E1$) and ($E2$) hold, there exist two nonzero solutions of (2.3). We label these solutions as a_1 and a_2, where $a_2 > x_1 > a_1 > 0$. Note that a_2 could fail to exist without ($E2$), if $\lim_{x\to\infty} W(x) > -h > 0$. Let $u_1(x), u_2(x)$ denote the corresponding functions defined by $u_i(x) = W(x) - W(x-a_i) + h$. Note that $u_i(x) = W(x) - W(x-a_i) + h = W(a_i - x) + W(x) + h = u(a_i - x)$ for all x. This yields the following symmetry statement.

PROPOSITION 2.1. *Each solution $u_i(x)$ of* (2.3) *is symmetric about $x = a_i/2$.*

With these definitions, we state one final hypothesis, as an alternative to ($H6$), that will be assumed when noted below:

($H6'$) $W(x_0) - W(a_2) + W(a_2 - a_1) > 0$.

PROPOSITION 2.2. *Assume ($H1$)–($H5$). Fix h such that ($E1$)–($E2$) hold and $a_1 < x_1$ such that $W(a_1) + h = 0$. The function $u_1(x)$ defined by* (2.1) *with $a = a_1$ does not represent a valid bump solution to* (1.2). *In fact, if we assume ($H6$) as well, then $u_1(x) < 0$ on all of $(0, a_1)$.*

Proof. By construction, $u_1(0) = 0$ and $x_0 < a_1 < x_1$. Note that $u_1'(x) = w(x) - w(a_1 - x)$. Since $a_1 < x_1$, it follows that $w(a_1) > w(0)$. Thus, $u_1'(0) = w(0) - w(a_1) < 0$. This establishes that $u_1(x)$ is not a valid bump.

Further, note that $u_1'(x) = 0$ requires $w(x) = w(a_1 - x)$. This occurs at $x = a_1/2$, consistent with the symmetry of $u_1(x)$ about $x = a_1/2$. However, we shall see that when ($H6$) holds, the equation $u_1'(x) = 0$ has no other solutions in $(0, a_1)$, proving the proposition. To see this, note that by ($H6$), if there exists $x \neq a_1/2$ in $(0, a_1)$ such that $u_1'(x) = 0$, then $(a_1 - x) - x^* = x^* - x$, or, equivalently, $a_1 = 2x^*$. But $a_1 < x_1 < x_1 + x_0 = 2x^*$, so this is not possible. □

Remark 2.3. Proposition 2.2 implies that a bump can only possibly exist when there exists $a_2 > x_1$ for which (2.3) holds. Thus, if $\lim_{x\to\infty} W(x) > -h$, in violation of ($E2$), then no bump exists.

Now, define the constant A as the smallest positive x value for which $W(x) = 0$, guaranteed to exist by ($E2$) since $h \leq 0$.

PROPOSITION 2.4. *Assume ($H1$)–($H5$). Fix h such that ($E1$)–($E2$) hold. If $0 < a_2 - a_1 < A$, then the function $u_2(x)$, defined by* (2.1) *with $a = a_2$, does not represent a valid bump solution to* (1.2).

Proof. We compute directly from equation (2.2) that

$$u_2(a_1) = W(a_1) + W(a_2 - a_1) - W(a_1) = W(a_2 - a_1)\,.$$

If $a_2 - a_1 < A$, then $u_2(a_1) < 0$. But $a_1 \in (0, a_2)$, so $u_2(x)$ is not a bump. □

Next we establish some results showing the existence of a valid bump in various cases. Note that if $\lim_{x\to\infty} W(x) = 0$ (see Figure 2), then we can make a_2 arbitrarily large by choosing h sufficiently close to 0. If $a_2/2 > x_1$, then $a_2 - a_1 > 2x_1 - a_1 >$

$a_1 > A$. Thus, when $a_2/2 > x_1$, Proposition 2.4 does not apply, and $u_2(a_1) > 0$. In fact, in this case, we can establish the existence of a bump without hypothesis $(H6)$ or $(H6')$, as addressed below in Theorem 2.5. However, as we shall see in subsection 2.4, a_2 can also become too large for a bump to exist. This motivates a final existence condition,

$(E3)$ $w(a_2 \pm x_0) < w(0)$.

As we make h more negative, such that $-h$ grows toward the peak of W, we will also need to impose $(H6)$ or $(H6')$ to ensure the existence of a bump.

THEOREM 2.5. *Assume that $(H1)$–$(H5)$ hold. Fix h such that $(E1)$–$(E3)$ hold and assume that $a_2/2 > x_1$. Then the function $u_2(x)$ defined by (2.1) with $a = a_2$, such that $-W(a_2) = h$, is a bump solution to (1.2), with $u_2(x) > 0$ if and only if $x \in (0, a_2)$.*

Proof. First, recall that $a_2 > x_1$, since $W(a_2) = -h > 0$ and $W'(a_2) = w(a_2) < 0$ (see Figure 2). Further, since $w(0) < 0$ and $w(x_1) = 0$, the hypotheses of the theorem together with $(H2)$–$(H5)$ imply that there exist exactly two positive values $x'' > x' > x_1$ such that $w(0) = w(x') = w(x'')$, and $a_2 \in (x' + x_0, x'' - x_0)$; see Figure 3. This gives $w(0) > w(a_2)$ and $a_2/2 > x_0$.

We now show that $u_2(x) > 0$ for $x \in (0, a_2)$. First, we consider $x \in (0, x_0]$. Note that

$$u_2'(x) = w(x) - w(a_2 - x) \tag{2.4}$$

from (2.2). In particular, $u_2'(0) = w(0) - w(a_2) > 0$. Since $a_2 > x' + x_0$, we have $a_2 - x > x'$ for all $x \in (0, x_0]$. Thus, $w(a_2 - x) < w(x)$ and $u_2'(x) > 0$ for all $x \in (0, x_0]$.

Next, suppose that $a_2/2 > x_1$. Now, $u_2'(x) = w(x) - w(a_2 - x) > 0$ on $(x_0, x_1]$ as well. This holds because on $(x_0, x_1]$, $w(x) \geq 0$, while $a_2 - x > a_2 - x_1 > x_1$, such that $w(a_2 - x) < 0$ by $(H2)$. It remains to show that $u_2(x) > 0$ for all $x \in (x_1, a_2)$. To do this, it suffices to show that $u_2(x) > 0$ for all $x \in (x_1, a_2/2]$, since symmetry (Proposition 2.1) then gives $u_2(x) > 0$ for all $x \in (0, a_2)$.

Equation (2.2) can be rewritten for $u = u_2(x)$ as

$$u_2(x) = (W(x) - W(a_2)) + W(a_2 - x), \tag{2.5}$$

using equation (2.3) and the fact that $W(x)$ is odd. We will show that $u_2(x)$ in (2.5) is the sum of two positive terms for $x \in (x_1, a_2/2]$. When $x_1 < x \leq a_2/2$, it follows that $a_2 - x_1 > a_2 - x \geq a_2/2 > x_1$. By construction, $W(x) > 0$ on $[x_1, a_2]$. Hence, $W(a_2 - x) > 0$ for all $x \in (x_1, a_2/2]$. Now, consider the first term in $u_2(x)$ in (2.5), namely, $W(x) - W(a_2)$, for $x \in (x_1, a_2/2]$. Since $W'(x) = w(x) < 0$ on (x_1, ∞) by $(H2)$, and $x_1 < x \leq a_2/2 < a_2$, we have $W(x) > W(a_2)$ for all $x \in (x_1, a_2/2]$. Thus, $u_2(x)$ is the sum of two positive terms, and hence is positive, on $(x_1, a_2/2]$, as claimed. This gives $u_2(x) > 0$ on $(0, a_2)$, as desired.

Finally, to complete the proof, we confirm that $u_2(x) < 0$ for all $x \in (a_2, \infty)$. Note that since $W(a_2) = -h > 0$, $u_2(x) < 0$ is equivalent to $W(x) < W(a_2) + W(x - a_2)$ by equation (2.3). Since $W(a_2) > 0$, we have $u_2(x) < 0$ for all x such that $W(x - a_2) \geq W(x)$. Since $W(x)$ decreases on (x_1, ∞), this implies that $u_2(x) < 0$ for $x - a_2 \geq x_1$, namely, $x \in [a_2 + x_1, \infty)$. Thus, it remains to consider $x \in (a_2, a_2 + x_1)$. We will show that $u_2'(x) < 0$ on $(a_2, a_2 + x_1)$, for $u_2'(x)$ given in (2.4), such that $u_2(x)$ remains negative there. Since $w(x - a_2) > 0$ on $(a_2 + x_0, a_2 + x_1)$ by $(H4)$, while $w(x) < 0$ on this interval by $(H2)$, it is obvious from (2.4) that $u_2'(x) < 0$ on $(a_2 + x_0, a_2 + x_1)$. It remains only to consider $x \in (a_2, a_2 + x_0]$. Condition $(E3)$ gives $w(a_2) < w(0)$, so

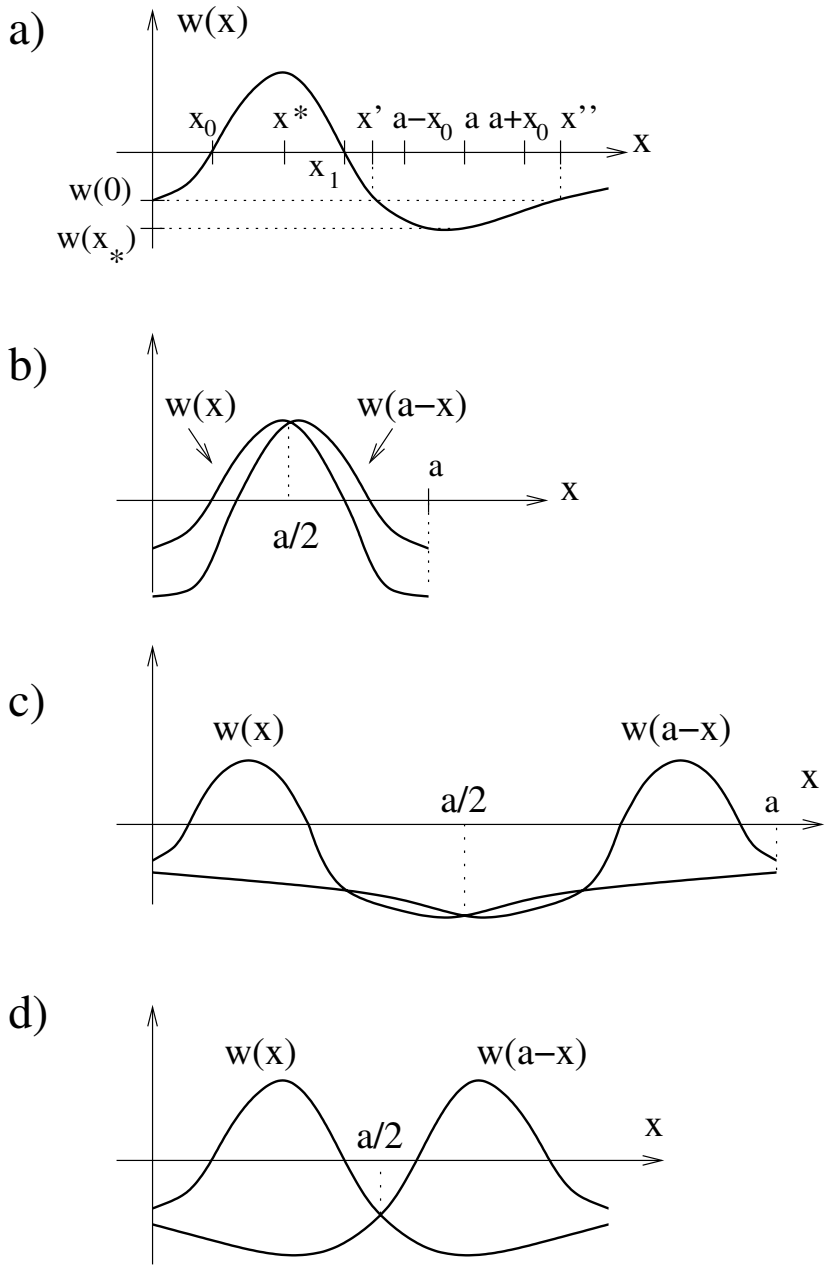

FIG. 3. *Graphical representation of Theorems* 2.5, 2.7, 2.9, *and* 2.13. *Here, a denotes* a_2 *from the theorems.* (a) *Illustration of the hypotheses of the theorems.* (b) *The relation of* $w(x), w(a_2 - x)$ *resulting from the proof of Theorem* 2.9, *if* $a_2/2 \leq x_1$. (c) *The relation of* $w(x), w(a_2 - x)$ *shown in Theorem* 2.13 *if* $a_2/2 \in (x_1, x_*]$. (d) *The relation of* $w(x), w(a_2 - x)$ *shown in Theorem* 2.13 *if* $a_2/2 > x_*$.

$u_2'(a_2) < 0$. For $x \in (a_2, a_2+x_0]$, we have $w(x) < w(0)$ by $(E3)$, while $w(x-a_2) > w(0)$ by $(H3)$. Thus, $u_2'(x)$ remains negative, as desired. ∎

Theorem 2.5 establishes the existence of a bump $u_2(x)$ when $a_2/2 > x_1$. Next, we consider the case of $a_2/2 \leq x_1$, corresponding to more negative choices of h. In this situation, we will prove two different theorems that invoke $(H6')$ and $(H6)$, respectively. Note that it is natural to interpret $(H6')$ as an assumption on the value of h, for fixed w. On the other hand, $(H6)$ is an assumption about the shape of w, independent of h. When we assume $(H6)$ below, we restrict the class of w considered, and we correspondingly restrict the shape of the bump produced (see Theorem 2.9).

Remark 2.6. Note that the proof that $u_2(x) < 0$ for all $x \in (a_2, \infty)$ does not require $a_2/2 > x_1$. Thus, in the proofs of Theorems 2.7 and 2.9 below, we will not repeat the corresponding arguments.

THEOREM 2.7. *Assume that w and h are chosen such that $(H1)$–$(H5)$, $(E1)$–$(E3)$, and $(H6')$ hold and such that $a_2/2 \leq x_1$. Then the function $u_2(x)$ defined by (2.1) with $a = a_2$, such that $-W(a_2) = h$, is a bump solution to (1.2), with $u_2(x) > 0$ if and only if $x \in (0, a_2)$.*

Proof. By symmetry (Proposition 2.1), it suffices to show that $u_2(x) > 0$ on $(0, a_2/2]$. From the proof of Theorem 2.5, we already have $u_2'(x) > 0$ on $(0, x_0]$. We will first consider $x \in (a_1, a_2/2]$ and then $x \in (x_0, a_1]$. Note that by $(H6')$, $W(a_2 - a_1) > W(a_2)$, so $a_2 - a_1 > a_1$, and thus the interval $(a_1, a_2/2]$ is nonempty. For $x \in (a_1, a_2/2]$, we have $a_2 - x \in (a_1, a_2)$, since

$$a_1 < x < a_2/2 \leq a_2 - x < a_2\,.$$

Thus, $W(a_2 - x) > -h > 0$, with a similar inequality for $W(x)$. Equation (2.2), together with the fact that W is odd, therefore gives

$$u(x) = W(x) + W(a_2 - x) + h > W(a_2 - x) > -h > 0$$

for $x \in (a_1, a_2/2]$.

Next, suppose $x \in (x_0, a_1]$. Note that over the range of positive x-values, the minimum value of W occurs at $x = x_0$, so

$$u(x) > W(x_0) + W(a_2 - x) + h =: F(x) \quad \text{for } x \in (x_0, a_1]\,. \tag{2.6}$$

$F(x_0) = u(x_0)$ by comparison of (2.2) and (2.6), and $u'(x) > 0$ on $(0, x_0]$ gives $u(x_0) > 0$, so $F(x_0) > 0$. Next, note that $F'(x) = -w(a_2 - x)$, so since $w(a_2 - x_0) < w(0) < 0$, it follows that $F'(x_0) > 0$.

Suppose that for some $x_f \in (x_0, a_1]$, $F'(x_f) = 0$. Then $w(a_2 - x_f) = 0$, so either $a_2 - x_f = x_0$ or $a_2 - x_f = x_1$ (see Figure 2). In the former case, we would have $x_f = a_2 - x_0 > x_1 > a_1$, however, so this cannot occur, and $a_2 - x_f = x_1$. Thus, $F''(x_f) = w'(a_2 - x_f) = w'(x_1) < 0$. Since $F(a_1) > 0$ by $(H6')$, the maximum principle implies that $F > 0$ on the entire interval $[x_0, a_1]$.

In summary, $u(x) > F(x) > 0$ on $(x_0, a_1]$. Thus, the proof is complete. ∎

Remark 2.8. Note that hypothesis $(H6')$ requires $a_2 - a_1 > A$. That is, if $a_2 - a_1 < A$, then $W(x_0)$, $-W(a_2)$, and $W(a_2 - a_1)$ are all negative terms, and $(H6')$ cannot hold. Thus $(H6')$ ensures that we are in a regime in which Proposition 2.4 does not apply.

To conclude this subsection, we show that under the symmetry hypothesis $(H6)$, there exists a bump $u_2(x)$ that is monotone increasing on $[0, a_2/2)$ and monotone decreasing on $(a_2/2, a_2]$, for $a_2/2 \leq x_1$.

THEOREM 2.9. *Assume that* $(H1)$–$(H6)$ *hold. Fix* h *such that* $(E1)$–$(E3)$ *hold and such that* $a_2/2 \le x_1$. *Then the function* $u_2(x)$ *defined by* (2.1) *with* $a = a_2$, *such that* $-W(a_2) = h$, *is a bump solution to* (1.2), *with* $u_2(x) > 0$ *if and only if* $x \in (0, a_2)$. *Moreover,* $u_2'(x) > 0$ *on* $[0, a_2/2)$ *and* $u_2'(x) < 0$ *on* $(a_2/2, a_2]$.

Proof. Again, from the proof of Theorem 2.5, we have $u_2'(x) > 0$ on $(0, x_0]$. Now, suppose that $a_2/2 \le x_1$. By the assumption of the theorem, $a_2 - x_0 > x' > x_1$. Therefore, $a_2/2 > (x_0 + x_1)/2 = x^*$. Together with $(H6)$, this implies that $w(a_2 - x) < w(x)$ remains true on $(0, x^*]$, that $w(a_2 - x) = w(x)$ precisely at $x = a_2/2 \in (x^*, a_2 - x^*)$, and $w(a_2 - x) > w(x)$ on $(a_2/2, a_2]$ (see Figures 2 and 3(a) and (b)). Thus, $u_2(x) > 0$ for all $x \in (0, a_2)$, with $u_2(a_2) = 0$, if $a_2/2 \le x_1$. ∎

COROLLARY 2.10. *Let* $w = w(x, \mu)$ *be continuous in* $\mu \in \mathbb{R}$ *and set* $W(x, \mu) = \int_0^x w(t, \mu)\, dt$. *Assume that* w *satisfies* $(H1)$–$(H5)$ *for all* μ *in a neighborhood of* $\mu = 0$ *and that* $w(x, 0)$ *satisfies* $(H6)$. *Then there exist* $\mu_1 < 0 < \mu_2$ *and a function* $a(\mu)$, *with* $a(0) = a_2$ *given by* $-W(a_2, 0) = h$, *such that a bump solution* $u_\mu(x)$ *of* (1.2) *exists, with* $u_\mu(x) > 0$ *if and only if* $x \in (0, a(\mu))$, *for all* $\mu \in (\mu_1, \mu_2)$.

Proof. By the implicit function theorem, since $W_x(a_2, 0) \neq 0$, a unique function $a(\mu)$ satisfying $W(a(\mu), \mu) + h = 0$ exists near $\mu = 0$, with $a(0) = a_2$. The existence of the bump solution $u_\mu(x)$ then follows immediately from the proof of Theorem 2.5, for $|\mu|$ sufficiently small. ∎

Remark 2.11. Without hypothesis $(H6)$, or some other restriction on the behavior of $w(x)$, there could be an unlimited variety of zeros of $u_2'(x)$ on $(0, a_2)$, depending on the relative rates of change of w to the left and right of x^*. In fact, without some hypothesis such as $(H6)$ or $(H6')$, $u_2(x)$ could become negative inside $(0, a_2)$, and the bump could fail to exist, as seen in Proposition 2.4. This issue is explored further in subsection 2.4.

Remark 2.12. The condition $(H6)$ as stated may seem to represent somewhat restrictive conditions to be achieved as an architecture of synaptic connections in a biological neuronal network. However, suppose we consider bumps as a form of memory. It is possible that for a given pattern of past experiences, only certain subnetworks within a coupled E-I network should be able to form bumps, corresponding to the particular memories stored in the network. The learning process could consist of the scaling of synaptic connections and their associated weights to develop particular architectural patterns. From this viewpoint, restrictions on synaptic architectures required for the appearance of bumps might be an essential feature of E-I networks, to prevent spurious overactivity. See the discussion in section 4 for consideration of related ideas.

2.3. The shape of the bump without $(H6)$ or $(H6')$. We have already seen that hypothesis $(H6)$ gives certain monotonicity properties for the bump $u_2(x)$ when $a_2/2 \le x_1$. We next characterize more generally how the shape of $u_2(x)$ depends on the position of a_2, without assuming $(H6)$ or $(H6')$, when $a_2/2 > x_1$.

THEOREM 2.13. *If* $a_2/2 \in (x_1, x_*]$, *then* u_2 *has a unique global maximum at* $x = a_2/2$. *If* $a_2/2 > x_*$, *then* $u_2'(x)$ *has at least three zeroes on* $(0, a_2)$, *including a local minimum of* $u_2(x)$ *at* $x = a_2/2$.

Proof. Suppose that $a_2/2 > x_1$. We look for zeroes of $u_2'(x)$, as given in equation (2.4). From the proof of Theorem 2.5, we already know that $u_2'(x) > 0$ on $(0, x_0]$. The condition $a_2/2 > x_1$ implies that

$$w(x_1) = 0 > w(a_2 - x_1), \tag{2.7}$$

so in fact $w(x) \geq 0 > w(a_2 - x)$ for all $x \in (x_0, x_1]$ and $u_2'(x) > 0$ on $(x_0, x_1]$. Suppose that $a_2/2 \leq x_*$, the point where $w(x)$ has its minimum (see Figure 3(a)), and define $\bar{x}$ by $a_2 - \bar{x} = x_*$. Then $\bar{x} = a_2 - x_* \leq x_*$. Thus, $w(a_2 - x) = w(x)$ at exactly one value $x \in (\bar{x}, x_*]$, namely, at $x = a_2/2$, and this is the only zero of $u_2'(x)$ in $(0, a_2)$. As in the previous case, this is a global maximum for $u_2(x)$ (see Figure 3(d)).

We now show that if $a_2/2 > x_*$, then in fact $u_2'(x) = w(a_2 - x) - w(x)$ has at least *three* zeroes (see Figure 3(c)). To see this, first note that inequality (2.7) still holds, since we still have $a_2/2 > x_1$. However, $w(x_*) < w(a_2 - x_*)$, since $a_2 - x_* > x_*$ and $w(x)$ has its minimum at $x = x_*$. Thus, $u_2'(x)$ has at least one zero on (x_1, x_*). For $x > x_*$, $w(x)$ is increasing by $(H3)$, while $w(a_2 - x)$ decreases until $x = a_2 - x_*$, at which point $w(x) > w(a_2 - x)$. Thus, exactly one additional zero of $u_2'(x)$ occurs on $(x_*, a_2 - x_*)$. Since $a_2/2 > x_*$, we have $a_2 - x_* > a_2/2$. As noted earlier, $u_2'(x)$ has a zero at $x = a_2/2$ from the form of (2.4); hence, this second zero must occur at $x = a_2/2$, and $u_2'(x)$ has at least one more zero for $x > a_2 - x_*$, by symmetry.

From (2.4), it follows that $u_2''(x) = w'(x) + w'(a_2 - x)$, such that $u_2''(a_2/2) = 2w'(a_2/2)$. When $a_2/2 > x_*$, we have $w'(a_2/2) > 0$ by $(H3)$, such that $u_2''(a_2/2) > 0$; that is, u_2 has a local minimum at $a_2/2$, completing the proof. ∎

Remark 2.14. Examples of bump solutions $u_2(x)$ of (2.1) with $a_2/2 < x_*$ and $a_2/2 > x_*$, respectively, are shown in Figure 4. These plots were generated by solving (2.1) numerically with a coupling function $w(x)$ defined in a piecewise manner on $[0, \infty)$ as

$$w(x) = \begin{cases} -Kx(x-1) - \epsilon, & x \in [0, 1), \\ -(x - 1 + \epsilon)e^{-b(x-1)}, & x \in [1, \infty) \end{cases} \tag{2.8}$$

for $K, b > 0$ and $0 < \epsilon < \min\{K/4, 1/b\}$, and then extended to be even on $(-\infty, \infty)$. This function satisfies $(H1)$. It also satisfies $(H2)$ and $(H4)$, with $x_0 = \frac{1}{2}[1 - \sqrt{1 - 4\epsilon/K}]$ and $x_1 = \frac{1}{2}[1 + \sqrt{1 - 4\epsilon/K}] < 1$. Assumptions $(H3)$ and $(H5)$ hold for this $w(x)$ as well, with $x^* = 1/2$ and $x_* = 1 + 1/b - \epsilon$. Finally, $w(x)$ is symmetric about $x^* = 1/2$ on (x_0, x_1), satisfying $(H6)$.

From (2.4), no matter what the value of a_2, we have $u_2'(a_2/2) = 0$. Thus, it is of interest to estimate $u_2(a_2/2)$.

PROPOSITION 2.15. *If $a_2/2 > a_1$ and $u_2(x) > 0$ on $(0, a_2)$, then $u_2(a_2/2) > -h$.*

Proof. If $a_2/2 > a_1$, then $a_2/2 \in (a_1, a_2)$, so $W(a_2/2) > -h$ (see Figure 2). From (2.2), this implies

$$u_2(a_2/2) = 2W(a_2/2) + h > W(a_2/2) > -h\,. \qquad \blacksquare$$

Combining Theorem 2.13 and Proposition 2.15 yields the following result.

COROLLARY 2.16. *If a bump $u_2(x)$ exists with $a_2/2 \in (x_1, x_*]$, then the activity level $u_2(x)$ attains a maximum value greater than $-h$. If a bump $u_2(x)$ exists with $a_2/2 > x_*$, then at the local activity minimum $a_2/2$, the activity level is bounded below by $-h$.*

2.4. Birth and death of bumps. We have seen that the function $u_2(x)$ is a bump for some values of a_2, but may fail to be a bump in some cases, such as $a_2 - a_1 < A$, as in Proposition 2.2. In fact, since $\lim_{x\to\infty} w(x) = 0$, we will see below that the interval of a values on which $u_2(x)$ is a valid bump is finite. Thus, a family of bump solutions, parametrized by bump length a, must be born at some finite value of a and must die at some larger finite value of a. In this subsection,

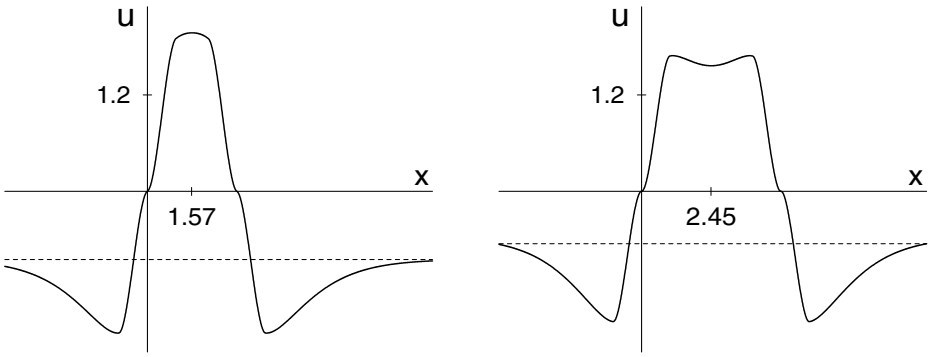

FIG. 4. *Bump solutions of* (2.1) *for the coupling function* $w(x)$ *given in* (2.8) *and extended in an even manner. Parameters used are* $K = 10.0, \epsilon = 0.1, b = 1.0$*, such that* $x_* = 1.9$*. Left: A bump with no local minimum, found with* $h = -0.85$*, such that* $a_2 = 3.15 < 2x_*$*. Right: A bump with a local minimum at* $a_2/2 > x_*$*, found with* $h = -0.57$*, such that* $a_2 = 4.90 > 2x_*$*. Dashed lines show the levels of* h*.*

we discuss possible mechanisms by which bumps may be created or destroyed as a varies (which can be achieved by varying h). We shall see that this does not occur through a "usual" bifurcation mechanism, such as a saddle-node bifurcation, and that when bumps arise, they do so with a finite amplitude. This contrasts with the situation when the coupling function $w(x)$ is derived from recurrent excitation and lateral inhibition, in which case bump amplitudes and widths may go to zero as a parameter varies.

In the following analysis, we will always assume $a > x_1$, corresponding to the possible bump solution $u_2(x)$, since $u_1(x)$ is never a valid bump. We will also assume that $W(a) > 0$, also necessary for a to represent a bump length since $h < 0$ in (2.3).

In general, there are two types of transitions through which a bump $u_2(x)$ may cease to exist as its size a varies, even without interaction with any other solutions. One possibility is that a bump may go negative on its interior; that is, it may develop a dip as in Figure 4, which may continue to drop until the minimum value of $u_2(x)$ on $(0, a)$ passes through 0. We refer to this as the *internal tangency* mechanism, since right at the transitional a value, we have $u_2(x) = u_2'(x) = 0$ for some $x \in (0, a)$. By (2.5),

$$u_2(a/2) = 2W(a/2) - W(a). \tag{2.9}$$

We will use (2.9) to show that $u_2(a/2) = 0$ can occur only at a unique value of $a > x_1$.

PROPOSITION 2.17. *There is at most one value of* $a > x_1$ *for which* $W(a) > 0$ *and* $u_2(a/2) = 0$*.*

Proof. Suppose $u_2(a_0/2) = 0$ and $W(a_0) > 0$ for $a_0 > x_1$. Then $W(a_0) > 0$ implies that $W(a_0/2) > 0$, by (2.9). Thus, $a_0/2 > A$, where A was defined as the smallest positive value for which $W(x) = 0$. Moreover, $W(a_0) = 2W(a_0/2)$ implies that $W(a_0) > W(a_0/2)$, so $a_0/2 < x_1$ (e.g., Figure 2).

Now, let $z(a) = 2W(a/2) - W(a)$. For $a/2 \in (A, x_1)$, $W'(a/2) > 0$, while $a > x_1$ gives $W'(a) < 0$. Thus, $z'(a) > 0$ and z can have at most one zero with $a/2 \in (A, x_1)$. Since $a_0/2$ must lie in this interval whenever $u_2(a_0/2) = 0$, this concludes the proof. ∎

Proposition 2.17 rules out the possibility that a family of bump solutions both arises and dies by passage of $u_2(a/2)$ through 0. However, it does not rule out the possibility that the birth and the death of the family are associated with dips on the interior of $(0, a)$ switching from negative to positive and from positive to negative, respectively. Indeed, it is possible that $u_2(a/2 - \delta) = 0$ for some $\delta \in (0, a/2)$, with $u_2(a/2+\delta) = 0$ as well by Proposition 2.1. Thus, there are infinitely many positions at which interior zeros of u_2 could develop, always occurring in groups of even numbers of dips, placed symmetrically about $a/2$.

An alternative to the internal tangency mechanism for birth and death of bumps is that $u_2'(0)$ (and by symmetry, $u_2'(a)$) may become zero and then negative (positive) as a varies. We refer to this transition as the *boundary tangency* mechanism. Note that $u_2'(0) = w(0) - w(a)$, where a is the length of $u_2(x)$. Thus, $u_2'(0) < 0$ for $a \in (x_1, x')$, and, since $\lim_{x\to\infty} w(x) = 0$, $u_2'(0) < 0$ for all $a > x''$ (see Figure 3). Hence, the boundary tangency mechanism ensures that the family of bumps can exist only on a finite interval of positive a values.

Note further that $u_2''(0) = w'(0) + w'(a) = w'(a)$. If $u_2'(0) = 0$ for some a at which a transition between bump existence and bump nonexistence occurs, then we must have $u_2''(0) > 0$ (see Figure 8 below). This implies that the boundary tangency mechanism can apply only for a values such that $w'(a) > 0$, corresponding to bump death for large a as $-h$ is lowered toward 0 (see Figures 2 and 3). However, as we have noted, $u_2'(0) < 0$ for a sufficiently close to (but above) x_1. Thus, bumps must be born through an internal transition from negativity to positivity (the internal tangency mechanism discussed above) as a increases sufficiently beyond x_1. We summarize the above discussion in the following proposition, stated in terms of loss of existing bumps as a decreases or increases.

PROPOSITION 2.18. *Suppose there exists a_2 such that a bump solution $u_2(x)$ exists, with $u_2(x) > 0$ precisely for $x \in (0, a_2)$. Then as a decreases from a_2, the bump is lost through the internal tangency mechanism. As a increases from a_2, the bump is lost through either the internal tangency mechanism or the boundary tangency mechanism. In the former case, at least one of the internal tangencies must be at $x \neq a/2$.*

Remark 2.19. These birth and death mechanisms suggest that there may exist multibump solutions that satisfy (1.2). The existence and stability of such solutions remain open for future investigation. Note that the existence of multibumps cannot be addressed using (2.1) directly, since multibumps are positive on multiple disjoint regions.

We conclude this subsection by considering a numerical example of bump birth and death. The example coupling function that we introduce here will also be considered in section 3. Define

$$w(x) = (x^2 - c)w_0(x) := (x^2 - c)(De^{-dx^2} - Be^{-bx^2}). \tag{2.10}$$

We will take $c = 0.5, D = 11, d = 0.05, B = 6$, and $b = 0.035$ as our parameter values unless otherwise stated. This satisfies $(H1)$–$(H5)$; the functions $w_0(x)$ and $w(x)$ for these parameters appear in Figure 5. We also show the corresponding function $W(x) = \int_0^x w(t)\,dt$ on a range of positive x values. Note that in this example, $\lim_{x\to\infty} W(x) > 0$.

For this example, we gradually increase a. We plot $u(a/2)$ versus a in Figure 6, where u satisfies equation (2.2) with h such that equation (2.3) holds. A bump solution is formed when $u(a/2)$ reaches 0, at about $a = a_b \approx 7.14$.

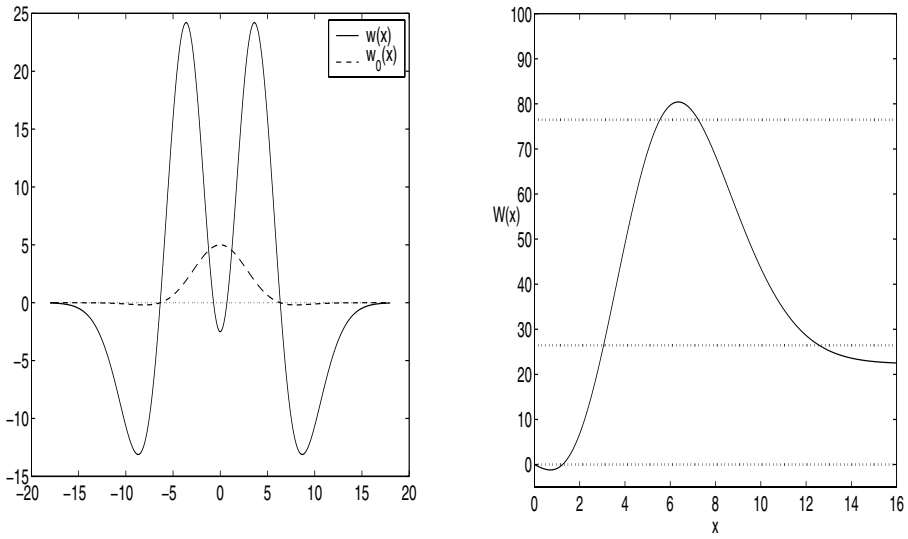

FIG. 5. *Coupling functions from* (2.10). *The left plot shows* $w(x), w_0(x)$ *with parameter values as given in the text following* (2.10). *The right plot shows* $W(x)$ *for these parameters. The dashed lines correspond to* $W(x) = 0$ *and to two special values of* $-h$ *for which bumps exist with spatially inhomogeneous coupling, discussed in section* 3.

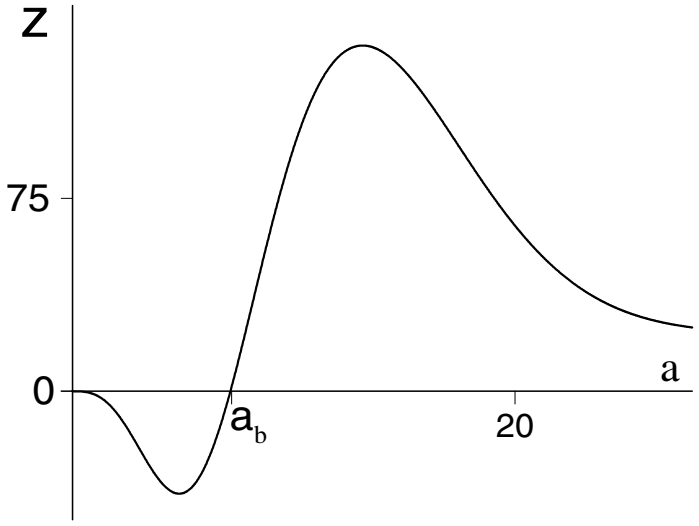

FIG. 6. *The value of* u *at* $a/2$ *plotted versus* a *for* $w(x)$ *from* (2.10). *Note that* $u(a/2) > 0$ *is necessary but not sufficient for bump existence. In this example, a family of bumps is born, as* h *(and thus* a*) is varied, as soon as* a *increases through* a_b*, such that* $u(a/2)$ *becomes positive. The bumps must die by a different mechanism, since* $u(a/2) > 0$ *for all* $a > a_b$.

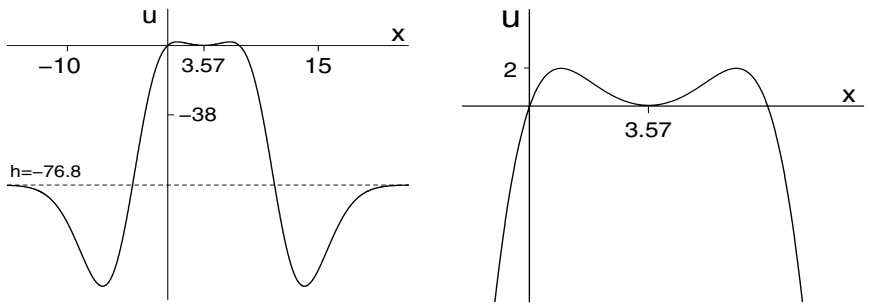

FIG. 7. *Solution $u_2(x)$ at birthpoint $a_b \approx 7.14$ (left), and blowup (right) showing internal tangency of the solution with the x-axis.*

In Figure 7, we plot the solution $u_2(x)$ with $a = a_b$. As a increases from a_b, the bumps that are born persist for an interval of a values; those found for two values of a appear in the top panels of Figure 8. Figure 8 also displays the death of the family of bumps as a continues to increase. At $a = a_d \approx 12.89$, $w(a) = w(0)$ such that $u_2'(0) = u_2'(a) = 0$. For $a > a_d$, bumps cannot exist; careful inspection shows that a representative solution to equations (2.2), (2.3), shown in the lower right plot, goes negative for small $x > 0$ and for x close to, but less than, a. This is not a valid bump solution.

2.5. Linear stability of the bump and bistability. To analyze the linear stability of the bump solution $u_2(x)$, we linearize (1.2) about $u_2(x)$. To compute the correct form of linearized equation, substitute $u = u_2(x) + v(x,t)$ into (1.2). This yields

$$\frac{\partial u}{\partial t} = \frac{\partial v}{\partial t} = -u_2(x) - v(x,t) + \int_{-\infty}^{\infty} w(x-y)H(u_2(y) - v(y,t))\,dy + h.$$

Derivation of the linear equation satisfied to first order by v requires expansion of the Heaviside function H about u_2. The result of this expansion yields [29, 19]

$$\begin{aligned} \frac{\partial v}{\partial t} &= -v + \frac{w(x)[v(0,t) - u_2(0)]}{|u_2'(0)|} + \frac{w(x-a_2)[v(a_2,t) - u_2(a_2)]}{|u_2'(a_2)|} \\ &= -v + \frac{w(x)v(0,t)}{u_2'(0)} - \frac{w(x-a_2)v(a_2,t)}{u_2'(a_2)}, \end{aligned} \tag{2.11}$$

since $u_2(0) = u_2(a_2) = 0$ by construction. Note that if v has its zeros in the same place as those of u, that is, $v(0) = v(a_2) = 0$, then $v' = -v$ and linear stability is immediate.

More generally, for linear stability, we consider perturbations of the form $v(x,t) = e^{\lambda t}v(x)$. Substitution of this expression into (2.11) and cancellation of $e^{\lambda t}$ terms yield the algebraic eigenvalue equation

$$(\lambda + 1)v(x) = w(x)v(0)/u_2'(0) - w(x-a_2)v(a_2)/u_2'(a_2). \tag{2.12}$$

Recall that $u_2'(x) = w(x) - w(x-a_2)$. Thus, (2.12) is equivalent to

$$(\lambda + 1)v(x) = \frac{w(x)v(0) + w(x-a_2)v(a_2)}{w(0) - w(a_2)}. \tag{2.13}$$

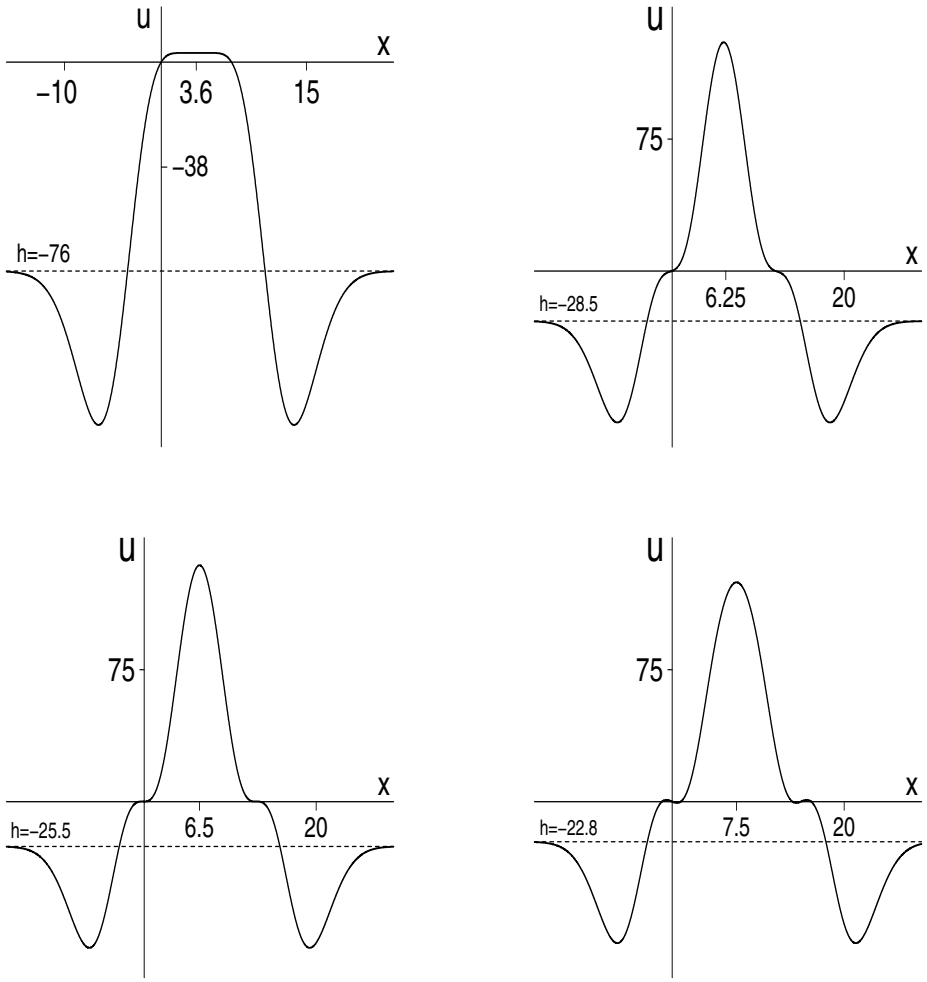

FIG. 8. *Solutions to equations* (2.2), (2.3) *at* $\epsilon = 0$: $a = 7.24$ *(upper left) just after bump birth,* $a = 12$ *(upper right) just before bump death,* $a = 12.89$ *(lower left) where bump death occurs, and* $a = 13$ *(lower right) just after bump death. Note that the solution shown in the lower right is not a valid solution to* (2.1).

Eigenvalues occur at those λ values for which (2.13) has a nontrivial solution $v(x)$. (Note that any such solution decays to 0 asymptotically, since $w(x), w(x - a_2)$ do.) Substitution of $x = 0$ and $x = a_2$ into (2.13) yields a pair of equations in the unknowns $v(0)$ and $v(a_2)$, namely,

$$(\lambda + 1)v(0) = \frac{w(0)v(0) + w(a_2)v(a_2)}{w(0) - w(a_2)}, \tag{2.14}$$

$$(\lambda + 1)v(a_2) = \frac{w(a_2)v(0) + w(0)v(a_2)}{w(0) - w(a_2)}.$$

If $v(a_2) = 0$, then $v(0) = 0$, and only the trivial solution $v \equiv 0$ satisfies (2.13). We

have already observed that perturbations with $v(0) = v(a_2) = 0$ cannot cause an instability, based on (2.11). Thus, assume that $v(a_2) \neq 0$. We use the first equation in (2.14) to write $v(0)$ as a function of $v(a_2)$. Upon substitution of this expression into the second equation in (2.14), cancellation of the nonzero quantity $v(a_2)$ multiplying each term, and algebraic manipulation, we obtain the following quadratic equation in λ:

$$\lambda^2 \left(w(0) - w(a_2)\right)^2 + \lambda \left(\left(w(0) - w(a_2)\right)^2 + w^2(a_2) - w^2(0)\right) = 0. \tag{2.15}$$

The solution $\lambda = 0$ of (2.15) corresponds to translation invariance of the bump. The other solution of (2.15) satisfies

$$\lambda = \frac{2w(a_2)\left(w(0) - w(a_2)\right)}{\left(w(0) - w(a_2)\right)^2}. \tag{2.16}$$

Recall that $w(a_2) < w(0) < 0$. Thus, the unique solution λ of equation (2.16) is real and negative, and the bump solution is linearly stable.

Note from (1.2) that $u = c := h + \int_{-\infty}^{\infty} w(x)\,dx$ is a stationary, spatially uniform solution, provided that $c > 0$. When this solution exists, the same linearization calculation that yields (2.11) yields the linearized stability equation $dv/dt = -v$, since for small perturbations $c - v > 0$, such that $H(c - v) = 1$. Thus, the spatially uniform state is linearly stable, when it exists, which implies that (1.2) features bistability, at least in terms of linear analysis. This is consistent with the findings of [20], in which a network of bursting thalamic cells with an effectively off-center form of coupling displayed bistability between a spatially localized and a spatially uniform state. In [20], however, the spatially uniform state corresponded to a complete absence of activity.

3. Spatially inhomogeneous coupling. It has been argued that the coupling between cells should be spatially inhomogeneous, reflecting local structural variations [2, 3]. In this section, we use analysis and numerics to consider how such a modification affects properties of bump solutions of (1.2). To this end, we consider bump solutions of the equation

$$\frac{\partial u(x,t)}{\partial t} = -u(x,t) + \int_{-\infty}^{\infty} w(x-y)p(y)H(u(y,t))\,dy + h. \tag{3.1}$$

To allow for concrete calculations and numerics, we mostly consider a spatial inhomogeneity used, for example, in [2], namely,

$$p(x) = 1 + \epsilon(1 + \cos(\rho x + \phi)). \tag{3.2}$$

Without loss of generality, we take $\rho = 1$.

In subsection 3.1, we will consider the special case of $\phi = 0$, restricting our attention to bumps on $(0, a)$. In subsection 3.2, we will address the general bump existence question for $p(x)$ given by (3.2). We shall see that, in contrast to the spatially homogeneous case, the presence of inhomogeneity implies that for fixed $p(x)$, for each bump starting point, there is only a small, discrete set of background input levels for which bumps can occur, each with a unique corresponding size. Based on the mechanisms that we observe with $p(x)$ given by (3.2), we expect qualitatively similar results for nonperiodic $p(x) = 1 + \epsilon p_0(x)$ (see Remark 3.4 at the end of the section). Further, at least for the case of $p(x)$ given by (3.2) and $w(x)$ given by (2.10), we find that among the possible bump sizes, there is a certain invariant size selected independent of ϕ and of bump starting position. Possible functional implications of these results are considered in the discussion in section 4.

3.1. Bumps on $(0, a)$ with no phase shift ($\phi = 0$). Note that spatial inhomogeneity in coupling may destroy spatial translation invariance of bump solutions. For clarity, we first consider the special case of bumps on $(0, a)$ with phase shift $\phi = 0$. We will illustrate the key observation that for a fixed spatial pattern of coupling (fixed ρ and ϕ) and a fixed starting point of an activity bump (here $x = 0$), there is only a small, discrete set of possible bump sizes that can be selected. That is, the spatial inhomogeneity induces a form of bump pinning.

As previously, a bump must satisfy $u(0) = u(a) = 0$ and $u(x) > 0$ if and only if $x \in (0, a)$, for some positive number a. If a bump solution $u(x)$ exists for some a, the Heaviside function H in equation (3.1) implies that $u(x)$ must satisfy

$$u(x) = \int_0^a w(x - \eta)p(\eta)\, d\eta + h \tag{3.3}$$

for that a. Thus, to find a bump solution, we first seek a for which $u(0) = u(a) = 0$, with $u(x)$ specified by (3.3).

The corresponding equations are

$$0 = \int_0^a w(\eta)p(\eta)\, d\eta + h \tag{3.4}$$

and

$$0 = \int_0^a w(a - \eta)p(\eta)\, d\eta + h. \tag{3.5}$$

Subtracting these two equations, i.e., (3.5)−(3.4), yields

$$g(a) := \int_0^a w(a - \eta)p(\eta)\, d\eta - \int_0^a w(\eta)p(\eta)\, d\eta = 0. \tag{3.6}$$

To find candidate values of a, we first seek solutions of $g(a) = 0$, given by

$$\int_0^a w(\eta)p(\eta)\, d\eta = \int_0^a w(a - \eta)p(\eta)\, d\eta. \tag{3.7}$$

Now, from the substitution $y = a - \eta$, note that

$$\int_0^a w(a - \eta)p(\eta)\, d\eta = \int_0^a w(y)p(a - y)\, dy.$$

But $p(a - y) = 1 + \epsilon(1 + \cos(a - y)) = 1 + \epsilon(1 + \cos a \cos y + \sin a \sin y)$. Hence, if $a = 2n\pi$ for any integer n, then $p(a - y) = p(y)$, and we find

$$g(2n\pi) = \int_0^a w(y)p(y)\, dy - \int_0^a w(\eta)p(\eta)\, d\eta = 0.$$

Thus, $a = 2n\pi$ solves $g(a) = 0$ for any integer n (see Figures 9 and 11). However, we also need (3.4), (3.5) to hold such that $u(0) = 0$ and $u(a) = 0$, which occurs only for those special values of n such that $-h = \int_0^{2n\pi} w(\eta)p(\eta)\, d\eta$ $(= \int_0^{2n\pi} w(2n\pi - \eta)p(\eta)\, d\eta$ since $g = 0)$, which may or may not be positive, as required.

Remark 3.1. This does not imply there is a special biological significance to bump sizes that are even integer multiples of π. If $\rho \neq 1$, then other zeros result here. The point is that the nature of the spatial variation $p(x)$ selects possible bump sizes.

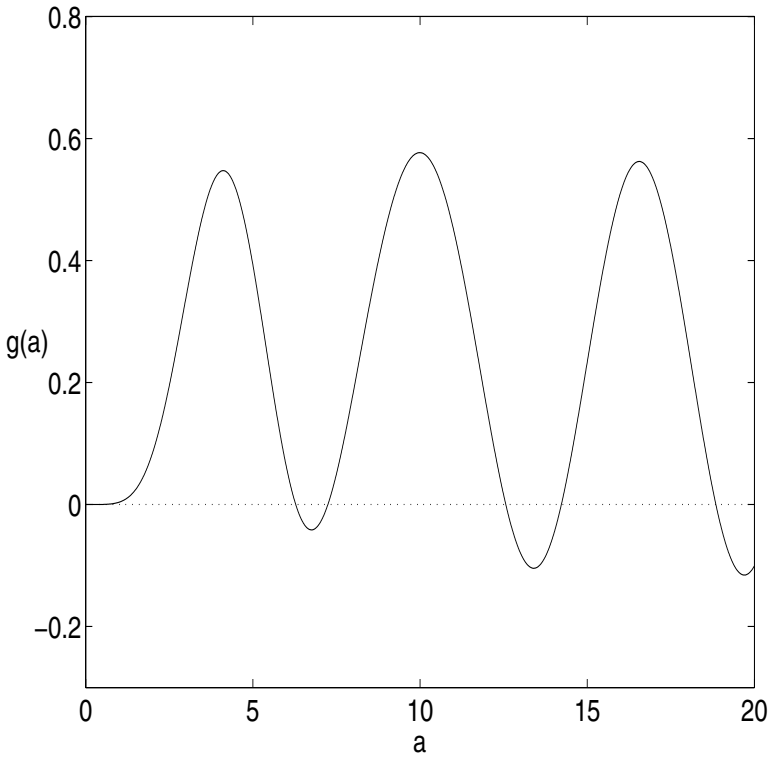

FIG. 9. *The function $g(a)$, defined in* (3.6)*, for $w(x)$ from* (2.10) *with our usual parameter values. Note that $g(0) = g(2\pi) = g(4\pi) = 0$ and that there are other zeros of g that are not even integer multiples of π.*

There also may be other solutions of $g(a) = 0$. We seek these numerically. To do so, we apply Matlab directly, and we also check our results by using XPPAUT [12] to solve an ordinary differential equation for $g(a)$, derived in the second subsection of the appendix.

We consider now the coupling function $w(x)$ defined in equation (2.10) in the previous section and shown in Figure 5, namely,

$$w(x) = (x^2 - c)w_0(x) := (x^2 - c)(De^{-dx^2} - Be^{-bx^2}),$$

with $c = 0.5, D = 11, d = 0.05, B = 6$, and $b = 0.035$ as usual.

The resulting $g(a)$, for $\epsilon = 0.01$, appears in Figure 9. Numerically, the zeros of $g(a)$ in the set of positive a are $\{2\pi, 7.25, 4\pi, 14.23, 6\pi, \ldots\}$, where the zeros that are not integer multiples of π form a single sequence in which the difference between subsequent elements tends to 2π, since $w(x)$ tends to 0 as $x \to \infty$. We find qualitatively similar results, namely, a countable collection of isolated zeros with similar behavior as $a \to \infty$, for a variety of other parameter sets for $w(x)$ with $\epsilon > 0$.

We note that in general, $g'(0) = g''(0) = g'''(0) = 0$ (see subsection 5.2 of the appendix for a proof). Moreover, we find from (5.8) in the appendix that

$$g^{(4)}(a) = -g''(a) - 3w''(a)p'(a) - 2w'(a)p''(a) + w'''(a)(p(0) - p(a)),$$

so $g^{(4)}(0) = 0$, while

$$g^{(5)}(a) = -g'''(a) - 4w'''(a)p'(a) - 5w''(a)p''(a) - 2w'(a)p'''(a) + w^{(4)}(a)(p(0) - p(a)),$$

so $g^{(5)}(0) = -5w''(0)p''(0) = 5\epsilon w''(0) > 0$. This gives a sense of the behavior of g near $a = 0$, which depends on ϵ.

Since $p(x) = 1 + O(\epsilon)$, it is obvious that the zeros of g do not depend on ϵ. More explicitly, the function $g(a)$ defined in (3.6) can be rewritten as

$$g(a) = \int_0^a w(\eta)p(a-\eta)\,d\eta - \int_0^a w(\eta)p(\eta)\,d\eta.$$

Upon substitution of definition (3.2) for p with $\rho = 1$ and $\phi = 0$ and application of a trigonometric identity for $\cos(a - \eta)$, this yields

$$g(a) = \epsilon\left[(\cos a - 1)\int_0^a w(\eta)\cos(\eta)\,d\eta + \sin a \int_0^a w(\eta)\sin(\eta)\,d\eta\right], \tag{3.8}$$

which will also be useful below.

Once we have found the zeros of g for a particular choice of parameters (including ϵ), it remains to check whether these really correspond to a values for which (3.4), (3.5) hold, for some $h < 0$. Only in that case will a bump possibly exist. Note that we restrict further to those a values such that

$$\frac{d}{da}\int_0^a w(\eta)p(\eta)d\eta = w(a)p(a) < 0, \tag{3.9}$$

since only a_2, but not a_1, gives a valid bump in the $\epsilon = 0$ case. In the example shown, the zeros $a \approx 7.25$ and $a = 4\pi$ of g are the only ones which satisfy (3.4), (3.5), and (3.9) for some $h < 0$. The corresponding h values for $\epsilon = 0$ are $h \approx -76.09$ and $h \approx -26.45$, respectively, although these depend on ϵ. The intersections of these values of h with $W(x)$ for $\epsilon = 0$ are displayed in Figure 5. In Figure 10, we plot the corresponding bump solution for $a \approx 7.25$ with $\epsilon = 0.1$. Figure 11 shows the bump solutions for $a = 4\pi$ with $\epsilon = 0, 0.1$, and 0.2, respectively. Note that the bump with $a \approx 7.25$ loses its symmetry for $\epsilon > 0$, while the bump with $a = 4\pi$ is symmetric about $a/2 = 2\pi$ for all ϵ by the 2π-periodicity of $\cos(x)$ and $\sin(x)$. Further, in both cases, the bump widths are independent of ϵ.

3.2. General case: Bumps on (b_1, b_2) with arbitrary ϕ. In this section, we will arrive at the following result: Given a spatial inhomogeneity of coupling of the form (3.2), with ϕ fixed, for any bump starting point b_1, there is a small, discrete set of possible bump sizes. Moreover, there is a subset of these sizes (possibly empty, but nonempty for the main example that we have been considering) which are possible for *all* choices of b_1 and ϕ.

In the general case, the bump existence equations become

$$0 = \int_{b_1}^{b_2} w(b_2 - \eta)p(\eta)\,d\eta + h \tag{3.10}$$

and

$$0 = \int_{b_1}^{b_2} w(b_1 - \eta)p(\eta)\,d\eta + h, \tag{3.11}$$

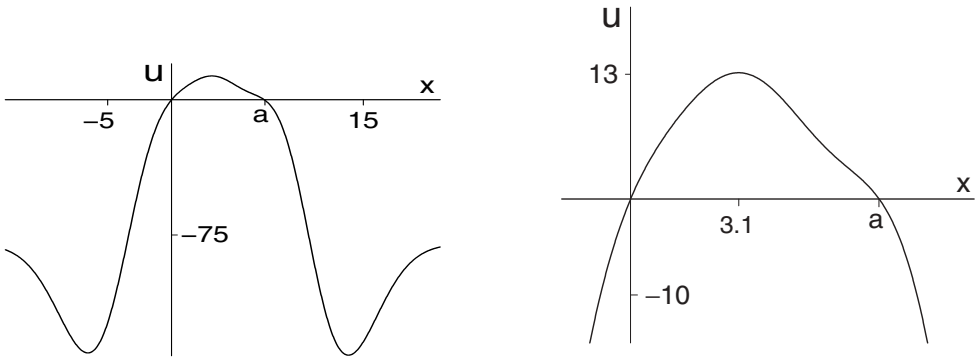

FIG. 10. *Solution at $a \approx 7.25$ and $\epsilon = .1$ (left) and blowup (right). Note that the solution is not symmetric around $x = \frac{a}{2}$ when $\epsilon > 0$ and a is not an even multiple of π.*

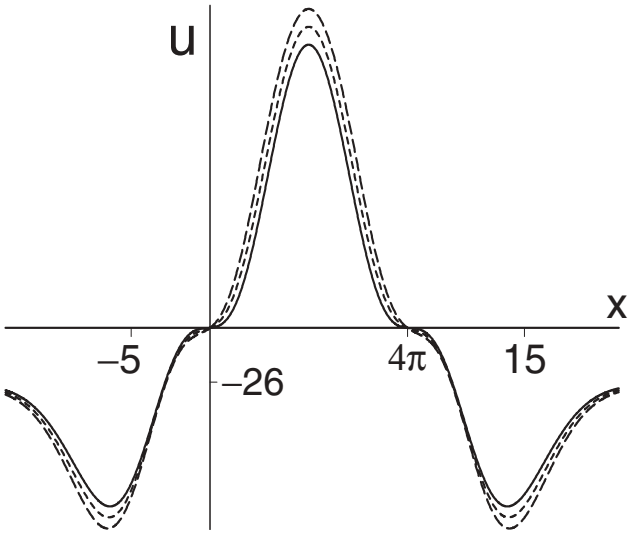

FIG. 11. *Solutions at $a = 4\pi$ and $\epsilon = 0$ (solid curve), $\epsilon = .1$ (dashed curve), and $\epsilon = .2$ (long dashed). Note that solutions are symmetric around $x = \frac{a}{2}$ when $\epsilon > 0$ and a is an even multiple of π.*

where we use (b_1, b_2) to denote the interval on which the bump is positive to avoid confusion with our earlier use of a_1, a_2. Again, we subtract to obtain

$$0 = \int_{b_1}^{b_2} w(b_2 - \eta)p(\eta)\,d\eta - \int_{b_1}^{b_2} w(b_1 - \eta)p(\eta)\,d\eta. \tag{3.12}$$

We seek solutions of (3.12), which are exactly the solutions of the following equation, attained by change of variables and by setting $z_i = b_i - \phi$ for $i = 1, 2$:

$$0 = g(z_1, z_2) := \int_0^{z_2 - z_1} w(y)p(b_2 - y)\,dy + \int_0^{z_2 - z_1} w(y)p(b_1 - y)\,dy. \tag{3.13}$$

It is not apparent by inspection that $g(z_1, z_2)$ as defined in (3.13) is a function of z_1, z_2 only. However, using the definition of p in (3.2) and trigonometric sum and difference

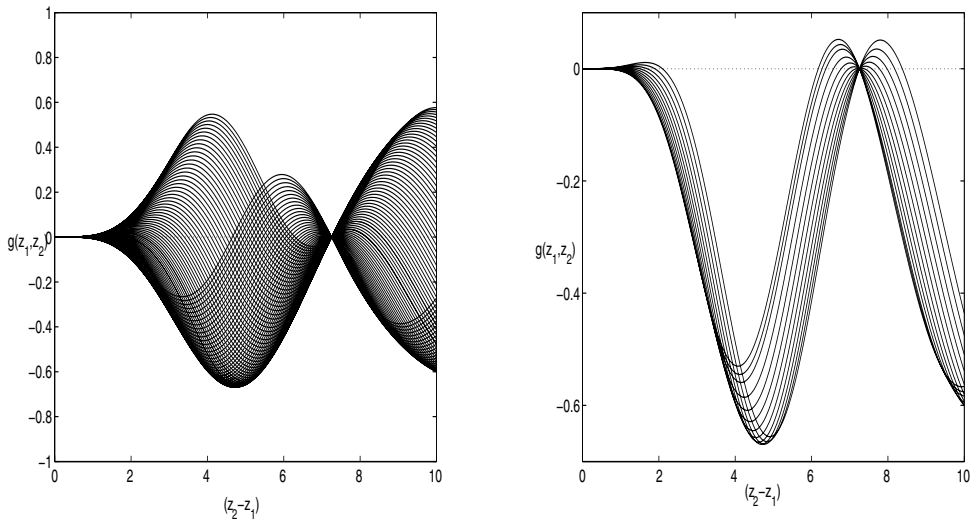

FIG. 12. *The function $g(z_1, z_2)$ given in* (3.14). *Each single curve in each plot shows $g(z_1, z_2)$ versus $z_2 - z_1$ for fixed z_1. Different curves correspond to different z_1 values. Note that $z_2 - z_1 \approx 7.25$ is a zero of $g(z_1, z_2)$ for all z_1. The right plot shows a closer view around $z_2 - z_1 \approx 7.25$, with fewer curves shown than on the left.*

identities, one can calculate that

$$g(z_1, z_2) = \epsilon \int_0^{z_2 - z_1} w(y) \left[\cos y(\cos z_2 - \cos z_1) + \sin y(\sin z_2 + \sin z_1)\right] dy. \tag{3.14}$$

Note that (3.8) corresponds to a special case of (3.14), with $z_1 = 0$. Further, as noted in subsection 3.1, the zeros of $g(z_1, z_2)$ are independent of $\epsilon > 0$.

Again, the realizable bump sizes, determined by (3.10), (3.11) with the restriction $h < 0$, are a subset of the set of the zeros of g. For fixed ϕ, if we start with $b_1 = \phi$ (that is, $z_1 = 0$), then we recover exactly the bump sizes found with $\phi = 0$. As b_1 is varied from ϕ (or, equivalently, z_1 is varied from 0), then we may pick out different bump sizes. *Some of these, however, may be invariant under changes in z_1.* Indeed, Figure 12 shows plots of $g(z_1, z_2)$ for $w(x)$ from (2.10) and $p(x)$ from (3.2). To produce this figure, z_1 was systematically varied (increasing from 0), and for each fixed z_1, z_2 was varied from z_1 up to $z_1 + 10$ to form an individual curve. The figure shows the resulting $g(z_1, z_2)$ values for each fixed z_1 plotted versus $z_2 - z_1$; that is, each curve has been translated so that it begins at $z_2 - z_1 = 0$, with $g = 0$ correspondingly. The value $z_2 - z_1 = z^* \approx 7.25$ gives a zero of g, corresponding to the existence of a bump solution with $h < 0$, for each starting position z_1. The close-up in the right panel of the figure shows how $\partial g(z_1, z_1 + z^*)/\partial z_2$ passes through 0 as z_1 is varied. Note that similar results were obtained with various other choices of parameter values in $w(x)$.

Remark 3.2. Since the bump size $z_2 - z_1 \approx 7.25$ is realized for all z_1, and since $z_i = b_i - \phi$, this size is invariant under changes in ϕ. That is, for any choice of ϕ and starting position b_1, if $b_2 \approx b_1 + 7.25$, then there is a bump solution $u(x)$ of width approximately equal to 7.25 such that $u(x) > 0$ precisely for $x \in (b_1, b_2)$. Although this solution retains its width, it will occur at different levels of h for different choices of b_1, b_2, ϕ.

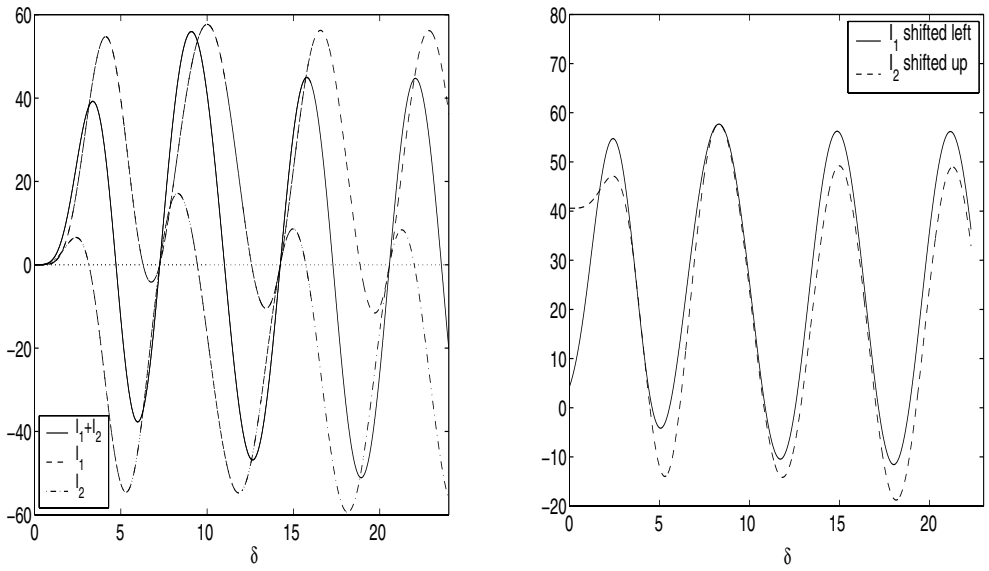

FIG. 13. *Components of* (3.16) *for* $w(x)$ *given in* (2.10) *with usual parameter values. The left plot shows* $I_1(\delta) + I_2(\delta)$ *(middle curve, solid),* $I_1(\delta)$ *(upper curve, dashed), and* $I_2(\delta)$ *(lower curve, dash-dotted), graphed versus* δ*. Note that zeros* δ *of* $I_1(\delta)$ *that are not even multiples of* π*, such as* $\delta \approx 7.25$*, are also zeros of* $I_2(\delta)$*. Since the plot appearance suggests that* $I_1(\delta), I_2(\delta)$ *might be shifted translates of each other, we illustrate graphically in the right plot that this is not the case.*

To understand why there is an invariant bump size, set $\delta = z_2 - z_1$ in (3.14), such that g becomes

$$g(z_1,\delta) = \epsilon \int_0^\delta w(y)\,[\,\cos z_1\,(\cos y(\cos\delta - 1) + \sin y \sin\delta) + \sin z_1\,(\sin y(\cos\delta + 1) - \cos y \sin\delta)]\; dy. \tag{3.15}$$

The function $g(z_1, \delta)$ has some obvious nontrivial zeros, such as $(z_1, \delta) = ((4m + 3)\pi/4, (4n + 1)\pi/2)$ and $(z_1, \delta) = ((4m + 1)\pi/4, (4n + 3)\pi/2)$ for any integers m, n, but these do not give bumps, as they do not solve (3.10), (3.11).

Note that when $z_1 = 0$, the definition of $g(z_1, \delta)$ in (3.15) reduces to (3.8) for $g(a)$ in the $\phi = 0$ case, which for $w(x)$ given by (2.10) with our usual parameter values has a zero at $a = z^* \approx 7.25$. Indeed, we can factor out $\cos z_1$ from the first term on the right-hand side of equation (3.15) and $\sin z_1$ from the second term to write

$$g(z_1,\delta) = \epsilon(\cos z_1 I_1(\delta) + \sin z_1 I_2(\delta)), \tag{3.16}$$

where $I_1(\delta) = 0$ for $\delta = 2\pi, z^*, 4\pi, \ldots$. If there are zeros of $I_2(\delta)$ within this set, then these represent potential bump sizes that are independent of starting position and phase (which were encoded in z_1). Numerical experiments suggest that the zeros of $I_1(\delta)$ that are not even multiples of π are also zeros of $I_2(\delta)$; see Figure 13.

Remark 3.3. Although we have not explored what happens with coupling functions $w(x)$ other than that given in (2.10), the form of (3.14), (3.15) strongly suggests that the phenomena observed here do not depend on the exact form of $w(x)$.

Remark 3.4. For general $p(x) = 1 + \epsilon p_0(x)$ with $p_0(x)$ not necessarily periodic, (3.10), (3.11) still apply, with bumps occurring when both are satisfied. One can also

solve (3.12) to find candidate bump endpoints b_1, b_2, with solutions independent of ϵ as above. Thus, we expect that for each fixed $p_0(x)$ and bump starting position b_1, there will be a small number of possible bump sizes selected. We do not know whether or not there will exist an invariant size, independent of starting position, for general $p_0(x)$, however.

4. Discussion. In this paper, we consider localized, stationary activity bump solutions of the rate model (1.1), which describes the evolution of activity in a neuronal population. Following previous work stemming from [1], we take $f(u(y,t)) = H(u(y,t))$, the Heaviside step function, which is an analytically tractable case that has been shown to organize solution structure for some more general forms of f [15]. A key new feature in this paper is that the coupling function $w(x)$ represents off-center coupling. Off-center coupling models the effective pattern of synaptic inputs to an excitatory population in an excitatory-inhibitory (E-I) network with no recurrent excitation, but rather E to I, I to E, and I to I connections.

In this setting, under certain assumptions, we prove that for nonzero h, (1.1) has exactly one time-independent, localized solution satisfying $u(x) > 0$ if and only if $x \in (0, a)$ for a positive, finite constant a. This shows that coupling need not be locally positive to allow for the existence of such a sustained, localized solution. Earlier results showed that the combination of recurrent excitation and long-range inhibition yields the existence of a pair of bump solutions, a linearly stable wider one and an unstable narrower one, to (1.1) [1, 13, 17, 4, 5]. Here we find that for off-center coupling, the unstable bump does not exist, while the single bump that does exist is linearly stable. The nonlinear stability of these bump solutions remains open for investigation.

We show that the range of activity levels h over which bumps can exist, and correspondingly the range of possible bump widths, is finite. Since there is at most a single bump for each h, this brings up the question of how bumps are born and disappear as h varies. We have discussed two types of mechanisms by which this may occur. One mechanism, which can apply to bump birth or death, is the appearance of a point or points inside $(0, a)$ at which u becomes negative. This fits in well with our results showing that a bump can develop an internal local minimum while remaining a valid bump, with $u > 0$ on $(0, a)$. The second mechanism, which can generate only bump death, not bump birth, is a loss of positivity at the edges $x = 0$ and $x = a$ of u. Numerically, we observe bump birth via the former mechanism and bump death via the latter. These mechanisms will not occur when the coupling function $w(x)$ is not off-center (i.e., when there is recurrent excitation). Further, we do not consider temporally dynamic solutions. It is possible that there may be interactions of time-dependent solutions with stationary bumps, which remain to be explored.

We also do not consider temporal details of synaptic dynamics. Our results require sufficiently strong long-range inhibition for bumps to exist with off-center coupling. Thus, our analysis supports the idea that when long-range inhibition is weak [10], slow synaptic dynamics may be necessary to allow for localized activity [20]. Even richer forms of pattern formation can be expected when models incorporating such additional features are considered in future work.

In section 4, we allow for spatial variations in coupling strength, which may correspond to regional structural variations in the brain [2]. Numerically, we observe that this induces bump pinning, such that for each fixed starting position, bumps exist for only a small, discrete set of background input levels h, each with a single corresponding width. Moreover, a unique invariant width is selected, which is possible

at all starting positions. The form of the relevant equations suggests that these results do not depend on the exact form of the coupling function $w(x)$ or on the fact that it is off-center, although this remains to be thoroughly explored. We provide mathematical insight into this size invariance (e.g., Figure 13), but we do not provide analytical proof that this size invariance must occur.

Is it physiologically plausible that spatial inhomogeneities in coupling strength could so severely limit the possible background input levels needed for bumps? We can only speculate on this issue. Since it is believed that attention has significant effects on neuronal activity across wide areas (for example, [11]), it seems possible that the background input level to a brain region could be related to attention. We know from experience that attention is needed to allow for effective working memory or navigation, for example; one needs to first pay attention to a stimulus if one wishes to remember it, and one needs to maintain focus on the memory of this stimulus to keep it "in mind" until it is internalized. Perhaps attention is the process of bringing overall network activity in an appropriate brain region to a level at which a bump can form and subsequently maintaining this level to sustain the localized bump. Since bump sizes are selected by integral conditions relating the spatially homogeneous and inhomogeneous parts of the coupling pattern, perhaps some part of cognitive decline with aging or disease could be associated with a loss of effectiveness of a subset of synaptic connections, which could compromise the "orthogonality" of the system.

Similarly, while a severe limitation on the number of possible bump sizes might initially seem computationally restrictive, there would be advantages to this limitation. In particular, suppose that only a unique bump size were realizable in a certain brain area and that bumps were always symmetric about their centers. If an activity level $u > 0$ were observed from one cell in that area (e.g., by a neuron postsynaptic to it from another area), this would immediately indicate the exact distance of the presynaptic cell from the center of any bump to which it belonged, and activity levels of two cells would suffice to indicate exactly which other cells were in the bump and with which activity levels. This allows for highly efficient decoding by the postsynaptic cell. Note that we observe the development of asymmetric bumps when the coupling is spatially inhomogeneous and the bump length is not an even integer multiple of 2π. Even without symmetry, inputs from a small number of cells in a bump would effectively convey information about the entire bump. Of course, this requires that the postsynaptic cell somehow "knows" that a bump exists in the presynaptic area, and is highly speculative, but nonetheless it suggests that there might be some computational relevance to the bump pinning phenomenon that we have observed.

5. Appendix.

5.1. Coupling profile. The activity levels $u_E(x,t)$ and $u_I(x,t)$ of coupled excitatory and inhibitory populations satisfy the model equations [28, 1, 19]

$$\begin{aligned} \tfrac{\partial u_E}{\partial t} &= -u_E + w_{EE} * f_E(u_E) - w_{IE} * f_I(u_I) + h_E, \\ \tau \tfrac{\partial u_I}{\partial t} &= -u_I + w_{EI} * f_E(u_E) - w_{II} * f_I(u_I) + h_I, \end{aligned} \tag{5.1}$$

where $w * f(u)$ denotes the convolution $\int_{-\infty}^{\infty} w(x-y) f(u(y,t))\, dy$, $f_i(u)$ is the firing rate function for population i, and w_{ij} denotes the synaptic connection function from population i to population j, which we take here to be nonnegative for all i, j. We consider (1.1) to represent a reduction of (5.1), with $w_{EE} \equiv 0$, to a single equation for the activity level of the excitatory population. The connection function $w(x)$ that we

consider in (1.1), as shown in Figure 1, corresponds to the time-independent input to the excitatory population that results when precisely those excitatory cells at $x = 0$ are active.

To derive the function shown in Figure 1, we therefore set the time derivatives in system (5.1) to zero. This gives $u_E = h_E - w_{IE} * f_I(u_I)$. We assume $h_E > 0$ and aim for an activity profile of u_E which has the form of $w(x)$ shown in Figure 1. This will imply that the activity of cells at $x = 0$ has the desired effect on the activity of the other cells in the excitatory population. For simplicity, assume that $w_{IE}(x)$ has a simple profile; for example, suppose that each inhibitory cell inhibits only those excitatory cells that share its x-coordinate. Then we seek an activity profile of u_I which has the qualitative form of $-w(x)$, for $w(x)$ shown in Figure 1.

Time-independence implies that $u_I = h_I + w_{EI} * f_E(u_E) - w_{II} * f_I(u_I)$. Further, the assumption that only those cells at $x = 0$ are active gives

$$u_I(x) = h_I + w_{EI}(x) - w_{II} * f_I(u_I), \tag{5.2}$$

although other positive coefficients of w_{EI} may result from non-Heaviside choices of f_E. Thus, the mathematical justification of off-center coupling for (1.1), as in Figure 1, may be achieved by finding a consistent solution of (5.2) having the qualitative form of $-w(x)$, for an appropriate firing rate function f_I. Note that (5.2) has a form very similar to that of the steady state equation (2.1) analyzed in this paper, but with a spatially varying input function, as studied, for example, in [1]. The desired solution would be positive on $(-\infty, -b) \cup (-a, a) \cup (b, \infty)$ for some $b > a > 0$. The proof of the existence of such a solution remains open.

5.2. Derivation of ODE. Recall that for $p(x) = 1 + \epsilon(1 + \cos x)$, we define

$$g(a) = \int_0^a w(a - \eta)p(\eta)\, d\eta - \int_0^a w(\eta)p(\eta)\, d\eta\,. \tag{5.3}$$

Thus, using integration by parts, the fact that $w(x)$ is even, and the fact that $w'(0) = 0$, we have

$$\begin{aligned} g'(a) &= p(a)(w(0) - w(a)) + \textstyle\int_0^a w'(a - \eta)p(\eta)\, d\eta \\ &= w(a)(p(0) - p(a)) + \textstyle\int_0^a w(a - \eta)p'(\eta)\, d\eta. \end{aligned} \tag{5.4}$$

Similarly,

$$g''(a) = -w(a)p'(a) + w'(a)(p(0) - p(a)) + \int_0^a w(\eta - a)p''(\eta)\, d\eta \tag{5.5}$$

and

$$\begin{aligned} g'''(a) = &- 2w'(a)p'(a) - w(a)p''(a) + w''(a)(p(0) - p(a)) + w(a)p''(0) \\ &+ \int_0^a w(\eta - a)p'''(\eta)\, d\eta\,. \end{aligned} \tag{5.6}$$

But since

$$p'''(\eta) = -p'(\eta),$$

(5.6) and (5.4) can be combined to give

$$g''' + g' = w(a)[p(0) - p(a) + p''(0) - p''(a)] - 2w'(a)p'(a) + w''(a)(p(0) - p(a))\,. \tag{5.7}$$

Finally, the fact that

$$p''(x) = -\epsilon \cos x$$

yields $p(x) + p''(x) = 1 + \epsilon$ for any x, such that $p(0) + p''(0) - (p(a) + p''(a)) = 0$. Thus, the ODE (5.7) simplifies to

$$g''' + g' = -2w'(a)p'(a) + w''(a)(p(0) - p(a)) = \epsilon(2w'(a)\sin a + w''(a)(1 - \cos a)). \tag{5.8}$$

Note that from (5.3), (5.4), (5.5), (5.6), it follows that

$$g(0) = g'(0) = g''(0) = g'''(0) = 0\,.$$

A MATHEMATICAL MODEL FOR THE SULPHUR DIOXIDE AGGRESSION TO CALCIUM CARBONATE STONES: NUMERICAL APPROXIMATION AND ASYMPTOTIC ANALYSIS*

D. AREGBA-DRIOLLET†, F. DIELE‡, AND R. NATALINI§

Abstract. We introduce a degenerate nonlinear parabolic system that describes the chemical aggression of calcium carbonate stones under the attack of sulphur dioxide. For this system, we present some finite element and finite difference schemes to approximate its solutions. Numerical stability is given under suitable CFL conditions. Finally, by means of a formal scaling, the qualitative behavior of the solutions for large times is investigated, and a numerical verification of this asymptotics is given. Our results are in qualitative agreement with the experimental behavior observed in the chemical literature.

Key words. chemical aggression, porous media, nonlinear parabolic equations, fast reaction limit, free boundary problems, finite element, finite differences

1. Introduction.

In this paper we introduce and investigate a differential model to describe the evolution of the chemical action of SO_2 (sulphur dioxide) in $CaCO_3$ (calcium carbonate) stones. Let Ω be a given region in $\mathbb{R}^n$, with $n = 1, 2, 3$, namely, our stone specimen. Our basic equations read, in their adimensional form, as

$$\begin{cases} \partial_t(\varphi(c)s) - \nabla \cdot (\varphi(c)\nabla s) = -\varphi(c)sc, \\ \\ \partial_t c = -\varphi(c)sc, \end{cases} \tag{1.1}$$

for $x \in \Omega$ and $t \in \mathbb{R}$. Here c and s are both nonnegative, since c stands for the local density of $CaCO_3$ and s for the porous concentration of SO_2, namely, the concentration taken with respect to the volume of the pores; here the porosity φ is a linear function of the density c. For this problem we also have to specify the initial and boundary conditions, according to the problem under examination.

There is an extensive chemical literature about the deterioration mechanisms of natural building stones [22, 23, 14, 26, 18, 8] in connection with problems concerning both modern and historical buildings. Acidity in the air is essentially caused by pollutants, such as sulphur and nitrogen oxides, which are emitted into the atmosphere by sources related to industry, transportation, and heating. These species are transformed, through complex reaction pathways, into gaseous nitric and nitrous acids and into acidic sulphates as suspended particles. Although in recent years the levels of

pollution in the urban areas of Europe have decreased, levels of HNO_3 and other aggressive pollutants such as sulphur dioxide and ozone have remained consistent. As is well known, SO_2 and NO_3 react with calcium carbonate stones to form sulphates and nitrates, which, due to their solubility in water, may be drained away or, if protected from the rain, may form crusts, which eventually exfoliate; see [8, 5]. Observe that the chemical deterioration is mainly expected to occur when the surface is wet. There is in fact a strong experimental relationship between deterioration and time of wetness [14].

Effective simulation tools seem to be crucial in considering the fine-scale evolution of reaction pathways, possibly in complex geometries, as requested by an improved policy of prevention and monitoring of chemical damage on historical monuments. For instance, it should be important to assist stakeholders to assign a degree of priority for an optimal scheduling of cleaning operations, also taking into account the local geometry and the exposure of the concerned stones. Actually, the standard methods used for studying the evolution of this kind of damage have been the development of models of atmospheric corrosion; they are based on the statistic determination on the ratio of dose and response of the materials. For instance, the Lipfert formula [19] was applied, using an extended database containing values taken in the field (i.e., meteorological value and pollution of the air). If this procedure could be meaningful for the determination of corrosion for civil uses, this approach is clearly insufficient for artistic and historical artwork.

In this paper we introduce a different approach in the framework of hydrodynamic models by using some basic physical relations, the balance laws of the chemical reactions, and the Fick law, and by neglecting the permeability of the medium. As a particular feature, the model takes into account the effects of sulphation on carbonate rocks, by assuming a direct (linear) dependence of porosity and diffusivity on the density of calcium carbonate. The main issue of our model will be a proper determination of the thickness of the gypsum crust ($CaSO_4 \cdot 2H_2O$) formed as a product of the reaction of SO_2 with calcium carbonate stones. There are two main advantages in this approach: it is possible to solve numerically the equations by finite element or finite difference methods, and also in several space dimensions and for geometrically complex domains; time asymptotic analysis in one space dimension yields a precise characterization of the behavior of the limit solutions, which are expressed in terms of a simple free boundary problem.

Global existence of smooth solutions for this system is considered in a separate work [12]. A more general model, which includes convective effects due to the pressure gradient, for stones with a greater permeability, will be introduced and studied in [1].

The paper is organized as follows. In section 2, we introduce in some detail a basic model starting from the main ideas of macroscopic modeling of filtration in porous media [3, 21]. Next, we propose some different numerical approximations, to both finite element and finite difference schemes, for the one-dimensional case, by proving some rigorous nonlinear stability and positivity results, under some proper CFL conditions. Numerical tests are given for comparison of the accuracy of different schemes. Finally, we investigate the asymptotic behavior of solutions and assess the agreement of the model with experimental tests. By scaling arguments, it is possible to show that the limit profile of solutions, for the case of the half-line $x > 0$ and with Dirichlet boundary conditions for s at $x = 0$, is given by the solution of a simple one-phase Stefan problem [20]. This approach is inspired by a related paper [15], where a similar model was considered, but with constant porosity and diffusivity.

The analytical verification of this asymptotic behavior will be considered in a future work. Here we just give a numerical verification, which actually yields quite precise information on the propagation of the main front and on the rate of convergence of the solution toward its limit profile.

In particular, it is worth mentioning that the limit profile has a free boundary $\zeta(t)$ which gives the right limit of the gypsum crust and evolves according to a diffusive law:

$$\zeta(t) = C\sqrt{t}. \tag{1.2}$$

This behavior is in good qualitative agreement with experimental data (see [22, 23, 18]) and in particular with the results of the new laboratory tests performed in [10], and the possibility of a successful calibration of the model against laboratory and in situ tests is shown.

2. Derivation of the model. In [18, 8] the authors conducted experimental studies involving the exposure of different types of marble to 10 and 300 ppm SO_2 atmospheres. It was then possible to estimate practically the extent of damage to marble due to an industrial environment. Analogous experiments were conducted with dolomite rocks [26]. Other laboratory tests and in situ measurements can be found in [22, 23, 6, 5].

Considering the mathematical description of the time evolution of the sulphation process, some models were proposed in [18] to give some measurements of the main physicochemical parameters. The different regions and time regimes were described by different parameters and then matched to fit the experimental behavior of the reaction. Here we develop a single mathematical model that in principle can take into account the full behavior of the solutions.

The path of reaction of SO_2 with calcite is revealed by the X-ray diffraction counts, which suggest that the reaction occurs in the following manner [2, 18]:

$$CaCO_3 + SO_2 + \frac{1}{2}H_2O \to CaSO_3 \cdot \frac{1}{2}H_2O + CO_2, \tag{2.1}$$

$$CaSO_3 \cdot \frac{1}{2}H_2O + \frac{1}{2}O_2 + \frac{3}{2}H_2O \to CaSO_4 \cdot 2H_2O \tag{2.2}$$

(see also [6, 9, 7, 26, 25]). The $CaSO_3$ (calcium sulphite) reaches equilibrium soon after the initial reaction, and then the amount of gypsum continues to increase with the progress of the reaction. Therefore we can assume a simplified one-step reaction:

$$CaCO_3 + SO_2 + \frac{1}{2}O_2 + 2H_2O \to CaSO_4 \cdot 2H_2O + CO_2. \tag{2.3}$$

We neglect all heat effects and assume the air contains enough water to give rise to the reaction. Moreover, we assume that the change in concentrations of oxygen (O_2), water (H_2O), and carbon dioxide (CO_2) does not affect the reaction.

Let Ω be the domain occupied by the specimen of calcite under consideration and set ρ_s for the concentration of SO_2; c for the density of $CaCO_3$; and g for the density of $CaSO_4 \cdot 2H_2O$. All quantities are defined with respect to the whole volume, incorporating both solid and gaseous material, and depend on the position $x \in \Omega$ and on time t. Since we are including the bulk volume in the definition of c, g, ρ_s, we will call them total concentrations or densities. We will define later the porous concentrations for SO_2.

Following [3], we assume that the total concentrations ρ_s and c satisfy the balance laws,

$$\partial_t \rho_s + \nabla \cdot (\rho_s \mathbf{V}_s) = \dot{r}_s, \tag{2.4}$$

$$\partial_t c = \dot{r}_c, \tag{2.5}$$

where $\mathbf{V}_s$ is the sulphur dioxide "fluid" velocity and $\dot{r}_s$, $\dot{r}_c$ are rates of production (or consumption) of sulphur dioxide and calcite.

Following the usual model for the rate of production, we have

$$\dot{r}_s = -m_s \omega, \qquad \dot{r}_c = -m_c \omega. \tag{2.6}$$

Here, m_s, m_c are the masses of single molecules of sulphur dioxide and calcite, and, to complete the notations, let us set m_g for the molecular mass of gypsum. The quantity $\omega > 0$ measures the rate of reaction and according to [18] is given by

$$\omega = A \left(\frac{\rho_s}{m_s} \right) \left(\frac{c}{m_c} \right). \tag{2.7}$$

In general, the constant A depends on the temperature and on the activation energy. In the present paper we shall neglect this dependence.

Assuming initial densities c_0 and g_0, for calcite and gypsum, we have the relation

$$c + \frac{m_c}{m_g} g = c_0 + \frac{m_c}{m_g} g_0, \tag{2.8}$$

which expresses the density of gypsum as a function of calcite.

Next, we introduce the porosity of the calcite specimen φ, which cannot be assumed constant, since the transformation of calcite in gypsum alters the volume of void (occupied by air and sulphur dioxide). Therefore, following [24], it is reasonable to regard it as a function of the amount of gypsum or, equivalently, as a function of the amount of calcite, that is, $\varphi = \varphi(c)$.

Let φ_0 be the porosity of the pure calcite specimen, i.e., for $c = c_0,\ g = 0$, and $\varphi_{\tilde{g}}$ the porosity of the final sulphate product, when all the calcium carbonate has been converted in gypsum, namely, when $c = 0$, $\tilde{g} = \frac{m_g}{m_c} c_0$. Then, according to the rigorous derivation in [1], we can express the porosity of the specimen during the reaction as a linear combination of these porosities:

$$\varphi(c) = \varphi_{\tilde{g}} + (\varphi_0 - \varphi_{\tilde{g}}) \frac{c}{c_0}. \tag{2.9}$$

We denote by s the porous concentration of SO_2, which is defined as the concentration taken with respect to the volume of the pores, which is related to the total concentration by

$$\rho_s = \varphi(c) s. \tag{2.10}$$

The seepage velocity $\mathbf{v}_s$ is related to the fluid velocity $\mathbf{V}_s$ by the classical Dupuit–Forchheimer relation

$$\mathbf{v}_s = \varphi(c) \mathbf{V}_s. \tag{2.11}$$

The balance laws for ρ_s and c become

$$\partial_t(\varphi(c)s) + \nabla \cdot (s\mathbf{v}_s) = -\left(\frac{A}{m_c}\right)\varphi(c)sc, \tag{2.12}$$

$$\partial_t c = -\left(\frac{A}{m_s}\right)\varphi(c)sc. \tag{2.13}$$

To close the system (2.12)–(2.13), we need an expression for the seepage velocity $\mathbf{v}_s$. In the following we make the main assumption of our model, namely, that all the contributions given by the pressure gradient to the seepage velocity can be neglected. As shown in [1], this corresponds to a zero permeability limit, which is a realistic assumption for many species of marble.

Therefore, we shall express $\mathbf{v}_s$ by the classical Fick law [21],

$$s\mathbf{v}_s = -D(c)\nabla s, \tag{2.14}$$

where $D(c) = d\varphi(c)$, and d is the (scalar) effective molecular diffusive coefficient. This yields

$$\partial_t(\varphi(c)s) = -\left(\frac{A}{m_c}\right)\varphi(c)sc + d\nabla \cdot (\varphi(c)\nabla s), \tag{2.15}$$

$$\partial_t c = -\left(\frac{A}{m_s}\right)\varphi(c)sc. \tag{2.16}$$

System (2.15)–(2.16) forms a closed set of nonlinear degenerate parabolic differential equations which have to be supplemented by initial conditions at time $t = 0$ for s and c, and by Dirichlet or Neumann boundary conditions for s. Let us also notice that in general we do not expect to give any boundary condition for c. Clearly, it is also possible to consider system (2.15)–(2.16) as a one parabolic equation coupled with an ordinary differential equation. Unfortunately, it is difficult to use this remark, since we have to take into account the strong coupling between s and c into the divergence term.

It is easy to see that we can recover the scaled model (1.1) just by taking the new variables

$$y = \sqrt{\frac{A}{dm_c}}x, \quad \tau = \frac{A}{m_c}t, \quad \tilde{s} = \frac{m_c}{m_s}s. \tag{2.17}$$

To improve the physical accuracy of our model, it should be possible to consider three main modifications. The first is to assume the dependence of the reaction rate A on the internal temperature and degree of wetness by introducing two supplementary equations related to the evolution of these quantities for some given initial and boundary conditions.

Another important modification arises if, according to [13], we consider a more general nonlinear Fick law,

$$s\mathbf{v}_s(Bs\,|\mathbf{v}_s| + 1) = -D\nabla s, \tag{2.18}$$

where B is the high concentration coefficient. The form (2.18) of the Fick law is best suited when the gradient of the concentration is very high.

Finally, let us mention that a more accurate model, which takes into account both the pressure gradient effects due to the Darcy law and the diffusivity given by the Fick law, will be considered in [1].

3. Numerical approximation in one space dimension. In this section we construct numerical schemes for the one-dimensional version of model (1.1),

$$\begin{cases} \partial_t \rho_s - \partial_x(\varphi(c)\partial_x s) = -\rho_s c, \\ \partial_t c = -\rho_s c \end{cases} \tag{3.1}$$

for $x \in [0,1]$, $t \geq 0$ and where we recall that $\rho_s = \varphi(c)s$ and $\varphi(c)$ is given by (2.9). In the following, we shall assume that the initial calcite density c_0 is a positive constant. Then, setting $\alpha = \frac{1}{c_0}(\varphi_0 - \varphi_{\tilde{g}})$ and $\beta = \varphi_{\tilde{g}}$, we can rewrite the function $\varphi(c)$ in the following form:

$$\varphi(c) = \alpha c + \beta. \tag{3.2}$$

In what follows, we shall assume that

$$\varphi_0 > \varphi_{\tilde{g}}, \tag{3.3}$$

with $\alpha, \beta > 0$ and $0 < \beta \leq \varphi(c) \leq \alpha c_0 + \beta < 1$. The case $\varphi_0 < \varphi_{\tilde{g}}$ is similar and can be considered by using the same arguments.

As initial conditions we have

$$\begin{cases} \rho_s(x,0) = 0, \\ c(x,0) = c_0, \end{cases} \tag{3.4}$$

where c_0 is a positive constant, and we impose the boundary conditions,

$$\begin{cases} \rho_s(0,t) = \rho_{s0}, \\ \dfrac{\partial \rho_s}{\partial x}(1,t) = 0. \end{cases} \tag{3.5}$$

Here ρ_{s0} is a positive constant. The case where ρ_{s0} is a bounded measurable positive function can be treated in the same way.

It is easy to see that s satisfies the same initial condition as ρ_s, and the boundary conditions read as

$$\begin{cases} s(0,t) = \dfrac{\rho_{s0}}{\varphi(c(0,t))}, \\ \dfrac{\partial s}{\partial x}(1,t) = 0 \end{cases} \tag{3.6}$$

with

$$c(0,t) = c_0 \mathrm{e}^{-\rho_{s0} t}. \tag{3.7}$$

Two methods of solving this problem are under consideration. First, we use a finite element method, looking for s as a continuous piecewise linear function and c as a piecewise constant function. The second method is a finite difference scheme, where the main unknowns are ρ_s and c. For some problems in one space dimension, finite element methods have an interpretation in terms of finite differences via mass lumping and staggered variables. However, the philosophies are quite different, and our aim is to study afterward two- or three-dimensional systems, with possibly complicated geometries. On the other hand, for the methods presented in this paper it is easier to modify the time discretization for the finite difference schemes. We compare these approaches and analyze the effect of time discretization modifications.

3.1. A finite element method. Following [12], we look for a smooth solution (s, c) of (3.1), (3.4), (3.6).

3.1.1. The scheme. To deal with the nonhomogeneous Dirichlet condition, we introduce the unknown $\sigma(x,t) = s(x,t) - s(0,t)$, and we denote $H = \{u \in H^1(]0,1[), u(0) = 0\}$. The first equation of (3.1) can be written as

$$\partial_t(\varphi\sigma) - \partial_x(\varphi(c)\partial_x\sigma) = F(\sigma, c, t),$$

and a variational formulation of the problem is as follows: find $(\sigma, c) \in C^1([0, +\infty[, H \times L^2(]0,1[))$ such that for all $(p, q) \in H \times L^2(]0,1[)$,

$$\left\{ \begin{array}{l} \partial_t \displaystyle\int_{]0,1[} \varphi\sigma p dx + \int_{]0,1[} \varphi\partial_x\sigma\partial_x p dx = \int_{]0,1[} pF dx, \\ \\ \partial_t \displaystyle\int_{]0,1[} cq dx = -\int_{]0,1[} \varphi(\sigma + s(0,.))cq dx. \end{array} \right. \tag{3.8}$$

Let us define a regular mesh

$$[0,1] = \cup_{1\le i\le N}[x_i, x_{i+1}], \quad x_i = (i-1)\Delta x, \quad \Delta x = 1/N.$$

We denote by $\{p_i, i = 1, \dots, N+1\}$ the classical P1 basis functions:

$$p_i(x) = \left\{ \begin{array}{ll} \frac{x - x_{i-1}}{\Delta x} & \text{if} \quad x \in [x_{i-1}, x_i], \\ \\ \frac{x_{i+1} - x}{\Delta x} & \text{if} \quad x \in [x_i, x_{i+1}], \\ \\ 0 & \text{else.} \end{array} \right.$$

For $i = 1, \dots, N$, we denote by q_i the characteristic function of $[x_i, x_{i+1}[$.

The solution (s, c) is approximated by

$$s_h(x,t) = \sum_{i=1}^{N+1} \xi_i(t)p_i(x), \quad c_h(x,t) = \sum_{k=1}^{N} \eta_k(t)q_k(x).$$

Moreover, we define $\rho_{s,h}(x,t) = \varphi(c_h(x,t))s_h(x,t)$.

The unknowns for s_h are located on the nodes, while the ones for c_h can be considered as approximations of the mean value of c on each cell $[x_i, x_{i+1}]$. The Dirichlet boundary condition at $x = 0$ is taken into account by putting $\xi_1(t) = \rho_{s0}/\varphi(\eta_1(t))$, according to (3.6), so that $\sigma_h = s_h - \xi_1 p_1$ and $(\sigma_h, c_h) \in C^1([0, +\infty[, V \times W)$, where $V = \text{lin}\{p_i, i = 2, \dots, N+1\}$ and $W = \text{lin}\{q_i, i = 1, \dots, N\}$.

In practice, as usual for this kind of problem we write a (false) variational approach formulation with $N+1$ basis functions $\{p_1, \dots, p_{N+1}\}$, and we put the Dirichlet condition a posteriori: for all $i = 1, \dots, N+1$, for all $k = 1, \dots, N$,

$$\left\{ \begin{array}{l} \partial_t \displaystyle\int_{]0,1[} \varphi_h s_h p_i dx + \int_{]0,1[} \varphi_h\partial_x s_h\partial_x p_i dx = -\int_{]0,1[} \varphi_h s_h c_h p_i dx, \\ \\ \partial_t \displaystyle\int_{]0,1[} c_h q_k dx = -\int_{]0,1[} \varphi_h s_h c_h q_k dx. \end{array} \right. \tag{3.9}$$

In this formula, φ_h is defined by

$$\varphi_h = \varphi(c_h).$$

The first set of equations in (3.9) is a differential system which is linear with respect to ξ:

$$\partial_t \sum_{j=1}^{N+1} \xi_j \int_{]0,1[} \varphi_h p_j p_i dx + \sum_{j=1}^{N+1} \xi_j \int_{]0,1[} \varphi_h \partial_x p_j \partial_x p_i dx$$

$$= - \sum_{j=1}^{N+1} \xi_j \int_{]0,1[} \varphi_h c_h p_j p_i dx, \quad i = 1, \dots, N+1.$$

As $\varphi_h = \sum_{k=1}^{N} \varphi(\eta_k) q_k$, it can be summarized as

$$\partial_t (M(\eta)\xi) + K(\eta)\xi = 0. \tag{3.10}$$

Denoting $\varphi(\eta_k) = \varphi_k$, the matrix $M(\eta)$ is defined by

$$M(\eta) = \frac{\Delta x}{6} \begin{pmatrix} 2\varphi_1 & \varphi_1 & 0 & \dots & 0 \\ \varphi_1 & 2(\varphi_1+\varphi_2) & \varphi_2 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & \varphi_{N-1} & 2(\varphi_{N-1}+\varphi_N) & \varphi_N \\ 0 & \dots & 0 & \varphi_N & 2\varphi_N \end{pmatrix},$$

and the matrix $K(\eta)$ is defined by

$$K(\eta) = \tfrac{1}{\Delta x} \begin{pmatrix} \varphi_1 & -\varphi_1 & 0 & \dots & 0 \\ -\varphi_1 & \varphi_1+\varphi_2 & -\varphi_2 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & -\varphi_{N-1} & \varphi_{N-1}+\varphi_N & -\varphi_N \\ 0 & \dots & 0 & -\varphi_N & \varphi_N \end{pmatrix}$$

$$+ \tfrac{\Delta x}{6} \begin{pmatrix} 2\varphi_1\eta_1 & \varphi_1\eta_1 & 0 & \dots & 0 \\ \varphi_1\eta_1 & 2(\varphi_1\eta_1+\varphi_2\eta_2) & \varphi_2\eta_2 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & \varphi_{N-1}\eta_{N-1} & 2(\varphi_{N-1}\eta_{N-1}+\varphi_N\eta_N) & \varphi_N\eta_N \\ 0 & \dots & 0 & \varphi_N\eta_N & 2\varphi_N\eta_N \end{pmatrix}.$$

The second equation of problem (3.9) can be written as

$$\Delta x\, \partial_t \eta_k = -\eta_k(\alpha\eta_k + \beta) \sum_{j=1}^{N+1} \xi_j(t) \int_{]x_k, x_{k+1}[} p_j(x) dx, \quad k = 1, \dots, N$$

or, equivalently,

$$\partial_t \eta_k = -\frac{(\xi_k + \xi_{k+1})}{2} \eta_k(\alpha\eta_k + \beta) = -\gamma_k \eta_k(\alpha\eta_k + \beta), \quad k = 1, \dots, N. \tag{3.11}$$

We now discretize in time. The approximated quantities at time $t_n = n\Delta t$ are denoted with a superscript n, and for $t \in [t_n, t_{n+1}[$ we put $s_h(x,t) = s_h^n(x)$, $c_h(x,t) = c_h^n(x)$.

In view of initial and boundary data we take

$$\begin{cases} \xi_1^0 = \dfrac{\rho_{s0}}{\varphi(c_0)}, \quad \xi_j^0 = 0 \quad \text{for } j = 2, \dots, N+1, \\ \\ \eta_k^0 = c_0 \qquad\qquad\qquad\quad \text{for } k = 1, \dots, N. \end{cases}$$

We first discretize (3.11) by fixing $\xi = \xi^n$ and solving exactly the equation. As α and β are positive, if the ξ_j^n and η_k^n are nonnegative, without any time step restriction, we obtain the intermediate value $\eta_k^{n+1/2}$:

$$\eta_k^{n+1/2} = \beta \eta_k^n \frac{\mathrm{e}^{-\gamma_k \beta \Delta t}}{\alpha \eta_k^n + \beta - \alpha \eta_k^n \mathrm{e}^{-\gamma_k \beta \Delta t}}. \tag{3.12}$$

Then, we solve the differential system (3.10) by the θ method ($\theta \in [0,1]$):

$$\frac{M(\eta^{n+1/2})\xi^{n+1} - M(\eta^n)\xi^n}{\Delta t} + (1-\theta)K(\eta^n)\xi^n + \theta K(\eta^{n+1/2})\xi^{n+1} = 0. \tag{3.13}$$

This is a linear tridiagonal system $UX = G$.

The boundary condition is taken into account by replacing g_1 by $\rho_{s0}/\varphi(\eta_1^{n+1/2})$, g_2 by $g_2 - u_{21}\rho_{s0}/\varphi(\eta_1^{n+1/2})$, u_{1j} by δ_{1j}, and u_{i1} by δ_{i1}. This modified linear system is symmetric and positive and can be easily solved, for example, by a Choleski method.

This method is first order in time, even if $\theta = 1/2$, because the matrices M and K depend on $\eta(t)$. When ξ^{n+1} is computed we can set

$$\eta_k^{n+1} = \eta_k^{n+1/2}$$

or improve the approximation with the second order Heun method: we solve exactly (3.11) with $\xi = \xi^{n+1}$ and initial value $\eta_k^{n+1/2}$. We obtain a second intermediate value $\eta_k^{n+1/2,1}$, and, finally, we set

$$\eta_k^{n+1} = \frac{\eta_k^n + \eta_k^{n+1/2,1}}{2}. \tag{3.14}$$

In the following, we call this finite element method FE-θ.

3.1.2. Stability. It is well known that the discrete maximum principle does not always hold in the finite element method. We have the following stability results.

PROPOSITION 3.1. *Suppose that* $\theta \in]1/3, 1]$ *and* $\Delta x^2 < \frac{3(3\theta-1)}{c_0}$. *If the time step satisfies the condition*

$$\frac{\Delta x^2}{\theta(6 - c_0 \Delta x^2)} < \Delta t \leq \frac{\Delta x^2}{(1-\theta)(3 + c_0 \Delta x^2)}, \tag{3.15}$$

then for all $x \in [0,1]$, $c_h(x,.)$ *is a nonincreasing function of* t *and for all* $t \geq 0$,

$$\rho_{s,h}(x,t) \geq 0, \quad c_h(x,t) \in]0, c_0].$$

Moreover, the condition (3.15) *is not empty.*

Proof. The result is true for $t \in [0, t_1[$. Suppose that for all $j = 1, \dots, N+1$ and all $k = 1, \dots, N$ we have $\xi_j^n \geq 0$ and $\eta_k^n \in]0, c_0]$. In view of (3.11) and (3.12), $0 < \eta_k^{n+1/2} \leq \eta_k^n$, and thus $0 < \varphi_k^{n+1/2} \leq \varphi_k^n$.

After the modifications due to boundary conditions, the system (3.13) has an $N\times N$ symmetric irreducibly diagonally dominant matrix, still denoted $U = M^{n+1/2}+ \Delta t\,\theta\, K^{n+1/2}$. Hence, U^{-1} is positive if $u_{ij} < 0$ for $j = i \pm 1$ and $u_{ii} > 0$ for all i [27].

In the right-hand side, we have for $i \geq 2$,

$$g_i = \sum_{j=i-1}^{i+1} \left(m_{ij}^n - (1-\theta)\Delta t k_{ij}^n\right) \xi_j^n, \quad \xi_1^n = \rho_{s0}/\varphi_1^n,$$

and

$$\begin{aligned} g_{2,\text{modified}} &= g_2 - \frac{u_{21}\rho_{s0}}{\varphi_1^{n+1/2}} \\ &= \sum_{j=2}^{3} \left(m_{2j}^n - (1-\theta)\Delta t k_{2j}^n\right) \xi_j^n \\ &\quad + \frac{\Delta t}{\Delta x}\left[1 - \frac{\Delta x^2}{6}\eta_1^n + \theta\frac{\Delta x^2}{6}(\eta_1^n - \eta_1^{n+1/2})\right]\rho_{s0}. \end{aligned} \tag{3.16}$$

Due to the condition on Δx and the fact that η is nonincreasing, the third line is nonnegative. Consequently, the positivity is preserved if the following requirements are fulfilled:

$$\begin{aligned} &m_{ij}^{n+1/2} + \theta\Delta t k_{ij}^{n+1/2} < 0 \qquad \text{for } j = i \pm 1, \;\; i \geq 2, \\ &m_{ii}^{n+1/2} + \theta\Delta t k_{ii}^{n+1/2} > 0 \qquad \text{for all } i \geq 2, \\ &m_{ij}^{n} - (1-\theta)\Delta t k_{ij}^{n} \geq 0 \qquad \text{for all } i \geq 2,\ j. \end{aligned} \tag{3.17}$$

For $j \neq i$, we have to consider $j = i - 1$:

$$k_{ij} = -\frac{\varphi_{i-1}}{\Delta x} + \frac{\Delta x}{6}\varphi_{i-1}\eta_{i-1} \leq 0.$$

Moreover, k_{ii} is positive. Hence, the second requirement of (3.17) is fulfilled. So is the third for $i \neq j$.

Consequently, we have to satisfy for all i and $j = i \pm 1$,

$$-\frac{m_{ij}^{n+1/2}}{\theta k_{ij}^{n+1/2}} < \Delta t \leq \frac{m_{ii}^n}{(1-\theta)k_{ii}^n}\,. \tag{3.18}$$

We have for $2 \leq i \leq N$,

$$\begin{aligned} \frac{m_{ii}}{(1-\theta)k_{ii}} &= \frac{\Delta x(\varphi_{i-1}+\varphi_i)}{3(1-\theta)\left(\dfrac{\varphi_{i-1}+\varphi_i}{\Delta x} + \dfrac{\Delta x(\varphi_{i-1}\eta_{i-1}+\varphi_i\eta_i)}{3}\right)} \\ &\geq \frac{\Delta x^2}{(1-\theta)\,(3 + c_0\Delta x^2)}\,. \end{aligned} \tag{3.19}$$

For $i = N + 1$ the same lower estimate holds. For $j = i - 1$,

$$\begin{aligned} -\frac{m_{ij}}{\theta k_{ij}} &= \frac{\Delta x\,\varphi_{i-1}}{6\theta\left(\dfrac{\varphi_{i-1}}{\Delta x} - \dfrac{\Delta x\varphi_{i-1}\eta_{i-1}}{6}\right)} \\ &\leq \frac{\Delta x^2}{\theta\,(6 - c_0\Delta x^2)}. \end{aligned} \tag{3.20}$$

The fact that condition (3.15) is not empty, i.e.,

$$\frac{\Delta x^2}{\theta(6-c_0\Delta x^2)} < \frac{\Delta x^2}{(1-\theta)(3+c_0\Delta x^2)},$$

is ensured by the conditions $\Delta x^2 < \frac{3(3\theta-1)}{c_0}$ and $\theta > 1/3$.

As it is enough to consider the case $\eta^{n+1} = \eta^{n+1/2}$, the proof is complete.

Remark 3.1. As usual, there is no upper limitation on Δt in the fully implicit case $\theta = 1$.

As far as we are concerned by the lower limitation on Δt, let us point out that, as is well known, if the matrix M is lumped, this limitation disappears.

If the data are small enough, we can prove a uniform bound for $\rho_{s,h}$. We fix the initial condition c_0, and we determine for which values of ρ_{s0} the bound exists.

In what follows, we denote $\varphi_0 = \varphi(c_0)$.

PROPOSITION 3.2. *We make the same assumptions as in Proposition* 3.1, *and we take* Δt *satisfying condition* (3.15). *If, moreover, the two inequalities*

$$\text{(i)} \qquad \Delta t < \frac{\beta^2 - \alpha\varphi_0\rho_{s0}}{\beta^2\rho_{s0}},$$

$$\text{(ii)} \qquad \rho_{s0} < \frac{\beta^2}{\alpha\varphi_0},$$

are true, then the numerical solution has the additional bound

$$0 \le \rho_{s,h}(x,t) \le \frac{\varphi_0}{\beta}\rho_{s0}. \tag{3.21}$$

Let us point out that condition (i) *on* Δt *does not restrict condition* (3.15) *if the space step* Δx *is small enough.*

Proof. By Proposition 3.1 positivity is preserved, and for all $n \ge 0$ and $i \in \{1,\dots,N\}$ we have

$$0 < \eta_i^{n+1/2} \le \eta_i^n \le c_0. \tag{3.22}$$

Let us denote $X_n = \max\{\xi_j^n, 1 \le j \le N+1\}$. For all $(x,t) \in [x_i, x_{i+1}[\times[t_n, t_{n+1}[$

$$\rho_{s,h}(x,t) = \varphi(\eta_i^n)\left[\xi_i^n p_i(x) + \xi_{i+1}^n p_{i+1}(x)\right].$$

Therefore,

$$0 \le \rho_{s,h}(x,t) \le \varphi_0 X_n,$$

and we have to show that

$$X_n \le \frac{\rho_{s0}}{\beta}. \tag{3.23}$$

This inequality is true for $n = 0$:

$$X_0 = \xi_1^0 = \frac{\rho_{s0}}{\varphi_0} \le \frac{\rho_{s0}}{\beta}.$$

Consider $n \ge 0$ and suppose that X_n satisfies (3.23). If $X_{n+1} = \xi_1^{n+1}$, then

$$X_{n+1} = \frac{\rho_{s0}}{\varphi_1^{n+1/2}} \le \frac{\rho_{s0}}{\beta}.$$

Suppose now that $X_{n+1} = \xi_i^{n+1}$ with $2 \le i \le N$. Our goal is to show that $X_{n+1} \le X_n$. By (3.17), we have

$$\sum_{j=i-1}^{i+1} \left(m_{ij}^{n+1/2} + \Delta t \theta k_{ij}^{n+1/2} \right) X_{n+1} \le \sum_{j=i-1}^{i+1} \left(m_{ij}^{n} - \Delta t (1-\theta) k_{ij}^{n} \right) X_n.$$

This inequality reads as

$$\begin{aligned} X_{n+1} \left[(\varphi_{i-1}^{n+1/2} + \varphi_i^{n+1/2}) + \Delta t \theta \left(\varphi_{i-1}^{n+1/2} \eta_{i-1}^{n+1/2} + \varphi_i^{n+1/2} \eta_i^{n+1/2} \right) \right] \\ \le X_n \left[(\varphi_{i-1}^{n} + \varphi_i^{n}) - \Delta t (1-\theta) \left(\varphi_{i-1}^{n} \eta_{i-1}^{n} + \varphi_i^{n} \eta_i^{n} \right) \right]. \end{aligned} \tag{3.24}$$

Using (3.22) and denoting

$$B = \frac{2}{\Delta x} \sum_{j=i-1}^{i+1} \left(m_{ij}^{n+1/2} + \Delta t \theta k_{ij}^{n+1/2} \right), \quad e_i = \eta_i^n - \eta_i^{n+1/2},$$

we obtain

$$B X_{n+1} \le X_n \left[B + \alpha (e_{i-1} + e_i) - \Delta t \left(\varphi_{i-1}^{n+1/2} \eta_{i-1}^{n+1/2} + \varphi_i^{n+1/2} \eta_i^{n+1/2} \right) \right].$$

Hence, $X_{n+1} \le X_n$ as soon as for all $i = 1, \dots, N$,

$$\alpha e_i - \Delta t \varphi_i^{n+1/2} \eta_i^{n+1/2} \le 0. \tag{3.25}$$

By (3.12) we have

$$e_i = \eta_i^n \frac{\varphi_i^n (1 - \mathrm{e}^{-\gamma_i \beta \Delta t})}{\alpha \eta_i^n + \beta - \alpha \eta_i^n \mathrm{e}^{-\gamma_i \beta \Delta t}},$$

and (3.25) can be written as

$$\alpha \varphi_i^n (1 - \mathrm{e}^{-\gamma_i \beta \Delta t}) - \Delta t \varphi_i^{n+1/2} \beta \mathrm{e}^{-\gamma_i \beta \Delta t} \le 0.$$

We are led to prove that $g(\Delta t) \le 0$ with $g(\tau) = \alpha \varphi_0 (1 - \mathrm{e}^{-\gamma_i \beta \tau}) - \tau \beta^2 \mathrm{e}^{-\gamma_i \beta \tau}$.

We have $g(0) = 0$, and recalling that $\gamma_i = \frac{1}{2}(\xi_i^n + \xi_{i+1}^n)$, it is easy to see that $g'(\tau) < 0$ as soon as conditions (i) and (ii) are satisfied.

The case where $X_{n+1} = \xi_{N+1}^{n+1}$ is identical.

As it is enough to consider the case $\eta^{n+1} = \eta^{n+1/2}$, the proof is complete.

3.2. Finite difference schemes. Here the main variables are $u = (\rho_s, c)$. Denoting $S(u) = -\rho_s c$ we can write

$$\begin{cases} \partial_t \rho_s - \partial_x \left(\varphi(c) \partial_x \dfrac{\rho_s}{\varphi(c)} \right) = S(u), \\ \\ \partial_t c = S(u). \end{cases} \tag{3.26}$$

3.2.1. The schemes. We again mesh $[0,1]$ with a step $\Delta x = 1/N$, and we denote

$$\lambda = \frac{\Delta t}{\Delta x}, \mu = \frac{\Delta t}{\Delta x^2}, x_{m-1/2} = m\Delta x, x_m = (m-0.5)\Delta x, X = (x_m)_{1\le m\le N}.$$

We look for u_m^n, an approximation of $\frac{1}{\Delta x}\int_{x_{m-1/2}}^{x_{m+1/2}} u(x,t_n)dx$, and we set $\mathbf{u}(t) = (\mathbf{u}_1(t),\dots,\mathbf{u}_m(t))^T$, a smooth function such that $\mathbf{u}_m(t_n) = u_m^n$. We also denote by $u^n = (u_m^n)_{1\le m\le N}$ the approximation of u at the time t_n.

It is clear that c_m^n plays the same role as η_k^n in the finite element method, while there is a staggering from vertices to cell centers between s and ρ_s.

The most simple, consistent approximation of $\partial_x\left(a(x)\partial_x r\right)$ by means of Taylor expansions is the following first order one:

$$\Delta_m(a,r) := \frac{(a_m + a_{m+1})(r_{m+1} - r_m) - (a_{m-1} + a_m)(r_m - r_{m-1})}{2\Delta x^2}. \tag{3.27}$$

Hence, a scheme which is comparable to the finite element method FE-θ is the following: $\rho_{s,m}^n$ being fixed, solve exactly the second equation of (3.26) and obtain

$$c_m^{n+1} = c_m^n \mathrm{e}^{-\Delta t \rho_{s,m}^n}.$$

Then discretize the first equation of (3.26) as follows:

$$\frac{\rho_{s,m}^{n+1} - \rho_{s,m}^n}{\Delta t} - \Delta_m\left(\varphi^n, \frac{\rho_s^n}{\varphi^n}\right) = S((1-\theta)\rho_{s,m}^n + \theta\rho_{s,m}^{n+1}, c_m^{n+1}) \tag{3.28}$$

with $\theta \in [0,1]$. In the following, we call this scheme FD1. We should have put a combination of explicit and implicit terms in the derivatives as well, but this leads to solving a linear system to find ρ_s, and we want to avoid that because we lose the simplicity of the approach. Let us remark, moreover, that considering the scheme

$$\begin{aligned}&\frac{\rho_{s,m}^{n+1} - \rho_{s,m}^n}{\Delta t} - (1-\theta)\Delta_m\left(\varphi^n, \frac{\rho_s^n}{\varphi^n}\right) - \theta\Delta_m\left(\varphi^{n+1}, \frac{\rho_s^{n+1}}{\varphi^{n+1}}\right)\\ &\quad = S((1-\theta)\rho_{s,m}^n + \theta\rho_{s,m}^{n+1}, c_m^{n+1})\end{aligned}$$

leads us to solve a nonsymmetric linear system, while the finite element matrices are symmetric.

A second semi-implicit approximation, which we call FD2, is the following:

$$\begin{cases} \dfrac{\rho_{s,m}^{n+1} - \rho_{s,m}^n}{\Delta t} - \Delta_m\left(\varphi^n, \dfrac{\rho_s^n}{\varphi^n}\right) = \dfrac{1}{2}\left[S(\rho_{s,m}^n, c_m^{n+1}) + S(\rho_{s,m}^{n+1}, c_m^n)\right], \\ \dfrac{c_m^{n+1} - c_m^n}{\Delta t} = \dfrac{1}{2}\left[S(\rho_{s,m}^n, c_m^{n+1}) + S(\rho_{s,m}^{n+1}, c_m^n)\right]. \end{cases} \tag{3.29}$$

Because the source term is quadratic, this scheme has an explicit representation:

$$\begin{cases} \dfrac{\rho_{s,m}^{n+1} - \rho_{s,m}^n}{\Delta t} = \dfrac{S(\rho_{s,m}^n, c_m^n)}{\delta} + \left(1 - \Delta t\dfrac{c_m^n}{2\delta}\right)\Delta_m\left(\varphi^n, \dfrac{\rho_s^n}{\varphi^n}\right), \\ \dfrac{c_m^{n+1} - c_m^n}{\Delta t} = \dfrac{S(\rho_{s,m}^n, c_m^n)}{\delta} - \Delta t\dfrac{c_m^n}{2\delta}\Delta_m\left(\varphi^n, \dfrac{\rho_s^n}{\varphi^n}\right) \end{cases} \tag{3.30}$$

with $\delta = 1 + \dfrac{\Delta t}{2}\left(c_m^n + \rho_{s,m}^n\right)$.

This discretization takes the interaction into account in a symmetric way, without computational cost. Notice also that for the single equation $y' = y^2$, the scheme $y^{n+1} = y^n + \Delta t y^{n+1} y^n$ is exact:

$$y^{n+1} = \frac{y^n}{1 - \Delta t y^n} \ .$$

Finally, we construct another scheme by remarking that

$$\Delta_m \left(\varphi, \frac{\rho_s}{\varphi} \right) = \Delta_m \left(1, \rho_s \right)$$

$$- \frac{1}{2\Delta x} \left[\left(\frac{\rho_{s,i}}{\varphi_i} + \frac{\rho_{s,i+1}}{\varphi_{i+1}} \right) \frac{\varphi_{i+1} - \varphi_i}{\Delta x} - \left(\frac{\rho_{s,i-1}}{\varphi_{i-1}} + \frac{\rho_{s,i}}{\varphi_i} \right) \frac{\varphi_i - \varphi_{i-1}}{\Delta x} \right].$$

This is a consistent centered approximation of $\partial_x(\varphi \partial_x \frac{\rho_s}{\varphi}) = \partial_{xx}\rho_s - \partial_x(\frac{\rho_s}{\varphi}\partial_x\varphi)$.

More generally, we can put system (3.26) under the semiconservative form,

$$\left\{ \begin{array}{l} \partial_t \rho_s + f(\rho_s, c, x, t)_x = B(\rho_s, c)_{xx} + S(\rho_s, c), \\ \\ \partial_t c = S(c, \rho_s), \end{array} \right. \tag{3.31}$$

where

$$B(\rho_s, c) = \rho_s, \quad f(\rho_s, c, x, t) = \rho_s \frac{\varphi'(c)}{\varphi(c)} c_x.$$

In the expression of f, c_x is considered as a known function of (x, t). In practice, a difference formula is used to compute it. Hence in what follows we no longer mention the (x, t) dependence in f. Let us denote $\mathbf{f} = (f, 0)$, $\mathbf{B} = (B, 0)$, $\mathbf{S} = (S, S)$. System (3.31) can be written as

$$\partial_t u + \mathbf{f}(u)_x = \mathbf{B}(u)_{xx} + \mathbf{S}(u). \tag{3.32}$$

Now the convective part may be approximated by any method for conservation law. The particular form of our system allows the flux vector splitting,

$$\mathbf{f}(u) = \mathbf{f}_+(u) - \mathbf{f}_-(u),$$

where $sp(\partial_u \mathbf{f}_\pm(u)) \subset [0, +\infty[$ and $\partial_u \mathbf{f}(u)$, $\partial_u \mathbf{f}_+(u)$ and $\partial_u \mathbf{f}_-(u)$ have a common basis of eigenvectors. In fact we have

$$\partial_u \mathbf{f} = \begin{pmatrix} \partial_{\rho_s} f & \partial_c f \\ 0 & 0 \end{pmatrix},$$

and it is sufficient to take

$$\mathbf{f}_+(u) = \begin{pmatrix} f_+(u) \\ 0 \end{pmatrix}, \quad \mathbf{f}_-(u) = \begin{pmatrix} f_-(u) \\ 0 \end{pmatrix},$$

where

$$f_+(u) = \left\{ \begin{array}{ll} f(u) & \text{if } \partial_{\rho_s} f(u) > 0, \\ 0 & \text{else} \end{array} \right. \quad \text{and} \quad f_-(u) = \left\{ \begin{array}{ll} -f(u) & \text{if } \partial_{\rho_s} f(u) < 0, \\ 0 & \text{else.} \end{array} \right.$$

Now, we can take the source term into account either like in FD1 or like in FD2. For example, let us take the same method as for FD1. The numerical scheme FD3 is the following:

(3.33)
$$\begin{cases} \rho_{s,m}^{n+1} = \rho_{s,m}^n - \lambda\left[-f_-(u_{m+1}^n) + f_+(u_m^n) + f_-(u_m^n) - f_+(u_{m-1}^n)\right] \\ \qquad\qquad +\mu\left[\rho_{s,m-1}^n - 2\rho_{s,m}^n + \rho_{s,m+1}^n\right] + \Delta t \;\; S((1-\theta)\rho_{s,m}^n + \theta\rho_{s,m}^{n+1}, c_m^{n+1}), \\ \\ c_m^{n+1} = c_m^n \mathrm{e}^{-\Delta t \rho_{s,m}^n}. \end{cases}$$

To take into account the initial and boundary conditions in each of these numerical schemes, we put

(3.34)
$$\begin{cases} \rho_{s,m}^0 = 0, \quad c_m^0 = c_0 & \text{for } 1 \le m \le N, \\ \rho_{s,0}^n = \rho_{s0}, \quad \rho_{s,N+1}^n = \rho_{s,N}^n & \text{for } n \ge 0. \end{cases}$$

In the following, if $\rho_{s,m} \ge 0$, we take

(3.35)
$$f_\pm(u_m) = \rho_{s,m}\left[\pm\frac{\varphi_{m+1} - \varphi_{m-1}}{2\varphi_m \Delta x}\right]_+ .$$

3.2.2. Higher order in time. To reach higher order in time for these three schemes, we remark that they all can be written in the conservative form:

$$\frac{u_m^{n+1} - u_m^n}{\Delta t} = G_m(u^{n+1}, u^n, \Delta t).$$

Moreover, when Δt tends to zero and u^n and Δx are fixed, u^{n+1} tends to u^n, and $G_m(u^{n+1}, u^n, \Delta t)$ has a limit $F_m(u^n)$. We obtain the semidiscretized scheme:

$$\mathbf{u}_m'(t_n) = F_m(\mathbf{u}(t_n)), \quad m = 1, \dots, N.$$

For FD1 and FD2, F_m is defined by

$$F_m(\mathbf{u}) = \left(\Delta_m\left(\varphi(\mathbf{c}), \frac{\rho_{\mathbf{s}}}{\varphi(\mathbf{c})}\right) + \mathbf{S}(\mathbf{u}), \mathbf{S}(\mathbf{u})\right).$$

For FD3, F_m is defined by

$$F_m(\mathbf{u}) = \left(\overline{\Delta}_m + \mathbf{S}(\mathbf{u}), \mathbf{S}(\mathbf{u})\right)$$

with

$$\overline{\Delta}_m = \frac{-f_-(u_{m+1}) + f_+(u_m) + f_-(u_m) - f_+(u_{m-1})}{\Delta x} + \frac{\rho_{s,m-1} - 2\rho_{s,m} + \rho_{s,m+1}}{\Delta x^2}.$$

This is a new starting point at which to apply a temporal scheme, solving on $[t_n, t_{n+1}]$ the ordinary differential system:

$$\mathbf{u}'(t) = F(\mathbf{u}(t)).$$

As a particular case, we may use an implicit method in order to have a large time step, and this involves the resolution of a nonlinear system. As we already have an implicit scheme with the finite element method, we prefer here to approximate u by

means of the second order Heun method or by the optimal third order strong-stability preserving (SSP) Runge–Kutta (RK) method given by

$$\begin{aligned} v^{(1)} &= u^n + \Delta t F(u^n), \\ v^{(2)} &= \frac{3}{4}u^n + \frac{1}{4}v^{(1)} + \frac{1}{4}\Delta t F(v^{(1)}), \\ u^{n+1} &= \frac{1}{3}u^n + \frac{2}{3}v^{(2)} + \frac{2}{3}\Delta t F(v^{(2)}) \end{aligned} \tag{3.36}$$

introduced in [11].

3.2.3. Stability. The finite difference schemes FD1, FD3 preserve positivity under a suitable time step restriction.

The choice of the third order RK scheme (3.36) was dictated by further stability consideration. In fact, as shown by Gottlieb, Shu, and Tadmor in [11], it is possible to relate the CFL condition for the temporal first order Euler scheme (3.33) to a strong stability property verified by the temporal third order scheme (3.36), at least for conservation laws. The rigorous extension of this property to the present case is beyond the aims of this paper, but we can expect that this scheme works for the same Δt used in the Euler time discretization, thanks to the dissipation induced by the diffusion and by the source terms.

PROPOSITION 3.3 (scheme FD1). *For all $n \geq 0$, all $m = 1, \ldots, N$,*

$$\rho_{s,m}^n \geq 0, \quad c_m^n \in [0, c_0] \tag{3.37}$$

under the time step restriction

$$\Delta t \leq \frac{\beta \Delta x^2}{\varphi_0 + \beta(1 + \Delta x^2 c_0(1-\theta))}. \tag{3.38}$$

Proof. It is clear that we have to check only the first order in time. From the expression of c_m^{n+1}, it is clear that if $\rho_{s,m}^n$ is nonnegative, then $c_m^{n+1} \in [0, c_m^n]$. This is true for $n = 0$. Let us suppose it is true for all $k \leq n$. Then $c_m^{n+1} \in [0, c_0]$ and

$$\beta \leq \varphi_m^n \leq \varphi_0. \tag{3.39}$$

Now we can write

$$\begin{aligned} \rho_{s,m}^{n+1}(1 + \Delta t \theta c_m^{n+1}) = \rho_{s,m}^n &\left[1 - \mu\left(1 + \frac{\varphi_{m+1}^n + \varphi_{m-1}^n}{2\varphi_m^n}\right) - \Delta t(1-\theta)c_m^{n+1}\right] \\ &+ \mu \rho_{s,m-1}^n \frac{\varphi_m^n + \varphi_{m-1}^n}{2\varphi_{m-1}^n} + \mu \rho_{s,m+1}^n \frac{\varphi_m^n + \varphi_{m+1}^n}{2\varphi_{m+1}^n}. \end{aligned} \tag{3.40}$$

Thus, positivity is ensured as soon as condition (3.38) is satisfied.

PROPOSITION 3.4 (scheme FD3 with (3.35)). *For all $n \geq 0$, all $m = 1, \ldots, N$,*

$$\rho_{s,m}^n \geq 0, \quad c_m^n \in [0, c_0] \tag{3.41}$$

under the time step restriction

$$\Delta t \leq \frac{2\beta \Delta x^2}{\varphi_0 + \beta(3 + 2\Delta x^2(1-\theta))}. \tag{3.42}$$

Proof. In view of (3.35) we can write

$$\begin{aligned}\rho_{s,m}^{n+1}(1+\Delta t\,\theta c_m^{n+1}) = \rho_{s,m}^n\left[1-\mu\left(\left|\frac{\varphi_{m+1}-\varphi_{m-1}}{2\varphi_m}\right|+2+\Delta x^2(1-\theta)c_m^{n+1}\right)\right]\\ +\rho_{s,m-1}^n\left(\lambda[\partial_{\rho_s}f(u_{m-1})]_+ +\mu\right)\\ +\rho_{s,m+1}^n\left(\lambda[-\partial_{\rho_s}f(u_{m+1})]_+ +\mu\right),\end{aligned} \tag{3.43}$$

and condition (3.42) follows by a straightforward computation.

Remark 3.2. In practice, we update Δt at each time step, and we use a less restrictive condition. More precisely, we require that in (3.40) or (3.43), for all $m = 1,\dots,N$, the coefficient of $\rho_{s,m}^n$ is nonnegative. By bounding c_m^{n+1} by c_m^n we use the numerical condition

$$\Delta t_n \le \frac{\Delta x^2}{\max_{1\le m\le N}\left[1+\frac{\varphi_{m+1}^n+\varphi_{m-1}^n}{2\varphi_m^n}+\Delta x^2(1-\theta)c_m^n\right]}$$

instead of condition (3.38). Similarly, instead of condition (3.42) we impose that

$$\Delta t_n \le \frac{\Delta x^2}{\max_{1\le m\le N}\left[\left|\frac{\varphi_{m+1}^n-\varphi_{m-1}^n}{2\varphi_m^n}\right|+2+\Delta x^2(1-\theta)c_m^n\right]}\,.$$

4. Numerical experiments. This section is devoted to some numerical experiments. It is more significant to perform our tests on the original unscaled model (2.15)–(2.16), even if we observe that with the change of variable (2.17) the shape of the solutions is not dependent on the given parameters. The data are fixed as follows:

$$\rho_{s0}=1,\ \ c_0=10,\ \ \alpha=0.01,\ \ \beta=0.1,\ \ m_c=100.09,\ \ m_s=64.06,\ \ d=1. \tag{4.1}$$

As shown in section 5, letting A go to infinity is equivalent to making the time go to infinity. First we take $A=1$ and the final time $T_{\max}=0.1$; the last paragraph of this section and section 5 are devoted to time asymptotics.

For $\theta=1$ and $\theta=0.5$, let us analyze the numerical order of accuracy γ defined by

$$\gamma=\log_2\left(\frac{||\rho(h)-\rho(h/2)||_1}{||\rho(h/2)-\rho(h/4)||_1}\right)$$

for each component of the solution at the final time $T_{\max}$. Here, $h=\Delta x$. We recall that schemes FD1 and FD3 are obtained by solving exactly the equation for c, and FD2 is obtained by a semi-implicit method. We call FD4 the scheme obtained by the same spatial discretization as for FD3, while the temporal resolution is the same semi-implicit one as FD2.

We first put $\theta=1$ and for FE, $\eta^{n+1}=\eta^{n+1/2}$. As there is no upper bound on Δt for the finite element method in this case, we have chosen $\Delta t=\Delta x$. The scheme is first order in time. We do not experiment with FD2 and FD4 here, because they correspond to $\theta=1/2$. We obtain Tables 1–3.

Scheme FD1, that is, when the nonlinear diffusion is approximated by formula (3.27), converges better than scheme FD3. For the finite element case, the choice of a large time step prevents one from a fast convergence. Nevertheless, the convergence

holds, and as shown in Figures 1 and 2, the solution is close to the one computed by FD1. Let us point out that a computation for $\Delta x = 0.0015625$ and $\Delta t = \Delta x$ is much faster than a computation for $\Delta x = 0.00625$ and $\Delta t = C\Delta x^2$.

Let us now make the same experiment with $\theta = 1/2$. In that case, for the finite element method, we choose the Heun method for η^{n+1} with formula (3.14). Tables 4–8 show that numerically FD1, FD2, and FE-1/2 are second order accurate, while FD3 and FD4 remain less than first order accurate. Let us recall that unless a is a constant, the formula (3.27) used in FD1 and FD2 is only first order in space, and that for FD1 the choice of θ affects only the source term and not the diffusion term. Therefore, second order was not expected. This result can be explained by the fact that here the variations of c and $a = \varphi(c)$ are small in space and in time; see Figure 1, for example. On the contrary, the semiconservative formulation (3.31) used to construct schemes FD3 and FD4 does not allow such a gain.

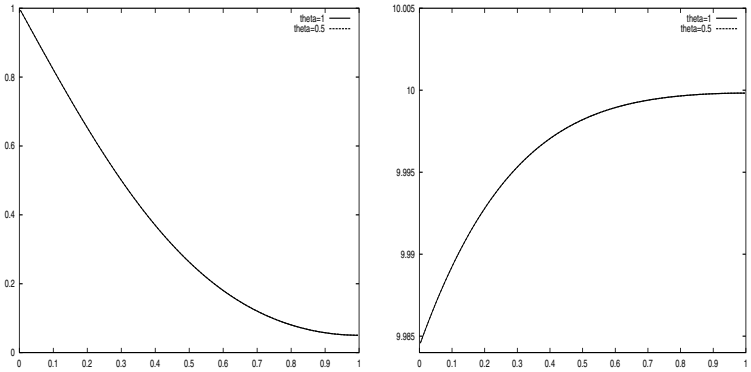

FIG. 4. *Finite differences: comparison among* $\theta = 0.5$ *and* $\theta = 1$, *with* $\triangle x = 0.00625$. *Left:* SO_2 *concentration; right: calcite density. Time* $t = 0.1$.

To end this part of the tests, in Tables 9 and 10 we give the numerical order for the third order time discretization applied to FD1 and FD2. The numerical order of accuracy is not sensitive to time order increasing, but the error $\|u(h) - u(h/2)\|_1$ is smaller. This is not surprising, since the spatial discretization remains unchanged. We do not present graphical results for high order in time discretizations because in all our experiments they coincide with what happens for first order. Taking into account that high time order makes the computation longer, we conclude that one should prefer first order schemes.

To complete these tests, we present some graphical results. In Figure 1, we compare the results for finite element and finite difference FD1 methods, for $\theta = 1$ and $\Delta x = 0.003125$. Then in Figure 2 we make the same comparison for $\Delta x = 0.0015625$, where both results coincide. In Figure 3 we show that for $\theta = 0.5$ finite element and finite difference FD1 methods give very similar results for $\Delta x = 0.00625$. This is because in this case both time steps are comparable, while for $\theta = 1$ we take $\Delta t = \Delta x$ in the finite element method. Hence, the figures confirm the observations made in the tables. We also remark that for finite difference method FD1, the results do not depend on the value of θ; see Figure 4. All these results are computed at time $t = 0.1$.

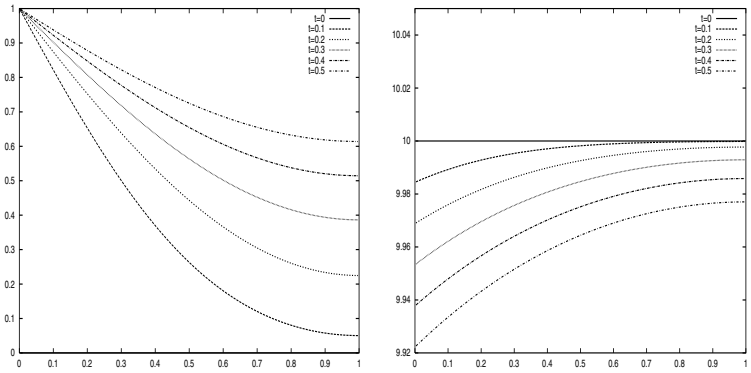

FIG. 5. *Solution from $t = 0$ to $t = 0.5$ with $A = 1$. Left: SO_2 concentration; right: calcite density.*

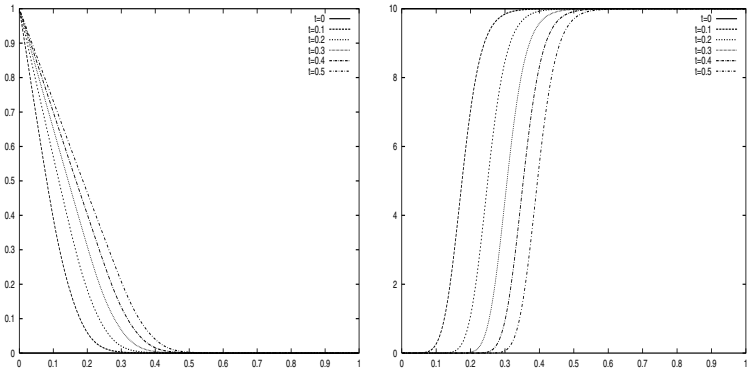

FIG. 6. *Solution from $t = 0$ to $t = 0.5$ with $A = 10000$. Left: SO_2 concentration; right: calcite density.*

From now on, we take $\theta = 0.5$, and we use the finite difference method FD1. Figure 5 shows the solution for different times, from $t = 0$ to $t = 0.5$, with $A = 1$.

Finally, we put $A = 10000$, and we plot the solution from $t = 0$ to $t = 0.5$ (Figure 6). The solution has a very different qualitative aspect: the transition zone is smaller as the interaction coefficient A increases, so that the calcite deterioration is more important for the boundary of the sample, while the interior is not touched by SO_2. The next section is devoted to the study of such solutions.

5. Qualitative behavior of the solutions. In this section we discuss, by means of a formal scaling, the qualitative behavior of the solutions for large times, and we give a numerical verification of this asymptotics. These results will be very useful in calibrating our model against experimental tests.

5.1. A scaling argument. Let us rewrite the system in the one-dimensional case and in the scaled form

$$\begin{cases} \partial_t(\varphi(c)s) - \partial_x(\varphi(c)\partial_x s) = -\varphi(c)sc, \\ \\ \partial_t c = -\varphi(c)sc. \end{cases} \tag{5.1}$$

For simplicity we assume that the domain is the half-line $x > 0$. Therefore we have to give the initial and boundary conditions. Here we consider the simple case of invariant data

$$s(x,0) = 0, \quad c(x,0) = c_0, \tag{5.2}$$

and

$$s(0,t) = \hat{s} \tag{5.3}$$

for two positive constant values $c_0,\ \hat{s}$.

Following [15], we make the scaling (kx, k^2t) in the unknowns, which yields

$$s^k(x,t) = s(kx,k^2t), \quad c^k(x,t) = c(kx,k^2t). \tag{5.4}$$

Clearly, the new unknowns satisfy the scaled problem

$$\begin{cases} \partial_t(\varphi(c)s) - \partial_x(\varphi(c)\partial_x s) = -k^2\varphi(c)sc, \\ \\ \partial_t c = -k^2\varphi(c)sc, \end{cases} \tag{5.5}$$

with the same initial boundary conditions.

Assume now that there exists the limit of the sequence (s^k, c^k) for $k \to \infty$. Namely, there exist (S, C), such that

$$(s^k, c^k) \to_{k\to\infty} (S, C), \tag{5.6}$$

in some suitable (strong) topology. Using the scaling properties of the sequence (s^k, c^k), we have that (S, C) is a self-similar weak solution to the problem

$$\begin{cases} \partial_t(\varphi(C)S - C) - \partial_x(\varphi(C)\partial_x S) = 0, \\ \\ CS = 0, \end{cases} \tag{5.7}$$

with the initial boundary conditions (5.2)–(5.3). Self-similarity is just a consequence of the definition of the limit under the scaling (kx, k^2t). Therefore we have that we can write

$$S(x,t) = \Sigma\left(\frac{x}{\sqrt{t}}\right), \quad C(x,t) = \Gamma\left(\frac{x}{\sqrt{t}}\right), \tag{5.8}$$

where $\Sigma,\ \Gamma$ are one-dimensional functions such that

$$\begin{cases} \frac{1}{2}\xi\left(\varphi(\Gamma)\Sigma - \Gamma\right)' + \left(\varphi(\Gamma)\Sigma'\right)' = 0, \\ \\ \Gamma\Sigma = 0, \end{cases} \tag{5.9}$$

and

$$\Sigma(0) = \hat{s}, \quad \lim_{\xi\to\infty}\Sigma(\xi) = 0, \quad \lim_{\xi\to\infty}\Gamma(\xi) = c_0. \tag{5.10}$$

Let us now give one explicit solution to problem (5.9)–(5.10). Since $\hat{s} > 0$, at least for small values of ξ we have that $\Sigma > 0$ and $\Gamma = 0$. Let $\xi_0 > 0$ be the supremum value of the set $\{\xi > 0 | \Sigma(\xi) > 0\}$. In the interval $(0, \xi_0)$, the function Σ satisfies

$$\frac{1}{2}\xi\Sigma' + \Sigma'' = 0,$$

which implies that, from the condition at infinity,

$$\Sigma(\xi) = \hat{s} - \alpha \int_0^{\xi} e^{-\frac{1}{4}\eta^2} d\eta \tag{5.11}$$

for some $\alpha > 0$. In particular, let ξ_0 be a finite value, i.e., such that $\Sigma(\xi_0) = 0$. Then, clearly,

$$\alpha = \frac{\hat{s}}{\int_0^{\xi_0} e^{-\frac{1}{4}\eta^2} d\eta}. \tag{5.12}$$

Let us continue our solution by setting $\Sigma \equiv 0$ for $\xi \geq \xi_0$. Considering the unknowns S and C, let us denote by $\zeta(t)$ the curve where $S = 0$, which is now given by the equation

$$\zeta(t) = \xi_0 \sqrt{t},$$

which gives

$$\zeta'(t) = \frac{\xi_0}{2\sqrt{t}}.$$

On the other side, we have to satisfy the Rankine–Hugoniot condition for the conservation law (5.9)–(5.10), which yields

$$\zeta'(t) = -\frac{(\partial_x s)(\zeta(t)-)}{c_0}. \tag{5.13}$$

Now, by equating the right-hand side in the equations we obtain

$$\alpha = \frac{\xi_0 c_0}{2} e^{\frac{1}{4}\xi_0^2}. \tag{5.14}$$

Therefore, by using (5.12), we obtain a relation for ξ_0:

$$F(\xi_0) := \xi_0 \int_0^{\xi_0} e^{\frac{1}{4}(\xi_0^2 - \eta^2)} d\eta = \frac{2\hat{s}}{c_0}. \tag{5.15}$$

Since $F(0) = 0$ and $\lim_{\xi \to \infty} F(\xi) = \infty$ and $F' > 0$, there exists $G = F^{-1}$, the inverse function of F, and we take as ξ_0 the unique value $\xi_0 = G(\frac{2\hat{s}}{c_0})$.

Let us resume our situation. There exists a self-similar weak solution of problem (5.9)–(5.10), which is given by

$$(S(x,t),\ C(x,t)) = \begin{cases} S = \hat{s} - \dfrac{\xi_0 c_0}{2} \displaystyle\int_0^{\frac{x}{\sqrt{t}}} e^{\frac{1}{4}(\xi_0^2 - \eta^2)} d\eta,\ \ C = 0,\ x \in (0, \xi_0\sqrt{t}), \\ \\ S = 0,\ C = c_0,\ x > \xi_0\sqrt{t}, \end{cases} \tag{5.16}$$

where ξ_0 is the unique solution of (5.15). If we restrict our attention to the unknown S, we find that it is just a weak solution to the one-phase Stefan problem,

$$\begin{cases} \partial_t S - \partial_{xx} S = 0 \ \ \text{for } x \in (0, \zeta(t)), \\ \\ S(x,0) = 0, \\ \\ S(\zeta(t), 0) = 0, \\ \\ \zeta'(t) = -\frac{(\partial_x s)(\zeta(t)-)}{c_0}. \end{cases} \tag{5.17}$$

As is well known [20], this problem has a unique explicit solution. Therefore we can find that the limit problem (5.8) also has a unique self-similar weak solution.

Let us now investigate the relation between this scaling and the asymptotic behavior of the solution (s, c) to (5.1), (5.2), (5.3). Assuming the limit (5.6), we have that, fixing $t = 1$,

$$(s(kx, k^2), c(kx, k^2)) = (s^k(x, 1), c^k(x, 1)) \to (S(x, 1), C(x, 1)) \quad \text{as } k \to \infty.$$

Now, setting $y = kx$ and $\tau = k^2$, we find that

$$\left(s(y,\tau) - S\left(\frac{y}{\sqrt{\tau}}, 1\right), c(y,\tau) - C\left(\frac{y}{\sqrt{\tau}}, 1\right)\right) \to (0,0) \quad \text{as } \tau \to \infty. \tag{5.18}$$

The rigorous proof of this result is beyond the aims of this paper and will be considered in a future work. In the following we present a consistent numerical verification of this asymptotic behavior.

5.2. A numerical study. Let us analyze numerically the asymptotic behavior of the solution. The following questions are under consideration:

- Does the approximate solution have the correct asymptotic limit?
- How does the front appear?
- What is the convergence rate to the limit?

We consider the unscaled model (2.15)–(2.16) with the previous parameters (4.1) and $A = 100$. Let us denote $g(\xi) = \int_0^\xi \mathrm{e}^{-x^2/4} dx$. The above results read

$$\lim_{t\to+\infty} s(x,t) - \sigma\left(\frac{x}{\sqrt{t}}\right) = 0, \quad \lim_{t\to+\infty} c(x,t) - \gamma\left(\frac{x}{\sqrt{t}}\right) = 0$$

with

$$\begin{cases} \sigma(\xi) = \dfrac{\rho_{s0}}{\varphi(0)}\left[1 - \dfrac{g(\xi)}{g(\xi_0)}\right] & \text{if } \xi < \xi_0, \quad 0 \text{ otherwise,} \\ \gamma(\xi) = c_0 & \text{if } \xi > \xi_0, \quad 0 \text{ otherwise.} \end{cases}$$

Here ξ_0 is the unique solution of

$$\xi \mathrm{e}^{\xi^2/4} g(\xi) = \frac{2\rho_{s0} m_c}{c_0 m_s}.$$

By strict convexity, Newton's method converges to solve this equation, and we find $\xi_0 = 0.545$ approximatively.

As mentioned in section 4, the fully implicit finite element method ($\theta = 1$) is the cheaper in terms of computation times, so we choose this method here. We compute the solution on a rather large space interval—$[0, 10]$—to avoid the influence of the right boundary condition. As the front position is $x(t) = \xi_0\sqrt{t}$, this allows us to compute the solution for $t < 300$. We take $\Delta x = 0.01$ and $\frac{\Delta t}{\Delta x} = 0.5$. To make sure that this choice is correct, we first compared the solution at $t = 10$ with the one obtained by explicit finite differences with $\frac{\Delta t}{\Delta x^2} = C$. Both results coincide; see Figure 7.

Figure 8 represents early times and the formation of the front. We have $c(0, t) = c_0 \mathrm{e}^{-At/m_s}$. This gives $c(0, 5) = 0.004$, and $10^{-7} < c(0, 10) < 10^{-6}$. In fact, after the time $t = 5$, we already observe the asymptotic profile on the calcite density.

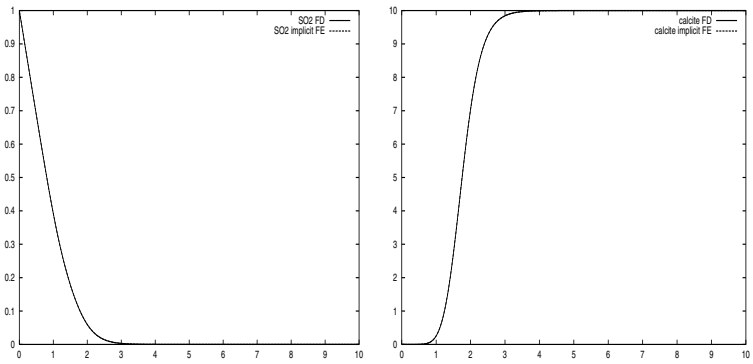

FIG. 7. *Comparison among implicit finite element methods and explicit finite difference methods. Left: SO_2 concentration; right: calcite density. Time $t = 10$.*

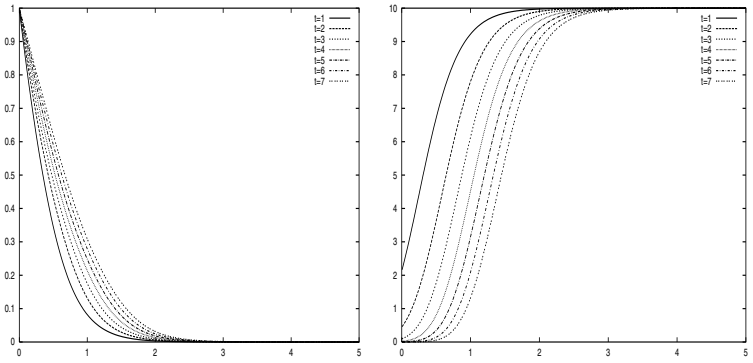

FIG. 8. *Front formation. Left: SO_2 concentration; right: calcite density.*

If we now compute the solution for large times and compare it to the theoretical limit, we obtain qualitatively a good agreement with our prediction, as shown in Figure 9, where we represent the solution with respect to an $x/\sqrt{t}$-scale, in order to observe the convergence to the asymptotic state. Let us study the convergence more carefully. As suggested by theoretical results [15], which were obtained for the case with constant porosity and constant diffusion, we expect that s converges on $\mathbb{R}_x^+$ while c converges out of the front. Let us denote

$$e_s(x,t) = \left| s(x,t) - \sigma\left(\frac{x}{\sqrt{t}}\right)\right|, \quad e_c(x,t) = \left| c(x,t) - \gamma\left(\frac{x}{\sqrt{t}}\right)\right|$$

and for $\delta \geq 0$, $t \geq 0$,

$$X(\delta,t) = \left\{ x \in \mathbb{R}^+, \ \left| \frac{x}{\sqrt{t}} - \xi_0 \right| \geq \delta \right\}.$$

For $p \in [1, +\infty]$, we study

$$E_s(A,p,\delta,t) = \|e_s(.,t)\|_{L^p(X(\delta,t))}, \quad E_c(A,p,\delta,t) = \|e_c(.,t)\|_{L^p(X(\delta,t))}.$$

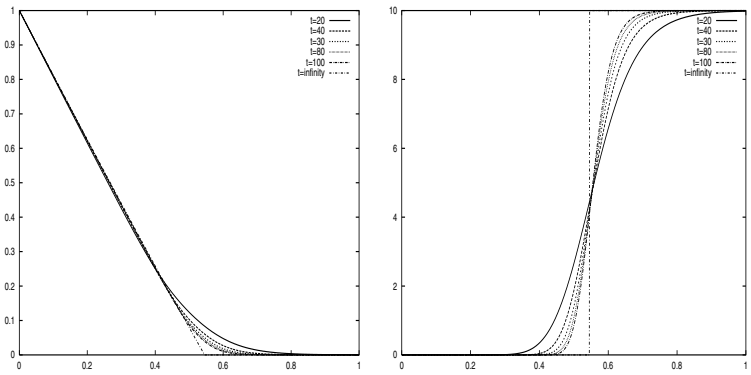

FIG. 9. *Large time behavior. Left: SO_2 concentration; right: calcite density, with respect to the $x/\sqrt{t}$-scale.*

If (s, c) is a solution of system (2.15)–(2.16) with $A = 1$, then the scaled function (s^k, c^k) defined in (5.4) is a solution of the same equations with $A = k^2$. Therefore, we have the following result.

PROPOSITION 5.1. *For any $p \in [1, +\infty]$, $\delta \geq 0$, $t \geq 0$,*

(5.19)
$$E_s(A, p, \delta, t) = A^{-1/2p} E_s(1, p, \delta, At), \quad E_c(A, p, \delta, t) = A^{-1/2p} E_c(1, p, \delta, At).$$

Suppose now that

$$E_s(A, p, \delta, t) = C_s(A, p, \delta) t^{-r_s}, \quad E_c(A, p, \delta, t) = C_c(A, p, \delta) t^{-r_c}.$$

Then

$$E_s(1, p, \delta, t) = A^{r_s + 1/2p} C_s(A, p, \delta) t^{-r_s},$$
$$E_c(1, p, \delta, t) = A^{r_c + 1/2p} C_c(A, p, \delta) t^{-r_c}.$$

Consequently, the convergence rates r_s, r_c do not depend on A. The other parameters are fixed by the physical properties of the calcite specimen and the SO_2. From these considerations, we conclude that these convergence rates may be considered as specific to the problem. We have determined them experimentally for $p = +\infty$, $p = 1$, $p = 2$.

As far as we are concerned with uniform convergence, the results are as expected—the SO_2 concentration converges uniformly on $\mathbb{R}^+$ and the calcite density does not:

$$\lim_{t \to +\infty} E_s(A, \infty, 0, t) = 0, \quad \lim_{t \to +\infty} E_c(A, \infty, 0, t) \neq 0.$$

We have then computed the maximum difference between the asymptotic limit and the computed solution, out of the front, for different values of δ in the range $[0.01\xi_0, 0.2\xi_0]$. For $\delta \geq 0.05\xi_0$ we observe that

$$\lim_{t \to +\infty} E_c(A, \infty, \delta, t) = 0.$$

These results are shown in Figure 10. In the legend we denoted $d = \delta/\xi_0$. The convergence rates are shown in Figure 11. As we evaluate them at each time step,

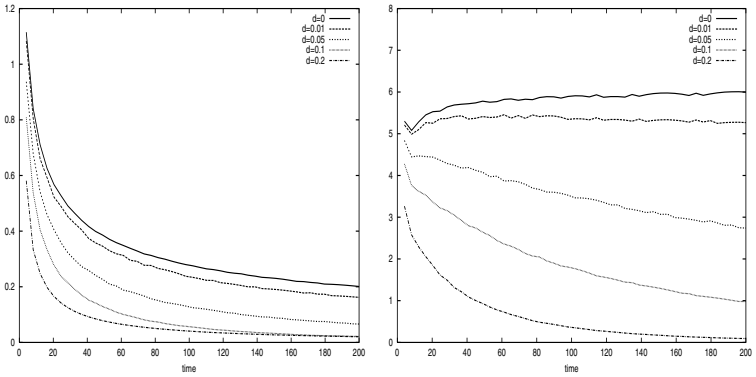

FIG. 10. *Maximal distance to asymptotic solution, out of the front, with respect to time. Left: SO_2 concentration; right: calcite density.*

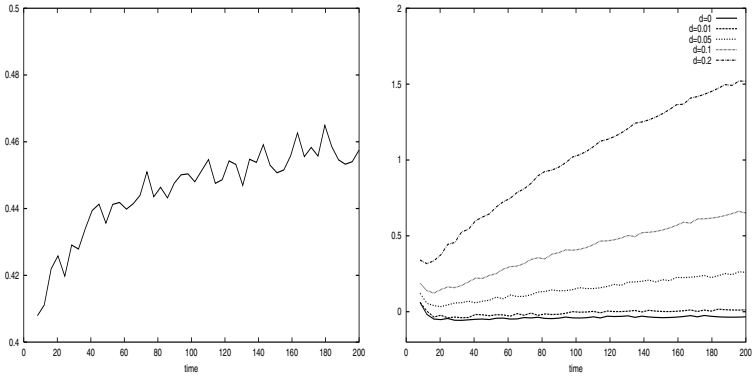

FIG. 11. *Convergence rate in maximum norm, with respect to time. Left: SO_2 concentration; right: calcite density.*

we obtain a function of time that is asymptotic to a constant value for large times. For SO_2, we show only the result for $\delta = 0$: we find that r_s is about 0.45. For the second variable, the convergence rate r_c is also about 0.4 for $\delta = 0.1\xi_0$. For the values considered here, it is an increasing function of δ. Observe that the rates begin to stabilize after the time $t = 5$, that is, the time for which we see the formation of the front.

The analysis of L^1 and L^2 convergences leads to similar results. In Figures 12 and 13, we represented the L^1 and L^2 distances of the computed solution to the theoretical limit, out of the front. As we already have uniform convergence of s on $\mathbb{R}^+$, it is clear that s converges also in L^p norm, and we actually observe it. With regard to the calcite density, we do not find out L^1 or L^2 convergence, where uniform convergence does not hold, although the curves for $\delta = 0.01\xi_0$ are slightly decreasing. Finally, Figures 14 and 15 give the convergence rates, and they are similar to the ones for the L^∞ norm. We also remark that these numerical results are in sharp contrast to the analytical results of [16, 4], where global strong convergence, i.e., up the front, of the reactive unknown c was proven for the case $\alpha = 0$, namely, in the constant porosity case. Actually, this convergence is observed also at the numerical level by using our

schemes. The main difference between the constant and the nonconstant porosity case is in the singular nonlinear term $\alpha c_x s_x$, which appears in the nonconstant case by developing all the derivatives in (1.1). Actually, this is the main difficulty toward obtaining a rigorous proof of (5.18).

5.3. Comparison with experimental results. The asymptotic profile (5.16) of our solutions shows that there exists a clear front of gypsum, which evolves as a linear function of $\sqrt{t}$. Let us notice here that this behavior has been experimentally observed in many independent tests; see, for instance, [22, 23, 7, 8, 17]. In connection with the present research, some new laboratory tests were performed in [10], and great care was given to force the monoaxial symmetry of the experiment and to establish a clear dependence of the speed of the front on the physical parameters.

Figure 16 presents on the left the numerical simulation of the evolution of the front, plotted as a function of $\sqrt{t}$, while the right presents the gypsum thickness values at different times, in the same scale, as given by the preliminary experimental results given in [10].

It is possible to observe a good qualitative agreement between the numerical

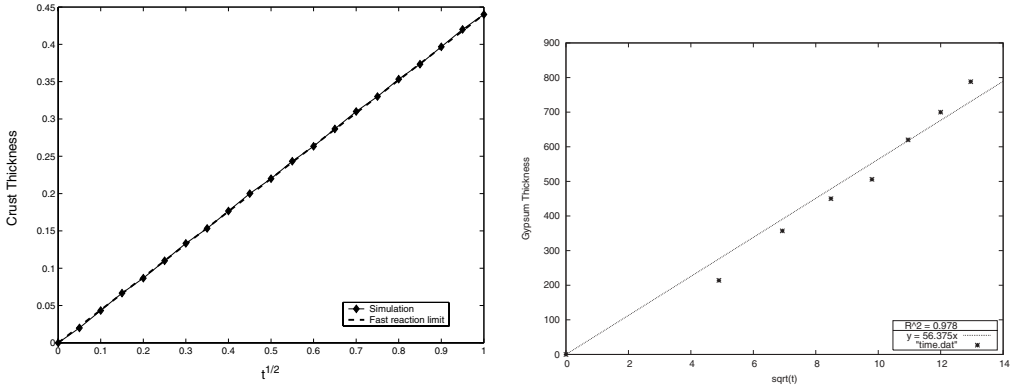

FIG. 16. *Left: Position of the calcite front as a function of $\sqrt{t}$. The simulated results were obtained using 300 finite elements, $\Delta t = 1/3000$, and $k = 10^5$. Right: Crust thickness measured in function of time reaction as obtained in the laboratory test in* [10].

prediction and the experimental data, which gives the possibility of a future calibration of the parameters on a larger set of data. In this way it will be possible to quantify the real damage phenomena on the stone materials.

6. Conclusion. We have considered a macroscopic hydrodynamic model for the evolution of the gypsum fronts in calcium carbonate stones, for which we have designed several finite element and finite difference discretizations. The finite element method involves the resolution of one tridiagonal linear system per time step. All the finite difference schemes have an explicit formulation and allow high order in time, but we have noticed that in our context, first order seems to be sufficient.

Our numerical experiments show that the approximations FD3 and FD4 are less efficient than the others. An interesting feature of the methods FE, FD1, and FD2 with $\theta = 1/2$ is that for short times they are numerically second order accurate. We have also observed that the implicit finite element method FE-1 can be used with a hyperbolic like time step $\Delta t = C.\Delta x$, which allows fast computations.

Numerical stability is established, and all those schemes give comparable shapes. We have produced asymptotic solutions for the model, and they are retrieved by the computational results. Moreover, this behavior is in qualitative agreement with the experimental tests. This is an important step in the validation of the model. In view of these encouraging facts, multidimensional computations on realistic complex geometries are now under consideration.

Acknowledgments. The authors would like to thank G. I. Barenblatt for valuable discussions about this work. We thank Rein van der Hout, Gianni Royer, Carlo Nitsch, and Maria Laura Santarelli, who read the first version of this manuscript and made many interesting remarks. EUCLIDEAN SHIFT-TWIST SYMMETRY IN POPULATION MODELS OF SELF-ALIGNING OBJECTS*

PAUL C. BRESSLOFF†

Abstract. We consider the symmetry properties of a general class of nonlocal population models describing the aggregation and alignment of oriented objects in two dimensions. Such objects could be at the level of molecules, cells, or whole organisms. We show that the underlying interaction kernel is invariant under the so-called shift-twist action of the Euclidean group acting on the space $\mathbf{R}^2 \times S^1$. This group action was previously studied within the context of a continuum model of primary visual cortex. We use perturbation methods to solve the eigenvalue problem arising from linearization about a homogeneous state, and then use equivariant bifurcation theory to identify the various types of doubly periodic patterns that are expected to arise when the homogeneous state becomes unstable. We thus establish that two distinct forms of spatio-angular order can occur, corresponding to scalar and pseudoscalar representations of the Euclidean group.

Key words. cell alignment, actin cytoskeleton, animal aggregation, Euclidean symmetry, self-organization, population models, integro-differential equations

1. Introduction.

A wide variety of self-organizing biological systems exhibit aggregation and alignment phenomena. These occur spontaneously due to mutual interactions between the individual elements of a population, in which both the relative position and the relative orientation of the individuals have a significant effect on the nature of the interactions. The underlying population can consist of molecules, cells, or whole organisms. A well-known example of the last category is the aggregation of animal herds, fish schools, and flocks of birds, in which the members of the group tend to align their bodies with each other and move in a common direction [14]. Such behavior provides a defense against predators. Examples at the cellular and molecular levels are the alignment of mammalian fibroblast cells within densely formed patches [10] and the alignment of actin filaments forming a scaffolding structure within a cell [22]. In order to investigate the important role of alignment in population survival and in the properties of biological materials, a number of continuum models of interacting oriented objects have been developed, with applications to animal social groups [19, 14, 6], fibroblasts [16, 17, 8], and actin [7, 12, 21]. All of these models are formulated in terms of integro-differential equations describing the evolution of the distribution of oriented elements in space. It is typically assumed that the interaction terms involve convolutions of the population distribution with some linear kernel. Convolutions with respect to orientation are natural, since an individual can interact with a neighboring cell having any relative orientation, whereas convolutions with respect to spatial position can be justified by assuming that signaling between individuals happens on a much faster time-scale than aggregation and alignment [15].

In this paper we investigate how symmetries of the interaction kernel determine the types of spatio-angular patterns that can emerge through a Turing-like instability of a homogeneous state. For concreteness, we focus on a diffusion-advection equation

for a population of oriented objects distributed in the two-dimensional plane. This corresponds to the second of three classes of model previously studied by Mogilner and Edelstein-Keshet [18], in which nonlocal interactions induce a rotation about the center of mass of each element as well as a linear drift of the center of mass in the plane. (The other two models are less realistic in the sense that they treat the alignment process as instantaneous, although they do exhibit the same qualitative behavior since they have the same underlying symmetries.) Mogilner and Edelstein-Keshet [18] solved the eigenvalue problem arising from a linear stability analysis of the homogeneous state in the case of a separable interaction kernel, that is, one in which variations in the strength of interaction with respect to relative orientation and relative position are uncorrelated. Such a kernel is invariant under the action of the product group $\mathbf{E}(2) \times \mathbf{O}(2)$, where $\mathbf{E}(2)$ denotes the Euclidean group of rigid body motions in the plane $\mathbf{R}^2$ and $\mathbf{O}(2)$ consists of rotations and reflection on the circle S^1. However, it is often found that individuals with similar orientations have stronger interactions when they are collinear in the plane, implying that the interaction kernel is nonseparable [6]. (A specific example of a nonseparable kernel was briefly considered in [18], but general symmetry properties were not addressed.) Here we show that these more realistic kernels are invariant with respect to the so-called *shift-twist* action of $\mathbf{E}(2)$ acting on the space $\mathbf{R}^2 \times S^1$, and we explore the consequences of this symmetry for pattern formation. Note that the same group action has recently been analyzed within the context of continuum models of the visual cortex, where the nonlocal interactions are mediated by axonal connections between neurons that are tuned to respond to oriented visual stimuli [3, 4]. Shift-twist invariant kernels also play a central role in a recently proposed computational algorithm for grouping and joining edges that form the boundaries of objects in a visual image [24].

We begin by describing the nonlocal population model for the aggregation and alignment of oriented objects in two dimensions and discussing its symmetry properties (section 2). We show that the resulting diffusion-advection equation is equivariant with respect to the shift-twist action of the Euclidean group due to the invariance of the underlying interaction kernel. We then use perturbation methods to solve the eigenvalue problem arising from linearization about a homogeneous state and determine marginal stability conditions (section 3). Finally, we use equivariant bifurcation theory to identify the various types of doubly periodic patterns that are expected to arise when the homogeneous state becomes unstable, and thus establish that two distinct forms of spatio-angular order can occur, corresponding to the so-called scalar and pseudoscalar representations of the Euclidean group (section 4). Interestingly, analogous results [5] have been obtained for the Landau–de Gennes model of a nematic liquid crystal [9], where the oriented objects are rod-like molecules that interact by electrostatic attraction or repulsion.

2. Description of the model and its symmetries. Let $f(\mathbf{r}, \theta, t)$ denote the distribution of oriented objects in a two-dimensional domain $\mathcal{D} \subset \mathbf{R}^2$ at time t with $\mathbf{r} \in \mathcal{D}$ and $-\pi < \theta \leq \pi$. It is assumed that the total number of objects N is conserved; that is, $\dot{N} = 0$ with

$$N = \int_{\mathcal{D}} \int_{-\pi}^{\pi} f(\mathbf{r}, \theta, t) \frac{d\theta}{2\pi} d^2\mathbf{r}. \tag{2.1}$$

In cases where the population grows (due to cell proliferation, for example), N may still be treated as a constant, provided that the growth process is adiabatic. The pop-

ulation distribution f is taken to evolve according to the diffusion-advection equation

$$\frac{\partial f}{\partial t} = D_1 \frac{\partial^2 f}{\partial \theta^2} + D_2 \nabla^2 f - \frac{\partial J_\theta}{\partial \theta} - \nabla \cdot \mathbf{J}_r. \tag{2.2}$$

Here D_1 and D_2 are angular and spatial diffusion constants, J_θ is the flux arising from changes in the orientation of objects, and $\mathbf{J}_r$ is the flux arising from motion in the plane:

$$J_\theta = f \frac{d\theta}{dt}, \quad \mathbf{J} = f \frac{d\mathbf{r}}{dt}. \tag{2.3}$$

Following Mogilner and Edelstein-Keshet [16, 18], we assume that inertial forces can be neglected so that the velocities are simply proportional to the driving forces,

$$\frac{d\theta}{dt} = \eta_1 F_\theta, \quad \frac{d\mathbf{r}}{dt} = \eta_2 \mathbf{F}_r. \tag{2.4}$$

The forces are taken to be conservative; that is, each can be expressed in terms of the gradient of an underlying potential function V:

$$F_\theta = \frac{\partial V}{\partial \theta}, \quad \mathbf{F}_r = \nabla V, \tag{2.5}$$

where V is given by the integral of f with respect to a linear kernel W,

$$V(\mathbf{r}, \theta) = W * f(\mathbf{r}, \theta) \equiv \int_{\mathcal{D}} \int_{-\pi}^{\pi} W(\mathbf{r}, \theta | \mathbf{r}', \theta') f(\mathbf{r}', \theta') \frac{d\theta}{2\pi} d^2\mathbf{r}. \tag{2.6}$$

(One could also consider a more general situation in which angular and planar motion are generated by two distinct potentials [18].) Substituting (2.3), (2.4), (2.5), and (2.6) into (2.2) leads to the following model equation:

$$\frac{\partial f}{\partial t} = D_1 \frac{\partial^2 f}{\partial \theta^2} + D_2 \nabla^2 f - \eta_1 \frac{\partial}{\partial \theta} \left(f \frac{\partial (W * f)}{\partial \theta} \right) - \eta_2 \nabla \cdot (f \nabla (W * f)). \tag{2.7}$$

2.1. The interaction kernel. We now specify the form of the interaction kernel W. Consider a local patch of individuals at point $\mathbf{r}$ with orientation θ. These will move in the plane and reorient as a result of the influence from other patches at $\mathbf{r}'$ with orientation θ' (see Figure 2.1(a)). It is likely that the interactions depend on three distinct factors [6, 18]: (i) the Euclidean distance $|\mathbf{r} - \mathbf{r}'|$, (ii) the relative orientation $\theta - \theta'$, and (iii) the relative alignment in the plane $\psi = \arg(\mathbf{r} - \mathbf{r}') - \theta$. One way to understand the third factor is to consider the case of parallel objects that are equidistant in the plane but are either collinear or flanking each other (see Figure 2.1(b)). Given the fact that each object is elongated, it is possible that collinear objects tend to influence each other more strongly than flanking objects. In the cellular or molecular case this would arise due to differences in the contact areas of the individuals, whereas in animal social groups this would reflect differences in the ability to sense individuals in different relative directions. In the latter case, the influence of individuals behind a given animal would also tend to be weaker than on the sides or front. If we assume that the three effects are independent, then the interaction kernel can be decomposed into the product form (see [6])

$$W(\mathbf{r}, \theta | \mathbf{r}', \theta') = G(|\mathbf{r} - \mathbf{r}'|) H(\theta - \theta') \Delta(\arg(\mathbf{r} - \mathbf{r}') - \theta). \tag{2.8}$$

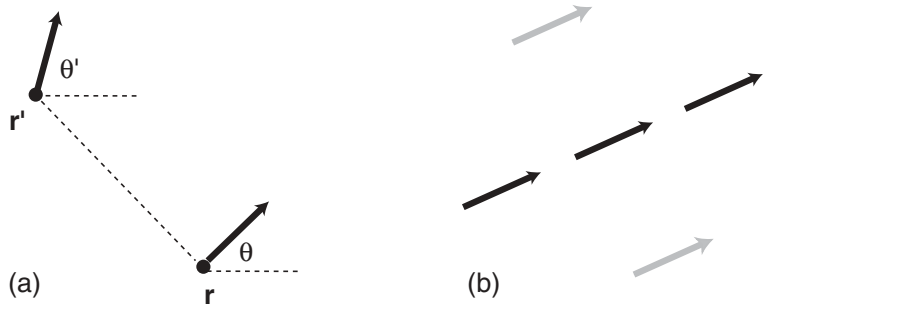

FIG. 2.1. (a) *Two oriented objects in the plane.* (b) *Difference in the influence of collinear (black) and flanking (gray) oriented objects.*

We now discuss each of the terms appearing in (2.8).

The strength of interactions decreases as a function of spatial separation so that $G(r)$ is a monotonically decreasing function of r. For concreteness, we take G to be a Gaussian

$$G(r) = \frac{1}{2\pi\sigma^2} \mathrm{e}^{-r^2/2\sigma^2}, \tag{2.9}$$

where σ denotes the effective range of interactions. We fix the spatial scale by setting $\sigma = 1$. Throughout this paper we assume that the range of interactions is at least a few orders of magnitude smaller than the size of the domain $\mathcal{D}$. This allows us to treat the spatial domain as infinite so that we can ignore boundary effects. The angular contribution $H(\theta)$ is assumed to be an even function of θ with one or more maxima whose locations are model-dependent. In the case of fibroblasts [18], interactions tend to favor parallel alignment which may be "head-to-head" ($\theta = 0$) or "head-to-tail" ($\theta = \pi$). This can be modeled by taking a bimodal function of the form

$$H(\theta) = [\cos 2\theta - \cos 2\theta_0]_+, \quad \theta_0 < \frac{\pi}{4}, \tag{2.10}$$

where $[x]_+ = x$ if $x > 0$ and $[x]_+ = 0$ if $x \le 0$, and θ_0 determines the width of the two maxima. If only "head-to-head" alignment is favored, then $H(\theta)$ can be modeled by the unimodal function

$$H(\theta) = [\cos\theta - \cos\theta_0]_+, \quad \theta_0 < \frac{\pi}{2}. \tag{2.11}$$

In the case of actin fibers [7], crosslinking proteins allow fibers to interact and bind at different configurations that include both parallel and orthogonal alignment. An example of an orthogonal interaction kernel is

$$H(\theta) = [\cos 2\theta_0 - \cos 2\theta]_+, \quad \theta_0 > \frac{\pi}{4}. \tag{2.12}$$

All three cases are illustrated in Figure 2.2. The final factor Δ is expected to be a positive function that is greater for coaligned elements than for flanking elements (at least in the case of parallel alignment). One possibility is to take

$$\Delta(\psi) = 1 + \beta\cos 2\psi, \quad \beta < 1. \tag{2.13}$$

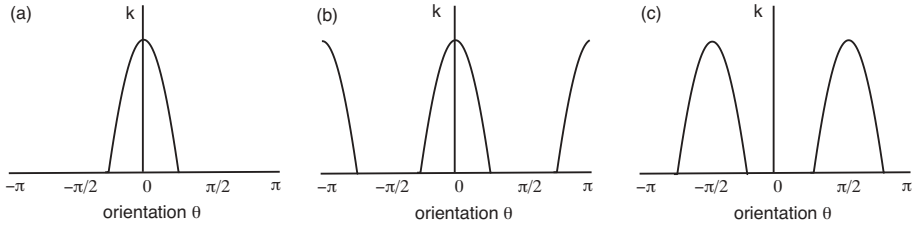

FIG. 2.2. *Orientation kernel $H(\theta)$ for different favored alignments:* (a) *unimodal parallel alignment,* (b) *bimodal parallel alignment,* (c) *orthogonal alignment.*

Note that as it stands the interaction kernel (2.8) is not symmetric under the interchange $(\mathbf{r},\theta) \leftrightarrow (\mathbf{r}',\theta')$. It is straightforward to modify the kernel so that it has such an exchange symmetry by taking

$$W(\mathbf{r},\theta|\mathbf{r}',\theta') = \frac{1}{2}H(\theta-\theta')\left[J(\mathbf{r}-\mathbf{r}',\theta)+J(\mathbf{r}-\mathbf{r}',\theta')\right], \tag{2.14}$$

where

$$J(\mathbf{r},\theta) = G(|\mathbf{r}|)\Delta(\arg(\mathbf{r})-\theta). \tag{2.15}$$

2.2. Euclidean symmetry. We now show that the nonseparable interaction kernel W given by (2.8) is invariant under the action of the Euclidean group $\mathbf{E}(2)$, which is composed of the (semidirect) product of $\mathbf{O}(2)$, the group of planar rotations and reflections, with $\mathbf{R}^2$, the group of planar translations. The action of the Euclidean group on $\mathbf{R}^2 \times \mathbf{S}^1$ is generated by

$$\begin{aligned} \mathbf{s}\cdot(\mathbf{r},\theta) &= (\mathbf{r}+\mathbf{s},\theta), \qquad \mathbf{s}\in\mathbf{R}^2, \\ \varphi\cdot(\mathbf{r},\theta) &= (R_\varphi\mathbf{r},\theta+\varphi), \qquad \varphi\in\mathbf{S}^1, \\ \kappa\cdot(\mathbf{r},\theta) &= (\kappa\mathbf{r},-\theta), \end{aligned} \tag{2.16}$$

where κ is the reflection $(x_1,x_2)\mapsto(x_1,-x_2)$ and R_φ is a rotation by φ. The corresponding group action on a function $a:\mathbf{R}^2\times\mathbf{S}^1\to\mathbf{R}$ is given by

$$\gamma\cdot a(P) = a(\gamma^{-1}\cdot P) \quad \text{for all } \gamma\in\mathbf{O}(2)\dot{+}\mathbf{R}^2, \tag{2.17}$$

where $P=(\mathbf{r},\theta)$, and the action on $W(P|P')$ is

$$\gamma\cdot W(P|P') = W(\gamma^{-1}\cdot P|\gamma^{-1}\cdot P').$$

The so-called shift-twist action in (2.16) reflects a crucial feature of the underlying interactions, namely that they tend to favor collinear parallel elements. This correlation between relative angular position and object orientation means that invariance of W under $\mathbf{E}(2)$ requires a rotation in the plane according to the *twist* $\mathbf{r}\to R_\varphi\mathbf{r}$ and a simultaneous rotation of object orientation according to the *shift* $\theta\to\theta+\varphi$ (see Figure 2.3). A similar argument holds for reflections.

Translation invariance of W given by (2.8) follows immediately from the spatial homogeneity of the interactions, which implies that

$$W(\mathbf{r}-\mathbf{s},\theta|\mathbf{r}'-\mathbf{s},\theta') = W(\mathbf{r},\theta|\mathbf{r}',\theta').$$

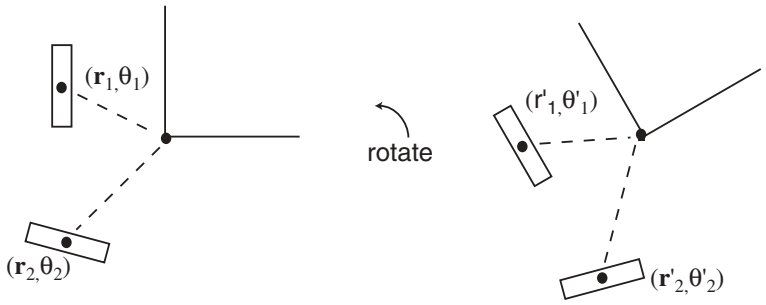

FIG. 2.3. *Action of a rotation by φ on two oriented objects located at planar positions $\mathbf{r}_1, \mathbf{r}_2$ and with internal orientations θ_1, θ_2. The action is of the form $(\mathbf{r}, \theta) \to (\mathbf{r}', \theta') = (R_\varphi \mathbf{r}, \varphi + \theta)$.*

Invariance with respect to a rotation by φ follows from

$$\begin{aligned} &W(R_{-\varphi}\mathbf{r}, \theta - \varphi | R_{-\varphi}\mathbf{r}', \theta' - \varphi) \\ &\quad = G(|R_{-\varphi}(\mathbf{r} - \mathbf{r}')|) H(\theta - \varphi - \theta' + \varphi) \Delta(\arg[R_{-\varphi}(\mathbf{r} - \mathbf{r}')] - \theta + \varphi) \\ &\quad = G(|\mathbf{r} - \mathbf{r}'|) H(\theta - \theta') \Delta(\arg(\mathbf{r} - \mathbf{r}') - \theta) \\ &\quad = W(\mathbf{r}, \theta | \mathbf{r}', \theta'). \end{aligned}$$

We have used the conditions $|R_\varphi \mathbf{r}| = |\mathbf{r}|$ and $\arg(R_{-\varphi}\mathbf{r}) = \arg(\mathbf{r}) - \varphi$. Finally, invariance under a reflection κ about the x-axis holds since

$$\begin{aligned} W(\kappa\mathbf{r}, -\theta | \kappa\mathbf{r}', -\theta') &= G(|\kappa(\mathbf{r} - \mathbf{r}')|) H(-\theta + \theta') \Delta(\arg[\kappa(\mathbf{r} - \mathbf{r}')] + \theta) \\ &= G(|\mathbf{r} - \mathbf{r}'|) H(\theta - \theta') \Delta(-\arg(\mathbf{r} - \mathbf{r}') + \theta) \\ &= W(\mathbf{r}, \theta | \mathbf{r}', \theta'). \end{aligned}$$

We have used the conditions $\arg(\kappa\mathbf{r}) = -\arg(\mathbf{r})$, $H(-\theta) = H(\theta)$, and $\Delta(-\psi) = \Delta(\psi)$. Finally, using identical arguments, it is straightforward to show that the modified kernel (2.14) is also invariant under the Euclidean group action (2.16).

Let us now determine how (2.7) transforms under the shift-twist action of the Euclidean group. Introducing the transformed coordinates $(\widetilde{\mathbf{r}}, \widetilde{\theta}) = \gamma^{-1}(\mathbf{r}, \theta)$ and setting $\widetilde{f}(\mathbf{r}, \theta) = f(\widetilde{\mathbf{r}}, \widetilde{\theta})$, etc., we see that (2.7) becomes

$$\frac{\partial \widetilde{f}}{\partial t} = D_1 \frac{\partial^2 \widetilde{f}}{\partial \widetilde{\theta}^2} + D_2 \widetilde{\nabla}^2 \widetilde{f} - \eta_1 \frac{\partial}{\partial \widetilde{\theta}} \left(\widetilde{f} \frac{\partial \widetilde{W * f}}{\partial \widetilde{\theta}} \right) - \eta_2 \widetilde{\nabla} \cdot (\widetilde{f} \widetilde{\nabla} \widetilde{W * f}). \tag{2.18}$$

Invariance of the weight kernel W implies that $\widetilde{W * f} = W * \widetilde{f}$:

$$\begin{aligned} W * f(\gamma^{-1}P, t) &= \int_{\mathbf{R}^2 \times \mathbf{S}^1} W(\gamma^{-1}P | P') f(P', t) dP' \\ &= \int_{\mathbf{R}^2 \times \mathbf{S}^1} W(P | \gamma P') f(P', t) dP' \\ &= \int_{\mathbf{R}^2 \times \mathbf{S}^1} W(P | P'') f(\gamma^{-1}P'', t) dP'', \end{aligned}$$

since $d[\gamma^{-1}P] = \pm dP$ and W is Euclidean invariant. It is also easy to establish that

all of the quadratic differential operators are Euclidean invariant, that is,

$$\frac{\partial}{\partial\widetilde{\theta}}\left(a\frac{\partial}{\partial\widetilde{\theta}}\right)=\frac{\partial}{\partial\theta}\left(a\frac{\partial}{\partial\theta}\right),\quad \widetilde{\nabla}\cdot(a\widetilde{\nabla})=\nabla\cdot(a\nabla) \tag{2.19}$$

for any scalar function $a(\mathbf{r},\theta)$. Hence,

$$\frac{\partial\widetilde{f}}{\partial t}=D_1\frac{\partial^2\widetilde{f}}{\partial\theta^2}+D_2\nabla^2\widetilde{f}-\eta_1\frac{\partial}{\partial\theta}\left(\widetilde{f}\frac{\partial W*\widetilde{f}}{\partial\widetilde{\theta}}\right)-\eta_2\nabla\cdot(\widetilde{f}\nabla W*\widetilde{f}). \tag{2.20}$$

If we rewrite (2.7) as an operator equation, namely,

$$\mathcal{F}_t[f]\equiv\frac{df}{dt}-\mathcal{F}[f]=0, \tag{2.21}$$

then it follows that $\gamma\mathcal{F}_t[f]=\mathcal{F}_t[\gamma f]=\mathcal{F}_t[\widetilde{f}]$. Thus $\mathcal{F}_t$ commutes with $\gamma\in\mathbf{E}(2)$, and $\mathcal{F}_t$ is said to be *equivariant* with respect to the symmetry group $\mathbf{E}(2)$ (see [13]). In sections 3 and 4 we show how the equivariance of the operator $\mathcal{F}_t$ with respect to the shift-twist action of $\mathbf{E}(2)$ has major implications for the nature of solutions bifurcating from a homogeneous steady state solution. In particular, equivariance implies that there exist two distinct forms of spatio-angular order, which are associated with scalar and pseudoscalar representations of the Euclidean group. Further details concerning the general approach used in this paper, as well as many illustrative examples, can be found in the recent excellent book on the role of symmetry in nonlinear dynamical systems by Golubitsky and Stewart [13].

3. Linear stability analysis. The first step in the analysis of pattern forming instabilities is to linearize (2.7) about the homogeneous solution $f(\mathbf{r},\theta)=\overline{f}$, where

$$\overline{f}=\frac{N}{2\pi A[\mathcal{D}]},\quad A[\mathcal{D}]=\int_{\mathcal{D}}d^2\mathbf{r}, \tag{3.1}$$

and to solve the resulting eigenvalue problem. In particular, we wish to find conditions under which the homogeneous solution becomes marginally stable due to the vanishing of one of the (degenerate) eigenvalues, and to identify the marginally stable modes. In the following we will consider the modified version of the interaction kernel given by (2.14).

3.1. Eigenvalue equation. Substitute

$$f(\mathbf{r},\theta,t)=\overline{f}+a(\mathbf{r},\theta)\mathrm{e}^{\lambda t} \tag{3.2}$$

into (2.7) and expand to first order in a. This generates the linear eigenvalue equation

$$\begin{aligned}\lambda a&=\widehat{L}a\\&\equiv D_1\frac{\partial^2 a}{\partial\theta^2}+D_2\nabla^2 a-\eta_1\overline{f}\frac{\partial^2(W*a)}{\partial\theta^2}-\eta_2\overline{f}\nabla^2(W*a).\end{aligned} \tag{3.3}$$

Since the homogeneous solution has full Euclidean symmetry, $\gamma\overline{f}=\overline{f}$ for all $\gamma\in\mathbf{E}(2)$, it follows that the linear operator $\widehat{L}$ is equivariant with respect to the Euclidean group action (2.16). This can be shown either by explicitly using (3.3) or by rewriting (2.7) in the form (2.21) and exploiting the equivariance of $\mathcal{F}$. In the latter case, linearizing both sides of the equation $\gamma\mathcal{F}[f]=\mathcal{F}[\gamma f]$ about $\overline{f}$ gives

$$\gamma\left(\mathcal{F}[\overline{f}]+D\mathcal{F}[\overline{f}](f-\overline{f})\right)=\mathcal{F}[\gamma\overline{f}]+D\mathcal{F}[\gamma\overline{f}](\gamma f-\overline{f}),$$

which implies that $\gamma\widehat{L} = \widehat{L}\gamma$ for all $\gamma \in \mathbf{E}(2)$, where $\widehat{L} = D\mathcal{F}[\overline{f}]$. Equivariance of $\widehat{L}$ determines the basic form of the eigenfunction solutions of (3.3); namely, they are given by irreducible representations of the group action (2.16) on the space $\mathbf{R}^2 \times \mathbf{S}^1$. We show this following similar arguments to those of Bressloff et al. [3, 4]. First, translation symmetry implies that the eigenfunctions can be expressed in the form

$$a(\mathbf{r},\theta) = u(\theta-\varphi)e^{i\mathbf{k}\cdot\mathbf{r}} + \text{c.c.}, \tag{3.4}$$

where c.c. denotes the complex conjugate, $\mathbf{k} = q(\cos\varphi, \sin\varphi)$, and

$$\begin{aligned}\lambda u(\theta) &= D_1\frac{\partial^2 u(\theta)}{\partial\theta^2} - D_2 q^2 u(\theta)\\ &\quad - \frac{\overline{f}}{2}\left[\eta_1\frac{\partial^2}{\partial\theta^2} - \eta_2 q^2\right]\int_{-\pi}^{\pi} H(\theta-\theta')\left[\widehat{J}(\mathbf{k},\theta+\varphi) + \widehat{J}(\mathbf{k},\theta'+\varphi)\right]u(\theta')\frac{d\theta'}{2\pi}.\end{aligned} \tag{3.5}$$

Here $\widehat{J}(\mathbf{k},\theta)$ is the Fourier transform of $J(\mathbf{r},\theta)$,

$$\widehat{J}(\mathbf{k},\theta) = \int_{\mathbf{R}^2} \mathrm{e}^{-i\mathbf{k}\cdot\mathbf{r}} J(\mathbf{r},\theta)d^2\mathbf{r}. \tag{3.6}$$

Euclidean symmetry further restricts the structure of the eigensolutions $u(\theta)$ of (3.5) as follows.

(i) The Fourier transform $\widehat{J}(\mathbf{k},\theta+\varphi)$ is independent of the direction $\varphi = \arg(\mathbf{k})$. This is easy to establish as follows:

$$\begin{aligned}\widehat{J}(\mathbf{k},\theta+\varphi) &= \int_{\mathbf{R}^2} \mathrm{e}^{-i\mathbf{k}\cdot\mathbf{r}} J(\mathbf{r},\theta+\varphi)d^2\mathbf{r}\\ &= \int_0^\infty\int_{-\pi}^{\pi} \mathrm{e}^{-iqr\cos(\psi-\varphi)} G(r)\Delta(\psi-\theta-\varphi)d\psi r dr\\ &= \int_0^\infty\int_{-\pi}^{\pi} \mathrm{e}^{-iqr\cos(\psi)} G(r)\Delta(\psi-\theta)d\psi r dr\\ &= \widehat{J}(q,\theta).\end{aligned} \tag{3.7}$$

Therefore, λ and $u(\theta)$ depend only on the magnitude $q = |\mathbf{k}|$ of the wavevector $\mathbf{k}$, and there is an infinite degeneracy due to rotational invariance. Note, however, that the eigenfunction (3.4) depends on $u(\theta-\varphi)$, which reflects the shift-twist action of the rotation group.

(ii) For each $\mathbf{k}$ the associated subspace of eigenfunctions

$$V_{\mathbf{k}} = \{u(\theta-\varphi)\mathrm{e}^{i\mathbf{k}\cdot\mathbf{r}} + \text{c.c.}\} \tag{3.8}$$

decomposes into two invariant subspaces,

$$V_{\mathbf{k}} = V_{\mathbf{k}}^+ \oplus V_{\mathbf{k}}^-, \tag{3.9}$$

corresponding to even and odd functions, respectively:

$$V_{\mathbf{k}}^+ = \{v \in V_{\mathbf{k}} : u(-\theta) = u(\theta)\} \quad \text{and} \quad V_{\mathbf{k}}^- = \{v \in V_{\mathbf{k}} : u(-\theta) = -u(\theta)\}. \tag{3.10}$$

This is a consequence of reflection invariance, as we now indicate. That is, let $\kappa_{\mathbf{k}}$ denote reflections about the wavevector $\mathbf{k}$ so that $\kappa_{\mathbf{k}}\mathbf{k} = \mathbf{k}$. Then $\kappa_{\mathbf{k}}a(\mathbf{r},\phi) =$

$a(\kappa_{\mathbf{k}}\mathbf{r}, 2\varphi - \phi) = u(\varphi - \phi)\mathrm{e}^{i\mathbf{k}\cdot\mathbf{r}}+$ c.c. Since $\kappa_{\mathbf{k}}$ is a reflection, any space that it acts on decomposes into two subspaces—one on which it acts as the identity I and one on which it acts as $-I$. The even and odd functions correspond to scalar and pseudoscalar representations of the Euclidean group studied in a more general context by Vivancos, Chossat, and Melbourne [1].

A further reduction of (3.5) can be achieved by expanding the 2π-periodic function $u(\theta)$ as a Fourier series with respect to θ:

$$u(\theta) = \sum_{n\in\mathbf{Z}} U_n \mathrm{e}^{in\theta}. \tag{3.11}$$

This then leads to the matrix eigenvalue equation

$$\lambda(q)U_n = [\mathbf{L}(q)\mathbf{U}]_n \equiv -A_n(q)U_n + \frac{1}{2}B_n(q)\sum_{m\in\mathbf{Z}} \widehat{J}_{n-m}(q)[H_m + H_n]U_m, \tag{3.12}$$

where

$$A_n(q) = D_1 n^2 + D_2 q^2, \quad B_n(q) = \overline{f}(\eta_1 n^2 + \eta_2 q^2) \tag{3.13}$$

and

$$\widehat{J}_n(q) = \int_{-\pi}^{\pi} \mathrm{e}^{-in\theta}\widehat{J}(q,\theta)\frac{d\theta}{2\pi} = \Delta_n \widehat{G}_n(q) \tag{3.14}$$

with

$$\widehat{G}_n(q) = \int_0^{\infty}\int_{-\pi}^{\pi} \mathrm{e}^{-iqr\cos(\psi)}\mathrm{e}^{-in\psi}G(r)d\psi r dr. \tag{3.15}$$

We have used (3.7) together with the Fourier series expansions

$$H(\theta) = \sum_{n\in\mathbf{Z}} \mathrm{e}^{in\theta}H_n, \quad \Delta(\psi) = \sum_{n\in\mathbf{Z}} \mathrm{e}^{in\psi}\Delta_n. \tag{3.16}$$

Note that $H_n^* = H_{-n} = H_n$ and $\Delta_n^* = \Delta_{-n} = \Delta_n$, since $H(\theta)$ and $\Delta(\theta)$ are assumed to be real even functions of θ. Equations (3.14) and (3.15) imply that

$$\widehat{J}_n(q)^* = (-1)^n \widehat{J}_{-n}(q), \quad \widehat{J}_{-n}(q) = \widehat{J}_n(q). \tag{3.17}$$

Denote the set of solutions to (3.12) by $\{(\lambda_j(q), \mathbf{U}_j(q)),\ j \in \mathbf{Z}\}$. We now establish conditions under which the eigenvalues $\lambda_j(q)$ are real for all $q \in \mathbf{R}$. The case $q = 0$ is trivial because $\widehat{J}_n(0) \sim \delta_{n,0}$ so that

$$\lambda_n(0) = -A_n(0) + B_n(0)H_n. \tag{3.18}$$

Therefore, we take $q \neq 0$. Introduce the inner product of two periodic functions $V(\theta), U(\theta)$ according to

$$\langle V|U\rangle = \int_{-\pi}^{\pi} V^*(\theta)U(\theta)\frac{d\theta}{2\pi} = \sum_{n\in\mathbf{Z}} V_n^* U_n = \langle \mathbf{V}|\mathbf{U}\rangle, \tag{3.19}$$

where V^* denotes the complex conjugate of V. The adjoint matrix $\mathbf{L}(q)^\dagger$ is then given by

$$[\mathbf{L}(q)^\dagger \mathbf{V}]_n \equiv -A_n(q)V_n + \frac{1}{2}\sum_{m\in\mathbf{Z}} \widehat{J}_{m-n}(q)^* B_m(q)[H_m + H_n]V_m. \tag{3.20}$$

Equation (3.17) implies that $\mathbf{L}(q)^\dagger$ and $\mathbf{L}(q)$ have the same set of eigenvalues,

$$\mathbf{L}(q)\mathbf{U}_j(q) = \lambda_j(q)\mathbf{U}_j(q), \quad \mathbf{L}(q)^\dagger \mathbf{V}_j(q) = \lambda_j(q)\mathbf{V}_j(q), \tag{3.21}$$

with the corresponding eigenvectors related according to

$$U_{j,n}(q) = (-1)^n B_n(q) V_{j,n}(q). \tag{3.22}$$

This relationship is invertible since $B_n(q) > 0$ for all $n \in \mathbf{Z}$ and $q \neq 0$. It further follows that

$$\begin{aligned} \lambda_j \langle \mathbf{V}_{j'} | \mathbf{U}_j \rangle &= \langle \mathbf{V}_{j'} | \mathbf{L}\mathbf{U}_j \rangle \\ &= \langle \mathbf{L}^\dagger \mathbf{V} | \mathbf{U} \rangle \\ &= \lambda_{j'}^* \langle \mathbf{V}_{j'} | \mathbf{U}_j \rangle. \end{aligned} \tag{3.23}$$

Hence, if $\lambda_j(q) \neq \lambda_{j'}(q)$ for $j \neq j'$, then the vectors $\mathbf{U}_j(q)$ and $\mathbf{V}_j(q)$ form a biorthogonal system with

$$\langle \mathbf{V}_{j'}(q) | \mathbf{U}_j(q) \rangle = \chi_j(q)\delta_{j,j'} \tag{3.24}$$

and

$$\chi_j(q) = \langle \mathbf{V}_j(q) | \mathbf{U}_j(q) \rangle = \sum_n (-1)^n B_n(q) |V_{j,n}(q)|^2. \tag{3.25}$$

It also follows that $\lambda_j(q) = \lambda_j^*(q)$ if $\chi_j(q) \neq 0$. The latter condition certainly holds for all $q \neq 0$ and $j \in \mathbf{Z}$ when $\Delta(\psi)$ is π-periodic,

$$\Delta(\psi) = \Delta(\psi + \pi), \tag{3.26}$$

corresponding to the situation in which collinear interactions are equally strong at the front and at the back (see Figure 2.1(b)). In this case $\Delta_n = 0$ and $\widehat{J}_n(q) = 0$ for all odd integers n, and $\mathbf{L}(q)$ becomes a real matrix that only couples together even-to-even or odd-to-odd components U_n. Hence, $\chi_j(q) = \pm\sum_n^{\pm} B_n(q)|V_{j,n}(q)|^2 \neq 0$, where $\sum_n^{\pm}$ denotes the sum over even and odd integers, respectively. The corresponding eigenfunctions satisfy either $U(\theta + \pi) = U(\theta)$ or $U(\theta + \pi) = -U(\theta)$ and can be taken to be real-valued. If $\Delta(\psi)$ is not π-periodic, then the eigenvalues $\lambda_j(q)$ are still real, provided that $\chi_j(q) \neq 0$ except at isolated points, which follows from the observation that $\lambda_j(q)$ is a continuous function of q. In this more general situation, however, the eigenfunctions $U(\theta)$ will be complex-valued.

3.2. Perturbation expansion. The calculation of the eigenvalues and eigenfunctions of the linearized equation (3.5), and hence the derivation of conditions for the marginal stability of the homogeneous state, has been reduced to the problem of solving the matrix equation (3.12). In general it is not possible to solve this equation exactly. Here we will carry out a perturbation expansion under the assumption that

the dependence of the interactions on relative direction in the plane is weak. In other words, we write

$$\Delta(\psi) = 1 + \beta\Psi(\psi), \quad 0 \leq \beta \ll 1, \quad |\Psi(\psi)| \leq 1 \text{ for all } \psi, \tag{3.27}$$

with $\Psi_0 = \int_{-\pi}^{\pi} \Psi(\psi)d\psi = 0$. Equation (3.12) can then be rewritten in the form

$$[\lambda(q) - W_n(q)]\, U_n = \beta \sum_{n\in\mathbf{Z}} \widehat{W}_{nm}(q)U_m, \tag{3.28}$$

where

$$W_n(q) = -A_n(q) + B_n(q)H_n\widehat{G}_0(q) \tag{3.29}$$

and

$$\widehat{W}_{nm}(q) = \frac{1}{2}B_n(q)[H_m + H_n]\Psi_{n-m}\widehat{G}_{n-m}(q) \tag{3.30}$$

with $A_n(q), B_n(q), \widehat{G}_n(q)$ given by (3.13) and (3.15). Equation (3.28) can then be solved by expanding as a power series in β and using degenerate perturbation theory.

Case $\beta = 0$. In the limiting case that the interaction kernel is independent of relative direction in the plane, $\beta = 0$, (3.28) reduces to the result previously obtained for separable kernels [18]: the eigenvalues are

$$\lambda_n(q) = W_n(q) = -(D_1n^2 + D_2q^2) + \overline{f}(\eta_1n^2 + \eta_2q^2)H_n\mathrm{e}^{-q^2/2} \tag{3.31}$$

with corresponding eigenfunctions

$$a_{n,\mathbf{k}}(\mathbf{r},\theta) = \mathrm{e}^{in\theta}\mathrm{e}^{i\mathbf{k}\cdot\mathbf{r}}, \quad |\mathbf{k}| = q. \tag{3.32}$$

We have used the result $\widehat{G}_0(q) = \mathrm{e}^{-q^2/2}$, which follows from substituting (2.9) into (3.15) and evaluating the resulting Gaussian integral. Note that the full interaction kernel W is invariant with respect to the group $\mathbf{E}(2)\times\mathbf{O}(2)$ so that the odd and even modes $a_{n,\mathbf{k}} \pm a_{-n,\mathbf{k}}$ are degenerate, that is, $\lambda_{-n}(q) = \lambda_n(q)$.

Case $\beta > 0$. For nonzero β, there is a q-dependent *splitting* of the pair of degenerate eigenvalues $\lambda_{\pm n}(q)$, $n \neq 0$, which separates out odd and even solutions. Denoting the characteristic size of such a splitting by $\delta\lambda = \mathcal{O}(\beta)$, we impose the condition that $\delta\lambda \ll \Delta W$, where $\Delta W = \min\{W_n - W_m, m \neq \pm n\}$. This ensures that the perturbation does not excite states associated with other eigenvalues of the unperturbed problem. We can then restrict ourselves to calculating perturbative corrections to the degenerate eigenvalues $\lambda_{\pm n}$ and their associated eigenfunctions. Therefore, introduce the power series expansions

$$\lambda_{\pm n} = W_n + \beta\lambda^{(1)}_{\pm n} + \beta^2\lambda^{(2)}_{\pm n} + \cdots \tag{3.33}$$

and

$$U_{\pm n,m} = z_{\pm n}\delta_{m,\pm n} + \beta U^{(1)}_{\pm n,m} + \beta^2 U^{(2)}_{\pm n,m} + \cdots, \tag{3.34}$$

where $\delta_{n,m}$ is the Kronecker delta function. Here $U_{n,m}$ is the mth component of the vector $\mathbf{U}_n$ associated with the eigenvalue λ_n. Substitute these expansions into the matrix eigenvalue equation (3.28) and systematically solve the resulting hierarchy of

equations to successive orders in β using degenerate perturbation theory along similar lines to [3]. This leads to the following results:

(i) the even (+) and odd (−) eigenvalues to $\mathcal{O}(\beta^2)$ are

$$\lambda_{\pm n}(q) = W_n(q) + \beta\left[\widehat{W}_{nn}(q) \pm \widehat{W}_{n,-n}(q)\right] + \beta^2 \sum_{0\le m\neq n} \frac{\left[\widehat{W}_{nm}(q) \pm \widehat{W}_{-n,m}(q)\right]\left[\widehat{W}_{mn}(q) \pm \widehat{W}_{m,-n}(q)\right]}{W_n - W_m}; \tag{3.35}$$

(ii) the corresponding eigenfunctions to $\mathcal{O}(\beta)$ are

$$a_{n,\mathbf{k}}(\mathbf{r},\theta) = \left[\cos(n\theta) + \beta \sum_{0\le m\neq n} U_m^+(q)\cos(m\theta)\right] \mathrm{e}^{i\mathbf{k}\cdot\mathbf{r}}; \tag{3.36}$$

$$a_{-n,\mathbf{k}}(\mathbf{r},\theta) = \left[\sin(n\theta) + \beta \sum_{0<m\neq n} U_m^-(q)\sin(m\theta)\right] \mathrm{e}^{i\mathbf{k}\cdot\mathbf{r}} \tag{3.37}$$

with $|\mathbf{k}| = q$ and

$$U_0^+(q) = \frac{\widehat{W}_{0n}(q)}{W_n - W_0}, \quad U_m^\pm(q) = \frac{\widehat{W}_{mn}(q) \pm \widehat{W}_{m,-n}(q)}{W_n - W_m}, \quad 0 < m \neq n. \tag{3.38}$$

It is important to stress that the splitting of even and odd branches for $\beta > 0$ is a consequence of the underlying shift-twist symmetry and thus occurs beyond the small β regime.

3.3. Marginal stability. We now determine the marginal stability boundaries in parameter space that separate regions of stability from regions of instability. Crossing one of these boundaries signals that one or more eigenvalues become positive and their corresponding eigenfunctions start to grow, leading to the formation of a self-organizing pattern. (Conservation of population number implies that there always exists one neutrally stable mode $q = 0, n = 0$, that is, $\lambda_0(0) = 0$.) For concreteness, we treat the rescaled diffusion coefficients $D_1 \to D_1\overline{f}, D_2 \to D_2\overline{f}$ as bifurcation parameters. An adiabatic increase in the mean density $\overline{f}$ due to a growth in population number or a contraction in the area occupied by the population then corresponds to a reduction in D_1 and D_2. This reduction can lead to one of four distinct types of instability, depending on which eigenmodes are first excited:

(I) if $q \neq 0, n = 0$, then a spatially periodic pattern forms without any angular order (aggregation without orientation);

(II) if $q = 0, n \neq 0$, then a pattern with angular order forms that is spatially uniform (orientation without aggregation);

(IIIa,b) if $q \neq 0, n \neq 0$, then a pattern with spatio-angular order forms, in which the angle of preferred orientation changes periodically in space even though the spatial density remains homogeneous. The invariance of the interaction kernel under Euclidean shift-twist symmetry implies that when $\beta > 0$, there are two kinds of spatio-angular patterns, corresponding to (a) even and (b) odd eigenmodes, respectively. Examples of such eigenmodes are shown in Figure 3.1 under the simplifying assumption that a particular harmonic component n dominates. The crucial observation is that the direction of preferred orientation is correlated with the direction

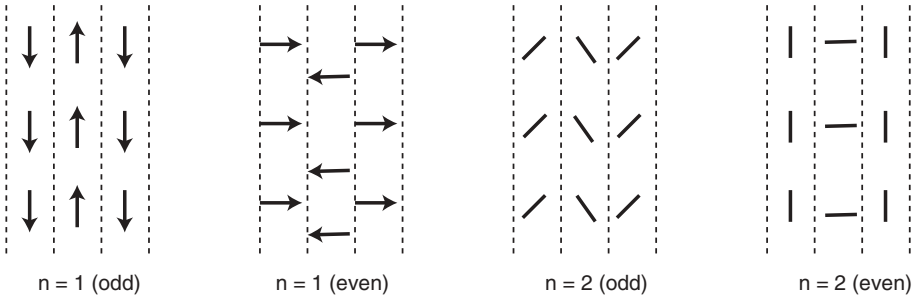

FIG. 3.1. *Examples of even ($a_{n,\mathbf{k}} = \cos(n\theta)e^{i\mathbf{k}\cdot\mathbf{r}} + c.c.$) and odd ($a_{n,\mathbf{k}} = \sin(n\theta)e^{i\mathbf{k}\cdot\mathbf{r}} + c.c.$) eigenmodes with spatio-angular order in the case of a horizontal wavevector $\mathbf{k} = (q, 0)$. If $n = 1$, then there is a unique direction of preferred orientation (indicated by an arrow). If $n = 2$, then there are two preferred directions of motion (indicated by a bar). The width of each vertical strip is π/q.*

of the wavevector $\mathbf{k}$, whereas there is no such correlation when $\beta = 0$ so that the distinction between odd and even solutions disappears.

3.3.1. Separable interaction kernel ($\beta = 0$). Before determining the effects of shift-twist symmetry on pattern forming instabilities of the homogeneous state, we first discuss the separable case previously analyzed by Mogilner and Edelstein-Keshet [18]. The eigenvalues for $\beta = 0$ are given by (3.31). In particular, when $n = 0$ we have (on setting $\overline{f} = 1$)

$$\lambda_0(q) = q^2\big(-D_2 + \eta_2 H_0 e^{-q^2/2}\big). \tag{3.39}$$

It is clear that $\lambda_0(q) < 0$ for all $q \neq 0$ if $D_2 > D_{2,0}$, where

$$D_{2,0} = \eta_2 H_0. \tag{3.40}$$

If $D_2 < D_{2,0}$, then the homogeneous state is unstable with respect to the excitation of eigenmodes over a range of wavenumbers that includes the origin so that $q \approx 0, n = 0$. Although this is a type I instability, the emerging pattern tends to involve long-wavelength spatial inhomogeneities. Therefore, the resulting stationary state could be treated as homogeneous on shorter spatial scales and thus be susceptible to secondary bifurcations associated with excitation of modes with $q \neq 0, n \neq 0$ (see below). Alternatively, the $n = 0$ modes could be stabilized by incorporating an additional contribution to the interaction kernel W in the form of a repulsive hard-core potential:

$$W(\mathbf{r}, \theta|\mathbf{r}', \theta') = G(\mathbf{r} - \mathbf{r}')H(\theta - \theta')\Delta(\arg(\mathbf{r} - \mathbf{r}') - \theta) - C\delta(\mathbf{r} - \mathbf{r}') \tag{3.41}$$

with $C > 0$. This modifies the $\beta = 0$ contribution to λ_0 according to

$$\lambda_0(q) = q^2\big(-D_2 + \eta_2 H_0 e^{-q^2/2} - H_0 C\big), \tag{3.42}$$

and the stability condition becomes $D_2 > D'_{2,0}$ with

$$D'_{2,0} = H_0(\eta_2 - C). \tag{3.43}$$

Now consider the branch of eigenmodes for a given n, $n \neq 0$, such that $H_n > 0$ (otherwise $\lambda_n(q) < 0$ for all q). Differentiating (3.31) with respect to q gives

$$\frac{d\lambda_n(q)}{dq} = q\left[-2D_2 + H_n\left(2\eta_2 - (\eta_1 n^2 + \eta_2 q^2)\right)\mathrm{e}^{-q^2/2}\right]. \tag{3.44}$$

This implies that $\lambda_n(q)$ has a maximum at $q = 0$ when $D_2 > D_{2,n}$ and a maximum at $q = q_c \neq 0$ when $D_2 < D_{2,n}$, where

$$D_{2,n} = H_n(\eta_2 - \eta_1 n^2/2). \tag{3.45}$$

Since

$$\lambda_n(0) = n^2[-D_1 + \eta_1 H_n], \tag{3.46}$$

it follows that $\lambda_n(q) < 0$ for all $n \neq 0$ when $D_2 > D_{2,n}$ and $D_1 > D_{1,n}$ with

$$D_{1,n} = \eta_1 H_n. \tag{3.47}$$

On the other hand, if $D_2 > D_{2,n}$ and $D_1 < D_{1,n}$, then there is a type II instability due to excitation of the eigenmode at $q = 0$. Finally, if $0 < D_2 < D_{2,n}$, then there is a type III instability due to excitation of the eigenmodes with wavenumber $q = q_c \neq 0$. This occurs at a critical value $D_1 = \mathcal{F}_n(D_2)$ with $\mathcal{F}_n$ a monotonically decreasing function such that $\mathcal{F}_n(D_{2,n}) = D_{1,n}$ and $\mathcal{F}_n(0) = D'_{1,n} > D_{1,n}$. Note that this last instability can occur only for integers n satisfying $n^2 < 2\eta_2/\eta_1$.

In order to determine the stability of the homogeneous state one now has to combine the stability conditions for all n. For concreteness, suppose the set of coefficients $\{H_n, n \neq 0\}$ has a maximum at $n = n_c$ such that $D_{j,n_c} > D_{j,n}$ for all $n \neq 0, n_c$. This leads to the stability diagram shown in Figure 3.2. In the absence of a repulsive contribution to the interaction kernel, the region of stability is given by the dark shaded region in Figure 3.2. Crossing the vertical boundary at $D_1 = D_{1,n_c}$ induces a type II instability, whereas crossing the horizontal boundary at $D_2 = D_{2,0}$ induces a type I instability. A type III instability can occur only through a secondary bifurcation. On the other hand, when there is a repulsive contribution to the potential, the stability region extends to include both the dark and light shaded regions. A type II instability now occurs on crossing the lower horizontal boundary at $D_2 = D'_{2,0}$, so that there is an additional curved boundary $D_1 = \mathcal{F}_{n_c}(D_2)$ for $D'_{2,0} < D_2 < D_{2,n_c}$. Crossing this boundary induces a type III instability, but there is no separation into even or odd patterns, since the separable interaction kernel is invariant under the standard Euclidean group action.

3.3.2. Nonseparable interaction kernel ($\beta > 0$). We now show that patterns with even or odd spatio-angular order can occur when $\beta > 0$. We take D_1 and D_2 to be close to the curved boundary of the stability region shown in Figure 3.2, where the unperturbed system undergoes a type III instability, and consider $\mathcal{O}(\beta)$ corrections to the eigenvalues $\lambda_{\pm n}(q)$ for $n = n_c$. Using (3.30) and (3.35) with $\Psi_0 = 0$, we find that $\lambda_{\pm n}(q) = -D_1 n^2 + \Lambda_{\pm n}(q) + \mathcal{O}(\beta^2)$, where

$$\Lambda_{\pm n}(q) = -D_2 q^2 + (\eta_1 n^2 + \eta_2 q^2) H_n\left[\mathrm{e}^{-q^2/2} \pm \beta \Psi_{2n} \widehat{G}_{2n}(q)\right]. \tag{3.48}$$

Suppose that $\Lambda_{\pm n}(q)$ has a unique maximum at $q = q_\pm \neq 0$. If $\Lambda_n(q_+) > \Lambda_{-n}(q_-)$, then the homogeneous state will become unstable at the critical point $D_1 = \Lambda_n(q_+)/n^2$

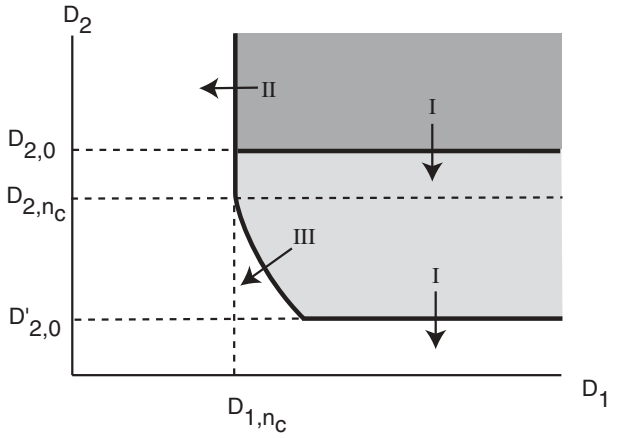

FIG. 3.2. *Stability diagram for the homogeneous state when $\beta = 0$. In the absence of a repulsive contribution to the interaction kernel, the region of stability is given by the dark shaded region. This extends to include the light shaded region when repulsion is included. The type of primary instability induced by crossing each boundary of the stability region is also indicated. (See text for details.)*

due to excitation of even eigenmodes with wavenumber q_+, whereas if $\Lambda_{-n}(q_-) > \Lambda_n(q_+)$, then the homogeneous state will become unstable at the critical point $D_1 = \Lambda_{-n}(q_-)/n^2$ due to excitation of odd eigenmodes with wavenumber q_-.

In order to determine whether an odd or even pattern arises, it is necessary to evaluate the function $\widehat{G}_{2n}(q)$ for the given Gaussian kernel (2.9). Rewriting (3.15) for even integers as

$$\widehat{G}_{2n}(q) = \int_0^\pi \mathrm{e}^{-2in\psi} \left[\int_0^\infty G(r) \cos(rq\cos\psi) r dr \right] d\psi$$

and using the Jacobi–Anger expansion

$$\cos(sq\cos\psi) = J_0(sq) + 2\sum_{m=1}^{\infty} (-1)^m J_{2m}(sq)\cos(2m\psi),$$

with $J_n(x)$ the Bessel function of integer order n, we find that $\widehat{G}_{2n}$ is related to G according to

$$\widehat{G}_{2n}(q) = (-1)^n \int_0^\infty G(r) J_{2n}(rq) r dr. \tag{3.49}$$

Substituting (2.9) into (3.49) and using standard properties of Bessel functions leads to the result

$$\widehat{G}_{2n}(q) = \frac{q\sigma\sqrt{2\pi}}{4} \mathrm{e}^{-\sigma^2 q^2/4} \left[I_{n-1/2}\left(\frac{\sigma^2 q^2}{4}\right) - I_{n+1/2}\left(\frac{\sigma^2 q^2}{4}\right) \right], \tag{3.50}$$

where I_ν is a modified Bessel function.

In Figure 3.3 we plot $\widehat{G}_{2n}(q)$ as a function of wavenumber q for $n = 0, 1, 2$. Note that $\widehat{G}_{2n}(q)$ alternates in sign with n, having a maximum for even n and a minimum for odd n. It follows that if $H_n \Psi_{2n} > 0$, then the homogeneous state destabilizes

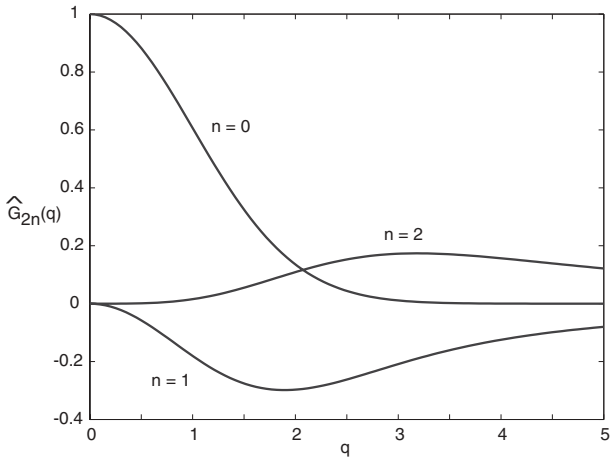

FIG. 3.3. *Plot of* $\widehat{G}_{2n}(q)$ *as a function of wavenumber* q *for* $n = 0, 1, 2$.

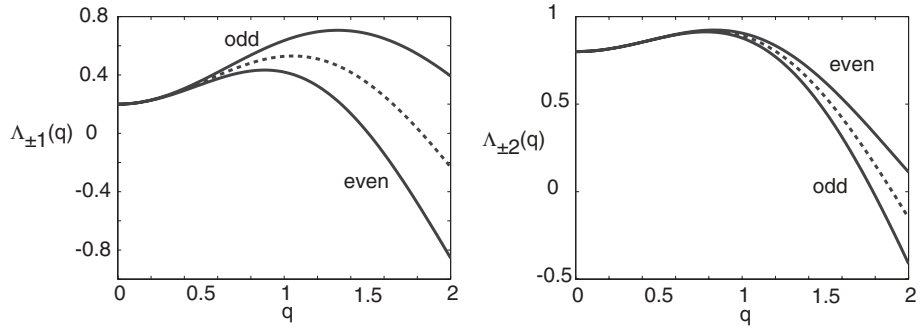

FIG. 3.4. *Plot of* $\Lambda_{\pm n}(q)$ *as a function of wavenumber* q *for* $n = 1, 2$. *Here* $D_2 = 0.2, \eta_1 = 0.3, \eta_2 = 1$, $H_n = 1$, *and* $\beta\Psi_{2n} = 0.5$. *The dashed curve represents the coalescence of the even and odd branches when* $\beta = 0$.

due to excitation of even (odd) eigenmodes when n is even (odd); the opposite result holds for $H_n\Psi_{2n} < 0$. Example dispersion curves $\Lambda_{\pm n}(q)$ are plotted in Figure 3.4 for $n = 1, 2$. Since $\max_q\{\Lambda_{-1}(q)\} > \max_q\{\Lambda_1(q), \Lambda_{\pm2}(q)/4\} > 0$ for the given parameter values, it follows that the critical eigenmodes are odd patterns with $n = 1$ (assuming $D_2 > D'_{2,0}$). Keeping the same parameters but setting $H_1 = 0$ would change the critical eigenmodes to even patterns with $n = 2$. For this particular example, the splitting of the even and odd modes around the critical point is small.

4. Doubly periodic patterns. Rotation symmetry implies that in the case of nonzero critical wavenumber q_c, the space of marginally stable eigenfunctions is infinite-dimensional, consisting of all solutions of the form $u(\theta - \varphi)e^{i\mathbf{k}_\varphi\cdot\mathbf{r}}$, where $u(\theta)$ is either an even or odd function of θ, $\mathbf{k}_\varphi = q_c(\cos\varphi, \sin\varphi)$, and $0 \le \varphi < 2\pi$. However, translation symmetry allows us to restrict the space of solutions of the original equation (2.7) to that of doubly periodic functions. This restriction is standard in many treatments of spontaneous pattern formation, but as yet it has no formal justification. However, there is a wealth of evidence from experiments on convecting fluids and chemical reaction-diffusion systems [23] indicating that such systems tend to generate

TABLE 4.1
Generators for the planar lattices and their dual lattices.

Lattice	$\boldsymbol{\ell}_1$	$\boldsymbol{\ell}_2$	$\hat{\boldsymbol{\ell}}_1$	$\hat{\boldsymbol{\ell}}_2$
Square	$(1,0)$	$(0,1)$	$(1,0)$	$(0,1)$
Hexagonal	$(1,\frac{1}{\sqrt{3}})$	$(0,\frac{2}{\sqrt{3}})$	$(1,0)$	$\frac{1}{2}(-1,\sqrt{3})$
Rhombic	$(1,-\cot\eta)$	$(0,\csc\eta)$	$(1,0)$	$(\cos\eta,\sin\eta)$

doubly periodic patterns in the plane when the homogeneous state is destabilized. Given such a restriction, the associated space of marginally stable eigenfunctions is finite-dimensional. A finite set of specific eigenfunctions can then be identified as candidate planforms, in the sense that they approximate time-independent solutions of (2.7) sufficiently close to the critical point where the homogeneous state loses stability.

Let $\mathcal{L}$ be a planar lattice; that is, choose two linearly independent vectors $\boldsymbol{\ell}_1$ and $\boldsymbol{\ell}_2$ and let

$$\mathcal{L} = \{2\pi d(m_1\boldsymbol{\ell}_1 + m_2\boldsymbol{\ell}_2) : m_1, m_2 \in \mathbf{Z}\},$$

where d is the lattice spacing. Note that $\mathcal{L}$ is a subgroup of the group of planar translations. A function $f : \mathbf{R}^2 \times \mathbf{S}^1 \to \mathbf{R}$ is *doubly periodic with respect to* $\mathcal{L}$ if

$$f(\mathbf{r}+\boldsymbol{\ell},\theta) = f(\mathbf{r},\theta)$$

for every $\boldsymbol{\ell} \in \mathcal{L}$. Let θ be the angle between the two basis vectors $\boldsymbol{\ell}_1$ and $\boldsymbol{\ell}_2$. We can then distinguish three types of lattice according to the value of θ: square ($\theta = \pi/2$), rhombic ($0 < \theta < \pi/2$, $\theta \neq \pi/3$), and hexagonal ($\theta = \pi/3$). After rotation, the generators of the planar lattices are given in Table 4.1 (for unit lattice spacing). Also shown are the generators of the dual lattice

$$\hat{\mathcal{L}} = \{d^{-1}(m_1\hat{\boldsymbol{\ell}}_1 + m_2\hat{\boldsymbol{\ell}}_2) : m_1, m_2 \in \mathbf{Z}\}$$

with $\boldsymbol{\ell}_i \cdot \hat{\boldsymbol{\ell}}_j = \delta_{i,j}$. Restriction to double periodicity means that the original Euclidean symmetry group is now restricted to the symmetry group of the lattice, $\Gamma = H_{\mathcal{L}} \dot{+} \mathbf{T}^2$, where $H_{\mathcal{L}}$ is the *holohedry* of the lattice, the subgroup of $\mathbf{O}(2)$ that preserves the lattice, and $\mathbf{T}^2$ is the two torus of planar translations modulo the lattice. Thus, the holohedry of the rhombic lattice is $\mathbf{D}_2$, the holohedry of the square lattice is $\mathbf{D}_4$, and the holohedry of the hexagonal lattice is $\mathbf{D}_6$.

Imposing double periodicity on the marginally stable eigenfunctions means restricting the lattice spacing d so that the critical wavevector $\mathbf{k}$ lies on the dual lattice. There are infinitely many choices for the lattice size that satisfy this constraint—we select the one for which q_c is the shortest length of a dual wavevector, that is, $q_c = d^{-1}$. Linear combinations of eigenfunctions that generate doubly periodic solutions corresponding to dual wavevectors of shortest length are given by

$$a(\mathbf{r},\theta) = \sum_{j=1}^{N} z_j u(\theta - \varphi_j) \mathrm{e}^{i\mathbf{k}_j\cdot\mathbf{r}} + \text{c.c.}, \tag{4.1}$$

where the z_j are complex amplitudes. Here $N = 2$ for the square lattice with $\mathbf{k}_1 = \mathbf{k}_c$ and $\mathbf{k}_2 = R_{\pi/2}\mathbf{k}_c$, where R_ξ denotes rotation through an angle ξ. Similarly, $N = 3$ for the hexagonal lattice with $\mathbf{k}_1 = \mathbf{k}_c$, $\mathbf{k}_2 = R_{2\pi/3}\mathbf{k}_c$, and $\mathbf{k}_3 = R_{4\pi/3}\mathbf{k}_c = -\mathbf{k}_1 - \mathbf{k}_2$. It follows that the space of marginally stable eigenfunctions can be identified with

the N-dimensional complex vector space spanned by the vectors $(z_1, \dots, z_N) \in \mathbf{C}^N$, with $N = 2$ for square or rhombic lattices and $N = 3$ for hexagonal lattices. It can be shown that these form Γ-irreducible representations. The actions of the group Γ on $\mathbf{C}^N$ can then be explicitly written down for both the odd and even cases [3, 4]. For example, on a hexagonal lattice, a translation $(\mathbf{r}, \theta) \to (\mathbf{r} + \mathbf{s}, \theta)$ induces the action

$$\gamma \circ (z_1, z_2, z_3) = (z_1 \mathrm{e}^{-i\xi_1}, z_2 \mathrm{e}^{-i\xi_2}, z_3 \mathrm{e}^{i(\xi_1+\xi_2)}), \tag{4.2}$$

where $\xi_j = \mathbf{k}_j \cdot \mathbf{s}$, a rotation $(\mathbf{r}, \theta) \to (R_{2\pi/3}\mathbf{r}, \theta + 2\pi/3)$ induces the action

$$\gamma \circ (z_1, z_2, z_3) = (z_3, z_1, z_2), \tag{4.3}$$

and a reflection κ across the x-axis (assuming $\mathbf{k}_c = q_c(1, 0)$) induces the action

$$\gamma \circ (z_1, z_2, z_3) = (z_1, z_3, z_2). \tag{4.4}$$

The next important observation is that, using weakly nonlinear analysis and perturbation methods, it is possible to reduce the infinite-dimensional system (2.7) to a finite set of coupled ODEs constituting an amplitude equation for $\mathbf{z}$,

$$\frac{dz_j}{dt} = F_j(\mathbf{z}), \quad j = 1, \dots, N, \tag{4.5}$$

which is equivariant with respect to the induced shift-twist action of the group Γ on $\mathbf{C}^N$. One can now use techniques from symmetric bifurcation theory to determine the equilibrium solutions that are likely to bifurcate from the homogeneous fixed point $\mathbf{z} = 0$. This analysis has been carried out elsewhere within the context of a continuum model of visual cortex [3, 4]. Since the population model (2.7) has the same Euclidean shift-twist symmetry as the cortical model, it has the same restrictions regarding the types of bifurcations from a homogeneous state that can occur. However, which particular bifurcation scenario is realized in practice may differ in the two models. That is, although symmetry considerations restrict the form of the nonlinear functions F_j appearing in the amplitude equation (4.5) [3, 4], the values of the coefficients multiplying terms at a particular order in z_j will be model-dependent. Determining these coefficients would require carrying out an explicit perturbation calculation. Here we focus on general aspects of the bifurcating solutions that can be deduced from symmetry principles. For completeness we briefly review a few basic definitions and results from equivariant bifurcation theory [13].

Isotropy subgroups. The symmetries of any particular equilibrium solution $\mathbf{z}$ form a subgroup called the *isotropy* subgroup of $\mathbf{z}$ defined by

$$\Sigma_{\mathbf{z}} = \{\sigma \in \Gamma : \ \sigma\mathbf{z} = \mathbf{z}\}. \tag{4.6}$$

More generally, we say that Σ is an isotropy subgroup of Γ if $\Sigma = \Sigma_{\mathbf{z}}$ for some $\mathbf{z} \in V$. Isotropy subgroups are defined up to some conjugacy. A group Σ is conjugate to a group $\widehat{\Sigma}$ if there exists $\sigma \in \Gamma$ such that $\widehat{\Sigma} = \sigma^{-1}\Sigma\sigma$. The *fixed-point subspace* of an isotropy subgroup Σ, denoted by $\mathrm{Fix}(\Sigma)$, is the set of points $\mathbf{z} \in V$ that are invariant under the action of Σ,

$$\mathrm{Fix}(\Sigma) = \{\mathbf{z} \in V : \ \sigma\mathbf{z} = \mathbf{z} \ \forall \ \sigma \in \Sigma\}. \tag{4.7}$$

Finally, the *group orbit* through a point $\mathbf{z}$ is

$$\Gamma\mathbf{z} = \{\sigma\mathbf{z} : \ \sigma \in \Gamma\}. \tag{4.8}$$

TABLE 4.2

Even planforms with $u(-\theta) = u(\theta)$. The hexagon solutions (0) and (π) have the same isotropy subgroup, but they are not conjugate solutions.

Lattice	Name	Planform eigenfunction
Square	Even square	$u(\theta)\cos x + u\left(\theta - \frac{\pi}{2}\right)\cos y$
	Even roll	$u(\theta)\cos x$
Rhombic	Even rhombic	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r}) + u(\theta-\eta)\cos(\mathbf{k}_2\cdot\mathbf{r})$
	Even roll	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r})$
Hexagonal	Even hexagon (0)	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r}) + u\left(\theta+\frac{\pi}{3}\right)\cos(\mathbf{k}_2\cdot\mathbf{r}) + u\left(\theta-\frac{\pi}{3}\right)\cos(\mathbf{k}_3\cdot\mathbf{r})$
	Even hexagon (π)	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r}) + u\left(\theta+\frac{\pi}{3}\right)\cos(\mathbf{k}_2\cdot\mathbf{r}) - u\left(\theta-\frac{\pi}{3}\right)\cos(\mathbf{k}_3\cdot\mathbf{r})$
	Even roll	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r})$

If $\mathbf{z}$ is an equilibrium solution of (4.5), then so are all other points of the group orbit (by equivariance). One can now adopt a strategy that restricts the search for solutions of (4.5) to those that are fixed points of a particular isotropy subgroup. In general, if a dynamical system is equivariant under some symmetry group Γ and has a solution that is a fixed point of the full symmetry group, then we expect a loss of stability to occur upon variation of one or more system parameters. Typically such a loss of stability will be associated with the occurrence of new solution branches with isotropy subgroups Σ smaller than Γ. One says that the solution has spontaneously broken symmetry from Γ to Σ. Instead of a unique solution with the full set of symmetries Γ, a set of symmetrically related solutions (orbits under Γ modulo Σ) each with symmetry group (conjugate to) Σ is observed.

Equivariant branching lemma (see [13]). The system of equations (4.5) has a fixed point $z = 0$ of the full symmetry group Γ. The equivariant branching lemma states that generically there exists a (unique) equilibrium solution bifurcating from the fixed point for each of the axial subgroups of Γ under the given group action—a subgroup $\Sigma \subset \Gamma$ is *axial* if $\dim \mathrm{Fix}(\Sigma) = 1$. The heuristic idea underlying this lemma is as follows. Let Σ be an axial subgroup and $\mathbf{z} \in \mathrm{Fix}(\Sigma)$. Equivariance of F then implies that

$$\sigma F(\mathbf{z}) = F(\sigma\mathbf{z}) = F(\mathbf{z}) \tag{4.9}$$

for all $\sigma \in \Sigma$. Thus $F(\mathbf{z}) \in \mathrm{Fix}(\Sigma)$ and the system of coupled ODEs (4.5) can be reduced to a single equation in the fixed-point space of Σ. Thus one can systematically identify the various expected primary bifurcation branches by constructing the associated axial subgroups and finding their fixed points. The calculation of these subgroups has been carried out elsewhere [3, 4], and the resulting even and odd planforms are listed in Tables 4.2 and 4.3.

One way to represent the planforms graphically is to indicate the direction(s) of preferred orientation at each point in space $\mathbf{r}$, that is, the orientations that maximize the state $a(\mathbf{r}, \theta)$ for fixed $\mathbf{r}$. This has been carried out elsewhere in the case of cortical patterns, where the preferred orientation corresponds to the orientation of a local visual stimulus that elicits the maximum response of a neuron at a particular location in the cortex [3, 4]. From a mathematical rather than a physical viewpoint, the only difference between the cortical patterns and those of the population model is that in the former case the functions $u(\theta)$ are always restricted to be π-periodic, and hence, the resulting spatio-angular patterns are line fields. As a simple example, consider a square lattice with $u(\theta) = \cos 2\theta$ or $u(\theta) = \sin 2\theta$ and $\mathbf{k}_c = 2\pi(1, 0)$. The

TABLE 4.3
Odd planforms with $u(-\theta) = -u(\theta)$.

Lattice	Name	Planform eigenfunction
Square	Odd square	$u(\theta)\cos x - u\left(\theta - \frac{\pi}{2}\right)\cos y$
	Odd roll	$u(\theta)\cos x$
Rhombic	Odd rhombic	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r}) + u(\theta-\eta)\cos(\mathbf{k}_2\cdot\mathbf{r})$
	Odd Roll	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r})$
Hexagonal	Odd hexagon	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r}) + u\left(\theta+\frac{\pi}{3}\right)\cos(\mathbf{k}_2\cdot\mathbf{r}) + u\left(\theta-\frac{\pi}{3}\right)\cos(\mathbf{k}_3\cdot\mathbf{r})$
	Triangle	$u(\theta)\sin(\mathbf{k}_1\cdot\mathbf{r}) + u\left(\theta+\frac{\pi}{3}\right)\sin(\mathbf{k}_2\cdot\mathbf{r}) + u\left(\theta-\frac{\pi}{3}\right)\sin(\mathbf{k}_3\cdot\mathbf{r})$
	Patchwork quilt	$u\left(\theta+\frac{\pi}{3}\right)\cos(\mathbf{k}_2\cdot\mathbf{r}) - u\left(\theta-\frac{\pi}{3}\right)\cos(\mathbf{k}_3\cdot\mathbf{r})$
	Odd roll	$u(\theta)\cos(\mathbf{k}_1\cdot\mathbf{r})$

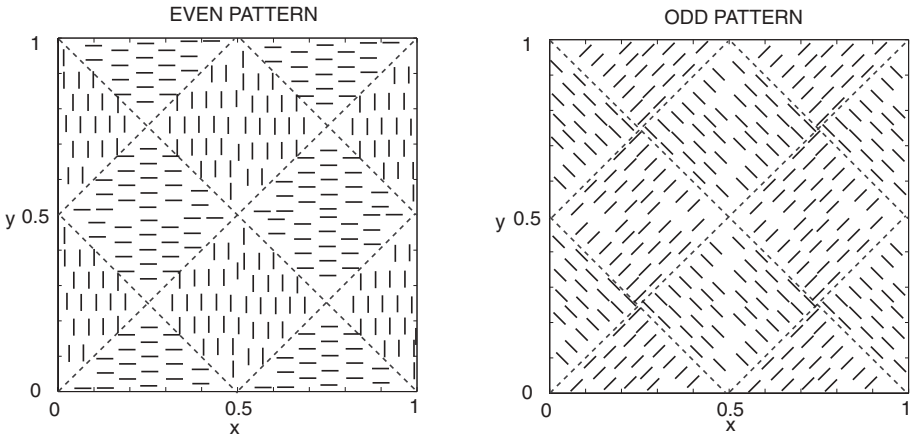

FIG. 4.1. *Line fields for even patterns ($u(\theta) = \cos 2\theta$) and odd patterns ($u(\theta) = \sin 2\theta$) in a fundamental domain of a square lattice. The domain is divided up into subregions where the preferred orientation (*mod π*) is uniform. The direction of orientation within each subregion is indicated by the small parallel bars, which could be interpreted as aligned objects at discretely sampled points within the subregion. Dashed lines indicate line singularities separating regions of different orientation.*

corresponding even and odd planforms (modulo an arbitrary translation) are

$$\begin{aligned} a_+(\mathbf{r},\theta) &= \cos 2\theta(\sin 2\pi x - \sin 2\pi y), \\ a_-(\mathbf{r},\theta) &= \sin 2\theta(\sin 2\pi x - \sin 2\pi y). \end{aligned} \tag{4.10}$$

In the case of the even eigenmode $a_+(\mathbf{r},\theta)$, the preferred orientation (mod π) at (x,y) is $\theta = 0$ when $\sin 2\pi x > \sin 2\pi y$ and $\theta = \pi/2$ when $\sin 2\pi x < \sin 2\pi y$. The corresponding preferred orientations of the odd eigenmode $a_-(\mathbf{r},\theta)$ are $\theta = \pi/4, 3\pi/4$. Note that line singularities occur for $\sin 2\pi x = \sin 2\pi y$, across which there are jumps in orientation preference. The resulting even and odd line fields are shown in Figure 4.1. Inclusion of higher harmonic contributions to the function $u(\theta)$ can lead to point rather than line singularities as well as sites containing more than one preferred orientation [4]. If there is no distinction between "head" and "tail," then solutions of the population model (2.7) will also be π-periodic. On the other hand, if there is such a distinction, then generically the resulting patterns will be represented by vector fields rather than line fields. In the case of a square lattice with $u(\theta) = \cos\theta$ or $u(\theta) = \sin\theta$ and $\mathbf{k}_c = 2\pi(1,0)$, the corresponding even and odd planforms (modulo

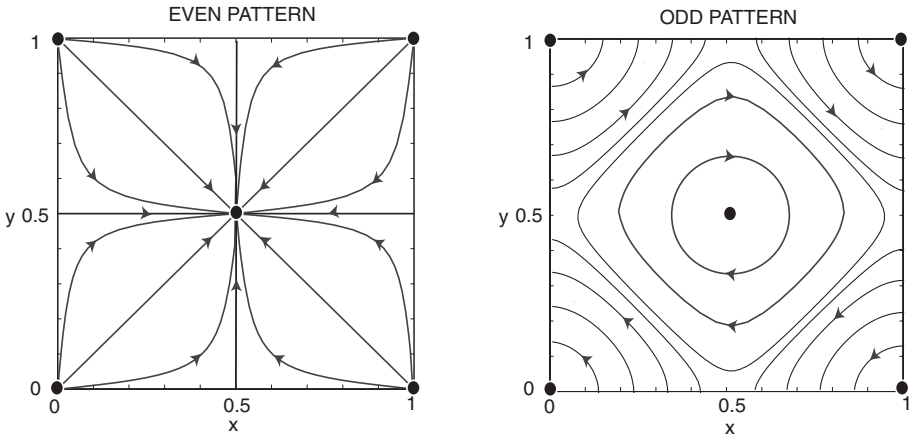

FIG. 4.2. *Vector fields for even patterns ($u(\theta) = \cos\theta$) and odd patterns ($u(\theta) = \sin\theta$) in a fundamental domain of a square lattice. The preferred orientation at a given point in the plane is given by the direction tangential to the flow line passing through that point. There is no preferred orientation at the singularities (indicated by filled circles).*

an arbitrary translation) are

$$\begin{aligned} a_+(\mathbf{r},\theta) &= \cos\theta \sin 2\pi x + \sin\theta \sin 2\pi y = A(\mathbf{r})\cos[\theta - \theta_+(\mathbf{r})], \\ a_-(\mathbf{r},\theta) &= \sin\theta \sin 2\pi x - \cos\theta \sin 2\pi y = A(\mathbf{r})\cos[\theta - \theta_-(\mathbf{r})], \end{aligned} \tag{4.11}$$

with $A(\mathbf{r}) = \sqrt{\sin^2 2\pi x + \sin^2 2\pi y}$ and

$$\theta_+(\mathbf{r}) = \tan^{-1}\frac{\sin 2\pi y}{\sin 2\pi x}, \quad \theta_-(\mathbf{r}) = \tan^{-1}\frac{-\sin 2\pi x}{\sin 2\pi y}. \tag{4.12}$$

It follows that the preferred orientation at position $\mathbf{r}$ is $\theta(\mathbf{r})$, provided that $A(\mathbf{r}) \neq 0$; otherwise there is no preferred orientation. Another way to state this is that the preferred orientation is determined by the flow lines of the vector fields,

$$\mathbf{V}_+ = \sin 2\pi x \frac{\partial}{\partial x} + \sin 2\pi y \frac{\partial}{\partial y}, \quad \mathbf{V}_- = -\sin 2\pi y \frac{\partial}{\partial x} + \sin 2\pi x \frac{\partial}{\partial y}, \tag{4.13}$$

except at the singularities $x = m\pi, y = m'\pi$ for integers m, m'. The resulting vector fields are shown in Figure 4.2. Note that if higher harmonics are included in the function $u(\theta)$, then it is possible for the flow lines to intersect, indicating that there can be more than one preferred orientation away from singularities.

5. Discussion. In this paper we have shown that a wide class of self-organizing biological systems have interactions that are invariant with respect to the shift-twist action of the Euclidean group, and that this has major implications for the types of patterns that can arise in these systems. Our main prediction is that patterns with spatio-angular order should exhibit correlations between the directions of preferred orientation and the underlying spatial orientation of the pattern (as determined by the wavevectors of the excited eigenmodes), and that there are two distinct types of correlation corresponding to scalar and pseudoscalar representations of the Euclidean group. In other words, given a spatially periodic variation in preferred orientation,

there is a correlation between the preferred orientation within a patch and the orientation of the boundaries of that patch. Whether or not such correlations are actually observed in real systems remains to be seen, although the line fields shown in Figure 4.1 are very suggestive of certain arrangements of fibroblasts where the cells appear to be oriented at approximately 45° to line singularities [18].

One of the simplifying assumptions in our analysis has been to restrict the spatial domain to be two-dimensional. This is appropriate for cells grown in vitro on a flat surface and for animal herds. On the other hand, cells in vivo and fish schools or bird flocks [20] are better described by a three-dimensional domain. In the three-dimensional case, the orientation of an individual is specified by points on a sphere (ϕ, θ) with $\phi \in [0, \pi]$ and $\theta \in [0, 2\pi)$. This suggests that the underlying symmetry group is $\mathbf{E}(3) \times \mathbf{O}(3)$ when the corresponding interaction kernel is separable with respect to spatial and angular coordinates. An interesting problem that follows from this is to determine the appropriate three-dimensional analogue of Euclidean shift-twist symmetry when the kernel is taken to be nonseparable. Another factor that would modify the symmetry group is the presence of an environmental gradient that biases the selection of a direction with which to align. Examples include migrating birds using the earth's magnetic field as a directional cue and fibroblasts aligning strongly with grooves on an artificial substrate.

BAYESIAN VIDEO DEJITTERING BY THE BV IMAGE MODEL*

JIANHONG SHEN†

Dedicated to all pioneering mathematicians in image and vision analysis, on whose shoulders we the younger generations are standing

Abstract. Line jittering, or random horizontal displacement in video images, occurs when the synchronization signals are corrupted in video storage media, or by electromagnetic interference in wireless video transmission. The goal of intrinsic video dejittering is to recover the ideal video directly from the observed jittered and often noisy frames. The existing approaches in the literature are mostly based on local or semilocal filtering techniques and autoregressive image models and are complemented by various image processing tools. In this paper, based on the statistical rationale of Bayesian inference, we propose the first variational dejittering model based on the bounded variation (BV) image model, which is global, clean and self-contained, and intrinsically combines dejittering with denoising. The mathematical properties of the model are studied based on the direct method of calculus of variations. We design one effective algorithm and present its computational implementation based on techniques from numerical partial differential equations (PDEs) and nonlinear optimizations.

1. Introduction.

The best way to describe video jittering is to quote from the recent remarkable monograph by Kokaram on motion picture restoration [20]:

> Video signals must contain synchronization information to allow the video display to properly locate lines and frames relative to each other in space and time. Noise in the video signal, or degradation of the storage medium on which the signal is stored (video tape) can cause the synchronization signals to be corrupted. This can cause the loss of "lock" in video digitizing and playback apparatus. The loss of line synchronization pulses will prevent the video manipulation device from locating the actual start and end of each line thus yielding random line displacements (line jitter) in the observed video images.

