4. Spectral decompositions of the hydroelastic problem. In this section we will write down the spectral expansions for the plate-water system. These expansions will be based closely on the expansions we have just derived for the case when the plate is absent. We find the generalized eigenfunctions from the solution for a unit incident wave together with the associated scattered waves generated by the coupling with the plate: their superpositions (incident + scattered) yield a generalized spectral basis for the coupled problem. Here we choose *outgoing* scattered waves, but the same result holds for scattered waves that are incoming.

4.1. The first-order formulation. We denote by $U_{\lambda,\kappa}$ the eigenfunctions in the presence of the plate, which correspond to the incident waves $\tilde{U}_{\lambda,\kappa}$ coming respectively from the right ($\kappa = \operatorname{sgn}(\lambda)$) and the left ($\kappa = -\operatorname{sgn}(\lambda)$). These are single frequency solutions: they satisfy the equation

$$\begin{pmatrix} 0 & 1+\chi_P\beta\partial_x^4 \\ \partial_n\mathbf{G} & 0 \end{pmatrix} U_{\lambda,\kappa} = \lambda U_{\lambda,\kappa},$$

and have the asymptotics

$$U_{\lambda,+1}(x) \sim \left(e^{+ikx} + S_{11}\,e^{-ikx}\right)\begin{pmatrix} \lambda^{-1} \\ 1 \end{pmatrix} \quad \text{as } x \to +\infty, \tag{4.1}$$
$$U_{\lambda,+1}(x) \sim \left(S_{12}\,e^{+ikx}\right)\begin{pmatrix} \lambda^{-1} \\ 1 \end{pmatrix} \quad \text{as } x \to -\infty,$$

and

$$U_{\lambda,-1}(x) \sim \left(S_{22}\,e^{-ikx}\right)\begin{pmatrix} \lambda^{-1} \\ 1 \end{pmatrix} \quad \text{as } x \to +\infty, \tag{4.2}$$
$$U_{\lambda,-1}(x) \sim \left(e^{-ikx} + S_{21}\,e^{+ikx}\right)\begin{pmatrix} \lambda^{-1} \\ 1 \end{pmatrix} \quad \text{as } x \to -\infty,$$

where S_{11}, S_{12}, S_{21}, and S_{22} are the reflection and transmission coefficients (which must be determined). We define the components of $U_{\lambda,\kappa}$ as

$$U_{\lambda,\kappa}(x) = \begin{pmatrix} \phi_{\lambda,\kappa}(x) \\ \xi_{\lambda,\kappa}(x) \end{pmatrix}.$$

Setting $\Phi_{\lambda,\kappa} = \mathbf{G}\phi_{\lambda,\kappa}$, the above eigenvalue problem amounts to the boundary value problem

$$\begin{aligned} &\Delta\Phi_{\lambda,\kappa} = 0, \qquad -h < z < 0, \\ &\partial_n\Phi_{\lambda,\kappa} = 0, \qquad z = -h, \\ &\lambda\Phi_{\lambda,\kappa} = \left(1+\chi_P\beta\partial_x^4\right)\xi_{\lambda,\kappa}, \qquad z = 0, \\ &\partial_n\Phi_{\lambda,\kappa} = \lambda\,\xi_{\lambda,\kappa}, \qquad z = 0, \end{aligned} \tag{4.3}$$

subject to the appropriate radiation conditions given by (4.1) and (4.2) plus the free edge boundary conditions (2.5). There are a number of methods which can be used to solve this problem. The equation was solved in [13] using a Green function for the water and plate. It was solved in [15] using a Green function for the water and an expansion in modes for the plate. The solution method is described in the appendix. Note that we are assuming that there is no point spectrum, i.e., that the floating elastic plate problem does not admit any trapped modes. While there is no proof that trapped modes do not exist, all evidence points to this conclusion. The present theory could be extended to include trapped modes, following [16, 5, 4]; it seems sensible not to do this since we strongly believe they do not exist.

Having found the generalized eigenfunctions, we need to determine their normalization; that is, we know that

$$\langle U_{\lambda,\kappa}, U_{\lambda',\kappa'}\rangle = q_\lambda^{-1}\,\delta(\lambda-\lambda')\,\delta_{\kappa\kappa'}, \tag{4.4}$$

but we have no easy way to determine q_λ. We can use a formal argument as was done in [12]. However, we can find this normalization using a very powerful result from spectral theory, namely that the normalization of the perturbed eigenfunctions is identical to the normalization of the free problem (i.e., the problem without the plate discussed previously). We do not present a proof of this here, but note that this has been done in many related situations. The first proofs were for the Schrödinger equation [16, 5] and for the Helmholtz equation [23]. Recently, a proof was given for water waves for a rigid floating body in infinite depth [3, 4]. The proof for the plate can be found following an argument similar to that given in [4]. In particular the eigenfunctions satisfy the following orthogonality conditions:

$$\langle U_{\lambda,\kappa}, U_{\lambda',\kappa'}\rangle_{\mathcal{V}} = 4\pi\left|\frac{d\lambda}{dk}\right|\delta_{\kappa\kappa'}\delta\left(\lambda-\lambda'\right).$$

This normalization agrees in the appropriate limit with the normalizations of [3, 12] for infinite depth and shallow water, respectively.

We can express the solution to (2.8) as a spectral expansion as we did for the free problem, except that we use the eigenfunctions $U_{\lambda,\kappa}$ defined by (4.3) and the space $\mathcal{V}$, i.e.,

$$U(t) = \frac{1}{4\pi}\int_{\mathbb{R}} e^{i\lambda t}\sum_{\kappa=\pm1}\langle U_0, U_{\lambda,\kappa}\rangle_{\mathcal{V}}\, U_{\lambda,\kappa}\left|\frac{dk}{d\lambda}\right| d\lambda, \quad \text{where} \quad U_0 = \begin{pmatrix}\phi_0\\ i\zeta_0\end{pmatrix}. \tag{4.5}$$

The calculation of the inner products can be simplified by observing that

$$\begin{aligned}\langle U_0, U_{\lambda,\kappa}\rangle_{\mathcal{V}} &= \langle \partial_n\mathbf{G}\phi_0, \phi_{\lambda,\kappa}\rangle_{\mathbb{R}_x} + \left\langle\left(1+\chi_P\beta\partial_x^4\right)i\zeta_0, \xi_{\lambda,\kappa}\right\rangle_{\mathbb{R}_x}\\ &= \langle \phi_0, \partial_n\mathbf{G}\phi_{\lambda,\kappa}\rangle_{\mathbb{R}_x} + \left\langle i\zeta_0, \left(1+\chi_P\beta\partial_x^4\right)\xi_{\lambda,\kappa}\right\rangle_{\mathbb{R}_x}\\ &= \langle \phi_0, \lambda\,\xi_{\lambda,\kappa}\rangle_{\mathbb{R}_x} + \langle i\zeta_0, \lambda\,\phi_{\lambda,\kappa}\rangle_{\mathbb{R}_x}\\ &= \lambda\left(\langle \phi_0, \xi_{\lambda,\kappa}\rangle_{\mathbb{R}_x} + \langle i\zeta_0, \phi_{\lambda,\kappa}\rangle_{\mathbb{R}_x}\right).\end{aligned} \tag{4.6}$$

4.2. The second-order formulation. The second-order spectral expansion follows from (2.21) and (3.10) exactly as with the first-order formulation. The equation for the eigenfunctions is

$$\partial_n\mathbf{H}\zeta_{\nu,\kappa} = \nu\zeta_{\nu,\kappa},$$

where we define the asymptotics so that $\zeta_{\nu,\kappa}$ corresponds to the incident wave free wave $\tilde{\zeta}_{\nu,\kappa}$ defined in (3.9), i.e.,

$$\begin{aligned}&\zeta_{\lambda,+1}(x) \sim e^{+ikx} + S_{11}\,e^{-ikx} \quad \text{as } x\to+\infty,\\ &\zeta_{\lambda,+1}(x) \sim S_{12}\,e^{+ikx} \quad \text{as } x\to-\infty,\end{aligned} \tag{4.7}$$

and

$$\begin{aligned}&\zeta_{\lambda,-1}(x) \sim S_{22}\, e^{-ikx} \quad \text{as } x \to -\infty,\\ &\zeta_{\lambda,-1}(x) \sim e^{-ikx} + S_{21}\, e^{+ikx} \quad \text{as } x \to +\infty.\end{aligned} \tag{4.8}$$

Setting $\Psi_{\nu,\kappa} = \mathbf{H}\zeta_{\nu,\kappa}$, the boundary value problem to solve is

$$\begin{aligned}&\Delta\Psi_{\nu,\kappa} = 0, \qquad -h < z < 0,\\ &\partial_n \Psi_{\nu,\kappa} = 0, \qquad z = -h,\\ &-\zeta_{\nu,\kappa} + \Psi_{\nu,\kappa} = \chi_P \left(\beta\partial_x^4\zeta_{\nu,\kappa} + \gamma\partial_n\Psi_{\nu,\kappa}\right), \qquad z = 0,\\ &\partial_n\Psi_{\nu,\kappa} = \nu\zeta_{\nu,\kappa}, \qquad z = 0,\end{aligned} \tag{4.9}$$

subject to the radiation conditions (4.7) and (4.8) and the free edge conditions (2.5). We solve this system by the method described in [8]. Note that (4.9) is equivalent to the boundary value problem (4.3) when the mass γ is zero, taking $\nu = \lambda^2$ and

$$\xi_{\lambda,\kappa} = i\,\zeta_{\lambda^2,\kappa} \quad \text{and} \quad \Phi_{\lambda,\kappa} = i\lambda^{-1}\,\Psi_{\lambda^2,\kappa}. \tag{4.10}$$

The orthogonality relations follow from those for the free problem given by (3.10), and therefore

$$\langle \zeta_{\nu,\kappa}, \zeta_{\nu',\kappa'}\rangle_{\mathcal{H}} = 2\pi \frac{d\nu}{dk}\delta_{\kappa\kappa'}\delta\left(\nu - \nu'\right).$$

The explicit expression of the time-dependent solution (2.24) to (2.21) is

$$\begin{aligned}\zeta(t) &= \mathrm{Re}\{\exp(i(\partial_n\mathbf{H})^{1/2}t)\eta_0\}\\ &= \mathrm{Re}\left\{\frac{1}{2\pi}\int_{\mathbb{R}^+} e^{i\sqrt{\nu}t}\sum_{\kappa=\pm1}\langle\eta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}}\,\zeta_{\nu,\kappa}\,\frac{dk}{d\nu}\,d\nu\right\},\end{aligned} \tag{4.11}$$

where we recall that $\eta_0 = \zeta_0 - i(\partial_n\mathbf{H})^{-1/2}\theta_0$ and $\theta_0 = \partial_n\mathbf{G}\phi_0$. The real part in this expression takes the form

$$\zeta(t) = \frac{1}{2\pi}\int_{\mathbb{R}^+}\sum_{\kappa=\pm1}\left(\cos(\sqrt{\nu}t)\,\langle\zeta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}} + \frac{\sin(\sqrt{\nu}t)}{\sqrt{\nu}}\,\langle\theta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}}\right)\zeta_{\nu,\kappa}\,\frac{dk}{d\nu}\,d\nu. \tag{4.12}$$

4.3. Agreement of the two expansions when $\gamma = 0$. The expression (4.12) coincides with (4.5) in the case where $\gamma = 0$. To see this, note that

$$\begin{aligned}\langle\zeta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}} &= \langle\zeta_0, (1 + \chi_P\beta\partial_x^4)\zeta_{\nu,\kappa}\rangle_{\mathbb{R}}\\ &= \langle\zeta_0, \psi_{\nu,\kappa}\rangle_{\mathbb{R}} \quad \text{with } \psi_{\nu,\kappa} = \Psi_{\nu,\kappa}\big|_{z=0}\end{aligned} \tag{4.13}$$

(where we used (4.9) with $\gamma = 0$), and similarly

$$\begin{aligned}\langle\theta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}} &= \langle\partial_n\mathbf{G}\phi_0, \psi_{\nu,\kappa}\rangle_{\mathbb{R}}\\ &= \langle\phi_0, \partial_n\mathbf{G}\psi_{\nu,\kappa}\rangle_{\mathbb{R}}\\ &= \nu\,\langle\phi_0, \zeta_{\nu,\kappa}\rangle_{\mathbb{R}}.\end{aligned} \tag{4.14}$$

Hence from (4.10), the inner product (4.6) becomes

$$\langle U_0, U_{\lambda,\kappa}\rangle_{\mathcal{V}} = \langle\zeta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}} - i\lambda^{-1}\langle\theta_0, \zeta_{\nu,\kappa}\rangle_{\mathcal{H}}.$$

Substituting this expression into (4.5) and considering the displacement only, we get

$$\zeta(t) = \frac{1}{4\pi}\int_{\mathbb{R}^+} e^{i\lambda t} \sum_{\kappa=\pm1} \left(\langle\zeta_0,\zeta_{\nu,\kappa}\rangle_{\mathcal{H}} - i\lambda^{-1}\langle\theta_0,\zeta_{\nu,\kappa}\rangle_{\mathcal{H}}\right)\zeta_{\nu,\kappa}\left|\frac{dk}{d\lambda}\right| d\lambda$$
$$+ \frac{1}{4\pi}\int_{\mathbb{R}^+} e^{-i\lambda t} \sum_{\kappa=\pm1} \left(\langle\zeta_0,\zeta_{\nu,\kappa}\rangle_{\mathcal{H}} + i\lambda^{-1}\langle\theta_0,\zeta_{\nu,\kappa}\rangle_{\mathcal{H}}\right)\zeta_{\nu,\kappa}\left|\frac{dk}{d\lambda}\right| d\lambda,$$

which is nothing but (4.12) using the change of variable $\lambda = \sqrt{\nu}$.

5. Numerical results. The numerical implementation of (4.5) and (4.11) is relatively straightforward once the eigenfunctions have been calculated by solving (4.3) and (4.9). We represent the solution to (4.3) and (4.9) at discrete points. We use this discrete representation to calculate the inner products using the expressions given by (4.6) and (4.13)–(4.14) and numerical quadrature. The final integral in (4.5) and (4.11) is calculated using the well-known FFT algorithm. The number of points in the frequency domain which are required to compute the solution depends strongly on the initial conditions; i.e., if the initial data is smooth (has few high frequency components), then fewer frequency calculations will be required. Furthermore, we require more points when the initial condition is under the plate because of the high frequencies of the free plate vibration (for our value of β) for a given initial smoothness. The case of an incident disturbance which is nonzero far from the plate also allows significant simplification, and this case is discussed below. We concentrate on making calculations similar to those in [12] for the purpose of comparison and checking. Of course the solution in [12] was valid only for shallow water, so we will extend the calculations to water of finite depth. The plate length is $b = 50$ and stiffness is $\beta = 2 \times 10^4$.

In order to compare with the results obtained in [12], we first consider a wave which is incoming from the left with initial potential given by

$$\phi_0\,(x) = e^{-(x+125)^2/350}$$

and with the corresponding displacement so that the pulse is traveling to the right in the absence of the plate. This means that the initial state $U_0 = (\phi_0, i\zeta_0)^T$ must have zero spectral components for the plane waves which propagate to the left, that is,

$$U(t) = \frac{1}{4\pi}\int_{\mathbb{R}} e^{i\lambda t}\,\langle U_0, U_{\lambda,-1}\rangle_{\mathcal{V}}\,U_{\lambda,-1}\left|\frac{dk}{d\lambda}\right| d\lambda, \quad \text{where} \quad U_0 = \begin{pmatrix}\phi_0\\ i\zeta_0\end{pmatrix}, \tag{5.1}$$

and we can deduce from the asymptotic form of the eigenfunctions that

$$\langle U_0, U_{\lambda,-1}\rangle = 2\int_{\mathbb{R}} e^{-ik(\lambda)x}\,\phi_0(x)\,dx.$$

This considerably simplifies the calculation of (5.1) and we can calculate it using the FFT of $\phi_0\,(x)$ and then an inverse FFT of (5.1).

The potential is shown in Figure 1 for water depth $h = 1$. This is identical to the equivalent figure in [12]. We now consider the effect of increasing the water depth so that the shallow plate approximation is no longer valid. Figures 2 and 3 show the evolution of the potential for the water depths $h = 5$ and $h = 20$, respectively.

In all these figures we used 512 values for λ from $-\pi$ to π to calculate $U_{\lambda,\kappa}$, and we used 4096 points (truncated with zeros) to compute the inverse FFT. Note that

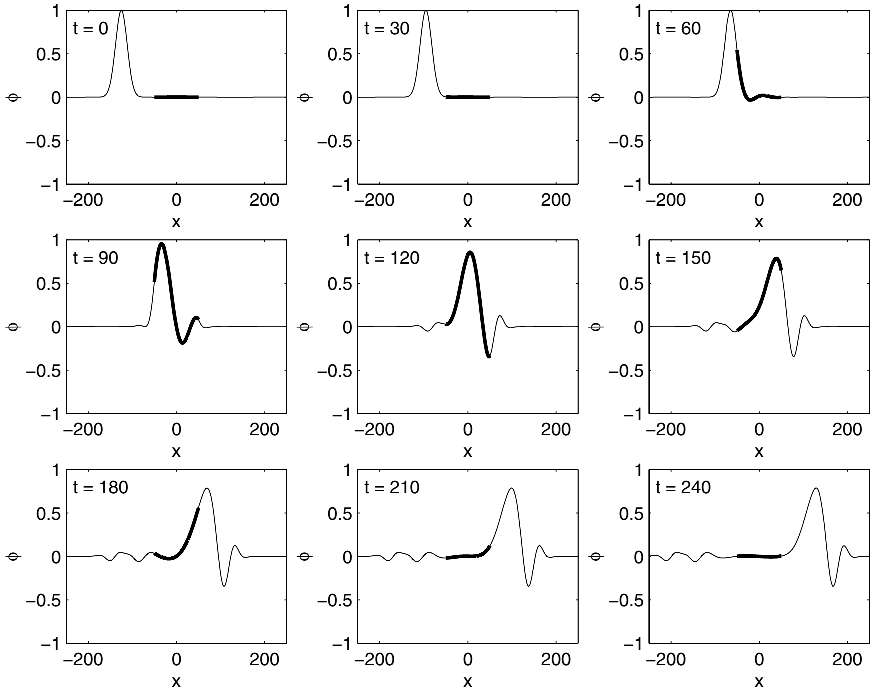

FIG. 1. *The evolution of the potential due to a pulse traveling to the right for the times shown. The plate is shown by the bold line.* $\beta = 2 \times 10^4$*,* $b = 50$*,* $\gamma = 0$*, and* $h = 1$*.*

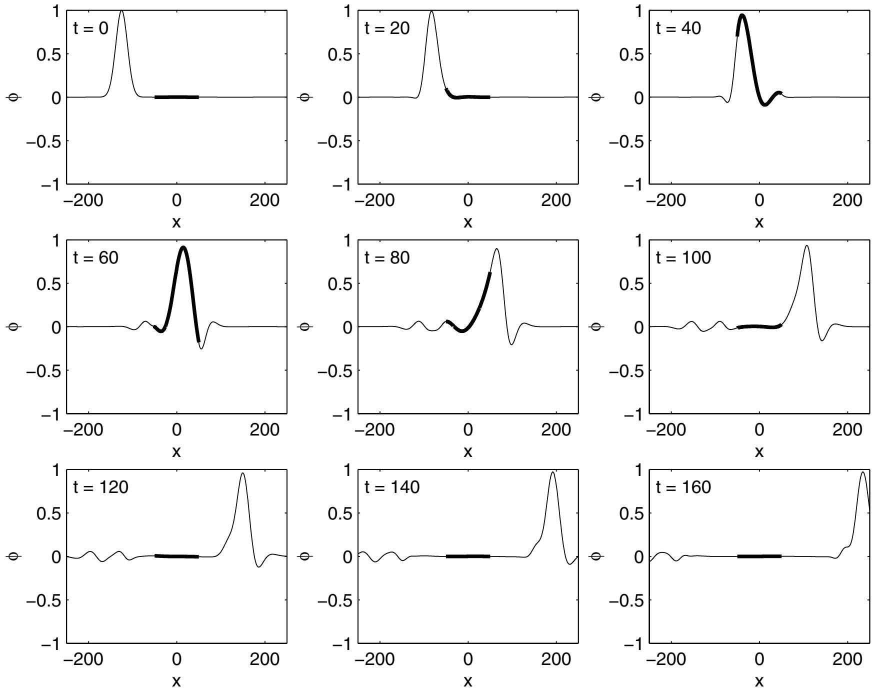

FIG. 2. *As for Figure* 1 *except that* $h = 5$*.*

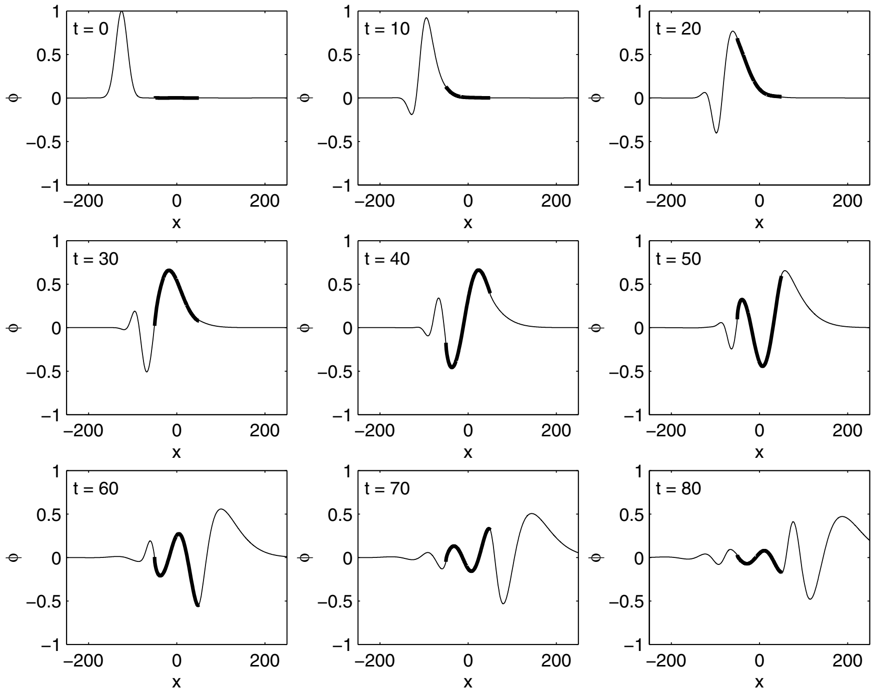

FIG. 3. *As for Figure* 1 *except that* $h = 20$.

we need to work with the variable λ to be able to use the FFT algorithm to calculate the solution in time.

We now consider the evolution of the plate released from an initial displacement. We use the same values as before; plate length is $b = 50$ and stiffness is $\beta = 2 \times 10^4$. The initial plate potential and displacement are given by

$$U_0 = \begin{pmatrix} 0 \\ ie^{-x^2/350} \end{pmatrix} \quad \text{and} \quad U_0 = \begin{pmatrix} 0 \\ ie^{-(x-50)^2/350} \end{pmatrix}$$

in Figures 4 and 5, respectively. The results for $h = 100$ agree closely with results calculated using the method of [19] valid for water of infinite depth.

Finally we investigate the effect of the parameter γ. Figure 6 shows the evolution of the symmetric displacement for $h = 5$ with $\gamma = 0$, 1, and 10. As expected, the effect of γ is small, even for the value $\gamma = 10$, which is highly unphysical.

In these figures we need to use the full expression of (4.5) and (4.11). Owing to the requirement for higher frequencies, we use 1024 values for λ spaced between -2π and 2π, and we again use 4096 points truncated with zeros for the inverse FFT.

6. Summary. We have presented the spectral theory for the two-dimensional linear wave problem of floating elastic plate on water of finite depth. Two theories, based on the first-order and second-order formulations of the problem, have been developed. The first-order theory was valid only when the plate was assumed massless, while the second-order theory allowed for the plate to have arbitrary mass. Both theories depended on different inner products in which the appropriate evolution operators were self-adjoint. The spectral theory solution was found by an expansion

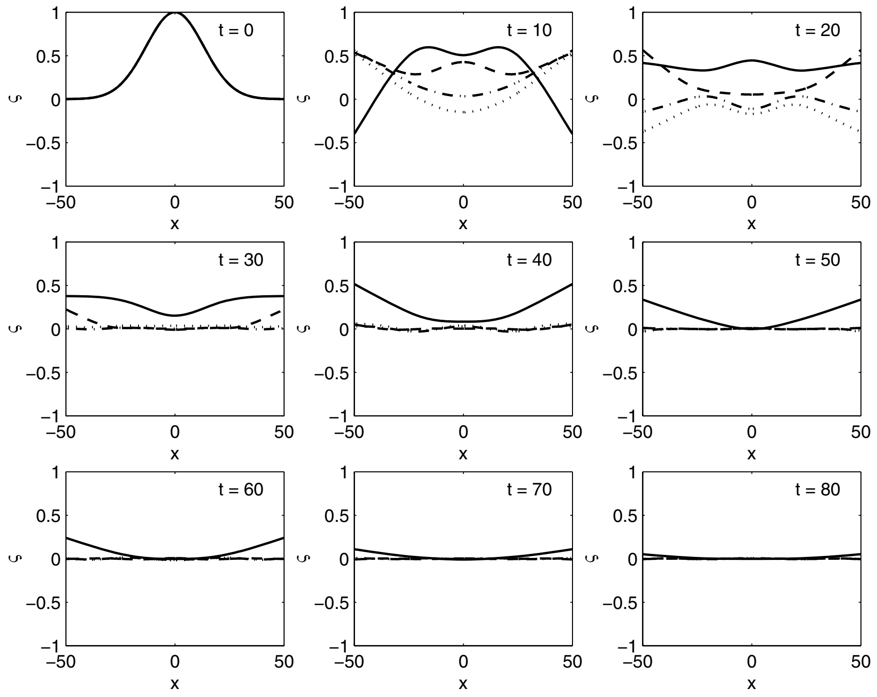

FIG. 4. *The evolution of a symmetric displacement for the times shown. $\beta = 2 \times 10^4$, $b = 50$, and $\gamma = 0$. The solid line is for $h = 1$, the dashed line for $h = 5$, the chained line for $h = 20$, and the dotted line for $h = 100$.*

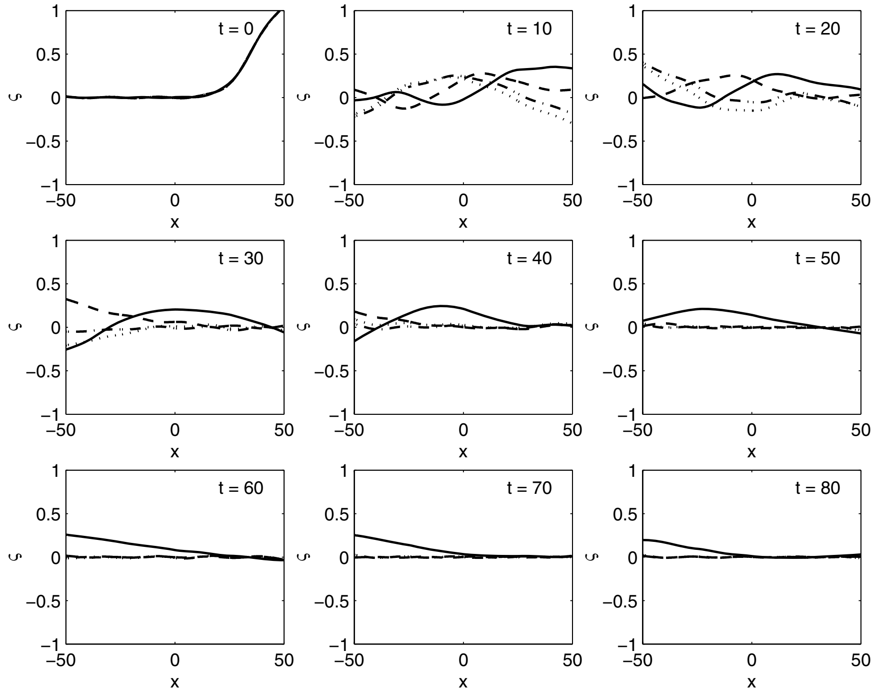

FIG. 5. *As for Figure 4 except the initial displacement is nonsymmetric.*

in the time-harmonic (single frequency solutions). We presented solutions for some simple forcings and showed that the solutions agreed with those found earlier by [12] and showed the effect of increasing the water depth and the mass on the solutions.

Appendix. Solution method to find the eigenfunctions. In this appendix the solution method used to calculate the single frequency solution is described. For the high values of the plate stiffness used here we require very high frequency solutions, and the numerical solution is challenging. We used a mode matching method based on [9] where the solution was found for a semi-infinite plate. However, unlike [9], where the equations were solved by the residue calculus method, our equations are solved by matrix inversion. This method was used recently in [8] to solve for multiple elastic plates. We will show the method only for the case of a wave which is incident from the right. We express the solution as

$$\text{(A.1)}\quad \Phi \text{ or } \Psi = \begin{cases} e^{ikx}\cosh k_0\left(z+h\right) + \displaystyle\sum_{n=0}^{\infty} a_n e^{ik_n x}\cosh k_n\left(z+h\right), & x > b, \\ \displaystyle\sum_{n=-2}^{\infty} b_n e^{i\kappa_n x}\cosh \kappa_n\left(z+h\right) + c_n e^{-i\kappa_n x}\cosh \kappa_n\left(z+h\right), & -b < x < b, \\ \displaystyle\sum_{n=0}^{\infty} d_n e^{-ik_n x}\cosh k_n\left(z+h\right), & x < -b. \end{cases}$$

In (A.1), k_0 is the negative real solution to the dispersion equation

$$k\tanh kh = \nu = \lambda^2 \tag{A.2}$$

(so $k_0 = -k(\nu)$), and k_n for $n > 0$ are the positive imaginary solutions to (A.2) ordered by increasing imaginary part. Under the plate there is a new dispersion equation given by

$$\left(\beta\kappa^5 + (1-\gamma\lambda^2)\right)\tanh \kappa h = \lambda^2. \tag{A.3}$$

We define κ_0 to be the negative real solution to (A.3), κ_n for $n > 0$ are the positive imaginary solutions to (A.3) ordered by increasing imaginary part, and κ_{-2} and κ_{-1} are the complex solutions with positive imaginary parts. This dispersion equation is discussed in detail in [2]. We should note that $a_0 = S_{11}$ and $d_0 = S_{12}$.

We calculate the solution numerically by matching these solutions at $x = \pm b$ and by imposing the edge conditions. First we truncate the sum at N, which gives a system with $4N + 8$ unknowns. We will obtain $4N + 4$ equations by matching the potential at $x = \pm b$ and taking the trivial inner product with respect to the N vertical eigenfunctions outside the plate, matching both the potential and its derivative. The final four equations will come from the free edge conditions.

If we match the potential at $x = b$ and take inner products with respect to the vertical eigenfunctions outside the plate, we obtain

$$d_{00}e^{ikb} + \mathbf{Da} = \mathbf{Mb} + \mathbf{Nc},$$

where $\mathbf{D}$ is the diagonal matrix (diagonal because the vertical eigenfunctions are orthogonal with respect to the trivial inner product) with entries

$$d_{ii} = \int_{-h}^{0} e^{ik_i b}\cosh^2 k_i\,(z+h)\,dz, \quad 0 \le i \le N,$$

and the entries of the matrices $\mathbf{M}$ and $\mathbf{N}$ (which are not square) are given by

$$m_{ij} = \int_{-h}^{0} e^{i\kappa_i b}\cosh\kappa_j\,(z+h)\cosh k_i\,(z+h)\,dz, \quad 0 \le i \le N, \quad -2 \le j \le N,$$

and

$$n_{ij} = \int_{-h}^{0} e^{-i\kappa_i b}\cosh\kappa_j\,(z+h)\cosh k_i\,(z+h)\,dz, \quad 0 \le i \le N, \quad -2 \le j \le N,$$

and $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ are the vectors whose entries are a_n, b_n, and c_n, respectively. We use a nonstandard numbering of the matrix entries which corresponds to the numbering of the roots of the dispersion equation. Obviously the integrals above can be found analytically, but the expressions for these are not included here. There are also ways of improving the stability of the matrix equations by an appropriate normalization, and these issues are discussed in [9]. We then match the derivative of the potential at $x = b$ and again take an inner product with respect to the vertical eigenfunctions outside the plate region, obtaining

$$ik\hat{d}_{00}e^{ikb} + \hat{\mathbf{D}}\mathbf{a} = \hat{\mathbf{M}}\mathbf{b} + \hat{\mathbf{N}}\mathbf{c},$$

where $\hat{\mathbf{D}}$ is the diagonal matrix with entries

$$\hat{d}_{ii} = \int_{-h}^{0} ik_i e^{ik_i b}\cosh^2 k_i\,(z+h)\,dz, \quad 0 \le i \le N,$$

and the entries of the matrices $\hat{\mathbf{M}}$ and $\hat{\mathbf{N}}$ are given by

$$\hat{m}_{ij} = \int_{-h}^{0} i\kappa_i e^{i\kappa_i b} \cosh \kappa_j (z+h) \cosh k_i (z+h) \, dz, \quad 0 \le i \le N, \quad -2 \le j \le N,$$

and

$$\hat{n}_{ij} = \int_{-h}^{0} -i\kappa_i e^{-i\kappa_i b} \cosh \kappa_j (z+h) \cosh k_i (z+h) \, dz, \quad 0 \le i \le N, \quad -2 \le j \le N.$$

A similar set of equations is derived by matching and taking an inner product at $x = -b$. The final four equations are obtained by imposing the free edge conditions, for example the conditions that

$$\lim_{x \uparrow b} \partial_x^2 \zeta = 0$$

implies that

$$\sum_{n=-2}^{N} \kappa_n^3 b_n e^{i\kappa_n b} \sinh \kappa_n h + \kappa_n^3 c_n e^{-i\kappa_n b} \sinh \kappa_n h = 0.$$

Some further simplifications are possible, symmetry arguments can be used to reduce the number of unknowns by a factor of two, and we can also use a wide spacing approximation if the frequency is high enough. These are not described here for the sake of brevity.

HYDRODYNAMIC LIMIT OF A FOKKER–PLANCK EQUATION DESCRIBING FIBER LAY-DOWN PROCESSES[*]

L. L. BONILLA[†], T. GÖTZ[‡], A. KLAR[§], N. MARHEINEKE[‡], AND R. WEGENER[¶]

Abstract. In this paper, a stochastic model for the turbulent fiber lay-down in the industrial production of nonwoven materials is extended by including a moving conveyor belt. In the hydrodynamic limit corresponding to large noise values, the transient and stationary joint probability distributions are determined using the method of multiple scales and the Chapman–Enskog method. Moreover, exponential convergence towards the stationary solution is proven for the reduced problem. For special choices of the industrial parameters, the stochastic limit process is an Ornstein–Uhlenbeck process. It is a good approximation of the fiber motion even for moderate noise values. Moreover, as shown by Monte-Carlo simulations, the limiting process can be used to assess the quality of nonwoven materials in the industrial application by determining distributions of functionals of the process.

Key words. stochastic differential equations, Fokker–Planck equation, asymptotic expansion, Ornstein–Uhlenbeck process

1. Introduction.

Nonwoven materials/fleece are webs of long flexible fibers that are used for composite materials (filters) as well as in the hygiene and textile industries. They are produced in melt-spinning operations: hundreds of individual endless fibers are obtained by the continuous extrusion of a molten polymer through narrow nozzles that are densely and equidistantly placed in a row at a spinning beam. The viscous/viscoelastic fibers are stretched and spun until they solidify due to cooling air streams. Before the elastic fibers lay down on a moving conveyor belt to form a web, they become entangled and form loops due to the highly turbulent air flows. The homogeneity and load capacity of the fiber web are the most important textile properties for quality assessment of industrial nonwoven fabrics. The optimization and control of the fleece quality require modeling and simulation of fiber dynamics and lay-down; in addition, it is necessary to determine the distribution of fiber mass and directional arrangement in the web.

The software FIDYST, developed on the basis of the mathematical model of [9] at the Fraunhofer ITWM, Kaiserslautern, enables numerical simulation of the spinning and deposition regime in the nonwoven production processes; cf. Figure 1. The interaction of the fiber with the turbulent air flows is described by a stochastic force in the momentum equation, which is derived, analyzed, and experimentally validated in [11, 12]. The resulting force model depends on the flow velocity which is split into mean and random parts following Reynolds' idea for the averaged Navier–Stokes

equations. The random force is modeled as white noise with a fluctuation-dependent amplitude that carries information of the kinetic turbulent energy, dissipation rate, and correlation lengths. Due to the huge amount of physical details incorporated in FIDYST, the simulations of the fiber spinning and lay-down usually require an extremely large computational effort and high memory storage. Hence, the optimization and control of the full process, and particularly of fleece quality, are difficult. Thus, a simplified stochastic model for the fiber lay-down process is presented in [5]. Under the assumption of a nonmoving conveyor belt, this model describes the position of the fiber on the transport belt by a stochastic differential system containing parameters that characterize the process. For example, the effect of air turbulence has to be identified from the full model and adapted to be used in the reduced one. Parameter identification can be obtained from a FIDYST-simulation of a single, relatively short fiber whose computation time is short even using the more complex model. Then, the reduced model can be used to calculate fast and efficiently the performance of hundreds of long fibers for fleece production. In [5] the associated Fokker–Planck equation and stationary solution are investigated for the case of a nonmoving conveyor belt. In this case, the model without noise is conservative and its equations, Hamiltonian. For small turbulence noise, stochastic averaging can be used to derive a stochastic equation for the energy and related functionals of the stochastic process. Moreover, their distributions can be analyzed. An analytic investigation of the corresponding Fokker–Planck equation has been performed in [7], ergodicity of the process has been proven, and explicit rates for the convergence to the stationary solution have been obtained.

In this paper, we extend the stochastic model of [5] to a more realistic fiber lay-down model with a moving transport belt; cf. section 2. In this case, the model equations are no longer Hamiltonian for zero noise. For both moving and nonmoving conveyor belts, we consider the case of large turbulence noise, $A \to \infty$, in which the probability density of the fiber becomes rapidly independent of the angle between the fiber and the direction of the conveyor's motion and the angle between the fiber and the position vector of its tip, respectively. In the case of a nonmoving belt, section 3 describes how to use the method of multiple scales in order to determine explicitly a reduced Smoluchowski equation for the fiber probability density, the stationary distribution, and the transient joint probability distributions, all from the associated Fokker–Planck equation. For a moving belt, the same magnitudes are determined using the Chapman–Enskog method [4, 1] in section 4. To leading order, the stationary distributions are of Gaussian type; in particular, for special choices of the process parameters, Ornstein–Uhlenbeck processes turn out to be the limit solutions. In section 5, exponential convergence towards the stationary solution of the reduced Fokker–Planck equation is proved by classical arguments. The numerical results in section 6 show that direct Monte-Carlo simulations of the fiber process agree quite well with the theoretical results even for moderate values of the noise strength A. In addition, certain functionals of the fiber (i.e., mass distributions) are essential for the quality assessment of nonwoven materials. We compare their distributions with the corresponding functionals for the limiting Ornstein–Uhlenbeck process.

2. The model. Consider a slender, elastic, nonextensible, and endless fiber in a lay-down regime. Let the fiber be produced with the spinning speed v_{spin}, excited into motion by a surrounding highly turbulent air flow and laid down on a conveyor belt moving with the velocity v_{belt}. Due to its slenderness, the fiber laid on the two-dimensional transport belt is described as a curve $\eta : \mathbb{R}_0^+ \to \mathbb{R}^2$. Choosing arc-length parameterization, the nonextensibility condition $\|d\eta/dt\| = 1$ holds by setting

$$d\eta = (\cos\alpha, \sin\alpha)\, dt,$$

where α denotes the angle of the fiber relative to the direction of motion e_1 of the transport belt. The reference point of the spinning process determined by the position of the nozzle moves in the coordinate system of the transport belt in the direction $-e_1$. Thus,

$$\xi(t) = \eta(t) - (-\kappa t e_1)$$

describes the deviation of the fiber from the reference point as a function of the arc-length parameter t, where $\kappa = v_{belt}/v_{spin} \in [0, 1]$ is the ratio between the belt and spinning speeds. Generalizing [5], we model (ξ, α) by the following stochastic differential system:

$$d\xi_1 = (\cos\alpha + \kappa)\, dt, \tag{2.1a}$$

$$d\xi_2 = \sin\alpha\, dt, \tag{2.1b}$$

$$d\alpha = c(\xi)\,(\xi_1 \sin\alpha - \xi_2 \cos\alpha)\, dt + A\, dW_t. \tag{2.1c}$$

Here, the change of the angle α is characterized by the deterministic buckling/coiling c of the fiber (which tends to turn it back to its reference point) and by the random fluctuations $A\, dW_t$ due to the interaction of the fiber with the external turbulent air flow; W denotes a one-dimensional Wiener process.

REMARK 2.1. *The general deterministic coiling behavior of flexible fibers has been studied, for example, in* [10, 8]. *The function c in our model prescribes its amplitude that depends on the lay-down process. c is a scalar-valued function for isotropic processes and a matrix-valued one for anisotropic processes* [5]. *For reasons that will become clear later on (cf.* (4.9)*), physically reasonable solutions can be expected only if* $\exp(-B(\xi) - k\xi_1)$ *is integrable for $k \in \mathbb{R}$, where $\partial_{\xi_i} B(\xi) = c(\xi)\xi_i$. A typical example satisfying this condition is $c(\xi) = 1$ since then $B(\xi) = (\xi_1^2 + \xi_2^2)/2$.*

REMARK 2.2. *The isotropic model considered here can be treated as dimensionless with $c(e_1) = 1$, for anisotropic lay-down processes with $1/2\,\mathrm{tr}(c(e_1)) = 1$. This corresponds to a scaled throwing (lay-down) range of order one. Consequently, the noise amplitude A characterizes the relation between stochastic and deterministic rates in the behavior of the system.*

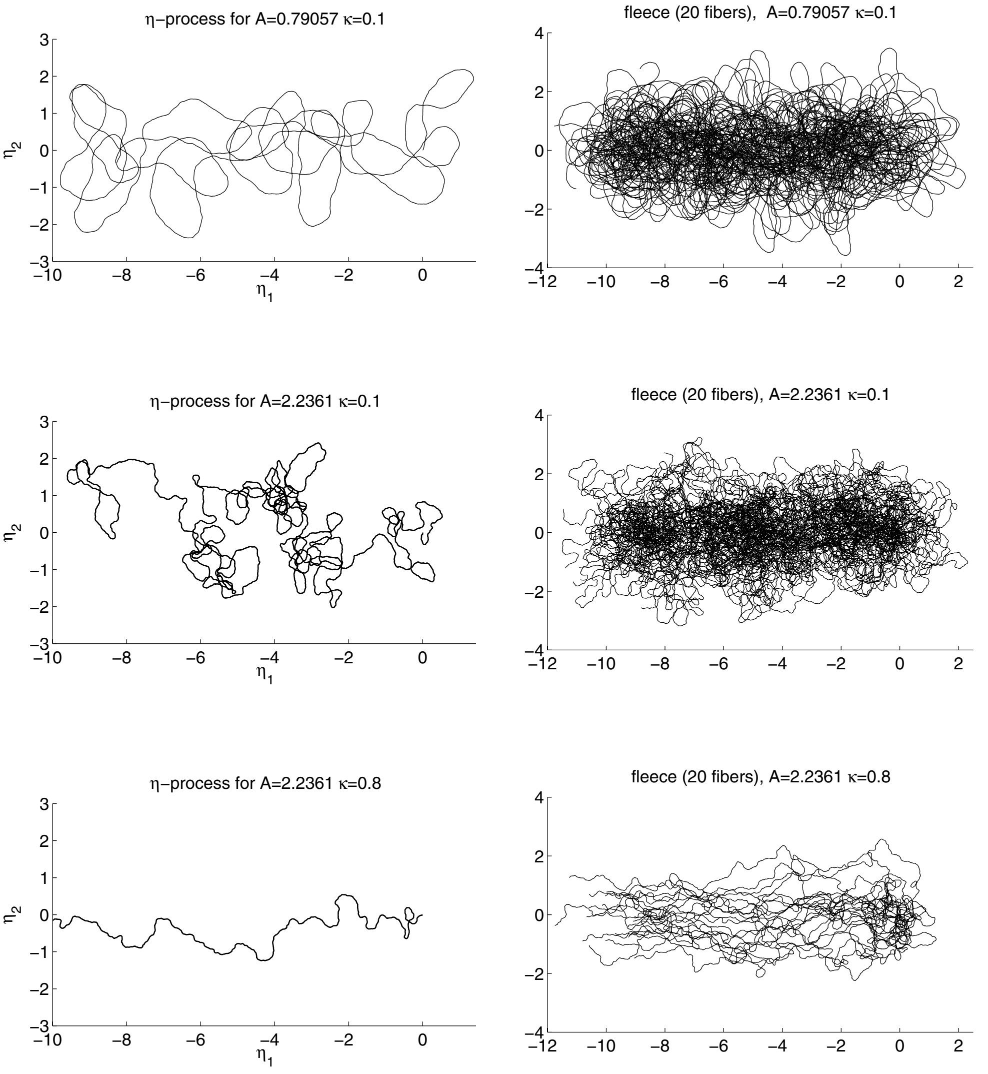

FIG. 2. *Left: η-path. Right: Associated fleece (*20 *fibers). Top to bottom:* $(A, \kappa) = \{(0.79, 0.1), (2.23, 0.1), (2.23, 0.8)\}$.

To illustrate our previous considerations, realizations of the processes η and ξ are exemplified in Figures 2 (left) and 3, respectively, where the parameters (A, κ) are selected in the set $(A, \kappa) = \{(0.79, 0.1), (2.23, 0.1), (2.23, 0.8)\}$, and $c(\xi) = 1$ is fixed. Superposing many fibers, i.e., η-paths, generates a nonwoven material whose properties depend on the industrial control parameters A, κ, and c; see Figure 2 (right) for 20 fibers. In this figure, the distance between two neighboring spinning nozzles is $d_{spin} = 2.5 \cdot 10^{-3}$, fleece length is $L_{fleece} = 10$, and fiber length is $T = L_{fleece}/\kappa$. For $\kappa \to 1$ the belt velocity coincides with the spinning speed such that the fibers lay down almost straight independent of turbulence noise. The smaller κ is, the more fiber material (length) can become entangled and form loops. The size of the

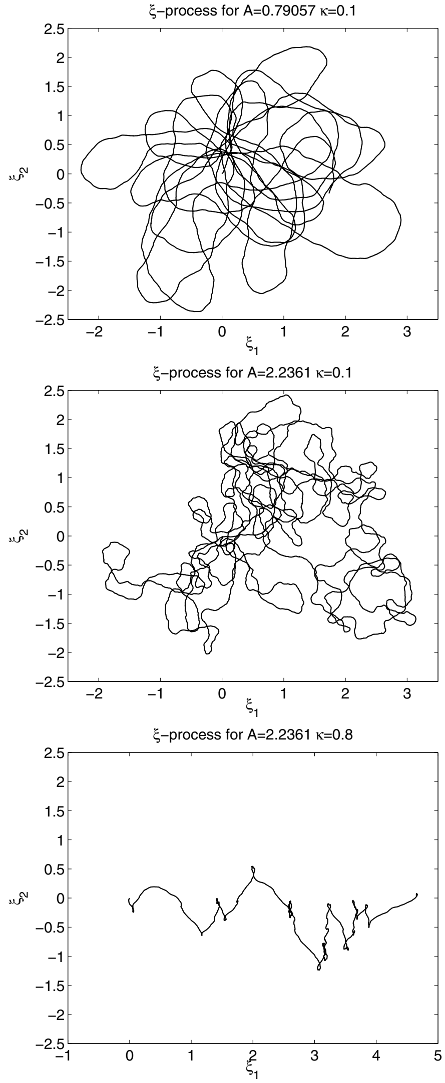

FIG. 3. *ξ-path, corresponding to Figure* 2. *Top to bottom:* $(A, \kappa) = \{(0.79, 0.1), (2.23, 0.1), (2.23, 0.8)\}$.

loops is thereby determined by the amplitude of the turbulence noise A. For small A the deterministic coiling/buckling radius dominates the fiber behavior, whereas a finer entanglement on various scales arises for large A. For the industrial application, nonwoven materials with a homogeneous distribution of mass and fiber orientation are desirable, and they typically have these characteristics for small κ and larger A. To get a deeper insight into the probability density of the underlying ξ-process (2.1), $p = p(\xi_1, \xi_2, \alpha, t)$, we consider its associated Fokker–Planck equation

$$(2.2) \quad \partial_t p + (\cos\alpha + \kappa)\, \partial_{\xi_1} p + \sin\alpha \partial_{\xi_2} p - \partial_\alpha \left[c(\xi)(-\xi_1 \sin\alpha + \xi_2 \cos\alpha) p\right] = \frac{A^2}{2} \partial_\alpha^2 p.$$

REMARK 2.3. *In the case of a nonmoving conveyor belt ($\kappa = 0$), the processes η*

and ξ coincide. Then, it is advantageous to introduce polar coordinates $\xi_1 = r\cos\varphi$, $\xi_2 = r\sin\varphi$, and $\beta = \alpha - \varphi$, and to define $b(r) = \|\xi\|\, c(\|\xi\|)$ as done in [5]. *The resulting system then reduces to two dimensions and the associated Fokker–Planck equation for (r,β) reads*

$$\partial_t p + \cos\beta\partial_r p + \left(b(r) - \frac{1}{r}\right)\partial_\beta\left(p\sin\beta\right) = \frac{A^2}{2}\partial_\beta^2 p. \tag{2.3}$$

In the following we determine the evolution and the stationary solution of the Fokker–Planck equations (2.2), (2.3) in the limit as $A \to \infty$. Note, since we embed our model in the context of dynamical systems and stochastic processes, we refer occasionally to the notation and interpretation of time for the fiber arc-length t.

3. The nonmoving conveyor belt. We start our investigation with the case of a nonmoving belt. This case is quite instructive and allows us to introduce the main ideas to also tackle the case of a moving belt. Let $\varepsilon = 1/A^2 \ll 1$. As already mentioned above, we introduce polar coordinates and obtain the Fokker–Planck equation

$$\partial_t p + \cos\beta\partial_r p + \left(b(r) - \frac{1}{r}\right)\partial_\beta\left(p\sin\beta\right) = \frac{1}{2\varepsilon}\partial_\beta^2 p \tag{3.1a}$$

for the density distribution $p(r,\beta,t)$ subject to the normalization condition

$$\int_{\mathbb{R}_+\times[-\pi,\pi]} p(r,\beta,t)\,dr\,d\beta = 1 \tag{3.1b}$$

and the initial condition

$$p(r,\beta,0) = p_0(r,\beta). \tag{3.1c}$$

Note that the stochastic term appears only in the angular coordinate. Hence, for dominating stochastic forcing, i.e., $\varepsilon \ll 1$, we expect a fast averaging over the β-coordinate. Dominant balance between diffusion and the time derivative of p implies a fast time scale $\tau = t/\varepsilon$. The relaxation to the stationary distribution will take much longer.

To capture the fast averaging over β and the slower convergence to the stationary solution, we use the method of multiple scales. Let us introduce two time scales: the fast scale $\tau = t/\varepsilon$ and a slow scale $T = \varepsilon t$. For the distribution function $p = p(r,\beta,t;\varepsilon)$ (which is 2π-periodic in β), we propose the following ansatz:

$$p = p^{(0)}(r,\beta,\tau,T) + \varepsilon p^{(1)}(r,\beta,\tau,T) + \varepsilon^2 p^{(2)}(r,\beta,\tau,T) + \cdots. \tag{3.2}$$

Inserting (3.2) into (3.1) and equating equal powers of ϵ in the resulting equations, we obtain a hierarchy of problems for the $p^{(m)}$. As we shall see, secular terms appear only in the equation for $p^{(2)}$, and their elimination requires the introduction of the slow scale $T = \epsilon t$. To leading order, we have to solve

$$Lp^{(0)} = 0, \tag{3.3a}$$

$$\int_{\mathbb{R}_+\times[-\pi,\pi]} p^{(0)}\,dr\,d\beta = 1, \tag{3.3b}$$

$$p^{(0)}(r,\beta,0,0) = p_0(r,\beta), \tag{3.3c}$$

where $L = \partial_\tau - \partial_\beta^2/2$ denotes the diffusion operator in the angular direction. Solving the parabolic equation (3.3a) yields

$$p^{(0)}(r,\beta,\tau,T) = \frac{1}{2\pi}\mathcal{P}(r,T) + \sum_{j\in\mathbb{Z}\setminus\{0\}} e^{ij\beta - j^2\tau/2} C_j(r), \tag{3.4a}$$

where

$$C_j(r) = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{-ij\beta} p_0(r,\beta)\, d\beta \tag{3.4b}$$

and

$$\mathcal{P}(r,0) = \frac{1}{2\pi}\int_{-\pi}^{\pi} p_0(r,\beta)\, d\beta \tag{3.4c}$$

are the Fourier coefficients of the initial condition.

In the case of a rotationally symmetric initial distribution $p_0 = p_0(r)$, all the coefficients C_j vanish identically. If the initial distribution is not symmetric, then the angular components $C_j e^{ij\beta - j^2\tau/2}$ are exponentially decaying with τ, i.e., the angular dependence of p is averaged out on the fast time scale τ. The relaxation to the stationary solution is determined by the behavior of $\mathcal{P}(r,T)$ on the long time scale T. Therefore, we will neglect the exponentially small terms $C_j e^{ij\beta - j^2\tau/2}$ in the following.

To determine the stationary solution $\mathcal{P}$, we proceed with the next terms of the expansion (3.2). The $\mathcal{O}(\varepsilon)$-problem reads as

$$\begin{aligned} Lp^{(1)} &= -\frac{\cos\beta}{2\pi}\left[\partial_r\mathcal{P} + \left(b(r) - \frac{1}{r}\right)\mathcal{P}\right], \\ \int_{\mathbb{R}_+\times[-\pi,\pi]} p^{(1)}\, dr\, d\beta &= 0, \\ p^{(1)}(r,\beta,0,0) &= 0. \end{aligned}$$

Again, solving the above parabolic problem yields

$$p^{(1)} = \frac{\mathcal{A}(r,T)}{2\pi} - \frac{\cos\beta}{\pi}\left[\partial_r\mathcal{P}(r,T) + \left(b - \frac{1}{r}\right)\mathcal{P}(r,T)\right],$$

where $\mathcal{A}(r,T)$ is a solution of the homogeneous problem, $L\mathcal{A} = 0$, such that $\int_0^\infty \mathcal{A}(r,T)\, dr = 0$ (normalization condition). At this order, we have two functions, $\mathcal{P}$ and $\mathcal{A}$, not yet determined. Hence, we proceed to the second order

$$\begin{aligned} Lp^{(2)} &= \frac{\cos^2\beta}{\pi}\partial_r\left[\partial_r\mathcal{P} + \left(b - \frac{1}{r}\right)\mathcal{P}\right] \\ &\quad + \left(b - \frac{1}{r}\right)\left[\partial_r\mathcal{P} + \left(b - \frac{1}{r}\right)\mathcal{P}\right]\partial_\beta\frac{\sin\beta\cos\beta}{\pi} - \frac{1}{2\pi}\partial_T\mathcal{P} \\ &\quad - \frac{\cos\beta}{2\pi}\left[\partial_r\mathcal{A} + \left(b(r) - \frac{1}{r}\right)\mathcal{A}\right] \\ &= \frac{1+\cos 2\beta}{2\pi}\partial_r\left[\partial_r\mathcal{P} + \left(b - \frac{1}{r}\right)\mathcal{P}\right] - \frac{1}{2\pi}\partial_T\mathcal{P} \end{aligned}$$

$$+\left(b-\frac{1}{r}\right)\left[\partial_r\mathcal{P}+\left(b-\frac{1}{r}\right)\mathcal{P}\right]\frac{\cos 2\beta}{\pi}$$
$$-\frac{\cos\beta}{2\pi}\left[\partial_r\mathcal{A}+\left(b(r)-\frac{1}{r}\right)\mathcal{A}\right].$$

To ensure the boundedness of $p^{(2)}$, the average of the right-hand side of the preceding equation over β should vanish. Otherwise a secular term proportional to T would be part of the solution $p^{(2)}$. This solvability condition yields

$$\partial_T\mathcal{P}=\partial_r\left[\partial_r\mathcal{P}+\left(b(r)-\frac{1}{r}\right)\mathcal{P}\right], \tag{3.5a}$$

where $\mathcal{P}$ also satisfies the normalization condition

$$\int_{\mathbb{R}_+}\mathcal{P}(r,T)\,dr=1, \tag{3.5b}$$

the initial condition (3.4c), and

$$\mathcal{P}(0,T)=\mathcal{P}(\infty,T)=0. \tag{3.5c}$$

Equation (3.5) is the reduced Fokker–Planck (Smoluchowski) equation, which determines the leading order approximation to the solution of the system (3.1), in the limit as $\varepsilon\to 0$, i.e., for dominating stochastic forcing.

The stationary solution $\mathcal{P}_s(r)$ satisfying (3.5) is given by

$$\mathcal{P}_s(r)=k\,re^{-B(r)}, \tag{3.6}$$

where $B'(r)=b(r)$ and k is the normalization constant. Note that $\mathcal{P}_s(r)$ is independent of the noise strength A, and is also the stationary solution of the full Fokker–Planck equation (3.1). The limiting stochastic differential equation (SDE) associated to (3.5) reads

$$dr=-\left(b(r)-\frac{1}{r}\right)dT+\sqrt{2}\,dW_T.$$

Remark 3.1. *In the generic case $b(r)=r$, we obtain $B(r)=r^2/2$ and the stationary solution*

$$\mathcal{P}_s(r)=re^{-r^2/2},$$

which is a rotational symmetric Gaussian distribution centered at the origin with variance 1. *The solution of its associated SDE*

$$dr=-\left(r-\frac{1}{r}\right)dT+\sqrt{2}\,dW_T$$

is a radially symmetric Ornstein–Uhlenbeck process. This can be concluded from the Fokker–Planck equation of the reduced process (3.5). *Defining the function $\tilde{\mathcal{P}}(\xi)=\mathcal{P}(r)/r$ for $\xi=(\xi_1,\xi_2)$ and $r=\sqrt{\xi_1^2+\xi_2^2}$, we obtain*

$$\partial_T\tilde{\mathcal{P}}=\nabla_\xi\cdot(\nabla_\xi+c(\xi)\xi)\,\tilde{\mathcal{P}} \tag{3.7}$$

with the associated SDE

$$d\xi = -c(\xi)\xi\, dT + \sqrt{2}\, dW_T.$$

For our special case $c(\xi) = 1$, the solution is the Ornstein–Uhlenbeck process. The probability density for this case can be calculated explicitly, as we will do in the next section.

Remark 3.2. *A direct solution of* (3.5) *for $b(r) = r$ can be performed in terms of a series expansion in Laguerre polynomials. For a normalized initial distribution we obtain*

$$\mathcal{P} = re^{-r^2/2} + a_1 e^{-2T} r \left(1 - \frac{r^2}{2}\right) e^{-r^2/2} + \sum_{\nu=2}^{\infty} a_\nu e^{-2\nu T} r e^{-r^2/2} L_\nu \left(\frac{r^2}{2}\right),$$

where the expansion coefficients are determined by the initial distribution

$$a_\nu = \frac{\int_{\mathbb{R}_+ \times [-\pi,\pi]} p_0(r,\beta)\, L_\nu(\frac{r^2}{2})\, dr\, d\beta}{2\pi \int_0^\infty e^{-x} [L_\nu(x)]^2\, dx}.$$

Remark 3.3. *We consider the full Fokker–Planck equation* (3.1)*. Even with a rotationally symmetric initial condition and the rotationally symmetric stationary solution* (3.6)*, terms depending on the angle β appear at intermediate times. This can be seen by computing the next term in the expansion* (3.2)

$$p^{(1)} = p^{(1)}(r, \beta, T) = -\frac{\cos\beta}{\pi} \left[\partial_r \mathcal{P} + \left(b(r) - \frac{1}{r}\right) \mathcal{P}\right],$$

which depends on β even though the initial condition and the stationary solution do not. This could have been already anticipated from the full Fokker–Planck equation, which does not admit time-dependent rotationally symmetric solutions.

4. The case of a moving conveyor belt. In the case of a moving belt, the Fokker–Planck equation (2.2) reads as

$$\partial_t p + ((s + \kappa e_1) \cdot \nabla_\xi)\, p - \partial_\alpha \left[c(\xi)\, (n \cdot \xi)\, p\right] = \frac{1}{2\varepsilon} \partial_\alpha^2 p, \tag{4.1}$$

where $s = (\cos\alpha, \sin\alpha)$ and $n = \partial_\alpha s = (-\sin\alpha, \cos\alpha)$ as well as $\varepsilon = 1/A^2$ are introduced to simplify the notations. The density distribution p satisfies the normalization condition

$$\int_{\mathbb{R}^2 \times [-\pi,\pi]} p(\xi, \alpha, t)\, d\xi\, d\alpha = 1.$$

Additionally we have the initial condition

$$p(\xi, \alpha, 0) = p_0(\xi, \alpha).$$

In the case of strong stochastic influence, i.e., $\varepsilon \ll 1$, we would like to follow the main ideas of the previous case for $\kappa = 0$, i.e., the nonmoving belt. However, the term proportional to κ generates secular terms in the equation for $p^{(1)}$. This indicates that the slow scale needed to get rid of the secular terms should be t. To leading order, the method of multiple scales would then give a hyperbolic reduced equation that does not describe the even slower relaxation towards a stationary solution on the scale $T = \epsilon t$. We need a perturbation method that yields a reduced equation with terms of different order in ϵ: the Chapman–Enskog method. As explained in [4] and [1], the Chapman–Enskog ansatz for the probability density is

$$p(\xi, \alpha, t; \epsilon) = \frac{1}{2\pi}\,\mathcal{P}(\xi, t; \epsilon) + \epsilon\, p^{(1)}(\xi, \alpha; \mathcal{P}) + \epsilon^2 p^{(2)}(\xi, \alpha; \mathcal{P}) + o(\epsilon^2). \tag{4.2}$$

The first term in this equation solves the leading order problem $\partial_\alpha^2 p = 0$. We have anticipated that after a transient in the fast scale $\tau = \epsilon t$, the slowly-varying density $\mathcal{P}$ becomes independent on α, as shown by the method of multiple scales. Of course, this ignores an initial layer that can be inferred from (3.4a): An additional term corresponding to $\sum_{j\in\mathbb{Z}\setminus\{0\}} e^{ij\beta - j^2 t/(2\epsilon)} C_j(r)$ in (3.4a) should be added to (4.2) to account for the effect of initial conditions, so that the probability density becomes

$$\begin{aligned} p(\xi, \alpha, t; \epsilon) = \frac{1}{2\pi}\,\mathcal{P}(\xi, t; \epsilon) + \sum_{j\in\mathbb{Z}\setminus\{0\}} \frac{e^{ij\alpha - j^2 t/(2\epsilon)}}{2\pi} \int_{-\pi}^{\pi} e^{-ija} p_0(\xi, a)\, da \\ + \epsilon\, p^{(1)}(\xi, \alpha; \mathcal{P}) + \epsilon^2 p^{(2)}(\xi, \alpha; \mathcal{P}) + o(\epsilon^2). \end{aligned} \tag{4.3}$$

The higher order terms $p^{(m)}$ depend on time only through their dependence on $\mathcal{P}$. Moreover, up to terms of order ϵ^2, we have

$$\partial_t \mathcal{P} = F^{(0)} + \varepsilon F^{(1)}. \tag{4.4}$$

$F^{(m)}$ are functionals of $\mathcal{P}$ to be determined so that the $p^{(m)}$ are bounded and 2π-periodic in α. Inserting (4.2) and (4.4) into (4.1), we find a hierarchy of problems. To ensure that $\mathcal{P}$ contains all the contributions from the homogeneous equations in the hierarchy, we have to impose the additional constraints

$$\int_{-\pi}^{\pi} p^{(m)}\, d\alpha = 0, \quad m = 1, 2, \ldots. \tag{4.5}$$

The following problem corresponds to the terms of order $\mathcal{O}(\varepsilon)$:

$$-\frac{1}{2}\,\partial_\alpha^2 p^{(1)} = -\,(s\cdot\nabla_\xi)\,\mathcal{P} - \kappa\partial_{\xi_1}\mathcal{P} - \partial_\alpha(c(\xi)\,(s\cdot\xi)\,\mathcal{P}) - F^{(0)},$$

together with (4.5). This problem has a normalized solution which is 2π-periodic in α provided that the average over one period of the right-hand side of the linear equation vanishes. This solvability condition yields $F^{(0)}$:

$$0 = \kappa\partial_{\xi_1}\mathcal{P} + F^{(0)}. \tag{4.6}$$

This condition means that the transport of $\mathcal{P}$ with the belt velocity κ in the ξ_1-direction occurs on the original time scale t. Furthermore, we get

$$p^{(1)} = -2\,[s\cdot(\nabla_\xi + c(\xi)\xi)\,\mathcal{P}],$$

which satisfies (4.5) for $m = 1$. Note that we have not added a term $\mathcal{A}(\xi, t)/(2\pi)$ to the right-hand side of this equation because of the condition (4.5) ensuring that all solutions of the homogeneous equation $\partial_\alpha^2\mathcal{A} = 0$ are included in $\mathcal{P}(\xi, t; \epsilon)$.

To determine the reduced Fokker–Planck equation in analogy to (3.5), we have to consider again the problem provided by terms of order $\mathcal{O}(\varepsilon^2)$

$$-\frac{1}{2}\,\partial_\alpha^2 p^{(2)} = -\left(s\cdot\nabla_\xi\right)p^{(1)} - \kappa\partial_{\xi_1}p^{(1)} - \partial_\alpha\left[c(\xi)\left(n\cdot\xi\right)p^{(1)}\right] - F^{(1)} + 2\left[s\cdot\left(\nabla_\xi + c(\xi)\xi\right)F^{(0)}\right],$$

together with (4.5). The solvability condition that the average of the right-hand side over one period in α should vanish yields $F^{(1)}$:

$$0 = \nabla_\xi\cdot\left(\nabla_\xi + c(\xi)\xi\right)\mathcal{P} - F^{(1)}. \tag{4.7}$$

Inserting the conditions (4.6) and (4.7) into (4.4) yields the reduced equation

$$\partial_t\mathcal{P} = \nabla_\xi\cdot\left(\varepsilon\nabla_\xi + \varepsilon c(\xi)\xi - \kappa e_1\right)\mathcal{P}. \tag{4.8}$$

This is the equation corresponding to (3.7); the difference lies in the transport term $\kappa\partial_{\xi_1}\mathcal{P}$. The stationary solution $\mathcal{P}_s(\xi)$ is characterized by

$$\nabla\cdot\left(\varepsilon\nabla + \varepsilon c(\xi)\xi - \kappa e_1\right)\mathcal{P}_s = 0$$

together with the normalization condition

$$\int_{\mathbb{R}^2}\mathcal{P}_s\,d\xi = 1.$$

The solution of this linear PDE is given by

$$\mathcal{P}_s(\xi) = ke^{-B(\xi)-\kappa\xi_1/\varepsilon}, \tag{4.9}$$

where $\nabla B(\xi) = c(\xi)\xi$ and k is the normalization constant. The associated SDE is

$$d\xi = -\epsilon c(\xi)\xi\,dt + \kappa e_1\,dt + \sqrt{2\epsilon}\,dW_t.$$

Remark 4.1. *In the case of a moving conveyor belt, the stationary distribution (4.9) depends on the noise, as $A = 1/\sqrt{\varepsilon}$. This contrasts with the case of the nonmoving belt, $\kappa = 0$, in which the stationary distribution is the same for deterministic ($A = 0$) or stochastic ($A > 0$) dynamics. Obviously, we obtain a stationary distribution independent of ε in the limit as $\varepsilon \to 0$ only if κ is proportional to $\varepsilon = 1/A^2$. This means we deal with the case of large A and small κ, and the turbulence noise happens to be of order $1/\sqrt{\kappa}$.*

Remark 4.2. *As in the case of the nonmoving belt, we consider the special case $c(\xi) = 1$, i.e., $b(r) = r$. Then, $B(\xi) = \xi_1^2/2 + \xi_2^2/2$ and we obtain the Ornstein–Uhlenbeck type process prescribed by*

$$d\xi = -\epsilon\xi\,dt + \kappa e_1\,dt + \sqrt{2\epsilon}\,dW_t \tag{4.10}$$

or, respectively,

$$\partial_t\mathcal{P} = \nabla\cdot\left(\varepsilon\nabla + \varepsilon\xi - \kappa e_1\right)\mathcal{P}.$$

Its stationary density distribution is Gaussian, centered at $\mu = (\kappa/\varepsilon, 0)$ with variance $\sigma^2 = 1$:

$$\mathcal{P}_s(\xi) = \frac{1}{2\pi}e^{-(\xi_1-\kappa/\varepsilon)^2/2-\xi_2^2/2}. \tag{4.11}$$

To investigate the relaxation to the stationary solution in more detail, we focus on the case $c(\xi) = 1$. To compute the density of the process explicitly, we assume that the initial distribution is a Dirac delta at some point $\mu_0 \in \mathbb{R}^2$. We make the following ansatz for the transient distribution

$$\mathcal{P}(\xi, t) = \frac{f(t)}{2\pi} e^{-(\xi-\mu(t)/\varepsilon)^2/(2\sigma(t))},$$

i.e., a Gaussian with moving center $\mu(t)$, variance $\sigma^2(t)$, and normalization constant $f(t)$. Plugging this ansatz into the reduced Fokker–Planck equation (4.8) and equating for all ξ_1, ξ_2 yields after some calculations

$$\begin{aligned} \frac{d\mu}{dt} &= \varepsilon\left(\kappa e_1 - \mu\right), \\ \frac{d\sigma}{dt} &= 2\varepsilon\left(1-\sigma\right), \\ \frac{df}{dt}\sigma + f\frac{d\sigma}{dt} &= 0. \end{aligned}$$

Together with the initial conditions $\mu(0) = \mu_0$, $\sigma(0) = 0$, and $f(0) = 1$, we obtain $f = 1/\sigma$ and the following motions of the mean and the standard deviation:

$$\begin{aligned} &\mu(t) = \kappa e_1(1 - e^{-\varepsilon t}) + \mu_0 e^{-\varepsilon t}, \\ &\sigma(t) = 1 - e^{-2\varepsilon t}. \end{aligned}$$

Compare this result with the explicit solution formulas for linear stochastic differential equations in [3].

Remark 4.3. *Note that the relaxation to the stationary solution, i.e., $\mu = \kappa e_1$ and $\sigma = 1$, happens on the slow time scale $T = \varepsilon t$. Furthermore, the decay rate for the standard deviation is twice the decay rate of the mean value.*

5. Convergence of the reduced Fokker–Planck equation. In the previous section we have derived the reduced Fokker–Planck equation (4.8)

$$\partial_t \mathcal{P} = \nabla \cdot \left(\varepsilon \nabla \mathcal{P} + \left(\varepsilon c \xi - \kappa e_1\right) \mathcal{P}\right)$$

in the case of dominating stochastic forcing $A^2 = 1/\varepsilon \gg 1$. The "relative velocity" κ of the lay-down process as well as the function $c = c(\xi)$ governing the deterministic fiber bending are still arbitrary. The stationary distribution $\mathcal{P}_s$ of (4.9) is of Gaussian type

$$\mathcal{P}_s(\xi) = k e^{-B(\xi) - \kappa \xi_1/\varepsilon}$$

with $\nabla B(\xi) = c(\xi)\xi$.

The convergence against this stationary solution can be proven by classical arguments; see, e.g., [2] for a recent discussion. Let us introduce the Kullback–Leibler relative entropy

$$S = \int \mathcal{P} \ln \frac{\mathcal{P}}{\mathcal{P}_s}. \tag{5.1}$$

Clearly, $S \geq 0$. The rate of dissipation of the entropy is given by

$$\partial_t S = \int \partial_t \mathcal{P} \ln \frac{\mathcal{P}}{\mathcal{P}_s} = \int \ln \frac{\mathcal{P}}{\mathcal{P}_s}\, \nabla \cdot \left[\varepsilon \nabla \mathcal{P} + (\varepsilon c \xi - \kappa e_1)\mathcal{P}\right]$$

and after integration by parts

$$\partial_t S = -\int \left[\nabla \ln \frac{\mathcal{P}}{\mathcal{P}_s}\right] \cdot \left[\varepsilon \nabla \mathcal{P} + (\varepsilon c \xi - \kappa e_1)\mathcal{P}\right].$$

Using the fact that $\varepsilon \nabla \mathcal{P}_s = -(\varepsilon c\xi - \kappa e_1)\mathcal{P}_s$, we get

$$\partial_t S = -\varepsilon \int \mathcal{P} \left(\nabla \ln \frac{\mathcal{P}}{\mathcal{P}_s}\right)^2 \leq 0.$$

Hence, the entropy is monotonically decaying in time and $S = 0$ if and only if $\mathcal{P} = \mathcal{P}_s$.

Applying the logarithmic Sobolev inequality [6], we obtain

$$\partial_t S \geq -2\varepsilon S \tag{5.2}$$

and hence a decay rate of $e^{-2\varepsilon t}$ for the entropy S. Using the Csiszar–Kullback inequality yields a decay rate of $e^{-\varepsilon t}$ for the $\mathcal{L}_1$-distance of $\mathcal{P}$ and $\mathcal{P}_s$.

6. Approximation quality of the Ornstein–Uhlenbeck process. In this section we investigate the process (2.1) with $c(\xi) = 1$ numerically and compare it with the limiting process for $A \to \infty$, i.e., (4.10):

$$d\xi = -\epsilon \xi \, dt + \kappa e_1 \, dt + \sqrt{2\epsilon}\, dW_t.$$

Its stationary probability density,

$$\mathcal{P}_s(\xi) = \frac{1}{2\pi} e^{-(\xi_1 - \kappa/\varepsilon)^2/2 - \xi_2^2/2},$$

is independent of ε for $\kappa A^2 = k$, $k \in \mathbb{R}$. To test how well $\mathcal{P}_s$ approximates the numerically obtained stationary probability distribution of the process (2.1), we compare both distributions for different values of A. Figure 4 shows the stationary marginal probability distributions for the components ξ_1 and ξ_2 when $k = 0.5$. The distributions are computed from 15000 Monte-Carlo simulations of the ξ-process (2.1); whereas the distribution functions for $A < 1$ are quite different from the marginals of $\mathcal{P}_s$ as they are qualitatively similar for $A = 1$ and show good agreement for $A > 2$. The $\mathcal{L}^\infty$- and $\mathcal{L}^2$-errors are less than 2% for $A > 2$ as illustrated in Figure 5. For $A > 2$ and $N = 15000$ Monte-Carlo simulations, the deviations of the stationary marginal probability distributions from the limiting marginals are within the range of the approximation error, i.e., of order $1/\sqrt{N} \sim 10^{-2}$. Consequently, the limit distribution is a good approximation of the true distributions—already for moderate values of A. However, we should note that the resulting "limit process" of our fiber model for $A \to \infty$, the Ornstein–Uhlenbeck process, is only continuous, not differentiable. Hence, its associated η-process $\eta(t) = \xi(t) - \kappa t e_1$, is not parameterized by arc-length and the lack of differentiability obviously affects the nonextensibility condition. In Figure 6 realizations of the Ornstein–Uhlenbeck (ξ-process of (4.10)) and its associated η-process are depicted and compared to our differentiable fiber process of section 2, assuming an initial value $\xi(0) = (0, 0)$, final time $T = 100$, and parameter values $\kappa = 0.1$, $A = 2.23$. Note that the same amount of fiber mass is laid down.

For the industrial application, it is important to know and control the mass distribution or other distributions of functionals of ξ. These distributions shed light into the structure of the fleece material and therefore may serve to assess its quality.

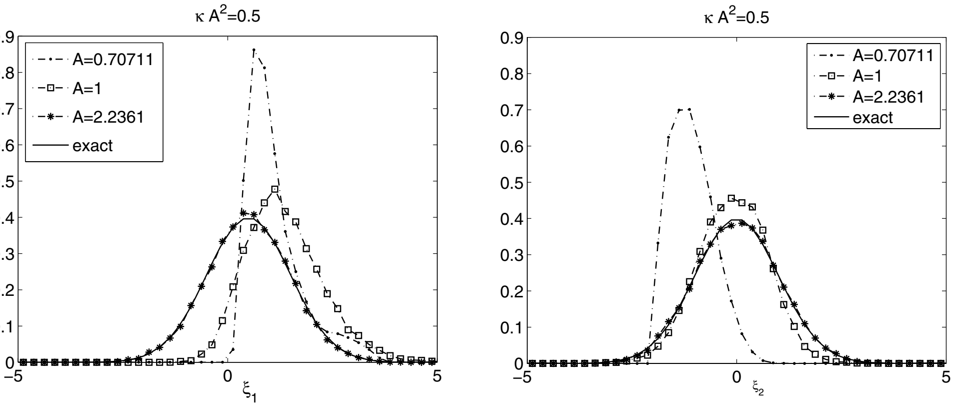

FIG. 4. *Stationary marginal distributions of ξ-components for $c = 1$, $\kappa A^2 = 0.5$, and several values of A.*

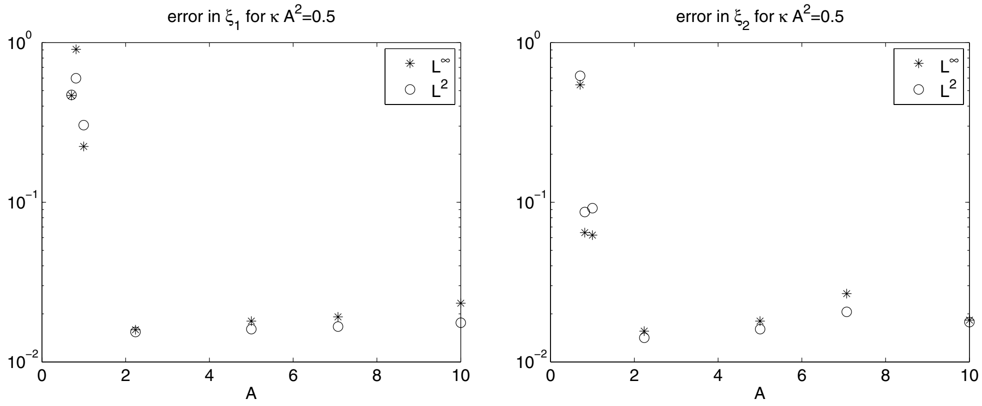

FIG. 5. *$\mathcal{L}^\infty$-error and $\mathcal{L}^2$-error between the stationary marginal distributions and the limiting ($A \to \infty$) stationary marginal distribution for different A.*

The fiber mass that lies in a prescribed spatial domain D can also be interpreted as the time the process stays in that domain. It is described by the distribution of the random variable

$$M = \int_{t_0}^{T} \chi_D(\eta(t))\, dt \tag{6.1}$$

for fixed T, $T > t_0$, with χ_D denoting the characteristic function of D. In the following we compare the distribution of (6.1) for the original fiber process given by (2.1) and the limit process (4.10). We evaluate the distribution of M numerically for the two processes and compare them using Monte-Carlo simulations for fixed $\kappa = 0.1$, $A = 2.23$. Figure 7 shows the probability distribution function (pdf) for the relative time that the respective ξ-processes, (2.1) and (4.10), spend in a square domain D. The square is centered at a point in the set $K = \{(0,0),(0,1),(1,0)\}$, its length may vary in the set $L = \{1, 0.5, 0.25\}$, initially at time $t_0 = 0$, $\xi(0) = (0,0)$, and the final time is $T = 100$. The respective means differ only by 1% which is within the order of the approximation error of the Monte-Carlo simulations. In contrast to this,

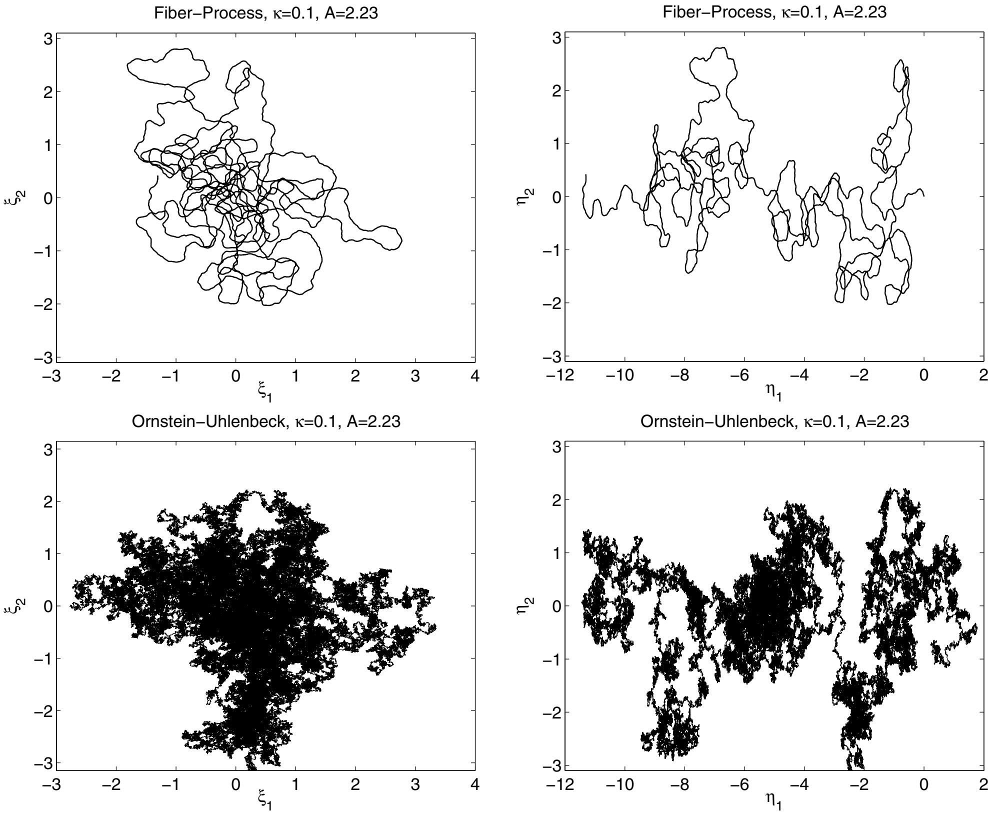

FIG. 6. *Differentiable fiber process (top) versus continuous Ornstein–Uhlenbeck limit process (bottom).*

the relative error of the standard deviations depends on the chosen size of the test domain: the smaller the domain, the higher the error—up to 14% for $L = 0.25$, but only 2% for $L = 1$.

Figure 8 compares the distributions of the mass of a single fiber laid down in a nonwoven web. This means we consider the distribution of (6.1) for the η-processes. We observe the same trend as for the ξ-processes for the relative time spent in a square D: a very good agreement for larger test domains and poor agreement for smaller domains. The symmetry axis for the η-processes is $\eta_2 = 0$. Hence, we consider domains with a certain distance d_{sym} from the center point to the symmetry axis: the larger d_{sym}, the lower the probability that mass lies in D. This tendency is amplified by the size of D: the smaller the test domain, the lower the probability. In contrast to this trend, the probability that mass is accumulated in small domains D is much higher for the Ornstein–Uhlenbeck process than for our fiber process. The reason is that a realization of the continuous Ornstein–Uhlenbeck can move more easily, whereas the differentiable fiber process stays longer in certain regions and therefore other regions are not covered.

Summarizing, the Ornstein–Uhlenbeck limit process approximates our fiber process well—not only as regards the joint probability distribution but also the mass distributions for test domains of size 1 which corresponds to the size of the throwing (lay-down) range of the fiber, but not for smaller domains.

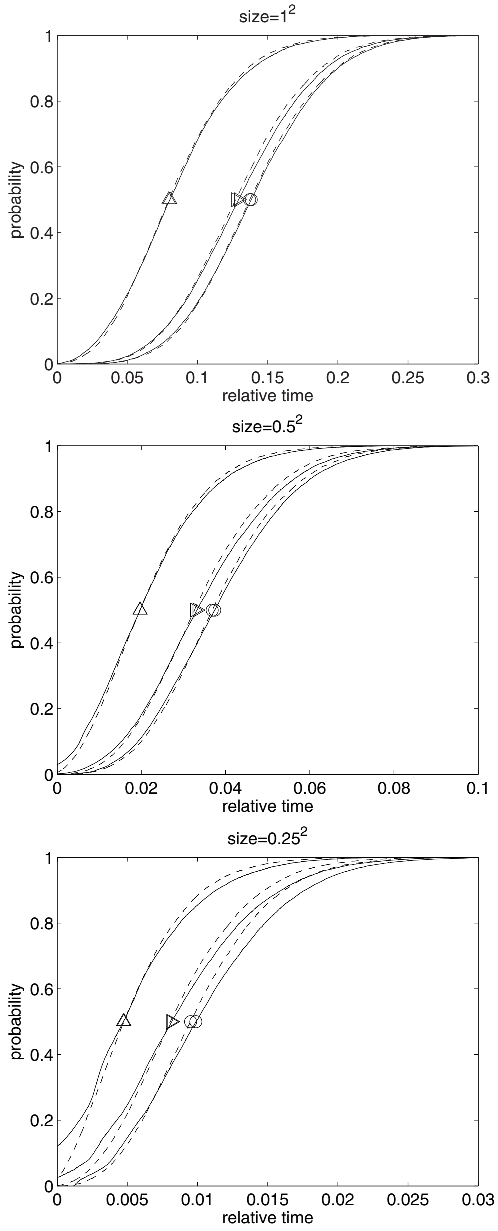

FIG. 7. *Pdf for the relative time that the fiber ξ-process (–) and the Ornstein–Uhlenbeck process (- -) spend in a square of size* $L^2 = \{1^2, 0.5^2, 0.25^2\}$ *(top to bottom), centered at* $K = \{(0,0),(0,1),(1,0)\}$ *(marked by* $\circ$, $\triangleright$, $\triangle$*).*

7. Conclusion. In this work we have presented an extended stochastic model for the fiber lay-down regime in a nonwoven production process that contains a moving conveyor belt. From the associated Fokker–Planck equation and using the method of multiple scales or the Chapman–Enskog technique, we have explicitly determined the limit processes and the stationary and transient joint probability distributions in the hydrodynamic limit, as $A \to \infty$. Quite generally and to leading order of these

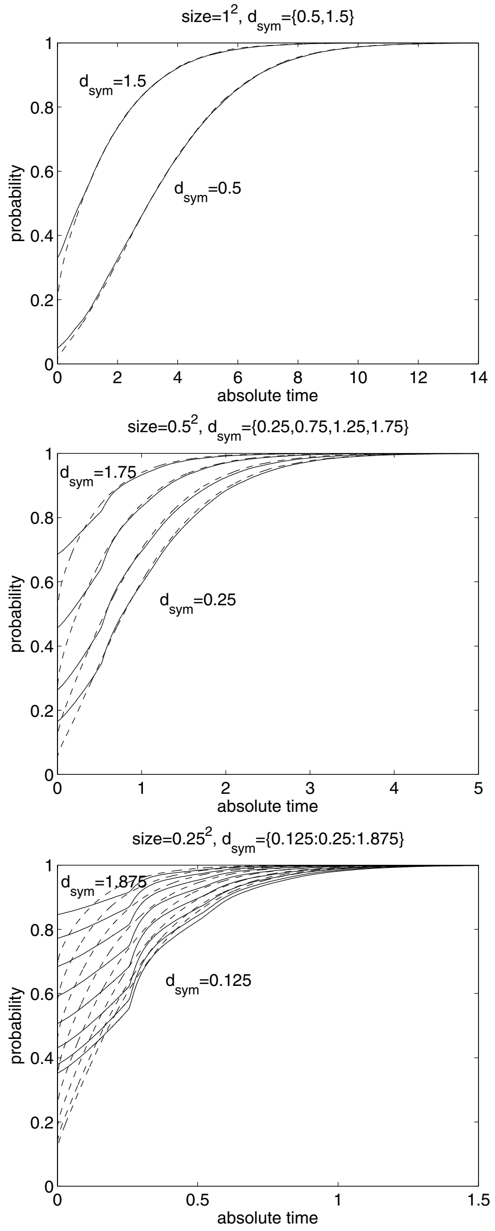

FIG. 8. *Pdf for the mass M of the fiber η-process (–) and the associated Ornstein–Uhlenbeck η-process (- -) laid in a square D, $|D| = L^2 = \{1^2, 0.5^2, 0.25^2\}$ (top to bottom), with different distances d_{sym} to the symmetry axis.*

perturbation methods, we have found that the limiting stationary distribution (as $A \to \infty$) approaches a Gaussian-type function. For the special choice $c = 1$ of the fiber coiling function, the limiting process is an Ornstein–Uhlenbeck process, and the mean of its stationary Gaussian distribution depends on the relation of "relative process velocity" and turbulence noise, κA^2. Already for moderate values of A, i.e., $A > 2$, this limiting distribution turns out to be a very good approximation according to our numerical simulations. Moreover, important distributions of functionals of the process, such as the mass distribution, are well approximated by the Ornstein–Uhlenbeck process for test squares D of the size of the typical throwing (lay-down) range of the fibers.

For the control and optimization of the production and quality of nonwoven materials, the parameters characterizing our model, c, A, κ, and samples sizes D, should be identified from FIDYST-simulations of the complete physical production process as well as from experimental data. If the ranges of these parameters are such that the limiting process studied in this work describes well the physical production, the fiber mass distribution in a fleece material could be determined from the superposition of many Ornstein–Uhlenbeck η-processes.

Acknowledgment. We thank Vincenzo Capasso for having brought us together to collaborate on this topic.

INVERSE BOUNDS OF TWO-COMPONENT COMPOSITES*

CHRISTIAN ENGSTRÖM†

Abstract. A method is presented for estimating microstructural parameters from permittivity measurements of two-component composites. This structural information is described by a particular positive measure in the Stieltjes integral representation of the effective permittivity. The dependence on the geometrical structure can be reduced to the problem of calculating the moments of the measure. We present a method that uses measurement data at a set of distinct frequencies or temperatures to calculate bounds on several moments. These inverse bounds are improved when the volume fraction is known or the material is isotropic. Composites with known geometrical structure illustrate the method.

Key words. effective permittivity, inverse bounds, Stieltjes series, Padé approximants

DOI. 10.1137/070683039

1. Introduction.

The bulk permittivity of composites is determined by the bulk properties of the components and the geometrical structure of the composite. In Bergman's representation of the effective permittivity the dependence on the geometry in a two-component composite is described by a particular positive measure [2, 15]. Various inverse algorithms for recovering this measure from experimental data have been developed [8, 9, 6, 25]. When the measure is recovered the volume fraction and the anisotropy of the material are given by the first two moments of the measure.

Based on Bergman's [2] representation, Milton [21] developed a general method for obtaining a hierarchy of bounds on the effective permittivity, given the first n moments. One disadvantage of the inverse algorithms above is that we lose the concept of bounds. The numerical methods cannot recover the measure when we have few or inaccurate measurements. Using the numerical approximations of the measure can then result in inaccurate values on the moments and, as a consequence, invalid bounds on effective properties.

Instead of seeking the measure, the measured bulk properties can be used directly to estimate the structural parameters. In other words, limits on the moments of the measure are derived directly. McPhedran, McKenzie, and Milton [18] and McPhedran and Milton [19] developed methods to estimate the volume fraction (the lowest-order moment) from measurement data. Cherkaeva and Golden [7] derived, in the case of measurements of lossy materials, explicit formulas for bounds on the volume fraction.

In two previous papers we proposed general methods for bounding the moments of the measure from measurements of real-valued [10] and complex-valued [11] bulk properties. Based on these inverse bounds, we develop a new algorithm that gives significantly tighter bounds on the lowest n moments.

Cross-property bounds incorporate information from measurements of one parameter to bound a related parameter. A general method for deriving these bounds is to apply Prager's method [23] on Bergman's and Milton's bounds [22]. Cross-property

bounds can also be expressed in terms of bounds on the moments [10]. Thus, the inverse algorithm in this paper can be used to bound several other physical phenomena, such as electrical and thermal conductivity, magnetism, diffusion, and flow in porous media.

Before proceeding to this problem, we give a description of the Bergman–Milton theory [2, 4, 5, 20, 21, 22] and how the hierarchy of bounds can be used to derive a hierarchy of inverse bounds on the moments. The presented algorithm is illustrated by composites with known structure.

2. Representation of the effective permittivity. Consider a two-component material modeled by the permittivity $\boldsymbol{\epsilon}$, where the components are homogeneous and isotropic with permittivity ϵ_1 and ϵ_2. Assume that the electric field $\boldsymbol{E}$ and the electric flux density $\boldsymbol{D}$ satisfy the linear constitutive relation $\boldsymbol{D}(\boldsymbol{x}) = \boldsymbol{\epsilon}(\boldsymbol{x})\boldsymbol{E}(\boldsymbol{x})$. In many instances, the characteristic length of inhomogeneities in the d-dimensional composite material is small compared with the wavelength but much larger than the atomic scale. In this case an effective (bulk) permittivity $\boldsymbol{\epsilon}_{\mathrm{e}}$ is defined via

$$\langle \boldsymbol{D} \rangle = \langle \boldsymbol{\epsilon} \boldsymbol{E} \rangle = \boldsymbol{\epsilon}_{\mathrm{e}} \langle \boldsymbol{E} \rangle, \tag{2.1}$$

which relates the average, $\langle \cdot \rangle$, of the electric flux density $\langle \boldsymbol{D} \rangle$ to the average of the electric field $\langle \boldsymbol{E} \rangle$. The notation $\langle \cdot \rangle$ means spatial average over all of $\mathbb{R}^d$ or ensemble average. The averaged fields have no oscillations on the length scale of the microstructure, since they are smoothed out, but they retain slow macroscopic variations. A mathematical justification of the homogenization rule (2.1) can, for example, be found in [16, p. 15]. Let ϵ_{e} be one of the eigenvalues in the matrix $\boldsymbol{\epsilon}_{\mathrm{e}}$. In a two-component mixture the effective permittivity ϵ_{e} has the Stieltjes integral representation [2, 15]

$$\epsilon_{\mathrm{e}}(\epsilon_1, \epsilon_2) = \epsilon_2 - \epsilon_2 G(s), \tag{2.2}$$

where

$$G(s) = \int_0^1 \frac{\mathrm{d}m(y)}{s - y}, \qquad s = \frac{\epsilon_2}{\epsilon_2 - \epsilon_1} \notin [0, 1]. \tag{2.3}$$

The positive (Borel) measure m is a purely geometric quantity, which depends on the structure but not on the values of the components. If the geometrical structure is identical, the single integral (2.3) gives the effective permittivity, independent of the values of the components.

Let $s = -1/z$ in the representation (2.3). The integral representation of G is then transformed to

$$\hat{G}(z) = -\frac{1}{z} G\left(-\frac{1}{z}\right) = \int_0^1 \frac{\mathrm{d}m(y)}{1 + zy}, \tag{2.4}$$

which is the standard form of a Stieltjes integral representation [1, p. 229].

3. Real-valued bounds on the permittivity. Partial information concerning the microstructure, such as the volume fraction, can be used to derive exact bounds on the effective permittivity [2, 22]. We use the Stieltjes series expansion

$$\epsilon_{\mathrm{e}} = \epsilon_2 + \epsilon_2 z \hat{G}(z) = \epsilon_2 F(z), \qquad F(z) = \sum_{n=0}^{\infty} c_n z^n, \tag{3.1}$$

where $z = -1/s = (\epsilon_1 - \epsilon_2)/\epsilon_2$ is the contrast and the coefficients c_n are given by the moments of the measure

$$c_{n+1} = (-1)^n \int_0^1 y^n \, \mathrm{d}m(y). \tag{3.2}$$

The constants c_n depend on the microstructure but not on the values of the two components. If the structure is the same, the single series (3.1) gives the effective permittivity, independent of the value of the components. The zero-order moment c_1 is the volume fraction of the component ϵ_1, and c_2 depends on the anisotropy in the material. In the case of a d-dimensional statistically isotropic composite, the second moment is $-c_1(1-c_1)/d$ (see [2]).

Assume real-valued materials with $\epsilon_2 > \epsilon_1$. When $-1 < z < 0$, the denominator $1 + zy$ is bounded between zero and one. We find that the integral (2.4) can be estimated by

$$\int_0^1 \frac{\mathrm{d}m(y)}{1+zy} \geq \int_0^1 \mathrm{d}m(y) = c_1. \tag{3.3}$$

This implies that the following inequality is satisfied:

$$\frac{\epsilon_\mathrm{e}}{\epsilon_2} = 1 + z\tilde{G}(z) \leq 1 + c_1 z. \tag{3.4}$$

That is, the effective permittivity is bounded from above by the arithmetic mean $c_1\epsilon_1 + (1-c_1)\epsilon_2$. This estimate is satisfied as an equality if the measure m is a point mass concentrated at $y = 0$.

To derive lower bounds on the effective permittivity we use a representation of the inverse of the effective permittivity. Define the auxiliary function $z\tilde{H}(z)$ by

$$(1 + z\tilde{H}(z))(1 + z\hat{G}(z)) = 1 + z, \tag{3.5}$$

which is equivalent to

$$1 + z\tilde{H}(z) = \frac{\epsilon_1}{\epsilon_\mathrm{e}}. \tag{3.6}$$

The new function $z\tilde{H}(z)$ has the same analytic properties as the original function $z\hat{G}(z)$ [1, 5]. That is, the scaled inverse permittivity has the representation

$$\left(\frac{\epsilon_\mathrm{e}}{\epsilon_1}\right)^{-1} = 1 + z\tilde{H}(z) = \tilde{F}(z), \quad \tilde{F}(z) = \sum_{n=0}^{\infty} \tilde{c}_n z^n, \tag{3.7}$$

where $\tilde{H}$ is the Stieltjes integral

$$\tilde{H}(z) = \int_0^1 \frac{\mathrm{d}\tilde{m}(y)}{1+zy} \tag{3.8}$$

and the coefficients $\tilde{c}_n$ are given by the moments of the measure

$$\tilde{c}_{n+1} = (-1)^n \int_0^1 y^n \, \mathrm{d}\tilde{m}(y). \tag{3.9}$$

Expanding the product of the series for $1 + z\hat{G}(z)$ and for $1 + z\tilde{H}(z)$ in (3.5) and collecting terms with the same powers of z shows that the coefficients c_n and $\tilde{c}_n$ in the two series are related according to

$$\tilde{c}_0 = 1, \quad \tilde{c}_1 = 1 - c_1, \quad \tilde{c}_n = -\sum_{k=0}^{n-1} \tilde{c}_k c_{n-k}. \tag{3.10}$$

The coefficient c_1 is the volume fraction of component one and $\tilde{c}_1$ is the volume fraction of component two. For all $\epsilon_2 > \epsilon_1$, the integral (3.8) can be estimated by

$$\int_0^1 \frac{\mathrm{d}\tilde{m}(y)}{1 + zy} \geq \int_0^1 \mathrm{d}\tilde{m}(y) = \tilde{c}_1. \tag{3.11}$$

This implies that the effective permittivity is bounded from below by the harmonic mean,

$$\epsilon_\mathrm{e} \geq \frac{\epsilon}{1 + \tilde{c}_1 z} = \frac{\epsilon_1}{1 + \tilde{c}_1 z} = \left(\frac{c_1}{\epsilon_1} + \frac{\tilde{c}_1}{\epsilon_2} \right)^{-1}. \tag{3.12}$$

The estimate is satisfied as an equality if the measure $\tilde{m}$ is a point mass concentrated at $y = 0$.

The convexity of the function $(1 + zy)^{-1}$ can be used to derive the Hashin–Shtrikman bounds, which are finer estimations of the integrals [16, p. 219]. Finer estimations become more and more tricky, and a systematic method for obtaining bounds is preferable.

A general method for obtaining a hierarchy of bounds using the analytic properties of the effective permittivity was developed by Bergman [3, 4] and Milton [20, 21]. Alternatively, known lower and upper bounds of the Stieltjes functions in the form of continued fractions or Padé approximants can be used. These approximation methods lead to identical bounds [13, 1].

The $\epsilon_{p,q}$ Padé approximant to ϵ_e is defined by the equation

$$\epsilon^{\mathrm{eff}}(z)Q(z) - P(z) = \mathcal{O}(z^{p+q+1}), \tag{3.13}$$

where P and Q are polynomials of degree at most p and q, respectively [1]. This equation gives us an approximation of the effective permittivity by the rational function

$$\epsilon_{p,q} = \frac{P(z)}{Q(z)} = \frac{a_0 + \cdots + a_p z^p}{1 + b_1 z + \cdots + b_q z^q}. \tag{3.14}$$

When $\epsilon_2 > \epsilon_1$ and $N \geq 1$, the N-point upper bounds ϵ_N^U are obtained by forming the approximations

$$\epsilon_{2M+1}^\mathrm{U} = \epsilon_2 \epsilon_{M+1,M}(F), \quad \epsilon_{2M}^\mathrm{U} = \epsilon_2 \epsilon_{M,M}(F), \tag{3.15}$$

of the Stieltjes series (3.1). For example, the arithmetic mean (3.4) is obtained from the $\epsilon_{1,0}$ Padé approximant of (3.1),

$$\epsilon_1^\mathrm{U} = (\epsilon_2 + c_1 \epsilon_2 z) = (c_1 \epsilon_1 + \tilde{c}_2 \epsilon_2). \tag{3.16}$$

Lower bounds on ϵ_e are given from Padé approximations of the series (3.7). The N-point lower bounds ϵ_N^L, when $\epsilon_2 > \epsilon_1$ and $N \geq 1$, are obtained from

$$\epsilon_{2M+1}^\mathrm{L} = \epsilon_1 [\epsilon_{M+1,M}(\tilde{F})]^{-1}, \qquad \epsilon_{2M}^\mathrm{L} = \epsilon_1 [\epsilon_{M,M}(\tilde{F})]^{-1}. \tag{3.17}$$

For example, the harmonic mean (3.12) corresponds to the $\epsilon_{1,0}$ Padé approximant of the expansion (3.7)

$$\epsilon_1^{\mathrm{L}} = \frac{\epsilon_1}{1+\tilde{c}_1 z} = \left(\frac{c_1}{\epsilon_1} + \frac{\tilde{c}_1}{\epsilon_2}\right)^{-1}. \tag{3.18}$$

The $\epsilon_{1,1}$ Padé approximant of the expansion (3.7) gives the lower bound

$$\epsilon_2^{\mathrm{L}} = \epsilon_1[\tilde{c}_1 - \tilde{c}_2 z][\tilde{c}_1 - \tilde{c}_2 z + \tilde{c}_1^2 z]^{-1}, \tag{3.19}$$

where $\tilde{c}_2 = -c_2 - c_1\tilde{c}_1$. In the isotropic case $c_2 = -c_1\tilde{c}_1/d$, the bound (3.19) is equivalent to the lower Hashin–Shtrikman bound. For this reason, we call c_2 the anisotropy parameter.

3.1. Complex-valued bounds on the permittivity. Bergman [3, 4] and Milton [20, 21] extended the real-valued bounds above to the complex case. We write these bounds in terms of bounds on the moments c_n. The minimum $c_n^{\min}$ and the maximum $c_n^{\max}$ of c_n are functions of the lower-order parameters $c_1, c_2, \ldots, c_{n-1}$. The extreme values can be determined by varying the c_n parameter in the n-point bounds and using that the n-point bounds are forbidden to violate the $(n-1)$-point bounds [10]. The volume fraction is of course bounded between zero and one. The bounds ϵ_2^{L} and ϵ_1^{U} are equal when $c_2 = 0$, and ϵ_2^{L} and ϵ_1^{L} are equal when $c_2 = -c_1\tilde{c}_1$. This implies the inequality

$$-c_1\tilde{c}_1 \le c_2 \le 0. \tag{3.20}$$

In the same way, we get the inequality

$$\frac{c_2^2}{c_1} \le c_3 \le -c_2\left(1 + \frac{c_2}{\tilde{c}_1}\right). \tag{3.21}$$

In the general case, when the values of the components are complex, the real segment $l = \{c_n;\, c_n^{\min} \le c_n \le c_n^{\max}\}$ is for fixed values on $c_1, c_2, \ldots, c_{n-1}$ mapped by $\epsilon_n^{\mathrm{L}}(c_n)$ and $\epsilon_n^{\mathrm{U}}(c_n)$ on a circle or a line segment. The bounds on the moments c_n give a parameterization of the lens-shaped boundary. For example, we get complex-valued bounds from the lens-shaped region bounded by

$$\epsilon_2^{\mathrm{L}}(\tilde{c}_2; \epsilon_1, \epsilon_2, \tilde{c}_1), \quad \epsilon_2^{\mathrm{U}}(c_2; \epsilon_1, \epsilon_2, c_1) \tag{3.22}$$

with the structural parameter c_2 varying between the endpoints in (3.20), and $\tilde{c}_2$ according to (3.10) related to c_2 by $\tilde{c}_2 = -c_2 - c_1\tilde{c}_1$.

Alternatively, we can describe the bounds $\epsilon_n^{\mathrm{L}}(c_n)$ and $\epsilon_n^{\mathrm{U}}(c_n)$ in terms of the points through which the circles pass [3, 20, 21].

4. Inverse bounds from permittivity measurements. In some cases, the volume fraction c_1 is known and the d-dimensional material is usually assumed to be isotropic $c_2 = -c_1(1-c_1)/d$. Higher-order moments depend on the detailed geometrical structure and are in most cases unknown. This gives us at most two coefficients in the series expansion (3.1), but in many cases even the volume fraction is uncertain.

The moments c_n can be expressed in terms of integrals over correlation functions [24, p. 520]. The calculations of higher-order correlation functions are in general very demanding [24]. The complex bounds on the effective permittivity in section

3.1 were parameterized in terms of bounds on the moments (3.20)–(3.22). We use inverse bounds from permittivity measurements to improve these geometry-independent bounds on the moments c_n that characterize the structure. This method avoids the cumbersome calculations of the correlation functions.

Bounds on the lowest-order moment c_1 (the volume fraction) have been derived using various methods [18, 19, 7, 10, 11]. In [10, 11] the author proposed general methods for deriving bounds on the higher-order moment c_n.

The inverse algorithm presented in section 4.1 applies to both the real-valued bounds in [10] and to the complex-valued bounds in [11]. In the examples in sections 5 and 6 we use complex-valued permittivities and bound the volume fraction c_1, the anisotropy parameter c_2, and c_3.

The $\epsilon_{1,1}$ Padé approximant to the series (3.1) gives an upper bound ϵ_2^{U} that in the isotropic case corresponds to the upper Hashin–Shtrikman bound [22, p. 574]. When $\epsilon_{\mathrm{e}} \notin \{\epsilon_1, \epsilon_2\}$, the upper bound ϵ_2^{U} can be inverted giving a bound on c_1 [11, 7]. Explicitly, the volume fraction is in the complex case bounded from below by [11, 7]

$$c_1^{\mathrm{L}} = \Im(z)\frac{(\Im(\epsilon^{\mathrm{eff}}) - \Im(\epsilon_2))^2 + (\Re(\epsilon^{\mathrm{eff}}) - \Re(\epsilon_2))^2}{|z|^2(\Im(\epsilon^{\mathrm{eff}})\Re(\epsilon_2) - \Re(\epsilon^{\mathrm{eff}})\Im(\epsilon_2))}. \tag{4.1}$$

In the same way, the generalization of the lower Hashin–Shtrikman bound ϵ_2^{L} [22, p. 574] can be inverted. Explicitly, the volume fraction is bounded from above by [11, 7]

$$c_1^{\mathrm{U}} = 1 - \Im(z)\frac{(\Im(\epsilon^{\mathrm{eff}}) - \Im(\epsilon_1))^2 + (\Re(\epsilon^{\mathrm{eff}}) - \Re(\epsilon_1))^2}{|z|^2(\Re(\epsilon^{\mathrm{eff}})\Im(\epsilon_1) - \Im(\epsilon^{\mathrm{eff}})\Re(\epsilon_1))}. \tag{4.2}$$

If the volume fraction c_1 is known, we derive in the same way bounds on the anisotropy parameter c_2. The $\epsilon_{2,1}$ Padé approximant to the series (3.1) gives an upper bound ϵ_3^{U} that in the isotropic case corresponds to the upper Beran bound [22, p. 574]. When $\epsilon_{\mathrm{e}} \notin \{\epsilon_1^{\mathrm{L}}, \epsilon_1^{\mathrm{U}}\}$, the upper bound ϵ_3^{U} can be inverted, giving a bound on c_2, and when $\epsilon_{\mathrm{e}} \notin \{\epsilon_2^{\mathrm{L}}, \epsilon_2^{\mathrm{U}}\}$, the $\epsilon_{2,2}$ Padé approximant can be inverted, giving a bound on c_3. Explicit bounds on the second moment c_2 can be found in [12].

A disadvantage with the inverse bounds above, and the corresponding bounds in the real case, is that the parameters $c_1, c_2, \ldots, c_{n-1}$ need to be known to bound c_n. Below we develop an algorithm that bounds $c_1, c_2, \ldots, c_n$ without any knowledge of the geometrical structure. Moreover, the bounds on the lower-order parameters are significantly tighter than in [10, 11].

The bounds on the moments depend on the geometrical structure. In order to study the dependence on the measure, we consider real-valued materials with $\epsilon_2 \geq \epsilon_1$. From the relation $\epsilon_1 \leq \epsilon_{\mathrm{e}} \leq \epsilon_2$ we have

$$0 \leq G(s) \leq \frac{1}{s} \leq 1. \tag{4.3}$$

Let $s = 1 + \delta$, $\delta > 0$. From the inequality above we have

$$1 \geq G(1+\delta) = \int_0^1 \frac{1}{1-y+\delta}\,\mathrm{d}m(y) \geq \frac{m(\{1\})}{\delta}, \tag{4.4}$$

which implies that the measure m of the set $\{1\}$ is zero, since $\delta > 0$ is arbitrary. The moments of the measure

$$c_{n+1} = (-1)^n \int_0^1 y^n\,\mathrm{d}m(y) \tag{4.5}$$

then vanish in the limit $n \to \infty$, and the absolute value of the moments $c_1, c_2, \dots$ form a nonincreasing sequence $|c_1| \geq |c_2| \dots$. The convergence rate of the moments c_n to zero depend strongly on the support of the measure. If m has no support close to $y = 1$, the convergence is exponential. The bounds c_1^{L} and c_1^{U} come close together when the volume fraction c_1 is low or high, and the bounds on c_2 come close together for anisotropic materials. The most challenging structures are therefore when the moments are the arithmetic mean of their maximum and minimum values, for example, when the first two moments are $c_1 = 1/2$ and $c_2 = -c_1\tilde{c}_1/2$, which in two dimensions corresponds to an isotropic material.

4.1. The inverse algorithm. Assume that we are given M sets of measurement data $\{\epsilon_1, \epsilon_1, \epsilon_{\mathrm{e}}\}$ and calculate the lower bound on the volume fraction c_1^{L} and the upper bound on the volume fraction c_1^{U} for all the sets. The tightest bounds on the volume fraction c_1 that can be obtained directly from the inverse bounds (4.1) and (4.2) are

$$(c_1^{\mathrm{L}})_1 = \max c_1^{\mathrm{L}}, \quad (c_1^{\mathrm{U}})_1 = \min c_1^{\mathrm{U}}, \tag{4.6}$$

where the maximum and minimum are taken over all data sets.

In the second step, fix $c_1 \in [(c_1^{\mathrm{L}})_1, (c_1^{\mathrm{U}})_1]$ and calculate the inverse bounds c_2^{L} and c_2^{U} for all M sets of measurement data. It is required that the anisotropy parameter c_2 for a fixed value on the volume fraction c_1 satisfy

$$\max c_2^{\mathrm{L}} \leq \min c_2^{\mathrm{U}}, \tag{4.7}$$

where the maximum and minimum are taken over all M data sets. This condition gives improved restrictions on the possible volume fraction c_1 and bounds on the anisotropy parameter c_2. The attainable values of (c_1, c_2) consist of a bounded region in the (c_1, c_2)-plane, denoted by Ω_2. We define

$$(c_1^{\mathrm{L}})_2 = \min\{c_1; c_1 \in \Omega_2\}, \tag{4.8}$$

$$(c_1^{\mathrm{U}})_2 = \max\{c_1; c_1 \in \Omega_2\} \tag{4.9}$$

and

$$(c_2^{\mathrm{L}})_2 = \min\{c_2; c_2 \in \Omega_2\}, \tag{4.10}$$

$$(c_2^{\mathrm{U}})_2 = \max\{c_2; c_2 \in \Omega_2\}. \tag{4.11}$$

The c_1-independent bounds $(c_2^{\mathrm{L}})_2$ and $(c_2^{\mathrm{U}})_2$ in Figure 4.1 do not take into account that the bounds on c_2 depend on c_1, but they can be used to simplify the algorithm.