Figure 1.1 displays a typical jittered video frame, in which horizontal image lines are randomly shuffled. In the current paper, we will not consider interframe correlation and jittering. Therefore the dejittering problem, i.e., to recover the original ideal image frame u from the observed jittered (and often noisy due to medium corruption) image frame u_0, is fundamentally a still image restoration problem.

For real analog videos, it is possible to recover the line synchronization information by cleaning the nonpicture parts of the video signals. This is the method of *time base correctors* [20]. It demands the availability of signal information that has nothing to do with the video or image content.

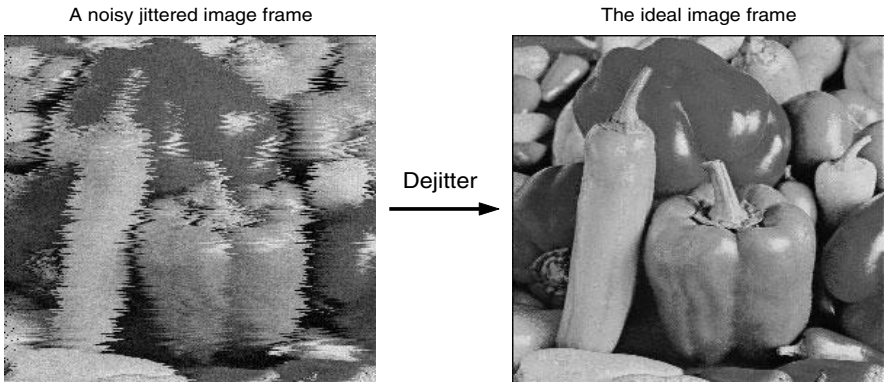

FIG. 1.1. *A noisy jittered image frame and the goal of dejittering.*

The idea of *intrinsic* video dejittering [21, 22], on the other hand, is to restore the ideal image frames directly from the observed jittered data. That is, as in the classical denoising or deblurring problems, one attempts to recover the ideal images solely based on intrinsic image structures (i.e., image prior models).

Thus in comparison, the intrinsic approach is more flexible and is applicable in more general settings. For instance, due to electromagnetic interference in the environment (especially intentional interference, as in battle fields), wireless image signals can experience very similar jittering problems, completely or partially. It is impossible to reconstruct the random and dynamic process of environmental interference, but it is still feasible to recover the original images based on their intrinsic structures.

In the pioneering works by Kokaram and colleagues [21, 22], intrinsic dejittering models are developed based on autoregressive image models, line registration, image interpolation, parameter estimation, and the filtering technique. The goal of the current paper is to address the dejittering problem with the help of calculus of variations and partial differential equations (PDEs), two novel modern tools in mathematical image and vision analysis (Miva).

Our main contributions are highlighted as follows.

(a) Treating dejittering as an image restoration problem, we propose the first variational dejittering model in the literature. The rationale of this deterministic model is the general statistical framework of Bayesian inference.
(b) The model is clean and self-contained, meaning that no other pre- or postprocessing steps are needed. Furthermore, it intrinsically combines the two processes of denoising and dejittering.
(c) We propose to apply the BV (bounded variation) image prior model for faithfully recovering the regularity of the jittered boundaries of image objects. The BV image model was first applied by Rudin and Osher [26] and Rudin, Osher, and Fatemi [27] for image denoising and deblurring. The most beautiful attribute of the BV image model is that it takes care of object boundaries automatically, without the pain of separating them from the *interior* homogeneous regions, which considerably eases the burden of both theory and computation.
(d) By applying the direct method of calculus of variations, we attempt to reveal some important mathematical properties of the proposed dejittering model, including uniqueness, existence, and convergence.

(e) For the nonlinear and nonconvex objective of our model, we design an iterative algorithm which alternately optimizes the image estimation and jittering estimation. This algorithm is then numerically implemented by techniques from computational PDEs and nonlinear optimization.

The organization of the paper is as follows. The statistical assumptions on the jittering and intensity noisy models are stated in section 2. In section 3, the proposed BV-based dejittering model is developed from the Bayesian rationale in decision and inference theory. In section 4, we study the associated admissible conditions and some fundamental properties of the model. The algorithm and its computational implementation are detailed in section 5, and are followed by three typical numerical examples. Section 6 concludes the paper with a brief summary.

2. The statistical jittering model. We begin with some necessary statistical assumptions or models for the line jittering process. For convenience, the image domain is assumed to be a horizontal stripe: $\Omega = \mathbb{R} \times (0, H)$, in which each point (x, y) is called a pixel.

Let $s = s(y)$ be a Gaussian homogeneous white noise on $y \in (0, H)$. That is, there exists no correlation between the jitters of two distinct horizontal lines:

$$\mathbf{E}[s(y_1)s(y_2)] = \sigma_s^2 \delta_{y_1, y_2},$$

where $\delta_{y_1,y_2} = 1$ if $y_1 = y_2$ and 0 otherwise, and σ_s^2 denotes the shared jittering variance. We shall always assume that $s(y)$ has zero mean.

The model of an infinitely long stripe domain Ω is then theoretically consistent with the assumption of Gaussian jitters, since the latter can be any real numbers.

Now suppose $u(x, y), (x, y) \in \Omega$ is the original ideal image to be displayed or transmitted. The horizontal line jittering process is modeled by $u \to u_s$:

$$u_s(x, y) = u(x + s(y), y), \quad (x, y) \in \Omega.$$

Thus generally u_s becomes a random field on Ω. In practice, due to electromagnetic or medium noise, the jittered image u_s is further polluted in terms of grey levels to u_0:

$$u_0(x, y) = u_s(x, y) + n(x, y), \quad (x, y) \in \Omega.$$

Here n denotes Gaussian homogenous white noise with mean 0 and variance σ_n^2, and has been assumed additive.

It shall be further assumed that the jittering s and intensity noise n are independent, since their physical causes are often uncorrelated in applications.

The dejittering problem can then be stated as follows. Suppose only one *single* observation u_0 is made. Find a suitable way to restore the original image u (to certain commercially acceptable standards, say).

This naturally falls into the scope of Bayesian inference: decision making or feature (in our case u) extraction based on observed data. Thus the spirit of our approach is tightly rooted in the Bayesian restoration framework.

3. Bayesian dejittering for BV images. The goal of dejittering is to estimate both the original ideal image u and the particular jitter s involved in the given single observation u_0. In the Bayesian framework, we are to maximize the posterior probability

$$p(u, s \mid u_0) = \frac{p(u_0 \mid u, s)p(u, s)}{p(u_0)}.$$

Jittering is caused by the corruption of the synchronizing signatures and is therefore independent of the image u, which leads to $p(u,s) = p(u)p(s)$. In addition, once the observation u_0 is given, $p(u_0)$ is simply a normalization constant and has no influence in terms of probability maximization. Taking either the logarithmic likelihood function, or formally in terms of statistical mechanics, the Gibbs' ensemble energy $E[\cdot] = -\frac{1}{\beta}\ln p(\cdot)$ (β denoting the reciprocal of the absolute temperature), we are to minimize the posterior "energy"

$$E[u,s \mid u_0] = E[u_0 \mid u,s] + E[s] + E[u].$$

The equality holds up to an additive "grounding" energy level. Throughout this paper, the notation $E[A|B]$ always denotes a functional of A, which depends on the *given* B as well. Both A and B can contain multiple components.

The *data model* $E[u_0 \mid u,s]$ easily follows from the Gaussian assumption:

$$u_0 = u_s + n = u(x + s(y), y) + n(x,y).$$

That is,

$$E[u_0 \mid u,s] = \lim_{R\to\infty} \frac{1}{2\sigma_n^2|\Omega_R|}\int_{\Omega_R}(u_0 - u_s)^2 dxdy, \tag{3.1}$$

where $\Omega_R = (-R,R)\times(0,H)$, and $|\Omega_R| = 2RH$ denotes its Lebesgue measure.

We have two priors: the line jittering model $E[s]$ and the image model $E[u]$. Since the former has been assumed Gaussian, we must have

$$E[s] = \frac{1}{2\sigma_s^2 H}\int_0^H s^2(y)dy. \tag{3.2}$$

Therefore, the key to the Bayesian dejittering approach is to adopt an appropriate image prior $E[u]$.

Identification of effective image priors is probably the most fundamental problem in the entire field of Miva. See, for example, the author's recent expository article in *SIAM News*, in which this viewpoint was explicitly expressed and emphasized [28]. There are a number of valuable image priors in the literature, which can be coarsely classified into two categories: stochastic and deterministic (see, e.g., the recent survey paper by Chan, Shen, and Vese [10]).

Stochastic image priors are typically based on either the lattice model and Gibbs' fields in statistical mechanics (Geman and Geman [14]), or statistical learning via techniques like multiscale filtering and the maximum entropy principle (Zhu and Mumford [32] and Zhu, Wu, and Mumford [33]).

Deterministic image priors emphasize more the property of regularities, in contrast to the focus on various spectral or multiscale statistical features in stochastic priors. Well-known examples include (a) the Sobolev image model $E_2[u] = \alpha\int_\Omega |\nabla u|^2 dxdy < \infty$ in the classical linear filtering theory; (b) the BV [15] model $E_{\rm tv}[u] = \alpha\int_\Omega |Du| < \infty$, first introduced to image restoration by Rudin, Osher, and Fatemi [27]; and (c) the Mumford–Shah [25] object-edge free boundary model

$$E_{\rm ms}[u,\Gamma] = E[u|\Gamma] + E[\Gamma] = \alpha\int_{\Omega\setminus\Gamma}|\nabla u|^2 dxdy + \beta\mathcal{H}^1(\Gamma) < \infty,$$

where Γ denotes the jump set or the collection of "edges," $\mathcal{H}^1$ the one-dimensional Hausdorff measure, and α and β two tunable weights. Recently, motivated by the image inpainting problem, we have also investigated high order geometric image models

such as the elastica model (Chan, Kang, and Shen [5]) and the Mumford–Shah–Euler image model (Esedoglu and Shen [13]), where high order geometric information such as the mean curvature is also taken into account.

In the current paper, we choose to work with the Rudin–Osher–Fatemi BV image model

$$E_{\mathrm{tv}}[u] = \alpha \int_{\Omega} |Du| < 0. \tag{3.3}$$

Notice that here $|Du|$ denotes the Radon measure of a BV function [15]. For the more restricted Sobolev $W^{1,1}$ images, $E_{\mathrm{tv}}[u]$ is simply the ordinary L^1 norm of ∇u. Numerous applications have demonstrated that the BV image model is well balanced in terms of fidelity in approximating generic images (especially those mainly containing man-made objects), theoretical tractability, and computational complexity [1, 3, 4, 6, 7, 8, 11, 18, 26, 27, 29]. Such advantages can also be witnessed in the rest of the paper. We refer to our most recent survey paper [9] for a concise overview of the role of the BV image model in Miva.

It is worth pointing out that *digitally* the BV image model can be approximately realized by certain adaptive (and thus nonlinear) autoregressive (AR) models (see, e.g., [2, 6, 20]). However, in the continuum limit, the rich mathematical theory of BV functions provides an independent, clean, and rigorous framework in both theory and computation [15, 4, 9].

The combination of the three models (3.1), (3.2), (3.3) leads to the complete Bayesian posterior "energy" to be minimized:

$$E[u, s \mid u_0] = \lim_{R\to\infty} \frac{\lambda_R}{2} \int_{\Omega_R} (u_0 - u_s)^2 dxdy + \frac{\mu}{2} \int_0^H s^2(y)dy + \alpha \int_{\Omega} |Du|, \tag{3.4}$$

where $\lambda_R = 1/(\sigma_n^2|\Omega_R|)$ and $\mu = 1/(\sigma_s^2 H)$. Notice that the total variation weight α is the only tunable parameter. The impossibility of having a universally working α is closely connected to the undefinability of a scale-invariant probability measure over "all" images (see the extraordinary recent work by Mumford and Gidas [24]).

The rest of the paper focuses on the properties and computation of this Bayesian dejittering model. In what follows, we first argue that model (3.4) has to be modified for allowing nontrivial solutions.

4. Properties of the model. So far the dejittering model (3.4) has been purely inspired by the statistical jittering model and the Gibbs' energy rationale. In this section, we (a) first rigorously define its admissible space, (b) then argue that model (3.4) has to be modified to yield meaningful solutions, and finally (c) study some important properties of the modified model.

4.1. Admissible conditions and correcting model (3.4). From the squared integration term in (3.4) defining the jittering variance s, it is necessary that $s = s(y) \in L^2(0, H)$.

The BV prior naturally requires that $u \in \mathrm{BV}(\Omega)$. By the Sobolev embedding theorem [15] (and its extension to the BV space), $\mathrm{BV}(\Omega)$ is embedded in $L^2(\Omega)$, implying that $\int_\Omega u^2(x, y)dxdy < \infty$.

For any $s \in L^2(0, H)$, define the jittering transform $T_s : \Omega \to \Omega$ by

$$T_s : (x, y) \to (x + s(y), y). \tag{4.1}$$

Then $T_s^{-1} = T_{-s}$. We now show that T_s is a Lebesgue isomorphism. Let $E \subset \Omega$ be any measurable set, and $|E|$ its Lebesgue measure. Denote the characteristic function or indicator of E by $1_E(x, y)$. Then it is easy to see that

$$1_{T_s E}(x, y) = 1_E \circ T_{-s}(x, y).$$

By Fubini's theorem,

$$\begin{aligned} |T_s E| &= \int_\Omega 1_E \circ T_{-s}(x, y)dxdy = \int_0^H dy \int_{\mathbb{R}} 1_E(x - s(y), y)dx \\ &= \int_0^H dy \int_{\mathbb{R}} 1_E(x, y)dx = \int_\Omega 1_E(x, y)dxdy = |E|. \end{aligned}$$

The jittering transform T_s is therefore a Lebesgue isomorphism. In particular, for any $u \in \mathrm{BV}(\Omega) \subset L^2(\|\cdot\|, \Omega)$,

$$u_s = u \circ T_s \in L^2(\Omega) \quad \text{and} \quad \|u_s\| = \|u\|. \tag{4.2}$$

Finally, the data model in (3.4) has been formally motivated by the *law of large numbers*:

$$\sigma_n^2 = \lim_{R\to\infty} \frac{1}{|\Omega_R|} \int_{\Omega_R} n^2(x, y)dxdy.$$

Due to the averaging over the entire infinite domain, we now show that model (3.4) leads to an unexpected dead end. The problem is fixed in the next subsection.

THEOREM 4.1. *Let u_0 be a given noisy jittered image in $L^2_{\mathrm{loc}}(\Omega)$. Suppose that there exists at least one $w(x, y) \in \mathrm{BV}(\Omega)$ such that*

$$\lim_{R\to\infty} \frac{1}{|\Omega_R|} \int_{\Omega_R} n^2(x, y)dxdy = \sigma_n^2$$

exists, with $n = u_0 - w_s = u_0 - w \circ T_s$. Then

$$(u = 0,\ s = 0) = \operatorname{argmin} E[u, s \mid u_0], \qquad E \text{ as in model (3.4)}.$$

Proof. The conclusion follows directly from

$$\lim_{R\to\infty} \frac{1}{|\Omega_R|} \int_{\Omega_R} (u_0 - w_s)^2 dxdy = \lim_{R\to\infty} \frac{1}{|\Omega_R|} \int_{\Omega_R} (u_0 - u_s)^2 dxdy,$$

for any $u \in \mathrm{BV}(\Omega)$, which we are now to prove. Define

$$\langle f, g\rangle_R = \int_{\Omega_R} f(x, y)g(x, y)dxdy, \quad \|f\|_R^2 = \langle f, f\rangle_R.$$

Notice that

$$\|u_0 - u_s\|_R^2 = \|u_0 - w_s\|_R^2 - 2\langle u_0 - w_s, u_s - w_s\rangle_R + \|u_s - w_s\|_R^2. \tag{4.3}$$

Now that $u, w \in \mathrm{BV}(\Omega)$, we must have $u_s - w_s = (u - w)_s \in L^2(\|\cdot\|, \Omega)$. Therefore,

$$\lim_{R\to\infty} \frac{1}{|\Omega_R|} \|u_s - w_s\|_R^2 = \lim_{R\to\infty} \frac{1}{|\Omega_R|} \|u_s - w_s\|^2 = 0.$$

For the cross term in (4.3), by the Schwarz inequality,

$$\frac{1}{|\Omega_R|}|\langle u_0 - w_s, u_s - w_s\rangle_R| \le \frac{1}{|\Omega_R|}\|u_0 - w_s\|_R \, \|u_s - w_s\|_R$$
$$= \left[\frac{1}{|\Omega_R|}\,\|n\|_R^2\right]^{\frac{1}{2}} \left[\frac{1}{|\Omega_R|}\,\|u_s - w_s\|_R^2\right]^{\frac{1}{2}}.$$

As $R \to \infty$, the first term converges to the standard deviation σ_n according to the assumption, but the second term vanishes as just shown. Therefore,

$$\lim_{R\to\infty} \frac{1}{|\Omega_R|}\langle u_0 - w_s, u_s - w_s\rangle_R = 0.$$

In combination, we are able to conclude that

$$\lim_{R\to\infty} \frac{1}{\|\Omega_R\|}\,\|u_0 - w_s\|_R^2 = \lim_{R\to\infty} \frac{1}{\|\Omega_R\|}\,\|u_0 - u_s\|_R^2.$$

This completes the proof. □

4.2. The corrected model and its properties. The problem is caused by averaging near infinity. In applications, images are given only on a bounded domain Ω_R and can be extended over the infinite stripe domain Ω by zero-padding. Thus to diminish the unnecessary role of the infinity, we propose to modify model (3.4) to

$$E[u, s \mid u_0] = \frac{\lambda}{2}\int_\Omega (u_0 - u_s)^2 dxdy + \frac{\mu}{2}\int_0^H s^2(y)dy + \alpha\int_\Omega |Du|, \tag{4.4}$$

where $\mu = 1/(\sigma_s^2 H)$ and $\lambda = \beta/\sigma_n^2$. Besides α, a new tunable parameter β is thus introduced. It is now easy to collect all the admissible conditions:

(a) the given jittered image $u_0 \in L^2(\Omega)$ and

(b) $u \in \mathrm{BV}(\Omega)$, and $s \in L^2(0, H)$.

As in the statistical framework, we define the corresponding "conditional" energies for $E[u, s \mid u_0]$:

$$E[u \mid u_0, s] = \frac{\lambda}{2}\int_\Omega (u_0 - u_s)^2 dxdy + \alpha\int_\Omega |Du| \quad \text{when } s \text{ is known}, \tag{4.5}$$

$$E[s \mid u_0, u] = \frac{\lambda}{2}\int_\Omega (u_0 - u_s)^2 dxdy + \frac{\mu}{2}\int_0^H s^2(y)dy \quad \text{when } u \text{ is known}. \tag{4.6}$$

Since $s \in L^2(0, H)$ is to at least model the rapid oscillations of random jittering, differential constraints (such as Sobolev norms or the BV norm) are generally inappropriate. (Of course, one is able to introduce them with small weights merely for the sake of Tikhonov regularization in inverse problems.) This makes the energy $E[u, s \mid u_0]$ in (4.4) lack the necessary compactness properties for establishing a general existence theorem. Uniqueness is jeopardized as well because of the lack of convexity (especially in s).

However, it is indeed possible to say more about the two "conditional" energies just defined, which will also be important for our algorithm in the next section.

THEOREM 4.2. *For any given jittering s, the minimizer in* $\mathrm{BV}(\Omega)$ *for* $E[u \mid u_0, s]$ *is unique. Furthermore if there exists a minimizing sequence which is bounded in* $L^1(\Omega)$*, then the minimizer indeed exists.*

We shall explain right after the proof why we need the extra boundedness condition for the existence part, which is often unnecessary for image processing problems on finite domains (see Chambolle and Lions [4], for example).

Proof. The jittering operator is linear: $(u+v)_s = u_s + v_s$ for any $u, v \in \mathrm{BV}(\Omega)$. Therefore it is straightforward to establish the strict convexity of $E[u \mid u_0, s]$, which leads to the uniqueness. We now prove the existence.

Let $(u^n)_n \subset \mathrm{BV}(\Omega)$ be a minimizing sequence of $E[u \mid u_0, s]$:

$$\lim_{n\to\infty} E[u^n \mid u_0, s] = \inf_{u\in \mathrm{BV}(\Omega)} E[u \mid u_0, s] < \infty.$$

In addition, assume that the sequence is bounded in $L^1(\Omega)$. There must exist an upper bound M, so that $e_n = E[u^n \mid u_0, s] \le M, n = 1, 2, \dots$, and

$$\int_\Omega |Du^n| \le \frac{1}{\alpha} e_n \le \frac{M}{\alpha}.$$

Therefore, $(u^n)_n$ is bounded in $\mathrm{BV}(\Omega)$. By the weak compactness property, there exist some $w = w(x, y) \in \mathrm{BV}(\Omega)$ and a subsequence, still denoted by $(u^n)_n$ for convenience, such that

$$u^n \to w \ \text{ in } \ L^1(\Omega) \quad \text{and} \quad \int_\Omega |Dw| \le \liminf_{n\to\infty} \int_\Omega |Du^n|.$$

The second half follows from the L^1 lower semicontinuity in $\mathrm{BV}(\Omega)$.

Possibly with another step of subsequence refinement, we can assume that

$$u^n(x, y) \to w(x, y), \quad \text{a.e.} \quad \text{on } \ \Omega.$$

Since the jittering transform $T_s : \Omega \to \Omega$ is a Lebesgue isomorphism, we must have as well

$$u^n_s(x, y) \to w_s(x, y), \quad \text{a.e.} \quad \text{on } \ \Omega.$$

Application of Fatou's lemma to the nonnegative sequence $g_n = (u_0 - u^n_s)^2$ leads to

$$\int_\Omega (u_0 - w_s)^2 dxdy \le \liminf_{n\to\infty} \int_\Omega (u_0 - u^n_s)^2 dxdy.$$

Eventually the above results enable us to conclude that

$$E[w|u_0, s] \le \liminf_{n\to\infty} E[u^n|u_0, s] = \inf_{u\in \mathrm{BV}(\Omega)} E[u \mid u_0, s].$$

Thus w has to be the (unique) minimizer of $E[u \mid u_0, s]$ in $\mathrm{BV}(\Omega)$. □

Remark. We now explain why the L^1 boundedness condition seems to be necessary. It is true that we can bound the L^2 norms of any minimizing sequence similarly to what has been done for the total variation norms in the proof:

$$\|u^n\|^2 = \|u^n_s\|^2 \le 2\|u_0\|^2 + \frac{4}{\lambda} e_n \le 2\|u_0\|^2 + \frac{4M}{\lambda}, \quad n = 1, 2, \dots .$$

If the domain Ω is finite, a Schwarz inequality immediately leads to a common bound on the L^1 norms:

$$\left[\int_\Omega |u(x, y)| dxdy\right]^2 \le \|u\|^2 \, |\Omega|.$$

However, in our case, $\Omega = \mathbb{R} \times (0, H)$ is an infinitely long stripe domain, for which the L^1 norms can indeed be unbounded. For example, define

$$u^n(x,y) = \frac{1}{(1+x^2)^{\frac{n+1}{2n}}}, \quad n = 1, 2, \dots,$$

which are translation invariant along the y direction. Then it is easy to show that

(a) the L^2 norms are bounded: $\|u^n\|^2 \le \pi H$;
(b) all $u^n \in \mathrm{BV}(\Omega)$ and their total variations are always $2H$ exactly; but
(c) their L^1 norms diverge to ∞ by the *monotone convergence theorem:*

$$\int_\Omega |u^n(x,y)|dxdy = H \int_{\mathbb{R}} \frac{1}{(1+x^2)^{\frac{n+1}{2n}}} dx \to H \int_{\mathbb{R}} \frac{1}{(1+x^2)^{\frac{1}{2}}} dx = \infty.$$

Thus it cannot be a Cauchy sequence in $L^1(\Omega)$. By the *monotone convergence theorem* again, it is not compact even in the topology of $L^1_{\mathrm{loc}}(\Omega)$.

One can say much less about the other conditional energy $E[s \mid u_0, u]$, due to the lack of convexity (for uniqueness) and enough regularity (for existence).

One nice property of $E[s \mid u_0, u]$ is that it is *separable* in terms of the horizontal and vertical directions. That is, it can be written as

$$E[s \mid u_0, u] = \int_0^H e(s(y), y)dy, \quad \text{with}$$
$$e(s(y), y) = \frac{\mu}{2} s(y)^2 + \frac{\lambda}{2} \int_{\mathbb{R}} (u_0(x,y) - u(x + s(y), y))^2 dx.$$

Having y fixed, we define $f_0(x) = u_0(x,y), f(x) = u(x,y)$, and $e(t) = e(t,y)$. Then the minimization of $E[s \mid u_0, u]$ is reduced to the minimization of every such single variable function $e(t)$ associated to each y. Notice that

$$e(t) = \frac{\mu}{2} t^2 + \frac{\lambda}{2} \int_{\mathbb{R}} (f_0(x) - f(x+t))^2 dx, \tag{4.7}$$

which is well defined for almost every $y \in (0, H)$ following Fubini's theorem. Notice that $e(t)$ is generally nonconvex, which leads to the uncertainty of uniqueness.

However, we are still able to establish the existence theorem and give an a priori bound on the minimizers.

THEOREM 4.3. *Suppose that $f_0, f \in L^2(\mathbb{R})$ in (4.7). Then*

(a) *$e(t)$ is a continuous function. In particular, the minimizer exists.*
(b) *Suppose $t = s$ is one minimizer of $e(t)$. Then*

$$|s| \le \sqrt{\lambda/\mu}\ (\|f_0\| + \|f\|).$$

Proof. For (a), take the continuity at $t = 0$, for example. Notice that

$$|\, \|f_0(x) - f(x+t)\| - \|f_0(x) - f(x)\| \,| \le \|f(x+t) - f(x)\|.$$

It is well known from Lebesgue integration theory that $f(x+t)$ converges to $f(x)$ in $L^p(\mathbb{R})$ for any $p \in [1, \infty)$ (excluding L^∞) as $t \to 0$. ($p = 2$ in our case.) Therefore $e(t)$ is indeed a continuous function. Since $e(t) \to +\infty$ as $t \to \pm\infty$, the global minima must be attainable at some finite locations. (b) follows easily from $\frac{\mu}{2} s^2 \le e(s) \le e(0)$. ∎

5. The algorithm and numerical results. In this section, we present an iterative algorithm to minimize $E[u, s \mid u_0]$ in (4.4). As one of the referees has kindly pointed out to us, such an algorithm generally falls into the category known in computer sciences as ICM, *iterated conditional models*.

The plan is to alternately minimize the two conditional energies $E[u \mid u_0, s]$ and $E[s \mid u_0, u]$ in (4.5) and (4.6), which were being studied above only in theory. Starting from a pair of initial guesses (u^0, s_0), we generate (u^{n+1}, s_{n+1}) from (u^n, s_n), $n = 0, 1, \dots$, by

$$u^{n+1} = \operatorname{argmin} E[u \mid u_0, s_n], \quad \text{followed by} \tag{5.1}$$

$$s_{n+1} = \operatorname{argmin} E[s \mid u_0, u^{n+1}]. \tag{5.2}$$

The motivation is clear: the current best jittering estimation s_n leads to an improved estimation of the target image u^{n+1}, which in return contributes to the updating of the jittering itself.

Since the energy $E[u, s \mid u_0]$ may have many local minima, convergence to the global minimum is generally unguaranteed. However, we are still able to show that the sequence $(u^n, s_n)_n$ is consistently "down-hill."

THEOREM 5.1. *Let $(u^n, s_n)_n$ be the sequence derived from the above iterative algorithm. Then for $n = 0, 1, \dots$,*

$$E[u^{n+1}, s_{n+1} \mid u_0] \le E[u^n, s_n \mid u_0].$$

Proof. From the energy definitions (3.2), (3.3), (4.4), (4.5), and (4.6), one has

$$\begin{aligned} E[u, s \mid u_0] &= E_{\mathrm{tv}}[u] + E[s \mid u_0, u] \\ &= E[s] + E[u \mid u_0, s]. \end{aligned}$$

Based on these two relations as well as the iteration formulae (5.1) and (5.2), one obtains

$$\begin{aligned} E[u^{n+1}, s_{n+1} \mid u_0] &= E_{\mathrm{tv}}[u^{n+1}] + E[s_{n+1} \mid u_0, u^{n+1}] \\ &\le E_{\mathrm{tv}}[u^{n+1}] + E[s_n \mid u_0, u^{n+1}] && \text{by (5.2)} \\ &= E[u^{n+1} \mid u_0, s_n] + E[s_n] \\ &\le E[u^n \mid u_0, s_n] + E[s_n] && \text{by (5.1)} \\ &= E[u^n, s_n \mid u_0]. \end{aligned}$$

This verifies the claim. ∎

The convergence of the sequence $(u^n, s_n)_n$ is still unclear, although our numerical results always seem to confirm it. (That is, numerically, the sequence invariably converges to some pair (u, s), which appears to be visually meaningful as judged by human observers.) What we are able to establish is the following weak theorem on convergence.

THEOREM 5.2. *Suppose the jittered image $u_0 \in L^2(\Omega)$ and $u_0(\cdot, y)$ is a continuous function in x for almost every $y \in (0, H)$. Let (u^n, s_n) be the sequence generated by the iterative scheme (5.1) and (5.2). Suppose that $(s_n)_n$ a.e. converges to some $s(y) \in L^2(0, H)$ and that $(\|u^n\|_{L^1})_n$ does not converge to ∞. Then there must exist a subsequence $(n_k)_k$ and some $u \in \mathrm{BV}(\Omega)$ so that $u^{n_k} \to u$ in $L^1(\Omega)$ and*

$$E[u, s \mid u_0] \le \lim_{n \to \infty} E[u^n, s_n \mid u_0].$$

Proof. By the preceding theorem, for any n,

$$E[u^n \mid u_0, s_n] \le E[u^n, s_n \mid u_0] \le E[u^0, s_0 \mid u_0].$$

Thus the bound on the total variations is immediate:

$$\int_\Omega |Du^n| \le \frac{1}{\alpha} E[u^0, s_0 \mid u_0], \qquad n = 1, 2, \dots .$$

Since $(\|u^n\|_{L^1})_n$ does not converge to ∞, there must exist a subsequence $(n'_k)_k$ so that $(u^{n'_k})_k$ is a bounded sequence in $L^1(\Omega)$. Therefore, $(u^{n'_k})_k$ is bounded in $\mathrm{BV}(\Omega)$. By the properties of weak compactness and L^1 lower semicontinuity, there must exist a refined subsequence $(n_k)_k$ and some $u \in \mathrm{BV}(\Omega)$ so that $u^{n_k} \to u$ in $L^1(\Omega)$ as $k \to \infty$ and

$$\int_\Omega |Du| \le \liminf_{k\to\infty} \int_\Omega |Du^{n_k}|. \tag{5.3}$$

Possibly with an extra step of subsequence refinement, we can also assume that $u^{n_k} \to u$, a.e. on Ω.

Secondly, since $s_n(y) \to s(y)$ a.e., by Fatou's lemma,

$$\int_0^H s^2(y)dy \le \liminf_{k\to\infty} \int_0^H s_{n_k}^2(y)dy. \tag{5.4}$$

As discussed in section 4.1, the jittering transform

$$T_s : (x, y) \to (x + s(y), y), \qquad (x, y) \in \Omega,$$

is a Lebesgue isomorphism, and $T_s^{-1} = T_{-s}$, which implies that

$$\int_\Omega (u_0 - u^n \circ T_{s_n})^2 dxdy = \int_\Omega (u_0 \circ T_{-s_n} - u^n)^2 dxdy.$$

Now that $s_n \to s$ a.e. on $(0, H)$, we must have, as $n \to \infty$,

$$T_{-s_n}(x, y) = (x - s_n(y), y) \to (x - s(y), y) = T_{-s}(x, y), \qquad \text{a.e. on } \Omega.$$

Since it is assumed that the observed data $u_0(\cdot, y)$ is a continuous function in x for *almost every* $y \in (0, H)$, we must have

$$u_0 \circ T_{-s_n} \to u_0 \circ T_{-s} \qquad \text{a.e. on } \Omega.$$

In combination with the a.e. convergence condition on $(u^{n_k})_k$, this implies that

$$u_0 \circ T_{-s_{n_k}} - u^{n_k} \to u_0 \circ T_{-s} - u \qquad \text{a.e. on } \Omega.$$

Therefore, Fatou's lemma again leads to

$$\int_\Omega (u_0 \circ T_{-s} - u)^2 dxdy \le \liminf_{k\to\infty} \int_\Omega (u_0 \circ T_{-s_{n_k}} - u^{n_k})^2 dxdy,$$

or equivalently,

$$\int_\Omega (u_0 - u_s)^2 dxdy \le \liminf_{k\to\infty} \int_\Omega (u_0 - u_{s_{n_k}}^{n_k})^2 dxdy. \tag{5.5}$$

The combination of the three bounds (5.3), (5.4), and (5.5) eventually completes the proof:

$$E[u, s \mid u_0] \le \liminf_{k\to\infty} E[u^{n_k}, s_{n_k} \mid u_0] = \lim_{n\to\infty} E[u^n, s_n \mid u_0].$$

The last equality follows from the monotonicity in the preceding theorem. □

Notice in the proof how the Lebesgue isomorphism property of the jittering transform allows us to stay away from the touchy issue of the convergence of $u^n_{s_n}$ to u_s. From the proof it is clear that the condition "$u_0(\cdot, y)$ is continuous in x" could be relaxed to "$u_0(\cdot, y)$ is continuous for almost every $x \in \mathbb{R}$."

Next we discuss the computational strategies for the two "conditional" optimization problems (4.5) and (4.6).

5.1. Algorithm for minimizing $E[u \mid u_0, s]$. Recall that, given u_0 and the current available jittering estimation s, the conditional energy for u is given by

$$E[u \mid u_0, s] = \frac{\lambda}{2}\int_\Omega (u_0 - u_s)^2 dxdy + \alpha \int_\Omega |Du|,$$

which is similar to the classical total variation (TV) denoising model of Rudin, Osher, and Fatemi [27], except that now the jittering $u_s = u \circ T_s$ is involved.

Formally, or assuming that $u \in W^{1,1}(\Omega)$ and $\int_\Omega |Du| = \int_\Omega |\nabla u| dxdy$, the first order variation on total variation leads to the well-known curvature derivative (see [27]) in the distributional sense:

$$-\alpha \nabla \cdot \left[\frac{\nabla u}{|\nabla u|}\right].$$

Secondly, the variation on the data model term gives

$$\lambda T_s^*(T_s u - u_0),$$

where $T_s u = u \circ T_s$ and T_s^* denotes the adjoint of T_s. Notice that $T_s^* = T_{-s} = T_s^{-1}$. Eventually we obtain the (formal) Euler–Lagrange equation

$$\frac{\partial E}{\partial u}[u \mid u_0, s] = \lambda(u - u_{0,-s}) - \alpha \nabla \cdot \left[\frac{\nabla u}{|\nabla u|}\right] = 0, \tag{5.6}$$

where $u_{0,-s} = (u_0)_{-s} = u_0 \circ T_{-s}$, with the natural Neumann boundary condition $\frac{\partial u}{\partial \vec{n}} = 0$.

Define $v_0 = u_{0,-s}$ for a given jitter s. To our great surprise, the Euler–Lagrange equation here is identical to that of the Rudin–Osher–Fatemi denoising model when applied to v_0.

Consequently, we are entitled to apply all computational techniques from the rich literature of TV denoising. First, instead of solving the singular equation (5.6), we solve its viscosity approximation:

$$\lambda(u - u_{0,-s}) - \alpha \nabla \cdot \left[\frac{\nabla u}{|\nabla u|_\epsilon}\right] = 0, \quad |a|_\epsilon = \sqrt{a^2 + \epsilon^2}, \tag{5.7}$$

for some small regularizing positive parameter ϵ. Furthermore, this nonlinear elliptic equation is solved by *lagged diffusivity iterations* [12], which is a natural linearization

technique. Let u^n be the current estimation for (5.7). Then u^n is updated to u^{n+1} by

$$\lambda(u^{n+1} - u_{0,-s}) - \alpha\nabla \cdot \left[\frac{\nabla u^{n+1}}{|\nabla u^n|_\epsilon}\right] = 0,$$

with the associated Neumann boundary conditions. To u^{n+1}, the original "diffusivity coefficient" $1/|\nabla u^{n+1}|_\epsilon$ is replaced by that from the previous step $1/|\nabla u^n|_\epsilon$. Convergence of the algorithm is well studied in [4, 12].

5.2. Algorithm for minimizing $E[s \mid u_0, u]$. Given the current best image estimation u, the "conditional" energy for the jittering s is given by

$$E[s \mid u_0, u] = \frac{\lambda}{2}\int_\Omega (u_0 - u_s)^2 dxdy + \frac{\mu}{2}\int_0^H s^2(y)dy. \tag{5.8}$$

As in the last part of section 4, for almost every (in the Lebesgue sense) given $y \in (0, H)$, define $f_0(x) = u_0(x, y)$ and $f(x) = u(x, y)$. Then the minimization of the functional $E[s \mid u_0, u]$ is reducible to one-dimensional energy functions in the form of

$$e(s) = \frac{\mu}{2}s^2 + \frac{\lambda}{2}\int_{\mathbb{R}} (f_0(x) - f(x+s))^2 dx. \tag{5.9}$$

This is a nonlinear function well defined for any given $f_0, f \in L^2(R)$. From the viscosity approximation, we can assume that u belongs to the Sobolev space $H^1(\Omega)$ [15]. By Fubini's theorem, for almost every $y \in (0, H)$, $f(x) = u(x, y) \in H^1(R)$.

The optimal line jittering s must satisfy

$$e'(s) = \mu s - \lambda\int_{\mathbb{R}} (f_0(x) - f(x+s))f'(x+s)dx = 0.$$

Notice that the integration is indeed well defined since $f_0, f(x+s), f'(x+s)$ are all square integrable. Let $\langle f, g\rangle$ denote the inner product in the Hilbert space $L^2(R)$. Then we can rewrite it by

$$e'(s) = \mu s - \lambda\langle f_0 - f(x+s), f'(x+s)\rangle. \tag{5.10}$$

If, furthermore, we assume that the current estimation $u \in H^2(\Omega)$, then Fubini's theorem again implies that $f'' \in L^2(R)$. We can then take the second order derivative following (5.10):

$$e''(s) = \mu + \lambda\langle f'(x+s), f'(x+s)\rangle - \lambda\langle f_0 - f(x+s), f''(x+s)\rangle. \tag{5.11}$$

Assume either the Neumann condition or vanishing condition at $\pm\infty : ff'(\pm\infty) = 0$. Then integration by parts gives

$$\langle -f(x+s), f''(x+s)\rangle = \langle f'(x+s), f'(x+s)\rangle,$$

and eventually

$$e''(s) = \mu + \lambda\langle f_0,\ -f''(x+s)\rangle. \tag{5.12}$$

Our algorithm for minimizing $e(s)$ is then based on the Newton–Raphson method. Starting from an initial guess s_0, we update s_n to s_{n+1} by

$$s_{n+1} = s_n - \frac{e'(s_n)}{e''(s_n)} = \frac{s_n\langle f_0, -f''(x+s_n)\rangle + \langle f_0 - f(x+s_n), f'(x+s_n)\rangle}{\langle f_0, -f''(x+s_n)\rangle + (\mu/\lambda)}. \tag{5.13}$$

Notice that $\lambda \propto 1/\sigma_n^2$ (see section 2). In the absence of intensity noise (corresponding to $\sigma_n = 0$), the ratio $\mu/\lambda = 0$. Then we have a much simpler formula:

$$s_{n+1} = s_n + \frac{\langle f_0 - f(x+s_n), f'(x+s_n)\rangle}{\langle f_0, -f''(x+s_n)\rangle}. \tag{5.14}$$

The feasibility of the algorithm relies on how robust the denominator $e''(s)$ stays away from 0 (i.e., pure convexity or concavity), at least when s is close to the optimal jittering. We now argue heuristically that indeed $e''(s)$ is reasonably well behaved, which has been observed from our numerical implementation as well. Suppose that the observed jittered one-dimensional image $f_0(x)$ has been generated from an image $g(x) \in H^1(R)$ with a jittering t, i.e., $f_0(x) = g(x+t) + n(x)$, where n denotes the Gaussian intensity white noise. Since n is independent of both g and f, or has rapid oscillatory behavior [23], we have

$$\langle f_0(x), -f''(x+s)\rangle = \langle g(x+t), -f''(x+s)\rangle = \langle g'(x+t), f'(x+s)\rangle,$$

where the last equality follows from integration by parts and the vanishing conditions at $\pm\infty$. Therefore, as the estimation pair (f, s) gets close to the genuine pair (g, t), $e''(s)$ is in the order of

$$\mu + \lambda\langle g'(x+t), g'(x+t)\rangle = \mu + \lambda\|g'(x)\|^2,$$

which certainly robustly stays away from the zero. As a byproduct, we also see that the quantity $\|g'(x)\|$ functions like an information measure: larger values mean richer variations in the image and more clues for robustly recovering the jittering.

5.3. Numerical simulation and results. We now briefly discuss some issues in the implementation of the above algorithms.

5.3.1. Neumann boundary jittering model. In numerical simulation and real applications, images are given on a finite square domain $\Omega_R = (-R, R) \times (0, H)$. We therefore need a boundary jittering model. In our simulation, we adopt what we have called the *Neumann boundary jittering model*. For any $s(y)$ and $(x, y) \in \Omega_R$: if $|x+s(y)| \le R$, we define $u_s(x, y) = u(x+s(y), y)$; otherwise, suppose $\pm(x+s(y)) > R$, then we define $u_s(x, y) = u(\pm R, y)$ in the sense of traces for BV functions [15]. The intensity noise model remains untouched:

$$u_0(x, y) = u_s(x, y) + n(x, y), \qquad \text{with Gaussian white noise } n(x, y). \tag{5.15}$$

5.3.2. Parameter tuning. On the fixed finite image domain Ω_R, the data model in both (3.4) and (4.4) bears the exact form following (5.15):

$$E[u_0 \mid u, s] = \frac{\lambda_R}{2}\int_{\Omega_R}(u_0 - u_s)^2 dxdy,$$

with $\lambda_R = 1/(\sigma_n^2|\Omega_R|)$. Therefore in terms of numerical simulation, the dejittering model becomes

$$E[u, s \mid u_0] = \frac{\lambda_R}{2}\int_{\Omega}(u_0 - u_s)^2 dxdy + \frac{\mu}{2}\int_0^H s(y)^2 dy + \alpha\int_{\Omega}|Du|.$$

It allows only one tunable parameter α, since both λ_R and μ are completely determined by the noise model (σ_n^2) and the jittering model (σ_s^2):

$$\lambda_R = \frac{1}{2\sigma_n^2 RH}, \qquad \mu = \frac{1}{\sigma_s^2 H}.$$

Numerically the variances are obtained from any statistical estimators.

FIG. 5.1. *TV-based Bayesian dejittering.*

5.3.3. Random jittering generation. In analog media, in principle a jitter s could be any real number. However in digital implementation, where the image domain Ω_R becomes a matrix of pixel dots, jitters can be restricted only to integers. One could simulate such integer jitters by the continuous Gaussian noise followed by a quantization step. In this paper, instead, we directly make use of the binomial noise $B(p, N)$ with an even integer $N = 2n$:

$$\text{Prob}(s = k) = \binom{N}{n+k} p^{n+k}(1-p)^{n-k}, \quad k = -n, -n+1, \dots, n-1, n.$$

From probability theory, one has

$$\mathbf{E}(s) = N(1-p) - n = n(1-2p), \qquad \sigma_s^2 = Np(1-p).$$

Since it is assumed in section 2 that the jittering has zero mean, we must have $p = 1/2$ and $\sigma_s^2 = N/4$. The *central limit theorem* confirms that Gaussian is still a good approximation. In our simulations, N is in the order of 100, which brings the standard deviation σ_s close to 5 pixels. Jittering with a several-pixel magnitude is already severe for real video tapes or television signals (see [20], for example).

5.3.4. Simulation examples. Finally, we present three numerical results derived from the model and its algorithm detailed above, and discuss their implications.

In Figure 5.1, from left to right are the initial noisy jittered image u_0, the first image estimation $u^1 = \text{argmin } E[u \mid u_0, s_0]$ with zero jittering $s_0(y) \equiv 0$, and the final dejittered output.

Ideally, we would expect that the standard deviation $\text{std}(s_n)$ for each intermediate jittering estimation s_n is exactly σ_s. But computationally there is always some deviation, possibly due to the random number generator being used, the limited number of samples in digital implementation, and the Newton–Raphson algorithm itself. Therefore, we could enforce $\text{std}(s_n) = \sigma_s$ by introducing an extra normalization step. The quality of the output indeed improves in such circumstances (see Figure 5.2).

In Figure 5.2, from left to right are the initial noisy jittered image u_0, the image estimation after the fifth round $u^6 = \text{argmin } E[u \mid u_0, s_5]$, and the similar image estimation based on the normalized jittering $\hat{s}_5 = s_5/\text{std}(s_5) \times \sigma_s$. (Here std denotes the statistical standard deviation.) If one compares the dejittered edges, the normalization step clearly improves their qualities.

Figure 5.3 shows the output when the TV dejittering model is applied to another standard test image. It is well known in the literature of variational methods

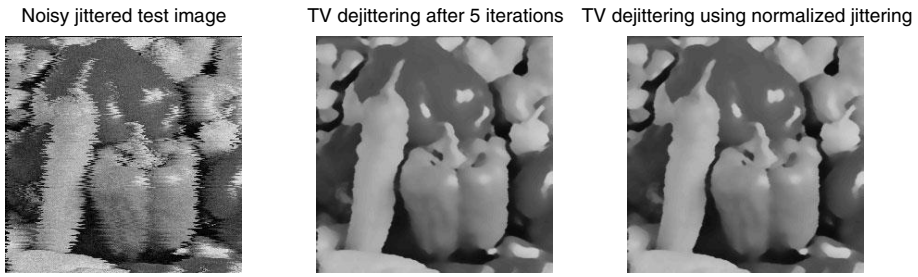

FIG. 5.2. *TV-based Bayesian dejittering with jittering normalization.*

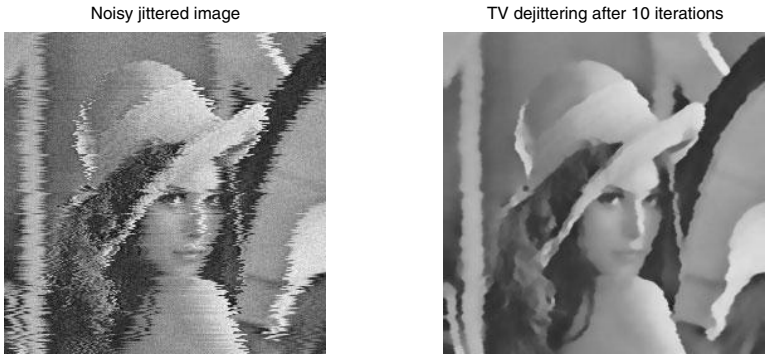

FIG. 5.3. *TV-based Bayesian dejittering applied to another standard test image. Pay attention to thin vertical structures and nonsmooth hair textures, to which the BV image model is only approximative.*

[3, 4, 9, 23] that the BV image model is only approximative in modeling textures like the hair region in the current image. Therefore, the smoothing effect (on highly oscillatory textures) in the dejittering output is intrinsic and unsurprising. Textures always impose great challenges in a variety of image processing tasks such as denoising, deblurring, inpainting, and segmentation [8, 16, 17, 23, 32, 33].

6. Conclusion. In this paper, based on the Bayesian rationale, we have proposed a novel variational model for video dejittering. The image model of bounded variations that we have applied, first introduced into image processing by Rudin and Osher [26] and Rudin, Osher, and Fatemi [27], is a powerful tool for restoring the regularity of randomly jittered objects.

We have studied the mathematical properties of the model based on the direct method of calculus of variations, the theory of functions with bounded variations, and various tools from analysis.

For the nonlinear and nonconvex energy functional, we have designed an algorithm based on alternately optimizing the image and jittering estimations. The algorithm is then numerically implemented by solving nonlinear PDEs (for image estimations) and by Newton–Raphson iterations. Typical numerical results are demonstrated.

This work again demonstrates the power of a good image model in image analysis. We expect that if the BV image model is replaced by the Mumford–Shah image model [25], many results should remain similar. (For example, such exchange has been very successful in image inpainting [13].)

If the random jitterings are correlated among different video frames, we expect that dynamic tools such as the Kalman filter [19, 30, 31] can play an important role in the process of modeling and computation.

Finally, it must be made clear that the current work only attempts to model some parts of the complex behavior of *real* jittering problems. For the sake of both enlightenment and inspiring future work, the author would like to quote an elegant paragraph from one of the referees (without editing):

> In real systems, jitter is almost always the combination of a random displacement and an underlying harmonic component. Any dejittering algorithm is going to have to rely on vertical image structure in order to realign the lines. All variants of single frame dejittering algorithms attempt to shift lines so as to increase vertical image smoothness. The heart of the dejittering problem is to tell the difference between vertical image features that are not straight and the harmonic component of jitter. This is extremely difficult to do, since there is (almost) no way to distinguish between dejittered images containing wavy but smooth vertical structures, and (those containing) straight and smooth structures. To add a further complication to the mix, the jitter is invariably caused by noise on the sync-tip signal. When that happens, not only is the line shifted, but the reference grey level is wrong, and then the actual DC line level changes from line to line.

As an intermediate stage between the current mathematical model and the realistic complexity elaborated in the preceding quotation, one could, for instance, study the scenario when the jittering s consists of two components:

$$s(y) = s_m(y) + s_n(y), \quad y \in (0, H),$$

where $s_m(y)$ denotes the *mean-field* or smooth jittering (with respect to the vertical variable y), and $s_n(y)$ still the Gaussian white noise. Then the prior model for jittering should be upgraded from (3.2) to

$$E[s] = E[s_m] + E[s_n] = \gamma \int_0^H |s_m'(y)|^p dy + \frac{1}{2\sigma_s^2 H} \int_0^H s_n^2(y) dy,$$

where γ denotes some suitable regularity weight, $p \geq 1$, and σ_s^2 the variance of the random component s_n. We leave further development along this line to interested readers.

Acknowledgments. The author would like to thank Gilbert Strang, Tony Chan, Stan Osher, and David Mumford for their invaluable teaching and inspirations, as well as the referees for their generous efforts in uplifting the quality of the current paper.

THE MILNE PROBLEM FOR HIGH FIELD KINETIC EQUATIONS*

N. BEN ABDALLAH†, I. M. GAMBA‡, AND AXEL KLAR§

Abstract. Half space problems of the linear Boltzmann equation with a constant driving force are considered. Such problems model boundary layers between kinetic zones and fluid zones described by a high field limit of the Boltzmann equation. Existence, uniqueness, and asymptotic behavior of solutions are studied for positive and negative driving forces. In the positive case, the force field accelerates the particles, and we show that the solution of the half space problem is determined only by the inflow data. In contrast, for negative forces, the behavior at infinity has to be prescribed in order to insure uniqueness. Due to the nonvanishing forces, the problem does not possess any entropy. The existence and uniqueness issues are dealt with by supersolution techniques, while the asymptotic behavior is analyzed by semiexplicit integration of the equations along the characteristics. In the case of relaxation time approximation, a fast numerical method for computing the asymptotic state method is presented and tested.

1. Introduction.

Macroscopic fluid models are usually obtained from kinetic equations in collision dominated situations. Diffusion scalings are used when the equilibrium states (for which collisions are transparent) carry no current. Depending on the specific collision phenomena taken into account, asymptotics methods based on scaling assumptions lead to various diffusion models like the drift-diffusion [29], the energy-transport [8, 18], or the spherical harmonics expansion (SHE) model [32, 31, 4, 21, 17, 16].

When the driving forces are strong enough that their effect is of the same order of magnitude as collisional effects, another scaling, called high field scaling, has to be used. For the linear Boltzmann operator, the limit equation has been formally shown by Poupaud [30] to be a linear convection equation with the convective term depending on the force field. When the force field is the gradient of a potential coupled through a mean field approximation, a nonlinear system is obtained with a first order correction corresponding to augmented diffusion and transport [12, 13].

Kinetic high field models and associated macroscopic models have been considered in [13, 12, 34, 30, 5]. Recent comparisons between kinetic multiscale domain decomposition and the Monte Carlo method were presented in [20, 1, 10].

However, up to now, no analysis of the kinetic boundary layer problem to find the correct boundary conditions for the fluid approximation has been performed. Such an analysis is also required if one wants to solve the matching problem for kinetic and macroscopic equations. Here, an interface region between the two equations has to be considered. The matching problem has to be solved, for example, for domain decomposition approaches simultaneously solving kinetic and macroscopic equations in different regions of the computational domain.

Boundary and interface regions are described by a transition layer where a stationary kinetic equation is solved. A standard assumption is that the layer has a slab symmetry, that is, the particle distribution is constant on surfaces parallel to the interface. Rigorous analysis of boundary value problems for linear transport kinetic equations in the absence of forces, known as the half space problem, and its corresponding limiting behavior in a strong collisional regime and long time scaling linear, as the length of the transition layer is comparable to the reference collision frequency, known as the Milne problem, was initiated [6] by means of spectral methods and semigroup theory.

For charged transport models, the force field gradient of the electrostatic potential is bounded along flat boundaries where the potential either is prescribed or is a solution of the corresponding mean field equation. In both cases, the force field will become a constant in the rescaled layer. In in the drift-diffusion regime due to weak force field forces, the rescaled force field vanishes. The corresponding half space and Milne problem was studied in [28], and computations for the corresponding fluid kinetic interface procedure for numerical implementations of hybrid methods were due to [35, 24].

For the case of strong force field regimes, one expects a slab symmetry whenever the curvature of the interface is small compared to the reciprocal of the mean free path and when the force field is normal to the interface. Consequently, the space coordinate reduces to, say, x the distance to the boundary or interface. After scaling it like $\frac{x}{\epsilon}$, where ϵ is the order magnitude of the mean free path, one has to solve a kinetic half space problem.

These strong force field scalings are characterized by nonstatistical equilibrium states $P = P(v)$; that is, they are $L^1_k(\mathcal{R}_v)$ space homogeneous solutions to the layer problem, with nonvanishing mean or first moment, which depend on the force field and on the Maxwellian in the kernel of the collision operator and the scattering function. This problem was treated by Trugman and Taylor [34] for the relaxation operator, and by Poupaud [30] for the general linear operator in three dimensions.

The first part of this paper treats the existence and uniqueness results for half space problems corresponding to strong force field scaling, both for positive and negative forces, and describes their corresponding asymptotic behavior, since from a practical point of view, the objects of great interest in obtaining boundary or matching conditions are the asymptotic states and the outgoing distribution (Albedo operator). The only assumption is that the boundary incoming data is a positive L^1_k bounded by a multiple of the state P.

In the case of positive forces, the force field accelerate the particles. Here we show that the solution of the half space problem is determined only by the inflow data. In fact, we prove that the unique solution $f(x, v)$ of the half space problem satisfies the condition that f_∞/P belongs to $L^\infty(\mathcal{R}^+_x \times \mathcal{R}_v)$. In addition $\lim_{x\to\infty} f(x, \cdot)/P$ converges to a proper factor n_∞. This factor is uniquely determined by the quotient of the mean of the solution, which is space independent, and the mean of the nonstatistical equilibrium state P, and thus it depends on the boundary data. This result indicates that under such strong forced scaling, the kinetic equation will admit an asymptotic

non-Maxwellian homogeneous stationary state; that is, under *strong acceleration*, the unscaled original kinetic solution should take a local stationary state which does not correspond to statistical equilibrium, whose asymptotic limit is a singularly perturbed augmented transport-diffusion converging to convective transport.

In contrast, for the case of strong negative forces, particles are slowed down, and under the same conditions for existence, one needs to prescribe the behavior of f at the right end of the layer in order to get uniqueness of the half space problem. In fact, we prove that for *any* given constant parameter n_∞, there exists a unique positive solution f_∞/P, belonging to $L^\infty(\mathcal{R}_x^+ \times \mathcal{R}_v)$, to the stationary problem in the rescaled layer, such that $\lim_{x\to\infty} f(x,\cdot)/P = n_\infty$. This essentially indicates that the behavior at infinity does not depend on the inflow boundary data.

A way to see the difference between the positive and negative force is that, in the former, the characteristic curves passing at $x = 0$ for the first order layer equation grow to $+\infty$ for $v > 0$ as $x \to \infty$, and come from $-\infty$ for $v < 0$. However, for the negative forced equation, the characteristic curves passing at $x = 0$ for $v > 0$ will turn back to intersect the axis $x = 0$ for $v < 0$. In particular for this second case, one may prescribe the behavior at infinity.

This anisotropic nature of the problem has as a consequence the lack of a natural entropy functional that controls the decay in space, such as it is possible to obtain in the low field scaling case. This motivates us to introduce new analytical methods based on comparison techniques by super- and subsolutions, namely, a maximum principle for solutions to kinetic stationary boundary value half space problems, basically introduced by Poupaud in [29] in order to treat boundary value problems for the stationary Vlasov–Maxwell system.

We recall that in the low field scaling case, the characteristic curves passing at $x = 0$ for the first order layer equation are all constant straight lines $v = v_o$ for all v_o, that is, all parallel to the x-axis. In particular, it has been shown that a corresponding boundary layer problem has a solution to the Milne problem given by an asymptotic behavior approaching a Maxwellian state, independent of forces [28]. In this case the boundary layer problem is similar to the one for a kinetic equation in the absence of forces, as treated in [6]. In both cases a diffusion limit arises, which may have a weak drift proportional to the field, corresponding to low field scaling.

In the second part of the paper, we describe a numerical procedure which computes n_∞, depending on the initial data, for the case of positive forces and a relaxation collision operator. It uses a classical Chapman–Enskog–type expansion to approximate the solution. We obtain a force field modified Marshak condition, which is a higher order correction to prescription of incoming fluxes. Our calculation recovers the classical Marshak condition for diffusion approximations as the force fields tends to zero. The method is seen to converge very fast numerically. It seems to give accurate results when compared to the available explicit solutions in some special cases. For approaches to the numerical solution of the standard half space problem in gas dynamics and semiconductor equations, we refer the reader to [2, 14, 22, 33], and for a mathematical investigation, to [3, 15, 23]. We expect a future implementation of very efficient hybrid computational schemes that will be able to link nonstatistical equilibrium scales by their anisotropic diffusion convective limits, as well as to solve the coupling of convective regions to diffusion regions by transition layer or interfaces, as is steadily observed in strongly doped device simulation under hot-electron regimes.

The paper is organized as follows. In section 2 we present the strong force field equations. Section 3 contains an analytical investigation of the half space problem for both the negative and positive forces. In both cases, existence and uniqueness results

with the asymptotic behavior at infinity are investigated. In section 4 the numerical procedure and some numerical results are presented in the case of relaxation operators.

2. High field kinetic equations. The drift-collision balance regime. We consider the semiclassical linear Boltzmann equation in dimensionless variables for an electron gas for a semiconducting material in the parabolic band approximation, with a strong force field scaling

$$\eta\partial_t f + v\cdot\nabla_z f + \frac{\eta}{\epsilon}E(z,t)\cdot\nabla_v f = \frac{1}{\epsilon}Q(f) \tag{2.1}$$

with $z, v \in \mathcal{R}^3$. The general linear collision operator under consideration is

$$Q(f) = \int s(v,v')[M(v)f(v') - M(v')f(v)]\,dv' = Q^+(f) - \sigma(v)f. \tag{2.2}$$

The scattering function $s(v,v')$ is symmetric and satisfies

$$0 < s_0 \le s(v,v') \le s_1 < +\infty \quad \text{and} \quad s(v,v') = s(v',v), \tag{2.3}$$

and σ denotes the collision frequency

$$\sigma(v) = \int s(v,v')M(v')\,dv', \tag{2.4}$$

whereas

$$Q^+(f) = \int s(v,v')f(v')M(v)\,dv' \tag{2.5}$$

is the gain operator. Throughout this paper the notation $\langle h\rangle$ stands for $\int h(v)\,dv$.

Here we use the standard notation $M(v)$ for the centered, reduced Maxwellian $M = (2\pi)^{-\frac{3}{2}}\exp(-\frac{v^2}{2})$.

As a motivation for this problem, we look at semiconductor modeling as the main example of a transport phenomenon that exhibits stationary nonequilibrium statistical states. Usually, the vector field $E = E(z,t) = -\nabla_z\Phi$ denotes the scaled electric force, which is determined by a Poisson equation for the potential Φ:

$$\nabla_z\cdot(\nabla_z\Phi) = \gamma\left(\frac{1}{\eta^d}\int_{\mathcal{R}^3} f dv - C(z)\right),$$

where γ is the inverse to the scaled Debye length of the device and $C(z)$, which denotes the ion background, is bounded, measurable, and largely varying. It is worth mentioning that strong force field scalings are present due to space inhomogeneities, such as short base channel devices, under strong forward bias that produces a region of positive charges inside the channel (i.e., $\gamma^{-1} \gg 0$). Such an effect is known as hot-electron transport. Under these assumptions on $C(z)$, classical potential theory implies that the solution of the Poisson equation in a bounded channel-like region yields a continuous bounded force field $E(z)$.

Because of this effect, assume dimensionless parameters η and γ both of order $O(1)$ and that ϵ, the scaled mean free path, is small. This scaling assumption corresponds to the drift-collision balance scaling introduced in [30, 13]. Such a scaling is realized, for instance, in the modeling of silicon doped diodes with $0.4\,\mu$m channel [20, 1, 10] under potential bias of 1eV. These simulations exhibit the formation of transition

layers in the drain junction, with a clear jump from a close to convective state in the channel region to a diffusion equilibrium at the contact. In addition, inside the channel, there is a clear region where the numerical probability distribution function, the solution to the approximated kinetic Poisson system, takes a definite state away from statistical equilibrium. Such a configuration corresponds to a relatively strong forced field scale with respect to collisions against a background. This may be the case for other collisional plasma physics applications under strong force fields.

The problem we want to study is related to the solution and its asymptotic behavior in a given layer of length ϵ. This layer is inversely proportional to the drift-collision scale associated with the reciprocal of the scaled mean free path of $o(\epsilon)$ for the kinetic problem under such a regime.

From now we focus on the problem of having a force field $E(x,t)$ given in a transition layer or boundary with a slab symmetry; that is, the particle distribution is constant on surfaces parallel to the interface. For the case of strong force field regimes, one expects such a slab symmetry whenever the curvature of the interface is small compared to the reciprocal of the mean free path and when the force field is normal to the interface.

In order to obtain the boundary or interface layer equations in a slab geometry, fix a point $\hat{z}$ on the boundary, assume that the electric force is orthogonal to the interface, and rescale as usual the space coordinate in the layer normal to the boundary with the mean free path ϵ, introducing the new coordinate x orthogonal to the boundary:

$$x = \frac{(\hat{z} - z) \cdot n}{\epsilon}.$$

Here, n denotes the outer normal to the boundary or interface. This transformation yields the new coordinates $(x, \hat{z})$ instead of z in the slab layer. To $O(1)$ one obtains, after applying the transformation to (2.1),

$$v \cdot n \partial_x f + \eta E \cdot \nabla_v f, = Q(f),$$

where, as $\epsilon \to 0$, the variable $x \in [0, \infty)$, and the field $E = E(x = 0, \hat{z}, t)$ does not depend on x and thus is constant. This problem has to be supplied with the ingoing function at the boundary, i.e., at $x = 0$; that is, $f(0, v)$, $v \cdot n > 0$, with n the outer normal to the boundary at $x = 0$. In order to have the force field E constant it is enough that the potential Φ is regular enough so that $\nabla\Phi$ is bounded at the slab boundary.

To simplify the problem, we assume from now on that the z_1-coordinate points in the direction of the normal, so that that $E = (E_1, 0, 0)$ and that $\tau = 1$, $\eta = 1$. Then the above reduces to the following one-dimensional problem:

$$v_1 \partial_{z_1} f + E_1 \partial_{v_1} f = Q^+(f) - \sigma(v) f,$$

with $x \in [0, \infty)$, $v_1 \in \mathcal{R}$, $f = f(z_1, v_1)$. Then $M(v)$ in the definition of Q^+ and σ reduces to the one-dimensional Maxwellian $M(v_1) = (2\pi)^{-\frac{1}{2}} \exp(-\frac{v_1^2}{2})$ for $v_1 \in \mathcal{R}$.

From now on, we use the notation $(x, v) \in \mathcal{R}^+ \times \mathcal{R}$ rather than (z_1, v_1). The Milne problem takes the following form:

$$\begin{aligned} v \partial_x f + E \partial_v f = Q(f) = Q^+(f) - \sigma(v) f, \\ \varphi(0, v) = k(v), \quad v > 0, \end{aligned} \tag{2.6}$$

with $x \in [0, \infty)$, $v \in \mathcal{R}$, and an ingoing positive function k satisfying the conditions stated below.

Before announcing the main theorems, we define the homogeneous solution $P_{\sigma,E}(v)$ as the unique function which satisfies

$$E\partial_v P = Q(P) = Q^+(P) - \sigma(v)P, \qquad \text{with } \langle P\rangle = 1, \tag{2.7}$$

using the notation

$$\langle P\rangle = \int P(v)dv. \tag{2.8}$$

In addition, for any integrable solution f of (2.6),

$$j = \langle vf\rangle \quad \text{is } x\text{-independent.} \tag{2.9}$$

The proof of this statement is trivial for any integrable solution.

Solvability of problem (2.7) in $L^\infty \cap L^1$ can be found in Trugman and Taylor [34] for the relaxation-type operator in one dimension. It has also been discussed in Frosali, Van der Mee, and Paveri-Fontana [19]. The most general result has been obtained by Poupaud [30], who finds solutions to (2.7) in L^1 for general linear collision operators in higher dimensions, depending on the integrability of the collision frequency. In addition he shows that the solution function P is unique and positive. Recently, this result has been generalized to the collision operators with Pauli-exclusion terms [7].

For completeness we recall the Poupaud solution representation to problem (2.7), obtained via spectral analysis [30] of the following linear integral operator:

$$\begin{aligned} P_E(v) &= L_E(Q^+(P))(v) \\ &= \int_0^\infty \exp\left(-\int_0^\tau \sigma(v-\mu E)d\,\mu\right)\int_{\mathcal{R}} s(v-\tau E,w)P_E(w)d\,w\,M(v-\tau E)d\,\tau \end{aligned} \tag{2.10}$$

for $E \neq 0$ such that $\langle P\rangle = 1$. The operator $L_E : L^1 \to L^1_\sigma$ is the inversion operator to $E\cdot\nabla_v + \sigma(v)$, defined by

$$L_E(f)(v) = \int_0^\infty \exp\left(-\int_0^\tau \sigma(v-\mu E)d\,\mu\right) f(v-\tau E)d\,\tau. \tag{2.11}$$

Poupaud proves that the integral equation (2.10) has a unique integrable (L^1) positive solution if and only if

$$\int_0^\infty \sigma(v+\mu E)d\,\mu = +\infty \qquad \text{a.e.} \tag{2.12}$$

In addition, the solution satisfies the property

$$P_E(v) = P_{-E}(-v). \tag{2.13}$$

It is clear that in our case, by (2.3), the scattering function $s(v,v')$ is bounded above and below by positive constants, so that the collision frequency $\sigma(v)$ function as defined in (2.4) satisfies the infinite integrability compatibility condition (2.12).

Moreover, the unique solution P to problem (2.7) has all moments bounded. Indeed by (2.2) and (2.3) the following moment recursion inequality holds:

$$\langle v^k P\rangle \le \frac{s_1}{s_0}\langle v^k M\rangle + E\langle v^{k-1}P\rangle. \tag{2.14}$$

In the particular case of a relaxation collision operator, when $s(v', v) = \tau^{-1}$,

$$Q(f)(v) = \frac{1}{\tau}\left(M(v)\int_{\mathcal{R}^3} f(v')dv' - f(v)\right) = \frac{\langle f\rangle M - f}{\tau}, \tag{2.15}$$

with τ the relaxation time, one obtains an explicit formula for the dominant P state, as the right-hand side of (2.10) is computable. Setting $\tau = 1$, without loss of generality, the probability distribution function P, a solution to (2.7) with the collisional form (2.15), is explicitly given, as originally computed in [19], by

$$P_E(v) = \frac{1}{2E}\exp\left(\frac{-\lambda}{E}\right) erfc\left(\lambda\sqrt{\frac{1}{2}}\right) \tag{2.16}$$

with $E > 0$, $\lambda = \frac{2}{E} - v$, and $erfc(x) = \frac{1}{2} + \frac{1}{\sqrt{\pi}}\int_0^x e^{-t^2}dt$.

In addition, moments are explicitly computed by a recursion formula [13], and, in the one-dimensional case, the first three satisfy

$$\begin{aligned}\langle vP_E\rangle &= E,\\ \langle v^2P_E\rangle &= 1 + 2E^2,\\ \langle v^3P_E\rangle &= 3E + 6E^3.\end{aligned}$$

The main result for the first part of the paper, *the Milne problem for strong force fields*, is stated as follows.

THEOREM 1 (positive force field). *Let $E > 0$ be a given positive real number. Let $P_{\sigma,E}$ (we shall also use the short notation P) be the solution of the space homogeneous equation* (2.7). *Assume that $0 \le k(v) \le KP(v)$ for some constant K. Then,* (2.6) *has a unique positive solution such that $f/P \in L^\infty(\mathcal{R}_x^+ \times \mathcal{R}_v)$. Moreover, there exists a constant $n_\infty = \frac{\langle vf\rangle}{\langle vP\rangle}$ such that*

$$\lim_{x\to+\infty} f(x, v) = n_\infty P(v) \quad \textit{pointwise.} \tag{2.17}$$

THEOREM 2 (negative force field). *Let $E < 0$ be a given negative real number. Let $P_{\sigma,E}$ (we shall also use the short notation P) be the solution of the space homogeneous equation* (2.7). *Assume that $0 \le k(v) \le KP(v)$ for some constant K. Then, for any given $n_\infty \in \mathcal{R}^+$, there exists a unique positive solution f_{n_∞} of* (2.6) *such that $f_{n_\infty}/P \in L^\infty(\mathcal{R}_x^+ \times \mathcal{R}_v)$ and*

$$\lim_{x\to+\infty} f_{n_\infty}(x, v) = n_\infty P(v) \quad \textit{pointwise.}$$

In both cases the integrability of f follows from the integrability of P.

3. Analysis of the Milne problem.

3.1. Properties independent of $sgn(E)$. We first start by showing that the current carried by the homogeneous solution P, that is $\langle vP\rangle$, has the same sign as E. Namely, we claim the following.

LEMMA 1. *The solution P of problem* (2.7) *with the linear collisional form* (2.2) *satisfies $E\langle vP\rangle > 0$ and $0 < E\langle v^3\, P\rangle < K < \infty$ if $E \neq 0$.*

Proof. In the case of relaxation the statement is trivial since, by (2.17), $E\langle vP\rangle = E^2$ and $E\langle v^3\, P\rangle = E^2 + 3E^4$.

For the general linear case, the collision operator is self-adjoint in the weighted space $L^2_M = \{f \in L^1_{loc},\ \int_{\mathcal{R}} f^2 M^{-1}\, dv < +\infty\}$, so that

$$\langle gQ(f)M^{-1}\rangle = \langle fQ(g)M^{-1}\rangle. \tag{3.1}$$

Since, by symmetrization,

$$\int Q(f)g\, dv = -\frac{1}{2}\int sMM'\left(\frac{f'}{M'} - \frac{f}{M}\right)(g' - g)\, dv\, dv, \tag{3.2}$$

it follows that for all monotone increasing H

$$\int Q(f)H\left(\frac{f}{M}\right) dv \le 0 \tag{3.3}$$

and

$$\int Q(f)H\left(\frac{f}{M}\right) dv = 0 \quad \text{if and only if} \quad f(v) = cM(v)$$

for any constant c.

Now, taking $H(\tau) = \ln \tau$, we obtain

$$\int Q(P)\ln\left(\frac{P}{M}\right) dv = \int Q(P)\left(\ln P + \frac{v^2}{2}\right) dv \le 0. \tag{3.4}$$

In addition, by (2.7), $E\frac{\partial P}{\partial v} = Q(P)$; then

$$0 \ge \int Q(P)\left(\ln P + \frac{v^2}{2}\right) dv = \int E\frac{\partial P}{\partial v}\left(\ln P + \frac{v^2}{2}\right) dv.$$

Since by integrability of P and $P\ln P$ the identity

$$\int \ln P \frac{\partial P}{\partial v} dv = \int_R \frac{\partial}{\partial v}(P\ln P - P) dv = 0$$

holds, then

$$E\int \frac{v^2}{2}\ \frac{\partial P}{\partial v}\, dv \le 0.$$

Thus, integrating by parts yields the first inequality

$$E\int vP\, dv \ge 0. \tag{3.5}$$

Next, we show that (3.5) cannot be zero if E is not zero. Indeed, if $E\int vP\, dv = 0$, then, by (3.4), $\int Q(P)\ln\frac{P}{M}\, dv = 0$, which implies $P = c\ M$, and thus P is a multiple of the Maxwellian. Therefore $E\frac{\partial M}{\partial v} = 0$ and $E \neq 0$, which is a contradiction since $\partial M/\partial v$ does not vanish.

Finally, the finiteness of moments for all orders follows from the moments recursion formula (2.14). □

THEOREM 3 (existence). *Let E be a given real number. Let P be the solution of the space homogeneous equation* (2.7). *Assume that $K_1P(v) \le k(v) \le K_2P(v)$ for*

some positive constants K_1 and K_2. Then there exist two solutions $(\underline{f}, \overline{f})$ of (2.6) called minimal and maximal solutions such that

$$K_1 P(v) \le \underline{f}(x,v) \le \overline{f}(x,v) \le K_2 P(x,v)$$

and such that any solution f of (2.6), such that $K_1 P(v) \le f(x,v) \le K_2 P(v)$, is trapped between $\underline{f}$ and $\overline{f}$:

$$\underline{f}(x,v) \le f(x,v) \le \overline{f}(x,v).$$

To construct a solution on the half real line $\mathcal{R}^+$, we first solve the problem on the interval $[0, L]$ and then let L tend to $+\infty$. To this end, we consider the problem

$$\begin{cases} v\varphi_x + E\varphi_v = Q(\varphi)(x,v), \\ \varphi(0,v) = k_1(v) \text{ for } v > 0, \\ \varphi(L,v) = k_2(v) \text{ for } v < 0. \end{cases} \tag{3.6}$$

LEMMA 2. *Assume that $K_1 P(v) \le k_{1,2}(v) \le K_2 P(v)$. Then (3.6) admits a unique solution φ such that $\varphi(x,v)/P(v) \in L^\infty([0,L] \times \mathcal{R}_v)$. Moreover,*

$$K_1 P(v) \le \varphi(x,v) \le K_2 P(x,v).$$

Proof. To prove the existence of a solution, we consider the mapping T_L defined by $f = T_L(g)$, where f is the unique solution of

$$\begin{cases} \sigma(v) f + v f_x + E f_v = Q^+(g)(x,v), \\ f(0,v) = k_1(v) \text{ for } v > 0, \\ f(L,v) = k_2(v) \text{ for } v < 0. \end{cases} \tag{3.7}$$

The function f exists by virtue of [29] and is unique since $\sigma \ge s_0 > 0$. Moreover, the maximum principle insures that $f \ge K_1 P(v)$ if $g \ge K_1 P(v)$ (and $f \le K_2 P(v)$ if $g \le K_2 P(v)$). Starting from $f_1(x,v) = K_1 P(v)$, we proceed as in [29] and define $f^n = T_L f^{n-1}$ and set $\varphi = \lim_{n \to +\infty} \frac{1}{n} \sum_{l=1}^n f_l$. It is then clear that $K_1 P \le f_n \le K_2 P$ and φ is a solution of (3.7) which satisfies $K_1 P \le \varphi \le K_2 P$.

The uniqueness follows by an entropy argument developed in [9]. For the sake of completeness, we detail this argument. We set h to be the difference between two solutions. Then h is a solution of

$$\begin{cases} v h_x + E h_v = Q(h), \\ h(0,v) = 0 \text{ for } v > 0, \\ h(L,v) = 0 \text{ for } v < 0. \end{cases}$$

Using the inequality $\int Q(h) sgn(h)\, dv \le 0$ and the fact that equality holds if and only if the sign of $h(x,v)$ does not depend on v, we obtain

$$\int_0^{+\infty} v|h(L,v)|\, dv - \int_{-\infty}^0 v|h(0,v)|\, dv = \int_0^L \int_{\mathcal{R}} Q(h) sgn(h)\, dv\, dx,$$

which implies that $h(0,v) = 0$ and $h(L,v) = 0$ for $v \in \mathcal{R}$ and that the sign of $h(x,v)$ does not depend on v. Setting $H = |h|$, since the collisional form is linear, then $Q^+(h) sgn(h) = Q^+(H)$. Therefore,

$$\begin{cases} \sigma(v) H + v H_x + E H_v = Q^+(H), \\ H(0,v) = 0 \text{ for } v \in \mathcal{R}, \\ H(L,v) = 0 \text{ for } v \in \mathcal{R}. \end{cases}$$

This implies that $H = 0$ after an integration along the characteristics.

Proof of existence Theorem 3. The maximal and minimal solutions are respectively obtained by solving problem (3.6), with $k_1 = k$ and $k_2 = K_2P$ (for the maximal solution) and $k_1 = k$ and $k_2 = K_1P$ (for the minimal solution). Indeed, define $f^+ = T_L^+(g)$ and $f^- = T_L^-(g)$ as the unique solutions of

$$\begin{cases} \sigma(v)f^+ + vf_x^+ + Ef_v^+ = Q^+(g)(x,v), \\ f^+(0,v) = k(v) \text{ for } v > 0, \\ f^+(L,v) = K_2P(v) \text{ for } v < 0, \end{cases} \tag{3.8}$$

$$\begin{cases} \sigma(v)f^- + vf_x^- + Ef_v^- = Q^+(g)(x,v), \\ f^-(0,v) = k(v) \text{ for } v > 0, \\ f^-(L,v) = K_1P(v) \text{ for } v < 0. \end{cases} \tag{3.9}$$

Then the maximal and minimal solutions are defined by $\overline{f}_L = T_L^+(\overline{f}_L)$ and $\underline{f}_L = T_L^-(\underline{f}_L)$, and so

$$K_1P(v) \le \underline{f}_L \le \overline{f}_L \le K_2P(v).$$

Moreover, $\overline{f}_L = \lim_{n\to+\infty}(T_L^+)^n(K_2P)$ (the sequence $((T_L^+)^n(K_2P))$ being pointwise decreasing) and $\underline{f}_L = \lim_{n\to+\infty}(T_L^-)^n(K_1P)$ (the sequence being pointwise increasing). The above constructed sequences satisfy the following monotonicity properties.

LEMMA 3. *If $L_1 \le L_2$, then $\overline{f}_{L_1} \ge \overline{f}_{L_2}$ and $\underline{f}_{L_1} \le \underline{f}_{L_2}$ on $[0, L_1] \times \mathcal{R}$.*

Proof. Let $L_1 \le L_2$ and $H = \overline{f}_{L_1} - \overline{f}_{L_2}$ on $[0, L_1] \times \mathcal{R}_v$; then H^m is the solution of

$$\begin{cases} vH_x + EH_v = Q(H), \\ H(0,v) = 0 \text{ for } v > 0, \\ H(L_1,v) = K_2P(v) - \overline{f}_{L_2}(L_1,v) \ge 0 \quad \text{for } v > 0. \end{cases}$$

Therefore $H \ge 0$ by virtue of Lemma 2. The inequality for $\underline{f}_L$ is obtained analogously. ∎

Let us now pass to the limit $L \to +\infty$. For this purpose, we notice that $K_1P(v) \le \underline{f}_L \le \overline{f}_L \le K_2P(v)$ and that $\underline{f}_L$ is increasing with respect to L, while $\overline{f}_L$ is decreasing with respect to L. The pointwise limits $\underline{f}$ and $\overline{f}$ of $\underline{f}_L$ and $\overline{f}_L$ as L tends to $+\infty$ are obviously solutions of the problem (2.6) and satisfy

$$K_1P \le \underline{f} \le \overline{f} \le K_2P.$$

The only thing left to show now is that any solution $f \in [K_1P, K_2P]$ of (2.6) is trapped between $\underline{f}$ and $\overline{f}$. To this aim, set $g = f - T_L^-(f)$. Then g is the solution of

$$\begin{cases} vg_x + Eg_v + \sigma g = 0, & \\ g(0,v) = 0, & v > 0, \\ g(L,v) = f(L,v) - K_1P(v) \ge 0, & v < 0, \end{cases}$$

which implies $g \ge 0$. Hence $T_L^-(f) \le f$. The maximum principle insures that $T_L^\pm(g_1) \le T_L^\pm(g_2)$ whenever $g_1 \le g_2$. Therefore $(T_L^-)^m(f) \le f$. However, $(T_L^-)^m(f) \ge (T_L^-)^m(K_1P)$. Since $\underline{f}_L = \lim_{m\to+\infty}(T_L^-)^m(K_1P)$, we deduce from the above inequality that $f \ge \underline{f}_L$ on $[0, L] \times \mathcal{R}$, which leads to $f \ge \underline{f}$. The inequality $f \le \overline{f}$ is obtained analogously. The proof of Theorem 3 is now complete. ∎

Next, we study the uniqueness and the asymptotic behavior for the solutions.

3.2. The Milne problem for strong positive forces. The aim of this section is to complete the proof of Theorem 1. First, we show *uniqueness*, that is, $\overline{f} = \underline{f}$ for arbitrary K_2. This proof, which is rather short, uses the asymptotic behavior to be shown next. However, we leave the asymptotic behavior for last, since its proof does not require uniqueness of the solutions.

THEOREM 4 (uniqueness for the case of strong positive forces). *Assume that* $E > 0$ *and that* $0 \le k \le KP$. *Then* $\overline{f}$ *and* $\underline{f}$ *coincide.*

First we prove the following proposition.

PROPOSITION 1. *Let* $h = \overline{f} - \underline{f}$. *Then* $\partial_x h \ge 0$, *and there exists* $\alpha \ge 0$ *such that*

$$\lim_{x \to +\infty} h(x, v) = \alpha P(v).$$

Proof. Take the function $h_{L,a}(x,v) = \overline{f}_{L+a}(x+a,v) - \underline{f}_{L+a}(x+a,v) - \overline{f}_L(x,v) + \underline{f}_L(x,v)$ for $a > 0$. Then $h_{L,a}$ satisfies

$$v\partial_x h_{L,a} + E\partial_v h_{L,a} = Q(h_{L,a})$$

and $h_{L,a}(0,v) \ge 0$ for $v > 0$, while $h_{L,a}(L,v) = 0$ for $v < 0$. Therefore $h_{L,a} \ge 0$ uniformly in L, which implies by passing to the limit $L \to +\infty$ that $h(x+a,v) - h(x,v) \ge 0$. Since a is arbitrary, then $\partial_x h \ge 0$. ∎

Proof of Theorem 4. Let $h = \overline{f} - \underline{f}$. By construction, $h \ge 0$.

However, because of the boundary condition at $x = 0$, $h(0,v) = 0$ for $v > 0$, and consequently the associated first moment j, which is x-independent, is nonpositive since $j = \langle vh \rangle = \int_{-\infty}^{0} vh \le 0$.

On the other hand, by Proposition 1, on the one hand, $\lim_{x \to +\infty} h(x,v) = \alpha P(v)$ for $\alpha \ge 0$, and on the other hand, by Lemma 1, $\alpha \langle vP \rangle \ge 0$.

Now, since $j = \langle vh \rangle$ is x-independent due to is limit at infinity, $0 \ge j = \alpha \langle vP \rangle \ge 0$. This is only possible if $\alpha = 0$.

Therefore, h is nonnegative, and by Proposition 1, increasing with respect to x and tends to zero as x tends to $+\infty$. Then h is identically equal to zero for all $x \ge 0$, for all v. ∎

Asymptotic behavior at ∞: Completion of the proof of Theorem 1. Without loss of generality, we renormalize the solution of (2.6) with respect to the constant K of the data. This is equivalent to treating the case $K = 1$. Therefore f solves

$$\begin{cases} \dfrac{v}{E} f_x + f_v + \dfrac{\sigma(v)}{E} f = \dfrac{1}{E} Q^+(f), \\ f(0,v) = k(v) \le P(v). \end{cases} \tag{3.10}$$

By (3.10), $0 \le f(x,v) \le P(v)$ for all v, and its first moment $j = \int_{\mathcal{R}} v f(x,v)\, dv$ is independent of x.

The strategy of the proof works as follows. First we shall prove a *key statement* in Theorem 5, which shows that if the first moment of the solution f of (3.10) is a proper fraction of the first moment of the homogeneous solution P, say by a factor $0 \le \lambda < 1$, then the spatial asymptotic behavior of f at infinity is given by exactly λP, which is the expected behavior for any solution of the initial value problem (3.10) at infinity. This result is equivalent to an a priori estimate, which means control on the spatial variation of the solutions by control on the variation of its first moment.

Second, we shall see that, in fact, the first moment of *any* solution to problem (3.10) is always a proper fraction of the first moment of the homogeneous solution of the problem; that is, $\lambda P(v)$ for some $0 \le \lambda < 1$.

Combining both results means that the spatial asymptotic behavior at infinite for f is actually $\lambda P(v)$. That is, the *quotient* between the first moments of the solution f and the homogeneous solution P and between the spatial asymptotic behavior solution of f and the homogeneous solution P, to problems (3.10) and (2.7), respectively, are both the same. In a sense, this is like a Harnack inequality for the kinetic problem.

In fact, these key estimates follow from Lemma 1, which states that if E is positive, then the first moment of the homogeneous solution P is positive. Thus we can make sense of a proper fraction of the first moment of the homogeneous state for a strong force scaling as well as all estimates that follow.

THEOREM 5. *If* $j = \int vf\,dv = \lambda \int vP \geq 0$, *with* $\lambda \in [0,1)$, *then*

$$\lim_{x\to+\infty} f(x,v) = \lambda P(v) = \frac{j}{\langle vP\rangle} P(v). \tag{3.11}$$

The proof of this theorem requires additional partial results that we write as lemmas and corollaries.

LEMMA 4 (initial control for the gain operator). *Assume* $\int vf\,dv = \langle vf\rangle = \lambda\langle vP\rangle > 0$ *for* $0 \leq \lambda < 1$. *Then*

$$Q^+(f) \leq \mu_0 Q^+(P) \quad \text{for all } x \geq 0, \tag{3.12}$$

where

$$0 < \mu_0 = 1 - \frac{s_0}{s_1}\frac{1-\lambda}{2v_0}\langle vP\rangle < 1, \tag{3.13}$$

where v_0 *satisfies*

$$0 < \int_{v_0}^{\infty} vP\,dv \leq \frac{1-\lambda}{2}\langle vP\rangle\,, \tag{3.14}$$

and the quotient $\frac{s_0}{s_1}$, *as defined in* (2.3), *measures the oscillation of the scattering rate function.*

Proof. From the existence result, it follows that $0 \leq f \leq P$. Since Q^+ is a positive linear operator,

$$Q^+(f)(v) = Q^+(P) - Q^+(P-f) \leq Q^+(P) - M(v)\int_0^{+\infty} s(v',v)\,(P-f)\,dv'. \tag{3.15}$$

Then, it is enough to prove that

$$M(v)\int_0^{+\infty} s(v',v)\,(P-f)\,dv' > \beta\; Q^+(P)(v) \quad \text{for some } \beta < 1. \tag{3.16}$$

In order to estimate (3.16), we use the hypothesis on the first moment of f and P, that is, if

$$\langle vf\rangle = \int_{-\infty}^{+\infty} vf\,dv = \lambda\int_{-\infty}^{+\infty} vP\,dv = \lambda\langle vP\rangle,$$

which yields the first moment flux estimate

$$\int_0^{+\infty} vf\,dv = -\int_{-\infty}^{0} vf\,dv + \lambda\langle vP\rangle \leq -\int_{-\infty}^{0} vP\,dv + \lambda\langle vP\rangle;$$

that subtracted from

$$\int_0^\infty vP = -\int_{-\infty}^0 vP + \langle vP\rangle$$

leads to the lower bound estimate for the first moment fraction of the difference between the stationary and homogeneous solution

$$\int_0^{+\infty} v(P-f)\,dv \geq (1-\lambda)\langle vP\rangle = \alpha. \tag{3.17}$$

The integrability of the first moment of the homogeneous solution P, and the fact that $\lambda < 1$, imply that there exists a $v_0 > 0$ such that

$$\int_{v_0}^{+\infty} vP\,dv \leq \left(\frac{1-\lambda}{2}\right)\langle vP\rangle = \frac{\alpha}{2}\,, \tag{3.18}$$

so that, since $vf > 0$ for $v \geq v_0 > 0$, also

$$\int_{v_0}^{+\infty} v(P-f)\,dv \leq \frac{\alpha}{2}\,. \tag{3.19}$$

Next, subtracting inequality (3.19) from inequality (3.17) leads to

$$\int_0^{v_0} v(P-f)\,dv \geq \frac{1-\lambda}{2}\langle vP\rangle. \tag{3.20}$$

Now, recalling that the scattering rate function $s = s(v', v)$ is bounded by $0 < s_0 \leq s(v', v) \leq s_1 < \infty$, multiplying and dividing the integrand by $s = s(v', v)$ yield a first moment flux fraction difference estimate by a fraction difference for the gain operator

$$\int_0^{v_0} v(P-f) = \int_0^{v_0} v\frac{s}{s}(P-f)\,dv \leq \frac{v_0}{s_0}\int_0^{v_0} s(v', v)(P-f)\,dv, \tag{3.21}$$

which combined with inequality (3.20) yields the following lower bound for the right-hand side of (3.21):

$$\int_0^{v_0} s(v', v)(P-f)\,dv \geq \frac{(1-\lambda)}{2v_0}s_0\langle vP\rangle = \frac{\alpha}{2}\frac{s_0}{v_0}\,. \tag{3.22}$$

In addition, since $\langle P\rangle = 1$, then $s_1 \geq \int_{-\infty}^{+\infty} s(v', v)P(v)\,dv \geq s_0$. Thus the right-hand side of (3.22) can be estimated as

$$\frac{\alpha}{2}\frac{s_0}{v_0} \geq \frac{\alpha}{2v_0}\frac{s_0}{s_1}\int_{-\infty}^{+\infty} s(v', v)P(v')\,dv' \;= \frac{\alpha}{2v_0}\frac{s_0}{s_1}Q^+(P), \tag{3.23}$$

where the fraction $\frac{s_0}{s_1} < 1$.

Since $P - f > 0$, inequalities (3.22) and (3.23) lead to

$$M(v)\int_0^{+\infty} s(v', v)(P-f)\,dv \geq M(v)\int_0^{v_0} s(v', v)(P-f)\,dv > \frac{\alpha}{2v_0}\frac{s_0}{s_1}Q^+(P)(v), \tag{3.24}$$

which yields the inequality (3.16) with $\beta = \frac{\alpha}{2v_0}\frac{s_0}{s_1}$.

Therefore (3.12) holds with

$$0 < \mu_0 = 1 - \frac{\alpha}{2v_0}\frac{s_0}{s_1} < 1, \qquad \alpha = (1-\lambda)\langle vP\rangle\,, \tag{3.25}$$

where v_0 is such that $\int_{v_0}^{+\infty} vP\,dv \le \frac{\alpha}{2}$. ∎

Remark. The choice of v_0 actually depends on the fact that the first moment of P is finite, that is, on the integrability properties of homogeneous solution P and its corresponding behavior at infinity, and not necessarily on the explicit form of P. This implies that these results can be extended to more general cases, as long as the first moment of P is strictly positive and the corresponding collision frequency is bounded below by a strictly positive constant and above by infinity.

LEMMA 5 (local control of f). *Let $x_k > 0$ such that*

$$Q^+(f) \le \mu_k Q^+(P) \tag{3.26}$$

for any $(x,v) \in D_k = \{(x,v),\, x \ge x_k,\, v \le \sqrt{2E(x-x_k)}\}$; then

$$f \le \mu_k P \quad \text{on } D_k. \tag{3.27}$$

Proof. Recall that $E > 0$. Now for any pair $(x',v') \in D_k$, then $x' \ge x_k$ and $x' = \frac{v'^2}{2E} + x''$, where $x'' > x_k$. Now let (x',v') be fixed (and so is x''), and consider the function $g(v) = f\big(\frac{v^2}{2E} + x'', v\big)$. The argument of the right-hand side of the previous equation lies in D_k, and we have

$$E\frac{\partial g}{\partial v} + \sigma(v)g = Q^+(f)\left(\frac{v^2}{2E} + x'', v\right), \tag{3.28}$$

so that $g(v) \to 0$ as $v \to -\infty$ (because $f(x,v) \le P$).

Now since, by assumption, $Q^+(f) \le \mu_k Q^+(P)$ in D_k, then subtracting the differential inequality from the homogeneous equation satisfied by P, multiplied by μ_0, the difference $g - \mu_k P$ satisfies the differential inequality with the condition in velocity at $-\infty$

$$\begin{aligned} &E\frac{\partial}{\partial v}(g - \mu_k P) + \sigma(v)(g - \mu_k P) \le 0,\\ &\lim_{v\to-\infty} g(v) - \mu_k P(v) = 0. \end{aligned} \tag{3.29}$$

Since $E > 0$, it implies $g \le \mu_k P$. In particular, taking $v = v'$, we get

$$f(x',v') \le \mu_k P(v') \ \text{ on } \ D_k. \tag{3.30}$$

The proof is completed. ∎

The strategy in order to show (3.11), the expected behavior at infinity for f, consists of constructing pairs (μ_{k+1}, x_{k+1}) for which the control of the gain operator of f by that of P is improved (see (3.26)), and so by Lemma 5, the control of f by P (see (3.27)) is also improved by the same factor μ_{k+1} in such a way that the limit of the sequence $\{\mu_k\}$ is equal to $\lambda \ge 0$, while the limit for $\{x_k\}$ tends to $+\infty$.

The construction of such sequences of pairs entails the following iterative procedure. First, construct iteratively the sequence (μ_k, x_k) starting from $x_0 = 0$ and μ_0 given by Lemma 4, for as long as $f \le \mu_k P$ and $0 \le \lambda < \mu_k$ for $k \ge 0$.

Second, find a pair (μ_{k+1}, x_{k+1}) such that (3.26) holds, that is, $x_{k+1} > x_k$ and $Q^+(f) \le \mu_{k+1} Q^+(P)$ on D_{k+1}, where $\mu_{k+1} \le \mu_k$, where the selection of (μ_{k+1}, x_{k+1}) depends on μ_k and λ in a control way so $\lim_{k\to\infty} \mu_k = \lambda$ as $x_k \to \infty$.

Finally, from Lemma 5, it follows that $f \le \mu_{k+1} P$ on D_{k+1}, for $0 \le \lambda < \mu_{k+1} < \mu_k < 1$.

This next lemma proves this second step.

LEMMA 6. *Let f satisfy the conditions of Lemmas 4 and 5 for a given pair (μ_k, x_k), and the corresponding D_k for $\lambda < \mu_k$, for $k \ge 0$. Then there exists a (μ_{k+1}, x_{k+1}) such that*

$$Q^+(f) \le \mu_{k+1} Q^+(P), \qquad 0 < \mu_{k+1} < \mu_k < 1 \ \text{in } D_k, \tag{3.31}$$

with $x_{k+1} \ge x_k$. Moreover, μ_{k+1} can be chosen so that

$$(\mu_k - \lambda) < C(\mu_k - \mu_{k+1})^2 \,, \qquad \text{with } C = 2\frac{s_1}{s_0}\frac{\langle v^3 P\rangle^3}{\langle v^P\rangle^{1/2}}. \tag{3.32}$$

Before proving Lemma 6, we state a corollary which follows immediately from Lemmas 5 and 6.

COROLLARY 1. *Let D_{k+1} be defined as in Lemma 5; then*

$$f \le \mu_{k+1} P, \qquad 0 < \mu_{k+1} < \mu_k < 1\,, \qquad \text{on } \ D_{k+1}. \tag{3.33}$$

Proof of Lemma 6. In order to prove (3.31) due to the linearity of the collision form, write

$$Q^+(f) = \mu_k Q^+(P) - Q^+(\mu_k P - f). \tag{3.34}$$

Since $f \le \mu_k P$ in D_k, then

$$M(v)\int_{-\infty}^{0} s(v,v')\,(\mu_k P(v') - f(x,v'))\,dv' \ge 0 \qquad \text{for } x \ge x_k,$$

with $x_k = \frac{v_k^2}{2E}$. Thus

$$Q^+(\mu_k P - f) \ge M(v)\int_0^{\infty} s(v,v')\,(\mu_k P(v') - f(x,v'))\,dv', \qquad x \ge x_k. \tag{3.35}$$

Our goal is to see that the right-hand side of (3.35) is bounded by a proper fraction of $\mu_k Q^+(P)$, that is,

$$M(v)\int_0^{\infty} s(v,v')\,(\mu_k P(v') - f(x,v'))\,dv' \ge \mu_{k+1} Q^+(P) \tag{3.36}$$

for $\mu_{k+1} < \mu_k$ and $x \ge x_{k+1} \ge x_k$, where x_{k+1} is to be determined.

Now, we know from Lemma 5 that $f \le \mu_k P$ on D_k and that, by assumption, $\langle vf\rangle = \lambda\langle vP\rangle$. Then, as in Lemma 4, since the set $\{x \ge x_k\} \times \{v \le 0\}$ is in D_k, this implies

$$-\int_{-\infty}^{0} vf\,dv \le -\mu_k \int_{-\infty}^{0} vP\,dv = -\mu_k\langle vP\rangle + \mu_k \int_0^{+\infty} vP$$

for $x \geq x_k$, which yields

$$\int_0^{+\infty} v(\mu_k P - f)\, dv \geq (\mu_k - \lambda)\langle vP\rangle = \alpha_k \quad \text{for} \quad x \geq x_k. \tag{3.37}$$

Next, we need to choose the set D_{k+1}, which means choosing v_{k+1} and the corresponding x_{k+1} such that we can control them, and $Q^+(f) \leq \mu_{k+1}, Q^+(P)$ for $x_{k+1} > x_k$ and for some $\mu_{k+1} < \mu_k$.

In order to see this fact, first since we can do this construction, as done in Lemma 4, for as long as $\mu_k > \lambda$, and by the integrability properties of the first moment of P, one can choose v_{k+1} such that

$$v_{k+1} \int_{v_{k+1}}^{+\infty} P\, dv \leq \int_{v_{k+1}}^{+\infty} vP\, dv \leq \frac{1}{2}(\mu_k - \lambda)\langle vP\rangle. \tag{3.38}$$

On the other hand, as a consequence of (2.14) and Lemma 1, the third moment of P is bounded, and

$$\int_{v_{k+1}}^{+\infty} vP\, dv \leq \frac{1}{v_{k+1}^2} \int_0^{\infty} v^3 P(v)\, dv \leq \frac{\langle v^3 P\rangle}{v_{k+1}^2} \quad \text{for all } v_{k+1} \geq 0\,.$$

Then, choose v_{k+1} large enough such that both (3.38) and

$$v_{k+1} \leq \frac{C}{\sqrt{\mu_k - \lambda}}, \quad \text{with} \quad C = \frac{\langle v^3 P\rangle}{\sqrt{2\langle vP\rangle}}, \tag{3.39}$$

are satisfied.

Hence, taking $x_{k+1} = \frac{v_{k+1}^2}{2E} + x_k$, it is clear that

$$\{(x,v) : x \geq x_{k+1},\ v \leq v_{k+1}\} \subset D_k, \quad \text{so that} \quad f(x,v) \leq \mu_k P(v). \tag{3.40}$$

Next, rewrite integral estimate (3.37) as

$$\int_0^{v_{k+1}} v(\mu_k P - f)\, dv + \int_{v_{k+1}}^{+\infty} v(\mu_k P - f)\, dv \geq (\mu_k - \lambda)\langle vP\rangle. \tag{3.41}$$

Also, since $\mu_k < 1$ and $f > 0$, from the estimate from below in (3.38) it follows that

$$\int_{v_{k+1}}^{\infty} (\mu_k P - f) \leq \int_{v_{k+1}}^{\infty} P \leq \frac{1}{2v_{k+1}}(\mu_k - \lambda)\langle vP\rangle; \tag{3.42}$$

then, combining (3.41) and (3.42) yields

$$v_{k+1} \int_0^{v_{k+1}} (\mu_k P - f) \geq \int_0^{v_{k+1}} v(\mu_k P - f) \geq \left(1 - \frac{1}{2v_{k+1}}\right)(\mu_k - \lambda)\langle vP\rangle. \tag{3.43}$$

Finally, this last estimate (3.43) leads to the one involving a fraction of the gain operator on the difference $\mu_k P - f$, as follows. First, recalling $0 < s_0 \leq s(v', v) \leq s_1$ and s_1 finite,

$$\int_0^{v_{k+1}} s(v, v')\,(\mu_k P(v') - f(x, v'))\, dv' \geq \left(1 - \frac{1}{2v_{k+1}}\right) \frac{s_0}{v_{k+1}}(\mu_k - \lambda)\langle vP\rangle. \tag{3.44}$$

Second, since $f \le P$ and $\mu_k < 1$, then

$$\begin{aligned}\int_{v_{k+1}}^{\infty} s(v',v)\,(\mu_k P(v') - f(x,v'))\,dv' &\ge -\frac{s_1}{v_{k+1}}(1-\mu_k)\int_{v_{k+1}}^{\infty} v'P(v')dv' \\ &\ge -\frac{s_1}{v_{k+1}}(1-\mu_k)\frac{1}{2v_{k+1}}(\mu_k-\lambda)\langle vP\rangle\end{aligned} \tag{3.45}$$

for any $x > x_{k+1}$.

Therefore, gathering (3.44) and (3.45), we obtain the following lower estimate for equation (3.35):

$$\begin{aligned}Q^+(\mu_k P - f) &\ge M(v)\int_0^{+\infty} s(v',v)\,(\mu_k P(v') - f(x,v'))\,dv' \\ &\ge M(v)\left[\Big(1-\frac{1}{2v_{k+1}}\Big)s_0 - \frac{1}{2v_{k+1}}s_1(1-\mu_k)\right]\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda) \\ &= M(v)\left[s_0 - \frac{1}{2v_{k+1}}(s_0+s_1) + \frac{s_1}{2}\frac{\mu_k}{v_{k+1}}\right]\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda) \\ &= M(v)\left(1 - \frac{1}{2v_{k+1}}\Big[\frac{s_0+s_1}{s_0}\Big] + \frac{1}{2v_{k+1}}\frac{s_1}{s_0}\mu_k\right)s_0\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda).\end{aligned} \tag{3.46}$$

Now, we can choose v_{k+1} even larger than the choices in (3.38) and (3.40) such that $\frac{1}{2v_{k+1}}[\frac{s_1}{s_0}\mu_k - \frac{s_0+s_1}{s_0}] < \frac{1}{2}$, and thus (3.46) leads to

$$Q^+(\mu_k P - f) \ge \frac{s_0}{2}\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda)M(v) \ge \frac{1}{2}\frac{s_0}{s_1}\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda)Q^+(P), \tag{3.47}$$

which, after combination with (3.34), leads to

$$Q^+(f) \le \mu_{k+1}Q^+(P), \tag{3.48}$$

where

$$\mu_{k+1} = \left(\mu_k - \frac{1}{2}\frac{s_0}{s_1}\frac{\langle vP\rangle}{v_{k+1}}(\mu_k-\lambda)\right). \tag{3.49}$$

Finally, from (3.39), v_{k+1} is such that $v_{k+1} \le C(\mu_k-\lambda)^{-1/2}$; then combining this with (3.49), we get

$$(\mu_k-\lambda) < C(\mu_k-\mu_{k+1})^2 \quad \text{with } C = 2\frac{s_1}{s_0}\frac{\langle v^3P\rangle}{\langle v^P\rangle^{1/2}}. \tag{3.50}$$

Hence, (3.32) holds as well, and thus the proof of Lemma 6 is now completed. ∎

We can now complete the proof of Theorem 5.

Proof of Theorem 5. For as long as $\mu_k > \lambda$, proceed constructing the sequence $\{x_k\}$ as in Lemma 6. If $\mu_k \le \lambda$, set $x_{k+1} = x_k$. In particular, since $\mu_k - \mu_{k+1} \to 0$, as k is large, inequality (3.32) implies

$$\lim_{k\to\infty}\mu_k - \lambda = 0 \quad \text{with} \quad \lim_{k\to\infty} x_k = +\infty,$$

which implies

$$\limsup_{k\to\infty} f(x_k,v) \le \lim_{k\to\infty}\mu_k P(v) \le \lambda P(v). \tag{3.51}$$

Conversely, applying Lemma 6 and Corollary 1 to $P - f$, since we have assumed $0 \le \lambda < 1$, then $0 \le \langle vP - vf\rangle \le (1-\lambda)\langle vP\rangle$, and also

$$\limsup_{k\to\infty}(P-f)(x_x, v) \le (1-\lambda)P(v) \le 0,$$

or equivalently,

$$\liminf_{k\to\infty} f(x_k, v) \ge \lambda P(v). \tag{3.52}$$

Finally, from the construction of the sequence, for μ_k either larger or smaller than λ, (3.51) and (3.52) imply that

$$\lim_{x\to\infty} f(x,v) = \lambda P(v),$$

so (3.11) holds. The proof of Theorem 5 is now completed. ∎

Finally, in order to complete the proof of the Theorem 1, we define $n_\infty = \frac{\langle vf\rangle}{\langle vP\rangle}$. Then we need to show that n_∞ is always a nonnegative proper fraction, since this has been an assumption in Theorem 5.

THEOREM 6. *If* $\langle vf\rangle = n_\infty\langle vP\rangle$, *then*

$$0 \le n_\infty \le 1. \tag{3.53}$$

Proof. First, we recall from the existence construction, if the boundary data is $0 < k(v) \le P(v)$, for $v > 0$, then $0 < f < P$ for all $x \ge 0$ and all v.

Now, argue by contradiction. If $n_\infty < 0$, take $g = f - n_\infty P$. Clearly $\langle vg\rangle = \langle v(f - n_\infty P)\rangle = 0$.

Therefore, applying Theorem 5 to g with $\lambda = 0$,

$$\lim_{x\to\infty} g(x,v) \le 0$$

or equivalently,

$$\lim_{x\to\infty} f(x,v) \le n_\infty P < 0,$$

contradicting $f > 0$ for all (x,v), $x \ge 0$.

Similarly, if $n_\infty > 1$, then take $g = n_\infty P - f$. Then, $g(x,v) < n_\infty P(v)$ and $\langle vg\rangle = 0$. Hence,

$$\lim_{x\to\infty}(n_\infty P - f) \le 0, \tag{3.54}$$

or equivalently,

$$n_\infty P(v) \le \lim_{x\to\infty} f(x,v) \le P(v),$$

which implies $n_\infty \le 1$, contradicting the assumption. Then (3.53) holds, so Theorem 6 is proven. ∎

Completion of Theorem 1. If $n_\infty < 1$, then, from Theorems 5 and 6,

$$\lim_{x\to\infty} f(x,v) = Kn_\infty P(v),$$

where n_∞ is the fraction of the first moment of $\frac{f}{K}$ with respect to the first moment of P. And, if $n_\infty = 1$ or, equivalently, $\langle v(K\,P - f)\rangle = 0$, one gets, as in (3.54), $0 \le \lim_{x\to\infty}(K\,P - f) \le 0$, since, by the existence, also $0 \le K\,P - f$. Hence

$$\lim_{x\to\infty} f(x,v) = K\,P(v).$$

The proof of Theorem 1 is now completed. □

As a corollary to Theorem 1 we have the following.

COROLLARY 2. *Assume that $E > 0$ and that $k(v) = n_\infty P(v)$. Then the unique solution of* (2.6) *is $n_\infty P(v)$.*

3.3. The Milne problem for strong negative forces. The aim of this subsection is the proof of Theorem 2. In the negative electric field case, we have proven that the upper and lower solutions coincide. This means that *the* solution of (2.6) can be obtained by solving a truncated problem (3.6) with $k_1 = k$ and k_2 arbitrary, the limit as L tends to $+\infty$ being only dependent on k. For positive electric fields, this will not be the case, and the solution *does* depend on the boundary condition k_2.

Proof of Theorem 2. We first proceed with the construction of a solution with the given asymptotic behavior; that is, we construct a solution f of (2.6) which behaves like $n_\infty P_{\sigma,E}(v)$ as x tends to $+\infty$. It is natural to consider the truncated problem

$$\begin{cases} v\partial_x f_L + E\partial_v f_L = Q(f_L)(x,v), \\ f_L(0,v) = k(v) \text{ for } v > 0, \\ f_L(L,v) = n_\infty P(v) \text{ for } v < 0. \end{cases} \tag{3.55}$$

Since $0 \le k(v) \le KP(v)$, the maximum principle insures that $0 \le f_L \le K_2 P$, where $K_2 = \max(n_\infty, K)$. Therefore, up to the extraction of a subsequence, f_L converges in L^∞_{loc} weak star towards a solution f of (2.6). Of course, since the convergence is only local in x, we cannot say anything at the moment about the asymptotic behavior of f. This is the purpose of the next step.

To analyze the asymptotic behavior, we consider the following truncated solutions:

$$\begin{cases} v\partial_x f^1_L + E\partial_v f^1_L = Q(f^1_L)(x,v), \\ f^1_L(0,v) = 0 \text{ for } v > 0, \\ f^1_L(L,v) = n_\infty P(v) \text{ for } v < 0, \end{cases} \tag{3.56}$$

$$\begin{cases} v\partial_x f^2_L + E\partial_v f^2_L = Q(f^2_L)(x,v), \\ f^2_L(0,v) = KP(v) \text{ for } v > 0, \\ f^2_L(L,v) = n_\infty P(v) \text{ for } v < 0. \end{cases} \tag{3.57}$$

Obviously, $f^1_L \le f_L \le f^2_L$. Considering the limits f^1 and f^2 of f^1_L and f^2_L, we have

$$f^1 \le f \le f^2.$$

Moreover,

$$f^2 = KP + \left(1 - \frac{K}{n_\infty}\right) f^1. \tag{3.58}$$

Besides, Proposition 1 insures that f^1 is increasing with respect to x. This implies the existence of α such that

$$\lim_{x\to+\infty} f_1(x,v) = \alpha P_{\sigma,E}(v).$$

It is enough to prove that $\alpha = n_\infty$, because (3.58) implies that f_2 also converges towards $n_\infty P$. Since f is sandwiched between f_1 and f_2, this implies that

$$\lim_{x\to+\infty} f(x,v) = n_\infty P_{\sigma,E}(v).$$

Let us now prove that $\alpha = n_\infty$. To this aim, we invert the x-axis direction by setting

$$g_L^1(x,v) = f_L^1(L-x,-v).$$

This function satisfies the equation

$$\text{(3.59)} \qquad \begin{cases} v\partial_x g_L^1 - E\partial_v g_L^1 = \widehat{Q}(g_L^1)(x,v), \\ g_L^1(0,v) = n_\infty P_{\widehat{\sigma},-E} \text{ for } v>0, \\ g_L^1(L,v) = 0 \text{ for } v<0, \end{cases}$$

where

$$\widehat{Q}(g)(v) = \int \widehat{\sigma}(v,v')(Mf' - M'f)dv', \qquad \widehat{\sigma}(v,v') = \sigma(-v,-v'),$$

and where we have noticed that

$$P_{\widehat{\sigma},-E}(v) = P_{\sigma,E}(-v).$$

With this transformation, we have replaced the electric field E by $-E$, and we are back to the positive force case. We know from Corollary 2 that the limit of $g_L^1(x,v)$ as L tends to $+\infty$ is nothing but $n_\infty P_{\widehat{\sigma},-E}(v)$. Therefore, we can pass to the limit in the current and get

$$\lim_{L\to+\infty} \langle v g_L^1\rangle = n_\infty \langle v P_{\widehat{\sigma},-E}\rangle = -n_\infty \langle v P_{\sigma,E}\rangle.$$

On the other hand, $\langle v g_L\rangle = -\langle v f_L^1\rangle$, which leads to

$$\lim_{L\to+\infty} \langle v g_L^1\rangle = -\langle v f^1\rangle = -\alpha \langle v P_{\sigma,E}\rangle.$$

As a consequence, $\alpha = n_\infty$, which is the desired result.

The proof of uniqueness is identical to that of Lemma 2 where the truncated case is considered. The details are left to the reader.

The proof of Theorem 2 is completed. ∎

4. A numerical method. As explained in the introduction, for the purpose of finding boundary or transition conditions we are interested only in the asymptotic state n_∞ and in the reflected density $f(0,v)$, $v<0$, of (2.6). In this section we will describe an approximation procedure to compute these values in the case of a relaxation collision operator.

Part of the motivation for studying this problem is that a direct discretization method to solve the half space problem is, in general, costly. The idea behind the method presented here is to solve the macroscopic equations associated with (2.6) and its adjoint equation and to use a Chapman–Enskog–type expansion as an approximate solution, which in the case of relaxation is an exact calculation where diffusion and transport coefficients depend explicitly on the force field E, via the moments of the distribution P, as shown in (2.17).

4.1. Computation of the asymptotic states. We consider the half space equation (2.6) in the relaxation case:

$$v\partial_x f + E\partial_v f = Q(f) = \langle f\rangle M - f, \qquad f(0,v) = k(v), \quad v > 0, \tag{4.1}$$

with $x \in [0,\infty)$ and $E > 0$ a constant. Due to Theorem 1 we have a unique solution f with $\lim_{x\to\infty} f(x,v) = n_\infty P(v)$, where P is the solution of (2.7). Our aim is to determine an accurate and efficient approximation of n_∞.

In addition to (4.1) we consider the corresponding adjoint equation using the weighted inner product $\langle fgP^{-1}\rangle$. It is given by

$$-v\partial_x g - P\partial_v(EgP^{-1}) = Q(gP^{-1}M)M^{-1}P. \tag{4.2}$$

Boundary conditions are

$$g(0,v) = 0, \quad v < 0.$$

A change of variables $v \to -v$ gives the equivalent equation

$$v\partial_x g + E\tilde{P}\partial_v(g\tilde{P}^{-1}) = Q(g\tilde{P}^{-1}M)M^{-1}\tilde{P}, \qquad g(0,v) = 0, \quad v > 0, \tag{4.3}$$

with $\tilde{P}(v) = P(-v)$.

This system is a particular case of the nonhomogeneous problem

$$v\partial_x g + E\tilde{P}\partial_v(g\tilde{P}^{-1}) = Q(g\tilde{P}^{-1}M)M^{-1}\tilde{P}, \qquad g(0,v) = k(v), \quad v > 0. \tag{4.4}$$

For this problem, we can prove the following theorem.

THEOREM 7. (i) *If $E < 0$ and $|k(v)| \le K\tilde{P}(v)$ for some constant K, then (4.4) has a unique solution such that $g/\tilde{P} \in L^\infty(\mathcal{R}_x^+ \times \mathcal{R}_v)$. This solution satisfies $|g(x,v)| \le K\tilde{P}(v)$.*

(ii) *If $E > 0$ and $|k(v)| \le K\tilde{P}(v)$ for some constant K, then, for any $j \in \mathcal{R}$, there exists a unique solution g of (4.4) such that $g\tilde{P} \in L^\infty(\mathcal{R}_x^+ \times \mathcal{R}_v)$ and $\int_{\mathcal{R}} vg(x,v)\,dv = j$. This unique solution is also characterized by the condition*

$$\lim_{x\to+\infty} g(x,v) = \frac{j}{\int v\tilde{P}\,dv}\,\tilde{P},$$

and g determines $n_\infty = \langle vf\rangle/\langle vP\rangle$ by

$$n_\infty = \int_{v>0} vk(v)g(0,v)P^{-1}(v)dv, \tag{4.5}$$

which is approximated by

$$n_\infty = \frac{\langle vk\rangle_+}{\langle vP\rangle_+} + \frac{\langle vP\rangle_-}{\langle vP\rangle\left\langle \frac{v}{1+Ev}P\right\rangle_+}\left(\left\langle \frac{v}{1+Ev}\left(k - \frac{\langle vk\rangle_+}{\langle vP\rangle_+}P\right)\right\rangle_+\right). \tag{4.6}$$

Proof. The proof of this theorem follows the same strategy as the proof of Theorems 1 and 2. We shall not redo this proof since it relies on exactly the same strategy, and we will give only some hints.

The first brick of the proof is the study of the homogeneous-in-x problem. It is clear that $\tilde{P}$ is a solution of

$$E\tilde{P}\partial_v(g\tilde{P}^{-1}) = Q(g\tilde{P}^{-1}M)M^{-1}\tilde{P}. \tag{4.7}$$

Actually, any solution g such that $g/\tilde{P} \in L^\infty$ is a multiple of $\tilde{P}$. Indeed, it is enough to prove that a solution g of (4.7) such that $\int g\,dv = 0$ is nothing but the identically vanishing function: to this end, we consider a function h which solves $E\partial_v h + Q(h) = g$. Such a solution exists since $\int g\,dv = 0$ (see [30]). Multiplying (4.7) by $h/\tilde{P}$ and integrating leads to $\int g^2\tilde{P}^{-1}\,dv = 0$.

The second property to be noticed is that $\int v\tilde{P}\,dv$ and E have opposite signs. This is why the sign of E is inverted in Theorem 7. With these remarks, one can reproduce the proofs of subsections 3.1 and 3.3 as well as the proof of Theorem 4 (subsection 3.2). We conjecture that the results of subsection 3.2 can be translated to the adjoint problem (4.4). This would imply that, in the case $E < 0$, the unique solution converges as x tends to $+\infty$ towards a multiple of $\tilde{P}$.

Let us now solve (4.3) approximately by proceeding similarly to the Chapman–Enskog expansion method. We recall that $E > 0$ in this section, so that $\langle vg\rangle$ has to be prescribed. Since the problem is linear, the solution is given up to a multiplication factor, and we choose g such that

$$\langle vg\rangle = -1.$$

The first step of the approximate resolution of (4.3) is to introduce a diffusion approximation: introducing an artificial small parameter δ, we consider

$$v\partial_x g + E\tilde{P}\partial_v(g\tilde{P}^{-1}) = \frac{1}{\delta}Q(g\tilde{P}^{-1}M)M^{-1}\tilde{P}. \tag{4.8}$$

Using the series expansion

$$g = g^0 + \delta g^1 + \cdots$$

in (4.8) and collecting terms of equal order in δ gives to $O(1)$

$$Q(g^0\tilde{P}^{-1}M) = 0$$

or

$$g^0 = \rho\tilde{P}. \tag{4.9}$$

To $O(\delta)$ we have

$$g^1 = M^{-1}\tilde{P}Q^{-1}\left[M\tilde{P}^{-1}(v\partial_x g^0 + E\tilde{P}\partial_v(g^0\tilde{P}^{-1}))\right].$$

Using (4.9) and $Q(vM) = -vM$, one obtains

$$g^1 = -v\tilde{P}\partial_x\rho.$$

The solvability conditions for the $O(\delta^2)$-equations give

$$\partial_x \langle v g^1 M \tilde{P}^{-1} \rangle + E \langle M \partial_v (g^1 \tilde{P}^{-1}) \rangle = 0.$$

Using the special form of g^1, this yields

$$\partial_x^2 \langle v^2 M \rangle \rho + E \partial_x \langle M \rangle \rho = 0$$

or the following equation for ρ:

$$\partial_x^2 \rho + E \partial_x \rho = 0. \tag{4.10}$$

Equation (4.10) is the drift-diffusion equation associated to the kinetic half space equation (4.2). We note that this is in contrast to (4.1). In this case the associated drift-diffusion equation is $\partial_x^2 \rho - E \partial_x \rho = 0$. The solution of (4.10) can be determined exactly up to two parameters:

$$\rho(x) = A e^{-Ex} + B, \quad \text{where} \quad A, B \in \mathcal{R}.$$

Next we compute an approximation $\hat{g}$ of g solving the following equation:

$$\begin{aligned} v \partial_x \hat{g} + E \tilde{P} \partial_v (\hat{g} \tilde{P}^{-1}) &= \rho \tilde{P} - \hat{g}, \\ \hat{g}(0, v) &= 0, \quad v > 0. \end{aligned} \tag{4.11}$$

This equation has been obtained from (4.3) by substituting the first order approximation $\rho \tilde{P}$ for g in $\langle g \tilde{P}^{-1} M \rangle$ into (4.3), where ρ is determined from the drift-diffusion equation (4.10). Notice that $\langle v \hat{g} \rangle$ is no longer independent of x. Now (4.11) can be further simplified by using the above approximation also in those terms in (4.11) involving E. One obtains

$$\begin{aligned} v \partial_x \hat{g} &= \rho(x) \tilde{P} - \hat{g}, \\ \hat{g}(0, v) &= 0, \quad v > 0. \end{aligned} \tag{4.12}$$

The solution of (4.12) can be given explicitly. Assuming boundedness at infinity of the solution, we get

$$\hat{g}(x, v) \tilde{P}^{-1} = \begin{cases} \dfrac{A}{1 - Ev} (e^{-Ex} - e^{-\frac{x}{v}}) + B(1 - e^{-\frac{x}{v}}), & v > 0, \\ \dfrac{A}{1 - Ev} e^{-Ex} + B\,, & v < 0. \end{cases}$$

In particular, $g(\infty, v) = B \tilde{P}$ and

$$\hat{g}(0, v) \tilde{P}^{-1} = \begin{cases} 0, & v > 0, \\ \dfrac{A}{1 - Ev} + B\,, & v < 0. \end{cases}$$

We determine A and B by

$$\left\langle v \begin{Bmatrix} \hat{g}(\infty, v) \\ \hat{g}(0, v) \end{Bmatrix} \right\rangle = -1,$$

the closest analogue to $\langle v g \rangle = -1$. This yields

$$B = -\frac{1}{\langle v \tilde{P} \rangle} = \frac{1}{\langle v P \rangle}$$

and

$$A = \frac{1}{\langle vP\rangle}\frac{\langle vP\rangle_-}{\langle \frac{v}{1+Ev}P\rangle_+}.$$

Here and in the following we use the notation

$$\langle f\rangle_+ = \int_{v>0} f(v)dv, \qquad \langle f\rangle_- = \int_{v<0} f(v)dv.$$

We mention that the g- approximation can be iterated considering the equation for the remaining term $g - \hat{g}$ instead of (4.3) and proceeding as before. Now, one transforms backwards, $v \to -v$, to get the desired approximation of the solution g of (4.2).

The following observation is crucial for the whole scheme: if f is a solution of (4.1) and g one of (4.2),

$$\begin{aligned}
&\partial_x(\langle vf(x,v)g(x,v)P^{-1}\rangle)\\
&\quad = \langle v(\partial_x f)(x,v)g(x,v)P^{-1}\rangle + \langle v(\partial_x g)(x,v)f(x,v)P^{-1}\rangle\\
&\quad = \langle [Q(f) - E\partial_v f]gP^{-1}\rangle\\
&\qquad + \langle f[EgP^{-1}\partial_v P - E\partial_v g - Q(gP^{-1}M)M^{-1}P]P^{-1}\rangle.
\end{aligned}$$

Since

$$\begin{aligned}
\langle Q(f)gP^{-1}\rangle &= \langle Q(f)(gP^{-1}M)M^{-1}\rangle\\
&= \langle fQ(gP^{-1}M)M^{-1}PP^{-1}\rangle
\end{aligned}$$

and

$$\begin{aligned}
\langle E\partial_v f g P^{-1}\rangle &= -\langle Ef\partial_v(gP^{-1})\rangle\\
&= -E\langle f(\partial_v g)P^{-1}\rangle + E\langle fg\partial_v PP^{-2}\rangle,
\end{aligned}$$

we get

$$\partial_x(\langle vf(x,v)g(x,v)P^{-1}\rangle) = 0.$$

In other words, $\langle v\varphi gP^{-1}\rangle$ is an invariant in x. Using this invariant, we get

$$\langle vf(\infty,v)g(\infty,v)P^{-1}(v)\rangle = \langle vf(0,v)g(0,v)P^{-1}(v)\rangle,$$

and substituting gives

$$\langle vn_\infty g(\infty,v)\rangle = \int_{v>0} vk(v)g(0,v)P^{-1}(v)dv.$$

Or, with $\langle vg(x,v)\rangle = 1$,

$$n_\infty = \int_{v>0} vk(v)g(0,v)P^{-1}(v)dv,$$

and thus (4.5) holds. In addition, since

$$g(0,v) \sim \hat{g}(0,v),$$

$\hat{g}$ is given by

$$\hat{g}(0,v)P^{-1} = \begin{cases} \dfrac{A}{1+Ev} + B, & v > 0, \\ 0, & v < 0, \end{cases}$$

with A and B determined above.

Altogether, we obtain

$$n_\infty = \frac{\langle vk\rangle_+}{\langle vP\rangle_+} + \frac{\langle vP\rangle_-}{\langle vP\rangle \left\langle \frac{v}{1+Ev}P\right\rangle_+} \left(\left\langle \frac{v}{1+Ev}\left(k - \frac{\langle vk\rangle_+}{\langle vP\rangle_+}P\right)\right\rangle_+ \right), \tag{4.13}$$

and so (4.6) holds and the proof of the theorem is completed. □

Remark. If $k(v) = \lambda P(v)$, we obtain from the above formula the correct value $n_\infty = \lambda$.

Remark. For E tending to 0 we have

$$\frac{1}{1+Ev} \sim 1 - Ev \sim 1 - Ev + O(E^2).$$

Moreover, $P \to M$ as $E \to 0$. Thus, one obtains in the limit the same result as, for example, in [22], namely,

$$n_\infty = \frac{\langle vk\rangle_+}{\langle vM\rangle_+} + \left\langle v^2\left(k - \frac{\langle vk\rangle_+}{\langle vM\rangle_+}M\right)\right\rangle_+.$$

4.2. Computation of the Albedo operator. The outgoing density $f(0,v)$, $v < 0$, of (4.1) can be computed as follows. We proceed in a similar same way as before; however, now $f(\infty, v) = n_\infty$ is known. We start directly with (4.1).

The drift-diffusion equation for this equation is determined by the same procedure as above. One obtains $\partial_x^2\rho - E\partial_x\rho = 0$. Looking for solutions bounded at infinity, one obtains

$$\rho = B,$$

B a constant. Substituting as before $\rho P(v)$ for f in $E\partial_v f$ and $\langle f\rangle$ in (4.1) gives

$$v\partial_x\hat{f} = \rho P - \hat{f},$$
$$\hat{f}(0,v) = k(v),\ v > 0.$$

The solution is

$$\hat{f}(x,v) = \begin{cases} k(v)e^{-\frac{x}{v}} + B(1 - e^{-\frac{x}{v}})P(v), & v > 0, \\ BP(v), & v < 0. \end{cases}$$

In particular, one obtains

$$\hat{f}(\infty, v) = BP(v)$$

and therefore $B = n_\infty$. Moreover, $\hat{f}(0,v) = n_\infty P(v)$, $v < 0$. Again, considering the equation for the remainder term $f - \hat{f}$, one obtains a better approximation of the outgoing function.

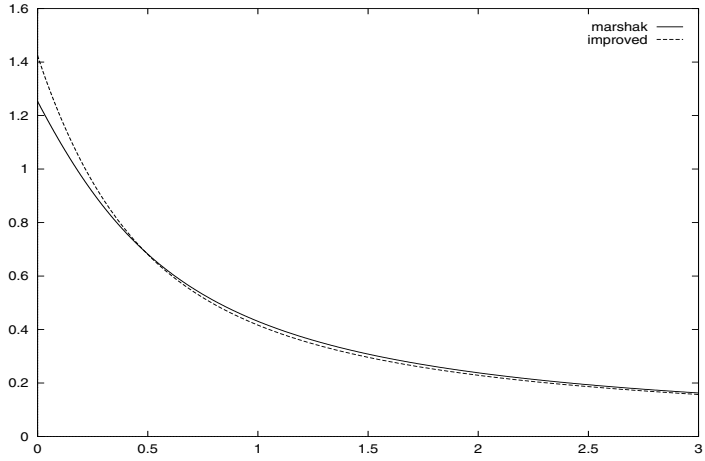

FIG. 1. *Asymptotic states for* $E \in [0, 3]$.

4.3. The Maxwell conditions. The following method was developed by Maxwell [27] and Marshak [26] (see also [6]) to derive approximate boundary conditions. In order to determine n_∞, one equalizes the half-fluxes at the boundary and at infinity, i.e.,

$$\int_{v>0} v\varphi(0,v)dv = \int_{v>0} v\varphi(\infty,v)dv,$$

which means in our context

$$n_\infty \int_{v>0} vP(v)dv = \int_{v>0} vk(v)dv$$

or

$$n_\infty = \frac{\langle vk\rangle_+}{\langle vP\rangle_+}. \tag{4.14}$$

This equality provides correct orders of magnitude in many situations. We observe that the value obtained by the procedure in section 4.1 obviously contains the term one obtains from the Marshak approximation (4.14). However, additionally, a correction term appears in (4.13). The Maxwell approximation of the outgoing distribution is simply

$$\varphi(0,v) = \varphi(\infty,v) = n_\infty P(v), \quad v < 0,$$

with n_∞ given by (4.14).

4.4. Numerical results. We used $k(v) = vM(v)$ to get in Figure 1 the asymptotic values for different values of the electric field $E > 0$. We computed these values by the approximations (4.14), labeled "marshak," and (4.13), labeled "variational." As E tends to 0 one obtains the same results as, for example, in [11, 22]: $n_\infty = 1.2533$ for the Maxwell–Marshak method and $n_\infty = 1.4245$ for the above approximation procedure, which is in case $E = 0$ equivalent to the so-called variational method; see, e.g., [25]. The true solution in this case is known: its numerical value is $n_\infty = 1.4371$.

DIFFUSIVE RELAXATION LIMIT OF MULTIDIMENSIONAL ISENTROPIC HYDRODYNAMICAL MODELS FOR SEMICONDUCTORS*

WEN-AN YONG†

Abstract. This work is concerned with multidimensional isentropic hydrodynamical models for semiconductors with short momentum relaxation time. With the help of the Maxwell iteration, we prove that, as the relaxation time tends to zero, periodic initial-value problems of a certain scaled hydrodynamical model have unique smooth solutions existing in the time interval where the classical drift-diffusion model has smooth solutions. Meanwhile, we justify a formal derivation of the latter from the former.

Key words. semiconductor models, diffusive relaxation limit, the Maxwell iteration, H^s-solutions, energy estimates

1. Introduction.

This work is concerned with the following scaled hydrodynamical model for semiconductors or plasmas:

$$\begin{aligned} &\partial_t n + \frac{1}{\epsilon}\operatorname{div}(nu) = 0,\\ &\partial_t(nu) + \frac{1}{\epsilon}\operatorname{div}(nu\otimes u) + \frac{1}{\epsilon}\nabla p(n) = \frac{n\nabla\phi}{\epsilon} - \frac{nu}{\epsilon^2},\\ &-\Delta\phi = \tilde{n}(x) - n. \end{aligned} \tag{1.1}$$

Here $n > 0, u$, and ϕ, as unknown functions of $(x,t) \in \mathbf{R}^d \times [0,+\infty)$ with $d \geq 1$, denote the electron density, velocity (d-vector), and electrostatic potential, respectively; $p = p(n)$ is a given strictly increasing function and denotes the pressure; $\tilde{n}(x)$ is the given background density of holes or ions; $\epsilon > 0$ is a parameter for the momentum relaxation time; and div, ∇, Δ, and $\otimes$ are the respective x-divergence operator, gradient operator, Laplacian, and symbol for the tensor products of two vectors. Note that the scaling

$$t = \epsilon\tilde{t}$$

converts (1.1) back into the original unipolar model in [1] with $\tilde{t}$ as its time variable. The scaled-time variable t was first introduced in [14] to study the relation between the hydrodynamical and drift-diffusion models [19, 18] (see (1.2) below).

It is known from [1, 16] that the hydrodynamical model describes some physical phenomena not accounted for in the classical drift-diffusion model. However, based on the previous results in [14, 6, 9] we expect that the two models give similar results

*Received by the editors May 8, 2003; accepted for publication (in revised form) October 24, 2003; published electronically July 2, 2004. when ϵ is small, which can be seen formally as follows. Applying the Maxwell iteration to the momentum equation in (1.1) gives

$$\begin{aligned} nu &= -\epsilon\nabla p(n) + \epsilon n\nabla\phi - \epsilon\,\mathrm{div}(nu\otimes u) - \epsilon^2\partial_t(nu)\\ &= -\epsilon\nabla p(n) + \epsilon n\nabla\phi + O(\epsilon^2). \end{aligned}$$

Substituting the truncation $nu = -\epsilon\nabla p(n) + \epsilon n\nabla\phi$ into the mass equation in (1.1), we arrive at the unipolar drift-diffusion model

$$\begin{aligned} \partial_t n &= \Delta p(n) - \mathrm{div}(n\nabla\phi),\\ -\Delta\phi &= \tilde{n}(x) - n. \end{aligned} \tag{1.2}$$

This is a parabolic-elliptic system, since $p(n)$ is strictly increasing.

The goal of this paper is to justify the above formal derivation of the drift-diffusion model for periodic IVPs (initial-value problems) with an emphasis on several space dimensions. For brevity, we deal with only the unipolar model (1.1). However, it is trivial to see that our arguments and results hold true for the bipolar model in [1, 16] and the hydrodynamical model for porous media discussed in [13].

In one space dimension, the above limit problem has been investigated by many authors in the compactness frameworks for nonsmooth solutions of conservation laws (see [14, 17, 6, 2, 3, 4]). However, the multidimensional limit problem is hardly studied in the literature, and [9, 8] are the only papers known to the author. In [9, 8], the authors considered (1.1) and the corresponding bipolar model with x in a bounded domain, assumed the existence of L^∞-solutions in an ϵ-independent time interval, and justified the relaxation limit in a compactness framework [13] for nonsmooth solutions.

In this paper, we revise the approach in [20] to study the multidimensional limit problem. Precisely, we assume that the drift-diffusion model (1.2) has a smooth solution (n,ϕ) with initial data $n(x,0) = n_0(x)$. Inspired by the Maxwell iteration above, we construct a formal approximation

$$n_\epsilon = n, \qquad n_\epsilon u_\epsilon = \epsilon n\nabla\phi - \epsilon\nabla p(n), \quad \phi_\epsilon = \phi \tag{1.3}$$

for the solution $(n^\epsilon, u^\epsilon, \phi^\epsilon)$ of (1.1) with initial data

$$n(x,0) = n_0(x), \qquad u(x,0) = \epsilon\nabla\phi(x,0) - \frac{\epsilon\nabla p(n_0)}{n_0}. \tag{1.4}$$

(Note that these initial data are in equilibrium.) Then we use energy methods to prove that $(n^\epsilon, u^\epsilon, \phi^\epsilon)$ exists in the finite time interval where n is well defined and can be expressed as

$$(n^\epsilon, u^\epsilon, \phi^\epsilon) = (n_\epsilon, u_\epsilon, \phi_\epsilon) + O(\epsilon^2) \tag{1.5}$$

in the Sobolev space $H^s(\mathbb{T}^d)$ with $s > d/2 + 1$. Furthermore, our conclusion implies that if the drift-diffusion model has a global smooth solution with n having a positive lower bound, then for any $T > 0$ there exists $\epsilon_0 > 0$ such that the hydrodynamical model has a unique smooth solution up to the time T when $\epsilon < \epsilon_0$. See Theorem 4.1 in section 4 for details.

Regarding the above result, we make the following remarks. First, (1.5) is more precise than the previous equations for weak solutions if the parabolic-elliptic system (1.2) has a smooth solution with n having a positive lower bound. For this assumption

about (1.2), the interested reader is referred to [5]. Second, it is not difficult to obtain results of the form (1.5) for more general periodic initial data by using the matched expansion method (see, e.g., [20, 10]) instead of the Maxwell iteration for the special data (1.4).

On the other hand, it does not seem easy to extend the above result for nonperiodic IVPs or initial-boundary value problems. In fact, when the initial data are not periodic, the Poisson equation for ϕ should be treated differently (see Proposition 2.1). And when initial-boundary value problems are concerned, new ideas are required to deal with the remaining (hyperbolic) part of the hydrodynamical model (1.1).

We note that, besides having the Poisson equation, the hydrodynamical models are essentially different from the hyperbolic systems studied in [10]. In fact, once the hydrodynamical models are rewritten as symmetrizable hyperbolic systems, the coefficients multiplying the spatial derivatives depend on the unknown in a stronger way than that in [10] (see Remark 2.1 in section 2). Because of this strong dependence, some key estimates in [10] have to be reconsidered, and our analysis depends heavily on the special nonlinear structure of the isentropic hydrodynamical models (see the proofs of Lemmas 4.2 and 4.3 in section 4).

Finally, let us mention that this work can be regarded as a contribution to the theory of diffusive limits for hyperbolic problems developed in [15]. Another limit problem for the hydrodynamical models is the large time behavior of the solutions [11], where stationary, instead of time-dependent, solutions of the drift-diffusion models are involved.

This paper is organized as follows. In section 2 we rewrite the hydrodynamical models as symmetrizable hyperbolic systems and review the convergence-stability lemma from [21]. Section 3 is devoted to the formal approximation (1.3). In section 4 we prove the validity of the formal approximation and conclude the existence of the solution to (1.1) in the time interval where n is well defined.

Notation. $|U|$ denotes some norm of a vector or matrix U. $L^2 = L^2(\mathbb{T}^d)$ is the space of square integrable (vector- or matrix-valued) functions on the d-dimensional unit torus $\Omega = (0,1]^d$. For a nonnegative integer s, $H^s = H^s(\mathbb{T}^d)$ is defined as the space of functions whose distribution derivatives of order $\le s$ are all in L^2. We use $\|U\|_s$ to denote the standard norm of $U \in H^s$, and $\|U\| \equiv \|U\|_0$. When A is a function of another variable t as well as x, we write $\|A(\cdot,t)\|_s$ to recall that the norm is taken with respect to x while t is viewed as a parameter. In addition, we denote by $C([0,T],\mathbf{X})$ (resp., $C^1([0,T],\mathbf{X})$) the space of continuous (resp., continuously differentiable) functions on $[0,T]$ with values in a Banach space $\mathbf{X}$.

2. Preliminaries. In this section, we write the hydrodynamical models as symmetrizable hyperbolic systems and review the convergence-stability lemma from [21]. To begin with, we recall the following elementary fact, which can be easily proven by using Fourier series.

PROPOSITION 2.1. *$\nabla\Delta^{-1}$ is a bounded linear operator on $L^2(\mathbb{T}^d)$.*

It is this proposition that requires the initial data to be periodic.

Now we write (1.1) as a symmetric hyperbolic system. To do this, we introduce the *enthalpy* $h = h(n) > 0$ defined for $n > 0$ and satisfying

$$h'(n) = \frac{p'(n)}{n}.$$

Since $p(n)$ is strictly increasing, so is $h(n)$. Thus, $h(n)$ has an inverse $n = n(h)$. Set

$$q(h) = p'(n(h)).$$

Then, for smooth solutions, (1.1) is equivalent to

$$\begin{gathered} q(h)^{-1}\left(\partial_t h+\frac{1}{\epsilon}u\cdot\nabla h\right)+\frac{1}{\epsilon}\operatorname{div}u=0,\\ \partial_t u+\frac{1}{\epsilon}u\cdot\nabla u+\frac{1}{\epsilon}\nabla h=\frac{\nabla\phi}{\epsilon}-\frac{u}{\epsilon^2},\\ -\Delta\phi=\tilde{n}(x)-n(h) \end{gathered} \tag{2.1}$$

or

$$\partial_t\begin{pmatrix}h\\u\end{pmatrix}+\frac{1}{\epsilon}\sum_{j=1}^{d}A_j(h,u)\partial_{x_j}\begin{pmatrix}h\\u\end{pmatrix}=\frac{1}{\epsilon^2}\begin{pmatrix}0\\\epsilon\nabla\Delta^{-1}(n(h)-\tilde{n})-u\end{pmatrix}. \tag{2.2}$$

Here the coefficients have the following structure:

$$\begin{gathered} A_j(h,u)=A_0^{-1}(h)C_j+u_jI_{d+1},\\ A_0(h)=\operatorname{diag}\left(\frac{1}{q(h)},I_d\right),\\ \text{each } C_j \text{ is a constant symmetric matrix,}\\ \text{and the first element } C_j^{11} \text{ in the first row of } C_j \text{ is zero,} \end{gathered} \tag{2.3}$$

where I_k denotes the unit matrix of order k and u_j is the jth component of u. Thus, (2.2) is a symmetrizable hyperbolic system with A_0 the symmetrizer.

Remark 2.1. Although (2.2) is of the form of the systems studied in [10], it is essentially different from them. In fact, a crucial assumption in [10] is that the coefficients A_j and the symmetrizer A_0 depend on the unknown $W\equiv(h,u)$ only through ϵW, that is, $A_j=A_j(\epsilon W)$ and $A_0=A_0(\epsilon W)$. This assumption is obviously not satisfied by our present system (2.2).

Thanks to Proposition 2.1, the local-in-time existence theory for periodic IVPs of first-order symmetrizable hyperbolic systems can be well applied to (2.2). Moreover, we recall the *convergence-stability lemma* in [21] for general singular limit problems of IVPs for quasi-linear first-order symmetrizable hyperbolic systems depending (singularly) on parameters in several space variables:

$$\begin{gathered} U_t+\sum_{j=1}^{d}A_j(U,\epsilon)U_{x_j}=Q(U,\epsilon),\\ U(x,0)=\bar{U}(x,\epsilon). \end{gathered} \tag{2.4}$$

Here ϵ represents a parameter in a topological space, $A_j(U,\epsilon)$ $(j=1,2,\dots,d)$ and $Q(U,\epsilon)$ are sufficiently smooth functions of $U\in G\subset\mathbf{R}^n$, and $\bar{U}(x,\epsilon)$ is a given initial-value function. For simplicity, we assume that $\bar{U}(x,\epsilon)$ is periodic in x with period $(1,1,\dots,1)\in\mathbf{R}^d$.

Assume $\bar{U}(x,\epsilon)\in G_0\subset\subset G$ for all (x,ϵ) and $\bar{U}(\cdot,\epsilon)\in H^s$ with $s>d/2+1$ an integer. Fix ϵ. According to the local existence theory for IVPs of symmetrizable hyperbolic systems (see Theorem 2.1 in [12]), there is a time interval $[0,T]$ so that (2.4) has a unique H^s-solution

$$U^\epsilon\in C([0,T],H^s).$$

Define

$$T_\epsilon = \sup\{T > 0 : U^\epsilon \in C([0,T], H^s)\}. \tag{2.5}$$

Namely, $[0, T_\epsilon)$ is the maximal time interval of H^s existence. Note that T_ϵ depends on G and may tend to zero as ϵ goes to a certain singular point, say 0.

In order to show that $\underline{\lim}_{\epsilon\to 0} T_\epsilon > 0$, which means the stability (see [7, 12]), we make the following assumption.

Convergence assumption. There exists $T_* > 0$ and $U_\epsilon \in L^\infty([0,T_*], H^s)$ for each ϵ, satisfying

$$\bigcup_{x,t,\epsilon} \{U_\epsilon(x,t)\} \subset\subset G,$$

such that for $t \in [0, \min\{T_*, T_\epsilon\})$,

$$\sup_{x,t} |U^\epsilon(x,t) - U_\epsilon(x,t)| = o(1),$$
$$\sup_t \|U^\epsilon(\cdot,t) - U_\epsilon(\cdot,t)\|_s = O(1)$$

as ϵ tends to the singular point.

With such a convergence assumption, we are in a position to state the following fact established in [21].

LEMMA 2.2. *Suppose $\bar{U}(x,\epsilon) \in G_0 \subset\subset G$ for all (x,ϵ), $\bar{U}(\cdot,\epsilon) \in H^s$ with an integer $s > d/2 + 1$, and that the convergence assumption holds. Let $[0, T_\epsilon)$ be the maximal time interval such that* (2.4) *has a unique H^s-solution $U^\epsilon \in C([0,T_\epsilon), H^s)$. Then*

$$T_\epsilon > T_*$$

for all ϵ in a neighborhood of the singular point.

Thanks to Lemma 2.2, our task is reduced to finding a $U_\epsilon(x,t)$ such that the convergence assumption holds. Below, we will use this lemma with G replaced by its compact subsets.

3. Formal approximations. In this section we propose a construction of the approximation U_ϵ in the convergence assumption for the hydrodynamical model (2.2). Let n solve the IVP of the unipolar drift-diffusion model (1.2) or

$$\begin{aligned} \partial_t n &= \Delta p(n) - \operatorname{div}(n\nabla\Delta^{-1}(n-\tilde{n})), \\ n(x,0) &= n_0(x). \end{aligned} \tag{3.1}$$

Inspired by the Maxwell iteration, we take

$$\begin{aligned} n_\epsilon &= n, \\ u_\epsilon &= \epsilon\nabla\Delta^{-1}(n-\tilde{n}) - \frac{\epsilon\nabla p(n)}{n}. \end{aligned} \tag{3.2}$$

Define

$$\begin{aligned} R = \frac{\partial_t u_\epsilon + u_\epsilon\cdot\nabla u_\epsilon/\epsilon}{\epsilon} &= \partial_t(\nabla\Delta^{-1}(n-\tilde{n}) - \nabla h) \\ &+(\nabla\Delta^{-1}(n-\tilde{n}) - \nabla h)\cdot\nabla(\nabla\Delta^{-1}(n-\tilde{n}) - \nabla h). \end{aligned} \tag{3.3}$$

Then we have

$$\partial_t n_\epsilon + \frac{1}{\epsilon}\operatorname{div}(n_\epsilon u_\epsilon) = 0,$$

$$\partial_t(n_\epsilon u_\epsilon) + \frac{1}{\epsilon}\operatorname{div}(n_\epsilon u_\epsilon \otimes u_\epsilon) + \frac{1}{\epsilon}\nabla p(n_\epsilon) = \frac{n_\epsilon \nabla\Delta^{-1}(n_\epsilon - \tilde{n})}{\epsilon} - \frac{n_\epsilon u_\epsilon}{\epsilon^2} + \epsilon n_\epsilon R,$$

or

$$\begin{aligned} q(h_\epsilon)^{-1}\left(\partial_t h_\epsilon + \frac{1}{\epsilon}u_\epsilon\cdot\nabla h_\epsilon\right) + \frac{1}{\epsilon}\operatorname{div} u_\epsilon &= 0, \\ \partial_t u_\epsilon + \frac{1}{\epsilon}u_\epsilon\cdot\nabla u_\epsilon + \frac{1}{\epsilon}\nabla h_\epsilon &= \frac{\nabla\Delta^{-1}(n_\epsilon - \tilde{n})}{\epsilon} - \frac{u_\epsilon}{\epsilon^2} + \epsilon R. \end{aligned} \tag{3.4}$$

Regarding (n_ϵ, u_ϵ), we have the following regularity result.

LEMMA 3.1. *Let $s > d/2$ be an integer. Assume $p \in C^\infty(0,\infty)$ and $p'(n) > 0$. If $n \in C([0,T_*], H^s) \cap C^1([0,T_*], H^{s-1})$ has a positive lower bound, then so does $h = h(n)$. Moreover, if $\tilde{n} \in H^{s-1}$, then $u_\epsilon \in C([0,T_*], H^{s-1}) \cap C^1([0,T_*], H^{s-2})$ and $R \in C([0,T_*], H^{s-2})$ in case $s > d/2 + 1$.*

The proof of this lemma is based on the well-known calculus inequalities in Sobolev spaces, which we state here for further reference and for the convenience of the reader.

LEMMA 3.2 (see, e.g., [12]). *Let s, s_1, and s_2 be three nonnegative integers and $s_0 = [d/2] + 1$.*

1. *If $s_3 = \min\{s_1, s_2, s_1 + s_2 - s_0\} \geq 0$, then $H^{s_1}H^{s_2} \subset H^{s_3}$. Here the inclusion symbol $\subset$ implies the continuity of the embedding.*

2. *Suppose $s \geq s_0 + 1$, $A \in H^s$, and $U \in H^{s-1}$. Then for all multi-indices α with $|\alpha| \leq s$, $\partial^\alpha(AU) - A\partial^\alpha U \in L^2$ and*

$$\|\partial^\alpha(AU) - A\partial^\alpha U\| \leq C_s\|A\|_s\|U\|_{|\alpha|-1}.$$

3. *Suppose $s \geq s_0$, $A \in C_b^s(G)$, and $V \in H^s(\Omega, G)$. Then $A(V(\cdot)) \in H^s$ and*

$$\|A(V(\cdot))\|_s \leq C_s|A|_s(1 + \|V\|_s^s).$$

Here and below, C_s denotes a generic constant depending only on s and d, and $|A|_s$ stands for $\sup_{\{U\in G, |\alpha|\leq s\}} |\partial_U^\alpha A(U)|$.

4. The main result. Having constructed the formal approximation (n_ϵ, u_ϵ) for the periodic IVP of the hydrodynamical model (2.2), we prove here the validity of the approximation under some regularity assumptions on the given data and an existence result for the IVP. The main result of this paper is stated as follows.

THEOREM 4.1. *Let $s > d/2 + 1$ be an integer. Suppose $p \in C^\infty(0,+\infty)$, $p'(n) > 0$, $\tilde{n} \in H^s(\mathbf{R}^d)$, and that the drift-diffusion model (3.1) has a solution $n \in C([0,T_*], H^{s+2}) \cap C^1([0,T_*], H^{s+1})$ with a positive lower bound.*

Then, for ϵ sufficiently small, the hydrodynamical model (2.2) with periodic initial data

$$\begin{aligned} h(x,0) &= h(n(x,0)), \\ u(x,0) &= \epsilon\nabla\Delta^{-1}(n(x,0) - \tilde{n}) - \frac{\epsilon\nabla p(n(x,0))}{n(x,0)} \end{aligned} \tag{4.1}$$

has a unique solution $(n^\epsilon, u^\epsilon) \in C([0,T_*], H^s)$, and there exists a constant $K > 0$, independent of ϵ but dependent on $T_* < \infty$, such that

$$\sup_{t\in[0,T_*]} \|(n^\epsilon - n_\epsilon, u^\epsilon - u_\epsilon)(\cdot,t)\|_s \leq K\epsilon^2. \tag{4.2}$$

Proof. Since $n \in C([0,T_*],H^{s+1})$ has a positive lower bound, there are two positive numbers a and b such that $h(n)$ takes values in $[2a,b]$. Denote by $[0,T_\epsilon)$ the maximal time interval where the symmetrizable hyperbolic system (2.2) with the initial data (4.1) has a unique H^s-solution (h^ϵ,u^ϵ) with values in $(a,2b)\times\mathbf{R}^d \equiv G$. Thanks to Lemma 2.2, it suffices to prove the error estimate in (4.2) for $t \in [0,\min\{T_*,T_\epsilon\})$.

To this end, we set

$$E = \begin{pmatrix} h_\epsilon - h^\epsilon \\ u_\epsilon - u^\epsilon \end{pmatrix} \equiv \begin{pmatrix} E^h \\ E^u \end{pmatrix}.$$

From the equations in (2.2) and (3.4) it follows that the error E satisfies

$$E_t + \frac{1}{\epsilon}\sum_{j=1}^d A_j(h^\epsilon,u^\epsilon)E_{x_j} = \frac{-1}{\epsilon^2}\begin{pmatrix} 0 \\ E^u \end{pmatrix} + \frac{1}{\epsilon}\begin{pmatrix} 0 \\ \nabla\Delta^{-1}(n(h_\epsilon)-n(h^\epsilon)) + \epsilon^2 R \end{pmatrix} + \frac{1}{\epsilon}\sum_{j=1}^d [A_j(h^\epsilon,u^\epsilon) - A_j(h_\epsilon,u_\epsilon)]\begin{pmatrix} h_{\epsilon x_j} \\ u_{\epsilon x_j} \end{pmatrix}.$$

We differentiate this equation with ∂^α (in x) for a multi-index α satisfying $|\alpha| \le s$ to get

$$E_{\alpha t} + \frac{1}{\epsilon}\sum_{j=1}^d A_j(h^\epsilon,u^\epsilon)E_{\alpha x_j} = \frac{-1}{\epsilon^2}\begin{pmatrix} 0 \\ E^u_\alpha \end{pmatrix} + F_1^\alpha + F_2^\alpha, \tag{4.3}$$

where

$$\begin{aligned} F_1^\alpha &= \frac{1}{\epsilon}\begin{pmatrix} 0 \\ \nabla\Delta^{-1}(n(h_\epsilon)-n(h^\epsilon)) + \epsilon^2 R \end{pmatrix}_\alpha, \\ F_2^\alpha &= \frac{1}{\epsilon}\sum_{j=1}^d \left([A_j(h^\epsilon,u^\epsilon) - A_j(h_\epsilon,u_\epsilon)]\begin{pmatrix} h_{\epsilon x_j} \\ u_{\epsilon x_j} \end{pmatrix}\right)_\alpha \\ &\quad + \frac{1}{\epsilon}\sum_{j=1}^d (A_j(h^\epsilon,u^\epsilon)E_{\alpha x_j} - (A_j(h^\epsilon,u^\epsilon)E_{x_j})_\alpha) \\ &\equiv f_1^\alpha + f_2^\alpha. \end{aligned}$$

For the sake of clarity, we divide the following arguments into lemmas.

LEMMA 4.2. *Under the conditions of Theorem* 4.1*, we have*

$$\frac{d}{dt}\int_\Omega e(E_\alpha)dx + \frac{2}{\epsilon^2}\|E^u_\alpha\|^2 \le 2\|E^u_\alpha\|\|F_1^\alpha\| + \frac{C}{\epsilon}\int_\Omega |\operatorname{div} u^\epsilon||E_\alpha|^2 dx + C\|E_\alpha\|\|F_2^\alpha\|.$$

Here $e(E_\alpha) = E_\alpha^* A_0(h^\epsilon,u^\epsilon)E_\alpha$, and C is a generic constant depending only on the range $[a,2b]$ of h^ϵ.

Proof. Since matrices $A_0^\epsilon \equiv A_0(h^\epsilon)$ and $A_0^\epsilon A_j^\epsilon \equiv A_0^\epsilon A_j(h^\epsilon,u^\epsilon)$ are symmetric, we

multiply (4.3) by $E_\alpha^* A_0^\epsilon$ to obtain

$$
\begin{aligned}
&e(E_\alpha)_t + \frac{1}{\epsilon}\sum_{j=1}^{d}(E_\alpha^* A_0^\epsilon A_j^\epsilon E_\alpha)_{x_j} \\
&\quad = \frac{-2}{\epsilon^2}\operatorname{Re} E_\alpha^* A_0^\epsilon \begin{pmatrix} 0 \\ E_\alpha^u \end{pmatrix} + 2\operatorname{Re} E_\alpha^* A_0^\epsilon F_1^\alpha \\
&\qquad + 2\operatorname{Re} E_\alpha^* A_0^\epsilon F_2^\alpha + E_\alpha^* \left\{ \frac{\partial}{\partial t} A_0^\epsilon + \frac{1}{\epsilon}\sum_{j=1}^{d} \frac{\partial}{\partial x_j}(A_0^\epsilon A_j^\epsilon) \right\} E_\alpha \\
&\quad \equiv I_1^\alpha + I_2^\alpha + I_3^\alpha + I_4^\alpha.
\end{aligned} \tag{4.4}
$$

Recall from (2.3) that

$$
A_0^\epsilon = \operatorname{diag}\left(\frac{1}{q(h^\epsilon)}, I_d \right).
$$

It is obvious that

$$
I_1^\alpha = -\frac{2}{\epsilon^2}|E_\alpha^u|^2 \quad \text{and} \quad I_2^\alpha \le 2|E_\alpha^u||F_1^\alpha|.
$$

On the other hand, since h^ϵ takes values in the compact set $[a, 2b]$, I_3^α is simply estimated as

$$
I_3^\alpha \le C|E_\alpha||F_2^\alpha|.
$$

Moreover, we use the relations in (2.3) and the h-equation in (2.1) to compute

$$
\begin{aligned}
&\partial_t A_0(h^\epsilon) + \frac{1}{\epsilon}\sum_{j=1}^{d} \partial_{x_j}(A_0(h^\epsilon)A_j(h^\epsilon, u^\epsilon)) \\
&\quad = A_0'(h^\epsilon)\left(\partial_t h^\epsilon + \frac{1}{\epsilon}\sum_{j=1}^{d} u_j^\epsilon \partial_{x_j} h^\epsilon \right) + \frac{1}{\epsilon}\sum_{j=1}^{d} \partial_{x_j} u_j A_0(h^\epsilon) \\
&\quad = \frac{\operatorname{div} u^\epsilon}{\epsilon}(A_0(h^\epsilon) - q(h^\epsilon)A_0'(h^\epsilon)).
\end{aligned}
$$

Thus, we have

$$
I_4^\alpha \le \frac{C|E_\alpha|^2|\operatorname{div} u^\epsilon|}{\epsilon}.
$$

Now we integrate (4.3) with respect to x over Ω and use the periodicity of the data to conclude the lemma. □

For the right-hand side of the inequality in Lemma 4.2, we have the following claim.

LEMMA 4.3. *Set*

$$
D = D(t) = \frac{\|E(\cdot, t)\|_s}{\epsilon}.
$$

Then, for $\epsilon < 1$,

$$
\begin{aligned}
|\operatorname{div} u^\epsilon| &\le C\epsilon + C\epsilon D,\\
\|E_\alpha^u\|\|F_1^\alpha\| &\le \frac{\|E_\alpha^u\|^2}{4\epsilon^2} + C\epsilon^4 + C(1+D^{2s})\|E^h\|_{|\alpha|}^2,\\
\|F_2^\alpha\| &\le \frac{C(1+D^s)\|E^u\|_{|\alpha|}}{\epsilon} + C(1+D^s)\|E\|_{|\alpha|}.
\end{aligned}
$$

Proof. Recall that

$$
u_\epsilon = \epsilon\nabla\Delta^{-1}(n-\tilde{n}) - \frac{\epsilon\nabla p(n)}{n}. \tag{4.5}
$$

Thus, for $s > s_0 = [d/2]+1$, we use the well-known embedding inequality to obtain

$$
|\operatorname{div} u^\epsilon| \le C\|\operatorname{div} u^\epsilon\|_{s_0} \le C\|\operatorname{div} u_\epsilon\|_{s_0} + C\|\operatorname{div}(u^\epsilon - u_\epsilon)\|_{s_0} \le C\epsilon + \epsilon D.
$$

Next we estimate $\|E_\alpha^u\|\|F_1^\alpha\|$. Since

$$
n(h_\epsilon) - n(h^\epsilon) = E^h \int_0^1 n'(h^\epsilon + \sigma E^h)d\sigma
$$

and the convexity of $[a, 2b]$ gives

$$
h^\epsilon(x,t) + \sigma E^h(x,t) = (1-\sigma)h^\epsilon + \sigma h_\epsilon \in [a, 2b]
$$

for all $(x,t,\sigma) \in \Omega \times [0, \min\{T_\epsilon, T_*\}) \times [0,1]$ and $\epsilon > 0$, it follows from Lemma 3.2 that

$$
\begin{aligned}
\|(n(h^\epsilon + E^h) - n(h^\epsilon))_\alpha\| &\le C\|E^h\|_{|\alpha|}\left\|\int_0^1 n'(h^\epsilon + \sigma E^h)d\sigma\right\|_s\\
&\le C\|E^h\|_{|\alpha|}\int_0^1 \|n'(h^\epsilon + \sigma E^h)\|_s d\sigma\\
&\le C\|E^h\|_{|\alpha|}\int_0^1 (1 + \|h^\epsilon + \sigma E^h\|_s^s)d\sigma\\
&\le C\|E^h\|_{|\alpha|}(1 + \|E^h\|_s^s) \le C\|E^h\|_{|\alpha|}(1+D^s).
\end{aligned} \tag{4.6}
$$

Here the last inequality has used $h^\epsilon + \sigma E^h = (\sigma-1)E^h + h_\epsilon$ and the boundedness of $\|h_\epsilon\|_s = \|h(n)\|_s$ indicated in Lemma 3.1. Thus, we deduce from Proposition 2.1 that

$$
\begin{aligned}
\|E_\alpha^u\|\|F_1^\alpha\| &\le \frac{\|E_\alpha^u\|}{\epsilon}(\epsilon^2\|R_\alpha\| + \|\nabla\Delta^{-1}(n(h_\epsilon) - n(h^\epsilon))_\alpha\|)\\
&\le \frac{\|E_\alpha^u\|}{\epsilon}(C\epsilon^2 + C\|(n(h_\epsilon) - n(h^\epsilon))_\alpha\|)\\
&\le \frac{\|E_\alpha^u\|^2}{4\epsilon^2} + C\epsilon^4 + C(1+D^{2s})\|E^h\|_{|\alpha|}^2.
\end{aligned}
$$

Now we turn to estimate $\|F_2^\alpha\| \le \|f_1^\alpha\| + \|f_2^\alpha\|$ with the help of Lemma 3.2. For f_1^α, from (2.3) we have

$$
A_j^\epsilon - A_j(h_\epsilon, u_\epsilon) = (u_j^\epsilon - u_{j\epsilon})I_{d+1} + ((A_0^\epsilon)^{-1} - A_0^{-1}(h_\epsilon))C_j.
$$

Since $C_j^{11} = 0$ as in (2.3) and $(A_0^\epsilon)^{-1} - A_0^{-1}(h_\epsilon) = \mathrm{diag}(q(h^\epsilon) - q(h_\epsilon), 0)$, it is clear that

$$((A_0^\epsilon)^{-1} - A_0^{-1}(h_\epsilon))C_j(h_\epsilon, u_\epsilon)^T = (q(h^\epsilon) - q(h_\epsilon))O(|u_\epsilon|).$$

Note that

$$\|q(h_\epsilon) - q(h^\epsilon)\|_{|\alpha|} \le C\|E^h\|_{|\alpha|}(1 + D^s)$$

can be proved in the same fashion as that used for (4.6). Thus, we use Lemma 3.2, the boundedness of $\|(h_\epsilon, u_\epsilon)(\cdot, t)\|_{s+1}$ indicated in Lemma 3.1, and (4.5) to conclude that

$$\begin{aligned}\epsilon\|f_1^\alpha\| &\le C\sum_j \|(h_\epsilon, u_\epsilon)_{x_j}\|_s\|u_j^\epsilon - u_{j\epsilon}\|_{|\alpha|} + C\sum_j \|q(h^\epsilon) - q(h_\epsilon)\|_{|\alpha|}\|u_{\epsilon x_j}\|_s \\ &\le C\|E^u\|_{|\alpha|} + C\epsilon(1 + D^s)\|E^h\|_{|\alpha|}.\end{aligned}$$

In the similar spirit, we estimate f_2^α. Since

$$\epsilon f_2^\alpha = \sum_{j=1}^d (u_j^\epsilon E_{\alpha x_j} - (u_j^\epsilon E_{x_j})_\alpha) + \sum_{j=1}^d ((A_0^\epsilon)^{-1}C_j E_{\alpha x_j} - ((A_0^\epsilon)^{-1}C_j E_{x_j})_\alpha)$$

due to (2.3), f_2^α can be bounded as

$$\begin{aligned}\epsilon\|f_2^\alpha\| &\le C\sum_{j=1}^d \|u_j^\epsilon\|_s\|E_{x_j}\|_{|\alpha|-1} + C\sum_{j=1}^d \|q(h^\epsilon)\|_s\|E_{x_j}^u\|_{|\alpha|-1} \\ &\le C(\|u^\epsilon - u_\epsilon\|_s + \|u_\epsilon\|_s)\|E\|_{|\alpha|} + C(1 + \|h^\epsilon\|_s^s)\|E^u\|_{|\alpha|} \\ &\le C\epsilon(1 + D)\|E\|_{|\alpha|} + C(1 + D^s)\|E^u\|_{|\alpha|}.\end{aligned}$$

Hence the estimate on $\|F_2^\alpha\|$ is obtained by putting the above together. This completes the proof. □

Substituting the estimates in Lemma 4.3 into the inequality in Lemma 4.2 yields

$$\frac{d}{dt}\int_\Omega e(E_\alpha)dx + \frac{1}{\epsilon^2}\|E_\alpha^u\|^2 \le C\epsilon^4 + C(1 + D^{2s})\|E\|_{|\alpha|}^2. \tag{4.7}$$

Note that $C^{-1}|E_\alpha|^2 \le e(E_\alpha) \le C|E_\alpha|^2$. We integrate (4.7) from 0 to T with $[0, T] \subset [0, \min\{T_\epsilon, T_*\})$ to obtain

$$\|E_\alpha(T)\|^2 + \frac{1}{\epsilon^2}\int_0^T \|E_\alpha^u(t)\|^2 dt \le CT\epsilon^4 + \int_0^T C(1 + D^{2s})\|E(t)\|_{|\alpha|}^2 dt.$$

Here we have used the fact that the initial data are in equilibrium. Summing up the last inequality over all α satisfying $|\alpha| \le s$, we get

$$\|E(T)\|_s^2 + \frac{1}{\epsilon^2}\int_0^T \|E^u(t)\|_s^2 dt \le CT_*\epsilon^4 + C\int_0^T (1 + D^{2s})\|E(t)\|_s^2 dt. \tag{4.8}$$

We apply Gronwall's lemma to (4.8) to get

$$\|E(T)\|_s^2 \le CT_*\epsilon^4 \exp\left[C\int_0^T \left(1 + D^{2s}\right) dt\right]. \tag{4.9}$$

Since $\|E\|_s = \epsilon D$, it follows from (4.9) that

$$D(T)^2 \le CT_*\epsilon^2 \exp\left[C\int_0^T \left(1 + D^{2s}\right) dt\right] \equiv \Phi(T). \tag{4.10}$$

Thus,

$$\Phi'(t) = C(1 + D^{2s})\Phi(t) \le C\Phi(t) + C\Phi^{s+1}(t).$$

Applying the nonlinear Gronwall-type inequality in [20] to the last inequality yields

$$\Phi(t) \le e^{CT*}$$

for $t \in [0, \min\{T_\epsilon, T_*\})$ if we choose ϵ so small that

$$\Phi(0) = CT_*\epsilon^2 < e^{-CT*}.$$

Because of (4.10), there exists a constant c, independent of ϵ, such that

$$D(T) \le c \tag{4.11}$$

for any $T \in [0, \min\{T_\epsilon, T_*\})$. Finally, the theorem is concluded from (4.9) with (4.11). This completes the proof. □

SINGULAR INTEGRALS, IMAGE SMOOTHNESS, AND THE RECOVERY OF TEXTURE IN IMAGE DEBLURRING*

ALFRED S. CARASSO†

Abstract. Total variation (TV) image deblurring is a PDE-based technique that preserves edges, but often eliminates vital small-scale information, or *texture*. This phenomenon reflects the fact that most natural images are not of bounded variation. The present paper reconsiders the image deblurring problem in Lipschitz spaces $\Lambda(\alpha, p, q)$, wherein a wide class of nonsmooth images can be accommodated. A new and fast FFT-based deblurring method is developed that can recover texture in cases where TV deblurring fails completely. Singular integrals, such as the Poisson kernel, are used to create an effective new image analysis tool that can calibrate the lack of smoothness in an image. It is found that a rich class of images $\in \Lambda(\alpha, 1, \infty) \cap \Lambda(\beta, 2, \infty)$, with $0.2 < \alpha,\ \beta < 0.7$. The Poisson kernel is then used to regularize the deblurring problem by appropriately constraining its solutions in $\Lambda(\alpha, 2, \infty)$ spaces, leading to new L^2 error bounds that substantially improve on the Tikhonov–Miller method. This so-called *Poisson Singular Integral* or *PSI* method is only one of an infinite variety of singular integral deblurring methods that can be constructed. The method is found to be well-behaved in both the L^1 and L^2 norms, producing results closely matching those obtained in the theoretically optimal, but practically unrealizable, case of true Wiener filtering. Deblurring experiments on synthetically defocused images illustrate the PSI method's very significant improvements over both the total variation and Tikhonov–Miller methods. In addition, successful reconstructions with *inexact* prior Lipschitz space information, highlight the robustness and practicality of the PSI method.

1. Introduction.

The space $BV(R^2)$ of functions of bounded variation, normed by the "total variation" seminorm $\int_{R^2} |\nabla f| dxdy$, plays an important role in much recent work in image analysis. See, e.g., [11], [13], [14], [15], [16], [20], [21], [26], [33], and [39]. In particular, highly successful applications of the total variation approach to image denoising have been well-documented. In contrast, total variation image deblurring is generally not well-behaved, and often results in unacceptable loss of fine scale information. This phenomenon is now believed traceable to an improper choice of function space [24]. The present paper reconsiders the image deblurring problem in Lipschitz spaces $\Lambda(\alpha, p, q)$, wherein a wide class of nonsmooth images can be accommodated. A new and fast FFT-based deblurring technique is developed that can demonstrably recover texture in cases where total variation deblurring fails completely. The approximation properties of certain singular integral operators are intimately linked to such Lipschitz spaces [3], [4], [36]. Here, these properties are

†Mathematical and Computational Sciences Division, National Institute of Standards and Technology, Gaithersburg, MD 20899 (alfred.carasso@nist.gov).

exploited in two distinct ways. In the first part of the paper, singular kernels are used to create an effective new FFT-based image analysis tool that can calibrate the lack of smoothness in an image. This tool can be used in contexts unrelated to deblurring, e.g., as a sharpness analysis tool in performance evaluation of imaging systems or image reconstruction software [38], or as a tool for detecting and quantifying "fine-structure" content in images. In the second part of the paper, singular integrals are used as regularization tools in the deblurring problem. Specifically, we show how to stabilize ill-posedness by using the Poisson kernel to impose a priori constraints, in appropriate $\Lambda(\alpha, p, \infty)$ spaces, on the desired nonsmooth deblurred image. This so-called *Poisson Singular Integral* or *PSI* method, is only one of an infinite variety of singular integral deblurring methods that can be constructed. In particular, Gaussian kernels may also be used, leading to the *Gaussian Singular Integral* or *GSI* method. Restricting attention to the case of defocus blurs, we derive L^2 error bounds for the PSI method for images in $\Lambda(\alpha, 2, \infty)$, and demonstrate robust recovery of fine structure in synthetically blurred images. Similar results hold for other types of blurs.

Extensive numerical experiments with known exact solutions indicate that the PSI method is remarkably well-behaved. In both the L^1 and L^2 norms, relative errors in the PSI method are found to closely approximate those obtained in the theoretically optimal, but practically unrealizable, case of *true* Wiener filtering. The latter method requires prior knowledge of the exact power spectra of both the noise and unknown desired sharp image, i.e., a total of $8N^2$ prior data values for a $2N \times 2N$ image. Since the PSI method requires only 4 prior data values, its ability to closely track Wiener filtering is especially noteworthy. The availability of reliable fast deblurring methods is of major significance in the case of nonsmooth images. The true value of the Lipschitz exponent α in the desired sharp image is usually not known in advance, although a plausible range of values for α can often be deduced. In section 10, we document the practicality and robustness of the PSI method, by showing that good quality reconstructions can often be obtained with *inexact*, but plausible, Lipschitz space information. Such initial restorations can then be refined interactively. Here, fast algorithms enable *simultaneous* computation and display of large numbers of trial deblurred images, resulting from multiple choices for α and/or some of the regularization parameters. We stress that the PSI method is exclusively intended for deblurring and is not intended for denoising.

2. Lack of smoothness of images. In [27], a new analytical framework for image processing is introduced, whereby a given image $f(x, y)$ is conceptualized as being the sum of three components, $f(x, y) = u(x, y) + v(x, y) + w(x, y)$. Loosely speaking, $u(x, y)$ contains the edges and the other high-priority information that is sufficient for object recognition, $v(x, y)$ contains the fine-scale details and other low-priority information that is often not necessary for recognition, and $w(x, y)$ represents noise. The $v(x, y)$ component is called *texture*. One example of $v(x, y)$ might be the hair in a photograph of a person's face. Another example of $v(x, y)$ might be the heat-shield tiles in an image of the Columbia space shuttle. The ability to resolve individual hairs is generally not necessary for identification. In several image processing tasks, such as compression, segmentation, or face recognition, this texture component can often be neglected. However, there are numerous other situations, such as in the ill-fated Columbia episode, where $v(x, y)$ may be of paramount interest. It is shown in [27] that only the $u(x, y)$ component can generally be expected to lie in $BV(R^2)$. In [24], it is proved that most natural images are *not* of bounded variation, because the texture component $v(x, y)$ generally has infinite total variation.

Denoising and deblurring are two basic image processing tasks where total variation restoration has been extensively applied. Such restoration can be accomplished most effectively by solving an initial value problem for an appropriate nonlinear anisotropic diffusion equation, using the stepwise marching scheme described in [26]. In deblurring, one typically starts with a degraded image $g(x,y)$ which differs from the desired true image $f(x,y)$ in that the $u(x,y)$ component is blurred but recognizable, the $v(x,y)$ component is seriously attenuated and often not recognizable, and the $w(x,y)$ component is usually small. Reconstructing $v(x,y)$ while keeping $w(x,y)$ small, is the prime objective in numerous medical, astronomical, industrial, and scientific contexts [9], [10]. However, while total variation deblurring sharpens $u(x,y)$ and keeps $w(x,y)$ small, the texture component $v(x,y)$ is often eliminated due to the "staircase effect" [13], [20], [29], [30], [39]. This is in accordance with the analyses in [24], [27].

Let $x = (x_1, x_2) \in R^2$. Postulating $f(x) \in BV(R^2)$ means that $f(x)$ is constrained to satisfy,

$$\int_{\mathbf{R^2}} |f(x+h) - f(x)|dx \leq Const\ |h|. \tag{1}$$

However, from the standpoint of modeling texture, it is advantageous to consider functions $f(x)$ satisfying weaker constraints, such as

$$\left\{\int_{\mathbf{R^2}} |f(x+h) - f(x)|^p dx\right\}^{1/p} \leq Const\ |h|^\alpha, \qquad 0 < \alpha < 1. \tag{2}$$

Such an f lies in $\Lambda(\alpha, p, \infty)$. With $0 < \alpha < 1,\ 1 \leq p < \infty$, the Lipschitz (Besov) spaces $\Lambda(\alpha, p, q)$ [36], [37], consist of the class of functions $f(x) \in L^p(R^2)$ with finite seminorm $\parallel f \parallel_{\alpha pq}$, where

$$\parallel f \parallel_{\alpha pq} = \left\{\int_{R^2} \left(|h|^{-\alpha} \parallel f(x+h) - f(x) \parallel_p\right)^q dh/|h|^2\right\}^{1/q}, \qquad 1 \leq q < \infty, \tag{3}$$

$$\parallel f \parallel_{\alpha p\infty} = \sup_{h \in R^2} \left\{|h|^{-\alpha} \parallel f(x+h) - f(x) \parallel_p\right\}, \qquad q = \infty. \tag{4}$$

For given p and q, functions with larger values of α are better behaved, or "smoother", than functions with smaller values of α, and functions in $\Lambda(\alpha, p, q_1)$ are smoother than functions in $\Lambda(\alpha, p, q_2)$ if $q_1 < q_2$. In fact, the following continuous embedding results are proved in [37, Theorem 9]

$$\Lambda(\alpha_2, p, q_1) \subset \Lambda(\alpha_1, p, q_2), \qquad 0 < \alpha_1 \leq \alpha_2 < 1;\ 1 \leq q_1 \leq q_2 \leq \infty. \tag{5}$$

Also, in R^2,

$$\Lambda(\alpha, p, q) \subset \Lambda(\beta, r, q), \qquad \alpha - 2/p = \beta - 2/r,\ \ p \leq r. \tag{6}$$

Let $r = 2$, let the pair (α, p) satisfy $2/(1+\alpha) < p \leq 2$, and let $\beta = 1 + \alpha - 2/p$. Then, $0 < \beta \leq \alpha$, and it follows from (5) and (6) that

$$\Lambda(\alpha, p, q) \subset \Lambda(\beta, 2, q) \subset \Lambda(\beta, 2, \infty) \subset L^2(R^2). \tag{7}$$

This result will be important in what follows.

For given fixed p with $1 < p < \infty$ and $q = 2p/(2+\alpha p)$, a class of Lipschitz spaces $\Lambda(\alpha, q, q) \subset L^p(R^2)$ is considered in [18], [19], and shown to contain common types of images. A method for empirically estimating image smoothness is developed in [18], [19], based on analyzing the behavior of *lossy wavelet compression* of the image $f(x, y)$. In [12], the spaces $\Lambda(\alpha, q, q) \subset L^2(R^2),\ q = 2/(1+\alpha)$, are advocated as being particularly appropriate for accommodating a rich variety of real images in an L^2 setting. Lossy wavelet compression is again used to estimate image smoothness, and values of α in the range $0.4 < \alpha < 0.75$ are reported in [12] for a class of 24 test images $\in \Lambda(\alpha, \frac{2}{1+\alpha}, \frac{2}{1+\alpha})$. Such α values are an indication of true image smoothness only when the image is largely *noise free.* If the noise component $w(x, y)$ is not sufficiently small, artificially low values of α must be expected. A basic limitation of the above wavelet compression approach is the restriction on q, which precludes consideration of the larger spaces $\Lambda(\alpha, p, \infty) \supset \Lambda(\alpha, p, q)$.

The present independent method of estimating image smoothness rests on an entirely different analytical basis, and requires neither wavelet expansions nor image compression. Instead, the method uses fast FFT algorithms to convolve the image with a specific type of kernel, and then analyzes how well this convolved image approximates the original image as the kernel approaches the Dirac δ-function. This simple direct approach permits consideration of the spaces $\Lambda(\alpha, p, \infty),\ 1 \le p < \infty$. The results obtained here are compatible with those obtained in [18], [19], [12], and [24]. We indeed find that most natural images are not of bounded variation, and that a rich variety of images $\in \Lambda(\alpha, 1, \infty)$ with $0.2 < \alpha < 0.7$.

Remark 1. We deal with high resolution images $f(x, y)$ of size 512×512 or 1024×1024 pixels. Such an $f(x, y)$ may be viewed as a piecewise constant or trigonometric polynomial approximation to the original intensity field $f^\infty(x, y)$, or as some other kind of finite dimensional representation of the infinite dimensional object f^∞. All norms are equivalent on a finite dimensional space. Hence, even if $f^\infty(x, y)$ is not of bounded variation, the discrete total variation norm for $f(x, y)$ is always finite, though it may be very large. To estimate smoothness properties of $f^\infty(x, y)$ by examination of the finite dimensional representation $f(x, y)$ requires some sagacity. In [18, section 4B, section 5B], the authors stress that in their method of estimating the value of α by monitoring the rate of convergence as a function of the number $\mathcal{N}$ of nonzero wavelet coefficients, one must restrict attention to *low values* of $\mathcal{N}$. At high values of $\mathcal{N}$, the fact that $f(x, y)$ is actually piecewise constant causes the error to decrease much too rapidly, resulting in an *artificially high* reading for α that diverges from true behavior in $f^\infty(x, y)$. This same finite dimensionality pitfall occurs in the present approach, but wears a different guise. See Remark 2 and the discussion surrounding Figures 1 and 2 below.

We shall use the spaces $\Lambda(\alpha, 1, \infty)$ and $\Lambda(\alpha, 2, \infty)$ for examining and classifying image smoothness. However, deblurring applications will be limited to the spaces $\Lambda(\beta, 2, \infty) \subset L^2(R^2)$, wherein all spaces $\Lambda(\alpha, p, q),\ 2/(1+\alpha) < p \le 2,\ 1 \le q \le \infty$, are continuously embedded. The spaces $\Lambda(\alpha, 2, \infty)$ will be shown to contain a rich and significant class of images.

3. The spaces $\Lambda(\alpha, p, q)$ and the Poisson singular integral. Define the Fourier transform $\hat{h}(\xi, \eta)$ of $h(x, y) \in L^1(R^2)$ by

$$\mathcal{F}\{h\} = \hat{h}(\xi, \eta) \equiv \int_{R^2} h(x, y) e^{-2\pi i(\xi x + \eta y)} dx dy. \tag{8}$$

For each fixed $t > 0$, consider the Poisson kernel in R^2

$$\psi(x, y, t) = \frac{t}{2\pi(x^2 + y^2 + t^2)^{3/2}}, \qquad (x, y) \in R^2. \tag{9}$$

We have

$$\hat{\psi}(\xi, \eta, t) = e^{-t\rho}, \qquad \rho = \sqrt{\xi^2 + \eta^2}. \tag{10}$$

For each $t > 0$, define the linear operator U^t on $L^p(R^2),\ 1 \le p < \infty$, by

$$U^t f = \int_{R^2} \psi(u, v, t) f(x - u, y - v) du dv. \tag{11}$$

It can be shown that $\lim_{t \downarrow 0} \parallel U^t f - f \parallel_p = 0$. Moreover, defining U^0 to be the identity operator, we have that for $s, t \ge 0,\ U^t U^s = U^{t+s}$. In fact, $\{U^t\}_{t \ge 0}$ is a holomorphic contraction semigroup on $L^p(R^2)$. See [3]. We may write $U^t = e^{-tA}$, where $-A$ is the infinitesimal generator of U^t. Here, A corresponds to the fractional differential operator $(-\Delta)^{1/2}$. Note that for $t > 0,\ U^t$ maps $L^p(R^2)$ into $D(A)$, so that $AU^t f$ is well-defined for arbitrary $f \in L^p$. In general, this is not the case for nonholomorphic semigroups. The Gauss singular integral, where the two-dimensional Gaussian kernel is used in lieu of ψ in (9), defines an analogous holomorphic semigroup W^t, with $A = -\Delta$. Many such singular integral semigroups S^t exist. A very rich variety can be constructed by *subordination* [7], [40]. For small $t > 0,\ S^t$ behaves as an approximate identity on L^p. There is a large literature on how well $S^t f$ approximates f as $t \downarrow 0$. See [3], [4], [5], [35], [36], [37], and the references therein. As $t \downarrow 0$, we have $\parallel S^t f - f \parallel_p = o(1)$ for arbitrary $f \in L^p$, $\parallel S^t f - f \parallel_p = O(t)$ if and only if $f \in D(A)$, and $\parallel S^t f - f \parallel_p = o(t)$ if and only if $S^t f = f$ for all $t \ge 0$. Thus, the optimal rate is always $O(t)$. Of particular interest in this paper is the case of *nonoptimal* approximation, where $f \notin D(A)$ yet retains sufficient smoothness that $\parallel S^t f - f \parallel_p = O(t^\alpha),\ 0 < \alpha < 1$, as $t \downarrow 0$. While complete theories exist for a wide class of singular kernels, the simplest such theory revolves around the Poisson semigroup U^t in (11). We have from [37, Theorem 4], the following result.

THEOREM 1. *Let $U^t,\ t > 0$, be the Poisson integral operator in* (11)*, and let $0 < \alpha < 1,\ 1 \le p, q < \infty$. Then, $f \in \Lambda(\alpha, p, q)$ if and only if*

$$\int_0^\infty \left(t^{-\alpha} \parallel U^t f - f \parallel_p\right)^q dt/t \ < \ \infty. \tag{12}$$

For $q = \infty$, we have $f \in \Lambda(\alpha, p, \infty)$ if and only if

$$\sup_{t>0} \ t^{-\alpha} \parallel U^t f - f \parallel_p \ < \ \infty. \tag{13}$$

Using the embedding results in (7) together with (13) leads to the following corollary.

THEOREM 2 (corollary). *Let $f \in \Lambda(\alpha, p, q)$, with $2/(1 + \alpha) < p \le 2$, and let $\beta = 1 + \alpha - 2/p$. Then, in the L^2 norm*

$$\sup_{t>0} \ t^{-\beta} \parallel U^t f - f \parallel_2 \ < \ \infty. \tag{14}$$

4. Periodized problems, the Poisson summation formula, and FFT algorithms. The above results can be used to fashion a practical image analysis tool. Theoretically, given any image $f(x,y)$ in $L^1(R^2)$, one could use the Fourier transform (8) to form

$$\mathcal{F}\left\{U^t f\right\} = e^{-t\rho}\hat{f}(\xi,\eta), \qquad \rho = \sqrt{\xi^2+\eta^2}, \tag{15}$$

for sequences of positive t-values tending to zero. Inverse transformation is always possible on account of the factor $e^{-t\rho}$, and this can be used to produce an infinite sequence of positive numbers $\mu_n = \{\| U^{t_n} f - f \|_1 / \| f \|_1\}$ with $t_n \downarrow 0$. If every such sequence (t_n, μ_n), ultimately lies below the curve $\mu(t) = C\ t^\alpha,\ 0 < t \leq \bar{t}$, for suitably chosen constants $C > 0$ and $0 < \alpha < 1$, then $\| U^t f - f \|_1 \leq C \| f \|_1\ t^\alpha$, as $t \downarrow 0$, and $f(x,y) \in \Lambda(\alpha, 1, \infty)$ by Theorem 1. However, this does not lead to a practical procedure.

On the other hand, Theorems 1 and 2 remain valid in the periodic case [36], [37]. Here, the image $f(x,y)$ and the kernel $\psi(x,y,t)$ in (9) are now periodized [5], [6]. Let Ω denote the unit square $-1/2 < x, y \leq 1/2$ in R^2. The image $f(x,y)$ is now viewed as originally defined on Ω from which it is extended by periodicity to all of R^2. Let

$$\hat{f}(\xi,\eta) = \int_\Omega f(x,y) e^{-2\pi i(\xi x + \eta y)} dxdy. \tag{16}$$

Define the periodized Poisson kernel $\psi^*(x,y,t)$ by

$$\psi^*(x,y,t) = \sum_{k,m=-\infty}^{\infty} \psi(x+k, y+m, t), \qquad t > 0, \quad (x,y) \in R^2, \tag{17}$$

and let

$$U^t f = \int_\Omega \psi^*(u,v,t) f(x-u, y-v) du dv, \qquad t > 0. \tag{18}$$

The Poisson summation formula, [1], [5], [6], [22], [37], can be used to show that the periodized Poisson kernel has a complex Fourier series with Fourier coefficients again given by (10), but where ξ, η are now *integers* running from $-\infty$ to $+\infty$. Moreover,

$$U^t f = \sum_{\xi,\eta=-\infty}^{\infty} e^{-t\rho}\hat{f}(\xi,\eta) e^{2\pi i(x\xi + y\eta)}, \qquad t > 0, \quad \rho = \sqrt{\xi^2+\eta^2}. \tag{19}$$

Again the factor $e^{-t\rho}$ assures uniform convergence of the Fourier series in (19). Let

$$f_N(x,y) = \sum_{\xi,\eta=-N}^{N} e^{-t\rho}\hat{f}(\xi,\eta) e^{2\pi i(x\xi + y\eta)}, \qquad t > 0, \quad \rho = \sqrt{\xi^2+\eta^2}. \tag{20}$$

Since $L^p(\Omega) \subset L^1(\Omega)$, $p > 1$, we may apply this approach to any $f \in L^p$, and $\| U^t f - f_N \|_p$ can be made arbitrarily small by choosing N large enough in (20). Next, given the $2J \times 2J$ digitized image $f(x,y)$ with $J > N$, the discrete Fourier transform [2] is now the appropriate numerical tool for analyzing this periodized problem. One can use FFT algorithms to form the Fourier coefficients $\hat{f}(\xi,\eta)$, $-J \leq \xi, \eta \leq J$, and then apply the filter $(e^{-t\rho} - 1)$ as in (15). An inverse FFT then yields an accurate approximation to $U^t f - f$ at each of the $2J \times 2J$ pixels, for each small $t > 0$. We

may then examine the discrete L^p relative error in Poisson approximation as $t \downarrow 0$, and locate constants C and α such that $\| U^t f - f \|_p \leq C \| f \|_p t^\alpha,\ 0 < t \leq \bar{t}$. In summary, we have constructed an accurate numerical procedure, based on correct mathematical analysis, for assessing membership in any $\Lambda(\alpha, p, \infty)$ space. Equally important, the values of C and α constitute a priori information that will be useful in stabilizing the ill-posed deblurring problem.

Remark 2. Analogously to the case of lossy wavelet compression discussed in Remark 1, there is a finite dimensionality pitfall in the above singular integral methodology that *necessitates the exclusion of very small values of* $t > 0$. Let $f^\infty(x, y)$ be the original image intensity field as in Remark 1, and assume that $f^\infty(x, y) \in \Lambda(0.5, p, \infty)$, so that $\| U^t f^\infty - f^\infty \|_p = O(\sqrt{t})$ as $t \downarrow 0$, by Theorem 1. Let $f(x, y)$ be the $2J \times 2J$ digitized image corresponding to $f^\infty(x, y)$. We shall show that at very small values of $t > 0$, the behavior of $\| U^t f - f \|_p$ *diverges* from true behavior in $f^\infty(x, y)$, resulting in a *false reading* for α. Let $S^t = e^{-tA}$ be any contraction semigroup on $L^p(R^2)$. As already pointed out, if $f \in D(A)$, $\| S^t f - f \|_p = O(t)$ as $t \downarrow 0$. This follows from

$$S^t f - f = \int_0^t \frac{d}{du}(S^u f) du = -\int_0^t S^u A f du, \tag{21}$$

so that $\| S^t f - f \|_p \leq t \| Af \|_p$, for all $t > 0$. In addition, $\| S^t f - f \|_p \approx t \| Af \|_p$, for all sufficiently small $t > 0$, because $S^u Af \approx Af$ for all sufficiently small u. In the above Poisson semigroup U^t, the unbounded operator A is defined as follows in Fourier space

$$\mathcal{F}\{Af\} = \rho \hat{f}(\xi, \eta), \qquad \rho = \sqrt{\xi^2 + \eta^2}. \tag{22}$$

Since the digitized $2J \times 2J$ image $f(x, y)$ is a trigonometric polynomial, it is always $\in D(A)$ and $\| Af \|_p$ is always finite, although it may be very large. Consequently, with a possibly large positive constant K, we always have $\| U^t f - f \|_p \leq Kt$ for all $t > 0$, as well as actual linear behavior $\| U^t f - f \|_p \approx Kt$ for all sufficiently small t, irrespective of the behavior of $\| U^t f^\infty - f^\infty \|_p$ at these same values of t. This phenomenon is well-illustrated in Figures 1 and 2 below.

5. Application to real images. The following examples illustrate the use of the Poisson singular integral approach. Our first example, in Figure 1, is the 512×512 Mandrill image highlighted in [24] as an example of an image $\notin BV(R^2)$. The above FFT procedure was used to obtain the L^1 and L^2 relative errors in Poisson approximation

$$\mu(t) = \| U^t f - f \|_p \,/\, \| f \|_p, \qquad p = 1, 2, \tag{23}$$

at 300 values of t given by $t_n = 0.5(0.95)^n,\ n = 1, 300$. For the L^1 norm, a plot of $\mu(t)$ versus t on a log-log scale produced the solid curve A in Figure 1. Least squares fitting was used to find the two distinct majorizing dashed straight lines Γ and Σ. For each dashed line, the y-axis intercept value obtained by least squares was slightly increased so as to make each line lie visibly above the solid curve A; however, the slope of each line remains the same as that obtained from least squares. The line Γ, defined by $\log \mu(t) = 3.2 + 0.994 \log t$, accurately captures the misleading linear trend in (23) for very small values of t, while being grossly inaccurate at larger values of t. It was obtained by excluding data corresponding to $\log t > -7$ from the least squares fit. The line Γ implies that $\| U^t f - f \|_1 < 24.53 \| f \|_1 t^{0.994}$

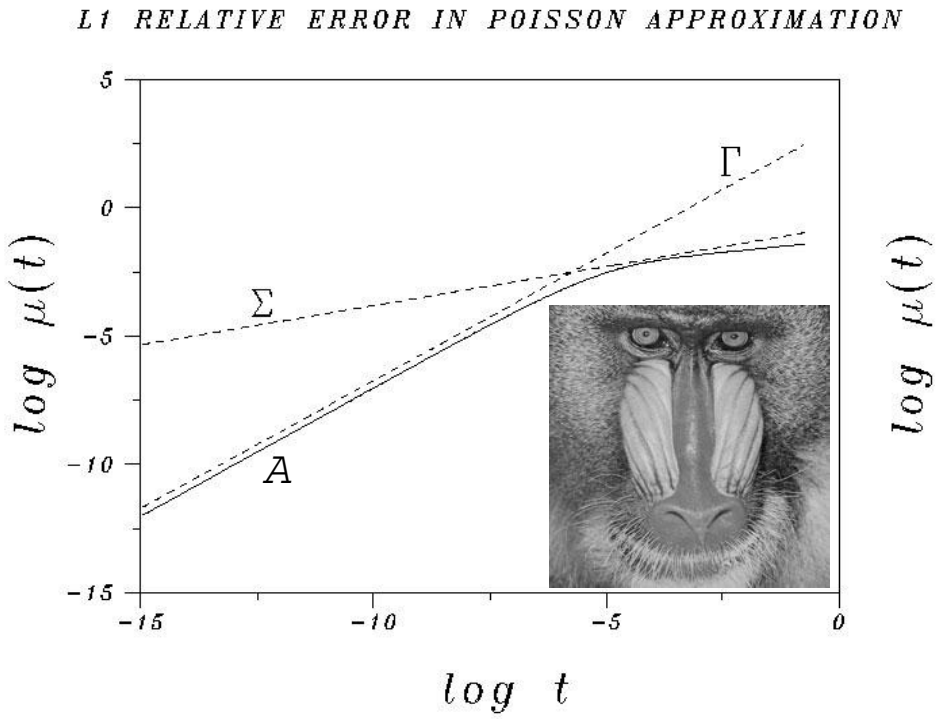

FIG. 1. 512×512 *Mandrill image was identified in* [24] *as not in* $BV(R^2)$. *This is confirmed in above graphical use of Theorem* 1, *using FFT techniques discussed in section* 4. *Solid curve A is a plot of* $\mu(t) = \| U^t f - f \|_1 / \| f \|_1$ *versus* t, *on a log-log scale. Majorizing dashed straight line* Γ, *defined by* $\log \mu(t) = 3.2 + 0.994 \log t$, *accurately captures linear behavior in* (23) *for very small values of* t, *but is grossly inaccurate at larger values of* t. *Linear behavior at very small* t *is misleading, and falsely implies that image is of bounded variation. (See Remarks* 1 *and* 2*). Majorizing dashed straight line* Σ, *defined by* $\log \mu(t) = -0.75 + 0.306 \log t$, *accurately reflects behavior for* $-6 \le \log t \le -1$, *while being grossly inaccurate at very small* t. *Behavior along* Σ *is taken to be true behavior in Mandrill image, implying image* $\in \Lambda(0.306, 1, \infty)$ *with* $\| U^t f - f \|_1 \le 0.472 \| f \|_1 t^{0.306}$, $0 < t \le 0.1$.

for all $t > 0$. As emphasized in Remark 2, this correct statement primarily reflects the fact that the 512×512 Mandrill image lies in a finite dimensional space; it *does not* describe the smoothness properties of the intensity field $f^{\infty}(x, y)$ that gave rise to the digitized Mandrill image. The majorizing dashed straight line Σ, defined by $\log \mu(t) = -0.75 + 0.306 \log t$, accurately reflects behavior of (23) for $-6 \le \log t \le -1$, while being grossly inaccurate at very small values of t. The line Σ was obtained by excluding all data corresponding to $\log t < -6$ from the least squares fit. Note that this still leaves over 100 data points remaining. The behavior along Σ indicates that $\| U^t f - f \|_1 \le 0.472 \| f \|_1 t^{0.306}$, $0 < t \le 0.1$, and this is taken to be the true behavior in the Mandrill image. From (13), this implies that the Mandrill image $\in \Lambda(0.306, 1, \infty)$, and hence, is not of bounded variation. The behavior in the L^2 norm is strikingly similar, and indicates the image $\in \Lambda(0.271, 2, \infty)$. Estimates of α in any other discrete L^p norm can be obtained similarly. All α estimates shown in this paper were obtained using the above procedure of constructing the line Σ in log-log plots of $\mu(t)$, after excluding all data corresponding to $\log t < -6$. As in [18,

section 5B], we have occasionally found contradictory examples where the value of α in the L^2 norm was greater than that in the L^1 norm. When that happened, a new Σ line was constructed for the L^2 trace, based on excluding data corresponding to $\log t < -5$. It is recommended that data for very small values of t always be included in log-log plots of $\mu(t)$, so as to enable clear identification of the spurious linear trend, prior to rejecting that part of the data.

Our second example, in Figure 2(A), is a 1024×1024 Whirlpool galaxy image, taken at the National Optical Astronomy Observatory, (NOAO/AURA/NSF), by T. Rector and M. Ramirez. As in the case of Figure 1, Poisson integral approximation in L^1 was used to obtain the solid curve A, and the line Σ_A was constructed using least squares. This procedure was repeated for the L^2 norm. The results indicate that Figure 2(A) satisfies $\| U^t f - f \|_1 \leq 0.6 \| f \|_1 t^{0.530}$, $0 < t \leq 0.1$, and that Figure 2(A) $\in \Lambda(0.530, 1, \infty) \cap \Lambda(0.462, 2, \infty)$. Interestingly, if we sharpen Figure 2(A) using the *APEX method* [9], we obtain the image in Figure 2(B). This enhanced image displays significant fine scale detail not readily visible in the original image, and strongly resembles a Whirlpool galaxy plate taken by Milton Humason in 1950 using the 200 inch Mt. Palomar telescope. See [34, plate 26]. Here, L^1 Poisson analysis produced the solid curve B and the majorizing line Σ_B. We find that Figure 2(B) $\in \Lambda(0.239, 1, \infty) \cap \Lambda(0.230, 2, \infty)$, and thus has substantially *lower* values of α than does Figure 2(A). This result is highly plausible. Presumably, any low-pass blurring process that may have affected Figure 2(A) would have attenuated fine scale features, and thereby *increased* the values of α. The result also indicates that APEX processing of image (A) produced relatively more sharpening in the L^1 norm than in the L^2 norm.

The nine images in Figure 3 and Table 1 form an interesting collection that includes natural as well as man made objects, exhibiting a wide range of sizes. The last row contains a nanoscale electron microscopy micrograph, a galactic scale object, and a cosmological scale structure. Along with the three images in Figures 1 and 2, this paper has applied the Poisson integral method to 12 high resolution images, and we have found that, in either $\Lambda(\alpha, 1, \infty)$ or $\Lambda(\alpha, 2, \infty)$, the values of α lie in the range $0.2 < \alpha < 0.7$. This range of values is compatible with that found in [12], [18], [19], using an entirely different method. Moreover, while $\Lambda(\alpha, 2, \infty)$ are smaller spaces than are $\Lambda(\alpha, 1, \infty)$, they are evidently wide enough to contain each of these 12 images, albeit with smaller values of α. Notice also that the values of the constant C in Table 1 are confined to a very narrow range in both L^1 and L^2.

Remark 3. Following [18], [19], the values of C and α reported in Table 1 and elsewhere in this paper, are given to two and three decimal places. Such precision must be viewed with skepticism. These values are based on the use of the Poisson operator U^t, together with the particular sequence $t_n = 0.5(0.95)^n$, $n = 1, 300$. Also, the specific interval $-6 \leq \log t \leq 0$ was chosen for the least squares fit to $\log \mu(t)$. However, different sequences t_n tending to zero might be used, as well as slightly larger or slightly smaller t-intervals for the least squares fit. In addition, the Gaussian operator G^t may be used in place of U^t, in which case the image Lipschitz exponent $\alpha = 2\delta$, where δ is the slope of the corresponding Σ line. It is found that such variations in the basic methodology result in slightly different values for C and α. For this reason, all reported values of C and α should probably be *rounded to one decimal place*. It may not be feasible to determine true image Lipschitz space parameters to higher place accuracy.

The PSI deblurring method to be described in section 7 below requires prior knowledge of the values of C and α in the desired unknown deblurred image. In

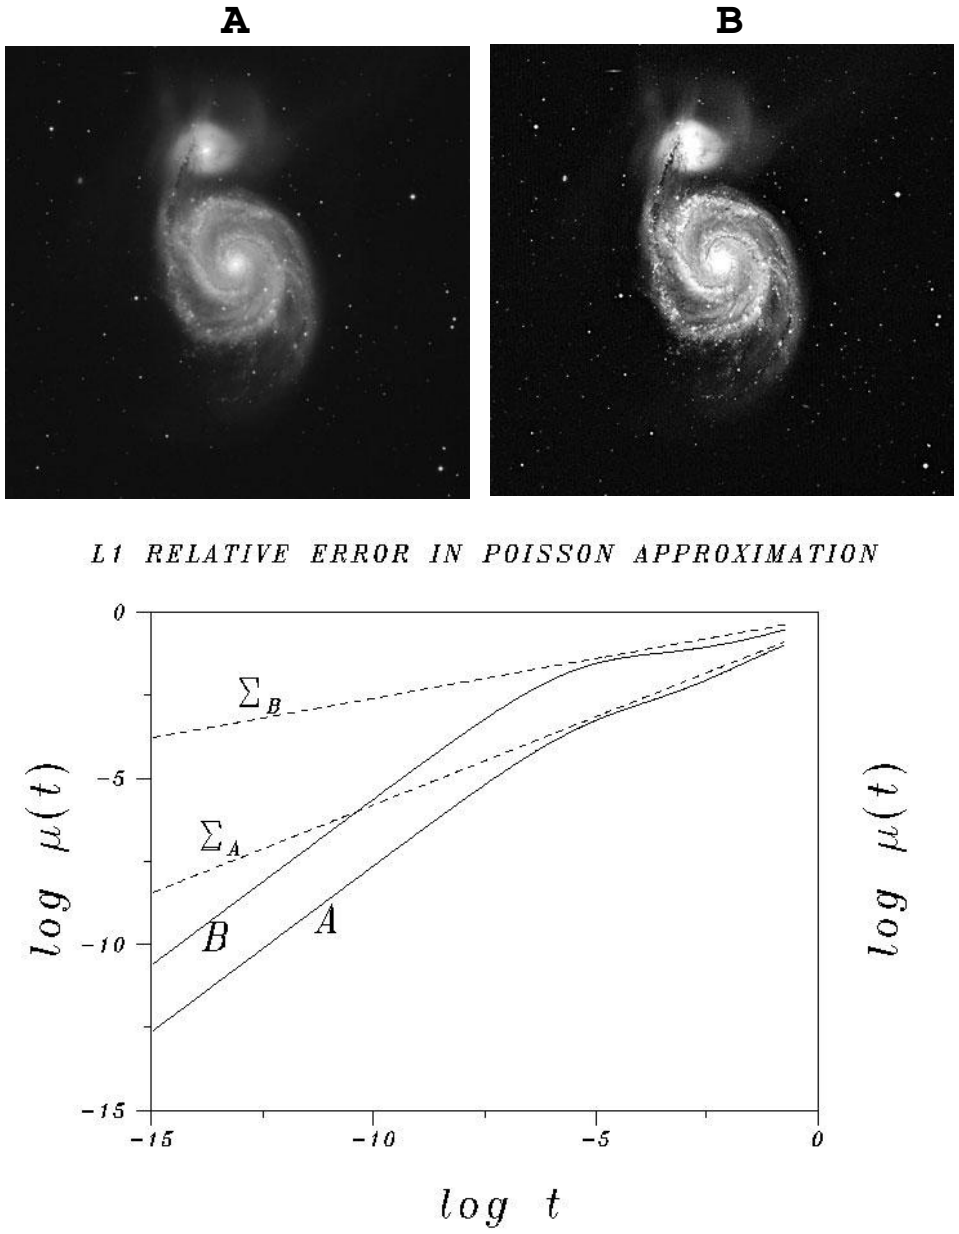

FIG. 2. *Whirlpool galaxy M*51. *Original and enhanced images have noticeably different* L^1 *Poisson traces* $\mu(t) = \| U^t f - f \|_1 / \| f \|_1$, *reflecting sharply distinct Lipschitz exponents.* (A) *Original* 1024×1024 *image taken by T. Rector and M. Ramirez, National Optical Astronomy Observatory, (NOAO/AURA/NSF).* L^1 *Poisson relative error* $\mu(t)$, *shown in solid trace A, is majorized by dashed straight line* Σ_A *defined by* $\log \mu(t) = -0.5 + 0.530 \log t$. *This implies that image* (A) $\in \Lambda(0.530, 1, \infty)$. (B) *Blind deconvolution of* (A) *using APEX method* [9], *brings out significant fine scale detail, and results in solid trace* B, *majorized by dashed straight line* Σ_B *defined by* $\log \mu(t) = -0.2 + 0.239 \log t$. *This indicates that deblurred image* (B) $\in \Lambda(0.239, 1, \infty)$. *Image* (B) *strongly resembles* [34, plate 26] *taken by Milton Humason using* 200 *inch Mt. Palomar telescope. For* $\log\ t < -7$, *solid traces* A *and* B *have identical slopes of* 0.994. *This confirms the observation in Remark* 2 *that behavior at very small* t *is artificial and disconnected from true image smoothness.*

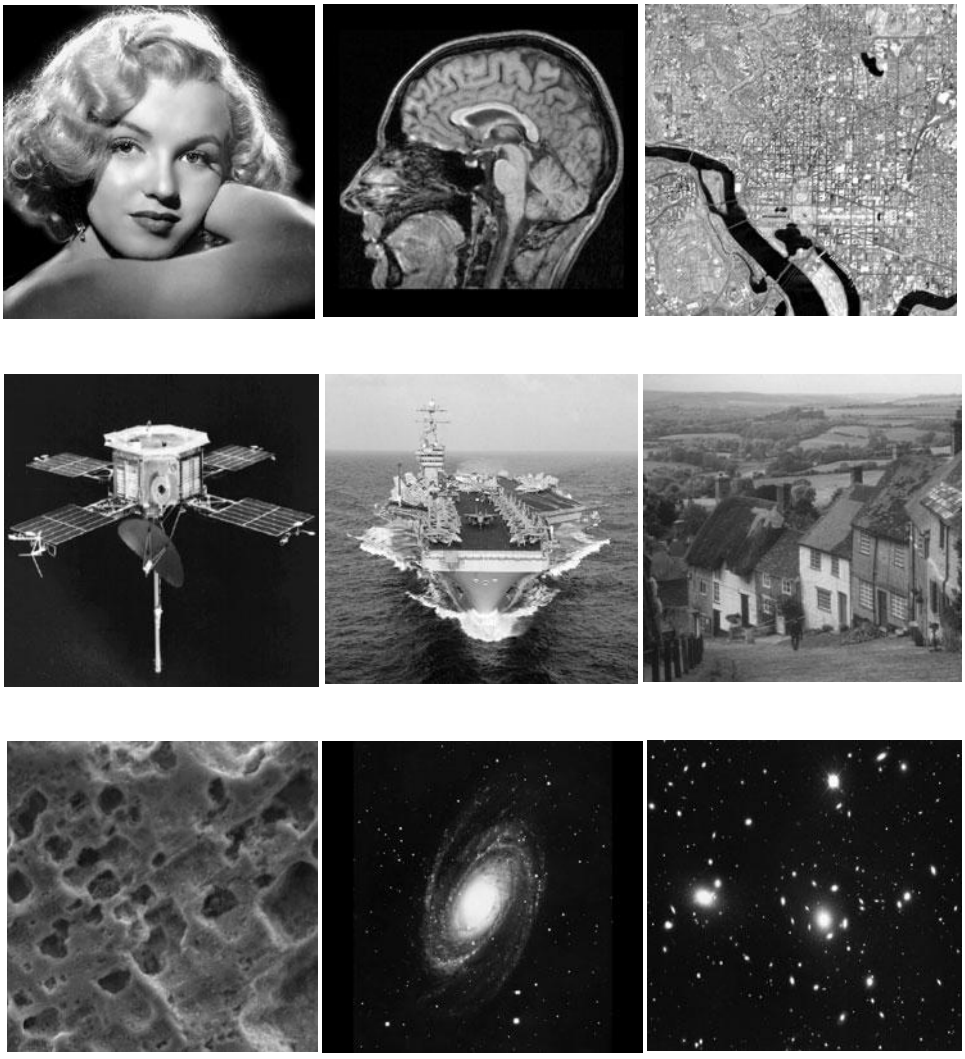

FIG. 3. *A significant class of high-resolution* 8*-bit images have Lipschitz exponents* α *in the range* $0.2 < \alpha < 0.7$*, in either* L^1 *or* L^2*, and are not of bounded variation.*

general, these values will not be known. However, as shown in Figure 2, it is reasonable to assume that α in the deblurred image will be *lower* than in the given blurred image, provided that image is relatively noise free. Inspection of Table 1, or of other more extensive tables pertaining to the types of images under consideration, may indicate plausible initial estimates for (C, α). As will be shown in section 10, the PSI method is sufficiently robust as to produce good quality reconstructions, even with *inexact* Lipschitz data. Moreover, given a fast algorithm, because of the narrow range of values involved in both C and α, it is feasible to refine such reconstructions by simultaneous computation and display of multiple trial restorations, based on neighboring values of (C, α). Efficient exploration in parameter space is usually the key to the successful solution of inverse problems, when such problems can be solved.

TABLE 1

Values of $(C,\ \alpha)$ *in* $\| U^t f - f \|_p \le C \| f \|_p t^\alpha,\ 0 < t \le 0.1,\ p = 1, 2$, *for each image* $f(x, y)$ *in Figure* 3, *when* U^t *is Poisson operator in* (19). *The* (C, α) *values shown below may be more meaningful if rounded to one decimal place. See Remark* 3.

Image	*Size*	$(C,\ \alpha)\ \in \Lambda(\alpha, 1, \infty)$	$(C,\ \alpha)\ \in \Lambda(\alpha, 2, \infty)$
Marilyn Monroe	512^2	$C = 0.77,\ \ \alpha = 0.565$	$C = 0.68,\ \ \alpha = 0.474$

6. Image deblurring in $L^2(R^2)$. We now consider the image deconvolution problem $Pf = g$ with a known *shift-invariant* point spread function (psf) $p(x, y)$,

$$Pf \equiv p(x, y) \otimes f(x, y) = g(x, y), \qquad g(x, y) = g_e(x, y) + n(x, y). \tag{24}$$

Here, $\otimes$ denotes convolution, $g(x, y)$ is the given recorded noisy blurred image, $g_e(x, y)$ is the hypothetical exact blurred image that would have been recorded in the absence of any noise, and $n(x, y)$, presumed small, represents the cumulative effects of all noise processes and other errors affecting final acquisition of the digitized array $g(x, y)$. The noise may be *multiplicative*. Neither $g_e(x, y)$ nor $n(x, y)$ are known, only their sum $g(x, y)$. Denoting the unknown exact sharp image by $f_e(x, y)$, we have

$$Pf_e = p(x, y) \otimes f_e(x, y) = g_e(x, y). \tag{25}$$

Given only (24), we seek a solution $f(x, y)$ in (24) such that $Pf \approx g$, *and* such that $\| f - f_e \|_2$ is small. To achieve this goal, some a priori information about f_e and n is always necessary. Most real images $f_e(x, y)$ contain fine scale features, sharp edges, and other kinds of nondifferentiable singularities. Deblurring techniques that impose stabilizing constraints in the form of prescribed bounds on partial derivatives of $f(x, y)$ in (24), are generally inapplicable, although they are often used. Penalties for such use include smoothing out of sharp features, and possible loss of vital diagnostic information. Indeed, the desire to accurately reconstruct edges and other sharp singularities was the principal reason for developing total variation methods. In fact, several deblurring methods actually exist that do not require prescribed bounds on derivatives [8].

A wide variety of blurs can be used as illustrative examples in (24). Here, we consider the case of uniform defocus blur, where the psf is proportional to the characteristic function of a disc of radius R. This is the so-called "pillbox" model [17], [25], [16], [31]. If $R > 0$ is the radius of the "circle of confusion", the psf for defocus blur is given by

$$p(x, y) = \begin{cases} (\pi R^2)^{-1}, & x^2 + y^2 \le R^2, \\ 0, & x^2 + y^2 > R^2. \end{cases} \tag{26}$$

This has a Fourier transform given by the "sombrero function" [23, p. 72]

$$\hat{p}(\xi, \eta) = 2J_1(R\rho)/(R\rho), \qquad \rho = \sqrt{\xi^2 + \eta^2}, \tag{27}$$

where $J_1(x)$ is the Bessel function of the first kind of order 1. In our numerical experiments below on $2N \times 2N$ images, the expression (27) is used to blur images by Fourier domain multiplication with a preselected $R > 0$, and (ξ, η) are integers with $-N \le \xi, \eta \le N$. Rather than interpret R as a radius, we simply observe that the severity of such a blur is determined by the number of zeroes[1] in $|\hat{p}(\rho)|$ on $0 < \rho \le N$.

6.1. True Wiener filtering and the Tikhonov–Miller method. Wiener filtering [32, p. 356], is an important example of a method that does not impose differentiability constraints. It assumes instead that the power spectra $|\hat{n}(\xi,\eta)|$ and $|\hat{f}_e(\xi,\eta)|$ of each of $n(x,y)$ and $f_e(x,y)$ are known. When this is the case, Wiener filtering produces a solution $f^w(x,y)$ in (24) defined as follows in Fourier space

$$\hat{f}^w(\xi,\eta) = \frac{\overline{\hat{p}}(\xi,\eta)\hat{g}(\xi,\eta)}{|\hat{p}(\xi,\eta)|^2 + |\hat{n}(\xi,\eta)|^2/|\hat{f}_e(\xi,\eta)|^2}, \tag{28}$$

where $\overline{z}$ denotes the complex conjugate of z. Under some additional conditions, it can be shown that $f^w(x,y)$ is an approximate solution of $Pf = g$ that *minimizes* the error $\| f - f_e \|_2$ over all $f \in L^2$. In practice, the power spectra $|\hat{n}(\xi,\eta)|$ and $|\hat{f}_e(\xi,\eta)|$ are very seldom known in advance, and true Wiener filtering is almost never realizable. However, the solution (28) is of considerable theoretical interest because of its optimality property. Note that numerous ad hoc versions of (28) exist, in which more readily available quantities are substituted in place of the required, but unavailable, true power spectra. Such versions are sometimes called Wiener filtering by an abuse of terminology. However, these substitute versions *do not* satisfy the Wiener optimality criterion, nor do they elicit the same degree of theoretical interest.

One of the best-known rigorously analyzable and feasible versions of Wiener filtering is the Tikhonov–Miller method [28], now considered canonical in image deblurring [25]. Significantly, this method makes no a priori assumptions regarding the statistical character of the data noise. For nondifferentiable images, Tikhonov–Miller restoration requires the following a priori information: an upper bound $\epsilon > 0$ for the L^2 norm of the noise $n(x,y)$ in the blurred image $g(x,y)$, and an upper bound M for the L^2 norm of the unblurred image f_e

$$\| n \|_2 = \| Pf_e - g \|_2 \le \epsilon, \qquad \| f_e \|_2 \le M, \qquad \epsilon/M \ll 1. \tag{29}$$

It is assumed that ϵ and M are compatible with the existence of an $f_e(x,y) \in L^2$ satisfying (29). Tikhonov–Miller restoration is defined as the unique function $f^\tau(x,y)$ such that

$$f^\tau(x,y) = Arg \min_{f \in L^2(R^2)} \left\{ \| Pf - g \|_2^2 + (\epsilon/M)^2 \| f \|_2^2 \right\}. \tag{30}$$

As will be seen from Theorem 3, where the Tikhonov–Miller method corresponds to the special case $\Gamma_{\overline{t}} = 0$, this minimum problem has a unique solution satisfying

$$Q_\tau f^\tau = P^* g, \qquad Q_\tau = P^* P + (\epsilon/M)^2 I. \tag{31}$$

Moreover, there holds the following best-possible error bound for Tikhonov–Miller reconstruction

$$\| f^\tau - f_e \|_2 \le \epsilon \sqrt{2} \, \| Q_\tau^{-1/2} \|_2, \tag{32}$$

[1] The first five positive zeroes of $J_1(x)$ are 3.83171, 7.01559, 10.17347, 13.32369, and 16.47063.

where

$$\| Q_\tau^{-1/2} \|_2 = \sup_{\xi,\eta} \left\{ |\hat{p}(\xi,\eta)|^2 + (\epsilon/M)^2 \right\}^{-1/2}. \tag{33}$$

Given the psf $p(x,y)$, together with the a priori information ϵ, M, one can always find the maximum value in the $2N \times 2N$ array on the right of (33). As in (28) we may implement (31) in Fourier space. We have

$$\hat{f}^\tau(\xi,\eta) = \frac{\overline{\hat{p}}(\xi,\eta)\hat{g}(\xi,\eta)}{|\hat{p}(\xi,\eta)|^2 + (\epsilon/M)^2}. \tag{34}$$

Moreover, from (29) and Parseval's relation

$$\int_{R^2} |\hat{n}(\xi,\eta)|^2 d\xi d\eta \le \epsilon^2, \qquad \int_{R^2} |\hat{f}_e(\xi,\eta)|^2 d\xi d\eta \le M^2. \tag{35}$$

Therefore, the Tikhonov–Miller method can be viewed as an approximate version of true Wiener filtering where the unavailable pointwise values of the spectra in (28) are replaced by more readily available integrals of these quantities. However, it may be anticipated that since true Wiener filtering requires prior knowledge in the form of $8N^2$ numbers for a $2N \times 2N$ image, whereas the Tikhonov–Miller method requires only 2, less accurate results must generally be expected from the latter method.

7. The Poisson Singular Integral (PSI) method for images $\in \Lambda(\alpha, 2, \infty)$. The preceding discussion was necessary to set the stage for the PSI method. Here, in addition to the a priori constraints (29), the behavior of $\| U^t f_e - f_e \|_2$ on $0 \le t \le \bar{t}$ is assumed known, as in the case of Table 1. The constants $C_{\bar{t}}$ and α are now used to place a further constraint on $f_e(x,y)$. For any $f \in L^2(R^2)$, we have on Fourier transforming $f - U^t f$ and using (10),

$$\mathcal{F}\left\{ f - U^t f \right\} = \left(1 - e^{-t\rho}\right) \hat{f}(\xi,\eta), \qquad \rho = \sqrt{\xi^2 + \eta^2}. \tag{36}$$

Therefore, from Parseval's theorem,

$$\int_0^t \| U^s f - f \|_2^2 \, ds = \int_0^t ds \int_{R^2} \left(1 - e^{-s\rho}\right)^2 |\hat{f}(\xi,\eta)|^2 d\xi d\eta. \tag{37}$$

For fixed $t > 0$, define $\hat{z}(\xi,\eta,t) \ge 0$ by

$$\hat{z}(\xi,\eta,t) = \left\{ \int_0^t \left(1 - e^{-s\rho}\right)^2 ds \right\}^{1/2} = \left\{ t + \frac{4e^{-t\rho} - e^{-2t\rho} - 3}{2\rho} \right\}^{1/2}. \tag{38}$$

It follows directly from the integral definition in (38) that for any fixed $t > 0$, $\hat{z}(\rho,t)$ is a strictly increasing function of ρ, and that $\hat{z}(0,0,t) = 0$. For fixed $t > 0$, define the linear operator $Z(t)$ in $L^2(R^2)$ by

$$Z(t)f = \int_{R^2} \hat{z}(\xi,\eta,t)\hat{f}(\xi,\eta) e^{2\pi i(\xi x + \eta y)} d\xi d\eta. \tag{39}$$

Then, from (37),

$$\int_0^t \| U^s f - f \|_2^2 \, ds = \| Z(t)f \|_2^2. \tag{40}$$

For any $f_e \in \Lambda(\alpha, 2, \infty)$, $0 < \alpha < 1$, we have $\| U^s f_e - f_e \|_2 \leq C_{\bar{t}} \| f_e \|_2 s^\alpha$, $0 \leq s \leq \bar{t}$, where $C_{\bar{t}}$ is a positive constant depending on $\bar{t}$, f_e and α. Therefore, with $\| f_e \|_2 \leq M$,

$$\| Z(\bar{t}) f_e \|_2^2 \leq \frac{C_{\bar{t}}^2 M^2 \bar{t}^{1+2\alpha}}{1+2\alpha}. \tag{41}$$

Define

$$\Gamma_{\bar{t}} = \left\{ \frac{1+2\alpha}{C_{\bar{t}}^2 \, \bar{t}^{1+2\alpha}} \right\}^{1/2}. \tag{42}$$

The exact image $f_e(x, y)$ satisfies the following a priori constraints:

$$\| Pf_e - g \|_2 \leq \epsilon, \qquad (\epsilon/M) \| f_e \|_2 \leq \epsilon, \qquad (\epsilon/M) \, \Gamma_{\bar{t}} \| Z(\bar{t}) f_e \|_2 \leq \epsilon. \tag{43}$$

Fix $\bar{t} > 0$, and consider the minimization problem

$$f^\psi(x, y) = Arg \min_{f \in L^2(R^2)} \left\{ \| Pf - g \|_2^2 + (\epsilon/M)^2 \left(\| f \|_2^2 + \Gamma_{\bar{t}}^2 \| Z(\bar{t}) f \|_2^2 \right) \right\}. \tag{44}$$

As will be seen in Theorem 3 below, this minimum problem has a unique solution satisfying

$$Q_\psi f^\psi = P^* g, \qquad Q_\psi = P^* P + (\epsilon/M)^2 \left\{ I + \Gamma_{\bar{t}}^2 Z(\bar{t})^* Z(\bar{t}) \right\}. \tag{45}$$

The function $f^\psi(x, y)$ in (44) is defined to be the PSI deblurred image. Moreover, there holds the following error bound for PSI deblurring

$$\| f^\psi - f_e \|_2 \leq \epsilon \sqrt{3} \, \| Q_\psi^{-1/2} \|_2, \tag{46}$$

where

$$\| Q_\psi^{-1/2} \|_2 = \sup_{\xi, \eta} \left\{ |\hat{p}(\xi, \eta)|^2 + (\epsilon/M)^2 \left(1 + \Gamma_{\bar{t}}^2 |\hat{z}(\xi, \eta, \bar{t})|^2 \right) \right\}^{-1/2}. \tag{47}$$

Given the psf $p(x, y)$, together with the a priori information ϵ, M, and $\Gamma_{\bar{t}}$, one can always find the maximum value in the $2N \times 2N$ array on the right of (47). Again, as in (28) and (34), f^ψ can be found explicitly in Fourier space. We have

$$\hat{f}^\psi(\xi, \eta) = \frac{\overline{\hat{p}}(\xi, \eta) \hat{g}(\xi, \eta)}{|\hat{p}(\xi, \eta)|^2 + (\epsilon/M)^2 \{ 1 + \Gamma_{\bar{t}}^2 |\hat{z}(\xi, \eta, \bar{t})|^2 \}}. \tag{48}$$

Equations (45)–(48) should be compared with equations (31)–(34). Tikhonov–Miller deblurring can then be seen as an extreme case of PSI deblurring, the case where $f_e(x, y)$ is presumed no smoother than the most general L^2 function, so that $\| U^t f_e - f_e \|_2 = o(1)$ as $t \downarrow 0$. This corresponds to $C_{\bar{t}} = \infty$ in (41), and hence, $\Gamma_{\bar{t}} = 0$ in (48).

THEOREM 3. *Fix $\bar{t} > 0$ and let the exact image $f_e(x, y)$ satisfy the a priori constraints* (43). *Let $f^\psi(x, y)$ minimize* (44), *and let Q_ψ be the positive self-adjoint operator on $L^2(R^2)$ given by*

$$Q_\psi = P^* P + (\epsilon/M)^2 \left\{ I + \Gamma_{\bar{t}}^2 Z(\bar{t})^* Z(\bar{t}) \right\}. \tag{49}$$

Then f^ψ is the unique solution of $Q_\psi f^\psi = P^* g$, and f^ψ satisfies

$$\begin{aligned} &\| Pf^\psi - g \|_2^2 + (\epsilon/M)^2 \left\{ \| f^\psi \|_2^2 + \Gamma_{\bar{t}}^2 \| Z(\bar{t}) f^\psi \|_2^2 \right\} \le 3\epsilon^2, \\ &\| P(f^\psi - f_e) \|_2^2 + (\epsilon/M)^2 \left\{ \| f^\psi - f_e \|_2^2 + \Gamma_{\bar{t}}^2 \| Z(\bar{t})(f^\psi - f_e) \|_2^2 \right\} \le 3\epsilon^2. \end{aligned} \tag{50}$$

This implies the L^2 error bound

$$\| f^\psi - f_e \|_2 \le \epsilon \sqrt{3} \| Q_\psi^{-1/2} \|_2, \tag{51}$$

where

$$\| Q_\psi^{-1/2} \|_2 = \sup_{\xi,\eta} \left\{ |\hat{p}(\xi,\eta)|^2 + (\epsilon/M)^2 \left(1 + \Gamma_{\bar{t}}^2 |\hat{z}(\xi,\eta,\bar{t})|^2 \right) \right\}^{-1/2}. \tag{52}$$

Proof. Let $\mathcal{H}$ denote the Hilbert space direct sum $L^2(R^2) \bigoplus L^2(R^2) \bigoplus L^2(R^2)$ with elements $[u,v,w]$, scalar product $([u_1,v_1,w_1],[u_2,v_2,w_2]) \equiv \langle u_1,u_2\rangle + \langle v_1,v_2\rangle + \langle w_1,w_2\rangle$, and norm $|||\ |||$. Let $\tilde{P} : L^2(R^2) \mapsto \mathcal{H}$ be defined by $\tilde{P}f = [Pf,\ \omega f,\ \omega\Gamma_{\bar{t}} Z(\bar{t}) f]$, where $\omega = (\epsilon/M)$, and let $\tilde{g} = [g,0,0]$. We seek to minimize $|||\tilde{P}f - \tilde{g}|||$ over all $f \in L^2(R^2)$. The normal equation $\tilde{P}^*\tilde{P}f^\psi = \tilde{P}^*\tilde{g}$ gives $Q_\psi f^\psi = P^* g$ with Q as in (49). By hypothesis $|||\tilde{P}f_e - \tilde{g}|||^2 \le 3\epsilon^2$. The minimizing element f^ψ is such that $\tilde{P}f^\psi$ is the orthogonal projection in $\mathcal{H}$ of $\tilde{g}$ on the range of $\tilde{P}$. By the Pythagorean theorem

$$|||\tilde{P}f^\psi - \tilde{g}|||^2 + |||\tilde{P}(f_e - f^\psi)|||^2 = |||\tilde{P}f_e - \tilde{g}|||^2 \le 3\epsilon^2. \tag{53}$$

This proves (50). We now establish (51). From (49), (50),

$$\| Q_\psi^{1/2}(f_e - f^\psi) \|_2^2 = \langle Q_\psi(f_e - f^\psi), (f_e - f^\psi)\rangle = |||\tilde{P}(f_e - f^\psi)|||^2 \le 3\epsilon^2. \tag{54}$$

Hence,

$$\| f_e - f^\psi \|_2 = \| Q_\psi^{-1/2} Q_\psi^{1/2}(f_e - f^\psi) \|_2 \le \epsilon\sqrt{3} \| Q_\psi^{-1/2} \|_2 . \tag{55}$$ ∎

8. A preliminary deblurring experiment. In the following controlled experiment, knowledge of the exact solution $f_e(x,y)$ is used to derive *exact* values for all parameters that constitute a priori information in each of the above three methods. Such exact knowledge is not available in practice. The experiment is primarily of theoretical interest. It is designed to illustrate major differences in behavior, and to properly locate the PSI method in relation to Wiener filtering and the Tikhonov–Miller method. The PSI method with *inexact* information is discussed in section 10.

The 8-bit 512×512 Marilyn Monroe image $f_e(x,y)$ in Figure 3 was synthetically defocused by Fourier domain multiplication with the expression in (27) using $R = 0.06$. This produced the exact blurred image $g_e(x,y)$. Multiplicative noise $n(x,y)$ was then added to g_e as follows. Each pixel value $g_e(x,y)$ was perturbed by adding to it the quantity $n(x,y) = 0.03\sigma(x,y)g_e(x,y)$, where $\sigma(x,y)$ is an array of uniformly distributed random numbers in the range $[-1,1]$. We term this process "adding 3% noise". With varying percentages, we shall use the same process in all our experiments. Note that no noise is thereby added at points where $g_e(x,y) = 0$. The resulting $g(x,y) = g_e(x,y) + n(x,y)$ is shown in Figure 4(A). We find $\| n \|_2 = \epsilon = 2.247$, and $\| f_e \|_1 = 107.59$, $\| f_e \|_2 = M = 131.13$. Therefore $\epsilon/M = 0.01713$. From Table

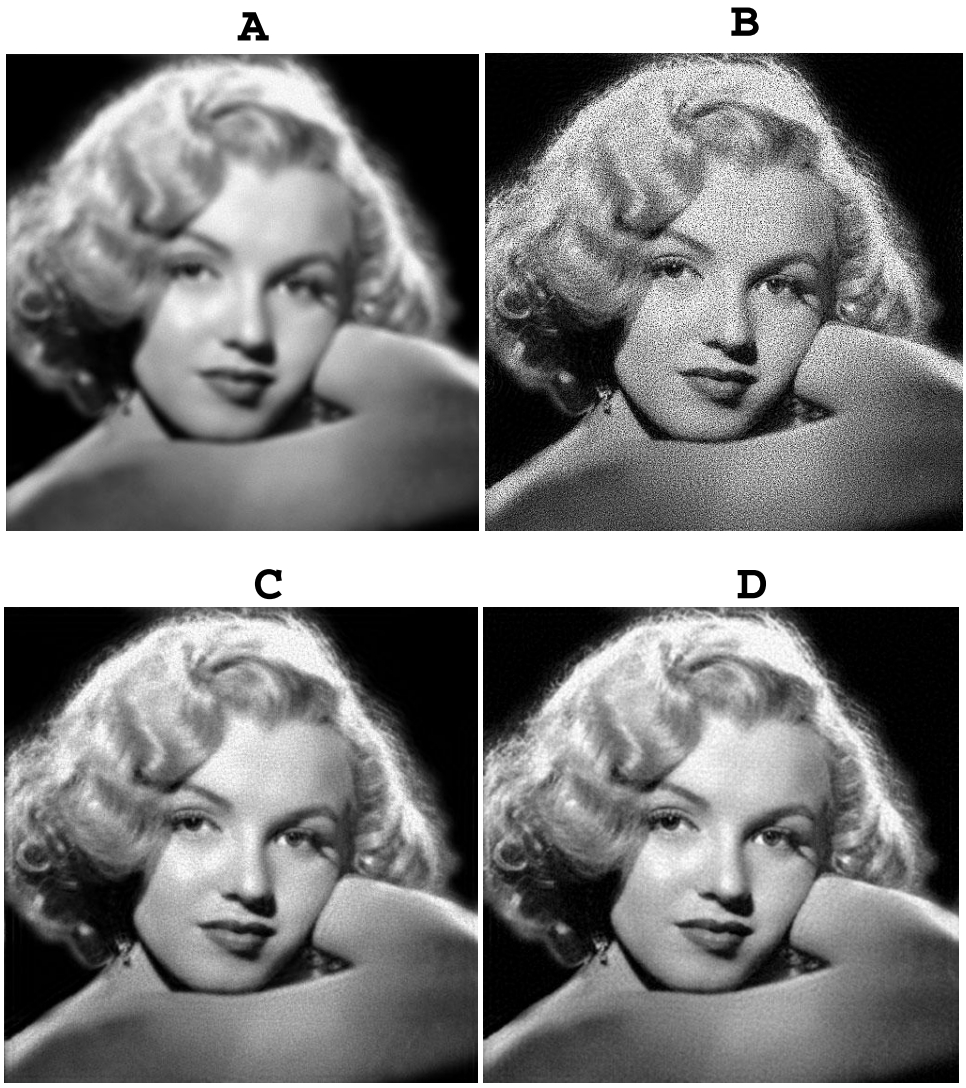

FIG. 4. *Instructive deblurring experiment with exact a priori information highlights significant differences in behavior in above three FFT-based methods.* (A) *Defocused Marilyn Monroe image with* $R = 0.06$ *and* 3% *multiplicative noise.* (B) *Tikhonov–Miller method with exact parameters* ϵ *and* M*, brings out significant noise.* (C) *PSI method with exact parameters* $\epsilon,\ M,\ \alpha = 0.474,\ C_{\bar{t}} = 0.68$. (D) *True Wiener filtering with exact power spectra* $|\hat{n}(\xi,\eta)|,\ |\hat{f}_e(\xi,\eta)|$. *Realizable PSI deblurring closely matches unrealizable true Wiener filtering.*

TABLE 2
Behavior in defocused Marilyn Monroe image in Figure 4.

Deblurring method	L^1 *relative error*	L^2 *relative error*
Tikhonov–Miller (B)	29.82%	34.17%
Poisson Singular Integral (C)	6.89%	9.04%
True Wiener filtering (D)	6.03%	7.88%

1, we have $\| U^t f_e - f_e \|_2 \leq 0.68 \| f \|_2 t^{0.474}$, $0 < t \leq 0.1$. With $\bar{t} = 0.1$, (42) gives $\Gamma_{\bar{t}} = 19.33$. Next, using FFT algorithms, we obtain the exact power spectra $|\hat{n}(\xi,\eta)|$, $|\hat{f}_e(\xi,\eta)|$. We are now ready to compare these three FFT-based procedures under optimal conditions for each method.

The Tikhonov–Miller reconstruction is shown in Figure 4(B). Significantly, this reconstruction is quite noisy, despite the use of *exact* values for ϵ and M. While the regularizing information in (29) prevents *explosive* noise amplification, it is obviously insufficient to prevent serious noise contamination. This is generally the case in the Tikhonov–Miller method. The PSI restoration is shown in Figure 4(C). Here, the additional information that $f_e \in \Lambda(\alpha, 2, \infty)$, together with the values of the constants $C_{\bar{t}}$ and α, were evidently decisive in eliminating noise. The Wiener filtered solution, shown in Figure 4(D), appears only slightly better than the PSI solution. However, the very major difference between true Wiener filtering and the approximate version known as the Tikhonov–Miller method, is another significant result brought out by this deblurring experiment.

It is instructive to study the L^1 and L^2 relative error pattern shown in Table 2. It is widely assumed in practice that the L^2 minimum error property of true Wiener filtering remains valid for the more feasible, approximate versions of such filtering. This is emphatically not the case. The Tikhonov–Miller relative errors are more than *four times larger* than the true Wiener errors. On the other hand, relative errors in the PSI method are only slightly larger than those for true Wiener filtering. Put another way, the PSI method appears to be a feasible procedure that can very substantially improve upon the Tikhonov–Miller method.

Insight into how this improvement comes about can be gained by an analysis of the respective error bounds for each method. Notice that each of the denominators on the right-hand sides of (34) and (48) are radially symmetric functions of (ξ,η), while this is not the case in (28). These denominators play a dual role. They define the actual regularization procedures in (34) and (48), and they define the resulting error bounds in (33) and (47). Because of the radial symmetry, a one-dimensional picture tells the whole story. Define the respective Tikhonov–Miller and PSI *error bound functions* $\theta_\tau(\xi)$, $\theta_\psi(\xi)$ as follows

$$
\begin{aligned}
\theta_\tau(\xi) &= \left\{ |\hat{p}(\xi,0)|^2 + (\epsilon/M)^2 \right\}^{-1/2}, \\
\theta_\psi(\xi) &= \left\{ |\hat{p}(\xi,0)|^2 + (\epsilon/M)^2 (1 + \Gamma_{\bar{t}}^2 |\hat{z}(\xi,0,\bar{t})|^2) \right\}^{-1/2}.
\end{aligned} \tag{56}
$$

In Figure 5, we plot $\theta_\tau(\xi)$ and $\theta_\psi(\xi)$ as determined by the actual parameter values that entered the deblurring experiment in Figure 4. The significant differences in these two curves translate into fundamental differences in the Fourier space regularization that defines the corresponding procedures. From (27), we see that $\theta_\tau(\xi)$ has a maximum of $M/\epsilon = 58.36$, at every point $\xi > 0$ where $J_1(0.06\ \xi) = 0$. There are 4 such points on $0 < \xi \leq 256$. The curve $\theta_\psi(\xi)$ also develops maxima at these same points, but these maxima are about *five times smaller* than those in $\theta_\tau(\xi)$, owing to the additional term involving $\hat{z}(\xi,0,\bar{t})$. Since the error estimate in each method is proportional to the maximum along the corresponding curve, it is natural to find substantially smaller errors in Figure 4(C) than in Figure 4(B).

9. Comparing total variation deblurring with PSI deblurring. The use of initial value PDE methods in image processing and computer vision has mushroomed into an important new branch of applied mathematics. The basic idea originates in

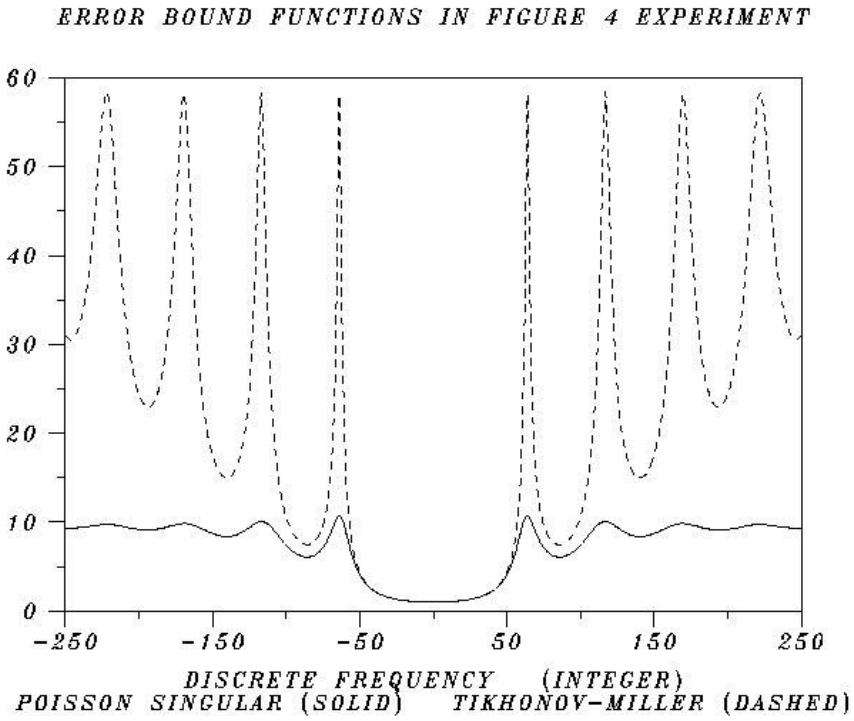

FIG. 5. *Plot of error bound functions $\theta_\tau(\xi)$ (dashed curve), and $\theta_\psi(\xi)$ (solid curve), as defined in* (56)*, for the deblurring experiment in Figure* 4*. Maximum value in θ_τ is more than five times larger than in θ_ψ. Qualitative difference in behavior in these two curves implies significant difference in Fourier domain regularization in the PSI and Tikhonov–Miller methods. Difference in maximum values explains large difference in L^2 relative errors in Figures* 4(B) *and* 4(C).

gradient descent methods for minimizing appropriate energy functionals. Instructive surveys of this general set of ideas may be found in [11] and [39].

The total variation approach introduced in [33] is one of the most popular PDE methods, and it is primarily designed to recover edges in the original image. Given the deconvolution problem $Pf = g$ as in (24), TV deblurring presupposes the exact sharp image $f_e(x, y) \in BV(R^2)$, and it produces an image $f^{tv}(x, y)$ defined by

$$f^{tv}(x,y) = Arg \min_{f \in BV(R^2)} \left\{ (\lambda/2) \parallel Pf - g \parallel_2^2 + \int_{R^2} |\nabla f| dxdy \right\}. \tag{57}$$

This means that $f^{tv}(x, y)$ is the solution of

$$P^* P f^{tv} - \lambda^{-1} \nabla . \left(\frac{\nabla f^{tv}}{|\nabla f^{tv}|} \right) = P^* g. \tag{58}$$

Here, $\lambda > 0$ is a regularization parameter that can be tuned. Provided the noise level in $g(x, y)$ is small, larger values of λ produce sharper images. Too large a value of λ leads to computational instability. Unlike the cases in (31) and (45), (58) is a nonlinear deconvolution problem that cannot be solved explicitly in Fourier space. In fact, considerable effort is generally required to obtain f^{tv} for large size imagery. In pure denoising applications, where $P = I$, this effort is usually warranted by the

quality of the resulting restoration. Recently, a new time dependent evolutionary approach to (58) has been developed [26], whereby $f^{tv}(x,y)$ is obtained as the steady state solution to the following nonlinear anisotropic diffusion problem

$$\text{(59)} \qquad \begin{cases} u_t = -\lambda|\nabla u|\ P^*(Pu-g) + |\nabla u|\ \nabla.\left(\nabla u/\{\sqrt{|\nabla u|^2+\beta}\}\right), \\ u(x,y,0) = g(x,y), \end{cases}$$

where the given blurred image $g(x,y)$ is used as the initial value. In addition, $u(x,y,t)$ satisfies homogeneous Neumann conditions at the boundary of the unit square Ω. In (59), $\beta > 0$ is a small constant designed to prevent division by zero. In [26, section 5], an efficient new explicit finite difference scheme for (59) is proposed. This scheme has improved stability and edge-enhancing properties, and converges rapidly to the desired steady state solution. Accordingly, we shall use that method in our total variation deblurring experiments.

This paper has drawn attention to the fact that most images are not smooth. The PSI method is predicated on locating $f_e(x,y)$ in the correct Lipschitz space, while TV deblurring assumes $f_e(x,y) \in BV(R^2)$. It may be argued that such refined smoothness measures are primarily applicable to $f^{\infty}(x,y)$, the original intensity field that gave rise to the digitized finite dimensional object $f_e(x,y)$, but may not be meaningful for $f_e(x,y)$ itself. Indeed, since all norms are equivalent in finite dimensional space, it remains to be seen whether such abstruse function space notions are ultimately of any computational significance.

Our first experiment involves a slightly defocused image with very little noise. The original sharp USS Eisenhower image is shown in Figure 6(A). Fourier space multiplication with (27) using $R = 0.03$, followed by the addition of 0.1% multiplicative noise, produced the blurred Figure 6(B). Because of the low noise level, we chose β small and λ large in (59), as recommended in [26]. With $\beta = 0.0001,\ \Delta t = 0.1(\Delta x)^2$ and $\lambda = 300$, we obtained Figure 6(C) at $T = 100\Delta t$. Higher values of λ were computationally unstable. Moreover, the resulting TV image did not improve if more time steps were taken. Figure 6(D) is the PSI deblurred image using exact values for $\epsilon,\ M$, and using $\alpha = 0.362,\ C_{\bar{t}} = 0.50$, from Table 1. Zooming on selected parts of the image in Figures 6(E) and 6(F), clearly shows significant loss of structural detail in the TV image, as compared with PSI deblurring. For completeness, the L^1 relative errors in this experiment were as follows: true Wiener filtering (not shown) 1.67%, PSI method 2.18%, TV deblurring 6.83%, and Tikhonov–Miller (not shown) 4.71%.

In our second experiment, the sharp English village image in Figure 7(A) was moderately defocused using $R = 0.06$, and 0.1% multiplicative noise was again added to form Figure 7(B). With β and Δt as in Figure 6(C), it was possible to choose $\lambda = 500$, and obtain Figure 7(C) at $T = 100\Delta t$. Again, no improvement was noted with more time steps. Figure 7(D) is the PSI deblurred image using the exact values for $\epsilon,\ M$, together with $\alpha = 0.439,\ C_{\bar{t}} = 0.55$, from Table 1. Because of the stronger blur, more information is now lost in TV deblurring. Zooming in on the first three houses in Figures 7(E) and 7(F), we see that the windows and roof shingles have been virtually eliminated in the TV image. The L^1 relative errors in this experiment were as follows: true Wiener filtering (not shown) 1.98%, PSI method 3.05%, TV deblurring 6.70%, and Tikhonov–Miller (not shown), 7.42%.

10. The PSI method with inexact Lipschitz data. The controlled experiments in sections 8 and 9 were designed to illustrate important theoretical points, and involved use of the PSI method with exact prior Lipschitz space data. In fact,

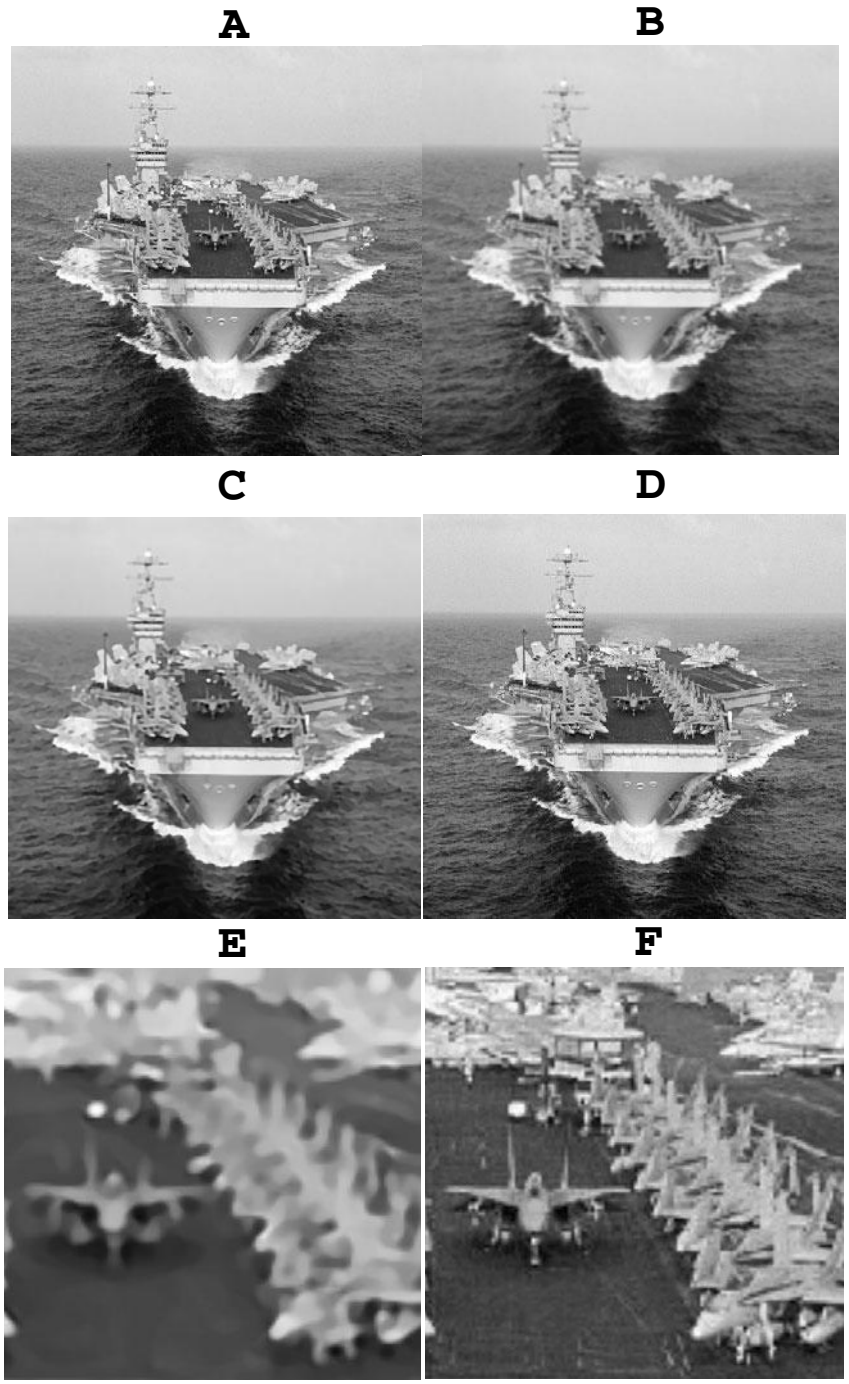

FIG. 6. *Comparison of total variation and PSI deblurring on mildly blurred image. TABLE 4
Behavior in strongly defocused USAF satellite image in Figure 9.