In a third step, fix $(c_1, c_2) \in \Omega_2$ and calculate the inverse bounds c_3^{L} and c_3^{U} for all M sets of measurement data. As above, we require that the parameter c_3 for a fixed value on c_1 and c_2 satisfy

$$\max c_3^{\mathrm{L}} \leq \min c_3^{\mathrm{U}}, \tag{4.12}$$

where the maximum and minimum are taken over all M data sets. This requirement gives further restrictions on the structural parameters c_1 and c_2. Moreover, we get restrictions on the possible values on the c_3. The attainable values of (c_1, c_2, c_3) consist of a bounded region in the (c_1, c_2, c_3)-space, denoted by Ω_3.

The same procedure can be used to an arbitrary order. In general, $c_1, \dots, c_{n-1}$-independent bounds are obtained from

$$(c_n^{\mathrm{L}})_m = \min\{c_n; c_n \in \Omega_m \subset \mathbb{R}^m\}, \tag{4.13}$$

$$(c_n^{\mathrm{U}})_m = \max\{c_n; c_n \in \Omega_m \subset \mathbb{R}^m\}, \tag{4.14}$$

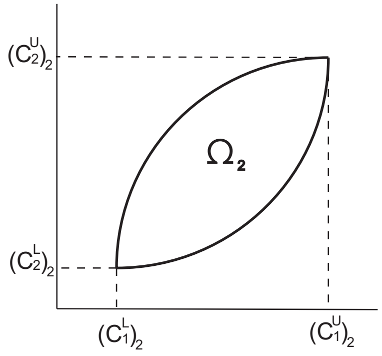

FIG. 4.1. *Region Ω_2 represents the attainable values of (c_1, c_2) after two steps in the algorithm.*

where m is the number of steps in the algorithm and $n = 1, 2, \ldots, m$. The tighter bounds Ω_m consist of a bounded region in $\mathbb{R}^m$ that for $m > 2$ is difficult to illustrate. Instead we use the bounds (4.13) and (4.14) in the presentation of bounds on higher-order structural parameters.

For the complex case, inverse bounds on higher-order moments c_n were derived in [11]. One disadvantage of the previous method [11] is that more steps in the algorithm do not improve the bounds on the lower-order moments. For example, the tightest possible bounds on the volume fraction with the previous method are equivalent to step one in the new method presented here. Every further step in the new algorithm improves the bounds on the volume fraction. In practice, the accuracy in the measurements limits the tightness of the bounds on the structural parameters c_n.

In many cases, partial information of the geometrical structure is available; for example, in the random case the composite is usually assumed to be isotropic, $c_2 = -c_1(1 - c_1)/d$. This knowledge can be used in the algorithm to derive tighter bounds on the volume fraction c_1 and on the higher-order parameters. The bounds on the structural parameters that were derived above can in principle be calculated analytically; however, the complexity in the formulas makes this difficult after a few steps of the algorithm. Below we present numerical calculations of the bounds when three steps of the algorithm are used.

5. Examples. The inverse algorithm in section 4.1 is illustrated by composites with known geometry. That is, we calculate bounds on the moments c_n and compare with the exact values. We give three examples of the method when no structural information is supposed to be known but information from measurements of the effective permittivity is available. We show that the size of the attainable values of (c_1, c_2), denoted by Ω_2, decreases for each step and present values on the bounds $(c_n^{\mathrm{L}})_m$ and $(c_n^{\mathrm{U}})_m$ when $n = 1, 2, 3$ and $m = 1, 2, 3$.

Three sets of measurements are used in all calculations in this section, but the number of sets is arbitrary. In all cases, we assume that component one is a frequency-independent material $\epsilon_1(\omega) = 3$ in the chosen range of frequencies. The second component is dispersive and is at the frequencies ω_0, ω_1, and ω_2 measured to be

$$\epsilon_2(\omega_0) = 4.1 + 4.5\mathrm{i}, \quad \epsilon_2(\omega_1) = 4.6 + 0.06\mathrm{i}, \quad \epsilon_2(\omega_2) = 3.7 + 0.04\mathrm{i}. \tag{5.1}$$

The values on the components were previously used in [11]. We use the same values in this paper to simplify the comparison between the methods. The algorithm presented

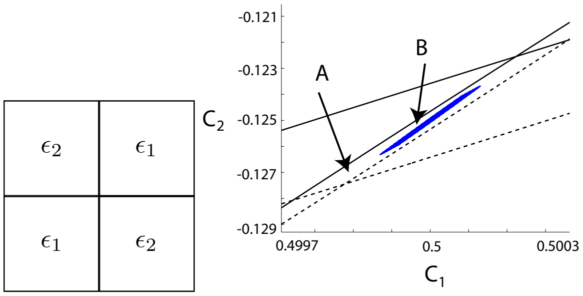

FIG. 5.1. *Left: The checkerboard structure, a two-dimensional and periodic geometry. Right: Bounds on the structural parameters c_1 and c_2 in the checkerboard case. The exact values on the parameters are $c_1 = 0.5$ and $c_2 = -0.125$. Region A, which is bounded by the two solid lines and the two dotted lines, represents the attainable values of (c_1, c_2) after two steps in the algorithm. Region B represents the possible values of (c_1, c_2) after three steps in the algorithm.*

TABLE 5.1

The table shows the bounds (4.13) and (4.14) using the checkerboard structure, $\epsilon_e = \sqrt{\epsilon_1\epsilon_2}$. The bounds are on the parameters c_1, c_2, and c_3 when one, two, and three steps in the algorithm are used.

c_1^L	c_1^U	c_2^L	c_2^U	c_3^L	c_3^U
0.4986	0.5014	-	-	-	-
0.4996	0.5004	-0.1281	-0.1219	-	-
0.4999	0.5001	-0.1263	-0.1237	0.0595	0.0655

in this paper gives very tight bounds from the measurement data (5.1). In section 6, we use measurements from a gold-magnesium oxide nanocomposite, which is a more challenging example.

5.1. The checkerboard. The two-dimensional checkerboard structure $\epsilon_e = \sqrt{\epsilon_1\epsilon_2}$ corresponds exactly to Bruggeman's formula at the percolation threshold $c_1 = 0.5$ [24]. From the Stieltjes inversion formula [1, 22] it follows that $\epsilon_e = \sqrt{\epsilon_1\epsilon_2}$ is obtained from the measure $\mathrm{d}m_C(y) = \frac{1}{\pi}\sqrt{(1-y)/y}\,\mathrm{d}y$. The moments (3.2) of m_C are

$$c_{n+1} = \begin{pmatrix} 1/2 \\ n+1 \end{pmatrix}, \tag{5.2}$$

where the first three moments of the measure are $c_1 = 0.5$, $c_2 = -0.125$, and $c_3 = 0.0625$. In this case, the moments converge very slowly to zero. The effective permittivities of the three sets (5.1) are in this case

$$\epsilon_e(\omega_0) = 3.91 + 1.727\mathrm{i}, \quad \epsilon_e(\omega_1) = 3.72 + 0.024\mathrm{i}, \quad \epsilon_e(\omega_2) = 3.33 + 0.018\mathrm{i}. \tag{5.3}$$

Figure 5.1 shows the possible values of (c_1, c_2) when the inverse algorithm above is used in two and three steps. The dashed lines $c_2^L(c_1)$ and the solid lines $c_2^U(c_1)$ are calculated from the sets (5.1) and (5.3) when $\epsilon_1 = 3$. The figure shows the tightest bounds on $c_2^L(c_1)$ and $c_2^U(c_1)$, which correspond to the frequencies ω_1 and ω_2. The bounds on (c_1, c_2) get tighter for every step in the algorithm, and additional sets of measurement data improve the bounds on the moments. Table 5.1 shows $(c_n^L)_m$ and $(c_n^U)_m$ when $n = 1, 2, 3$ and $m = 1, 2, 3$. The algorithm gives only bounds on c_1 in the first step, but the inequalities (3.20) and (3.21) always hold. In this case, we have the

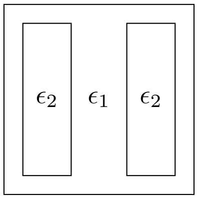

FIG. 5.2. *The geometry used to generate the result shown in Figure* 5.3 *and in Table* 5.2. *Two rods with length* 0.8 *and width* 0.25 *are located, at distance* 0.3 *apart, in a unit square. The volume fraction is then* $c_1 = 0.6$. *The applied field is oriented perpendicular to the rods.*

bounds $-0.25 \leq c_2 \leq 0$ and $0 \leq c_3 \leq 0.126$ after the first step. The bounds on the lower-order moments come closer together for each step in the algorithm.

5.2. Rational functions. A rational effective permittivity ϵ_{e} corresponds in the Stieltjes integral representation (2.2) to a sum of Dirac measures. The rational function ϵ_3^{U} (3.15) is obtained from a sum of two Dirac measures, that we formally write

$$\mathrm{d}m_{3\mathrm{U}}(y) = \frac{c_2^2}{c_3}\delta\left(y + \frac{c_3}{c_2}\right)\mathrm{d}y + \frac{c_1 c_3 - c_2^2}{c_3}\delta(y)\,\mathrm{d}y. \tag{5.4}$$

At the extreme point $c_3 = c_3^{\min} = c_2^2/c_1$ the measure (5.4) corresponds to ϵ_2^{U}, which is the Maxwell–Garnett formula [22]. The arithmetic mean ϵ_1^{U} is obtained from the measure $m_{3\mathrm{U}}$ when $c_2 \to c_2^{\max} = 0$. The moments of the measure (5.4) are

$$c_{n+1} = \frac{c_2^2}{c_3}\left(\frac{c_3}{c_2}\right)^n, \quad n = 1, 2, \ldots. \tag{5.5}$$

Hence, the moments converge exponentially to zero. We use the values $c_1 = 0.5$, $c_2 = -0.125$, and $c_3 = 0.0625$ on the lowest three moments, which equals the three lowest moments in the checkerboard case (5.2). The values on the components (5.1) imply that the effective permittivity $\epsilon_{\mathrm{e}} = \epsilon_3^{\mathrm{U}}$ in the three cases is

$$\epsilon_{\mathrm{e}}(\omega_0) = 3.87 + 1.70\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\omega_1) = 3.72 + 0.024\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\omega_2) = 3.33 + 0.018\mathrm{i}. \tag{5.6}$$

The inverse algorithm gives $0.498 \leq c_1 \leq 0.5001$ in the first step and, to numerical accuracy, the exact values on c_1, c_2, and c_3 after three steps in the algorithm.

5.3. An anisotropic example. Using the same material parameters as above, we also give an example in the anisotropic and periodic case, Figure 5.2. The effective permittivity and the moments $c_1 = 0.6$, $c_2 = -0.125$, and $c_3 = -0.1841$ were for this periodic structure numerically calculated in [10]. The numerical values on the permittivity at the frequencies ω_0, ω_1, and ω_2 are

$$\epsilon_{\mathrm{e}}(\omega_0) = 3.9426 + 0.9852\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\omega_1) = 3.5147 + 0.01554\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\omega_2) = 3.253 + 0.01306\mathrm{i}. \tag{5.7}$$

Figure 5.3 shows the attainable values of (c_1, c_2) after two and three steps in the inverse algorithm.

The dashed lines $c_2^{\mathrm{L}}(c_1)$ and the solid lines $c_2^{\mathrm{U}}(c_1)$ are calculated from the sets (5.1) and (5.7) when $\epsilon_1 = 3$. The figure shows the tightest bounds on $c_2^{\mathrm{L}}(c_1)$ and $c_2^{\mathrm{U}}(c_1)$, which correspond to the frequencies ω_1 and ω_2. Table 5.2 presents the bounds

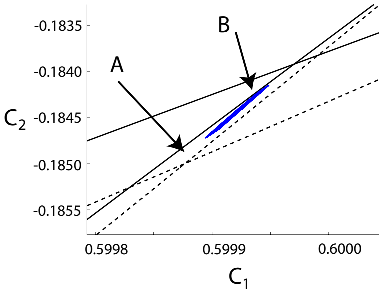

FIG. 5.3. *Bounds on the moments c_1 and c_2 using the anisotropic geometry in Figure* 5.2. *The numerical values on the parameters are $c_1 = 0.6$ and $c_2 = -0.1841$* [10]. *Region A, which is bounded by the two solid lines and the two dotted lines, represents the attainable values of* (c_1, c_2) *after two steps in the algorithm. TABLE 5.2

The table shows the bounds (4.13) *and* (4.14) *using the geometry depicted in Figure* 5.2. *The bounds are on the parameters c_1, c_2, and c_3 when one, two, and three steps in the inverse algorithm are used.*

c_1^L	c_1^U	c_2^L	c_2^U	c_3^L	c_3^U
0.5984	0.6001	-	-	-	-
0.5999	0.6000	-0.1853	-0.1838	-	-
0.5999	0.6000	-0.1847	-0.1841	0.0950	0.0964

(4.13) and (4.14) on the three lowest moments after one, two, and three steps in the algorithm. The inequalities (3.20) and (3.21) give the bounds $-0.25 \leq c_2 \leq 0$ and $0 \leq c_3 \leq 0.149$ after the first step.

The geometry and the values on the components were previously used in [10, 11]. Here we obtain tight bounds on the lowest three moments without any previous knowledge about the structure.

6. Nanocomposites. The effective permittivity belongs to the wedge bounded by the rays $\epsilon_0^{\mathrm{L}} = t\epsilon_1$ and $\epsilon_0^{\mathrm{U}} = t\epsilon_2$, $0 \leq t \leq \infty$ (see [22]). In a metal/dielectric nanocomposite the angle between the rays is large compared to the dielectric case, which results in less tight bounds on the moments c_n. We give an example where the composite is composed of gold and magnesium oxide and measured at the optical wavelengths $\lambda_0 = 300\,\mathrm{nm}$, $\lambda_1 = 500\,\mathrm{nm}$, $\lambda_2 = 700\,\mathrm{nm}$, and $\lambda_3 = 900\,\mathrm{nm}$. The permittivity of gold is [17]

$$\epsilon_1(\lambda_0) = -1.23 + 5.78\mathrm{i}, \quad \epsilon_1(\lambda_1) = -2.27 + 3.81\mathrm{i} \tag{6.1}$$

and

$$\epsilon_1(\lambda_2) = -16.79 + 1.07\mathrm{i}, \quad \epsilon_1(\lambda_3) = -32.00 + 2.04\mathrm{i}. \tag{6.2}$$

The magnesium oxide is lossless at optical wavelengths: $\epsilon_2(\lambda_0) = 3.26$, $\epsilon_2(\lambda_1) = 3.05$, $\epsilon_2(\lambda_2) = 3.00$, and $\epsilon_2(\lambda_3) = 2.98$ [14]. We use the effective permittivity $\epsilon_{\mathrm{e}} = \epsilon_3^{\mathrm{U}}$ and the moments $c_1 = 0.5$, $c_2 = -0.125$, and $c_3 = 0.0625$. The gold-magnesium oxide composite has the effective permittivities

$$\epsilon_{\mathrm{e}}(\lambda_0) = 3.24 + 3.18\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\lambda_1) = 2.73 + 3.48\mathrm{i} \tag{6.3}$$

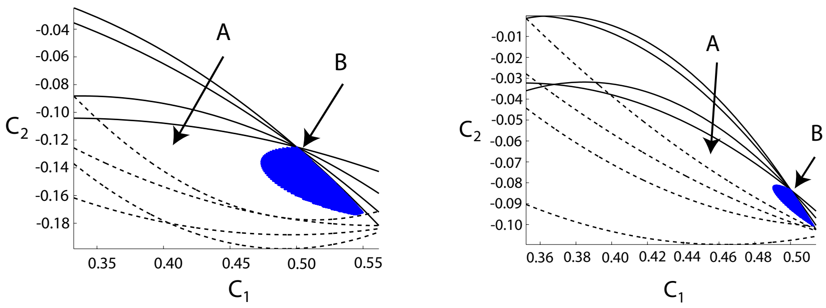

FIG. 6.1. *The nanocomposite: Bounds on the structural parameters c_1 and c_2 using $\epsilon_{\mathrm{e}} = \epsilon_3^{\mathrm{U}}$. 0.352	0.514	-	-	-	-
0.398	0.513	-0.101	-0.037	-	-
0.490	0.513	-0.101	-0.081	0.0593	0.0788

and

$$\epsilon_{\mathrm{e}}(\lambda_2) = 0.625 + 0.314\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\lambda_3) = -0.344 + 0.513\mathrm{i}. \tag{6.4}$$

Figure 6.1 shows the possible values of the lowest two moments c_1 and c_2 after two and three steps in the inverse algorithm. Table 6.1 presents the bounds (4.13) and (4.14) on the moments c_1, c_2, and c_3 after one, two, and three steps in the algorithm. The identical measure is used in section 5.2, where the inverse algorithm determines c_1, c_2, and c_3 from the three sets (5.1) and (5.6) when $\epsilon_1 = 3$ for the frequencies ω_0, ω_1, and ω_2.

The convergence rate of the moments depends strongly on the measure m. Assume that the first three moments are $c_1 = 0.5$, $c_2 = -c_1\tilde{c}_1/3 = -0.0833$, and $c_3 = 0.06$. The effective permittivity from the measure (5.4) is for the gold-magnesium oxide composite. Then

$$\epsilon_{\mathrm{e}}(\lambda_0) = 2.05 + 2.63\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\lambda_1) = 1.64 + 1.97\mathrm{i} \tag{6.5}$$

and

$$\epsilon_{\mathrm{e}}(\lambda_2) = -4.00 + 0.42\mathrm{i}, \quad \epsilon_{\mathrm{e}}(\lambda_3) = -9.92 + 0.79\mathrm{i}. \tag{6.6}$$

Figure 6.1 shows the possible values of the lowest two moments c_1 and c_2 after two and three steps in the inverse algorithm, and Table 6.2 presents the bounds (4.13) and (4.14) on the moments c_1, c_2, and c_3 after one, two, and three steps in the algorithm. If we assume that the material is known to be a three-dimensional isotropic composite, $c_2 = -c_1\tilde{c}_1/3$, the algorithm gives the tighter bounds $0.490 \leq c_1 \leq 0.500$ and $0.060 \leq c_3 \leq 0.063$.

7. Conclusions. We have presented a method to calculate structural parameters (moments) from measured bulk properties of two-component composites, based on the inverse bounds in [10, 11]. The method gives tight bounds on the volume fraction c_1 and also bounds on the higher-order structural parameters c_2 and c_3 after three steps in the algorithm. The tightness of the bounds is sensitive to the geometry and the contrast. The bounds are tighter for low-contrast materials and for anisotropic materials. The results can be improved, e.g., tighter bounds on low-order moments can be calculated, if at least one of the structural parameters is known or additional measurement data is available.

The presented method can be extended to handle inaccurate measurement data. Importantly, the method in this paper can be used together with arbitrary large error bars on the measurement data and will still produce correct bounds on the structural parameters. If the error bars are too large, however, the method can only reproduce the fundamental bounds on c_n. A first step in this direction was considered in [12] where an algorithm based on the inverse bounds in [11] was used.

TRAVELING WAVES IN A BIOREMEDIATION MODEL*

SHANGBING AI†

Abstract. We study a bioremediation model that arises in restoring ground water and soil contaminated with organic pollutants. It describes an in situ bioredimedation scenario in which a sorbing substrate of contaminated soil is degraded by indigenous microorganisms in the presence of an injected nonsorbing electron acceptor. The model relates to the coupling of the advection, dispersion, and biological reaction simultaneously for the substrate, electron acceptor, and the total biomass by two advection-reaction-diffusion equations and an ODE. We establish the existence of traveling waves for the model with wider classes of kinetic functions. Our result generalizes previous results for this model which were established only for multiplicative Monod kinetics. In addition, the proof of our result, which is based on a dynamical systems approach, is simpler.

Key words. biodegradation model, traveling waves, shooting argument

1. Introduction.

In situ bioremediation makes use of microorganisms to transfer hazardous chemicals into nontoxic products in places where contaminants are a concern. Because it is less costly, safer, and faster than conventional treatment methods, this technology has found wide applications in the cleanup of groundwater and soils polluted with chlorinated solvents, fuel hydrocarbons, and explosives [8, 19, 20]. Through the injection of growth nutrients and electron acceptors into the contaminated site, the organic pollutants serving as substrates are broken down through the metabolism of the microorganisms. This is a complex process which involves physical, chemical, and biological reactions as well as interactions between microorganisms and the physical condition of the subsurface, such as fluid flow rates, media heterogeneity, and contaminant availability. The success of bioremediation is determined by key factors that control or limit the performance of the microorganisms. Mathematical modeling has been extensively used for understanding this process and identifying these key factors therefore to provide guidance in the improvement of in situ bioremediation technology [2, 3, 4, 7]. In recent years, analytical study of traveling wave solutions for various bioremediation models becomes of interest to researchers in this area [1, 9, 10, 12, 16]. Via analyzing the traveling waves, one can answer questions such as: how fast does the incoming nutrient front travel? what is the contaminant removal rate? which parameters are most significant in controlling the degradation rate? etc.

In this paper, we consider traveling waves for a basic one-dimensional bioremediation model that has been discussed in papers of Odencrantz [13, 14], Odencrantz, Valocchi, and Rittman [15], Valocchi, Odencrantz, and Rittman [22], and Oya and Valocchi [16]. The model relates to the coupling of the advection, dispersion, and biological reaction simultaneously for the substrate, electron acceptor, and the total biomass. It is assumed (cf. [1]) that (i) microbes are attached to the aquifer particles in the soil and thus do not move, (ii) the acceptor is nonsorbing and thus travels

through the soil at pore water velocity v, and (iii) the substrate is sorbing and travels at the retarded velocity $1/R$ with the retardation factor $R > 1$. Let $S(x,t)$, $A(x,t)$, and $M(x,t)$ be the concentrations of the substrate, acceptor, and microorganisms, respectively. Then the mass balance equations for S, A, and M are

$$\left\{\begin{array}{l} S_t = \frac{d}{R}S_{xx} - \frac{v}{R}S_x - \frac{1}{R}f(S,A,M), \\ A_t = dA_{xx} - vA_x - \gamma f(S,A,M), \\ M_t = -b(M - M_0) + \beta f(S,A,M), \end{array}\right. \tag{1.1}$$

where d is the hydrodynamic dispersion coefficient, γ is the coefficient equal to the mass of A utilized by the biomass per unit mass of the substrate degraded, b is the cell decay coefficient for the biomass M, M_0 is the neutral background biomass concentration, β is the cell yield coefficient for the electron donor, and the reaction function f describes the biodegradation rate, which has been taken to be the so-called multiplicative Monod kinetics

$$f = f(S,A,M) = qM\left(\frac{S}{K_S + S}\right)\left(\frac{A}{K_A + A}\right), \tag{1.2}$$

where q is the maximum specific rate of the substrate utilization, and K_S, K_A are the half-maximum rate concentrations of the substrate S and the acceptor A.

In the above model, the condition $R > 1$ physically means that the advective velocity of the substrate S is slower than that of the acceptor A so that there is a region overlap where the two concentrations mix. In this region, known as a biologically active zone (BAZ), microorganisms actively grow by consuming the nutrient and degrading the substrates and the three components travel together. It is Oya and Valocchi [16] who, via numerical simulations, first observed traveling waves with constant wave speeds that consist of monotonically increasing fronts in S, monotonically decreasing fronts in A, and pulses for M. They then analytically studied the traveling wave solutions of (1.1) of the form $(S(\xi), A(\xi), M(\xi))$ with a constant wave speed c ($\xi = x - ct$) that satisfy the boundary value problem

$$\left\{\begin{array}{l} dS_{\xi\xi} + (Rc - v)S_\xi = f, \\ dA_{\xi\xi} + (c - v)A_\xi = \gamma f, \\ cM_\xi = b(M - M_0) - \beta f, \end{array}\right. \tag{1.3}$$

and

$$(S,A,M)(-\infty) = (0, A_0, M_0), \quad (S,A,M)(\infty) = (S_0, 0, M_0), \tag{1.4}$$

and $S(\xi) > 0$, $A(\xi) > 0$, and $M(\xi) > 0$ for all $\xi \in \mathbb{R}$, where A_0 and S_0 are positive constants, representing the input of the nutrient concentration and the output of the pollutant concentration. Note that the background bacteria population M_0 is the unique equilibrium between cell growth and decay. The asymptotic conditions (1.4) can be explained as follows (cf. [1]): at $-\infty$, behind the BAZ, the substrate has been completely degraded, the acceptor level is equal to its injection level, and the microorganism population has returned to its equilibrium level; at ∞, ahead of the BAZ, the soil remains undisturbed and contaminated, and thus the substrate, acceptor, and microorganisms are all equal to their initial levels. By formally adding the appropriate multiples of the first two equations of (1.3) and integrating over $\mathbb{R}$, Oya and Valocchi obtained the following explicit formula for c:

$$c = \frac{v(A_0 + \gamma S_0)}{A_0 + \gamma R S_0}. \tag{1.5}$$

Using this formula they could predict the removal rate of the substrate and determine the important parameters that control this rate.

Subsequently, Murray and Xin [12] established rigorously the existence of solutions of (1.3)–(1.4) under the condition $R > 1$. They also obtained the following estimates for the biomass M:

$$M_0 < M(\xi) \leq M_0 + \frac{\beta(R-1)A_0S_0}{A_0 + \gamma S_0}. \tag{1.6}$$

Note that the upper bound for M is independent of the reaction function f. Recently, Beck, Doelman, and Kaper [1] reestablished the existence of solutions of (1.3)–(1.4) in the case that both half saturation constants K_S and K_A are sufficiently large. Using a change of coordinates, they reduced the problem into a singular perturbed one, for which they were able to apply the theory of the geometric singular perturbations. As they noted, their method provides further insight into the geometric structure of the traveling wave solutions, which are useful in studying the stability of these wave fronts.

The above three references [1, 12, 16] all considered the case where the reaction function f takes the form in (1.2). However, the bioreaction in bioremediation is not limited to the Monod equation. Instead, depending on the nature of the pollutants, the kinetic term in the model may take other forms. For example, when microbial growth is inhibited by the substrate, such as phenol degradation [11, 17, 21], the biodegradation function f can be described by the Haldane inhibition model

$$f = qM\left(\frac{S}{K_S + S + S^2/K_I}\right)\left(\frac{A}{K_A + A}\right),$$

where K_I is the inhibition constant. Biodegradation of certain organic compounds is also described by the Moser equation [6]

$$f = qM\left(\frac{S^n}{K_S + S^n}\right)\left(\frac{A}{K_A + A}\right),$$

where n is the order of the enzyme reaction. The first order kinetic function $f = qMSA$ was discussed in [14]. There are numerous other kinetic models that are available. Generally speaking, the selection of a kinetic model appropriate to the conditions of the site being modeled is difficult because the differences among the models are not fully understood.

In this paper, we extend the works in [1, 12, 16] to a large class of kinetic models, including those mentioned above. We prove that there exist traveling waves for all of these kinetic models. This indicates biologically that the system (1.1) can be applied to model the bioremediation of broader categories of organic pollutants. Our main result is as follows.

Theorem 1.1. *Assume that $R > 1$ and that f satisfies*

$$\begin{cases} f(S, A, M) = \varphi_1(S)\varphi_2(A)\varphi_3(M), \\ f \text{ is } C^2 \text{ in a neighborhood of } (S_0, 0, M_0), \\ \varphi_i \text{ is locally Lipschitz on } (0, \infty) \quad (i = 1, 2, 3), \\ \varphi_i > 0 \quad \text{on } (0, \infty) \quad (i = 1, 2, 3), \\ \varphi_1(0) = \varphi_2(0) = 0. \end{cases} \tag{1.7}$$

Then (1.3)–(1.4) *admits a traveling wave solution* (S, A, M, c) *with* c *given in* (1.5). *Moreover,* M *satisfies* (1.6) *and, for all* $\xi \in \mathbb{R}$,

$$\left\{\begin{array}{ll} 0 < S(\xi) < S_0, & 0 < S'(\xi) < \frac{v(R-1)A_0S_0}{d(A_0+\gamma RS_0)}, \\ 0 < A(\xi) < A_0, & -\frac{\gamma v(R-1)A_0S_0}{d(A_0+\gamma RS_0)} < A'(\xi) < 0. \end{array}\right. \tag{1.8}$$

We prove Theorem 1.1 in the next section by a different approach from those in [1, 12]. The approach in [12] is to apply the Leary–Schauder degree theory to a regularized system with Dirichlet boundary conditions on a large but finite interval and then to pass to the infinite line and remove the regularization. This method involves many rather delicate a priori estimates that apparently depend on the specific form of f given in (1.2). Our approach is a dynamical systems approach; namely, we directly study flows of (1.3) in the phase space with an aid of the stable manifold theorem and then apply a simple shooting argument. This approach is commonly used for planar systems and, generally speaking, is difficult for higher dimensional systems. For the system (1.3), it turns out that this approach is simpler and yields a much shorter proof. An outline of the proof is presented after the proof of Lemma 2.2. We conclude this paper with a short summary.

Before ending this section we give the following remark. The problem (1.3)–(1.4) does not have any positive solutions if $0 < R \leq 1$. To see this, we assume on the contrary that (1.3)–(1.4) has a positive solution (S, A, M). Note that $c - v \geq 0$ from (1.5). Using the second equation of (1.3) and $A(-\infty) = 0$, we obtain

$$A'(\xi) = \frac{\gamma}{d}\int_{-\infty}^{\xi} e^{-\frac{c-v}{d}(\xi-\eta)} f(S(\eta), A(\eta), M(\eta))\, d\eta > 0 \qquad \forall \xi \in \mathbb{R},$$

which yields that $A(\infty) = 0$ is impossible.

2. Proof of Theorem 1.1. Throughout this section, we assume that $R > 1$. Let c be defined in (1.5). We have that

$$b_1 := Rc - v = \frac{v(R-1)A_0}{A_0+\gamma RS_0} > 0, \quad b_2 := -(c-v) = \frac{\gamma v(R-1)S_0}{A_0+\gamma RS_0} = \frac{\gamma S_0}{A_0}b_1 > 0.$$

Employing the rescalings

$$\begin{array}{l} \tilde{b}_1 = \dfrac{b_1}{d}, \quad \alpha = \dfrac{1}{S_0 d}, \quad \tilde{b}_2 = \dfrac{b_2}{d}, \quad \tilde{\gamma} = \dfrac{\gamma}{A_0 d}, \quad b_3 = \dfrac{b}{c}, \quad \tilde{\beta} = \dfrac{\beta}{M_0 c}, \\ \tilde{S} = \dfrac{S}{S_0}, \quad \tilde{A} = \dfrac{A}{A_0}, \quad \tilde{M} = \dfrac{M}{M_0}, \quad \tilde{f}(\tilde{S}, \tilde{A}, \tilde{M}) = f(S, A, M), \quad z = -\xi, \end{array}$$

we reduce (1.3) and (1.4) into (after dropping the tildes)

$$\left\{\begin{array}{l} S'' - b_1S' = \alpha f, \\ A'' + b_2A' = \gamma f, \\ M' = -b_3(M-1) + \beta f, \end{array}\right. \tag{2.1}$$

and

$$(S, A, M)(-\infty) = (1, 0, 1), \quad (S, A, M)(\infty) = (0, 1, 1), \tag{2.2}$$

where "prime" is d/dz. Therefore, in order to prove Theorem 1.1, it suffices to establish the following theorem.

THEOREM 2.1. *Assume that b_1, b_2, b_3, α, β, and γ are positive constants satisfying $\alpha b_2 = \gamma b_1$ and that f satisfies* (1.7) *with $S_0 = A_0 = M_0 = 1$. Then* (2.1)–(2.2) *admits a solution* (S, A, M) *such that, for* $z \in \mathbb{R}$,

$$(2.3)\qquad \begin{cases} 0 < S(z) < 1, \quad -b_1 < S'(z) < 0, \\ 0 < A(z) < 1, \quad 0 < A'(z) < b_2, \\ 1 < M(z) < 1 + \beta b_1/\alpha. \end{cases}$$

We remark that if the diffusion coefficients in the first two equations of (1.3) are distinct, then with slight modifications of the above rescalings we can still reduce (1.3) into the system (2.1), yielding that Theorem 1.1 also holds in this more general case. Noting that all bounds in (2.3) are independent of f, this observation plays a key role in the last part of the proof of Theorem 2.1.

In order to prove Theorem 1.1, we need the following lemma.

LEMMA 2.2. (i) *If* (S, A, M) *is a solution of* (2.1)–(2.2), *then* (S, T, A, M) *is a solution of*

$$(2.4)\qquad \begin{cases} S' = T, \\ T' = \alpha f + b_1 T, \\ A' = -(\gamma b_1/\alpha)(S-1) + (\gamma/\alpha)T - b_2 A, \\ M' = \beta f - b_3(M-1), \end{cases}$$

and

$$(2.5)\qquad (S, T, A, M)(-\infty) = (1, 0, 0, 1), \quad (S, T, A, M)(\infty) = (0, 0, 1, 1).$$

Conversely, if (S, T, A, M) *is a solution of* (2.4)–(2.5), *then* (S, A, M) *is a solution of* (2.1)–(2.2).

(ii) *The line* $T = b_1(S-1)$, $A = 0$, *and* $M = 1$ *in the* (S, T, A, M)*-phase space lies on the unstable manifold* W^u *of* (2.4) *at* $(1, 0, 0, 1)$.

(iii) *If* (S, T, A, M) *is a solution of* (2.4) *that satisfies the boundary condition at* $-\infty$ *in* (2.5) *with its maximal existence interval* $(-\infty, \omega)$, *then, for* $z \in (-\infty, \omega)$,

$$(2.6)\qquad \begin{cases} T(z) - b_1[S(z) - 1] = \alpha \int_{-\infty}^{z} f(S(\eta), A(\eta), M(\eta))\, d\eta, \\ A'(z) = \gamma \int_{-\infty}^{z} e^{-b_2(z-\eta)} f(S(\eta), A(\eta), M(\eta))\, d\eta, \\ A(z) = (\gamma/b_2) \int_{-\infty}^{z} [1 - e^{-b_2(z-\eta)}] f(S(\eta), A(\eta), M(\eta))\, d\eta, \\ M(z) = 1 + \beta \int_{-\infty}^{z} e^{-b_3(z-\eta)} f(S(\eta), A(\eta), M(\eta))\, d\eta. \end{cases}$$

If, in addition, $S(z) > 0$, $T(z) < 0$ *for all* $z \in (-\infty, \omega)$ *and* $A(z) > 0$ *for all sufficiently negative* z, *then* $\omega = \infty$, $(S, T, A, M)(\infty) = (0, 0, 1, 1)$ *and, for* $z \in \mathbb{R}$,

$$(2.7)\qquad \begin{cases} 0 < S(z) < 1, \quad b_1[S(z) - 1] < T(z) < 0, \\ 0 < A(z) < \frac{\gamma b_1}{\alpha b_2}[1 - S(z)], \quad 0 < A'(z) < \frac{\gamma b_1}{\alpha}[1 - S(z)], \\ 1 < M(z) < 1 + \frac{\beta b_1}{\alpha}[1 - S(z)], \end{cases}$$

and, in particular, (2.3) *holds.*

Proof. (i) and (ii) can be verified directly. Equation (2.6) follows directly from (2.4) and the boundary condition at $-\infty$ in (2.5). We now show (2.7). First, the assumptions in this part imply $f(S(z), A(z), M(z)) > 0$ for all sufficiently negative z which together with the second, third, and fourth equations in (2.6) yields that $A(z) > 0$, $A'(z) > 0$, $M(z) > 1$, and $f(S(z), A(z), M(z)) > 0$ for all $z \in (-\infty, \omega)$. Consequently, the first equation in (2.6) yields the first inequality for T in (2.7) and $\int_{-\infty}^{z} f(S(\eta), A(\eta), M(\eta))\, d\eta < (b_1/\alpha)[1 - S(z)]$ which together with the second, third, and fourth equations in (2.6) yields the upper bounds for A, A', and M in (2.7). This shows (2.7). Finally, using these estimates and the fact that $(0,0,1,1)$ is an equilibrium point of (2.4), we conclude that $\omega = \infty$ and $(S,T,A,M)(\infty) = (0,0,1,1)$. $\square$

Now we outline the proof of Theorem 2.1 given later. From Lemma 2.2(i) it suffices to show that the problem (2.4)–(2.5) has a solution. We start with analyzing the local dynamics of (2.4) at $(1,0,0,1)$. Simple algebra yields, at $(1,0,1)$, $D_S f = \varphi_1'(1)\varphi_2(0)\varphi_3(1) = 0$, $D_M f = \varphi_1(1)\varphi_2(0)\varphi_3'(1) = 0$, and

$$\sigma := D_A f = \varphi_1(1)\varphi_2'(0)\varphi_3(1) \geq 0, \tag{2.8}$$

and so the coefficient matrix for the linearized system of (2.4) at $(1,0,0,1)$ is

$$E = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & b_1 & \alpha\sigma & 0 \\ -\gamma b_1/\alpha & \gamma/\alpha & -b_2 & 0 \\ 0 & 0 & \beta\sigma & -b_3 \end{pmatrix},$$

and the eigenvalues of E are

$$\begin{cases} \lambda_1 := b_1, \\ \lambda_2 := \frac{1}{2}\left(-b_2 + \sqrt{b_2^2 + 4\gamma\sigma}\right), \\ \lambda_3 := \frac{1}{2}\left(-b_2 - \sqrt{b_2^2 + 4\gamma\sigma}\right), \\ \lambda_4 = -b_3. \end{cases} \tag{2.9}$$

It follows that $\lambda_3 < 0$, $\lambda_4 < 0$, $\lambda_1 > 0$, and $\lambda_2 > 0$ if $\sigma > 0$ and $\lambda_2 = 0$ if $\sigma = 0$. Hence, (2.4) has a two-dimensional local unstable manifold W^u_{loc} at $(1,0,0,1)$ if $\sigma > 0$ and a one-dimensional unstable manifold and one-dimensional center manifold if $\sigma = 0$. Note that, from (2.8), $\sigma = 0$ if and only if $\varphi_2'(0) = 0$. We proceed the proof of Theorem 2.1 in three cases based on $0 < \lambda_2 < \lambda_1$, or $\lambda_1 < \lambda_2$, or either $\lambda_2 = 0$ or $\lambda_1 = \lambda_2$.

Case 1. We consider $0 < \lambda_2 < \lambda_1$. Then there is a unique one-dimensional strongly unstable manifold on W^u_{loc} that is tangent to the eigenvector p_1 at $(1,0,0,1)$ and indeed lies on the line $T = b_1(S-1)$, $A = 0$, and $M = 1$ from Lemma 2.2(ii); the rest flows on W^u_{loc} are all tangent to the eigenvector p_2 at $(1,0,0,1)$. We take a continuous "circular arc" Γ_1 on W^u_{loc} whose projection on the (S,T)-plane is displayed in the left figure in Figure 1, and then show that (i) the components $S(z)$, $T(z)$, and $A(z)$ of every solution starting on Γ_1 at $z = 0$ satisfy $S(z) < 1$, $T(z) < 0$, and $A(z) > 0$ for all sufficiently negative z; (ii) for each solution starting near one end of Γ_1 with $T(0) > 0$, there exists a $z_0 \in \mathbb{R}$ such that $T(z_0) = 0$, $T'(z_0) > 0$, $T(z) < 0$ for $z < z_0$ and $S(z) > 0$ for $z \leq z_0$ (i.e., $T = 0$ occurs before $S = 0$ does); (iii) for any solution starting near the other end of Γ_1 with $T(0) < 0$, there is a $\bar{z}_0$ such that $S(\bar{z}_0) = 0$, $S(z) > 0$ for $z < \bar{z}_0$, and $T(z) < 0$ for $z \leq \bar{z}_0$ (i.e., $S = 0$ occurs before $T = 0$ does). Using the fact that $S = 0$ and $T = 0$ cannot occur at the same time, we conclude by a shooting argument that there is a point on Γ_1 such that the solution of (2.4) starting at this point satisfies $S > 0$ and $T < 0$ on $(-\infty, \omega)$, which gives a desired solution by Lemma 2.2(iii).

Case 2. We consider $\lambda_1 < \lambda_2$. Then the unique one-dimensional strongly unstable manifold on W^u_{loc} is tangent to the eigenvector p_2 at $(1,0,0,1)$, and the rest flows on W^u_{loc} are all tangent to the eigenvector p_1 at $(1,0,0,1)$. We take a continuous "circular

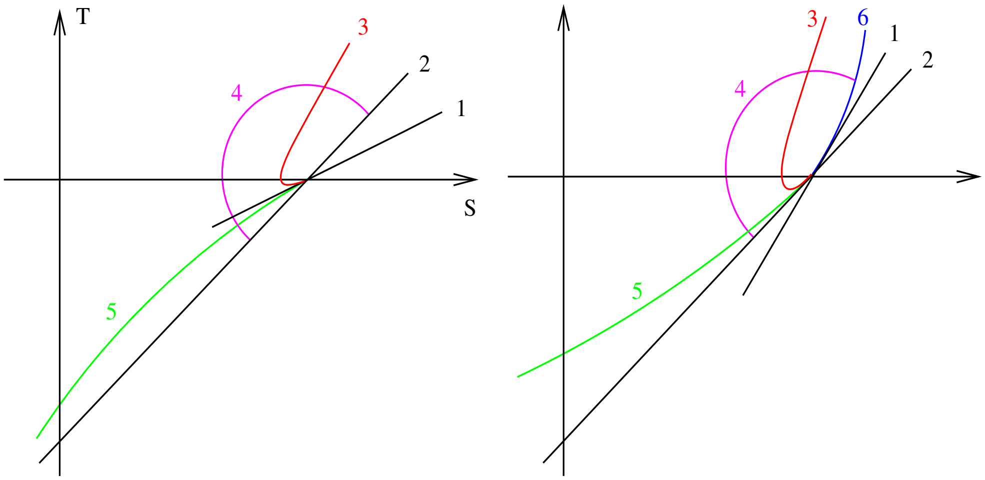

FIG. 1. *In the left and right figures, the curves sketched are the projections of the curves in the (S,T,A,W)-phase space into the (S,T)-plane corresponding to $0<\lambda_2<\lambda_1$ and $\lambda_1<\lambda_2$, respectively: curve* 1 *is the projection of the eigenvector p_2, curve* 2 *is the line $T=b_1(S-1)$, which is parallel to the projection of the eigenvector p_1, curve* 4 *is the projection of Γ_1 (resp., Γ_2) which is taken on W^u_{loc}, curves* 3 *and* 5 *are the projections of two solution curves of* (2.4) *passing through Γ_1 (resp., Γ_2) at $z=0$, and curve* 6 *in the right figure is the projection of the strongly unstable manifold which is tangent to p_2.*

arc" Γ_2 on W^u_{loc} whose projection on the (S,T)-plane is displayed in the right figure in Figure 1, and then show that the statements (i), (ii), and (iii) in Case 1 hold after all Γ_1 there are replaced by Γ_2. Then using the same shooting argument as used in Case 1 shows that there is a point on Γ_2 such that the solution of (2.4) starting at this point gives a desired solution in this case.

Case 3. We consider either $\lambda_2=0$ or $\lambda_1=\lambda_2$. We first construct approximating systems to (2.4) with each positive integer n

$$\left\{\begin{array}{l} S'=T,\\ T'=b_1T+\alpha f_n,\\ A'=-(\gamma b_1/\alpha)(S-1)+(\gamma/\alpha)T-b_2A,\\ M'=-b_3(M-1)+\beta f_n, \end{array}\right. \tag{2.10}$$

where $f_n(S,A,M)=\varphi_1(S)[\varphi_2(A)+\frac{1}{n}A]\varphi_3(M)$, which clearly satisfies (1.7) with $S_0=A_0=M_0=1$. Let $\sigma_n:=\varphi_1(1)[\varphi_2'(0)+\frac{1}{n}]\varphi_3(1)=\sigma+\frac{1}{n}\varphi_1(1)\varphi_3(1)$, $\lambda_{1,n}:=b_1$, and $\lambda_{2,n}:=\frac{1}{2}\left(-b_2+\sqrt{b_2^2+4\gamma\sigma_n}\right)$. It follows that $\lambda_{1,n}<\lambda_{2,n}$ if $\lambda_1=\lambda_2$ and $n\geq 1$, and $0<\lambda_{2,n}<\lambda_{1,n}$ if $\lambda_2=0$ and $n\geq n_0$ for some $n_0>0$. Note that $\lambda_{1,n}$ and $\lambda_{2,n}$ are two positive eigenvalues of the linearized system of (2.10) at $(1,0,0,1)$. Then applying the results from Cases 1 and 2 to (2.10) for each $n\geq n_0$ yields a sequence of solutions (S_n,T_n,A_n,M_n) of (2.10) which have the same estimates given in (2.3) that are independent of n. Then, applying the Arzela–Ascoli theorem (cf. [5]) on the interval $[-k,k]$ for each positive integer k and then using a diagonal selection process yields a subsequence $(S_{n_k},T_{n_k},A_{n_k},M_{n_k})$ that converges uniformly on any compact subset of $\mathbb{R}$, whose limit function gives a desired solution of (2.4) in this case.

Proof of Theorem 2.1. As discussed previously, we first assume that λ_1 and λ_2 are both positive and $\lambda_1\neq\lambda_2$. We then find that

$$p_1 = \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix}, \qquad p_2 = \begin{pmatrix} 1 \\ \lambda_2 \\ \frac{\lambda_2(\lambda_2-\lambda_1)}{\alpha\sigma} \\ \frac{\beta\lambda_2(\lambda_2-\lambda_1)}{\alpha(\lambda_2+b_3)} \end{pmatrix}$$

are the eigenvectors of E associated with λ_1 and λ_2, respectively. It follows from the stable manifold theorem that (2.4) has a two-dimensional local unstable manifold W^u_{loc} near $(1,0,0,1)$ which is tangent to the plane spanned by p_1 and p_2. More precisely, we make change of variables

$$\begin{pmatrix} S-1 \\ T \\ A \\ M-1 \end{pmatrix} = P \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} := [p_1, p_2, p_3, p_4] \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix},$$

where p_3 and p_4 are (generalized) eigenvectors of E associated with λ_3 and λ_4, respectively, transform (2.4) into

$$x' = (P^{-1}EP)x + G(x), \qquad P^{-1}EP := \begin{pmatrix} Q_1 & 0 \\ 0 & Q_2 \end{pmatrix}, \tag{2.11}$$

where $Q_1 = \left(\begin{smallmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{smallmatrix}\right)$ and $G(x) = O(|x|^2)$, and correspondingly transform W^u_{loc} into a two-dimensional local unstable manifold $\widetilde{W}^u_{loc}$ of (2.11) at $x = 0$ which is tangent to the (x_1, x_2)-plane. Consequently, $\widetilde{W}^u_{loc}$ can be written as the graph of

$$x_3 = h_1(x_1, x_2) = O(x_1^2 + x_2^2), \qquad x_4 = h_2(x_1, x_2) = O(x_1^2 + x_2^2),$$

where x_1 and x_2 are sufficiently small, and the x_1 and x_2 components of the flows of (2.11) on $\widetilde{W}^u_{loc}$ satisfy a planar system

$$x_1' = \lambda_1 x_1 + N_1(x_1, x_2), \qquad x_2' = \lambda_2 x_2 + \widetilde{N}_2(x_1, x_2)x_2, \tag{2.12}$$

where $N_1(x_1, x_2) = O(x_1^2 + x_2^2)$ and $\widetilde{N}_2(x_1, x_2) = O(\sqrt{x_1^2 + x_2^2})$. We note that the factor x_2 in the nonlinear term $\widetilde{N}_2(x_1, x_2)x_2$ is due to the fact that x_1-axis in the x space corresponds to the line $T = \lambda_1(S-1)$, $A = 0$, and $M = 1$ in the (S, T, A, M) space (indeed, this fact also implies that $h_1(x_1, 0) = 0$ and $h_2(x_1, 0) = 0$ so that we can write $h_1(x_1, x_2) = \tilde{h}_1(x_1, x_2)x_2$ and $h_2(x_1, x_2) = \tilde{h}_2(x_1, x_2)x_2$, correspondingly). To proceed further, we need to distinguish two cases based on whether $0 < \lambda_2 < \lambda_1$ or $\lambda_1 < \lambda_2$.

Case 1. Assume that $0 < \lambda_2 < \lambda_1$. We first fix a $\delta > 0$ so small that the set $x_1^2 + x_2^2 \leq \delta^2$ is negatively invariant for (2.12), the unstable manifold of (2.4)

$$W^u_{loc}(\delta) := \left\{ \begin{pmatrix} S \\ T \\ A \\ M \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix} + P \begin{pmatrix} x_1 \\ x_2 \\ h_1(x_1, x_2) \\ h_2(x_1, x_2) \end{pmatrix} : x_1^2 + x_2^2 \leq \delta^2 \right\} \tag{2.13}$$

is negatively invariant and, furthermore, $S > 0$ and $M > 0$ if $(S, T, A, M) \in W^u_{loc}(\delta)$. Hence, if $(x_1(z), x_2(z))$ is a solution of (2.12) with $x_1^2(0) + x_2^2(0) \leq \delta^2$, then, for all $z \in (-\infty, 0]$, $x_1^2(z) + x_2^2(z) \leq \delta^2$, and

$$\begin{pmatrix} S(z)-1 \\ T(z) \\ A(z) \\ M(z)-1 \end{pmatrix} = x_1(z)p_1 + x_2(z)p_2 + O\Big(x_1^2(z) + x_2^2(z)\Big) \tag{2.14}$$

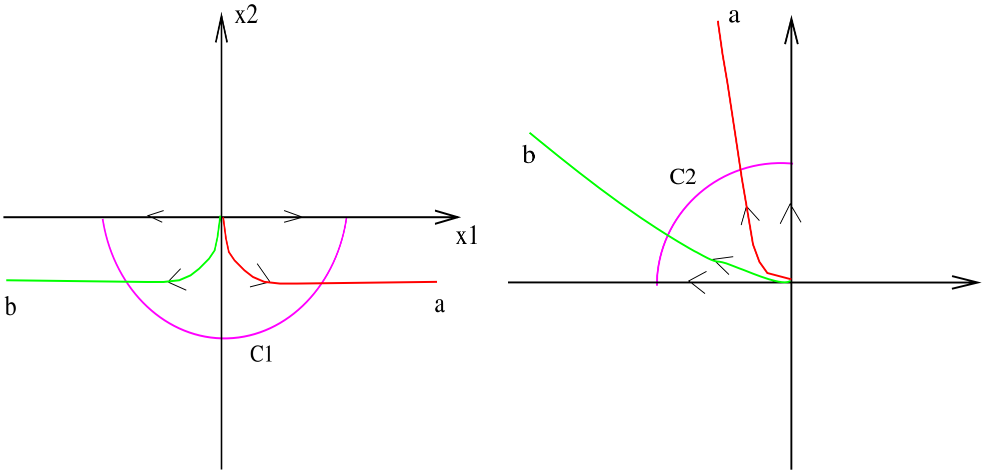

FIG. 2. *In the left figure, curve C_1 and four arrowed solution curves of system* (2.12) *are sketched in the (x_1, x_2)-plane: C_1 corresponds to curve* 4 *in the left figure of Figure* 1*, curve* a *to curve* 3*, curve* b *to curve* 5*, x_1-axis to curve* 2*, and x_2-axis to curve* 1*. In the right figure, curve C_2 and four arrowed solution curves of system* (2.17) *are sketched in the $(\tilde{x}_1, x_2)$-plane: C_2 corresponds to curve* 4 *in the right figure of Figure* 1*, curve* a *to curve* 3*, curve* b *to curve* 5*, $\tilde{x}_1$-axis to curve* 2*, and x_2-axis to curve* 6*.*

is a solution of (2.4) lying on $W^u_{loc}(\delta)$ for $z \in (-\infty, 0]$.

We now consider the solutions of (2.12) with initial values $(x_{10}(\theta), x_{20}(\theta)) = (\delta\cos\theta, \delta\sin\theta)$ with $\theta \in [-\pi, 0]$ on the lower half of the circle C_1: $x_{10}^2 + x_{20}^2 = \delta^2$; see the left figure in Figure 2. One can verify easily that the image of C_1 under the linear mapping P^{-1} defines the continuous curve Γ_1 as described in the outline of the proof of Theorem 2.1. Note that, in this case, the x_1-axis is the strongly one-dimensional unstable manifold of (2.12) (correspondingly, the line $T = b_1(S-1)$, $A = 0$, and $M = 1$ is the strongly one-dimensional unstable manifold of (2.4)). Therefore, for $\theta \in (-\pi, 0)$, we obtain from (2.12) that, as $z \to -\infty$,

$$\begin{pmatrix} x_1(z,\theta) \\ x_2(z,\theta) \end{pmatrix} = \nu_\theta e^{\lambda_2 z}\left[\begin{pmatrix} 0 \\ 1 \end{pmatrix} + O(e^{\lambda_2 z})\right] \tag{2.15}$$

for some $\nu_\theta \neq 0$. It then follows from (2.14) that, as $z \to -\infty$,

$$\begin{pmatrix} S_\theta(z) - 1 \\ T_\theta(z) \\ A_\theta(z) \\ M_\theta(z) - 1 \end{pmatrix} = \nu_\theta e^{\lambda_2 z}\left[p_2 + O(e^{\lambda_2 z})\right]. \tag{2.16}$$

Note that, for $\theta \in (-\pi, 0)$, $x_{20}(\theta) < 0$. It follows from (2.12) that, for $z < 0$,

$$x_2(z,\theta) = x_{20}(\theta) e^{\int_0^z [\lambda_2 + \widetilde{N}_2(x_1(\eta,\theta), x_2(\eta,\theta))]\, d\eta} < 0,$$

which yields from (2.15) that $\nu_\theta < 0$. Hence, from the signs of the components of p_2 and (2.16) we get $S_\theta(z) - 1 < 0$, $T_\theta(z) < 0$, and $A_\theta(z) > 0$ for all sufficiently negative z. Since $S_\theta > 0$ and $M_\theta > 0$ on $(-\infty, 0]$, (2.6) in Lemma 2.2(iii) gives $A_\theta > 0$, $M_\theta > 1$, and $f(S_\theta, A_\theta, M_\theta) > 0$ on $(-\infty, 0]$. Thus, we conclude that (a) $T_\theta = 0$ occurs at most once in $(-\infty, 0]$ since at such a point $T'_\theta = \alpha f(S_\theta, A_\theta, M_\theta) > 0$; (b) if $T_\theta(0) < 0$, then $T_\theta(z) < 0$ for all $z \in (-\infty, 0]$.

Next, note that, for $\theta = 0$, $(x_{10}(0), x_{20}(0)) = (\delta, 0)$ and (2.14) yield that $S_\theta(0) > 1$ and $T_\theta(0) = \lambda_1(S_\theta(0) - 1) > 0$. Then, the continuity of S_θ and T_θ in both z and θ implies $S_\theta(z) - 1 > 0$ and $T_\theta(z) > 0$ for z sufficiently close to 0 and $\theta \in (-\pi, 0)$ sufficiently close to 0. This together with the conclusions (a) and (b) yields that, for $\theta \in (-\pi, 0)$ sufficiently close to 0, T_θ changes sign exactly once in $(-\infty, 0)$. Note that, for any $\theta \in [-\pi, 0]$, $S^2_\theta(z) + T^2_\theta(z) > 0$ for any z in its domain (for if this is not true, the uniqueness theorem would yield $S_\theta \equiv 0$ and $T_\theta \equiv 0$, contradicting that $S^2_\theta(0) + T^2_\theta(0) > 0$). Therefore, letting

$$\Theta_1 = \left\{ \theta \in (-\pi, 0) : \exists z_\theta \in \mathbb{R} \text{ such that } \left\{ \begin{array}{l} T_\theta(z_\theta) = 0, \\ T_\theta < 0 \text{ on } (-\infty, z_\theta), \\ S_\theta > 0 \text{ on } (-\infty, z_\theta] \end{array} \right. \right\},$$

we see that Θ_1 contains all $\theta \in (-\pi, 0)$ sufficiently close to 0. Furthermore, for any $\theta \in \Theta_1$, by virtue of (2.6) and $S_\theta > 0$ on $(-\infty, z_\theta]$ we have $A_\theta > 0$, $M_\theta > 1$, $f(S_\theta, A_\theta, M_\theta) > 0$ on $(-\infty, z_\theta]$, and, consequently, $T'_\theta = \alpha f(S_\theta, A_\theta, M_\theta) > 0$ at $z = z_\theta$, which together with the conclusion (a) above and the continuity of $(S_\theta, T_\theta, A_\theta, M_\theta)$ in z and θ yields that Θ_1 is open (relative to the interval $(-\pi, 0)$).

Now, we define

$$\Theta_2 := \left\{ \theta \in (-\pi, 0) : \exists \bar{z}_\theta \in \mathbb{R} \text{ such that } \left\{ \begin{array}{l} S_\theta(\bar{z}_\theta) = 0, \\ S_\theta > 0 \text{ on } (-\infty, \bar{z}_\theta), \\ T_\theta < 0 \text{ on } (-\infty, \bar{z}_\theta] \end{array} \right. \right\},$$

and claim that, if $\theta \in (-\pi, 0)$ sufficiently close to $-\pi$, then $\theta \in \Theta_2$. This is because, for $\theta = -\pi$, $(S_{-\pi}, T_{-\pi})$ lies on the line $T = b_1(S - 1)$ with $T_{-\pi} < 0$, and, as $\theta \to -\pi$, the fact that $T_\theta(0) \to T_{-\pi}(0) < 0$ and the conclusion (b) above yields that $T_\theta < 0$ on $(-\infty, 0]$; furthermore, since there is a finite $\bar{z}_{-\pi} > 0$ such that $S_{-\pi}(\bar{z}_{-\pi}) = 0$, $S_{-\pi} > 0$ on $[0, \bar{z}_{-\pi})$, and $T_{-\pi} < 0$ on $[0, \bar{z}_{-\pi}]$, the continuity of S_θ and T_θ in z and θ yields that there is a $\bar{z}_\theta$ such that $S_\theta(\bar{z}_\theta) = 0$, $S_\theta > 0$ on $[0, \bar{z}_\theta)$, and $T_\theta < 0$ on $[0, \bar{z}_\theta]$. This shows the above claim. Since $T'_\theta(\bar{z}_\theta) < 0$ for any $\theta \in \Theta_2$, the same reasoning above yields that Θ_2 is open.

Since Θ_1 and Θ_2 are open and disjointed, the connectedness of the interval $(-\pi, 0)$ yields that there is a $\theta = \theta^* \in (-\pi, 0) \setminus (\Theta_1 \cup \Theta_2)$ so that $S_{\theta^*} > 0$ and $T_{\theta^*} < 0$ on its domain $(-\infty, \omega)$ (here we again used the fact that S_{θ^*} and T_{θ^*} cannot equal zero at the same z). Then, applying Lemma 2.2(iii) yields that $(S_{\theta^*}, T_{\theta^*}, A_{\theta^*}, M_{\theta^*})$ gives a desired solution of (2.4).

Case 2. Assume that $\lambda_1 < \lambda_2$. In this case, (2.12) has a unique strongly unstable manifold $x_1 = h(x_2)$ that is tangent to the x_2-axis (cf. [18]). We straighten this manifold by introducing $\tilde{x}_1 = x_1 - h(x_2)$ and use the identity (due to the local invariance of this manifold) $\lambda_1 h(x_2) + N_1(h(x_2), x_2) = h'(x_2)[\lambda_2 x_2 + \tilde{N}_2(h(x_2), x_2)x_2]$ to write (2.12) as, in terms of the new variables $(\tilde{x}_1, x_2)$,

$$(2.17) \qquad \left\{ \begin{array}{l} \tilde{x}'_1 = \lambda_1 \tilde{x}_1 + \tilde{N}_1(\tilde{x}_1, x_2)\tilde{x}_1, \\ x'_2 = \lambda_2 x_2 + \tilde{N}_2(\tilde{x}_1 + h(x_2), x_2)x_2, \end{array} \right.$$

where

$$\begin{aligned} \tilde{N}(\tilde{x}_1, x_2)\tilde{x}_1 = {} & N_1(\tilde{x}_1 + h(x_2), x_2) - N_1(h(x_2), x_2) \\ & - h'(x_2)[\tilde{N}_2(h(x_2), x_2) - \tilde{N}_2(\tilde{x}_1 + h(x_2), x_2)]x_2. \end{aligned}$$

As in Case 1, we fix a $\delta > 0$ so small that the set $\tilde{x}_1^2 + x_2^2 \le \delta^2$ is negatively invariant for (2.17), the unstable manifold $W^u_{loc}(\delta)$ of (2.4) is negatively invariant, and $S > 0$ and $M > 0$ if $(S, T, A, M) \in W^u_{loc}(\delta)$, where $W^u_{loc}(\delta)$ is defined in the same way as in (2.13) except that each x_1 in $(x_1, x_2, h_1(x_1, x_2), h_2(x_1, x_2))^\top$ is replaced by $\tilde{x}_1 + h(x_2)$ and that $x_1^2 + x_2^2 \le \delta^2$ is replaced by $\tilde{x}_1^2 + x_2^2 \le \delta$. Hence, if $(\tilde{x}_1, x_2)$ is a solution of (2.17) with $\tilde{x}_1^2(0) + x_2^2(0) \le \delta^2$, then, for all $z \in (-\infty, 0]$, $\tilde{x}_1^2(z) + x_2^2(z) \le \delta^2$, and

$$\begin{pmatrix} S(z) - 1 \\ T(z) \\ A(z) \\ M(z) - 1 \end{pmatrix} = \tilde{x}_1(z) p_1 + x_2(z) p_2 + O(\tilde{x}_1^2(z) + x_2^2(z)) \tag{2.18}$$

is a solution of (2.4) lying on $W^u_{loc}(\delta)$ for $z \in (-\infty, 0]$. We note that, in the $(\tilde{x}_1, x_2, x_3, x_4)$-coordinate system, $\tilde{x}_1$-axis corresponds to the line $T = b_1(S - 1)$, $A = 0$, and $M = 1$, and the curve defined by $\{(\tilde{x}_1 + h(x_2), x_2, h_1(\tilde{x}_1 + h(x_2), x_2), h_2(\tilde{x}_1 + h(x_2), x_2)) : \tilde{x}_1 = 0, |x_2| \le \delta\}$ corresponds to the strongly unstable manifold of (2.4) which is tangent to p_2.

Therefore, we consider the initial values $(\tilde{x}_{10}(\theta), x_{20}(\theta))$ on the quarter of the circle C_2: $\tilde{x}_1^2 + x_2^2 = \delta^2$ lying in the second quadrant with $\tilde{x}_{10}(\theta) = \delta \cos\theta < 0$ and $x_{20}(\theta) = \delta \sin\theta > 0$ for $\theta \in [\pi/2, \pi]$; see the right figure in Figure 2. The image of C_2 under the mapping $\hat{P}$ defines the curve Γ_2 as described in the outline of the proof of Theorem 2.1, where $\hat{P}$ is the composition function defined by $\hat{P} = P^{-1} \circ \tilde{P}^{-1}$, and here $\tilde{P}$ is the nonlinear mapping $\tilde{P}(\tilde{x}_1, x_2, x_3, x_4) = (\tilde{x}_1 + h(x_2), x_2, x_3, x_4)$. It follows from (2.17) that, for $\theta \in (\pi/2, \pi)$, there is a $\mu_\theta \ne 0$ such that, as $z \to -\infty$,

$$\begin{pmatrix} \tilde{x}_1(z, \theta) \\ x_2(z, \theta) \end{pmatrix} = \mu_\theta e^{\lambda_1 z} \left[\begin{pmatrix} 1 \\ 0 \end{pmatrix} + O(e^{\lambda_1 z}) \right], \tag{2.19}$$

and, from (2.18),

$$\begin{pmatrix} S_\theta(z) - 1 \\ T_\theta(z) \\ A_\theta(z) \\ M_\theta(z) - 1 \end{pmatrix} = \mu_\theta e^{\lambda_1 z} \left[\begin{pmatrix} 1 \\ \lambda_1 \\ 0 \\ 0 \end{pmatrix} + O(e^{\lambda_1 z}) \right]. \tag{2.20}$$

Since $\theta \in (\pi/2, \pi)$, $x_{10}(\theta) = \delta \cos\theta < 0$, it follows that, for $z \in (-\infty, 0]$,

$$\tilde{x}_1(z, \theta) = x_{10}(\theta) e^{\int_0^z [\lambda_1 + \tilde{N}_1(\tilde{x}(\eta, \theta), x_2(\eta, \theta))] \, d\eta} < 0.$$

This implies from (2.19) that $\mu_\theta < 0$, and then (2.20) yields $0 < S_\theta(z) < 1$, $T_\theta(z) < 0$, and $M_\theta(z) > 0$ for all sufficiently negative z. However, since the third component of p_1 is zero, we are unable to determine the sign of $A_\theta(z)$ near $z = -\infty$ from (2.20). In order to see this sign, noting that, as $z \to -\infty$,

$$\begin{aligned} A_\theta'' + b_2 A_\theta' - \gamma\sigma A_\theta &= -\gamma \Big\{ [\varphi_1(S_\theta) - \varphi_1(1)] \varphi_2(A_\theta) \varphi_3(1) \\ &\quad + \varphi_1(1)[\varphi_2(A_\theta) - \varphi_2'(0) A_\theta] \varphi_3(M_\theta) \\ &\quad + \varphi_1(1) \varphi_2'(0) A_\theta [\varphi_3(M_\theta) - \varphi_3(1)] \Big\} \\ &= O(e^{\lambda_1 z}) A_\theta, \end{aligned}$$

we obtain by the variation of constant formula that there is a $\tilde{\mu}_\theta \neq 0$ such that, as $z \to -\infty$,

$$\begin{pmatrix} A_\theta(z) \\ A'_\theta(z) \end{pmatrix} = \tilde{\mu}_\theta e^{\lambda_2 z} \left[\begin{pmatrix} 1 \\ \lambda_2 \end{pmatrix} + O(e^{\lambda_1 z}) \right]. \tag{2.21}$$

We claim that $\tilde{\mu}_\theta > 0$. If not, then (2.21) implies that $A_\theta(z) < 0$ for all sufficiently negative z. This together with (2.6) implies that $A_\theta < 0$, $M_\theta < 1$, and $f(S_\theta, A_\theta, M_\theta) < 0$ for all $z \in (-\infty, 0]$. (Note that, if necessary, we redefine $\varphi_3(M)$ for $M < 1/2$ such that $\varphi_3(M) = \varphi_3(1/2)$.) Then, using the first equation in (2.6) yields $T_\theta(0) - b_1[S_\theta(0) - 1] < 0$, which contradicts our choice of θ. Therefore, we must have $\tilde{\mu}_\theta > 0$ and so $A_\theta(z) > 0$ for all sufficiently negative z, as expected. Consequently, we have that $f(S_\theta, A_\theta, M_\theta) > 0$ on $(-\infty, 0]$, and we then conclude as in Case 1 that (a) $T_\theta = 0$ occurs at most once in $(-\infty, 0)$ since at such a point $T'_\theta = \alpha f(S_\theta, A_\theta, M_\theta) > 0$; (b) if $T_\theta(0) < 0$, then $T_\theta(z) < 0$ for all $z \in (-\infty, 0]$.

Next, we define the sets Θ_1 and Θ_2 in the same way as those in Case 1 except that $\theta \in (-\pi, 0)$ is replaced by $\theta \in (\pi/2, \pi)$ in each of those definitions. In a similar manner we show that Θ_1 contains all such $\theta \in (\pi/2, \pi)$ that are sufficiently close to $\pi/2$, and Θ_2 contains all such $\theta \in (\pi/2, \pi)$ that are sufficiently close to π. Consequently, the same shooting argument used in Case 1 yields that there exists at least one $\theta^{**} \in (\pi/2, \pi) \setminus (\Theta_1 \cup \Theta_2)$ such that the solution $(S_\theta, T_\theta, A_\theta, M_\theta)$ of (2.4) with $\theta = \theta^{**}$ gives a desired solution.

It remains to consider Case 3.

Case 3. We assume that either $\lambda_1 = \lambda_2$ or $\lambda_2 = 0$. As discussed in the outline of the proof of Theorem 2.1, we consider the approximating systems (2.10) with $n \geq n_0$ to which we are able to apply the results obtained in Cases 1 and 2 to obtain a sequence of solutions (S_n, T_n, A_n, M_n) of (2.10) that satisfy (2.5) and the estimates in (2.3). Since these estimates do not depend on n, using the equations in (2.10) we see that T'_n and M'_n are uniformly bounded on $\mathbb{R}$. Then, applying the Arzela–Ascoli theorem on $[-k, k]$ for each positive integer k and then using a diagonal selection process yield that there is a subsequence $(S_{n_k}, T_{n_k}, A_{n_k}, M_{n_k})$ that converges uniformly on any compact subset of $\mathbb{R}$, with its limit denoted by (S, T, A, M). Clearly, (S, T, A, M) is a solution of (2.4) on $\mathbb{R}$ and satisfies (2.3) in which the strict inequality signs "<" (resp., ">") are replaced by "$\leq$" (resp., "'$\geq$"). Consequently, since $S' = T \leq 0$ and $A' \geq 0$ on $\mathbb{R}$, the limits $(S(\pm\infty), A(\pm\infty))$ exist. Since M and $f(S, A, M)$ are bounded on $\mathbb{R}$, it follows from the last equation of (2.4) that M must satisfy the last equation in (2.6) which together with $f(S(z), A(z), M(z)) \to 0$ as $z \to \pm\infty$ yields that $M(\pm\infty) = 1$. By means of the first two equations in (2.1), we see that S'', A'' are bounded on $\mathbb{R}$ which together with $S' \leq 0$ and $A' \geq 0$ yields $T(\pm\infty) = A'(\pm\infty) = 0$. Therefore, $(S(\pm\infty), T(\pm\infty), A(\pm\infty), M(\pm\infty))$ must be equilibria of (2.4). Since all equilibria of (2.4) are given by $(S^*, 0, 0, 1)$ and $(0, 0, A^*, 1)$ for $A^* \geq 0$ and $S^* \geq 0$, it follows that $A(-\infty) = 0$, $S(\infty) = 0$, and then sending $z \to \pm\infty$ in the third equation of (2.4) yields $A(\infty) = 1$ and $S(-\infty) = 1$. Finally, we need to show (2.3). We first show that $A > 0$ on $\mathbb{R}$. For if not, since $A' \geq 0$, there is $z_0 \in \mathbb{R}$ such that $A = 0$ on $(-\infty, z_0]$ and $A > 0$ on (z_0, ∞), and then by the local uniqueness theorem it follows that $S' = b_1[S(z) - 1]$, $A \equiv 0$, and $M \equiv 1$ on $\mathbb{R}$, which is impossible. Thus $A > 0$ on $\mathbb{R}$. Next, we show that $S > 0$ on $\mathbb{R}$. For if not, since $S' \leq 0$, there is a $z_1 \in \mathbb{R}$ such that $S = 0$ on $[z_1, \infty)$ and $S > 0$ on $(-\infty, z_1)$, and again the local uniqueness theorem implies that $S \equiv 0$, $A' + b_2 A = 0$, and $M \equiv 1$ on $\mathbb{R}$, which is also impossible. This ensures $S > 0$ on $\mathbb{R}$. Hence, by virtue of $M \geq 1$, we have $f = f(S, A, M) > 0$ on $\mathbb{R}$.

Consequently, applying Lemma 2.2(iii) yields (2.7) and thereby (2.3). This completes the proof of Theorem 2.1. □

3. Conclusions. In this paper we have studied a basic bioremediation model that characterizes the essentials of a biodegradation process. The model describes the interactions between a dissolved contaminant, an injected nutrient, and single microbial species. We have established that, in a biologically active zone, the dissolved solute concentration and the advancing nutrient concentration move together as traveling fronts, while the bacteria concentration travels along as a traveling pulse. This confirms some earlier numerical observations. Compared to the existing results in the literature, the main improvement of our result lies in the application of a much broader range of kinetics which are more biologically realistic than the multiplicative Monod kinetics when modeling different kinds of pollutants. The estimates we obtained for traveling waves and their wave speeds provide qualitative and quantitative information on the concentrations of contaminant, nutrient, and bacteria as well as the removal rates of pollutants, and help identify key parameters in the model. We have employed a new dynamical systems approach in the proof of our main result, which produces a shorter and simpler proof. A future work will be investigating the uniqueness of the traveling waves in the sense that, for each wave speed, there is a unique traveling wave solution of the model.

CUCKER–SMALE FLOCKING UNDER HIERARCHICAL LEADERSHIP*

JACKIE (JIANHONG) SHEN†

Abstract. A mathematical theory on flocking serves the foundation for several ubiquitous multiagent phenomena in biology, ecology, sensor networks, and economics, as well as social behavior like language emergence and evolution. Directly inspired by the recent fundamental works of Cucker and Smale on the construction and analysis of a generic flocking model, we study the emergent behavior of Cucker–Smale flocking under *hierarchical leadership*. The rates of convergence towards asymptotically coherent group patterns in different scenarios are established. The consistent convergence towards coherent patterns may well reveal the advantages and necessities of having leaders and leadership in a complex (biological, technological, economic, or social) system with sufficient intelligence.

Key words. bio-flocking, leaders, leadership, Cucker–Smale model, dynamic graphs, graph Laplacian, Fiedler number, convergence, perturbation, free will

1. Introduction and motivations.

1.1. General background on flocking. Flocking, a universal phenomenon of multiagent interactions, has gained increasing interest from various research communities in biology, ecology, robotics and control theory, and sensor networks, as well as sociology and economics.

(i) (biology and ecology) The emergent behavior of bird flocks, fish schools, wolf packs, elephant herds, or bacteria aggregations, for example, has long been a major research topic in population and behavioral biology and ecology [4, 7, 8, 11, 12, 17, 23, 24].

(ii) (robotics and control) The coordination and cooperation among multiple mobile agents (robots or sensors) have been playing central roles in sensor networking, with broad applications in military, environmental control, and various field tasks [14, 25].

(iii) (economy and languages) Emergent economic behavior, such as a common belief in a price system in a complex market environment, is also intrinsically connected to flocking. The emergence of a common language in primitive societies is yet another example of a coherent collective behavior emerging within a complex system [8, 9].

The present work can largely be categorized into the biology realm, and has been directly inspired by the recent mathematical works of Cucker and Smale [7, 8], as the title suggests. Mathematical abstraction and rigorous analysis are more the focus herein than actual biological or physical realizability or feasibility. As in physics, the study of idealized models can often shed light on various observed patterns in the real world, *if* such models can indeed capture the very essence.

In biology and physics, the main goal of flocking study is to be able to interpret, model, analyze, predict, and simulate various flocking or multiagent aggregating behavior. Most works have been focusing on modeling and simulation [15, 27]. See, for example, the several important models investigated by Flierl et al. [12] (and their stochastic formulation). The more recent paper of Parrish, Viscido, and Grünbaum [18] also provides a comprehensive comparison among some major existing models and their governing variables (in the context of fish schooling). Quantitative analysis (as in [7, 8, 14]) on the asymptotic rates of emergence and convergence, on the other hand, has been relatively rare.

Mathematical efforts are gradually gaining strength in this multidisciplinary area. In the continuum limit, for example, there have been several recent efforts made by Bertozzi's group [23, 24], in which global swarming (i.e., with densely populated agents) patterns are modeled and analyzed via suitable spatiotemporal differential equations. Discrete-to-continuum limits of interacting particle systems have also been investigated by the same group [2, 11] recently. Consistent and generic mathematical analysis has been very much in an early stage for many biological aggregation phenomena. In the current paper, following the recent remarkable works of Cucker and Smale [7, 8] on flocking analysis, we attempt to further extend such research.

1.2. Cucker–Smale flocking model. Given a flock of k agents (birds, fish, wolves, etc.) labeled $i = 1, 2, \dots, k$, the Cucker–Smale flocking model is specified by the *nonlinear* autonomous dynamic system:

$$\begin{cases} \dot{x}_i(t) = v_i, \\ \dot{v}_i(t) = \sum_{j \in \mathcal{L}(i)} a_{ij}(x)(v_j - v_i), \qquad i = 1:k,\ t > 0, \end{cases} \tag{1.1}$$

where $x_i(t)$ and $v_i(t)$ are 3D (three-dimensional, which is nonessential) position and velocity vectors at time t, $x = (x_1, \dots, x_k) \in (\mathbb{R}^3)^k$, and $\mathcal{L}(i) \subseteq \{1, \dots, k\}$ denotes the subgroup of agents that directly influence agent i. Furthermore, the *connectivity coefficients* $a_{ij}(x)$ take the form

$$a_{ij}(x) = w(|x_i - x_j|^2) \qquad \text{for some nonnegative weight profile } w(y).$$

In the current paper, by *Cucker–Smale flocking model*, we require as in [7, 8] that the interaction weight function $w(y)$ take the form

$$w(y) = \frac{H}{(1+y)^\beta} \qquad \text{or} \qquad w(y) \geq \frac{H}{(1+y)^\beta}, \tag{1.2}$$

where H and β are two positive system parameters. One shall see that the two ($=$ vs. $\geq$) make no difference in the analysis hereafter as long as $w(y)$ is bounded and sufficiently smooth (also see [7]). We also must point out that this model has been put in a more general and abstract setting in the subsequent work of Cucker and Smale [8].

The look of system (1.1) is not entirely new. For example, the 2D model studied by Vicsek et al. [27] is very similar in that v_i's share the same magnitude (or speed), while their heading directions θ_i's satisfy a similar set of equations.

It is the particular choice of the connectivity coefficients in (1.2) that has made the Cucker–Smale model mathematically more attractive. Vicsek et al.'s model (in discrete time) [27] can be considered as taking the following cut-off weight function:

$$w(y) = w_r(y) = 1_{y \leq r^2}(y), \qquad \mathcal{L}(i) \equiv \{1, \dots, k\} \quad \forall i.$$

That is, two distinct agents, x_i and x_j, interact if and only if they are within a distance of $r > 0$, which is assigned a priori and fixed throughout. Moreover, the nonzero weights are uniformly 1's. The lack of long-range interactions has made the model very difficult to analyze. For example, the remarkable efforts of Jadbabaie, Lin, and Morse [14] on emergence analysis avoided the actual dynamic dependence of a_{ij} on the configuration x. Instead, they focused on an altered setting that involves switching controls. The convergence results obtained for this approach, however, rely on the infinite time-sequence of states of the system.

The main results of Cucker and Smale [7] can be summarized as follows: when $\beta < 1/2$, the flock converge to some translating rigid structure (moving at a constant velocity) *unconditionally*, i.e., regardless the initial configuration; and when $\beta \geq 1/2$, the initial velocities and positions have to satisfy certain compatible conditions so that the entire flock can converge asymptotically.

In summary, in the modeling and analysis of Cucker and Smale [7, 8], not only are the conditions for pattern emergence easily verifiable (i.e., by checking the initial conditions), but the role of long-range interaction is also clearly quantified. A smaller β signifies more intense long-range interactions among agents, while a bigger β leads to much weaker ones. It has been shown that the critical exponent $\beta_c = 1/2$ is sharp and necessary. Previously, the connection between global pattern emergence and individual action rules has often only been observed experimentally or addressed empirically. (Vicsek et al. [27], for example, experimentally observed phase transition induced by population density ρ and random fluctuation η. A higher density corresponds to more interaction among agents, or loosely, smaller β in the Cucker–Smale model.)

1.3. Motivations and main results of current work. In the current work, we investigate the emergent behavior of Cucker–Smale flocking under hierarchical leadership (HL), which will be defined in detail in the next section.

Roughly, an HL flock is one whose members can be ordered in such a way that lower-rank agents are led and only led by some agents of higher ranks. As explained in more detail in section 2, for HL flocks, it is often either nontrivial or impossible to define a "fixed" inner product so that the Fiedler number of the associated (graph) Laplacian can be exploited, which is the key to the original work of Cucker and Smale [7] and its subsequent generalization [8]. The current work thus takes a somewhat different approach in order to fully benefit from the characteristic structures of HL.

As far as applications are concerned, there are two types of HL: passive and active.

(A) (passive/transient leadership)

(A.1) (disturbed bird flocks) In nature, certain types of leadership emerge in a transient and dynamic fashion and are often prompted by a specific environment. For a disturbed bird flock at rest, for example, the bird that first senses the approach of an unexpected pedestrian or predator often takes flight first, warns others, and first gains full speed, and consequently flies ahead of the entire flock and serves as a virtual leader.

(A.2) (driving in a traffic) During rush hours, each individual driver mainly maneuvers according to the moving patterns of several cars right ahead in the visual field. Thus a chain of leadership naturally arises and extends linearly along the traffic. The leadership here is also prompted by the environment rather than being intrinsic among the stranger drivers.

(B) (active/intrinsic leadership)

(B.1) (governmental/military hierarchies) Such hierarchical leadership is inherent in various social groups or structures, and often leads to more efficient management. Examples include the chain of President–Governor–Mayor in the governmental system, and the military chain of command from the Commander-in-Chief all the way down to the soldiers.

(B.2) (social animals) For some social animals such as monkeys, wolves, or elephants [4], the group or social status of each member is clearly recognized by others, is stably maintained, and guides the action of each individual in the hierarchies. (See also the recent work of Couzin et al. [4] for nonhierarchical but "effective" leadership.)

Our main results are the three theorems summarized below. All HL flocks are assumed to have Cucker–Smale connectivity introduced in the preceding subsection.

(i) (section 3) For an HL $(k+1)$-flock marching at a sufficiently small *discrete* time step h, under a similar classification scheme according to whether $\beta < \beta_c$, $= \beta_c$, or $> \beta_c$, as in Cucker and Smale [7, 8], the velocities of the flock converge at a rate of $O(\rho_h^n n^{k-1})$, where the factor $\rho_h \in (0,1)$ depends only on h, system parameters, and the initial configuration of the flock. The critical exponent is given by $\beta_c = 1/(2k)$, instead of $\beta_c = 1/2$ in the original work of Cucker and Smale [7]. (For a 2-flock (with $k = 1$) they are the same. For $k > 1$, the β_c herein could be overrestrictive and due to the deficiency of the particular methodology adopted.)

(ii) (section 4) For an HL flock under continuous-time dynamics, when $\beta < 1/2$, there exists some $B > 0$, such that the velocities of the flock converge at an exponential rate of $O(e^{-Bt})$. The constant B depends only on the system parameters and the initial configuration of the flock. (From the simple calculation on an HL 2-flock, $\beta_c = 1/2$ is sharp in order to achieve *unconditional* convergence.)

(iii) (section 5) For an HL $(k+1)$-flock $[0, 1, \ldots, k]$ of which the overall leader agent 0 takes a free-will acceleration $\dot{v}_0 = f(t)$ (thus the system is no longer autonomous), as long as the overall leader behaves moderately so that $f(t) = O((1+t)^{-\mu})$ for some $\mu > k$, the velocities of the flock will still converge at a rate of $O((1+t)^{-(\mu-k)})$ when $\beta < 1/2$. (By (ii) where $f \equiv 0$, $\beta_c = 1/2$ is again sharp for unconditional convergence.)

We also mention that Jadbabaie, Lin, and Morse [14] also studied (under discrete time and working with Vicsek et al.'s orientation model [27]) the effect of a *single* leader moving at a *fixed constant* velocity. As mentioned above, due to the difficulty in dealing with configuration-dependent dynamics, the authors switched to the study of an altered *control* problem (under the assumption of intermittent joint connectivity).

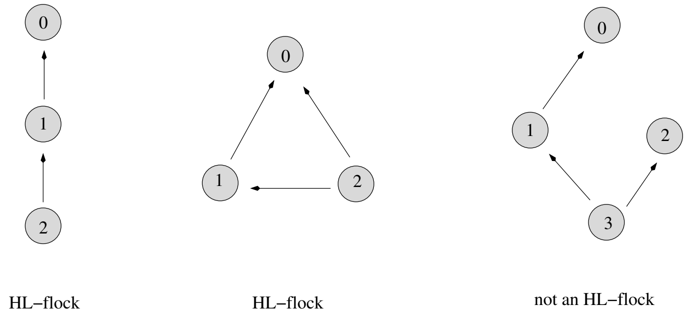
In addition to the three main sections mentioned above, definitions and further detailed background will be introduced in section 2. The conclusion is drawn in section 6.

2. HL flocks and definability of compatible inner products.

2.1. Flocks under hierarchical leadership (HL flocks).

DEFINITION 2.1 (an HL flock). *A $(k+1)$-flock is said to be under* hierarchical leadership *if the agents (birds, fish, wolves, etc.) can be labeled* $[0, 1, \ldots, k]$, *such that*

(i) $a_{ij} = a_{\text{agent } i \text{ led by } j} \neq 0$ *implies that* $j < i$; *and*



HL−flock HL−flock not an HL−flock

Fig. 2.1. *Two examples of HL flocks and one example of a non-HL flock. The arrow $i \to j$ means that agent i is led by agent j, or, equivalently, $a_{ij} > 0$. Visually, it means that i looks up to j.*

(ii) *if we define the* leader set *of each agent i by*

$$\mathcal{L}(i) = \{j \mid a_{ij} > 0\},$$

then for any $i > 0$, $\mathcal{L}(i) \neq \varnothing$ (nonempty).
If so, the flock is called an HL flock.

Notice that the second condition requires that, except for agent 0, all the others must be subject to some leadership. On the other hand, the first condition implies that $\mathcal{L}(0) = \varnothing$. Thus agent 0 is the overall leader (*direct or indirect*) for the entire flock. Figure 2.1 depicts the connectivity structure of two HL flocks and one non-HL flock.

Proposition 2.2 (connectivity matrix of an HL flock). *A $(k+1)$-flock is an HL flock if and only if after some ordered labeling $[0, 1, \dots, k]$ the connectivity matrix $K = (a_{ij})_{0 \le i,j \le k}$ is lower triangular and, for any row $i > 0$, there exists at least one positive off-diagonal element a_{ij}.*

Subject to convenience, in what follows a generic HL flock shall be denoted by either $[0, 1, \dots, k]$ or $[1, \dots, k]$. Following a setting similar to Cucker and Smale [7] or Chung [3], define the graph Laplacian matrix by

$$L = D - K, \qquad D = \operatorname{diag}(d_0, \dots, d_k), \qquad d_i = \sum_j a_{ij}. \tag{2.1}$$

Similarly, define the two (nonorthogonally) complementing subspaces of $\mathbb{R}^{k+1}$:

$$\Delta = \operatorname{span}\left\{ \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix}_{k+1} \right\} \quad \text{and} \quad \mathbb{R}^k = \left\{ \begin{pmatrix} 0 \\ x_1 \\ \vdots \\ x_k \end{pmatrix} \mid x_i's \in \mathbb{R} \right\}.$$

Then it is easy to see that

$$\Delta = \operatorname{Ker}(L), \qquad \mathbb{R}^k = \operatorname{Range}(L) \text{ is } L\text{-invariant}.$$

Notice that the kernel assertion is directly guaranteed by the second condition of an HL flock, without which the kernel could be larger.

From now on, as in Cucker and Smale [7, 8], we shall consider only the restriction of the Laplacian on the reduced space $\mathbb{R}^k$. Then it becomes nonsingular and shall still be denoted by L for convenience. *We also must point out that when applied to actual flocking, the reduced Laplacian L is applied to $\mathbb{R}^{3k}$ (instead of $\mathbb{R}^k$) via the three spatial dimensions individually.*

2.2. Definability of compatible inner products. The general framework of Cucker and Smale [7] relies upon the Fiedler number of the Laplacian operator L, i.e., the smallest positive eigenvalue in the reduced space. In particular, it assumes the existence of a fixed inner product $\langle \cdot, \cdot \rangle$ such that

$$\langle Lv, v \rangle \geq \xi \langle v, v \rangle \qquad \text{for any } v \in \mathbb{R}^k. \tag{2.2}$$

Then an a priori lower bound on $\xi = \xi(x)$ constitutes the core to the convergence results established by Cucker and Smale [7, 8]. Below we show, however, that such inner products could fail to exist for nonsymmetric systems like HL flocks.

THEOREM 2.3. *Consider the special HL $(k+1)$-flock $[0, 1, \ldots, k]$ such that $\mathcal{L}(i) = \{i-1\}$ for $i > 0$, and an instant when $a_{i,i-1} \equiv a$ for some fixed $a > 0$ and any $i > 0$. Then the smallest eigenvalue is $\xi = a$, but there exists no inner product $\langle \cdot, \cdot \rangle$ in the reduced space $\mathbb{R}^k$ such that*

$$\langle Lv, v \rangle \geq a \langle v, v \rangle, \qquad v \in \mathbb{R}^k.$$

Proof. It is easy to see that the (reduced) Laplacian L is given by

$$L = L_a = \begin{bmatrix} a & 0 & \dots & 0 & 0 \\ -a & a & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & -a & a \end{bmatrix}_{k \times k}.$$

In particular, $L_a = aL_1$, and it suffices to prove the case when $a = 1$. If such an inner product did exist, one would have

$$\langle L_1 v, v \rangle \geq \langle v, v \rangle \quad \text{or} \quad \langle Jv, v \rangle \geq 0,$$

where $J = L_1 - Id$. Notice that $Jv = (0, -z_1, \ldots, -z_{k-1})^T$ for $v = (z_1, \ldots, z_k)^T$.

Let $\{e_1, \ldots, e_k\}$ denote the canonical basis of $\mathbb{R}^k$, and define

$$G = (g_{ij}) = (\langle e_i, e_j \rangle)_{k \times k}$$

to be the associated Grammian matrix of the inner product. Then G must be positive definite. For any $v = (z_1, \ldots, z_k)^T$, one has

$$\langle v, Jv \rangle = v^T G \cdot Jv = (z_1, \ldots, z_k)(g_{ij})(0, -z_1, \ldots, -z_{k-1})^T.$$

Consider a special vector of the form $w = w_t = (0, \ldots, 0, 1, t)^T \in \mathbb{R}^k$. Then

$$\langle w_t, Jw_t \rangle = (0, \ldots, 0, 1, t)(g_{ij})(0, \ldots, 0, 1)^T = g_{k-1,k} + g_{k,k} t.$$

Notice that $g_{k,k} = \langle e_k, e_k \rangle > 0$. Then for any

$$t < -\frac{|g_{k-1,k}|}{g_{k,k}},$$

one must have $\langle w_t, Jw_t \rangle < 0$, which is contradictory. ∎

Even when such compatible inner products do exist, for a general nonsymmetric flock, they often depend on the configuration of the flock, and are thus time-dependent. This causes much inconvenience or a potential impasse for the Cucker–Smale approach in [7, 8]. The efforts in the current work follow a different approach by exploiting the specific structures of HL flocks.

3. Discrete-time emergence. Recall that in continuous time, the Cucker–Smale flocking model is given by

$$\begin{cases} \dot{x} = v, \\ \dot{v} = -L_x v, \qquad t > 0, \end{cases} \tag{3.1}$$

where the reduced Laplacian $L = L_x$ is defined as in (2.1) and both x and v are considered in the reduced (quotient) space. For a $(k+1)$-flock, both of them belong to $\mathbb{R}^{3k}$.

Fix a discrete time step $h > 0$. Define

$$x[n] = x(nh), \qquad v[n] = v(nh), \quad \text{and} \quad L_n = L_{x[n]}.$$

(Note: the parenthesis-bracket correspondence follows the convention in digital signal processing [22].) Then the continuous-time system (3.1) is discretized to

$$\begin{cases} x[n+1] = x[n] + hv[n], \\ v[n+1] = S[n]v[n], \qquad n = 0, 1, \ldots, \end{cases} \tag{3.2}$$

where $S[n] = S^h[n] = Id - hL_n$.

For an HL $(k+1)$-flock $[0, 1, \ldots, k]$, recall that the reduced Laplacian is given by

$$L_n = \begin{bmatrix} d_1[n] & 0 & \ldots & 0 & 0 \\ -a_{21}[n] & d_2[n] & \ldots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ -a_{k1}[n] & -a_{k2}[n] & \ldots & -a_{k,k-1}[n] & d_k[n] \end{bmatrix}_{k \times k}. \tag{3.3}$$

For $i > 0$, since the leader set $\mathcal{L}(i) \neq \varnothing$, we have

$$d_i[n] = \sum_{j=1}^{k} a_{ij}[n] = \sum_{j \in \mathcal{L}[i]} a_{ij}[n] > 0. \tag{3.4}$$

Under the Cucker–Smale model, one has for any $j \in \mathcal{L}(i)$

$$a_{ij}[n] = \frac{H}{\left(1 + |\tilde{x}_j[n] - \tilde{x}_i[n]|^2 / 2\right)^{\beta}}, \tag{3.5}$$

where $\tilde{x}_i$ denotes the original 3D position vector of agent i (and the factor $1/2$ is for convenience). In the reduced quotient space, one has $x_i = \tilde{x}_i - \tilde{x}_0 \in \mathbb{R}^3$ since the original configuration vector $\tilde{x} \in \mathbb{R}^{3(k+1)}$ and the reduced representation $x \in \mathbb{R}^{3k}$ are connected via

$$\tilde{x} = \begin{bmatrix} \tilde{x}_0 \\ \tilde{x}_1 \\ \vdots \\ \tilde{x}_k \end{bmatrix} = \begin{bmatrix} \tilde{x}_0 \\ \tilde{x}_0 \\ \vdots \\ \tilde{x}_0 \end{bmatrix} + \begin{bmatrix} 0 \\ \tilde{x}_1 - \tilde{x}_0 \\ \vdots \\ \tilde{x}_k - \tilde{x}_0 \end{bmatrix} = \begin{bmatrix} \tilde{x}_0 \\ \tilde{x}_0 \\ \vdots \\ \tilde{x}_0 \end{bmatrix} + \begin{bmatrix} 0 \\ x \end{bmatrix}.$$

As a result, for any pair $i, j > 0$,

$$|\tilde{x}_i - \tilde{x}_j|^2 = |x_i - x_j|^2 \leq 2(|x_i|^2 + |x_j|^2) \leq 2|x|^2.$$

In combination with (3.4) and (3.5), this implies that under the Cucker–Smale connectivity,

$$d_i[n] \geq \frac{H}{(1+|x[n]|^2)^{\beta}}, \qquad i > 0. \tag{3.6}$$

Assume, as in Cucker and Smale [7], that under suitable initial conditions (according to whether $\beta <, =$, or $> \beta_c = 1/(2k)$), one has the uniform bound on the reduced position vector:

$$|x[n]|^2 \leq B_h \qquad \text{for } n = 0, 1, \ldots, \tag{3.7}$$

where B_h is a constant bound depending only on h, the system parameters H and β, as well as the initial configuration. (The existence of B_h is a crucial ingredient of the proof and will be further addressed immediately after this main line.) Then one has, for any $n \geq 0$ and $i > 0$,

$$d_i[n] \geq d_* = \frac{H}{(1+B_h)^{\beta}}. \tag{3.8}$$

Proposition 3.1 (uniform elementwise bound on S). *For $0 < h < \frac{1}{2kH}$, $S_{ij}[n] \geq 0$ for any i, j, and*

$$\max_{i,j} S_{ij}[n] \leq 1 - hd_* := \rho_h, \qquad n = 0, 1, \ldots. \tag{3.9}$$

Proof. By definition,

$$S[n] = Id - hL_n \begin{bmatrix} 1-hd_1[n] & 0 & \ldots & 0 & 0 \\ ha_{21}[n] & 1-hd_2[n] & \ldots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ ha_{k1}[n] & ha_{k2}[n] & \ldots & ha_{k,k-1}[n] & 1-hd_k[n] \end{bmatrix}_{k\times k}.$$

Under the condition on h, for the off-diagonals $i > j$, we have

$$S_{ij}[n] = ha_{ij} \leq hH < \frac{1}{2k} \leq \frac{1}{2}.$$

For the diagonals, since $a_{ij} \leq H$, we have $d_i \leq (k-1)H$, and

$$S_{ii}[n] = 1 - hd_i \geq 1 - h(k-1)H > 1 - \frac{1}{2} = \frac{1}{2}.$$

Therefore,

$$\max_{ij} S_{ij}[n] = \max_i S_{ii}[n] = 1 - h \min_i d_i \leq 1 - hd_*,$$

which completes the proof. □

Next, our goal is to be able to control the growth rate of the matrix iteration:

$$S[n]S[n-1]\cdots S[0] \qquad \text{as } n \to \infty.$$

Normally, such asymptotic behavior is investigated via the so-called joint spectral radius (e.g., Rota and Strang [19], Daubechies and Lagarias [10], or Shen [20, 21]),

$$\lim_{n\to\infty} \|S[n]S[n-1]\cdots S[0]\|^{\frac{1}{n}},$$

which is often too complex to be feasible since the matrices evolve and generally do not commute. The approach below resembles the Lebesgue dominant convergence theorem in analysis [16].

Definition 3.2 (domination). *A matrix $B = (b_{ij})$ is said to be dominated by another matrix $C = (c_{ij})$ of equal dimensions if*

$$|b_{ij}| \leq c_{ij} \qquad \text{for any } i, j.$$

If so, we write $B \prec C$.

Proposition 3.3. *There exists some constant α, such that whenever $B \prec C$,*

$$\|B\| \leq \alpha \|C\|.$$

Here α depends only on the type of matrix norm adopted.

Proof. All norms in a finite-dimensional Banach space are equivalent. Therefore, it suffices to establish the inequality under any special matrix norm. Consider the Fröbenius norm:

$$\|B\|^2 = \text{trace}(BB^T) = \sum_{i,j} b_{ij}^2 \leq \sum_{i,j} c_{ij}^2 = \text{trace}(CC^T) = \|C\|^2,$$

with $\alpha = 1$ (the superscript T here denotes the transpose). The general constant α resurfaces when another norm is used instead. □

Proposition 3.4. *Suppose $B_i \prec C_i$ for $i = 0, \ldots, n$. Then*

$$B_n B_{n-1} \cdots B_0 \prec C_n C_{n-1} \cdots C_0.$$

The proof is trivial. Next we define a "complete" lower triangular matrix $T = (t_{ij})_{k\times k}$ by

$$t_{ij} = \begin{cases} 1, & i \geq j; \\ 0 & \text{otherwise.} \end{cases}$$

Then the elementwise bound established in Proposition 3.1 directly implies the following.

Corollary 3.5. *Let $\rho_h = 1 - hd_*$ as in Proposition* 3.1*. Then*

$$S[n] \prec \rho_h T, \quad \text{and} \quad S[n-1] \cdots S[0] \prec \rho_h^n T^n, \qquad n = 0, 1, \ldots.$$

Lemma 3.6. *Let $T = (t_{ij})_{k\times k}$ be defined as above. Then $\|T^n\| = O(n^{k-1})$.*

Proof. Denote by J the $k \times k$ lower triangular matrix whose nonzero elements are all 1's and are *only* distributed right below the diagonal, e.g., the 3×3 case,

$$J = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

Then it is easy to see that

$$T = I + J + \cdots + J^{k-1}.$$

Since $J^k = J^{k+1} = \cdots = 0_{k\times k}$, one can also write

$$T = \sum_{m=0}^{\infty} J^m.$$

More generally, for any t with $|t| < 1$, one can define

$$T(t) = \sum_{m=0}^{\infty} t^m J^m = (I - tJ)^{-1}.$$

Then

$$T(t)^n = (I - tJ)^{-n} = \sum_{m=0}^{\infty} \binom{-n}{m} (-t)^m J^m = \sum_{m=0}^{k-1} \binom{n+m-1}{m} t^m J^m.$$

Letting $t \to 1$, we have

$$T^n = \lim_{t \to 1} T(t)^n = \sum_{m=0}^{k-1} \binom{n+m-1}{m} J^m \prec O(n^{k-1})T.$$

The proof is then complete via Proposition 3.3. □

Combining all the preceding results in this section, we have arrived at the following conclusion.

THEOREM 3.7. *In the discrete-time Cucker–Smale model* (3.2) *for an HL* $(k+1)$*-flock, for any sufficiently small marching step h (as in* (3.7)*, Proposition* 3.1*, and Cucker and Smale* [7, 8]*), there exists some* $\rho_h \in (0, 1)$ *under the conditions similar to* [7, 8] *based upon whether* $\beta <, =,$ *or* $> \beta_c = 1/(2k)$*, such that*

$$S[n] \cdots S[0] \prec O(\rho_h^n n^{k-1})T.$$

In particular, one has

$$|v[n]| \leq O(\rho_h^n n^{k-1})|v[0]|, \qquad n \to \infty.$$

The order constant in $O(\cdot)$ *depends only on the size k of the flock.*

We point out that the polynomial growth rate $O(n^{k-1})$ (coming from T^n in Lemma 3.6) is characteristic of triangular HL flocks. A "full" system would make the approach here infeasible since

$$\begin{bmatrix} 1 & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 1 \end{bmatrix}_{k \times k}^n = \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} \begin{pmatrix} 1 & \cdots & 1 \end{pmatrix} \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} \cdots\cdots \begin{pmatrix} 1 & \cdots & 1 \end{pmatrix} = k^{n-1} \begin{bmatrix} 1 & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 1 \end{bmatrix}.$$

The exponential growth rate k^n would thus overpower ρ_h^n and lead to an exponential blowup.

Finally, we further address the important issue raised earlier in the proof concerning the boundedness condition in (3.7): $|x[n]|^2 \leq B_h$ for all n. The existence of the convergence factor ρ_h has crucially depended on such a bound B_h. On the other hand, the very existence of B_h, as we intend to show now, depends on ρ_h. This *entanglement* is characteristic of the nonlinear Cucker–Smale flocking model (as well as in Vicsek et al. [27] and Jadbabaie, Lin, and Morse [14]) and makes this type of model difficult to analyze. In the rest of the section, we introduce the brilliant approach of Cucker and Smale in unraveling such entanglement, which then genuinely completes the proof.

Lemma 3.8. *For any given integer $k \geq 1$ and $t \in [0, 1)$, one has*

$$\sum_{m=0}^{\infty} t^m m^{k-1} \leq (k-1)!(1-t)^{-k}. \tag{3.10}$$

Proof. Notice that the equality holds when $k = 1$. Generally, for any $t \in [0, 1)$,

$$\begin{aligned}(k-1)!(1-t)^{-k} &= (k-1)! \sum_{m=0}^{\infty} \binom{-k}{m} (-t)^m \\ &= (k-1)! \sum_{m=0}^{\infty} \binom{m+k-1}{k-1} t^m \\ &= \sum_{m=0}^{\infty} (m+k-1) \cdots (m+1) t^m \\ &\geq \sum_{m=0}^{\infty} m^{k-1} t^m,\end{aligned}$$

which completes the proof. □

We now apply the self-bounding technique developed by Cucker and Smale in [7, 8] to establish the bound $\left|x[n]\right|^2 \leq B_h$ that is crucially needed in the proof of Theorem 3.7. It also explains the origin of the critical exponent $\beta_c = 1/(2k)$ and its role.

We thus return to the step in (3.7). This time, instead of assuming a priori that $\left|x[n]\right|^2 \leq B_h$ for *all* $n \geq 0$, we proceed as follows. Fix any discrete time mark N, and define

$$|x|_* = \max_{0 \leq n \leq N} |x|[n], \qquad N_* \in \operatorname{argmax}_{0 \leq n \leq N} |x|[n], \tag{3.11}$$

and similarly define

$$d_* = \frac{H}{(1 + |x|_*^2)^{\beta}}. \tag{3.12}$$

Thus $|x|_*$ could be considered as a "localized" version of B_h, restricted in any designated *finite* time segment $[0, N]$.

Then all the earlier analysis and results hold up to the bounding formula on $|v|[n]$ in Theorem 3.7, as long as one restricts n to be within $[0, N]$. In particular for $\rho_h = 1 - hd_*$,

$$|v|[n] \leq A \rho_h^n n^{k-1}, \qquad n = 0, \dots, N,$$

where the constant A depends only on k but on neither n nor N.

Therefore, by the first equation of HL flocking in (3.2), for any $n \in [0, N]$,

$$\begin{aligned}|x|[n] &\leq |x|[0] + \sum_{m=0}^{n-1} |x[m+1] - x[m]| = |x|[0] + h \sum_{m=0}^{n-1} |v[m]| \\ &\leq |x|[0] + Ah \sum_{m=0}^{n-1} \rho_h^m m^{k-1} \leq |x|[0] + Ah \sum_{m=0}^{\infty} \rho_h^m m^{k-1} \\ &\leq |x|[0] + (k-1)! Ah (1 - \rho_h)^{-k}.\end{aligned}$$

In particular, for $n = N_*$,

$$|x|_* = |x|[N_*] \le |x|[0] + (k-1)!Ah(1-\rho_h)^{-k}.$$

Now that

$$(1-\rho_h)^{-k} = h^{-k}d_*^{-k} = (hH)^{-k}(1+|x|_*^2)^{\beta k},$$

one has the Cucker–Smale type of self-bounding inequality for the unknown $|x|_*$:

$$|x|_* \le |x|[0] + (k-1)!Ah(hH)^{-k}(1+|x|_*^2)^{\beta k}.$$

Define $Z = (1+|x|_*^2)^{1/2}$. Then

$$Z \le 1 + |x|_* \le c + bZ^{2\beta k}, \tag{3.13}$$

with $c = 1 + |x|[0]$ and $b = (k-1)!Ah(hH)^{-k}$.

The rest of the analysis then goes exactly as in Cucker and Smale [7, 8]. Define

$$F(z) = z - bz^s - c, \qquad \text{with } s = 2\beta k \quad \text{and} \quad z > 0.$$

Then when $s < 1$, the nonlinear function $F(z)$ has a unique zero z_* after which F stays positive. Since $F(Z) \le 0$, one thus must have $Z \le z_*$, or

$$|x|_* \le Z \le z_*.$$

Now that z_* depends only on c and b, which are independent of the preassigned time mark N, we have obtained the uniform bound

$$|x|[N] \le |x|[N_*] = |x|_* \le z_* \qquad \forall\ N = 0, 1, \ldots.$$

Thus $B_h = z_*^2$ is the uniform bound needed in the proof of Theorem 3.7. This is the case when $\beta \le \beta_c = 1/(2k)$.

The other two cases, when $\beta = \beta_c$ and $\beta > \beta_c$ (corresponding to $s = 1$ and $s > 1$ for $F(z)$), can be analyzed exactly in the same manner as in Cucker and Smale [7, 8], and will be omitted here. In particular, in both cases, there will be *sufficient*-type conditions on the initial configurations in order for the bound B_h to exist. In the third case, $\beta > \beta_c$, there will also be a more stringent upper bound on the time marching size h. We refer the reader to Cucker and Smale for the detailed analysis on $F(z)$ in these two cases. This completes the proof of Theorem 3.7.

In the next section, we investigate the emergent behavior of the continuous-time HL flocking using quite different methods. There, the results hint that the unconditional convergence range $\beta \in [0, 1/(2k))$ just established might still be extendable onto $[0, 1/2)$, as in Cucker and Smale [7]. Thus the critical exponent $\beta_c = 1/(2k)$ might be further improved if other alternative approaches are to be investigated in the future.

4. Continuous-time emergence.

Let $[1, \ldots, k]$ be an HL k-flock in that order, connected via the Cucker–Smale strength with parameters β and H as in (1.2). In this section, we establish the emergence behavior for the entire flock when $\beta < 1/2$, via the methods of induction and perturbation. The associated intuition is as follows. If the subflock $[1, \ldots, i-1]$ almost reaches convergence, it shall look like a rigid one-body to agent i. Then $[1, \ldots, i-1, i]$ is not far from a simpler two-agent flock. Our goal is to develop rigorous mathematical analysis to quantify and support this perspective. (In this section, we shall work with $[1, \ldots, k]$ instead of $[0, 1, \ldots, k]$ due to the lack of advantage of introducing index 0.)

4.1. The property of positivity. The general properties to be established in this subsection are characteristic of the Cucker–Smale flocking model. They could be useful for any future works on the model, on top of their roles in the proof of the main results of this section.

Let $x_i, v_i \in \mathbb{R}^3$ denote the 3D position and velocity vectors of agent i. Recall that the Cucker–Smale flocking model is given by

$$\begin{cases} \dot{x}_i = v_i, \\ \dot{v}_i = -(L_x v)_i = \sum_{j \in \mathcal{L}(i)} a_{ij}(x)(v_j - v_i) \end{cases} \tag{4.1}$$

for $t > 0$, $i = 1, \ldots, k$, and $x = (x_1, x_2, \ldots, x_k) \in \mathbb{R}^{3k}$. The Cucker–Smale connectivity strength is specified by

$$a_{ij}(x) = \frac{H}{(1 + |x_j - x_i|^2)^\beta}, \qquad j \in \mathcal{L}(i).$$

(As mentioned earlier in the introduction, changing "=" to "≥" does not affect the subsequent analysis as long as the $a_{ij}(x)$'s are bounded and sufficiently smooth.) Given a solution $(x(t), v(t))$ to the continuous Cucker–Smale model (4.1), we write for convenience

$$a_{ij}(t) = a_{ij}(x(t)) \quad \text{and} \quad L_t = L_{x(t)}.$$

Let $\eta = (\eta_1, \eta_2, \ldots, \eta_k)^T \in \mathbb{R}^k$ be k scalars, and consider the following system of ordinary differential equations:

$$\dot{\eta} = -L_t \eta, \qquad t > 0, \qquad \text{given } \eta^0 = \eta\big|_{t=0}. \tag{4.2}$$

Componentwise, we have

$$\dot{\eta}_i = \sum_{j \in \mathcal{L}(i)} a_{ij}(t)(\eta_j - \eta_i), \qquad i = 1, \ldots, k. \tag{4.3}$$

THEOREM 4.1 (positivity). *Suppose $\eta_i^0 \geq 0$ for $i = 1, \ldots, k$. Then for all $t > 0$ and i, $\eta_i(t) \geq 0$.*

Proof. For any agent i in the flock, define

$$\begin{aligned} &\mathcal{L}^0(i) = \{i\}, \\ &\mathcal{L}^m(i) = \mathcal{L}(\mathcal{L}^{m-1}(i)), \qquad \text{all } m\text{th level leaders of } i, \quad \text{and} \\ &[\mathcal{L}](i) = \mathcal{L}^0(i) \cup \mathcal{L}^1(i) \cup \mathcal{L}^2(i) \cdots, \qquad \text{all leaders of } i\text{, direct or indirect.} \end{aligned} \tag{4.4}$$

Then it is easy to see that system (4.3) applied to $[\mathcal{L}](i)$ is always self-contained, i.e., $(\eta_j \mid j \in [\mathcal{L}](i))$ is not influenced by any variables in $(\eta_j \mid j \notin [\mathcal{L}](i))$ (but certainly not vice versa).

For convenience, we shall call the restriction of system (4.2) or (4.3) on the subflock $[\mathcal{L}](i)$ the $[\mathcal{L}](i)$-*system.* Then it suffices to establish the theorem for each $[\mathcal{L}](i)$ system. In Figure 4.1, we have sketched an example of the hierarchies of leaders of a given agent i.

Suppose otherwise that the theorem were false on an $[\mathcal{L}](i)$-system for some particular agent i. There would exist some $\bar{j} \in [\mathcal{L}](i)$ and $\bar{t} > 0$ such that $\eta_{\bar{j}}(\bar{t}) < 0$. Define

$$t_* = \inf\{t > 0 \mid \text{there exists some } j \in [\mathcal{L}](i), \text{ such that } \eta_j(t) < 0\}.$$

Then $0 \leq t_* \leq \bar{t} < \infty$, and we claim additionally the following.

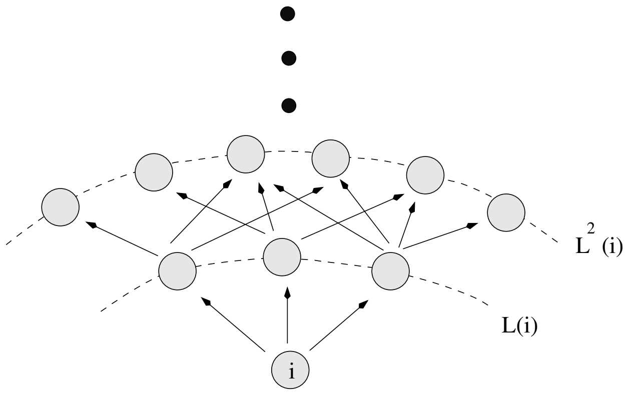


FIG. 4.1. *The leaders of an agent i at different levels:* $\mathcal{L}^0(i) = \{i\}, \mathcal{L}(i), \mathcal{L}^2(i), \ldots$.

(i) For any $j \in [\mathcal{L}](i)$, $\eta_j(t_*) \geq 0$.

(ii) There must exist some $\hat{j} \in [\mathcal{L}](i)$ and a sequence of moments (t_n) such that $t_n > t_*$, $t_n \to t_*$ as $n \to \infty$, and $\eta_{\hat{j}}(t_n) < 0$.

(iii) There must exist some $j_* \in [\mathcal{L}](\hat{j})$, such that $\eta_{j_*}(t_*) > 0$.

(i) and (ii) result directly from the definition of t_*. Suppose otherwise that (iii) were false. Then for any $j \in [\mathcal{L}](\hat{j})$, one must have $\eta_j(t_*) = 0$ by (i). Consider the $[\mathcal{L}](\hat{j})$-system after t_*:

$$\dot{\eta}_j = \sum_{l \in \mathcal{L}(j)} a_{jl}(t)(\eta_l - \eta_j), \qquad j \in [\mathcal{L}](\hat{j}), \quad t > t_*.$$

Since this is a homogeneous system with zero initial conditions at $t = t_*$, by the uniqueness theorem of ODEs (e.g., [13]), the solution to the $[\mathcal{L}](\hat{j})$-system must be identically zero: $\eta_j(t) \equiv 0$ for any $t > t_*$ and $j \in [\mathcal{L}](\hat{j})$. Now that $\hat{j} \in [\mathcal{L}](\hat{j})$, one must have $\eta_{\hat{j}}(t) \equiv 0$ for all $t > t_*$, which contradicts property (ii). Thus (iii) holds.

Define

$$\hat{m} = \min\{m \geq 0 \mid \text{there exists some } j_* \in \mathcal{L}^m(\hat{j}), \text{ such that } \eta_{j_*}(t_*) > 0\}.$$

Properties (ii) and (iii) imply that $0 < \hat{m} < \infty$. Then by iteratively differentiating the $[\mathcal{L}](\hat{j})$-system, one can easily establish

$$\eta_{\hat{j}}(t_*) = \eta'_{\hat{j}}(t_*) = \cdots = \eta_{\hat{j}}^{(\hat{m}-1)}(t_*) = 0, \qquad \eta_{\hat{j}}^{(\hat{m})}(t_*) > 0,$$

which contradicts property (ii). Thus the theorem must hold and the proof is complete. □

The most important consequence is the following bounding capability.

THEOREM 4.2 (boundedness of velocities under evolution). *The Cucker–Smale model* (4.1) *has the following closedness properties.*

(i) *Suppose Ω is a convex compact domain in $\mathbb{R}^3$, and for any agent i, initially $v_i(t = 0) \in \Omega$. Then for any $t > 0$ and i, $v_i(t) \in \Omega$.*

(ii) *In particular, let $D_0 = \max_i |v_i(t = 0)|$. Then $|v_i(t)| \leq D_0$ for all $t > 0$ and i.*

Proof. Since the closed ball $B_{D_0}(0)$ in $\mathbb{R}^3$ is convex and compact, (ii) is implied by (i). It suffices to establish (i).

Given any unit vector $n \in S^2$ and any vector $a \in \mathbb{R}^3$, we first claim that if

$$n \cdot (v_i - a)\big|_{t=0} \geq 0 \qquad \forall\, i,$$

then $n \cdot (v_i(t) - a) \geq 0$ remains valid for all $t > 0$ and i. To proceed, define $\eta_i = n \cdot (v_i - a)$.

$$\begin{aligned}\dot{\eta} &= n \cdot \dot{v}_i \\ &= n \cdot \left(\sum_{j \in \mathcal{L}(i)} a_{ij}(t)(v_j - v_i) \right) \\ &= n \cdot \left(\sum_{j \in \mathcal{L}(i)} a_{ij}(t) \left[(v_j - a) - (v_i - a) \right] \right) \\ &= \sum_{j \in \mathcal{L}(i)} a_{ij}(t)(\eta_j - \eta_i) \\ &= -(L_t \eta)_i.\end{aligned}$$

Then by the preceding theorem, the claim is indeed valid: $\eta_i(t) \geq 0$ for all $t > 0$ and i.

For any compact convex domain Ω, let $p : S^2 \to \mathbb{R}^3$ be its support function, so that for any unit direction $n \in S^2$, $a = p(n)$ has the property that $a \in \partial\Omega$ and the closed flat half-space

$$\pi_{a,-n} = \{x \in \mathbb{R}^3 \mid (-n) \cdot (x - a) \geq 0\}$$

contains Ω. When the domain is convex but not strictly convex, $p(n)$ could be a set of points, which, however, does not influence the argument herein (since the above half-spaces anchored at different points of $p(n)$ would be the same). Furthermore, we have

$$\Omega = \bigcap_{n \in S^2} \pi_{p(n),-n}.$$

Since each half-space has just been shown invariant under the Cucker–Smale evolution, we conclude that Ω must be invariant as well under the evolution, which completes the proof. □

4.2. Perturbation and induction. We now first prepare a lemma. Together with the boundedness property just established above, it facilitates the later analysis on the emergent behavior of HL flocks.

LEMMA 4.3. *Suppose $x(t), v(t) \in \mathbb{R}^3$ (which could be considered as $x_2 - x_1$ and $v_2 - v_1$ for a 2-flock), and satisfy the perturbed 2-flock system* parametrized *by some $T > 0$:*

$$\begin{cases} \dot{x} = v(t), \\ \dot{v} = -a_T(x,t)v(t) + \varepsilon_T(t), \qquad t \geq 0. \end{cases} \tag{4.5}$$

Assume in addition that the following conditions hold.

(i) $a_T(x,t) \geq \frac{H}{(1+|x|^2)^\beta}$, *with $\beta < 1/2$.*

(ii) $\varepsilon_T \in \mathbb{R}^3$, *and*

$$|\varepsilon_T(t)| \leq a e^{-b(t+T)^\eta} \qquad \textit{for some } \eta \in (0,1]. \tag{4.6}$$

(iii) *$|v(t)| \le D_0$ for all $t \ge 0$, and $|x_0| \le R_0 + D_0 T$.*

Here H, β, a, b, η, D_0, and R_0 are given constants independent of T. Let $(x^T(t), v^T(t))$ denote the dependency on T. Then

$$|v^T(T)| \le Ae^{-BT^{(1-2\beta)\wedge\eta^-}}, \tag{4.7}$$

where $\eta^- = \eta - \delta$ for any small but positive δ when $\eta < 1$, and $\eta^- = 1$ when $\eta = 1$, and A and B are two constants depending only upon H, β, a, b, η^-, D_0, and R_0 (but not T). The notation $a \wedge b$ represents $\min(a, b)$.

Before proceeding to the proof of the lemma, we first make two comments on the conditions.

(1) The all-time bound $|v(t)| \le D_0$ seems very stringent but is now natural by Theorem 4.2 in the preceding subsection.

(2) As outlined in the beginning of the current section, the lemma will be applied during the induction process going from the subflock $[1, \dots, i-1]$ to $[1, \dots, i]$. To agent i, the perturbation factor $\varepsilon_T(t)$ comes from the exponentially small deviation of the leading subflock $[1, \dots, i-1]$ from reaching exact consensus.

Proof. From the equation for v, we have

$$\langle v, \dot{v} \rangle = -a_T(x,t)\langle v, v \rangle + \langle v, \varepsilon_T(t) \rangle, \qquad \text{or}$$
$$|v| \cdot |v|_t = \frac{1}{2}\left(|v|^2\right)_t = -a_T|v|^2 + \langle v, \varepsilon_T(t) \rangle.$$

Assuming that v is never identically zero on any nonempty open time interval (note that the opposite scenario trivializes the lemma on any such interval, and the following argument would need only a minor modification), one has

$$\begin{aligned} |v|_t &\le -a_T|v| + |\varepsilon_T| \\ &\le -\frac{H}{(1+|x|^2)^\beta}|v| + ae^{-b(t+T)^\eta} \end{aligned}$$

by conditions (i) and (ii). By $\dot{x} = v$ and (iii),

$$\begin{aligned} |x| &\le |x_0| + \int_0^t |v|(\tau)d\tau \\ &\le R_0 + D_0T + D_0t = R_0 + D_0(t+T). \end{aligned}$$

As a result,

$$|v|_t \le -\frac{H}{(1+(R_0+D_0(t+T))^2)^\beta}|v| + ae^{-b(t+T)^\eta}.$$

Then by Gronwall-type integration,

$$\begin{aligned} |v(t)| &\le |v_0|e^{-\int_0^t \frac{H}{(1+(R_0+D_0(\tau+T))^2)^\beta}d\tau} + a\int_0^t e^{-b(\tau+T)^\eta} \cdot e^{-\int_\tau^t \frac{H}{(1+(R_0+D_0(s+T))^2)^\beta}ds}d\tau \\ &\le D_0 \cdot e^{-\frac{Ht}{(1+(R_0+D_0(t+T))^2)^\beta}} + \frac{a}{b\eta}T^{1-\eta}e^{-bT^\eta}. \end{aligned}$$

We denote $v(t)$ by $v^T(t)$ to indicate its dependency on T. Then

$$\begin{aligned} |v^T(T)| &\le D_0 \cdot e^{-\frac{H \cdot T}{(1+(R_0+2D_0T)^2)^\beta}} + \frac{\tilde{a}(a,b,\eta^-)}{b\eta^-}e^{-bT^{\eta^-}} \\ &\le D_0e^{-\tilde{H}(H,R_0,D_0,\beta)T^{1-2\beta}} + C(a,b,\eta^-)e^{-bT^{\eta^-}} \qquad \text{(when } T \ge 1\text{)} \\ &\le Ae^{-BT^{(1-2\beta)\wedge\eta^-}}, \end{aligned}$$

where the two constants A and B are independent of T. Also notice that when $\eta = 1$, the monomial factor $T^{1-\eta} = 1$ and the lowering from η to η^- is unnecessary in the first line. Finally, since $|v^T(t)| \le D_0$ by the given conditions, by suitably increasing A, the condition $T \ge 1$ in the last second line can actually be removed. This completes the proof. ◻

We are now ready to state and prove the main theorem.

THEOREM 4.4 (convergence of an HL flock). *Let* $[1, 2, \dots, k]$ *be a Cucker–Smale flock under hierarchical leadership with* $\beta < 1/2$. *Then for some* $B > 0$, *which depends only on the initial configuration and all the system parameters, one has*

$$\max_{1\le i,j\le k} |v_i(t) - v_j(t)| = O(e^{-Bt}), \qquad t > 0. \tag{4.8}$$

Proof. We prove the theorem by induction on the subflocks, from $[1, \dots, l-1]$ to $[1, \dots, l]$ (see Figure 4.2).

First we show that the theorem holds for a 2-flock $[1, 2]$. By definition, the leader set $\mathcal{L}(2)$ is nonempty and has to be $\mathcal{L}(2) = \{1\}$, i.e., $a_{21} > 0$. Let $x = x_2 - x_1$ and $v = v_2 - v_1$. Then

$$\begin{cases} \dot{x} = v, \\ \dot{v} = \dot{v}_2 - \dot{v}_1 = \dot{v}_2 = a_{21}(v_1 - v_2) = -a_{21}v. \end{cases}$$

Here $a_{21} = a_{21}(x) = \frac{H}{(1+|x|^2)^\beta}$, with $\beta < 1/2$. Then Cucker and Smale's analysis in [7] still applies directly, and $|v(t)| = O(e^{-Bt})$ for some $B > 0$.

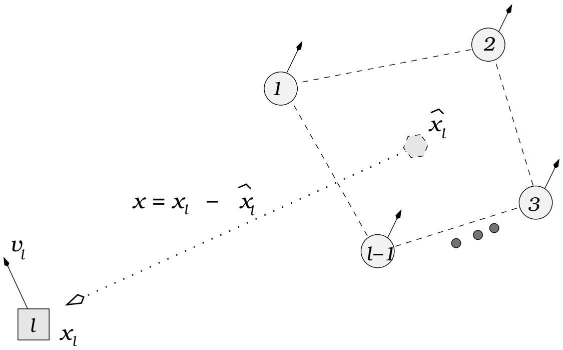

FIG. 4.2. *The induction process from* $[1, \dots, l-1]$ *to* $[1, \dots, l-1, l]$ *reduces the* l*-flock system to a perturbed* 2*-flock system.*

Assuming that the theorem holds for the subflock $[1, \dots, l-1]$, we now intend to show that it must be true for $[1, \dots, l-1, l]$ as well for $l > 2$. As a result, the main focus shall be the agent l.

By induction, there exists some $b > 0$, such that

$$\max_{i,j\in\{1,\dots,l-1\}} |v_i(t) - v_j(t)| = O(e^{-bt}), \qquad t \to \infty. \tag{4.9}$$

Define the average velocity (of the direct leaders of agent l) by

$$\hat{v}_l(t) = \frac{1}{d_l} \sum_{i\in\mathcal{L}(l)} v_i(t), \qquad \text{with } d_l = \#\mathcal{L}(l).$$

Then for any $j \in \mathcal{L}(l)$,

$$|v_j(t) - \hat{v}_l(t)| \le \frac{1}{d_l} \sum_{i \in \mathcal{L}(l)} |v_j - v_i| = O(e^{-bt}) \tag{4.10}$$

by the induction assumption. Similarly, define

$$\hat{x}_l(t) = \frac{1}{d_l} \sum_{i \in \mathcal{L}(l)} x_i(t) \quad \text{and} \quad x(t) = x_l(t) - \hat{x}_l(t), \quad v(t) = v_l(t) - \hat{v}_l(t).$$

Then $\dot{x} = v$, and

$$\begin{aligned} \dot{v} = \dot{v}_l - \frac{d\hat{v}_l}{dt} &= \sum_{j \in \mathcal{L}(l)} a_{lj} \cdot (v_j - v_l) - \frac{d\hat{v}_l}{dt} \\ &= \sum_{j \in \mathcal{L}(l)} a_{lj} \cdot (\hat{v}_l - v_l) + \underbrace{\sum_{j \in \mathcal{L}(l)} a_{lj} \cdot (v_j - \hat{v}_l) - \frac{d\hat{v}_l}{dt}}_{\varepsilon(t)}. \end{aligned} \tag{4.11}$$

Since each $\dot{v}_i$ $(i \in \mathcal{L}(l))$ is the linear combination of some $(v_j - v_i)$'s with $j \in \mathcal{L}(i) \subseteq \{1, \dots, l-1\}$, by (4.9), one must have

$$\frac{d\hat{v}_l}{dt} = O(e^{-bt}).$$

Similarly, due to (4.10) and the boundedness of the a_{lj}'s, one has

$$\left| \sum_{j \in \mathcal{L}(l)} a_{lj} \cdot (v_j - \hat{v}_l) \right| = O(e^{-bt}).$$

In combination, we conclude that

$$|\varepsilon(t)| \le c e^{-bt}, \qquad t > 0, \quad \text{for some } c > 0. \tag{4.12}$$

On the other hand, define

$$a = \sum_{j \in \mathcal{L}(l)} a_{lj} = \sum_{j \in \mathcal{L}(l)} \frac{H}{(1 + |x_j - x_l|^2)^\beta}. \tag{4.13}$$

Then (4.11) simply becomes

$$\dot{v} = -av + \varepsilon. \tag{4.14}$$

Define $g(s) = \frac{H}{(1+s)^\beta}$ with $s \ge 0$. Then $g(s)$ is convex, and

$$\frac{1}{d_l} \sum_{j \in \mathcal{L}(l)} g(s_j) \ge g\left(\frac{1}{d_l} \sum_{j \in \mathcal{L}(l)} s_j \right).$$

As a result, when $s_j = |x_j - x_l|$,

$$\sum_{j \in \mathcal{L}(l)} \frac{H}{(1 + |x_j - x_l|^2)^\beta} \ge d_l \frac{H}{\left(1 + \frac{1}{d_l} \sum_{j \in \mathcal{L}(l)} |x_j - x_l|^2\right)^\beta}. \tag{4.15}$$

By the least-squares principle,

$$\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|x_l-x_j|^2=|\overbrace{x_l-\hat{x}_l}^{x}|^2+\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|x_j-\hat{x}_l|^2, \tag{4.16}$$

since $\hat{x}_l$ is the center or mean of $\{x_j \mid j\in\mathcal{L}(l)\}$. By the induction assumption on the consensus of $[1,\ldots,l-1]\supseteq\mathcal{L}(l)$, it is easy to establish that there exists some $M>0$, such that

$$\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|x_j-\hat{x}_l|^2\le M-1. \tag{4.17}$$

(Simply notice that the induction assumption guarantees the exponentially small deviations of the v_j's from $\hat{v}_l$.) Combining (4.13)–(4.17), we have

$$a=a(x,t)\ge\frac{d_lH}{(M+|x|^2)^\beta}\ge\frac{\tilde{H}}{(1+|x|^2)^\beta}, \tag{4.18}$$

where the updated constant $\tilde{H}=\tilde{H}(H,d_l,M,\beta)$. (Notice that the notation $a(x,t)$ summarizes all the influence from $\{x_j \mid j\in\mathcal{L}(l)\}$ into the t-variable.)

The combination of (4.12), (4.14), and (4.18) leads to the reduced system

$$\begin{cases}\dot{x}=v,\\ \dot{v}=-a(x,t)v+\varepsilon(t),\end{cases} \tag{4.19}$$

with $a(x,t)\ge\frac{\tilde{H}}{(1+|x|)^\beta}$ and $|\varepsilon(t)|\le ce^{-bt}$. In order to apply Lemma 4.3, further define

$$D_0=2\max_{1\le i\le k}|v_i(t=0)| \quad\text{and}\quad R_0=2\max_{1\le i\le k}|x_i(t=0)|. \tag{4.20}$$

Then by Theorem 4.2, we have

$$|v_i(t)|\le\frac{D_0}{2}\qquad\forall\ i\text{ and }t>0.$$

Consequently,

$$|v(t)|\le\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|v_j-v_l|\le\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}D_0=D_0. \tag{4.21}$$

Similarly, for any $T>0$,

$$\begin{aligned}|x(T)-x(0)|&\le|x_l(T)-x_l(0)|+\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|x_j(T)-x_j(0)|\\ &\le\frac{D_0}{2}T+\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}\frac{D_0}{2}T=D_0T.\end{aligned}$$

As a result,

$$\begin{aligned}|x(T)|&\le|x(0)|+D_0T\\ &\le|x_l(0)|+\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}|x_j(0)|+D_0T\\ &\le\frac{R_0}{2}+\frac{1}{d_l}\sum_{j\in\mathcal{L}(l)}\frac{R_0}{2}+D_0T=R_0+D_0T.\end{aligned} \tag{4.22}$$

To conclude, for any $T > 0$, if we define

$$x^T(t) = x(t+T), \quad v^T(t) = v(t+T), \quad a_T(x^T, t) = a(x^T, t+T), \quad \text{and} \quad \varepsilon_T(t) = \varepsilon(t+T),$$

then

$$\begin{cases} \dot{x}^T = v^T, \\ \dot{v}^T = -a_T(x^T, t)v^T + \varepsilon_T(t), \qquad t > 0, \end{cases}$$

and all three conditions of Lemma 4.3 are satisfied (with $\eta = 1$). Therefore, there must exist two positive constants $\tilde{A}$ and $\tilde{B}$, such that for any $T > 0$,

$$|v(2T)| = |v^T(T)| \le \tilde{A}e^{-\tilde{B}T^{(1-2\beta)\wedge 1}} = \tilde{A}e^{-\tilde{B}T^{1-2\beta}}.$$

Since T is arbitrary, we therefore must have, after adjusting the constants,

$$|v(t)| \le \hat{A}e^{-\hat{B}t^{1-2\beta}}, \qquad t > 0, \qquad \text{for some constants } \hat{A} \text{ and } \hat{B}.$$

Moreover, since $\beta < 1/2$ by assumption, one then must have

$$\int_0^\infty |v(t)|dt < \infty,$$

which in return implies that there exists some constant $M > 0$, such that

$$|x(t)| \le M, \qquad t > 0.$$

Then by repeating the similar calculation in the proof of Lemma 4.3, assisted by this new constant bound $|x| \le M$ instead of $|x| \le R_0 + D_0(t+T)$ there, one arrives at

$$|v(t)| \le A'e^{-B't} \qquad (\text{since } \eta = 1)$$

for two positive constants A' and B' independent of t. Combined with the induction base (4.9), we thus conclude that the theorem must hold true for the subflock $[1, \dots, l-1, l]$ with the exponent coefficient $B = B' \wedge b$. This completes the proof. □

5. HL flocking under a free-will leader. In this section, partially inspired by the preceding perturbation methods, we investigate a more realistic scenario in which the ultimate leader agent 0 (in an HL flock $[0, 1, \dots, k]$) can have a *free-will acceleration*, instead of merely flying with a constant velocity.

The following phenomenon is not uncommon near lakes, grasslands, or any open spaces where a flock of birds often visits. When the flock is initially approached by an unexpected pedestrian or a predator from a corner on the outer rim, the bird which takes off first (and alerts others subsequently) generally takes a curvy flying path before it reaches a stable flying pattern with an almost constant velocity. Such a bird gains the full speed fast, flies ahead of the entire flock, and serves as a virtual overall leader.

For an HL flock $[0, 1, \dots, k]$, in addition to the Cucker–Smale system

$$(5.1) \qquad \begin{cases} \dot{x}_i = v_i(t), \\ \dot{v}_i = \sum_{j \in \mathcal{L}(i)} a_{ij}(x)(v_j(t) - v_i(t)), \qquad i > 0, \end{cases}$$

we now also impose for the ultimate leader agent 0

$$\begin{cases} \dot{x}_0 = v_0, \\ \dot{v}_0 = f(t), \qquad t > 0, \end{cases} \tag{5.2}$$

coupled with a given set of initial conditions. For convenience, we shall call $f(t)$ the *free-will acceleration* of the leader. In combination, the new system is no longer autonomous.

The main goal of this section is to establish the following theorem.

THEOREM 5.1. *Suppose an HL $(k+1)$-flock $[0, \dots, k]$ with a free-will leader satisfies both* (5.1) *and* (5.2)*, with the Cucker–Smale connectivity strength of $\beta < 1/2$. In addition, assume that the leader's free-will acceleration satisfies*

$$|f(t)| = O((1+t)^{-\mu}), \qquad \textit{with some exponent } \mu > k.$$

Then the flock still has the following emergent behavior:

$$\max_{0 \le i,j \le k} |v_i - v_j|(t) = O\left((1+t)^{-(\mu-k)}\right).$$

We first make two comments regarding why one should expect to put some regularity conditions on the leader's behavior in order for a coherent pattern to emerge asymptotically.

(1) Intuitively, if the leader keeps changing its velocity substantially, it will be more difficult for the entire flock to follow and behave coherently. An extreme example is a flock with a *drunken* leader which flies in a Brownian random path. Then the entire flock cannot be expected to synchronize with the unpredictable motion of the leader instantaneously.

(2) In the theorem, the decaying constraint $\mu > k$ depends on the size k of the flock. Thus qualitatively speaking, it requires the leader to exert less free will when the flock is larger, in order to lead a coherent flock asymptotically. Consider the special hierarchical leadership under a *linear chain of command*:

$$k \to k-1 \to \cdots \to 1 \to 0.$$

The tail agent k has to go through all the k intermediate stages to sense any move that the leader is making. Thus intuitively, there will be a long time delay in between, and the leader has to be tempered enough to allow its distantly connected followers to respond coherently.

We now prepare a lemma that is similar to Lemma 4.3. Since the new nonautonomous system does not necessarily have the positivity property, we take a slightly different approach.

LEMMA 5.2. *Let $x, v, g \in \mathbb{R}^3$ satisfy*

$$\begin{cases} \dot{x} = v(t), \\ \dot{v} = -a(x,t)v(t) + g(t). \end{cases}$$

Suppose that

$$a(x,t) \ge \frac{H}{(1+|x|^2)^\beta} \qquad \textit{for some } \beta < 1/2, \textit{ and}$$
$$|g(t)| = O\left((1+t)^{-\eta}\right), \qquad \textit{with some constant } \eta > 1.$$

Then $|v(t)| = O((1+t)^{-(\eta-1)})$ *with the order constant depending only on the initial conditions* $x(t=0)$, $v(t=0)$, *and* H, β, *and* η.

Proof. From the second equation, one has

$$|v| \cdot |v|_t = \left(\frac{v^2}{2}\right)_t = \langle v, v_t\rangle = -a\langle v, v\rangle + \langle v, g\rangle \leq -a|v|^2 + |v| \cdot |g|.$$

Assume that v does not vanish identically on any nonempty open intervals for the same reason as in the proof of Lemma 4.3. Then one has

$$|v|_t \leq -a|v| + |g|, \qquad t > 0.$$

Fix any time $T > 0$, and define

$$|x|_* = \sup_{t \leq T} |x|(t) \quad \text{and} \quad a_* = \inf_{t \leq T} \frac{H}{(1+|x|^2)^\beta} = \frac{H}{(1+|x|_*^2)^\beta}. \tag{5.3}$$

Then one has

$$|v|_t \leq -a_*|v| + |g|, \qquad t \in [0, T]. \tag{5.4}$$

Since a_* is constant, integration yields

$$|v|(t) \leq |v|(0)e^{-a_* t} + \int_0^t |g|(\tau)e^{-a_*(t-\tau)}d\tau.$$

In particular, for any $t < T$,

$$|v|(t) \leq |v|(0) + \int_0^t |g|(\tau)d\tau \leq |v|(0) + \int_0^\infty |g(\tau)|d\tau := A_0.$$

(Since $\eta > 1$ by assumption, the integral of $|g|$ is finite.) Now that A_0 is independent of the time mark T, we conclude that the last upper bound must hold for *any* $t > 0$: $|v|(t) \leq A_0$, $t > 0$. Therefore, from the first equation $\dot{x} = v(t)$, one has

$$|x|(t) \leq |x|(0) + \int_0^t |v|(\tau)d\tau \leq B_0 + A_0 t, \quad t > 0,$$

where $B_0 = |x|(0)$. In particular, for any time mark $T > 0$, the quantities in (5.3) are subject to

$$|x|_* \leq B_0 + A_0 T \quad \text{and} \quad a_* \geq \frac{H}{[1+(B_0+A_0T)^2]^\beta}.$$

We then go back and integrate inequality (5.4) again, but from $T/2$ to T this time:

$$\begin{aligned}
|v|(T) &\leq |v|(T/2)e^{-\frac{a_*T}{2}} + \int_{T/2}^T |g|(\tau)e^{-a_*(T-t)}dt \\
&\leq A_0 e^{-\frac{HT/2}{[1+(B_0+A_0T)^2]^\beta}} + \int_{T/2}^\infty |g|(t)dt \\
&\leq A_0 e^{-\tilde{H}(A_0,B_0,\beta)(1+T)^{1-2\beta}} + \int_{T/2}^\infty O\left((1+t)^{-\mu}\right)dt \\
&= A_0 e^{-\tilde{H}(1+T)^{1-2\beta}} + O\left((1+T)^{-(\mu-1)}\right).
\end{aligned}$$

Since $\beta < 1/2$, we conclude that

$$|v|(T) = O\left((1+T)^{-(\mu-1)}\right),$$

where the constant in $O(\cdot)$ is independent of T. Since T is arbitrary, the lemma is established. □

We are now ready to prove Theorem 5.1. Details on some similar calculations will be directed to the proof of Theorem 4.4.

Proof. It suffices to prove the following more general result:

$$\max_{0\le i,j\le l} |v_i - v_j|(t) = O\left((1+t)^{-(\mu-l)}\right), \qquad t > 0, \tag{5.5}$$

for any subflock $[0, 1, \ldots, l]$ and $l \ge 1$.

When $l = 1$, define $x = x_1 - x_0$ and $v = v_1 - v_0$. Then $\dot{x} = v$, and

$$\dot{v} = \dot{v}_1 - \dot{v}_0 = a_{10}(v_0 - v_1) - f = -a_{10}v - f.$$

By the definition of an HL flock, $\mathcal{L}(1) \ne \varnothing$, and it has to be agent 0, implying that a_{10} is subject to the Cucker–Smale formula. Then by the preceding lemma (with $\eta = \mu$), one has

$$|v|(t) = O\left((1+t)^{-(\mu-1)}\right),$$

and (5.5) holds.

Suppose now that (5.5) is true for the subflock $[0, 1, \ldots, l-1]$ with $2 \le l \le k$, so that

$$\max_{0\le i,j\le l-1} |v_i - v_j|(t) = O\left((1+t)^{-(\mu-l+1)}\right). \tag{5.6}$$

As in the proof of Theorem 4.4, define the average features of the direct leaders of agent l by

$$\hat{x}_l = \frac{1}{d_l}\sum_{j\in\mathcal{L}(l)} x_j \quad \text{and} \quad \hat{v}_l = \frac{1}{d_l}\sum_{j\in\mathcal{L}(l)} v_j, \qquad d_l = \#\mathcal{L}(l),$$

and $x = x_l - \hat{x}_l$ and $v = v_l - \hat{v}_l$.

Then as in the proof of Theorem 4.4, one has $\dot{x} = v$ and

$$\begin{aligned} \dot{v} &= -a(x,t)\cdot v + g_l(t), \qquad \text{with} \\ g_l(t) &= \sum_{j\in\mathcal{L}(l)} a_{lj}\cdot(v_j - \hat{v}_l) - \frac{d\hat{v}_l}{dt}, \\ a(x,t) &= \sum_{j\in\mathcal{L}(l)} a_{lj}(x_l - x_j). \end{aligned}$$

We first estimate g_l. Since $|a_{lj}| \le H$ and $\mathcal{L}(l) \subseteq [0, 1, \ldots, l-1]$, by the induction assumption (5.6), the first term in g_l must be of the order $O((1+t)^{-\eta})$ with $\eta = \mu - l + 1$. For the remaining second term in g_l, let $1_{0\in\mathcal{L}(l)}$ denote the logical variable, which is 1 when agent 0 belongs to $\mathcal{L}(l)$, and 0 otherwise. Then

$$\frac{d\hat{v}_l}{dt} = \frac{1}{d_l}\sum_{j\in\mathcal{L}(l)} \dot{v}_j = 1_{0\in\mathcal{L}(l)}\cdot\frac{1}{d_l}\dot{v}_0 + \frac{1}{d_l}\sum_{j\in\mathcal{L}(l)\setminus\{0\}} \dot{v}_j.$$

Notice that $\dot{v}_0 = f(t) = O((1+t)^{-\mu})$, and each $\dot{v}_j$ with $j \in \mathcal{L}(l) \setminus \{0\}$ is some linear combination of $(v_s - v_j)$ with the s's in $\mathcal{L}(j) \subseteq [0, 1, \ldots, l-1]$. Thus by the induction assumption (5.6), one must have $\frac{d\hat{v}_l}{dt} = O((1+t)^{-\eta})$ with $\eta = \mu - l + 1$.

We now estimate $a(x,t)$. Since $\mu > k$ by the given condition, we have $\mu - l + 1 > k - l + 1 = 1$. As a result, by the induction assumption on the subflock $[0, 1, \ldots, l-1]$, for any $i, j \le l-1$,

$$\begin{aligned} |x_i - x_j|(t) &\le |x_i - x_j|(0) + \int_0^t |v_i - v_j|(\tau)d\tau \\ &\le |x_i - x_j|(0) + \int_0^\infty O\left((1+\tau)^{-(\mu-l+1)}\right)d\tau < \infty \qquad \forall\, t > 0. \end{aligned}$$

Therefore the boundedness property in (4.17) still holds, and the same calculation in the proof of Theorem 4.4 leads to

$$a(x,t) \ge \frac{\tilde{H}}{(1+|x|^2)^\beta}$$

for some constant $\tilde{H} = \tilde{H}(H, d_l, \beta, f, \text{initial conditions of } [0, \ldots, l-1])$.

Combining the estimations on g_l and a, one sees that $x(t)$ and $v(t)$ satisfy a perturbed system as in Lemma 5.2 with $\eta = \mu - l + 1$. Therefore, by Lemma 5.2,

$$|v_l - \hat{v}_l|(t) = |v|(t) = O\left((1+t)^{-(\eta-1)}\right) = O\left((1+t)^{-(\mu-l)}\right).$$

Now that by the induction assumption, for any $j \le l-1$, one must have

$$|v_j - \hat{v}_l|(t) = O\left((1+t)^{-(\mu-l+1)}\right), \quad \text{since } |v_j - v_i| = O\left((1+t)^{-(\mu-l+1)}\right) \quad \forall\, i \in \mathcal{L}(l).$$

Therefore, for any $j \le l-1$,

$$|v_l - v_j| \le |v_l - \hat{v}_l| + |v_j - \hat{v}_l| = O\left((1+t)^{-(\mu-l)}\right).$$

This completes the proof of (5.6), and thus the entire theorem. □

COROLLARY 5.3. *Under the same statements as in the preceding theorem, suppose $\mu > k+1$. Then there exists a constant configuration $(d_{ij})_{0 \le i,j \le k}$ with $d_{ij} \in \mathbb{R}^3$, such that*

$$\lim_{t \to \infty} (x_i(t) - x_j(t)) = d_{i,j}, \qquad 0 \le i, j \le k,$$

and the convergence rate is $O\left((1+t)^{-(\mu-k-1)}\right)$.

6. Conclusion. In this paper, we have investigated the emergent behavior of Cucker–Smale flocking under the structure of *hierarchical leadership* (HL). The convergence rates are established for both discrete-time and continuous-time HL flocks, as well as for HL flocks under an overall leader with free-will accelerations. In all these scenarios, the consistent convergence towards some asymptotically coherent patterns may reveal the advantages and necessities of having leaders and leadership in a complex (biological, technological, economic, or social) system with sufficient intelligence and memory.

As reviewed in the introduction section, there have been explosive multidisciplinary efforts in recent years in advancing this emerging area of multiagent complex systems with biological or intelligence signatures (as opposed to more traditional and *passive* particle systems in physics). The innate complexities (associated with multiagency, probing and sensing, intelligence, and dynamical reorganization and transience) have made rigorous mathematical analysis of such systems highly challenging. Therefore, to no one's surprise, the aim of most contemporary works has been to

(i) construct complex models that reproduce specific biological phenomena or design technology-driven applications, e.g., for ant armies, elephant herds, or robotic or sensor networks; and

(ii) simulate (via computing) these complex models, fine-tuning model parameters to obtain good approximations of the targeted biological or technological flocking phenomena.

As is well known in information theory [5] or the most recent learning theory (e.g., Vapnik [26] and Cucker and Smale [6]), a universal tradeoff always exists between the *complexity* of a model and its so-called *generalization* power, or the power of interpretation. Most practical flocking models in the several disciplines mentioned above have mainly attempted to reproduce faithful real-life flocking behavior, i.e., the *interpretation* power. Typically, these models involve many interacting terms, often nonlinear, nonconvex, or nonlocal. They are built upon good heuristic intuition but defy attempts at rigorous mathematical analysis.

On the other hand, recently the collective efforts of a group of mathematicians, including, for example, Cucker, Smale, Bertozzi, and their colleagues, have been focused on scaling down some model complexity at the necessary loss of certain interpretation power. The reduced models become more tractable mathematically, and also offer their developers deeper insights into more involved versions of the models. As in other major branches of complexity study, e.g., fluid dynamics or statistical mechanics [1], complexity reduction has often been made possible by

(a) incorporating suitable symmetries and invariants;

(b) reducing the number of significant signals or governing variables; and

(c) introducing topological, combinatorial, or dynamical structures,

as witnessed in the Cucker–Smale model [7, 8] and the current work.

It is within this general picture of multidisciplinary flocking modeling that the present work should be embedded. This author, and probably other interested researchers from the applied mathematics community as well, will continue to increase model complexities subject to mathematical rigor and analytic tractability.

Acknowledgments. The author thanks both Professors Steve Smale and Felipe Cucker for their generosity in sharing their ideas on their developing frameworks. This work would not have been possible without the patient daily guidance, encouragement, and numerous suggestions from Prof. Smale. The author is profoundly grateful for the tender care of Prof. Smale and Prof. David McAllester, as well as for the generous visiting support from the Toyota Technological Institute (TTI-C) on the campus of the University of Chicago during the fall semester of 2006. The author also thanks his former Ph.D. advisor, Prof. Gil Strang, for directing him to the works of Prof. Iain Couzin on effective leadership. Without the initial inspiration from Professor Andrea Bertozzi or her constant support and encouragement to the author, the present work also could not have come into existence. Finally, the author acknowledges delightfully the professional help from the referees and managing editor.

NEURAL TIMING IN HIGHLY CONVERGENT SYSTEMS*

COLLEEN MITCHELL† AND MICHAEL REED‡

Abstract. In order to study how the convergence of many variable-response neurons on a single target can sharpen timing information, we investigate the limit as the number of input neurons and the number of incoming spikes required to fire the target both get large with the ratio fixed. We prove that the standard deviation of the firing time of the target cell goes to zero in this limit, and we derive the asymptotic forms of the density and the standard deviation near the limit. We use the theorems to understand the behavior of octopus cells in the mammalian cochlear nucleus.

1. Introduction.

A fundamental question in neurobiology is to understand how the central nervous system (CNS) can perform accurate and reliable calculations with neurons that are intrinsically variable and unreliable devices. Three more concrete versions of the question have received much attention: (1) How can network and/or cellular properties sharpen timing information or create accurate coincidence detectors? (2) How can synchronous activity in large groups of neurons be created and maintained? (3) Under what circumstances can intrinsic noise improve information processing capabilities?

The first question has long been studied in the auditory brainstem because it is experimentally accessible and because cellular, behavioral, and psychoacoustic experiments show that the auditory system can make extremely fine timing distinctions in the microsecond (or even nanosecond) range, even though individual neurons in the auditory nerve (AN) show latency standard deviations of approximately one millisecond in repeated trials with the same sound [25, 10, 45, 33, 50]. Lord Rayleigh [34] first proposed that the auditory system uses binaural timing distinctions to localize sound, and Jeffress [21] proposed the first neural mechanism based on delay lines and coincidence detection. Colburn [8] clearly formulated the question of how the auditory system can detect small time differences, given the noise in the AN, and went on to create some of the first mathematical models [9]. Important experimental studies include those of Rhode and Smith [37, 38] and Goldberg and Brown [14].

All fibers of the AN synapse on cells of the cochlear nucleus (CN). There are many different cell types in the CN that receive different numbers of AN synapses and have different response properties. Two experimental properties have received continuing attention from experimentalists and modelers. First, several CN cell types show "onset" responses; that is, they fire a single spike shortly after the initiation of the sound; the time lag is called the latency. The standard deviation of latency in AN fibers under repeated trials is of the order of 1 msec, but the standard deviation of latency in some

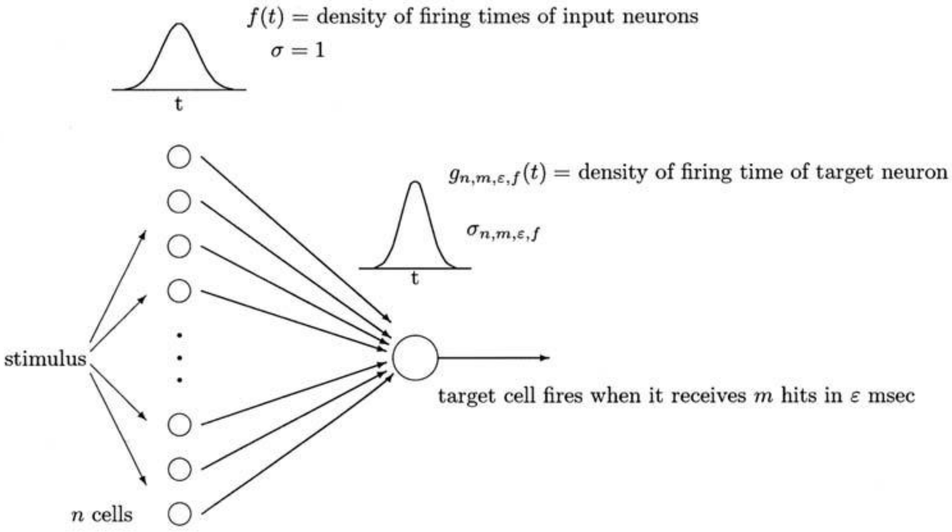
onset units of the CN is as much as an order of magnitude lower. Second, AN fibers phase lock to low frequency sounds, and this phase locking is even better in some CN units. Burkitt and Clark [4, 5] use numerical simulations of leaky integrate-and-fire models to study how convergence of inputs effects both the onset response and the increase in synchrony seen in target cells. Kalluri and Delgutte [23, 24] have created a computational model using leaky integrate-and-fire for the CN target cells and an adaptively filtered Poisson processes to model spike trains along each of the convergent AN fibers. They are interested in determining what properties of the target cell—the filtered Poisson process in AN fibers, the convergence from AN fibers to the target, and adaptation in the hair cells—cause the target neuron to have an onset response with low spontaneous rate. Young, Rothman, and coworkers [51, 39, 40, 41, 42, 43] have conducted experiments and used numerical simulations of biophysical models to investigate how the response properties of CN neurons depend on the details of their channel kinetics. Similarly, Cai, Walsh, and McGee [6, 7] used simulations of biophysical models to investigate the onset response of octopus cells in the CN using the physiological properties discovered by Oertel and coworkers [15, 13, 32].

The overall goal of this computational modeling was to investigate how convergence, detailed biophysics of CN neurons, and the known properties of auditory spike trains give rise to onset responses, higher synchrony, and the sharpening of timing in CN neurons. The numerical computations of the above investigators suggest strongly that there is a connection between the amount of convergence and the sharpening of timing information. However, their models are so elaborate and have so many parameters that it is difficult to make precise the mechanisms by which convergence sharpens timing. For this reason, we have been studying the much simpler model described below in which convergence and the sharpening of timing are isolated as the objects of study. The simplicity of the model allows us to use the tools of probability theory and mathematical statistics to prove theorems that make precise the relationship between convergence and the sharpening of timing. The previous numerical modeling and our theorems not only contribute to understanding the auditory brainstem but also address question (1) and by implication question (2) if several of these systems are connected in series. In other auditory brainstem work, Svirskis et al. [48] investigate through experiment and biophysical modeling the properties of medial superior olive neurons that make them excellent coincidence detectors and propose that coincidence detection is improved in some circumstances by a noisy background. Thus their work relates directly to the ideas of stochastic resonance in neural systems put forward by Greenwood et al. [17] and Stemmler [47] and so addresses question (3).

In our simple convergence model (see Figure 1), there are n identical input neurons, and all receive the same stimulus. Each fires a single action potential at a time selected independently from a probability density f with standard deviation 1 msec. The axons of the n neurons are of equal length and project to one target neuron that fires a single action potential the first time that it has received m inputs in the previous ε msec. Of course, the target neuron may not fire at all in response to a particular stimulus. We denote the conditional density of the time of firing of the target neuron, given that it fires, by $g_{n,m,\varepsilon,f}$ and its standard deviation by $\sigma_{n,m,\varepsilon,f}$, since both will depend on n, m, ε, and f. If $\sigma_{n,m,\varepsilon,f} < 1$ msec, then we say that timing has been sharpened. A change of variables shows that there is a scaling law $\sigma_{n,m,\varepsilon,f} = s\sigma_{n,m,\frac{\varepsilon}{s},f_s}$, where $f_s(t) \equiv sf(st)$, so there is no loss in generality in taking the standard deviation of the input density f to be 1 msec [35, 29].

Although the formulation of the problem is simple, it is difficult or impossible to derive closed form expressions for $g_{n,m,\varepsilon,f}$ and $\sigma_{n,m,\varepsilon,f}$ except in very special cases.



$f(t)$ = density of firing times of input neurons
$\sigma = 1$
t
$g_{n,m,\varepsilon,f}(t)$ = density of firing time of target neuron
$\sigma_{n,m,\varepsilon,f}$
t
stimulus
target cell fires when it receives m hits in ε msec
n cells

FIG. 1. *The basic model. The target cell receives n independently and identically distributed inputs and fires the first time it receives m within ε msec.*

Additionally, Monte Carlo simulations [35] show that, for n and f fixed, $\sigma_{n,m,\varepsilon,f}$ can have surprisingly complicated behavior as a function of m, the numbers of hits required, and ε, the size of the time window. For example, even for simple choices of f (uniform, exponential, normal) and $n = 10$, $\sigma_{n,m,\varepsilon,f}$ is sometimes monotone and sometimes nonmonotone as a function of either m or ε with the other held fixed. In these circumstances, it is natural to ask whether the behavior of $\sigma_{n,m,\varepsilon,f}$ is simpler in certain asymptotic limits. As $\varepsilon \to \infty$, the neuron will surely fire at the time of the mth hit, so $\sigma_{n,m,\infty,f}$ is given by order statistics, which is well understood. In the literature this model is called the (nonleaky) integrate-and-fire model. It is used by Marsalek, Koch, and Maunsell [27], it is the simplest model used by Burkitt and Clark [4], and it is the "analytic coincidence detector model" of Kalluri and Delgutte [23]. Thus those models are a special case of our model. Mitchell [29, 30] considered the singular asymptotic limit $\varepsilon \to 0$, proved that

$$g_{n,m,\varepsilon,f} \to \frac{f^m}{\int f^m} \tag{1}$$

independent of n, and derived an asymptotic form for $g_{n,m,\varepsilon,f}$ and $\sigma_{n,m,\varepsilon,f}$ near the limit.

In this paper, we study the limit as $n \to \infty$, $m \to \infty$ with the ratio $\frac{m}{n}$ held fixed. There are good theoretical and experimental reasons to think that this limit is important. First, it is relatively easy to see (Theorem 2.1 below), under reasonable hypotheses on f, that $\sigma_{n,m,\varepsilon,f} \to 0$ as $n \to \infty$ with m held fixed. That is, one can sharpen up timing as much as one wants by assuming a model with n large, for example by choosing $m = 1$, in which case the target always fires at first hit. Young, Robert, and Schofner [51] already pointed out that if f is exponential and $m = 1$, then $\sigma_{n,1,\varepsilon,f} = \frac{1}{n}$. The trouble is that many neurons (in particular those in the auditory nerve) have high spontaneous firing rates, and so with high n and low m the target cell will have a high spontaneous rate, which ruins its role as a neuron that measures the time since the stimulus. Thus it is natural to ask whether taking both n *and* m large can produce a system that sharpens timing dramatically but also has a very low spontaneous rate. The approximate calculations of Burkitt and Clark [4] and the numerical simulations of Kalluri and Delgutte [23] suggest strongly that there should be a clean asymptotic limit as $n \to \infty$ with $\frac{m}{n}$ held fixed. Furthermore, there is good reason to think that octopus cells in the cochlear nucleus operate near this asymptotic limit. Oertel [32] has found that the octopus cells receive up to 100 inputs from AN fibers and that between 20 and 50 hits within a small time window are required to make them fire.

In section 2, we answer the above question by showing that $\sigma_{n,m,\varepsilon,f} \to 0$ as $n \to \infty$, $m \to \infty$, with $\frac{m}{n}$ fixed. In section 3, we derive the asymptotic forms of $g_{n,m,\varepsilon,f}$ and $\sigma_{n,m,\varepsilon,f}$ near the limit. And in section 4, we apply the results to octopus cells.

2. Limit theorems as $n \to \infty$. Let $\{X_i\}_{i=1}^n$ denote the n independently and identically distributed random variables for the firing times of the inputs. Assume that the X_i's have density $f(x)$, continuous distribution $F(x)$, and finite mean and standard deviation. We will use T_n to denote the random variable for the firing time of the output (a formal definition is given in (6)). For some of the results below we also assume that there is an x_o so that

$$\int_{-\infty}^{x_o} f(x)\,dx = 0 \quad \text{and} \quad \int_{x_o}^{x+a} f(x)\,dx \ > 0 \quad \text{for all } \ a > 0. \tag{2}$$

This is reasonable biologically since the input neurons cannot respond before the stimulus (and perhaps not for some fixed delay afterwards).

We first consider the case where $n \to \infty$ while m and ε are fixed.

THEOREM 2.1. *Let f be a given probability density satisfying* (2), *and let $0 < \varepsilon \leq \infty$ and m be fixed. Then, as $n \to \infty$, the following hold*:

(i) *The probability that the target cell fires $\longrightarrow 1$.*

(ii) *$g_{n,m,\varepsilon,f} \longrightarrow \delta_{x_o}$; that is, $T_n \longrightarrow x_0$ in distribution. Further, T_n converges in probability to the point mass at x_o.*

(iii) *If f has compact support, then $\sigma_{n,m,\varepsilon,f} \longrightarrow 0$.*

Proof. Let $a > 0$ be given, and define $\gamma \equiv \int_{x_o}^{x_o+a} f(x)\,dx \ > 0$. Let Y_i be the random variable with value 1 if $x_o \leq X_i \leq x_o + a$ and zero otherwise. Then, for each k,

$$P\left\{\sum_{i=1}^n Y_i = k\right\} \ = \ \gamma^k(1-\gamma)^{n-k}\binom{n}{k},$$

so that

$$P\left\{\sum_{i=1}^n Y_i < m\right\} = \sum_{k=0}^{m-1} \gamma^k(1-\gamma)^{n-k}\binom{n}{k} \ \leq \ C\beta^n, \tag{3}$$

where β satisfies $1-\gamma < \beta < 1$. The constants β and C depend on m and γ but not on n, and so

$$P\left\{\sum_{i=1}^n Y_i \geq m\right\} \to 1 \quad \text{ as } \ n \to \infty. \tag{4}$$

Let S denote the event that the target cell fires and T_n be the time of firing. If we choose $a = \varepsilon$, then

$$P\{S\} \;\geq\; P\{S \cap \{x_o \leq T_n \leq x_o + \varepsilon\}\} \;=\; P\{\textstyle\sum_{i=1}^{n} Y_i \geq m\},$$

so (i) follows from (4). For all $0 < a \leq \varepsilon$,

$$P\{\{x_o \leq T_n \leq x_o + a\}|S\} = P\{S \cap \{x_o \leq T_n \leq x_o + a\}\}/P\{S\} \quad \to 1 \tag{5}$$

as $n \to \infty$, which proves (ii).

To prove (iii) without assuming compact support, we would need to prove a uniform integrability condition. We will prove such a condition in the case of the main theorem of this section (Theorem 2.3) but omit it here. If we assume that f does have compact support, which is a reasonable hypothesis from a biological perspective, then it is easy to check that $E(T_n|S) \to x_o$ and $E(T_n^2|S) \to x_o^2$ as $n \to \infty$, which gives (iii).

Theorem 2.1 shows, as expected, that if it takes a fixed number of hits in an ε time window to fire the target cell, then one can achieve any improvement in accuracy one wants by taking n large enough. This confirms the general belief in the literature [51, 4, 23] that greater convergence sharpens timing information. However, notice the important hypothesis that m is held fixed. Example 2.1 shows that if m is not fixed, then increasing convergence may make timing worse. Example 2.2 shows that, given a firing mechanism at the target cell, the answer to the question of whether timing gets better of worse depends on f. Thus one should be very careful about drawing general conclusions from simulations, since the results may depend on the form chosen for the noise.

Example 2.1. If $m = n$, $\varepsilon = \infty$, and f is exponential, the standard deviation of the firing times is monotone increasing. This is because the cell will fire when the last (nth) hit arrives. For large n this will be somewhere out in the tail of the distribution. See Table 1 for values. The final entry is computed using the asymptotic behavior of the nth order statistic [44]. Note that this case is not covered by Theorem 2.2 below because $\varepsilon = \infty$. It is also not covered by Theorem 2.3 below because the set $\{x \,|\, F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is empty.

Example 2.2. If $m = n$, $\varepsilon = \infty$, and f is uniform, the standard deviation of the firing times is monotone decreasing. This is because the nth hit out of n will be likely

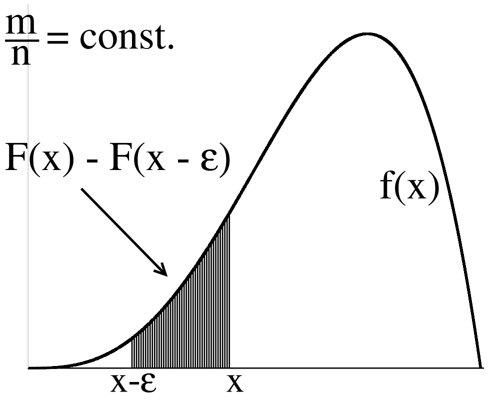

FIG. 2. *An example density to illustrate the derivation of T. T is the smallest value for x so that the area under the density curve between $x - \varepsilon$ and x is at least $\frac{m}{n}$.*

to be close to the right edge of the distribution. Note that this case is not covered by Theorem 2.2 below because $\{x \,|\, F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is not empty. It is also not covered by Theorem 2.3 below because $F(x) - F(x-\varepsilon)$ is not increasing at T.

We now consider the more interesting case where $n \to \infty$ with $\frac{m}{n}$ fixed. To see the intuition, consider the particular f depicted in Figure 2. For any x, we expect that approximately the fraction $F(x) - F(x-\varepsilon)$ of n selections from f should lie in the interval $[x-\varepsilon, x]$. Thus if $F(x) - F(x-\varepsilon) \geq \frac{m}{n}$, we expect that m or more selections will lie in $[x-\varepsilon, x]$, and thus x is certainly a candidate for the firing time of the target cell. Recall that the cell fires the *first* time that it gets m hits in an ε interval. Therefore, we define

$$T \;=\; \inf_x \left\{ x \,|\, F(x) - F(x-\varepsilon) \geq \frac{m}{n} \right\}$$

and expect that for large n the firing time should be close to T. Of course, depending on f, there may be no points in the set $\{x \,|\, F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$.

For the proofs below, we need to introduce some machinery. For each set of n independent selections, $\{X_i\}_{i=1}^n$, from f, we consider the *sample distribution function*

$$F_n(x) \;\equiv\; \frac{1}{n}\sum_{i=1}^{n} I(X_i \leq x),$$

where I is the indicator function taking value 1 if $X_i \leq x$ and 0 otherwise. We can now define the random variable for the output firing time T_n in terms of F_n. Choose any $M > T$, and define the random variable T_n to be

$$T_n \;=\; \inf_x \left\{ x \,|\, F_n(x) - F_n(x-\varepsilon) \geq \frac{m}{n} \right\} \tag{6}$$

if the set is nonempty and $T_n = M$ otherwise.

For n large it is known that $F_n(x)$ is a good approximation to $F(x)$. This is expressed via the *Kolmogorov–Smirnov distance*,

$$D_n \;\equiv\; \sup_{-\infty < x < \infty} |F_n(x) - F(x)|.$$

The classical Glivenko–Cantelli lemma (for a proof, see [2]) states that $D_n \to 0$ with probability one.

Theorem 2.2. *Suppose that $0 < \varepsilon < \infty$ and $0 < \frac{m}{n} \leq 1$ are fixed and that the set $\{x \mid F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is empty. Then the probability that the target cell fires converges to zero as $n \to \infty$.*

Proof. Since F is continuous and $\{x \mid F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is empty, there exists $\alpha > 0$ so that

$$F(x) - F(x-\varepsilon) \ \leq \ \frac{m}{n} - \alpha \quad \text{for all } x.$$

Therefore,

$$\begin{aligned} P\{\text{target cell fires}\} &= P\{\text{at least } m \text{ hits in } \ [x-\varepsilon, x] \text{ for some } x\} \\ &= P\{\text{at least } m \text{ hits in } \ (x-\varepsilon, x] \text{ for some } x\} \\ &= P\left\{F_n(x) - F_n(x-\varepsilon) \geq \frac{m}{n} \ \text{ for some } \ x\right\} \\ &\leq P\{F_n(x) - F(x) + F(x-\varepsilon) - F_n(x-\varepsilon) \geq \alpha \ \text{ for some } \ x\} \\ &\leq P\{2D_n \geq \alpha\}, \end{aligned}$$

which converges to zero by the Glivenko–Cantelli lemma. Thus, the probability that the target cell fires goes to zero as $n \to \infty$.

Theorem 2.3. *Suppose that the set $\{x \mid F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is nonempty, and define T as above. Suppose that $F(x) - F(x-\varepsilon)$ is strictly increasing at T and that $0 < \varepsilon \leq \infty$ and the ratio $0 < \frac{m}{n} \leq 1$ are fixed. Then, as $n \to \infty$, the following hold*:

(i) *The probability that the target cell fires* $\longrightarrow 1$.

(ii) $g_{n,m,\varepsilon,f} \longrightarrow \delta_T$; *that is*, $T_n \longrightarrow T$ *in distribution. Further*, T_n *converges to the point mass at T with probability one.*

(iii) $\sigma_{n,m,\varepsilon,f} \longrightarrow 0$.

Proof. To prove (i), note that, by the strict monotonicity at T, the set $\{x \mid F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is nonempty. Note that here we have used only that the set is not empty, but we use the stronger monotonicity hypothesis for the proof of (ii). Thus, there is an $\bar{x}$ so that $F(\bar{x}) - F(\bar{x}-\varepsilon) \equiv \gamma > \frac{m}{n}$. Let Y_i be the random variable that has value 1 if X_i is in $[\bar{x}-\varepsilon, \bar{x}]$ and 0 otherwise. The Y_i are independent Bernoulli random variables with mean γ. Thus,

$$\begin{aligned} P\{Y_1 + \cdots + Y_n < m\} \ &= \ P\left\{\frac{Y_1 + \cdots + Y_n}{n} - \gamma < \frac{m}{n} - \gamma\right\} \\ &\longrightarrow 0 \end{aligned}$$

as $n \to \infty$ by the weak law of large numbers. If there are m or more of the X_i in the particular interval $[\bar{x}-\varepsilon, \bar{x}]$, the target cell fires, and so (i) is proved.

To prove (ii), let $0 < \mu < M - T$ be given, where M is the constant from the definition of T_n (6). We note that the continuity of F and the fact that $F(x) \to 0$ as $x \to -\infty$ imply that there is an $\alpha > 0$ so that

$$\sup_{x < T-\mu} (F(x) - F(x-\varepsilon)) < \frac{m}{n} \ - \ \alpha. \tag{7}$$

Further, by the continuity of F and monotonicity at T, there is a $\beta > 0$ so that

$$\sup_{x < T+\mu} (F(x) - F(x-\varepsilon)) > \frac{m}{n} \ + \ \beta. \tag{8}$$

We will show that $P\{|T_n - T| > \mu\} \to 0$ as $n \to \infty$. First,

$$\begin{aligned} P\{T_n < T - \mu\} &= P\left\{\exists x < T - \mu \,|\, F_n(x) - F_n(x-\varepsilon) \geq \frac{m}{n}\right\} \\ &\leq P\{\exists x < T - \mu \,|\, F_n(x) - F_n(x-\varepsilon) - (F(x) - F(x-\varepsilon)) \geq \alpha\} \\ &\leq P\{2D_n > \alpha\}. \end{aligned}$$

Similarly,

$$\begin{aligned} P\{T_n > T + \mu\} &= P\left\{F_n(x) - F_n(x-\varepsilon) < \frac{m}{n} \ \ \forall x < T + \mu\right\} \\ &\leq P\{F(x) - F(x-\varepsilon) - F_n(x) + F_n(x-\varepsilon) > \beta \ \ \forall x < T + \mu\} \\ &\leq P\{2D_n > \beta\}. \end{aligned}$$

In each case the probability converges to zero by the Glivenko–Cantelli lemma, which proves (ii). Note that since D_n converges with probability one, so does T_n. This in turn implies convergence in distribution.

To prove (iii) we need to show that the sequences $\{T_n\}$ and $\{T_n^2\}$ are uniformly integrable (for a proof, see [44]), i.e., that $\lim_{c\to\infty} \sup_n \int_c^\infty x g_{n,m,\varepsilon,f} dx = 0$ and that $\lim_{c\to\infty} \sup_n \int_c^\infty x^2 g_{n,m,\varepsilon,f} dx = 0$. We begin by bounding the density of T_n, $g_{n,m,\varepsilon,f}$, which we will abbreviate $g_n(x)$. In [30] we derived an explicit integral formula for $g_n(x)$. It is more convenient to write this expression in terms of the ordered inputs known as the order statistics. Let Y_i be the ith order statistic, i.e., the random variable which is the ith smallest of the X_i's. Let $f_{\{Y_i|T_n=Y_i\}}(x)$ denote the conditional density of Y_i given that $T_n = Y_i$, and let P_i be the probability that $T_n = Y_i$. The density $g_n(x)$ of T_n is the normalized sum from m to n of these conditional densities:

$$g_n(x) \;=\; \frac{\sum_{i=m}^n f_{\{Y_i|T_n=Y_i\}}(x) P_i}{P(\text{success})}. \tag{9}$$

Using the joint density of the Y_i's, we can compute $f_{\{Y_i|T_n=Y_i\}}(x)$ by integrating over the appropriate event:

$$\begin{aligned} &f_{\{Y_i|T_n=Y_i\}}(x) \\ &= \frac{1}{P_i} n! f(x) \int_{\Omega_3} \prod_{j=i+1}^{n} f(y_j) \int_{\Omega_2} \prod_{j=i-m+1}^{i-1} f(y_j) \int_{\Omega_1} \prod_{j=1}^{j=i-m} f(y_j) \prod_{j=1}^{i-1} dy_j \prod_{j=i+1}^{n} dy_j, \end{aligned} \tag{10}$$

where Ω_1, Ω_2, and Ω_3 are the sets

$$\begin{aligned} \Omega_1 &= \{y_1 < \cdots < y_{i-m} \ \text{ and } y_k < y_{k+m-1} - \varepsilon \text{ for } k = 1, \ldots, i-m\}, \\ \Omega_2 &= \{x - \varepsilon < y_{i-m+1} < \cdots < y_{i-1} < x\}, \\ \Omega_3 &= \{x < y_{i+1} < \cdots < y_n\}. \end{aligned}$$

The sets Ω_1, Ω_2, and Ω_3 correspond to the statements that the first $i-1$ arriving hits do not fire the cell, that the ith does, and that the remaining times can be anything.

We can attain a bound on the integral by replacing Ω_1 with the larger set

$$\Omega_1 = \{y_1 < \cdots < y_{i-m} \ \text{ and } \ y_{i-m} < x - \varepsilon\}.$$

Next we can integrate explicitly to obtain the bound on the conditional density

$$f_{\{Y_i|T_n=Y_i\}}(x) \leq \frac{1}{P_i} n! f(x) \frac{(1-F(x))^{n-i}}{(n-i)!} \frac{(F(x) - F(x-\varepsilon))^{m-1}}{(m-1)!} \frac{F(x-\varepsilon)^{i-m}}{(i-m)!}.$$

Summing over i in (9) gives the bound

$$g_n(x) \leq \frac{1}{P(\text{success})} n! \frac{(1-(F(x)-F(x-\varepsilon)))^{n-m}}{(n-m)!} \frac{(F(x)-F(x-\varepsilon))^{m-1}}{(m-1)!} f(x).$$

For large c, $F(x)-F(x-\varepsilon)$ goes to zero. We can make a straightforward calculation using Stirling's formula to show that $n!\frac{(1-(F(x)-F(x-\varepsilon)))^{n-m}}{(n-m)!}\frac{(F(x)-F(x-\varepsilon))^{m-1}}{(m-1)!}$ is uniformly bounded independent of n for $F(x)-F(x-\varepsilon)$ sufficiently small. Specifically if c is large enough so that $F(x)-F(x-\varepsilon) < \frac{a^a}{(a-1)^{a-1}}$ for all $x > c$, where a is the ratio n/m, then there is a constant A so that $g_n(x) \leq \frac{A}{P(\text{success})} f(x)$ for all $x > c$. Since f has a finite mean and standard deviation, this bound implies that $\{T_n\}$ and $\{T_n^2\}$ are both uniformly integrable, and so $E(T_n) \to T$ and $E(T_n^2) \to T^2$, which proves (iii).

Theorem 2.3 shows that if $F(x) - F(x-\varepsilon)$ crosses $\frac{m}{n}$ the first time it reaches $\frac{m}{n}$, then the firing time will converge to the point mass at this time as $n \to \infty$. The following two examples show that while most sets of parameters will be covered in the above theorems, we have not addressed what will happen if $F(x) - F(x-\varepsilon)$ is not increasing at T but rather reaches $\frac{m}{n}$ and is constant for some time or reaches $\frac{m}{n}$ and immediately drops back down. This situation is unlikely in the biological context but is of mathematical interest. Example 2.3 shows that if f is exponential, then either Theorem 2.2 or 2.3 will apply unless $F(x_o+\varepsilon)$ is exactly $\frac{m}{n}$. In Example 2.4 we discuss various cases in which the hypotheses of Theorem 2.3 are, or are not, satisfied.

Example 2.3. If f is exponential, then $F(x)-F(x-\varepsilon)$ will be monotone increasing from x_o to $x_o+\varepsilon$ and monotone decreasing for $x > x_o+\varepsilon$. If the value of $F(x)-F(x-\varepsilon)$ at its peak, namely $F(x_o+\varepsilon)$, is greater than $\frac{m}{n}$, then T will be less than ε and the hypotheses of Theorem 2.3 will be satisfied, so the standard deviation will go to zero (see Figure 3(A)). If, on the other hand, the value at the peak is less than $\frac{m}{n}$, then the set $\{x \,|\, F(x) - F(x-\varepsilon) \geq \frac{m}{n}\}$ is empty and the hypotheses of Theorem 2.2 will be satisfied, so the probability of firing will go to zero. It is of mathematical interest to study what will happen in the borderline case where $F(x_o+\varepsilon)$ is exactly $\frac{m}{n}$.

Example 2.4. Let $x_o < x_1 < y_o < y_1$ and suppose that the support of the density f consists of the two intervals $[x_o, x_1]$ and $[y_o, y_1]$. In addition, suppose that $x_1 - x_o < \varepsilon$, $y_1 - y_o < \varepsilon$, and $y_o - x_1 > \varepsilon$, so the intervals are small and well separated compared to ε. Let $p = \int_{x_o}^{x_1} f(x)\,dx$ and $q = \int_{y_o}^{y_1} f(x)\,dx$. There are several cases to consider. If $p > \frac{m}{n}$, then $x_o < T < x_1$ and the "strictly increasing" hypothesis holds, so the conclusions of Theorem 2.3 hold. If $p < \frac{m}{n}$ and $q < \frac{m}{n}$, then the probability of firing goes to zero as $n \to \infty$ with $\frac{m}{n}$ fixed by Theorem 2.2. If $p < \frac{m}{n}$ and $q > \frac{m}{n}$, then $y_o < T < y_1$ and again the "strictly increasing" hypothesis holds, so the conclusions of Theorem 2.3 hold. Finally, suppose that $\frac{m}{n} = \frac{1}{2}$ and that $p = q = \frac{1}{2}$. Then $T = x_1$ but the "strictly increasing" hypothesis does not hold. The number of hits in the first region is given by the binomial $B(n,p)$. Thus the probability of firing in this first interval, $P(B(n,p) \geq m)$, converges to $\frac{1}{2}$ as $n \to \infty$ with $\frac{m}{n}$ fixed. A straightforward argument shows that the conditional density (conditioned on firing in the first interval) converges to δ_{x_1}. The same arguments show that if the neuron does not fire in the first interval, then it has probability $\frac{1}{2}$ of firing in the second interval, and the conditional density (conditioned on firing in the second interval) converges to δ_{y_1}. Therefore, as $n \to \infty$ with $\frac{m}{n}$ fixed, the density (conditioned on firing) converges to $\frac{2}{3}\delta_{x_1} + \frac{1}{3}\delta_{y_1}$. Thus, if the "strictly increasing at T" hypothesis does not hold, the conclusions of Theorem 2.3 may not hold.

3. The asymptotic form. We will now prove the asymptotic normality of T_n. We will consider the case where, in addition to the left edge hypothesis (2) we assume that $T < x_0 + \varepsilon$. This means that there is more than m/n probability in the interval $(x_0, x_0 + \varepsilon)$, i.e., $F(x_o + \varepsilon) - F(x_o) > m/n$, and therefore that $F(x - \varepsilon) = 0$ for all $x < x_o + \varepsilon$.

THEOREM 3.1. *Suppose that $T < x_0 + \varepsilon$; then T_n is asymptotically normal with mean T and standard deviation*

$$\sigma_c = \frac{\left(\frac{m}{n}\left(1 - \frac{m}{n}\right)\right)^{1/2}}{f(T)n^{1/2}}. \tag{11}$$

We call the standard deviation σ_c because it is a result of the convergence studied in sections 1 and 2.

Proof. Fix t and let

$$G_n(t) = P\left(\frac{T_n - T}{\sigma_n} \le t\right).$$

We wish to show that $G_n(t) \to \Phi(t)$, where Φ is the cumulative distribution for the standard normal. We begin by rewriting $G_n(t)$ using the definition of T_n given in (6):

$$\begin{aligned} G_n(t) &= P(T_n \le T + t\sigma_n) \\ &= P\left(\exists x \le T + t\sigma_n | F_n(x) - F_n(x - \varepsilon) \ge \frac{m}{n}\right). \end{aligned}$$

Since $\sigma_n \to 0$ as $n \to \infty$ and $T < x_0 + \varepsilon$, there is an $\bar{n}$ such that for all $n \ge \bar{n}$, $T + t\sigma_n < x_0 + \varepsilon$. Therefore if $n \ge \bar{n}$ and $x \le T + t\sigma_n$, $F(x - \varepsilon) = 0$. Note that, by the definition of F_n, if $F(x - \varepsilon)$, then the probability of a hit before $x - \varepsilon$ is zero and $F_n(x - \varepsilon)$ is also zero for all n. So, for $n \ge \bar{n}$,

$$\begin{aligned} G_n(t) &= P\left(\exists x \le T + t\sigma_n | F_n(x) \ge \frac{m}{n}\right) \\ &= P\left(F_n(T + t\sigma_n) \ge \frac{m}{n}\right), \end{aligned}$$

where we have used the monotonicity of F_n. Notice that since $F(T - \varepsilon) = 0$, the value T is just the value of the $\frac{m}{n}$th quantile, which we will denote ξ. The $\frac{m}{n}$th quantile is defined by $\xi = \inf\{x : F(x) \ge \frac{m}{n}\}$. The proof rests upon the asymptotic normality of the sample $\frac{m}{n}$th quantile, ξ_n, defined by $\xi_n = \inf\{x : F_n(x) \ge \frac{m}{n}\}$. ξ_n is asymptotically normal with mean ξ and standard deviation σ_n [44]. Now we can write G_n in terms of the quantiles:

$$G_n(t) = P(\xi_n \le \xi + t\sigma_n).$$

Therefore the asymptotic normality of the sample quantile implies the asymptotic normality of T_n.

It is the hypothesis that $T < x_0 + \varepsilon$ that makes the proof of Theorem 3.1 easy by reducing the question to the asymptotic behavior of quantiles. Intuitively, the hypothesis means that there is a lot of probability close to the initial point x_0. Example 3.1 shows that this hypothesis is biologically reasonable. Example 3.2 shows what can happen if this hypothesis is violated and gives a conjecture for the general case.

Example 3.1. For AN neurons, the density f looks like a (translated, smoothed) exponential [25, 51, 49] with standard deviation approximately 1 msec. In Figure 3(A)

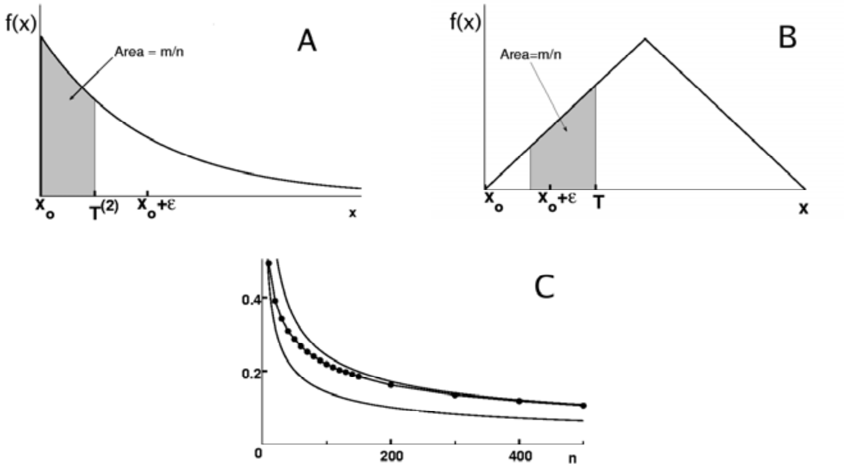

Fig. 3. *Examples illustrating the importance of the hypothesis* $T < x_o + \varepsilon$ *in Theorem* 3.1. *Panel* (A) *shows the density for the exponential as in Example* 3.1. *The shaded portion has area* $\frac{m}{n}$, *and one can see that* $T^{(2)} = x_o + \ln\frac{5}{3} < x_o + \varepsilon$ *so that Example* 3.1 *satisfies the hypotheses of Theorem* 3.1. *Similarly, the shaded portion in panel* (B) *has area* $\frac{m}{n}$, *but in this case* $T = 1.7 - \sqrt{6} > x_o + \varepsilon$ *so that Theorem* 3.1 *does not apply. Panel* (C) *compares results of Monte Carlo simulations (data are the dots on the middle curve) to the predictions of Theorem* 3.1 *(bottom curve,* σ_c*). We see that the theorem does not apply, but that our conjecture (top curve,* $\bar{\sigma}_c$*) for this more general case is supported.*

we show the exponential distribution (starting at x_0) with standard deviation 1 msec. It is easy to check that $T = x_0 + \ln\frac{n}{n-m}$. Consider three cases $\frac{m_1}{n_1} = .2$, $\frac{m_2}{n_2} = .4$, and $\frac{m_3}{n_3} = .5$, which will have corresponding $T^{(1)} = x_0 + \ln\frac{5}{4}$, $T^{(2)} = x_0 + \ln\frac{5}{3}$, and $T^{(3)} = x_0 + \ln 2$. Thus, if $\varepsilon = 1$ msec, which is reasonable for octopus cells [15, 32] and many other neurons, we will have $T^{(i)} < x_0 + \varepsilon$ in all three cases, so Theorem 3.1 applies.

Example 3.2. On the other hand, suppose that f is the piecewise linear "hat" distribution (see Figure 3(B)). In order to have standard deviation 1 msec, the density is supported on the interval $[-\sqrt{6}\sqrt{6}]$ (so $x_o = \sqrt{6}$). In all of the cases above $T^{(i)} > x_o + \varepsilon$, and so Theorem 3.1 does not apply. For example if $\frac{m}{n} = .2$, then $T = -\sqrt{6} + 1.7 \approx -0.75$. In this case the standard deviation does not converge to the value σ_c given in Theorem 3.1 but instead to another higher value. We conjecture that in this case T_n will be asymptotically normal with mean T and standard deviation

$$\bar{\sigma}_c = \frac{\left(\frac{m}{n}\left(1 - \frac{m}{n}\right)\right)^{1/2}}{(f(T) - f(T - \varepsilon))n^{1/2}}.$$

Figure 3(C) shows the values for σ_c (bottom curve), $\bar{\sigma}_c$ (top curve), and the standard deviation computed using Monte Carlo simulations as in [35] (middle curve; each dot was computed using 100,000 trials). We can see that for large n the values do not approach σ_c but rather $\bar{\sigma}_c$, supporting our conjecture.

4. Applications to octopus cells. The latency of a neuron in the auditory system is the length of time between the start of a sound and the time of the first action potential produced by the neuron. In mammals, AN neurons, which provide the input to the auditory brainstem, have latencies in the range 2 to 8 msec, with standard deviations of approximately 1 msec under repeated trials [25]. The auditory system must use group properties of these highly variable inputs to extract sharp timing information so that the animal can make time distinctions in the low microsecond range. According to Oertel et al. [32], much of this processing is done by octopus cells in the cochlear nucleus that "detect coincident firing within populations of auditory nerve fibers and convey acoustic information in precisely timed action potentials." It is estimated that octopus cells receive synapses from roughly 60 to 100 AN neurons (i.e., $60 \leq n \leq 100$) and require that 20% to 50% of these synapses be activated by incoming action potentials within 1 msec in order fire an action potential (i.e., $\varepsilon =$ 1 msec and $0.2 \leq \frac{m}{n} \leq 0.5$) [32, 15]. It is therefore of interest to test whether the predictions of the theorems in this paper are consistent with the observed in vivo and in vitro behavior of octopus cells. For some parameter choices we can also make more specific predictions for optimal values of m and n.

The histograms of latencies in AN neurons are quite variable but look roughly like smoothed exponential distributions. Thus, we shall assume that f is exponential with standard deviation 1 msec, and it follows that $T = x_o + \log \frac{n}{n-m}$. If $\varepsilon \geq T$, which holds for all cases considered below (see Example 3.1 above), then $F(T-\varepsilon) = 0$, and the asymptotic formula (11) has the simple form

$$\sigma_c^2 = \frac{\frac{m}{n}}{(1-\frac{m}{n})n}. \tag{12}$$

If we evaluate σ_c for n and m in the physiological ranges given above, we obtain values in the range 0.05 msec to 0.13 msec (Table 2). Oertel et al. report that the standard deviations of latencies of octopus cells in response to sounds are approximately 0.1 msec [32], so the formula (11) certainly predicts the order of magnitude improvement of timing seen in vivo in octopus cells.

TABLE 2
Values of σ_c.

n	m	σ_c (msec)
100	20	0.05
100	33	0.07
100	50	0.10
60	30	0.13

We can use (12) to explore a variety of questions about the physiology of octopus cells. First we ask why n isn't larger than the range 60–100. σ_c is the standard deviation in the latency of the octopus cell due to the variation in firing times of the inputs. However, there are other sources of variation. The AN neurons that synapse on the octopus cell may have somewhat different axonal lengths and diameters, both of which will affect arrival times. Second, due to such factors as the diffusion of neurotransmitter across the synaptic cleft, the finite number of postsynaptic receptors, and the variation in the local membrane chemistry, the integration of synaptic inputs by the octopus cell will have variation under repeated trials even if the timing of the inputs is the same. Assuming that these other factors are independent of the noise in the firing times of the inputs, and denoting the corresponding standard deviation by σ_{other}, we have $\sigma_o^2 = \sigma_c^2 + \sigma_{other}^2$. Fortunately, the experiments in [15], where shocks are applied to the nerve root, give a good estimate, $\sigma_{other} = 0.05$ msec. Figure 4 shows the behavior of σ_o as a function of n in two cases, $\frac{m}{n} = \frac{1}{2}$ and $\frac{m}{n} = \frac{1}{5}$, that are

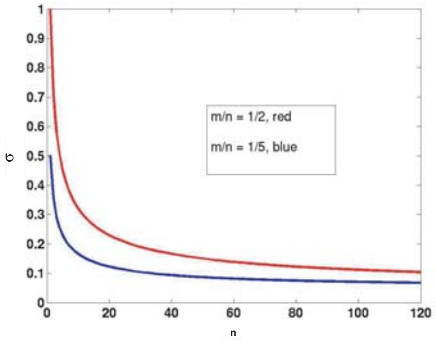

FIG. 4. *Predicted values of the standard deviation of the latency of octopus cells, σ_o, for different values of n.*

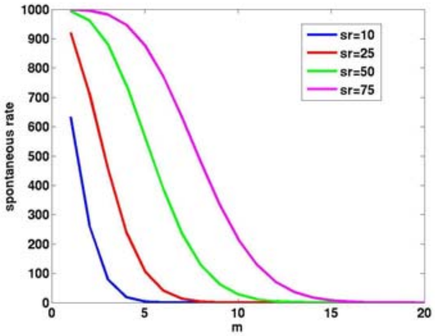

FIG. 5. *Predicted values of the spontaneous rate of the octopus cell as a function of m with $n = 100$ and four different assumptions about the spontaneous rate, r, of AN neurons.*

the expected extremes for the ratio $\frac{m}{n}$. In both cases there is not much extra decrease in σ_o after $n = 60$ and very little after $n = 100$.

Many AN neurons have high or very high spontaneous rates, even ranging as high as 100 spikes/sec [25, 19]. If n is high and m is low, then many of the successful firings of the octopus cell will be spontaneous, i.e., unrelated to input. However, it is known that octopus cells have essentially no spontaneous rate [37, 38, 46]. Thus, it is a natural question to ask how large m must be so that the spontaneous rate of the octopus cell in our model is 1 spike/sec or less. Assume $\varepsilon = 1$ msec, and suppose that each incoming AN neuron has a spontaneous rate of r spikes/msec. Then, the probability that any particular AN neuron delivers a spike within a 1 msec interval is approximately r. Assuming that the AN neurons are independent, the probability of m or more incoming spikes within the 1 msec interval is approximately

$$Prob\{\#\text{incoming hits} \geq m\} = \sum_{k=m}^{n} \binom{n}{k} r^k (1-r)^{n-k}, \tag{13}$$

and thus the spontaneous firing rate of the octopus cell in spikes/sec, denoted by $SR(r, n, m)$, will be approximately 1000 times the probability in (13). Figure 5 shows the graphs of $SR(r, n, m)$ as functions of m for $n = 100$ and for four different choices of r. If the incoming AN fibers have spontaneous rates of $r = .075$ spikes/msec

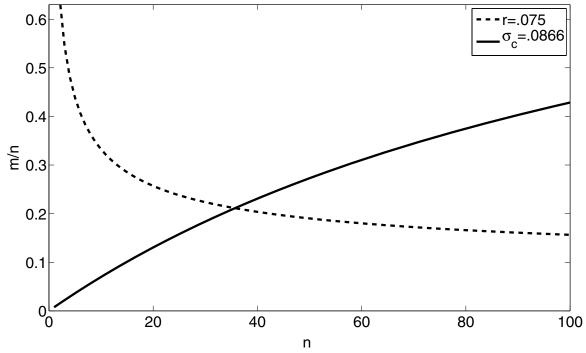

FIG. 6. *The region of the* $(\frac{m}{n}, n)$ *plane for which* $\sigma_o \leq 0.1$ *and the octopus cell has a spontaneous firing rate* ≤ 1 *spike/sec is the region below the solid curve and above the dashed curve.*

(75 spikes/sec), $SR(.075, 100, m)$ does not go below 1 spike/sec until $m = 18$. Thus the model, with $n = 100$, predicts that m is 18 or higher, which corresponds well with the estimates of experimentalists [15, 32, 13].

We can also allow both $\frac{m}{n}$ and n to be free and ask what is the region in the $(n, \frac{m}{n})$ plane that gives the observed physiological behavior. First, we require that the standard deviation of the latency of the octopus cell satisfy $\sigma_o \leq 0.1$ msec. Since $\sigma_o^2 = \sigma_c^2 + \sigma_{other}^2$, this is equivalent to the requirement that $\sigma_c^2 \leq .1^2 - .05^2$. Equation (12) can be rearranged to give a bound on $\frac{m}{n}$ in terms of this maximum allowable standard deviation:

$$\frac{m}{n} \leq \frac{(\sigma_c^2)n}{1 + (\sigma_c^2)n}. \tag{14}$$

Second, we require that the spontaneous firing rate of the octopus cell be less than the maximum value $r_{max} = .001$ spike/msec or 1 spike/sec. Using (13) and the normal approximation to the binomial gives

$$\frac{m}{n} \geq \Phi^{-1}(1 - r_{max})\sqrt{\frac{r(1-r)}{n}} + r, \tag{15}$$

where Φ is the cumulative distribution function of the standard normal and r is the spontaneous rate of the incoming neurons. The points below the solid curve in Figure 6 satisfy (14), and the points above the dashed curve satisfy (15) in the case $r = .075$ spikes/msec.

In Figure 6 we assumed that the standard deviation of f is 1 msec and that the spontaneous rate of the AN neurons $r = 75$spikes/sec. For other assumptions the curves are somewhat different. For example, instead of choosing $\sigma_c = .0866$, we could recognize that it is not particularly beneficial to require that σ_c be smaller than σ_{other}. In this case we require that σ_c be roughly the same as σ_{other} so that both are equal to .05 msec and repeat the above calculations (shown in Figure 7), predicting a much smaller region of possible values for m and n. In this case we require $n \geq 80$ and that $\frac{m}{n}$ be between 18% and 20%. This is within the experimental estimates but suggests a much smaller range of optimal values. From this calculation we can predict that ideally n should be near the high end of its range, close to 100, and that m should be near the low end of its range, close to 20.

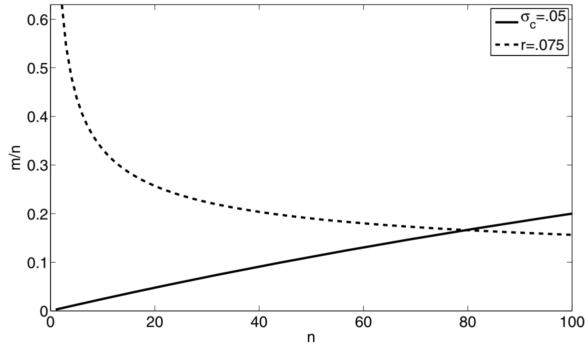

FIG. 7. *The region of the* $(\frac{m}{n}, n)$ *plane for which* $\sigma_c \leq 0.05$ *and the octopus cell has a spontaneous firing rate* ≤ 1 *spike/sec is the region below the solid curve and above the dashed curve. In both Figures* 6 *and* 7*, we assume that the standard deviation of* f *is* 1 *msec and that the spontaneous rate of the AN neurons* $r = 75$ *spikes/sec.*

5. Discussion. The model given in Figure 1 was formulated to allow a mathematical investigation of how convergence (the number of incoming neurons, n) and the number of hits required to make the target cell fire, m, affect the sharpening of timing information when the firing times of the incoming neurons are noisy. The main theorem (Theorem 2.3) shows that if $n \to \infty$ and $m \to \infty$ with $\frac{m}{n}$ fixed, then the standard deviation of the time of firing of the target cell goes to zero. The physiological significance of the result is that timing can be sharpened by taking both n large and m large (to avoid spontaneous firing of the target). That there should be a theorem like this was suggested by the approximate calculations of Burkitt and Clark [4] and the numerical simulations of Kalluri and Delgutte [23]. In section 3 we derived approximate formulas for $g_{n,m,\varepsilon,f}$ and $\sigma_{n,m,\varepsilon,f}$ near the limit. In section 4, we used the asymptotic formula for $\sigma_{n,m,\varepsilon,f}$ to study octopus cells of the mammalian cochlear nucleus and saw that the predictions of the mathematical model correspond quite well to experimental observations.

We hope that the theorems proved in this paper can be a first step in proving theorems about more complicated and difficult neurophysiological questions. One such question is the improved phase locking of CN neurons compared to the phase locking in the AN [19, 22, 43, 4, 23], which is universally believed to occur because of convergence of many AN fibers on CN target cells. The mathematical situation here is more complicated, since typically one models the firing pattern in individual AN fibers by a Poisson process whose parameter $\lambda(t)$ depends on the sound; for example, $\lambda(t)$ would be periodic for a pure tone. The quantity of interest is the distribution of spike times of the target cell modulo the nearest multiple of the period. For some cells the target cell may fire at first hit, while for other cells many subthreshold hits in a small time window may be necessary for firing. Because of the background noise caused by the high spontaneous rates of many AN fibers, this may be an excellent use of the theory of stochastic resonance [17, 47]. To prove such theorems one would need to represent the noise as stochastic processes rather than making the simple approximations that we have used in section 4. Another such question is how synchronous firing of large groups of neurons in the CNS is created and maintained. Such firing has been proposed as central to "binding" mechanisms in the visual system [12, 26, 28], the improvement of coordination of motor systems in the cerebellum [20], and the creation of the γ

rhythm [3]. The approximation theorem in section 3 is a natural starting point for studying synfire chains [1, 11, 36, 18] that have both noise and high convergence from level to level. Many of the models for these systems involve inhibition, so an important step would be the extension of the results in [35, 30] and this paper to include inhibitory neurons.

In applying our model to octopus cells we have simplified the biological situation in several ways. First, AN neurons synapse serially on the large dendrites of octopus cells, not directly on the cell body as in our model. Oertel has shown [32] that the AN neurons that carry higher frequency sounds (they fire on average earlier) synapse further out on the dendrite, and the AN neurons that carry lower frequency sounds (they fire on average later) synapse closer to the cell body. Golding, Ferragamo, and Oertel [16] conclude that this arrangement on the dendrite, as well as the thickness of the dendrite and special channel properties, insure that the influence of each AN neuron arrives (on average) at the cell body at the same time, which justifies our assumption that all the AN neurons synapse directly on the cell body.

A much more serious simplification is that we have ignored the detailed biophysics of synapses and the postsynaptic membrane. All the biophysics is contained in the two parameters, ε, the time window, and m, the number of hits required in that time window to fire the target cell. We believe that the results in section 4 show conclusively that our model, with these two simple parameters, explains why octopus cells improve the standard deviation of timing by one order of magnitude and why octopus cells have no spontaneous rates. Of course, the *values* of these two parameters arise from the detailed biophysics of the synapses and postsynaptic membrane.

Finally, it is reasonable to ask whether octopus cells, or indeed any neurons, have sharp time windows as we assume in our model. Ferragamo and Oertel [13] have conducted a detailed study of the potential of the postsynaptic membrane of octopus cells. They showed that it is the rate of rise of the potential (dependent on the rate of arrival of incoming spikes) that determines whether the octopus cell fires. This is exactly what one would expect if the octopus cell had a sharp time window. If the rate of rise is high enough, then there will be enough incoming spikes in the time window, and if the rate of rise is too slow, then there will not be enough incoming spikes in the time window. More generally, we have studied a number of frequently used nonlinear models for the biophysics of postsynaptic membranes and have shown that, in reasonable parameter ranges, they have quite sharp time windows. These results will appear in a subsequent publication [31].

Acknowledgments. The authors are very grateful to Professor Donata Oertel, who raised many of the questions discussed in section 4. We would also like to thank Matthew Moehlmann, who wrote the code for the Monte Carlo simulation in Example 3.2.

STABILITY OF TRAFFIC FLOW BEHAVIOR WITH DISTRIBUTED DELAYS MODELING THE MEMORY EFFECTS OF THE DRIVERS[*]

RIFAT SIPAHI[†], FATIHCAN M. ATAY[‡], AND SILVIU-IULIAN NICULESCU[§]

Abstract. Stability analysis of a single-lane microscopic car-following model is studied analytically from the perspective of delayed reactions of human drivers. In the literature, the delayed reactions of the drivers are modeled with discrete delays, which assume that drivers make their control decisions based on the stimuli they receive from a point of time in the history. We improve this model by introducing a distribution of delays, which assumes that the control actions are based on information distributed over an interval of time in history. Such an assumption is more realistic, as it takes into consideration the memory capabilities of the drivers and the inevitable heterogeneity of their delay times. We calculate exact stability regions in the parameter space of some realistic delay distributions. Case studies are provided demonstrating the application of the results.

Key words. memory, distributed delay, traffic dynamics, traffic flow stability

1. Introduction.

Traffic behavior has been an important research topic since the 1930s, with the of aim of reducing the undesirable social (e.g., vehicle accidents) and economic (for example, congestion and increasing pollution) effects of increasingly complex traffic loads. For this purpose, one needs a good understanding of traffic dynamics, in which many parameters or constraints play an important role, such as the physical conditions of highways, mechanical properties of vehicles, psychological states of the drivers, traffic laws, on- and off-ramps, multiple lanes, traffic density, etc. The literature contains various models addressing different phenomena; see, e.g., the survey [12] and the references therein.

Among the parameters that play a major role in traffic behavior, there exists a critical one which has been recognized as early as the 1950s [4], namely the *time delay.* It mainly originates due to the time needed by human drivers for sensing, being conscious, and performing control actions [7]. Consequently, traffic dynamics, and ultimately its mathematical models, *inherently* carry *time delays.* See, e.g., [2, 23, 19, 18, 26, 27] for some delay models and related discussions.

Stability characterizations of traffic models may be quite different when time delays are taken into account; for instance, a stable delay-free dynamics may become unstable when delays are considered. Therefore, a thorough stability analysis of the dynamics in the time delay domain is necessary. Without entering into details, we shall consider a continuous-time microscopic car-following model proposed in [4, 21] to describe traffic behavior. What distinguishes this study is the idea of incorporating *distributed delays* in order to represent the memory of the drivers.

Human-in-the-loop modeling. From the perspective of control theory, traffic flow can be seen as human-in-the-loop dynamics [16], since human drivers play the major role in the evolution of the traffic flow. Such a dynamical structure exhibits richer and more complicated features not only due to the challenges of modeling human beings, but also due to the delayed control actions of the drivers, which distinguishes them from fast response characteristics of sensors and controllers. On the other hand, *the modeling of time-delays* representing the behavior of the drivers is a challenge. Models in the existing literature make use of discrete delays [2, 27, 23], which describe an action of the driver at time t that is based on what is experienced at a point of time $t - \tau$, $\tau \geq 0$, in the past. The stability of the arising dynamics has been studied by several authors from various perspectives. See [2, 6, 18, 19] for the utilization of nonlinear optimal velocity functions relating headway versus desired velocity; [19, 18, 20] for one- and two dimensional bifurcation analysis as well as phase diagrams characterizing oscillations, collision, and the stopping motion nature of the traffic flow; [27] for incorporating human driver modeling into traffic flow where human adaptation and anticipation are considered along with multiple vehicle following strategies and phase diagrams revealing collisions, oscillations, and accident-free traffic flow; and [23] for the stability analysis of traffic flow in which multiple discrete time-delays corresponding to different time scales of reaction of human drivers against velocity and headway changes are taken into account.

We note, however, that discrete-delay models can have their shortcomings. For instance, regarding τ as a fixed unchanging quantity with known value would ignore the possibility that the dynamics may possess inherent "memory" effects which use the past history of the received information. Especially for the traffic flow, the presence of human drivers suggests that memory effects should be taken into consideration. Moreover, the behavior of individual drivers and their reactions are not identical, and in reality exhibit a distribution of inhomogeneous behavior. Therefore, the use of a model taking into account the distributed nature of the delays will yield a better representation of reality. Such an argument has also some potential in modeling the dynamics of human-in-the-loop systems [16], which will ultimately open new research directions for designing driver assistance or semiactive controllers that can guide the human beings for a safer drive in uncertain environments.

In the present work, motivated by the above reasoning, we model the delayed action/decision of human drivers using distributed delays. The physical basis of the model is the fact that the drivers perform their decisions based on what they continuously observe (during a memory window) from the evolving traffic flow, during which some information is retained and used in the decision-making process. These decisions are clearly limited by the capacity of the memory, i.e., the size of the memory window, which will be an important parameter in the analysis.

Objective and approach. The main objectives of the paper are to (a) study the stability margin of the traffic flow dynamics over a microscopic car-following model in the parameter space defining the memory effects, and (b) discuss the analytical and physical interpretations of the results for several practical traffic scenarios.

For the stability analysis, we use a frequency-domain approach combined with some simple geometric ideas, and give necessary and sufficient conditions for the stability of the dynamics. In this context, we also explore whether the stability region consists of a single connected set or of several "islands" (also called *pockets*) of stability. We note that in the present text the stability is robust against small delay variations (section 2); thus small delay perturbations do not induce instability; see some discussions in [24, 10, 17, 15]. The focus of the work here is an analytical study of the effects of distributed delays on the stability of traffic flow.

Moreover, it is shown in [1] that distributed memory enhances the stability margin in a network stabilization scheme. It is interesting to see whether a similar stability-enhancing feature also exists in traffic flow dynamics when the drivers make use of the past history of the traffic evolution in their decision-making, which would clearly have significance in realistic traffic modeling.

To model memory effects one can use common delay distributions, namely γ-distribution with and without a gap, uniform distribution. As discussed below, the first two cases are easier to handle, whereas the uniform distribution needs a more careful treatment. This mainly originates from a characteristic equation which does not exactly fit into standard classes treated in the literature, in that (i) the delay terms appear not only in exponential terms but also in the coefficients, (ii) the characteristic equation includes complex coefficients, which does not carry the features of those with real coefficients as treated in the literature [24, 17, 10, 15], (iii) there exist two independent delay parameters; stability investigations under the presence of more than one delay is quite complicated [9, 17, 22, 25, 24, 15].

The key ideas of our analysis are based on decoupling the dynamics into lower dimensions and introducing an interconnection scheme interpretation from control feedback systems theory. Such an analysis is the key to the complete analytical treatment of the arising characteristic equation. Connections with existing approaches and methodologies will be made in the following sections. In section 2, we present the microscopic car-following model and the spatial configuration of vehicles in traffic. Section 3 introduces some preliminaries, and section 4 is devoted to the main results on the stability analysis, where analytical and geometrical arguments for deriving the stability results are developed. Section 5 illustrates the results with numerical examples for several traffic scenarios, and a brief summary in section 6 concludes the presentation.

Notation. We use $\mathbb{R}$ for real numbers, where an additional $+$ or $-$ sign as a subscript indicates the positive and negative real numbers, respectively. Similarly, $\mathbb{C}_+$ and $\mathbb{C}_-$ denote complex numbers with positive and negative real parts, respectively. The imaginary axis of the complex plane is denoted by $j\mathbb{R}$, where $j = \sqrt{-1}$. We use $s \in \mathbb{C}$ for the Laplace variable, whose values on the imaginary axis are denoted by $s = j\omega$ for $\omega \in \mathbb{R}$. The eigenvalues of the matrix A are represented by $\lambda_i(A)$. $\angle z$ denotes the argument of the complex number z.

2. Microscopic car-following model with distributed delays. Although undesirable, the presence of time-delays in the process of decision making and performing a control action by human drivers is neither avoidable nor negligible (e.g., [27, 26, 2, 23]). In this section, we develop memory effects on a conceptual microscopic car-following model.

Microscopic car-following model. In order to understand the behavior of traffic flow and to propose ways to avoid its undesirable effects (congestion, accidents, economic losses, time losses, degradation of the quality of the environment), various mathematical models have been proposed in the literature [8, 12, 6, 18, 27, 26]. Despite the available results, the topic still offers open problems today.

A main direction in traffic research is focused on highway traffic models [27, 19, 12, 6], since travel times on highways are longer and travel speed is relatively high, and health and economic issues are largely at risk [12]. Furthermore, in most cases a single-lane problem is considered. Such an assumption is quite realistic and also allows one to obtain further insight on the problem due to its simpler mathematical formulation. This type of model also forms the main focus in our study. A single-lane traffic flow, in which a chain of vehicles travels at a constant velocity (so-called quasi steady-state) without changing lanes, is considered. We use a *microscopic model* in which the dynamics of individual vehicles and drivers is taken into account. Despite the simplicity of the model, an *analytical* stability investigation becomes nontrivial due to the presence of time-delays, as we present below. Furthermore, there exist various complications in realistically modeling human beings and their delayed reactions.

The primary interest in this work is to shed light, from the perspective of memory effects of human drivers, on the stability of traffic behavior. As a starting point in this new direction, the linear stability analysis of the perturbations around the constant-velocity solutions will be of particular interest in order to reveal the stability features with respect to the parametric domain defining the memory effects. In order to achieve this, a linear mathematical model inspired by earlier work is introduced in what follows. Due to the linear stability analysis, however, the mathematical model considered here is not dependent on some additional parameters defining the traffic, such as dependence on headway, drivers' sensitivity as a function of headway, acceleration and deceleration characteristics, human anticipation, etc. Readers are directed to the work in [6, 12, 20, 27] for more elaborate models.

Discrete-delay models. Many studies in the literature model the time-delayed actions of the drivers by a discrete delay τ. One such microscopic car-following model is given as [4, 12, 21, 23]

$$\dot{v}_i(t) = \kappa_i(v_{i-1}(t-\tau) - v_i(t-\tau)). \tag{2.1}$$

This model represents the dynamics of the velocity perturbations v_i around constant-velocity solutions (the equilibrium at which *all* vehicles travel at a constant velocity V) of the traffic flow. The parameter $\kappa_i > 0$ denotes the sensitivity of a driver to the velocity difference between his vehicle and the one in front, and gives a measure of the driver's reactivity (aggressiveness) based on his experience and knowledge of the environment. For further information on discrete-delay models, refer to [2, 6, 18, 20, 27]; on the links between the stability features of discrete-delay models and Hopf bifurcations, some interesting arguments can be found in [18, 20, 19]; and on the phase diagrams of traffic flow characterizing collisions, oscillations, and accident-free flow, see [20, 27]. The cited references are also valuable sources for various mathematical models over which additional parameters not considered here, such as headway, sensitivity, acceleration, and deceleration dependence can be studied.

Distributed delay model. By incorporating a general memory effect, $f(\tau)$, into the system (2.1), we arrive at the following generalized model:

$$\dot{v}_i(t) = \kappa_i \int_0^\infty f(\tau)(v_{i-1}(t-\tau) - v_i(t-\tau))\, d\tau, \tag{2.2}$$

where we assume that the delay kernel f is a measurable function of exponential order. When f is a Dirac delta function, (2.2) reduces to the discrete delay model (2.1). See above for discussions of earlier work on discrete delay models.

Delay distributions. We will consider the following common distribution functions f in the model (2.2):

(1) *Uniform distribution.* For $\delta > 0$ and $h \geq 0$, the distribution

$$f(\tau) = \begin{cases} 1/\delta & \text{if } h < \tau < h + \delta, \\ 0 & \text{otherwise,} \end{cases} \tag{2.3}$$

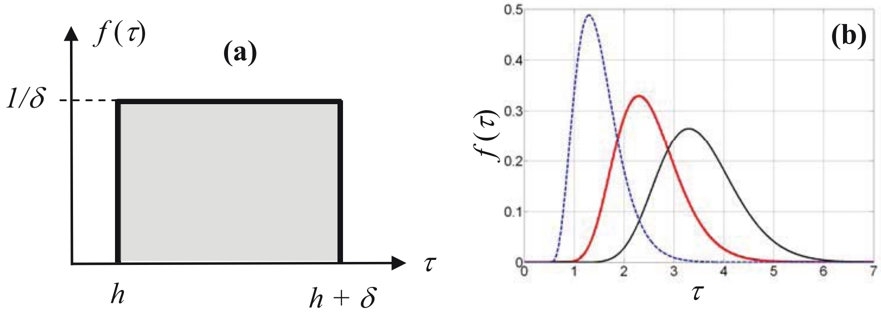

FIG. 2.1. (a) *Uniform distribution with h being dead-time and δ being size of the memory window.* (b) *γ-distribution with gap, $h = 0.5$, for $p = 5$ (dashed curve), $p = 10$ (thick curve), $p = 20$ (thin curve), where $pq = 1$.*

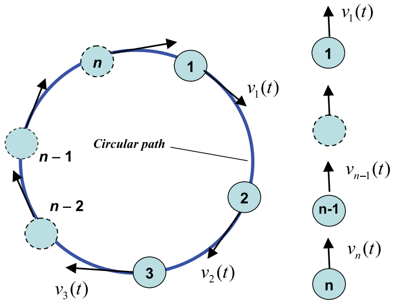

FIG. 2.2. *Ring and linear configurations of the traffic model with n vehicles.*

represents an average of the information available in the short-term memory, and can be considered as a first order approximation to a more complicated distribution; see Figure 2.1(a). It will be of interest to see how h (corresponding to some dead-time before the perception of the sensory input by the driver) and the window size δ affect the stability.

(2) *γ-distribution with and without gap.* We have

$$f(\tau) = \begin{cases} \dfrac{(\tau-h)^{p-1}e^{-(\tau-h)/q}}{q^p\Gamma(p)} & \text{if } \tau \geq h, \\ 0 & \text{if } \tau < h, \end{cases} \tag{2.4}$$

where p, q are positive parameters of the distribution, Γ denotes the gamma function, and the gap $h \geq 0$ represents the dead-time. The mean value of f is $h + pq$, and the variance is pq^2 (which exist for $p > 2$), which is a measure of the length of the memory window, q being a scaling factor ($q = 1$, mean value $= h + p$, variance $= p$). It will be of interest to see how the quantities h, p, and q affect stability. See in Figure 2.1(b) the γ-distribution with gap for various p values keeping pq fixed.

Spatial configuration of the model. We consider two widely utilized configurations (Figure 2.2) with n number of vehicles: (a) vehicles traveling around a ring, and (b) vehicles arranged along a linear path. In the linear configuration, the vehicle in front (for which we use the convention of labeling with index $i = 1$) travels at a constant velocity, i.e., $\dot{v}_1(t) = 0$. Hence, the linear configuration can be derived from the circular one by setting $\kappa_1 = 0$.

3. Problem statement and preliminaries. The system (2.2) can be expressed in vector form as

$$\dot{\mathbf{v}}(t) = \int_0^\infty J\mathbf{v}(t-\tau)f(\tau)\,d\tau, \tag{3.1}$$

where $\mathbf{v} = (v_1, \dots, v_n)$ and $J \in \mathbf{R}^{n\times n}$ is a configuration matrix weighted by the driver sensitivities κ_i. For the *circular* form of the configuration in Figure 2.2, it is obvious that $v_0 = v_n$; thus the appropriate index selection in (2.2) becomes $i = 1, \dots, n$. Consequently, the matrix J takes the form

$$J = \begin{pmatrix} -\kappa_1 & 0 & \cdots & 0 & \kappa_1 \\ \kappa_2 & -\kappa_2 & 0 & \cdots & 0 \\ 0 & \kappa_3 & -\kappa_3 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \kappa_n & -\kappa_n \end{pmatrix}. \tag{3.2}$$

The configuration matrix for the linear arrangement of vehicles is obtained by setting $\kappa_1 = 0$, and it is denoted by J'.

The characteristic equation for (3.1) is given by

$$\chi(s) = \det[sI - JF(s)] = 0, \tag{3.3}$$

where $F(s)$ is the Laplace transform of f. We assume the generic case that J is diagonalizable; that is, its eigenvectors form a basis for $\mathbb{R}^n$. Then (3.3) can be expressed as $\chi(s) = \prod_{i=1}^n (s - \lambda_i(J)F(s)) = 0$, where $\lambda_i(J)$ is the ith eigenvalue of J. In the remainder of the text, λ_i will denote $\lambda_i(J)$ unless otherwise stated. The roots corresponding to the ith factor of χ, i.e., the solutions s of the equation

$$\chi_i(s) \triangleq s - \lambda_i F(s) = 0, \tag{3.4}$$

determine the fate of perturbations along the ith eigenvector of J. The perturbations die out if and only if Re(s) < 0 for all solutions s of (3.4). As the stability depends on the spectrum of J, the following properties will be needed in the analysis.

LEMMA 3.1. *The configuration matrix J has a simple zero eigenvalue, and all its remaining eigenvalues have negative real parts. Furthermore, $|\lambda_i| \le 2\kappa_{\max}$, $i = 1, \dots, n$, where $\kappa_{\max} = \max\{\kappa_i\}$. If $\kappa_i = \kappa$ for all i, then the eigenvalues of J are given by*

$$\lambda_i = \kappa(e^{j2\pi(i-1)/n} - 1), \qquad i = 1, \dots, n. \tag{3.5}$$

If J' denotes the matrix obtained from J by setting $\kappa_1 = 0$, then the eigenvalues of J' are real and given by $0, -\kappa_2, -\kappa_3, \dots, -\kappa_n$.

Proof. The rows of J sum to zero, implying that zero is an eigenvalue corresponding to the eigenvector $(1, 1, \dots, 1)^\top$. The circular configuration corresponds to a (weighted) directed graph which is strongly connected; that is, there is a directed path from every vertex to any other vertex. It follows that zero is a simple eigenvalue of the graph Laplacian matrix, which is equal to J in the present case. Furthermore, by Gershgorin's theorem [13], the eigenvalues of J are located in the union of discs

$$\lambda_i \in \bigcup_{\ell=1}^n \mathcal{B}(-\kappa_\ell) = \mathcal{B}(-\kappa_{\max}), \tag{3.6}$$

where $\mathcal{B}(r) = \{s \in \mathbb{C} : |s - r| \leq |r|\}$ is the disc centered at $r \in \mathbb{R}$ with radius $|r|$. Hence, all nonzero eigenvalues of J have negative real parts since $\kappa_i > 0$ for all i. Moreover, $|\lambda_i| \leq 2\kappa_{\max}$ by (3.6). One can also directly calculate the characteristic polynomial of J by an easy expansion by cofactors to obtain

$$\prod_{i=1}^{n}(\lambda + \kappa_i) - \prod_{i=1}^{n}\kappa_i = 0. \tag{3.7}$$

So, if $\kappa_i = \kappa$ for all i, then $(\lambda/\kappa + 1)^n = 1$; i.e., $\lambda/\kappa + 1$ are the nth roots of unity, which yields (3.5). The spectrum of J' follows from (3.7) by setting $\kappa_1 = 0$. □

We make the convention of labeling the zero eigenvalue of J as λ_1, and denote the corresponding eigenvector as $v_1 = (1, 1, \ldots, 1)^\top$. Hence, $\mathrm{Re}(\lambda_i) < 0$ for $i \geq 2$. Note that $s = 0$ is a solution of (3.4) when $i = 1$. This is the indicator of the rigid body rotation of the whole configuration of vehicles, and consequently the stability of the configuration is determined by the roots of the modified characteristic equation

$$\hat{\chi}(s) = \prod_{i=2}^{n}(s - \lambda_i F(s)) = 0. \tag{3.8}$$

Hence, car-following dynamics given by (2.2) is stable if all solutions s of (3.8) have negative real parts.

Remark 3.2. *Notice that all roots of the delay-free form of* (3.8) *are stable, as per Lemma* 3.1. *This forms only the starting point of the stability analysis. The main results presented in the following section reveal the necessary and sufficient conditions for the complete stability analysis of* (2.2) *with respect to the parametric domain of interest: delay distribution $f(\tau)$ and the spectrum of J. Readers are directed to some other models in the earlier cited references for the incorporation of additional parameters that may play a role in the stability of traffic dynamics.*

4. Main results.

We first introduce an interconnection scheme idea for the characteristic equation (3.8), which will allow a geometric approach to the stability analysis by an appropriate separation of parameters.

4.1. Interconnection scheme interpretation.

Consider first the uniform distribution (2.3), whose Laplace transform is

$$F(s) = \frac{e^{-sh}(1 - e^{-s\delta})}{s\delta}. \tag{4.1}$$

Note that $F(s) \to e^{-sh}$ as $\delta \to 0$, corresponding to the fact that f approaches a Dirac delta at h, where one recovers the discrete-delay model (2.1) with $\tau = h$. Using (4.1) in (3.4) gives

$$\chi_i(s) = s - \lambda_i e^{-sh}\frac{1 - e^{-s\delta}}{s\delta} = 0. \tag{4.2}$$

The singularity of χ_i at zero is removable since $\lim_{s\to 0}\chi_i(s) = -\lambda_i$. Hence by defining $\chi_i(0) = -\lambda_i$, we can treat χ_i as an analytical function and use arguments based on the continuous dependence of its roots on the parameters. In particular, since $\lambda_i \neq 0$ for $i \geq 2$, by Lemma 3.1, the following result is immediate.

Lemma 4.1. *$s = 0$ is not a solution to* (4.2) *for $i = 2, \ldots, n$.*

We rearrange (4.2) as

$$H_i(s)\cdot\Delta(s) = 1, \quad i = 2,\dots,n, \tag{4.3}$$

$$\text{where}\quad H_i(s) = \frac{\lambda_i e^{-sh}}{s}, \qquad \Delta(s) = \frac{1-e^{-s\delta}}{s\delta}. \tag{4.4}$$

The advantage of the form (4.3) lies mainly in the separation of the parameter δ and the eigenvalues of J, which will simplify the analysis. Similarly, for the γ-distribution we have $F(s) = e^{-hs}(qs+1)^{-p}$, and the corresponding characteristic equation can be expressed as an interconnection scheme,

$$H_i(s)\cdot\Delta_\gamma(s) = \frac{\lambda_i e^{-sh}}{s}\cdot\frac{1}{(qs+1)^p} = 1. \tag{4.5}$$

Note that $|\Delta_\gamma(j\omega)| \leq 1\ \forall\omega\in\mathbf{R}$, for any q.

4.2. Stability analysis. Given λ_i, the roots of (3.8) depend continuously on the parameters of the distribution $f(\tau)$ (see [5]). The method for stability analysis can then be summarized as follows. (a) Check the stability of the delay-free dynamics (3.8). (b) Calculate the characteristic roots on the imaginary axis, $s = j\omega$, of the interconnection scheme $H_i(s)\Delta(s) - 1 = 0$. (c) Check in which direction $s = j\omega$ crosses the imaginary axis with respect to the parametric domain of interest. Notice that the characteristic equation in (4.2) does not necessarily exhibit complex conjugate s solutions if $\lambda_i \in \mathbb{C}$.

We present below the stability analysis of (4.3) for the case of uniform distribution. The technique is easily extendable to γ-distribution with and without a gap with the construct of the interconnection scheme. The challenges in assessing the stability are (i) analysis should be performed in the multiple parameter space (h,δ,λ_i); (ii) the interconnection scheme carries complex coefficients; (iii) one of the parameters from (i), δ, appears both in an exponent and in the denominator of the interconnection scheme. The complications (i)–(iii) prevent our benefiting from many stability analysis techniques [3, 24, 17, 22, 15]. Before we introduce how to tackle these difficulties, we start with some conditions for the roots of (4.3) to exhibit imaginary axis crossings.

The following algorithm enables the calculation of the curves in the (h,δ) domain on which (4.3) has a solution of the form $s = j\omega$.

Computation algorithm for $s = j\omega$ and (h,δ) pairs. Given λ_i, the characteristic roots $s = j\omega$ crossing the imaginary axis and the corresponding parameter pairs (h,δ) can be exhaustively computed as follows. First, we write the magnitude condition in (4.3), at $s = j\omega$, which allows us to compute δ independently from h. (This is a direct consequence of the separation feature introduced by the interconnection scheme interpretation.) Second, on the same equation (4.2), we write the argument condition, which yields h.

Step 1. Define the continuous function $f_\Delta : \mathbb{R}\to\mathbb{R}_+$ by

$$f_\Delta(u) = \begin{cases} \sin^2 u/u^2, & u\neq 0,\\ 1, & u = 0.\end{cases} \tag{4.6}$$

Let

$$u = \frac{\delta\omega}{2}\in\mathbb{R}. \tag{4.7}$$

Step 2. By substituting (4.7) into the magnitude of (4.3),

$$|H_i(j\omega)|^2|\Delta(j\omega)|^2 = 1, \tag{4.8}$$

one obtains

$$\frac{|\lambda_i|^2}{(\omega)^2} f_\Delta(u) = 1, \tag{4.9}$$

which can be alternatively written as

$$f_\Delta(u)\frac{|\lambda_i|^2\delta^2}{4u^2} = 1 \Rightarrow f_\Delta(u) = \frac{4u^2}{|\lambda_i|^2\delta^2} = ku^2, \tag{4.10}$$

where $k = 4/(|\lambda_i|^2\delta^2)$.