Deblurring method	L^1 *relative error*	L^2 *relative error*
Tikhonov–Miller (Not shown)	37.95%	33.56%
Total Variation (B)	32.91%	31.82%
PSI based on similar object (C)	20.69%	16.83%
True Wiener filtering (D)	17.50%	13.04%

the PSI method is a robust method of great practical significance that can produce useful reconstructions even with *inexact* Lipschitz data. Inspection of Table 1 shows that the values of (C, α) are typically confined to a narrow range. Indeed, a plausible guess for (C, α) might be $(0.5, 0.5)$ in many cases. In other situations, a sharp image of a similar object might provide useful values for (C, α). Such initial reconstructions can then be interactively refined through *fast* simultaneous computation and display of multiple trial PSI images, corresponding to neighboring (C, α) values. We now give two examples that show how good such *initial* reconstructions can be.

Figure 8(A) is an 8-bit 512×512 synthetically defocused Ingrid Bergman image, obtained using (27) with $R = 0.12$, followed by adding 0.5% multiplicative noise. Total variation deblurring using the scheme in [26, section 5], with $\lambda = 400,\ \beta = 0.0001$, and $T = 150\Delta t$, produces the lifeless, mannequin-like appearance shown in Figure 8(B). However, the PSI method with the plausible guess $\alpha = 0.5,\ C_{\frac{1}{t}} = 0.5$, produces Figure 8(C). This initial reconstruction is already in good qualitative agreement with the true Wiener image in Figure 8(D). The L^1 and L^2 relative errors in Table 3 indicate that the PSI method, even with such inexact data, significantly improves upon the Tikhonov–Miller and total variation methods.

Our final experiment involves the strongly defocused USAF satellite image in Figure 9(A), where $R = 0.25$ and 0.5% multiplicative noise was added. As may be expected in such a severely blurred image, total variation deblurring, shown in Figure 9(B), results in severe loss of structural detail. Here, the Mariner 5 image shown in Figure 3 may be considered a "similar" object, and the corresponding $\Lambda(\alpha, 2, \infty)$ information in Table 1, $C = 0.99,\ \alpha = 0.417$, may be used in the PSI method. Remarkably, this produces the reconstruction shown in Figure 9(C). While faint honeycomb artifacts are visible against the dark background in Figure 9(C), this initial PSI image is an excellent approximation to the optimal true Wiener image shown in Figure 9(D). Relative errors in this experiment are shown in Table 4.

In Figure 4, the PSI method's improvement over the Tikhonov–Miller method can be traced to the fact that the constraints in (29) allowed the solution to be *too rough*. In Figures 6 through 9, PSI's improvement over the total variation method stems from the fact that the minimum principle (57) forces the solution to be *too smooth*. Apparently, the use of singular integrals to calibrate image smoothness, together with the direct use of that information in constraining the solutions of the deblurring problem, constitutes an important new idea in image deconvolution.

SELF-SIMILAR BLOW-UP IN HIGHER-ORDER SEMILINEAR PARABOLIC EQUATIONS*

C. J. BUDD†, V. A. GALAKTIONOV‡, AND J. F. WILLIAMS§

Abstract. We study the Cauchy problem in $\mathbb{R}\times\mathbb{R}_+$ for one-dimensional $2m$th-order, $m>1$, semilinear parabolic PDEs of the form ($D_x=\partial/\partial x$)

$$u_t=(-1)^{m+1}D_x^{2m}u+|u|^{p-1}u, \text{ where } p>1, \quad \text{and} \quad u_t=(-1)^{m+1}D_x^{2m}u+e^u$$

with bounded initial data $u_0(x)$. Specifically, we are interested in those solutions that blow up at the origin in a finite time T. We show that, in contrast to the solutions of the classical second-order parabolic equations $u_t=u_{xx}+u^p$ and $u_t=u_{xx}+e^u$ from combustion theory, the blow-up in their higher-order counterparts is asymptotically *self-similar*. In particular, there exist exact nontrivial self-similar blow-up solutions, $u_*(x,t)=(T-t)^{-1/(p-1)}f(y)$ in the case of the polynomial nonlinearity and $u(x,t)=-\ln(T-t)+f(y)$ for the exponential nonlinearity, where $y=x/(T-t)^{1/2m}$ is the backward higher-order heat kernel variable. The profiles $f(y)$ satisfy related semilinear ODEs that share the same non–self-adjoint higher-order linear differential operators. We show that there are *at least* $2\lfloor\frac{m}{2}\rfloor$ nontrivial self-similar solutions to the full PDEs. Numerical solution of the ODEs for $m=2$ and 3 supports this, and the time dependent solutions of the PDEs for $m=2$ are then studied by using a scale invariant adaptive numerical method. It is shown that those functions $f(y)$, which have the simplest spatial shape (e.g., a single maximum), correspond to *stable* self-similar solutions. A further countable subset of nonsimilarity blow-up patterns can be constructed by linearization and matching with similarity solutions of a first-order Hamilton–Jacobi equation.

Key words. semilinear parabolic equation, blow-up, similarity solutions, asymptotic behavior

1. Introduction.

Scaling and self-similarity have been known since the 1930s to give a fundamental insight into many systems that develop singularities in finite time. A general treatment of blow-up processes naturally occurred in the 1930s–1950s in the context of N. N. Semenov's chain reaction theory, adiabatic explosion, and combustion theory (the first blow-up result was by O.M. Todes [43]); see [26, section 15] and [48]. On the other hand, in the same period there was a strong influence from the study of blow-up singularities in gas dynamics; in particular, the intense explosion (focusing) problem, admitting similarity solutions of the second kind, was considered by Bechert, Guderley, and Sedov in the 1940s; see [4, p. 127] and [49]. Another classical area of blow-up processes in the 1960s was nonlinear optics, where the main model is the nonlinear (cubic) Schrödinger equation defined in $\mathbb{R}^2$ or $\mathbb{R}^3$ that admits blow-up self-focusing solutions; see the references in [42].

1.1. On second-order semilinear and quasi-linear heat equations from combustion theory: Singularity formation.

Because of their importance to many applications, canonical equations from combustion theory such as the nonstationary

semilinear one-dimensional *Frank-Kamenetskii equation* [19] (the solid fuel model [48]),

$$u_t = u_{xx} + e^u, \quad x \in \mathbb{R}, \ t > 0, \tag{1.1}$$

and its counterpart with a power nonlinearity,

$$u_t = u_{xx} + u^p, \quad x \in \mathbb{R}, \ t > 0, \quad \text{with exponent } p > 1 \quad (u(x,t) \ge 0), \tag{1.2}$$

have been well studied for the past thirty years. It is known that these both exhibit singularities in finite time. While exact self-similar solutions are known to exist for the related second-order reaction-diffusion *quasi-linear* problems (see references to Chapter 4 in [40] and [8])

$$u_t = (|u_x|^\sigma u_x)_x + e^u \quad \text{or} \quad u_t = (u^\sigma u_x)_x + u^p \quad \text{with} \ \ \sigma > 0, \tag{1.3}$$

it is somewhat paradoxical that none exist for the above semilinear problems. Instead, the generic stable asymptotic blow-up behavior is described by approximate similarity solutions satisfying first-order Hamilton–Jacobi equations; see the references in the books [5, 40] and the surveys [35, 23]. For example, in the quasi-linear problem (1.3) with the power nonlinearity u^p, for any $p > 1$ and $\sigma > 0$, there exists an *exact* nontrivial self-similar solution of the form

$$u_S(x,t) = (T-t)^{-1/(p-1)} f(y), \quad y = \frac{x}{(T-t)^{(p-1-\sigma)/2(p-1)}}, \tag{1.4}$$

where T is the finite blow-up time and f is not identically constant and solves a related ODE; see [40, Chapter 4]. Other types of blow-up in quasi-linear heat equations via Hamilton–Jacobi asymptotics are described in [24, Chapters 9, 10].

In comparison, for the semilinear equation (1.2), looking for the same similarity solution

$$u_S(x,t) = (T-t)^{-1/(p-1)} f(y), \quad y = \frac{x}{(T-t)^{1/2}}$$

yields that, for the corresponding ODE, the only nonzero similarity profile is the trivial constant one $f \equiv \beta^\beta$, where $\beta = \frac{1}{p-1}$. Such nonexistence results are known from the 1970s; see [31] ($p = 3$), [1] ($p > 1$), and [27] for the corresponding equation in $\mathbb{R}^N$ with $1 < p \le \frac{N+2}{(N-2)_+}$. This means that, for a wide "dense" subset of general solutions $u(x,t)$ blowing up at $t = T$ at the origin $x = 0$, the similarity rescaling satisfies (see [22, 28])

$$\theta(y,t) \equiv (T-t)^{1/(p-1)} u(x,t) \to \beta^\beta \quad \text{as } t \to T^-$$

uniformly on compact subset in y. The spatial variation of the blow-up solutions can be observed on larger subsets, and the generic asymptotic behavior is as follows:

$$u(x,t) = [(p-1)(T-t)(1 + C_* \eta^2)]^{-1/(p-1)} (1 + o(1)) \tag{1.5}$$

uniformly on compact subsets in $\eta = x/[(T-t)|\ln(T-t)|]^{1/2}$, where the constant $C_* = \frac{p-1}{4p}$ does not depend on initial data (nor, in fact, on the space dimension). The non–scaling-invariant "hot-spot variable" η with an extra logarithmic factor was first formally derived in 1972 (see [31]) and was rigorously established twenty years later

(see [7, 18, 30, 37, 45, 46] and the survey [23]). The stable behavior (1.5) is essentially equivalent to the fact that the ODE for the self-similar solutions, which is obtained by a symmetry reduction of the original PDE, has no solution (other than the constant one) with an appropriate decay rate at infinity. Comparing (1.4) and (1.5) shows that nonexistence of nontrivial ODE similarity profiles implies a fundamental change of the basic spatial scale of singularity formation phenomena. The observation that the blow-up behavior of these second-order problems is only approximately self-similar with a new logarithmically perturbed backward heat kernel variable is an essential feature of many related reaction diffusion problems and the corresponding parabolic equations under consideration.

1.2. Main higher-order semilinear models, results, and plan of the paper. Higher-order semilinear parabolic equations arise in many physical applications such as thin film theory, convection-explosion theory, lubrication theory, flame and wave propagation (the Kuramoto–Sivashinsky equation and the extended Fisher–Kolmogorov equation), phase transition at critical Lifschitz points, bistable systems, and applications to structural mechanics. The effect of fourth-order terms on self-focusing problems in nonlinear optics has also recently been considered in [17, 6]. Indeed, fourth- (and higher-) order terms are increasingly recognized as being significant in many physical models, which has led to the burgeoning literature including the recent book [39], which lists a number of models and references. Therefore, it is important to know whether higher-order semilinear equations exhibit singularity behavior analogous to their classical second-order counterparts where the exact self-similar behavior is unavailable.

In the present paper we show that the higher-order generalizations of the second-order model (1.1), the *extended Frank-Kamenetskii equation*,

$$u_t = (-1)^{m+1} D_x^{2m} u + e^u, \quad x \in \mathbb{R},\ t > 0 \quad (D_x = \partial/\partial x), \tag{1.6}$$

and of (1.2),

$$u_t = (-1)^{m+1} D_x^{2m} u + |u|^{p-1} u, \quad x \in \mathbb{R},\ t > 0, \tag{1.7}$$

have self-similar blow-up solutions, and hence their evolution is somewhat simpler than in the case $m = 1$, though, of course, for $m > 1$ the problem of rigorous justification of the results becomes much more delicate. Fundamentally, we would like to understand the importance of the semilinear structure in (1.6) and (1.7) and its role in self-similarity. This study is an attempt to further mathematical understanding of higher-order parabolic equations and, in particular, the corresponding singularity formation phenomena, an area of increasing physical and mathematical importance. In particular, a model, admitting blow-up, from convection-explosion theory has been described in [33] and takes the form

$$u_t = -u_{xxxx} - [(2 - (u_x)^2) u_x]_x - \alpha u + q e^{su}. \tag{1.8}$$

Here the formation of such finite time singularities was shown to be self-similar [25] with a number of analogous properties to the generic equations (1.7) and (1.6).

In section 2 we introduce the relevant mathematical definitions, formulation of similarity variables, and rescaled equations. In section 3 we present the properties of the underlying linearized operator, which governs the "dynamics" of both equations (1.6) and (1.7) near certain blow-up solutions.

In section 4 we consider an extension of the linearized problem that makes clear the structure of the subset of nonlinear evolution patterns. In particular, we analyze bifurcation points associated with the linearized operator and present an argument for the existence of self-similar solutions. This analytic argument is strengthened with numerical and asymptotic evidence. Section 5 is devoted to the asymptotic behavior of the solutions close to bifurcation points.

Lastly, in sections 6 and 7 we construct the blow-up profiles asymptotically and compare them with numerical solutions of both the ODE for the self-similar profile and rescaled profiles from simulations of the full PDEs. A number of our results and techniques can be applied to the blow-up of radially symmetric solutions of the N-dimensional semilinear equations

$$u_t = -(-\Delta)^m u + |u|^{p-1}u \quad \text{and} \quad u_t = -(-\Delta)^m u + e^u.$$

Spectral properties of the corresponding linearized operators in $L^2_\rho(\mathbf{R}^N)$ can be found in [15, 20].

This paper is mainly devoted to the study of self-similar blow-up for higher-order semilinear parabolic equations, though we discuss some related center manifold structures. Countable spectra of other blow-up patterns that are approximately self-similar and are constructed by matching of different asymptotic regions are studied in [20]; see also [25] for (1.8).

2. Finite time blow-up solutions and similarity variables.

2.1. Blow-up solutions. Central to singularity formation phenomena for $2m$th-order reaction-diffusion equations is the concept of finite time blow-up, where the solution of the Cauchy problem with uniformly bounded initial data $u_0(x)$ becomes unbounded at some time $T \in \mathbb{R}_+$ in the sense that $u(x,t)$ exists and is classical on any time-interval $[0,T']$ with $T' \in (0,T)$ and

$$\sup_{x\in\mathbb{R}} |u(x,t)| \to \infty \quad \text{as } t \to T^-. \tag{2.1}$$

Finite time blow-up for higher-order semilinear and quasi-linear parabolic equations is well known from the 1970s. There are several techniques for proving blow-up, including the concavity methods [35], test functions methods [38] (see also [14] and references therein), and an extension of Kaplan's idea based on derivation of an ordinary differential inequality for the first Fourier coefficient of the solutions [21, 10].

2.2. Similarity variables and rescaled PDEs. Finite time blow-up singularities involve a delicate balance between the spatial and temporal derivatives and the reaction terms driving the blow-up. This balance is made naturally apparent by considering the scaling invariance of the underlying PDE. This scaling structure is also important for the numerical methods employed in integrating the full PDE; see section 5.

Because of their semilinear structure, the PDEs (1.6) and (1.7) have similar scaling symmetries, so that (1.7) is invariant with respect to the scaling transformations

$$t \mapsto \lambda t, \quad x \mapsto \lambda^{1/2m} x, \quad u \mapsto \lambda^{-1/(p-1)} u \quad \text{for all } \lambda > 0,$$

while (1.6) is invariant under the group of transformations

$$t \mapsto \lambda t, \quad x \mapsto \lambda^{1/2m} x, \quad u \mapsto u - \ln \lambda.$$

Without loss of generality we may assume that the solution $u(x,t)$ blows up at finite time $t=T$ in the sense of (2.1), and the blow-up set $B[u_0]$ defined by

$$B[u_0]=\big\{x\in I:\ \exists\ \{x_k\}\to x,\ \{t_k\}\to T^-\ \text{such that}\ u(x_k,t_k)\to\infty\big\} \tag{2.2}$$

contains the origin, $0\in B[u_0]$. Motivated by this assumption and looking for invariants of the above groups of transformations, we introduce the following self-similar spatial variable:

$$y=\frac{x}{(T-t)^{1/2m}}:\mathbb{R}\to\mathbb{R},\quad t\in[0,T),$$

and the new time variable

$$\tau=-\ln(T-t):(0,T)\to(\tau_0,\infty)\quad\text{with}\ \ \tau_0=-\ln T.$$

Then for the polynomial nonlinearity we define a new dependent variable (the rescaled solution) $\theta(y,\tau)$ by

$$u(x,t)=(T-t)^{-1/(p-1)}\theta(y,\tau) \tag{2.3}$$

and for the exponential nonlinearity by

$$u(x,t)=-\ln(T-t)+\theta(y,\tau). \tag{2.4}$$

Rescaling (1.7) in terms of the new variables by substituting (2.3), we obtain the following PDE for the rescaled solution θ:

$$\theta_\tau=\boldsymbol{\mathcal{L}}\theta+G_p(\theta),\quad y\in\mathbb{R},\ \tau>\tau_0,\quad\text{where}\ \ G_p(\theta)=|\theta|^{p-1}\theta-\frac{1}{p-1}\,\theta, \tag{2.5}$$

and the linear differential operator $\boldsymbol{\mathcal{L}}$ is given by

$$\boldsymbol{\mathcal{L}}\equiv(-1)^{m+1}D_y^{2m}-\frac{y}{2m}\,D_y. \tag{2.6}$$

Similarly, rescaling (1.6) leads to the PDE

$$\theta_\tau=\boldsymbol{\mathcal{L}}\theta+G_e(\theta),\quad y\in\mathbb{R},\ \tau>\tau_0,\quad\text{where}\ \ G_e(\theta)=e^\theta-1. \tag{2.7}$$

It is important that, unlike the well understood case $m=1$, for any $m>1$ the operators on the right-hand sides *are not potential*, and (2.5) and (2.7) do not possess Lyapunov functions.

2.3. Preliminaries: Local and asymptotic properties of self-similar solutions. Exact (not just asymptotic) self-similar solutions are those that are invariant under the group of transformations, i.e., correspond to suitable stationary solutions $\theta(y)$ that are independent of the rescaled time τ. Any exact self-similar solution to (1.7) takes the form

$$u_S(x,t)=(T-t)^{-1/(p-1)}f(y), \tag{2.8}$$

where $f(y)$ satisfies the ODE

$$\boldsymbol{\mathcal{L}}f+G_p(f)=0\quad\text{in}\ \ \mathbb{R}. \tag{2.9}$$

It is natural to impose the symmetry conditions at the origin

$$f'(0) = f'''(0) = \cdots = f^{(2m-1)}(0) = 0. \tag{2.10}$$

Then a stable (generic) self-similar solution with a suitable similarity profile f in (2.8) means that, for a sufficiently wide and dense subset of global symmetric nonstationary solutions to (2.5), there holds

$$\theta(y,\tau) \to f(y) \quad \text{as} \quad \tau \to \infty$$

in a suitable metric. For such a stable similarity solution (2.8) to have nonvanishing trace in the limit $t \to T^-$ and to rule out constant solutions, we need to impose a special decay condition on $f(y)$ as $y \to \infty$. In particular, we will demand that there exist a finite limit $u(x,t) \to u(x,T^-)$ as $t \to T^-$ for arbitrarily small fixed $|x| > 0$.

2.3.1. Asymptotic behavior at infinity. First we need to describe possible asymptotics of small solutions to (2.5) satisfying $f(y) \to 0$ as $y \to +\infty$. Consider the linearization of (2.9) about $f = 0$,

$$\boldsymbol{\mathcal{L}} f - \frac{1}{p-1} f = 0, \quad y > 0. \tag{2.11}$$

Setting $z = y^\nu$ with $\nu = \frac{2m}{2m-1}$ reduces it to

$$f^{(2m)} - a_1 f' - a_2 z^{-1} f + \mathbf{B}(z) f = 0, \tag{2.12}$$

where $a_1 = (-1)^{m+1} \frac{1}{2m} \nu^{1-2m}$, $a_2 = (-1)^{m+1} \frac{1}{p-1} \nu^{-2m}$, and

$$\mathbf{B}(z) f = \sum_{j=1}^{2m-1} \gamma_j z^{j-2m} f^{(j)}$$

is a linear operator with bounded coefficients as $z \to \infty$, where the first coefficient of derivative f' is of order $O(z^{1-2m})$. By the perturbation theory of higher-order linear ODEs (see Chapters III–V in [12]), we have that the leading terms of exponentially decaying solutions are described by the operator in (2.12) with constant coefficients,

$$f^{(2m)} - a_1 f' = 0. \tag{2.13}$$

Setting $f = e^{pz}$, $p \neq 0$, gives the characteristic equation $p^{2m} - a_1 p = 0$, whence

$$p^{2m-1} = a_1 = \frac{(-1)^{m+1}}{2m\nu^{2m-1}} \equiv \rho_0^{2m-1} (-1)^{m+1}, \quad \text{where } \rho_0 > 0. \tag{2.14}$$

For any $m \geq 1$, there exist $2m-1$ roots $\{p_0, p_1, \dots, p_{2m-2}\}$ given by

$$p_k = \rho_0 e^{i(2k+1)\pi/(2m-1)}, \ m = 2l; \quad p_k = \rho_0 e^{i2\pi k/(2m-1)}, \ m = 2l+1, \tag{2.15}$$

where $m-1$ roots have negative real parts ($\operatorname{Re} p_k < 0$). These correspond to $l \leq k \leq 3l-2$ for even $m = 2l$ and $l+1 \leq k \leq 3l$ for odd $m = 2l+1$. The linearized equation (2.11) has a κ_m-dimensional subspace of exponentially decaying solutions as $y \to \infty$, where $\kappa_m = 2m-3$ for m even and $\kappa_m = 2(m-1)$ for m odd. For the second-order case $m = 1$, it is empty.

On the other hand, (2.12) admits a solution with algebraic decay (rather than exponential) as $z \to \infty$ described by the first-order operator

$$-a_1 f' - a_2 z^{-1} f = 0 \quad \Longrightarrow \quad f(z) = c\, z^{-(2m-1)/(p-1)}.$$

Existence of solutions with such a decay for the perturbed equation (2.12) is established by a standard expansion analysis by calculating solutions via Kummer-type series converging uniformly for $z \gg 1$. For the linearized equation (2.11), the leading order behavior is algebraic,

$$f(y) = C|y|^{2m/(p-1)}(1 + o(1)) \quad \text{as } y \to \infty, \text{ with } C \neq 0. \tag{2.16}$$

In summary, these results yield that (2.11) admits a

$$(\kappa_m{+}1)\text{-dimensional subset of admissible solutions as } y \to \infty. \tag{2.17}$$

Actually, for the nonlinear equation (2.9) we are going to look for profiles $f(y)$ having the algebraic decay (2.16). Then for such similarity solutions (2.8), the limit-time profile is bounded for any $x \neq 0$ and is given by

$$u_S(x, T^-) = C|x|^{-2m/(p-1)}.$$

Asymptotic and numerical computations suggest that the solutions of (2.9) which satisfy (2.16) are *isolated* and that the constant C plays a role of a *nonlinear* eigenvalue. In section 5 we give an asymptotic formula for one value of C valid in a certain limit.

Likewise for (1.6), the self-similar solution is given by

$$u_S(x, t) = -\ln(T - t) + f(y), \tag{2.18}$$

where the function $f(y)$ satisfies the ODE

$$\boldsymbol{\mathcal{L}} f + G_e(f) = 0 \tag{2.19}$$

with the symmetry conditions (2.10). We look for similarity profiles $f(y) \to -\infty$ "slowly" as $y \to \infty$. The limit $\lim_{f \to -\infty} G_e(f) = -1$, so we first consider the "linearized" equation

$$\boldsymbol{\mathcal{L}} f = 1. \tag{2.20}$$

Setting $f(y) = -2m \ln y + g(y)$ for $y > 0$, we obtain

$$\boldsymbol{\mathcal{L}} g = 1 + 2m\, \boldsymbol{\mathcal{L}} \ln y \,=\, 2m(-1)^{m+1} D_y^{2m} \ln y = O(y^{-2m}) \quad \text{as } y \to +\infty. \tag{2.21}$$

As above, the homogeneous equation $\boldsymbol{\mathcal{L}} g = 0$ has a κ_m-dimensional subspace of exponentially decaying solutions. The nonhomogeneous equation (2.21) has solutions $g(y) = C + o(1)$ as $y \to +\infty$, so that (2.17) holds for (2.20), admitting a $\kappa_m + 1$-dimensional subset of solutions satisfying

$$f(y) = -2m \ln |y| + C + o(1) \quad \text{as} \quad y \to \infty. \tag{2.22}$$

In this case the limit-time profile is given by

$$u_S(x, T^-) = -2m \ln |x| + C,$$

where again the constant $C \in \mathbb{R}$ is a certain isolated nonlinear eigenvalue which can be approximated asymptotically.

Obviously, ODEs (2.9) and (2.19) admit constant solutions $f^*_{p,e}$ satisfying

$$G_p(f^*_p) = 0,\ f^*_p = \beta^\beta, \quad \text{and} \quad G_e(0) = 0,\ f^*_e = 0,$$

respectively. The trivial solution $f = 0$ also solves (2.9). The linearizations of the operator $\boldsymbol{\mathcal{L}} + G_p$ about β^β and $\boldsymbol{\mathcal{L}} + G_e$ about 0 coincide and are equal to $\boldsymbol{\mathcal{L}} + I$, where I is the identity operator. The spectral properties of this nonsymmetric operator in a weighted L^2-space play an important part in our analysis and help to describe the perturbation of the solutions from the constant state. They are essential to describe the long time dynamics of both of the PDEs (2.5) and (2.7). We will describe the properties of the linearized operator in the next section.

3. Spectral properties of $\boldsymbol{\mathcal{L}}$ and its adjoint. In this section we study the spectral properties of the linear differential operator $\boldsymbol{\mathcal{L}}$ and its adjoint $\boldsymbol{\mathcal{L}}^*$ given by

$$\boldsymbol{\mathcal{L}}^* = (-1)^{m+1} D_y^{2m} + \frac{1}{2m}\, y \frac{d}{dy} + \frac{1}{2m}\, I. \tag{3.1}$$

Both operators are nonsymmetric and do not admit a self-adjoint extension. To determine the nature of the stability of the constant solution and also to apply the Fredholm alternative to computing asymptotic solutions of the ODEs, it is necessary to determine the spectrum and corresponding eigenfunctions of both $\boldsymbol{\mathcal{L}}$ and $\boldsymbol{\mathcal{L}}^*$. We present some results from [15] and [20] which describe these.

3.1. The fundamental solution. We start by determining the spectrum and the eigenfunctions of the adjoint operator $\boldsymbol{\mathcal{L}}^*$. In order to find the null eigenfunction, we begin with the fundamental solution of the corresponding linear $2m$th-order parabolic operator. Consider the linear equation

$$u_t = (-1)^{m+1} D_x^{2m} u \quad \text{in } \mathbb{R} \times \mathbb{R}_+. \tag{3.2}$$

The fundamental solution of (3.2) has the standard self-similar form

$$b(x,t) = t^{-1/2m} F(y), \quad y = \frac{x}{t^{1/2m}}. \tag{3.3}$$

Substituting $b(x,t)$ into (3.2) yields that the radially symmetric profile $F(y)$ is the unique even square integrable solution of the linear ODE

$$\boldsymbol{\mathcal{L}}^* F = 0 \quad \text{in } \mathbb{R} \tag{3.4}$$

and is a null eigenfunction of $\boldsymbol{\mathcal{L}}^*$. Taking a Fourier transform leads to

$$F(y) = \alpha \int_0^\infty e^{-s^{2m}} \cos(sy) ds. \tag{3.5}$$

The coefficient α is chosen to normalize $\int F = 1$, so that

$$\alpha = \left(\int_0^\infty \int_0^\infty e^{-s^{2m}} \cos(sy)\, ds\, d\eta \right)^{-1}.$$

The rescaled kernel $F(\eta)$ then satisfies a standard pointwise estimate (see [16])

$$|F(y)| \le d_1 e^{-d_2 |y|^\nu} \quad \text{in } \mathbb{R},$$

where d_1 and d_2 are positive constants. Applying the Fourier transform to (3.2) and performing the rescaling, we have

$$\mathcal{F}(b(\cdot,t))(\xi) = e^{-\xi^{2m}t} \quad \text{and} \quad \hat{F}(\omega) = \mathcal{F}(F(\cdot))(\omega) = e^{-\omega^{2m}}. \tag{3.6}$$

3.2. The discrete real spectrum and eigenfunctions of the adjoint operator $\boldsymbol{\mathcal{L}^*}$. We describe the spectrum $\sigma(\boldsymbol{\mathcal{L}}^*)$ of the adjoint operator in the weighted space $L^2_{\rho^*}(\mathbf{R})$ with the exponential weight

$$\rho^*(y) = e^{a|y|^\nu} > 0 \quad \text{in } \mathbb{R}, \quad \nu = \frac{2m}{2m-1}, \tag{3.7}$$

where $a < 2d_2$ is a sufficiently small positive constant. Denoting by $\langle\cdot,\cdot\rangle_*$ and $\|\cdot\|_*$ the corresponding inner product and induced norm, respectively, we introduce a Hilbert space of functions $H^{2m}_{\rho^*}(\mathbb{R})$ with the inner product and norm

$$\langle v, w\rangle_* = \int_{\mathbb{R}} \rho^*(y) \sum_{k=0}^{2m} D^k v(y)\, \overline{D^k w(y)}\, dy, \qquad \|v\|_*^2 = \int_{\mathbb{R}} \rho^*(y) \sum_{k=0}^{2m} |D^k v(y)|^2\, dy.$$

Then $H^{2m}_{\rho^*}(\mathbb{R}) \subset L^2_{\rho^*}(\mathbb{R}) \subset L^2(\mathbb{R})$, and $\boldsymbol{\mathcal{L}}^*$ is a bounded linear operator from $H^{2m}_{\rho^*}(\mathbb{R})$ to $L^2_{\rho^*}(\mathbb{R})$. With these definitions, the spectral properties of the operator $\boldsymbol{\mathcal{L}}$ are given by the following lemma.

LEMMA 3.1. (i) *The spectrum of $\boldsymbol{\mathcal{L}}^*$ (and hence of $\boldsymbol{\mathcal{L}}$) comprises real simple eigenvalues only,*

$$\sigma(\boldsymbol{\mathcal{L}}^*) = \left\{ \lambda_k = -\frac{k}{2m},\ k = 0, 1, 2, \dots \right\}. \tag{3.8}$$

(ii) *The eigenfunctions $\psi^*_k(y)$ are given by*

$$\psi^*_k(y) = \frac{(-1)^k}{\sqrt{k!}} D^k F(y) \tag{3.9}$$

and form a complete subset in $L^2(\mathbf{R})$ and in $L^2_{\rho^*}(\mathbf{R})$. (Here F is as defined in (3.5).)

(iii) *The resolvent $(\boldsymbol{\mathcal{L}}^* - \lambda I)^{-1} : L^2_{\rho^*}(\mathbb{R}) \to L^2_{\rho^*}(\mathbb{R})$ is a compact integral operator.*

Most importantly, the operators $\boldsymbol{\mathcal{L}}^*$ and $\boldsymbol{\mathcal{L}}$ have zero Morse index (no eigenvalues have positive real part).

3.3. The polynomial eigenfunctions of the operator $\boldsymbol{\mathcal{L}}$. We now consider the operator (2.6) in the weighted space $L^2_\rho(\mathbb{R})$ ($\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ are the inner product and the norm), with the exponentially decaying weight function

$$\rho(y) \equiv \frac{1}{\rho^*(y)} = e^{-a|y|^\nu} > 0, \tag{3.10}$$

and ascribe to $\boldsymbol{\mathcal{L}}$ the domain $H^{2m}_\rho(\mathbb{R})$ that is dense in $L^2_\rho(\mathbb{R})$. Then $\boldsymbol{\mathcal{L}} :\ H^{2m}_\rho(\mathbb{R}) \to L^2_\rho(\mathbb{R})$ is a bounded linear operator, $\boldsymbol{\mathcal{L}}^*$ is adjoint to $\boldsymbol{\mathcal{L}}$, and, denoting by $\langle\cdot,\cdot\rangle$ the inner product on $L^2(\mathbb{R})$, we have

$$\langle \boldsymbol{\mathcal{L}} v, w\rangle = \langle v, \boldsymbol{\mathcal{L}}^* w\rangle \quad \text{for any } v \in H^{2m}_\rho(\mathbb{R}),\ w \in H^{2m}_{\rho^*}(\mathbb{R}). \tag{3.11}$$

The eigenfunctions of $\boldsymbol{\mathcal{L}}$ take a particularly simple polynomial form and are as follows.

LEMMA 3.2. (i) *The eigenfunctions $\psi_k(y)$ of $\boldsymbol{\mathcal{L}}$ are polynomials in y of order k given by*

$$\psi_k(y) = \frac{1}{\sqrt{k!}} \sum_{j=0}^{\lfloor -\lambda_k \rfloor} \frac{(-1)^{mj}}{j!} D^{2mj} y^k, \quad k = 0, 1, 2, \dots , \tag{3.12}$$

and form a complete subset in $L^2_\rho(\mathbb{R})$. (Here $\lfloor \cdot \rfloor$ denotes the integer part.)

(ii) *$\boldsymbol{\mathcal{L}}$ has compact resolvent $(\boldsymbol{\mathcal{L}} - \lambda I)^{-1}$ in $L^2_\rho(\mathbb{R})$.*

COROLLARY 3.3. *With the definition* (3.9) *of the adjoint basis, integrating by parts, we have that the orthonormality condition holds*

$$\langle \psi_k, \psi_l^* \rangle = \delta_{k,l} \quad \textit{for any } k, l \geq 0, \tag{3.13}$$

where $\delta_{\kappa,l}$ is the Kronecker delta.

COROLLARY 3.4. *If $m = 2$, then there are coefficients α_j (depending on k) such that, for $k = 4r + 2$ and $k = 4r$,*

$$\psi_{4r+2} = y^2 \sum_{j=0}^{r} \alpha_j y^{4j} \quad \textit{and} \quad \psi_{4r} = \sum_{j=0}^{r} \alpha_j y^{4j}, \qquad \alpha_0 \neq 0.$$

For example, if $m = 2$ (a case we consider in detail first), then the first four even eigenfunctions are

$$\psi_0(y) = 1, \quad \psi_2(y) = \frac{y^2}{\sqrt{2}}, \quad \psi_4(y) = \frac{(y^4 + 24)}{\sqrt{24}}, \quad \psi_6(y) = \frac{y^2(720 + y^4)}{\sqrt{6!}}, \tag{3.14}$$

with corresponding eigenvalues $0, -\frac{1}{2}, -1, -\frac{3}{2}$.

4. Local asymptotic analysis: Invariant subspaces and bifurcation points. In this section we use the spectral properties of the linearized operators to determine the local stability of the constant solutions of the rescaled PDEs (2.5) and (2.7). We begin with the linearized stability analysis and describe invariant subspaces.

4.1. Invariant eigenspaces. Since the nonlinearities under consideration satisfy $G_p'(\beta^\beta) = G_e'(0) = 1$, let us consider solutions of (2.5) and (2.7) as perturbations of the constant solution of the form

$$\theta(y, \tau) = f^* + g(y, \tau) \quad \text{with} \quad \|g\| \ll 1.$$

In both cases g satisfies a perturbed PDE

$$g_\tau = (\boldsymbol{\mathcal{L}} + I)g + \bar{G}(g), \quad \text{where } \bar{G}(g) = G(f^* + g) - g, \tag{4.1}$$

with a quadratic nonlinear perturbation $\bar{G}$,

$$\bar{G}(g) = c_2 g^2 + c_3 g^3 + \cdots \quad \text{as} \quad g \to 0, \tag{4.2}$$

and the coefficients depending on the nonlinearity, $c_2 = \frac{1}{2}$, $c_3 = \frac{1}{6}, \dots$ for G_e and $c_2 = \frac{1}{2}p(p-1)^{1/(p-1)}$, $c_3 = \frac{1}{6}p(p-1)^{2/(p-1)}(p-2), \dots$ for G_p.

In what follows, we restrict our attention to symmetric in x solutions $u = u(|x|, t)$ and hence to symmetric in y rescaled solutions $\theta = \theta(|y|, \tau)$ and $g = g(|y|, \tau)$. In

the space $L^2_{0,\rho}(\mathbb{R})$ of symmetric functions, it follows from (3.8) that $\boldsymbol{\mathcal{L}} + I$ has the spectrum

$$\sigma(\boldsymbol{\mathcal{L}} + I) = \left\{ \tilde{\lambda}_k = 1 - \frac{k}{2m},\ k = 0, 2, 4, \dots \right\}. \tag{4.3}$$

Let $\tilde{L}^2_{0,\rho} \subseteq L^2_{0,\rho}$ be the subspace of eigenfunction expansions, where $\{\psi_k\}$ is closed, obtained as the closure of the subset of finite sums $\{v = \sum c_k \psi_k\}$ in the norm $\|\cdot\|$ [15]. Then

$$\tilde{L}^2_{0,\rho}(\mathbb{R}) = E^u(0) \oplus E^c(0) \oplus E^s(0),$$

where $E^u(0)$, $E^c(0)$, and $E^s(0)$ are the unstable, center, and stable subspaces of $\boldsymbol{\mathcal{L}} + I$ given by

$$\begin{aligned} E^u(0) &= \mathrm{Span}\{\psi_0, \psi_2, \dots, \psi_{2m-2}\}, \\ E^c(0) &= \mathrm{Span}\{\psi_{2m}\}, \\ E^s(0) &= \mathrm{Span}\{\psi_{2m+2},\ \psi_{2m+4}, \dots\}. \end{aligned}$$

In particular, the dimension of the unstable subspace is precisely m.

Consider the two one-dimensional unstable subspaces corresponding to positive eigenvalues of the operator $\boldsymbol{\mathcal{L}} + I$, namely

$$\tilde{\lambda}_0 = 1,\ \ \psi_0(y) = 1 \quad \text{and} \quad \tilde{\lambda}_2 = 1 - \frac{1}{m},\ \ \psi_2(y) = \frac{y^2}{\sqrt{2}}. \tag{4.4}$$

As is usual in blow-up problems, the first unstable mode with $k = 0$ corresponds to the instability of blow-up behavior with respect to perturbations of the blow-up time T.

In contrast, the second mode with $k = 2$ describes an actual instability of the constant solution which is in the direction of $\psi_2(y)$ and is in the space of rescaled solutions having the same fixed blow-up time T. From our asymptotic calculations and numerical experiments we expect that the orbits that arise from the instability of the constant solution in the PDEs (2.7) and (2.5) when $m > 1$ are uniformly bounded and stabilize to one of the self-similar solutions. Namely, the first such unstable mode with $\tilde{\lambda}_2 = 1 - \frac{1}{m} > 0$ gives a heteroclinic connection of f^* with a nonconstant stable (generic) similarity profile $f_1(y)$.

It is significant that when $m = 1$, there is no such unstable mode. In contrast, the dimension of the unstable subspace is one corresponding only to the change in the blow-up time. The eigenfunction ψ_2 then has eigenvalue zero, and the behavior of the perturbations of the constant solution must be studied on the center manifold. It is this which leads to the approximate self-similar behavior (1.5) described in the introduction.

Before performing some formal invariant manifold analysis for higher-order PDEs, note that the main properties of connecting equilibria and transversality of intersections of the corresponding stable and unstable manifolds are known for the one-dimensional second-order parabolic equations

$$u_t = u_{xx} + f(x, u) \quad \text{in } (0,1) \times \mathbb{R}_+, \quad u = 0 \text{ at } x = 0, 1 \text{ for } t > 0,$$

and were obtained in [29, 3] and [11] using Sturm's theorem on the nonincrease of the number of zeros (intersections) of solutions to linear second-order parabolic equations. This Sturmian property is not true for the fourth- and higher-order parabolic

equations (owing to the lack of a maximum principle in these cases), for which there are some particular results (see references in [39]), and in general the structure of connecting orbits remains an important open problem.

4.2. The center subspace. Consider the center subspace $E^c(0)$ in the case of general m. From Lemma 3.2, it follows that the null eigenfunction of the operator $\boldsymbol{\mathcal{L}}$ is given by ψ_{2m} so that

$$\tilde{\lambda}_{2m} = 0 \quad \text{and} \quad \psi_{2m}(y) = \frac{[y^{2m} + (-1)^m (2m)!]}{\sqrt{(2m)!}}\,. \tag{4.5}$$

We now present a simple calculation showing that the behavior on the center manifold is semistable.

PROPOSITION 4.1. *Let $g(\cdot,\tau) \in H^{2m}_{0,\rho}(\mathbb{R})$ exhibit the center subspace dominance, i.e.,*

$$g(\cdot,\tau) = a_{2m}(\tau)\psi_{2m}(\cdot) + w(\cdot,\tau) \quad \textit{for } \tau \gg 1, \tag{4.6}$$

where $w(\cdot,\tau) \in \mathcal{L}^{\perp}\{\psi_{2m}\}$ and $w(\cdot,\tau) = o(\|g(\cdot,\tau)\|) = o(|a_{2m}(\tau)|)$ as $\tau \to \infty$. Then

$$a_{2m}(\tau) = -\frac{1}{\gamma_0 \tau}(1 + o(1)) \quad \textit{as } \tau \to \infty, \textit{ where } \gamma_0 = c_2 \langle (\psi_{2m})^2, \psi^*_{2m} \rangle \neq 0. \tag{4.7}$$

It follows from (4.7) that $a_{2m}(\tau)$ cannot change sign in any neighborhood of $\tau = \infty$, meaning a one-sided instability of the center manifold behavior.

Proof. We look for a solution of (4.1) via a uniformly convergent eigenfunction expansion

$$g(\cdot,\tau) = \sum a_k(\tau)\psi_k(\cdot). \tag{4.8}$$

Substituting this expression into (4.1) and multiplying by ψ^*_k in $L^2(\mathbb{R})$, we arrive at a dynamical system for the expansion coefficients

$$\dot{a}_k = \tilde{\lambda}_k a_k + \langle \bar{G}(g), \psi^*_k \rangle, \quad k = 0, 2, \dots\,. \tag{4.9}$$

Consider an equation for the coefficient a_{2m} with $\tilde{\lambda}_{2m} = 0$. In view of assumption (4.6) and (4.2), assuming that $|a_{2m}(\tau)| \ll 1$, it follows that

$$\dot{a}_{2m} = (\gamma_0 + o(1)) a^2_{2m} \quad \text{for } \tau \gg 1. \tag{4.10}$$

Calculating γ_0 by using the adjoint eigenfunction $\psi^*_{2m} = D^{2m}_y F/\sqrt{2m!}$ and (4.5), we obtain that

$$\gamma_0 = c_2 (-1)^{m+1} \sqrt{(2m!)} \left(\frac{(4m)!}{[(2m)!]^2} - 2 \right). \tag{4.11}$$

Integrating (4.10) as a standard ODE, we deduce that any small solution for $\tau \gg 1$ has the asymptotic behavior (4.7). ∎

It follows from the quadratic "ODE" (4.10) that the center manifold behavior exhibits a typical semistable ("saddle-node") structure. Because the constant profile β^β is only semistable, small perturbations in the unstable direction may evolve to self-similar solutions. We present some evidence for this conjecture and the role of the parity of m in sections 5 and 6.

In view of known spectral and sectorial properties of operators $\boldsymbol{\mathcal{L}}$ and $\boldsymbol{\mathcal{L}}^*$ [15, 20], we expect that the center (and stable; see section 7) manifold behavior can be justified by the invariant manifold theory in interpolation spaces; see [36, Chapter 9].

4.3. Bifurcation points. In this subsection we extend the ODEs (2.9) and (2.19) for similarity profiles and consider the family of ODEs with a parameter $\mu \geq 0$:

$$(-1)^{m+1} D_y^{2m} f - \mu f' y + G(f) = 0 \quad \text{for } y > 0 \text{ with conditions (2.10).} \tag{4.12}$$

Recall that, for single-point blow-up, we need to impose an extra condition (of the type (2.16) or (2.22) with $\frac{1}{2m} \mapsto \mu$) on the decay of $f(y)$ at infinity.

If we take $\mu = \frac{1}{2m}$ and the appropriate nonlinearity, $G = G_p$ or G_e, then we obtain the ODEs (2.9) and (2.19) for the rescaled self-similar profiles. More generally, suitable solutions of (4.12) depend smoothly upon $\mu \approx \frac{1}{2m}$ and coincide with the self-similar solutions when $\mu = \frac{1}{2m}$. In either case we define a corresponding linearized operator $\boldsymbol{\mathcal{L}}_\mu$ by

$$\boldsymbol{\mathcal{L}}_\mu = (-1)^{m+1} D_y^{2m} - \mu y D_y + I \equiv \boldsymbol{\mathcal{L}} + \left(1 - \mu + \frac{1}{2m}\right) I. \tag{4.13}$$

Changing the independent variable to

$$y = \frac{z}{(2m\mu)^{1/2m}}, \tag{4.14}$$

we have

$$\frac{1}{2m\mu} \boldsymbol{\mathcal{L}}_\mu = (-1)^{m+1} D_z^{2m} - \frac{1}{2m} z \frac{d}{dz} + \frac{1}{2m\mu} I \equiv \boldsymbol{\mathcal{L}} + \frac{1}{2m\mu} I. \tag{4.15}$$

Hence $\boldsymbol{\mathcal{L}}_\mu : H^{2m}_{0,\rho}(\mathbb{R}) \to L^2_{0,\rho}(\mathbb{R})$ is a bounded linear operator (with a change in the coefficient a in the weight function (3.10) if necessary). By Lemma 3.1, the spectrum $\boldsymbol{\mathcal{L}}_\mu$ in the space $L^2_{0,\rho}(\mathbb{R})$ of radial functions is given by

$$\sigma(\boldsymbol{\mathcal{L}}_\mu) \equiv 2m\mu\, \sigma\left(\boldsymbol{\mathcal{L}} + \frac{1}{2m\mu} I\right) = \{1 - 2\mu l,\ l = 0, 1, 2, \dots\}, \tag{4.16}$$

with eigenfunctions ψ_{2l} as before, rescaled according to the transformation (4.14).

We next compute bifurcation points from the constant solution f^*. Since the weight function (3.10) is exponentially decaying as $y \to \infty$, in general, the inclusion $f \in H^{2m}_\rho$ does not imply the boundedness of f, unlike the adjoint case of the increasing weight (3.7), where $H^{2m}_\rho \subset C$. Nonlinearity $G(f)$ is not uniformly Lipschitz continuous on bounded subsets from H^{2m}_ρ. Therefore, we truncate the nonlinearity in (4.12) by replacing G by G_n, which satisfies

$$G_n(f) \equiv G(f) \quad \text{for } |f| \leq n, \ \ n = 1, 2, \dots,$$

and $G_n(f)$ is sufficiently smooth and uniformly Lipschitz continuous in $\mathbb{R}$. For $G = G_e$, we need only perform the truncation for $f > n$. We have

$$G_n(f) \to G(f) \quad \text{as } n \to \infty \text{ uniformly on compact subsets.}$$

Replacing the full problem by the truncated one

$$(-1)^{m+1} D_y^{2m} f - \mu y f' + G_n(f) = 0 \tag{4.17}$$

is permissible because we are interested in bounded solutions f, for which the nonlinearities $G_p(f)$ and $G_e(f)$ have finite range.

PROPOSITION 4.2. *For any $m \geq 1$, the values of μ for which the spectrum of $\boldsymbol{\mathcal{L}}_\mu$ contains zero,*

$$1 - 2\mu l = 0 \implies \mu_l = \frac{1}{2l}, \quad l = 1, 2, \dots , \tag{4.18}$$

are bifurcation points for problem (4.17).

Proof. Using rescaling (4.14) and setting $f = f^* + g$, equation (4.17) takes the form

$$(\boldsymbol{\mathcal{L}} - I)g = \tilde{\mu} g + (1 + \tilde{\mu}) G_n(g), \quad \text{where } \tilde{\mu} = -1 - \frac{1}{2m\mu}. \tag{4.19}$$

Consider the Hammerstein operator $(\boldsymbol{\mathcal{L}} - I)^{-1} G_n$. By Lemma 3.2, $(\boldsymbol{\mathcal{L}} - I)^{-1}$ is a compact operator in $L^2_{0,\rho}$ with simple eigenvalues $\{-1/(1 + \frac{l}{m}) \leq -1,\ l = 0, 1, 2, \dots\}$. By construction, G_n is uniformly Lipschitz continuous, $|G_n(g)| \leq C_1 + C_2|g|$ in $\mathbb{R}$, and hence $G_n : L^2_{0,\rho} \to L^2_{0,\rho}$. Therefore, the product $(\boldsymbol{\mathcal{L}} - I)^{-1} G_n$ is a compact operator in $L^2_{0,\rho}$; see [34, Chapter V]. Hence, in the nonlinear integral equation written as a fixed point problem

$$g = \mathbf{A}(g, \tilde{\mu}) \equiv \tilde{\mu} (\boldsymbol{\mathcal{L}} - I)^{-1} g + (1 + \tilde{\mu}) (\boldsymbol{\mathcal{L}} - I)^{-1} G_n(g), \tag{4.20}$$

bifurcation from the origin occurs iff $\tilde{\mu}$ coincides with characteristic values of $(\boldsymbol{\mathcal{L}} - I)^{-1}$ (simple eigenvalues of $\boldsymbol{\mathcal{L}} - I$), i.e., at $\tilde{\mu}_l = -1 - \frac{l}{m}$ (see [34]). This yields (4.18). ∎

Passing to the limit $n \to \infty$, some of the bifurcation sub-branches (which are not of physical interest) may disappear, so that we always need to check which sub-branches are available for $n = \infty$. On the other hand, it is interesting to know for which values of μ, less or greater than μ_l, there exist nonconstant solutions and how many. Since the spectrum of the Frechet derivative $\mathbf{A}'(0, \tilde{\mu}_l)$,

$$\sigma(\mathbf{A}'(0, \tilde{\mu}_l)) = \left\{ \frac{(1 + \frac{l}{m})}{(1 + \frac{k}{m})},\ k = 0, 1, 2, \dots \right\}, \tag{4.21}$$

always contains 1 (for $k = l$), the local asymptotic behavior of bifurcation branches for $\mu \approx \mu_l$ is a delicate problem, and often there exist at least two solutions even in the cases of analytic nonlinearities; see a general theory in [44]. Therefore we will need an extra matching analysis to specify "correct" branches, which have the required behavior at infinity and hence correspond to single-point blow-up similarity profiles.

It is important to mention the main reason for extending the operator (2.6) in (2.9) and (2.19) to the operator in (4.12) parameterized by μ. Setting $\mu = 0$, in the case of the polynomial nonlinearity with $G = G_p$, we recover a well-studied Hamiltonian system (see [2] and the book [39]), and the solutions considered in this case can, in principle, be followed as μ increases to the physically important value of $\frac{1}{2}m$. Alternatively, by setting μ close to the bifurcation points (4.18), we can construct asymptotic descriptions of solutions that are local perturbations of the constant solution. This calculation is presented in the next section. Once we have constructed such solutions, we may again extend varying μ to determine branches of solutions that persist until the value $\mu_m = \frac{1}{2}m$.

In other words, problem (4.12) for $\mu \in [0, \frac{1}{2m}]$ describes the *transition* phenomenon between Hamiltonian systems for $\mu = 0$, with a potential and leading self-adjoint differential operators, and the singularity formation problem for $\mu = \frac{1}{2m}$, with no potential structure or symmetry properties of operators involved.

4.4. Conjecture on existence of self-similar solutions. For any $m > 1$, the question of the solvability of problem (4.12) for $\mu = \frac{1}{2}m$ (with the appropriate decay of $f(y)$ at infinity) and of the number of solutions seem to be very hard. Proving solvability is a multidimensional problem of matching of the $(\kappa_m{+}1)$-dimensional bundle of orbits as $y \to \infty$ (see (2.17)) with the m-dimensional bundle at $y \approx 0$ depending on the parameters $\{f(0), f''(0), \dots, f^{(2m-2)}(0)\}$ (a multidimensional shooting problem whose complexity increases dramatically as m increases). For $m = 1$, such a problem for quasi-linear equations (1.3) is well understood in one dimension (see [40] and [8]), though a complete proof of the number, finite or infinite, of solutions for equations in $\mathbb{R}$ and in $\mathbb{R}^N$ is still missing.

We now use the above local bifurcation analysis to estimate the number of solutions from below. In view of Proposition 4.2, there exist branches of solutions $f(y;\mu)$ emanating at $\mu = \frac{1}{2l}$ from constant solutions $f = f^*$ for each value of $l = 1, \dots, m-1$ (though we still do not know which bifurcation branches correspond to single point blow-up profiles with required decay at infinity). In particular, if we fix m, then a self-similar solution occurs at $\mu_m = \frac{1}{2m}$. However, there are $m-1$ bifurcation points at $\mu_l = \frac{1}{2l} > \mu_m = \frac{1}{2m}$ for $l = 1, \dots, m-1$. The numerical calculations of section 6 strongly imply that each such bifurcation leads to a branch of solutions $f(y)$ with far-field behavior of the type (2.16) or (2.22) persisting until μ_m, giving rise to a self-similar solution. Furthermore, due to the semistability properties of the center manifold patterns (see further comments in section 5), we expect from the observations of the previous section that there is an additional solution of the ODE when m is even. This detail is also supported by both the asymptotic calculations presented in section 5 and the numerical calculations of section 6. Combining these observations, let us state the following conjecture suggested by our understanding of the dynamics of the linearized operator, asymptotic constructions, and a number of numerical experiments.

CONJECTURE 4.3. *For all $m > 1$, the problems* (2.19) *and* (2.9) *have at least* $2\lfloor \frac{m}{2} \rfloor$ *(self-similar) solutions.*

Hence, we conjecture that the nonexistence of exact self-similar blow-up solutions is a feature only of the second-order semilinear equations, not of all the semilinear equations of the forms (1.6) and (1.7). This conjecture is indeed a lower bound and is based only on properties of the linear operator presented in this paper. In fact, we expect that there are $m(m-1)$ solutions. This estimate is topological and characterizes a typical matching of two multidimensional bundles at $y = \infty$ and $y = 0$, respectively, in the presence of sufficiently strong oscillatory character of the ODE; see further results below.

Further, we note that bifurcations in the limit problem (4.12) hold for arbitrary $L^2_{0,\rho}$-solutions of (4.19), not necessarily satisfying the appropriate decay conditions at infinity. There may also exist nonconstant solutions that correspond to stabilization as $y \to \infty$ to another equilibrium,

$$f(y) \to \beta^\beta \ \text{ for } \ G = G_p \quad \text{and} \quad f(y) \to 0 \ \text{ for } \ G = G_e. \tag{4.22}$$

One can see from (2.8) and (2.18) that these self-similar solutions create *global blow-up*, where

$$u(x,t) \to \infty \quad \text{as } \ t \to T^- \ \text{ uniformly in } \ \mathbb{R}. \tag{4.23}$$

Such behavior is unavailable for $m = 1$ as the dimension of the stable manifold about f^* is $2(m-1)$ for m odd. For $m > 1$, no such solutions have yet been detected, numerically or otherwise.

5. The asymptotic behavior of the solutions close to the bifurcation points. In this section we again consider μ to be a continuous parameter in (4.12) and construct an asymptotic description of solutions $f(y;\mu)$ (with the appropriate decay at infinity; see a precise statement below) for μ close to the bifurcation points at $\mu_l = \frac{1}{2l}$. We set

$$\mu = \mu_l + \sigma_l \varepsilon \quad \text{with } 0 < \varepsilon \ll 1 \text{ and } \sigma_l^2 = 1, \tag{5.1}$$

and look for solutions to the ODEs in $\mathbb{R}_+$ for $l = 1, 2, \dots,$

$$(-1)^{m+1} f^{(2m)} - (\mu_l + \sigma_l \varepsilon)\, y f' + G_p(f) = 0, \tag{5.2}$$

$$(-1)^{m+1} f^{(2m)} - (\mu_l + \sigma_l \varepsilon)\, y f' + G_e(f) = 0. \tag{5.3}$$

We seek solutions with symmetry conditions (2.10) satisfying the decay condition

$$f(y) = C y^{-1/(p-1)\mu}(1 + o(1)) \quad \text{or} \quad f(y) = -\frac{1}{\mu} \ln y + C + o(1) \quad \text{as } y \to +\infty. \tag{5.4}$$

Here $\sigma_l = \pm 1$ indicates the direction that the branch departs from the constant solution, which we shall show depends upon l and m. Because of the polynomial structure of the eigenfunctions of the linear operator $\boldsymbol{\mathcal{L}}$ (and hence of $\boldsymbol{\mathcal{L}}_\mu$), the asymptotic calculations are similar in spirit for each bifurcation point, $\mu = \frac{1}{2l}$, although for each order $2m$ of the differential operator there are m slightly different types of expansion. As such, we will illustrate the calculations by first considering the case $m = 2$ close to arbitrary bifurcation points, then close to the particular bifurcation points of interest to fourth-order PDEs, namely, $\mu_1 = \frac{1}{2}$ and $\mu_2 = \frac{1}{4}$. Lastly, we construct solutions close to the specific bifurcation points $\mu_m = \frac{1}{2m}$ for the case of general m to complement the calculations of the center manifold behavior described in the previous section and our conjecture regarding the existence of self-similar solutions of the ODE when $\mu = \frac{1}{2m}$.

5.1. The case of fourth-order ODEs: $m = 2$. We shall first consider the two ordinary differential problems, namely finding the slowly growing/bounded solutions of the fourth-order equations with $l = 1, 2, \dots,$

$$-f'''' - (\mu_l + \sigma_l \varepsilon)\, y f' + |f|^{p-1} f - \frac{1}{p-1} f = 0, \tag{5.5}$$

$$-f'''' - (\mu_l + \sigma_l \varepsilon)\, y f' + e^f - 1 = 0. \tag{5.6}$$

The calculation proceeds by identifying three key regions in which asymptotic solutions of three different scalings of the above equations are derived. The three different asymptotic descriptions of the solutions are then matched together. The first region is given by considering solutions for which $\varepsilon^\gamma y$ is small and where

$$\gamma = \begin{cases} \frac{1}{4l} \text{ for } l \text{ odd}, \\ \frac{1}{2l} \text{ for } l \text{ even}. \end{cases} \tag{5.7}$$

Here the solution is near constant, and we can express the solution in terms of the eigenfunctions of the linear operator $\boldsymbol{\mathcal{L}}_\mu$ in (4.13). Next is a midrange region, for which $\varepsilon^{-\gamma} < y < e^{1/\varepsilon}$, where the appropriately rescaled differential equations reduce to an integrable first-order equation. Lastly, there is the region $\{y > e^{1/\varepsilon}\}$, where the solution satisfies the far-field behavior (5.4).

5.1.1. The behavior of $f(y)$ for $\varepsilon^\gamma y \ll 1$. We begin by seeking solutions of (5.5) and (5.6), which are valid for small $\varepsilon^\gamma|y|$ and which are close to the constant solutions of the respective nonlinearities. Consider the corresponding equation (4.20) for fixed points. Since, by (4.21), 1 is an eigenvalue of $\mathbf{A}'(0,\tilde{\mu}_l)$ with the one-dimensional eigenspace E_l, according to the general branching theory [44, Chapter 5], in this special case we seek solutions of the form of the rational series

$$f(y) = f_0 + \varepsilon^q f_1(y) + \varepsilon^{2q} f_2(y) + \cdots, \tag{5.8}$$

where we define $f_0 = f^*$. For convenience, we perform this equivalent expansion analysis directly for the ODEs and avoid using the integral equation (4.20) with compact operators. The exponent $q = 1/n$ with an unknown integer $n \geq 1$ is to be determined from the solvability of the corresponding nonlinear systems on the expansion coefficients (the branching equation). Since $\dim E_l = 1$, the branching equation is always one-dimensional. Note that, for analytic nonlinearities, i.e., (5.6) with any odd p and (5.5), in the case of one- (or two-) dimensional eigenspace E_l, finite solvability of such systems (existence of a finite number of solutions) implies convergence of the series (5.8) for sufficiently small ε, although we can expect there to be at least two different bifurcating branches of solutions; see [44, pp. 209–211]. We then determine the correct branch by matching to solutions with the appropriate decay properties at infinity.

The rational power q of the order parameter depends on the coefficients of the branching equation, which are different depending on whether l is even or odd. Substituting the expansion (5.8) into the ODEs leads, at lowest order, to an ODE for $f_1(y)$ of the form

$$\boldsymbol{\mathcal{L}}_{1/2l} f_1 \equiv -f_1'''' - \frac{1}{2l}\, y f_1' + f_1 = 0.$$

Accordingly, the leading order approximation to $f - f_0$ is given by a linear multiple of the eigenfunction $\psi_{2l}((2/l)^{1/4}y)$; see (4.14). From the description of the spectrum of the operator $\boldsymbol{\mathcal{L}}$ given in Lemma 3.1, using Corollary 3.4, we know that (as $m = 2$) the transformed operator $\boldsymbol{\mathcal{L}}_{1/2l}$ has null eigenfunctions ψ_{2l} which are polynomials and which take the form

$$\psi_{2l}(y) = y^2 \sum_{j=0}^{(l-1)/2} \alpha_j y^{4j} \quad \text{for } l \text{ odd} \qquad \text{and} \qquad \psi_{2l}(y) = \sum_{j=0}^{l/2} \alpha_j y^{4j} \quad \text{for } l \text{ even},$$

as defined by (3.12) after the change of variable $y \mapsto y(2/l)^{1/4}$.

The difference between the cases of l even and l odd is as follows. In the asymptotic expansion, the higher powers of $f_1(y)$ become forcing terms to equations involving the operator $\boldsymbol{\mathcal{L}}_{1/2l} f_j$. In the case of odd l, these terms will always be polynomials in y^4. These may have no contribution, which resonates with the null eigenfunction ψ_{2l} of $\boldsymbol{\mathcal{L}}$. In contrast, the powers of $f_1(y)$ for even l will always have contributions, which resonate with $\psi_{2l}(y)$. As a consequence, the cases l even and l odd lead to distinctly different forms of asymptotic expansion, in particular $q = \frac{1}{2}$ for odd l and $q = 1$ for even l. In other words, for l even and odd the branching equation changes its type. Generically, there will be m distinct expansions in powers of $\varepsilon^{i/m}$, $i = 1, 2, \ldots, m$; see a general classification in [44, section 12].

A. *The case of $m = 2$ and l odd.* We take $l = 2r+1$ so that the bifurcation point is at $\mu = 1/(4r+2)$, $r = 0, 1, \ldots$. We express $f(y)$ as an asymptotic expansion ($q = \frac{1}{2}$)

$$f = f_0 + \varepsilon^{1/2} f_1 + \varepsilon f_2 + \varepsilon^{3/2} f_3 + \cdots. \tag{5.9}$$

This expansion corresponds to the case of the branching equation described in Theorem 12.2 in [44], where there exist two solutions either for $\mu < \mu_l$ or for $\mu > \mu_l$. Substituting the expansion (5.9) into either (5.5) or (5.6) gives a sequence of ODE problems of the form

$$O(\varepsilon^{1/2}): \quad \boldsymbol{\mathcal{L}}_{1/2l} f_1 \equiv -f_1'''' - \frac{1}{4r+2}\, y f_1' + f_1 = 0, \tag{5.10}$$

$$O(\varepsilon): \quad \boldsymbol{\mathcal{L}}_{1/2l} f_2 = -c_2 f_1^2, \tag{5.11}$$

$$O(\varepsilon^{3/2}): \quad \boldsymbol{\mathcal{L}}_{1/2l} f_3 = \sigma_l y f_1' - 2c_2 f_1 f_2 - c_3 f_1^3, \dots, \tag{5.12}$$

where $c_2, c_3, \dots$ are as given in (4.2). In each case we seek solutions from $H^{0,2m}_{\rho}(\mathbb{R})$. In view of asymptotic properties for linearized operators in section 2, the solutions are assumed to grow slowly (at worst polynomially) as y increases and will ultimately be matched to solutions of the ODEs (5.2) and (5.3) that have the correct behavior at infinity, (5.4).

As observed above, it follows from (4.16) that the lowest-order equation (5.10) can be solved in terms of a rescaling of the null eigenfunction ψ_{2l} of $\boldsymbol{\mathcal{L}}_{2l}$. Applying in (3.12) the scaling $y \mapsto (2/(2r+1))^{1/4} y$, it follows that there is a constant α such that

$$f_1(y) = \alpha \tilde{f}_1(y), \quad \text{where } \tilde{f}_1(y) = \sum_{j=0}^{r} \left(\frac{2r+1}{2}\right)^{j-r-1/2} \frac{1}{j!} D^{4j} y^{4r+2}. \tag{5.13}$$

For example, $f_1(y) = \alpha y^2$ when $r = 0$ and $\mu = \frac{1}{2}$. Here the constant α is unspecified at this level of expansion and will be determined by a solvability condition for the higher-order terms.

The Fredholm alternative gives the orthogonality condition for the second equation (5.11) at order ε to have a solution in $H^{2m}_{0,\rho}(\mathbb{R})$,

$$\langle f_1^2, \psi^*_{2l} \rangle = 0, \tag{5.14}$$

where $\psi^*_{2l} = \psi^*_{2l}((2/l)^{1/4} y)$ defined in (3.9) is the eigenfunction of the adjoint operator $\boldsymbol{\mathcal{L}}^*_{1/2l}$. If $r = 0$ and $l = 1$, then the first three even eigenfunctions of $\boldsymbol{\mathcal{L}}_{1/2}$ are given in (3.14). Since ψ_2^* is the null eigenfunction of $\boldsymbol{\mathcal{L}}^*_{1/2l}$, it follows that $\langle \psi_2^*, \psi_0 \rangle = 0$ and $\langle \psi_2^*, \psi_4 \rangle = 0$. Hence $\langle \psi_2^*, y^4 \rangle = \langle \psi_1, f_1^2 \rangle = 0$, so that the orthogonality (5.14) holds and there exist solutions of (5.11) at this order. This is the lack of resonance condition, which we described earlier.

For arbitrary r, by (5.13),

$$f_1^2(y) = \alpha^2 \sum_{j=0}^{2r} a_j y^{4j+4},$$

and we find a particular polynomial solution of (5.11) in the form

$$\alpha^2 \tilde{f}_2(y) = -c_2 \alpha^2 \sum_{j=-1}^{2r} b_j y^{4j+4}. \tag{5.15}$$

Substituting it into the equation and equating the coefficients gives

$$b_{2r} = -a_{2r}, \quad b_{-1} = 4!\, b_0 \quad \text{and} \tag{5.16}$$

$$b_j = \frac{2r+1}{2(r-j)-1} \left[a_j + b_{j+1} \frac{(8+4j)!}{(4+4j)!} \right] \quad \text{for } j = 2r-1, \dots, 0. \tag{5.17}$$

Hence, the orthogonality condition (5.14) holds. The general solution of (5.11) is given by

$$f_2(y) = \alpha^2 \tilde{f}_2(y) + \alpha_1 \tilde{f}_1(y), \tag{5.18}$$

where α_1 is an extra real unknown.

The unknowns α and α_1 are determined by applying the Fredholm alternative at the next orders of expansion. In (5.12), similar to (5.14), the solvability condition is given by

$$\left\langle \sigma_l y f_1' - 2c_2 f_1 f_2 - c_3 f_1^3, \psi_{2l}^* \right\rangle = 0. \tag{5.19}$$

Substituting (5.13) and (5.18) yields the algebraic equation

$$\alpha A - \alpha^3 B + \alpha\alpha_1 C = 0, \tag{5.20}$$

where $A = \langle \sigma_l y f_1', \psi_{2l}^* \rangle$, $B = \langle c_3 \tilde{f}_1^3 + 2c_2 \tilde{f}_1 \tilde{f}_2, \psi_{2l}^* \rangle$, and the third coefficient C vanishes by the first solvability criterion (5.14),

$$C = -2C_2 \langle \tilde{f}_1^2, \psi_{2l}^* \rangle = 0. \tag{5.21}$$

Equation (5.20) is a cubic equation for the first unknown α only, $\alpha(\alpha^2 - \sigma_l \gamma) = 0$, where γ can be computed explicitly. The $\alpha = 0$ case simply corresponds to the constant solution (the trivial expansion (5.9)) and can be discarded. Hence, we have two solutions

$$\alpha = \pm\sqrt{\sigma_l \gamma}\,. \tag{5.22}$$

The sign of σ_l is thus the same as that of γ, while the sign of α follows from matching to the far field solution (see section 5.2). In general, the second unknown α_1 (together with an extra one α_3 obtained from the homogeneous equation (5.12), etc.) is to be determined from the solvability conditions of equations for the coefficients f_4, $f_5, \ldots$ of higher-order perturbations. Although not presented, higher approximations follow in a similar manner to those here.

Example 1. To illustrate this calculation, we now look at the two cases of $l = 1$ and $l = 3$ for the quadratic nonlinearity with $p = 2$, where $G_p(f) = |f|f - f$. These are chosen so that the corresponding bifurcation points at $\mu = \frac{1}{2}$ and $\mu = \frac{1}{6}$ are on either side of the "self-similar" value of $\mu_2 = \frac{1}{4}$, as indicated in Figure 1.

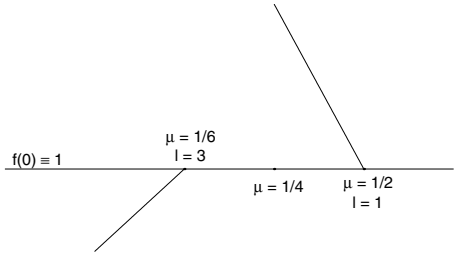

FIG. 1. *Sketch of the bifurcation points under consideration.*

The first bifurcation point: $\mu_1 = \frac{1}{2}$ ($l = 1$, $r = 0$). As observed above, when $l = 1$, we have $f_0 = 1$ and $f_1 = \alpha y^2$. A simple calculation then gives $f_2 = \alpha^2(y^4 + 24)$, and expansion (5.9) takes the form

$$f(y) = 1 + \alpha\varepsilon^{1/2} y^2 + \varepsilon\left[\alpha^2(y^4 + 24) + \alpha_1 y^2\right] + \varepsilon^{3/2} f_3(y) + \cdots. \tag{5.23}$$

Observe that since $c_3 = 0$, the solvability condition (5.19) for f_3 is then given by

$$\langle 2\sigma_1\alpha y^2 - 2\alpha^3 y^2(y^4+24), \psi_2^*\rangle = 0, \quad \psi_2^* = \psi_2^*(2^{1/4}y). \tag{5.24}$$

To calculate α, we exploit the fact that $\hat{\psi}_2^*(\omega) = -\omega^2 e^{-\omega^4}/\sqrt{2}$ by (3.6) and (3.9). Recall also that if a function $f(y)$ has Fourier transform $\hat{f}(\omega)$, then

$$\langle f, y^{2n}\rangle = (-1)^n \hat{f}^{(2n)}(0). \tag{5.25}$$

Taking $\psi_2^* = \psi_2^*(2^{1/4}y)$ yields $\langle \psi_2^*(2^{1/4}y), y^2\rangle = 1/2^{1/4}$ and $\langle \psi_2^*(2^{1/4}y), y^6\rangle = -180/2^{1/4}$, the solvability condition (5.24) reduces to the cubic equation $\sigma_1\alpha + 156\alpha^3 = 0$, and hence

$$\sigma_1 = -1 \quad \text{and} \quad \alpha = \pm\frac{1}{\sqrt{156}} = \pm\frac{\sqrt{39}}{78}, \tag{5.26}$$

so that (5.23) yields

$$f(y) = 1 \pm \varepsilon^{1/2}\frac{y^2}{\sqrt{156}} + \varepsilon\left(\frac{1}{156}(y^4+24) + \alpha_1 y^2\right) + \cdots. \tag{5.27}$$

The sign of α will be determined by matching to the solution in the midrange. We show presently that $\alpha < 0$ so that

$$f(y) = 1 - \varepsilon^{1/2}\frac{y^2}{\sqrt{156}} + \varepsilon\left(\frac{1}{156}(y^4+24) + \alpha_1 y^2\right) + \cdots,$$

and, in particular, since $\varepsilon > 0$,

$$f(0) = 1 + \frac{2}{13}\,\varepsilon + \cdots > 1. \tag{5.28}$$

The resulting branch thus bifurcates to the left and exists locally only for $\mu < \frac{1}{2}$; there is no possible matching to a decaying solution for $\mu > \frac{1}{2}$. The numerical calculations reported in the next section indicate that the branch persists globally, so that solutions exist at the self-similar value $\mu_2 = \frac{1}{4}$.

The third bifurcation point: $\mu_l = \frac{1}{6}$ ($l = 3$, $r = 1$). We again have $f_0 = 1$, and now $f_1(y) = \alpha(y^6 + 540y^2)$ and $f_2 = \alpha^2(y^{12} - 32400y^8 - 164170800y^4 - 3940099200)$, so that the expansion is

$$\begin{aligned} f = {} & 1 + \varepsilon^{1/2}\alpha\left(y^6 + 540y^2\right) \\ & + \varepsilon[\alpha^2\left(y^{12} - 32400y^8 - 164170800y^4 - 3940099200\right) + \alpha_1\tilde{f}_1] + \cdots. \end{aligned}$$

A similar (but much longer) analysis of the orthogonality condition (5.19) with eigenfunction $\psi_6((2/3)^{1/4}y) = (y^6+540y^2)/12\sqrt{5}$ then indicates that the branch again bifurcates to the left and exists locally for $\mu < \frac{1}{6}$.

B. *The case of $m = 2$ and l even.* In the case $l = 2r$ the bifurcation occurs at the point $\mu_{2r} = \frac{1}{4r}$. Because of the presence of a constant term in the eigenfunction ψ_{2l}, the effect of the "forcing terms" yf' comes in at lower order than in the previous case. This leads to a standard asymptotic expansion for $f(y)$ of the form (cf. Theorem 12.1 in [44])

$$f = f_0 + \varepsilon f_1 + \varepsilon^2 f_2 + \cdots. \tag{5.29}$$

Substituting this expression for f into (5.5) or (5.6) gives

$$O(\varepsilon): \qquad \boldsymbol{\mathcal{L}}_{1/2l} f_1 \equiv -f_1'''' - \frac{1}{4r}\, y f_1' + f_1 = 0, \tag{5.30}$$

$$O(\varepsilon^2): \qquad \boldsymbol{\mathcal{L}}_{1/2l} f_2 = \sigma_l y f_1' - c_2 f_1^2. \tag{5.31}$$

As before, we express f_1 as a multiple of the (scaled) eigenfunction $\psi_{2l}(r^{-1/4}y)$,

$$f_1(y) = \alpha \tilde{f}_1(y) \equiv \alpha \sum_{j=0}^{r} \frac{r^{j-r}}{j!} D^{4j} y^{4r}. \tag{5.32}$$

The value of α is determined by considering the solvability condition for (5.31) at $O(\varepsilon^2)$. From the analysis above, it follows that, for f_2 to exist, we must have

$$\langle \sigma_l y f_1' - c_2 f_1^2, \psi_{2l}^* \rangle = 0 \quad \text{with } \psi_{2l}^* = \psi_{2l}^* \left(\left(\frac{2}{l} \right)^{1/4} y \right). \tag{5.33}$$

This leads to a quadratic equation in α of the form $\alpha(\alpha - \gamma) = 0$, where γ may again be determined explicitly. This is the case of a unique nontrivial solution existing for both $\mu > \mu_l$ and $\mu < \mu_l$, and again we will need an extra matching argument to determine the correct sub-branch.

To illustrate this calculation, we again take $p = 2$, $G_p(f) = |f|f - f$ and now consider the case of $l = 2$. This is an especially important value as it corresponds to $\mu_2 = \frac{1}{4}$, at which the self-similar solution exists. In this case we have $f_0 = 1$ and $f_1 = \alpha(y^4 + 24)$. The solvability condition for α is now

$$\langle \sigma_2 y f_1' - f_1^2, \psi_4^*(y) \rangle = \langle 4\sigma_2 \alpha y^4 - \alpha^2 (y^4 + 24)^2, \psi_4^*(y) \rangle = 0.$$

We have that $\hat{\psi}_4^*(\omega) = \omega^4 e^{-\omega^4}/2\sqrt{6}$, and it follows that the quadratic equation satisfied by α is given by

$$96\sigma_2 \alpha + 39168\alpha^2 = 0 \quad \Longrightarrow \quad \alpha = -\frac{1}{408}\, \sigma_2. \tag{5.34}$$

We show presently that, to match with the midrange, we have to have $\alpha < 0$ so that $\sigma_2 = 1$. Hence

$$f(y) = 1 - \frac{\varepsilon}{408} \left(y^4 + 24 \right) + \varepsilon^2 \left[\tilde{f}_2(y) + \alpha_1 \tilde{f}_1(y) \right] + \cdots, \tag{5.35}$$

where the third term (actually we do not need to compute it) explains the spatial nonmonotonicity of such a solution. If $\varepsilon > 0$, then

$$f(0) = 1 - \frac{1}{17}\, \varepsilon + O(\varepsilon^2) < 1. \tag{5.36}$$

5.1.2. The midrange $\boldsymbol{\varepsilon^\gamma < y < e^{1/\varepsilon}}$. The midrange behavior is governed by the solutions of a first-order equation, which is different for each nonlinearity. However, the calculation now takes the same form for both l even and odd and uses a regular asymptotic expansion. To study the midrange, we rescale the underlying ODEs in space according to the transformation

$$s = \varepsilon^\gamma y \geq 0 \qquad (\gamma \text{ as in (5.7)}). \tag{5.37}$$

The outer limit of the inner region can be matched to the midrange region by taking s to be small and y to be large.

A. *The case* $G_p(f) = |f|^{p-1}f - \frac{1}{p-1}\,f$. Under the spatial rescaling (5.37), equation (5.5) becomes

$$-\varepsilon^{4\gamma} f'''' - (\mu_l + \sigma_l \varepsilon)\, s f' + |f|^{p-1} f - \frac{1}{p-1}\, f = 0, \quad l = 1, 2, \dots , \tag{5.38}$$

where $' = d/ds$. To solve this, we pose a regular asymptotic expansion

$$f = f_0 + \varepsilon^{4\gamma} f_1 + \varepsilon^{8\gamma} f_2 + \cdots . \tag{5.39}$$

To leading order we have simply the first-order ODE $-\frac{1}{2l} y f_0' + |f_0|^{p-1} f_0 - \frac{1}{p-1} f_0 = 0$, which has a family of bounded positive exact solutions

$$f_0(s) = [(p-1) + \kappa s^{2l}]^{-1/(p-1)}, \tag{5.40}$$

where $\kappa > 0$ is a positive constant.

Note that, for *small* s, we have

$$f_0(s) = \beta^\beta \left(1 - \frac{\kappa}{(p-1)^2} s^{2l} + \frac{p\kappa^2}{2(p-1)^4} s^{4l} + O(s^{8l})\right), \tag{5.41}$$

while for *large* s,

$$f_0(s) = \kappa^{-1/(p-1)} s^{-2l/(p-1)} + \cdots . \tag{5.42}$$

We now consider the next term in the asymptotic expansion, looking at the two cases of small s and large s separately. The function f_1 satisfies the equation

$$-\frac{1}{2l}\, s f_1' + \left[\frac{p}{(p-1) + \kappa s^{2l}} - \frac{1}{(p-1)}\right] f_1 = \sigma_l s f_0' + f_0'''' .$$

We consider for simplicity the case of $p = 2$, and look at the three cases of $l = 1, 2$, and 3.

If $l = 1$, then $4\gamma = 1$, and for small s we have $f_0(s) = 1 - \kappa s^2 + \frac{1}{2}\kappa^2 s^4 + \cdots$; thus the leading order contribution to $\sigma_l s f_0' + f_0''''$ is simply $12\kappa^2$, and hence we have, to leading order as $s \to 0$,

$$f_1(s) = 12\kappa^2 + \cdots .$$

If $l = 2$, then $4\gamma = 1$, and for small s, $f_0(s) = 1 - \kappa s^4 + \frac{1}{2}\kappa^2 s^8 + \cdots$ so that, to leading order,

$$f_1(s) = -24\kappa + \cdots .$$

If $l = 3$, then $4\gamma = 1/3$, and for small s, $f_0(s) = 1 - \kappa s^6 + \frac{1}{2}\kappa^2 s^{12} + \cdots$ so that, to leading order, $f_0'''' = -360\kappa s^2$ and

$$f_1(s) = -540\kappa s^2 + \cdots .$$

We conclude that the small s limit of the midrange solution is

$$f = 1 - \kappa s^2 + \frac{1}{2}\,\kappa^2 s^4 + \cdots + \varepsilon(12\kappa^2 + \cdots) \quad \text{if} \quad l = 1, \tag{5.43}$$

$$f = 1 - \kappa s^4 + \frac{1}{2}\,\kappa^2 s^8 + \cdots - \varepsilon(24\kappa + \cdots) \quad \text{if} \quad l = 2, \tag{5.44}$$

$$f = 1 - \kappa s^6 + \frac{1}{2}\,\kappa^2 s^{12} + \cdots - \varepsilon(540\kappa^2 s^2 + \cdots) \quad \text{if} \quad l = 3. \tag{5.45}$$

In terms of the original variable y we have

$$f = 1 - \varepsilon^{1/2}\kappa y^2 + \varepsilon\kappa^2\left(\frac{1}{2}\,y^4 + 12\right) + \cdots \quad \text{if} \quad l = 1, \tag{5.46}$$

$$f = 1 - \varepsilon\kappa(y^4 + 24) + \frac{1}{2}\,\varepsilon^2\kappa^2 y^8 + \cdots \quad \text{if} \quad l = 2, \tag{5.47}$$

$$f = 1 - \varepsilon^{1/2}\kappa(y^6 + 540y^2) + \frac{1}{2}\,\varepsilon\kappa^2 y^{12} + \cdots \quad \text{if} \quad l = 3. \tag{5.48}$$

We can now consider matching the above expressions to the expansions given in the last sections.

If $l = 1$, then comparing with (5.27), we have a perfect match, provided that $\kappa = -\alpha$. As $\kappa > 0$, it follows that $\alpha = -1/\sqrt{156}$. Thus in the midrange when $l = 1$ we have

$$f_0(y) = \left(1 + \frac{\varepsilon^{1/2}y^2}{\sqrt{156}}\right)^{-1}.$$

As remarked earlier, this bifurcation branch exists only if $\mu < \frac{1}{2}$.

If $l = 2$, then comparing with (5.35), we again have a perfect match if $\kappa = -\alpha > 0$. In the midrange when $l = 2$ there holds

$$f_0(y) = \left(1 + \frac{1}{408}\,\varepsilon^{1/2}y^4\right)^{-1}.$$

Note that this expression is only meaningful if $\epsilon > 0$. As in this case $\sigma_2 = 1$, it follows that locally the branch of solutions that bifurcates from $\mu = \frac{1}{4}$ exists only if $\mu > \frac{1}{4}$. Numerically we observe that this curve continues globally for values of $\mu < \frac{1}{4}$, and hence there is a fold bifurcation at some point $\mu = \mu_* > \frac{1}{4}$, with a *nonzero* solution on the branch existing at $\mu = \frac{1}{4}$. This corresponds to a self-similar solution distinct from that lying on the branch bifurcating from the point $\mu = \frac{1}{2}$. The existence of such a solution is consistent with the semistability of the center manifold determined in section 4.

If $l = 3$, then comparing with the inner expansion, we again have a match if $\kappa = -\alpha > 0$, and in the midrange

$$f_0(y) = (1 - \alpha\varepsilon^{1/2}y^6)^{-1} \quad (\alpha < 0).$$

Now consider the behavior for $s \gg 1$ when $p = 2$. For these values of s, to leading order, the function f_1 satisfies the ODE $-\mu_l s f_1' - f_1 = -2l\sigma_l/\kappa s^{2l} + \cdots$; hence,

$$f_1(s) = \frac{4l^2\sigma_l \ln s}{\kappa s^{2l}} + \cdots \quad \text{as } s \to \infty\,.$$

Or, returning to the original variable y,

$$f(y) = \frac{1}{\kappa\varepsilon^{l/2}y^{2l}}\left(1 + 4l^2\sigma_l \ln y + \cdots\right) \quad \text{as} \quad y \to \infty. \tag{5.49}$$

B. *The case of* $G = e^f - 1$. Under the same spatial rescaling as before, (5.6) becomes

$$-\varepsilon f'''' - (\mu_l + \sigma_l\varepsilon)\, s f' + e^f - 1 = 0, \quad l = 1, 2, \ldots\,.$$

Posing expansion (5.39), substituting into the ODE, and solving the leading order equation gives

$$f_0(s) = -\ln(1+\kappa s^{2l}). \tag{5.50}$$

The analysis now proceeds as above, and again matching in the limit $s \to 0$ fixes $\kappa > 0$.

5.1.3. Far field behavior. The correct far field behavior is determined by assuming slow growth in both (5.2) and (5.3), $f''''(y) \to 0$ as $y \to \infty$, and hence $|f|f \ll f$ for small $f > 0$ there in (5.5), while $e^f \ll 1$ for $f \ll -1$ in (5.6). In the case of (5.5), this gives

$$f = Cy^{-1/\mu}(1+o(1)) \equiv Cy^{-2l/(1+2l\sigma_l\varepsilon)}(1+o(1)) \quad \text{as } y \to \infty.$$

Expanding this for $\varepsilon \ll 1$, we have

$$f = Cy^{-2l}(1+4l^2\sigma_l\varepsilon \ln y) + \cdots \quad (\varepsilon|\ln y| \ll 1).$$

This matches with (5.49) if $C = 1/\kappa\varepsilon^{l/2}$ (note that $\kappa = |\alpha|/\varepsilon$ for $l = 3$).

5.2. Bifurcations from $\mu_m = \frac{1}{2m}$ for general m. As remarked, for $m = 2$ we can also postulate existence of the new profile f_2 from the shape of the branch associated with $\mu_2 = \frac{1}{4}$, as the branch leaves the bifurcation point to the right and then is expected to fold back. In fact, this behavior can be understood for general m.

For all m, the bifurcation point $\mu_m = \frac{1}{2m}$ is associated with a zero eigenvalue of the linearized operator $\boldsymbol{\mathcal{L}} + I$ in the PDE (4.1). Further evidence for the existence of a nonlinear pattern associated with this point comes from the local structure of the bifurcation diagram. Looking for small solutions near this point, we solve

$$(-1)^{m+1}D_y^{2m}f - \mu_m y D_y f + f + \sigma_m \varepsilon y D_y f + \bar{G}(f - f_0) = 0,$$

where $\bar{G}$ is the quadratic perturbation (4.2). At $\mu_m = \frac{1}{2m}$ we have the regular expansion (5.29), and expanding as before gives

$$\mathcal{L}_{1/2m} f_1 = 0 \quad \Longrightarrow \quad f_1 = \alpha\left[y^{2m} + (-1)^m(2m)!\right] \quad \text{with unknown } \alpha \in \mathbb{R}.$$

At the next order we have

$$\mathcal{L}_{1/2m} f_2 = \sigma_m y f_1' - c_2 f_1^2 = 2m\sigma_m \alpha y^{2m} - c_2\alpha^2\left([(2m)!]^2 + 2(-1)^m(2m)!y^{2m} + y^{4m}\right). \tag{5.51}$$

By the Fredholm alternative this can be solved only if

$$\left\langle 2m\sigma_m\alpha y^{2m} - c_2\alpha^2\left([(2m)!]^2 + 2(-1)^m(2m)!y^{2m} + y^{4m}\right), \psi_{2m}^*(y)\right\rangle = 0.$$

By (3.9), $\hat{\psi}_{2m}^*(\omega) = \omega^{2m}e^{-2m}/\sqrt{(2m)!}$ so that, after a little manipulation noting that

$$\langle 1, \psi_{2m}^*\rangle = 0, \quad \langle y^{2m}, \psi_{2m}^*\rangle = (2m)!, \quad \langle y^{4m}, \psi_{2m}^*\rangle = (-1)^{m+1}(2m)!,$$

the solvability condition becomes

$$2m\sigma_m\alpha(2m)! - c_2\alpha^2(-1)^{m+1}\left((4m)! - 2[(2m)!]^2\right) = 0.$$

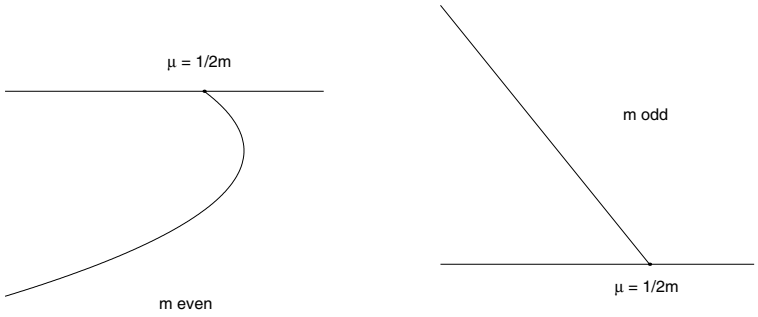

FIG. 2. *Schematic of the distinction between even and odd m.*

Thus the solvability condition implies that

$$\alpha = (-1)^{m+1}\frac{\sigma_m}{c_2}\frac{2m(2m)!}{(4m)! - 2[(2m)!]^2} \tag{5.52}$$

and hence

$$f(y) = f_0 + (-1)^{m+1}\varepsilon\frac{\sigma_m}{c_2}\frac{2m(2m)!}{(4m)! - 2[(2m)!]^2}\left(y^{2m} + (-1)^m(2m)!\right) + \cdots .$$

However, to match with the midrange, we require that $f_1 \to -\infty$ as $y \to \infty$, i.e., $\alpha < 0$ in (5.52), which sets

$$\sigma_m = (-1)^m \quad \text{for} \quad \varepsilon > 0.$$

Hence, by (5.1) for even m, the branches initially increase in μ and thus, if they have folded back, contribute an extra similarity profile $f_m(y)$ at $\mu = \frac{1}{2m}$, whereas there need be no such contribution for odd m; see Figure 2.

The existence of a *second* self-similar solution to the ODE in the case $m = 2$ is suggested by the center manifold analysis in Proposition 4.1. More precisely, consider the *unstable* center manifold behavior (4.6) for any even m,

$$g(y,\tau) = -\frac{1}{\gamma_0\tau}\psi_{2m}(y) + \cdots \to 0 \quad \text{as } \tau \to -\infty, \tag{5.53}$$

where $\psi_{2m} > 0$ is given by (4.5). We suppose that $g(\cdot,\tau)$ becomes sufficiently large as $\tau \approx -0$. Hence, $g(y,\tau) < 0$ for $\tau \ll -1$ on any compact subset in y, i.e., the corresponding solution of the PDE (2.5) (or (2.7)) satisfies $\theta(y,\tau) = \beta^\beta + g(y,\tau) < \beta^\beta$. Such a solution can be extended as above to satisfy $\theta(y,\tau) \to 0$ as $y \to \infty$; see also [20]. This shows that such an orbit cannot be a heteroclinic connection $\beta^\beta \to 0$, since for $\tau \approx -0$ this would mean that $|\theta(y,\tau)|$ gets essentially smaller than the constant blow-up profile β^β. Hence $\theta(y,\tau)$ cannot correspond to a solution $u(x,t)$ of the PDE that blows up at the fixed $t = T$; see L^∞-estimates of the blow-up rate in [10] and [21]. Therefore, this $\theta(\cdot,\tau)$ can be assumed to describe an orbital connection $\beta^\beta \to f_m(y)$ to a new nontrivial similarity profile f_m existing at $\mu = \mu_m$. Note that, by construction, it is expected that a certain approximated order occurs, meaning that $f_m(y) \lesssim \beta^\beta$ in $\mathbb{R}$ in a natural sense.

On the other hand, for odd m's, $\psi_{2m}(y)$ in (4.5) changes sign and we do not have such a contradiction. (One can see that an orbital connection $\beta^\beta \to 0$ is possible; see such a center manifold pattern in [25].)

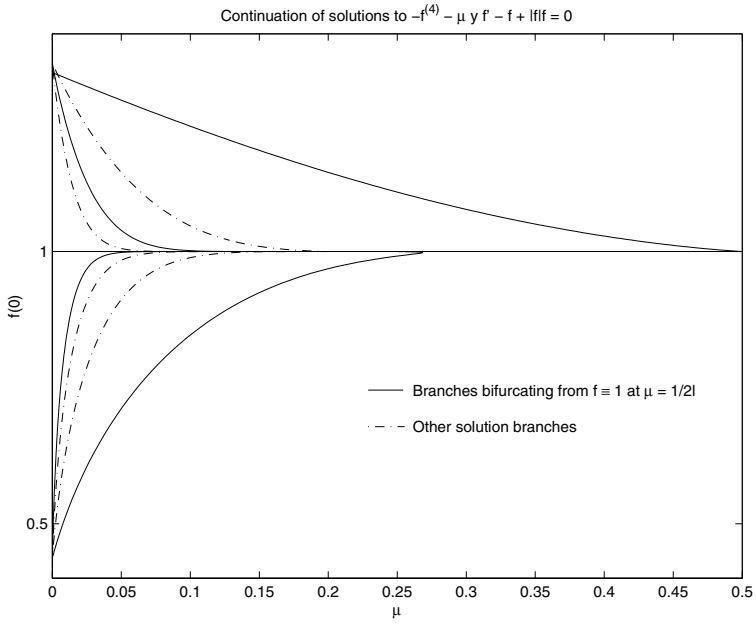

FIG. 3. *Bifurcation diagram for* $m = 2$.

6. Numerical calculations of the self-similar profiles. We next present a numerical calculation of the solutions of the problem (4.12) parameterized by μ and taking $G_p(f) = |f|f - f$ for $p = 2$. (As indicated from the analysis of the previous sections, the case $G_e(f) = e^f - 1$ is fundamentally the same and is omitted for the sake of brevity.) This calculation allows us to extend the asymptotic analysis of the previous section, and, in particular, to study the global behavior of the branches that bifurcate from the first two bifurcation points at $\mu_1 = \frac{1}{2}$ and $\mu_2 = \frac{1}{4}$. The solutions were obtained using a collocation code that guarantees a small residual tolerance [41]. The initial points on each curve were obtained by setting $\mu = 0$. The continuation of each solution was then done by using the pseudo arc-length routine in AUTO [13]. Symmetry conditions were imposed at the origin, and minimal growth was enforced at the far field by solving the problem on the finite interval $(0, 1000)$ and setting the highest derivatives to zero at the right-hand boundary.

6.1. The fourth-order case $m = 2$. In Figure 3 we present the results of the numerical calculations for different values of the parameter μ, looking at the fourth-order differential equations given by taking $m = 2$. In this figure we use $f(0)$ as a measure of the size of the solution. The existence of branches bifurcating from each of the points $\mu_l = \frac{1}{2l}$ (displayed as solid lines) is clear. Also plotted in dashed lines are other solutions obtained from continuing solutions from $\mu = 0$ that do not bifurcate from the constant solution $f \equiv 1$. In this format it is difficult to distinguish the solutions that bifurcate from the linear spectrum from the additional "nonlinear" solutions. To make this distinction clear we plot the same solutions in Figure 4 using the L^2_ρ-norm as the solution measure.

We observe first that the curve bifurcating from $\mu_1 = \frac{1}{2}$ appears to exist for all values of $\mu \in [0, \frac{1}{2}]$ and, in particular, there is a nonconstant solution $f_s(y)$ (the subscript s denotes stable; see section 7) of (4.12) for the value of $\mu_2 = \frac{1}{4}$. This

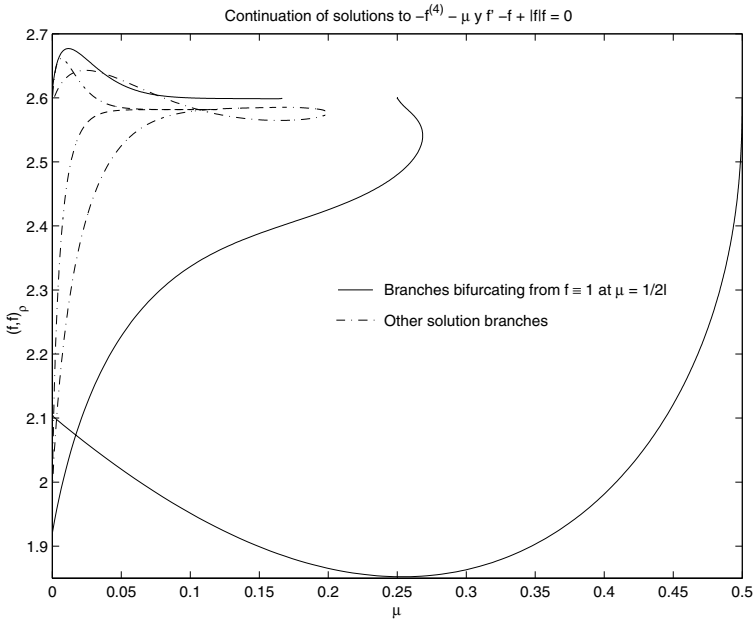

FIG. 4. *Bifurcation diagram for* $m = 2$ *in* L^2_ρ.

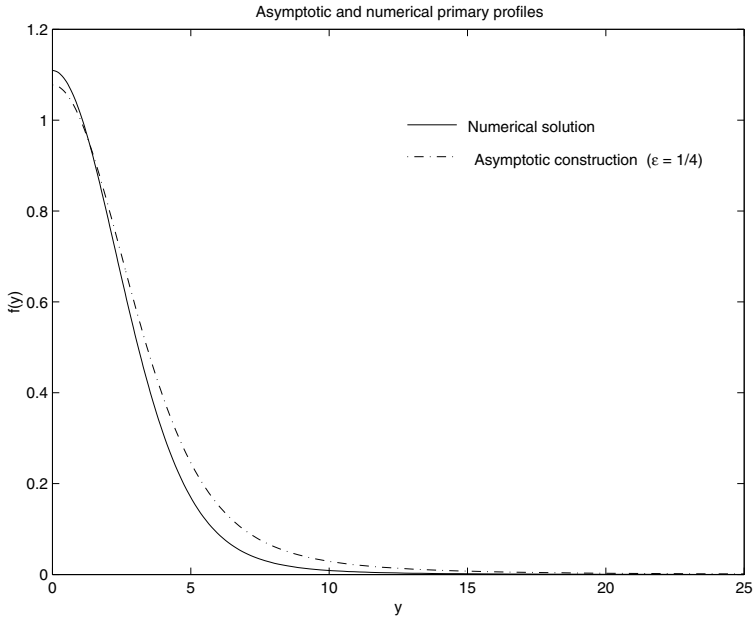

FIG. 5. *Comparison of asymptotic and numeric solutions.*

solution gives a self-similar solution of the underlying PDE (1.7). In Figure 5 we compare the numerical solution to the boundary-value problem (2.9), (2.10) with the asymptotic construction (5.27). In Figure 6 we present an enlargement of Figure 3

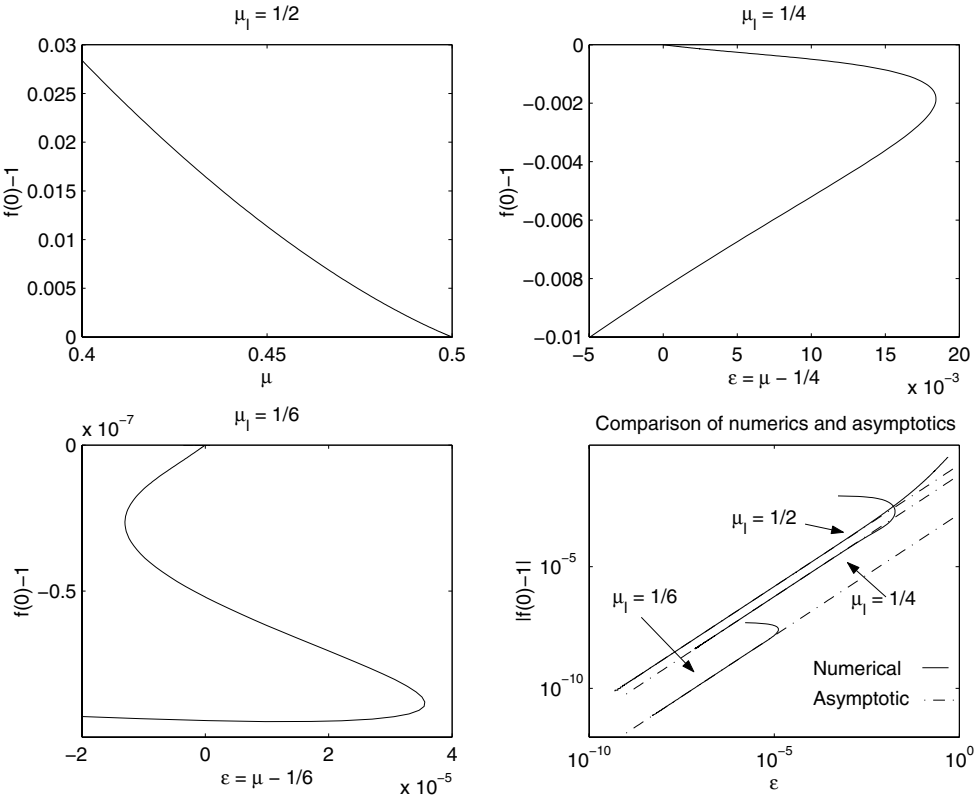

FIG. 6. *Detail of branches at* $\mu = \frac{1}{2}, \frac{1}{4}, \frac{1}{6}$ *for* $m = 2$ *and* $p = 2$.

close to the point $\mu = \frac{1}{2}$, allowing a direct comparison with the asymptotic calculation of $f(0)$ given by (5.28).

In contrast, the curve bifurcating from $\mu = \frac{1}{4}$ appears to exist for all $\mu \in [0, \frac{1}{4} + \delta]$, where δ is a small positive constant. This behavior can be seen more clearly in the enlargement of Figure 3 close to $\mu = \frac{1}{4}$, which is presented in Figure 6. Again, we can compare this figure to the asymptotic calculation of $f(0)$ given by (5.36), and the associated discussion on the unstable center manifold behavior in section 5, which predicts the existence of the bifurcating curve for a range of values of $\varepsilon > \frac{1}{4}$. This asymptotic calculation is clearly valid only for a small range of values of $\mu > \frac{1}{4}$, and the curve of solutions folds back at $\mu \simeq 0.26841\ldots$.

In particular, we observe a second nonzero solution $f_u(y)$ (the subscript u denotes unstable; see section 7) of (4.12) at $\mu = \frac{1}{4}$. The existence of this solution implies the existence of a further self-similar solution of the PDE. As remarked earlier, this result is consistent with the semistability of the center manifold when $m = 2$. The profiles of the two distinct self-similar solutions $f_s(y)$ and $f_u(y)$ are given in Figure 7.

Observe that the form of $f_s(y)$ is qualitatively similar to the profile of the solution computed close to $\mu = \frac{1}{2}$ and described asymptotically in the previous section. In particular, it appears to be a monotone decreasing function of y. In contrast, the self-similar solution $f_u(y)$ is *increasing* for small values of y and decreasing for larger values. This possible small nonmonotonicity in the expansion (5.35) is described by the terms $O(\varepsilon^2)$.

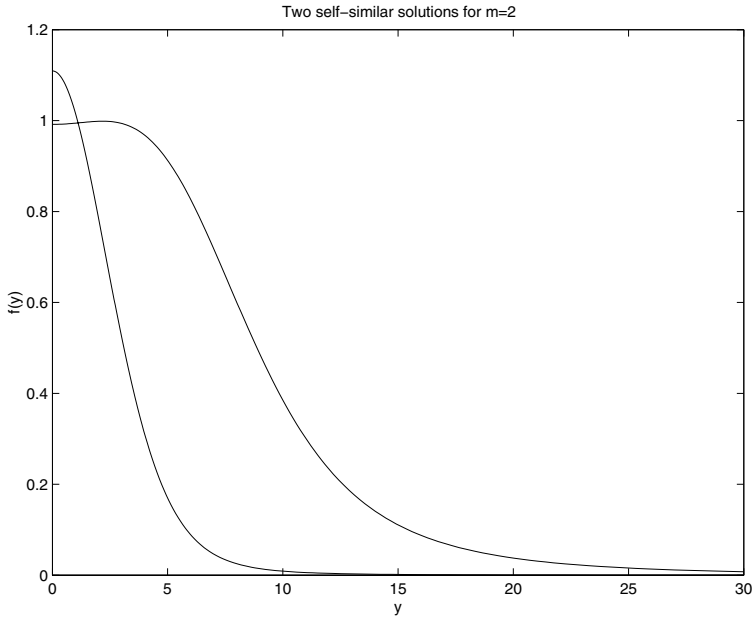

FIG. 7. *The two self-similar profiles f_s, f_u for $m = 2$.*

We also present in Figure 6 a detail of the neighborhood of $\mu = \frac{1}{6}$. Although this branch does not lead to a self-similar solution, its local form is interesting. As predicted by the asymptotic analysis, it bifurcates to the left but then folds back twice locally before continuing backwards to $\mu = 0$. Following these calculations, we make the following conjecture.

CONJECTURE 6.1. *If $m = 2$, then each of the curves bifurcating from the point $\mu_l = \frac{1}{2l}$ continues globally to include the point $\mu = 0$ and has $l - 1$ fold bifurcations in the vicinity of μ_l.*

Such fold bifurcations can occur [34] if

$$0 \in \sigma(\boldsymbol{\mathcal{L}}_\mu + G'(f)I). \tag{6.1}$$

This equation determines a difficult eigenvalue problem for higher-order operators with nonconstant coefficients. The eigenvalues of this problem correspond to the turning points of the solution branches indicated in Figure 6.

Lastly, in Figure 6 we compare our asymptotic construction of the bifurcation diagram with the numerical computations. Away from all folds, the agreement is excellent even with only a linear approximation.

6.2. The sixth-order case $m = 3$. A bifurcation diagram similar to Figure 3, and now for the case of the sixth order differential equations when $m = 3$, is presented in Figure 8. The far-field boundary condition is (5.4).

This picture is qualitatively similar to Figure 3, with the solutions at $\mu_3 = \frac{1}{6}$ being of interest. As before, the monotone decreasing (in a neighborhood of the origin) solution bifurcating from $\mu = \frac{1}{2}$ extends backwards to $\mu_3 = \frac{1}{6}$, as does the solution bifurcating from $\mu = \frac{1}{4}$. This leads to two self-similar solutions f_s and f_u. A detail of Figure 8 in the neighborhood of $\mu = \frac{1}{6}$ is given in Figure 9. As predicted by

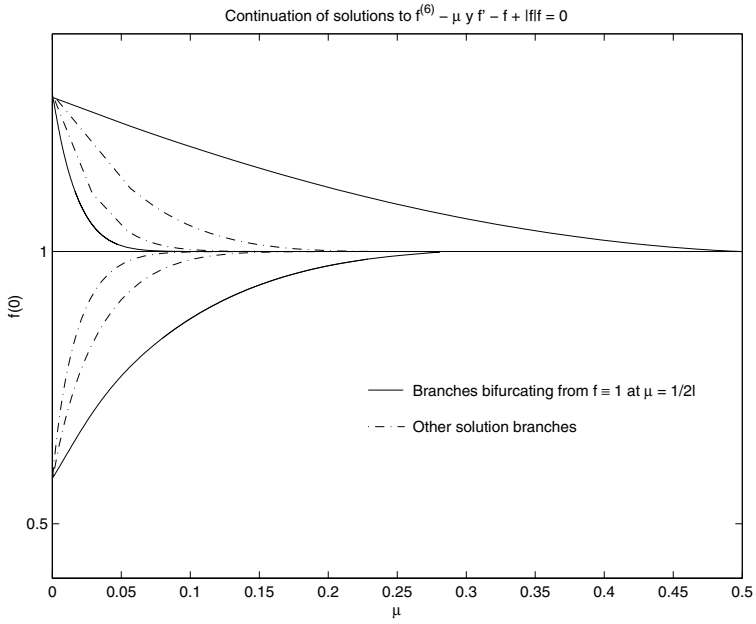

FIG. 8. *Bifurcation diagram for* $m = 3$.

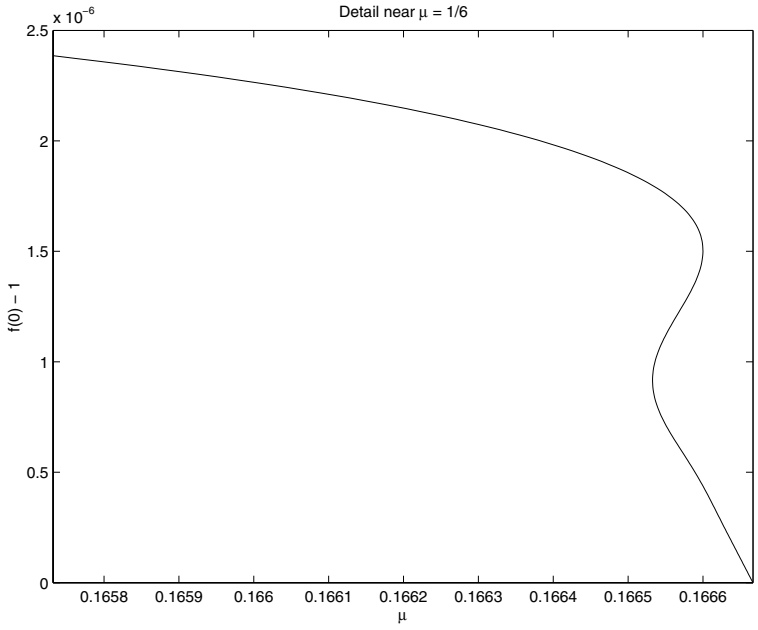

FIG. 9. *Detail of bifurcation diagram for* $m = 3$ *near* $\mu = \frac{1}{6}$.

the asymptotic analysis of section 5, this curve bifurcates *to the left*, and there are no nonzero (and hence no self-similar) solutions on this branch when $\mu = \frac{1}{4}$. Consistent with the previous analysis, we observe two self-similar solutions associated with the unstable subspace and none associated with the center subspace.

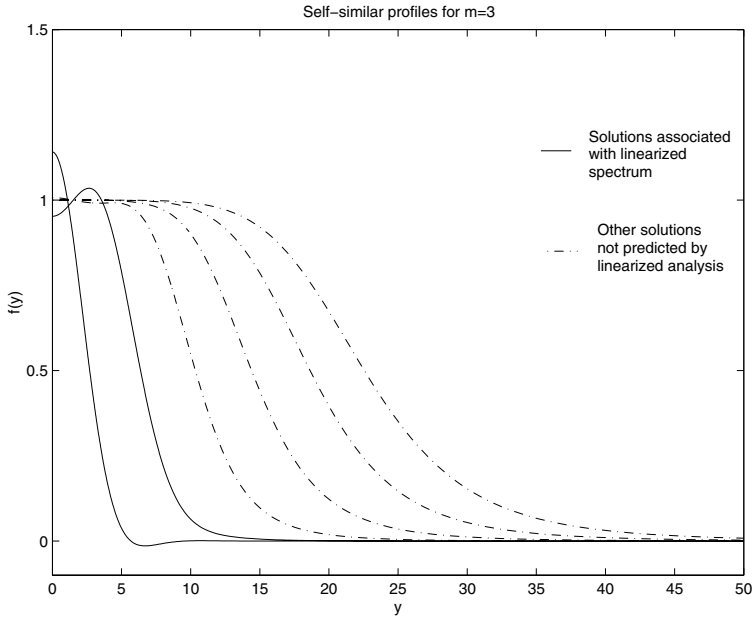

FIG. 10. *Six self-similar profiles for $m = 3$, of which two arise from the analytic bifurcation analysis and four do not.*

A plot of f_s and f_u is given in Figure 10. It is of special interest that, for this value of m, we see *four* other self-similar solutions that arise from paths that start at $\mu = 0$. These are also plotted in Figure 9. Observe that $2 + 4 = 6 = m(m-1)$ for $m = 3$; cf. the last comment in section 4.

7. Numerical simulations of the solutions of the PDE. While the self-similar solutions of (1.7) and (1.6) are important, they give only a partial picture of the overall dynamical behavior of the solutions of these systems. For example, we have not even established whether the self-similar solutions are stable. As we have mentioned, for $m > 1$, the operators in (2.5) and (2.7) are not potentials and do not generate gradient flows as in the second-order case. For $m = 1$, a Lyapunov function exists and this essentially simplifies the asymptotic analysis; see the first results in [22] for $N = 1$ and in [27, 28] for $N \geq 1$. Moreover, compactness of the rescaled orbits $\{\theta(\tau), \tau > \tau_0\}$ remains an open problem (the only known L^∞-estimate for the blow-up rate is a lower one [10, 21]). This makes the asymptotic stability for higher-order equations extremely difficult.

In this section we investigate the dynamics of (1.7) in the case of $m = 2$ by using a *scale-invariant* adaptive numerical method. A general description of the philosophy and implementation of these methods is given in [32, 9, 47] and the references therein. Scale-invariant methods are extremely well suited to computing the solution of systems of PDEs, which have solutions blowing up in finite time and which are also invariant under the action of scaling symmetries. In particular, the underlying PDE is semi-discretized in *space* by using a collocation method on a moving grid. This leads to a system of (stiff) ODEs, which are then solved by using an implicit method. The spatial grid is chosen to *equidistribute* a monitor function $M(u)$ chosen to be

$$M(u) = |u|^{p-1}. \tag{7.1}$$

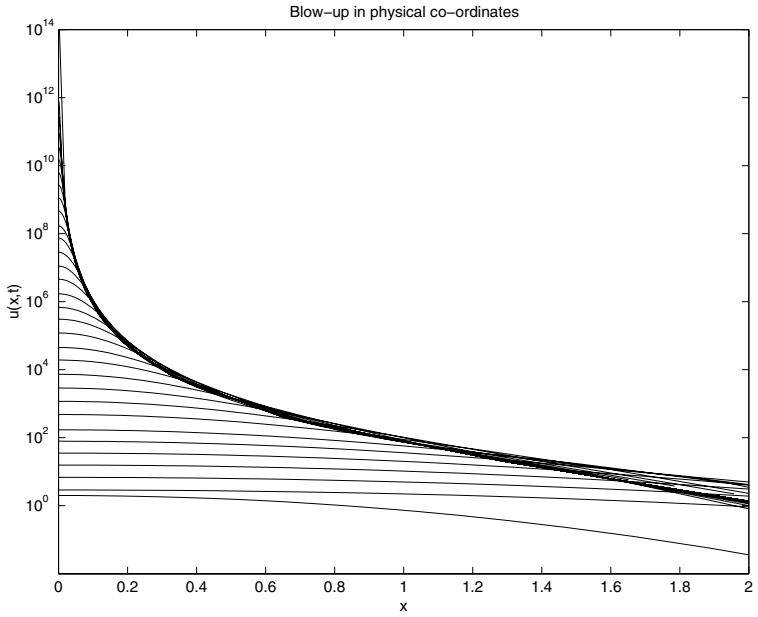

FIG. 11. *The solution of* (1.7) *in the physical variables.*

By doing this, mesh points are clustered where $M(u)$, and hence u is large. The particular choice of $M(u)$ given above leads to a discrete system of equations that is invariant to changes in the scale of the solution and gives relative truncation errors that are *independent of scale*. This is the key to the accuracy of the numerical calculations of this section.

Example 2. For the first calculation we consider the polynomial nonlinearity in (1.7) with as initial data the function

$$u_0(x) = 2e^{-x^2}.$$

First, we present the evolution of this data in the original variables in Figure 11; here the formation of the singularity can be seen clearly. In Figure 12 we present *the same* data, this time in the scaled variables θ and y. Here, the blow-up time T is estimated by a least squares fit of $u(0,t) = f_0/(T-t)^{1/(p-1)}$, with both f_0 and T unknown. The most significant aspect of this figure is that the solutions rapidly converge (exponentially in τ) to the first monotone function $f_s(y)$. The solution of the ODE (2.9) is plotted on Figure 12 for comparison and is indistinguishable from the large τ solutions to the full PDE.

Example 3. For our final calculation, we take as initial data the second solution to (2.9), the solution that extends from the bifurcation point $\mu_2 = \frac{1}{4}$,

$$u(x,0) = f_u(x).$$

This is seen to be unstable. While remaining close to the initial data as the PDE solution increases over several orders of magnitude, eventually the rescaled solution converges to the primary profile as in Example 2; see Figure 13.

Calculations have also been done for the case of the exponential nonlinearity and are fundamentally the same as those presented here; see also [25].

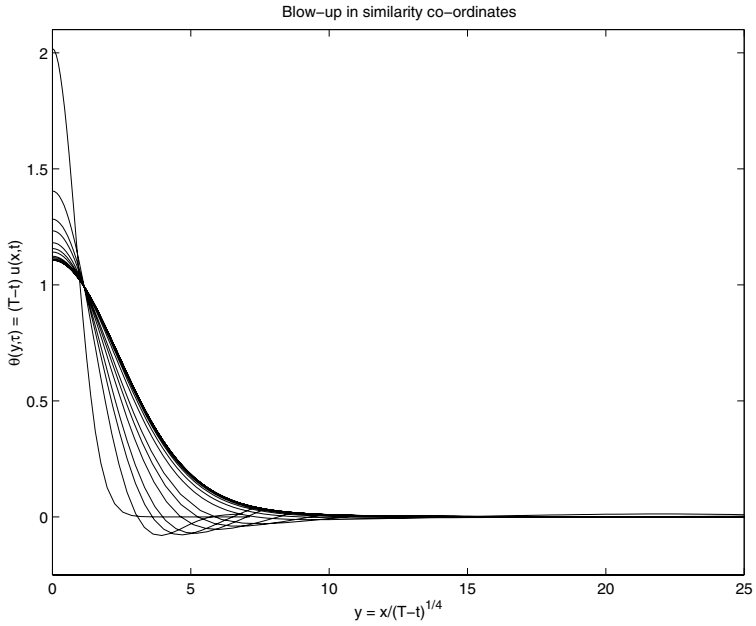

FIG. 12. *The solution of* (1.7) *in the rescaled variables.*

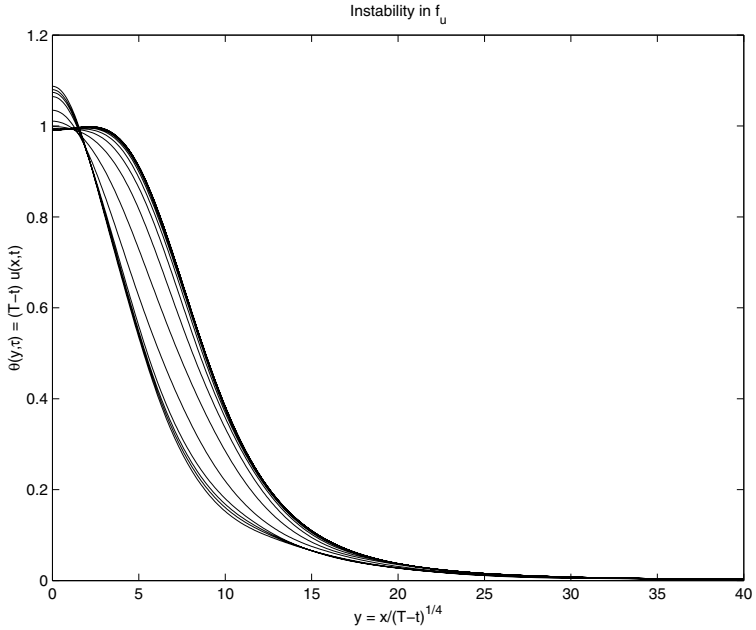

FIG. 13. *The solution of* (1.7) *in the rescaled variables.*

8. Conclusions. It is clear from this study that the (self-similar) behavior of the blow-up solutions of a relatively straightforward higher-order PDE is quite different, and in a sense simpler, than that of related second-order equations. It is very likely that similar behavior will be observed in a much wider class of higher-order equations.

The numerical and asymptotic calculations presented in this paper have suggested a number of open questions in analysis, which deserve further investigation, in particular a fully rigorous proof of the existence of the self-similar solutions and the uniqueness and stability of the "most" monotone stable profiles. We leave this as a subject for future study.

Acknowledgments. The authors wish to thank J.F. Toland for several useful discussions.

TIME REVERSAL FOR DISPERSIVE WAVES IN RANDOM MEDIA*

JEAN-PIERRE FOUQUE†, JOSSELIN GARNIER‡, AND ANDRÉ NACHBIN§

Abstract. Refocusing for time reversed waves propagating in disordered media has recently been observed experimentally and studied mathematically. This surprising effect has many potential applications in domains such as medical imaging, underwater acoustics, and wireless communications. Time refocusing for one-dimensional acoustic waves is now mathematically well understood. In this paper the important case of one-dimensional dispersive waves is addressed. Time reversal is studied in reflection and in transmission. In both cases we derive the self-averaging properties of time reversed refocused pulses. An asymptotic analysis allows us to derive a precise description of the combined effects of randomness and dispersion. In particular, we study an important regime in transmission, where the coherent front wave is destroyed while time reversal of the incoherent transmitted wave still enables refocusing.

Key words. dispersive waves, inhomogeneous media, asymptotic theory, time reversal

1. Introduction.

Time reversal for ultrasound has been extensively studied by Fink and his collaborators at the "Laboratoire Ondes et Acoustique" in Paris; for a description of these experiments we refer, for instance, to the papers [11, 12]. A time reversal mirror is, roughly speaking, a device which is capable of receiving an acoustic signal in time, keeping it in memory, and sending it back into the medium in the reversed direction of time. Time reversal refocusing properties are well understood mathematically for one-dimensional acoustic waves propagating in random media [9] and for three-dimensional waves in layered media [16] or in the paraxial regime [3, 6, 23, 5, 4].

In this paper we consider a case of dispersive waves, namely the Boussinesq model derived in [20]. We first revisit time reversal for reflected signals generated by a pulse sent in a random half-space. The main property of time reversal is the refocusing of the pulse with a shape that depends only on the statistical properties of the medium, and not on the particular realization. This has been mathematically studied in the high-frequency regime for acoustic waves in [9]. We extend this result to the case of dispersive waves. In Theorem 6.1 we derive the deterministic shape of the refocused pulse, which depends on the statistical properties of the medium and the strength of the dispersion. This result is obtained in the regime of weak fluctuations of the medium, a correlation length of the order of magnitude of the pulse carrier wavelength, and long distances of propagation. The underlying asymptotic analysis is based on the techniques of separation of scales presented, for instance, in [2]. In particular, we generalize the system of transport equations that characterize the multiple scattering of the wave.

Time reversal refocusing can also be obtained from transmitted waves generated by a pulse propagating through a slab of random medium. For dispersive waves, in contrast with acoustic waves, there is an interesting regime where the coherent front wave is destroyed. We show in this paper that by time reversing the incoherent part of the transmitted wave it is still possible to refocus at the source. We provide a precise analysis of the interplay between randomness and dispersion. In particular, Theorem 7.1 gives the precise description of the refocused pulse.

One potential application discussed in this paper is the characterization by waveform inversion for water waves of the initial sea surface displacement due to tsunamigenic earthquakes [24]. In [24] an adjoint method is proposed. In the synthetic numerical experiments presented there, a shallow water system in two space dimensions is used for the forward propagation, while a linear adjoint method is adopted for the backward identification of the tsunami source. The authors claim that, in principle, the adjoint method can be applied to nonlinear hydrodynamic models. Their method is also applied to real tide gauge series for the small Gorringe Tsunami of 1969, indicating improvements over previous methods. Here we consider a one-dimensional dispersive system, which is valid for longer propagation distances than the hyperbolic shallow water system. Recently we have produced the first analysis for the time reversal of a nonlinear, one-dimensional hyperbolic shallow water system [13]. In particular, we have shown how randomness dramatically improves time reversal experiments. In [13] we have shown that in the presence of randomness one can perform time reversal beyond the shock propagation distance. Randomness acts as an apparent viscosity and regularizes the shock. Extension to linear hyperbolic systems in higher dimensions has been accomplished, for example, in [16]. Hence time reversal for more realistic models in higher dimensions is a promising technique.

Another important fact, regarding applications, is that we have accomplished a mathematical theory for both the time reversal of dispersive waves (the present paper) and also for weakly nonlinear hyperbolic waves [13]. These two papers are important steps in obtaining a mathematical theory for the time reversal of weakly dispersive weakly nonlinear waves, namely solitary waves. This might have a great impact on other models supporting solitons. As a consequence of these two papers, numerical experiments were performed for the time reversal of solitary waves [14].

The paper is organized as follows. In section 2 we introduce the Boussinesq equation including randomness and dispersion, and we describe the different scales arising in the problem. In section 3 we show how the wave can be decomposed into left- and right-propagating modes in the dispersive nonrandom case. This decomposition is crucial in the following sections where the analysis of the random case is performed. In section 4 we establish the system satisfied by the right- and left-going waves in the random case. We also give the integral representation of the transmitted and reflected waves in terms of the mode transmission and reflection coefficients. In section 5 we introduce the time reversal procedures in reflection (TRR) and in transmission (TRT) and derive the corresponding integral representations for the time reversed waves. The two subsequent sections are devoted to the asymptotic analysis of the refocused pulses and comparisons with numerical simulations.

2. The terrain-following Boussinesq model. We consider the Boussinesq equation that describes the evolution of surface waves in shallow channels [20]:

$$M(z)\frac{\partial \eta}{\partial t} + \frac{\partial u}{\partial z} = 0, \tag{2.1}$$

$$\frac{\partial u}{\partial t} + \frac{\partial \eta}{\partial z} - \beta \frac{\partial^3 u}{\partial z^2 \partial t} = 0, \tag{2.2}$$

where η is the wave elevation, u is the depth-averaged velocity, and z and t are the space and time coordinates, respectively. The spatial variations of the coefficient M are imposed by the bottom profile

$$M(z) = 1 + \varepsilon m(z),$$

where 1 stands for the constant mean depth and the dimensionless small parameter ε characterizes the size of the relative fluctuations of the bottom modeled by the zero-mean stationary random process $m(z)$. The process m is assumed to be bounded by a deterministic constant, differentiable, and to have strong mixing properties, such as a rapidly decaying function [22]. We may think, for instance, that $m(z) = f(\nu(z))$, where f is a smooth bounded function and ν is a stationary Gaussian process with Gaussian autocorrelation function and we assume that $\mathbb{E}[f(\nu(0))] = 0$. Note that in that case the realizations of the process ν are of class $\mathcal{C}^\infty$ almost surely. This hypothesis is consistent with the terrain-following coordinate system adopted in deriving (2.1)–(2.2) [20].

We consider the problem on the finite slab $-L \le z \le 0$, where boundary conditions will be imposed at $-L$ and 0 corresponding to a pulse entering the slab from the right at $z = 0$. The quantities of interest, the transmitted and reflected waves, will be observed in time at the extremities $z = -L$ and $z = 0$, respectively.

The coefficient β measures the dispersion strength. In this paper we consider the case where the dispersion parameter β is either of order 1 or small. We consider a pulse whose support is comparable to the correlation length of the random medium, that is, of order 1. In order to see the effect of the small random fluctuations, we consider a long distance of propagation. As we shall see, the interesting regime arises when the propagation distance is of order $1/\varepsilon^2$.

3. The propagating modes of the homogeneous Boussinesq equation. Consider the homogeneous Boussinesq equation (with $m \equiv 0$):

$$\frac{\partial \eta}{\partial t} + \frac{\partial u}{\partial z} = 0, \tag{3.1}$$

$$\frac{\partial u}{\partial t} + \frac{\partial \eta}{\partial z} - \beta \frac{\partial^3 u}{\partial z^2 \partial t} = 0, \tag{3.2}$$

with a smooth initial condition

$$u(t = 0, z) = u_0(z), \qquad \eta(t = 0, z) = \eta_0(z).$$

Taking the space Fourier transform

$$\check{u}(t, k) = \frac{1}{2\pi} \int u(t, z) \exp(ikz) dz, \qquad \check{\eta}(t, k) = \frac{1}{2\pi} \int \eta(t, z) \exp(ikz) dz,$$

the Boussinesq equation (3.1)–(3.2) reduces to a set of ordinary differential equations:

$$\frac{\partial \check{\eta}}{\partial t} = ik\check{u}, \tag{3.3}$$

$$\left(1 + \beta k^2\right) \frac{\partial \check{u}}{\partial t} = ik\check{\eta}. \tag{3.4}$$

Introducing the pulsation corresponding to the wavenumber k through the *dispersion relation*

$$\omega(k) = \frac{k}{\sqrt{1+\beta k^2}}, \tag{3.5}$$

we get closed form expressions for the solutions:

$$\begin{aligned}
\check{u}(t,k) &= \frac{1}{2}\left(\check{u}_0(k) + \frac{\omega}{k}\check{\eta}_0(k)\right)\exp(i\omega t) + \frac{1}{2}\left(\check{u}_0(k) - \frac{\omega}{k}\check{\eta}_0(k)\right)\exp(-i\omega t),\\
\check{\eta}(t,k) &= \frac{1}{2}\left(\frac{k}{\omega}\check{u}_0(k) + \check{\eta}_0(k)\right)\exp(i\omega t) - \frac{1}{2}\left(\frac{k}{\omega}\check{u}_0(k) - \check{\eta}_0(k)\right)\exp(-i\omega t).
\end{aligned}$$

From these expressions we can conclude that any solution can be decomposed as the superposition of left-propagating modes $(u^{(l)}, \eta^{(l)})$ and right-propagating modes $(u^{(r)}, \eta^{(r)})$:

$$\begin{aligned}
u(t,z) &= u^{(r)}(t,z) + u^{(l)}(t,z),\\
\eta(t,z) &= \eta^{(r)}(t,z) + \eta^{(l)}(t,z),
\end{aligned}$$

where

$$\begin{aligned}
u^{(r)}(t,z) &= \int \frac{1}{2}\left(\check{u}_0(k) + \frac{\omega}{k}\check{\eta}_0(k)\right)\exp\left(i\omega(k)t - ikz\right)dk,\\
\eta^{(r)}(t,z) &= \int \frac{k}{2\omega}\left(\check{u}_0(k) + \frac{\omega}{k}\check{\eta}_0(k)\right)\exp\left(i\omega(k)t - ikz\right)dk,\\
u^{(l)}(t,z) &= \int \frac{1}{2}\left(\check{u}_0(k) - \frac{\omega}{k}\check{\eta}_0(k)\right)\exp\left(-i\omega(k)t - ikz\right)dk,\\
\eta^{(l)}(t,z) &= -\int \frac{k}{2\omega}\left(\check{u}_0(k) - \frac{\omega}{k}\check{\eta}_0(k)\right)\exp\left(-i\omega(k)t - ikz\right)dk.
\end{aligned}$$

This decomposition will be used in the nonhomogeneous case in the next section. In [18] a hyperbolic mode decomposition was used as an approximation for the right- and left-propagating modes. Here the mode decomposition is exact for dispersive waves.

4. Propagator formulation. In this section we first express the scattering problem as a two-point boundary value problem in the frequency domain, and then rewrite it as an initial value problem in terms of the propagator. This is the standard approach for acoustic equations [2] that we generalize to the dispersive case using the decomposition introduced in the previous section.

4.1. Mode propagation in the frequency domain. We consider the random Boussinesq equation (2.1)–(2.2) and take the time Fourier transform

$$\hat{u}(\omega,z) = \frac{1}{2\pi}\int u(t,z)\exp(-i\omega t)dt, \qquad \hat{\eta}(\omega,z) = \frac{1}{2\pi}\int \eta(t,z)\exp(-i\omega t)dt,$$

so that the system reduces to a set of ordinary differential equations:

$$\left(1 - \beta\omega^2(1+\varepsilon m(z))\right)\frac{\partial\hat{\eta}}{\partial z} + i\omega\hat{u} - \varepsilon\beta\omega^2 m'(z)\hat{\eta} = 0, \tag{4.1}$$

$$\frac{\partial\hat{u}}{\partial z} + i\omega\left(1+\varepsilon m(z)\right)\hat{\eta} = 0, \tag{4.2}$$

where m' stands for the spatial derivative of m. We introduce the wavenumber k corresponding to the pulsation ω,

$$k(\omega) = \frac{\omega}{\sqrt{1-\beta\omega^2}}, \tag{4.3}$$

so that we can decompose the wave into *right-going modes* A^ε and *left-going modes* B^ε over distances of propagation of order $1/\varepsilon^2$. We show explicitly the dependence on the small parameter ε:

$$A^\varepsilon(\omega,z) = \frac{1}{2}\left(\hat\eta\left(\omega,\frac{z}{\varepsilon^2}\right) + \frac{k}{\omega}\hat u\left(\omega,\frac{z}{\varepsilon^2}\right)\right), \tag{4.4}$$

$$B^\varepsilon(\omega,z) = \frac{1}{2}\left(\hat\eta\left(\omega,\frac{z}{\varepsilon^2}\right) - \frac{k}{\omega}\hat u\left(\omega,\frac{z}{\varepsilon^2}\right)\right). \tag{4.5}$$

The modes $(A^\varepsilon, B^\varepsilon)$ satisfy

$$\begin{aligned}\frac{\partial A^\varepsilon}{\partial z} &= -\frac{ik}{\varepsilon^2}A^\varepsilon - \frac{ik}{2\varepsilon}m\left(\frac{z}{\varepsilon^2}\right)(A^\varepsilon+B^\varepsilon) + \frac{\beta k^2}{2\varepsilon}m'\left(\frac{z}{\varepsilon^2}\right)(A^\varepsilon+B^\varepsilon)\\ &\quad - \frac{i\omega^2}{2k\varepsilon^2}\left(\frac{1}{1-\beta\omega^2(1+\varepsilon m(z/\varepsilon^2))} - \frac{1}{1-\beta\omega^2}\right)(A^\varepsilon - B^\varepsilon)\\ &\quad + \frac{\beta\omega^2}{2\varepsilon}m'\left(\frac{z}{\varepsilon^2}\right)\left(\frac{1}{1-\beta\omega^2(1+\varepsilon m(z/\varepsilon^2))} - \frac{1}{1-\beta\omega^2}\right)(A^\varepsilon+B^\varepsilon),\end{aligned} \tag{4.6}$$

$$\begin{aligned}\frac{\partial B^\varepsilon}{\partial z} &= \frac{ik}{\varepsilon^2}B^\varepsilon + \frac{ik}{2\varepsilon}m\left(\frac{z}{\varepsilon^2}\right)(A^\varepsilon+B^\varepsilon) + \frac{\beta k^2}{2\varepsilon}m'\left(\frac{z}{\varepsilon^2}\right)(A^\varepsilon+B^\varepsilon)\\ &\quad - \frac{i\omega^2}{2k\varepsilon^2}\left(\frac{1}{1-\beta\omega^2(1+\varepsilon m(z/\varepsilon^2))} - \frac{1}{1-\beta\omega^2}\right)(A^\varepsilon - B^\varepsilon)\\ &\quad + \frac{\beta\omega^2}{2\varepsilon}m'\left(\frac{z}{\varepsilon^2}\right)\left(\frac{1}{1-\beta\omega^2(1+\varepsilon m(z/\varepsilon^2))} - \frac{1}{1-\beta\omega^2}\right)(A^\varepsilon+B^\varepsilon).\end{aligned} \tag{4.7}$$

We expand the last terms of the right-hand sides up to $O(\varepsilon^3)$ terms

$$\frac{\omega^2}{1-\beta\omega^2(1+\varepsilon m(z/\varepsilon^2))} - \frac{\omega^2}{1-\beta\omega^2} = \varepsilon\beta k^4 m\left(\frac{z}{\varepsilon^2}\right) + \varepsilon^2\beta^2k^6m^2\left(\frac{z}{\varepsilon^2}\right) + O(\varepsilon^3), \tag{4.8}$$

where the $O(\varepsilon^3)$ is a term that can be bounded by $\varepsilon^3\beta^3k^8\|m\|_\infty^3/(1-\varepsilon\beta k^2\|m\|_\infty)$. We now look at the waves along the *frequency-dependent modified characteristics* defined by

$$a^\varepsilon(\omega,z) = A^\varepsilon(\omega,z)\exp\left(\frac{ikz}{\varepsilon^2}\right)\exp\left(-\frac{\varepsilon\beta k^2}{2}m\left(\frac{z}{\varepsilon^2}\right) - \frac{\varepsilon^2\beta^2k^4}{4}m\left(\frac{z}{\varepsilon^2}\right)^2\right), \tag{4.9}$$

$$b^\varepsilon(\omega,z) = B^\varepsilon(\omega,z)\exp\left(-\frac{ikz}{\varepsilon^2}\right)\exp\left(-\frac{\varepsilon\beta k^2}{2}m\left(\frac{z}{\varepsilon^2}\right) - \frac{\varepsilon^2\beta^2k^4}{4}m\left(\frac{z}{\varepsilon^2}\right)^2\right), \tag{4.10}$$

which satisfy the linear equation

$$\frac{\partial}{\partial z}\begin{pmatrix} a^\varepsilon \\ b^\varepsilon\end{pmatrix}(\omega,z) = Q^\varepsilon(\omega,z)\begin{pmatrix} a^\varepsilon \\ b^\varepsilon\end{pmatrix}(\omega,z). \tag{4.11}$$

The complex 2×2 matrix Q^ε is given by

$$Q^\varepsilon(\omega,z) = \begin{pmatrix} Q_1^\varepsilon(\omega,z) & Q_2^\varepsilon(\omega,z)e^{\frac{2ikz}{\varepsilon^2}} \\ \overline{Q_2^\varepsilon}(\omega,z)e^{-\frac{2ikz}{\varepsilon^2}} & \overline{Q_1^\varepsilon}(\omega,z)\end{pmatrix} \tag{4.12}$$

FIG. 4.1. *Scattering problem.*

with

$$Q_1^\varepsilon(\omega, z) = -\frac{ik}{2\varepsilon}\left(1+\beta k^2\right) m\left(\frac{z}{\varepsilon^2}\right) - \frac{i\beta^2 k^5}{2} m^2\left(\frac{z}{\varepsilon^2}\right) + O(\varepsilon), \tag{4.13}$$

$$Q_2^\varepsilon(\omega, z) = -\frac{ik}{2\varepsilon}\left(1-\beta k^2\right) m\left(\frac{z}{\varepsilon^2}\right) + \frac{\beta k^2}{2\varepsilon} m'\left(\frac{z}{\varepsilon^2}\right) + \frac{i\beta^2 k^5}{2} m^2\left(\frac{z}{\varepsilon^2}\right)$$

$$+ \frac{\beta^2 k^4}{2} m\left(\frac{z}{\varepsilon^2}\right) m'\left(\frac{z}{\varepsilon^2}\right) + O(\varepsilon). \tag{4.14}$$

The small terms of order ε come from the $O(\varepsilon^3)$ term in the expansion (4.8).

4.2. Boundary values. We assume that a left-going pulse is incoming from the right and is scattered into a reflected wave at $z = 0$ and a transmitted wave at $z = -L/\varepsilon^2$ (see Figure 4.1).

The incoming pulse shape is given by the elevation function $f(t)$, where f is assumed to be a L^1 function compactly supported in the Fourier domain:

$$u_{inc}(t, z=0) = -\int \frac{\omega}{k(\omega)} \hat{f}(\omega) \exp(i\omega t) d\omega, \tag{4.15}$$

$$\eta_{inc}(t, z=0) = \int \hat{f}(\omega) \exp(i\omega t) d\omega, \tag{4.16}$$

with $\mathrm{supp}(\hat{f}) \subset (-1/\sqrt{\beta}, 1/\sqrt{\beta})$. We also impose a radiation condition at $-L/\varepsilon^2$ corresponding to the absence of right-going waves at the left-hand side of the slab $[-L/\varepsilon^2, 0]$. The two-point boundary value problem consisting of the system (4.11) for $z \in [0, L]$, together with the conditions

$$b^\varepsilon(\omega, z=0) = \hat{f}(\omega), \qquad a^\varepsilon(\omega, z=-L) = 0,$$

is then well posed.

4.3. Propagator. It is convenient to transform the two-point boundary value problem into an initial value problem by introducing the propagator $Y^\varepsilon(\omega, -L, z)$, which is a complex 2×2 matrix solution of

$$\frac{\partial Y^\varepsilon}{\partial z}(\omega, -L, z) = Q^\varepsilon(\omega, z) Y^\varepsilon(\omega, -L, z), \qquad Y^\varepsilon(\omega, -L, z=-L) = Id_{\mathbb{C}^2}$$

such that

$$Y^\varepsilon(\omega, -L, z) \begin{pmatrix} a^\varepsilon(\omega, -L) \\ b^\varepsilon(\omega, -L) \end{pmatrix} = \begin{pmatrix} a^\varepsilon(\omega, z) \\ b^\varepsilon(\omega, z) \end{pmatrix}.$$

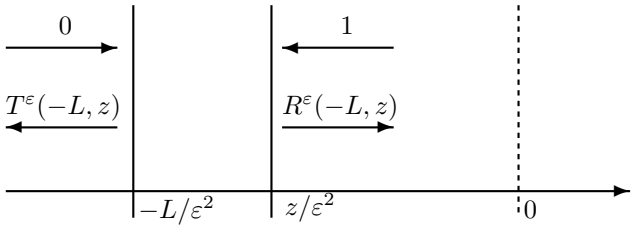

FIG. 4.2. *Reflection and transmission coefficients.*

By the form (4.12) of the matrix Q^ε, if the column vector $(a_1^\varepsilon, b_1^\varepsilon)^T$ is solution of (4.11) with the initial conditions

$$a_1^\varepsilon(\omega,-L)=1, \quad b_1^\varepsilon(\omega,-L)=0, \tag{4.17}$$

then the column vector $(\overline{b_1^\varepsilon}, \overline{a_1^\varepsilon})^T$ is another solution linearly independent of the first solution, so that the propagator matrix Y^ε can be written as

$$Y^\varepsilon(\omega,-L,z)=\begin{pmatrix} a_1^\varepsilon & \overline{b_1^\varepsilon} \\ b_1^\varepsilon & \overline{a_1^\varepsilon} \end{pmatrix}(\omega,z).$$

Note also that the matrix Q^ε has zero trace because $\overline{Q_1^\varepsilon} = -Q_1^\varepsilon$. As a consequence, the determinant of Y^ε is conserved, and $(a_1^\varepsilon, b_1^\varepsilon)$ satisfies the relation

$$\det Y^\varepsilon = |a_1^\varepsilon|^2 - |b_1^\varepsilon|^2 = 1. \tag{4.18}$$

We can now define the *transmission and reflection coefficients* $T^\varepsilon(\omega,-L,z)$ and $R^\varepsilon(\omega,-L,z)$, respectively, for a slab $[-L,z]$ by (see also Figure 4.2)

$$Y^\varepsilon(\omega,-L,z)\begin{pmatrix} 0 \\ T^\varepsilon(\omega,-L,z) \end{pmatrix} = \begin{pmatrix} R^\varepsilon(\omega,-L,z) \\ 1 \end{pmatrix}.$$

In terms of the propagator entries, they are given by

$$R^\varepsilon(\omega,-L,z)=\frac{\overline{b_1^\varepsilon}}{\overline{a_1^\varepsilon}}(\omega,z), \quad T^\varepsilon(\omega,-L,z)=\frac{1}{\overline{a_1^\varepsilon}}(\omega,z),$$

and they satisfy the closed form nonlinear differential system

$$\frac{\partial R^\varepsilon}{\partial z} = 2Q_1^\varepsilon(\omega,z)R^\varepsilon - e^{-\frac{2ikz}{\varepsilon^2}}\overline{Q_2^\varepsilon}(\omega,z)(R^\varepsilon)^2 + e^{\frac{2ikz}{\varepsilon^2}}Q_2^\varepsilon(\omega,z), \tag{4.19}$$

$$\frac{\partial T^\varepsilon}{\partial z} = -T^\varepsilon\left(e^{-\frac{2ikz}{\varepsilon^2}}\overline{Q_2^\varepsilon}(\omega,z)R^\varepsilon + \overline{Q_1^\varepsilon}(\omega,z)\right), \tag{4.20}$$

with the initial conditions at $z=-L$

$$R^\varepsilon(\omega,-L,z=-L)=0, \quad T^\varepsilon(\omega,-L,z=-L)=1.$$

Note that (4.18) implies the conservation of energy relation

$$|R^\varepsilon|^2 + |T^\varepsilon|^2 = 1 \tag{4.21}$$

and in turn the uniform boundedness of the transmission and reflection coefficients. Note also that R^ε and T^ε are the reflection and transmission coefficients for the modified characteristics (4.9)–(4.10). In terms of the real characteristics, the reflection and transmission coefficients are R^ε and $T^\varepsilon \exp(-ikL/\varepsilon^2)$, respectively.

4.4. Quantities of interest. The transmitted wave at time t, denoted by $(u^\varepsilon_{tr}, \eta^\varepsilon_{tr})$, is the left-going wave, which admits the following integral representation in terms of the transmission coefficients:

$$u^\varepsilon_{tr}\left(t, z=-\frac{L}{\varepsilon^2}\right) = -\int \frac{\omega}{k(\omega)}\hat{f}(\omega)T^\varepsilon(\omega,-L,0)\exp\left(i\omega t - ik(\omega)\frac{L}{\varepsilon^2}\right)d\omega, \tag{4.22}$$

$$\eta^\varepsilon_{tr}\left(t, z=-\frac{L}{\varepsilon^2}\right) = \int \hat{f}(\omega)T^\varepsilon(\omega,-L,0)\exp\left(i\omega t - ik(\omega)\frac{L}{\varepsilon^2}\right)d\omega. \tag{4.23}$$

Similarly, the reflected wave $(u^\varepsilon_{ref}, \eta^\varepsilon_{ref})$ can be expressed in terms of the reflection coefficients as

$$u^\varepsilon_{ref}(t, z=0) = \int \frac{\omega}{k(\omega)}\hat{f}(\omega)R^\varepsilon(\omega,-L,0)\exp\left(i\omega t\right)d\omega, \tag{4.24}$$

$$\eta^\varepsilon_{ref}(t, z=0) = \int \hat{f}(\omega)R^\varepsilon(\omega,-L,0)\exp\left(i\omega t\right)d\omega. \tag{4.25}$$

These are the quantities that we will use as new initial conditions for the time reversal experiments.

5. Time reversal setups.

5.1. Time reversal in reflection (TRR). The first step of the time reversal procedure consists of recording the reflected signal at $z = 0$ up to a certain time. It turns out that as $\varepsilon \to 0$ the interesting asymptotic regime arises when we record the signal up to a large time of order $1/\varepsilon^2$, which we denote by t_1/ε^2 with $t_1 > 0$. In the context of shallow water waves, one records only the elevation η_{ref}. If the recording were sufficiently long, one could deduce the depth-averaged velocity u_{ref} by using (4.24), (4.25), but this is not usually the case. If the recording is done over an approximately flat region, then, through (4.15), (4.16) and the proper zero-padding for Fourier transforming the elevation data $\eta_{ref} \equiv f$, the consistent incoming velocity field for the time reversal experiment can be well approximated. The zero-padding is due to the cut-off function of the recorded signal, as explained below.

In the second step of the time reversal procedure a piece of the recorded signal is cut using a cut-off function $s \mapsto G_{t_1}(\varepsilon^2 s)$, where the support of G_{t_1} is included in $[0, t_1]$:

$$\eta^\varepsilon_{ref,cut}\left(\frac{t}{\varepsilon^2}\right) = \eta^\varepsilon_{ref}\left(\frac{t}{\varepsilon^2}\right)G_{t_1}(t).$$

One then time reverses that piece of signal and re-emits the corresponding elevation field with a two-fold amplification. No velocity field is generated. This gives rise to a new wave that can be decomposed as the sum of a right-going wave and a left-going wave. The right-going wave propagates freely in the homogeneous right half-space, and it can be forgotten. The left-going wave is the new incoming signal. Accordingly, the elevation of the time reversed wave sent back into the medium is given by

$$\begin{aligned}\eta^\varepsilon_{inc(TRR)}\left(\frac{t}{\varepsilon^2}, z=0\right) &= \eta^\varepsilon_{ref}\left(\frac{t_1-t}{\varepsilon^2}\right)G_{t_1}(t_1-t)\\ &= \frac{1}{\varepsilon^2}\int\int \exp\left(\frac{i\omega(t_1-t)}{\varepsilon^2}\right)\hat{\eta}^\varepsilon_{ref}(\omega')\hat{G}_{t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right)d\omega' d\omega\\ &= \frac{1}{\varepsilon^2}\int\int \exp\left(\frac{i\omega(t-t_1)}{\varepsilon^2}\right)\overline{\hat{\eta}^\varepsilon_{ref}}(\omega')\overline{\hat{G}}_{t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right)d\omega' d\omega,\end{aligned} \tag{5.1}$$

where *TRR* stands for "time reversal in reflection." Here we have used the fact that η^ε_{ref} is a real-valued signal, and also that $k(-\omega) = -k(\omega)$, by (4.3), which is actually a direct consequence of the *time reversibility* of the Boussinesq equation. The new incoming (left-going) velocity is given by

$$u^\varepsilon_{inc(TRR)}\left(\frac{t}{\varepsilon^2}, z=0\right) = -\frac{1}{\varepsilon^2}\int\int \frac{\omega}{k(\omega)} e^{\frac{i\omega(t-t_1)}{\varepsilon^2}} \overline{\hat\eta^\varepsilon_{ref}}(\omega')\overline{\hat G}_{t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right) d\omega' d\omega. \tag{5.2}$$

A right-going velocity wave is also generated, but it propagates freely with the right-going elevation wave mentioned above, and it can be forgotten as well. Note that the reason why we have amplified the generated elevation field by a factor two is that it gives rise to two counter-propagating waves which both contain half of the generated energy.

The new incoming signal (5.1)–(5.2) repropagates into the same medium and generates a new reflected signal which we observe at the time $t_2/\varepsilon^2 + t$, that is, around the time t_2/ε^2 in the scale of the initial pulse $f(t)$. In terms of the reflection coefficients the observed reflected elevation signal is given by

$$\eta^\varepsilon_{ref(TRR)}\left(\frac{t_2}{\varepsilon^2}+t, z=0\right) = \int \hat\eta^\varepsilon_{inc(TR)}(\omega) R^\varepsilon(\omega, -L, 0) e^{\frac{i\omega t_2}{\varepsilon^2}+i\omega t} d\omega.$$

Substituting the expression of $\hat\eta^\varepsilon_{inc(TRR)}$ into this equation yields the following representation of the reflected signal:

$$\eta^\varepsilon_{ref(TRR)}\left(\frac{t_2}{\varepsilon^2}+t, z=0\right) = \frac{1}{\varepsilon^2}\int\int e^{i\omega t} e^{\frac{i\omega(t_2-t_1)}{\varepsilon^2}} \overline{\hat f}(\omega')\overline{\hat G}_{t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right) \times R^\varepsilon(\omega, -L, 0)\overline{R^\varepsilon}(\omega', -L, 0) d\omega' d\omega.$$

After the change of variable $\omega' = \omega - \varepsilon^2 h$, the representation becomes

$$\eta^\varepsilon_{ref(TRR)}\left(\frac{t_2}{\varepsilon^2}+t, z=0\right) = \int\int e^{i\omega t} e^{\frac{i\omega(t_2-t_1)}{\varepsilon^2}} \overline{\hat f}(\omega-\varepsilon^2 h)\overline{\hat G}_{t_1}(h) \times R^\varepsilon(\omega, -L, 0)\overline{R^\varepsilon}(\omega-\varepsilon^2 h, -L, 0) dh\, d\omega. \tag{5.3}$$

Note that, by (4.21), the reflection coefficients are bounded, and we shall show in section 6 that the rapid phase $\exp(i\omega(t_2-t_1)/\varepsilon^2)$ averages out the integral except when $t_2 = t_1$. This means that refocusing can be observed only at the time $t_2/\varepsilon^2 = t_1/\varepsilon^2$. The precise description of the refocused pulse, taking into account the interaction between randomness and dispersion, will be carried out in section 6.

5.2. Transmitted front wave. Before going into time reversal in transmission, we give an integral representation for the *coherent transmitted wavefront* observed at $z = -L/\varepsilon^2$ around the effective arrival time L/ε^2. By (4.23), the transmitted elevation front is given by

$$\eta^\varepsilon_{tr}\left(\frac{L}{\varepsilon^2}+t, z=-\frac{L}{\varepsilon^2}\right) = \int e^{i\omega t} e^{i(\omega-k(\omega))\frac{L}{\varepsilon^2}} \hat f(\omega) T^\varepsilon(\omega, -L, 0) d\omega. \tag{5.4}$$

Note that expressions like $t + L$ arise because constants have been set to one, so that the mean velocity is one. Due to dispersion, $k(\omega)$ is different from ω (see (4.3)). As a consequence, if $\beta = O(1)$, then the rapid phase $\exp(i(\omega - k(\omega))L/\varepsilon^2)$ makes the integral vanish as $\varepsilon \to 0$. This is in dramatic contrast with the hyperbolic case ($\beta = 0$),

where the coherent transmitted wave persists in this regime as a manifestation of the well known O'Doherty–Anstey theory studied in [8, 17, 25] in various situations.

In the dispersive case, the front will be present if the dispersion parameter β is small enough. This has been characterized and observed numerically in [18]. In particular, in the regime where $\beta = \varepsilon^2\beta_0$, we can derive the precise shape of the front resulting from the interplay of randomness and dispersion. In that regime, by expanding the dispersion relation $\omega \mapsto k(\omega)$, we get that the front is given by

$$\eta^\varepsilon_{tr}\left(\frac{L}{\varepsilon^2}+t, z=-\frac{L}{\varepsilon^2}\right) = \int e^{i\omega t}e^{-i\beta_0\omega^3 L}\hat{f}(\omega)T^\varepsilon(\omega,-L,0)d\omega + O(\varepsilon^2).$$

The transmission coefficients are given by $T^\varepsilon(\omega,-L,0) = 1/\overline{a^\varepsilon_1}(\omega,0)$, where a^ε_1 satisfies (4.11) with the initial conditions (4.17). In the case $\beta = \varepsilon^2\beta_0$, the entries of the matrix Q^ε can be expanded as

$$Q^\varepsilon_1(\omega,z)|_{\beta=\beta_0\varepsilon^2} = -\frac{ik}{2\varepsilon}m\left(\frac{z}{\varepsilon^2}\right) + O(\varepsilon),$$
$$Q^\varepsilon_2(\omega,z)|_{\beta=\beta_0\varepsilon^2} = -\frac{ik}{2\varepsilon}m\left(\frac{z}{\varepsilon^2}\right) + O(\varepsilon),$$

so that we get the same system as in the hyperbolic case up to terms of order ε. The limit of η^ε_{tr} has been derived for the hyperbolic case with small fluctuations [2, 25]. In our case the derivation of the limit follows the same lines except for the deterministic phase $\exp(-i\beta_0\omega^3 L)$ due to the small dispersion. The process $(\eta^\varepsilon_{tr}(\frac{L}{\varepsilon^2}+t, z=-\frac{L}{\varepsilon^2}))_{t\in(-\infty,+\infty)}$ converges in the space of the continuous and bounded functions to

$$\eta_{tr}(t) = \int \hat{f}(\omega)\exp\left(i\omega\left(t-\frac{\sqrt{\gamma(0)}}{\sqrt{2}}B_L\right) - \frac{\omega^2\gamma(\omega)}{4}L - i\beta_0\omega^3 L\right)d\omega,$$

where B_L is a standard Brownian motion and γ is

$$\gamma(\omega) = \int_0^\infty \mathbb{E}[m(0)m(z)]e^{2i\omega z}dz. \tag{5.5}$$

Using convolution operators, the transmitted front can be written in a simpler form

$$\eta_{tr}(t) = f * K\left(t-\frac{\sqrt{\gamma(0)}}{\sqrt{2}}B_L\right), \tag{5.6}$$

which means that a random Gaussian centering appears through the Brownian motion B_L, while the pulse shape spreads in a deterministic way through the convolution by the kernel K,

$$K(t) = K_r * K_d(t).$$

Here K_d is the scaled Airy function [1]

$$K_d(t) = \frac{1}{(3\beta_0 L)^{1/3}}\mathrm{Ai}\left(-\frac{t}{(3\beta_0 L)^{1/3}}\right),$$

and the Fourier transform of K_r is

$$\hat{K}_r(\omega) = \exp\left(-\frac{\omega^2\gamma(\omega)L}{4}\right).$$

Note that the kernel K depends both on randomness (through the function γ) and on dispersion (through the parameter β_0). This stochastic formulation is in agreement with the formulation presented in [18] for small β and was validated numerically with the same code used in this paper.

Observe that a dispersion parameter $\beta = O(1)$ or even $O(\varepsilon^p)$ with $p < 2$ leaves a fast phase in the integral representation of the transmitted front, as can be seen in (5.4). This implies a dramatic spreading of the pulse for a propagation distance of order $1/\varepsilon^2$, so that no coherent front pulse can be observed at the output $z = -L/\varepsilon^2$. In that case we are led to perform time reversal using the coda of the transmitted wave containing the incoherent fluctuations.

5.3. Time reversal in transmission (TRT). We now come back to the case of a dispersion parameter β of order 1. The time reversal procedure consists of recording the transmitted coda signal at $z = -L/\varepsilon^2$ over the time interval $[(L + t_0)/\varepsilon^2, (L + t_1)/\varepsilon^2]$. A piece of the recorded signal is cut using a cut-off function $s \mapsto G_{t_0,t_1}(\varepsilon^2 s - L)$, where the support of G_{t_0,t_1} is included in $[t_0, t_1]$:

$$\eta^\varepsilon_{tr,cut}\left(\frac{t}{\varepsilon^2}\right) = \eta^\varepsilon_{tr}\left(\frac{L+t}{\varepsilon^2}, z = -\frac{L}{\varepsilon^2}\right) G_{t_0,t_1}(t).$$

One then time reverses that piece of signal and sends it back into the same medium. As in section 5.1 one usually (only) records the elevation η_{tr}. Since the velocity field is not recorded, one actually generates the time reversed elevation field with an amplification by two, which in turn generates two counter-propagating waves with equal energies. Numerically we can record both the wave elevation and the velocity field. We will present examples comparing these two cases and show that the refocused pulse is the same. The elevation of the wave sent back is given by

$$\begin{aligned}\eta^\varepsilon_{inc(TRT)}\left(\frac{t}{\varepsilon^2}, z = -\frac{L}{\varepsilon^2}\right) &= \eta^\varepsilon_{tr}\left(\frac{L+t_1-t}{\varepsilon^2}, z = -\frac{L}{\varepsilon^2}\right) G_{t_0,t_1}(t_1 - t)\\ &= \frac{1}{\varepsilon^2}\int\int \exp\left(\frac{i\omega(t_1-t)}{\varepsilon^2}\right)\hat\eta^\varepsilon_{tr}(\omega')\hat G_{t_0,t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right)d\omega' d\omega,\end{aligned}$$

where $\hat\eta^\varepsilon_{tr}$ is the Fourier transform of the shifted received signal $t \mapsto \eta^\varepsilon_{tr}(\frac{L+t}{\varepsilon^2}, z = -\frac{L}{\varepsilon^2})$:

$$\hat\eta^\varepsilon_{tr}(\omega) = e^{i(\omega - k(\omega))\frac{L}{\varepsilon^2}}\hat f(\omega) T^\varepsilon(\omega, -L, 0).$$

Also $\eta^\varepsilon_{inc(TRT)}$ reads as

$$\eta^\varepsilon_{inc(TRT)}\left(\frac{t}{\varepsilon^2}, z = -\frac{L}{\varepsilon^2}\right) = \frac{1}{\varepsilon^2}\int\int \exp\left(\frac{i\omega(t-t_1)}{\varepsilon^2}\right)\overline{\hat\eta^\varepsilon_{tr}}(\omega')\overline{\hat G}_{t_0,t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right)d\omega' d\omega.$$

Let us denote by $\tilde R^\varepsilon$ and $\tilde T^\varepsilon$ the reflection and transmission coefficients for the experiment corresponding to a right-going input wave incoming from the left (see Figure 5.1). Using the propagator Y^ε defined in section 4.3, $\tilde R^\varepsilon$ and $\tilde T^\varepsilon$ obey the relation

$$Y^\varepsilon(\omega, -L, 0)\begin{pmatrix} 1 \\ \tilde R^\varepsilon(\omega, -L, 0)\end{pmatrix} = \begin{pmatrix} \tilde T^\varepsilon(\omega, -L, 0) \\ 0\end{pmatrix}.$$

In terms of the propagator entries they are given by

$$\tilde R^\varepsilon(\omega, -L, 0) = -\frac{b^\varepsilon_1}{a^\varepsilon_1}(\omega, 0), \qquad \tilde T^\varepsilon(\omega, -L, 0) = \frac{1}{a^\varepsilon_1}(\omega, 0),$$

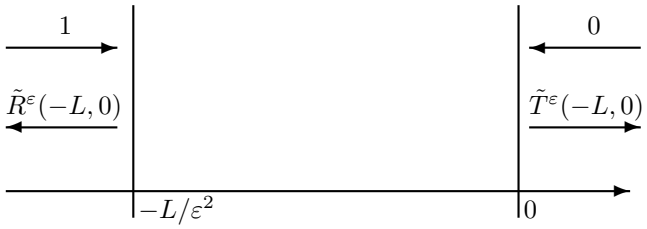

FIG. 5.1. *Adjoint reflection and transmission coefficients for time reversal.*

which shows that

$$\tilde{T}^\varepsilon(\omega,-L,0)=T^\varepsilon(\omega,-L,0).$$

Accordingly, the new incoming signal repropagates into the same medium and generates a new transmitted signal, which we observe at the time t_2/ε^2+t, that is, around the time t_2/ε^2 in the scale of the initial pulse $f(t)$. In terms of the transmission coefficients, the observed transmitted elevation signal is given by

$$\eta^\varepsilon_{tr(TRT)}\left(\frac{t_2}{\varepsilon^2}+t,z=0\right)=\int\hat{\eta}^\varepsilon_{inc(TRT)}(\omega)T^\varepsilon(\omega,-L,0)e^{\frac{i\omega t_2}{\varepsilon^2}+i\omega t}e^{-ik(\omega)\frac{L}{\varepsilon^2}}d\omega.$$

Substituting the expression of $\hat{\eta}^\varepsilon_{inc(TRT)}$ into this equation yields the following representation of the new transmitted signal:

$$\eta^\varepsilon_{tr(TRT)}\left(\frac{t_2}{\varepsilon^2}+t,z=0\right)=\frac{1}{\varepsilon^2}\int\int e^{i\omega t}e^{\frac{i\omega(t_2-t_1-L)}{\varepsilon^2}}\overline{\hat{f}}(\omega')\overline{\hat{G}}_{t_0,t_1}\left(\frac{\omega-\omega'}{\varepsilon^2}\right)$$
$$\times e^{i(k(\omega')-k(\omega))\frac{L}{\varepsilon^2}}e^{-i(\omega'-\omega)\frac{L}{\varepsilon^2}}T^\varepsilon(\omega,-L,0)\overline{T^\varepsilon}(\omega',-L,0)d\omega'd\omega.$$

After the change of variable $\omega'=\omega-\varepsilon^2h$, the representation becomes

$$\eta^\varepsilon_{tr(TRT)}\left(\frac{t_2}{\varepsilon^2}+t,z=0\right)=\int\int e^{i\omega t}e^{\frac{i\omega(t_2-t_1-L)}{\varepsilon^2}}\overline{\hat{f}}(\omega-\varepsilon^2h)\overline{\hat{G}}_{t_0,t_1}(h)$$
$$\times e^{i(k(\omega-\varepsilon^2h)-k(\omega))\frac{L}{\varepsilon^2}}e^{ihL}T^\varepsilon(\omega,-L,0)\overline{T^\varepsilon}(\omega-\varepsilon^2h,-L,0)dh\;d\omega. \tag{5.7}$$

The precise asymptotics of the transmitted wave will be carried out in section 7. It is easily seen that the refocusing will only take place if $t_2=L+t_1$ due to the fast phase.

5.4. TRT in homogeneous medium. One application of TRT is source reconstruction when the medium is known. This is motivated by the problem of waveform inversion for water waves studied in [24], where the goal is to characterize the initial sea surface displacement due to tsunamigenic earthquakes. Mathematically, in the context of this paper, the source inversion problem consists of performing TRT. The repropagation of the time reversed transmitted wave is performed by solving numerically the corresponding wave equation. In the case of the time reversal experiment for a dispersive homogeneous medium, we observe a transmitted signal and would like to recover both the location and the pulse shape of the source. This implies the recompression of the dispersive oscillatory coda of the transmitted wave. Dispersion helps with the source location identification. This is in contrast with (traveling) hyperbolic waves in a homogeneous medium.

Taking $T^\varepsilon = 1$ in (5.7) gives the transmitted signal in homogeneous medium. Observe that the quantities become independent of ε, so that ε can be taken to be equal to 1. We then get

$$\eta_{tr(TRT)}(t_1 + L + t, z) = \int\int e^{i\omega t - ik(\omega)z} \overline{\hat{f}}(\omega - h) \overline{\hat{G}}_{t_0,t_1}(h) e^{i(k(\omega-h)-k(\omega))L} e^{ihL} dh \; d\omega,$$

where we look at two cases, as follows.

(a) Hyperbolic case. If $\beta = 0$, then $k(\omega) = \omega$, and so the transmitted wave is

$$\eta_{tr(TRT)}(t_1 + L + t, z) = \int\int e^{i\omega(t-z)} \overline{\hat{f}}(\omega - h) \overline{\hat{G}}_{t_0,t_1}(h) dh \; d\omega,$$

which yields a traveling wave

$$\eta_{tr(TRT)}(t_1 + L + t, z) = (G_{t_0,t_1} f)(z - t).$$

On the one hand, it is impossible to retrieve the source location from this traveling wave. On the other hand, as soon as the support of the cut-off function is larger than the pulse width, then the reconstruction of the pulse shape is perfect.

(b) Dispersive case. If $\beta \neq 0$ and $(\beta L)^{1/3}$ is much larger than the pulse width, then

$$\eta_{tr(TRT)}(t_1 + L + t, z) = K_{z,L} * f(z - t),$$

where the kernel $K_{z,L}$ is given by

$$\begin{aligned} K_{z,L}(t) &= K_z * K_L(t), \\ K_z(t) &= \frac{1}{(3\beta z)^{1/3}} \mathrm{Ai}\left(\frac{t}{(3\beta z)^{1/3}}\right), \\ \hat{K}_L(\omega) &= G_{t_0,t_1}\left(((1 + \beta k(\omega)^2)^{3/2} - 1)L\right). \end{aligned}$$

The Airy kernel K_z results from the action of dispersion on the refocused pulse around the original source location. Let us define $z_c = T_w^3/(3\beta)$, where T_w is the pulse width. If $z < -z_c$, then pulse refocusing is not yet completed and the oscillatory tail is not yet recompressed. If $z > z_c$, then the pulse starts developing the dispersive tail again. When $z \in [-z_c, z_c]$, the oscillatory tail vanishes and the kernel $K_z$is close to a Dirac mass. This shows that *dispersion enhances the resolution of the source location* since z_c decays with increasing β. However *the reconstruction of the source shape is blurred by dispersive effects* since the cut-off function G deletes a frequency band that becomes larger as β is larger.

6. Asymptotics of the refocused pulse in reflection. From now on we assume that β is of order 1. The integral representation (5.3) of the reflected signal shows that the autocorrelation function of the reflection coefficient at two nearby frequencies will play an important role.

6.1. The frequency autocorrelation function of the reflection coefficient. We shall study the symmetric version

$$U^\varepsilon_{1,1}(\omega, h, z) = R^\varepsilon\left(\omega + \frac{\varepsilon^2 h}{2}, -L, z\right) \overline{R^\varepsilon}\left(\omega - \frac{\varepsilon^2 h}{2}, -L, z\right),$$

and we shall extend the approach developed in [2, 7] to the dispersive case. It is necessary to consider a family of moments so as to get a closed system of equations. We thus introduce for $n, p \in \mathbb{N}$

$$U^{\varepsilon}_{n,p}(\omega, h, z) = \left(R^{\varepsilon}\left(\omega + \frac{\varepsilon^2 h}{2}, -L, z\right)\right)^n \left(\overline{R^{\varepsilon}}\left(\omega - \frac{\varepsilon^2 h}{2}, -L, z\right)\right)^p.$$

Denoting

$$k'(\omega) = \frac{\partial k}{\partial \omega}(\omega) = \frac{1}{(1-\beta\omega^2)^{3/2}} = (1+\beta k^2)^{3/2} \tag{6.1}$$

and using the Riccati equation (4.19) satisfied by R^{ε}, we deduce

$$\begin{aligned}\frac{\partial U^{\varepsilon}_{n,p}}{\partial z} &= 2(n-p)Q^{\varepsilon}_1 U^{\varepsilon}_{n,p} + Q^{\varepsilon}_2 e^{\frac{2ik(\omega)z}{\varepsilon^2}}\left(ne^{ik'(\omega)hz}U^{\varepsilon}_{n-1,p} - pe^{-ik'(\omega)hz}U^{\varepsilon}_{n,p+1}\right)\\ &\quad + \overline{Q^{\varepsilon}_2} e^{-\frac{2ik(\omega)z}{\varepsilon^2}}\left(pe^{ik'(\omega)hz}U^{\varepsilon}_{n,p-1} - ne^{-ik'(\omega)hz}U^{\varepsilon}_{n+1,p}\right)\end{aligned}$$

starting from

$$U^{\varepsilon}_{n,p}(\omega, h, z = -L) = \mathbf{1}_0(n)\mathbf{1}_0(p),$$

where $\mathbf{1}_0(n) = 1$ if $n = 0$ and 0 otherwise. Taking a shifted scaled Fourier transform with respect to h,

$$V^{\varepsilon}_{n,p}(\omega, \tau, z) = \frac{k'(\omega)}{2\pi}\int e^{ihk'(\omega)(\tau-(n+p)z)}U^{\varepsilon}_{n,p}(\omega, h, z)dh,$$

we get

$$\begin{aligned}\frac{\partial V^{\varepsilon}_{n,p}}{\partial z} &= -(n+p)\frac{\partial V^{\varepsilon}_{n,p}}{\partial \tau} + 2(n-p)Q^{\varepsilon}_1 V^{\varepsilon}_{n,p}\\ &\quad + Q^{\varepsilon}_2 e^{\frac{2ik(\omega)z}{\varepsilon^2}}\left(nV^{\varepsilon}_{n-1,p} - pV^{\varepsilon}_{n,p+1}\right) + \overline{Q^{\varepsilon}_2} e^{-\frac{2ik(\omega)z}{\varepsilon^2}}\left(pV^{\varepsilon}_{n,p-1} - nV^{\varepsilon}_{n+1,p}\right)\end{aligned}$$

starting from

$$V^{\varepsilon}_{n,p}(\omega, \tau, z = -L) = \delta(\tau)\mathbf{1}_0(n)\mathbf{1}_0(p).$$

Applying a diffusion-approximation theorem [2, section 3] establishes that the processes $V^{\varepsilon}_{n,p}$ converge to diffusion processes as $\varepsilon \to 0$. In particular, the expectations $\mathbb{E}[V^{\varepsilon}_{n,n}(\omega, \tau, z)]$, $n \in \mathbb{N}$, converge to $W_n(\omega, \tau, z)$, which obey the closed system of transport equations

$$\begin{aligned}&\frac{\partial W_n}{\partial z} + 2n\frac{\partial W_n}{\partial \tau} = \frac{1}{2}\alpha_\beta(\omega)k(\omega)^2 n^2\left(W_{n+1} + W_{n-1} - 2W_n\right),\\ &W_n(\omega, \tau, z = -L) = \delta(\tau)\mathbf{1}_0(n),\end{aligned} \tag{6.2}$$

where

$$\alpha_\beta(\omega) = \alpha(k(\omega))(1+\beta k(\omega)^2)^2 = \frac{\alpha(\omega/\sqrt{1-\beta\omega^2})}{(1-\beta\omega^2)^2} \tag{6.3}$$

and α is proportional to the power spectral density of the random process m:

$$\alpha(k) = \int_0^\infty \mathbb{E}[m(0)m(z)]\cos(2kz)dz. \tag{6.4}$$

Note that the limit transport equations (6.2) have the same form as those obtained in the nondispersive case in [2]. The difference is contained in the rate coefficient $\alpha_\beta(\omega)k(\omega)^2$, which is simply $\alpha_0(\omega)\omega^2$ in the hyperbolic case. We then get the limit of the autocorrelation function of the reflection coefficient:

$$\mathbb{E}\left[R^\varepsilon\left(\omega+\frac{\varepsilon^2 h}{2},-L,0\right)\overline{R^\varepsilon}\left(\omega-\frac{\varepsilon^2 h}{2},-L,0\right)\right]\overset{\varepsilon\to 0}{\longrightarrow}\int\Lambda^L_{ref}(\omega,\tau)e^{-ih\tau}d\tau, \tag{6.5}$$

$$\Lambda^L_{ref}(\omega,\tau)=k'(\omega)^{-1}W_1(\omega,k'(\omega)^{-1}\tau,0). \tag{6.6}$$

The quantity $W_1(\omega,\tau,0)$ is obtained through the system of transport equations (6.2), which we study in the next section.

6.2. Analysis of the transport equations. We can interpret the transport equation (6.2) in terms of a jump Markov process. Let us introduce the process $(N_t)_{t\geq 0}$ with state space $\mathbb{N}$ and infinitesimal generator

$$\mathcal{L}\phi(N)=\frac{1}{2}\alpha_\beta(\omega)k(\omega)^2N^2\left(\phi(N+1)+\phi(N-1)-2\phi(N)\right).$$

As in [2], we deduce

$$\int_{\tau_0}^{\tau_1}W_1(\omega,\tau,0)d\tau=\mathbb{P}_1\left(\int_0^L 2N_s ds\in[\tau_0,\tau_1],\ N_L=0\right),$$

where $\mathbb{P}_{p_0}$ stands for the probability over the distribution of the jump process starting from $N_0=p_0$. Taking $\tau_0=0$ and $\tau_1=\infty$ yields

$$\mathbb{E}\left[|R^\varepsilon|^2(\omega,-L,0)\right]\overset{\varepsilon\to 0}{\longrightarrow}\mathbb{P}_1(N_L=0).$$

It is remarkable that the generating function of the jump process can be expressed in terms of the expectation of some functional of the diffusion process $(\theta_t)_{t\geq 0}$:

$$d\theta_t=\sqrt{\alpha_\beta(\omega)}k(\omega)dB_t+\frac{1}{2}\alpha_\beta(\omega)k(\omega)^2\coth(\theta_t)dt. \tag{6.7}$$

We have

$$\mathbb{E}_{p_0}\left[z^{N_t}\right]=\mathbb{E}\left[\tanh\left(\frac{\theta_t}{2}\right)^{2p_0}\ \middle|\ \theta_0=2\ \mathrm{argtanh}(\sqrt{z})\right],$$

where $\mathbb{E}_{p_0}$ stands for the expectation with respect to the distribution of the jump process starting from $N_0=p_0$. In particular,

$$\mathbb{E}\left[|R^\varepsilon|^2(\omega,-L,0)\right]\overset{\varepsilon\to 0}{\longrightarrow}\mathbb{P}_1(N_L=0)=\mathbb{E}\left[\tanh\left(\frac{\theta_L}{2}\right)^2\ \middle|\ \theta_0=0\right].$$

As the probability density function of the diffusion process (θ_t) is known [21], we get

$$\mathbb{E}\left[|R^\varepsilon|^2(\omega,-L,0)\right]\overset{\varepsilon\to 0}{\longrightarrow}1-\frac{4}{\sqrt{\pi}}\exp\left(-\frac{L}{l_\beta(\omega)}\right)\int_0^\infty\frac{x^2e^{-x^2}}{\cosh\left(2\sqrt{L/l_\beta(\omega)}x\right)}dx,$$

where the localization length $l_\beta(\omega)$ of the mean transmittance is affected by the dispersion

$$l_\beta(\omega) = \frac{8}{\alpha_\beta(k(\omega))k(\omega)^2} = \frac{8(1-\beta\omega^2)^3}{\alpha(\omega/\sqrt{1-\beta\omega^2}))\omega^2}. \tag{6.8}$$

If the power spectral density of the process m can be considered as constant $\alpha(k) \equiv \alpha_0$, that is to say, when the correlation length of the medium is smaller than the typical wavelength of the pulse, then the above expression of the localization length shows that *dispersion enhances localization effects*. The decay of the localization length as a function of frequency is faster in the dispersive case than in the hyperbolic case. This has been observed numerically in [18].

6.3. The refocused pulse. Choosing $t_2 = t_1$ in (5.3) shows that the refocused pulse at $z = 0$ is given by the integral representation

$$\begin{aligned}\eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+t, z=0\right) = \int\int e^{i\omega t}\overline{\hat{f}}(\omega-\varepsilon^2 h)\overline{\hat{G}}_{t_1}(h) \\ \times R^\varepsilon(\omega,-L,0)\overline{R^\varepsilon}(\omega-\varepsilon^2 h,-L,0)dh\, d\omega.\end{aligned} \tag{6.9}$$

The main result of this section is the *self-averaging property* of the refocused pulse. This is shown in the following theorem, which gives the convergence of the refocused pulse to a deterministic shape.

THEOREM 6.1. *For any $T > 0$, $\delta > 0$,*

$$\mathbb{P}\left(\sup_{t\in[-T,T]}\left|\eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+t, z=0\right) - \eta_{ref(TRR)}(t)\right| > \delta\right) \overset{\varepsilon\to 0}{\longrightarrow} 0,$$

where $\eta_{ref(TRR)}$ is the deterministic pulse shape:

$$\eta_{ref(TRR)}(t) = \left(f(-\,\cdot) * K_{TRR}(\cdot)\right)(t). \tag{6.10}$$

The Fourier transform of the kernel K_{TRR} is the convolution of the time-inverted cut-off function G_{t_1} with the density $\tau \mapsto \Lambda^L_{ref}(\omega,\tau)$ evaluated at 0:

$$\hat{K}_{TRR}(\omega) = \left(G_{t_1}(-\,\cdot) * \Lambda^L_{ref}(\omega,\cdot)\right)(0) = \int G_{t_1}(\tau)\Lambda^L_{ref}(\omega,\tau)d\tau. \tag{6.11}$$

Proof. The first step consists of proving the tightness (i.e., the relative compactness) in the space of continuous trajectories (equipped with the topology associated to the sup norm over the compact subsets) of the family of continuous processes

$$\left(\left(\eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+t, z=0\right)\right)_{-\infty<t<\infty}\right)_{\varepsilon>0}.$$

From (6.9) and the uniform bound $|R^\varepsilon| \le 1$, it is easily seen that the quantity $|\eta^\varepsilon_{ref(TRR)}(t_1/\varepsilon^2 + t, z = 0)|$ is uniformly bounded by

$$\int |\hat{G}(h)|dh \times \int |\hat{f}(\omega)|d\omega,$$

which we assume finite. The modulus of continuity

$$\Omega^\varepsilon(s) = \sup_{|s_1-s_2|\le s} \left| \eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+s_1, z=0\right) - \eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+s_2, z=0\right)\right|$$

is bounded by

$$\Omega^\varepsilon(s) \le \int |\hat{G}(h)|dh \times \int \sup_{|s_1-s_2|\le s} |e^{i\omega(s_2-s_1)}-1||\hat{f}(\omega)|d\omega,$$

which goes to zero as $s \to 0$ uniformly with respect to ε, by Lebesgue's theorem, and ensures tightness.

Taking the expectation in (6.9) and using (6.5), we get the convergence of the first moment:

$$\begin{aligned}\lim_{\varepsilon\to 0} \mathbb{E}\left[\eta^\varepsilon_{ref(TRR)}\left(\frac{t_1}{\varepsilon^2}+t, z=0\right)\right] &= \int\int e^{i\omega t}\overline{\hat{f}}(\omega)\overline{\hat{G}}_{t_1}(h)\int e^{-ih\tau}\Lambda^L_{ref}(\omega,\tau)d\tau dh d\omega \\ &= \int\int e^{i\omega t}\overline{\hat{f}}(\omega)G_{t_1}(\tau)\Lambda^L_{ref}(\omega,\tau)d\tau d\omega \\ &= \left(f(-\,.) * K_{TRR}(.)\right)(t) = \eta_{ref(TRR)}(t).\end{aligned}$$

In order to prove the convergence in probability of $\eta^\varepsilon_{ref(TRR)}(t_1/\varepsilon^2+t, z=0)$ to the deterministic refocused pulse $\eta_{ref(TRR)}$, we compute its second moment and show that it converges to the square of the first moment obtained above. This computation has been done in the acoustic case [9] using the moment analysis of the reflected signal established in [7]. The second moment involves the moment of the product of the reflection coefficients at four frequencies. The presence of the cut-off function G_{t_1} used in time reversal automatically pairs the frequencies. The moment analysis then shows that the reflection coefficients for the two pairs become independent, which proves the result. The same techniques apply to the dispersive case since the Riccati equation (4.19) for the reflection coefficient has the same form as in the acoustic case. □

As for acoustic waves, the case of a large slab (L large) leads to explicit formulas for the refocused pulse. This is developed in the following section.

6.4. Large slab. For acoustic waves the hyperbolicity of the equations makes the reflected quantities of interest independent of L for L large enough. This leads to explicit formulas for the power spectral density Λ^L_{ref}. In our context of dispersive waves, the velocities of the waves are still bounded as we consider a pulse with compactly supported spectrum. For this reason, the power spectral density also becomes independent of L for L large enough. Applying the same approach as in [2] (where the case of acoustic waves was addressed), we get that the function Λ^L_{ref} converges as L grows to infinity to the limit density

$$\Lambda^\infty_{ref}(\omega,\tau) = \frac{\kappa_\beta(\omega)\omega^2}{\left(1+\kappa_\beta(\omega)\omega^2\tau\right)^2}, \tag{6.12}$$

where

$$\kappa_\beta(\omega) = \frac{\alpha_\beta(\omega)k(\omega)^2}{4\omega^2 k'(\omega)} = \frac{\alpha(\omega/\sqrt{1-\beta\omega^2})}{4\left(1-\beta\omega^2\right)^{3/2}}.$$

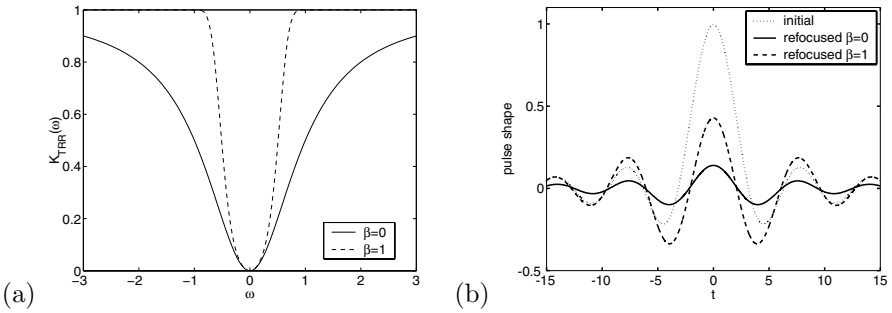

FIG. 6.1. *Fourier transform of the convolution kernel* K_{TRR} (a) *and refocused pulse* (b). *We consider a square cut-off function* $G(t) = \mathbf{1}_{[0,t_1]}(t)$, *and we assume* $\alpha(\omega) \equiv 4$, $t_1 = 1$. *The initial pulse has sinc shape* $f(t) = \sin(t)/t$, *and its spectrum is* $\hat{f}(\omega) = (1/2)\mathbf{1}_{[-1,1]}(\omega)$. *(Note that* $\beta = 1$ *corresponds to a very dispersive configuration.)*

The deterministic refocused pulse is then given by (6.10) with the explicit Λ^{∞}_{ref} derived in this section. Taking, for instance, a square cut-off function $G_{t_1}(t) = \mathbf{1}_{[0,t_1]}(t)$, the kernel K_{TRR} reads as a high-band filter because its Fourier transform is

$$\hat{K}_{TRR}(\omega) = \frac{\kappa_\beta(\omega)\omega^2 t_1}{1 + \kappa_\beta(\omega)\omega^2 t_1}. \tag{6.13}$$

An example is presented in Figure 6.1. The cut-off frequency of the filter $\hat{K}_{TRR}$ decays with increasing dispersion parameter β. This shows that time reversal focusing in reflection is more efficient in the dispersive case than in the hyperbolic case. This is consistent with the observation that localization effects are enhanced in the presence of dispersion (see (6.8)).

7. Asymptotics of refocused pulse in transmission.

7.1. The frequency autocorrelation function of the transmission coefficient. We study here the autocorrelation function of the transmission coefficient at two nearby frequencies. We first define a new family of processes indexed by $n, p \in \mathbb{N}$,

$$\tilde{U}^{\varepsilon}_{n,p}(\omega, h, z) = U^{\varepsilon}_{n,p}(\omega, h, z) T^{\varepsilon}\left(\omega + \frac{\varepsilon^2 h}{2}, -L, z\right) \overline{T^{\varepsilon}}\left(\omega - \frac{\varepsilon^2 h}{2}, -L, z\right),$$

which satisfy

$$\begin{aligned}\frac{\partial \tilde{U}^{\varepsilon}_{n,p}}{\partial z} &= 2(n-p)Q^{\varepsilon}_1 \tilde{U}^{\varepsilon}_{n,p} + Q^{\varepsilon}_2 e^{\frac{2ik(\omega)z}{\varepsilon^2}}\left(n e^{ik'(\omega)hz}\tilde{U}^{\varepsilon}_{n-1,p} - (p+1)e^{-ik'(\omega)hz}\tilde{U}^{\varepsilon}_{n,p+1}\right) \\ &\quad + \overline{Q^{\varepsilon}_2} e^{-\frac{2ik(\omega)z}{\varepsilon^2}}\left(p e^{ik'(\omega)hz}\tilde{U}^{\varepsilon}_{n,p-1} - (n+1)e^{-ik'(\omega)hz}\tilde{U}^{\varepsilon}_{n+1,p}\right)\end{aligned}$$

starting from

$$\tilde{U}^{\varepsilon}_{n,p}(\omega, h, z = -L) = \mathbf{1}_0(n)\mathbf{1}_0(p).$$

Taking a shifted scaled Fourier transform with respect to h,

$$\tilde{V}^{\varepsilon}_{n,p}(\omega, \tau, z) = \frac{k'(\omega)}{2\pi}\int e^{ihk'(\omega)(\tau - (n+p)z)}\tilde{U}^{\varepsilon}_{n,p}(\omega, h, z)dh,$$

we get

$$\frac{\partial \tilde{V}^{\varepsilon}_{n,p}}{\partial z} = -(n+p)\frac{\partial \tilde{V}^{\varepsilon}_{n,p}}{\partial \tau} + 2(n-p)Q^{\varepsilon}_1 \tilde{V}^{\varepsilon}_{n,p}$$
$$+ Q^{\varepsilon}_2 e^{\frac{2ik(\omega)z}{\varepsilon^2}} \left(n\tilde{V}^{\varepsilon}_{n-1,p} - (p+1)\tilde{V}^{\varepsilon}_{n,p+1} \right) + \overline{Q^{\varepsilon}_2} e^{-\frac{2ik(\omega)z}{\varepsilon^2}} \left(p\tilde{V}^{\varepsilon}_{n,p-1} - (n+1)\tilde{V}^{\varepsilon}_{n+1,p} \right)$$

starting from

$$\tilde{V}^{\varepsilon}_{n,p}(\omega, \tau, z = -L) = \delta(\tau)\mathbf{1}_0(n)\mathbf{1}_0(p).$$

Applying a diffusion-approximation theorem [2, section 3.14] establishes that the processes $\tilde{V}^{\varepsilon}_{n,p}$ converge to diffusion processes as $\varepsilon \to 0$. In particular, the expectations $\mathbb{E}[\tilde{V}^{\varepsilon}_{n,n}(\omega, \tau, z)]$ converge to $\tilde{W}_n(\omega, \tau, z)$, which obey the closed system of transport equations

$$\frac{\partial \tilde{W}_n}{\partial z} + 2n\frac{\partial \tilde{W}_n}{\partial \tau} = \frac{1}{2}\alpha_\beta(\omega)k(\omega)^2 \left((n+1)^2\tilde{W}_{n+1} + n^2\tilde{W}_{n-1} - ((n+1)^2 + n^2)\tilde{W}_n \right),$$
$$\tilde{W}_n(\omega, \tau, z = -L) = \delta(\tau)\mathbf{1}_0(n).$$

We then get the limit of the autocorrelation function of the transmission coefficient:

$$\mathbb{E}\left[T^{\varepsilon}\left(\omega + \frac{\varepsilon^2 h}{2}, -L, 0 \right) \overline{T^{\varepsilon}}\left(\omega - \frac{\varepsilon^2 h}{2}, -L, 0 \right) \right] \overset{\varepsilon \to 0}{\longrightarrow} \int \Lambda^L_{tr}(\omega, \tau) e^{-ih\tau} d\tau, \tag{7.1}$$

$$\Lambda^L_{tr}(\omega, \tau) = k'(\omega)^{-1} \tilde{W}_0(\omega, k'(\omega)^{-1}\tau, 0). \tag{7.2}$$

7.2. Analysis of the transport equations. We can interpret the transport equation in terms of a jump Markov process as in section 6.2. Let us introduce the process $(\tilde{N}_t)_{t \geq 0}$ with state space $\mathbb{N}$ and infinitesimal generator:

$$\tilde{\mathcal{L}}\phi(\tilde{N}) = \frac{1}{2}\alpha_\beta(\omega)k(\omega)^2 \left((\tilde{N}+1)^2(\phi(\tilde{N}+1) - \phi(\tilde{N})) + \tilde{N}^2(\phi(\tilde{N}-1) - \phi(\tilde{N})) \right).$$

Note that $\tilde{\mathcal{L}}$ is the adjoint of the generator $\mathcal{L}$ of the process $(N_t)_{t \geq 0}$, which means that $(\tilde{N}_t)_{t \geq 0}$ is the time reversed process of $(N_t)_{t \geq 0}$. We have

$$\int_{\tau_0}^{\tau_1} \tilde{W}_0(\omega, d\tau, 0) = \tilde{\mathbb{P}}_0 \left(\int_0^L 2\tilde{N}_s ds \in [\tau_0, \tau_1],\ \tilde{N}_L = 0 \right), \tag{7.3}$$

where $\tilde{\mathbb{P}}_{p_0}$ stands for the probability over the distribution of the jump process starting from $\tilde{N}_0 = p_0$. The generating function of the jump process is again expressed in terms of the expectation of some functional of the diffusion process $(\theta_t)_{t \geq 0}$ defined by (6.7):

$$\tilde{\mathbb{E}}_{p_0}\left[z^{\tilde{N}_t} \right] = \mathbb{E}\left[\left(1 - \tanh\left(\frac{\theta_t}{2} \right)^2 \right) \tanh\left(\frac{\theta_t}{2} \right)^{2p_0} \ \middle|\ \theta_0 = 2\ \mathrm{argtanh}(\sqrt{z}) \right].$$

It should be noted also that $\tilde{W}_0$ is not a density with respect to the Lebesgue measure over $\mathbb{R}^+$ (while W_1 is a density, as seen in section 6.2). It consists actually of the sum of a Dirac mass at 0 and a density:

$$\tilde{W}_0(\omega, d\tau, 0) = p_{\omega,d}\delta_0(d\tau) + \tilde{W}_{0,c}(\omega, d\tau, 0).$$

This expression is obtained by disintegrating the right-hand side of (7.3) over the first jump time of the process $(\tilde{N})_{t\geq 0}$. The weight of the Dirac mass is

$$p_{\omega,d} = \exp\left(-\frac{4L}{l_\beta(\omega)}\right),$$

while the absolutely continuous part is given by

$$\int_0^{\tau_1} \tilde{W}_{0,c}(\omega,\tau,0)d\tau = \int_0^L \frac{4}{l_\beta(\omega)} e^{\frac{-4(L-t)}{l_\beta(\omega)}} \tilde{\mathbb{P}}_1\left(\int_0^t 2\tilde{N}_s ds \in [0,\tau_1],\ \tilde{N}_t = 0\right) dt.$$

It seems impossible to derive a closed form expression for the density part. We can either derive expansions or perform numerical simulations based on Monte-Carlo simulations of the random jump process $(\tilde{N}_t)_{t\geq 0}$. For instance, we can expand $\tilde{W}_{0,c}$ for small τ. Indeed, if $\tau_1 \ll l_\beta(\omega)$, then

$$\tilde{\mathbb{P}}_1\left(\int_0^t 2\tilde{N}_s ds \in [0,\tau_1],\ \tilde{N}_t = 0\right) \simeq \frac{2\tau_1}{l_\beta(\omega)} \exp\left(-\frac{4t}{l_\beta(\omega)}\right),$$

so that

$$\tilde{W}_{0,c}(\omega,\tau,0) \overset{\tau \ll l_\beta(\omega)}{\simeq} \exp\left(-\frac{4L}{l_\beta(\omega)}\right) \frac{8L}{l_\beta(\omega)^2}.$$

This approximate expression will be used in the next section to give a closed form expression of the refocused pulse in a particular regime.

7.3. The refocused pulse. The following theorem expresses the self-averaging property of the refocused pulse.

THEOREM 7.1. *For any $T > 0$, $\delta > 0$,*

$$\mathbb{P}\left(\sup_{t\in[-T,T]} \left|\eta^\varepsilon_{tr(TRT)}\left(\frac{t_1+L}{\varepsilon^2} + t, z = 0\right) - \eta_{tr(TRT)}(t)\right| > \delta\right) \overset{\varepsilon\to 0}{\longrightarrow} 0,$$

where $\eta_{tr(TRT)}$ is the refocused pulse shape:

$$\eta_{tr(TRT)}(t) = \left(f(-\,\cdot) * K_{TRT}(\cdot)\right)(t). \tag{7.4}$$

The Fourier transform of the kernel is the convolution of the time-inverted cut-off function G_{t_0,t_1} with the density $\tau \mapsto \Lambda^L_{tr}(\omega,\tau)$ evaluated at $(1-k'(\omega))L$:

$$\begin{aligned}\hat{K}_{TRT}(\omega) &= \left(G_{t_0,t_1}(-\,\cdot) * \Lambda^L_{tr}(\omega,\cdot)\right)((1-k'(\omega))L) \\ &= \int G_{t_0,t_1}(\tau - (1-k'(\omega))L)\Lambda^L_{tr}(\omega,d\tau).\end{aligned} \tag{7.5}$$

Proof. The proof follows the same lines as that of Theorem 6.1 with the transport equations corresponding to the transmission problem. ∎

Homogeneous dispersive case. Assume here that randomness is absent ($\alpha_\beta(\omega) \equiv 0$). Then $\Lambda^L_{tr}(\omega,\tau) = \delta_0(\tau)$, so that

$$\hat{K}_{TRT}(\omega) = G_{t_0,t_1}((k'(\omega)-1)L),$$

which is consistent with the results of section 5.4 at $z = 0$.

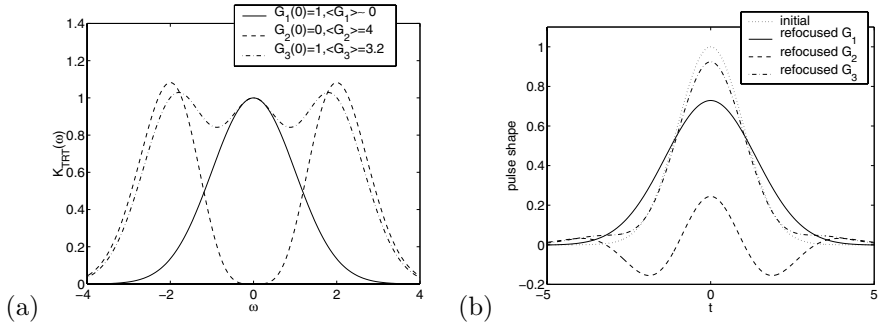

FIG. 7.1. *Fourier transform of the convolution kernel* K_{TRT} (a) *and refocused pulse* (b). *We consider the three cut-off functions* G_1, G_2, G_3 *described within the text. Here we assume* $\alpha(\omega) \equiv 1$, $L = 1$. *The initial pulse has Gaussian shape* $f(t) = \exp(-t^2/2)$.

Random nondispersive case. Assume here that $\beta = 0$. Consider an input pulse f which is such that the power spectral density of the process m can be considered as constant over the spectral range $[-\omega_{max}, \omega_{max}]$ of f: $\alpha(\omega) \equiv \alpha_0$. Finally, assume that we record a small piece of the transmitted wave in the sense that the cut-off function G_{t_0,t_1} has its support in $[t_0, t_1]$ such that $t_0 < 0$ and $t_1 > 0$ with $\alpha_0 \omega_{max}^2 t_1 \ll 1$. Then

$$\hat{K}_{TRT}(\omega) = e^{-\frac{\alpha_0 \omega^2 L}{2}} \left(G_{t_0,t_1}(0) + \frac{\alpha_0^2 \omega^4 L}{8} \langle G_{t_0,t_1} \rangle \right),$$

where $\langle G_{t_0,t_1} \rangle = \int_0^\infty G_{t_0,t_1}(t)dt$, so that

$$\eta_{tr(TRT)}(t) = G_{t_0,t_1}(0) \left(f(-\,\cdot) * K_{TRT,1}(\cdot) \right)(t) + \langle G_{t_0,t_1} \rangle \left(f(-\,\cdot) * K_{TRT,2}(\cdot) \right)(t),$$

$$\hat{K}_{TRT,1}(\omega) = e^{-\frac{\alpha_0 \omega^2 L}{2}},$$

$$\hat{K}_{TRT,2}(\omega) = \frac{\alpha_0^2 \omega^4 L}{8} e^{-\frac{\alpha_0 \omega^2 L}{2}}.$$

The convolution kernel $K_{TRT,1}$ results from the double action of the O'Doherty–Anstey theory on the front pulse in forward and backward directions. Of course this contribution completely vanishes if we do not record the front of the pulse ($G_{t_0,t_1}(0) = 0$). The convolution kernel $K_{TRT,2}$ is a filter that retains only the frequencies around $1/\sqrt{\alpha_0 L}$, those which can probe the medium without being completely reflected by the strong localization effect.

7.4. Numerical illustrations. We would like to illustrate results obtained in the previous section. We consider the hyperbolic random case discussed in subsection 7.3. In Figure 7.1 we plot the Fourier transform of the kernel K_{TRT} for three different time reversal calculations corresponding to three different cut-off functions G_{t_0,t_1} that we shall denote by G_1, G_2, and G_3. In the first calculation, we record only the front pulse and send it back into the medium $G_1(0) = 1$, $\langle G_1 \rangle \ll L$. We may think, for instance, that

$$G_1(t) = \cos^2\left(\frac{t}{t_1}\right) \mathbf{1}_{[-\pi t_1/2, \pi t_1/2]}(t),$$

with $\alpha_0 \omega_{max}^2 t_1 \ll 1$ and $t_1 \ll L$. The refocused pulse results from the action of the O'Doherty–Anstey theory, and its shape is the convolution of the initial pulse shape with the kernel $K_{TRT,1}$ (solid line, Figure 7.1).

In the second calculation, we record a small piece of the coda but not the front pulse $G_2(0) = 0$, $\langle G_2 \rangle = 4L$. We may think, for instance, that

$$G_2(t) = \frac{8L}{\pi t_1} \sin^2\left(\frac{t}{t_1}\right) \mathbf{1}_{[0,\pi t_1]}(t),$$

with $\alpha_0 \omega_{max}^2 t_1 \simeq 0.1 - 0.2$. Only medium range frequencies have been recorded, so that the refocused pulse shape is the convolution of the initial pulse shape with the kernel $K_{TRT,2}$ (dashed line, Figure 7.1).

In the third calculation, we record both the front pulse and a piece of the coda, so that $G_3(0) = 1$, $\langle G_3 \rangle \simeq 3.2L$. We may think, for instance, that

$$G_3(t) = \frac{6.4L}{\pi t_1} \sin^2\left(\frac{t + t_0}{t_1}\right) \mathbf{1}_{[-\pi t_0, \pi(t_1 - t_0)]}(t),$$

with $\alpha_0 \omega_{max}^2 t_1 \simeq 0.1 - 0.2$ and $t_0 \simeq \sqrt{\pi t_1^3/(6.4L)}$. In such a case a broad range of frequencies are recorded, and the cut-off function has been chosen in such a way that the weighted sum of the two kernels $K_{TRT,1}$ and $K_{TRT,2}$ define a kernel K_{TRT} with a large band of frequencies (dash-dotted line, Figure 7.1). As a result, the refocused pulse is close to the initial pulse.

It has been observed experimentally [10] that retransmitting part of the coda produces better refocusing than resending the front. This observation addresses spatial refocusing, while in this paper we focus our attention on time refocusing. The above illustrations show that the contributions of the coda and the front to the refocused pulse are actually complimentary. The contribution of the front is concerned with the low-frequency components of the pulse, while the contribution of the coda is concerned with the high-frequency components of the pulse. If we extrapolate this observation to three-dimensional configurations, then we can understand the quoted experimental observation in the sense that the high-frequency components are the ones that are expected to give the precise location of the source point.

7.5. TRT numerical experiments and application to source reconstruction. In this section we further illustrate TRT. A numerical method for the nonlinear terrain-following Boussinesq equation has been fully described in [19]. In this section we describe time reversal experiments in transmission by performing numerical experiments corresponding to the linearized terrain-following Boussinesq system (2.1)–(2.2). The initial wave elevation profile is incoming from the left and is given either by a Gaussian $\eta_0(z) = f(z) = \exp(-z^2/0.05)$ or by its spatial derivative $f'(z)$, as displayed in Figure 7.2. The corresponding initial velocity field is calculated in order to generate only a right-propagating mode, as presented in section 3. This is easily done by performing the inverse FFT of $\check{u} \equiv (\omega/k)\check{f}$.

7.5.1. Previous numerical results in related configurations. In a previous article by Fouque and Nachbin [15], TRR numerical experiments were conducted with a weakly nonlinear shallow water system. In particular, formula (6.10) (for the refocused pulse shape in reflection) was numerically captured in the hyperbolic ($\beta = 0$) case. The corresponding formula in [15] reads as (6.10) with K_{TRR}, as given by expression (6.13), with $\kappa_{(\beta=0)}(\omega) = \alpha(\omega)/4$. A weakly nonlinear example was also presented showing that formula (6.10) with $\beta = 0$ still holds as a good approximation. As a consequence of these early results, a complete nonlinear hyperbolic theory has been recently developed by the present authors [13]. Subsequently [14, 19] nonlinear

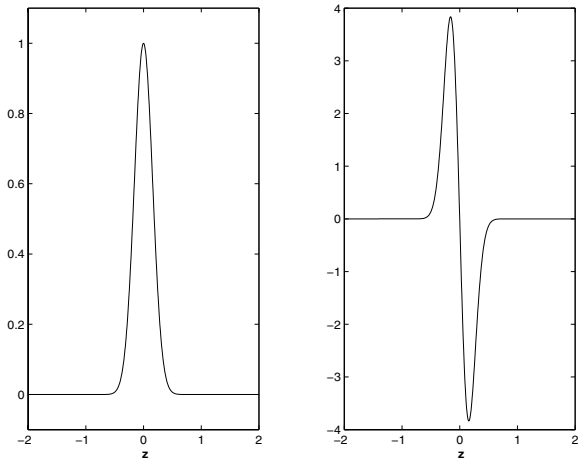

FIG. 7.2. *Initial wave elevation profiles considered in the experiments.*

experiments were further extended, and several numerical experiments for TRR were presented for both linear and weakly nonlinear dispersive waves, including solitary waves. Theory is not yet available for weakly dispersive, weakly nonlinear (solitary) waves.

Connecting the above comments and previous results with the present paper, we recall that numerical results for the transmitted front (as at the end of section 5.2) were presented by Grajales and Nachbin in [18]. The present numerical code captured quantitatively the composition of both kernels K_d and K_r, defined through (5.6). One should keep in mind that the present stochastic O'Doherty–Anstey formulation in transmission is more general than the deterministic theory given in [18], in part because it does not necessarily rely on β being small and also because it displays the *self-averaging* property. Moreover, time reversal was not addressed in [18].

Hence it is important to note that the transmission formula (5.6) plays an essential role in expression (5.7), which converges asymptotically to the TRT formula (7.4). The limiting form (7.1) of the frequency autocorrelation function was studied in section 7.1 and is characterized by the solution $\tilde{W}_0$ of a transport equation, as indicated in (7.2). In contrast to the TRR problem it is not possible to derive a closed form expression for the power spectral density Λ^L_{tr}, as mentioned at the end of section 7.2. One can derive expansions or perform Monte-Carlo simulations with the corresponding jump process. On the other hand, in the TRR problem this was made possible with the large slab hypothesis (section 6.4), leading to a closed form expression for Λ^∞_{ref}. Thus extracting quantitative information from expression (7.4) is a complex task, particularly due to the difficulty of computing Λ^L_{tr}.

Our strategy for presenting numerical results that address the theoretical expression for TRT is as follows. In section 7.3 a dispersive regime was identified where TRT can be easily checked: the homogeneous dispersive case. It has never been verified that the oscillatory effect of the Airy kernel can be completely recompressed, even for large values of β where we end up completely losing track of the initial pulse shape. Phases are scrambled due to dispersion but recompressed (reorganized) through time reversal. This will be shown below.

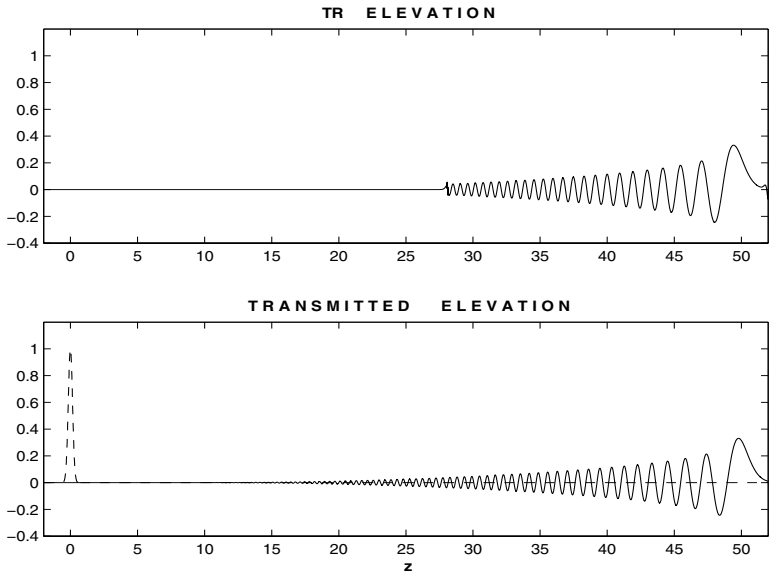

FIG. 7.3. *Bottom graph: the complete transmitted wave elevation. The initial condition is given by a dashed line. Dispersive propagation ($\beta = 0.01$) over a flat bottom. Top graph: cut-off wave elevation profile to be time reversed and sent back towards the origin.*

The next step is to add randomness. In forward transmission the dispersive O'Doherty–Anstey attenuation mechanism has been quantitatively validated in [18], for a specific realization. Note that these are two separate ways of addressing the two main mechanisms encoded in Λ_{tr}^{L}: the dispersive and the incoherent coda production and recompression. Finally, in the absence of a closed form expression for Λ_{tr}^{L}, we proceed to qualitatively verifying the combined effect for the dispersive TRT in a random environment.

7.5.2. New experiments for dispersive TRT. The new experiments of interest are in the TRT regime illustrating how, in particular, it can be applied to source reconstruction (i.e., waveform inversion).

We first consider the homogeneous dispersive case discussed above. In this problem a Gaussian pulse will be gradually transformed into an Airy function (cf. section 5.4, case (b)). An oscillatory tail develops behind the wavefront due to dispersion, as displayed in Figure 7.3. TRT will recompress the oscillatory tail, and the initial waveform is obtained as indicated in the sequence of Figure 7.4. In these experiments we used the Gaussian pulse (of approximately unit width) for the right-propagating initial elevation, together with its consistent (right-going) dispersive velocity profile ($\beta = 0.01$). Both the wave elevation η and the wave velocity u were recorded for time reversion. Hence no right-going mode was produced in the time reversed experiment.

Dispersion is then increased to a level where we will completely lose track of the initial pulse shape. Let $\beta = 0.1$, and consider the derivative of a Gaussian for the initial profile $\eta_0(z)$. In Figure 7.5 we present the forward experiment (in the top graph), having only a right-going mode. Time evolves from bottom trace to the top. The final trace (at the top) shows that we have completely lost track of the initial profile highlighted in the bottom trace. Both η and u are recorded and time reversed. Hence

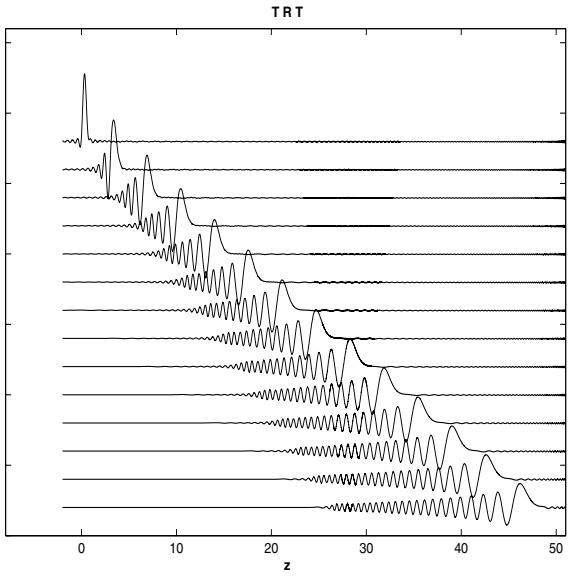

FIG. 7.4. *Time reversal in transmission (TRT) over a flat bottom. The initial profile was a Gaussian at the origin. The time reversed profile is the trace at the bottom. Time evolves from bottom to top at time increments of* 3.6 *units. Complete refocusing is observed in the top trace. The dispersion level is* $\beta = 0.01$.

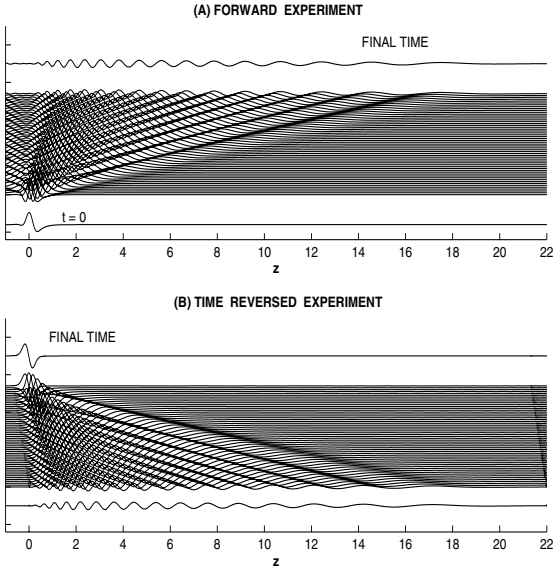

FIG. 7.5. *TRT over a flat bottom. The initial profile is a derivative of a Gaussian at the origin (bottom trace of graph* (A)*). Time evolves from bottom to top. Full recompression is observed in graph* (B)*. The dispersion level has been increased to* $\beta = 0.1$.

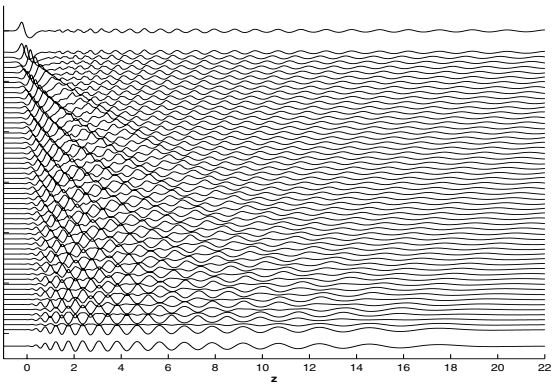

FIG. 7.6. *TRT over a flat bottom. Time evolves from bottom to top. The TR wave elevation (bottom trace) was amplified by a factor of two, while the velocity field u was not used for TR.*

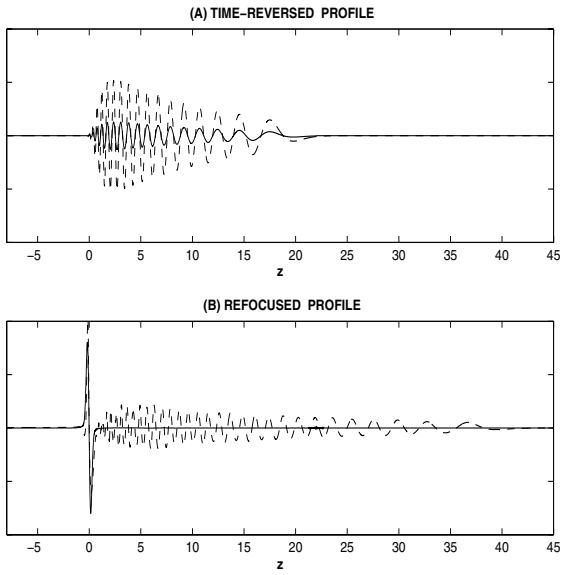

FIG. 7.7. (A) *Solid line: the recorded η; dashed line: the amplified η for time reversion.* (B) *Refocused pulse for the amplified experiment of Figure* 7.6 *(dashed line) and for the experiment in Figure* 7.5 *(solid line).*

a left-propagating mode is generated for the time reversed experiment. In the bottom graph of Figure 7.5 we clearly see the full recompression as predicted in section 5.4.

Next we consider the case where we record only the wave elevation η. For the time reversal experiment we re-emit this elevation field with a two-fold amplification. The corresponding dynamics is presented in Figure 7.6. We clearly see that, as recompression takes place along the left-propagating mode, there is a small dispersive wave propagating to the right. In Figure 7.7(A) we have the "doubled" time reversed profile compared to the recorded profile. In Figure 7.7(B) we see that the refocused pulse is the same for both experiments considered with $\beta = 0.1$. The oscillatory coda seen in

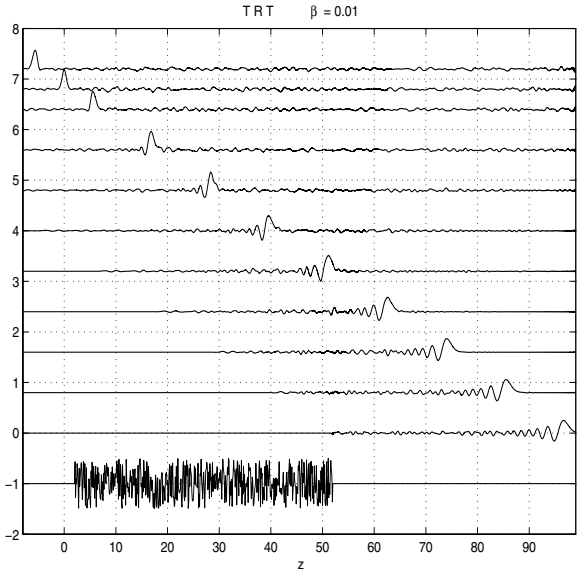

FIG. 7.8. *TRT over a random topography. The fluctuation level is* 50% *and the correlation length is* $\varepsilon = 0.1$. *The realization of the topography used for the simulation is given at the bottom. Just above the topography we have the wave elevation profile used for time reversion. Then time evolves from bottom to top in increments of* 11.52 *time units. The expected refocusing time takes place at half the time increment used and is therefore graphed accordingly.*

Figure 7.7(B) is due to the right-propagating mode in the "amplified" experiment.

We now repeat both TRT experiments in the presence of a random topography expressed through the coefficient $M(z)$. In these experiments both η and u are used in the time reversed data. In Figure 7.8 a realization of the random topography is given at the bottom of the graph, together with the transmitted wave elevation which will be time reversed and sent back into the random medium. Note that to the left of the (transmitted) oscillatory coda we have (small) incoherent radiation. At the correct time the deterministic front, coda, and random radiation recompress to give rise to (a reduced version of) the original waveform, namely a Gaussian. The correct time is exactly the time for the wave to reach the origin ($t = 97.92$). This was the time up to which the time reversed signal was originally recorded. Note, however, that the resolution of the source location is rather poor. The three upper curves in Figure 7.8 show almost the same waveform. This is of course an expected consequence of the hyperbolicity of the equations.

Our final illustration of TRT considers strong dispersive effects. In the previous example we had $\beta = 0.01$. Now we consider a value ten times larger. We now adopt the Gaussian's derivative as the initial wave elevation profile. This function has more energy on higher Fourier modes than the Gaussian. Thus the effect of dispersion will be even more noticeable. In Figure 7.9 we see the topography realization at the very bottom of the figure. Above the topography we find the transmitted wave elevation profile to be used in the time reversal experiment. This profile was recorded after 95.4 time units. The corresponding velocity profile is reversed. From bottom to top, the next three curves correspond to times $t = 91.8, 95.4$ (the expected refocusing time), and 99 time units. Only at time $t = 95.4$ do we have the original initial profile. At neigh-

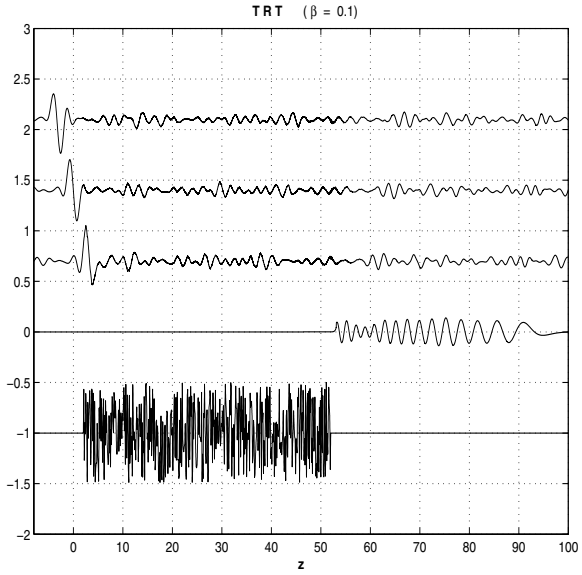

FIG. 7.9. *TRT over a random topography. The dispersion level has been increased* 10 *times* ($\beta = 0.1$). *The trace at the bottom represents the time reversed wave elevation profile. The three following curves (from bottom to top) correspond to times* $t = 91.8$, 95.4 *(the expected refocusing time), and* 99 *time units. The topography's fluctuation level is* 50%, *and the correlation length is* $\varepsilon = 0.1$.

boring times we see the effect of dispersion. At $t = 91.8$ we see that the oscillatory coda (here ahead of the left-propagating pulse) is still being recompressed. At time $t = 99$ the pulse starts developing the usual dispersive coda behind it. The wave source is located at the origin with a much higher accuracy than in the hyperbolic case. The source location is precisely the point between coda recompression and coda generation. Note that from the TR initial profile (at the bottom of Figure 7.9) it is very difficult to predict the source's waveform, while TRT has naturally performed the waveform inversion. We are currently working on the extension of these results and applications to higher dimensions. A good numerical model and bathymetric information can be invaluable tools for performing the time reversed dynamics and waveform inversion.

8. Conclusion. In this paper we have addressed the time reversal for waves governed by a random dispersive Boussinesq system. We have demonstrated that source location by time reversal is more effective in the dispersive case than in the hyperbolic case, because the source location is precisely the point between coda recompression and coda generation. Our analysis also shows that dispersion enhances localization effects in random medium. As a result, time reversal focusing in reflection (resp., in transmission) is more efficient (resp., less efficient) in the dispersive case than in the hyperbolic case, as indicated in Figure 6.1(a). Extension to more general dispersion relations is straightforward. The only but important hypothesis is that the addressed dispersion relation $k(\omega)$ should be an odd function so that it preserves time reversibility. These statements can also be generalized to some extent to three-dimensional configurations. In 3D configurations the pulse refocuses in time and in space [12, 6]. Accordingly, even in absence of dispersion source localization is possible, as it is given

by the point where the refocused wave reaches its climax. However, we conjecture that dispersion improves the resolution of the source location, as the pulse spreading is enhanced when propagating away from the original source location. Furthermore, the spectral phase modulations are larger in the presence of dispersion, so that only close wavenumbers are phase-matched. We can thus expect that dispersion enhances the statistical stability as well as the super-resolution in spatial refocusing described in [3, 6, 23], and in time refocusing as described in this paper.

ANALYSIS OF STRESS-DRIVEN GRAIN BOUNDARY DIFFUSION. PART I*

JON WILKENING†, LEN BORUCKI‡, AND J. A. SETHIAN§

Abstract. The stress-driven grain boundary diffusion problem is a continuum model of mass transport phenomena in microelectronic circuits due to high current densities (electromigration) and gradients in normal stress along grain boundaries. The model involves coupling many different equations and phenomena, and difficulties such as nonlocality, complex geometry, and singularities in the stress tensor have left open such mathematical questions as existence of solutions and compatibility of boundary conditions. In this paper and its companion, we address these issues and establish a firm mathematical foundation for this problem.

We use techniques from semigroup theory to prove that the problem is well posed and that the stress field relaxes to a steady state distribution which, in the nondegenerate case, balances the electromigration force along grain boundaries. Our analysis shows that while the role of electromigration is important, it is the interplay among grain growth, stress generation, and mass transport that is responsible for the diffusive nature of the problem. Electromigration acts as a passive driving force that determines the steady state stress distribution, but it is not responsible for the dynamics that drive the system to steady state.

We also show that stress singularities may develop near grain boundary junctions; however, stress components directly involved in the diffusion process remain finite for all time. Thus, we have identified a mechanism by which large "hidden" stresses may develop that are not directly involved in the diffusion process but may play a role in void nucleation and stress-induced damage.

Key words. grain boundary, diffusion, electromigration, elasticity, semigroups

1. Introduction.

A microelectronic circuit consists of a silicon substrate with doped regions that function as circuit elements (transistors, diodes, resistors, and capacitors), metal lines and vias (interconnects) that connect the circuit elements together, intermetallic dielectric material that keeps the interconnects in place and insulated from each other, various oxide layers and diffusion barriers that are primarily needed in the manufacturing stage to control the doping process and keep the metal from diffusing into the silicon, and passivation to keep all the components in place and protected [28, 33].

A typical interconnect line might be an alloy of Al-0.5%Cu, have dimensions of $0.5 \times 0.5 \times 300$ microns, and carry a current density of 20 $m\text{A}/\mu m^2$. As electrons

flow through the line, they are scattered by imperfections in the crystal lattice of the metal and impart momentum to the ion cores. This "electron wind" force is stronger than the opposing direct force of the electric field, so ions are transported in the same direction as the flow of electrons. This process is known as electromigration; it is a dominant failure mechanism in microelectronic devices.

Grain boundaries, void surfaces, and passivation interfaces are fast diffusion paths along which the diffusion constant typically is seven to eight orders of magnitude higher than in the grains; therefore, most of the mass transport occurs at these locations. The inhomogeneous redistribution of atoms leads to the development of stresses in the line. Stress gradients along grain boundaries and surface tension at void surfaces both contribute to the flux of atoms, usually opposing the electromigration term and increasing the lifetime of the line. Significant residual stresses left over from thermal contraction during the manufacturing process also affect the formation of voids and the transport of atoms.

As microelectronic circuits become smaller and current densities become higher, failure due to electromigration damage becomes an ever increasing problem in the design of circuits. Many theoretical models have been proposed to explain the role of various combinations of electromigration, stress gradients, diffusion, temperature, anisotropy, surface tension, and hillock formation on the mass transport of atoms in the bulk grains, along void surfaces, along grain boundaries, and at passivation interfaces. A useful reference written from the engineering perspective is the review article by Ho and Kwok [14]; see also [27]. The concept of the electron wind force was formulated by Fiks [9] and by Huntington and Grone [15]. In his experimental work in the 1970s, Blech [2] studied the behavior of thin films of aluminum and titanium-nickel when large currents were passed through them and demonstrated the existence of a threshold current density below which no damage occurs, which varies inversely with the stripe length. Shortly thereafter, Blech and Herring [3] offered the explanation that stress gradients were developing along grain boundaries in the sample to counter the electron wind force, but they could be sustained only up to a critical threshold. Once this threshold was reached, there was no physical mechanism to stop the transport of material, and the stripe eroded at one end and formed hillocks at the other.

Recent models of these phenomena were described by Mullins [21], Cocks and Gill [6], Korhonen et al. [18], Sarychev et al. [25], and Kirchheim [17]. The Mullins paper presents a nice overview of mass transport along surfaces and grain boundaries and discusses cobble creep and grain boundary grooving. The paper by Cocks and Gill gives a variational approach to the dynamics of grain boundary motion associated with decreasing grain boundary area; they did not include stress in their model. The papers [25] and [17] deal primarily with electromigration, stress-driven diffusion, and vacancy generation in the grains, while [18] focuses on electromigration and grain boundary diffusion. The latter three papers use a statistical argument about the orientation of the grain boundaries in order to model the stress as a scalar variable instead of a tensor; one should keep in mind, however, that for any particular sample, the grain boundaries have a specific geometry, and singularities can occur in the stress field that are ignored with this simplifying assumption.

Bower, Craft, Fridline, and collaborators use an advancing front algorithm to generate a sequence of adaptive, evolving finite element meshes to study grain growth, void evolution, hillock formation, and grain boundary sliding for possibly anisotropic materials responding to stress, surface tension, thermal expansion, and electromi-

gration; see, e.g., [4, 10]. They use interesting semi-implicit techniques to overcome timestep limitations due to the stiffness of the equations, and they use Lagrange multipliers to determine the normal stress along grain boundaries.

An alternative approach based on the theory described in this paper is presented in [30, 26], where a new singularity capturing the least squares finite element method is developed to study the effect of singularities in the stress field on the grain boundary diffusion process. Further references to the literature on numerical methods for grain growth and void evolution may be found there.

Mathematical analysis of the partial differential equations involved is largely absent in the electromigration literature. There are several reasons for this. First, there is no universal agreement in the electromigration community on exactly how all the phenomena fit together, especially at junctions where grain boundaries meet voids or other grain boundaries, and the process of void nucleation is far from understood. Second, the problem is very complicated, with many different (stiff) phenomena coupled together in a nonlocal, nonlinear way. Growth rates depend on taking derivatives of stress components along grain boundaries and curvatures along surfaces. Boundary conditions specify the gradient of the normal stress at junctions where the stress field is singular. Many of the equations couple the displacement field to the stress field, and it is difficult to visualize how this constrains the evolution of the system. Both displacement and flux boundary conditions are specified at junctions where grain boundaries meet the outer walls; in simpler problems such as the heat equation, this would overspecify the boundary conditions. As a result of these and similar difficulties, one typically has a long list of equations reflecting various principles such as mass conservation and chemical potential continuity that one would like to use as a model. But occasionally, incomplete physical reasoning can lead to mathematically ill-posed problems; therefore, it is important to develop a rigorous justification for the collection of equations to ensure a self-consistent model.

The goal of this paper is to provide a mathematical framework in which we can analyze a modest subset of the phenomena mentioned above. We assume there are no voids in the structure, and we work within the framework of linear elasticity (small strain and small grain growth). This may be thought of as the linearization of a nonlinear grain boundary migration theory. Most of the difficult problems mentioned above persist in this setting. The equations are nonlocal and couple together many different stiff phenomena that relate rates of change of displacement jumps to spatial derivatives of the normal stress. The boundary conditions specify the gradient of the normal stress at locations where the stress tensor becomes singular. And the geometry of the problem involves the complicated branching structure of a grain boundary network which does not have a natural ordering or orientation of its segments. The same approach is taken in [30].

In section 2, we exhibit the equations in dimensionless form and briefly describe the physical considerations that lead to these equations. Our main contribution here is to model the net grain growth along the grain boundary Γ as the jump in a normal component of the displacement across Γ, thinking of it as a scalar function g defined on Γ. This is identical to what Bower and Craft did in [4], except that they viewed each side of the grain boundary as a moving interface (in parallel with their treatment of void surfaces) and did not single out g as important. They derived an equation for the change Δg (denoted Δu_n in their paper) in a timestep but used it only to update the displacements $\mathbf{u}$ on each side of the grain boundary. The advantage of treating g as a time evolving *function* defined on the grain boundary (which is

fixed in the reference configuration) is that we are able to recast the problem as an ordinary differential equation on a Hilbert space and to apply techniques of semigroup theory to prove the equations are well posed. The difficulties due to nonlocality, the existence of singularities, and the complicated nature of the boundary conditions are all absorbed into two unbounded operators L and S, which turn out to possess many nice properties, such as self-adjointness, discrete spectra, and positivity (or negativity). An overview of this procedure is given in section 3, and full details are presented in section 6.

In section 4, we define the grain boundary normal stress problem and the operator S, which is a type of Dirichlet-to-Neumann map that maps the displacement jump g across Γ to the normal stress $\eta = \mathbf{n} \cdot \sigma \mathbf{n}$ on Γ. We state the important properties of S (which are proved in the companion paper [31]) and identify a new class of grain boundaries, which we call *degenerate*. Throughout this paper, we assume the grain boundary network is nondegenerate in order to simplify the presentation. The degenerate case is dealt with in [31].

In section 5, we analyze the operator L $(= -\frac{\partial^2}{\partial s^2})$ on the grain boundary network. The most important properties of this operator are that it is positive and self-adjoint, its domain $\mathcal{D}(L)$ consists only of functions that satisfy continuity and flux boundary conditions (useful for proving that the normal stress η has these properties), and the domain of $L^{\frac{1}{2}}$ is precisely $H^1(\Gamma)$ (useful in specifying the Hilbert space in which η evolves). The boundary conditions of chemical potential continuity and flux balance at junctions turn out to be exactly what are needed for these results to hold.

In section 6, we show that the equation governing the evolution of normal stress (namely, $\eta_t = SL\eta$) generates an analytic semigroup $\{E_t : t \geq 0\}$ of bounded linear operators on $H^1(\Gamma)$. The primary difficulties that arise have to do with the fact that L (and in the degenerate case, S) has a nontrivial finite dimensional kernel which must be dealt with using projections. We also discuss the role of electromigration as a passive driving force, the enforcement of boundary conditions, and the development of stress singularities near corners and grain boundary junctions.

Finally, in the Appendix, we study an infinite interconnect line with a single grain boundary running through its center, which provides insight into the nature of the diffusion process without the complication of boundary conditions and singularities.

2. Problem statement. In this section, we describe a two dimensional continuum model of electromigration and stress-driven grain boundary diffusion in the linear regime of small strain, small grain growth elasticity. The reference configuration (including the location of the grain boundary in the reference configuration) remains fixed, while the stress and displacement fields defined on this domain evolve in time.

A grain is a region where the atoms are aligned in a regular lattice. A grain boundary is an interface between two grains where the lattice structure becomes disorganized as the lattice alignment changes from one side to the other. In our (continuum) model, we ignore details of lattice alignment and assume all grain boundaries have equivalent properties.

The grain boundaries are assumed to be fast diffusion paths along which atoms are transported much more easily than in the bulk grains. At each point on the grain boundary, we have a flux J of atoms traveling along the grain boundary. J has units of surface flux ($\mathrm{cm}^{-1}\mathrm{s}^{-1}$), where we consider our two dimensional domain to have a thickness δ in the third dimension. If a portion of the grain boundary has more atoms flowing into it than out, the atoms incorporate themselves into the lattice of the adjacent grains and cause the grains to move apart to make room for the new

atoms. At the same time there will be a net flux of atoms out of other regions of the grain boundary, where atoms are removed from the lattice of each grain and the grains move together so as not to leave a gap.

Although our analysis of this problem does not rely on the grain boundaries being straight, we have omitted curvature-driven grain boundary motion from our model. For this reason, we assume that the grain boundaries are initially straight and that as grain growth occurs, the appropriate fraction of atoms attaches to each side of the grain boundary so that Γ remains fixed in the spatial (stressed) configuration. We adopt an Eulerian viewpoint where the reference configuration on which the stress and displacement fields are defined is the spatial configuration, and the natural (unstressed) shape of each grain changes in time as material is added to (or removed from) its boundary. For a given deformation φ mapping the natural state to the stressed state, the displacement is defined as $\mathbf{u}(x) = x - \varphi^{-1}(x)$ instead of $\varphi(x) - x$. The linearized equations of elasticity [20, 5] are the same in the material and Eulerian viewpoints.

We assume the interconnect line consists of several disjoint bounded polygonal grains Ω_k, and we denote their union (an open set) by $\Omega = \bigcup_k \Omega_k$. $\overline{\Omega}$ is assumed to be connected; see Figure 2.1. We denote the outer boundary (the "walls") of the domain by $\Gamma_0 = \partial(\overline{\Omega})$ and the grain boundary network by $\Gamma = (\partial\Omega \setminus \Gamma_0)^-$. Γ consists of N closed line segments $\Gamma = \bigcup_{j=1}^{N} \Gamma_j$. Each segment is given an arbitrary orientation (a unit tangent vector $\mathbf{t}_j$) and an arclength parameter s which increases in the $\mathbf{t}_j$ direction. The unit normal $\mathbf{n}_j$ points from right to left facing along $\mathbf{t}_j$. We do not impose the Young condition, requiring that grain boundaries meet at 120° angles, since it is not required for well posedness unless curvature is included as a driving force.

The net grain growth g is defined on Γ as the jump in normal component of displacement across the grain boundary:

$$g(x) := [\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{n}_j \qquad (x \in \Gamma_j). \tag{2.1}$$

It represents the distance the original grains have separated to accommodate the new material that occupies that space; see Figure 2.2. In the Eulerian picture, $g(x) = [\varphi^{-1}(x^-) - \varphi^{-1}(x^+)] \cdot \mathbf{n}$ is the amount that opposite sides of the grain boundary at x would overlap if the grains were allowed to pass through each other to achieve their stress-free shapes. This overlap corresponds to new material added during the diffusion process.

In Figure 2.3, we list the equations and boundary conditions in nondimensional form. We choose an arbitrary length scale L ($\sim 1\mu$m) and define the timescale $t_0 = \frac{kTL^3}{\nu_b D_b \Omega_a^2 \mu}$, where k is the Boltzmann constant, T is temperature, D_b is the diffusion constant for grain boundary surface diffusion at temperature T, ν_b is the number of participating atoms per unit area, Ω_a is the volume of an atom in the atomic lattice, and μ is the shear modulus. See [21] for typical values of these parameters. We then define the dimensionless variables

$$\tilde{x} = \frac{x}{L}, \quad \tilde{t} = \frac{t}{t_0}, \quad \tilde{\mathbf{u}} = \frac{\mathbf{u}}{L}, \quad \tilde{\sigma} = \frac{\sigma}{\mu}, \quad \tilde{\psi} = \frac{|Z^*|e}{\Omega_a \mu}\psi, \quad \tilde{J} = \frac{\Omega_a t_0}{L^2} J, \quad \text{etc.}, \tag{2.2}$$

and rewrite the equations (see [4, 30]) in terms of these variables (dropping the tildes). Z^*e is a phenomenological effective charge for an ion in the lattice; $e = |e|$ is the elementary electric charge; and for a good conductor [21, 29], $Z^* \approx -5$. This means the electron wind force is stronger than the opposing direct force of the electric field.

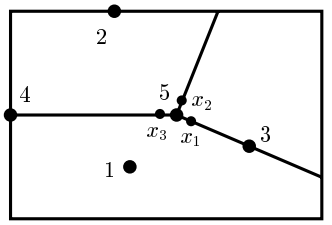
5a. $g(x_1)\mathbf{n}_1 + g(x_2)\mathbf{n}_2 + g(x_3)\mathbf{n}_3 = 0$
5b. $\eta(x_1) = \eta(x_2) = \eta(x_3)$
5c. $\partial_{s_1}(\eta + \psi) + \partial_{s_2}(\eta + \psi) + \partial_{s_3}(\eta + \psi) = 0$



Initial Condition: $g \equiv 0$

FIG. 2.3. *Summary of equations and boundary conditions. Segments are assumed (in this figure only) to be parameterized away from the triple junction to avoid minus signs.*

The electric potential ψ is found by solving the Laplace equation under the assumption that the grain boundaries do not significantly affect the flow of current in the line. The displacement field $\mathbf{u}$ is found by solving the Lamé equations of linearized elasticity (assuming plane strain). The stress tensor satisfies Hooke's law,

$$\sigma = 2\mu\epsilon + \lambda \operatorname{tr}(\epsilon) I, \tag{2.3}$$

where λ and μ are the Lamé coefficients, $\epsilon_{ij} = \frac{1}{2}(\partial_i u_j + \partial_j u_i)$ are the components of the strain tensor, and $\operatorname{tr}(\cdot)$ is the trace operator; see [20, 5].

Referring to Figure 2.3, 2a enforces the requirement that the displacement is zero at the outer walls (passivation). In 3a, we assume that the grains do not slide tangentially relative to each other, and we define the displacement jump g. In 3b, we enforce the local balance of forces (tractions) across the grain boundary, which together with the no-sliding assumption implies that all components of the stress tensor are continuous across grain boundaries. In 3c, we define the normal stress η on the grain boundary, which is well defined by 3b.

Equation 3d in Figure 2.3 is the main evolution equation, which gives the grain growth rate in terms of the normal stress and the electrostatic potential. This equation is a consequence of the continuity equation, the Einstein–Nernst equation, the Blech–Herring model of the chemical potential of an atom in a grain boundary of a stressed solid [3, 30], and electromigration:

$$\partial_t g + \Omega_a \partial_s J = 0 \qquad \text{(continuity equation)}, \tag{2.4}$$

$$J = -\tfrac{\nu_b D_b}{kT} \partial_s \mu_b \qquad \text{(Einstein–Nernst, } \mu_b = \text{chemical potential)}, \tag{2.5}$$

$$\mu_b = \mu_0 - \Omega_a \sigma_{nn} \qquad \text{(Blech–Herring, } \mu_0 = \text{const)}, \tag{2.6}$$

$$\partial_s \mu_b \to \partial_s \mu_b + Z^* e\, \partial_s \psi \qquad \text{(electron wind force, } Z^* e < 0), \tag{2.7}$$

$$J = \tfrac{\nu_b D_b}{kT} (\Omega_a \partial_s \sigma_{nn} + |Z^* e|\, \partial_s \psi) \quad \text{(flux before nondimensionalizing)}. \tag{2.8}$$

Note that qualitatively, atoms are transported from regions of compression to regions of tension and travel against the electric field $\mathbf{E} = -\nabla\psi$ in the same direction that electrons flow. Here, $\partial_s \psi$ is the derivative of $\psi\big|_\Gamma$ with respect to arc length, so $-\partial_s \psi = \mathbf{E} \cdot \mathbf{t}$ is the component of the electric field along the grain boundary.

Equation 4a in Figure 2.3 follows from 2a and 3a but is worth recording as a boundary condition on g. Equation 4b enforces zero flux at gb-wall junctions: atoms are not allowed to flow in or out of the network where the grain boundary meets passivation, so global mass conservation should hold. Equation 5a is a compatibility requirement following from 3a: if we start in one grain and follow the jump in displacement around a triple junction, we have to end up with the original displacement when we return. (The point x_i here is infinitesimally close to the triple junction on segment i.) Finally, equations 5b and 5c enforce chemical potential continuity and flux balance at triple junctions, respectively.

3. Strategy. Thus far, each equation represents either a definition (of g or η) or some physical requirement such as chemical potential continuity or mass conservation. The next task is to find a way to organize them so that mathematical questions such as well posedness can be addressed. One major challenge is to identify the role played by singularities in the stress field near junctions and to understand the sense in which 4b, 5b, and 5c of Figure 2.3 can be expected to hold in light of these singularities. Another goal is to find a way to untangle the equations and boundary conditions in order to handle the nonlocal nature of expressions relating the displacement jump g

to the normal stress η; placing local constraints on one imposes (rather awkward) global constraints on the other via the Lamé equations. It is not immediately obvious that the evolution 3d is compatible with conditions 4a–5c.

Our approach is to recast the problem as an ordinary differential equation on a Hilbert space, writing the equation in terms of the normal stress η and absorbing all the boundary conditions into the operators. In this way we take advantage of linearity and gain insight into the role played by each of the boundary conditions in the well posedness of the problem.

3.1. A type of Dirichlet-to-Neumann map. Equations 1a–3c in Figure 2.3 can be thought of as providing a mapping between the jump in displacement g and the normal stress η. If we are given one (in some appropriate space), the other can be determined by solving the elasticity equations. There is a duality between g and η embodied in the energy relation

$$E = -\frac{1}{2}\int_\Gamma \eta g \, ds, \tag{3.1}$$

relating the elastic energy stored in the grains to the work done at the grain boundaries to accommodate the accumulation or depletion of atoms there. See the companion paper [31] for further details.

We denote the operator that maps a given grain growth function g on Γ to the corresponding normal stress η by

$$S : \mathcal{D}(S) \to L^2(\Gamma) : g \mapsto \eta \qquad \text{(grain growth to normal stress map)}. \tag{3.2}$$

Although S is unbounded, it turns out to be self-adjoint and negative (essentially due to (3.1)), and its domain is dense in $L^2(\Gamma)$. Moreover, S has a compact pseudoinverse B such that SB is the identity (nondegenerate case) or differs from the identity by a finite rank projection (degenerate case). These properties are discussed in section 4 and proved in [31].

3.2. The second derivative operator. We define the operator $L : \mathcal{D}(L) \to L^2(\Gamma)$ to be the negative of the second derivative operator with respect to arc length on each grain boundary segment. If η is twice continuously differentiable on each Γ_j and satisfies certain boundary conditions at the junctions, then $\eta \in \mathcal{D}(L)$ and the restriction of $L\eta$ to the interior of Γ_j is given by

$$L\eta(x) = -\frac{\partial^2 \eta}{\partial s^2} \qquad (x \in \Gamma_j^o). \tag{3.3}$$

In section 5 we will show that boundary conditions 4b, 5b, and 5c from Figure 2.3 enforcing mass conservation and chemical potential continuity are exactly what are needed for some of the most useful properties of L on the unit interval to carry over to the more complicated branching structure of a grain boundary network. In particular, L is self-adjoint, positive, and densely defined, and its kernel is finite dimensional. Moreover, if $L^{\frac{1}{2}}$ is modified by a finite rank projection to remove its kernel, it becomes an isomorphism from $H^1(\Gamma)$ onto $L^2(\Gamma)$, which is important in our proof of well posedness.

3.3. An ordinary differential equation on a Hilbert space. The evolution of the jump in displacement g is governed by equation 3d of Figure 2.3, namely,

$$g_t = -\partial_s^2(\eta + \psi) = L(Sg + \psi). \tag{3.4}$$

Applying S to (3.4), we obtain

$$\eta_t = SL(\eta + \psi). \tag{3.5}$$

The term ψ is acting as a passive driving force in (3.4) and (3.5). In general, if the equation

$$\frac{dx}{dt} = Ax, \qquad x(0) = x_0, \tag{3.6}$$

generates a strongly continuous semigroup $\{E_t : t \geq 0\}$ of bounded linear operators on a Banach space X [13, 32, 16, 1], then for $f \in X$ the solution to the equation

$$\dot{x} = A(x + f), \qquad x(0) = x_0, \tag{3.7}$$

is given by

$$x(t) = E_t(x_0 + f) - f \qquad (t \geq 0). \tag{3.8}$$

In section 6, we will show that the equation

$$\eta_t = SL\eta, \qquad \eta(x, t = 0) = \eta_0(x), \tag{3.9}$$

generates such a semigroup in $H^1(\Gamma)$, so the evolution of the normal stress η with initial condition η_0 (usually taken to be zero) is given by

$$\eta(t) = E_t(\eta_0 + \psi) - \psi. \tag{3.10}$$

In the nondegenerate case, the evolution of g may be obtained directly from that of η via $g(t) = B\eta(t)$, but in the degenerate case this is not so. In both cases, the normal stress η evolves to a steady state stress distribution, but in the degenerate case the displacement jump g can grow linearly without bound along certain growth modes which are not suppressed by the stress-driven diffusion mechanism. The picture is suggestive of continental drift in plate tectonics, but the underlying physical mechanism is entirely different; see [31].

4. The grain boundary normal stress problem. In this section we describe the interface boundary conditions that are imposed when solving the Lamé equations, introduce the notion of degeneracy of a grain boundary network, and define the operators S and B. Rigorous proofs of the key properties of S and B are presented in the companion paper [31].

DEFINITION 4.1 (grain boundary normal stress). *Given a function $\eta \in L^2(\Gamma)$, find the displacement field $\mathbf{u} \in H^1(\Omega)^2$ satisfying $\mu\Delta\mathbf{u} + (\lambda + \mu)\nabla(\nabla \cdot \mathbf{u}) = 0$ in the interior of each grain subject to the boundary conditions*

$$\mathbf{u}(x) = \mathbf{0} \qquad (x \in \Gamma_0), \tag{4.1}$$

$$[\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{t}_j = 0 \qquad (x \in \Gamma_j), \tag{4.2}$$

$$[\sigma(x^+) - \sigma(x^-)]\mathbf{n}_j = \mathbf{0} \qquad (x \in \Gamma_j), \tag{4.3}$$

$$\mathbf{n}_j \cdot \sigma(x)\mathbf{n}_j = \eta(x) \qquad (x \in \Gamma_j). \tag{4.4}$$

Here $H^1(\Omega)$ denotes the set $\{w \in L^2(\Omega) : w|_{\Omega_k} \in H^1(\Omega_k)\}$, so the jump in normal component of displacement $[\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{n}_j$ is permitted to be nonzero for $x \in \Gamma_j$.

To make sense of the boundary condition (4.4) for a general $\eta \in L^2(\Gamma)$, a suitable notion of weak solution must be defined. This is done in [31], where it is shown that for certain "degenerate" grain boundary networks, additional compatibility conditions must be satisfied by η for a solution $\mathbf{u}$ to exist, and when it does exist, it is not unique. This situation may be characterized as follows.

DEFINITION 4.2. *A grain boundary network is said to be* degenerate *if there exists a nonzero displacement field* $\mathbf{u}$ *consisting of infinitesimal rigid body motions*

$$u_1\big|_{\Omega_k} = a_k - c_k y, \quad u_2\big|_{\Omega_k} = b_k + c_k x \quad (a_k, b_k, c_k \text{ constants}) \tag{4.5}$$

such that the boundary conditions (4.1)–(4.4) *hold with* $\eta \equiv 0$. *The jump in normal component of displacement across grain boundaries is permitted to be nonzero.*

In other words, degeneracy occurs when stress-free infinitesimal rigid body motions exist (grain by grain) that are zero at the outer walls and satisfy a no-sliding condition across grain boundaries. An algorithm for finding the degeneracies of any grain boundary network is presented in [31], where it is shown that degeneracy is a consequence of pathologies such as junction angles greater than 180° or a large number of quadruple (or higher) order junctions. In this paper we explicitly assume the grain boundary network is nondegenerate, leaving the general case to [31]. This substantially simplifies our proof of well posedness while retaining the key ideas.