The following proposition is immediate using Steps 1–2 above.

Proposition 4.2 (frequency-sweeping characterization [17]). *$s = j\omega$ is a root of (4.3) if and only if $\omega \leq |\lambda_i|$.*

Proof. It is clear from (4.6) and (4.7) that $|H_i(j\omega)| = |\lambda_i|/|\omega| > 1$ should be satisfied such that (4.8) holds. □

Step 3. One simply *sweeps* u and obtains ω from (4.9).

Step 4. Using u and ω from Step 3, solve for δ from (4.7).

Step 5. Define next

$$\lambda_i = |\lambda_i|e^{j\phi_i} \quad \text{with } \phi_i = \angle\lambda_i, \tag{4.11}$$

where $\phi \in (\pi/2, 3\pi/2)$ as per Lemma 3.1, and use the argument condition on (4.3) to compute h.

Step 6. Rearrange (4.3) as

$$e^{-j\omega h} = \frac{-\delta(\omega)^2}{\lambda_i(1 - e^{-j\delta\omega})},$$

from which one obtains the following by equating the arguments of both sides:

$$h = \frac{1}{\omega}[-\pi + \phi_i + \angle(1 - \cos(\delta\omega) + j\sin(\delta\omega)) + 2\pi\ell], \quad \ell \in \mathbb{Z}. \tag{4.12}$$

Step 7. Using (4.7), it is clear that $\angle(1 - \cos(\delta\omega) + j\sin(\delta\omega)) = \tan^{-1}\left(\frac{\cos u}{\sin u}\right) = \frac{\pi}{2} - u$, simplifying (4.12) to

$$h = \frac{1}{\omega}\left(-\frac{\pi}{2} + \phi_i - u + 2\pi\ell\right). \tag{4.13}$$

Proposition 4.3. *There exists a connected stability region of the traffic flow dynamics (2.2) in the parameter space (h, δ) that includes the origin $(h, \delta) = (0, 0)$. The bounds of this region on the δ and h axes are respectively given by*

$$\bar{h} = \min_{2\leq i\leq n}\left(\frac{2\phi_i - \pi}{2|\lambda_i|}\right) \quad \textit{and} \quad \bar{\delta} = \min_{2\leq i\leq n}\left(-\frac{(2\phi_i - \pi)^2}{2|\lambda_i|\cos(\phi_i)}\right). \tag{4.14}$$

Remark 4.4. *We shall show later that the stability region mentioned in the above proposition is actually the unique stability region in the parameter space.*

Proof. When $h = \delta = 0$, the distribution function in (2.3) is a Dirac delta whose Laplace transform equals 1. From (4.2), the characteristic roots are $s = \lambda_i$, $i = 2, \ldots, n$, where $\mathrm{Re}(\lambda_i) < 0$ by Lemma 3.1. Thus, (2.2) is stable for $(h, \delta) = (0, 0)$. Consequently, the stability region in the (h, δ) parameter domain contains an open neighborhood of the origin $(h, \delta) = (0, 0)$ [5]. We next calculate the stability margins along the δ- and h-axes.

Stability when $\delta = 0$. For $\delta \to 0$ the characteristic equation (4.2) becomes

$$s = \lambda_i e^{-sh}. \tag{4.15}$$

Equation (4.15) has a stable root for $h = 0$ (see Proposition 4.3), and stability is lost if a characteristic root crosses the imaginary axis for some $h \neq 0$. Thus, the stability is preserved between $h = 0$ and the minimum positive h for which (4.15) has a solution $s = j\omega$. This minimum h is computed as follows. By Lemma 4.1, the magnitude condition on (4.15) yields $\omega = \mp|\lambda_i|$, and the argument condition requires

$$h = \frac{1}{|\lambda_i|}\left(-\frac{\pi}{2} \mp \phi_i + 2\pi\ell\right), \quad \ell \in \mathbb{Z}, \tag{4.16}$$

with $+\phi_i$ when $\omega > 0$. Using the above equation, one obtains the smallest positive h, $\bar{h}$ as given in (4.14). Hence, when $\delta = 0$, (4.2) is stable for $h \in [0, \bar{h})$.

Stability when $h = 0$. The smallest positive value of δ for which stability is lost is denoted by $\bar{\delta}$; that is, the stability interval along δ-axis is $\delta \in [0, \bar{\delta})$. The characteristic equation (4.2) when $h = 0$ is

$$\frac{\delta s^2}{\lambda_i} + e^{-s\delta} - 1 = 0. \tag{4.17}$$

Letting $s = j\omega$, solving for the exponential term, and equating the magnitude conditions of both sides, one easily obtains δ:

$$\delta = -\frac{2|\lambda_i|\cos(\phi_i)}{\omega^2}. \tag{4.18}$$

Moreover, solving the exponential term in (4.17), equating the arguments of both sides, substituting δ from (4.18), and noting that $\omega \neq 0$ by Lemma 4.1, we obtain

$$\omega = \frac{2|\lambda_i|\cos(\phi_i)}{\angle(-\cos(2\phi_i) + j\sin(2\phi_i)) \pm 2\pi\ell}, \quad \ell = 0, 1, 2, \ldots,$$

which simplifies and gives rise to δ

$$\omega = \frac{2|\lambda_i|\cos(\phi_i)}{\pi - 2\phi_i \mp 2\pi\ell}, \quad \delta = -\frac{(\pi - 2\phi_i \mp 2\pi\ell)^2}{2|\lambda_i|\cos(\phi_i)}. \tag{4.19}$$

When $\delta = 0$ the dynamics is stable. Following the root continuity arguments [5], the stability is lost for the smallest positive δ, which is attained when $\ell = 0$ and equal to $\bar{\delta}$ as given in (4.14). □

Characterization of the geometry of the stability boundaries. The stability boundaries are among those curves in the (h, δ) parametric domain which give rise to an $s = j\omega$ solution in the interconnection scheme. In order to characterize the geometry of the stability boundaries, one has to establish the link from u domain

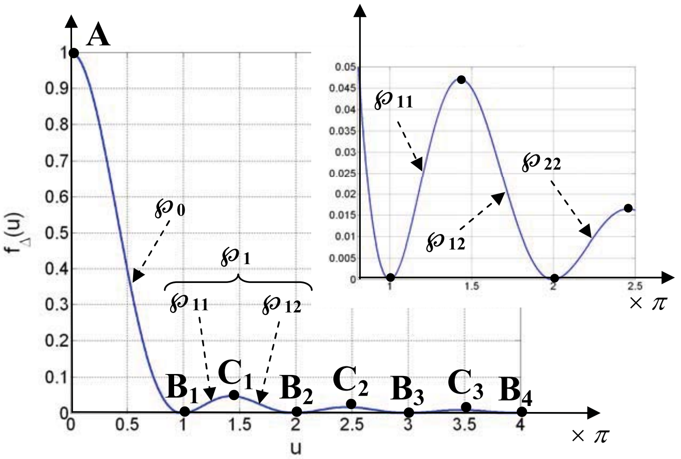

FIG. 4.1. *$f_\Delta(u)$ versus u. B_ℓ and C_ℓ are end points and the local maxima of the segments $\wp_\ell$, $\ell > 0$, respectively.*

to (h, δ). To achieve this, we give some definitions first. Define the extrema points of f_Δ function with $A(f_\Delta(0))$, $B_\ell(f_\Delta(\ell\pi))$, and $C_\ell(f_\Delta((2\ell+1)\pi/2))$, $\ell = 1, 2, 3, \ldots$; see Figure 4.1. Partition $f_\Delta(u)$ into segments and label each one of them as follows: $\wp_0 = f_\Delta(u)$ with $u \in [0, \pi]$; $\wp_{\ell,\ell} = f_\Delta(u)$ with $u \in [\ell\pi, (2\ell+1)\pi/2]$; $\wp_{\ell,\ell+1} = f_\Delta(u)$ with $u \in [(2\ell+1)\pi/2, 2\ell\pi]$, $\ell = 1, 2, 3, \ldots$. Obviously,

$$f_\Delta = \bigcup_{\ell \geq 0} \wp_\ell, \quad \text{where } \wp_\ell = \wp_{\ell,\ell} \bigcup \wp_{\ell,\ell+1} \quad \forall \ell > 0. \tag{4.20}$$

Notice that each of the "segments" $\wp_0$, $\wp_{\ell,\ell}$, and $\wp_{\ell,\ell+1}$ as a function is monotonic with respect to the variable u, as seen in Figure 4.1. The points B_ℓ and C_ℓ in this figure correspond to the end points and the local maxima of the segments $\wp_\ell$, $\ell > 0$, respectively. Due to the symmetry of the function f_Δ, $f(u) = f(-u)$, and by (4.7), we will restrict our subsequent analysis to positive ω, $\omega > 0$.

Monotonicity properties. We will now utilize the monotonicity properties of the "segments" of $f_\Delta(u)$ in order to explain how their mapping in (h, δ) forms. We first comment on the extremities in u and (h, δ) domains. Given λ_i, at point A we have $f_\Delta(u = 0) = 1$; hence from (4.8), $\omega = |\lambda_i|$ and from (4.7), $\delta = 0$. At the end points of $\wp_\ell$, that is B_ℓ and $B_{\ell+1}$, we have $\lim_{u \to \ell\pi} f_\Delta(u) \to 0^+$; thus for a solution of the interconnection scheme in the form of $s = j\omega$ to exist, it is clear from (4.9) that $\omega \to 0^+$. Therefore, the image of B_ℓ and $B_{\ell+1}$ on (h, δ) space corresponds to infinity, since these curves are open-ended curves.

Recall that if $s = j\omega$ solution of the interconnection scheme exists, then (4.10) holds. This indicates that u solutions of (4.8) lie at the intersection points of the curve $f_\Delta(u)$ and the parabola u^2 parameterized by k. This relationship is generically depicted in Figure 4.2(a) for various k values and for positive $u > 0$. Notice from (4.10) that δ is inversely proportional to k.

Let us now elaborate on Figure 4.2(a), since it depicts the geometry of the solution points in u (such as points C, D, E, and F), which we will use for characterizing the corresponding geometry in the (h, δ) domain. Denote this correspondence from u domain to (h, δ) domain by $f_\Delta(u) \mapsto \zeta(h, \delta) : \mathbb{R}_+ \mapsto \mathbb{R} \times \mathbb{R}_+$. Next, define ζ_0, $\zeta_{\ell,\ell}$,

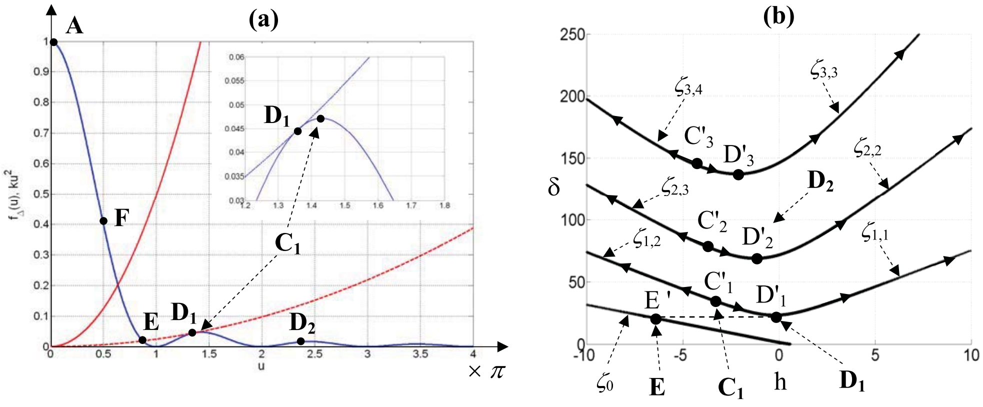

FIG. 4.2. (a) *Generic depiction of f_Δ and ku^2 versus u, where the parabola sweeps the first quadrant counterclockwise with increasing k. Inset: Distinction between points D_1 and C_1.* (b) *The mapping of the intersection points between f_Δ and ku^2 to the (h, δ) domain ($C_i \mapsto C'_i$, $D_i \mapsto D'_i$, $E \mapsto E'$, etc.). Arrows indicate decreasing direction of ω.*

and $\zeta_{\ell,\ell+1}$ segments in the (h, δ) domain that correspond to the segments $\wp_0$, $\wp_{\ell,\ell}$, and $\wp_{\ell,\ell+1}$, respectively, in u domain, and similarly, let $\zeta_\ell = \zeta_{\ell,\ell} \bigcup \zeta_{\ell,\ell+1}$ $\forall \ell > 0$. Figure 4.2(b) presents generically some of these curves in the (h, δ) domain, where E' corresponds to E of Figure 4.2(a); D'_1, D'_2, D'_3, etc., are the mappings of the points at which the parabola in Figure 4.2(a) is tangent to $\wp_{11}$, $\wp_{22}$, $\wp_{33}$, etc., segments (shown in Figure 4.1), respectively; C'_1, C'_2, C'_3, etc., are the mappings of the local maxima points C'_1, C'_2, C'_3, etc., at which the maximum omega on a respective ζ_ℓ, $\ell > 0$, curve. The points C_ℓ can also be seen as the end points of $\zeta_{\ell,\ell}$ and $\zeta_{\ell,\ell+1}$ curves.

Notice that, for a given λ_i, intersection points in Figure 4.2(a) for fixed k give rise to fixed δ, as per (4.10). For instance, for a particular selection of k, the parabola may intersect $\wp_{1,1}$ and $\wp_{1,2}$, giving rise to two points, one on $\zeta_{1,1}$ and the other on the $\zeta_{1,2}$ curve. Furthermore, all such points are earmarked by ω. See the two points in Figure 4.3(c)–(d) labeled with ω_1 and ω_2 as an example.

REMARK 4.5. *The ζ_0 curve in Figure* 4.2(b) *is due to mapping of the $\wp_0$ segment; see also Figure* 4.3(a)–(b)*. For the remaining segments, we state the following. For a given k, any two points at the intersection of the parabola and the segment $\wp_\ell$, $\ell > 0$, give rise to two points on the ζ_ℓ curve; see Figure* 4.3(c)–(d)*. These two points are generated by two distinct u values, the larger of which corresponds to the larger ω as per* (4.9)*. It is clear from* (4.13) *that larger u corresponds to smaller h. Consequently, the point marked by ω_1 in Figure* 4.3(c)–(d) *arises from the intersection between ku^2 and $\wp_{1,2}$; thus it lies on the $\zeta_{1,2}$ curve, and $\omega_1 > \omega_2$ holds. The arrows on ζ curves in Figure* 4.2(b) *and Figure* 4.3(c)–(d) *indicate the direction of decreasing ω on the respective curves. Finally, the point marked with C_ℓ indicates the location of maximum ω attained on the curve ζ_ℓ, $\ell > 0$, which is clearly due to the local maximum of the f_Δ curve in the interval $u \in (\pi, 2\pi)$ (maximum u thus maximum ω as per* (4.13)*). Figure* 4.3 *presents separately the way in which the first two curves ($\wp_0 \mapsto \zeta_0$ and $\wp_1 \mapsto \zeta_1$) are generated.*

PROPOSITION 4.6 (crossing curve characterization). *The boundary of the stability region defined in Proposition* 4.3 *and depicted in Figure* 4.3 *arises from the correspondence $\wp_0(u) \mapsto \zeta_0(h, \delta)$. The necessary and sufficient condition forming this boundary in the (h, δ) domain is obtained only from the interval $u \in [0, \pi/2)$.*

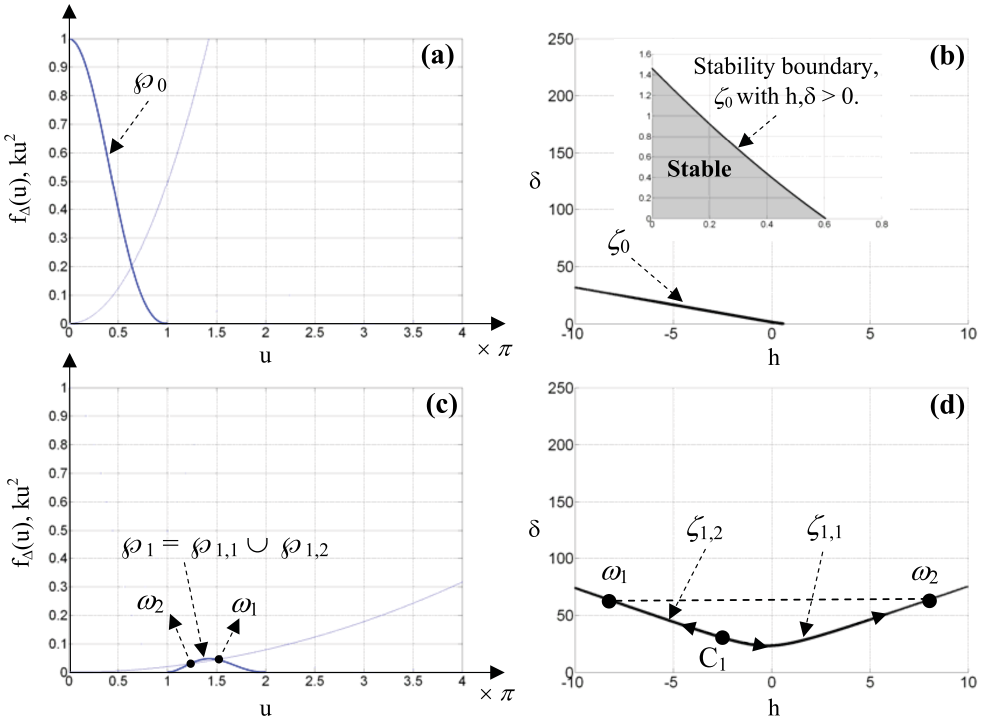

FIG. 4.3. (a)–(b) *Mapping of* $\wp_0$ *to* ζ_0. (c)–(d) *Mapping of* $\wp_1 = \wp_{1,1} \cup \wp_{1,2}$ *to* $\zeta_1 = \zeta_{1,1} \cup \zeta_{1,2}$ *(*$\wp_{1,i} \mapsto \zeta_{1,i}$*, for* $i = 1, 2$*). Arrows indicate the decreasing direction of* ω*, which attains its maximum on a respective* ζ_ℓ *curve at point* C_ℓ*,* $\ell > 0$.

Proof. (i) *Condition* $u \in [0, \pi/2)$. By Proposition 4.3, the stability boundary intersecting the h axis, $\bar{h}$, is created when $\delta = 0$. Since $\delta = 0$ corresponds to $u = 0$, starting from $u = 0$, tracing the intersection points of the parabola ku^2 and the curve $\wp_0$, one extracts the boundary of the single connected stability region in (h, δ). On this boundary, δ is monotonically increasing considering (4.7) and Proposition 4.8. To complete the proof, one should take into account the constraint of $h > 0$. Hence, δ should increase until h becomes zero. This occurs when the boundary of the stability region intersects the δ-axis at $\bar{\delta}$; see Proposition 4.3. The u value corresponding to $\bar{\delta}$ is $u = \omega\delta/2 < \pi/2$ as per (4.19).

(ii) *Necessary and sufficient condition.* There exists no u interval other than $u \in [0, \pi/2)$ that gives rise to a (h, δ) point on the stability boundary, since $f_\Delta(u)$ values attained in the interval $u \in [0, \pi/2)$ cannot be attained by any $u > \pi/2$. Hence $u \in [0, \pi/2)$ is necessary and sufficient for the computation of this boundary. □

REMARK 4.7. *Geometrically, the interval* $u \in [0, \pi/2)$ *corresponds to the segment* AF *in Figure* 4.2(a).

PROPOSITION 4.8 (local monotonicity property). *On the stability boundary, increasing* k *monotonically decreases* u *and* δ *solutions arising from the intersection points between* $f_\Delta(u)$ *and the parabola* ku^2.

Proof. From (4.10), $k = f_\Delta(u)/u^2$. The variation of k with respect to u is $\frac{dk}{du} = f'_\Delta(u)\frac{1}{u^2} - \frac{2}{u^3} f_\Delta(u)$. Since $f_\Delta(u) > 0$ and $f'_\Delta(u) < 0$ in the interval $u \in [0, \pi/2)$ defining the stability boundary, dk/du is negative. Recall that δ and k are inversely proportional; thus δ on the stability boundary is decreasing for increasing k. □

Readers are directed to the work in [11] as an example of the deployment of monotonicity ideas which gives rise to the characterization of the geometry of stability regions of a class of delay differential equations.

LEMMA 4.9. *dh/du on the stability boundary is nonpositive for all $u \in [0, \frac{\pi}{2})$.*

Proof. From (4.9), $\omega^2 = f_\Delta |\lambda_i|^2$. For $u \in [0, \pi/2)$, one can take $\omega = \sqrt{f_\Delta}|\lambda_i| = \sin(u)|\lambda_i|/u$ for studying the variations of h in (4.13). Note that the h variation on the stability boundary is obtained for $\ell = 0$; see Proposition 4.3. Hence, the variation of h along the stability boundary is found as

$$\frac{d}{du}\frac{(\phi_i - \pi/2 - u)u}{|\lambda_i|\sin(u)} = -\frac{A(u)\phi_i + B(u)}{2|\lambda_i|\sin^2(u)}, \tag{4.21}$$

where $A(u) = 2u\cos u - 2\sin u$ and $B(u) = 4u\sin u - u\pi\cos u - 2u^2\cos u + \pi\sin u$. Notice that $A(u) < 0$ for all $u \in (0, \pi/2)$ since $u < \tan(u)$ in this interval; thus the inequality in (4.21) becomes $A(u)\phi_i + B(u) > 0$, which can be rewritten as

$$-\frac{B(u)}{A(u)} > \phi_i \quad \forall u \in \left(0, \frac{\pi}{2}\right),$$

where in our case $\phi_i \in (\pi/2, 3\pi/2)$. Consequently, it is sufficient to prove that $-B(u)/A(u) > 3\pi/2$, that is,

$$\frac{2u - \pi}{u - \pi} - \frac{u}{\tan(u)} < 0 \quad \forall u \in \left(0, \frac{\pi}{2}\right).$$

The fact that the above inequality holds can be seen from Figure 4.4. Although an analytical proof can be given, the algebraic manipulations are rather involved and thus omitted. □

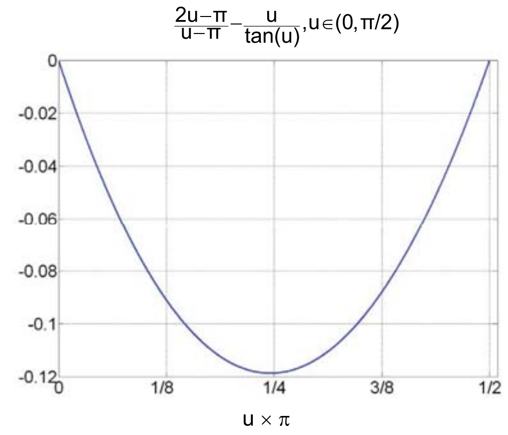

FIG. 4.4. *Plot of* $\frac{2u-\pi}{u-\pi} - \frac{u}{\tan(u)}$ *versus* u*,* $u \in (0, \pi/2)$*.*

REMARK 4.10. *By Proposition* 4.8 *and Lemma* 4.9*, increasing u corresponds to increasing δ and decreasing h. Hence, on the stability boundary, we have the property* $\frac{\partial\delta}{\partial u}\frac{\partial u}{\partial h} = \frac{\partial\delta}{\partial h} < 0$.

REMARK 4.11. *Since parameter u depicting the stability boundary is bounded as per Proposition* 4.6*, all ω satisfying the interconnection scheme belong to the set* $\Gamma_\omega = \{\omega \mid H_i(j\omega)\Delta(j\omega) - 1 = 0,\ u = \delta\omega/2,\ u \in [0, \pi/2)\}$. *As such, the imaginary roots on the stability boundary are given by the set $j\Gamma_\omega$. From* (4.9)*, one can obtain*

Γ_ω as $\Gamma_\omega = (\sqrt{2}|\lambda_i|/\pi, |\lambda_i|]$. This interval of ω is obviously a subset of the interval claimed in Proposition 4.2, since the interval of u creating the stability boundary is now restricted as $u \in [0, \pi/2)$.

Let us comment on the remaining part of the $\wp_0$ curve, $u \in (\pi/2, \pi)$. Following part (i) of the above proof, we state that corresponding h values obtained by u, $u \in (\pi/2, \pi)$, are all negative and thus ignored. Values of h on the curves obtained by the shifting $2\pi\ell/\omega$, $\ell = 1, 2, \ldots$, as per (4.13), however, may become positive, and thus should be carefully treated.

PROPOSITION 4.12 (crossing curves property). *The curves $\zeta_{\ell,\ell}$ and $\zeta_{\ell,\ell+1}$, $\ell \geq 1$, do not intersect the stability boundary formed by ζ_0.*

Proof. It is sufficient to prove $\inf_{\delta\in(\zeta_{\ell,\ell}\cup\zeta_{\ell,\ell+1})} \delta > \sup_{\delta\in\zeta_0} \delta$. From Proposition 4.8, it is clear that $\inf_{\delta\in(\zeta_{\ell,\ell}\cup\zeta_{\ell,\ell+1})} \delta$ arises from the $u = u_1$ value at point D_1 in Figure 4.2. As per Propositions 4.6 and 4.8, $\sup_{\delta\in\zeta_0} \delta$ is found at $u = \pi/2$ (point F in Figure 4.2). Since $u_1 > \pi/2$, using Proposition 4.8, one can see that the inequality $\inf_{\delta\in(\zeta_{\ell,\ell}\cup\zeta_{\ell,\ell+1})} \delta > \sup_{\delta\in\zeta_0} \delta$ holds. □

It is now proven that ζ_0 does not intersect with the remaining $\zeta_{\ell,i}$ ($i = \ell, \ell+1$, $\ell \geq 1$) segments; however, one also needs to show *stability properties* around the regions bordered by all the ζ curves in order to reveal the stability regions in the parametric domain of (h, δ). The following proposition helps achieve this.

PROPOSITION 4.13 (crossing direction along h, for δ fixed). *Given λ_i and δ, the crossing direction of the imaginary root(s) $s = j\omega$ along the h-axis is independent of the delays $h + \frac{2\pi}{\omega}\ell$, $\ell = 0, 1, \ldots$, creating these imaginary roots.*

Proof. The characteristic equation χ_i in (4.2) can be expressed as $\chi_i = s - \lambda_i e^{-sh}\Delta(s) = 0$ using (4.4). Then, the sensitivity expression at $s = j\omega$, after suppressing the arguments to conserve space, becomes

(4.22)

$$S(j\omega) = \left.\frac{ds}{dh}\right|_{s=j\omega} = \left(-\frac{\partial\chi_i}{\partial h}\left(\frac{\partial\chi_i}{\partial s}\right)^{-1}\right)_{s=j\omega} = -\left.\frac{s\lambda_i e^{-sh}\Delta}{1+\lambda_i e^{-sh}(h\Delta - \Delta')}\right|_{s=j\omega},$$

where $\Delta' = \frac{\partial\Delta}{\partial s}$. The above equation simplifies to

$$S(j\omega) = -\left.\frac{s\Delta}{\lambda_i^{-1}e^{sh} + h\Delta - \Delta'}\right|_{s=j\omega}. \tag{4.23}$$

Let $S(j\omega) = \frac{S_{NR}(\omega)+jS_{NI}(\omega)}{S_{DR}(\omega)+jS_{DI}(\omega)}$ with $S_{NR}, S_{NI}, S_{DR}, S_{DI} \in \mathbb{R}$. Then the real part of (4.23), which indicates the crossing direction of the $s = j\omega$ root across the imaginary axis, becomes

$$\Re\left(S(j\omega)\right) = \frac{S_{NR}S_{DR} + S_{NI}S_{DI}}{S_{DR}^2 + S_{DI}^2}. \tag{4.24}$$

Notice that if $\operatorname{sgn}(\Re\left(S(j\omega)\right)) = +1$ (or -1), this will indicate an imaginary axis crossing from left to right (or from right to left) half of the complex plane. Since the denominator of (4.24) is positive, it is dropped for studying the sign. Consequently, the numerator of (4.24) will determine the crossing direction, which becomes

$$\omega\left(\Im(\Delta)\left(h\Re(\Delta) - \Re(\Delta') + \Re\left(\frac{e^{jh\omega}}{\lambda_i}\right)\right) - \Re(\Delta)\left(h\Im(\Delta) - \Im(\Delta') + \Im\left(\frac{e^{jh\omega}}{\lambda_i}\right)\right)\right)$$

$$= \omega\left(\Im(\Delta)\left(-\Re(\Delta') + \Re\left(\frac{e^{jh\omega}}{\lambda_i}\right)\right) - \Re(\Delta)\left(-\Im(\Delta') + \Im\left(\frac{e^{jh\omega}}{\lambda_i}\right)\right)\right). \tag{4.25}$$

After some manipulations and dropping $\omega > 0$, this yields

$$\operatorname{sgn}\left(\Re\left(S(j\omega)\right)\right) = \operatorname{sgn}\left(\Im\left(\bar{\Delta}(j\omega)(\Delta'(j\omega) - \lambda_i^{-1}e^{jh\omega})\right)\right), \tag{4.26}$$

where $\bar{\Delta}(j\omega)$ is the complex conjugate of $\Delta(j\omega)$. Notice that the above equation is independent of h due to the exponential terms $e^{jh\omega}$ remaining unchanged for the selection of $h + \frac{2\pi}{\omega}\ell$, $\ell = 0, 1, \ldots$. □

REMARK 4.14. *The invariance feature of the root sensitivity expression in* (4.26) *enables an effective tool which helps reveal the stability/instability regions of the traffic dynamics in the entire* $(h, \delta) \in \mathbb{R}_+^2$ *parametric domain.*

We finally develop some ideas in the following borrowing from the implicit function theorem in order to study the smoothness and stability transition behavior around the ζ_0 curve in (h, δ) domain.

4.3. Local vs. global characterization. We elaborate on the geometry of ζ_0 from the implicit function theorem [14], which states that, on the imaginary axis, the characteristic equation $a(s, h, \delta)|_{s=j\omega} = H_i(j\omega)\Delta(j\omega) - 1 = 0$ may be used to locally express h and δ in terms of ω as an implicit function, in the form of $(h, \delta) = \varphi(\omega)$, if $da/d\omega \neq 0$ holds. This condition is nothing but the definition of the existence of *regular points* that allows the implementation of the implicit function theorem locally.

By the help of the interconnection scheme interpretation and the monotonicity ideas, the local representation can be extended. Following the theorem, one first classifies the points on ζ_0 in the (h, δ) domain. Such a classification identifies whether the implicit function theorem is applicable or not on the function $a(s, h, \delta) = 0$. Parameter δ is continuous on ζ_0, and its variation with respect to k is nonzero. Similar arguments also hold for h; see Proposition 4.6). The smoothness and nonzero derivative of the variables h on ζ_0 indicate that ζ_0 consists of only "regular points." This suffices to show that the theorem is applicable around *any* local point of ζ_0. By introducing the variable u along with the interconnection scheme, which only scales ω, we manage to separately express $h = \varphi_1(u)$ and $\delta = \varphi_2(u)$ *globally* on the stability boundary ζ_0.

So far we have shown the existence and the geometry of the stability region connected to the origin of the parametric domain (h, δ), intersecting the h and δ axis. In the following, the characterization of the stability/instability transition of the dynamics in (h, δ) using (4.2) is presented. For this objective, we use the idea based on the implicit function theorem [9], along with the separation of variables h and δ via the interconnection scheme that we have considered.

Take the characteristic equation $a(s, h, \delta) = H_i\Delta - 1 = 0$. When s moves along the imaginary axis, an (h, δ) pair moves along $\zeta_0(h, \delta)$. Let us first define the following for a given $\omega \in \Gamma_\omega$ on the $\zeta_0(h, \delta)$ curve:

$$R_0 = \Re\left(\frac{j}{s}\frac{\partial a(s, h, \delta)}{\partial s}\right)_{s=j\omega}, \quad R_1 = -\Re\left(\frac{1}{s}\frac{\partial a(s, h, \delta)}{\partial h}\right)_{s=j\omega},$$

$$I_0 = \Im\left(\frac{j}{s}\frac{\partial a(s, h, \delta)}{\partial s}\right)_{s=j\omega}, \quad I_1 = -\Im\left(\frac{1}{s}\frac{\partial a(s, h, \delta)}{\partial \tau_\nu}\right)_{s=j\omega},$$

$$R_2 = -\Re\left(\frac{1}{s}\frac{\partial a(s, h, \delta)}{\partial \delta}\right)_{s=j\omega}, \quad I_2 = -\Im\left(\frac{1}{s}\frac{\partial a(s, h, \delta)}{\partial \delta}\right)_{s=j\omega}.$$

By Lemma 4.1, $a(s,h,\delta)=0$ is an analytical function, and using the implicit function theorem, the tangent of $\zeta_0(h,\delta)$ is expressed as

$$\text{(4.27)} \qquad \begin{pmatrix} dh/d\omega \\ d\delta/d\omega \end{pmatrix} = \begin{pmatrix} R_1 & R_2 \\ I_1 & I_2 \end{pmatrix}^{-1} \begin{pmatrix} R_0 \\ I_0 \end{pmatrix} = \frac{1}{R_1I_2-R_2I_1} \begin{pmatrix} R_0I_2-I_0R_2 \\ I_0R_1-R_0I_1 \end{pmatrix},$$

provided that $R_1I_2-R_2I_1\neq 0$. In order to characterize the stability transition, one needs to consider h and δ as functions of $s=\mu+j\omega$. Since the tangent of $\zeta_0(h,\delta)$ along the positive direction (i.e., increasing ω direction) is $(dh/d\omega, d\delta/d\omega)$, the normal to the $\zeta_0(h,\delta)$ curve pointing to the left-hand side of the positive direction is $(-d\delta/d\omega, dh/d\omega)$. Also, as a pair of complex conjugate roots of $a(s,h,\delta)=0$ crosses the imaginary axis at $s=j\omega$ to $\mathbb{C}_+$, (h,δ) moves along the direction $(\partial h/\partial\mu, \partial\delta/\partial\mu)$. So, if the inner product of this vector with the normal vector is positive, i.e.,

$$\text{(4.28)} \qquad \left(\frac{\partial h}{\partial\omega}\frac{\partial\delta}{\partial\mu}-\frac{\partial\delta}{\partial\omega}\frac{\delta h}{\partial\mu}\right)_{s=j\omega} > 0,$$

then the region on the left of the stability curve $\zeta_0(h,\delta)$ at $s=j\omega$ has two more unstable roots than the right of $\zeta_0(h,\delta)$ curve. On the other hand, if the inner product is negative, then the region on the left of the stability curve $\zeta_0(h,\delta)$ has two fewer unstable roots than the region on its right. Similar to the tangency condition defined in (4.27), we can express $(\partial h/\partial\mu, \partial\delta/\partial\mu)$ as in the following:

(4.29)

$$\begin{pmatrix} \partial h/\partial\mu \\ \partial\delta/\partial\mu \end{pmatrix} = \begin{pmatrix} R_1 & R_2 \\ I_1 & I_2 \end{pmatrix}^{-1} \begin{pmatrix} I_0 \\ -R_0 \end{pmatrix} = \frac{1}{R_1I_2-R_2I_1} \begin{pmatrix} R_0R_2+I_0I_2 \\ -R_0R_1-I_0I_1 \end{pmatrix}.$$

Proposition 4.15. *Given any (h,δ) pair on the stability curve $\zeta_0(h,\delta)$, the inequality* (4.28) *is always satisfied.*

Proof. Simple manipulations show that $\left(\frac{\partial h}{\partial\omega}\frac{\partial\delta}{\partial\mu}-\frac{\partial\delta}{\partial\omega}\frac{\delta h}{\partial\mu}\right)_{s=j\omega}>0$ if

$$\text{(4.30)} \qquad R_2I_1-R_1I_2=\left(\frac{|\lambda_i|}{\omega}\right)^2\frac{4\sin^2(\delta\omega/2)-\delta\omega\sin(\delta\omega)}{(\delta\omega)^3}>0.$$

As per (4.7) and from Proposition 4.6, for $u\in(0,\pi/2)$, the inequality in (4.30) can be alternatively studied over

$$\text{(4.31)} \qquad 2\sin^2(u)-u\sin(2u)>0, \quad u\neq 0.$$

This inequality always holds since it can be rewritten in the form of a well-known trigonometric property, $\sin(u)/u>\cos(u)$, in the interval $u\in(0,\pi/2)$. For the case when $u=0$, we state that f_Δ is continuous and its derivative exists at $u=0$; therefore similar arguments on the smoothness of ζ_0 hold for $u=0$ as well. □

Remark 4.16. *Since the region below ζ_0 is known to be stable, Proposition* 4.15 *indicates that the region on the other side of ζ_0 has two unstable roots. Also, with the above proof, the smoothness of the stability curve ζ_0 is guaranteed.*

γ-distribution with and without a gap. We finally comment on the γ-distribution with and without gap. By (4.5), the characteristic equation is

$$\text{(4.32)} \qquad s(qs+1)^p-e^{-hs}\lambda_i=0.$$

When $h=0$, the above equation becomes a polynomial in s whose stability is easy to determine. At the origin of the parameter domain $(p,q)=(0,0)$, the characteristic equation becomes $s - \lambda_i = 0$, which is stable by Lemma 4.1. For $p \neq 0$ or $q \neq 0$, the stability can be studied by numerical computation of the roots or by using the jury test. In the example case studies, we will study the stability of (4.32) via numerical computations.

When the γ-distribution has a positive gap h, the analysis is more complicated. In the parametric domain of (p, q), the problem reduces to assuring the stability of the dynamics (2.2) with respect to λ_i and gap h. We study the stability in the (h, q) parametric domain by taking fixed p values. The procedure is as follows. Using the fact that eigenvalues of J are in complex conjugate pairs, one can reform the characteristic equation directly from (3.8) with real coefficients and perform the stability analysis for various selections of fixed p in the domain of (h, q). We mention that there exist various techniques in the literature to handle this analysis [17, 10, 22, 24].

5. Illustrative examples. In the following, some example cases are presented to demonstrate the memory effects on the stability of traffic flow dynamics and their physical interpretations. The developed theory equally allows one to study various scenarios such as the influence of the number of vehicles, presence of nonidentical drivers, aggressiveness of drivers, etc. In order to preserve coherence among the example cases, we will present the case when the drivers are identical (thus $\kappa_i = \kappa$) and compare the arising stability features of traffic dynamics with respect to aggressiveness of the drivers κ and the two spatial configurations given in Figure 2.2.

5.1. Uniform distribution. We take $\kappa_i = \kappa = 1.5$ and $\kappa_i = \kappa = 2$, respectively, which are in the same order of magnitude with those given in [2]. Figure 5.1(a) depicts the stability region for the ring configuration. The region shaded by light gray, Φ_1, represents the stability domain when $\kappa = 2$. When $\kappa = 1.5$, the stability region is enlarged by an additional region labeled as Φ_2 (dark grey); hence $\Phi_1 \cup \Phi_2$ becomes the stability region.

From Figure 5.1(a) we conclude that for both κ values the size of the memory window that is "tolerable" (to maintain stability) is the widest when $h = 0$. With a nonzero dead-time ($h \neq 0$) the allowable window size becomes narrower and eventually disappears.

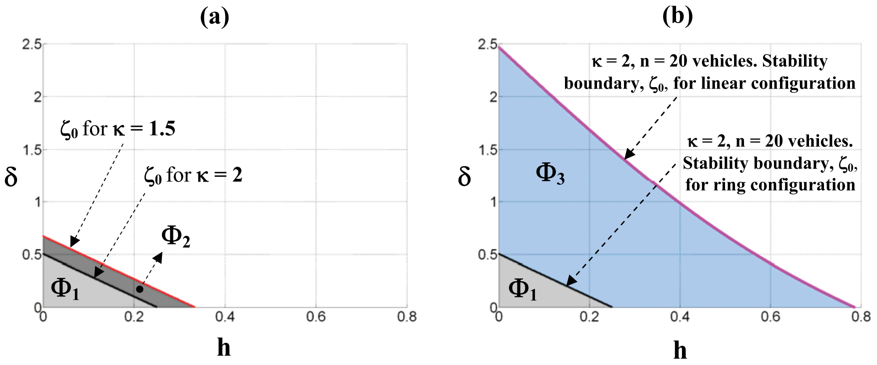

FIG. 5.1. (a) *The size of the memory window* δ *(sec) versus* h *(sec) for the system* (2.2) *with uniformly distributed delays* (2.3) *and* $n = 20$ *vehicles. The shaded area is the stability region.* (b) *Comparison of stability regions for ring and linear spatial configuration of vehicles, with* $\kappa = 2$ *and* $n = 20$ *vehicles.*

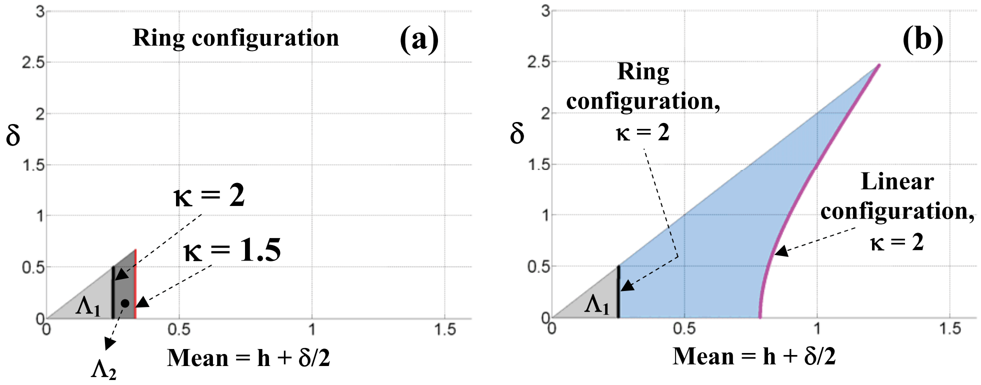

Fig. 5.2. *Stability regions in the parameters mean delay and memory size, for* $n = 20$ *vehicles.* (a) *Ring configuration for* $\kappa = 1.5$ *and* $\kappa = 2$, (b) *comparison between linear and ring configurations with* $\kappa = 2.0$.

5.1.1. Stability regions for ring and linear configurations. We now compare the stability regions for the different spatial configurations of the vehicles depicted in Figure 2.2. Figure 5.1(b) compares the stability regions for $n = 20$ vehicles. The regions labeled by Φ_1 in subfigures (a) and (b) are identical. Thus, the linear configuration offers an enhancement in the stability by the additional Φ_3 region.

The stability enhancement in the linear configuration can be explained mathematically. In a global sense, one can state a measure of the stability enhancement by how large $\bar{h}$ and $\bar{\delta}$ are. This can be easily checked by the results in Proposition 4.3. By Lemma 3.1, the eigenvalues of the configuration matrix J' are real in the linear configuration, implying $\phi = \pi$. For this setting of ϕ, it can be verified from (4.14) that $\bar{h}$ and $\bar{\delta}$ attain their maximum values: $\bar{h} = \frac{\pi}{2\kappa_{\max}}$ and $\bar{\delta} = \frac{\pi^2}{2\kappa_{\max}}$. This can be proven by assuming identical drivers with special form of λ_i as per (3.5), which can be used in (4.14) to show that as $\phi \to \pi$, the stability margins increase on both h and δ axes.

Physically, the linear configuration represents more degrees of freedom in the coupled dynamics, since the leading car is not restricted by the traffic, whereas in the ring configuration the motion of each vehicle plays a role in determining stability, thus limiting larger stability regions.

5.1.2. Stability with respect to mean delay versus memory size. We now present stability regions in the parameter domain *mean delay* $(h+\delta/2)$ versus *memory size* (δ). The mean of the uniform distribution represents the averaged effects of the memory, and it converges to the discrete delay case as the memory size approaches zero. Hence, the mean can also be seen as a link from discrete to distributed delays.

The traffic scenario is the same as in section 5.1. We first take a ring configuration of $n = 20$ vehicles with identical drivers and depict the stability regions in the new parametric domain. Thus, the stability pictures in Figure 5.1(a) correspond to those in Figure 5.2(a). The region Φ_1 is distorted in the new domain, $h \times \delta \to (h + \delta/2) \times \delta : \Phi_1 \mapsto \Lambda_1$, and similarly $(\Phi_1 \cup \Phi_2) \mapsto (\Lambda_1 \cup \Lambda_2)$. Figure 5.2(b) compares the stability regions for the ring and linear configurations, for $\kappa = 2.0$. The labeled regions correspond to those in Figure 5.1(b) as $\Phi_1 \mapsto \Omega_1$, and $(\Phi_1 \cup \Phi_2) \mapsto (\Omega_1 \cup \Omega_2)$.

Figure 5.2(a) shows how overaggressive drivers (large κ) cause instability, unless

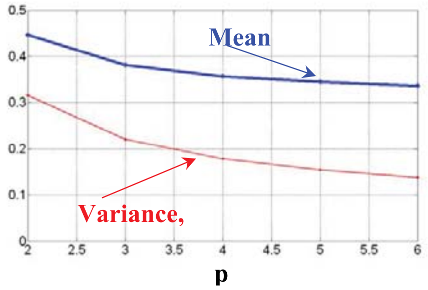

FIG. 5.3. (a) *Maximum allowable mean delay and the corresponding variance of the γ-distribution* ($h = 0$) *for varying p values.* (b) *Crossing boundary in mean vs. variance of the γ-distribution* ($h = 0$).

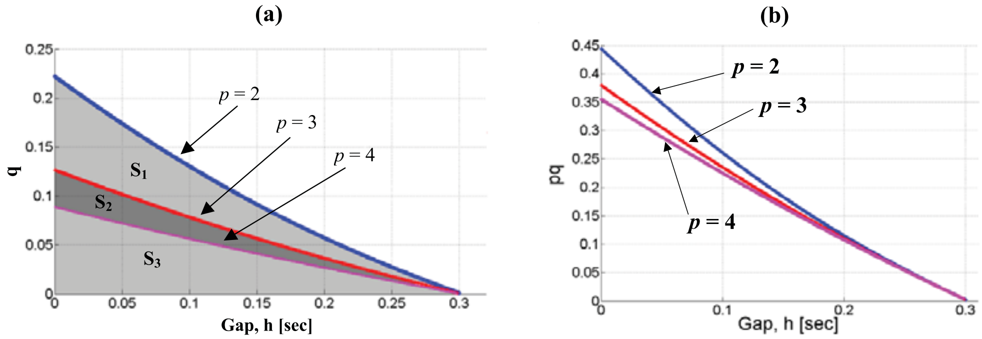

FIG. 5.4. (a) *Stability regions in* (h, q) *domain for various values of the parameter p of the γ-distribution with gap.* (b) *Corresponding stability boundaries in* (h, pq) *domain.*

the mean delay and the memory window are reduced, i.e., they can react almost instantaneously. This is analogous to feedback control systems where high gains may cause instability. Figure 5.2(b) shows that the linear configuration of the vehicles allows larger memory windows that can be utilized by the drivers without inducing instability. For this particular example, the allowable memory size (that preserves stability) in linear configuration of the vehicles is five times more than that of the ring configuration. An interesting observation from Figure 5.2(b) is that if the mean delay is relatively large (e.g., $h + \delta/2 = 1$ in linear configuration), stability is still possible, but too small or too large window sizes yield instability. In contrast, for smaller values of mean delay, the window size can even become zero, resuming the discrete delay case. This clearly shows the nontrivial qualitative effects of distributed delays.

5.2. γ-distribution with and without gap. We consider $n = 3$ vehicles and identical drivers with $\kappa = 2$. For $h = 0$ and $p \in [2, 6]$, we identify the maximum allowable q for which the characteristic equation (4.32) remains stable. Using these q values, the mean pq and the variance pq^2 of the distribution are plotted with respect to the parameter p in Figure 5.3. Notice that for smaller p the variance becomes larger, which corresponds to larger mean delay. This is also an indication of larger stability regions. In other words, increasing the variance of the delay distribution for a fixed mean delay enlarges the stability region.

In the case of a nonzero gap h, i.e., in the presence of a dead-time, the stability regions are shown in Figure 5.4(a) as p values. The shaded zones S_3, $S_2 \cup S_3$, and

$S_1 \cup S_2 \cup S_3$ correspond to stability regions for $p = 4$, $p = 3$, and $p = 2$, respectively. The subplots in Figure 5.4 have the same color coding. Note that the influence changing p on the stability region is more pronounced for small values of h than for larger values. We emphasize that, when modeling memory effects, the presence of a gap may not be negligible since the dynamics may become sensitive even to a small gap.

6. Conclusions. We have studied the stability of a single-lane microscopic car-following model in the parametric domain describing the delayed reactions of human drivers. In contrast to the literature, we have modeled such delayed reactions based on the "memory capabilities" of human drivers, which assumes that control actions are based on a "memory window" distributed over the the time history of the traffic flow dynamics. The resulting system with distributed delays offers a more realistic model, although the corresponding stability analysis becomes more difficult. In the analytical development of the paper, we have derived necessary and sufficient conditions for the stability of the traffic flow with distributed delays. Numerical examples have been given for two common delay distributions, two spatial configurations, and a realistic set of parameter values. The results show some nontrivial effects of distributed delays and reiterate that the modeling and analysis of traffic holds many mathematical challenges.

Acknowledgments. SHOCK SOLUTIONS FOR PARTICLE-LADEN THIN FILMS*

BENJAMIN P. COOK†, ANDREA L. BERTOZZI†, AND A. E. HOSOI‡

Abstract. We derive a lubrication model describing gravity-driven thin film flow of a suspension of heavy particles in viscous fluid. The main features of this continuum model are an effective mixture viscosity and a particle settling velocity, both depending on particle concentration. The resulting equations form a 2×2 system of conservation laws in the film thickness $h(x, t)$ and in ϕh, where $\phi(x, t)$ is the particle volume fraction. We study flows in one dimension under the constant flux boundary condition, which corresponds to the classical Riemann problem, and we find the system can have either double-shock or singular shock solutions. We present the details of both solutions and examine the effects of the particle settling model and of the microscopic length scale b at the contact line.

Key words. thin liquid films, contact lines, Riemann problem, systems of conservation laws, suspension flow, sedimentation, singular shocks

1. Introduction.

The flow of thin viscous films [44] is of great importance to many problems in science and engineering. Flows in thin films can result from slow processes such as spreading [17] and evaporation [6] or stronger driving forces such as capillarity [38] or gravity [21]. As shown by Huppert in [21], gravity-driven films on an incline can be described roughly by the conservation law

$$\frac{\partial h}{\partial t} + \frac{\partial}{\partial x} h^3 = 0 \tag{1.1}$$

for the film thickness h. However, in many cases, there exist large gradients in h and dry regions where $h = 0$, requiring more complex models that incorporate capillary forces and the thermodynamic wetting process.

Wetting occurs as a fluid domain evolves, moving in particular the contact line, where the solid, liquid, and vapor phases meet. Despite the fundamental importance of contact lines to fluid dynamic boundary conditions, many of their basic properties are not fully understood [2, 13]. The standard no-slip boundary condition is inadequate near a moving contact line [14, 20], and two common contact line models either allow a small slip velocity [20] or assume a thin "precursor" film rather than a dry substrate [55]. These models have contributed to understanding the capillary ridge that often develops near the contact line [3, 16, 19, 23, 28, 55], the rupture of thin films [39, 57], the contact angle that the free surface makes with the substrate [16, 23, 25, 50], and the relevance of the material composition of the fluid and substrate [12, 24, 50]. A "fingering" instability observed in [21] which deforms the contact line in

some driven films has also motivated analysis [3, 55], simulation [28], and experiments [12, 24, 50] on thin film flow.

Film flows of more complex materials are much less understood. For dry granular flows, air can frequently be neglected, and the central modeling challenge is to determine an appropriate constitutive relation [26]. Replacing the fluid with a suspension, however, introduces the possibility of phase segregation, allowing new behaviors not seen in pure fluids and only recently observed in film flows [54, 59]. Segregation of viscous suspensions can be driven by gravity [59], but has also been observed with neutrally buoyant particles in thin films [54] and in the related Hele–Shaw flow [53]. Direct numerical simulation of suspension flows considering individual particles is computationally demanding, and existing methods do not account for the complexities of a contact line [49, 58]; consequently, continuum models play an essential role in understanding these flows.

Continuum descriptions of viscous suspensions involve three main effects: an "effective viscosity" greater than that of the suspending fluid [30, 52], the settling of heavy particles due to gravity [11], and particle fluxes thought to result from particle interactions in the presence of shear [34]. Various models have incorporated some or all of these effects [40, 42, 45, 47]; however, only a limited number of flow geometries have been studied, most commonly the one-dimensional Couette and Poiseuille flows (for exceptions see [15]). In particular Schaflinger, Acrivos, and Zhang [47] model a gravity-driven thin film, though they do not consider variation in the flow direction caused by gravitational segregation that we model below.

Our work is motivated by the experiment and model described by Zhou et al. in [59]. The experiment consists of a gravity-driven film of a dense ($\geq 17\%$ by volume) suspension of glass beads in oil which flows down an inclined plane under constant flux upstream conditions. They observed three different particle behaviors in this experiment, depending on the inclination angle and particle concentration of the initially well-mixed suspension, which they summarized in a phase diagram. At low inclination angles and concentrations, the particles settle out of the flow, leaving a film of clear fluid, while at intermediate angles and concentrations the suspension appeared well mixed for the duration of the experiment. At high angles and concentrations the particles accumulate near the moving contact line in a "particle-rich ridge." They also observed that while the well-known fingering instability [21] occurs in the first two regimes, it is largely suppressed when the ridge appears. Their new model describes this third regime, characterized by spatially varying rheology, which appears to have no analogue in pure fluid motion.

Zhou et al. derived their model by treating the mixture locally as a Newtonian fluid, which allows the use of standard lubrication techniques. The two-phase flow is described by an overall velocity determined from the local value of a concentration-dependent effective viscosity, and a settling velocity of the heavy particles relative to the fluid. They derived a system of two coupled fourth-order evolution equations for the film thickness and particle concentration, and argued that the essential dynamics are determined by a system of conservation laws obtained by retaining only the first-order terms. They also presented double-shock solutions for this system depending on the parameter b appearing in their contact line model, which represents the thickness of a precursor film appearing ahead of the bulk flow. They compared these solutions to the experimentally observed ridge, and noted that the calculated speeds of the two shocks become nearly equal at small values of b. Their calculations, however, were not sufficient to determine whether the shock speeds actually coincide at some finite $b^* > 0$, an important issue since this would call into question the existence of solutions for $b < b^*$. Furthermore, they described the physical derivation and the shock solutions only briefly.

The purpose of the present work is to give a more complete derivation of this model describing the ridge regime, and to more thoroughly characterize its shock solutions, including their dependence on b. Aspects of these solutions motivate a revision of the particle settling model, which appears later in the manuscript. In section 2 we present a full derivation following the assumptions of Zhou et al., which was not included in their work. While the equations we derive are slightly different, they appear to have the same qualitative behavior. As in [59] we present two forms of the model equations. The "full system" including fourth-order terms due to surface tension is beyond the scope of our subsequent analysis, but nonetheless important for a faithful description and for modeling phenomena such as the capillary ridge and the fingering instability. The first-order "reduced system," which we study in section 4, is expected though not guaranteed to approximate the full system away from the contact line. In section 3 we recall the classical theory for hyperbolic systems of conservation laws, and in section 4 we apply these methods to the reduced system. For double-shock solutions, we find the two shock speeds do become equal at a certain precursor thickness b, below which the equations have no classical solution. In section 5 we compare this case to the mathematical theory of singular shocks, in which a delta mass is concentrated at the discontinuity. We study one approximate singular shock solution and find the particle concentration exceeds the limit of close packing, suggesting this form of the model is inaccurate at high concentrations. We propose a modified form for the settling velocity in section 6 which causes both the particle and fluid velocities to vanish at close packing, and we find the resulting equations appear to be well-posed for all precursor thicknesses. We summarize our results in section 7, concluding that the modified equations appear more realistic, though a comparison with the fourth-order system and/or with experiments is still needed to establish their ultimate validity.

2. Derivation. Two common methods for describing binary mixtures in a continuum framework are the "two-fluid" and the "mixture" or "one-fluid" models [56]. The two-fluid model balances forces on the two components separately, with the forces of interaction appearing explicitly as a function of the two velocities. It therefore requires a separate viscosity for each phase. The one-fluid model balances forces on the mixture as a whole, using an effective viscosity, and postulates a form for the relative velocity between the two components. Since empirical formulae are readily available for the effective mixture viscosity and settling velocity, we follow Zhou et al. in using the one-fluid model. We also note that the fluid and particle velocities are nearly equal, so the one-fluid equations describing average and relative velocities can be expected to be less strongly coupled than their two-fluid counterparts.

Deriving a one-fluid model involves balancing forces first for the mixture as a whole, without regard to interactions between the two components. In the present case inertia is negligible, and these forces are just gravity and viscous stress. We use an empirical expression for the latter in which the mixture is considered a Newtonian fluid, with an effective viscosity depending on the particle volume fraction ϕ. For a fluid of kinematic viscosity μ_f one form for this relation is [30, 52]

$$\mu(\phi) = \mu_f(1 - \phi/\phi_m)^{-2}, \tag{2.1}$$

where $\phi_m \approx 0.67$ is the random packing fraction of spheres. This viscosity leads to a stress tensor of the form

$$\mathbf{\Pi} = p\mathbf{I} - \frac{1}{2}\mu(\phi)\left[\nabla\mathbf{v} + (\nabla\mathbf{v})^T\right], \tag{2.2}$$

where p is the fluid pressure and $\mathbf{v}$ is a velocity characterizing the motion of the mixture. Since the two mixture components in general have different velocities, say v_f and v_p for the fluid and particulate phases, respectively, $\mathbf{v}$ must be some average of the two. Much of the experimental literature deals with neutrally buoyant mixtures, in which the two velocities are the same and the distinction is unnecessary, but in this case the question is relevant. We argue that since the constitutive model involves neither inertia nor gravity, it should be independent of the masses of the two phases. Therefore we select the volume-averaged velocity: defining

$$\mathbf{v} = (1-\phi)\mathbf{v_f} + \phi\mathbf{v_p}, \qquad \mathbf{v_{rel}} = \mathbf{v_p} - \mathbf{v_f} \tag{2.3}$$

thus comprises the one-fluid model for the mixture, and the individual phase velocities can be recovered by

$$\mathbf{v_p} = \mathbf{v} + (1-\phi)\mathbf{v_{rel}}, \qquad \mathbf{v_f} = \mathbf{v} - \phi\mathbf{v_{rel}}. \tag{2.4}$$

The average velocity satisfies the Stokes equations:

$$\nabla\cdot\mathbf{\Pi} = \rho(\phi)\mathbf{g}, \qquad \nabla\cdot\mathbf{v} = 0, \tag{2.5}$$

where $\rho(\phi)$ is the mixture density and $\mathbf{g}$ is the gravitational field. The density is given by $\rho(\phi) = \rho_f(1+\Delta\phi)$, where $\Delta = (\rho_p - \rho_f)/\rho_f$ and ρ_f and ρ_p are the densities of the fluid and particulate phases.

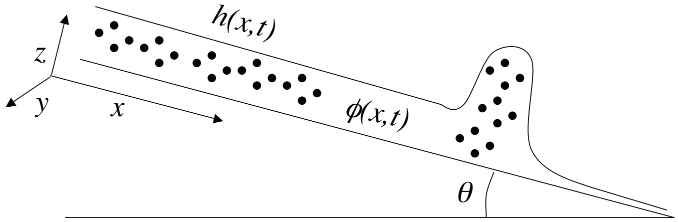

FIG. 2.1. *Geometry of the film problem. While our derivation will allow* y *dependence, we study the* y*-independent case. Our model assumes* ϕ *is independent of* z*.*

We now define the problem geometry as in Figure 2.1, considering an advancing film that coats a plane inclined at the angle θ. In deriving the equation for $\mathbf{v}$, we follow the standard methods used for pure fluid films [17, 44]. The lubrication approximation, valid at small Reynolds numbers and geometric aspect ratios, assumes $\mathbf{v}$ lies in the $\mathbf{x}$-$\mathbf{y}$ plane and $\left|\frac{\partial\mathbf{v}}{\partial z}\right| \gg \max\left(\left|\frac{\partial\mathbf{v}}{\partial x}\right|, \left|\frac{\partial\mathbf{v}}{\partial y}\right|\right)$. Correspondingly, we now consider all velocities to be two-dimensional vectors, as well as the gradient $\nabla = \mathbf{x}\frac{\partial}{\partial x} + \mathbf{y}\frac{\partial}{\partial y}$, and define $g_\perp = \mathbf{g}\cdot\mathbf{z} = |\mathbf{g}|\cos\theta$ and $\mathbf{g}_\parallel = \mathbf{g} - g_\perp\mathbf{z} = (|\mathbf{g}|\sin\theta)\mathbf{x}$. In this notation, the Stokes equations now read

$$\frac{\partial p}{\partial z} = -\rho(\phi)g_\perp, \tag{2.6a}$$

$$\nabla p = \mu(\phi)\frac{\partial^2\mathbf{v}}{\partial z^2} + \rho(\phi)\mathbf{g}_\parallel. \tag{2.6b}$$

The Laplace–Young boundary condition states that the pressure at the free surface, $z = h(x,y)$, is given by

$$p\left(x,y,h(x,y)\right) = -\gamma\nabla^2 h(x,y), \tag{2.7}$$

where γ is the coefficient of surface tension. The pressure is then determined by

$$p(x,y,z) = -\gamma\nabla^2 h(x,y) + \int_z^{h(x,y)} \rho(\phi(x,y,z'))g_\perp dz' \tag{2.8}$$

from the depth and particle concentration of the film. Here it is convenient to assume the particle concentration is independent of the z coordinate, so that the integral in (2.8) is merely $\rho(\phi)g_\perp(h-z)$. We will discuss this assumption further in our treatment below of particle motion.

Combining (2.6b) and (2.8) and defining $P(x,y) = -\gamma\nabla^2 h + \rho(\phi)g_\perp h$, we have

$$\nabla P - zg_\perp\rho'(\phi)\nabla\phi = \mu(\phi)\frac{\partial^2\mathbf{v}}{\partial z^2} + \rho(\phi)\mathbf{g}_\parallel. \tag{2.9}$$

The boundary conditions of interest are no stress ($\partial\mathbf{v}/\partial z = 0$) at the free interface and no slip ($\mathbf{v} = 0$) at the solid interface. Equation (2.9) can now be integrated twice in z with the constants of integration determined by these conditions, to arrive at the equation

$$\mu(\phi)\mathbf{v} = \left(hz - \frac{z^2}{2}\right)(\rho(\phi)\mathbf{g}_\parallel - \nabla P) + \frac{1}{2}(h^2 z - z^3/3)g_\perp\nabla\rho(\phi) \tag{2.10}$$

for the volume-averaged velocity. Integrating once more gives the depth-averaged velocity

$$\mathbf{v_{av}} = \frac{h^2}{3\mu(\phi)}\left[\gamma\nabla\nabla^2 h - g_\perp\left(\nabla(\rho(\phi)h) - \frac{5}{8}h\nabla\rho(\phi)\right) + \rho(\phi)\mathbf{g}_\parallel\right]. \tag{2.11}$$

Modeling the relative velocity due to particle settling turns out to be more difficult. Recall that in the above lubrication analysis, we have assumed the particles are evenly distributed across the film depth. This may seem unrealistic because the normal component of gravity is pulling the particles toward the solid substrate, but this model is concerned with the particle-rich ridge regime occurring at high angles and concentrations, in which Zhou et al. found that particles do not settle out of the flow. A similar effect was also observed in a thin film experiment [54] performed by Timberlake and Morris with neutrally buoyant particles: they found higher concentrations near the free surface, and attributed this to a shear-induced particle flux such as Leighton and Acrivos describe in [34]. This flux consists of a nonlinear diffusion in the presence of shear, and in inhomogeneous flows an additional migration of particles away from regions of high shear. Schaflinger, Acrivos, and Zhang, in their model for film flow [47], balance gravity-driven settling with only the diffusive flux, and find steady state solutions in which the concentration increases with depth. While the corresponding problem including both diffusion and migration remains unsolved, Carpen and Brady found nonmonotone concentration profiles in a model for the related inclined Poiseuille flow [9] and also showed that these profiles are unstable due to heavy material suspended above lighter material. Thus it is unclear whether the actual concentration profile for film flow increases or decreases with depth, so we find it reasonable to consider the simplest case, a uniform depth profile.

We begin our model of the relative motion with the settling velocity

$$\mathbf{v_s} = \frac{2a^2\Delta\rho_f\mathbf{g}_\parallel}{9\mu_f} \tag{2.12}$$

of a single sphere of radius a in $\mathbb{R}^3$, while noting that this expression neglects the effects of the solid boundary, the free surface, and other particles. Equation (2.12) uses $\mathbf{g}_\|$ because particles were not observed to settle vertically in the ridge regime. The problem of determining settling rates of concentrated mixtures is complex, even in the idealized case of monodisperse spherical particles in a large domain [11]. Some of the challenges are summing the interactions between spheres, which decay only as $1/r$ in Stokes flows, and interpreting theoretical results that imply divergent fluctuations about the mean particle velocity [5, 8]. Since there is no general agreement of theoretical and numerical results with experiments, sedimentation is commonly modeled by an empirical hindered settling function,

$$\mathbf{v_{rel}} = f(\phi)\mathbf{v_s}, \tag{2.13}$$

such as the Richardson–Zaki function (see [46])

$$f_{RZ}(\phi) = (1-\phi)^n, \qquad n \approx 5. \tag{2.14}$$

We also seek a correction to represent the impeding effect of the solid substrate on particle motion. A similar problem involving a sphere falling next to a vertical wall has been solved approximately by the method of images [18], leading to the series solution

$$\mathbf{v_{rel}} = \left(1 - \frac{259}{256}\left(\frac{a}{z}\right) + \frac{9}{16}\left(\frac{a}{z}\right)\log\left(\frac{a}{z}\right) - \frac{1}{16}\left(\frac{a}{z}\right)^3 + \frac{15}{256}\left(\frac{a}{z}\right)^4 + \cdots\right)\mathbf{v_s} \tag{2.15}$$

for the velocity, where $z > a$ is the distance from the center of the particle to the wall. The important quantity in a lubrication model is the depth-averaged velocity, which in the case of particle settling can be interpreted as $(1/h)\int_a^h \mathbf{v}(z)dz$. Figure 2.2 shows this average for a range of the nondimensional parameter h/a, along with the simpler function that we will use to approximate wall effects:

$$w(h) = \frac{A(h/a)^2}{\sqrt{1 + \left[A(h/a)^2\right]^2}} \tag{2.16}$$

with $A = 1/18$. This function has the desired properties $w \approx 0$ for $h < a$, $w \approx 1$ for $h \gg a$, and unlike (2.15) is differentiable and positive on $(0, \infty)$. We have chosen the parameter A so that this function resembles (2.15), but since the latter neglects the net flow and the effects of other particles it should mainly be viewed as a correction to ensure $\mathbf{v_{rel}} \to 0$ for very thin films.

For lack of a comprehensive theory incorporating both wall effects and hindered settling, we simply assume the effects are multiplicative, obtaining the settling velocity

$$\mathbf{v_{rel}} = f(\phi)w(h)\mathbf{v_s} \tag{2.17}$$

relative to the fluid which we interpret as a depth average. We assume f refers to f_{RZ} until section 6, when we consider another settling function. The velocities $\mathbf{v_{rel}}$ in (2.17) and $\mathbf{v_{av}}$ in (2.11) complete the one-fluid description (2.3). The evolution equations

$$\frac{\partial h}{\partial t} + \nabla\cdot(h\mathbf{v_{av}}) = 0, \qquad \frac{\partial \phi h}{\partial t} + \nabla\cdot(\phi h\mathbf{v_p}) = 0 \tag{2.18}$$

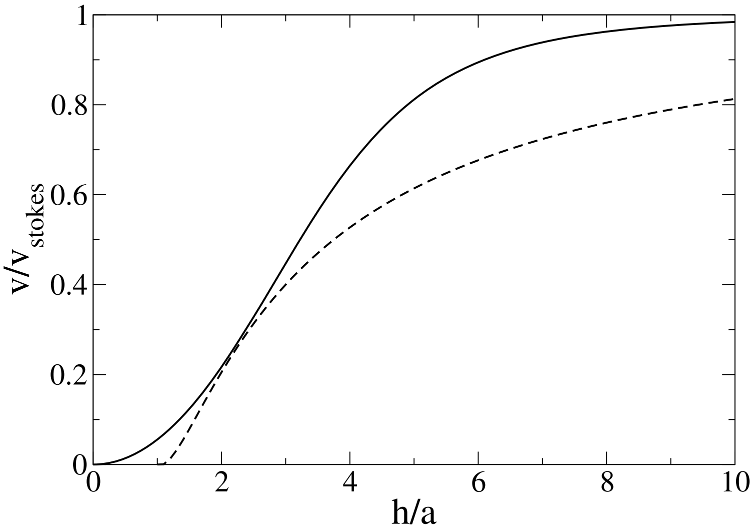

FIG. 2.2. *Our correction representing the impeding effect of the solid boundary on a single particle's settling velocity (solid), and the depth average of* (2.15) *(dashed).*

follow from conservation of volume in both the mixture as a whole and, using (2.4), in the particulate phase. Note that (2.18) differs from the model proposed by Zhou et al., which incorrectly used conservation of mass. Identifying $\mathbf{v_{av}}$ in (2.18) with $\mathbf{v}$ in (2.4) and inserting (2.11) and (2.17) into (2.18) then gives the complete system

$$\text{(2.19a)}\quad \frac{\partial h}{\partial t} + \nabla\cdot\left(\frac{h^3}{3\mu(\phi)}\left[\gamma\nabla\nabla^2 h - g_\perp\left(\nabla(\rho(\phi)h) - \frac{5}{8}h\nabla\rho(\phi)\right) + \rho(\phi)\mathbf{g}_\parallel\right]\right) = 0,$$

$$\frac{\partial(\phi h)}{\partial t} + \nabla\cdot\left(\frac{\phi h^3}{3\mu(\phi)}\left[\gamma\nabla\nabla^2 h - g_\perp\left(\nabla(\rho(\phi)h) - \frac{5}{8}h\nabla\rho(\phi)\right) + \rho(\phi)\mathbf{g}_\parallel\right]\right.$$

$$\text{(2.19b)}\quad \left. + \phi h(1-\phi)f(\phi)w(h)\mathbf{v_s}\right) = 0.$$

Next we nondimensionalize the equations for the constant flow rate problem, with the rescaling used in [3] for a clear fluid. If the upstream gate height h_0 represents a typical film thickness, then the first- and fourth-order terms in (2.19) are comparable at a length scale $x_0 = (\ell^2 h_0)^{1/3}$, where $\ell = \sqrt{\gamma/\rho_f g_\parallel}$ is the capillary length. The time derivative is on the same scale as well if $t \sim t_0 = (3\mu_f/\gamma)x_0\ell^2/h_0^2$, and the corresponding capillary number is $Ca \equiv \mu_f x_0/\gamma t_0 = h_0^2/3\ell^2$. Defining $\tilde{h} = h/h_0$, $\tilde{x} = x/x_0$, $\tilde{t} = t/t_0$, $\tilde{\rho}(\phi) = 1 + \Delta\phi$, $\tilde{\mu}(\phi) = (1-\phi/\phi_m)^{-2}$, $\tilde{w}(\tilde{h}) = w(h)$, and dropping the tildes, and replacing ∇ with $\partial/\partial x$ in anticipation of a y-independent solution, we obtain the dimensionless system

$$\text{(2.20a)}\quad \frac{\partial h}{\partial t} + \frac{\partial}{\partial x}\left(\frac{h^3}{\mu(\phi)}\left[h_{xxx} - D(\theta)\left((\rho(\phi)h)_x - \frac{5}{8}h\rho(\phi)_x\right) + \rho(\phi)\right]\right) = 0,$$

$$\frac{\partial(\phi h)}{\partial t} + \frac{\partial}{\partial x}\left(\frac{\phi h^3}{\mu(\phi)}\left[h_{xxx} - D(\theta)\left((\rho(\phi)h)_x - \frac{5}{8}h\rho(\phi)_x\right) + \rho(\phi)\right]\right.$$

$$\text{(2.20b)}\quad \left. + v_s\phi h(1-\phi)f(\phi)w(h)\right) = 0.$$

Note that the inclination angle θ has been scaled out, and now appears only in the parameter $D(\theta) = (3Ca)^{1/3} \cot \theta$ measuring the relative importance of the second-order terms.

Before introducing the boundary conditions, a discussion is necessary of the microscopic contact-line physics, for which we rely on literature dealing with pure fluids. It has been shown [14] that the no-slip boundary condition we have employed above requires infinite viscous energy dissipation in the vicinity of a moving contact line. This singularity is removed if the fluid-solid boundary condition is modified to allow finite slip [20], which generally takes the form

$$\mathbf{v}|_{z=0} = b \left.\frac{\partial \mathbf{v}}{\partial z}\right|_{z=0}, \tag{2.21}$$

where b is a length on the order of the molecular size. This slip length has been observed experimentally and is known to be particularly large (on the order of microns [33]) for polymer liquids such as the PDMS used in [59]. Another technique used to model the contact line derives from attractive Van der Waals forces between the fluid and solid, which for many wetting films (again including PDMS on acrylic) causes a precursor film of microscopic thickness to extend ahead of the apparent contact line [1, 10]. Modeling this precursor explicitly is a complex thermodynamic problem at a microscopic length scale; however, it has been shown that the effect of the precursor on the macroscopic fluid problem can be approximated by incorporating this length scale into the fluid boundary condition [13]. Models that simply impose a thickness b for the precursor have been used successfully [3, 55] and been seen to give similar predictions to the slip model with the same value of b [41, 51]. In both cases b is difficult to know precisely and is often treated as an unknown parameter. Meaningful values range from perhaps 100 μm for a prewet surface down to 1 nm for a smooth, dry surface.

In this work, we choose the precursor model because it preserves the symmetry of the Riemann problem, discussed in section 3 below, and will present results for a range of thicknesses. With an inflow at concentration ϕ_L and a precursor of nondimensional thickness $b \ll 1$ and concentration ϕ_R, the initial conditions for the constant flow rate problem are

$$(h, \phi)|_{t=0} = \begin{cases} (1, \phi_L) & \text{if} \quad x < 0, \\ (b, \phi_R) & \text{if} \quad x > 0. \end{cases} \tag{2.22}$$

In addition to b, ϕ_R is also a model parameter not determined by the bulk flow, and must be specified. The appropriate value of ϕ_R may vary: for a prewet surface it may be equal to ϕ_L, while in a microscopic precursor it is probably zero. We mainly consider $\phi_R = \phi_L$ for definiteness, but also discuss $\phi_R = 0$.

The large-scale behavior of lubrication equations such as (2.20) is often well described by the corresponding first-order system, obtained by simply dropping all higher-order terms. This reduced system,

$$\frac{\partial h}{\partial t} + \frac{\partial}{\partial x}\left(h^3 \rho(\phi)/\mu(\phi)\right) = 0, \tag{2.23a}$$

$$\frac{\partial(\phi h)}{\partial t} + \frac{\partial}{\partial x}\left(\phi h^3 \rho(\phi)/\mu(\phi) + v_s \phi h(1-\phi) f(\phi) w(h)\right) = 0, \tag{2.23b}$$

corresponds to a rescaling of (2.19) with $x \gg x_0$ and $t \gg t_0$; however, we study it below because it allows solutions to be understood as simple shocks and rarefactions, while retaining the essential convective dynamics.

Zhou et al. [59] presented numerical evidence that first-order and fourth-order models agree well for this problem. This agreement is also seen in the homogeneous case ($\phi \equiv 0$, or $\phi \equiv \phi_0 > 0$ with $a = 0$), where (2.23) reduces to (1.1). The Riemann problem for that equation features simple shock solutions; however, it was first studied by Huppert with Dirac mass initial data, which leads to rarefaction-shock solutions (defined in section 3) that compare favorably to a constant-volume experiment [21]. Such correspondence between full and reduced systems is not guaranteed, however: Bertozzi, Münch, and Shearer [4] studied a variant of (1.1) in which Marangoni forcing competes with gravity, and they described examples of more complex shock structures for which the first-order and fourth-order solutions do not agree. Similar lubrication models have given rise to pairs of equations describing a thin film containing surfactant [22, 35]. Also related are models for sedimenting mixtures in which the particle concentration exhibits kinematic shocks [31].

3. The Riemann problem for systems of conservation laws. This section reviews the theory of systems of nonlinear conservation laws in one dimension, of which (2.23) is an example. This class contains equations of the form

$$\frac{\partial U}{\partial t} + \frac{\partial}{\partial x} F(U) = 0, \qquad U, F(U) \in \Omega \subset \mathbb{R}^n. \tag{3.1a}$$

Although initial-value problems for (3.1a) are not in general well-posed, there is a large body of analytical techniques for finding and characterizing solutions when they exist [32]. The analysis is especially simplified for the Riemann problem, in which the initial data is a step function

$$U(x,0) = \begin{cases} U_L & \text{if} \quad x < 0, \\ U_R & \text{if} \quad x > 0, \end{cases} \tag{3.1b}$$

such as (2.22) with uniform concentration.

Both the equation and initial data of the Riemann problem can be expressed in terms of the single variable $\xi = x/t$, and this symmetry extends to solutions as well. Imposing this form on the solution reduces the problem to finding a heteroclinic orbit for the autonomous system

$$\left[J\big(U(\xi)\big) - \xi I\right] \dot{U}(\xi) = 0, \tag{3.2a}$$

$$U(-\infty) = U_L, \qquad U(+\infty) = U_R, \tag{3.2b}$$

where $J(U)$ is the Jacobian derivative of the flux function F. Smooth solutions of (3.1a), known as rarefactions, are therefore either constant or vary along integral curves R_i of a Jacobian eigenvector r_i. For this reason, most existence results apply to strictly hyperbolic systems, in which the eigenvalues are real and distinct.

Equation (3.2a) also requires that rarefaction solutions be parametrized by the corresponding eigenvalue λ_i, which is possible only if λ_i is strictly increasing on R_i between U_L and U_R. We discuss here the simplified case when F satisfies the genuine nonlinearity condition, which states that λ_i varies strictly monotonically along R_i for all i and R_i; we consider the more general case in the appendix.

In a genuinely nonlinear system, $R_i(U)$ consists of two connected curves $R_i^+(U) = \{U' \in R_i(U) \mid \lambda_i(U') > \lambda_i(U)\}$ and $R_i^-(U) = \{U' \in R_i(U) \mid \lambda_i(U') < \lambda_i(U)\}$, and a connecting orbit exists when $U_L = U$ and $U_R \in R_i^+(U)$, or $U_R = U$ and $U_L \in R_i^-(U)$. Consequently smooth solutions do not exist for general data, and solutions are generally sought from the larger class of weak solutions.

A weak solution to the conservation law (3.1a) is an L^∞ function $U(x,t)$ that in addition to the initial condition satisfies

$$\int_{x_1}^{x_2} \big(U(x,t_2) - U(x,t_1)\big)dx + \int_{t_1}^{t_2} \big(F(U(x_2,t)) - F(U(x_1,t))\big)dt = 0 \tag{3.3}$$

for all $x_2 > x_1$ and $t_2 > t_1 > 0$. This includes all smooth solutions to (3.1a), but also allows discontinuities along a curve $x = st$ that satisfies the vector Rankine–Hugoniot condition

$$F(U^+) - F(U^-) = s\big(U^+ - U^-\big), \tag{3.4}$$

where U^- and U^+ are the values of U on either side of the discontinuity. The Hugoniot locus $H(U^-)$ is defined as the set of U^+ that satisfy (3.4) for some s. (Note that while the symmetry of (3.4) implies $U_2 \in H(U_1)$ is equivalent to $U_1 \in H(U_2)$, it does not follow that $H(U_1) = H(U_2)$.)

Such weak solutions are not unique, however, and a method must be chosen to select a single solution. Various criteria, known as entropy conditions, have been proposed in order to distinguish the shock, or admissible discontinuity, from any other weak solutions. One condition, the method of viscous profiles, is motivated by the fact that conservation laws often appear physically as approximations to higher-order regularized equations such as

$$\frac{\partial}{\partial t}U^\epsilon + \frac{\partial}{\partial x}F(U^\epsilon) = \epsilon\frac{\partial^2}{\partial x^2}U^\epsilon, \tag{3.5}$$

which are well-posed for $\epsilon > 0$. A solution to (3.1a), according to this method, should be stable in the sense that it appears as the pointwise limit in x, t of solutions U_ϵ to (3.5) as $\epsilon \to 0$. This condition has the advantage of a clearly desirable physical interpretation that assures shock solutions are unique; however, it has the drawback of being difficult to verify.

A simpler method from the analytical perspective is the Lax entropy condition, which is equivalent to the viscous profile condition for a certain class of scalar conservation laws. This method relies on strict hyperbolicity to index the eigenvalues λ_i of $J(U)$ in increasing order for each U. These eigenvalues represent the characteristic speeds at which the equation propagates information, as can be seen in rarefaction solutions to the Riemann problem in the persistence of the left state U_L for $x \le \lambda_i(U_L)t$ and the right state U_R for $x \ge \lambda_i(U_R)t$. The Lax entropy condition requires the discontinuity to be continually reinforced by conflicting information from a single characteristic field, i.e., it moves with a speed s that satisfies

$$\lambda_i(U_L) > s > \lambda_i(U_R) \tag{3.6}$$

for exactly one i. That characteristic is emphasized by calling the discontinuity an i-shock.

In a neighborhood of any U the Hugoniot locus $H(U)$ consists of two smooth curves intersecting at U, and the four branches leaving U correspond to the four cases of 1- or 2-shocks with U as the right or left state. We denote the continuations of these branches by U_i^+ if U is the left state and U_i^- if U is the right state. The allowable connections $C_i^+(U_L) = R_i^+(U_L) \cup S_i^+(U_L)$ through the ith characteristic also locally form a smooth curve for each i. The variation of an i-shock or i-rarefaction solution is confined to the interval $\{\xi : \min(\lambda_i(U_L), \lambda_i(U_R)) < \xi < \max(\lambda_i(U_L), \lambda_i(U_R))\}$, so compound connections can be generated by stringing together waves of different characteristics as long as ξ increases with i. In fact, $\{C_i^+\}_{i=1}^n$ locally generate a smooth coordinate system, so if U_R is sufficiently close to U_L, the Riemann problem is well-posed.

Existence of solutions for large data depends on the topology of $H(U)$. A famous example of a system with no solutions for certain Riemann data is the Keyfitz–Kranzer equation (5.1) [29], in which $H(U)$ is compact. A bounded Hugoniot locus implies a bound on the strength of a shock, and consequently some large-data Riemann problems have no weak solutions. Section 5 describes a theory for such systems relating the regularized profiles to a Dirac mass; however, this theory is far from complete.

A final complication to the selection of weak solutions is the nature of the regularization actually present in the physical system. The Lax and Oleinik conditions are intended to admit those shocks that appear as viscous limits under the simplest possible regularization. If the actual regularization is different, the viscous profiles could converge to a weak solution other than that selected by the entropy criteria. This possibility is indeed relevant to conservation laws describing thin films, which are generally regularized by nonlinear fourth-order capillary terms such as in (2.20). In fact, a scalar thin film equation with similar regularization is known to select an entropy-violating double-shock solution, rather than the single-shock entropy solution [4].

4. Particular solutions. The system (2.23) is physically meaningful for $h > 0$ and $0 \leq \phi < \phi_m$, or equivalently $0 \leq v < \phi_m u$ in terms of the conserved quantities $u \equiv h$ and $v \equiv \phi h$. While the above theory depends on the latter parameterization, the equations are most simply expressed in terms of the physical variables h and ϕ, which we will use to present our results.

As shown in Figure 4.1, the equations using (2.14) are not strictly hyperbolic near the maximum concentration, where the eigenvalues become complex and the equations become elliptic. It is not clear whether this feature is desired in a model of the thin film. Change of type certainly complicates the mathematical question of well-posedness for such a system, but the parabolic system (2.20) is well-posed regardless of the first-order approximation. Also models proposed for dry granular materials result variously in hyperbolic, parabolic, and elliptic equations, so physically the change of type does not seem altogether unreasonable. Equations (2.23) are also not genuinely nonlinear on the entire domain; the significance of this is discussed in the appendix.

Since h has been rescaled to unity and θ appears only in the time scale, solutions to (2.23), (2.22) depend on ϕ_L, ϕ_R, b, and a. Although the relative values of ϕ_L and ϕ_R appear to be important, we consider only the cases $\phi_R = \phi_L$ and $\phi_R = 0$, which are most likely to occur in experiments. The value of ϕ_L itself appears to have only qualitative significance. The particle radius a has two effects: the time scale is proportional to a^2, and the film thickness at which the wall effect cutoff occurs (the inflection point of $w(h)$) is proportional to a. The appropriate range for a is fairly small, however; as for $a > 0.2$ discrete particle effects may be important, and for small a the relative velocity vanishes as a^2, so we use $a = 0.1$ for all calculations. The precursor thickness b is the most important parameter, but before discussing its effects we describe a typical solution.

We choose $(h_L, \phi_L) = (1.0, 0.3)$ as a representative left (upstream) state, and display in Figure 4.1 the four connection curves (1-shock, 1-rarefaction, 2-shock, 2-rarefaction) containing points that can be reached directly from this state. The rar-

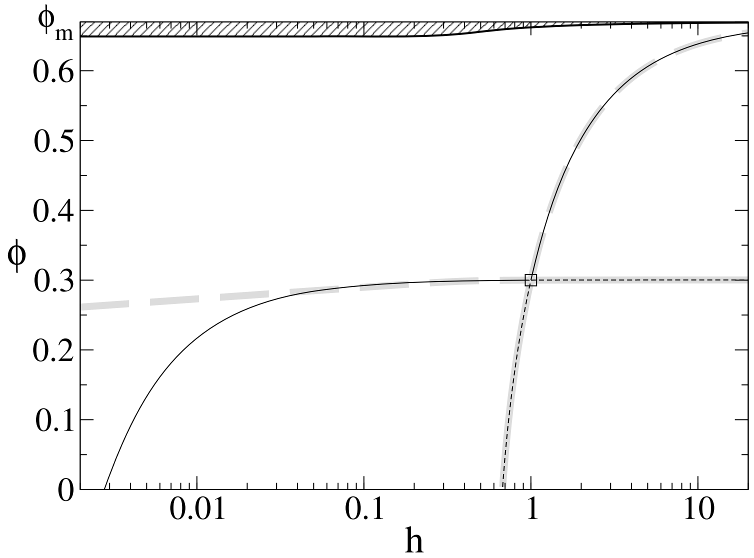

FIG. 4.1. *The phase space of the reduced model, and the connections from* $(h_0, \phi_0) = (1.0, 0.3)$, □. *The system is hyperbolic except in the shaded region. Black lines represent shock connections and gray represents rarefactions. Solid lines are connections to the right, i.e., the* (h_0, ϕ_0) *is the left state, and dashed lines are connections to the left. 1-waves and 2-waves can be distinguished by their slope at* (h_0, ϕ_0)*: 2-waves are nearly horizontal at this scale. Except at very small h, the shocks and rarefactions nearly coincide.*

efaction curves have been integrated from (3.2a) by a Runge–Kutta method, and $H(U_L)$ has been calculated by eliminating s from (3.4) at each point and solving the resulting equations for u and v. For a given shock connection, the shock speed can be recovered by substituting u and v back into (3.4).

For a specified right state (b, ϕ_R) representing the precursor, a solution can be determined by finding an intersection between the two connection diagrams, since the intersection represents an intermediate state that connects to both the left and right boundary conditions through shocks and/or rarefactions. In Figure 4.2 we have plotted the possible shock-shock connections for four values of b with $\phi_R = \phi_L$. At $b = 0.1$ there is a solution with a 1-shock from the upstream state to an intermediate height and concentration slightly larger, and a 2-shock from this intermediate state to the precursor. As the precursor becomes thinner, the height and concentration of this intermediate state increase. For $b = 0.01$ the intermediate state is approximately $(h, \phi) = (1.1757, 0.3663)$. In Figure 4.3 we compare this connection with a numerical solution with the same initial data and find that both shock speeds and the height and concentration of the ridge are in agreement. The numerical solution was calculated using the Lax–Friedrichs finite difference method with grid spacing 3.3×10^{-7} and time step 3.3×10^{-7}.

At $b = 0.008$ the Hugoniot locus has undergone a bifurcation such that the 1- and 2-shock curves are no longer distinct, and an additional connected component has appeared. Inspection of the shock speed and characteristic speeds along these curves reveals that various sections correspond to 1-shocks, 2-shocks, or are not admissible at all. There is still a shock-shock connection for $b = 0.008$ that satisfies the Lax entropy condition; however, at $b = 0.0015$ there are no longer any intersections, and therefore no solution. We discuss this last case in section 5, and in section 6 describe

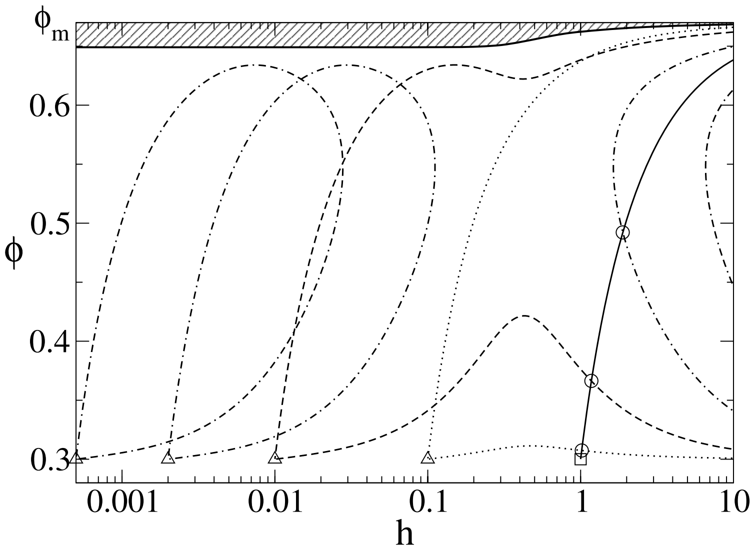

FIG. 4.2. *1-shock connections (solid line) from an upstream state* $(h_L, \phi_L) = (1.0, 0.3)$ (□) *and 1- and 2-shock connections from four precursor states* $(h_R, \phi_R) = (b, 0.3)$ (△)*, where* $b = 0.1$ *(dot),* 0.01 *(dash),* 0.002 *(dot-dash), and* 0.0005 *(dot-dash-dash). The solutions involve an intermediate state between the two shocks, marked by* ○*. As b becomes small, the Hugoniot locus undergoes a bifurcation and ultimately fails to produce a shock solution.*

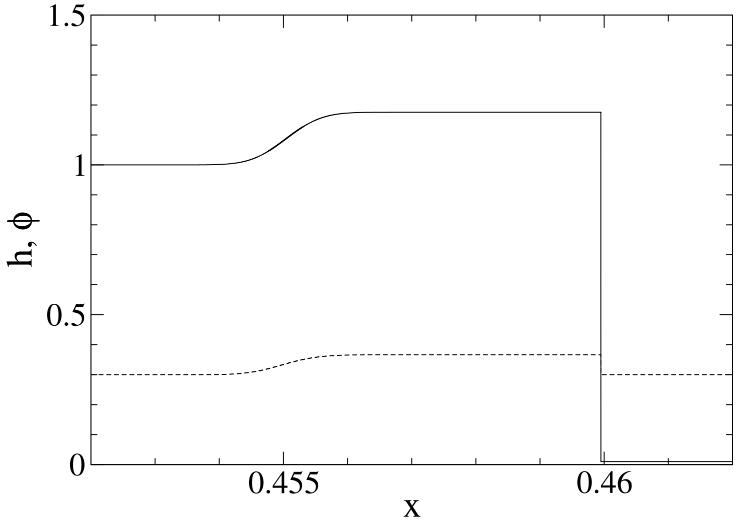

FIG. 4.3. *Film thickness (solid) and concentration (dashed) of a numerical solution of the conservation laws at* $t = 1$*, with* $(h_L, \phi_L) = (1.0, 0.3)$ *and* $(h_R, \phi_R) = (0.01, 0.3)$*. The intermediate state (between the shocks) is* $(h, \phi) = (1.1757, 0.3663)$*, as calculated in Figure* 4.2*. a change to the hindered settling function that ensures a solution does exist.

If the concentration in the precursor is taken to be 0 rather than ϕ_L, double-shock solutions still occur for moderately small b, and again no solution exists for smaller b. At larger b, another type of solution occurs consisting of a 1-rarefaction and a

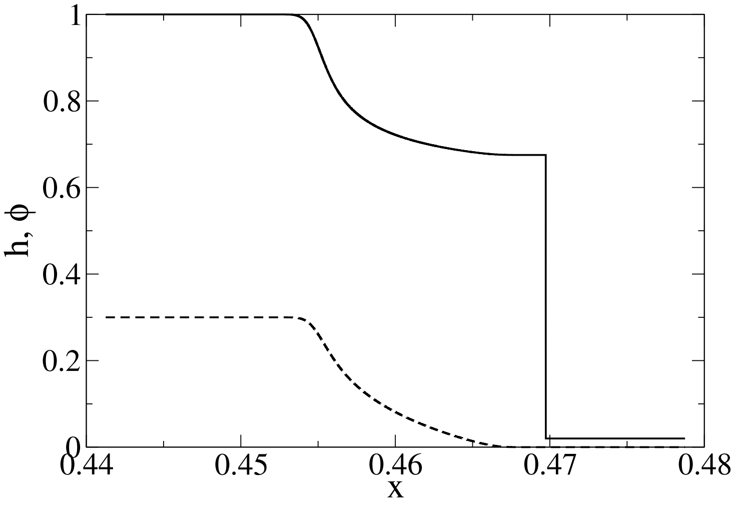

FIG. 4.4. *Numerical solution of the conservation laws at* $t = 1$*, with* $(h_L, \phi_L) = (1.0, 0.3)$ *and* $(h_R, \phi_R) = (0.02, 0)$*, corresponding to a* 1*-rarefaction and* 2*-shock. 2-shock, with both h and ϕ in the intermediate state less than their values at the left. A numerical solution for this case is shown in Figure 4.4, again computed using the Lax–Friedrichs method in a moving frame.

As found by Zhou et al., the double-shock solutions agree qualitatively with the particle-rich ridge seen in experiments. The consistent trend is toward a thicker and more concentrated ridge as the b becomes smaller, until the solution ceases to exist. While it is difficult to know what value to use for b for a given experiment, this trend does indicate that a prewet surface or a more strongly wetting fluid-solid combination will result in a relatively smaller and less concentrated ridge. Very small values of b for which there is no solution are harder to interpret, since it is possible that solutions to the full system (2.20) display behavior that cannot be approximated by first-order equations. The problem of nonexistence is avoided, however, in the modified equations introduced below in section 6, which indicate a simple continuation of the trend toward thicker ridges. In contrast the rarefaction-shock solutions obtained with a fairly thick and particle-free precursor are unlike anything seen in experiments. These solutions are characterized by a thinner, particle-depleted region near the contact line which is created as the advancing film is diluted by the clear fluid in the precursor, and this effect is enhanced as the resulting drop in viscosity causes the depleted region to spread downstream. Perhaps this behavior may be observable with a sufficiently thick and particle-free prewet surface.

5. Singular shocks. The problem of nonexistence due to nontrivial Hugoniot topology has been studied before, and a weaker form of solution known as a singular shock has been described. An illustrative example is the Keyfitz–Kranzer equation [29]

$$\frac{\partial}{\partial t}\begin{pmatrix} u \\ v \end{pmatrix} + \frac{\partial}{\partial x}\begin{pmatrix} u^2 - v \\ \frac{1}{3}u^3 - u \end{pmatrix} = 0, \tag{5.1}$$

which is everywhere both strictly hyperbolic and genuinely nonlinear, but for all $U = (u, v)$ the Hugoniot locus is compact, specifically figure-eight shaped. Thus shocks can only connect states that are sufficiently close, and certain Riemann problems have no classical solution.

In [27], Kranzer and Keyfitz present three sequences of functions $U^\epsilon(\xi = x/t)$ to (5.1) that approximately solve (5.1) as $\epsilon \to 0$ but are also singular in this limit. The first sequence results from an asymptotic expansion of the solution to the regularized equation

$$\frac{\partial U}{\partial t} + \frac{\partial}{\partial x} F(U) = \epsilon t \frac{\partial^2 U}{\partial x^2} \tag{5.2}$$

in ϵ, and the second and third are explicitly constructed from C^∞ functions and piecewise constant functions. They introduce a space of measures in which these sequences converge to a limit involving Dirac-like masses superimposed on a classical shock. They also propose overcompression as an admissibility requirement for singular shocks, i.e., (3.6) must hold for both characteristics; if singular shocks are accepted under this restriction, (5.1) is well-posed for all Riemann data. However, these conclusions are restricted to (5.1). Also, Kranzer and Keyfitz emphasize that while the limiting measures appear as limits of approximate solutions, no well-defined criterion has been proposed by which the limits themselves can be called solutions.

Sever discusses the selection mechanism for singular shocks in a more general context in [48]. For a distribution solution

$$U(x,t) = M(t)\delta(x - st) + \begin{cases} U_L & \text{if } x < st, \\ U_R & \text{if } x > st \end{cases} \tag{5.3}$$

characterized by a point mass $M(t)$ located at $x = st$, conservation implies the singular mass must satisfy

$$\frac{dM}{dt} = s(U_R - U_L) - \big[F(U_R) - F(U_L)\big]. \tag{5.4}$$

Since the speed s is unknown, this is an undetermined system for the $n+1$ parameters dM/dt, s. For (5.1), Kranzer and Keyfitz determined unique solutions by requiring the first component of M to vanish, justified by an argument specific to that system. Sever writes that this last constraint generally comes from properties of the system such as symmetry groups or a convex entropy function. The proper constraint for system (2.23) is not yet apparent.

Equations (2.23) with regularization (3.5) also show behavior consistent with a singular shock. In order to investigate this, numerical solutions were generated with a fully implicit centered difference scheme on a moving nonuniform grid. The number of grid points at each mesh size was fixed; however, every 10 time steps the grids were rearranged using cubic interpolation as necessary to center the area of maximum resolution around the singularity. Meanwhile the entire computational domain moved at a constant speed chosen to approximately match the speed of the discontinuity. The scaling of the regularized solution satisfies $U^\epsilon(x,t) = U^1(\epsilon x, \epsilon t)$, so rather than take $\epsilon \to 0$ we fixed $\epsilon = 1$ and evaluated the solution at long times.

Figure 5.1 contains the results of this calculation. Both components of the singular mass increase linearly in time, as required by (5.4), and the singularity is overcompressive. As the singularity evolves in time the maximum height and concentration grow, and at $t \approx 3 \times 10^8$ the concentration exceeds the packing fraction. Clearly this solution does not describe the physical problem. While the nonlinear fourth-order diffusion in (2.20) may behave differently than the linear second-order diffusion studied here, possibly resulting in realistic solutions for the full model, the modification to

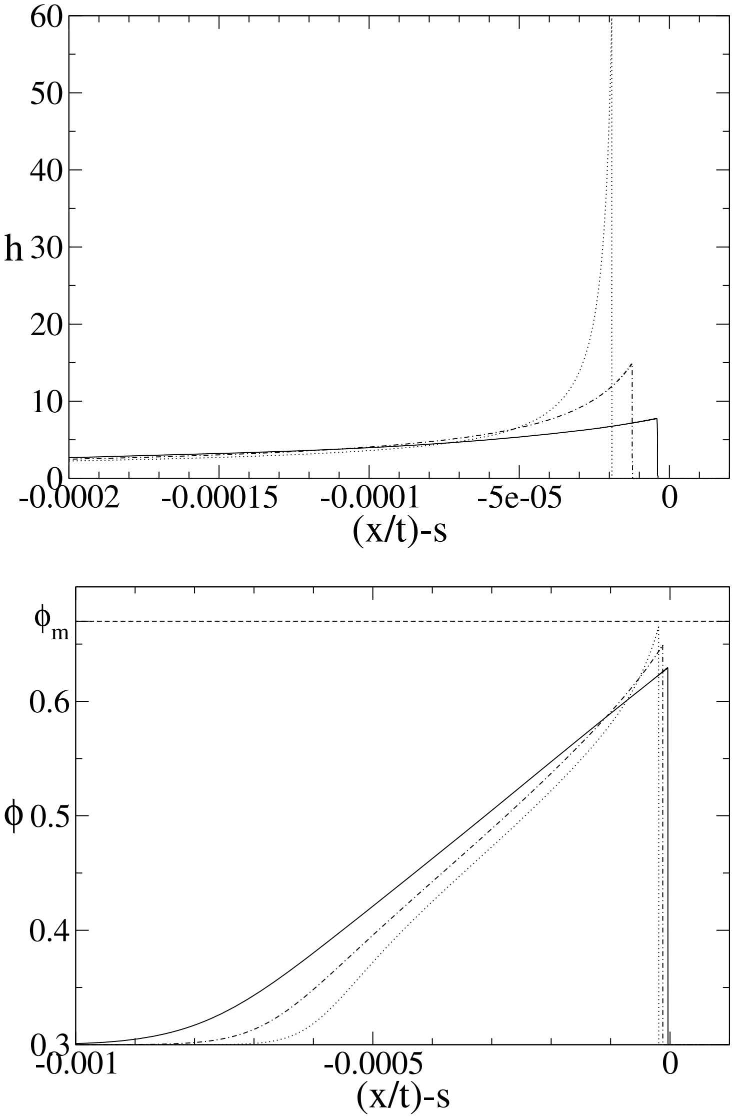

FIG. 5.1. *Film thickness (top) and particle concentration (bottom), from numerical solutions of the regularized system* (3.5) *in the singular shock regime, with* $b = 0.001$, $\phi_0 = 0.3$, *and* $\epsilon = 1$, *calculated on a grid moving at speed* $s = 0.45547$ *and evaluated at times* 5×10^7 *(solid),* 1×10^8 *(dot-dash), and* 2×10^8 *(dot).*

the model introduced in section 6 suggests the crucial issue is the high-concentration physics, rather than any divergence between the first- and fourth-order equations.

6. Alternative settling function. In this section we propose a modification to the unregularized system (2.23) that prevents the concentration from exceeding ϕ_m. We begin with a heuristic explanation of how (2.14) may be incompatible with (2.1) in the limit $\phi \to \phi_m$. The volume-averaged velocity is controlled by $\mu(\phi)^{-1}$, which vanishes in this limit, while $f_{RZ}(\phi)$, and hence the relative flux, is nonzero. This imposes a forward flux of particles with no net volume flux, requiring fluid

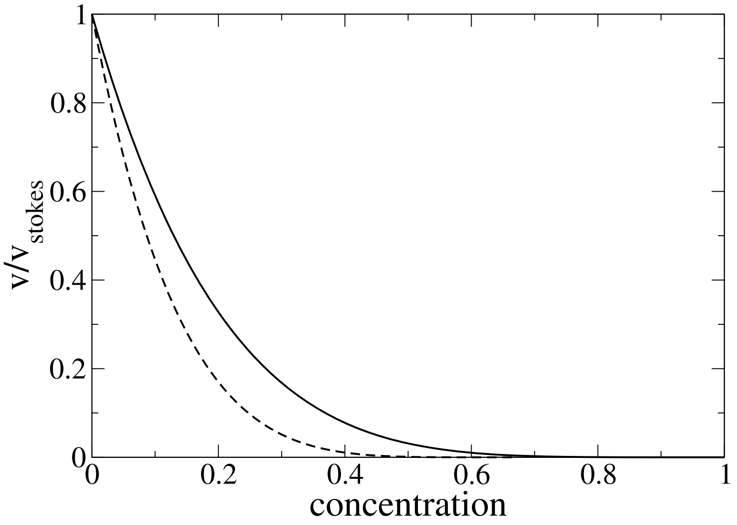

Fig. 6.1. *Two forms of the hindered settling function. The Richardson–Zaki function (solid line) given by* (2.14) *vanishes at concentration* 1.0*; the Buscall et al. function (dashed line) given by* (6.1) *vanishes at the packing fraction* $\phi_m = 0.67$.

therefore to move backward. This situation is probably unrealistic, because the limit $\mu(\phi) \to \infty$ is intended to model the case when the particles are packed tightly enough to prevent any shear flow. In that case, it seems more appropriate to model the particles as an immobile porous medium, with a Darcy's law flux of pure fluid and $\mathbf{v_{rel}} < 0$. Incorporating such a transition into the current model presents challenges, as the particle velocity must be specified relative to the laboratory frame rather than the fluid, essentially changing to a two-fluid model at high concentrations. A much simpler alternative is to simply let $\mathbf{v_{rel}}$ vanish along with $\mathbf{v}$ at $\phi = \phi_m$; this is readily accomplished by using the hindered settling function proposed by Buscall et al. [7],

$$f_B(\phi) = (1 - \phi/\phi_m)^5, \tag{6.1}$$

instead of (2.14). The two settling functions are plotted in Figure 6.1.

With this modification, solving the Riemann problem is simplified in two significant ways: the equations are strictly hyperbolic throughout the relevant domain Ω, and the bifurcation causing shock solutions to break down does not occur. In Figure 6.2 we have plotted shock-shock connections for four values of b. These solutions exist even for very small precursors, so the system appears to be well-posed regardless of b. Figure 6.3 summarizes the manner in which the type of solution depends on the settling function and the Riemann data.

In Figures 6.4–6.5, we compare the shock solutions to the two systems and their dependence on the precursor b. The behavior of the Hugoniot curves in the $f_{RZ}(\phi)$ system, shown in Figure 4.2, implies the intermediate height and concentration approach a maximum value at a critical precursor thickness $b = b_* \approx 9 \times 10^{-4}$, below which there is no meaningful solution. As $b \to 0$ in the $f_B(\phi)$ system, the intermediate height increases apparently without bound and the concentration approaches ϕ_m. We also observed in both limits that the speeds of the 1- and 2-shocks become approximately equal, indicating that the ridge, located between the shocks, is compressed horizontally while growing vertically.

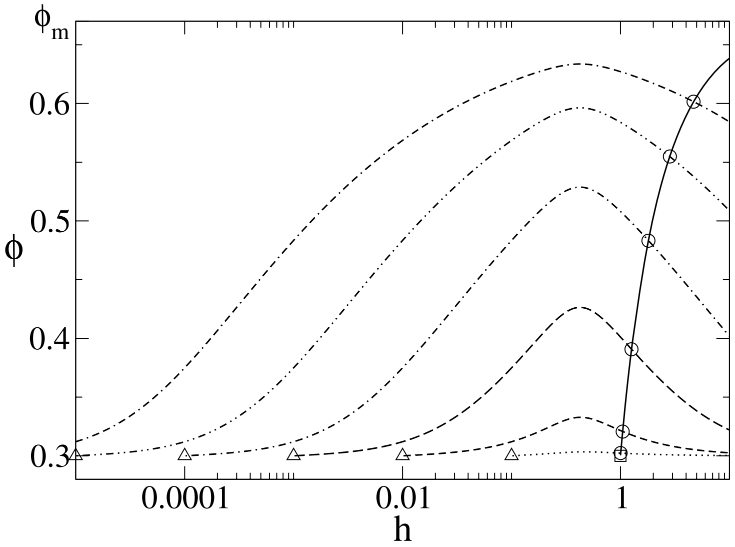

FIG. 6.2. *Shock connections using the settling function $f_B(\phi)$ instead of $f_{RZ}(\phi)$. The bifurcation that caused some initial data to have no solution no longer occurs. The solid line is the* 1*-shock connection from* (h_L, ϕ_L) (□), *and the* 2*-shocks are plotted from various precursors* (△) *given by* $b = 10^{-1}$ *(dot),* 10^{-2} *(short dash),* 10^{-3} *(long dash),* 10^{-4} *(dot-dash),* 10^{-5} *(dot-dot-dash), and* 10^{-6} *(dot-dash-dash). 7. Conclusion. In section 2, we derived a lubrication model for particle-laden films in the case where particle settling occurs only in the direction of flow. We did not analyze this fourth-order system, but rather the associated first-order reduced model; analogies with similar problems suggest this may be a reasonable approximation to the full system. While establishing correspondence between the reduced and full models is beyond the scope of this paper, the potential correspondence motivates our main result, a complete characterization of the first-order problem and a discussion of its possible connections to experiments.

The most important parameter in the reduced system is the precursor thickness b. When b is large enough, this system has a double-shock solution in qualitative agreement with the experimentally observed particle-rich ridge, while for smaller b, there is no classical solution. If the concentration in the precursor is the same as in the upstream source, these are the only two cases; setting the precursor concentration to zero allows a third possibility of a rarefaction-shock solution that has not been seen in experiments. We have confirmed the converging shock speeds that Zhou et al. reported in their preliminary discussion of the double-shock solutions, and we find that the speeds appear to become equal precisely (at the same value of b) when the classical shock solution breaks down.

At precursor thicknesses for which classical solutions do not exist, we have investigated a simple regularization of the equations for which the solution resembles a singular shock. These solutions are not at all realistic, partly because the growing delta mass at the shock location means the height is unbounded as $t \to \infty$, and partly because the close packing concentration ϕ_m is eventually exceeded.

A heuristic explanation was offered in section 6 for this exotic behavior: inspecting the limiting fluxes as $\phi \to \phi_m$ suggests the relative velocity should also vanish in this limit. This can be achieved by substituting the hindered settling function (6.1) of Buscall et al. for that of Richardson and Zaki, and the resulting Riemann problem appears to be well-posed for all precursor thicknesses. Thus physical arguments and the expectation of a well-posed first-order system both suggest that functions such as $f_B(\phi)$ that vanish at ϕ_m are most appropriate for this problem.

Many interesting questions remain unanswered regarding this model. More work is needed to determine how well the present results concerning the first-order system (2.23) approximate the full fourth-order system (2.20). Also of interest is the stability of the two-dimensional model (2.19) with respect to fingering patterns, as the experiments of Zhou et al. found the instability to be suppressed when a particle-rich ridge develops [59]. Other questions arise from the limitations of the current model. Explaining the three distinct settling behaviors observed by Zhou et al. requires a more general model considering particle settling in the normal direction, perhaps balanced by a shear-induced particle flux as in [47]. In addition to explaining the phase diagram, such a model could help determine whether the assumption in the current model—that particle concentration is constant across the film depth—is realistic. Changes to the model may also be needed to describe very high concentrations, as suggested in section 6, because contact forces between particles can be expected to become important.

Appendix. Genuine nonlinearity. While most physical systems are strictly hyperbolic, systems arising naturally are often not genuinely nonlinear. In the Euler equations of compressible flow, one characteristic field is linearly degenerate: $r_i \cdot \nabla\lambda_i \equiv 0$. For this characteristic, $R_i(U)$ and $S_i(U)$ coincide and connections take the form of contact discontinuities, which satisfy (3.4) with the inequalities in (3.6) replaced by equality. More generally, when the variation of λ_i along R_i changes sign, the strict inequality in (3.6) becomes too restrictive and a more general entropy condition is needed to select which contact discontinuities are admissible solutions.

For a scalar conservation law, genuine nonlinearity is simply the strict convexity (or concavity) of the flux function F. If the function changes concavity, contact discontinuities are chosen by the Oleinik condition [43], which states that the shock speed $s(U_L, U_R)$ satisfies

$$s(U_L, U_R) \le s(U_L, U) \tag{A.1}$$

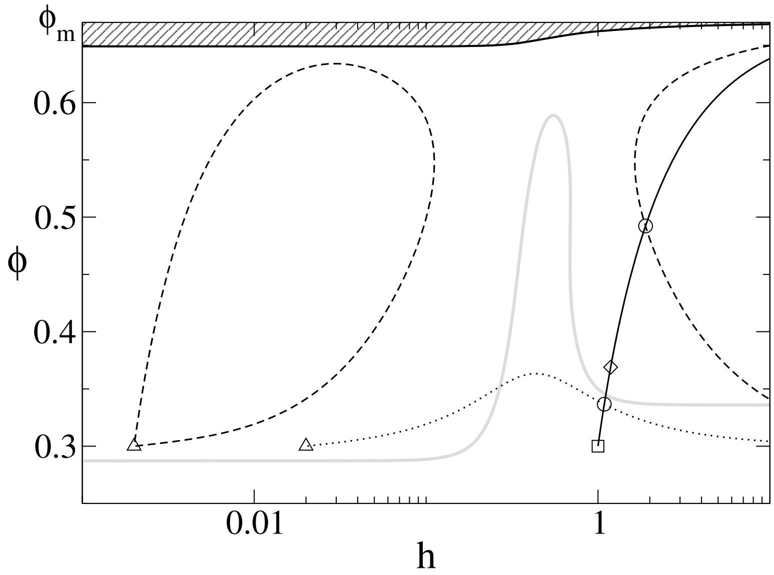

FIG. A.1. *Failure of genuine nonlinearity for* (2.23)*:* $\nabla\lambda_1 \cdot r_1 = 0$ *on the gray line. for every U between U_L and U_R. Liu has generalized the Oleinik condition to 2×2 [36] and $n \times n$ systems [37] by requiring (A.1) to hold for all $U \in H(U_L)$ between U_L and U_R. Both Liu's and Oleinik's conditions reduce to (3.6) for a genuinely nonlinear system. While potentially only a bounded segment of $H(U_L)$ could be available for discontinuous waves, relaxing condition (3.6) provides more solutions by allowing both continuous and discontinuous waves in the same characteristic. Liu provides an existence proof by constructing such a compound wave. This connection involves a shock to the first point U_* satisfying $s(U_L, U_*) = \lambda_i(U_*)$, followed by a rarefaction from U_* to $U_R \in R_i^+(U_*)$. The point U_* is both the first local minimum of s along $H(U_L)$, hence the last point for which Liu's entropy condition is satisfied, and the first point for which $\lambda_i \geq s$, necessary for a continuing rarefaction wave.

In (2.23), $r_1 \cdot \nabla\lambda_1 = 0$ holds along the curve shown in Figure A.1. For $(h_L, \phi_L) = (1, 0.3)$ the branches S_1^+ and R_1^- nearly coincide, so this branch represents to good approximation the states accessible through a 1-shock, 1-rarefaction compound wave as well. In Figure A.2 the eigenvalue and shock speed are plotted on this curve as a function of ϕ. For $\phi < \phi_L$, both speeds increase away from U_L, indicating a simple rarefaction. With $\phi_L < \phi_* \approx 0.369$, the shock speed is strictly decreasing with ϕ so the connection is a shock satisfying the Liu–Oleinik condition. This case includes the solutions described in section 4 for $b = 0.1$ and $b = 0.01$. For $\phi > \phi_*$ neither simple wave is feasible, but a contact discontinuity from ϕ_L to ϕ_* can connect with a rarefaction from ϕ_* to ϕ because λ_1 is now both increasing and greater than the shock speed.

This compound wave is in practice difficult to distinguish from a simple shock. As noted above, the states accessible to a compound wave are nearly the same states lying

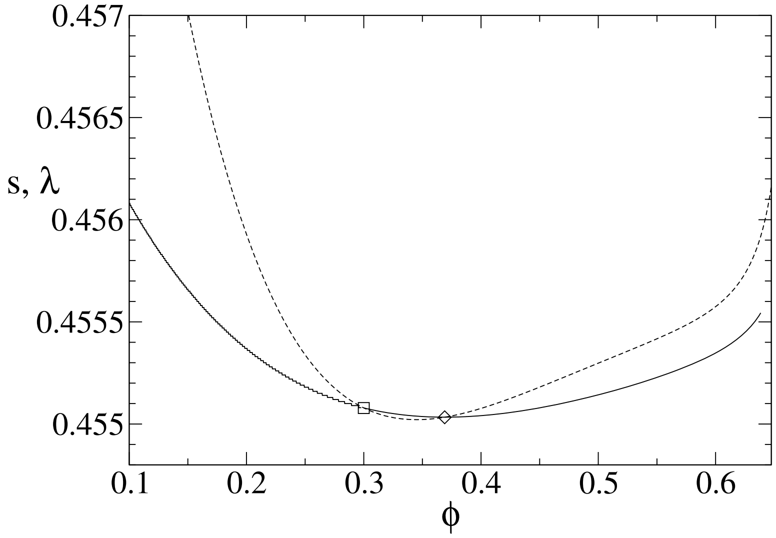

FIG. A.2. *Rarefaction speeds (dashed line) and shock speeds (solid) for the connections along the first characteristic from a left state* $(h_L, \phi_L) = (1.0, 0.3)$ (□) *(corresponding to Figure* 4.1*), plotted as a function of the concentration* ϕ_R *at the right state. The linear degeneracy curve in Figure* A.1 *indicates the location of the minimum characteristic speed. If* $\phi_R > \phi_* \approx 0.37$ (◇)*, a single shock solution is not admissible and the solution consists of a hybrid shock-rarefaction wave.*

on R_1 or S_1, so the constant state U_I appearing between 1-waves and 2-waves cannot easily be used to identify the compound wave. Additionally, Figure A.2 demonstrates that λ_1 changes very slowly along its characteristic at intermediate concentrations, so, for instance, in the presence of numerical diffusion, the rarefaction appears indistinguishable from a shock. Thus although some solutions are necessarily compound waves, their observable properties (other than failing to satisfy the Lax condition) are similar to those of a simple shock.

IDENTIFICATION AND CHARACTERIZATION OF A MOBILE SOURCE IN A GENERAL PARABOLIC DIFFERENTIAL EQUATION WITH CONSTANT COEFFICIENTS*

STEVEN KUSIAK† AND JOHN WEATHERWAX‡

Abstract. We discuss an inverse source problem for a general parabolic differential equation in $\mathbb{R}^n \times \mathbb{R}_+$ with constant coefficients and a source whose strength and support may vary with time. We demonstrate that a knowledge of the solution on any bounded open set $\mathcal{M}$ in $\mathbb{R}^n$ located away from the source for any fixed time $T \geq 0$ determines the so-called carrier support (originally defined in the article "Notions of support for far fields" [J. Sylvester, *Inverse Problems*, 22 (2006), pp. 1273–1288] as a nontrivial subset of the support of the true source) at that coincident time. Additionally, we provide a reconstruction algorithm which can locate the time-varying position of the carrier support of the assumed unknown source with extremely few discrete (possibly nonuniform) measurements taken on such an open set over a wide range of regularity classes of the source. Finally, we provide a few numerical examples which illustrate the efficacy and robustness of this location and tracking method.

Key words. inverse problems, diffusion, partial differential equations

1. Introduction.

Remote sensing endeavors, especially those in connection with modern defense and industrial quality control applications, have evolved significantly in recent years in both their technologies and the realistic scenarios they address. In particular, the release of toxic or impure substances into an environment of interest, urban or otherwise, by either intentional or unintentional means has become an outstanding contemporary problem of considerable and immediate importance and consequence. Recently, many promising technologies, such as those presented in [12, 7, 4, 6, 14, 13], have been created which can remotely detect the presence of foreign materials in a region of interest and estimate their concentration as a function of position and time, provided one has ample knowledge of the diffusion field on either large spatial measurement sets or over long periods of time, or both. Clearly, however, we can never hope to simultaneously monitor vast regions of space in many real-world settings, nor can we tolerate the need for long periods of measurement time, or indefinite ones for that matter. Hence, there is an immediate need to possess the capability to quickly detect and determine the location(s) and output strength(s) of life-threatening, or otherwise destructive, sources with extremely limited measurements in space and time of such diffusing substances.

An immediate extension of the work developed in [10] and more recently in [16] is made in this article that efficiently treats the problem of determining the location

of a (potentially mobile) source in a generalized advection-diffusion environment with extremely limited real-world resources. For instance, the technology lends itself extremely well to the problem of the airborne release of a life-threatening substance aboveground or in an underground subway system. Specifically, in n-dimensional space, if the concentration of the diffusing substance can be measured on a small, coarsely sampled or highly distributed, n-dimensional array of sensors, at a single snapshot in time, then we can robustly, and expeditiously, determine the location of the source with considerable accuracy in the presence of considerable measurement noise. Hence, with a collection of such time snapshots of measurement data, we further show that we are able to locate the time-varying position of a moving source and track its current location. Such a capability is of tremendous value to time-sustained source release problems across a variety of scenarios.

We begin the analytical treatment of this problem by considering the general nonhomogeneous second order parabolic partial differential equation

$$(\partial_t - L_x)u(x,t) = f(x,t), \quad u(x,0) = 0, \quad (x,t) \in \mathbb{R}^n \times \mathbb{R}_+, \quad n \geq 1, \tag{1.1}$$

where we define the elliptic operator L_x as

$$L_x := \sum_{i,j=1}^{n} a_{i,j}\partial_{x_i}\partial_{x_j} + \sum_{j=1}^{n} b_j\partial_{x_j} + c,$$

which governs such things as the molecular diffusion of gases, or particulates, generated by the autonomous source f throughout $x \in \mathbb{R}^n$ and over time $t \in \mathbb{R}_+$. For the purposes of clarity we will limit ourselves to the treatment of the case where L_x has constant coefficients. We note, however, that much of the following analysis and framework suits the more general case of coefficients which at least vary with position. This is in fact the aim of future work.

In the treatment to follow we will assume that the source may be decomposed into the product of a temporally dependent function $s \geq 0$ with a potentially spatially dependent and mobile one $g \geq 0$, such that

$$f(x,t) = g(x - \gamma(t))s(t) \geq 0 \quad \forall\ (x,t) \in \mathbb{R}^n \times \mathbb{R}_+,$$

where, a priori, g is assumed to be compactly supported for each time t within the domain $B_R(p)$, i.e., the ball of radius R and center p, and $\gamma : [0,T] \to \mathbb{R}^n$, $T \geq 0$. Moreover, we assume that the structure of the strength function s is such that s identically vanishes for values of $t < 0$ and takes the form of regular or possibly singular distribution for values of $t \geq 0$, e.g., the Dirac-delta distribution or the Heaviside function.

Characterization of the source amounts to determining the (possibly time-varying) carrier support—which we will define in detail shortly, and for more detail refer the reader to [16]—of the source f, which we will assume to be strictly positive for this article. The concept of the carrier support generalizes that of the so-called scattering support, which was originally defined and analyzed in much detail in [10]. In short, for any differential operator, such as $P = \partial_t - L_x$, which admits the concept of the unique continuation principle (UCP),[1] the carrier support of the measured field u on $\mathcal{M}$ at time T in the differential equation $Pu = f$, where f is compactly supported,

[1] Suppose $Pu = 0$ in some domain $\mathcal{V}$. Then if u restricted to an open subset $\mathcal{M} \subset \mathcal{V}$ vanishes, the UCP implies that u vanishes throughout the larger domain $\mathcal{V}$.

is that subset of the support of f such that there exists an equivalent source $\tilde{f} = \tilde{g}\tilde{s}$ (with $\tilde{f}$ residing in the same regularity class as f, and where $\tilde{f} \neq f$ in the sense of distributions) in the sense that $Pu = \tilde{f}$ everywhere on the complement of the support of f. We summarize this concept with the following definition.

Definition 1.1 (carrier support). *Let P be a differential operator which admits the UCP such that $Pu = f$ on $\mathcal{V}$ and* supp $f \subset \Omega \subsetneq \mathcal{V}$*, and let P possess the fundamental solution E_P. Then, for some open set $\mathcal{M} \subset \mathcal{V}$, where $\overline{\mathcal{M}} \cap \overline{\Omega} = \emptyset$, and $\tau \leq T$,*

$$\text{carr supp } u(\cdot, T)|_{\mathcal{M}} := \bigcap_{E_P * \tilde{f} = u(\cdot, T)|_{\mathcal{M}}} \text{ch supp } \tilde{f}(\cdot, \tau), \quad 0 \leq \tau \leq T,$$

where ch *denotes the convex hull.*

In summary, this definition states that the carrier support of the solution u restricted to the set $\mathcal{M}$ is that common set over all possible sets such that there exists a compactly supported source away from $\mathcal{M}$ such that u on $\mathcal{M}$ may be generated by such a candidate source $\tilde{f}$, i.e., $P\tilde{u} = \tilde{f}$ on $\mathcal{V}$ and $\tilde{u}$ agrees with u on $\mathcal{V} \backslash \text{ch supp } f$.

We should also remark that this definition implies that there exists the possibility that the source generating the data u on $\mathcal{M}$ could have existed previous to time T, i.e., $T \geq \tau$. This means that the solution as observed on $\mathcal{M}$ is that of a now-extinct source that last existed at time τ whose support was last on supp $\tilde{g}(\cdot, \tau)$. This may be summarized through the following (identity) example. Let $H_\tau(t)$ denote the Heaviside function,[2] and suppose for $0 \leq \tau_1 < \tau_2$ that

$$f(x, t) = \delta_{\gamma(t)}(x)\left(H_{\tau_1}(t) - H_{\tau_2}(t)\right)$$

moves along the trajectory $\gamma : [0, T] \to \mathbb{R}^n$. Then

$$\text{carr supp } u(\cdot, t)|_{\mathcal{M}} = \begin{cases} \emptyset, & t < \tau_1, \\ \text{supp } \delta_{\gamma(t)}(x), & \tau_1 \leq t \leq \tau_2, \\ \text{supp } \delta_{\gamma(\tau_2)}(x), & t \geq \tau_2. \end{cases}$$

It should be mentioned that this is a very desirable phenomenon, in that detection of the location of an impulse-like source released at time $\tau \geq 0$ can be made with the observed data u on $\mathcal{M}$ at time $t \geq \tau$. This amounts to the ability to track mobile time-sustained sources and determine the point of detonation of impulse-like ones, both of which are invaluable capabilities for a variety of modern and future endeavors across many disciplines and industries.

We note that even though—as we shall come to prove in the following section—we can determine the current location, or that final one when the source's strength was last nonzero, with a snapshot of the current diffusion field on $\mathcal{M}$, we cannot reconstruct the entirety of γ over all times subsequent to t. In particular this means we may analytically extend the solution u of the homogeneous equation $(\partial_t - L_x)u = 0$ back to time t^* at which minimal time u was the solution of a nonhomogeneous equation of the form $(\partial_t - L_x)u = \tilde{f} \neq 0$. Again, we shall revisit this concept in further detail and provide all the necessary technical arguments which support this notion in the following section and in the proof of our main result (Theorem 3.2) in section 3.

[2] For a test function $\phi \in C^\infty(\mathbb{R}^n \times \mathbb{R})$, for $\delta_{\gamma(t)} H_\tau \in \mathcal{E}'(\mathbb{R}^n) \otimes \mathcal{D}'(\mathbb{R})$, we define the action of the distributional pairing $\langle \delta_{\gamma(t)} H_\tau, \phi \rangle = \int_\tau^\infty \int_{\mathbb{R}_x} \phi(x, t)\delta(x - \gamma(t))dxdt$.

Several results have been presented to date which can determine the actual support of the source and its strength function s as a function of time; see, for example, [12, 7, 4, 6]. The fundamental difference between these methods and that to follow in this article is that we require knowledge of the scalar diffusion field only at single snapshots in time on some (possibly small) open subset of the ambient space $\mathbb{R}^n$ which we will assume to be disjointly located from the source in question. Since we require far less information than that required in these previous works, we might expect to fail to fully characterize the source in all its attributes. We shall come to see that this is indeed the case, and that what we can estimate with this limited information is that of the carrier support of the instantaneous support of the true source f at each point $T \geq 0$ in time. We accomplish this by following a strategy similar in nature to the one presented in the articles [10, 11]. Essentially, we employ a unique continuation-like strategy for the assumed positive solution which, together with the Picard theorem, gives us a way to uniquely determine the carrier support at any time T. We will describe these ideas in much further detail in a subsequent section.

We again stress the importance of having measurements on some limited finite domain located away from the source, and which need not surround the source, which serves such applications as source-release problems in complex urban environments, and atmospheric or reservoir problems. More important, if the source is moving, we wish to determine its trajectory, and current location, for purposes of perhaps its rapid neutralization, i.e., the source is emitting toxic or impure substances into a domain of interest.

We will make several assumptions on the nature of the coefficients appearing in L_x and of that of the bounded open set $\mathcal{M} \subset \mathbb{R}^n$, where will assume to know the scalar values of the time-varying field $u(x,t)$; for instance, we require $\mathcal{M}$ to have a smooth boundary for the purposes of maintaining well-behaved norms of the solution on such sets of interest. Additionally, we will define a few function spaces of interest in which our solutions of the main problem will uniquely exist.

Remark 1. *In the analysis to follow in the upcoming section, we will assume that the following conditions hold:*

- *$\partial_t - L_x$ is parabolic on $\mathbb{R}^n \times \mathbb{R}$, i.e.,*

$$\sum_{i,j=1}^{n} a_{i,j}\xi_i\xi_j > 0, \quad \mathbb{R} \ni \xi_i, \xi_j \neq 0.$$

- *$c \leq 0$.*
- *The matrix of coefficients $a_{i,j}$ is positive definite and invertible.*

Remark 2. *Additionally, for $-n/2 < \sigma_1 \leq 0$ and $-1/2 < \sigma_2 \leq 0$, we define the function spaces*[3]

$$\overset{o}{H}{}^{\sigma_1}_{+}(\overline{\Omega}) = \{g \in H^{\sigma_1}(\mathbb{R}^n) \ : \ g \geq 0, \quad \operatorname{supp} g \subset \overline{\Omega}\},$$

where H^σ is the usual Sobolev space of regularity $\sigma \in \mathbb{R}$, and similarly

$$H^{\sigma_1}_{+}(\mathbb{R}) = \{g \in H^{\sigma_1}(\mathbb{R}) \ : \ g \geq 0\}.$$

Using these conventions we define the positive space of sources, i.e., distributions,

$$f \in \overset{o}{H}{}^{\sigma_1}_{+}(\overline{\Omega}) \bigotimes \overset{o}{H}{}^{\sigma_2}_{+}([0,T])$$

[3] We wish to include singular temporal and spatial distributions such as the Dirac-delta distribution in the larger collection of positive sources; hence we are interested in taking $0 \geq \sigma_1 > -n/2$ and $0 \geq \sigma_2 > -1/2$.

and the space of restricted solutions

$$u|_{\mathcal{M}} \in L^2_+\left([0,T], L^2_+(\mathcal{M})\right),$$

where

$$L^2_+(\mathbb{R}^n) = \{g \in L^2(\mathbb{R}^n) \ : \ g \geq 0\}.$$

In order to minimize symbolic clutter and ease notation a bit, we make the identification

$$X_f^{\sigma_1,\sigma_2}(\Omega,T) = \overset{o}{H}{}^{\sigma_1}_+(\overline{\Omega}) \bigotimes \overset{o}{H}{}^{\sigma_2}_+([0,T])$$

and note that its dual space admits the representation

$$\left(X_f^{\sigma_1,\sigma_2}\right)' = H^{-\sigma_1}_+(\mathbb{R}^n) \bigotimes H^{-\sigma_2}_+(\mathbb{R}_+)$$

for any finite T and bounded $\mathcal{M}$. Finally, we note that since $0 \leq -\sigma_1 < n/2$ and $0 \leq -\sigma_2 < 1/2$, by (complex) interpolation, i.e., see, for instance, [17, *p.* 277],

$$[L^2(\mathbb{R}^n), H^k(\mathbb{R}^n)]_\theta = H^{k\theta}(\mathbb{R}^n), \quad k = 0, 1, 2, \ldots, \quad 0 \leq \theta \leq 1,$$

we have the inclusion

$$H^n_+(\mathbb{R}^n) \bigotimes H^1_+(\mathbb{R}_+) \subset \left(X_f^{\sigma_1,\sigma_2}\right)' \subset L^2_+(\mathbb{R}^n) \bigotimes L^2_+(\mathbb{R}_+).$$

This last fact will be important for us in characterizing the behavior of the solution in the following section on the forward problem.

The plan of the remainder of the paper is as follows. In section 2 we discuss the forward problem. Namely, we describe how, given a well-defined source, f generates the solution u and develop the appropriate mapping characterizations between the two. In section 3, we focus on the inverse source problem, which again is to locate the support of f from measurements of the diffusion field u taken on some open region which is disjoint and distant from the assumed unknown source f. In this section we prove uniqueness results for the time-varying reconstruction of the carrier support of f as well as develop a viable reconstruction method which estimates it with little, sparse, and possibly nonuniformly sampled data. Section 4 considers a few numerical examples which robustly illustrate the simplicity and effectiveness of this reconstruction algorithm for a spatially stationary, impulse-like point-source release in one dimension and a time-sustained, moving point source in a convective two-dimensional environment.

2. The forward problem. We begin this section by noting that the solution of (1.1) is well known and may be constructed with the aid of a fundamental solution which we will call Z; see [5, 3] for the original details of this parametrix-based method. Specifically, let $A = \det a_{i,j}$ and $a^{i,j}$ be the determinant and matrix inverse of the positive definite matrix a, respectively. Then

$$u(x,t) = \int_0^t \int_{\mathbb{R}^n_y} Z(x,y,t,\tau) f(y,\tau) dy d\tau, \tag{2.1}$$

where

$$Z(x,y,t,\tau) = W(x,y,t,\tau) + \int_{\tau}^{t} \int_{\mathbb{R}_z^n} W(x,z,t,s)\Phi(z,y,s,\tau)dzds$$

and where we define

$$W(x,y,t,\tau) = [(4\pi(t-\tau))^n A]^{-1/2} \exp\left(- \sum_{i,j=1}^{n} \frac{a^{i,j}(x_i - y_i)(x_j - y_j)}{4(t-\tau)} \right)$$

and lastly require that Φ satisfy

$$\Phi(x,y,t,\tau) = (L_x - \partial_t)W(x,y,t,\tau) + \int_{\tau}^{t} \int_{\mathbb{R}_z^n} (L_x - \partial_t)W(x,z,t,s)\Phi(z,y,s,\tau)dzds.$$

For convenience we will denote the action of Z acting on f as simply $\mathcal{Z}f$. Furthermore, we will denote the restriction of $\mathcal{Z}$ to observations on $\mathcal{M}$ and limited to sources f having compact support on Ω as $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ in what is to follow. Additionally, we note that we will write $Z(x-y,t-\tau)$ in the place of $Z(x,y,t,\tau)$ when it appears in the context of the kernel of the convolution integral which maps the source f to the solution u.

We recall some important properties established in [5]. We use them to prove the following boundedness and denseness result.

PROPOSITION 2.1 (local boundedness of the solution on $\mathcal{M}$). *Given the assumptions detailed earlier in Remarks* 1 *and* 2, *then for each* $T \geq 0$, $\mathcal{Z} : X_f^{\sigma_1,\sigma_2}(\Omega,T) \to L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$ *and has dense range in the latter space.*

Proof. First, for $x \in \mathbb{R}^n \backslash \overline{\Omega}$,

$$\begin{aligned} |u(\cdot,T)|^2 &= \left| \int_0^T \int_{\Omega} Z(x-y,T-\tau)f(y,\tau)dyd\tau \right|^2 \\ &= \left| \langle Z, f \rangle_{L^2(\Omega\times[0,T])} \right|^2 \\ &\leq \|Z(x-\cdot,T-\cdot)\|^2_{\left(X_f^{\sigma_1,\sigma_2}\right)'} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} \\ &\leq \|Z(x-\cdot,T-\cdot)\|^2_{\left(X_f^{n/2,1/2}\right)'} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} \\ &\leq \|Z(x-\cdot,T-\cdot)\|^2_{\left(X_f^{n,1}\right)'} \|f\|^2_{X_f^{\sigma_1\cdot\sigma_2}(\Omega,T)}. \end{aligned}$$

Then, according to the Malgrange–Ehrenpreis theorem, the remainder of the proof follows immediately from the fact that $Z(x-\cdot,T-\cdot)$ is smooth on $\mathcal{M}$, i.e., that

$$\int_K \|Z(x-\cdot,T-\cdot)\|^2_{\left(X_f^{n,1}\right)'} dx < \infty$$

for all compact subsets K in $\mathbb{R}^n \backslash \overline{\Omega}$.

We now employ some supporting facts of interest discussed and proven in Chapter 1, and Theorems 1 and 15, of [5] which help us to establish the claim that $\mathcal{Z}$ as a map from $X_f^{\sigma_1,\sigma_2}(\Omega,T)$ into $L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$ has dense range in $L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$. We first note, as given on page 28 of [5], that Z and its adjoint are related through the identity

$$Z(x,y,t,\tau) = Z^*(y,x,\tau,t), \quad t > \tau.$$

We also remark that, again under the assumptions made in Remark 1, Z is a positive kernel, in the sense that the action of Z on any nonnegative source f must be greater than or equal to zero. Next, we examine the homogeneous integral equation for the unknown function $v \in L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$,

$$(\mathcal{Z}^* v)(x,t) = 0. \tag{2.2}$$

Since v is nonnegative, in addition to the action $\mathcal{Z}^*$ on any nonnegative function in its domain, then it follows that (2.2) admits only the trivial solution $v = 0$. Hence, according to Proposition 2.3 on page 46 of [9], $\mathcal{Z}$ as a map from $X_f^{\sigma_1,\sigma_2}(\Omega, T)$ to $L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$ has dense range in $L^2_{+,loc}(\mathbb{R}^n \backslash \overline{\Omega})$. □

We now consider a unique continuation principle for general parabolic differential equations. Friedman [5] has shown the following proposition for $p_0 = (x_0, t_0) \in \mathbb{R}^n \times \mathbb{R}_+$ and

$$\begin{aligned} N(p_0) = \{(x,t) \in \mathbb{R}^n \times \mathbb{R}_+ \,:\, 0 \le t \le t_0, \text{ and the cylinder } \{x\} \times [0,t] \\ \text{centered at } p_0 \text{ is simply connected as } t \text{ increases}\}. \end{aligned}$$

Proposition 2.2. *If $(\partial_t - L_x)u \le 0$ ($(\partial_t - L_x)u \ge 0$) in $\mathbb{R}^n \times \mathbb{R}_+$ and if u has a positive maximum (negative minimum) which is attained at $p_0 = (x_0, t_0)$, then $u(p) = u(p_0)$ for all $p \in N(p_0)$.*

This proposition implies that should u vanish on any open, simply connected subset of $\mathbb{R}^n$ for any $T \ge 0$, then u must vanish everywhere such that u remains a (homogeneous) solution of $(\partial_t - L_x)u = 0$. This property is essential in the range characterization to follow and to our estimation of the carrier support of $u(\cdot, T)|_{\mathcal{M}}$.

We now turn our attention to a few fundamental properties of the restriction of $\mathcal{Z}$ to the sets $\mathcal{M}$ and Ω, which we call $\mathcal{Z}|_{(\mathcal{M},\Omega)}$, and note that it is especially important for our inverse problem of determining the location of the unknown source f given measurements away from, but not necessarily surrounding, it. In what follows, $\mathcal{R}(\mathcal{Z}|_{(\mathcal{M},\Omega)})$ denotes the range of $\mathcal{Z}|_{(\mathcal{M},\Omega)}$.

Proposition 2.3. *Let $\Omega_{1,2} \in \mathbb{R}^n$ be two convex open sets whose closures have empty intersection, and suppose $\overline{\mathcal{M}} \cap (\overline{\Omega}_1 \cup \overline{\Omega}_2) = \emptyset$. Then*

$$\mathcal{R}\left(\mathcal{Z}|_{(\mathcal{M},\Omega_1)}\right) \cap \mathcal{R}\left(\mathcal{Z}|_{(\mathcal{M},\Omega_2)}\right) = \{0\}.$$

Proof. Let $\overline{\Omega}_1 \cap \overline{\Omega}_2 = \emptyset$ and let

$$\begin{aligned} (\partial_t - L_x)u_1 &= f_1, \quad \operatorname{supp} f_1(\cdot,t) \subset \Omega_1, \\ (\partial_t - L_x)u_2 &= f_2, \quad \operatorname{supp} f_2(\cdot,t) \subset \Omega_2 \end{aligned}$$

such that u_1 and u_2 do not vanish on $\mathcal{M}$. Next, let $v = u_1 - u_2$. Then v satisfies

$$\begin{aligned} (\partial_t - L_x)v &= f_1 \quad \text{on } \Omega_1, \\ (L_x - \partial_t)v &= f_2 \quad \text{on } \Omega_2, \end{aligned}$$

so that $v = u_1$ on Ω_1 and $v = -u_2$ on Ω_2. Hence, $u_{1,2}$ vanish on $\Omega_{2,1}$, respectively. Then, by Proposition 2.2, u_1 and u_2 must also vanish on $\mathbb{R}^n \backslash \Omega_{2,1}$. Hence, $u_{1,2} \equiv 0$ on $\mathcal{M}$. This is a contradiction. □

We now consider the remainder of the fundamental properties of the restricted mapping $\mathcal{Z}|_{(\mathcal{M},\Omega)}$.

PROPOSITION 2.4. *Let $\mathcal{M}$ and Ω be open subsets of $\mathbb{R}^n$ such that $\Omega \supset \operatorname{supp} f(\cdot, t)$ for all time $t \in [0,T]$ and assume $\overline{\mathcal{M}} \cap \overline{\Omega} = \emptyset$. Then, for all $T \geq 0$, $\mathcal{Z}|_{(\mathcal{M},\Omega)} : X_f^{\sigma_1,\sigma_2}(\Omega, T) \to L^2_+(\mathcal{M})$ is a compact linear map and has dense range in the latter space.*

Proof. Let $f \in X_f^{\sigma_1,\sigma_2}(\Omega, T)$. Since $Z(x - \cdot, t - \cdot) \in C^\infty_+(\mathbb{R}^n \backslash \overline{\Omega} \times [0,T])$ by the Malgrange–Ehrenpreis theorem, for each $T \geq 0$ we have

$$\begin{aligned}
\|(\mathcal{Z}|_{(\mathcal{M},\Omega)} f)(\cdot, T)\|^2_{L^2_+(\mathcal{M})} &= \int_{\mathcal{M}} \left| \int_0^T \int_\Omega Z(x-y, T-\tau) f(y,\tau) dy d\tau \right|^2 dx \\
&= \int_{\mathcal{M}} \left| \langle Z, f \rangle_{L^2_+(\mathbb{R}^n \times [0,T])} \right|^2 dx \\
&\leq \int_{\mathcal{M}} \|Z(x - \cdot, T - \cdot)\|^2_{\left(X_f^{\sigma_1,\sigma_2}\right)'} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} dx \\
&\leq \int_{\mathcal{M}} \|Z(x - \cdot, T - \cdot)\|^2_{\left(X_f^{n/2,1/2}\right)'} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} dx \\
&\leq \int_{\mathcal{M}} \|Z(x - \cdot, T - \cdot)\|^2_{\left(X_f^{n,1}\right)'} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} dx \\
&\leq C_{1,n,\Omega,\mathcal{M}} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)},
\end{aligned}$$

where $C_{1,n,\Omega,\mathcal{M}}$ is a constant given by

$$C_{1,n,\Omega,\mathcal{M}} = n\mu(\mathcal{M}) \max_{\mathcal{M}} \|Z(x - \cdot, T - \cdot)\|^2_{\left(X_f^{n,1}\right)'} < \infty.$$

Now, since

$$\|Z(x - \cdot, T - \cdot) f\|^2_{H^n_+(\mathcal{M})} = \|Z(x - \cdot, T - \cdot) f\|^2_{L^2_+(\mathcal{M})} + \left\| \sum_{k,i=1}^n \partial^k_{x_i} Z(x - \cdot, T - \cdot) f \right\|^2_{L^2_+(\mathcal{M})},$$

Dirichlet's theorem and the same arguments above imply that

$$\left\| \sum_{k,i=1}^n \partial^k_{x_i} Z(x - \cdot, T - \cdot) f \right\|^2_{L^2_+(\mathcal{M})} \leq C_{2,n,\Omega,\mathcal{M}} \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)},$$

where

$$C_{2,n,\Omega,\mathcal{M}} = n\mu(\mathcal{M}) \max_{\substack{\mathcal{M} \\ 1 \leq k \leq n}} \|Z(x - \cdot, T - \cdot)\|^2_{\left(X_f^{k,1}\right)'} < \infty.$$

Hence, $\mathcal{Z}$ is bounded between $\overset{o}{H}{}^{\sigma_1}_+(\overline{\Omega}) \bigotimes \overset{o}{H}{}^{\sigma_2}_+([0,T])$ and $H^n_+(\mathcal{M})$. Finally, since the inclusion maps

$$H^n_+(\mathcal{M}) \overset{i}{\hookrightarrow} H^{n-1}_+(\mathcal{M}) \overset{i}{\hookrightarrow} \cdots \overset{i}{\hookrightarrow} H^1_+(\mathcal{M}) \overset{i}{\hookrightarrow} L^2_+(\mathcal{M})$$

are compact (see, for example, Theorem 6.98 in [15]), so must it be that $\mathcal{Z}$ is compact from the source space $\overset{o}{H}{}^{\sigma_1}_+(\overline{\Omega}) \bigotimes \overset{o}{H}{}^{\sigma_2}_+([0,T])$ into $L^2_+(\mathcal{M})$ for each T.

Lastly, $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ has dense range in $L^2_+(\mathcal{M})$ since, according to Proposition 2.1, the adjoint equation posed on $\mathbb{R}^n \times \mathbb{R}_+$,

$$\mathcal{Z}^* v(x,t) = 0,$$

implies $v(x,t)$ vanishes throughout $\mathbb{R}^n \times \mathbb{R}$, and again according to Proposition 2.3 on page 46 of [9], while linearity of $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ is clear. □

Of interest to us in the following section on the inverse problem is the existence of the Hilbert adjoint of this restricted operator. This result follows as a corollary to the previous proposition. That is, we obtain the following.

COROLLARY 2.5 (Hilbert adjoint). *Let $\mathcal{M}$ and Ω be open subsets of $\mathbb{R}^n$ such that $\Omega \supset \operatorname{supp} f(\cdot,T)$ and assume $\overline{\mathcal{M}} \cap \overline{\Omega} = \emptyset$. Then, for all $T \in \mathbb{R}_+$, $\mathcal{Z}|^*_{(\mathcal{M},\Omega)} : L^2_+(\mathcal{M}) \to X^{\sigma_1,\sigma_2}_f(\Omega,T)$ exists as a bounded linear map. Moreover,*

$$\left(\mathcal{Z}|^*_{(\mathcal{M},\Omega)} u\right)(x,T) = \int_{\mathcal{M}} Z(z-x,T)u(z,T)dz.$$

Proof. Let $f \in X^{\sigma_1,\sigma_2}_f(\Omega,T)$ and suppose $u(\cdot,T) \in L^2_+(\mathcal{M})$. Since $\mathcal{M}$, Ω, and T are all bounded, then each of the spaces on which they integrate is sigma finite, and hence we may interchange all orders of integration. We arrive at the formula for $\mathcal{Z}|^*_{(\mathcal{M},\Omega)}$ by noting that

$$\begin{aligned}
\langle u(\cdot,T)|_{\mathcal{M}}, \mathcal{Z}|_{(\mathcal{M},\Omega)} f\rangle_{L^2_+(\mathcal{M})} &= \int_{\mathcal{M}} u(x,T) \int_0^T \int_{\Omega} Z(x-y,T-\tau) f(y,\tau)dyd\tau dx \\
&= \int_0^T \int_{\Omega} \int_{\mathcal{M}} u(x,T) Z(x-y,T-\tau)dxf(y,\tau)dyd\tau \\
&= \langle \mathcal{Z}|^*_{(\mathcal{M},\Omega)} u(\cdot,T)|_{\mathcal{M}}, f\rangle_{L^2_+(\mathbb{R}^n\times[0,T])}.
\end{aligned}$$

Hence,

$$\left(\mathcal{Z}|^*_{(\mathcal{M},\Omega)} u\right)(x,T) = \int_{\mathcal{M}} Z(z-x,T)u(z,T)dz.$$

Similarly, we complete the proof by noting that

$$\begin{aligned}
\left|\langle u(\cdot,T)|_{\mathcal{M}}, \mathcal{Z}|_{(\mathcal{M},\Omega)} f\rangle_{L^2_+(\mathcal{M})}\right|^2 &= \left|\int_{\mathcal{M}} u(x,T) \int_0^T \int_{\Omega} Z(x-y,T-\tau) f(y,\tau)dyd\tau dx\right|^2 \\
&= \left|\int_0^T \int_{\Omega} \int_{\mathcal{M}} u(x,T) Z(x-y,T-\tau)dxf(y,\tau)dyd\tau\right|^2 \\
&= \left|\langle \mathcal{Z}|^*_{(\mathcal{M},\Omega)} u(\cdot,T)|_{\mathcal{M}}, f\rangle_{L^2_+(\mathbb{R}^n\times[0,T])}\right|^2 \\
&\le \|\mathcal{Z}|^*_{(\mathcal{M},\Omega)} u(\cdot,T)|_{\mathcal{M}}\|^2_{\left(X^{\sigma_1,n/2}_f(\Omega,T)\right)'} \|f\|^2_{X^{\sigma_1,\sigma_2}_f(\Omega,T)} \\
&< \infty. \quad \square
\end{aligned}$$

To ease notation, in what follows $\mathcal{R}\left(\mathcal{Z}|_{X^{\sigma_1,\sigma_2}_f(\Omega,T)}\right)$ denotes the range of $\mathcal{Z}$ restricted to positive sources supported on the set Ω and observations limited to $\mathcal{M}$. Additionally, we will use the shorthand $\mathcal{Z}$ to denote $\mathcal{Z}|_{(\mathcal{M},\Omega)}$. Finally, if Ω is a set in

$\mathbb{R}^n$, then $N_\epsilon(\Omega)$ denotes the union of the set Ω and a neighborhood of its boundary, so that Ω is strictly contained in $N_\epsilon(\Omega)$ for each $\epsilon > 0$.

We are now able to fully characterize the range of $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ acting on distributions in the space $X_f^{\sigma_1,\sigma_2}(\Omega, T)$ for various sets Ω, without specifying their regularity parameter $\sigma = (\sigma_1, \sigma_2) \in \mathbb{R}^2$. This will prove of much use in the numerical implementation and of the forthcoming result. That is, we have the following.

PROPOSITION 2.6. *Let $\Omega_{1,2}$ be bounded convex subsets of $\mathbb{R}^n$ with smooth boundaries. Then*

$$\mathcal{R}(\mathcal{Z}|_{X_f^{\sigma_1,\sigma_2}(\overline{\Omega}_1\cap\overline{\Omega}_2,T)}) \subset \mathcal{R}(\mathcal{Z}|_{X_f^{\sigma_1,\sigma_2}(\overline{\Omega}_1,T)})\cap\mathcal{R}(\mathcal{Z}|_{X_f^{\sigma_1,\sigma_2}(\overline{\Omega}_2,T)}) \subset \mathcal{R}(\mathcal{Z}|_{X_f^{0,0}(N_\epsilon(\Omega_1\cup\Omega_2),T)}).$$

Proof. Let $t \in [0, T]$ and let $\Omega_{1,2}$ be as stated above. The left lower containment follows from the fact that for $f_{1,2} \in X_f^{\sigma_1,\sigma_2}(\Omega_{1,2}, T)$, the trivial extension of the form

$$\tilde{f}_1(x,t) = \begin{cases} f_1(x,t), & (x,t) \in \overline{\Omega}_1 \times [0,T], \\ 0, & x \notin \overline{\Omega}_1, \end{cases}$$

ensures the containment.

Next, in the spirit of the proof of Lemma 3.6 in [10] let $f_{1,2} \in X_f^{\sigma_1,\sigma_2}(\Omega_{1,2}, T)$ such that for each T, $\mathcal{Z}f_1 = \mathcal{Z}f_2 = u|_\mathcal{M}$. Then, by the unique continuation principle given in Proposition 2.2, we have

$$(\mathcal{Z}f_1)(x,T) = (\mathcal{Z}f_2)(x,T), \quad x \in \mathbb{R}^n\backslash(\Omega_1 \cup \Omega_2).$$

Let $\phi \in C^\infty(\mathbb{R}^n \times [0, T])$ be a smooth cut-off function satisfying

$$\phi(x,t) = \begin{cases} 1, & (x,t) \in \mathbb{R}^n\backslash N_\epsilon(\Omega_1 \cap \Omega_2) \times [0,T], \\ 0, & (x,t) \in N_{\epsilon/2}(\Omega_1 \cap \Omega_2) \times [0,T]. \end{cases}$$

Then, for

$$v(x,t) = \begin{cases} \phi(x,t)u_1(x,t), & (x,t) \in \mathbb{R}^n\backslash\Omega_1 \times [0,T], \\ \phi(x,t)u_2(x,t), & (x,t) \in \mathbb{R}^n\backslash\Omega_2 \times [0,T], \\ 0, & (x,t) \in \Omega_1 \cap \Omega_2 \times [0,T], \end{cases}$$

it follows that $v \in C_+^\infty(\mathbb{R}^n \times [0, T])$ and that $(\partial_t - L_x)v = f_3 \in C_+^\infty(\mathbb{R}^n \times [0, T])$ such that

$$(\mathcal{Z}f_3)(x,T) = u_1(x,T) = u_2(x,T), \quad x \notin \Omega_1 \cap \Omega_2.$$

More importantly,

$$(\mathcal{Z}f_3)(x,T) = u_1(x,T) = u_2(x,T), \quad x \in \mathcal{M},$$

where $f_3 \in X_f^{0,0}(N_\epsilon(\Omega_1 \cap \Omega_2), T)$. □

3. The inverse source problem. We present our main result (theorem) concerning the estimation of the time-varying carrier support in this section. The main result presented here owes itself in part to Picard's theorem. This theorem essentially provides a denumerable representation of a compact linear operator A between two Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ in terms of the operator's singular system, as well as a means to assess whether a given element of the second space $\mathcal{H}_2$ is also an element of the closure of the range of A. We take a moment to state the theorem and refer to [1] for its proof and further commentary.

Theorem 3.1 (Picard). *Let $A : \mathcal{H}_1 \to \mathcal{H}_2$ be a compact linear operator from the Hilbert space $\mathcal{H}_1$ into the Hilbert space $\mathcal{H}_2$ with singular system $\{\lambda_n, \varphi_n, \psi_n\}_{n=1}^{\infty}$, i.e.,*

$$A\varphi_n = \lambda_n \psi_n$$

and

$$A^* \psi_n = \lambda_n \varphi_n,$$

and let $\langle \cdot, \cdot \rangle$ denote the inner product on $\mathcal{H}_2$. Then the equation $Af = g$ is solvable if and only if $g \in N(A^*)^{\perp}$ and

$$\sum_{n=1}^{\infty} \frac{|\langle g, \psi_n \rangle|^2}{\lambda_n^2} < \infty.$$

Moreover, any $\tilde{f}$ of the form

$$\tilde{f} = \sum_{n=1}^{\infty} \frac{\langle g, \psi_n \rangle}{\lambda_n} \varphi_n$$

solves $A\tilde{f} = g$.

Given Picard's theorem and our previous range characterizations of the operator $\mathcal{Z}|_{(\mathcal{M},\Omega)}$, presented in the previous section, we now have a test which can determine whether the carrier support of the field u on $\mathcal{M}$ at time T is fully within some set of interest Ω by means of testing the convergence of the sum

$$\|\tilde{f}\|^2_{X_f^{\sigma}(\Omega,T)} = \sum_{n=1}^{\infty} \left| \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T) \rangle}{\lambda_n^{(\sigma)}} \right|^2,$$

where

$$\tilde{f}(x,t) = (\mathcal{Z}|^*_{(\mathcal{M},\Omega)} \mathcal{Z}|_{(\mathcal{M},\Omega)})^{-1} \mathcal{Z}|^*_{(\mathcal{M},\Omega)} u(\cdot,T)|_{\mathcal{M}}, \quad (x,t) \in \Omega \times [0,T],$$

and where the functions $\psi_n^{(\sigma)}(\cdot,T)$, $\varphi_n^{(\sigma)}(\cdot,T)$, and $\lambda_n^{(\sigma)}$—which depend on the regularity parameter $\sigma = (\sigma_1, \sigma_2)$ and the sets of interest $\mathcal{M}$ and Ω—are defined through the relationships

$$\left(\mathcal{Z}|^*_{(\mathcal{M},\Omega)} \psi_n^{(\sigma)} \right)(x,T) = \lambda_n^{(\sigma)} \varphi_n^{(\sigma)}(x,t), \quad 0 \le t \le T,$$

and

$$\left(\mathcal{Z}|_{(\mathcal{M},\Omega)} \varphi_n^{(\sigma)} \right)(x,T) = \lambda_n^{(\sigma)} \psi_n^{(\sigma)}(x,T).$$

If the sum does not converge, then we are able to conclude that the carrier support of $u(\cdot,T)|_{\mathcal{M}}$ at time T is not fully within the test region Ω.

We formalize this statement with the main theorem of this section.

THEOREM 3.2 (carrier support). *Let $f \in X_f^{\sigma_1,\sigma_2}(\Omega, T)$. Suppose further that $\Omega \subset \mathbb{R}^n$ is bounded with a smooth boundary and let $\mathcal{Z}|^*_{(\mathcal{M},\Omega)}$ denote the Hilbert adjoint of $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ such that $\mathcal{Z}|^*_{(\mathcal{M},\Omega)} : L^2_+(\mathcal{M}) \to X_f^{\sigma_1,\sigma_2}(\Omega, T)$. Suppose further that*

$$\left(\mathcal{Z}|_{(\mathcal{M},\Omega)}\varphi_n^{(\sigma)}\right)(x,T) = \lambda_n^{(\sigma)}\psi_n^{(\sigma)}(x,T).$$

Then, for each fixed T,

$$\text{carr supp } u(\cdot,T)|_{\mathcal{M}} \subset \Omega \quad \Leftrightarrow \quad \sum_{n=1}^{\infty} \left| \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle}{\lambda_n^{(\sigma)}} \right|^2 < \infty.$$

Proof. Suppose carr supp $u(\cdot,T)|_{\mathcal{M}} \subset \Omega$. Then, by definition of the carrier support, there exists a source $f \in X_f^{\sigma_1,\sigma_2}(\Omega,T)$ supported on a subset of Ω such that for each T, $(\mathcal{Z}|_{(\mathcal{M},\Omega)}f)(x,T) = u(\cdot,T)|_{\mathcal{M}}$, where $u(\cdot,T)|_{\mathcal{M}} \in \mathcal{R}\left(\mathcal{Z}|_{X_f^{\sigma_1,\sigma_2}(\Omega,T)}\right)$. Since $\mathcal{Z}$ is a compact linear operator between the two Hilbert spaces exhibited in the previous proposition, it admits the representation

$$\mathcal{Z} = \sum_{n=1}^{\infty} \lambda_n^{(\sigma)}\psi_n^{(\sigma)} \otimes \varphi_n^{(\sigma)}$$

such that the action of $\mathcal{Z}$ on f may be written as

$$(\mathcal{Z}f)(x,T) = \sum_{n=1}^{\infty} \lambda_n^{(\sigma)}\langle f, \varphi_n^{(\sigma)}\rangle \psi_n^{(\sigma)}(x,T), \quad x \in \mathcal{M}.$$

Since the left and right eigenfunctions, $\psi_n^{(\sigma)}$ and $\varphi_n^{(\sigma)}$, satisfy

$$\mathcal{Z}^*\psi_n^{(\sigma)} = \lambda_n^{(\sigma)}\varphi_n^{(\sigma)}$$

we note that

$$\begin{aligned}
\langle f, \varphi_n^{(\sigma)}\rangle &= \int_0^T \int_\Omega f(x,\tau)\varphi^{(\sigma)}(x,\tau)dxd\tau \\
&= \langle f, \mathcal{Z}^*\psi_n^{(\sigma)}/\lambda_n^{(\sigma)}\rangle \\
&= \overline{1/\lambda_n^{(\sigma)}}\langle \mathcal{Z}f, \psi_n^{(\sigma)}\rangle \\
&= \overline{1/\lambda_n^{(\sigma)}}\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle.
\end{aligned}$$

Bessel's inequality states

$$\sum_{n=1}^{\infty} |\langle f, \varphi_n^{(\sigma)}\rangle|^2 \leq \|f\|^2_{X_f^{\sigma_1,\sigma_2}(\Omega,T)} < \infty.$$

Hence,

$$\sum_{n=1}^{\infty} \left| \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle}{\lambda_n^{(\sigma)}} \right|^2 < \infty.$$

Now, suppose $u(\cdot,T)|_{\mathcal{M}} \in \mathcal{R}(\mathcal{Z}|_{X_f^{\sigma_1,\sigma_2}(\Omega,T)})$, where the closure of the latter space is $L_+^2(\mathcal{M})$, which we established in Proposition 2.1, and suppose the Picard sum

$$\sum_{n=1}^{\infty} \left| \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle}{\lambda_n^{(\sigma)}} \right|^2$$

converges. Let f be any source of the form

$$f(x,t) = \sum_{n=1}^{\infty} \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle}{\lambda_n^{(\sigma)}} \varphi_n^{(\sigma)}(x,t), \quad (x,t) \in \Omega \times [0,T].$$

Then, since each $\varphi_n^{(\sigma)}$ is supported on Ω, any such source will have similar such support. Also, its nontrivial image, a fact from Proposition 2.3, under $\mathcal{Z}$ is in $L_+^2(\mathcal{M})$ for each T. Finally,

$$\|\mathcal{Z}f\|_{L_+^2(\mathcal{M})}^2 = \sum_{n=1}^{\infty} |\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle|^2 \le \|u(\cdot,T)\|_{L_+^2(\mathcal{M})}^2 < \infty.$$

Hence, carr supp $u(\cdot,T)|_{\mathcal{M}} \subset \Omega$. □

Our main result provides us with a reconstruction algorithm which can determine the time-dependent carrier support of the field $u|_{\mathcal{M}}$. We describe this algorithm in the form of the following

Corollary 3.3. *Let Ω be an open bounded convex subset of $\mathbb{R}^n$, and let $\{\lambda_n^{(\sigma)}, \psi_n^{(\sigma)}, \varphi_n^{(\sigma)}\}$ be the singular system for $\mathcal{Z}|_{(\mathcal{M},\Omega)}$. Then*

$$\text{carr supp } u(\cdot,T)|_{\mathcal{M}} = \bigcap \Omega \quad \textit{such that} \quad \sum_{n=1}^{\infty} \left| \frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_n^{(\sigma)}(\cdot,T)\rangle}{\lambda_n^{(\sigma)}} \right|^2 < \infty.$$

Proof. Let Ω be an open bounded convex set and suppose that the infinite series in Corollary 3.3 converges. Then there exists a source $g^{(\Omega)}$, depending on Ω, in $X_f^{\sigma_1,\sigma_2}(\Omega,T)$ such that $\mathcal{Z}|_{(\mathcal{M},\Omega)} g^{(\Omega)} = u(\cdot,T)|_{\mathcal{M}}$. Taking the intersection of the supports of all such g's then yields

$$\bigcap \Omega = \bigcap_{\mathcal{Z}|_{(\mathcal{M},\Omega)} g^{(\Omega)} = u|_{\mathcal{M}}} \text{supp ch } g^{(\Omega)} = \text{carr supp } u(\cdot,T)|_{\mathcal{M}}. \qquad \square$$

This summability test offers a theoretical and computational basis for the determination and ultimate reconstruction of the carrier support of $u(\cdot,T)|_{\mathcal{M}}$. Numerically speaking, however, there is some issue of how to actually sum the infinite series. The fact that the operator $\mathcal{Z}|_{(\mathcal{M},\Omega)}$ is compact and smoothing tells us that zero is either an eigenvalue or a point of accumulation. It turns out that zero is a point of accumulation and so the singular values $\lambda_n^{(\sigma)}$ rapidly converge to zero, thereby creating a computational instability problem if we seek to sum the series numerically. Hence, either the summability test needs to be regularized in some manner or we need to pursue another approach which is linked to the infinite series.

4. Numerical examples. We now consider two numerical examples which demonstrate the ability of the proposed theorem to locate the positions of two localized sources. In the first case, we consider the delta-function impulse source $f(x,t) =$

$\delta_p(x)\delta_0(t) \in \mathcal{E}'(\mathbb{R}) \otimes \mathcal{E}'(\mathbb{R})$. Here, we study the two problems of having knowledge of the scalar diffusion field away from the source with a nontrivial convection field flowing in the downstream sense; i.e., the measurement set is, say, to the left of the source, while the flow field moves from the left to the right. We examine this problem in the two cases where, in the first, we have values of u at some fixed time larger than zero sampled uniformly on our measurement interval, and where, in the second, these values are measured in a nonuniform fashion. In short, in both situations, the minimum of the logarithm of the truncated moving Picard sum is evidently observable and location of the impulse point source is readily accomplished.

In the second case, we study another convective problem, specifically in two-dimensional space $\mathbb{R}^2$. In this case we allow the source to be a sustained one in time—once it has "turned on"—and allow it to move through space along a T^*-period track or orbit $\gamma(t)$, of lifetime T^*, i.e.,

$$f(x,t) = \delta_{\gamma(t)}(x)(H_0(t) - H_{T^*}(t)).$$

For this problem we present only the case with uniform measurements on $\mathcal{M}$, now in $\mathbb{R}^2$, yet we are able to clearly demonstrate that the instantaneous tracking, or location, of the localized source may be done in a very robust fashion, as evidenced by the comparison of the exhibited true and reconstructed source trajectories.

For simplicity in the numerical generation of the data and the numerical implementation of the main results of this article we assume the coefficients in parabolic operator L_x take the form

$$\begin{aligned} &a = I \text{ on } \mathbb{R}^n, \quad n = 1,2,\\ &b = \begin{cases} -1 & \text{on } \mathbb{R}^1,\\ -(1,0) & \text{on } \mathbb{R}^2, \end{cases}\\ &c = 0. \end{aligned}$$

This means our governing equations of interest in the one- and two-dimensional cases are

$$\left(\partial_t + \partial_x - \partial_x^2\right) u(x,t) = f(x,t), \quad (x,t) \in \mathbb{R} \times \mathbb{R}_+,$$

and

$$\left(\partial_t + \partial_x - \partial_x^2 - \partial_y^2\right) u(x,y,t) = f(x,y,t), \quad (x,y,t) \in \mathbb{R} \times \mathbb{R}_+ \times \mathbb{R}_+.$$

REMARK 3. *In the following numerical experiments the variable c will now, instead, denote a coordinate value in either $\mathbb{R}$ or $\mathbb{R}^2$, depending on whether we are addressing the inverse problem on the real line or on the real plane, which will be evidently clear from the associated context. This coordinate value represents the center, and hence the preferable letter c, of certain test domains of interest (Ω_c), which will be moved around the larger space of interest and will be centered at the various points c to follow.*

Location, and tracking of the moving source, is accomplished by covering the totality of the search space of interest Ω_s with candidate test domains of the forms

$$\Omega_c^{(1,2)} = \Omega_0^{(1,2)} + \{c_j\},$$

where in $\mathbb{R} \ni c_j$ we have

$$\Omega_0^{(1)} = [0, 1/10]$$

and in $\mathbb{R}^2 \ni c$ we define

$$\Omega_0^{(2)} = [0, 1/10] \times [0, 1/10],$$

and by seeking to minimize the objective function

$$J(\Omega_c) = \|\mathcal{Z}|^{\dagger}_{(\mathcal{M},\Omega_c)} u(\cdot, T)|_{\mathcal{M}}\|^2.$$

Here, † denotes the pseudoinverse.

In summary, when the test set Ω_c fully contains the carrier support of the source, then the objective function should take on small values; contrarily, when such a test domain does not fully contain the source it should be singular. We acknowledge that the phrasing "small values" is indeed rather ambiguous; however, in the numerical examples to follow, we observe a global minimum value of the objective function when the test domain is exactly centered on the support of the true source. Furthermore, we add that the test domain position centers are taken as

$$\mathbb{R} \ni c_j = \{-10 + j/20\}, \quad j = 0, 1, 2, \ldots, 400,$$

and

$$\mathbb{R}^2 \ni c_j = (-2 + j/20, 0 + j/20), \quad j = 0, 1, 2, \ldots, 80.$$

We end this section, which discusses the overall strategy pursued in the generation of the numerical evaluation of the results presented in this article, with a few words on the simulated data used in this evaluation. In summary, we discretize the standard action of $\mathcal{Z}f$ and employ a Newton–Cotes-type numerical integration scheme to generate its approximation on discretely sampled points of $\mathcal{M}$. More importantly, so as to not perpetrate an inverse crime, we corrupt these approximations with considerable white noise in the levels of approximately 5%, 10%, and 30%.

4.1. Locating a stationary impulse source in $\mathbb{R}$. In this section the scalar field is generated by the discretization scheme (via the standard rectangle rule) of the integral

$$(4.1)\quad u(x,T) = \int_0^T \int_{\mathbb{R}} \frac{e^{-\frac{|x-(T-\tau)-y|^2}{4(T-\tau)}}}{\sqrt{4\pi(T-\tau)}} \delta_p(y)\delta_0(\tau)dyd\tau = \frac{1}{\sqrt{4\pi T}} \int_{\mathbb{R}} e^{-\frac{|x-T-y|^2}{4T}} \delta_p(y)dy$$

and again subsequently corrupted by various levels of white noise to avoid committing the standard inverse crime. We examine the data taken over the discretely sampled uniform domain,

$$\mathcal{M}_1 = \{-1.0, -0.8, -0.6, -0.4, -0.2, 0.0, 0.2, 0.4, 0.6, 0.8, 1.0\} \subset \mathbb{R},$$

and the nonuniform domain,

$$\mathcal{M}_2 = \{-0.14, -0.178, -.21, -.23, -.49, -0.8, -0.01, 0.62, 0.81, 0.90, 1.0\} \subset \mathbb{R}.$$

We examine three instances of noise-corrupted data, in the amounts 10, 20, and 30 dB—which amounts to 32.0%, 10.0%, and 3.2% relative signal-to-noise ratio. For relative time $T = 10$ after impulse release, for the discrete samplings taken on $\mathcal{M}_1$ and $\mathcal{M}_2$, we observe that the running truncated Picard series are each minimized

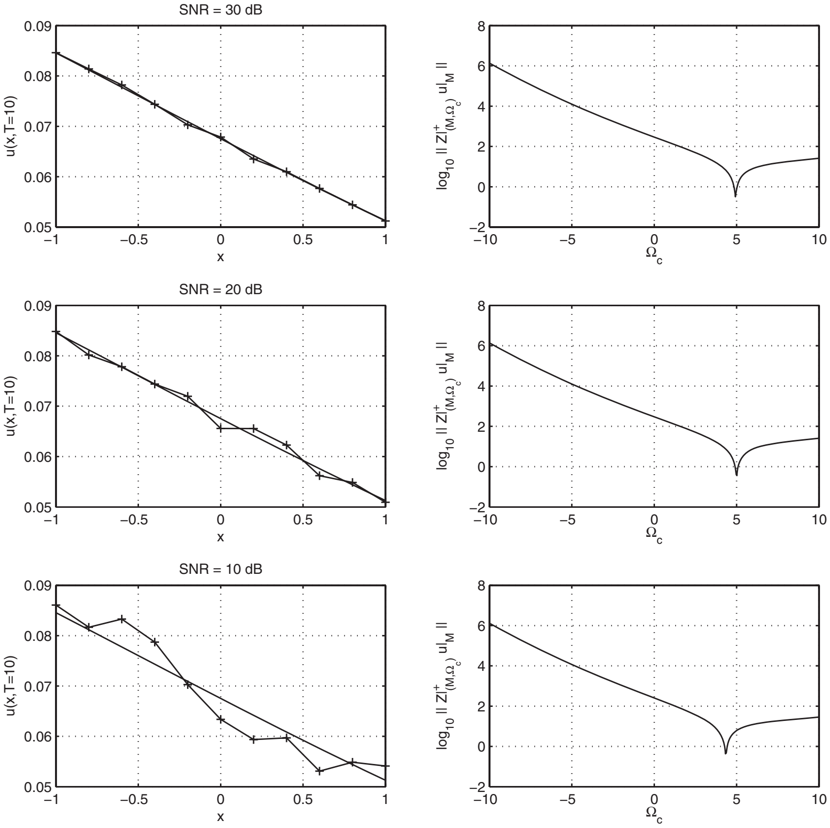

FIG. 1. *The exact and measured (noise-corrupted) diffusion fields and the norm of the associated truncated Picard test series on a uniform measurement grid.*

at, or very near, the point of the impulse release, which is $p = 5.0$ in all cases. This observation is very helpful in establishing the fact that the discrete samplings taken on general sets of observation $\mathcal{M}$ are not restricted to such things as equally spaced gridded points. Rather, any collection of discrete points which are coplanar in $\mathbb{R}^n$ will suffice. Moreover, numerical investigations have shown that larger random samplings yield better conditioned systems than for the analogous case of equally separated points, when the number of samplings is the same in both instances. For commercial purposes, this is both necessary and highly advantageous. Figures 1 and 2 demonstrate the efficacy of locating the localized source, again at $p = 5$, when we have uniform measurements on $\mathcal{M}_1$ and nonuniform ones on $\mathcal{M}_2$.

4.2. Locating a sustained moving source in $\mathbb{R} \times \mathbb{R}_+ \times \mathbb{R}_+$. As in the previous subsection, we begin with the description of the integral which we discretize, and corrupt with ample random noise, which provides our simulated data. Here, we present the numerical method used to construct the numerical solution to the two-dimensional forward problem. We begin by considering the two-dimensional heat equation with a time-dependent source $g((x,y) - \gamma(t))s(t)$ located at $(x_s(t), y_s(t)) = \gamma(t)$ and given by

$$\left(\partial_t + \partial_x - \partial_x^2 - \partial_y^2\right) u(x,y,t) = g((x,y) - \gamma(t))s(t).$$

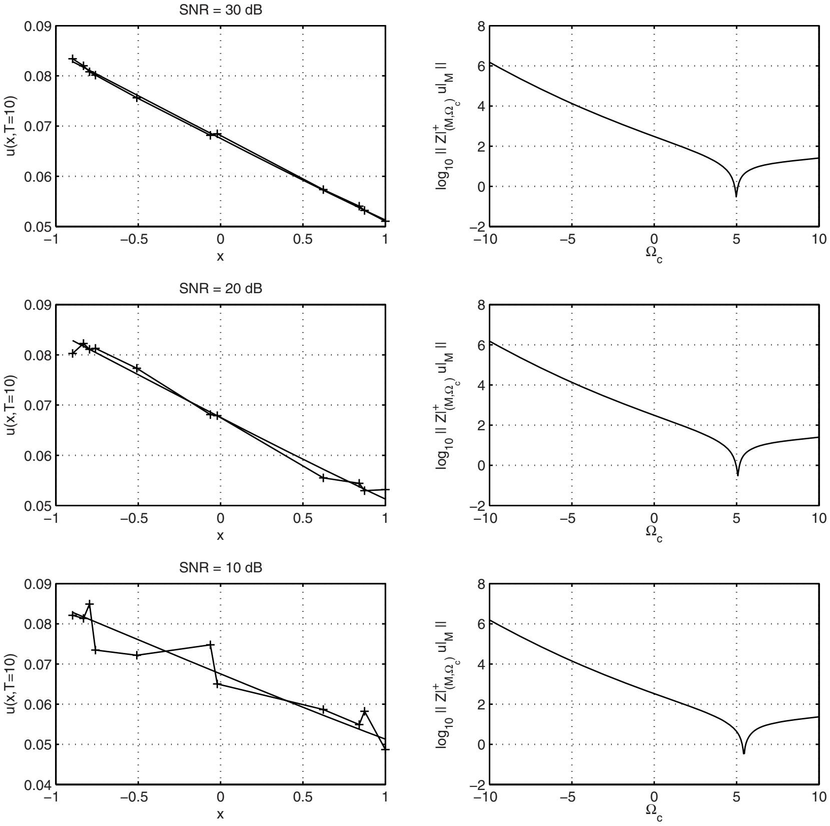

FIG. 2. *The exact and measured (noise-corrupted) diffusion fields and the norm of the associated truncated Picard test series on a nonuniform (random) measurement grid.*

Following [2] the fundamental solution for the above operator (defined over all space) is given by

$$Z(x-\xi_1, y-\xi_2, t-\tau) = \frac{1}{4\pi(t-\tau)} e^{-\frac{((x-\xi_1)-(t-\tau)+(y-\xi_2))^2}{4(t-\tau)}}.$$

In our two-dimensional simulation problem we are interested in solving the inverse source problem for the convective-diffusion equation on the half space

$$\Pi_+ = [-\infty, \infty] \times [0, \infty],$$

where we assume there is no flux of the field over the boundary $\{y = 0\}$, i.e., $\partial_y u(x, 0, t) = 0$ for all x and t. This problem then resembles (in one less dimension) the problem of some form of elevated source release in, say, a large but local neighborhood of the atmosphere and its contact with the ground. Then, in this case, using the method of images (see [8, 2]), we form the Green's function

$$\tilde{Z}(x-\xi_1, y-\xi_2, t-\tau) = Z(x-\xi_1, y-\xi_2, t-\tau) + Z(x-\xi_1, y+\xi_2, t-\tau),$$

which satisfies our boundary condition.

To solve the diffusion equation with a time- and spatially dependent source term one can integrate it against such a Green's function to obtain

$$u(x,y,T) = \int_0^T \int_{\mathbb{R}_{\xi_1}} \int_{\mathbb{R}_{\xi_2}} \tilde{Z}(x-\xi_1, y-\xi_2, T-\tau) f(\xi_1,\xi_2,\tau) d\xi_1 d\xi_2 d\tau. \tag{4.2}$$

Due to the the weak singularity at $\tau = T$, the numerical integration requires special treatment. To perform the integration we used a member of the semiopen quadrature rules [18] that do not explicitly evaluate their integrand at the limit of the integration range where the singularity exists. The explicit scheme selected for this investigation is given by (for an integrand $f(x)$ that is singular at the left endpoint x_1)

$$\int_{x_1}^{x_N} f(x)dx = h\left[\frac{23}{12}f_2 + \frac{7}{12}f_3 + f_4 + f_5 + \cdots + f_{N-2} + \frac{13}{12}f_{N-1} + \frac{5}{12}f_N\right]. \tag{4.3}$$

Note that substituting the expression $v = T - \tau$ in (4.2) results in the singular limit at the left-hand endpoint, to which (4.3) can be applied.

We employed the source moving along the figure-eight-like lemniscate over one period (of 10 units), which then goes extinct, i.e., in this case

$$f(x,y,t) = \delta_{(\cos\frac{2\pi t}{10}, \sin\frac{4\pi t}{10})}(x,y)(H_0(t) - H_{10}(t)), \quad (x,y) \in \Pi_+.$$

Moreover, our data was then sampled on the grid of points

$$\mathcal{M} = \{0, 1/2, 1\} \times \{0, 1/2, 1\}$$

at snapshots in time corresponding to every 1/10 of unitless time. We demonstrate the outcome of this numerical experiment in Figures 3, 4, 5, and 6. We use a signal-to-noise level of 25 dB, which again corresponds to 5.6% relative error between the signal strength and that of the additive white noise. The truncation value N which defines the dimension of the singular system used in the truncated Picard series test is chosen so that the singular values obey $\lambda_n^{(0,0)} < 10^{-4}$ for each $n > N$, that is, our TSVD tolerance is 0.0001. We used this value as we found the singular values $\lambda_n^{(0,0)}$ rapidly approach zero after this value. Hence, our method of regularization is based on the philosophy of principle component analysis. That is, we found the tolerance criterion $\lambda_n^{(0,0)} \geq 10^{-4}$ yielded the principle (dominant) components of the (pseudoinverted) operator in question.

Figure 3 shows the entire ensemble of the reconstructed truncated Picard series over all the test domains at time $T = 1.0$. The colored surface is the value of the logarithm of the truncated series

$$\|\tilde{f}_j\|_{X_f^0(\Omega,T)} = \left(\sum_{n=1}^{N}\left|\frac{\langle u(\cdot,T)|_{\mathcal{M}}, \psi_{n,j}^{(0)}(\cdot,T)\rangle}{\lambda_{n,j}^{(0)}}\right|^2\right)^{1/2}.$$

Figure 4 shows the same objective-type function as the previous one in Figure 3, only here we look from beneath to better observe the minimum located near the coordinate pair $(2\pi/10, 4\pi/10)$.

After obtaining the global minimum of the objective function which locates the (potentially mobile) source, we then use smaller moving, time-adaptive test domains of interest to locate the source, knowing with 100% certainty that the source and its

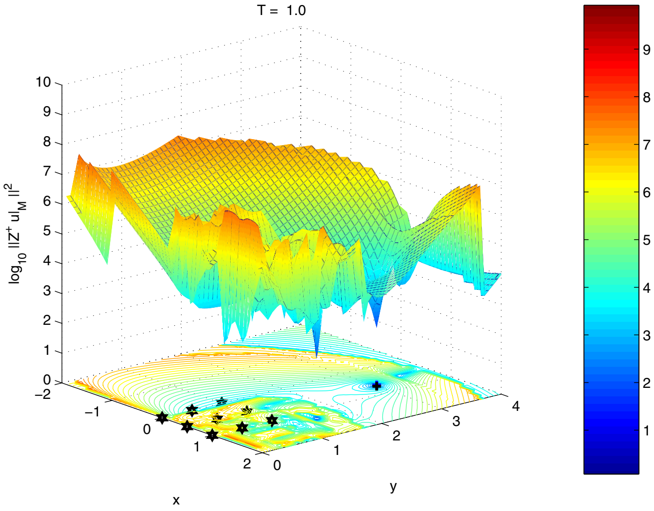

FIG. 3. *Numerical truncated Picard tests at time $T = 1.0$ for the localized two-dimensional moving source over the fully tessellated domain.*

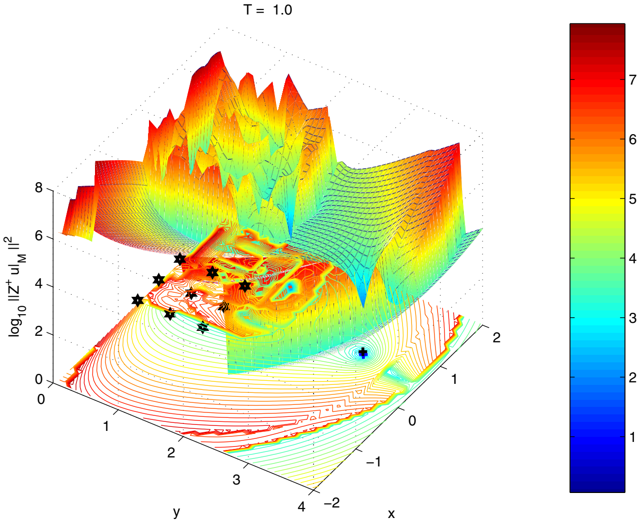

FIG. 4. *Inverted view of the former numerical truncated Picard tests at time $T = 1.0$ for the localized two-dimensional moving source over the fully tessellated domain.*

carrier support reside with each such test domain. Using the most previous estimates of the coordinates of the autonomous source, $(\hat{x}_{j-1}, \hat{y}_{j-1})$, this adaptive search domain is formed as

$$\Omega_j = [\hat{x}_{j-1} - 1/4, \hat{x}_{j-1} + 1/4] \times [\hat{y}_{j-1} - 1/4, \hat{y}_{j-1} + 1/4], \quad j \geq 1.$$

Clearly, we do this to make the computations as efficient as possible and avoid unnecessary searching. This idea and its results are presented in Figure 5, which shows the localized inversions at the time snapshots $T = 2.0$, $T = 4.0$, $T = 6.0$, $T = 8.0$, $T = 10.0$, and $T = 12.0$.

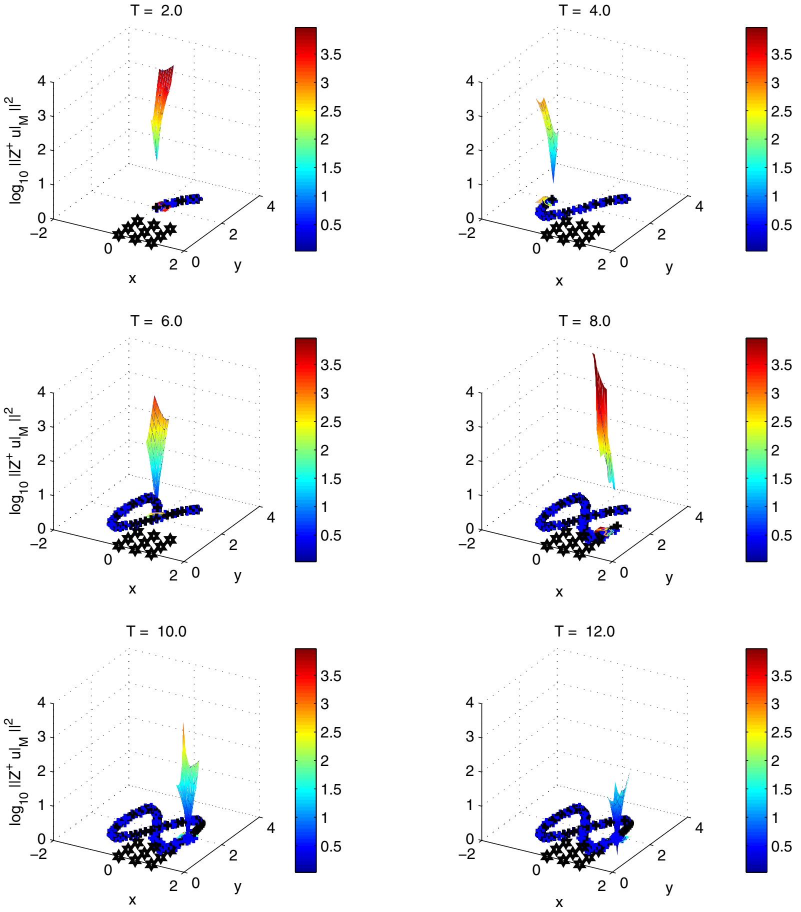

FIG. 5. *Localized numerical truncated Picard tests at the time snapshots* $T = 2.0$, $T = 4.0$, $T = 6.0$, $T = 8.0$, $T = 10.0$, *and* $T = 12.0$.

Finally, in Figure 6 we show the true track of the source, and its locations at the discrete snapshots in time, along with the estimated or reconstructed track and its instantaneous estimated positions. We remark that at time $T = 10.0$, when the source turns off, i.e., $s(10) = 0$, the carrier support's location remains constant, up to the noise and ill-posedness of the problem. That is, in the event of perfect data and a very well conditioned linear system, the source estimate would remain fixed at point $(1, 2)$.

5. Summary and conclusions. We have demonstrated that a simple knowledge of the instantaneous scalar field u on any bounded open set $\mathcal{M}$ located away from the (possibly time-varying) support of a source f is sufficient to estimate a nontrivial subset of the actual convex hull of the support of the source which we have called the carrier support of $u|_{\mathcal{M}}$. Additionally, we have provided and examined a viable numerical implementation of this result which can estimate, to essentially arbitrary precision, the trajectory of the carrier support over time, and hence track the moving source in real time, without a priori assumptions on the regularity of the source.

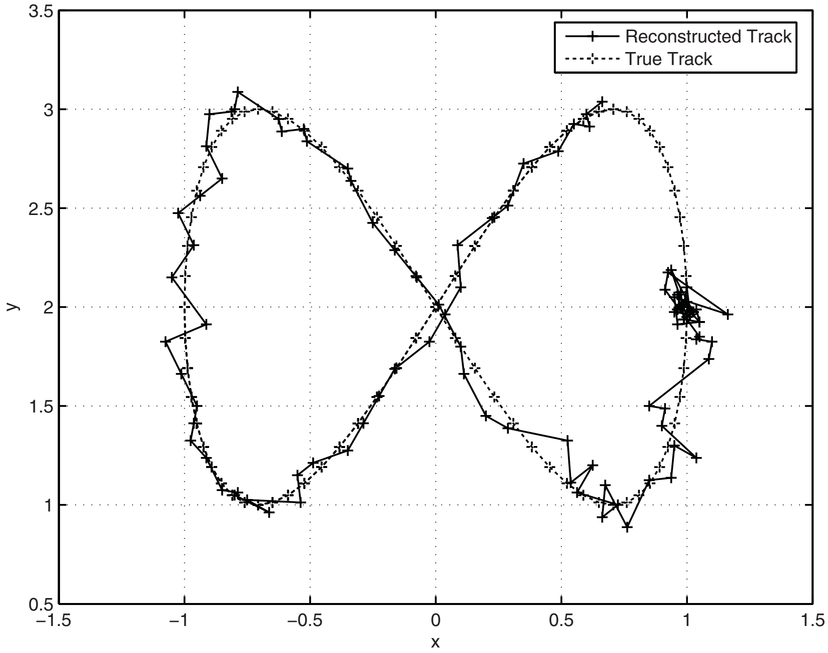

FIG. 6. *The discretely sampled true two-dimensional source track and the reconstructed (estimated) source track for the one-period sustained source.*

Moreover, we have shown that nonuniform sampling of the bounded and open measurement set $\mathcal{M}$ works as effectively as a uniform one. This result is important as it suggests that a wide collection of point samples distributed over a large domain of interest constitutes a robust methodology to locate and track sources of interest in a variety of applied problems, such as complex convective urban environments or large (aquatic) reservoir-like problems. In each of these, the robust and timely location of the effluent source is critical in nature, and may be accomplished with the few, sparse, and possibly nonuniformly sampled data assumed known in the analysis in this article.

In brief we mention that the concept of the carrier support does not provide us with a direct method which allows us to estimate the source strength as a function of time, and that this is certainly a significant problem of interest. In some simple cases, such as for constant coefficients of L_x, it may well be the case that by simply examining the local behavior of the objective function near the source, and observing it diminish in size over time, we may conclude that the source is no longer emitting into the system of interest and has become extinct. However, when the coefficients of L_x become more complex, such a simple observation may not persist. In such cases we propose an additional (forthcoming) technique which can estimate the strength of s over the time interval of measurements, $[0, T]$, which is based on a combination of the results provided here and some analysis of the Laplace transform of the governing equations of our main problem. Additionally, the current framework developed here accommodates the location and tracking of a source having but one component. The extension of the result to the problem of sources having multiple disjoint components is of much interest and is underway at the time of this writing.

Clearly, many future paths of research exist and warrant pursuit, foremost among them being a sensitivity analysis of how this method performs when the coefficients are known only to within some specified tolerance of their true values. Additional work consists of treating the problem in a stochastic setting, where these coefficients are not known instantaneously, as we have assumed throughout this article; rather they are known to possess certain distributional moments and belong to certain distributional families. Again, the possibilities for interesting and valuable future work are many indeed.

DIFFEOMORPHIC SURFACE FLOWS: A NOVEL METHOD OF SURFACE EVOLUTION*

SIRONG ZHANG†, LAURENT YOUNES‡, JOHN ZWECK§, AND J. TILAK RATNANATHER¶

Abstract. We describe a new class of surface flows, diffeomorphic surface flows, induced by restricting diffeomorphic flows of the ambient Euclidean space to a surface. Different from classical surface PDE flows such as mean curvature flow, diffeomorphic surface flows are solutions of integro-differential equations in a group of diffeomorphisms. They have the potential advantage of being both topology-invariant and singularity free, which can be useful in computational anatomy and computer graphics. We first derive the Euler–Lagrange equation of the elastic energy for general diffeomorphic surface flows, which can be regarded as a smoothed version of the corresponding classical surface flows. Then we focus on diffeomorphic mean curvature flow. We prove the short-time existence and uniqueness of the flow, and study the long-time existence of the flow for surfaces of revolution. We present numerical experiments on synthetic and cortical surfaces from neuroimaging studies in schizophrenia and auditory disorders. Finally we discuss unresolved issues and potential applications.

1. Introduction.

Surface evolution is both an important tool and an intriguing focus of mathematical research in geometric analysis, e.g., [5], and geometric PDEs, e.g., [37]. It also has been extensively applied in image processing, e.g., [3], and computer vision and interface modeling, e.g., [38]. In this paper, we develop and study a novel method of surface evolution under the action of the diffeomorphisms of the ambient Euclidean space.

We are interested in flows that can minimize surface area or mean curvature of a surface without inducing changes in topology or creating singularities. Therefore, it is natural to consider surface flows that are described by diffeomorphisms of the ambient Euclidean space. Motivated by the general framework of deformable template theory [17], we study transformations acting on objects, rather than the objects themselves. More specifically, we analyze flows on a group of diffeomorphisms of Euclidean space, rather than studying flows on the surfaces themselves. The foundations of this general framework have been rigorously established and have enabled comparisons to be made between deformable objects; see [11, 32] and the references therein. The theory has been successfully applied to image matching problems in which landmarks [24],

curves [14], or surface patches [41] evolve under diffeomorphisms of Euclidean space. Here we use this framework in a variational setting, in an approach that is reminiscent of shape optimization methods [10].

In this paper, we transform variational formulations of classical surface flows (that minimize geometrical properties such as area, elastic energy, or total curvature) into optimization problems on a group of diffeomorphisms. This approach leads to solving the corresponding Euler–Lagrange equations as evolutions in the group that induce, via the group action, stable evolutions of surfaces. We call such flows *diffeomorphic surface flows*.

In the last decade, there have been studies on geometric flows such as the celebrated mean curvature flow, e.g., [12] and references therein, surface diffusion flow, e.g., [13], and the Willmore flow, e.g., [27, 26]. The equations for these surface flows are second or fourth order parabolic PDEs which require sophisticated numerical methods, e.g., [9]. Moreover, these flows can change surface topology and introduce singularities, e.g., [12, 29, 30].

We show that diffeomorphic surface flows can be regarded as smooth versions of the corresponding classical surface flows. They flow to minimize the energy while preserving surface topology and do not break down due to finite-time singularities since they are induced from the evolution of diffeomorphisms. Moreover, these flows are solutions of integro-differential equations on the diffeomorphism group, which are somewhat easier to discretize than the PDEs that govern the classical surface flows.

A major motivation for this work came from a desire to smooth triangulated cortical surfaces that are generated by marching cubes or tetrahedra isosurface algorithms [28, 18] based on a threshold derived from the segmentation of volumetric images of the brain, e.g., [35, 36]. In addition, topological defects generated by isosurface algorithms can be corrected by multiscale and morphological operations, e.g., [20, 21]. The end result is a triangulated surface that may contain several anomalous protrusions which may distort the true curvature of the surface and thus confound the interpretation of possible biological processes in disease such as neuronal migration of tissues, e.g., [1, 4]. Smoothing flows could be used to minimize these distortions. However, it is important that the topological properties of the surfaces be preserved to reflect the inherent biology at the scale of the voxel resolution of 0.5mm^3 or 1mm^3 and to not generate additional artifacts.

Algorithms for smoothing "noisy" surfaces have been the focus of intense efforts in the computer vision field, e.g., [23, 45]. Unfortunately little effort has been made to apply these sophisticated algorithms to cortical surfaces without losing accuracy and simplification. Among the earliest such algorithms, Joshi et al. [25] used the approach of Hamann [19] for generating local quadratic approximations to a discrete surface in order to locally smooth triangulated meshes and thus curvature. More sophisticated algorithms have since been developed. Among the most recent such methods are PDE algorithms based on the powerful level set method, e.g., [39, 43, 7], which, however, may lead to topological changes or singularities that may confound biological inference.

In this paper, we will present some encouraging preliminary results in which cortical surfaces are smoothed using diffeomorphic surface flows. In future work we will further develop the method and apply it in statistical analysis of cortical surfaces.

The organization of the paper is as follows. In section 2 we describe the mathematical background on flows of diffeomorphisms, classical surface energies, and the variational formulation for the surface flow. In section 2.3 we derive the Euler–Lagrange equations for diffeomorphic surface flows for a general elastic energy before focusing our attention on diffeomorphic mean curvature flow. In section 3 we prove the short-time existence of the solution of the diffeomorphic mean curvature flow equation and discuss the long-time existence for surfaces of revolution. In section 4 we describe a numerical implementation of the method, and in section 5 we present the results of our numerical simulations. Finally, unresolved issues and future directions are discussed in section 6.

2. Mathematical background.

2.1. Flows of diffeomorphisms. The set of diffeomorphisms, φ, of $\mathbb{R}^3$ forms a group under the operation of composition of mappings. Following the theory of flows of diffeomorphisms [11, 40], we introduce a Hilbert space V of smooth vector fields on $\mathbb{R}^3$, which is assumed to be continuously included in $\mathcal{X}_0^1(\mathbb{R}^3)$, the set of all C^1 vector fields that converge to zero (with their first derivatives) at infinity, equipped with the supremum norm. Any time-dependent vector field, $\nu_t : \mathbb{R} \to V$, generates a trajectory, φ_t, in the group of diffeomorphisms by

$$\frac{\partial \varphi_t}{\partial t} \circ \varphi_t^{-1} = \nu_t, \tag{2.1}$$

with initial condition $\varphi_0 = \mathrm{Id}$. We let $\mathcal{G}$ denote the group generated by all solutions φ_t of (2.1) with $\nu_s \in V$ for all $s \leq t$ and $\max_{s \leq t} \|\nu_s\|_V < \infty$. (The fact that this set forms a group is proved, for example, in [40].) We shall also use the notation $\mathcal{G}_V$ to make explicit the dependence of this group on the Hilbert space V.

We want to implement gradient descent algorithms in the group of diffeomorphisms, which is an issue often referred to as *shape optimization* [10]. A basic notion in this context is the one of *shape differential.* Given a scalar function F defined on $\mathcal{G}_V$ and an element $\varphi \in \mathcal{G}_V$, the shape differential of F at φ, denoted $\partial F(\varphi)$, is (if it exists) the linear form on V ($\partial F(\varphi) \in V^*$) defined by

$$\partial F(\varphi).v = \frac{d}{d\varepsilon} F((\mathrm{id} + \varepsilon v) \circ \varphi).$$

Assume that, for each φ, a dot product $\langle\, . \,\rangle_\varphi$ is defined on V^*. The gradient of F at φ with respect to this dot product, denoted $\nabla F(\varphi)$, is then defined by the following identity: for all $m \in V^*$,

$$\langle \partial F(\varphi), m \rangle_\varphi = m.\nabla F(\varphi).$$

The associated gradient descent algorithm is the flow defined by

$$\frac{d\varphi}{dt} = -\nabla F(\varphi) \circ \varphi. \tag{2.2}$$

By the chain rule, we can write

$$\frac{d}{dt} F(\varphi) = \frac{d}{d\varepsilon} F((\mathrm{id} - \varepsilon \nabla F(\varphi)) \circ \varphi) = -\|\partial F(\varphi)\|_\varphi^2, \tag{2.3}$$

which shows that the algorithm does indeed minimize F. If $\nabla F(\varphi)$ is a smooth vector field over a time interval $[0, T]$, then φ in (2.2) is the flow associated to an ODE and therefore a diffeomorphism.

We denote by K the duality operator between V^* and V, defined by $m.v = \langle Km, v \rangle_V$ for $m \in V^*$ and $v \in V$. The assumption that V is continuously included in

$\mathcal{X}_0^1(\mathbb{R}^3)$ implies that K is a kernel operator, making V a reproducing kernel Hilbert space [2, 42]. Indeed, for $a \in \mathbb{R}^3$, the linear form $m = a \otimes \delta_x$ defined by $m.v = a^T v(x)$ is continuous on V, so that $K(a \otimes x) \in V$ is well defined and obviously linear in a. This defines a mapping (also denoted K) from $\mathbb{R}^3 \times \mathbb{R}^3$ to $GL_3(\mathbb{R})$ by

$$K(x, y)a = K(a \otimes \delta_x)(y). \tag{2.4}$$

A key point here is that V can be specified by the definition of its kernel. In our case, K will be chosen as a scalar Gaussian kernel (or more precisely by a Gaussian kernel multiplied by the identity matrix). The corresponding Hilbert space (at scale σ) is defined by

$$V_\sigma = \left\{ v = K^{1/2}u = \int_{\mathbb{R}^3} e^{-\frac{2\|x-y\|^2}{\sigma^2}} u(y)dy,\ u \in L^2(\mathbb{R}^3) \right\}, \tag{2.5}$$

where the inner product on V_σ is defined by $\langle K^{1/2}u, K^{1/2}u' \rangle_V = \langle u, u' \rangle_{L^2}$. The associated kernel is $K = (K^{1/2})^2$, which is proportional to $\exp(-\|x - y\|^2/(2\sigma^2))$.

The dual dot product on V^* comes straightforwardly from the fact that K is a duality operator, yielding

$$\langle m, \tilde{m} \rangle_{V^*} = m.(K\tilde{m}).$$

The φ-dependent dot product $\langle\, .\, ,\, .\, \rangle_\varphi$ used in this paper will be weighted versions of this dual product, taking the form

$$\langle m, \tilde{m} \rangle_\varphi = \langle \rho_\varphi m, \rho_\varphi \tilde{m} \rangle_{V^*} = m.(\rho_\varphi K(\rho_\varphi \tilde{m})),$$

where ρ_φ is a nonnegative scalar function and $(\rho_\varphi m).v := m(\rho_\varphi v)$. The associated gradient descent algorithm becomes

$$\frac{d\varphi}{dt} = -(\rho_\varphi K(\rho_\varphi \partial F(\varphi))) \circ \varphi. \tag{2.6}$$

We now describe how this is implemented, with a suitable choice for ρ_φ, for surface evolution.

2.2. Surface energy.

We consider the general surface energy functional [34, 22]

$$E(\Sigma) = \int_\Sigma (\alpha + \beta H^2 - \gamma G)d\sigma, \quad \text{where} \quad \alpha \geq 0,\ \beta \geq \gamma \geq 0, \tag{2.7}$$

where H and G are the mean and Gauss curvature of Σ, respectively. This elastic energy functional is a linear combination of three basic energy functionals:

- area: $U(\Sigma) = \int_\Sigma d\sigma$,
- Willmore energy: $U(\Sigma) = \int_\Sigma 4H^2 d\sigma$, and
- total curvature: $U(\Sigma) = \int_\Sigma (4H^2 - 2G)d\sigma = \int_\Sigma (k_1^2 + k_2^2)d\sigma$, where k_1, k_2 are principal curvatures.

These energy functionals can be locally minimized using the classical surface flows known as mean curvature (area-minimizing), Willmore, and total curvature flow, respectively.

We generate diffeomorphic surface flows as follows. If Σ_0 is the initial surface, we can define $F(\varphi) = E(\varphi(\Sigma_0))$. We then let $\Sigma_t = \varphi_t(\Sigma_0)$, where φ_t is given by (2.6).

2.3. Euler–Lagrange equation. In this section, we derive the gradient flow equation for the diffeomorphic surface flow minimizing the elastic energy. From section 2.2, we first compute the variation of the energy. The following lemma is due to Nitsche [34]. For simplicity, we suppose that all surfaces are *oriented and closed.* Let the surface be $\Sigma(p)$ and its variation be $\Sigma_\varepsilon(p) = \Sigma(p) + \varepsilon\nu(p)$.

LEMMA 2.1 (variation of elastic energy). *For surface elastic energy, $E(\Sigma) = \int_\Sigma (\alpha + \beta H^2 - \gamma G) d\sigma$, the energy variation is*

$$\frac{\partial}{\partial\varepsilon} E(\Sigma_\varepsilon)_{|\varepsilon=0} = \int_\Sigma \alpha\nu^\perp H - \beta\nu^\perp(\Delta_\Sigma H + 2H(H^2 - G))d\sigma, \tag{2.8}$$

where $\nu^\perp = \langle \nu, N\rangle$ is the normal component of the vector field ν, Δ_Σ is the intrinsic Laplace operator, and N is the surface normal.

A proof may be found in Willmore [44, pp. 279–282].

Remark 1. For a closed surface, the term with γ is absent since by the Gauss–Bonnet theorem, the integral of the Gauss curvature is a constant.

This lemma directly provides the expression of the shape derivative of F at φ, since, for $\Sigma = \varphi(\Sigma_0)$, $((\mathrm{id} + \varepsilon v) \circ \varphi)(\Sigma_0) = \Sigma + \varepsilon v(\Sigma)$, yielding

$$\partial F(\varphi).\nu = \int_\Sigma \alpha\nu^\perp H - \beta\nu^\perp(\Delta_\Sigma H + 2H(H^2 - G))d\sigma.$$

Now, from (2.6), we obtain the diffeomorphic evolution equations, in which we assume that ρ_φ depends on φ only via the deformed surface Σ, hence employing the notation $\rho_\varphi = \rho_\Sigma$ and $\Sigma_t = \varphi_t \circ \Sigma_0$:

$$\begin{aligned} \frac{\partial\varphi_t(y)}{\partial t} &= -\rho_{\Sigma_t}(\varphi_t(y)) \\ &\quad \cdot \int_{q\in\Sigma_t} \big(\alpha H - \beta(\Delta_{\Sigma_t} H + 2H(H^2 - G))\big) K(\varphi_t(y), q)\rho_{\Sigma_t}(q) N(q) d\sigma_t(q). \end{aligned} \tag{2.9}$$

We define ρ_Σ as an area normalization factor as follows. Define, for a surface Σ, the local area function

$$a_\Sigma(p) = \int_{q\in\Sigma} K(p, q) d\sigma. \tag{2.10}$$

We then set

$$\rho_\Sigma(p) = a_\Sigma(p)^{-1/2}. \tag{2.11}$$

Choosing this normalization ensures that the right-hand sides in the diffeomorphic flows have the same dimensions as the corresponding classical flows (e.g., 1/length for the mean curvature flow). Doing so, the large-scale behavior (relative to the width of the kernel) is expected to be similar for both flows.

Although all quantities introduced so far are defined on the whole space, we are primarily interested in the evolution of the surface $\Sigma_t = \varphi_t \circ \Sigma_0$. Hence, for the area and Willmore energy functionals, the equations that govern the flow of each point $p = \varphi_t(y)$ on the closed surface Σ_t are given by the following integro-differential equations:

- diffeomorphic mean curvature flow ($\alpha = 1$ and $\beta = 0$):

$$\frac{\partial p}{\partial t} = -a_{\Sigma_t}^{-1/2}(p) \int_{q\in\Sigma_t} K(p, q) H(q) a_{\Sigma_t}^{-1/2}(q) N(q) d\sigma_t, \tag{2.12}$$

- diffeomorphic Willmore flow ($\alpha = 0$ and $\beta = 1$):

$$(2.13)\quad \frac{\partial p}{\partial t} = a_{\Sigma_t}^{-1/2}(p) \cdot \int_{q\in\Sigma_t} K(p,q)(\Delta_{\Sigma_t} H(q) + 2H(q)(H^2(q) - G(q)))a_{\Sigma_t}^{-1/2}(q)N(q)d\sigma_t.$$

We will use these formulae in the numerical implementation in section 4. Notice that they are similar to the corresponding equations for the classical mean curvature and Willmore flows. The diffeomorphic surface flows have the same energy minimizing property as their classical counterparts, but since they are diffeomorphisms, they preserve the topology of the surface. In the next section, we focus only on diffeomorphic mean curvature flow.

3. Diffeomorphic mean curvature flow. From now on, we use the Gaussian kernel function

$$(3.1)\qquad K(p,q) = e^{-\frac{\|p-q\|^2}{2\sigma^2}}.$$

Here σ is the kernel size, which corresponds (up to a change in the normalization factor) to the reproducing kernel of V_σ given by (2.5).

The flow equation is therefore given by

$$(3.2)\qquad \frac{\partial \varphi_t(y)}{\partial t} = -a_{\Sigma_t}(\varphi_t(y))^{-1/2} \int_{q\in\Sigma_t} e^{-\frac{\|\varphi_t(y)-q\|^2}{2\sigma^2}} H(q)a_{\Sigma_t}(q)^{-1/2}N(q)d\sigma_t,$$

with the initial condition $\varphi_0 = \mathrm{id}$. As indicated by (2.3), this is an area-minimizing flow for the surface Σ_t, with the explicit formula

$$\frac{d|\Sigma_t|}{dt} = -\int_{\Sigma_t^2} e^{-\frac{\|p-q\|^2}{2\sigma^2}} \left(\frac{H(p)N(p)}{\sqrt{a_{\Sigma_t}(p)}}\right)^T \left(\frac{H(q)N(q)}{\sqrt{a_{\Sigma_t}(q)}}\right) d\sigma_t(p)d\sigma_t(q).$$

3.1. Short-time existence of solution. The classical flows are local flows and by PDE theory, there are short-time solutions for smooth initial data. Because of the integro-differential form of diffeomorphic surface flows, short-time existence follows from standard ODE arguments on Banach spaces.

Theorem 1 (short-time existence and uniqueness). *For any initial compact smooth surface, there exists a unique solution for the flow equation* (3.2) *in a small time interval* $[0, t_0]$.

Proof. Consider the space $A = \mathbb{R}^3 \times \mathrm{GL}_3(\mathbb{R}) \times \mathrm{Bil}(\mathbb{R}^3, \mathbb{R}^3)$, where the last factor is the set of bilinear functions from $\mathbb{R}^3 \times \mathbb{R}^3$ to $\mathbb{R}^3$. A generic element of A will be denoted $Q = (\varepsilon, F, S)$, and we will consider the Banach space B of continuous functions $Q(\cdot) : \mathbb{R}^3 \to A$, with the supremum norm

$$(3.3)\qquad \|Q\| = \|\varepsilon\|_\infty + \|F\|_\infty + \|S\|_\infty.$$

Here $\varepsilon(y)$ is a C^2 vector field that converges to zero (with its first and second derivatives) at infinity, and $F(y)$ and $S(y)$ are first and second derivatives of $\varepsilon(y)$.

Letting $\varphi(y) = y + \varepsilon(y)$, we first embed (3.2) in an ODE on B. We rewrite the right-hand side of (3.2) using integrals over Σ_0. Covering Σ_0 with local charts $f : U \to \Sigma_0$, we have that $\Sigma_t(y) = \varphi_t \circ f(y)$. Suppose that $\{f_u, f_v, N_0\}$ is an orthonormal basis at the point y. Then, using $N(t,\varphi(y)) = d\varphi^{-T}N_0/\|d\varphi^{-T}N_0\|$ [6] and the expression for the mean curvature in coordinates (omitting the subscript t), we have

$$\begin{aligned}H(t,\varphi) = \frac{1}{\|d\varphi f_u \times d\varphi f_v\|^2\,\|d\varphi^{-T}N_0\|^2}\Big(&\langle d\varphi^{-1}d^2\varphi(f_u,f_u)+f_{uu},N_0\rangle\|d\varphi f_v\|^2\\ &+\langle d\varphi^{-1}d^2\varphi(f_v,f_v)+f_{vv},N_0\rangle\|d\varphi f_u\|^2\\ &-2\langle d\varphi^{-1}d^2\varphi(f_u,f_v)+f_{uv},N_0\rangle\langle d\varphi f_u, d\varphi f_v\rangle\Big).\end{aligned}$$

Defining the quadratic forms on $T\Sigma = d\varphi T\Sigma_0$,

$$A_\varphi(g,h) = \langle d\varphi^{-1}d^2\varphi(d\varphi^{-1}g, d\varphi^{-1}h), N_0\rangle \tag{3.4}$$

and

$$II_\varphi(g,h) = -\langle d\varphi^{-1}g, dN_0 d\varphi^{-1}h\rangle, \tag{3.5}$$

and using the fact that $\|d\varphi f_u \times d\varphi f_v\| = |\det D\varphi|\,\|d\varphi^{-T}N_0\|$, we can rewrite

$$H(t,\varphi) = \frac{\operatorname{trace}(A_\varphi)+\operatorname{trace}(II_\varphi)}{|\det D\varphi|^2\,\|d\varphi^{-T}N_0\|^4}. \tag{3.6}$$

So, the evolution equation can be written as

$$\begin{aligned}\frac{\partial\varphi_t(y)}{\partial t} &= -a_\Sigma(\varphi_t(y))^{-1/2}\\ &\cdot\int_{\Sigma_0} e^{-\frac{\|\varphi_t(x)-\varphi_t(y)\|^2}{2\sigma^2}}\frac{\operatorname{trace}(A_{\varphi_t})+\operatorname{trace}(II_{\varphi_t})}{|\det D\varphi_t|\,\|d\varphi_t^{-T}N_0\|^4}a_\Sigma(\varphi_t(x))^{-1/2}d\varphi_t^{-T}N_0(x)d\sigma_0,\end{aligned} \tag{3.7}$$

with

$$a_\Sigma(\varphi(y)) = \int_{\Sigma_0} e^{-\frac{\|\varphi(x)-\varphi(y)\|^2}{2\sigma^2}}|\det D\varphi|\,\|d\varphi^{-T}N_0\|d\sigma_0(x).$$

Introducing $d\varphi = \mathrm{Id} + d\varepsilon = \mathrm{Id} + F$ and $d^2\varphi = d^2\varepsilon = S$, (3.7) takes the form

$$\frac{d\varepsilon}{dt} = J_0(\varepsilon, F, S). \tag{3.8}$$

The time evolution of F is obtained by computing the differential of this equation with respect to the space variable. Since in (3.7), the variable y appears only in evaluations of φ (not its derivatives), it is clear that the evolution of F will also take the form $dF/dt = J_1(\varepsilon, F, S)$. Since the same argument can be made for S, we obtain the fact that (ε, F, S) follows an ODE in B of the form

$$\frac{d\varepsilon}{dt} = J_0(\varepsilon,F,S),\quad \frac{dF}{dt} = J_1(\varepsilon,F,S),\quad \frac{dS}{dt} = J_2(\varepsilon,F,S). \tag{3.9}$$

It is clear now that J_0, J_1, J_2 are integrals of rational functions of ε, F, S which are well defined in a neighborhood of $(\varepsilon, F, S) = (0,0,0)$. This ensures short-term existence of solutions of the system in B.

It remains to show that, if (ε, F, S) is a solution of this system, the first component, ε, is in fact a solution of (3.8) with initial condition $\varepsilon_0 = 0$. For this it suffices to

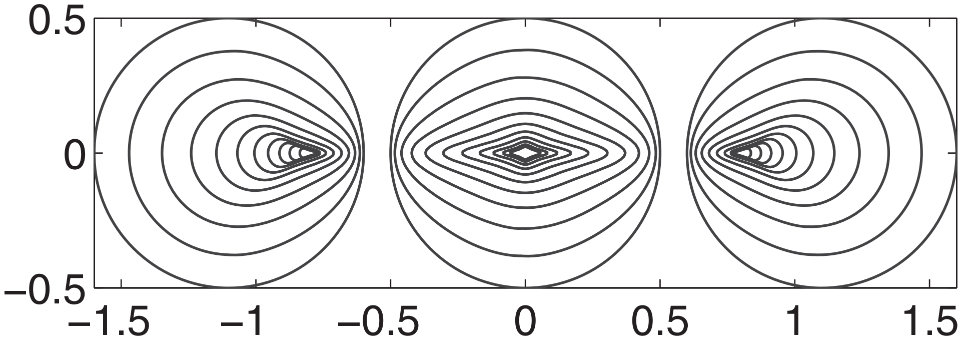

FIG. 1. *Interaction of three nearby spheres during the diffeomorphic mean curvature flow. The initial radius of all spheres is* 0.5*, and the minimum distance among them is* 0.1*. The kernel size is* $\sigma = 0.3$*, and the stopping time is* $T = 1$*.*

prove that ε is twice differentiable, with its first and second differentials given by F and S. This follows from standard arguments for ODEs, and we omit the details here. Finally, it is easy to see that we have a unique solution $\varphi(y) = y + \varepsilon(y)$ for the original flow equation (3.2). □

Remark 2. The result in Theorem 1 also holds for the more general diffeomorphic surface evolution

$$\frac{\partial \varphi_t(y)}{\partial t} = a_{\Sigma_t}^{-1/2}(\varphi_t(y)) \cdot \int_{q\in\Sigma_t} K(\varphi_t(y), q) f(q, N(q), dN(q), d^2N(q), \dots, d^mN(q)) a_{\Sigma_t}^{-1/2}(q) d\sigma_t,$$

where f has continuous derivatives for each variable, Σ_0 is a smooth surface, m is an integer, and N is the surface normal. The proof follows along the same general lines as the proof we gave above. We rewrite the integral as an integral on the original surface and the function f as a function $G(\varphi, d\varphi, d^2\varphi, \dots, d^{m+1}\varphi)$. Then the equations of the derivatives of $d\varphi, d^2\varphi, \dots, d^{m+1}\varphi$ involve only the derivatives of the kernel and G.

We can show that the solution φ is in fact a diffeomorphism by standard arguments using Gronwall's lemma [46, Chap. 10].

THEOREM 2 (diffeomorphism). *If* φ_t *is the solution of the flow equation* (3.2) *on the interval* $[0, T]$*, then* φ_t *is a diffeomorphism for all* $t \in [0, T]$*.*

We have the following important consequence.

COROLLARY 1 (topology invariance and singularity free). *The solution of the flow equation* (3.2) *at each time t gives a smooth surface with the same topology as the initial surface as long as the solution exists.*

We are obviously interested in the long-time existence of the flow. Numerical evidence and analysis for simple surfaces so far suggest that the flow has a long-time solution. However, the interactions between remote parts of a surface make the long-time behavior difficult to analyze (see, for example, Figure 1). Analyzing the proof of Theorem 1, we see that being able to extend a solution beyond a given time $t < t_0$ depends only on the regularity of the surface at time t. More precisely, a standard lower-bound of how far a current solution of an ODE in a Banach space can be extended beyond t is directly related to the Lipschitz constant of the ODE. In our proof, the Lipschitz properties of the system rely on the surface only via upper-bounds on the second derivative of the normal in (3.6) and via lower-bounds on the local area a_Σ. So solutions of (3.9) can be extended in time as long as the surface does not develop singularities.

A consequence of this analysis is that, if we can exhibit an evolution starting at some Σ_0 on some interval $[0, T]$ on which the total curvature of the evolving surface remains bounded from above and the local area remains bounded from below, then this evolution is the only solution of (3.2) starting at Σ_0.[1] This property will be used in the next section when we provide simplified equations for surfaces of revolution.

3.2. Surfaces of revolution. In this subsection we analyze the diffeomorphic mean curvature flow for a surface of revolution, Σ. Because of the uniqueness of solutions, the solution of (3.2) must preserve rotational symmetry. Consequently, it suffices to evolve the profile curve of Σ. Therefore, here we derive an equation for the evolution of the profile curve for the diffeomorphic mean curvature flow equation (3.2). It is much more computationally efficient to solve the equation for the profile curve than it is to solve the full flow equation (3.2) for a triangulated surface.

We parameterize a surface of revolution by

$$\mathbf{x}(u, v) = (\alpha(u)\cos v, \alpha(u)\sin v, \beta(u)). \tag{3.10}$$

Here $u \in [-1, 1]$, $v \in [0, 2\pi]$, and the profile curve $\gamma(u) = (\alpha(u), \beta(u))$ satisfies suitable conditions. For a closed curve, we need $\alpha > 0$, while for an open curve, we require that $\alpha \geq 0$ with $\alpha = 0$ only at the end points, and also $\beta' = 0$ at the end points. Here and below α', β' denote the derivatives of the functions α, β. The orientation of the curve is taken to be counterclockwise.

We now derive the induced flow equation for the profile curve. First, we have

$$N = \frac{(-\beta'\cos v, -\beta'\sin v, \alpha')}{\sqrt{(\alpha')^2 + (\beta')^2}}, \tag{3.11}$$

$$d\sigma = \alpha\sqrt{(\alpha')^2 + (\beta')^2}dudv, \qquad 2H = \frac{\beta'}{\alpha\sqrt{(\alpha')^2 + (\beta')^2}} + \kappa, \tag{3.12}$$

where κ is the curvature of the profile curve and the normal vector N is outward pointing.

Using these expressions, we can characterize the evolution of the profile curve $\mathbf{x}(u, 0) = (\alpha(u), 0, \beta(u))$ as follows:

$$\begin{aligned}
&\frac{\partial\alpha(u)}{\partial t} = -a(u)^{-1/2}\\
&\cdot\int_{-1}^{1} e^{-\frac{1}{2\sigma^2}((\alpha(u)-\alpha(u_t))^2+(\beta(u)-\beta(u_t))^2)} g_1(\alpha(u)\alpha(u_t))H(u_t)\alpha(u_t)\beta'(u_t)a(u_t)^{-1/2}du_t,\\
&\frac{\partial\beta(u)}{\partial t} = a(u)^{-1/2}\\
&\cdot\int_{-1}^{1} e^{-\frac{1}{2\sigma^2}((\alpha(u)-\alpha(u_t))^2+(\beta(u)-\beta(u_t))^2)} g_0(\alpha(u)\alpha(u_t))H(u_t)\alpha(u_t)\alpha'(u_t)a(u_t)^{-1/2}du_t,\\
&a(u) = \int_{-1}^{1} e^{-\frac{1}{2\sigma^2}((\alpha(u)-\alpha(u_t))^2+(\beta(u)-\beta(u_t))^2)} g_0(\alpha(u)\alpha(u_t))\alpha(u_t)\sqrt{\alpha'(u_t)^2 + \beta'(u_t)^2}du_t,
\end{aligned} \tag{3.13}$$

[1] Total curvature plays a role in the analysis of the classical mean curvature flow [12, Thm. 3.4].

where

$$g_1(x) = \int_0^{2\pi} e^{x(\cos(v)-1)/\sigma^2}\cos(v)dv, \qquad g_0(x) = \int_0^{2\pi} e^{x(\cos(v)-1)/\sigma^2}dv.$$

For a discrete profile curve consisting of finite line segments, (3.13) is a system of ODEs which has a short-time solution and can be solved numerically using MATLAB. In section 5 we use this system of ODEs to study the long-time behavior of the solution for surfaces of revolution.

For the classical mean curvature flow of a surface of revolution the only possible singularities are on the axis of revolution [12]. We conjecture that for a closed profile curve if the curvature is bounded, then $\alpha > 0$ for all time. In fact, numerical results suggest that an even stronger result is true.

Conjecture 1 (long-time solution for surfaces of revolution). *There exists a unique solution for the flow equation* (3.13) *for all* $t \geq 0$.

3.3. Sphere evolution. When the surface is the sphere, we have an explicit solution for the diffeomorphic mean curvature flow equation.

Proposition 1 (sphere evolution). *If the initial surface* Σ_0 *is a sphere of radius* R_0*, then the solution of the diffeomorphic mean curvature flow* (3.2) *exists for all time, and at each time* t *the surface* Σ_t *is a sphere of radius* R_t*, where* R_t *satisfies the equation*

$$\frac{dR_t}{dt} = -\frac{(R_t^2+\sigma^2)e^{-2R_t^2/\sigma^2} + R_t^2 - \sigma^2}{R_t^3(1-e^{-2R_t^2/\sigma^2})}. \tag{3.14}$$

Proof. By symmetry and from the uniqueness of solutions, the evolving surface remains a sphere at all times. Equation (3.14) is a direct application of the general formulae with $\alpha(u_t) = R_t\cos(\pi u_t/2)$, $\beta(u_t) = R_t\sin(\pi u_t/2)$ at $u_0 = 1$. For example,

$$\begin{aligned} a_{\Sigma_t}(1) &= 2\pi\int_{-1}^{1} e^{-\frac{R_t^2}{\sigma^2}(1-\sin\frac{\pi u_t}{2})} R_t^2\frac{\pi}{2}\cos\frac{\pi u_t}{2}du_t \\ &= 2\pi R_t^2 e^{-\frac{R_t^2}{\sigma^2}}\int_{-1}^{1} e^{\frac{R_t^2 z}{\sigma^2}}dz \\ &= 2\pi\sigma^2(1-e^{-\frac{2R_t^2}{\sigma^2}}). \end{aligned}$$

Similar computations can be done for the other integral, leading to (3.14). One can check that the function $f(r)$,

$$r \mapsto -\frac{(r^2+\sigma^2)e^{-2r^2/\sigma^2} + r^2 - \sigma^2}{r^3(1-e^{-2r^2/\sigma^2})},$$

is well defined and differentiable over $\mathbb{R}$ (including 0), vanishes at 0, and is negative for $r > 0$. This implies that solutions starting at $R_0 > 0$ decrease without reaching 0, and can be extended to infinite time. □

A Taylor expansion of the equation at $R_t = 0$ yields $dR_t/dt \simeq -(2/3\sigma^2)R_t$ at $t = 0$, yielding an exponential decay of the radius.

By a similar argument, we can show that the following proposition holds.

Proposition 2 (cylinder evolution). *The evolution of a circular (infinite) cylinder exists and is unique for all* $t \geq 0$.

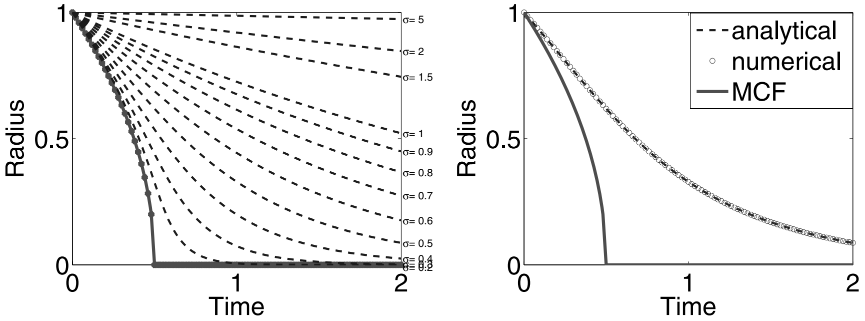

Fig. 2. *Diffeomorphic mean curvature flow of a sphere. Left: Flows with different kernel sizes, σ (dotted curves). The classical mean curvature flow is indicated by the solid curve with stars. Right: Validation of the numerical algorithm in section* 4 *(circles) by comparison with the analytical solution from Theorem* 1 *(dashed curves) with $\sigma = 0.5$. The classical mean curvature flow is indicated by the solid curve.*

We leave the proof to the reader. In this case, the first order expansion for the evolution of the radius is $dR_t/dt \simeq -(1/2\sigma^2)R_t$, yielding here also an exponential decay, at a rate slower than for the sphere.