DEFINITION 4.3. *When the grain boundary network is nondegenerate, the normal stress to grain growth operator* $B : L^2(\Gamma) \to L^2(\Gamma) : \eta \mapsto g$ *is defined via*

$$(B\eta)(x) = [\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{n}_j \qquad (x \in \Gamma_j), \tag{4.6}$$

where $\mathbf{u}$ *is the (unique) solution to the grain boundary normal stress problem corresponding to* η.

Remark 4.4. As discussed in Figure 2.2, this definition is independent of the orientation chosen for each segment Γ_j.

DEFINITION 4.5. *When the grain boundary network is nondegenerate, the operator* $S : \mathcal{D}(S) \to L^2(\Gamma) : g \mapsto \eta$ *is defined as the inverse of* B. *In other words,* $\mathcal{D}(S) := \text{range}(B)$ *and for* $y \in \mathcal{D}(S)$, Sy *is the unique* x *such that* $Bx = y$.

THEOREM 4.6. B *is self-adjoint, negative, and compact.* S *is self-adjoint, negative, closed, and densely defined. In the nondegenerate case considered here,* B *is also injective and has dense range.*

Proof. See [31] for the proof. ∎

Remark 4.7. The domain $\mathcal{D}(S)$ is quite complicated due to the variety of ways self-similar solutions of the Lamé equations can behave near grain boundary junctions; see [26, 30]. In particular, even for smooth functions η that are continuous at junctions, $g = B\eta$ generally will be discontinuous at junctions and exhibit infinite slopes. As a result, it would be very difficult to define S directly by setting up a boundary value problem specifying g along Γ such that the resulting normal stress η is always meaningful in the trace sense. By defining S as we have, we can derive its properties by studying the compact operator B, which is well defined for all $\eta \in L^2(\Gamma)$. Moreover, this approach allows us to explain how it is possible to impose boundary conditions involving the normal stress at junctions where the stress tensor develops singularities: the components directly involved in the diffusion process remain finite and well behaved for all time (and satisfy the boundary conditions) while other components of the stress tensor blow up; see section 6.4.

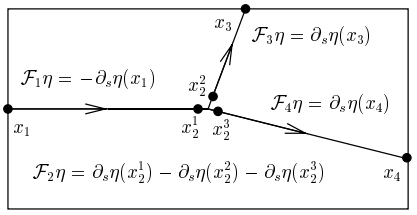


FIG. 5.1. *The flux $\mathcal{F}_i\eta$ into junction i is a sum over incident segments j of slopes $\pm\partial_s\eta$.*

5. The Poisson equation on the grain boundary network. In this section we show that the operator L is self-adjoint and positive, that there is a compact pseudoinverse G for L such that $I - LG$ is a finite rank projection onto $\ker(L)$ in $L^2(\Gamma)$, and that $A^{\frac{1}{2}} := (L + I - LG)^{\frac{1}{2}}$ is an isomorphism from $H^1(\Gamma)$ onto $L^2(\Gamma)$. We also characterize $\mathcal{D}(L)$ and $\mathcal{D}(L^{\frac{1}{2}})$ and identify the kernel of L as the set of functions that are constant on each connected component of Γ. Although these facts are well known in the case of the Neumann problem on the unit interval, several nonobvious tricks must be used to prove them for a network, and notation must be introduced that can cleanly handle the lack of a natural ordering and orientation for the grain boundary segments. In particular, we point out that not every function on a network with loops has a continuous antiderivative (unless its integral around each loop is zero).

5.1. Boundary conditions. As discussed in section 3.2, the operator L is the negative of the second derivative operator with respect to arc length on each grain boundary segment. If η is twice continuously differentiable on each segment and satisfies the boundary conditions

$$\begin{array}{ll} 1. & \eta \text{ is continuous at } x_i \\ 2. & \mathcal{F}_i\eta = 0 \end{array} \qquad (i \text{ any junction label}), \tag{5.1}$$

then the restriction of $L\eta$ to the interior of Γ_j is given by

$$L\eta(x) = -\frac{\partial^2\eta}{\partial s^2} \qquad (x \in \Gamma_j^o). \tag{5.2}$$

Here $\mathcal{F}_i$ is a flux operator for junction i, defined by

$$\mathcal{F}_i\eta = (-1)^{k_i}\partial_s\eta(x_i) \qquad (x_i \text{ a gb-wall junction}), \tag{5.3}$$

$$\mathcal{F}_i\eta = \sum_{j=1}^{p_i}(-1)^{k_i^j}\partial_s\eta(x_i^j) \quad (x_i \text{ a gb junction of order } p_i), \tag{5.4}$$

where x_i^j is infinitesimally close to junction x_i on segment j and k_i^j is 0 or 1 depending on whether segment j is parameterized toward or away from x_i; see Figure 5.1. At junctions where a grain boundary meets an outer wall, only the second condition in (5.1) is imposed since the first condition is automatic.

5.2. Integration by parts on the network. Let $C(\Gamma)$ denote the space of continuous functions on Γ, and let $\widetilde{C}(\Gamma)$ denote the space of functions f continuous on the interiors of the Γ_j with well-defined limits $f(x_i^j)$ at the endpoints x_i of Γ_j but with possibly different limiting values at x_i when approached from different segments.

Differentiation is defined segment by segment, where we recall that each segment is given an arbitrary orientation along which the arc length parameter increases. We define

$$\widetilde{C}^r(\Gamma) = \{f : f^{(k)} \in \widetilde{C}(\Gamma),\ 0 \le k \le r\}. \tag{5.5}$$

For $f \in \widetilde{C}(\Gamma)$, we write

$$\left[f\right]_\Gamma = \sum_j \left[f(x^j_{i_1(j)}) - f(x^j_{i_0(j)})\right], \tag{5.6}$$

where $i_0(j)$ and $i_1(j)$ are the junction indices of the initial and final endpoints of segment j. We note that although both sides of (5.7) and (5.8) depend on the orientation chosen for each segment, the identities

$$\left[f'g\right]_\Gamma = \sum_i g(x_i)\mathcal{F}_i f \qquad \left(f \in \widetilde{C}^1(\Gamma)\ g \in C(\Gamma)\right) \tag{5.7}$$

and

$$\int_\Gamma f'g\,ds = \left[fg\right]_\Gamma - \int_\Gamma g'f\,ds \qquad \left(f, g \in \widetilde{C}^1(\Gamma)\right) \tag{5.8}$$

are valid for any particular choice. It follows that

$$(Lu, v) = (u, Lv) \qquad \left(u, v \in \widetilde{C}^2(\Gamma) \text{ and satisfy (5.1)}\right) \tag{5.9}$$

holds independently of the orientations chosen for each segment; i.e., the boundary value problem $Lu = \lambda u$ subject to the boundary conditions (5.1) is self-adjoint.

5.3. Construction of a Green's function. In this section we construct a Green's function $G_l(x, y)$ for the operator $L + l^2$, where l is any positive real number. Since L has a nontrivial kernel, there is no Green's function when $l = 0$. We begin by defining an auxiliary function

$$K_l(x, y) = \begin{cases} 0, & x, y \text{ on different segments,} \\ k_l(a_j, s_j(x), s_j(y)), & x, y \in \Gamma_j, \end{cases} \tag{5.10}$$

where $a_j = |\Gamma_j|$ is the length of Γ_j, $s_j(x) = |x - x_{i_0(j)}|$ is the value of the arc length parameter along Γ_j at x, and $k_l(a, x, y)$ is the Green's function for $-\partial_x^2 + l^2$ on the interval $(0, a)$ with Dirichlet boundary conditions; see Figure 5.2. For $(0 \le x \le y \le a)$, we have

$$k_l(a, x, y) = k_l(a, y, x) = \left(\cosh ly \frac{\sinh la}{l} - \cosh la \frac{\sinh ly}{l}\right) \frac{\sinh lx}{\sinh la}. \tag{5.11}$$

To get G_l from K_l, we have to fix the flux boundary conditions at each junction. Let n be the number of junctions, and define the linear operator $T_l : \mathbb{R}^n \to \mathbb{R}^n$ as follows. For $w \in \mathbb{R}^n$, let $u_{l,w}$ be the unique function in $C(\Gamma)$ which satisfies

$$u_{l,w}(x_i) = w_i, \quad \partial_s^2 u_{l,w} = l^2 u_{l,w}. \tag{5.12}$$

Explicitly, on segment Γ_j, we set

$$u_{l,w}(x) = w_{i_0(j)} \cosh ls_j(x) + \left[w_{i_1(j)} - w_{i_0(j)} \cosh la_j\right] \frac{\sinh ls_j(x)}{\sinh la_j}. \tag{5.13}$$

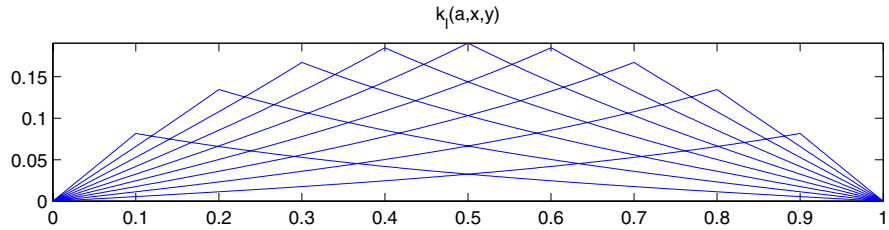

FIG. 5.2. *The function $k_l(a,x,y)$ satisfies $-\partial_x^2 k_l = l^2 k_l$ on $(0,y)$ and (y,a), is zero at $x=0$ and $x=a$, and has a unit (negative) jump in slope at $x=y$. In this plot, $a=1$, $l=2$, and $y=0.1,\dots,0.9$. Note that $\lim_{y\to 0}\frac{\partial}{\partial x}\big|_{x=0} k_l(a,x,y)=1$ with a similar result as $y\to 1$.*

Now we define the ith component of $T_l w$ to be the flux of $u_{l,w}$ into junction i:

$$(T_l w)_i = \mathcal{F}_i u_{l,w}. \tag{5.14}$$

Thus T_l converts values at junctions into fluxes at junctions of the solution to (5.12).

We next show that T_l is invertible. Suppose that $T_l w = 0$, i.e., that $\mathcal{F}_i u_{l,w} = 0$ at each junction. We wish to conclude that $u_{l,w} \equiv 0$, so we proceed by contradiction. Multiplying by (-1) if necessary, we assume the maximum value of $u_{l,w}$ is positive. The maximum cannot occur in the interior of a segment or at a gb-wall junction because the slope would be zero at such a maximum, while (5.12) would require that the second derivative be positive. It also cannot occur at a triple junction because the sum of the outward slopes is zero at such a junction: if any is positive it is not a maximum, and if each is zero we use (5.12) again. Thus we reach a contradiction and conclude that T_l is invertible.

To correct the flux boundary conditions of K_l to obtain G_l, we define $w_l(y) \in \mathbb{R}^n$ to give the values at the junctions of the solution to $\partial_x^2 u = l^2 u$ with the same junction fluxes as $K(\cdot,y)$:

$$w_l(y) = T_l^{-1}\left(\{\mathcal{F}_i K(\cdot,y)\}_{i=1}^n\right) \qquad (y \text{ not an endpoint}). \tag{5.15}$$

Note that $\mathcal{F}_i K(\cdot,y)$ is nonzero only when y is on a segment incident to junction i, and by (5.11), as y approaches junction i we have

$$\lim_{y\to x_i}\left(\{\mathcal{F}_k K(\cdot,y)\}_{k=1}^n\right) = -e_i \in \mathbb{R}^n. \tag{5.16}$$

We define $G_l(x,y)$ by

$$G_l(x,y) = \begin{cases} K(x,y) - u_{l,w_l(y)}(x), & y \text{ not an endpoint}, \\ u_{l,T_l^{-1}(e_i)}(x), & y = x_i. \end{cases} \tag{5.17}$$

By (5.16), $G_l(x,y)$ is continuous on $\Gamma\times\Gamma$, and by construction, for fixed y in the interior of some segment, $G_l(x,y)$ as a function of x satisfies the boundary conditions (5.1). It is readily verified using the corresponding property of $k_l(a,x,y)$ that the operator

$$\mathcal{G}_l f(x) = \int_\Gamma G_l(x,y) f(y)\, dy \tag{5.18}$$

is the inverse of $L + l^2$ in the sense that for all $f \in C(\Gamma)$ and all $u \in \widetilde{C}^2(\Gamma) \cap C(\Gamma)$ satisfying (5.1),

$$(L + l^2)\mathcal{G}_l f = f, \qquad \mathcal{G}_l(L + l^2)u = u. \tag{5.19}$$

$\mathcal{G}_l$ is self-adjoint since L is self-adjoint, and as a result, $G_l(x, y) = G_l(y, x)$ for all $x, y \in \Gamma$.

THEOREM 5.1. *There exists an orthonormal basis $\{\varphi_n\}_{n=1}^{\infty}$ for $L^2(\Gamma)$ and an increasing sequence of nonnegative numbers λ_n growing without bound such that*

$$\varphi_n \in \widetilde{C}^{\infty}(\Gamma) \cap C(\Gamma), \tag{5.20}$$

$$\mathcal{F}_i \varphi_n = 0 \qquad (i \text{ any junction label}), \tag{5.21}$$

$$L\varphi_n = \lambda_n^2 \varphi_n. \tag{5.22}$$

The domain of L satisfies

$$\{f \in \widetilde{C}^2(\Gamma) : f \text{ satisfies (5.1)}\} \subset \mathcal{D}(L) \subset \{f \in \widetilde{C}^1(\Gamma) : f \text{ satisfies (5.1)}\}. \tag{5.23}$$

Proof. In the standard way [7, 8], we can show that $\mathcal{G}_l$ is a self-adjoint, compact operator on $L^2(\Gamma)$; thus $\mathcal{G}_l$ has a complete orthonormal set $\{\varphi_n\}_{n=1}^{\infty}$ of eigenfunctions with eigenvalues converging to zero. It is also readily shown that for all $f \in L^1(\Gamma) \supset L^2(\Gamma)$,

$$\mathcal{G}_l f \in \{\eta \in \widetilde{C}^1(\Gamma) \,:\, \eta \text{ satisfies the boundary conditions (5.1)}\}; \tag{5.24}$$

hence the eigenfunctions are continuous and satisfy flux boundary conditions. Differentiating (5.18), it follows that if $f \in \widetilde{C}^r(\Gamma)$, then $\mathcal{G}_l f \in \widetilde{C}^{r+2}(\Gamma)$; thus the eigenfunctions belong to $\widetilde{C}^{\infty}(\Gamma)$ by a bootstrap argument. By (5.19), they are eigenfunctions of $L + l^2$ with reciprocal eigenvalues. Since $L + l^2$ is invertible for $l > 0$, we conclude that the eigenvalues of L form an unbounded sequence of nonnegative numbers $\{\lambda_n^2\}$. Finally, (5.23) holds when we *redefine* L to be $\mathcal{G}_l^{-1} - l^2$. Then $\mathcal{D}(L) = \operatorname{ran}(\mathcal{G}_l)$, so the first inclusion follows from (5.19) and the second from (5.24). ∎

5.4. The kernel of *L*. The segments Γ_j of the grain boundary network can be grouped together into connected components as sets in $\mathbb{R}^2$. We decompose the numbers $1, \dots, N$ into a collection $\mathcal{J}$ of disjoint sets such that each $J \in \mathcal{J}$ is the set of indices of the segments Γ_j that belong to component $\Gamma_J = \cup_{j \in J} \Gamma_j$. We number these subsets arbitrarily $\mathcal{J} = \{J_1, \dots, J_d\}$ and define the functions $e_k \in L^2(\Gamma)$ for $1 \le k \le d$ by

$$e_k(x) = \begin{cases} |\Gamma_{J_k}|^{-\frac{1}{2}}, & x \in \Gamma_{J_k}, \\ 0 & \text{otherwise.} \end{cases} \tag{5.25}$$

Here $|\Gamma_{J_k}| = \sum_{j \in J_k} |\Gamma_j|$ is the sum of the lengths of the segments making up component k. Note that each e_k is continuous at all junctions since all segments that meet at a junction belong to the same connected component.

PROPOSITION 5.2. *The functions $\{e_k\}_{k=1}^{d}$ form a basis for* $\ker(L)$.

Proof. Theorem 5.1 ensures that $\ker(L)$ is finite dimensional and is spanned by functions $\{\varphi_1, \dots, \varphi_{d'}\}$ satisfying (5.20)–(5.22) with $\lambda_n = 0$. Since each e_k also satisfies these conditions, we have $d' \ge d$, and it remains to show that any $\varphi \in \ker(L)$ is constant on each connected component. Suppose not. Then there is a segment Γ_{j*}

on which φ is not constant. Since $L\varphi = 0$, φ is linear on each segment. Starting with Γ_{j^*}, there is a path to an outer wall along which φ strictly increases. This is because φ satisfies (5.21), so if φ increases along a segment as we approach a triple junction, it must also increase along one of the other segments as we leave the junction. Since φ strictly increases along the path, no interior node can be revisited, and eventually the path reaches a wall with a positive slope, which contradicts (5.21). ∎

5.5. An isomorphism. In this section we show that $L^{\frac{1}{2}}$ becomes an isomorphism from $H^1(\Gamma)$ onto $L^2(\Gamma)$ if we modify it slightly to eliminate its kernel. It will be useful to define the operators

$$P = I - \sum_{n=1}^{d} (\cdot, \varphi_n)\varphi_n, \qquad A = L + \sum_{n=1}^{d} (\cdot, \varphi_n)\varphi_n. \tag{5.26}$$

Note that P is the orthogonal projection onto the subspace

$$\operatorname{ran}(L) = \ker(L)^{\perp} = \left\{ f \in L^2(\Gamma) \,:\, \int_{\Gamma_{J_k}} f\, ds = 0,\ 1 \le k \le d \right\} \tag{5.27}$$

and $L = AP = PA$. A and P are self-adjoint since the φ_n are orthogonal.

THEOREM 5.3. *For any absolutely continuous f such that $f' \in L^2(\Gamma)$, if we write $f = \sum a_n \varphi_n$, then*

$$\|f\|^2 = \sum_{n=1}^{\infty} |a_n|^2, \qquad \|f'\|^2 = \sum_{n=1}^{\infty} |a_n \lambda_n|^2. \tag{5.28}$$

There is a constant C such that

$$\|f\|_{L^2} \le \|A^{-\frac{1}{2}} f\|_{H^1} \le C \|f\|_{L^2} \qquad \big(f \in L^2(\Gamma)\big); \tag{5.29}$$

i.e., $A^{-\frac{1}{2}}$ is an isomorphism from $L^2(\Gamma)$ onto $H^1(\Gamma)$ and is therefore compact as an operator on $L^2(\Gamma)$. The domain of $L^{\frac{1}{2}}$ is $H^1(\Gamma)$, which requires continuity but imposes no constraints on the derivatives at junctions.

Proof. On each segment, we have

$$\varphi_n(x) = c_{n,j} \cos(\lambda_n s_j(x) - \theta_{n,j}) \qquad (x \in \Gamma_j). \tag{5.30}$$

We define

$$\psi_n = \lambda_n^{-1} \varphi_n' \qquad (n > d). \tag{5.31}$$

Note that ψ_n is *not* continuous on Γ but is zero at gb-wall junctions and satisfies appropriate jump conditions at triple junctions so that

$$\big[\psi_n g\big]_{\Gamma} = 0 \qquad (g \in C(\Gamma)). \tag{5.32}$$

We claim that $\{\psi_n\}_{n>d}$ is an orthonormal basis for the subset of functions $f \in L^2$ such that f is the derivative of an absolutely continuous function in $C(\Gamma)$. This subset will not be all of L^2 as soon as there are loops in the grain boundary network, since the integral around a loop must be zero for a continuous antiderivative to exist. By (5.8), we have the orthogonality condition

$$\int_{\Gamma} \psi_n \psi_m = \lambda_n^{-1} \left(\big[\varphi_n \psi_m\big]_{\Gamma} - \int_{\Gamma} \psi_m' \varphi_n \right) = \int_{\Gamma} \varphi_m \varphi_n = \delta_{mn}. \tag{5.33}$$

To prove completeness, suppose $W \in C(\Gamma)$ is absolutely continuous and $w = W'$ belongs to L^2. Suppose further that for all $n > d$, we have

$$\int_\Gamma w\psi_n = 0. \tag{5.34}$$

We must show that $w \equiv 0$. Integrating by parts, we obtain

$$\int_\Gamma w\psi_n = \big[W\psi_n\big]_\Gamma - \int_\Gamma \psi_n' W = \lambda_n \int_\Gamma W\varphi_n = 0 \qquad (n > d). \tag{5.35}$$

Since $\{\varphi_n\}_{n=1}^\infty$ is a basis, we conclude that W is a linear combination of $\varphi_1, \dots, \varphi_d$. Thus W is a constant on each connected component of Γ and $w = W' = 0$, as desired.

For any $f \in L^2$, we may expand $f = \sum_{n=1}^\infty a_n\varphi_n$ and apply the Parseval identity to conclude that $\|f\|^2 = \sum |a_n|^2$. If f is absolutely continuous and its derivative is in L^2, then we have $f' = \sum_{n>d} b_n\psi_n$ with

$$b_n = \int_\Gamma f'\psi_n = \big[f\psi_n\big]_\Gamma - \int_\Gamma f\psi_n' = \lambda_n \int_\Gamma f\varphi_n = \lambda_n a_n. \tag{5.36}$$

Since $\lambda_n = 0$ for $n \le d$, the Parseval identity gives the result $\|f'\|^2 = \sum_1^\infty |\lambda_n a_n|^2$. Therefore we have

$$\begin{aligned} \|f\|_{H^1}^2 &= \|f\|_{L^2}^2 + \|f'\|_{L^2}^2 = \sum_{n=1}^\infty (1+\lambda_n^2)|a_n|^2, \\ \|A^{\frac12} f\|_{L^2}^2 &= \sum_{n=1}^d |a_n|^2 + \sum_{n=d+1}^\infty \lambda_n^2 |a_n|^2. \end{aligned} \tag{5.37}$$

As a result, we obtain

$$\|A^{\frac12} f\|_{L^2} \le \|f\|_{H^1} \le C\|A^{\frac12} f\|_{L^2} \qquad \big(f \in H^1(\Gamma)\big), \tag{5.38}$$

with $C = \lambda_*^{-1}\sqrt{1+\lambda_*^2}$, where $\lambda_* = \lambda_{d+1}$ is the smallest nonzero eigenvalue of $L^{\frac12}$. ∎

DEFINITION 5.4. *The operator G is defined via*

$$G = A^{-1} - \sum_{n=1}^d (\cdot, \varphi_n)\varphi_n. \tag{5.39}$$

G is the pseudoinverse of L in the sense that they have the same kernel and eigenfunctions with reciprocal (or zero) eigenvalues. The properties of A imply that G is self-adjoint and compact on $L^2(\Gamma)$ and satisfies $G = PA^{-1} = A^{-1}P$ and $LG = P$.

6. Dynamics. In this section we show that if the grain boundary network is nondegenerate, then the equation

$$\eta_t = SL\eta, \qquad \eta(0) = \eta_0, \tag{6.1}$$

generates an analytic semigroup $\{E_t : t \ge 0\}$ of bounded linear operators on $H^1(\Gamma)$. See [31] for the degenerate case and the books [13, 32, 16, 1] for background information on semigroup theory. As mentioned in section 3.3, the solution $\eta(t)$ when the electromigration force is present is given by

$$\eta(t) = E_t(\eta_0 + \psi) - \psi. \tag{6.2}$$

The boundary conditions on η enforcing chemical potential continuity and flux balance at junctions hold as a consequence of the analyticity of E_t and the properties of the domain $\mathcal{D}(SL)$. The role of singularities in the stress field near corners and junctions is also discussed.

6.1. The semigroup generated by SL. In this section we show that there is a Riesz basis (a basis equivalent to an orthonormal basis [11]) for $H^1(\Gamma)$ consisting of eigenfunctions of SL. This allows us to exhibit the semigroup operator E_t explicitly, study its properties, and approximate it numerically [30, 26]. Throughout this section, we assume the grain boundary network is nondegenerate so that B is injective and $SB = I$ on $L^2(\Gamma)$.

LEMMA 6.1. *Let us denote* $\ker(L) = \operatorname{span}\{e_k\}_{k=1}^d$ *by* $\{e\}$. *Then*

$$\ker(SL) = \{e\}, \qquad \operatorname{ran}(SL) = \{Be\}^\perp. \tag{6.3}$$

Proof. SL is densely defined in $L^2(\Gamma)$ since $\mathcal{D}(S)$ is dense, A^{-1} is bounded with dense range, and $\mathcal{D}(SL) = A^{-1}\mathcal{D}(S)$. Clearly $\{e\} \subset \ker(SL)$. Since S is injective on its domain, if $Lx \in \mathcal{D}(S)$ is nonzero, so is SLx. Thus $\ker(SL) = \{e\}$ as claimed. Suppose $y = SLx$. Then $By = Lx$ belongs to $\operatorname{ran}(L) = \{e\}^\perp$, so $(y, Be) = 0$ for all $e \in \ker(L)$, as claimed. ∎

LEMMA 6.2. *The (nonorthogonal) projection on* $L^2(\Gamma)$ *given by*

$$Q \text{ projects along } \{e\} \text{ onto } \{Be\}^\perp \tag{6.4}$$

is well defined.

Proof. Since B is injective, $\{e\}$ and $\{Be\}$ have the same dimension. We must show that $\{e\} \cap \{Be\}^\perp = \{0\}$. Suppose $x \in \{e\} \cap \{Be\}^\perp$. Then $(x, Bx) = 0$, which implies $x = 0$ since B is self-adjoint and negative definite. ∎

Remark 6.3. Q may be written explicitly as $I - (\cdot, w_k)e_k$ (summation implied), where $w_k = (Be_j)\alpha_{jk}$ and $(e_i, Be_j)\alpha_{jk} = \delta_{ik}$. Since the L^2 inner product $(\cdot, w_k)$ is a bounded linear functional on $H^1(\Gamma)$ and $e_k \in H^1(\Gamma)$, Q is also a well-defined projection on $H^1(\Gamma)$. By contrast, the L^2 adjoint $Q^* = I - (\cdot, e_k)w_k$ is generally not defined on $H^1(\Gamma)$ due to the possibility of singularities in the arc length derivative of w_k near junctions.

LEMMA 6.4. *The following diagram is commutative in the sense that for each block* $X \underset{g}{\overset{f}{\rightleftarrows}} Y$ *we have* $f \circ g = id_Y$ *and* $g \circ f = id_{\mathcal{D}(f)}$:

$$\{Be\}^\perp \underset{Q}{\overset{P}{\rightleftarrows}} \{e\}^\perp \underset{G}{\overset{L}{\rightleftarrows}} \{e\}^\perp \underset{B}{\overset{S}{\rightleftarrows}} \{Be\}^\perp . \tag{6.5}$$

Proof. P and Q both project along $\{e\}$, so $PQ = P$ and $QP = Q$. Since $\operatorname{ran}(P) = \{e\}^\perp$ and $\operatorname{ran}(Q) = \{Be\}^\perp$, the block involving P and Q is commutative. Since LG is the identity on $\{e\}^\perp$ and GL is the identity on $\mathcal{D}(L) \cap \{e\}^\perp = \operatorname{ran}(G)$, the block involving L and G is commutative. If $(x, Be) = 0$, then $(Bx, e) = 0$, so B maps $\{Be\}^\perp$ to $\{e\}^\perp$. Since SB is the identity on $L^2(\Gamma)$ and BS is the identity on $\mathcal{D}(S) = \operatorname{ran}(B)$, the block involving S and B is commutative. ∎

THEOREM 6.5. *There is a Riesz basis* $\{\phi_k\}$ *for* $H^1(\Gamma)$ *and a nonincreasing, unbounded sequence of numbers* $\lambda_k \le 0$ *such that* $SL\phi_k = \lambda_k\phi_k$.

Proof. The operator $K = G^{\frac{1}{2}}Q^*BQG^{\frac{1}{2}}$ is compact and self-adjoint, so there is an orthonormal basis $\{\varphi_k\}$ for $L^2(\Gamma)$ such that $K\varphi_k = \mu_k\varphi_k$, ($\mu_k \in \mathbb{R}$, $\mu_k \to 0$). Note

that $\mu_k = (\varphi_k, K\varphi_k) = (QG^{\frac{1}{2}}\varphi_k, BQG^{\frac{1}{2}}\varphi_k) \le 0$, with equality iff $QG^{\frac{1}{2}}\varphi_k = 0$. Note that $\ker(QG^{\frac{1}{2}}) = \ker(G^{\frac{1}{2}}) = \{e\}$ since $\ker(Q) = \{e\}$ and $\operatorname{ran}(G^{\frac{1}{2}}) \subset \{e\}^\perp$. We may therefore assume $\mu_1, \dots, \mu_d = 0$, and the remaining μ_k form an increasing sequence of negative numbers converging to zero. Note that

$$QGQ^*B(QG^{\frac{1}{2}}\varphi_k) = \mu_k(QG^{\frac{1}{2}}\varphi_k). \tag{6.6}$$

From the above remarks, we know $QG^{\frac{1}{2}}\varphi_k$ is nonzero for $k > d$. We define

$$\phi_k = \left\{ \begin{array}{ll} \varphi_k, & k = 1, \dots, d \\ QG^{\frac{1}{2}}\varphi_k, & k > d \end{array} \right\}, \quad \lambda_k = \left\{ \begin{array}{ll} 0, & k = 1, \dots, d \\ \mu_k^{-1}, & k > d \end{array} \right\}. \tag{6.7}$$

From the definition of Q, it follows that $Q^*B = BQ$, so $QGBQ\phi_k = \mu_k\phi_k$. If $k \le d$, then $SL\phi_k = 0$ since $\phi_k \in \{e\}$. Otherwise, $Q\phi_k = \phi_k$ and Lemma 6.4 gives $SL\phi_k = SL(\mu_k^{-1}QGB\phi_k) = \lambda_k\phi_k$. It is readily verified that for $k \ge 1$,

$$\phi_k = \left[(I - P) + QG^{\frac{1}{2}}\right]\varphi_k, \qquad \varphi_k = \left[(I - Q) + L^{\frac{1}{2}}\right]\phi_k. \tag{6.8}$$

Since $[I - P + QG^{\frac{1}{2}}]$ is bounded from $L^2(\Gamma)$ to $H^1(\Gamma)$ and its inverse $[I - Q + L^{\frac{1}{2}}]$ is bounded in the other direction, they are isomorphisms. Thus the ϕ_k form a Riesz basis for $H^1(\Gamma)$ as claimed. ∎

THEOREM 6.6. *The initial value problem $\eta_t = SL\eta$, $\eta(0) = \eta_0$ generates an analytic semigroup $\{E_t : t \ge 0\}$ of bounded linear operators on $H^1(\Gamma)$.*

Proof. Since the ϕ_k form a Riesz basis, the mapping from $H^1(\Gamma)$ to l^2 giving the coefficients of the expansion $\eta_0 = \sum_k a_k\phi_k$ is an isomorphism, and there is a constant C independent of η_0 such that $C^{-2}\|\eta_0\|_{H^1}^2 \le \sum_{k=1}^\infty |a_k|^2 \le C^2\|\eta_0\|_{H^1}^2$. These coefficients may be determined via

$$a_k = ([I - Q + L^{\frac{1}{2}}]\eta_0, \varphi_k) = (\eta_0, \phi_k^*), \qquad \phi_k^* = [I - Q^* + L^{\frac{1}{2}}]\varphi_k, \tag{6.9}$$

where $(\cdot, \cdot)$ is the $L^2(\Gamma)$ inner product. For $\eta_0 \in H^1(\Gamma)$ we define

$$E_t\eta_0 = \textstyle\sum_k a_k e^{\lambda_k t}\phi_k, \qquad a_k = (\eta_0, \phi_k^*). \tag{6.10}$$

E_t is bounded for any $t \ge 0$ since $\lambda_k \le 0$ for all k, and hence $\|E_t\eta_0\|_{H^1} \le C^2\|\eta_0\|_{H^1}$. E_0 is clearly the identity on $H^1(\Gamma)$, and $E_{t+s} = E_tE_s$ since $(\phi_j, \phi_k^*) = \delta_{jk}$. For fixed η_0, the mapping $t \mapsto E_t\eta_0$ is continuous for $t \ge 0$ since

$$\|E_t\eta_0 - E_s\eta_0\|_{H^1} \le C\left(\sum_{k=1}^N |a_k(e^{\lambda_k t} - e^{\lambda_k s})|^2 + \sum_{k=N+1}^\infty |a_k|^2\right)^{\frac{1}{2}} \tag{6.11}$$

may be made arbitrarily small by choosing N large enough to make the second term small and then s close enough to t to make the first term small. Note that for any fixed $t > 0$ and $\eta_0 \in H^1(\Gamma)$ we have

$$\left\|\frac{E_{t+h}\eta_0 - E_t\eta_0}{h} - SLE_t\eta_0\right\|_{H^1} \le C\left(\sup_{k\ge1}\left|t^{-1}f_1(\lambda_k t)f_2(\lambda_k h)\right|\right)\left(\sum_{k=1}^\infty |a_k|^2\right)^{\frac{1}{2}}, \tag{6.12}$$

where $f_1(z) = ze^z$ and $f_2(z) = \frac{1}{z}(e^z - 1) - 1$. The supremum may be made arbitrarily small by taking h sufficiently close to zero since f_1 and f_2 are bounded on

the negative real axis, $\lim_{z\to-\infty} f_1(z) = 0$, and $\lim_{z\to 0} f_2(z) = 0$. Thus we see that SL is the generator of $\{E_t : t \geq 0\}$. To show that this semigroup is analytic, we need only check that $\limsup_{t\downarrow 0} t\|SLE_t\| < \infty$, which follows from $t\|SLE_t\eta_0\|_{H^1} \leq C\left(\sup_k |f_1(\lambda_k t)|\right)\left(\sum_1^\infty |a_k|^2\right)^{1/2} \leq C^2 e^{-1}\|\eta_0\|_{H^1}$. ∎

Remark 6.7. Equation (6.10) leads to a useful numerical method in which ϕ_k, ϕ_k^*, and λ_k are computed by approximating $QGBQ$ (which has the same eigenfunctions as SL with reciprocal or zero eigenvalues) using a singularity capturing least squares finite element method; see [30, 26].

Remark 6.8. Since E_t is an operator on $H^1(\Gamma)$ and the formula for the evolution of normal stress is given by

$$\eta(t) = E_t(\eta_0 + \psi) - \psi, \tag{6.13}$$

we should verify that ψ belongs to $H^1(\Gamma)$. Since ψ is the solution to the Laplace equation on a domain with corners, it is smooth in the interior of Ω with singularities of the form

$$r^\lambda \phi(\theta) \qquad (\lambda = \pi/\omega \geq 1/2) \tag{6.14}$$

near reentrant corners of opening angle $\omega \leq 2\pi$ [12, 19]. As a result, the restriction of ψ to Γ is continuous on Γ, differentiable in the interior of each Γ_j, and its derivative with respect to arc length cannot diverge at the endpoints faster than $s^{(\lambda_{\min}-1)}$. (It will diverge at all only if the grain boundary terminates at a reentrant corner of the domain.) If we assume that Ω has no cracks with $\omega = 2\pi$ or, if it has cracks, that the crack tips do not lie on grain boundaries, then $\lambda_{\min} > \frac{1}{2}$ and $\psi \in H^1(\Gamma)$ as claimed.

6.2. The steady state stress distribution. Since $\lambda_1 = \cdots = \lambda_d = 0$, E_t leaves $\{e\} = \ker(SL)$ invariant. Since $\lambda_k \leq \lambda_{d+1} < 0$ for $k > d$, E_t takes any vector in $\{Be\}^\perp = \mathrm{ran}(SL)$ to zero as $t \to \infty$. More precisely, one may show [31] that $\lim_{t\to\infty} E_t = I - Q$ in norm. Thus

$$\eta_{\text{steady}} = \lim_{t\to\infty} \eta(t) = (I - Q)(\eta_0 + \psi) - \psi. \tag{6.15}$$

As a result, in the nondegenerate case there are constants c_j such that

$$\eta_{\text{steady}} = -\psi + c_j e_j \qquad \text{(summation implied)}. \tag{6.16}$$

We also observe that $(\eta_{\text{steady}} - \eta_0) = -Q(\eta_0 + \psi) \in \{Be\}^\perp$, so

$$(\eta_{\text{steady}} - \eta_0, Be_k) = 0 \qquad (1 \leq k \leq d). \tag{6.17}$$

Since B is self-adjoint, this implies $(g_{\text{steady}} - g_0, e_k) = 0$, which is a statement of mass conservation on each connected component of Γ. Using (6.16) and (6.17), we have

$$c_j(e_j, Be_k) = (\eta_0 + \psi, Be_k) \qquad (1 \leq k \leq d), \tag{6.18}$$

which determines the c_j uniquely due to the fact that the $d\times d$ matrix with components (e_j, Be_k) is invertible. Note that the steady state flux $\partial_s(\eta_{\text{steady}}+\psi)$ is zero; this ceases to be true in the degenerate case [31], where (6.16) has additional nonconstant terms.

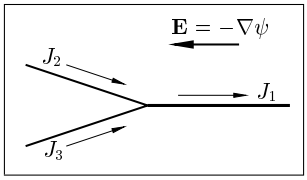

FIG. 6.1. *The electric field can lead to a flux imbalance at a triple (or wall) junction which must be immediately compensated by stress gradients to satisfy mass conservation. As a result, ψ generally will not lie in $\mathcal{D}(L)$ although $\eta(t) + \psi \in \mathcal{D}(L)$ when $t > 0$.*

6.3. Boundary conditions. ψ does not necessarily satisfy zero flux boundary conditions at junctions, and therefore, although $\psi \in \mathcal{D}(L^{1/2})$, it is not necessarily in $\mathcal{D}(L)$; see Figure 6.1. On the other hand, because E_t is analytic, we have range$(E_t) \subset \mathcal{D}(SL)$ for all $t > 0$. Therefore $\eta(t)$ in (6.13) has the property that

$$\eta(t) + \psi \in \mathcal{D}(L) \qquad (t > 0). \tag{6.19}$$

This implies chemical potential continuity and flux balance at all junctions for $t > 0$ (conditions 4b, 5b, and 5c in Figure 2.3). The grain growth function g may be obtained from η via $g(t) = B\eta(t)$, which automatically satisfies the compatibility conditions 4a and 5a of Figure 2.3 by virtue of the definition of B in (4.6). We have therefore proved that the grain boundary diffusion problem is well posed.

6.4. Stress singularities at junctions. It is well known that solutions to elliptic systems (such as the Lamé equations) on domains with corners and interface junctions exhibit singularities at these junctions. In the current case, as the normal stress η evolves on the grain boundary network, the stress and displacement fields in the bulk grains evolve as the solution to the grain boundary normal stress problem with η specified on Γ; see Definition 4.1. The general theory [30, 19, 24] states that the singular part of the solution may be written as a sum of power solutions (each component of the form $r^\lambda \phi(\theta)$ in local polar coordinates) to the *homogeneous* boundary value problem. As a result, the singular part of the solution near a given junction satisfies boundary conditions (4.1)–(4.4) with $\eta \equiv 0$ along the grain boundaries entering the junction. Although a different linear combination of stress components will generally diverge as the junction is approached along Γ, $\mathbf{n} \cdot \sigma\mathbf{n}$ will remain finite and well behaved, and all boundary conditions in Figure 2.3 describe quantities that remain finite despite the singularities. The corresponding displacement jump g will also remain finite, although it will generally exhibit infinite slopes and discontinuities (compatible with the boundary conditions) at junctions.

We have therefore demonstrated a mechanism through which stress components directly involved in the mass transport process remain bounded and well behaved while other "hidden" stress components grow very large and develop singularities; these components may be responsible for void nucleation and stress-induced damage but are omitted from commonly used scalar stress-generation models. In [30, 26], the first several terms in the asymptotic expansion for $\mathbf{u}$ and σ are computed a priori and added to the finite element basis to improve accuracy without mesh refinement. These singular functions often are very complicated, with singularity exponents clustered together in the complex plane.

Appendix. Infinite interconnect line.

In this section, we work out an exact solution to the stress-driven grain boundary diffusion problem $g_t = -\eta_{xx}$ for an infinite interconnect line with a single grain

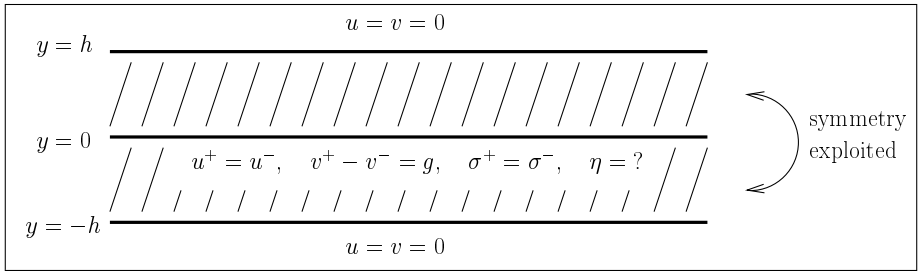

FIG. A.1. *The geometry and boundary conditions for the infinite strip.*

boundary running through the center. This provides useful insight about the nature of the diffusion process without the complication of boundary conditions at junctions or singularities in the stress field. The approach is to solve the elastic equations for a sinusoidal grain growth g and then use separation of variables and the Fourier transform to determine the evolution for an arbitrary initial condition.

A.1. Elastic equations for sinusoidal grain growth. Suppose the grain boundary coincides with the x-axis, and let h denote the width of each grain, as shown in Figure A.1. If we let $u = u_1$, $v = u_2$ and define κ, α, β, γ, and τ by

$$\kappa = \frac{\lambda + 3\mu}{\lambda + \mu}, \qquad \sigma = \mu \begin{pmatrix} \alpha - \gamma & \tau \\ \tau & \alpha + \gamma \end{pmatrix}, \qquad \beta = \frac{2}{\kappa + 1}(v_x - u_y), \tag{A.1}$$

then complex variable methods in plane elasticity [22, 30] can be used to guarantee the existence of holomorphic ϕ and ψ (known as Muskhelishvili functions) such that

$$\begin{aligned} \alpha + i\beta &= 2\phi', \\ \gamma + i\tau &= \bar{z}\phi'' + \psi', \\ u + iv &= \frac{1}{2}\left(\kappa\phi - z\bar{\phi}' - \bar{\psi}\right). \end{aligned} \tag{A.2}$$

By symmetry, for any displacement jump $g(x)$ the variables in the top grain will be related to the variables in the bottom grain via

$$u^+(x,y) = u^-(x,-y), \qquad v^+(x,y) = -v^-(x,-y), \tag{A.3}$$

$$\alpha^+(x,y) = \alpha^-(x,-y), \qquad \beta^+(x,y) = -\beta^-(x,-y), \tag{A.4}$$

$$\gamma^+(x,y) = \gamma^-(x,-y), \qquad \tau^+(x,y) = -\tau^-(x,-y). \tag{A.5}$$

Thus it is sufficient to restrict attention to the top grain. At $y = h$, we impose Dirichlet boundary conditions $u = v = 0$. Along the grain boundary, the four conditions $u^+ = u^-$, $v^+ - v^- = g$, $\alpha^+ + \gamma^+ = \alpha^- + \gamma^-$, $\tau^+ = \tau^-$ reduce to

$$\tau = 0, \qquad v = \frac{g}{2} \qquad \text{(boundary conditions along grain boundary)}. \tag{A.6}$$

We observe that in the limit as $h \to \infty$, these boundary conditions coincide with the problem of a rigid stamp without friction on a half-space and can be solved using singular integrals [23]. We omit details since the result for finite h covers this case in the limit.

For finite h, the singular integral approach does not work (at least not easily), so instead we take g of the form

$$g(x) = c_1 \cos \omega x + c_2 \sin \omega x \tag{A.7}$$

and make an ansatz for the form of the Muskhelishvili functions:

$$\phi = (a_1 + ia_2)\cos \omega z + (a_3 + ia_4)\sin \omega z, \tag{A.8}$$

$$\psi = (a_5 + ia_6)\cos \omega z + (a_7 + ia_8)\sin \omega z + (a_9 + ia_{10})z\cos \omega z + (a_{11} + ia_{12})z \sin \omega z. \tag{A.9}$$

We wish to determine if there are real coefficients a_i for which the boundary conditions are satisfied. We begin by constructing the 4×12 real matrix $A_0(\omega, \kappa, h, x)$ whose ith column contains the boundary conditions $u(y = h)$, $v(y = h)$, $v(y = 0)$, $\tau(y = 0)$ for the ϕ and ψ corresponding to a_i. For example, the second column corresponds to $\phi = i \cos \omega z$, $\psi = 0$:

$$\operatorname{col}_2(A_0) = \frac{1}{2}\begin{pmatrix} \omega h \sin \omega x \cosh \omega h - \omega x \cos \omega x \sinh \omega h + \kappa \sin \omega x \sinh \omega h \\ -\omega h \cos \omega x \sinh \omega h - \omega x \sin \omega x \cosh \omega h + \kappa \cos \omega x \cosh \omega h \\ -\omega x \sin \omega x + \kappa \cos \omega x \\ -2\omega^2 x \cos \omega x \end{pmatrix}. \tag{A.10}$$

Next we define the 16×12 real matrix $A(\omega, \kappa, h)$ by expanding each row of A_0 into four rows containing the coefficients of $\cos(\omega x)$, $\sin(\omega x)$, $x\cos(\omega x)$, $x\sin(\omega x)$. To satisfy the boundary conditions (A.6), we need to find $a \in R^{12}$ such that $Aa = b$, where b contains the desired coefficients of the terms $\cos(\omega x)$, $\sin(\omega x)$, $x\cos(\omega x)$, $x\sin(\omega x)$ in the boundary conditions. Explicitly, b and the second column of A are given by

$$b = \frac{1}{2}\begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ c_1 \\ c_2 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \qquad \operatorname{col}_2(A) = \frac{1}{2}\begin{pmatrix} 0 \\ \omega h \cosh \omega h + \kappa \sinh \omega h \\ -\omega \sinh \omega h \\ 0 \\ -\omega h \sinh \omega h + \kappa \cosh \omega h \\ 0 \\ 0 \\ -\omega \cosh \omega h \\ \kappa \\ 0 \\ 0 \\ -\omega \\ 0 \\ 0 \\ -2\omega^2 \\ 0 \end{pmatrix}. \tag{A.11}$$

We verify that a solution exists by computing the nullspace of A^T symbolically and checking that $b \in (\ker A^T)^\perp = \text{image } A$. We then select 12 linearly independent rows of A (and the corresponding rows of b) and solve $Aa = b$ symbolically. The resulting a determines ϕ and ψ, which we use to compute $\eta = \sigma_{22} = \alpha + \gamma$ along the grain boundary. This has to be done only once since the parameters such as κ and h appear

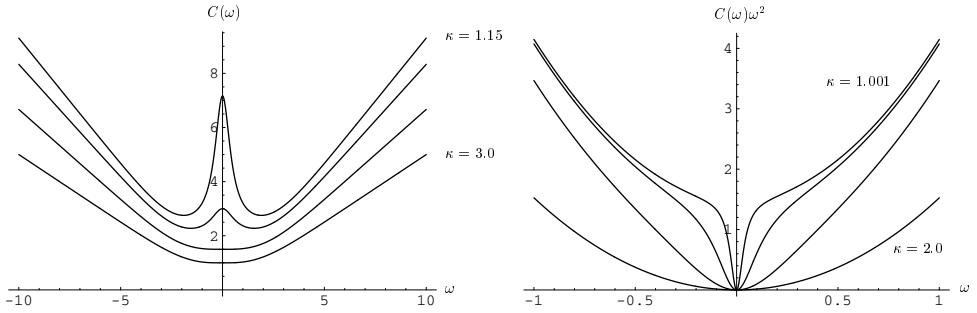

FIG. A.2. *Left: plot of $C(\omega)$ for $h = 1$ and $\kappa = 1.15, 1.4, 2.0, 3.0$. Right: plot of the dissipation rate $C(\omega)\omega^2$ for $h = 1$ and $\kappa = 1.001, 1.01, 1.1, 2.0$. Note that $C(\omega)$ diverges in the incompressible ($\kappa \to 1$), long wavelength ($\omega \to 0$) limit and that although $C(\omega)$ is not monotonic for $\kappa < 2$, $C(\omega)\omega^2$ is monotonic for $\omega \geq 0$. The envelope of the graphs of $C(\omega)\omega^2$ is $\frac{3}{2} + \frac{27}{10}\omega^2$ near the origin as $\kappa \to 1$.*

symbolically. All of this, including the construction of A_0 and A via (A.2), (A.8), and (A.9), can be done without difficulty using Mathematica or Maple.

The result of this computation is that along the grain boundary, η is a constant multiple of g for any c_1, c_2, ω:

$$\eta(x) = -C(\omega)g(x), \qquad C(\omega) = \frac{\omega[1 + \kappa^2 + 4h^2\omega^2 + 2\kappa\cosh 2h\omega]}{(1+\kappa)[\kappa \sinh 2h\omega - 2h\omega]}. \tag{A.12}$$

A plot of $C(\omega)$ for a few values of κ is given in Figure A.2. For large and small ω, we see that $C(\omega)$ has the asymptotic form

$$C(\omega) = \frac{2\omega}{1+\kappa} \qquad (|h\omega| \gg 1), \tag{A.13}$$

$$C(\omega) = \frac{1}{h}\left\{\frac{\kappa+1}{2(\kappa-1)} - \frac{(\kappa-2)(\kappa-3)}{3(\kappa-1)^2}(h\omega)^2 + \cdots\right\} \qquad (|h\omega| \ll 1). \tag{A.14}$$

A.2. Evolution for an arbitrary initial condition. The fact that $\eta(x) = -C(\omega)g(x)$ when g varies harmonically allows us to use the Fourier transform to solve the grain boundary diffusion problem for an arbitrary initial condition $g(x, t = 0)$. Note that the solution to $g_t = -\eta_{xx}$ with $g(x, t = 0) = \cos\omega x$ is given by

$$g(x,t) = e^{-C(\omega)\omega^2 t}\cos\omega x. \tag{A.15}$$

This gives the time evolution of each Fourier mode. If we write g at $t = 0$ as

$$g(x,0) = \int_{-\infty}^{\infty} e^{i\omega x}\hat{g}(\omega,0)\,d\omega, \tag{A.16}$$

then at any later time g will be

$$g(x,t) = \int_{-\infty}^{\infty} e^{i\omega x}\hat{g}(\omega,t)\,d\omega = \int_{-\infty}^{\infty} e^{i\omega x}e^{-C(\omega)\omega^2 t}\hat{g}(\omega,0)\,d\omega. \tag{A.17}$$

It is instructive to compare the dissipation rate $C(\omega)\omega^2$ to that for the heat equation and the linearized surface diffusion equation:

Dissipation Rate	Equation
$b\omega^2$	$u_t = bu_{xx} \quad (b > 0)$
$C(\omega)\omega^2$	$g_t = -\eta_{xx}$
$b\omega^4$	$u_t = -bu_{xxxx} \quad (b > 0)$

From Figure A.2 and (A.12)–(A.14), we see that low-frequency modes decay like the heat equation with $b = (\kappa+1)[2h(\kappa-1)]^{-1}$, whereas high-frequency modes decay as $\exp(-b|\omega|^3)$ with $b = 2(1+\kappa)^{-1}$, which is halfway between the heat equation and the linearized surface diffusion equation.

ANALYSIS OF STRESS-DRIVEN GRAIN BOUNDARY DIFFUSION. PART II: DEGENERACY*

JON WILKENING†, LEN BORUCKI‡, AND J. A. SETHIAN§

Abstract. The stress-driven grain boundary diffusion problem is a continuum model of mass transport phenomena in microelectronic circuits due to high current densities (electromigration) and gradients in normal stress along grain boundaries. The model involves coupling many different equations and phenomena, and difficulties such as nonlocality, complex geometry, and singularities in the stress tensor have left open such mathematical questions as existence of solutions and compatibility of boundary conditions. In this paper and its companion, we address these issues and establish a firm mathematical foundation for this problem.

We study the properties of a type of Dirichlet-to-Neumann map that involves solving the Lamé equations with interesting interface boundary conditions. We identify a new class of degenerate grain boundary networks that lead to unsuppressed linear growth modes that are suggestive of continental drift in plate tectonics. We use techniques from semigroup theory to prove that the problem is well posed and that the stress field relaxes to a steady state distribution which may or may not completely balance the electromigration force. In the latter (degenerate) case, the displacements continue to grow without bound along stress-free modes.

Key words. grain boundary, diffusion, electromigration, elasticity, semigroups

1. Introduction.

Electromigration is a diffusion process in which high current densities act as a driving force to transport ions in a metallic lattice in the direction of electron flow by transferring momentum through scattering [10]. As microelectronic circuits become smaller and current densities become higher, failure due to electromigration damage in interconnect lines becomes an everincreasing problem in the design of circuits. Grain boundaries, void surfaces, and passivation interfaces are fast diffusion paths along which the diffusion constant typically is seven to eight orders of magnitude higher than in the grains; therefore, most of the mass transport occurs at these locations. The inhomogeneous redistribution of atoms leads to the development of stresses in the line. Stress gradients along grain boundaries and surface tension at void surfaces both contribute to the flux of atoms, usually suppressing electromigration and increasing the lifetime of the line.

Many experimental, theoretical, and numerical studies have been done to investigate the role of various combinations of electromigration, stress gradients, surface

diffusion, temperature, and anisotropy on the transport of atoms in the bulk grains, along void surfaces, along grain boundaries, and at passivation interfaces. We refer the reader to the companion paper [13] for a discussion of this literature.

The goal of this paper and its companion [13] is to provide a rigorous treatment of a modest subset of the mass transport phenomena that occur in microelectronic circuits. In particular, our model is two dimensional and neglects void evolution, curvature-driven grain boundary motion, plastic deformation, and thermal effects. Instead, we focus on the coupling of electromigration to stress generation, which is difficult due to nonlocality, stiffness, complex geometry, and stress singularities at junctions where boundary conditions involving normal stress are imposed.

In [13], we describe the problem physically, state the equations and boundary conditions, find an exact solution for an infinite interconnect line, recast the problem for a finite geometry as an ordinary differential equation on a Hilbert space involving two unbounded operators L and S, analyze the operator L, and prove that the problem is well posed (using techniques from semigroup theory) under the simplifying assumption that the grain boundary network is nondegenerate. We summarize many of these results in section 2.

In section 3, we prove that S (a type of Dirichlet-to-Neumann map) is self-adjoint, negative, closed, and densely defined. These properties are stated (omitting proofs) in [13] and play an essential role in our analysis of the nondegenerate and general cases. To define S, we study weak solutions to the grain boundary normal stress problem. This leads us to identify a new class of degenerate grain boundary networks for which S has a nontrivial (but always finite dimensional) kernel. We use an energy argument to prove self-adjointness and negativity, and we present a counting argument that is useful for characterizing degeneracy.

In section 4, we prove that the equation governing the evolution of normal stress on the grain boundary network Γ generates an analytic semigroup of bounded linear operators on $H^1(\Gamma)$. We also show how to use this semigroup to determine the evolution of displacement and stress inside each grain, which is a nontrivial task since the grain boundary normal stress problem is not uniquely solvable in the degenerate case without additional information about the jump in displacement across Γ. We show that the stress field relaxes to a steady state distribution which may or may not completely balance the electromigration force along grain boundaries. In the latter (degenerate) case, the displacement field describing the motion of the grains continues to grow without bound along stress-free modes, leading to behavior that resembles continental drift in plate tectonics.

We remark that such growth modes are quite harmless to an interconnect line. They correspond to a gradual transport of material from one side of each participating grain to the other, causing it to continually drift to avoid misfit with its neighbors, but not leading to stress generation or voiding.

2. Preliminaries. We model the interconnect line as a union $\Omega = \bigcup_{k=1}^{M} \Omega_k$ of disjoint polygonal grains, as shown in Figure 2.1. We denote the outer boundary (the "walls") of the domain by Γ_0, and we denote the grain boundary network by $\Gamma = \bigcup_{j=1}^{N} \Gamma_j$. Each line segment Γ_j is given an arbitrary orientation (a unit tangent vector $\mathbf{t}_j$) and an arc length parameter s which increases in the $\mathbf{t}_j$ direction. The unit normal $\mathbf{n}_j$ points from right ($-$) to left ($+$) facing along $\mathbf{t}_j$. The net grain growth g is defined on Γ as the jump in normal component of displacement across the grain

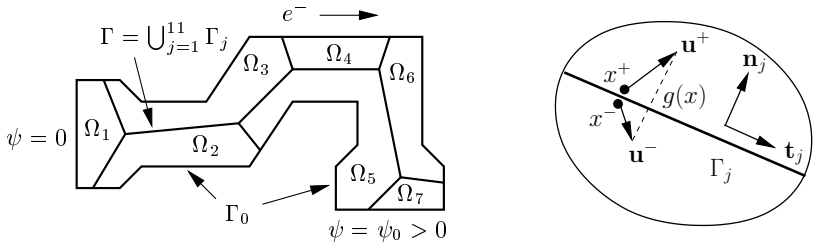

FIG. 2.1. *Left: geometry of an interconnect line. Right: $g(x)$ is the jump in normal component of displacement across Γ at x.*

boundary:

$$g(x) := [\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{n}_j \qquad (x \in \Gamma_j). \tag{2.1}$$

It represents the distance the original grains have separated to accommodate the new material that occupies that space; see Figure 2.1. Note that g evolves as a function defined on Γ as $\mathbf{u}$ evolves on Ω; both Γ and Ω remain *fixed* in the reference configuration. The sign of g is independent of the orientation chosen for the segment.

The electric potential ψ is found by solving the Laplace equation subject to the boundary conditions $\psi = 0$ and $\psi = \psi_0$ at the two ends of the interconnect line and $\partial_n \psi = 0$ on all other walls. We assume the grain boundaries do not significantly affect the flow of electrons in the line, so boundary conditions are specified along Γ_0 only; Γ is invisible to ψ.

Each grain is assumed to deform elastically (assuming plane strain) and to satisfy the Lamé equations of linearized elasticity, $\mu \Delta \mathbf{u} + (\lambda + \mu) \nabla (\nabla \cdot \mathbf{u}) = \mathbf{0}$. The outer walls are assumed to be perfectly rigid, giving the two boundary conditions

$$\mathbf{u}(x) = \mathbf{0} \qquad (x \in \Gamma_0). \tag{2.2}$$

Along grain boundaries, four interface boundary conditions are specified:

$$\mathbf{u}(x^+) - \mathbf{u}(x^-) = g(x)\mathbf{n_j} \qquad (x \in \Gamma_j), \tag{2.3}$$

$$\sigma(x^+)\mathbf{n_j} = \sigma(x^-)\mathbf{n_j} \qquad (x \in \Gamma_j). \tag{2.4}$$

In other words, grains are not allowed to slide tangentially, the jump in normal component of displacement is specified to be $g(x)$, and both components of traction balance across the grain boundary. The traction condition is justified because we have adopted an Eulerian viewpoint for the meaning of displacement; see [13]. For a given deformation φ, $\mathbf{u}(x)$ is defined to be $x - \varphi^{-1}(x)$ rather than $\varphi(x) - x$. As a result, $g(x)\mathbf{n}_j = \varphi^{-1}(x^-) - \varphi^{-1}(x^+)$ rather than $\varphi(x^+) - \varphi(x^-)$ (the latter is shown in Figure 2.1). The material and Eulerian viewpoints have the same linearization.

After nondimensionalizing [13], the flux J of atoms along the grain boundary is given by $J = \partial_s(\eta + \psi)$. Here $\eta = \mathbf{n} \cdot \sigma \mathbf{n}$ is the normal stress along the grain boundary, $\psi = \psi\big|_\Gamma$ is the restriction of the electric potential to the grain boundary, and ∂_s is the derivative with respect to arc length along the grain boundary. The continuity equation expressing mass conservation is $\partial_t g + \partial_s J = 0$; hence the evolution of net grain growth is governed by

$$\partial_t g = -\partial_s^2(\eta + \psi) = L(Sg + \psi). \tag{2.5}$$

Here $L = -\frac{\partial^2}{\partial s^2}$ is the negative of the second derivative operator with respect to arc length on each grain boundary segment, and S maps a displacement jump g defined on Γ to the corresponding normal stress η on Γ by solving the Lamé equations, as discussed above. If we apply the operator S to both sides of (2.5), we obtain a differential equation for η:

$$\partial_t \eta = SL(\eta + \psi). \tag{2.6}$$

The solution to this equation is given by $\eta(t) = E_t(\eta + \psi) - \psi$, where $\{E_t : t \geq 0\}$ is the strongly continuous semigroup of linear operators generated by SL; see section 4. The solution to (2.5) is more complicated; it will be discussed in section 4.3.

Boundary conditions for chemical potential continuity and flux balance at junctions are enforced by requiring that $\eta + \psi$ belongs to the domain $\mathcal{D}(L)$ for $t > 0$; see [13]. Similarly, to ensure that g is actually a displacement jump, i.e., that there exists a displacement field $\mathbf{u}$ on Ω satisfying (2.3), we require that $g \in \mathcal{D}(S)$ for $t > 0$.

The domain $\mathcal{D}(S)$ is difficult to characterize; see section 3.3. To describe the domain $\mathcal{D}(L)$, it is useful to establish further notation. Let $C(\Gamma)$ denote the space of continuous functions on Γ, and let $\widetilde{C}(\Gamma)$ denote the space of functions f continuous on the interiors of the Γ_j with well-defined limits $f(x_i^j)$ at the endpoints x_i of Γ_j but with possibly different limiting values at x_i when approached from different segments. Differentiation is defined segment by segment, where we recall that each segment is given an arbitrary orientation along which the arc length parameter increases. We define

$$\widetilde{C}^r(\Gamma) = \{f : f^{(k)} \in \widetilde{C}(\Gamma),\ 0 \leq k \leq r\}. \tag{2.7}$$

Then the domain $\mathcal{D}(L)$ satisfies

$$\{f \in \widetilde{C}^2(\Gamma) : f \text{ satisfies } (*)\} \ \subset\ \mathcal{D}(L)\ \subset\ \{f \in \widetilde{C}^1(\Gamma) : f \text{ satisfies } (*)\}, \tag{2.8}$$

where $(*)$ refers to continuity and flux boundary conditions at all junctions. In other words, $f \in \widetilde{C}^r(\Gamma)$ satisfies $(*)$ if $f \in C(\Gamma)$ and at each junction x_i, $\sum_j \pm f'(x_i^j) = 0$, where the sum is over segments incident to x_i and the sign depends on whether the segment is parameterized toward or away from the junction.

Other key properties of L (all proved in [13]) are as follows. L is self-adjoint and positive. Its kernel consists of the functions

$$e_k(x) = \begin{cases} |\Gamma_{J_k}|^{-\frac{1}{2}}, & x \in \Gamma_{J_k}, \\ 0 & \text{otherwise.} \end{cases} \tag{2.9}$$

Here J_k is the set of indices such that $\Gamma_{J_k} := \cup_{j \in J_k} \Gamma_j$ is the kth connected component of Γ (treated as a point set in $\mathbb{R}^2$), and $|\Gamma_{J_k}| = \sum_{j \in J_k} |\Gamma_j|$ is the sum of the lengths of the segments making up component k. Let $d = \dim \ker(L)$, and define

$$P = I - \sum_{k=1}^{d} (\cdot, e_k) e_k, \quad A = L + \sum_{k=1}^{d} (\cdot, e_k) e_k, \quad G = A^{-1} - \sum_{n=1}^{d} (\cdot, e_k) e_k, \tag{2.10}$$

where $(\cdot, \cdot)$ is the L^2 inner product on Γ. Then P is the orthogonal projection onto the subspace

$$\operatorname{ran}(L) = \ker(L)^{\perp} = \left\{ f \in L^2(\Gamma)\ :\ \int_{\Gamma_{J_k}} f\, ds = 0,\ 1 \leq k \leq d \right\}, \tag{2.11}$$

and we have $L = AP = PA$, $LG = P$, and $GL = P\big|_{\mathcal{D}(L)}$. $A^{\frac{1}{2}}$ is an isomorphism from $H^1(\Gamma)$ to $L^2(\Gamma)$, where $H^1(\Gamma)$ consists of all $f \in C(\Gamma)$ which are absolutely continuous with (weak) derivative $f' \in L^2(\Gamma)$. Finally, $\mathcal{D}(L^{\frac{1}{2}}) = H^1(\Gamma)$.

3. Elasticity with interface boundary conditions. In this section we give rigorous definitions of the operators S and B, define weak solutions to the Lamé equations with appropriate interface boundary conditions along grain boundaries, and introduce the notion of degeneracy of a grain boundary network. We prove that S and B are self-adjoint and negative on $L^2(\Gamma)$, that the former is closed and densely defined, and that the latter is compact. We also provide a precise characterization of grain boundary degeneracy that is easy to check numerically.

In the previous section, we described S as a type of Dirichlet-to-Neumann operator that takes a displacement jump g on the grain boundary, solves the Lamé equations subject to the boundary conditions (2.2)–(2.4), and returns the normal stress η on Γ. For technical reasons, it is preferable to define S as the pseudoinverse of B, where B takes a specified normal stress η on the grain boundary, solves the Lamé equations subject to the boundary conditions

$$\mathbf{u}(x) = \mathbf{0} \qquad (x \in \Gamma_0), \tag{3.1}$$

$$[\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{t}_j = 0 \qquad (x \in \Gamma_j), \tag{3.2}$$

$$[\sigma(x^+) - \sigma(x^-)]\mathbf{n}_j = \mathbf{0} \qquad (x \in \Gamma_j), \tag{3.3}$$

$$\mathbf{n}_j \cdot \sigma(x)\mathbf{n}_j = \eta(x) \qquad (x \in \Gamma_j), \tag{3.4}$$

and returns the jump in the normal component of displacement

$$(B\eta)(x) = [\mathbf{u}(x^+) - \mathbf{u}(x^-)] \cdot \mathbf{n}_j \qquad (x \in \Gamma_j). \tag{3.5}$$

The primary obstacle to this approach is that in the case of degeneracy, η must satisfy further conditions for a solution $\mathbf{u}$ to exist, and these solutions are not unique. In this case, we define B using appropriate projections so that its pseudoinverse S has the physical meaning described previously.

3.1. Boundary conditions. To impose Dirichlet boundary conditions at walls and no-slip boundary conditions across grain boundaries, we employ a Hilbert subspace H of $H^1(\Omega)^2$ defined as the kernel of appropriate trace operators. Recall that the inner product of the Sobolev space $H^1(\Omega)^2$ is given by

$$(\mathbf{u}, \mathbf{v}) = \int_\Omega (\mathbf{u} \cdot \mathbf{v} + \nabla \mathbf{u} : \nabla \mathbf{v}) dx, \tag{3.6}$$

where $(\nabla \mathbf{u})_{ij} = \partial_j u_i$ and $A : B = \sum_{ij} A_{ij} B_{ij}$. Note that the values of $\mathbf{u}$ in this space do not communicate across grain boundaries—the restriction of $\mathbf{u}$ to each Ω_k can be any function in $H^1(\Omega_k)^2$. The trace operators defined below map, respectively, a vector field $\mathbf{u} \in H^1(\Omega)^2$ to its value at the walls, to its jump in tangential component across grain boundaries, and to its jump in normal component across grain boundaries. We use γ_0 and γ_t to define the Hilbert space H given by

$$H = \left\{ \mathbf{u} \in H^1(\Omega)^2 \;\middle|\; \gamma_0 \mathbf{u} = \mathbf{0},\ \gamma_t \mathbf{u} = 0 \right\}. \tag{3.7}$$

We will need γ_n in section 3.3 to define weak solutions and also to define the operator B. Recall that N and M are the number of grain boundary segments and the

number of regions, respectively:

$$\Omega = \bigcup_{k=1}^{M} \Omega_k, \qquad \Gamma = \bigcup_{j=1}^{N} \Gamma_j, \qquad \Gamma_0 = \text{outer walls.} \tag{3.8}$$

THEOREM 3.1. *The following trace operators are compact:*

$$\gamma_0 : H^1(\Omega)^2 \to L^2(\Gamma_0)^2 : \mathbf{u} \mapsto \mathbf{u}\big|_{\Gamma_0}, \tag{3.9}$$

$$\gamma_t : H^1(\Omega)^2 \to L^2(\Gamma) : \mathbf{u} \mapsto \left([\mathbf{u}\big|_{\Gamma_1^+} - \mathbf{u}\big|_{\Gamma_1^-}] \cdot \mathbf{t}_1 \, , \, \ldots \, , \, [\mathbf{u}\big|_{\Gamma_N^+} - \mathbf{u}\big|_{\Gamma_N^-}] \cdot \mathbf{t}_N \right), \tag{3.10}$$

$$\gamma_n : H^1(\Omega)^2 \to L^2(\Gamma) : \mathbf{u} \mapsto \left([\mathbf{u}\big|_{\Gamma_1^+} - \mathbf{u}\big|_{\Gamma_1^-}] \cdot \mathbf{n}_1 \, , \, \ldots \, , \, [\mathbf{u}\big|_{\Gamma_N^+} - \mathbf{u}\big|_{\Gamma_N^-}] \cdot \mathbf{n}_N \right). \tag{3.11}$$

Here $\mathbf{u}\big|_{\Gamma_j^+}$ *is the trace of* $\mathbf{u}$ *on* Γ_j *from the left (i.e., the trace of* $\mathbf{u}\big|_{\Omega_k}$ *on* Γ_j*, where* Ω_k *lies to the left of* Γ_j*),* $\mathbf{u}\big|_{\Gamma_j^-}$ *is the trace of* $\mathbf{u}$ *on* Γ_j *from the right, and we have identified* $L^2(\Gamma)$ *with* $L^2(\Gamma_1) \times \cdots \times L^2(\Gamma_N)$.

Proof. Since Γ_0 is also a union of line segments, it suffices to show that for any region Ω_k and boundary segment $X \subset \partial\Omega_k$, the composite map

$$\mathbf{u} \mapsto \mathbf{u}\big|_{\Omega_k} \mapsto \left(\mathbf{u}\big|_{\Omega_k}\right)\big|_{\partial\Omega_k} \mapsto \left(\mathbf{u}\big|_{\Omega_k}\right)\big|_X \tag{3.12}$$

is compact. The first and last maps are just restriction operators from $H^1(\Omega)^2$ to $H^1(\Omega_k)^2$ and $L^2(\partial\Omega_k)^2$ to $L^2(X)^2$, so they are bounded. Since Ω_k is a polygon, it has a Lipschitz boundary, and hence [1, 4, 5] the trace operator

$$\gamma_k : H^1(\Omega_k)^2 \to H^{\frac{1}{2}}(\partial\Omega_k)^2 \tag{3.13}$$

is bounded. But $H^{\frac{1}{2}}(\partial\Omega_k)^2$ is compactly embedded in $L^2(\partial\Omega_k)^2$, so the middle map in (3.12) is compact, as required. ∎

3.2. Degenerate grain boundary networks. In this section we define the notion of grain boundary degeneracy, which characterizes the existence of unsuppressed growth modes consisting of stress-free infinitesimal rigid body motions in each grain. We also describe an algorithm for determining whether a given grain boundary network is degenerate and, if it is, for finding these modes. We present a counting argument that strongly suggests that grain geometries with convex grains and very few quadruple or higher order junctions will be nondegenerate. We verify numerically that randomly generated grain boundary networks with convex grains are indeed nondegenerate.

DEFINITION 3.2. *A grain boundary network* Γ *is said to be* degenerate *if* H *contains a nonzero function* $\mathbf{u}$ *consisting of infinitesimal rigid body motions (defined below) on each grain.*

To gain geometric insight, we construct a procedure for testing the degeneracy of a given grain boundary network. An infinitesimal rigid body motion is a displacement field of the form

$$u_1(x, y) = a - cy, \qquad u_2(x, y) = b + cx, \tag{3.14}$$

where a, b, c are arbitrary real numbers. Let (x_k, y_k) be some fixed point in Ω_k, and let r_k be a characteristic length scale for the kth grain. For any $\mathbf{u} \in H(\Omega)^2$ consisting

of infinitesimal rigid body motions, there are parameters a_k, b_k, and c_k for each region such that

$$\mathbf{u}\big|_{\Omega_k} = \left(a_k - c_k \frac{y - y_k}{r_k},\, b_k + c_k \frac{x - x_k}{r_k}\right). \tag{3.15}$$

We wish to determine if there is a nontrivial choice of these parameters such that the corresponding $\mathbf{u}$ belongs to H. We define the vector w by

$$w = (a_1, b_1, c_1, \ldots, a_M, b_M, c_M)^T \tag{3.16}$$

and construct a matrix A with $3M$ columns such that

$$Aw = 0 \;\Leftrightarrow\; \mathbf{u}_w \in H. \tag{3.17}$$

Clearly, if Ω_k touches an outer wall, then the condition that $\gamma_0 \mathbf{u} = 0$ requires that $a_k = b_k = c_k = 0$. We assume that the M_0 outer grains appear first in the list, and we let

$$A_{ij} = \delta_{ij} \qquad (1 \le i \le 3M_0,\, 1 \le j \le 3M) \tag{3.18}$$

so that A has the block structure

$$A = \begin{pmatrix} I & 0 \\ * & A' \end{pmatrix}. \tag{3.19}$$

Note that A is injective iff A' is injective. For each edge that borders a grain with index $k > M_0$, we add a row to A to impose the condition that $\gamma_t \mathbf{u} = 0$. Explicitly, letting (x, y) be any point on edge j and denoting the left and right grains by l and k, the row added to A enforces the equation

$$\left(a_l - c_l \frac{y - y_l}{r_l} - a_k + c_k \frac{y - y_k}{r_k},\, b_l + c_l \frac{x - x_l}{r_l} - b_k - c_k \frac{x - x_k}{r_k}\right) \cdot \mathbf{t}_j \;=\; 0, \tag{3.20}$$

which is clearly linear in the components of w. Note that adding $\alpha \mathbf{t}_j$ to (x, y) does not affect the validity of this equation, so if it holds for one point on the edge, it holds at all points on the edge.

The number of edges that contribute an equation to A can be computed as follows. Let $\Omega' = \cup_{k=M_0+1}^{M} \Omega_k$, and consider the planar graph $\Gamma' = \partial\Omega'$. For example, in Figure 3.1(a), Γ' consists of the eight segments bordering unshaded regions. The Euler relation

$$n + f - e = 1 \qquad (\Gamma' \text{ connected}) \tag{3.21}$$

gives the relationship between the number of vertices, regions, and edges of this graph, where we use 1 instead of 2 since we do not count the unbounded region. If $\overline{\Omega'}$ is multiply connected, this formula holds for each of the c connected subgraphs of Γ', so (3.21) should be modified to read

$$n + f - e = c \qquad (\Gamma' \text{ has } c \text{ connected components}). \tag{3.22}$$

Let n_p be the number of vertices with p incident edges. Then since each edge has two endpoints, we have

$$\sum_{p=2}^{\infty} p n_p = 2e. \tag{3.23}$$

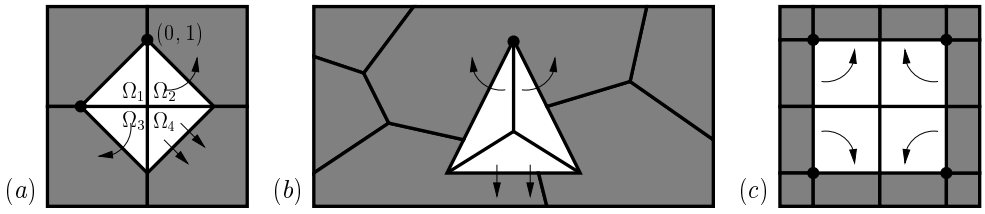

FIG. 3.1. *Examples of degenerate grain boundary networks.* (a) Ω' *has four regions and eight edges, so* A' *has* $12-8=4$ *more columns than rows. This also could have been obtained using* (3.24) *with* $n_3=4, n_4=1$. *The arrows represent one of the functions* $\mathbf{u}$ *in the four dimensional space* H_d, *namely,* $\mathbf{u}\big|_{shaded}=\mathbf{u}\big|_{\Omega_1}=\mathbf{0}$, $\mathbf{u}\big|_{\Omega_2}=(1-y,x)$, $\mathbf{u}\big|_{\Omega_3}=(y,-1-x)$, $\mathbf{u}\big|_{\Omega_4}=(1,-1)$. (b) A' *has six rows and nine columns. Note that nonconvexity in the outer grains allows all nodes of* Ω' *to have* $p=3$, *whereas normally* $n_2\geq 3$. (c) *This time* A' *has the same number of rows and columns, yet it still has a one dimensional kernel since the sign pattern* $+-+-$ *is periodic at a quadruple junction.*

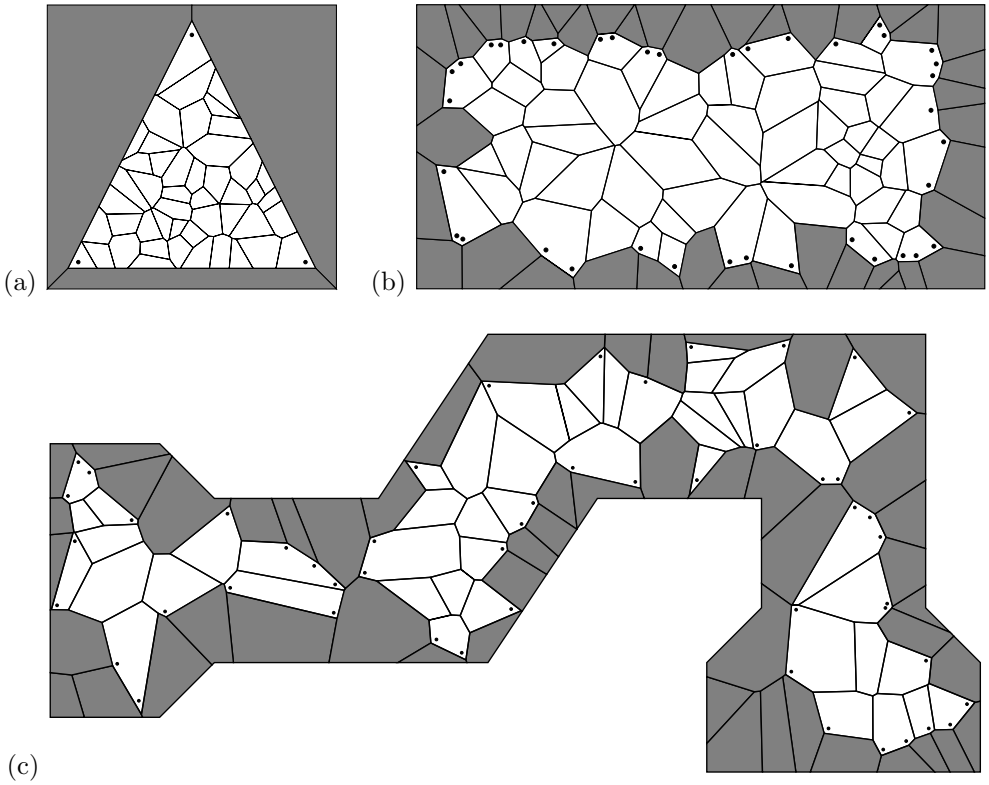

FIG. 3.2. *Typical examples of the geometries generated while computing the condition numbers in Table* 3.1. *Each* • *marks a corner with* $p=2$ *incident edges. All other junctions of* Γ' *have* $p=3$. *Triple junctions often occur clustered together in random Voronoi diagrams, giving the appearance of higher order junctions; this does not give rise to poorly conditioned matrices* A'. *Large shear forces may develop across short edges in such cases if there is not enough redundancy in the other equations (e.g., in case* (a) *here), but that is not a relevant issue when deciding whether a grain boundary network is degenerate. Since at least three corners with* $p=2$ *are needed to traverse the outer boundary of each connected component of* Γ', $e-3f$ *in* (3.24) *is guaranteed to be nonnegative.* (a) *Same number of equations as unknowns* ($e=3f$). (b) $n_2=38$, *so there are* $n_2-3=35$ *more equations than unknowns.* (c) $n_2=51$ *and* $c=3$, *so* $e-3f=42$. *Nonconvexity of grains at outer walls due to reentrant corners clearly will not lead to the difficulties that arose in Figure* 3.1(b).

TABLE 3.1

Condition number of A' for randomly generated Voronoi diagrams. The geometry labels correspond to Figure 3.2*, which shows examples of* (a)-50, (b)-100, *and* (c)-100. *In case* (a)*, we add three outer regions to the Voronoi diagram so that the number of equations is equal to the number of unknowns (a worst-case scenario). Geometries* (b) *and* (c) *are more realistic, although they tend to have more pathologies (such as clustered triple points and short edges) than would likely be found in a real grain boundary network. All the matrices tested were extremely well conditioned, which supports our conjecture that if each grain is convex and no quadruple or higher order junctions occur in the grain boundary network, then Γ is nondegenerate.*

Geometry	Regions	Trials	max	min	mean	std dev
(a)	200	10000	172.6	31.7	37.8	3.2
(a)	100	10000	48.4	21.6	26.2	2.1
(a)	50	10000	35.0	14.4	18.2	1.6
(b)	200	10000	31.8	13.0	16.8	1.3
(b)	100	10000	31.5	8.2	11.1	1.1
(c)	200	10000	26.8	7.4	9.9	1.1
(c)	100	10000	21.4	4.5	6.9	1.1

Multiplying (3.22) by 3 and subtracting (3.23), we obtain

$$e - 3f = \sum (3-p)n_p - 3c \qquad (A' \text{ is an } e \times 3f \text{ matrix}). \tag{3.24}$$

Since each region of Ω' contributes three unknowns and each edge contributes one equation, we see that a necessary condition for the grain boundary network to be nondegenerate is that the right-hand side be nonnegative—otherwise A' will have more columns than rows, and hence a nontrivial kernel. This necessary condition is automatically satisfied if each grain is convex and $n_p = 0$ for $p > 3$, i.e., if we require that all grain boundary junctions be gb-wall or triple junctions: traversing the outer boundary of each of the c components of $\overline{\Omega'}$, we will encounter at least three changes in direction of more than 180 degrees; each of these angles contributes to n_2 since the third segment must prevent nonconvex outer grains (the grains touching walls), and thus $n_2 \geq 3c$. Some examples of degenerate grain boundary networks are shown in Figure 3.1.

CONJECTURE 3.3. *If each Ω_k is convex and no quadruple or higher order junctions occur in the grain boundary network, then Γ is nondegenerate.*

To test this conjecture, we wrote a PERL program to choose M points at random in a polygonal domain U, compute the Voronoi diagram of these points, chop Voronoi regions that cross ∂U, set up the matrix A', and call Matlab to compute its condition number as the ratio of largest to smallest singular value. The points (x_k, y_k) are taken to be the average of the vertices of grain k, and r_k is taken to be $\sqrt{\text{area}_k/\pi}$. The purpose of x_k, y_k, and r_k is to improve the condition number of A' by scaling the effect of c_k to be commensurate with a_k and b_k. The PERL program repeats the above procedure many times (opening a pipe to Matlab at the beginning) and computes the minimum, maximum, mean, and standard deviation of the condition numbers. The results are summarized in Table 3.1. Typical examples of the resulting grain boundary structures are shown in Figure 3.2. Although convex grains do not necessarily arise from Voronoi diagrams, we see no reason that these would not be a good representative sample, especially in light of the fact that *all* the matrices A' that we generated in this way were extremely well conditioned even for grain boundary networks where several triple points had almost coalesced into higher order junctions.

Even if the conjecture is false, this numerical experiment shows that "typical" grain boundary networks are nondegenerate, and we have provided a method for

finding all degeneracies of any grain boundary network (possibly containing nonconvex grains and higher order junctions):

PROCEDURE 3.4 (finding all degeneracies). *Construct the matrix A, find a basis $w_1, \dots, w_q$ for its kernel, and record the corresponding displacements $\mathbf{u}_1, \dots, \mathbf{u}_q$ using* (3.15) *and* (3.16). *These are a basis for the subspace H_d of stress-free (grain by grain) infinitesimal rigid body motions in H.*

DEFINITION 3.5. *A* degenerate grain growth mode *is a function $h \in L^2(\Gamma)$ of the form $h = \gamma_n(\mathbf{u})$ for some $\mathbf{u} \in H_d$. We denote the space of such functions by $\gamma_n(H_d)$.*

Remark 3.6. We will see later that $\ker(S) = \ker(B) = \gamma_n(H_d)$.

LEMMA 3.7. *γ_n is injective on H_d. Thus if $\{\mathbf{u}_k\}_{k=1}^q$ is a basis for H_d, then the functions $h_k = \gamma_n(\mathbf{u}_k)$ form a basis for $\gamma_n(H_d)$.*

Proof. Suppose $\mathbf{u} \in H_d$ and $\gamma_n(\mathbf{u}) = 0$. Then, since $H_d \subset H$, we also have $\gamma_t(\mathbf{u}) = 0$ and $\gamma_0(\mathbf{u}) = 0$. Thus $\mathbf{u}$ is continuous across grain boundaries, is zero on the outer walls, and consists of infinitesimal rigid body motions on each grain. Continuity across grain boundaries implies that the rigid body parameters are the same in each grain, for if l and r index the parameters on either side of a grain boundary segment, then

$$\begin{aligned} a_l - a_r - (c_l - c_r)y &= 0, \\ b_l - b_r + (c_l - c_r)x &= 0 \end{aligned} \tag{3.25}$$

for each (x, y) on the segment. Using two points on the grain boundary, we find $c_l = c_r$, so (3.25) implies $a_l = a_r$ and $b_l = b_r$. Dirichlet conditions at the walls then give that $a = b = c = 0$ in all grains, as required. ∎

Remark 3.8. We may assume the h_k are orthonormal in $L^2(\Gamma)$ (using a Gram–Schmidt procedure, if necessary).

THEOREM 3.9. *Each $h \in \gamma_n(H_d)$ has zero mass on every connected component of the grain boundary network:*

$$\int_{\Gamma_{J_i}} h \, ds = 0 \qquad (i = 1, \dots, d). \tag{3.26}$$

Proof. Let $\mathbf{u} \in H_d$, $h = \gamma_n \mathbf{u}$, and $i \in \{1, \dots, d\}$. Define

$$K_i = \{k : \Omega_k \text{ does not touch } \Gamma_0 \text{ but does touch } \Gamma_{J_i}\}, \tag{3.27}$$

$$J_i' = \{j \in J_i : \Gamma_j \text{ borders an } \Omega_k \text{ which doesn't touch } \Gamma_0\}. \tag{3.28}$$

In Figure 3.3, J_1' contains 12 segment indices, K_1 contains 4 region indices, J_2' contains 6 indices, K_2 contains 3 indices, and J_3' and K_3 are empty. Since $\mathbf{u}$ is an infinitesimal rigid body motion on each grain, it is divergence free, so for $1 \le k \le M$ we have

$$\int_{\partial\Omega_k} \mathbf{u} \cdot \mathbf{n} \, ds = \iint_{\Omega_k} \nabla \cdot \mathbf{u} \, dx = 0 \qquad (\mathbf{n} = \text{outward unit normal}). \tag{3.29}$$

Summing (3.29) over $k \in K_i$ (with an empty sum meaning zero), we obtain

$$0 = \sum_{k \in K_i} \int_{\partial\Omega_k} \mathbf{u} \cdot \mathbf{n} \, ds = \sum_{j \in J_i'} \int_{\Gamma_j} [\mathbf{u}(x^-) - \mathbf{u}(x^+)] \cdot \mathbf{n}_j \, ds = \int_{\Gamma_{J_i}} -h \, ds. \tag{3.30}$$

Here we have used the following facts: $\mathbf{n}_j$ is the unit inward normal on the left $(+)$ grain and the unit outward normal on the right $(-)$ grain; the condition $\gamma_0 \mathbf{u} = \mathbf{0}$

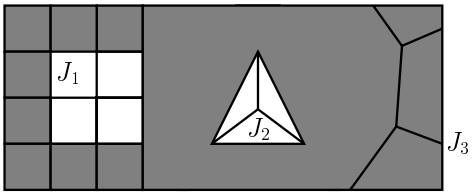

FIG. 3.3. *Shown here, Γ consists of three connected components Γ_{J_i}, so $\dim\ker(L) = 3$. The space H_d (and hence $\ker(S)$) is four dimensional (one degree of freedom in the unshaded structure on the left, three in the middle; see Figure* 3.1*). Each $\mathbf{u} \in H_d$ is zero on the shaded grains.*

implies that $\mathbf{u}$ is zero on any Ω_k touching an outer wall since $\mathbf{u}$ consists of infinitesimal rigid body motions; if $j \in J_i'$, then Γ_j borders either one or two Ω_k with $k \in K_i$—in the former case, $\mathbf{u}(x^{\pm})$ is zero on the other side because that region touches a wall; if $k \in K_i$, all boundary segments Γ_j of Ω_k have $j \in J_i'$; finally, $h = \gamma_n \mathbf{u}$ is zero on the segments Γ_j with $j \in J_i \setminus J_i'$ since both adjacent regions touch a wall. Figure 3.4 illustrates a similar argument in the next section. ∎

3.3. Weak solutions. In this section, we define weak solutions of the grain boundary normal stress and displacement jump problems, and we give rigorous definitions of the operators B and S. Many complications arise in the case of degenerate grain boundaries that make the analysis difficult. We prove that B is compact, self-adjoint, and negative, and we show that $\ker(B) = \gamma_n(H_d)$. The operator S is defined as the pseudoinverse of B, inheriting self-adjointness and negativity.

We will need to make use of the bilinear form

$$a(\mathbf{u}, \mathbf{v}) := \int_\Omega \sigma(\mathbf{u}) : \varepsilon(\mathbf{v})\, dx = \int_\Omega [\lambda\, (\nabla \cdot \mathbf{u})(\nabla \cdot \mathbf{v}) + 2\mu\, \varepsilon(\mathbf{u}) : \varepsilon(\mathbf{v})]\, dx, \tag{3.31}$$

which induces the seminorm $\|\mathbf{u}\|_a = \sqrt{a(\mathbf{u}, \mathbf{u})}$ on $H^1(\Omega)^2$. Here

$$\varepsilon(\mathbf{u})_{ij} = \frac{1}{2}(\partial_i u_j + \partial_j u_i), \qquad \sigma(\mathbf{u}) = \lambda \operatorname{tr} \varepsilon(\mathbf{u}) I + 2\mu\varepsilon(\mathbf{u}), \tag{3.32}$$

and there is clearly a constant C such that

$$\|\mathbf{u}\|_a \le C\|\mathbf{u}\|_{H^1(\Omega)^2} \qquad \left(\mathbf{u} \in H^1(\Omega)^2\right). \tag{3.33}$$

For any $\eta \in L^2(\Gamma)$, we define the linear functional $l_\eta \in H'$ by

$$l_\eta(\mathbf{v}) = -(\eta, \gamma_n \mathbf{v})_{L^2(\Gamma)} = -\int_\Gamma (\eta)(\gamma_n \mathbf{v})\, ds \qquad (\mathbf{v} \in H). \tag{3.34}$$

Note that

$$\|l_\eta\|_{H'} \le \|\gamma_n\|_{\mathcal{L}(H^1(\Omega)^2, L^2(\Gamma))} \|\eta\|_{L^2(\Gamma)}. \tag{3.35}$$

DEFINITION 3.10. *A weak solution to the grain boundary normal stress problem for a given normal stress $\eta \in L^2(\Gamma)$ is a function $\mathbf{u} \in H$ which satisfies*

$$a(\mathbf{u}, \mathbf{v}) = -\int_\Gamma (\eta)(\gamma_n \mathbf{v})\, ds \qquad (\mathbf{v} \in H). \tag{3.36}$$

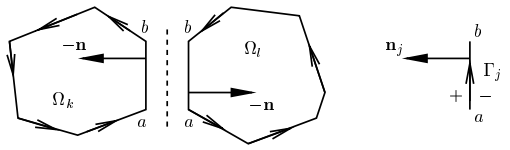

FIG. 3.4. *The contribution of a particular grain boundary segment to* $\sum_k \int_{\partial\Omega_k} \mathbf{v}\big|_{\Omega_k} \cdot \sigma\mathbf{n}$ *contains precisely one term from the left grain and one term from the right grain. Segments on the outer walls do not contribute since* $\gamma_0\mathbf{v} = 0$.

PROPOSITION 3.11. *Any classical solution is a weak solution.*

Proof. Suppose $\mathbf{u}$ is a classical solution with corresponding stress tensor σ and $\mathbf{v} \in H$. Then on Ω_k we have

$$\begin{aligned}(3.37)\qquad \int_{\partial\Omega_k} \mathbf{v}\big|_{\Omega_k} \cdot (\sigma\mathbf{n})\, ds &= \int_{\Omega_k} \partial_j\,(v_i\sigma_{ij})\, dx = \int_{\Omega_k} \overbrace{(\partial_j\sigma_{ij})}^{0}\, v_i + \sigma_{ij}\,(\partial_j v_i)\, dx \\ &= \int_{\Omega_k} \sigma_{ij}\left(\frac{\partial_j v_i + \partial_i v_j}{2}\right) dx = \int_{\Omega_k} \sigma : \varepsilon(\mathbf{v})\, dx = a_k(\mathbf{u}\big|_{\Omega_k},\, \mathbf{v}\big|_{\Omega_k}).\end{aligned}$$

When we sum over all regions, the right-hand side becomes $a(\mathbf{u}, \mathbf{v})$, and the left-hand side becomes a sum over all segments of Γ with one term coming from the left grain and one term coming from the right grain; see Figure 3.4. Since $\gamma_t\mathbf{v} = 0$ and σ is continuous across each segment, the sum of these two terms for the jth segment is

$$(3.38)\qquad \int_{\Gamma_j} (\mathbf{v}^+ \cdot \sigma(-\mathbf{n}_j))\, ds + \int_{\Gamma_j} (\mathbf{v}^- \cdot \sigma\mathbf{n}_j)\, ds = -\int_{\Gamma_j} (\gamma_n\mathbf{v})\mathbf{n}_j \cdot \sigma\mathbf{n}_j\, ds.$$

Summing over all segments and using the boundary condition $\sigma_{nn} = \eta$, we obtain (3.36) as desired. ∎

PROPOSITION 3.12. *If the grain boundary network is degenerate, then a necessary condition for a weak solution to exist is that* $\eta \perp \gamma_n(H_d)$. *If a solution does exist, it is only defined modulo* H_d.

Proof. Fix η, and suppose a solution $\mathbf{u}$ exists. For any $\mathbf{w} \in H_d$, we use (3.36) to conclude that

$$(3.39)\qquad -\int_\Gamma (\eta)(\gamma_n\mathbf{w})\, ds = a(\mathbf{u}, \mathbf{w}) = \int_\Omega \sigma(\mathbf{u}) : \overbrace{\varepsilon(\mathbf{w})}^{0}\, dx = 0.$$

Thus η is orthogonal to $\gamma_n\mathbf{w}$. For any $\mathbf{v} \in H$ we have $a(\mathbf{w}, \mathbf{v}) = 0$, so

$$(3.40)\qquad a(\mathbf{u} + \mathbf{w}, \mathbf{v}) = a(\mathbf{u}, \mathbf{v}) = -\int_\Gamma (\eta)(\gamma_n\mathbf{v})\, ds,$$

and $\mathbf{u} + \mathbf{w}$ is also a weak solution. ∎

DEFINITION 3.13. *We define the space* $\tilde{H}$ *by the relation* $\gamma_n(\tilde{H}) \subset \gamma_n(H_d)^\perp$:

$$(3.41)\qquad \tilde{H} = \{\mathbf{u} \in H \;\big|\; l_h(\mathbf{u}) = 0 \text{ whenever } h \in \gamma_n(H_d)\}.$$

Remark 3.14. Since γ_n is injective on H_d, $\mathbf{u} \equiv 0$ is the only (grain by grain) infinitesimal rigid body motion in $\tilde{H}$, i.e., $\tilde{H} \cap H_d = \{0\}$. Since the codimension of $\tilde{H}$ is at most $q := \dim H_d$ by (3.41), the decomposition $H = \tilde{H} \oplus H_d$ holds.

THEOREM 3.15. *The bilinear form $a(\cdot,\cdot)$ is coercive on $\tilde{H}$, and therefore $\|\cdot\|_a$ is a norm on $\tilde{H}$ equivalent to the one inherited from $H^1(\Omega)^2$.*

Proof. Since $\lambda \geq 0$ and $\mu > 0$, it suffices to show that there is a $c > 0$ such that

$$\|\mathbf{u}\|_\varepsilon^2 := \int_\Omega \varepsilon(\mathbf{u}) : \varepsilon(\mathbf{u})\, dx \geq c \int_\Omega [\mathbf{u}\cdot\mathbf{u} + \nabla\mathbf{u} : \nabla\mathbf{u}]\, dx = c\|\mathbf{u}\|_{\tilde{H}}^2 \qquad \left(\mathbf{u} \in \tilde{H}\right). \tag{3.42}$$

Suppose not. Then there is a sequence of unit vectors $\mathbf{u}_n \in \tilde{H}$ such that

$$\|\mathbf{u}_n\|_\varepsilon^2 \to 0. \tag{3.43}$$

Since the unit ball of $H^1(\Omega)^2$ is compact in $L^2(\Omega)^2$, there is a subsequence which converges in $L^2(\Omega)^2$. Replacing the original sequence with the subsequence, we may assume

$$\|\mathbf{u}_m - \mathbf{u}_n\|_{L^2(\Omega)^2}^2 \to 0 \qquad (m, n \to \infty). \tag{3.44}$$

Since each Ω_k is polygonal, Korn's inequality [4, 3] guarantees the existence of positive constants c_k such that

$$\int_{\Omega_k} \varepsilon(\mathbf{u}) : \varepsilon(\mathbf{u})\, dx + \|\mathbf{u}\|_{L^2(\Omega_k)^2}^2 \geq c_k \|\mathbf{u}\|_{H^1(\Omega_k)^2}^2 \qquad \left(\mathbf{u} \in H^1(\Omega_k)^2\right). \tag{3.45}$$

Letting $c = \min_k c_k$ and summing over all regions, we obtain

$$\|\mathbf{u}\|_\varepsilon^2 + \|\mathbf{u}\|_{L^2(\Omega)^2}^2 \geq c\|\mathbf{u}\|_{H^1(\Omega)^2}^2 \qquad \left(\mathbf{u} \in H^1(\Omega)^2\right). \tag{3.46}$$

Replacing $\mathbf{u}$ by $\mathbf{u}_m - \mathbf{u}_n$ in (3.46) and using (3.43) and (3.44), we find that $\{\mathbf{u}_n\}$ is a Cauchy sequence in $\tilde{H}$. We let $\mathbf{u}^* = \lim_n \mathbf{u}_n$ and note that because $\|\cdot\|_\varepsilon$ is continuous in $H^1(\Omega)^2$, $\|\mathbf{u}^*\|_\varepsilon = \lim_n \|\mathbf{u}_n\|_\varepsilon = 0$. Thus $\varepsilon(\mathbf{u}^*) \equiv 0$. It is straightforward to show [3] that the only solutions to $\varepsilon(\mathbf{u}) \equiv 0$ on a domain U are infinitesimal rigid body motions. Thus $\mathbf{u}^*\big|_{\Omega_k}$ is an infinitesimal rigid body motion for each k, and by Remark 3.14, $\mathbf{u}^* \equiv \mathbf{0}$. But this is impossible since we must also have $\|\mathbf{u}^*\|_{\tilde{H}} = \lim_n \|\mathbf{u}_n\|_{\tilde{H}} = 1$. Therefore $a(\cdot,\cdot)$ is coercive on $\tilde{H}$ as claimed. ∎

PROPOSITION 3.16. *If $\eta \in L^2(\Gamma)$ is nonzero, then $l_\eta \in H'$ is nonzero.*

Proof. We define

$$\mathcal{C} = \{\eta \in \widetilde{C}^1(\Gamma) \cap C(\Gamma) \;\big|\; \eta = 0 \text{ at all junctions}\}, \tag{3.47}$$

where $\widetilde{C}^r(\Gamma)$ was defined in (2.7), and we claim that

$$\mathcal{C} \subset \{\eta \in L^2(\Gamma) \;\big|\; \exists\, \mathbf{v} \in H \text{ s.t. } \eta = \gamma_n \mathbf{v}\}. \tag{3.48}$$

To see this, let $\eta \in \mathcal{C}$, and extend η to $C(\Gamma \cup \Gamma_0)$ by setting $\eta = 0$ on the outer walls. Decompose η into a sum

$$\eta = \sum_k \eta_k, \qquad \eta_k = \frac{1}{2}\eta\big|_{\partial\Omega_k}. \tag{3.49}$$

Since each restriction η_k is C^1 on the (closed) segments of $\partial\Omega_k$ and zero at the corners, the x- and y-components ξ_k^1, ξ_k^2 of $-\eta_k\mathbf{n}$ also have this property ($\mathbf{n}$ is the outward unit normal). This is sufficient to ensure that each ξ_k^i belongs to $H^1(\partial\Omega_k) \subset H^{\frac{1}{2}}(\partial\Omega_k)$, which implies [5] that there are functions $v_k^i \in H^1(\Omega_k)$ whose trace is equal to ξ_k^i

on the boundary. Defining $\mathbf{v} \in H$ grain by grain to have components v_k^1, v_k^2 proves (3.48). Since $\mathcal{C}$ is dense in $L^2(\Gamma)$ and (3.48) holds, we have

$$l_\eta = 0 \quad \Rightarrow \quad \eta \perp \mathcal{C} \quad \Rightarrow \quad \eta = 0 \quad \text{a.e.} \tag{3.50}$$

as desired. ∎

COROLLARY 3.17. *If $\eta \in \gamma_n(H_d)^\perp$ is nonzero, then l_η is nonzero in $\tilde{H}'$.*

Proof. Such an l_η is nonzero when acting on H and is zero on H_d, so it must be nonzero on $\tilde{H}$ due to $H = \tilde{H} \oplus H_d$. ∎

DEFINITION 3.18. *The projection R is defined as the orthogonal projection in $L^2(\Gamma)$ onto $\gamma_n(H_d)^\perp$. Explicitly, we have*

$$R = I - \sum_{k=1}^{q} (\cdot, h_k) h_k, \tag{3.51}$$

where the h_k form an L^2-orthonormal basis for $\gamma_n(H_d)$, as discussed in Remark 3.8.

THEOREM 3.19 (weak solutions). *For any $\eta \in L^2(\Gamma)$, there exists a unique weak solution $\mathbf{u}[\eta] \in \tilde{H}$ to the grain boundary normal stress problem with normal stress $R\eta$ on Γ. There is a constant C independent of η such that*

$$\|\mathbf{u}[\eta]\|_{H^1(\Omega)^2} \leq C \|\eta\|_{L^2(\Gamma)}. \tag{3.52}$$

Moreover, if $\mathbf{u} \equiv 0$, then $\eta \in \gamma_n(H_d)$.

Proof. We produce a candidate solution $\mathbf{u} \in \tilde{H}$ using the Lax–Milgram theorem and the fact that $a(\cdot, \cdot)$ is bounded and coercive on $\tilde{H}$ while $l_{R\eta}$ is a bounded linear functional on $\tilde{H}$. The solution $\mathbf{u}$ is the unique function in $\tilde{H}$ satisfying

$$a(\mathbf{u}, \mathbf{v}) = l_{R\eta}(\mathbf{v}) \qquad (\mathbf{v} \in \tilde{H}), \tag{3.53}$$

which we must show holds for all $\mathbf{v} \in H$. Since $H = \tilde{H} \oplus H_d$, it suffices to check the result for $\mathbf{v} \in H_d$: we have $a(\mathbf{u}, \mathbf{v}) = 0$ since $\mathbf{v}$ is a rigid body motion on each grain, and $l_{R\eta}(\mathbf{v}) = -(R\eta, \gamma_n \mathbf{v}) = 0$ since R projects onto $\gamma_n(H_d)^\perp$. Equation (3.52) follows from coercivity, (3.53), and (3.35):

$$c\|\mathbf{u}\|^2 \leq a(\mathbf{u}, \mathbf{u}) \leq \|l_{R\eta}\| \, \|\mathbf{u}\| \leq \|\gamma_n\| \, \|R\| \, \|\mathbf{u}\| \, \|\eta\|. \tag{3.54}$$

If $\eta \notin \gamma_n(H_d)$, then $R\eta$ satisfies the hypothesis of Corollary 3.17, so $l_{R\eta}$ is nonzero in $\tilde{H}'$. By (3.53), the solution $\mathbf{u}$ cannot be identically zero. ∎

DEFINITION 3.20. *The operator $B : L^2(\Gamma) \to L^2(\Gamma)$ is defined via*

$$B\eta := \gamma_n \mathbf{u}[\eta]. \tag{3.55}$$

Note that in the case of grain boundary degeneracy, $\mathbf{u}[\eta]$ involves a projection of η and a selection criterion for choosing among the nonunique solutions in H.

THEOREM 3.21. *B is compact, self-adjoint, and negative and satisfies*

$$\ker(B) = \gamma_n(H_d). \tag{3.56}$$

Proof. B is compact because $\eta \mapsto \mathbf{u}[\eta]$ is bounded and γ_n is compact. Using (3.36) and the fact that $(\eta, w)_{L^2} = (R\eta, w)_{L^2}$ for $w \in \gamma_n(\tilde{H})$, we have

$$\int_\Gamma \eta_0 B\eta_1 \, ds = \int_\Gamma \eta_0 \gamma_n \mathbf{u}[\eta_1] \, ds = \int_\Gamma (R\eta_0)(\gamma_n \mathbf{u}[\eta_1]) \, ds = -a(\mathbf{u}[\eta_0], \mathbf{u}[\eta_1]). \tag{3.57}$$

Since $a(\cdot,\cdot)$ is symmetric and coercive on $\tilde{H}$, B is self-adjoint and negative:

$$(\eta_0, B\eta_1)_{L^2} = (\eta_1, B\eta_0)_{L^2}, \qquad (\eta_0, B\eta_0)_{L^2} \le 0 \qquad \left(\eta_0, \eta_1 \in L^2(\Gamma)\right). \tag{3.58}$$

Note that $(\eta, B\eta)_{L^2}$ is related to the elastic energy stored in the grains:

$$E = \frac{1}{2} a\left(\mathbf{u}[\eta], \mathbf{u}[\eta]\right) = -\frac{1}{2}\int_\Gamma \eta B\eta \, ds \qquad \left(\eta \in L^2(\Gamma)\right). \tag{3.59}$$

Since $E = 0$ iff $\mathbf{u} \equiv 0$, and $\mathbf{u}[\eta] \equiv 0$ precisely when $\eta \in \gamma_n(H_d)$, we find that $\ker(B) = \gamma_n(H_d)$ as claimed. ∎

DEFINITION 3.22. *The operator S is defined to be the pseudoinverse of B.*

Remark 3.23. Since B is self-adjoint and compact, it has an orthonormal eigendecomposition $B = \sum_1^\infty \beta_k(\cdot, \chi_k)\chi_k$ with $(\beta_1 = \cdots = \beta_q = 0)$ and the remaining β_k forming an increasing sequence of negative numbers converging to zero. S is defined as $S = \sum_1^\infty \alpha_k(\cdot, \chi_k)\chi_k$, where $\alpha_k = 0$ for $k \le q$ and $\alpha_k = 1/\beta_k$ for $k > q$. Since S is defined with respect to an orthonormal basis, we know it is self-adjoint, densely defined, and negative, and its range is $\gamma_n(H_d)^\perp$. Note that the operators S and B satisfy $SB = R$, $BS = R\big|_{\mathcal{D}(S)}$.

DEFINITION 3.24. *A solution of the grain boundary displacement jump problem for a given $g \in \mathcal{D}(S)$ is a solution $\mathbf{u}$ of the normal stress problem with $\eta = Sg$, subject to the additional requirement that $\gamma_n \mathbf{u} = g$.*

THEOREM 3.25. *For any $g \in \mathcal{D}(S)$ there is a unique solution $\mathbf{u}(g)$ of the grain boundary displacement jump problem.*

Proof. Suppose $g \in \mathcal{D}(S)$. Since γ_n is injective on H_d and $\text{range}(I - R) = \gamma_n(H_d)$, there is a unique $\mathbf{u}_d[g] \in H_d$ such that $\gamma_n(\mathbf{u}_d[g]) = (I - R)g$. Clearly

$$\mathbf{u}(g) = \mathbf{u}_d[g] + \mathbf{u}[Sg] \tag{3.60}$$

is the desired solution, where $\mathbf{u}[Sg]$ is the unique solution in $\tilde{H}$ with normal stress Sg specified on Γ; see Proposition 3.12 and note that $\gamma_n(\mathbf{u}(g)) = (I - R)g + BSg = g$. ∎

Remark 3.26. In the degenerate case, the condition $\gamma_n \mathbf{u} = g$ removes the indeterminacy of the solution to the normal stress problem. As a result, the operator S truly maps g to the corresponding normal stress η, whereas B has nonphysical projections built into it for the convenience of being defined on all of $L^2(\Gamma)$.

Remark 3.27. The domain $\mathcal{D}(S)$ is quite complicated due to the variety of ways self-similar solutions of the Lamé equations can behave near grain boundary junctions; see [9, 12]. In particular, even for smooth functions η that are continuous at junctions, $g = B\eta$ generally will be discontinuous at junctions and exhibit infinite slopes. As a result, it would be very difficult to define weak solutions to the grain boundary displacement jump problem directly (without using the grain boundary normal stress problem) and to characterize those g for which the resulting normal stress η is meaningful in the trace sense. The above approach allows us to define S and derive its properties via the compact operator B, which avoids these complications.

4. Dynamics. In this section we show that the equation

$$\eta_t = SL\eta, \qquad \eta(0) = \eta_0, \tag{4.1}$$

generates an analytic semigroup $\{E_t : t \ge 0\}$ of bounded linear operators on $H^1(\Gamma)$. As mentioned previously, the solution $\eta(t)$ when the electromigration force is present

is then given by

$$\eta(t) = E_t(\eta_0 + \psi) - \psi. \tag{4.2}$$

The boundary conditions on $\eta(t) + \psi$ at junctions hold for $t > 0$ as a consequence of the analyticity of E_t and the properties of $\mathcal{D}(SL)$. We will also show that the evolution of grain growth is given by

$$g(t) = R_1 B\eta(t) + (I - R_1)g_0 + [(I - R_1)L\psi]t, \tag{4.3}$$

where R_1 is a projection with kernel of dimension $q = \dim\ker S$ (the degree of degeneracy of the grain boundary network). The term that grows linearly in time corresponds to a continual transport of material around the grains, leading to stress-free rigid body motions in each grain suggestive of continental drift in plate tectonics.

4.1. Semigroup theory. We briefly review the elements of semigroup theory we will need in what follows. A family $\{E_t : t \geq 0\}$ of bounded linear operators on a Banach space X is called a *strongly continuous semigroup* if

$$\begin{aligned} &\text{(i)} && E_{t+s} = E_t E_s \quad (t, s \geq 0), \\ &\text{(ii)} && E_0 = id_X, \\ &\text{(iii)} && t \mapsto E_t x \text{ is continuous on } [0, \infty) \text{ for each fixed } x \in X. \end{aligned} \tag{4.4}$$

If $\|E_t\| \leq 1$ for all $t \geq 0$, $\{E_t\}$ is called a *contraction semigroup*. The *infinitesimal generator* A of a strongly continuous semigroup $\{E_t\}$ is given by

$$Ax = \lim_{h \to 0^+} [E_h x - x]/h \qquad (x \in \mathcal{D}(A)), \tag{4.5}$$

where $\mathcal{D}(A)$ is the set of all $x \in X$ for which the limit exists. It can be proved [2] that $\mathcal{D}(A)$ is dense in X, that A on $\mathcal{D}(A)$ is a closed operator, and that for $x \in \mathcal{D}(A)$, $t \mapsto E_t x$ is continuously differentiable and satisfies

$$\frac{d}{dt} E_t x = AE_t x = E_t Ax \qquad (0 \leq t < \infty). \tag{4.6}$$

The semigroup $\{E_t\}$ is said to be differentiable if $E_t X \subset \mathcal{D}(A)$ for $t > 0$, in which case [2] it is infinitely differentiable and for each $t > 0$ the operators $E_t^{(n)}$ given by

$$E_t^{(n)} x := \frac{d^n}{dt^n} E_t x = A^n E_t x \tag{4.7}$$

are bounded and satisfy

$$E_t^{(n)} x = (E'_{t/n})^n x \qquad (t > 0). \tag{4.8}$$

A differentiable semigroup is said to be analytic if

$$\limsup_{t \to 0} t\|E'_t\| = \alpha < \infty, \tag{4.9}$$

which is equivalent [11] to having a holomorphic extension E_λ given locally by

$$E_\lambda x = \sum_{n=0}^{\infty} \frac{(\lambda - t)^n}{n!} E_t^{(n)} x \qquad \left(t > 0, \quad |\lambda - t| < \frac{t}{\alpha e}, \quad x \in X\right). \tag{4.10}$$

THEOREM 4.1. *If X is a Hilbert space and A is a closed, densely defined, negative, self-adjoint operator on X, then A is the infinitesimal generator of a contraction semigroup $\{E_t\}$ with holomorphic extension $\{E_\lambda : \operatorname{Re}\lambda > 0\}$, and $\alpha \leq e^{-1}$ in* (4.9).

Proof. See [7, 14]. □

4.2. The semigroup generated by SL. The main obstacle to solving (4.1) is that although S and L are each self-adjoint, they do not commute, and hence SL is not self-adjoint. If L were invertible, the obvious thing to do in this situation (see, e.g., [8]) would be to define a new variable $y = L^{\frac{1}{2}}\eta$, use Theorem 4.1 to obtain the solution $y(t)$ of the equation

$$y_t = L^{\frac{1}{2}} S L^{\frac{1}{2}} y, \qquad y(0) = y_0, \tag{4.11}$$

with $y_0 = L^{\frac{1}{2}}\eta_0$, and check that $\eta = L^{-\frac{1}{2}} y$ satisfies (4.1). Since L has a d dimensional kernel, we cannot directly obtain η from y in this way, and we will instead rely on the knowledge that $y(t) - y_0 \in \operatorname{ran}(L^{\frac{1}{2}} S L^{\frac{1}{2}})$ for all time while $\eta(t) - \eta_0 \in \operatorname{ran}(SL)$.

CONVENTION 4.2. *Generic elements of* $\ker(L)$ *and* $\ker(S)$ *will be denoted* e *and* h *so that the notation* $\{e, Gh\}$*, for example, represents the space* $\ker(L) \oplus G\ker(S)$.

Recall from (2.10) and (3.51) that we have defined $d = \dim\{e\}$, $q = \dim\{h\}$, and P and R as the orthogonal projections onto $\{e\}^\perp$ and $\{h\}^\perp$, respectively:

$$P = I - \sum_{k=1}^{d} (\cdot, e_k) e_k, \qquad R = I - \sum_{k=1}^{q} (\cdot, h_k) h_k. \tag{4.12}$$

By Theorem 3.9, we know $\{e\} \perp \{h\}$; hence P and R commute. Moreover, B is injective on $\{e\}$ (and G on $\{h\}$) since $\{e\} \cap \ker(B) = \{e\} \cap \{h\} = \{0\}$.

LEMMA 4.3. *The following identities hold:*

$$\begin{aligned} &\ker(SL) = \{e, Gh\}, \quad \ker(LS) = \{Be, h\}, \quad \ker(L^{\frac{1}{2}} S L^{\frac{1}{2}}) = \{e, G^{\frac{1}{2}} h\}, \\ &\operatorname{ran}(SL) = \{Be, h\}^\perp, \quad \operatorname{ran}(LS) = \{e, Gh\}^\perp, \quad \operatorname{ran}(L^{\frac{1}{2}} S L^{\frac{1}{2}}) = \{e, G^{\frac{1}{2}} h\}^\perp. \end{aligned} \tag{4.13}$$

Proof. SL is densely defined in $L^2(\Gamma)$ since $\mathcal{D}(S)$ is dense, G is bounded with range dense in $\{e\}^\perp$, and $\mathcal{D}(SL) = \{e\} \oplus G\mathcal{D}(S)$. Likewise $\mathcal{D}(LS) = \{h\} \oplus B\mathcal{D}(L)$ and $\mathcal{D}(L^{\frac{1}{2}} S L^{\frac{1}{2}}) = \{e\} \oplus G^{\frac{1}{2}}[\{h\} \oplus B\mathcal{D}(L^{\frac{1}{2}})]$ are dense in $L^2(\Gamma)$. Clearly, $\ker(SL) \supset \{e, Gh\}$. Since $\{h\} \subset \{e\}^\perp$ and LG is the identity on $\{e\}^\perp$, the only vectors mapped to $\{h\}$ by L belong to $\{e, Gh\}$, so the reverse inclusion also holds. A similar argument establishes $\ker(LS) = \{Be, h\}$. For $\ker(L^{\frac{1}{2}} S L^{\frac{1}{2}})$, we use

$$(x, L^{\frac{1}{2}} S L^{\frac{1}{2}} x) = 0 \quad \Leftrightarrow \quad -(|S|^{\frac{1}{2}} L^{\frac{1}{2}} x, |S|^{\frac{1}{2}} L^{\frac{1}{2}} x) = 0 \quad \Leftrightarrow \quad |S|^{\frac{1}{2}} L^{\frac{1}{2}} x = 0 \tag{4.14}$$

and argue as in the other two cases. The result $\operatorname{ran}(SL) \subset \ker(LS)^\perp$ follows from the fact that $(SL)^* = LS$, and $\operatorname{ran}(SL) \supset \{Be, h\}^\perp$ is a consequence of Lemma 4.9 below. Similar arguments give $\operatorname{ran}(LS)$ and $\operatorname{ran}(L^{\frac{1}{2}} S L^{\frac{1}{2}})$. ∎

Remark 4.4. Since $\{e\} \perp \{Gh\}$, $\{Be\} \perp \{h\}$ and $\{e\} \perp \{G^{\frac{1}{2}} h\}$, the kernels in (4.13) all have dimension $d + q = \dim\{e\} + \dim\{h\}$.

DEFINITION 4.5. *We define the (nonorthogonal) projections* P_1*,* R_1*, and* Q *on* $L^2(\Gamma)$ *via*

$$P_1 \text{ projects along } \{e\} \text{ onto } \{Be\}^\perp, \tag{4.15}$$

$$R_1 \text{ projects along } \{h\} \text{ onto } \{Gh\}^\perp, \tag{4.16}$$

$$Q \text{ projects along } \{e, Gh\} = \ker(SL) \text{ onto } \{Be, h\}^\perp = \operatorname{ran}(SL). \tag{4.17}$$

Remark 4.6. In general, if X and Y are finite dimensional subspaces of the same dimension such that $X \cap Y^\perp = \{0\}$, the projection along X onto $Y^\perp$ exists and is

given by $I-(\cdot,w_k)x_k$ (summation is implied). Here $\{x_k\}$ is a basis for X, $\{y_k\}$ is a basis for Y, $w_k=y_j\alpha_{jk}$, and $(x_i,y_j)\alpha_{jk}=\delta_{ik}$. To verify that P_1, R_1, and Q are well defined, we must check the condition $X\cap Y^\perp=\{0\}$.

Suppose $x\in\{e\}\cap\{Be\}^\perp$. Then $(x,Bx)=-(|B|^{\frac12}x,|B|^{\frac12}x)=0$, which implies $x\in\{h\}$. Since $\{e\}\perp\{h\}$, $x=0$ as required. An identical argument works for R_1.

Suppose $x\in\{e,Gh\}\cap\{Be,h\}^\perp$. Then there is $e_0\in\{e\}$ and $h_0\in\{h\}$ such that $x=e_0+Gh_0$. Since $x\perp\{h\}$ and $e_0\perp h_0$, we have $(x,h_0)=(Gh_0,h_0)=0$. Since G is self-adjoint and positive, this implies $h_0\in\{e\}$ so that $x=e_0+0$. But now we have $x\in\{e\}\cap\{Be\}^\perp$, which implies $x=0$ from the above argument.

Remark 4.7. Note that there are $w_k\in\{Be\}$ and $z_k\in\{Gh\}$ such that

$$P_1=I-\sum_{k=1}^{d}(\cdot,w_k)e_k,\qquad R_1=I-\sum_{k=1}^{q}(\cdot,z_k)h_k. \tag{4.18}$$

As a result, in addition to being bounded in $L^2(\Gamma)$, P_1 is also bounded as an operator on $H^1(\Gamma)$ since the e_k belong to this space. On the other hand, the L^2 adjoint $P_1^*=I-(\cdot,e_k)w_k$ is not necessarily defined on $H^1(\Gamma)$ due to the possibility of singularities in the derivative of w_k near junctions. Similarly, R_1^* is a projection in $H^1(\Gamma)$ while R_1 generally is not due to discontinuities in the h_k at junctions.

Remark 4.8. Q may be written $Q=P_1R_1^*$ since $\{e\}\perp\{Gh\}$ and $\{e\}\perp\{h\}$.

LEMMA 4.9. *The following diagrams are commutative in the sense that for each block* $X\underset{g}{\overset{f}{\rightleftarrows}}Y$ *we have* $f\circ g=id_Y$ *and* $g\circ f=id_{\mathcal{D}(f)}$*:*

(4.19)

$$\{e,G^{\frac12}h\}^\perp\underset{G^{\frac12}}{\overset{L^{\frac12}}{\rightleftarrows}}\{e,Gh\}^\perp\underset{R_1}{\overset{R}{\rightleftarrows}}\{e,h\}^\perp\underset{B}{\overset{S}{\rightleftarrows}}\{Be,h\}^\perp\underset{P_1}{\overset{P}{\rightleftarrows}}\{e,h\}^\perp\underset{G^{\frac12}}{\overset{L^{\frac12}}{\rightleftarrows}}\{e,G^{\frac12}h\}^\perp,$$

$$\{Be,h\}^\perp\underset{P_1}{\overset{P}{\rightleftarrows}}\{e,h\}^\perp\underset{G}{\overset{L}{\rightleftarrows}}\{e,Gh\}^\perp\underset{R_1}{\overset{R}{\rightleftarrows}}\{e,h\}^\perp\underset{B}{\overset{S}{\rightleftarrows}}\{Be,h\}^\perp. \tag{4.20}$$

Proof. P and P_1 both project along $\{e\}$, so $PP_1=P$ and $P_1P=P_1$. Since $\{e\}\perp\{h\}$, both projections leave $\{h\}^\perp$ invariant. Since $\mathrm{ran}(P)=\{e\}^\perp$ and $\mathrm{ran}(P_1)=\{Be\}^\perp$, the blocks involving P and P_1 are commutative. Identical arguments may be used for the blocks involving R and R_1.

Note that if $(x,Gh)=0$, then $(Gx,h)=0$; i.e., G maps $\{Gh\}^\perp$ into $\{h\}^\perp$. Since LG is the identity on $\{e\}^\perp$ (recall $\mathcal{D}(L)=\mathrm{ran}(G)\oplus\{e\}$) and GL is the identity on $\{e\}^\perp\cap\mathcal{D}(L)$, the blocks involving L and G are commutative. Identical arguments may be used for the remaining blocks. ∎

DEFINITION 4.10. *We say that* T *is the* pseudoinverse *of the bounded operator* K *on the Hilbert space* H *if there are closed subspaces* X *and* Y *(not necessarily orthogonal) such that* $H=X\oplus Y$, $\ker(T)=X=\ker(K)$, *and*

$$TKy=y\quad(y\in Y),\qquad KTy=y\quad(y\in Y\cap\mathcal{D}(T)). \tag{4.21}$$

In particular, we require $\mathrm{ran}(K)\subset\mathcal{D}(T)$.

LEMMA 4.11. *Such a* T *is closed.*

Proof. First we claim that $\mathrm{ran}(T)=Y$. Clearly, (4.21) implies $\mathrm{ran}(T)\supset Y$. To prove the reverse inclusion, suppose $x_1+y_1=T(x_2+y_2)$ with $x_i\in X$, $y_i\in Y$. Then $Ky_1=KTy_2=y_2$, so $y_1=TKy_1=Ty_2=x_1+y_1$, which implies $x_1=0$ as required.

Now suppose $a_k \to a$, $Ta_k \to b$. We must show $Ta = b$. Note that $b \in Y$ since each $Ta_k \in Y$ and Y is closed. Decompose $a_k = x_k + y_k$ and $a = x + y$ using $H = X \oplus Y$. Then $y_k \to y$ since the projection along X onto Y is continuous. We also know $y_k = KTy_k = KTa_k \to Kb$ since K is continuous. Thus $y = Kb$ and $a = x + y \in \mathcal{D}(T)$. Finally, $Ta = Ty = TKb = b$ since $b \in Y$. ∎

Remark 4.12. If there is an eigenbasis for K, then it is an eigenbasis for both operators, and the eigenvalues are reciprocal or zero. When K is not self-adjoint, this definition differs from the usual definition in linear algebra that T and K should have the same SVD bases (exchanging left and right singular vectors) with reciprocal (or zero) singular values. The current definition is more useful for eigenvalue problems while the usual one is more useful for least squares problems. The definitions coincide when T and K are self-adjoint.

THEOREM 4.13. *The following pseudoinverse relationships hold:*

$$L^{\frac{1}{2}} S L^{\frac{1}{2}} = \operatorname{pinv}(G^{\frac{1}{2}} Q^* B Q G^{\frac{1}{2}}), \tag{4.22}$$

$$SL = \operatorname{pinv}(QGBQ), \tag{4.23}$$

$$LS = \operatorname{pinv}(Q^* B G Q^*). \tag{4.24}$$

Proof. Since $SR = S$ and $LP = L$, the left-to-right compositions in (4.19) and (4.20) are $L^{\frac{1}{2}} S L^{\frac{1}{2}}$ and SL, respectively. Because P_1 leaves $\{h\}^\perp$ invariant, Q and P_1 agree on $\{h\}^\perp$. Likewise Q^* and R_1 agree on $\{e\}^\perp$, so the right-to-left compositions are $G^{\frac{1}{2}} Q^* B Q G^{\frac{1}{2}}$ and QGQ^*B, respectively.

Clearly, $K := G^{\frac{1}{2}} Q^* B Q G^{\frac{1}{2}}$ annihilates $X := \{e, G^{\frac{1}{2}} h\} = \ker(L^{\frac{1}{2}} S L^{\frac{1}{2}})$, and (4.19) ensures that (4.21) holds with $T := L^{\frac{1}{2}} S L^{\frac{1}{2}}$, $Y := \{e, G^{\frac{1}{2}} h\}^\perp$ as required.

The operator QGQ^*B does not have the same kernel as $T := SL$; however, this is easily corrected using $K := QGQ^*BQ$ instead. We then have $\ker(K) = \ker(T) = \{e, Gh\} =: X$ by (4.13) and (4.17). Equation (4.20) implies that (4.21) holds with $Y := \{Be, h\}^\perp$, which complements X in $L^2(\Gamma)$ since Q is a well-defined projection. Finally, by Remark 4.8 and the identities $R_1^* G R_1 = R_1^* G = G R_1$, $P_1^* B P_1 = P_1^* B = B P_1$, it follows that $QGQ^*BQ = QGBQ$. The proof for LS is similar. ∎

LEMMA 4.14. *Equation* (4.11) *generates an analytic contraction semigroup* $\{\tilde{E}_t : t \geq 0\}$ *of bounded linear operators on* $L^2(\Gamma)$. *For each* $t \geq 0$, $P\tilde{E}_t P = \tilde{E}_t P$.

Proof. We showed that $L^{\frac{1}{2}} S L^{\frac{1}{2}}$ has dense domain in the proof of Lemma 4.3. It is closed by Lemma 4.11 and Theorem 4.13, self-adjoint since L and S are self-adjoint, and negative since S is negative:

$$(x, L^{\frac{1}{2}} S L^{\frac{1}{2}} x) = (L^{\frac{1}{2}} x, S L^{\frac{1}{2}} x) \leq 0. \tag{4.25}$$

Theorem 4.1 may therefore be applied to conclude that $L^{\frac{1}{2}} S L^{\frac{1}{2}}$ is the generator of an analytic contraction semigroup $\{\tilde{E}_t : t \geq 0\}$ of bounded linear operators. Since $\operatorname{ran}(L^{\frac{1}{2}} S L^{\frac{1}{2}}) \subset \{e\}^\perp$, for $y_0 \in L^2(\Gamma)$ we have

$$(\tilde{E}_t y_0, e_k) = (\tilde{E}_0 y_0, e_k) + \int_0^t (L^{\frac{1}{2}} S L^{\frac{1}{2}} \tilde{E}_s y_0, e_k)\, ds = (y_0, e_k). \tag{4.26}$$

Hence $\tilde{E}_t$ leaves $\{e\}^\perp$ invariant, and $P\tilde{E}_t P = \tilde{E}_t P$ as claimed. ∎

THEOREM 4.15. *The family* $\{E_t : t \geq 0\}$ *given by*

$$E_t = (I - P_1) + P_1 G^{\frac{1}{2}} \tilde{E}_t L^{\frac{1}{2}} \tag{4.27}$$

is an analytic semigroup in $H^1(\Gamma)$. Its infinitesimal generator is SL.

Proof. Since $G^{\frac12}$ is bounded from L^2 to H^1, $L^{\frac12}$ is bounded from H^1 to L^2, and P_1 is bounded in H^1, there is a $C>0$ such that $\|P_1G^{\frac12}\tilde E_tL^{\frac12}\|_{H^1}\le C\|\tilde E_t\|_{L^2}$; therefore, each E_t is bounded in $H^1(\Gamma)$. Property (4.4)(iii) follows similarly: pick $x\in H^1$, and let $y=L^{\frac12}x$; then we have

$$\|(E_t-E_s)x\|_{H^1}=\|P_1G^{\frac12}(\tilde E_t-\tilde E_s)y\|_{H^1}\le C\|(\tilde E_t-\tilde E_s)y\|_{L^2}\underset{t\to s}{\longrightarrow}0. \tag{4.28}$$

Properties (4.4)(i) and (4.4)(ii) follow immediately from (4.27) and the corresponding properties of $\tilde E$, using the relations

$$P_1P=P_1,\quad PP_1=P,\quad L^{\frac12}=L^{\frac12}P,\quad G^{\frac12}L^{\frac12}=P=L^{\frac12}G^{\frac12},\quad P\tilde E_sP=\tilde E_sP. \tag{4.29}$$

The analyticity may be seen by computing

$$\limsup_{t\to0}t\|E_t'\|_{H^1}\le C\limsup_{t\to0}t\|\tilde E_t'\|_{L^2}<\infty. \tag{4.30}$$

To prove that the generator of E_t is SL, we first note that

$$L^{\frac12}E_t=L^{\frac12}P_1G^{\frac12}\tilde E_tL^{\frac12}=P\tilde E_tL^{\frac12}=\tilde E_tL^{\frac12} \tag{4.31}$$

and compute

$$E_t'=P_1G^{\frac12}\big(L^{\frac12}SL^{\frac12}\tilde E_t\big)L^{\frac12}=P_1PSL^{\frac12}\big(L^{\frac12}E_t\big)=P_1SLE_t=SLE_t. \tag{4.32}$$

∎

Proposition 4.16. *There is a Riesz basis $\{\phi_k\}$ for $H^1(\Gamma)$ and a nonincreasing, unbounded sequence of numbers $\lambda_k\le0$ such that $SL\phi_k=\lambda_k\phi_k$.*

Proof. Since $G^{\frac12}Q^*BQG^{\frac12}$ is self-adjoint and compact, the spectral theorem gives an L^2 orthonormal basis of eigenfunctions $\{\varphi_k\}_{k=1}^\infty$, which by Theorem 4.13 is also an eigenbasis of $L^{\frac12}SL^{\frac12}$: φ_k is either in the kernel of both operators, or it is an eigenfunction of each with reciprocal eigenvalues. Since S is negative, the eigenvalues λ_k of $L^{\frac12}SL^{\frac12}$ satisfy $\lambda_k\le0$. Since $L^{\frac12}SL^{\frac12}$ commutes with P, we may assume the φ_k are also eigenfunctions of P (with eigenvalue 0 or 1). Define

$$\phi_k=\begin{cases}\varphi_k, & P\varphi_k=0,\\ P_1G^{\frac12}\varphi_k & \text{otherwise.}\end{cases} \tag{4.33}$$

In the first case we have $SL\phi_k=0$. In the second, we obtain

$$SLP_1G^{\frac12}\varphi_k=SL^{\frac12}\varphi_k=P_1SL^{\frac12}\varphi_k=P_1G^{\frac12}L^{\frac12}SL^{\frac12}\varphi_k=\lambda_kP_1G^{\frac12}\varphi_k. \tag{4.34}$$

The ϕ_k are related to the φ_k via

$$\phi_k=\big[(I-P)+P_1G^{\frac12}\big]\varphi_k,\qquad \varphi_k=\big[(I-P_1)+L^{\frac12}\big]\phi_k. \tag{4.35}$$

Since $[I-P+P_1G^{\frac12}]$ is bounded from $L^2(\Gamma)$ to $H^1(\Gamma)$ and its inverse $[I-P_1+L^{\frac12}]$ is bounded in the other direction, they are isomorphisms. Thus the ϕ_k form a Riesz basis (a basis equivalent to an orthonormal basis [6]) for $H^1(\Gamma)$ as claimed. ∎

Remark 4.17. Equation (4.27) could also have been written

$$E_t=[I-P+P_1G^{\frac12}]\,\tilde E_t\,[I-P_1+L^{\frac12}]. \tag{4.36}$$

Remark 4.18. For $\eta_0 \in H^1(\Gamma)$, the coefficients in the expansion $\eta_0 = \sum_k a_k \phi_k$ can be determined via

$$a_k = ([I - P_1 + L^{\frac{1}{2}}]\eta_0, \varphi_k)_{L^2} = (\eta_0, \phi_k^*)_{L^2}, \qquad \phi_k^* = [I - P_1^* + L^{\frac{1}{2}}]\varphi_k. \tag{4.37}$$

The ϕ_k^* are eigenfunctions of LS with eigenvalues λ_k since $LS\phi_k^* = [(SL - P_1 SL)^* + LSL^{\frac{1}{2}}]\varphi_k = \lambda_k L^{\frac{1}{2}}\varphi_k = \lambda_k \phi_k^*$. They belong to $L^2(\Gamma)$ but need not belong to $H^1(\Gamma)$ due to possible singularities in $\partial_s \phi_k^*$ at junctions. For $\eta_0 \in H^1(\Gamma)$ the expansions

$$\eta_0 = \sum_{k=1}^{\infty} a_k \phi_k, \qquad E_t \eta_0 = \sum_{k=1}^{\infty} a_k e^{\lambda_k t}\phi_k, \qquad a_k = (\eta_0, \phi_k^*)_{L^2(\Gamma)}, \tag{4.38}$$

hold in $H^1(\Gamma)$. Note that the L^2 norm of ϕ_k^* diverges as $k \to \infty$, but when $\eta_0 \in H^1(\Gamma)$, the inner products a_k in (4.38) do not; they are square summable.

Remark 4.19. The expansions (4.38) lead to a useful numerical method in which the ϕ_k, ϕ_k^*, and λ_k are computed by approximating the pseudoinverse $\mathrm{pinv}(SL) = QGBQ$ using a singularity-capturing least squares finite element method; see [12, 9].

PROPOSITION 4.20. $\lim_{t\to\infty} E_t = I - Q$ *in norm.*

Proof. Recall that $\dim\ker(SL) = d + q$ so that $\lambda_1 = \cdots = \lambda_{d+q} = 0$. Since $\{\phi_k\}_{k=1}^{d+q}$ is a basis for $\mathrm{range}(I - Q)$, we have

$$[E_t - (I - Q)]\eta_0 = \sum_{k=d+q+1}^{\infty} a_k e^{\lambda_k t}\phi_k. \tag{4.39}$$

Since the mapping $\eta_0 \mapsto \langle a_k\rangle_{k=1}^{\infty}$ with $a_k = (\eta_0, \phi_k^*)_{L^2}$ is an isomorphism from $H^1(\Gamma)$ to l^2, there is a constant C such that

$$\|(E_t - I + Q)\eta_0\|_{H^1} \le Ce^{\lambda^* t}\|\eta\|_{H^1} \qquad (t \ge 0,\ \eta_0 \in H^1(\Gamma)) \tag{4.40}$$

with $\lambda^* = \lambda_{d+q+1} < 0$. Thus $\|E_t - (I - Q)\|_{H^1} \le Ce^{\lambda^* t} \to 0$ as $t \to \infty$ as claimed. ∎

Remark 4.21. Since E_t is an operator on $H^1(\Gamma)$ and the formula for the evolution of normal stress is given by

$$\eta(t) = E_t(\eta_0 + \psi) - \psi, \tag{4.41}$$

we should verify that ψ belongs to $H^1(\Gamma)$. This is done in the companion paper [13].

Remark 4.22. Since E_t is analytic, we have $\mathrm{ran}(E_t) \subset \mathcal{D}(SL)$ for all $t > 0$. Therefore $\eta(t)$ in (4.41) has the property that

$$\eta(t) + \psi \in \mathcal{D}(L) \qquad (t > 0). \tag{4.42}$$

Thus although ψ does not necessarily satisfy zero flux boundary conditions at junctions, the normal stress η immediately compensates so that for all $t > 0$, flux balance holds. As long as there is a displacement jump $g(t)$ compatible with the evolution of $\eta(t)$, we have proved that the grain boundary diffusion problem is well posed.

4.3. The evolution of *g*. In the nondegenerate case, the evolution of g is easily determined from the evolution of η in (4.41) via

$$g(t) = B\eta(t) \qquad \text{(nondegenerate case)}. \tag{4.43}$$

The situation becomes much more complicated (and rather interesting) in the degenerate situation where the subspace $\{h\} = \ker(S) = \ker(B)$ is nontrivial. In that case, each function in $\{h\}$ is a growth mode which is not suppressed by the grain boundary diffusion process. If such a mode h is activated by ψ, it will grow linearly in time without bound, as will the corresponding $\mathbf{u} \in H_d$ such that $\gamma_n \mathbf{u} = h$; see Definition 3.5. The nonlinear picture in which $\mathbf{u}$ is replaced by a collection of genuine (as opposed to infinitesimal) rigid body motions on each grain resembles continental drift in plate tectonics, at least superficially. The steady state stress distribution does not fully cancel the flux due to electromigration, and material is continually transported around the participating grains, causing them to drift in order to avoid misfit with their neighbors as material is removed from one side and deposited on the other.

THEOREM 4.23. *The evolution of g is given by*

$$g(t) = R_1 B\eta(t) + (I - R_1)g_0 + [(I - R_1)L\psi]t. \tag{4.44}$$

Proof. Recall that the projections R and R_1 may be written

$$R = I - \sum_{k=1}^{q} (\cdot, h_k)h_k, \quad R_1 = I - \sum_{k=1}^{q} (\cdot, z_k)h_k \quad \big(h_k \in \{h\}, z_k \in \{Gh\}\big). \tag{4.45}$$

Note that $(I - R_1)L = \sum_{k=1}^{q} (\cdot, Lz_k)h_k$ is actually a bounded operator on $L^2(\Gamma)$, so its domain may be extended from $\mathcal{D}(L)$ to $L^2(\Gamma)$. Since $\ker(S) = \{h\}$, we see that $S(I - R_1) = 0$. Therefore

$$Sg = SB\eta = R\eta = \eta, \tag{4.46}$$

where the last step follows from the fact that $\eta_0 := Sg_0 \in \operatorname{ran}(R)$ and

$$\eta_t = SL(\eta + \psi) \quad \Rightarrow \quad \eta - \eta_0 \in \operatorname{ran}(SL) \subset \operatorname{ran}(R). \tag{4.47}$$

We next use $R_1 R = R_1$ and $BS = R\big|_{\mathcal{D}(S)}$ to conclude that

$$g(0) = R_1 BSg_0 + (I - R_1)g_0 = g_0. \tag{4.48}$$

Finally, we check that g solves the evolution equation $g_t = L(Sg + \psi)$:

$$\begin{aligned} g_t &= R_1 BSL(\eta + \psi) + (I - R_1)L\psi \\ &= R_1 L(Sg + \psi) + (I - R_1)L\psi \\ &= L(Sg + \psi) - [(I - R_1)L](Sg + \psi - \psi) \\ &= L(Sg + \psi). \end{aligned} \tag{4.49}$$

In the last step, we used the fact that $(I - R_1)LSg = 0$ since $\operatorname{ran}(LS) \subset \{Gh\}^{\perp} = \ker(I - R_1)$ by (4.13) and (4.16). In the second-to-last step we were careful not to break up $(I - R_1)L$ when acting on ψ since the latter may not belong to the domain of L. In contrast, the function $(Sg + \psi)$ belongs to $\mathcal{D}(L)$ for $t > 0$, as discussed in Remark 4.22. ∎

Remark 4.24. Once $g(t)$ is known, the stress and displacement fields inside the grains are uniquely determined as the solution to the grain boundary displacement jump problem; see Definition 3.24 and Theorem 3.25.

5. Conclusion. The stress-driven grain boundary diffusion problem involves coupling many different equations and phenomena that lead to interesting behavior due to the interplay between nonlocality, singular behavior, and complex geometry. By posing the problem as an evolution of functions defined on the grain boundary, we were able to use methods of semigroup theory to answer fundamental questions of existence, uniqueness, and appropriateness of boundary conditions. In the process, we discovered a class of degenerate grain boundaries that exhibit interesting behavior.

Placing this problem back into the larger model, which includes void and vacancy evolution, grain boundary sliding, etc., it would be interesting to study the behavior of the solution in the vicinity of a junction where a void meets a grain boundary. Here again, questions of appropriate boundary conditions arise, thermodynamic arguments are murky, and singularities in the stress tensor and electric field together with the stiffness inherent in grain boundary diffusion and curvature-driven surface diffusion make the problem difficult to attack theoretically and numerically.

ON THE EVOLUTION OF DOMAIN WALLS IN HARD FERROMAGNETS*

PAOLO PODIO-GUIDUGLI† AND GIUSEPPE TOMASSETTI†

Abstract. We propose a sharp-interface theory for the dynamics of domain walls in highly anisotropic ("hard") ferromagnetic bodies. Starting from the Gilbert equation, we consider the asymptotic regime when the hardness parameter goes to infinity, and we use the technique of matched expansions to derive a system of two evolution equations for the domain wall, regarded as a smooth surface. The first equation, apart for a nonlocal forcing term, has the standard form for a surface set in motion according to its mean curvature. The second relates the normal velocity to the internal structure of the domain wall.

Key words. micromagnetics, domain walls, matched asymptotic expansions, motion by curvature

1. Introduction.

The formation and the evolution of magnetic domains are the core subject in the mathematical modeling of saturated ferromagnetic bodies. A *magnetic domain* is a region in space where, at a given time, the *magnetization*, a unit vector, has constant direction. Adjacent domains are separated by thin zones where the magnetization direction undergoes large spatial changes; for all practical purposes, these zones can be modeled as sharp interfaces, the *domain walls*. Magnetic domains and their walls are collectively referred to as *domain-wall structures*.

Domain structures are usually observed in static circumstances. To predict their evolution is the goal of *dynamic micromagnetics*, a discipline that was first constituted as a chapter of continuum mechanics in 1963 by Brown [4]. Brown, building on a path-breaking paper by Landau and Lifshitz [16] that appeared in 1935, coined the name "micromagnetics" for the study in a variational format of the static problem of domain formation; it seems that the term "dynamic micromagnetics" was first used in [6], in 1996.

The variational theory of micromagnetics interprets domain structures as the result of minimizing a suitable energy functional [4, 18, 2, 13]. In particular, the occurrence of patchwise-constant energy minimizers accounts for the formation of magnetic domains and domain walls. Dynamic micromagnetics is a much less developed theory, centered about the *(Landau–Lifshitz–) Gilbert equation* [16, 9, 22], a nonlinear parabolic PDE that rules the evolution of the magnetization in a rigid ferromagnet (or, more generally, in a ferromagnet being at mechanical rest, in a sense made precise in [6, 3]). The existence of global-in-time weak solutions to this equation has been established [29, 3], as has their characteristic nonuniqueness [1]; their form has been studied numerically [20].

Here we concentrate on the evolution problem of domain walls, however they were

formed. We propose to view a domain wall as a smooth surface $\mathcal{S}$ whose dynamics, in the absence of deformations, is a direct consequence of the Gilbert equation alone. Implementing a way to obtain an evolution equation for $\mathcal{S}$ first proposed in [27] (see also [28]), we take the anisotropy modulus as the parameter inducing the asymptotic regime we consider, and we assume that a solution to the Gilbert equation can be constructed by matching two regular expansions, the one holding in a tubular neighborhood of $\mathcal{S}$, the other away from $\mathcal{S}$; roughly speaking, the matching conditions yield the desired evolution equation. This equation has the form, apart for the typically nonlocal forcing term, of the classic equation of motion of a surface by its own curvature.

Hubert and Schäfer [13, p. 215] describe well the role and significance to be ascribed to micromagnetics: "The calculation of domain wall structures is by far the most important contribution of micromagnetics to the analysis of magnetic domains. This is true for two reasons: experimentally, domain walls are difficult to access because they change their properties at surfaces where they can be primarily observed. Also, it is in most cases difficult to isolate a single wall from its neighbours to measure its properties. Usually, domain walls interact in a complicated network." In connection with this last remark, we believe that our finding an evolution equation for a single wall opens the way to a study of wall junctions.

Our paper is organized as follows. In section 2 we detail the form of the Gilbert equation on which we base our study. In section 3 we illustrate the static solution of the Gilbert equation due to Landau and Lifshitz [16], a suitable preliminary to a dynamic solution that we also illustrate, the traveling-wave solution, first discovered by Walker [30], which mimics the motion of a flat wall in an infinite body under the action of a uniform external magnetic field parallel to the wall plane. In section 4 we delineate the asymptotic regime under which our motion equations will emerge as a consequence of the Gilbert equation. In sections 5 and 6 we address the derivation of those equations using the method of matched asymptotic expansions. Both our approach and our methods, as well as our results, differ from those of authors who have looked at the same problem before us (and in greater generality, because they have not ignored mechanical deformation, as we do). We briefly discuss their findings, and compare them with ours, in section 7.

2. The Gilbert equation. For a rigid and saturated ferromagnetic body, here identified for short with a domain Ω of $\mathbb{R}^3$, the evolution of the magnetization $\mathbf{m}$, a unimodular vector field on $\Omega \times (0,T)$, is modeled by the Landau–Lifshitz equation, which we write in the Gilbert format:

$$\gamma^{-1}\dot{\mathbf{m}} = \mathbf{m} \times (\mathbf{h}_{\text{eff}} + \mathbf{d}) \quad \text{in } \Omega \times (0,T), \quad \gamma < 0, \tag{2.1}$$

where γ is the opposite of the *gyromagnetic ratio*, $\mathbf{h}_{\text{eff}}$ is the *effective field*, and $\mathbf{d}$ is the *dissipation field* [9, 21].

For the effective field, we take

$$\mathbf{h}_{\text{eff}} = \alpha\Delta\mathbf{m} + \beta(\mathbf{e}\cdot\mathbf{m})\mathbf{e} + \mathbf{h} + \mathbf{h}_{\text{ext}}. \tag{2.2}$$

Here, (i) $\alpha > 0$ is the *exchange constant*, $\beta > 0$ the *anisotropy constant*, and $\mathbf{e}$ a unit vector parallel to the *easy axis* of magnetization of the material; (ii) $\mathbf{h}$ is the *stray field*, defined to be the only $L^2(\mathbb{R}^3)$ solution of the *Maxwell equations* in the quasi-static approximation, namely,

$$\operatorname{curl}\mathbf{h} = \mathbf{0}, \quad \operatorname{div}\mathbf{h} = -\operatorname{div}(\chi_\Omega\mathbf{m}) \quad \text{in } \mathbb{R}^3 \times (0,T), \tag{2.3}$$

with χ_Ω the characteristic function of Ω; and (iii) $\mathbf{h}_{\text{ext}}$ is the *external field*, a forcing term that can be chosen at will. Our choice for the dissipation field is standard:

$$\mathbf{d} = -\mu\dot{\mathbf{m}}, \quad \mu > 0, \tag{2.4}$$

with μ the *dissipation constant*. (See [21] for a discussion of other thermodynamically admissible dissipation mechanisms in ferromagnets.) As explained in the appendix to [27],

$$\dim[\gamma] = (\text{time})^{-1}, \quad \dim[\mu] = \text{time}, \quad \dim[\alpha] = (\text{length})^2,$$

and β is dimensionless; consequently, both $\mathbf{h}$ and $\mathbf{h}_{\text{ext}}$ are dimensionless as well.

With these constitutive prescriptions, the Gilbert equation takes the form we study here, namely,

$$\gamma^{-1}\dot{\mathbf{m}} + \mu\mathbf{m}\times\dot{\mathbf{m}} = \mathbf{m}\times(\alpha\Delta\mathbf{m} + \beta(\mathbf{m}\cdot\mathbf{e})\mathbf{e} + \mathbf{h} + \mathbf{h}_{\text{ext}}) \quad \text{in } \Omega\times(0,T). \tag{2.5}$$

In the next section we review some known explicit and exact solutions to this equation.

3. Flat walls. Consider an infinite body ($\Omega \equiv \mathbb{R}^3$) composed of a uniaxial material so oriented as to have $\mathbf{e} = \mathbf{c}_3$ (with $\mathbf{c}_3$ the third vector of a given orthonormal basis), and look for solutions

$$\mathbf{m} = \mathbf{m}(x_1, t) \tag{3.1}$$

of the Gilbert equation (2.5) whose spatial dependence is only through the first coordinate x_1 of the typical point $\mathbf{x} \in \Omega$ and such that

$$\lim_{x_1\to\pm\infty} \mathbf{m}(x_1, t) = \pm\mathbf{c}_3$$

at all times t. For such solutions, the Maxwell equations (2.3) yield

$$\mathbf{h}(x_1, t) = -(\mathbf{m}(x_1, t)\cdot\mathbf{c}_1)\mathbf{c}_1 + \mathbf{h}_\infty(t). \tag{3.2}$$

We dispose of the space constant $\mathbf{h}_\infty$ by asking that

$$\lim_{x_1\to\pm\infty} \mathbf{h}(x_1, t) = \mathbf{0} \tag{3.3}$$

at all times. The Gilbert equation then becomes

$$\gamma^{-1}\dot{\mathbf{m}} + \mu\mathbf{m}\times\dot{\mathbf{m}} = \mathbf{m}\times(\alpha\mathbf{m}'' + \mathbf{T}\,\mathbf{m}) \quad \text{in } \mathbb{R}\times(0,T), \tag{3.4}$$

where $(\cdot)'$ denotes differentiation with respect to x_1 and where

$$\mathbf{T} = \beta\mathbf{c}_3\otimes\mathbf{c}_3 - \mathbf{c}_1\otimes\mathbf{c}_1. \tag{3.5}$$

3.1. The static solution of Landau and Lifshitz. A time-independent solution of type (3.1) was found by Landau and Lifshitz [16] for the case when the external field is everywhere null. In this case (3.4) becomes

$$\mathbf{0} = \mathbf{m}\times(\alpha\mathbf{m}'' + \mathbf{T}\,\mathbf{m}) \quad \text{in } \mathbb{R}. \tag{3.6}$$

If we parametrize $\mathbf{m}$ by means of two scalar fields ϑ and φ (Figure 3.1) such that

$$\begin{aligned} \mathbf{m}(\vartheta,\varphi) &= \cos\vartheta\,\mathbf{c}_3 + \sin\vartheta\,\mathbf{t}(\varphi), \quad \vartheta\in[0,\pi], \\ \mathbf{t}(\varphi) &= \sin\varphi\,\mathbf{c}_1 + \cos\varphi\,\mathbf{c}_2, \quad \varphi\in[-\pi,\pi[, \end{aligned} \tag{3.7}$$

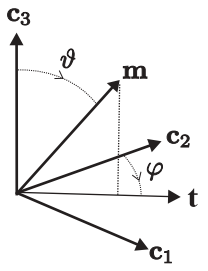

FIG. 3.1. *Parametrization of* $\mathbf{m}$.

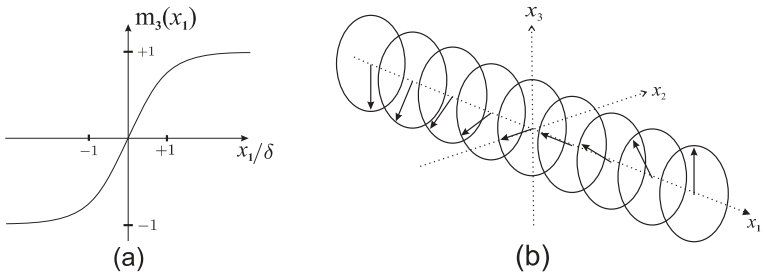

FIG. 3.2. *Wall profile.*

then the Landau–Lifshitz solution has the form

$$\begin{aligned} &\vartheta(x_1) = \arccos \tanh \frac{x_1}{\delta}, \\ &\varphi(x_1) = 0 \end{aligned} \tag{3.8}$$

with

$$\delta = \left(\frac{\alpha}{\beta}\right)^{\frac{1}{2}}. \tag{3.9}$$

Landau and Lifshitz found this solution by minimizing over the set of unimodular vector fields $\mathbf{m}$ on $\mathbb{R}$ the functional

$$\mathbf{m} \mapsto \int_{-\infty}^{+\infty} \left(\alpha|\mathbf{m}'|^2 - \mathbf{m}\cdot\mathbf{T}\mathbf{m}\right) dx_1,$$

whose Euler–Lagrange equation is (3.6). We see from (3.8) that, at a large distance from the origin (that is to say, for $|x_1/\delta| \gg 1$), the magnetization is nearly parallel to the easy axis ($\mathbf{m}(x_1) \times \mathbf{e} \simeq \mathbf{0}$), its direction being determined by the sign of x_1. The body can be thought of as partitioned into two infinite *magnetic domains*, $x_1 < -\delta$ (where $\mathbf{m} \simeq \mathbf{e}$) and $\delta < x_1$ (where $\mathbf{m} \simeq -\mathbf{e}$), separated by the *domain wall*, a transition layer of thickness 2δ within which the magnetization undergoes most of its overall 180° rotation in a plane perpendicular to $\mathbf{c}_1$ (Figure 3.2); the accompanying stray field is everywhere null. The situation depicted in Figure 3.2(b) is commonly referred to as a *Bloch wall*.

3.2. Walker's dynamic solution. The Landau–Lifshitz solution was generalized by Walker [30] to the case when the external field has the form

$$\mathbf{h}_{\text{ext}} = -H\,\mathbf{c}_3 \tag{3.10}$$

with H a real constant such that

$$|H| < \frac{1}{2}\gamma\mu. \tag{3.11}$$

The traveling-wave solution found by Walker is

$$\begin{aligned} \vartheta(x_1,t) &= \arccos\tanh\frac{x_1 - v_H t}{\delta_H}, \\ \varphi(x_1,t) &= \varphi_H. \end{aligned} \tag{3.12}$$

The Walker solution coincides with the Landau–Lifshitz solution for an observer moving with velocity $v_H\mathbf{c}_1$ because, at each time t, the dissipation associated with the evolution of the magnetization $\mathbf{m}$ is exactly compensated by the working of the external field $\mathbf{h}_{\text{ext}}$ [23]. For Walker, the vector $\mathbf{m}$ must lie in a plane through the easy axis forming an angle φ_H with the plane of the domain wall such that

$$\sin(2\varphi_H) = -\frac{2}{\gamma\mu}\,H, \tag{3.13}$$

whence the bounds (3.11) on the applied field H; $\mathbf{m}$ is nearly parallel to the easy axis, everywhere except in a layer whose thickness is of the order

$$\delta_H = \left(\frac{\alpha}{\beta + \sin^2\varphi_H}\right)^{\frac{1}{2}} \tag{3.14}$$

(cf. $(3.8)_2$ and (3.9)).

All in all, the Walker solution pictures a flat domain wall moving with velocity

$$v_H = \frac{1}{\mu}\left(\frac{\alpha}{\beta + \sin^2\varphi_H}\right)^{\frac{1}{2}} H \tag{3.15}$$

in the direction of the x_1-axis.[1]

What we learn from this explicit solution of the Gilbert equation is that two material parameters happen to be of special importance in the dynamics of domain walls: the *wall thickness* δ and the *wall mobility*

$$\nu := \lim_{H\to 0}\frac{v_H}{H} = \frac{\delta}{\mu}\,. \tag{3.16}$$

Indeed, these two parameters play a crucial role in tuning the asymptotics yielding our sharp-interface theory, what we do in the next section.

4. Basic scalings. Given a length scale L and a time scale T, we introduce the dimensionless independent variables

$$\tilde{\mathbf{x}} = L^{-1}\mathbf{x}, \quad \tilde{t} = T^{-1}t. \tag{4.1}$$

Then, the material parameters in the Gilbert equation (2.5) scale as

$$\tilde{\gamma} = T\gamma, \quad \tilde{\mu} = T^{-1}\mu, \quad \tilde{\alpha} = L^{-2}\alpha. \tag{4.2}$$

[1] Combining (3.15) with (3.11) yields a bound on $|v_H|$, referred to as the "breakdown velocity" [13].

As noted in section 2, the anisotropy constant β carries no dimension and hence is not affected by the scaling (4.1). A dimensionless version of the Gilbert equation (2.5) is

$$\beta\,\tilde{\delta}^{-1}\,\tilde{\nu}(\tau\,\dot{\mathbf{m}}+\mathbf{m}\times\dot{\mathbf{m}})=\mathbf{m}\times(\tilde{\delta}^2\Delta\mathbf{m}+(\mathbf{m}\cdot\mathbf{e})\mathbf{e}+\beta^{-1}(\mathbf{h}+\mathbf{h}_{\rm ext})), \tag{4.3}$$

where the dimensionless wall thickness and mobility are defined by

$$\tilde{\delta}=\left(\frac{\tilde{\alpha}}{\beta}\right)^{\frac{1}{2}},\quad \tilde{\nu}=\frac{\tilde{\delta}}{\tilde{\mu}}, \tag{4.4}$$

and where

$$\tau=(\gamma\mu)^{-1}. \tag{4.5}$$

The physical assumption that underlies our sharp-interface theory under construction is that *β is as large as necessary to make the wall thickness as small as desired*. One way to achieve this is to identify our smallness parameter with β^{-1}:

$$\beta=\varepsilon^{-1}. \tag{4.6}$$

Then, we stipulate that *the dimensionless wall thickness scales like ε and the dimensionless wall mobility scales like* 1:

$$\tilde{\delta}=\varepsilon,\quad \tilde{\nu}=1. \tag{4.7}$$

To achieve this, we choose L and T as follows:

$$L=\varepsilon^{-1/2}\,\alpha^{1/2},\quad T=\varepsilon^{-1}\mu. \tag{4.8}$$

With these choices, (4.3) becomes

$$\varepsilon^2\,(\tau\,\dot{\mathbf{m}}+\mathbf{m}\times\dot{\mathbf{m}})=\mathbf{m}\times\left(\varepsilon^2\Delta\mathbf{m}+(\mathbf{e}\cdot\mathbf{m})\mathbf{e}+\varepsilon(\mathbf{h}+\mathbf{h}_{\rm ext})\right). \tag{4.9}$$

When ε is small, exchange interactions become negligible with respect to anisotropy interactions, and we expect $\mathbf{m}$ to quickly converge toward a local minimum of the anisotropy energy. Hence, in a short time, the region Ω presents itself as partitioned into magnetic domains, in each of which $\mathbf{m}$ is nearly parallel to $\mathbf{e}$. Thin transition layers, the domain walls, separate neighboring domains with opposite magnetization. As anticipated in the introduction, we disregard the process of domain formation and focus on the evolution of domain boundaries, in the limit for $\varepsilon\downarrow 0$ when they are expected to become surfaces. To simplify matters, we take $\Omega=\mathbb{R}^3$ so that the Maxwell equations take the form

$$\operatorname{curl}\mathbf{h}=\mathbf{0},\quad \operatorname{div}(\mathbf{h}+\mathbf{m})=0\quad \text{in } \mathbb{R}^3\times(0,T) \tag{4.10}$$

and need not be scaled.

5. Time and space differentiation following a moving surface. Let $\mathcal{S}_t=\mathcal{S}(t)$ be a smooth oriented surface, smoothly evolving over the time interval $\mathcal{T}\subset(0,T)$. For each $t\in\mathcal{T}$, let $\mathcal{W}_t$ be a *tubular neighborhood* of $\mathcal{S}_t$ of thickness $2h_t$, that is to say, an open set of $\mathbb{R}^3$ in one-to-one correspondence with the set $\mathcal{S}_t\times(-h_t,+h_t)$ by way of the mapping

$$\mathcal{S}_t\times(-h_t,+h_t)\ni(\mathbf{s},d)\ \leftrightarrow\ \mathbf{s}+d\,\mathbf{n}_t(\mathbf{s})=\mathbf{x}\in\mathcal{W}_t, \tag{5.1}$$

where $\mathbf{n}_t(\mathbf{s})$ denotes the positively oriented unit normal to $\mathcal{S}_t$ at its point $\mathbf{s}$. We take $\mathcal{T}$ short enough for the set

$$\mathcal{W} := \bigcap_{t\in\mathcal{T}} \mathcal{W}_t$$

to be open and nonempty; needless to say, $\mathcal{W}$ contains a tubular neighborhood of $\mathcal{S}_t$ for all $t \in \mathcal{T}$. For each $\mathbf{x} \in \mathcal{W}$ and for each $t \in \mathcal{T}$, we denote by $\hat{\mathbf{s}}_t$ the *projection* of $\mathbf{x}$ on $\mathcal{S}_t$ and by $\hat{d}_t$ the *signed distance* of $\mathbf{x}$ from $\mathcal{S}_t$. Precisely, we set

$$\mathbf{s} = \hat{\mathbf{s}}_t(\mathbf{x}), \quad d = \hat{d}_t(\mathbf{x}); \tag{5.2}$$

we also set, consistently,

$$\mathbf{n} = \hat{\mathbf{n}}_t(\mathbf{x}) := \mathbf{n}_t(\hat{\mathbf{s}}_t(\mathbf{x})). \tag{5.3}$$

5.1. Some preparatory results. For each $\varepsilon > 0$ fixed, we introduce the *scaled* signed distance

$$r_\varepsilon = \hat{r}_\varepsilon(\mathbf{x}, t) := \varepsilon^{-1}\hat{d}_t(\mathbf{x}) \tag{5.4}$$

and consider the following identity over $\mathcal{W} \times \mathcal{T}$:

$$\hat{\mathbf{s}}_t(\mathbf{x}) + \varepsilon\, \hat{r}_\varepsilon(\mathbf{x}, t)\, \hat{\mathbf{n}}_t(\mathbf{x}) = \mathbf{x}. \tag{5.5}$$

Differentiating (5.5) with respect to t and taking the scalar product of both sides with $\mathbf{n}$ we get

$$r_\varepsilon^{\bullet} = -\varepsilon^{-1} v, \tag{5.6}$$

where

$$v = \hat{v}_t(\mathbf{x}) := \hat{\mathbf{s}}_t^{\bullet}(\mathbf{x}) \cdot \hat{\mathbf{n}}_t(\mathbf{x}) \tag{5.7}$$

is the *normal velocity* of the surface $\mathcal{S}_t$ at point $\hat{\mathbf{s}}_t(\mathbf{x})$.

Differentiating (5.5) with respect to $\mathbf{x}$ and using the fact that

$$\operatorname{grad} d = \mathbf{n}, \tag{5.8}$$

we obtain that

$$\operatorname{grad}\mathbf{s} = \mathbf{P} - \varepsilon\, r_\varepsilon \operatorname{grad}\mathbf{n}, \quad \mathbf{P} = \hat{\mathbf{P}}_t(\mathbf{x}) := \mathbf{1} - \hat{\mathbf{n}}_t(\mathbf{x}) \otimes \hat{\mathbf{n}}_t(\mathbf{x}). \tag{5.9}$$

Next, we differentiate with respect to $\mathbf{x}$ relation (5.3) and use the chain rule to get

$$\operatorname{grad}\mathbf{n} = (\partial_{\mathbf{s}}\mathbf{n}_t)\operatorname{grad}\mathbf{s} = -\mathbf{L}\operatorname{grad}\mathbf{s}, \tag{5.10}$$

where the *Weingarten tensor* $\mathbf{L}$ of the surface $\mathcal{S}_t$ can be thought of as a tensor field over $\mathcal{W} \times \mathcal{T}$ according to the following definition:

$$\mathbf{L} = \hat{\mathbf{L}}_t(\mathbf{x}) := -\partial_{\mathbf{s}}\mathbf{n}_t\,|_{\mathbf{s}=\hat{\mathbf{s}}_t(\mathbf{x})}. \tag{5.11}$$

As is well known,

$$\mathbf{LP} = \mathbf{L}. \tag{5.12}$$

Combining (5.9), (5.10), and (5.12), we arrive at

$$\operatorname{grad}\mathbf{n} = -\mathbf{L} + \varepsilon\, r_\varepsilon\, \mathbf{L}\operatorname{grad}\mathbf{n}. \tag{5.13}$$

We take the trace of both sides of (5.13) and obtain

$$\operatorname{div}\mathbf{n} = -k + \varepsilon\, r_\varepsilon\, \mathbf{L}\cdot\operatorname{grad}\mathbf{n}, \tag{5.14}$$

where

$$k = \hat{k}_t(\mathbf{x}) := \operatorname{tr}\hat{\mathbf{L}}_t(\mathbf{x}) \tag{5.15}$$

is twice the mean curvature of $\mathcal{S}_t$ at point $\mathbf{s} = \hat{\mathbf{s}}_t(\mathbf{x})$.

5.2. Time rate, gradient, Laplacian, and curl of a vector field. Let now

$$\mathbf{v} = \mathbf{v}(\mathbf{x}, t)$$

be a smooth vector field over $\mathbb{R}^3 \times \mathcal{T}$. For each $\varepsilon > 0$ fixed, the *inner representation* of $\mathbf{v}$ is delivered by the map $\check{\mathbf{v}}_\varepsilon$ over $\mathbb{R}\times\mathcal{W}\times\mathcal{T}$ defined by

$$\check{\mathbf{v}}_\varepsilon(r, \mathbf{x}, t) := \mathbf{v}(\hat{\mathbf{s}}_t(\mathbf{x}) + \varepsilon\, r\, \hat{\mathbf{n}}_t(\mathbf{x}), t). \tag{5.16}$$

A consequence of this definition is that, for each $(r, \mathbf{x}, t) \in \mathbb{R}\times\mathcal{W}\times\mathcal{T}$ fixed, the relation

$$\check{\mathbf{v}}_\varepsilon(r, \mathbf{x} + \alpha\, \hat{\mathbf{n}}_t(\mathbf{x}), t) = \check{\mathbf{v}}_\varepsilon(r, \mathbf{x}, t) \tag{5.17}$$

holds identically for α in the open neighborhood of 0 where

$$\hat{\mathbf{s}}_t(\mathbf{x}) = \hat{\mathbf{s}}_t(\mathbf{x} + \alpha\, \hat{\mathbf{n}}_t(\mathbf{x})).$$

We now differentiate with respect to t the identity

$$\mathbf{v}(\mathbf{x}, t) = \check{\mathbf{v}}_\varepsilon(\hat{r}_\varepsilon(\mathbf{x}, t), \mathbf{x}, t), \tag{5.18}$$

so as to obtain

$$\mathbf{v}^\bullet = r_\varepsilon^\bullet\, \partial_r \check{\mathbf{v}}_\varepsilon + \partial_t \check{\mathbf{v}}_\varepsilon, \tag{5.19}$$

that is, recalling (5.6),

$$\mathbf{v}^\bullet = -\varepsilon^{-1}\, v\, \partial_r \check{\mathbf{v}}_\varepsilon + \partial_t \check{\mathbf{v}}_\varepsilon. \tag{5.20}$$

Next, we differentiate (5.18) with respect to $\mathbf{x}$ and obtain

$$\operatorname{grad}\mathbf{v} = \partial_r \check{\mathbf{v}}_\varepsilon \otimes \operatorname{grad} r_\varepsilon + \partial_{\mathbf{x}} \check{\mathbf{v}}_\varepsilon, \tag{5.21}$$

which we rewrite as

$$\operatorname{grad}\mathbf{v} = \varepsilon^{-1} \partial_r \check{\mathbf{v}}_\varepsilon \otimes \mathbf{n} + \partial_{\mathbf{x}} \check{\mathbf{v}}_\varepsilon, \tag{5.22}$$

using (5.4) and (5.8).

We are now in a position to compute both the Laplacian and the curl of $\mathbf{v}$ in terms of its inner representation.

As to the Laplacian, taking the divergence of both sides of (5.22), we find that

$$\Delta \mathbf{v} = \varepsilon^{-1}(\operatorname{grad}(\partial_r \check{\mathbf{v}}_\varepsilon))\,\mathbf{n} + \varepsilon^{-1}(\operatorname{div}\mathbf{n})\,\partial_r \check{\mathbf{v}}_\varepsilon + \operatorname{div}\partial_{\mathbf{x}} \check{\mathbf{v}}_\varepsilon, \tag{5.23}$$

where

$$\operatorname{grad}(\partial_r \check{\mathbf{v}}_\varepsilon) = -\varepsilon^{-1}\partial_{rr}\check{\mathbf{v}}_\varepsilon \otimes \mathbf{n} + \partial_{\mathbf{x}}\partial_r \check{\mathbf{v}}_\varepsilon. \tag{5.24}$$

But, since differentiation of (5.17) with respect to r and α yields

$$(\partial_{\mathbf{x}}(\partial_r \check{\mathbf{v}}_\varepsilon))\mathbf{n} = \mathbf{0}, \tag{5.25}$$

substitution of (5.14) and (5.24) into (5.23) yields

$$\Delta \mathbf{v} = \varepsilon^{-2}\partial_{rr}\check{\mathbf{v}}_\varepsilon - \varepsilon^{-1}\partial_r \check{\mathbf{v}}_\varepsilon + \operatorname{div}\partial_{\mathbf{x}}\check{\mathbf{v}}_\varepsilon + r_\varepsilon(\mathbf{L}\cdot\operatorname{grad}\mathbf{n})\,\partial_r\check{\mathbf{v}}_\varepsilon. \tag{5.26}$$

As to the curl, again from (5.22) we deduce that

$$\operatorname{curl}\mathbf{v} = \varepsilon^{-1}\mathbf{n}\times\partial_r\check{\mathbf{v}}_\varepsilon + (\partial_{\mathbf{x}}\check{\mathbf{v}}_\varepsilon - (\partial_{\mathbf{x}}\check{\mathbf{v}}_\varepsilon)^T)_\times, \tag{5.27}$$

where $\mathbf{W}_\times$ denotes the axial vector associated to the skew tensor $\mathbf{W}$.

5.3. Estimates. Equations (5.22), (5.20), (5.26), and (5.27) yield the following estimates:

$$\mathbf{v}^{\bullet} = -\varepsilon^{-1}\,v\,\partial_r\check{\mathbf{v}}_\varepsilon + O(1), \tag{5.28}$$

$$\operatorname{grad}\mathbf{v} = \varepsilon^{-1}\partial_r\check{\mathbf{v}}_\varepsilon\otimes\mathbf{n} + O(1), \tag{5.29}$$

$$\Delta\mathbf{v} = \varepsilon^{-2}\partial_{rr}\check{\mathbf{v}}_\varepsilon - \varepsilon^{-1}k\partial_r\check{\mathbf{v}}_\varepsilon + O(1), \tag{5.30}$$

$$\operatorname{curl}\mathbf{v} = \varepsilon^{-1}\mathbf{n}\times\partial_r\check{\mathbf{v}}_\varepsilon + O(1), \tag{5.31}$$

$$\operatorname{div}\mathbf{v} = \varepsilon^{-1}\partial_r\check{\mathbf{v}}_\varepsilon\cdot\mathbf{n} + O(1). \tag{5.32}$$

6. Matched asymptotics. For convenience, let us repeat here the system (4.9)–(4.10):

$$\begin{gathered}\varepsilon^2\,(\tau\,\dot{\mathbf{m}} + \mathbf{m}\times\dot{\mathbf{m}}) = \mathbf{m}\times\big(\varepsilon^2\Delta\mathbf{m} + (\mathbf{e}\cdot\mathbf{m})\mathbf{e} + \varepsilon(\mathbf{h}+\mathbf{h}_{\text{ext}})\big),\\ \operatorname{curl}\mathbf{h} = \mathbf{0},\quad \operatorname{div}(\mathbf{h}+\mathbf{m}) = 0.\end{gathered} \tag{6.1}$$

We recall that the independent variables in (6.1) are the dimensionless variables $\tilde{\mathbf{x}}$ and $\tilde{t}$ defined in (4.1); to lighten our notation, we omit the superposed tildes until, in subsection 6.4, we return to the original space and time variables.

We assume that there is a positive constant $\bar{\varepsilon}$ such that for each $\varepsilon\in(0,\bar{\varepsilon})$, the system (6.1) has a solution $(\mathbf{m}_\varepsilon,\ \mathbf{h}_\varepsilon)$ defined on $\mathbb{R}^3\times\mathcal{T}$. We also assume that the surface $\mathcal{S}_t$ introduced in the previous section splits $\mathbb{R}^3$ into a pair of disjoint regions $\mathcal{D}_t^+$ and $\mathcal{D}_t^-$ having $\mathcal{S}_t$ as their common boundary, and that, at each time $t\in\mathcal{T}$, the limits

$$\begin{aligned}\mathbf{m}_0(\mathbf{x},t) &= \lim_{\varepsilon\to 0}\mathbf{m}_\varepsilon(\mathbf{x},t),\\ \mathbf{h}_0(\mathbf{x},t) &= \lim_{\varepsilon\to 0}\mathbf{h}_\varepsilon(\mathbf{x},t)\end{aligned} \tag{6.2}$$

exist at each point $\mathbf{x}\in\mathbb{R}^3\setminus\mathcal{S}_t$, with

$$\mathbf{m}_0(\mathbf{x},t) = \begin{cases} -\mathbf{e} & \text{if } \mathbf{x}\in\mathcal{D}_t^-,\\[2ex] +\mathbf{e} & \text{if } \mathbf{x}\in\mathcal{D}_t^+,\end{cases} \tag{6.3}$$

and with $\mathbf{h}_0(\cdot,t)$ a smooth field on $\mathbb{R}^3\setminus\mathcal{S}_t$. Furthermore, we let

$$\begin{aligned}\check{\mathbf{m}}_\varepsilon(r,\mathbf{x},t)&=\mathbf{m}_\varepsilon(\hat{\mathbf{s}}(\mathbf{x},t)+\varepsilon\, r\,\hat{\mathbf{n}}(\mathbf{x},t),t),\\ \check{\mathbf{h}}_\varepsilon(r,\mathbf{x},t)&=\mathbf{h}_\varepsilon(\hat{\mathbf{s}}(\mathbf{x},t)+\varepsilon\, r\,\hat{\mathbf{n}}(\mathbf{x},t),t)\end{aligned}\tag{6.4}$$

be the inner representations of $\mathbf{m}_\varepsilon$ and $\mathbf{h}_\varepsilon$ for each $\varepsilon\in(0,\bar{\varepsilon})$ (see definition (5.16)), and we assume that the limits

$$\begin{aligned}\check{\mathbf{m}}_0(r,\mathbf{x},t)&=\lim_{\varepsilon\to 0}\check{\mathbf{m}}_\varepsilon(r,\mathbf{x},t),\\ \check{\mathbf{h}}_0(r,\mathbf{x},t)&=\lim_{\varepsilon\to 0}\check{\mathbf{h}}_\varepsilon(r,\mathbf{x},t)\end{aligned}\tag{6.5}$$

exist for each $(r,\mathbf{x},t)\in\mathbb{R}\times(\mathbb{R}^3\setminus\mathcal{S}_t)\times\mathcal{T}$. The following *matching conditions* will soon prove crucial to our developments:

$$\begin{aligned}\lim_{r\to\pm\infty}\check{\mathbf{m}}_0(r,\mathbf{x},t)&=\lim_{d\to 0\pm}\mathbf{m}_0(\hat{\mathbf{s}}_t(\mathbf{x})+d\,\hat{\mathbf{n}}_t(\mathbf{x}),t),\\ \lim_{r\to\pm\infty}\check{\mathbf{h}}_0(r,\mathbf{x},t)&=\lim_{d\to 0\pm}\mathbf{h}_0(\hat{\mathbf{s}}_t(\mathbf{x})+d\,\hat{\mathbf{n}}_t(\mathbf{x}),t)\end{aligned}\tag{6.6}$$

for each $(\mathbf{x},t)\in\mathcal{W}\times\mathcal{T}$. The reader may consult [7] or [5, 8] for justifications of (6.6). As to a motivation, we note that, for each fixed pair $(\mathbf{x},t)\in\mathcal{W}\times\mathcal{T}$, the inner representation of the field $\mathbf{m}_\varepsilon$ can be written in the alternative forms

$$\check{\mathbf{m}}_\varepsilon(r,\mathbf{x},t)=\mathbf{m}_\varepsilon(\hat{\mathbf{s}}_t(\mathbf{x})+\varepsilon r\,\hat{\mathbf{n}}_t(\mathbf{x}),t)=\mathbf{m}_\varepsilon(\hat{\mathbf{s}}_t(\mathbf{x})+d\,\hat{\mathbf{n}}_t(\mathbf{x}),t)=\check{\mathbf{m}}_\varepsilon\left(\frac{d}{\varepsilon},\mathbf{x},t\right),$$

where the real variables r and d satisfy

$$r^{-1}\,d=\varepsilon;$$

hence, both r^{-1} and d tend to null with ε at a smaller rate than ε itself — both as $\varepsilon^{1/2}$, say.

Finally, we recall that all solutions of the Gilbert equation must have constant modulus. For an expansion such as

$$\mathbf{m}_\varepsilon=\mathbf{m}_0+\varepsilon\,\mathbf{m}_1+o(\varepsilon)$$

to be consistent with the requirement that

$$|\mathbf{m}_\varepsilon|=1,$$

the approximations of $\mathbf{m}_\varepsilon$ must be such that

$$|\mathbf{m}_0|=1,\quad \mathbf{m}_0\cdot\mathbf{m}_1=0,\quad \text{etc.}\tag{6.7}$$

6.1. The zeroth-order magnetization field. For each $(\mathbf{x},t)\in\mathcal{W}\times\mathcal{T}$, the relations (6.5) and the estimates (5.28) and (5.30) yield

$$\begin{aligned}\mathbf{m}_\varepsilon(\mathbf{s}_t(\mathbf{x})+\varepsilon\, r\,\mathbf{n}_t(\mathbf{x}))&=\check{\mathbf{m}}_0(r,\mathbf{x},t)+O(\varepsilon),\\ \mathbf{h}_\varepsilon(\mathbf{s}_t(\mathbf{x})+\varepsilon\, r\,\mathbf{n}_t(\mathbf{x}))&=\check{\mathbf{h}}_0(r,\mathbf{x},t)+O(\varepsilon),\\ \dot{\mathbf{m}}_\varepsilon(\mathbf{s}_t(\mathbf{x})+\varepsilon\, r\,\mathbf{n}_t(\mathbf{x}))&=-\varepsilon^{-1}v\,\partial_r\check{\mathbf{m}}_0(r,\mathbf{x},t)+O(1),\\ \Delta\mathbf{m}_\varepsilon(\mathbf{s}_t(\mathbf{x})+\varepsilon\, r\,\mathbf{n}_t(\mathbf{x}))&=\varepsilon^{-2}\partial_{rr}\check{\mathbf{m}}_0(r,\mathbf{x},t)+O(\varepsilon^{-1}).\end{aligned}\tag{6.8}$$

Substituting (6.8) into the scaled Gilbert equation $(6.1)_1$, and letting $\varepsilon\downarrow 0$, we obtain the following ODE for $\check{\mathbf{m}}_0(\cdot,\mathbf{x},t)$:

$$\check{\mathbf{m}}_0\times(\partial_{rr}\mathbf{m}_0+(\mathbf{e}\otimes\mathbf{e})\check{\mathbf{m}}_0)=\mathbf{0}\quad\text{in }\mathbb{R};\tag{6.9}$$

the field $\check{\mathbf{m}}_0$ must be unimodular to satisfy $(6.7)_1$, and it must comply with the conditions at infinity resulting from the assumption (6.3) and the matching condition $(6.6)_1$, namely,

$$\lim_{r\to\pm\infty} \check{\mathbf{m}}_0(r) = \pm\mathbf{e}. \tag{6.10}$$

To construct a solution to the nonlinear boundary-value problem (6.9)–(6.10), we look for smooth solutions $\mathbf{v} : \mathbb{R} \to S^2$ to the problem

$$\begin{cases} \mathbf{v}\times\mathbf{D}\mathbf{v} = \mathbf{0} \quad \text{in } \mathbb{R}, \quad \mathbf{D}\mathbf{v} := \mathbf{v}'' + (\mathbf{e}\cdot\mathbf{v})\mathbf{e}, \\ \lim\limits_{r\to\pm\infty} \mathbf{v}(r) = \pm\mathbf{e}. \end{cases} \tag{6.11}$$

(Here a superscript prime denotes differentiation.)

We preliminarily note that if $\mathbf{v}(r)$ is a solution of (6.11), then the field

$$\mathbf{v}_{\rho,\varphi}(r) := \mathbf{R}_{\mathbf{e}}(\varphi)\mathbf{v}(r-\rho) \tag{6.12}$$

is a solution as well, whatever the translation $\rho \in \mathbb{R}$ and whatever the angle $\varphi \in (-\pi, +\pi)$ of the rotation $\mathbf{R}_{\mathbf{e}}(\varphi)$ about the easy axis.[2] The identities

$$\mathbf{v}'\times\mathbf{D}\mathbf{v} + \mathbf{v}\times\mathbf{D}\mathbf{v}' = \mathbf{0} \tag{6.13}$$

and

$$(\mathbf{e}\times\mathbf{v})\times\mathbf{D}\mathbf{v} + \mathbf{v}\times\mathbf{D}(\mathbf{e}\times\mathbf{v}) = \mathbf{0} \tag{6.14}$$

obtain by differentiating with respect to ρ and ϕ, respectively, the identity

$$\mathbf{v}_{\rho,\phi}\times\mathbf{D}\mathbf{v}_{\rho,\phi} = \mathbf{0}, \tag{6.15}$$

and evaluating the resulting expression at $\rho = \phi = 0$.[3]

We show in the appendix that smooth solutions to problem (6.11) have the form

$$\mathbf{v}(r) = \tanh(r-\rho)\mathbf{e} + \frac{1}{\cosh(r-\rho)}\,\mathbf{t}, \quad \rho\in\mathbb{R}, \ \ \mathbf{t}\cdot\mathbf{e} = 0 \tag{6.16}$$

(compare with the Landau–Lifshitz and Walker solutions). Accordingly, we assign to the zeroth-order magnetization field inside the domain wall the form

$$\check{\mathbf{m}}_0(r,\mathbf{x},t) = \tanh(r-\rho(\mathbf{s}_t(\mathbf{x}),t))\,\mathbf{e} + \frac{1}{\cosh(r-\rho(\mathbf{s}_t(\mathbf{x}),t))}\,\mathbf{t}(\mathbf{s}_t(\mathbf{x}),t) \tag{6.17}$$

with $\rho(\cdot,t)$ and $\mathbf{t}(\cdot,t)$ two smooth fields on $\mathcal{S}_t$, the latter being unimodular and orthogonal to the easy axis. Not only does this vector field solve problem (6.9)–(6.10) but it also satisfies two identities corresponding, respectively, to (6.13) and (6.14):

$$\begin{aligned} &\partial_r\check{\mathbf{m}}_0\times\mathbf{D}\check{\mathbf{m}}_0 + \check{\mathbf{m}}_0\times\mathbf{D}\,\partial_r\check{\mathbf{m}}_0 = \mathbf{0}, \\ &(\mathbf{e}\times\check{\mathbf{m}}_0)\times\mathbf{D}\check{\mathbf{m}}_0 + \check{\mathbf{m}}_0\times\mathbf{D}(\mathbf{e}\times\check{\mathbf{m}}_0) = \mathbf{0}, \end{aligned} \tag{6.18}$$

[2] Recall that

$$\mathbf{R}_{\mathbf{e}}(\varphi) = \mathbf{I} + \sin\varphi\,\mathbf{E} + (1-\cos\varphi)(\mathbf{e}\otimes\mathbf{e} - \mathbf{I}), \quad \mathbf{E}_\times = \mathbf{e}.$$

Needless to say, whatever ρ and φ,

$$|\mathbf{v}_{\rho,\varphi}(r)| = |\mathbf{v}(r-\rho)| \quad \text{for all } r\in\mathbb{R}.$$

[3] In fact, relation (6.13) also follows from differentiating the first of (6.11) with respect to r; a completely analogous relation holds for $\mathbf{v}''$, $\mathbf{v}'''$, etc.

where now

$$\mathbf{D}\mathbf{v} = \partial_{rr}\mathbf{v} + (\mathbf{e}\cdot\mathbf{v})\mathbf{v} \quad \text{for } \mathbf{v} = \check{\mathbf{v}}(r,\mathbf{x},t). \tag{6.19}$$

In addition, as is easy to verify on the basis of (6.17),

$$\lim_{r\to\pm\infty} \partial_r \check{\mathbf{m}}_0(r,\mathbf{x},t) = \mathbf{0}, \quad \lim_{r\to\pm\infty} \partial_{rr} \check{\mathbf{m}}_0(r,\mathbf{x},t) = \mathbf{0}. \tag{6.20}$$

6.2. The zeroth-order stray field. We now use the Maxwell equations to compute $\check{\mathbf{h}}_0$, the lowest-order term of the stray field inside the domain wall.

In view of $(6.5)_2$, (5.31), and (5.32), we have that

$$\begin{aligned} &\operatorname{curl} \mathbf{h}_\varepsilon = \varepsilon^{-1}\mathbf{n}\times\partial_r\check{\mathbf{h}}_0 + O(1),\\ &\operatorname{div} \mathbf{h}_\varepsilon = \varepsilon^{-1}\partial_r\check{\mathbf{h}}_0\cdot\mathbf{n} + O(1). \end{aligned} \tag{6.21}$$

Substituting (6.21) into (4.10) and letting $\varepsilon \downarrow 0$, we get

$$\partial_r\check{\mathbf{h}}_0\times\hat{\mathbf{n}} = \mathbf{0}, \quad \partial_r(\check{\mathbf{h}}_0 + \check{\mathbf{m}}_0)\cdot\hat{\mathbf{n}} = 0. \tag{6.22}$$

The associated boundary conditions are

$$\lim_{r\to\pm\infty} \check{\mathbf{h}}_0(r,\mathbf{s},t) = \lim_{d\to 0\pm} \mathbf{h}_0(\mathbf{s} + d\,\hat{\mathbf{n}}(\mathbf{s},t),t) \tag{6.23}$$

(cf. $(6.6)_2$).

The solution of (6.22)–(6.23) is

$$\check{\mathbf{h}}_0(r,\mathbf{s},t) = \langle\!\langle \mathbf{h}_0 + (\mathbf{m}_0\cdot\mathbf{n})\mathbf{n}\rangle\!\rangle(\mathbf{s},t) - (\check{\mathbf{m}}_0(r,\mathbf{s},t)\cdot\hat{\mathbf{n}}(\mathbf{s},t))\hat{\mathbf{n}}(\mathbf{s},t); \tag{6.24}$$

moreover, the jump conditions

$$[\![\mathbf{h}_0\times\hat{\mathbf{n}}]\!](\mathbf{s},t) = \mathbf{0}, \quad [\![(\mathbf{h}_0 + \mathbf{m}_0)\cdot\hat{\mathbf{n}}]\!](\mathbf{s},t) = \mathbf{0} \tag{6.25}$$

hold at all points $\mathbf{s}\in\mathcal{S}_t$. Here, for φ a field on $\mathbb{R}^3\times(0,T)$, we denote by

$$\langle\!\langle\varphi\rangle\!\rangle(\mathbf{s},t) = \lim_{d\to 0}\frac{1}{2}\left(\varphi(\mathbf{s}+d\mathbf{n},t) + \varphi(\mathbf{s}-d\mathbf{n},t)\right) \tag{6.26}$$

and

$$[\![\varphi]\!](\mathbf{s},t) = \lim_{d\to 0+}\left(\varphi(\mathbf{s}+d\mathbf{n},t) - \varphi(\mathbf{s}-d\mathbf{n},t)\right), \tag{6.27}$$

respectively, the *mean value* and the *jump* of φ at point $\mathbf{s}\in\mathcal{S}_t$. We note here for later use the identity

$$[\![\varphi\psi]\!] = \langle\!\langle\varphi\rangle\!\rangle[\![\psi]\!] + [\![\varphi]\!]\langle\!\langle\psi\rangle\!\rangle, \tag{6.28}$$

whence

$$[\![\varphi\varphi]\!] = 2\,\langle\!\langle\varphi\rangle\!\rangle[\![\varphi]\!]. \tag{6.29}$$

6.3. The first-order magnetization field. We now assume that the inner representation of $\mathbf{m}_\varepsilon$ admits a regular expansion up to the first order:

$$\check{\mathbf{m}}_\varepsilon(r,\mathbf{x},t) = \check{\mathbf{m}}_0(r,\mathbf{x},t) + \varepsilon\check{\mathbf{m}}_1(r,\mathbf{x},t) + o(\varepsilon). \tag{6.30}$$

As a consequence of this assumption and (6.10), we have, among other things, that

$$\lim_{r\to\pm\infty} \check{\mathbf{m}}_1(r,\mathbf{x},t) = \mathbf{0}. \tag{6.31}$$

Furthermore, we can replace relation $(6.8)_4$ by the sharper estimate

$$\Delta\mathbf{m}_\varepsilon = \varepsilon^{-2}\partial_{rr}\check{\mathbf{m}}_0 - \varepsilon^{-1}(k\,\partial_r\mathbf{m}_0 - \partial_{rr}\mathbf{m}_1) + O(1). \tag{6.32}$$

Substituting (6.32) into the scaled Gilbert equation $(6.1)_1$, and using (6.9), we obtain

$$\varepsilon\left(\check{\mathbf{m}}_1\times\mathbf{D}\check{\mathbf{m}}_0 + \check{\mathbf{m}}_0\times\mathbf{D}\check{\mathbf{m}}_1 + \check{\mathbf{b}}_0\right) + O(\varepsilon^2) = \mathbf{0}, \tag{6.33}$$

where $\mathbf{D}$ is defined as in (6.19) and

$$\check{\mathbf{b}}_0 := \sigma v\,\partial_r\check{\mathbf{m}}_0 + \check{\mathbf{m}}_0\times(\mathbf{h}_{\rm ext} + \check{\mathbf{h}}_0 + (v-k)\partial_r\check{\mathbf{m}}_0); \tag{6.34}$$

note that $\check{\mathbf{b}}_0\cdot\check{\mathbf{m}}_0 = 0$. Hence, for each fixed $(\mathbf{x},t)\in\mathcal{W}\times\mathcal{T}$, the field $\check{\mathbf{m}}_1(\cdot,\mathbf{x},t)$ must satisfy the ODE

$$\check{\mathbf{m}}_0\times\mathbf{D}\check{\mathbf{m}}_1 + \check{\mathbf{m}}_1\times\mathbf{D}\check{\mathbf{m}}_0 + \check{\mathbf{b}}_0 = \mathbf{0} \tag{6.35}$$

as well as the boundary conditions at infinity expressed by (6.31). We now derive two *solvability conditions* for the linear problem ruled by (6.35) and (6.31).

First, taking the dot product of both sides of (6.35) with $\check{\mathbf{m}}_0\times\partial_r\check{\mathbf{m}}_0$, we find[4]

$$\partial_r\check{\mathbf{m}}_0\cdot\mathbf{D}\check{\mathbf{m}}_1 - (\partial_r\check{\mathbf{m}}_0\cdot\check{\mathbf{m}}_1)(\check{\mathbf{m}}_0\cdot\mathbf{D}\check{\mathbf{m}}_0) + \check{\mathbf{m}}_0\times\partial_r\check{\mathbf{m}}_0\cdot\check{\mathbf{b}}_0 = 0,$$

or rather

$$(\mathbf{A}_0\check{\mathbf{m}}_1 + \check{\mathbf{b}}_0\times\check{\mathbf{m}}_0)\cdot\partial_r\check{\mathbf{m}}_0 = 0, \tag{6.36}$$

where

$$\mathbf{A}_0 := \mathbf{D} - (\check{\mathbf{m}}_0\cdot\mathbf{D}\check{\mathbf{m}}_0)\mathbf{I}. \tag{6.37}$$

With the use of (6.20) and (6.31), an integration by parts over the real line yields

$$\int_{-\infty}^{+\infty}(\mathbf{A}_0\check{\mathbf{m}}_1)\cdot\partial_r\check{\mathbf{m}}_0\,dr = \int_{-\infty}^{+\infty}(\mathbf{A}_0\check{\mathbf{m}}_0)\cdot\partial_r\check{\mathbf{m}}_1\,dr. \tag{6.38}$$

[4]We exploit the fact that $\check{\mathbf{m}}_0$ is orthogonal both to $\partial_r\check{\mathbf{m}}_0$ (because $|\check{\mathbf{m}}_0| = 1$) and to $\check{\mathbf{m}}_1$ (because of $(6.7)_2$) and apply two consequences of the vectorial identity

$$(\mathbf{a}\times\mathbf{b})\cdot(\mathbf{d}\times\mathbf{c}) = (\mathbf{a}\cdot\mathbf{d})(\mathbf{b}\cdot\mathbf{c}) - (\mathbf{d}\cdot\mathbf{b})(\mathbf{a}\cdot\mathbf{c}),$$

namely,

$$(\mathbf{a}\times\mathbf{b})\cdot(\mathbf{a}\times\mathbf{c}) = \mathbf{b}\cdot\mathbf{c}, \text{ for } \mathbf{a} \text{ unimodular and orthogonal either to } \mathbf{b} \text{ or to } \mathbf{c}$$

and

$$(\mathbf{a}\times\mathbf{b})\cdot(\mathbf{d}\times\mathbf{c}) = -(\mathbf{d}\cdot\mathbf{b})(\mathbf{a}\cdot\mathbf{c}), \text{ for } \mathbf{a} \text{ orthogonal to } \mathbf{d}.$$

But,

$$\mathbf{A}_0 \partial_r \check{\mathbf{m}}_0 \cdot \check{\mathbf{m}}_1 = \mathbf{0}, \tag{6.39}$$

as is proven by taking the dot product of both sides of $(6.18)_1$ with $\check{\mathbf{m}}_0 \times \check{\mathbf{m}}_1$. Thus, integration of (6.36) gives

$$\int_{-\infty}^{+\infty} \check{\mathbf{m}}_0 \times \check{\mathbf{b}}_0 \cdot \partial_r \check{\mathbf{m}}_0 \, dr = 0. \tag{6.40}$$

Equation (6.40) is the first of the solvability conditions we are after. The other obtains quite similarly, by taking the dot product of both sides of (6.35) with $\check{\mathbf{m}}_0 \times \mathbf{e}$, integrating the resulting scalar equation over the real line, and using the identity $(6.18)_2$; all in all,

$$\int_{-\infty}^{+\infty} (\check{\mathbf{m}}_0 \times \check{\mathbf{b}}_0) \cdot (\check{\mathbf{m}}_0 \times \mathbf{e}) \, dr = 0. \tag{6.41}$$

In (6.40) and (6.41) the fields $\check{\mathbf{m}}_0$, $\partial_r \check{\mathbf{m}}_0$ are specified by (6.17) and the field $\check{\mathbf{b}}_0$ by (6.34). An explicit computation, where use is made of the fact that both $\partial_r \check{\mathbf{m}}_0$ and $\check{\mathbf{b}}_0$ are orthogonal to $\check{\mathbf{m}}_0$ and of the identity (6.29), gives (6.40) the form

$$g(\hat{v}(\mathbf{s},t) - \hat{k}(\mathbf{s},t)) + \hat{f}\,(\mathbf{s},t) = 0, \tag{6.42}$$

where the coefficient g, a constant, is defined to be

$$g = \int_{-\infty}^{+\infty} |\partial_r \check{\mathbf{m}}_0|^2 \, dr \tag{6.43}$$

and where the forcing term is

$$\hat{f}(\mathbf{s},t) = (\mathbf{h}_{\rm tot} \cdot [\![\mathbf{m}_0]\!])(\mathbf{s},t), \quad \mathbf{h}_{\rm tot} := \langle\!\langle \mathbf{h}_0 \rangle\!\rangle + \mathbf{h}_{\rm ext}. \tag{6.44}$$

Likewise, (6.41) takes the form

$$(\mathbf{e} \cdot [\![\mathbf{m}_0]\!])\, \tau\, \hat{v} + \mathbf{e} \times \mathbf{t} \cdot \Big(\pi \mathbf{h}_{\rm tot} + (\hat{\mathbf{n}} \otimes \hat{\mathbf{n}})(\pi \langle\!\langle \mathbf{m}_0 \rangle\!\rangle - g\, \mathbf{t}) \Big) = 0. \tag{6.45}$$

Now, with the use of (6.17), it is easy to evaluate the integral in (6.43) and find

$$g = 2. \tag{6.46}$$

Moreover, it follows from assumption (6.3) that the jump and mean of $\mathbf{m}_0$ across the domain wall are, respectively,

$$[\![\mathbf{m}_0]\!] = 2\mathbf{e}, \quad \langle\!\langle \mathbf{m}_0 \rangle\!\rangle = \mathbf{0}. \tag{6.47}$$

Consequently, we rewrite (6.42) and, respectively, (6.45) as follows:

$$\begin{aligned} &\hat{v}(\mathbf{s},t) - \hat{k}(\mathbf{s},t) + \hat{h}(\mathbf{s},t) = 0, \quad \hat{h}(\mathbf{s},t) := \mathbf{e} \cdot \mathbf{h}_{\rm tot}(\mathbf{s},t); \\ &2\tau\, \hat{v} + \mathbf{e} \times \mathbf{t} \cdot \big(\pi \mathbf{h}_{\rm tot} - 2\, (\hat{\mathbf{n}} \otimes \hat{\mathbf{n}}) \mathbf{t} \big) = 0. \end{aligned} \tag{6.48}$$

6.4. The evolution equations of the domain wall. The last step of our derivation consists in scaling equations (6.48) back to the original variables $\mathbf{x}$ and t. This is achieved by replacing v and k, respectively, by $L^{-1}\,T\,v$ and $L\,k$, so as to obtain

$$\nu^{-1}v - \sigma k + h = 0 \tag{6.49}$$

and

$$2\tau\nu^{-1}v + (\mathbf{e}\times\mathbf{t})\cdot\big(\pi\mathbf{h}_{\rm tot} - 2\,(\hat{\mathbf{n}}\otimes\hat{\mathbf{n}})\mathbf{t}\big) = 0, \tag{6.50}$$

where

$$\nu := \frac{1}{\mu}\left(\frac{\alpha}{\beta}\right)^{\frac{1}{2}}, \quad \sigma := (\alpha\beta)^{\frac{1}{2}}. \tag{6.51}$$

(It follows from (4.6) and (4.8) that $L = (\alpha\beta)^{1/2}$ and $T = \beta\mu$.)

Equation (6.49) determines the evolution of the domain wall $\mathcal{S}_t$, whose motion appears to be driven by its own current mean curvature and by a generally *nonlocal* forcing term. It is precisely this last feature that distinguishes (6.49) from the formally identical equations that describe the motion of sharp grain boundaries or solidification fronts according to their *mobility* ν and *surface tension* σ, under the *driving force* $f := -h$ (see, e.g., [10, 11]). From $(6.44)_2$ and $(6.48)_1$ we have that the forcing term h has the form

$$h(\mathbf{s},t) = \mathbf{e}\cdot(\langle\!\langle\mathbf{h}_0\rangle\!\rangle + \mathbf{h}_{\rm ext})(\mathbf{s},t),$$

where, given $\mathcal{S}_t$, the stray field $\mathbf{h}_0$ is the solution of the system of PDEs

$$\operatorname{curl}\mathbf{h}_0 = \mathbf{0}, \quad \operatorname{div}\mathbf{h}_0 = 0 \qquad \text{in } \mathbb{R}^3 - \mathcal{S}_t,$$

subject to the jump conditions

$$[\![\mathbf{h}_0]\!]\cdot\hat{\mathbf{n}} = 2\mathbf{e}\cdot\hat{\mathbf{n}}, \quad [\![\mathbf{h}_0]\!]\times\hat{\mathbf{n}} = \mathbf{0} \qquad \text{on } \mathcal{S}_t.$$

While (6.49) determines v, (6.50) determines $\mathbf{t}$ and hence provides information on the zeroth-order magnetization inside the domain wall. Note that the requirement that (6.50) admits a solution sets a restriction on the possible values of v. Remarkably, this restriction yields Walker's breakdown velocity when flat walls are considered.

6.5. Comparison with Walker's solution. With a view toward using Walker's solution as a benchmark for our theory, we consider the case when $\mathcal{S}_t$ is a plane parallel to the easy axis $\mathbf{e}$, with unit normal $\mathbf{c}_1$. Just as in subsection 3.2, we assume that the spatial dependence of all fields of interest is only through the first coordinate x_1, and that the easy axis coincides with $\mathbf{c}_3$; we also assume that the external field has the form (3.10), and we maintain the prescription (3.3) that the stray field $\mathbf{h}$ vanishes at $x_1 = \pm\infty$, which implies, in the present case, that $\mathbf{h}$ is everywhere null.

Under these circumstances, (6.49) becomes

$$v = \nu H = \frac{1}{\mu}\left(\frac{\alpha}{\beta}\right)^{\frac{1}{2}} H, \tag{6.52}$$

which agrees with (3.15) for $\beta \gg 1$. Moreover, with the use of the representation $(3.7)_2$ for $\mathbf{t}$, (6.50) becomes

$$v = -\nu\tau^{-1}\cos\varphi\sin\varphi. \tag{6.53}$$

Combining (6.52) and (6.53), we recover both (3.13) and the bounds (3.11) on H. Thus, even in this respect, the predictions of our theory are consistent with Walker's.

7. Concluding remarks. In saturated ferromagnets, neither magnetic domains nor domain walls have an observable, definite physical substance: their presence and shape do not seem to reflect differences in composition or texture. Thus, in principle, domain structures should correspond to specific classes of solutions to certain initial and boundary value problems based on the Gilbert equation: for rigid ferromagnets, there should be no need for any further balance principle.[5]

This is why we chose to derive our evolution equation for a domain wall from the Gilbert equation, by way of matched asymptotics. Admittedly, with such an approach, the desired result is anticipated by the very start, in that one does not prove, but assumes, that a domain wall is well described as a smooth and smoothly evolving surface. Given this, the governing equations follow, under assumptions on scaling exponents that, no matter how reasonable and well motivated, are best justified *a posteriori* by the inspection of the phenomenology they encompass.[6]

Needless to say, our results are not applicable to situations where the Gilbert equation would not hold (e.g., they would not be applicable to unsaturated ferromagnets, for which materials, however, the concept of magnetic domain would *stricto sensu* be in the need of a reformulation) or to situations that the Gilbert equation ignores, such as the *pinning* of domain walls. (Indeed, it is only after an evolution equation for domain walls is made available that a discussion of pinning can be started; the same applies to a discussion of *domain-wall junctions*.)

There have been few previous attempts to model domain-wall evolution, among which we mention the work of Slonczewsky [26] (see also [17]) and the works of Jiang [15], Maugin and Fomethe (see [19], where reference is given to other related papers by the same authors and by Maugin, alone and with different coworkers), and James [14]. This is no place for a detailed analysis of the conceptual differences between our approach and those in these papers; for such an analysis, we refer the reader to our forthcoming paper [24]. Over and beyond their differences in method and scope, what is derived in all the papers by Jiang, Maugin and Fomethe, and James is a formula for the driving force; direct geometric contributions to wall motion, such as the curvature term in (6.49), are absent (they are not in Slonczewsky's work). The other ingredient of all models in [15, 19, 14] is a functional relation

$$v = \mathcal{V}(f) \tag{7.1}$$

between normal velocity and driving force, a relation that is postulated, not derived, and is regarded as constitutive. Since wall motion is viewed as an essentially dissipative phenomenon, the form of $\mathcal{V}$ is restricted by the requirement that

$$fv \geq 0. \tag{7.2}$$

In view of the above, we can compare our formula for the driving force,

$$f = -(\langle\!\langle \mathbf{h}_0 \rangle\!\rangle + \mathbf{h}_{\text{ext}}) \cdot [\![\mathbf{m}_0]\!], \tag{7.3}$$

[5] The form of the Gilbert equation we study is consistent with thermodynamics [21]. Yet, it could happen that a dissipation principle would be of use to separate physically significant evolutions from others having only a mathematical life [3].

[6] Different governing equations would follow from scaling assumptions other than those we made. For example, $\dot{\mathbf{m}}$ appears in two addenda of the Gilbert equation (2.5), namely, $\gamma^{-1}\dot{\mathbf{m}}$ and $\mu\mathbf{m}\times\dot{\mathbf{m}}$. There are then two different characteristic times built into the equation, one for each of these terms. As the second of (4.8) makes clear, our scaling selects the "slow" time $\beta\,\mu$ and therefore excludes any account in the domain-wall evolution of the "jerking term" $\mu\mathbf{m}\times\dot{\mathbf{m}}$.

with those derived by Jiang [15], Maugin and Fomethe [19], and James [14], so specialized as to ignore mechanical deformation. We find that (7.3) agrees with Jiang's (3.26) and with the combination of Maugin and Fomethe's (4.28) and (6.2); instead, James' (92) reads, in our notations,

$$f = -[\![(\mathbf{h}_0 + \mathbf{h}_{\text{ext}}) \cdot \mathbf{m}_0]\!], \tag{7.4}$$

or rather, with the use of (6.28),

$$f = -(\langle\!\langle \mathbf{h}_0 \rangle\!\rangle + \mathbf{h}_{\text{ext}}) \cdot [\![\mathbf{m}_0]\!] - [\![\mathbf{h}_0]\!] \cdot \langle\!\langle \mathbf{m}_0 \rangle\!\rangle. \tag{7.5}$$

Appendix. In this section, we address the problem of finding a C^2-solution to the boundary value problem

$$\begin{aligned} &\mathbf{v} \times (\mathbf{v}'' + (\mathbf{v} \cdot \mathbf{e})\mathbf{e}) = \mathbf{0} \quad \text{in } \mathbb{R}, \\ &\lim_{r \to \pm\infty} \mathbf{v}(r) = \pm\mathbf{e}, \end{aligned} \tag{7.6}$$

with the constraint

$$|\mathbf{v}| = 1. \tag{7.7}$$

We begin by noting that an admissible solution of (7.6) must satisfy the following first-order differential conditions:

$$\begin{aligned} &\mathbf{v}' \cdot \mathbf{v} = 0; \\ &\mathbf{v}' \cdot (\mathbf{v} \times \mathbf{e}) = 0; \\ &|\mathbf{v}'|^2 + (\mathbf{v} \cdot \mathbf{e})^2 = \kappa^2, \text{ a constant.} \end{aligned} \tag{7.8}$$

The first of (7.8) is a straightforward consequence of (7.7). To obtain $(7.8)_2$, take the scalar product of both sides of $(7.6)_1$ with $\mathbf{e}$, use the identity $\mathbf{v} \times \mathbf{v}'' = (\mathbf{v} \times \mathbf{v}')'$, and then integrate the resulting equation with the aid of the boundary conditions $(7.6)_2$. As to $(7.8)_3$, by taking the scalar product of both sides of $(7.6)_1$ with $\mathbf{v} \times \mathbf{v}'$, obtain

$$\mathbf{v}' \cdot \mathbf{v}'' + (\mathbf{v} \cdot \mathbf{e})(\mathbf{v} \cdot \mathbf{e})' = 0, \tag{7.9}$$

then integrate.

Every solution of (7.6)–(7.7) can be given a provisional partial representation as

$$\mathbf{v}(r) = \alpha(r)\mathbf{e} + \beta(r)\mathbf{t}(r), \tag{7.10}$$

provided that, for all $r \in \mathbb{R}$,

(i) $\mathbf{t}(r)$ is a unimodular vector orthogonal to the easy axis:

$$|\mathbf{t}(r)| = 1, \quad \mathbf{t}(r) \cdot \mathbf{e} = 0; \tag{7.11}$$

(ii) the scalars $\alpha(r)$, $\beta(r)$ satisfy

$$\alpha^2(r) + \beta^2(r) = 1 \tag{7.12}$$

and, moreover,

$$\lim_{r \to \pm\infty} \alpha(r) = \pm 1, \quad \lim_{r \to \pm\infty} \beta(r) = 0. \tag{7.13}$$

Note that taking

$$|\alpha(r)| \equiv 1, \quad \beta(r) \equiv 0 \tag{7.14}$$

would not yield a continuous solution to problem (7.6)–(7.7). Needless to say, the functions α and β we introduce and manipulate here have nothing to do with, respectively, the exchange modulus and the anisotropy modulus, which everywhere else in this paper we have denoted by those same Greek letters.

With this representation for the solutions, the differential relations (7.8) become

$$\begin{aligned} &\alpha'\alpha + \beta'\beta = 0; \\ &\beta^2 \mathbf{t} \times \mathbf{t}' = \mathbf{0}; \\ &\alpha'^2 + \beta'^2 + \beta^2 |\mathbf{t}'|^2 + \alpha^2 = \kappa^2. \end{aligned} \tag{7.15}$$

A consequence of $(7.15)_1$, (7.12), and $(7.13)_2$ is that

$$(1 - \beta^2)\alpha'^2 = \beta^2 \beta'^2. \tag{7.16}$$

On the other hand, it follows from $(7.15)_2$ and $(7.11)_1$ that

$$\beta^2 \mathbf{t}' = \mathbf{0}, \tag{7.17}$$

so that $(7.15)_3$ becomes

$$\alpha'^2 + \beta'^2 + \alpha^2 = \kappa^2. \tag{7.18}$$

Substituting (7.16) in (7.18) multiplied by $(1 - \beta^2)$, we obtain

$$\beta'^2 + (1 - \beta^2)^2 = (1 - \beta^2)\kappa^2. \tag{7.19}$$

Taking the limits of (7.19) for $r \to \pm\infty$ in the light of $(7.13)_2$, we see that β'^2 tends to $(\kappa^2 - 1)$, a constant that must be null, for otherwise $\beta(r)$ could not have finite limits as $r \to \pm\infty$ and thus, in particular, it could not satisfy $(7.13)_2$. Then, since

$$\kappa^2 = 1,$$

(7.19) becomes

$$\beta'^2 = \beta^2(1 - \beta^2), \tag{7.20}$$

while $(7.15)_3$ and (7.20) imply that

$$\alpha'^2 = (1 - \alpha^2)^2. \tag{7.21}$$

It follows from (7.20) that β can never vanish. Indeed, were $\beta(r_0) = 0$ for some $r_0 \in \mathbb{R}$, then

$$\beta^2(r) = \int_{r_0}^{r} 2\beta\beta' \leq \int_{r_0}^{r} (\beta^2 + \beta'^2) \leq 2 \int_{r_0}^{r} \beta^2,$$

where the last inequality is a consequence of (7.20). With this, an application of the Gronwall lemma would lead to the unacceptable conclusion that $\beta(r) \equiv 0$ in $\mathbb{R}$ (cf. $(7.14)_2$).

But, if $\beta(r)$ is never null, then (7.17) implies that $\mathbf{t}(r)$ is a constant vector. Furthermore, $\alpha^2(r) < 1$ for all $r \in \mathbb{R}$, and (7.21) reduces to the ODE for α[7]

$$\alpha' = 1 - \alpha^2, \tag{7.22}$$

whose solutions have the form

$$\alpha(r) = \tanh(r - \rho), \quad \rho \in \mathbb{R}, \tag{7.23}$$

and satisfy the boundary conditions $(7.13)_1$.

Acknowledgments. We gratefully acknowledge the valuable comments of two referees.

NUMERICAL SOLUTION OF THE CAUCHY PROBLEM FOR THE STATIONARY SCHRÖDINGER EQUATION USING FADDEEV'S GREEN FUNCTION*

MASARU IKEHATA† AND SAMULI SILTANEN‡

Abstract. Numerical solution of the Cauchy problem for the stationary Schrödinger equation in a bounded two-dimensional domain is discussed. The solution algorithm is based on the properties of Faddeev's Green function. Numerical examples with computer-simulated data are presented, including an application to the inverse potential problem of electrocardiography.

Key words. Cauchy problem, stationary Schrödinger equation, exponentially growing solution, Faddeev's Green function, electrocardiography

1. Introduction.

The Cauchy problem for an elliptic equation is an ill-posed problem appearing in engineering, medical imaging, and geophysics. One important application is to recover the stationary temperature inside a given body from the temperature and heat flux on the boundary of the body. Another application is the inverse problem of electrocardiography, or determination of electric voltage potential on the surface of the heart from measurements on the skin.

We consider the Cauchy problem for the stationary Schrödinger equation. Let $n = 2, 3$ and let $\Omega \subset \mathbb{R}^n$ be a bounded connected domain with Lipschitz boundary. Let $u \in H^2(\Omega)$ satisfy

$$(-\Delta + V)u = 0 \qquad \text{in } \Omega, \tag{1}$$

where $V = V(x)$ is a known, essentially bounded and complex-valued function. We denote by ν the unit outward normal vector field to $\partial\Omega$. Given a nonempty open subset $\Gamma \subset \Omega$, the pair

$$\left(u|_\Gamma, \frac{\partial u}{\partial \nu}\Big|_\Gamma \right)$$

is called the Cauchy data of u on Γ. It is well known that the Cauchy data of u on Γ uniquely determines u in Ω. See [15] for recent uniqueness and stability results of Cauchy problems for general partial differential equations. We are interested in finding an analytic formula and a regularized algorithm for calculating the value of u at a given point in Ω.

In the case $V = 0$, (1) becomes the Laplace equation. In two dimensions the Cauchy problem for the Laplace equation is equivalent to the corresponding Cauchy

problem for the Cauchy–Riemann system of equations provided Ω is simply connected. Carleman [4] gave an explicit formula for calculating the value of the solution of the Cauchy–Riemann system of equations from the Cauchy data on a part of the boundary of a domain having a special shape. In [10] Goluzin and Krylov established a generalization of the formula in the simply connected domain. We refer the reader to [1, 20, 36] for other formulae and related results in complex analysis.

In the higher-dimensional case Yarmukhamedov [34, 35] gave explicit formulae of the Carleman type for the Laplace equation for special Ω and Γ. His result covers also the case when V is a constant function [37]. For constant coefficient partial differential equations several formulae of the Carleman type are described in Tarkhanov [29]. The approach is based on the uniqueness of the Cauchy problem, or equivalently, the Runge approximation property of the governing equations. The common point of their methods is the construction of special fundamental solutions $\Phi_\tau(x, y)$ for the governing equation that depend on a large parameter τ and have the following property: for a fixed $y \in \Omega$ the Cauchy data of $\Phi_\tau(\,\cdot\,, y)$ on $\partial\Omega \setminus \Gamma$ decay as $\tau \longrightarrow \infty$. Following M. M. Lavrent'ev [19], we call those fundamental solutions Carleman functions for the governing equation, Ω and Γ. Explicit construction of Carleman functions for (1) for general Ω and Γ in three dimensions is an interesting open problem.

In [13] the first author gave a formula of the Carleman type for (1) for general V and particular Ω and Γ. Here we present its minor modification given in [14]. The set Ω is the intersection of a convex open set with the half-space $x_n > 0$, and Γ is the part of $\partial\Omega$ satisfying $x_n > 0$. Let us describe the result in the two-dimensional case. The construction of the formula is divided into three steps: first, given $y \in \Omega$, let $D \subset \Omega \cap \{x_2 < y_2\}$ be the interior of a triangle with vertex at y. Second, construct the exponentially growing solution v_τ of Sylvester and Uhlmann [28] for the Schrödinger equation

$$(-\Delta + \tilde{V})v_\tau = \chi_D e^{\tau(x_2-y_2)+i\tau x_1} \quad \text{in } \mathbb{R}^2, \tag{2}$$

where $\tilde{V}$ is the zero extension of V outside Ω. Then the restriction of v_τ to Ω satisfies the equation

$$(-\Delta + V)v_\tau = \chi_D e^{\tau(x_2-y_2)+i\tau x_1} \quad \text{in } \Omega. \tag{3}$$

Third, establish the following asymptotic behavior as $\tau \to \infty$:

$$\int_D e^{\tau(x_2-y_2)+i\tau x_1} u(x)dx \sim \frac{C_D}{2\tau^2} e^{i\tau y_1} u(y), \tag{4}$$

where C_D is a nonzero constant. A combination of (3) and (4) yields the following formula for the solution u of (1):

$$u(y) = \lim_{\tau\to\infty} u_\tau(y), \tag{5}$$

where

$$u_\tau(y) := \frac{2\tau^2 e^{-i\tau y_1}}{C_D} \int_\Gamma \left(\frac{\partial u}{\partial \nu} v_\tau - \frac{\partial v_\tau}{\partial \nu} u \right) d\sigma(x). \tag{6}$$

The construction of exponentially growing solutions is based on the properties of Faddeev's Green function [8],

$$G_\zeta(x) := \frac{e^{i\zeta\cdot x}}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{e^{ix\cdot\xi}}{|\xi|^2 + 2\zeta\cdot\xi} d\xi, \qquad \zeta \in \mathbb{C}^2 \setminus 0, \quad \zeta\cdot\zeta = 0. \tag{7}$$

Therefore one may consider (5) as a new application of G_ζ in addition to inverse boundary value problems and inverse scattering problems (see [31] for the problems).

We present a numerical implementation of (6) in dimension two. The ill-posed Cauchy problem is regularized by choosing τ small enough for the numerical computation to be robust against noise in the data. The main computational task is numerical evaluation of the exponentially growing solutions and their normal derivatives. For this we present an improvement of the algorithm for G_ζ given in [26] and write the derivatives of G_ζ in terms of itself and explicit formulae. The exponentially growing solutions and their derivatives can be computed combining the above with the algorithm introduced in [22] (a modification of the fast Lippmann–Schwinger equation solver of Vainikko [32, 24]). These algorithms have independent interest in the fields of electrical impedance tomography and inverse scattering.

We review some earlier numerical works on the Cauchy problem for the elliptic equation. The constant coefficient case has been studied by Leitão [21], Berntsson and Eldén [2], Cheng et al. [6], Kabanikhin and Karchevsky [16], and Háo and Lesnic [12]. The method of quasi reversibility proposed by Lattés and Lions [18] covers the variable coefficient case, and Klibanov and Santosa [17] gave an explicit estimate of the convergence rate. However, in the proof of the convergence, the uniqueness of the Cauchy problem is essential.

The present solution algorithm does not require uniqueness of the Cauchy problem for the convergence proof, and its implementation does not involve solution of boundary value problems. The computational effort is divided into two parts: first, evaluation of $v_\tau|_\Gamma$ and $\partial v_\tau/\partial\nu|_\Gamma$ for given y, V, Ω, and τ and, second, evaluation of u_τ for given Cauchy data. The second computation is very fast since it is essentially linear filtering of the data. The method can thus be applied to real-time monitoring of fixed targets with changing Cauchy data.

This paper is organized as follows. In section 2 we give details of the reconstruction formula. In section 3 we discuss the stability of our method when applied to noisy data. In section 4 we describe some properties of Faddeev's Green function and show how to evaluate it numerically. In section 5 we describe a numerical implementation of (6). We illustrate the algorithm in sections 6 and 7 by numerical examples using computer-simulated noisy data.

2. Background of the method. Throughout the paper we assume that Ω is the intersection of the open unit disc $B = \{x \in \mathbb{R}^2 \,|\, |x| < 1\}$ with the half-plane $\{x \in \mathbb{R}^2 \,|\, x_2 > t\}$ with $-1 < t < 1$ and that Cauchy data is given on $\Gamma = \{x \in \partial B \,|\, x_2 > t\}$. There is no loss of generality with this simplification of the geometry of Ω since any simply connected domain with a smooth boundary can be conformally mapped to the case when $t = 0$ (see Figure 2.1). However, in section 7 we will consider the case when $t \neq 0$.

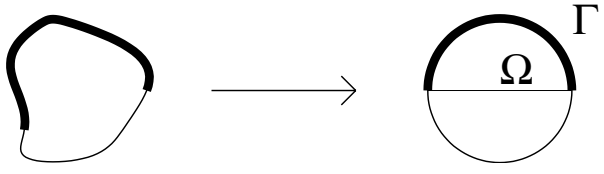

FIG. 2.1. *Conformal mapping of a domain onto the upper half of the unit disc.*

Let u be an $H^2(\Omega)$ solution of the stationary Schrödinger equation

$$-\Delta u + Vu = 0 \quad \text{in } \Omega, \tag{8}$$

where V belongs to the following class.

DEFINITION 2.1. *The potential V is admissible if V is C^2 in each component of $\Omega \setminus c$, where $c = \cup_{j=1}^{J} c_j$ with $c_j \subset \Omega$ compact, piecewise C^1 curves for which $c_i \cap c_j$ is a discrete set if $i \neq j$.*

The set D mentioned in the introduction is defined as follows.

DEFINITION 2.2. *Given $y = (y_1, y_2) \in \Omega$, let $L, p, q \in \mathbb{R}$ satisfy $0 < L \leq y_2 - t$ and*

$$-\sqrt{1-(y_2-L)^2} < y_1 + p < y_1 + q < \sqrt{1-(y_2-L)^2}. \tag{9}$$

We call the interior of the triangle with vertices

$$y = (y_1, y_2),\ y' = (y_1 + p, y_2 - L),\ y'' = (y_1 + q, y_2 - L) \tag{10}$$

a triangular patch D at y (see Figure 2.2). Although not explicitly indicated, D depends on the point y and the parameters L, p, q. D is an open subset of Ω and satisfies $D \subset \{x \,|\, x_2 < y_2\}$.

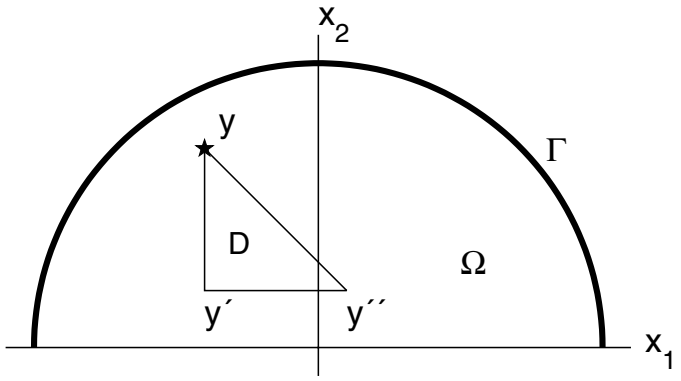

FIG. 2.2. *Geometry of the problem for $t = 0$. Domain Ω is the intersection of the unit disc with the upper half-space $x_2 > 0$. The set $\Gamma \subset \partial\Omega$ is drawn as a thick curve. The reconstruction point y is marked with a star, and one possible choice for the triangular patch D is drawn below y.*

In what follows, we take for simplicity $t = 0$.

Let χ_D denote the characteristic function of D. Let $\tilde{V}$ denote the zero extension of V outside Ω. By Sylvester and Uhlmann [28], for large $\tau \gg 1$ there exists the unique solution w_τ of the integral equation

$$\begin{aligned} w_\tau(x) + \int_{\mathbb{R}^2} g_\tau(x-z)\{\tilde{V}(z) - \chi_D(z)\} w_\tau(z) dz \\ = -\int_{\mathbb{R}^2} g_\tau(x-z)\{\tilde{V}(z) - \chi_D(z)\} dz \end{aligned} \tag{11}$$

such that for $-1 < \delta < 0$

$$\|w_\tau\|_\delta \equiv \left(\int_{\mathbb{R}^2} |w_\tau(x)|^2 (1+|x|^2)^\delta dx \right)^{\frac{1}{2}} = O\left(\frac{1}{\tau}\right). \tag{12}$$

Here g_τ is defined for any $\tau > 0$ by

$$g_\tau(x) = \frac{1}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{e^{ix\cdot\xi} d\xi}{|\xi|^2 + 2\tau(\xi_1 - i\xi_2)}. \tag{13}$$

Note that g_τ satisfies $\{\Delta + 2i\tau(\partial_1 - i\partial_2)\} g_\tau(x) + \delta(x) = 0$ in $\mathbb{R}^2$.

For any $\tau > 0$ the function

$$v_\tau^0(x) = e^{\tau(x_2 - y_2)} e^{i\tau x_1}, \quad x \in \mathbb{R}^2,$$

is harmonic and has the following properties:

If $x_2 > y_2$, then $|v_\tau^0|$ is exponentially growing as $\tau \longrightarrow \infty$.

If $x_2 < y_2$, then $|v_\tau^0|$ is exponentially decaying as $\tau \longrightarrow \infty$.

We see that

$$v_\tau^0(x) g_\tau(x) = e^{-\tau y_2} G_{(\tau, -i\tau)}(x), \tag{14}$$

where $G_{(\tau,-i\tau)}$ is Faddeev's Green function (7). Then one knows that the functions $v'_\tau \equiv v_\tau^0(1 + w_\tau)$ become the solutions of the equation

$$-\Delta v'_\tau + \tilde{V} v'_\tau = \chi_D v'_\tau \quad \text{in } \mathbb{R}^2$$

and satisfy $v'_\tau \sim v_\tau^0$ as $\tau \to \infty$ in the sense that (12) holds. Define

$$v_\tau = v'_\tau|_\Omega. \tag{15}$$

Since $v'_\tau \in H^2_{\mathrm{loc}}(\mathbb{R}^2)$, v_τ is an $H^2(\Omega)$ solution of the equation

$$-\Delta v_\tau + V v_\tau = \chi_D v_\tau \quad \text{in } \Omega.$$

Now, by Theorem 2.1 of [13]

$$u(y) = \lim_{\tau\to\infty} u_\tau(y) = \lim_{\tau\to\infty} \frac{2\tau^2 e^{-i\tau y_1}}{C_D} \int_\Gamma \left(\frac{\partial u}{\partial \nu} v_\tau - \frac{\partial v_\tau}{\partial \nu} u \right) d\sigma(x), \tag{16}$$

where

$$C_D := \frac{2L(q-p)}{(L - ip)(L - iq)}. \tag{17}$$

The proof uses the estimate $\|w_\tau\|_{L^\infty(\Omega)} = O(\frac{1}{\tau})$ which comes from (2.11) of Proposition 2.3 in [27] and the well-known fact that the growth rate of $\|w_\tau\|_{H^2(\Omega)}$ with respect to τ is at most algebraic.

Note that one can give a simpler choice of v_τ appearing in (16). This is done in [14]. More precisely, for large $\tau \gg 1$ there exists the unique solution w'_τ of the integral equation

$$w'_\tau(x) + \int_{\mathbb{R}^2} g_\tau(x - z) \tilde{V}(z) w'_\tau(z) dz = \int_{\mathbb{R}^2} g_\tau(x - z) \chi_D(z) dz \tag{18}$$

such that for $-1 < \delta < 0$ we have $\|w'_\tau\|_\delta = O(1/\tau)$. Then

$$v''_\tau = v_\tau^0 w'_\tau \tag{19}$$

satisfies the equation $-\Delta v''_\tau + \tilde{V} v''_\tau = \chi_D v_\tau^0$ in $\mathbb{R}^2$. A trivial modification of the proof of Theorem 2.1 of [13] shows that (16) holds with the choice

$$v_\tau = v''_\tau|_\Omega. \tag{20}$$

In this case we use only the algebraic growth of $\|w'_\tau\|_{H^2(\Omega)}$ with respect to τ. Hereafter we consider v_τ given by (20) and not by (15).

3. Stability of the method. In this section we consider the case when the Cauchy data of u on Γ contains noise. Let $M > 0$ satisfy

$$\|V\|_{L^\infty(\Omega)} \leq M.$$

Given $y \in \Omega$ choose a triangular patch D at y according to Definition 2.2. Fix $\delta \in]-1, 0[$. Using a perturbation argument, (2.7) in Proposition 2.1 in [23], and the argument made for the proof of (2.53) in Lemma 2.11 of [23], one obtains the unique solvability of (18). More precisely, there exist positive constants $C_1(M)$ and $C_2(M)$ (independent of y and D) such that for $\tau > C_1(M)$ the equation (18) has a unique solution w'_τ satisfying the estimate

$$\tau\|w'_\tau\|_\delta + \|\nabla w'_\tau\|_\delta + \tau^{-1}\sum_{i,j=1}^{2}\|\partial_i\partial_j w'_\tau\|_\delta \leq C_2(M). \tag{21}$$

For v_τ given by (20) and $(f, g) \in L^2(\Gamma) \times L^2(\Gamma)$ define

$$S_\tau(f, g)(y) = \frac{2\tau^2 e^{-i\tau y_1}}{C_D}\int_\Gamma \left(gv_\tau - \frac{\partial v_\tau}{\partial \nu} f\right) d\sigma.$$

Let $E = (E_1, E_2) \in L^2(\Gamma) \times L^2(\Gamma)$ be additive noise on the Cauchy data on Γ. Denote $\|E\| = (\|E_1\|^2_{L^2(\Gamma)} + \|E_2\|^2_{L^2(\Gamma)})^{1/2}$.

The problem is to calculate an approximate value of $u(y)$ from

$$S_\tau\left(u|_\Gamma + E_1, \left.\frac{\partial u}{\partial \nu}\right|_\Gamma + E_2\right)(y)$$

with $\tau > C_1(M)$ when $\|E\|$ is small. One cannot choose extremely large τ since such a selection enlarges the effect of noise. The suitable choice of τ is just the problem of regularizing the formula (16).

In order to describe a result quantitatively and show the effect of the choice of D we prepare two lemmas.

LEMMA 3.1. *Assume that u belongs to the space of Hölder continuous functions $C^{0,\theta}(\overline{D})$ with $0 < \theta \leq 1$. Then for all $\tau > 0$ we have*

$$\begin{aligned}&\left|\tau^2 e^{-\tau(y_2+iy_1)}\int_D u(x)e^{\tau(x_2+ix_1)}dx - \frac{C_D}{2}u(y)\right| \\ &\leq \frac{q-p}{L}\|u\|_{C^{0,\theta}(\overline{D})}\left\{(\tau L+1)e^{-\tau L} + \left(\frac{\operatorname{diam} D}{L}\right)^\theta \frac{C_\theta}{\tau^\theta}\right\},\end{aligned} \tag{22}$$

where C_θ is a positive constant depending only on θ, and q, p, L are as in Definition 2.2.

Proof. See [13, Lemma 2]. □

LEMMA 3.2. *Let $0 < \epsilon < 1$ and y satisfy $y_2 > \epsilon$. There exists such a positive constant $C_{M,\epsilon}$ depending on M and ϵ that for any $u \in H^2(\Omega)$ and v_τ with $\tau > C_1(M)$ given by (20) the following estimate holds:*

$$\left|\tau^2 e^{-i\tau y_1}\int_{\partial\Omega\setminus\Gamma}\left(\frac{\partial u}{\partial \nu}v_\tau - \frac{\partial v_\tau}{\partial \nu}u\right)d\sigma\right| \leq C_{M,\epsilon}\|u\|_{H^2(\Omega)}\tau^3 e^{-\frac{\tau\epsilon}{2}}. \tag{23}$$

Proof. Using (19), (20), (21), and the estimate $|e^{\tau(x_2-y_2)}| \le e^{-\tau\varepsilon/2}$ for $x \in \Omega_\varepsilon$ we obtain

$$\|v_\tau\|_{H^2(\Omega_\epsilon)} \le C'_M \tau e^{-\frac{\tau\epsilon}{2}}, \tag{24}$$

where $\Omega_\epsilon = \{x \in \Omega \,|\, 0 < x_2 < \epsilon/2\}$ and C'_M is a positive constant independent of ϵ. Since $\partial\Omega_\epsilon$ is Lipschitz, we have the following consequence of a general trace theorem [11]: for any $\phi \in H^2(\Omega_\varepsilon)$ we have

$$\|\nabla\phi\|_{L^2(\partial\Omega_\varepsilon)} + \|\phi\|_{L^2(\partial\Omega_\varepsilon)} \le C_\varepsilon \|\phi\|_{H^2(\Omega_\varepsilon)}. \tag{25}$$

Combining (24) and (25) yields (23). ∎

Now we discuss the problem mentioned above. Integration by parts yields

$$\tau^2 e^{-i\tau y_1} \int_\Gamma \left(\frac{\partial u}{\partial \nu} v_\tau - \frac{\partial v_\tau}{\partial \nu} u \right) d\sigma = \tau^2 e^{-\tau(y_2+iy_1)} \int_D u(x) e^{\tau(x_2+ix_1)} dx + \tau^2 e^{-i\tau y_1} \int_{\partial\Omega\setminus\Gamma} \left(\frac{\partial u}{\partial \nu} v_\tau - \frac{\partial v_\tau}{\partial \nu} u \right) d\sigma.$$

Recalling (6), we rewrite

$$\frac{C_D}{2} u_\tau(y) = \frac{C_D}{2} u(y) + \left\{ \tau^2 e^{-\tau(y_2+iy_1)} \int_D u(x) e^{\tau(x_2+ix_1)} dx - \frac{C_D}{2} u(y) \right\} + \tau^2 e^{-i\tau y_1} \int_{\partial\Omega\setminus\Gamma} \left(\frac{\partial u}{\partial \nu} v_\tau - \frac{\partial v_\tau}{\partial \nu} u \right) d\sigma.$$

This together with (22) and (23) yields

$$|u_\tau(y) - u(y)| \frac{|C_D|}{2} \le \frac{q-p}{L} \|u\|_{C^{0,\theta}(\overline{D})} \left\{ (\tau L + 1) e^{-\tau L} + \left(\frac{\operatorname{diam} D}{L} \right)^\theta \frac{C_\theta}{\tau^\theta} \right\} + C_{M,\epsilon} \|u\|_{H^2(\Omega)} \tau^3 e^{-\frac{\tau\epsilon}{2}}. \tag{26}$$

This is an error estimate of the formula (16), and the order of the convergence is $O(\tau^{-\theta})$ as $\tau \longrightarrow \infty$.

Write

$$S_\tau \left(u|_\Gamma + E_1, \left. \frac{\partial u}{\partial \nu} \right|_\Gamma + E_2 \right)(y) = u_\tau(y) + S_\tau(E_1, E_2)(y).$$

From (17) one has

$$|C_D| = \frac{2L(q-p)}{\sqrt{L^2+p^2}\sqrt{L^2+q^2}} \le 2. \tag{27}$$

Recalling (19) and (20), from (21) we have

$$\|v_\tau\|_{H^2(\Omega)} \le C'_M \tau e^{\tau(1-y_2)}, \qquad \tau > C_1(M), \tag{28}$$

where C'_M is a positive constant. Using (27), (28), and the trace theorem we see that there exists a positive constant C''_M such that

$$\left| S_\tau \left(u|_\Gamma + E_1, \left. \frac{\partial u}{\partial \nu} \right|_\Gamma + E_2 \right)(y) - u_\tau(y) \right| \frac{|C_D|}{2} \le C''_M \|E\| \tau^3 e^{\tau(1-y_2)}. \tag{29}$$

Let $A > 0$ satisfy

$$\|u\|_{H^2(\Omega)} \leq A. \tag{30}$$

By the Sobolev imbedding theorem, one can choose a positive constant C'_θ depending on $0 < \theta < 1$ such that for all $v \in H^2(\Omega)$

$$\|v\|_{C^{0,\theta}(\overline{\Omega})} \leq C'_\theta \|v\|_{H^2(\Omega)}. \tag{31}$$

Now from (26), (29), (30), and (31) we obtain

$$\begin{aligned}
&\sup_{\|E\| \leq \eta} \left| S_\tau \left(u|_\Gamma + E_1, \left. \frac{\partial u}{\partial \nu} \right|_\Gamma + E_2 \right)(y) - u(y) \right| |C_D| \\
&\quad \leq \frac{q-p}{L} C'_\theta A \left\{ (\tau L + 1) e^{-\tau L} + \left(\frac{\operatorname{diam} D}{L} \right)^\theta \frac{C_\theta}{\tau^\theta} \right\} \\
&\quad + C_{M,\epsilon} A \tau^3 e^{-\frac{\tau \epsilon}{2}} + C''_M \eta \tau^3 e^{\tau(1-y_2)}.
\end{aligned} \tag{32}$$

The last term of this right-hand side estimates the speed of enlarging the effect of noise. We choose a suitable $\tau > C_1(M)$ depending on η in such a way that for this τ the right-hand side converges to zero as $\eta \longrightarrow 0$. There should be several choices of τ. Here we ignore the exponential decaying terms in the right-hand side of (32) and consider minimizing the remaining term $f(\tau; \eta)$ with respect to $\tau > C_1(M)$:

$$f(\tau; \eta) = \frac{\alpha}{\tau^\theta} + \beta \eta \tau^3 e^{\tau(1-y_2)},$$

where

$$\alpha = \frac{q-p}{L} C'_\theta A \left(\frac{\operatorname{diam} D}{L} \right)^\theta C_\theta; \qquad \beta = C''_M.$$

Since $\lim_{\tau \longrightarrow 0} f(\tau; \eta) = \infty$ and $\lim_{\tau \longrightarrow \infty} f(\tau; \eta) = \infty$, $f(\tau; \eta)$ attains its minimum value in a point in the interval $]0, \infty[$. The point has to satisfy the equation $f'(\tau; \eta) = 0$. This is equivalent to the equation

$$\tau^{\theta+3} \{3 + (1 - y_2)\tau\} e^{\tau(1-y_2)} = \frac{\alpha \theta}{\beta \eta}. \tag{33}$$

This equation has a unique positive solution and can be written as

$$\tau = \tau \left(\frac{\alpha \theta}{\beta \eta}, y_2 \right) = \frac{1}{1 - y_2} w \left(\frac{\alpha \theta}{\beta \eta} (1 - y_2)^{\theta+3} \right),$$

where $w = w(s), s > 0$, is the unique positive solution of the equation

$$w^{\theta+3}(3 + w) e^w = s. \tag{34}$$

If $\tau(\alpha\beta/\beta\eta, y_2) \leq C_1(M)$, then $f(\tau; \eta)$ does not attain its greatest lower bound in the interval $]C_1(M), \infty[$. So we assume that the magnitude of the noise η satisfies

$$\tau \left(\frac{\alpha \theta}{\beta \eta}, y_2 \right) > C_1(M).$$

This is equivalent to the inequality

$$C_1(M)^{\theta+3}\{3+(1-y_2)C_1(M)\}e^{C_1(M)(1-y_2)} < \frac{\alpha\theta}{\beta\eta},$$

that is,

$$\eta < \frac{\alpha\theta C_1(M)^{-(\theta+3)}e^{-C_1(M)(1-y_2)}}{\beta\{3+(1-y_2)C_1(M)\}}. \tag{35}$$

From (33) we have

$$\min_{\tau>C_1(M)} f(\tau;\eta) = f\left(\tau\left(\frac{\alpha\theta}{\beta\eta},y_2\right);\eta\right) = \frac{\alpha}{\tau(\frac{\alpha\theta}{\beta\eta},y_2)^{\theta}}\left\{1+\frac{\theta}{3+(1-y_2)\tau(\frac{\alpha\theta}{\beta\eta},y_2)}\right\}; \tag{36}$$

for $\tau = \tau(\alpha\theta/\beta\eta, y_2)$,

$$e^{-\tau L} = \left(\frac{\beta\eta}{\alpha\theta}\right)^{\frac{L}{1-y_2}}\{\tau^{\theta+3}(3+(1-y_2)\tau)\}^{\frac{L}{1-y_2}}, \tag{37}$$

$$e^{-\tau\epsilon/2} = \left(\frac{\beta\eta}{\alpha\theta}\right)^{\frac{\epsilon/2}{1-y_2}}\{\tau^{\theta+3}(3+(1-y_2)\tau)\}^{\frac{\epsilon/2}{1-y_2}}. \tag{38}$$

It is easy to see that, from (34), we have $w(s)\sim\log s$ as $s\longrightarrow\infty$, and one concludes that, as $\eta\longrightarrow 0$,

$$\tau\left(\frac{\alpha\theta}{\beta\eta},y_2\right) \sim \frac{1}{1-y_2}\log\left\{\frac{\alpha\theta}{\beta\eta}(1-y_2)^{\theta+3}\right\}. \tag{39}$$

Therefore the order of blowing up of τ is $|\log\eta|$ as $\eta\longrightarrow 0$. Moreover, from (34) one knows that $w(s)\sim(s/3)^{1/(\theta+3)}$ as $s\longrightarrow 0$. Then, for fixed η that satisfies the condition

$$\eta < \min_{y_2>\epsilon}\frac{\alpha\theta C_1(M)^{-(\theta+3)}e^{-C_1(M)(1-y_2)}}{\beta\{3+(1-y_2)C_1(M)\}} = \frac{\alpha\theta C_1(M)^{-(\theta+3)}e^{-C_1(M)(1-\epsilon)}}{\beta\{3+(1-\epsilon)C_1(M)\}},$$

we obtain, as $y_2\longrightarrow 1$,

$$\tau\left(\frac{\alpha\theta}{\beta\eta},y_2\right)\sim\left(\frac{\alpha\theta}{3\beta\eta}\right)^{\frac{1}{\theta+3}}.$$

Note that from (36), (37), (38), and (39) we obtain, for $\tau=\tau(\alpha\theta/\beta\eta,y_2)$,

$$\sup_{\|E\|\le\eta}\left|S_\tau\left(u|_\Gamma+E_1,\left.\frac{\partial u}{\partial\nu}\right|_\Gamma+E_2\right)(y)-u(y)\right||C_D| = O(|\log\eta|^{-\theta})$$

as $\eta\longrightarrow 0$. This is a regularized formula of (16).

It should be noted that the above type of argument for choosing τ is due to Lavrent'ev [19]. Therein he gave a regularization of Carleman's original formula.

We remark also that the conformal mapping depicted in Figure 2.1 deforms the potential in such a way that the bound M can become very large. This in turn makes the error estimates worse and can have an impact on the quality of the numerical solution.

4. Faddeev's Green function.

4.1. Definitions and basic properties. Consider the differential operator $\Delta_\zeta := \Delta + 2i\zeta \cdot \nabla$ with $\zeta \in \mathbb{C}^2 \setminus 0$ satisfying $\zeta \cdot \zeta = 0$. Any such ζ can be written in the form $\zeta = (k, \pm ik)$ for some $k \in \mathbb{C} \setminus 0$. We consider fundamental solutions

$$g_k^\pm(x) = \frac{1}{(2\pi)^2} \int_{\mathbb{R}^2} \frac{e^{ix\cdot\xi}}{|\xi|^2 + 2k(\xi_1 \pm i\xi_2)} d\xi, \qquad k \in \mathbb{C} \setminus 0, \tag{40}$$

satisfying

$$-\Delta_{(k,\pm ik)} g_k^\pm(x) = \Big(-\Delta - 2ik\Big(\frac{\partial}{\partial x_1} \pm i\frac{\partial}{\partial x_2}\Big)\Big) g_k^\pm(x) = \delta(x). \tag{41}$$

Then Faddeev's Green function (7) takes the form

$$G_{(k,\pm ik)}(x) = e^{ik(x_1 \pm ix_2)} g_k^\pm(x), \qquad k \in \mathbb{C} \setminus 0. \tag{42}$$

We see from (40) that the two types of fundamental solutions are related by

$$g_k^-(x) = \overline{g_{\bar k}^+(-x)}. \tag{43}$$

Moreover, coordinate changes in (40) give the following symmetries:

$$g_k^+(x) = g_1^+(kx), \qquad g_k^+(x) = \overline{g_{\bar k}^+(-\bar x)}, \qquad g_k^+(x) = e_{-k}(x)\overline{g_k^+(x)}, \tag{44}$$

where $e_{-k}(x) = \exp(-i(kx + \bar k \bar x))$. It is easy to see from (13), (43), and (44) that

$$g_\tau(x) = g_\tau^-(x) = \overline{g_\tau^+(-x)} = \overline{g_1^+(-\tau x)}. \tag{45}$$

4.2. Numerical evaluation of g_1^+. We improve here the algorithm for g_1^+ given in [25, 26]. Divide the plane into disjoint regions $D_1, \dots, D_7$ as in Figure 4.1. We describe how to numerically evaluate $g_1^+(x)$ accurately in each region.

In region $D_1 = \{|x| \le R_1\}$ with $R_1 = 5.5$ we use formulae (3.10) and (3.12) of [3]:

$$g_1^+(x) = -\frac{e^{-ix}}{4\pi}\Big(2\gamma + \log|x|^2 + \sum_{n=1}^{\infty} \frac{(ix)^n + (-i\bar x)^n}{nn!}\Big), \tag{46}$$

where $\gamma \approx 0.577215665$ is the Euler–Mascheroni constant. The infinite sum in (46) is truncated at $n = 23$.

In region D_3 we use formula (82) of [25]:

$$g_1(x) = \frac{e^{-ix_1}}{2\pi} \mathrm{Re}\left[-e^{ix_1} \sum_{j=0}^{N} \frac{j!}{(ix)^{j+1}} + \frac{(N+1)! e^{ix_1}}{(-x)^{N+1}} \int_0^\infty \frac{e^{-t(x_1+ix_2)}}{(t-i)^{N+2}} dt \right]. \tag{47}$$

We use $N = 6$ and implement the one-dimensional integration of the exponentially decaying integrand with Gaussian quadrature.

For region D_2 we modify (47) using residue calculus:

$$\int_0^\infty \frac{e^{-ix_2 t - x_1 t}}{(t-i)^{N+2}} dt = (1+i) \int_0^\infty \frac{e^{-is(x_2+x_1) + s(x_2 - x_1)}}{(s + is - i)^{N+2}} ds. \tag{48}$$

This modification ensures exponential decay of the integrand.

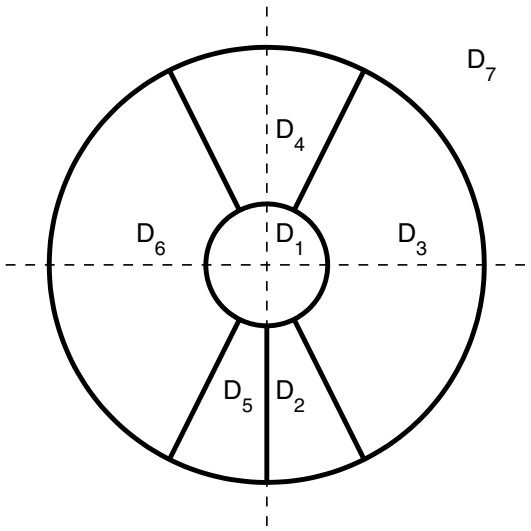

FIG. 4.1. *Computational regions $D_1, \dots, D_7$ dividing the plane into disjoint parts. The radii of the two circles are $R_1 = 5.5$ and $R_2 = 25$. The slopes of the skew lines dividing regions are either 2 or -2. It is irrelevant for the algorithm how the boundary points are divided between the regions.*

For region D_4 we modify (47) using residue calculus:

$$\int_0^\infty \frac{e^{-ix_2t-x_1t}}{(t-i)^{N+2}}dt = -i\int_0^\infty \frac{e^{-x_2s+ix_1s}}{(-is-i)^{N+2}}ds. \tag{49}$$

Again, the modified integrand decays exponentially.

For regions D_5 and D_6 we use the reflectional symmetry

$$g_1^+(-x_1, x_2) = \overline{g_1^+(x_1, x_2)} \tag{50}$$

and the algorithms for reflected regions D_2 and D_3 described above.

In region $D_7 = \{|x| \geq R_2\}$ with $R_2 = 25$ we set $N = 9$ and ignore the term with the integral in (47).

Let us comment on the choice of the radii R_1, R_2. The choice of R_1 is a trade-off: if R_1 is small, then only a few terms are needed in the truncated power series (46) to achieve desired accuracy, but on the other hand, the numerical integrations in formulae (47), (48), and (49) require many quadrature points to achieve the same accuracy. The choice $R_1 = 5.5$ gives a good balance but is not proven to be optimal. For radii $R_1 > 1$ formula (46) leads to faster computation and less memory consumption than the previous approach based on the Poisson kernel used in [25, 26]. The choice of R_2 is a similar trade-off between accuracy and computational speed.

4.3. Derivatives. As shown in [25], we can write derivatives of $g_k^\pm$ as follows.

LEMMA 4.1. *Define the functions $g_k^\pm(x)$ by (40) for $k \in \mathbb{C} \setminus 0$. Then*

$$\frac{\partial g_k^+}{\partial x_1}(x) = -\frac{1}{4\pi x} - \frac{e_{-k}(x)}{4\pi \bar{x}} - ikg_k^+(x), \tag{51}$$

$$\frac{\partial g_k^+}{\partial x_2}(x) = +\frac{1}{4\pi i x} - \frac{e_{-k}(x)}{4\pi i \bar{x}} + kg_k^+(x), \tag{52}$$

$$\frac{\partial g_k^-}{\partial x_1}(x) = -\frac{1}{4\pi\bar{x}} - \frac{e_{-\bar{k}}(x)}{4\pi x} - ikg_k^-(x), \tag{53}$$

$$\frac{\partial g_k^-}{\partial x_2}(x) = -\frac{1}{4\pi i\bar{x}} + \frac{e_{-\bar{k}}(x)}{4\pi ix} - kg_k^-(x), \tag{54}$$

where $e_{-k}(x) = \exp(-i(kx + \bar{k}\bar{x}))$, $x = x_1 + ix_2$, *and* $\bar{x} = x_1 - ix_2$.

Proof. By (43) and (44) it is enough to consider g_1^- and apply the chain rule.

Denote $\partial = (\partial/\partial x_1 - i\partial/\partial x_2)/2$. Let us compute $\partial g_1^-(x)$. By (40) we have

$$\partial g_1^-(x) = \frac{i}{2}\frac{1}{(2\pi)^2}\int_{\mathbb{R}^2}\frac{e^{ix\cdot\xi}}{\xi_1 + i\xi_2 + 2}d\xi = \frac{ie^{-2ix_1}}{2(2\pi)^2}\int_{\mathbb{R}^2}\frac{e^{ix\cdot\xi}}{\xi_1 + i\xi_2}d\xi. \tag{55}$$

Furthermore,

$$\frac{2}{i}\frac{1}{(2\pi)^2}\int_{\mathbb{R}^2}\frac{e^{ix\cdot\xi}}{\xi_1 + i\xi_2}d\xi = \frac{1}{\pi(x_1 + ix_2)}. \tag{56}$$

Combining (55) and (56) we get

$$\partial g_1^-(x) = -\frac{e^{-i2x_1}}{4\pi(x_1 + ix_2)}. \tag{57}$$

Next we determine $\bar{\partial} g_1^-(x)$. Combining (57) and (44) gives

$$-\frac{e^{i2x_1}}{4\pi(x_1 - ix_2)} = \overline{\partial g_1^-(x)} = \bar{\partial}\,\overline{g_1^-(x)} = \bar{\partial}e^{i(x+\bar{x})}g_1^-(x) = ie^{i2x_1}g_1^-(x) + e^{i2x_1}\bar{\partial}g_1^-(x),$$

and we have

$$\bar{\partial}g_1^-(x) = -\frac{1}{4\pi(x_1 - ix_2)} - ig_1^-(x). \tag{58}$$

Now formulae (57) and (58) yield the claim for $\tau = 1$ since $\partial_1 g_1^- = \partial g_1^- + \bar{\partial}g_1^-$ and $\partial_2 g_1^- = -i(\bar{\partial}g_1^- - \partial g_1^-)$. ∎

We remark that with formulae (51)–(54) any derivatives of Faddeev's Green functions can be written in terms of the Green functions themselves and explicit expressions. For instance,

$$\bar{\partial}G_{(\tau,-i\tau)}(x) = \bar{\partial}[e^{i\tau\bar{x}}g_\tau^-(x)] = e^{i\tau\bar{x}}[i\tau g_\tau^-(x) + \bar{\partial}g_\tau^-(x)] = -\frac{e^{i\tau(x_1 - ix_2)}}{4\pi(x_1 - ix_2)}. \tag{59}$$

This indicates a relationship between Faddeev's Green function and Fok–Kuni's Carleman function in the complex domain [9].

5. Numerical solution of the Cauchy problem. We discuss step by step the numerical implementation of formula (6) with fixed $y \in \Omega$.

5.1. Integration on Γ. We must choose a numerical quadrature for Γ. This is a collection of points $x^{(k)} \in \Gamma$ with $k = 1, \ldots, K$ and corresponding weights $w^{(k)}$ satisfying

$$\int_\Gamma f d\sigma \approx \sum_{k=1}^{K} w^{(k)} f(x^{(k)}). \tag{60}$$

Suitable choices are, e.g., Simpson's rule or Gaussian quadrature.

5.2. Discussion of data. We must evaluate the Cauchy data $u|_\Gamma$ and $\frac{\partial u}{\partial \nu}|_\Gamma$ on the quadrature points $x^{(k)} \in \Gamma$. How this can be done depends on the way the data are given in a particular application. We discuss here one possibility for evaluating the trace; the normal derivative can be treated similarly.

Assume that our knowledge of $u|_\Gamma$ is a finite collection of noisy point samples:

$$m_j := u(\tilde{z}^{(j)}) + \varepsilon_j, \qquad \tilde{z}^{(j)} \in \Gamma, \quad j = 1, \dots, J_0, \tag{61}$$

where ε_j for $j = 1, \dots, J_0$ are independent Gaussian, real-valued, zero-mean random variables with standard deviation $\sigma > 0$.

Define $z^{(k)} = (\cos\theta_k, \sin\theta_k) \in \Gamma$ with $\theta_k = (k-1)\pi/(J-1)$ with $k = 1, \dots, J$ and $J \geq J_0$. Assume that the data points $\tilde{z}^{(j)}$ are included in the evaluation points:

$$\tilde{z}^{(j)} = z^{(k_j)}, \qquad j = 1, \dots, J_0, \quad 1 \leq k_j \leq J. \tag{62}$$

Next we approximate $u(z^{(k)})$ under the a priori assumption that u is smooth.

Denote by $U = [U_1, \dots, U_J]^T = [u(z^{(1)}), \dots, u(z^{(J)})]^T$ the unknown values and by $m = [m_1, \dots, m_J]^T$ the measured data. We use Tikhonov regularization [30] with second derivative penalty. That is, we solve the optimization problem

$$\hat{U} := \arg \min_U \{\|\mathcal{R}U - m\|_2^2 + \alpha \|\mathcal{D}U\|_2^2\}. \tag{63}$$

The first term in the penalty functional (63) describes how well U fits the data m. The matrix $\mathcal{R}$ implements (62): each row of $\mathcal{R}$ has all zeros except the entry 1 in the k_jth column. The second term in (63) expresses our a priori knowledge on u: we know that u is smooth, so we take the matrix $\mathcal{D} : \mathbb{R}^J \to \mathbb{R}^{J-2}$ to be the second-order difference matrix

$$\mathcal{D}(U)_k = \frac{1}{(\Delta\theta)^2}(U_{k+1} - 2U_k + U_{k-1}), \qquad k = 2, \dots, J-1.$$

The parameter $\alpha > 0$ is the regularization parameter: the greater α is, the stronger we require smoothness from the reconstruction. It is practical to write (63) in the stacked form as explained by Varah [33]:

$$\begin{bmatrix} \mathcal{R} \\ \sqrt{\alpha}\mathcal{D} \end{bmatrix} U = \begin{bmatrix} m \\ 0 \end{bmatrix}. \tag{64}$$

The regularized solution $\hat{U}$ is the least squares solution of (64).

Finally, we interpolate the values $u(x^{(k)})$ at the quadrature points in (60) with spline interpolation from the recovered values $u(z^{(k)})$. Under the smoothness assumption this does not produce significant error.

5.3. Choosing the triangle D. We need a systematic choice for $D = D(y)$. The analysis in section 3 suggests the following:

1. Better results are expected in the domain $y_2 \geq 1/2$ if one chooses $L = y_2$. This is because $L \geq 1 - y_2$ and the convergence rate of (37) is better than Hölder.
2. The constant $|C_D|$ should be as large as possible because the inverse of $|C_D|$ enlarges the error (32).
3. Note that $\operatorname{diam} D/L \geq 1$ and cannot be small.

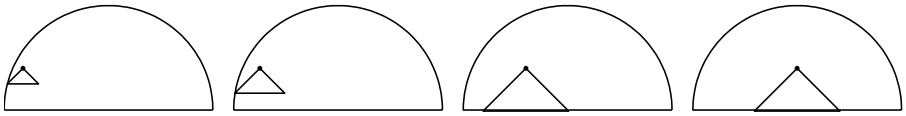

FIG. 5.1. *Triangular patches D corresponding to some y.*

We take vertices of the triangle enclosing D to be

$$(y_1, y_2), \qquad (y_1 - L, y_2 - L), \qquad (y_1 + L, y_2 - L), \tag{65}$$

with $L > 0$ taken as large as possible while still having $D \subset \Omega$. See Figure 5.1.

Now $p = -L$ and $q = L$, so

$$C_D = \frac{2L(q-p)}{(L-ip)(L-iq)} = \frac{4L^2}{L^2(1+i)(1-i)} = 2. \tag{66}$$

Note that in light of (27) this choice of C_D maximizes $|C_D|$.

5.4. Computing exponentially growing solutions. We want to evaluate the function v_τ given by (20) at the points $x^{(k)} \in \Gamma$ for $k = 1, \ldots, K$. We have $v_\tau|_\Gamma = v_\tau^0 w'_\tau|_\Gamma$ with w'_τ solving (18). In the case $V \equiv 0$, solving (18) amounts to computing a convolution. If $V \neq 0$, write (18) in the form

$$[I + g_\tau * (\tilde{V} \cdot\ )] w'_\tau = f, \tag{67}$$

where $f = g_\tau * \chi_D$. A numerical solution method for (67) is described in [22]. It is a modification of Vainikko's fast Lippmann–Schwinger solver [32, section 2]. This method is valid for potentials in the class of Definition 2.1.

Given an integer $m > 1$, the outcome of the solution algorithm is the set

$$\{w'_\tau(x^{(\ell)})\}_{\ell=1}^{M^2},$$

where the evaluation points $x^{(\ell)}$ belong to the Cartesian grid

$$\begin{aligned} &\mathcal{G}_m = \{jh \,|\, j \in \mathbb{Z}_m^2\}, \\ &\mathbb{Z}_m^2 = \{j = (j_1, j_2) \in \mathbb{Z}^2 \,|\, -2^{m-1} \le j_l < 2^{m-1},\ l = 1, 2\}, \end{aligned} \tag{68}$$

where $s > 1$ is a real number, $M = 2^m$, and $h = 2s/M$.

5.5. Computing derivatives of exponentially growing solutions. We need the values $\partial v_\tau / \partial \nu(x^{(k)})$ for $k = 1, \ldots, K$. We show that it is enough to evaluate w'_τ in addition to explicit formulae.

Take $\tau > 0$ and let w'_τ be the solution of $w'_\tau = g_\tau * \chi_D - g_\tau * (\tilde{V} w'_\tau)$. The derivatives $\partial_j w'_\tau$ for $j = 1, 2$ are given by

$$\partial_j w'_\tau = -(\partial_j g_\tau) * (\tilde{V} w'_\tau - \chi_D). \tag{69}$$

Using Lemma 4.1 we get

$$\begin{aligned}
\frac{\partial v_\tau}{\partial \nu} &= e^{-\tau y_2}\frac{\partial(e^{i\tau\bar{x}}w'_\tau)}{\partial \nu} = e^{-\tau y_2}\left[\nu_1\frac{\partial(e^{i\tau\bar{x}}w'_\tau)}{\partial x_1}+\nu_2\frac{\partial(e^{i\tau\bar{x}}w'_\tau)}{\partial x_2}\right]\\
&= e^{\tau(x_2-y_2)}e^{i\tau x_1}[i\tau\nu_1 w'_\tau+\tau\nu_2 w'_\tau-(\nu_1(\partial_1 g_\tau)+\nu_2(\partial_2 g_\tau))*(\tilde{V}w'_\tau-\chi_D)]\\
&= e^{\tau(x_2-y_2)}e^{i\tau x_1}\left[i\tau\nu_1 w'_\tau+\tau\nu_2 w'_\tau\right.\\
&\qquad -\nu_1\left(-\frac{1}{4\pi\bar{x}}-\frac{e_{-\bar{\tau}}(x)}{4\pi x}-i\tau g_\tau\right)*(\tilde{V}w'_\tau-\chi_D)\\
&\qquad \left.-\nu_2\left(-\frac{1}{4\pi i\bar{x}}+\frac{e_{-\bar{\tau}}(x)}{4\pi i x}-\tau g_\tau\right)*(\tilde{V}w'_\tau-\chi_D)\right] \qquad (70)\\
&= \frac{e^{\tau(x_2-y_2)}e^{i\tau x_1}}{4\pi}\left[\left(\nu_1\left(\frac{1}{\bar{x}}+\frac{e^{-i2\tau x_1}}{x}\right)+\nu_2\left(\frac{1}{i\bar{x}}-\frac{e^{-i2\tau x_1}}{ix}\right)\right)*(\tilde{V}w'_\tau-\chi_D)\right],
\end{aligned}$$

where we used formulae (53) and (54) and the real-valuedness of τ. Note the cancellation of four terms containing w'_τ resulting from the identity $w'_\tau = -g_\tau * (\tilde{V}w'_\tau - \chi_D)$.

5.6. Choosing τ. Theoretically, the larger $\tau > 0$ is, the closer $u_\tau(y)$ is to $u(y)$. However, too large τ leads to computations involving exponentially large numbers and numerical instability. This is even more so when the data is noisy. Thus τ must be chosen large enough for the approximation $u(y) \approx u_\tau(y)$ to be accurate enough but small enough to avoid instability. We discussed the optimal choice of τ theoretically in section 3, and in section 6 we study several choices of τ numerically.

6. Numerical results for $V \equiv 0$.

6.1. The model problem. Let $u = \mathrm{Re}((x_1 + ix_2)^4)$ be the harmonic function to be recovered from its Cauchy data on

$$\Gamma = \{x_1 + ix_2 = e^{i\theta} \,|\, 0 < \theta < \pi\} \subset \partial\Omega. \qquad (71)$$

See Figure 6.1 for a contour plot of u in the domain Ω together with plot of trace of u and plot of $\partial u/\partial\nu$.

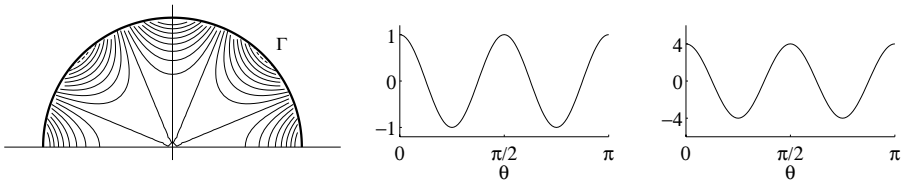

FIG. 6.1. *Left: contour plot of the harmonic function u in the domain Ω. Middle: plot of the trace $u|_\Gamma$ as function of angular parameter θ. Right: plot of normal derivative $\partial u/\partial\nu|_\Gamma$.*

6.2. Details of implementation.

Step 1*: Integration on* Γ. According to a given y, we divide Γ into three intervals:

$$0 < \theta < \tilde{\theta}, \qquad \tilde{\theta} < \theta < \pi - \tilde{\theta}, \qquad \pi - \tilde{\theta} < \theta < \pi.$$

Here $0 < \tilde{\theta} < \pi/2$ is chosen so that, roughly, the largest values of the integrand are in the interval containing $\pi/2$. We take $\tilde{\theta} = (70/360)\cdot 2\pi$. We choose K_0 Gaussian

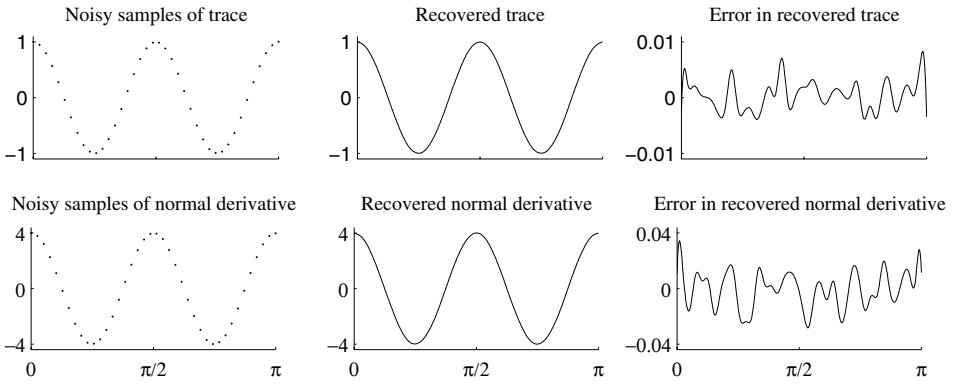

FIG. 6.2. *Simulation of noisy Cauchy data of u satisfying Laplace's equation. In each plot, the abscissa is the angular parameter θ for the curve $\Gamma = \{e^{i\theta} \,|\, 0 < \theta < \pi\}$.*

quadrature points for each interval leading to a quadrature rule of $K = 3K_0$ evaluation points for Γ.

Step 2*: Evaluation of data.* The Cauchy data of u are given by explicit formulae:

$$u|_\Gamma(\theta) = \cos 4\theta, \qquad \left.\frac{\partial u}{\partial \nu}\right|_\Gamma (\theta) = 4\cos 4\theta. \tag{72}$$

We produce simulated noisy data following the discussion in section 5.2. Set $\tilde{z}^{(j)} = (\cos\phi_j, \sin\phi_j)$ with $\phi_j = (j-1)\pi/(J_0 - 1)$ with $j = 1, \ldots, J_0 = 40$. We compute noisy samples as

$$u(\tilde{z}^{(j)}) + 0.003\,\varepsilon_j, \qquad \frac{\partial u}{\partial \nu}(\tilde{z}^{(j)}) + 0.012\,\varepsilon'_j, \tag{73}$$

where ε_j and ε'_j are normally distributed independent random numbers with standard deviation $\sigma = 1$. See Figure 6.2.

To recover the smooth data using Tikhonov regularization, we take

$$\theta_k = (k-1)\pi/(J-1), \qquad z^{(k)} = (\cos\theta_k, \sin\theta_k) \text{ for } k = 1, \ldots, J = 391.$$

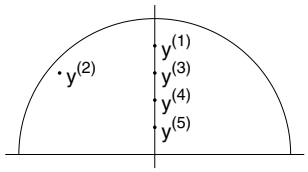
The result of solving (64) with regularization parameter $\alpha = 4$ is shown in Figure 6.2. The choice of α was based on visual inspection. The L^2 norm for the noise introduced in section 3 is $E \approx 0.02$.

Step 3*: Choosing the triangle D and computing C_D.* We implement the choice given in section 5.3. For any y, we start by $L = y_2$. Generally, this leads to $D \not\subset \Omega$. Then, we replace L with $L/2$ so many times that $D \subset \Omega$. Then we replace L with $L + 0.01$ as many times as possible while still having $D \subset \Omega$. We have $C_D = 2$.

Step 4*: Evaluation of v_τ.* With fixed y and given choice of $D = D(y)$ and $\tau = \tau(y)$, we substitute $V \equiv 0$ into (18):

$$w'_\tau(x) = \int_{\mathbb{R}^2} g_\tau(x-z)\chi_D(z)dz = \int_D g_\tau(x-z)dz.$$

So we need to integrate over D to find $w'_\tau(x)$ for a given $x \in \Gamma$. We use Gaussian product quadrature with $\tilde{K}_0^2 = \tilde{K}$ evaluation points. As indicated in section 4, we have available a numerical algorithm for g_τ, so Step 4 is complete.



$$y^{(1)} = (0, 4/5)$$
$$y^{(2)} = (-7/10, 3/5)$$
$$y^{(3)} = (0, 3/5)$$
$$y^{(4)} = (0, 2/5)$$
$$y^{(5)} = (0, 1/5)$$

FIG. 6.3. *Special points for examining the convergence of* $u_\tau(y^{(j)})$ *to* $u(y^{(j)})$.

Step 5*: Evaluation of* $\partial v_\tau/\partial\nu$. We have $v_\tau(x) = e^{-\tau y_2}e^{i\tau\bar{x}}w'_\tau(x)$, where $w'_\tau(x) = g_\tau * \chi_D$. Compute

$$\frac{\partial v_\tau}{\partial x_1} = e^{-\tau y_2}e^{i\tau\bar{x}}\left(i\tau w'_\tau(x) + \frac{\partial w'_\tau}{\partial x_1}\right). \tag{74}$$

Further, using Lemma 4.1,

$$\frac{\partial w'_\tau}{\partial x_1} = \frac{\partial g_\tau}{\partial x_1} * \chi_D = \left(-\frac{1}{4\pi\bar{x}} - \frac{e_{-\tau}(x)}{4\pi x}\right) * \chi_D - i\tau w'_\tau. \tag{75}$$

A combination of (74) and (75) yields

$$\frac{\partial v_\tau}{\partial x_1} = -e^{-\tau y_2}e^{i\tau\bar{x}}\left(\frac{1}{4\pi\bar{x}} + \frac{e_{-\tau}(x)}{4\pi x}\right) * \chi_D. \tag{76}$$

We can compute $\partial v_\tau/\partial x_2$ in a similar fashion. Note that on Γ the normal vector ν takes the simple form $\nu(x) = (x_1, x_2)$. Thus we get

$$\left.\frac{\partial v_\tau}{\partial\nu}\right|_\Gamma = -\frac{e^{-\tau y_2}e^{i\tau\bar{x}}}{4\pi}\Big(\frac{x_1}{\bar{x}} + \frac{x_1 e_{-\tau}(x)}{x} + \frac{x_2}{i\bar{x}} - \frac{x_2 e_{-\tau}(x)}{ix}\Big) * \chi_D. \tag{77}$$

Step 6*: Choosing* τ. We want to find a suitable τ experimentally. So we will compute u_τ with τ varying in the interval $[10, 80]$. We study convergence of u_τ to u at the points $y^{(1)}, \ldots, y^{(5)}$ given in Figure 6.3. We plot $u_\tau(y^{(j)})$ for $j = 1, \ldots, 5$ as functions of τ in Figure 6.4. Note that numerical instability occurs when τ is large. This is due to finite precision of the computation and the exponential functions appearing in the reconstruction formula.

6.3. Results for ideal data. We now have a complete numerical algorithm for u_τ. Since it is numerically impossible to compute u_τ for y_2 close to zero, we choose the computational reconstruction domain as

$$\Omega' = \left\{y \in \Omega \,|\, y_2 \geq \frac{1}{8}\right\}. \tag{78}$$

We compute $u_\tau(y)$ in Ω' for $\tau = 10, 40, 70$ on a collection of 1382 evaluation points inside the upper half of the unit disc. For integration on Γ we choose $K = 360$ quadrature points, and for integration on D we take a product rule with $\tilde{K} = 25^2 = 625$ points. We show the functions u, u_{20}, u_{40}, and u_{70} in Figure 6.5.

We see that the quality of the reconstruction varies depending on y_2 and τ. In particular, we observe that each plot with fixed τ has a region of acceptable reconstruction always containing a neighborhood of the point $(0, 1)$. Furthermore, when τ grows, the region of acceptable reconstruction shrinks, but the quality of

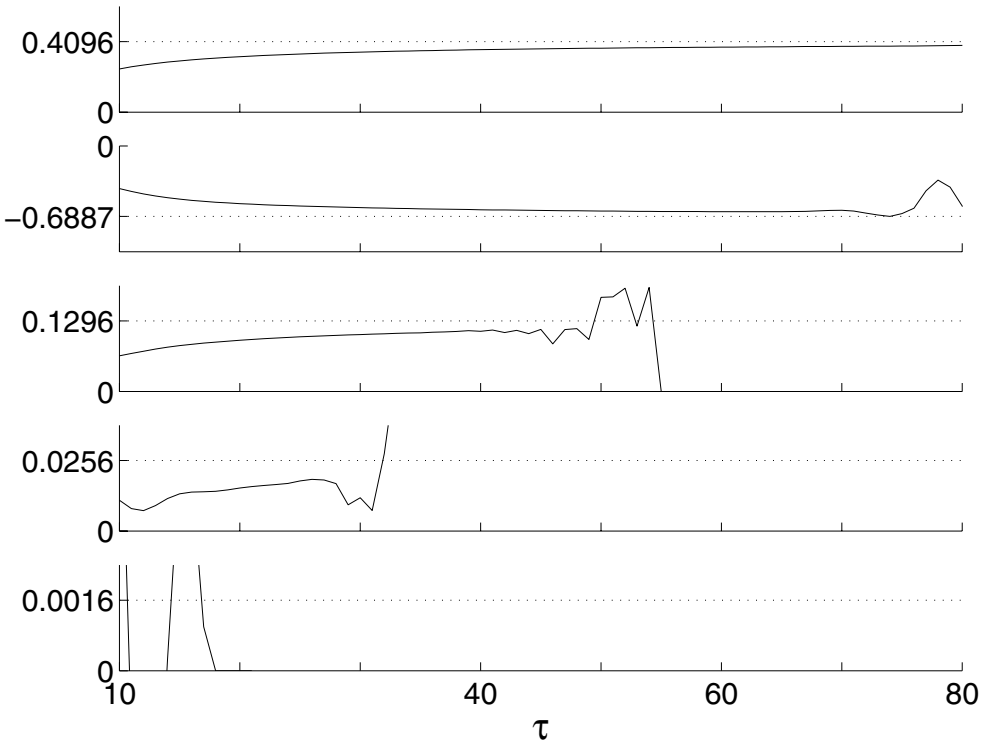


FIG. 6.4. *Convergence study for the Laplace equation. From top to bottom: plot of the real part of the function* $\tau \mapsto u_\tau(y^{(j)})$ *for* $j = 1, 2, 3, 4, 5$. *The theoretical limit values for these functions when* $\tau \to \infty$ *are marked in the plots. Note that numerical instability makes the computation inaccurate when* τ *grows. Divergence appears with smaller* τ *values for those reconstruction points that are deeper inside* Ω.

TABLE 6.1

Relative errors in u_τ *computed from ideal Cauchy data of a solution* u *to Laplace's equation. Left: relative* L^2 *errors* $E_2(t,\tau)$. *Right: relative* L^∞ *errors* $E_\infty(t,\tau)$. *In these tables, "—" stands for "greater than* 1000%." *For definitions of* E_2 *and* E_∞, *see* (79).

	$t = 1/8$	1/2	7/8
$\tau = 10$	53%	47%	45%
40	923%	16%	14%
70	—	—	9%

	$t = 1/8$	1/2	7/8
$\tau = 10$	91%	91%	33%
40	—	46%	10%
70	—	—	6%

reconstruction in the acceptable region is better than with smaller τ. For quantitative examination of this property we introduce the following norms for measuring the error of reconstructions. Given $0 < t < 1$ and $\tau > 0$, we consider the relative errors

$$E_2(t,\tau) = \frac{\|u - u_\tau\|_{L^2(\Omega_t)}}{\|u\|_{L^2(\Omega_t)}}, \qquad E_\infty(t,\tau) = \frac{\|u - u_\tau\|_{L^\infty(\Omega_t)}}{\|u\|_{L^\infty(\Omega_t)}}, \tag{79}$$

where $\Omega_t = \{y \in \Omega \,|\, y_2 > t\}$. The errors are given in Table 6.1.

For one choice of τ, the computation takes about 4 hours with MATLAB 6.5 running on a desktop PC computer with an Intel Pentium IV 2.8 GHz processor and 1 GB memory. In practical applications the collection of recovery points y and a good

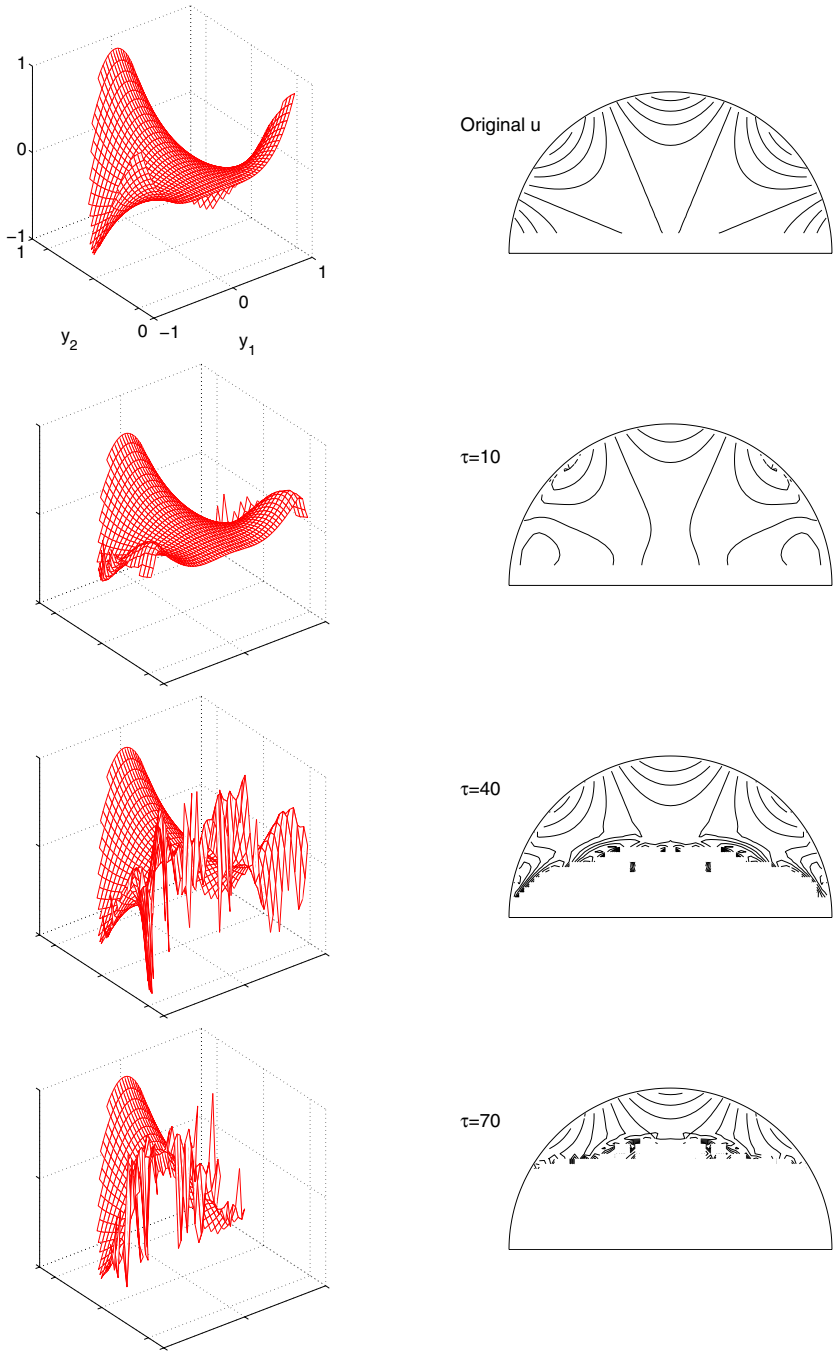

FIG. 6.5. *Results for the Laplace equation and ideal data. Top left: mesh plot of the original harmonic function u. Top right: contour plot of u. Similarly, from top to bottom, we show mesh and contour plots of the reconstructions u_{10}, u_{40}, and u_{70}. The axis limits are the same in all mesh plots, allowing easy comparison. We do not plot any function values greater than* 1 *in absolute value since numerical instability causes extremely large (incorrect) values in the reconstructions, and visualizing these values would obscure the acceptable parts of the reconstructions. Note that the greater τ is, the better the reconstruction is for points (y_1, y_2) with y_2 near* 1.

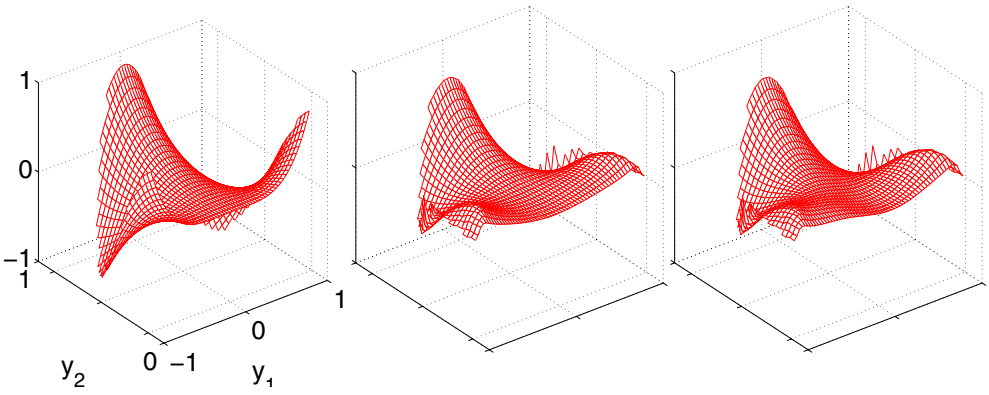

FIG. 6.6. *Results for the Laplace equation and noisy data. Left: mesh plot of the original harmonic function u. Middle: recovery of u with spatially varying τ from data with noise level* 0.3%. *Right: recovery of u with spatially varying τ from data with noise level* 0.6%.

choice for τ can be fixed. Then traces $v_\tau|_{\partial\Omega}$ and the normal derivatives $\partial v_\tau/\partial\nu|_{\partial\Omega}$ according to each y need be computed only once and saved. Then recovery of $u(y)$ with given Cauchy data takes in this case only a couple of seconds.

It can be seen in Figure 6.5 that near those parts of the boundary that are almost parallel to the y_2 axis, the quality of the reconstruction is bad. This is related to the smaller triangular patch D used there, leading to slower convergence.

6.4. Results for noisy data. We compute the functions u_7, u_{10}, and u_{12} using noisy Cauchy data. The results are similar to the nonnoisy case, the main difference being that the region of acceptable results shrinks with considerably smaller τ values. To achieve a uniform level of regularization, we choose τ as a function of y as follows:

$$\tau = \tau(y) = 6 + 6y_2^3,$$

so deep inside Ω we use a smaller value of τ, leading to less oscillation. Since the τ values used were relatively small, we did not need so many quadrature points for numerical integration. For integration on Γ we choose $K = 36$ quadrature points, and for integration on D we take a product rule with $\tilde{K} = 7^2 = 49$ points.

For the result, see the middle plot in Figure 6.6. The recovered solution has 38% relative $L^2(\Omega')$ error. To examine the robustness of our method against noise, we produce noisy data with double standard deviation in the random errors in (73). We repeat the recovery process, leading to a result having 41% relative $L^2(\Omega')$ error; see the rightmost plot in Figure 6.6. The relative difference between the two reconstructions in $L^2(\Omega')$ is only 6% although the noise level was doubled. The computation of each of the two reconstructions took 5 minutes.

7. Numerical results for $V \neq 0$. We present a two-dimensional example roughly modelling the inverse potential problem in cardiology.

7.1. The Cauchy problem in cardiology. A beating heart produces an electrical field inside the body, and the resulting voltage distribution can be measured with electrodes placed on the skin. This is called electrocardiography (ECG). The

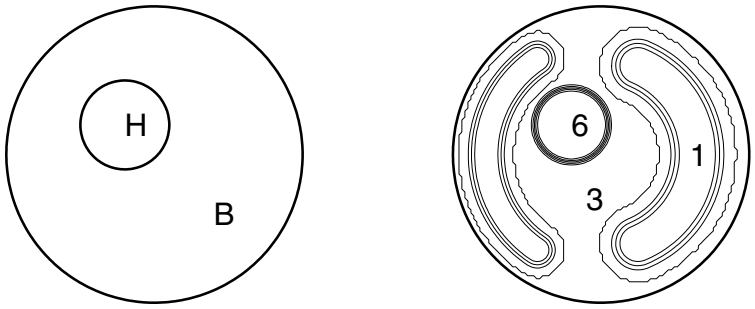

FIG. 7.1. *Left: the domain of the conductivity equation is the annulus* $\tilde{\Omega} = B \setminus H$. *Right: contour plot of the twice differentiable conductivity distribution on* B.

inverse potential problem of cardiology is of clinical interest: *given the ECG measurements and the conductivity distribution of the body, what is the voltage potential on the surface of the heart?*

We present a two-dimensional quasi-static model of the above inverse problem. Let the unit disc $B = \{x \in \mathbb{R}^2 \,|\, |x| < 1\}$ model a cross section of human thorax, and assume that the heart is located on the disc H with center at $(-0.2, 0.2) \in B$ and radius 0.3. Further, we model the electrical conductivity $\gamma : B \to \mathbb{R}$ of the body with a strictly positive $C^2(\overline{B})$ function taking value 6 in the heart, 1 in the lungs, and 3 in the background. These values approximate the tissue conductivities during perfusion. See Figure 7.1.

Electric current inside the heart results in the following boundary value problem for the electric voltage potential $\tilde{u}$ in the annulus $\tilde{\Omega} = B \setminus H$:

$$\nabla \cdot \gamma \nabla \tilde{u} = 0 \text{ in } \tilde{\Omega}, \quad \tilde{u}|_{\partial H} = f, \quad \left.\frac{\partial \tilde{u}}{\partial \nu}\right|_{\partial B} = 0, \tag{80}$$

where we assumed that the outer boundary ∂B is perfectly insulated.

We create our example by setting $f(x_1, x_2) = (x_1 + 0.5)(x_2 - 0.2)$ in (80), qualitatively resembling a voltage distribution depicted on page 386 in [7]. We solve the elliptic boundary value problem (80) with the finite element solver of MATLAB's PDE toolbox using 14848 triangles in the domain $\tilde{\Omega}$. See Figure 7.2.

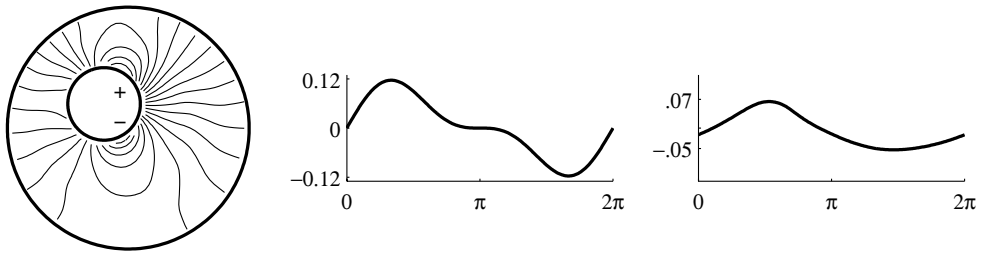

FIG. 7.2. *Left: contour plot of the solution* $\tilde{u}$ *of the conductivity equation* (80). *Middle: voltage potential* $\tilde{u}|_{\partial H}$ *on the surface of the heart as a function of the angular variable* θ *corresponding to the parametrization* $\partial H = \{(-0.2 + 0.3\cos\theta, 0.2 + 0.3\sin\theta) \in \mathbb{R}^2 \,|\, 0 \le \theta < 2\pi\}$. *Right: voltage potential* $\tilde{u}|_{\partial B}$ *as a function of the angular variable* θ *corresponding to the parametrization* $\partial B = \{(\cos\theta, \sin\theta) \in \mathbb{R}^2 \,|\, 0 \le \theta < 2\pi\}$. *Axis limits in the two plots are the same to allow quantitative comparison.*

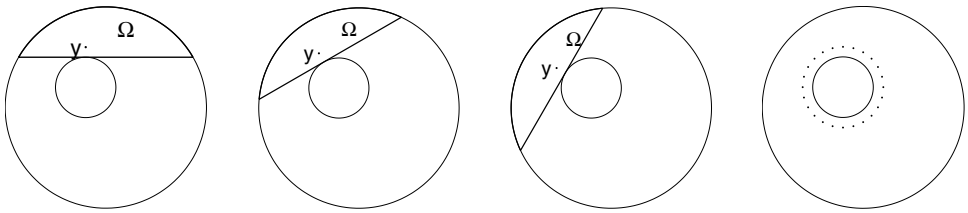

FIG. 7.3. *In the rightmost picture are* 24 *reconstruction points on the circle* S *defined in* (83) *at distance* 0.1 *from the surface of the heart. For each reconstruction point we choose a domain* Ω *that coincides after rotation with a canonical domain described in section* 2.

Application of the techniques of this paper requires transforming the conductivity equation (80) into the Schrödinger equation. Set

$$V(x) = \frac{\Delta\sqrt{\gamma(x)}}{\sqrt{\gamma(x)}}. \tag{81}$$

Since $\gamma \in C^2(\overline{B})$, we have $V \in C^0(\tilde{\Omega}) \subset L^\infty(\tilde{\Omega})$. (The norm of the particular potential we use is approximately $\|V\|_{L^\infty(\tilde{\Omega})} \approx 293$, so our example is not a small perturbation of the harmonic case.) It is straightforward to check that $u := \gamma^{1/2}\tilde{u}$ satisfies the equation

$$(-\Delta + V)u = 0 \qquad \text{in } \tilde{\Omega}. \tag{82}$$

Because $\gamma \equiv 3$ in a neighborhood of ∂B, we know the Cauchy data of u on ∂B:

$$u|_{\partial B} = \sqrt{3}\tilde{u}|_{\partial B}, \qquad \left.\frac{\partial u}{\partial \nu}\right|_{\partial B} = 0.$$

Equation (82) is valid only outside the heart. We choose a collection of computational domains Ω as shown in Figure 7.3; each of these domains coincides after rotation with a canonical domain described in section 2. We cannot choose our recovery points right at the surface of the heart because the set D would then be empty, so we choose 24 points on the circle S given by

$$S = \{(-0.2 + 0.4\cos\theta, 0.2 + 0.4\sin\theta) \in \mathbb{R}^2 \,|\, 0 \le \theta < 2\pi\}. \tag{83}$$

Thus we reconstruct the voltage at distance 0.1 from the surface of the heart. See Figure 7.3.

7.2. Details of implementation. We assume that the domain Ω is (possibly after rotation) of the canonical form with $-1 < t < 1$ described in section 2. The Neumann data of u vanish, we need only compute

$$u_\tau(y) = -\frac{2\tau^2 e^{-i\tau y_1}}{C_D} \int_\Gamma \frac{\partial v_\tau}{\partial \nu} u \, d\sigma(x). \tag{84}$$

Step 1*: Integration on* Γ. We choose K Gaussian quadrature points on Γ. There is no need to divide Γ into subintervals as done in section 6.2 since we use so small a value of τ that the integrand is roughly of the same order of magnitude throughout Γ.

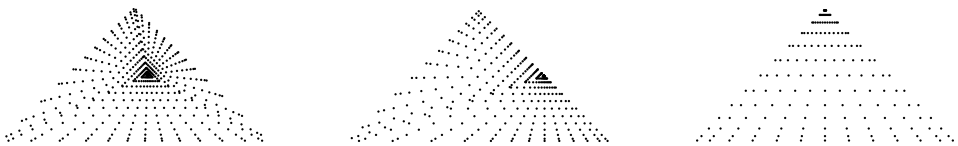

FIG. 7.4. *Product Gaussian quadratures on the triangular patch D with 13×13 points in polar coordinates. Left: the origin is inside D. Middle: the origin is on the boundary of D. Right: the origin is at the corner of D.*

Step 2*: Evaluation of data.* The experimental setup in [7] uses 24 electrodes with 2% noise level. We simulate that measurement with

$$\tilde{u}(\tilde{z}^{(j)}) + 0.0022\,\varepsilon_j,$$

where $\tilde{z}^{(j)} = (\cos\phi_j, \sin\phi_j)$ with $\phi_j = (j-1)2\pi/J_0$ with $j = 1, \ldots, J_0 = 24$ and ε_j are normally distributed independent random numbers with standard deviation 1.

We use Tikhonov regularization to recover a smooth approximation to the actual voltage. In the notation of section 5.2, we have $J_0 = 24$, $J = 144$, and $\alpha = 2$. Since we reconstruct the trace on the full circle, we include requirement of periodicity into the regularization. Relative $L^2(\partial\Omega)$ error in the reconstruction of the trace $\tilde{u}|_{\partial\Omega}$ is 0.033, and relative $L^\infty(\partial\Omega)$ error is 0.032.

Step 3*: Choosing the triangle D and computing C_D.* We take $L = 0.1$ and use the choice given in section 5.3 leading to $C_D = 2$.

Step 4*: Evaluation of v_τ.* We need to solve the Lippmann–Schwinger-type equation $[I + g_\tau * (\tilde{V}\cdot\,)]w'_\tau = f$ as explained in section 5.4. The problem is the evaluation of

$$f(x^{(\ell)}) = (g_\tau * \chi_D)(x^{(\ell)}) = \int_D g_\tau(x^{(\ell)} - y)dy, \quad \ell = 1, 2, \ldots, M^2. \tag{85}$$

Since $g_\tau(x)$ has a logarithmic singularity at $x = 0$, numerical integration in (85) becomes problematic when $x^{(\ell)}$ belongs to D or is close to the boundary ∂D. We overcome this problem by writing the integral in polar coordinates and using product Gaussian quadrature; due to the product measure $rdrd\phi$ the integrand is bounded and continuous since $\lim_{r\to 0} r\log r = 0$. We need only to go through the tedious task of writing the integration domain as a function of ϕ and $r(\phi)$. We do not bore the reader with the details of dividing the algorithm into 19 subcases and performing the necessary trigonometric calculations but instead show some resulting quadrature points in Figure 7.4.

Step 5*: Evaluation of $\partial v_\tau/\partial\nu$.* From (70) we see that the normal derivative of v_τ appearing in (84) is given by

$$\begin{aligned}
&-\frac{e^{\tau(x_2-y_2)}e^{i\tau x_1}}{4\pi}\left[\left(\nu_1\left(\frac{1}{\bar{x}} + \frac{e^{-i2\tau x_1}}{x}\right) + \nu_2\left(\frac{1}{i\bar{x}} - \frac{e^{-i2\tau x_1}}{ix}\right)\right) * \chi_D\right] \\
&+\frac{e^{\tau(x_2-y_2)}e^{i\tau x_1}}{4\pi}\left[\left(\nu_1\left(\frac{1}{\bar{x}} + \frac{e^{-i2\tau x_1}}{x}\right) + \nu_2\left(\frac{1}{i\bar{x}} - \frac{e^{-i2\tau x_1}}{ix}\right)\right) * \tilde{V}w'_\tau\right] \\
&\equiv I_1 + I_2.
\end{aligned}$$

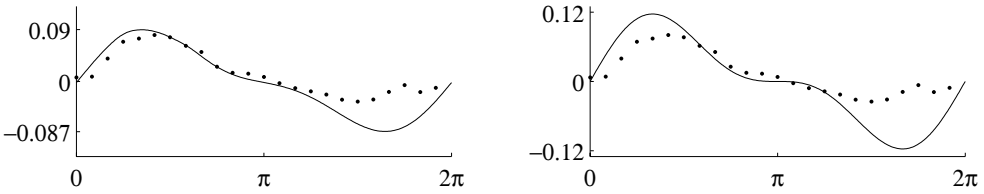

FIG. 7.5. *Left: true voltage potential at distance* 0.1 *from the boundary of the heart is plotted as a solid line. Reconstructed voltage potential values are plotted as dots. See Figure* 7.3 *for the reconstruction points. Right: true voltage potential at the boundary of the heart (solid line) and the same reconstructed voltage potentials as in the left plot (dots). The abscissa in both plots is the angular parameter of the circle around the heart.*

Note that I_2 vanishes when $V = 0$, and therefore I_2 can be seen as a correction term compensating for nonzero V. The computation of I_1 was already described for the case $V = 0$.

Given an integer $m > 1$, the outcome of Step 4 is the set $\{w'_\tau(x^{(\ell)})\}_{\ell=1}^{M^2}$, where the evaluation points $x^{(\ell)}$ belong to the grid (68). It is then natural to implement the integral in I_2 simply with the midpoint rule.

Step 6*: Choosing* τ*.* We take $\tau = 4, 6, 8, 10, 12$.

7.3. Results. To compute (84) we choose $K = 70$ for integrating over Γ, and for all integrations over D we take $\tilde{K} = 15^2 = 225$ quadrature points. We take $m = 7$, or $M = 128$ in the Lippmann–Schwinger solver. We compute u_τ with $\tau = 4, 6, 8, 10, 12$ and find that the reconstructions with $\tau > 6$ are oscillatory, and $\tau = 6$ gives a better result than $\tau = 4$. We thus choose $\tau = 6$.

The plot on the left in Figure 7.5 shows the superposition of reconstructed voltage potential $\gamma^{-1/2}u_6$ and the actual potential *on the circle* S *containing the reconstruction points*. We find that the maximum relative absolute error of the reconstruction is 86%. Diagnostically, the most interesting part of the reconstruction is the angular interval $0 \le \theta \le \pi$. In this interval, the maximum and average relative absolute errors are 25% and 10%, respectively.

However, we are interested in the voltage potential at the boundary of the heart. We simply consider our reconstruction of the voltage on S to be an approximation to the voltage on ∂H. The plot on the right in Figure 7.5 shows a comparison of these two quantities. Maximum relative absolute error in the reconstruction as compared to the voltage potential at the boundary of the heart is 1.07. In the interval $0 \le \theta \le \pi$, the maximum and average relative absolute errors are 43% and 21%, respectively.

The computation took 4 hours.

7.4. Discussion. Unlike in many works on the inverse potential problem of ECG, such as [7], we do not assume that the tissue between the skin and the surface of the heart is homogeneous. If the electric conductivity of the body is known, e.g., by electrical impedance tomography [5], our method thus allows more accurate modelling of the problem.

The worst-case performance of our algorithm is not impressive: the maximum relative error is 1.07. However, this worst error appears near the posterior surface of the heart (facing the back), which is far away from the boundary. The anterior surface of the heart (facing the chest) is diagnostically more important. Relative error on the

anterior surface, defined as $0 \leq \theta \leq \pi$ in the notation of Figure 7.2, is on average 21% and at most 43%. This result is somewhat better than the 30%–50% error reported in [7], where conductivity was taken to be constant.

Instead of quantitative reconstruction of the voltage, we might want to know the location of the maximum voltage potential on the anterior surface of the heart. The true maximum appears at $\theta_0 = 1.05$ (in radians), and the reconstruction attains its maximum at $\tilde{\theta}_0 = 1.31$. The error in the reconstructed angle is 15 degrees.

The main advantage of our method is modelling the conductivity, and the main source of error is the inherent problem that we cannot recover the voltage at the surface of the heart but slightly away from it. As mentioned in the introduction, there are other methods capable of dealing with nonconstant conductivities and additionally providing reconstruction right at the surface of the heart. However, those methods typically involve solution of boundary value problems, which is computationally intensive. Our reconstruction method is very fast after the initial computational load, and it could thus be better suited for real-time monitoring. Also, modelling the movement of a beating heart for the solution of boundary value problems is difficult, and our approach of reconstructing a little bit away from the heart might be considered an advantage.

Our tissue model assumes that the conductivity is differentiable although in reality it is discontinuous, but since many regularized electrical impedance tomography reconstructions produce a differentiable approximation to the conductivity, this is perhaps not so serious. The most obvious drawback of the presented algorithm is the two-dimensional approximation. However, the theory behind our method covers the three-dimensional case, and a similar algorithm can be designed in three dimensions. This is left for a future study.

SEMICLASSICAL APPROXIMATION OF ELECTRON-PHONON SCATTERING BEYOND FERMI'S GOLDEN RULE*

C. RINGHOFER†, M. NEDJALKOV‡, H. KOSINA§, AND S. SELBERHERR§

Abstract. We derive a quantum mechanical correction to the semiclassical Fermi golden rule operator for scattering of electrons in a crystal. This correction takes into account the fact that electron-phonon interaction is not instantaneous in quantum mechanics. The corrective term is derived via an oscillatory, i.e., weak, limit in the Levinson equation for large timescales.

Key words. asymptotic analysis, quantum mechanics, Levinson equation, Wigner functions, Fermi's golden rule, Boltzmann equation

AMS subject classifications. 65N35, 65N05

DOI. 10.1137/S0036139903428914

1. Introduction.

It is generally accepted that the dominant collision mechanism for electron transport in crystals is scattering of electrons by phonons, i.e., with vibrations of the crystal lattice. In a semiclassical description this collision mechanism is described by the Fermi golden rule. In the absence of an electric field and in the spatially homogeneous case, the evolution of the effective single electron density function is then given by the Boltzmann equation

$$\begin{aligned} &\text{(a)} \quad \partial_t f(p,t) = Q_{FGR}[f](p,t) \\ &\qquad\qquad := \int dp' [S_{FGR}(p,p') f(p',t) - S_{FGR}(p',p) f(p,t)], \\ &\text{(b)} \quad S_{FGR}(p,p') = [A^- \delta(\varepsilon(p) - \varepsilon(p') - \hbar\omega) + A^+ \delta(\varepsilon(p) - \varepsilon(p') + \hbar\omega)], \end{aligned} \tag{1.1}$$

where p denotes the momentum vector and $\varepsilon(p) = \frac{|p|^2}{2m_*}$ denotes the energy associated with the momentum p. The Fermi golden rule states that during a collision the electron gains or loses an amount $\hbar\omega$ of energy from the crystal lattice by annihilation or generation of a phonon. We remark that the Boltzmann equation (1.1) models instantaneous collisions; i.e., the momentum of an electron changes instantaneously from p' to p during a collision event.

Semiclassical transport theory based on the Boltzmann equation neglects several effects which originate from the quantum mechanical nature of the charge carriers, such as a collisional broadening due to the finite lifetime of the carrier momentum eigenstate, collision retardation, and the intracollisional field effect due to the action of the electric field during the scattering process [11]. To describe these effects a quantum kinetic equation has to be adopted which takes the finiteness of the scattering duration into account. An appropriate kinetic equation describing the interaction of a single electron with the equilibrium phonon system of a semiconductor has been proposed

by Levinson [6]. Restricting ourselves to the case of a spatially uniform semiconductor and vanishing electric field, the Levinson equation is of the form

$$
\begin{aligned}
&\text{(a)} \quad \partial_t f(p,t) = Q[f](p,t) \\
&\qquad\qquad := \int_0^t dt' \int dp' [S(p,p',t-t')f(p',t') - S(p',p,t-t')f(p,t')], \\
&\text{(b)} \quad S(p,p',t) = \frac{2VF^2 n}{(2\pi\hbar)^3} \cos\left[\frac{t}{\hbar}(\varepsilon(p) - \varepsilon(p') - \hbar\omega)\right] \\
&\qquad\qquad + \frac{2VF^2(n+1)}{(2\pi\hbar)^3} \cos\left[\frac{t}{\hbar}(\varepsilon(p) - \varepsilon(p') + \hbar\omega)\right], \\
&\qquad \varepsilon(p) = \frac{|p|^2}{2m_*}, \quad n = \frac{1}{\exp(\beta\hbar\omega) - 1}.
\end{aligned} \tag{1.2}
$$

The symbols in (1.2) have the following meaning: $\hbar F$ denotes the electron-phonon interaction matrix element, $\hbar\omega$ the phonon energy, V the normalization volume, m_* the effective electron mass, n the Bose–Einstein distribution, and $\beta = (k_B T)^{-1}$ the inverse temperature of the phonon system. Note that, other than the Fermi golden rule equation (1.1), the Levinson equation (1.2) is nonlocal in time, and the effect of a collision is actually felt for all future times. Therefore the Levinson equation is able to model some of the effects mentioned above, which become increasingly relevant as the dimensions of modern semiconductor devices decrease, and, consequently, fast relaxation processes play a more prominent role. The Levinson equation can be derived from the quantum mechanical many body problem for one electron and an arbitrary number of phonons, i.e., from an infinite system of Schrödinger equations for the wave functions $\psi_n(p, q_1, \ldots, q_n, t)$, where p is the electron momentum vector and the q_j denote the phonon momenta. ψ_n describes the state of the system for one electron and n phonons, and ψ_n is coupled to ψ_{n-1} and ψ_{n+1} via coupling terms in the Fröhlich Hamiltonian, modelling the creation and annihilation of phonons. The function f is then the Wigner function corresponding to the phonon trace of the density matrix. We refer the reader to [1], [3], [4], [5] for an overview of the derivation. The Levinson equation represents the weak coupling limit of this system, which means that only electron-phonon interactions of first order are retained. An interaction starts at some time, say t_1, when one half of the phonon momentum is transferred to the electron, and gets completed at some time t_2, when the second half of the phonon momentum is transferred (see, e.g., [4], [9]). These partial processes capture the emission and absorption of both real and virtual phonons. The weak coupling limit implies that during the period $t_2 - t_1$ of a particular interaction no other interaction can start. In other words, only a sequence of completed interactions is considered. The time between two interactions is determined by the frequency F given by the interaction matrix element, whereas the duration of the interaction depends on the frequency of the lattice vibrations, ω. Therefore, $F \ll \omega$ must hold. A result of the weak coupling limit is that no powers higher than F^2 appear in (1.2)(b). To our knowledge, a completely rigorous mathematical derivation of the Levinson equation from the many body problem for the Fröhlich Hamiltonian is still outstanding. However, for the purpose of this paper, we will assume the Levinson equation (1.2) to be valid.

Remark: The Levinson equation results from an asymptotic expansion of the Fröhlich Hamiltonian for small coupling coefficients [1], [3]. While there obviously is a density matrix formulation of the Levinson equation, which is given by the Fourier

transform of (1.2), the corresponding density matrix cannot simply be written as a superposition of pure state wave functions, and therefore the positive definiteness of the Wigner function f in (1.2) cannot be guaranteed automatically.

The objective of the present paper is to relate (1.2) to the Fermi golden rule (1.1). While much simpler than the original many body equation, the Levinson equation still poses significant challenges because of its nonlocality in time and rapid oscillations due to the presence of the term $t/\hbar$ in the integral kernel in (1.2). It is mentioned in the original work [6] that in the classical limit $\hbar \to 0$ the scattering rate S in (1.2)(b) will be replaced by the Fermi golden rule (cf. [2]).

In the present paper we prove the convergence of the Levinson operator Q in (1.2) to the Fermi golden rule operator Q_{FGR} for large timescales, and more importantly, in addition to the golden rule the first order term in the asymptotic expansion is derived. The result is a correction to the Fermi golden rule, which better reflects the effects of finite collision times. The resulting corrected operator is structurally of the form

$$Q_C[f] = \int dp' [S_C(p, p', \partial_t) f(p', t) - S_C(p', p, \partial_t) f(p, t)], \tag{1.3}$$

where the corrected scattering rate S_C contains the Fermi golden rule rate S_{FGR} and a correction term that involves the time derivative of the density function. However, the corrected operator Q_C in (1.3) is still local in time, in the sense that it is not an integral operator in time, and therefore the resulting transport equation is much simpler to solve than the Levinson equation (1.2). More precisely, we prove that the Levinson operator Q converges weakly, in zeroth order to Q_{FGR}, and in first order to the corrected operator Q_C. The considered regime is one of large timescales, i.e., timescales which are much larger than $1/\omega$, where ω is the frequency with which the lattice vibrates.

This paper is organized as follows. In section 2 we introduce an appropriate dimensionless form of the Levinson equation (1.2) which contains a dimensionless parameter $\lambda = (\omega t_0)^{-1}$, where t_0 is the timescale under consideration. Section 3 contains the asymptotic analysis for $\lambda \to 0$. We prove that $Q = Q_C + o(\lambda)$, $Q_C = Q_{FGR} + \lambda Q_1$ holds in a weak sense, i.e., when integrated against a fixed test function. The main result of the paper, the form of Q_C, is given at the end of section 3 in formula (3.10). Section 4 is devoted to numerical experiments. First the asymptotic result of section 3 is verified. This result states only the weak convergence of Q to Q_C and not the convergence of the solution f of the Levinson equation to the solution of the corresponding transport equation containing Q_C. The approximation of the solution of the transport equation is verified numerically in section 4 as well. The numerical solution of the transport equation involving the operator Q_C in (1.3) is nontrivial because this equation is implicit. We propose a solution method which is amenable to particle discretizations.

2. Scaling. We start by bringing the Levinson equation (1.2) into an appropriate dimensionless form. Choosing scales p_0, t_0 for the momentum p and the time t, and rescaling S by s_0, we set

$$f(p,t) = \frac{1}{p_0^3} f_s(p_s, t_s), \quad S(p, p', t) = s_0 S_s(p_s, p_s', t_s),$$
$$\varepsilon(p) = \frac{p_0^2}{m_*} \varepsilon_s(p_s), \quad p_s = \frac{p}{p_0}, \quad t_s = \frac{t}{t_0},$$

where m_* denotes the effective electron mass, and we obtain

$$\begin{aligned}
&\text{(a)}\quad \partial_{t_s} f_s(p_s,t_s) = s_0 t_0^2 p_0^3 \int_0^{t_s} dt'_s \int dp'_s [S_s(p_s,p'_s,t_s-t'_s) f_s(p'_s,t'_s) \\
&\qquad\qquad - S_s(p'_s,p_s,t_s-t'_s) f_s(p_s,t'_s)], \\
&\text{(b)}\quad S_s(p_s,p'_s,t_s) = \frac{2VF^2 n}{s_0(2\pi\hbar)^3} \cos\left[\frac{t_0 p_0^2 t_s}{m_*\hbar}\left(\varepsilon_s(p_s)-\varepsilon_s(p'_s)-\frac{m_*\hbar\omega}{p_0^2}\right)\right] \\
&\qquad + \frac{2VF^2(n+1)}{s_0(2\pi\hbar)^3} \cos\left[\frac{t_0 p_0^2 t_s}{m_*\hbar}\left(\varepsilon_s(p_s)-\varepsilon_s(p'_s)+\frac{m_*\hbar\omega}{p_0^2}\right)\right],
\end{aligned} \tag{2.1}$$

where, in the case of parabolic bands, $\varepsilon_s(p_s) = \frac{|p_s|^2}{2}$ holds. For the rest of this paper we will restrict ourselves to parabolic bands and assume that the matrix element F of the electron-phonon interaction is constant with respect to momentum.

The parameter s_0 can be chosen more or less freely, since it cancels as soon as (2.1)(b) is inserted into (2.1)(a). We choose $s_0 = \frac{1}{t_0^2 p_0^3}$, which ensures that the resulting equation varies on an $O(1)$ scale in time. The key issue is now to choose an appropriate scale p_0 for the momentum variable. A natural choice is to scale the phonon energy to unity, which gives $p_0^2 = m_*\hbar\omega$. Furthermore, we will consider the Levinson equation on a timescale that is much larger than the timescale on which the lattice vibrates. Therefore we set $t_0 = (\lambda\omega)^{-1}$, where λ denotes a dimensionless parameter. We drop the subscript s from here on and obtain

$$\begin{aligned}
\partial_t f(p,t) &= \int_0^t dt' \int dp' [S(p,p',t-t') f(p',t') - S(p',p,t-t') f(p,t')], \\
S(p,p',t) &= \frac{2VF^2}{\lambda^2(2\pi)^3}\sqrt{\frac{m_*^3}{\hbar^3\omega}}\left(n\cos\left[\frac{t}{\lambda}(\varepsilon(p)-\varepsilon(p')-1)\right]\right. \\
&\qquad \left. + (n+1)\cos\left[\frac{t}{\lambda}(\varepsilon(p)-\varepsilon_s(p')+1)\right]\right).
\end{aligned}$$

Since the scattering rate varies on a timescale of order $\frac{1}{\lambda}$, the amplitude should be of the same order to keep the integral of order $O(1)$, which is obtained by setting

$$\lambda^2 = \frac{2VF^2(n+1)}{(2\pi)^3}\sqrt{\frac{m_*^3}{\hbar^3\omega}}. \tag{2.2}$$

This gives a scaled equation of the form

$$\begin{aligned}
&\text{(a)}\quad \partial_t f(p,t) = Q_\lambda[f](p,t) \\
&\qquad\qquad := \int_0^t dt' \int dp' [S_\lambda(p,p',t-t') f(p',t') - S_\lambda(p',p,t-t') f(p,t')], \\
&(b)\quad S_\lambda(p,p',t) = \sum_{\nu=\pm 1} \frac{a_\nu}{\lambda}\cos\left[\frac{t}{\lambda}(\varepsilon(p)-\varepsilon(p')+\nu)\right], \quad a_{-1} = \frac{n}{n+1}, \quad a_1 = 1.
\end{aligned} \tag{2.3}$$

Thus we consider an asymptotic regime where the quantity λ defined by (2.2) is small, and consider the asymptotic behavior of the collision operator in the Levinson equation for timescales $t_0 = (\lambda\omega)^{-1}$, which are much larger than the scale on which the lattice vibrates.

We conclude this section with the following observation, giving a heuristic argument for the convergence to the Fermi golden rule operator. Changing variables in the integral in (2.3)(a), we obtain

$$Q_\lambda[f](p,t) = \int_0^{t/\lambda} d\tau \int dp' [\lambda S_\lambda(p,p',\lambda\tau) f(p',t-\lambda\tau) - \lambda S_\lambda(p',p,\lambda\tau) f(p,t-\lambda\tau)],$$
$$\lambda S_\lambda(p,p',\lambda\tau) = \sum_{\nu=\pm 1} a_\nu \cos[\tau(\varepsilon(p) - \varepsilon(p') + \nu)].$$

If the term $\lambda S_\lambda(p,p',\lambda\tau)$, which is actually independent of λ, would decay for large τ, we could Taylor-expand the solution f and obtain in zeroth order

$$\partial_t f(p,t) = \int_0^\infty d\tau \int dp' [\lambda S(p,p',\lambda\tau) f(p',t) - \lambda S(p',p,\lambda\tau) f(p,t)],$$

which makes the collision operator local in time. The corresponding scattering rate would then be given by

$$\int_0^\infty \lambda S(p,p',\lambda\tau) d\tau = \sum_{\nu=\pm 1} a_\nu \int_0^\infty \cos[\tau(\varepsilon(p) - \varepsilon(p') + \nu)] d\tau,$$

and the integral over the cosine produces the δ-function in the Fermi golden rule. This heuristic argument has been given in [1], [3], [5]. Although S does not decay for large times, this result still holds, but the limit process is oscillatory; i.e., we have to compute a weak limit for $\lambda \to 0$. The computation of this weak limit is the subject of the present paper.

3. Asymptotics. In this section we derive the asymptotic behavior of the collision operator Q_λ in (2.3) for $\lambda \to 0$ and show that Q_λ indeed converges to the Fermi golden rule operator in the weak sense. More importantly, we are able to derive the first order term in the asymptotic expansion. This enables us to obtain a corrected Fermi golden rule operator which is still local in time, and thus a corrected Boltzmann equation which better reflects the effects of finite collision times. The main result of this section is stated in Theorem 3.2, which gives an asymptotic expression for the Levinson operator Q_λ in (2.3) up to terms of order $o(\lambda)$ in the weak sense. This approximation is still local in time in the sense that it depends only on the values of the density function f at time t and on its time derivative. The first order approximation is, although local in time, only given in a weak sense in p since the scattering rates in the loss term will contain integrals which exist only as principal value. The form of the resulting approximate collision operator is given in formulas (3.7) and (3.10).

Since we are considering a weak limit, we will define, for a given density f, the functional

$$Y_\lambda(f,\psi) = \int_0^\infty dt \int dp \psi(p,t) Q_\lambda[f](p,t)$$

for a smooth test function ψ, and investigate the limiting behavior of $Y_\lambda(f,\psi)$ for $\lambda \to 0$. It will be convenient to rewrite Y_λ using the adjoint of the collision operator. Interchanging the integration variables p and p' in the first part of (2.3)(a) gives

$$\text{(3.1)} \quad \begin{aligned} &\text{(a)} \quad Y_\lambda(f,\psi) = \int_0^\infty dt \int dp [f(p,t) Q_\lambda^{adj}[\psi](p,t)], \\ &\text{(b)} \quad Q_\lambda^{adj}[\psi](p,t) = \int_t^\infty dt' \int dp' [S_\lambda(p',p,t'-t)(\psi(p',t') - \psi(p,t'))], \end{aligned}$$

where we have also interchanged the time variables t, t'. In this form it is easy to see that the collision operator Q_λ conserves mass locally in time since the adjoint operator $Q_\lambda^{adj}(\psi)$ equals zero for test functions ψ which are constant in the momentum direction. The functional Y_λ represents a convolution in time and is therefore best expressed through Fourier transforms. To this end, we extend the definition (3.1)(b) of the adjoint collision operator $Q_\lambda^{adj}[\psi](p,t)$ for negative time. We define the Fourier transforms of the truncated density function f and the test functions by

$$\hat{f}(p,\tau) = \frac{1}{\sqrt{2\pi}} \int dt[H(t)f(p,t)e^{-i\tau t}], \qquad \hat{\psi}(p,\tau) = \frac{1}{\sqrt{2\pi}} \int dt[\psi(p,t)e^{-i\tau t}], \tag{3.2}$$

where $H(t)$ denotes the Heaviside function. From now on all integrals are to be understood as being over the whole real line or all of $\mathbb{R}^3$ unless stated explicitly otherwise. We have the following.

PROPOSITION 3.1. *In terms of the Fourier transform of the truncated density function f and the test function ψ, the functional $Y_\lambda(f,\psi)$ is given by*

$$\text{(a)} \quad Y_\lambda(f,\psi) = \int dp \int d\tau \{\hat{f}^*(p,\tau)\hat{Q}_\lambda^{adj}[\psi](p,\tau)\},$$

$$\text{(b)} \quad \hat{Q}_\lambda^{adj}[\psi](p,\tau) = \frac{1}{2} \sum_{\nu,\sigma=\pm 1} a_\nu \int dp' \left[\frac{\pi}{\lambda} \delta\left(\frac{\sigma}{\lambda} w_\nu(p',p) - \tau \right) + \frac{1}{i(\sigma w_\nu(p',p) - \lambda\tau)} \right] [\hat{\psi}(p',\tau) - \hat{\psi}(p,\tau)], \tag{3.3}$$

where * denotes the complex conjugate and $w_\nu(p',p) = \varepsilon(p') - \varepsilon(p) + \nu$ holds.

Proof of Proposition 3.1. If we define the Fourier transform of the adjoint operator $Q_\lambda^{adj}[\psi]$ by

$$\hat{Q}_\lambda^{adj}[\psi](p,\tau) = \frac{1}{\sqrt{2\pi}} \int dt \int dt' \int dp' H(t'-t) S_\lambda(p',p,t'-t)[\psi(p',t') - \psi(p,t')]e^{-i\tau t}, \tag{3.4}$$

the functional Y_λ becomes

$$Y_\lambda(f,\psi) = \int d\tau \int dp[\hat{f}^*(p,\tau)\hat{Q}^{adj}[\psi](p,\tau)],$$

where from here on * will denote the complex conjugate. In order to compute the Fourier transform of the adjoint collision operator Q^{adj}, we have to essentially compute the Fourier transform of the function $H(t)\cos(ut)$ as a distribution in t. We choose a sufficiently smooth test function $\phi(t)$, which is compactly supported in time, and compute the integral

$$\int dt[H(t)\cos(ut)\phi(t)].$$

We split the integrand into its even and odd parts by writing

$$\cos(ut)\phi(t) = a(u,t) + \partial_t b(u,t),$$

where a and b are both real and even functions in time. These functions are given by

$$a(u,t) = \frac{1}{2}\cos(ut) \sum_{\gamma=\pm 1} \phi(\gamma t), \qquad b(u,t) = -\frac{1}{2} \int_{|t|}^{\infty} ds \left[\cos(us) \sum_{\gamma=\pm 1} \gamma\phi(\gamma s) \right]$$

and are both compactly supported in time as well. Their Fourier transforms in time satisfy

$$\hat{a}(u,\tau) = \frac{1}{4}\sum_{\sigma,\gamma=\pm 1} \hat{p}hi(\gamma\tau - \sigma u), \qquad \hat{b}(u,\tau) = \frac{1}{4i\tau}\sum_{\sigma,\gamma=\pm 1} \gamma\hat{p}hi(\gamma\tau - \sigma u)$$

and are both well defined, also for $\tau \to 0$. Since both a and b are even functions of t, we can extend the integral now over the whole real line and write

$$\begin{aligned}\int dt[H(t)\cos(ut)\phi(t)] &= \int_0^\infty \cos(ut)\phi(t)dt = \frac{1}{2}\int a(u,t)dt - b(u,0)\\ &= \frac{\sqrt{2\pi}}{2}\hat{a}(u,0) - \frac{1}{\sqrt{2\pi}}\int \hat{b}(u,\tau)d\tau.\end{aligned}$$

Inserting the expressions for the Fourier transforms of a and b gives

$$\int dt[H(t)\cos(ut)\phi(t)] = \frac{1}{4\sqrt{2\pi}}\sum_{\sigma,\gamma=\pm 1}\left\{\pi\hat{p}hi(-\sigma u) - \int \frac{\gamma}{i\tau}\hat{p}hi(\gamma\tau - \sigma u)d\tau\right\}.$$

Shifting the integration variable in the second term gives, since the result does not depend on the summation index γ anymore,

$$\int dt[H(t)\cos(ut)\phi(t)] = \frac{1}{2\sqrt{2\pi}}\sum_{\sigma=\pm 1}\left\{\pi\hat{p}hi(-\sigma u) - \int \frac{\hat{p}hi(\tau)}{i(\tau+\sigma u)}d\tau\right\}.$$

Finally, we introduce a δ-function to have a more compact notation, obtaining that

$$\int dt[H(t)\cos(ut)\phi(t)] = \frac{1}{2\sqrt{2\pi}}\sum_{\sigma=\pm 1}\int\left[\pi\delta(\tau+\sigma u) - \frac{1}{i(\tau+\sigma u)}\right]\hat{p}hi(\tau)d\tau$$

holds for all test functions $\phi(t)$ which are compactly supported in t. Thus, in a weak sense, i.e., when integrated against the Fourier transform of compactly supported test functions,

$$[\widehat{H(t)\cos(ut)}](\tau) = \frac{1}{2\sqrt{2\pi}}\sum_{\sigma=\pm 1}\left[\pi\delta(\tau+\sigma u) + \frac{1}{i(\tau+\sigma u)}\right]$$

holds. Equipped with this, we can express the convolution integral for $\hat{Q}^{adj}$ in (3.4) as

$$\begin{aligned}\hat{Q}^{adj}[\psi](p,\tau) &= \sqrt{2\pi}\int dp'\{[H(t)\widehat{S_\lambda(p')},p,t)](-\tau)[\hat{\psi}(p',\tau) - \hat{\psi}(p,\tau)]\}\\ &= \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int dp'\left[\frac{\pi}{\lambda}\delta\left(\frac{\sigma}{\lambda}w_\nu(p',p) - \tau\right)\right.\\ &\qquad\left. + \frac{1}{i(\sigma w_\nu(p',p) - \lambda\tau)}\right][\hat{\psi}(p',\tau) - \hat{\psi}(p,\tau)],\\ w_\nu(p',p) &:= \varepsilon(p') - \varepsilon(p) + \nu. \qquad \square\end{aligned}$$

We now change to energy-angle variables. We make the coordinate transformation in momentum space of the form

$$p \to (\varepsilon(p), p_0), \quad p_0 := \frac{p}{|p|},$$

where p_0 is a vector living only on the unit sphere. Carrying out this coordinate transformation in integrals and directional derivatives in the radial direction for the parabolic band energy $\varepsilon(p) = \frac{|p|^2}{2}$, this means

$$\int f(p)dp = \int_0^\infty d\varepsilon \int dp_0 f(\varepsilon, p_0)\sqrt{2\varepsilon}, \quad \int 1 dp_0 = 4\pi, \quad p^T \nabla_p f(p) = 2\varepsilon \partial_\varepsilon f(\varepsilon, p_0),$$

and the functional $Y_\lambda(f, \psi)$ in (3.3) is given by

$$\text{(a)} \quad Y_\lambda(f,\psi) = \int_0^\infty d\varepsilon \int dp_0 \int d\tau \left\{ \sqrt{2\varepsilon} \hat{f}^*(\varepsilon, p_0, \tau) \hat{Q}_\lambda^{adj}[\psi](\varepsilon, p_0, \tau) \right\},$$

$$\begin{aligned} \text{(b)} \quad \hat{Q}_\lambda^{adj}[\psi](\varepsilon, p_0, \tau) = \frac{1}{2} \sum_{\nu,\sigma=\pm 1} a_\nu \int_0^\infty d\varepsilon' \int dp_0' \\ \times \sqrt{2\varepsilon'} \Bigg[\pi \delta(\varepsilon' - \varepsilon + \nu - \sigma\lambda\tau) \\ + \frac{\sigma}{i(\varepsilon' - \varepsilon + \nu - \sigma\lambda\tau)} \Bigg] [\hat{\psi}(\varepsilon', p_0', \tau) - \hat{\psi}(\varepsilon, p_0, \tau)], \end{aligned} \tag{3.5}$$

where we have made use of the identity $\frac{1}{\lambda}\delta(\frac{z}{\lambda}) = \delta(z)$ and the fact that the δ-function is even. We now give the weak expansion of the collision operator Q_λ as follows.

THEOREM 3.2. *For any fixed test function $\psi(\varepsilon, p_0, t)$ whose Fourier transform in time $\hat{\psi}(\varepsilon, p_0, \tau)$ decays sufficiently fast, the value of the functional $Y_\lambda(f, \psi)$ can be written as*

$$\text{(a)} \quad Y_\lambda(f,\psi) = Y_0(f,\psi) + \lambda Y_1(f,\psi) + o(\lambda), \tag{3.6}$$

with Y_0 and Y_1 given by

$$\begin{aligned} \text{(b)} \quad Y_0(f,\psi) = \sum_{\nu=\pm 1} a_\nu \int_0^\infty d\varepsilon \int dp_0 \int_0^\infty d\varepsilon' \int dp_0' \int_0^\infty dt \\ \pi \delta(\varepsilon' - \varepsilon + \nu) \sqrt{2\varepsilon'}\sqrt{2\varepsilon} f(\varepsilon, p_0, t)[\psi(\varepsilon', p_0', t) - \psi(\varepsilon, p_0, t)], \end{aligned}$$

$$\begin{aligned} \text{(c)} \quad Y_1(f,\psi) = -\sum_{\nu=\pm 1} a_\nu \int_0^\infty d\varepsilon \int dp_0 \int_0^\infty d\varepsilon' \int dp_0' \int_0^\infty dt \\ \ln(|\varepsilon' - \varepsilon + \nu|) \partial_{\varepsilon'} \partial_\varepsilon \left(\sqrt{2\varepsilon'}\sqrt{2\varepsilon} f(\varepsilon, p_0, t) \partial_t [\psi(\varepsilon', p_0', t) - \psi(\varepsilon, p_0, t)] \right). \end{aligned}$$

The proof of Theorem 3.2 is deferred to the end of this section.

Remark: In the usual Cartesian coordinates this means that the collision operator Q_λ is given in weak form by

$$\text{(a)} \quad Q_\lambda[f] = Q_0[f] + \lambda Q_1[f] + o(\lambda), \tag{3.7}$$

$$\text{(b)} \quad Q_0[f](p,t) = \sum_{\nu=\pm 1} \pi a_\nu \int dp' [\delta(\varepsilon - \varepsilon' + \nu) f(p', t) - \delta(\varepsilon' - \varepsilon + \nu) f(p, t)],$$

$$\begin{aligned} \text{(c)} \quad \int dp [\phi(p) Q_1[f](p,t)] = \sum_{\nu=\pm 1} a_\nu \int dp \int dp' \\ \ln(|\varepsilon' - \varepsilon + \nu|) \frac{1}{4\varepsilon\varepsilon'} (p^T \nabla p)((p')^T \nabla_{p'}) \left[\sqrt{4\varepsilon\varepsilon'} \partial_t f(p,t)(\phi(p') - \phi(p)) \right], \end{aligned}$$

where the first order term Q_1 is formulated weakly in the momentum direction only, in order to guarantee that the integrals converge. What remains of the nonlocality in time of the Levinson operator Q_λ in (2.3) is that the operator Q_1 in (3.7)(c) acts on the time derivative of the density function f.

Remark: Theorem 3.2 states only the weak convergence of the Levinson operator (1.2) towards the Fermi golden rule operator (1.1)(b) and not the convergence of solutions of the Levinson equation towards solutions of the corresponding Boltzmann equation. Since solutions of the Boltzmann equation remain nonnegative for nonnegative initial data, a weak convergence result for solutions would actually imply that the Wigner function and its density matrix equivalent would remain nonnegative definite for all time.

Note that Theorem 3.2 holds only for a fixed function f which is independent of λ. However, its validity can be extended by considering a filtered collision operator, since convolution integrals are commutative. If we choose a test function ψ which is of the form $\psi(p,t) = \phi(p)\Gamma(s-t)$ for any s, whose Fourier transform is given by $\hat{\psi}(p,\tau) = \phi(p)\hat{\Gamma}(\tau)^* e^{i\tau s}$, then the Fourier transform of the convolution kernel can be transferred onto the Fourier transform of f, and (3.3)(a) reads

$$Y_\lambda(f_\lambda,\psi) = \sqrt{2\pi}\int dp \int d\tau\{\hat{f}^*_\lambda(p,\tau)\hat{\Gamma}^*(\tau)\hat{Q}^{adj}_\lambda[\phi(p)\delta(t-s)](p,\tau)\}.$$

Theorem 3.2 will still hold as long as the function $\hat{f}^*_\lambda(p,\tau)\hat{\Gamma}(\tau)$ decays sufficiently fast in the variable τ. This means that, even for a function which is oscillating rapidly in time, the filtered operator

$$Q^F_\lambda[f_\lambda](p,t) = \int \Gamma(t-s)Q_\lambda[f_\lambda](p,s)ds \tag{3.8}$$

will satisfy

$$Q^F_\lambda[f_\lambda] = Q_0[f^F_\lambda] + \lambda Q_1[f^F_\lambda] + o(\lambda) \tag{3.9}$$

pointwise in t, where the filtered signal $f^F_\lambda(p,t)$ is given by

$$\hat{f}^F_\lambda(p,\tau) = \sqrt{2\pi}\hat{\Gamma}(\tau)\hat{f}_\lambda(p,\tau), \qquad f^F_\lambda(p,t) = \int \Gamma(t-s)H(s)f_\lambda(p,s)ds.$$

The unscaled equation. Finally, we reverse the scaling of section 2 and write the corrected Fermi golden rule in dimensional variables. Undoing the scaling and choosing the strong form gives the following corrected Boltzmann equation:

$$\partial_t f(p,t) = \int dp' S_0(p,p')f(p',t) - \kappa_0(p)f(p,t) + \int dp' S_1(p,p')\partial_t f(p',t) - \partial_t\kappa_1(p)f(p,t). \tag{3.10}$$

The transition rates S_j and the out-scattering rates κ_j are

$$S_0(p,p') = \frac{V}{(2\pi\hbar)^3}\sum_{\nu=\pm1}\frac{2\pi}{\hbar}M^2\left(n+\frac{1}{2}+\frac{\nu}{2}\right)\delta(\varepsilon(p)-\varepsilon(p')+\nu\hbar\omega),$$

$$S_1(p,p') = \frac{V}{(2\pi\hbar)^3}\sum_{\nu=\pm1}2M^2\left(n+\frac{1}{2}+\frac{\nu}{2}\right)\frac{1}{(\varepsilon(p)-\varepsilon(p')+\nu\hbar\omega)^2},$$

$$\kappa_j(p) = \int dp' S_j(p',p), \quad j=0,1,$$

where $M = \hbar F$ holds, and it should again be pointed out that the strong form of the collision operator is purely formal; i.e., the integral in the out-scattering rate κ_1 is actually infinite, and the first order term has to be formulated in the weak form (3.7).

We conclude this section with the proof of Theorem 3.2.

Proof of Theorem 3.2. We start by writing (3.5) in a more compact form as

(3.11)
$$Y_\lambda(f,\psi) = \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau A_\sigma'(\varepsilon' - \varepsilon + \nu - \sigma\lambda\tau) B(\varepsilon,\varepsilon',p_0,p_0',\tau)\sqrt{2\varepsilon'}^{+},$$

where we have formally extended the integrals with respect to the energy variables ε, ε' over the whole real line and denote by $\sqrt{z}^{+}$ the truncated root; i.e., $\sqrt{z}^{+} = 0$ for $z < 0$ holds. This notation will simplify the further derivation. Here the function $A(u)$, its derivative $A'(u)$, and B are given by

(3.12)
$$\text{(a)}\quad A_\sigma(u) = \pi H(u) - i\sigma \ln(|u|), \qquad A_\sigma'(u) = \pi\delta(u) - \frac{i\sigma}{u},$$
$$\text{(b)}\quad B(\varepsilon,\varepsilon',p_0,p_0',\tau) = \sqrt{2\varepsilon}^{+}\hat{f}^{*}(\varepsilon,p_0,\tau)[\hat{\psi}(\varepsilon',p_0',\tau) - \hat{\psi}(\varepsilon,p_0,\tau)].$$

Shifting the ε' variable in (3.11) gives

$$Y_\lambda(f,\psi) = \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau A_\sigma'(\varepsilon' - \varepsilon + \nu) B(\varepsilon,\varepsilon' + \sigma\lambda\tau,p_0,p_0',\tau)\sqrt{2(\varepsilon' + \sigma\lambda\tau)}^{+}.$$

In principle, we are now going to Taylor-expand the function B with respect to the variable ε'. This is admissible since the variable ε' only appears in the argument of the test function $\hat{\psi}$ in the definition of B, and therefore the function $\partial_{\varepsilon'}B$ decays sufficiently fast in ε' as well. However, care has to be taken with the various singularities appearing in the integrals. We remove the singularity in the function A_σ' by integrating by parts with respect to ε and obtain

$$Y_\lambda(f,\psi) = \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau \; A_\sigma(\varepsilon' - \varepsilon + \nu)\partial_\varepsilon B(\varepsilon,\varepsilon' + \sigma\lambda\tau,p_0,p_0',\tau)\sqrt{2(\varepsilon' + \sigma\lambda\tau)}^{+}.$$

Now we Taylor-expand the function B with respect to the variable ε' and write

(3.13)
$$\partial_\varepsilon B(\varepsilon,\varepsilon' + \sigma\lambda\tau,p_0,p_0',\tau) = \partial_\varepsilon B(\varepsilon,\varepsilon',p_0,p_0',\tau) + \sigma\lambda\tau\partial_\varepsilon\partial_{\varepsilon'}B(\varepsilon,\varepsilon',p_0,p_0',\tau) + O(\lambda^2).$$

This is admissible since the function B is compactly supported in the variable ε'. Next we formally expand the volume element $\sqrt{2\varepsilon'}^{+}$ and write

$$\sqrt{2(\varepsilon' + \sigma\lambda\tau)}^{+} = \sqrt{2\varepsilon'}^{+} + \frac{\sigma\lambda\tau H(\varepsilon')}{\sqrt{2\varepsilon'}} + \frac{\lambda\sigma\tau}{(\varepsilon')^{\alpha}}R_\alpha(\varepsilon',\lambda\sigma\tau) \tag{3.14}$$

for some α, which of course is, at this point, only a definition for the remainder term R_α. Inserting (3.13) and (3.14) into the definition for $Y_\lambda(f,\psi)$, and neglecting the $O(\lambda^2)$ terms in (3.13), gives

$$Y_\lambda = Y_0 + \lambda Y_1 + \lambda Y_{2\lambda} + O(\lambda^2)$$

with

$$\begin{aligned}
&Y_0(f,\psi)\\
&= \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau A'_\sigma(\varepsilon'-\varepsilon+\nu)\sqrt{2\varepsilon'}^{+} B(\varepsilon,\varepsilon',p_0,p_0',\tau),\\
&Y_1(f,\psi)\\
&= \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau A_\sigma(\varepsilon'-\varepsilon+\nu)\sigma\tau\partial_{\varepsilon'}\partial_\varepsilon(\sqrt{2\varepsilon'}^{+} B(\varepsilon,\varepsilon',p_0,p_0',\tau)),\\
&Y_{2\lambda}(f,\psi)\\
&= \frac{1}{2}\sum_{\nu,\sigma=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau A_\sigma(\varepsilon'-\varepsilon+\nu)\frac{\sigma\tau}{(\varepsilon')^\alpha}\\
&\qquad \times \partial_\varepsilon B(\varepsilon,\varepsilon'+\sigma\lambda\tau,p_0,p_0',\tau)R_\alpha(\varepsilon',\lambda\sigma\tau).
\end{aligned}$$

Inserting the definition of the function A_σ from (3.12), we see that odd terms in σ will cancel in Y_0, and the even terms in σ will cancel in Y_1, giving

$$\begin{aligned}
&Y_0(f,\psi)\\
&= \sum_{\nu=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau\pi\delta(\varepsilon'-\varepsilon+\nu)\sqrt{2\varepsilon'}^{+} B(\varepsilon,\varepsilon',p_0,p_0',\tau),\\
&Y_1(f,\psi)\\
&= -\sum_{\nu=\pm 1} a_\nu \int d\varepsilon \int dp_0 \int d\varepsilon' \int dp_0' \int d\tau \ln(|\varepsilon'-\varepsilon+\nu|)i\tau\partial_{\varepsilon'}\partial_\varepsilon\left(\sqrt{2\varepsilon'}^{+} B(\varepsilon,\varepsilon',p_0,p_0',\tau)\right).
\end{aligned}$$

Reversing the Fourier transforms in time gives (3.6)(b,c). The term Y_0 produces the Fermi golden rule, and the term Y_1 the $O(\lambda)$ correction to it. It remains to estimate the term $Y_{2\lambda}$. Since the singularity in the integrand A_σ in ε' is only logarithmic, the integrals will converge for $\alpha < 1$. It therefore remains to choose α such that R_α remains uniformly bounded in ε'; i.e., we can write

(3.15)
$$|Y_{2\lambda}(f,\psi)| \le const \max\{|R_\alpha(\varepsilon',\lambda\sigma\tau)|,\ 0\le\varepsilon'<\infty,\ |\tau|\le K\} \quad \text{for } 0<\alpha<1,$$

where we only have to consider a finite range for τ, since the test function $\hat{\psi}$ can be assumed to be compactly supported. Thus we have to estimate the term

$$\max\{|R_\alpha(\varepsilon',z)|,\ 0\le\varepsilon'<\infty,\ |z|\le\lambda K\}.$$

According to (3.14), R_α is given by

$$R_\alpha(\varepsilon',z) = (\varepsilon')^\alpha\left[\frac{\sqrt{2(\varepsilon'+z)}^{+}-\sqrt{2\varepsilon'}^{+}}{z} - \frac{H(\varepsilon')}{\sqrt{2\varepsilon'}}\right]$$

or

$$R_\alpha(\varepsilon', z) = \begin{pmatrix} (\varepsilon')^\alpha \left[\dfrac{-\sqrt{2\varepsilon'}}{z} - \dfrac{1}{\sqrt{2\varepsilon'}} \right] & \text{for } 0 \le \varepsilon' \le \max\{-z, 0\} \\ (\varepsilon')^\alpha \left[\dfrac{\sqrt{2(\varepsilon'+z)} - \sqrt{2\varepsilon'}}{z} - \dfrac{1}{\sqrt{2\varepsilon'}} \right] & \text{for } \max\{-z, 0\} \le \varepsilon' \end{pmatrix}, \tag{3.16}$$

where the first row is relevant only for $z < 0$. If we choose $\alpha > \frac{1}{2}$, then we can estimate

$$(\varepsilon')^\alpha \left| \frac{-\sqrt{2\varepsilon'}}{z} - \frac{1}{\sqrt{2\varepsilon'}} \right| \le \sqrt{2}(-z)^{\alpha-1/2} + \frac{1}{\sqrt{2}}(-z)^{\alpha-1/2} = O(\lambda^{\alpha-1/2}) \quad \text{for } 0 \le \varepsilon' \le -z,$$

which takes care of the first row of (3.16). To estimate the second row of (3.16), we rewrite the expression as

$$\begin{aligned} &\left| (\varepsilon')^\alpha \left[\frac{\sqrt{2(\varepsilon'+z)} - \sqrt{2\varepsilon'}}{z} - \frac{1}{\sqrt{2\varepsilon'}} \right] \right| \\ &\quad = \frac{(\varepsilon')^\alpha}{\sqrt{2\varepsilon'}} \left| \frac{1 - \sqrt{1+\frac{z}{\varepsilon'}}}{1+\sqrt{1+\frac{z}{\varepsilon'}}} \right| = \frac{|z|^{\alpha-1/2}}{\sqrt{2}} \left| \frac{z}{\varepsilon'} \right|^{1/2-\alpha} \left| \frac{1 - \sqrt{1+\frac{z}{\varepsilon'}}}{1+\sqrt{1+\frac{z}{\varepsilon'}}} \right| \\ &\quad \le \frac{|z|^{\alpha-1/2}}{\sqrt{2}} \max_{-1 \le x < \infty} \left\{ |x|^{1/2-\alpha} \left| \frac{1-\sqrt{1+x}}{1+\sqrt{1+x}} \right| \right\} = O(\lambda^{\alpha-1/2}) \quad \text{for } \alpha > \frac{1}{2}. \end{aligned}$$

Thus, in summary, $\max\{|R_\alpha(\varepsilon', \lambda\sigma\tau)|, 0 \le \varepsilon' \le K, |\tau| \le K\} = O(\lambda^{\alpha-1/2})$ will hold for any $\alpha > \frac{1}{2}$, and because of (3.15), $Y_{2\lambda}(f, \psi) = O(\lambda^{\alpha-1/2})$ will hold for any $\frac{1}{2} < \alpha < 1$. Therefore $\lambda Y_{2\lambda}$ is actually a term of order $o(\lambda)$, although not of order $O(\lambda^2)$, and can be neglected in the first order approximation. Inserting the definition (3.12)(b) for the function B into Y_0, Y_1 and reversing the Fourier transforms gives the result. ∎

4. Numerical results. In this section we verify the asymptotic analysis of the previous section numerically. This verification will consist of two parts. The first part is concerned directly with the weak approximation of the operator Q_λ by $Q_0 + \lambda Q_1$, i.e., with the verification of Theorem 3.2. The more interesting question is of course in what sense the solution of the zero field Levinson equation (1.2) is approximated by the solution of the corresponding approximate equation. To answer this question rigorously we would need some form of stability or entropy estimate for the Levinson equation (1.2). This will be the subject of future work. Nevertheless, the second part of this section is devoted to a numerical study of this question, i.e., a numerical comparison of the solution of the Levinson equation to the solution of an appropriate approximate problem based on the result in Theorem 3.2.

Discretization of the collision operators. For reasons of computational simplicity, we choose a finite difference discretization of the involved collision operators Q_0, Q_1, and Q_λ. While the discretization of the full collision operator Q_λ in (2.3) and the zero order term Q_0 in (3.7)(b) (the Fermi golden rule) by finite differences is straightforward, some care has to be taken when discretizing the first order term Q_1 in (3.7)(c), since it is only formulated in a weak sense. This means that the corresponding strong formulation of the operator Q_1 will contain diverging integrals.

Integrating (3.6)(c) by parts to obtain the strong version of Q_1 gives

$$Q_1[f](p,t) = \int dp'[S_1(p,p')\partial_t f(p',t) - S_1(p',p)\partial_t f(p,t)]$$

with the first order scattering cross section S_1 given by

$$S_1(p,p') = \sum_{\nu=\pm 1} \frac{a_\nu}{(\varepsilon(p) - \varepsilon(p') + \nu)^2}, \tag{4.1}$$

and the resulting integral will be infinite in the strong formulation. We therefore discretize the first order operator Q_1 in a weak difference form. We start by choosing a mesh in energy and time direction of the form

$$M_\varepsilon = \{\varepsilon : \varepsilon = j\Delta\varepsilon,\ j = 0,1,\dots\}, \quad \Delta\varepsilon = \frac{1}{K}, \qquad M_t = \{t : t = n\Delta t,\ n = 0,1,\dots\},$$

where we choose $\Delta\varepsilon$ conveniently in such a way that the emission/absorption energy, which is equal to unity in our scaling, is an integer multiple of the mesh size. The density function f can be assumed to be a function of the energy only, so $f = f(\varepsilon,t)$ holds. Using parabolic bands ($\varepsilon = \frac{|p|^2}{2}$), integrals with respect to the momentum p are approximated by

$$\int f(p,t)dp \approx \Delta\varepsilon \sum_{j=0}^{\infty} f(j\Delta\varepsilon,t)dp(j\Delta\varepsilon), \quad dp(\varepsilon) := 4\pi\sqrt{2\varepsilon}.$$

The full collision operator Q_λ in (2.3) is now approximated by

$$\begin{aligned} Q_\lambda[f](j\Delta\varepsilon, n\Delta t) := \Delta t\Delta\varepsilon \sum_{n'=0}^{n}\sum_{j'=0}^{\infty} dp(j'\Delta\varepsilon) \\ \times[S_\lambda(j\Delta\varepsilon, j'\Delta\varepsilon, (n-n')\Delta t)f(j'\Delta\varepsilon, n'\Delta t) \\ - S_\lambda(j'\Delta\varepsilon, j\Delta\varepsilon, (n-n')\Delta t)f(j\Delta\varepsilon, n'\Delta t)] \end{aligned}$$

with S_λ given as in (2.3)(c). The Fermi golden rule operator Q_0 is discretized by

$$Q_0[f](j\Delta\varepsilon,t) = \sum_{\nu=\pm 1} \pi a_\nu[dp((j+\nu K)\Delta\varepsilon)f((j+\nu K)\Delta\varepsilon,t) - dp((j-\nu K)\Delta\varepsilon)f(j\Delta\varepsilon,t)], \tag{4.2}$$

where, for notational simplicity, we simply set $dp(\varepsilon) = 0$ for $\varepsilon < 0$. The first order collision operator Q_1 in (3.7)(c) is given in its weak formulation by

$$\begin{aligned} \int dp(\varepsilon)[\phi(\varepsilon)Q_1[f](\varepsilon,t)]d\varepsilon = 16\pi^2 \sum_{\nu=\pm 1} a_\nu \int d\varepsilon \int d\varepsilon' \\ \times \ln(|\varepsilon' - \varepsilon + \nu|)\partial_\varepsilon\partial_{\varepsilon'}\left[\sqrt{4\varepsilon\varepsilon'}\partial_t f(\varepsilon,t)(\phi(\varepsilon') - \phi(\varepsilon))\right]. \end{aligned}$$

In this weak formulation the integrals are guaranteed to converge. It is therefore allowed to truncate the logarithmic singularity in the integral kernel. We define

$$\ln^0(j\Delta\varepsilon) = \begin{cases} \ln(j\Delta\varepsilon), & j > 0, \\ \ln(\Delta\varepsilon), & j = 0, \end{cases}$$

and discretize Q_1 in a weak finite difference sense by requiring that

$$\begin{aligned}\Delta\varepsilon \sum_{j=0}^{\infty} dp(j\Delta\varepsilon)[\phi(j\Delta\varepsilon)Q_1[f](j\Delta\varepsilon, n\Delta t)] \\ = 16\pi^2(\Delta\varepsilon)^2 \sum_{\nu=\pm 1} a_\nu \sum_{j=0}^{\infty}\sum_{j'=0}^{\infty} \\ \ln^0(|j'-j+\nu K|\Delta\varepsilon) D_j^+ D_{j'}^+ \left[\sqrt{4jj'}\Delta\varepsilon D_n^+ f(j\Delta\varepsilon, n\Delta t)(\phi(j'\Delta\varepsilon)-\phi(j\Delta\varepsilon))\right]\end{aligned}$$

hold for all grid-test-functions ϕ. Here D^+ denotes the usual forward difference operators acting on the respective indices; i.e.,

$$\begin{aligned}&\text{(a)} \quad D_j^+ f(j\Delta\varepsilon, t) = \frac{f((j+1)\Delta\varepsilon, t) - f(j\Delta\varepsilon, t)}{\Delta\varepsilon}, \\ &\text{(b)} \quad D_n^+ f(\varepsilon, n\Delta t) = \frac{f(\varepsilon, (n+1)\Delta t) - f(\varepsilon, n\Delta t)}{\Delta t},\end{aligned} \tag{4.3}$$

holds. Expressing the first order collision operator in a strong form on the discrete level, i.e., choosing a discrete δ-function for the test function ϕ, gives

(4.4)
$$\begin{aligned}&Q_1[f](j\Delta\varepsilon, n\Delta t) \\ &= \Delta\varepsilon \sum_{j'=0}^{\infty} dp(j\Delta\varepsilon)[S_1(j\Delta\varepsilon, j'\Delta\varepsilon) D_n^+ f(j'\Delta\varepsilon, n\Delta t) - S_1(j'\Delta\varepsilon, j\Delta\varepsilon) D_n^+ f(j\Delta\varepsilon, n\Delta t)],\end{aligned}$$

with the discrete scattering cross section S_1 given by

$$S_1(j\Delta\varepsilon, j'\Delta\varepsilon) = \sum_{\nu=\pm 1} a_\nu D_j^- D_{j'}^- \ln^0 |(j-j'+\nu K)\Delta\varepsilon|,$$

which is the appropriate approximation to the singular integral kernel (4.1). Here D^- denotes the backward differencing operator, analogously to the definition of D^+ in (4.3).

We now proceed to verify Theorem 3.2 numerically. Besides the verification of the asymptotic analysis of the previous section, the purpose of this exercise is also to gain some confidence in the weak difference discretization before computing asymptotic solutions to the Levinson equation. More precisely, we will verify the consequence of Theorem 3.2 given in (3.9), namely that the smoothed version of the full collision operator Q_λ applied to a highly oscillatory function is approximated by the zero- and first order terms Q_0 and Q_1 applied to the smoothed function. Figure 1 shows the signal chosen for this verification, which consists of the function $f(\varepsilon, t) = (1 + \cos(20t))/(1 + 3\varepsilon^2)$, i.e., a smooth function of ε modulated by a rapid oscillation in time. Figure 2 shows the filtered signal $f^F(\varepsilon, t)$, obtained by convoluting f with a Gaussian in time. We now compute $Q_\lambda[f]$ and the corresponding smoothed version $Q_\lambda^F[f]$ according to (3.8) and compare the result to $(Q_0 + \lambda Q_1)[f^F]$. As a measure for the approximation we chose the energy given by the formula

$$\langle \varepsilon Q \rangle(t) = \Delta\varepsilon \sum_{j=0}^{\infty} dp(j\Delta\varepsilon) j\Delta\varepsilon Q(j\Delta\varepsilon, t).$$

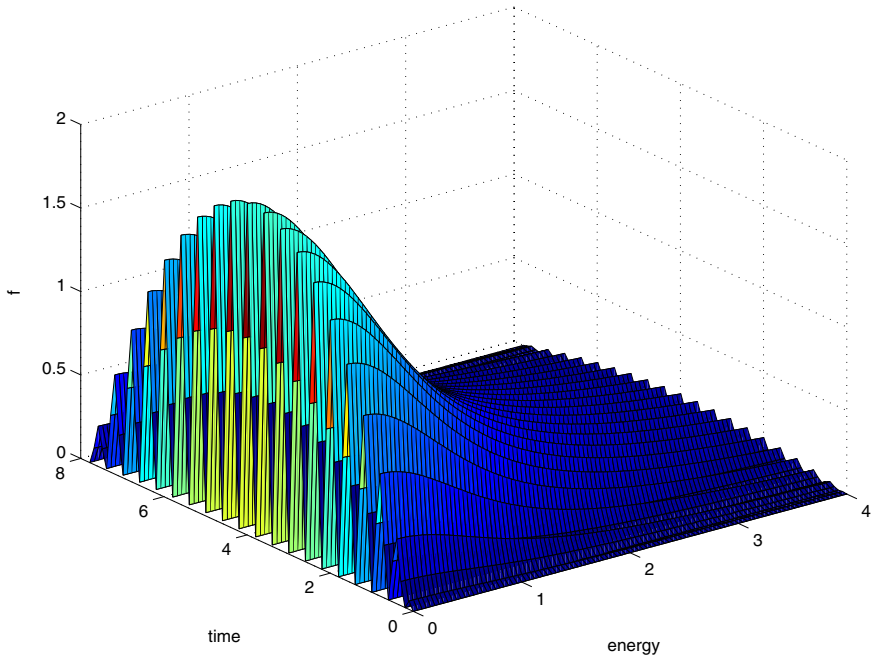

FIG. 1. *Unfiltered signal.*

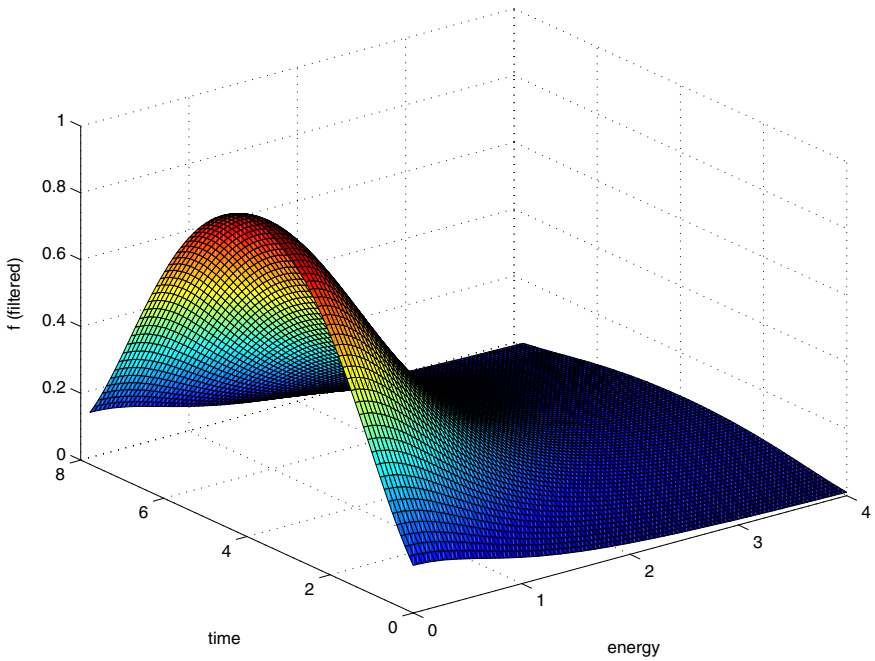

FIG. 2. *Filtered signal.*

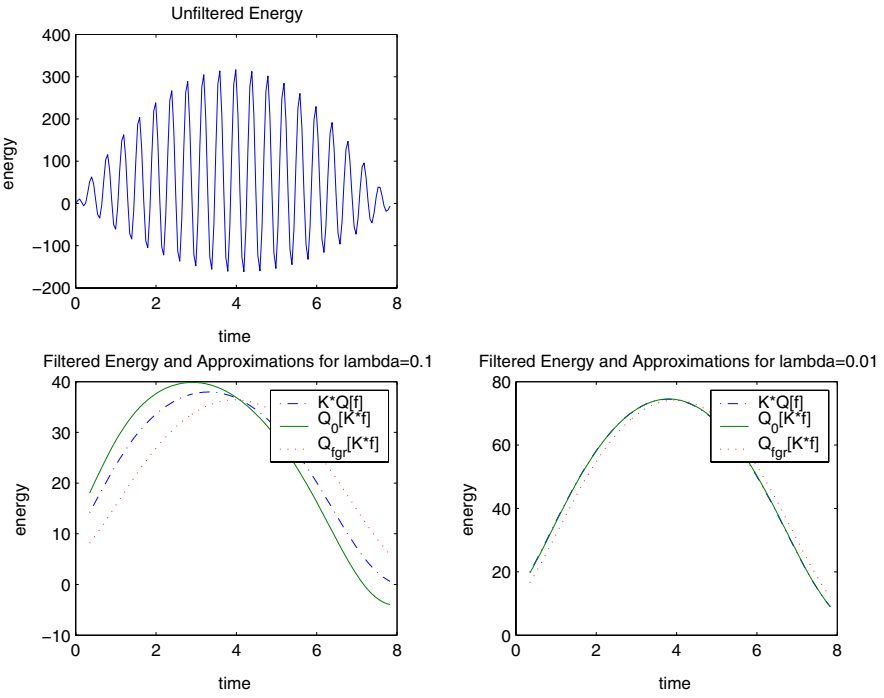

FIG. 3. *Comparison of energies.*

Figure 3 shows the highly oscillatory energy $\langle \varepsilon Q_\lambda[f] \rangle$ and compares $\langle \varepsilon Q_\lambda^F[f] \rangle$ to the values of $\langle \varepsilon Q_0[f^F] \rangle$ and $\langle \varepsilon (Q_0[f^F] + \lambda Q_1[f^F]) \rangle$ for $\lambda = 0.1$ and $\lambda = 0.01$. Figure 3 first confirms that the smoothed collision operator converges to the Fermi golden rule applied to the smoothed signal pointwise in time and that the approximation is improved by adding the first order correction, which is a direct consequence of the weak convergence given in Theorem 3.2.

We now turn to the more interesting question of whether, and in what sense, the solution of the zero field Levinson equation (1.2) is approximated by the solution of the asymptotic equation

$$\partial_t f = Q_0[f] + \lambda Q_1[f]. \tag{4.5}$$

To this end, we will compute with more realistic parameters. F in (1.2)(b) denotes the frequency of a particular lattice state and is given by the formula

$$F(\xi) = \sqrt{\frac{q^2 \hbar \omega}{2V|\xi|^2 \varepsilon_0} \left(\frac{1}{\varepsilon_\infty} - \frac{1}{\varepsilon_s} \right)}, \tag{4.6}$$

where ξ is the momentum vector corresponding to the lattice state, ε_0 is the dielectricity constant (for vacuum), and ε_∞ and ε_s are the usual corrections to ε_0, taking into account the property of the crystal. The values for the physical parameters in

section 1 are summarized in the table below:

Symbol	Value	Unit	Meaning
q	$1.602 * 10^{-19}$	C	Electron charge
$\hbar$	$1.054 * 10^{-34}$	$\mathrm{kgm}^2/\mathrm{sec}$	Planck constant
h	$6.626196 * 10^{-34}$	$\mathrm{kgm}^2/\mathrm{sec}$	$h = 2\pi\hbar$
m_*	$0.063 * 0.109 * 10^{-31}$	kg	Effective electron mass
$\hbar\omega$	0.036	eV	Emission/absorption energy
ε_0	$8.85 * 10^{-12}$	$\frac{C}{V\mathrm{m}}$	Dielectricity constant (vacuum)
ε_∞	10.92	1	
ε_s	12.9	1	

We are considering the system at room temperature; i.e., the inverse temperature β in section 2 has a value of $\beta = 40(eV)^{-1}$, which gives a value of $n = 0.3105$ for the occupation number n. We consider only a single lattice state corresponding to the lattice being in equilibrium; i.e., we choose $|\xi|^2 = \frac{m_*}{\beta}$. Using these values, one computes a value of $\lambda = 0.0113$ for the dimensionless parameter λ, which suggests that we are in the appropriate asymptotic regime.

The asymptotic solution of the Levinson equation. The solution of the asymptotic equation (4.5) is complicated by the following facts. First, the equation is implicit in time, since the first order perturbation operator Q_1 acts on the time derivative of the solution f. Second, the implicit term is nonlocal in the energy variable, and third, this nonlocal implicit integral term contains a singular kernel. These factors make the actual numerical solution of (4.5) highly nontrivial. One could, for instance, be tempted to replace the time derivative of the density function in Q_1 in first order by $Q_0[f]$ and solve the explicit equation

$$\partial_t f = Q_0[f] + \lambda \int dp[S_1(p,p')Q_0[f](p',t) - S_1(p',p)Q_0[f](p,t)] \tag{4.7}$$

instead. It is, however, relatively easy to see (and has been verified numerically) that (4.7) is ill posed. At the level of computational complexity considered in this paper it would be feasible to directly discretize (4.5) using an implicit time discretization. We would then have to consider the artificial numerical diffusion generated by implicit methods, which is a major factor since we want to compare asymptotic solutions to the highly oscillatory solution of the Levinson equation. It should be pointed out here that we have made life particularly simple by considering solutions which are functions of energy only. As soon as we would introduce a field term, or consider spatially inhomogeneous problems, we would have to resort to some form of particle-based discretization, and the solution of implicit equations would become a major issue. With an eye to the future particle-based solution of inhomogeneous problems, the easiest way out of this dilemma is to actually solve for the asymptotic expansion of f given by (4.5). That is, to write $f = f_0 + \lambda f_1$ and to solve the system

$$\text{(a)} \quad \partial_t f_0 = Q_0[f_0], \qquad \text{(b)} \quad \partial_t f_1 = Q_0[f_1] + Q_1[f_0]. \tag{4.8}$$

Now the time derivative of the zero order term f_0, which appears in (4.8)(b), can be replaced by (4.8)(a), and we actually solve

$$\begin{aligned} &\text{(a)} \quad \partial_t f_0 = Q_0[f_0], \\ &\text{(b)} \quad \partial_t f_1 = Q_0[f_1] + \int dp[S_1(p,p')Q_0[f_0](p',t) - S_1(p',p)Q_0[f_0](p,t)]. \end{aligned} \tag{4.9}$$

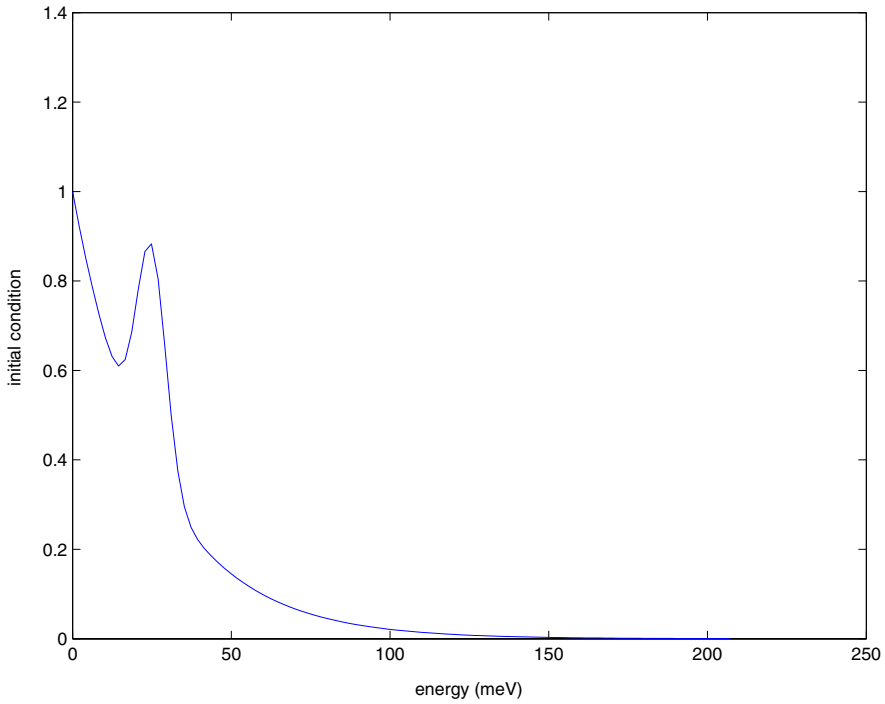

FIG. 4. *Initial condition for the Levinson equation.*

Equation (4.9)(a) is just the Boltzmann equation with the Fermi golden rule operator, and (4.9)(b) is also the same Boltzmann equation with an additional source term, which could be discretized using weighted particles. It is in this form that the numerical experiments below have been carried out, using the discretizations (4.2) and (4.4) for the operators Q_1 and Q_2.

We choose as initial condition (shown in Figure 4) the equilibrium Maxwellian with a second peak added. Thus we expect the second peak to be eliminated by the evolution of the Levinson equation as time advances. Figure 5 shows the solution f_λ of the Levinson equation (1.2) as a function of energy and time, and it exhibits the expected oscillations in time, albeit not to the same extent as the test example. To compare this solution with the asymptotic solution of (4.9), we smooth it in the same way as in the test example, i.e., by convoluting it with a Gaussian in time, shown in Figure 6. Figure 7 shows the solution of (4.9) for the same parameters. Figure 8 compares the full solution f_λ of the Levinson equation to the solution f_0 of the Fermi golden rule and $f_0 + \lambda f_1$ of (4.9) at different points in time. We observe that the solution f_0 of the Fermi golden rule has essentially reached steady state, while the full solution f_λ still evolves, i.e., the quantum effect causes a significantly longer relaxation time. This behavior is captured more or less by the asymptotic solution $f_0 + \lambda f_1$.

The structure of the equilibrium solution for the Fermi golden rule is determined by the fact that we have chosen a simple constant value of the lattice state frequency F in (4.6), corresponding to a δ-function collision potential [10]. This implies that the kernel of the Fermi golden rule operator Q_0 contains not only Maxwellians, but Maxwellians multiplied by arbitrary $\hbar\omega$-periodic functions of energy [7], [8], [12]. The steps in the equilibrium solution in the lower-right panel of Figure 8 represent the

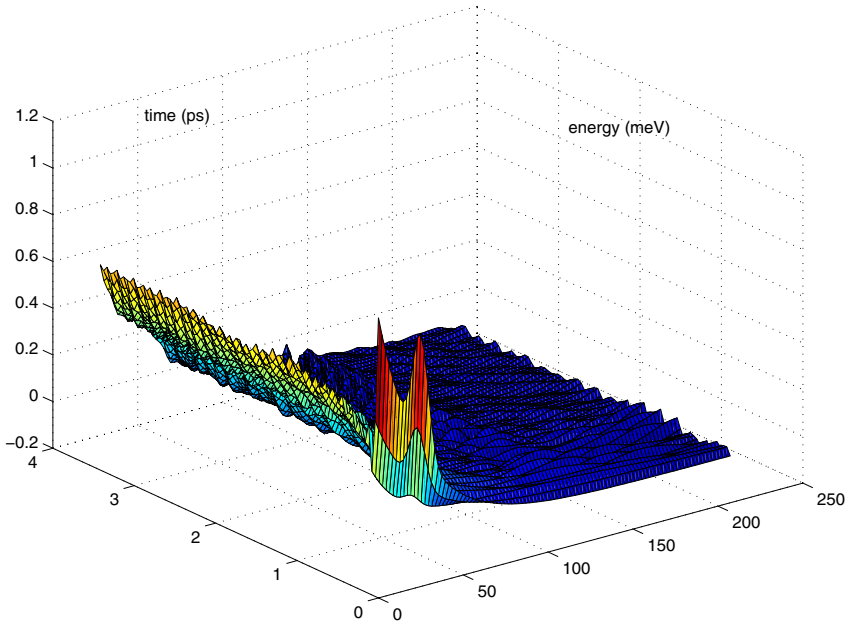

FIG. 5. *Solution of the Levinson equation.*

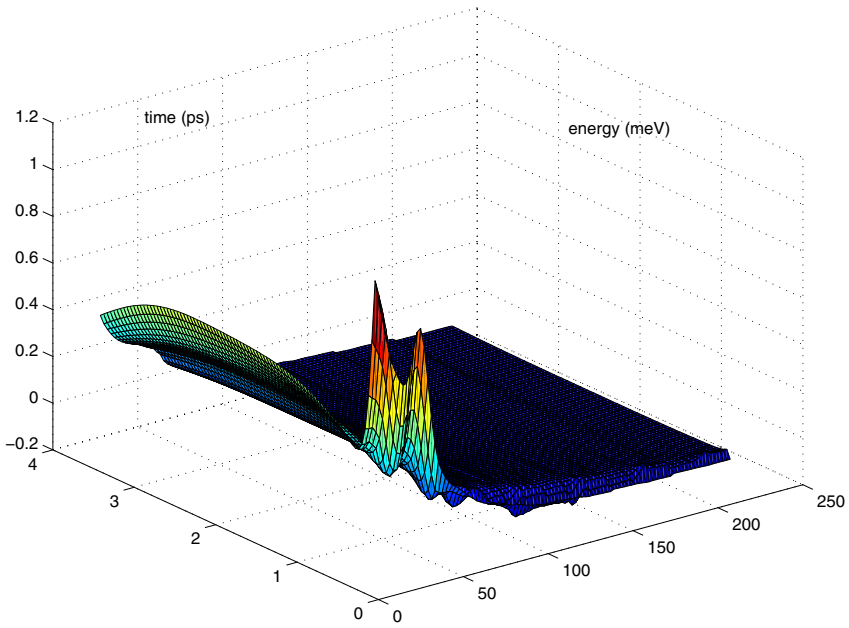

FIG. 6. *Filtered solution of the Levinson equation.*

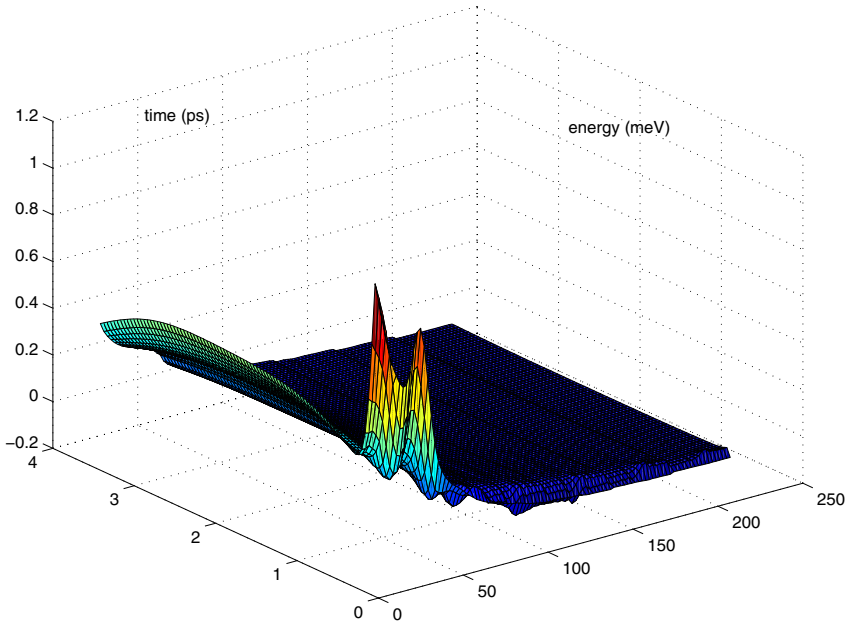

FIG. 7. *Approximate solution of the Levinson equation.*

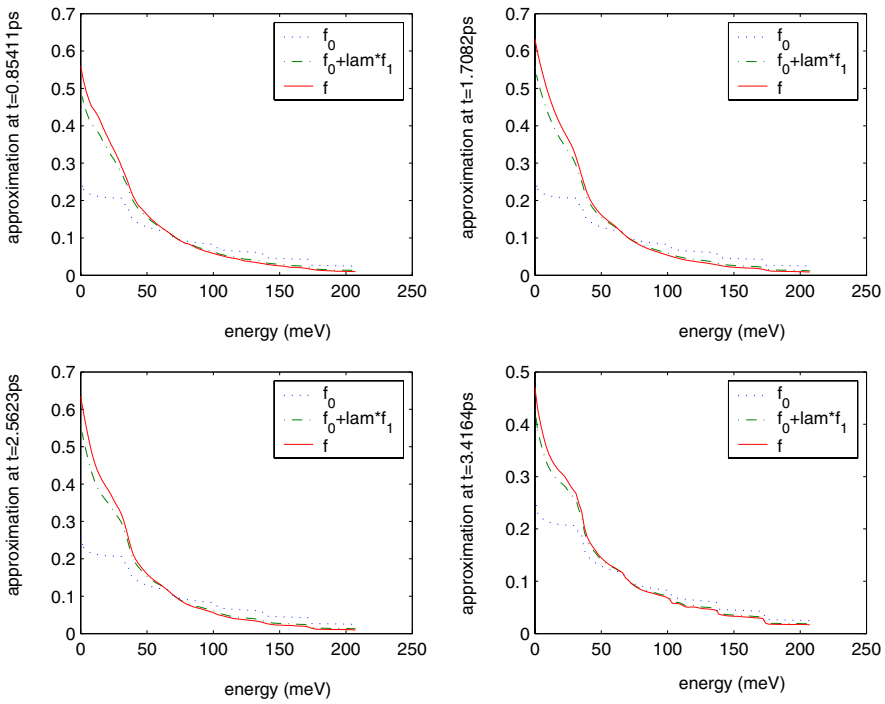

FIG. 8. *Snaphots of the solution and its approximations.*

projection of the initial solution into this space.

We were unable to continue the comparison beyond the given point in time due to memory constraints, since the solution of the Levinson equation requires time steps much smaller than λ to resolve the oscillations, and the storage of all previous time steps because of its nonlocality in time. It should be pointed out that the solution of the asymptotic system (4.9) does not suffer from these constraints, and (4.9) could be solved with much larger time steps on much longer timescales. The asymptotic solution $f_0 + \lambda f_1$ will eventually, however, converge to the same equilibrium solution, since the system (4.9) clearly has the same steady states as the original Fermi golden rule equation (1.2). Thus the quantum corrections give, at least in the absence of an electric field term, a purely transient effect.

5. Conclusions. Based on the Levinson equation, which in turn is derived from a weak interaction limit for the many body Schrödinger equation, we have derived a corrective term to the semiclassical Fermi golden rule collision operator. This corrective term is only mildly nonlocal in time in the sense that it is a local operator acting on the time derivative of the density function. It therefore renders itself much more easily to simulations on long timescales than did the original Levinson operator. We have shown the weak convergence of the corrected operator to the Levinson operator; i.e., we have proven the oscillatory limit for large times. Furthermore, we have demonstrated numerically the convergence of the solution to the Levinson equation towards the system resulting from the corresponding asymptotic expansion. From a numerical standpoint the complexity of this system is equivalent to that of solving a standard Boltzmann equation with additional source terms.

RETROFOCUSING OF ACOUSTIC WAVE FIELDS BY ITERATED TIME REVERSAL*

B. LARS G. JONSSON†, MATS GUSTAFSSON‡, VAUGHAN H. WESTON§, AND MAARTEN V. DE HOOP¶

Abstract. In the present paper an iterative time-reversal algorithm that retrofocuses an acoustic wave field to its controllable part is established. For a fixed temporal support, i.e., transducer excitation time, the algorithm generates an optimal retrofocusing in the least-squares sense. Thus the iterative time-reversal algorithm reduces the temporal support of the excitation from the requirement of negligible remaining energy to the requirement of controllability. The time-reversal retrofocusing is analyzed from a boundary-control perspective where time reversal is used to steer the acoustic wave field towards a desired state. The wave field is controlled by transducers located at subsets of the boundary, i.e., the controllable part of the boundary. The time-reversal cavity and time-reversal mirror cases are analyzed. In the cavity case, the transducers generate a locally plane wave in the fundamental mode through a set of ducts. Numerical examples are given to illustrate the convergence of the iterative time-reversal algorithm. In the mirror case, a homogeneous half space is considered. For this case the analytic expression for the retrofocused wave field is given for finite temporal support. It is shown that the mirror case does not have the same degree of steering as the cavity case. It is also shown that the pressure can be perfectly retrofocused for infinite temporal support. Two examples are given that indicate that the influence of the evanescent part of the wave field is small.

Key words. time reversal, retrofocusing, wave splitting, acoustic

1. Introduction.

Time-reversal acoustics is based on recording the wave field using a set of transducers, time-reversing the recorded signal, and retransmitting the result. The retransmitted wave field propagates back in the medium towards its source of origin [5, 9, 10, 12, 13]. In this paper, the time-reversal approach is analyzed from a boundary-control perspective [2, 3] in which time reversal is used to steer the acoustic wave field towards a desired state, corresponding to the original state. The boundary is divided into a controllable and an uncontrollable part. On the controllable part of the boundary, transducers are used to record or generate the acoustic wave field. The uncontrollable part of the boundary is assumed to be acoustically hard [26].

Both the time-reversal cavity and the time-reversal mirror have been extensively studied by Fink and coworkers; see, e.g., [5, 9, 10, 12, 13]. The cavity and mirror cases describe measurement situations with transducers surrounding the original source and only occupying a limited angular area, respectively. Applications of time-reversal

algorithms include lithotripsy, pulse focusing, medical imaging, inverse scattering [10, 13], and optimal distinguishability measurements [6, 7]. The time-reversal approach gives a perfect retrofocusing if the transducers surround the original source, i.e., the time-reversal cavity, and the wave field is recorded until the wave field is quiescent; see, e.g., [2]. If the conditions for local energy decay are satisfied [1, 23], the retrofocusing error can be made arbitrarily small as observation or measurement time approaches infinity. An analysis of the super-resolving property of the time-reversal mirror is presented in [4]. Applications to communications are given in [19].

From boundary control theory, it is known that transducers can steer the wave field towards an arbitrary field distribution if the region is controllable [3, 22]. If the configuration is not controllable, an optimal control produces an optimal retrofocused wave field. The present paper establishes an iterative time-reversal algorithm that retrofocuses an acoustic wave field to its controllable part. The obtained iterative time-reversal algorithm reduces the temporal support of the transducer excitation from the requirement of negligible remaining energy to the requirement of controllability. In particular, for a fixed temporal support of the excitation, the algorithm generates an optimal retrofocusing in the least-squares sense. The characteristics of the transducers are included.

The considered cavity is a bounded domain with a perforated acoustically hard boundary. Transducers induce the wave field through the fundamental (or plane wave) mode in a set of ducts [26]. Numerical examples are given to illustrate the convergence of the iterative time-reversal algorithm. In the mirror case, a homogeneous half space is considered. For this case, it is shown that the pressure can be perfectly retrofocused for infinite temporal support. For finite temporal support the algorithm gives an optimal control for the propagating part of the wave field. A closed-form representation for the retrofocused wave field, with finite temporally supported excitation, from an initial Dirac-pressure source is given. Its behavior in the long time limit is calculated. Two examples of retrofocusing of a pressure source are given, and the influence of the evanescent part of the wave is discussed. In both the cavity and the mirror the iterated time-reversal procedure does not make use of the medium properties of the interior.

The optimal measurements [6, 7] are discussed in the sense of maximal measured least-squares distinguishability of a scattering operator relative to a reference scattering operator. The obtained algorithm is the limit of a renormalized series of iterated time reversals. It is noted in [6] that the limit of this renormalized series is a time-harmonic, frequency tuned wave form that corresponds to the frequency such that the largest eigenvalue of the squared time-reversed reflection operator attains its maximum in a given frequency interval. The algorithm in the present paper uses *the sum* of the iterated squared time-reversed response operators to obtain the retrofocusing of an initially prescribed field. Thus the resulting control for retrofocusing has a multifrequency content, as opposed to the algorithms proposed in [6, 7].

The present paper begins with a short discussion of the boundary control of acoustic wave fields. Transducers are introduced, and their restrictions on the boundary conditions are analyzed. In section 3, the sufficient conditions for optimal boundary control with respect to a least-squares measure is given. As the first example we consider the case where the material parameters are unknown; see section 4. In section 5, a cavity with acoustically hard walls and attached ducts is analyzed. Numerical examples are given. The time-reversal algorithm is shown to efficiently retrofocus the field of an initial pulse source. In section 6, the mirror case is analyzed for a homogeneous material. The optimal control for measurements with negligible evanescent

part is derived. For the nonnegligible evanescent part of the measured response, the closed-form expression for the time reversal of an initial pressure source is derived. Here we utilize a constant wavespeed to obtain an analytical expression. It is shown that, for an initial pressure distribution, the evanescent part of the control has a marginal influence on the resulting field in the long excitation time limit. Section 7 is a discussion of the results.

2. The acoustic wave field and boundary control.

2.1. The control state. In this section we state the acoustic equations, the boundary conditions, and initial values assumed in the further analysis. The goal is to focus the acoustic wave field to a desired state at a given finite time. To quantify the focusing, relative to the desired state, we use a weighted L^2 measure, in the form of an energy functional. We also introduce the boundary control, the admittance operator, a representation of the characteristics of a transducer, and the response operator due to a boundary control.

The control state is an acoustic wave field in the domain $\Omega \in \mathbb{R}^3$ and time interval $[0, T]$. The boundary of the domain, $\partial\Omega$, is assumed to be piecewise C^1, and thus the normal to the boundary is well defined almost everywhere. At the open subset $\Gamma_{\mathrm{t}} \subset \partial\Omega$, *the controllable part of the boundary*, we have a set of transducers that are used to generate an acoustic wave field in the domain. The control state at time t is represented by the pressure, $p = p(\boldsymbol{x}, t)$, and the particle velocity, $\boldsymbol{v} = \boldsymbol{v}(\boldsymbol{x}, t)$. Given a desired final state, $\{p_T, \boldsymbol{v}_T\}$, we quantify the degree of focusing between the control state at time T, $\{p(\cdot, T), \boldsymbol{v}(\cdot, T)\}$, and the desired state, with the weighted L^2 functional

$$\mathcal{J} = \frac{1}{2} \int_{\Omega} (\kappa(\boldsymbol{x}) |p(\boldsymbol{x}, T) - p_T(\boldsymbol{x})|^2 + \rho(\boldsymbol{x}) |\boldsymbol{v}(\boldsymbol{x}, T) - \boldsymbol{v}_T(\boldsymbol{x})|^2) \, \mathrm{dV}(\boldsymbol{x}). \tag{2.1}$$

The control state $\{p, \boldsymbol{v}\}$ satisfies the source-free acoustic equations

$$\begin{cases} \kappa(\boldsymbol{x}) \partial_t p + \nabla \cdot \boldsymbol{v} = 0 \\ \rho(\boldsymbol{x}) \partial_t \boldsymbol{v} + \nabla p = \boldsymbol{0} \end{cases} \quad \text{for } \boldsymbol{x} \in \Omega \text{ and } t \in [0, T], \tag{2.2}$$

where the compressibility $\kappa(\boldsymbol{x})$ and the density $\rho(\boldsymbol{x})$ model the interaction between the acoustic wave field and the material. To ensure the existence of solutions, it is assumed that material parameters κ and ρ are positive and belong to $\mathrm{L}^\infty(\Omega)$; i.e., the parameters are bounded and measurable. No explicit knowledge of the parameters is assumed, except that they belong to the mentioned class. In the process of retrofocusing, we assume the initial conditions

$$p(\boldsymbol{x}, 0) = 0 \quad \text{and} \quad \boldsymbol{v}(\boldsymbol{x}, 0) = \boldsymbol{0} \quad \text{for } \boldsymbol{x} \in \Omega. \tag{2.3}$$

In our model the transducers are supported on the controllable part Γ_{t} of the boundary; see Figure 5.1. Given a boundary control [22], $p_+ = p_+(\boldsymbol{x}, t)$, $\boldsymbol{x} \in \Gamma_{\mathrm{t}}$, the characteristics of the transducers determine how the field is induced in the domain. Here, we model the transducer characteristic with the transducer's admittance operator $\mathcal{Y}$ that maps its domain $\mathcal{D} \subset \mathrm{L}^2$ to L^2 and is invertible. Thus the boundary condition at the controllable part of the boundary, Γ_{t} (see Figure 2.1) takes the form,

$$\frac{(\mathcal{Y}p)(\boldsymbol{x}, t) + v_{\mathrm{n}}(\boldsymbol{x}, t)}{2} = p_+(\boldsymbol{x}, t) \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{t}} \text{ and } t \in [0, T], \tag{2.4}$$

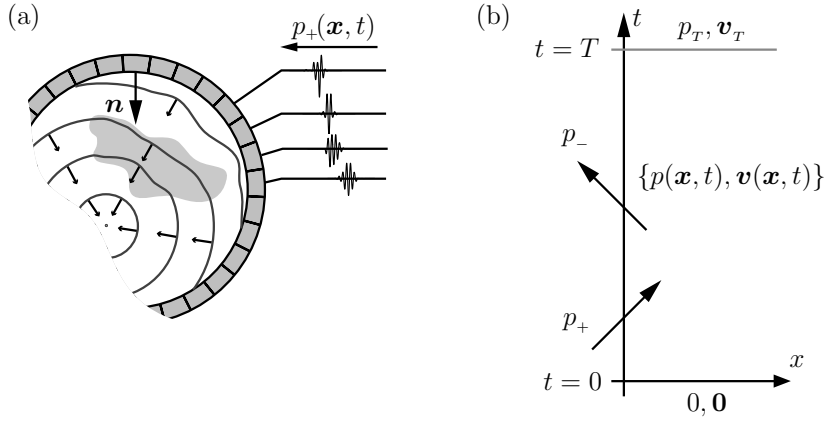

FIG. 2.1. *The control state*: *The boundary control p_+ is prescribed at the boundary, and given quiescent initial conditions, we measure the response p_-. The desired final state $\{p_T, \boldsymbol{v}_T\}$ is shown as the state at time $t = T$ in panel* (b).

where v_n is the normal component of the particle velocity, i.e., $v_\mathrm{n} = \boldsymbol{v} \cdot \boldsymbol{n}$ and $\boldsymbol{n}$ is the inward unit normal vector to the boundary; see Figure 2.1(a). The boundary condition above is said to be in the velocity normalization [16, 17, 18]. The case with $\mathcal{Y} = 1$ in (2.4) represents boundary conditions in the form of a locally plane wave propagating inward into the domain, i.e., in the $\boldsymbol{n}$-direction [26], and this case is considered in section 5. The time-reversal mirror case with the transducer modeled by the wave splitting operator [18] is considered in section 6.

The remaining, noncontrollable, enclosed part of the boundary, the wall that we denote as *the uncontrollable part* of the boundary, $\Gamma_\mathrm{w} = \partial\Omega \setminus \Gamma_\mathrm{t}$ (see, e.g., Figure 5.1), is made of a particular material with characteristics $\mathcal{U}$, giving the boundary condition

$$(\mathcal{U}p)(\boldsymbol{x},t) + v_\mathrm{n}(\boldsymbol{x},t) = 0 \quad \text{for } \boldsymbol{x} \in \Gamma_\mathrm{w} \text{ and } t \in [0,T]. \tag{2.5}$$

Here, $\mathcal{U}$ is a continuous mapping from L^2 to L^2. Observe that $\mathcal{U} = 0$ in (2.5) corresponds to an acoustically hard (uncontrollable) boundary. We use this as an example.

The operators $\mathcal{Y}$ and $\mathcal{U}$ are chosen such that the acoustic wave equation is well posed with this boundary condition [20, section 8.2]. The Kreiss–Lorenz class of boundary conditions is of the type $p_\mathrm{in} = \mathcal{C}p_\mathrm{out}+$ source terms, where p_in and p_out are defined as the eigenvectors to the matrix of the normal to the boundary-derivative, in our case $p \pm v_\mathrm{n}$. For this class of boundary conditions, there is a requirement on the principal part size of the coupling term $\mathcal{C}$. In our case, $\mathcal{C} = (\mathcal{Y}^{-1} - 1)(\mathcal{Y}^{-1} + 1)^{-1}$. In the examples that we consider, $\mathcal{Y} = 1$ or $p_\mathrm{out} = 0$, and hence the coupling term vanishes. For a more detailed discussion and more general boundary conditions, see [20]. The above discussion holds also for the uncontrollable part of the boundary, i.e., for $\mathcal{U}$.

We assume that the transducers can also be used as receivers, and we measure the outgoing field component, p_-, at the boundary; see Figure 2.1(b). This component is given by

$$p_-(\boldsymbol{x},t) = \frac{(\mathcal{Y}p)(\boldsymbol{x},t) - v_\mathrm{n}(\boldsymbol{x},t)}{2} \quad \text{for } \boldsymbol{x} \in \Gamma_\mathrm{t} \text{ and } t \in [0,T]. \tag{2.6}$$

The relation between the boundary control p_+ and the measured outgoing field component p_-, for zero initial conditions, is the response operator $\mathcal{R}$, which is also called the scattering operator or reflection operator [6, 7],

$$p_-(\boldsymbol{x},t) = (\mathcal{R}p_+)(\boldsymbol{x},t) \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{t}} \text{ and } t \in [0,T]. \tag{2.7}$$

Given a boundary control, we assume that we can obtain its response by measurements on the domain, i.e., using the transducers to measure the response to the given boundary control.

In our formulation, the boundary control is not uniquely determined. There are many acoustic wave field configurations where it is clear that several boundary controls minimize $\mathcal{J}$. One such example is a homogeneous slab where we consider long enough excitation times such that the wave field can pass through the slab. The final internal field in the slab does not depend on fields that have left the slab, and hence the control is not unique.

2.2. The observation states. In this section, we define the notion of initial observation, an observation, and an observation state. The observation of an observation state is used in constructing the boundary control for the control state.

To distinguish between the control states and the field used for observation, we introduce the notation $\{q(\boldsymbol{x},t), \boldsymbol{u}(\boldsymbol{x},t)\}$ for the observation state at times $t \in [-T,0]$. The observation state $\{q, \boldsymbol{u}\}$ solves (2.2), and for convenience we let the observation take place in the time interval $[-T,0]$.

We define the initial observation state through its initial conditions

$$q(\boldsymbol{x},-T) = p_T(\boldsymbol{x}) \quad \text{and} \quad \boldsymbol{u}(\boldsymbol{x},-T) = -\boldsymbol{v}_T(\boldsymbol{x}) \quad \text{for } \boldsymbol{x} \in \Omega. \tag{2.8}$$

The observation of the initial observation state is carried out with the receivers coinciding with the transducers for the control state; i.e., the measurement in terms of the field at the boundary is

$$q_-(\boldsymbol{x},t) = \frac{(\mathcal{Y}q)(\boldsymbol{x},t) - u_{\mathrm{n}}(\boldsymbol{x},t)}{2} \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{t}} \text{ and } t \in [-T,0]. \tag{2.9}$$

Consequently, the boundary condition for the controllable part of the boundary takes the form

$$\frac{(\mathcal{Y}q)(\boldsymbol{x},t) + u_{\mathrm{n}}(\boldsymbol{x},t)}{2} = q_+ \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{t}} \text{ and } t \in [-T,0]. \tag{2.10}$$

The initial observation is thus given by $q_-^{(0)} = q_-$, setting $q_+ = 0$ in (2.10). On the uncontrollable part of the boundary, the field satisfies the boundary condition (cf. (2.5))

$$(\mathcal{U}q)(\boldsymbol{x},t) + u_{\mathrm{n}}(\boldsymbol{x},t) = 0 \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{w}} \text{ and } t \in [-T,0]. \tag{2.11}$$

The relation between q_- and q_+ and the initial conditions are, by the superposition principle,

$$q_-(\boldsymbol{x},t) = (\mathcal{R}q_+)(\boldsymbol{x},t) + q_-^{(0)}(\boldsymbol{x},t) \quad \text{for } \boldsymbol{x} \in \Gamma_{\mathrm{t}} \text{ and } t \in [-T,0], \tag{2.12}$$

where $\mathcal{R}$ coincides with the $\mathcal{R}$ in (2.7) since q_- and p_- are both the measured response with the same receivers from the acoustic wave equations with identical domains and type of boundary conditions.

With the above given information about the response operator and the initial observation, we will search for an optimal boundary control, i.e., the control applied in (2.4) such that the resulting control state at time T minimizes the least-squares functional $\mathcal{J}$ in (2.1), for a given $\{p_T, \boldsymbol{v}_T\}$.

3. Retrofocusing by time reversal. The time-reversal operator $\mathcal{T}$ is defined as

$$(\mathcal{T}p)(\boldsymbol{x},t) = p(\boldsymbol{x},-t). \tag{3.1}$$

If $\{p,\boldsymbol{v}\}$ solves the acoustic wave equation (2.2), then so does $\{\mathcal{T}p, -\mathcal{T}\boldsymbol{v}\}$.

3.1. Energies. In this section, we define the energy corresponding to the acoustic wave field, and reformulate the least-squares functional $\mathcal{J}$ on the interior of the domain into a functional on the boundary.

The energy at time t of the observation state $\{q(\boldsymbol{x},t), \boldsymbol{u}(\boldsymbol{x},t)\}$ is defined by

$$E[q,\boldsymbol{u}](t) = \frac{1}{2}\int_\Omega (\kappa(\boldsymbol{x})|q(\boldsymbol{x},t)|^2 + \rho(\boldsymbol{x})|\boldsymbol{u}(\boldsymbol{x},t)|^2)\,\mathrm{dV}(\boldsymbol{x}). \tag{3.2}$$

Energy conservation is given as

$$E[q,\boldsymbol{u}](0) - E[q,\boldsymbol{u}](-T) = \int_{-T}^0 \int_{\partial\Omega} q(\boldsymbol{x},t)u_{\mathrm{n}}(\boldsymbol{x},t)\mathrm{dS}(\boldsymbol{x})\,\mathrm{d}t, \tag{3.3}$$

by the Gauss theorem with the direction of a normal unit vector as in Figure 2.1(a).

To rewrite $\mathcal{J}$ in a form more suitable for our analysis, consider the summation of the equations for p, $\boldsymbol{v}$ and $\mathcal{T}q$, $\mathcal{T}\boldsymbol{u}$:

$$\begin{cases} \kappa(\boldsymbol{x})\partial_t(p-\mathcal{T}q) + \nabla\cdot(\boldsymbol{v}+\mathcal{T}\boldsymbol{u}) = 0 \\ \rho(\boldsymbol{x})\partial_t(\boldsymbol{v}+\mathcal{T}\boldsymbol{u}) + \nabla(p-\mathcal{T}q) = \boldsymbol{0} \end{cases} \quad \text{for } \boldsymbol{x}\in\Omega \text{ and } t\in[0,T]. \tag{3.4}$$

Multiplication of the equations with $p-\mathcal{T}q$ and $v+\mathcal{T}u$, respectively, and integration over time and space together with the Gauss theorem gives

$$\begin{aligned} &\int_\Omega \kappa(\boldsymbol{x})|p(\boldsymbol{x},t)-(\mathcal{T}q)(\boldsymbol{x},t)|^2 + \rho(\boldsymbol{x})|\boldsymbol{v}(\boldsymbol{x},t)+(\mathcal{T}\boldsymbol{u})(\boldsymbol{x},t)|^2\,\mathrm{dV}(\boldsymbol{x})\big|_{t=0}^T \\ &\quad = \int_0^T\int_{\partial\Omega} (p(\boldsymbol{x},t)-(\mathcal{T}q)(\boldsymbol{x},t))(v_{\mathrm{n}}(\boldsymbol{x},t)+(\mathcal{T}u_{\mathrm{n}})(\boldsymbol{x},t))\mathrm{dS}(\boldsymbol{x})\,\mathrm{d}t. \end{aligned} \tag{3.5}$$

Let $E_0 = E[q,\boldsymbol{u}](0)$, and recall that at $t=0$, $p=0$ and $\boldsymbol{v}=0$. Now, using the initial condition for q, $\boldsymbol{u}$ from (2.8), the left-hand side at $t=T$ is $\mathcal{J}$, and at $t=0$ is $-E_0$. Thus

$$\mathcal{J} = E_0 + \int_0^T\int_{\partial\Omega} (p(\boldsymbol{x},t)-(\mathcal{T}q)(\boldsymbol{x},t))(v_{\mathrm{n}}(\boldsymbol{x},t)+(\mathcal{T}u_{\mathrm{n}})(\boldsymbol{x},t))\mathrm{dS}(\boldsymbol{x})\,\mathrm{d}t. \tag{3.6}$$

3.2. Controllability. In this section, we show that the uncontrollable subspace of the wave-field solutions is orthogonal to the controllable subspace of wave-field solutions. We introduce the concept of "equal fields on the boundary."

In general, it is not possible to retrofocus the wave field to the desired wave field $\{p_T, \boldsymbol{v}_T\}$. At best the wave field retrofocuses to its controllable part, i.e., to the part of $\{p_T, \boldsymbol{v}_T\}$ that is possible to reach from the boundary. This projection to the

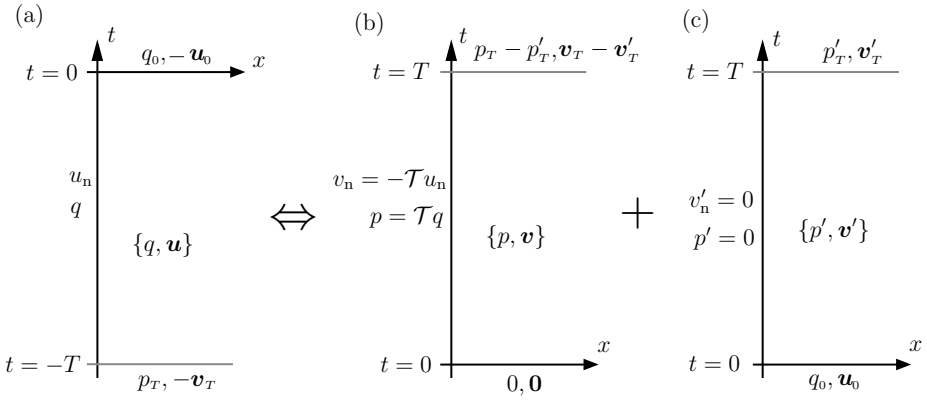

FIG. 3.1. *Controllable and uncontrollable subspaces for the equal fields on the boundary. Boundary fields such that* $p = \mathcal{T} q$ *and* $v_n = -\mathcal{T} u_n$ *decompose the original state into its controllable and uncontrollable parts.* (a) *In the observation state, the wave field is decomposed into the observed boundary field* $\{q, u_n\}$ *and the nonobserved remaining field* $\{q_0, -\boldsymbol{v}_0\}$. (b) *In the control state, the boundary field* (2.6) *is time-reversed and retransmitted into the region.* (c) *The error term corresponds to the nonobservable and noncontrollable part of the wave field.*

controllable part is achieved when the boundary fields are identical in the control and observation state, viz.,

$$p = \mathcal{T} q \quad \text{and} \quad v_n = -\mathcal{T} u_n \quad \text{when } \boldsymbol{x} \in \Gamma_t \text{ and } t \in [0, T]. \tag{3.7}$$

This goal of retrofocusing cannot always be achieved. For an example of imperfect retrofocus, see section 6. We denote the condition (3.7) as the "equal fields on the boundary" condition. If the "equal fields on the boundary" condition is achieved, it gives a constructive description of the controllable, uncontrollable, observable, and unobservable parts of the wave field. Observe that it is not possible to enforce (3.7) for the acoustic wave equation together with arbitrary initial data. In general, one set of boundary condition (2.4), (2.5), uniquely determines both the pressure and the particle velocity in the region. In this section, we examine what the "equal fields at the boundary" condition implies. In section 3.3 it is shown that the time reversal approach can be used to achieve the "equal fields on the boundary" condition from well posed initial boundary value problems if the admittance operator commutes with the time-reversal operator and the uncontrollable part of the boundary is acoustically hard or soft.

The observation (measurement) of the response of a boundary control p_+ and an initial state $\{p_0(\boldsymbol{x}), \boldsymbol{v}_0(\boldsymbol{x})\}$ is expressed as

$$p_- = \mathcal{R} p_+ + \mathcal{O}_{\Gamma_t}(p_0, \boldsymbol{v}_0) \quad \text{for } \boldsymbol{x} \in \Gamma_t \text{ and } t \in [0, T], \tag{3.8}$$

where $\mathcal{O}_{\Gamma_t}$ is a linear map from $L^2(\Omega)$ to $L^2(\Gamma_t \times [0, T])$. The unobservable initial states, N_Ω, are defined as

$$N_\Omega = \{\{p_0, \boldsymbol{v}_0\} \in L^2(\Omega) : \mathcal{O}_{\Gamma_t}(p_0, \boldsymbol{v}_0) = 0 \in L^2(\Gamma_t \times [0, T])\}, \tag{3.9}$$

i.e., they form the null space of $\mathcal{O}_{\Gamma_t}$ and thus a closed linear subspace of L^2_Ω. We define the observable initial states as the orthogonal complement to N_Ω, and $N^\perp_\Omega$ is a closed linear subspace of L^2_Ω; hence $L^2_\Omega = N_\Omega \oplus N^\perp_\Omega$. Solving the control problem (2.2)–(2.4)

for some p_+, and its corresponding observation problem (2.2), (2.8), (2.10), and (2.11) for some q_+, gives the corresponding field $\{p, v_\mathrm{n}\}$ and $\{q, u_\mathrm{n}\}$ at the controllable part of the boundary Γ_t. If this field for some given p_+, q_+ satisfies (3.7), then from the superposition principle (see Figure 3.1) we note that the controllable and uncontrollable parts of the wave field coincide with the observable and unobservable parts. In the next section, we derive a sufficient condition on the transducer admittance $\mathcal{Y}$ so that the "equal fields on the boundary" condition is achievable.

Now, since L^2_Ω is a Hilbert space with the κ, ρ-weighted standard inner product, the least-squares functional (2.1) is minimized by projecting the desired state on the controllable subspace, $\mathrm{N}^\perp_\Omega$. This follows from the orthogonal projection theorem in Hilbert spaces; see, e.g., [25]. The final state $\{p_T - p'_T, \boldsymbol{v}_T - \boldsymbol{v}'_T\}$ is the controllable part of the original state $\{p_T, \boldsymbol{v}_T\}$. The error $\{p'_T, \boldsymbol{v}'_T\}$ is the uncontrollable (and unobserved) part of the original state. In other words with p_T, $\boldsymbol{v}_T$ and p'_T, $\boldsymbol{v}'_T$ defined as above, then

$$\int_\Omega (\kappa(\boldsymbol{x})(p_T(\boldsymbol{x}) - p'_T(\boldsymbol{x}))p'_T(\boldsymbol{x}) + \rho(\boldsymbol{x})(\boldsymbol{v}_T(\boldsymbol{x}) - \boldsymbol{v}'_T(\boldsymbol{x})) \cdot \boldsymbol{v}'_T(\boldsymbol{x}))\,\mathrm{dV}(\boldsymbol{x}) = 0. \tag{3.10}$$

To derive this, we use energy estimates of the three problems depicted in Figure 3.1. For an acoustically hard or soft uncontrollable part of the boundary, the energy balance of Figure 3.1(a) takes the form

$$E[p_T, \boldsymbol{v}_T] + \int_{-T}^{0} \int_{\Gamma_\mathrm{t}} q u_\mathrm{n} \mathrm{dS}\,\mathrm{d}t = E[q_0, \boldsymbol{u}_0], \tag{3.11}$$

while for Figure 3.1(b)

$$\int_0^T \int_{\Gamma_\mathrm{t}} p v_\mathrm{n} \mathrm{dS}\,\mathrm{d}t = E[p_T - p'_T, \boldsymbol{v}_T - \boldsymbol{v}'_T], \tag{3.12}$$

and for Figure 3.1(c), $E[q_0, \boldsymbol{u}_0] = E[p'_T, \boldsymbol{v}'_T]$. The "equal field on the boundary" condition gives $p v_\mathrm{n} = -\mathcal{T} q \mathcal{T} u_\mathrm{n}$. Combining the three energy balance equations gives the identity

$$E[p_T, \boldsymbol{v}_T] = E[p'_T, \boldsymbol{v}'_T] + E[p_T - p'_T, \boldsymbol{v}_T - \boldsymbol{v}'_T]. \tag{3.13}$$

Expansion of the right-hand side gives

$$\begin{aligned} &E[p'_T, \boldsymbol{v}'_T] + E[p_T - p'_T, \boldsymbol{v}_T - \boldsymbol{v}'_T] \\ &= E[p_T, \boldsymbol{v}_T] + 2\int_\Omega (\kappa(\boldsymbol{x})(p_T(\boldsymbol{x}) - p'_T(\boldsymbol{x}))p'_T(\boldsymbol{x}) + \rho(\boldsymbol{x})(\boldsymbol{v}_T(\boldsymbol{x}) - \boldsymbol{v}'_T(\boldsymbol{x})) \cdot \boldsymbol{v}'_T(\boldsymbol{x}))\,\mathrm{dV}(\boldsymbol{x}). \end{aligned} \tag{3.14}$$

Substitution of (3.14) into (3.13) and canceling $E[p_T, \boldsymbol{v}_T]$ gives the orthogonality condition (3.10).

Thus, if it is possible to generate "equal fields on the boundary," we are able to reconstruct the controllable part of the final state $\{p_T - p'_T, \boldsymbol{v}_T - \boldsymbol{v}'_T\}$.

3.3. Iterated time-reversal retrofocusing. In this section, a well-posed iterative algorithm is introduced to solve the condition (3.7) of "equal fields on the boundary" for a class of transducer admittances.

Using a standard energy argument in Figure 3.1(b), with either $p = \mathcal{T} q$ or $v_3 = -\mathcal{T} u_3$ for $x \in \Gamma_\mathrm{t}$ and either acoustically soft, $p = 0$, or acoustically hard, $v_3 = 0$, for $x \in \Gamma_\mathrm{w}$, the interior field is uniquely determined.

The "equal boundary fields condition" (3.7) can be rewritten in the observed quantities $\{p_-, q_-\}$ and the boundary controls $\{p_+, q_+\}$ using (2.4), (2.6), (2.9), and (2.10). We find

$$\begin{cases} \mathcal{Y}^{-1}p_+ + \mathcal{Y}^{-1}p_- = \mathcal{T}\mathcal{Y}^{-1}q_+ + \mathcal{T}\mathcal{Y}^{-1}q_-, \\ p_+ - p_- = -\mathcal{T}q_+ + \mathcal{T}q_-, \end{cases} \qquad \boldsymbol{x} \in \Gamma_{\mathrm{t}},\ t \in [0,T]. \tag{3.15}$$

In terms of the response operator (2.12) we note that, for a given boundary control q_+ and given initial observation $q_-^{(0)}$, we have $q_- = \mathcal{R}q_+ + q_-^{(0)}$.

If (3.15) admits a solution, elimination of q_- and p_- in (3.15) gives that p_+ and q_+ satisfy the system of equations

$$\begin{cases} p_+ = \frac{1}{2}(\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} + \mathcal{T})\mathcal{R}q_+ + \frac{1}{2}(\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} - \mathcal{T})q_+ + \frac{1}{2}(\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} + \mathcal{T})q_-^{(0)}, \\ q_+ = \frac{1}{2}(\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} + \mathcal{T})\mathcal{R}p_+ + \frac{1}{2}(\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} - \mathcal{T})p_+, \end{cases} \tag{3.16}$$

for $\boldsymbol{x} \in \Gamma_{\mathrm{t}}$ and $t \in [0,T]$. If the admittance commutes with the time reversal, i.e.,

$$\mathcal{Y}\mathcal{T} = \mathcal{T}\mathcal{Y}, \tag{3.17}$$

then the requirement (3.16) simplifies to the linear system

$$\begin{cases} p_+ = \mathcal{T}\mathcal{R}q_+ + \mathcal{T}q_-^{(0)}, \\ q_+ = \mathcal{T}\mathcal{R}p_+, \end{cases} \quad \text{or} \quad \begin{pmatrix} 1 & -\mathcal{T}\mathcal{R} \\ -\mathcal{T}\mathcal{R} & 1 \end{pmatrix} \begin{pmatrix} p_+ \\ q_+ \end{pmatrix} = \begin{pmatrix} \mathcal{T}q_-^{(0)} \\ 0 \end{pmatrix}. \tag{3.18}$$

This system can be solved in a variety of ways if the response operator $\mathcal{R}$ is known. In the case where only the action of $\mathcal{R}$ on an incident field is known, as in our case, the system is preferably solved by iterative methods. If $\mathcal{R}$ is sufficiently small, i.e., the spectral radius of $\mathcal{R}$ in L^2 is smaller than 1, an iterative scheme of the Jacobi type [29] converges. This gives the iterated time-reversal algorithm

$$\begin{cases} p_+^{(n)} = \mathcal{T}\mathcal{R}q_+^{(n-1)} = \mathcal{T}q_-^{(n-1)} \\ q_+^{(n)} = \mathcal{T}\mathcal{R}p_+^{(n)} = \mathcal{T}p_-^{(n)} \end{cases} \qquad \text{for } n = 1, 2, \ldots, \tag{3.19}$$

where $q_-^{(0)}$ is the initial measurement; see Figure 3.2 and section 2.2. If $\|\mathcal{R}q_+^{(n)}\|_{\mathrm{L}^2} = \|q_+^{(n)}\|_{\mathrm{L}^2}$ for any n, say n^*, then the algorithm has converged and can be terminated. In this case the input field does not give any contribution to the final field and would just repeat itself. The boundary control and the final state are given by

$$p_+ = \sum_{n=1}^{N} p_+^{(n)} = \sum_{n=1}^{N} (\mathcal{T}\mathcal{R})^{2n}\mathcal{T}q_-^{(0)} \quad \text{and} \quad \{p_T, \boldsymbol{v}_T\} = \sum_{n=1}^{N} \{p_T^{(n)}, \boldsymbol{v}_T^{(n)}\}, \tag{3.20}$$

respectively. Here $N = \min(n^*, \infty)$. The iterated time-reversal algorithm (3.19) is initiated by recording the output field, $q_-^{(0)}$, generated by the original state $\{p_T, -\boldsymbol{v}_T\}$. This recorded output field is time-reversed and re-emitted into the domain. Recording and time reversal of the corresponding output field iterates the algorithm.

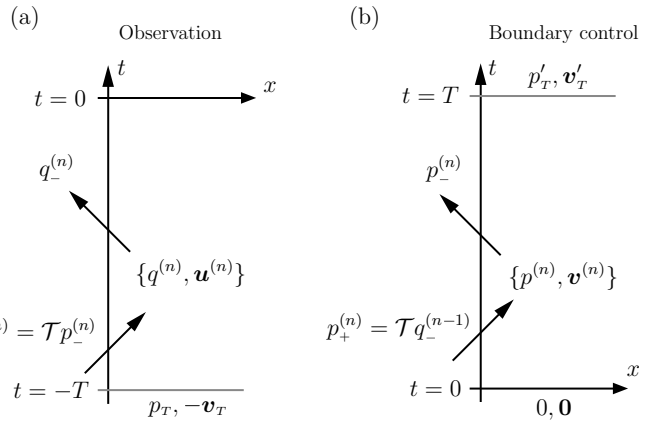

FIG. 3.2. *The iterated time-reversal algorithm.* (b) *an observation* $q_-^{(n-1)}$ *is time-reversed and used as a boundary control, to produce the output fields and the final state* $\{p_T^{(n)}, \boldsymbol{v}_T^{(n)}\}$ *and the output* $p_-^{(n)}$. (a) *the output,* $p_-^{(n)}$, *is recorded, time-reversed, and used as boundary control for the observation states, to produce the observation* $q_-^{(n)}$, *that, once again, is used to improve the final state.*

4. Example: Time-reversal retrofocusing. In this section, the theory of section 3 is applied to the problem of retrofocusing a wave field towards its initial state when both the initial state and the material parameters of the object are unknown. This problem has been thoroughly analyzed by Fink and coworkers; see, e.g., [10, 11, 12, 13]. In the time-reversal retrofocusing it is assumed that an initial state $\{q_T, \boldsymbol{u}_T\}$ exists in the object at time $t = -T$. This initial wave field is generated either by sources inside the object or by a field on the surface of the object. Since the material parameters and the original field distribution, in general, are unknown, the distribution of the retrofocused field is not known. However, it is known that the field retrofocuses towards its original field distribution.

The output $q_-^{(0)}$ is recorded at the boundary Γ_t for times $-T < t < 0$; see Figure 4.1(a). This initial observed field is time-reversed and re-emitted into the

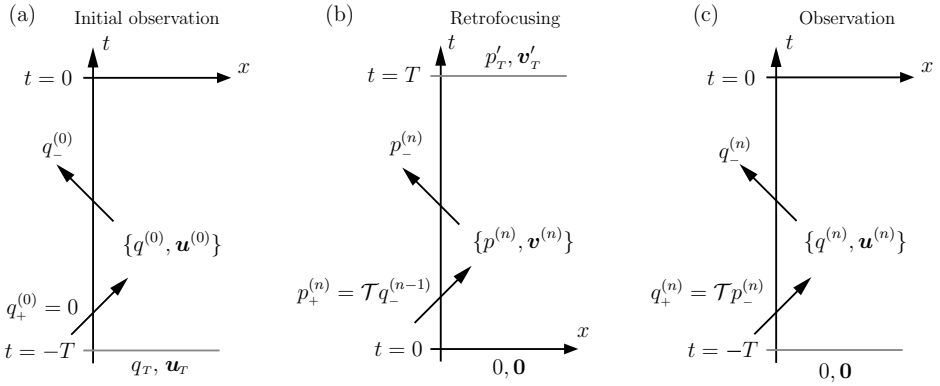

FIG. 4.1. *Iterated time-reversal retrofocusing.* (a) *The output field is recorded from the original field as the initial observation or the initial step of the algorithm* $n = 0$. (b) *in the retrofocusing, the recorded output* $q_-^{(n-1)}$ *is time-reversed and re-emitted into the domain to produce the final state* $\{p_T^{(n)}, -\boldsymbol{v}_T^{(n)}\}$ *and the output* $p_-^{(n)}$. (c) *in the observation, the output* $p_-^{(n)}$ *is time-reversed and re-emitted into the domain to give the output* $q_-^{(n)}$.

domain; see Figure 4.1(b). The retrofocusing is carried out with the iterative time-reversal algorithm (3.19). From section 3, it is concluded that the final state $\{p'_T, -\boldsymbol{v}'_T\}$ coincides with the controllable part of the initial state, $\{q_T, \boldsymbol{u}_T\}$. Observe that the retrofocusing does not require knowledge of the initial state nor of the material parameters. Moreover, if the initial state and the material parameters are unknown, the distribution of the retrofocused wave field is also unknown.

5. Example: Time-reversal cavity.

5.1. Acoustically hard boundary with ducts. In this section, the acoustically hard boundary cavity is considered, with transducers and receivers in the form of narrow ducts. The particular form of the transducers and receivers corresponds to a simple admittance operator. We present a numerical simulation in three dimensions of the retrofocusing and the resulting fields.

The cavity is a bounded region with a perforated acoustically hard boundary. The perforations are located in the end of a set of ducts. The wave field is induced through the perforations Γ_{t}; see Figure 5.1. If the ducts are sufficiently narrow and long, it is only the fundamental mode that propagates, i.e., a locally plane wave, propagating in the $\boldsymbol{n}$-direction; see [24, 26]. In this case the admittance operator reduces to a scalar constant,

$$\mathcal{Y} = \mathcal{Y}_0 = \sqrt{\kappa_0/\rho_0}. \tag{5.1}$$

The sufficient condition (3.17) of commutation between the admittance operator and the time-reversal operator is trivially satisfied. Moreover, the energy balance (3.3) gives $\|\mathcal{R}q_+^{(n)}\|_{\mathrm{L}^2} \leq \|q_+^{(n)}\|_{\mathrm{L}^2}$ for all n, and hence the algorithm (3.19) converges. (Here, the norm, $\|\cdot\|_{\mathrm{L}^2}$, is the L^2-norm over space and time.) The uncontrollable part of the boundary is acoustically hard, i.e., $\mathcal{U} = 0$. For this case the iterated time-reversal focusing algorithm (3.19) reduces to $p_+^{(n)} = \mathcal{T}q_-^{(n-1)}$ and $q_+^{(n)} = \mathcal{T}p_-^{(n)}$.

5.2. Numerical results. To illustrate the iterated time-reversal algorithm, a numerical example is presented. A cubic cavity with side length $L = 1$ and four horns

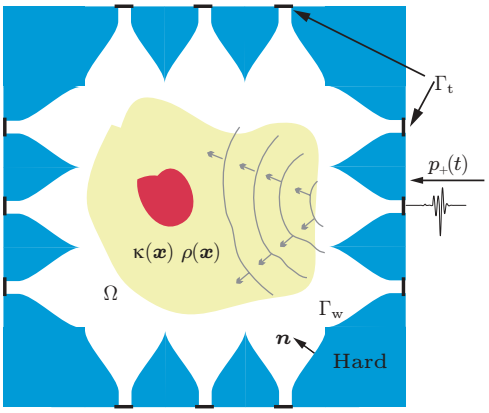

FIG. 5.1. *The cavity geometry. The boundary of the cavity is divided into the transducer surface, Γ_{t}, at the wave guide openings, and the acoustically hard wall, Γ_{w}. The transducers induce the boundary control, $p_+(\boldsymbol{x}, t)$, as a locally plane wave propagating in the $\boldsymbol{n}$-direction, where $\boldsymbol{n}$ is the inward unit normal.*

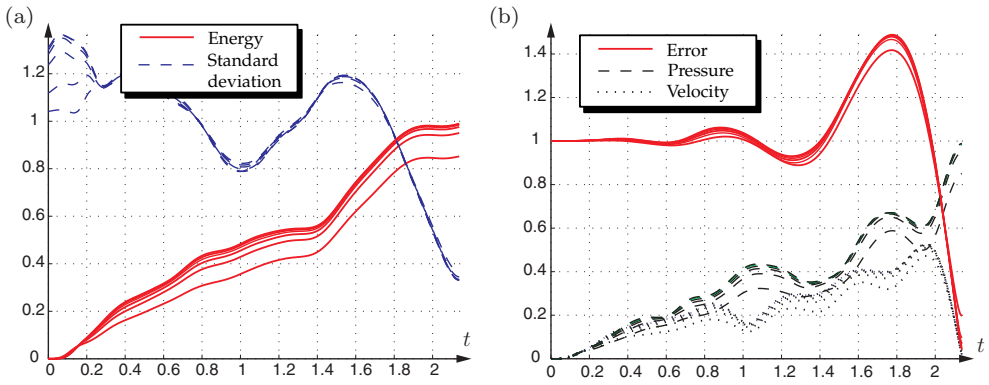

FIG. 5.2. *Example of a focused pressure in the cavity. Each improvement of the respective family of lines above is obtained by including one more term in the sum* (3.20). *The vertical axes show nondimensional values where the energies, the standard deviation, and the error are normalized with respect to the original energy, a uniform field distribution, and the error of quiescent fields, respectively.* (a) *The field energy is concentrated at* $T = 2.2\,\mathrm{s}$. *The standard deviation of the energy around its center point is minimized at the focusing time* T. (b) *The error term is* $\sqrt{\mathcal{J}}$, *where* $\mathcal{J}$ *is the least-square functional. The pressure part of the energy dominates the velocity part at the focusing time* T.

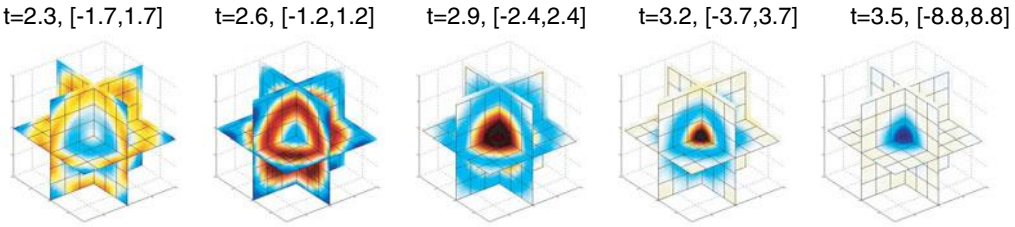

FIG. 5.3. *Example of a retrofocused pressure in the cavity; the range is given in brackets. The focusing time is* $T = 3.5$. *Note that the pressure amplitude range at* $t = 3.2$ *is considerably smaller than at* $t = 3.5$, (3.7 *versus* 8.8)*; hence the concentration of the field is highest at* $t = 3.5$. *Also note the extended region with "gray" at* $t = 3.2$.

attached to each side is considered. The acoustic wave equation is solved with a standard leap-frog scheme, where the cavity, the horns, and the ducts are discretized on an equidistant grid with discretization $L/82$. The fundamental mode is induced with a Huygens surface in the ducts, and the ducts are terminated with a perfectly matched layer. The temporal step is chosen according to the CFL condition [31] to minimize the numerical dispersion.

In Figure **??**(a), the first two moments of the energy distribution are depicted. It is obvious that the field energy is concentrated around the focusing time $T = 2.2$. At these times the energy is centered around the focusing point. The concentration of the energy is measured with the variation of the energy. The variation is scaled such that an energy with uniform distribution has unit variation. From the variation curve, it is clear that the wave field is concentrated around the focusing point at the focusing time but that the wave field is not concentrated for other times. The field energy of each field component is shown in Figure **??**(b). The retrofocused field for a case with retrofocusing at $T = 3.5$ is illustrated in Figure 5.3.

6. Example: Time-reversal mirror. For the time-reversal mirror, we consider the half space $\Omega = \{\boldsymbol{x} : x_3 \geq 0\}$, with homogeneous material parameters $\kappa = \kappa_0$ and $\rho = \rho_0$. The transducers are located at the plane $\Gamma_{\mathrm{t}} = \{\boldsymbol{x} \in \mathbb{R}^3 : \ x_3 = 0\}$. Thus we assume that the transducers can prescribe a boundary condition on the entire plane; cf. (2.4).

6.1. The impedance operator. A nonreflective admittance operator [16, 17, 32, 33] is given here as an explicit integral operator, as well as its adjoint with respect to the standard L^2-inner product.

The characteristics of the transducers and receivers are modeled by the wave splitting admittance operator [18], $\mathcal{Y}$, with symbol [30, 8]

$$\boldsymbol{y}(\tilde{\boldsymbol{\xi}}, s) = s^{-1}\sqrt{s^2\kappa_0\rho_0 + \tilde{\xi}^2}, \tag{6.1}$$

where s is the Laplace transform variable corresponding to time and $\tilde{\boldsymbol{\xi}} = (\xi_1, \xi_2)$ is the transverse Fourier variable corresponding to $\tilde{\boldsymbol{x}} = (x_1, x_2)$. We use the notation $\tilde{x} = |\tilde{\boldsymbol{x}}|$ and $\tilde{\xi} = |\tilde{\boldsymbol{\xi}}|$ to denote the norms of $\tilde{\boldsymbol{x}}$ and $\tilde{\boldsymbol{\xi}}$, respectively. Let $\mathcal{L}$ denote the temporal Laplace transform and $\mathcal{F}$ denote the spatial transverse Fourier transform; the $\mathcal{Y}$ acting of the pressure can be expressed in terms of the symbol as

$$(\mathcal{Y}p)(x, v) = \mathcal{L}^{-1}\mathcal{F}^{-1}(y(\tilde{\boldsymbol{\xi}}, s)p(\tilde{\boldsymbol{\xi}}, x_3, s)), \tag{6.2}$$

where we have used $p(\tilde{\boldsymbol{\xi}}, x_3, s)$ to denote the Laplace and Fourier transforms of $p(x, t)$.

The above square root is taken with the branch-cut at the negative real axis, i.e., $\sqrt{s^2} = s$, when $\operatorname{Re} s > 0$. An energy renormalization of the field removes the constant material parameters in the acoustic wave equation (2.2) [14, p. 37] and consequently in (6.1). The inverse of the admittance, the impedance, satisfies the transform relation

$$\frac{s}{\sqrt{s^2 + \tilde{\xi}^2}} = \mathcal{F}\mathcal{L}\frac{\delta'(t - |\tilde{\boldsymbol{x}}|)}{2\pi|\tilde{\boldsymbol{x}}|} \tag{6.3}$$

for $t \geq 0$, which follows from a straightforward calculation. Thus the time-space representation of the impedance operator action is

$$(\mathcal{Y}^{-1}p_+)(\tilde{\boldsymbol{x}}, t) = \int_{\mathbb{R}^2}\int_0^t \frac{\delta'(t - t' - |\tilde{\boldsymbol{x}} - \tilde{\boldsymbol{x}}'|)}{2\pi|\tilde{\boldsymbol{x}} - \tilde{\boldsymbol{x}}'|} p_+(\tilde{\boldsymbol{x}}', t')\,\mathrm{d}t'\,\mathrm{d}x_1'\,\mathrm{d}x_2' \tag{6.4}$$

for sufficiently smooth controls, p_+. Here, $\boldsymbol{x} \in \Gamma_{\mathrm{t}}$, $t \in [0, T]$.

In section 6 and the appendices, we use Fourier and Laplace transforms. To utilize their properties, we consider the case that all fields, p, $\boldsymbol{v}$ and q, $\boldsymbol{u}$, have temporal support contained in $[0, T]$. Consequently, the time-reversal operator is redefined as

$$(\mathcal{T}p_+)(\boldsymbol{x}, t) = p_+(\boldsymbol{x}, T - t), \quad \boldsymbol{x} \in \Omega, \ t \in [0, T]. \tag{6.5}$$

For section 6 and forward we use (6.5) instead of (3.1). As the system is linear and independent of starting time, the change of definition of $\mathcal{T}$ is only a matter of shifting the solution with respect to time.

$\mathcal{T}$ does not commute with an admittance $\mathcal{Y}$ of the form (6.1). Indeed, observe that the adjoint $\mathcal{Y}^*$ of $\mathcal{Y}$ with respect to the standard L^2-inner product over time and space at the boundary is

$$((\mathcal{Y}^*)^{-1}p_+)(\tilde{\boldsymbol{x}}, t) = \int_{\mathbb{R}^2}\int_t^T \frac{\delta'(t' - t - |\tilde{\boldsymbol{x}} - \tilde{\boldsymbol{x}}'|)}{2\pi|\tilde{\boldsymbol{x}} - \tilde{\boldsymbol{x}}'|} p_+(\tilde{\boldsymbol{x}}', t')\,\mathrm{d}t'\,\mathrm{d}x_1'\,\mathrm{d}x_2'. \tag{6.6}$$

It follows that $\mathcal{Y}$ is not self-adjoint. By the variable substitution $\tau = T - t'$, we obtain

$$\begin{aligned}((\mathcal{Y}^*)^{-1}p_+)(\tilde{\boldsymbol{x}},t) &= \mathcal{T}\int_{\mathbb{R}^2}\int_0^t \frac{\delta'(t-\tau-|\tilde{\boldsymbol{x}}-\tilde{\boldsymbol{x}}'|)}{2\pi|\tilde{\boldsymbol{x}}-\tilde{\boldsymbol{x}}'|}(\mathcal{T}p_+)(\tilde{\boldsymbol{x}}',\tau)\,\mathrm{d}\tau\,\mathrm{d}x_1'\,\mathrm{d}x_2' \\ &= (\mathcal{T}\mathcal{Y}^{-1}\mathcal{T}p_+)(\tilde{\boldsymbol{x}},t).\end{aligned} \tag{6.7}$$

6.2. Nonsolvability of "equal fields on the boundary." In this section, we show that for the time-reversal mirror configuration with boundary condition (2.4) and admittance operator (6.4), the given algorithm does not have an optimal boundary control. We derive an approximate boundary control that agrees with the equation for optimal boundary control in the nonevanescent part of the measured field.

For the homogeneous half space, with transducer characteristics $\mathcal{Y}^{-1}$ as in (6.4), the boundary condition (2.4) is equivalent to a splitting of the field into an in- and an outgoing constituent at the boundary [14, 15, 16, 17]. Thus a transducer with the (6.4) characteristics is perfectly matched to the domain and does not introduce any transducer mismatch reflections. Hence, as the medium is homogeneous, the response operator vanishes; i.e., $\mathcal{R}p_+ = 0$, likewise $\mathcal{R}q_+ = 0$.

If we consider the solvability of the requirement of "equal fields on the boundary," with (6.7) the equations (3.15) reduce to

$$(\mathcal{Y}^{-1} + (\mathcal{Y}^*)^{-1})p_+ = 2(\mathcal{Y}^*)^{-1}\mathcal{T}q_-^{(0)}. \tag{6.8}$$

The operator $(\mathcal{Y}^{-1} + (\mathcal{Y}^*)^{-1})$ is not invertible everywhere on the range of $(\mathcal{Y}^*)^{-1}$. Thus the requirement of "equal fields on the boundary" is too strong a condition for this admittance. To analyze this situation we rewrite the least-squares functional, $\mathcal{J}$, with the definitions of the boundary control and its observations, as

$$\mathcal{J} = E_0 + \int_0^T \int_{\Gamma_t} (\mathcal{Y}^{-1}p_+ - \mathcal{T}\mathcal{Y}^{-1}(q_+ + q_-^{(0)}))(p_+ + \mathcal{T}(q_+ - q_-^{(0)}))\,\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}t. \tag{6.9}$$

The least-squares functional $\mathcal{J}$ does not have any critical points for this choice of admittance. To see this, we denote the above integral over time and boundary by the inner product $\langle\cdot,\cdot\rangle_{\Gamma_t\times[0,T]}$, and we observe that the field is real-valued and that the operator $\mathcal{Y}^{-1}$ maps real-valued functions into real-valued functions. Upon determining the variation with respect to p_+, we find the requirement for critical points to be

$$\begin{aligned}\langle \mathcal{D}\mathcal{J}, \delta p_+\rangle_{\Gamma_t\times[0,T]} &= 2\,\mathrm{Re}\langle(\mathcal{Y}^{-1} + (\mathcal{Y}^*)^{-1})p_+ - (\mathcal{T}\mathcal{Y}^{-1} + (\mathcal{Y}^*)^{-1}\mathcal{T})q_-^{(0)} \\ &\quad + ((\mathcal{Y}^*)^{-1}\mathcal{T} - \mathcal{T}\mathcal{Y}^{-1})q_+, \delta p_+\rangle_{\Gamma_t\times[0,T]} = 0\end{aligned} \tag{6.10}$$

for all $\delta p_+ \in \mathrm{L}^2$. Using property (6.7), we find that (6.10) simplifies to

$$\langle(\mathcal{Y}^{-1} + (\mathcal{Y}^*)^{-1})p_+, \delta p_+\rangle_{\Gamma_t\times[0,T]} = \langle 2(\mathcal{Y}^*)^{-1}\mathcal{T}q_-^{(0)}, \delta p_+\rangle_{\Gamma_t\times[0,T]} \tag{6.11}$$

for all $\delta p_+ \in \mathrm{L}^2$. This equation is equivalent to (6.8), and to confirm its nonsolvability for general $q_-^{(0)}$, we apply Parseval's formula to (6.11) and obtain

$$\mathrm{H}(\omega^2 - \tilde{\xi}^2)\frac{|\omega|}{\sqrt{\omega^2-\tilde{\xi}^2}}p_+(\tilde{\boldsymbol{\xi}},\omega) = \lim_{\eta\to 0^+}\frac{(\eta - \mathrm{i}\omega)}{\sqrt{(\eta-\mathrm{i}\omega)^2+\tilde{\xi}^2}}\mathrm{e}^{-\mathrm{i}\omega T}q_-^{(0)}(\tilde{\xi},-\omega), \tag{6.12}$$

where $\mathrm{H}(\cdot)$ is the Heaviside (step) function. It is obvious that (6.12) does not have a solution for all $q_-^{(0)}$, in particular for $|\omega| < \tilde{\xi}$, since the left-hand side is zero while the right-hand side can be nonzero, depending on $q_-^{(0)}$. In the Fourier domain for the corresponding Green's function the frequency region $|\omega| < \tilde{\xi}$ is the nonpropagating part of the field; hence we denote the part where $q_-^{(0)} \neq 0$ for $|\omega| < \tilde{\xi}$ as *the evanescent part* of $q_-^{(0)}$ (cf., e.g., [26]). Thus the "equal fields on the boundary condition" is not applicable in the time-reversal mirror, and thus the algorithm does not yield an optimum for this case.

We conclude that for general $q_-^{(0)} \in \mathrm{L}^2$ the least-squares functional, $\mathcal{J}$, does not have a critical point in terms of the field at the boundary. However, if $q_-^{(0)}$ does not have an evanescent part, then $\mathcal{J}$ has a critical point and the corresponding optimal control is

$$p_+ = \mathcal{T} q_-^{(0)}\big|_{|\omega| \geq \tilde{\xi}}. \tag{6.13}$$

6.3. Approximate boundary controls. As shown in section 6.2 it is only possible to satisfy the equal fields on the boundary condition for the propagating part of the wave field. Hence, it is not clear how to choose the control in the nonpropagating or evanescent part of the wave field. Here, we consider three different controls, labeled $p_+^{(1)}$, $p_+^{(2)}$, and $p_+^{(3)}$, that satisfy (6.11) in the propagating regime.

Case one. $p_+^{(1)}$ is the particle-velocity normalized control; i.e., observation of the initial state $q_-^{(0)}$ is measured in particle-velocity normalization, time-reversed, and retransmitted, viz.,

$$p_+^{(1)} = \mathcal{T} q_-^{(0)}. \tag{6.14}$$

Case two. To construct $p_+^{(2)}$, we begin with a consideration of the control problem in pressure normalization. The boundary condition and the measurement take the form

$$\frac{p + \mathcal{Y}^{-1} v_3}{2} = p_{+,\mathrm{N_p}}^{(2)} \quad \text{and} \quad m_{(2)} = \frac{p - \mathcal{Y}^{-1} v_3}{2}. \tag{6.15}$$

Now consider a measurement of the initial pressure pulse in this normalization $m_{(2)}$, time-reversed and retransmitted, viz., $p_{+,\mathrm{N_p}}^{(2)} = \mathcal{T} m_{(2)}$. The result from this control is the second case. To express this for particle-velocity normalization we utilize the linearity of the problem to obtain that the control $p_+^{(2)}$ in the form

$$p_+^{(2)} = \mathcal{Y} \mathcal{T} \mathcal{Y}^{-1} q_-^{(0)} \tag{6.16}$$

yields the same internal field as $p_{+,\mathrm{N_p}}^{(2)}$, but with the particle-velocity boundary conditions.[1] Note that (6.7) gives the relations $\mathcal{Y}\mathcal{T}\mathcal{Y}^{-1} = \mathcal{T}\mathcal{Y}^{*}\mathcal{Y}^{-1} = \mathcal{Y}(\mathcal{Y}^{-1})^{*}\mathcal{T}$.

Case three. The control $p_+^{(3)}$ is the linear combination of the first two cases, i.e.,

$$p_+^{(3)} = p_+^{(1)} + p_+^{(2)} = (1 + \mathcal{Y}(\mathcal{Y}^{-1})^{*})\mathcal{T} q_-^{(0)}. \tag{6.17}$$

Note from (6.12) that $p_+^{(3)}$ cuts out the nonpropagating part for the $q_-^{(0)}$. The results of Case three are discussed in section 6.7.

[1] The fields inside the domain from the controls $p_+^{(2)}$ and $p_{+,\mathrm{N_p}}^{(2)}$ with the respective normalized boundary conditions are the same. This is utilized to explicitly calculate the response of $p_+^{(2)}$; see Appendix C.

6.4. Control operators. In this section, we derive the control operators for the respective normalizations of p_+, for boundary data with temporal duration T, i.e., an operator that takes the boundary control to the respective final states at $t = T$.

The control operator in particle velocity-normalization is defined as

$$\{p^{(1)}(\cdot, T),\ \boldsymbol{v}^{(1)}(\cdot, T)\} = \mathcal{W}_{\mathrm{v}} p_+^{(1)}. \tag{6.18}$$

To derive the explicit form of $\mathcal{W}_{\mathrm{v}}$, we solve the acoustic wave equation, (2.2), and (2.3), together with the transducer boundary condition (2.4) and quiescent initial conditions. We obtain (see Appendix A.1)

$$p^{(1)}(\boldsymbol{x}, T) = \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} \partial_{t'}(\mathrm{H}(t') p_+^{(1)}(\tilde{\boldsymbol{x}}', t'))\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t' \tag{6.19}$$

and

$$\boldsymbol{v}^{(1)}(\boldsymbol{x}, T) = -\nabla \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} p_+^{(1)}(\tilde{\boldsymbol{x}}', t')\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t'. \tag{6.20}$$

The control operator in the pressure normalization, $\mathcal{W}_{\mathrm{p}}$, is obtained by solving the acoustic wave equation with transducer boundary condition (6.15) and quiescent initial conditions. We obtain (see Appendix C)

$$p^{(2)}(\boldsymbol{x}, T) = -\partial_3 \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} p_{+,\mathrm{N_p}}^{(2)}(\tilde{\boldsymbol{x}}', t')\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t' \tag{6.21}$$

and

$$\boldsymbol{v}^{(2)}(\boldsymbol{x}, T) = \nabla \partial_3 \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} \int_0^{t'} p_{+,\mathrm{N_p}}^{(2)}(\tilde{\boldsymbol{x}}', t'')\, \mathrm{d}t''\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t'. \tag{6.22}$$

Thus we have an explicit expression for the control operator in both normalizations, expressed in terms of a common Green's function. Note that the form of the control operators has the typical retarded time dependence that is associated with hyperbolic systems.

6.5. The solution operator. In this section, we use the solution operator with initial conditions corresponding to a pressure pulse to derive the field at the boundary. We also construct the boundary controls for the two cases (6.14) and (6.16).

To construct the boundary controls, $p_+^{(1)}$, $p_{+,\mathrm{N_p}}^{(2)}$, corresponding to an initial pressure pulse, the time-reversed output field component is needed as data. It is obtained by solving the acoustic equations (2.2) with the initial value $\{p_T, -\boldsymbol{v}_T\}$ at $t = 0$. The solution is (see [21])

$$\begin{pmatrix} q(\boldsymbol{x}, t) \\ \boldsymbol{u}(\boldsymbol{x}, t) \end{pmatrix} = \begin{pmatrix} \partial_t & -\nabla\cdot \\ -\nabla & I\partial_t \end{pmatrix} \int_{\mathbb{R}^3} \frac{\delta(t - |\boldsymbol{x} - \boldsymbol{x}'|)}{4\pi|\boldsymbol{x} - \boldsymbol{x}'|} \begin{pmatrix} p_T(\boldsymbol{x}') \\ -\boldsymbol{v}_T(\boldsymbol{x}') \end{pmatrix} \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}x_3', \tag{6.23}$$

for an irrotational initial velocity, i.e., $\nabla \times \boldsymbol{v}_T = 0$. Now, to generate the output field component at the boundary $\Gamma_{\mathrm{t}} = \{\boldsymbol{x} \in \mathbb{R}^3 : x_3 = 0\}$, we assume that $\operatorname{supp} p_T$ and $\operatorname{supp} \boldsymbol{v}_T$ are bounded and contained in the half space $x_3 > 0$. Furthermore, we impose a transparent boundary condition at Γ_{t}, i.e., no reflection at the boundary $x_3 = 0$.

For the measurement of the outgoing wave (2.9) this is equivalent to measurement with perfectly matched receivers of the solution to (2.2) at the boundary.

To obtain an explicit representation of the field, we let the initial field be a pulse in the pressure, with source point $\tilde{\boldsymbol{x}} = 0$, $x_3 = z_0 > 0$, that is,

$$p_T(\boldsymbol{x}) = \delta(\tilde{\boldsymbol{x}})\,\delta(x_3 - z_0) \quad \text{and} \quad \boldsymbol{v}_T = 0. \tag{6.24}$$

The choice of pulse (6.24) substituted into (6.23) makes the field $\{q, \boldsymbol{u}\}$ into the components of the pressure Green's function. At the boundary, its $\{q, u_3\}$-component becomes

$$\begin{aligned}\begin{pmatrix} q(\tilde{\boldsymbol{x}},0,t) \\ u_3(\tilde{\boldsymbol{x}},0,t)\end{pmatrix} &= \begin{pmatrix} \partial_t \\ -\partial_3\end{pmatrix} \int_{\mathbb{R}^3} \frac{\delta(t-|\boldsymbol{x}-\boldsymbol{x}'|)}{4\pi|\boldsymbol{x}-\boldsymbol{x}'|}\,\delta(\tilde{\boldsymbol{x}}')\,\delta(x_3'-z_0)\,\mathrm{d}x_1'\,\mathrm{d}x_2'\,\mathrm{d}x_3'\Big|_{x_3=0} \\ &= \begin{pmatrix} \partial_t \\ \partial_{z_0}\end{pmatrix} \frac{\delta(t-\sqrt{\tilde{x}^2+z_0^2})}{4\pi\sqrt{\tilde{x}^2+z_0^2}}.\end{aligned} \tag{6.25}$$

This field is measured by transducers yielding $q_-^{(0)}$ and $m_{(2)}$, respectively; see (2.6) and (6.15).

The transducer is perfectly matched to the domain, equivalent to a transparent boundary condition, and measures the velocity normalized out-going component of the wave; cf. [18]. As the receiver and transducer characteristics are identical, the measured response $\{q_-^{(0)}, m_{(2)}\}$ in the respective normalizations, Cases one and two, is (cf. (2.6), (6.15))

$$q_-^{(0)}(\tilde{\boldsymbol{x}},t) = \frac{1}{2}((\mathcal{Y}q)(\tilde{\boldsymbol{x}},0,t) - u_3(\tilde{\boldsymbol{x}},0,t)), \tag{6.26}$$

$$m_{(2)}(\tilde{\boldsymbol{x}},t) = \frac{1}{2}(q(\tilde{\boldsymbol{x}},0,t) - (\mathcal{Y}^{-1}u_3)(\tilde{\boldsymbol{x}},0,t)). \tag{6.27}$$

Substituting the expressions for $\{q, u_3\}$ (cf. (6.25)) into (6.26) and (6.27) gives (see Appendix A.2 and Appendix C)

$$q_-^{(0)}(\tilde{\boldsymbol{x}},t) = -\partial_{z_0}\frac{\delta(t-\sqrt{\tilde{x}^2+z_0^2})}{4\pi\sqrt{\tilde{x}^2+z_0^2}}, \tag{6.28}$$

$$m_{(2)}(\tilde{\boldsymbol{x}},t) = \partial_t\frac{\delta(t-\sqrt{\tilde{x}^2+z_0^2})}{4\pi\sqrt{\tilde{x}^2+z_0^2}}. \tag{6.29}$$

The measurements, $\{q_-^{(0)}, m_{(2)}\}$, of the field at the surface start at time $t = 0$. We notice the expected delayed arrival in the measurement, because the initial pulse is at depth $x_3 = z_0$. The "measurement" ends at $t = T$ and, in general, the field at this time is nonzero. Hence, to describe the measured field, we have to introduce a step function that removes the field after $t = T$. Now, time reversal in accordance with (6.5) of $q_-^{(0)}$ and $m_{(2)}$ are the controls that we search for,

$$p_+^{(1)}(\tilde{\boldsymbol{x}},t) = \mathrm{H}(t)q_-^{(0)}(\tilde{\boldsymbol{x}},T-t) = -\mathrm{H}(t)\partial_{z_0}\frac{\delta(T-t-\sqrt{\tilde{x}^2+z_0^2})}{4\pi\sqrt{\tilde{x}^2+z_0^2}}, \tag{6.30}$$

$$p_{+,\mathrm{N_p}}^{(2)}(\tilde{\boldsymbol{x}},t) = \mathrm{H}(t)m_{(2)}(\tilde{\boldsymbol{x}},T-t) = -\mathrm{H}(t)\partial_t\frac{\delta(T-t-\sqrt{\tilde{x}^2+z_0^2})}{4\pi\sqrt{\tilde{x}^2+z_0^2}}. \tag{6.31}$$

6.6. Retrofocused fields and their properties. Here, the explicit form of the retrofocused field in Case one is used to analyze the long time limit of the retrofocused field. In the long time limit, Case one retrofocuses the pressure perfectly, modulo a numerical factor, whereas the particle velocity shows a nonzero remainder and is hence not perfectly retrofocused. We also give the explicit form of the pressure for Case two. We also show a number of graphs describing the degree of retrofocusing versus time duration of the measured data.

For the boundary control (6.30) we can explicitly obtain the final state as distributions, denoted by $\{p^{(1)}(\cdot,T),\boldsymbol{v}^{(1)}(\cdot,T)\}$, for any finite time T. To this end, substitute the control $p_+^{(1)}$ of (6.30) into (6.19) and (6.20). Integration with respect to time gives the response,

(6.32)
$$\begin{aligned} p^{(1)}(\boldsymbol{x},T) &= -\partial_{z_0}\partial_t \int_{\mathbb{R}^2} \mathrm{H}(t-|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|)\frac{\delta(T-t+|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|-\sqrt{(\tilde{x}')^2+z_0^2})}{8\pi^2|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2+z_0^2}}\,\mathrm{d}x_1'\,\mathrm{d}x_2'\Bigg|_{t=T} \\ &= \frac{-z_0}{4\pi^2 x_3\tilde{x}^2}\partial_3 \frac{\tilde{x}^2-x_3^2+z_0^2}{([T^2-x_3^2-(\tilde{x}-\sqrt{T^2-z_0^2})^2][(\tilde{x}+\sqrt{T^2-z_0^2})^2+x_3^2-T^2])_+^{1/2}} \end{aligned}$$

and

(6.33)
$$\begin{aligned} \boldsymbol{v}^{(1)}(\boldsymbol{x},T) &= \nabla\partial_{z_0}\int_{\mathbb{R}^2} \mathrm{H}(t-|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|)\frac{\delta(T-t+|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|-\sqrt{(\tilde{x}')^2+z_0^2})}{8\pi^2|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2+z_0^2}}\,\mathrm{d}x_1'\,\mathrm{d}x_2'\Bigg|_{t=T} \\ &= \nabla\Bigg[\frac{-z_0T}{\pi^2(4\tilde{x}^2z_0^2+(\tilde{x}^2+x_3^2-z_0^2)^2)} \\ &\qquad \frac{\tilde{x}^2-x_3^2+z_0^2}{([T^2-x_3^2-(\tilde{x}-\sqrt{T^2-z_0^2})^2][(\tilde{x}+\sqrt{T^2-z_0^2})^2+x_3^2-T^2])_+^{1/2}}\Bigg]. \end{aligned}$$

For details we refer to Appendix B.

The analogous derivation for Case two follows the substitution of the boundary control $p_{+,\mathrm{N_p}}^{(2)}$ of (6.31) into (6.21) and (6.22). Upon integration (see Appendix C), we find that

(6.34)
$$\begin{aligned} p^{(2)}(\boldsymbol{x},T) &= \frac{-1}{4\pi^2\tilde{x}^2}\partial_3 \frac{\tilde{x}^2-x_3^2+z_0^2}{([T^2-x_3^2-(\tilde{x}-\sqrt{T^2-z_0^2})^2][(\tilde{x}+\sqrt{T^2-z_0^2})^2+x_3^2-T^2])_+^{1/2}} \end{aligned}$$

and

(6.35)
$$\begin{aligned} \boldsymbol{v}^{(2)}(\boldsymbol{x},T) = -\nabla\partial_3\int_{\mathbb{R}^2}\Bigg(&\mathrm{H}\left(T-\sqrt{(\tilde{x}')^2+z_0^2}\right)\frac{\delta(\sqrt{(\tilde{x}')^2+z_0^2}-|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|)}{8\pi^2|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2+z_0^2}} \\ &-\delta\left(T-\sqrt{(\tilde{x}')^2+z_0^2}\right)\frac{\mathrm{H}(\sqrt{(\tilde{x}')^2+z_0^2}-|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|)}{8\pi^2|\boldsymbol{x}-\tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2+z_0^2}}\Bigg)\mathrm{d}x_1'\,\mathrm{d}x_2'. \end{aligned}$$

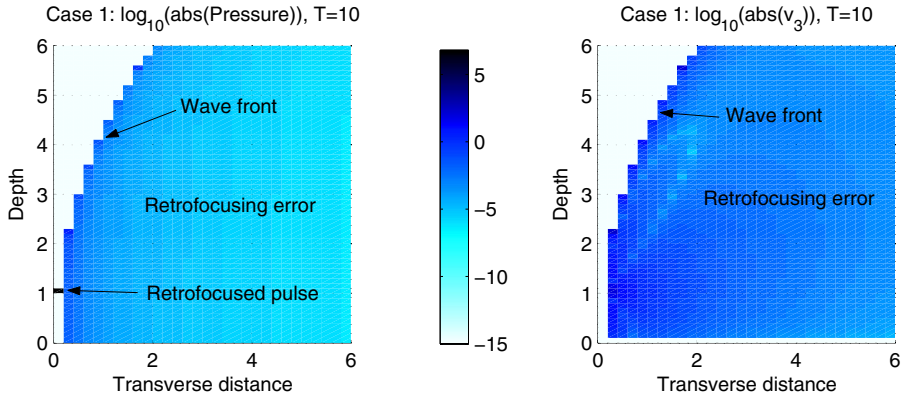

FIG. 6.1. *The retrofocused $p^{(1)}$ and $v_3^{(1)}$, for $T = 10$, with initial state a Dirac pulse at $z_0 = 1$, $\tilde{\boldsymbol{x}} = 0$, and its boundary control $p_+^{(1)}$. The pressure to high degree, concentrated to $x_3 = 0$, $z_0 = 1$, with a small retrofocus error, and the velocity have no corresponding concentration; cf.* (6.36). *The graphs show that the boundary control, $p_+^{(1)}$, is imposed at depth $x_3 = 0$ and has a support at $x_3 = 0$ and $\tilde{x} \leq \sqrt{T^2 - z_0^2}$. In the graph, notice the out-going wave front with radius $T = 10$ with center located at all $\tilde{\boldsymbol{x}}$ such that $|\tilde{\boldsymbol{x}}| = \sqrt{T^2 - z_0^2}$, here at $\{\tilde{x}, x_3\} = \{\sqrt{99}, 0\}$, due to the finite time cut-off of the measurement. Recall that the graphs are distributions; hence the graphs are smoothed around the wave front set.*

The difference in pressure between the pressure normalization and the particle-velocity normalization is the factor z_0/x_3. Furthermore, observe that v_3 is zero on the x_3-axis for $x_3 \neq z_0$. The integration of the first term in (6.35) is analogous to the normal particle-velocity normalization; cf. (B.21).

The first observation on the above final state is that $p^{(1)}$, $p^{(2)}$, and $v_3^{(1)}$ depend only on $\tilde{x}$ and not on $\tilde{\boldsymbol{x}}$; i.e., they are independent of polar angle—the angle between x_1 and x_2. The denominator $(\dots)_+^{1/2}$ describes wave fronts induced from the nonzero field at the end of a finite measurement time. These wave fronts are centered on the circle $x_3 = 0$, $\{\tilde{\boldsymbol{x}} : \tilde{x} = \sqrt{T^2 - z_0^2}\}$. The cut-off in $(\dots)_+^{1/2}$, with the polar angle symmetry, results in a field having a domain shape that resembles a donut, cut horizontally just below the middle. A cross section of the field is shown in Figure 6.1 for $T = 10$; i.e., the excitation time equals ten times the time it takes for the initial pulse to reach the surface.

With the retrofocusing of this pulse, note that for an expansion as $T \to \infty$,

$$p^{(1)} = \frac{z_0}{4\pi^2}(T^{-1}\tilde{x}^{-3} + (2T)^{-3}(\tilde{x}^{-1} + 2\tilde{x}^{-3}(x_3^2 + z_0^2) + 3\tilde{x}^{-5}(x_3^2 - z_0^2))) + \mathrm{O}(T^{-5})$$

and

$$v_3^{(1)} = \frac{x_3 z_0((x_3^2 - z_0^2)^2 - 3\tilde{x}^4 - 2\tilde{x}^2(x_3^2 + z_0^2))}{\pi^2 \tilde{x}(\tilde{x}^4 + (x_3^2 - z_0^2)^2 + 2\tilde{x}^2(x_3^2 + z_0^2))^2} + \mathrm{O}(T^{-2}), \tag{6.36}$$

together with

$$\begin{pmatrix} v_1^{(1)} \\ v_2^{(1)} \end{pmatrix} = \left(\frac{z_0(3\tilde{x}^2 + 4z_0^2)}{2\pi^2 \tilde{x}^2(\tilde{x}^2 + 4z_0^2)} \begin{pmatrix} \cos\theta \\ \sin\theta \end{pmatrix} + \mathrm{O}((x_3 - z_0)^2) \right) + \mathrm{O}(T^{-2}), \tag{6.37}$$

where θ is the polar angle. Furthermore, at the axis $\tilde{x} = 0$ the retrofocused field is supported only at $x_3 = z_0$. In Figure 6.2 we plot the pressure away from the singular

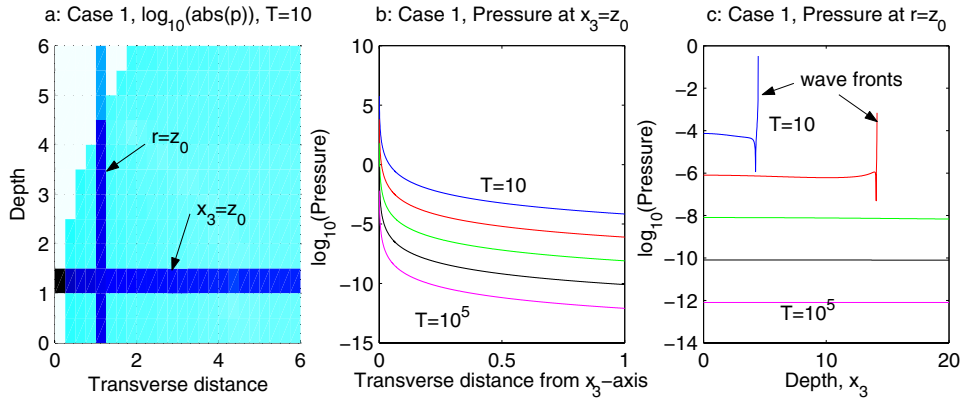

FIG. 6.2. *Plots of the pressure for different excitation times T. In graph* (b) *and* (c) *each lower line corresponds to the T values* 10, 10^2, 10^3, 10^4, 10^5. (a) *The black lines indicates where the values in graphs* (b) *and* (c) *are taken.* (b) *At $x_3 = z_0$ we see the damping to the Dirac pulse, for the area around the singular point.* (c) *At $r := |\tilde{\boldsymbol{x}}| = z_0$ we see that the fields damp as T increases; the endings of the two top lines result from reaching the wave front; cf. Figure* 6.2(a).

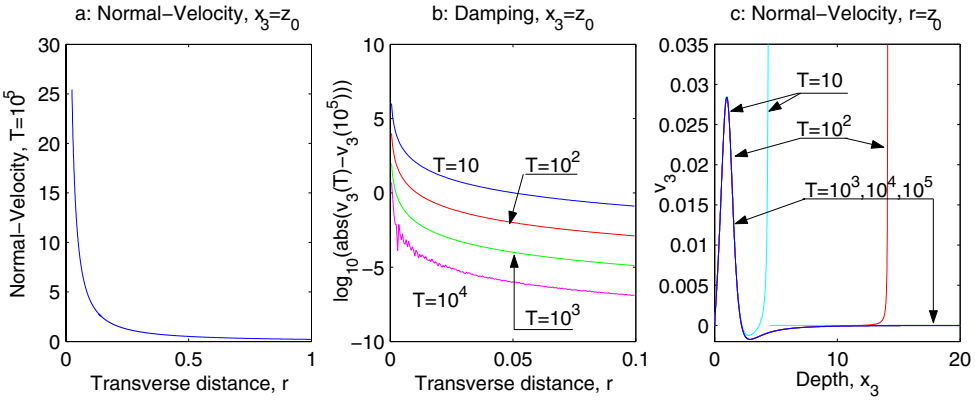

FIG. 6.3. *Plots of $v_3^{(1)}$ for a source at depth $z_0 = 1$ and its boundary control $p_+^{(1)}$.* (a) *The "remaining" field as T becomes large; cf.* (6.36). (b) *Plots $\log_{10}(|v_3^{(1)}(T) - v_3^{(1)}(t = 10^5)|)$ for $T = 10$, 10^2, 10^3, 10^4, along $x_3 = z_0$. In the lowest line the unevenness is due to numerical inaccuracies.* (c) *Plot of $v_3^{(1)}$ along $r := |\tilde{\boldsymbol{x}}| = z_0$ for times $T = 10$ to -20^5. All lines start along the same "remaining" velocity at $x_3 = 0$. The first to deviate is $v_3^{(1)}(T = 10)$, which encounters its wave front at $x_3 \approx 4$ (cf. Figure* 6.1(b)*); the next to go off to infinity is $T = 10^2$, which encounters its wave front at $x_3 \approx 15$.*

point for different excitation times T. It is apparent that the field is rapidly damped with respect to T and $\tilde{x}$. The analogous plots for v_3 are shown in Figure 6.3, where it is apparent that v_3 rapidly approaches its remaining, nonzero, distribution.

In the limit $T \to \infty$ we obtain for the pressure (see Appendix D)

$$\lim_{T\to\infty} \int p^{(1)}(\tilde{\boldsymbol{x}}, x_3, T)\phi(\tilde{x}, x_3)\,\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}x_3 = \frac{1}{2}\phi(0, z_0), \tag{6.38}$$

for a compactly supported test function ϕ. This result agrees with the result presented in [14], obtained by an argument that utilized symmetries of the cavity case.

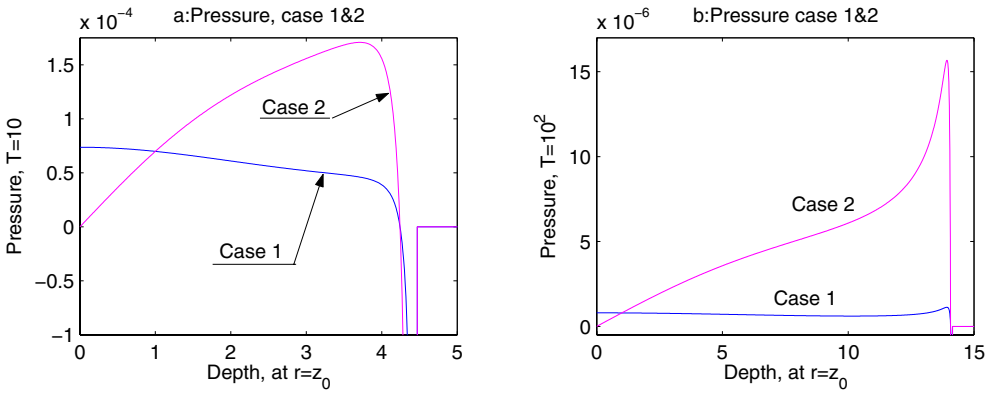

FIG. 6.4. *Comparison between Cases one and two. The plots are along* $r := |\tilde{\boldsymbol{x}}| = z_0$. (a) *The pressure, for* $T = 10$. *The wave front appears at* $r \approx 4$. (b) *The same plot as in Figure* 6.4(a) *but with* $T = 10^2$.

Thus we obtain a perfect retrofocusing in the pressure component, modulo an amplitude factor of 2, in the presence of an evanescent component in the control. The factor of 2 appears since the "controllable part" of the wave field is essentially half of the original wave field, the up-going part of the original pressure pulse that reaches the surface.

We cannot expect a perfect retrofocusing of the pure pressure pulse state for controls on only the half plane, as such controls can only generate "down-going" waves, whereas the pure pressure pulse contains fields that radiate in all directions. The residual of the velocity component ensures that the generated, retrofocused field remains down-going, and hence the velocity component remains nonzero, i.e., not perfectly "retrofitted" to zero.

6.7. Influence of the evanescent part of the boundary control. Here, we discuss the influence of the evanescent part of the boundary control on the resulting fields.

As we noted in section 6.3, the two given boundary controls differ only in the evanescent part, and thus by comparing the responding fields of the respective cases, we compare controls that differ only in the evanescent region. As we derived only the pressure component of the pressure normalized fields explicitly, let us study the difference in pressure. The pressure field differs only by a factor x_3/z_0, and hence the difference is independent of time. To understand the difference between the retrofocused fields we plot the pressure for $\tilde{x} = z_0$; see Figure 6.4.

For Case one, we proved that, as $T \to \infty$, the pressure concentrates at the source point $x_3 = z_0$, $\tilde{x} = 0$. The appearance of the factor x_3/z_0 for Case two does not change the conclusion for $T \to \infty$, as $x_3/z_0 = 1$ at the source point. From the plots in Figure 6.4 we notice the apparent difference between the two cases, but upon observation of the amplitudes involved we conclude that, for sufficiently large T, the evanescent part of the control has a negligible influence. As both cases of controls have a pressure component that converges to a pulse, so must their sum, the response to $p_+^{(3)}$, as the acoustic wave equation is linear.

As we have already shown that the sum of the two controls does not have an evanescent part, and the sum still converges to the pressure Dirac pulse, the influence

of the evanescent part in the long time limit on the pressure component of the final state is small. As the initial pressure is a Dirac pulse, this implies that for any initial state with quiescent velocity and nonzero pressure distribution, the evanescent part of the field has a marginal effect for sufficiently long excitation times.

7. Discussion. The use of time reversal in experiments and theory, both for linear acoustics and electromagnetics, has increased rapidly in the last years. Here, we have developed an iterative time-reversal algorithm for the purpose of retrofocusing that differs from the iterative time-reversal algorithms described by Fink and colleagues [2, 5, 9, 10, 11, 12, 13, 27] and Cheney and coworkers [6, 7]. The algorithms are identical in the first step where they reduce to classical time reversal. The present algorithm retrofocuses the wave field towards the controllable part of its originating distribution; i.e., it uses the transducers in an optimal way to recreate the original (initial) wave field. This is achieved by the construction of identical fields at the transducers in the original and retrofocused states. In contrast to this, the iterative time-reversal algorithm described in [6, 7, 13] retransmit the wave field such that the reflection is maximized. This produces a focusing on the largest scatterer and largest eigenfunction in [13] and [6, 7], respectively.

The iterative time-reversal algorithm is especially useful in strongly multiple scattering cases such as the cavity described in section 5. For this type of geometry, a few iterations improve the retrofocusing, as illustrated by the numerical examples. For the time-reversal mirror examined in this paper, the iterative time-reversal algorithm reduces to the classical time reversal since the homogeneous half space is nonreflecting. But also in this case, the boundary control analysis shows that the iterative time-reversal algorithm is optimally retrofocusing, in the least-squares sense, when the evanescent part of the measured wave field is negligible.

In the half space geometry, both a direct time reversal of the recorded wave field and a weighted time reversal are considered. The two controls differ only in the evanescent part of the wave field. The analytic representation of the pressure field is given for the two controls when the initial field is a pressure Dirac pulse. As expected, the retrofocusing is not perfect; i.e., only the controllable part of the wave field is retrieved. In this case the controllable part is essentially half of the wave field since only the up-going part [18] of the original pressure pulse reaches the surface and is retransmitted as a down-going wave field. The retrofocused field concentrates around the initial pulse point, and as the excitation time approaches infinity, the pressure pulse retrofocuses to half the initial pulse. However, the velocity component does not vanish in the large time limit since the resulting field has to remain down-going.

Appendix A. Calculations on the half space.

A.1. Derivation of the control operator. Here, we give the explicit derivations to obtain the control operator for the particle-velocity normalization.

To derive the control operator for the homogeneous half space, we solve the system of equations

$$\begin{cases} \partial_t p + \nabla \cdot \boldsymbol{v} = 0, & \boldsymbol{x} \in \Omega, \quad t \in (0, T], \\ \partial_t \boldsymbol{v} + \nabla p = 0, & \boldsymbol{x} \in \Omega, \quad t \in (0, T], \\ p = 0,\ \boldsymbol{v} = 0, & \boldsymbol{x} \in \Omega, \quad t = 0, \\ \dfrac{1}{2}(\mathcal{Y} p + v_3) = p_+^{(1)}, & \boldsymbol{x} \in \partial\Omega, \quad t \in [0, T], \end{cases} \tag{A.1}$$

where the boundary condition is in the particle-velocity normalization.

We Laplace transform the field in time, and with the use of $p(\boldsymbol{x},0)=0$ and $\boldsymbol{v}(\boldsymbol{x},0)=0$, together with the enforced causality, the resulting field is analytic for $\operatorname{Re} s \geq 0$. Furthermore, the correspondence $\partial_t \to s$ holds. We Fourier transform the transverse coordinates, $\tilde{\boldsymbol{x}} \to \tilde{\boldsymbol{\xi}}$, and upon eliminating the transverse particle-velocities, we obtain the "two-way" equation for linear acoustic waves

$$\begin{cases} (\partial_3 + \boldsymbol{a}) f(\tilde{\boldsymbol{\xi}}, x_3, s) = 0, & x_3 > 0, \\ \boldsymbol{y} p + v_3 = p_+^{(1)}(\tilde{\boldsymbol{\xi}}, s), & x_3 = 0, \\ s\boldsymbol{v}_\perp(\tilde{\boldsymbol{\xi}}, x_3, s) + \mathrm{i}\tilde{\boldsymbol{\xi}} p(\tilde{\boldsymbol{\xi}}, x_3, s) = 0, & x_3 > 0, \end{cases} \tag{A.2}$$

$f = (p, v_3)$ and where the admittance operator symbol, $\boldsymbol{y}$, is defined in (6.1). Here, the acoustic system's matrix, $\boldsymbol{a}$, has the form

$$\boldsymbol{a} = \begin{pmatrix} 0 & s \\ s + s^{-1}\tilde{\xi}^2 & 0 \end{pmatrix}. \tag{A.3}$$

The formal solution to (A.2) is derived through wave splitting; see, e.g., [14, 15, 16, 17]. Also notice the freedom of "normalization," pointed out in [16, 17, 18]; the normalization is arbitrary and related to the transducer characteristics, where we have chosen the boundary condition in the particle-velocity normalization; i.e., $p_+^{(1)}$ is of "dimension" particle-velocity. The formal solution to (A.2) is

$$\begin{cases} f(\tilde{\boldsymbol{\xi}}, x_3, s) = \mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}} \boldsymbol{\eta}^+ p_+^{(1)}(\tilde{\boldsymbol{\xi}}, s), \\ \boldsymbol{v}_\perp(\tilde{\boldsymbol{\xi}}, x_3, s) = -\dfrac{\mathrm{i}\tilde{\boldsymbol{\xi}}}{s} \mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}} (\boldsymbol{\eta}^+ p_+^{(1)}(\tilde{\boldsymbol{\xi}}, s))_1, \end{cases} \tag{A.4}$$

where $\boldsymbol{\eta}^+$, $(\boldsymbol{\eta}^-)$ is the eigenvector corresponding to the positive (negative) eigenvalue, $\pm\sqrt{s^2+\tilde{\xi}^2}$ of $\boldsymbol{a}$, and has the form, in particle-velocity normalization,

$$\boldsymbol{\eta}^\pm = \begin{pmatrix} \dfrac{s}{\sqrt{s^2+\tilde{\xi}^2}} \\ \pm 1 \end{pmatrix}. \tag{A.5}$$

With the above reformulations, the symbol of the control operator, $\mathcal{W}_{\mathrm{v}}$, becomes

$$\boldsymbol{w}^+ = \mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}} \begin{pmatrix} \dfrac{s}{\sqrt{s^2+\tilde{\xi}^2}} \\ -\dfrac{\mathrm{i}\tilde{\boldsymbol{\xi}}}{\sqrt{s^2+\tilde{\xi}^2}} \\ 1 \end{pmatrix}. \tag{A.6}$$

To transform this operator back into space and time, we observe the identity

$$\mathcal{F}^{-1} \frac{\mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}}}{\sqrt{s^2+\tilde{\xi}^2}} = \int_0^\infty \frac{\tilde{\xi}\, \mathrm{J}_0(\tilde{\xi}\tilde{x}) \mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}}}{2\pi\sqrt{s^2+\tilde{\xi}^2}}\, \mathrm{d}\tilde{\xi} = \frac{\mathrm{e}^{-s|\boldsymbol{x}|}}{2\pi|\boldsymbol{x}|}, \tag{A.7}$$

by using Purdnikov, Brychkov and Marichev's relation 2.12.10.10 [28]. Thus

$$\mathcal{L}^{-1}\mathcal{F}^{-1} \frac{\mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}}}{\sqrt{s^2+\tilde{\xi}^2}} = \frac{\delta(t-|\boldsymbol{x}|)}{2\pi|\boldsymbol{x}|}, \tag{A.8}$$

and as the inverse transform of this integral kernel is known, we express the symbol of the control operator, $\boldsymbol{w}^+$, in terms of the above kernel as

$$\begin{pmatrix} p \\ \tilde{\boldsymbol{v}} \\ v_3 \end{pmatrix} = (\boldsymbol{w}^+ p_+^{(1)})(\tilde{\boldsymbol{\xi}}, x_3, s) = \begin{pmatrix} s \\ -\mathrm{i}\tilde{\boldsymbol{\xi}} \\ -\partial_3 \end{pmatrix} \frac{\mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}}}{\sqrt{s^2+\tilde{\xi}^2}} p_+^{(1)}(\tilde{\boldsymbol{\xi}}, s), \tag{A.9}$$

where $\tilde{\boldsymbol{v}} = \{v_1, v_2\}$. Using (A.8) on (A.9), we find that

$$p(\boldsymbol{x}, T) = \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} \partial_{t'}(\mathrm{H}(t') p_+^{(1)}(\tilde{\boldsymbol{x}}', t'))\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t' \tag{A.10}$$

and

$$\boldsymbol{v}(\boldsymbol{x}, T) = -\nabla \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} p_+^{(1)}(\tilde{\boldsymbol{x}}', t')\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t'. \tag{A.11}$$

Thus we have an explicit expression for the control operator, when the boundary condition is in the particle-velocity normalization. The control operator gives the field inside the domain, once the control at the boundary is known.

A.2. The measured data. In this section a calculation to obtain the explicit form of the measured field at the boundary for Case one is presented.

From (6.26) we have that the measured data has the form

$$q_-^{(0)}(\tilde{\boldsymbol{x}}, t) = \frac{1}{2}((\mathcal{Y}q)(\tilde{\boldsymbol{x}}, 0, t) - u_3(\tilde{\boldsymbol{x}}, 0, t)). \tag{A.12}$$

In the Laplace–Fourier domain the equivalent field has the representation

$$q_-^{(0)}(\tilde{\boldsymbol{\xi}}, s) = \frac{1}{2}\left(s^{-1} q(\tilde{\boldsymbol{\xi}}, 0, s)\sqrt{s^2+\tilde{\xi}^2} - u_3(\tilde{\boldsymbol{\xi}}, 0, s)\right). \tag{A.13}$$

With the relation (A.8) we Laplace–Fourier transform the field $\{q(\tilde{\boldsymbol{x}}, 0, t), u_3(\tilde{\boldsymbol{x}}, 0, t)\}$ at the boundary; cf. (6.25). Substituting the result into (A.13) gives

$$\begin{pmatrix} q(\tilde{\boldsymbol{\xi}}, 0, s) \\ u_3(\tilde{\boldsymbol{\xi}}, 0, s) \end{pmatrix} = \frac{1}{2}\mathrm{e}^{-z_0\sqrt{s^2+\tilde{\xi}^2}} \boldsymbol{\eta}^-(\tilde{\boldsymbol{\xi}}, s) \Rightarrow q_-^{(0)}(\tilde{\boldsymbol{\xi}}, s) = \frac{1}{2}\mathrm{e}^{-z_0\sqrt{s^2+\tilde{\xi}^2}}, \tag{A.14}$$

where $\boldsymbol{\eta}^-$ is an eigenvector of $\boldsymbol{a}$ in the particle-velocity normalization; see (A.5). In the time-space domain, using (A.8), we find that

$$q_-^{(0)}(\tilde{\boldsymbol{x}}, t) = -\partial_{z_0} \frac{\delta(t - \sqrt{\tilde{x}^2 + z_0^2})}{4\pi\sqrt{\tilde{x}^2 + z_0^2}}. \tag{A.15}$$

Appendix B. The field in the domain for control $p_+^{(1)}$. Given the control $p_+^{(1)}$ in (6.30), we substitute it into (6.19) and (6.20). Below we explicitly calculate the two resulting distributions.

B.1. The pressure component. In this section we give a detailed derivation of the pressure distribution for Case one.

Let us introduce the help quantities,

$$R_1 = \sqrt{(\tilde{x}')^2 + z_0^2}, \qquad R_2 = \sqrt{|\tilde{\boldsymbol{x}} - \tilde{\boldsymbol{x}}'|^2 + x_3^2}, \quad \text{and} \quad \tau = T - t. \tag{B.1}$$

The pressure, $p^{(1)}$, with the use of (B.1) is represented as

$$\begin{aligned} p^{(1)}(\boldsymbol{x},t) &= -\partial_{z_0}\partial_t \int_{\mathbb{R}^2} \mathrm{H}(t-R_2)\frac{\delta(\tau+(R_2-R_1))}{8\pi^2 R_1 R_2}\,\mathrm{d}x_1'\,\mathrm{d}x_2' \\ &= \partial_{z_0}x_3^{-1}\partial_3 \int_{\mathbb{R}^2} \mathrm{H}(t-R_2)\frac{\delta(\tau+(R_2-R_1))}{8\pi^2 R_1}\,\mathrm{d}x_1'\,\mathrm{d}x_2'. \end{aligned} \tag{B.2}$$

The delta Dirac traces out a curve for $\tilde{\boldsymbol{x}}'$; to find the curve consider the $\tilde{\boldsymbol{x}}'$ such that $R_1 - R_2 - \tau = 0$:

$$\begin{gathered} R_1^2 = (\tau+R_2)^2 = \tau^2 + R_2^2 + 2\tau R_2 \Leftrightarrow \\ -\tau\sqrt{x_3^2+|\tilde{\boldsymbol{x}}-\tilde{\boldsymbol{x}}'|^2} = (\tilde{x}^2 + x_3^2 - z_0^2 + \tau^2)/2 - \tilde{\boldsymbol{x}}\cdot\tilde{\boldsymbol{x}}' \Leftrightarrow \\ \tau^2(x_3^2+\tilde{x}^2+(\tilde{x}')^2 - 2\tilde{\boldsymbol{x}}\cdot\tilde{\boldsymbol{x}}') = ((\tilde{x}^2+x_3^2-z_0^2+\tau^2)/2 - \tilde{\boldsymbol{x}}\cdot\tilde{\boldsymbol{x}}')^2 \Leftrightarrow \\ \tau^2(x_3^2+\tilde{x}^2) - A^2/4 = -\tau^2(\tilde{x}')^2 + (\tilde{\boldsymbol{x}}\cdot\tilde{\boldsymbol{x}}')^2 - A(\tilde{\boldsymbol{x}}\cdot\tilde{\boldsymbol{x}}'); \end{gathered} \tag{B.3}$$

hence $\delta(R_1 - R_2 - \tau)$ traces out a conical section. Here,

$$A = \tilde{x}^2 + x_3^2 - z_0^2 + \tau^2. \tag{B.4}$$

We observe the freedom of choice in the coordinates $\tilde{\boldsymbol{x}}'$, and hence we choose the particular coordinate system for $\tilde{\boldsymbol{x}}'$ such that $\tilde{\boldsymbol{x}} = (\tilde{x}, 0)$. This is equivalent to rotating the coordinate system of $\tilde{\boldsymbol{x}}'$. The compatibility condition imposed on the solution associated with the square roots is

$$-\operatorname{sgn}(\tau) = \operatorname{sgn}(\tilde{x}^2 + x_3^2 - z_0^2 + \tau^2 - 2\tilde{x}x_1'), \tag{B.5}$$

as is observed from the second line of (B.3). Now we rewrite (B.3) into a more standard form for conical sections,

$$c = (\tilde{x}^2 - \tau^2)(x_1' - x_1^0)^2 - \tau^2(x_2')^2, \tag{B.6}$$

and hence the set of $\{x_1', x_2'\}$, which fulfills (B.6), traces out a curve in space. In this case

$$x_1^0 = \tilde{x}\frac{A/2-\tau^2}{\tilde{x}^2-\tau^2} \quad \text{and} \quad c = \tau^2(x_3^2+\tilde{x}^2) - \frac{A^2}{4} + (\tilde{x}^2-\tau^2)(x_1^0)^2. \tag{B.7}$$

We notice that if $\tilde{x} > \tau$, the curve traced out is a hyperbola; when $\tilde{x} < \tau$, it is an ellipse; and when $\tilde{x} = \tau$, it is a line parallel to x_1'-axis.

In evaluating the integral (B.2) we consider only the limiting case when $t = T$, i.e., $\tau = 0$. Thus the integral reduces to

$$p^{(1)}(\boldsymbol{x},T) = \frac{1}{x_3}\partial_{z_0}\partial_3 \int_{\mathbb{R}^2} \mathrm{H}(T-R_2)\frac{\delta(R_2-R_1)}{8\pi^2 R_1}\,\mathrm{d}x_1'\,\mathrm{d}x_2'. \tag{B.8}$$

We find that

$$x_1^0 = \frac{A}{(2\tilde{x})} = \frac{\tilde{x}}{2}\left(1 + \frac{x_3^2-z_0^2}{\tilde{x}^2}\right), \quad c = 0,\ A = \tilde{x}^2 + x_3^2 - z_0^2, \tag{B.9}$$

and the conical curve (B.6) collapses into the line

$$x_1' = x_1^0 \Rightarrow x_1 = \frac{\tilde{x}}{2}\left(1 + \frac{x_3^2-z_0^2}{2\tilde{x}^2}\right). \tag{B.10}$$

This line fulfills the compatibility condition (B.5), and hence it is a solution.

To evaluate the integral we introduce a change of coordinates, $\Psi = R_1 - R_2$, and the arc length, s, along the line (B.10). The integral in those coordinates collapses into an integral with integrand

$$(R_2|\nabla\Psi|)^{-1}\,\mathrm{d}s = \tilde{x}^{-1}\,\mathrm{d}x_2'. \tag{B.11}$$

To see this, first note that

$$\mathrm{d}s = \sqrt{1+\left(\frac{\partial x_1'}{\partial x_2'}\right)^2}\,\mathrm{d}x_2' = \mathrm{d}x_2' \tag{B.12}$$

and

$$(R_1R_2)^2|\nabla'(R_1-R_2)|^2_{\Psi=0} = |(R_2-R_1)\tilde{\boldsymbol{x}}' + R_1\tilde{\boldsymbol{x}}|^2_{\Psi=0} = R_1^2\tilde{x}^2|_{\Psi=0}, \tag{B.13}$$

where we have used $R_1 = R_2$, or equivalently $x_1' = x_1^0$. Hence, the pressure integral becomes

$$p^{(1)}(\boldsymbol{x},T) = \frac{1}{8\pi^2\tilde{x}x_3}\partial_{z_0}\partial_3\int_{\mathbb{R}}\mathrm{H}(T-R_1)|_{R_1=R_2}\,\mathrm{d}x_2', \tag{B.14}$$

i.e., the length of the line, $x_1' = x_1^0$, inside the circle described by $\mathrm{H}(T-R_1)$. The height, x_2', where $x_1' = x_1^0$ crosses the circle, is

$$\begin{aligned} &T^2 = z_0^2 + (x_1')^2 + (x_2')^2|_{x_1'=x_1^0} = z_0^2 + (x_1^0)^2 + (x_2')^2 \Rightarrow \\ &x_2' = \pm\sqrt{T^2 - z_0^2 - (x_1^0)^2}, \end{aligned} \tag{B.15}$$

and hence

$$p^{(1)}(\boldsymbol{x},T) = \frac{1}{4\pi^2\tilde{x}x_3}\partial_{z_0}\partial_3\left(\sqrt{T^2-(z_0^2+(x_1^0)^2)}\mathrm{H}\left(T-\sqrt{z_0^2+(x_1^0)^2}\right)\right). \tag{B.16}$$

We now let the derivative with respect to the parameter z_0 act on the distribution. We first observe that

$$\partial_{z_0}\sqrt{T^2-(z_0^2+(x_1^0)^2)} = \frac{-z_0(x-x_1^0)}{\tilde{x}\sqrt{T^2-z_0^2-(x_1^0)^2}}, \tag{B.17}$$

so that

$$\begin{aligned} p^{(1)}(\boldsymbol{x},T) &= \frac{-z_0}{4\pi^2x_3\tilde{x}^2}\partial_3\frac{\tilde{x}-x_1^0}{(T^2-z_0^2-(x_1^0)^2)_+^{1/2}} \\ &= \frac{-z_0}{4\pi^2x_3\tilde{x}^2}\partial_3\frac{\tilde{x}^2-x_3^2+z_0^2}{(4\tilde{x}^2(T^2-z_0^2)-A^2)_+^{1/2}}. \end{aligned} \tag{B.18}$$

We rewrite the denominator in the form

$$\left(\left[T^2-x_3^2-\left(\tilde{x}-\sqrt{T^2-z_0^2}\right)^2\right]\left[\left(\tilde{x}+\sqrt{T^2-z_0^2}\right)^2+x_3^2-T^2\right]\right)_+^{1/2}, \tag{B.19}$$

where the plus sign indicates that we consider it as a generalized function, and the value within the outer parentheses must be positive. With (B.18) and (B.19) we have obtained the pressure inside the domain corresponding to the control $p_+^{(1)}$. It is a distribution, and is considered as acting on smooth test functions.

B.2. The velocity component. With the same notation as in the previous section, we write the particle velocity inside the domain for the boundary control $p_+^{(1)}$, in the limit $t = T$, as

$$\boldsymbol{v}^{(1)}(\boldsymbol{x}, T) = \nabla\partial_{z_0} \int_{\mathbb{R}^2} \mathrm{H}(T - R_2) \frac{\delta(R_2 - R_1)}{8\pi^2 R_1 R_2} \,\mathrm{d}x_1' \,\mathrm{d}x_2'. \tag{B.20}$$

With the change to the arc-length coordinates, we have (cf. (B.11))

$$\boldsymbol{v}^{(1)}(\boldsymbol{x}, T) = \nabla \frac{1}{8\pi^2\tilde{x}} \partial_{z_0} \int_{\mathbb{R}} \frac{\mathrm{H}(T - R_2)}{R_1}\bigg|_{R_1=R_2} \mathrm{d}x_2'. \tag{B.21}$$

Analogous to the derivation leading up to (B.10), the condition $R_1 = R_2$ is equivalent to $x_1' = x_1^0$, and hence

$$R_1|_{x_1'=x_1^0} = ((x_1^0)^2 + z_0^2 + (x_2')^2)^{1/2}. \tag{B.22}$$

The integral is straightforward once we notice that the step function imposes the boundary value of x_2' (see (B.15))

$$\begin{aligned} &\boldsymbol{v}^{(1)}(\boldsymbol{x}, T) \\ &= \nabla \left[\frac{1}{8\pi^2\tilde{x}} \partial_{z_0} \ln \left(\left| x_2' + \sqrt{(x_2')^2 + z_0^2 + (x_1^0)^2} \right| \right) \right] \Big|_{x_2'=\{x_2': R_1|_{x_1'=x_1^0}=T\}} \\ &= \nabla \left[\frac{1}{8\pi^2\tilde{x}} \partial_{z_0} \left(\ln \left(\frac{T + \sqrt{T^2 - z_0^2 - (x_1^0)^2}}{T - \sqrt{T^2 - z_0^2 - (x_1^0)^2}} \right) \mathrm{H}\left(T - c^{-1}\sqrt{z_0^2 + (x_1^0)^2} \right) \right) \right]. \end{aligned} \tag{B.23}$$

Upon evaluating the derivative with respect to z_0, we obtain

$$\boldsymbol{v}^{(1)}(\boldsymbol{x}, T) = \nabla \left(\frac{z_0}{4\pi^2\tilde{x}^2} \frac{T(x_1^0 - \tilde{x})}{(T^2 - z_0^2 - (x_1^0)^2)_+^{1/2} (z_0^2 + (x_1^0)^2)} \right), \tag{B.24}$$

where the generalized function in the denominator is the same as for the pressure (B.17) and can be rewritten as (B.19).

Appendix C. The response field for Case two. To obtain the response for the control in Case two, we start to examine the characteristics of our transducers. The derivation in Appendices A and B is for the particle-velocity normalization of the boundary condition, both for the control and for the measurement. If we use the pressure normalization instead of velocity normalization, then the boundary condition takes the form (cf. (6.15))

$$\frac{p + \mathcal{Y}^{-1} v_3}{2} = p_{+,\mathrm{N_p}}^{(2)} \quad \text{and} \quad m_{(2)} = \frac{q - \mathcal{Y}^{-1} u_3}{2}. \tag{C.1}$$

The control operator is then expressed in terms of the eigenvector in the pressure normalization; i.e., $\boldsymbol{\eta}^+$ in (A.4) is replaced by $\boldsymbol{\eta}_{(2)}^+$, where

$$\boldsymbol{\eta}_{(2)}^{\pm} = \begin{pmatrix} 1 \\ \pm s^{-1}\sqrt{s^2 + \tilde{\xi}^2} \end{pmatrix}. \tag{C.2}$$

Thus the symbol of the control operator, $\boldsymbol{w}^{+}_{(2)}$, in this normalization is

$$\begin{pmatrix} p \\ \tilde{\boldsymbol{v}} \\ v_3 \end{pmatrix} = \left(\boldsymbol{w}^{+}_{(2)} p^{(2)}_{+,\mathrm{N_p}}\right)(\tilde{\boldsymbol{\xi}}, x_3, s) = \begin{pmatrix} -\partial_3 \\ s^{-1}\mathrm{i}\tilde{\boldsymbol{\xi}}\partial_3 \\ s^{-1}\partial_3^2 \end{pmatrix} \frac{\mathrm{e}^{-x_3\sqrt{s^2+\tilde{\xi}^2}}}{\sqrt{s^2+\tilde{\xi}^2}} p^{(2)}_{+,\mathrm{N_p}}(\tilde{\boldsymbol{\xi}}, s). \tag{C.3}$$

Using (A.8), we obtain the control operator as

$$p(\boldsymbol{x}, T) = -\partial_3 \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} p^{(2)}_{+,\mathrm{N_p}}(\tilde{\boldsymbol{x}}', t')\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t' \tag{C.4}$$

and

$$\boldsymbol{v}(\boldsymbol{x}, T) = \nabla\partial_3 \int_0^T \int_{\mathbb{R}^2} \frac{\delta(T - t' - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{2\pi|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|} \int_0^{t'} p^{(2)}_{+,\mathrm{N_p}}(\tilde{\boldsymbol{x}}', t'')\, \mathrm{d}t''\, \mathrm{d}x_1'\, \mathrm{d}x_2'\, \mathrm{d}t'. \tag{C.5}$$

Hence, the normalization of the boundary condition changes the field, as expected; cf. (6.19) and (6.20). The change related to the different transducer normalizations can be compared to solving a partial differential equation with the Neumann and Dirichlet boundary conditions, respectively.

The field from the pressure pulse at the surface in (6.25), $\{q, u_3\}$, is independent of normalization, but we measure particle-velocity (see (C.1)); thus in the pressure normalization the measured signal becomes

$$\begin{pmatrix} q(\tilde{\boldsymbol{\xi}}, 0, s) \\ u_3(\tilde{\boldsymbol{\xi}}, 0, s) \end{pmatrix} = \frac{s\mathrm{e}^{-z_0\sqrt{s^2+\tilde{\xi}^2}}}{2\sqrt{s^2+\tilde{\xi}^2}} \boldsymbol{\eta}^{-}_{(2)}(\tilde{\boldsymbol{\xi}}, s) \Rightarrow m_{(2)}(\tilde{\boldsymbol{\xi}}, s) = \frac{s\mathrm{e}^{-z_0\sqrt{s^2+\tilde{\xi}^2}}}{2\sqrt{s^2+\tilde{\xi}^2}} \tag{C.6}$$

in the transform domain, and hence

$$m_{(2)}(\tilde{\boldsymbol{x}}, t) = \partial_t \frac{\delta(t - \sqrt{\tilde{x}^2 + z_0^2})}{4\pi\sqrt{\tilde{x}^2 + z_0^2}}. \tag{C.7}$$

Thus the control corresponding to the $m_{(2)}$ measurement is given by

$$p^{(2)}_{+,\mathrm{N_p}} = \mathrm{H}(t) m_{(2)}(\tilde{\boldsymbol{x}}, T - t) = -\mathrm{H}(t)\partial_t \frac{\delta(T - t - \sqrt{\tilde{x}^2 + z_0^2})}{4\pi\sqrt{\tilde{x}^2 + z_0^2}}. \tag{C.8}$$

We substitute the control (C.8) into (C.4) and (C.5) to obtain

$$p^{(2)}(\boldsymbol{x}, T) = \partial_3 z_0^{-1} \partial_{z_0} \int_{\mathbb{R}^2} \mathrm{H}(T - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|) \frac{\delta(|\boldsymbol{x} - \tilde{\boldsymbol{x}}'| - \sqrt{(\tilde{x}')^2 + z_0^2})}{8\pi^2|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|}\, \mathrm{d}x_1'\, \mathrm{d}x_2' \tag{C.9}$$

and

$$\boldsymbol{v}^{(2)}(\boldsymbol{x}, T) = -\nabla\partial_3 z_0^{-1} \partial_{z_0} \int_{\mathbb{R}^2} \mathrm{H}\left(T - \sqrt{(\tilde{x}')^2 + z_0^2}\right) \frac{\mathrm{H}(\sqrt{(\tilde{x}')^2 + z_0^2} - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{8\pi^2|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|}\, \mathrm{d}x_1'\, \mathrm{d}x_2'. \tag{C.10}$$

We rewrite (C.10) by evaluating ∂_{z_0}; thus

$$\begin{aligned} \boldsymbol{v}^{(2)}(\boldsymbol{x}, T) = -\nabla\partial_3 \int_{\mathbb{R}^2} & \mathrm{H}\left(T - \sqrt{(\tilde{x}')^2 + z_0^2}\right) \frac{\delta(\sqrt{(\tilde{x}')^2 + z_0^2} - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{8\pi^2|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2 + z_0^2}} \\ & - \delta\left(T - \sqrt{(\tilde{x}')^2 + z_0^2}\right) \frac{\mathrm{H}(\sqrt{(\tilde{x}')^2 + z_0^2} - |\boldsymbol{x} - \tilde{\boldsymbol{x}}'|)}{8\pi^2|\boldsymbol{x} - \tilde{\boldsymbol{x}}'|\sqrt{(\tilde{x}')^2 + z_0^2}}\, \mathrm{d}x_1'\, \mathrm{d}x_2'. \end{aligned} \tag{C.11}$$

The evaluation of (C.9) is analogous to the corresponding case in the particle velocity normalization (see (B.8)), and thus we obtain

(C.12)
$$p^{(2)}(\boldsymbol{x},T) = \frac{-1}{4\pi^2\tilde{x}^2}\partial_3\left(\frac{\tilde{x}^2 - x_3^2 + z_0^2}{([T^2 - x_3^2 - (\tilde{x} - \sqrt{T^2 - z_0^2})^2][(\tilde{x} + \sqrt{T^2 - z_0^2})^2 + x_3^2 - T^2])_+^{1/2}}\right).$$

Appendix D. The pressure response distribution for $T \to \infty$. In this section, we give the details for the calculation of the limit $T \to \infty$ of the pressure response (6.32) in Case one.