Recall that for the classical mean curvature flow, a sphere vanishes into a point and the circular cylinder into the y axis at finite time [12]. However, the diffeomorphic mean curvature flow preserves surface topology for all times.

In the left panel of Figure 2 we compare the classical mean curvature flow for a sphere to the diffeomorphic mean curvature flow for a range of kernel sizes, σ. Notice that for the mean curvature flow the surface collapses to a point at time $t = 0.5$, whereas for all kernel sizes the solution of the diffeomorphic mean curvature flow exists for all times. Moreover, from the evolution equation (3.14), it is not hard to prove that for the unit sphere, as the kernel size converges to zero, the solution of the diffeomorphic mean curvature flow converges to that of the mean curvature flow over the interval $0 \leq t \leq 0.5$. This suggests the following conjecture.

Conjecture 2 (mean curvature flow limit). *Suppose, for an initial compact smooth surface, that the mean curvature flow exists for all times $t \in [0, T]$. Then for any time $T_1 < T$, on the time interval $[0, T_1]$ the diffeomorphic mean curvature flow converges uniformly to the mean curvature flow as the kernel size goes to zero.*

4. Numerical implementation.

In this section we give the details of the numerical implementation of diffeomorphic surface flows via the Runge–Kutta method. We focus on two aspects: the estimation of geometric quantities such as the normal and curvature on discrete surfaces, and the ODE solver for diffeomorphic surface flows.

4.1. Discrete differential geometry of surfaces.

Surfaces are discretized as triangulated meshes. Consequently, to numerically solve the diffeomorphic surface flow equations, we need to define discrete geometry quantities that approximate the normal and curvature functions on a smooth surface. Several such discretization methods have been described in the literature but none is universally used [19, 15, 31, 8]. We will use the discrete differential operators method of Meyer et al. [31], which is easy to implement and suitable for our examples.

Given a triangulated mesh with vertices v_i and faces f_j, the vertex one-ring $R_1(i)$ of a vertex v_i is the set of all adjacent vertices, and the face one-ring $F_1(i)$ of v_i is the set of all faces containing v_i. We determine the geometry at each vertex from the vertex one-ring of that vertex. If none of the triangles in $F_1(i)$ is obtuse, we define the area $A(v_i)$ at the vertex v_i to be the Voronoi area of that vertex:

$$A_{\text{Voronoi}} = \frac{1}{8} \sum_{j \in R_1(i)} (\cot \alpha_{ij} + \cot \beta_{ij}) \|v_i - v_j\|, \tag{4.1}$$

where α_{ij} and β_{ij} are the two angles opposite the edge $v_i v_j$ in the two triangles sharing that edge. However, if some of the triangles in $F_1(i)$ are obtuse, we define the area $A(v_i)$ to be the mixed area A_{mixed} described in [31].

Then the mean curvature normal vector $\overline{HN}$ at v_i is given by

$$\overline{HN}(v_i) = \frac{1}{4A(v_i)} \sum_{j \in R_1(i)} (\cot \alpha_{ij} + \cot \beta_{ij})(v_i - v_j). \tag{4.2}$$

We can also obtain the normal, mean curvature, and Gauss curvature formulae [31], which are not used in this paper.

4.2. ODE solution. We evolve a triangulated surface via its vertices; i.e., the surface vertices are used to discretize the flow equation (3.2). The resulting ODE system is solved numerically using a Runge–Kutta method.

The algorithm is as follows.

Algorithm 1. ODE solver for diffeomorphic surface flow.

```
1: Initialize the flow time $T$ and kernel size $\sigma$
2: Initialize surface with $v_i$ and $F_j$
3: Generate the one-ring neighborhood structure $R_1(i)$ and $F_1(i)$ for each vertex
4: while $t < T$ do
5:    Compute the geometry of the surface $\overline{HN}_i = \overline{HN}(v_i)$ and $A_i = A_{\text{mixed}}(v_i)$
6:    Compute the Gaussian kernel weights $K_{ij} = K(v_i, v_j)$
7:    Compute the local area weights $\text{loc}_i = (\sum_{j=\text{all}} K_{ij} A_j)^{-0.5}$
8:    Compute the flow speed term $u_i = -\text{loc}_i \sum_{j=\text{all}} K_{ij}\, \text{loc}_j\, \overline{HN}_j A_j$
9:    Obtain the new vertices from a Runge–Kutta solver $v_i = RK(v_i, u_i)$
10: end while
11: Output the surface
```

Remark 3. We did not attempt to determine an automatic stopping condition. We simply stopped after time T.

Remark 4. It is possible to use implicit ODE solvers.

Remark 5. In step 8, for each i it is possible to sum only over those indices j for which the Gaussian kernel K_{ij} exceeds a small threshold. Alternatively, for large kernel size one could use the fast Gauss transform [16].

Remark 6. For mean curvature flows of surfaces of revolution, we used a public-domain MATLAB toolbox for level set methods [33]. For mean curvature flows of triangulated meshes we used Algorithm 1 but with $u_i = -\overline{HN}_i$.

5. Results. We used MATLAB to implement the algorithm on a Pentium IV 3.2 GHz machine with 2 GB of RAM. In general for a synthetic surface with 7200 faces and 3600 vertices, one loop takes about 10 seconds. However, for cortical surface applications we used a C++ implementation that takes about 1 second per loop for a surface with 5000 vertices.

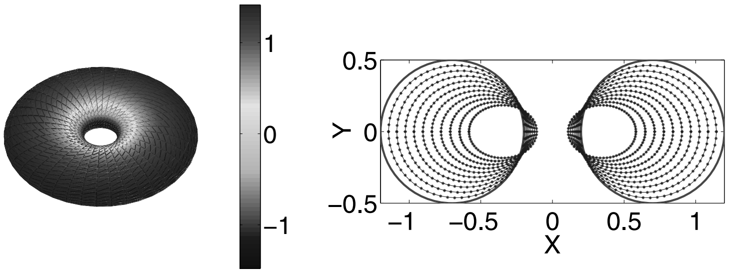

Fig. 3. *Flow of a fat torus. Left: The fat torus with mean curvature indicated by the grayscale. Right: Comparison between the profile curves obtained using the ODE solution of* (3.13) *for surfaces of revolution and those obtained using the numerical algorithm in section* 4.2*, respectively, indicated by dashed curves and plus symbols. The initial profile curve is shown with the two largest solid circles. Here $T = 0.5$, and $\sigma = 0.3$.*

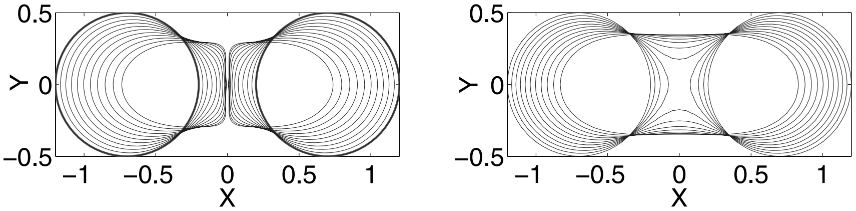

Fig. 4. *Comparison of flows for the fat torus. Left: Diffeomorphic mean curvature flow with $\sigma = 0.1$ and $T = 0.25$ obtained using the ODE algorithm for surfaces of revolution. Right: Classical mean curvature flow with $T = 0.2$.*

Sphere. In the right panel of Figure 2 we show the diffeomorphic mean curvature flow of a sphere for a kernel size of $\sigma = 0.3$ computed using Algorithm 1 (circles) and using the ODE (3.14) for the radius of the sphere (dashed curve). The agreement between the two methods is excellent. For comparison, we show the result for the classical mean curvature flow with a solid curve. For the algorithm, we generated an initial sphere with 642 vertices and 1280 faces using recursive subdivision of a cube. The solution of the ODE (3.14) was obtained using the MATLAB function ode45. As shown in Figure 1, three disconnected spheres can influence one another. It would be very interesting but difficult to analyze the long-time behavior of such interactions.

Circular torus. The circular torus was generated by rotating a circle about the y axis. The triangulated mesh had 3600 vertices and 7200 faces. We chose a "fat" torus with inner radius 0.2 and outer radius 1.2, as shown in Figure 3. In the right panel of Figure 3 we examined the solutions of the diffeomorphic mean curvature flow, obtained both by solving the surface of revolution flow equation (3.13) using the MATLAB function ode45 and by flowing the triangulated surface using Algorithm 1 indicated by dashed curves and plus symbols. The initial surface is represented by the two largest circles. The close agreement between the two sets of curves provides a mutual validation of both algorithms. For the surface flow we obtain the profile curves from the discrete surface by projecting the evolving base curves onto the plane.

Figure 4 provides a comparison between diffeomorphic flow with small σ (left)

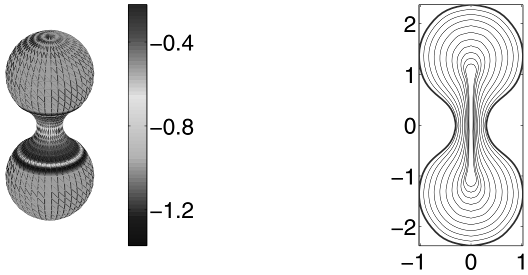

FIG. 5. *The flow of a dumbbell. Left: The dumbbell with mean curvature coloring. Right: The diffeomorphic mean curvature flow with $\sigma = 0.3$ and $T = 1$.*

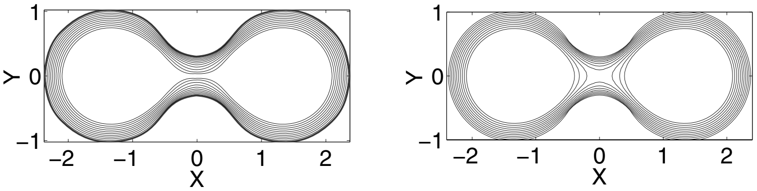

FIG. 6. *Comparison of flows for the dumbbell in Figure 5. Left: Diffeomorphic mean curvature flow with $\sigma = 0.1$ and $T = 0.25$. Right: Mean curvature flow with $T = 0.25$.*

and classical mean curvature flow (right). For the latter, the profile curve reaches the y axis, changes topology, and eventually becomes a sphere. On the other hand, for the diffeomorphic mean curvature flow, part of the curve very closely approaches the y axis but slows down as time increases to infinity and does not actually reach the y axis. In fact, the profile curve flows towards a semicircular shape. This experiment also illustrates the scale-dependent aspect for diffeomorphic flows. In Figures 3 (right) and 4 (left), diffeomorphic flows starting from the same surfaces have very different evolutions. The large value of σ in the first figure prevents the torus from collapsing on itself as it does in the second case, which is much closer to mean curvature evolution.

Dumbbell. Figures 5 and 6 show results for a dumbbell generated by a curve with neck shape $y = x^2 + c$ and $c = 0.3$. In the right-hand panel of Figure 6 we see that for the classical mean curvature flow, the thin neck breaks down and the dumbbell becomes two spheres. However, the diffeomorphic mean curvature flow does not break down even though, as we see in the right-hand panel of Figure 5, it flows towards two spheres connected by a very thin tube. One likely explanation for this shape is that the cylindrical part flows faster than the spherical part where the width of the neck is smaller than the kernel size.

Dumbbell with asymmetric ends. To illustrate typical problems encountered in real applications, we constructed a dumbbell shape with asymmetric ends. Figure 7 shows promising results. For classical mean curvature flow, the smaller end vanished quickly unlike in the diffeomorphic mean curvature flow.

Cortical surfaces. Figure 8 illustrates the application of diffeomorphic and classical mean curvature flows to a superior temporal gyrus cortical surface [35]. The voxel resolution of the image volume from which this surface was generated was 1 mm^3. For the diffeomorphic flows we used a kernel size of $\sigma = 0.3$. For surfaces with boundary,

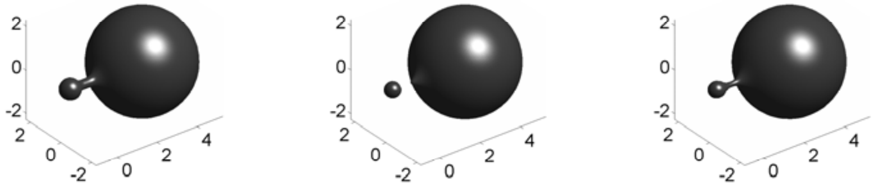

Fig. 7. *Comparison of flows for a dumbbell with asymmetric ends. Left: The dumbbell with asymmetric ends. Middle: Mean curvature flow for $T = 0.025$. Right: Diffeomorphic mean curvature flow with kernel size $\sigma = 0.1$ and $T = 0.025$.*

we simply flow the boundary vertex along with the closest interior vertex. The top row indicates the smoothing effect of both flows. Magnified views of a crest region of the surface indicate that mean curvature flow results in singular folds unlike diffeomorphic flows. Furthermore, the left-hand panel of Figure 9 shows that Hausdorff distances between the original surface and the final surfaces are within one voxel. The smoothing effect of the flows is also reflected in the mean curvature histograms in the right-hand panel of Figure 9.

6. Discussion. In this study, we proposed diffeomorphic surface flows as an alternative to classical mean curvature and Willmore flows. We obtained the flow equation for the elastic energy of a closed surface and proved the short-time existence and uniqueness of the flow. Then we examined the diffeomorphic mean curvature flow both by analyzing the case of a surface of revolution and by numerical experiments on arbitrary discrete surfaces. Our conjecture is that the solution continues to be well behaved for long times while preserving some of the characteristics of classical mean curvature flows (such as smoothing and decreasing area).

Furthermore, in computational anatomy applications, diffeomorphic surface flows can be used to evolve submanifolds of the brain such as planum temporale, superior temporal gyrus (STG), and cingulate cortical surfaces in neuroimaging studies of schizophrenia and auditory disorders. They can also be used for smoothing where the speed is controlled by changing the kernel size without changing the topology.

Diffeomorphic flows, while they clearly avoid topological changes, cannot, however, be considered as smoothing flows. Since they generate a diffeomorphic evolution, they cannot make a surface smoother (in terms of the number of derivatives) than it was initially. In particular, they cannot deal with surfaces corrupted by white noise. They can, however, have some smoothing effect, in the sense that they reduce the curvature of the surfaces on which they operate. There is an important scale factor in this regard, related to the scale of the kernel. Bumps larger than the kernel size will in general be removed in a way similar to classical flows, whereas small bumps are likely to survive after long time intervals. The choice of the kernel size therefore needs to be adapted to the roughness of the surface.

Several open problems remain. Among the numerical issues, there is a need to improve the discretization methods, especially in the case of the Willmore flow for which the computation of higher derivatives is a potential source of instability.

We have already mentioned the issue of long-term existence of the flow. As discussed in this paper, this requires controlling the smoothness of the surface during the evolution, which is made difficult by nonlocal interactions. The limit behavior of the evolution as the kernel size tends to zero is another open problem. It seems

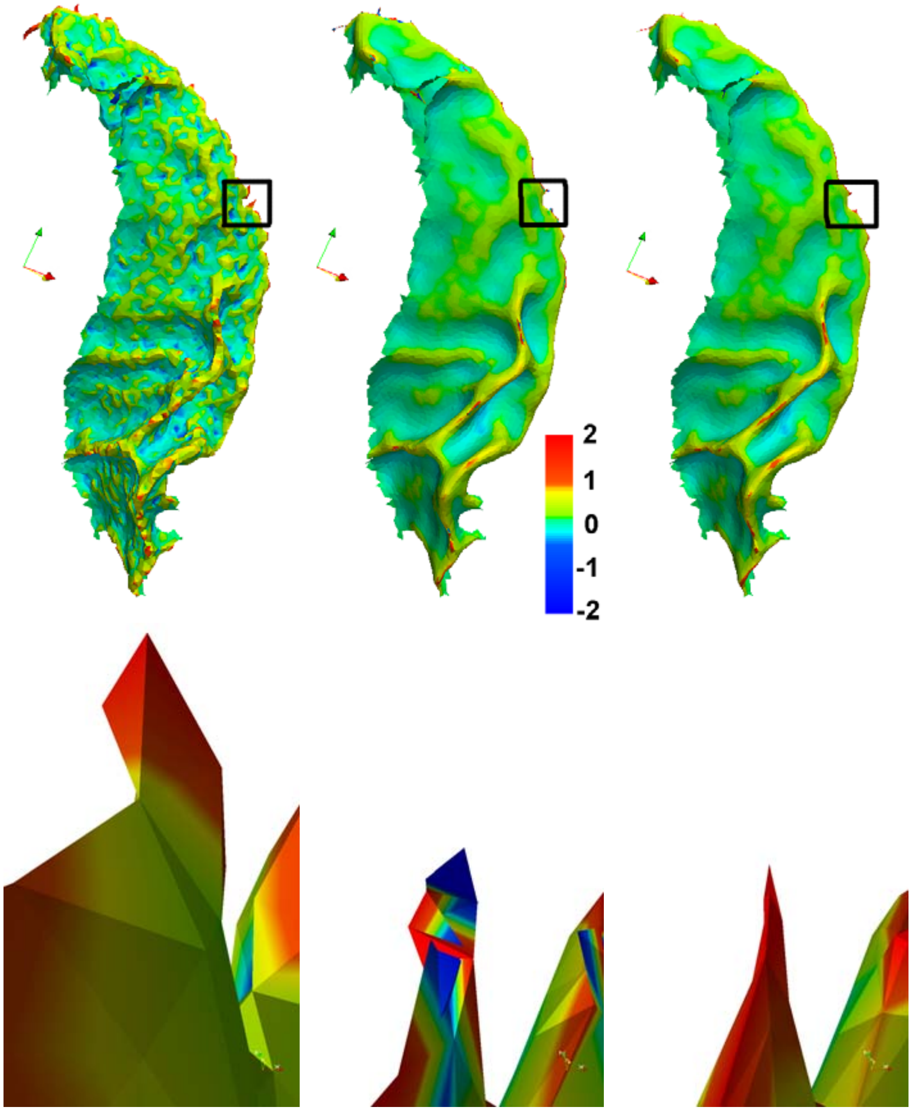

Fig. 8. *The top row shows STG cortical surfaces at $T = 0$ (left), $T = 1$ with mean curvature flow (middle), and $T = 1$ with diffeomorphic mean curvature flow using $\sigma = 0.3$ (right). Mean curvature is indicated by the vertical color bar. The bottom row shows the corresponding magnified view of the crest on the STG which is a subset of the region within the black borders indicated in the top row. The irregular color pattern in the magnified view of the mean curvature flow indicates that singularities occurred during the evolution with triangles crossing over.*

reasonable to expect that it should somewhat resemble the classical flows, but the nature of the convergence (and proof) needs to be investigated.

Another interesting issue, related to long-term evolution, is to characterize the limit shapes of the shrinking surfaces for the diffeomorphic mean curvature flow. Our experiments seem to indicate that such limit shapes exist and are not restricted to spheres.

It would be interesting also, for theoretical and practical purposes, to consider numerical schemes in which the kernel size is allowed to evolve with time, starting with

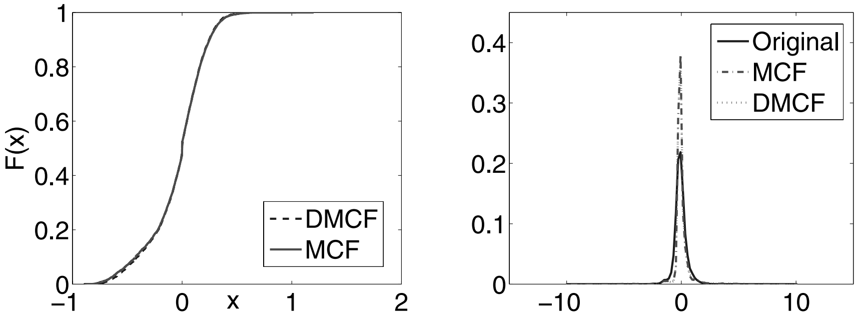

FIG. 9. *Left: Cumulative density function profiles of the oriented distances between the original surface and final surfaces. Right: Mean curvature histograms of the original and final surfaces at* $T = 1$.

a rigid evolution and progressively decreasing spatial smoothing to get closer to the mean curvature flow. The question here is to define sufficient conditions for such an annealed scheme that ensure a diffeomorphic evolution while providing a smoothing effect similar to that of the standard mean curvature flow.

While these topics provide interesting sources of future work, diffeomorphic surface flows already represent a promising family of surface evolutions. Initial experiments in this paper demonstrate several important features, regarding, in particular, the absence of topological change, that make them appropriate for a large range of practical situations.

Acknowledgments. We thank the reviewers for their extensive comments, and Dr. M. I. Miller, Dr. Y. Cao, and Dr. J. Glaunès for helpful discussions.

THE NONLINEAR CRITICAL LAYER FOR KELVIN MODES ON A VORTEX WITH A CONTINUOUS VELOCITY PROFILE[*]

S. A. MASLOWE[†] AND N. NIGAM[†]

Abstract. We consider in this paper the propagation of neutral modes along a vortex with velocity profile $\bar{V}(r)$, r being the radial coordinate. In the linear inviscid stability theory for swirling flows, modes that are singular at some value of r denoted r_c, the critical point, are particularly significant. The singularity can be dealt with by adding viscous and/or nonlinear effects within a thin critical layer centered on the critical point. At high Reynolds numbers, the case of most interest in applications such as aeronautics and geophysical fluid dynamics, nonlinearity is the appropriate choice, although viscosity may still play a subtle role. We determine here the scaling and equations that govern the nonlinear critical layer. The method of characteristics is then employed to obtain an exact solution of the governing inviscid system composed of four coupled PDEs, of which two are nonlinear and two are linear. Finally, assuming zero phase change across the critical layer, solutions are obtained for the outer eigenvalue problem demonstrating the existence of modes not possible in a linear theory. This result may have important implications for the short wave cooperative instability mechanism that has received so much attention in the context of aircraft trailing vortices.

Key words. waves on vortices, Kelvin modes, nonlinear critical layers

1. Introduction.

The propagation of helical perturbations to a columnar vortex seems to have been studied first by Lord Kelvin, whose results were published in 1880. In cylindrical coordinates (r, θ, z), the problem involves the investigation of infinitesimal perturbations (u_r, u_θ, u_z) superimposed on a flow with velocity profile $\{0, \bar{V}(r), 0\}$. Kelvin considered the case of a fluid in rigid rotation, i.e., $\bar{V} = \Omega_0 r$ contained within a cylinder of radius a. A single equation can be obtained for the pressure perturbation, and it is Bessel's equation of order m, where m is the azimuthal wavenumber. Imposition of the boundary conditions at $r = 0$ and $r = a$ leads to an eigenvalue problem for the frequency $\omega = \omega(k, m)$, where k is the axial wavenumber. The review article by Ash and Khorrami [1] is a convenient reference for the details.

In this paper, we are primarily interested in waves propagating on an unbounded vortex, and a model that has often been employed to study this phenomenon is the discontinuous Rankine vortex with velocity profile

$$\bar{V}(r) = \begin{cases} \Omega_0 r, & 0 \le r \le a, \\ \frac{\Omega_0 a^2}{r}, & r > a. \end{cases}$$

The solutions on either side of the discontinuity of vorticity at $r = a$ are matched using kinematic and pressure conditions, and this leads to an eigenvalue problem for the dispersion relation. Bessel functions are again involved, and the modal solutions obtained are termed Kelvin modes. The monograph by Saffman [2] details the analysis and presents dispersion curves for different azimuthal wavenumbers.

Much of the recent research on the stability of vortices is motivated by the aircraft trailing vortex problem. A pair of counterrotating vortex filaments serves as a model that has been widely studied as representing the vortices shed from the wingtips of aircraft which, if they are jumbo jets, pose a major hazard to following aircraft. Given that the strength of the trailing vortices is related to the weight of the aircraft, it is clear that any smaller aircraft attempting to land behind the new Airbus A380 is at serious risk.

A number of theoretical investigations have treated the problem of a vortex subject to an external strain, this being a way of modelling the strain induced on one member of a pair of trailing vortices by the other. A long wave instability first explained by Crow [3] initially received the most attention, but more recently the short wave cooperative instability mechanism (often termed the elliptic instability) has attracted a great deal of interest. The latter mechanism involves interacting Kelvin waves. Specifically, Moore and Saffman [4] showed that for an arbitrary strained vortex two neutral modes are coupled by the strain field if a certain resonance condition is satisfied. They derived an approximate expression for the growth rate of the resonant modes by an asymptotic analysis valid when the strain field is small. The first quantitative investigation of this instability was by Tsai and Widnall [5], who employed the discontinuous Rankine vortex in their calculations. They found that the most unstable perturbations corresponded to a pair of Kelvin modes having zero frequency and azimuthal wavenumbers $m = \pm 1$.

Real vortices, however, have continuous profiles, and the use of Rankine vortices in theoretical studies was criticized in the review article by Spalart [6] (see section 2.2). Clearly, it is important to ask what effect the use of a profile whose vorticity is continuous might have on this instability mechanism. Sipp and Jacquin [7] have, in fact, recently done so, and they concluded that the "Widnall instabilities" will not occur because of the presence of a critical layer in the continuous case. Their argument, which is correct as far as it goes, is based on linear viscous stability calculations for the Lamb–Oseen vortex $\bar{V}(r) = (1 - e^{-r^2})/r$ which show that the neutral Kelvin modes required for the resonant interaction discussed in [4] and [5] would be damped in the continuous case.

In this paper, we reexamine the question and investigate the effect of retaining nonlinear terms in the critical layer rather than viscous terms, as is usually done in the theory of hydrodynamic stability. This is of interest in its own right as part of the theory of Kelvin modes, and its pertinence to the cooperative elliptic instability mechanism provides further motivation. The possibility that nonlinear critical layer modes could be neutral rather than damped was, in fact, suggested in [7, p. 265]. In section 3, we will determine a parameter that measures the relative importance of nonlinearity to viscosity. The larger the Reynolds number, the smaller the perturbation amplitude needs to be for nonlinearity to be the appropriate choice. A number sometimes cited as representative for trailing vortices behind jumbo jets is $Re = 10^7$. Clearly, this is large enough to motivate the formulation of a nonlinear approach. Even if the turbulence usually present is accounted for by introducing an effective Reynolds number, this value is still very large. Gerz and Ehret [8], in an investigation of the influence of wingtip vortices on atmospheric pollution caused by the jet exhaust, estimate the effective Re as $6 \cdot 10^5$ for the wake behind a Boeing 747.

Although the foregoing discussion focused on the trailing vortex problem, the results are pertinent to other applications in engineering and geophysical fluid dynamics. In turbomachinery, for example, the flow through a duct is sometimes modelled by representing the flow by a superposition of a solid body rotation and a potential axial vortex [9]. And in geophysical fluid dynamics, an important application is to hurricanes. In their numerical simulations of a hurricane, Chen, Brunet, and Yau [10] find that absorption of vortex Rossby waves at the critical level leads to an acceleration of the mean wind in the lower troposphere (the location of the critical layer is indicated in Figure 11 of their paper).

Before presenting the analysis, it is worth noting that the critical point singularity in a stratified shear flow has a very similar behavior to that occurring in a vortex. It is therefore possible to anticipate certain results based on those that have been demonstrated for stratified shear flows. For example, Miles [11] proved that when the local Richardson number is everywhere greater than 1/4, all singular modes must decay according to linear theory. However, when the critical layer is nonlinear and inviscid, singular neutral modes have been shown to exist (see section 3.1.1 of the review article by Maslowe [12]). For Kelvin modes on vortices, we will show that the same is true; i.e., inviscid nonlinear modes exist in regions of parameter space where they would be damped if viscosity were used to deal with the critical layer. As a result, we revive the possibility not only of cooperative instabilities but of other instability mechanisms that have been observed experimentally in which Kelvin modes interact to destroy vortices. In the experiments of Maxworthy, Hopfinger, and Redekopp [13], for example, unstable interactions between axisymmetric and helical waves were observed, the outcome of which depended on the amplitude of the axisymmetric mode.

The reason that neutral modes with nonlinear critical layers can exist when they would be damped in a linear, viscous theory is a direct result of the absence of any phase change across the singular critical point. This means essentially that terms with branch points are written simply as absolute values, whereas in the viscous theory, a term with a branch point at $r = r_c$ is written as $|r - r_c|\, e^{i\,\phi}$ for $r < r_c$, and the phase change ϕ is nonzero. In either case, the result must be derived by determining what outer solution can be matched to the critical layer solution.

Before proceeding with the analysis, we mention briefly that the simpler two-dimensional case of waves propagating only in the azimuthal direction, i.e., $k = 0$, has been investigated recently by Le Dizès [14] and by Balmforth, Smith, and Young [15]. Each paper points out the relevance of the results to plasma physics, as well as to vortices. The critical layer analysis in [14] is closer to our own, one reason being that the waves are forced in [15] and may be transient, but some brief comparisons will be made after presenting our own analysis for helical modes.

2. Formulation and outer expansion. We consider small-amplitude helical perturbations to a vortex with azimuthal velocity profile $\bar{V}(r)$ and a corresponding radial pressure distribution $\bar{p}(r)$. Away from the critical layer, the perturbations are sinusoidal with phase $\xi = kz + m\theta - \omega t$ and, because we are dealing with neutral modes, it will be convenient to use ξ as an independent variable. The momentum and continuity equations can then be written as

$$\left(\frac{m}{r}\,u_\theta - \omega\right)\frac{\partial u_r}{\partial \xi} + u_r\,\frac{\partial u_r}{\partial r} - \frac{u_\theta^2}{r} + k\,u_z\,\frac{\partial u_r}{\partial \xi} = -\frac{\partial p^*}{\partial r} + \frac{1}{Re}\,\frac{\partial^2 u_r}{\partial r^2}, \tag{2.1a}$$

$$\left(\frac{m}{r}\,u_\theta - \omega\right)\frac{\partial u_\theta}{\partial \xi} + u_r\,\frac{\partial u_\theta}{\partial r} + \frac{u_r\,u_\theta}{r} + k\,u_z\,\frac{\partial u_\theta}{\partial \xi} = -\frac{m}{r}\frac{\partial p^*}{\partial \xi} + \frac{1}{Re}\,\frac{\partial^2 u_\theta}{\partial r^2}, \tag{2.1b}$$

$$\left(\frac{m}{r}\,u_\theta - \omega\right)\frac{\partial u_z}{\partial \xi} + u_r\,\frac{\partial u_z}{\partial r} + k\,u_z\,\frac{\partial u_z}{\partial \xi} = -k\frac{\partial p^*}{\partial \xi} + \frac{1}{Re}\,\frac{\partial^2 u_z}{\partial r^2}, \tag{2.1c}$$

$$\text{and}\quad \frac{\partial (r\,u_r)}{\partial r} + m\,\frac{\partial u_\theta}{\partial \xi} + k\,r\,\frac{\partial u_z}{\partial \xi} = 0. \tag{2.1d}$$

Our analysis being primarily inviscid, we have retained in the above momentum equations only those viscous terms involving second derivatives with respect to r, because these terms will be the largest in the critical layer.

The scaling employed in the foregoing equations deserves some discussion because we wish to identify parameter regimes where analytical progress is possible. To begin, we denote by Ω_0 the angular velocity of the vortex at its center and use this to scale the frequencies and time. A characteristic length scale for the vortex denoted a is used to nondimensionalize r and the wavenumber k, while $\Omega_0\, a$ is employed to scale the velocities. Finally, the dimensionless pressure p^* is obtained by dividing the actual pressure by $\rho\,\Omega_0^2\, a^2$, where ρ is the constant density. After introducing this scaling into the momentum equations, the Reynolds number $Re = a^2\Omega_0/\nu$, where ν is the kinematic viscosity.

We next consider the linear, inviscid theory because it describes the perturbation to leading order in the outer region. A separation of variables can be achieved in the linearized equations by writing

$$u_r = \varepsilon\, u(r) \sin\xi, \tag{2.2a}$$

$$u_\theta = \bar{V}(r) + \varepsilon\, v(r) \cos\xi, \tag{2.2b}$$

$$u_z = \varepsilon\, w(r) \cos\xi, \tag{2.2c}$$

$$\text{and} \qquad p^* = \bar{p}(r) + \varepsilon\, p(r) \cos\xi, \tag{2.2d}$$

where $\varepsilon \ll 1$ is a dimensionless amplitude parameter. After linearizing and then substituting (2.2a)–(2.2d) into (2.1a)–(2.1d), we obtain the system

$$\gamma(r)\, u = 2\,\frac{\bar{V}}{r}\, v - p\,', \tag{2.3a}$$

$$\gamma(r)\, v = \frac{1}{r}\,(r\bar{V})'\, u - \frac{m}{r}\, p, \tag{2.3b}$$

$$\gamma(r)\, w = -k\, p, \tag{2.3c}$$

$$(r\, u)' = m\, v + k\, r\, w, \tag{2.3d}$$

where

$$\gamma(r) = m\,\frac{\bar{V}}{r} - \omega = m\,\bar{\Omega} - \omega. \tag{2.4}$$

Critical point singularities occur at any value of r for which $\gamma(r) = 0$.

Equations (2.3a)–(2.3d) can be combined into a single second order differential equation for $u(r)$, namely,

$$\gamma^2 D\{SD_* u\} - \left\{\gamma^2 + \frac{m\gamma}{r^2}\left(D[SD(r\bar{V})] - 3\,\frac{S}{r} D(r\bar{V})\right) - 2\,\bar{V}\, k^2\,\frac{S}{r}\, Q(r)\right\} u = 0, \tag{2.5}$$

where

$$D = \frac{d}{dr}, \quad D_* = \frac{d}{dr} + \frac{1}{r}, \quad S = \frac{r^2}{m^2 + k^2 r^2}, \quad \text{and} \quad Q(r) = \frac{D(r\bar{V})}{r}.$$

$Q(r)$ can be recognized as the vorticity of the mean flow nondimensionalized with respect to Ω_0, the angular velocity at the center of the vortex.

Equation (2.5) can be obtained from the equation derived by Howard and Gupta [16] for swirling flows by setting the axial velocity $W = 0$ in equation (18) of [16].

Noting the similarity of their equation (18) to the Taylor–Goldstein equation governing stratified shear flows, Howard and Gupta derived a Richardson number 1/4 stability theorem for swirling flows, employing an integral approach as in Howard's earlier paper on stratified flows [17]. This theorem, however, was limited to axisymmetric, i.e., $m = 0$, perturbations, thus underlining the importance of perturbations with $m \neq 0$, where only a bound on the growth rate could be obtained.

The mathematical similarities to the case of a stratified shear flow are nonetheless useful, and it will be seen that in our analysis the paper by Miles [18] is most pertinent. Miles used Frobenius expansions near the critical point to derive a number of important results, including the Richardson number 1/4 theorem. Following his approach and notation, we expand all terms in (2.5) around the critical point r_c to obtain a solution valid locally having the form

$$u(r) = A\,u_+(r) + B\,u_-(r), \tag{2.6}$$

where

$$u_\pm(r) = (r - r_c)^{\frac{1}{2}\,(1 \pm \nu)}\,w_\pm(r) \tag{2.7}$$

and the functions $w_\pm(r)$ are regular in the neighborhood of r_c. We have defined a local Richardson number analogous to the one arising in stratified shear flows by

$$J_c = \frac{2\,k^2\,\bar{V}_c\,Q_c}{r_c\,(\gamma_c')^2}, \tag{2.8}$$

and the parameter ν in (2.7) is related to J_c by $\nu = (1 - 4\,J_c)^{1/2}$.

Miles used arguments based on the variation of the Reynolds stress to prove a number of useful results that apply to singular neutral modes. For example, within the framework of linear theory, a neutral mode comprising part of a stability boundary must be proportional to one or the other of the Frobenius solutions. Even though the expression for the Reynolds stress is quite different in cylindrical coordinates, we show in the appendix that the same conclusion applies here; i.e., on a stability boundary with $J_c < 1/4$, the case we treat in this paper, either A or B must be zero in (2.6).

There are two exceptional cases, however, that should be mentioned. First, when J_c is small, the second term in the series for $w_-(r)$ in (2.7) is very large, becoming infinite as $J_c \to 0$. That case is of interest in the vortex problem because it arises, for example, when r_c is far from the center and the vorticity Q_c is then small. The Frobenius solution u_- in (2.6) can then be replaced by a linear combination of u_+ and u_- that is well behaved as $J_c \to 0$; the associated nonlinear critical layer theory has been developed by Caillol and Maslowe [19]. The second exceptional case occurs when J_c is greater than 1/4 so that the Frobenius exponents are complex. We do not treat that case here, but it does arise, for example, when there is an external forcing. Let us proceed now to the derivation of the critical layer equations for the case of $J_c \sim O(1)$ with ν real.

3. Critical layer scaling and governing equations.

There are several ways to determine the scaling for the nonlinear critical layer. Of these, the most direct is to try to get a balance between linear inertial terms and the nonlinear terms with the largest derivatives in r. Because we are dealing with a system, however, different equations yield different results. For the present Kelvin wave problem, either the v or the w momentum equation in (2.1) leads to the correct scaling, but that was not obvious a priori. That being the case, it is a great help to have an alternative method. The most reliable is to examine several terms in the outer expansion which proceeds in powers of ε, the amplitude parameter. The power of ε where the expansion first breaks down yields the critical layer thickness. We illustrate this below, but first the behavior of all variables near r_c in the linear problem must be determined.

Let us concentrate on the case $J_c < 1/4$ corresponding to (2.6)–(2.8). The most singular Frobenius solution is the one with the minus sign in front of ν; we denote this exponent δ. Because the pressure perturbation satisfies an equation nearly identical to the one satisfied by u (see p. 244 of [2]), it will have the same behavior near r_c. Although not a trivial exercise, consideration of the system (2.3a)–(2.3d) leads to the conclusion that

$$v \sim (r - r_c)^{\delta-1}, \quad w \sim (r - r_c)^{\delta-1}, \quad \text{and} \quad p \sim (r - r_c)^{\delta}, \tag{3.1}$$

where to be consistent with the first of equations (2.3)

$$\left(\frac{dp}{dr} - \frac{2\bar{V}}{r}\, v\right)_c \sim (r - r_c)^{1+\delta}. \tag{3.2}$$

Considering now higher order terms in the outer expansion, if we were to write (2.2) as an expansion in powers of ε, then the $O(\varepsilon^2)$ terms would involve second harmonics, and in particular (2.2a) would include a term $u_2(r)\sin 2\xi$. A single nonhomogeneous second order ODE can be derived for $u_2(r)$ by following exactly the same steps that were used to obtain (2.5), the equation for $u(r)$, from (2.3a)–(2.3d). (A detailed derivation of the Howard–Gupta equation is given in section 2.4 of [1].) For the purpose at hand, however, only the most singular of the nonhomogeneous terms need be considered. The foregoing procedure leads to the result that $u_2 \sim (r-r_c)^{2\delta-2}$, and we see that the first two terms in the expansion for u_r become the same order of magnitude when $(r - r_c) \sim \varepsilon^{\frac{1}{2-\delta}}$.

From the behavior deduced immediately above, we find that appropriate independent variables in the nonlinear critical layer are

$$\xi = k\, z + m\, \theta - \omega\, t \qquad \text{and} \qquad R = \frac{r - r_c}{\varepsilon^{\beta}}, \qquad \text{where} \qquad \beta = \frac{1}{2-\delta}. \tag{3.3}$$

When $k = 0$, $\delta = 0$ and $\beta = 1/2$, as in [14] and [15]. With the critical layer thickness now determined, we can deduce from (2.2b) that in a frame of reference rotating with the angular velocity at the critical point, the magnitude of the azimuthal velocity perturbation is equal to that of the mean flow. This follows by expanding $\bar{V}$ in a Taylor series about r_c, and from the behavior of $v(r)$ as given by (3.1), it can be seen that $\varepsilon\, v(r)$ is the same order of magnitude as the mean flow when $(r - r_c) \sim O(\varepsilon^{\beta})$. Noting that point, an appropriate scaling for $V(R, \xi)$, the azimuthal velocity in the critical layer, is given by

$$u_\theta - \bar{V}_c \sim \bar{V}_c{}'(r - r_c) + \varepsilon\, v(r) \cos\xi = \varepsilon^{\beta}[V(R, \xi) + \bar{\Omega}_c\, R], \tag{3.4}$$

where the R-term is included because it simplifies the governing equations. The remaining dependent variables in the case $J_c < 1/4$ (but not small) are scaled as

$$u_r = \varepsilon^{2\beta} U(R, \xi), \quad u_z = \varepsilon^{\beta} W(R, \xi), \quad \text{and} \quad p^* - \frac{1}{2}\, \bar{\Omega}_c{}^2 r^2 = \varepsilon^{2\beta} P(R, \xi). \tag{3.5}$$

Now substituting (3.3)–(3.5) into the governing equations (2.1), the nonlinear critical layer equations to lowest order are the following:

$$r_c \frac{\partial P}{\partial R} - 2\,\bar{V}_c V = 0, \tag{3.6a}$$

$$2\,\frac{\bar{V}_c}{r_c} U + \frac{m}{r_c}\frac{\partial P}{\partial \xi} = -\left[U\frac{\partial V}{\partial R} + \left(\frac{m}{r_c}V + kW\right)\frac{\partial V}{\partial \xi}\right] + \lambda\,\frac{\partial^2 V}{\partial R^2}, \tag{3.6b}$$

$$k\frac{\partial P}{\partial \xi} = -\left[U\frac{\partial W}{\partial R} + \left(\frac{m}{r_c}V + kW\right)\frac{\partial W}{\partial \xi}\right] + \lambda\,\frac{\partial^2 W}{\partial R^2}, \tag{3.6c}$$

(3.6d) and $r_c\frac{\partial U}{\partial R} + m\frac{\partial V}{\partial \xi} + kr_c\frac{\partial W}{\partial \xi} = 0.$

The parameter $\lambda = 1/Re\,\varepsilon^{3\beta}$; taking $\lambda \ll 1$, means that the nonlinear critical layer thickness ε^{β} is greater than that of the viscous critical layer, whose thickness is $Re^{-1/3}$. In most applications outside of the laboratory, that condition will be satisfied easily.

The critical layer problem is highly nonlinear, and the solution even at lowest order involves all the harmonics. In matching to the outer expansion, however, we can ignore higher harmonics because they decay more rapidly at large R than those terms involving the primary mode. After expanding the reduced pressure in (3.5) in a Taylor series about r_c and transforming to inner variables, we obtain the following asymptotic conditions:

$$U \sim u_0\,R^{\delta}\sin\xi, \quad V \sim \frac{\gamma_c' r_c}{m}\,R + v_0\,R^{\delta-1}\cos\xi, \quad W \sim w_0\,R^{\delta-1}\cos\xi,$$

$$\text{and} \qquad P \sim \frac{\gamma_c'\bar{V}_c}{m}\,R^2 + p_0\,R^{\delta}\cos\xi \qquad \text{as} \qquad R \to \infty. \tag{3.7}$$

Of the four constants u_0, v_0, w_0, and p_0, one is arbitrary. A convenient choice is $p_0 = 1$, and the system (2.3) can then be used to express the other three constants in terms of this constant.

3.1. The $\boldsymbol{\lambda = 0}$ limit. Given that the Reynolds number is very large in most applications, the $\lambda = 0$ limit is clearly of considerable interest even though we expect viscosity to still play a subtle role. For example, arbitrary functions that arise in integrating the governing PDEs can be determined uniquely only by introducing a small viscosity. Moreover, in related earlier studies thin viscous layers were required along streamlines separating open and closed regions in order for the vorticity and velocity components to be continuous. Most of the flow field is inviscid, though, and an exact solution of the system (3.6) will now be presented for that case.

We begin by writing the system (3.6) in the following matrix form:

$$\mathbf{A}(\mathbf{u})\,\frac{\partial \mathbf{u}}{\partial \xi} + \mathbf{B}(\mathbf{u})\,\frac{\partial \mathbf{u}}{\partial R} = \mathbf{c}, \tag{3.8}$$

where $\mathbf{A}$ and $\mathbf{B}$ are 4×4 matrices and the vectors $\mathbf{u}$ and $\mathbf{c}$ are given by

$$\mathbf{u}(R,\xi) = \begin{pmatrix} P(R,\xi) \\ U(R,\xi) \\ V(R,\xi) \\ W(R,\xi) \end{pmatrix} \qquad \text{and} \qquad \mathbf{c} = \begin{pmatrix} 2\,\Omega_c V(R,\xi) \\ -2\,\Omega_c U(R,\xi) \\ 0 \\ 0 \end{pmatrix}. \tag{3.9}$$

The matrices $\mathbf{A}$ and $\mathbf{B}$ are given by

$$\mathbf{A}(\mathbf{u}) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ \frac{m}{r_c} & 0 & \alpha & 0 \\ k & 0 & 0 & \alpha \\ 0 & 0 & m & kr_c \end{pmatrix}, \quad \mathbf{B}(\mathbf{u}) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & U(R,\xi) & 0 \\ 0 & 0 & 0 & U(R,\xi) \\ 0 & r_c & 0 & 0 \end{pmatrix},$$

where $\alpha(R,\xi) = (m/r_c)V(R,\xi) + kW(R,\xi)$.

It is clear that $\mathbf{B}(\mathbf{u})$ becomes singular when $U = 0$. This tells us that solving the system by the method of lines (using a spectral collocation method in the ξ direction followed by integration in the R variable) will lead to a numerically stiff system since (3.6a)–(3.6d) turn into a system of differential-algebraic equations. Indeed, when $U = 0$, we are led to the constraints $V = 0$, $P =$ *constant*, $W =$ *constant*. This is also the reason why the small-λ limit of equations (3.6) is difficult (in the sense of stability) to simulate numerically. We should also note that the low-rank behavior of $\mathbf{A}(\mathbf{u})$ does not present computational difficulties. In order to deal with the possibly singular behavior of $\mathbf{B}$, we now introduce an alternate solution strategy.

3.2. Solution by the method of characteristics. If we denote by $\frac{dR}{d\xi} = \frac{1}{\mu}$ the slope of the characteristics, they are given by the roots of the characteristic polynomial $|\mathbf{A} - \mu\mathbf{B}| = 0$. For the system (3.6), this condition yields

$$det(\mathbf{A} - \mu\mathbf{B}) = \mu^2 r_c(\alpha - \mu U)^2 = 0,$$

where $\alpha = (m/r_c)V + kW$. Even though the system is not totally hyperbolic, i.e., there are only two characteristic directions, it develops that we can still solve (3.6) by integrating along the two characteristic directions given by

$$\frac{dR}{d\xi} = \frac{U}{(m/r_c)V + kW} \qquad \text{and} \qquad \frac{d\xi}{dR} = 0. \tag{3.10}$$

In accordance with the above result, we define a family of characteristics by

$$\left(\frac{\partial R}{\partial s}\right)_\tau = U \qquad \text{and} \qquad \left(\frac{\partial \xi}{\partial s}\right)_\tau = \frac{m}{r_c}\,V + kW, \tag{3.11}$$

where s measures distance along a characteristic and τ is a parameter identifying a particular characteristic. Eliminating $\frac{\partial P}{\partial \xi}$ from the azimuthal and axial momentum equations in (3.6) and using the characteristic equations (3.11), we obtain the following integral:

$$r_c\, V + 2\,\bar{V}_c\, R - \frac{m}{k}\, W = F(\tau). \tag{3.12}$$

A second integral can be obtained along the same family of characteristics by writing the directional derivative for the pressure, namely,

$$\left(\frac{\partial P}{\partial s}\right)_\tau = \left(\frac{\partial P}{\partial R}\right)_\xi \left(\frac{\partial R}{\partial s}\right)_\tau + \left(\frac{\partial P}{\partial \xi}\right)_R \left(\frac{\partial \xi}{\partial s}\right)_\tau. \tag{3.13}$$

Expressions for $\partial P/\partial R$ and $\partial P/\partial \xi$ are provided by (3.6a) and (3.6c), i.e., the radial and axial momentum equations. The characteristic equations (3.11) yield the other partial derivatives, and substitution of these four partial derivatives into (3.13) then allows us to integrate with respect to s to obtain the following expression for the pressure:

$$P = a_0\,\frac{m}{k}\,R\,W + \left(a_0 R - \frac{m}{kr_c^2}\,W\right) F(\tau) - a_0 \bar{V}_c R^2 - \frac{1}{2}\left[1 + \left(\frac{m}{kr_c}\right)^2\right] W^2 + G(\tau), \tag{3.14}$$

where $a_0 = 2\,\bar{V}_c/r_c^2$.

The arbitrary functions $F(\tau)$ and $G(\tau)$ are determined by matching to the outer solution and will be specified below. First, however, two more equations are required to complete the solution. One is provided by the radial momentum equation; i.e., (3.6a) gives us a simple expression for $\frac{\partial P}{\partial R}$, and we can integrate along the vertical lines $\xi = \mathit{const.}$, because they are characteristics. The fourth relationship that we require is obtained not by integrating along a characteristic but by defining the parameter τ in such a way that the continuity equation is satisfied; the characteristics $\tau = \mathit{const.}$ are then analogous to the streamlines in two-dimensional flows. Specifically, we require τ to satisfy the conditions

$$\frac{\partial \tau}{\partial \xi} = U \qquad \text{and} \qquad \frac{\partial \tau}{\partial R} = -(m/r_c)V - kW. \tag{3.15}$$

The numerical procedure that we use is to begin the integration at a large value of $|R|$ and then integrate toward the center of the critical layer. This allows us to determine an expression for τ that is valid as $R \to \infty$ that we can use to begin the integration. First, we integrate the second of equations (3.15); the resulting expression for τ contains an arbitrary function of ξ which can then be determined by differentiating with respect to ξ and comparing with the asymptotic behavior of U given in (3.7). It can be verified that the following expression for τ satisfies (3.15), as well as being consistent with the asymptotic conditions (3.7) and the continuity equation:

$$\tau = -\gamma_c' \frac{R^2}{2} - u_0 \, |R|^\delta \cos \xi. \tag{3.16}$$

Noting that $\tau \sim R^2$ for large $|R|$, it can be seen that $F \sim \sqrt{\tau}$ in (3.12) and that $G \sim \tau$ in (3.14). By substituting into (3.12) and (3.14) and using the asymptotic conditions (3.7), we find more precisely that

$$F(\tau) = (r\,\bar{V})_c' \sqrt{-2\,\tau/\gamma_c'} \qquad \text{and} \qquad G = \frac{2\,\bar{V}_c\,(r\,\bar{V})_c'}{\gamma_c'\,r_c^2}\,\tau. \tag{3.17}$$

3.3. Numerical procedure. As mentioned in the previous section, we begin integration of the characteristic equations for P, V, W, and the radial variable R at large initial values of R. We first locate $\tau(\xi)$ for this large value of R using (3.16). The values of $\tau(\xi)$ will subsequently be decreased by a *fixed* amount, d_τ, which in turn changes V, W, and R through the second of equations (3.15). We implement a backward Euler update:

$$d_\tau = (\tau - \tau_{old}) = -\left(\frac{m}{r_c}V + kW\right)(R_{old} - R). \tag{3.18}$$

Here the subscripts $_{old}$ refer to the values of the variable at the previous τ-step. We also write an Euler update to compute the new values of P in terms of its current values, and use this to update V, W, and R. We are thus led to a nonlinear system of four equations comprising (3.12), (3.14), (3.18), and

$$r_c(P - P_{old}) - 2\bar{V}_c V(R - R_{old}) = 0.$$

The nonlinear system needs to be solved for the new values of (P, V, W, R) at each τ-step. The manifold on which these solutions evolve seems particularly sensitive to initial guesses in V and W; hence, we retain only the updated P and R values from each iteration. We can then explicitly calculate from these the updated values of V and W. We note here that though it may seem appealing to solve for V and W in terms of P and R using (3.12) and (3.14), the latter is a quadratic in W. This would force us to make a choice for the sign of the root (and is, indeed, the source of the numerical sensitivity to initial guesses in V and W). Instead, we use all four equations to derive explicit expressions for V and W in terms of the other variables.

Certain constants must be fixed in order to initiate the integration from above and below the critical layer, so the procedure is discussed briefly here. If we assume that in crossing the critical layer there is no phase change, then absolute values are used to deal with the branch point at r_c in (2.5)–(2.7), the Frobenius solution for u. Two limiting cases were treated in [19]; in the first, it was assumed that the vorticity $Q_c \ll 1$, whereas the second case assumed waves that are long in the axial direction, i.e., $k \ll 1$. In both limits, it was found as in previous nonlinear critical layer studies that there was no phase change across the critical layer. It is therefore likely that the same result is generally true for vortical flows with $J_c < 1/4$. Consistent with the assumption of zero phase change, we take u_0 in (3.7) to be the same on both sides of the critical layer, in which case U will be an even function. Observing that U is differentiated with respect to R in the continuity equation, i.e., the last of equations (3.6), it is clear that V and W will be odd functions of R so that u_0 and w_0 in (3.7) must have opposite signs above and below the critical layer. Similar considerations lead us to conclude that P is an even function.

The foregoing considerations were used to compute the solution illustrated in Figures 3.1–3.4 for a Lamb–Oseen vortex profile. Initial values were obtained from (3.7), and the computation was initiated at large values of τ on both sides of the critical layer; i.e., τ is even in R. This beginning value of τ depends on the choice of k, r_c, and γ_c'.

In Figure 3.1, we present the characteristics R and pressures P obtained by the procedure described above. We repeated the procedure with several values of d_τ, and present the converged solutions. We show the results of two experiments; in Figures 3.1(a) and 3.1(c), $k = 0.36$, $m = 1$, $r_c = 1.4$, $\gamma_c' = -0.424907$. In Figures 3.1(b) and 3.1(d), $k = 0.18$, $m = 1$, $r_c = 0.88$, $\gamma_c' = -0.53425$. The procedure used is to decrease τ in increments of 0.05 until a characteristic is reached that goes beyond the corners at $R = 0$ and $\xi = \pm\pi$. This occurs on the characteristic $\tau = 2.4$ in the first experiment and on $\tau = 1.0$ in the second.

For clarity, only a few of the characteristics are shown. The similarity of Figures 3.1(a) and 3.1(c) compared with the streamline patterns in the stratified shear flow computations in Figure 2 of Maslowe [20] is striking, even including a cusp at the corners. Although the characteristics are not streamlines in our problem, they do serve the same purpose mathematically by providing a solution of the continuity equation; thus to this extent comparisons are valid.

Figure 3.2 shows that the nonlinear critical layer equations (3.8)–(3.9) completely eliminate the singular behavior exhibited by the linear problem. We show the fields for the azimuthal and axial velocity components V and W, respectively, because these are the most singular according to (3.8). We again chose $k = 0.36$, $r_c = 1.4$, $\gamma_c' = -0.424960$. For this particular example, $\delta = 0.230$, so that $v \sim |r - r_c|^{-0.770}$ as $|r - r_c| \to 0$ in the outer problem and w has the same behavior.

Our solution is not yet complete because we must still deal with the region of closed characteristics. In addition, there are discontinuities in V and W at the corners where the separatrices meet, although the radial velocity U is continuous. Distor-

Particularly note the cusp-like behavior near $R = 0$ at $\xi = \pm\pi$.*

tions in the mean flow, as well as thin viscous layers, would be needed to completely eliminate these discontinuities. This is not surprising in view of previous research on nonlinear critical layers in stratified shear flows. Both Haberman [21], in the small Richardson number case, and Troitskaya [22], who studied the forced wave problem with $J_c > 1/4$, found that a temperature jump took place across the critical layer and the vorticity was also discontinuous. The need for these mean flow corrections in our Kelvin wave problem is clear in Figure 3.2(b), where the axial velocity component W is illustrated and it can be seen that W is discontinuous at the corners $(R, \xi) = (0, \pm\pi)$.

While such a vortex sheet is permitted in an inviscid problem, mean flow distortions are required to make this a valid solution in the sense of being the limit of a viscous flow as $Re \to \infty$. A comprehensive study of the $\lambda \sim O(1)$ problem would be required with consideration given to the limit as $\lambda \to 0$. Although we have not

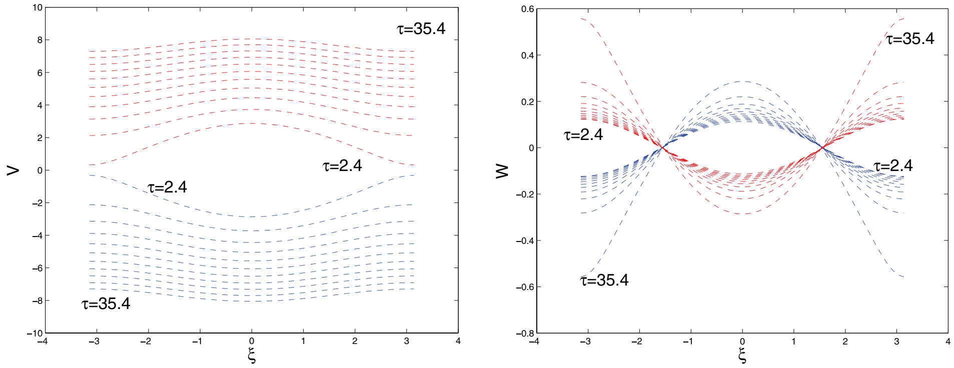

Fig. 3.2. *Shown are curves of V and W as functions of ξ for different τ-steps. Left: the V-component of velocity. Right: the W-component of velocity. For both, $k = 0.36$, $r_c = 1.4$.*

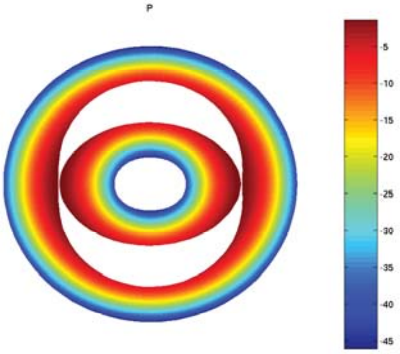

Fig. 3.3. *The characteristic solution for the pressure P, in (r, ξ) coordinates. Here $\xi \in [-\pi, \pi]$. Recall $R = \frac{r-r_c}{\epsilon^\beta}$; in this plot, $R \in [-8.29, 8.29]$. We have scaled the radial variable to enable easier reading of the graph. Note that P is continuous as we move across the critical layer.*

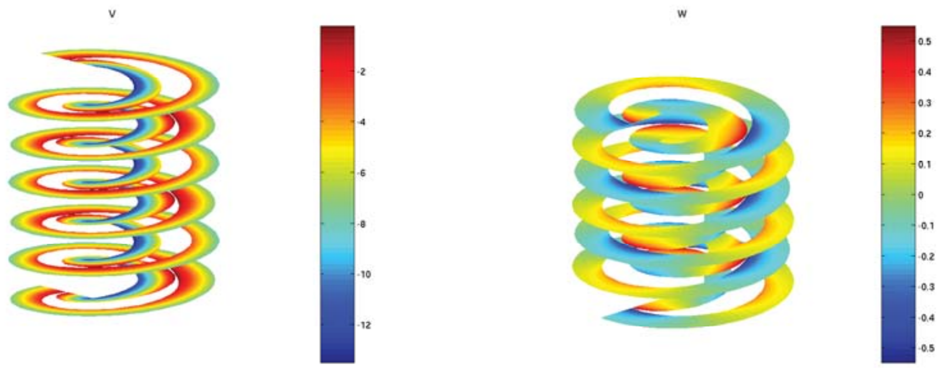
yet completed such an analysis, we can still anticipate to some extent the changes in mean flow based on the results in [21] and [22] and the small vorticity analysis of Caillol and Maslowe [19]. Before discussing these distortions further, however, let us proceed to the analysis of the closed characteristics region because related issues arise there.

3.4. The closed characteristics region. For a steady inviscid two-dimensional flow, a general solution of the Euler equations is $\nabla^2\psi = f(\psi)$, where ψ is the streamfunction and the function f is arbitrary. By considering a small viscous perturbation to the basic flow, Batchelor [23] proved that $\nabla^2\psi$, the vorticity, must be a constant within a region of closed streamlines. The value of the constant can be determined only by matching to the solution outside the separatrix. This is the counterpart of a difficulty here, namely, that the functions $F(\tau)$ and $G(\tau)$ are no longer determined by the outer region. We follow a procedure comparable to what is done in the case of a plane parallel flow, but the three-dimensionality of the present problem naturally adds complications.

To begin, we can exploit the analogy between rotating and stratified flows. For a stratified flow, Grimshaw [24] extended Batchelor's result by showing that the temper-



(a) $V(r, \theta, z)$

(b) $W(r, \theta, z)$

FIG. 3.4. *V and W as functions of r, θ, and z for a fixed t. Recall that P, V, W are periodic in $\xi = m\theta + kz - \omega t$. The spirals correspond to the surfaces $(10(r_c + R(\xi)), \theta, z)$ for varying τ (the radial variable is scaled to improve readability). The colors on the surfaces indicate the values of V and W.*

ature is constant within a region of closed streamlines. This is intuitively reasonable because both the vorticity and the thermal energy equation are diffusion equations, for the vorticity and heat, respectively. If we compare the first of equations (3.6) with the vertical momentum equation for a stratified flow, it can be seen that the azimuthal velocity V is the equivalent of the temperature. In both cases, the pressure gradient balances some force, the buoyancy force or the linearized centrifugal force. We will therefore assume that the axial component of vorticity $\frac{\partial V}{\partial R} + \bar{\Omega}_c$ is constant in the region of closed flow. This was proved in [19] for the small vorticity case by projecting onto a plane $z = const.$, and it must be nearly true in general. Integrating now with respect to R, we obtain the following expression for $V(R, \xi)$ inside the separatrices:

$$V(R, \xi) = (\bar{\Omega}_c + G_0)\, R + g(\xi), \tag{3.19}$$

where G_0 is the axial component of vorticity in the original frame of reference. We fix G_0 by matching the velocity V at $\xi = 0$ and determine $g(\xi)$ by matching V along the separatrices. It develops that we must take $g(\xi) = 0$ in order to preserve the symmetry in our solution.

The determination of $W(\xi, R)$ is less clear cut. As an approximation, we will again assume that the vorticity, this time the azimuthal component, is constant within the separatrices. In the critical layer, to lowest order, the azimuthal vorticity is given by $-\frac{\partial W}{\partial R}$, and, as a result, we obtain

$$W(R, \xi) = H_0\, R + h(\xi), \tag{3.20}$$

where H_0 and $h(\xi)$ are determined in the same way as their counterparts governing V and again symmetry requires $h(\xi) = 0$.

Returning now to the question of changes in the mean flow as the critical layer is crossed, to account for these we would include $O(\varepsilon^{\beta})$ mean flow components $\bar{V}_1(r)$ and $\bar{W}_1(r)$, say, in equations (2.2). These would then be expanded in Taylor series about the critical point r_c, and additional terms would appear in the matching conditions for V and W in (3.7). We included such terms in order to investigate their effect on a trial and error basis, and, as expected from earlier studies, including these mean flow jumps does remove some of the discontinuities. Viscosity, however, is still required to smooth out derivatives in velocity that appear in the equations defining the vorticity. The results of these experiments are not presented here because the procedure is not rigorous. It is nonetheless worth mentioning that a sign change in $\frac{\partial W}{\partial R}$ seems necessary to eliminate the discontinuity in W at the corners $(R, \xi) = (0, \pm\pi)$. It turned out, surprisingly, that introducing a jump in the mean flow vorticity gradient $Q(r)$ was the most effective way to accomplish this; i.e., as a consequence of nonlinearity, a change in $\bar{V}$ can significantly modify the behavior of W.

4. The eigenvalue problem. We now outline the procedure for solving (2.5) numerically for neutral modes with no phase change across the critical point. Results will be presented for the Lamb–Oseen vortex profile $\bar{V}(r) = (1 - e^{-r^2})/r$. The range of integration is from $r = 0$ to $r \to \infty$, and, because (2.5) has a regular singular point at $r = 0$ and an irregular singular point at infinity, series solutions are required at both ends. A Runge–Kutta method was used to carry out the integration.

Near the origin, the solution can be represented by a Frobenius expansion having the form

$$u = u_0\, r^{|m|-1}\, [1 + \zeta_1 r^2 + O(r^4)],$$

so that the radial perturbation velocity vanishes at the center of the vortex except in the case $m = 1$, the so-called bending mode, and then is continuous. Far from the center of the vortex, the velocity profile can be approximated as a potential vortex so that $\bar{V} \sim r^{-1}$. For a potential vortex, the pressure perturbation satisfies a modified Bessel equation (see pp. 341–342 of [1]) so that the pressure can be approximated using the asymptotic expansion for K_m, the solution that decays exponentially. To determine an expression for u valid for large r, the asymptotic result for p can then be substituted into the first two equations of the system (2.3) to obtain

$$u \sim u_\infty \frac{e^{-kr}}{\sqrt{kr}} \left(1 + \frac{\kappa_1}{kr} + \frac{\kappa_2}{k^2 r^2} + O[(kr)^{-3}]\right).$$

Near the critical layer, we employ a linear combination of the two Frobenius solutions, as in (2.6) and (2.7). Using the above conditions to initiate the integration, we integrate toward the critical layer from either side. All variables are real, and if we let $2\,\eta = |r - r_c|$ and choose $B = 1$ as the arbitrary constant, then as the critical layer is approached from the vortex center, we write

$$u(\eta^-) = A\, u_+(\eta^-) + u_-(\eta^-) \quad \text{or else} \quad u(\eta^+) = A\, u_+(\eta^+) + u_-(\eta^+)$$

if the critical layer is approached from outside. Requiring u'/u, as well as the constant A to be the same on either side of the critical layer, gives us enough conditions to determine the constants u_0 and u_∞, as well as the dispersion relation $\omega(k)$ for a given value of m.

In Figure 4.1, a dispersion curve is illustrated for the bending mode $m = 1$. The local Richardson number at the critical point is also shown. The bending mode is the most important, and it is clear from Figures 5 and 11 of Leweke and Williamson [25] that this is the mode that arises naturally in their experiments. Because the $m = 1$ mode essentially disappears in the $k = 0$ limit treated in [14] and [15], the importance of generalizing the theory to helical modes is evident. The solutions that we obtained

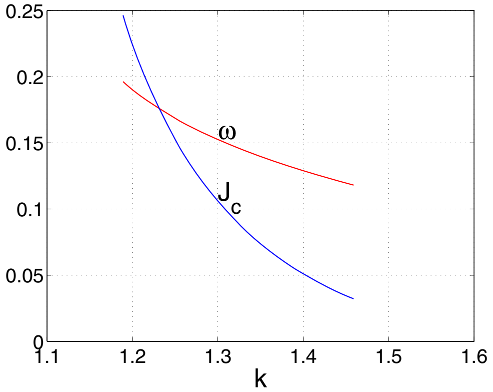


Fig. 4.1. *The dispersion relation $\omega(k)$ and Richardson number at the critical point defined in (2.8) for the $m = 1$ bending mode.*

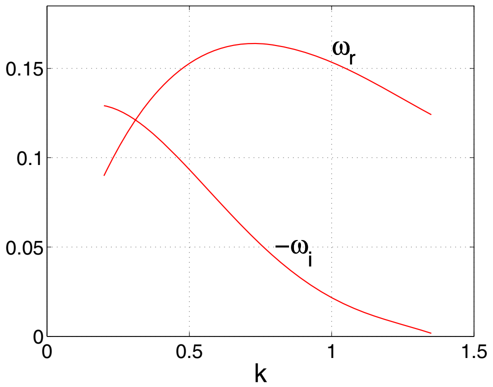

Fig. 4.2. *Variation of the frequency and decay rate ω_i as a function of wavenumber according to linear theory for a Lamb–Oseen vortex $\bar{V}(r) = \left(1 - \exp(-r^2)\right)/r$.*

for $m \geq 2$ had very large values of k, never being smaller than 7.80. Given that short waves are damped by viscosity this is likely the reason that they are not observed in the experiments.

To compare the results when there is a phase change with those in Figure 4.1, we have written a program that avoids the singularity in (2.5) by indenting the contour of integration. Because γ_c' is negative, the integration path passes above the singularity in the complex r plane, corresponding to the viscous limit as $Re \to \infty$ or to the initial value problem as $t \to \infty$. The damping rate is quite large for long waves, but it is small for $k \geq 1.20$. This may mean that it takes very little nonlinearity to generate a neutral mode if the wavelength is not long. The reason that the frequencies in Figures 4.1 and 4.2 are not far apart for $k \geq 1.4$ is that $r_c \geq 2.8$ and the singularity is weak that far from the center of the vortex. It is practically a potential vortex there, so how the singularity is crossed has little effect on the frequency for a given wavelength.

5. Conclusions. The differential equation governing the eigenvalue problem for helical waves propagating on a vortex has a critical point singularity if for some value of r the frequency $\omega = m\bar{\Omega}(r)$, where $\bar{\Omega}(r)$ is the angular velocity of the vortex. Our paper treats the class of waves for which this condition is satisfied and for which ε, a dimensionless amplitude parameter, is small enough so that linear theory is a good approximation outside a thin critical layer. At high Reynolds numbers, however, we have shown that nonlinear effects cannot be neglected in this layer even if ε is very small. Whether nonlinearity or viscosity is dominant depends on the parameter $\lambda = 1/(Re\,\varepsilon^{3\beta})$, where $1/2 > \beta > 2/3$. It can be recognized that $\lambda^{1/3}$ is the ratio of the viscous to the nonlinear critical layer thickness, so the conditions for validity of the classical viscous theory are not only $\varepsilon \ll 1$ but $\varepsilon^{\beta} \ll Re^{-1}$ as well. This limits the role of the linear viscous theory to laboratory experiments, where the Reynolds number is much smaller than in such applications as aircraft trailing vortices.

In our analysis of the nonlinear critical layer, the similarities were noted between the helical modes on a vortex and the propagation of nonlinear waves in a stratified shear flow. This enabled us to benefit from the knowledge gained in studies of the latter. In particular, we know that the scaling and details of the matching depend very much on the value of J_c, the local Richardson number at the critical point (i.e., the equivalent local Richardson number defined in (2.8) above). There are three different regimes corresponding to J_c greater than $1/4$, J_c less than $1/4$, and finally $J_c \sim O(\varepsilon^{1/2})$. Even for the stratified shear flow critical layer, however, questions remain to be answered about the mean flow distortion because only the cases of $J_c \sim O(\varepsilon^{1/2})$ [21] and $J_c > 1/4$ [22] have been treated.

The system of four coupled PDEs that govern the nonlinear critical layer was derived in section 3, and these equations are the same in all three regimes. The matching conditions, however, are different in the three cases. We have focused primarily on the Richardson number less than $1/4$ case, but for some vortex profiles the case $J_c > 1/4$ may also be of interest, particularly if there is some external forcing. An analytical solution of the inviscid governing equations was found by the method of characteristics in section 3.1, and this solution shows that the problem is highly nonlinear. One measure of the nonlinearity is that within the critical layer, all the higher harmonics are the same order of magnitude as the fundamental perturbation mode. Another is that there are discontinuities in the mean flow, particularly in the axial velocity induced by the wave. While vortex sheets are often employed as models in inviscid fluid dynamics, in real flows a thin shear layer is present in which viscosity is required to smooth out the discontinuity.

An analysis of the case where Q_c, the vorticity, is small at the critical point [19] confirmed that both the azimuthal and axial vorticity components are different on either side of the critical layer. The complexity of that analysis made it clear that a numerical solution of equations (3.6) including viscosity, i.e., with $\lambda \sim O(1)$, would be desirable in order to avoid having to deal with higher order terms in both the inner and outer expansions. We have initiated such a study and have been successful in obtaining solutions of (3.6) for moderate values of λ. Dealing with small values, however, is a computational challenge that will be overcome only after we have devised a way to solve (3.6) and (3.7) as a boundary value problem. That means finding a way to impose the asymptotic behavior below the critical layer without knowing the phase change in advance, as was done by Haberman [26] for the unstratified parallel shear flow, where the singularity, being logarithmic, is not as strong.

To conclude, we address the question of observability of the nonlinear waves described in this paper, whether in the atmosphere, the laboratory, or in numerical simulations. The mathematical similarities to the corresponding stratified shear flow problem make this the obvious place to look for some idea of what might be expected. Stratified shear flows with nonlinear critical layers have a structure resembling radar observations of what meteorologists call Kelvin–Helmholtz billows (see section 3 of [20]). Despite the fact that these billows contain localized turbulent layers, the large scale coherence of the wave is maintained. However, in the laboratory it has not yet been possible to achieve large enough Reynolds numbers to compare with the theory. As a consequence, its greatest utility has been in numerical simulations, where structural details first revealed by the nonlinear critical layer theory appeared several years later in computational work (see section 5 of [12] and section 4.6 of [27]).

Despite the mathematical analogies, the physical context is sufficiently different that it is not clear to what extent experience with stratified shear flows can be extrapolated to the trailing vortex problem. In the latter case, even though the flow is often laminar in the vortex core, its environment and upstream history are such that it is likely to be turbulent elsewhere in an aircraft wake. Of course, nonlinear waves play a role in some turbulence theories, but it would be difficult to identify a nonlinear wave in observations because of the danger in making detailed measurements. Numerical simulations are a possibility, but the Reynolds numbers are too low in computations reported to date. It would appear, therefore, that experiments offer the most promise. The paper by Delisi and Robins [28] reports an investigation to determine the effect of stratification on the trajectory of a pair of vortices. There is a table in their paper giving the Reynolds numbers for experiments reported in several papers. These are all large enough so that with only a slight forcing, a wave could be generated satisfying the requirements of our theory, and such experiments are currently under consideration. Suppose we consider a small perturbation with $\varepsilon = 0.03$ at the value $Re = 2.5 \cdot 10^4$ of the experiments in [28]. The calculation is not sensitive to the value of β; using $J_c = 0.09$ to compute β, we find that $\lambda = 0.01$, which is clearly in the nonlinear critical layer regime.

Appendix: Variation of the Reynolds stress. It is well known in hydrodynamic stability theory that valuable information about neutral modes can be obtained by evaluating the Reynolds stress for an unstable perturbation and then taking the limit as the growth rate tends to zero. From the energy equation for an unstable perturbation, as discussed in the review article by Stuart [29], it can be seen that the energy exchange between the mean flow and the perturbation is given by the integral

$$E = -\int_0^{r_1} \bar{\Omega}'(r)\, \overline{U_r U_\theta}\, r^2\, dr,$$

where the Reynolds stress $\tau = -\overline{U_r U_\theta}$. In this appendix we use capital letters for the velocity fluctuations, as in most texts on turbulence. The overline signifies an average over one wavelength in ξ, and we write the radial perturbation velocity as

$$U_r = \hat{U}_r\,(r)\, e^{i\,\xi} + \hat{U}_r^*\,(r)\, e^{-\,i\,\xi},$$

where $*$ indicates the complex conjugate.

The complex amplitude $\hat{U}_r$ is a combination of the two Frobenius solutions

$$\hat{U}_r = AX^+(r) + BX^-(r),$$

where X^+ and X^- are identical to the series $u_\pm$ in (2.6) and (2.7) above. The reason for changing our notation is to agree with that used by Miles [18] in order to permit comparison with his very similar development for stratified shear flows. One small difference is that, owing to the cylindrical geometry, the lower limit of our domain is $r = 0$.

In order to compute τ, the Reynolds stress, we need an expression for $\hat{U}_\theta\,(r)$. The system (2.3) yields a simple relationship between $\hat{U}_\theta\,(r)$ and $\hat{U}_r\,(r)$, namely,

$$\hat{U}_\theta = S\left[k^2\frac{Q}{\gamma} + \frac{m}{r}\,D_*\right]\hat{U}_r.$$

Using this expression now for $\hat{U}_\theta$, the Reynolds stress can be expressed in terms of the Frobenius solutions as follows:

$$\begin{aligned}\tau &= 2S(r)\frac{m}{r}\,\mathrm{Im}\Big[\hat{U}_r'\hat{U}_r^*\Big]\\ &= 2S(r)\frac{m}{r}\,\mathrm{Im}\Big[|A|^2X^{*+}X^{'+} + |B|^2X^{*-}X^{'-} + A^*BX^{*+}X^{'-} + AB^*X^{*-}X^{'+}\Big].\end{aligned}$$

The differential equation satisfied by the Reynolds stress is

$$\begin{aligned}\frac{d\tau}{dr} &= 2mD\left(\frac{S(r)}{r}\right)\mathrm{Im}(\hat{U}_r'\hat{U}_r^*) - 2\frac{m}{r}S(r)\,\mathrm{Im}\Big[\hat{U}_r''\hat{U}_r^*\Big] = -4m\frac{S(r)}{r^2}\,\mathrm{Im}\Big[\hat{U}_r'\hat{U}_r^*\Big]\\ &= -2\,\frac{\tau}{r}, \quad \text{which is readily integrated to obtain} \quad \tau(r) = \frac{\tau_0}{r^2}.\end{aligned}$$

The r^{-2} behavior of τ contrasts with the case of a parallel shear flow, where $\tau =$ *const.*; however, in both cases we must consider the possibility of the constant being discontinuous across r_c, as in the case of the Blasius boundary layer, for example.

For the vortices that are of primary interest in this paper, $\tau_0 = 0$ for $r < r_c$, because the Reynolds stress must be finite at $r = 0$. And, with the exception of the limiting case $J_c \to 0$, the Frobenius solutions (2.7) show that $\tau = 0$ at the critical point. Therefore, we must also have $\tau_0 = 0$ for $r > r_c$. If J_c is less than 1/4, the Reynolds stress near the critical point is given by

$$-\overline{U_rU_\theta} = 2\nu m r_c\frac{S(r_c)}{r^2}\,\mathrm{Im}[AB^*], \qquad r > r_c,$$

$$\text{and} \qquad -\overline{U_rU_\theta} = 2\nu m r_c\frac{S(r_c)}{r^2}\,\mathrm{Im}[AB^*\,e^{-i\pi(1+\nu)}], \qquad r < r_c.$$

It follows that either $A = 0$ or $B = 0$, as was shown by Miles for stratified shear flows.

For $J_c > 1/4$, on the other hand, the corresponding expressions are

$$-\overline{U_rU_\theta} = -\mu m r_c\frac{S(r_c)}{r^2}(|B|^2 - |A|^2), \qquad r > r_c,$$

$$\text{and} \qquad -\overline{U_rU_\theta} = -\mu m r_c\frac{S(r_c)}{r^2}(|A|^2e^{\pi\mu} - |B|^2e^{-\pi\mu}), \qquad r < r_c,$$

where $\mu = (4\,J_c - 1)^{1/2}$. The stress is zero when $|B| = |A|\,e^{\pi\mu}$. Finally, if there is no phase change, as is the case when the critical layer is nonlinear, the constants A and B are real, so a neutral mode can be a linear combination of both Frobenius solutions.

Acknowledgments. The authors are indebted to Stéphane LeDizès for suggesting this investigation and to Philippe Caillol and Dominique Perrault-Joncas for assistance in carrying out parts of the analysis and computation. Thomas Leweke has been most helpful in sharing with us his expertise on aircraft trailing vortices.

PARTIALLY REFLECTED DIFFUSION*

A. SINGER[†], Z. SCHUSS[‡], A. OSIPOV[§], and D. HOLCMAN[¶]

Abstract. The radiation (reactive or Robin) boundary condition for the diffusion equation is widely used in chemical and biological applications to express reactive boundaries. The underlying trajectories of the diffusing particles are believed to be partially absorbed and partially reflected at the reactive boundary; however, the relation between the reaction constant in the Robin boundary condition and the reflection probability is not well defined. In this paper we define the partially reflected process as a limit of the Markovian jump process generated by the Euler scheme for the underlying Itô dynamics with partial boundary reflection. Trajectories that cross the boundary are terminated with probability $P\sqrt{\Delta t}$ and otherwise are reflected in a normal or oblique direction. We use boundary layer analysis of the corresponding master equation to resolve the nonuniform convergence of the probability density function of the numerical scheme to the solution of the Fokker–Planck equation in a half-space, with the Robin constant κ. The boundary layer equation is of the Wiener–Hopf type. We show that the Robin boundary condition is recovered if and only if trajectories are reflected in the conormal direction $\boldsymbol{\sigma n}$, where $\boldsymbol{\sigma}$ is the (possibly anisotropic) constant diffusion matrix and $\boldsymbol{n}$ is the unit normal to the boundary. Otherwise, the density satisfies an oblique derivative boundary condition. The constant κ is related to P by $\kappa = rP\sqrt{\sigma_n}$, where $r = 1/\sqrt{\pi}$ and $\sigma_n = \boldsymbol{n}^T\boldsymbol{\sigma n}$. The reflection law and the relation are new for diffusion in higher dimensions.

1. Introduction.

The Fokker–Planck equation (FPE) with radiation (also called reactive or Robin) boundary conditions is widely used to describe diffusion in a biological cell with chemical reactions on its surface [1], [2], [3], [4], [5], [6], [7], [8], [9]. The Robin boundary conditions are used in [2], [4], [5], [6] as a homogenization of mixed Dirichlet–Neumann boundary conditions given on scattered small absorbing windows in an otherwise reflecting boundary. The mixed boundary conditions may represent, e.g., ligand binding or pumping out ions at sites on the boundary of a biological cell and no flux through the remaining boundary. The reactive rate constant in the Robin boundary conditions is chosen in the homogenization process so that the decay rate of the survival probability is the same as that in the mixed Dirichlet–Neumann boundary value problem.

The definition of the Itô stochastic dynamics

$$\dot{x} = a(x,t) + \sqrt{2\sigma(x,t)}\,\dot{w} \tag{1.1}$$

on the positive axis with total or partial reflection at the origin was given first by Feller [10] for the one-dimensional case with $a(x,t)$ and $\sigma(x,t)$ independent of t, as a limit of Itô processes, which are terminated when they reach the boundary or moved instantaneously to a point $x=\rho_j>0$ with probability p_j. When $p_j\to 1$ and $\rho_j\to 0$ with

$$\lim_{j\to\infty}\frac{1-p_j}{\rho_j}=c, \tag{1.2}$$

where c is a constant, the partially reflected process converges to a limit. The transition probability density function (pdf) of the limit process, $p(y,t\,|\,x,s)\,dy=\Pr\{x(t)\in(y,y+dy)\mid x(s)=x\}$, is the solution of the FPE

$$\frac{\partial p(y,t\,|\,x,s)}{\partial t}=-\frac{\partial[a(y,t)p(y,t\,|\,x,s)]}{\partial y}+\frac{\partial^2[\sigma(y,t)p(y,t\,|\,x,s)]}{\partial y^2} \tag{1.3}$$

or, equivalently,

$$\frac{\partial p(y,t\,|\,x,s)}{\partial t}=-\frac{\partial J(y,t\,|\,x,s)}{\partial y}\quad\text{for all}\quad y,x>0,$$

where

$$J(y,t\,|\,x,s)=a(y,t)p(y,t\,|\,x,s)-\frac{\partial[\sigma(y,t)p(y,t\,|\,x,s)]}{\partial y}, \tag{1.4}$$

is the flux. The initial condition is

$$p(y,t\,|\,x,s)\to\delta(y-x)\quad\text{as}\quad t\downarrow s, \tag{1.5}$$

and the radiation boundary condition is

$$-J(0,t\,|\,x,s)=\kappa p(0,t\,|\,x,s), \tag{1.6}$$

where κ is a constant related to the constant c and to the values of the coefficients at the boundary. The no flux and Dirichlet boundary conditions are recovered if $c=0$ or $c=\infty$, respectively. Feller's method does not translate into a Brownian dynamics simulation of the limit process, because his approximations are continuous-time Itô processes. Skorokhod [11] defines the reflection process inside the boundary. Several numerical schemes have been proposed for simulating this process (see, e.g., [11], [12], [13], [14]). The main issue there is to approximate the local time spent on the boundary.

The definition of a diffusion process with absorbing or reflecting boundaries as limits of Markovian jump processes, which is the basis for all simulations, gives in the limit diffusion processes with well-defined boundary behavior. However, the definition of a diffusion process with partially reflecting boundaries as a limit of Markovian jump processes gives different diffusions for different jump processes. This is expressed in different relations between the termination probability of the jump process and the boundary conditions for the FPEs (see, e.g., [8]). The process $x(t)$ defined by (1.1) with partially absorbing boundaries can be defined as the limit of the solutions of the Markovian jump processes generated by the Euler scheme

$$x_{\Delta t}(t+\Delta t)=x_{\Delta t}(t)+a(x_{\Delta t}(t),t)\Delta t+\sqrt{2\sigma(x_{\Delta t}(t),t)}\,\Delta w(t,\Delta t)\quad\text{for}\quad t\geq s, \tag{1.7}$$

$$x_{\Delta t}(s)=x \tag{1.8}$$

in the interval $x > 0$, for $0 \leq t - s \leq T$, with $\Delta t = T/N$, $t - s = iT/N$ ($i = 0, 1, \ldots, N$), where for each t the random variables $\Delta w(t, \Delta t)$ are normally distributed and independent with zero mean and variance Δt. The partially absorbing boundary condition for (1.7) has to be chosen so that the pdf $p_{\Delta t}(x, t)$ of $x_{\Delta t}(t)$ converges to the solution of (1.3)–(1.6). At a partially reflecting boundary for (1.7), the trajectories are reflected with probability (w.p.) R and otherwise terminated (absorbed), once they cross the origin. We show below that keeping R constant (e.g., $R = 1/2$) as $\Delta t \to 0$ leads to the convergence of the pdf $p_{\Delta t}(x, t)$ to the solution of the FPE with an absorbing rather than the Robin boundary condition. Thus the reflection probability R must increase to 1 as $\Delta t \to 0$ in order to yield the Robin condition (1.6). Moreover, the reactive constant κ is related to the limit

$$\lim_{\Delta t \to 0} \frac{1 - R}{\sqrt{\Delta t}} = P. \tag{1.9}$$

The reflecting boundary condition is recovered for $P = 0$, while the absorbing boundary condition is obtained for $P = \infty$. Motivated by these considerations, we design the following simple boundary behavior for the simulated trajectories that cross the boundary, identified by $x_{\Delta t}(t) + a(x_{\Delta t}(t), t)\Delta t + \sqrt{2\sigma(x_{\Delta t}(t), t)}\,\Delta w < 0$:

(1.10)
$$x_{\Delta t}(t + \Delta t) = \begin{cases} -(x_{\Delta t}(t) + a(x_{\Delta t}(t), t)\Delta t + \sqrt{2\sigma(x_{\Delta t}(t), t)}\,\Delta w) & \text{w.p. } 1 - P\sqrt{\Delta t}, \\ \text{terminate trajectory otherwise.} \end{cases}$$

The exiting trajectory is normally reflected w.p.

$$R = 1 - P\sqrt{\Delta t} \tag{1.11}$$

and is otherwise terminated (absorbed). The scaling of the termination probability with $\sqrt{\Delta t}$ reflects the fact that the discrete unidirectional diffusion current at any point, including the boundary, is $O(1/\sqrt{\Delta t})$ (see [15], [16]). This means that the number of discrete trajectories hitting or crossing the boundary in any finite time interval increases as $1/\sqrt{\Delta t}$. Therefore, to keep the efflux of trajectories finite as $\Delta t \to 0$, the termination probability of a crossing trajectory, $1 - R$, has to be $O(\sqrt{\Delta t})$. The pdf $p_{\Delta t}(x, t)$, however, does not converge to the solution $p(x, t)$ of (1.3)–(1.6) on the boundary, as discussed in section 2. This is due to the formation of a boundary layer, as is typical for diffusion approximations of Markovian jump processes that jump over the boundary [17], [18], [19]. The boundary layer equations are typically Wiener–Hopf integral equations. The Wiener–Hopf boundary layer equation for the particular case of a partially reflected Brownian motion on the positive axis (i.e., $a(x, t) = 0$ and $\sigma(x, t) = \sigma$ in (1.7)) was recently solved in [8], and the relationship $\kappa = P\sqrt{\sigma}/\sqrt{\pi}$ was found.

The convergence of the pdf of an Euler scheme has been studied in [20], [21] for the higher-dimensional problem with oblique reflection. Bounds on the integral norm of the approximation error are given for the solution of the backward Kolmogorov equation. These, however, do not resolve the boundary layer of the pdf of the numerical solution. The solution of the forward equation for the Euler scheme converges nonuniformly to the solution of the FPE due to the appearance of a boundary layer in the first order spatial derivative. This distorts the boundary flux and gives incorrect boundary conditions. A boundary layer expansion is needed to capture the boundary phenomena.

The derivation of the radiation condition has a long history. Collins and Kimball [22] (see also [23]) derived the radiation boundary condition (1.6) for the limit $p(x,t) = \lim_{\Delta t\to 0} p_{\Delta t}(x,t)$ from an underlying discrete random walk model on a semi-infinite one-dimensional lattice with partial absorption at the endpoint. Their model assumes constant diffusion coefficient and vanishing drift, for which they find the reactive constant in terms of the absorption probability and the diffusion coefficient. Previous simulation schemes that recover the Robin boundary condition [1], [24], [25], [26], [27] make use of the explicit solution to the half-space FPE with linear drift term and constant diffusion coefficient with a Robin condition. In [28] and the references therein, the specular reflection method near a reflecting boundary has been shown to be superior to other methods such as rejection, multiple rejection, and interruption.

An apparent paradox arises when using (1.7) and other schemes: while the pdf $p_{\Delta t}(y,t\,|\,x,s)$ of the solution of (1.7), (1.8), (1.10), (1.11) converges to the solution of the FPE (1.3) and the initial condition (1.5), each approximant $p_{\Delta t}(y,t\,|\,x,s)$ does not satisfy the boundary condition (1.6), not even approximately; that is, the error does not decay as $\Delta t \to 0$. For a general diffusion coefficient and drift term, the boundary condition is not satisfied even for the case of a reflecting boundary condition. This problem plagues other schemes as well. The apparent paradox is due to the nonuniform convergence of $p_{\Delta t}(y,t\,|\,x,s)$ to the solution $p(y,t\,|\,x,s)$ of the FPE, caused by a boundary layer in $p_{\Delta t}(y,t\,|\,x,s)$, as is typical of boundary behavior of diffusion approximations to Markovian jump processes. The limit $p(y,t\,|\,x,s)$, however, satisfies the boundary condition (1.6) for some κ. Our analysis can be extended to other schemes in a straightforward way. It is well known that the Euler scheme produces an $O(\sqrt{\Delta t})$ error in estimating the mean first passage time to reach an absorbing boundary. There are several recipes to reduce the discretization error to $O(\Delta t)$ [29], [30], [31], [32], [33]. Another manifestation of the boundary layer is that the approximation error of the pdf near absorbing or reflecting boundaries is $O(\sqrt{\Delta t})$, and some methods, including [1], [34], reduce this error to $O(\Delta t)$. Thus, we expect the formation of a boundary layer of size $O(\sqrt{\Delta t})$ for the Euler scheme (1.7) with the boundary behavior (1.10).

This paper is concerned with the convergence of the partially reflecting Markovian jump process generated by (1.7), (1.10) in one and higher dimensions. We show that this scheme, with the additional requirement that the pdf converges to the solution of the FPE with a given Robin boundary condition, defines a unique diffusion process with partial reflection at the boundary. This definition is then generalized to higher dimensions. In contrast to Collins and Kimball's [22] discrete scheme, this definition is not restricted to lattice points, and the drift and diffusion coefficients may vary. The advantage of the current suggested design (1.10) is its simplicity, which is both easily and efficiently implemented and amenable to analysis. There is no need to make any assumptions on the structure of the diffusion coefficient or the drift. From the theoretical point of view, it serves as a physical interpretation for the behavior of diffusive trajectories near a reactive boundary.

Our main result in the one-dimensional case is the relation between the reactive "constant" $\kappa(t)$ and the absorption parameter P for the dynamics (1.1) on the positive axis with drift and with a variable diffusion coefficient,

$$\kappa(t) = rP\sqrt{\sigma(0,t)}, \quad r = \frac{1}{\sqrt{\pi}}. \tag{1.12}$$

The relation (1.12) is new for diffusion with variable coefficients. The value $r = 1/\sqrt{\pi}$ is different from values obtained for other schemes, e.g., from the value $r = 1/\sqrt{2}$, predicted by the discrete random walk theory of radiation boundaries [22]. Values of r for other schemes are given in [8]. We show the effect of using (1.12) in numerical simulations.

The scheme (1.10) is generalized to diffusion with drift and anisotropic constant diffusion matrix $\boldsymbol{\sigma}(t)$ in the half-space, $x_1 > 0$, with partial oblique reflection. We show that the Robin boundary condition is recovered if and only if trajectories are reflected in the direction of the unit vector

$$\boldsymbol{v} = \frac{\boldsymbol{\sigma n}}{\|\boldsymbol{\sigma n}\|}, \tag{1.13}$$

where $\boldsymbol{n}$ is the unit normal to the boundary. The radiation parameter $\kappa(\boldsymbol{x}, t)$ in the d-dimensional Robin boundary condition and the absorption parameter $P(\boldsymbol{x})$ are related by

$$\kappa(\boldsymbol{x}, t) = rP(\boldsymbol{x})\sqrt{\sigma_n(t)}, \quad x_1 = 0, \tag{1.14}$$

with r given in (1.12) and $\sigma_n(t) = \boldsymbol{n}^T\boldsymbol{\sigma}(t)\boldsymbol{n}$. The relation (1.14) is new for higher-dimensional diffusion in a half-space with drift and anisotropic diffusion matrix.

In the most common case of constant isotropic diffusion our result extends to domains with curved boundaries. This is due to the fact that a smooth local mapping of the domain to a half-space with an orthogonal system of coordinates preserves the constant isotropic diffusion matrix, though the drift changes according to Itô's formula. In this case the vector $\boldsymbol{v}$ coincides with the normal $\boldsymbol{n}$.

2. Boundary layer analysis in one dimension.

The aim of the boundary layer analysis below is to examine the convergence of the pdf $p_{\Delta t}(y, t \,|\, x, s)$ of the solution $x_{\Delta t}(t)$ of (1.7), (1.8) to the solution $p(y, t \,|\, x, s)$ of (1.3)–(1.6), and to find the relation between the parameter P of (1.10) and the reactive constant κ in (1.6). Using abbreviated notation, the pdf $p_{\Delta t}(y, t \,|\, x, s) = p_{\Delta t}(y, t)$ satisfies the forward Kolmogorov equation [15], [16], [17], [18], [19], [35]

$$\begin{aligned} p_{\Delta t}(y, t + \Delta t) = \int_0^\infty \frac{p_{\Delta t}(x, t)}{\sqrt{4\pi\sigma(x, t)\Delta t}} &\left\{ \exp\left[-\frac{(y - x - a(x, t)\Delta t)^2}{4\sigma(x, t)\Delta t} \right] \right. \\ &\left. + (1 - P\sqrt{\Delta t}) \exp\left[-\frac{(y + x + a(x, t)\Delta t)^2}{4\sigma(x, t)\Delta t} \right] \right\} dx. \end{aligned} \tag{2.1}$$

For $P = 0$ the pdf $p_{\Delta t}(y, t)$ satisfies the boundary condition

$$\frac{\partial p_{\Delta t}(0, t)}{\partial y} = 0, \tag{2.2}$$

which is obtained by differentiation of (2.1) with respect to y at $y = 0$. If $P \neq 0$, we obtain

$$\frac{\partial p_{\Delta t}(0, t + \Delta t)}{\partial y} = \frac{p_{\Delta t}(0, t)P}{\sqrt{4\pi\sigma(0, t)}} + O(\sqrt{\Delta t}), \tag{2.3}$$

which holds also in the limit $\Delta t \to 0$. However, the order of the limits $\Delta t \to 0$ and $y \downarrow 0$ matters; indeed,

$$\lim_{\Delta t \to 0} \lim_{y \downarrow 0} \frac{\partial p_{\Delta t}(y, t)}{\partial y} \neq \lim_{y \downarrow 0} \lim_{\Delta t \to 0} \frac{\partial p_{\Delta t}(y, t)}{\partial y}. \tag{2.4}$$

The limit of (2.3) is not the boundary condition that the limit function $p(y,t) = \lim_{\Delta t\to 0} p_{\Delta t}(y,t)$ (for $y > 0$) satisfies. To find the boundary condition of $p(y,t)$, in either case $P = 0$ or $P \neq 0$, we show below that $p(y,t)$ satisfies the FPE (1.3) and the initial condition (1.5) for all $y > 0$. Since for $P = 0$ the simulation preserves probability (the population of trajectories),

$$0 = \frac{d}{dt}\int_0^\infty p(x,t)\,dx = -\frac{\partial[\sigma(0,t)p(0,t)]}{\partial y} + a(0,t)p(0,t) = J(0,t). \tag{2.5}$$

Equation (2.5) is the no flux boundary condition. The discrepancy between (2.5) and (2.2) is due to the nonuniform convergence of $p_{\Delta t}(y,t)$ to its limit $p(y,t)$ in the interval. There is a boundary layer of width $O(\sqrt{\Delta t})$, in which the boundary condition (2.2) for $p_{\Delta t}(y,t)$ changes into the boundary condition (2.5) that $p(y,t)$ satisfies. To analyze the discrepancy between (2.2) and (2.5), we introduce the local variable $y = \eta\sqrt{\Delta t}$ and the boundary layer solution

$$p_{BL}(\eta,t) = p_{\Delta t}(\eta\sqrt{\Delta t},t). \tag{2.6}$$

Changing variables $x = \xi\sqrt{\Delta t}$ in the integral (2.1) gives

$$\begin{aligned} p_{BL}(\eta,t+\Delta t) = \int_0^\infty \frac{p_{BL}(\xi,t)}{\sqrt{4\pi\sigma(\xi\sqrt{\Delta t},t)}} &\left\{ \exp\left[-\frac{\left(\eta-\xi-a(\xi\sqrt{\Delta t},t)\sqrt{\Delta t}\right)^2}{4\sigma(\xi\sqrt{\Delta t},t)}\right]\right. \\ &\left. + (1-P\sqrt{\Delta t})\exp\left[-\frac{\left(\eta+\xi+a(\xi\sqrt{\Delta t},t)\sqrt{\Delta t}\right)^2}{4\sigma(\xi\sqrt{\Delta t},t)}\right]\right\} d\xi. \end{aligned} \tag{2.7}$$

The boundary layer solution has an asymptotic expansion in powers of $\sqrt{\Delta t}$:

$$p_{BL}(\eta,t) \sim p_{BL}^{(0)}(\eta,t) + \sqrt{\Delta t}\,p_{BL}^{(1)}(\eta,t) + \Delta t\,p_{BL}^{(2)}(\eta,t) + \cdots. \tag{2.8}$$

Expanding all functions in (2.7) in powers of $\sqrt{\Delta t}$ and equating similar orders, we obtain integral equations that the asymptotic terms of (2.8) must satisfy. The leading order $O(1)$ term gives the Wiener–Hopf-type equation on the half-line

$$p_{BL}^{(0)}(\eta,t) = \int_0^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\left\{\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right] + \exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\} d\xi \tag{2.9}$$

for $\eta > 0$. The kernel

$$K(\eta,\xi) = \exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right] + \exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right] \tag{2.10}$$

is an even function of η and ξ; i.e., $K(\eta,\xi) = K(-\eta,\xi) = K(\eta,-\xi) = K(-\eta,-\xi)$. Therefore, we extend $p_{BL}^{(0)}(\xi,t)$ to the entire line as an even function ($p_{BL}^{(0)}(\xi,t) = p_{BL}^{(0)}(-\xi,t)$) and rewrite (2.9) as

$$p_{BL}^{(0)}(\eta,t) = \int_{-\infty}^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right] d\xi \tag{2.11}$$

for $-\infty < \eta < \infty$. The only solution of the integral equation (2.11) is the constant function, that is, $p^{(0)}_{BL}(\eta,t) = f(t)$, independent of η. This follows immediately from the Fourier transform of (2.11), whose right-hand side is a convolution.

Away from the boundary layer the solution admits an outer solution expansion

$$p_{OUT}(y,t) \sim p^{(0)}_{OUT}(y,t) + \sqrt{\Delta t} p^{(1)}_{OUT}(y,t) + \cdots , \tag{2.12}$$

where $p^{(0)}_{OUT}$ satisfies the Fokker–Planck equation (1.3) and the initial condition (1.5). Indeed, the integrals in (2.1) are of Laplace type with the small parameter Δt. For interior points $y \gg \sqrt{\Delta t}$, the second integral, which represents only boundary interactions, is negligible relative to the first. We change variables in (2.1) by setting

$$\eta = \frac{y - x - a(x,t)\Delta t}{\sqrt{2\sigma(x,t)\Delta t}},$$

and extend integration over the entire line in the first integral and expand all functions in powers of $\sqrt{\Delta t}$. The resulting integrals are moments of the normal distribution. We obtain

$$\frac{p_{\Delta t}(y,t+\Delta t) - p_{\Delta t}(y,t)}{\Delta t} = -\frac{\partial[a(y,t)p_{\Delta t}(y,t)]}{\partial y} + \frac{\partial^2[\sigma(y,t)p_{\Delta t}(y,t)]}{\partial y^2} + O(\sqrt{\Delta t}).$$

The leading term in the expansion of $p_{\Delta t}(y,t)$ is $p^{(0)}_{OUT}(y,t)$, which therefore satisfies the Fokker–Planck equation (1.3). The initial condition (1.5) is recovered from the Gaussian integral as $\Delta t \to 0$. The boundary condition that $p^{(0)}_{OUT}(y,t)$ satisfies can be determined only after the boundary layer is resolved by matching. The leading order matching condition of the boundary layer and the outer solutions is

$$\lim_{\eta\to\infty} p^{(0)}_{BL}(\eta,t) = p^{(0)}_{OUT}(0,t).$$

Therefore

$$p^{(0)}_{BL}(\eta,t) = p^{(0)}_{OUT}(0,t). \tag{2.13}$$

The matching condition at order $\sqrt{\Delta t}$ gives

$$\eta \frac{\partial p^{(0)}_{OUT}(0,t)}{\partial y} + p^{(1)}_{OUT}(0,t) \sim p^{(1)}_{BL}(\eta,t) \quad \text{for} \quad \eta \to \infty,$$

which means that $p^{(1)}_{BL}(\eta,t)$ is asymptotically a linear function of η; therefore the limit of its derivative is a constant. Thus the matching condition reduces to

$$\lim_{\eta\to\infty} \frac{\partial p^{(1)}_{BL}(\eta,t)}{\partial \eta} = \frac{\partial p^{(0)}_{OUT}(0,t)}{\partial y}. \tag{2.14}$$

The first order boundary layer term satisfies the integral equation

(2.15)

$$p^{(1)}_{BL}(\eta,t) = \int_0^\infty \frac{p^{(1)}_{BL}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}} \left\{ \exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right] + \exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right] \right\} d\xi$$

$$
\begin{aligned}
&- P\int_0^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]d\xi\\
&- \frac{\sigma_y(0,t)}{2\sigma(0,t)}\int_0^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\,\xi\left\{\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]+\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi\\
&+ \frac{\sigma_y(0,t)}{4\sigma(0,t)^2}\int_0^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\,\xi\left\{(\eta-\xi)^2\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]+(\eta+\xi)^2\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi\\
&+ \frac{2a(0,t)}{4\sigma(0,t)}\int_0^\infty \frac{p_{BL}^{(0)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\left\{(\eta-\xi)\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]-(\eta+\xi)\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi.
\end{aligned}
$$

Evaluating explicitly the last four integrals in (2.15) and using (2.13) gives

$$
\begin{aligned}
p_{BL}^{(1)}(\eta,t) = {}&\int_0^\infty \frac{p_{BL}^{(1)}(\xi,t)}{\sqrt{4\pi\sigma(0,t)}}\left\{\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]+\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi\\
&- \frac{P}{2}\,p_{OUT}^{(0)}(0,t)\operatorname{erfc}\left(\frac{\eta}{2\sqrt{\sigma(0,t)}}\right)\\
&+ \frac{\sigma_y(0,t)-a(0,t)}{\sqrt{\pi\sigma(0,t)}}p_{OUT}^{(0)}(0,t)\exp\left[-\frac{\eta^2}{4\sigma(0,t)}\right].
\end{aligned}
\tag{2.16}
$$

Differentiating (2.16) with respect to η and integrating by parts, we obtain

$$
\begin{aligned}
\frac{\partial p_{BL}^{(1)}(\eta,t)}{\partial\eta} = {}&\frac{1}{\sqrt{4\pi\sigma(0,t)}}\int_0^\infty \frac{\partial p_{BL}^{(1)}(\xi,t)}{\partial\eta}\left\{\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]-\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi\\
&+ \frac{P}{2\sqrt{\pi\sigma(0,t)}}\,p_{OUT}^{(0)}(0,t)\exp\left[\frac{-\eta^2}{4\sigma(0,t)}\right]-\frac{\sigma_y(0,t)-a(0,t)}{2\sqrt{\pi}\,\sigma(0,t)^{3/2}}p_{OUT}^{(0)}(0,t)\,\eta\exp\left[\frac{-\eta^2}{4\sigma(0,t)}\right].
\end{aligned}
\tag{2.17}
$$

Setting

$$
g(\eta,t)=\frac{\partial p_{BL}^{(1)}(\eta,t)}{\partial\eta}-\frac{P}{2\sqrt{\pi\sigma(0,t)}}\,p_{OUT}^{(0)}(0,t)\exp\left[-\frac{\eta^2}{4\sigma(0,t)}\right],
\tag{2.18}
$$

we rewrite (2.17) as

$$
g(\eta,t)=\phi(\eta,t)+\frac{1}{\sqrt{4\pi\sigma(0,t)}}\int_0^\infty g(\xi,t)\left\{\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]-\exp\left[-\frac{(\eta+\xi)^2}{4\sigma(0,t)}\right]\right\}d\xi,
\tag{2.19}
$$

where

$$
\begin{aligned}
\phi(\eta,t) = {}&\frac{P}{\sqrt{8\pi\sigma(0,t)}}\,p_{OUT}^{(0)}(0,t)\exp\left[\frac{-\eta^2}{8\sigma(0,t)}\right]\operatorname{erf}\left(\frac{\eta}{\sqrt{8\sigma(0,t)}}\right)\\
&- \frac{\sigma_y(0,t)-a(0,t)}{2\sqrt{\pi}\,\sigma(0,t)^{3/2}}p_{OUT}^{(0)}(0,t)\,\eta\exp\left[\frac{-\eta^2}{4\sigma(0,t)}\right].
\end{aligned}
\tag{2.20}
$$

Since $\phi(\eta,t)$ is an odd function of η, we can define $g(\eta,t)$ for negative values as an odd function by setting $g(\eta,t)=-g(-\eta,t)$ for $\eta<0$. Then (2.19) can be rewritten as

$$
g(\eta,t)=\phi(\eta,t)+\frac{1}{\sqrt{4\pi\sigma(0,t)}}\int_{-\infty}^\infty g(\xi,t)\exp\left[-\frac{(\eta-\xi)^2}{4\sigma(0,t)}\right]d\xi,
\tag{2.21}
$$

which in Fourier space is

$$\hat{g}(k,t) = \frac{\hat{\phi}(k,t)}{1-\exp[-\sigma(0,t)k^2]}. \tag{2.22}$$

Using the Wiener–Hopf method, we decompose

$$\hat{g}(k,t) = \hat{g}_+(k,t) + \hat{g}_-(k,t), \tag{2.23}$$

where $g_+(\eta) = g(\eta)\chi_{[0,\infty)}(\eta)$, $g_-(\eta) = g(\eta)\chi_{(-\infty,0]}(\eta)$. The Fourier transform $\hat{g}(k,t)$ exists in the sense of distributions, and $\hat{g}_\pm(k,t)$ are analytic in the upper and lower halves of the complex plane, respectively. Taylor's expansion of $\hat{\phi}(k,t)$ in (2.20) gives

$$\hat{\phi}(k,t) = 2ip^{(0)}_{OUT}(0,t)\left\{\frac{P\sqrt{\sigma(0,t)}}{\sqrt{\pi}} - [\sigma_y(0,t) - a(0,t)]\right\}k + O(k^3) \quad \text{as} \quad k \to 0. \tag{2.24}$$

The nonzero poles of (2.22) split evenly between $\hat{g}_+(k,t)$ and $\hat{g}_-(k,t)$, and using $\hat{g}_+(k,t) = -\hat{g}_-(-k,t)$, the pole at the origin gives

$$\hat{g}_+(k,t) = ip^{(0)}_{OUT}(0,t)\left\{\frac{P}{\sqrt{\pi\sigma(0,t)}} - \frac{\sigma_y(0,t) - a(0,t)}{\sigma(0,t)}\right\}\frac{1}{k} + O(k) \quad \text{as} \quad k \to 0. \tag{2.25}$$

Inverting the Fourier transform $\hat{g}_+(k,t)$, by closing the contour of integration around the lower half-plane, we obtain

$$\lim_{\eta\to\infty} \frac{\partial p^{(1)}_{BL}(\eta,t)}{\partial\eta} = p^{(0)}_{OUT}(0,t)\left\{\frac{P}{\sqrt{\pi\sigma(0,t)}} - \frac{\sigma_y(0,t) - a(0,t)}{\sigma(0,t)}\right\}. \tag{2.26}$$

The matching condition (2.14) implies

$$\frac{\partial p^{(0)}_{OUT}(0,t)}{\partial y} = p^{(0)}_{OUT}(0,t)\left\{\frac{P}{\sqrt{\pi\sigma(0,t)}} - \frac{\sigma_y(0,t) - a(0,t)}{\sigma(0,t)}\right\}. \tag{2.27}$$

Multiplying by $\sigma(0,t)$ and rearranging, we obtain the radiation boundary condition

$$-J(0,t) = \frac{\partial}{\partial y}\left[\sigma(0,t)p^{(0)}_{OUT}(0,t)\right] - a(0,t)p^{(0)}_{OUT}(0,t) = \frac{P\sqrt{\sigma(0,t)}}{\sqrt{\pi}}p^{(0)}_{OUT}(0,t). \tag{2.28}$$

Since $p(y,t) = p^{(0)}_{OUT}(y,t)$, the reactive "constant" in (1.6) is

$$\kappa(t) = \frac{P\sqrt{\sigma(0,t)}}{\sqrt{\pi}}. \tag{2.29}$$

3. Numerical simulations in one dimension.

The explicit analytical solution of the FPE (1.3) with the initial condition (1.5) and the radiation boundary condition (1.6) for the case of vanishing drift ($a = 0$) and constant diffusion coefficient ($\sigma(x,t) = \sigma$) was first given by Bryan in 1891 [36] (see [37, sect. 14.2, p. 358]):

$$\begin{aligned} p(x,t\,|\,x_0) = {}& \frac{1}{\sqrt{4\pi\sigma t}}\left[\exp\left\{-\frac{(x-x_0)^2}{4\sigma t}\right\} + \exp\left\{-\frac{(x+x_0)^2}{4\sigma t}\right\}\right] \\ & - \frac{\kappa}{\sigma}\exp\left\{\frac{\kappa(x+x_0+\kappa t)}{\sigma}\right\}\operatorname{erfc}\left[\frac{x+x_0+2\kappa t}{\sqrt{4\sigma t}}\right]. \end{aligned} \tag{3.1}$$

The first term in (3.1) is the fundamental solution of (1.3) and (1.5) with a reflecting boundary condition, whereas the second term may be transformed into

$$-\frac{\kappa}{\sqrt{\pi\sigma^3 t}}\int_0^\infty \exp\left\{-\frac{\kappa\xi}{\sigma}\right\}\exp\left\{-\frac{(x+x_0+\xi)^2}{4\sigma t}\right\}d\xi,$$

which represents the density due to a line of exponentially decreasing sinks extending from $-x_0$ to $-\infty$. The method of Laplace transforming (1.3) with respect to t was later employed [1], [38] to obtain explicit analytical solution for the FPE (1.3)–(1.5) with a constant diffusion coefficient and a (not necessarily vanishing) constant drift term $a(x,t)=a$:

$$\begin{aligned} &p(x,t\,|\,x_0)\\ &\quad=\frac{1}{\sqrt{4\pi\sigma t}}\left[\exp\left\{-\frac{(x-x_0-at)^2}{4\sigma t}\right\}+\exp\left\{-\frac{ax_0}{\sigma}-\frac{(x+x_0-at)^2}{4\sigma t}\right\}\right]\\ &\qquad-\frac{2\kappa+a}{2\sigma}\exp\left\{\frac{ax+\kappa[x+x_0+(\kappa+a)t]}{\sigma}\right\}\operatorname{erfc}\left[\frac{x+x_0+(2\kappa+a)t}{\sqrt{4\sigma t}}\right]. \end{aligned} \tag{3.2}$$

Setting $\kappa=0$ in (3.2) reduces to Smoluchowski's [39] explicit analytical solution for a reflecting boundary with a constant drift term, while setting $a=0$ reduces to Bryan's solution (3.1).

We conducted several numerical experiments in which $n=10^7$ trajectories were simulated according to the Euler scheme (1.7) with the boundary behavior (1.10). The diffusion coefficient was constant $\sigma=1$, and the reactive constant was $\kappa=1$, giving $P=\sqrt{\pi}$ in (2.29). The trajectories were initially located at $x_0=1$, and their statistics were collected at time $t=1$ and compared to the predicted $p(x,t=1\,|\,x_0=1)$. The convergence of the scheme was tested by using four different time steps, $\Delta t=10^{-1},10^{-2},10^{-3},10^{-4}$.