We rewrite the denominator of (6.32) in the more convenient form

(D.1)
$$p^{(1)}(\boldsymbol{x},T) = \frac{-z_0}{4\pi^2 x_3\tilde{x}^2}\partial_3\left(\frac{\tilde{x}^2 - x_3^2 + z_0^2}{([(\sqrt{T^2 - z_0^2} + \sqrt{T^2 - x_3^2})^2 - \tilde{x}^2][\tilde{x}^2 - (\sqrt{T^2 - z_0^2} - \sqrt{T^2 - x_3^2})^2])_+^{1/2}}\right).$$

In the limit $T \to \infty$, let $\phi = \phi(\tilde{\boldsymbol{x}}, x_3)$ be a compactly supported test function, i.e., smooth and bounded. We require that

$$\operatorname{supp}\phi \subset \{\boldsymbol{x} \in \mathbb{R}^3 : x_3 > 0\} \quad \text{and} \quad \operatorname{diam}\phi \le D_\phi, \tag{D.2}$$

for some fixed number $D_\phi > 0$. As we are interested only in the limit $T \to \infty$, we require that $T \gg z_0$. Let us define the pressure functional $p_f = p_f(T)$ as

$$p_f = \int_{\mathbb{R}^3_+ \cap \operatorname{supp}\phi} p^{(1)}(\boldsymbol{x},T)\phi(\tilde{\boldsymbol{x}}, x_3)\,\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}x_3. \tag{D.3}$$

By partial integration we push the derivative to the test function to obtain

$$\begin{aligned} p_f = &\int_{\mathbb{R}^3_+ \cap \operatorname{supp}\phi} \frac{z_0}{4\pi^2}\left(\partial_3\frac{\phi(\tilde{\boldsymbol{x}}, x_3)}{x_3}\right) \\ &\times \frac{(\tilde{x}^2 - x_3^2 + z_0^2)\,\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}x_3}{\tilde{x}^2([(\sqrt{T^2 - z_0^2} + \sqrt{T^2 - x_3^2})^2 - \tilde{x}^2][\tilde{x}^2 - (\sqrt{T^2 - z_0^2} - \sqrt{T^2 - x_3^2})^2])_+^{1/2}}. \end{aligned} \tag{D.4}$$

We eliminate the appearance of T in the integrand with the change of variables

$$\check{z}_0 = \frac{z_0}{\sqrt{T^2 - z_0^2}}, \qquad \check{x}_3 = \frac{x_3}{\sqrt{T^2 - z_0^2}}, \qquad \check{r} = \frac{\tilde{x}}{\sqrt{T^2 - z_0^2}}, \tag{D.5}$$

giving $\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}x_3 = (T^2 - z_0^2)^{3/2}\check{r}\,\mathrm{d}\check{r}\,\mathrm{d}\check{x}_3\,\mathrm{d}\theta$. With this change of variables the denominator takes the form

$$(\dots)_+^{1/2} = (T^2 - z_0^2)\left(\left[\left(1 + \sqrt{1 - \check{x}_3^2 + \check{z}_0^2}\right)^2 - \check{r}^2\right]\left[\check{r}^2 - \left(1 - \sqrt{1 - \check{x}_3^2 + \check{z}_0^2}\right)^2\right]\right)_+^{1/2}.$$

For notational convenience let

(D.6)
$$\psi(\check{r}\cos\theta, \check{r}\sin\theta, \check{x}_3, T) = \frac{\check{z}_0}{2\pi}\frac{\partial}{\partial\check{x}_3}\frac{\phi(\sqrt{T^2 - z_0^2}\check{r}\cos\theta, \sqrt{T^2 - z_0^2}\check{r}\sin\theta, \sqrt{T^2 - z_0^2}\check{x}_3)}{\check{x}_3}.$$

The limit of the integration, $\mathbb{R}^3_+ \cap \operatorname{supp}\phi$, in the new variables is included in the set

$$(\check{x}_3 - \check{z}_0)^2 + \check{r}^2 \le \frac{D_\phi^2}{T^2 - z_0^2} \equiv \check{D}_\phi^2, \tag{D.7}$$

for sufficiently large T. Hence, we only have to consider small $\check{r}$ and $|\check{x}_3 - \check{z}_0|$ as we make T arbitrary large. In particular, we can expand the test function ψ around $\check{r} = 0$: $\psi(\check{\boldsymbol{x}}, x_3) = \psi(0, 0, x_3, T) + \check{r}\psi_{\check{x}_1}\cos\theta + \check{r}\psi_{\check{x}_2}\sin\theta + \mathrm{O}(\check{r}^2)$. As the integrand, apart from the test function, is independent of θ, we obtain

$$\begin{aligned} p_f = &\int_{\sqrt{(\check{x}_3-\check{z}_0)^2+\check{r}^2}\le\check{D}_\phi} (\psi(0,0,\check{x}_3,T) + \mathrm{O}(T^{-2})) \\ &\times \frac{(\check{r}^2 - \check{x}_3^2 + \check{z}_0^2)\,\mathrm{d}\check{r}\,\mathrm{d}\check{x}_3}{\check{r}([(1+\sqrt{1-\check{x}_3^2+\check{z}_0^2})^2 - \check{r}^2][\check{r}^2 - (1-\sqrt{1-\check{x}_3^2+\check{z}_0^2})^2])_+^{1/2}}. \end{aligned} \tag{D.8}$$

The $\check{r}$-integral can be integrated exactly, but as we are only interested in the limit $T \to \infty$, we simplify the above expression as both $|\check{x}_3 - \check{z}_0|$ and $\check{r}$ are bounded above by $\check{D}_\phi = \mathrm{O}(T^{-1}) \ll 1$ for sufficiently large T. Applying Taylor expansion gives

$$1 + \sqrt{1-\check{x}_3^2+\check{z}_0^2} = 2 + \mathrm{O}(T^{-1}), \qquad 1 - \sqrt{1-\check{x}_3^2+\check{z}_0^2} = \frac{\check{x}_3^2 - \check{z}_0^2}{2} + \mathrm{O}(T^{-2}), \tag{D.9}$$

and hence

$$(\dots)_+^{1/2} = ([4\check{r}^2 - (\check{x}_3^2 - \check{z}_0^2)^2])_+^{1/2} + \mathrm{O}(T^{-1}). \tag{D.10}$$

Thus the pressure functional becomes

$$p_f = \int_{\sqrt{(\check{x}_3-\check{z}_0)^2+\check{r}^2}\le\check{D}_\phi} \frac{\check{r}^2 - \check{x}_3^2 + \check{z}_0^2}{\check{r}[4\check{r}^2 - (\check{x}_3^2 - \check{z}_0^2)^2]_+^{1/2}} \psi(0,0,\check{x}_3,T)\,\mathrm{d}\check{r}\,\mathrm{d}\check{x}_3 + \cdots. \tag{D.11}$$

The disk $\sqrt{(\check{x}_3 - \check{z}_0)^2 + \check{r}^2} \le \check{D}_\phi$, together with the step function indicated by the plus sign on $(\dots)_+^{1/2}$, is depicted in Figure D.1. With the change of variables

$$\check{r} = \frac{|\check{x}_3^2 - \check{z}_0^2|u}{2} = \frac{\zeta u}{2}, \tag{D.12}$$

we find

$$p_f = \int_{|\check{x}_3-\check{z}_0|f(\check{x}_3)\le 2\check{D}_\phi} \int_1^{2\zeta^{-1}\sqrt{\check{D}_\phi^2-(\check{x}_3-\check{z}_0)^2}} \psi(0,0,\check{x}_3,T) \frac{\zeta^2u^2/4 - \check{x}_3^2 + \check{z}_0^2}{\zeta u(u^2-1)^{1/2}}\,\mathrm{d}u\,\mathrm{d}\check{x}_3 + \cdots,$$

where $f(\check{x}_3) = \sqrt{4 + (\check{x}_3 + \check{z}_0)^2}$. Upon integrating, we have

$$\begin{aligned} p_f = -\int_{|\check{x}_3-\check{z}_0|f(\check{x}_3)\le 2\check{D}_\phi} \psi(0,0,\check{x}_3,T) \Bigg(&\frac{(\check{x}_3^2 - \check{z}_0^2)\pi}{2|\check{x}_3^2 - \check{z}_0^2|} - \frac{1}{4}\sqrt{4\check{D}_\phi^2 - 4(\check{x}_3 - \check{z}_0)^2 - \zeta^2} \\ &- \frac{\check{x}_3^2 - \check{z}_0^2}{\zeta}\arctan(\zeta(4\check{D}_\phi^2 - (\check{x}_3 - \check{z}_0)^2 - \zeta^2)^{-1/2})\Bigg)\mathrm{d}\check{x}_3 + \cdots. \end{aligned}$$

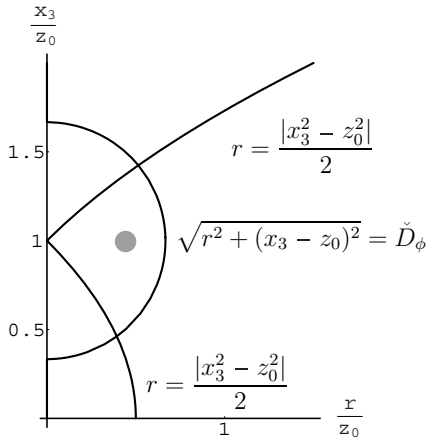

FIG. D.1. *The triangle with the gray dot is the area of integration. The outer circle bounds the domain of ψ, and the cut-off, $(\dots)_+^{1/2}$, is shown as the two lines entering the half-circle.*

Observe that on the given interval we have the upper bound

$$\frac{1}{4}\sqrt{4\check{D}_\phi^2 - 4(\check{x}_3 - \check{z}_0)^2 - \zeta^2} \le \frac{\check{D}_\phi}{2}; \tag{D.13}$$

this, together with the facts that the square root is a continuous function and that the test function is bounded above, gives that the integral of this term vanishes as $T \to \infty$. For the arctan term, we observe that it is continuous at $\check{x}_3 = \check{z}_0$, since $\arctan\epsilon = \epsilon + \cdots$, and furthermore, on the given interval

$$|\operatorname{sgn}(\check{x}_3^2 - \check{z}_0^2)\arctan(\zeta(4\check{D}_\phi^2 - (\check{x}_3 - \check{z}_0)^2 - \zeta^2)^{-1/2})| \le \frac{\pi}{2}; \tag{D.14}$$

thus, as the test function is bounded, this term also gives a vanishing contribution to the integral.

With the above considerations the pressure functional becomes

$$p_f = -\frac{\pi}{2}\int_{|\check{x}_3 - \check{z}_0| f(\check{x}_3) \le 2\check{D}_\phi} \psi(0,0,\check{x}_3,T)\frac{\check{x}_3^2 - \check{z}_0^2}{|\check{x}_3^2 - \check{z}_0^2|}\,\mathrm{d}\check{x}_3 + \mathrm{O}(T^{-1}). \tag{D.15}$$

If we now substitute the expression for ψ, (D.6), we find that

$$p_f = -\frac{\check{z}_0}{4}\int_{|\check{x}_3 - \check{z}_0| f(\check{x}_3) \le 2\check{D}_\phi} \left(\partial_{\check{x}_3}\frac{\phi(0,\check{x}_3\sqrt{T^2 - z_0^2})}{\check{x}_3}\right)\operatorname{sgn}(\check{x}_3^2 - \check{z}_0^2)\,\mathrm{d}\check{x}_3 + \mathrm{O}(T^{-1}). \tag{D.16}$$

This integral is evaluated as

$$\begin{aligned} p_f &= \frac{\check{z}_0}{4}\int_{|\check{x}_3 - \check{z}_0| f(\check{x}_3) \le 2\check{D}_\phi} \phi\left(0,\check{x}_3\sqrt{T^2 - z_0^2}\right)(\check{x}_3^{-1}\partial_{\check{x}_3}\operatorname{sgn}(\check{x}_3^2 - \check{z}_0^2))\,\mathrm{d}\check{x}_3 + \mathrm{O}(T^{-1}) \\ &= \frac{1}{2}\phi(0,z_0) + \mathrm{O}(T^{-1}). \end{aligned} \tag{D.17}$$

In the integration we used that z_0 is always in the domain $|\check{x}_3 - \check{z}_0| f(\check{x}_3) \leq 2\check{D}_\phi$, for sufficiently small $\check{D}_\phi$ or correspondingly for large enough T. In the limit $T \to \infty$ we find that the distribution reduces to a delta Dirac at $\tilde{\boldsymbol{x}} = 0$ and $x_3 = z_0$. Hence, in the limit we get back half the original pressure pulse in the pressure component.

A NOISE CONTROL PROBLEM ARISING IN A FLOW DUCT*

PHILIPPE DESTUYNDER† AND JOCELYNE VÉTILLARD†

Abstract. Let us consider a one dimensional flow in a cylindrical tube, a portion of which is flexible. It can be a shell structure or a membrane equipped with actuators in order to reduce and if possible to cancel the acoustic perturbations transferred by the flow. The goal of this paper is to discuss the efficiency of such a noise insulator in a mathematical framework.

Key words. aeroacoustics, fluid-structure, control of noise, flow duct

1. Introduction. The modelling of aeroacoustic waves in an air flow coupled with a flexible structure is an old but difficult problem, which still contains a lot of unrevealed secrets [18], [17]. A cornerstone of such systems is the reflection of different wave speeds on the boundaries or at a geometrical discontinuity. Such phenomena can occur in a much more complex way at the interface between an air flow and a flexible structure. For instance, local waves like Stoneley waves [9] can appear and be acoustically predominant, at least locally [7]. More generally the question of local waves is a difficult problem in fluid-structure interactions, and the mathematical tools available are not yet well adapted to such analysis. The reason is that the approaches which make use of Fourier series or eigenmodes expansions are based on energetic approximations which do not represent correctly the local behavior of wave models, especially when the media are inhomogeneous. Phenomena occurring at a low frequency but with a very short wave length can certainly be better analyzed using Fourier transform (with respect to space coordinates). In such a formulation local behavior is transformed into global behavior. However, special technical strategies are necessary because Fourier transforms cannot be applied straightforwardly to inhomegeneous media. Another alternative consists of using special eigenmodes like the so-called Steklov ones. This is the approach used in this paper, but on a very restricted model. The difficulties mentioned here are magnified when a control model is considered. A lot of new mechanical phenomena arise and significantly disturb the certainties of the engineers. Therefore we think that it could be better to restrict our ambitions to a simple one dimensional model coupling a flexible structure with a fluid. Our goal is to prove that very strange mechanical behaviours can occur in such a class of aeroacoustic problems and to discuss the efficiency of a control system in order to suppress exactly any acoustic perturbation in the flow or in the structure. The first section gives a presentation of the model used and few useful properties. The flutter analysis is carried out in the third section, and the control problem is defined in the fourth one. Then a mathematical study of the adjoint state functions, performed in section five, enables one to prove a few controllability results in the sixth section. The method is an adaptation of the H.U.M. method of Lions [21]. The characterization of spaces for the control functions is performed in section 7 and is based on an idea

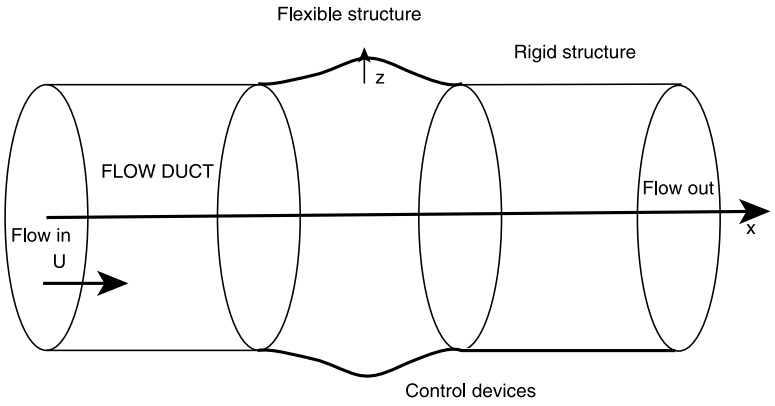

FIG. 1. *The flow duct and the flexible structure.*

introduced by Zuazua (quoted in [21]). The last part (section 8) suggests a discussion on the stability of the classical optimal control loop compared to the controllability results obtained previously.

2. The aeroacoustic model coupled with a flexible structure. We consider the steady flow of a fluid through a duct like that of Figure 1. A flow is travelling through it. It is assumed that this steady flow is uniform with the velocity U. The acoustic waves can be modelled by a potential function, say φ, which is a solution of the following partial differential equation, where c_f is the sound speed in the fluid:

$$\frac{\partial^2\varphi}{\partial t^2} + 2U\frac{\partial^2\varphi}{\partial x\partial t} + (U^2 - c_f^2)\frac{\partial^2\varphi}{\partial x^2} = ac_f^2\left(\frac{\partial z}{\partial t} + U\frac{\partial z}{\partial x}\right)\chi_{[L_1,L_2]}(x), \tag{1}$$

where z is the normal displacement of the flexible structure which is positioned between $x = L_1$ and $x = L_2$. (It is a wave equation but written in a moving frame at the velocity U ($x' = x - Ut$), and therefore we substitute the time derivative $\frac{\partial.}{\partial t}$ by $\frac{\partial.}{\partial t} + U\frac{\partial.}{\partial x}$.) The characteristic function of the segment $[L_1, L_2]$ is denoted by $\chi_{[L_1,L_2]}$, and a is a geometrical coefficient function of the cross section of the duct. The term $\frac{\partial z}{\partial t} + U\frac{\partial z}{\partial x}$ is due to the continuity of the normal velocity between the flexible structure and the wall of the duct (see Figure 2). More precisely, the term $U\frac{\partial z}{\partial x}$ comes from the rotation of the normal to the interface. Another kind of junction including a smart device will also be considered in this paper. It is obtained, for instance, by a direct control of the position of a part of the tube or by a prescribed acoustic pressure using skin loud speakers. This control is denoted by w. It is assumed for the sake of simplicity that its support is on a segment $]\alpha, \beta[$ inside the flexible structure, but its position could be anywhere along the flow duct. The full justification of such a model will be given in a forthcoming paper using the asymptotic method based on the small parameters representing the transverse dimensions of the duct and of the structure.

Then the new model is

$$\frac{\partial^2\varphi}{\partial t^2} + 2U\frac{\partial^2\varphi}{\partial x\partial t} + (U^2 - c_f^2)\frac{\partial^2\varphi}{\partial x^2} = ac_f^2\left(\frac{\partial z}{\partial t} + U\frac{\partial z}{\partial x}\right)\chi_{[L_1,L_2]}(x) + w\chi_{[\alpha,\beta]}(x). \tag{2}$$

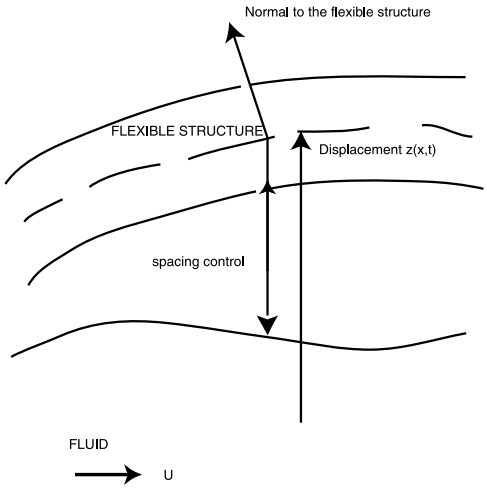

FIG. 2. *The smart system.*

The segment $[\alpha, \beta]$ can be quite small compared to the length of the structure. This is precisely one advantage of the system that we study: the mechanical effect of the control on the flow duct is extended to the whole length of the structure even if the control device is restricted to the subsegment $[\alpha, \beta]$. In fact, this control system is not necessary for proving the exact controllability of the coupled model, as we prove in the following. But it enables one to regularize the control functions used on the structure which is specified later on. Another point is that the boundary layer in the fluid is not taken into account in the model (1) or (2). It is true that the viscosity would contribute to changing the conclusions of the present study; however, it has been omitted in this paper for the sake of brevity and also because the parabolic behavior of the wall law is a real difficulty for the mathematical analysis [10]. At the extremities of the duct, the boundary conditions are not obvious at all from a mechanical point of view (in our opinion at least!). A first attempt in [5] was to prescribe homogeneous Dirichlet boundary conditions on the potential function φ. This facilitates the control analysis of the coupled system considerably, but it should be confessed that this is not a very realistic condition. A more physically founded one consists of prescribing the mass flow. Let us explain how it can be written mathematically. Let us first recall from classical fluid mechanics that the acoustic pressure p_a and the mass density variation ϱ_a are such that (ϱ_0 is the mass density of the steady flow)

$$p_a = c_f^2 \varrho_a = -\varrho_0 \left[\frac{\partial \varphi}{\partial t} + U \frac{\partial \varphi}{\partial x} \right]. \tag{3}$$

Let us denote by D the mass flow at the extremities of the duct. If S is the cross-section area, the variation of D at first order is

$$\delta D = S \left[\varrho_0 \frac{\partial \varphi}{\partial x} + U \varrho_a \right]. \tag{4}$$

Therefore, from (3) and (4), one deduces that (we set $M = U/c_f^2$, which is the Mach

number and is assumed to be smaller than 1 in all the text)

$$\delta D = -S\frac{U\varrho_0}{c_f^2}\left[\frac{\partial\varphi}{\partial t} + U\left(1-\frac{1}{M^2}\right)\frac{\partial\varphi}{\partial x}\right]. \tag{5}$$

Finally, the conservation of the mass flow at the extremities of the flow duct will be written as

$$\left[\frac{\partial\varphi}{\partial t} + U\left(1-\frac{1}{M^2}\right)\frac{\partial\varphi}{\partial x}\right](0,t) = \left[\frac{\partial\varphi}{\partial t} + U\left(1-\frac{1}{M^2}\right)\frac{\partial\varphi}{\partial x}\right](L,t) = 0 \qquad \forall t \in]0,T[. \tag{6}$$

From the mathematical point of view, the previous condition corresponds to the normal derivative with respect to the operator involved in (1) and (2). The function φ is defined up to an arbitrary constant (with respect to the coordinate x). This constant has no physical meaning, and we eliminate it by a convenient condition for the mathematical aspects of our analysis. Therefore we prescribe the additional condition that was not necessary for a Dirichlet condition:

$$\int_{L_1}^{L_2} \varphi = 0 \ \ \forall t \in]0,T[. \tag{7}$$

In the following it will be convenient to use the definition

$$H_m^1(]0,L[) = \left\{ \psi \in H^1(]0,L[),\ \int_{L_1}^{L_2} \psi = 0 \right\}. \tag{8}$$

Let us now introduce a variational formulation for (1) or (2), assuming that there is a smooth enough solution (it will be justified in the following). By multiplying (1) or (2) by an arbitrary element ψ in the space $H^1(]0,L[)$ and integrating by parts, we obtain, because of (6),

$$\begin{aligned} \forall \psi \in H^1(]0,L[), \qquad & \int_0^L \frac{\partial^2\varphi}{\partial t^2}\psi + U\int_0^L \left(\frac{\partial^2\varphi}{\partial x \partial t}\psi - \frac{\partial\varphi}{\partial t}\frac{\partial\psi}{\partial x}\right) + (c_f^2 - U^2)\int_0^L \frac{\partial\varphi}{\partial x}\frac{\partial\psi}{\partial x} \\ & = ac_f^2 \int_{L_1}^{L_2} \left(\frac{\partial z}{\partial t} + U\frac{\partial z}{\partial x}\right)\psi + \int_\alpha^\beta w\psi. \end{aligned} \tag{9}$$

Let us notice that if we choose $\psi = \frac{\partial\varphi}{\partial t}$ in (9), assuming again that there exists a solution which is smooth enough, one has the first energetic invariant relation

$$\begin{aligned} & \frac{\partial}{\partial t}\left[\frac{1}{2}\int_0^L \left(\frac{\partial\varphi}{\partial t}\right)^2 + \frac{c_f^2 - U^2}{2}\int_0^L \left(\frac{\partial\varphi}{\partial x}\right)^2\right] \\ & = ac_f^2 \int_{L_1}^{L_2} \frac{\partial z}{\partial t}\frac{\partial\varphi}{\partial t} + U\frac{\partial z}{\partial t}\frac{\partial\varphi}{\partial x} + aUc_f^2 \frac{\partial}{\partial t}\left[\int_{L_1}^{L_2} \frac{\partial z}{\partial x}\varphi\right] + \int_\alpha^\beta w\frac{\partial\varphi}{\partial t} \end{aligned} \tag{10}$$

or else

$$\begin{aligned} & \left[\frac{1}{2}\int_0^L \left(\frac{\partial\varphi}{\partial t}\right)^2 + \frac{c_f^2 - U^2}{2}\int_0^L \left(\frac{\partial\varphi}{\partial x}\right)^2 - aUc_f^2 \int_{L_1}^{L_2} \frac{\partial z}{\partial x}\varphi\right]_0^t \\ & = ac_f^2 \int_0^t \int_{L_1}^{L_2} \left(\frac{\partial\varphi}{\partial t} + U\frac{\partial\varphi}{\partial x}\right)\frac{\partial z}{\partial t} + \int_0^t \int_\alpha^\beta w\frac{\partial\varphi}{\partial t}. \end{aligned} \tag{11}$$

Concerning the flexible structure, one can consider that it is a membrane or a shell. In the first case, the normal displacement z is a solution of

$$(12)\qquad \begin{cases} \dfrac{\partial^2 z}{\partial t^2} - c_s^2 \dfrac{\partial^2 z}{\partial x^2} = -b\left(\dfrac{\partial \varphi}{\partial t} + U\dfrac{\partial \varphi}{\partial x}\right) + u\chi_{[\alpha,\beta]} \quad \forall (x,t) \in]L_1, L_2[\times]0,T[\,, \\ z(L_1,t) = z(L_2,t) = 0 \quad \forall t \in]0,T[\,, \end{cases}$$

where c_s is the wave speed in the structure, b is a geometrical coefficient which also involves the ratio between the mass density of the fluid and that of the structure, and, finally, u is the external control force applied on the segment $[\alpha,\beta] \subset [L_1, L_2]$ of the structure. This control is the most important in our study. In fact, it is sufficient for proving an exact controllability of the solution of the coupled system.

If the structure is a clamped shell, then z is solution of

$$(13)\qquad \begin{cases} \dfrac{\partial^2 z}{\partial t^2} + D\left[\dfrac{\partial^4 z}{\partial x^4} + \gamma^4 z\right] = -b\left(\dfrac{\partial \varphi}{\partial t} + U\dfrac{\partial \varphi}{x}\right) + u\chi_{[\alpha,\beta]} \quad \forall (x,t) \in]L_1, L_2[\times]0,T[\,, \\ z(L_1,t) = \dfrac{\partial z}{\partial x}(L_1,t) = z(L_2,t) = \dfrac{\partial z}{\partial x}(L_2,t) = 0 \quad \forall t \in]0,T[\,, \end{cases}$$

where D is the bending modulus of the shell in the direction x_1 and γ is the Batdorf coefficient of the shell. Here again if z is a smooth enough solution of (12) or (13), one has the following:

(a) for a membrane structure,

$$(14)\qquad \frac{\partial}{\partial t}\left[\frac{1}{2}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial t}\right)^2 + \frac{c_s^2}{2}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial x}\right)^2\right] = -b\int_{L_1}^{L_2}\left(\frac{\partial \varphi}{\partial t} + U\frac{\partial \varphi}{\partial x}\right)\frac{\partial z}{\partial t} + \int_\alpha^\beta u\frac{\partial z}{\partial t};$$

(b) for a shell structure,

$$(15)\qquad \frac{\partial}{\partial t}\left[\frac{1}{2}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial t}\right)^2 + \frac{D}{2}\int_{L_1}^{L_2}\left(\frac{\partial^2 z}{\partial x^2}\right)^2 + \gamma^4 z^2\right] = -b\int_{L_1}^{L_2}\left(\frac{\partial \varphi}{\partial t} + U\frac{\partial \varphi}{\partial x}\right)\frac{\partial z}{\partial t} + \int_\alpha^\beta u\frac{\partial z}{\partial t}.$$

It is possible to combine (11)–(14) or (11)–(15) in order to derive an energy invariance. Let us set

$$(16)\qquad X = (\varphi, z)(x,t)$$

and

$$(17)\qquad \begin{cases} a^m(X,X) = (c_f^2 - U^2)\displaystyle\int_0^L \left(\frac{\partial \varphi}{\partial x}\right)^2 + \frac{ac_f^2c_s^2}{b}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial x}\right)^2 - 2aUc_f^2\int_{L_1}^{L_2}\frac{\partial z}{\partial x}\varphi, \\ a^c(X,X) = (c_f^2 - U^2)\displaystyle\int_0^L \left(\frac{\partial \varphi}{\partial x}\right)^2 + \frac{ac_f^2c_s^2}{b}\int_{L_1}^{L_2}\left(\frac{\partial^2 z}{\partial x^2}\right)^2 - 2aUc_f^2\int_{L_1}^{L_2}\frac{\partial z}{\partial x}\varphi. \end{cases}$$

A solution of the coupled model (9)–(12) or (13) is such that (we set $a = a^m$ *or* a^c, depending on whether the structure is a membrane or a shell)

$$(18)\qquad \frac{\partial}{\partial t}\left[\frac{1}{2}\int_0^L \left(\frac{\partial \varphi}{\partial t}\right)^2 + \frac{ac_f^2}{2b}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial t}\right)^2 + \frac{1}{2}a(X,X)\right](t) = \frac{ac_f^2}{b}\int_\alpha^\beta u\frac{\partial z}{\partial t} + \int_\alpha^\beta w\frac{\partial \varphi}{\partial t}.$$

Let us now introduce a change of variables by setting

$$
\begin{aligned}
&X(x,t) = e^{\lambda t}\tilde{X}(x,t),\ \ X=(\varphi,z),\ \tilde{X}=(\tilde{\varphi},\tilde{z}), \qquad \text{where}\\
&\lambda\in R,\ (\tilde{\varphi},\tilde{z})\in H^1(]0,L[)\times H_0^1(]L_1,L_2[).
\end{aligned}
\tag{19}
$$

Then $\tilde{X}$ satisfies

$$
\begin{aligned}
&\frac{\partial}{\partial t}\left[e^{2\lambda t}\left(\int_0^L\left\{\left(\frac{\partial\tilde{\varphi}}{\partial t}\right)^2+2\lambda\tilde{\varphi}\frac{\partial\tilde{\varphi}}{\partial t}\right\}+\frac{ac_f^2}{b}\int_{L_1}^{L_2}\left\{\left(\frac{\partial\tilde{z}}{\partial t}\right)^2+2\lambda\tilde{z}\frac{\partial\tilde{z}}{\partial t}\right\}+\frac{ac_f^2}{b}+a_\lambda(\tilde{X},\tilde{X})\right)\right]\\
&=\frac{2ac_f^2}{b}\int_\alpha^\beta e^{\lambda t}u(x,t)\left(\frac{\partial\tilde{z}}{\partial t}+\lambda\tilde{z}\right)dx+2\int_\alpha^\beta e^{\lambda t}w(x,t)\left(\frac{\partial\tilde{\varphi}}{\partial t}+\lambda\tilde{\varphi}\right)dx,
\end{aligned}
\tag{20}
$$

where we have used the notation

$$
a_\lambda(\tilde{X},\tilde{X})=\lambda^2\left(\int_0^L\tilde{\varphi}^2+\frac{ac_f^2}{b}\int_{L_1}^{L_2}\tilde{z}^2\right)+a(\tilde{X},\tilde{X}).
\tag{21}
$$

It is useful to notice that, from physical arguments, the coefficients a and b are both strictly positive. The stability of a solution can therefore be discussed with $u=w=0\ \forall(x,t)\in]\alpha,\beta[\times]0,T[$. The basic point is to characterize the eigenvalues of the bilinear form $a(.,.)$. If all of them are positive, then the system is stable because the global energy remains bounded with respect to time. But if there exist negative eigenvalues, one can always choose λ large enough that the following quantity remains positive:

$$
\text{pseudoenergy}=\int_0^L\left\{\left(\frac{\partial\tilde{\varphi}}{\partial t}\right)^2+2\lambda\tilde{\varphi}\frac{\partial\tilde{\varphi}}{\partial t}\right\}+\frac{ac_f^2}{b}\int_{L_1}^{L_2}\left\{\left(\frac{\partial\tilde{z}}{\partial t}\right)^2+\lambda\tilde{z}\frac{\partial\tilde{z}}{\partial t}\right\}+a_\lambda(\tilde{X},\tilde{X}).
$$

The terms $\int_{L_1}^{L_2}\tilde{\varphi}\frac{\partial\tilde{\varphi}}{\partial t}$ and $\int_{L_1}^{L_2}\tilde{z}\frac{\partial\tilde{z}}{\partial t}$ can be bounded using the Cauchy–Schwarz inequality. For instance,

$$
\lambda\int_{L_1}^{L_2}\tilde{\varphi}\frac{\partial\tilde{\varphi}}{\partial t}\le\frac{\lambda^2}{2}\int_0^L(\tilde{\varphi})^2+\frac{1}{2}\int_0^L\left(\frac{\partial\tilde{\varphi}}{\partial t}\right)^2,
$$

and the same thing can be used for z. In fact, it will appear in the following that the generalized Steklov eigenvalue problem can be useful in characterizing the velocities U_c at which a flutter phenomenon (i.e., an unstability) can occur.

3. Existence, uniqueness, and stability of solutions.

3.1. Eigenmodes for the fluid. The first step is to define the eigenmodes of vibration for the fluid. Assuming that the structure is rigid, we set

$$
\begin{cases}
-(c_f^2-U^2)\dfrac{d^2\Phi^f}{dx^2}=\lambda^f\Phi^f,\ \ 0<x<L,\ \ \displaystyle\int_{L_1}^{L_2}\Phi^f=0,\\
\dfrac{d\Phi^f}{dx}(0)=\dfrac{d\Phi^f}{dx}(L)=0,\ \ \displaystyle\int_0^L|\Phi^f|^2=1.
\end{cases}
\tag{22}
$$

It is classical that in this particular case the solution (Φ_n^f,λ_n^f) can be computed analytically. Another useful set of functions for our analysis is the generalized Steklov

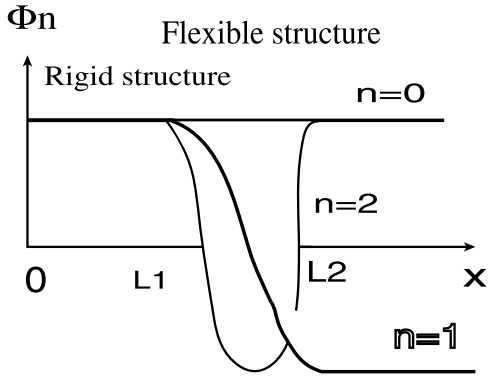

FIG. 3. *The generalized Steklov eigenmodes.*

one, which is defined as the solution of

$$\text{(23)}\qquad \begin{cases} -(c_f^2 - U^2)\dfrac{d^2\Phi^{sk}}{dx^2} = \lambda^{sk}\Phi^{sk}\chi_{[L_1,L_2]}, \;\; 0 < x < L, \\ \dfrac{d\Phi^{sk}}{dx}(0) = \dfrac{d\Phi^{sk}}{dx}(L) = 0, \;\; \displaystyle\int_{L_1}^{L_2} |\Phi^{sk}|^2 = 1, \; \Phi_n^{sk} \in H_m^1(]0, L[), \end{cases}$$

where $\chi_{[L_1,L_2]}$ is the characteristic function of the segment $[L_1, L_2]$. Here again the eigenmodes can be computed analytically (see Figure 3). It is interesting for our purpose to give their expressions:

$$\text{(24)}\qquad \begin{cases} \Phi_n^{sk}(x) = \pm A, \; 0 < x < L_1, \; L_2 < x < L, \\ \Phi_n^{sk}(x) = A\cos\left(\dfrac{n\pi(x - L_1)}{L_2 - L_1}\right), \;\; A = \sqrt{\dfrac{2}{L_2 - L_1}}, \\ \lambda_n^{sk} = \dfrac{n^2\pi^2(c_f^2 - U^2)}{(L_2 - L_1)^2}. \end{cases}$$

An important property for our purpose is the next one:

$$\forall n \geq 1, \qquad \int_{L_1}^{L_2} \Phi_n^{sk}(x)dx = 0.$$

Let us now consider a function φ in the space $H^1(]0, L[)$. We associate the new function $\delta\varphi$ defined by

$$\text{(25)}\qquad \delta\varphi = \varphi - \frac{1}{L_2 - L_1}\int_{L_1}^{L_2} \varphi(x)dx.$$

The second term on the right-hand side is a constant function on $]0, L[$. Furthermore, we have the property

$$\int_{L_1}^{L_2} \delta\varphi = 0, \quad \text{and hence} \quad \delta\varphi \in H_m^1(]0, L[),$$

which proves that $\delta\varphi$ is orthogonal to constant functions in the space $L^2(]L_1, L_2[)$. Therefore, from the min-max theorem applied to the generalized Steklov problem, one obtains (let us recall that we assumed that $U < c_f$!)

$$\forall \varphi \in H^1(]0, L[),\ (c_f^2 - U^2)\int_0^L \left|\frac{d\varphi}{dx}\right|^2 = (c_f^2 - U^2)\int_{L_1}^{L_2} \left|\frac{d\delta\varphi}{dx}\right|^2 \geq \lambda_1^{sk}\int_{L_1}^{L_2} |\delta\varphi|^2. \tag{26}$$

Furthermore,

$$\begin{cases} \forall z \in H_0^1(]L_1, L_2[),\ \dfrac{ac_s^2c_f^2}{b}\displaystyle\int_{L_1}^{L_2}\left|\frac{dz}{dx}\right|^2 - 2aUc_f^2\int_{L_1}^{L_2}\frac{dz}{dx}\varphi \\ \qquad\qquad = \dfrac{ac_f^2c_s^2}{b}\left[\displaystyle\int_{L_1}^{L_2}\left(\frac{dz}{dx} - \frac{Ub}{c_s^2}\delta\varphi\right)^2 - \frac{U^2b^2}{c_s^4}\int_{L_1}^{L_2}|\delta\varphi|^2\right]. \end{cases} \tag{27}$$

Therefore ($\delta\varphi$ is defined from φ by (25)),

$$\begin{cases} \forall X = (\varphi, z) \in H^1(]0, L[) \times H_0^1(]L_1, L_2[), \\ a^m(X, X) \geq \left[\lambda_1^{sk} - \dfrac{abc_f^2U^2}{c_s^2}\right]\displaystyle\int_{L_1}^{L_2}|\delta\varphi|^2 + \frac{ac_f^2c_s^2}{b}\int_{L_1}^{L_2}\left(\frac{\partial z}{\partial x} - \frac{Ub}{c_s^2}\delta\varphi\right)^2. \end{cases} \tag{28}$$

Finally, if the following condition is satisfied (we set $\eta_1^{sk}(c_f^2 - U^2) = \lambda_1^{sk}$),

$$(c_f^2 - U^2)\eta_1^{sk} > abU^2\left(\frac{c_f}{c_s}\right)^2,$$

or else (U_c is called a critical velocity for the steady flow)

$$U < U_c = \frac{c_f}{\sqrt{1 + \dfrac{ab}{\eta_1^{sk}}\left(\dfrac{c_f}{c_s}\right)^2}} < c_f, \tag{29}$$

then one obtains from (18)

$$a^m(X, X) \geq c_0[|\varphi|_{1,0L}^2 + ||z||_{1,L_1L_2}^2],$$

and therefore there exists a positive constant c_1 such that

$$\begin{aligned} &\left(\left|\left|\frac{\partial\varphi}{\partial t}\right|\right|_{0,0L}^2 + \left|\left|\frac{\partial z}{\partial t}\right|\right|_{0,0L}^2 + |\varphi|_{1,0L}^2 + ||z||_{1,L_1L_2}^2\right)(t) \\ &\leq c_1\left[\left(\left|\left|\frac{\partial\varphi}{\partial t}\right|\right|_{0,0L}^2 + \left|\left|\frac{\partial z}{\partial t}\right|\right|_{0,0L}^2 + |\varphi|_{1,0L}^2 + ||z||_{1,L_1L_2}^2\right)(0) + \int_0^t\int_\alpha^\beta u^2(x,\xi)dxd\xi\right]. \end{aligned} \tag{30}$$

Remark 1. From the expression of the Steklov eigenvalue λ_1^{sk}, we deduce that

$$\eta_1^{sk} = \frac{\pi^2}{(L_2 - L_1)^2},$$

that $\lambda_1^{sk} \to \infty$ when $|L_2 - L_1| \to 0$, and therefore, from (29), $U_c \to c_f$. Conversely, when $|L_2 - L_1|\sqrt{ab} \to \infty$, one has the asymptotic behavior for the critical value U_c:

$$U_c \simeq c_s\frac{\pi}{|L_2 - L_1|}\frac{1}{\sqrt{ab}}.$$

Remark 2. For a shell structure, one has

$$\forall z \in H_0^2(]L_1, L_2[), \qquad \frac{Dac_f^2}{b}\left[\int_{L_1}^{L_2}\left|\frac{d^2z}{dx^2}\right|^2 + \gamma^4 z^2\right] \geq \frac{Dac_f^2\pi^2}{b(L_2-L_1)^2}\int_{L_1}^{L_2}\left|\frac{dz}{dx}\right|^2,$$

and thus similar results can be obtained. For instance, one obtains the new critical value for the steady flow velocity:

$$U_c = \frac{c_f}{\sqrt{1 + \dfrac{abc_f^2(L_2-L_1)^2}{D\pi^2}}}. \tag{31}$$

3.2. The eigenmodes for the flexible structure. Let us introduce now the eigenvectors of the flexible structure (for a membrane, for instance), which can be explicited analytically:

$$\begin{cases} -c_s^2\dfrac{d^2Z^s}{dx^2} = \lambda^s Z^s, \quad L_1 < x < L_2, \\ Z^s(L_1) = Z^s(L_2) = 0, \quad \displaystyle\int_{L_1}^{L_2}|Z^s|^2 = 1. \end{cases} \tag{32}$$

The solutions are

$$Z_n^s(x) = \sqrt{\frac{2}{L_2-L_1}}\sin\left(\frac{n\pi(x-L_1)}{L_2-L_1}\right). \tag{33}$$

A similar system can be explicated for a shell structure.

3.3. Existence and uniqueness of solutions for $U < c_f$. In order to simplify the presentation, we restrict the analysis to the case of a membrane structure, but it could be extended to a shell. Let us introduce the following approximation spaces:

$$\begin{cases} V^N = \left\{\varphi = \displaystyle\sum_{1\leq n\leq N}\alpha_n\Phi_n^f\right\}, \\ Z^N = \left\{z = \displaystyle\sum_{1\leq n\leq N}\beta_n Z_n^s\right\}. \end{cases} \tag{34}$$

Then the approximate solution $(\varphi^N, z^N) \in C^1([0,T]; V^N \times Z^N)$ is defined as the unique solution of the finite dimensional differential equation

$$\begin{cases} \forall\psi \in V^N, & \displaystyle\int_0^L \frac{\partial^2\varphi^N}{\partial t^2}\psi + U\int_0^L\left(\frac{\partial^2\varphi^N}{\partial x\partial t}\psi - \frac{\partial\varphi^N}{\partial t}\frac{\partial\psi}{\partial x}\right) \\ & \qquad + (c_f^2 - U^2)\displaystyle\int_0^L\frac{\partial\varphi^N}{\partial x}\frac{\partial\psi}{\partial x} \\ & \qquad = ac_f^2\displaystyle\int_{L_1}^{L_2}\left(\frac{\partial z^N}{\partial t} + U\frac{\partial z^N}{\partial x}\right)\psi + \int_\alpha^\beta w\psi, \\ \forall v \in Z^N, & \displaystyle\int_{L_1}^{L_2}\frac{\partial^2 z^N}{\partial t^2}v + c_s^2\int_{L_1}^{L_2}\frac{\partial z^N}{\partial x}\frac{\partial v}{\partial x} \\ & \qquad = -b\displaystyle\int_{L_1}^{L_2}\left(\frac{\partial\varphi^N}{\partial t} + U\frac{\partial\varphi^N}{\partial x}\right)v + \int_\alpha^\beta uv. \end{cases} \tag{35}$$

The initial conditions satisfied by (φ^N, z^N) are defined from those of the continuous model by taking the L^2 projection of both (φ^N, z^N) and $(\frac{\partial \varphi^N}{\partial t}, \frac{\partial z^N}{\partial t})$. The existence and uniqueness theorem is then derived from a priori energy estimates by setting $\psi = \frac{\partial \varphi^N}{\partial t}$ and $v = \frac{\partial z^N}{\partial t}$ in (35) when $U < U_c$. Then the weak convergence of a subsequence to a weak solution of the variational coupled model can be proved from classical strategies. When $U_c < U < c_f$, a spectrum translation can be used as we mentioned in (19)–(20). But even if existence and uniqueness are still true, an unstability can appear. For details concerning the existence and uniqueness theorem, we refer to the paper [6]. In order to characterize more precisely the unstabilities which can occur for $U > U_c$ (U_c is only a lower bound), let us consider the particular case where $L_1 = 0$ and $L_2 = L$. In such a configuration the Steklov basis Φ_n^{sk} is identical to the one used for the fluid Φ_n^f. The solution (φ, z) of the coupled model can be expanded in the basis of the eigenmodes of the fluid, on the one hand, and of the structure, on the other hand. Therefore we set (because $\{\Phi_n^f\}$ and $\{Z_n^s\}$ are Hilbert bases of, respectively, $H^1(]0, L[)$ and $H_0^1(]0, L[)$)

$$\left\{ \begin{array}{l} \varphi(x,t) = \displaystyle\sum_{n\geq 1} \alpha_n(t)\Phi_n^f(x), \\ \\ z(x,t) = \displaystyle\sum_{n\geq 1} \beta_n(t) Z_n^s(x), \end{array} \right. \tag{36}$$

where we recall that

$$\Phi_n^f(x) = \sqrt{\frac{2}{L}} \cos\left(\frac{n\pi x}{L}\right), \qquad Z_n^s(x) = \sqrt{\frac{2}{L}} \sin\left(\frac{n\pi x}{L}\right).$$

Introducing these expressions of φ and z into the variational formulation, we obtain (the control functions u and w are supposed to be zero and one can observe that the second term in the fluid equation disappears)

$$\left\{ \begin{array}{l} \dfrac{\partial^2 \alpha_n}{\partial t^2} + \mu_n^2(c_f^2 - U^2)\alpha_n - a c_f^2 U \mu_n \beta_n = 0, \\ \\ \dfrac{\partial^2 \beta_n}{\partial t^2} + \mu_n^2 c_s^2 \beta_n - bU\mu_n \alpha_n = 0 \end{array} \right. \tag{37}$$

(we set $\mu_n = \frac{n\pi}{L}$ for the sake of brevity). The solutions $(\alpha_n, \beta_n)(t)$ can be analyzed from the eigenvalues of the *stiffness matrix* of (37). Let us denote them by λ. They are the solutions of the characteristic equation of (37):

$$\lambda^2 + \lambda\mu_n^2(c_s^2 + c_f^2 - U^2) + \mu_n^4(c_f^2 - U^2)c_s^2 - ab\mu_n^2 U^2 c_f^2 = 0. \tag{38}$$

If $\lambda \in R$, then one can check directly that $\lambda > 0$ (see the product and the sum of the roots). Then the solutions (α_n, β_n) are stable (i.e., sine and cosine functions of time with pulsation equal to $\sqrt{\lambda}$). But if λ is a complex number, the solutions of (37) can be exponentially increasing with respect to time. In fact, using an eigenvector basis (assuming that the two eigenvalues are distinct), (37) can also be written as

follows:

$$\frac{\partial^2 \xi_n}{\partial t^2} + (d_0 \pm i d_1)\xi_n = 0, \tag{39}$$

where $d_0 \pm i d_1$ are the roots of (38). Thus, whatever is the sign of d_1, one of the two roots of the characteristic equations of (37) leads to an exponentially increasing solution with respect to time. The point is to characterize the critical velocity U_f at which the discriminant of (38) is zero, because for $U = 0$ the two roots are real and positive, and their product remains also positive. One obtains

$$U^4\mu_n^4 - 2\mu_n^2 U^2(\mu_n^2(c_f^2 - c_s^2) - 2abc_f^2) + \mu_n^4(c_f^2 - c_s^2)^2 = 0. \tag{40}$$

There exist real and positive roots in U to this equation if and only if

$$\begin{cases} \text{(i) } \mu_n^2(c_f^2 - c_s^2) - abc_f^2 < 0 & \text{(real roots)}, \\ \text{(ii) } \mu_n^2(c_f^2 - c_s^2) - 2abc_f^2 < 0 & \text{(positivity of the real parts of the roots)}. \end{cases} \tag{41}$$

The first condition implies the second one. Let us recall that we assumed that $U < c_f$ and for physical reasons the numbers a and b are both positive. Therefore the flutter phenomenon occurs if and only if $c_s < c_f$ and for the values of n (if there are any!) such that

$$\mu_n < \frac{\sqrt{ab}}{\sqrt{1 - \left(\dfrac{c_s}{c_f}\right)^2}}. \tag{42}$$

Hence, only a finite number of values of n lead to a flutter mechanism. All of them correspond to homogeneous boundary conditions at the extremities of the tube ($x = 0$ and $x = L$). However, the acoustic pressure is not zero at these points. More realistic cases (i.e., $0 < L_1 < L_2 < L$) can be treated numerically using a finite element method, but unfortunately, not analytically. From a mechanical point of view, the flutter phenomenon is a coupling between two eigenmodes which have the same frequencies. One captures the energy from the steady flow, and the other stores it. In fact, the flutter mechanism is generally destructive and thus avoided. Nevertheless it can be interesting to use the phenomenon in order to increase the efficiency of the control system that we discuss in the following. The principle would be to transfer the acoustic energy from the flow into the structure and to kill it there. But clearly such a strategy can be catastrophic whenever the control system fails. It is worth noting that the condition $c_s < c_f$ is precisely the same as that which enables the existence of local waves in two dimensional or three dimensional fluid-structure interaction. This surprising aspect has been discussed in [11]. Concerning the Stoneley waves in inhomogeneous structures, one can refer to Stoneley [27], Cagniard [1], or Fung [9]. From a mechanical point of view the existence of local waves enables us to store energy in a close neighborhood of the structure. This is also what happens in the flutter mechanism.

In the next section we discuss the control law for a steady flow velocity which is smaller than the critical value U_c. Using the change of unknowns defined at (19), one can extend the result to the more general case: $U_c \leq U < c_f$. Unfortunately the analysis that has been developed in this paper cannot be extended to the supersonic case.

4. The control problem. Let us consider a system of initial conditions for the coupled model

$$\text{(43)}\qquad \begin{cases} \varphi(x,0)=\varphi_0(x), \quad \dfrac{\partial\varphi}{\partial t}(x,0)=\varphi_1(x) & \forall x\in\,]0,L[\,,\\ z(x,0)=z_0(x), \quad \dfrac{\partial z}{\partial t}(x,0)=z_1(x) & \forall x\in\,]L_1,L_2[\,, \end{cases}$$

Furthermore we assume that

$$\varphi_0\in H^1(]0,L[),\ \varphi_1\in L^2(]0,L[),\ z_0\in H_0^1(]L_1,L_2[),\ z_1\in L^2(]L_1,L_2[).$$

Then the solution of the coupled model is such that (it is assumed that $(u,w)\in [L^2(\,]\alpha,\beta[\times]0,T[\,)]^2$)

$$\text{(44)}\qquad \begin{cases} \varphi\in C^0([0,T];H^1(]0,L[))\cap C^1([0,T];L^2(]0,L[)),\\ z\in C^0([0,T];H_0^1(]L_1,L_2[))\cap C^1([0,T];L^2(]L_1,L_2[)). \end{cases}$$

Let us now define the following criterion as a function of the control variables $(u,w)\in[L^2(\,]\alpha,\beta[\times]0,T[\,)]^2$, where A,B,C,D and ε are positive constants:

$$\text{(45)}\qquad \begin{cases} J^\varepsilon(u,w)=\dfrac{A}{2}\displaystyle\int_0^L\left|\frac{\partial\varphi}{\partial t}(x,T)\right|^2+\frac{B}{2}\int_0^L\left|\frac{\partial\varphi}{\partial x}(x,T)\right|^2\\ \qquad\quad +\dfrac{C}{2}\displaystyle\int_{L_1}^{L_2}\left|\frac{\partial z}{\partial t}(x,T)\right|^2+\frac{D}{2}\int_{L_1}^{L_2}\left|\frac{\partial z}{\partial x}(x,T)\right|^2+\frac{\varepsilon}{2}\int_0^T\int_\alpha^\beta(u^2+w^2)(x,t). \end{cases}$$

Let us point out that the two control variables have been located at the same place. This is not necessary for our analysis, but it enables a few helpful simplifications. The existence and uniqueness of a solution to the next optimization problem is clear because of the strict convexity, the continuity, and the coerciveness of J^ε :

$$\text{(46)}\qquad \begin{cases} \min\ \ J^\varepsilon(u,w),\\ (u,w)\in[L^2(]\alpha,\beta[\times]0,T[)]^2. \end{cases}$$

In order to characterize the solution of (46), it is very convenient (in fact, it is necessary) to introduce the adjoint state function—say, ψ and d, which are the Lagrange multipliers of the fluid and of the structural equation, respectively. They are the solution of

$$\text{(47)}\qquad \begin{cases} \dfrac{\partial^2\psi}{\partial t^2}+2U\dfrac{\partial^2\psi}{\partial x\partial t}+(U^2-c_f^2)\dfrac{\partial^2\psi}{\partial x^2}\\ \qquad =b\left(\dfrac{\partial d}{\partial t}+U\dfrac{\partial d}{\partial x}\right)\chi_{[L_1,L_2]}(x)\quad \forall(x,t)\in\,]0,L[\times]0,T[\,,\\ \left[\dfrac{\partial\psi}{\partial t}+U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\psi}{\partial x}\right](0,t)=\left[\dfrac{\partial\psi}{\partial t}+U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\psi}{\partial x}\right](L,t)=0\quad \forall t\in\,]0,T[\,,\\ \dfrac{\partial^2 d}{\partial t^2}-c_s^2\dfrac{\partial^2 d}{\partial x^2}=-ac_f^2\left(\dfrac{\partial\psi}{\partial t}+U\dfrac{\partial\psi}{\partial x}\right)\quad \forall(x,t)\in\,]L_1,L_2[\times]0,T[\,,\\ d(L_1,t)=d(L_2,t)=0\ \forall t\in\,]0,T[\,, \end{cases}$$

and the final conditions are adjusted such that the gradient of J^ε could be represented

simply in the space $[L^2(]\alpha,\beta[\times]0,T[)]^2$. Thus we set

$$
\left\{\begin{array}{l}
d(x,T) = C\dfrac{\partial z}{\partial t}(x,T)\ \forall x \in]L_1,L_2[\,,\\
\dfrac{\partial d}{\partial t}(x,T) = -ac_f^2 A\dfrac{\partial \varphi}{\partial t}(x,T) - Dz(x,T)\ \forall x \in]L_1,L_2[\,,\\
\psi(x,T) = A\dfrac{\partial \varphi}{\partial t}(x,T)\ \forall x \in]0,L[\,,\\
\dfrac{\partial \psi}{\partial t}(x,T) = -2AU\dfrac{\partial^2 \varphi}{\partial x \partial t}(x,T) + bC\dfrac{\partial z}{\partial t}(x,T)\chi_{[L_1,L_2]} + B\dfrac{\partial^2 \varphi}{\partial x^2}(x,T)\\
\qquad\qquad + \left(AU + \dfrac{BM^2}{U(M^2-1)}\right)\left[\dfrac{\partial \varphi}{\partial t}(L,T)\delta_L(x) - \dfrac{\partial \varphi}{\partial t}(0,T)\delta_0(x)\right].
\end{array}\right. \tag{48}
$$

It is worth noting that if

$$
B = A(c_f^2 - U^2) \tag{49}
$$

(where $M = \frac{U}{c_f} < 1$), then the Dirac distributions which appear in the expression of $\frac{\partial \psi}{\partial t}(x,T)$ are canceled. Anyway, a simple computation leads to the following expressions for the derivatives of J^ε with respect to the control functions u and w:

$$
\left\{\begin{array}{l}
\dfrac{\partial J^\varepsilon}{\partial u}(u,w) = d + \varepsilon u \quad \text{on }]\alpha,\beta[\times]0,T[\,,\\[2ex]
\dfrac{\partial J^\varepsilon}{\partial w}(u,w) = \psi + \varepsilon w \quad \text{on }]\alpha,\beta[\times]0,T[\,.
\end{array}\right. \tag{50}
$$

The existence and uniqueness of a solution to the dual system (47)–(48) are not obvious, because the initial data for the primal model are not smooth enough. Usually one can use a series of eigenvectors in order to characterize the solution of a time dependent system (cf. Lions [20]). In our case this method cannot be applied because there is no spectral theorem for this coupled model. This is due to a loss of symmetry in the coupling terms and also to the first order derivatives with respect to the time variable. But another strategy can be used. We set

$$
\left\{\begin{array}{l}
\tilde{\psi}(x,t) = \tilde{\psi}_0(x) + \displaystyle\int_T^t \psi(x,s)ds,\\[2ex]
\tilde{d}(x,t) = \tilde{d}_0(x) + \displaystyle\int_T^t d(x,s)ds,
\end{array}\right. \tag{51}
$$

and from a quite classical computation we obtain that $(\tilde{\psi},\tilde{d})$ is a solution of

$$
\left\{\begin{array}{l}
\dfrac{\partial^2 \tilde{\psi}}{\partial t^2} + 2U\dfrac{\partial^2 \tilde{\psi}}{\partial x \partial t} + (U^2 - c_f^2)\dfrac{\partial^2 \tilde{\psi}}{\partial x^2}\\
\qquad = b\left(\dfrac{\partial \tilde{d}}{\partial t} + U\dfrac{\partial \tilde{d}}{\partial x}\right)\chi_{[L_1,L_2]}(x) \quad \forall (x,t) \in]0,L[\times]0,T[\,,\\
\left[\dfrac{\partial \tilde{\psi}}{\partial t} + U\left(1 - \dfrac{1}{M^2}\right)\dfrac{\partial \tilde{\psi}}{\partial x}\right](0,t) = \left[\dfrac{\partial \tilde{\psi}}{\partial t} + U\left(1 - \dfrac{1}{M^2}\right)\dfrac{\partial \tilde{\psi}}{\partial x}\right](L,t) = 0\ \forall t \in]0,T[\,,\\
\dfrac{\partial^2 \tilde{d}}{\partial t^2} - c_s^2\dfrac{\partial^2 \tilde{d}}{\partial x^2} = -ac_f^2\left(\dfrac{\partial \tilde{\psi}}{\partial t} + U\dfrac{\partial \tilde{\psi}}{\partial x}\right)\ \forall (x,t) \in]L_1,L_2[\times]0,T[\,,\\
\tilde{d}(L_1,t) = \tilde{d}(L_2,t) = 0\ \forall t \in]0,T[\,,
\end{array}\right. \tag{52}
$$

and the boundary conditions are

$$
(53)\quad \begin{cases} \tilde{d}(L_1,t)=\tilde{d}(L_2,t)=0 \quad \forall t\in\,]0,T[\,, \\ \left(\dfrac{\partial\tilde{\psi}}{\partial t}+U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\tilde{\psi}}{\partial x}\right)(x,t) \\ \qquad\qquad =\psi(x,T)+U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\tilde{\psi}_0}{\partial x}(x) \quad \forall (x,t)\in\{0,L\}\times\,]0,T[\,. \end{cases}
$$

The functions $(\tilde{\psi}_0,\tilde{d}_0)$ are chosen such that the right-hand sides of (52)–(53) are zero. Hence we set

$$
(54)\quad \begin{cases} -(c_f^2-U^2)\dfrac{\partial^2\tilde{\psi}_0}{\partial x^2}-Ub\dfrac{\partial\tilde{d}_0}{\partial x}=-\left(\dfrac{\partial\psi}{\partial t}(x,T)+2U\dfrac{\partial\psi}{\partial x}(x,T)-bd(x,T)\right), \\ -c_s^2\dfrac{\partial^2\tilde{d}_0}{\partial x^2}+aUc_f^2\dfrac{\partial\tilde{\psi}_0}{\partial x}=-\left(\dfrac{\partial d}{\partial t}(x,T)+ac_f^2\psi(x,T)\right), \\ \tilde{d}_0\in H_0^1(]L_1,L_2[), \qquad \tilde{\psi}_0\in H^1(]0,L[), \\ \dfrac{\partial\tilde{\psi}_0}{\partial x}(x)=\dfrac{M^2}{U(1-M^2)}\psi(x,T)=A\dfrac{\partial\varphi}{\partial x}(x,T)\ \forall x\in\{0,L\}. \end{cases}
$$

The final conditions that should be satisfied by $(\tilde{\psi},\tilde{d})$ are

$$
(55)\quad \begin{cases} \tilde{\psi}(x,T)=\tilde{\psi}_0(x)\ \forall x\in\,]0,L[\,, \\ \dfrac{\partial\tilde{\psi}}{\partial t}(x,T)=\psi(x,T)=A\dfrac{\partial\varphi}{\partial x}(x,T)\ \forall x\in\,]0,L[\,, \end{cases}
$$

$$
(56)\quad \begin{cases} \tilde{d}(x,T)=\tilde{d}_0(x)\ \forall x\in\,]L_1,L_2[\,, \\ \dfrac{\partial\tilde{d}}{\partial t}(x,T)=d(x,T)=C\dfrac{\partial z}{\partial t}(x,T)\ \forall x\in\,]L_1,L_2[\,. \end{cases}
$$

The existence and uniqueness of $(\tilde{\psi},\tilde{d})$ can then be obtained by the same result as that used for (φ,z) (i.e., the primal solution). Furthermore, one can check directly that (ψ,d), obtained by taking the time derivative of $(\tilde{\psi},\tilde{d})$, is the solution of the dual model (47)–(48). The only point to be checked is the existence and uniqueness of $(\tilde{\psi}_0,\tilde{d}_0)$. Let us therefore first introduce the notation

$$
X_0=(\tilde{\psi}_0,\tilde{d}_0)\in H^1(]0,L[)\times H_0^1(]L_1,L_2[),
$$

and then the bilinear form

$$
(57)\quad a_0(X_0,X_0)=(c_f^2-U^2)\int_0^L\left(\frac{\partial\tilde{\psi}_0}{\partial x}\right)^2+\frac{bc_s^2}{ac_f^2}\int_{L_1}^{L_2}\left(\frac{\partial\tilde{d}_0}{\partial x}\right)^2-2bU\int_{L_1}^{L_2}\left(\frac{\partial\tilde{d}_0}{\partial x}\right)\tilde{\psi}_0,
$$

and finally the linear form $l_0(.)$ defined by

$$
(58)\quad \begin{cases} l_0(X_0)=A(c_f^2-U^2)\displaystyle\int_0^L\frac{\partial\varphi}{\partial x}(x,T)\frac{\partial\tilde{\psi}_0}{\partial x}(x)-2AU\int_0^L\frac{\partial\varphi}{\partial t}(x,T)\frac{\tilde{\psi}_0}{\partial x}(x) \\ \qquad\qquad +bC\displaystyle\int_{L_1}^{L_2}\int_{L_1}^{L_2}\frac{\partial z}{\partial t}(x,T)\tilde{\psi}_0(x). \end{cases}
$$

First, $a_0(.,.)$ and $l_0(.)$ are respectively bilinear and linear. Furthermore, they are both continuous on the space $H^1(]0,L[)\times H_0^1(]L_1,L_2[)$ as soon as (φ,z), which appears in

the definition of $l_0(.)$, is a solution of the primal model with a finite energy initial condition. The last point to be checked in order to apply the Lax–Milgram theorem concerns the coerciveness of $a_0(.,.)$. In fact, it has already been proved in (28) when $U < U_c$. For $U > U_c$ one can use the Garding inequality based on a compactness argument [15]. Let us now discuss the regularity of the solution (ψ, d) and/or that of (φ, z). It is dependent on the initial conditions. If the energy of the initial condition is finite, then the solution (φ, z) is in the space

$$C^0([0,T]; H^1(]0,L[) \times H_0^1(]L_1,L_2[)) \cap C^1([0,T]; L^2(]0,L[) \times L^2(]L_1,L_2[)).$$

But taking the time or space derivatives of (φ, z) (and also of (ψ, d)), the same regularity can be obtained if the initial conditions and the control functions are smooth enough. Unfortunately a restriction appears again for the space derivatives because at $x = L_1$ and $x = L_2$ the functions z (and d) are continuous, but this is not true for the first order derivative. Hence one can only apply the previous method to first order derivatives with respect to the space coordinate. Nevertheless this is a sufficient regularity for our purpose in the multiplier method that we use in the next section.

5. Energy estimates on the adjoint state. Several a priori estimates can be obtained from the multiplier method of Lions [21]. Then from several additional tricks introduced by Lions [21] and Zuazua [31] we can derive local estimates which are useful for characterizing the initial data, and which can be exactly controlled with control functions in the space $L^2(]\alpha,\beta[\times]0,T[)$. All the following computations are performed assuming that the dual fields (ψ, d) are smooth enough. This is possible because of the regularity results mentioned previously. Then the inequalities obtained are extended by a density argument. The method being quite standard, we refer to the book of Lions [21] for the details.

5.1. Lagrangian invariants. Let us multiply (47) by $\frac{\partial \psi}{\partial t}$ and $\frac{\partial d}{\partial t}$. Then by integrating with respect to time from 0 to T and with respect to the space coordinate x, one obtains the following identities:

$$\epsilon(t) = \epsilon(0) \quad \forall t \in [0,T], \tag{59}$$

where ϵ is a pseudoenergy defined by

$$\left\{ \begin{array}{l} \epsilon(t) = \dfrac{1}{2}\displaystyle\int_0^L \left(\frac{\partial \psi}{\partial t}\right)^2 + \frac{b}{2ac_f^2}\int_{L_1}^{L_2} \left(\frac{\partial d}{\partial t}\right)^2 \\ \qquad + \dfrac{(c_f^2 - U^2)}{2}\displaystyle\int_0^L \left(\frac{\partial \psi}{\partial x}\right)^2 + \frac{bc_s^2}{2ac_f^2}\int_{L_1}^{L_2} \left(\frac{\partial d}{\partial x}\right)^2 - bU\int_{L_1}^{L_2} \frac{\partial d}{\partial x}\psi. \end{array} \right. \tag{60}$$

Then from (28), and if $U < U_c$, there exist two positive constants—say, c_0 and c_1—such that

$$c_0 E(t) \le \epsilon(t) \le c_1 E(t), \tag{61}$$

where $E(t)$ is the global energy of the fluid and the structure (but without the coupling term) and which is defined by

$$\left\{ \begin{array}{l} E(t) = \dfrac{1}{2}\displaystyle\int_0^L \left(\frac{\partial \psi}{\partial t}\right)^2 + \frac{b}{2ac_f^2}\int_{L_1}^{L_2} \left(\frac{\partial d}{\partial t}\right)^2 \\ \qquad + \dfrac{(c_f^2 - U^2)}{2}\displaystyle\int_0^L \left(\frac{\partial \psi}{\partial x}\right)^2 + \frac{bc_s^2}{2ac_f^2}\int_{L_1}^{L_2} \left(\frac{\partial d}{\partial x}\right)^2. \end{array} \right. \tag{62}$$

The difference between $\epsilon(t)$ and $E(t)$ is the coupling term, which is connected to the transfer of energy from the steady flow to the flexible structure through the compressible flow (transient waves), or conversely. The mechanical meaning of $E(t)$ is clear because it is just the sum of the energy of the fluid and that of the structure up to multiplicative constants.

Remark 3. The quantity $E(t)$ is the square of a norm as soon as $U < c_f$. However, from (59) and the inequalities (61), we proved that there exist four constants c_2, c_3, c_4, and c_5 such that

$$\text{(63)} \qquad \begin{cases} c_2 E(0) \le \epsilon(t) \le c_3 E(0), \\ c_4 E(0) \le E(t) \le c_5 E(t). \end{cases}$$

5.2. Eulerian invariants. Let us consider a point x_0 of the axis $\overrightarrow{ox}$; it will be specified later on. Let us now set $q = x - x_0$ ($\frac{\partial q}{\partial x} = 1$!). Then, by multiplying (47) by $\frac{\partial \psi}{\partial x} q$ for the fluid equation and by $\frac{\partial d}{\partial x} q$ for the structural equation, we obtain

$$\text{(64)} \quad \begin{cases} \text{(a)} \displaystyle\int_0^T \int_0^L \frac{\partial^2 \psi}{\partial t^2} \frac{\partial \psi}{\partial x} q + 2U \int_0^T \int_0^L \frac{\partial^2 \psi}{\partial x \partial t} \frac{\partial \psi}{\partial x} q + (U^2 - c_f^2) \int_0^T \int_0^L \frac{\partial^2 \psi}{\partial x^2} \frac{\partial \psi}{\partial x} q \\ \qquad\qquad = b \displaystyle\int_0^T \int_{L_1}^{L_2} \left(\frac{\partial d}{\partial t} + U \frac{\partial d}{\partial x} \right) \frac{\partial \psi}{\partial x} q, \\ \text{(b)} \displaystyle\int_0^T \int_{L_1}^{L_2} \frac{\partial^2 d}{\partial t^2} \frac{\partial d}{\partial x} q - c_s^2 \int_0^T \int_{L_1}^{L_2} \frac{\partial^2 d}{\partial x^2} \frac{\partial d}{\partial x} q \\ \qquad\qquad = -a c_f^2 \displaystyle\int_0^T \int_{L_1}^{L_2} \left(\frac{\partial \psi}{\partial t} + U \frac{\partial \psi}{\partial x} \right) \frac{\partial d}{\partial x} q. \end{cases}$$

Then from several integrations by parts one deduces that

$$\text{(65)} \quad \begin{cases} \text{(a)} \left[\displaystyle\int_0^L \frac{\partial \psi}{\partial t} \frac{\partial \psi}{\partial x} q \right]_0^T + U \left[\int_0^L \left(\frac{\partial \psi}{\partial x} \right)^2 q \right]_0^T - \frac{1}{2} \left[\left(\frac{\partial \psi}{\partial t} \right)^2 q \right]_0^L \\ + \dfrac{U^2 - c_f^2}{2} \left[\displaystyle\int_0^T \left(\frac{\partial \psi}{\partial x} \right)^2 q \right]_0^L + \frac{1}{2} \int_0^T \int_0^L \left(\frac{\partial \psi}{\partial t} \right)^2 \frac{\partial q}{\partial x} - \frac{U^2 - c_f^2}{2} \int_0^T \int_0^L \left(\frac{\partial \psi}{\partial x} \right)^2 \frac{\partial q}{\partial x} \\ \qquad\qquad = -b \left[\displaystyle\int_{L_1}^{L_2} \left(\frac{\partial d}{\partial x} \right) \psi q \right]_0^T - b \int_0^T \int_{L_1}^{L_2} \frac{\partial d}{\partial t} \psi \frac{\partial q}{\partial x} \frac{\partial q}{\partial x} \\ \qquad\qquad + b \displaystyle\int_0^T \int_{L_1}^{L_2} \frac{\partial d}{\partial x} \frac{\partial \psi}{\partial t} q + bU \int_0^T \int_{L_1}^{L_2} \frac{\partial \psi}{\partial x} \frac{\partial d}{\partial x} q, \\ \text{(b)} \left[\displaystyle\int_{L_1}^{L_2} \frac{\partial d}{\partial t} \frac{\partial d}{\partial x} q \right]_0^T - \frac{1}{2} \left[\left(\frac{\partial d}{\partial t} \right)^2 q \right]_{L_1}^{L_2} + \frac{1}{2} \int_0^T \int_{L_1}^{L_2} \left(\frac{\partial d}{\partial t} \right)^2 \frac{\partial q}{\partial x} \\ \qquad\qquad - \dfrac{c_s^2}{2} \left[\displaystyle\int_0^T \left(\frac{\partial d}{\partial x} \right)^2 q \right]_{L_1}^{L_2} + \frac{c_s^2}{2} \int_0^T \int_{L_1}^{L_2} \left(\frac{\partial d}{\partial x} \right)^2 \frac{\partial q}{\partial x} \\ \qquad\qquad = -a c_f^2 \displaystyle\int_0^T \int_{L_1}^{L_2} \left(\frac{\partial \psi}{\partial t} + U \frac{\partial \psi}{\partial x} \right) \frac{\partial d}{\partial t} q. \end{cases}$$

Multiplying the second relation by the coefficient $\frac{b}{ac_f^2}$ and adding this to (a), we obtain

$$
\begin{cases}
\dfrac{1}{2}\displaystyle\int_0^T\int_0^L\left(\frac{\partial\psi}{\partial t}\right)^2+\frac{c_f^2-U^2}{2}\int_0^T\int_0^L\left(\frac{\partial\psi}{\partial x}\right)^2+\frac{b}{2ac_f^2}\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\right)^2 \\
+\dfrac{bc_s^2}{2ac_f^2}\displaystyle\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial x}\right)^2+b\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\psi\right) \\
+\left[\displaystyle\int_0^L\frac{\partial\psi}{\partial t}\frac{\partial\psi}{\partial x}q+U\int_0^L\left(\frac{\partial\psi}{\partial x}\right)^2q+b\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial x}\psi\right)q+\frac{b}{ac_f^2}\int_{L_1}^{L_2}\frac{\partial d}{\partial t}\frac{\partial d}{\partial x}q\right]_0^T \\
=\dfrac{1}{2}\left[\displaystyle\int_0^T\left(\frac{\partial\psi}{\partial t}\right)^2q+(c_f^2-U^2)\left(\frac{\partial\psi}{\partial x}\right)^2q\right]_0^L+\frac{b}{2ac_f^2}\left[\int_0^T\left(\frac{\partial d}{\partial t}\right)^2q+c_s^2\left(\frac{\partial d}{\partial x}\right)^2q\right]_{L_1}^{L_2}.
\end{cases}
\tag{66}
$$

This equality enables one to prove a regularity result on the boundary term (as an element of the space $L^2(]0,T[)$), but the main point is the inverse inequality, which will give very interesting information on the control law. The method is similar to the one introduced by Lions [21] and his coworkers [14], [29]. The new difficulty in our study concerns the coupling term

$$b\int_0^T\int_{L_1}^{L_2}\frac{\partial d}{\partial t}\psi.$$

The first point consists in noting that for any $\alpha>0$

$$\left|b\int_0^T\int_{L_1}^{L_2}\frac{\partial d}{\partial t}\psi\right|\le\frac{b\alpha}{2}\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\right)^2+\frac{b}{2\alpha}\int_0^T\int_{L_1}^{L_2}\psi, \tag{67}$$

and if we introduce the smallest eigenvalue $\lambda_1^{sk}=\eta_1^{sk}(c_f^2-U^2)$ of the generalized Steklov problem (see (24)), we get

$$\left|b\int_0^T\int_{L_1}^{L_2}\frac{\partial d}{\partial t}\psi\right|\le\frac{b\alpha}{2}\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\right)^2+\frac{b}{2\alpha\eta_1^{sk}}\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial\psi}{\partial x}\right)^2. \tag{68}$$

Let us assume that the following geometrical condition is satisfied for a given Mach number M (one has $\eta_1^{sk}=\frac{\pi^2}{(L_2-L_1)^2}$):

$$ab<\eta_1^{sk}(1-M^2)\frac{\pi^2}{(L_2-L_1)^2}(1-M^2).$$

Then if the steady flow velocity U satisfies

$$U<c_f\sqrt{1-\frac{ab}{\eta_0^{sk}}}=U_0, \tag{69}$$

then one can find a number $\alpha > 0$ such that

$$
\begin{cases}
\dfrac{1}{2}\displaystyle\int_0^T\int_0^L\left(\frac{\partial\psi}{\partial t}\right)^2+\left(\frac{c_f^2-U^2}{2}-\frac{b}{2\alpha\eta_1^{sk}}\right)\int_0^T\int_0^L\left(\frac{\partial\psi}{\partial x}\right)^2 \\
+\left(\dfrac{b}{2ac_f^2}-\dfrac{b\alpha}{2}\right)\displaystyle\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\right)^2+\frac{c_s^2 b}{2ac_f^2}\int_0^T\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial x}\right)^2 \\
-2T_0\displaystyle\sup_{t\in[0,T]}\left[\frac{1}{2}\int_0^L\left(\frac{\partial\psi}{\partial t}\right)^2\right. \\
\qquad\left.+\left(\dfrac{c_f^2-U^2}{2}\right)\displaystyle\int_0^L\left(\frac{\partial\psi}{\partial x}\right)^2+\frac{b}{ac_f^2}\left(\frac{1}{2}\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial t}\right)^2+\frac{c_s^2}{2}\int_{L_1}^{L_2}\left(\frac{\partial d}{\partial x}\right)^2\right)\right] \\
\le\dfrac{1}{2}\left[\displaystyle\int_0^T\left(\frac{\partial\psi}{\partial t}\right)^2 q+(c_f^2-U^2)\left(\frac{\partial\psi}{\partial x}\right)^2 q\right]_0^L+\frac{b}{2ac_f^2}\left[\int_0^L\left(\frac{\partial d}{\partial t}\right)^2 q+c_s^2\left(\frac{\partial d}{\partial x}\right)^2 q\right]_{L_1}^{L_2},
\end{cases}
\tag{70}
$$

where we have set

$$
T_0=\min_{\theta>0}\left(\max\left(\frac{L}{c_f-U}+\frac{b}{\theta\eta_1^{sk}},\left(\frac{L_2-L_1}{ac_s c_f^2}+\theta\right)b\right)\right). \tag{71}
$$

Finally, setting

$$
\kappa=\max_{\alpha>0}\left(\min\left(1-\frac{b}{\alpha\eta_1^{sk}(c_f^2-U^2)},1-a\alpha c_f^2\right)\right) \tag{72}
$$

and because of (59), one obtains (see (69))

$$
\begin{cases}
(\kappa c_5 T-2T_0)E(0) \\
\le\dfrac{1}{2}\left[\displaystyle\int_0^T\left(\frac{\partial\psi}{\partial t}\right)^2 q+(c_f^2-U^2)\int_0^T\left(\frac{\partial\psi}{\partial x}\right)^2 q\right]_0^L \\
+\dfrac{b}{2ac_f^2}\left[\displaystyle\int_0^T\left(\frac{\partial d}{\partial t}\right)^2 q+\ c_s^2\int_0^T\left(\frac{\partial d}{\partial x}\right)^2 q\right]_{L_1}^{L_2}.
\end{cases}
\tag{73}
$$

Remark 4. The estimate (73) makes sense only if $\kappa > 0$. But one can notice that this condition is obvious if a or b is zero. This points out that the restriction is fully connected to the coupling between the fluid and the structure.

Remark 5. The assumptions required for justifying (73) are

$$
\begin{cases}
U<c_f\sqrt{1-\dfrac{ab}{\eta_1^{sk}}}<c_f, \\
ab<\eta_1^{sk}(1-M^2)=\dfrac{\pi^2}{(L_2-L_1)^2}(1-M^2), \\
U<\dfrac{c_f}{\sqrt{1+\dfrac{abc_f^2}{\eta_1^{sk}c_s^2}}}=U_c\ \ (<c_f!).
\end{cases}
\tag{74}
$$

But from the boundary conditions (recalling that $M = \frac{U}{c_f} < 1$),

$$\left\{ \begin{array}{ll} \dfrac{\partial d}{\partial t} = 0 & \text{for } x = L_1 \text{ and } L_2, \\ \dfrac{\partial \psi}{\partial t} = U \left(\dfrac{1}{M^2} - 1 \right) \dfrac{\partial \psi}{\partial x} & \text{for } x = 0 \text{ and } L, \end{array} \right. \tag{75}$$

and then assuming that (74) is satisfied, one deduces, setting $q = x - \frac{L_1+L_2}{2}$, that

$$\left\{ \begin{array}{l} (\kappa c_5 T - 2T_0) E(0) \leq \dfrac{L}{2} c_f^2 \left(\dfrac{1-M^2}{M^2} \right) \left[\displaystyle\int_0^T \left(\frac{\partial \psi}{\partial x} \right)^2 (0) + \left(\frac{\partial \psi}{\partial x} \right)^2 (L) \right] \\ \qquad + \dfrac{b(L_2 - L_1)}{2ac_f^2} \left[\displaystyle\int_0^T c_s^2 \left(\frac{\partial d}{\partial x} \right)^2 (L_1) + c_s^2 \left(\frac{\partial d}{\partial x} \right)^2 (L_2) \right]. \end{array} \right. \tag{76}$$

Remark 6. The coefficients a and b can be expressed with respect to the mass density of the structure—say, ϱ_s—and of the fluid (at rest)—say, ϱ_f—but also using the thickness of the structure—say, 2ε—and the inner radius of the flow duct—say, R. One has $ab = \frac{1}{\varepsilon R} \frac{\varrho_f}{\varrho_s}$.

6. Asymptotic behavior of the control problem when $\varepsilon \to 0$. Let us first introduce a formal asymptotic expansion of $(\varphi^\varepsilon, z^\varepsilon, u^\varepsilon)$ which is solution of the optimal control problem. Thus we set

$$\left\{ \begin{array}{l} (\varphi^\varepsilon, z^\varepsilon, u^\varepsilon) = (\varphi^0, z^0, u^0) + \varepsilon(\varphi^1, z^1, u^1) + \cdots, \\ (\psi^\varepsilon, d^\varepsilon) = (\psi^0, d^0) + \varepsilon(\psi^1, d^1) + \cdots. \end{array} \right. \tag{77}$$

Nothing guarantees the validity of this expansion. However, a convergence result will be proved when $\varepsilon \to 0$ as soon as the exact controllability conditions are satisfied. The first step consists in identifying the terms of order zero and one. The terms of order one enable us to characterize the optimal control u^0. In fact, this limit control is exactly the one given by the so-called H.U.M. method of Lions [21]. A few additional difficulties arise because of the coupling and the instabilities which can appear when the velocity U is large enough.

6.1. Identification of terms of order zero. By introducing (77) into the equations satisfied by $(\varphi^\varepsilon, z^\varepsilon, u^\varepsilon)$ and by equating the terms of same order in ε, one obtains the following necessary conditions:

(a) For the primal model,

$$\left\{ \begin{array}{l} \dfrac{\partial^2 \varphi^0}{\partial t^2} + 2U \dfrac{\partial^2 \varphi^0}{\partial x \partial t} + (U^2 - c_f^2) \dfrac{\partial^2 \varphi^0}{\partial x^2} \\ \qquad = ac_f^2 \left(\dfrac{\partial z^0}{\partial t} + U \dfrac{\partial z^0}{\partial x} \right) \chi_{[L_1, L_2]}(x) \quad \forall (x,t) \in]0, L[\times]0, T[, \\ \left[\dfrac{\partial \varphi^0}{\partial t} + U \left(1 - \dfrac{1}{M^2} \right) \dfrac{\partial \varphi^0}{\partial x} \right] (0,t) \\ \qquad = \left[\dfrac{\partial \varphi^0}{\partial t} + U \left(1 - \dfrac{1}{M^2} \right) \dfrac{\partial \varphi^0}{\partial x} \right] (L,t) = 0 \quad \forall t \in]0, T[, \\ \dfrac{\partial^2 z^0}{\partial t^2} - c_s^2 \dfrac{\partial^2 z^0}{\partial x^2} = -b \left(\dfrac{\partial \varphi^0}{\partial t} + U \dfrac{\partial \varphi^0}{\partial x} \right) \quad \forall (x,t) \in]L_1, L_2[\times]0, T[, \\ z^0(L_1, t) = z^0(L_2, t) = 0 \quad \forall t \in]0, T[. \end{array} \right. \tag{78}$$

The initial conditions satisfied by (φ^0, z^0) are those defined in (43).

(b) For the adjoint model,

$$
\left\{
\begin{array}{l}
\dfrac{\partial^2\psi^0}{\partial t^2} + 2U\dfrac{\partial^2\psi^0}{\partial x\partial t} + (U^2 - c_f^2)\dfrac{\partial^2\psi^0}{\partial x^2} \\
\qquad = b\left(\dfrac{\partial d^0}{\partial t} + U\dfrac{\partial d^0}{\partial x}\right)\chi_{[L_1,L_2]}(x) \quad \forall (x,t) \in]0,L[\times]0,T[\,, \\
\left[\dfrac{\partial\psi^0}{\partial t} + U\left(1 - \dfrac{1}{M^2}\right)\dfrac{\partial\psi^0}{\partial x}\right](0,t) \\
\qquad = \left[\dfrac{\partial\psi^0}{\partial t} + U\left(1 - \dfrac{1}{M^2}\right)\dfrac{\partial\psi^0}{\partial x}\right](L,t) = 0 \quad \forall t \in]0,T[\,, \\
\dfrac{\partial^2 d^0}{\partial t^2} - c_s^2\dfrac{\partial^2 d^0}{\partial x^2} = -ac_f^2\left(\dfrac{\partial\psi^0}{\partial t} + U\dfrac{\partial\psi^0}{\partial x}\right) \quad \forall (x,t) \in]L_1,L_2[\times]0,T[\,, \\
d^0(L_1,t) = d^0(L_2,t) = 0 \quad \forall t \in]0,T[\,.
\end{array}
\right. \tag{79}
$$

The final conditions satisfied by (ψ^0, d^0) are those defined in (48).

(c) For the optimality equations when two controls functions are used,

$$
d^0(x,t) = \psi^0(x,t) = 0 \ \ \forall (x,t) \in]\alpha,\beta[\times]0,T[\,. \tag{80}
$$

Remark 7. The existence and uniqueness of a solution to systems (78) and (79) can be obtained by the same method used for $(\varphi^\varepsilon, z^\varepsilon)$ and $(\psi^\varepsilon, d^\varepsilon)$.

Remark 8. From (80) and using the inverse inequality, we prove in the following that:

$$
(\psi^0, d^0) = 0.
$$

However, this inverse inequality will give much more information on the control and also on the space of initial data which can be controlled. Many of technical tricks are necessary, which are developed in section 7.

6.2. Exact controllability of noise in the duct with only the structural control. In this section we consider that there is only one control, which is the one applied on the structure (i.e., $w = 0$ and only u is active). The optimality condition is now restricted to the following one:

$$
d^0(x,t) = 0 \ \ \forall (x,t) \in]\alpha,\beta[\times]0,T[\,. \tag{81}
$$

This corresponds to a very simple version of the Holmgrem theorem for a coupled fluid-structure model. From (80) and using the structural equation, one deduces that

$$
\frac{\partial\psi^0}{\partial t} + U\frac{\partial\psi^0}{\partial x}(x,t) = 0 \ \ \forall (x,t) \in]\alpha,\beta[\times]0,T[\,.
$$

Therefore there exists a function k such that on $\ ]\alpha,\beta[\times]0,T[$

$$
\psi^0(x,t) = k(x - Ut).
$$

But from the fluid equation one has

$$
\frac{\partial^2\psi^0}{\partial t^2} + 2U\frac{\partial^2\psi^0}{\partial x\partial t} + (U^2 - c_f^2)\frac{\partial^2\psi^0}{\partial x^2} = -c_f^2\frac{\partial^2 k}{\partial x^2}(x - Ut) = 0 \ \ \forall (x,t) \in]\alpha,\beta[\times]0,T[\,,
$$

and therefore there exist two constants F and G such that

$$\psi^0(x,t) = F(x-Ut) + G \ \ \forall (x,t) \in]\alpha,\beta[\times]0,T[\,. \tag{82}$$

Let us now multiply the equations of the adjoint state by $(\frac{\partial \psi^0}{\partial t}, \frac{\partial d^0}{\partial t})$, and let us integrate on $]0,\alpha[$ and $]\beta,L[$ separately. Because $d(\alpha,t) = d(\beta,t) = 0 \ \forall t \in]0,T[$ and $d^0(x,t) = 0 \ \forall (x,t) \in]\alpha,\beta[\times]0,T[$, from the expression of ψ^0 on $]\alpha,\beta[\times]0,T[$ given at (82), we obtain

$$\begin{cases} \dfrac{\partial .}{\partial t}[\epsilon^{0\alpha}] = -UF^2c_f^2, \\ \dfrac{\partial .}{\partial t}[\epsilon^{\beta L}] = UF^2c_f^2, \end{cases} \tag{83}$$

where $\epsilon^{0\alpha}$ (respectively, $\epsilon^{\beta L}$) is the quantity defined at (60), but where the integrals are restricted to $]0,\alpha[$ (respectively, $]\beta,L[$). By integrating (83) from 0 to t, we deduce that

$$\begin{cases} \epsilon^{0\alpha}(t) = \epsilon^{0\alpha}(0) - UFc_f^2t, \\ \epsilon^{\beta L}(t) = \epsilon^{\beta L}(0) + UFc_f^2t. \end{cases} \tag{84}$$

It is worth noting that for $U < U_c$ (see (29)) the quantity $\epsilon^{0\alpha}(t)$ is positive. Hence for t large enough, one has necessarily $F = 0$. But it is necessary to get rid of this time condition which depends on F. Therefore we use again the multiplier method with the equations satisfied by the adjoint state. The multipliers are $\frac{\partial \psi^0}{\partial x}(x-x_0)$ and $\frac{\partial d^0}{\partial x}(x-x_0)$ with, respectively, $x_0 = 0$ for the set $]0,\alpha[$ and $x_0 = L$ for $]\beta,L[$. Assuming again that $U < U_c$ (see (29)), one deduces from a computation similar to the one which led to (66) that the following inequalities hold:

$$\begin{cases} \displaystyle\int_0^T \epsilon^{0\alpha}(t) - T_0(\epsilon^{0\alpha}(0) + \epsilon^{0\alpha}(T)) \le \frac{\alpha}{2}F^2Tc_f^2, \\ \displaystyle\int_0^T \epsilon^{\beta L}(t) - T_0(\epsilon^{\beta L}(0) + \epsilon^{\beta L}(T)) \le \frac{L-\beta}{2}F^2Tc_f^2, \end{cases} \tag{85}$$

where T_0 is a constant homogeneous to time and which could be adjusted separately on $]0,\alpha[$ and $]\beta,L[$. From (85) and using (84), we deduce that, for instance, on $]\beta,L[$ one has

$$\int_0^T \epsilon^{\beta L}(t) - 2T_0\epsilon^{\beta L}(0) - UT_0TF^2c_f^2 \le \frac{L-\beta}{2}F^2Tc_f^2, \tag{86}$$

or else

$$(T-2T_0)\epsilon^{\beta L}(0) + \frac{UF^2c_f^2}{2}T^2 - T_0TUFc_f^2 \le \frac{L-\beta}{2}F^2Tc_f^2. \tag{87}$$

One can arrange the previous expression such that

$$(T-2T_0)\epsilon^{\beta L}(0) + \frac{F^2c_f^2}{2}T(UT - 2T_0U - (L-\beta)) \le 0. \tag{88}$$

Let us consider that $T > 2T_0 + \frac{L-\beta}{U}$. Such a condition is possible if and only if $U > 0$. Then we conclude that $F = 0$. Thus we can also conclude that $\epsilon^{\beta L}(0) = 0$. From the

final condition which should be satisfied by $\psi^0(x,T)$ (see (48)), and because $\varphi^0(x,t)$, we prescribe on ϕ^0 the following condition ((see (7)):

$$\int_{L_1}^{L_2} \varphi^0(x,t)dx = 0 \ \forall t \in [0,T]; \tag{89}$$

one can also ensure that $G = 0$. Finally, we proved that

$$(\psi^0, d^0) = 0 \quad \forall (x,t). \tag{90}$$

When the steady velocity U is zero, then the function ψ^0 is linear with respect to the coordinate x on $]\alpha,\beta[\times]0,T[$. This proves that steady flows cannot be controlled even if they satisfy all the equations of the model for ψ^0, d^0. Let us summarize the previous results in the following theorem.

THEOREM 1. *Let us consider a set of initial data for the coupled model* $(\varphi_0, \varphi_1, z_0, z_1)$*, which are assumed to be smooth enough and such that* φ^0 *satisfies* (7)*. Then if* d^0 *is zero on the set* $]\alpha,\beta[\times]0,T[$*, and if*

(i) $T > 2T_0 + \frac{L-\beta}{U}$*, where* T_0 *is defined at* (71)*,*

(ii) U *satisfies* (74)*,*

then

$$(\psi^0, d^0) \equiv 0.$$

If $U = 0$*, then one only has* $\psi^0(x,t) = Fx + G$*.*

Remark 9. The results obtained in (89) are still true even if the control w^0 is also applied. But the proof is much easier in this latter case because the optimality condition implies directly that $\psi^0 = 0 \ \forall (x,t) \in]\alpha,\beta[$. This can be checked directly on the proof given previously. If the controllability is a general result which doesn't require the introduction of w (the second control function), it will enable us to characterize an exact control (u,w) in the space $[L^2(]\alpha,\beta[\times]0,T[)]^2$ for finite energy initial data.

Remark 10. The condition on T is not classical in control theory (see Lions [21]), but it can also be physically interpreted. First, for $U = 0$ it cannot be satisfied, because the information cannot travel with the particles along the duct and because the boundary conditions that we chose for the steady flow (i.e., uniform velocity) cannot be controlled. For $U \neq 0$ the condition on T means that a perturbation introduced at one extremity of the flow duct can cross the full length of the duct and return at the entrance. But it is also necessary to add the time necessary for the steady flow to cross the uncontrolled portion of the duct $(L - \beta)$.

Remark 11. A simple consequence of (89) is that the control (u^0, w^0) is exact. However, it is not yet defined. This is the goal of the next section.

Remark 12. A similar result to the one given in this section can be obtained for a control which is only applied to the fluid (i.e., $u = 0$ and $w \neq 0$).

6.3. Identification of terms of order one. The model characterizing $(\varphi^1, z^1, \psi^1 d^1)$ is similar to the one characterizing the terms of order zero. But only few of the equations are necessary in order to define (u^0, w^0), which is the formal limit (at this step) of $(u^\varepsilon, w^\varepsilon)$ when ε tends to zero. First, let us note that the optimality conditions give

$$u^0 + d^1 = 0, \ w^0 + \psi^1 = 0 \qquad \forall (x,t) \in]\alpha,\beta[\times]0,T[\,. \tag{91}$$

Then, setting $(u^0, w^0) = -(d^1, \psi^1)$ in the equations satisfied by (φ^0, z^0), we obtain

$$
\left\{
\begin{array}{l}
\forall \delta\varphi \in H^1(]0,L[),\ \displaystyle\int_0^L \frac{\partial^2\varphi^0}{\partial t^2}\delta\varphi + U\int_0^L \left(\frac{\partial^2\varphi^0}{\partial x\partial t}\delta\varphi - \frac{\partial\varphi^0}{\partial t}\frac{\partial\delta\varphi}{\partial x}\right) \\
\qquad\qquad + (c_f^2 - U^2)\displaystyle\int_0^L \frac{\partial\varphi^0}{\partial x}\frac{\partial\delta\varphi}{\partial x} \\
\qquad = ac_f^2\displaystyle\int_{L_1}^{L_2}\left(\frac{\partial z^0}{\partial t} + U\frac{\partial z^0}{\partial x}\right)\delta\varphi - \int_\alpha^\beta \psi^1\delta\varphi, \\
\forall \delta z \in H_0^1(]L_1, L_2[),\ \displaystyle\int_{L_1}^{L_2}\frac{\partial^2 z^0}{\partial t^2}\delta z + c_s^2\int_{L_1}^{L_2}\frac{\partial z^0}{\partial x}\frac{\partial\delta z}{\partial x} \\
\qquad = -b\displaystyle\int_{L_1}^{L_2}\left(\frac{\partial\varphi^0}{\partial t} + U\frac{\partial\varphi^0}{\partial x}\right)\delta z - \int_\alpha^\beta d^1\delta z.
\end{array}
\right. \tag{92}
$$

Let us assume that $(\delta\varphi, \delta z)$ is a solution of the adjoint state (as for (φ^1, d^1)). Thus we obtain (because at $t = T$, φ^0, $\frac{\partial\varphi^0}{\partial t}$, z^0, $\frac{\partial z^0}{\partial t}$ are zero)

$$
\left\{
\begin{array}{l}
\displaystyle\int_0^T\int_\alpha^\beta d^1\delta z + \psi^1\delta\varphi = \int_0^L \frac{\partial\varphi^0}{\partial t}(x,0)\delta\varphi(x,0) - \int_0^L \varphi^0(x,0)\frac{\partial\delta\varphi}{\partial t}(x,0) \\
+ 2U\displaystyle\int_0^L \frac{\partial\varphi^0}{\partial x}(x,0)\delta\varphi(x,0) - ac_f^2\int_{L_1}^{L_2} d^0(x,0)\delta\varphi(x,0) \\
+\displaystyle\int_{L_1}^{L_2}\frac{\partial z^0}{\partial t}(x,0)\delta z(x,0) - \int_{L_1}^{L_2} z^0(x,0)\frac{\partial\delta z^0}{\partial t}(x,0) + b\int_{L_1}^{L_2}\varphi^0(x,0)\delta z(x,0).
\end{array}
\right. \tag{93}
$$

Setting

$$
\left\{
\begin{array}{ll}
\Phi_0 = (\psi^1, d^1)(x,0), & \Phi_1 = \left(\dfrac{\partial\psi^1}{\partial t}, \dfrac{d^1}{\partial t}\right)(x,0), \\
\delta\Phi_0 = (\delta\psi, \delta z)(x,0), & \delta\Phi_1 = \left(\dfrac{\partial\delta\psi^1}{\partial t}, \dfrac{\partial\delta d^1}{\partial t}\right)(x,0),
\end{array}
\right. \tag{94}
$$

we introduce the following bilinear and linear forms:

$$
\left\{
\begin{array}{l}
\Lambda(\Phi, \delta\Phi) = \displaystyle\int_0^T\int_\alpha^\beta d^1\delta z + \psi^1\delta\varphi, \\
\qquad \text{where } \Phi = (\Phi_0, \Phi^1) \text{ and } \delta\Phi = (\delta\Phi_0, \delta\Phi^1), \\
L(\delta\Phi) = \displaystyle\int_0^L \frac{\partial\varphi^0}{\partial t}(x,0)\delta\varphi(x,0) - \int_0^L \varphi^0(x,0)\frac{\partial\varphi}{\partial t}(x,0) \\
+ 2U\displaystyle\int_0^L \frac{\partial\varphi^0}{\partial x}(x,0)\delta\varphi(x,0) - ac_f^2\int_{L_1}^{L_2} z^0(x,0)\delta\varphi(x,0) \\
+\displaystyle\int_{L_1}^{L_2}\frac{\partial z^0}{\partial t}(x,0)\delta z(x,0) - \int_{L_1}^{L_2} z^0(x,0)\frac{\partial\delta z}{\partial t}(x,0) + b\int_{L_1}^{L_2}\varphi^0(x,0)\delta z(x,0).
\end{array}
\right. \tag{95}
$$

Hence (92) can be formulated as follows:

$$
\left\{
\begin{array}{l}
\text{find } \Phi \in V^* \text{ such that} \\
\forall \delta\Phi \in V^*,\ \Lambda(\Phi, \delta\Phi) = L(\delta\Phi).
\end{array}
\right. \tag{96}
$$

The space V^* is not yet defined; it is the completed space with respect to the norm

$$\Phi \in [H^1(]0,L[) \times L^2(]0,L[), H_0^1(]L_1,L_2[) \times L^2(]L_1,L_2[)] \ \rightarrow \ \sqrt{\Lambda(\Phi,\Phi)}.$$

Conversely, if Φ solution of (96) can be found, one has

$$\left\{\begin{array}{l} \forall \delta\Phi \in V^*, \ \displaystyle\int_0^L \frac{\partial \varphi^0}{\partial t}(x,T)\delta\varphi(x,T) - \int_0^L \varphi^0(x,T)\frac{\partial \varphi}{\partial t}(x,T) \\ \quad + 2U\displaystyle\int_0^L \frac{\partial \varphi^0}{\partial x}(x,T)\delta\varphi(x,T) - ac_f^2\int_{L_1}^{L_2} z^0(x,T)\delta\varphi(x,T) \\ \quad + \displaystyle\int_{L_1}^{L_2} \frac{\partial z^0}{\partial t}(x,T)\delta z(x,T) - \int_{L_1}^{L_2} z^0(x,T)\frac{\partial \delta z}{\partial t}(x,T) \\ \quad + b\displaystyle\int_{L_1}^{L_2} \varphi^0(x,T)\delta z(x,T) = 0. \end{array}\right. \tag{97}$$

Because, on the one hand, the space V^* contains $[H^1(]0,L[)\times L^2(]0,L[), H_0^1(]L_1,L_2[)\times L^2(]L_1,L_2[)]$, and on the other hand, the final value (at time $t=T$) of $(\delta\varphi,\delta z)$ can be chosen arbitrarily in this space (it is sufficient to reverse the time and to choose the initial value obtained for $(\delta\Phi)$!), one deduces from (97) that (as soon as the initial data are such that the expression (97) make sense, i.e., the initial data should be smooth enough)

$$\varphi^0(x,T) = \frac{\partial \varphi^0}{\partial t}(x,T) = 0 \quad \forall x \in]0,L[,$$

and

$$z^0(x,T) = \frac{\partial z^0}{\partial t}(x,T) = 0 \ \ \forall x \in]L_1,L_2[.$$

There are still two important points to justify: the characterization of the space V^* and the construction of the exact control, and then the convergence of the sequences $(u^\varepsilon, w^\varepsilon)$ to (u^0,w^0) when $\varepsilon \to 0$ (and even the one of u^ε to u^0 if only the structural control is used).

7. Construction of an exact control. In this section we make use of a technical method given in the book of Lions [21] and due to Zuazua. There are four steps which basically make use of the inequalities obtained by the multiplier method as in section 4. Let us first state the results that we are going to prove.

THEOREM 2. *Let $\Lambda(.,.)$ be the symmetrical and bilinear form defined at* (95). *For T large enough, there exists a strictly positive constant—say, c_0—such that*

$$\forall X \in V^\#, \ \ \Lambda(\Phi,\Phi) \geq c_0\left[||\Phi_0||_{0,0L}^2 + ||\Phi_1||_{[H^1(]O,L[)]'}^2 + ||D_0||_{0,0L}^2 + ||D_1||_{-1,0L}^2\right], \tag{98}$$

where $X = (\Phi_0,\Phi_1,D_0,D_1)$ is the initial condition for the adjoint state for (ϕ^1,d^1).

THEOREM 3. *Let*

$$\varphi^0(x,0) \in H^1(]0,L[), \ \ \frac{\partial \varphi}{\partial t}(x,0) \in L^2(]0,L[),$$

and

$$z^0(x,0) \in H_0^1(]L_1,L_2[), \ \ \frac{\partial z^0}{\partial t}(x,0) \in L^2(]L_1,L_2[).$$

Then $L(.)$ defined at (96) *is a linear and continuous form on the space*

$$V^{\#} = L^2(]0,L[) \times [H^1(]0,L[)]' \times L^2(]L_1,L_2[) \times H^{-1}(]L_1,L_2[).$$

Remark 13. The dual space $(H^1(]0,L[))'$ is isomorphic to $H^{-1}(]0,L[) \times R^2$. The two scalar components are the coefficients of the Dirac distributions at both end of the segment $]0,L[$. Therefore the term $\int_0^L \varphi(x,0)\frac{\partial\delta\varphi}{\partial t}(x,0)$ should be written more precisely using a duality product between $H^1(]0,L[)$ and its dual space. But this would not lead to new phenomena or new difficulties. The discussion would be quite different for the two dimensional cases that are considered in [7].

From Theorems 2 and 3, we can deduce the following controllability result.

THEOREM 4. *Let $(\varphi_0,\ \varphi_1\ z_0,\ z_1)$ be a set of initial conditions for the coupled system lying in the space*

$$H_m^1(]0,L[) \times L^2(]0,L[) \times H_0^1(]L_1,L_2[) \times L^2(]L_1,L_2[).$$

Then there exists an exact control (u^0,w^0) in the space $[L^2(]\alpha,\beta[\times]0,T[)]^2$.

Proof of the Theorem 4. Because of Theorems 2 and 3, one can claim that the variational equation (96) has a unique solution, say (φ^1,d^1). The exact control $(u^0,w^0)(x,t)$ is then given by $-(\varphi^1,d^1)(x,t)\chi(x)$ because of (97). □

Proof of the Theorem 2. There are several steps in our proof. They are rather technical and mainly rest upon the multiplier method.

Step 1. Let us set $q=(x-x_0)t(t-T)$, where $x_0 \in]\alpha,\beta[$. Then we consider the equations of the coupled dual model, which should be satisfied by (ψ^1,d^1). They can be written as follows:

$$(99)\quad \begin{cases} \dfrac{\partial^2\psi^1}{\partial t^2} + 2U\dfrac{\partial^2\psi^1}{\partial x\partial t} + (U^2-c_f^2)\dfrac{\partial^2\psi^1}{\partial x^2} \\ \qquad = b\left(\dfrac{\partial d^1}{\partial t} + U\dfrac{\partial d^1}{\partial x}\right)\chi_{[L_1,L_2]}(x) \quad \forall (x,t)\in]0,L[\times]0,T[, \\ \left[\dfrac{\partial\psi^1}{\partial t} + U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\psi^1}{\partial x}\right](0,t) \\ \qquad = \left[\dfrac{\partial\psi^1}{\partial t} + U\left(1-\dfrac{1}{M^2}\right)\dfrac{\partial\psi^1}{\partial x}\right](L,t) = 0 \quad \forall t\in]0,T[, \\ \dfrac{\partial^2 d^1}{\partial t^2} - c_s^2\dfrac{\partial^2 d^1}{\partial x^2} = -ac_f^2\left(\dfrac{\partial\psi^1}{\partial t} + U\dfrac{\partial\psi^1}{\partial x}\right) \quad \forall (x,t)\in]L_1,L_2[\times]0,T[, \\ d^1(L_1,t) = d^1(L_2,t) = 0 \quad \forall t\in]0,T[. \end{cases}$$

Let us multiply each of these equations by $\frac{\partial\psi^1}{\partial x}q$ and $\frac{\partial d^1}{\partial x}q$, and for $\eta>0$ let us integrate on $]\alpha,\beta[\times]\eta,T-\eta[$, where $]\alpha,\beta[$ is the segment on which the controls are applied. Thus from a computation similar to the one we did previously, we obtain, where c_1 is a constant which tends to the infinity when $\eta\to 0$,

$$(100)\quad \begin{cases} \displaystyle\int_\eta^{T-\eta}\left[\left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2-U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2\right]_\alpha^\beta + \frac{ac_f^2}{b}\left[\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right]_\alpha^\beta \\ \displaystyle\le c_1\left[\int_0^T\int_\alpha^\beta \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2-U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right]. \end{cases}$$

But one can also apply the multiplier method on the set $]0,\eta[\times]\alpha,\beta[$ and then, by upper bounding the energy on $]0,\eta[\times]0,L[$, we obtain $\left(\text{with } q = x - \frac{\alpha+\beta}{2}\right)$

$$\left\{\begin{array}{l} \displaystyle\int_0^\eta \left[\left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2\right]_\alpha^\beta + \frac{ac_f^2}{b}\left[\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right]_\alpha^\beta \\ \leq 2\eta E(0), \end{array}\right. \tag{101}$$

where $E(0)$ is the energy of the global system defined at (62) and for $t = 0$. Thus by adding (100) and (101), one can conclude that

$$\left\{\begin{array}{l} \displaystyle\int_0^T \left[\left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2\right]_\alpha^\beta + \frac{ac_f^2}{b}\left[\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right]_\alpha^\beta \\ \displaystyle\leq c_1\left[\int_0^T\int_\alpha^\beta \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right] \\ + c_2\eta E(0). \end{array}\right. \tag{102}$$

Step 2. Let us now consider the segment $]0,\alpha[$, and we define two functions, say, $q_f = x$ and $q_s = x - L_1$. Then by multiplying the two equations (99) by $\frac{\partial\psi^1}{\partial x}q_f$ and $\frac{\partial d^1}{\partial x}q_s$, respectively, one obtains that (for $U < U_c$) there exists a positive constant c and a time delay T_0 such that

$$\left\{\begin{array}{l} \displaystyle\int_0^T\int_0^\alpha \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\} \\ \displaystyle - T_0\left\{\left[\int_0^\alpha \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right](0)\right. \\ \displaystyle\left. + \left[\int_0^\alpha \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right](T)\right\} \\ \displaystyle\leq \left[\int_0^T \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right](\alpha). \end{array}\right. \tag{103}$$

The time T_0 (or at least an upper bound) has been defined similarly in (71). The same inequality as (103) can also be written on the segment $[\beta, L]$. By adding these two and choosing for T_0 the largest one (one could compute the best constant depending on the geometry of the system), we obtain the inverse inequality for the coupled system:

$$\left\{\begin{array}{l} \displaystyle\left[\int_0^T \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right](\alpha) \\ \displaystyle + \left[\int_0^T \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right](\beta) \\ \displaystyle + \left[\int_0^T\int_\alpha^\beta \left(\frac{\partial\psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial\psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right] \\ \displaystyle\geq \tilde{c}(T - 2T_0 - 4\eta)E(0), \end{array}\right. \tag{104}$$

where $\tilde{c}$ is a new positive constant. Finally, we proved that for a constant $\tilde{\tilde{c}}$, one has

$$\left\{ \begin{array}{l} \left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial \psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right] \\ \qquad\qquad \geq \tilde{\tilde{c}}(T - 2T_0 - 4\eta)E(0). \end{array} \right. \tag{105}$$

Step 3. Following again a strategy introduced by Lions [21], we apply the multiplier method to (99) with the multipliers $\psi^1 t(t-T)(x-x_0)$ and $d^1 t(t-T)(x-x_0)$ and by integrating over $]\alpha, \beta[\times]0, T[$. Thus we obtain from a standard computation (see [21])

$$\left\{ \begin{array}{l} \left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)\left(\frac{\partial \psi^1}{\partial x}\right)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2\left(\frac{\partial d^1}{\partial x}\right)^2\right\}\right] \\ \leq \left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)(\psi^1)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2 (d^1)^2\right\}\right] \\ \qquad\qquad + 2\eta E(0). \end{array} \right. \tag{106}$$

Step 4. From (104) and (105) we can conclude that there exists a new constant—say, c—such that

$$\left\{ \begin{array}{l} (T - 2T_0 - 6\eta)E(0) \\ \leq \left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)(\psi^1)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2 (d^1)^2\right\}\right]. \end{array} \right. \tag{107}$$

Hence the right-hand side of (106) defines the square of a norm on the initial data $(\varphi_0, \varphi_1, z_0, z_1)$ in the space $(E(0) < \infty)$:

$$V = [H^1(]0, L[) \times L^2(]0, L[), H_0^1(]L_1, L_2[) \times L^2(]L_1, L_2[)].$$

Step 5. The last step of the proof of Theorem 4 rests on a compactness argument. Thus we are going to prove that there exists a positive constant—say again, c—such that

$$\left\{ \begin{array}{l} \left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + (c_f^2 - U^2)(\psi^1)^2 + \frac{ac_f^2}{b}\left\{\left(\frac{\partial d^1}{\partial t}\right)^2 + c_s^2 (d^1)^2\right\}\right] \\ \leq c\left[\displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \psi^1}{\partial t}\right)^2 + \left(\frac{\partial d^1}{\partial t}\right)^2\right]. \end{array} \right. \tag{108}$$

The method is classical in numerical analysis; therefore, we only sketch it. Let us assume that (108) is false. Then for any integer number n there exists an element $X^n \in V$ such that (where $E(0)(X^n)$ defined at (62) is the square of a norm on V)

$$\forall n > 0,\ E(0)(X^n) \simeq ||X^n||_V^2 = 1,\ \int_0^T \int_\alpha^\beta \left(\frac{\partial d^n}{\partial t}\right)^2 + \left(\frac{\partial \psi^n}{\partial t}\right)^2 \leq \frac{1}{n}, \tag{109}$$

where (Ψ^n, d^n) is the solution of (99) with the initial conditions X^n. From the weak compactness of unit balls in Hilbert spaces, one can extract from X_n a subsequence denoted $X^{n'}$ and such that

$$X^n \to X^* \text{ in } V \text{ weakly.}$$

But one has also

$$(\psi^{n'}, d^{n'}) \to (\psi^*, d^*) \text{ weakly in the space of solutions (see section 3),}$$

where (ψ^*, d^*) is the solution of (99) with the initial condition $X^* \in V$. However, from (109), one deduces that

$$\int_0^T \int_\alpha^\beta \left(\frac{\partial d^*}{\partial t}\right)^2 + \left(\frac{\partial \psi^*}{\partial t}\right)^2 \leq \varliminf_{n' \to \infty} \int_0^T \int_\alpha^\beta (d^{n'})^2 + (\psi^{n'})^2 = 0,$$

and therefore

$$\frac{\partial \psi^*}{\partial t} = \frac{\partial d^*}{\partial t} = 0 \qquad \forall (x,t) \in]\alpha, \beta[\times]0, T[\,.$$

Setting

$$\bar{\psi}^* = \frac{\partial \psi^*}{\partial t} \text{ and } \bar{d}^* = \frac{\partial d^*}{\partial t},$$

one deduces that, on the one hand,

$$\bar{\psi}^* = \bar{d}^* = 0 \ \ \forall (x,t) \in]\alpha, \beta[\times]0, T[\,;$$

following the proof given in section 3, one deduces that

$$\bar{\psi}^* = 0 \ \ \forall (x,t) \in]0, L[\times]0, T[\text{ and } \bar{d}^* = 0 \ \ \forall (x,t) \in]L_1, L_2[\times]0, T[\,.$$

Thus, ψ^* and d^* are both time independent. From (99) we obtain that

$$\text{(110)} \qquad \begin{cases} -(c_f^2 - U^2)\dfrac{\partial^2 \psi^*}{\partial x^2} = bU \dfrac{\partial d^*}{\partial x} \chi_{[L_1, L_2]} \ \ \forall (x,t) \in]0, L[\times]0, T[\,, \\ -c_s^2 \dfrac{\partial^2 d^*}{\partial x^2} = -a c_f^2 \dfrac{\partial \psi^*}{\partial x} \ \ \forall (x,t) \in]L_1, L_2[\times]0, T[\,, \\ \dfrac{\partial \psi^*}{\partial x}(0) = \dfrac{\partial \psi^*}{\partial x}(L) = d^*(L_1) = d(L_2) = 0. \end{cases}$$

Because $U < U_c$, we can deduce that

$$d^* = 0, \ \ \psi^* = \text{constant},$$

and because $\psi^* \in H_m^1(]0, L[)$, one has (see (7))

$$\int_{L_1}^{L_2} \psi^* = 0$$

and finally

$$\psi^* = 0.$$

This is in contradiction to (109), and the inequality (108) is true.

Step 6. Let us consider for a given set of initial conditions—say, $(\Phi_0, \Phi_1, D_0, D_1)$—the solution (φ, z) of the coupled system. Then we set

$$\text{(111)} \qquad \begin{cases} \tilde{\psi}(x,t) = \tilde{\psi}_0(x) + \displaystyle\int_T^t \psi(x,s) ds, \\ \tilde{d}(x,t) = \tilde{d}_0(x) + \displaystyle\int_T^t d(x,s) ds. \end{cases}$$

The initial terms $(\tilde{\psi}_0, \tilde{d}_0)$ are chosen such that $(\tilde{\psi}, \tilde{d})$ is also a solution of the adjoint system (52). The definitions of these terms are specified in (54). By applying the inequalities (76) and (108), we deduce that there exists a constant c such that

$$\left\{ \begin{array}{l} c\big[||\Phi_0||^2_{0,OL} + ||\Phi_1||^2_{[H^1(]O,L[)]'} + ||D_0||^2_{0,L_1L_2} + ||D_1||^2_{1,L_1L_2}\big] \\ \qquad \leq \displaystyle\int_0^T \int_\alpha^\beta \left(\frac{\partial \tilde{\psi}}{\partial t}\right)^2 + \left(\frac{\partial \tilde{d}}{\partial t}\right)^2, \end{array} \right. \tag{112}$$

and finally from (111), we deduce that Theorem 2 is proved. □

8. Convergence of the least square control to the exact control when $\varepsilon \to 0$. In practical application it is more convenient to use the optimal control $(u^\varepsilon, w^\varepsilon)$. However, the stability of the method is strongly dependent on the convergence when ε tends to zero to the exact control, when it exists. Let first state the result that we are proving in this section.

THEOREM 5. *Let us assume that the assumptions of Theorem* 4 *are satisfied. Then one has the following convergence result:*

$$\lim_{\varepsilon \to 0} ||u^\varepsilon - u^0||^2_{L^2(]\alpha,\beta[\times]0,T[)} + ||w^\varepsilon - w^0||^2_{L^2(]\alpha,\beta[\times]0,T[)} = 0.$$

Remark 14. The order of convergence with respect to ε can be obtained by the computation of the term of order one in the asymptotic expansion with respect to ε. But it depends on additional regularity of the initial data in order to make sure that u^1 and w^1 are effectively in the space $L^2(]\alpha,\beta[\times]0,T[)$. Nevertheless, from interpolation techniques, one can adjust the order of convergence with respect to ε when this regularity is not satisfied. We refer to the book by Lions [22].

Proof of Theorem 5. Let us set $(u, w) = (u^0, w^0)$ in the criterion J^ε. Because it is an exact control, the corresponding final state is zero. Thus we obtain the following upper bound:

$$J^\varepsilon(u^\varepsilon, w^\varepsilon) \leq J^\varepsilon(u^0, w^0) = \frac{\varepsilon}{2} \int_0^T \int_\alpha^\beta (u^0)^2 + (w^0)^2.$$

Therefore the sequence $(u^\varepsilon, w^\varepsilon)$ is bounded with respect to ε in the space $\big[L^2(]\alpha,\beta[\times]0,T[)\big]^2$. Furthermore, one has

$$\begin{aligned} &\frac{A}{2}\int_0^L \left|\frac{\partial \varphi}{\partial t}(x,T)\right|^2 + \frac{B}{2}\int_0^L \left|\frac{\partial \varphi}{\partial x}(x,T)\right|^2 \\ &+ \frac{C}{2}\int_{L_1}^{L_2} \left|\frac{\partial z}{\partial t}(x,T)\right|^2 + \frac{D}{2}\int_{L_1}^{L_2} \left|\frac{\partial z}{\partial x}(x,T)\right|^2 \leq c\varepsilon. \end{aligned}$$

Thus, from classical analysis, we deduce the "strong" continuity of the solution of the coupled model with respect to the right-hand side $(u^\varepsilon, w^\varepsilon)$ in $\big[L^2(]\alpha,\beta[\times]0,T[)\big]^2$, and therefore the strong convergence of the solution $(\varphi^\varepsilon, z^\varepsilon)(x,t)$ tends also to $(\varphi^0, z^0)(x,t)$ with ε in the space mentioned in Theorem 5. The last point concerns the strong convergence of the control $(u^\varepsilon, w^\varepsilon)$ to the H.U.M. control (u^0, w^0) in the space $\big[L^2(]\alpha,\beta[\times]0,T[)\big]^2$. From the upper bound mentioned at the beginning of the proof, one has the following:

$$\int_0^T \int_\alpha^\beta (u^\varepsilon - u^0)^2 + (w^\varepsilon - w^0)^2$$
$$= \int_0^T \int_\alpha^\beta (u^\varepsilon)^2 + (w^\varepsilon)^2 - 2\int_0^T \int_\alpha^\beta u^\varepsilon u^0 + w^\varepsilon w^0 + \int_0^T \int_\alpha^\beta (u^0)^2 + (w^0)^2$$
$$\leq 2\left[\int_0^T \int_\alpha^\beta (u^0)^2 + (w^0)^2 - (u^\varepsilon u^0 + w^\varepsilon w^0)\right] \to 0 \quad \text{when } \varepsilon \to 0.$$

This completes the proof of Theorem 5. ∎

Remark 15. In practical applications it is usually more convenient to use the least square control because it can be more easily computed. But this is only true if the system can be exactly controlled. In other words, when ε tends to zero, there could be a singular perturbation known as a stiff problem if there were no exact control in the space $[L^2(\alpha, \beta[\times]0, T[)]^2$. Nevertheless, if only one control is used (the structural one), we proved that the system could be exactly controlled, but nothing has been proved concerning the space of initial data which could be exactly controlled with a control u^0 in $L^2(\alpha, \beta[\times]0, T[)$. There exist a few tricks in order to obtain an exact control for any initial data with finite energy (for both the fluid and the structure). But unfortunately the control are no longer in L^2. They contain Dirac distributions at both time extremities. The details of the method mentioned also in [7] for fluid-structure problems can be found again in [21].

9. Conclusion. A simple one dimensional model in aeroacoustics, coupled with a structure, has been discussed in this paper. The goal was to analyze the solutions of the coupled model and to point out the possibility of a flutter phenomenon. Then we discussed the exact controllability of any perturbations in the fluid or/and in the structure. For sake of simplicity in the explanation we have restricted the discussion to a membrane model for the structure. It has been proved that one control applied to a small part of the structure is sufficient for obtaining an exact control. However, a stability (inverse inequality) result has only been proved for a couple of controls: one applied to the flexible structure and the other on the walls of the flow duct. This restriction is due to mathematical difficulties but also to a subsonic shock wave which can appear at the extremity of the structure where the rotations can be discontinuous. (In fact, the terms involved are $U\frac{\partial z}{\partial x}(L_1, t)$ and $U\frac{\partial z}{\partial x}(L_2, t)$.) When $U = 0$ (i.e., no steady flow), the difficulty disappears. One basic point is that the exact control still works if the critical velocity for the flutter apparition is overtaken. But obviously the cost of the control can also be exponentially increasing with respect to time. A lot of improvements can be suggested. First one could introduce a wall law in order to take into account the viscosity of the fluid. But the mathematical structure of the operator is changed and nonlocal energy bounds from the control area are much more complicated to derive (see, for instance, the difficulties encountered for Stokes equations [8], [2], [3] [10]). Another point is that the one dimensional model is certainly insufficient in order to reproduce reality. Some improvements could be forecast by a better modelling of the control devices themselves. Two dimensional modelling is clearly more realistic, especially for reproducing local waves which can appear at the interface between the fluid and the structure. One possibility seems to use an asymptotic method, where the small parameters are the transverse dimensions of the structure compared to the length of the flow duct and the ratio between the smallest period of the coupled system and the time control delay T.

Acknowledgment. The authors are very grateful to Caroline Fabre for her valuable advice and suggestions when we were writing this paper.

GUIDED WAVES IN A PHOTONIC BANDGAP STRUCTURE WITH A LINE DEFECT*

HABIB AMMARI† AND FADIL SANTOSA‡

Abstract. Numerical simulations have shown that when a line of defects is introduced into a photonic bandgap structure, waves can be guided along the line. It has been conjectured that the mechanism responsible for the guidance phenomenon is the introduction of a spectrum in the bandgap by the defect. The purpose of this work is to give a mathematical framework for understanding this phenomenon. We show that there exist solutions of the scalar wave equation that is localized near the line defects that behave like guided modes. Moreover, these solutions can be parameterized by a frequency spectrum that is continuous and can cover parts of the original bandgap. The frequency of the guided modes depends on a wave number parameter and can be interpreted as a dispersion relation. We illustrate the main findings of the investigation in a numerical example.

Key words. photonic bandgap structures, line defect, guided waves, spectral analysis

1. Introduction.

The purpose of this work is the study of wave propagation in an infinite periodic structure with a line defect. The medium under consideration is periodic with the exception of a row of identical defects. Without the defect, the periodic medium is assumed to have a bandgap, which is an interval of frequencies at which waves cannot propagate.

It has been observed in numerical simulations that line defects can support guided modes which propagate along the row of defect. Moreover, these modes are highly confined near the row, with frequencies lying in the bandgap of the infinite periodic structure.

When a defect is introduced into the perfect array, i.e., a perturbation with compact support, it is possible to create a midgap defect mode, which is a highly localized standing wave whose frequency ω lies in the bandgap [6, 7]. What is less clear is how a medium with an infinite line of defects behaves. It has been observed through numerical experiments that propagating modes which are localized near the line of defects can be produced [4, 14, 13]. The goal of this work is to understand how these propagating modes are created and what properties they possess. For this purpose, we use the theory developed by Figotin and Klein [6, 7]. This work is a first step in rigorously explaining the guidance phenomenon in photonic bandgap structures.

In this work, we model wave propagation using the scalar Helmholtz equation in two dimensions, corresponding to transverse electric (TE) mode electromagnetic waves. The spectrum, which is the frequency parameter of Helmholtz's equation, is analyzed. What this work does not address is the fundamental question of whether the spectrum in question is absolutely continuous. Instead, we prove that guided

modes can be created by introducing line defects. We also provide a description for these guided modes. Our work does not answer the question of whether the bandgap could be filled in by the new spectrum.

The paper is organized as follows. The problem statement is given in section 2. This is followed by a brief review of known results about waves in an infinite periodic medium. Section 4 considers the spectral problem in an infinite strip with Bloch conditions on the sides. The strip problem is the basis from which we build a framework to analyze the spectral problem in a medium with a line defect. The strip problem with a defect is analyzed in section 5. We remark on the construction of guided waves in section 6. Section 7 contains numerical calculations that illustrate the main findings of this work. The paper ends with a discussion.

2. Problem statement. Consider a two-dimensional periodic medium characterized by the dielectric constant $\epsilon_{\rm p}(x_1, x_2)$. We assume that it is an L^∞ function satisfying

$$0 < \epsilon_- \le \epsilon_{\rm p}(x) \le \epsilon_+ < \infty$$

and is unit periodic, i.e.,

$$\epsilon_{\rm p}(x_1 + 1, x_2) = \epsilon_{\rm p}(x_1, x_2), \quad \epsilon_{\rm p}(x_1, x_2 + 1) = \epsilon_{\rm p}(x_1, x_2).$$

To this perfect array, we introduce a line defect which is represented by a perturbation to the dielectric property $\delta\epsilon(x_1, x_2)$. The perturbation is confined to the cells over the x_1-axis and is periodic in x_1,

$$\begin{aligned} &\delta\epsilon(x_1, x_2) = 0, && |x_2| > 1/2, \\ &\delta\epsilon(x_1 + 1, x_2) = \delta\epsilon(x_1, x_2). \end{aligned}$$

The medium with defect then has dielectric constant

$$\epsilon(x_1, x_2) = \epsilon_{\rm p}(x_1, x_2) + \delta\epsilon(x_1, x_2).$$

It is assumed that ϵ is still a strictly positive bounded measurable function. The object of this work is the study of Helmholtz equation

$$\Delta u + \omega^2 \epsilon u = 0, \quad (x_1, x_2) \in \mathbb{R}^2. \tag{1}$$

The Helmholtz equation is a model for TE-mode electromagnetic wave propagation in two dimensions. We view the frequency squared, ω^2, as the spectral parameter and investigate the spectrum of the operator

$$-\frac{1}{\epsilon}\Delta.$$

The approach is to compare the spectrum with that when the medium is periodic, i.e., one with dielectric constant $\epsilon_{\rm p}(x)$.

It is well known that the medium $\epsilon_{\rm p}(x)$ can have bandgaps, i.e., intervals of values ω for which propagating waves cannot exist [5, 10]. While necessary conditions under which bandgaps exist in general are not known, Figotin and Kuchment have produced an example of a high-contrast periodic medium where bandgaps exist and can be characterized [8, 9].

Moreover, it is also known that when a defect is introduced into the perfect array, i.e., a perturbation to $\epsilon_{\rm p}$ with compact support, it is possible to create a defect

mode, which is a solution to Helmholtz's equation with exponential decay, and with frequency ω which lies in the bandgap [6, 7]. The work cited also provided estimates of the decay rates, which we do not use in the present work. A lot less is known about the case in which there is an infinite line of defects such as $\epsilon(x)$. Although numerical experiments have provided evidence that waves that are localized near the line of defects can be produced, little analytical results are known for this case. The goal of this work is to investigate the spectral problem of (1) to reveal the guidance phenomena.

3. Periodic problem. We first consider the properties of the periodic structure without defect. The known results, particularly those that will be useful for this work, are presented. We consider the Bloch waves $w(x, \alpha)$ satisfying

$$\Delta w + \omega^2 \epsilon_{\mathrm{p}} w = 0, \quad x \in \mathbb{R}^2, \tag{2a}$$

$$w(x_1 + 1, x_2, \alpha_1, \alpha_2) = w(x_1, x_2, \alpha_1, \alpha_2) e^{i\alpha_1}, \tag{2b}$$

$$w(x_1, x_2 + 1, \alpha_1, \alpha_2) = w(x_1, x_2, \alpha_1, \alpha_2) e^{i\alpha_2}. \tag{2c}$$

When a solution to the above exists for a given vector α, the function $w(x, \alpha)$ corresponds to plane wave-like solutions with the vector $\alpha = (\alpha_1, \alpha_2)$ playing the role of wave number.

Another way to characterize this eigenvalue problem is by introducing

$$w(x, \alpha) = \psi(x, \alpha) e^{i\alpha \cdot x}.$$

It can be shown that ψ satisfies

$$(\nabla + i\alpha) \cdot (\nabla + i\alpha)\psi + \omega^2 \epsilon_{\mathrm{p}} \psi = 0 \tag{3a}$$

with periodic boundary conditions

$$\psi(x_1 + 1, x_2, \alpha_1, \alpha_2) = \psi(x_1, x_2, \alpha_1, \alpha_2), \tag{3b}$$

$$\psi(x_1, x_2 + 1, \alpha_1, \alpha_2) = \psi(x_1, x_2, \alpha_1, \alpha_2). \tag{3c}$$

We can view the above as an eigenvalue problem to find ω given the vector α. It can be shown that this eigenvalue problem admits an infinity of solutions, with frequencies $\omega_n(\alpha)$, where the index $n = 1, 2, \ldots$ provides an ordering for the eigenvalues. The function $\omega_n(\alpha)$ is referred to as the dispersion relation for the nth modes. The corresponding eigenfunctions, the Bloch waves, are denoted by $w_n(x, \alpha)$, and it will be useful to consider the pairs $\{\omega_n(\alpha), w_n(x, \alpha)\}_{n=1}^{\infty}$.

The periodicity of the eigenvalue problem above induces periodicity in the dispersion relation $\omega_n(\alpha)$ as a function of α. That is, $\omega_n(\alpha)$ is periodic with period $P := [0, 2\pi]^2$. If $\epsilon_{\mathrm{p}} \in C^{\infty}([0, 1]^2)$, ω_n are analytic functions of α everywhere on P except on subsets of measure zero where their multiplicity changes. In particular, they are continuous for all α [15, 3]. The set of Bloch waves, as α varies in P, and $n = 1, 2, \ldots$, is complete in $L^2(\mathbb{R}^2)$ [11]. Therefore, any solution of the wave equation

$$\Delta u + \omega^2 \epsilon_{\mathrm{p}} u = 0$$

can be expressed as a linear combination of Bloch waves.

Let I_n denote the interval of values of $\omega_n^2(\alpha)$ for $\alpha \in P$. Then the spectrum of the periodic operator $-\Delta/\epsilon_{\mathrm{p}}$ is

$$\Sigma(\epsilon_{\mathrm{p}}) = \bigcup_{n=1}^{\infty} I_n.$$

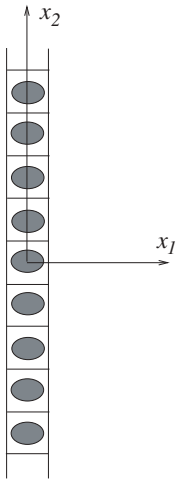

FIG. 1. *A vertical strip from the periodic medium.*

It is further known that for some $\epsilon_{\mathrm{p}}(x)$, there are bandgaps, i.e., $\Sigma(\epsilon_{\mathrm{p}})$ does not cover $[0,\infty)$. Let us suppose this is the case and let this gap be the interval $\Gamma(\epsilon_{\mathrm{p}}) =]a,b[$. Physically, it means that a wave of frequency $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$ cannot propagate in the medium. The existence of the gap is a problem studied in [8, 9], where it is shown that for a high-contrast medium of a particular geometry, the bandgap can be characterized. More general questions about gaps are still open [10].

3.1. Green's function. The Green's function for Helmholtz's equation with a periodic medium satisfies

$$\Delta G + \lambda^2 \epsilon_{\mathrm{p}} G = \delta(x-y).$$

The following is described in [6, 7, 2]:

- For $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$, the Green's function is exponentially decaying away from y:

$$|G(x,y;\lambda)| \leq C_1 e^{-C_2|x-y|}. \tag{4a}$$

- The function

$$G(x,y;\lambda) - \frac{1}{2\pi}\log|x-y| \tag{4b}$$

  is continuous for $|x-y| \to 0$.

4. The strip. With the introduction of the line defect as described in section 2, the medium loses periodicity in the x_2-direction. It is, however, still periodic in the x_1-direction. We will exploit this fact in our analysis. For now, we investigate the periodic problem on the strip as shown in Figure 1, and we view the x_1-direction quasi-momentum α_1 as a parameter on the interval $[0, 2\pi]$.

4.1. Characterization of the periodic problem in the strip. Let $O = (-\frac{1}{2}, \frac{1}{2}) \times \mathbb{R}$ denote the strip in Figure 1. Consider the Bloch wave $w(x,\alpha)$ as a function of x and α_2, parameterized by α_1. For each $\alpha_1 \in [0, 2\pi]$, we solve

$$\Delta u_{\alpha_1} + \nu_{\alpha_1}^2(\alpha_2)\epsilon_{\mathrm{p}}(x)u_{\alpha_1} = 0 \quad \text{in } O \tag{5a}$$

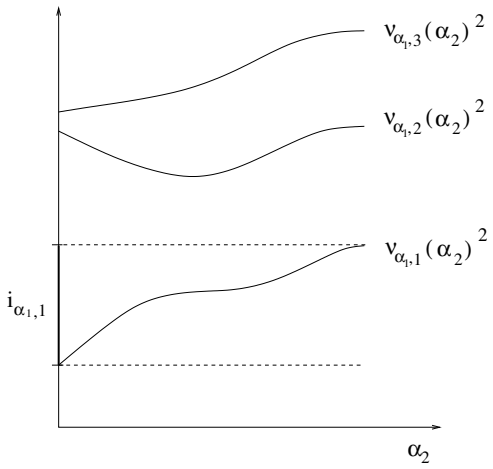

FIG. 2. *Dispersion relation $\nu_{\alpha_1,n}(\alpha_2)$ for a fixed α_1.*

with boundary conditions

$$u_{\alpha_1}(x_1+1,x_2) = u_{\alpha_1}(x_1,x_2)e^{i\alpha_1}, \tag{5b}$$

$$u_{\alpha_1}(x_1,x_2+1) = u_{\alpha_1}(x_1,x_2)e^{i\alpha_2}. \tag{5c}$$

Consider the problem for a fixed α_1. Now choose a value for α_2. The eigenvalue problem (5) admits an infinity of solutions $\{\nu_{\alpha_1,n}(\alpha_2), u_{\alpha_1,n}(x,\alpha_2)\}_{n=1}^{\infty}$. The dispersion relation and the Bloch waves in (2) are recovered as

$$\omega_n(\alpha_1,\alpha_2) = \nu_{\alpha_1,n}(\alpha_2), \quad w_n(x,\alpha_1,\alpha_2) = u_{\alpha_1,n}(x,\alpha_2).$$

For each fixed α_1, we view $\nu_{\alpha_1,n}(\alpha_2)$ as a dispersion relation. A sketch of what such a dispersion relation might look like is provided in Figure 2.

For a fixed α_1, the spectrum of the operator on the strip is

$$\sigma_{\alpha_1}(\epsilon_{\mathrm{p}}) = \bigcup_{n=1}^{\infty} i_{\alpha_1,n},$$

where $i_{\alpha_1,n}$ is the interval for the values of $\nu^2_{\alpha_1,n}(\alpha_2)$ for $\alpha_2 \in [0,2\pi]$. We recover

$$I_n = \bigcup_{\alpha_1} i_{\alpha_1,n} \quad \text{and} \quad \Sigma(\epsilon_{\mathrm{p}}) = \bigcup_{\alpha_1} \sigma_{\alpha_1}(\epsilon_{\mathrm{p}}).$$

The spectrum $\sigma_{\alpha_1}(\epsilon_{\mathrm{p}})$ may have a bandgap for a given α_1. Let us denote it by $\gamma_{\alpha_1}(\epsilon_{\mathrm{p}})$. The bandgap of the periodic medium $\Gamma(\epsilon_{\mathrm{p}})$ is contained in the intersection of γ_{α_1}

$$\Gamma(\epsilon_{\mathrm{p}}) \subset \bigcap_{\alpha_1} \gamma_{\alpha_1}(\epsilon_{\mathrm{p}}).$$

4.2. Green's function in the strip. We will next study the Green's function for the strip for a fixed α_1. For frequency λ such that λ^2 is in the gap $\Gamma(\epsilon_{\mathrm{p}})$, the Green's function can be constructed using the partial Floquet transform. The strip

Green's function satisfies

$$\Delta g_{\alpha_1} + \lambda^2 \epsilon_{\mathrm{p}} g_{\alpha_1} = \delta_{\alpha_1}(x-y) = \sum_{j\in\mathbb{Z}} \delta(x_1 + j - y_1, x_2 - y_2) e^{ij\alpha_1}, \tag{6a}$$

$$g_{\alpha_1}(x_1+1, x_2, y_1, y_2; \lambda) = g_{\alpha_1}(x_1, x_2, y_1, y_2; \lambda) e^{i\alpha_1}. \tag{6b}$$

LEMMA 1. *Suppose that $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$. Then the Green's function is related to the whole-space Green's function through*

$$g_{\alpha_1}(x_1, x_2, y_1, y_2; \lambda) = \sum_{j\in\mathbb{Z}} G(x_1 + j, x_2, y_1, y_2; \lambda) e^{ij\alpha_1}. \tag{7}$$

Moreover, $g_{\alpha_1}(\cdot, y; \lambda)$ is in $L^2_{\mathrm{loc}}(\mathbb{R}^2)$.

Proof. Suppose that $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$. Then, clearly, for any fixed $y = (y_1, y_2)$ $x = (x_1, x_2) \to \sum_{j\in\mathbb{Z}} G(x_1 + j, x_2, y_1, y_2; \lambda) e^{ij\alpha_1}$ defines a function in $L^2_{\mathrm{loc}}(\mathbb{R}^2)$ which satisfies (6b) almost everywhere on $\mathbb{R}^2$. Indeed, we have in a distribution sense

$$\begin{aligned}
&(\Delta + \lambda^2 \epsilon_{\mathrm{p}}) \sum_{j\in\mathbb{Z}} G(x_1 + j, x_2, y_1, y_2; \lambda) e^{ij\alpha_1} \\
&= \sum_{j\in\mathbb{Z}} (\Delta + \lambda^2 \epsilon_{\mathrm{p}}) G(x_1 + j, x_2, y_1, y_2; \lambda) e^{ij\alpha_1} \\
&= \sum_{j\in\mathbb{Z}} \delta(x_1 + j - y_1, x_2 - y_2) e^{ij\alpha_1}.
\end{aligned}$$

Since $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$, the strip Green's function g_{α_1} defined by (7) is the unique solution to (6). ∎

Let us define a regular part of g_{α_1} as the series

$$r_{\alpha_1}(x_1, x_2, y_1, y_2; \lambda) = \sum_{j\in\mathbb{Z}, j\neq 0} G(x_1 + j, x_2, y_1, y_2; \lambda) e^{ij\alpha_1}, \tag{8}$$

whose terms are well defined for $(x_1, y_1) \in (-\frac{1}{2}, \frac{1}{2})^2$. By (4), the series in (8) converges uniformly for (x, y) in compact subsets of $O \times O$. Therefore, as for the local behavior of g_{α_1}, i.e., when $|x - y| \to 0$, the following result of logarithmic singularity holds from (4).

LEMMA 2. *Suppose that $\lambda^2 \in \Gamma(\epsilon_{\mathrm{p}})$. Then the function*

$$g_{\alpha_1}(x, y; \lambda) - \frac{1}{2\pi} \log|x - y|$$

is continuous as $|x - y| \to 0$.

Proof. In any open set $\mathcal{K}$ that does not contain a point $(y_1 - j, y_2)$, $j \in \mathbb{Z}$, the regular part r_{α_1} satisfies

$$(\Delta + \lambda^2 \epsilon_{\mathrm{p}}) r_{\alpha_1} = 0 \text{ in } \mathcal{D}'(\mathcal{K}).$$

But r_{α_1} is in $L^2_{\mathrm{loc}}(\mathbb{R}^2)$ so that, applying classical results on elliptic regularity together with the Sobolev embedding theorem, we obtain that r_{α_1} is a continuous function in $\mathcal{K}$. Lemma 2 then follows immediately from the logarithmic behavior (4b) of $G(x, y; \lambda)$. ∎

For $(x_1, y_1) \in (-\frac{1}{2}, \frac{1}{2})^2$ it follows from the exponential decay property (4) that the regular part r_{α_1} defined by (8) is a continuous function of α_1 and therefore the following continuity result holds.

LEMMA 3. *If $\lambda^2 \in \Gamma(\epsilon_{\rm p})$, then the map $\alpha_1 \in [0, 2\pi] \mapsto$ the operator with kernel $g_{\alpha_1}(.,.;\lambda) \in \mathcal{D}'(\mathbb{R}^2) \times \mathcal{D}'(\mathbb{R}^2)$, mapping $L^2(O)$ to $L^2(O)$ is continuous.*

If $\lambda^2 \in \Gamma(\epsilon_{\rm p})$, then, by (4), all the terms in (7) are exponentially decaying as $|x_2 - y_2| \to +\infty$, and so is their sum.

LEMMA 4. *Suppose that $\lambda^2 \in \Gamma(\epsilon_{\rm p})$. Then there exist positive constants C_2 and C_3 such that*

$$|g_{\alpha_1}(x, y; \lambda)| \leq C_3 e^{-C_2|x_2 - y_2|} \quad \text{as } |x_2 - y_2| \to \infty.$$

Proof. Combining

$$\sqrt{(x_1 + j - y_1)^2 + (x_2 - y_2)^2} \leq |x_1 + j - y_1| + |x_2 - y_2|$$

with the fact that the series $\sum_{j\in\mathbb{Z}} e^{-C_2|x_1+j-y_1|}$ is uniformly bounded for $(x_1, y_1) \in (-\frac{1}{2}, \frac{1}{2})^2$, it is readily seen by using the exponential decay property (4a) of G that for $(x_1, y_1) \in (-\frac{1}{2}, \frac{1}{2})^2$ the estimates

$$\begin{aligned} |g_{\alpha_1}(x, y; \lambda)| &\leq C_1 \sum_{j\in\mathbb{Z}} e^{-C_2\sqrt{(x_1+j-y_1)^2+(x_2-y_2)^2}} \\ &\leq C_1 e^{-C_2|x_2-y_2|} \sum_{j\in\mathbb{Z}} e^{-C_2|x_1+j-y_1|} \leq C_3 e^{-C_2|x_2-y_2|} \end{aligned}$$

hold for some positive constant C_3. ∎

4.3. Preliminary results. The following preliminary results will be useful in the subsequent sections for understanding the behavior of the strip when a defect is introduced.

We shall use quite standard quasi-periodic L^2-based Sobolev spaces to measure regularity of functions which satisfy the Bloch condition in the x_1-direction. The space $L^2_{\alpha_1}(O)$ is the set of restrictions on O of functions u such that $e^{-i\alpha_1 x_1}u(x_1, x_2) \in L^2(\mathbb{R}^2/2\pi\mathbb{Z})$. The space $H^1_{\alpha_1}(O)$ is the set of restrictions on O of functions u which satisfy $e^{-i\alpha_1 x_1}u(x_1, x_2) \in H^1(\mathbb{R}/2\pi\mathbb{Z} \times \mathbb{R})$. These functions are, along with all their first derivatives, in $L^2(O)$ and satisfy the Bloch condition

$$u(1, x_2) = u(0, x_2)e^{i\alpha_1}.$$

We also introduce for $\gamma > 0$ the weighted Sobolev space:

$$\mathcal{H}_{\alpha_1,\gamma}(O) = \left\{ f \in H^1_{\alpha_1}(O) : \int_O e^{\gamma|x_2|}(|f|^2 + |\nabla f|^2)(x_1, x_2)\, dx_1\, dx_2 < +\infty \right\}.$$

Let Ω be a region centered at the origin

$$\Omega \subset\subset \left\{ |x_1| < \frac{1}{2}, |x_2| < h, h > 0 \right\}.$$

The defect we will later introduce on the strip is supported in Ω. Define the operator

$$\begin{aligned} &A_{\alpha_1}(\lambda) : L^2_{\alpha_1}(O) \to L^2_{\alpha_1}(O), \\ &u \mapsto A_{\alpha_1}(u) = \int_\Omega g_{\alpha_1}(x, y; \lambda)q(y)u(y)dy, \end{aligned}$$

where $q \in L^\infty(\overline{\Omega})$ is either $q \geq 0$ or $q \leq 0$ almost everywhere in Ω.

Since the Green's function g_{α_1} decays exponentially in x_2 and has logarithmic singularity, we are guaranteed that there exists a constant $\gamma > 0$ such that $A_{\alpha_1}(\lambda)(L^2_{\alpha_1}(O)) \subset \mathcal{H}_{\alpha_1,\gamma}(O)$. Using the fact that the embedding $\mathcal{H}_{\alpha_1,\gamma}(O) \hookrightarrow L^2_{\alpha_1}(O)$ is compact, for any $\gamma > 0$ [1], we conclude that the operator $A_{\alpha_1}(\lambda)$ is a compact operator.

LEMMA 5. *For any fixed $\lambda^2 \in \Gamma(\epsilon_{\rm p})$ and $\alpha_1 \in [0, 2\pi]$, the operator $A_{\alpha_1}(\lambda)$ is a compact operator.*

The eigenvalue problem

$$A_{\alpha_1}(\lambda)(v) = \mu(\lambda, \alpha_1)v \tag{9}$$

can be rewritten as

$$\mu(\lambda, \alpha_1)v\chi_\Omega = \chi_\Omega\Big(\Delta + \lambda^2\epsilon_{\rm p}\Big)^{-1}(q\chi_\Omega v),$$

where χ_Ω is the characteristic function of the region Ω. If we set

$$\psi = \begin{cases} \sqrt{q}v\chi_\Omega & \text{if } q \geq 0, \\ \sqrt{-q}v\chi_\Omega & \text{if } q \leq 0, \end{cases}$$

we obtain that the eigenvalue problem (9) is equivalent to

$$\operatorname{sgn}(q)\mu(\lambda, \alpha)\psi = \mathcal{A}_{\alpha_1}(\lambda)\psi,$$

where

$$\mathcal{A}_{\alpha_1}(\lambda) = \begin{cases} \sqrt{q}\chi_\Omega\Big(\Delta + \lambda^2\epsilon_{\rm p}\Big)^{-1}\sqrt{q}\chi_\Omega & \text{if } q \geq 0, \\ \sqrt{-q}\chi_\Omega\Big(\Delta + \lambda^2\epsilon_{\rm p}\Big)^{-1}\sqrt{-q}\chi_\Omega & \text{if } q \leq 0. \end{cases}$$

Here $\big(\Delta + \lambda^2\epsilon_{\rm p}\big)^{-1} : L^2_{\alpha_1}(O) \to L^2_{\alpha_1}(O)$ is defined by $\big(\Delta + \lambda^2\epsilon_{\rm p}\big)^{-1}(f) = v$, where v is the unique solution in $H^1_{\alpha_1}(O)$ of $(\Delta + \lambda^2\epsilon_{\rm p})v = f$ in O.

LEMMA 6. *The operator $\mathcal{A}_{\alpha_1}(\lambda)$ is a compact self-adjoint operator.*

Since $\big(\Delta + \lambda^2\epsilon_{\rm p}\big)^{-1}$ is a monotonically decreasing, norm-continuous operator of $\lambda^2 \in \Gamma(\epsilon_{\rm p})$, the following holds.

LEMMA 7. *Let $\alpha_1 \in [0, 2\pi]$. The map $\lambda^2 \in \Gamma(\epsilon_{\rm p}) \mapsto \mathcal{A}_{\alpha_1}(\lambda)$ is norm-continuous and operator monotone decreasing for both positive and negative q.*

Now, given $\lambda^2 \in \Gamma(\epsilon_{\rm p})$ and $\alpha_1 \in [0, 2\pi]$, the spectrum of the self-adjoint compact operator $\mathcal{A}_{\alpha_1}(\lambda)$ consists of eigenvalues of finite multiplicity with 0 being the only possible point of accumulation. Let $\mu_1^+(\lambda, \alpha_1) \geq \mu_2^+(\lambda, \alpha_1) \geq \cdots \geq 0$ and $\mu_1^-(\lambda, \alpha_1) \leq \mu_2^-(\lambda, \alpha_1) \leq \ldots 0$ be infinite sequences of, respectively, the positive and negative eigenvalues of $\mathcal{A}_{\alpha_1}(\lambda)$, repeated according to their multiplicity. The sequence $\mu_i^-(\lambda, \alpha_1), i = 1, 2, \ldots$, can be obtained by applying the min-max principle to the operator $\chi_{(-\infty,0]}(\mathcal{A}_{\alpha_1}(\lambda))\mathcal{A}_{\alpha_1}(\lambda)$; similarly, we obtain $-\mu_i^+(\lambda, \alpha_1), i = 1, 2, \ldots$, by applying the min-max principle to the operator $-\chi_{[0,+\infty)}(\mathcal{A}_{\alpha_1}(\lambda))\mathcal{A}_{\alpha_1}(\lambda)$.

As a consequence of Lemma 7, the following λ-dependence of the eigenvalues $\mu_i^\pm(\lambda, \alpha_1)$ of $\mathcal{A}_{\alpha_1}(\lambda)$ holds.

LEMMA 8. *The functions $\mu_i^\pm(\lambda, \alpha_1)$ are monotonically decreasing continuous functions of $\lambda^2 \in \Gamma(\epsilon_{\rm p})$ for each $i = 1, 2, \ldots$.*

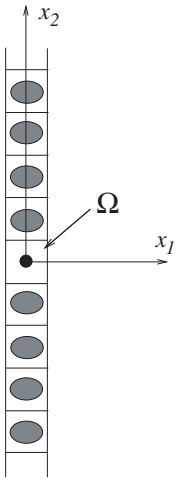

FIG. 3. *A vertical strip with a defect at the origin.*

On the other hand, the following α_1-dependence of the eigenvalues $\mu_i^{\pm}(\lambda, \alpha_1)$ on α_1 is an immediate consequence of Lemma 3.

LEMMA 9. *Let $\lambda^2 \in \Gamma(\epsilon_{\rm p})$. The functions $\mu_i^{\pm}(\lambda, \alpha_1)$ are continuous functions of $\alpha_1 \in [0, 2\pi]$ for each $i = 1, 2, \ldots$.*

5. Defect in the strip. To the strip in Figure 1 we introduce a defect centered at the origin. Let ϵ and $\epsilon_{\rm p}$ differ only in the region Ω which is contained in $(-\frac{1}{2}, \frac{1}{2}) \times (-h, h)$, as indicated in Figure 3. Again, we view α_1 as a parameter and consider the eigenvalue problem of finding $u_{\alpha_1} \in H^1_{\alpha_1}(O)$ satisfying

$$\Delta u_{\alpha_1} + \omega_{\alpha_1}^2 \epsilon(x) u_{\alpha_1} = 0 \quad \text{in } O. \tag{10}$$

Note that we have implicitly required u_{α_1} to satisfy the Bloch condition in the x_1-direction by putting it in $H^1_{\alpha_1}(O)$. We cannot apply the Bloch condition in the x_2-direction since the problem is no longer periodic in that direction. We will consider the spectrum $\sigma_{\alpha_1}(\epsilon)$ for a fixed α_1. In particular, we will look at defect modes introduced by the defect.

5.1. Stability of the essential spectrum. We define unbounded mappings

$$B^p_{\alpha_1} : L^2_{\alpha_1}(O, \epsilon_{\rm p}(x)dx) \to L^2_{\alpha_1}(O, \epsilon_{\rm p}(x)dx), \quad B^p_{\alpha_1} = -\Delta,$$
$$B_{\alpha_1} : L^2_{\alpha_1}(O, \epsilon(x)dx) \to L^2_{\alpha_1}(O, \epsilon(x)dx), \quad B_{\alpha_1} = -\Delta.$$

Denote by $\sigma_{\alpha_1}(\epsilon_{\rm p})$ and $\sigma_{\alpha_1}(\epsilon)$ the essential spectra of the operators $B^p_{\alpha_1}$ and B_{α_1}, respectively.

Instead of working directly with $B^p_{\alpha_1}$ and B_{α_1}, we will work with

$$A^p_{\alpha_1} = (-\Delta)^{-\frac{1}{2}} \epsilon_{\rm p} (-\Delta)^{-\frac{1}{2}} \text{ and } A_{\alpha_1} = (-\Delta)^{-\frac{1}{2}} \epsilon (-\Delta)^{-\frac{1}{2}}.$$

It is easily seen that $\omega^2_{\alpha_1} \in \sigma_{\alpha_1}(\epsilon_{\rm p})$ if and only if $\frac{1}{\omega^2_{\alpha_1}} \in \sigma_{\rm ess}(A^p_{\alpha_1})$. Similarly, $\omega^2_{\alpha_1} \in \sigma_{\alpha_1}(\epsilon)$ if and only if $\frac{1}{\omega^2_{\alpha_1}} \in \sigma_{\rm ess}(A_{\alpha_1})$. Next, let

$$C = A^p_{\alpha_1} - A_{\alpha_1} = (-\Delta)^{-\frac{1}{2}} (\epsilon_{\rm p} - \epsilon)(-\Delta)^{-\frac{1}{2}}.$$

Note that by assumption $(\epsilon_{\rm p} - \epsilon)$ has compact support. Therefore, the operator C maps functions in $L^2_{\alpha_1}(O)$ into $\mathcal{H}_{\alpha_1,\gamma}(O)$. By the compactness of the embedding $\mathcal{H}_{\alpha_1,\gamma}(O) \hookrightarrow L^2_{\alpha_1}(O)$, the perturbation C is a relatively compact perturbation of $A^p_{\alpha_1}$. Hence, as a consequence of Weyl's theorem [12], it follows that $\sigma_{\rm ess}(A^p_{\alpha_1}) = \sigma_{\rm ess}(A_{\alpha_1})$, and so the following lemma holds.

LEMMA 10. *For a fixed α_1, and perturbations*

$$q = \epsilon_{\rm p} - \epsilon$$

supported in $\Omega \subset\subset (-\frac{1}{2}, \frac{1}{2}) \times (-h, h)$, the essential spectrum $\sigma_{\alpha_1}(\epsilon_{\rm p})$ is stable; i.e.,

$$\sigma_{\alpha_1}(\epsilon_{\rm p}) = \sigma_{\alpha_1}(\epsilon).$$

5.2. Spectrum of the strip. From Lemma 10 it is readily seen that the spectrum of the strip (for a fixed $\alpha_1 \in [0, 2\pi]$) in the gap $\Gamma(\epsilon_{\rm p})$ consists only of isolated eigenvalues of finite multiplicity, which can accumulate only at the edges of the gap $\Gamma(\epsilon_{\rm p})$. Let us consider the eigenvalue problem (10), where the eigenvalue $\omega^2_{\alpha_1} \in \Gamma(\epsilon_{\rm p})$.

The eigenvector u_{α_1} satisfies

$$\Delta u_{\alpha_1} + \omega^2_{\alpha_1} \epsilon_{\rm p}(x) u_{\alpha_1} = \omega^2_{\alpha_1} (\epsilon_{\rm p}(x) - \epsilon(x)) \chi_\Omega u_{\alpha_1} \quad \text{in } O.$$

Since $\omega^2_{\alpha_1} \in \Gamma(\epsilon_{\rm p})$, u_{α_1} solves the Lippman–Schwinger integral equation

$$u_{\alpha_1}(x) = \omega^2_{\alpha_1} \int_\Omega g_{\alpha_1}(x, y; \omega_{\alpha_1}) q(y) u_{\alpha_1}(y)\, dy,$$

where $q(y) = \epsilon_{\rm p}(y) - \epsilon(y)$ is supported in Ω. This implies that

$$\operatorname{sgn}(q) \frac{1}{\omega^2_{\alpha_1}} \sqrt{|q|} \chi_\Omega u_{\alpha_1} = \mathcal{A}_{\alpha_1}(\omega_{\alpha_1})(\sqrt{|q|} \chi_\Omega u_{\alpha_1}).$$

Conversely, if $\varphi(\omega_{\alpha_1}, \alpha_1)$ is an eigenvector of $\mathcal{A}_{\alpha_1}(\omega_{\alpha_1})$ with eigenvalue $\operatorname{sgn}(q)\frac{1}{\omega^2_{\alpha_1}}$, then $\int_\Omega g_{\alpha_1}(x, y; \omega_{\alpha_1}) \varphi(\omega_{\alpha_1}, \alpha_1)(y)\, dy$ is an eigenvector of (10) with eigenvalue $\omega^2_{\alpha_1} \in \Gamma(\epsilon_{\rm p})$. As a consequence of the results stated in the above section for $\mathcal{A}_{\alpha_1}(\lambda)$, where $\lambda^2 \in \Gamma(\epsilon_{\rm p})$, the following results on the spectrum of the strip hold.

THEOREM 1. *For a fixed $\alpha_1 \in [0, 2\pi]$, and perturbations $q = \epsilon_{\rm p} - \epsilon$ supported in $\Omega \subset\subset (-\frac{1}{2}, \frac{1}{2}) \times (-h, h)$ we have*

- *if $q \geq 0$, the eigenvalues ω_{α_1} of (10) in the gap $\Gamma(\epsilon_{\rm p})$ coincide with the set of the solutions of the equations*

$$\mu^+_i(\lambda, \alpha_1) = \frac{1}{\lambda^2}, \qquad i = 1, 2, \dots,$$

  where $\mu^+_i(\lambda, \alpha_1)$ are the positive eigenvalues of the operator $\mathcal{A}_{\alpha_1}(\lambda)$; moreover, if $\varphi(\lambda, \alpha_1)$ is an eigenvector of the operator $\mathcal{A}_{\alpha_1}(\lambda)$ with eigenvalue $\mu^+_i(\lambda, \alpha_1) = \frac{1}{\lambda^2}$, then $\int_\Omega g_{\alpha_1}(x, y; \lambda) \varphi(\lambda, \alpha_1)(y)\, dy$ is an exponentially localized in x_2-direction eigenvalue of (10).
- *if $q \leq 0$, the eigenvalues ω_{α_1} of (10) in the gap $\Gamma(\epsilon_{\rm p})$ coincide with the set of the solutions of the equations*

$$\mu^-_i(\lambda, \alpha_1) = -\frac{1}{\lambda^2}, \qquad i = 1, 2, \dots,$$

  where $\mu^-_i(\lambda, \alpha_1)$ are the negative eigenvalues of the operator $\mathcal{A}_{\alpha_1}(\lambda)$. Moreover, if $\varphi(\lambda, \alpha_1)$ is an eigenvector of the operator $\mathcal{A}_{\alpha_1}(\lambda)$ with eigenvalue $\mu^-_i(\lambda, \alpha_1) = -\frac{1}{\lambda^2}$, then $\int_\Omega g_{\alpha_1}(x, y; \lambda) \varphi(\lambda, \alpha_1)(y)\, dy$ is an exponentially localized in x_2-direction eigenvalue of (10).

The following result is an immediate consequence of Theorem 1. It gives a criterion for the absence of eigenvalues of (10).

COROLLARY 1. *Problem* (10) *has no eigenvalues in the gap* $\Gamma(\epsilon_{\mathrm{p}})$ *for small* $||\epsilon_{\mathrm{p}} - \epsilon||_{L^\infty(\Omega)}$.

5.3. Filling in the gap. The result of Theorem 1 provides a way by which we can interpret the guided mode spectrum. However, it does not tell us about the general properties, such as absolute continuity, of the spectrum of the wave operator in a medium with a line defect. What we can say is that it is possible for the bandgap of the periodic medium, $\Gamma(\epsilon_{\mathrm{p}})$, to be filled in (partially or totally) by the introduction of the line defect. To see this, assume for now that $q > 0$, and let $\alpha_1^0 \in [0, 2\pi]$ be such that there exists a solution to

$$\mu_i^+(\lambda, \alpha_1^0) = \frac{1}{\lambda^2}$$

for some i, which we denote by $\omega^2_{\alpha_1^0,i}$. We argue by Lemma 9 that for α_1 in an open neighborhood of α_1^0, there exists a solution λ to

$$\mu_i^+(\lambda, \alpha_1) = \frac{1}{\lambda^2},$$

and this solution is a continuous function of α_1. Therefore, as α_1 is varied over the neighborhood of α_0, we trace out the solution set $\omega_{\alpha_1,i}$. The values $\omega^2_{\alpha_1,i}$ fill out part (or all) of the gap $\Gamma(\epsilon_{\mathrm{p}})$.

Let us draw a conceptual figure of the fill-in process. In Figure 4, the horizontal axis is α_1 and the vertical axis is frequency. For the periodic medium ϵ_{p}, we calculate the passband for each value of α_1. The passbands are intervals in frequency, which is

$$\bigcup_n i_{\alpha_1,n},$$

where $i_{\alpha_1,n}$ is as in section 4.1. To display the spectrum of the wave operator in the periodic medium, we draw these intervals vertically on the ω-α_1 plane at horizontal position α_1. When we are done, we are left with two (or more) disjoint regions, such as those shown in Figure 4. The dark regions correspond to values of α_1 and frequencies at which waves can propagate.

We have indicated the point α_0 on the figure and suppose there is a corresponding eigenvalue $\omega_{\alpha_1^0}$ of (10). As we vary α_1 in the neighborhood of α_1^0, we obtain solutions ω_{α_1}, which when displayed in the figure trace out a curve that fills (or partially fills) the gap. This is indicated in the figure. We denote the interval of α_1 over which such eigenvalues exist by A_1. The results we obtained so far conclude only that A_1 is nonempty. Detailed information, such as connectivity of A_1, is unknown. The picture gets a little more complicated if there are multiple solutions at a given α_1^0, producing multiple curves. It is hoped that the numerical examples, to be presented in the last section, will give some insight into this and other questions.

6. Guided propagation. Our medium, with a line defect lying along the x_1-axis, can guide waves so that they propagate along the x_1-direction. Such a wave will be a linear combination of the guided modes. Each guided mode is an eigenfunction of (10) and decays exponentially away from the origin in x_2. Let us suppose that we have found guided modes for α_1 in A_1 and the corresponding frequencies for these

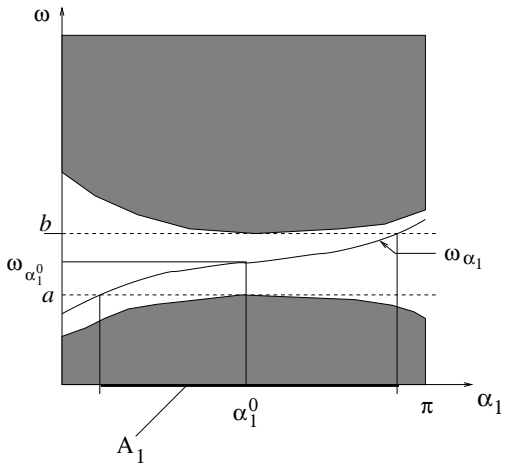

FIG. 4. *A conceptual figure depicting the fill-in process of the bandgap. The vertical axis is frequency. The dark regions correspond to values of* α_1 *and frequencies at which waves can propagate in the periodic medium. The gap above corresponds to the bandgap of the periodic medium. When a defect is introduced, a point spectrum is created for some values of* α_1*. These points trace out a curve in the gap. In the example, a complete fill-in is indicated.*

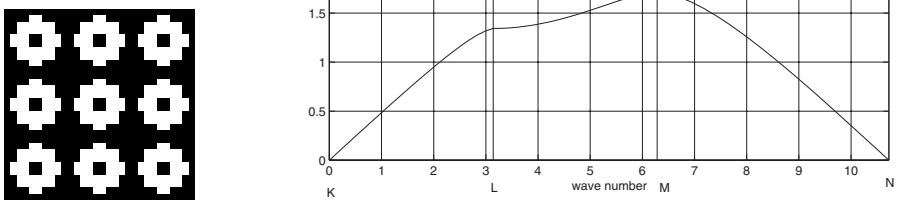

FIG. 5. *The periodic medium and its spectrum. Light region corresponds to* $\epsilon = 9$ *and dark region to* $\epsilon = 1$*. Note the presence of the gaps around* 1.7 *and* 2.7*.*

modes are ω_{α_1}. We denote the associated eigenfunctions by $u_{\alpha_1}(x)$. Then a guided wave in this medium has the representation

$$U(x,t) = \int_{\alpha_1 \in A_1} C_{\alpha_1} u_{\alpha_1}(x) e^{i\omega_{\alpha_1} t} d\alpha_1,$$

where C_{α_1} is the mode amplitude function. Such a wave would propagate like a pulse along the x_1-axis. Its dispersion relation along the x_1-direction is given by ω_{α_1}, with group velocity given by $d\omega_{\alpha_1}/d\alpha_1$.

7. Numerical experiment. We consider a periodic structure with permittivity ϵ_{p} taking a value of 1 or 9. The medium is shown in Figure 5 (left), where the dark region corresponds to low index. We use finite difference approximations to solve (3) for values of α on the boundary of the Brioullin zone:

$$KL = \{0 \le \alpha_1 \le \pi, \alpha_2 = 0\}, \quad LM = \{0 \le \alpha_2 \le \pi, \alpha_1 = \pi\},$$
$$MN = \{0 \le \alpha_1 \le \pi, \alpha_2 = \alpha_1\}.$$

The resulting values of $\omega_n(\alpha)$ are displayed in Figure 5 (right). Note the presence of a small gap near 1.7 and a larger one near 2.7.

The problem involving a line defect is considered next. We start by solving the strip eigenvalue problem (5) for the periodic medium ϵ_{p}. We do this by creating a strip of 19 cells and applying the Bloch condition with parameter α_2 at the top and at the bottom of the strip. The Bloch condition has to be modified to reflect the strip geometry:

$$u_{\alpha_1}(x_1, x_2 + 19) = u_{\alpha_1}(x_1, x_2)e^{i19\alpha_2}.$$

We choose α_1 and solve for eigenvalues $\nu_{\alpha_1,n}(\alpha_2)$ as α_2 is sampled over the interval $[0, \pi/19]$. The first 25 eigenvalues are found for each case and are displayed as points with horizontal coordinate α_1. The resulting picture is shown in Figure 6 (top). The points lie in the dark regions indicated in the conceptual version shown in Figure 4. Note that the gap in question is the one around 2.7 from Figure 5.

Next, a defect is introduced. The strip with the defect can be seen in Figure 6 (bottom). The calculation described above is repeated with the defect. With the Bloch condition at the top and bottom, we are essentially performing a supercell computation. The defect produces the fill-in described in section 5, which we display in Figure 6 (bottom). For each α_1 the eigenvalues calculated for different samples of α_2 are slightly different. The dense placement of points vertically has now become more broken. What can be clearly seen is that the boundary between the empty region and the region populated with dots remains in place. Moreover, we now see the presence of an additional set of points running from the lower left to the upper right. Of these points, those that lie within the gap correspond to the guided modes and trace out the dispersion curve of the modes. To verify that this is the case, we selected the points that lie in the bandgap of the periodic medium. Note that because we are using the supercell method, each defect spectrum is calculated as many times as we sample α_2. For each of these points, we calculate the associated eigenfunction $u_{\alpha_1}(x, \alpha_2)$ and display its absolute value. In Figure 7, we show the absolute value of the guided modes for different α_1. Note that the modes become more concentrated near the defect for higher values of α_1. In this example, the set of α_1 for which we have guided modes is smaller than the interval $[-\pi, \pi]$.

We ran two more examples with different defects. In the first case, shown in Figure 8 (top), the defect produces two defect modes in the gap at most values of α_1. The fill-in is total. In the second case, Figure 8, bottom, the fill-in is only partial. A bandgap, slightly smaller, still exists.

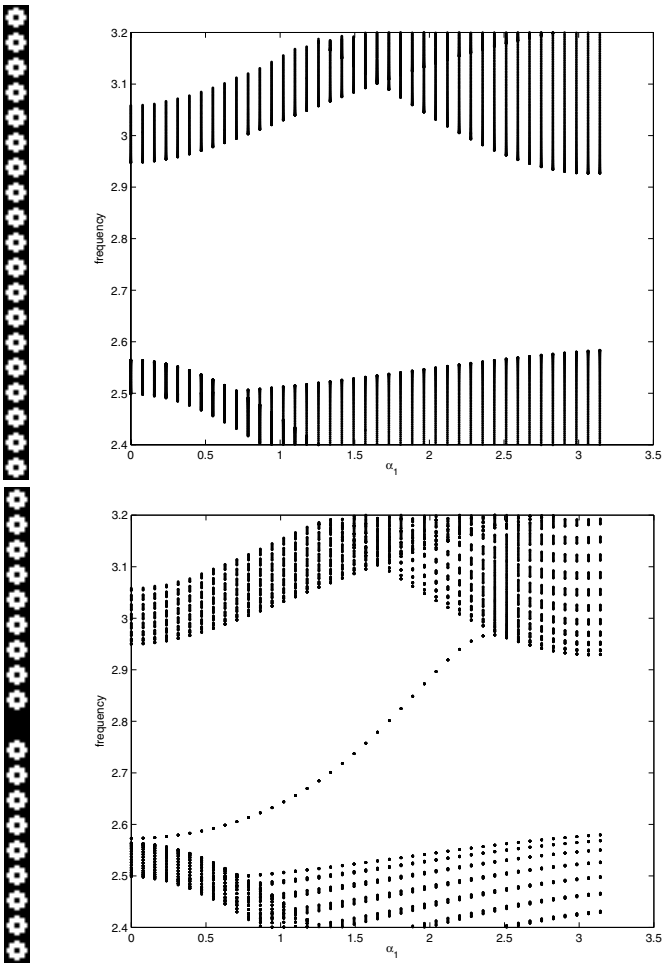

FIG. 6. *The spectrum of the periodic strip and the strip with a defect. The images of the strips are given on the left. The graph for the periodic medium is calculated for comparison with that of the medium with defect. On the top, note the white region corresponding to the gap. On the bottom, note that the boundary of the white region is not changed for the perturbed medium. The only difference is the creation of a point spectrum (a curve) which fills the gap.*

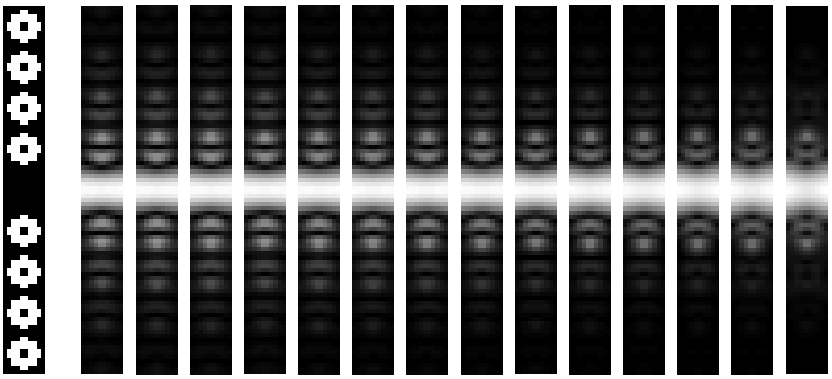

FIG. 7. *The medium and the guided modes intensity sampled at various values of* α_1.

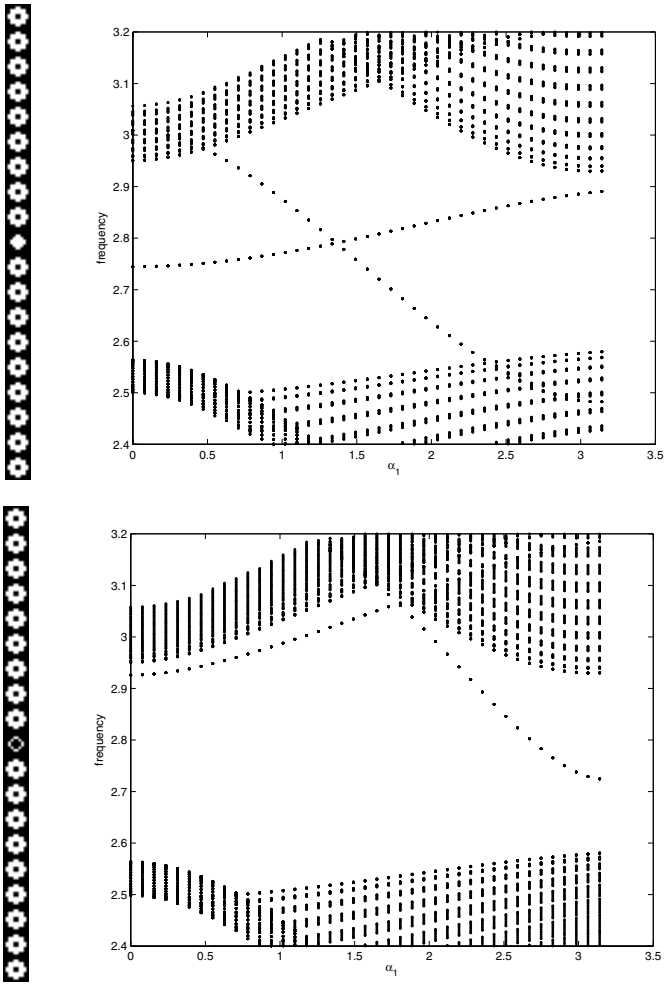

FIG. 8. *Spectra of the strip with two different defects. Images of the strip are given on the left. Note that a complete fill-in has occurred in the first case. Moreover, there are multiple guided modes at each* α_1. *In the second case, the fill-in is partial.*

8. Discussion. We have provided a mathematical framework by which wave guidance phenomena in a photonic bandgap structure with line defect can be understood. The key idea is to analyze the spectral properties of Helmholtz's equation in a strip. Using Weyl's theorem, we have shown that the essential spectrum of the periodic medium is stable to the introduction of the defect. The new spectrum created by the defect corresponds to guided modes and has a dispersion relation that can fill (or partially fill) the bandgap of the periodic medium. The main findings of this work are further illustrated in numerical examples.

The question of absolute continuity of the spectrum, while of great importance, is beyond the scope and techniques of the present work. Our theoretical result shows that if a line defect creates a guided mode, there should be a continuum of these modes parameterized by wave number α_1 over an open interval, covering an open interval of the bandgap in frequency. The numerical results show that for some perturbations, the coverage is complete, thus filling in the bandgap, while for other perturbations,

the fill-in is only partial. Our method also does not reveal what happens near the band edges. Numerical calculations presented here indicate that guided modes with frequencies up to the band edges are possible. It is not known how these modes decay in the x_2-direction.

Finally, we remark that it would be useful to take this work and produce a kind of approximate theory that is as simple to use as that employed in modeling guided waves in optical fibers. This and other issues mentioned indicate possibilities for further investigation.

Acknowledgments. This collaboration was initiated during the first author's visit to the Institute for Mathematics and Its Applications in July 2001. The authors express their gratitude to the referees who carefully read an earlier version of this paper. Their valuable suggestions have been incorporated into the present version.

CLOSED-FORM SOLUTIONS FOR PERPETUAL AMERICAN PUT OPTIONS WITH REGIME SWITCHING*

X. GUO† AND Q. ZHANG‡

Abstract. This paper studies an optimal stopping time problem for pricing perpetual American put options in a regime switching model. An explicit optimal stopping rule and the corresponding value function in a closed form are obtained using the "modified smooth fit" technique. The solution is then compared with the numerical results obtained via a dynamic programming approach and also with a two-point boundary-value differential equation (TPBVDE) method.

Key words. Markov chain, optimal stopping time, American options, regime switching, modified smooth fit principle

DOI. 10.1137/S0036139903426083

1. Introduction.

Given a probability space $(\Omega, \mathcal{F}, P)$, consider a process $X(t)$ which satisfies (in a strong sense) a stochastic differential equation of the following form:

$$dX(t) = X(t)\mu_{\epsilon(t)}dt + X(t)\sigma_{\epsilon(t)}dW(t), \qquad X(0) = x, \tag{1}$$

where $\epsilon(t) \in \{1, \ldots, S\}$ is a finite-state continuous-time Markov chain and $W(t)$ is a standard Wiener process. Here $\epsilon(t)$ and $W(t)$ are defined on $(\Omega, \mathcal{F}, P)$ and are independent. Moreover, for a given $\epsilon(t) = i$, μ_i and σ_i $(i = 1, \ldots, S)$ are constants and known.

The $X(t)$ governed by (1) is generally referred to as a process with "regime switching (or shifts)" or "a Markov modulated (geometric) Brownian motion." There is a substantial body of literature on this type of model studied from different perspectives. See, for instance, Di Masi, Kabanov, and Runggaldier [3] for mean variance hedging issues; Guo [5, 7] for closed-form solutions for pricing European and perpetual lookback options; Yao, Zhang, and Zhou [23] for numerical algorithms for computing European stock options; Zhang [24] for suboptimal selling rules for investors; and Zhang and Yin [25] for portfolio optimization problems.

In light of the celebrated Black–Scholes geometric Brownian motion model (see Black and Scholes [1] and Samuelson [20]), which corresponds to a special case of (1) with $\mu_1 = \cdots = \mu_S$ and $\sigma_1 = \cdots = \sigma_S$, the primary motivation for the incorporation of the Markov chain $\epsilon(t)$ is the conviction that various economic factors (e.g., interest rates, quarterly GDP) and general information (e.g., corporate news releases, quarterly earnings reports) could be major catalysts for stock fluctuations. In addition, a finite-state Markov chain has been proved to be simple yet rich enough to characterize the uncertainty in many discrete events. These convictions have been further substantiated by numerical studies: Yao, Zhang, and Zhou [23] showed that the infamous "volatility smile" can be created with a Markov chain of a single jump, instead of the more complicated stochastic volatility model by Renault and Touzi [17].

Our results. In this paper we consider an optimal stopping problem that arises in pricing American put options, in the framework of this regime switching model. An American option is a derivative that gives its holder the option but not the obligation of exercising a share of stock at his/her choice of time τ ($T \geq \tau \geq 0$), with a payoff of $(K - X_\tau)^+ = \max(0, K - X_\tau)$. Here, T is the *expiration date* and K is the *strike price*. It is well known that under a risk-neutral measure, the value (or the price) of this option is the expected discounted value of its future cash flow. (For more details, readers are referred to Duffie [4] and the references therein for risk-neutral option pricing for general models, to Guo [6] for the regime switching models, and to Karatzas [10] for the mathematical formulation of the American option pricing problem in the context of optimal stopping problems.) In particular, when $T = \infty$, the option becomes perpetual, and our optimal stopping problem becomes the evaluation of

$$V^*(x,i) = \sup_{0\leq\tau\leq\infty} E[e^{-r\tau}(K - X(\tau))^+ \mid X(0) = x, \epsilon(0) = i]. \tag{2}$$

Here, $r > 0$ is the discounted factor, and τ is an $\mathcal{F}_t = \sigma\{(W(s), \epsilon(s)) \mid s \leq t\}$-stopping time.

We derive an optimal stopping rule for (2) and its corresponding value functions for $S = 2$ (see Remark 3.5). We show that the optimal stopping times are of threshold type, with the technique of modified smooth fit. The main ingredient of the optimality proof is Dynkin's formula.

It is worth mentioning that a special case of this problem with no switching (i.e., $\mu_1 = \mu_2, \sigma_1 = \sigma_2$) was solved by McKean [14], and it is referred to in what follows as "the McKean problem." His result is the earliest instance in which optimal stopping problems were related to option pricings. See also Jacka [9] and Robbins, Sigmund, and Chow [19] for related literature on optimal stopping.

Organization. In section 2, we provide a detailed derivation of the closed-form solution to (2). The optimality proof is given in section 3. In section 4, we numerically compare the closed-form solution with numerical results derived from other previous approaches, namely the dynamic programming approach (see Guo [7]) and the TPB-VDE (two-point boundary-value differential equation) method (see Zhang [24]). The paper concludes with additional discussion and open problems in section 5.

2. The derivation of solutions. Given (1), we will study problem (2) with a two-state Markov chain (see Remark 3.5) for the general case K. Without loss of generality, we assume that $\sigma_1 \neq \sigma_2$ (see Remark 3.1) and that the Markov chain has a generator of the form

$$\begin{pmatrix} -\lambda_1 & \lambda_1 \\ \lambda_2 & -\lambda_2 \end{pmatrix}, \tag{3}$$

with $\lambda_1, \lambda_2 > 0$.

Recall that when there is no regime switching, this problem corresponds to a McKean problem [14] for which there exists a threshold x^* such that the optimal stopping rule is $\tau^* = \inf\{t > 0 : X(t) \notin (x^*, \infty)\}$, and the corresponding value function

$$\begin{aligned} V^*(x) &= \sup_{0\leq\tau\leq\infty} E[e^{-r\tau}(K - X(\tau))^+ | X(0) = x] \\ &= E[e^{-r\tau^*}(K - X(\tau^*))^+ | X(0) = x] \end{aligned}$$

is given by

$$V^*(x) = \begin{cases} (K - x^*)(x/x^*)^\gamma & \text{if } x > x^*, \\ K - x & \text{if } x \le x^*. \end{cases}$$

Now, with a two-state Markov chain and with $\sigma_1 \neq \sigma_2$, it is easy to see that $(X(t), \epsilon(t))$ is a joint Markov process (see Guo [7]). Therefore, it is natural to conjecture that the optimal stopping rule is also of threshold type, except that the threshold should vary depending on the state $\epsilon(t)$. In other words, we expect the existence of two thresholds $x_1, x_2 \le K$, so that the optimal stopping rule is given as

$$\tau^* = \inf\{t \ge 0 \ \mid \ (X(t), \epsilon(t)) \notin D\},$$

where

$$D = \{(x, i) \ \mid \ V^*(x, i) > (K - x)^+\}.$$

The set D is referred to as the *continuation region*. Using τ^*, the corresponding value functions are

$$V^*(x, i) = E[e^{-r\tau^*}(K - X(\tau^*))^+ \ \mid \ X(0) = x, \epsilon(0) = i]. \tag{4}$$

We consider the case when D can be represented by two threshold levels x_1 and x_2, i.e.,

$$D = \{(x, 1) \ \mid \ x \in (x_1, \infty)\} \cup \{(x, 2) \ \mid \ x \in (x_2, \infty)\}.$$

Notice that x_1 and x_2 should depend on r, K, $\mu_i, \sigma_i, \lambda_i$. For any x_1 and x_2, there are only three possibilities, $x_1 < x_2$, $x_1 > x_2$, and $x_1 = x_2$. In the next sections we discuss each of these cases and derive the values of these thresholds x_i as well as the corresponding value functions (denoted as $V_i(x)$) obtained from exercising this type of stopping rule. We will then prove the optimality of these value functions, i.e., $V^*(x, i) = V_i(x)$, in Theorem 3.1.

2.1. Case 1: $x_1 < x_2 \le K$. At any given time t, if $\epsilon(t) = 1$ and $X(t) \le x_1$, then one should stop immediately and obtain a payoff of $(K - X(t))^+$; this follows from the definition of x_1 and x_2. However, if $X(t) \le x_1$ with $\epsilon(t) = 2$, it is not optimal to stop until $X(t) \le x_2$. In view of Ito's differential rule, this is translated into a set of differential equations. For $x \in [x_1, x_2]$, we have

$$\begin{cases} (r + \lambda_1)V_1(x) &= x\mu_1 V_1'(x) + \dfrac{1}{2}x^2\sigma_1^2 V_1''(x) + \lambda_1(K - x), \\ V_2(x) &= K - x; \end{cases} \tag{5}$$

for $x \in [x_2, \infty)$,

$$\begin{cases} (r + \lambda_1)V_1(x) &= x\mu_1 V_1'(x) + \dfrac{1}{2}x^2\sigma_1^2 V_1''(x) + \lambda_1 V_2(x), \\ (r + \lambda_2)V_2(x) &= x\mu_2 V_2'(x) + \dfrac{1}{2}x^2\sigma_2^2 V_2''(x) + \lambda_2 V_1(x); \end{cases} \tag{6}$$

and for $x \in [0, x_1]$,

$$V_1(x) = V_2(x) = K - x. \tag{7}$$

Now, (6) has an associated characteristic function

$$g_1(\beta)g_2(\beta) = \lambda_1\lambda_2, \tag{8}$$

where

$$g_1(\beta) = \lambda_1 + r - \left(\mu_1 - \frac{1}{2}\sigma_1^2\right)\beta - \frac{1}{2}\sigma_1^2\beta^2,$$
$$g_2(\beta) = \lambda_2 + r - \left(\mu_2 - \frac{1}{2}\sigma_2^2\right)\beta - \frac{1}{2}\sigma_2^2\beta^2.$$

Moreover, this characteristic function has four distinct roots $\beta_1 < \beta_2 < 0 < \beta_3 < \beta_4$ (see Guo [7]), such that the general form of the solution to (6) is given by

$$\begin{aligned} V_1(x) &= \sum_{i=1}^{4} A_i x^{\beta_i}, \\ V_2(x) &= \sum_{i=1}^{4} B_i x^{\beta_i}, \end{aligned}$$

with $B_i = l_i A_i$ and $l_i = l(\beta_i) = \frac{g_1(\beta_i)}{\lambda_1} = \frac{\lambda_2}{g_2(\beta_i)}$.

Note that when $x \to \infty$, $V_1(x)$ and $V_2(x)$ are bounded. Thus, the positive powers of x should be eliminated so that

$$\begin{aligned} V_1(x) &= A_1 x^{\beta_1} + A_2 x^{\beta_2}, \\ V_2(x) &= B_1 x^{\beta_1} + B_2 x^{\beta_2}. \end{aligned} \tag{9}$$

Next, we turn our attention to (5). The first equation is an inhomogeneous equation whose solution can be written as

$$V_1(x) = C_1 x^{\gamma_1} + C_2 x^{\gamma_2} + \phi(x), \tag{10}$$

where $\phi(x)$ is a special solution and γ_1, γ_2 are the two real roots of

$$\mu_1\gamma + \frac{1}{2}\sigma_1^2\gamma(\gamma - 1) = r + \lambda_1.$$

In particular, when $r + \lambda_1 - \mu_1 \neq 0$, one can choose

$$\phi(x) = \frac{\lambda_1 K}{r + \lambda_1} - \frac{\lambda_1 x}{r + \lambda_1 - \mu_1}. \tag{11}$$

Now, we want to solve for A_1, A_2, C_1, C_2, x_1, and x_2. To this end, appropriate boundary conditions are needed. Applying the smooth fit at x_2, conditions $V_2(x+) = V_2(x-)$ and $V_2'(x+) = V_2'(x-)$ suggest

$$\begin{cases} l_1 A_1 x_2^{\beta_1} + l_2 A_2 x_2^{\beta_2} &= K - x_2, \\ \beta_1 l_1 A_1 x_2^{\beta_1} + \beta_2 l_2 A_2 x_2^{\beta_2} &= -x_2. \end{cases} \tag{12}$$

Similarly, the smoothness of $V_1(x)$ at x_1 and x_2 yields

$$\begin{cases} A_1 x_2^{\beta_1} + A_2 x_2^{\beta_2} &= C_1 x_2^{\gamma_1} + C_2 x_2^{\gamma_2} + \phi(x_2), \\ \beta_1 A_1 x_2^{\beta_1} + \beta_2 A_2 x_2^{\beta_2} &= \gamma_1 C_1 x_2^{\gamma_1} + \gamma_2 C_2 x_2^{\gamma_2} + x_2 \phi'(x_2), \end{cases} \tag{13}$$

and

$$\begin{cases} C_1 x_1^{\gamma_1} + C_2 x_1^{\gamma_2} + \phi(x_1) &= K - x_1, \\ \gamma_1 C_1 x_1^{\gamma_1} + \gamma_2 C_2 x_1^{\gamma_2} + x_1 \phi'(x_1) &= -x_1. \end{cases} \tag{14}$$

Combining the above three equations and following some algebraic manipulation, we obtain an algebraic equation for x_1 and x_2:

$$\begin{pmatrix} x_1^{-\gamma_1} & 0 \\ 0 & x_1^{-\gamma_2} \end{pmatrix} F_1(x_1) = \begin{pmatrix} x_2^{-\gamma_1} & 0 \\ 0 & x_2^{-\gamma_2} \end{pmatrix} F_2(x_2), \tag{15}$$

where

$$F_1(x_1) = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \begin{pmatrix} K - x_1 - \phi(x_1) \\ -x_1 - x_1 \phi'(x_1) \end{pmatrix}$$

and

$$F_2(x_2) = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ \beta_1 l_1 & \beta_2 l_2 \end{pmatrix}^{-1} \begin{pmatrix} K - x_2 \\ -x_2 \end{pmatrix} - \begin{pmatrix} \phi(x_2) \\ x_2 \phi'(x_2) \end{pmatrix} \right].$$

In particular, if $r + \lambda_1 - \mu_1 \neq 0$, where $\phi(x_1)$ is in the form of (11), then

$$F_1(x_1) = a_1 + a_2 x_1$$

and

$$F_2(x_2) = b_1 + b_2 x_2.$$

Here

$$a_1 = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{rK}{r+\lambda_1} \\ 0 \end{pmatrix}, \qquad a_2 = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{\mu_1 - r}{r+\lambda_1-\mu_1} \\ \frac{\mu_1 - r}{r+\lambda_1-\mu_1} \end{pmatrix},$$

$$b_1 = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ \beta_1 l_1 & \beta_2 l_2 \end{pmatrix}^{-1} \begin{pmatrix} K \\ 0 \end{pmatrix} + \begin{pmatrix} -\frac{\lambda_1 K}{r+\lambda_1} \\ 0 \end{pmatrix} \right],$$

$$b_2 = \begin{pmatrix} 1 & 1 \\ \gamma_1 & \gamma_2 \end{pmatrix}^{-1} \left[- \begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} l_1 & l_2 \\ \beta_1 l_1 & \beta_2 l_2 \end{pmatrix}^{-1} \begin{pmatrix} 1 \\ 1 \end{pmatrix} + \begin{pmatrix} \frac{\lambda_1}{r+\lambda_1-\mu_1} \\ \frac{\lambda_1}{r+\lambda_1-\mu_1} \end{pmatrix} \right].$$

The coefficients are given by

$$\begin{pmatrix} A_1 \\ A_2 \end{pmatrix} = \begin{pmatrix} l_1 x_2^{\beta_1} & l_2 x_2^{\beta_2} \\ \beta_1 l_1 x_2^{\beta_1} & \beta_2 l_2 x_2^{\beta_2} \end{pmatrix}^{-1} \begin{pmatrix} K - x_2 \\ -x_2 \end{pmatrix}, \qquad \begin{pmatrix} B_1 \\ B_2 \end{pmatrix} = \begin{pmatrix} l_1 A_1 \\ l_2 A_2 \end{pmatrix},$$

and

$$\begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \begin{pmatrix} x_1^{\gamma_1} & x_1^{\gamma_2} \\ \gamma_1 x_1^{\gamma_1} & \gamma_2 x_1^{\gamma_2} \end{pmatrix}^{-1} \begin{pmatrix} K - x_1 - \phi(x_1) \\ -x_1 - x_1 \phi'(x_1) \end{pmatrix}.$$

With these coefficients, the value functions become

$$V_1(x) = \begin{cases} A_1 x^{\beta_1} + A_2 x^{\beta_2} & \text{if } x > x_2, \\ C_1 x^{\gamma_1} + C_2 x^{\gamma_2} + \phi(x) & \text{if } x_1 < x \le x_2, \\ K - x & \text{if } x \le x_1, \end{cases}$$

$$V_2(x) = \begin{cases} B_1 x^{\beta_1} + B_2 x^{\beta_2} & \text{if } x > x_2, \\ K - x & \text{if } x \le x_2. \end{cases} \tag{16}$$

2.2. Case 2: $x_2 < x_1 \le K$. The derivation of this case is analogous to that of $x_1 < x_2$, and we only summarize the results below.

Let $\widetilde{\gamma}_1$ and $\widetilde{\gamma}_2$ be the roots of

$$\mu_2 \gamma + \frac{1}{2}\sigma_2^2 \gamma(\gamma - 1) = r + \lambda_2,$$

and $\widetilde{\phi}(x)$ be a solution to

$$(r + \lambda_2) V_2(x) = x\mu_2 V_2'(x) + \frac{1}{2} x^2 \sigma_2^2 V_2''(x) + \lambda_2 (K - x).$$

Then, x_1, x_2 satisfy

$$\begin{pmatrix} x_1^{-\widetilde{\gamma}_1} & 0 \\ 0 & x_1^{-\widetilde{\gamma}_2} \end{pmatrix} \widetilde{F}_1(x_1) = \begin{pmatrix} x_2^{-\widetilde{\gamma}_1} & 0 \\ 0 & x_2^{-\widetilde{\gamma}_2} \end{pmatrix} \widetilde{F}_2(x_2), \tag{17}$$

with

$$\widetilde{F}_1(x_1) = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} \widetilde{l}_1 & \widetilde{l}_2 \\ \beta_1 \widetilde{l}_1 & \beta_2 \widetilde{l}_2 \end{pmatrix}^{-1} \begin{pmatrix} K - x_1 \\ -x_1 \end{pmatrix} - \begin{pmatrix} \phi(x_1) \\ x_1 \phi'(x_1) \end{pmatrix} \right]$$

and

$$\widetilde{F}_2(x_2) = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \begin{pmatrix} K - x_2 - \phi(x_2) \\ -x_2 - x_2\phi'(x_2) \end{pmatrix},$$

where $\widetilde{l}_i = 1/l_i$.

In particular, if $r + \lambda_2 - \mu_2 \neq 0$, then $\widetilde{\phi}(x)$ is given by

$$\widetilde{\phi}(x) = \frac{\lambda_2 K}{r + \lambda_2} - \frac{\lambda_2 x}{r + \lambda_2 - \mu_2},$$

and

$$\widetilde{F}_1(x_1) = \widetilde{a}_1 + \widetilde{a}_2 x_1,$$

$$\widetilde{F}_2(x_2) = \widetilde{b}_1 + \widetilde{b}_2 x_2,$$

where

$$\widetilde{a}_1 = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \left[\begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} \widetilde{l}_1 & \widetilde{l}_2 \\ \beta_1\widetilde{l}_1 & \beta_2\widetilde{l}_2 \end{pmatrix}^{-1} \begin{pmatrix} K \\ 0 \end{pmatrix} + \begin{pmatrix} -\frac{\lambda_2 K}{r+\lambda_2} \\ 0 \end{pmatrix} \right],$$

$$\widetilde{a}_2 = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \left[- \begin{pmatrix} 1 & 1 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} \widetilde{l}_1 & \widetilde{l}_2 \\ \beta_1\widetilde{l}_1 & \beta_2\widetilde{l}_2 \end{pmatrix}^{-1} \begin{pmatrix} 1 \\ 1 \end{pmatrix} + \begin{pmatrix} \frac{\lambda_2}{r+\lambda_2-\mu_2} \\ \frac{\lambda_2}{r+\lambda_2-\mu_2} \end{pmatrix} \right],$$

$$\widetilde{b}_1 = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{rK}{r+\lambda_2} \\ 0 \end{pmatrix}, \qquad \widetilde{b}_2 = \begin{pmatrix} 1 & 1 \\ \widetilde{\gamma}_1 & \widetilde{\gamma}_2 \end{pmatrix}^{-1} \begin{pmatrix} \frac{\mu_2 - r}{r+\lambda_2-\mu_2} \\ \frac{\mu_1 - r}{r+\lambda_2-\mu_2} \end{pmatrix}.$$

In short, if $x_1 > x_2$, then the corresponding value functions are

$$V_1(x) = \begin{cases} \widetilde{A}_1 x^{\beta_1} + \widetilde{A}_2 x^{\beta_2} & \text{if } x > x_1, \\ K - x & \text{if } x \leq x_1, \end{cases}$$

$$V_2(x) = \begin{cases} \widetilde{B}_1 x^{\beta_1} + \widetilde{B}_2 x^{\beta_2} & \text{if } x > x_1, \\ \widetilde{C}_1 x^{\widetilde{\gamma}_1} + \widetilde{C}_2 x^{\widetilde{\gamma}_2} + \widetilde{\phi}(x) & \text{if } x_2 < x \leq x_1, \\ K - x & \text{if } x \leq x_2, \end{cases} \tag{18}$$

with

$$\begin{pmatrix} \widetilde{A}_1 \\ \widetilde{A}_2 \end{pmatrix} = \begin{pmatrix} x_1^{\beta_1} & x_1^{\beta_2} \\ \beta_1 x_1^{\beta_1} & \beta_2 x_1^{\beta_2} \end{pmatrix}^{-1} \begin{pmatrix} K - x_1 \\ -x_1 \end{pmatrix}, \qquad \begin{pmatrix} \widetilde{B}_1 \\ \widetilde{B}_2 \end{pmatrix} = \begin{pmatrix} l_1\widetilde{A}_1 \\ l_2\widetilde{A}_2 \end{pmatrix},$$

and

$$\begin{pmatrix} \widetilde{C}_1 \\ \widetilde{C}_2 \end{pmatrix} = \begin{pmatrix} x_2^{\widetilde{\gamma}_1} & x_2^{\widetilde{\gamma}_2} \\ \widetilde{\gamma}_1 x_2^{\widetilde{\gamma}_1} & \widetilde{\gamma}_2 x_2^{\widetilde{\gamma}_2} \end{pmatrix}^{-1} \begin{pmatrix} K - x_2 - \widetilde{\phi}(x_2) \\ -x_2 - x_2\widetilde{\phi}'(x_2) \end{pmatrix}.$$

2.3. Case 3: $x_1 = x_2 = x^* \le K$. In this case, we have, for $x \ge x^*$,

$$V_1(x) = A_1 x^{\beta_1} + A_2 x^{\beta_2},$$
$$V_2(x) = B_1 x^{\beta_1} + B_2 x^{\beta_2},$$

and $V_1(x) = V_2(x) = K - x$ for $x \in [0, x^*]$. The smooth fit scheme leads to

$$\begin{cases} A_1(x^*)^{\beta_1} + A_2(x^*)^{\beta_2} &= K - x^*, \\ \beta_1 A_1(x^*)^{\beta_1} + \beta_2 A_2(x^*)^{\beta_2} &= -x^*, \end{cases} \tag{19}$$

and

$$\begin{cases} B_1(x^*)^{\beta_1} + B_2(x^*)^{\beta_2} &= K - x^*, \\ \beta_1 B_1(x^*)^{\beta_1} + \beta_2 B_2(x^*)^{\beta_2} &= -x^*. \end{cases} \tag{20}$$

Necessarily, we have $A_1 = B_1$ and $A_2 = B_2$, and therefore, $V_1 = V_2$.

Defining $V(x) = V_1(x) = V_2(x)$, then for $x > x^*$, the first equation in (6) reduces to

$$rV(x) = x\mu_i V'(x) + \frac{1}{2}x^2\sigma_i^2 V''(x),$$

for both $i = 1, 2$. This implies

$$V_1(x) = V_2(x) = \begin{cases} \dfrac{(K - x^*)x^\beta}{(x^*)^\beta} & \text{if } x > x^*, \\ K - x & \text{if } x \le x^*, \end{cases}$$

where $x^* = K\beta/(\beta - 1)$ and β is the negative solution of

$$r - \left(\mu_i - \frac{1}{2}\sigma_i^2\right)\beta - \frac{1}{2}\sigma_i^2\beta^2 = 0$$

for $i = 1$ or $i = 2$.

3. Optimality of the solution. Now, we prove the optimality of $V_i(x)$ and x_i for $i = 1, 2$ derived in the previous section. For general results on stochastic calculus, we refer to the books by Karatzas and Shreve [11], McKean [15], and Revuz and Yor [18].

Recall

$$V^*(x, i) = \sup_\tau E[e^{-r\tau}(K - X(\tau))^+ \mid X(0) = x, \epsilon(0) = i].$$

Then we must prove the following claim.

THEOREM 3.1. *Suppose that* (15) (resp., (17)) *has a solution* (x_1^*, x_2^*) *such that* $0 < x_1^* \le K$ *and* $0 < x_2^* \le K$. *Assume* $V_i(x) > (K-x)^+$ *on* (x_i^*, ∞) *and* $\mu_i \ge 0$ *for* $i = 1, 2$. *Define*

$$D = \{(x, i) \mid V_i(x) > (K-x)^+\},$$

and let

$$\tau^* = \inf\{t \ge 0 \mid (X(t), \epsilon(t)) \notin D\}.$$

Then τ^* *is an optimal stopping time, and* $V_i(x)$ *are value functions (i.e.,* $V_i(x) = V^*(x, i)$*) and are given by* (16) (resp., (18)).

Proof. It is easy to see that $V_i(\infty) = 0$, $i = 1, 2$, and

$$D = \{(x, 1) \mid x \in (x_1^*, \infty)\} \cup \{(x, 2) \mid x \in (x_2^*, \infty)\}.$$

For any $v(x, i) \in C^2$, define

$$\mathcal{L}v(x,i) = x\mu_i \frac{\partial v(x,i)}{\partial x} + \frac{1}{2}x^2\sigma_i^2 \frac{\partial^2 v(x,i)}{\partial x^2} + \lambda_i(v(x, 3-i) - v(x,i)) - rv(x,i).$$

Let $v(x, i) = V_i(x)$. Then $\mathcal{L}v \le 0$ on $(x, i) \in D$. Using Dynkin's formula, we have

$$d(e^{-rt}v(X(t), \epsilon(t))) = e^{-rt}\mathcal{L}v(X(t), \epsilon(t))dt + d(\text{martingale}).$$

For any stopping time τ, it follows, from a smooth approximation approach for variational inequalities in Øksendal [16, p. 204], that

$$v(x,i) \ge E[e^{-r\tau}v(X(\tau), \epsilon(\tau))] \ge E[e^{-r\tau}(K - X(\tau))^+]. \tag{21}$$

To show the optimality of τ^*, note that if $\tau^* < \infty$, then $v(X(\tau^*), \epsilon(\tau^*)) = (K - X(\tau^*))^+$. In this case, Dynkin's formula yields $v(x, i) = E[e^{-r\tau^*}(K - X(\tau^*))^+]$. Otherwise, let

$$D_k = D \cap \{x < k\}, \quad \text{for } k = 1, 2, \ldots.$$

Let $\tau_k = \inf\{t \ge 0 \mid (X(t), \epsilon(t)) \notin D_k\}$. Then we can show that $\tau_k \to \tau^*$ a.s. Moreover, as in Zhang [24, Theorems 4.5 and 4.6], we can show that, for each k, $\tau_k < \infty$ a.s. Using the definition of τ_k, we have, for $k > K$,

$$v(X(\tau_k), \epsilon(\tau_k)) = v(X(\tau_k), \epsilon(\tau_k))I_{\{X(\tau_k)=k\}} + v(X(\tau_k), \epsilon(\tau_k))I_{\{X(\tau_k)<k\}}.$$

Note that

$$v(X(\tau_k), \epsilon(\tau_k))I_{\{X(\tau_k)<k\}} = (K - X(\tau_k))^+ I_{\{X(\tau_k)<k\}} \le (K - X(\tau_k))^+.$$

Moreover, note that $0 \le v(x, i) \le K$ and $e^{-r\tau_k}I_{\{X(\tau_k)=k\}} \to 0$, as $k \to \infty$, a.s. It follows that

$$E[e^{-r\tau_k}v(X(\tau_k), \epsilon(\tau_k))I_{\{X(\tau_k)=k\}}] \to 0.$$

Therefore, we have, as $k \to \infty$,

$$v(x,i) \le E[e^{-r\tau_k}v(X(\tau_k), \epsilon(\tau_k)] \le E[e^{-r\tau^*}(K - X(\tau^*))^+].$$

Combining this with (21), we have

$$v(x,i) = E[e^{-r\tau^*}(K - X(\tau^*))^+].$$

This completes the proof.

Remark 3.1. As mentioned earlier, when $\sigma_1 \neq \sigma_2$, $\epsilon(t)$ becomes observable from the quadratic variation of $X(t)$ by Ito's calculus (see McKean [14]) and yields the joint Markov structure of $(X(t), \epsilon(t))$. This is one of the key points for our analysis. Although the case $\sigma_1 = \sigma_2$ is of independent interest from the filtering perspective since $\epsilon(t)$ is no longer observable (see Wonham [22] for estimating the probability distribution of $\epsilon(t)$, Liptser and Shiryayev [13] for general filtering, and Zhang [26, 27] for state detection and hybrid filtering), the option pricing problem is exactly the McKean problem, since a Girsanov transformation will reduce the regime switching model to the Black–Scholes model.

Remark 3.2. When $\lambda_1\lambda_2 = 0$, the corresponding $\epsilon(t)$ reduces to a single jump process, and the value functions can be solved sequentially using our method.

Remark 3.3. The optimality proof in Theorem 3.1 indicates the uniqueness of the value functions and that of the corresponding x_i's. Moreover, the assumption $V_i(x) > (K - x)^+$ or the existence of x_1, x_2 would be redundant if we assume the C^1 smoothness at the boundary x_1, x_2.

Remark 3.4. The assumption $\mu_i \geq 0$ guarantees that $e^{-rt}v(X(t), \epsilon(t))$ is a supermartingale. This is not restrictive in general. Indeed, it is standard in risk-neutral option pricing to have $\mu_1 = \mu_2 = r \geq 0$, following a change of measure via the Girsanov transformation.

Remark 3.5. It is clear from our analysis that a closed-form solution is possible if and only if K, the number of states of $\epsilon(t)$, equals two, since in general an algebraic equation of order $2K$ needs to be solved.

4. Numerical simulation. In this section we perform numerical experiments to compare the analytical solutions with the TPBVDE solutions studied in Zhang [24], together with the numerical results derived from a dynamic programming (DP) approach.

To this end, we first briefly review both DP and TPBVDE methods.

4.1. Dynamic programming. The DP approach we adopt here is built on the discretization method of the regime switching model proposed by Guo [6].

For a fixed T, let us divide the interval $[0, T]$ into N subintervals such that $T = Nh$. Moreover, if we define

$$u_i = e^{\sigma_i\sqrt{h}}, \quad l_i = e^{-\lambda_i h}, \quad d = e^{-rh}, \tag{22}$$

$$p_i = \frac{\mu_i h + \sigma_i\sqrt{h} - 0.5\sigma_i^2 h}{2\sigma_i\sqrt{h}}, \quad p_i + q_i = 1, \tag{23}$$

then the discrete counterpart of the process $(X(t), \epsilon(t))$ becomes the two-dimensional Markov chain (X_n, ϵ_n) that satisfies the recurrence

$$(X_n, \epsilon_n) = \eta_n^{(\epsilon_n, \epsilon_{n-1})}(X_{n-1}, \epsilon_{n-1}), \tag{24}$$

where $\eta_n^{i,j}$ are independently and identically distributed (i.i.d.) random variables taking values u_j with probability $p_j(\chi_{i,1-j} + (-1)^{\chi_{i,1-j}}e^{-\lambda_j h})$ and $1/u_j$ with probability

$(1-p_j)(\chi_{i,1-j}+(-1)^{\chi_{i,1-j}}e^{-\lambda_j h})$, respectively, where $(i,j=1,2)$ and

$$\chi(i,j)=\begin{cases}1, & i=j=1,2,\\ 0, & i\neq j.\end{cases}$$

In other words, (X_n,ϵ_n) is a random walk taking values on the set $(u_1^m u_2^n,i)$ with $i=1,2$ and $m,n=0,\pm1,\pm2,\ldots$ such that X_n represents the stock price at time n and ϵ_n the state of the market at time n.

Furthermore, the optimal stopping problem in question becomes

$$\widetilde{V}_i(x)=\sup_{\tau\in\{1,2,\ldots,\}}E[d^n(K-X_n)^+|\epsilon_0=i,X_0=x]. \tag{25}$$

Given the Markov chain $X=((X_n,\epsilon_n),\mathcal{F}_n,P)$, the optimal stopping problem (25) can be derived via the following dynamic programming principle:

$$\begin{aligned}
W_0(x) &= (K-x)^+,\\
Z_0(x) &= (K-x)^+,\\
W_m(x) &= \max\Big\{W_{m-1}(x),dp_1l_1W_{m-1}(u_1x)+dl_1q_1W_{m-1}\left(\tfrac{x}{u_1}\right)\\
&\qquad +d(1-l_1)p_2Z_{m-1}(u_2x)+d(1-l_1)q_2Z_{m-1}\left(\tfrac{x}{u_2}\right)\Big\},\\
Z_m(x) &= \max\Big\{Z_{m-1}(x),dp_2l_2Z_{m-1}(u_2x)+dl_2q_2Z_{m-1}\left(\tfrac{x}{u_2}\right)\\
&\qquad +(1-l_2)dp_1W_{m-1}(u_1x)+(1-l_2)dq_1W_{m-1}\left(\tfrac{x}{u_1}\right)\Big\}.
\end{aligned}$$

It is clear that $W_m(x),Z_m(x)$ are nondecreasing sequences, and

$$\widetilde{V}_1(x)=\lim_{n\to\infty}W_n(x),$$

$$\widetilde{V}_2(x)=\lim_{n\to\infty}Z_n(x).$$

Evidently, $\widetilde{V}_1(x)$ and $\widetilde{V}_2(x)$ are bounded nonnegative decreasing functions, and $\widetilde{V}_1(x)\geq(K-x)^+$, $\widetilde{V}_2(x)\geq(K-x)^+$. They are also called the least excessive dominating functions.

If we define

$$x_1=\min\left\{x\geq0,\min_{i\in\{1,2\}}\widetilde{V}_i(x)=(K-x)^+\right\}$$

and

$$x_2=\min\left\{x\geq0,\max_{i\in\{1,2\}}\widetilde{V}_i(x)=(K-x)^+\right\},$$

then x_1,x_2 are the so-called free boundary for the stopping rule.

With proper smooth conditions, $\widetilde{V}_i(x)$ coincides with $V(x,i)$ and hence with $V^*(x,i)$. For more detailed discussions on the least excessive dominating function and its application in option pricing, interested readers are referred to Guo [7] and Shiryayev et al. [21].

4.2. The TPBVDE approach. The TPBVDE approach was proposed by Zhang [24] to derive certain selling rules of threshold type. The stopping rule is to stop whenever the underlying stock price reaches two predefined bounds, an upper bound B or a lower bound A:

$$\tau_0 = \inf\{t > 0 \mid X(t) \notin (A, B)\}.$$

This rule is suboptimal since it limits the holder's choice to a smaller class of stopping times. If one takes $A = x^*$ and $B = \infty$ in Case 3, then it leads to a preferable stopping rule of $\tau_0 = \tau^*$.

The basic idea is to first choose a region of (A, B) so that for any given $0 \le a < b$,

$$X(0)e^{-b} \le A \le X(0)e^{-a},$$

$$X(0)e^{a} \le B \le X(0)e^{b}.$$

Next, we choose A and B within this interval to maximize

$$E[e^{-r\tau}(K - X(\tau)^+].$$

With this given A and B, the value function can thus be derived via analysis of a TPBVDE. (See [24] for details.)

4.3. Numerics. This section will report the numerical comparison results. First, we take

$$r = 3, \quad \mu_1 = \mu_2 = 3, \quad K = 5,$$

$$\lambda_1 = \lambda_2 = 100, \quad \sigma_1 = 9, \quad \sigma_2 = 5,$$

and compare the closed-form solution with the numerical solutions from the DP and TPBVDE methods; for the latter, we use the lower bound $a = 0$ and upper bounds $b = 3, b = 10$. The numerical results are plotted in Figure 1 and labeled with $V^{\mathrm{e}}(x, i)$, $V^{\mathrm{DP}}(x, i)$, $V^{\mathrm{b}=3}(x, i)$, and $V^{\mathrm{b}=10}(x, i)$, accordingly.

After 4000 iterations, with $N = 100,000$ and $h = 0.0001$, we obtain the threshold levels $(x_1^*, x_2^*) = (0.454, 0.617)$ for the DP approach, in comparison to the $(x_1^*, x_2^*) = (0.441, 0.614)$ derived from the closed-form solution.

Figure 2 confirms $V_i(x) \ge (K - x)^+$ and illustrates the differences of these value functions. As is shown, the accuracy of the two-point value method improves with increases in the upper bound b. The DP approach approximates the exact solutions better than the TPBVDE method for $b = 3$, while the converse is true with $b = 10$. In addition, these differences equal zero on the intervals (x_1^*, ∞) and (x_2^*, ∞) for $\epsilon(0) = 1$ or 2, respectively.

Next, we check the monotonicity of these threshold levels with respect to σ_i and λ_i. First, we vary σ_1 and keep all other parameters fixed. The resulting (x_1^*, x_2^*) are listed in Table 1. Both threshold levels x_1^* and x_2^* decrease with decreasing σ_1. This shows that a larger σ_1 leads to a higher option premium and therefore a smaller threshold level.

We then vary λ_1. The result in Table 2 implies that both x_1^* and x_2^* increase with λ_1 increasing: this is because a larger λ_1 implies a shorter period for $\epsilon(t)$ staying at

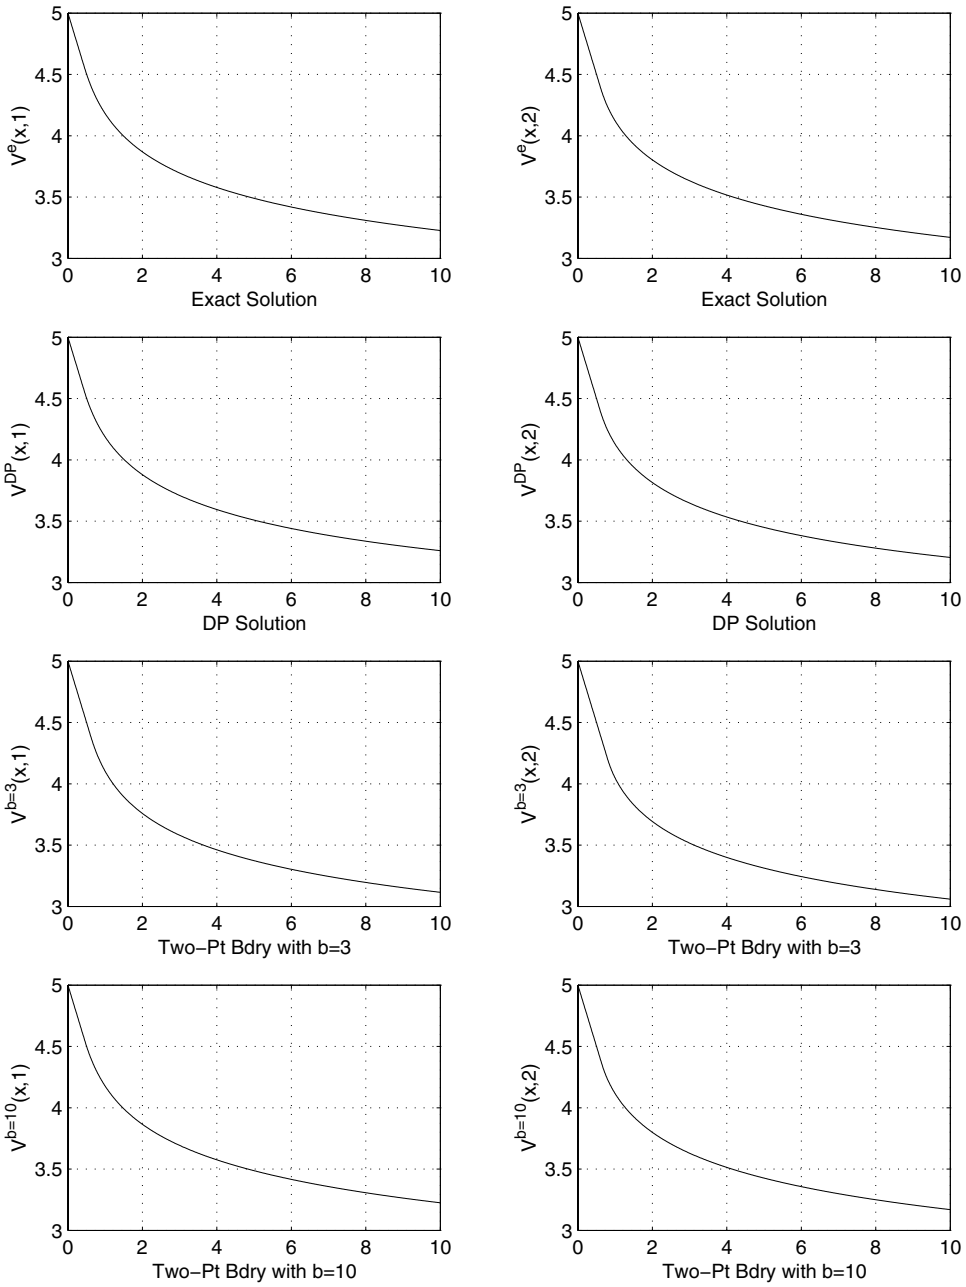

FIG. 1. *Value functions.*

$\epsilon(t) = 1$ and a smaller weight on $\sigma_1 = 9$ ($> \sigma_2 = 5$), which leads to smaller average volatility.

These monotonicity properties may be better explained using the average volatility $\overline{\sigma} = \sqrt{\nu_1\sigma_1^2 + \nu_2\sigma_2^2}$, where (ν_1, ν_2) is the stationary distribution corresponding to the generator of $\epsilon(t)$. The results in Tables 1 and 2 suggest that both x_1^* and x_2^*

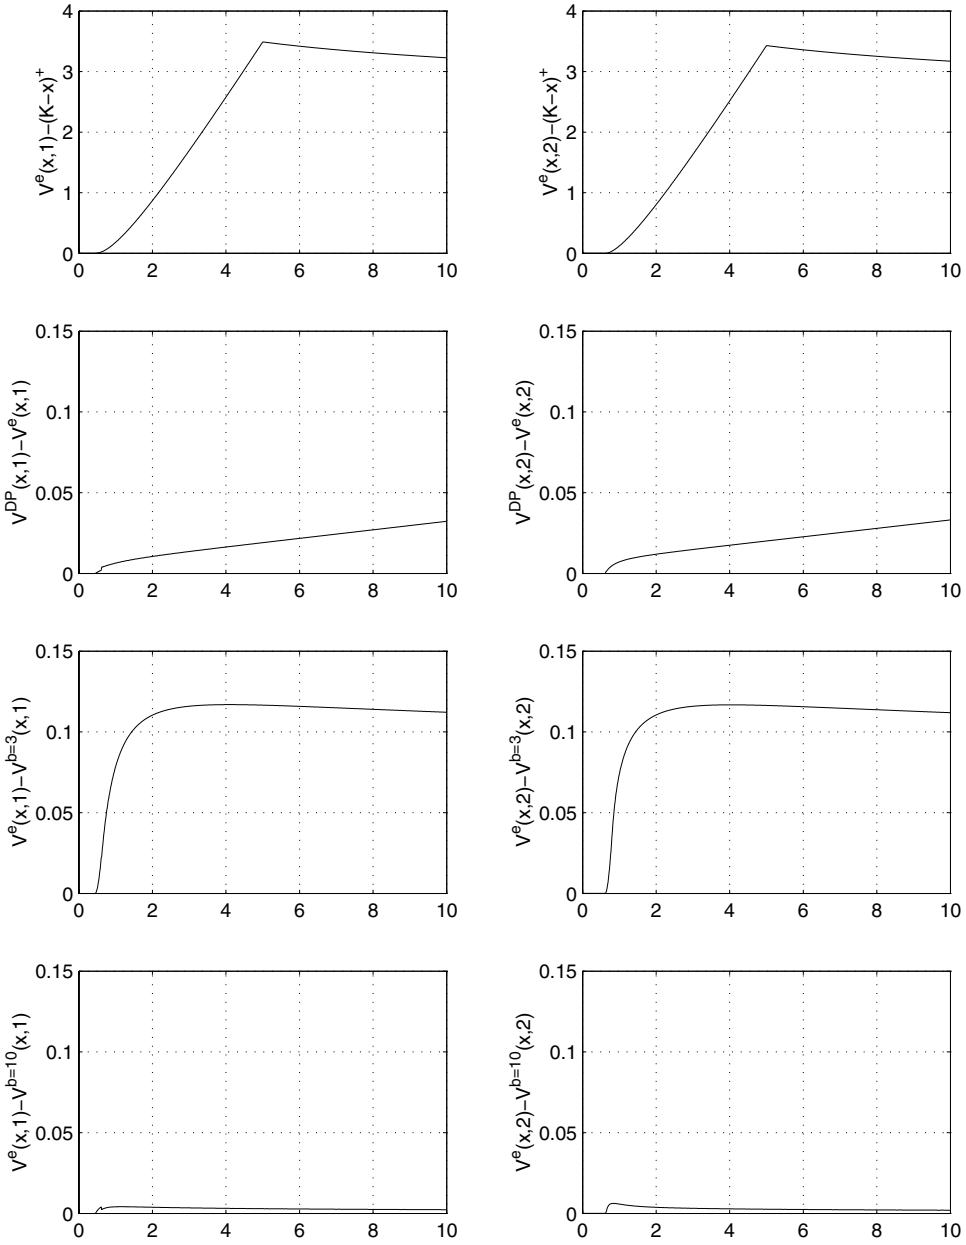

FIG. 2. *Differences between value functions.*

decrease with decreasing $\overline{\sigma}$.

Not surprisingly, the convergence rate of the DP approach depends on the choice of parameters. This in essence has to do with the specific discretization method of the underlying diffusion process. For example, with the same parameters specified above and with perturbations on the magnitude of r, we found that the smaller the r, the longer the computational time.

TABLE 1
Dependency on σ_1, given $\sigma_2 = 5$.

σ_1	7	8	9	10	11	12
Exact	(.646,.764)	(.531,.683)	(.441,.614)	(.369,.554)	(.312,.505)	(.266,.462)
DP	(.660,.773)	(.545,.687)	(.454,.617)	(.381,.557)	(.324,.506)	(.277,.465)

TABLE 2
Dependency on λ_1, given $\lambda_2 = 100$.

λ_1	80	90	100	110	120	130
Exact	(.425,.596)	(.433,.605)	(.441,.614)	(.448,.621)	(.456,.629)	(.463,.637)
DP	(.437,.599)	(.446,.607)	(.454,.617)	(.461,.624)	(.469,.632)	(.476,.640)

As far as total CPU usage is concerned, the DP approach took substantially longer time than the closed-form and the TPBVDE methods. For example, with a basic Linux 7.2 i386 system, it took a little more than 30 minutes for our DP solution to complete 4000 iterations, while it took just seconds for both the exact and TPBVDE methods.

5. Concluding remarks. In this paper we have derived a closed-form solution to the optimal stopping problem for pricing perpetual American put options in a regime switching model.

It remains to be seen whether there are alternative methods for deriving the solution. One obvious candidate is the first passage time technique, which was exploited in solving the McKean problem (McKean [14] and Karlin and Taylor [12]). However, despite the two promising features that (i) $(X(t), \epsilon(t))$ is jointly Markovian and (ii) the free boundaries are of threshold type, it seems hard to explicitly solve the integral equation system using results of the first passage time for regime switching models (derived in Guo [8]). The main obstacle seems to be the instantaneous jump due to the regime switching.

It is also of interest to extend our analysis to the case when T is finite. Needless to say, this case would be mathematically interesting and practically appealing. However, a closed-form solution for a finite time horizon problem with regime switching is difficult to obtain. Even the special case with no regime switching remains an open problem to date. Moreover, with all the structural insights gained from the infinite case, it is not even clear whether the boundary is monotonic; i.e., will $x_1 < x_2$ imply $x_1(T) < x_2(T)$? Assuming this monotonicity condition a priori, Buffington and Elliott [2] extended our analysis and obtained certain properties for the value functions of American put options with $T < \infty$.

Nevertheless, our hope is that the closed-form solutions in this paper will provide better understanding of and some insight into the nature of optimal stopping rules, and our approach can be useful for numerical approximations of long-term American options.

Acknowledgments. We thank the referees for a very careful reading of the manuscript and many constructive suggestions.

MINIMAL ROTATIONALLY INVARIANT BASES FOR HYPERELASTICITY*

GREGORY H. MILLER†

Abstract. Rotationally invariant polynomial bases of the hyperelastic strain energy function are rederived using methods of group theory, invariant theory, and computational algebra. A set of minimal basis functions is given for each of the 11 Laue groups, with a complete set of rewriting syzygies. The ideal generated from this minimal basis agrees with the classic work of Smith and Rivlin [*Trans. Amer. Math. Soc.*, 88 (1958), pp. 175–193]. However, the structure of the invariant algebra described here calls for fewer terms, beginning with the fourth degree in strain, for most groups.

Key words. elasticity, hyperelasticity, symmetry, integrity basis, Gröbner bases

1. Introduction.

In 1958 Smith and Rivlin [20] derived a set of so-called integrity bases: a finite set of homogeneous polynomial functions of the strain, unique to each of 11 sets of symmetry groups (the Laue groups) which govern the symmetry of the strain energy function. These invariants were derived using theorems for the invariants of permutation groups (e.g., Weyl [25]). By "basis" it is meant that any arbitrary symmetry-invariant polynomial may be rewritten as a polynomial in these basis functions. Since the number of invariant homogeneous polynomials is unbounded, the discovery of a finite basis makes the problem of hyperelastic constitutive modeling tractable (and, indeed, far simpler than constructing a symmetry-invariant function as an expansion in symmetry-correct fourth- and higher-order elastic constant tensors). The integrity bases are particularly important for modeling time-dependent large deformation solid mechanics. Examples of computational methods requiring properly invariant hyperelastic descriptions include [15, 16, 14].

Since the important classification by Smith and Rivlin, a number of significant advances have been made in computational tools for algebra, particularly the theory of Gröbner bases, which has opened powerful new approaches to the study of group invariants (e.g., [24]). In this paper the elastic integrity bases are rederived using these new algorithmic approaches. The main point of this paper is to reexamine the invariant structure of hyperelastic materials using these modern methods. It will be shown that the integrity bases of Smith and Rivlin are correct in the sense that their integrity bases are finite bases which generate the correct invariant polynomial ideals. However, for most symmetry groups a number of syzygies exist which interrelate the invariant basis polynomials, and therefore their bases are not minimal (syzygies and minimality are described in this context in, e.g., [22]). It will be shown that for most groups, beginning at degree 4 in the Cauchy tensor (equivalently, the Lagrangian

strain tensor), the Smith and Rivlin integrity bases imply the existence of unnecessary polynomial terms.

In section 2 properties of the strain energy function are reviewed. This section sets the thermodynamic context for subsequent more mathematical sections and identifies the Cauchy tensor as the key fundamental variable controlling hyperelasticity. In section 3 the group theoretical properties of the 32 crystallographic point groups are described as they relate to the Cauchy tensor. Section 4 extends group theory to describe the algebraic structure of polynomial invariants of each group. Algebraic algorithms are described briefly in section 5 and used to construct a complete set of invariants. Simplifying relations among these invariants, syzygies are described in the appendix. A complete set of "rewriting syzygies" is presented, with which one could cast an arbitrary invariant polynomial into a minimal form. Select syzygies are also presented which demonstrate the algebraic dependence of "secondary invariants" upon the "primary invariants." Concluding remarks are made in section 6.

2. The strain energy function. The fundamental kinematic variable that governs hyperelasticity is the deformation tensor

$$F_{\alpha\beta} = \frac{\partial x_\alpha}{\partial a_\beta}, \tag{2.1}$$

which describes the deformation of a spatial (Eulerian) frame x with respect to a material (Lagrangian) frame a. The internal energy $\mathcal{E}$ is some function of the nine components of F, entropy S, and possibly other material constitutive parameters: $\mathcal{E} = \mathcal{E}(F, S)$.

Since the internal energy is a scalar function, its value must be independent of the reference frame of the observer. Thus, an observer utilizing a reference frame $\hat{x}$ will interpret the laboratory reference frame x rotated through an arbitrary orthogonal rotation Q ($Q^{-1} = Q^T$) and translated by an arbitrary vector $\hat{x}_0$:

$$\hat{x} = \hat{x}_0 + Qx, \tag{2.2}$$

$$\hat{F} = QF. \tag{2.3}$$

The possibly time-dependent translation $\hat{x}_0$ is independent of the material reference frame $\{a\}$ and therefore does not affect the observer's deformation tensor $\hat{F}$. In the observer's frame, the internal energy would be $\hat{\mathcal{E}} = \hat{\mathcal{E}}(QF, S)$. And so, for the internal energy to be independent of the reference frame of the observer, the function must depend not on the components of F individually but upon some combination of them that removes the dependence on Q.

One way of removing the Q-dependence is to factor $\hat{F}$ into a matrix of pure stretches and a matrix of rotations. The so-called right-polar decomposition of F is

$$F = RU, \tag{2.4}$$

where R is a rotation ($R^{-1} = R^T$) and U is symmetric. This decomposition is unique, with

$$U^T U = F^T F = F^T Q^T Q F = \hat{F}^T \hat{F}. \tag{2.5}$$

Instead of solving (2.5) for the six independent components of U, one might use directly the six independent components of C—the Cauchy tensor (or "right Cauchy–Green tensor")

$$C = F^T F, \tag{2.6}$$

$$\mathcal{E} = \mathcal{E}(C, S). \tag{2.7}$$

These manipulations determine the functional dependence of the internal energy in such a way as to make the result independent of the reference frame of an observer. The Cauchy tensor remains, however, dependent upon the orientation of the material with respect to the material reference frame a. For crystals with no rotational symmetry, this result is adequate, and one may without loss of generality construct hyperelastic equations of state (2.7) that are consistent with all symmetry constraints.

There are 230 space groups that classify the symmetry of single crystals. These are based upon 32 crystallographic point groups, which derive from consideration of rotations and reflections (reflections may also be referred to as improper S_1 rotations; collectively such operations will be called simply "rotations"), and become 230 upon consideration of translations consistent with the rotational symmetry. To discuss rotational invariance it is sufficient to consider the point groups. Of these 32 point groups, only two (C_1 and C_i) are correctly modeled by (2.7) without additional considerations of symmetry. The remaining 30 point groups classify materials which are symmetric with respect to certain discrete symmetry operations $\bar{\pi}$ on the atomic coordinates in the material reference frame:

$$\check{a} = \bar{\pi}^{-1} a, \tag{2.8}$$

$$\check{F} = F\bar{\pi}, \tag{2.9}$$

$$\check{C} = \bar{\pi}^T C \bar{\pi}. \tag{2.10}$$

For the internal energy to be invariant with respect to each of these discrete rotational mappings, one must have

$$\mathcal{E} = \mathcal{E}(C, S) = \mathcal{E}(\bar{\pi}^T C \bar{\pi}, S) \quad \forall\ \bar{\pi} \in \bar{\Gamma}^{\bar{G}}, \tag{2.11}$$

where $\bar{\Gamma}^{\bar{G}}$ represents the set of rotation operations of the crystallographic point group $\bar{G}$ of the material (the symbols $\bar{\pi}$, $\bar{\Gamma}$, $\bar{G}$, etc. are used here to describe the group properties in the $\mathbb{R}^3$ coordinate space; the symbols π, Γ, G, etc. will denote the corresponding extension of these group properties to the $\mathbb{R}^6$ space of the unique Cauchy tensor elements).

3. Group theory. The crystallographic point groups may be described by a finite number of 3×3 matrices which rotate a vector, reflect it across a plane, or combinations thereof. The set $\bar{\Gamma}$ of these matrices $\bar{\pi}$ are a representation of a group algebra $\bar{G}$, which means (1) multiplication is associative, $(\bar{\pi}_\alpha \bar{\pi}_\beta)\bar{\pi}_\gamma = \bar{\pi}_\alpha(\bar{\pi}_\beta \bar{\pi}_\gamma)$ for each $\bar{\pi}_\alpha, \bar{\pi}_\beta, \bar{\pi}_\gamma \in \bar{\Gamma}$; (2) that for each $\bar{\pi}_\alpha, \bar{\pi}_\beta \in \bar{\Gamma}$, the product $\bar{\pi}_\alpha \bar{\pi}_\beta$ is also contained in $\bar{\Gamma}$; (3) there exists an identity $\bar{E} \in \bar{\Gamma}$ such that $\bar{E}\bar{\pi}_\alpha = \bar{\pi}_\alpha \bar{E} = \bar{\pi}_\alpha$ for each $\bar{\pi}_\alpha \in \bar{\Gamma}$; and (4) for each $\bar{\pi}_\alpha \in \bar{\Gamma}$, there exists an inverse $\bar{\pi}_\alpha^{-1}$ such that $\bar{\pi}_\alpha \bar{\pi}_\alpha^{-1} = \bar{E}$.

One may use the property (2.10) to construct a set of 6×6 matrix operators π_1

$$\pi_1 = \begin{pmatrix} \bar{\pi}_{11}^2 & \bar{\pi}_{21}^2 & \bar{\pi}_{31}^2 & 2\bar{\pi}_{31}\bar{\pi}_{21} & 2\bar{\pi}_{11}\bar{\pi}_{31} & 2\bar{\pi}_{11}\bar{\pi}_{21} \\ \bar{\pi}_{12}^2 & \bar{\pi}_{22}^2 & \bar{\pi}_{32}^2 & 2\bar{\pi}_{22}\bar{\pi}_{32} & 2\bar{\pi}_{32}\bar{\pi}_{12} & 2\bar{\pi}_{22}\bar{\pi}_{12} \\ \bar{\pi}_{13}^2 & \bar{\pi}_{23}^2 & \bar{\pi}_{33}^2 & 2\bar{\pi}_{33}\bar{\pi}_{23} & 2\bar{\pi}_{33}\bar{\pi}_{13} & 2\bar{\pi}_{23}\bar{\pi}_{13} \\ \bar{\pi}_{12}\bar{\pi}_{13} & \bar{\pi}_{22}\bar{\pi}_{23} & \bar{\pi}_{32}\bar{\pi}_{33} & \bar{\pi}_{22}\bar{\pi}_{33}+\bar{\pi}_{32}\bar{\pi}_{23} & \bar{\pi}_{12}\bar{\pi}_{33}+\bar{\pi}_{32}\bar{\pi}_{13} & \bar{\pi}_{12}\bar{\pi}_{23}+\bar{\pi}_{22}\bar{\pi}_{13} \\ \bar{\pi}_{11}\bar{\pi}_{13} & \bar{\pi}_{21}\bar{\pi}_{23} & \bar{\pi}_{31}\bar{\pi}_{33} & \bar{\pi}_{21}\bar{\pi}_{33}+\bar{\pi}_{31}\bar{\pi}_{23} & \bar{\pi}_{11}\bar{\pi}_{33}+\bar{\pi}_{31}\bar{\pi}_{13} & \bar{\pi}_{11}\bar{\pi}_{23}+\bar{\pi}_{21}\bar{\pi}_{13} \\ \bar{\pi}_{11}\bar{\pi}_{12} & \bar{\pi}_{21}\bar{\pi}_{22} & \bar{\pi}_{31}\bar{\pi}_{32} & \bar{\pi}_{21}\bar{\pi}_{32}+\bar{\pi}_{31}\bar{\pi}_{22} & \bar{\pi}_{11}\bar{\pi}_{32}+\bar{\pi}_{31}\bar{\pi}_{12} & \bar{\pi}_{11}\bar{\pi}_{22}+\bar{\pi}_{21}\bar{\pi}_{12} \end{pmatrix} \tag{3.1}$$

that transform the six-dimensional vector $\eta = (C_{11}, C_{22}, C_{33}, C_{23}(= C_{32}), C_{13}(= C_{31}), C_{12}(= C_{21}))^T$, or in Voigt notation $(C_1, C_2, C_3, C_4, C_5, C_6)^T$, according to

$$\check{\eta} = \pi_1 \eta. \tag{3.2}$$

In the language of Murnaghan [18, Ch. 3], the matrices π_1 are *symmetrized* Kronecker products of the transformation matrices $\bar{\pi}^T$. The d-form matrices π_d introduced below are symmetrized Kronecker d-powers of the transformations π_1.

Note that the set Γ of matrices π_1, formed from the elements $\bar{\pi} \in \bar{\Gamma}$ of group $\bar{G}$, define a group algebra G that may be different from $\bar{G}$ (e.g., [8]). In particular, the transformation matrices (3.1) effectively introduce inversion symmetry where none may have existed in the original group. Thus, as with Laue diffraction, the 32 crystallographic point groups reduce immediately to the 11 Laue groups.

A linear combination κ of elements of the Cauchy tensor is invariant to all symmetry operations if for each $\pi_1 \in \Gamma$ one has $\kappa = \pi_1 \kappa$; thus κ must be an eigenvector of each matrix π_1 with eigenvalue 1. Or

$$\kappa = \mathcal{P}_R \kappa, \tag{3.3}$$

with

$$\mathcal{P}_R = \frac{1}{|\Gamma|} \sum_{\pi_1 \in \Gamma} \pi_1 \tag{3.4}$$

and $|\Gamma|$ the cardinality of the group. $\mathcal{P}_R$ is the Reynolds operator, a special case of the more general symmetry projection operator which projects a vector onto an irreducible representation of the group (e.g., [6, Ch. 6]). The Reynolds operator projects a vector onto the unique totally symmetric representation. $\mathcal{P}_R$ is a projection, ${\mathcal{P}_R}^2 = \mathcal{P}_R$, by virtue of the property of groups that $\pi_{1\alpha}\Gamma = \Gamma$ for all $\pi_{1\alpha} \in \Gamma$. Consequently, the eigenvalues of $\mathcal{P}_R$ are all either 0 or 1. And, therefore, the number N_1 of linearly independent degree-1 invariant vectors is given by the number of unity eigenvalues of $\mathcal{P}_R$, which is equal to the trace of $\mathcal{P}_R$:

$$N_1 = \text{trace}(\mathcal{P}_R) = \frac{1}{|\Gamma|} \sum_{\pi_1 \in \Gamma} \text{trace}(\pi_1). \tag{3.5}$$

To evaluate this equation for any group, one tabulates the symmetry operations by type (Table 3.1 displays the operations of each group and their assumed orientation with respect to the assumed orthogonal Lagrangian coordinate system a). The numbers of symmetry operations π_1, by type and group Γ, are given in Table 3.2. The traces may be calculated from the eigenvalues listed in Table 3.3.

Invariants of higher degree lie in the $\binom{6+d-1}{d}$-dimensional space formed by the unique combinations of degree-d monomials (e.g., a basis for degree-2 monomials is given by the 21 homogeneous terms $C_i C_{j \geq i}$ in a process analogous to that described by (3.1)). From the matrices π_1, so-called d-form matrices π_d may be constructed easily to represent the action of the symmetry operations on the degree-d terms. The number N_d of linearly independent degree-d symmetry-invariant terms are constructed as in the degree-1 case with

$$\mathcal{P}_{R,d} = \frac{1}{|\Gamma|} \sum_{\pi_d \in \Gamma} \pi_d, \tag{3.6}$$

TABLE 3.1

Settings for those crystallographic point groups with planes and axes (Wulff stereographic projections). Bold lines are mirror planes. Open and closed circles are general positions, above and below plane $z = 0$, respectively. Closed symbols with n-fold symmetry are rotation axes, and mixed open-closed symbols with n-fold symmetry are improper rotations.

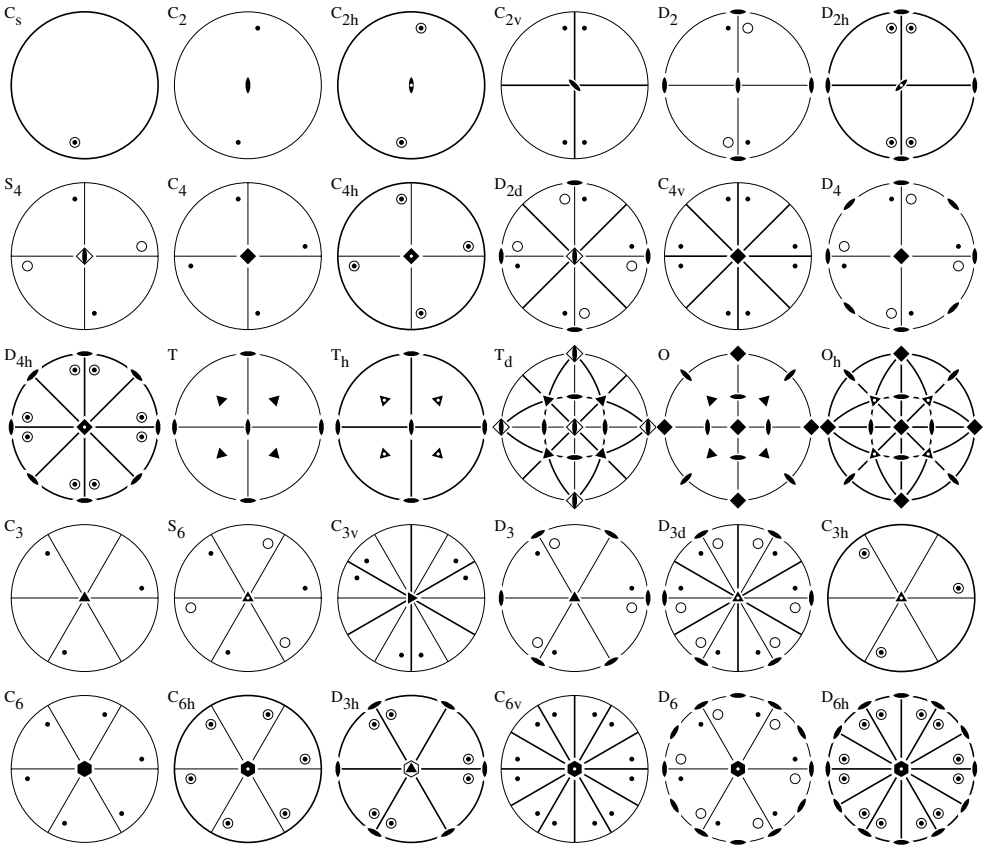

TABLE 3.2

Number of distinct occurrences of operations π in the crystallographic point groups, in the $\mathbb{R}^6$ space of the Cauchy tensor. The symbols used here are Schoenflies notation: E is the identity, I is inversion on all three orthogonal axes, C_n is an n-fold rotation, S_n is an improper n-fold rotation, and $\sigma = S_1$ is a mirror reflection.

Group Γ	$\lvert\Gamma\rvert$	E, I	C_2, σ	C_3, S_6	C_4, S_4	C_6, S_3

TABLE 3.3
Eigenvalues of the point group operators π in the space $\mathbb{R}^6$ of the Cauchy tensor.

Operator π_1		Eigenvalues					
E	I	1	1	1	1	1	1
C_2	σ	1	1	1	1	-1	-1
C_3	S_6	1	1	$e^{\frac{2\pi i}{3}}$	$e^{\frac{2\pi i}{3}}$	$e^{-\frac{2\pi i}{3}}$	$e^{-\frac{2\pi i}{3}}$
C_4	S_4	1	1	-1	-1	$e^{\frac{\pi i}{2}}$	$e^{-\frac{\pi i}{2}}$
C_6	S_3	1	1	$e^{\frac{\pi i}{3}}$	$e^{-\frac{\pi i}{3}}$	$e^{\frac{2\pi i}{3}}$	$e^{-\frac{2\pi i}{3}}$

$$N_d = \operatorname{trace}(\mathcal{P}_{R,d}) = \frac{1}{|\Gamma|}\sum_{\pi_d\in\Gamma}\operatorname{trace}(\pi_d). \tag{3.7}$$

In practice it is not necessary to actually create the matrices π_d. The eigenvalues of the d-form matrices π_d are $\lambda_1^{d_1}\cdots\lambda_6^{d_6}$, with λ_i representing the ith eigenvalue of π_1, and with the exponents d_i subject to $d_1+\cdots+d_6=d$. Therefore,

$$\operatorname{trace}(\pi_d) = \sum_{d_1+\cdots+d_6=d}\lambda_1^{d_1}\cdots\lambda_6^{d_6}. \tag{3.8}$$

For completeness, one has also the scalar degree-0 term: the number "1." This polynomial invariant of degree 0 is generated by $\pi_0 = 1$, whence $N_0 = 1$.

Via the projections $\mathcal{P}_{R,d}$ group theory provides a method for the construction of all linearly independent degree-d symmetry-invariant homogeneous polynomials. The number of such polynomials is unbounded, however, since for any degree d the number of terms is at least as large as $\binom{N_1+d-1}{d}$—the number of distinct degree-d polynomials formed from by multiplying together different combinations of degree-1 polynomials.

A finite polynomial basis, a set of invariant polynomials from which all others may be constructed, exists. The number of terms in this basis and some properties of it are provided by theorems of invariant theory described below. The construction of the actual invariant polynomial bases is accomplished with the Gröbner basis methods of computational algebra, described in the subsequent section.

4. Invariant theory. The Hilbert series $\Phi(z)$ (also known as Poincaré's series) is a polynomial in the dummy variable z where the coefficient of z^n is the number of polynomial invariants of degree n. Spencer's generating functions [21], used in the study of invariants in continuum mechanics, are particular instances of the Hilbert series constructed by different means than those employed here. Following Sturmfels [24, Theorem 2.2.1] after [17],

$$\begin{aligned}
\Phi(z) &= \sum_{d=0}^{\infty} N_d z^d = \frac{1}{|\Gamma|}\sum_{\pi_1\in\Gamma}\sum_{d=0}^{\infty}\sum_{d_1+\cdots+d_6=d}\lambda_1^{d_1}\cdots\lambda_6^{d_6}z^d,\\
&= \frac{1}{|\Gamma|}\sum_{\pi_1\in\Gamma}\sum_{d_1,\ldots,d_6=0}^{\infty}\lambda_1^{d_1}\cdots\lambda_6^{d_6}z^{d_1+\cdots+d_6}\\
&= \frac{1}{|\Gamma|}\sum_{\pi_1\in\Gamma}\prod_{n=1}^{6}\left(1+(\lambda_n z)+(\lambda_n z)^2+\cdots\right)\\
&= \frac{1}{|\Gamma|}\sum_{\pi_1\in\Gamma}\prod_{n=1}^{6}\frac{1}{(1-\lambda_n z)} = \frac{1}{|\Gamma|}\sum_{\pi_1\in\Gamma}\frac{1}{\det(I-\pi_1 z)},
\end{aligned} \tag{4.1}$$

where $\lambda_\alpha = \lambda_\alpha(\pi_1)$, and where one assumes that $|z|<1$.

TABLE 4.1
Contributions of point group operators to the Hilbert series.

Operation π_1	Hilbert series contribution
E, I	$\dfrac{1}{(1-z)^6}$
C_2, σ	$\dfrac{1}{(1-z)^4(1+z)^2} = \dfrac{1}{(1-z)^2(1-z^2)^2}$
C_3, S_6	$\dfrac{1}{(1-z)^2(1+z+z^2)^2} = \dfrac{1}{(1-z^3)^2}$
C_4, S_4	$\dfrac{1}{(1-z^2)^2(1+z^2)} = \dfrac{1}{(1-z^2)(1-z^4)}$
C_6, S_3	$\dfrac{1}{(1-z)^2(1-z+z^2)(1+z+z^2)} = \dfrac{(1+z)}{(1-z)(1-z^6)}$

By means of this result, it is apparent that the Hilbert series for a given crystallographic point group may be algebraically constructed by summing factors $1/\det(I - \pi_1 z)$ corresponding to the individual operators π_1 that occur in the point group. These factors are summarized in Table 4.1.

One may then construct the Hilbert series according to the formula

$$\Phi_\Gamma(z) = \frac{1}{|\Gamma|}\left[\frac{N(E,I)}{(1-z)^6} + \frac{N(C_2,\sigma)}{(1-z)^2(1-z^2)^2} + \frac{N(C_3,S_6)}{(1-z^3)^2} + \frac{N(C_4,S_4)}{(1-z^2)(1-z^4)} + \frac{N(C_6,S_3)(1+z)}{(1-z)(1-z^6)}\right], \tag{4.2}$$

where $N(\pi, \dots)$ is the number of occurrences of symmetry operators $\pi, \dots \in \Gamma$, tabulated for the crystallographic point groups in Table 3.2.

Finite groups have the Cohen–Macaulay property of commutative algebra (e.g., [23]), which has significance for this project in that it implies that certain important properties of the invariant group algebra may be deduced by appropriate factorizations of the Hilbert series, called "Molien functions" or "Hironaka decompositions":

$$\Phi(z) = \frac{\sum_{i=0}^{t-1} z^{e_i}}{\prod_{j=1}^{n}(1-z^{d_j})}. \tag{4.3}$$

The interpretation of these factorizations is that there exist n *primary invariants* θ which comprise a "homogeneous system of parameters" (HSOP), with degrees $d_i = \deg(\theta_i)$, and where n is the number of variables (six for the Cauchy tensor elements). These are represented in the denominator of the Molien function. Since a factor $1/(1-z^d)$ contributes (multiplicatively) $1+z^d+z^{2d}+z^{3d}+\cdots$ to the Hilbert series, these factors are unrestricted in a polynomial representation. The numerator represents the t *secondary invariants* ϕ, with degrees $e_j = \deg(\phi_j)$ and cardinality

$$t = \frac{1}{|\Gamma|}\prod_{i=1}^{n} d_i, \tag{4.4}$$

including the degree-0 term "1." Since factors z^e in the numerator contribute only z^e (multiplicatively) to the Hilbert series, the implication is that these factors occur at most once in a polynomial representation.

TABLE 4.2

Molien factorizations of the Hilbert series of crystallographic point groups in the $\mathbb{R}^6$ space of the Cauchy tensor.

Groups Γ	Molien function
triclinic $C_1,\ C_i$	$\dfrac{1}{(1-z)^6}$
monoclinic $C_s,\ C_2,\ C_{2h}$	$\dfrac{1+z^2}{(1-z)^4(1-z^2)^2}$
orthorhombic $C_{2v},\ D_2,\ D_{2h}$	$\dfrac{1+z^3}{(1-z)^3(1-z^2)^3}$
tetragonal $S_4,\ C_4,\ C_{4h}$	$\dfrac{1+z^2+4z^3+z^4+z^6}{(1-z)^2(1-z^2)^3(1-z^4)}$
tetragonal $D_{2d},\ C_{4v},\ D_4,\ D_{4h}$	$\dfrac{1+2z^3+z^6}{(1-z)^2(1-z^2)^3(1-z^4)}$
cubic $T,\ T_h$	$\dfrac{1+3z^3+2z^4+2z^5+3z^6+z^9}{(1-z)(1-z^2)^2(1-z^3)^2(1-z^4)}$
cubic $T_d,\ O,\ O_h$	$\dfrac{1+z^3+z^4+z^5+z^6+z^9}{(1-z)(1-z^2)^2(1-z^3)^2(1-z^4)}$

hexagonal $D_{3h},\ C_{6v},\ D_6,\ D_{6h}$	$\dfrac{1+z^3+z^4+z^5+z^6+z^9}{(1-z)^2(1-z^2)^2(1-z^3)(1-z^6)}$

A consequence of the Molien function is that all symmetry-invariant polynomial functions P of the Cauchy tensor may be expressed in the form

$$P(\{\theta\},\{\phi\}) = \sum_{\alpha=0}^{t-1} \phi_\alpha P_\alpha(\{\theta\}), \tag{4.5}$$

where $P_\alpha(\{\theta\})$ is an arbitrary polynomial in the primary invariants, and where each secondary invariant ϕ_α occurs at most once. For all groups henceforth let $\phi_0 = 1$, and consider only nontrivial secondary invariants.

Molien factorizations of the crystallographic point groups, constructed using (4.2) for the invariants of the Cauchy tensor terms, are given in Table 4.2. These functions are fully reduced in that there is no common algebraic factor to both numerator and denominator, and in this sense the implied size of the invariant set is minimal. These factorizations are not unique. For example, the factorization displayed for group C_{2v} implies primary invariants of degree $1,1,1,2,2,2$ and one nontrivial secondary invariant of degree 3. However, multiplication of numerator and denominator by $(1+z)$ gives the function

$$\frac{1+z+z^2+z^4}{(1-z)^2(1-z^2)^4}, \tag{4.6}$$

implying primary invariants of degree $1,1,2,2,2,2$ and three nontrivial secondary invariants of degree $1,2,4$. If the form given in Table 4.2 exists, then the alternative form (4.6) is not minimal. The question of existence must be settled by constructing the algebraically independent basis functions of the group and partitioning them into primary and secondary invariants (e.g., [19, p. 101]). It will be shown that HSOPs of the degrees indicated by the reduced functions in Table 4.2 exist.

Since secondary ϕ_α is an invariant, so is ϕ_α^2. However, ϕ_α^2 is not represented in the Hilbert series. Thus, the invariant ϕ_α^2 must be expressible by some polynomial of the form (4.5). This implies the existence of syzygies—polynomial equalities that relate the secondary and primary invariants. A set of syzygies may be found to serve as "rewriting rules" for systematic conversion of a general polynomial $P(\{\theta\},\{\phi\})$ into the minimal form given by the right-hand side of (4.5).

An HSOP is a minimal set of algebraically independent polynomials, with cardinality 6, equal to the number of independent variables in C. There cannot be more algebraically independent homogeneous polynomials, and so any additional polynomial (in particular, the secondary invariants) must possess an algebraic dependence upon the primary invariants. The algebraic relations expressing a particular secondary invariant in terms of the primary ones are also expressible as syzygies.

The six primary invariants of each crystal point group are therefore algebraic (vs. polynomial) invariants; all polynomial invariants are expressible as algebraic functions of the primary invariants. This settles a conundrum regarding the number of degrees of freedom. The elastic Cauchy tensor has six degrees of freedom, and there are six algebraic invariants. The additional apparent degrees of freedom represented by the number of secondary invariants (aside from the trivial one, 1, of degree zero) are a consequence of assuming a polynomial form for the invariant energy function.

5. Computational algebra: Gröbner bases. In $\mathbb{R}^3$, the space of material coordinates a, and in $\mathbb{R}^6$, the space of Cauchy tensor components, some matrix operations of the groups (e.g., corresponding to rotations through $2\pi/3$) contain factors of $\sqrt{3}/2$. However, polynomials generated through the Reynolds operator contain only integer coefficients, so it is sufficient to study the properties of $\mathbb{Q}[C]$, the ring over rational numbers $\mathbb{Q}$ of polynomials in the Cauchy tensor elements C. Let $F=\{f_i | f_i \in \mathbb{Q}[C],\ f_i = \mathcal{P}_R f_i\}$ be some set of invariant polynomials. The ideal generated by F, $I(F)$ is the set of all polynomials $p_1 f_1 + p_2 f_2 + \cdots$, $p_i \in \mathbb{Q}[C]$, that are dependent on elements of F; i.e., $g \in I(F)$ and $h \in \mathbb{Q}[C]$ implies that $gh \in I(F)$, and $g, f \in I(F)$ implies that $g+f \in I(F)$. The objective is to construct the smallest basis F consisting of homogeneous invariant polynomials, with degrees consistent with the Molien function of the group, such that $I(F)$ is equal to the complete invariant ideal $I(\mathbb{Q}[C]^G)$ (see, e.g., [23, 4] and [3] for algebra concepts, and the latter also for Gröbner bases).

Algorithms designed to address this problem require the capability of deciding whether some polynomial f is in the ideal $I(F)$. The solution is to construct a special basis $\mathcal{GB}(F)$, the Gröbner basis, with $I(\mathcal{GB}(F)) = I(F)$. That is, $\mathcal{GB}$ is an alternative basis that generates the same ideal as F. The key property of a Gröbner basis is that for any $f \in I(F)$, $f \to_{\mathcal{GB}} 0$: f is reducible to zero by successive steps of a Euclidean reduction algorithm. The reduction property is linked to a notion of term order; a unique reduced Gröbner is specified by the basis F, and a specification of the term order $\succ$.

Group theory shows how, using the Reynolds operator, invariant polynomials may be generated, and from the Molien function one has an idea of what the degrees of primary and secondary invariants may be. Given a set of six homogeneous polynomial functions with degrees that are compatible with their being primary invariants, the first task is to show whether or not they are an HSOP. An algorithm for this task is given by Sturmfels [24, algorithm 2.5.3]. First, one uses the Reynolds operator[1] to generate a set of homogeneous polynomial invariants $\theta'(C)$ of the Cauchy tensor elements. Next, construct a polynomial basis set $F = \{\theta'_1 - y_1, \dots, \theta'_6 - y_6\}$ in the variables C and new slack variables y, with lexicographic order $C_1 > \cdots > C_6 > y_1 > \cdots > y_6$. This is an "elimination order" that systematically eliminates terms in C from the head of each polynomial in the basis during construction of the Gröbner basis (the head term is the greatest with respect to the specified order—lexicographic in this case). Generate the Gröbner basis $\mathcal{GB}(F)$. Let $\mathcal{GB}' = \mathcal{GB}(F) \cap \mathbb{Q}[y]$ be the set of polynomials found in $\mathcal{GB}(F)$ containing only variables y. If $\mathcal{GB}' = \emptyset$, then $\{\theta'\}$ are algebraically independent; they may be chosen to comprise the HSOP of the group. If $\mathcal{GB}' \neq \emptyset$, then the functions contained in $\mathcal{GB}'$ represent polynomial equations $P(y_1, y_2, \dots, y_6) = 0$ which represent syzygies among the variables y hence amongst the functions θ'. This property will be exploited to determine syzygies.

The second task is the determination of secondary invariant polynomials [24, algorithm 2.5.14]. Begin with $F = \{\theta\}$, the set of primary invariants, and let $\phi = \emptyset$ be the set of discovered secondary invariants. Compute $\mathcal{GB} = \mathcal{GB}(F)$ with respect to any valid term order. For each degree indicated in the numerator of the Molien function, use the Reynolds operator to construct a set of linearly independent homogeneous invariants. Those candidate polynomials ϕ' that reduce to zero with $\mathcal{GB}$ have a polynomial dependence on $\{\theta\}$ and are not valid secondary invariants. Those ϕ' that do not reduce to zero are secondary invariants; $\phi := \phi \cup \{\phi'\}$.

To deduce rewriting syzygies, i.e., syzygies of the form $\phi_i \phi_j = p_0 + \sum_k p_k \phi_k$, $p_i \in \mathbb{Q}[\theta]$, another algorithm based on Gröbner bases has been proposed [24, algorithm 2.5.6]. One computes the Gröbner basis of $F = \{\theta_1 - y_1, \dots, \theta_6 - y_6, \phi_1 - z_1 \dots\}$ in the variables C and slack variables y and z. Sturmfels recommends the variable order $C_1 > \cdots > C_6 > y_1 > \cdots > y_6 > z_1 > \cdots$ and suggests the following term order $\succ$. Term $C^\alpha y^\beta z^\gamma \succ C^{\alpha'} y^{\beta'} z^{\gamma'}$ if $C^\alpha > C^{\alpha'}$ in the purely lexicographic order, or if $C^\alpha = C^{\alpha'}$ and $y^\beta > y^{\beta'}$ in the degree lexicographic order, or if $C^\alpha = C^{\alpha'}$ and $y^\beta = y^{\beta'}$ and $z^\gamma > z^{\gamma'}$ in the purely lexicographic order. The resulting Gröbner basis will contain the desired syzygies.

To compute syzygies relating one secondary invariant ϕ_i to the primary invariants, essentially the same procedure is employed. The Gröbner basis of $F = \{\theta_1 - y_1, \dots, \theta_6 - y_6, \phi_i - z\}$ is computed in the variables $C_1 > \cdots > C_6 > y_1 > \cdots > y_6 > z$ with an order that eliminates the variables C. Good success was found using a matrix order (e.g., [9]) that first selects for graded degree (using the degrees in C as weights), then selects for degree in the variables C, and then enforces reverse lexicographical ordering on the C and y blocks. As suggested by Bayer and Stillman [2], the reverse lexicographical refinement was substantially more efficient than purely lexicographical order.

The construction of Gröbner bases is given by a simple algorithm by Buchberger [5], but the simplicity of the algorithm belies the complexity of the computational

[1] Note that the Reynolds operator does depend on the "setting," or orientation, of the symmetry axes given in Table 3.1. To this point in the manuscript, only the setting-independent eigenvalues of the operations have been used.

task. The maximum degree computed in a Gröbner basis may be as large as doubly exponential in the number of variables used [13]; and integer or rational coefficients have been reported to contain as many as $\mathcal{O}(10^5)$ significant decimal figures with basis functions containing $\mathcal{O}(1)$ coefficients [1]. Thus, poor algorithmic choices (and there are many choices one is free to make) render even simple basis calculations impossible. To control these issues directly, implementations of Buchberger's algorithm and the F_4 variant of this algorithm by Faugére [7] were constructed in C++ using GMP [12] to represent and manipulate arbitrary precision integers. Superfluous pairs were eliminated using the method of Gebauer and Möller [10], and selection strategies used the "sugar" phantom degree order method of [11]. The F_4 algorithm has been reported to be on the order of 10 times faster than the equivalent Buchberger method. Our implementation of F_4 modifies the selection criterion as follows. Let deg_W be a W-graded degree, chosen so all polynomials are W-homogeneous (e.g, weights w_i correspond to the degree of a variable when expressed in the common basis of C elements). An F_4 row echelon calculation containing polynomials of different deg_W may be immediately block diagonalized according to deg_W. Including polynomials of different deg_W in a row echelon calculation does not affect the correctness of the method, but in practice it is found that selecting only those pairs whose deg_W are equal and as small as possible improves efficiency.

The results of these algorithms applied to the 11 Laue groups are presented below. The following subsections present the computed invariant bases, with elements distinguished as being primary or secondary invariants. In all cases the minimal factorizations displayed in Table 4.2 are realized. In the appendix, a complete set of rewriting syzygies is presented. Application of these equations may transform any polynomial $P(\{\theta\},\{\phi\})$ into the minimal form given by (4.5). These are offered in proof of the simplification implied by the Molien factorizations. Also presented in the appendix is a representative example of an algebraic dependence syzygy, a polynomial of the form $P(\phi_\alpha,\theta_1,\ldots,\theta_6)$ which demonstrates the algebraic dependence of the secondary invariants. Several such algebraic dependence syzygies also appear in the set of rewriting syzygies. Note that the computation of these algebraic dependence syzygies is difficult, and several such syzygies have thus far defied computation. With the algorithms used, the relevant Gröbner basis calculation may consume all available core memory (8Gb) in the span of a few days.

5.1. Triclinic groups C_1 and C_i. The group C_1 contains no symmetry operations aside from the identity E. The group C_i contains only the identity and a center of inversion. With respect to the action of these groups on the Cauchy tensor components, the groups are therefore identical. Since no Cauchy tensor components are mixed by the action of these groups, there are no nontrivial Reynolds projections. The basis for these groups consists of the Cauchy tensor components, all primary invariants.

$$\theta_1 = C_6, \tag{5.1}$$

$$\theta_2 = C_5, \tag{5.2}$$

$$\theta_3 = C_4, \tag{5.3}$$

$$\theta_4 = C_3, \tag{5.4}$$

$$\theta_5 = C_2, \tag{5.5}$$

$$\theta_6 = C_1. \tag{5.6}$$

5.2. Monoclinic groups C_s, C_2, C_{2h}. A single secondary invariant exists for this group. An invariant basis is

$$\theta_1 = C_4, \tag{5.7}$$
$$\theta_2 = C_3, \tag{5.8}$$
$$\theta_3 = C_2, \tag{5.9}$$
$$\theta_4 = C_1, \tag{5.10}$$
$$\theta_5 = C_6^2, \tag{5.11}$$
$$\theta_6 = C_5^2, \tag{5.12}$$
$$\phi_1 = C_5 C_6. \tag{5.13}$$

5.3. Orthorhombic groups C_{2v}, D_2, D_{2h}. A single secondary invariant of degree 3 exists:

$$\theta_1 = C_3, \tag{5.14}$$
$$\theta_2 = C_2, \tag{5.15}$$
$$\theta_3 = C_1, \tag{5.16}$$
$$\theta_4 = C_6^2, \tag{5.17}$$
$$\theta_5 = C_5^2, \tag{5.18}$$
$$\theta_6 = C_4^2, \tag{5.19}$$
$$\phi_1 = C_4 C_5 C_6. \tag{5.20}$$

5.4. Tetragonal groups S_4, C_4, C_{4h}. An invariant basis obeying the Molien factorization of Table 4.2 is

$$\theta_1 = C_3, \tag{5.21}$$
$$\theta_2 = C_1 + C_2, \tag{5.22}$$
$$\theta_3 = C_6^2, \tag{5.23}$$
$$\theta_4 = C_4^2 + C_5^2, \tag{5.24}$$
$$\theta_5 = C_1^2 + C_2^2, \tag{5.25}$$
$$\theta_6 = C_4^4 + C_5^4, \tag{5.26}$$
$$\phi_1 = (C_1 - C_2) C_6, \tag{5.27}$$
$$\phi_2 = (C_4^2 - C_5^2) C_6, \tag{5.28}$$
$$\phi_3 = C_4 C_5 C_6, \tag{5.29}$$
$$\phi_4 = C_1 C_4^2 + C_2 C_5^2, \tag{5.30}$$
$$\phi_5 = (C_1 - C_2) C_4 C_5, \tag{5.31}$$
$$\phi_6 = C_4 C_5 (C_4^2 - C_5^2), \tag{5.32}$$
$$\phi_7 = \phi_3 \phi_4. \tag{5.33}$$

5.5. Tetragonal groups D_{2d}, C_{4v}, D_4, D_{4h}. The invariant relations for these groups are also relatively simple:

$$\theta_1 = C_3, \tag{5.34}$$
$$\theta_2 = C_1 + C_2, \tag{5.35}$$
$$\theta_3 = C_6^2, \tag{5.36}$$

$$\theta_4 = C_4^2 + C_5^2, \tag{5.37}$$
$$\theta_5 = C_1^2 + C_2^2, \tag{5.38}$$
$$\theta_6 = C_4^4 + C_5^4, \tag{5.39}$$
$$\phi_1 = C_4 C_5 C_6, \tag{5.40}$$
$$\phi_2 = C_1 C_4^2 + C_2 C_5^2, \tag{5.41}$$
$$\phi_3 = \phi_1 \phi_2. \tag{5.42}$$

5.6. Cubic groups T, T_h and groups T_d, O, O_h. Group T_d is subset of group T; they share the same primary invariants and several secondary invariants. Those secondary invariants found in group T but absent from T_d are denoted by an asterisk:

$$\theta_1 = C_1 + C_2 + C_3, \tag{5.43}$$
$$\theta_2 = C_4^2 + C_5^2 + C_6^2, \tag{5.44}$$
$$\theta_3 = C_1^2 + C_2^2 + C_3^2, \tag{5.45}$$
$$\theta_4 = C_4 C_5 C_6, \tag{5.46}$$
$$\theta_5 = C_1^3 + C_2^3 + C_3^3, \tag{5.47}$$
$$\theta_6 = C_4^4 + C_5^4 + C_6^4, \tag{5.48}$$
$$\phi_1 = C_1 C_4^2 + C_2 C_5^2 + C_3 C_6^2, \tag{5.49}$$
$$\phi_2 = \phi_1^2, \tag{5.50}$$
$$\phi_3 = \phi_1^3, \tag{5.51}$$
$$(*) \quad \phi_4 = C_1 C_6^2 + C_2 C_4^2 + C_3 C_5^2, \tag{5.52}$$
$$(*) \quad \phi_5 = \phi_4^2, \tag{5.53}$$
$$(*) \quad \phi_6 = C_1^2 C_3 + C_1 C_2^2 + C_2 C_3^2, \tag{5.54}$$
$$\phi_7 = C_1^2 C_4^2 + C_2^2 C_5^2 + C_3^2 C_6^2, \tag{5.55}$$
$$(*) \quad \phi_8 = C_1^2 C_6^2 + C_2^2 C_4^2 + C_3^2 C_5^2, \tag{5.56}$$
$$\phi_9 = C_1 C_4^4 + C_2 C_5^4 + C_3 C_6^4, \tag{5.57}$$
$$(*) \quad \phi_{10} = C_1 C_4^2 C_6^2 + C_2 C_4^2 C_5^2 + C_3 C_5^2 C_6^2, \tag{5.58}$$
$$(*) \quad \phi_{11} = C_4^4 C_6^2 + C_4^2 C_5^4 + C_5^2 C_6^4. \tag{5.59}$$

It is interesting to note that the groups T and T_d share the same primary invariants. Consider (A.62), an algebraic dependence syzygy for ϕ_4, which occurs in T but not in T_d. The coefficients of ϕ_4^m, $m \in (0, 6)$, in (A.62) are expressed in terms of θ, and therefore the coefficients are invariant with respect to both T and T_d. However, the roots of this syzygy are not invariant. In T the roots ϕ of (A.62) describe an orbit of size 6 under the action of the reflection symmetry operations found in T but not in T_d.

5.7. Trigonal groups C_3, S_6. An invariant basis is

$$\theta_1 = C_3, \tag{5.60}$$
$$\theta_2 = C_1 + C_2, \tag{5.61}$$
$$\theta_3 = (C_1 - C_2)^2 + C_6^2, \tag{5.62}$$
$$\theta_4 = C_4^2 + C_5^2, \tag{5.63}$$
$$\theta_5 = C_6^3 - 3C_6(C_1 - C_2)^2, \tag{5.64}$$

$$\theta_6 = C_5(C_5^2 - 3C_4^2), \tag{5.65}$$
$$\phi_1 = C_4(C_1 - C_2) + C_5C_6, \tag{5.66}$$
$$\phi_2 = \phi_1^2, \tag{5.67}$$
$$\phi_3 = \phi_1^3, \tag{5.68}$$
$$\phi_4 = C_5(C_1 - C_2) - C_4C_6, \tag{5.69}$$
$$\phi_5 = C_5(C_1 - C_2)^2 + 2C_4C_6(C_1 - C_2) - C_5C_6^2, \tag{5.70}$$
$$\phi_6 = 2C_4C_5(C_1 - C_2) + C_6(C_4^2 - C_5^2), \tag{5.71}$$
$$\phi_7 = C_4(C_1 - C_2)^2 - 2C_5C_6(C_1 - C_2) - C_4C_6^2, \tag{5.72}$$
$$\phi_8 = (C_1 - C_2)(C_4^2 - C_5^2) - 2C_4C_5C_6, \tag{5.73}$$
$$\phi_9 = C_4(C_4^2 - 3C_5^2), \tag{5.74}$$
$$\phi_{10} = (C_1 - C_2)^2(3C_1 + C_2) - C_6^2(C_1 - 5C_2), \tag{5.75}$$
$$\phi_{11} = \phi_1\phi_4. \tag{5.76}$$

5.8. Trigonal groups C_{3v}, D_3, D_{3d}. An invariant basis is

$$\theta_1 = C_3, \tag{5.77}$$
$$\theta_2 = C_1 + C_2, \tag{5.78}$$
$$\theta_3 = (C_1 - C_2)^2 + C_6^2, \tag{5.79}$$
$$\theta_4 = C_4^2 + C_5^2, \tag{5.80}$$
$$\theta_5 = C_4(C_4^2 - 3C_5^2), \tag{5.81}$$
$$\theta_6 = (C_1 - C_2)^2(3C_1 + C_2) - C_6^2(C_1 - 5C_2), \tag{5.82}$$
$$\phi_1 = C_4(C_1 - C_2) + C_5C_6, \tag{5.83}$$
$$\phi_2 = \phi_1^2, \tag{5.84}$$
$$\phi_3 = \phi_1^3, \tag{5.85}$$
$$\phi_4 = C_4(C_1 - C_2)^2 - 2C_5C_6(C_1 - C_2) - C_4C_6^2, \tag{5.86}$$
$$\phi_5 = (C_1 - C_2)(C_4^2 - C_5^2) - 2C_4C_5C_6. \tag{5.87}$$

5.9. Hexagonal groups C_{3h}, C_6, C_{6h}. An invariant basis is

$$\theta_1 = C_3, \tag{5.88}$$
$$\theta_2 = C_1 + C_2, \tag{5.89}$$
$$\theta_3 = (C_1 - C_2)^2 + C_6^2, \tag{5.90}$$
$$\theta_4 = C_4^2 + C_5^2, \tag{5.91}$$
$$\theta_5 = C_6^3 - 3C_6(C_1 - C_2)^2, \tag{5.92}$$
$$\theta_6 = 9C_4^6 + 45C_4^4C_5^2 + 15C_4^2C_5^4 + 11C_5^6, \tag{5.93}$$
$$\phi_1 = 2C_4C_5(C_1 - C_2) + C_6(C_4^2 - C_5^2), \tag{5.94}$$
$$\phi_2 = \phi_1^2, \tag{5.95}$$
$$\phi_3 = \phi_1^3, \tag{5.96}$$
$$\phi_4 = (C_1 - C_2)(C_4^2 - C_5^2) - 2C_4C_5C_6, \tag{5.97}$$
$$\phi_5 = (C_1 - C_2)^2(3C_1 + C_2) - C_6^2(C_1 - 5C_2), \tag{5.98}$$
$$\phi_6 = (3C_4^2 + C_5^2)(C_1 - C_2)^2 + 4C_4C_5C_6(C_1 - C_2) + C_6^2(C_4^2 + 3C_5^2), \tag{5.99}$$
$$\phi_7 = (C_1C_5 - C_2C_5 - C_4C_6)(C_1C_4 - C_2C_4 + C_5C_6), \tag{5.100}$$

$$\phi_8 = 4C_4C_5(C_1 - C_2)(3C_4^2 + C_5^2) + C_6(3C_4^4 + 6C_4^2C_5^2 - 5C_5^4), \tag{5.101}$$

$$\phi_9 = 8C_4C_5^3C_6 - (C_1 - C_2)(3C_4^4 - 6C_4^2C_5^2 - C_5^4), \tag{5.102}$$

$$\begin{aligned}\phi_{10} = {} & 4C_4C_5^3(C_1 - C_2)^2 - 4C_4C_5^3C_6^2 - (C_1 - C_2) \\ & \times (3C_4^4C_6 - 6C_4^2C_5^2C_6 - C_5^4C_6),\end{aligned} \tag{5.103}$$

$$\phi_{11} = -C_4C_5(C_4^2 - 3C_5^2)(3C_4^2 - C_5^2). \tag{5.104}$$

5.10. Hexagonal groups D_{3h}, C_{6v}, D_6, D_{6h}. An invariant basis for these groups is

$$\theta_1 = C_3, \tag{5.105}$$

$$\theta_2 = C_1 + C_2, \tag{5.106}$$

$$\theta_3 = (C_1 - C_2)^2 + C_6^2, \tag{5.107}$$

$$\theta_4 = C_4^2 + C_5^2, \tag{5.108}$$

$$\theta_5 = (C_1 - C_2)^2(3C_1 + C_2) - C_6^2(C_1 - 5C_2), \tag{5.109}$$

$$\theta_6 = 9C_4^6 + 45C_4^4C_5^2 + 15C_4^2C_5^4 + 11C_5^6, \tag{5.110}$$

$$\phi_1 = (C_1 - C_2)(C_4^2 - C_5^2) - 2C_4C_5C_6, \tag{5.111}$$

$$\phi_2 = \phi_1^2, \tag{5.112}$$

$$\phi_3 = \phi_1^3, \tag{5.113}$$

$$\begin{aligned}\phi_4 = {} & (C_1 - C_2)^2(3C_4^2 + C_5^2) + 4C_4C_5C_6 \\ & \times (C_1 - C_2) + C_6^2(C_4^2 + 3C_5^2),\end{aligned} \tag{5.114}$$

$$\phi_5 = 8C_4C_5^3C_6 - (C_1 - C_2)(3C_4^4 - 6C_4^2C_5^2 - C_5^4). \tag{5.115}$$

6. Conclusions. The invariant bases presented above agree with those presented by Smith and Rivlin [20] and are identical in the sense that they generate the same ideal. In many cases the particular form of the invariants differs. This has no significance and is merely an artifact of the particular methods used. For example, in the group T the invariants K presented by Smith and Rivlin are related to the invariants θ and ϕ in (5.43)–(5.59) via $\theta_1 = K_1$, $\theta_2 = K_4$, $\theta_3 = K_1^2 - 2K_2$, $\theta_4 = K_0$, $\theta_5 = K_1^3 - 3K_1K_2 + 3K_3$, $\theta_6 = K_4^2 - 2K_5$, $\phi_1 = K_1K_4 - K_7 - K_8$, $\phi_4 = K_8$, $\phi_6 = K_1K_2 - K_9 - 3K_3$, $\phi_7 = K_1^2K_4 - K_1K_7 - K_1K_8 + K_{12} - K_2K_4$, $\phi_8 = K_1K_8 - K_2K_4 + K_{13}$, $\phi_9 = K_1K_4^2 - K_4K_8 - K_4K_7 - K_1K_5 + K_{11}$, $\phi_{10} = K_{14}$, and $\phi_{11} = K_4K_5 - K_{10} - 3K_6$ (with $K_0 = \sqrt{K_6} = C_4C_5C_6$). By writing the K's in terms of θ's and ϕ's, it is apparent on inspection that K_1, K_4, K_2, K_0, K_3, and K_5 form an HSOP and a set of primary invariants of minimal degree indicated in Table 4.2. Likewise, K_7, K_8, K_9, K_{12}, K_{13}, K_{11}, K_{14}, and K_{10} are valid secondary invariants. To make a complete set of secondary invariants, one could include both K_7^2 and K_8^2 of degree 6 and one of K_7^3 or K_8^3 of degree 9.

The following truncated series displays the difference between the Hilbert series implied by the Smith and Rivlin integrity bases and the invariants deduced above in their Molien form. The Smith and Rivlin results differ beginning with fourth-degree (in C) polynomials.

$$C_2: \quad z^4+4z^5+13z^6+32z^7+71z^8+140z^9+259z^{10}+448z^{11}+742z^{12}+\cdots, \tag{6.1}$$

$$D_{3h}: \quad z^7+4z^8+10z^9+23z^{10}+45z^{11}+83z^{12}+\cdots. \tag{6.10}$$

Appendix. Syzygies.

The invariant bases for the triclinic groups C_1 and C_i contain no secondary invariants and hence no syzygies.

A.1. Monoclinic groups C_s, C_2, C_{2h}. This syzygy is a rewriting expression and also displays the algebraic dependence of the secondary invariant upon the HSOP:

$$\phi_1^2 = \theta_5\theta_6. \tag{A.1}$$

A.2. Orthorhombic groups C_{2v}, D_2, D_{2h}. An obvious syzygy exists:

$$\phi_1^2 = \theta_4\theta_5\theta_6. \tag{A.2}$$

This is a rewriting expression and displays the algebraic dependence.

A.3. Tetragonal groups S_4, C_4, C_{4h}. Again, the algebraic dependence syzygies are included in the set of rewriting syzygies. Rewriting syzygies for $\phi_7\phi_\alpha$ are omitted since they may be simply constructed by rewriting $\phi_3(\phi_4\phi_\alpha)$ or $\phi_4(\phi_3\phi_\alpha)$.

$$\phi_1^2 = -\theta_3\left[\theta_2^2 - 2\theta_5\right], \tag{A.3}$$

$$\phi_1\phi_2 = -\theta_2\theta_3\theta_4 + 2\theta_3\phi_4, \tag{A.4}$$

$$\phi_1\phi_3 = \theta_3\phi_5, \tag{A.5}$$

$$\phi_1\phi_4 = \frac{1}{2}\theta_2\theta_4\phi_1 - \frac{1}{2}\left[\theta_2^2 - 2\theta_5\right]\phi_2, \tag{A.6}$$

$$\phi_1\phi_5 = -\left[\theta_2^2 - 2\theta_5\right]\phi_3, \tag{A.7}$$

$$\phi_1\phi_6 = -\theta_2\theta_4\phi_3 + 2\phi_7, \tag{A.8}$$

$$\phi_2^2 = -\theta_3\left[\theta_4^2 - 2\theta_6\right], \tag{A.9}$$

$$\phi_2\phi_3 = \theta_3\phi_6, \tag{A.10}$$

$$\phi_2\phi_4 = -\frac{1}{2}\left[\theta_4^2 - 2\theta_6\right]\phi_1 + \frac{1}{2}\theta_2\theta_4\phi_2, \tag{A.11}$$

$$\begin{aligned}\phi_2\phi_5 &= \phi_1\phi_6\\ &= -\theta_2\theta_4\phi_3 + 2\phi_7,\end{aligned} \tag{A.12}$$

$$\phi_2\phi_6 = -\left[\theta_4^2 - 2\theta_6\right]\phi_3, \tag{A.13}$$

$$\phi_3^2 = \frac{1}{2}\theta_3\left[\theta_4^2 - \theta_6\right], \tag{A.14}$$

$$\phi_3\phi_4 = \phi_7, \tag{A.15}$$

$$\phi_3\phi_5 = \frac{1}{2}\left[\theta_4^2 - \theta_6\right]\phi_1, \tag{A.16}$$

$$\phi_3\phi_6 = \frac{1}{2}\left[\theta_4^2 - \theta_6\right]\phi_2, \tag{A.17}$$

$$\phi_4^2 = -\frac{1}{2}\left[\theta_2^2\theta_6 + \theta_4^2\theta_5 - 2\theta_5\theta_6\right] + \theta_2\theta_4\phi_4, \tag{A.18}$$

$$\phi_4\phi_5 = \frac{1}{2}\theta_2\theta_4\phi_5 - \frac{1}{2}\left[\theta_2^2 - 2\theta_5\right]\phi_6, \tag{A.19}$$

$$\phi_4\phi_6 = -\frac{1}{2}\left[\theta_4^2 - 2\theta_6\right]\phi_5 + \frac{1}{2}\theta_2\theta_4\phi_6, \tag{A.20}$$

$$\phi_5^2 = -\frac{1}{2}\left[\theta_2^2\theta_4^2 - \theta_2^2\theta_6 - 2\theta_4^2\theta_5 + 2\theta_5\theta_6\right], \tag{A.21}$$

$$\phi_5\phi_6 = -\frac{1}{2}\theta_2\theta_4\left[\theta_4^2 - \theta_6\right] + \left[\theta_4^2 - \theta_6\right]\phi_4, \tag{A.22}$$

$$\phi_6^2 = -\frac{1}{2}\left[\theta_4^4 - 3\theta_4^2\theta_6 + 2\theta_6^2\right]. \tag{A.23}$$

A.4. Tetragonal groups D_{2d}, C_{4v}, D_4, D_{4h}. Algebraic dependence syzygies coincide with the rewriting syzygies for these groups:

$$\phi_1^2 = \frac{1}{2}\theta_3\left[\theta_4^2 - \theta_6\right], \tag{A.24}$$

$$\phi_2^2 = -\frac{1}{2}\left[\theta_2^2\theta_6 + \theta_4^2\theta_5 - 2\theta_5\theta_6\right] + \theta_2\theta_4\phi_2. \tag{A.25}$$

A.5. Cubic groups T, T_h and groups T_d, O, O_h. The rewriting syzygies for this group are complicated and do not contain all algebraic dependence syzygies. Note that the rewriting syzygies for invariants of group T_d are expressed in terms of primaries θ and only those secondary invariants of group T_d.

$$\begin{aligned}\phi_1^4 = {}& \frac{1}{36}\left[2\theta_1^4\theta_2^4 - 7\theta_1^4\theta_2^2\theta_6 - 12\theta_1^4\theta_2\theta_4^2 + 3\theta_1^4\theta_6^2 - 10\theta_1^2\theta_2^4\theta_3\right.\\ &+ 28\theta_1^2\theta_2^2\theta_3\theta_6 + 54\theta_1^2\theta_2\theta_3\theta_4^2 - 12\theta_1^2\theta_3\theta_6^2 + 14\theta_1\theta_2^4\theta_5\\ &- 36\theta_1\theta_2^2\theta_5\theta_6 - 108\theta_1\theta_2\theta_4^2\theta_5 + 18\theta_1\theta_5\theta_6^2 - 6\theta_2^4\theta_3^2 + 15\theta_2^2\theta_3^2\theta_6\\ &\left.+ 54\theta_2\theta_3^2\theta_4^2 - 9\theta_3^2\theta_6^2\right] - \frac{1}{18}\left[2\theta_1^3\theta_2^3 - 12\theta_1^3\theta_2\theta_6 - 18\theta_1^3\theta_4^2\right.\\ &- 21\theta_1\theta_2^3\theta_3 + 51\theta_1\theta_2\theta_3\theta_6 + 108\theta_1\theta_3\theta_4^2 + 21\theta_2^3\theta_5 - 45\theta_2\theta_5\theta_6\\ &\left.- 162\theta_4^2\theta_5\right]\phi_1 - \frac{1}{36}\left[19\theta_1^2\theta_2^2 + 15\theta_1^2\theta_6 + 15\theta_2^2\theta_3 - 45\theta_3\theta_6\right]\phi_2\\ &+ \frac{4}{3}\theta_1\theta_2\phi_3 - \frac{1}{36}\left[\theta_1^2 - 3\theta_3\right]\left[5\theta_2^3 - 9\theta_2\theta_6 - 54\theta_4^2\right]\phi_7\\ &+ \frac{1}{18}\left[2\theta_1^3 - 9\theta_1\theta_3 + 9\theta_5\right]\left[\theta_2^2 - 3\theta_6\right]\phi_9,\end{aligned} \tag{A.26}$$

ANALYTICAL SOLUTIONS OF A GROWTH MODEL FOR A MELT REGION INDUCED BY A FOCUSED LASER BEAM*

ANTOINE SAUCIER†, JEAN-YVES DEGORCE‡, AND MICHEL MEUNIER‡

Abstract. We consider processes in which a focused laser beam is used to induce the melting of silicium. The first goal of this paper is to propose a simple three-dimensional (3D) model of this melting process. Our model is partly based on an energy balance equation. This model leads to a nontrivial ODE describing the evolution in time of the dimension of the melt region. The second goal of this paper is to obtain approximate analytical solutions of this ODE. After using basic solution methods, we propose an original geometrical method to derive asymptotic solutions for time $\to \infty$. These solutions turn out to be the most useful for the description of this process.

Key words. focused laser beam, melting of material, three-dimensional (3D) modeling, ODE, analytic solution, asymptotic solution, geometrical method

1. Introduction.

Focusing an energetic pulsed photon beam on a material usually leads to a localized heating, possibly followed by atomic vaporization and even by an ejection of materials, a process called ablation [5]. All these mechanisms contribute to the dissipation of the laser beam energy into the materials. The time and spatial distribution of these dissipation phenomena depend on the localized heat source parameters and on the materials' properties. In this paper, we assume that the beam does not cause any ablation and that all the incoming energy is dissipated into heat, which leads to a local increase of temperature and to a melt region. The object of this study is the time evolution of the melt region size.

In general, these heating and melting effects constitute a three-dimensional (3D) heat flow problem usually solved numerically [4]. An analytical solution, even approximate, is very interesting because it allows analyzing the influence of the various physical parameters involved. Actually, simplifications to a one-dimensional (1D) heat flow problem have been proposed by many authors [9], [7], [6] for the case of a large beam dimension when compared to the heat diffusion length. However, for a long pulsed focused beam with beam dimension comparable to or smaller than the melt depth, the lateral heat flow is on the same order of magnitude as the perpendicular component. It follows that the 1D approximation is no longer valid. Nonlinear boundary conditions arising from a moving solid-liquid interface make exact analytical solutions of the 3D heat flow equation very difficult.

In this paper, we present a simplified 3D model based on an energy balance equation. This model was first introduced in [3] with a brief justification and with an emphasis on the comparison with experimental results. In this paper, our first goal is to present a *complete derivation* of this model (section 2), with an emphasis on the

nature of the approximations used. Our model leads to an ODE that describes the evolution in time of the dimension of the melt region for a material irradiated by a focused laser beam. The second goal of this paper is to obtain *approximate analytical solutions* of this ODE. In section 3, we analyze this ODE in detail using classical analytical and numerical methods. In sections 4 and 5, we derive asymptotic solutions for $t \to \infty$, using a possibly original geometrical method. Finally, in section 6, we compare the accuracy of the approximate solutions.

2. The model. Our model is based on four main hypotheses that we present and justify in the following.

2.1. Hypothesis A: The focused laser beam can be treated as a point heat source. In this paper, we assume that the laser beam is orthogonal to the flat material surface. A focused laser beam is most often characterized by a Gaussian curve of width r_0. The light intensity varies according to $I(r) = I_0 \ \exp(-(r/r_0)^2)$, where r is the distance from the beam center in a direction perpendicular to the beam. The heat diffusion characteristic length scale for a material of heat diffusivity D is usually defined by $d(t) = \sqrt{D\ t}$. $d(t)$ is an estimate of the heat front penetration depth at time t, assuming that the laser is turned on at $t = 0$.

A 1D model of the heating process is obtained if $r_0 >> d$. In this limit, the beam radius can be regarded as infinite. For an isotropic material, the resulting isothermals are planes which are perpendicular to the laser beam. If the beam is perpendicular to the flat material surface, then the isothermals are planes which are parallel to this surface.

A 3D model of the heating process is obtained if $r_0 << d(t)$. Photons entering a material are absorbed progressively. It follows that the light intensity within the material decreases according to an exponential law (Beers's law) characterized by a penetration depth ℓ (the inverse of the absorptivity). We develop our model of the heating process in the *point source approximation framework*, where both r_0 and ℓ are much smaller than the diffusion length, i.e.,

$$\begin{cases} r_0 << \sqrt{D\ t_{\rm p}} & \text{and} \\ \ell << \sqrt{D\ t_{\rm p}}, \end{cases} \tag{2.1}$$

where $t_{\rm p}$ is the pulse width and $d(t_{\rm p}) = \sqrt{D\ t_{\rm p}}$ is the diffusion length. We emphasize that the point source approximation (2.1) implies that our model is not expected to be valid or accurate for $t \approx 0$.

2.2. Hypothesis B: Heat losses at the surface of the melt domain are negligible during the whole melting process. Heat losses occur through two interfaces: the flat upper surface of the melt domain and the liquid-solid interface. In this section, we compare the magnitudes of these heat losses.

On one hand, it is a well-known experimental observation that the flat surface of the liquid domain has approximately the shape of a disk. On the other hand, the liquid-solid interface is a surface which is attached to the circumference of this disk. During the melting process, this surface is symmetric with respect to an axis going through the point heat source in the direction perpendicular to the solid-air plane. This symmetry implies that the area $\mathcal{A}$ of the liquid-solid interface can be expressed solely as a function of the disk radius r, i.e., $\mathcal{A} = \mathcal{A}(r)$. If we assume that the liquid-solid interface is not flat, then its area $\mathcal{A}(r)$ will be at least as large as

the area of the disk, i.e.,

$$\frac{\pi\ r^2}{\mathcal{A}(r)} \leq 1 \tag{2.2}$$

for $r > 0$.

Let us consider the ratio of the heat diffusion losses through these two surfaces. This ratio is $R = \frac{J_{\text{liquid/air}}}{J_{\text{liquid/solid}}}$, where $J_{\text{liquid/air}}$ and $J_{\text{liquid/solid}}$ are the heat fluxes through each interface. We use

$$\begin{cases} J_{\text{liquid/air}} &= \kappa_{\text{air}}\ \pi\ r^2 \quad \| \nabla T_{\text{air}} \|, \\ J_{\text{liquid/solid}} &= \kappa_{\text{solid}}\ \mathcal{A}(r) \quad \| \nabla T_{\text{solid}} \|, \end{cases} \tag{2.3}$$

where $(\kappa_{\text{air}}, \kappa_{\text{solid}})$ are the heat conductivities of the air and of the solid, respectively, and $(\| \nabla T_{\text{air}} \|, \| \nabla T_{\text{solid}} \|)$ are the magnitudes of the temperature gradients at the liquid surface in the air and in the solid, respectively. Using (2.3), the ratio R takes the form

$$R = \frac{\pi\ r^2}{\mathcal{A}(r)}\ \frac{\kappa_{\text{air}}}{\kappa_{\text{solid}}}\ \frac{\| \nabla T_{\text{air}} \|}{\| \nabla T_{\text{solid}} \|}. \tag{2.4}$$

If the solid and the air are at the same temperature initially, then we expect the temperature gradients at both interfaces to have similar magnitudes during the whole melting process, i.e., $\|\nabla T_{\text{air}}\| \approx \|\nabla T_{\text{solid}}\|$, and therefore $R \approx \frac{\pi\ r^2}{\mathcal{A}(r)}\ \frac{\kappa_{\text{air}}}{\kappa_{\text{solid}}}$. The inequality (2.2) then implies that R has an upper bound:

$$R \leq \frac{\kappa_{\text{air}}}{\kappa_{\text{solid}}}. \tag{2.5}$$

In general, the heat conductivity of gases is typically 100 times smaller than for solids, and therefore (2.5) implies that $R < 1/100$. Consequently, it seems reasonable to neglect heat losses in the air during the melting process. This kind of approximation has been discussed in the literature by Wood and Geist [8], who also took into account convection in the air and radiations.

2.3. Hypothesis C: The melt domain is hemispherical. We shall see that this hypothesis is essentially a consequence of the hypotheses A and B. We assume that the following three conditions are satisfied: the solid material is isotropic; the heat source is a point source (hypothesis A); the surface of the melt domain is effectively a thermal insulator (hypothesis B). It follows from these hypotheses that the temperature distribution has a *spherical symmetry*, i.e., that $T = T(r)$, where r is the distance from the point source.

The existence of a spherical symmetry can be understood by comparing our problem with another similar problem. Consider a point heat source within an *infinite* isotropic solid material, instead of a semi-infinite material. In this case, the temperature has obviously a spherical symmetry. Moreover, this symmetry implies that the heat flux going through an arbitrary plane containing the point heat source vanishes at each point of this plane. It follows that the problem with a spherical symmetry has exactly the same boundary condition (i.e., zero heat flux along a plane containing the source) as our problem in a semi-infinite material. For this reason, we expect the two problems to have the same symmetry.

Convective flow driven either by buoyancy or surface tension does not have enough time to develop for durations shorter than 1 μs, which is the laser pulse width in our application [1]. It follows that convection does not break the spherical symmetry.

Spherical symmetry implies that the isothermals are hemispherical. The liquid-solid interface, which is an isothermal, is therefore hemispherical.

2.4. Hypothesis D: Everything happens as if the heat flux at the surface of the melt region was transported instantaneously to the solid-liquid interface. In this section, we estimate the heat flux which crosses the liquid-solid interface. During a fixed time interval τ, the laser releases a constant quantity of energy which is absorbed at the top surface of the melt domain. This energy is used to heat the melt fluid, to melt a hemispherical shell of solid, and to heat the solid via diffusion. The thermal energy is transferred to the liquid-solid interface via conduction in the melt phase (convection being negligible).

In the framework of the Stefan problem [2], the energy density balance during a time lapse dt is evaluated at the moving liquid-solid interface (Figure 2.1):

$$j_{\text{in}}\ dt = j_{\text{out}}\ dt + L\ dr, \tag{2.6}$$

where j_{in} is the heat flux that reaches the interface inside the melt fluid, j_{out} is the heat flux diffused into the solid at the liquid-solid interface, and $L\ dr$ is the heat flux used to melt a region of solid of depth dr.

We integrate the energy balance equation (2.6) over the hemispherical shell of radius r and divide by dt to obtain the heat transfer rate balance

$$\int_{\text{interface}} j_{\text{in}}\ dS = j_{\text{out}}\ 2\pi r^2 + L\ \frac{dr}{dt}\ 2\pi r^2. \tag{2.7}$$

According to hypothesis B, we neglect heat losses in the air. It follows that the heat transfer rate $\int_{\text{interface}} j_{\text{in}}\ dS$ is the power provided by the laser (that we denote by P) minus the power used to heat the melt fluid (that we denote by $\frac{dE_{\text{h}}}{dt}$):

$$\int_{\text{interface}} j_{\text{in}}\ dS = P - \frac{dE_{\text{h}}}{dt}. \tag{2.8}$$

Substituting (2.8) into (2.7) yields

$$P = j_{\text{out}}\ 2\pi r^2 + L\ \frac{dr}{dt}\ 2\pi r^2 + \frac{dE_{\text{h}}}{dt}. \tag{2.9}$$

We approximate j_{out} by the linearization

$$j_{\text{out}} = -\kappa_{\text{s}}\ \left(\frac{\partial T}{\partial r}\right)_{r=r_{\text{m}}} \approx \frac{\kappa_{\text{s}}\ \Delta_{\text{s}}T}{\xi\sqrt{D\ t}}, \tag{2.10}$$

where κ_{s} is heat conductivity of the solid phase, r_{m} is the radius of the melt region, $\Delta_{\text{s}}T \equiv T_{\text{m}} - T_{\text{s}}$, T_{m} and T_{s} are the silicium fusion temperature and the solid silicium temperature far from the melt region, respectively (T_{s} equals the room temperature T_{room}), D is the thermal diffusivity in the solid at the fusion temperature T_{m}, $\sqrt{D\ t}$ is the heat diffusion characteristic length scale of the solid, and ξ is a geometry dependent constant usually fixed to 1.

The energy used to heat a hemisphere of melt solid satisfies

$$\frac{dE_h}{dt} = c_\ell\ \frac{2}{3}\ \pi\ r^3\ \frac{dT_\ell}{dt}, \tag{2.11}$$

where c_ℓ is the liquid silicium specific heat and T_ℓ is the mean temperature of the liquid silicium.

Substituting (2.10) and (2.11) into (2.9) leads to the energy transfer rate balance equation

$$P = \frac{\kappa_{\mathrm{s}}\ \Delta_{\mathrm{s}}T}{\xi\sqrt{D\ t}}\ 2\pi r^2 + L\ \frac{dr}{dt}\ 2\pi r^2 + c_\ell\ \frac{2}{3}\ \pi\ r^3\ \frac{dT_\ell}{dt}. \tag{2.12}$$

We will now compare the magnitude of the three terms

$$\begin{cases} P_{\mathrm{diffusion}} = \frac{\kappa_{\mathrm{s}}\ \Delta_{\mathrm{s}}T}{\xi\sqrt{D\ t}}\ 2\ \pi\ r^2, \\ P_{\mathrm{melting}} = L\ \frac{dr}{dt}\ 2\ \pi\ r^2, \\ P_{\mathrm{liquid\ heating}} = c_\ell\ \frac{2}{3}\ \pi\ r^3\ \frac{dT_\ell}{dt}. \end{cases} \tag{2.13}$$

In the second and third equations of (2.13), the instantaneous rates $\frac{dr}{dt}$ and $\frac{dT_\ell}{dt}$ are unknown a priori. However, the average rates can be estimated. For a time lapse τ, the average rates are defined by $\frac{dr}{dt}|_{\mathrm{mean}} = r/\tau$ and $\frac{dT_\ell}{dt}|_{\mathrm{mean}} = \frac{\Delta_\ell T}{\tau}$. In this problem, the laser beam power is constant and the size of the melt pool grows with time. Because the volume to heat increases as time passes, we expect both dr/dt and dT_ℓ/dt to decrease with time, i.e., to have negative second derivatives. This implies that *the average rates are larger than the instantaneous rates*. Substituting the average rates into (2.13) yields

$$\begin{cases} P_{\mathrm{diffusion}} = \frac{\kappa_{\mathrm{s}}\ \Delta_{\mathrm{s}}T}{\xi\sqrt{D\ t}}\ 2\ \pi\ r^2, \\ P_{\mathrm{melting}} \le L\ \frac{r}{\tau}\ 2\ \pi\ r^2, \\ P_{\mathrm{liquid\ heating}} \le c_\ell\ \frac{2}{3}\ \pi\ r^3\ \frac{\Delta_\ell T}{\tau}. \end{cases} \tag{2.14}$$

We use parameter values which are close to the ones observed experimentally for a focused laser beam on silicium, i.e., $r = 1\ \mu$m, $D = 0.1\ \mathrm{cm}^2/\mathrm{s}$, $\kappa_{\mathrm{s}} = 0.3\ \mathrm{W}/(\mathrm{cm}\ ^\circ\mathrm{K})$, $\Delta_\ell T = T_{\mathrm{vapor(Si)}} - T_{\mathrm{melt(Si)}} = 900\ ^\circ$K (by using the vaporization temperature of silicium, we overestimate $P_{\mathrm{liquid\ heating}}$), $\Delta_{\mathrm{s}}T = T_{\mathrm{melt(Si)}} - T_{\mathrm{room}} = 1400\ ^\circ$K, $c_{\mathrm{l}} = 0.91\ \mathrm{J}/(\mathrm{g}\ ^\circ\mathrm{K})$, $\tau = 1\ \mu$s, and $L = 4129\ \mathrm{J}/(\mathrm{cm}^3)$. Equation (2.14) leads to

$$\begin{cases} P_{\mathrm{diffusion}} = 0.083\ \mathrm{W}, \\ P_{\mathrm{melting}} \le 0.025\ \mathrm{W}, \\ P_{\mathrm{liquid\ heating}} \le 0.0017\ \mathrm{W}. \end{cases} \tag{2.15}$$

For short times, i.e., $t \le t_{\mathrm{p}}$, we expect both $r(t)$ and $T_\ell(t)$ to increase rapidly with time and consequently the instantaneous rates dr/dt and dT_ℓ/dt should be close to their average values. It follows that we can use the upper bounds in the second and third lines of (2.15) as estimates of P_{melting} and $P_{\mathrm{liquid\ heating}}$, which leads to $P_{\mathrm{melting}}/P_{\mathrm{liquid\ heating}} \approx 15$. $P_{\mathrm{liquid\ heating}}$ is therefore the smallest contribution to the energy balance, which is dominated by $P_{\mathrm{diffusion}}$ and P_{melting}. Combining the latter two contributions, we get

$$\frac{P_{\mathrm{liquid\ heating}}}{P_{\mathrm{diffusion}} + P_{\mathrm{melting}}} < \frac{2}{100}. \tag{2.16}$$

The energy stored by the heating fluid is therefore quite small compared to the energy transported by conduction and the energy used to melt the solid. In the following, we make the hypothesis that $P_{\mathrm{liquid\ heating}}$ can be neglected. It follows that the energy transferred by the laser during consecutive equal length time intervals can be regarded

as an *incompressible train* of equal size energy grains. Since the energy used to heat the fluid is negligible, then for each grain of energy entering the fluid at the upper surface, there is another grain of energy (emitted earlier) that exits the fluid at the liquid-solid interface. In other words, everything happens *as if* the energy entering the liquid at the top surface was transported instantaneously at the liquid-solid interface.

2.5. Derivation of the ODE based on the model hypotheses. According to hypothesis C, the melt region can be described by a hemisphere of radius r, as shown in Figure 2.1. We will therefore focus on the description of $r(t)$ as a function of the time t. According to the point heat source hypothesis A, the condition of validity of our model is

$$r(t) >> r_0, \tag{2.17}$$

where r_0 is the beam radius.

According to hypothesis D, we neglect the third term of (2.12) (on the right-hand side) to obtain

$$P = \frac{\kappa_s \, \Delta_s T}{\xi \sqrt{D \, t}} \, 2\pi r^2 + L \, 2\pi r^2 \, \frac{dr}{dt}. \tag{2.18}$$

Introducing the dimensionless quantities

$$x \equiv \, 2 \, \pi \, \frac{r}{r_0}, \quad \tau = 4 \, \pi^2 \, \frac{D \, t}{r_0^2}, \quad p = \frac{P}{D \, L \, r_0}, \tag{2.19}$$

we can rewrite (2.18) in the equivalent form

$$\frac{dx}{d\tau} = \frac{p}{x^2} - \frac{A}{\tau^{1/2}}, \tag{2.20}$$

where we introduce the dimensionless material-properties-only constant

$$A \equiv \frac{\kappa_s \, \Delta_s T}{\xi \, D \, L}. \tag{2.21}$$

For most materials, $A \approx 1$. With typical values for D (0.1 cm^2/s), L (4129 J/cm^3), $\Delta_s T$ (1400 K), r_0 (10^{-4} cm), and $P = 1$ W, we get $\tau \approx 4 \times 10^8 \, t$ and $p \approx 25$. Using the first quantity in (2.19), the constraint (2.17) implies that $x >> 2\pi$.

2.6. Initial value. The laser beam is turned on at $\tau = 0$ and is kept on afterward. The size of the melt region is zero at $\tau = 0$, and therefore it seems natural to use the initial value $x(0) \equiv x_0 = 0$. However, the differential equation (2.20) happens to be *singular* at $\tau = 0$ and $x = 0$. These singularities deserve a few comments.

First, we should stress that according to hypothesis A (point source approximation), we do not expect our model to be valid for $r = 0$. Indeed, the assumption (2.1) implies that $r(t) >> r_0$ and $t >> \frac{r_0^2}{D}$. Let us nevertheless consider our model in the limit $r \to 0$ and $t \to 0$.

The origin of the singularity at $t = 0$ is the term $\frac{\kappa_s \, \Delta_s T}{\xi \sqrt{D \, t}} \, 2\pi r^2$ in (2.18). The parameter $\Delta_s T \equiv T_m - T_{room}$ is fixed in our model, whereas in reality $\Delta_s T = 0$ for $t = 0$. Indeed, the medium does not melt instantaneously and therefore the temperature at the laser beam impact point increases rapidly from its initial value T_{room} to reach the melt value T_m. As expected, our equation does not correctly model this part of the heating process, which causes the singularity at time zero.

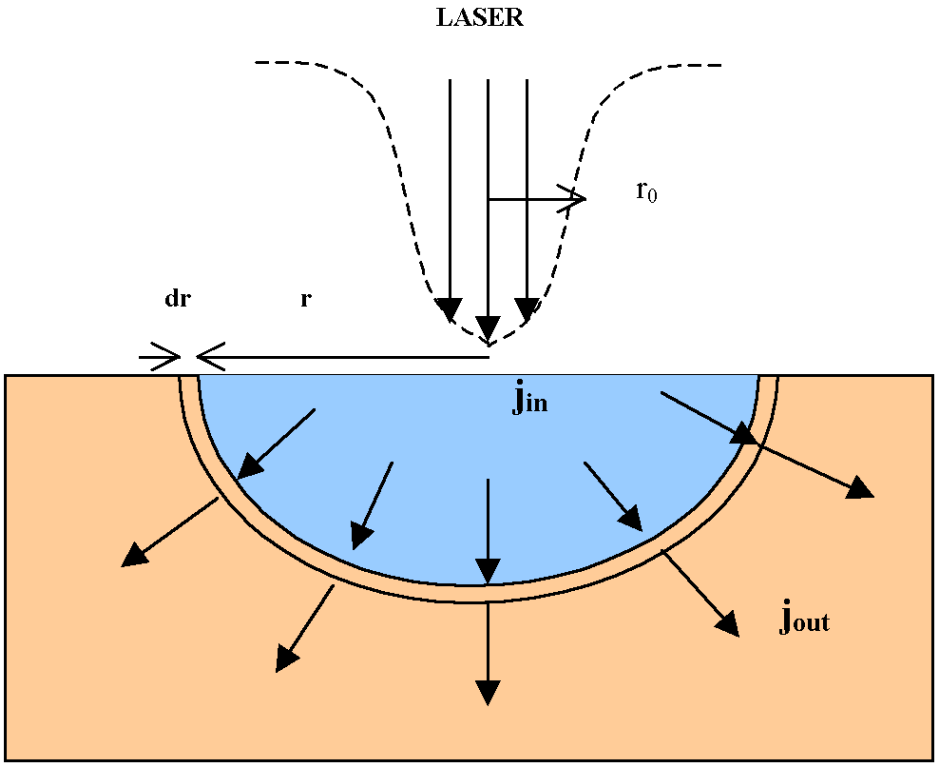

FIG. 2.1. *Schematics showing the hemispherical melt region of a semiconductor irradiated by a focused beam.*

The singularity at $r = 0$ is more physical because we expect $\frac{dr}{dt}$ to be very large for $t \approx 0$. Indeed, for $t \approx 0$ the finite power from the laser beam is transferred to a tiny hemisphere, which naturally causes the material to melt rapidly and consequently $\frac{dr}{dt}$ to be very large. In numerical simulations, we have to consider initial values such that $r_0 > 0$, even if it is not consistent with the physics of the problem. As a compromise, we will consider solutions with $r_0 > 0$ in the limit $r_0 \to 0^+$.

2.7. A preliminary simplification of the ODE. The change of variables

$$R = p^{-1}\, x \quad , \quad \theta = p^{-2}\, \tau \tag{2.22}$$

transforms (2.20) into

$$\frac{dR}{d\theta} = f(R,\theta) \equiv \frac{1}{R^2} - \frac{A}{\sqrt{\theta}}, \tag{2.23}$$

which contains only one parameter (i.e., $A \geq 0$), instead of two (i.e., A and p). In the following, we will study the ODE (2.23) with the initial condition $R(0) \equiv R_0 > 0$. The restriction $x >> 2\pi$ implies that $R >> 0.25$ (i.e., $R >> 2\pi/p$ with $p = 25$). According to (2.22), the solutions of (2.20) and (2.23) are directly related by $x(\tau, x_0) = p\ R(p^{-2}\tau, R_0)$. If $R_0 = x_0 \approx 0$, then

$$x(\tau) = p\ R(p^{-2}\tau). \tag{2.24}$$

In the following, we will assess the accuracy of approximate analytical solutions by comparison with numerical solutions, for which we use $A = 0.75$, which is the value of A corresponding to silicium.

3. Basic considerations.

3.1. Separability and integrating factor. Equation (2.23) is a nonlinear first order nonautonomous ODE. If $A = 0$, then (2.23) becomes $\frac{dR}{d\theta} = \frac{1}{R^2}$, which is *separable*, and the solution is

$$R(\theta) = (3\,\theta + R_0^3)^{1/3}. \tag{3.1}$$

However, if $A > 0$, then (2.23) is *not separable*. Moreover, an integrating factor that depends only on R or only on θ does not exist.

3.2. Sign of the derivative and direction field. Equation (2.23) can be rewritten in the equivalent form

$$\frac{dR}{d\theta} = -\frac{A}{R^2\sqrt{\theta}}\left(R + \frac{\theta^{1/4}}{\sqrt{A}}\right)\left(R - \frac{\theta^{1/4}}{\sqrt{A}}\right), \tag{3.2}$$

which shows that the function

$$\rho_0(\theta) \equiv \frac{\theta^{1/4}}{\sqrt{A}} \tag{3.3}$$

plays a special role. On one hand, $\rho_0(\theta)$ satisfies $f(\rho_0(\theta), \theta) = 0$. On the other hand, it follows from (3.2) that

$$\begin{cases} dR/d\theta < 0 & \text{if} \quad R > \rho_0(\theta), \\ dR/d\theta > 0 & \text{if} \quad R < \rho_0(\theta). \end{cases} \tag{3.4}$$

The inequalities (3.4) suggest that orbits have a tendency to remain close to $\rho_0(\theta)$, i.e., that $\rho_0(\theta)$ *is an asymptotic solution* for $\theta \to \infty$. This is indeed the case, in the sense that $\dot{\rho}_0(\theta) - f(\rho_0(\theta), \theta) = \frac{\theta^{-3/4}}{4\sqrt{A}} \to 0$ as $\theta \to \infty$. The *direction field* (DF) of (2.23) was plotted in Figure 3.1 for $A = 0.75$ and $0 \le \theta \le 1$. The DF is *horizontal* on the solid curve $R = \rho_0(\theta)$. The DF is pointing downward along the R-axis, which indicates that orbits dive down for $\theta \approx 0$ and $R(0) > 0$. However, the large θ behavior of the field is consistent with an increasing $R(\theta)$ as θ increases.

3.3. Singularities and numerical solutions. Equation (2.23) is *singular* at $R = 0$ and $\theta = 0$, which is problematic for initial values of the form $R(0) = R_0 > 0$. The singularity at $\theta = 0$ can be circumvented with the change of variable $s = \sqrt{\theta}$, which transforms (2.23) into

$$\frac{dR}{ds} = 2\left(-A + \frac{s}{R^2}\right). \tag{3.5}$$

Equation (3.5) is no longer singular at $s = 0$ but remains singular at $R = 0$. We obtained our numerical solutions[1] by solving (3.5) and then by replacing s by $\sqrt{\theta}$. With this method, we obtained several numerical solutions corresponding to different values of $R_0 > 0$ (Figure 3.2).

[1] In this paper, numerical solutions were obtained with the *Mathematica* function NDSolve, which switches between a nonstiff Adams method and a stiff Gear method.

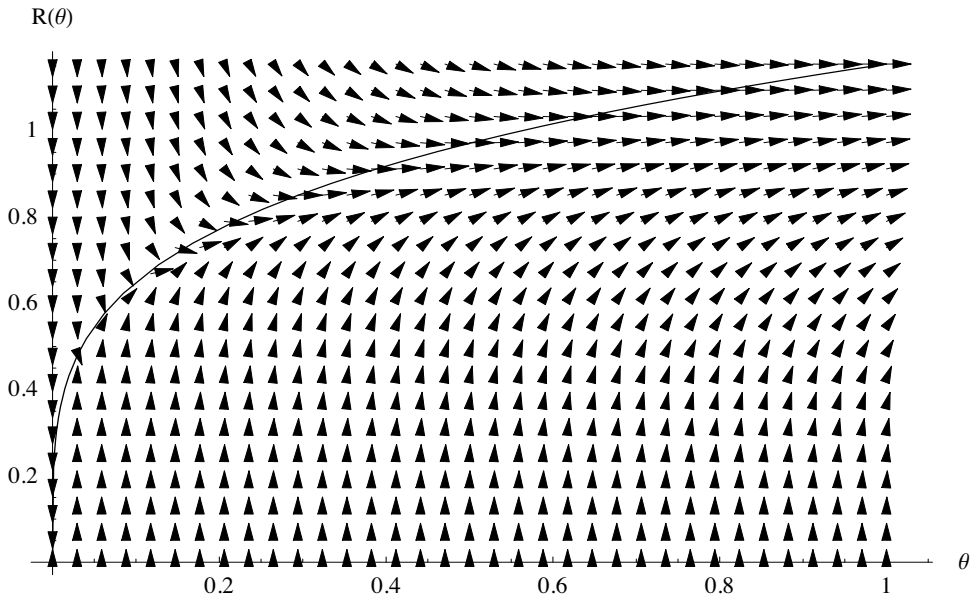

FIG. 3.1. *DF of* (2.23) *for* $A = 0.75$. *The solid curve represents the set of points for which the DF is horizontal, i.e.,* $R = \rho_0(\theta) \equiv \theta^{1/4}/\sqrt{A}$.

Considering Figure 3.2, the first important observation is that $R(\theta, R_0)$ is virtually independent of R_0 for large enough θ. This is fortunate because we did not know a priori which value to choose for R_0. Figure 3.2 informs us that any $R_0 < 0.1$ leads essentially to the same solution for $\theta >> 0.002$. The second observation is that the validity condition $R >> 0.25$ corresponds approximately to the *validity range* $\theta >> \theta_1 \equiv 0.002$.

3.4. Anomalous behavior of $R(\theta)$ around $\theta = 0$. The physics of this problem implies that the melt region expands with time. However, as clearly seen on the DF, all solutions with $R_0 > 0$ dive down in the neighborhood of $\theta = 0$ before eventually going up again. This peculiar behavior occurs in the region where the ODE is not valid. To be cautious, it is important to see if this anomaly can overlap the validity range $\theta > \theta_1$ of the ODE.

We analyzed the behavior of $R(\theta)$ as $\theta \to 0$ in Appendix A and found that

$$\begin{cases} \text{If } R_0 > 0, \ R(\theta) \sim R_0 - 2\ A\ \sqrt{\theta} + \frac{1}{R_0^2}\ \theta, \\ \text{If } R_0 \approx 0, \ \ R(\theta) \sim (3\ \theta)^{1/3} \end{cases} \tag{3.6}$$

as $\theta \to 0$. Solutions with $R_0 > 0$ and $R_0 \approx 0$ are qualitatively different. Indeed, if $R_0 \approx 0$, then $R(\theta)$ *increases* for all $\theta \geq 0$, as it should. However, if $R_0 > 0$, then $R(\theta)$ *decreases*, reaches a minimum around $\theta_{\min} = A^2\ R_0^4$, and then increases ($R(\theta)$ is U-shaped). If we consider, for instance, a solution obtained with $R_0 = 0.001$, then we get $\theta_{\min} \approx 5.6 \times 10^{-13} << \theta_1 = 0.002$. Hence the anomalous behavior (3.6) occurs at very short times and does not overlap the validity range $\theta > \theta_1$ of the ODE.

3.5. Perturbation solution for A small. The solution for $A = 0$ is known exactly, i.e., $R(\theta) = (R_0^3 + 3\ \theta)^{1/3}$, and we assume that $0 \leq A \leq 1$. In this context, it is appropriate to look for a perturbation solution that would be valid for A small. If

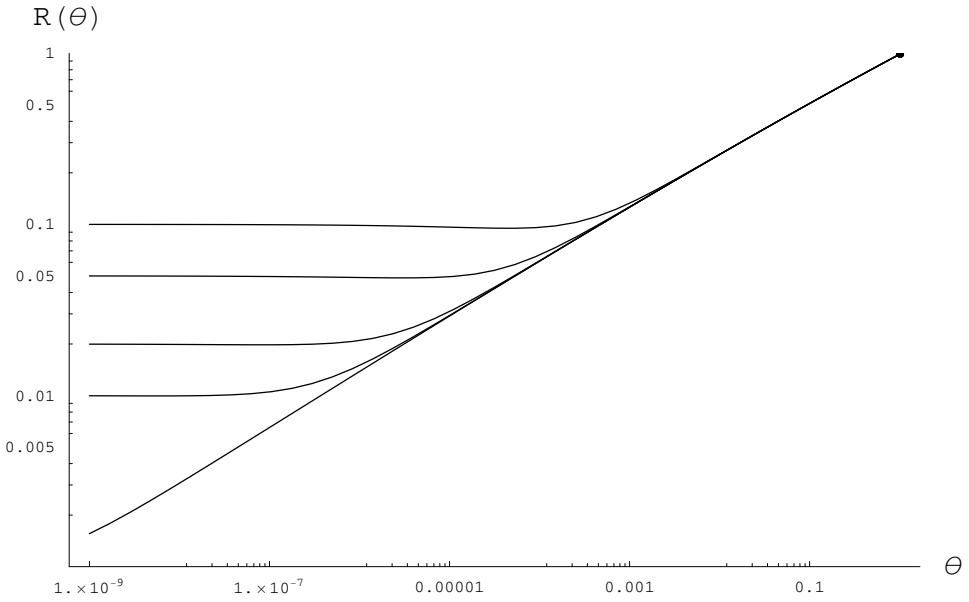

FIG. 3.2. *Numerical solutions for the initial values* $R(0) = (0.001, 0.01, 0.02, 0.05, 0.1)$.

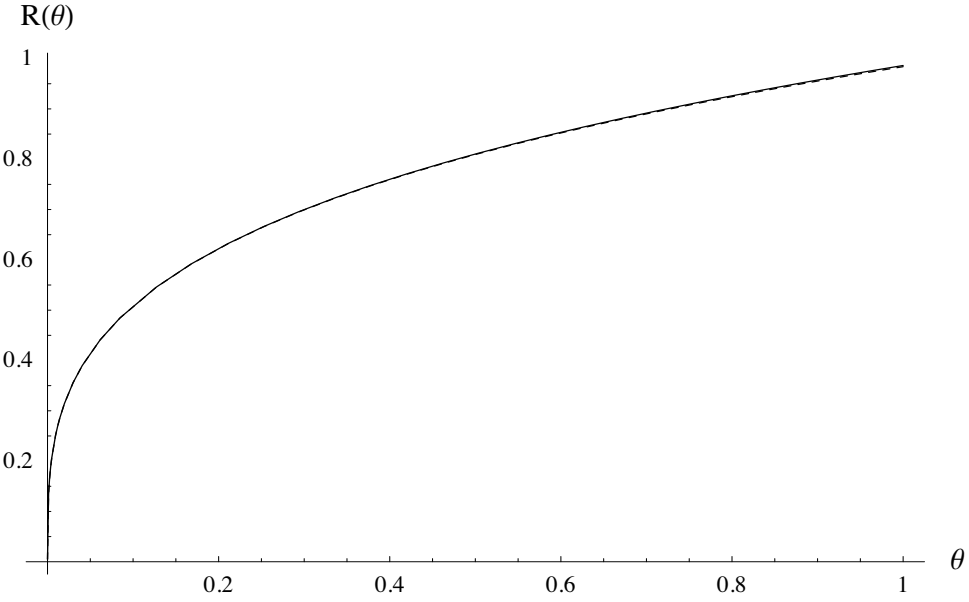

FIG. 3.3. *The solid curve is a numerical solution with* $R(0) = 0.001$ *and* $A = 0.75$*, while the dotted curve is the perturbation solution* (3.8)*. The curves are superposed; i.e., the agreement is excellent.*

we search for a solution of the form

$$R(\theta) = \sum_{n=0}^{\infty} A^n \; R_n(\theta), \tag{3.7}$$

where the R_ns are unknown functions and $R(0) = 0$, then it is straightforward to show (see Appendix B) that the perturbation method leads to the series

$$R(\theta) = (3\ \theta)^{1/3} - \frac{6}{7}\ \sqrt{\theta}\ A + \frac{3}{49}\ (3\ \theta)^{2/3}\ A^2 - \frac{8\ 3^{1/3}}{343}\ \theta^{5/6}\ A^3 - \frac{711}{12005}\ \theta\ A^4 + \frac{4824\ 3^{2/3}}{924385}\ \theta^{7/6}\ A^5 + O(A)^6. \tag{3.8}$$

As shown in Figure 3.3, an excellent agreement of (3.8) with numerical solutions is obtained for $0 \leq \theta \leq 1$.

3.6. Dependence of the solution on the parameter A. We notice that (3.8) can be written in the form $R(\theta) = \sum_{n=0}^{5} c_n\ (\theta^{1/6})^{n+2}\ A^n$, where the c_ns are real coefficients. Factorizing $\theta^{1/3}$ yields $R(\theta) = \theta^{1/3}\ \sum_{n=0}^{5} c_n\ (A\ \theta^{1/6})^n$, which suggests that the solution with $R_0 = 0$ has the general form

$$R(\theta) = \theta^{1/3}\ F(A\ \theta^{1/6}), \tag{3.9}$$

where F is an unknown function. Substituting (3.9) into (2.23) and using the change of variable $u = A\ \theta^{1/6}$ lead to

$$\frac{dF}{du} = \frac{6\ (1 - u\ F^2) - 2\ F^3}{u\ F^2}. \tag{3.10}$$

Equation (3.10) does not depend explicitly on A, and therefore (3.9) is indeed correct in general. The initial condition for (3.10) is $F(0) = 3^{1/3}$, which follows from $R(\theta) \sim (3\ \theta)^{1/3}$ as $\theta \to 0$. Equation (3.10) is a *key equation* that allows us to recover the MacLaurin series of $F(u)$ directly, i.e., without using the perturbation method. Consider, for instance, $F'(0)$. According to (3.10), $F'(0)$ has an indeterminate form $0/0$. However, using l'Hôspital's rule yields $F'(0) = \lim_{u\to 0} \frac{-6\ (F^2 + 2\ u\ F\ F') - 6\ F^2\ F'}{F^2 + 2\ u\ F\ F'} = -6 - 6\ F'(0) \Rightarrow F'(0) = -6/7$, which is correct according to (3.8). Higher order derivatives can also be obtained to recover the whole expansion, i.e., $F(u) = 3^{1/3} - \frac{6}{7}\ u + \frac{9\ 3^{2/3}}{49}\ u^2 - \frac{8\ 3^{1/3}}{343}\ u^3 - \frac{711}{12005}\ u^4 + \frac{4824\ 3^{2/3}}{924385}\ u^5 + O(u)^6$.

4. Asymptotic behavior for $\theta \to \infty$. In the spirit of the geometrical methods of Poincaré, we will try to locate the orbit $R(\theta)$ by examining its distance with respect to a reference curve. We have seen previously that the curve $R = \rho_0(\theta)$, defined by (3.3), is an asymptotic solution as $\theta \to \infty$. We will therefore choose $R = \rho_0(\theta)$ as our reference curve. We consider the time evolution of the distance function $U(\theta)$ defined by

$$U(\theta) \equiv \frac{1}{2}\left(R(\theta) - \rho_0(\theta)\right)^2. \tag{4.1}$$

A time derivative gives $\frac{dU}{d\theta} = (R - \rho_0)(\dot{R} - \dot{\rho}_0) = (R - \rho_0)(f(R,\theta) - \dot{\rho}_0)$. The factor $f(R,\theta) - \dot{\rho}_0$ has two roots $R = \pm\ \rho_1(\theta)$, which yields the factorization

$$\frac{dU}{d\theta} = -\ \frac{(1 + 4\ A^{3/2}\ \theta^{1/4})}{4\ \sqrt{A}\ R^2\ \theta^{3/4}}\ (R + \rho_1(\theta))(R - \rho_0(\theta))(R - \rho_1(\theta)), \tag{4.2}$$

where

$$\rho_1(\theta) = \frac{2\ A^{1/4}\ \theta^{3/8}}{\sqrt{1 + 4\ A^{3/2}\ \theta^{1/4}}}. \tag{4.3}$$

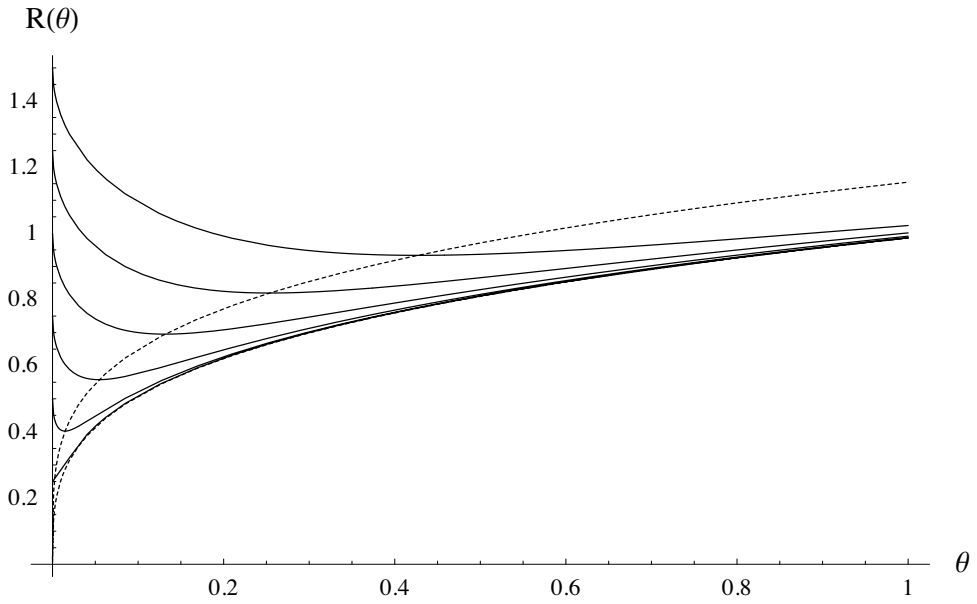

FIG. 4.1. *Dotted lines: Functions $\rho_0(\theta)$ (top) and $\rho_1(\theta)$ (bottom). Solid lines are orbits with different values of $R(0) > 0$, i.e., $(0.01, 0.1, 0.25, 0.5, 0.75, 1, 1.25, 1.5)$. The solutions that correspond to $R(0) = 0.01$ and 0.01 are superposed. Here $A = 0.75$.*

The functions $\rho_0(\theta)$ and $\rho_1(\theta)$, which are plotted in Figure 4.1 for $A = 0.75$, satisfy

$$\rho_0(\theta) > \rho_1(\theta) > 0 \tag{4.4}$$

for all $\theta > 0$ as long as $A > 0$. It follows from (4.2) and (4.4) that

$$\begin{cases} \frac{dU}{d\theta} < 0 & \text{if} \quad R > \rho_0(\theta) \ \text{ or } \ R < \rho_1(\theta), \\ \frac{dU}{d\theta} > 0 & \text{if} \quad \rho_0(\theta) < R < \rho_1(\theta), \\ \frac{dU}{d\theta} = 0 & \text{if} \quad R = \rho_0(\theta) \text{ or } R = \rho_1(\theta). \end{cases} \tag{4.5}$$

In other words, the *crescent-shaped zone* bounded by the curves $R = \rho_0(\theta)$ and $R = \rho_1(\theta)$ is *attractive* for all orbits that are outside the crescent. If $R(0) > 0$, then the orbit is in the region $R > \rho_0(\theta)$ initially, i.e., outside the crescent. If $R(0) = 0$, then according to (3.6) we have $R(\theta) \sim (3\ \theta)^{1/3}$ as $\theta \to 0$, and consequently the orbit lies between the two curves $\rho_0(\theta)$ and $\rho_1(\theta)$ initially. Indeed, $\rho_1(\theta) \sim 2\ A^{1/4}\ \theta^{3/8}$ as $\theta \to 0$, and one shows easily that $2\ A^{1/4}\ \theta^{3/8} < (3\ \theta)^{1/3} < \theta^{1/4}/\sqrt{A}$ as $\theta \to 0$. In summary, the orbit is initially located either *above* the reference curve $R = \rho_0(\theta)$ (for $R_0 > 0$), or *between* $\rho_0(\theta)$ and $\rho_1(\theta)$ (for $R_0 = 0$).

If the orbit starts *above* $R = \rho_0(\theta)$, then it follows from the first line of (4.5) that $R(\theta)$ gets closer to $\rho_0(\theta)$ as θ increases. This behavior is illustrated by the numerical solutions displayed in Figure 4.1. All orbits with $R(0) > 0$ *cross* the curve $R = \rho_0(\theta)$ because the DF is horizontal on this curve. Once inside the *crescent-shaped* region $\rho_0(\theta) < R < \rho_1(\theta)$, then the second line of (4.5) implies that the orbit $R(\theta)$ *goes away* from the upper boundary of the crescent $R = \rho_0(\theta)$. We are going to prove that this orbit *cannot cross the bottom curve* $R = \rho_1(\theta)$ because this would imply $\dot{U}(\theta) > 0$, which is not possible *on* and *below* this curve according to (4.5).

First,

$$\dot{U} = (\rho_0 - R)(\dot{\rho}_0 - \dot{R}) = (\rho_0 - R)\ \dot{D}, \tag{4.6}$$

where $D(\theta) \equiv \rho_0(\theta) - R(\theta)$. The distance $D(\theta)$ satisfies

$$\dot{D} = \dot{\rho}_0(\theta) - \dot{R}(\theta) = \dot{\rho}_0(\theta) - \dot{\rho}_1(\theta) + \dot{\rho}_1(\theta) - \dot{R}(\theta) = \dot{D}_0 + \dot{\rho}_1(\theta) - \dot{R}(\theta), \tag{4.7}$$

where $D_0(\theta) \equiv \rho_0(\theta) - \rho_1(\theta)$ is the distance between the two curves. It can be shown that $\dot{D}_0 > 0$ for all $\theta > 0$; i.e., the distance separating the two curves increases. If we assume that an orbit crosses the curve $R = \rho_1(\theta)$ *from above*, then this orbit has to satisfy $\dot{R} < \dot{\rho}_1 \Rightarrow \dot{\rho}_1(\theta) - \dot{R}(\theta) > 0$ *at the crossing point*. Since $\dot{D}_0 > 0$ and $\dot{\rho}_1(\theta) - \dot{R}(\theta) > 0$ at the crossing point, (4.7) implies that $\dot{D} > 0$. Since $R < \rho_0$ and $\dot{D} > 0$ at the crossing point, it follows from (4.6) that $\dot{U} > 0$, which is not possible *on* or *below* the curve $R = \rho_1(\theta)$ according to (4.5). Hence there is no crossing point.

The orbit *must therefore remain within the crescent*, while going away from the upper curve $R = \rho_0(\theta)$. Orbits that start *within the crescent*, and, in particular, the orbit with $R_0 = 0$, also remain within the crescent for all $\theta > 0$ (for the same reasons). It can be shown that $\lim_{\theta\to\infty} \rho_0(\theta) - \rho_1(\theta) = 1/(8\ A^2)$. Hence the orbit is *sandwiched between two curves that are separated by an asymptotically finite constant distance* and goes away from the upper curve. Numerical solutions (Figure 4.1) indicate that the limit orbit is much closer to $\rho_1(\theta)$ (bottom curve) than to $\rho_0(\theta)$ for $A = 0.75$. It follows that a possible asymptotic behavior for the orbit is

$$R(\theta) \sim \frac{2\ A^{1/4}\ \theta^{3/8}}{\sqrt{1 + 4\ A^{3/2}\ \theta^{1/4}}}\ +\ \mathrm{C}(A, R_0)\ \ \text{as}\ \ \theta \to \infty, \tag{4.8}$$

where $\mathrm{C}(A, R_0) << 1/(8\ A^2)$. Numerical solutions suggest that $\mathrm{C}(A, R_0)$ could be independent of R_0. $\rho_1(\theta)$ satisfies (2.23) asymptotically as $\theta \to \infty$. Indeed, as $\theta \to \infty$, we have $\dot{\rho}_1(\theta) - f(\rho_1(\theta), \theta) \sim \frac{1}{4\sqrt{A}\ \theta^{3/4}} \to 0$. Finally, let us stress that (4.8) has exactly the functional form (3.9), with $F(u) = (2\ u^{1/4})/(\sqrt{1 + 4\ u^{3/2}})$.

5. More accurate asymptotic solutions for $\theta \to \infty$. The asymptotic solution $\rho_1(\theta)$ was shown to be an improvement on the first guess $\rho_0(\theta)$. One may hope that a similar procedure could allow us to further improve the solution. Let us therefore consider the distance function

$$V(\theta) \equiv \frac{1}{2}\left(R(\theta) - \rho_1(\theta)\right)^2. \tag{5.1}$$

Taking the time derivative and factorizing as previously yield

$$\dot{V}(\theta) = -a(\theta)(R + \rho_2(\theta))(R - \rho_1(\theta))(R - \rho_2(\theta)), \tag{5.2}$$

where $\rho_2(\theta) > 0$ and $a(\theta) > 0$ are given by

$$\begin{aligned} \rho_2(\theta) &= \frac{2\ \left(1 + 4\ A^{3/2}\ \theta^{1/4}\right)^{3/4}\ \theta^{5/16}}{\sqrt{3\ A^{1/4} + 4\ A\ \left(1 + 4\ A^{3/2}\ \theta^{1/4}\right)^{3/2}\ \theta^{1/8} + 8\ A^{7/4}\ \theta^{1/4}}}, \\ a(\theta) &= \frac{3\ A^{1/4} + 4\ A\ \left(1 + 4\ A^{3/2}\ \theta^{1/4}\right)^{3/2}\ \theta^{1/8} + 8\ A^{7/4}\ \theta^{1/4}}{4\ R^2\ \left(1 + 4\ A^{3/2}\ \theta^{1/4}\right)^{3/2}\ \theta^{5/8}}. \end{aligned} \tag{5.3}$$

It can be shown that $\rho_2(\theta) > \rho_1(\theta)$ for all $\theta > 0$, which implies with (5.2) that

$$\begin{aligned} &\dot{V}(\theta) < 0 \text{ if } R > \rho_2(\theta) \text{ or } R < \rho_1(\theta), \\ &\dot{V}(\theta) > 0 \text{ if } \rho_1(\theta) < R < \rho_2(\theta); \end{aligned} \tag{5.4}$$

i.e., the crescent region bounded by the curves $R = \rho_1(\theta)$ and $R = \rho_2(\theta)$ is *attractive*. The situation is therefore similar to the previous case in the sense that we have identified another crescent-shaped region which is *attractive* for orbits that are outside this region. However, the arguments that we used in section 4 to prove that orbits entering this crescent are trapped no longer holds in this case. Indeed, the problem is that $\dot{\rho}_2 - \dot{\rho}_1 < 0$; i.e., the two curves get closer to each other as θ increases (which can be shown numerically for $A = 0.75$).

We cannot establish with the same argument that the orbit stays inside this new crescent, but we can at least claim that $\rho_2(\theta)$ is an asymptotic solution because $\rho_2(\theta) \sim \theta^{1/4}/\sqrt{A}$ as $\theta \to \infty$. We may ask if $\rho_2(\theta)$ is a better approximation of $R(\theta)$ than $\rho_1(\theta)$ for $0 \le \theta \le 1$. Numerical solutions (Figure 5.1) indicate that the orbits with $R_0 \approx 0$ are closer to $\rho_2(\theta)$ than to $\rho_1(\theta)$. In Figure 5.1, a low value of A was used to get a clearly visible spacing between the curves bounding the crescent. Indeed, for $A = 0.75$ the curves $\rho_1(\theta)$ and $\rho_2(\theta)$ are almost superposed. We can therefore propose the asymptotic solution

$$R(\theta) \sim \frac{2\ (1 + 4\ A^{3/2}\ \theta^{1/4})^{3/4}\ \theta^{5/16}}{\sqrt{3\ A^{1/4} + 4\ A\ (1 + 4\ A^{3/2}\ \theta^{1/4})^{3/2}\ \theta^{1/8} + 8\ A^{7/4}\ \theta^{1/4}}} \tag{5.5}$$

as $\theta \to \infty$, which is more accurate than $\rho_1(\theta)$ for $0 \le \theta \le 1$. As shown in Figure 5.2, $\rho_2(\theta)$ appears to be a good asymptotic solution. Moreover, the range of validity of $\rho_2(\theta)$ is broader if $R(0) \approx 0$, which is precisely the limit we are interested in.

Remark. The iterative process that allowed us to find $\rho_1(\theta)$ and $\rho_2(\theta)$, starting with $R = \rho_0(\theta)$, can be summarized as follows. In both cases, the new curve $R = \rho_{n+1}(\theta)$ bounding the crescent zone is the positive root of the equation

$$f(\rho_{n+1}, \theta) = \dot{\rho}_n(\theta), \tag{5.6}$$

where $\rho_n(\theta)$ is the previous curve. Using (2.23), (5.6) leads to the iteration formula

$$\rho_{n+1}(\theta) = \frac{\theta^{1/4}}{\sqrt{\sqrt{\theta}\ \dot{\rho}_n(\theta) + A}}. \tag{5.7}$$

Roughly speaking, (5.7) is a kind of *backward Picard iteration*, because we iterate a derivative instead of an integration. We notice that $\rho_n(0) = 0$ for all n and consequently the initial value $R(0) = 0$ is conserved exactly during iteration. Using the initial value $\dot{\rho}_{-1}(\theta) = 0$, we can iterate (5.7) to get successively $\rho_0(\theta)$, $\rho_1(\theta)$, and $\rho_2(\theta)$. It might be possible to generalize this iterative process to find asymptotic solutions for other ODEs.

6. Conclusions. The only *exact* result that we derived about the solution of the ODE (2.23) with $R(0) \approx 0$ is the functional form (3.9). Using (2.22), (3.9) leads to

$$x(\tau, p) = (p\ \tau)^{1/3}\ F(A\ p^{-1/3}\ \tau^{1/6}), \tag{6.1}$$

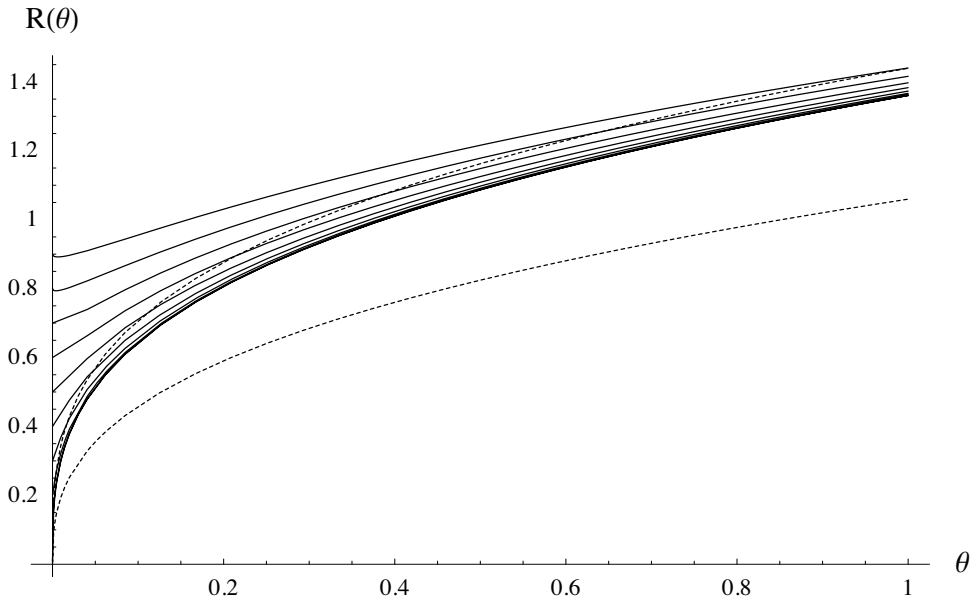

FIG. 5.1. *Results obtained with* $A = 0.1$. *The solid curves are numerical solutions obtained with* $R_0 = (0.01, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9)$. *Solutions with* $R_0 = 0.01,\ 0.1$ *are superposed. The dashed curves are* $R = \rho_1(\theta)$ *(bottom) and* $R = \rho_2(\theta)$ *(top). In the range* $0 \leq \theta \leq 1$, *orbits that enter the crescent remain in the crescent, move away from* $R = \rho_2(\theta)$ *as expected, but remain nevertheless closer to* $R = \rho_2(\theta)$ *than to* $R = \rho_1(\theta)$.

where F satisfies the ODE (3.10). Equation (6.1) could be useful to represent experimental data obtained with varying beam power p.

To compare the three approximate analytical solutions obtained in this paper, we plotted in Figure 6.1 (top) their relative errors (in percent) with respect to the numerical solution, using $A = 0.75$ and $R_0 = 0.001$. The perturbation solution (3.8) is the most accurate over most of the range, except for $\theta > 0.4$, where the asymptotic solution $R = \rho_2(\theta)$ is more accurate (using more terms in the perturbation solution would increase its accuracy). The asymptotic solution $R = \rho_2(\theta)$ is the second best approximation and its error has a minimum around $\theta = 0.004$. The third best approximation is $R = \rho_1(\theta)$.

The solution $R = \rho_1(\theta)$ is attractive because of its greatest simplicity. In spite of its slightly lower accuracy, we are going to see that this solution is the most useful in practice. First, we should first remember that the ODE studied in this paper is derived from an approximate model. In particular, the melt region is not exactly hemispherical and the model ODE is valid only for $\theta >> \theta_1 = 0.002$, for, say, $\theta \geq 0.02$. Knowing that experimental errors lie in the range of 5–10% [3], we can therefore conclude that the error in the approximate solutions of the model equations is smaller than the error in experimental measurement. From this standpoint, the most interesting solution is the one that offers a good compromise between simplicity and accuracy. From this perspective, the asymptotic solution $R(\theta) = \rho_1(\theta)$ is the simplest and has an error smaller than 3% in the validity range $\theta \geq 0.02$. More importantly, *this error decreases as* θ *increases*, which is not the case for the perturbation solution. To introduce explicitly the dependence on the beam power p, we can combine (2.24) and

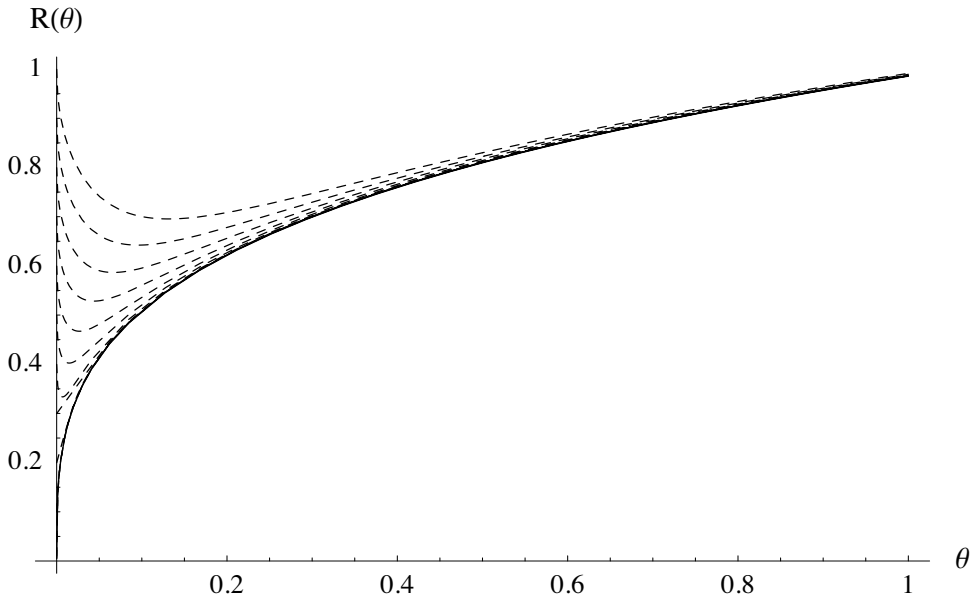

FIG. 5.2. *Results obtained with $A = 0.75$. The dashed curves are numerical solutions obtained with different positive values of $R(0) > 0$. The solid curve is the asymptotic solution $R = \rho_2(\theta)$.*

(4.3) to obtain

$$x(\tau, p) = \frac{2\ A^{1/4}\ p^{1/4}\ \tau^{3/8}}{\sqrt{1 + 4\ A^{3/2}\ p^{-1/2}\ \tau^{1/4}}}, \tag{6.2}$$

which gives an error smaller than 3% for $\tau \geq 12.5$, which corresponds to $t \geq 0.03\ \mu s$. A satisfactory comparison of the model (6.2) with experimental data is presented in [3].

We will conclude on a note about the geometrical method that we used to derive the asymptotic solution $R = \rho_1(\theta)$. This possibly original method leads us to three increasingly accurate asymptotic solutions $\rho_0(\theta)$, $\rho_1(\theta)$, and $\rho_2(\theta)$ that could be obtained by iterating the formula

$$f(\rho_{n+1}, \theta) = \frac{d}{d\theta}\ \rho_n(\theta) \tag{6.3}$$

starting with $\rho_{-1}(\theta) = 0$. In (6.3), f is the function that defines the ODE, i.e., $\frac{dR}{d\theta} = f(R, \theta)$. Roughly speaking, (6.3) is a kind of *backward Picard iteration*, because we iterate a derivative instead of an integration. It would be interesting to see if the iterative process (6.3) could be generalized to find approximate solutions for other ODEs.

Appendix A. Asymptotic behavior of $R(\theta)$ as $\theta \to 0$ for $A > 0$.

To study $R(\theta)$ around $\theta = 0$, we will make the hypothesis

$$R(\theta) \sim R_0 + c\ \theta^{\alpha} \tag{A.1}$$

as $\theta \to 0$, where $\alpha > 0$ and c is a constant. Substituting (A.1) into (2.23) yields

$$\frac{c\ \alpha}{\theta^{1-\alpha}} = -\frac{A}{\theta^{1/2}} + \frac{1}{(R_0 + c\ \theta^{\alpha})^2}. \tag{A.2}$$

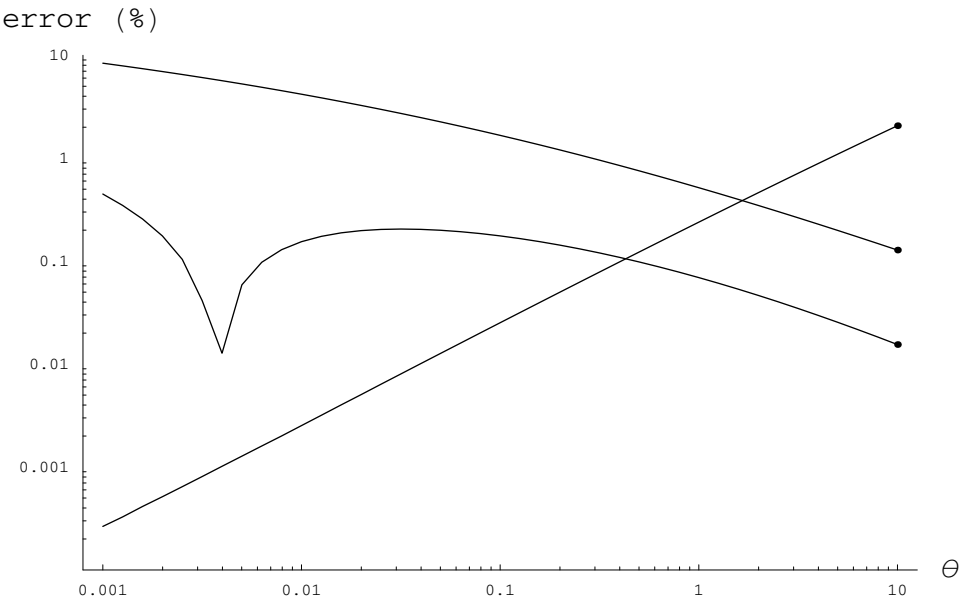

FIG. 6.1. *Comparison of the approximate solutions for* $A = 0.75$ *and* $R_0 = 0.001$. *We plotted the relative error in % with respect to the numerical solution, versus* θ. *Top-left: Error on* $R = \rho_1(\theta)$. *Center-left: Error on* $R = \rho_2(\theta)$. *Bottom-left: Error on the perturbation solution* (3.8).

If $R_0 > 0$, then the term $\frac{A}{\theta^{1/2}}$ on the right-hand side of (A.2) dominates as $\theta \to 0$. It follows that $c\ \alpha = -A$ and $1 - \alpha = 1/2 \Rightarrow \alpha = 1/2$, which in turn implies $c = -2A$. Hence, we have the asymptotic behavior

$$\text{If } R_0 > 0\ ,\ R(\theta) \sim R_0 - 2\ A\ \sqrt{\theta} \tag{A.3}$$

as $\theta \to 0$; i.e., *the orbit dives downward* before it eventually returns to an increasing regime. If $R_0 = 0$, (A.2) becomes

$$\frac{c\ \alpha}{\theta^{1-\alpha}} = -\frac{A}{\theta^{1/2}} + \frac{1}{c^2\ \theta^{2\alpha}}. \tag{A.4}$$

One must examine two cases. First, if we assume that $2\alpha > 1/2 \Rightarrow \alpha > 1/4$, then the term $1/(c^2\ \theta^{2\alpha})$ (right-hand side of (A.4)) dominates as $\theta \to 0$, and therefore $c\ \alpha = 1/c^2$ and $1 - \alpha = 2\ \alpha \Rightarrow \alpha = 1/3$, which also implies $c = 3^{1/3}$. Second, if we assume instead that $2\alpha < 1/2 \Rightarrow \alpha < 1/4$, then we must have $1 - \alpha = 1/2 \Rightarrow \alpha = 1/2$, which contradicts our assumption $\alpha < 1/4$. Hence, for $R_0 = 0$, we have the following asymptotic behavior:

$$\text{If } R_0 = 0,\ R(\theta) \sim (3\ \theta)^{1/3} \tag{A.5}$$

as $\theta \to 0$, which is consistent with (3.1).

Comparing (A.3) with (A.5), we see that solutions are qualitatively different for $R_0 > 0$ and $R_0 = 0$. Indeed, $R(\theta)$ *increases* if $R_0 = 0$, whereas it *decreases* if $R_0 > 0$. According to the DF, $R(\theta)$ should return rapidly to an increasing regime even if $R_0 > 0$. To see how this return occurs, we may try to find a better approximation of $R(\theta)$ around $\theta = 0$ with a MacLaurin expansion. Equation (3.5) implies that the derivatives of $R(s)$ are well defined at $s = 0$ as long as $R_0 > 0$, and therefore

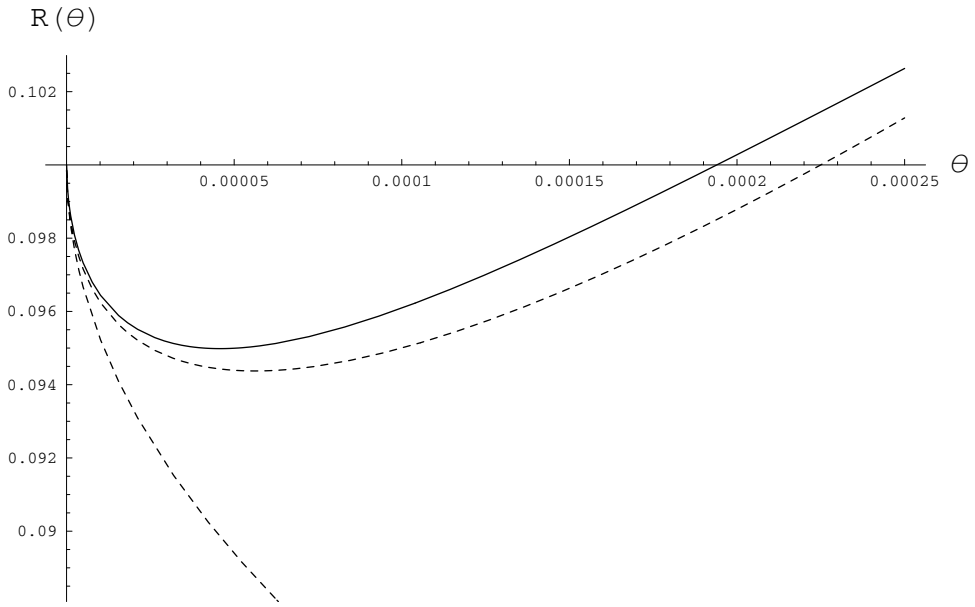

FIG. A.1. *Behavior of $R(\theta)$ around $\theta = 0$ for $R_0 = 0.1$. Here $A = 0.75$, and $\theta_{\min} \approx 0.000056$. The solid line is a numerical solution, and the dashed curves are $R_0 - 2\ A\ \sqrt{\theta}$ (going down) and $R_0 - 2\ A\ \sqrt{\theta} + \frac{1}{R_0^2}\ \theta$ (going back up).*

$R(s) = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{d^n R}{ds^n}(0)\ s^n$. Using (3.5) to compute the derivatives $\frac{d^n R}{ds^n}(0)$ leads to $R(s) = R_0 - 2\ A\ s + \frac{s^2}{R_0^2} + \frac{8\ A}{3\ R_0^3}\ s^3 + (\frac{6\ A^2}{R_0^4} - \frac{1}{2\ R_0^5})\ s^4 + O(s)^5$, and replacing s by $\theta^{1/2}$ gives

$$R(\theta) = R_0 - 2\ A\ \theta^{1/2} + \frac{\theta}{R_0^2} + \frac{8\ A}{3\ R_0^3}\ \theta^{3/2} + O(\theta)^2. \tag{A.6}$$

The first three terms of (A.6) give the approximation $\tilde{R}(\theta) \equiv R_0 - 2\ A\ \theta^{1/2} + \frac{\theta}{R_0^2}$. The minimum of $\tilde{R}(\theta)$ occurs at $\theta_{\min} = A^2\ R_0^4$. As shown in Figure A.1, $\tilde{R}(\theta)$ describes fairly well the behavior of $R(\theta)$ around $\theta = 0$ for $R_0 > 0$.

Appendix B. Perturbation solution.

Substituting (3.7) into (2.23) yields

$$\sum_{n=0}^{\infty} A^n\ \dot{R}_n(\theta) = -\frac{A}{\sqrt{\theta}} + \frac{1}{(\sum_{n=0}^{\infty} A^n\ R_n(\theta))^2}. \tag{B.1}$$

Expanding the rightmost term of (B.1) in Taylor series around $A = 0$ to order 2 yields

$$\dot{R}_0 + \dot{R}_1\ A + \dot{R}_2\ A^2 = -\frac{A}{\sqrt{\theta}} + \frac{1}{R_0^2} - \frac{2}{R_0^3}\ R_1\ A + \left(\frac{3R_1^2}{R_0^4} - \frac{2}{R_0^3}\right)\ A^2, \tag{B.2}$$

where $\dot{f} \equiv \frac{df}{d\theta}$ for any function f. Identifying the terms of order 0, 1, and 2 yields

$$\begin{aligned} \dot{R}_0 &= \frac{1}{R_0^2}, \\ \dot{R}_1 &= -\frac{1}{\sqrt{\theta}} - \frac{2}{R_0^3}\, R_1, \\ \dot{R}_2 &= \frac{3R_1^2}{R_0^4} - \frac{2}{R_0^3}\, R_2. \end{aligned} \tag{B.3}$$

We will solve (B.3) with the initial value $R(0) = 0$. The solution of the first equation of (B.3) is $R_0(\theta) = (3\ \theta)^{1/3}$. Substituting $R_0(\theta)$ into the second equation of (B.3), we get

$$\dot{R}_1 + \frac{2}{3\ \theta}\, R_1 = -\frac{1}{\sqrt{\theta}}. \tag{B.4}$$

Fortunately, (B.4) is a nonhomogeneous *linear equation*. Its general solution is $R_1(\theta) = -\frac{6}{7}\ \sqrt{\theta} + \frac{\mathrm{C}}{\theta^{2/3}}$, where C is an arbitrary constant. The initial condition $R_1(0) = 0$ then imposes $\mathrm{C} = 0$ so that

$$R_1(\theta) = -\frac{6}{7}\ \sqrt{\theta}. \tag{B.5}$$

Using previous results for $R_0(\theta)$ and $R_1(\theta)$, the third equation of (B.3) becomes

$$\dot{R}_2 + \frac{2}{3\ \theta}\, R_2 = \frac{k_1}{\theta^{1/3}}, \tag{B.6}$$

where $k_1 = 4\ 3^{2/3}/49$, which is again a linear nonhomogeneous ODE. Its general solution is $R_2(\theta) = \frac{3}{49}\ (3\ \theta)^{2/3} + \frac{\mathrm{C}}{\theta^{2/3}}$, where C is an arbitrary constant. The initial condition $R_2(0) = 0$ again implies $\mathrm{C} = 0$, and therefore

$$R_2(\theta) = \frac{3}{49}\ (3\ \theta)^{2/3}. \tag{B.7}$$

This process can be continued, and the equations remain linear and easy to solve. The first six terms lead to the expansion (3.8).

Acknowledgments. We thank Christiane Rousseau, Pavel Winternitz, and Malidi Ahamadi for their comments on the early stages of this work. We also thank the anonymous referees for their subtle comments and constructive criticism.

NONLINEAR COUNTERPROPAGATING WAVES, MULTISYMPLECTIC GEOMETRY, AND THE INSTABILITY OF STANDING WAVES*

THOMAS J. BRIDGES† AND FIONA E. LAINE-PEARSON†

Abstract. Standing waves are a fundamental class of solutions of nonlinear wave equations with a spatial reflection symmetry, and they routinely arise in optical and oceanographic applications. At the linear level they are composed of two synchronized counterpropagating periodic traveling waves. At the nonlinear level, they can be defined abstractly by their symmetry properties. In this paper, general aspects of the modulational instability of standing waves are considered. This problem has difficulties that do not arise in the modulational instability of traveling waves. Here we propose a new geometric formulation for the linear stability problem, based on embedding the standing wave in a four-parameter family of nonlinear counterpropagating waves. Multisymplectic geometry is shown to encode the stability properties in an essential way. At the weakly nonlinear level we obtain the surprising result that standing waves are modulationally unstable only if the component traveling waves are modulation unstable. Systems of nonlinear wave equations will be used for illustration, but general aspects will be presented, applicable to a wide range of Hamiltonian PDEs, including water waves.

Key words. modulation instability, variational principles, periodic waves, hyperbolic PDEs, water waves

1. Introduction.

When considering spatially periodic solutions of nonlinear wave equations on the real line, there are two "canonical" classes of temporally periodic solutions: traveling waves and standing waves. Standing waves arise naturally when the system has a reflection symmetry. In this paper the linear stability problem for standing waves is considered.

To illustrate the basic issues, consider the prototype nonlinear wave equation

$$\mathbf{u}_{tt} - \mathbf{C}\mathbf{u}_{xx} + \nabla V(\mathbf{u}) = 0, \quad \mathbf{u} \in \mathbb{R}^m, \quad x \in \mathbb{R}, \tag{1.1}$$

where $\mathbf{C}$ is a symmetric, positive definite, $m \times m$ matrix; $V : \mathbb{R}^m \to \mathbb{R}$ is a given smooth function; and ∇ is the standard gradient on $\mathbb{R}^m$. This class of wave equations appears in a wide range of applications. An example is DNA modeling [30], where a typical case would be $m = 2$, $\mathbf{C} = \mathrm{diag}(1, c^2)$, and $V(\mathbf{u}) = \cos(u_1 + u_2) - 2\cos u_1 - 2\cos u_2$.

For the system (1.1) a standing wave is a spatially periodic and temporally periodic solution which is invariant under reflection $x \mapsto -x$. (A precise definition of standing wave will be given in section 3.)

Suppose a standing wave solution of (1.1) exists and denote it by $\hat{\mathbf{u}}(x,t)$. This existence problem is itself highly nontrivial due to the potential for small divisors. (The relevance of this issue is discussed in section 7.) The linearized stability equation for $\hat{\mathbf{u}}$ is then $\mathbf{u}_{tt} - \mathbf{u}_{xx} + D^2V(\hat{\mathbf{u}})\mathbf{u} = 0$. A modulational instability is a solution of the type $\mathbf{u}(x,t) = \mathrm{Re}(\mathrm{e}^{i\alpha x}\mathbf{v}(x,t))$, where $\mathbf{v}(x,t)$ is periodic in x of the same period as $\hat{\mathbf{u}}(x,t)$ and α is real with $0 < |\alpha| << 1$, and $\|\mathbf{v}\|$ is exponentially growing in

time. Basic technical issues are associated with this instability problem, such as an appropriate function space in which to define the spectral problem, but these issues will not be considered here. There is a more fundamental issue associated with modulational instability that arises even when we suppose that the basic state $\hat{\mathbf{u}}(x,t)$ is a classical solution of (1.1) and a smooth function of the wavenumber and frequency. It is this fundamental issue, which can be attributed to the fact that standing waves are related to a pair of synchronized counterpropagating traveling waves, that we will address here.

Before considering the counterpropagation property of standing waves, it is worth recalling the analogous linear stability problem for traveling waves. Let $\mathbf{u}(x,t) = \hat{\boldsymbol{\phi}}(\theta)$ be a periodic traveling wave solution of (1.1), where $\theta = \omega t + kx + \theta_0$. The solution $\hat{\boldsymbol{\phi}}$ is a 2π-periodic function of θ, ω is the frequency, and k is the wavenumber. The distinction between stability of traveling waves and standing waves can already be seen at small amplitude. Therefore consider two well-known methods for determining whether the traveling wave is modulationally unstable: the Whitham theory [29] and the use of modulation equations such as the nonlinear Schrödinger (NLS) equation.

According to the Whitham modulation theory, a weakly nonlinear wave of amplitude A, of a nonlinear wave equation that can be derived from a Lagrangian formulation, is modulationally unstable if

$$\omega_0''(k)\,\omega_2(k) < 0, \tag{1.2}$$

where $\omega_0(k)$ is the frequency of the linearized wave and $\omega_2(k)$ is the weakly nonlinear correction to the frequency, that is, $\omega(k) = \omega_0(k) + \omega_2(k)|A|^2 + \cdots$ [29].

Using formal asymptotic methods, an NLS equation can be derived for the weakly nonlinear amplitude $A(X,T)$, by letting $\hat{\phi}(\theta) = A(X,T)\mathrm{e}^{\theta} + \text{c.c.} + \cdots$,

$$\mathrm{i}A_T + \tfrac{1}{2}\omega_0''(k)\,A_{XX} = \sigma\,|A|^2 A$$

(cf. [28]; see also [16] for a rigorous justification of this approach for scalar nonlinear wave equations). The basic weakly nonlinear traveling wave is represented in this equation as a solution of the form $A(X,T) = A_0\mathrm{e}^{\mathrm{i}\omega T}$, $A_0 \in \mathbb{C}$, and this state is linearly unstable precisely when (1.2) is satisfied.

Now, the modulational instability of traveling waves, particularly the weakly nonlinear limit, is well understood, from physical, numerical, and rigorous points of view.

The case of standing waves is more difficult. Surprisingly, there is no generalization of the Whitham theory to treat the modulational instability of standing waves. The only theory in the literature that has been proposed for the modulation instability of standing waves is the use of modulation equations (Knobloch and Pierce [18]; see also [17]).

At the linear level, standing waves reduce to a pair of synchronized counterpropagating waves. Therefore one might suspect that a pair of nonlinearly coupled NLS equations of the form

$$\begin{aligned} \mathrm{i}A_T + \mathrm{i}c_g\,A_X &= \tfrac{1}{2}\omega_0''(k)A_{XX} - \sigma\,|A|^2A + 2\sigma(k)\,|B|^2A, \\ \mathrm{i}B_T - \mathrm{i}c_g\,B_X &= \tfrac{1}{2}\omega_0''(k)B_{XX} - \sigma\,|B|^2B + 2\sigma(k)\,|A|^2B \end{aligned} \tag{1.3}$$

would be a suitable model for modulation instability of standing waves. Indeed, in equation (3.3) of Okamura [23], a coupled NLS system of this form is proposed to model the instability of standing waves. The above system was derived specifically to model standing water waves, but the argument is similar for standing waves of any

nonlinear wave equation, although the coefficients in (1.3) would differ. A standing wave is represented in this system by a solution of the form $A = B = B_0 e^{i\omega T}$.

However, Knobloch and Pierce [18] argue that this coupled set of equations is not valid, and this observation is confirmed by the rigorous analysis of Pierce and Wayne [25] and Bambusi, Carati, and Ponno [2]. They argue that the coupling term needs to be replaced by mean-field coupling terms,

$$\begin{aligned} iA^+_T &= \tfrac{1}{2}\omega_0''(k)A^+_{X_+X_+} - \sigma(k)|A^+|^2A^+ + \beta(k)\Lambda^+(A^+)\,A^+, \\ -iA^-_T &= \tfrac{1}{2}\omega_0''(k)A^-_{X_-X_-} - \sigma(k)|A^-|^2A^- + \beta(k)\Lambda^-(A^-)\,A^-, \end{aligned} \tag{1.4}$$

where $X_\pm = X \mp c_g T$ and $\Lambda^\pm(A^\pm) = \frac{1}{P_\pm}\int_0^{P_\pm} |A^\pm|^2\,dX_\pm$.

The distinction between (1.3) and (1.4) is significant as they do not give equivalent results on modulational instability of standing waves. The rational asymptotics presented in [18, 17], and the rigorous theory of [25, 2], provide strong support for the validity of (1.4).

Modulation equations have severe limitations, however. For example, the above modulation equations are limited to weakly nonlinear standing waves. In this paper we present a new theoretical framework for studying the modulational instability of standing waves. The theory is global (i.e., not restricted to small amplitude) and is based on a new variational principle.

Restricting the new theory to small amplitude waves, it predicts the same instability as the modulation equation (1.4). Since the theory presented here is significantly different from the theory used by Okamura and Knobloch and Pierce, it provides additional support for the validity of the modulation instability predicted by (1.4). Physically, the weakly nonlinear result is quite surprising, since weakly nonlinear periodic standing waves are modulationally unstable only if the component weakly nonlinear traveling waves are unstable. However, this correspondence between the instability of traveling and standing waves will not in general carry over to finite-amplitude standing waves.

The theory here will be developed for the modulation instability of standing wave solutions of Hamiltonian PDEs. The theoretical framework has two parts: first, standing waves can be characterized by a constrained variational principle that encodes information about the linear stability problem. Second, by formulating and studying the linear stability problem directly, we show how the information from the variational principle appears explicitly in the linear stability problem. The main result is that the stability exponents for all long-wave instabilities of standing waves of any amplitude (for which they exist) are determined by the roots of a quartic polynomial whose coefficients can be determined explicitly from the existing standing wave.

The obvious variational principle for standing waves does not provide enough information about the linear stability problem. Surprisingly, we find that the natural approach is to embed the family of standing waves in a four-parameter family, initially, construct a variational principle for this larger family, and then take the limit to the original two-parameter family. The argument in favor of this approach is provided by the analogy of standing waves as synchronized counterpropagating waves: the larger parameter family provides information about how the component counterpropagating waves might break up due to instability.

Conservative PDEs can be analyzed from a Lagrangian, Hamiltonian, or multisymplectic Hamiltonian viewpoint. However, neither the Lagrangian nor the classical Hamiltonian perspective provides sufficient geometry to give abstract results—that

is, results that rely only on the Hamiltonian structure and are independent of the particular PDE. It is the multisymplectic formulation of Hamiltonian PDEs that provides sufficient geometry for a general theory. The class of Hamiltonian PDEs that we consider in canonical form is

$$\mathbf{M}Z_t + \mathbf{K}Z_x = \nabla S(Z), \quad Z \in \mathbb{R}^n, \tag{1.5}$$

where $\mathbf{M}$ and $\mathbf{K}$ are constant $n \times n$ skew-symmetric matrices and $S : \mathbb{R}^n \to \mathbb{R}$ is a given smooth function. An example of the multisymplectification process is given in section 2. Most Hamiltonian PDEs can be cast into this form, including water waves, and other examples can be found in [6, 7, 9] and references therein.

Abstractly, these systems can still be characterized as Lagrangian PDEs by considering Lagrangians in the canonical form

$$\mathscr{L} = \int\int \mathrm{L}(Z, Z_t, Z_x)\,\mathrm{d}x\,\mathrm{d}t \quad \text{with} \quad \mathrm{L}(Z, Z_t, Z_x) = \tfrac{1}{2}\langle \mathbf{M}Z_t, Z\rangle + \tfrac{1}{2}\langle \mathbf{K}Z_x, Z\rangle - S(Z), \tag{1.6}$$

where $\langle\cdot,\cdot\rangle$ is a standard inner product on $\mathbb{R}^n$. This Lagrangian, however, retains all the geometry—two symplectic structures and the scalar function S—of the multisymplectic formulation.

An outline of the paper is as follows. In section 2, an example is given of multisymplectification, using (1.1) as an example. In section 3 standing waves are defined and it is shown that a consequence of the definition is that the momentum is identically zero. New variational principles for standing waves and standing waves embedded in a four-parameter family of counterpropagating waves are presented in section 4. There is an interesting connection between the geometry of $\mathbf{O}(2)$-equivariant finite-dimensional Hamiltonian systems, such as the spherical pendulum, and nonlinear wave equations on the real line with periodic boundary conditions, and this connection is explored in Appendix A. The details of the stability analysis for weakly nonlinear and finite-amplitude standing waves are presented in sections 6 and 7.

The small divisor issue that appears in the analysis of standing waves is outside the scope of this paper, but the issue is briefly discussed in section 7. One of the main motivations for studying the modulational instability of standing waves is their importance in the water-wave problem. The theory developed here does not apply directly, but we speculate on some of the implications for water waves in section 8.

2. Multisymplectifying systems of nonlinear wave equations. The theory for instability of standing waves will be developed for the general class of PDEs (1.5). In this section, the general class of nonlinear wave equations (1.1) will be used to illustrate the transformation to multisymplectic form. In sequence, a Lagrangian, a classical Hamiltonian, and then a multisymplectic Hamiltonian formulation of this system will be presented.

The canonical form of the Lagrangian for (1.1) is

$$\mathscr{L} = \int_{\mathscr{V}} \mathrm{L}(\mathbf{u}, \mathbf{u}_t, \mathbf{u}_x)\,\mathrm{d}x \wedge \mathrm{d}t, \quad \mathrm{L}(\mathbf{u}, \mathbf{u}_t, \mathbf{u}_x) = \tfrac{1}{2}\mathbf{u}_t \cdot \mathbf{u}_t - \tfrac{1}{2}\mathbf{u}_x \cdot \mathbf{C}\mathbf{u}_x - \mathrm{V}(\mathbf{u}), \tag{2.1}$$

where $\mathscr{V}$ represents the volume in (x, t) space, and $\cdot$ represents the standard inner product on $\mathbb{R}^m$.

The canonical Hamiltonian formulation for the nonlinear wave equation is obtained by taking the Legendre transform with respect to time only, $\mathbf{v} = \frac{\partial \mathrm{L}}{\partial \mathbf{u}_t} = \mathbf{u}_t$,

and then the governing equations take the form

(2.2)
$$\frac{\partial}{\partial t}\begin{pmatrix}\mathbf{u}\\ \mathbf{v}\end{pmatrix}=\begin{bmatrix}\mathbf{0} & \mathbf{I}\\ -\mathbf{I} & \mathbf{0}\end{bmatrix}\begin{pmatrix}\delta\mathscr{H}/\delta\mathbf{u}\\ \delta\mathscr{H}/\delta\mathbf{v}\end{pmatrix},\qquad \mathscr{H}(\mathbf{u},\mathbf{v})=\int_{\mathbb{R}}\left[\frac{1}{2}\mathbf{v}\cdot\mathbf{v}+\frac{1}{2}\mathbf{u}_x\cdot\mathbf{C}\mathbf{u}_x+V(\mathbf{u})\right]\,\mathrm{d}x.$$

This Hamiltonian formulation of the nonlinear wave equation has been widely used in analysis (see [19] and references therein). However, a disadvantage of this formulation, when studying pattern formation, is that the Hamiltonian function and symplectic structure associated with (2.2) require specification of a space of functions over the x direction a priori. In the case of modulation instabilities, the basic state is periodic in space but the perturbation class will be in general quasi-periodic. In other words, we may want to determine the spatial variation of the solution set a posteriori.

Multisymplecticity puts space and time on an equal footing. The governing equations are obtained by taking a Legendre transform with respect to all directions,

$$\mathbf{v}=\frac{\partial \mathrm{L}}{\partial \mathbf{u}_t}=\mathbf{u}_t\quad\text{and}\quad \mathbf{w}=\frac{\partial \mathrm{L}}{\partial \mathbf{u}_x}=-\mathbf{C}\mathbf{u}_x.$$

The Legendre transform generates a new Hamiltonian functional,

$$S(\mathbf{u},\mathbf{v},\mathbf{w})=\mathbf{v}\cdot\mathbf{u}_t+\mathbf{w}\cdot\mathbf{u}_x-\mathrm{L}=\tfrac{1}{2}\mathbf{v}\cdot\mathbf{v}-\tfrac{1}{2}\mathbf{w}\cdot\mathbf{C}^{-1}\mathbf{w}+V(\mathbf{u}). \tag{2.3}$$

This function can be thought of as generated by a total Legendre transform as above, or it can be viewed as a secondary Legendre transform: $-S$ is the Legendre transform of the Hamiltonian density H in (2.2).

Now, the new Lagrangian for the system is in standard form for a generalization of Hamilton's principle,

$$\mathscr{L}=\iint \mathrm{L}(\mathbf{u},\mathbf{v},\mathbf{w})\,\mathrm{d}x\wedge\mathrm{d}t,\quad \mathrm{L}(\mathbf{u},\mathbf{v},\mathbf{w})=\mathbf{v}\cdot\mathbf{u}_t+\mathbf{w}\cdot\mathbf{u}_x-S(\mathbf{u},\mathbf{v},\mathbf{w}), \tag{2.4}$$

and the governing equations are given by

$$\begin{aligned}0&=\mathrm{L}_{\mathbf{u}}=-\mathbf{v}_t-\mathbf{w}_x-S_{\mathbf{u}}=-\mathbf{v}_t-\mathbf{w}_x-\nabla V(\mathbf{u}),\\ 0&=\mathrm{L}_{\mathbf{v}}=\mathbf{u}_t-S_{\mathbf{v}}=\mathbf{u}_t-\mathbf{v},\\ 0&=\mathrm{L}_{\mathbf{w}}=\mathbf{u}_x-S_{\mathbf{w}}=\mathbf{u}_x+\mathbf{C}^{-1}\mathbf{w},\end{aligned}$$

using standard fixed endpoint conditions for the variations. While the PDE is now expressed as a first-order system, it has a multisymplectic structure which is awkward for analysis. It can be written in the form $\mathbf{M}Z_x+\mathbf{K}Z_x=\nabla S(Z)$ with $Z\in\mathbb{R}^{3m}$, but the pair of symplectic operators, $\mathbf{M}$ and $\mathbf{K}$, act on $\mathbb{R}^{3m}$ and are always degenerate. This structure can be improved by observing that $\mathbf{v}$ and $\mathbf{w}$ satisfy the constraint $\mathbf{C}^{-1}\mathbf{w}_t+\mathbf{v}_x=0$. Therefore add this constraint to the Lagrangian with vector-valued Lagrange multiplier $\mathbf{p}$, that is,

$$\begin{aligned}\mathscr{L}&=\int_{\mathscr{V}}\mathrm{L}(\mathbf{u},\mathbf{v},\mathbf{w},\mathbf{p})\,\mathrm{d}x\wedge\mathrm{d}t,\\ \mathrm{L}(\mathbf{u},\mathbf{v},\mathbf{w},\mathbf{p})&=\mathbf{v}\cdot\mathbf{u}_t+\mathbf{w}\cdot\mathbf{u}_x-S(\mathbf{u},\mathbf{v},\mathbf{w})+\mathbf{p}\cdot(\mathbf{C}^{-1}\mathbf{w}_t+\mathbf{v}_x).\end{aligned}$$

The governing equations are now

$$
\begin{aligned}
0 = \mathrm{L}_{\mathbf{u}} &= -\mathbf{v}_t - \mathbf{w}_x - S_{\mathbf{u}} = -\mathbf{v}_t - \mathbf{w}_x - \nabla V(\mathbf{u}),\\
0 = \mathrm{L}_{\mathbf{v}} &= \mathbf{u}_t - S_{\mathbf{v}} - \mathbf{p}_x = \mathbf{u}_t - \mathbf{p}_x - \mathbf{v},\\
0 = \mathrm{L}_{\mathbf{w}} &= \mathbf{u}_x - S_{\mathbf{w}} - \mathbf{C}^{-1}\mathbf{p}_t = -\mathbf{C}^{-1}\mathbf{p}_t + \mathbf{u}_x + \mathbf{C}^{-1}\mathbf{w},\\
0 = \mathrm{L}_{\mathbf{p}} &= \mathbf{C}^{-1}\mathbf{w}_t + \mathbf{v}_x = \mathbf{C}^{-1}\mathbf{w}_t + \mathbf{v}_x
\end{aligned}
$$

or

$$
\begin{bmatrix} 0 & -\mathbf{I} & 0 & 0 \\ \mathbf{I} & 0 & 0 & 0 \\ 0 & 0 & 0 & -\mathbf{C}^{-1} \\ 0 & 0 & \mathbf{C}^{-1} & 0 \end{bmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \\ \mathbf{w} \\ \mathbf{p} \end{pmatrix}_t + \begin{bmatrix} 0 & 0 & -\mathbf{I} & 0 \\ 0 & 0 & 0 & -\mathbf{I} \\ \mathbf{I} & 0 & 0 & 0 \\ 0 & \mathbf{I} & 0 & 0 \end{bmatrix} \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \\ \mathbf{w} \\ \mathbf{p} \end{pmatrix}_x = \begin{pmatrix} \nabla \mathrm{V}(\mathbf{u}) \\ \mathbf{v} \\ -\mathbf{C}^{-1}\mathbf{w} \\ 0 \end{pmatrix}. \tag{2.5}
$$

This system can be expressed in canonical multisymplectic form (1.5) with $n = 4m$, and indeed, in this case, $\mathbf{M}$ and $\mathbf{K}$ define symplectic structures on $\mathbb{R}^{4m}$. The two symplectic structures do not commute in general, unless $\mathbf{C} = \mathbf{I}$, since

$$
[\mathbf{M}, \mathbf{K}] = \mathbf{MK} - \mathbf{KM} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \otimes (\mathbf{I} - \mathbf{C}^{-1}).
$$

In the scalar case $m = 1$, scaling can be introduced so that $\mathbf{M}$ and $\mathbf{K}$ always commute.

In summary, the main point of this section is that the system of nonlinear wave equations (1.1) can be characterized in terms of geometric properties: two symplectic structures, and a scalar-valued function $S(Z)$, on a finite-dimensional phase space: $Z \in \mathbb{R}^n$.

A property of the nonlinear wave equation (1.1) that is important for the existence of standing waves is reversibility in x. If $\mathbf{u}(x,t)$ is a solution of (1.1), then $\mathbf{u}(-x,t)$ is also a solution. In the multisymplectification of (1.1), this reversibility is represented by the action

$$
\mathbf{r} \cdot Z(x,t) = \mathbf{R}Z(-x,t) \quad \text{with} \quad \mathbf{R} = \mathrm{diag}(\mathbf{I}, \mathbf{I}, -\mathbf{I}, -\mathbf{I}) \in \mathbb{R}^{4m \times 4m}. \tag{2.6}
$$

The involution $\mathbf{R}$ and its associated action satisfy

$$
\mathbf{RM} = \mathbf{MR}, \quad \mathbf{RK} = -\mathbf{KR}, \quad \text{and} \quad S(\mathbf{r} \cdot Z) = S(Z). \tag{2.7}
$$

In turn, the properties (2.7) imply that $\mathbf{r} \cdot Z$ is a solution of the wave equation in the form (1.5) whenever Z is.

The system of nonlinear wave equations (1.1) is reversible in t as well, and a multisymplectic t-reversor can also be defined, but t-reversibility will not be needed in the general theory for standing waves.

3. Standing wave solutions of Hamiltonian PDEs. The theory for standing waves can be developed based only on the geometric properties of the multisymplectic formulation. Therefore, as in the previous section, we will assume that the PDE has been transformed to a multisymplectic Hamiltonian PDE, and we take the following general class of PDEs as the starting point for the analysis:

$$\mathbf{M}Z_t + \mathbf{K}Z_x = \nabla S(Z), \quad Z \in \mathbb{R}^n. \tag{3.1}$$

The only hypotheses on (3.1) are that $\mathbf{M}$ and $\mathbf{K}$ are constant $n \times n$ skew-symmetric matrices and $S : \mathbb{R}^n \to \mathbb{R}$ is a given smooth function (at least twice continuously differentiable), which does not depend explicitly on x or t. On $\mathbb{R}^n$, the standard inner product will be denoted by $\langle \cdot, \cdot \rangle$.

For the existence of standing waves, we will require that the system (3.1) is x-reversible with a multisymplectic action of the reversor,

$$\mathbf{r} \cdot Z(x,t) = \mathbf{R}Z(-x,t) \tag{3.2}$$

for some isometric involution $\mathbf{R} : \mathbb{R}^n \to \mathbb{R}^n$ satisfying the identities (2.7) (with $\mathbf{M}$, $\mathbf{K}$ and S associated with (3.1)). In this setting, an abstract definition of a standing wave can be given.

DEFINITION. *A solution $\widehat{Z}(x,t)$ of* (3.1) *is called a* standing wave *if it is periodic in both x and t and satisfies $\mathbf{r} \cdot \widehat{Z}(x,t) = \widehat{Z}(x,t)$.*

Curiously, we cannot find anywhere in the literature where a general definition of standing waves for nonlinear PDEs has heretofore been given.

It is sometimes remarked that standing waves are spatially periodic waves with zero momentum. However, we can show that zero momentum is a *consequence* of the above definition.

What is momentum? The momentum here is defined to be the conserved quantity given by Noether's theorem associated with the translation invariance in x of the PDE. If (3.1) represents a physical system, this conserved quantity may indeed be the physical momentum. An application of Noether's theorem to the Lagrangian (1.6) (see Appendix B for this argument) shows that the appropriate form for the momentum on a space of functions that are 2π periodic in x is

$$\mathscr{I}(Z) = \oint \frac{1}{2}\langle \mathbf{M}Z_x(x,t), Z(x,t)\rangle \, \mathrm{d}x \quad \text{where} \quad \oint (\ ) \, \mathrm{d}x := \frac{1}{2\pi}\int_0^{2\pi} (\ ) \, \mathrm{d}x. \tag{3.3}$$

Given this expression for momentum, we can show that $\mathscr{I}(\widehat{Z}) = 0$ if $\widehat{Z}(x,t)$ is a standing wave solution of (3.1):

$$\begin{aligned}
\mathscr{I}(\mathbf{r}\cdot Z) &= \oint \tfrac{1}{2}\langle \mathbf{M}\mathbf{R}(Z(-x,t))_x, \mathbf{R}Z(-x,t)\rangle \, \mathrm{d}x \quad \text{(by definition)} \\
&= -\oint \tfrac{1}{2}\langle \mathbf{M}\mathbf{R}Z_x(-x,t), \mathbf{R}Z(-x,t)\rangle \, \mathrm{d}x \\
&= -\oint \tfrac{1}{2}\langle \mathbf{R}\mathbf{M}Z_x(-x,t), \mathbf{R}Z(-x,t)\rangle \, \mathrm{d}x \quad (\text{using } \mathbf{R}\mathbf{M} = \mathbf{M}\mathbf{R}) \\
&= -\oint \tfrac{1}{2}\langle \mathbf{M}Z_x(-x,t), Z(-x,t)\rangle \, \mathrm{d}x \quad (\text{since } \mathbf{R} \text{ is an isometry}) \\
&= -\oint \tfrac{1}{2}\langle \mathbf{M}Z_x(x,t), Z(x,t)\rangle \, \mathrm{d}x \\
&\quad (\text{using the change of variable } x \mapsto -x \text{ and periodicity}) \\
&= -\mathscr{I}(Z).
\end{aligned}$$

Therefore, if $\widehat{Z}(x,t)$ is a standing wave and so $\mathbf{r}\cdot\widehat{Z} = \widehat{Z}$, it is immediate that $\mathscr{I}(\widehat{Z}) = 0$.

4. Variational principles for standing waves and counterpropagating waves. At the linear level, a standing wave consists of a pair of synchronized counterpropagating waves,

$$Z(x,t) = A\xi\, \mathrm{e}^{\mathrm{i}(\omega t + kx)} + A\xi\, \mathrm{e}^{\mathrm{i}(\omega t - kx)} + \text{c.c.},$$

where $A \in \mathbb{C}$ is a complex amplitude and $\xi \in \mathbb{C}^n$ is an eigenvector associated with the linearization of (3.1). A natural generalization of this form to finite amplitude is to look for *nonlinear* solutions of the form

$$Z(x,t) = \widehat{Z}(\theta_1,\theta_2), \quad \theta_1 = \omega t + kx + \theta_1^o, \quad \theta_2 = \omega t - kx + \theta_2^o, \tag{4.1}$$

where θ_j^o are arbitrary constant phases and $\widehat{Z}$ is a 2π-periodic function of θ_1 and θ_2.

Substituting the form (4.1) into (3.1) results in

$$\omega\,\mathbf{M}\left(\frac{\partial\widehat{Z}}{\partial\theta_1} + \frac{\partial\widehat{Z}}{\partial\theta_2}\right) + k\,\mathbf{K}\left(\frac{\partial\widehat{Z}}{\partial\theta_1} - \frac{\partial\widehat{Z}}{\partial\theta_2}\right) = \nabla S(\widehat{Z}). \tag{4.2}$$

The operators $\mathbf{M}\partial_{\theta_j}$ and $\mathbf{K}\partial_{\theta_j}$ are formally self-adjoint operators on a space of doubly periodic functions. Hence, treating ω and k as Lagrange multipliers, (4.2) can be interpreted as the necessary condition for a constrained variational principle. Let

$$\mathscr{A}(Z) = \int_{\mathbb{T}^2} \tfrac{1}{2}\langle \mathbf{M}(\partial_{\theta_1} + \partial_{\theta_2})Z, Z\rangle\, \mathrm{d}\theta \quad \text{and} \quad \mathscr{B}(Z) = \int_{\mathbb{T}^2} \tfrac{1}{2}\langle \mathbf{K}(\partial_{\theta_1} - \partial_{\theta_2})Z, Z\rangle\, \mathrm{d}\theta,$$

where $\int_{\mathbb{T}^2}(\ )\,\mathrm{d}\theta := (2\pi)^{-2}\int_0^{2\pi}\int_0^{2\pi}(\ )\,\mathrm{d}\theta_1\mathrm{d}\theta_2$. The constrained variational principle is then to find critical points of $\mathscr{S}$, $S(Z)$ averaged over $\mathbb{T}^2$, subject to fixed values of the constraints $\mathscr{A}$ and $\mathscr{B}$. It follows from standard Lagrange multiplier theory that this constrained variational principle is nondegenerate when

$$\det\begin{bmatrix} \mathscr{A}_\omega & \mathscr{A}_k \\ \mathscr{B}_\omega & \mathscr{B}_k \end{bmatrix} \neq 0. \tag{4.3}$$

This variational principle gives a global characterization of any state of (3.1) which is periodic in both x and t. It includes a characterization of standing waves and traveling waves. The special case of strictly traveling waves was considered in [7], and it is shown there that the sign of the determinant (4.3) carries information about linear stability.

Another way to view this variational principle is as a generalization to the spatiotemporal setting of the classical variational principle for periodic solutions of *finite-dimensional* Hamiltonian systems: find critical points of the energy (Hamiltonian) on level sets of the action on a space of periodic functions, with the frequency ω as a Lagrange multiplier. For finite-dimensional Hamiltonian systems this variational principle has been widely used to prove the existence of periodic solutions (cf. [20] and references therein). However, the variational principle associated with (4.1) is more difficult to work with for the case of standing waves. Although standing waves are periodic solutions, the fact that there is an infinite number of modes can cause problems with small divisors (see section 7).

The form of the solution (4.1) is not the most general form for a pair of counterpropagating waves. When considering the linear stability problem for standing waves, it will turn out that a somewhat more general variational principle will be crucial for getting a geometric characterization of linear instability of standing waves. The idea is to embed the family of standing waves in a *four*-parameter family of counterpropagating waves, with the standing wave obtained as a limiting two-parameter case.

Consider the more general class of solutions of (3.1); let

$$Z(x,t) = \widehat{Z}(\theta_1,\theta_2) \quad \text{with} \quad \theta_j = \omega_j\, t + k_j\, x + \theta_j^o, \quad j = 1,2, \tag{4.4}$$

where $\widehat{Z}$ is again a 2π-periodic function of both θ_1 and θ_2. The significant difference here is that the state $\widehat{Z}$ now depends on four parameters, and the interpretation as two counterpropagating waves that are not necessarily synchronized is now evident. Indeed, in general, they may even be propagating in the same direction. However, it is the case of counterpropagating waves, near synchronized standing waves, that is of greatest interest here, that is, $k_1 + k_2 \approx 0$ and $\omega_1 - \omega_2 \approx 0$.

The function $\widehat{Z}$ now satisfies

$$\omega_1 \mathbf{M}\frac{\partial \widehat{Z}}{\partial \theta_1} + \omega_2 \mathbf{M}\frac{\partial \widehat{Z}}{\partial \theta_2} + k_1 \mathbf{K}\frac{\partial \widehat{Z}}{\partial \theta_1} + k_2 \mathbf{K}\frac{\partial \widehat{Z}}{\partial \theta_2} = \nabla \mathscr{S}(\widehat{Z}), \tag{4.5}$$

where $\mathscr{S}$ is S averaged over θ_1 and θ_2. Equation (4.5) can be interpreted as the Lagrange necessary condition for the constrained variational principle: find critical points of S averaged over $\mathbb{T}^2$ restricted to level sets of the four functionals

$$\mathscr{A}_j(Z) = \int_{\mathbb{T}^2} \tfrac{1}{2}\langle \mathbf{M}\partial_{\theta_j} Z, Z\rangle \,\mathrm{d}\theta \quad \text{and} \quad \mathscr{B}_j(Z) = \int_{\mathbb{T}^2} \tfrac{1}{2}\langle \mathbf{K}\partial_{\theta_j} Z, Z\rangle \,\mathrm{d}\theta, \quad j = 1,2. \tag{4.6}$$

The Lagrange necessary condition can be written

$$\nabla \mathscr{S}(\widehat{Z}) = \omega_1\, \nabla \mathscr{A}_1(\widehat{Z}) + \omega_2\, \nabla \mathscr{A}_2(\widehat{Z}) + k_1\, \nabla \mathscr{B}_1(\widehat{Z}) + k_2\, \nabla \mathscr{B}_2(\widehat{Z}). \tag{4.7}$$

The frequencies ω_1, ω_2 and the wavenumbers k_1, k_2 appear as Lagrange multipliers. Using standard Lagrange multiplier theory, this constrained variational principle is nondegenerate if

$$\det \begin{bmatrix} \frac{\delta \mathscr{A}}{\delta \omega} & \frac{\delta \mathscr{A}}{\delta k} \\ \frac{\delta \mathscr{B}}{\delta \omega} & \frac{\delta \mathscr{B}}{\delta k} \end{bmatrix} \neq 0, \quad \text{where} \quad \frac{\delta \mathscr{A}}{\delta \omega} = \begin{pmatrix} \frac{\partial \mathscr{A}_1}{\partial \omega_1} & \frac{\partial \mathscr{A}_1}{\partial \omega_2} \\ \frac{\partial \mathscr{A}_2}{\partial \omega_1} & \frac{\partial \mathscr{A}_2}{\partial \omega_2} \end{pmatrix}, \tag{4.8}$$

with similar expressions for the 2×2 matrices $\frac{\delta \mathscr{A}}{\delta k}, \frac{\delta \mathscr{B}}{\delta \omega}, \frac{\delta \mathscr{B}}{\delta k}$. It is the two-parameter subfamily of two-wave interactions that correspond to standing waves that is of interest. Given a function $\widehat{Z}(\theta_1,\theta_2)$ satisfying this variational principle, a standing wave is recovered formally by taking the limit to synchronized counterpropagating waves

$$\omega_1 \to \omega, \quad k_1 \to k, \quad \omega_2 \to \omega, \quad \text{and} \quad k_2 \to -k$$

if the limits exist. This limit is taken *after* the Jacobian matrices in (4.8) are computed.

At first sight, this limit might seem a bit questionable: taking the limit on a torus from irrational values to a resonance? However, there is additional structure

here. The translation invariance in x restricted to periodic functions along with the x-reversibility generates the group $\mathbf{O}(2)$. Translation invariance in time restricted to periodic functions generates an action of $\mathbb{S}^1$. Combining these groups gives $\mathbf{O}(2)\times\mathbb{S}^1$: a *toral symmetry*. The toral symmetry is almost enough structure to allow for smooth variation of parameters on the torus. Indeed, if the system was finite-dimensional, this would be true, and this case is discussed briefly in Appendix A. The obstacle to smoothness for the above limit leading to standing waves is again the potential for small divisors due to a countable number of purely imaginary eigenvalues (see section 7).

5. Stability analysis of nonlinear standing waves. It is in the study of the stability of standing waves that the importance of the embedding of standing waves in the four-parameter family becomes apparent. In this section the linear stability problem for standing waves is formulated and it is shown that the entries in the determinant (4.8) appear in the linear stability analysis in a central way. The strategy is to linearize (3.1) about the full four-parameter two-wave interaction. Then, after the stability condition is deduced, the limit to standing waves is taken.

Substitute $Z(x,t)=\widehat{Z}(\theta_1,\theta_2)+\widehat{U}(\theta_1,\theta_2,x,t)$, where $\widehat{Z}$ is the wave (4.4) and $\widehat{U}$ is a perturbation, into (3.1) and linearize about $\widehat{Z}$,

$$\mathbf{M}\widehat{U}_t+\mathbf{K}\widehat{U}_x=\mathbf{L}(\theta_1,\theta_2)\widehat{U}, \tag{5.1}$$

where

$$\begin{aligned}\mathbf{L}(\theta_1,\theta_2)&=D^2\mathscr{S}(\widehat{Z})-\mathbf{M}\left[\omega_1\frac{\partial}{\partial\theta_1}+\omega_2\frac{\partial}{\partial\theta_2}\right]-\mathbf{K}\left[k_1\frac{\partial}{\partial\theta_1}+k_2\frac{\partial}{\partial\theta_2}\right]\\&=D^2\mathscr{S}(\widehat{Z})-\omega_1D^2\mathscr{A}_1(\widehat{Z})-\omega_2D^2\mathscr{A}_2(\widehat{Z})-k_1D^2\mathscr{B}_1(\widehat{Z})-k_2D^2\mathscr{B}_2(\widehat{Z}).\end{aligned} \tag{5.2}$$

The operator $\mathbf{L}$ is a linear partial differential operator with nonconstant (periodic) coefficients depending on θ_1 and θ_2. Introduce a class of perturbations of modulation type

$$\widehat{U}(\theta_1,\theta_2,x,t)=\mathrm{Re}\left(U(\theta_1,\theta_2)\mathrm{e}^{\lambda t+\mathrm{i}\alpha x}\right),$$

where $\lambda\in\mathbb{C}$ is the stability exponent and $\alpha\in\mathbb{R}$ is the modulation parameter associated with the x-direction. The eigenvalue problem for $(\lambda,U(\theta_1,\theta_2))$ is then

$$\mathbf{L}(\theta_1,\theta_2)U=\lambda\mathbf{M}U+\mathrm{i}\alpha\mathbf{K}U. \tag{5.3}$$

Definition. *If there exists a solution $U(\theta_1,\theta_2)$ of (5.3) which is 2π-periodic in θ_1 and θ_2, for some $\lambda\in\mathbb{C}$ and $\alpha\in\mathbb{R}$, with $\mathrm{Re}(\lambda)>0$, then we say that the basic state $\widehat{Z}(\theta_1,\theta_2)$ is linearly unstable or* spectrally unstable.

The application of this definition and the development of the geometric stability condition are not rigorous. For example, identification of the precise space of functions in which $U(\theta_1,\theta_2)$ might exist is beyond the scope of this paper. The obstacle to rigor is the potential small divisor problem, which would result in the range of the operator $\mathbf{L}$ not being closed. In some special cases, for example, if there is enough symmetry [9], the theory can be made rigorous using a Lyapunov–Schmidt reduction.

The eigenvalue problem (5.3) is still a PDE in θ_1 and θ_2. It has considerable structure (combination of symmetric and antisymmetric operators), but we do not

expect to be able to analyze this spectral problem completely. However, we can get complete results on *long-wave* instability, that is, when $|\alpha| \ll 1$. In this case, the geometry of (4.4) can be used to give a geometric characterization of the spectrum for α small. Eigenvalue problems of this type have been studied geometrically before in a different but related context [9, section 5], and therefore we can appeal to those results.

The kernel of $\mathbf{L}(\theta_1, \theta_2)$ has (at least) two elements,

$$\mathrm{Ker}(\mathbf{L}) \supseteq \mathrm{span}\left\{ \frac{\partial \widehat{Z}}{\partial \theta_1}, \frac{\partial \widehat{Z}}{\partial \theta_2} \right\}, \tag{5.4}$$

and this can be verified by differentiating (4.7) with respect to θ_1 and θ_2. Assume that these two functions are the only elements in the kernel, a property that is generically satisfied. (For certain parameter values, the kernel might be larger.) Then look for long-wave instabilities $\alpha \ll 1$ by expanding U in a Taylor series. Consider the ansatz

$$U = c_1 \left(\widehat{Z}_{\theta_1} + \lambda \widehat{Z}_{\omega_1} + \mathrm{i}\alpha \widehat{Z}_{k_1} \right) + c_2 \left(\widehat{Z}_{\theta_2} + \lambda \widehat{Z}_{\omega_1} + \mathrm{i}\alpha \widehat{Z}_{k_2} \right) + \mathcal{O}(|\lambda|^2 + |\alpha|^2), \tag{5.5}$$

where $\mathbf{c} = (c_1, c_2)$ are arbitrary complex constants. By differentiating (4.7) with respect to ω_1, ω_2, k_1, and k_2 it can be verified that this expression is indeed the solution to (5.3) to leading order.

It is worth remarking here that it is precisely in the leading-order expression for U that the deformation from standing waves to the general two-wave interaction is necessary. Four derivatives of $\widehat{Z}$ with respect to parameters are needed in (5.5), whereas if there was just one frequency and one wavenumber, only $\widehat{Z}_\omega$ and $\widehat{Z}_k$ would be available for (5.5).

Since $\mathbf{L}$ is formally self-adjoint, the solvability condition for (5.3) is

$$\begin{aligned} [\![\widehat{Z}_{\theta_1}, \lambda \mathbf{M} U + \mathrm{i}\alpha \mathbf{K} U]\!] &= 0, \\ [\![\widehat{Z}_{\theta_2}, \lambda \mathbf{M} U + \mathrm{i}\alpha \mathbf{K} U]\!] &= 0, \end{aligned}$$

where

$$[\![f, g]\!] = \int_{\mathbb{T}^2} \langle f(\theta_1, \theta_2), g(\theta_1, \theta_2) \rangle \, \mathrm{d}\theta = \frac{1}{(2\pi)^2} \int_0^{2\pi} \int_0^{2\pi} \langle f(\theta_1, \theta_2), g(\theta_1, \theta_2) \rangle \, \mathrm{d}\theta_1 \mathrm{d}\theta_2.$$

This solvability condition still contains the unknown function U, but we have a leading-order expression for U. Substituting the leading-order expression for U into the solvability condition leads to the pair of algebraic equations

$$\left[\mathbf{N}_0 \lambda^2 + \mathrm{i}\alpha\lambda \mathbf{N}_1 + (\mathrm{i}\alpha)^2 \mathbf{N}_2 + \cdots \right] \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{5.6}$$

where $\mathbf{N}_j$, $j = 0, 1, 2$, are 2×2 matrices depending only on the properties of the basic wave $\widehat{Z}$. The derivation of the expression for $\mathbf{N}_0$ will be given, and then the result for the other two will be stated. From the solvability condition we have that

$$\mathbf{N}_0 = \begin{bmatrix} \int_{\mathbb{T}^2} \langle \widehat{Z}_{\theta_1}, \mathbf{M} \widehat{Z}_{\omega_1} \rangle \, \mathrm{d}\theta & \int_{\mathbb{T}^2} \langle \widehat{Z}_{\theta_1}, \mathbf{M} \widehat{Z}_{\omega_2} \rangle \, \mathrm{d}\theta \\ \int_{\mathbb{T}^2} \langle \widehat{Z}_{\theta_2}, \mathbf{M} \widehat{Z}_{\omega_1} \rangle \, \mathrm{d}\theta & \int_{\mathbb{T}^2} \langle \widehat{Z}_{\theta_2}, \mathbf{M} \widehat{Z}_{\omega_2} \rangle \, \mathrm{d}\theta \end{bmatrix}.$$

However, by differentiating the functionals (4.6) with respect to ω_1 and ω_2 we find that the matrix simplifies to

$$\mathbf{N}_0 = -\begin{bmatrix} \frac{\partial \mathscr{A}_1}{\partial \omega_1} & \frac{\partial \mathscr{A}_1}{\partial \omega_2} \\ \frac{\partial \mathscr{A}_2}{\partial \omega_1} & \frac{\partial \mathscr{A}_2}{\partial \omega_2} \end{bmatrix} = -\frac{\partial \mathscr{A}}{\partial \omega}.$$

Similarly, $\mathbf{N}_1 = -\frac{\partial \mathscr{A}}{\partial k} - \frac{\partial \mathscr{B}}{\partial \omega}$ and $\mathbf{N}_2 = -\frac{\partial \mathscr{B}}{\partial k}$, and so (5.6) reduces to

$$\left(\lambda^2 \frac{\delta \mathscr{A}}{\delta \omega} + \mathrm{i}\alpha\lambda \left(\frac{\delta \mathscr{A}}{\delta k} + \frac{\delta \mathscr{B}}{\delta \omega}\right) + (\mathrm{i}\alpha)^2 \frac{\delta \mathscr{B}}{\delta k} + \cdots\right) \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

Therefore, if $|\lambda| + |\alpha|$ is sufficiently small and the matrix (4.8) is nondegenerate, the *long-wave stability* of the basic two-wave interaction is determined by the quartic

$$\begin{aligned} \Delta(\lambda, \alpha) &= \det\left[\lambda^2 \frac{\delta \mathscr{A}}{\delta \omega} + \mathrm{i}\alpha\lambda \left(\frac{\delta \mathscr{A}}{\delta k} + \frac{\delta \mathscr{B}}{\delta \omega}\right) + (\mathrm{i}\alpha)^2 \frac{\delta \mathscr{B}}{\delta k}\right] \\ &= \det\left[\sigma^{\mathrm{T}} \otimes \mathbf{I}_2 \begin{pmatrix} \delta \mathscr{A}/\delta \omega & \delta \mathscr{A}/\delta k \\ \delta \mathscr{B}/\delta \omega & \delta \mathscr{B}/\delta k \end{pmatrix} \sigma \otimes \mathbf{I}_2\right], \quad \sigma = \begin{pmatrix} \lambda \\ \mathrm{i}\alpha \end{pmatrix}. \end{aligned} \tag{5.7}$$

The second form shows that central role played by the nondegeneracy condition from the constrained variational principle of section 4.

Expanding out the determinant in (5.7) leads to a quartic polynomial for λ,

$$\Delta(\lambda, \alpha) = a_4\lambda^4 + a_3\lambda^3 + a_2\lambda^2 + a_1\lambda + a_0 \tag{5.8}$$

with

$$\begin{aligned} a_4 &= \det\left(\frac{\delta \mathscr{A}}{\delta \omega}\right), \\ a_3 &= \mathrm{i}\alpha \mathrm{Tr}\left(\frac{\delta \mathscr{A}}{\delta \omega}^{\#} \left(\frac{\delta \mathscr{A}}{\delta k} + \frac{\delta \mathscr{B}}{\delta \omega}\right)\right), \\ a_2 &= -\alpha^2 \det\left(\frac{\delta \mathscr{A}}{\delta k} + \frac{\delta \mathscr{B}}{\delta \omega}\right) - \alpha^2 \mathrm{Tr}\left(\frac{\delta \mathscr{A}}{\delta \omega}^{\#} \frac{\delta \mathscr{B}}{\delta k}\right), \\ a_1 &= -\mathrm{i}\alpha^3 \mathrm{Tr}\left(\frac{\delta \mathscr{B}}{\delta k}^{\#} \frac{\delta \mathscr{A}}{\delta k} + \frac{\delta \mathscr{B}}{\delta \omega}\right), \\ a_0 &= \alpha^4 \det\left(\frac{\delta \mathscr{B}}{\delta k}\right), \end{aligned} \tag{5.9}$$

where the superscript # indicates adjugate, i.e.,

$$\mathbf{C}^{\#} = \begin{pmatrix} c_1 & c_2 \\ c_2 & c_3 \end{pmatrix}^{\#} = \mathbf{J}^{-1}\mathbf{C}\mathbf{J} = \begin{pmatrix} c_3 & -c_2 \\ -c_2 & c_1 \end{pmatrix}, \quad \text{where } \mathbf{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

This stability quartic applies to both standing waves and the deformed two-wave interaction, which may have independent interest. Given a basic four-parameter wave, $(\widehat{Z}; \omega_1, \omega_2, k_1, k_2)$, the coefficients of the quartic can in principle be computed, and then the quartic solved for the four roots, thereby determining whether there is a long-wave instability.

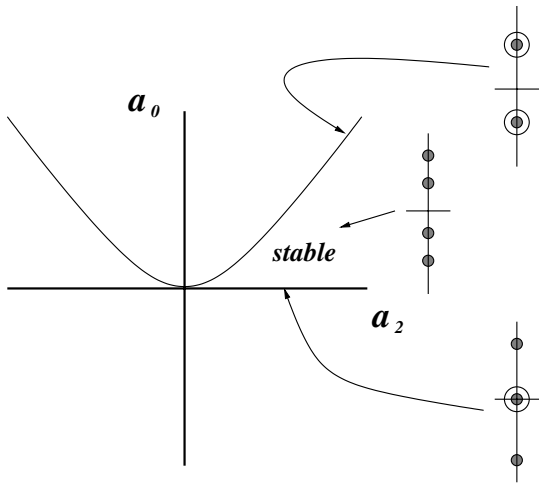

FIG. 1. *Position of the roots of the quartic* $\Delta(\lambda,\alpha)=0$ *when* $a_1=a_3=0$ *and* $a_4=1$*, showing the stable region and its boundary in the* (a_2,a_0) *plane. In all other regions there is at least one unstable root.*

5.1. The stability quartic when $a_1=a_3=0$. A special case of the quartic that can be analyzed in detail is when $a_1=a_3=0$. This case will not arise in general for standing waves at finite amplitude, but it does arise in the limit as the amplitude of the wave tends to zero—the weakly nonlinear limit.

In the analysis of the stability quartic $\Delta(\lambda,\alpha)=0$, the term "instability" will mean that there is at least one root of $\Delta(\lambda,\alpha)=0$ with positive real part, and "stability" will mean that all four roots are purely imaginary and simple (spectral stability). We have the following complete classification of the roots of (5.8) when $a_1=a_3=0$:

$$\begin{aligned} a_4a_0<0 &\Rightarrow \text{instability},\\ a_4a_0\geq 0 \text{ but } a_4a_2<0 &\Rightarrow \text{instability},\\ a_4a_0>0 \text{ but } a_4a_2=0 &\Rightarrow \text{instability},\\ a_4a_0>0 \text{ and } a_4a_2>0 \text{ but } a_2^2-4a_4a_0<0 &\Rightarrow \text{instability},\\ a_4a_0>0,\ a_4a_2>0 \text{ and } a_2^2-4a_4a_0>0 &\Rightarrow \text{stability}. \end{aligned}$$

There are also two special cases where the spectrum is purely imaginary but there are multiple eigenvalues. When $a_0a_4=0$, $a_2a_4>0$, and $a_2^2-4a_4a_0>0$, there is a pair of distinct purely imaginary eigenvalues and a double zero eigenvalue. When $a_4a_0>0$, $a_4a_2>0$ but $a_2^2-4a_4a_0=0$ there is a pair of purely imaginary eigenvalues each of multiplicity two. These special cases lie on the boundary of the region of stability, as illustrated in Figure 1.

6. Instability of weakly nonlinear standing waves. The purpose of this section is threefold. It illustrates in the simplest possible setting how the variational principle and stability theory accumulate information on the spectral problem. It shows explicitly the importance of the limit from the four-parameter two-wave interaction to the two-parameter standing wave. Third, it shows that the theory of this paper recovers the modulation instability predicted by coupled NLS equations with mean-field coupling.

To construct weakly nonlinear counterpropagating waves, take a Fourier ansatz,

(6.1)
$$\begin{aligned}\widehat{Z}(\theta_1,\theta_2) = {} & A_1\boldsymbol{\xi}_1 e^{i\theta_1} + \overline{A_1\boldsymbol{\xi}_1}e^{-i\theta_1} + A_2\boldsymbol{\xi}_2 e^{i\theta_2} + \overline{A_2\boldsymbol{\xi}_2}e^{-i\theta_2} \\ & + \Upsilon_{20} + \Upsilon_{21}e^{2i\theta_1} + \overline{\Upsilon_{21}}e^{-2i\theta_1} + \Upsilon_{22}e^{2i\theta_2} + \overline{\Upsilon_{22}}e^{-2i\theta_2} \\ & + \Upsilon_{23}e^{i(\theta_1+\theta_2)} + \overline{\Upsilon_{23}}e^{-i(\theta_1+\theta_2)} + \Upsilon_{24}e^{i(\theta_1-\theta_2)} + \overline{\Upsilon_{24}}e^{-i(\theta_1-\theta_2)} + \cdots,\end{aligned}$$

where $\theta_j = k_j x + \omega_j t$ $(j = 1, 2)$, A_1 and A_2 are complex amplitudes, and $\boldsymbol{\xi}_1$ and $\boldsymbol{\xi}_2$ have unit length. This ansatz is substituted into the Lagrangian (1.6),

(6.2)
$$\begin{aligned}\overline{\mathscr{L}}(A_1, A_2, \boldsymbol{\xi}_1, \boldsymbol{\xi}_2, \mu_1, \mu_2, \Upsilon, \dots) = {} & \mathscr{S}(\widehat{Z}) - \omega_1\mathscr{A}_1 - \omega_2\mathscr{A}_2 - k_1\mathscr{B}_1 - k_2\mathscr{B}_2 \\ & - \mu_1(\|\boldsymbol{\xi}_1\|^2 - 1) - \mu_2(\|\boldsymbol{\xi}_2\|^2 - 1).\end{aligned}$$

Here, μ_1 and μ_2 are Lagrange multipliers associated with the constraints on $\boldsymbol{\xi}_1$ and $\boldsymbol{\xi}_2$. The vectors $\boldsymbol{\xi}_j$ are eigenvectors of a linear Hermitian operator, and the Lagrange multipliers μ_j give a way of extending the dispersion relation to the nonlinear case in a coordinate-free way.

Formally solving this finite-dimensional Lagrangian system leads to the reduced Lagrangian

$$\overline{\mathscr{L}} = \mu_1|A_1|^2 + \mu_2|A_2|^2 + \tfrac{1}{2}\sigma_{11}|A_1|^4 + \sigma_{12}|A_1|^2|A_2|^2 + \tfrac{1}{2}\sigma_{22}|A_2|^4 + \cdots$$

and to amplitude equations for A_1 and A_2 of the general form

(6.3)
$$\begin{aligned}A_1\left(\mu(\omega_1, k_1) + \sigma_{11}|A_1|^2 + \sigma_{12}|A_2|^2 + \cdots\right) = 0, \\ A_2\left(\mu(\omega_2, k_2) + \sigma_{12}|A_1|^2 + \sigma_{22}|A_2|^2 + \cdots\right) = 0.\end{aligned}$$

To leading order, the Lagrange multipliers μ_1 and μ_2 are the dispersion relation for the linearized problem evaluated at (ω_1, k_1) and (ω_2, k_2), respectively. To compute the elements needed for the stability analysis, we need the functionals $\mathscr{A}_j$ and $\mathscr{B}_j$. To leading order they are

$$\mathscr{A}_j(\omega, k) = -\frac{\partial}{\partial\omega_j}\mu_j(\omega, k)|A_j|^2 + \cdots \quad \text{and} \quad \mathscr{B}_j(\omega, k) = -\frac{\partial}{\partial k_j}\mu_j(\omega, k)|A_j|^2 + \cdots,$$

where $(\omega, k) := (\omega_1, \omega_2, k_1, k_2)$. These expressions are verified by substituting (6.1) into the functionals (4.6). Using these expressions we compute

$$\frac{\delta\mathscr{A}}{\delta\omega} = \begin{bmatrix} \frac{\partial\mathscr{A}_1}{\delta\omega_1} & \frac{\partial\mathscr{A}_1}{\delta\omega_2} \\ \frac{\partial\mathscr{A}_2}{\delta\omega_1} & \frac{\partial\mathscr{A}_2}{\delta\omega_2} \end{bmatrix} = \begin{bmatrix} \frac{\partial}{\partial\omega_1}a_1|A_1|^2 + a_1\frac{\partial}{\partial\omega_1}|A_1|^2, & a_1\frac{\partial}{\partial\omega_2}|A_1|^2 \\ a_2\frac{\partial}{\partial\omega_1}|A_2|^2, & \frac{\partial}{\partial\omega_2}a_2|A_2|^2 + a_2\frac{\partial}{\partial\omega_2}|A_2|^2 \end{bmatrix} + \cdots,$$

where $a_j = -\frac{\partial}{\partial\omega_j}\mu_j$, $j = 1, 2$. Now apply the standing wave limit to this matrix,

(6.4)
$$\omega_2 \to \omega_1 := \omega, \quad k_2 \to -k_1 := -k, \quad |A_2| \to |A_1| := |A|,$$

to find

$$\frac{\delta\mathscr{A}}{\delta\omega} = -D_\omega^2\Lambda^{-1} + D_{\omega\omega}|A|^2\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \cdots,$$

where $D(\omega,k)=\lim_{\to \mathrm{SWs}}\mu_1(\omega_1,k_1)=\lim_{\to \mathrm{SWs}}\mu_2(\omega_2,k_2)$, and

$$\Lambda:=\begin{bmatrix}a & b\\ b & a\end{bmatrix}=\lim_{\to \mathrm{SWs}}\begin{bmatrix}\sigma_{11} & \sigma_{12}\\ \sigma_{12} & \sigma_{22}\end{bmatrix}.$$

Similarly we find

$$\frac{\delta\mathscr{A}}{\delta k}=-D_\omega D_k\,\Lambda^{-1}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+D_{\omega k}|A|^2\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+\cdots,$$

$$\frac{\delta\mathscr{B}}{\delta\omega}=\left(\frac{\delta\mathscr{A}}{\delta k}\right)^T=-D_\omega D_k\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\Lambda^{-1}+D_{\omega k}|A|^2\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+\cdots,$$

and so

$$\frac{\delta\mathscr{A}}{\delta k}+\frac{\delta\mathscr{B}}{\delta\omega}=-\frac{2a}{|\Lambda|}D_\omega D_k\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+2D_{\omega k}|A|^2\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+\cdots.$$

For the third term in the matrix (5.7),

$$\frac{\delta\mathscr{B}}{\delta k}=-D_k^2\frac{\Lambda}{|\Lambda|}+D_{kk}|A|^2\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}+\cdots.$$

Now, the stability quartic (5.8) in the standing wave limit takes the form

$$\Delta(\lambda,\alpha)=a_4\lambda^4+a_3\lambda^3+a_2\lambda^2+a_1\lambda+a_0$$

with

$$\begin{aligned}
a_4&=\det\left(\frac{\delta A}{\delta\omega}\right)=\frac{D_\omega^4}{|\Lambda|}-\frac{2a}{|\Lambda|}D_\omega^2D_{\omega\omega}|A|^2+\cdots,\\
a_3&=\mathrm{i}\alpha\mathrm{Tr}\left(\frac{\delta A}{\delta\omega}^{\#}\left(\frac{\delta A}{\delta k}+\frac{\delta B}{\delta\omega}\right)\right)=0,\\
a_2&=-\alpha^2\det\left(\frac{\delta A}{\delta k}+\frac{\delta B}{\delta\omega}\right)-\alpha^2\mathrm{Tr}\left(\frac{\delta A}{\delta\omega}^{\#}\frac{\delta B}{\delta k}\right)\\
&=-\alpha^2\left(-\frac{2}{|\Lambda|}D_\omega^2D_k^2+\frac{2a}{|\Lambda|}(-D_\omega^2D_{kk}-D_k^2D_{\omega\omega}+4D_\omega D_kD_{\omega k})|A|^2+\cdots\right)\\
a_1&=(\mathrm{i}\alpha)^3\mathrm{Tr}\left(\frac{\delta B}{\delta k}^{\#}\left(\frac{\delta A}{\delta k}+\frac{\delta B}{\delta\omega}\right)\right)=0,\\
a_0&=\alpha^4\det\left(\frac{\delta B}{\delta k}\right)=\alpha^4\left(\frac{D_k^4}{|\Lambda|}-\frac{2a}{|\Lambda|}D_k^2D_{kk}|A|^2+\cdots\right).
\end{aligned}$$

Let

$$\delta = -D_\omega^2 D_{kk} - D_k^2 D_{\omega\omega} + 2D_\omega D_k D_{\omega k} = \det \begin{bmatrix} D_{\omega\omega} & D_{\omega k} & D_\omega \\ D_{k\omega} & D_{kk} & D_k \\ D_\omega & D_k & 0 \end{bmatrix}. \tag{6.5}$$

Then, to summarize, the stability quartic in the standing wave limit is

$$\Delta(\lambda,\alpha) = \det\left[\lambda^2 \frac{\delta\mathscr{A}}{\delta\omega} + \mathrm{i}\alpha\lambda\left(\frac{\delta\mathscr{A}}{\delta k} + \frac{\delta\mathscr{B}}{\delta\omega}\right) + (\mathrm{i}\alpha)^2 \frac{\delta\mathscr{B}}{\delta k}\right] = a_4\lambda^4 + a_2(\mathrm{i}\alpha)^2\lambda^2 + a_0(\mathrm{i}\alpha)^4$$

with

$$\begin{aligned} a_4 &= +\frac{D_\omega^4}{|\Lambda|} - \frac{2a}{|\Lambda|} D_\omega^2 D_{\omega\omega}|A|^2 + \cdots, \\ a_2 &= -\frac{2}{|\Lambda|} D_\omega^2 D_k^2 + \frac{2a}{|\Lambda|}(\delta + 2D_\omega D_k D_{\omega k})|A|^2 + \cdots, \\ a_0 &= +\frac{D_k^4}{|\Lambda|} - \frac{2a}{|\Lambda|} D_k^2 D_{kk}|A|^2 + \cdots. \end{aligned}$$

Apply the stability-instability classification in section 5.1, which requires the expressions

$$\begin{aligned} a_0 a_4 &= \frac{D_\omega^4 D_k^4}{|\Lambda|^2} + \cdots > 0, \\ -a_2 a_4 &= \frac{2}{|\Lambda|^2} D_k^2 D_\omega^6 + \cdots > 0, \\ a_2^2 - 4a_0 a_4 &= -16\, a\delta\, \frac{D_\omega^2 D_k^2}{|\Lambda|^2}|A|^2 + \cdots . \end{aligned}$$

Hence, from the stability-instability classification in section 5.1, if we assume the conditions

$$D_\omega \neq 0, \quad D_k \neq 0, \quad \det(\Lambda) \neq 0, \quad a \neq 0, \quad \text{and} \quad \delta \neq 0$$

are satisfied, we can conclude, for $|A|$ sufficiently small, that the stability quartic (5.7) has an unstable eigenvalue if and only if

$$a\delta > 0.$$

A significant feature of this result is that the instability of standing waves is independent of the standing wave frequency correction. To see this, go back to (6.3) and take the standing wave limit,

$$\begin{aligned} A_1\left(D(\omega,k) + a\,|A_1|^2 + b\,|A_2|^2 + \cdots\right) &= 0, \\ A_2\left(D(\omega,k) + b\,|A_1|^2 + a\,|A_2|^2 + \cdots\right) &= 0. \end{aligned} \tag{6.6}$$

Hence

$$\begin{aligned} \omega^{TW} &= \omega_0 - \frac{a}{D_\omega}|A_1|^2 + \cdots, \quad A_2 = 0, \\ \omega^{SW} &= \omega_0 - \frac{(a+b)}{D_\omega}|A_1|^2 + \cdots, \quad A_2 = A_1. \end{aligned}$$

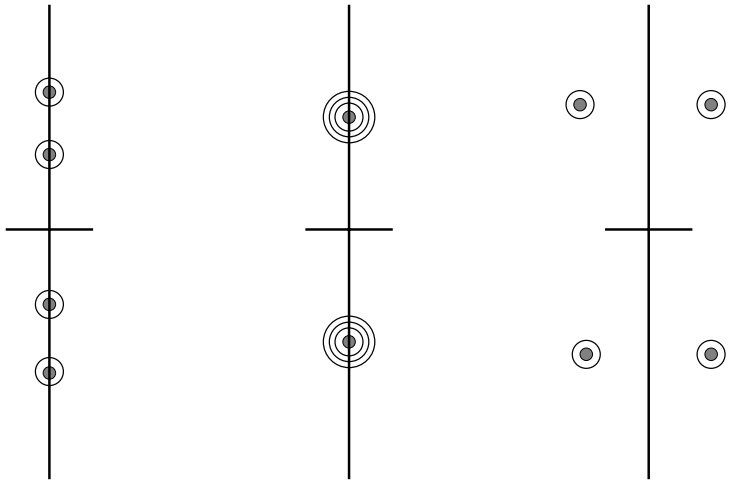

FIG. 2. *Schematic of the position of the eigenvalues at the threshold of instability for weakly nonlinear standing waves.*

Although the weakly nonlinear correction to the frequency for standing waves depends on b, the modulation instability at low amplitude is independent of b. Effectively, the stability problem decouples at low amplitude.

To confirm that a weakly nonlinear traveling wave has the same instability condition as the standing wave, we can compare $a\delta > 0$ with the Whitham condition. If $D(\omega_0(k), k) = 0$ and $D_\omega \neq 0$, then $D_\omega \omega_0'(k) + D_k = 0$ and so

$$\omega_0''(k) = \frac{1}{D_\omega^3} \det \begin{bmatrix} D_{\omega\omega} & D_{\omega k} & D_\omega \\ D_{k\omega} & D_{kk} & D_k \\ D_\omega & D_k & 0 \end{bmatrix} = \frac{1}{D_\omega^3} \delta.$$

From the above expression for the frequency of the traveling waves, ω^{TW}, we have that $\omega_2 = -a/D_\omega$ and so

$$\text{sign}(a\delta) = \text{sign}\left(-\omega_2 D_\omega\, \omega_0''(k) D_\omega^4\right) = -\text{sign}(\omega_0''(k)\omega_2),$$

showing that $a\delta > 0$ is equivalent to $\omega_0''(k)\omega_2 < 0$.

This instability condition for weakly nonlinear standing waves agrees with the instability condition derived by Knobloch and Pierce [18], obtained from the coupled NLS equations with mean-field terms for counterpropagating waves.

For finite-amplitude standing waves, the instability of standing waves will in general differ from the instability of traveling waves. It is an interesting open problem to determine precisely how this instability will change for finite amplitude standing waves. It can be studied either by carrying the amplitude expansion to the next order or numerically.

There is another subtle difference between the traveling wave instability and standing wave instability, which shows up even for weakly nonlinear standing waves. For the standing wave, the unstable subspace is twice as large as the case of traveling waves. A schematic is shown in Figure 2. This figure shows the temporal eigenvalues of the linear stability problem for weakly nonlinear standing waves, with

instability arising through a collision of eigenvalues of opposite signature. Note that each eigenvalue is double, and so the unstable subspace is four-dimensional (whereas for traveling waves it is two-dimensional). The multiple eigenvalues will not persist for finite-amplitude standing waves, suggesting that the behavior of the instability for finite-amplitude standing waves will be more dramatic than traveling waves in general and weakly nonlinear standing waves in particular.

6.1. Example: Calculations for a scalar nonlinear wave equation. An elementary example of the theory is obtained by considering the scalar nonlinear wave equation: (1.1) with $m = 1$. Let $V(u)$ be any smooth function with leading Taylor expansion

$$V(u) = \frac{1}{2}a_1u^2 + \frac{1}{3}a_2u^3 + \frac{1}{4}a_3u^4 + \cdots, \quad a_1 > 0.$$

Then a straightforward calculation leads to the reduced Lagrangian

$$\overline{\mathscr{L}} = \mu_1|A_1|^2 + \mu_2|A_2|^2 + \tfrac{1}{2}\sigma_{11}|A|^4 + \sigma_{12}|A_1|^2|A_2|^2 + \tfrac{1}{2}\sigma_{22}|A_2|^4 + \cdots$$

with $\mu_j(\omega, k) = k_j^2 - \omega_1^2 + a_1$, $\sigma_{11} = \sigma_{22} = -\frac{5}{3a_1}a_2^2 + \frac{9}{4}a_3$, and

$$\sigma_{12} = -2a_2^2\left(\frac{1}{a_1} + \frac{1}{a_1 - (\omega_1+\omega_2)^2 + (k_1+k_2)^2} + \frac{1}{a_1 - (\omega_1-\omega_2)^2 + (k_1-k_2)^2}\right) + 3a_3.$$

Computing the parameter Jacobian (4.8) and taking the limit $\omega_2 \to \omega_1 := \omega$ and $k_2 \to -k_1 := -k$ we find

$$D(\omega, k) = k^2 - \omega^2 + a_1, \quad \delta = -8a_1, \quad \text{and} \quad a = \lim_{\to \mathrm{SWs}} \sigma_{11} = \sigma_{11},$$

and so $a\delta = -8a_1(-\frac{5}{3a_1}a_2^2 + \frac{9}{4}a_3)$. Hence both traveling waves and standing wave solutions of (1.1) are unstable in the weakly nonlinear limit whenever

$$20a_2^2 - 27a_1a_3 > 0 \quad \text{and} \quad a_1 > 0.$$

The instability of finite-amplitude standing wave solutions of even this scalar nonlinear wave equation is an open problem, but the theory of this paper can be applied, given (either numerical or analytic) expressions for the finite-amplitude standing waves.

7. Small divisors and the equivariant Lyapunov center theorem. The obstacle to a rigorous proof of the existence of smooth families of standing waves and the linear stability theory is a potential small divisor problem. This issue can be illustrated by considering the scalar version of the nonlinear wave equation (1.1), which can be written

$$u_{tt} - u_{xx} + a_1u = V'(u) - a_1u,$$

where $a_1 = V''(0)$ is some positive real number. In application of the implicit function theorem to the existence of standing waves, linear systems of the type of the left-hand side have to be inverted on the complement of its kernel, on a space of space-time periodic functions. Such systems can be written in the general form

$$V_t = \mathbf{L}V + \mathbf{f}(x,t), \quad \mathbf{L} = \begin{bmatrix} 0 & I \\ \partial_{xx} - a_1 & 0 \end{bmatrix},$$

where $\mathbf{f}(x,t)$ is a vector-valued periodic function of x and t. Now, the spectrum of $\mathbf{L}$ on a space of 2π-periodic functions is

$$\lambda_n = \mathrm{i}\sqrt{n^2 + a_1} := \mathrm{i}\omega_n, \quad n \in \mathbb{Z}.$$

The spectrum consists of a countable number of purely imaginary eigenvalues. Now, a_1 can be chosen so that

$$\lambda_1 j - \lambda_n \neq 0, \quad j \geq 1,\ n \neq 1,$$

which is the usual nonresonance condition of the Lyapunov center theorem. However, the distance $|\omega_1 j - \omega_n|$ may tend to zero as j, n tend to infinity, creating a small divisor problem. In other words, a frequency ω_n when n is large enough may get arbitrarily close to a resonant multiple of ω_1.

Effectively, what is needed is a version of the Lyapunov center theorem in infinite dimensions. The first result of this type is due to Craig and Wayne [12] and uses Nash–Moser theory to overcome the small divisor problem. However, the resulting branches of periodic solutions are not smooth but lie on a Cantor-like subset of parameter space.

By imposing the stronger diophantine condition on the frequencies

$$|\omega j - \omega_n| \geq \frac{\gamma}{j}, \quad j \geq 1, \quad n \geq 2, \quad \text{for some } \gamma > 0,$$

Bambusi [1] and Bambusi and Paleari [4] prove that the ordinary implicit function can be used, and this leads to partial smoothness of branches of periodic solutions.

These results are encouraging, but they still do not provide sufficient smoothness for the limits required in section 5. Moreover, the present analysis uses symmetry in a central way, and so an equivariant version of the Lyapunov center theorem [22] generalized to infinite dimensions would be required. Some intriguing results in this direction are given by Bambusi and Gaeta [3].

8. Instability of standing water waves. One of the most interesting examples of standing waves is standing water waves. These waves are most commonly observed and studied in the context of sloshing of fluid in a vessel. However, they are also a central part of pattern formation in the open ocean. The first nonlinear theory for standing waves was proposed by Rayleigh [27]. Indeed, he showed that they arise naturally along with traveling waves in any analysis of weakly nonlinear space and time periodic water waves. Since Rayleigh's work there has been a wide range of analytical and numerical theories for standing waves; see [11] for a list of references.

Recently, progress has been made in developing a rigorous theory for existence of standing waves. In finite depth small divisors arise, and a rigorous proof in this case for weakly nonlinear standing waves has been given by Plotnikov and Toland [26]. The proof uses a Nash–Moser framework, and therefore the branches of periodic solutions are not smooth, certainly not smooth enough to embed them in a higher parameter family. Surprisingly, the problem in infinite depth is more difficult. The kernel of the linearized problem is infinite-dimensional and the dispersion relation is algebraic, but recent significant progress has been made [14, 15].

For weakly nonlinear standing waves, stability results have been reported by Okamura [23] and Knobloch and Pierce [18] using modulation equations. The paper [18] gives the first correct analytic result for instability of weakly nonlinear standing waves. For finite-amplitude standing waves, the only results in the literature on the linear

stability is the work of Mercer and Roberts [21]. There are several interesting results in [21]. They compute long-wave instabilities at finite amplitude (called subharmonic instabilities there). They compute the action ($\mathscr{A}_1$ here) as a function of frequency (ω_1 here) and show that there is a point where $\partial_{\omega_1}\mathscr{A}_1 = 0$. This latter point will have an effect on the modulation instability at that point.

The theory of this paper suggests a new approach to the numerical computation of standing waves. The standing waves should be embedded in a four-parameter family and then the elements of (4.8) computed to study a wider range of stability properties. This embedding would not increase computation time (for standing waves or four-parameter two-wave interaction, the solution is expanded in a double Fourier series) but would increase the range of parameter space. However, it is only the parameter space *near the standing waves* that is of interest, and the computation of the functionals and their parameter dependence is a secondary calculation.

On a formal level one can draw a number of conclusions about the instability of standing water waves from the theory reported in this paper. First, the water-wave problem can be formulated as a multisymplectic system [6, 7] and the framework of this paper applied. For weakly nonlinear standing waves the conclusion for deep water is immediate: weakly nonlinear standing waves are unstable to a Benjamin–Feir instability in the same way that traveling waves are unstable. This is in agreement with the results of [18]. Further numerical calculations would be needed to test the theory of this paper at large amplitude to compare with and extend the results of [21].

The case of standing waves in finite depth may also have mean flow generation. For traveling waves, it is well known that reducing the depth creates a mean flow that stabilizes the Benjamin–Feir instability. Therefore an interesting open problem would be to determine the effect of mean flow on the stability of standing water waves in finite depth. Results obtained using modulation equations by Knobloch and Pierce [18] suggest that the weakly nonlinear finite-depth standing waves are affected by mean flow in exactly the same way as traveling waves. However, the role of mean flow in the stability of *finite-amplitude* standing waves is an open question.

9. Concluding remarks. The basic strategy here—embed a multiperiodic, say, N-periodic, pattern in an N-wave interaction with $2N$ parameters, compute parameter Jacobians, then take a limit to the original N-parameter wave to obtain stability information—has wider applicability. For example, in [10] this idea is generalized to determine stability conditions for short-crested Stokes waves in three space dimensions.

Short-crested Stokes waves are solutions of the form

$$Z(x,y,t) = \widehat{Z}(\theta_1,\theta_2), \quad \theta_1 = kx + \ell y + \omega t, \quad \theta_2 = kx - \ell y + \omega t.$$

They are three-parameter doubly periodic solutions and have been widely studied by oceanographers and engineers because they arise as a secondary bifurcation from classical Stokes waves and are known to influence sand transport. Short-crested waves are a generalization of standing waves in the sense that they can be characterized as synchronized oblique traveling waves, and in the limit as the angle between the two waves becomes zero they reduce to standing waves.

There are a number of open questions in the fluid mechanics literature about their stability. The theory of this paper generalizes to this problem in a straightforward way. The short-crested wave is embedded in the six-parameter two-phase wavetrain $Z(x,y,t) = \widehat{Z}(\theta_1,\theta_2)$ but with

$$\theta_j = \omega_j t + k_j x + \ell_j y + \theta_j^o, \quad j = 1,2.$$

These waves, when characterized by a constrained variational principle, generate the 6×6 matrix

$$\begin{pmatrix} \frac{\delta \mathscr{A}}{\delta \omega} & \frac{\delta \mathscr{A}}{\delta k} & \frac{\delta \mathscr{A}}{\delta \ell} \\ \frac{\delta \mathscr{B}}{\delta \omega} & \frac{\delta \mathscr{B}}{\delta k} & \frac{\delta \mathscr{B}}{\delta \ell} \\ \frac{\delta \mathscr{C}}{\delta \omega} & \frac{\delta \mathscr{C}}{\delta k} & \frac{\delta \mathscr{C}}{\delta \ell} \end{pmatrix}.$$

Proceeding as in section 5, a stability theory can be developed that predicts all long-wave instabilities using the entries of the above matrix. The complete details are given elsewhere [10].

Another generalization of interest is the study of the stability of *hexagonal* ocean patterns by embedding them in a three-phase wave train—with nine parameters—and then following the strategy in this paper to develop a theory for long-wave instability.

Appendix A. $O(2)$-invariant Hamiltonian systems and the spherical pendulum. Some insight into the geometry of nonlinear wave equations on the real line with periodic boundary conditions and x-reflection symmetry can be gained by examining the finite-dimensional analogue. This analogy is useful for illustrating the toral structure, but the analogy can be taken only so far, since the most interesting consequence for nonlinear wave equations—the geometry of modulational instability—is absent in finite dimensions.

Consider a Hamiltonian system on $\mathbb{R}^4$ with standard symplectic operator $\mathbf{J}$,

$$\mathbf{J}U_t = \nabla H(U), \quad U \in \mathbb{R}^4, \tag{A.1}$$

and suppose H is smooth and the system is $\mathbf{O}(2)$-equivariant. That is, there is a representation Γ of $\mathbf{O}(2)$ acting on $\mathbb{R}^4$ such that H is Γ-invariant and the action of Γ is symplectic [22]. Near a Γ-invariant equilibrium there are generically two classes of periodic solutions: traveling waves and standing waves [22].

The canonical example of an $\mathbf{O}(2)$-equivariant Hamiltonian system is the spherical pendulum (see [22, 5]), and it is sufficient to restrict attention to this example. For the spherical pendulum, the geometry and nature of solutions can be seen explicitly. The traveling waves are the conical pendulum solutions, and standing waves are the planar pendulum solutions. There are two traveling waves (one rotating clockwise and one rotating counterclockwise), and there is an $\mathbf{SO}(2)$ orbit of standing waves (the plane of motion of the planar pendulum can be rotated around). The standing waves of the spherical pendulum have zero angular momentum.

There is another well-known class of solutions of the spherical pendulum: the toral solutions which have a smoothly varying rotation number and nonzero angular momentum. These are sometimes called *relative periodic orbits*. Physically, they correspond to a precessing planar pendulum.

The solutions of the spherical pendulum can be usefully viewed in the energy-momentum space, as shown in Figure 3, where E represents the value of the energy and I represents the value of the momentum. The standing waves are along the $I = 0$ axis. The traveling waves correspond to minima of the energy restricted to level sets of the momentum and lie along the two curves shown. There are no solutions associated with (I, E) values below the traveling wave curves, and the region between the two curves excluding $I = 0$ is filled with toral solutions with smoothly varying rotation number.

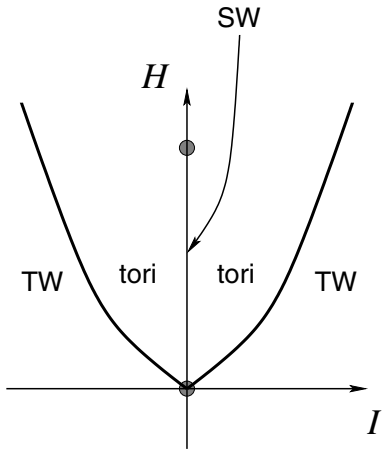

FIG. 3. *Schematic of the energy-momentum space for the spherical pendulum. The two highlighted points on the line of zero momentum are the two equilibria (vertical up and vertical down) of the spherical pendulum.*

A periodic solution, of period $T = \frac{2\pi}{\omega}$, of a finite-dimensional Hamiltonian system such as (A.1) can be characterized by a variational principle: a critical point of H restricted to level sets of the action,

$$\mathscr{A} = \frac{1}{2\pi}\int_0^{2\pi} A(U)\,\mathrm{d}\theta, \quad A(U) = \frac{1}{2}\langle \mathbf{J}U_\theta, U\rangle, \tag{A.2}$$

with the frequency, ω, a Lagrange multiplier. The Lagrange necessary condition for this variational principle is

$$\nabla H - \omega \nabla A = \nabla H - \omega \mathbf{J} U_\theta = 0, \quad \theta = \omega\, t + \theta^o.$$

A standing wave state would have the additional requirement that it is invariant under reflection (the reflection subgroup of $\mathbf{O}(2)$).

Now we come to the main point of this section. Can the limit $I \to 0$ be taken in the class of toral solutions leading to a standing wave?

Consider embedding the standing wave in a toral solution. Let $U(t) = \widehat{U}(\theta_1, \theta_2)$ with $\theta_j = \omega_j t + \theta_j^o$ for $j = 1, 2$. Then a variational characterization is again natural, and the Lagrange necessary condition is

$$\nabla H - \omega_1 \nabla A_1 - \omega_2 \nabla A_2 = \nabla H(\widehat{Z}) - \omega_1 \mathbf{J}\partial_{\theta_1}\widehat{U} - \omega_2 \mathbf{J}\partial_{\theta_2}\widehat{U} = 0, \quad \widehat{U} : \mathbb{T}^2 \to \mathbb{R}^4. \tag{A.3}$$

It follows from standard Lagrange multiplier theory that a state satisfying (A.3) is nondegenerate when

$$\det \begin{bmatrix} \frac{\partial \omega_1}{\partial I_1} & \frac{\partial \omega_1}{\partial I_2} \\ \frac{\partial \omega_2}{\partial I_1} & \frac{\partial \omega_2}{\partial I_2} \end{bmatrix} \neq 0, \tag{A.4}$$

where I_1 and I_2 represent values of the two actions. Now, solutions of this variational principle are smooth functions of the frequencies, away from the singularities (the

two equilibrium points and the two branches of traveling waves). This can be seen explicitly using the integrability of the spherical pendulum [13], but it follows more generally from symmetry. The more surprising smoothness result is that the frequency map (A.4) exists—in the limit from a toral state to the line $I = 0$—and is well defined (away from the two equilibrium points). Suppose I_2 represents the angular momentum in (A.4); then Horosov [13] proves that

$$\lim_{I_2\to 0} \det \begin{bmatrix} \frac{\partial\omega_1}{\partial I_1} & \frac{\partial\omega_1}{\partial I_2} \\ \frac{\partial\omega_2}{\partial I_1} & \frac{\partial\omega_2}{\partial I_2} \end{bmatrix} = \det \begin{bmatrix} \left(\frac{\partial\omega_1}{\partial I_1}\right)^0 & 0 \\ 0 & \left(\frac{\partial\omega_2}{\partial I_2}\right)^0 \end{bmatrix} = \left(\frac{\partial\omega_1}{\partial I_1}\right)^0 \left(\frac{\partial\omega_2}{\partial I_2}\right)^0 \neq 0. \tag{A.5}$$

Although the limit $I_2 \to 0$ results in a degeneration from a toral solution to a periodic solution, the toral frequency map does not degenerate! This nondegeneracy arises because the planar pendulum solutions lie on a torus and so the tangent space of the *manifold* of standing waves is two-dimensional. The first term in the product on the right-hand side of (A.5) is the change in frequency with amplitude (or energy) of the planar pendulum, and the second term in the product just says that the second frequency changes smoothly in going from negative to positive angular momentum (or vice versa).

The above geometry is also central to the standing wave problem associated with nonlinear wave equations on the real line. In the second variational principle in section 4, the standing wave is being embedded in a generalized multisymplectic relative-periodic orbit. In other words, geometrically there should be a smooth variation of the parameters. This would be true of any finite-dimensional approximation of the standing wave problem. In the limit as the number of modes goes to infinity, the small divisor issue again appears.

Appendix B. Multisymplectic Noether theory and momentum conservation. In this appendix, classical Noether theory is applied to the Lagrangian in the canonical multisymplectic form (1.6). A Lagrangian $\mathscr{L} = \int\int \mathrm{L}(Z, Z_t, Z_x)\,\mathrm{d}x\wedge\mathrm{d}t$, with $Z(x,t)$ vector valued, which does not depend explicitly on x, has a symmetry with generator $\mathbf{v} = \frac{\partial}{\partial x}$. Using Noether's theorem [24, section 4.4], this symmetry generates a conservation law,

$$\mathrm{I}(Z)_t + \mathrm{P}(Z)_x = 0$$

with

$$\mathrm{I}(Z) = \left\langle Z_x, \frac{\partial \mathrm{L}}{\partial Z_t} \right\rangle \quad \text{and} \quad \mathrm{P}(Z) = \left\langle Z_x, \frac{\partial \mathrm{L}}{\partial Z_x} \right\rangle - \mathrm{L}(Z, Z_t, Z_x),$$

where $\langle\cdot,\cdot\rangle$ is the standard inner product on $\mathbb{R}^n$. Applying these formulas to L in canonical form,

$$\mathrm{L}(Z, Z_t, Z_x) = \tfrac{1}{2}\langle \mathbf{M}Z_t, Z\rangle + \tfrac{1}{2}\langle \mathbf{K}Z_x, Z\rangle - S(Z),$$

leads to

$$\mathrm{I}(Z) = \tfrac{1}{2}\langle \mathbf{M}Z_x, Z\rangle, \quad \mathrm{P}(Z) = S(Z) - \tfrac{1}{2}\langle \mathbf{M}Z_t, Z\rangle.$$

This conservation law can be confirmed by direct calculation,

$$\begin{aligned}
\mathrm{I}(Z)_t &= \frac{1}{2}\langle \mathbf{M}Z_{xt}, Z\rangle + \frac{1}{2}\langle \mathbf{M}Z_x, Z_t\rangle \\
&= \frac{\partial}{\partial x}\left(\frac{1}{2}\langle \mathbf{M}Z_t, Z\rangle\right) - \langle \mathbf{M}Z_t, Z_x\rangle \quad \text{(using skew-symmetry of } \mathbf{M}\text{)} \\
&= \frac{\partial}{\partial x}\left(\frac{1}{2}\langle \mathbf{M}Z_t, Z\rangle\right) - \langle \nabla S(Z) - \mathbf{K}Z_x, Z_x\rangle \quad \text{(substituting for } \mathbf{M}Z_t \text{ using (3.1))} \\
&= \frac{\partial}{\partial x}\left(\frac{1}{2}\langle \mathbf{M}Z_t, Z\rangle - S(Z)\right) \quad \text{(using skew-symmetry of } \mathbf{K}\text{)},
\end{aligned}$$

and hence $\mathrm{I}(Z)_t + (S(Z) - \frac{1}{2}\langle \mathbf{M}Z_t, Z\rangle)_x = 0$.

NONCRYSTALLOGRAPHIC MOTION OF A DISLOCATION AS A FINE MIXTURE OF RECTILINEAR PATHS*

TIZIANA ARMANO† AND PAOLO CERMELLI†

Abstract. In this work we discuss the convergence of an approximation scheme for the solution, near an attractor, of a discontinuous dynamical system arising in the theory of dislocations in crystalline solids. It is well known that dislocations can move only along a finite number of crystallographic directions: in two dimensions, the resulting trajectories are piecewise rectilinear paths. However, in special situations such as near an attractor, dislocations are forced to move along curved paths: we characterize this class of motions as fine mixtures of crystallographic motions, using the notion of generalized curves due to Young, and we explicitly compute the parametrized measure associated to a sequence of polygonals. The result is then used to motivate a simple numerical scheme and show that it is physically consistent. Numerical simulations based on this scheme are also presented and discussed.

Key words. dislocation motion, dislocations and cracks, force on a dislocation, Young measures

1. Introduction.

The goal of this work is to study a special problem arising in the theory of defects in crystalline materials.

Specifically, we are interested in studying the motion of a screw dislocation in a cylindrical crystalline elastic body. Dislocations are the most common line defects in crystals, and their mobility is responsible for the plastic behavior and the ductility of most metals [6], [7], [8].

We use here the model developed by Cermelli and Gurtin [2] to describe the motion of a dislocation. Under some simplified hypotheses, the motion of a rectilinear dislocation can be described in terms of the motion of the intersection point of the defect line with an orthogonal plane. Peculiar to crystalline materials is the fact that such points are restricted to move along special directions, the so-called glide or slip directions (glide and slip planes in a general three-dimensional framework).

In elastic materials, a state of stress induces a force on a dislocation, the so-called Peach–Köhler force (see [2], [3], [4], and [9]) and the defect moves parallel to the direction on which the projection of this force is maximal (maximum dissipation criterion). Hence, the motion of a dislocation can be viewed as the solution of a dynamical system in a plane domain, obtained by projecting the Peach–Köhler force on the crystallographic directions. Since the number of such directions in a crystal is finite, it follows that the trajectories are piecewise rectilinear paths.

The general properties of this dynamical system have been studied in [2]; we focus here on a special situation, namely, the motion near a curve S which is an attractor. The dislocation is attracted by S: when it reaches it, it cannot escape (since it would violate the maximum dissipation criterion), but it cannot move along S either, since it would, in general, violate the crystallographic restriction on the direction of motion.

†Dipartimento di Matematica, Università di Torino, Via Carlo Alberto 10, I–10123 Torino, Italy (tiziana.armano@unito.it, paolo.cermelli@unito.it).

Hence, it seems natural to approximate the motion of the defect on S by a sequence of polygonals, which are piecewise parallel to the crystallographic directions but do not necessarily satisfy the maximum dissipation criterion at all times.

The main result of this paper is the proof that if such a sequence is a maximizing sequence for the dissipation, it converges to a unique smooth motion on S, which we refer to as *fine cross slip*.[1]

To study the limits of maximizing sequences we make use of the notion of generalized curves due to Young, in their recent formulation known as parametrized (or Young) measures in the literature on the calculus of variations. Young measures provide a richer characterization of finely oscillating sequences than their weak limits. We compute the Young measure associated to sequences of polygonals maximizing the dissipation, and we characterize fine cross slip as a fine mixture of crystallographic rectilinear motions, with weights depending on the direction of the attractor S.

From the mathematical point of view, the problem is equivalent to finding the solution of a dynamical system, in a neighborhood of an attracting curve at which the velocity field is multivalued. If the solution is computed numerically by any time-discretized scheme, the trajectory oscillates finely near the attractor, on a polygonal which is only approximately a solution of the original dynamical system. We show that any approximation scheme based on choosing a time step h determines, as $h \to 0$, a maximizing sequence for the dissipation and therefore converges to a unique smooth motion on S, which can be described as a fine mixture of crystallographic motions. Further, the limit motion coincides with the fine cross slip introduced above.

Finally, we present the results of numerical simulations of the motion of a screw dislocation in a domain with a crack or a rigid inclusion, based on the approximation scheme described above.

We also discuss an explicit example for which the velocity field, the attracting curves, and the motion by fine cross slip can be computed analytically. The numerical results support our theoretical considerations: the solution near the attracting curve, as computed by classical ODE solvers (such as Euler and Runge–Kutta), shows a good agreement with the limit motion on the attracting curve.

2. Statement of the problem. We summarize in this section the model discussed in [2]. Consider an elastic cylinder $B = \Omega \times \mathbb{R}$, where Ω is a domain in $\mathbb{R}^2$. A *screw Volterra dislocation* is a singular displacement field on B which can be constructed by the following ideal procedure [12]: first cut the cylinder B along a vertical half-plane Π, then translate one of the faces along the cut by a constant vertical vector $\boldsymbol{b}$, glue back the faces along Π, and let the cylinder relax to an elastic equilibrium state (Figure 2.1). The resulting displacement field, measured with respect to the initial configuration, is smooth in $B \setminus \Pi$ but is discontinuous across Π with constant jump $\boldsymbol{b}$. The vertical line $\partial\Pi$ is called the *dislocation line*, and $\boldsymbol{b}$ is the *Burgers vector*. To avoid dealing with discontinuous displacement fields, it can be shown that a screw dislocation can be characterized equivalently in terms of a deformation field on $B \setminus \partial\Pi$, singular at $\partial\Pi$. In simple cases, the deformation field generated by a dislocation is independent of the vertical coordinate, and the problem admits a two-dimensional formulation in terms of planar fields on Ω, which are singular at $\boldsymbol{z} = \partial\Pi \cap \Omega$ [2].

Precisely, let Ω be a domain in $\mathbb{R}^2$, with Cartesian coordinates (x, y) and associated basis $(\boldsymbol{e}_1, \boldsymbol{e}_2)$, and let $\boldsymbol{x}$ denote a generic point in Ω.

[1] Fine cross slip of screw dislocations has indeed been experimentally observed (see, e.g., [5] and [7]).

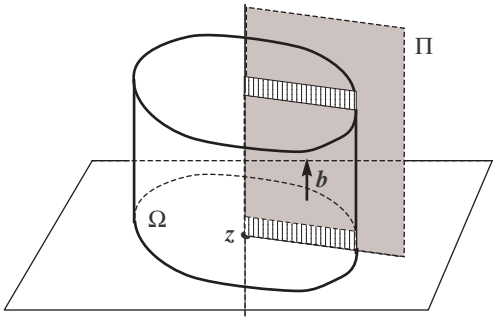

FIG. 2.1. *A screw Volterra dislocation in the cylinder* $\Omega \times \mathbb{R}$.

Fix a defect position $\boldsymbol{z} \in \Omega$ and consider the solution $u : \Omega \to \mathbb{R}$ of the Neumann problem

$$\begin{cases} \Delta u = 0 & \text{in } \Omega, \\ \dfrac{\partial u}{\partial n} = -\boldsymbol{g}_0 \cdot \boldsymbol{n} + \sigma_0 & \text{on } \partial\Omega, \end{cases} \tag{2.1}$$

where Δ is the Laplace operator, $\partial/\partial n$ is the normal time derivative on $\partial\Omega$, $\boldsymbol{n}$ is the outward unit normal to $\partial\Omega$, and

$$\boldsymbol{g}_0 = \boldsymbol{g}_0(\boldsymbol{x}, \boldsymbol{z}) = \frac{b}{2\pi|\boldsymbol{x} - \boldsymbol{z}|^2}\, \boldsymbol{e}_3 \times (\boldsymbol{x} - \boldsymbol{z}), \tag{2.2}$$

where b is a real constant, $\boldsymbol{e}_3 = \boldsymbol{e}_1 \times \boldsymbol{e}_2$ is a unit vector in $\mathbb{R}^3$ orthogonal to the plane containing Ω (so that $\boldsymbol{e}_3 \times (\cdot)$ represents a counterclockwise $\pi/2$-rotation in the Ω-plane), and $\sigma_0 = \sigma_0(\boldsymbol{x})$ is an assigned function on $\partial\Omega$. The field u represents the regular part of the displacement due to the dislocation at $\boldsymbol{z}$, while $\boldsymbol{g}_0$ is related to the singular part of the deformation.

For each fixed $\boldsymbol{z} \in \Omega$, the Neumann problem (2.1) has a unique smooth solution[2] (modulo an additive constant), which we henceforth denote by

$$u = u(\boldsymbol{x}, \boldsymbol{z}), \qquad \boldsymbol{x} \in \Omega. \tag{2.3}$$

Consider now the smooth vector field in Ω,

$$\boldsymbol{\jmath}(\boldsymbol{x}) = b\, \nabla u(\boldsymbol{x}, \boldsymbol{x}) \times \boldsymbol{e}_3, \qquad \boldsymbol{x} \in \Omega, \tag{2.4}$$

where $\nabla u(\boldsymbol{x}, \boldsymbol{x}) = \nabla_{\boldsymbol{x}} u(\boldsymbol{x}, \boldsymbol{z})|_{\boldsymbol{z}=\boldsymbol{x}}$ is the gradient of the solution $u(\boldsymbol{x}, \boldsymbol{z})$ of (2.1), for a dislocation located at $\boldsymbol{z} = \boldsymbol{x}$. The vector field $\boldsymbol{\jmath}(\boldsymbol{x})$ depends only on the domain Ω and the boundary conditions σ_0 and may be identified to the Peach–Köhler force on a dislocation located at $\boldsymbol{x} \in \Omega$.

[2]The solution u of (2.1) can be represented explicitly with the help of Green's formula,

$$u(\boldsymbol{x}, \boldsymbol{z}) = -\int_{\partial\Omega} N(\boldsymbol{x}, \boldsymbol{\xi}(s)) \left(\sigma_0(\boldsymbol{\xi}(s)) - \frac{b}{2\pi|\boldsymbol{\xi}(s) - \boldsymbol{z}|^2}\, \boldsymbol{n}(\boldsymbol{\xi}(s)) \cdot \boldsymbol{e}_3 \times (\boldsymbol{\xi}(s) - \boldsymbol{z}) \right) ds + \mathrm{c},$$

where $N(\boldsymbol{x}, \boldsymbol{\xi})$ is the Neumann function for the domain Ω, $\boldsymbol{\xi}(s)$ is a parametrization of $\partial\Omega$ with arc length s, and c is a constant.

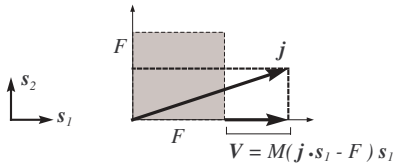

FIG. 2.2. *The definition of the vector field* $\boldsymbol{V}$.

Let now t denote time and $[0,T]$ be the time interval of interest. To study the behavior of a defect under the action of the force (2.4), consider a dislocation motion

$$\boldsymbol{z} : [0,T] \to \Omega.$$

Introducing the (finite) set of *crystallographic directions*

$$\mathcal{C} = \{\boldsymbol{s}_1, \dots, \boldsymbol{s}_n\}$$

with $\boldsymbol{s}_i$ fixed unit vectors in $\mathbb{R}^2$, the basic physical idea is that a dislocation can only move parallel to a crystallographic direction $\boldsymbol{s} \in \mathcal{C}$ on which the projection of the force $\boldsymbol{\jmath} \cdot \boldsymbol{s}$ is maximal, provided this is greater than a given threshold F, the so-called Peierls force (Figure 2.2). Therefore, we write the basic equation governing the motion of a dislocation as

$$\dot{\boldsymbol{z}} = \boldsymbol{V}(\boldsymbol{z}), \quad \boldsymbol{z} \in \Omega, \tag{2.5}$$

where the superposed dot denotes time derivative and where the vector field $\boldsymbol{V}$ is defined by

$$\boldsymbol{V}(\boldsymbol{x}) := \begin{cases} \boldsymbol{0} & \text{if } \boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{s} \le F \ \ \forall \boldsymbol{s} \in \mathcal{C}, \\ M\,(\boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{e}(\boldsymbol{x}) - F)\,\boldsymbol{e}(\boldsymbol{x}) & \text{otherwise,} \end{cases} \tag{2.6}$$

where $M > 0$ and $F \ge 0$ are given constants and $\boldsymbol{e}(\boldsymbol{x}) \in \mathcal{C}$ is determined by the *maximum dissipation criterion*, i.e., the requirement that the projection of $\boldsymbol{\jmath}(\boldsymbol{x})$ on $\boldsymbol{e}(\boldsymbol{x})$ be maximal, i.e.,

$$\boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{e}(\boldsymbol{x}) = \max_{\boldsymbol{s} \in \mathcal{C},\, \boldsymbol{\jmath} \cdot \boldsymbol{s} > F} \{\boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{s}\}. \tag{2.7}$$

Notice that $\boldsymbol{e}(\boldsymbol{x})$ takes its values in the finite set $\mathcal{C}$ and, if not identically constant, cannot be continuous in the whole Ω, which implies that also $\boldsymbol{V}(\boldsymbol{x})$ cannot be continuous in Ω. More precisely, it may happen that at some point $\boldsymbol{x}$ the maximization problem (2.7) admits two solutions: at such points the field $\boldsymbol{e}(\boldsymbol{x})$, and by consequence also $\boldsymbol{V}(\boldsymbol{x})$, is multivalued. Indeed, $\boldsymbol{\jmath} \cdot \boldsymbol{s}$ can have at most two maxima in $\mathcal{C}$ for $\boldsymbol{\jmath}$ given. Assume in fact that there exist three distinct unit vectors $\boldsymbol{s}_1$, $\boldsymbol{s}_2$, $\boldsymbol{s}_3$ such that $\boldsymbol{\jmath} \cdot \boldsymbol{s}_1 = \boldsymbol{\jmath} \cdot \boldsymbol{s}_2 = \boldsymbol{\jmath} \cdot \boldsymbol{s}_3$; then the endpoints of $\boldsymbol{s}_1$, $\boldsymbol{s}_2$, and $\boldsymbol{s}_3$ belong to the same straight line perpendicular to $\boldsymbol{\jmath}$, which is impossible since the $\boldsymbol{s}_i$ are unit vectors.

A detailed analysis of the phase portrait of the dynamical system (2.5) was performed in [2], where it is shown that Ω splits into (i) regions where $\boldsymbol{V}(\boldsymbol{x}) = \boldsymbol{0}$, and the dislocation is stationary; (ii) *single slip regions* $R(\boldsymbol{s})$ (open regions in $\mathbb{R}^2$), in which $\boldsymbol{e}(\boldsymbol{x}) = \boldsymbol{s}$ is constant; and (iii) curves S on which $\boldsymbol{e}(\boldsymbol{x})$ is multivalued, which can be further subdivided into *cross-slip curves*, *sources*, and *attracting curves* according to the relative orientation of the curve S and the vectors $\boldsymbol{e}(\boldsymbol{x})$ (Figure 2.3).

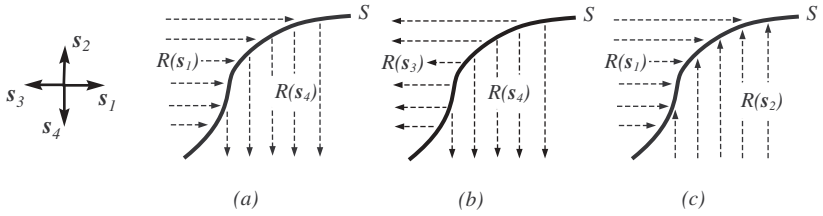

FIG. 2.3. (a) *Cross-slip curve;* (b) *source;* (c) *attracting curve—separating two single-slip regions.*

The motion of a dislocation, solution of (2.5), can be described as follows. Consider, to fix ideas, a dislocation initially at $\boldsymbol{z}_0 \in R(\boldsymbol{s}_1)$. The evolution equation (2.5) reduces to

$$\dot{\boldsymbol{z}} = V_1(\boldsymbol{z})\boldsymbol{s}_1$$

with $V_1(\boldsymbol{z}) = M(\boldsymbol{\jmath}(\boldsymbol{z}) \cdot \boldsymbol{s}_1 - F)$. Hence, the dislocation moves along a straight line parallel to $\boldsymbol{s}_1$, until it reaches some point at the boundary of $R(\boldsymbol{s}_1)$. If this point belongs to a curve on which $\boldsymbol{e}(\boldsymbol{x})$ is multivalued, two situations may occur. If the curve is a cross-slip curve, separating two single slip regions $R(\boldsymbol{s}_1)$ and (say) $R(\boldsymbol{s}_4)$ (corresponding to the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_4$), then the solution can be prolonged across the curve, and the dislocation moves into $R(\boldsymbol{s}_4)$ on a straight line parallel to $\boldsymbol{s}_4$; this phenomenon is known as *cross slip* (Figure 2.3(a)). If the curve is an attractor, then the solution of (2.5) cannot be prolonged into the adjacent region, since it would violate the maximum dissipation criterion (Figure 2.3(c)).

Hence, the problem seems to be ill-posed in the presence of an attractor. To remove the ambiguity, it was suggested in [2] that, when the dislocation reaches an attractor S, it continues to move along it according to an evolution equation of the form

$$\dot{\boldsymbol{z}} = \boldsymbol{w}(\boldsymbol{z}) \quad \text{with } \boldsymbol{w}(\boldsymbol{z}) = V_{12}(\boldsymbol{z})(\alpha_1(\boldsymbol{z})\boldsymbol{s}_1 + \alpha_2(\boldsymbol{z})\boldsymbol{s}_2), \tag{2.8}$$

where $V_{12}(\boldsymbol{z}) := \boldsymbol{\jmath}(\boldsymbol{z}) \cdot \boldsymbol{s}_1 - F = \boldsymbol{\jmath}(\boldsymbol{z}) \cdot \boldsymbol{s}_2 - F$, and α_1, α_2 are determined by solving

$$\begin{cases} \alpha_1 + \alpha_2 = 1, \\ \alpha_1(\boldsymbol{s}_1 - \boldsymbol{s}_2) \cdot (\nabla \boldsymbol{\jmath})\boldsymbol{s}_1 + \alpha_2(\boldsymbol{s}_1 - \boldsymbol{s}_2) \cdot (\nabla \boldsymbol{\jmath})\boldsymbol{s}_2 = 0. \end{cases} \tag{2.9}$$

The resulting smooth motion of the dislocation, referred to as *fine cross slip*, is therefore noncrystallographic, since it does not occur along a crystallographic direction $\boldsymbol{s} \in \mathcal{C}$. The purpose of the next section is to show that motion by fine cross slip (2.8) can be realized as the limit of a sequence of infinitesimal cross slips across the attracting curve S and to provide a basis for a numerical scheme based on the maximum dissipation criterion.

Remark. Letting

$$\hat{V}(\boldsymbol{e}, \boldsymbol{\jmath}) := \begin{cases} 0 & \text{if } \boldsymbol{\jmath} \cdot \boldsymbol{e} \le F, \\ M(\boldsymbol{\jmath} \cdot \boldsymbol{e} - F) & \text{if } \boldsymbol{\jmath} \cdot \boldsymbol{e} > F, \end{cases} \tag{2.10}$$

we may rewrite condition (2.7) as the requirement that motion may occur only in those directions $\boldsymbol{e}$ which maximize the *dissipation* $\hat{V}(\boldsymbol{s}, \boldsymbol{\jmath})\boldsymbol{\jmath} \cdot \boldsymbol{s}$, i.e.,

$$\hat{V}(\boldsymbol{e}, \boldsymbol{\jmath})\, \boldsymbol{\jmath} \cdot \boldsymbol{e} = \max_{\boldsymbol{s} \in \mathcal{C}} [\hat{V}(\boldsymbol{s}, \boldsymbol{\jmath})\, \boldsymbol{\jmath} \cdot \boldsymbol{s}], \tag{2.11}$$

provided that $\hat{V}(\boldsymbol{e},\boldsymbol{\jmath}) > 0$. The equivalence of (2.7) and (2.11) follows from the fact that the function $M(\xi - F)\xi$ is monotonic with respect to ξ for $\xi > F$.

3. Convergence of sequences of admissible polygonals. We study here the motion of a dislocation near an attracting curve, in order to justify (2.8) rigorously. From now on we regard the vector field $\boldsymbol{\jmath}(\boldsymbol{x})$ in (2.4) as assigned and smooth in Ω.

Let $\boldsymbol{z} : [0,T] \to \Omega$ be a given motion (not necessarily a solution of (2.5), (2.7), and (2.6)). Writing

$$\dot{\boldsymbol{z}}(t) = V(t)\boldsymbol{e}(t), \quad t \in [0,T], \tag{3.1}$$

with $V = |\dot{\boldsymbol{z}}|$ and $\boldsymbol{e} = \dot{\boldsymbol{z}}/|\dot{\boldsymbol{z}}|$, we say that $\boldsymbol{z}$ is *admissible* if

(i) $\boldsymbol{z}$ is continuous and piecewise smooth,

(ii) the direction of motion $\boldsymbol{e}(t)$ belongs to the set of crystallographic directions, and the velocity is a function of the projection of the force on that direction,[3] i.e.,

$$\boldsymbol{e}(t) \in \mathcal{C} \quad \text{and} \quad V(t) = \hat{V}(\boldsymbol{e}(t), \boldsymbol{\jmath}(\boldsymbol{z}(t))), \tag{3.2}$$

at each time t, with $\hat{V}$ given by (2.10).

An admissible motion does not necessarily satisfy the maximum dissipation criterion at all times, but its trajectory is a polygonal with edges parallel to the crystallographic directions.

We assume from now on that the set of crystallographic directions is

$$\mathcal{C} = \{\boldsymbol{s}_1, \boldsymbol{s}_2, -\boldsymbol{s}_1, -\boldsymbol{s}_2\} \tag{3.3}$$

with $\boldsymbol{s}_1 = \boldsymbol{e}_1$ and $\boldsymbol{s}_2 = \boldsymbol{e}_2$, and we consider two adjacent single slip regions $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$, connected open sets in Ω such that[4] $\overline{R(\boldsymbol{s}_1)} \cap \overline{R(\boldsymbol{s}_2)} \neq \emptyset$ and $\overline{R(\boldsymbol{s}_1)} \cap \partial\Omega = \emptyset$, $\overline{R(\boldsymbol{s}_2)} \cap \partial\Omega = \emptyset$. By definition, in $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$ the dissipation is maximal in the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$, respectively, i.e.,

$$\begin{cases} \boldsymbol{x} \in R(\boldsymbol{s}_1) \Rightarrow \boldsymbol{s}_1 \cdot \boldsymbol{\jmath}(\boldsymbol{x}) > \boldsymbol{s} \cdot \boldsymbol{\jmath}(\boldsymbol{x}) & \forall \boldsymbol{s} \in \mathcal{C},\ \boldsymbol{s} \neq \boldsymbol{s}_1, \\ \boldsymbol{x} \in R(\boldsymbol{s}_2) \Rightarrow \boldsymbol{s}_2 \cdot \boldsymbol{\jmath}(\boldsymbol{x}) > \boldsymbol{s} \cdot \boldsymbol{\jmath}(\boldsymbol{x}) & \forall \boldsymbol{s} \in \mathcal{C},\ \boldsymbol{s} \neq \boldsymbol{s}_2. \end{cases} \tag{3.4}$$

Also, we assume that

$$\boldsymbol{\jmath}(\boldsymbol{x})\cdot\boldsymbol{s}_1 > F \ \text{ and } \ \boldsymbol{\jmath}(\boldsymbol{x})\cdot\boldsymbol{s}_2 > F, \quad \boldsymbol{x} \in \overline{R(\boldsymbol{s}_1)} \cup \overline{R(\boldsymbol{s}_2)}.$$

3.1. The definition of attracting curve. Let

$$G(\boldsymbol{x}) := (\boldsymbol{s}_2 - \boldsymbol{s}_1) \cdot \boldsymbol{\jmath}(\boldsymbol{x}), \tag{3.5}$$

and assume that $\boldsymbol{\jmath}$ is such that $\nabla G \neq 0$ in Ω. By definition,

$$G(\boldsymbol{x}) < 0 \ \text{ for } \ \boldsymbol{x} \in R(\boldsymbol{s}_1) \quad \text{and} \quad G(\boldsymbol{x}) > 0 \ \text{ for } \ \boldsymbol{x} \in R(\boldsymbol{s}_2),$$

so that, by the smoothness of G and the fact that $\nabla G \neq 0$, the set

$$S = \overline{R(\boldsymbol{s}_1)} \cap \overline{R(\boldsymbol{s}_2)}$$

[3] For $\boldsymbol{z}$ continuous and piecewise smooth, $\dot{\boldsymbol{z}}$ is the right time derivative at corner points.

[4] Here $\bar{R}$ denotes the closure of a set $R \subset \Omega$.

is a smooth curve on which G vanishes, i.e.,

$$G(\boldsymbol{x}) = 0 \Leftrightarrow \boldsymbol{s}_1 \cdot \boldsymbol{\jmath}(\boldsymbol{x}) = \boldsymbol{s}_2 \cdot \boldsymbol{\jmath}(\boldsymbol{x}), \quad \boldsymbol{x} \in S. \tag{3.6}$$

We say that S is an *attracting curve* for $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$ if it satisfies the supplementary conditions

$$\boldsymbol{s}_1 \cdot \nabla G(\boldsymbol{x}) > 0, \quad \boldsymbol{s}_2 \cdot \nabla G(\boldsymbol{x}) < 0, \quad \boldsymbol{x} \in S. \tag{3.7}$$

Hence, at an attracting curve, $\boldsymbol{s}_1$ points into $R(\boldsymbol{s}_2)$ and $\boldsymbol{s}_2$ points into $R(\boldsymbol{s}_1)$ (Figure 2.3(c)). We denote by

$$\boldsymbol{\tau} = \boldsymbol{e}_3 \times \frac{\nabla G}{|\nabla G|}$$

the tangent vector to S.

No admissible motion satisfying the maximum dissipation criterion can originate from an attracting curve S. To see this, consider an admissible motion along $\boldsymbol{s}_1$ with initial point on S: by $(3.7)_1$, G is increasing along $\boldsymbol{s}_1$, and the dislocation moves into the single slip region $R(\boldsymbol{s}_2)$. But in this region the dissipation is maximal in the direction $\boldsymbol{s}_2$, and the maximum dissipation criterion is violated.

Moreover, writing

$$\begin{cases} V_1(\boldsymbol{x}) := \hat{V}(\boldsymbol{s}_1, \boldsymbol{\jmath}(\boldsymbol{x})) = M(\boldsymbol{s}_1 \cdot \boldsymbol{\jmath}(\boldsymbol{x}) - F), \\ V_2(\boldsymbol{x}) := \hat{V}(\boldsymbol{s}_2, \boldsymbol{\jmath}(\boldsymbol{x})) = M(\boldsymbol{s}_2 \cdot \boldsymbol{\jmath}(\boldsymbol{x}) - F) \end{cases} \tag{3.8}$$

for the admissible velocities in the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ at $\boldsymbol{x} \in \overline{R(\boldsymbol{s}_1)} \cup \overline{R(\boldsymbol{s}_2)}$, (3.6) implies that $V_1(\boldsymbol{x}) = V_2(\boldsymbol{x})$ at $\boldsymbol{x} \in S$, and we denote by

$$V(\boldsymbol{x}) := V_1(\boldsymbol{x}) = V_2(\boldsymbol{x}), \quad \boldsymbol{x} \in S,$$

their common value. However, since at S the maximum dissipation criterion admits both $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ as solutions, the vector field $\boldsymbol{V}$ in (2.6) is multivalued, with values

$$V(\boldsymbol{x})\boldsymbol{s}_1 \quad \text{and} \quad V(\boldsymbol{x})\boldsymbol{s}_2$$

at $\boldsymbol{x} \in S$.

3.2. Admissible polygonals. We study here admissible motions that do not necessarily satisfy the maximum dissipation criterion. By definition, an admissible motion $\boldsymbol{z}$ is a time-parametrized polygonal with sides parallel to the crystallographic directions $\boldsymbol{s}_i \in \mathcal{C}$ and piecewise continuous speed given by (2.10). Restricting to admissible motions occurring in $\overline{R(\boldsymbol{s}_1)} \cup \overline{R(\boldsymbol{s}_2)}$ along the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ only, we have

$$\text{either} \quad \dot{\boldsymbol{z}}(t) = V_1(\boldsymbol{z}(t))\boldsymbol{s}_1 \quad \text{or} \quad \dot{\boldsymbol{z}}(t) = V_2(\boldsymbol{z}(t))\boldsymbol{s}_2$$

for $t \in [0, T]$, where V_1 and V_2 are given by (3.8) and $\dot{\boldsymbol{z}}(t)$ is the right time derivative at the corner points of the polygonal.

Hence, an admissible polygonal is a piecewise smooth curve

$$\boldsymbol{z}(t) = x(t)\boldsymbol{s}_1 + y(t)\boldsymbol{s}_2$$

such that there exists a partition $\{[\tau_i, \tau_{i+1}]\}$ of the time interval $[0,T]$ with $i = 0,1,2,\dots$, for which

(3.9)
$$x(t) = \begin{cases} \text{given by } t - \tau_{2j} = \displaystyle\int_{x(\tau_{2j})}^{x(t)} \frac{d\xi}{V_1(\boldsymbol{z}(\tau_{2j}) + (\xi - x(\tau_{2j}))\boldsymbol{s}_1)}, & t \in [\tau_{2j}, \tau_{2j+1}], \\ x(\tau_{2j+1}), & t \in [\tau_{2j+1}, \tau_{2j+2}], \end{cases}$$

and

(3.10)
$$y(t) = \begin{cases} y(\tau_{2j}), & t \in [\tau_{2j}, \tau_{2j+1}], \\ \text{given by} \\ t - \tau_{2j+1} = \displaystyle\int_{y(\tau_{2j+1})}^{y(t)} \frac{d\eta}{V_2(\boldsymbol{z}(\tau_{2j+1}) + (\eta - y(\tau_{2j+1}))\boldsymbol{s}_2)}, & t \in [\tau_{2j+1}, \tau_{2j+2}]. \end{cases}$$

Since V_1 and V_2 are continuous in $\overline{R(\boldsymbol{s}_1)} \cup \overline{R(\boldsymbol{s}_2)}$, they are also bounded on compact subsets, and this in turn implies the following property of admissible motions.

PROPOSITION 3.1. *For any $\boldsymbol{z}_0 \in \overline{R(\boldsymbol{s}_1)} \cup \overline{R(\boldsymbol{s}_2)}$ there exists $T > 0$ such that the set of all admissible motions originating from $\boldsymbol{z}_0$ is bounded in $W^{1,\infty}((0,T),\mathbb{R}^2)$.*

3.3. Sequences of admissible motions. The natural notion of convergence for sequences of admissible motions should account for the fact that the velocity oscillates between the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ and therefore may converge only in average. Weak-$*$ convergence in $W^{1,\infty}((0,T),\mathbb{R}^2)$ serves the purpose. We say that a sequence of Lipschitz motions $\{\boldsymbol{z}_k\}$ converges weak-$*$ in $W^{1,\infty}((0,T),\mathbb{R}^2)$ if there exists a motion $\boldsymbol{\xi} \in W^{1,\infty}((0,T),\mathbb{R}^2)$ such that $\boldsymbol{z}_k \to \boldsymbol{\xi}$ strongly in $C([0,T],\mathbb{R}^2)$ and $\dot{\boldsymbol{z}}_k \overset{*}{\rightharpoonup} \dot{\boldsymbol{\xi}}$ in $L^\infty([0,T],\mathbb{R}^2)$, i.e.,

$$\sup_{t\in[0,T]} |\boldsymbol{z}_k(t) - \boldsymbol{\xi}(t)| \to 0$$

and

$$\int_I (\dot{\boldsymbol{z}}_k(t) - \dot{\boldsymbol{\xi}}(t))\, dt \to 0$$

for any interval $I \subset [0,T]$, provided $\{\dot{\boldsymbol{z}}_k(t)\}$ is bounded in $L^\infty([0,T],\mathbb{R}^2)$.

The weak limit of a sequence of admissible motions is characterized by the Young measure associated to the sequence of the velocities (see Young [13] or, for a more recent approach, [10]). Consider in fact a sequence $\{\boldsymbol{w}_k : (0,T) \to \mathbb{R}^2\}$ converging weak-$*$ to $\boldsymbol{w}_0$ in $L^\infty((0,T),\mathbb{R}^2)$. A Young measure associated with the sequence $\{\boldsymbol{w}_k\}$ is a family of probability measures $\{\nu_t\}_{t\in(0,T)}$ in $\mathbb{R}^2$ which depends measurably on t, i.e., for any $\varphi : \mathbb{R}^2 \to \mathbb{R}$ continuous, the function

$$\bar{\varphi}(t) = \int_{\mathbb{R}^2} \varphi(\boldsymbol{w}) d\nu_t(\boldsymbol{w}) \tag{3.11}$$

is measurable. The fundamental property of ν_t is that, for any continuous φ, the sequence $\{\varphi(\boldsymbol{w}_k)\}$ converges (modulo a subsequence) weak-$*$ to $\bar{\varphi}$ in $L^\infty((0,T),\mathbb{R})$, i.e.,

$$\int_I \varphi(\boldsymbol{w}_k(t))\, dt \to \int_I \int_{\mathbb{R}^2} \varphi(\boldsymbol{w}) d\nu_t(\boldsymbol{w})\, dt, \tag{3.12}$$

for any interval $I \subset [0,T]$, provided that $\{\varphi(\boldsymbol{w}_k)\}$ is bounded in $L^\infty([0,T],\mathbb{R})$. In particular, the weak limit $\boldsymbol{w}_0$ is the expected value of $\boldsymbol{w}$ with respect to ν_t, i.e.,

$$\boldsymbol{w}_0(t) = \int_{\mathbb{R}^2} \boldsymbol{w}\, d\nu_t(\boldsymbol{w}). \tag{3.13}$$

An explicit characterization of ν_t is as follows. For every measurable $E \subset \mathbb{R}^2$,

$$\nu_t(E) = \lim_{R\to 0} \lim_{k\to+\infty} \frac{|\{s \in (t-R, t+R) \,:\, \boldsymbol{w}_k(s) \in E\}|}{2R}, \tag{3.14}$$

where $|\cdot|$ denotes the Lebesgue measure on $\mathbb{R}$.

THEOREM 3.2. *Consider a sequence of admissible polygonals $\boldsymbol{z}_k(t)$ in the directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$, converging weak-$*$ in $W^{1,\infty}((0,T),\mathbb{R}^2)$ as $k \to +\infty$ to a Lipschitz motion $\boldsymbol{\xi} \in W^{1,\infty}((0,T),\mathbb{R}^2)$. Then the Young measure associated to the sequence $\{\dot{\boldsymbol{z}}_k\}$ is*

$$\nu_t = \lambda_1(t)\, \delta_{V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1} + \lambda_2(t)\, \delta_{V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2}, \qquad t \in (0,T), \tag{3.15}$$

with $\delta_{V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1}$ and $\delta_{V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2}$ Dirac measures localized at $V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1$ and $V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2$, respectively, and

$$\lambda_1(t) = \frac{\dot{\boldsymbol{\xi}}(t)\cdot \boldsymbol{s}_1}{V_1(\boldsymbol{\xi}(t))}, \qquad \lambda_2(t) = \frac{\dot{\boldsymbol{\xi}}(t)\cdot \boldsymbol{s}_2}{V_2(\boldsymbol{\xi}(t))}. \tag{3.16}$$

Proof. We use property (3.14) to compute the measure ν_t associated to $\{\dot{\boldsymbol{z}}_k\}$. Fix $\bar{t} \in (0,T)$, and consider the sets

$$E_{1,\epsilon} = \{\boldsymbol{w} \in \mathbb{R}^2 \,:\, \boldsymbol{w} = w\boldsymbol{s}_1,\ w \in (V_1(\boldsymbol{\xi}(\bar{t})) - \epsilon, V_1(\boldsymbol{\xi}(\bar{t})) + \epsilon)\},$$
$$E_{2,\epsilon} = \{\boldsymbol{w} \in \mathbb{R}^2 \,:\, \boldsymbol{w} = w\boldsymbol{s}_2,\ w \in (V_2(\boldsymbol{\xi}(\bar{t})) - \epsilon, V_2(\boldsymbol{\xi}(\bar{t})) + \epsilon)\}$$

for fixed $\epsilon > 0$, and

$$E_1 = \{V_1(\boldsymbol{\xi}(\bar{t}))\boldsymbol{s}_1\}, \quad E_2 = \{V_2(\boldsymbol{\xi}(\bar{t}))\boldsymbol{s}_2\}.$$

We want to compute

$$\nu_{\bar{t}}(E_{1,\epsilon}) = \lim_{R\to 0} \lim_{k\to+\infty} \frac{|I_{1,k,\epsilon}|}{2R} \quad \text{and} \quad \nu_{\bar{t}}(E_{2,\epsilon}) = \lim_{R\to 0} \lim_{k\to+\infty} \frac{|I_{2,k,\epsilon}|}{2R},$$

where

$$I_{1,k,\epsilon} = \{s \in (\bar{t}-R, \bar{t}+R) \,:\, \dot{\boldsymbol{z}}_k(s) \in E_{1,\epsilon}\},$$
$$I_{2,k,\epsilon} = \{s \in (\bar{t}-R, \bar{t}+R) \,:\, \dot{\boldsymbol{z}}_k(s) \in E_{2,\epsilon}\}.$$

Since every polygonal $\boldsymbol{z}_k$ is admissible, it satisfies (3.2), and

$$\text{either} \quad \dot{\boldsymbol{z}}_k(t) = V_1(\boldsymbol{z}_k(t))\boldsymbol{s}_1 \quad \text{or} \quad \dot{\boldsymbol{z}}_k(t) = V_2(\boldsymbol{z}_k(t))\boldsymbol{s}_2 \tag{3.17}$$

for $t \in [0,T]$, with V_1 and V_2 given by (3.8). Hence, since $V_1(\boldsymbol{z}_k(t)) \to V_1(\boldsymbol{\xi}(t))$ and $V_2(\boldsymbol{z}_k(t)) \to V_2(\boldsymbol{\xi}(t))$ uniformly in t it follows that $\dot{\boldsymbol{z}}_k(s) \in E_{1,\epsilon} \cup E_{2,\epsilon}$ for $s \in (\bar{t}-R, \bar{t}+R)$ for k sufficiently large and R sufficiently small. Hence, by (3.14), if E does not contain either $E_{1,\epsilon}$ or $E_{2,\epsilon}$, then $\nu_{\bar{t}}(E) = 0$, so that the measure $\nu_{\bar{t}}$ is concentrated

on $E_{1,\epsilon}$ and $E_{2,\epsilon}$. Since ϵ is arbitrary, $\nu_{\bar t}(E_{1,\epsilon})$ and $\nu_{\bar t}(E_{2,\epsilon})$ are independent of ϵ, and since (see [11])

$$\nu_{\bar t}(E_1) = \inf_{\epsilon}\{\nu_{\bar t}(E_{1,\epsilon})\}, \qquad \nu_{\bar t}(E_2) = \inf_{\epsilon}\{\nu_{\bar t}(E_{2,\epsilon})\},$$

it follows that the measure $\nu_{\bar t}$ is concentrated on E_1 and E_2, so that (3.15) holds with

$$\lambda_1(\bar t) = \nu_{\bar t}(E_1), \qquad \lambda_2(\bar t) = \nu_{\bar t}(E_2).$$

Moreover, admissibility implies that $|I_{1,k,\epsilon}|+|I_{2,k,\epsilon}| = |I_{1,k,\epsilon}\cup I_{2,k,\epsilon}| = |(\bar t-R, \bar t+R)| = 2R$, and passing to the limit this in turn implies that

$$\lambda_1 + \lambda_2 = 1, \tag{3.18}$$

an identity which is also an immediate consequence of the fact that $\nu_{\bar t}$ is a probability measure. Finally, by (3.13),

$$\dot{\boldsymbol{\xi}}(\bar t\,) = \int_{\mathbb{R}^2} \boldsymbol{w}\, d\nu_{\bar t}(\boldsymbol{w}) = \lambda_1(\bar t\,)\, V_1(\boldsymbol{\xi}(\bar t\,))\boldsymbol{s}_1 + \lambda_2(\bar t\,)\, V_2(\boldsymbol{\xi}(\bar t\,))\boldsymbol{s}_2,$$

from which (3.16) follows. □

Notice that since the velocity of the limit motion is

$$\dot{\boldsymbol{\xi}}(t) = \lambda_1(t)V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 + \lambda_2(t)V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2, \tag{3.19}$$

it follows that the weak limit of a sequence of admissible motions is not necessarily admissible but can be represented as a fine mixture of crystallographic motions in the admissible directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$.

COROLLARY 3.3. *Let S be an attracting curve separating two single slip regions $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$: any sequence of admissible polygonals $\boldsymbol{z}_k(t)$ with directions $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ such that*

$$\operatorname{dist}(\boldsymbol{z}_k(t), S) \to 0, \tag{3.20}$$

uniformly in $t \in [0,T]$ as $k \to +\infty$, converges weak-$*$ in $W^{1,\infty}((0,T),\mathbb{R}^2)$ (and, in particular, uniformly) to a smooth motion $\boldsymbol{\xi}(t)$ on S with velocity

$$\dot{\boldsymbol{\xi}}(t) = \frac{V(\boldsymbol{\xi}(t))}{\boldsymbol{\tau}(\boldsymbol{\xi}(t))\cdot(\boldsymbol{s}_1+\boldsymbol{s}_2)}\ \boldsymbol{\tau}(\boldsymbol{\xi}(t)), \tag{3.21}$$

where $\boldsymbol{\tau}$ is the unit tangent vector to S and $V(\boldsymbol{x}) := V_1(\boldsymbol{x}) = V_2(\boldsymbol{x})$ the speed evaluated at $\boldsymbol{x} \in S$ (see (3.8)). Moreover, the Young measure associated to the sequence $\{\dot{\boldsymbol{z}}_k\}$ is

$$\nu_t = \lambda_1(\boldsymbol{\xi}(t))\,\delta_{V(\boldsymbol{\xi}(t))\boldsymbol{s}_1} + \lambda_2(\boldsymbol{\xi}(t))\,\delta_{V(\boldsymbol{\xi}(t))\boldsymbol{s}_2} \tag{3.22}$$

with

$$\lambda_1(\boldsymbol{x}) = \frac{\boldsymbol{\tau}(\boldsymbol{x})\cdot\boldsymbol{s}_1}{\boldsymbol{\tau}(\boldsymbol{x})\cdot(\boldsymbol{s}_1+\boldsymbol{s}_2)}, \qquad \lambda_2(\boldsymbol{x}) = \frac{\boldsymbol{\tau}(\boldsymbol{x})\cdot\boldsymbol{s}_2}{\boldsymbol{\tau}(\boldsymbol{x})\cdot(\boldsymbol{s}_1+\boldsymbol{s}_2)} \tag{3.23}$$

for a.e. $\boldsymbol{x} \in S$.

Proof. Since every polygonal $\boldsymbol{z}_k$ is admissible, it satisfies (3.2) and (2.10), i.e.,

$$\text{either} \quad \dot{\boldsymbol{z}}_k(t) = V_1(\boldsymbol{z}_k(t))\boldsymbol{s}_1 \quad \text{or} \quad \dot{\boldsymbol{z}}_k(t) = V_2(\boldsymbol{z}_k(t))\boldsymbol{s}_2,$$

for $t \in [0,T]$. Hence, since V_1 and V_2 are bounded in a neighborhood of S, the sequence $\{\boldsymbol{z}_k\}$ is bounded in $W^{1,\infty}((0,T),\mathbb{R}^2)$ (see Proposition 3.1), so that there exists a subsequence (not relabeled) extracted from $\{\boldsymbol{z}_k\}$, converging weak-$*$ to a parametrized curve $\boldsymbol{\xi} \in W^{1,\infty}((0,T),\mathbb{R}^2)$. By (3.20), $\boldsymbol{\xi}(t) \in S$ for all $t \in T$. Writing

$$\dot{\boldsymbol{\xi}} = W\boldsymbol{\ell}, \tag{3.24}$$

with $\boldsymbol{\ell}(t) = \dot{\boldsymbol{\xi}}(t)/|\dot{\boldsymbol{\xi}}(t)|$ the unit vector of $\dot{\boldsymbol{\xi}}(t)$, and applying (3.16) and (3.18) we find

$$\lambda_1 + \lambda_2 = \frac{\dot{\boldsymbol{\xi}} \cdot \boldsymbol{s}_1}{V_1} + \frac{\dot{\boldsymbol{\xi}} \cdot \boldsymbol{s}_2}{V_2} = 1,$$

from which it follows that

$$W = \frac{V_1(\boldsymbol{\xi})V_2(\boldsymbol{\xi})}{\boldsymbol{\ell} \cdot (V_1(\boldsymbol{\xi})\boldsymbol{s}_2 + V_2(\boldsymbol{\xi})\boldsymbol{s}_1)}. \tag{3.25}$$

Also, writing

$$\lambda_1 = \frac{\dot{\boldsymbol{\xi}} \cdot \boldsymbol{s}_1/V_1}{\dot{\boldsymbol{\xi}} \cdot (\boldsymbol{s}_1/V_1 + \boldsymbol{s}_2/V_2)} = \frac{V_2\dot{\boldsymbol{\xi}} \cdot \boldsymbol{s}_1}{\dot{\boldsymbol{\xi}} \cdot (V_2\boldsymbol{s}_1 + V_1\boldsymbol{s}_2)},$$

and recalling (3.24), we also obtain the coefficients of the Young measure associated to $\{\dot{\boldsymbol{z}}_k\}$ in the form

$$\lambda_1 = \frac{V_2(\boldsymbol{\xi})\boldsymbol{\ell} \cdot \boldsymbol{s}_1}{\boldsymbol{\ell} \cdot (V_2(\boldsymbol{\xi})\boldsymbol{s}_1 + V_1(\boldsymbol{\xi})\boldsymbol{s}_2)}, \qquad \lambda_2 = \frac{V_1(\boldsymbol{\xi})\boldsymbol{\ell} \cdot \boldsymbol{s}_2}{\boldsymbol{\ell} \cdot (V_2(\boldsymbol{\xi})\boldsymbol{s}_1 + V_1(\boldsymbol{\xi})\boldsymbol{s}_2)}. \tag{3.26}$$

Now, the function $\boldsymbol{\xi}$ defines a motion on S; hence $\boldsymbol{\ell} = \boldsymbol{\tau}$ (the unit tangent to S) in (3.25) and (3.26), and recalling that $V_1 = V_2 =: V$ on S and S is smooth, we obtain (3.21), (3.22) and (3.23).

Finally, notice that (3.21) uniquely defines a smooth motion on S, and its expression does not depend on the subsequence of $\{\boldsymbol{z}_k\}$ used to construct it. Hence, we can conclude that every converging subsequence has the same limit, so that the original sequence $\{\boldsymbol{z}_k\}$ converges to $\boldsymbol{\xi}$. □

Notice that although each admissible motion $\boldsymbol{z}_k(t)$ does not necessarily satisfy the maximum dissipation criterion for all $t \in [0,T]$, the sequence $\boldsymbol{z}_k$ is a maximizing sequence for the dissipation, since the limit motion $\boldsymbol{\xi}$ satisfies the maximum dissipation criterion (recall, however, that the limit motion is not admissible). To see this, let $J(\boldsymbol{x}) := \boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{s}_1 = \boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{s}_2$ and $V(\boldsymbol{x}) := V_1(\boldsymbol{x}) = V_2(\boldsymbol{x})$ for $\boldsymbol{x} \in S$ (see (3.6)). The maximum dissipation (among all admissible motions) at $\boldsymbol{x} \in S$ is (see (2.11) and (3.4))

$$\max_{\boldsymbol{s} \in \mathcal{C}} \{\hat{V}(\boldsymbol{s}, \boldsymbol{\jmath}(\boldsymbol{x}))\, \boldsymbol{\jmath}(\boldsymbol{x}) \cdot \boldsymbol{s}\} = J(\boldsymbol{x})V(\boldsymbol{x}), \tag{3.27}$$

while the dissipation relative to the limit motion $\boldsymbol{\xi}(t)$ is

$$\boldsymbol{\jmath}(\boldsymbol{\xi}(t)) \cdot \dot{\boldsymbol{\xi}}(t) = \frac{V(\boldsymbol{\xi}(t))}{\boldsymbol{\tau}(\boldsymbol{\xi}(t)) \cdot (\boldsymbol{s}_1 + \boldsymbol{s}_2)}\, \boldsymbol{\jmath}(\boldsymbol{\xi}(t)) \cdot \boldsymbol{\tau}(\boldsymbol{\xi}(t)) = V(\boldsymbol{\xi}(t))J(\boldsymbol{\xi}(t)), \tag{3.28}$$

since $\boldsymbol{\jmath} = J(\boldsymbol{s}_1 + \boldsymbol{s}_2)$, and these expressions coincide at $\boldsymbol{x} = \boldsymbol{\xi}(t)$.

Also, it is not difficult to prove that (3.21) coincides with (2.8). In fact, solving system $(2.8)_2$ and recalling (3.5), we obtain

$$\begin{cases} \alpha_1 = \dfrac{(\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_2}{(\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_2 - (\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_1} = \dfrac{\nabla G\cdot \boldsymbol{s}_2}{\nabla G\cdot \boldsymbol{s}_2 - \nabla G\cdot \boldsymbol{s}_1}, \\ \alpha_2 = \dfrac{-(\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_1}{(\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_2 - (\boldsymbol{s}_2 - \boldsymbol{s}_1)\cdot(\nabla \boldsymbol{\jmath})\boldsymbol{s}_1} = -\dfrac{\nabla G\cdot \boldsymbol{s}_1}{\nabla G\cdot \boldsymbol{s}_2 - \nabla G\cdot \boldsymbol{s}_1}, \end{cases}$$

with G given by (3.5). Now, noting that $\nabla G\cdot \boldsymbol{s}_2 = \nabla G\cdot \boldsymbol{e}_3\times \boldsymbol{s}_1 = -\boldsymbol{e}_3\times \nabla G\cdot \boldsymbol{s}_1 = -|\nabla G|\boldsymbol{\tau}\cdot \boldsymbol{s}_1$, and $\nabla G\cdot \boldsymbol{s}_1 = -\nabla G\cdot \boldsymbol{e}_3\times \boldsymbol{s}_2 = \boldsymbol{e}_3\times \nabla G\cdot \boldsymbol{s}_2 = |\nabla G|\boldsymbol{\tau}\cdot \boldsymbol{s}_2$, we find

$$\alpha_1 = \frac{\boldsymbol{\tau}\cdot \boldsymbol{s}_1}{\boldsymbol{\tau}\cdot \boldsymbol{s}_1 + \boldsymbol{\tau}\cdot \boldsymbol{s}_2}, \qquad \alpha_2 = \frac{\boldsymbol{\tau}\cdot \boldsymbol{s}_2}{\boldsymbol{\tau}\cdot \boldsymbol{s}_1 + \boldsymbol{\tau}\cdot \boldsymbol{s}_2},$$

which yields (3.21), recalling that V_{12} coincides with V in our present notation.

3.4. Sequences of admissible polygonals maximizing the dissipation. In this section we show that every sequence of polygonals maximizing the dissipation converges to the smooth motion $\boldsymbol{\xi}$ on S given by (3.21).

For $\boldsymbol{x}\in\Omega$, let $V_M(\boldsymbol{x})$ and $\boldsymbol{e}_M(\boldsymbol{x})$ denote the speed and direction of motion selected by the maximum dissipation criterion (2.11) among all admissible velocity fields, i.e., such that

$$V_M(\boldsymbol{x})\boldsymbol{e}_M(\boldsymbol{x})\cdot \boldsymbol{\jmath}(\boldsymbol{x}) = \max_{\boldsymbol{s}\in\mathcal{C}}\{\hat{V}(\boldsymbol{s},\boldsymbol{\jmath}(\boldsymbol{x}))\,\boldsymbol{s}\cdot \boldsymbol{\jmath}(\boldsymbol{x})\}, \tag{3.29}$$

where $\hat{V}$ is given by (2.10). Notice that although $\boldsymbol{e}_M(\boldsymbol{x})$ is in general multivalued at S, the maximum dissipation (3.29) is single valued everywhere. Consider the function $D\colon \Omega\times\mathbb{R}^2\to\mathbb{R}$ defined by

$$D(\boldsymbol{x},\boldsymbol{w}) = \boldsymbol{\jmath}(\boldsymbol{x})\cdot(V_M(\boldsymbol{x})\boldsymbol{e}_M(\boldsymbol{x}) - \boldsymbol{w})\,. \tag{3.30}$$

For a given motion $\boldsymbol{z}\in W^{1,\infty}((0,T),\mathbb{R}^2)$ the real function $D(\boldsymbol{z}(t),\dot{\boldsymbol{z}}(t))$ belongs to $L^\infty((0,T),\mathbb{R})$ and measures the difference between the maximum possible dissipation and the actual dissipation at each time.