The first experiment corresponds to a vanishing drift $a=0$. Figure 1 shows the convergence of the numerical scheme to the analytic solution (3.1). The rate of convergence of the numerical scheme to the analytic solution is $\sqrt{\Delta t}$. This is demonstrated, for example, by the survival probability

$$p_{sur}(x_0,t)=\int_0^\infty p(x,t\,|\,x_0)\,dx$$

of finding the trajectory inside the domain at time t, that is, the probability that the trajectory was not absorbed prior to t. Integrating (3.1) gives $p_{sur}(1,1)=0.77095\ldots$ for $\sigma=\kappa=1$. The survival probability is estimated numerically by the ratio of the number of survived (unabsorbed) trajectories n_{sur} and the total number of simulated trajectories $n=10^7$. Table 1 shows that the convergence rate of the estimated survival probability to its analytic value is $\sqrt{\Delta t}$, as predicted by our boundary layer analysis. The statistical estimation (variance) error due to the finite number of simulated trajectories is $\sqrt{p_{sur}(1-p_{sur})/n}=0.00013\ldots$, which is an order of magnitude smaller than the smallest (bias) error obtained for $\Delta t=10^{-4}$ (see Table 1).

In the second experiment, the drift term $a=-1$ shifts the density leftward and causes more trajectories to react with the boundary. Figure 2 shows the convergence of the numerical scheme to the analytic solution (3.2).

The final experiment corresponds to a reflecting boundary, $P=\kappa=0$, and a constant nonvanishing drift toward the boundary $a=-1$. We simulated $n=10^8$ trajectories to obtain a finer resolution at the boundary. Figure 3 shows a comparison

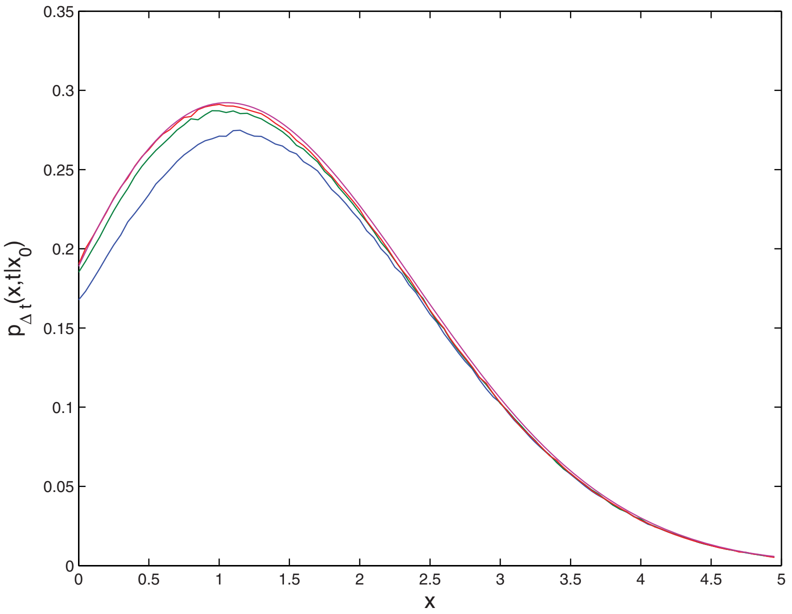

Fig. 1. *No drift: the analytical solution* (3.1) *(magenta) and the three numerical densities* $\Delta t = 10^{-1}$ *(blue),* $\Delta t = 10^{-2}$ *(green),* $\Delta t = 10^{-3}$ *(red) approaching it from below. The numerical density of* $\Delta t = 10^{-4}$ *is not shown because it is difficult to distinguish it from the analytic density. (Parameters:* $\sigma = \kappa = x_0 = t = 1$, $a = 0$, $P = \sqrt{\pi}$, $n = 10^7$.*)*

Survival probability: the difference between the analytic value of the survival probability $p_{sur} = 0.77095\ldots$ *and its numerical estimation* n_{sur}/n *decreases by roughly* $\sqrt{10}$ *whenever* Δt *is decreased by an order of magnitude. (Parameters:* $\sigma = \kappa = x_0 = t = 1$, $a = 0$, $n = 10^7$.*)*

Δt	n_{sur}	$p_{sur} - n_{sur}/n$
10^{-1}	7253450	0.0456
10^{-2}	7577156	0.0132
10^{-3}	7670969	0.0039
10^{-4}	7698523	0.0011

between the analytical solution (3.2) and the numerical densities for $\Delta t = 10^{-1}, 10^{-2}$. The no flux condition $J = 0$ of a reflecting boundary together with (1.4) gives a negative boundary derivative, $p_y(0,t) = -p(0,t) < 0$. In particular, the analytic solution (3.2) satisfies $p_y(0,1) = -p(0,1) = -(2+\sqrt{\pi})/(2\sqrt{\pi}) \approx -1.06$. The numerical densities, however, are flat at the boundary. Their first derivatives vanish at the boundary, as predicted in (2.2) and shown in Figure 3. The first derivative changes from 0 to $O(1)$ on an interval of length $O(\sqrt{\Delta t})$, manifesting a boundary layer behavior, though there is no such behavior in the density itself.

4. Diffusion in $\mathbb{R}^d$ with partial oblique reflection at the boundary. We consider the d-dimensional stochastic dynamics

$$\dot{\boldsymbol{x}} = \boldsymbol{a}(\boldsymbol{x},t) + \sqrt{2}\boldsymbol{B}(t)\,\dot{\boldsymbol{w}} \tag{4.1}$$

in the half-space

$$\Omega = \{\boldsymbol{x} = (x_1, x_2, \ldots, x_d) \in \mathbb{R}^d : x_1 > 0\},$$

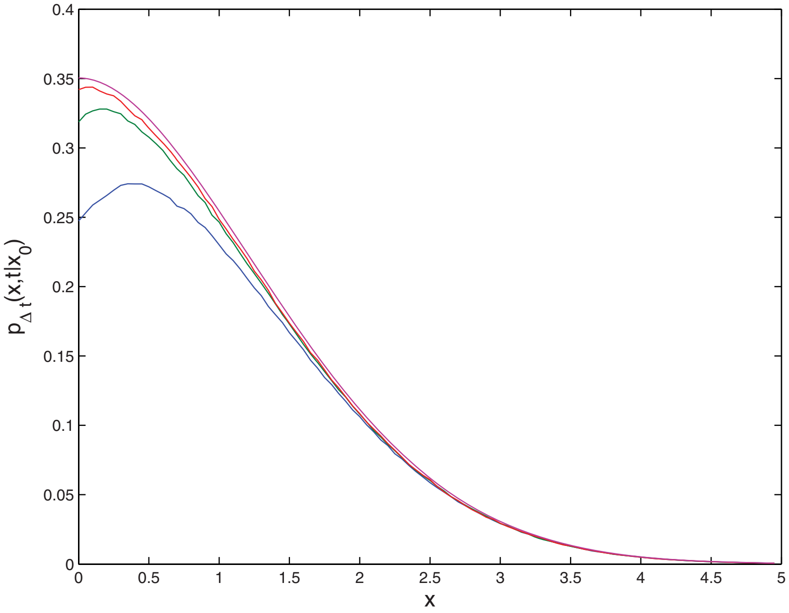

FIG. 2. *Drift, $a = -1$: the analytical solution* (3.2) *(magenta) and the numerical densities $\Delta t = 10^{-1}$ (blue), $\Delta t = 10^{-2}$ (green), $\Delta t = 10^{-3}$ (red) that approach it from below. (Parameters: $\sigma = \kappa = x_0 = t = 1$, $P = \sqrt{\pi}$, $n = 10^7$.)*

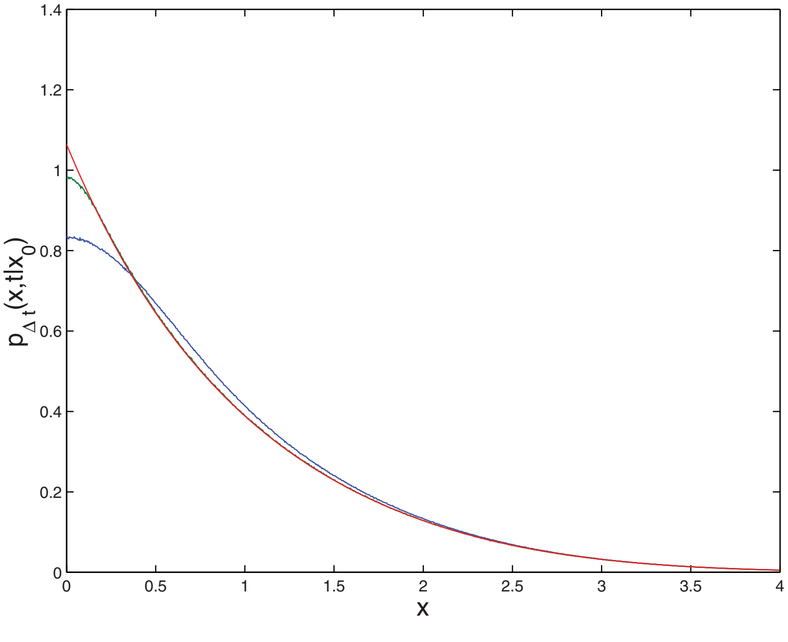

FIG. 3. *Drift, $a = -1$, reflecting boundary $P = \kappa = 0$: the analytic solution* (3.2) *(red) and the numerical densities $\Delta t = 10^{-1}$ (blue) and $\Delta t = 10^{-2}$ (green) with $n = 10^8$ simulated trajectories to obtain a finer boundary resolution. (Parameters: $\sigma = \kappa = x_0 = t = 1$.)*

where $\boldsymbol{w}$ is a vector of d independent Brownian motions and we assume that the diffusion tensor $\boldsymbol{\sigma}(t) = \boldsymbol{B}(t)\boldsymbol{B}^T(t)$ is uniformly positive definite for all $t \geq s$. The case of space-dependent diffusion involves many technically complicated calculations and will be considered in a separate paper. We use henceforth the abbreviation $\boldsymbol{\sigma}(t) = \boldsymbol{\sigma}$. The radiation condition (1.6) becomes

$$-\boldsymbol{J}(\boldsymbol{y},t\,|\,\boldsymbol{x},s)\cdot\boldsymbol{n} = \kappa(\boldsymbol{y},t)p(\boldsymbol{y},t\,|\,\boldsymbol{x},s), \quad \text{for} \quad \boldsymbol{y}\in\partial\Omega,\ \boldsymbol{x}\in\Omega, \tag{4.2}$$

where the components of the flux vector $\boldsymbol{J}(\boldsymbol{y},t\,|\,\boldsymbol{x},s)$ are defined by

$$J^k(\boldsymbol{y},t\,|\,\boldsymbol{x},s) = -[a^k(\boldsymbol{y},t)p(\boldsymbol{y},t\,|\,\boldsymbol{x},s)] + \sum_{j=1}^{d}\frac{\partial}{\partial y_j}\left[\sigma^{j,k}p(\boldsymbol{y},t\,|\,x,s)\right], \tag{4.3}$$

where $\sigma^{j,k}$ are the elements of the diffusion matrix $\boldsymbol{\sigma}$. The Fokker–Plank equation for the pdf of $\boldsymbol{x}(t)$ can be written as

$$\frac{\partial p(\boldsymbol{y},t\,|\,\boldsymbol{x},s)}{\partial t} = -\nabla_{\boldsymbol{y}}\cdot\boldsymbol{J}(\boldsymbol{y},t\,|\,\boldsymbol{x},s) \quad \text{for all} \quad \boldsymbol{y},\boldsymbol{x}\in\Omega. \tag{4.4}$$

If $\boldsymbol{x}\in\Omega$, but

$$\boldsymbol{x}' = \boldsymbol{x} + \boldsymbol{a}(\boldsymbol{x},t)\Delta t + \sqrt{2}\boldsymbol{B}(t)\,\Delta\boldsymbol{w}(t,\Delta t) \notin \Omega,$$

the Euler scheme for (4.1) with oblique reflection in $\partial\Omega$ reflects the point $\boldsymbol{x}'$ obliquely in the constant direction of $\boldsymbol{v}$ to a point $\boldsymbol{x}''\in\Omega$, as described below. First, we denote by $\boldsymbol{x}'_B$ the normal projection of a point $\boldsymbol{x}'$ on $\partial\Omega$, that is, $\boldsymbol{x}'_B = \boldsymbol{x}' - (\boldsymbol{x}'\cdot\boldsymbol{n})\boldsymbol{n}$. Then we write the Euler scheme for (4.1) with partially reflecting boundary as

$$\boldsymbol{x}(t+\Delta t) = \begin{cases} \boldsymbol{x}' \quad \text{for} \quad \boldsymbol{x}'\in\Omega, \\ \boldsymbol{x}'' \quad \text{w.p.} \quad 1 - P\left(\boldsymbol{x}'_B\right)\sqrt{\Delta t} \quad \text{if} \quad \boldsymbol{x}'\notin\Omega, \\ \text{terminate trajectory w.p. } P\left(\boldsymbol{x}'_B\right)\sqrt{\Delta t} \quad \text{if} \quad \boldsymbol{x}'\notin\Omega. \end{cases} \tag{4.5}$$

The value of the termination probability $P\left(\boldsymbol{x}'_B\right)\sqrt{\Delta t}$, which varies continuously in the boundary, is evaluated at the normal projection of the point $\boldsymbol{x}'$ on the boundary. The oblique reflection in the direction of the unit vector $\boldsymbol{v}$ ($v_1 \neq 0$) is defined by

$$\boldsymbol{x}'' = \boldsymbol{x}' - \frac{2x'_1}{v_1}\boldsymbol{v}. \tag{4.6}$$

Note that $x''_1 = -x'_1$ guarantees that the reflected point of a crossing trajectory is inside the domain Ω. The fact that the normal components of $\boldsymbol{x}''$ and $\boldsymbol{x}'$ are of equal lengths makes the high-dimensional boundary layer analysis similar to that in one dimension. Normal reflection corresponds to $\boldsymbol{v} = \boldsymbol{n} = (1,0,\dots,0)$.

We note that for a point $\boldsymbol{y}\in\Omega$, we can write $\Pr\{\boldsymbol{x}'' = \boldsymbol{y}\} = \Pr\{\boldsymbol{x}' = \boldsymbol{y}'\}$, where

$$\boldsymbol{y} = \boldsymbol{y}' - \frac{2\boldsymbol{y}'\cdot\boldsymbol{n}}{v_1}\boldsymbol{v} \tag{4.7}$$

is the oblique reflection of $\boldsymbol{y}'$ (see Figure 4). Given $\boldsymbol{y}$, (4.7) defines $\boldsymbol{y}'$ as

$$\boldsymbol{y}' = \boldsymbol{y} - 2\frac{y_1}{v_1}\boldsymbol{v}. \tag{4.8}$$

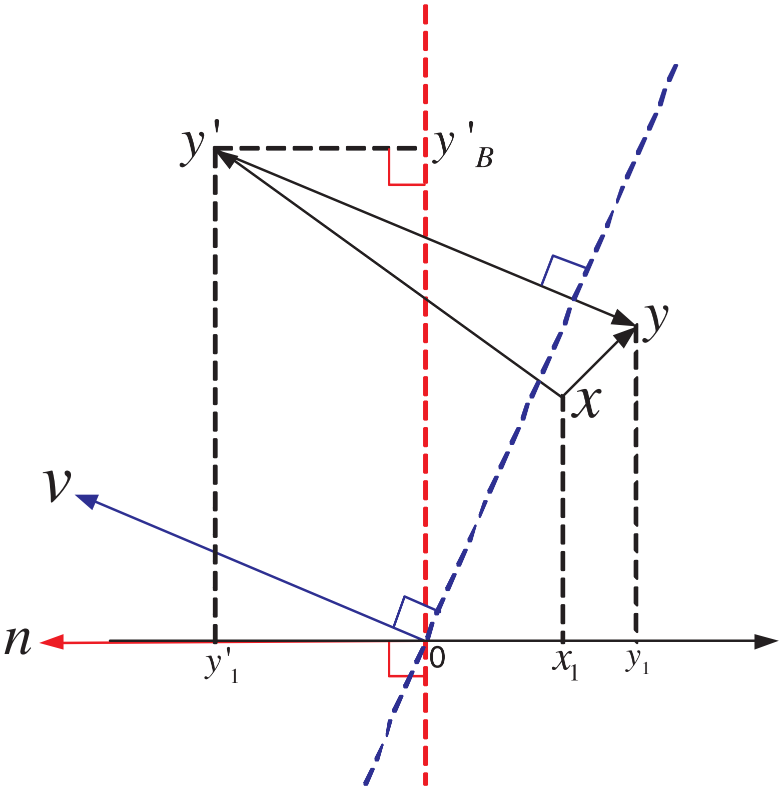

FIG. 4. *A simulated trajectory can get from* $\boldsymbol{x}$ *to* $\boldsymbol{y}$ *in a single time step* Δt *in two different ways:* (i) *directly from* $\boldsymbol{x}$ *to* $\boldsymbol{y}$*, without crossing the boundary, and* (ii) *by crossing the boundary from* $\boldsymbol{x}$ *to* $\boldsymbol{y}'$ *and reflection in the oblique direction* $\boldsymbol{v}$ *with probability* $1-P(\boldsymbol{y}'_B)\sqrt{\Delta t}$ *to* $\boldsymbol{y}$*. The reflection law* (4.5)–(4.7) *satisfies* $y'_1=-y_1$*.*

As in the one-dimensional case, the forward Kolmogorov equation is

$$p_{\Delta t}(\boldsymbol{y},t+\Delta t)=\int_{x_1>0}\frac{p_{\Delta t}(\boldsymbol{x},t)}{(4\pi\Delta t)^{d/2}\sqrt{\det\boldsymbol{\sigma}}}\left\{\exp\left[-\frac{\mathcal{B}(\boldsymbol{x}+\boldsymbol{a}(\boldsymbol{x},t)\Delta t,\boldsymbol{y})}{4\Delta t}\right]\right.$$
$$\left.+\left(1-P(\boldsymbol{y}'_B)\sqrt{\Delta t}\right)\exp\left[-\frac{\mathcal{B}(\boldsymbol{x}+\boldsymbol{a}(\boldsymbol{x},t)\Delta t,\boldsymbol{y}')}{4\Delta t}\right]\right\}d\boldsymbol{x},\tag{4.9}$$

where

$$\mathcal{B}(\boldsymbol{x},\boldsymbol{y})=(\boldsymbol{x}-\boldsymbol{y})^T\boldsymbol{\sigma}^{-1}(\boldsymbol{x}-\boldsymbol{y}).\tag{4.10}$$

We construct a boundary layer of width $O(\sqrt{\Delta t})$ in the normal direction to the boundary. The layer extends infinitely in the $d-1$ directions tangent to the boundary

$$p_{BL}(\eta_1,y_2,\dots,y_d,t)=p_{\Delta t}(\eta_1\sqrt{\Delta t},y_2,\dots,y_d,t).\tag{4.11}$$

In other words, $p_{BL}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)=p_{\Delta t}(\eta_1\sqrt{\Delta t}\,\boldsymbol{n}+\boldsymbol{y}_B,t)$, where $\boldsymbol{y}_B=(0,y_2,y_3,\dots,y_d)$. As in the one-dimensional case, we assume the asymptotic expansion

$$p_{BL}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)\sim p_{BL}^{(0)}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)+\sqrt{\Delta t}\,p_{BL}^{(1)}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)+\cdots\tag{4.12}$$

and substitute

$$\boldsymbol{x} = \boldsymbol{y}_B + \sqrt{\Delta t}\,\boldsymbol{\xi} \tag{4.13}$$

in the integral (4.9). We obtain

$$\begin{aligned} p_{BL}(\eta_1 \boldsymbol{n} + \boldsymbol{y}_B, t + \Delta t) = \int_{\xi_1 > 0} & \frac{p_{BL}(\xi_1 \boldsymbol{n} + \boldsymbol{y}_B + \sqrt{\Delta t}\,\boldsymbol{\xi}_B, t)}{(4\pi)^{d/2}\sqrt{\det \boldsymbol{\sigma}}} \\ \times & \left\{ \exp\left[-\frac{\mathcal{B}(\boldsymbol{\xi} + \boldsymbol{a}(\boldsymbol{y}_B, t)\sqrt{\Delta t}, \eta_1 \boldsymbol{n})}{4} \right] + (1 - P(\boldsymbol{y}'_B)\sqrt{\Delta t}) \right. \\ \times & \left. \exp\left[-\frac{1}{4}\mathcal{B}\left(\boldsymbol{\xi} + \boldsymbol{a}(\boldsymbol{y}_B, t)\sqrt{\Delta t},\ \eta_1 \boldsymbol{n} - \frac{2\eta_1}{v_1}\boldsymbol{v} \right) \right] \right\} d\boldsymbol{\xi} + O(\Delta t). \end{aligned} \tag{4.14}$$

We calculate separately the integral of the first and second terms in the braces. Substituting

$$\boldsymbol{z} = \boldsymbol{\sigma}^{-1/2}(\boldsymbol{\xi} - \eta_1 \boldsymbol{n}) \tag{4.15}$$

in the first integral of (4.14) transforms the domain of integration into

$$\boldsymbol{z} \cdot \tilde{\boldsymbol{n}} > -\frac{\eta_1}{\sqrt{\sigma_n}}, \tag{4.16}$$

where $\tilde{\boldsymbol{n}} = \frac{\boldsymbol{\sigma}^{1/2}\boldsymbol{n}}{\|\boldsymbol{\sigma}^{1/2}\boldsymbol{n}\|}$ is a unit vector and $\sigma_n = \boldsymbol{n}^T \boldsymbol{\sigma} \boldsymbol{n} = \|\boldsymbol{\sigma}^{1/2}\boldsymbol{n}\|^2$. Similarly, we transform the second integral by substituting $\boldsymbol{z}' = \boldsymbol{\sigma}^{-1/2}\left(\boldsymbol{\xi} - \eta_1 \boldsymbol{n} + \frac{2\eta_1}{v_1}\boldsymbol{v}\right)$. Using the expansion (4.12), we obtain at the leading order the integral equation

$$\begin{aligned} & p^{(0)}_{BL}(\eta_1 \boldsymbol{n} + \boldsymbol{y}_B, t) \\ & = \frac{1}{(4\pi)^{d/2}} \int_{\boldsymbol{z}\cdot\tilde{\boldsymbol{n}} > -\frac{\eta_1}{\sqrt{\sigma_n}}} p^{(0)}_{BL}\left((\eta_1 + \sqrt{\sigma_n}\,\boldsymbol{z}\cdot\tilde{\boldsymbol{n}})\boldsymbol{n} + \boldsymbol{y}_B, t\right) \exp\left[-\frac{\|\boldsymbol{z}\|^2}{4} \right] d\boldsymbol{z} \\ & \quad + \frac{1}{(4\pi)^{d/2}} \int_{\boldsymbol{z}'\cdot\tilde{\boldsymbol{n}} > \frac{\eta_1}{\sqrt{\sigma_n}}} p^{(0)}_{BL}\left((-\eta_1 + \sqrt{\sigma_n}\,\boldsymbol{z}'\cdot\tilde{\boldsymbol{n}})\boldsymbol{n} + \boldsymbol{y}_B, t\right) \exp\left[-\frac{\|\boldsymbol{z}'\|^2}{4} \right] d\boldsymbol{z}'. \end{aligned}$$

Integrating in the $d-1$ directions orthogonal to $\tilde{\boldsymbol{n}}$ yields

$$\begin{aligned} p^{(0)}_{BL}(\eta_1 \boldsymbol{n} + \boldsymbol{y}_B, t) & = \frac{1}{\sqrt{4\pi}} \int_{-\frac{\eta_1}{\sqrt{\sigma_n}}}^{\infty} p^{(0)}_{BL}\left((\eta_1 + \sqrt{\sigma_n}\,u)\boldsymbol{n} + \boldsymbol{y}_B, t\right) \exp\left[-\frac{u^2}{4} \right] du \\ & + \frac{1}{\sqrt{4\pi}} \int_{\frac{\eta_1}{\sqrt{\sigma_n}}}^{\infty} p^{(0)}_{BL}\left((-\eta_1 + \sqrt{\sigma_n}\,u)\boldsymbol{n} + \boldsymbol{y}_B, t\right) \exp\left[-\frac{u^2}{4} \right] du \\ & = \frac{1}{\sqrt{4\pi\sigma_n}} \int_0^{\infty} p^{(0)}_{BL}\left(u\boldsymbol{n} + \boldsymbol{y}_B, t\right) \left\{ \exp\left[-\frac{(u - \eta_1)^2}{4\sigma_n} \right] + \exp\left[-\frac{(u + \eta_1)^2}{4\sigma_n} \right] \right\} du. \end{aligned}$$

This is the same leading order integral equation as that of the one-dimensional case (2.9); thus the solution is independent of η_1, and matching to the outer solution gives

$$p^{(0)}_{BL}(\eta_1 \boldsymbol{n} + \boldsymbol{y}_B, t) = p^{(0)}_{OUT}(\boldsymbol{y}_B, t). \tag{4.17}$$

To evaluate the $O(\sqrt{\Delta t})$ terms, we expand in the first integral in (4.14)

$$\begin{aligned}\mathcal{B}(\boldsymbol{\xi}+\boldsymbol{a}(\boldsymbol{y}_B,t)\sqrt{\Delta t},\eta_1\boldsymbol{n}) &= (\boldsymbol{\xi}-\eta_1\boldsymbol{n})\cdot\boldsymbol{\sigma}^{-1}(\boldsymbol{\xi}-\eta_1\boldsymbol{n})\\ &\quad+\sqrt{\Delta t}\,2\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{\sigma}^{-1}(\boldsymbol{\xi}-\eta_1\boldsymbol{n}),\end{aligned}\tag{4.18}$$

and in the second integral

$$\begin{aligned}\mathcal{B}\left(\boldsymbol{\xi}+\boldsymbol{a}(\boldsymbol{y}_B,t)\sqrt{\Delta t},\ \eta_1\boldsymbol{n}-\frac{2\eta_1}{v_1}\boldsymbol{v}\right) &= \left(\boldsymbol{\xi}-\eta_1\boldsymbol{n}+\frac{2\eta_1}{v_1}\boldsymbol{v}\right)\cdot\boldsymbol{\sigma}^{-1}\left(\boldsymbol{\xi}-\eta_1\boldsymbol{n}\frac{2\eta_1}{v_1}\boldsymbol{v}\right)\\ &\quad+\sqrt{\Delta t}\,2\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{\sigma}^{-1}\left(\boldsymbol{\xi}-\eta_1\boldsymbol{n}\frac{2\eta_1}{v_1}\boldsymbol{v}\right).\end{aligned}\tag{4.19}$$

The $O(\sqrt{\Delta t})$ contribution of the drift term for the first exponential term is

$$\begin{aligned}&-\frac{1}{4}\int_{\xi_1>0}\frac{p_{OUT}^{(0)}(\boldsymbol{y}_B,t)}{(4\pi)^{d/2}\sqrt{\det\boldsymbol{\sigma}}}\exp\left\{-\frac{\mathcal{B}(\boldsymbol{\xi},\eta_1\boldsymbol{n})}{4}\right\}\left[2\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{\sigma}^{-1}(\boldsymbol{\xi}-\eta_1\boldsymbol{n})\right]d\boldsymbol{\xi}\\ &=-\frac{1}{4}\frac{p_{OUT}^{(0)}(\boldsymbol{y}_B,t)}{\sqrt{4\pi}}2\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{\sigma}^{-1/2}\tilde{\boldsymbol{n}}\int_{-\eta_1/\sqrt{\sigma_n}}^{\infty}ue^{-u^2/4}\,du\\ &=-\frac{1}{2}\frac{p_{OUT}^{(0)}(\boldsymbol{y}_B,t)}{\sqrt{\pi\sigma_n}}\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\exp\left\{\frac{-\eta_1^2}{4\sigma_n}\right\}.\end{aligned}\tag{4.20}$$

The second exponential has the same contribution, so the overall contribution of the drift to the $O(\sqrt{\Delta t})$ term is

$$-\frac{p_{OUT}^{(0)}(\boldsymbol{y}_B,t)}{\sqrt{\pi\sigma_n}}\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\exp\left\{\frac{-\eta_1^2}{4\sigma_n}\right\}.\tag{4.21}$$

Now, we expand

$$\begin{aligned}&p_{BL}^{(0)}\left((\eta_1+\sqrt{\sigma_n}\,\boldsymbol{z}\cdot\tilde{\boldsymbol{n}})\boldsymbol{n}+\boldsymbol{y}_B+\sqrt{\Delta t}\,(\boldsymbol{\sigma}^{1/2}\boldsymbol{z})_B,t\right)=p_{BL}^{(0)}\left((\eta_1+\sqrt{\sigma_n}\,\boldsymbol{z}\cdot\tilde{\boldsymbol{n}})\boldsymbol{n}+\boldsymbol{y}_B,t\right)\\ &+\sqrt{\Delta t}\,\nabla p_{BL}^{(0)}\left((\eta_1+\sqrt{\sigma_n}\,\boldsymbol{z}\cdot\tilde{\boldsymbol{n}})\boldsymbol{n}+\boldsymbol{y}_B,t\right)\cdot(\boldsymbol{\sigma}^{1/2}\boldsymbol{z})_B+O(\Delta t).\end{aligned}\tag{4.22}$$

Together with (4.17), the expansion (4.22) reduces to

$$\begin{aligned}&p_{BL}^{(0)}\left((\eta_1+\sqrt{\sigma_n}\,\boldsymbol{z}\cdot\tilde{\boldsymbol{n}})\boldsymbol{n}+\boldsymbol{y}_B+\sqrt{\Delta t}\,(\boldsymbol{\sigma}^{1/2}\boldsymbol{z})_B,t\right)\\ &=p_{OUT}^{(0)}\left(\boldsymbol{y}_B,t\right)+\sqrt{\Delta t}\,\nabla p_{OUT}^{(0)}\left(\boldsymbol{y}_B,t\right)\cdot(\boldsymbol{\sigma}^{1/2}\boldsymbol{z})_B+O(\Delta t).\end{aligned}$$

Integrating as above, we obtain the $O(\sqrt{\Delta t})$ integral equation as

$$\begin{aligned}&p_{BL}^{(1)}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)\\ &=\frac{1}{\sqrt{4\pi\sigma_n}}\int_0^{\infty}p_{BL}^{(1)}\left(u\boldsymbol{n}+\boldsymbol{y}_B,t\right)\left\{\exp\left[-\frac{(u-\eta_1)^2}{4\sigma_n}\right]+\exp\left[-\frac{(u+\eta_1)^2}{4\sigma_n}\right]\right\}du\\ &\quad-\frac{P\left(\boldsymbol{y}_B'\right)p_{OUT}^{(0)}\left(\boldsymbol{y}_B,t\right)}{\sqrt{4\pi\sigma_n}}\int_0^{\infty}\exp\left[-\frac{(u+\eta_1)^2}{4\sigma_n}\right]du\\ &\quad+\frac{1}{\sqrt{4\pi}}\int_{\frac{\eta_1}{\sqrt{\sigma_n}}}^{\infty}\nabla p_{OUT}^{(0)}(\boldsymbol{y}_B,t)\cdot\left(2\boldsymbol{\sigma}^{1/2}u\tilde{\boldsymbol{n}}-\frac{2\eta_1}{v_1}\boldsymbol{v}\right)_B\exp\left[-\frac{u^2}{4}\right]du\\ &\quad-\frac{p_{OUT}^{(0)}(\boldsymbol{y}_B,t)}{\sqrt{\pi\sigma_n}}\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\exp\left\{\frac{-\eta_1^2}{4\sigma_n}\right\}.\end{aligned}$$

Differentiating with respect to η_1 and integrating by parts (as was done in the one-dimensional case), we arrive at the integral equation

$$\begin{aligned}
&\frac{\partial p^{(1)}_{BL}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)}{\partial n}\\
&= \frac{1}{\sqrt{4\pi\sigma_n}}\int_0^\infty \frac{\partial p^{(1)}_{BL}\left(u\boldsymbol{n}+\boldsymbol{y}_B,t\right)}{\partial n}\left\{\exp\left[-\frac{(u-\eta_1)^2}{4\sigma_n}\right]-\exp\left[-\frac{(u+\eta_1)^2}{4\sigma_n}\right]\right\}du\\
&\quad-\frac{P\left(\boldsymbol{y}'_B\right)p^{(0)}_{OUT}\left(\boldsymbol{y}_B,t\right)}{\sqrt{4\pi\sigma_n}}\exp\left[\frac{-\eta_1^2}{4\sigma_n}\right]\\
&\quad+\nabla p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\cdot\left\{-\frac{1}{\sqrt{\pi\sigma_n}}\left[\frac{\boldsymbol{\sigma n}}{\sigma_n}-\frac{\boldsymbol{v}}{v_1}\right]\eta_1\exp\left[\frac{-\eta_1^2}{4\sigma_n}\right]-\boldsymbol{v}\frac{\operatorname{erfc}\left(\frac{\eta_1}{2\sqrt{\sigma_n}}\right)}{v_1}\right\}_B\\
&\quad+\frac{p^{(0)}_{OUT}(\boldsymbol{y}_B,t)}{\sqrt{\pi\sigma_n}}\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\frac{\eta_1}{2\sigma_n}\exp\left[\frac{-\eta_1^2}{4\sigma_n}\right].
\end{aligned}$$

The Wiener–Hopf method requires the extension of the erfc function discontinuously as an odd function, that is, to define $\widetilde{\operatorname{erfc}}(x)=\operatorname{sgn}(x)\operatorname{erfc}(|x|)$. Following the calculations of the one-dimensional case, it remains to determine the small k behavior of the Fourier transform of $\widetilde{\operatorname{erfc}}(x)$. Using

$$(4.23)\qquad \int_{-\infty}^{\infty}\widetilde{\operatorname{erfc}}\left(\frac{\eta}{2\sqrt{\sigma_n}}\right)\exp\{ik\eta\}\,d\eta\sim 2ik\int_0^\infty\operatorname{erfc}\left(\frac{\eta}{2\sqrt{\sigma_n}}\right)\eta\,d\eta=2ik\sigma_n,$$

we obtain, as in (2.24),

$$\begin{aligned}
\hat{\phi}(k)\sim 2ik\Bigg\{&\frac{P\left(\boldsymbol{y}'_B\right)p^{(0)}_{OUT}\left(\boldsymbol{y}_B,t\right)\sqrt{\sigma_n}}{\sqrt{\pi}}-2\sigma_n\nabla p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\cdot\left[\frac{\boldsymbol{\sigma n}}{\sigma_n}-\frac{\boldsymbol{v}}{2v_1}\right]_B\\
&+p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\Bigg\}\quad\text{as}\quad k\to 0.
\end{aligned}$$

Therefore,

$$\begin{aligned}
&\lim_{\eta_1\to\infty}\frac{\partial p^{(1)}_{BL}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)}{\partial n}\\
&=\left\{\frac{P\left(\boldsymbol{y}'_B\right)p^{(0)}_{OUT}\left(\boldsymbol{y}_B,t\right)}{\sqrt{\pi\sigma_n}}-2\nabla p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\cdot\left[\frac{\boldsymbol{\sigma n}}{\sigma_n}-\frac{\boldsymbol{v}}{2v_1}\right]_B+p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\frac{\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}}{\sigma_n}\right\}.
\end{aligned}$$

Combining with the matching condition

$$(4.24)\qquad \lim_{\eta\to\infty}\frac{\partial p^{(1)}_{BL}(\eta_1\boldsymbol{n}+\boldsymbol{y}_B,t)}{\partial n}=\frac{\partial p^{(0)}_{OUT}(\boldsymbol{y}_B,t)}{\partial n},$$

we obtain

$$\begin{aligned}
&\frac{\partial p^{(0)}_{OUT}(\boldsymbol{y}_B,t)}{\partial n}\\
&=\left\{\frac{P\left(\boldsymbol{y}_B\right)p^{(0)}_{OUT}\left(\boldsymbol{y}_B,t\right)}{\sqrt{\pi\sigma_n}}-2\nabla p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\cdot\left[\frac{\boldsymbol{\sigma n}}{\sigma_n}-\frac{\boldsymbol{v}}{2v_1}\right]_B+p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\frac{\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}}{\sigma_n}\right\}.
\end{aligned}$$

The requirement that the pdf of the limiting diffusion process satisfies the Robin boundary condition leads to the only possible choice,

$$\boldsymbol{v} = \frac{\boldsymbol{\sigma n}}{\|\boldsymbol{\sigma n}\|}. \tag{4.25}$$

Otherwise, we obtain an oblique derivative boundary condition. Since $\boldsymbol{y}'_B \to \boldsymbol{y}_B$ as $\Delta t \to 0$, we obtain the Robin boundary condition

$$\begin{aligned}-\boldsymbol{J}_{OUT}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n} &= \nabla p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\cdot\boldsymbol{\sigma n} - p^{(0)}_{OUT}(\boldsymbol{y}_B,t)\boldsymbol{a}(\boldsymbol{y}_B,t)\cdot\boldsymbol{n}\\ &= \frac{P\left(\boldsymbol{y}_B\right)p^{(0)}_{OUT}\left(\boldsymbol{y}_B,t\right)\sqrt{\sigma_n}}{\sqrt{\pi}}.\end{aligned}$$

The reflection direction $\boldsymbol{v}$ of crossing trajectories is the conormal direction $\boldsymbol{\sigma n}$. Normal reflection (i.e., replacing $\boldsymbol{v}$ by $\boldsymbol{n}$) gives rise to the boundary normal flux if and only if $\boldsymbol{n}$ is an eigenvector of the diffusion tensor $\boldsymbol{\sigma}$. The limit of the outer solution as $\Delta t \to 0$ is the solution of the Fokker–Planck equation (4.4) with the radiation boundary condition

$$-\boldsymbol{J}(\boldsymbol{y},t)\cdot\boldsymbol{n} = \kappa(\boldsymbol{y})p\left(\boldsymbol{y},t\right) \quad \text{for} \quad \boldsymbol{y}\in\partial\Omega, \tag{4.26}$$

where the reactive "constant" is

$$\kappa(\boldsymbol{y}) = \frac{P(\boldsymbol{y})\sqrt{\sigma_n}}{\sqrt{\pi}}. \tag{4.27}$$

Note that normal reflection will not recover the normal flux of the radiation condition if $\boldsymbol{n}$ is not an eigenvector of $\boldsymbol{\sigma}$.

5. Numerical simulations in two dimensions. To illustrate the conormal reflection law (4.25) in the Euler scheme (4.5)–(4.7) in the half-plane $x \geq 0$, we ran several numerical experiments. The simulations show the convergence of the pdf of the numerical solution to that of the FPE with the radiation boundary condition (4.26)–(4.27). Unlike in the one-dimensional case, no explicit solution of the anisotropic Robin problem for the FPE in the half-plane is available, so we compare the statistics of the simulated trajectories with a numerical solution of the FPE. The latter is constructed by the stable Crank–Nicolson scheme on lattice points, where in each time step the sparse linear system is solved by the conjugate gradient method.

In all numerical experiments the initial point is $(x_0, y_0) = (0.3, 0)$, and the statistics are collected at time $T = 0.5$. We choose the reactive constant $\kappa = 1$ and the diffusion matrix $\boldsymbol{B}$ in (4.1),

$$\boldsymbol{B} = \begin{pmatrix} 0.3 & 0.4 \\ 0 & 1 \end{pmatrix},$$

which gives the anisotropic diffusion tensor

$$\boldsymbol{\sigma} = \boldsymbol{B}\boldsymbol{B}^T = \begin{pmatrix} 0.25 & 0.4 \\ 0.4 & 1 \end{pmatrix}.$$

We simulate $n = 10^7$ trajectories with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$ in each experiment.

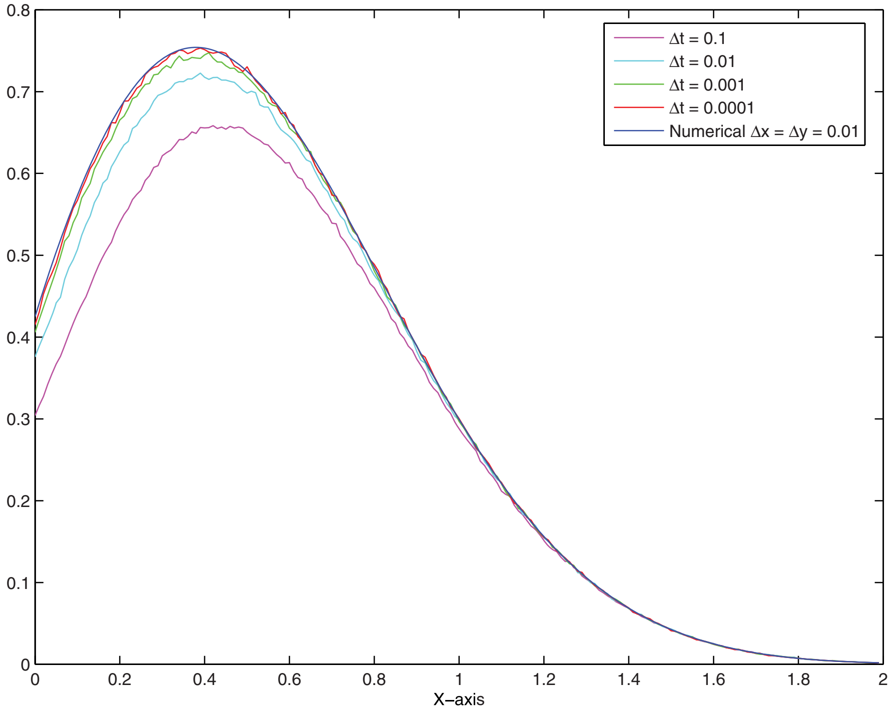

Fig. 5. *The marginal density of $x(T)$ with no drift and correct oblique reflection (the first experiment). The numerical solution of the FPE (blue) with grid size $\Delta x = 0.01$ and estimates from the simulation of $n = 10^7$ trajectories with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$.*

In the first experiment the drift vanishes ($\boldsymbol{a} = \mathbf{0}$). The normal $\boldsymbol{n} = (1, 0)$ and the conormal $\boldsymbol{\sigma n} = (0.25, 0.4)$ point in different directions. The simulated trajectories are reflected in the conormal direction according to the prescription (4.25). The simulated and the numerical solutions of the FPE give the marginal densities shown in Figures 5 and 6. Figure 5 shows the marginal density of $x(T)$,

$$p(x, T \,|\, x_0, y_0) = \int_{-\infty}^{\infty} p(x, y, T \,|\, x_0, y_0)\, dy,$$

while Figure 6 shows the marginal density of $y(T)$,

$$p(y, T \,|\, x_0, y_0) = \int_{0}^{\infty} p(x, y, T \,|\, x_0, y_0)\, dx.$$

Table 2 gives the computed survival probability and indicates the convergence rate.

We illustrate the importance of using the correct reflection law in the second experiment, in which the simulated trajectories are reflected in the normal direction $\boldsymbol{n} = (1, 0)$. Clearly, the marginal density of $x(T)$ coincides with that of the first experiment, because both oblique and normal reflections have the same x-coordinate (see (4.6)). However, the plot of the marginal density of $y(T)$ differs significantly from that in the previous experiment. It is apparent from the comparison to the numerical solution of the FPE that the simulation does not recover the Robin boundary condition in the limit $\Delta t \to 0$ (see Figure 7). Note that the peak of the density is at $y > 0$,

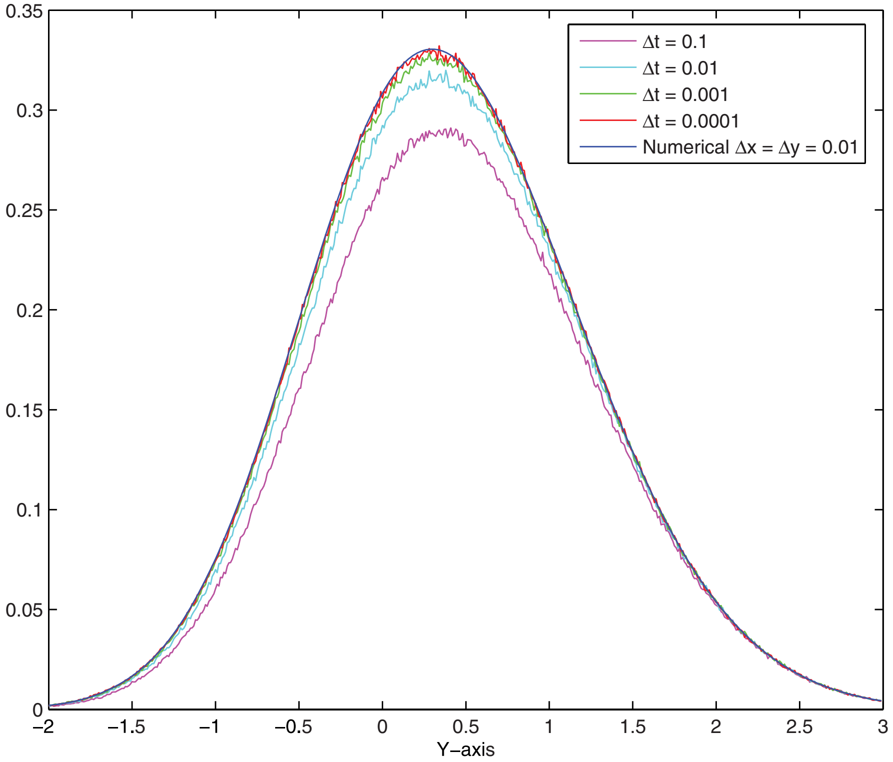

Fig. 6. *The marginal density of $y(T)$ with no drift and correct oblique reflection (the first experiment). The numerical solution of the FPE (blue) with grid size $\Delta x = 0.01$ and estimates from the simulation of $n = 10^7$ trajectories with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$.*

Table 2

Survival probability for $\boldsymbol{a} = \mathbf{0}$. The third column lists the error between the numerical value of the survival probability $p_{sur} = 0.6799545$ from the solution of the FPE and its estimate n_{sur}/n from the simulation. The error decreases by about $\sqrt{10}$ whenever Δt is decreased by an order of magnitude, indicating the convergence rate $\sqrt{\Delta t}$ of the simulation.

Δt	n_{sur}	$p_{sur} - n_{sur}/n$
10^{-1}	5986662	0.0814708
10^{-2}	6449991	0.0351379
10^{-3}	6707318	0.0094052
10^{-4}	6775672	0.0025698

though the reflection is normal. This is due to the anisotropy of the diffusion tensor, which causes the probability flux density vector to have a positive y component.

In the third experiment the drift is the constant vector $\boldsymbol{a} = (-1, 0)$, and the diffusion tensor is as in the first experiment. The density is shifted toward the boundary (see Figures 8 and 9). The results are summarized in Table 3.

6. Summary and discussion. We have defined a diffusion process with partially reflecting boundary as a limit of Markovian jump processes generated by the Euler scheme for the dynamics in a half-space with partial absorption of exiting trajectories and partial oblique reflection in the boundary. We derived an expression for the radiation constant in the Robin boundary condition for the one-dimensional

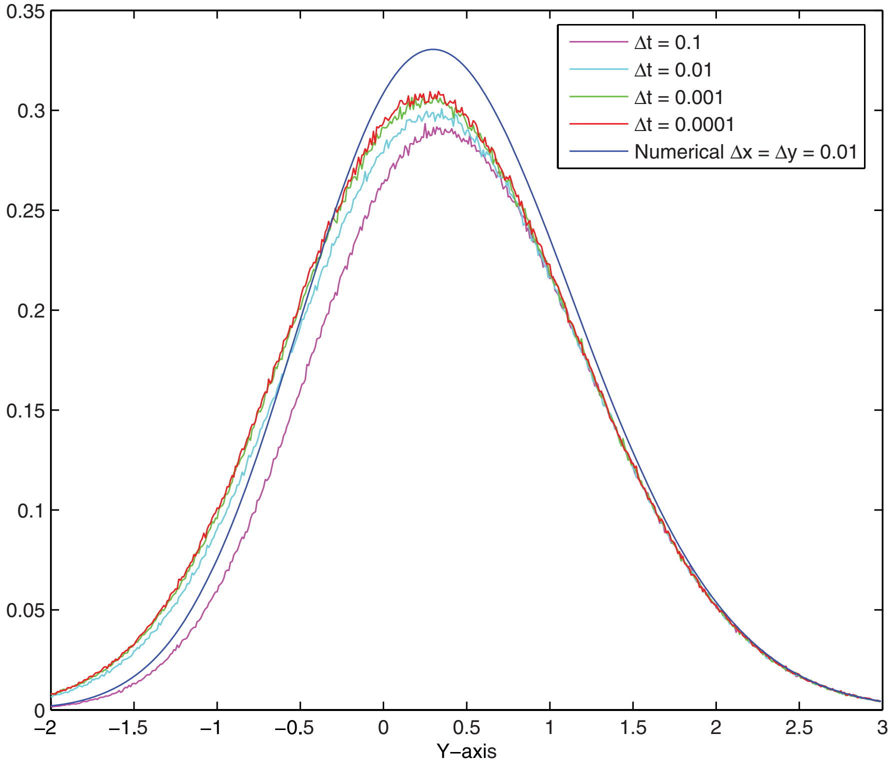

FIG. 7. *The marginal density of $y(T)$ with no drift and with normal reflection (the second experiment). The numerical solution of the FPE (blue) with grid size $\Delta x = 0.01$ and estimates from the simulation of $n = 10^7$ trajectories with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$.*

Fokker–Planck equation for the case of diffusion with variable drift and diffusion coefficients, as a function of the absorption probability. We found that the Euler scheme for a diffusion in a half-space with variable drift and constant anisotropic diffusion has to be reflected in a particular oblique direction in order to recover the Robin boundary condition. Also for this case we found the radiation "constant" as a function of the local absorption probability on the boundary. We found a boundary layer of width $O(\sqrt{\Delta t})$ in the pdf of the Euler scheme and solved the boundary layer equation, which is of Wiener–Hopf type.

The boundary layer of $p_{\Delta t}(y,t)$ makes the calculation of the boundary flux nontrivial. The net boundary flux of the simulation profile $p_{\Delta t}(y,t)$ is

$$(6.1) \qquad -J_{\Delta t}(0,t) = \lim_{\Delta t \to 0} \frac{1}{\Delta t} \frac{P\sqrt{\Delta t}}{\sqrt{4\pi\sigma\Delta t}} \int_{-\infty}^{0} dy \int_{0}^{\infty} p_{\Delta t}(x,t) \exp\left\{-\frac{(x-y)^2}{4\pi\sigma\Delta t}\right\} dx,$$

which is the probability of the trajectories that propagate out of the domain per unit time, discounted by the probability of trajectories returned into the domain by the partially reflecting Euler scheme. Changing the order of integration and then changing the variable of integration into $z = x/2\sqrt{\sigma\Delta t}$ gives

$$(6.2) \quad -J_{\Delta t}(0,t) = P\sqrt{\sigma} \int_{0}^{\infty} \operatorname{erfc}(z) p_{\Delta t}(2z\sqrt{\sigma\Delta t},t)\, dz = \frac{P\sqrt{\sigma}}{\sqrt{\pi}} p_{BL}^{(0)}(0,t) + O(\sqrt{\Delta t}).$$

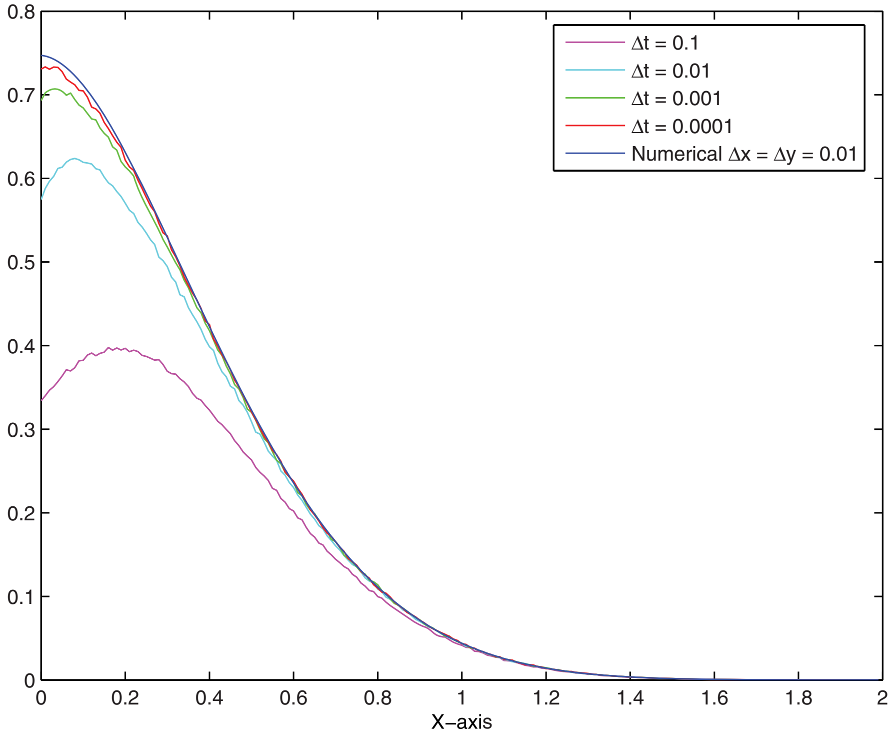

FIG. 8. *The marginal density of $x(T)$ with drift $\boldsymbol{a} = (-1, 0)$ and correct oblique reflection (the third experiment). The numerical solution of the FPE (blue) with grid size $\Delta x = 0.01$ and estimates from the simulation of $n = 10^7$ trajectories with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$.*

This straightforward calculation of the flux gives the correct radiation constant, provided that

$$p_{BL}^{(0)}(0,t) = p_{OUT}^{(0)}(0,t). \tag{6.3}$$

The latter, however, depends on the mode of reflecting a trajectory from x' outside to x'' inside the domain. We have shown that for $x'' = -x'$ the provision holds; however, for other schemes, e.g., $x'' = -\alpha x'$ $(\alpha \neq 1)$, the provision (6.3) fails in general, though (6.2) still holds. On the other hand, the differential form of the flux, (1.4), has to be obtained from (6.1) in the limit $\Delta t \to 0$, which is not the case for $p_{\Delta t}(y,t)$, though it is for $p_{OUT}(y,t)$. This shows up in spades in the multidimensional case, because although (6.3) holds for any direction of reflection, the differential form of the flux is obtained in the limit only if the correct direction of oblique reflection is chosen.

The generalization of the multidimensional case to domains with curved boundaries and to a variable diffusion tensor $\boldsymbol{\sigma}(\boldsymbol{x},t)$ is not straightforward and will be done separately. Note that if the diffusion tensor is constant, but anisotropic, a local orthogonal mapping of the boundary to a plane converts the diffusion tensor from constant to variable, as can be seen from Itô's formula. However, as mentioned in section 1, in the most common case of constant isotropic diffusion, our result extends to domains with curved boundaries because the mapping leaves the Laplacian unchanged, though the drift changes according to Itô's formula. In this case the vector $\boldsymbol{v}$ coincides with the normal $\boldsymbol{n}$.

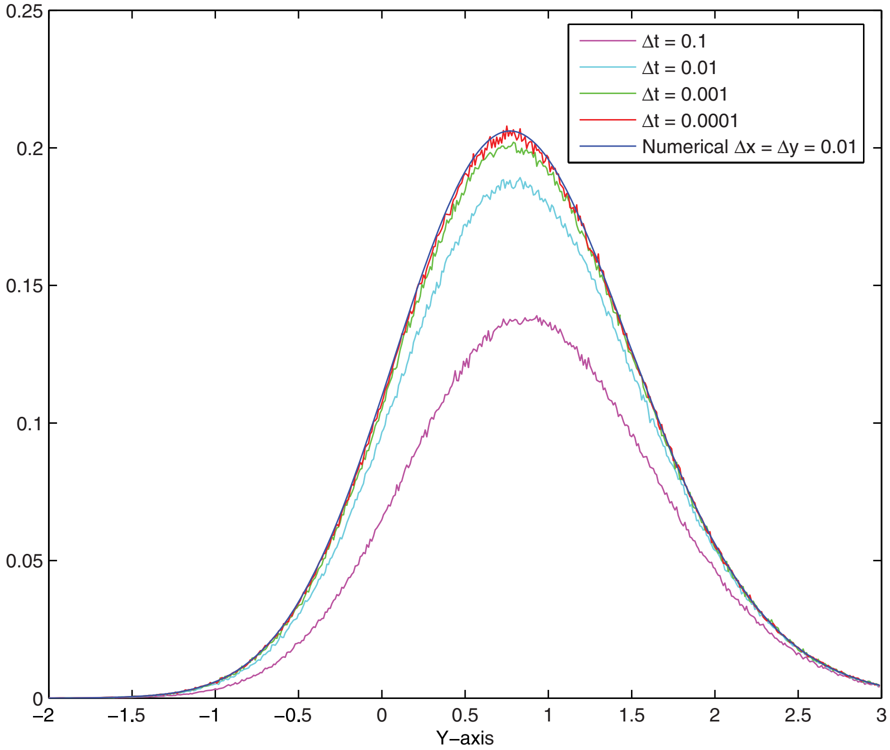

FIG. 9. *The third experiment ($\boldsymbol{a} = (-1, 0)$, correct oblique reflection): y-marginal densities. The numerical solution (blue) is compared to four simulated solutions (with time steps $\Delta t = 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}$). $n = 10^7$. Resolution: $\Delta x = 0.01$.*

TABLE 3

Survival probability for $\boldsymbol{a} = (-1, 0)$. The third column lists the error between the numerical value of the survival probability $p_{sur} = 0.3722893$ from the solution of the FPE and its estimate n_{sur}/n from the simulation.

Δt	n_{sur}	$p_{sur} - n_{sur}/n$

A MATHEMATICAL MODEL FOR THE STEADY ACTIVATION OF A SKELETAL MUSCLE[*]

J.-P. GABRIEL[†], L. M. STUDER[‡], D. G. RÜEGG[§], AND M.-A. SCHNETZER[¶]

Abstract. A skeletal muscle is composed of motor units, each consisting of a motoneuron and the muscle fibers it innervates. The input to the motor units is formed of electrical signals coming from higher motor centers and propagated to the motoneurons along a network of nerve fibers. Because of its complexity, this network still escapes actual direct observations. The present model describes the steady state activation of a muscle, i.e., of its motor units. It incorporates the network as an unknown quantity and, given the latter, predicts the input-force relation (activation curve) of the muscle. Conversely, given a suitable activation curve, our model enables the recovery of the network. This step is performed by using experimental data about the activation curve, and the whole activation process of a muscle can then be theoretically investigated. In this way, this approach provides a link between the macroscopic (activation curve) and microscopic (network) levels. From a mathematical viewpoint, solving the preceding inverse problem is equivalent to solving an integral equation of a new type.

1. Introduction.

The activation of a muscle is a fascinating phenomenon involving complex and subtle physiological processes. Muscles responsible for voluntary motions are called striated (or skeletal) and are composed of motor units (MUs) consisting of a motoneuron (MN) together with the muscle fibers under its control. Depending on the muscle, the number of MUs can vary from ten up to several thousands. The MNs are located in the spinal chord and are connected to the central nervous system (CNS) through nerve fibers (input fibers) propagating the signal (input) in the form of electrical impulses called action potentials (APs).

When an AP reaches an MN through a (synaptic) contact, it modifies the electrical potential of its membrane, generating a so-called excitatory postsynaptic potential (EPSP). On a given MN, the effects of different APs are supposed to be additive. When the membrane potential reaches a specific threshold value, the MN starts generating APs which are transmitted to the muscle fibers and induce their contractions. As the activity of the input fibers increases, new stronger MUs are recruited (size principle). Additionally already active MUs enhance their forces, a process called frequency modulation [8, 9]. As soon as all MUs are recruited, frequency modulation is the only way for a muscle to increase its force. For simplicity reasons, we consider here only stationary isometric contractions and we assume that the total muscle force

is given by the sum of all MU forces. The input-force relation of a muscle or its graph is alternatively called the *activation curve*.

MUs are ordered according to their maximal (tetanic) contraction forces t. The way input fibers activate MNs is extremely complex and the details of a corresponding network are not yet understood. On the level of an MN, this network, also called synaptic weight and denoted $g(t)$ (or sometimes g), is the missing quantity in our approach. Observations provide information about the shape of an activation curve. Our model is then used to recover g from this information (inverse problem). At this point, all aspects of the activation process of a muscle can be predicted.

For an arbitrary but fixed network, let $F(t)$ be the muscle force as a function of the last recruited MU. Clearly $F(t)$ has to be an increasing function of t. It will be seen that $g(t)$ can be deduced directly from $F(t)$ and it is thus sufficient to focus on the last function. $F(t)$ turns out to be a solution of an integral equation of the form

$$F(t) = \int_a^t k(s, F(s), F(t))\, ds, \tag{1}$$

and our task will be to solve (1). The presence of $F(t)$ in the kernel of (1) has striking consequences: on one hand this integral equation is not a classical Volterra equation and thus belongs to an extended type; on the other hand it admits infinitely many discontinuous solutions. Fortunately this equation has a unique continuous solution and this property turns out to be equivalent to increasingness. Since $F(t)$ is increasing in t, (1) admits one and only one physiologically meaningful solution. By using the latter, (1) can be reduced to a classical Volterra equation whose analytical and numerical properties are well known.

Analysis shows that the activation process has the following interesting properties:

(a) Similarly to the notion of the standard normal random variable in probability theory, there exists a standard hyperbolic muscle from which the activation curve of any muscle can be obtained.

(b) Despite the large number of parameters involved in the model, any activation curve is totally determined by a unique number called the activation factor.

(c) Several functionals related to the activation process can be introduced and characterized analytically, e.g., the ratio of the forces due to frequency modulation and recruitment.

All the published models of the MN pool-muscle complex (MNPMC) quantitatively describe the relation between the input to the MN pool and the muscle force [17, 18, 43, 12] or the electromyogram [12]. The models are similar in their structure but differ in the choice of the quantities given a priori. In the literature, all MNPMC models have been reduced to the following three unknowns: (1) the synaptic weight, (2) the MU population, and (3) the activation curve or the electromyogram. Since two of the unknowns can be given and the third one can be deduced from the model, we have three possible configurations: (1) and (2) are given and (3) is computed [17, 12]; (1) and (3) are given and (2) is computed [43]; and—the approach that we propose—the MU population (2) and the activation curve (3) are given and the synaptic weight (1) is determined. The main reason for this choice is that data at the level of the MNs are available for both unknowns (2) and (3) but not for unknown (1). As mentioned above, this configuration also leads to a new and interesting mathematical problem.

1.1. The model. We expose here the mathematical aspects of the model developed in [42], where a thorough discussion of the physiological hypotheses can be found. We focus mainly on equation (1), which is the key to the present investigation.

Since a typical skeletal muscle contains several hundred MUs, it is adequate to represent the MU population by a density function ρ. Choosing the tetanic contraction force t as variable, we get $t \in [t_{min}, t_{max}] \mapsto \rho(t)$, where t_{min} and t_{max} are the tetanic forces of the weakest and strongest MUs and the number of MUs in the pool is given by $\int_{t_{min}}^{t_{max}} \rho(s)\, ds$. All our considerations hold for all integrable and almost everywhere (a.e.) strictly positive functions ρ. We assume that t_{min} and t_{max} are given through ρ.

The global input In to the MNPMC is defined as the sum of all AP frequencies [43]. Each fiber contacts each MN of the pool and its activity induces EPSP conductance changes in the postsynaptic membrane. The EPSPs generated by single input fibers are smaller than 100 μV [15], the activity of these fibers is asynchronous [7], and the voltage threshold for APs is about 12 mV [5]. These three experimental findings imply that the variations of the membrane potential are smaller than 1% of the threshold voltage and are therefore neglected in the model. The EPSP conductances are thus represented by their time averages in the present time-independent approach. Due to the lack of precise information and for simplicity reasons, we assume that the EPSP conductance G_{EPSP} of each MN is proportional to the input:

$$G_{EPSP}(In) = g\, In, \tag{2}$$

where the MN-dependent factor g is the *synaptic weight*. This linearity assumption entails some restrictions on the MN connectivity [42].

The inactive (or subthreshold) MN is modeled with a single compartment and a homogeneous, electrically isolated membrane obeying Ohm's law. The total membrane current i_{tot} is the sum of the capacitive and ionic currents:

$$i_{tot} = C\, \dot{U} + \sum_k G_k\, (U - E_k), \tag{3}$$

where U is the membrane potential, $\dot{U}$ the time derivative of U, G_k the conductance of ion k, E_k its equilibrium potential, and C the membrane capacity. Three types of ionic conductances are distinguished: (a) a transmitter-sensitive conductance G_k^E caused by the synaptic input, (b) a voltage-dependent conductance G_k^U generating APs and E_k^U its equilibrium potential, and (c) a leakage conductance G_L and E_L its equilibrium potential. Clearly, we have $G_{EPSP} = \sum_k G_k^E$. For lack of data about particular MNs that are activated by synaptic input, we rely on data from current injection experiments [24]. The capacitive current is 0 in the steady state and since the membrane is isolated, the total current is equal to the injected current i_{inj}. Consequently, (3) can be rewritten $i_{inj} = \sum_k G_k^E (U - E_k) + \sum_k G_k^U (U - E_k^U) + G_L(U - E_L) = G_{EPSP}\, (U - \frac{\sum_k G_k^E\, E_k}{G_{EPSP}}) + \sum_k G_k^U (U - E_k^U) + G_L\, (U - E_L)$. Introducing the variable $V := U - E_L$, the reversal potential of the EPSP current $E_{EPSP} := \frac{\sum_k G_k^E\, E_k}{G_{EPSP}} - E_L$, and $E_k^V := E_k^U - E_L$, we then get

$$i_{inj} = G_{EPSP}\, (V - E_{EPSP}) + \sum_k G_k^U\, (V - E_k^V) + G_L\, V. \tag{4}$$

The current $i_{EPSP} := G_{EPSP}\, (V - E_{EPSP})$ will be called the *EPSP induced current.*

A subthreshold MN is inactive as long as it receives synaptic inputs without generating APs. During subthreshold depolarizations, there is a small increase of the sodium conductance which tends to depolarize the membrane and a small increase of the potassium conductance which tends to hyperpolarize the membrane. Since the two currents are in opposite directions, they tend to cancel each other (ultimately, this could be quantitatively derived from the Hodgkin–Huxley equations [22]). Therefore, we assume that the voltage-dependent channels are closed in subthreshold MNs, and consequently, the voltage-dependent currents are 0. Moreover, if $i_{inj} = 0$, the membrane potential corresponding to the EPSP is denoted V_{EPSP} and (4) becomes

$$G_{EPSP}\,(V_{EPSP} - E_{EPSP}) + G_L\,V_{EPSP} = 0. \tag{5}$$

According to (2) and (5), the membrane potential as a function of the input is

$$V_{EPSP}(In) = \frac{g\,In\,E_{EPSP}}{G_L + g\,In}. \tag{6}$$

The threshold input In_T is the maximum input an MN can receive in the subthreshold state. It evokes an EPSP equal to the firing threshold voltage V_T and therefore satisfies $V_{EPSP}(In_T) = V_T$. Assuming that all MNs of the pool have the same firing threshold [42], (6) at threshold provides

$$\tilde{g} = \frac{V_T}{(E_{EPSP} - V_T)\,In_T}, \tag{7}$$

where $\tilde{g} := \frac{g}{G_L}$ is called *relative synaptic weight*. Two quantities in (7) are MU-dependent, namely, the relative synaptic weight and the threshold input. According to (7), it is equally adequate to determine either one of them.

Fitting the frequency-injected current relations with a straight line with slope κ [42, 24], the MN firing frequency $\nu(G_{EPSP}, i_{inj})$ as a function of G_{EPSP} and i_{inj} is given by

$$\nu(0, i_{inj}) = \kappa\,(i_{inj} - i_T) + \nu_T \text{ if } i_{inj} \geq i_T \text{ and 0 otherwise,} \tag{8}$$

where ν_T is the *threshold frequency* and i_T the *threshold current*. Estimations of their values have been determined with current injection experiments on MNs [25].

The relation between the frequency evoked by a synaptic input and the injected current is not at all simple since i_{EPSP}, but not i_{inj}, depends on the membrane potential. We look for an injected current $i_{inj}(G_{EPSP})$ which evokes the same frequency as the synaptic input, namely, $\nu(G_{EPSP}, 0) = \nu(0, i_{inj}(G_{EPSP}))$.

Let us suppose that such a current exists for all values of G_{EPSP}: $i_{inj}(G_{EPSP}) = -i_{EPSP}$. Although the membrane potential of active MNs varies, we replace it by a constant virtual potential V_A which is independent of the firing frequency and is supposed to have similar effects as the time-varying membrane potential. In this approach, we set $V_A = V_T$ and we get $i_{inj}(G_{EPSP}) = G_{EPSP}\,(E_{EPSP} - V_T)$. By inserting (2) and (7) into the last equation, we obtain $i_{inj}(G_{EPSP}(In)) = \frac{G_L\,V_T\,In}{In_T}$. Since $In = In_T$ at threshold, the injected threshold current is $i_T = G_L\,V_T$.

The frequency-force relation of an MU during maintained contractions is built by fitting data obtained by injecting long-lasting currents of different intensities into MNs [26]. The MU force is given by

$$f(\nu) = t\,(1 - c\,\exp(-\gamma\,(\nu - \nu_T))), \tag{9}$$

where t is the MU tetanic contraction force, ν_T is its threshold frequency, and γ controls the shape of the curve. The number c determines the fraction of the tetanic force at recruitment according to $f(\nu_T) = t\,(1 - c)$. Since MUs are parameterized by their tetanic contraction forces t, the threshold input $In_T(t)$ is the smallest value necessary to recruit the MU with tetanic force t. Equation (8), $i_T = G_L\,V_T$, and (9) lead to the following representation of the MU transfer function:

$$f(t, In) := t\left(1 - c\,\exp\left(-\alpha\frac{In - In_T(t)}{In_T(t)}\right)\right) \text{ if } In > In_T(t) \text{ and 0 otherwise,} \tag{10}$$

where $\alpha := \gamma\,\kappa\,G_L\,V_T$.

In muscles with parallel fibers, the total muscle force is the sum of the contraction forces of its MUs, and thus its activation curve is $\mathcal{F}(In) = \int_{t_{min}}^{t_{max}} \rho(s)\,f(s, In)\,ds$. Figure 1 depicts the different steps leading from In to $\mathcal{F}(In)$.

muscle force

FIG. 1. *Steps for the construction of the activation curve $\mathcal{F}(In)$.*

According to the size principle [21], MUs are recruited according to their tetanic contraction force during muscle activation; i.e., weaker MUs are recruited before stronger MUs. Therefore, the threshold input $In_T(t)$ activates all MUs with tetanic forces smaller than or equal to t. Replacing In by $In_T(t)$, we obtain

$$\mathcal{F}(In_T(t)) = \int_{t_{min}}^{t} \rho(s)\,f(s, In_T(t))\,ds. \tag{11}$$

Human subjects who superimposed ballistic contractions on background activities of different levels [38] provided information to determine the unknown function $In_T(t)$. The data suggest that the force generated by two inputs In_1 and In_2 is the sum of the forces induced by the single inputs. If In_0 denotes the minimal input necessary to recruit the smallest MU of the pool, we get the functional equation $\mathcal{F}(In_0 + In_1 + In_2) = \mathcal{F}(In_0 + In_1) + \mathcal{F}(In_0 + In_2)$. Its unique nonnegative solution with $\mathcal{F}(In_0) = 0$ is (see [1]) $\mathcal{F}(In) = k\,(In - In_0)$. This is the equation of a straight line with slope k. After recruitment, the activation curve is strictly concave. Since no additional force due to newly recruited MUs is available, it is an integral of strictly concave functions given in (10). Consequently, the affine ("linear" in [42]) relation can hold exclusively during recruitment. In a forthcoming paper, we will show that the possible activation curves are not limited to affine functions.

It should also be noted that the value of In corresponding to the end of recruitment is not specified a priori. This is a "free boundary" which will be determined by the model.

One could wonder whether a muscle response, which is not exactly additive, can be reasonably approximated by an additive function or not. The following results [29] shed some light on this question: a function $f : \mathbb{R} \to \mathbb{R}$ is called ϵ-additive if $|f(x+y) - f(x) - f(y)| \le \epsilon$ for all $x, y \in \mathbb{R}$. It can be seen that, if g is additive, any function f fulfilling $|f(x) - g(x)| \le \epsilon$ for all $x \in \mathbb{R}$ is 3ϵ-additive. Conversely, it can be proved that, for any ϵ-additive function f, there exists a unique additive function $g : \mathbb{R} \to \mathbb{R}$ such that $|f(x) - g(x)| \le \epsilon$, given by $g(x) = \lim_{n\to\infty} \frac{f(nx)}{n}$. As a consequence, if a muscle response $\mathcal{F}$ is only ϵ-additive, then there exists an additive function g contained in a band of width 2ϵ around $\mathcal{F}$. Moreover, if $\mathcal{F}$ is either bounded above or measurable, then g is continuous.

Replacing In by $In_T(t)$ as above, we get, for $t \in [t_{min}, t_{max}]$, $\mathcal{F}(In_T(t)) = k\,(In_T(t) - In_0)$, and with (10) and (11),

$$\mathcal{F}(In_T(t)) = \int_{t_{min}}^{t} h(s)\ \left(1 - c\ \exp\left(-\alpha \frac{\mathcal{F}(In_T(t)) - \mathcal{F}(In_T(s))}{\mathcal{F}(In_T(s)) + \Delta}\right)\right)\ ds, \tag{12}$$

where $h(t) = t\,\rho(t)$ is the force density function of the muscle and $\Delta = k\,In_0$.

Equation (12) contains the parameters α, c, Δ, and h [42]. Experimental observations suggest that α [24, 26, 2] and c [27] are MU-independent, and, in the present approach, we assume muscle independence. On the basis of experimental data, α was set to 1.14 and c to 0.9 [42], but the forthcoming general discussion is valid for all $\alpha > 0$, $0 < c < 1$, and $\Delta > 0$. A muscle is thus specified by Δ and h. In_0 cannot be measured experimentally, and in [42] it was assumed to be the same for all muscles. This assumption is however not required here.

2. The integral equation.

2.1. General considerations. Equation (12) is an integral equation for the unknown function $\mathcal{F}(In_T(t))$. By introducing the notation $F(t) = \mathcal{F}(In_T(t))$, (12) takes the form

$$F(t) = \int_{t_{min}}^{t} h(s)\ \left(1 - c\ \exp\left(-\alpha \frac{F(t) - F(s)}{F(s) + \Delta}\right)\right)\ ds, \qquad t \in [t_{min}, t_{max}]. \tag{13}$$

With our assumptions about ρ, the preceding integral has to be understood in the Lebesgue sense and, for obvious physiological reasons, we look for nonnegative solutions.

Equation (13) is not of Volterra type because its kernel

$$k(s, F(s), F(t)) := h(s)\ \left(1 - c\ \exp\left(-\alpha \frac{F(t) - F(s)}{F(s) + \Delta}\right)\right)$$

involves $F(t)$ and not only s, t, and $F(s)$. If (13) has a nonnegative locally bounded solution $F(t)$, $t \in [t_{min}, t_{max}]$, for $\alpha > 0$, $0 < c < 1$, and $\Delta > 0$, it may admit discontinuous solutions. Indeed, as a consequence of the dominated convergence theorem, for every sequence $(t_n)_{n\in\mathbb{N}}$, $t_n \in [t_{min}, t_{max}]$, with $\lim_{n\to\infty} t_n = t$ and $\lim_{n\to\infty} F(t_n) = \gamma$, we have $\lim_{n\to\infty} \int_{t_{min}}^{t_n} k(s, F(s), F(t_n))\, ds = \int_{t_{min}}^{t} k(s, F(s), \gamma)\, ds$. Thus (13) admits a locally bounded solution discontinuous at $t^* \in [t_{min}, t_{max}]$ if and only if the set $A_{t^*} = \{x \in \mathbb{R};\ x = \int_{t_{min}}^{t^*} k(s, F(s), x)\, ds\}$ contains an element $\beta \neq F(t^*)$. Indeed, if the preceding property holds, the function $F^*(t)$ taking the values β at $t = t^*$ and $F(t)$ elsewhere is obviously a discontinuous solution of (13), and the converse is clear. It can be seen, for example, numerically, that A_t contains two elements for t large enough.

2.2. The hyperbolic muscle. The presence of $F(t)$ in the kernel of (13) rules out most of the arguments of the classical theory of integral equations. It is not clear whether this equation admits a solution or not, and this point is important because, in our model, (13) governs the activation of a muscle.

Since ρ is strictly positive a.e., the function $H(t) = \int_{t_{min}}^{t} h(s)\, ds$, $t \in [t_{min}, t_{max}]$, is strictly increasing and hence invertible. Let us note that $H(t)$ is the force of the muscle when all MUs up to level t produce their tetanic force and $H(t_{max}) = F_{max}$.

By introducing $K(a,b) = 1 - c\exp(-\alpha\frac{b-a}{a+\Delta})$, $a, b \in \mathbb{R}_+ = [0, +\infty)$, (13) can be written $F(v) = \int_{t_{min}}^{v} K(F(u), F(v))\, h(u)\, du$. Since H is strictly increasing and absolutely continuous, the change of variable $u = H^{-1}(s)$ leads to $F(v) = \int_{H(t_{min})}^{H(v)} K(F(H^{-1}(s)), F(v))\, ds$ for $v \in [t_{min}, t_{max}]$. Without risk of confusion we write $H(v) = t$ and because $H(t_{min}) = 0$, $H(t_{max}) = F_{max}$, we obtain $F(H^{-1}(t)) = \int_0^t K(F(H^{-1}(s)), F(H^{-1}(t)))\, ds$ for $t \in [0, F_{max}]$. By defining $Y(t) := F(H^{-1}(t))$ and $T = F_{max}$, we get

$$(14) \qquad Y(t) = \int_0^t \left(1 - c\, \exp\left(-\alpha \frac{Y(t) - Y(s)}{Y(s) + \Delta}\right)\right) ds, \qquad t \in [0, T].$$

Since (14) describes the activation of a muscle whose MU density is the hyperbola $\rho(t) = \frac{1}{t}$ $(t > 0)$, it is natural to call it *hyperbolic*. Clearly, such a muscle has no physiological reality since any interval $(0, T]$ contains infinitely many of its MUs. This theoretical muscle is nevertheless interesting. By playing with the notation, we get

$$(15) \qquad F(t) = Y(H(t)), \quad t \in [t_{min}, t_{max}],$$

and we see that the force of an arbitrary muscle can be deduced from that of a hyperbolic one. It is therefore enough to study (14).

2.3. Existence and unicity of a physiological solution. Straightforward computations provide the following theorem.

THEOREM 1. *Let $0 < c < 1$, $\alpha > 0$, $\Delta > 0$, and $a, b \in \mathbb{R}_+ \mapsto K(a,b) = 1 - c\exp(-\alpha\frac{b-a}{a+\Delta})$.*

(a) *$K(a,b)$ together with the partial derivatives $K_a(a,b)$, $K_b(a,b)$, and $K_{bb}(a,b)$ are continuous and bounded.*

(b) *$K_a(a,b) < 0$, $K_b(a,b) > 0$, $K_{bb}(a,b) < 0$, and $K(a,b)$ is thus a concave function in the variable b.*

We first prove the existence and unicity of a nonnegative solution of (14) for small values of T. For $0 < T < \infty$, the set $E_T = \{f : [0,T] \mapsto \mathbb{R};\ f$ is measurable and bounded$\}$, equipped with the metric $d(f,g) := \sup_{t\in[0,T]} |f(t) - g(t)|$, is a complete metric space. Since uniform convergence preserves nonnegativity, $E_T^+ = \{f \in E_T; f \geq 0\}$ is a closed subset of E_T and hence also a complete metric space. Clearly, a solution of (14) is a fixed point of the operator $A_T f(t) = \int_0^t K(f(s), f(t))\, ds$, $t \in [0, T]$, $f \in E_T^+$, which maps E_T^+ into itself. According to Theorem 1, the mean value theorem can be applied to $K(a, b)$ and provides, for any $f, g \in E_T^+$: $d(A_T f, A_T g) \leq 2\, T\, M\, d(f, g)$, where $M := \sup_{a,b \in \mathbb{R}_+}(|K_a(a, b)|, |K_b(a, b)|)$. We conclude that A_T admits a unique fixed point for $T < \frac{1}{2\, M}$ since it is a contraction, and we prove the following theorem.

THEOREM 2. *For $T < \frac{1}{2\, M}$, (14) admits a unique nonnegative solution in E_T^+.*

Physiologically, a solution $Y(t)$ of (14) represents the force developed by a hyperbolic muscle, all of whose MUs, up to level t, are recruited. Therefore, Y has to be a nondecreasing function with $Y(0) = 0$, and any such solution will be called *physiological*. Since $0 < 1 - c \leq K(a, b) \leq 1$ for $0 \leq a \leq b$, we get $0 \leq Y(t) \leq t$ for $t \in [0, T]$, and Y is an element of $S_T := \{f \in E_T;\ f \text{ is nondecreasing, } 0 \leq f(t) \leq t,\ t \in [0, T]\}$. Clearly, $S_T \subset E_T^+$ and every element f of S_T satisfies $f(0) = 0$.

We now prove the existence of a physiological solution of (14) for an arbitrary $T > 0$ and start by recalling the following.

THEOREM OF SCHAUDER (see [41]). *Any nonempty compact and convex subset of a normed space has the fixed point property; i.e., every continuous mapping of such a subset into itself has at least one fixed point.*

THEOREM OF HELLY (see [6]). *Let $(f_n)_{n \in \mathbb{N}}$ be a sequence of uniformly bounded, nondecreasing, and right continuous functions defined over an interval in $\mathbb{R}$. Then there exist a subsequence $(f_{n_k})_{k \in \mathbb{N}}$ and a nondecreasing right continuous function f such that $\lim_{k \to \infty} f_{n_k}(t) = f(t)$, for all continuity points t of f.*

THEOREM 3. *Every sequence in S_T contains a subsequence converging in the mean of order 1 to an element of S_T. Furthermore, S_T is nonempty and convex.*

Proof. For any sequence $(f_n)_{n \in \mathbb{N}}$ in S_T, the functions $t \in [0, T] \longmapsto f_n^+(t) = \lim_{h \downarrow 0} f_n(t + h)$ are also in S_T and right continuous. According to Helly's theorem, there exist a subsequence $(n_k)_{k \in \mathbb{N}}$ and a nondecreasing right continuous function f^+ such that $f_{n_k}(t)$ converges to $f^+(t)$, as $k \to \infty$, for every continuity point t of f^+ in $[0, T]$. Since f^+ is in S_T and the exceptional set is at most countable, the convergence takes place a.e. and hence in measure. Furthermore, the sequence, being uniformly bounded by T, is uniformly integrable, and we conclude to its convergence in the mean of order 1. Because nonemptyness and convexity of S_T are obvious, the proof is complete. □

Since Schauder's theorem requires a normed space, we introduce $E_T^* = E_T$ (mod a.e.) equipped with the L_1 norm. Let us recall that an element of E_T^* is an equivalence class of functions which are equal a.e. to a representative. Hence, S_T^* is the subset of E_T^* such that each equivalence class contains an element of S_T. S_T^* is nonempty and convex. Since every sequence in S_T^* has a corresponding sequence of representatives in S_T, S_T^* is also a compact subset of the normed space E_T^* as a consequence of the first part of Theorem 3.

Let f^* be the equivalence class in S_T^* of an element $f \in S_T$. Since $f = f'$ (a.e.) for elements in S_T implies that $A_T f = A_T f'$ (a.e.), we can define A_T^* over S_T^* with $A_T^* f^* = (A_T f)^*$ because it is independent of the representative.

THEOREM 4. *A_T^* is a continuous mapping of S_T^* into itself.*

Proof. Let f be a nondecreasing representative of f^* in S_T. Since $0 < 1 - c \leq K(a, b) \leq 1$ for $0 \leq a \leq b$, we get $0 \leq A_T f(t) \leq t$ for $t \in [0, T]$. Furthermore, $K(a, b)$ is nonnegative and increasing in the second variable for $a, b \geq 0$, and consequently, for $0 \leq t \leq t' \leq T$, we have $A_T f(t) = \int_0^t K(f(s), f(t))\, ds \leq \int_0^{t'} K(f(s), f(t'))\, ds =$

$A_T f(t')$. Therefore, $A_T f$ is an element of S_T and $A_T^* f^*$ belongs to S_T^* since a.e. equalities are preserved by A_T. To prove the continuity assertion, let us consider a sequence $(f_n^*)_{n\in\mathbb{N}}$ in S_T^* which converges to $\tilde{f}^*$ in L_1. Since S_T^* is closed as a compact subset of a Hausdorff space, we conclude that $\tilde{f}^*$ belongs to S_T^*. Furthermore, convergence in L_1 entails convergence in measure, and, for any σ-finite measure, the latter is equivalent to the statement "every subsequence contains a subsequence converging a.e." By using this property and the boundedness and continuity of $K(.,.)$, we get the desired result via the dominated convergence theorem. □

THEOREM 5. *For every* $T > 0$, (14) *admits a physiological solution.*

Proof. Schauder's theorem provides the existence of a fixed point f^* of A_T^* in S_T^*. For any nondecreasing representative f of the latter, we have $A_T f = f$ (a.e.) in $[0, T]$. The exceptional set E having measure 0, its complementary E^c is dense in $[0, T]$, and for every $t \in E^c$, one can define $f_-(t)$ as the left-hand limit of f over E^c since f is nondecreasing and bounded. The function $\tilde{f}(t) := \lim_{s\uparrow t} f(s)$ is nonnegative and nondecreasing. By using the boundedness and continuity of $K(.,.)$ and the dominated convergence theorem, one can show that $\tilde{f}$ satisfies $A_T\tilde{f}(t) = \tilde{f}(t)$ for every t in $[0, T]$, and the proof is complete. □

We prove that increasingness and continuity are equivalent properties for solutions of (14).

LEMMA 6. *Let* $f : [a, b] \mapsto \mathbb{R}$ *be continuous and* $f(a) = f(b)$. *For every* $\delta > 0$, *there exist* $a \le t < t' \le b$ *with* $0 < t' - t < \delta$ *and* $f(t) = f(t')$.

Proof. The property clearly holds if f is constant. Otherwise, replacing f by $-f$ if necessary, we can assume that f admits a maximum $M \neq f(a)$ at t^* in the open interval (a, b). Choosing $\lambda < M$ sufficiently close to M, the intermediate value theorem for continuous functions implies the existence of $a < t < t^* < t' < b$, such that $f(t) = f(t') = \lambda$ and t, t' are as close as we want to t^*. Let us note that if f is not constant, it is even possible to choose t and t' so that $f(s) \neq f(a)$ for all $s \in [t, t']$. □

THEOREM 7. *A continuous solution of* (14) *starting at* 0 *is strictly increasing.*

Proof. We first show that strict positivity of a continuous solution Y of (14) over an interval $J \subset (0, T]$ entails its injectivity. Assuming the contrary, one can find $a < b$ in J with $Y(a) = Y(b)$. According to the preceding lemma, there exist $t < t'$ in J, as close as we want, with $Y(t) = Y(t') = \lambda > 0$ and, from (14), we deduce $0 = Y(t') - Y(t) = \int_t^{t'} K(Y(s), \lambda)\, ds$. Since $K(\lambda, \lambda) > 0$ and K is continuous over $\mathbb{R}_+^2$, $K(Y(s), \lambda) > 0$ over $[t, t']$ for t, t' sufficiently close to each other. Therefore, the preceding integral is positive and we get a contradiction.

To prove the theorem, we observe that the form of the kernel K implies the existence of a neighborhood of $(0, 0)$ in $\mathbb{R}^2$ over which $K(.,.) > 0$. Since $Y(0) = 0$ and Y is continuous, there exists $0 < t_0 < T$, such that for all $0 \le s \le t \le t_0$, $K(Y(s), Y(t)) > 0$ and hence $Y(t) > 0$ over $(0, t_0]$. Consequently, Y is injective and hence increasing over $[0, t_0]$. A first zero of Y after t_0 would violate its injectivity over an interval of positivity, and the proof is complete. □

The following lemma will be used to discuss the converse of the preceding result. In what follows, we shall use the notation $f_x := \frac{\partial f}{\partial x}$ for a function f.

LEMMA 8. *Let* Y, $Y(0) = 0$, *be a nondecreasing solution of* (14) *defined over some interval* $[0, T]$ *and* $G(a, b) := \int_0^a K(Y(s), b)\, ds$ *for* $(a, b) \in [0, T] \times \mathbb{R}$. *The function* G *has the following properties:* (a) *For every fixed* $a \in [0, T]$, $G(a, b)$ *is a strictly increasing and concave function of* b. (b) $G(a, b)$ *is continuous.* (c) $G_b(a, b)$

is continuous, and the same property holds for $G_a(a,b)$ *if* Y *is continuous.* (d) *If* Y *is continuous, so are* $G(t,Y(t))$ *and* $G_b(t,Y(t))$ *as functions of* t.

Proof. Strict monotonicity in (a) is obvious and concavity follows from the fact that it is preserved by integration. Properties (b) and (c) can be deduced from the dominated convergence theorem and suitable estimations, and (d) is obvious. □

THEOREM 9. *Any nondecreasing solution of* (14) *starting at* 0 *is continuously differentiable.*

Proof. Let $\tilde{Y}$ defined over $[0,T]$ ($\tilde{Y}(0)=0$) be a nondecreasing solution of (14) and Y the function of its right-hand limits. Y is nondecreasing and right continuous, and, by a density argument, continuity of $\tilde{Y}$ and Y are equivalent. Moreover, the dominated convergence theorem provides $Y(t)=\int_0^t K(\tilde{Y}(s),Y(t))\,ds$ and since $\tilde{Y}(t)=Y(t)$ (a.e.), $Y(t)$ is also a solution of (14). Because of the concavity property (a) in Lemma 8, for every $t\in[0,T]$, $G(t,y)=y$ admits at most two solutions, one of them being $Y(t)$ since $G(t,Y(t))=Y(t)$. Moreover, if for a given t the preceding equation has two distinct solutions $y_1(t)<y_2(t)$, then $G_b(t,y_2(t))<1$ and $G_b(t,y_1(t))>1$.

According to Theorem 2, over a sufficiently small right-hand interval of 0, (14) admits a unique nonnegative solution in the space of bounded measurable functions. As a consequence, $Y(t)$ is the unique solution of $G(t,y)=y$ for t small enough. The function G satisfies all regularity conditions of the implicit function theorem [41]. Since $G(0,0)=0$ and $G_b(0,0)=0<1$, the latter entails the existence of a unique continuous function y such that $y(0)=0$ and $G(t,y(t))-y(t)=0$ over a right-hand neighborhood of 0. The preceding unicity property implies $Y\equiv y$ for t small enough and continuity entails $G_b(t,Y(t))<1$ over some right-hand interval of 0. Hence there is an interval $[0,\beta)$ of maximal length β over which $G_b(t,Y(t))<1$.

If Y is not continuous over $[0,\beta)$, then there is a point of discontinuity $t_0\neq 0$ because Y is continuous for small values of t. Y is right continuous and since it is increasing, its left and right-hand limits at t_0 satisfy $Y(t_0^-)<Y(t_0^+)=Y(t_0)$. According to the implicit function theorem, there exists a unique continuous function y_0 defined over an open interval I_{t_0} containing t_0, such that $y_0(t_0)=Y(t_0)$ and $G(t,y_0(t))=y_0(t)$ for $t\in I_{t_0}$. Since $G_b(t_0,Y(t_0))<1$, the continuity of y_0 implies the existence of $t<t_0$ in I_{t_0}, with $G_b(t,y_0(t))<1$ and $Y(t_0^-)<y_0(t)$. Because $Y(t)\leq Y(t_0^-)$, we obtain the configuration $G(t,Y(t))=Y(t)$, $G(t,y_0(t))=y_0(t)$, $G_b(t,Y(t))<1$, $G_b(t,y_0(t))<1$, and $Y(t)\neq y_0(t)$. This is a contradiction of the concavity of $G(t,b)$ in the variable b, and Y is continuous over $[0,\beta)$ and thus identical to $\tilde{Y}$.

The function $G_b(a,b)$ is continuous and, because of (c) in Lemma 8, the continuity of Y implies that of $G_a(a,b)$. Consequently, G is continuously differentiable and, according to another version of the implicit function theorem [10, 11], every locally defined continuous solution y provided by the last theorem is also differentiable. Since Y is continuous over $[0,\beta)$, local unicity implies local identity of y and Y and entails the differentiability of the latter over $[0,\beta)$.

In the following considerations, every interchange of integration and derivation can be justified with the dominated convergence theorem. For $t\in[0,T]$ we introduce $\phi(t):=G_b(t,Y(t))=\int_0^t\frac{\alpha\, c}{Y(s)+\Delta}(\exp(-\alpha\frac{Y(t)-Y(s)}{Y(s)+\Delta}))\,ds$. Writing $'=\frac{d}{dt}$ and using the differentiability of Y, for every $t\in[0,\beta)$ we get

$$\phi'(t)=K_b(Y(t),Y(t))+\frac{1-c}{1-\phi(t)}\int_0^t K_{bb}(Y(s),Y(t))\,ds. \tag{16}$$

We now suppose that $\beta<T$ and claim that $\sup_{t\in[0,\beta)}\phi(t)=m<1$. If not, $m=1$ as a consequence of the definition of β, and by using the mean value theorem of differential calculus, one can choose an increasing sequence $(t_n)_{n\in\mathbb{N}}$ such that $t_n \uparrow \beta$ as $n \to \infty$ and $\phi'(t_n) \geq 0$ for every $n \in \mathbb{N}$. The first term in (16) is positive and bounded, and the integral is negative and bounded away from 0. Since $0 < c < 1$, the quotient before the integral tends to $+\infty$ as $t \uparrow \beta$. According to (16), $\phi'(t_n) < 0$ for n sufficiently large, and we get a contradiction and conclude that $m < 1$.

Because of the monotonicity of Y, $Y(t) \leq Y(\beta)$ for all $t \in [0, \beta)$, and thus, for any sequence $u_n \uparrow \beta$, we have $\int_0^{u_n} \frac{\alpha\, c}{Y(s)+\Delta}(\exp(-\alpha\frac{Y(\beta)-Y(s)}{Y(s)+\Delta}))\, ds \leq \phi(u_n) \leq m$. Letting $n \to \infty$ in the integral, we get $\phi(\beta) \leq m < 1$ and thus $G_b(\beta, Y(\beta)) < 1$. Applying once more the implicit function theorem, we get a unique continuous function y^+ defined over an open interval I_β containing β with $y^+(\beta) = Y(\beta)$, $G(t, y^+(t)) = y^+(t)$ over I_β, and $G_b(t, y^+(t)) < 1$ for every t sufficiently close to β. If $Y \equiv y^+$ does not hold over a right-hand open neighborhood of β, then one can find a sequence $v_n \downarrow \beta$ as $n \to \infty$, such that $Y(v_n) \neq y^+(v_n)$ for every n. Monotonicity and concavity entail $Y(\beta) \leq Y(v_n) < y^+(v_n)$, and hence $Y(v_n) \to Y(\beta)$ as $n \to \infty$. Concavity again implies that $G_b(v_n, Y(v_n)) > 1$, and thus, letting $n \to \infty$, $G_b(\beta, Y(\beta)) \geq 1$, which is a contradiction. Since $Y \equiv y^+$ on a right-hand open interval of β, $G_b(t, Y(t)) < 1$ for all sufficiently small t to the right of β, which is a contradiction of its maximality. Consequently $\beta = T$ and Y is continuous over $[0, T]$. Moreover, Y is also differentiable, and the relations $Y'(t) = \frac{1-c}{1-\phi(t)} = \frac{1-c}{1-G_b(t,Y(t))}$ show that it is even continuously differentiable and $Y'(t) > 0$ over $[0, T]$. □

We would like to stress that, in Theorem 9, the condition $0 < c < 1$ plays a delicate role. Indeed, let us assume that $c = 1$ and look for a solution of (14) of the form $Y(t) = a\, I_{(t^*,+\infty)}(t)$, where I denotes the indicator function and t^* and a have to be specified. For $t \leq t^*$, (14) is satisfied since both sides are equal to 0. For $t > t^*$, it reduces to $a = t^*\,(1 - \exp(-\frac{\alpha\, a}{\Delta}))$. By choosing t^* so that $\frac{t^*\alpha}{\Delta} > 1$ and the positive solution of the preceding equation for a, we get a discontinuous nondecreasing solution of (14).

Collecting all the preceding results, we get the following theorem.

THEOREM 10. *The following properties are equivalent for a solution Y of* (14) *with $Y(0) = 0$:* (a) *Y is physiological, i.e., nondecreasing,* (b) *Y is strictly increasing,* (c) *Y is continuous, and* (d) *Y is continuously differentiable and Y' is strictly positive.*

It is interesting to note that although (14) admits possibly discontinuous solutions, any physiological solution is automatically continuously differentiable.

THEOREM 11. *Equation* (14) *admits a unique physiological solution.*

This uniqueness result can be deduced from Gronwall's inequality and the fact that, according to the proof of Theorem 9, $\phi(t) < 1$ over $[0, T]$. We propose another argument which will also provide a nice way to get the solution of (14).

Proof. We proved that every nondecreasing solution Y of (14) over $[0, T]$ is strictly increasing and continuously differentiable with a strictly positive and bounded derivative. Consequently, $X = Y^{-1}$ has the same properties as Y and $Y(X(t)) = t$ for every $t \geq 0$. In particular, the derivative of X, denoted x, is continuous. Performing the change of variables $s = X(u)$ and $v = X(t)$ in (14) and rewriting s and t instead of u and v, we get

$$t = \int_0^t x(s)\left(1 - c\,\exp\left(-\alpha\frac{t-s}{s+\Delta}\right)\right) ds. \tag{17}$$

Equation (17) is a linear Volterra equation of the first kind for x, the derivative of X (inverse function of Y). Since the kernel of (17) satisfies all the conditions of Theorem

1.3.5 in [4], this equation admits a unique continuous solution, and thus Theorem 11 is proved. □

It is interesting to note that (17) has an interpretation. Indeed, it is an integral equation for the force density function x of a muscle whose force is t if its MUs up to level t are recruited.

For continuous x, derivation and integration by parts of (17) provide, respectively,

$$x(t) = \frac{1}{1-c} - \frac{\alpha\, c}{1-c}\int_0^t x(s)\frac{1}{s+\Delta}\exp\left(-\alpha\frac{t-s}{s+\Delta}\right) ds \quad \text{and} \tag{18}$$

$$X(t) = \frac{t}{1-c} - \frac{\alpha\, c}{1-c}\int_0^t X(s)\frac{t+\Delta}{(s+\Delta)^2}\exp\left(-\alpha\frac{t-s}{s+\Delta}\right) ds. \tag{19}$$

The last two equations are linear Volterra equations of the second kind, for which theory and numerical treatments are well known [4, 14, 32].

Let us remark that existence and unicity of Y for every $T > 0$ automatically provide a unique solution of (14) defined over $[0,\infty)$.

We would like to point out that Theorem 10 together with the preceding arguments also lead to the existence of an increasing and continuously differentiable solution of (14). However, Schauder's theorem provides the existence of a nondecreasing solution without continuity assumption and thus without Theorem 10. Both approaches are interesting, and methodological diversity is always welcome for the treatment of future investigations.

3. Properties of the physiological solution.

In the following, x will be the unique continuous solution of (17) defined over $[0,+\infty)$ and $X(t) = \int_0^t x(s)\,ds$. As can be seen in (18), x depends on the parameters α, c, and $\Delta = k\,In_0$. Since α and c are fixed and muscle-independent, x, X, and Y will be considered as functions of the two variables $t \geq 0$ and $\Delta > 0$ and written $x(t,\Delta)$, $X(t,\Delta)$, and $Y(t,\Delta)$.

THEOREM 12. *For every fixed $\Delta > 0$, the following properties hold:* (a) $x(t,\Delta)$ *is continuously differentiable in the variable t,* (b) $x(0,\Delta) = \frac{1}{1-c}$, (c) $0 < x(t,\Delta) \leq (1-c)^{-1}$ *for every $t > 0$,* (d) $0 < X(t,\Delta) \leq \frac{t}{1-c}$ *for every $t > 0$,* (e) *as a function of t, $\frac{X(t,\Delta)}{t}$ is decreasing over $(0,\infty)$, and* (f) *as a function of u, $\frac{Y(u,\Delta)}{u}$ is increasing over $(0,\infty)$.*

Proof. Part (a) follows from the facts that (18) is again differentiable in t and that the result involves only continuous functions. Since the integrand in (18) is bounded, letting $t \to 0$, we get (b). The second inequality in (c) follows from (18) and $x(t,\Delta) = X_t(t,\Delta) > 0$. Integrating (c) provides (d). To prove (e), we have to show that $\frac{\partial}{\partial t}(\frac{X(t,\Delta)}{t}) = \frac{1}{t}\,(x(t,\Delta) - \frac{X(t,\Delta)}{t}) \leq 0$, that is, $\frac{X(t,\Delta)}{t} \geq x(t,\Delta)$ for $t > 0$. We divide (19) by t and obtain $\frac{X(t,\Delta)}{t} = \frac{1}{1-c} + \int_0^t K(s,t)\,\frac{s}{t}\frac{t+\Delta}{s+\Delta}\frac{X(s,\Delta)}{s}\,ds = \frac{1}{1-c} + \int_0^t \tilde{K}(s,t)\,\frac{X(s,\Delta)}{s}\,ds$, where $K(s,t) := -\frac{\alpha\, c}{1-c}\frac{1}{s+\Delta}\exp(-\alpha\frac{t-s}{s+\Delta})$ is the kernel of (18). We observe that $\tilde{K}(s,t) = K(s,t)\frac{s}{t}\frac{t+\Delta}{s+\Delta}$. A straightforward computation based on kernel iterations shows that the corresponding resolvents $R(s,t)$ and $R'(s,t)$ also satisfy $R'(s,t) = R(s,t)\frac{s}{t}\frac{t+\Delta}{s+\Delta}$. Obviously for $\Delta > 0$ and $0 < s \leq t$, we have $\frac{s}{t}\frac{t+\Delta}{s+\Delta} < 1$, and according to the general theory [4], we can write $\frac{X(t,\Delta)}{t} = (1-c)^{-1} + (1-c)^{-1}\int_0^t R'(s,t)\,ds = (1-c)^{-1} + (1-c)^{-1}\int_0^t R(s,t)\frac{s}{t}\frac{t+\Delta}{s+\Delta}\,ds \geq (1-c)^{-1} + (1-c)^{-1}\int_0^t R(s,t)\,ds = x(t,\Delta)$. The last inequality clearly holds if $R(s,t) \leq 0$, and it is enough to prove the latter. The resolvent formula [4] provides $-R(s,t) = \frac{\alpha\, c}{1-c}\frac{1}{s+\Delta}\exp(-\alpha\frac{t-s}{s+\Delta}) + \int_s^t R(s,u)\,\frac{\alpha\, c}{1-c}\frac{1}{u+\Delta}\exp(-\alpha\frac{t-u}{u+\Delta})\,du$. Applying the changes of variables $u = v - \Delta$ and then $v = \exp(w)$ and rewriting $t' = \ln(t + \Delta)$, $s' = \ln(s + \Delta)$, for fixed s', $-R'(s', t') = -R(\exp(s') - \Delta, \exp(t') - \Delta)$ is a solution of the convolution-type integral equation $-R'(s', t') = f(t') + \int_{s'}^{t'} R'(s', w)\, h(t' - w)\, dw$, where $f(t') = \frac{\alpha\, c}{1-c} \frac{1}{\exp(s')} \exp(-\alpha \frac{\exp(t') - \exp(s')}{\exp(s')})$ and $h(t') = \frac{\alpha\, c}{1-c} \exp(\alpha - \alpha \exp(t'))$. Since $\frac{f(T)}{f(t)} = \exp(-\alpha\, e^{-s'}\, (e^T - e^t)) \le \exp(-\alpha\, e^{-s}(e^T - e^t)) = \frac{h(T-s)}{h(t-s)}$ for $0 \le s' \le s < T < t$, according to Theorem 6.1 in [32], we conclude to $R'(s', t') \le 0$.

For $t_1 = Y(u_1, \Delta)$ and $t_2 = Y(u_2, \Delta)$, $t_1 < t_2$ implies $u_1 < u_2$. By using (e) and $Y(t, \Delta) = X^{-1}(t, \Delta)$ in the variable t, we get $\frac{u_1}{Y(u_1,\Delta)} = \frac{X(Y(u_1,\Delta),\Delta)}{Y(u_1,\Delta)} = \frac{X(t_1,\Delta)}{t_1} \ge \frac{X(t_2,\Delta)}{t_2} = \frac{X(Y(u_2,\Delta),\Delta)}{Y(u_2,\Delta)} = \frac{u_2}{Y(u_2,\Delta)}$, and (f) is proved. □

THEOREM 13. *For every* $\lambda > 0$, $t \ge 0$, $u \ge 0$, *and* $\Delta > 0$, *we have* (a) $x(t, \lambda\Delta) = x(\frac{t}{\lambda}, \Delta)$, (b) $x(\lambda t, \Delta) = x(t, \frac{\Delta}{\lambda})$, (c) $x(\lambda t, \lambda\Delta) = x(t, \Delta)$, (d) $X(\lambda t, \lambda\Delta) = \lambda X(t, \Delta)$, (e) $Y(\lambda u, \lambda\Delta) = \lambda Y(u, \Delta)$, *and* (f) $Y_\Delta(u, \Delta) + u Y_u(u, \Delta) = Y(u, \Delta)$.

Proof. For every $\lambda > 0$, (17) yields $t = \int_0^t x(s, \Delta)(1 - c \exp(-\alpha \frac{\lambda t - \lambda s}{\lambda s + \lambda\Delta}))\, ds$. By using the change of variable $s = \frac{z}{\lambda}$ and ultimately replacing $\lambda\, t$ by t, we get $t = \int_0^t x(\frac{z}{\lambda}, \Delta)(1 - c \exp(-\alpha \frac{t-z}{z+\lambda\Delta}))\, dz$. However, according to (17), we also have $t = \int_0^t x(z, \lambda\Delta)(1 - c \exp(-\alpha \frac{t-z}{z+\lambda\Delta}))\, dz$. Since (17) admits a unique continuous solution, we conclude that $x(z, \lambda\, \Delta) = x(\frac{z}{\lambda}, \Delta)$ for all possible values of their arguments. This is equivalent to (a) and (b), and writing $z = \lambda\, s$ yields (c). Part (d) follows from $X(\lambda t, \lambda\Delta) = \int_0^{\lambda t} x(\frac{z}{\lambda}, \Delta) dz = \int_0^{\lambda t} x(z, \lambda\Delta) dz = \lambda \int_0^t x(s, \Delta) ds = \lambda X(t, \Delta)$. By using Theorem 13(d) and the fact that, for fixed Δ, Y is the inverse function of X, we can write $\lambda t = Y(X(\lambda t, \lambda\Delta), \lambda\Delta) = Y(\lambda X(t, \Delta), \lambda\Delta) = \lambda Y(X(t, \Delta), \Delta)$. The equality $Y(\lambda X(t, \Delta), \lambda\Delta) = \lambda Y(X(t, \Delta), \Delta)$ is valid for every $t \ge 0$. Because $X(t, \Delta)$ is strictly increasing in t, we substitute $u = X(t, \Delta)$, and (e) is proved. According to Theorem 13(e), $Y(u, \Delta) = \Delta Y(\frac{u}{\Delta}, 1)$, and the differentiability of Y with respect to u entails that with respect to Δ.

For any differentiable function $F(u)$, $\frac{d}{dv} F(v)|_{\lambda u} = \frac{1}{\lambda} \frac{d}{du} F(\lambda u)$, and thus $Y_v(v, 1)|_{\frac{u}{\Delta}} = \Delta Y_u(\frac{u}{\Delta}, 1) = Y_u(u, \Delta)$. By using Theorem 13(e) again, $Y_\Delta(u, \Delta) = \frac{\partial}{\partial\Delta}(\Delta Y(\frac{u}{\Delta}, 1)) = Y(\frac{u}{\Delta}, 1) + \Delta(-\frac{u}{\Delta^2}) Y_v(v, 1)|_{\frac{u}{\Delta}}$ and $Y_\Delta(u, \Delta) = \frac{1}{\Delta} Y(u, \Delta) - \frac{u}{\Delta} Y_u(u, \Delta)$. The last equality is equivalent to (f). The latter, which is the differential equivalent of (e), provides a partial differential equation for Y. Unfortunately, the initial condition is given along a characteristic curve and is equivalent to a solution of (17). □

THEOREM 14. *Let* $x_\infty := (1 - c \int_0^1 \exp(-\alpha \frac{1-s}{s})\, ds)^{-1}$.

(a) *For every* $t \ge 0$, $\lim_{\Delta\uparrow\infty} x(t, \Delta) = \frac{1}{1-c}$.

(b) *For every* $t > 0$, $\lim_{\Delta\downarrow 0} x(t, \Delta) = x_\infty$ *and* $\lim_{\Delta\downarrow 0} x(0, \Delta) = \frac{1}{1-c}$.

(c) *For every* $\Delta > 0$, $\lim_{t\uparrow\infty} x(t, \Delta) = x_\infty$.

Proof. By using the continuity of x, $x(0, \Delta) = \frac{1}{1-c}$, and Theorem 13(a), we get $\frac{1}{1-c} = \lim_{t\downarrow 0} x(t, \Delta) = \lim_{\lambda\uparrow\infty} x(\frac{t}{\lambda}, \Delta) = \lim_{\lambda\uparrow\infty} x(t, \lambda\Delta) = \lim_{\Delta\uparrow\infty} x(t, \Delta)$, and (a) is proved.

It is enough to consider (b) for $t > 0$. For every $0 < t < t^*$ and $\Delta > 0$, according to Theorem 13(c), we have $x(t, \Delta) = x(\frac{t}{t^*} t^*, \frac{t}{t^*} \frac{t^*}{t} \Delta) = x(t^*, \frac{t^*}{t} \Delta)$. Let $\Delta_n \downarrow 0$ and $x(t, \Delta_n) \to \liminf_{\Delta\downarrow 0} x(t, \Delta)$ as $n \uparrow \infty$. The preceding equality entails $\liminf_{\Delta\downarrow 0} x(t, \Delta) = \lim_{n\uparrow\infty} x(t, \Delta_n) = \lim_{n\uparrow\infty} x(t^*, \frac{t^*}{t} \Delta_n) \ge \liminf_{\Delta\downarrow 0} x(t^*, \Delta)$. Since for the same reasons the converse inequality also holds, we conclude that $\liminf_{\Delta\downarrow 0}\ x(t, \Delta) = \liminf_{\Delta\downarrow 0} x(t^*, \Delta)$. Hence, for $t > 0$, $\liminf_{\Delta\downarrow 0} x(t, \Delta)$ is independent of t, and the same property holds for $\limsup_{\Delta\downarrow 0} x(t, \Delta)$. By using (Δ_n) such that $\lim_{n\to\infty} x(t, \Delta_n) = \underline{x}$, (17) and the dominated convergence theorem provide

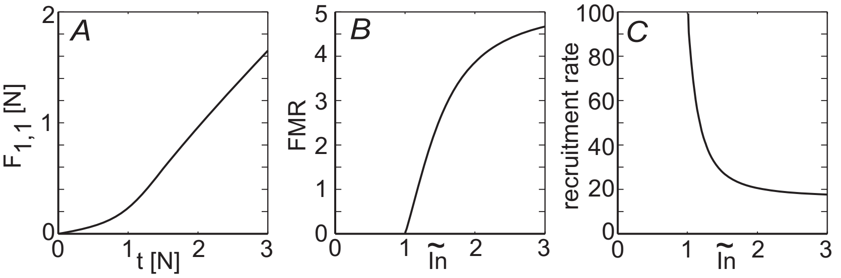

FIG. 2. A: *Force of the standard hyperbolic muscle as a function of the tetanic force of the last recruited MU.* B: *Frequency modulation to recruitment ratio (FMR).* C: *Recruitment rate.*

$t = \int_0^t \underline{x}\,(1 - c\exp(-\alpha\frac{t-s}{s}))\,ds$. Replacing s by $s\,t$ in the preceding integral leads to $\underline{x} = (1 - c\int_0^1 \exp(-\alpha\frac{1-s}{s})\,ds)^{-1} = x_\infty$. Since the same argument holds for $\overline{x} = \limsup_{\Delta\downarrow 0} x(t,\Delta)$, we conclude that $\underline{x} = \overline{x} = x_\infty$, and the proof of (b) is complete.

(c) follows from (b), with $\lim_{t\uparrow\infty} x(t,\Delta) = \lim_{\lambda\downarrow 0} x(\frac{t}{\lambda},\Delta) = \lim_{\lambda\downarrow 0} x(t,\lambda\Delta) = \lim_{\Delta\downarrow 0} x(t,\Delta) = x_\infty$. □

The existence of the limits in the next theorem follows from the monotonicity properties discussed above.