Fix $\boldsymbol{z}_0\in S$ and consider the set of admissible curves originating from $\boldsymbol{z}_0$:

$$\begin{aligned}\mathcal{A} = \big\{\boldsymbol{z}:[0,T]\to\mathbb{R}^2 :\ & \boldsymbol{z} \text{ piecewise smooth, } \boldsymbol{z}(0) = \boldsymbol{z}_0\in S \quad \text{and} \\ & \text{either} \quad \dot{\boldsymbol{z}}(t) = V_1(\boldsymbol{z}(t))\boldsymbol{s}_1 \quad \text{or} \quad \dot{\boldsymbol{z}}(t) = V_2(\boldsymbol{z}(t))\boldsymbol{s}_2,\ t\in[0,T]\big\}\,,\end{aligned}$$

where $\dot{\boldsymbol{z}}$ denotes the right time derivative at corner points of the polygonals.

By definition

$$D(\boldsymbol{z}(t),\dot{\boldsymbol{z}}(t))\geq 0 \qquad \forall \boldsymbol{z}\in\mathcal{A},\forall t\in[0,T], \tag{3.31}$$

although D can be negative for some nonadmissible motion.

Consider now the functional associated to D,

$$E(\boldsymbol{z}) = \int_0^T D(\boldsymbol{z}(t),\dot{\boldsymbol{z}}(t))\,dt = \int_0^T \boldsymbol{\jmath}(\boldsymbol{z}(t))\cdot(V_M(\boldsymbol{z}(t))\boldsymbol{e}_M(\boldsymbol{z}(t)) - \dot{\boldsymbol{z}}(t))\,dt, \tag{3.32}$$

defined for $\boldsymbol{z} \in W^{1,\infty}((0,T),\mathbb{R}^2)$. By the discussion following (3.7), no admissible motion satisfying the maximum dissipation criterion can originate from S, so that E is strictly positive on $\mathcal{A}$. Indeed, as we shall show in the next section,

$$\inf_{\boldsymbol{z}\in\mathcal{A}} E(\boldsymbol{z}) = 0, \tag{3.33}$$

and the infimum is not attained on $\mathcal{A}$.

THEOREM 3.4. *Any sequence of admissible polygonals $\{\boldsymbol{z}_k\} \subset \mathcal{A}$ minimizing E (or, equivalently, maximizing the dissipation), i.e., such that*

$$\lim_{k\to+\infty} E(\boldsymbol{z}_k) = 0, \tag{3.34}$$

converges weak-$*$ in $W^{1,\infty}((0,T),\mathbb{R}^2)$ to the smooth motion $\boldsymbol{\xi}(t)$ on S, whose velocity is (3.21).

Proof. By Corollary 3.3, it is enough to prove that every sequence of admissible curves $\{\boldsymbol{z}_k\}$ minimizing E converges to a motion on S.

Notice first that, by Proposition 3.1, $\mathcal{A}$ is bounded in $W^{1,\infty}((0,T),\mathbb{R}^2)$, and every sequence $\{\boldsymbol{z}_k\} \subset \mathcal{A}$ admits a subsequence (not relabeled) which converges weak-$*$ in $W^{1,\infty}((0,T),\mathbb{R}^2)$ to a (in general nonadmissible) Lipschitz motion $\boldsymbol{\xi}$. In particular,

$$\lim_{k\to+\infty} \int_I \dot{\boldsymbol{z}}_k(t)\,dt = \int_I \dot{\boldsymbol{\xi}}(t)\,dt$$

for every interval $I \subset [0,T]$, and by Theorem 3.2 (see (3.19)),

$$\dot{\boldsymbol{\xi}}(t) = \lambda_1(t)\,V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 + \lambda_2(t)\,V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2. \tag{3.35}$$

Assume now that $\{\boldsymbol{z}_k\}$ is a minimizing sequence for E. Since all $\boldsymbol{z}_k$ are admissible, the integrand $D(\boldsymbol{z}_k(t),\dot{\boldsymbol{z}}_k(t))$ is nonnegative for all t, so that (3.34) is equivalent to weak-$*$ convergence of $D(\boldsymbol{z}_k(t),\dot{\boldsymbol{z}}_k(t))$ to zero, i.e.,

$$\lim_{k\to+\infty} \int_I D(\boldsymbol{z}_k(t),\dot{\boldsymbol{z}}_k(t))\,dt = 0,$$

for every interval $I \subset [0,T]$. Moreover, since $D(\boldsymbol{x},\boldsymbol{w})$ is continuous with respect to $\boldsymbol{x}$ and affine in $\boldsymbol{w}$, it is continuous under weak-$*$ convergence, and

$$\lim_{k\to+\infty} \int_I D(\boldsymbol{z}_k(t),\dot{\boldsymbol{z}}_k(t))\,dt = \int_I D(\boldsymbol{\xi}(t),\dot{\boldsymbol{\xi}}(t))\,dt.$$

Hence,

$$\int_I D(\boldsymbol{\xi}(t),\dot{\boldsymbol{\xi}}(t))\,dt = 0 \tag{3.36}$$

for any interval $I \subset [0,T]$.

We now show by contradiction that $\boldsymbol{\xi}(t) \in S$ for all $t \in [0,T]$. Suppose, to fix ideas, that $\boldsymbol{\xi}(t) \in R(\boldsymbol{s}_1)$ for $t \in (0,\epsilon)$, and recall that $\boldsymbol{\xi}(0) \in S$. Since by definition $V_M(\boldsymbol{x})\boldsymbol{\jmath}(\boldsymbol{x})\cdot\boldsymbol{e}_M(\boldsymbol{x}) = V_1(\boldsymbol{x})\boldsymbol{s}_1\cdot\boldsymbol{\jmath}(\boldsymbol{x})$ in $R(\boldsymbol{s}_1)$, (3.36) yields

$$\int_0^\epsilon \boldsymbol{\jmath}(\boldsymbol{\xi}(t))\cdot(V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 - \dot{\boldsymbol{\xi}}(t))\,dt = 0,$$

which becomes in turn, by (3.35),

$$0 = \int_0^\epsilon \boldsymbol{\jmath}(\boldsymbol{\xi}(t)) \cdot ((1-\lambda_1(t))V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 - \lambda_2(t)\, V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2)\; dt$$
$$= \int_0^\epsilon (1-\lambda_1(t))\,(V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 \cdot \boldsymbol{\jmath}(\boldsymbol{\xi}(t)) - V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2 \cdot \boldsymbol{\jmath}(\boldsymbol{\xi}(t)))\; dt,$$

and since $V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 \cdot \boldsymbol{\jmath}(\boldsymbol{\xi}(t)) > V_2(\boldsymbol{\xi}(t))\boldsymbol{s}_2 \cdot \boldsymbol{\jmath}(\boldsymbol{\xi}(t))$ in $R(\boldsymbol{s}_1)$, the integrand is nonnegative, and we obtain

$$\lambda_1(t) = 1, \quad \lambda_2(t) = 0,$$

a.e. in $(0,\epsilon)$. Hence $\boldsymbol{\xi}$ is admissible and

$$\dot{\boldsymbol{\xi}}(t) = V_1(\boldsymbol{\xi}(t))\boldsymbol{s}_1 \quad \text{and} \quad \boldsymbol{\xi}(0) \in S,$$

which is a contradiction since, by $(3.7)_2$, any admissible motion in the direction $\boldsymbol{s}_1$ originating from S necessarily occurs in the region $R(\boldsymbol{s}_2)$ for some time interval containing $t = 0$. Repeating this argument for any interval $[\epsilon, \epsilon']$, it follows that $\boldsymbol{\xi}(t) \in S$ for each $t \in [0,T]$, so that, in particular, $\operatorname{dist}(\boldsymbol{z}_k(t), S) \to 0$ uniformly in t, and we can apply Corollary 3.3 to obtain the thesis. □

4. Explicit construction of a sequence of polygonals maximizing the dissipation. The results of the previous section provide a theoretical justification of the evolution equation (2.8) postulated in [2] for a dislocation moving on an attracting curve, but they can also be used to motivate a simple numerical scheme which involves only a time-discretized ODE solver of the dynamical system (2.5).

The idea is as follows. Assume that the field $\boldsymbol{\jmath}$, and by consequence the vector field $\boldsymbol{V}(\boldsymbol{x})$ in (2.6), is known. Since, away from the attracting curve, the motion of the dislocation is a solution of the dynamical system (2.5), it can be computed by any time-discretized numerical method for ODEs, for instance a simple Euler method. To be specific, choose an initial point in $R(\boldsymbol{s}_1)$, and propagate the dislocation along $\boldsymbol{s}_1$ by solving numerically (2.5) with time step h. Since S is an attracting curve, the solution $\boldsymbol{z}(t)$ approaches S as time increases. At some time t_0, it happens that $\boldsymbol{z}(t_0) \in R(\boldsymbol{s}_1)$, but $\boldsymbol{z}(t_0+h)$, which is obtained by propagating $\boldsymbol{z}(t_0)$ using $\boldsymbol{V}(\boldsymbol{z}(t_0)) = V_1(\boldsymbol{z}(t_0))\boldsymbol{s}_1$, belongs to $R(\boldsymbol{s}_2)$. In other terms, since the time steps are discretized, the dislocation crosses S and moves for a time interval strictly smaller than h along $\boldsymbol{s}_1$ into the region $R(\boldsymbol{s}_2)$, thereby violating the maximum dissipation criterion.

At the next iterative step, the point $\boldsymbol{z}(t_0+h) \in R(\boldsymbol{s}_2)$ is propagated in the $\boldsymbol{s}_2$ direction using the "correct" value $\boldsymbol{V}(\boldsymbol{z}(t_0+h)) = V_2(\boldsymbol{z}(t_0+h))\boldsymbol{s}_2$ and again approaches the attractor S. Iterating the procedure, we obtain a zig-zag approximation of the motion near the attracting curve S, which only requires the knowledge of the vector field (2.6) away from S.

This motion is a numerical approximation of an admissible polygonal, which however does not satisfy the maximum dissipation criterion at all times. The purpose of this section is to construct a sequence of admissible polygonals consistent with the above argument and to show that it maximizes the dissipation as the time step $h \to 0$, which implies in turn that, by Theorem 3.4, it converges as $h \to 0$ to the smooth non-admissible motion on S given by (3.21).

We now make this idea precise. Let S be an attracting curve separating $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$ as in section 3.1. Fix $h = T/k$ with k integer, and choose $\boldsymbol{z}_0 = x_0\boldsymbol{s}_1 + y_0\boldsymbol{s}_2 \in S$.

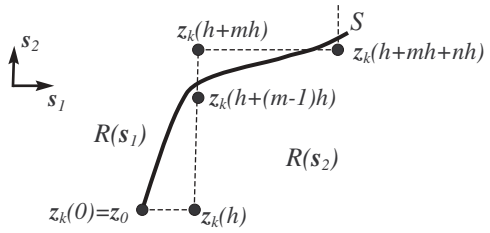

FIG. 4.1. *Approximating polygonal.*

For $t \in [0, h)$, let $\boldsymbol{z}_k(t)$ be the rectilinear motion in the direction $\boldsymbol{s}_1$ solution of

$$\dot{\boldsymbol{z}} = V_1(\boldsymbol{z})\boldsymbol{s}_1$$

with initial condition $\boldsymbol{z}_0$, i.e., writing $\boldsymbol{z}_k(t) = x_k(t)\boldsymbol{s}_1 + y_k(t)\boldsymbol{s}_2$,

$$\begin{cases} x_k(t) \text{ is defined by} \quad t = \displaystyle\int_{x_0}^{x_k(t)} \frac{d\xi}{V_1(\boldsymbol{z}_0 + (\xi - x_0)\boldsymbol{s}_1)}, \qquad t \in [0, h). \\ y_k(t) \equiv y_0, \end{cases}$$

Since, by (3.7), $\boldsymbol{s}_1$ at S points into the single slip region $R(\boldsymbol{s}_2)$, it follows that $\boldsymbol{z}_k(t) \in R(\boldsymbol{s}_2)$ for $t \in [0, h)$. Should the motion continue along $\boldsymbol{s}_1$, it would further violate the maximum dissipation criterion, and therefore at time $t = h$ the motion switches to the preferred direction $\boldsymbol{s}_2$. Consider now the solution of

$$\dot{\boldsymbol{z}} = V_2(\boldsymbol{z})\boldsymbol{s}_2$$

for $t \geq h$, with initial condition $\boldsymbol{z}_k(h)$, and denote this solution by $\bar{\boldsymbol{z}}(t)$. Since S is an attractor for $R(\boldsymbol{s}_2)$, there exists a time $\bar{t}$ such that $\bar{\boldsymbol{z}}(\bar{t}) \in S$, so that there exists an integer m such that $\bar{\boldsymbol{z}}(h + (m-1)h) \in R(\boldsymbol{s}_2)$ but $\bar{\boldsymbol{z}}(h + mh) \in R(\boldsymbol{s}_1)$. We let $\boldsymbol{z}_k(t) = \bar{\boldsymbol{z}}(t)$ for $t \in [h, h + mh]$, i.e.,

$$\begin{cases} x_k(t) \equiv x_k(h), \\ y_k(t) \text{ defined by} \quad t - h = \displaystyle\int_{y_k(h)}^{y_k(t)} \frac{d\eta}{V_2(\boldsymbol{z}_k(h) + (\eta - y_k(h))\boldsymbol{s}_2)}, \qquad t \in [h, h + mh). \end{cases}$$

Again, since $\boldsymbol{z}_k(h + mh) \in R(\boldsymbol{s}_1)$, to satisfy the maximum dissipation criterion the motion switches to the preferred direction $\boldsymbol{s}_1$ at time $t = h + mh$ and moves toward the attractor S (Figure 4.1).

The above procedure can now be iterated, and we obtain an admissible polygonal

$$\boldsymbol{z}_k(t) = x_k(t)\boldsymbol{s}_1 + y_k(t)\boldsymbol{s}_2, \tag{4.1}$$

defined on all $[0, T]$, where $x_k(t)$ and $y_k(t)$ are defined by relations analogous to (3.9) and (3.10), with the τ_i now integer multiples of h.

PROPOSITION 4.1. *The sequence of polygonals* $\{\boldsymbol{z}_k\}$ *defined by* (4.1) *converges to* S*, i.e.,*

$$\operatorname{dist}(\boldsymbol{z}_k(t), S) \to 0, \tag{4.2}$$

uniformly in $t \in [0, T]$*, as* $k \to +\infty$.

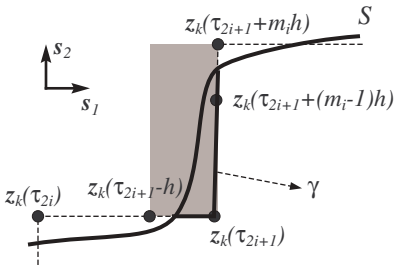

FIG. 4.2. *Proof of Proposition* 4.1.

Proof. We know that $V_1(\boldsymbol{x})$ and $V_2(\boldsymbol{x})$ are bounded in a neighborhood $\mathcal{U}$ of S, and we denote by $W = \max(\max_{\mathcal{U}} V_1, \max_{\mathcal{U}} V_2)$ the maximum speed in $\mathcal{U}$. Also, denote by $U = \min(\min_{\mathcal{U}} V_1, \min_{\mathcal{U}} V_2)$ the minimum speed in $\mathcal{U}$, and assume that $U > 0$.

Consider a typical portion γ of the polygonal $\boldsymbol{z}_k(t)$ lying in $\mathcal{U}$ between two successive intersections with S (Figure 4.2). Assume, to fix ideas, that $\gamma \in R(\boldsymbol{s}_2)$, so that the first intersection with S occurs in the portion of γ parallel to $\boldsymbol{s}_1$, with the second intersection occurring in the portion of γ parallel to $\boldsymbol{s}_2$. Let $[\tau_{2i}, \tau_{2i+1}]$ and $[\tau_{2i+1}, \tau_{2i+2}]$ be the time intervals corresponding to the rectilinear segments of $\boldsymbol{z}_k$ parallel to $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$, respectively, and such that $\tau_{2i+1} - \tau_{2i} = n_i h$ and $\tau_{2i+2} - \tau_{2i-1} = m_i h$, with n_i and m_i integers (see (3.9) and (3.10)).

Notice now that (3.7) is equivalent to

$$\boldsymbol{s}_1 \cdot \boldsymbol{\tau}(\boldsymbol{x}) > 0, \qquad \boldsymbol{s}_2 \cdot \boldsymbol{\tau}(\boldsymbol{x}) > 0, \qquad \boldsymbol{x} \in S,$$

with $\boldsymbol{\tau}$ the tangent vector to S, and this in turn implies that, since S is bounded, there exists $\alpha > 0$ such that $\alpha < \boldsymbol{s}_1 \cdot \boldsymbol{\tau}(\boldsymbol{x})$ and $\boldsymbol{s}_2 \cdot \boldsymbol{\tau}(\boldsymbol{x}) < 1 - \alpha$.

Hence, the portion of S between two successive intersections with the polygonal lies in the shaded rectangle in Figure 4.2, and

$$\operatorname{dist}(\boldsymbol{x}, S) \le |\boldsymbol{z}_k(\tau_{2i+1} + m_i h) - \boldsymbol{z}_k(\tau_{2i+1} - h)|, \qquad \boldsymbol{x} \in \gamma.$$

But

$$\begin{aligned} |\boldsymbol{z}_k(\tau_{2i+1} + m_i h) - \boldsymbol{z}_k(\tau_{2i+1} - h)| &\le |\boldsymbol{z}_k(\tau_{2i+1}) - \boldsymbol{z}_k(\tau_{2i+1} - h)| \\ &+ |\boldsymbol{z}_k(\tau_{2i+1} + m_i h) - \boldsymbol{z}_k(\tau_{2i+1})| \le Wh + Wm_i h = Wh(1 + m_i). \end{aligned}$$

To prove the thesis it is enough to show that all m_i are bounded as $k \to +\infty$ (or equivalently $h \to 0$). But this is true since (see Figure 4.2)

$$\frac{U(m_i - 1)h}{Wh} \le \frac{y_k(\tau_{2i+1} + (m_i - 1)h) - y_k(\tau_{2i+1})}{x_k(\tau_{2i+1}) - x_k(\tau_{2i+1} - h)} \le \max_{\boldsymbol{x} \in S} \frac{\boldsymbol{s}_2 \cdot \boldsymbol{\tau}(\boldsymbol{x})}{\boldsymbol{s}_1 \cdot \boldsymbol{\tau}(\boldsymbol{x})} \le \frac{1 - \alpha}{\alpha},$$

an analogous assertion holding for n_i. This proves uniform convergence. ∎

We can now apply Corollary 3.3 to conclude that the sequence $\{\boldsymbol{z}_k(t)\}$ converges uniformly to the smooth motion $\boldsymbol{\xi}$ on S, and the discussion in the paragraph containing (3.27) and (3.28) can be used to show that $\{\boldsymbol{z}_k(t)\}$ maximizes the dissipation.

The following proposition is an independent proof of the maximizing property.

PROPOSITION 4.2. *The sequence of polygonals* $\{\boldsymbol{z}_k\}$ *defined by* (4.1) *maximizes the dissipation, i.e.,*

$$\lim_{k \to +\infty} E(\boldsymbol{z}_k) = 0. \tag{4.3}$$

Proof. Denote by

$$D_k(t) := D(\boldsymbol{z}_k(t), \dot{\boldsymbol{z}}_k(t))$$

the integrand of E. We shall prove that $D_k(t) \to 0$ uniformly in t (in particular, strongly in $L^\infty((0,T),\mathbb{R})$). Indeed, for each k, $D_k(t) = 0$ except when the maximum dissipation criterion is not satisfied, i.e., for those time intervals A_q, $q = 1, \dots, Q$, for which motion occurs in the $\boldsymbol{s}_1$ direction but $\boldsymbol{z}_k(t) \in R(\boldsymbol{s}_2)$, and for those time intervals B_q, $q = 1, \dots, Q$, for which motion occurs in the $\boldsymbol{s}_2$ direction but $\boldsymbol{z}_k(t) \in R(\boldsymbol{s}_1)$. Notice that $|A_q|, |B_q| < h$ by construction. Hence, we can write

$$D_k(t) = \begin{cases} 0, & t \in [0,T] \setminus (\cup_q (A_q \cup B_q)), \\ \boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (V_2(\boldsymbol{z}_k(t))\boldsymbol{s}_2 - V_1(\boldsymbol{z}_k(t))\boldsymbol{s}_1), & t \in \cup_q A_q, \\ \boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (V_1(\boldsymbol{z}_k(t))\boldsymbol{s}_1 - V_2(\boldsymbol{z}_k(t))\boldsymbol{s}_2), & t \in \cup_q B_q. \end{cases}$$

On the other hand, by (3.8),

$$\begin{aligned} &\boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (V_2(\boldsymbol{z}_k(t))\boldsymbol{s}_2 - V_1(\boldsymbol{z}_k(t))\boldsymbol{s}_1) \\ &\quad = M\big[\boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (\boldsymbol{s}_2 - \boldsymbol{s}_1)\big]\,\big[\boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (\boldsymbol{s}_2 + \boldsymbol{s}_1) - F\big] = G(\boldsymbol{z}_k(t))\, Z(t) \end{aligned}$$

with $Z(t) = M[\boldsymbol{\jmath}(\boldsymbol{z}_k(t)) \cdot (\boldsymbol{s}_2 + \boldsymbol{s}_1) - F]$ and G defined by (3.5). Notice that $0 < Z(t) < C$ for some constant C. Hence we can write

$$D_k(t) = \begin{cases} 0, & t \in [0,T] \setminus (\cup_q (A_q \cup B_q)), \\ Z(t)|G(\boldsymbol{z}_k(t))|, & t \in \cup_q (A_q \cup B_q). \end{cases}$$

Write $A_q = [t_1, t_2]$, so that $\boldsymbol{z}_k(t_1) \in S$ and $\boldsymbol{z}_k(t) \in R(\boldsymbol{s}_2)$ for $t_1 < t \le t_2$. Since G is smooth and $\boldsymbol{z}_k(t)$ is also smooth for $t \in A_q$,

$$G(\boldsymbol{z}_k(t)) = G(\boldsymbol{z}_k(t_1)) + \big[\nabla G(\boldsymbol{z}_k(t_1)) \cdot \boldsymbol{s}_1\big]\,\big[V_1(\boldsymbol{z}_k(t_1))(t - t_1)\big] + o(h).$$

But ∇G and V_1 are bounded in a neighborhood of S, and $G(\boldsymbol{z}_k(t_1)) = 0$ since $\boldsymbol{z}_k(t_1) \in S$, and $t - t_1 < h$. Hence there exists a constant $K > 0$ such that

$$0 \le D_k(t) < Kh \quad \forall t \in [0,T],$$

and $D_k(t) \to 0$ uniformly in t as $k \to +\infty$ (i.e., as $h \to 0$), and the thesis is proved. ∎

5. Numerical simulations. In this section we present the results of numerical simulations of (2.1) and (2.5) for two different plane domains. The basic steps are as follows:

- We solve the Neumann problem (2.1) by a finite element method, for each position $\boldsymbol{z}$ of the dislocation varying on a square grid in Ω. The result is then inserted into (2.4) to determine the Peach–Köhler force $\boldsymbol{\jmath}$ on the same grid.
- Once the force field has been determined, the velocity field $\boldsymbol{V}$ in (2.6) results by projecting the force onto the crystallographic directions $\boldsymbol{s}_i \in \mathcal{C}$ and choosing the actual direction of motion by the maximum dissipation criterion. Plotting $\boldsymbol{V}$ in Ω gives some information about the phase portrait of the dynamical system (2.5), such as the form of the single slip regions, and the presence of cross-slip or attracting curves.

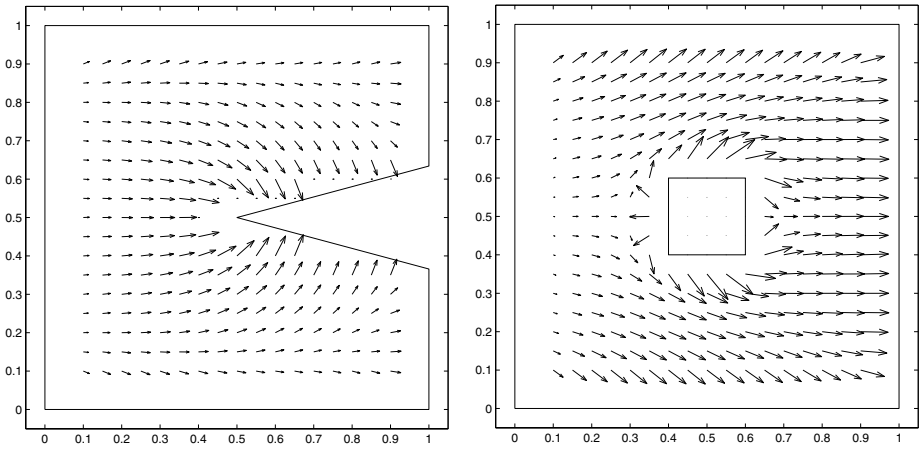

FIG. 5.1. *Plot of the vector field $\boldsymbol{\jmath}$ in Ω corresponding to shear stress boundary conditions $\sigma_0 = -1$ on the lower side of the square, $\sigma_0 = 1$ on the upper side, and $\sigma_0 = 0$ elsewhere. Left: cracked domain; right: domain clamped to a rigid inclusion.*

- Finally, we solve the dynamical system (2.5) numerically for initial conditions near an attracting curve S. We use Euler and Runge–Kutta methods in which the values of the velocity field $\boldsymbol{V}$ are determined again by solving (2.1) at each time step. Indeed, consistent with the discussion in section 4, the solution oscillates finely along the attracting curve.

In particular, we assume without loss of generality that[5]

$$M = 1, \quad F = 0,$$

and the involved domains have the following form:

(i) The first is a square domain without a wedge of angle ψ_0, i.e.,

$$\Omega = Q \backslash \left\{ (x,y) : \frac{1}{2} \le x \le 1, \frac{1}{2} - \left(\tan\frac{\psi_0}{2}\right)\left(x - \frac{1}{2}\right) \le y \le \frac{1}{2} + \left(\tan\frac{\psi_0}{2}\right)\left(x - \frac{1}{2}\right) \right\},$$

where $Q = [0,1] \times [0,1]$, and with boundary conditions

$$\sigma_0 = \begin{cases} +1 & \text{on the upper side of } Q : \{y = 1\}, \\ -1 & \text{on the lower side of } Q : \{y = 0\}, \\ 0 & \text{otherwise.} \end{cases}$$

In terms of the original three-dimensional cylindrical body, this corresponds to a shear force parallel to $\boldsymbol{e}_3$ applied to two opposite sides of the cylinder.

The field $\boldsymbol{\jmath}(\boldsymbol{x})$ representing the force on a screw dislocation in Ω is plotted in Figure 5.1 (left).

Assuming that the set $\mathcal{C}$ of crystallographic directions is as in (3.3), with $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ now given by

$$\boldsymbol{s}_1 = \frac{1}{\sqrt{2}}(\boldsymbol{e}_1 - \boldsymbol{e}_2), \qquad \boldsymbol{s}_2 = \frac{1}{\sqrt{2}}(\boldsymbol{e}_1 + \boldsymbol{e}_2), \tag{5.1}$$

[5] M is the mobility of the dislocation, which can be adjusted by rescaling time; F is the Peierls–Nabarro threshold: when $F > 0$ there are regions in which $\boldsymbol{V}(\boldsymbol{x}) = \boldsymbol{0}$ and the dislocation does not move, but elsewhere the phase portrait remains qualitatively the same as when $F = 0$.

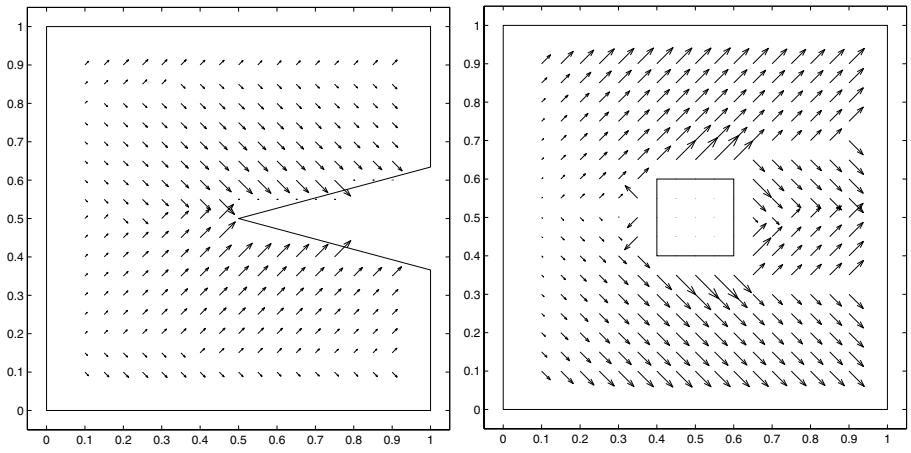

FIG. 5.2. *Plot of the vector field* $\boldsymbol{V}$ *in* Ω (*same boundary conditions as above*) *with crystallographic directions* $\boldsymbol{s}_1 = \frac{1}{\sqrt{2}}(\boldsymbol{e}_1 - \boldsymbol{e}_2)$ *and* $\boldsymbol{s}_2 = \frac{1}{\sqrt{2}}(\boldsymbol{e}_1 + \boldsymbol{e}_2)$. *Left: cracked domain; right: domain with a rigid inclusion.*

the resulting velocity field $\boldsymbol{V}(\boldsymbol{x})$ is plotted in Figure 5.2 (left). Notice that as $\psi_0 \to 0$ the domain becomes a square with a planar crack. Indeed, near the tip of the wedge, our results are consistent with the qualitative behavior of the analytical solution (6.2): the segment $S = \{0 < x < 1/2, y = 1/2\}$ is an attracting curve (see the next section).

Finally, we show in Figure 5.3 (left) some trajectories of the vector field (2.6). The trajectories have been computed by the Euler method. Notice that one of the trajectories is a fine polygonal oscillating near the attracting curve $y = 1/2$.

(ii) The second domain is a square clamped to a rigid inclusion:

$$\Omega = Q \setminus Q' \quad \text{with} \quad Q' = \left\{(x,y) : \frac{1}{2} - \frac{L}{2} \le x \le \frac{1}{2} + \frac{L}{2},\ \frac{1}{2} - \frac{L}{2} \le y \le \frac{1}{2} + \frac{L}{2}\right\},$$

and with Neumann conditions on the boundary of the outer square ∂Q,

$$\sigma_0 = \begin{cases} +1 & \text{on the upper side of } Q : \{y = 1\}, \\ -1 & \text{on the lower side of } Q : \{y = 0\}, \\ 0 & \text{on the lateral sides of } Q : \{x = 0\} \text{ and } \{x = 1\}, \end{cases}$$

and tangential-derivative conditions on the boundary of the inclusion Q', of the form

$$\boldsymbol{t} \cdot \nabla u = -\boldsymbol{g}_0 \cdot \boldsymbol{t} \quad \text{on} \quad \partial Q', \tag{5.2}$$

where $\boldsymbol{t}$ is the unit tangent vector to $\partial Q'$ and $\boldsymbol{g}_0$ is given by (2.2). The boundary conditions (5.2) may be interpreted as displacement boundary conditions, which correspond to clamping the cylinder to a rigid inclusion.

Notice in fact that, for any fixed $\boldsymbol{z}_0 \in \Omega$, the loop $\partial Q'$ does not encircle the singularity at $\boldsymbol{z}_0$. Hence, letting $\boldsymbol{g} = \boldsymbol{g}_0(\boldsymbol{x}, \boldsymbol{z}_0) + \nabla u(\boldsymbol{x}, \boldsymbol{z}_0)$, there exists a function w on $\partial Q'$ such that $\boldsymbol{g} \cdot \boldsymbol{t} = dw/ds$, with s the arc parameter on $\partial Q'$. Interpreting w as the total displacement at the boundary of Q', the condition $w = \text{const.}$ on $\partial Q'$ is equivalent to $dw/ds = 0$, which corresponds to (5.2).

The field $\boldsymbol{\jmath}(\boldsymbol{x})$ representing the force on a screw dislocation is plotted in Figure 5.1 (right). Assuming again that the set of crystallographic directions is as in (5.1), the resulting velocity field $\boldsymbol{V}(\boldsymbol{x})$ is plotted in Figure 5.2 (right).

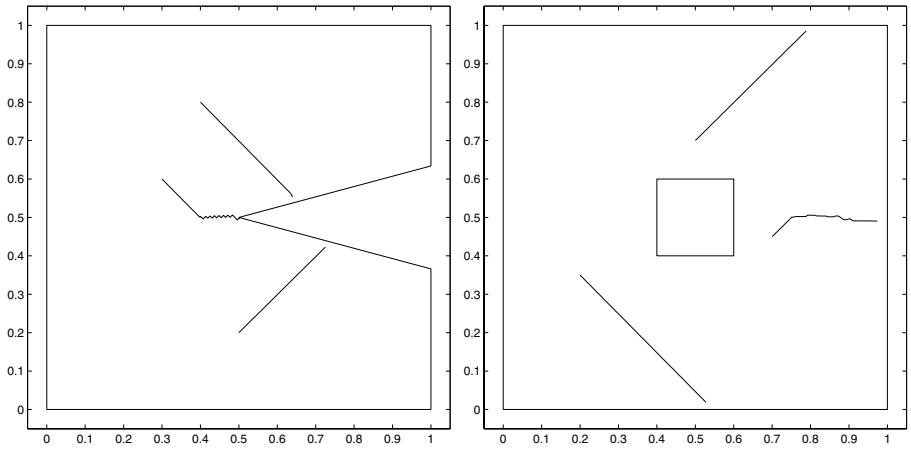

FIG. 5.3. *Some trajectories of the vector field* $\boldsymbol{V}$ *for a cracked domain and a domain with a rigid inclusion.*

Finally, we show in Figure 5.3 (right) some trajectories of the vector field (2.5). The trajectories have been computed by the Euler method. As before, notice that one of the trajectories is a fine polygonal oscillating near the attracting curve $y = 1/2$.

6. An explicit solution for a dislocation in an infinite domain with a crack. The dynamical system governing the motion of a single dislocation can be determined explicitly for some simple geometries, such as an unbounded domain with a rectilinear crack (corresponding to an unbounded cylinder with a plane crack parallel to the axis of the cylinder). Consider the plane domain

$$\Omega = \mathbb{R}^2 \setminus \{x \geq 0, y = 0\}$$

and rewrite (2.1), with $\sigma_0 = 0$, in the form

$$\begin{cases} \operatorname{Div} \boldsymbol{g} = 0 & \text{in } \Omega \setminus \{\boldsymbol{z}\}, \\ \boldsymbol{g} \cdot \boldsymbol{n} = 0 & \text{at } \partial\Omega \end{cases} \tag{6.1}$$

with $\boldsymbol{g} = \boldsymbol{g}_0 + \nabla u$ and $\boldsymbol{z} = (x_0, y_0) \in \Omega$. The explicit solution of (6.1) can be obtained using complex variables, by the procedure outlined in [1] as follows. Letting

$$\boldsymbol{g}(\boldsymbol{x}) = g_1(\boldsymbol{x})\boldsymbol{e}_1 + g_2(\boldsymbol{x})\boldsymbol{e}_2 \quad \text{with } \boldsymbol{x} = (x, y),$$

denote by $g = g(w)$ the complex function defined by

$$g(w) = g_1(w) - ig_2(w) \quad \text{with } w = x + iy.$$

Then it can be proved that [1]

$$g(w) = \frac{b}{2\pi i}\left(\frac{h'(w)}{h(w) - h(z)} + \frac{\bar{h}(z)h'(w)}{1 - \bar{h}(z)h(w)}\right),$$

where $h(w)$ is a conformal mapping from Ω into the unit disk and $z = x_0 + iy_0$. In particular, we may choose

$$h(w) = \frac{1 + i\sqrt{w}}{1 - i\sqrt{w}}$$

with $\sqrt{w}$ the principal determination of the complex square root, i.e., $\sqrt{w} = \sqrt{r}e^{i\varphi/2}$ for $w = re^{i\varphi}$ and $0 < \varphi < 2\pi$. We obtain

$$g(w) = \frac{b}{4\pi i\sqrt{w}} \frac{\sqrt{z} - \overline{\sqrt{z}}}{(\sqrt{w} - \sqrt{z})(\sqrt{w} - \overline{\sqrt{z}})}.$$

Notice that, near the tip of the crack, for $w = re^{i\varphi}$, the solution is singular:

$$|\boldsymbol{g}| \sim \frac{1}{\sqrt{r}} \quad \text{as} \quad r \to 0.$$

The same technique allows us to compute explicitly the force on the dislocation. Write

$$\boldsymbol{\jmath}(\boldsymbol{z}) = j_1(\boldsymbol{z})\boldsymbol{e}_1 + j_2(\boldsymbol{z})\boldsymbol{e}_2,$$

and consider the corresponding complex function

$$j(z) = j_1(z) - ij_2(z) \quad \text{with } z = \ x_0 + iy_0.$$

Then it can be proved that [1]

$$j(z) = \frac{b^2}{2\pi} \left\{ \frac{h''(z)}{2h'(z)} + \frac{\bar{h}(z)h'(z)}{1 - |h(z)|^2} \right\}$$

with $h(z)$ the conformal mapping from Ω into the unit disk introduced above. A lengthy calculation yields

$$\begin{aligned} j(z) &= \frac{b^2(-3\sqrt{z} + \overline{\sqrt{z}})}{8\pi z(\sqrt{z} - \overline{\sqrt{z}})} = \frac{ib^2}{16\pi r_0 \sin(\varphi_0/2)}(3e^{-i\varphi_0/2} - e^{-3i\varphi_0/2}) \\ &= \frac{b^2}{16\pi r_0 \sin(\varphi_0/2)} \left\{ \left(3\sin\frac{\varphi_0}{2} - \sin\frac{3\varphi_0}{2} \right) + i\left(3\cos\frac{\varphi_0}{2} - \cos\frac{3\varphi_0}{2} \right) \right\} \end{aligned}$$

for $z = r_0 e^{i\varphi_0}$, from which it follows that the Cartesian components of the force on a dislocation at $\boldsymbol{z} = r_0(\cos\varphi_0, \sin\varphi_0)$ are given by

(6.2)
$$\boldsymbol{\jmath}(\boldsymbol{z}) = \frac{b^2}{16\pi r_0 \sin(\varphi_0/2)} \left\{ \left(3\sin\frac{\varphi_0}{2} - \sin\frac{3\varphi_0}{2} \right) \boldsymbol{e}_1 + \left(-3\cos\frac{\varphi_0}{2} + \cos\frac{3\varphi_0}{2} \right) \boldsymbol{e}_2 \right\}.$$

Notice that $\boldsymbol{\jmath}$ is singular at the crack tip, as $r_0 \to 0$, and at the crack boundary, as $\varphi_0 \to 0, 2\pi$.

To determine the phase portrait, we must determine the single slip regions and their boundaries. Assuming that the set $\mathcal{C}$ of crystallographic directions is (3.3), with $\boldsymbol{s}_1$ and $\boldsymbol{s}_2$ given by (5.1), the single slip regions and the attracting curves can be determined explicitly. In fact, computing $\boldsymbol{\jmath} \cdot \boldsymbol{s}_1$ and $\boldsymbol{\jmath} \cdot \boldsymbol{s}_2$, we obtain

$$\boldsymbol{\jmath}(r_0, \varphi_0) \cdot \boldsymbol{s}_1 > \boldsymbol{\jmath}(r_0, \varphi_0) \cdot \boldsymbol{s}_2 \Leftrightarrow \cos\frac{\varphi_0}{2} \left(3 - 2\cos^2\frac{\varphi_0}{2} \right) > 0 \Leftrightarrow \varphi_0 \in (0, \pi),$$

so that the single slip regions $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$ are the upper and lower half-plane, respectively.

The curve S separating $R(\boldsymbol{s}_1)$ and $R(\boldsymbol{s}_2)$ is an attracting curve, given by the relation $\boldsymbol{\jmath}(r_0, \varphi_0) \cdot \boldsymbol{s}_1 = \boldsymbol{\jmath}(r_0, \varphi_0) \cdot \boldsymbol{s}_2$, and is therefore the negative real half-line $\varphi_0 = \pi$.

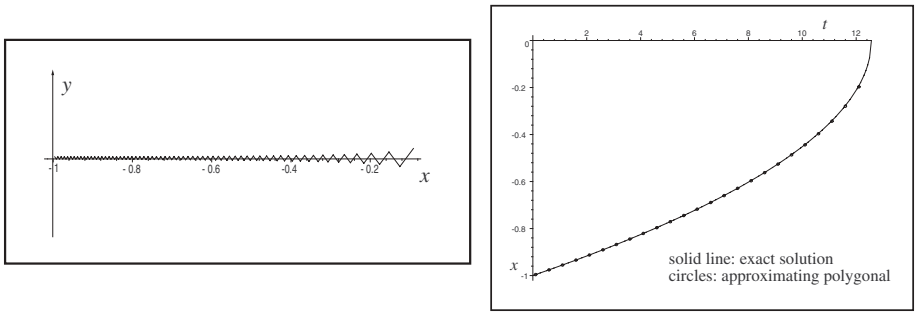

FIG. 6.1. *Left: trajectory of an approximating polygonal near the tip of the crack for* $h = 0.1$ (*Euler method*)*; right: comparison of the limit motion* $x(t)$ *and the horizontal component of the approximating polygonal.*

The smooth motion on S corresponding to fine cross-slip can be detemined explicitly: since

$$\boldsymbol{\jmath}(r_0, \pi) = \frac{1}{4\pi r_0}\boldsymbol{e}_1,$$

letting $\boldsymbol{\xi}(t) = x(t)\boldsymbol{e}_1$, the homogenized evolution equation (3.21) becomes

$$\dot{x}_0 = \frac{1}{8\pi|x_0|},$$

whose solution with the initial condition $x(0) = -1$ is

$$x(t) = -\frac{1}{2\pi}\sqrt{4\pi - t}. \tag{6.3}$$

Hence the dislocation reaches the tip of the crack at $x = 0$ in finite time.

In Figure 6.1 we compare the exact solution (6.3) with the horizontal component of the numerical solution (Euler method) of the dynamical system (2.5). The agreement is good already for the time step $h = 0.1$.

RUPTURE OF A SURFACTANT-COVERED THIN LIQUID FILM ON A FLEXIBLE WALL*

OMAR K. MATAR† AND SATISH KUMAR‡

Abstract. The rupture of a surfactant-covered thin liquid film on a flexible wall is studied in this paper. Evolution equations for the deflections of the air-liquid and wall-liquid interfaces and surfactant surface concentration are derived using lubrication theory, and their linear and nonlinear stability characteristics are investigated. Our linear stability results indicate that increases in the level of damping, the longitudinal wall tension, and the relative magnitude of Marangoni stresses have a stabilizing influence. Numerical simulations of the evolution equations are used to investigate the nonlinear characteristics of the instability. In all cases considered, the surfactant concentration decreases in the rupture region as rupture is approached, and the resulting Marangoni flows retard but do not prevent rupture. Self-similar rupture is examined and power-law scalings are extracted for different parameter values. These appear to be unchanged from those for rigid substrates, evidently because the van der Waals forces that drive the instability dominate the rupture dynamics.

Key words. thin liquid films, flexible walls, surfactants, rupture

1. Introduction.

Flow in thin viscous films has been the subject of numerous studies in the literature due to its obvious importance in a wide range of industrial and biomedical applications [1]. Many of these studies have addressed the problem of film rupture, where the film either rests on a solid horizontal support [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13] or is freely suspended [14, 15, 16, 17, 18, 19, 20, 21, 22]. The former situation, for instance, models the spreading of liquids and surfactant solutions on the surface of a solid or of another liquid that rests on a solid wall. The latter situation, on the other hand, represents the rupture of a soap film or of the continuous film which accompanies the coalescence of two droplets in an emulsion. A number of these studies have examined the evolution and self-similar nature of film thickness solutions as rupture is approached in the presence [9, 10, 11] and absence [4, 15, 13] of surfactant. In all cases, rupture is driven by intermolecular interactions such as van der Waals, hydration, depletion, or electrostatic forces, which come into operation for very small film thicknesses, typically on the order of 100 nm or less [23]. Studies of film rupture on solid walls generally assume that the solid is rigid. In this work, we relax that assumption and examine the rupture of a surfactant-covered thin liquid film on a flexible wall.

From a scientific standpoint, the rupture of thin liquid films on flexible walls is of interest because it is a problem of elastohydrodynamics: the study of the interaction between flowing fluids and flexible elastic structures. Such problems have

been examined by hydrodynamicists for years; examples include the use of flexible boundaries to delay the transition to turbulence [24], the modeling of airflow in the lungs [25] and blood flow in the heart [26], the use of rubber-covered rolls in coating processes to reduce defects [27], and flow instabilities near gel-like polymer interfaces [28]. Elastohydrodynamic problems are challenging because they involve two coupled media whose interface is often a free boundary. However, to our knowledge, elastohydrodynamic phenomena associated with film rupture have yet to be examined. From a practical standpoint, such a study may be relevant to several applications. The first involves the creation of textured or topographically patterned solids: if thin-film rupture leads to deformation of the underlying solid, then it may be possible to use rupture as a way to create surface features on the solid. The second application involves human lungs, where airways are flexible walls lined with a thin liquid film [29, 30]. If the film becomes thin enough, intermolecular forces may drive rupture and this in turn may deform the walls and lead to airway closure. Halpern and Grotberg have applied lubrication theory to study the instabilities associated with this system, but their analysis does not include intermolecular forces such as van der Waals interactions [29, 30]. Finally, studies of film rupture on flexible walls may be relevant in modeling the adhesion of cells and vesicles to solid substrates as discussed by Ramos de Souza, Gallez, and coworkers [20, 21, 22]. Here, the liquid-air interface would represent the cell or vesicle membrane, whereas the flexible wall would represent a soft substrate. If the wall is sufficiently compliant, it could become deformed during film rupture and this may modify the dynamics of cell or vesicle adhesion.

As a model system in the present work, we consider the linear stability and nonlinear evolution of a thin liquid film covered with an insoluble surfactant that rests on a flexible wall and is driven to rupture by van der Waals forces. Although other intermolecular forces may be present and lead to scenarios such as the formation of steady patterns [20, 21, 22], we restrict ourselves to van der Waals forces in this first study since our focus is on film rupture. Using lubrication theory, coupled evolution equations are derived for the deflection of the air-liquid and wall-liquid interfaces as well as for the surfactant concentration. A linear stability analysis and numerical simulations are conducted to determine the behavior of the film at the onset of the instability and as rupture is approached, respectively. This is carried out over a wide range of system parameters, which encompass the limits of weak and strong wall damping and longitudinal tension, and in the presence and absence of surfactant. Our results indicate that increasing the relative significance of wall damping retards (accelerates) the onset of van der Waals–driven film rupture for low (high) wall tensions; increasing wall tension was also found to delay rupture for all the damping coefficients examined. Moreover, the presence of Marangoni stresses [31], which arise due to gradients in the local surfactant concentration, exerts a stabilizing influence, acting to oppose the van der Waals–driven thinning process.

The rest of this paper is organized as follows. Details of the problem formulation are given in section 2, while results of the linear stability analysis are presented in section 3. A discussion of the numerical solutions together with a brief description of the numerical method employed to carry out the computations are provided in section 4. Finally, concluding remarks are given in section 5.

2. Formulation.

2.1. Governing equations. We consider a thin film of an incompressible Newtonian fluid of initial thickness $\mathcal{H}$, lateral extent $\mathcal{L}$, viscosity μ, and density ρ resting on a flexible wall. The air-liquid interface, which is bounded from above by an invis-

cid gas, is covered by an initially uniform dilute concentration of insoluble surfactant, $\Gamma_m \ll \Gamma_\infty$, where Γ_∞ represents the concentration at saturation. The analysis in the present work is restricted to planar geometry with coordinate system (x, y, z) and velocity field $\mathbf{u} = (u, 0, w)$, where x, y, and z denote the horizontal, transverse, and vertical coordinates, respectively, while $\mathbf{u}$ denotes the velocity field in which u and w represent the horizontal and vertical components of the velocity field, respectively. The origin of the z coordinate coincides with the midpoint of the initially undisturbed film thickness, such that the instantaneous location of the air-liquid interface is at $z = h + \mathcal{H}/2$, while the wall-liquid interface is located at $z = -\eta - \mathcal{H}/2$. Here, h and η denote deflections of the air-liquid and wall-liquid interfaces from their initially uniform states.

The film dynamics are governed by the equations of conservation of mass and momentum, respectively, given by

$$\nabla \cdot \mathbf{u} = 0, \tag{1}$$

$$\rho \left(\mathbf{u}_t + \mathbf{u} \cdot \nabla \mathbf{u} \right) = -\nabla \left(p + \phi \right) + \mu \nabla^2 \mathbf{u}, \tag{2}$$

where p represents pressure and $\phi = A/(\mathcal{H} + h + \eta)^3$ is an energy per unit volume corresponding to the van der Waals component of the disjoining pressure, in which A is the so-called Hamaker constant [23]; subscript notation denotes differentiation with respect to the spatial variables and time unless otherwise stated. Note that we have assumed the film to be sufficiently thin so that gravitational effects are negligible.

Equations (1) and (2) are complemented by an appropriate set of boundary conditions. At the air-liquid interface, $z = h + \mathcal{H}/2$, we have the normal and shear stress balances, respectively, given by

$$\mathbf{n} \cdot \mathbf{T} \cdot \mathbf{n} = \sigma \kappa, \tag{3}$$

$$\mathbf{n} \cdot \mathbf{T} \cdot \mathbf{t} = \nabla_s \sigma \cdot \mathbf{t}. \tag{4}$$

In (3) and (4), σ denotes the local value of the surface tension coefficient; $\mathbf{n} = (-h_x, 1)/\Delta$ and $\mathbf{t} = (1, h_x)/\Delta$, in which $\Delta \equiv (1 + h_x^2)^{1/2}$, denote the outward pointing unit normal and unit tangent to the air-liquid interface; and $\kappa = \nabla_s \cdot \mathbf{n}$ is the curvature where $\nabla_s = (\mathbf{I} - \mathbf{nn}) \cdot \nabla$ is the surface gradient operator. Also appearing in (3) and (4) is the film stress tensor:

$$\mathbf{T} = -p\mathbf{I} + \mu \left(\nabla \mathbf{u} + \nabla \mathbf{u}^T \right), \tag{5}$$

where $\mathbf{I}$ is the identity tensor. The kinematic boundary condition at $z = h + \mathcal{H}/2$ is expressed by

$$h_t + u_s h_x = w_s, \tag{6}$$

where the subscript s represents quantities evaluated at $z = h + \mathcal{H}/2$. The velocity field in the film must also satisfy the no-slip and kinematic boundary conditions at the wall-liquid interface, $z = -\eta - \mathcal{H}/2$:

$$u_w = 0, \tag{7}$$

$$\eta_t + u_w \eta_x = -w_w, \tag{8}$$

where the subscript w represents quantities evaluated at $z = -\eta - \mathcal{H}/2$.

The dynamics of the surfactant present at $z = h + \mathcal{H}/2$ are governed by the mass conservation equation [32]

$$\Gamma_t + (\nabla_s \cdot \mathbf{n})\Gamma(\mathbf{n} \cdot \mathbf{u}) + \nabla_s \cdot (\mathbf{u}_s \Gamma) = \mathcal{D}_s \nabla_s^2 \Gamma + J, \tag{9}$$

where $\mathcal{D}_s$ is a surface diffusion coefficient, which we will take to be constant, and J denotes a sorptive flux, which will be neglected in the present work since insoluble surfactants are considered. Note that σ depends on Γ through the equation of state [31],

$$\sigma = \sigma_o - (-\sigma_\Gamma)_{\Gamma=0}\Gamma, \tag{10}$$

where σ_o denotes the surface tension of the uncontaminated air-liquid interface while $-\sigma_\Gamma$ is a measure of surfactant activity.

Our model for the wall dynamics is very similar to that used by Halpern and Grotberg in their studies of liquid film dynamics inside flexible tubes [29, 30]. The wall is assumed to be infinitely long, isotropic, and impermeable with thickness δ, density ρ_w, and damping coefficient g. In addition, the wall is assumed to be sufficiently thin so that when a longitudinal (horizontal) tension of magnitude T_l is applied, it acts uniformly across the wall thickness. (Under these conditions, stresses due to bending may be neglected [33, 34].)

The film aspect ratio, $\epsilon \equiv \mathcal{H}/\mathcal{L}$, is taken to be small, which permits the use of lubrication theory, and in the limit $\epsilon \ll 1$, it can be shown that longitudinal deflections of the wall are much smaller than those in the vertical direction [35, 33, 29]. The relevant relation governing the wall deflections is given by

$$\frac{\rho_w \delta g \eta_t}{\Delta_w} - \frac{T_l \eta_{xx}}{\Delta_w^3} = -\mathbf{n}_w \cdot \mathbf{T} \cdot \mathbf{n}_w, \tag{11}$$

where $\mathbf{n}_w = (-\eta_x, 1)/\Delta_w$ is the unit normal to the wall-liquid interface in which $\Delta_w = (1 + \eta_x^2)^{1/2}$. The relevant scalings are presented next.

2.2. Scaling. The governing equations and boundary conditions are rendered dimensionless via the scalings for the hydrodynamic variables,

$$x = \mathcal{L}\tilde{x}, \quad z = \mathcal{H}(\tilde{z}, \tilde{h}, \tilde{\eta}), \quad u = \mathcal{U}\tilde{u}, \quad w = \epsilon\mathcal{U}\tilde{w}, \quad t = (\mathcal{L}/\mathcal{U})\tilde{t}, \quad p = \mathcal{P}\tilde{p}, \tag{12}$$

and for σ and Γ,

$$\Gamma = \Gamma_m \tilde{\Gamma}, \quad \sigma = \sigma_m + \mathcal{S}\tilde{\sigma}, \tag{13}$$

where $\mathcal{S} \equiv \sigma_o - \sigma_m$ is the spreading coefficient in which σ_m is the surface tension of the air-liquid interface when $\Gamma = \Gamma_m$. Here, $\mathcal{L} \equiv \mathcal{H}^2 (\sigma_m/A)^{1/2}$, $\mathcal{U} \equiv A/(\mu\mathcal{H}\mathcal{L})$, and $\mathcal{P} \equiv A/\mathcal{H}^3$, reflecting a balance between van der Waals, capillary, and viscous forces. Note that for typical values, $\mathcal{H} \sim 10^{-4}$ cm, $A \sim 10^{-13}$ erg, and $\sigma_m \sim 10$ dyne/cm, we have $\epsilon = \mathcal{H}/\mathcal{L} \sim O(10^{-3})$.

2.3. Lubrication theory. Substitution of the relevant scalings into the governing equations and boundary conditions yields the following set of dimensionless equations for the liquid film and surfactant concentration to leading order in ϵ (after suppressing the tilde):

$$u_x + w_z = 0, \tag{14}$$

$$0 = -(p+\phi)_x + u_{zz} + O(\epsilon^2, \epsilon \mathrm{Re}), \tag{15}$$

where $\phi = 1/(1+h+\eta)^3$,

$$0 = -p_z + O(\epsilon^2, \epsilon^3 \mathrm{Re}), \tag{16}$$

where $\mathrm{Re} \equiv \rho \mathcal{U}\mathcal{H}/\mu$ is the Reynolds number,

$$p = -h_{xx} + O(\epsilon^2) \qquad \text{at} \quad z = h + \frac{1}{2}, \tag{17}$$

$$u_z = \mathcal{M}\sigma_x + O(\epsilon^2) \qquad \text{at} \quad z = h + \frac{1}{2}, \tag{18}$$

where $\mathcal{M} \equiv \mathcal{S}\mathcal{H}^2/A$ is a Marangoni parameter, representing the magnitude of Marangoni stresses to van der Waals forces,

$$h_t + u_s h_x = w_s \qquad \text{at} \quad z = h + \frac{1}{2}, \tag{19}$$

$$u_w = 0 \qquad \text{at} \quad z = -\eta - \frac{1}{2}, \tag{20}$$

$$\eta_t = -w_w \qquad \text{at} \quad z = -\eta - \frac{1}{2}, \tag{21}$$

$$\Gamma_t + (u_s \Gamma)_x = \frac{\Gamma_{xx}}{\mathrm{Pe}} \qquad \text{at} \quad z = h + \frac{1}{2}. \tag{22}$$

Here, $\mathrm{Pe} \equiv \mathcal{U}\mathcal{L}/\mathcal{D}_s$ denotes the Peclet number, a ratio of the time scale for surfactant diffusion to that for surfactant convection.

Integration of (16) and application of (17) leads to the fact that the leading order pressure is independent of z and is given by

$$p = -h_{xx}. \tag{23}$$

Following the integration of (15) and application of (18) and (20), the leading order horizontal velocity is obtained:

$$u(x,z,t) = (p+\phi)_x \left[\frac{z^2}{2} - z\left(\frac{1}{2}+h\right) - \left(\frac{1}{2}+\eta\right)\left(\frac{3}{4}+h+\frac{\eta}{2}\right)\right] + \mathcal{M}\sigma_x \left(z + \frac{1}{2} + \eta\right). \tag{24}$$

Using continuity (and the Leibniz rule), (19) may be reexpressed as

$$h_t + \eta_t + Q_x = 0, \tag{25}$$

in which Q, the flow rate, is given by

$$Q = \int_{-(\frac{1}{2}+\eta)}^{\frac{1}{2}+h} u dz. \tag{26}$$

Substitution of (24) into (26) yields

$$Q = \frac{1}{2}(1+h+\eta)^2 \sigma_x - \frac{1}{3}(1+h+\eta)^3 (p+\phi)_x. \tag{27}$$

The dimensionless equation of state relating σ to Γ is given by

$$\sigma = 1 - \Gamma. \tag{28}$$

Hence, the evolution equation governing the dynamics of h becomes

$$h_t = -\eta_t + \left[\frac{1}{2}(1+h+\eta)^2 \mathcal{M}\Gamma_x - \frac{1}{3}(1+h+\eta)^3 \left(h_{xx} - \frac{1}{(1+h+\eta)^3}\right)_x\right]_x. \tag{29}$$

The velocity at $z = h + 1/2$, u_s, is given by

$$u_s = -\frac{1}{2}(1+h+\eta)^2 (p+\phi)_x + (1+h+\eta)\mathcal{M}\sigma_x. \tag{30}$$

Substitution of (30), along with (28), into (22) yields the following dimensionless evolution equation for Γ:

$$\Gamma_t = \left[(1+h+\eta)\mathcal{M}\Gamma\Gamma_x - \frac{1}{2}(1+h+\eta)^2 \Gamma \left(h_{xx} - \frac{1}{(1+h+\eta)^3}\right)_x\right]_x + \frac{\Gamma_{xx}}{\mathrm{Pe}}. \tag{31}$$

The dimensionless evolution equation governing the wall deflection is given by

$$\epsilon^2 \mathcal{R}\mathcal{G}\eta_t - \epsilon^2 \mathcal{T}\eta_{xx} + h_{xx} = 0 + O(\epsilon), \tag{32}$$

where $\mathcal{R} \equiv \rho_w \delta/(\rho\mathcal{H})$ represents the ratio of the mass of the wall to that of the fluid, $\mathcal{G} \equiv \rho g \mathcal{H}^2/\mu$ reflects the relative importance of wall damping to fluid damping, while $\mathcal{T} \equiv T_l \mathcal{H}^2/A$ corresponds to the ratio of the wall longitudinal tension to van der Waals forces.

Equation (29) is fully coupled to (31) and (32). Note that in the limit $\eta \to 0$ and $1 + h \to h$, (29), (31), and (32) reduce to the evolution equations for a surfactant covered thin liquid film resting on a rigid support (except for rescalings) [4].

For parameter values typical of terminal bronchioles [29], $\rho_w \sim 1$ g cm^{-3}, $\delta \sim 10^{-3}$ cm, $g \sim 10$ s^{-1}, $\mu \sim 10^{-2}$ poise, $T_l \sim 10$ dynes cm^{-1}, $\mathcal{R} \sim O(10)$, $\mathcal{G} \sim O(10^{-5})$, and $\mathcal{T} \sim O(10^6)$. This suggests that, for this setting, the wall is weakly damped and highly tensile longitudinally. It may therefore be possible to rescale $\mathcal{T}$ such that $\mathcal{T} = \hat{\mathcal{T}}/\epsilon^2$ with $\hat{\mathcal{T}} \sim O(1)$ and to eliminate the transient term in (32) to leading order:

$$-\hat{\mathcal{T}}\eta_{xx} + h_{xx} = 0 + O(\epsilon^2). \tag{33}$$

In fact, it is possible to consider different situations: $\epsilon^2\mathcal{R}\mathcal{G} \sim O(\epsilon^2)$ or $\epsilon^2\mathcal{R}\mathcal{G} \sim O(1)$, corresponding to either a weakly or strongly damped wall, respectively, and $\epsilon^2\mathcal{T} \sim O(\epsilon^2)$ or $\epsilon^2\mathcal{T} \sim O(1)$, which represent weak or strong longitudinal tension, respectively. These situations will be considered in the following sections. First, however, the linear stability characteristics of the system are analyzed.

3. Linear stability analysis. To gain insight into the problem and to provide a useful check on the performance of the numerical scheme utilized for the solution of the governing equations, a linear stability analysis is conducted. Equations (29), (31), and (32) are linearized using normal modes:

$$(h, \eta, \Gamma)(x,t) = (0, 0, \Gamma_0) + (H, F, G)\, e^{\omega t} e^{ikx}, \tag{34}$$

where $h = 0$, $\eta = 0$, and $\Gamma = \Gamma_0$ denote the spatially uniform base state and H, F, and G denote the amplitude of the initially infinitesimal applied disturbance of (real)

wavenumber k whose potentially complex growth rate is given by ω. Substitution of (34) into (29), (31), and (32) and neglecting quadratic and higher order terms in the perturbations leads to the following coupled algebraic eigenvalue equations:

$$\omega H = -\omega F - \frac{1}{2}\mathcal{M}k^2 G - \frac{1}{3}k^4 H + k^2\left(H + F\right), \tag{35}$$

$$\omega G = -\left(\mathcal{M}\Gamma_0 + \frac{1}{\mathrm{Pe}}\right)k^2 G - \frac{1}{2}\Gamma_0 k^4 H + \frac{3}{2}\Gamma_0 k^2\left(H + F\right), \tag{36}$$

$$\epsilon^2\mathcal{R}\mathcal{G}\omega F = -\epsilon^2\mathcal{T}k^2 F + k^2 H. \tag{37}$$

Equations (35)–(37) are then expressed in matrix form. Setting the determinant of this matrix to zero yields a characteristic equation for the growth rate:

$$\begin{aligned}(\epsilon^2\mathcal{R}\mathcal{G})\omega^3 + k^2\left(\epsilon^2\mathcal{T} + 1 + \epsilon^2\mathcal{R}\mathcal{G}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right]\right)\omega^2 \\ + k^4\left(\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 - 1 + \epsilon^2\mathcal{R}\mathcal{G}\left[\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right]\left[\frac{k^2}{3} - 1\right] + \epsilon^2\mathcal{T}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right]\right)\omega \\ - k^6\left(\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right)\left(1 - \epsilon^2\mathcal{T}\left[\frac{k^2}{3} - 1\right]\right) = 0.\end{aligned} \tag{38}$$

Solution of this equation using Mathematica yields dispersion curves, which represent the dependence of $Re[\omega]$ on k as a function of system parameters. The existence of a band of wavenumbers for a given set of parameters over which $Re[\omega] > 0$ signifies the presence of a linear instability.

For a weakly damped wall, that is, for $\epsilon^2\mathcal{R}\mathcal{G} \ll 1$, (38) reduces to

$$\begin{aligned}(\epsilon^2\mathcal{T} + 1)\omega^2 + k^2\left(\epsilon^2\mathcal{T}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right] + \frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 - 1\right)\omega \\ - k^4\left[\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right]\left[1 - \epsilon^2\mathcal{T}\left(\frac{k^2}{3} - 1\right)\right] = 0,\end{aligned} \tag{39}$$

while for a weakly (longitudinally) tensile wall, (38) reduces to

$$\begin{aligned}\left(\epsilon^2\mathcal{R}\mathcal{G}\right)\omega^3 + k^2\left(\epsilon^2\mathcal{R}\mathcal{G}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right] + 1\right)\omega^2 \\ + k^4\left(\epsilon^2\mathcal{R}\mathcal{G}\left[\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right]\left[\frac{k^2}{3} - 1\right] + \frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 - 1\right)\omega - k^6\left(\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right) = 0,\end{aligned} \tag{40}$$

and, in the absence of surfactant, we have

$$(\epsilon^2\mathcal{R}\mathcal{G})\omega^2 + k^2\left(\epsilon^2\mathcal{T} + 1 + \epsilon^2\mathcal{R}\mathcal{G}\left[\frac{k^2}{3} - 1\right]\right)\omega + k^4\left(-1 + \epsilon^2\mathcal{T}\left[\frac{k^2}{3} - 1\right]\right) = 0. \tag{41}$$

For the case of a very highly damped or a very highly (longitudinally) tensile wall, corresponding to $\epsilon^2\mathcal{R}\mathcal{G} \gg 1$ and $\epsilon^2\mathcal{T} \gg 1$, respectively, (38) reduces to

$$\omega^2 + k^2\left(\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right)\omega + k^4\left(\frac{k^2}{3} - 1\right)\left(\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right) = 0, \tag{42}$$

which corresponds to the equation describing the linear stability characteristics of a thin viscous film resting on a rigid horizontal support undergoing van der Waals driven rupture in the presence of surfactant-induced Marangoni stresses [12].

From (38), the wavenumber corresponding to the cutoff mode, k_c, for which $\omega = 0$, is expressed by

$$k_c = \sqrt{3\left(\frac{1+\epsilon^2\mathcal{T}}{\epsilon^2\mathcal{T}}\right)}. \tag{43}$$

Inspection of (43), which represents a generalization of k_c for a rupturing thin film resting on a flexible wall, reveals that the cut-off mode is unaffected either by the presence of surfactant, in agreement with previous work [3, 4, 12, 36], or the effect of wall damping. Note that for $\epsilon^2\mathcal{T} \gg 1$, $k_c = \sqrt{3}$ [37, 4, 12, 36], which reflects a balance between van der Waals and capillary forces only. Marangoni stresses and wall damping effects will, however, have an influence on the magnitude of the wavenumber corresponding to the so-called most dangerous mode and its associated maximal growth rate. Also note that for $\epsilon^2\mathcal{T} \ll 1$, $k_c \sim \sqrt{3/(\epsilon^2\mathcal{T})}$, which indicates that the equations may become ill posed in the limit of very weak longitudinal tension; this can also be ascertained on inspection of (40). We leave this case aside and concentrate in the present section on film rupture on a highly tensile wall in the limits of weak and significant damping, which we consider next.

3.1. Weakly damped, highly tensile wall. Here, we set $\mathcal{T} = \hat{\mathcal{T}}/\epsilon^2$ and $\mathcal{RG} \sim O(1)$; (38) becomes

$$\begin{aligned}(\hat{\mathcal{T}}+1)\omega^2 + k^2\left(\hat{\mathcal{T}}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right] + \frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 - 1\right)\omega \\ - k^4\left[\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right]\left[1 - \hat{\mathcal{T}}\left(\frac{k^2}{3} - 1\right)\right] = 0.\end{aligned} \tag{44}$$

Thus, ω is given by

$$\omega_{\pm} = \frac{\left(-k^4(\hat{\mathcal{T}}[Q_1 + \frac{k^2}{3} - 1] + Q_1 - 1)\left[1 \pm \left(1 + \frac{4(\hat{\mathcal{T}}+1)Q_2\left(1-\hat{\mathcal{T}}\left(\frac{k^2}{3}-1\right)\right)}{\left(\hat{\mathcal{T}}\left(Q_1 - 1 + \frac{k^2}{3}\right) + Q_1 - 1\right)^2}\right)^{1/2}\right]\right)}{2(\hat{\mathcal{T}}+1)}, \tag{45}$$

in which $Q_1 \equiv \mathcal{M}\Gamma_0 + 1/\mathrm{Pe}$ and $Q_2 \equiv (\mathcal{M}\Gamma_0/4) + 1/\mathrm{Pe}$; here, k_c is given by (43). In Figure 1, we show the effect of varying $\hat{\mathcal{T}}$ on the behavior of the dispersion curves with $\Gamma_0 = 1$, $\mathcal{M} = 1$, and $\mathrm{Pe} = 100$. (We consider only ω_+, the dominant mode.) Clearly, increasing $\hat{\mathcal{T}}$ decreases k_c and the magnitudes of the growth rate and most dangerous mode. Thus, longitudinal tension exerts a stabilizing influence.

Next we investigate the effect of Marangoni stresses on the dispersion curves. Since the parameters $\mathcal{M}$ and Γ_0 arise as a product in (45), only one of these parameters will be varied. Inspection of Figure 2, which shows the effect of varying $\mathcal{M}$ on the linear stability characteristics, reveals that increasing $\mathcal{M}$ stabilizes the flow, decreasing the magnitude of ω_+, in agreement with previous studies of film rupture on rigid solid substrates [3, 4, 12, 36]. It is worthy of mention that the magnitude of k_c remains unaltered, in agreement with (43), and the changes in ω_+ rapidly saturate with increasing $\mathcal{M}$. We have also found that the dispersion curves exhibit a very weak dependence on Pe (not shown) for physically realizable Pe values.

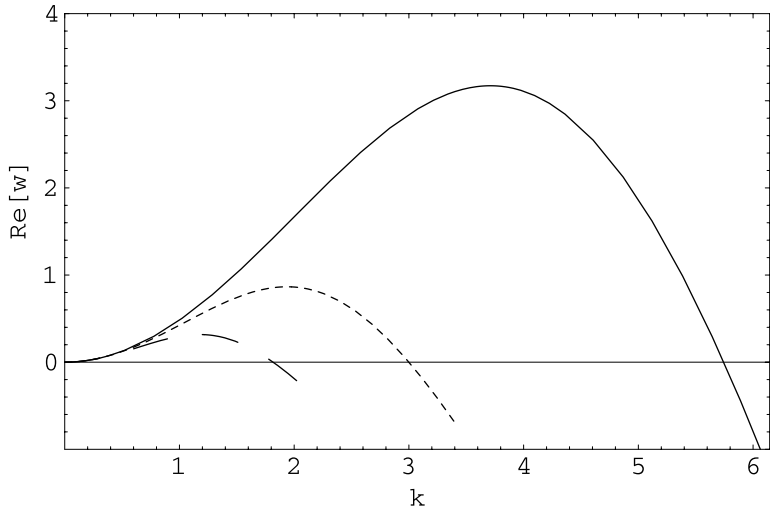

FIG. 1. *The effect of varying* $\hat{\mathcal{T}}$ *on the dispersion curves obtained via the solution of* (45) *with* $\hat{\mathcal{T}} = 0.1$ *(solid lines),* $\hat{\mathcal{T}} = 0.5$ *(short-dashed lines), and* $\hat{\mathcal{T}} = 10$ *(dashed lines),* $\Gamma_0 = 1$, $\mathcal{M} = 1$, *and* $\mathrm{Pe} = 100$.

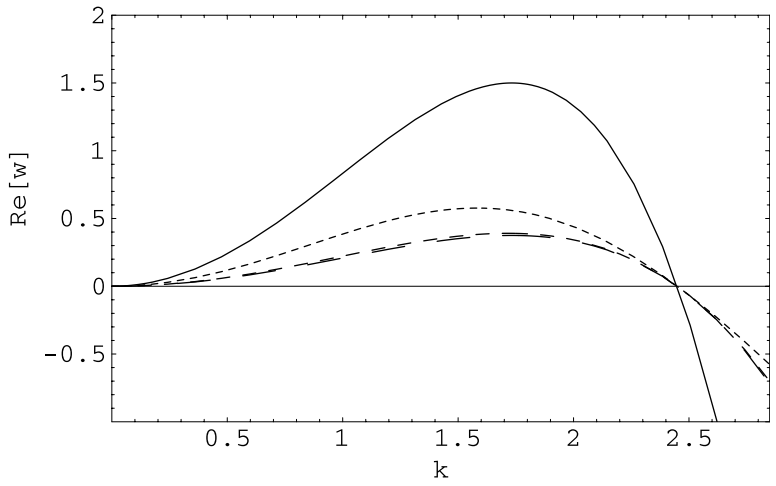

FIG. 2. *The effect of varying* $\mathcal{M}$ *on the dispersion curves obtained via the solution of* (45) *with* $\mathcal{M} = 0$ *(solid lines),* $\mathcal{M} = 1$ *(short-dashed lines),* $\mathcal{M} = 10$ *(dashed lines), and* $\mathcal{M} = 10^5$ *(long-dashed lines),* $\hat{\mathcal{T}} = 1$, $\Gamma_0 = 1$, *and* $\mathrm{Pe} = 100$.

3.2. Strongly damped, highly tensile wall. We turn our attention to the case of a highly tensile, strongly damped wall. Here, $\mathcal{T}$ remains as $\mathcal{T} = \hat{\mathcal{T}}/\epsilon^2$ and we set $\mathcal{RG} = \hat{\mathcal{B}}/\epsilon^2$ with $\hat{\mathcal{B}} \sim O(1)$. We note that inclusion of significant wall damping reintroduces temporal variations of wall deflections, which corresponds to the term proportional to ω^3 in (38); this term had been omitted from the previous section. Equation (38) then becomes

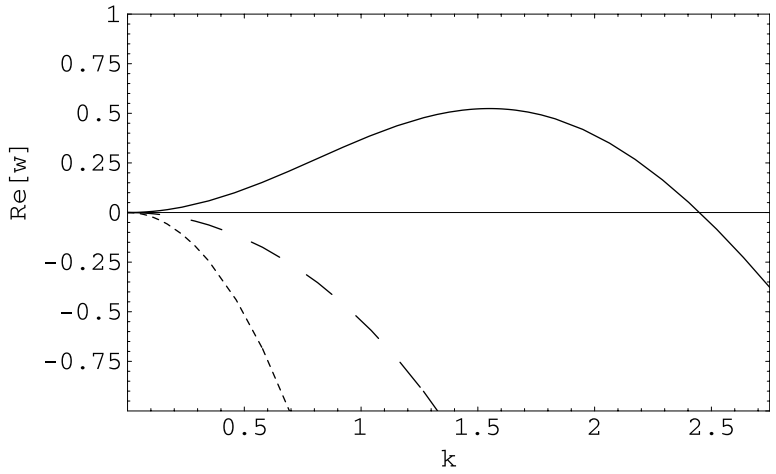

FIG. 3. *Dispersion curves obtained via the solution of* (46) *with* $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$ *and* $\mathrm{Pe} = 100$*:* ω_1 *(solid line),* ω_2 *(short-dashed line), and* ω_3 *(dashed line), which are the three roots of* (46)*. Here,* ω_1 *and* ω_2 *are complex conjugates while* ω_3 *is a real root of* (46).

$$\begin{aligned}\hat{\mathcal{B}}\omega^3 &+ k^2\left(\hat{\mathcal{T}} + 1 + \hat{\mathcal{B}}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right]\right)\omega^2 \\ &+ k^4\left(\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 - 1 + \hat{\mathcal{B}}\left[\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right]\left[\frac{k^2}{3} - 1\right]\right. \\ &\left. + \hat{\mathcal{T}}\left[\frac{1}{\mathrm{Pe}} + \mathcal{M}\Gamma_0 + \frac{k^2}{3} - 1\right]\right)\omega - k^6\left(\frac{1}{\mathrm{Pe}} + \frac{\mathcal{M}\Gamma_0}{4}\right)\left(1 - \hat{\mathcal{T}}\left[\frac{k^2}{3} - 1\right]\right) = 0. \end{aligned} \tag{46}$$

Equation (46), which is a third-order polynomial in ω, was solved using standard Mathematica routines for different parameters. Figure 3 shows the three solutions, ω_i $(i = 1, 2, 3)$, as a function of k for a case where all physical parameters are represented: $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$ and $\mathrm{Pe} = 100$. In subsequent plots in this subsection only the dominant mode will be shown.

In Figure 4, we show the effect of varying $\hat{\mathcal{B}}$ on the dispersion curves with the rest of the parameter values remaining unaltered from Figure 3. Increasing $\hat{\mathcal{B}}$, which corresponds to an increase in the magnitude of wall damping, results in a decrease of the growth rate and a shift of the most dangerous mode toward smaller wavenumbers. Increasing the relative magnitude of longitudinal tension by increasing $\hat{\mathcal{T}}$ has a stabilizing effect, which is similar to that of increasing $\hat{\mathcal{B}}$; this is shown in Figure 5. We have also investigated the effect of Marangoni stresses on the linear stability characteristics in the presence of wall damping. Our results (not shown) indicate that increasing $\mathcal{M}$ (or, equivalently, Γ_0) and Pe stabilizes the flow in this case as well.

Although linear theory provides insight into the destabilizing mechanisms and a reasonable estimate of the rupture time, this theory breaks down as rupture is approached since the magnitude of the disturbances is no longer negligibly small and nonlinearities become significant. Numerical solution of the fully nonlinear evolution equations is necessary in that case; this is considered in the following section.

4. Numerical simulations. In this section, we present results from numerical simulations of the governing equations. We begin with a concise description of the

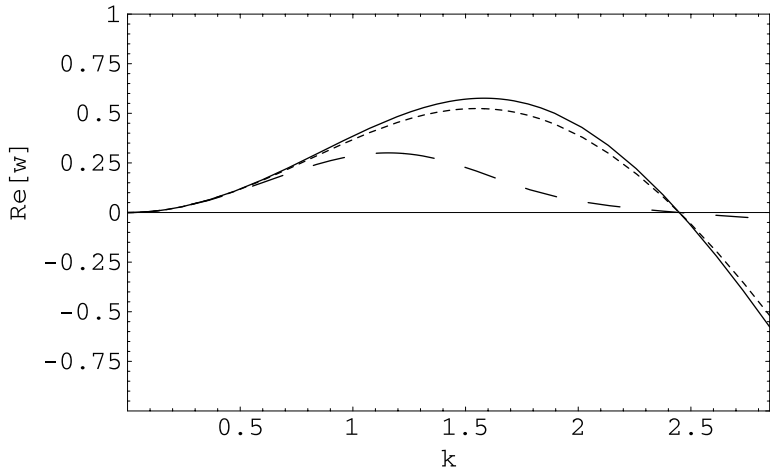

FIG. 4. *The effect of varying* $\hat{\mathcal{B}}$ *on the dispersion curves obtained via the solution of* (46): $\hat{\mathcal{B}} = 0.01$ *(solid line),* $\hat{\mathcal{B}} = 1$ *(short-dashed line), and* $\hat{\mathcal{B}} = 100$ *(dashed line). The rest of the parameter values are the same as those used to generate Figure* 3.

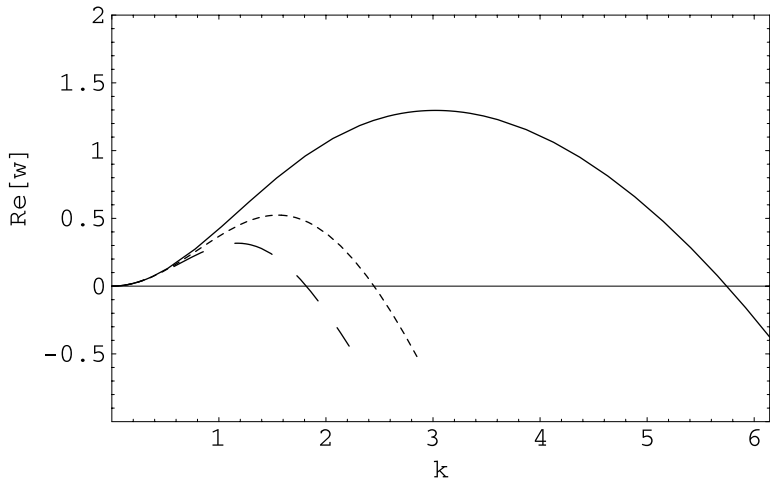

FIG. 5. *The effect of varying* $\hat{\mathcal{T}}$ *on the dispersion curves obtained via the solution of* (46): $\hat{\mathcal{T}} = 0.1$ *(solid line),* $\hat{\mathcal{T}} = 1$ *(short-dashed line), and* $\hat{\mathcal{T}} = 10$ *(dashed line). The rest of the parameter values are the same as those used to generate Figure* 4.

methods employed in the numerical solution of these equations, and then we examine in detail the cases of uncontaminated and surfactant-covered films.

4.1. Numerical procedure. We have used an efficient solver, EPDCOL [38, 39], which has been used for the solution of nonlinear parabolic partial differential equations in related problems involving film rupture and thread breakup [13, 12, 40, 36, 19]. This routine uses finite element collocation to discretize the spatial derivatives and Gear's method in time. Typically 6,000 grid points were used on a computational grid of length $L = 3.6$ dimensionless units. Convergence was achieved on refinement of the spatial mesh by increasing the number of grid points up to 10,000.

Numerical solutions are obtained starting from the initial conditions

$$h(x,0) = \eta(x,0) = A\cos(kx), \qquad \Gamma(x,0) = \Gamma_0, \tag{47}$$

which correspond to a periodic disturbance to $h = 0$ with $A\ \varepsilon\ (10^{-3}, 0.2)$. These solutions are subject to the boundary conditions on h and Γ,

$$h_x = h_{xxx} = 0 \quad \text{at} \quad x = 0, L, \tag{48}$$

$$\Gamma_x = 0 \quad \text{at} \quad x = 0, L, \tag{49}$$

and the conditions on η,

$$\text{either} \qquad \eta_x = 0 \qquad \text{or} \qquad \eta = 0 \quad \text{at} \quad x = 0, L. \tag{50}$$

Physically, the Neumann conditions correspond to a flow which is even about the origin; these conditions, which will give rise to spatially periodic solutions, are appropriate when considering a thin film resting on a wall of infinite lateral extent. The Dirichlet conditions, on the other hand, correspond to a wall of finite lateral extent, fixed at both ends. We shall focus mainly on the former case and examine the latter case only briefly.

We have checked that the numerical solutions are consistent with the predictions of linear theory. This can be confirmed on inspection of Figure 6, in which the natural logarithm of $\delta h(t)$, which is half the difference between the maximal and minimal values of h at time t, is plotted normalized by its initial value, $\delta h(0)$. The parameter values used correspond to the wavenumber associated with the most dangerous mode with all the relevant mechanisms represented: $k = 1.75$, $A = 10^{-3}$, $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$, $\mathrm{Pe} = 100$, and the number of grid points used is 6,000. Inspection of Figure 6(a) reveals excellent agreement between the numerical solution and linear theory over the initial stages of the rupture process with deviations occurring at later stages when the amplitude of the perturbations is large and the nonlinearities no longer negligible. These deviations coincide with the onset of rapid thinning of the film, as shown in Figure 6(b), which depicts the evolution of the minimal total film thickness toward rupture for the same parameter values as in Figure 6(a). The wavenumber of the initial perturbation used in the validation studies is also used to generate the results shown in all subsequent figures but with $A = 0.1$ except for Figure 7. Note that the most dangerous mode associated with each set of parameters could have been used. However, to conduct a parametric study in which the effect of various physical mechanisms is investigated, the same initial conditions were used and only the relevant parameter is varied. As in the study of other problems involving film rupture, we have found that the details of the numerical solutions in the initial stages of the breakup process depend on the choice of initial conditions. The solutions as rupture is approached in the vicinity of the rupture region, however, are very weakly dependent on initial conditions.

In the following section, solutions of the evolution equations, (29), (31), and (32), are presented for a wide range of parameter values with particular attention paid to the structure of the film near rupture and the dependence of the estimated rupture time, t_r, on system parameters; here, t_r corresponds to the time at which computations were halted since spatial derivatives could not be resolved accurately. We shall begin by considering the evolution to rupture of a surfactant-covered film. We then explore the effect of varying $\hat{B}$ and $\hat{T}$ on the time to rupture as well as the structure of contaminated and uncontaminated films near rupture. This is then followed by a brief examination of self-similar rupture in the presence of surfactant and wall flexibility.

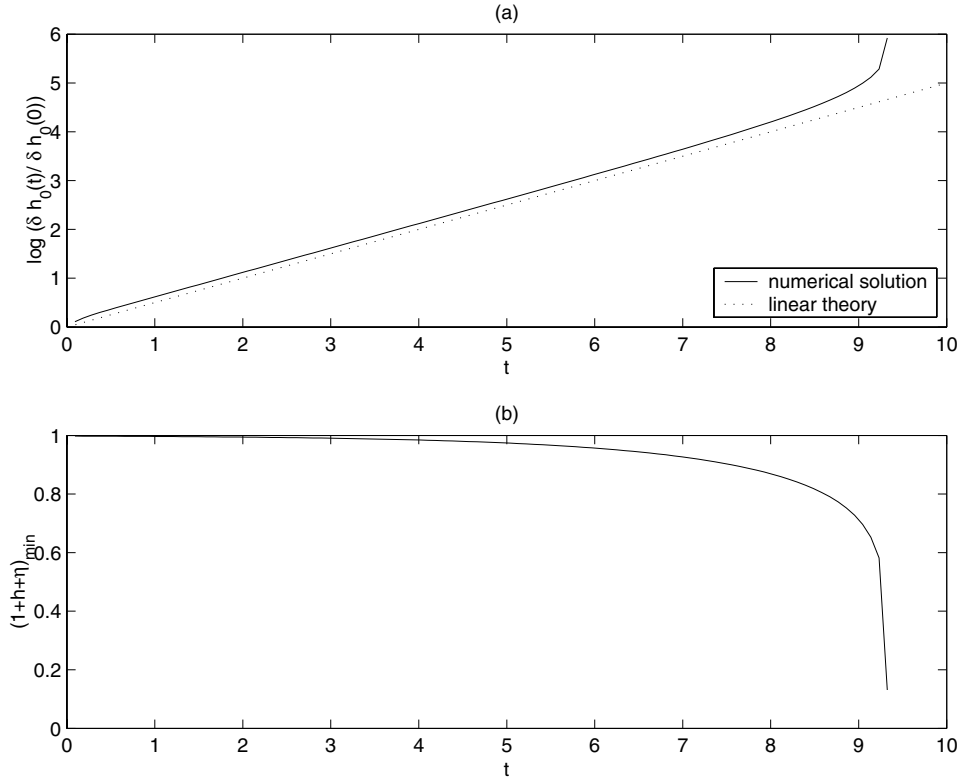

FIG. 6. *Validation of the numerical procedure.* (a) *Comparison of the numerical solutions with the predictions of linear theory;* (b) *variation of the minimum total film thickness,* $(1 + h + \eta)_{\min}$*, with time. The parameter values are* $A = 10^{-3}$*,* $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$*, and* $\mathrm{Pe} = 100$*;* 6,000 *grid points were used.*

4.2. Parametric study. We consider first the system in the presence of surfactant and all relevant mechanisms, such as wall damping and longitudinal tension, in order to examine a typical development of the film thickness and surfactant concentration toward rupture; this is shown in Figure 7 with $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$ and $\mathrm{Pe} = 100$. The magnitude of van der Waals forces rises beneath the depression in the film, driving fluid away from this region, causing further thinning and, eventually, film rupture. The thinning of the film is transmitted to the underlying flexible wall resulting in its deformation; the wall-liquid interface assumes a similar shape to that of the air-liquid interface. For this choice of parameters, surfactant is also driven away from the rupture region, resulting in the surfactant concentration increasing on either side of the thinning region. This then drives a reverse Marangoni flow that opposes the van der Waals–driven thinning. This flow, however, succeeds only in retarding rather than preventing film rupture. The parametric dependence of the surfactant concentration profile on $\hat{\mathcal{T}}$ and $\hat{\mathcal{B}}$ as rupture is approached will be examined below.

Next, we concentrate on uncontaminated films and study the effect of $\hat{\mathcal{B}}$ and $\hat{\mathcal{T}}$ on the estimated rupture time, t_{r}. Figure 8 is a semilog plot of the dependence of t_{r} on $\hat{\mathcal{T}}$ with $\hat{\mathcal{B}}$ varying parametrically. Inspection of this figure shows clearly that for a fixed value of $\hat{\mathcal{B}}$, t_{r} is largely independent of $\hat{\mathcal{T}}$ for small $\hat{\mathcal{T}}$ values and increases

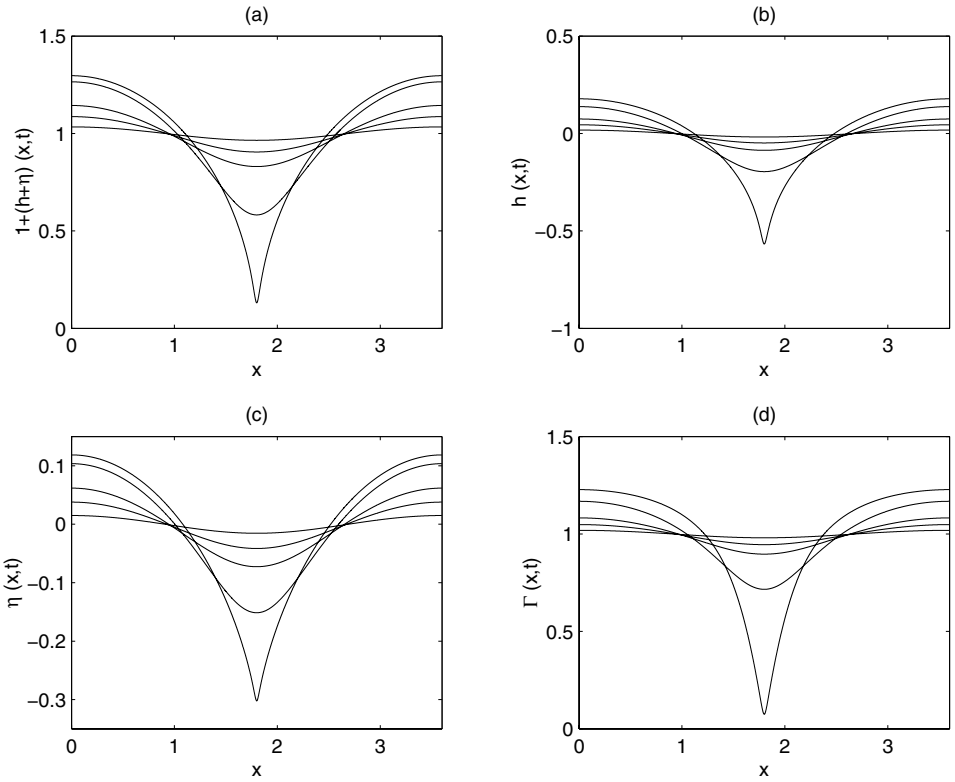

FIG. 7. *Evolution of the total film thickness,* $1+h+\eta$*, shown in* (a)*, the deflections of the air-liquid and liquid-solid interfaces, shown in* (b) *and* (c)*, respectively, and the surfactant concentration,* Γ*, shown in* (d)*, toward rupture. The parameter values are* $A = 10^{-3}$*,* $\hat{\mathcal{B}} = \hat{\mathcal{T}} = \mathcal{M} = \Gamma_0 = 1$*, and* $\mathrm{Pe} = 100$*.*

significantly beyond $\hat{\mathcal{T}} \sim O(1)$. This suggests that increasing the magnitude of the wall longitudinal tension promotes film stability. Furthermore, for a given value of $\hat{\mathcal{T}}$, increasing $\hat{\mathcal{B}}$ results in an increase (decrease) in t_{r} for small (large) $\hat{\mathcal{T}}$ values. Thus, an increase in wall damping exerts a stabilizing influence on the dynamics in the case of weak wall tension and accelerates rupture slightly in the limit of significant wall tension. Note that in the limit of large longitudinal tension and significant wall damping, the rigid wall dynamics are recovered, as will be shown in section 4.3.

We now examine the effect of $\hat{\mathcal{B}}$ and $\hat{\mathcal{T}}$ on the structure of the film as rupture is approached. As can be ascertained on inspection of Figure 9, which shows the variation of the film profile before rupture with $\hat{\mathcal{T}}$ and $\hat{\mathcal{B}}$, small values of $\hat{\mathcal{T}}$ and $\hat{\mathcal{B}}$ give rise to highly localized film rupture accompanied by damped oscillations away from the rupture location. The amplitude of these oscillations, however, is dampened further following an increase in either $\hat{\mathcal{T}}$ or $\hat{\mathcal{B}}$. Thus, increasing the magnitude of either wall damping or longitudinal tension results in localized thinning and eventual rupture. Moreover, comparison of Figure 9(a) and Figure 10(a) reveals that the overall structure of the film thickness profile remains qualitatively very similar despite the absence of surfactant.

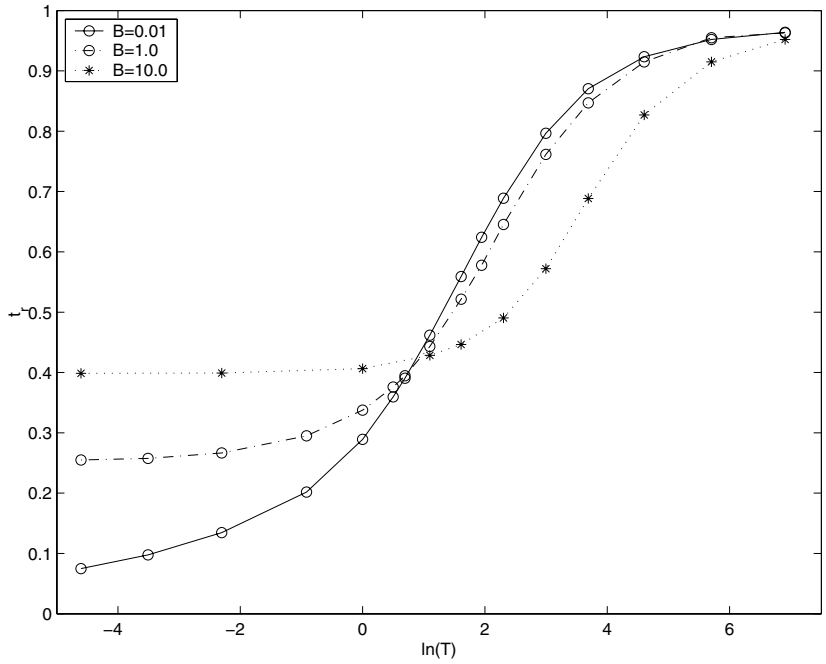

FIG. 8. *Dependence of the estimated rupture time on $\hat{\mathcal{T}}$ with $\hat{\mathcal{B}}$ varying parametrically for the uncontaminated case with $A = 0.1$.*

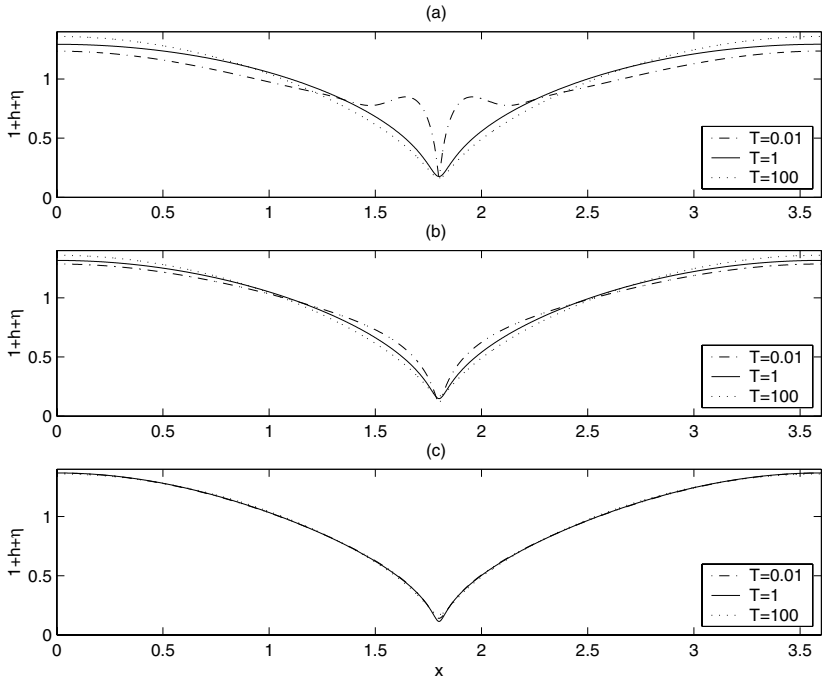

FIG. 9. *Dependence of the total thickness profile of a surfactant-free film before rupture on $\hat{\mathcal{T}}$ with $\hat{\mathcal{B}}$ varying parametrically and $A = 0.1$.* (a) $\hat{\mathcal{B}} = 0.01$, (b) $\hat{\mathcal{B}} = 1$, *and* (c) $\hat{\mathcal{B}} = 10$.

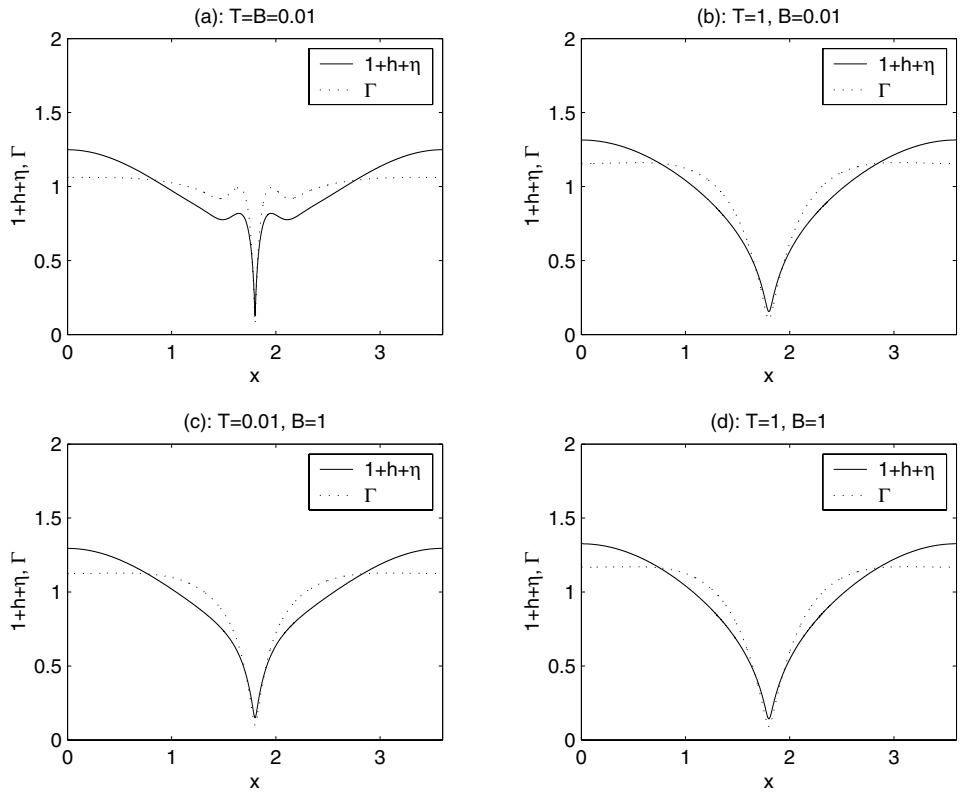

FIG. 10. *Dependence of the total thickness and surfactant concentration profiles before rupture on* $\hat{\mathcal{T}}$ *and* $\hat{\mathcal{B}}$ *with* $A = 0.1$, $\Gamma_0 = 1$, $\mathcal{M} = 1$, *and* $\mathrm{Pe} = 100$.

The effect of changing $\hat{\mathcal{T}}$ and $\hat{\mathcal{B}}$ on the total film thickness and surfactant concentration as rupture is approached is also interesting to explore. In all the cases considered, the behavior of the surfactant concentration, Γ, appears to mimic closely that of the total film thickness, as shown in Figure 10. Van der Waals–driven thinning leads to the advection of fluid and surfactant away from the thinning region, producing a rapid decrease in the thickness and surfactant concentration in that region of very similar rate (Figure 11). An increase in the value of $\hat{\mathcal{T}}$ from 0.01 to 1 while keeping $\hat{\mathcal{B}} = 0.01$ results in considerable damping of the oscillations in the film thickness and surfactant concentration as rupture is approached (see Figures 10(a) and (b)). Finally, either increasing $\hat{\mathcal{B}}$ from 0.01 to 1, while leaving $\hat{\mathcal{T}} = 0.01$ (Figure 10(c)), or having $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$ (Figure 10(d)) results in a very similar behavior.

We also explore the effect of $\mathcal{M}$ on the structure of the total film thickness profile in two limits: weak damping and longitudinal tension, and significant damping and longitudinal tension. Figures 12(a) and (b) show that an increase in $\mathcal{M}$ with $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$ and $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 0.01$, respectively, $\Gamma_0 = 1$, and $\mathrm{Pe} = 100$, results in retardation of the thinning process. This is due to interface rigidification, which is brought about via a Marangoni-driven reverse flow that counteracts the van der Waals–driven thinning process. A similar effect is brought about via an increase in Γ_0 or Pe (not shown). These findings are in line with the predictions of linear theory.

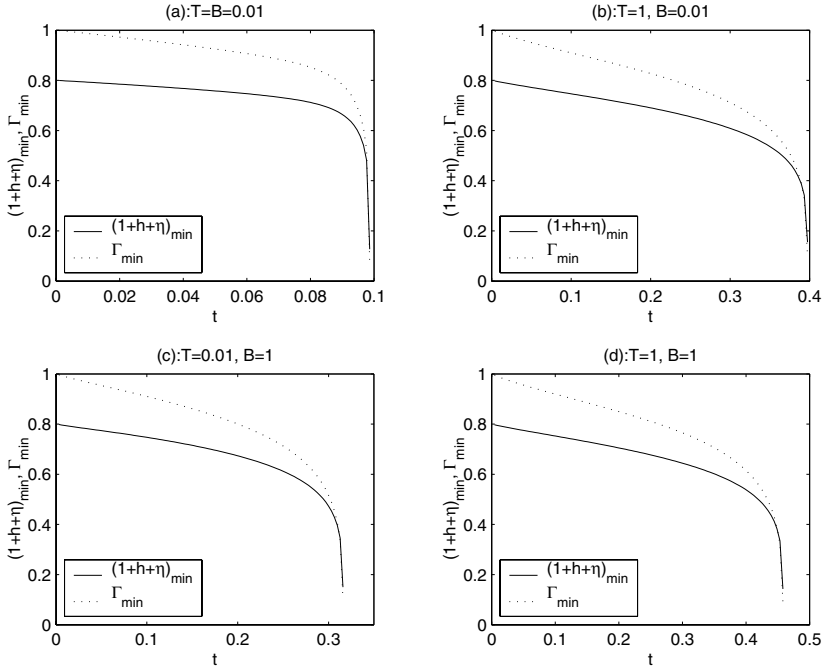

FIG. 11. *Dependence of the total thickness and surfactant concentration at the rupture location on* $\hat{\mathcal{T}}$ *and* $\hat{\mathcal{B}}$*; the rest of the parameter values remain unchanged from Figure* 10.

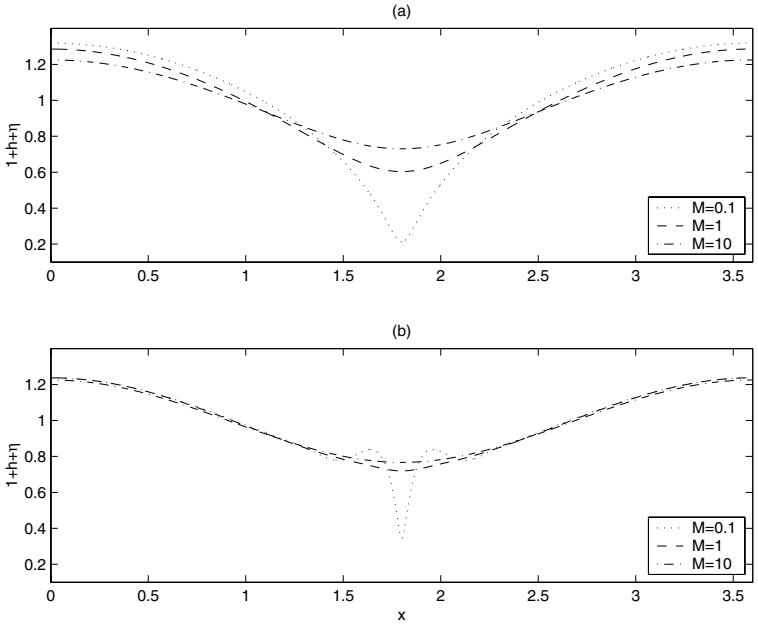

FIG. 12. *Structural dependence of the total film thickness profile on* $\mathcal{M}$ *with* $\Gamma_0 = 1$*, and* $\mathrm{Pe} = 100$. (a) $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$ *and* $t = 0.348$*;* (b) $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 0.01$ *and* $t = 0.077$*; the value of* $A = 0.1$ *was used in all cases shown.*

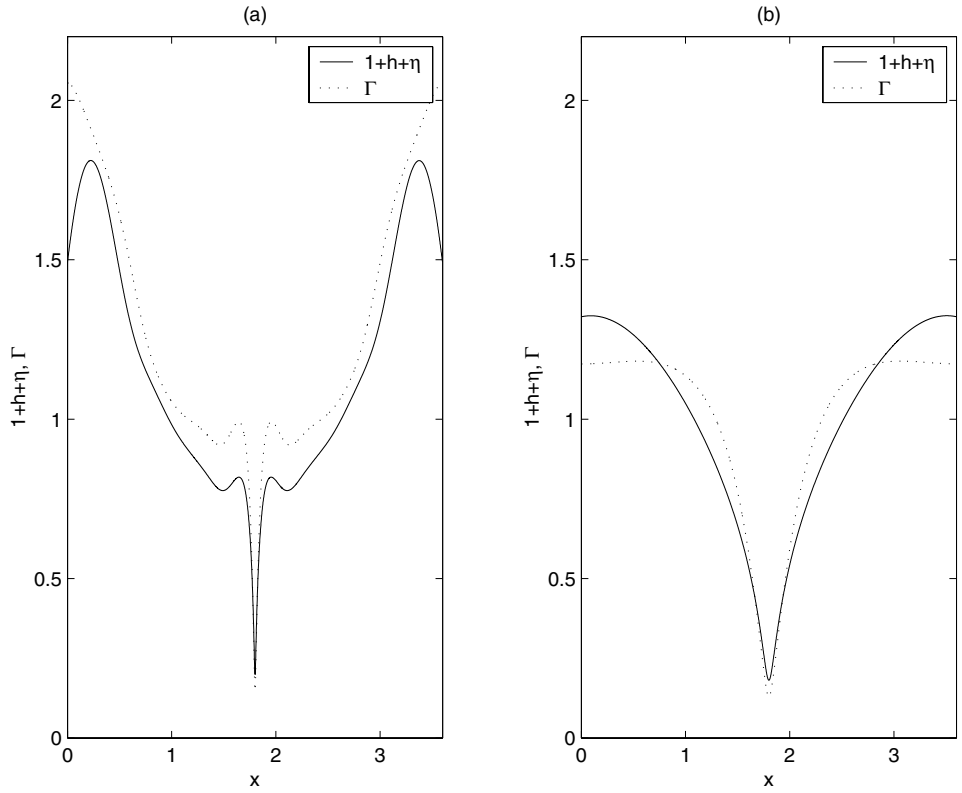

FIG. 13. *Effect of imposing fixed boundary conditions: the total film thickness and surfactant concentration at* $t = 9.869 \times 10^{-2}$ *with* $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 0.01$ *are shown in* (a) *and at* $t = 0.45515$ *with* $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$ *in* (b). *The rest of the parameter values are* $A = 0.1$, $\Gamma_0 = 1$, $\mathcal{M} = 1$, *and* $\mathrm{Pe} = 100$.

Finally, we examine briefly the effect of altering the boundary conditions on the dynamics. Figure 13 shows the total film thickness and surfactant concentration before rupture in the limits of weak tension and wall damping ($\hat{\mathcal{T}} = \hat{\mathcal{B}} = 0.01$) in (a) and significant tension and damping ($\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$) in (b); the rest of the parameter values used are $\Gamma_0 = \mathcal{M} = 1$ and $\mathrm{Pe} = 100$. In the weak tension and damping limit, imposition of fixed boundary conditions on η, $\eta = 0$ at $x = 0$ and L, results in a relatively large buildup of fluid and surfactant near the boundaries while leaving the film thickness and surfactant concentration relatively unaltered in the vicinity of the rupture location. In the limit of significant wall tension and damping, the profiles bear a close resemblance to those shown in Figure 7, which have been generated subject to Neumann boundary conditions in the vicinity of the rupture location. Small discrepancies arise, however, near the edges of the spatial domain due to differences in the imposed boundary conditions.

4.3. Self-similar rupture. Here, we examine the possibility of self-similar rupturing solutions for a thin liquid film resting on a flexible support. Similar studies have been conducted for the case of thin films on a rigid support [9, 10, 11, 18, 13, 12] and free films [18, 19] in the presence [13, 12, 19] and absence [9, 10, 11, 18] of surfactant. The growth rate of a perturbation to the interface increases under the action of van der Waals forces and decreases due to capillarity resulting in a dominant balance,

which yields $H_{xx} \sim 1/H^3$; here, H is the total film thickness. The rate of change of the total film thickness is then proportional to $H/\tau \sim (H/x)^4 \sim (1/x^2)$, from which it then follows that $x \sim \tau^{2/5}$ and $H \sim \tau^{1/5}$, where $\tau = t_r - t$ in which t_r represents the estimated rupture time. This dominant balance between van der Waals, capillary, and viscous forces renders the Marangoni terms in the evolution equations subdominant. As a result, the evolution equations for the surfactant concentration and film thickness become structurally similar. Consistency of these equations then dictates that $\Gamma \sim \tau^{3/10}$, which is similar to previous findings involving studies of thin-film stability on a rigid substrate [12, 13].

We compare the above scaling arguments against scalings extracted directly from the numerical solutions of the evolution equations. In Figure 14 we follow the approach previously adopted in the literature [9, 18, 19] and show log-log plots of the film curvature and the surfactant concentration evaluated at the rupture location against the minimal film thickness; this approach removes the need for an accurate estimate of the rupture time. Here, the slopes of the curvature and concentration curves provide an estimate of the ratio of the self-similar exponent of the film thickness and surfactant concentration, respectively. In all cases considered, the surfactant concentration decreases sharply as rupture is approached, as shown in Figure 11. Inspection of Figure 14(b) reveals that the slopes of the curves are in agreement with the predicted scalings for H and Γ. This, in turn, provides some evidence for consistency of our numerical simulations with the predicted power-law scalings as rupture is approached up to the point where the computations were halted due to the increasingly singular nature of the spatial derivatives.

Finally, we compare our findings in the limit of large wall damping and longitudinal tension with the case of a thin surfactant covered film resting on a rigid substrate [4, 12]. Inspection of Figure 15, which depicts the temporal variation of the minimal total film thickness, the total film thickness and concentration profiles before rupture, and a log-log plot of the curvature and concentration against the minimal thickness with $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 10^3$, $\Gamma_0 = \mathcal{M} = 1$, and $\mathrm{Pe} = 100$, reveals close agreement with the rupture dynamics involving a rigid substrate. In fact, the curves shown in Figure 15 are virtually indistinguishable. These results, which are to be expected, provide a further check on the accuracy of the numerical procedure used to carry out the computations.

The results presented in this section indicate that as rupture is approached, the van der Waals–driven thinning leads to a surfactant-free region. Marangoni stresses become progressively weaker as rupture is approached, leading to a balance between van der Waals, capillary, and viscous forces. Similar results were obtained in related problems involving thin films and slender threads (see, for example, [12, 13, 19, 40]). Furthermore, due to the $1/h^3$ dependence of the van der Waals interactions, it is plausible that these forces would overwhelm wall effects. Thus, it appears that the wall becomes enslaved to the rupturing film, leaving the self-similar scalings unaltered.

5. Conclusions. In this paper, we have investigated the nonlinear evolution and rupture of a thin liquid film covered with insoluble surfactant that rests on a flexible support and is bounded from above by air (inviscid gas). Evolution equations for the deflection of the air-liquid and wall-liquid interfaces and the surfactant concentration were derived using lubrication theory. These equations are parameterized by dimensionless groups which reflect the relative importance of wall to fluid damping, wall longitudinal tension to van der Waals forces, Marangoni stresses to van der Waals forces, and surface diffusion time to convection time.

Both the linear and the nonlinear stability characteristics of these equations have

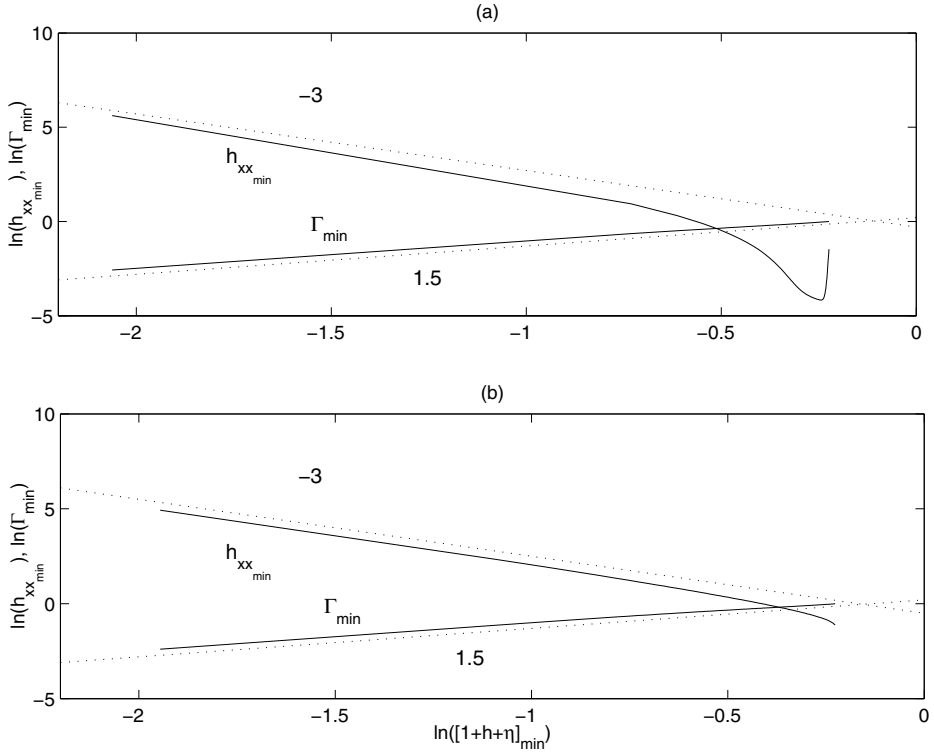

FIG. 14. *Log-log plots of the film curvature and surfactant concentration at the rupture location as a function of the minimal total thickness: parametric dependence of self-similar scalings on* $\hat{\mathcal{T}}$ *and* $\hat{\mathcal{B}}$. (a) $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 0.01$; (b) $\hat{\mathcal{T}} = \hat{\mathcal{B}} = 1$. *The scalings are shown by the dotted lines of constant slope. The rest of the parameter values remain unchanged from Figure* 13.

been investigated. In the linear regime, increasing the level of wall damping exerted a stabilizing influence, as did an increase in the wall longitudinal tension and relative magnitude of Marangoni stresses. It is worth noting that the wavenumber corresponding to the cutoff mode was found to be independent of wall damping and physicochemical parameters, depending only on the longitudinal tension.

In the nonlinear regime, van der Waals forces grow beneath perturbations and drive flow away from that region, giving rise to rapid thinning and driving the film thickness toward rupture. The behavior of the total film thickness and surfactant concentration as rupture is approached was similar in all cases considered: the surfactant concentration decreases in the rupture location as rupture is approached, which drives a Marangoni reverse flow from the adjoining regions of relatively higher concentration to the rupturing region that retards but does not prevent rupture. When both wall longitudinal tension and damping are weak, damped oscillations in the film thickness are observed. For weak longitudinal tension, increasing the damping retards the rupture time, whereas for strong longitudinal tension, the opposite effect in observed.

The self-similar nature of film rupture on a flexible wall was also briefly examined. The total film thickness and surfactant concentration exhibit power-law behavior as rupture is approached with power-law scalings which are consistent with a dominant balance of van der Waals, capillary, and viscous forces. These scalings are identical to those obtained by previous investigators who studied the rupture of thin clean and

contaminated liquid films resting on rigid substrates [9, 10, 11, 18, 13, 12]. The reason for this may be related to the $1/h^3$ dependence of the van der Waals forces, which dominates the dynamics as rupture is approached.

Our results may also have consequences for the practical applications that motivated this work. Based on our nonlinear simulations, it appears plausible that film rupture could be used to create patterns on compliant substrates provided that the damping and tension in the substrate are not too strong. It is unclear whether film rupture would promote airway closure in the lungs, given that there is a circumferential tension in cylindrical airways that does not appear in our planar model; this tension may have a significant impact on the problem dynamics. Nevertheless, given that the wall does deform on film rupture, our results raise the question of whether such a deformation will lead to airway damage. To the extent that film rupture is important in cell and vesicle adhesion to solid surfaces, it also appears plausible that adhesion dynamics would be different near a compliant substrate than a rigid one since the former can undergo significant deformation. Of course, verification of such a conjecture will require a more detailed model and corresponding experiments.

Acknowledgment. We thank the referees for a number of helpful comments.

FORWARD SCATTERING SERIES AND SEISMIC EVENTS: FAR FIELD APPROXIMATIONS, CRITICAL AND POSTCRITICAL EVENTS*

BOGDAN G. NITA†, KENNETH H. MATSON‡, AND ARTHUR B. WEGLEIN†

Abstract. Inverse scattering series is the only nonlinear, direct inversion method for the multidimensional, acoustic or elastic equation. Recently developed techniques for inverse problems based on the inverse scattering series [Weglein et al., *Geophys.*, 62 (1997), pp. 1975–1989; *Top. Rev. Inverse Problems*, 19 (2003), pp. R27–R83] were shown to require two mappings, one associating nonperturbative description of seismic events with their forward scattering series description and a second relating the construction of events in the forward to their treatment in the inverse scattering series. This paper extends and further analyzes the first of these two mappings, introduced, for 1D normal incidence, in Matson [*J. Seismic Exploration*, 5 (1996), pp. 63–78] and later extended to two dimensions in Matson [*An Inverse Scattering Series for Attenuating Elastic Multiples from Multicomponent Land and Ocean Bottom Seismic Data*, Ph.D. thesis, Department of Earth and Ocean Sciences, University of British Columbia, Vancouver, BC, Canada, 1997]. It brings a new and more rigorous understanding of the mathematics and physics underlying the calculation of terms in the forward scattering series and the events in the seismic model. The convergence of the series for 1D acoustic models is examined, and the earlier precritical analysis is extended to critical and postcritical reflections. An explanation is proposed for the divergence of the series for postcritical incident planewaves.

Key words. scattering theory, forward problem, critical reflections, postcritical reflections

1. Introduction.

Scattering theory is a form of perturbation theory. In seismic exploration, it relates the propagation of a wave in an actual medium with the propagation of the wave in a reference medium and a perturbation operator which describes the difference between the two media. The forward problem (or forward modeling) is to construct the actual wave-field, given the reference wave-field and the perturbation operator; the inverse problem is to construct the perturbation operator, given the reference wave-field everywhere and the actual wave-field on a measurement surface. The relation between these three quantities is nonlinear and cannot be given, at least so far, in a closed form in either the forward or the inverse problem. This relationship takes the form of a series which, when convergent, constructs the actual wave-field and the perturbation operator.

Inverse scattering series is the only nonlinear, direct inversion method for the multidimensional, acoustic or elastic equation. Early tests on the convergence of the entire series for an acoustic medium by Carvalho [4] were not favorable for real world application. Weglein and collaborators then developed the "subseries method" for the inverse problem (for a description and a complete history, see Weglein et al. [13] and references therein). The overall undertaking of the inverse scattering series was broken up into four tasks, which otherwise would be performed simultaneously by the series acting upon the input data. The four tasks are 1. elimination of the free surface

multiples, 2. elimination of the internal multiples, 3. locating where rapid changes in the medium properties occur (imaging), and 4. determining the changes at those locations (inversion). These tasks were associated with subseries of the full series, subseries which, if identified, would perform their job as if no other task existed in the series. Two immediate advantages of this separation of tasks are the favorable convergence properties of the subseries and the ability to judge the effectiveness of each step before proceeding on to the next. To facilitate the identification of the task-specific subseries in the inverse series, two maps have to be constructed (see [12]): one map associates seismic events with their forward scattering series description, while the second relates the construction of events in the forward to their usage in the inverse scattering series. In this paper we advance the analysis of the first of these mappings, introduced, for 1D (one-dimensional) normal incidence, by Matson [6] and later extended by Matson to two dimensions [7].

The forward series takes as input the information about the wave-field propagating through the reference medium and about the perturbation operator and outputs the wave-field everywhere in the actual medium. This process can be regarded as creating data (primaries, free surface multiples, internal multiples) for a given model; in practice, the forward series is never used for this purpose due to its inefficiency: it takes an infinite number of terms to create any single event. The events recorded in a seismic experiment are used by the inverse series to find the perturbation and, although the relation between their creation in the forward and their exploitation in the inverse series is not one-to-one, certain analogies could provide useful hints or at least point to where various activities reside in the inverse series. The forward series does not hint at whether events will be signal or noise in the full inverse series; it only suggests where one might look for that answer in the subseries. Take multiples, for example: it turns out that the inverse scattering subseries made of terms that mimic the diagrams for multiples in the forward series is responsible for attenuating/removing such multiples from the data [1].

The forward scattering series models seismic events in a fundamentally different way from conventional nonperturbative theory, where seismic waves propagate through the medium with different velocities and are reflected and transmitted at media boundaries. To construct one event alone, the forward series needs a sequence of terms which can be viewed as a succession of propagations in the reference medium separated by different orders of scattering interactions with a point scatterer; the different terms in the perturbation series correspond to the number of scattering interactions a wave experiences. Even with these differences taken into account, the wave-field output by the forward scattering series has to agree, when the series converges, with the well-known nonperturbative results for any given seismic experiment. Precritical data has been studied by Matson [7], who showed that the expected (from wave-theory) reflected wave-field is constructed by the convergent forward scattering series in a 2D (two-dimensional) experiment. This study brings new understanding about the physical interpretation of these previous results; it also shows that the same forward series converges for critical angles and diverges for postcritical, and an explanation of this divergence is proposed.

The plan for this paper is as follows. In section 2 we present the mathematical description for the forward scattering series for a 3D (three-dimensional) earth, both in operator and nonoperator form; in section 3, following Matson [7], we apply this description to a specific, 2D seismic model, and discuss the convergence of the forward scattering series for that model. Section 4 presents an alternative method for

solving for the terms in the series using saddle point analysis, which, in this setting, is equivalent to far field approximation. Section 5 presents the physical interpretation of the approximations performed in section 4. Section 6 shows the convergence of the forward scattering series for this model at the critical angle, and section 7 proposes an explanation for the divergence of the series for postcritical events. Some conclusions are given in section 8. Although in this paper we mainly focus on application of the scattering theory to seismic exploration, we mention that the same methods and discussions apply to other areas of explorative sciences like medical imaging, whole earth exploration, etc.

2. Forward scattering series. In operator form, the differential equations describing wave propagation in an actual and a reference medium can be written as

$$\mathbf{LG} = -\mathbf{I} \tag{2.1}$$

and

$$\mathbf{L}_0\mathbf{G}_0 = -\mathbf{I}, \tag{2.2}$$

where $\mathbf{L}$, $\mathbf{L}_0$ and $\mathbf{G}$, $\mathbf{G}_0$ are the actual and reference differential and Green's operators, respectively, for a single temporal frequency and $\mathbf{I}$ is the identity operator. The above equations (2.1) and (2.2) assume that the source and receiver signatures have been deconvolved. The perturbation, $\mathbf{V}$, and the scattered field operator, ψ_s, are defined as

$$\mathbf{V} = \mathbf{L} - \mathbf{L}_0, \tag{2.3}$$

$$\psi_{\mathbf{s}} = \mathbf{G}-\mathbf{G}_0. \tag{2.4}$$

The fundamental equation of scattering theory, the Lippmann–Schwinger equation, relates ψ_s, $\mathbf{G}_0$, $\mathbf{V}$, and $\mathbf{G}$ (see, e.g., [10]):

$$\psi_s = \mathbf{G}-\mathbf{G}_0 = \mathbf{G}_0\mathbf{V}\mathbf{G}. \tag{2.5}$$

When $\mathbf{G}$ corresponds to the pressure field in an inhomogeneous acoustic medium, an example of $\mathbf{L}$, $\mathbf{L}_0$, and $\mathbf{V}$ is (see, e.g., [5])

$$\mathbf{L} = \frac{\omega^2}{\kappa} + \nabla\cdot\left(\frac{1}{\rho}\nabla\right), \tag{2.6}$$

$$\mathbf{L}_0 = \frac{\omega^2}{\kappa_0} + \nabla\cdot\left(\frac{1}{\rho_0}\nabla\right), \tag{2.7}$$

and

$$\mathbf{V} = \omega^2\left(\frac{1}{\kappa} - \frac{1}{\kappa_0}\right) + \nabla\cdot\left[\left(\frac{1}{\rho} - \frac{1}{\rho_0}\right)\nabla\right], \tag{2.8}$$

where κ, κ_0, ρ, and ρ_0 are the actual and reference bulk moduli and densities, respectively. If the density is constant $(\rho = \rho_0 = const.)$, the above expressions become

$$\mathbf{L} = \frac{\omega^2}{\kappa}, \tag{2.9}$$

$$\mathbf{L}_0 = \frac{\omega^2}{\kappa_0}, \tag{2.10}$$

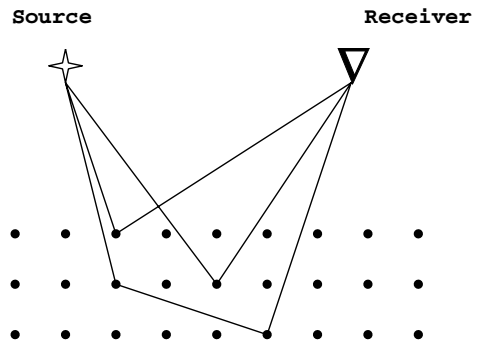

FIG. 2.1. *Graphical representation of the terms in the forward scattering series: the first term is an integral over all* 1*-interaction events, the second term is an integral over all* 2*-interactions events, etc.*

and

$$\mathbf{V} = \omega^2 \left(\frac{1}{\kappa} - \frac{1}{\kappa_0} \right). \tag{2.11}$$

For an elastic isotropic actual and a homogeneous reference medium, the expressions for $\mathbf{L}$, $\mathbf{L}_0$, and $\mathbf{V}$ are different and given, e.g., in [9].

Equation (2.5) can be expanded in an infinite series by repeatedly substituting $\mathbf{G} = \mathbf{G}_0 - \mathbf{G}_0\mathbf{V}\mathbf{G}$ into the right-hand side to obtain

$$\psi_s \equiv \mathbf{G} - \mathbf{G}_0 = \mathbf{G}_0\mathbf{V}\mathbf{G}_0 + \mathbf{G}_0\mathbf{V}\mathbf{G}_0\mathbf{V}\mathbf{G}_0 + \cdots \quad . \tag{2.12}$$

This series constructs the scattered field operator ψ_s as a series of terms formed as propagations in the reference medium ($\mathbf{G}_0$) and interactions with the inhomogeneity ($\mathbf{V}$). Note that the nth term in this series is of order n in the perturbation operator $\mathbf{V}$ and, in fact, can be written as $(\psi_s)_n \equiv \mathbf{G}_0 (\mathbf{V}\mathbf{G}_0)^n$.

For the previous example (constant density case), define $k_0 = \frac{\omega}{c_0}$ and $\alpha = \left(1 - \frac{c_1^2}{c_0^2}\right)$, where c_1 and c_0 are the actual and the reference medium velocities, respectively; the series becomes

$$\begin{aligned} \psi_s\left(\mathbf{r}_g|\mathbf{r}_s;\omega\right) = & \int_{\mathbf{V}} G_0\left(\mathbf{r}_g|\mathbf{r}';\omega\right) k_0^2 \alpha\left(\mathbf{r}'\right) G_0\left(\mathbf{r}'|\mathbf{r}_s;\omega\right) d\mathbf{r}' \\ & + \int_{\mathbf{V}} G_0\left(\mathbf{r}_g|\mathbf{r}';\omega\right) k_0^2 \alpha\left(\mathbf{r}'\right) \int_{\mathbf{V}} G_0\left(\mathbf{r}'|\mathbf{r}'';\omega\right) k_0^2 \alpha\left(\mathbf{r}''\right) G_0\left(\mathbf{r}''|\mathbf{r}_s;\omega\right) d\mathbf{r}'' d\mathbf{r}' \\ & + \cdots, \end{aligned} \tag{2.13}$$

where the integrals are 3D volume integrals taken over the inhomogeneity $\mathbf{V}$. For an easy physical interpretation of this series, consider the perturbation $\mathbf{V}$ to be composed of point scatterers separated by the reference medium. The first term in the series for the scattered field (2.13) represents a summation over all 1-interaction events, i.e., events formed from a wave propagating from the source location $\mathbf{r}_s$ to the scatterer location at $\mathbf{r}'$, $G_0\left(\mathbf{r}'|\mathbf{r}_s;\omega\right)$, interacting with the scatterer at $\mathbf{r}'$, $k_0^2\alpha\left(\mathbf{r}'\right)$, and propagating to the receiver location at $\mathbf{r}_g$, $G_0(\mathbf{r}_g|\mathbf{r}';\omega)$. The second term represents a summation over all 2-interaction events and so on. Note that, as stated before, the propagations between source, receiver, and scatterers occur only in the reference medium, i.e., with the Green's function G_0, even though the speed of the wave in the actual medium is different from the speed of the wave in the reference medium. A picture of the physical interpretation of these terms is shown in Figure 2.1.

3. A 2D seismic profile. Matson [6, 7] describes the propagation of a wave-field in a given 1D or 2D medium, using the forward scattering series. We use the same 2D model in this paper to give an alternate derivation, and a physical interpretation for that derivation, for the Matson [7] result. The model is a half-space earth with no lateral variance and an interface at z_1; the scattering perturbation for this model is, therefore,

$$V(z') = k_0^2 \alpha H(z' - z_1), \tag{3.1}$$

where, as before, $\alpha = 1 - c_0^2/c_1^2$, c_1 is the velocity in the second medium, c_0 is the velocity in the reference medium, and H is the Heaviside step function.

The propagations in the reference medium are described by the 2D Green's function (see, e.g., [2])

$$G_0(x_g, z_g|x_s, z_s; \omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{ik_s(x_g - x_s)} e^{i\nu_{0s}|z_g - z_s|}}{2i\nu_{0s}} dk_s, \tag{3.2}$$

where k_s and ν_{0s} are the horizontal and the vertical wavenumber, respectively, of the reference medium ($\nu_{0s}^2 + k_s^2 = \omega^2/c_0^2$). Rewriting G_0 as

$$G_0(x_g, z_g|x_s, z_s; \omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{-ik_s x_s}}{2i\nu_{0s}} \phi_0(x_g, z_g|k_s, z_s; \omega) dk_s \tag{3.3}$$

with $\phi_0(x_g, z_g|k_s, z_s; \omega) = e^{i(k_s x_g + \nu_{0s}|z_g - z_s|)}$, it is apparent that G_0 represents a superposition of weighted planewaves. This motivates the use of a planewave component as the incident wave with the remark that one can construct solutions for point sources from planewave solutions by performing the above-mentioned weighted integration. Denote by P the actual wave-field and by P_0, P_1, etc., the corresponding term in the forward scattering series. For simplicity consider the source location to be (0, 0); the Born series takes the form

$$\begin{aligned} P(x_g, z_g|k; \omega) = {} & e^{i(kx_g + \nu_0 z_g)} \\ & + \int_{z_1}^{\infty} \int_{-\infty}^{\infty} \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{ik_g(x_g - x')} e^{i\nu_{0g}|z_g - z'|}}{2i\nu_0} dk_g k_0^2 \alpha P_0(x', z'|k; \omega) dx' dz' \\ & + \int_{z_1}^{\infty} \int_{-\infty}^{\infty} \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{ik_g(x_g - x')} e^{i\nu_{0g}|z_g - z'|}}{2i\nu_0} dk_g k_0^2 \alpha P_1(x', z' > z_1|k; \omega) dx' dz' \\ & + \cdots . \end{aligned} \tag{3.4}$$

Note that the incoming wave hits all the scatterers at once; each scatterer then emits a cylindrical wave which propagates to the receiver or to another scatterer. Each term in the forward series represents the response, at the receiver, after a certain number of interactions: the zeroth term represents the direct arrival, the first term represents the wave-field after one interaction with a point scatterer, and so on. To construct even the simplest event, one needs an infinite number of terms in the forward series. To obtain the total wave-field at the receiver we have to solve the integrals in the previous expression. Following Matson [7], we solve for the first term in the series

$$P_1(x_g, z_g|k; \omega) = \int_{z_1}^{\infty} \int_{-\infty}^{\infty} \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{e^{ik_g(x_g - x')} e^{i\nu_{0g}|z_g - z'|}}{2i\nu_0} dk_g k_0^2 \alpha e^{i(kx' + \nu_0 z')} dx' dz'. \tag{3.5}$$

Begin by switching the order of integration so that the integration with respect to dx' is performed first. Hence

(3.6)
$$P_1(x_g, z_g|k;\omega) = \frac{1}{2\pi}\int_{z_1}^{\infty}\int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty} e^{i(k-k_g)x'}dx'\right)e^{ikgx_g}e^{i\nu_{0g}|z_g-z'|}e^{i\nu_0 z'}\frac{k_0^2\alpha}{2i\nu_{0g}}dk_g dz'.$$

Using

$$\int_{-\infty}^{\infty} e^{i(k-k_g)x'}dx' = 2\pi\delta(k_g-k), \tag{3.7}$$

P_1 becomes

$$P_1(x_g, z_g|k;\omega) = \int_{z_1}^{\infty}\int_{-\infty}^{\infty}\delta(k_g-k)e^{ikgx_g}e^{i\nu_{0g}|z_g-z'|}e^{i\nu_0 z'}\frac{k_0^2\alpha}{2i\nu_{0g}}dk_g dz'. \tag{3.8}$$

Using the properties of the delta function, we see that the inside integral switches $k_g \to k$ and hence $\nu_{0g} \to \nu_0$, and so the expression becomes

$$P_1(x_g, z_g|k;\omega) = \frac{k_0^2\alpha}{2i\nu_0}e^{ikx_g}\int_{z_1}^{\infty} e^{i\nu_0|z_g-z'|}e^{i\nu_0 z'}dz'. \tag{3.9}$$

There are two cases to be considered at this point: $z_g < z_1$ for the reflected P_1 and $z_g > z_1$ for the transmitted part. The first enters into the series for the total reflected field, while the second is used either in the series for transmitted wave-field or for the calculation of P_2 (reflected or transmitted). We have

$$P_1(x_g, z_g < z_1|k;\omega) = \frac{k_0^2\alpha}{2i\nu_0}e^{ikx_g}e^{-i\nu_0 z_g}\int_{z_1}^{\infty} e^{i\nu_0 2z'}dz'. \tag{3.10}$$

The last integral,

$$\int_{z_1}^{\infty} e^{i\nu_0 2z'}dz', \tag{3.11}$$

is not defined in the Riemannian sense because the integrand oscillates, preserving its amplitude towards infinity. We are going to define this integral to be the value of the antiderivative of the integrand calculated at its finite boundary z_1, i.e.,

$$\int_{z_1}^{\infty} e^{i\nu_0 2z'}dz' = -\frac{e^{i\nu_0 2z_1}}{2i\nu_0}. \tag{3.12}$$

This definition is consistent with considering that the reference medium is attenuating the wave-field which will vanish at infinity. The attenuation is introduced in the equations through an imaginary part in the velocity c_0 (see [2, Chapter 5, equations 5.87 and 5.88]) so that the new velocity c_0^{new} is

$$\frac{1}{c_0^{new}} = \frac{1}{c_0} + i\varepsilon,$$

with ε being a small parameter such that $\varepsilon > 0$ for $\omega > 0$. It is easy to see that, with this new effective velocity, the value of the integral is indeed the one defined in (3.12).

The final expression for P_1 is hence

$$P_1(x_g, z_g < z_1|k;\omega) = \frac{k_0^2\alpha}{4\nu_0^2} e^{ikx_g} e^{i\nu_0(2z_1 - z_g)}. \tag{3.13}$$

The same integration procedure is used for the calculation of P_2, P_3, etc. The calculated series for the scattered field (also denoted by P) is

$$P(x_g, z_g < z_1|k;\omega) = e^{ikx_g} e^{i\nu_0(2z_1 - z_g)} \left[\frac{1}{4}\frac{k_0^2\alpha}{\nu_0^2} + \frac{1}{8}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^2 + \frac{5}{64}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^3 + \cdots \right] \tag{3.14}$$

and indicates a certain regularity after some algebraic operations: the series is recognized to be the Taylor series of $\sqrt{1 - \frac{k_0^2\alpha}{\nu_0^2}}$ about $\frac{k_0^2\alpha}{\nu_0^2} = 0$ (a rigorous proof is given in the appendix). The ratio test indicates that the series converges for $\left|\frac{k_0^2\alpha}{\nu_0^2}\right| < 1$. By writing $\nu_0 = k_0 \cos\theta$, with θ being the incidence angle of the incoming planewave, this condition becomes

$$\sin\theta < \frac{c_0}{c_1} < \left(1 + \cos^2\theta\right)^{1/2}. \tag{3.15}$$

This last relation can be viewed in the following two ways:

1. First, for a fixed incidence angle θ, this is a restriction on the velocity contrast between the reference and the actual medium. In particular, for $\theta = 0$ (normal incidence) the left inequality is satisfied for any two velocities; the right inequality becomes $c_0 < \sqrt{2}c_1$, a result obtained in Matson [6].
2. Second, for a fixed velocity model, the restriction is on the incident angle. Note that, given any two velocities c_0 and c_1, one of the two inequalities is automatically satisfied. For $c_0 > c_1$, the condition reads $\frac{c_0}{c_1} < (1 + \cos^2\theta)^{1/2}$ or $\sin^2\theta < 1 + \alpha$ with $\alpha < 0$.

For $c_0 < c_1$, the condition becomes $\sin\theta < \frac{c_0}{c_1}$ or $\theta < \theta_c$, where θ_c is the critical angle $\theta_c = \sin^{-1}(c_0/c_1)$. When the series converges, the limit is

$$2\frac{\nu_0^2}{k_0^2\alpha}\left[1 - \sqrt{1 - \frac{k_0^2\alpha}{\nu_0^2}}\right] - 1 = \frac{\nu_0 - \nu_1}{\nu_0 + \nu_1}, \tag{3.16}$$

and so the final expression for the reflected field is

$$P(x_g, z_g < z_1|k;\omega) = \frac{\nu_0 - \nu_1}{\nu_0 + \nu_1} e^{ikx_g} e^{i\nu_0(2z_1 - z_g)}, \tag{3.17}$$

which is the expected result from nonperturbative theory (see, e.g., [2]).

4. An alternative derivation using saddle point approximations. The calculation of

$$P_1(x_g, z_g|k;\omega) = \int_{z_1}^{\infty}\int_{-\infty}^{\infty} \frac{1}{2\pi}\left(\int_{-\infty}^{\infty} \frac{e^{ik_g(x_g - x')} e^{i\nu_{0g}|z_g - z'|}}{2i\nu_0} dk_g\right) k_0^2\alpha e^{i(kx' + \nu_0 z')} dx'dz' \tag{4.1}$$

contains a reordering of integrals: in the original expression the dk_g integral should be solved first, then the dx', and finally the dz' integral. As we saw in the previous

section, the calculations are greatly simplified if the dx' integration is performed first, then the dk_g, and finally the dz' integration. However, this kind of operation has to be performed with great care since it might impose some restrictions, which might change the result obtained from solving the integrals in the original order.

The theorem which deals with interchanging integrals is Fubini's theorem. It states that when a function f is integrable on $R^n = R^k \times R^m$, the iterated integrals of f over R^k and R^m exist and

$$\int_{R^n} f = \int_{R^k}\int_{R^m} f(x,y)dydx = \int_{R^m}\int_{R^k} f(x,y)dxdy. \tag{4.2}$$

The theorem gives sufficient conditions for interchanging the order of integrals, but those conditions are not necessary. For example, you can have a function non-integrable over R^n for which the integration in both directions would yield the same result. The only way to show that the interchange of integrals does not hold is to calculate the integrals in both direction and obtain different results. However, to calculate the dk_g integral first in the expression (4.1) means to find a closed form for the Green's function (3.2), which is not possible. For an in-depth analysis of the cylindrical functions, see [11].

In this section we show that the interchange of integrals yields the same result as the far field approximation of the integrals in question. The Fubini theorem does not apply here because the function to be doubly integrated is not integrable. To be more specific, the integral representation of the Dirac delta function,

$$\int_{-\infty}^{\infty} e^{i(k-k_g)x'}dx', \tag{4.3}$$

is meaningless in the strict Riemannian sense.

Recalculate P_1 using saddle point approximations for the two integrals involved without switching the order of integration, and show that the result is the one obtained in Matson [7]. Saddle point or stationary phase approximation gives the leading asymptotic behavior of generalized Fourier integrals, i.e., of the form $\int_{-\infty}^{\infty} F(p)e^{\omega f(p)}dp$, having stationary points, i.e., points p_s such that $f'(p_s) = 0$. The idea of the method is to use the analyticity of the integrand to justify deforming the path of integration to a new path on which $f(p)$ has a constant imaginary path. How the contour is deformed depends on the singularities and branch cuts of the integrand. Once this has been done, the integral may be found asymptotically ($\omega \to \infty$) to be

$$\int_{-\infty}^{\infty} F(p)e^{\omega f(p)}dp \ \sim \left|\frac{2\pi}{\omega f''(p_s)}\right|^{1/2} F(p_s)e^{isign\left(f''(p_s)\right)\frac{\pi}{4}} \exp\left[\omega f(p_s)\right]. \tag{4.4}$$

To calculate P_1 in (4.1), start by rewriting

$$G_0 = \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{e^{ik_g(x_g-x')}e^{i\nu_{0g}\left|z_g-z'\right|}}{2i\nu_0}dk_g \tag{4.5}$$

as

$$G_0 = \frac{1}{2\pi}\int_{-\infty}^{\infty} F(p)e^{\omega f(p)}dp, \tag{4.6}$$

where

$$F(p) = \frac{1}{2i\sqrt{1/c_0^2 - p^2}} \tag{4.7}$$

and

$$f(p) = i\left[p(x_g - x') + |z_g - z'|\sqrt{\frac{1}{c_0^2} - p^2}\right], \tag{4.8}$$

p being the horizontal slowness $p = \frac{k_g}{\omega}$. Note that, due to the square root, $F(p)$ defines two branch cuts in the complex p plane; the branch cuts are hyperbolas in the first and third quadrant and are running very close to the coordinate axis. (For a full discussion of the branch cuts of F, see [2, Box 6.2].) By definition, branch cuts are lines of discontinuities for $F(p)$ and here are given by $Im\sqrt{1/c_0^2 - p^2} = 0$. This means that when the new integration path (see Figure 6.6 in [2]) intersects these branch cuts, $F(p)$ is discontinuous and hence not analytic. This apparent problem can be avoided if we relax the condition $Im\sqrt{1/c_0^2 - p^2} \geq 0$ along the integration path. Instead we allow $Im\sqrt{1/c_0^2 - p^2}$ to change sign at each branch cut intersection which, for the integration path, is equivalent to a transition to a different Riemann sheet. The integrand looses physical interpretation while on another Riemann sheet but gains analyticity. However, the two intersections with the branch cut insure two sign changes and the emergence of the integrand with the correct sign at the saddle point. (Eventually the integrand is going to be expanded in a Taylor series at that point, and the rest of the path is going to be discarded.) To calculate the location of the saddle point, equate the derivative of f with zero; this gives

$$p_s = \frac{x_g - x'}{c_0 d'}, \tag{4.9}$$

with $d' = \sqrt{(z_g - z')^2 + (x_g - x')^2}$. Calculate

$$f(p_s) = i\frac{d'}{c_0}, \tag{4.10}$$

$$f''(p_s) = -\frac{ic_0 d'^3}{|z_g - z'|^2}, \tag{4.11}$$

$$F(p_s) = \frac{c_0 d'}{2i\,|z_g - z'|}, \tag{4.12}$$

and plug them into the above formula (4.4) to obtain

$$G_0 \sim \frac{1}{4\pi i}\left(\frac{2\pi c_0}{i\omega d'}\right)^{1/2} e^{ik_0 d'}. \tag{4.13}$$

(Compare with the approximation for $i\pi H_0^{(1)}(\omega/c_0 d')$, the Green's function for the 2D Helmholtz equation, where $H_0^{(1)}$ is the Hankel function of the first kind, given by formula (5.3.69) in [8].) With this approximation, expression (4.1) for P_1 becomes

$$P_1(x_g, z_g|k;\omega) = \frac{1}{4\pi i}\int_{z_1}^{\infty}\int_{-\infty}^{\infty} e^{ik_0 d'}\left(\frac{2\pi c_0}{i\omega d'}\right)^{1/2} k_0^2 \alpha e^{i(kx' + \nu_0 z')} dx' dz' \tag{4.14}$$

or

$$P_1(x_g, z_g|k;\omega) = \frac{k_0^{3/2}\alpha}{2\pi i}\sqrt{\frac{\pi}{2i}}\int_{z_1}^{\infty} e^{i\nu_0 z'}\int_{-\infty}^{\infty}\frac{e^{i\omega\left(\frac{d'}{c_0}+\frac{k}{\omega}x'\right)}}{\sqrt{d'}}dx'dz'. \tag{4.15}$$

Again, the innermost integral has the form

$$I = \int_{-\infty}^{\infty} F(x')e^{\omega f(x')}dx' \tag{4.16}$$

with $F(x') = \frac{1}{\sqrt{d'}}$ and $f(x') = i(\frac{d'}{c_0} + \frac{k}{\omega}x')$. Note that the integrand has no branch cuts this time since $d' = \sqrt{(z_g - z')^2 + (x_g - x')^2}$ is always positive; the saddle point is x'_s such that

$$x_g - x'_s = |z_g - z'|\,\frac{k}{\nu_0}, \tag{4.17}$$

and so we have

$$f(x'_s) = i\left(\frac{\nu_0}{\omega}\,|z_g - z'| + \frac{k}{\omega}x_g\right), \tag{4.18}$$

$$f''(x'_s) = \frac{ic_0^2\nu_0^3}{\omega^3\,|z_g - z'|}, \tag{4.19}$$

and

$$F(x'_s) = \frac{1}{\sqrt{|z_g - z'|}}\sqrt{\frac{c_0\nu_0}{\omega}}. \tag{4.20}$$

Using the same high frequency approximation (4.4), we find

$$\int_{-\infty}^{\infty}\frac{e^{i\omega\left(\frac{d'}{c_0}+\frac{k}{\omega}x'\right)}}{\sqrt{d'}}dx' \sim \frac{1}{\nu_0}\sqrt{\frac{2\pi i\omega}{c_0}}e^{i\left(\nu_0|z_g - z'| + kx_g\right)}. \tag{4.21}$$

Substituting this into the expression (4.15) for P_1, we obtain

$$P_1(x_g, z_g|k;\omega) = \frac{k_0^2\alpha}{2i\nu_0}e^{ikx_g}\int_{z_1}^{\infty} e^{i\nu_0|z_g - z'|}e^{i\nu_0 z'}dz', \tag{4.22}$$

which is the same result as that obtained before by switching the order of integration. The rest of the terms in the series for P can be similarly shown to resemble the expressions given by Matson [7].

5. Physical interpretation of the approximations. The two far field approximations performed in the previous derivation have an easily understandable physical interpretation. The approximation of the first integral in the expression of P_1 represents the most important contribution arriving at the receiver from each point scatterer (see Figure 5.1).

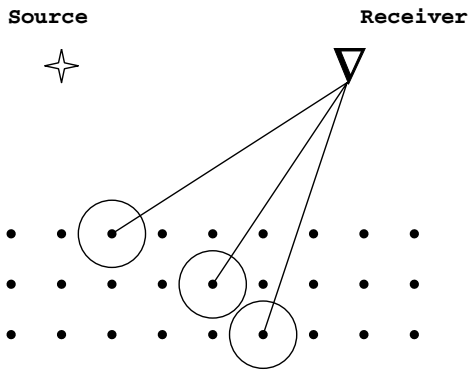

FIG. 5.1. *The physical interpretation of the approximation of the first integral in the calculation of* P_1.

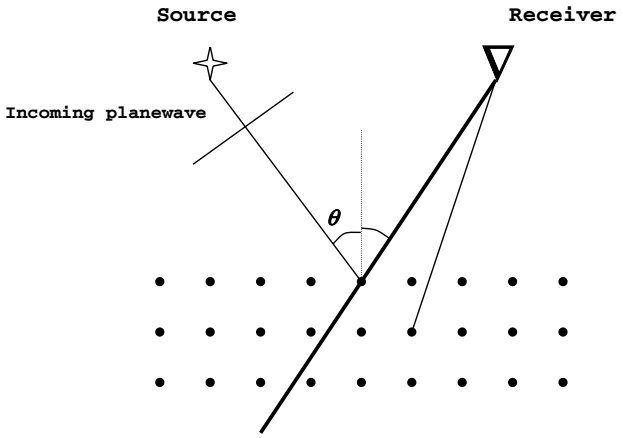

FIG. 5.2. *The physical interpretation of the approximation of the second integral in the calculation of* P_1.

As the figure shows, each scatterer behaves as a point source producing a wave propagating in all directions described by the Green's function given by (3.2). However, when the integral is approximated using saddle point techniques, only the direction of propagation bringing in the highest contribution is kept. The result given by (4.13),

$$G_0 \sim \frac{1}{4\pi i}\left(\frac{2\pi c_0}{i\omega d'}\right)^{1/2} e^{ik_0 d'}, \tag{5.1}$$

represents the part arriving from the scatterer to the receiver along the straight line connecting them, multiplied by a coefficient which accounts for the dismissal of all the other directions.

The approximation of the second integral in the expression of P_1 picks out the most important contribution arriving at the receiver from the totality of incoming rays. Here, the main contribution is found to be the one from the rays that make an angle equal to the incident's planewave angle with the vertical (see Figure 5.2); this

can be seen from the expression of the saddle point for the x' integration:

$$x_g - x'_s = |z_g - z'| \frac{k'}{\nu_0}. \tag{5.2}$$

The last integral in the expression of P_1 is a 1D integral along the thick line shown in Figure 5.2. Even though the parameter of integration is z', there is a certain relation between z' and x', given by (5.2), such that the direction of integration is tilted at an angle equal to the incident angle rather than vertical. The lack of symmetry in this last integral is expected since the model is not symmetric: the discussion here is for a planewave component of a line source and a line receiver. It is anticipated that the symmetry would be recovered in the line source–line receiver case.

6. Convergence at the critical angle. The forward scattering series for the reflected wave-field for the model discussed in this paper is (see Matson [7])

$$P(x_g, z_g < z_1|k;\omega) = e^{ikx_g} e^{i\nu_0(2z_1 - z_g)} \left[\frac{1}{4}\frac{k_0^2\alpha}{\nu_0^2} + \frac{1}{8}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^2 + \frac{5}{64}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^3 + \cdots \right]. \tag{6.1}$$

The ratio test shows convergence for $|\frac{k_0^2\alpha}{\nu_0^2}| < 1$, divergence for $|\frac{k_0^2\alpha}{\nu_0^2}| > 1$, and is inconclusive for $|\frac{k_0^2\alpha}{\nu_0^2}| = 1$. When $c_0 < c_1$, this last condition is equivalent to $\frac{k_0^2\alpha}{\nu_0^2} = 1$, which in turn is equivalent to $\theta = \theta_c$; i.e., the incident angle is the critical angle. In other words, the forward series is convergent for precritical incidence and divergent for postcritical incidence; no information is found about the critical incidence. For a critical incident planewave, the series becomes

$$P(x_g, z_g < z_1|k;\omega) = e^{ikx_g} e^{i\nu_0(2z_1 - z_g)} \left[\frac{1}{4} + \frac{1}{8} + \frac{5}{64} + \frac{7}{128} + \cdots \right]. \tag{6.2}$$

Rewrite

$$R = \frac{1}{4} + \frac{1}{8} + \frac{5}{64} + \frac{7}{128} + \cdots = \sum_{n=2}^{\infty} \frac{1}{n!} \frac{1\cdot 3\cdot 5 \ldots (2n-3)}{2^{n-1}} = \sum_{n=1}^{\infty} \frac{\Gamma(n+1/2)}{(n+1)!\Gamma(1/2)}. \tag{6.3}$$

Note that the series has the form $\sum_{n=2}^{\infty} a_n$ with $a_n = \frac{1}{n!}\frac{1\cdot 3\cdot 5\ldots(2n-3)}{2^{n-1}}$, and so

$$\lim_{n\to\infty} n\left(\frac{a_n}{a_{n+1}} - 1\right) = \lim_{n\to\infty} n\left(\frac{2n+2}{2n-1} - 1\right) = \frac{3}{2} > 1. \tag{6.4}$$

Hence Raabe's convergence test shows convergence. (For a full discussion of this convergence test, see [3].) The conclusion is that the forward scattering series for this model converges at the critical angle as well. Note that, in this case, the sum of the series, which corresponds to the reflection coefficient, is $R = 1$.

7. Postcritical divergence. For a $c_0 < c_1$ model, the forward series converges for precritical and critical incidence and diverges for postcritical incidence. From wave nonperturbative theory, the reflection coefficient R, which should be constructed by the forward scattering series, is

- $R = \frac{\nu_0 - \nu_1}{\nu_0 + \nu_1} < 1$ for precritical incidence. In this case both ν_0 and ν_1 are real.

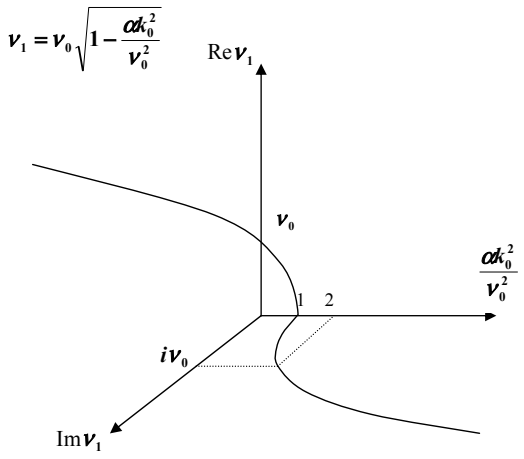

FIG. 7.1. *The graph of* ν_1 *as a function of* $\frac{\alpha k_0^2}{\nu_0^2}$.

- $R = 1$ for critical incidence. In this case $\nu_1 = 0$.
- $R = \frac{\nu_0 - \nu_1}{\nu_0 + \nu_1}$ for postcritical incidence. In this case ν_1 is purely imaginary, and hence R is complex. However, $|R| = 1$, and the complexity of R is attributed to a phase-shift of the emerging wave after hitting the interface due to the evanescent waves created in the second medium.

The term $\alpha k_0^2/\nu_0^2 = 1 - \nu_1^2/\nu_0^2$ is > 1 exactly when ν_1 becomes imaginary. In fact, if for this case one writes $R = e^{i\varepsilon}$, where ε is the phase-shift of the wave-field, then $\alpha k_0^2/\nu_0^2 = 1 + \tan^2 \varepsilon/2$, enforcing the earlier statement that the divergence is due to the phase-shift of the reflected wave. In other words, it is the impossibility of constructing a complex number ν_1 as a series of real numbers (powers of ν_0) which leads to the divergence of the series. The graph of ν_1 as a function of $\alpha k_0^2/\nu_0^2$ is shown in Figure 7.1.

For $c_0 < c_1$we have that $\alpha > 0$, so we are looking at the positive x-axis of the graph; if the velocity model is fixed, αk_0^2 is a constant. The vertical wavenumber of the propagating wave in the actual medium, ν_1, is equal to ν_0 when $\alpha k_0^2/\nu_0^2 = 0$, i.e., at normal incidence. When $\alpha k_0^2/\nu_0^2 = 1$ (at critical incidence), ν_1 is zero, showing that there is no propagation into the second medium. When $\alpha k_0^2/\nu_0^2 > 1$ (postcritical incidence), ν_1 is complex, and it becomes unrecoverable by a Taylor series written at $\alpha k_0^2/\nu_0^2 = 0$; the series is now divergent. For $c_0 > c_1$ it seems like this problem does not exist. In this case there is no critical angle, and so the vertical wavenumber ν_1 never becomes complex. However, the series inherits the divergent behavior for $\alpha k_0^2/\nu_0^2 < -1$ due to the singularity at $\alpha k_0^2/\nu_0^2 = 1$. For any value of $\alpha k_0^2/\nu_0^2$ outside the unit sphere centered at the origin the series will diverge due to that same singularity.

8. Conclusion. We have shown that the interchange of certain integrals in the calculation of terms in the forward scattering series yields the same result as the far field approximations of those integrals. The later approach allows the study of the restrictions imposed on the model by the former approach and provides new insights and physical interpretations for the terms in the forward scattering series. It is also anticipated that the new method would be more practical in the study of more complicated models (e.g., line source and receiver).

We have also proved the convergence of the forward scattering series at critical angle for the model of Matson [7] and provided an explanation for the divergence of the series for postcritical incident angles. The divergence is due to the inability of the forward scattering series to construct a complex vertical wavenumber from a series of real terms. Several possibilities for extending this result exist. First, one could introduce imaginary terms in the calculated series by using more than just the leading asymptotic behavior of the integral representation of the Hankel function, or of the dx' integral involved in the calculations. Second, one could try to make use of the evanescent part of the wave-field emanating from the scatterers to construct a complex vertical wavenumber. The evanescent part is always discarded when the asymptotic behavior of the integral representation of the Hankel function is considered; using it is attractive because it makes sense intuitively to construct an evanescent wave in the actual medium using evanescent waves in the reference medium. Third, an imaginary term in the reference velocity, and hence complex terms in the forward scattering series, could be brought in by the introduction of an absorptive reference medium. These ideas will be considered in future research.

Appendix. In section 3 we indicated how to calculate the first few terms in the forward scattering series for the reflected wave-field in a 2D vertically varying medium. We stated there that the calculated series for the scattered field for that specific model is (see (3.14))

(A.1)
$$P(x_g, z_g|\, k;\omega) = e^{ikx_g} e^{i\nu_0(2z_1 - z_g)} \left[\frac{1}{4}\frac{k_0^2\alpha}{\nu_0^2} + \frac{1}{8}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^2 + \frac{5}{64}\left(\frac{k_0^2\alpha}{\nu_0^2}\right)^3 + \cdots \right],$$

which is recognized to be the Taylor series for $\sqrt{1 - k_0^2\alpha/\nu_0^2}$ about $\frac{k_0^2\alpha}{\nu_0^2} = 0$ after some algebraic operations are performed on it. In this section we provide a rigorous proof of this statement. The proof will proceed as follows: first we will write down the general term for the transmitted wave-field and show by induction that the expression is correct; then we will use it to calculate the general term for the reflected wave-field and show that it corresponds to the general term in the aforementioned Taylor series. The need for the general term for the transmitted field is obvious since the iteration step occurs in the transmitted wave rather than the reflected one. Once the general term for the transmitted wave-field, P_n^T, is obtained, the general term for the reflected wave-field, P_n^R, is obtained by calculating

(A.2)
$$\begin{aligned} &P_{n+1}^R\,(x_g, z_g < z_1|\, k;\omega) \\ &= \int_{z_1}^{\infty} dz' \int_{-\infty}^{\infty} dx' \frac{1}{2\pi} \left(\int_{-\infty}^{\infty} \frac{e^{ik_g(x_g - x')} e^{i\nu_{0g}|z_g - z'|}}{2i\nu_0} dk_g \right) k_0^2\alpha P_n^T\,(x', z'|\, k;\omega)\,. \end{aligned}$$

To simplify the writing we introduce the notation

(A.3)
$$\frac{k_0^2\alpha}{\nu_0^2} = X$$

and

(A.4)
$$S_n = \frac{X^n}{2^n n!}\,(1+R)^{n+1}\,,$$

where

$$(1+R) = \frac{2}{X}\left[1 - Taylor\left(\sqrt{1-X}\right)\right] \tag{A.5}$$

and $Taylor\left(\sqrt{1-X}\right)$ stands for the Taylor series of $\sqrt{1-X}$ about $X=0$. Notice that S_n is a series in X of lowest order n. Also denote by S_n^j the coefficient of the jth order in S_n, and notice that all these coefficients are zero for $j<n$.

We will prove by induction that the general term for the transmitted wave-field P_n^T for $n \geq 1$ is

$$P_n^T\left(x_g, z_g > z_1 \middle| \, k;\omega\right) = e^{ikx_g} e^{i\nu_0 z_g} X^n \sum_{l=0}^{n} \left[-i\nu_0\left(z_g - z_1\right)\right]^l S_l^n. \tag{A.6}$$

The first step of the induction is to verify this relation for $n=1$, i.e., to check that

$$P_1^T = e^{ikx_g} e^{i\nu_0 z_g} X\left\{S_0^1 + \left[-i\nu_0\left(z_g - z_1\right)\right] S_1^1\right\}. \tag{A.7}$$

Note that $S_0^1 = 1/4$ and $S_1^1 = 1/2$, and hence this is the expression (2.25) found in Matson [7]. For the second step of the induction we assume that the relation (A.6) for P_n^T is true, and we calculate P_{n+1}^T and show that it has the same form; i.e., we want to prove that

$$P_{n+1}^T\left(x_g, z_g > z_1 \middle| \, k;\omega\right) = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} \sum_{l=0}^{n+1} \left[-i\nu_0\left(z_g - z_1\right)\right]^l S_l^{n+1}. \tag{A.8}$$

We have

$$\begin{aligned} P_{n+1}^T &= \int_{z_1}^{\infty} dz' \int_{-\infty}^{\infty} dx' \frac{1}{2\pi}\left(\int_{-\infty}^{\infty} \frac{e^{ik_g\left(x_g - x'\right)} e^{i\nu_{0g}\left|z_g - z'\right|}}{2i\nu_0} dk_g\right) k_0^2 \alpha P_n^T\left(x', z' \middle| \, k;\omega\right) \\ &= \int_{z_1}^{\infty} dz' \int_{-\infty}^{\infty} dx' \frac{1}{2\pi}\left(\int_{-\infty}^{\infty} \frac{e^{ik_g\left(x_g - x'\right)} e^{i\nu_{0g}\left|z_g - z'\right|}}{2i\nu_0} dk_g\right) \\ &\qquad \times k_0^2 \alpha e^{ikx'} e^{i\nu_0 z'} X^n \sum_{l=0}^{n} \left[-i\nu_0\left(z' - z_1\right)\right]^l S_l^n. \end{aligned} \tag{A.9}$$

We now solve the dk_g and the dx' by either one of the two methods described in the text and obtain

$$\begin{aligned} P_{n+1}^T &= \int_{z_1}^{\infty} dz' \frac{k_0^2 \alpha}{2i\nu_0} e^{ikx_g} e^{i\nu_0\left|z_g - z'\right|} e^{i\nu_0 z'} X^n \sum_{l=0}^{n} \left[-i\nu_0\left(z' - z_1\right)\right]^l S_l^n \\ &= e^{ikx_g} X^{n+1} \frac{\nu_0}{2i} \int_{z_1}^{\infty} dz' e^{i\nu_0\left|z_g - z'\right|} e^{i\nu_0 z'} \sum_{l=0}^{n} \left[-i\nu_0\left(z' - z_1\right)\right]^l S_l^n \\ &= e^{ikx_g} X^{n+1} \frac{(-i\nu_0)}{2} \sum\nolimits_{l=0}^{n} \int_{z_1}^{\infty} dz' e^{i\nu_0\left|z_g - z'\right|} e^{i\nu_0 z'} \left[-i\nu_0\left(z' - z_1\right)\right]^l S_l^n. \end{aligned} \tag{A.10}$$

We split the integral into two integrals in order to be able to evaluate the absolute

value and get

$$P_{n+1}^T = e^{ikx_g} X^{n+1} \frac{(-i\nu_0)}{2} \sum_{l=0}^{n} \left\{ \int_{z_1}^{z_g} dz' e^{i\nu_0 z_g} \left[-i\nu_0 (z'-z_1)\right]^l S_l^n + \int_{z_g}^{\infty} dz' e^{i\nu_0(2z'-z_g)} \left[-i\nu_0 (z'-z_1)\right]^l S_l^n \right\}. \tag{A.11}$$

The first integral has an easy solution; the second is a bit more tedious since it involves integration by parts. After solving the two integrals, we find

(A.12)

$$\begin{aligned} P_{n+1}^T = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} \Bigg\{ & \sum_{l=0}^{n} \frac{S_l^n}{2(l+1)} \left[-i\nu_0 (z_g - z_1)\right]^{l+1} \\ & + \frac{(-i\nu_0)}{2} \Bigg[S_0^n (-i\nu_0)^0 \left(-\frac{1}{2i\nu_0} \right) \\ & \quad + S_1^n (-i\nu_0)^1 \left(-\frac{1}{2i\nu_0}(z_g - z_1) + \frac{1}{(2i\nu_0)^2} \right) \\ & \quad + S_2^n (-i\nu_0)^2 \left(-\frac{1}{2i\nu_0}(z_g - z_1)^2 + \frac{2}{(2i\nu_0)^2}(z_g - z_1) - \frac{2}{(2i\nu_0)^3} \right) \\ & \quad \vdots \\ & \quad + S_n^n (-i\nu_0)^n \left(\frac{-1}{2i\nu_0}(z_g - z_1)^n + \frac{n}{(2i\nu_0)^2}(z_g - z_1)^{n-1} + \cdots + \frac{(-1)^{n+1} n!}{(2i\nu_0)^{n+1}} \right) \Bigg] \Bigg\}. \end{aligned}$$

Grouping together the terms with like powers of $[-i\nu_0 (z' - z_1)]$ in the expression above, we find

(A.13)

$$\begin{aligned} P_{n+1}^T = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} \Bigg\{ & \left[-i\nu_0 (z_g - z_1)\right]^{n+1} \frac{S_n^n}{2(n+1)} \\ & + \left[-i\nu_0 (z_g - z_1)\right]^{n} \left(\frac{S_{n-1}^n}{2n} + \frac{S_n^n}{2} \frac{1}{2} \right) \\ & + \left[-i\nu_0 (z_g - z_1)\right]^{n-1} \left(\frac{S_{n-2}^n}{2(n-1)} + \frac{S_n^n}{2} \frac{n}{2^2} + \frac{S_{n-1}^n}{2} \frac{1}{2} \right) \\ & + \left[-i\nu_0 (z_g - z_1)\right]^{n-2} \left(\frac{S_{n-3}^n}{2(n-2)} + \frac{S_n^n}{2} \frac{n(n-1)}{2^3} + \frac{S_{n-1}^n}{2} \frac{n-1}{2^2} + \frac{S_{n-2}^n}{2} \frac{1}{2} \right) \\ & \vdots \\ & + \left[-i\nu_0 (z_g - z_1)\right]^{1} \left(\frac{S_0^n}{2} + \frac{S_n^n}{2} \frac{n(n-1)\ldots 2}{2^n} + \frac{S_{n-1}^n}{2} \frac{(n-1)\ldots 2}{2^{n-1}} + \cdots + \frac{S_1^n}{2} \frac{1}{2} \right) \\ & + \left[-i\nu_0 (z_g - z_1)\right]^{0} \left(0 + \frac{S_n^n}{2} \frac{n!}{2^{n+1}} + \frac{S_{n-1}^n}{2} \frac{(n-1)!}{2^n} + \cdots + \frac{S_1^n}{2} \frac{1!}{2^2} + \frac{S_0^n}{2} \frac{1}{2} \right) \Bigg\}. \end{aligned}$$

We next show that the coefficients of $[-i\nu_0 (z_g - z_1)]^j$ in the above expression are exactly equal to S_j^{n+1}, and hence this last expression is the one required for the second step of the induction (see (A.8)).

For the first coefficient recall that, by definition, we have

$$S_n = \frac{X^n}{2^n n!}\left(1+R\right)^{n+1}, \tag{A.14}$$

and hence we can write

$$S_{n+1} = \frac{X^{n+1}}{2^{n+1}(n+1)!}\left(1+R\right)^{n+2} = \frac{X}{2(n+1)}\left(1+R\right)S_n. \tag{A.15}$$

This is an equality of two series, which implies that the coefficients of identical powers from both sides are equal. By equating the coefficients of the $n+1$ power, we obtain

$$S_{n+1}^{n+1} = \frac{1}{2(n+1)}S_n^n. \tag{A.16}$$

For the second coefficient we start with the identity

$$S_n = \frac{X^n}{2^n n!}\left(1+R\right)^{n+1} \tag{A.17}$$

and rewrite it as

$$S_n = \frac{X^n}{2^n n!}\left(1+R\right)^n\left(1+R\right) = \frac{X}{2n}S_{n-1} + \frac{X^n}{2^n n!}R\left(1+R\right)^n. \tag{A.18}$$

By equating the coefficients of the $n+1$ power from both sides, we find

$$S_n^{n+1} = \frac{1}{2n}S_{n-1}^n + \frac{1}{4}S_n^n, \tag{A.19}$$

where we have used that the coefficient of the first power of X in the expression for R is $1/4$.

For the third coefficient we start with the identity

$$S_{n-1} = \frac{X^{n-1}}{2^{n-1}(n-1)!}\left(1+R\right)^n \tag{A.20}$$

and rewrite it as

$$S_{n-1} = \frac{X}{2(n-1)}S_{n-2} + \frac{X^{n-1}}{2^{n-1}(n-1)!}R\left(1+R\right)^{n-2} + \frac{X^{n-1}}{2^{n-1}(n-1)!}R^2\left(1+R\right)^{n-2}. \tag{A.21}$$

By equating the coefficients of the $n+1$ power from both sides, we find

$$S_{n-1}^{n+1} = \frac{1}{2(n-1)}S_{n-2}^n + \frac{1}{4}S_{n-1}^n + \frac{n}{8}S_n^n. \tag{A.22}$$

For this last expression we have used again the fact that the coefficient of the first power of X in the expression for R is $1/4$.

The procedure outlined for these first three coefficient can be continued without difficulty to show that all the coefficients in the expression (A.13) coincide with those in (A.8). This concludes the second step of the induction and hence the proof that the expression for the transmitted wave-field P_n^T is

$$P_n^T\left(x_g, z_g > z_1 \middle| \, k;\omega\right) = e^{ikx_g}e^{i\nu_0 z_g}X^n\sum_{l=0}^{n}\left[-i\nu_0\left(z_g - z_1\right)\right]^l S_l^n. \tag{A.23}$$

The general term in the forward scattering series representation (3.14) for the reflected wave-field can hence be calculated using the following formula:

(A.24)

$$P_{n+1}^{R}\left(x_g, z_g < z_1 \middle| \, k;\omega\right) = \int_{z_1}^{\infty} dz' \int_{-\infty}^{\infty} dx' \frac{1}{2\pi} \left(\int_{-\infty}^{\infty} \frac{e^{ik_g(x_g-x')} e^{i\nu_{0g}\left|z_g-z'\right|}}{2i\nu_0} dk_g \right) k_0^2 \alpha P_n^T\left(x', z' \middle| \, k;\omega\right).$$

Introducing the expression for P_n^T, we find

$$P_{n+1}^{R} = \int_{z_1}^{\infty} dz' \int_{-\infty}^{\infty} dx' \frac{1}{2\pi} \left(\int_{-\infty}^{\infty} \frac{e^{ik_g(x_g-x')} e^{i\nu_{0g}\left|z_g-z'\right|}}{2i\nu_0} dk_g \right) k_0^2 \alpha e^{ikx'} e^{i\nu_0 z'} X^n$$

(A.25)
$$\times \sum_{l=0}^{n} \left[-i\nu_0\left(z'-z_1\right)\right]^l S_l^n.$$

Solving for the dx' and the dk_g integrals gives

(A.26)
$$P_{n+1}^{R} = e^{ikx_g} X^{n+1} \frac{(-i\nu_0)}{2} \int_{z_1}^{\infty} dz' \sum_{l=0}^{n} \left[-i\nu_0\left(z'-z_1\right)\right]^l S_l^n e^{i\nu_0(2z'-z_g)}.$$

Notice that this integral has been dealt with before: it is the integral appearing in the second part of (A.11), and its solution is given in the second part of (A.12). However, the limits of integration are different: the solution for our integral may be obtained from the second part of (A.12) by replacing z_g with z_1. This substitution cancels most of the terms, and the result is

(A.27)
$$P_{n+1}^{R} = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} \frac{(-i\nu_0)}{2} \left[-S_0^n \frac{1}{2i\nu_0} - S_1^n \frac{1}{2^2 i\nu_0} - \cdots - S_n^n \frac{n!}{2^{n+1} i\nu_0} \right]$$

or

(A.28)
$$P_{n+1}^{R} = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} \frac{1}{4} \left[S_0^n + \frac{S_1^n}{2^1} 1! + \frac{S_2^n}{2^2} 2! + \cdots + \frac{S_n^n}{2^n} n! \right].$$

Again, the sum inside the square brackets is an expression that we have already analyzed before: it is the coefficient of $\left[-i\nu_0\left(z_g-z_1\right)\right]^0$ in (A.13). It was shown there that

(A.29)
$$\frac{1}{4} \left[S_0^n + \frac{S_1^n}{2^1} 1! + \frac{S_2^n}{2^2} 2! + \cdots + \frac{S_n^n}{2^n} n! \right] = S_0^{n+1},$$

and hence the expression for P_{n+1}^{R} becomes

(A.30)
$$P_{n+1}^{R}\left(x_g, z_g < z_1 \middle| \, k;\omega\right) = e^{ikx_g} e^{i\nu_0 z_g} X^{n+1} S_0^{n+1}.$$

Recall from (A.4) and (A.5) that S_0^{n+1} represents the coefficient of the $n+1$ degree in the series for $1+R$, and hence it is the coefficient of the $n+1$ degree in the Taylor series for $\sqrt{1-k_0^2\alpha/\nu_0^2}$ about $\frac{k_0^2\alpha}{\nu_0^2}=0$ after some algebraic operations are performed on it. The total scattered field P is the summation of all P_n^R and hence it represents the full Taylor series for $\sqrt{1-k_0^2\alpha/\nu_0^2}$ about $\frac{k_0^2\alpha}{\nu_0^2}=0$ after some algebraic operations are performed on it.

GINZBURG–LANDAU MODEL IN THIN LOOPS WITH NARROW CONSTRICTIONS*

JACOB RUBINSTEIN†, MICHELLE SCHATZMAN‡, AND PETER STERNBERG†

Abstract. We consider the Ginzburg–Landau model for a superconducting thin ring in the presence of an applied field. The ring is constricted, and we derive an asymptotic form for the energy as the ring thickness tends to zero. The constriction leads in the limit to a jump condition for the order parameter, yielding a transmission condition across the weak link of the type postulated by de Gennes for superconducting/normal/superconducting junctions.

Key words. Ginzburg–Landau energy, asymptotic analysis, constricted rings

DOI. 10.1137/S0036139903434456

1. Introduction.

The Josephson effect models the peculiar flow of currents through a normal thin layer, called a junction, separating two bulk superconducting samples. The fundamental feature of this effect is an expression for the current as a function of the phase difference across the junction:

$$J = J_M \sin[\phi]. \tag{1.1}$$

The parameter J_M is the maximal current that the junction can transmit, and $[\phi]$ denotes the difference between the phase of the superconducting wave function on the two ends of the junction.

Josephson predicted relation (1.1) from the microscopic Bardeen–Cooper–Schrieffer (BCS) theory [14]. Soon thereafter, it was realized that a similar expression, as well as some other features of the junction, can also be derived by ad hoc models that are coupled to the macroscopic Ginzburg–Landau (GL) model of superconductivity. In particular de Gennes [7] modeled the junction through a set of linear conditions relating the wave function and its derivatives on the two sides of the thin normal layer. Similar equations were written also in [1]. Alternatively, other authors, and, in fact, most of the physics literature on the subject (e.g., [21], [2]) use (1.1) as a basic paradigm and supplement it with equations and arguments based on the GL theory and classical electromagnetism.

It is therefore desirable to develop a theory for Josephson junctions that is built up coherently and directly upon the GL model. One way to do so is to model the normal layer into the GL energy functional. This was done in [5], [9], [10], [12], [11], and [20]. In particular it was shown in [20] that a large variety of junctions can be modeled in this way, leading to different types of current flow patterns.

The purpose of the paper is to construct, directly from the GL equations, a "geometrical" Josephson junction. Such junctions, called "weak links" in the literature,

are characterized by a sharp constriction in the thickness of the sample [16]. We shall show below that under appropriate selection of the sample geometry and its scaling, the GL model converges to a new model that provides in a natural way the linear relations postulated by de Gennes. The convergence is established rigorously in section 2, with the proof inspired in part by an analogous convergence result in the field of elasticity [6]. In section 3 we discuss some implications of the convergence result. Finally, we should mention the work in [15], as it also relates to variational problems in constricted domains, though in the context of micromagnetics. While in our problem, the asymptotic limit leads us to a one-dimensional problem, the limit in [15] is in general two-dimensional.

2. Formulation. We begin with a description of the geometry of the region Ω_ε to be occupied by the sample. To this end, we introduce a continuous, piecewise linear function $g_\varepsilon : [-\pi, \pi] \to \mathbb{R}^1$ that will govern the thickness of the ring. Fixing any positive number $p < 1$, we define g_ε via

$$g_\varepsilon(y_1) = (\varepsilon^{1-p} - 2\varepsilon)\,|y_1| + 2\varepsilon^{1+p} \quad \text{for} \quad |y_1| \le \varepsilon^p, \tag{2.1}$$

$$g_\varepsilon(y_1) = \varepsilon \quad \text{for} \quad \varepsilon^p \le |y_1| \le \pi. \tag{2.2}$$

We then define a ring-shaped region $\Omega_\varepsilon \subset \mathbb{R}^3$ of thickness g_ε as the image of the cylinder

$$\mathcal{C} = \{(y_1, y_2, y_3) : -\pi \le y_1 \le \pi,\ 0 \le y_2^2 + y_3^2 < 1\} \tag{2.3}$$

under the mapping $T_\varepsilon : \mathbb{R}^3 \to \mathbb{R}^3$ given by

$$x = T_\varepsilon(y_1, y_2, y_3) = \big((1 + g_\varepsilon(y_1)y_2)\cos y_1, (1 + g_\varepsilon(y_1)y_2)\sin y_1, g_\varepsilon(y_1)y_3\big). \tag{2.4}$$

That is, $\Omega_\varepsilon \equiv T_\varepsilon(\mathcal{C})$. Note, in particular, that in (x_1, x_2, x_3)-space, the variable y_1 corresponds to the polar angle in the x_1x_2-plane and that the ring Ω_ε has uniform thickness ε except near the constriction at $y_1 = 0$. See Figure 1.

We will use the following nondimensional version of the GL energy functional

$$G_\epsilon(u, \mathbf{A}) = \frac{1}{\varepsilon^2}\int_{\Omega_\epsilon}\left(|(i\nabla + \mathbf{A})u|^2 + \frac{\nu^2}{2}\left(|u|^2 - \mu^2\right)^2\right)dx + \frac{1}{\varepsilon^2}\int_{\mathbb{R}^3}|\nabla \times \mathbf{A} - \mathbf{H}^e|^2\,dx. \tag{2.5}$$

Here $u : \Omega_\varepsilon \to \mathbb{C}$ is the order parameter, $\mathbf{A} : \mathbb{R}^3 \to \mathbb{R}^3$ is the magnetic potential associated with the magnetic field $\mathbf{H}$ through $\nabla \times \mathbf{A} = \mathbf{H}$, and $\mathbf{H}^e$ is a given, smoothly varying, applied magnetic field directed along the x_3-axis and taken to be independent of the coordinate x_3. The quantities ν and μ are material parameters with μ^2 proportional to the difference between the critical temperature T_c and the temperature of the sample [20]. We assume we are in the superconducting temperature regime where this difference is positive. One could scale μ out by setting it to be one, but we retain it in order to use it later on as a bifurcation parameter. The energy G_ε has been scaled so that the minimum energy remains uniformly bounded away from both zero and infinity for small ε.

We would like to investigate the asymptotic behavior of minimizers to (2.5), and this will require a precise description of function spaces over which the minimization

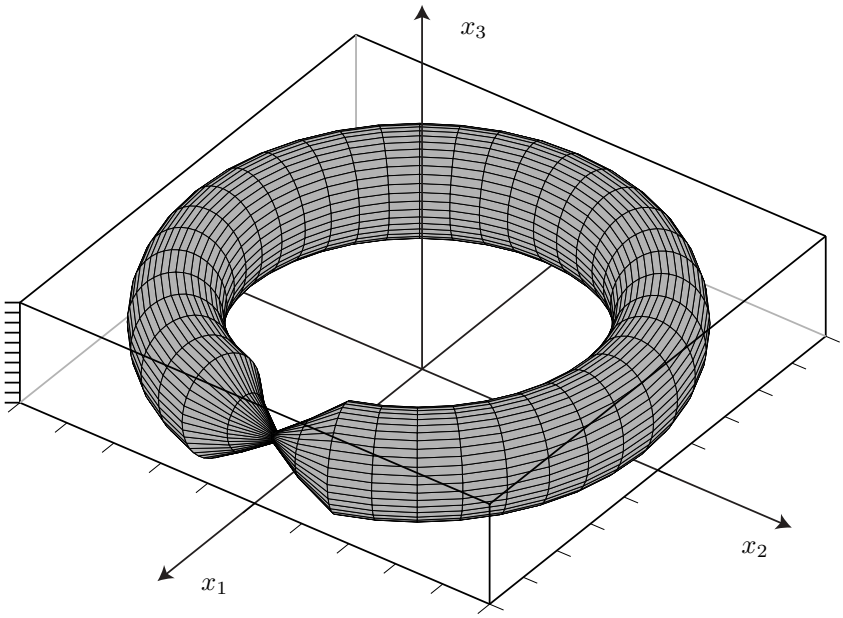

FIG. 1. *The constricted ring* Ω_ε.

is to take place. For the order parameter u we shall take competitors in the standard Sobolev space $W^{1,2}(\Omega_\varepsilon;\mathbb{C})$ consisting of square-integrable functions with square-integrable first derivatives. For the magnetic potential $\mathbf{A}$ we introduce the space $\mathcal{H}$ as the completion of the set

$$\{\phi \in C^\infty(\mathbb{R}^3;\mathbb{R}^3) : \phi \text{ compactly supported}\}$$

with respect to the norm $\|\nabla\phi\|_{L^2(\mathbb{R}^3;\mathbb{R}^3)} = (\int_{\mathbb{R}^3} |\nabla\phi|^2\, dx)^{1/2}$. Then we define $\mathcal{H}_0$ to be

$$\mathcal{H}_0 = \{\phi \in \mathcal{H} : \operatorname{div}\phi = 0\}$$

and consider competitors $\mathbf{A}$ satisfying $\mathbf{A} - \mathbf{A}^e \in \mathcal{H}_0$, where $\mathbf{A}^e = \mathbf{A}^e(x_1, x_2)$ is the applied magnetic potential satisfying

$$\nabla \times \mathbf{A}^e = \mathbf{H}^e \quad \text{and } \operatorname{div}\mathbf{A}^e = 0 \quad \text{in } \mathbb{R}^3, \tag{2.6}$$

$$\mathbf{A}^e \cdot (0,0,1) = 0 \quad \text{in } \mathbb{R}^3. \tag{2.7}$$

Condition (2.7) holds by our assumptions on $\mathbf{H}^e$, while we can arrange for the zero divergence condition by a suitable choice of gauge.

Through a rather standard application of the direct method in the calculus of variations, along with standard elliptic regularity theory, one obtains the following.

THEOREM 2.1. *For all positive* $\varepsilon < 1$*, there exists a pair* $(u^\varepsilon, \mathbf{A}^\varepsilon)$ *solving the variational problem*

$$\inf_{\{u\in W^{1,2}(\Omega_\varepsilon;\mathbb{C}),\mathbf{A}-\mathbf{A}^e\in\mathcal{H}_0\}} G_\varepsilon(u,\mathbf{A}). \tag{2.8}$$

The function u^ε is smooth in Ω_ε, while the function $\mathbf{A}^\varepsilon$ is smooth in $\mathbb{R}^3 \setminus \partial\Omega_\varepsilon$ and continuously differentiable across $\partial\Omega$. Furthermore, the minimizers satisfy the GL system

$$(i\nabla + \mathbf{A}^\varepsilon)^2 u^\varepsilon = \nu^2(|u^\varepsilon|^2 - \mu^2)u^\varepsilon \quad \text{in} \quad \Omega_\varepsilon, \tag{2.9}$$

$$\begin{aligned} &\nabla \times \nabla \times (\mathbf{A}^\varepsilon - \mathbf{A}^e) = -\Delta(\mathbf{A}^\varepsilon - \mathbf{A}^e) \\ &= \begin{cases} \frac{i}{2}(\overline{u^\varepsilon}\nabla u^\varepsilon - u^\varepsilon \nabla \overline{u^\varepsilon}) - |u^\varepsilon|^2 \mathbf{A}^\varepsilon & \text{for } x \in \Omega_\varepsilon, \\ 0 & \text{for } x \in \mathbb{R}^3 \setminus \overline{\Omega_\varepsilon} \end{cases} \end{aligned} \tag{2.10}$$

and the boundary condition

$$(i\nabla + \mathbf{A}^\varepsilon)u^\varepsilon \cdot \mathbf{n} = 0 \quad \text{on} \quad \partial\Omega_\varepsilon. \tag{2.11}$$

Here $\bar{\cdot}$ denotes complex conjugation and $\mathbf{n}$ denotes the outer unit normal along $\partial\Omega_\varepsilon$.

Finally, the order parameter u^ε satisfies the condition

$$|u^\varepsilon| \le \mu \quad \text{in} \quad \overline{\Omega_\varepsilon}. \tag{2.12}$$

Application of the direct method in establishing the existence of minimizers to the GL energy can be found, for instance, in [8] or [19]. The regularity theory in this context can be found, for instance, in [13]. Inequality (2.12) is an easy consequence of the maximum principle; see, e.g., [8].

PROPOSITION 2.2. *There exist positive constants C_1 and C_2 independent of ε such that*

$$G_\varepsilon(u^\varepsilon, \mathbf{A}^\varepsilon) \le C_1 \quad \text{and} \tag{2.13}$$

$$\int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx \le C_2 \varepsilon^2. \tag{2.14}$$

Furthermore, one has the uniform convergence

$$\|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^\infty(B_R(0);\mathbb{R}^3)} \to 0 \quad \text{as} \quad \varepsilon \to 0 \quad \text{for every } R > 0, \tag{2.15}$$

where $B_R(0) = \{x \in \mathbb{R}^3 : |x| < R\}$. Condition (2.15) in particular implies that

$$\sup_{y \in \mathcal{C}} |\mathbf{A}^\varepsilon(T_\varepsilon(y)) - \mathbf{A}^e(\cos y_1, \sin y_1, 0)| \to 0 \quad \text{as} \quad \varepsilon \to 0. \tag{2.16}$$

Proof. The bound (2.13) follows immediately by comparing the energy of the minimizer to that of the pair $(\mu, \mathbf{A}^e)$:

$$G_\varepsilon(u^\varepsilon, \mathbf{A}^\varepsilon) \le G_\varepsilon(\mu, \mathbf{A}^e) = \frac{\mu^2}{\varepsilon^2} \int_{\Omega_\varepsilon} |\mathbf{A}^e|^2 \, dx \le \frac{\mu^2 \mathrm{vol}(\Omega_\varepsilon)}{\varepsilon^2} \|\mathbf{A}^e\|^2_{L^\infty(\Omega_\varepsilon)} \le C_1$$

since $\mathrm{vol}(\Omega_\varepsilon) = \mathcal{O}(\varepsilon^2)$.

We next establish the convergence (2.15) and the bound (2.14) using (2.13) by decomposing G_ε as

$$\begin{aligned} \varepsilon^2 G_\varepsilon(u^\varepsilon, \mathbf{A}^\varepsilon) &= \int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx + i \int_{\Omega_\varepsilon} (\overline{u^\varepsilon}\nabla u^\varepsilon - u^\varepsilon \nabla \overline{u^\varepsilon}) \cdot \mathbf{A}^\varepsilon \, dx \\ &+ \int_{\Omega_\varepsilon} |u^\varepsilon|^2 |\mathbf{A}^\varepsilon|^2 + \frac{\nu^2}{2}(|u^\varepsilon|^2 - \mu^2)^2 \, dx + \int_{\mathbb{R}^3} |\nabla \times (\mathbf{A}^\varepsilon - \mathbf{A}^e)|^2 \, dx. \end{aligned} \tag{2.17}$$

Applying (2.12), we find that

$$\left| i \int_{\Omega_\varepsilon} (\overline{u^\varepsilon} \nabla u^\varepsilon - u^\varepsilon \nabla \overline{u^\varepsilon}) \cdot \mathbf{A}^\varepsilon \, dx \right| \leq 2\mu \int_{\Omega_\varepsilon} |\nabla u^\varepsilon| \, |\mathbf{A}^\varepsilon| \, dx$$
$$\leq \frac{1}{2} \int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx + C(\mu) \int_{\Omega_\varepsilon} |\mathbf{A}^\varepsilon|^2 \, dx.$$

Hence, (2.13) and (2.17) yield the bound

$$\int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx \leq 2C_1 \varepsilon^2 + C(\mu) \int_{\Omega\varepsilon} |\mathbf{A}^\varepsilon|^2 \, dx$$
$$\leq 2C_1 \varepsilon^2 + C(\mu) \left(\|\mathbf{A}^\varepsilon - \mathbf{A}^e\|^2_{L^\infty(\Omega_\varepsilon;\mathbb{R}^3)} + \|\mathbf{A}^e\|^2_{L^\infty(\Omega_\varepsilon;\mathbb{R}^3)} \right) \mathrm{vol}\,(\Omega_\varepsilon). \tag{2.18}$$

Now we turn to (2.10) satisfied by the difference $\mathbf{A}^\varepsilon - \mathbf{A}^e$ and utilize the fact that this difference lies in $\mathcal{H}_0$. This decay at infinity allows us to express it via the fundamental solution to the Laplacian in $\mathbb{R}^3$:

$$\mathbf{A}^\varepsilon - \mathbf{A}^e = \int_{\Omega_\varepsilon} \Gamma(x - z) f^\varepsilon(z) \, dz, \tag{2.19}$$

where $\Gamma(x) \equiv \frac{1}{4\pi|x|}$ and $f^\varepsilon(z) \equiv \frac{i}{2}(\overline{u^\varepsilon} \nabla u^\varepsilon - u^\varepsilon \nabla \overline{u^\varepsilon}) - |u^\varepsilon|^2 \mathbf{A}^\varepsilon$.

Given any $R > 0$, one readily checks that

$$\int_{\Omega_\varepsilon} |\Gamma(x - z)|^2 \, dz \leq C(R),$$

provided $|x| \leq R$, so that by Hölder's inequality, we obtain

$$\|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^\infty(B_R(0);\mathbb{R}^3)} \leq \sqrt{C(R)} \, \|f^\varepsilon\|_{L^2(\Omega_\varepsilon)}. \tag{2.20}$$

Then writing

$$f^\varepsilon = \frac{i}{2}(\overline{u^\varepsilon} \nabla u^\varepsilon - u^\varepsilon \nabla \overline{u^\varepsilon}) - |u^\varepsilon|^2 (\mathbf{A}^\varepsilon - \mathbf{A}^e) - |u^\varepsilon|^2 \mathbf{A}^e,$$

we can combine inequalities (2.12), (2.18), and (2.20) to conclude that

$$\|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^\infty(B_R(0);\mathbb{R}^3)}$$
$$\leq C \left(\|\nabla u^\varepsilon\|_{L^2(\Omega_\varepsilon;\mathbb{R}^3)} + \|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^2(\Omega_\varepsilon;\mathbb{R}^3)} + \|\mathbf{A}^e\|_{L^2(\Omega_\varepsilon;\mathbb{R}^3)} \right) \tag{2.21}$$
$$\leq C \left(\varepsilon + \|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^\infty(\Omega_\varepsilon;\mathbb{R}^3)} \sqrt{\mathrm{vol}\,\Omega_\varepsilon} + \|\mathbf{A}^e\|_{L^\infty(\Omega_\varepsilon;\mathbb{R}^3)} \sqrt{\mathrm{vol}\,\Omega_\varepsilon} \right),$$

where again C depends on R. Hence we obtain (2.15) in that

$$\|\mathbf{A}^\varepsilon - \mathbf{A}^e\|_{L^\infty(B_R(0);\mathbb{R}^3)} \leq C\varepsilon \tag{2.22}$$

for some constant C independent of ε but depending on R, μ, C_1, and $\mathbf{A}^e$. Then (2.14) follows from (2.15) and (2.18). ∎

Our characterization of the asymptotic behavior of the sequence of minimizers $\{u^\varepsilon\}$ is most conveniently carried out using the variables (y_1, y_2, y_3) defined in (2.4). Thus, we introduce the notation

$$U^\varepsilon(y_1, y_2, y_3) := u^\varepsilon(T_\varepsilon(y_1, y_2, y_3)). \tag{2.23}$$

PROPOSITION 2.3. *There exists a subsequence* $\{\varepsilon_j\} \to 0$ *and a function* $U^0 \in BV(\mathcal{C};\mathbb{C})$ *such that* $U^{\varepsilon_j} \to U^0$ *in* $L^1(\mathcal{C};\mathbb{C})$. *Furthermore,* U^0 *is a function of* y_1 *only.*

Here $BV(\mathcal{C};\mathbb{C})$ denotes the space of complex-valued functions of bounded variation. The compactness assertion is based on the fact that sequences uniformly bounded in $W^{1,1}(\mathcal{C};\mathbb{C})$ (hence in BV) contain L^1-convergent subsequences; cf., e.g., [22, section 5.3].

Proof. To reiterate, the goal is a uniform $W^{1,1}(\mathcal{C};\mathbb{C})$-bound on the sequence $\{U^\varepsilon\}$. Such a bound will come from (2.14) once we express $\int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx$ in terms of U^ε.

To this end, one carries out a lengthy but routine calculation to obtain

$$\int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx = \frac{1}{2} \int_{\mathcal{C}} a_{ik} \big(U^\varepsilon_{y_i} \overline{U^\varepsilon}_{y_k} + \overline{U^\varepsilon}_{y_i} U^\varepsilon_{y_k} \big) \, dy, \tag{2.24}$$

where the 3×3 matrix A with entries $a_{ik} = a_{ik}(y_1, y_2, y_3)$ can be written in the form

$$A = \frac{1}{(1 + g_\varepsilon(y_1) y_2)} \big(B + D \big) \tag{2.25}$$

with

$$B = \begin{pmatrix} g_\varepsilon(y_1)^2 & -g_\varepsilon(y_1) g'_\varepsilon(y_1) y_2 & -g_\varepsilon(y_1) g'_\varepsilon(y_1) y_3 \\ -g_\varepsilon(y_1) g'_\varepsilon(y_1) y_2 & 1 + g'_\varepsilon(y_1)^2 y_2^2 & g'_\varepsilon(y_1)^2 y_2 y_3 \\ -g_\varepsilon(y_1) g'_\varepsilon(y_1) y_3 & g'_\varepsilon(y_1)^2 y_2 y_3 & 1 + g'_\varepsilon(y_1)^2 y_3^2 \end{pmatrix} \tag{2.26}$$

and

$$D = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 2 g_\varepsilon(y_1) y_2 + g_\varepsilon(y_1)^2 y_2^2 \end{pmatrix}. \tag{2.27}$$

At this point, we appeal to [6], where the eigenvalues of the matrix B are explicitly calculated and found to be given by the formulas

$$\begin{aligned} \lambda_1 &= \frac{1 + g_\varepsilon(y_1)^2 + g'_\varepsilon(y_1)^2 (y_2^2 + y_3^2)}{2} \\ &\quad - \frac{\sqrt{[1 + g_\varepsilon(y_1)^2 + g'_\varepsilon(y_1)^2 (y_2^2 + y_3^2)]^2 - 4 g_\varepsilon(y_1)^2}}{2}, \end{aligned} \tag{2.28}$$

$$\begin{aligned} \lambda_2 &= \frac{1 + g_\varepsilon(y_1)^2 + g'_\varepsilon(y_1)^2 (y_2^2 + y_3^2)}{2} \\ &\quad + \frac{\sqrt{[1 + g_\varepsilon(y_1)^2 + g'_\varepsilon(y_1)^2 (y_2^2 + y_3^2)]^2 - 4 g_\varepsilon(y_1)^2}}{2}, \end{aligned} \tag{2.29}$$

$$\lambda_3 = 1.$$

Note, in particular, that $\lambda_2, \lambda_3 \geq 1$, while expansion of (2.28) reveals that

$$\frac{g_\varepsilon^2}{1 + g_\varepsilon^2 + (g'_\varepsilon)^2} \leq \lambda_1 \leq g_\varepsilon^2 \quad \text{for small } \varepsilon. \tag{2.30}$$

Let us now denote the eigenvalues of A by μ_1, μ_2, and μ_3. Since A is a regular perturbation of B, it follows easily that

$$\lim_{\varepsilon \to 0} |\mu_2 - \lambda_2| = 0 \quad \text{and} \quad \lim_{\varepsilon \to 0} |\mu_3 - 1| = 0. \tag{2.31}$$

Also, expanding $\det A$ along its last row, one readily checks that

$$(1 + g_\varepsilon(y_1)y_2)^3 \det A = \det B + \mathcal{O}(g_\varepsilon^3) \quad \text{as } \varepsilon \to 0. \tag{2.32}$$

Then phrasing (2.32) in terms of λ_i and μ_i and using (2.30) and (2.31), it is not hard to verify that

$$|\mu_1 - \lambda_1| = o(g_\varepsilon^2). \tag{2.33}$$

Hence, up to terms of order $o(g_\varepsilon^2)$,

$$\frac{g_\varepsilon^2}{1 + g_\varepsilon^2 + (g_\varepsilon')^2} \le \mu_1 \le g_\varepsilon^2. \tag{2.34}$$

If we then introduce the quantity

$$a_\varepsilon(y_1) := \frac{g_\varepsilon(y_1)^2}{\varepsilon^2\big(1 + g_\varepsilon(y_1)^2 + (g_\varepsilon'(y_1))^2\big)}, \tag{2.35}$$

we can combine (2.14), (2.24), (2.31), and (2.34) to conclude that

$$\begin{aligned} \int_{\mathcal{C}} a_\varepsilon \left|U^\varepsilon_{y_1}\right|^2 dy &\le \frac{1}{2\varepsilon^2} \int_{\mathcal{C}} a_{ik}\big(U^\varepsilon_{y_i}\overline{U^\varepsilon}_{y_k} + \overline{U^\varepsilon}_{y_i} U^\varepsilon_{y_k}\big)\, dy \\ &= \frac{1}{\varepsilon^2} \int_{\Omega_\varepsilon} |\nabla u^\varepsilon|^2 \, dx \le C_2. \end{aligned} \tag{2.36}$$

Hence,

$$\int_{\mathcal{C}} \left\{ g_\varepsilon(y_1)^2 \left|U^\varepsilon_{y_1}\right|^2 + \left|U^\varepsilon_{y_2}\right|^2 + \left|U^\varepsilon_{y_3}\right|^2 \right\} dy \le C\varepsilon^2 \tag{2.37}$$

for some constant C independent of ε. In particular, it follows that

$$\int_{\mathcal{C}} \left|U^\varepsilon_{y_2}\right|^2 + \left|U^\varepsilon_{y_3}\right|^2 dy \to 0 \quad \text{as } \varepsilon \to 0. \tag{2.38}$$

Arguing as in [6, Theorem 6.1], this leads to control of $\{\|\nabla U^\varepsilon\|_{L^1(\mathcal{C})}\}$ via (2.36), as follows:

$$\begin{aligned} \int_{\mathcal{C}} |\nabla U^\varepsilon| \, dy &= \int_{\mathcal{C}} \frac{1}{\sqrt{a_\varepsilon}} \sqrt{a_\varepsilon}\, |\nabla U^\varepsilon| \, dy \\ &\le \left(\int_{\mathcal{C}} \frac{1}{a_\varepsilon} \, dy \right)^{1/2} \left(\int_{\mathcal{C}} a_\varepsilon \, |\nabla U^\varepsilon|^2 \, dy \right)^{1/2} \\ &\le C_2^{1/2} \left(\int_{\mathcal{C}} \frac{1}{a_\varepsilon} \, dy \right)^{1/2}. \end{aligned} \tag{2.39}$$

Referring back to assumptions (2.1)–(2.2), we note that

$$\int_{-\pi}^{\pi} \frac{1}{a_\varepsilon(y_1)} \, dy_1 \to 2\pi + 1 \quad \text{as } \varepsilon \to 0. \tag{2.40}$$

In light of the bound (2.12), we see that

$$\|U^\varepsilon\|_{W^{1,1}(\mathcal{C})} < C,$$

and the L^1-convergence of a subsequence $\{U^{\varepsilon_j}\}$ to a $BV(\mathcal{C};\mathbb{C})$ function U^0 follows. In view of (2.38), one sees that U^0 is independent of y_2 and y_3. ∎

Next we wish to identify a limiting energy for G_ε. To this end, we introduce notation for the tangential component of the applied potential restricted to the unit circle:

$$A_1^e(y_1) \equiv \mathbf{A}^e(\cos y_1, \sin y_1, 0) \cdot (-\sin y_1, \cos y_1, 0). \tag{2.41}$$

We also introduce the function λ_ε via the formula

$$\frac{1}{a_\varepsilon(y_1)} = 1 + \lambda_\varepsilon(y_1). \tag{2.42}$$

One can easily check that the $\lambda_\varepsilon \, dy_1 \overset{*}{\rightharpoonup} \delta_0$ weakly as measures so that

$$\frac{1}{a_\varepsilon} \, dy_1 \overset{*}{\rightharpoonup} 1 \, dy_1 + \delta_0. \tag{2.43}$$

This allows us to establish a generalization of Theorem 6.2 of [6]. To state the result, we define the functional G_0 acting on functions in $L^1((-\pi, \pi); \mathbb{C})$ by the formula

$$G_0(U) = \begin{cases} \int_{(-\pi,\pi)\setminus\{0\}} \left(\left| (i\frac{d}{dy_1} + A_1^e)U \right|^2 + \frac{\nu^2}{2}(|U|^2 - \mu^2)^2 \right) dy_1 + |U^+ - U^-|^2 \\ \qquad \text{if } U \in W^{1,2}((-\pi,\pi) \setminus \{0\}; \mathbb{C}), \quad U(-\pi) = U(\pi), \\ \qquad +\infty \quad \text{otherwise,} \end{cases} \tag{2.44}$$

where

$$U^+ = \lim_{y_1 \to 0^+} U(y_1) \quad \text{and} \quad U^- = \lim_{y_1 \to 0^-} U(y_1).$$

We point out that the condition $U \in W^{1,2}((-\pi, \pi) \setminus \{0\}; \mathbb{C})$ in particular implies that U can be continuously defined on $[-\pi, 0]$ and on $[0, \pi]$; see, e.g., [22].

We then will prove the following.

THEOREM 2.4. *The function U^0 provided by Proposition* 2.3 *lies in the space $W^{1,2}((-\pi, \pi) \setminus \{0\}; \mathbb{C})$ and minimizes G_0.*

Proof. The identification of U^0 as a minimizer of G_0 will be achieved through two claims. First we will show that

$$\liminf_{\varepsilon_j \to 0} G_{\varepsilon_j}(u^{\varepsilon_j}, \mathbf{A}^{\varepsilon_j}) \geq \pi G_0(U^0). \tag{2.45}$$

Then we will show that for any $V \in L^1((-\pi, \pi); \mathbb{C})$, there exists a sequence $\{v^\varepsilon\} \subset W^{1,2}(\Omega_\varepsilon; \mathbb{C})$ such that

$$\lim_{\varepsilon \to 0} G_\varepsilon(v^\varepsilon, \mathbf{A}^e) = \pi G_0(V). \tag{2.46}$$

Using the minimizing property of $\{(u^\varepsilon, \mathbf{A}^\varepsilon)\}$, we can then combine (2.45) and (2.46) to obtain $G_0(U^0) \leq G_0(V)$ as asserted. Of course, it will then also follow that $U^0 \in W^{1,2}((-\pi, \pi) \setminus \{0\}; \mathbb{C})$.

Proof of claim (2.45). For this argument it will be convenient to work in a different gauge. Specifically, we take an applied magnetic potential to still satisfy condition (2.7) but now also to satisfy

$$\mathbf{A}^e(x_1, x_2) \cdot (x_1, x_2, 0) = 0 \quad \text{for } x_1^2 + x_2^2 = 1. \tag{2.47}$$

We can achieve this if we drop the divergence-free requirement and insist only that $\operatorname{div} \mathbf{A}^e = 0$ in $\{x : x_1^2 + x_2^2 < 1\}$ by replacing $\mathbf{A}^e$ with $\mathbf{A}^e - \nabla\phi$, where ϕ is any smooth extension to $\mathbb{R}^3$ of the solution to

$$\begin{aligned} \Delta\phi &= 0 \quad \text{in } x_1^2 + x_2^2 < 1, \\ \nabla\phi \cdot (x_1, x_2, 0) &= \mathbf{A}^e \cdot (x_1, x_2, 0) \quad \text{on} \quad x_1^2 + x_2^2 = 1. \end{aligned}$$

Note that a solution ϕ exists in light of the divergence-free condition on $\mathbf{A}^e$ inside the disc, and the solution is independent of x_3 since the original $\mathbf{A}^e$ was as well. Consequently, $\mathbf{A}^e - \nabla\phi$ will, in particular, still satisfy (2.7).

We observe that as a consequence of (2.7) and (2.47), we have that

$$|\mathbf{A}^e(\cos y_1, \sin y_1, 0)| = |A_1^e(y_1)| \quad \text{for } -\pi \le y_1 \le \pi \tag{2.48}$$

(cf. (2.41)).

For the remainder of the proof, we then replace the original $\mathbf{A}^e$ by $\mathbf{A}^e - \nabla\phi$, $\mathbf{A}^\varepsilon$ by $\mathbf{A}^\varepsilon - \nabla\phi$, and u^ε by $u^\varepsilon e^{-i\phi}$. Of course, through gauge-invariance, we have that $G_\varepsilon(u^\varepsilon, \mathbf{A}^\varepsilon) = G_\varepsilon(u^\varepsilon e^{-i\phi}, \mathbf{A}^\varepsilon - \nabla\phi)$. We will not introduce new notation, but through an abuse of notation we still denote these three quantities using their original designations. We should also remark that this change does not affect the estimates (2.15) and (2.16) measuring the L^∞-norm of $\mathbf{A}^\varepsilon - \mathbf{A}^e$ since this difference is unchanged by the gauge transformation.

Discarding the nonnegative term $\int_{\mathbb{R}^3} |\nabla \times \mathbf{A}^{\varepsilon_j} - \mathbf{H}^e|^2 \, dx$, we begin with the decomposition of G_{ε_j} as

$$\begin{aligned} G_{\varepsilon_j}(u^{\varepsilon_j}, \mathbf{A}^{\varepsilon_j}) \ge{}& \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} |\nabla u^{\varepsilon_j}|^2 \, dx + \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} i(\overline{u^{\varepsilon_j}} \nabla u^{\varepsilon_j} - u^{\varepsilon_j} \nabla \overline{u^{\varepsilon_j}}) \cdot \mathbf{A}^{\varepsilon_j} \, dx \\ &+ \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} |u^{\varepsilon_j}|^2 |\mathbf{A}^\varepsilon|^2 \, dx + \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} \frac{\nu^2}{2} (|u^{\varepsilon_j}|^2 - \mu^2)^2 \, dx. \end{aligned} \tag{2.49}$$

We will analyze the limit of each of the four terms above separately. Most crucial is the first term, where in light of (2.36) we have

$$\begin{aligned} \liminf_{\varepsilon_j \to 0} \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} |\nabla u^{\varepsilon_j}|^2 \, dx &\ge \liminf_{\varepsilon_j \to 0} \int_{\mathcal{C}} a_{\varepsilon_j}(y_1) \left| U_{y_1}^{\varepsilon_j} \right|^2 dy \\ &= \liminf_{\varepsilon_j \to 0} \int_{\mathcal{C}} \left| a_\varepsilon(y_1) U_{y_1}^{\varepsilon_j} \right|^2 \frac{1}{a_{\varepsilon_j}(y_1)} \, dy. \end{aligned}$$

Then conditions (2.40) and (2.43) allow for an appeal to [6, Theorem 6.2], to conclude that

$$\liminf_{\varepsilon_j \to 0} \frac{1}{\varepsilon_j^2} \int_{\Omega_{\varepsilon_j}} |\nabla u^{\varepsilon_j}|^2 \, dx \ge \pi \int_{(-\pi,\pi)\setminus\{0\}} \left| \frac{d\, U^0}{d\, y_1} \right|^2 dy_1 + \pi \left| (U^0)^+ - (U^0)^- \right|^2. \tag{2.50}$$

(See also [3] and [4].)

It remains to determine the limits of the last three integrals on the right-hand side of (2.49). To this end, we fix a positive number δ, and denote by $\mathcal{C}_\delta$ the set $\{y \in \mathcal{C} : |y_1| > \delta\}$. It then follows from (2.37) that $\{U^\varepsilon\}$ is bounded uniformly in $W^{1,2}(\mathcal{C}_\delta; \mathbb{C})$. Hence, we conclude from (2.38) and the Sobolev embedding theorem (see, e.g., [22]) that

$$U^{\varepsilon_{j_k}} \rightharpoonup V^0 \quad \text{in} \quad W^{1,2}(\mathcal{C}_\delta; \mathbb{C}) \quad \text{and} \tag{2.51}$$

$$U^{\varepsilon_{j_k}} \to V^0 \quad \text{in} \quad L^q(\mathcal{C}_\delta; \mathbb{C}) \quad \text{for all} \quad q < 6 \tag{2.52}$$

for some $W^{1,2}(\mathcal{C}_\delta;\mathbb{C})$ function V^0 that is independent of y_2 and y_3. In light of Proposition 2.3, we may then identify $V^0 = U^0$ and observe that the convergences above must hold along the full sequence $\{\varepsilon_j\}$. We caution, however, that the $W^{1,2}(\mathcal{C}_\delta;\mathbb{C})$-norm of U^0 depends on δ, so we should not in general expect that $U^0 \in W^{1,2}(\mathcal{C};\mathbb{C})$.

Since the Jacobian of the mapping T_ε given by (2.4) is found to be $g_\varepsilon(y_1)^2(1 + g_\varepsilon(y_1)y_2)$, one uses (2.1)–(2.2), (2.12), and (2.52) to calculate the limit of the last term of (2.49), as follows:

$$\begin{aligned}
&\lim_{\varepsilon_j\to 0}\int_{\Omega_{\varepsilon_j}} \frac{\nu^2}{2\varepsilon_j^2}(|u^{\varepsilon_j}|^2-\mu^2)^2\,dx\\
&=\lim_{\varepsilon_j\to 0}\int_{\mathcal{C}} \frac{\nu^2}{2\varepsilon_j^2}(|U^{\varepsilon_j}|^2-\mu^2)^2 g_{\varepsilon_j}(y_1)^2(1+g_\varepsilon(y_1)y_2)\,dy\\
&=\lim_{\varepsilon_j\to 0}\int_{\mathcal{C}_\delta} \frac{\nu^2}{2}(|U^{\varepsilon_j}|^2-\mu^2)^2\,dy+\mathcal{O}(\delta)\\
&=\int_{\mathcal{C}_\delta} \frac{\nu^2}{2}(|U^0|^2-\mu^2)^2\,dy+\mathcal{O}(\delta)\\
&=\pi\int_{\{\delta<|y_1|<\pi\}} \frac{\nu^2}{2}(|U^0|^2-\mu^2)^2\,dy_1+\mathcal{O}(\delta). \qquad (2.53)
\end{aligned}$$

Similarly, in light of (2.48), (2.16), and (2.52), we have for the second to last integral in (2.49) that

$$\begin{aligned}
&\lim_{\varepsilon_j\to 0}\frac{1}{\varepsilon_j^2}\int_{\Omega_{\varepsilon_j}} |u^{\varepsilon_j}|^2\,|\mathbf{A}^{\varepsilon_j}|^2\,dx\\
&=\lim_{\varepsilon_j\to 0}\frac{1}{\varepsilon_j^2}\int_{\mathcal{C}} |U^{\varepsilon_j}(y)|^2\,|\mathbf{A}^{\varepsilon_j}(y)|^2\,g_{\varepsilon_j}(y_1)^2(1+g_{\varepsilon_j}(y_1)y_2)\,dy\\
&=\lim_{\varepsilon_j\to 0}\frac{1}{\varepsilon_j^2}\int_{\mathcal{C}} |U^{\varepsilon_j}(y)|^2\,|\mathbf{A}^{e}(\cos y_1,\sin y_1,0)|^2\,g_{\varepsilon_j}(y_1)^2(1+g_{\varepsilon_j}(y_1)y_2)\,dy\\
&=\lim_{\varepsilon_j\to 0}\frac{1}{\varepsilon_j^2}\int_{\mathcal{C}} |U^{\varepsilon_j}(y)|^2\,|A_1^{e}(y_1)|^2\,g_{\varepsilon_j}(y_1)^2(1+g_{\varepsilon_j}(y_1)y_2)\,dy\\
&=\lim_{\varepsilon_j\to 0}\int_{\mathcal{C}_\delta} |U^{\varepsilon_j}|^2\,|A_1^{e}|^2\,dy+\mathcal{O}(\delta)\\
&=\int_{\mathcal{C}_\delta} |U^0|^2\,|A_1^{e}|^2\,dy_1+\mathcal{O}(\delta)\\
&=\pi\int_{\{\delta<|y_1|<\pi\}} |U^0|^2\,|A_1^{e}|^2\,dy_1+\mathcal{O}(\delta). \qquad (2.54)
\end{aligned}$$

Finally, we turn to the limit of the remaining integral in (2.49), namely,

$$\liminf_{\varepsilon_j\to 0}\frac{1}{\varepsilon_j^2}\int_{\Omega_{\varepsilon_j}} i(\overline{u^{\varepsilon_j}}\nabla u^{\varepsilon_j}-u^{\varepsilon_j}\nabla\overline{u^{\varepsilon_j}})\cdot\mathbf{A}^{\varepsilon_j}\,dx. \qquad (2.55)$$

Another straightforward but laborious calculation based on the change of variables

$x = T_\varepsilon(y)$ leads to the fact that

$$\begin{aligned}
&\int_{\Omega_{\varepsilon_j}} i(\overline{u^{\varepsilon_j}}\nabla u^{\varepsilon_j} - u^{\varepsilon_j}\nabla\overline{u^{\varepsilon_j}})\cdot \mathbf{A}^{\varepsilon_j}\,dx \\
&= \int_{\mathcal{C}} i\left(\overline{U^{\varepsilon_j}}U^{\varepsilon_j}_{y_1} - U^{\varepsilon_j}\overline{U^{\varepsilon_j}}_{y_1}\right)\left[(-\sin y_1, \cos y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j})\right]\frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2}\,dy \\
&\quad + \int_{\mathcal{C}} i\left(\overline{U^{\varepsilon_j}}U^{\varepsilon_j}_{y_2} - U^{\varepsilon_j}\overline{U^{\varepsilon_j}}_{y_2}\right)\left[(\cos y_1, \sin y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j})\right]\frac{g_{\varepsilon_j}(y_1)}{\varepsilon_j^2}\,dy \\
&\quad + \int_{\mathcal{C}} i\left(\overline{U^{\varepsilon_j}}U^{\varepsilon_j}_{y_2} - U^{\varepsilon_j}\overline{U^{\varepsilon_j}}_{y_2}\right)\left[(\sin y_1, -\cos y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j})\right]\frac{g_{\varepsilon_j}(y_1)g'_{\varepsilon_j}(y_1)y_2}{\varepsilon_j^2}\,dy \\
&\quad + \int_{\mathcal{C}} i\left(\overline{U^{\varepsilon_j}}U^{\varepsilon_j}_{y_3} - U^{\varepsilon_j}\overline{U^{\varepsilon_j}}_{y_3}\right)\left[(0,0,1)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j})\right]\frac{g_{\varepsilon_j}(y_1)(1+g_{\varepsilon_j}(y_1)y_2)}{\varepsilon_j^2}\,dy \\
&\quad + \int_{\mathcal{C}} i\left(\overline{U^{\varepsilon_j}}U^{\varepsilon_j}_{y_3} - U^{\varepsilon_j}\overline{U^{\varepsilon_j}}_{y_3}\right)\left[(\sin y_1, -\cos y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j})\right]\frac{g_{\varepsilon_j}(y_1)g'_{\varepsilon_j}(y_1)y_3}{\varepsilon_j^2}\,dy \\
&= I + II + III + IV + V.
\end{aligned} \tag{2.56}$$

In light of (2.47) and (2.16), we see that

$$\begin{aligned}
\left|(\cos y_1, \sin y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j}(y))\right| &\le |(\cos y_1, \sin y_1, 0)\cdot \mathbf{A}^{e}(\cos y_1, \sin y_1, 0)| \\
&\quad + \left|(\cos y_1, \sin y_1, 0)\cdot (\mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j}(y)) - \mathbf{A}^{e}(\cos y_1, \sin y_1, 0)\right| \\
&\le \left\|\mathbf{A}^{\varepsilon_j}(T_{\varepsilon_j}(y)) - \mathbf{A}^{e}(\cos y_1, \sin y_1, 0)\right\|_{L^\infty(\mathcal{C})} \to 0 \quad \text{as } \varepsilon \to 0
\end{aligned}$$

and that $|(0,0,1)\cdot \mathbf{A}^{\varepsilon_j}| \to 0$ as well, using (2.7). Hence we can apply Hölder's inequality, (2.12), and (2.37) to see that

$$|II| + |IV| \le \mu\left(\frac{\left\|g_{\varepsilon_j}\right\|_{L^\infty(0,2\pi)}}{\varepsilon_j^2}\right)\cdot o(1)\cdot\left(\int_{\mathcal{C}} \left|U^{\varepsilon_j}_{y_2}\right|^2 + \left|U^{\varepsilon_j}_{y_3}\right|^2\,dy\right)^{1/2} \to 0 \tag{2.57}$$

as $\varepsilon \to 0$.

Next, observe that since $|(\sin y_1, -\cos y_1, 0)\cdot \mathbf{A}^{\varepsilon_j}|$ is uniformly bounded in $\mathcal{C}$, and since $|g'_{\varepsilon_j}| = \mathcal{O}(\varepsilon^{1-p})$ (cf. (2.1)), through (2.37) one calculates that

$$|III + V| \le \mu\left(\frac{\left\|g_{\varepsilon_j}g'_{\varepsilon_j}\right\|_{L^\infty((0,2\pi))}}{\varepsilon_j^2}\right)\left(\int_{\mathcal{C}} \left|U^{\varepsilon_j}_{y_2}\right|^2 + \left|U^{\varepsilon_j}_{y_3}\right|^2\,dy\right)^{1/2} \to 0 \tag{2.58}$$

as well.

Consequently, we conclude from (2.56), (2.57), and (2.58) that

$$\lim_{\varepsilon_j\to 0}\int_{\Omega_{\varepsilon_j}} i(\overline{u^{\varepsilon_j}}\nabla u^{\varepsilon_j} - u^{\varepsilon_j}\nabla\overline{u^{\varepsilon_j}})\cdot \mathbf{A}^{\varepsilon_j}\,dx = \lim_{\varepsilon_j\to 0} I. \tag{2.59}$$

We now split the integral I into two integrals over the regions $\mathcal{C}_\delta$ and $\mathcal{C}\setminus\mathcal{C}_\delta$, which we label as I_1 and I_2, respectively.

We first treat the limit of I_2. Through (2.12) and (2.16), we find that

$$|I_2| \le C \int_{-\delta}^{\delta} \int_{\{y_2^2+y_3^2<1\}} \left|U_{y_1}^{\varepsilon_j}\right| \frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2}\, dy_2\, dy_3\, dy_1.$$

As a consequence of (2.1) and (2.37), we obtain that

$$\begin{aligned}
&\int_{-\delta}^{\delta} \int_{\{y_2^2+y_3^2<1\}} \left|U_{y_1}^{\varepsilon_j}\right| \frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2}\, dy_2\, dy_3\, dy_1 \\
&\le \left(\int_{-\delta}^{\delta} \int_{\{y_2^2+y_3^2<1\}} \frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2} \left|U_{y_1}^{\varepsilon_j}\right|^2 dy_2\, dy_3\, dy_1 \right)^{1/2} \left(\int_{-\delta}^{\delta} \int_{\{y_2^2+y_3^2<1\}} \frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2}\, dy_2\, dy_3\, dy_1 \right)^{1/2} \\
&\le C \left(\int_{-\delta}^{\delta} \int_{\{y_2^2+y_3^2<1\}} 1\, dy_2\, dy_3\, dy_1 \right)^{1/2} \le C\delta^{1/2}.
\end{aligned}$$

Hence, we conclude that

$$\lim_{\varepsilon_j \to 0} |I_2| \le C\delta^{1/2}. \tag{2.60}$$

Turning to I_1, through an appeal to (2.2), (2.16), (2.48), (2.51), and (2.52), we may compute

$$\begin{aligned}
&\lim_{\varepsilon_j \to 0} I_1 \\
&= \lim_{\varepsilon_j \to 0} \int_{\{\delta<|y_1|<\pi\}} \int_{\{y_2^2+y_3^2<1\}} i \left(\overline{U^{\varepsilon_j}} U_{y_1}^{\varepsilon_j} - U^{\varepsilon_j} \overline{U^{\varepsilon_j}}_{y_1} \right) [(-\sin y_1, \cos y_1, 0) \cdot \mathbf{A}^{\varepsilon_j}] \frac{g_{\varepsilon_j}(y_1)^2}{\varepsilon_j^2}\, dy \\
&= \lim_{\varepsilon_j \to 0} \int_{\{\delta<|y_1|<\pi\}} \int_{\{y_2^2+y_3^2<1\}} i \left(\overline{U^{\varepsilon_j}} U_{y_1}^{\varepsilon_j} - U^{\varepsilon_j} \overline{U^{\varepsilon_j}}_{y_1} \right) A_1^e\, dy \\
&= \pi \int_{\{\delta<|y_1|<\pi\}} \int_{\{y_2^2+y_3^2<1\}} i \left(\overline{U^0} U_{y_1}^0 - U^0 \overline{U^0}_{y_1} \right) A_1^e\, dy_1.
\end{aligned}$$

Applying (2.57), (2.58), (2.60), and (2.61) to (2.56), we finally obtain

$$\begin{aligned}
&\lim_{\varepsilon_j \to 0} \int_{\Omega_{\varepsilon_j}} i(\overline{u^{\varepsilon_j}} \nabla u^{\varepsilon_j} - u^{\varepsilon_j} \nabla \overline{u^{\varepsilon_j}}) \cdot \mathbf{A}^{\varepsilon_j}\, dx \\
&\quad = \pi \int_{\{\delta<|y_1|<\pi\}} i \left(\overline{U^0} U_{y_1}^0 - U^0 \overline{U^0}_{y_1} \right) A_1^e\, dy_1 + \mathcal{O}(\delta^{1/2}).
\end{aligned} \tag{2.61}$$

Combining (2.50), (2.53), (2.54), and (2.61) and letting $\delta \to 0$, we establish (2.45).

Proof of claim (2.46). We may assume $V \in W^{1,2}((-\pi,\pi) \setminus \{0\}; \mathbb{C})$ and $V(-\pi) = V(\pi)$, since otherwise the construction of a sequence satisfying (2.46) is trivial. In order to highlight the fact that, in general, V' will be singular at $y_1 = 0$, we denote by $h \in L^2((-\pi,\pi); \mathbb{C})$ the regular part of the derivative of V, that is, the part which is absolutely continuous with respect to Lebesgue measure. Hence,

$$\int_{-\pi}^{0} h(y_1)\, dy_1 = V^- - V(-\pi) \quad \text{and} \quad \int_{0}^{\pi} h(y_1)\, dy_1 = V(\pi) - V^+, \tag{2.62}$$

where V^- and V^+ denote the left- and right-hand limits of V at $y_1 = 0$, respectively.

We proceed to define a sequence $\{V^\varepsilon\} \subset W^{1,2}((-\pi,\pi);\mathbb{C})$ satisfying $V^\varepsilon(\pi) = V^\varepsilon(-\pi)$ and from this we will define the sequence $\{v^\varepsilon\} \subset W^{1,2}(\Omega_\varepsilon;\mathbb{C})$ verifying (2.46) by viewing the argument of V^ε as the polar angle in a cylindrical coordinate system on $\mathbb{R}^3$. Note that the polar angle is precisely the variable y_1 as defined in (2.4).

To this end, recall the definition of the sequence $\{\lambda_\varepsilon\}$ given in (2.42) and denote by β_ε the quantity

$$\beta_\varepsilon := \int_{-\pi}^{\pi} \lambda_\varepsilon(y_1)\, dy_1.$$

A routine calculation shows that

$$\int_{-\varepsilon^p}^{\varepsilon^p} \lambda_\varepsilon(y_1)\, dy_1 = 1 + \mathcal{O}(\varepsilon^p), \quad \text{while} \quad \int_{\{|y_1|>\varepsilon^p\}} \lambda_\varepsilon(y_1)\, dy_1 = \mathcal{O}(\varepsilon^2), \tag{2.63}$$

so, in particular, we have $\beta_\varepsilon = 1 + \mathcal{O}(\varepsilon^p)$.

Now we are prepared to define the sequence $\{V^\varepsilon\} \subset W^{1,2}((-\pi,\pi);\mathbb{C})$ via the formula

$$V^\varepsilon(y_1) = \int_{-\pi}^{y_1} \left\{ h(s) + \frac{1}{\beta_\varepsilon}(V^+ - V^-)\lambda_\varepsilon(s) \right\} ds + V(-\pi). \tag{2.64}$$

This construction follows that found in [4].

With the aid of (2.62) and the periodicity of V, one sees that $V^\varepsilon(-\pi) = V^\varepsilon(\pi)$, and with the aid of (2.63), one readily checks that

$$|V^\varepsilon - V| + |(V^\varepsilon)' - V'| \le C\varepsilon^2 \quad \text{a.e. on} \quad \{|y_1| > \varepsilon^p\}, \tag{2.65}$$

while

$$|V^\varepsilon - V| \le \left|V^+ - V^-\right| \quad \text{a.e. on} \quad \{|y_1| < \varepsilon^p\}. \tag{2.66}$$

We also observe that $V^\varepsilon \to V$ in $L^1((-\pi,\pi);\mathbb{C})$ and that $(V^\varepsilon)' \overset{*}{\rightharpoonup} V'$ as measures on $(-\pi,\pi)$.

In light of the periodicity of V^ε we can now define the sequence $\{v^\varepsilon\} \subset W^{1,2}(\Omega_\varepsilon;\mathbb{C})$ through the relation $v^\varepsilon(x) = V^\varepsilon(\tan^{-1}(x_2/x_1)) = V^\varepsilon(y_1)$. We proceed to verify (2.46) by decomposing the energy $G_\varepsilon(v^\varepsilon, \mathbf{A}^e)$ and studying the limit of each term in the same manner as was done in the proof of claim (2.45).

We write

$$\begin{aligned} G_\varepsilon(v^\varepsilon, \mathbf{A}^e) &= \frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon} |\nabla v^\varepsilon|^2\, dx + \frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon} i(\overline{v^\varepsilon}\nabla v^\varepsilon - v^\varepsilon \nabla \overline{v^\varepsilon}) \cdot \mathbf{A}^e\, dx \\ &+ \frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon} |v^\varepsilon|^2 |\mathbf{A}^e|^2\, dx + \frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon} \frac{\nu^2}{2}(|v^\varepsilon|^2 - \mu^2)^2\, dx. \end{aligned} \tag{2.67}$$

First note that through (2.24) one has

$$\begin{aligned} \frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon} |\nabla v^\varepsilon|^2\, dx &= \frac{1}{2\varepsilon^2}\int_{\mathcal{C}} a_{ik}\big(V^\varepsilon_{y_i}\overline{V^\varepsilon}_{y_k} + \overline{V^\varepsilon}_{y_i} V^\varepsilon_{y_k}\big)\, dy \\ &= \pi \int_{-\pi}^{\pi} \frac{g_\varepsilon(y_1)^2}{\varepsilon^2(1+g_\varepsilon(y_1)y_2)} \left|\frac{d\,V^\varepsilon}{d\,y_1}\right|^2 dy_1 \\ &= \pi \int_{-\pi}^{\pi} a_\varepsilon(y_1) \left|\frac{d\,V^\varepsilon}{d\,y_1}\right|^2 dy_1 + o(1) \quad \text{as} \quad \varepsilon \to 0. \end{aligned}$$

Thus, from (2.42) and (2.64) we see that

$$\begin{aligned}
&\frac{1}{\pi}\lim_{\varepsilon\to 0}\frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon}\left|\nabla v^\varepsilon\right|^2\,dx\\
&=\lim_{\varepsilon\to 0}\int_{-\pi}^{\pi}a_\varepsilon(y_1)\left|h(y_1)+\frac{1}{\beta_\varepsilon}(V^+-V^-)\lambda_\varepsilon(y_1)\right|^2\,dy_1\\
&=\lim_{\varepsilon\to 0}\int_{-\pi}^{\pi}\left|a_\varepsilon(y_1)h(y_1)+\frac{1}{\beta_\varepsilon}(V^+-V^-)a_\varepsilon(y_1)\lambda_\varepsilon(y_1)\right|^2\frac{1}{a_\varepsilon(y_1)}\,dy_1\\
&=\lim_{\varepsilon\to 0}\int_{-\pi}^{\pi}\left|a_\varepsilon(y_1)h(y_1)+\frac{1}{\beta_\varepsilon}(V^+-V^-)(1-a_\varepsilon(y_1))\right|^2(1+\lambda_\varepsilon(y_1))\,dy_1\\
&=\lim_{\varepsilon\to 0}\left\{\int_{-\pi}^{\pi}a_\varepsilon(y_1)^2\left|h(y_1)\right|^2\,dy_1+\frac{1}{\beta_\varepsilon^2}\left|V^+-V^-\right|^2+\int_{-\pi}^{\pi}(1-a_\varepsilon(y_1))f_\varepsilon(y_1)\,dy_1\right\},
\end{aligned}$$

where in the last integral we have introduced the real-valued function f_ε so as to include all the remaining terms coming from expanding the square in the previous line. One readily checks that $\|f_\varepsilon\|_{L^\infty((-\pi,\pi))}\le C$ for some C independent of ε. Then, since $a_\varepsilon\to 1$ in $L^1((-\pi,\pi))$ and $\beta_\varepsilon\to 1$, we conclude that

$$\frac{1}{\pi}\lim_{\varepsilon\to 0}\frac{1}{\varepsilon^2}\int_{\Omega_\varepsilon}\left|\nabla v^\varepsilon\right|^2\,dx=\int_{-\pi}^{\pi}\left|V'\right|^2\,dy_1+\left|V^+-V^-\right|^2. \tag{2.68}$$

Turning to the next integral on the right-hand side of (2.67), we see from (2.56), with u^ε replaced by v^ε and $\mathbf{A}^\varepsilon$ replaced by $\mathbf{A}^e$, that

$$\begin{aligned}
&\int_{\Omega_\varepsilon}i(\overline{v^\varepsilon}\nabla v^\varepsilon-v^\varepsilon\nabla\overline{v^\varepsilon})\cdot\mathbf{A}^e\,dx\\
&=\int_{\mathcal{C}}i\left(\overline{V^\varepsilon}V^\varepsilon_{y_1}-V^\varepsilon\overline{V^\varepsilon}_{y_1}\right)\mathbf{A}^e(T_\varepsilon)\cdot(-\sin y_1,\cos y_1,0)\frac{g_\varepsilon(y_1)^2}{\varepsilon^2}\,dy\\
&=\pi\int_{-\pi}^{\pi}i\left(\overline{V^\varepsilon}V^\varepsilon_{y_1}-V^\varepsilon\overline{V^\varepsilon}_{y_1}\right)A_1^e\frac{g_\varepsilon(y_1)^2}{\varepsilon^2}\,dy_1+\mathcal{O}(\varepsilon).
\end{aligned}$$

Here we have used the fact that $|\mathbf{A}^e(T_\varepsilon)\cdot(-\sin y_1,\cos y_1,0)|=A_1^e+\mathcal{O}(\varepsilon)$.

Hence, from (2.65) we have

$$\begin{aligned}
&\frac{1}{\pi}\int_{\Omega_\varepsilon}i(\overline{v^\varepsilon}\nabla v^\varepsilon-v^\varepsilon\nabla\overline{v^\varepsilon})\cdot\mathbf{A}^e\,dx\\
&=\int_{\{|y_1|>\varepsilon^p\}}i\left(\overline{V^\varepsilon}V^\varepsilon_{y_1}-V^\varepsilon\overline{V^\varepsilon}_{y_1}\right)A_1^e\frac{g_\varepsilon(y_1)^2}{\varepsilon^2}\,dy_1\\
&\quad+\int_{\{|y_1|<\varepsilon^p\}}\bullet\quad dy_1\quad+\quad\mathcal{O}(\varepsilon)\\
&=\int_{\{|y_1|>\varepsilon^p\}}i\left(\overline{V}V_{y_1}-V\overline{V}_{y_1}\right)A_1^e\,dy_1\\
&\quad+\int_{\{|y_1|<\varepsilon^p\}}i\left(\overline{V^\varepsilon}V^\varepsilon_{y_1}-V^\varepsilon\overline{V^\varepsilon}_{y_1}\right)A_1^e\frac{g_\varepsilon(y_1)^2}{\varepsilon^2}\,dy_1+\mathcal{O}(\varepsilon).
\end{aligned}\tag{2.69}$$

Now as a consequence of (2.35), (2.42), and (2.64), we can estimate this last term as follows:

$$\begin{aligned}
&\left| \int_{\{|y_1|<\varepsilon^p\}} i\left(\overline{V^\varepsilon} V^\varepsilon_{y_1} - V^\varepsilon \overline{V^\varepsilon}_{y_1}\right) A_1^e \frac{g_\varepsilon(y_1)^2}{\varepsilon^2}\, dy_1 \right| \\
&\le C \int_{\{|y_1|<\varepsilon^p\}} a_\varepsilon(y_1) \left|V^\varepsilon_{y_1}\right| \, dy_1 \\
&\le C \int_{\{|y_1|<\varepsilon^p\}} a_\varepsilon(y_1) \left|h(y_1)\right| \, dy_1 + C\left|V^+ - V^-\right| \int_{\{|y_1|<\varepsilon^p\}} a_\varepsilon(y_1) \frac{1}{\beta_\varepsilon} \left|\lambda_\varepsilon(y_1)\right| \, dy_1 \\
&= C \int_{\{|y_1|<\varepsilon^p\}} a_\varepsilon(y_1) \left|h(y_1)\right| \, dy_1 + C\left|V^+ - V^-\right| \int_{\{|y_1|<\varepsilon^p\}} \frac{1}{\beta_\varepsilon} \left|1 - a_\varepsilon(y_1)\right| \, dy_1 = \mathcal{O}(\varepsilon^p).
\end{aligned} \tag{2.70}$$

Combining (2.69) and (2.70) and passing to the limit as $\varepsilon \to 0$ we conclude that

$$\lim_{\varepsilon\to 0} \int_{\Omega_\varepsilon} i(\overline{v^\varepsilon}\nabla v^\varepsilon - v^\varepsilon \nabla \overline{v^\varepsilon}) \cdot \mathbf{A}^e \, dx = \pi \int_{-\pi}^{\pi} i\left(\overline{V} V_{y_1} - V \overline{V}_{y_1}\right) A_1^e \, dy_1. \tag{2.71}$$

Finally, one finds that the limits of the last two integrals in (2.67) are given by

$$\begin{aligned}
&\lim_{\varepsilon\to 0} \frac{1}{\varepsilon^2} \int_{\Omega_\varepsilon} \left\{ \left|v^\varepsilon\right|^2 \left|\mathbf{A}^e\right|^2 + \frac{\nu^2}{2}(\left|v^\varepsilon\right|^2 - \mu^2)^2 \right\} dx \\
&= \pi \int_{-\pi}^{\pi} \left\{ \left|V\right|^2 \left|A_1^e\right|^2 + \frac{\nu^2}{2}(\left|V\right|^2 - \mu^2)^2 \right\} dy_1
\end{aligned} \tag{2.72}$$

as an easy consequence of (2.65) and (2.66) using a calculation similar to that carried out in (2.53) and (2.54).

Claim (2.46) follows by combining (2.68), (2.71), and (2.72). ∎

3. Discussion. In this section we discuss some physical implications of the one-dimensional model (2.44). We start by observing that adding a suitable parameter to the geometric characterization of the constriction enables us to control the relative magnitude of the different terms in the limit functional G_0 (2.44). For example, if we replace (2.1)–(2.2) by

$$g_\varepsilon(y_1) = (\varepsilon^{1-p} - 2\sqrt{b}\varepsilon)\left|y_1\right| + 2\sqrt{b}\varepsilon^{1+p} \quad \text{for} \quad 0 \le |y_1| \le \varepsilon^p, \tag{3.1}$$

$$g_\varepsilon(y_1) = \varepsilon \quad \text{for} \quad \varepsilon^p \le |y_1| \le \pi, \tag{3.2}$$

where b is a fixed positive parameter, then we obtain the modified limit functional

$$G_0(U) = \begin{cases} \int_{(-\pi,\pi)\setminus\{0\}} \left(\left| (i\frac{d}{dy_1} + A_1^e)U \right|^2 + \frac{\nu^2}{2}(|U|^2 - \mu^2)^2 \right) dy_1 + b\left|U^+ - U^-\right|^2 \\ \qquad \text{if} \quad U \in W^{1,2}((-\pi,\pi)\setminus\{0\};\mathbb{C}), \quad U(-\pi) = U(\pi), \\ \qquad +\infty \quad \text{otherwise.} \end{cases} \tag{3.3}$$

To simplify the presentation in this section, we replace A_1^e by A and use θ to denote the variable y_1. Equating the first variation of G_0 to zero, we obtain the following jump condition at the weak point ($\theta = 0$):

$$\left(\frac{d}{d\theta} - iA\right) U^+ = \left(\frac{d}{d\theta} - iA\right) U^- = b\left(U^+ - U^-\right). \tag{3.4}$$

Multiplying both sides of (3.4) by $\overline{U^+}$ and taking the imaginary part of the obtained complex-valued expression, we find

$$J^+ := \operatorname{Im}\left(\left(\frac{dU^+}{d\theta} - iAU^+\right)\overline{U^+}\right) = -b\operatorname{Im}\left(U^-\overline{U^+}\right). \tag{3.5}$$

The object J^+ is the supercurrent immediately after ($\theta = 0^+$), the weak link. Similarly we multiply both sides of (3.4) by $\overline{U^-}$ and obtain

$$J^- := \operatorname{Im}\left(\left(\frac{dU^-}{d\theta} - iAU^-\right)\overline{U^-}\right) = b\operatorname{Im}\left(U^+\overline{U^-}\right). \tag{3.6}$$

We therefore deduce that $J^+ = J^-$; i.e., the current is conserved across the junction.

In contrast to the continuity of the supercurrent, the order parameter U and its derivative are *not* continuous across the junction. To write the jump in the amplitude's derivative, we express U in a polar form, $U = \rho e^{i\phi}$. Now, taking the real part of (3.4) multiplied by U^+, we obtain after a quick calculation

$$\frac{d\rho^+}{d\theta} = b\left(\rho^+ - \rho^-\cos(\phi^+ - \phi^-)\right), \tag{3.7}$$

where as before, the superscripts $\cdot^+$ and $\cdot^-$ denote evaluation on either side of $\theta = 0$. Similarly we find

$$\frac{d\rho^-}{d\theta} = b\left(\rho^+\cos(\phi^+ - \phi^-) - \rho^-\right). \tag{3.8}$$

Applying the polar form of U to the current formula (3.5), we get

$$J^+ = J^- = b\rho^+\rho^-\sin(\phi^+ - \phi^-). \tag{3.9}$$

This is the celebrated Josephson formula (cf. (1.1)). Moreover we derived an explicit expression for J_M. It is important to observe that in contrast to most models of Josephson junctions (see, e.g., [2] or [21]), in the model being presented here, the order parameter is *not* continuous at the junction. We point out that our equations form a special case of an ad hoc model due to de Gennes (cf. (7.66) of [7]). In this model, de Gennes postulates that the pair $\left(U^+, (\frac{d}{d\theta} - iA)U^+\right)$ is linearly related to the pair $\left(U^-, (\frac{d}{d\theta} - iA)U^-\right)$ through multiplication by a 2×2 matrix he denotes by M. To make the comparison precise, we recast our connection formula across the junction in the form

$$U^+ = U^- + \frac{1}{b}\left(\frac{d}{d\theta} - iA\right)U^-, \tag{3.10}$$

$$\left(\frac{d}{d\theta} - iA\right)U^+ = \left(\frac{d}{d\theta} - iA\right)U^-. \tag{3.11}$$

Using the notation of [7], we can then identify $M_{11} = M_{22} = 1,\ M_{12} = \frac{1}{b},\ M_{21} = 0$.

The collapse of the three-dimensional domain Ω_ε onto a one-dimensional wire is analogous to similar limits computed in, e.g., [5] and [18]. The new feature here is the strong effect of inhomogeneities in the wire. To demonstrate the effect of the term proportional to b in (3.3), we consider the particular problem of phase transition

in thin wires with constrictions. It is known that the critical temperature in one-dimensional rings depends upon the magnetic flux threading the hole bounded by the ring. This was discovered experimentally by Little and Parks about 40 years ago and has been well established theoretically since then [17]. We proceed to compute this dependency using the model given by G_0. The critical temperature is associated with μ, as we explained below (2.5), while μ, in turn, is determined by the eigenvalue problem that is obtained through linearizing the Euler–Lagrange equation associated with G_0 about the normal state $U \equiv 0$. We refer to [11] for a justification of this statement. The linearized equation is

$$\left(\frac{d}{d\theta} - iA\right)^2 U + (\nu\mu)^2 U = 0, \tag{3.12}$$

together with the jump conditions (3.10)–(3.11) enforced at $\theta = 0$ and periodic boundary conditions at the endpoints $\theta = \pm\pi$.

Proceeding as in [11], we make a gauge transformation $U(\theta) \to U(\theta)e^{i\int_0^\theta A}$. This simplifies the eigenvalue problem (3.12) into

$$\frac{d^2}{d\theta^2}U + (\nu\mu)^2 U = 0 \quad \text{for } -\pi < \theta < 0 \text{ and } 0 < \theta < \pi, \tag{3.13}$$

coupled with the boundary conditions

$$\begin{aligned} &U(-\pi) = U(\pi)e^{i\Phi}, \quad U'(-\pi) = U'(\pi)e^{i\Phi}, \\ &U^+ = U^- + \frac{1}{b}(U')^- \quad \text{at } \theta = 0, \\ &(U')^+ = (U')^- \quad \text{at } \theta = 0, \end{aligned}$$

where $\Phi := \int_{-\pi}^{\pi} A\, d\theta$ is the magnetic flux through the hole bounded by the ring. After writing U in terms of sines and cosines, we obtain through a simple calculation the following transcendental equation for μ:

$$\cos(2\pi\nu\mu) - \frac{\nu\mu}{2b}\sin(2\pi\nu\mu) = \cos\Phi. \tag{3.14}$$

Notice that in the limit $b \to \infty$, the order parameter is continuous, and (3.14) reduces to the clean ring limit [11].

We wish to compare (3.14) to the analogous one obtained in [11]. In [11], a junction is modeled not through a constriction but rather through a modification of the one-dimensional GL energy in a thin region corresponding to angular values $0 \le \theta \le d$, where $d \ll 1$. Specifically, one replaces the potential term $\frac{\nu^2}{2}(|u|^2 - \mu^2)^2$ in (2.5) for these θ-values with the term $\frac{\alpha}{d}|u|^2$, where $\alpha > 0$ is a parameter related to the strength of the junction. Then carrying out an asymptotic analysis of the normal/superconducting phase transition in the small d limit, one finds that the corresponding eigenvalue μ solves the transcendental equation

$$\cos 2\pi\mu + \frac{\alpha}{2\mu}\sin 2\pi\mu = \cos\Phi. \tag{3.15}$$

A comparison of the two phase transition curves corresponding to (3.14) and (3.15) with $\nu = b = \alpha = 1$ can be found in Figure 2. We note that qualitatively the two transition curves coming from the two different models are quite similar, though the

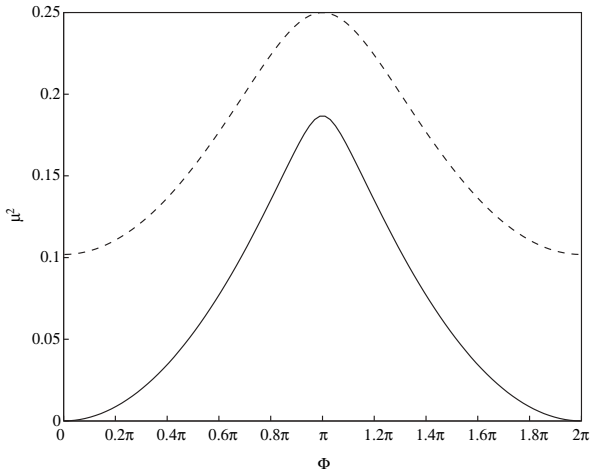

FIG. 2. *Comparison of phase transition curves μ^2 versus Φ for the constricted model (solid) and the modified GL model (dashed).*

transition temperature for the model from [11] is lower (higher μ). Another distinction is that in the model from [11], the curve does not pass through the origin. That is, even for zero magnetic flux through the ring, the transition temperature in that model is lower than the critical temperature associated with the normal/superconducting phase transition in the absence of any applied magnetic field for a ring without normal inclusions. This is not the case in the constricted model.

Returning to the general question of Josephson junctions, we comment that de Gennes did not distinguish between different kinds of junctions. Together with earlier investigations (see [11] and [20]) we are able now to identify two distinguished kinds of junctions. The first kind is a classical SNS junction, where a thin normal layer separates two bulk superconducting samples. Under appropriate scaling it can be shown then that the current is proportional to the sin of the magnetic flux threading through the hole bounded by the wire, but the amplitude of the order parameter is continuous [11]. The second class consists of a geometric weak link (our constriction). Here the current is a periodic function of the phase jump, but the topological constraint implied by the ring is not as strong as in the first class in that the phase is no longer required to jump by a multiple of 2π along the ring. Finally, we point out the heuristics behind our construction. For sufficiently narrow constrictions, it is energetically preferable for the minimizer to have a rapid transition across the link with less drastic variations in the bulk. In this light, the specific geometry of the constriction given by the graph of g_ε is not crucial.