THEOREM 15. *For every* $\Delta > 0$, *we have* (a) $\lim_{t\uparrow\infty} \frac{X(t,\Delta)}{t} = x_\infty$, (b) $\lim_{t\downarrow 0} \frac{X(t,\Delta)}{t} = \frac{1}{1-c}$, (c) $\lim_{u\uparrow\infty} \frac{Y(u,\Delta)}{u} = \frac{1}{x_\infty}$, *and* (d) $\lim_{u\downarrow 0} \frac{Y(u,\Delta)}{u} = 1 - c$.

Proof. (a) follows from Theorem 14(a) and the fact that ordinary convergence implies convergence in the Cesaro sense. Since $X(0,\Delta) = 0$, the definition of the right-hand derivative at 0 provides (b). Part (d) follows from the same argument applied to the inverse function Y. To prove (c), for fixed Δ we substitute $t = Y(u,\Delta)$ in (a) and use $x_\infty = \lim_{t\uparrow\infty} \frac{X(t,\Delta)}{t} = \lim_{u\uparrow\infty} \frac{X(Y(u,\Delta),\Delta)}{Y(u,\Delta)} = \lim_{u\uparrow\infty} \frac{u}{Y(u,\Delta)}$. □

3.1. Representation of the physiological solution. The use of Theorem 13 requires caution with units. For simplicity of notation, we introduce two rules:

- The argument of $F_{(h,\Delta)}$ and $\tilde{F}_{(h,\Delta)}$ is always expressed in Newtons.
- The presence or absence of units attributed to $F_{(h,\Delta)}$ and Y is imposed by the context.

Since α and c are muscle-independent, the solution F of (13),

$$F(t) = \int_{t_{min}}^{t} h(s)\,\left(1 - c\,\exp\left(-\alpha\frac{F(t) - F(s)}{F(s) + \Delta}\right)\right)\,ds, \qquad t \in [t_{min}, t_{max}],$$

depends only on h and Δ and is therefore denoted $F_{(h,\Delta)}$. Recall that a muscle with $h \equiv 1$ was called hyperbolic, and with the new notation we have $F_{(1,\Delta)}(t) = Y(t,\Delta)$ for all $t \geq 0$. By using Theorem 13(e) and (15), we get $F_{(h,\Delta)}(t) = Y(H(t),\Delta) = \Delta Y(\frac{H(t)}{\Delta},1) = \Delta F_{(1,1)}(\frac{H(t)}{\Delta})$. $F_{(1,1)}$ is the solution of (13) for $h \equiv 1$ and $\Delta = 1$, a muscle which will be called *standard hyperbolic* (Figure 2A). Introducing the relative force $\tilde{F}_{(h,\Delta)}(t) := \frac{F_{(h,\Delta)}(t)}{F_{max}}$, we get

$$\tilde{F}_{(h,\Delta)}(t) = \frac{\Delta}{F_{max}} F_{(1,1)}\left(\frac{H(t)}{\Delta}\right) = \frac{\Delta}{F_{max}} F_{(1,1)}\left(\frac{\frac{H(t)}{F_{max}}}{\frac{\Delta}{F_{max}}}\right) = A F_{(1,1)}\left(\frac{\tilde{H}(t)}{A}\right),$$

where $\tilde{H}(t) := \frac{H(t)}{F_{max}}$ and $A := \frac{\Delta}{F_{max}}$, a unit-free number. Thus

$$\tilde{F}_{(h,\Delta)}(t) = AF_{(1,1)}\left(\frac{\tilde{H}(t)}{A}\right) \tag{20}$$

shows that the solution of (13) for an arbitrary muscle can be derived from $F_{(1,1)}$, which is the inverse function of the solution $X(t,1)$ of (19) with $\Delta = 1$: $X(t,1) = \frac{t}{1-c} - \frac{\alpha c}{1-c}\int_0^t X(s,1)\frac{t+1}{(s+1)^2}\exp(-\alpha\frac{t-s}{s+1})\,ds$. The values of $F_{(1,1)}$ can therefore be computed very accurately once and for all and then memorized for subsequent computations (Figure 2A).

The relative synaptic weight. By using $In_T(t) = \frac{F_{(h,\Delta)}(t)}{k} + In_0$, (7), and (20), the relative synaptic weight as a function of the tetanic force t is given by

$$\tilde{g}(t) = \frac{V_T}{(E_{EPSP} - V_T)In_0(F_{(1,1)}(\frac{\tilde{H}(t)}{A}) + 1)}. \tag{21}$$

The range of $\tilde{g}$ is

$$[\tilde{g}(t_{max}), \tilde{g}(t_{min})] = \left[\frac{V_T}{(E_{EPSP} - V_T)In_0(F_{(1,1)}(\frac{1}{A}) + 1)}, \frac{V_T}{(E_{EPSP} - V_T)In_0}\right]$$

and is thus independent of the shape of the MU distribution.

The trace of the muscle in $\tilde{g}(t)$ appears in $\tilde{H}(t)$ and A. According to the preceding results, there always exists a unique relative synaptic weight providing a given affine muscle response during recruitment. Since $F_{(1,1)}(\frac{\tilde{H}(t)}{A})$ is strictly increasing in t, $\tilde{g}(t)$ is strictly decreasing. The integrability of ρ and (21) imply that $\rho(t) \overset{a.e.}{=} \frac{\Delta}{t}\frac{d}{dt}F^{-1}_{(1,1)}(\frac{V_T}{(E_{EPSP}-V_T)In_0\tilde{g}(t)} - 1)$. For fixed values of Δ and In_0 (or equivalently for fixed k and In_0) and once two densities equal a.e. have been identified, there is a one-to-one correspondence between the relative synaptic weight and the MU density function.

4. Activation of the muscle and related functionals. The study of the activation of a muscle is simplified by normalization of the input $\tilde{In} = \frac{In}{In_0}$ and the muscle force $\tilde{\mathcal{F}} = \frac{\mathcal{F}}{F_{max}}$. The curve given by $\tilde{In} \mapsto \tilde{\mathcal{F}}(\tilde{In})$ will be called the *relative activation curve*. During recruitment, the latter is given by $\tilde{\mathcal{F}}(\tilde{In}) = \frac{\Delta}{F_{max}}(\tilde{In} - 1)$ (Figure 3A). The unit-free number $A = \frac{\Delta}{F_{max}}$ in (20) is the slope of the preceding straight line and is called the *activation factor* (denoted S in [42]). It is remarkable that A depends on ρ only through its first moment F_{max}.

Recruitment ratio. The *recruitment ratio* is the fraction Q of the force at the end of recruitment and the maximal force of the muscle. As a ratio of two forces, Q is a unit-free number. By using (20), we can write $Q = AF_{(1,1)}(\frac{H(t_{max})}{\Delta})$. Since $H(t_{max}) = F_{max}$ and $A = \frac{\Delta}{F_{max}}$, the recruitment ratio (Figure 3C) depends on A only since

$$Q(A) = A\,F_{(1,1)}\left(\frac{1}{A}\right). \tag{22}$$

Since $F_{(1,\Delta)}(t) = Y(t,\Delta)$, $Q(A) = \frac{Y(\frac{1}{A},1)}{\frac{1}{A}}$, and because of Theorem 12(f), it is a decreasing function of A. Therefore, by using Theorem 15(c) and (d), for all $A > 0$

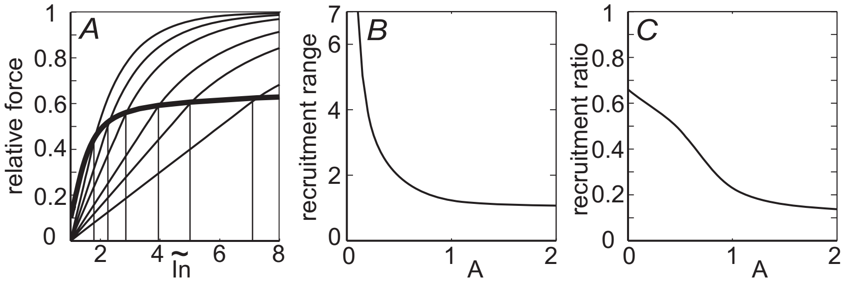

FIG. 3. A: *Relative activation curves and end-recruitment curve as a function of the relative input. They are obtained by projection of the curves in Figure* 4 *in the* $(\tilde{In}, A)$ *plane.* B: *Relative recruitment range* $R(A)$. C: *Recruitment ratio* $Q(A)$.

we have $1 - c = \lim_{u\downarrow 0} \frac{Y(u,1)}{u} \le Q(A) \le \lim_{u\uparrow\infty} \frac{Y(u,1)}{u} = x_\infty^{-1}$. For the estimated values $\alpha = 1.14$ and $c = 0.9$, we get $0.1 \le Q(A) \le 0.66$ for all $A > 0$ and thus for all muscles.

Relative recruitment range. We call *relative recruitment range* R the smallest relative input range within which all MUs are recruited. It is also the factor by which the threshold input of the smallest MU of the pool has to be multiplied in order to recruit all MUs. Since $\tilde{In}_T(t_{min}) = 1$, we have $R = \tilde{In}_T(t_{max}) - 1$. Since A is the slope of the relative activation curve during recruitment (affine range), we have $R = \frac{Q}{A}$. Because of (22), R is a function of A only, given by $R = F_{(1,1)}(\frac{1}{A})$ and thus decreasing (Figure 3B).

If $A \to \infty$, then $R(A) \to 0$ and $Q(A) \to 0.1$, meaning that all MUs tend to have the same threshold and be instantaneously recruited. The muscle force is then close to 10% of the maximal muscle force since, at recruitment, each MU contracts at 10% of its tetanic force ($1 - c = 0.1$). If $A \to 0$, then $R(A) \to +\infty$ and $Q(A) \to 0.66$. The muscle force increases with a slope close to 0. Each recruited MU increases its firing frequency nearly to the tetanic contraction force until the next is recruited. Thus frequency modulation and recruitment develop parallel to each other, and at completion of the MU recruitment, the muscle force approaches 66% of its maximal force.

Relative activation surface. We know that $\mathcal{F}(In) = \int_{t_{min}}^{t_{max}} \rho(s) f(s, In)\, ds$, where $f(s, In) = s\,(1 - c\exp(-\alpha\frac{In - In_T(s)}{In_T(s)}))$ if $In > In_T(s)$ and 0 otherwise. According to (7) and (21), we have

$$\tilde{In}_T(s) = F_{(1,1)}\left(\frac{\tilde{H}(s)}{A}\right) + 1, \quad s \in [t_{min}, t_{max}]. \tag{23}$$

By using the preceding relations and the change of variable $u = \overline{H}(s)$, for $\tilde{In} \ge 1$, we get

$$\tilde{\mathcal{F}}(\tilde{In}) = \int_0^1 I_{\{u \le AF_{(1,1)}^{-1}(\tilde{In}-1)\}} \left(1 - c\,\exp\left(-\alpha \frac{\tilde{In} - (F_{(1,1)}(\frac{u}{A}) + 1)}{F_{(1,1)}(\frac{u}{A}) + 1}\right)\right) du, \tag{24}$$

I_E denoting the indicator function of the set E. For fixed α and c, we see that $\tilde{\mathcal{F}}(\tilde{In})$ is a function of $\tilde{In}$ and A only. Therefore, it can be interpreted as a surface Σ, called the *relative activation surface* (Figure 4) and denoted $\tilde{\mathcal{F}}(A, \tilde{In})$.

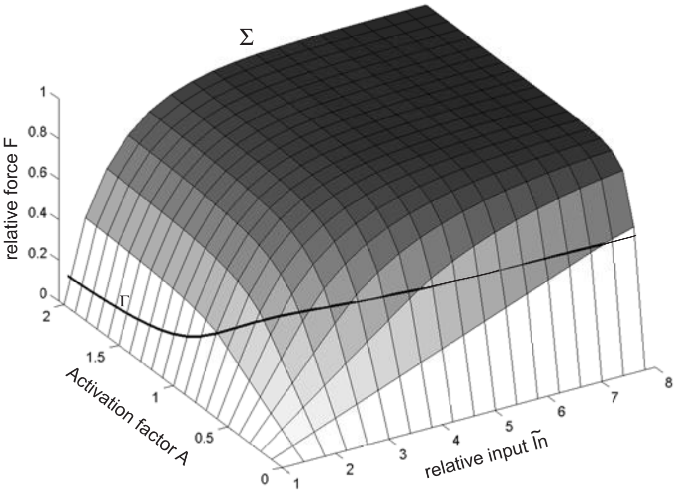

FIG. 4. *The relative activation surface, the relation between the relative input, the activation factor, and the relative force. Vertical sections parallel to the $(\tilde{F}, \tilde{I}n)$ planes are the relative activation curves. The interconnected ends of the relative activation curves give the recruitment boundary curve (bold line).*

Since the function $\hat{F}_{(1,1)}$ is strictly increasing, (24) implies the equivalence of $A_1 < A_2$ and $\tilde{\mathcal{F}}(A_1, \tilde{I}n) < \tilde{\mathcal{F}}(A_2, \tilde{I}n)$ for all $\tilde{I}n > 1$. Consequently, their projections on the (input, force) plane (Figure 3A) never intersect each other for $\tilde{I}n > 1$. The end of the affine part of an activation curve is a point on Σ corresponding to the end of recruitment. The set of these points defines a curve Γ called the *recruitment boundary curve* (bold line in Figure 4). One of the parametric forms of Γ is $0 < A \mapsto (A, 1 + R(A), Q(A))$. We can project Γ on three different planes:

(a) The projection on $(A, \tilde{\mathcal{F}})$ provides the recruitment ratio $Q(A)$ (Figure 3C).

(b) The projection on $(A, \tilde{I}n)$ provides, up to a translation, the relative recruitment range $R(A)$ (Figure 3B).

(c) The projection on $(\tilde{I}n, \tilde{\mathcal{F}})$ provides the end-recruitment curve. Simple computations lead to its representation $\tilde{I}n \mapsto \frac{\tilde{I}n - 1}{F^{-1}_{(1,1)}(\tilde{I}n - 1)}$ (Figure 3A), which, according to Theorem 12(e), is an increasing function.

The vertical sections of Σ parallel to the $(\tilde{I}n, \tilde{\mathcal{F}})$ plane are the relative activation curves, and according to (24), each one of them is determined by A only (Figure 3A).

Relative force contributions due to recruitment and frequency modulation and related functions. The total muscle force is the sum of the contributions due to recruitment and frequency modulation $\mathcal{F}(\tilde{I}n) = \mathcal{F}^{rec}(\tilde{I}n) + \mathcal{F}^{mod}(\tilde{I}n)$. Dividing by F_{max}, we get $\tilde{\mathcal{F}}(\tilde{I}n) = \tilde{\mathcal{F}}^{rec}(\tilde{I}n) + \tilde{\mathcal{F}}^{mod}(\tilde{I}n)$. It is sufficient to compute $\tilde{\mathcal{F}}^{rec}$, which is the fraction $(1 - c)$ of the maximal force produced by all recruited MUs for the input $\tilde{I}n$. Thus $\tilde{\mathcal{F}}^{rec}(\tilde{I}n) = (1 - c)\frac{H(t(\tilde{I}n))}{F_{max}}$, where $t(\tilde{I}n)$ is the tetanic force of the strongest MU recruited by the relative input $\tilde{I}n$. By using (23), we get $\tilde{I}n = F_{(1,1)}(\frac{H(t(\tilde{I}n))}{\Delta}) + 1$, and hence,

$$\tilde{\mathcal{F}}^{rec}(\tilde{I}n) = \begin{cases} (1 - c)\, A\, F^{-1}_{(1,1)}(\tilde{I}n - 1) & \text{if } 1 \le \tilde{I}n \le \tilde{I}n(t_{max}), \\ 1 - c & \text{if } \tilde{I}n > \tilde{I}n(t_{max}). \end{cases} \tag{25}$$

Again we see that the relative muscle forces due to recruitment and to frequency modulation, as functions of $\tilde{In}$, depend only on the activation factor. Straightforward computations provide the unit independent quotients for $1 \leq \tilde{In} \leq In_T(t_{max})$:

$$\frac{\mathcal{F}^{rec}}{\mathcal{F}}(\tilde{In}) = \frac{\tilde{\mathcal{F}}^{rec}}{\tilde{\mathcal{F}}}(\tilde{In}) = (1-c)\frac{F^{-1}_{(1,1)}(\tilde{In}-1)}{\tilde{In}-1},$$

$$\frac{\mathcal{F}^{mod}}{\mathcal{F}^{rec}}(\tilde{In}) = \frac{\tilde{\mathcal{F}}^{mod}}{\tilde{\mathcal{F}}^{rec}}(\tilde{In}) = \frac{1}{1-c}\frac{\tilde{In}-1}{F^{-1}_{(1,1)}(\tilde{In}-1)} - 1.$$

We call the *recruitment rate* the number $100\,\frac{\tilde{\mathcal{F}}^{rec}}{\tilde{\mathcal{F}}}$ (Figure 2C) since it gives, at the end of recruitment, the percentage of the force due to recruitment. The ratio $\frac{\tilde{\mathcal{F}}^{mod}}{\tilde{\mathcal{F}}^{rec}}$ will be called *frequency modulation to recruitment ratio* or simply *FMR* (Figure 2B).

According to Theorem 12(e), $\frac{\tilde{\mathcal{F}}^{rec}}{\tilde{\mathcal{F}}}$ is decreasing and $\frac{\tilde{\mathcal{F}}^{mod}}{\tilde{\mathcal{F}}^{rec}}$ increasing. Both functions are muscle-independent as long as recruitment is not achieved. At the end of recruitment (*e.r.*), we have $\tilde{In} - 1 = R(A)$ and thus

$$\frac{\mathcal{F}^{rec}}{\mathcal{F}}|_{e.r.} = \frac{\tilde{\mathcal{F}}^{rec}}{\tilde{\mathcal{F}}}|_{e.r.} = \frac{(1-c)}{Q(A)}, \qquad \frac{\mathcal{F}^{mod}}{\mathcal{F}^{rec}}|_{e.r.} = \frac{\tilde{\mathcal{F}}^{mod}}{\tilde{\mathcal{F}}^{rec}}|_{e.r.} = \frac{1}{1-c}\,Q(A) - 1.$$

The last two quantities depend only on A, and according to Theorem 12(f), the first one is increasing and the second one is decreasing. For fixed values of Δ, the same properties hold for the variable F_{max} instead of A.

Recruitment gain. The *recruitment gain*, introduced in [28] in the context of H-reflexes, is the "size of threshold differences to recruit additional MUs." The situation is simple in the case of the H-reflex since MUs are activated only once during this reflex and rate modulation is thus nonexistent. The recruitment gain corresponds to the derivative, during recruitment, of the number of active MUs with respect to the relative input. It is given by $Rg(\tilde{In}) = \frac{d}{d\tilde{In}}\int_{t_{min}}^{t(\tilde{In})} \rho(s)\,ds = \rho(t(\tilde{In}))\frac{d}{d\tilde{In}}t(\tilde{In})$. As we have seen before, $t(\tilde{In}) = H^{-1}(\Delta F^{-1}_{(1,1)}(\tilde{In}-1))$, and by differentiating both sides with respect to $\tilde{In}$ and denoting $' = \frac{d}{d\tilde{In}}$, we obtain $\rho(t(\tilde{In}))\,t(\tilde{In})\,t'(\tilde{In}) = \Delta(F^{-1}_{(1,1)})'(\tilde{In}-1)$. Finally, the last three equations lead to

$$Rg(\tilde{In}) = \frac{\Delta(F^{-1}_{(1,1)})'(\tilde{In}-1)}{H^{-1}(\Delta F^{-1}_{(1,1)}(\tilde{In}-1))}.$$

In contrast to the preceding relations derived in this section, $Rg(\tilde{In})$ depends on the particular muscle via H and Δ.

5. Discussion. The relative synaptic weight, which specifies the efficacy of the synaptic input to the individual MNs, cannot be determined with the present experimental techniques. However, every model of the MNPMC requires this quantity, and we present here an approach allowing its computation. A main feature of the model is that it is based on a known behavior of the activation curve during recruitment. Indirect measurements [38] indicate that this function is affine during recruitment, and this turns out to be sufficient to determine the relative synaptic weight. The MNPMC model can now be used to compute various functionals related to the muscle activation. They provide a deeper insight into the processes occurring during muscle activation and also yield values for missing experimental data required for more complex models of the MNPMC. The computed relative synaptic weight has been implemented in a time-dependent model which considers each MU individually [36, 39].

Normalizing the force by the maximal muscle force F_{max} and the input by the threshold input In_0 is the source of several advantages. In this new frame, the slope k of the activation curve during recruitment is transformed into the activation factor $A = \frac{kIn_0}{F_{max}}$. The signature in A of the muscle MU population is F_{max}, the first moment of ρ. One could have expected a more intricate dependence since ρ is an arbitrary nonnegative and integrable function.

The activation factor is the parameter which governs completely the activation process of a muscle in our model. Indeed, the relative activation surface depends on $\tilde{I}n$ and A. It turns out that the relative activation curve depends only on A (even after recruitment is completed), entailing that the recruitment boundary curve Γ, the end-recruitment curve γ, the relative activation curves, the relative recruitment ratio Q, and the relative recruitment range $R(A)$ depend only on A.

It is also quite remarkable that the ratios $\frac{\tilde{\mathcal{F}}^{mod}}{\tilde{\mathcal{F}}^{rec}} = \frac{\mathcal{F}^{mod}}{\mathcal{F}^{rec}}$ and $\frac{\tilde{\mathcal{F}}^{rec}}{\tilde{\mathcal{F}}} = \frac{\mathcal{F}^{rec}}{\mathcal{F}}$, as long as recruitment is not achieved, depend only on the function $F^{-1}_{(1,1)}$ and are thus totally independent of the muscle. Of course, the values of these ratios depend on A at the end of recruitment. However, the relative synaptic weight depends on In_0 and A, and finally, the recruitment gain $Rg(\tilde{I}n)$ depends on Δ and ρ. As in [45], several functionals become muscle-independent or depend only on the activation factor.

The preceding normalization also allows for the comparison of muscles with different strengths, as described in [42] for the first dorsal interosseus, a small hand muscle, and the gastrocnemius, a much stronger leg muscle.

We proved that for fixed values of k and In_0, the MU population density ρ and the relative synaptic weight $\tilde{g}$ are linked by a one-to-one relation. The MU population ρ of a muscle can therefore be recovered from the synaptic weight and conversely is a feature which might be used by the CNS. If the properties of an MU population change by a lesion or a pathological situation such as muscular dystrophy, or simply by disuse or training, an input to the MN pool does not result in the force expected by the CNS. As a consequence, the relative synaptic weight in the MN pool might be readjusted in order to achieve the activation curve required for a properly working motor control. Sensory input from muscle spindles and additional sensors might play a major role in such a feedback system. This hypothesis could be tested in patients with motor diseases, in subjects participating at bed rest and thus concerned with muscle atrophy, or in subjects undergoing a force training.

The activation curve is composed of an affine part, prescribed a priori during recruitment, followed by a nonaffine portion due to frequency modulation only. Our model predicts that the affine part can be maintained up to at most 66% of the maximal muscle force, a situation achievable with a slope approaching 0. For muscle forces above the relative recruitment range, the slope of the activation curve is steadily decreasing. As a consequence, relatively strong inputs are required to adjust high force levels. The activation curve has not yet been investigated in muscles with a large activation factor where the nonaffine range extends over an important domain of the input. However, there is evidence that an affine relationship holds in the working range of the human soleus muscle. Unpublished data (D. G. Ruegg and T. H. Kakebeeke) show that humans are able to voluntarily contract the soleus muscle up to only about 60% of its maximal force, and the activation curve is affine over that range, suggesting that the behavior of the soleus is compatible with our model.

In this way, the CNS might limit the muscle's working field to the affine range, a possibly very useful property. Indeed, motor centers that are hierarchically above the MN pool would be faced with a fixed activation curve. Consequently, a control mechanism at the spinal level would be sufficient to adjust the synaptic weight in order to maintain the activation curve, when changes in the MU population are induced by training, disuse, or disease. Moreover, the whole activation curve is automatically adjusted by the affine part since it depends only on its slope, namely, the activation factor. The verification of this property requires subjects with a modified MU density function.

RANDOM COVERING OF MULTIPLE ONE-DIMENSIONAL DOMAINS WITH AN APPLICATION TO DNA SEQUENCING*

MICHAEL C. WENDL†

Abstract. Classical results for randomly covering a one-dimensional domain are generalized to multiple domains. The density function for the number of gaps is derived in the context of Bell's polynomials. Limiting forms are determined as well. The multiple domain configuration is a good model for DNA sequencing scenarios in which the target is fragmented, e.g., filtered DNA libraries and macronuclear genomes. Large-scale sequencing efforts are now starting to focus on such projects. Fragmentation effects are most prominent for small targets but vanish for very large targets. Here, the current model converges with classical theory. Pyrosequencing has been suggested as a viable, much cheaper alternative for large filtered projects. However, our model indicates that a recently demonstrated microscale Sanger reaction will likely be far more effective.

Key words. coverage, probabilistic modeling, sequence redundancy

1. Introduction.

The basic problem of covering a one-dimensional domain with randomly placed segments has been studied extensively for over a century [40]. The probability density function (PDF) for gaps has been described for the unit circle [41], as have moments of coverage [38] and asymptotic characteristics [18, 23, 39]. The real line has been similarly examined [13].

A notable result emerging from this work is Stevens's theorem [40, 41]. Suppose there are i trials, which are not independent of each other. If the probability for any specific σ of these trials to have outcome Γ is $f(\sigma)$, regardless of the outcomes for the remaining $i-\sigma$ trials, then the PDF for γ instances of Γ is

$$P(i,\Gamma=\gamma) \;=\; C_{i,\gamma} \sum_{\sigma=0}^{i-\gamma} C_{i-\gamma,\sigma}\;(-1)^{\sigma}\; f(\sigma+\gamma)\,, \tag{1.1}$$

where $C_{i,\gamma}$ are the binomial coefficients. The relationship between (1.1) and the standard inclusion-exclusion approach is readily demonstrated [16, 28]. In his paper, Stevens [41] went on to show, via straightforward geometric arguments, that the number of gaps in coverage for a circular domain of unit circumference is governed by the kernel probability $f(\sigma) = (1-\sigma\,\varphi)_+^{i-1}$, where i is the number of random covering segments, φ is the fractional length of each segment, and $(t)_+ = \max(0,t)$.

The eminent mathematician-scientist Harold Jeffreys offered one of the more colorful interpretations of the one-dimensional problem [14]. He imagined a bicyclist passing through an intersection strewn with tacks. Upon emerging, the rider wants to know if any tacks have been picked up in her tire but can only glance down at short random intervals as she moves down the road. If each glance covers a fraction φ of the tire circumference, what is the probability that the whole tire has been examined

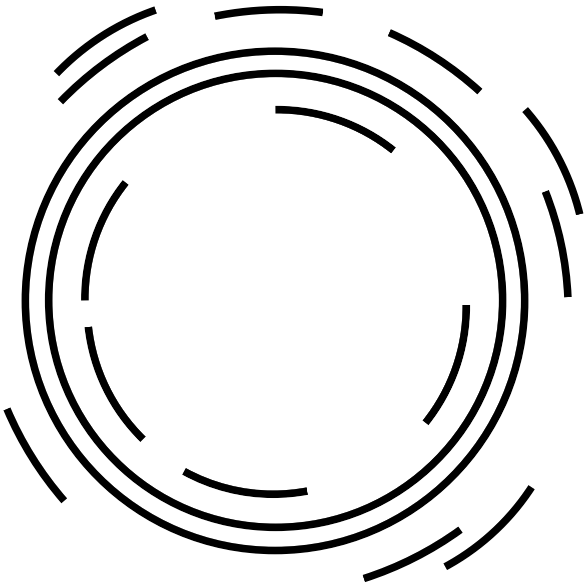

FIG. 1.1. *Schematic of the shotgun covering process for double-stranded DNA. The target is shown as two concentric circles, representing equivalent lengths of complimentary nucleotide sequence. Covering fragments for the outer and inner strands are depicted as arcs lying outside and inside the circles, respectively. The circularized configuration is characteristic of numerous DNA molecules, for example, bacterial chromosomes, genomic plasmids, mitochondrial DNA, and cloned fragments (e.g., bacterial artificial chromosomes (BACs), fosmids, plasmid subclones, etc.).*

after i glances? According to (1.1), the solution is $P\,(i, \Gamma = 0)$, the instance in which there are no observational gaps.

Aside from its mathematical significance [17] and the perhaps surprising relevance to cycling, the one-dimensional configuration is a useful abstraction for a variety of physical problems. Here, we are interested in its singularly important role in modeling DNA processing, particularly the various random "shotgun" strategies for sequencing and mapping [32]. DNA is a nonbranching biopolymer, usually of high molecular weight. Biochemical limitations preclude direct experimental characterization of DNA molecules, for example, at the level of chromosomes or whole genomes. However, smaller fragments can readily be resolved by methods such as Sanger's chain-termination sequencing reaction [37]. On a conceptual level, the shotgun approach consists of nothing more than randomly oversampling a library of suitably small fragments with the objective of covering a larger domain of interest [1, 11]. A number of models have been devised for shotgun processing [29, 35], and these have been shown to be special cases of Stevens's equation (our (1.1)) [46].

One of the factors that has not yet been adequately considered is target multiplicity, of which perhaps the simplest illustration is the double-stranded configuration of DNA itself. For example, if random covering fragments are derived from phage clones, the actual strand from which any particular fragment originates is not known (Figure 1.1). Existing theories tacitly assume that all fragments come from the same strand, meaning that strand information is essentially lost. However, computational algorithms that assemble these fragments find overlaps by checking both the actual sequence and its reverse complement. (The latter is a fragment's representation on the opposite strand deduced from Watson–Crick base-pairing rules.) In effect, strand information is restored ex post facto. Biologists consider closure on both strands, independent of one another, to be important for fully resolving a desired DNA sequence [8, 21]. In particular, this allows detection of strand-specific anomalies [15].

The issue of stranding implies that we are actually dealing with the random, simultaneous covering of two domains, as shown in Figure 1.1. As with the standard independently and identically distributed (IID) assumption for spatial distribution of the fragments, one could presume fragments to be IID over the domains as well. Incidentally, the problem depicted in Figure 1.1 is really the correct analogue to Jeffreys's bicyclist, where the rider glances randomly at both the back and front tires; Jeffreys's original interpretation applies strictly to unicycles!

Quite a few scenarios in DNA sequencing actually demand the generalization of this idea to larger numbers of domains. For example, the most recalcitrant genomes are not directly amenable to the conventional whole genome shotgun method. Biologists have developed various filtering techniques to identify and remove those regions that cannot be resolved using current technology [47]. The filtering process cleaves the original target into thousands of smaller domains (essentially the individual genes). The required shotgun procedure is then performed on the collective set of domains. A similar multiple-target scenario arises with organisms having macronuclear genomes that consist of thousands of small chromosomal structures [12, 33].

Another area of growing interest is the so-called *metagenomic* project, where a community of microbe types is extracted and sequenced directly, i.e., without the need for culturing [10, 20, 30, 36, 43]. Here, there may be as many as 10^5 distinct microbial DNA targets [2]. Strictly speaking, a number of more traditional scenarios are also multiple-target problems—the whole genome shotgun method applied to multichromosome organisms (tens of domains) [42], whole genome reads projected over large-insert libraries (hundreds to tens of thousands of domains, depending upon the project) [34], and clone mapping projects (tens of domains) [24].

Existing theoretical work is limited, either focusing on relevant expected values [45] or assuming distribution of segments according to an expected value argument [31]. Here, we report a more comprehensive characterization of the multiple-domain problem based on the PDF and its limiting forms. These results are applied to a number of unresolved issues in DNA sequencing.

Let us take Γ as the random variable representing the number of gaps in a problem having an arbitrary number of domains N, over which i covering segments have been randomly placed. Here, Γ is the total number of gaps, i.e., the sum of the numbers of gaps over all the individual target domains. This interpretation corresponds to the biological motivations of the problem, especially that of characterizing closure probabilities for the overall DNA target. Each target domain has a length $\Delta > 0$, while each covering segment has a length Λ, where $0 < \Lambda < \Delta$. Consequently, the total target size is $N\Delta$. We do not consider the configuration $\Lambda = \Delta$, as it reduces to the classical occupancy problem [16, 28], which does not exhibit the type of gaps we are interested in here. Segment placements are presumed to be IID within each domain as well as over the N domains. Relevant dimensionless groups are the domain ratio $\varphi = \Lambda/\Delta$, the target ratio φ/N, and the covering redundancy $\rho = i\varphi/N$. The latter can be thought of as the number of segments covering the average target position.

2. The multiple-domain kernel probability.

The kernel probability $f(\sigma)$ in (1.1) is the probability of gaps after σ specific segments, regardless of the gap status associated with all other remaining segments. It can be derived by a straightforward geometric argument for $N = 1$, as shown by Stevens [41]. For $N > 1$, we must also consider the combinatorial aspect of how these σ particular segments can be partitioned over the various N domains. The multiple-domain kernel function is then given by the following constructs.

LEMMA 2.1. *Let x_k be the probability of realizing any given configuration of the i segments over the N domains, where σ specific segments are partitioned in a certain permutation over k of the domains. Then*

$$x_k \; = \; N^{-i} \prod_{\beta=1}^{k} (N - \beta + 1)\,,$$

where $k \in \{1, 2, \ldots, \sigma\}$.

Proof. Probability x_k is a function of two components—one representing the σ segments partitioned in a specified way over the k domains and the other for the remaining $i - \sigma$ nonpartitioned segments, which can be distributed in any manner over all N domains. These components are clearly independent of one another so that x_k is simply the product of the two individual probabilities.

Consider a particular permutation of the σ partitioned segments. Let any k of these segments be placed on any k distinct domains. The remaining $\sigma - k$ segments in the partition must then each fall on a specific domain to satisfy the given permutation. The probability of this event is

$$\frac{N-0}{N} \times \frac{N-1}{N} \times \frac{N-2}{N} \times \cdots \times \frac{N-k+1}{N} \times \left(\frac{1}{N}\right)^{\sigma-k} .$$

There are $N^{i-\sigma}$ ways of placing the remaining $i - \sigma$ nonpartition segments over all N domains. Each of these arrangements is equiprobable, giving a probability of $N^{-(i-\sigma)}$ for any specific one. The product of these two expressions yields

$$\left(\frac{1}{N}\right)^{i-\sigma} \left(\frac{1}{N}\right)^{\sigma-k} \prod_{\beta=1}^{k} \left(\frac{N-\beta+1}{N}\right),$$

from which Lemma 2.1 follows directly. $\square$

LEMMA 2.2. *Let $\Pi(\sigma)$ be the geometric probability for gaps appearing after the σ partitioned segments described in Lemma 2.1 for the union of all configurations of the remaining $i - \sigma$ segments over the N domains. $\Pi(\sigma)$ connotes the partition $g_1^{\nu_1} g_2^{\nu_2} \cdots g_\sigma^{\nu_\sigma}$, where the number of islands hosting the given partitioned segments is $k = \nu_1 + \nu_2 + \cdots + \nu_\sigma$. The probability is*

$$\Pi(\sigma) \; = \; (N - \sigma\varphi)^{i-\sigma} \prod_{\beta=1}^{\sigma} (1 - \beta\varphi)_+^{(\beta-1)\,\nu_\beta} .$$

Proof. This expression can be demonstrated via systematic enumeration, according to how the $i - \sigma$ nonpartition segments can be distributed among all N domains. Each arrangement is mutually exclusive of all others, so the union is evaluated by simple summation. The geometric probability is formulated along the lines of Stevens's argument [41] for each distinct arrangement of segments. That is, a domain of interest hosts $1 \le \pi \le \sigma$ of the partitioned segments, along with $0 \le j \le i - \sigma$ of the nonpartitioned segments. Stevens's term, localized for this domain, can be written in the form $(1 - \pi\,\varphi)_+^{\pi+j-1}$.

A partition can be represented in the general form $g_1^{\nu_1} g_2^{\nu_2} \cdots g_\sigma^{\nu_\sigma}$, where $\sigma = 1\nu_1 + 2\nu_2 + \cdots + \sigma\nu_\sigma$ specific segments are partitioned over $k = \nu_1 + \nu_2 + \cdots + \nu_\sigma$ domains of interest. That is, each g_π represents one of these domains, which hosts π of the σ segments. This partitional notation implies a left-to-right arrangement of the k domains, though the ordering is simply a convenience. Now, consider all configurations where j of the $i - \sigma$ nonpartitioned segments are "mixed in" with the partitioned segments; i.e., they reside in some manner on the same k domains where the partitioned segments lie. Then, the remaining $i - \sigma - j$ segments must lie on the other $N - k$ domains.

We must first quantify the joint geometric probabilities for all the different ways that the j nonpartitioned segments can be distributed over the k domains. For example, if all j reside on the leftmost g_1 domain, we have a geometric probability of the form

$$\underbrace{(1 - 1\,\varphi)_+^{1+j-1}\,(1 - 1\,\varphi)_+^{1+0-1} \cdots (1 - 1\,\varphi)_+^{1+0-1}}_{\nu_1 \text{ such terms representing all ``} g_1 \text{'' domains}}\,(1 - 2\,\varphi)_+^{2+0-1} \cdots (1 - \sigma\,\varphi)_+^{\sigma+0-1} \; .$$

Note that all j nonpartition segments are assigned to the leftmost term representing the leftmost g_1 domain. This expression would also have a coefficient $C_{i-\sigma,j}$ to account for the number of ways to pick j segments from the collection of $i - \sigma$ nonpartition segments. Also, there is an implied multiplier of unity, indicating that there is only one way to assign the j segments to this single domain.

In a similar fashion, we then consider all the remaining ways of distributing the j nonpartitioned segments over the k domains, formulating the appropriate joint geometric probability in each case. In addition to the $C_{i-\sigma,j}$ coefficient for the number of ways of picking the j segments, we have the appropriate k-nomial coefficient $j!/(j_1! j_2! \cdots j_k!)$, where $j_1 + j_2 + \cdots + j_k = j$, to account for the number of ways of assigning the j segments to the k domains. All of these joint geometric probabilities are summed, and the result is multiplied by $(N-k)^{i-\sigma-j}$, which represents the number of ways the $i - \sigma - j$ remaining nonpartitioned segments could be assigned to the other $N - k$ domains. The resulting summation S_j is such that one can factor out the product

$$(1 - 1\,\varphi)_+^{1-1} \cdots (1 - \sigma\,\varphi)_+^{\sigma-1} \;=\; \prod_{\beta=1}^{\sigma} (1 - \beta\varphi)_+^{(\beta-1)\,\nu_\beta} \;=\; \mathfrak{P} \, .$$

Note that the $(\,)_+$ limiters continue to govern the positivity of $\mathfrak{P}$, and because $\mathfrak{P}$ is a multiplicative factor, these limiters are superfluous for the remaining Stevens-type terms in the summation. Consequently, the overall expression can be written

$$S_j \;=\; (N-k)^{i-\sigma-j} \cdot C_{i-\sigma,j} \cdot \mathfrak{P} \cdot \Big[(1 - 1\,\varphi)^j \;+\; \cdots \;+\; (1 - \sigma\,\varphi)^j \Big] \; ,$$

where the $(\,)_+$ notation has been dropped from the summed terms. These terms collapse via the multinomial theorem, and, after some algebraic manipulation, this expression can be written

$$S_j \;=\; (N-k)^{i-\sigma-j} \cdot C_{i-\sigma,j} \cdot \mathfrak{P} \cdot \Big[\nu_1\,(1 - 1\,\varphi) \;+\; \cdots \;+\; \nu_\sigma\,(1 - \sigma\,\varphi) \Big]^j \; .$$

By factoring further, S_j reduces to

$$S_j \;=\; (N-k)^{i-\sigma-j} \cdot C_{i-\sigma,j} \cdot \mathfrak{P} \cdot (k - \sigma\varphi)^j \; .$$

Considering the union of all cases for $j \in \{0, 1, \ldots, i - \sigma\}$, we find

$$\Pi(\sigma) \;=\; \mathfrak{P} \cdot \sum_{j=0}^{i-\sigma} C_{i-\sigma,j} \cdot (N-k)^{(i-\sigma)-j} \cdot (k - \sigma\varphi)^j \;,$$

which itself collapses via the binomial theorem into Lemma 2.2. □

Theorem 2.3. *The kernel probability for the multiple-domain covering problem can be cast in terms of Bell's exponential polynomials* [3, 9]

$$f(\sigma) \;=\; \sum_{\Pi(\sigma)} \frac{\sigma!\, x_k}{\nu_1!\, \nu_2! \,\cdots\, \nu_\sigma!} \left(\frac{g_1}{1!}\right)^{\nu_1} \left(\frac{g_2}{2!}\right)^{\nu_2} \!\cdots \left(\frac{g_\sigma}{\sigma!}\right)^{\nu_\sigma} \;,$$

where the x_k are probabilities given by Lemma 2.1 *and the set partitions $g_1^{\nu_1} g_2^{\nu_2} \cdots g_\sigma^{\nu_\sigma}$ represent the probabilities given by Lemma* 2.2.

Proof. The kernel probability for σ specific segments can be found by considering the union of all the ways to both partition these σ specific segments and assign the remaining $i - \sigma$ nonspecific segments over the N domains. That is, $f(\sigma)$ is the summation over all the segment configurations of $P_c P_g$, which are probability of the configuration itself and the geometric gap probability associated with the configuration, respectively.

The probabilities for all configurations having a common permutation of the σ partitioned segments are identical, as discussed in Lemma 2.1. Thus, x_k is the factored configurational probability that multiplies the corresponding sum of geometric probabilities given by Lemma 2.2. Finally, the coefficients in Bell's polynomials account for how many ways a given partition can be permuted. □

As an example, consider the partitioning of exactly four segments. Theorem 2.3 takes the form

$$f(4) \;=\; 1\, g_4\, x_1 \;+\; \left(4\, g_3\, g_1 \;+\; 3\, g_2^2\right) x_2 \;+\; 6\, g_2\, g_1^2\, x_3 \;+\; 1\, g_1^4\, x_4 \,. \tag{2.1}$$

The g_4 partition indicates that all four segments lie on one domain, $g_3\, g_1$ specifies three segments on one domain with the fourth on another, etc. Polynomial coefficients indicate the number of ways each partition can be permuted. Stevens's problem for a single domain [41] can be thought of as a special case of Theorem 2.3 in which only the first term of each polynomial σ is retained. That is, $f(\sigma) = 1 g_\sigma x_1$, where $x_1 = 1$ and g_σ is Stevens's geometric probability.

3. Asymptotic limiting cases. Although the results in the previous section are exact, there are well-known limitations for evaluating Bell's polynomials as σ becomes large. Complications arise primarily as a result of growing N because terms are needed up to x_N in each polynomial. Here, we report two asymptotic limiting cases that are of biological relevance.

First asymptotic limit. Consider the case of a finite, fixed target size, but where the target itself becomes progressively more fragmented. In the limit, the size of the individual target domains approaches the covering segment length. This scenario implies that φ/N can be held at certain constant values such that $\varphi \to 1$. Here, Stevens's solution shows that for any given domain

$$P(i = 1, \Gamma = \gamma) = \begin{cases} 0 & : \quad \gamma = 0, \\ 1 & : \quad \gamma = 1, \end{cases} \qquad \text{and} \qquad P(i \geq 2, \Gamma = \gamma) \to \begin{cases} 1 & : \quad \gamma = 0, \\ 0 & : \quad \gamma = 1 \end{cases}$$

as well as $P\,(i, \Gamma \geq 2) = 0$. Consequently, finding the distribution of gaps among the target domains is asymptotically equivalent to the problem of determining the distribution of domains having exactly one segment each. The latter is a variation of the classical occupancy problem [16, 28].

Within the combinatorial context of our analysis thus far, the most straightforward solution for this case is given by the following construct.

THEOREM 3.1. *The probability distribution P_1 for the first asymptotic case $\varphi \to 1$ is*

$$P_1\,(i, \Gamma = \gamma) \;=\; N^{-i} \sum_{\Pi(i)} \frac{i!}{\nu_1!\,\nu_2!\,\cdots\,\nu_i!\,(1!)^{\nu_1}\,(2!)^{\nu_2}\cdots(i!)^{\nu_i}}\;\delta_{\gamma,\nu_1}(N)_k\,,$$

where δ is the Kronecker delta, $(N)_k = N\,(N{-}1)\cdots(N{-}k{+}1)$, and $\Gamma \in \{0, 1, 2, \ldots, N\}$.

Proof. Bell's coefficient (the quotient) gives the number of ways to realize a given partition of i segments over $k = \nu_1 + \nu_2 + \cdots + \nu_\sigma$ specific domains, where ν_1 of these domains have exactly one segment each. There are $(N)_k$ permutations of a k-bin arrangement so that the product of the two values is the total number of ways to find the ν_1 domains of interest among the N total domains. The enumeration is summed over all partitions, tallying only those where $\nu_1 = \gamma$ via the Kronecker delta. There are N^i possible configurations of the i segments over the N domains. Assuming each is equally likely, the probability is the quotient of the above enumeration and N^i. □

One can actually find the distribution of domains having any desired number of segments by simply adjusting the second subscript on δ appropriately. Other combinatorial results for this problem are available as well [28]. Unfortunately, such solutions are not terribly practical from a computational standpoint for reasons already discussed above. A more amenable form comes directly from probability theory [16]:

$$P_1\,(i, \Gamma = \gamma) \;=\; \frac{(-1)^\gamma\,N!\,i!}{\gamma!\,N^i} \sum_{j=\gamma}^{\min(N,i)} \frac{(-1)^j\,(N-j)^{i-j}}{(j-\gamma)!\;(N-j)!\;(i-j)!}\,. \tag{3.1}$$

Computing each PDF using (3.1) requires evaluation of $(N+1)(N+2)/2$ terms for the usual case of interest, i.e., $i \geq N$.

Second asymptotic limit. We can extend the previous concept to the scenario where the original target is infinitely large. Specifically, the target is fragmented into $N \to \infty$ domains such that $\varphi \to 1$ (thus $\varphi/N \to 0$). This variation once again has a direct analogue in the corresponding occupancy problem, which converges to a Poisson process if the rate remains bounded. That is, the distribution for the second asymptotic case approaches

$$P_2\,(i, \Gamma = \gamma) \;=\; \frac{\exp\,(-\lambda)\,\lambda^\gamma}{\gamma!}\,, \tag{3.2}$$

where the rate is $\lambda = i \exp\,(-i/N)$ [16].

4. Discussion.

Shotgun DNA sequencing is a comparatively new research tool to the biomedical sciences [1, 11], yet it is already responsible for numerous discoveries of fundamental importance. Sequencing projects continue to be guided almost exclusively by the collective empirical experience of the sequencing community, with little to no input from theoretical foundations. This is largely attributable to the fact that the latter have not evolved sufficiently to treat many of the biologically relevant phenomena of sequencing.

Lander and Waterman developed what most biologists consider to be the standard model almost two decades ago [29]. This theory provides the expected value of gaps based on the assumption of a single, monolithic DNA target. In fact, subsequent work has focused almost entirely on the monolithic target [35, 46]. Yet, many sequencing scenarios now routinely involve fragmented targets, as outlined above. Wendl and Barbazuk [45] have extended the standard theory to multiple domains of linear molecules, but their model still considers only expected values. Here, boundary conditions (i.e., "edge-effects") appreciably influence sequencing progress. However, expected value analysis is of little use for circular configurations. Indeed, it is fairly straightforward to show that the expected number of gaps for a fragmented target is identical to the Lander–Waterman expression if the target is large enough. This suggests that the influences of fragmentation may be more subtle.

Here, we illustrate a few applications of the theory for which fragmentation is known, or at least presumed, to play a role. Unless otherwise stated, a covering segment length of 1,000 is assumed. This value represents the current limit of what can be resolved by the chain-termination sequencing reaction [37] on a sustained basis. Each calculation uses 700 digits behind the decimal point. We will also abbreviate DNA nucleotide bases and base-pairs as "nuc" and "bp," respectively.

Trends under increasing fragmentation. How does the gap census evolve as targets become progressively more fragmented? This question has some practical bearing on DNA sequencing projects, especially for sample-related calculations that depend upon the variance [22].

First, let us examine fragmentation in the mild to moderate range. In general, the PDF becomes increasingly diffuse, but the degree to which this occurs is highly dependent upon the parameters. Consider, for example, the case $\varphi/N = 1/80$, which corresponds to the shotgun sequencing of a standard double-stranded 40,000 bp fosmid clone [26]. The total target size is 80,000 nuc. Figure 4.1 shows gap PDFs for three configurations—a single 80,000 nuc target, four 20,000 nuc target domains, and eighty 1,000 nuc domains. The last configuration corresponds to the first asymptotic limit in (3.1). Functions are shown for light redundancy $\rho = 1$ and moderate redundancy $\rho = 4$. Note that we calculate ρ based on the total number of nucleotides. Consequently, our definition differs by a factor of two from the casual, more common usage of ρ, which does not consider stranding.

Graphical resolution shows no difference between the single monolithic target $N = 1$ and a mildly fragmented target consisting of $N = 4$ domains. Differences for these two configurations would be noticeable only for smaller target sizes, e.g., those characteristic of single gene islands (see below). Consequently, it appears that the issue of stranding we described above can be neglected in most cases of biological interest. It also appears that mild fragmentation will not have a significant effect for most projects, especially since read lengths will often be somewhat less than 1000 bp. Conversely, the first asymptotic case (3.1) does differ to some degree. For example, the PDF is clearly more diffuse at $\rho = 1$, although this configuration shows a significant trend toward convergence at $\rho = 4$.

At the opposite extreme is the scenario where a very large target is fragmented into numerous very small domains. Such is the case, for example, when filtering schemes are used to extract and sequence the gene complement of large genomes [47] or when sequencing certain genomes that are inherently highly fragmented [12, 33]. In particular, filtering something like the maize genome gives a target size on the order of 5×10^8 bp with about 2×10^5 islands [47]. In these scenarios, one finds complete

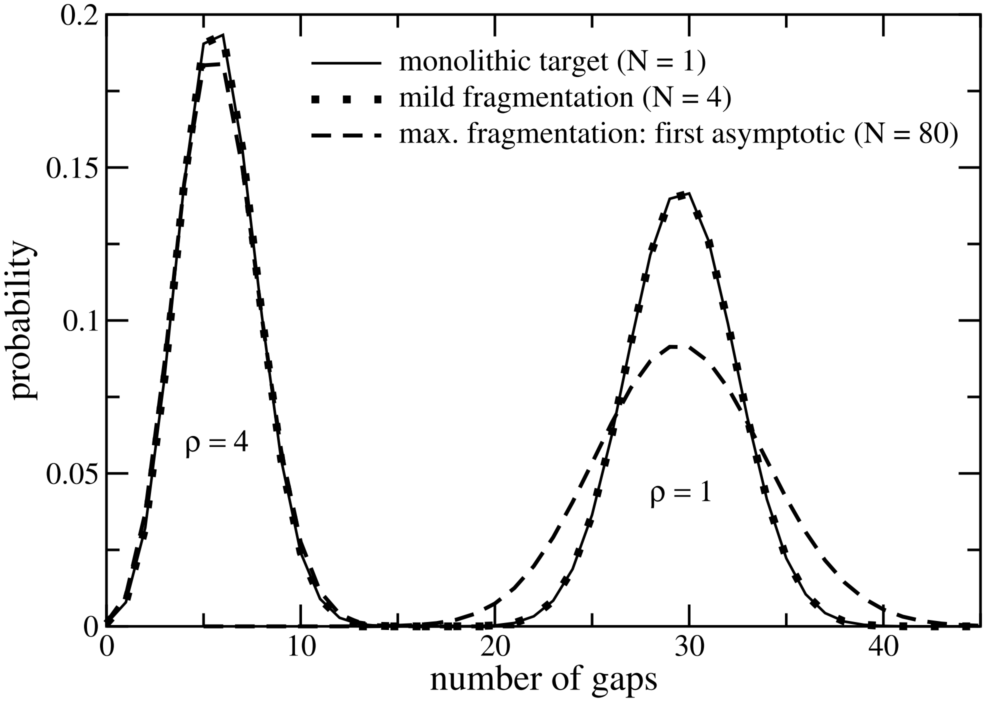

Fig. 4.1. *Gap density functions at* 1*-fold and* 4*-fold redundancies for a fosmid-class target at various levels of fragmentation.*

convergence with the classical theory for monolithic targets; i.e., the influence of fragmentation vanishes. The Poisson rate in the second asymptotic limit (3.2) is equivalent to $\lambda = i \exp(-\rho)$ since $\varphi \to 1$. The binomial PDF for monolithic targets, e.g., equation (9) in [46], associates a Bernoulli probability of $\exp(-\rho)$ with i trials. Consequently, it converges to this same expression for large targets.

In summary, these results indicate that φ is a strong variable when φ/N is relatively large. Conversely, the process is essentially independent of φ as φ/N becomes vanishingly small.

The stopping problem. One of the more practical questions that arises in all sequencing projects is when to halt the random phase of processing. This is the so-called *stopping problem*. Appreciable economic consequences revolve around this decision because subsequent directed procedures are at least an order of magnitude more expensive per unit sequence recovered. Incidentally, the nonrandom continuation is required because non-IID characteristics become apparent at higher redundancies, making it difficult to achieve a $\gamma = 0$ "base-perfect" sequence using the random method alone.

Although early work established $\rho = 10$ as the nominal "full shotgun" stopping point [48], the matter is still debated. For example, Bouck et al. [6] advise $\rho \leq 6$, while Blakesley et al. [4] recommend $\rho \geq 8$. Draft sequences have been reported for as low as $\rho \approx 3.5$ [49] and as high as $\rho \approx 17.5$ [19]. Although one finds sequence redundancies distributed somewhat uniformly between 5-fold and 15-fold, they do not correlate with any gross genome features, e.g., genome size [44]. In short, available data indicate that there is no commonly accepted system by which stopping points should be chosen.

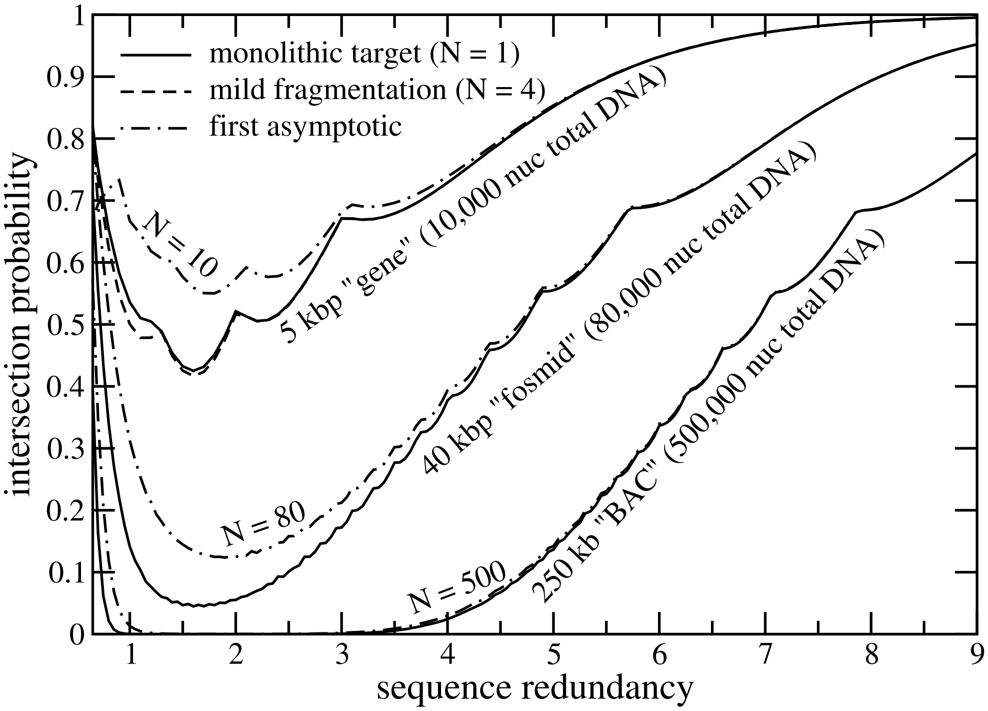

Fig. 4.2. *Intersection probabilities for three classes of DNA target.*

Wendl [44] proposed a quantity called the intersection probability $P_\cap$ to quantify stopping points probabilistically. The idea is based on the simple observation that pairs of density functions separated by intervals of $\rho = 1$ share increasing fractions of their event spaces as ρ grows. $P_\cap$ is the tail probability calculated from the overlap. This implies that any differences in two identical but independent projects become more attributable to stochastic variation rather than the disparity in their redundancies.

Figure 4.2 shows the intersection probability plotted as a function of redundancy for three classes of genomic targets—a 5 kbp gene-sized island, a 40 kbp fosmid clone, and a 250 kbp BAC clone. The trends confirm a number of earlier observations. First, fragmentation tends to be important only in scenarios where the total target size is small. For example, the effect of mild fragmentation ($N = 4$) is apparent only for the 5 kbp gene island at low redundancy. Likewise, the state of maximal fragmentation (the first asymptotic) rapidly converges to the classical result. In particular, it is almost indistinguishable from the $N = 1$ curve for the BAC. It appears that the classical model could be used to calculate $P_\cap$ in many cases. For smaller targets, the effect of fragmentation, though mild, suggests halting the random phase earlier than for the equivalent nonfragmented project.

The second trend echoes what previous work has found with respect to $P_\cap$ for genome coverage: larger projects should be sequenced to higher redundancies [44]. In other words, successive PDFs spaced 1-fold units of redundancy apart are more isolated from one another in larger projects. This clearly applies whether a genomic target is fragmented or not. Results shown in Figure 4.2 advise substantially lower redundancies for large-insert clone targets than what is often specified at the present time. For example, the $P_\cap = 0.3$ threshold implies limiting redundancies to something less than 4 and 6 for fosmids and BACs, respectively. This is most in line with the empirical findings of Bouck et al. [6].

Cost optimization of filtered projects. With the completion of the human genome project [25], many large-scale efforts are now shifting to even more recalcitrant, repeat-laden genomes, e.g., maize. Current thinking holds that standard whole genome methods are unlikely to succeed here, which has prompted proposals for various forms of genomic filtering [47]. Filtration schemes produce numerous low-copy, sequenceable islands, thereby circumventing many of the well-known problems of genomic assembly. Maximizing read length is not nearly as critical in these scenarios, and this has led to growing debate surrounding proper choice of read length [7].

One of the more relevant aspects on which to judge this question would certainly be cost, specifically overall project cost. Traditional Sanger sequencing instruments, e.g., the ABI 3730xl, provide "full-length" reads but at relatively high per-read expenditures [25]. Conversely, newer platforms such as the 454 GS-20 pyrosequencer yield short, much lower-cost reads [27]. Let us assume that high-throughput labs can generate Sanger 3730xl reads and GS-20 pyrosequencing reads for about \$0.44 and \$0.013 each, respectively. Instruments based on a recent demonstration of dramatically scaled-down Sanger reactions [5] will be future contenders as well. Such devices should easily be able to sequence for about one-tenth the cost of the current generation of Sanger-based machines.

Figure 4.3 shows overall project cost for sequencing a filtered maize library as a function of the amount of random sequence. The latter is quantified by the intersection probability rather than standard redundancy because it provides for scale-free comparisons [44]. Results are all generated using the second asymptotic limit in (3.2). We specify read lengths of 719, 556, and 110, respectively, for traditional Sanger reads [47], next-generation Sanger reads [5], and pyrosequencing reads [27]. We also examine three thresholds for detecting overlaps [29]: 30, 40, and 50 bp. These correspond, respectively, to minimum, typical, and highly conservative values [47].

The plot shows a number of notable trends. First, the current landscape clearly favors pyrosequencing over traditional Sanger sequencing, although not by as much as we might intuitively expect based on the > 30-fold difference in unit costs. The pyrosequencing technique yields a larger project in the sense of φ/N, meaning that comparatively higher redundancies are needed to obtain given milestones of $P_\cap$. This effect was shown in Figure 4.2 and is discussed extensively in [44].

The economics of pyrosequencing reads are quite sensitive to how much overlap is required for detection, whereas this sensitivity is not much of a factor for Sanger data. This is somewhat intuitive, since a given overlap consumes a larger fraction of read length for the former. Conversely, traditional Sanger reads are tied more strongly to $P_\cap$ than pyrosequencing reads. $P_\cap$ is a free parameter, and its choice will have a larger bearing on total project cost for Sanger data.

The next-generation Sanger data show the more surprising results. We have assumed a plausible unit cost of just over 4 cents per read—roughly 3-fold higher than that for pyrosequencing. Yet, the overall project cost predictions are significantly lower. Moreover, these data show little sensitivity to $P_\cap$ and are almost constant with respect to the overlap detection threshold. Various commentators have advocated decreasing unit costs or increasing read length, but it is clearly their combination that is most important.

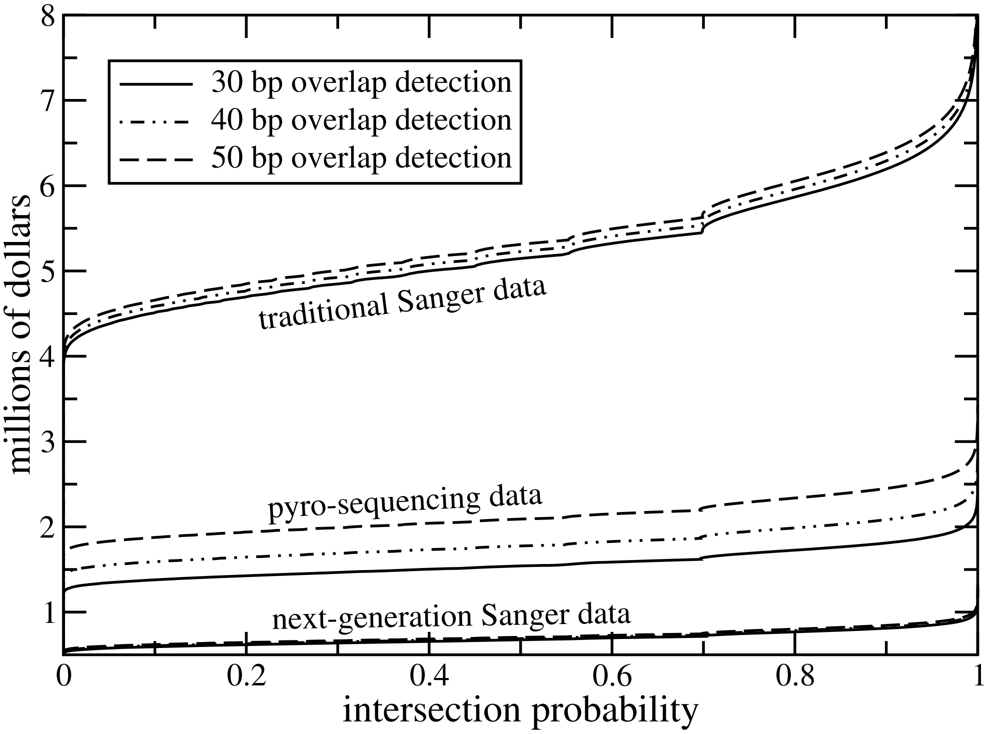

FIG. 4.3. *Project cost estimates for sequencing a filtered* 540 *Mb maize library using three different methods of data generation.*

5. Closing remarks. The problem of randomly covering multiple domains is sufficiently interesting from a mathematical perspective but also provides a good model for many scenarios of DNA sequencing. Investigators have yet to devise a suitable a priori model of cloning bias, so results for Sanger-generated data should be considered in this context. Pyrosequencing does not utilize bacterial cloning, so its predictions are probably somewhat more realistic.

Commercial instruments that eventually implement the miniaturized Sanger paradigm [5] will almost surely realize unit costs even lower than what we have presumed here. It is also likely that read lengths could be extended further. With respect to overall cost of de novo sequencing projects, our results suggest that this approach is much more promising than other techniques that emphasize read cost at the expense of read length.

Acknowledgments. The author gratefully acknowledges discussions with B. Barbazuk (Donald Danforth Plant Science Center) and J. Wallis (Washington University) regarding various aspects of this work and suggestions from one of the anonymous referees that improved the presentation.

THE FACTORIZATION METHOD FOR ELECTRICAL IMPEDANCE TOMOGRAPHY IN THE HALF-SPACE*

MARTIN HANKE† AND BIRGIT SCHAPPEL†

Abstract. We consider the inverse problem of electrical impedance tomography in a conducting half-space, given electrostatic measurements on its boundary, i.e., a hyperplane. We first provide a rigorous weak analysis of the corresponding forward problem and then develop a numerical algorithm to solve an associated inverse problem. This inverse problem consists of the reconstruction of certain inclusions within the half-space which have a different conductivity than the background. To solve the inverse problem we employ the so-called factorization method of Kirsch, which so far has only been considered for the impedance tomography problem in bounded domains. Our analysis of the forward problem makes use of a Liouville-type argument which says that a harmonic function in the entire two-dimensional plane must be a constant if some weighted L^2-norm of this function is bounded.

Key words. electrical impedance tomography, half-space problem, factorization method

1. Introduction.

Electrical impedance tomography (EIT) is a technique to recover information of the interior of a conducting object from electrostatic measurements taken on its boundary. In mathematical terms, this amounts to recovering information about the spatially varying (nonnegative) conductivity σ in the elliptic partial differential equation

$$\nabla \cdot \sigma \nabla u = 0 \qquad \text{in } B \tag{1.1}$$

from Neumann and Dirichlet boundary values of all stationary electric potentials u. This inverse boundary value problem goes back to Calderón [8] who considered (1.1) in a *bounded* domain B, provoking substantial interest in the medical imaging community.

In geoelectric applications, on the other hand, the domain B and its boundary are typically very large compared to the small fraction of its boundary where data can be measured. Therefore it makes sense to reconsider the inverse boundary value problem for (1.1) in *unbounded* domains B with *unbounded* boundary ∂B, with the half-space being the most obvious and prominent example. Another application for this model problem concerns the automatic recognition of gesture input for interactive displays, called touchless interaction, which has recently been considered by van Berkel and Lionheart [26]. Finally, in its original medical context, the half-space problem may serve as an appropriate model for certain mammography systems (cf., e.g., [2, 16, 22]) where measurements are taken on only a small portion of the patient's skin.

For the half-space B, Druskin [11] has shown that the conductivity can be reconstructed from the knowledge of the boundary data on a subdomain $\Gamma \subset \partial B$, provided that B can be subdivided into a finite set of domains with piecewise smooth boundaries and constant conductivities, respectively. In this paper we are concerned with

†Institut für Mathematik, Johannes Gutenberg-Universität Mainz, 55099 Mainz, Germany (hanke@math.uni-mainz.de, schappel@math.uni-mainz.de).

numerical algorithms to reconstruct the conductivity σ or partial information about it. In general, reconstruction methods can be divided into iterative and direct methods (we refer to Borcea [4, 5] for a relatively recent survey with the focus on bounded domains), but concerning unbounded domains B we are aware only of previous algorithms based on linearization with or without an outer iteration; cf. Lukaschewitsch, Maass, and Pidcock [20, 21], Mueller, Isaacson, and Newell [22], and the references therein. Iterative methods require the repeated solution of forward problems in each iteration, i.e., differential equations, which tends to be extremely time-consuming. We therefore present a noniterative reconstruction algorithm which can be used to detect abrupt local deviations of the conductivity from a homogenous background conductivity.

Our method is a variation of the so-called *factorization method* which goes back to an idea of Kirsch [18] in the context of inverse scattering and has been applied successfully to the impedance tomography problem by Brühl [6, 7]. In these and subsequent papers all authors have formulated the problem in either bounded domains or all of $\mathbb{R}^n$, thus avoiding the difficulties that arise with domains with unbounded boundaries. Here we employ a general framework developed by Gebauer [12] to adapt this method to the case of the half-space

$$B = \mathbb{R}^n_+ = \{x \in \mathbb{R}^n : x \cdot e_n > 0\},$$

with $e_n \in \mathbb{R}^n$ a given unit vector, the inner normal vector on ∂B. Most results will be presented for the case $n = 3$, but at the end of this paper we will give a short summary of the two-dimensional case.

For our approach we assume a constant background conductivity $\sigma_{\mathbf{1}} = \mathbf{1}$, where $\mathbf{1}$ is the function identically 1, and consider conductivities of the form

$$\sigma(x) = \begin{cases} \kappa(x), & x \in \overline{\Omega}, \\ 1, & x \in \mathbb{R}^3_+ \setminus \overline{\Omega}, \end{cases} \tag{1.2}$$

where $\Omega \subset B$ is a finite collection of separated and bounded domains with sufficiently smooth boundary $\Sigma = \partial\Omega$, and for which $\mathbb{R}^n_+ \setminus \overline{\Omega}$ is connected. Below we will denote by ν the normal of Σ pointing into Ω.

The positive conductivity $\kappa \in L^\infty(\Omega)$ is assumed to be significantly higher or lower than the background conductivity; i.e., there exists $\varepsilon > 0$ such that

$$\kappa(x) \geq 1 + \varepsilon \quad \text{or} \quad \varepsilon \leq \kappa(x) \leq 1 - \varepsilon \qquad \text{for } x \in \overline{\Omega}. \tag{1.3}$$

By means of the factorization method we provide an explicit characterization of the inclusions Ω in terms of the (local) Neumann–Dirichlet operator Λ_σ which maps Neumann boundary values of a potential u in (1.1) to its Dirichlet boundary values.

We should mention that in principle it should be possible to relax the assumption that the background conductivity is constant. However, the numerical implementation of our method will then become much more difficult, as the algorithm requires the availability of the associated Neumann function.

The paper is organized as follows: We first introduce appropriate function spaces to deal with the forward problem (1.1) in the half-space $B = \mathbb{R}^3_+$, and then clarify our notion of weak solutions of (1.1) and their existence. The inverse problem and some preliminary statements will be specified in section 3. Then, in sections 4 and 5 we prove the characterization of inclusions from the knowledge of Λ_σ. In section 6 we comment on our numerical algorithm and present some reconstructions based on simulated data. To conclude, we briefly comment in section 7 on the necessary modifications of our theory in two space dimensions.

In an appendix we establish a Liouville-type result for harmonic functions in the plane which we use to show that certain apparently different function spaces over $\mathbb{R}^3_+$ which have been introduced in the literature, and which are relevant for our problem, are essentially the same.

2. Function spaces and weak solutions of the forward problem. The forward problem associated with impedance tomography in the half-space is the Neumann problem

$$\nabla \cdot \sigma \nabla u = 0 \quad \text{in } \mathbb{R}^3_+, \qquad -\sigma \frac{\partial u}{\partial e_3} = f \quad \text{on } \mathbb{R}^2, \tag{2.1}$$

together with an appropriate growth condition near infinity. Problem (2.1) represents the physical process of injecting a current f into the upper half-space $B = \mathbb{R}^3_+$ from its boundary. In this section the conductivity σ is assumed to be bounded and strictly positive in $\mathbb{R}^3_+$. In (2.1) and in the remainder of this paper, we always identify the boundary of $\mathbb{R}^3_+$ with $\mathbb{R}^2$, with straightforward abuse of notation.

Care has to be taken concerning the correct behavior of $u(x)$ for $|x| \to \infty$ which is reflected by the choice of appropriate function spaces for the solution u. For example, physically relevant solutions of problem (2.1)—like the fundamental solution of the Laplace equation—need not belong to the Sobolev space $H^1(\mathbb{R}^3_+)$.

Example 2.1 (see [21]). For $\sigma = \mathbf{1}$ and $f(y) = (1+|y|^2)^{-3/2}$, a solution of (2.1) is given by $u(x) = |x + e_3|^{-1}$. It is easy to see that u does not belong to $L^2(\mathbb{R}^3_+)$; however, the gradient of u is square integrable on $\mathbb{R}^3_+$.

To construct a suitable function space we recall the following familiar definitions and notation. For a (possibly unbounded) domain $G \subset \mathbb{R}^3$ we take $C_0^\infty(G)$ to be the set of all functions $u \in C^\infty(G)$ with compact support $\operatorname{supp} u$, and let

$$C_0^\infty(\overline{G}) = \{u|_G : u \in C_0^\infty(\mathbb{R}^3)\}.$$

Furthermore, $\mathcal{D}'(G)$ is the set of distributions, i.e., the continuous linear functionals on $C_0^\infty(G)$.

In view of the physical setting (and in accordance with Example 2.1) it appears appropriate to restrict our attention to solutions of (2.1) with finite energy, which means that the H^1-seminorm of u is finite. Note that this seminorm is actually a norm on $C_0^\infty(\overline{\mathbb{R}^3_+})$ because constant functions do not belong to this set. We write $H(\mathbb{R}^3_+)$ for the closure of $C_0^\infty(\overline{\mathbb{R}^3_+})$ with respect to this norm, denoted subsequently by $\|\cdot\|_{H(\mathbb{R}^3_+)}$. According to Boulmezaoud [3], this space coincides with the weighted Sobolev space

$$\{u \in \mathcal{D}'(\mathbb{R}^3_+) : (1+|x|^2)^{-1/2} u \in L^2(\mathbb{R}^3_+),\ \nabla u \in L^2(\mathbb{R}^3_+)^3\}. \tag{2.2}$$

Obviously, we have $H(\mathbb{R}^3_+) \subset H^1_{\text{loc}}(\mathbb{R}^3_+)$, and for every bounded domain $G \subset \mathbb{R}^3_+$ the restriction operator $u \mapsto u|_G$ is continuous as a mapping from $H(\mathbb{R}^3_+) \to H^1(G)$. We point out here that for the two-dimensional case the analogous completion of $C_0^\infty(\overline{\mathbb{R}^2_+})$ with respect to the H^1-seminorm does not yield a space of distributions (cf. Deny and Lions [10]), and we refer to section 7 for the modifications which are necessary in two space dimensions.

It has been shown by Janßen [17] that every function $u \in H(\mathbb{R}^3_+)$ has a trace in

$$L^{2,1}(\mathbb{R}^2) = \{g : (1+|y|^2)^{-1/2} g \in L^2(\mathbb{R}^2)\},$$

and that the trace operator is continuous with respect to the norm

$$\|g\|^2_{L^{2,1}(\mathbb{R}^2)} = \int_{\mathbb{R}^2} (1+|y|^2)^{-1} g^2(y)\,\mathrm{d}y$$

of $L^{2,1}(\mathbb{R}^2)$. Note that the dual space of $L^{2,1}(\mathbb{R}^2)$ can be identified with

$$L^{2,-1}(\mathbb{R}^2) = \{f : (1+|y|^2)^{1/2} f \in L^2(\mathbb{R}^2)\}$$

using $L^2(\mathbb{R}^2)$ as a pivot space in the Gelfand triple. The associated norm of $L^{2,-1}(\mathbb{R}^2)$ is denoted by $\|\cdot\|_{L^{2,-1}(\mathbb{R}^2)}$, the dual pairing between $L^{2,-1}(\mathbb{R}^2)$ and $L^{2,1}(\mathbb{R}^2)$ by

$$\langle f, g\rangle_{\mathbb{R}^2} = \int_{\mathbb{R}^2} f(y)g(y)\,\mathrm{d}y.$$

Now we return to the Neumann problem (2.1) for $u \in H(\mathbb{R}^3_+)$. The corresponding weak formulation follows in the usual way by making use of Green's formula for $u, v \in H(\mathbb{R}^3_+)$ established in [3]: Find $u \in H(\mathbb{R}^3_+)$ such that

$$\int_{\mathbb{R}^3_+} \sigma\nabla u\cdot\nabla v\,\mathrm{d}x = \int_{\mathbb{R}^2} fv\,\mathrm{d}y \qquad \text{for all } v \in H(\mathbb{R}^3_+). \tag{2.3}$$

Problem (2.3) is well defined for every $f \in L^{2,-1}(\mathbb{R}^2)$, and a standard application of the Lax–Milgram lemma establishes existence of a unique solution $u \in H(\mathbb{R}^3_+)$ of (2.3) with

$$\|u\|_{H}(\mathbb{R}^3_+) \le c\|f\|_{L^{2,-1}(\mathbb{R}^2)} \tag{2.4}$$

for some constant $c > 0$ depending only on the conductivity σ. We call u the weak solution of problem (2.1).

Example 2.2. If $\sigma = \mathbf{1}$, i.e., if we consider the Laplace equation, then

$$u(x) = \frac{1}{2\pi}\int_{\mathbb{R}^2} \frac{f(y)}{|x-y|}\,\mathrm{d}y, \qquad x \in \mathbb{R}^3_+, \tag{2.5}$$

is the physically relevant classical solution of problem (2.1) provided that f is continuous and that there exists a positive and monotonic function $\varepsilon \in L^1(\mathbb{R}^+)$ such that $|f(y)| \le \varepsilon(|y|)$; see, e.g., Dautray and Lions [9, Chapter II]. In particular, for $f(y) = (1+|y|^2)^{-3/2}$ this yields the function u of Example 2.1. For arbitrary $f \in L^{2,-1}(\mathbb{R}^2)$ the integral representation (2.5) defines the weak solution $u \in H(\mathbb{R}^3_+)$, as is most easily seen by using the Kelvin transformation; see [25] for further details.

Remark 2.3. In principle one can alternatively start with $C^\infty(\mathbb{R}^3_+)$ instead of $C_0^\infty(\overline{\mathbb{R}^3_+})$ and consider for some $\alpha \ge 0$ the completion $W^1_\alpha(\mathbb{R}^3_+)$ of

$$\{u \in C^\infty(\mathbb{R}^3_+) : (1+|x|^2)^{-1/2-\alpha/2}u \in L^2(\mathbb{R}^3_+),\ \nabla u \in L^2(\mathbb{R}^3_+)^3\}$$

with respect to the norm

$$\|u\|^2_{W^1_\alpha(\mathbb{R}^3_+)} = \int_{\mathbb{R}^3_+} (1+|x|^2)^{-1-\alpha}u^2(x)\,\mathrm{d}x + \int_{\mathbb{R}^3_+} |\nabla u(x)|^2\,\mathrm{d}x; \tag{2.6}$$

cf. [17] and [21]. With an argument due to Hanouzet [15, Théorème I.1] it can be shown that for $\alpha = 0$ this space coincides with $H(\mathbb{R}^3_+)$.

Because of a Poincaré-type inequality established in [21, Theorem 2.10], the spaces $W^1_\alpha(\mathbb{R}^3_+)$ with $\alpha > 1/2$ are all the same and contain $H(\mathbb{R}^3_+)$ as a closed subspace; we denote this space by $H_{1/2+}(\mathbb{R}^3_+)$ and remark that $H(\mathbb{R}^3_+)$ is a proper subspace of $H_{1/2+}(\mathbb{R}^3_+)$ because the latter includes the constants. As we will prove in the appendix, we have, in fact,

$$H_{1/2+}(\mathbb{R}^3_+) = H(\mathbb{R}^3_+) \oplus \operatorname{span}\{\mathbf{1}\}; \tag{2.7}$$

i.e., $H_{1/2+}(\mathbb{R}^3_+)$ is made up only from $H(\mathbb{R}^3_+)$ and the constants.

Yet another variant, considered in [21], is to start with C^∞-functions in $\mathbb{R}^3_+$ which are vanishing for $|x| \to \infty$. The completion of this space with respect to the norm (2.6) always yields the space $H(\mathbb{R}^3_+)$ no matter what value of $\alpha \geq 0$ is used [25, Appendix A].

Thus, both of the aforementioned variants lead essentially to the same notion of a weak solution of problem (2.1), for the constants always belong to the null space of the differential operator under consideration.

3. Basic properties of the inverse problem. Now we are going to specify somewhat further the impedance tomography problem we consider in this paper. We shall assume throughout that the conductivity σ has the form given in (1.2), (1.3) and recall that, by virtue of (2.4), we have a well-defined bounded linear operator from $L^{2,-1}(\mathbb{R}^2)$ into $H(\mathbb{R}^3_+)$ which maps a given boundary current $f \in L^{2,-1}(\mathbb{R}^2)$ onto the induced potential $u_\sigma \in H(\mathbb{R}^3_+)$. By passing on to the trace of u_σ on $\mathbb{R}^2$ we obtain the *Neumann–Dirichlet operator*

$$\Lambda^g_\sigma : L^{2,-1}(\mathbb{R}^2) \to L^{2,1}(\mathbb{R}^2), \qquad f \mapsto u_\sigma|_{\mathbb{R}^2}.$$

Here, the superscript g stands for *global*, because for practical purposes it is often sufficient to restrict the attention to currents f supported on some bounded subset $\Gamma \subset \mathbb{R}^2$, and also to confine oneself to taking measurements of u_σ only on Γ. This gives rise to the so-called *local Neumann–Dirichlet operator*

$$\Lambda^\ell_\sigma : L^2(\Gamma) \to L^2(\Gamma), \qquad f|_\Gamma \mapsto u_\sigma|_\Gamma.$$

It is easy to check that there holds

$$\Lambda^\ell_\sigma = P\Lambda^g_\sigma P', \tag{3.1}$$

where P is the projection

$$P : L^{2,1}(\mathbb{R}^2) \to L^2(\Gamma), \qquad g \mapsto g|_\Gamma,$$

and

$$P' : L^2(\Gamma) \to L^{2,-1}(\mathbb{R}^2), \qquad f \mapsto \begin{cases} f(y), & y \in \Gamma, \\ 0, & y \in \mathbb{R}^2 \setminus \Gamma, \end{cases}$$

is the dual operator of P.

Our inverse problem is now the following:

> *Let the conductivity σ be of the form* (1.2) *with κ as in* (1.3)*, and let Λ^g_σ—or Λ^ℓ_σ for some bounded and relatively open subset $\Gamma \subset \mathbb{R}^2$, respectively—be given. How can we reconstruct the support of κ, i.e., the discontinuities of σ?*

Before we proceed to derive a constructive answer to this question, we list some elementary properties of the operators Λ_σ^g and Λ_σ^ℓ.

LEMMA 3.1.

(i) $\Lambda_\sigma^\ell : L^2(\Gamma) \to L^2(\Gamma)$ *is compact, self-adjoint, and positive.*

(ii) *Let* $f \in L^{2,-1}(\mathbb{R}^2)$*, and let* $\sigma_1, \sigma_2 \in L^\infty(\mathbb{R}^3_+)$ *with* $\sigma_1, \sigma_2 \geq \varepsilon$ *almost everywhere in* $\mathbb{R}^3_+$*. Then, if* $\sigma_1 \leq \sigma_2$*, we have*

$$\langle f, \Lambda_{\sigma_1}^g f\rangle_{\mathbb{R}^2} \geq \langle f, \Lambda_{\sigma_2}^g f\rangle_{\mathbb{R}^2}.$$

Proof. Consider some bounded domain $G \subset \mathbb{R}^3_+$ with $\Gamma \subset \partial G$. Then, as mentioned before, the operator which restricts $u \in H(\mathbb{R}^3_+)$ to $u|_G \in H^1(G)$ is bounded, and the trace operator from $H^1(G)$ to $L^2(\Gamma)$ is compact. Hence, Λ_σ^ℓ is compact.

Let $0 \neq f, \tilde{f} \in L^2(\Gamma)$, and $u_\sigma, \tilde{u}_\sigma \in H(\mathbb{R}^3_+)$ be the solutions of (2.3) with $f' = P'f$ and $\tilde{f}' = P'\tilde{f}$, respectively. Then by virtue of (3.1) we have

$$\langle f, \Lambda_\sigma^\ell \tilde{f}\rangle_{L^2(\Gamma)} = \langle f', \Lambda_\sigma^g \tilde{f}'\rangle_{\mathbb{R}^2} = \int_{\mathbb{R}^3_+} \sigma \nabla u_\sigma \cdot \nabla \tilde{u}_\sigma \,\mathrm{d}x = \langle \tilde{f}, \Lambda_\sigma^\ell f\rangle_{L^2(\Gamma)}.$$

Thus Λ_σ^ℓ is self-adjoint. With $f = \tilde{f}$ we obtain, using (1.3), that

$$\langle f, \Lambda_\sigma^\ell f\rangle_{L^2(\Gamma)} = \int_{\mathbb{R}^3_+} \sigma |\nabla u_\sigma|^2 \,\mathrm{d}x \geq \varepsilon \int_{\mathbb{R}^3_+} |\nabla u_\sigma|^2 \,\mathrm{d}x = \varepsilon \|u_\sigma\|^2_{H(\mathbb{R}^3_+)},$$

and hence, Λ_σ^ℓ is positive.

Now, let $f \in L^{2,-1}(\mathbb{R}^2)$ be given, and let $u_{\sigma_1}, u_{\sigma_2} \in H(\mathbb{R}^3_+)$ be the weak solutions of (2.1) for the two conductivities σ_1 and σ_2, respectively. From (2.3) it follows that u_{σ_1} is the unique minimizer in $H(\mathbb{R}^3_+)$ of the quadratic energy functional

$$\frac{1}{2}\int_{\mathbb{R}^3_+} \sigma_1 \,|\nabla u|^2 \,dx - \langle f, u\rangle_{\mathbb{R}^2}$$

with minimum value $-\frac{1}{2}\langle f, u_{\sigma_1}\rangle_{\mathbb{R}^2}$. Therefore

$$\begin{aligned} -\frac{1}{2}\langle f, \Lambda_{\sigma_1}^g f\rangle_{\mathbb{R}^2} &= \frac{1}{2}\int_{\mathbb{R}^3_+} \sigma_1 \,|\nabla u_{\sigma_1}|^2 \,\mathrm{d}x - \langle f, u_{\sigma_1}\rangle_{\mathbb{R}^2} \\ &\leq \frac{1}{2}\int_{\mathbb{R}^3_+} \sigma_1 \,|\nabla u_{\sigma_2}|^2 \,\mathrm{d}x - \langle f, u_{\sigma_2}\rangle_{\mathbb{R}^2} \\ &\leq \frac{1}{2}\int_{\mathbb{R}^3_+} \sigma_2 \,|\nabla u_{\sigma_2}|^2 \,\mathrm{d}x - \langle f, u_{\sigma_2}\rangle_{\mathbb{R}^2} = -\frac{1}{2}\langle f, \Lambda_{\sigma_2}^g f\rangle_{\mathbb{R}^2}, \end{aligned} \tag{3.2}$$

which was to be shown. □

Our approach to the solution of the inverse problem is based on a comparison of the measured Neumann–Dirichlet operator Λ_σ^g or Λ_σ^ℓ with the reference operator $\Lambda_{\mathbf{1}}^g$ or $\Lambda_{\mathbf{1}}^\ell$, respectively, corresponding to the homogeneous background with conductivity $\mathbf{1}$. From Lemma 3.1 we immediately conclude the following.

COROLLARY 3.2. *Under the assumptions* (1.2), (1.3), $\Lambda_\sigma^g - \Lambda_{\mathbf{1}}^g$ *as well as* $\Lambda_\sigma^\ell - \Lambda_{\mathbf{1}}^\ell$ *are self-adjoint and positive (resp., negative) if* $\kappa \leq 1 - \varepsilon$ *(resp.,* $\kappa \geq 1 + \varepsilon$*).*

Proof. An adaptation of the proof of Lemma 3.1(i) establishes that Λ_σ^g and $\Lambda_{\mathbf{1}}^g$ are self-adjoint. For the remainder of the proof we consider only the case where $\kappa \leq 1 - \varepsilon$

for some $\varepsilon > 0$; the other case is treated similarly. For this situation we obtain from Lemma 3.1 that

$$\langle f, (\Lambda_\sigma^g - \Lambda_{\mathbf{1}}^g) f\rangle_{\mathbb{R}^2} = \langle f, \Lambda_\sigma^g f\rangle_{\mathbb{R}^2} - \langle f, \Lambda_{\mathbf{1}}^g f\rangle_{\mathbb{R}^2} \geq 0 \tag{3.3}$$

for every $f \in L^{2,-1}(\mathbb{R}^2)$; moreover, strict inequality holds in (3.2), and thus in (3.3), if the two potentials u_σ and $u_{\mathbf{1}}$ occurring in the proof of Lemma 3.1 are different.

Thus, assuming equality in (3.3) for some $f \in L^{2,-1}(\mathbb{R}^2)$, we can conclude that

$$0 = \langle f, \Lambda_\sigma^g f\rangle_{\mathbb{R}^2} - \langle f, \Lambda_{\mathbf{1}}^g f\rangle_{\mathbb{R}^2} = \int_\Omega (\kappa - 1)|\nabla u_{\mathbf{1}}|^2 \,\mathrm{d}x,$$

and hence, $u_{\mathbf{1}}$ is constant in Ω. Since $u_{\mathbf{1}}$ is harmonic in $\mathbb{R}^3_+$, this implies that it is constant in the entire half-space. It follows that $f = 0$, which proves that $\Lambda_\sigma^g - \Lambda_{\mathbf{1}}^g$ is positive.

For the local Neumann–Dirichlet operators we consider $f \in L^2(\Gamma)$, and set $f' = P'f$. By virtue of (3.1) we obtain

$$\langle f, (\Lambda_\sigma^\ell - \Lambda_{\mathbf{1}}^\ell) f\rangle_{L^2(\Gamma)} = \langle f', (\Lambda_\sigma^g - \Lambda_{\mathbf{1}}^g) f'\rangle_{\mathbb{R}^2},$$

where the latter is positive according to the first part of this proof, unless $f = 0$. Therefore $\Lambda_\sigma^\ell - \Lambda_{\mathbf{1}}^\ell$ is also a positive operator. □

4. The framework for the factorization method. In what follows our notation will no longer make explicit whether we are talking about local or global measurements; i.e., we write Λ_σ for either Λ_σ^g or Λ_σ^ℓ. Furthermore, we denote by $T = \mathbb{R}^2$ or $T = \Gamma$ the domain, on which measurements shall be taken. In accordance with this notation, we let $H(T)$ be either $L^{2,1}(\mathbb{R}^2)$ or $L^2(\Gamma)$, respectively.

To simplify the presentation we will assume throughout that Ω consists of only one connected component. Our theory extends to the general case, and whenever necessary we will point out the appropriate modifications for this more general situation (see also [24]).

We want to apply the general framework of Gebauer and therefore adopt his notation from [12] in what follows. We first introduce, similar to $H(B) = H(\mathbb{R}^3_+)$, a function space $H(Q)$ on $Q = B \setminus \overline{\Omega}$ by closing $C_0^\infty(\overline{Q})$ with respect to the H^1-seminorm, which will be denoted by $\|\cdot\|_{H(Q)}$. The space $H(Q)$ has properties similar to those of $H(B)$. In particular, there is a continuous trace operator $\gamma_{Q\to T}$ from $H(Q)$ to $H(T)$, and $H(Q)$ is continuously embedded in $H^1(G \setminus \overline{\Omega})$ for any bounded neighborhood $G \subset \mathbb{R}^3_+$ of Ω. For $u \in H(Q)$ we can thus define a normalized trace operator

$$\gamma_{Q\to\Sigma} v = v - \frac{\mathbf{1}}{|\Sigma|}\int_\Sigma v \,\mathrm{d}o, \qquad v \in H(Q). \tag{4.1}$$

Here, $|\Sigma|$ is the volume of the surface Σ, and $\gamma_{Q\to\Sigma}$ is a bounded and surjective operator from $H(Q)$ onto

$$H(\Sigma) = \left\{ v \in H^{1/2}(\Sigma) : \int_\Sigma v \,\mathrm{d}o = 0 \right\}.$$

In accordance with $H(\Sigma)$ we also introduce the function space

$$H(\Omega) = \left\{ w \in H^1(\Omega) : \int_\Sigma w \,\mathrm{d}o = 0 \right\},$$

which, again, can be equipped with the H^1-seminorm, so that the usual trace operator $\gamma_{\Omega\to\Sigma}$ maps $H(\Omega)$ continuously onto $H(\Sigma)$. We mention that the need for a Poincaré-type inequality is the reason to enforce vanishing means over Σ for elements from $H(\Omega)$.[1]

The framework of Gebauer also requires a linkage between the spaces $H(B)$, $H(Q)$, and $H(\Omega)$. In particular, we need to define "restriction operators" $E_Q : H(B) \to H(Q)$ and $E_\Omega : H(B) \to H(\Omega)$. In fact, we can take the natural restriction for E_Q, i.e., $E_Q u = u|_Q$, but we need to be more careful in the definition of E_Ω: Similarly to (4.1), we let

$$E_\Omega u = u|_\Omega - \frac{\mathbf{1}}{|\Sigma|}\int_\Sigma u \,\mathrm{d}o, \qquad u \in H(B), \tag{4.2}$$

such that the compatibility condition $\gamma_{Q\to\Sigma}E_Q = \gamma_{\Omega\to\Sigma}E_\Omega$ holds true.

Classical extension operators

$$\gamma^-_{Q\to\Sigma} : H(\Sigma) \to H(Q) \qquad \text{and} \qquad \gamma^-_{\Omega\to\Sigma} : H(\Sigma) \to H(\Omega)$$

yield continuous right inverses of the two "trace operators." Note that $\gamma_{\Omega\to\Sigma}$ has a continuous extension to the classical trace operator $\hat{\gamma}_{\Omega\to\Sigma} : H^1(\Omega) \to H^{1/2}(\Sigma)$, and likewise, $\gamma^-_{\Omega\to\Sigma}$ has a continuous extension to a right inverse $\hat{\gamma}^-_{\Omega\to\Sigma} : H^{1/2}(\Sigma) \to H^1(\Omega)$ of $\hat{\gamma}_{\Omega\to\Sigma}$ by setting $\hat{\gamma}^-_{\Omega\to\Sigma}\mathbf{1} = \mathbf{1}$.

In addition we need to construct continuous right inverses E^-_Q and E^-_Ω of E_Q and E_Ω, respectively. To this end we set

$$E^-_\Omega w = \begin{cases} w & \text{on } \Omega, \\ \gamma^-_{Q\to\Sigma}\gamma_{\Omega\to\Sigma} w & \text{on } Q, \end{cases} \qquad \text{and} \qquad E^-_Q v = \begin{cases} \hat{\gamma}^-_{\Omega\to\Sigma} v|_\Sigma & \text{on } \Omega, \\ v & \text{on } Q. \end{cases}$$

It follows, e.g., from Renardy and Rogers [23, Lemma 6.85], that these piecewise defined functions belong to $H^1_{\mathrm{loc}}(\mathbb{R}^3_+)$, and that E^-_Ω and E^-_Q are continuous operators. Moreover, we obviously have the compatibility requirement that $E_Q E^-_\Omega w = 0$ whenever $\gamma_{\Omega\to\Sigma} w = 0$. The corresponding requirement for the case that $\gamma_{Q\to\Sigma} v = 0$ for $v \in H(Q)$ is slightly more complicated: In this case we necessarily have that $v|_\Sigma$ is constant over Σ, and hence, $\hat{\gamma}^-_{\Omega\to\Sigma} v|_\Sigma$ is a constant also. This shows that the restriction of $E^-_Q v$ to Ω is a constant function, and hence $E_\Omega E^-_Q v = 0$ by virtue of (4.2).

Finally, given

$$\psi \in H'(\Sigma) = \left\{ \psi \in H^{-1/2}(\Sigma) : \int_\Sigma \psi \,\mathrm{d}o = 0 \right\},$$

the variational problem

$$\int_Q \nabla v \cdot \nabla w \,\mathrm{d}x = \int_\Sigma \psi w \,\mathrm{d}o \qquad \text{for all } w \in H(Q) \tag{4.3}$$

has a unique solution $v \in H(Q)$, and this solution can be used to introduce the operator

$$L : H'(\Sigma) \to H(T), \qquad \psi \mapsto v|_T, \tag{4.4}$$

[1] When Ω consists of more than one connected component, the elements of $H(\Sigma)$ and $H(\Omega)$ need to have a vanishing mean over each connected component of Σ. The trace operator (4.1) then needs to be modified accordingly, i.e., by subtracting from v different constants on the different components of Σ. A similar comment applies to the restriction operator E_Ω of (4.2).

which will play a fundamental role in what follows. As in section 2, it can be shown that v is the physically relevant (weak) solution of the exterior Neumann problem

$$\Delta v = 0 \quad \text{in } Q, \qquad \frac{\partial v}{\partial \nu} = \psi \quad \text{on } \Sigma, \qquad \frac{\partial v}{\partial e_3} = 0 \quad \text{on } \mathbb{R}^2. \tag{4.5}$$

Now we can formulate our first main result, using the notation $\mathcal{R}(A)$ to denote the range space of some operator A.

THEOREM 4.1. *Under the assumptions* (1.2), (1.3), *there holds*

$$\mathcal{R}\big(|\Lambda_\sigma - \Lambda_{\mathbf{1}}|^{1/2}\big) = \mathcal{R}(L),$$

where L is given by (4.4).

Proof. The assertion is an immediate consequence of Theorem 3.1 in [12]. Except for the straightforward discussion of the bilinear forms occurring in [12], we have already verified all the assumptions of this theorem. Making use of the standard identification of $H'(\Sigma)$ with the dual space of $H(\Sigma)$, employing $L^2(\Sigma)$ as pivot space in the Gelfand triple, it is also obvious that the operator L of (4.4) is nothing but a reformulation of the operator L defined in [12]. □

We mention that the operator L of (4.4) and its dual operator appear naturally in a factorization of the difference of the two measurement operators,

$$\Lambda_\sigma - \Lambda_{\mathbf{1}} = LFL'$$

(cf. [12]), hence the name of the factorization method. Within the framework of Gebauer, an explicit derivation of this factorization and the operator F, in particular, is not necessary. In fact, a specification of F requires the introduction of some additional diffraction problems, similar to the ones in [6, 7]: Since we never need to return to this operator, we omit the details here, but rather refer the reader to [25] or the aforementioned papers for the details.

5. The range test.

The range identity of Theorem 4.1 can be exploited to characterize the set Ω, since the range of L is easy to describe.

THEOREM 5.1. *Let $z \in \mathbb{R}^3_+$ be arbitrarily chosen. Then, for every $d \in \mathbb{R}^3 \setminus \{0\}$ the function*

$$g_{z,d}(x) = \frac{d \cdot (x-z)}{|x-z|^3}, \qquad x \in T, \tag{5.1}$$

belongs to $\mathcal{R}(L)$ if and only if $z \in \Omega$.

Proof. We first observe that $g_{z,d} = u_{z,d}|_T$, where

$$u_{z,d}(x) = \frac{1}{2}\, d \cdot \nabla_z \left(\frac{1}{|x-z|} + \frac{1}{|x-z'|} \right), \qquad x \in \mathbb{R}^3_+ \setminus \{z\},$$

is the superposition of two dipole potentials in z and z'. Here, $z' = z - 2(z \cdot e_3)e_3$ is the reflection of z with respect to the plane $\mathbb{R}^2$. Therefore, $u_{z,d}$ is a harmonic function in $\mathbb{R}^3_+ \setminus \{z\}$ with zero flux across $\mathbb{R}^2$. Moreover, $u_{z,d}$ belongs to $H(Q)$ if and only if $z \in \Omega$. Therefore, if $z \in \Omega$ and $\psi = \psi_{z,d}$ is the flux of $u_{z,d}$ across Σ into Ω, then $u_{z,d}$ is the solution of the exterior Neumann problem (4.5). Note that $\psi_{z,d}$ belongs to $H^{-1/2}(\Sigma)$; see, e.g., Girault and Raviart [13, Theorem 2.5]. Finally, we have for

$z \in \Omega$ that

$$\begin{aligned}\int_\Sigma \psi_{z,d}\,\mathrm{d}o_x &= \frac{1}{2}\, d\cdot\nabla_z \left(\int_\Sigma \frac{\partial}{\partial\nu_x}\frac{1}{|x-z|}\,\mathrm{d}o_x + \int_\Sigma \frac{\partial}{\partial\nu_x}\frac{1}{|x-z'|}\,\mathrm{d}o_x \right)\\ &= \frac{1}{2}\, d\cdot\nabla_z\big(4\pi\mathbf{1}(z)\big) = 0\end{aligned}$$

(see, e.g., [19, Example 6.16]), which shows that $\psi_{z,d} \in H'(\Sigma)$. We therefore have proved that $L\psi_{z,d} = g_{z,d}$, i.e., that $g_{z,d} \in \mathcal{R}(L)$ for $z \in \Omega$.

Now let $z \in \mathbb{R}^3_+ \setminus \Omega$, and assume that $g_{z,d} \in \mathcal{R}(L)$, i.e., that $g_{z,d} = L\psi$ for some $\psi \in H'(\Sigma)$. This is equivalent to the statement that $g_{z,d} = v|_T$, where $v \in H(Q)$ is the weak solution of (4.5). Thus, $u_{z,d}$ and v are two harmonic functions in $\mathbb{R}^3_+ \setminus (\{z\} \cup \overline{\Omega})$ which share the same Cauchy data on $\mathbb{R}^2$. By the uniqueness of the Cauchy problem (see, e.g., [9, Chapter II]) the two functions must be the same in $\mathbb{R}^3_+ \setminus (\{z\} \cup \overline{\Omega})$. This, however, contradicts the fact that $u_{z,d}$ has a singularity in z and, hence, does not belong to $H(Q)$. Therefore we have shown that $g_{z,d} \notin \mathcal{R}(L)$ whenever $z \in \mathbb{R}^3_+ \setminus \Omega$. □

As a corollary of Theorems 4.1 and 5.1 we obtain the following useful range test to decide whether some point $z \in \mathbb{R}^3_+$ belongs to Ω or not.

Corollary 5.2. *A point $z \in \mathbb{R}^3_+$ belongs to Ω if and only if the function $g_{z,d}$ of Theorem* 5.1 *belongs to the range of $|\Lambda_\sigma - \Lambda_{\mathbf{1}}|^{1/2}$.*

6. Numerical results. We now present a numerical realization of the range test of Corollary 5.2 for simulated data in three space dimensions. Data are given on $T = \Gamma = [0,2]^2$, shown as the somewhat darker area of the bounding plane in the subsequent figures. In all examples to follow, data have been generated by a boundary element method, with the conductivity within the inclusion being set to $\kappa = 0.5$. Modifications of κ have a negligible effect on the reconstructions, provided that (1.3) is satisfied for any small ε; this has been demonstrated convincingly in [7] for bounded domains in two space dimensions.

A very detailed discussion of the general approach for implementing the range test can be found in [7, 14], so here we focus mainly on the differences that are important for this half-space problem.

The first major difference is the fact that data are given on a two-dimensional interval rather than a one-dimensional interval. We have found it convenient to use tensor products of piecewise constant Haar wavelets (with vanishing mean over Γ) as current patterns and to expand the simulated potentials in the same orthogonal basis. The data we use thus correspond to the Galerkin projection of $\Lambda_\sigma - \Lambda_{\mathbf{1}}$ onto the space of the particular current patterns. All our computations use the corresponding first 1023 basis functions, which are far more than is required for the resolution of our reconstructions due to the inevitable presence of noise in the data.

Figure 6.1 reveals a second major difference from the results in [7, 14], which appears to be a characteristic property of the factorization method in three space dimensions. The eigenvalues of $\Lambda_\sigma - \Lambda_{\mathbf{1}}$ do not obey a strict geometric decay; rather, they tend to come in clusters of increasing size. Note that, in theory, the function $g_{z,d}$ belongs to the range of $|\Lambda_\sigma - \Lambda_{\mathbf{1}}|^{1/2}$ if and only if the corresponding Picard series

$$\sum_{j=1}^{\infty} \frac{\langle g_{z,d}, v_j\rangle^2_{L^2(\Gamma)}}{|\lambda_j|} \tag{6.1}$$

converges; here v_j, $j \in \mathbb{N}$, are the orthonormal eigenfunctions of $\Lambda_\sigma - \Lambda_{\mathbf{1}}$, and λ_j are the associated eigenvalues. In [7, 14] we have estimated the geometric decay of the

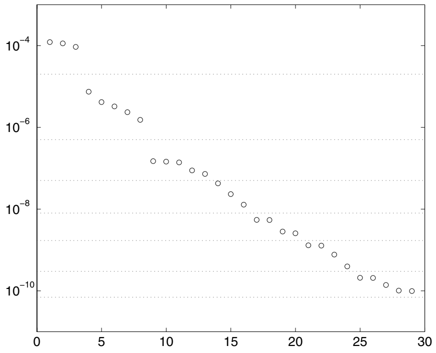

FIG. 6.1. *First test case: eigenvalues of* $\Lambda_\sigma - \Lambda_{\mathbf{1}}$.

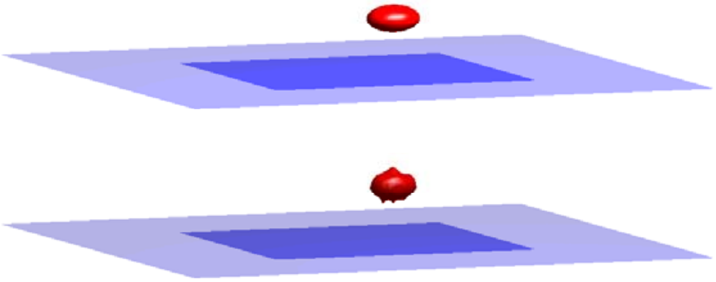

FIG. 6.2. *First test case: an ellipsoidal object (top) and its reconstruction (bottom).*

individual terms of this series to decide whether we believe that (6.1) converges or not. Here, instead, we have decided to average the eigenvalue clusters and investigate the root convergence factor of the geometric decay of the associated partial sums. The eigenvalue plot in Figure 6.1 (and similarly in Figure 6.4) contains dotted lines to indicate the eigenvalues that were considered to be clustered. The clustering has always been performed manually and is optimized to some extent to improve the quality of the reconstructions. Eigenvalue clusters below 10^{-10} have been ignored (except for section 6.4).

6.1. First test case. In the first example, which we have already mentioned, the object to be reconstructed is an ellipsoid with center in $P = (1.2, 0.8, 0.4)$ as shown in Figure 6.2. Its semiaxes are aligned with the coordinate axes and have radii $r_1 = 0.2$, $r_2 = 0.15$, and $r_3 = 0.1$. This isosurface plot is based on a certain average of the root convergence factors obtained from nine different dipole moments d_k, $k = 1, \dots, 9$. (We refer the reader to [25] for further details.) We emphasize, as this might be difficult to see, that the reconstruction is at the correct place and has about the right size. It is only the boundary which is not accurate. Alternatively, we have also evaluated the series (6.1) for the respective range of eigenvalues and have used this function of z for a surface plot, as was done, e.g., by Kirsch in [18]. However, this gave somewhat inferior reconstructions.

6.2. Second test case. Our second example (see Figures 6.3 and 6.4) consists of two objects. One is an ellipsoid with center in $P = (0.4, 0.4, 0.4)$ and radii

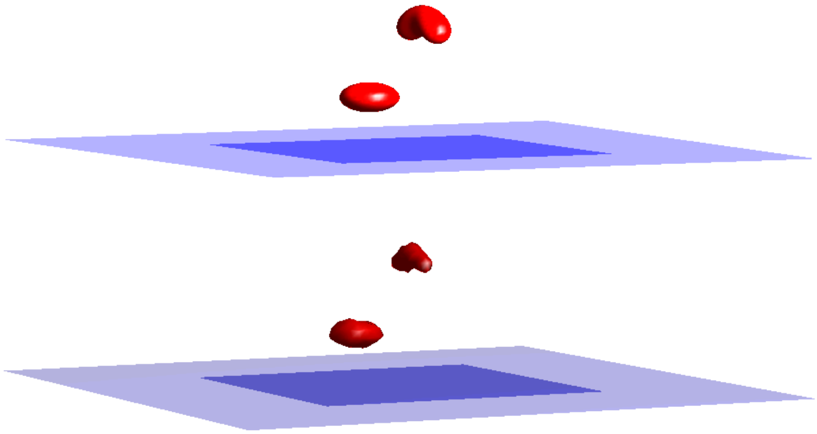

FIG. 6.3. *Second test case: two objects (top) and their reconstruction (bottom).*

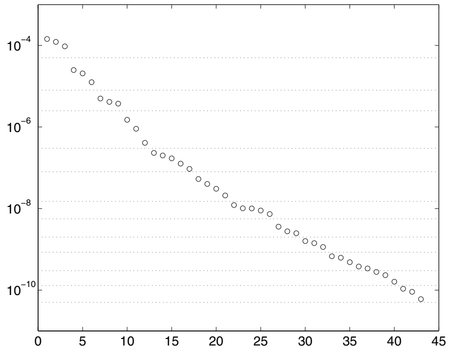

FIG. 6.4. *Eigenvalues for the second test case.*

$r_1 = r_2 = 0.2$ and $r_3 = 0.1$, respectively; again, the semiaxes are aligned with the coordinate axes. The other object has the shape of a kidney and is located around the point $Q = (1.2, 1.2, 0.8)$. The corresponding reconstructions are again at the correct locations. Note that the nonconvexity of the kidney is still well depicted, although it is a little farther away from Γ. On the other hand, its reconstruction is somewhat too small. If the nonconvex boundary is turned upwards, however, the reconstruction is qualitatively worse.

6.3. Third test case. The third test case is similar to the previous one, but now the ellipsoidal object is moved off to the side; i.e., its orthogonal projection onto $\mathbb{R}^2$ is outside of Γ; see Figure 6.5. More precisely, the ellipsoid of the second test case now has its center at $R = (-0.2, -0.2, 0.4)$. Our method reconstructs both objects at their true locations, but the reconstruction of the ellipsoid exhibits typical shady artifacts, similar to two-dimensional reconstructions shown in [14].

6.4. Fourth test case. For the next experiment we return to the ellipsoid from our first example, and increase its vertical distance to the plane. Figure 6.6 shows the reconstructions for three snapshots. As one expects, the quality deteriorates with

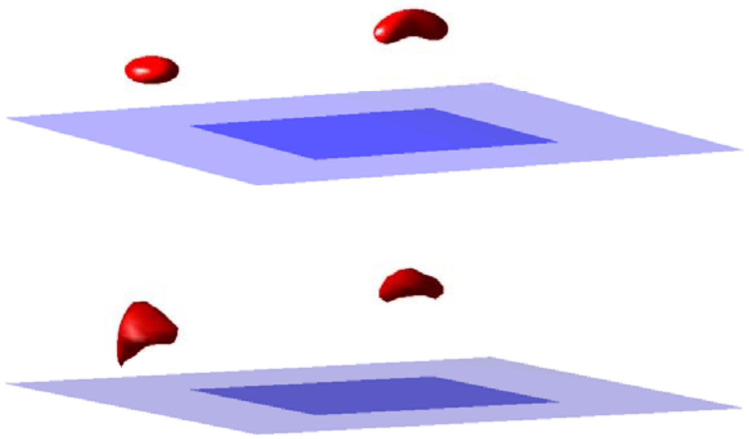

FIG. 6.5. *Third test case: two objects (top), one being off to the side, and their reconstruction (bottom).*

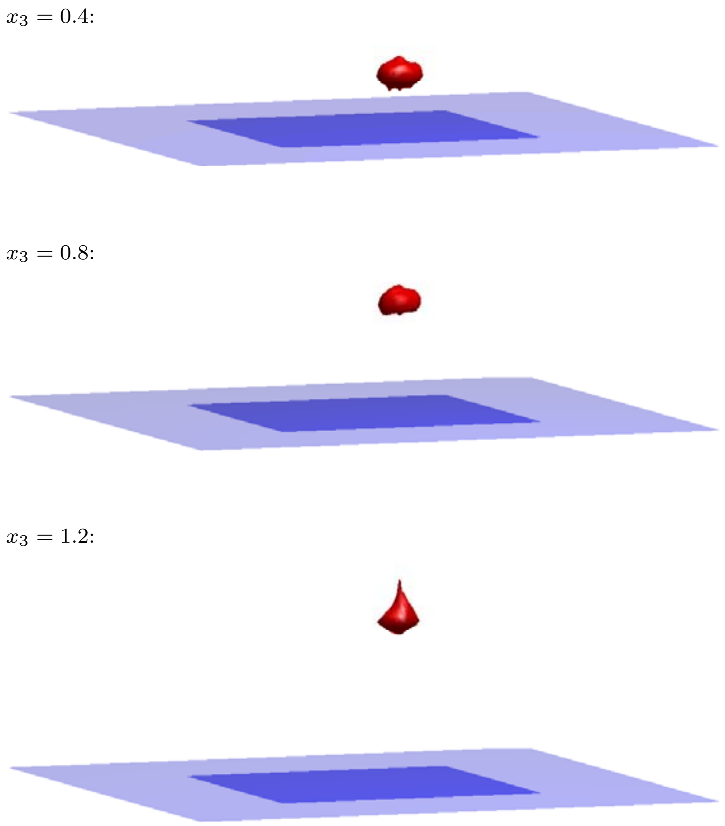

$x_3 = 0.4$:

$x_3 = 0.8$:

$x_3 = 1.2$:

no noise:

0.1% noise:

1% noise:

FIG. 6.8. *Reconstructions in the presence of noise.*

increasing distance x_3, measured at the center of the ellipsoid; see Figure 6.6. For these reconstructions we have used a slightly larger range of eigenvalues, going down to 10^{-12}.

6.5. Fifth test case. In a final study, we investigate the influence of noise on our reconstructions. To this end we superpose the data of our first test case (cf. Figure 6.2) with 0.1% and 1% noise, respectively. (These noise levels refer to the L^2-norms of the noise over the L^2-norm of the exact data.) Figure 6.7 shows the resulting eigenvalues of $\Lambda_\sigma - \Lambda_{\mathbf{1}}$. It is easy to see how the eigenvalues level off in the presence of noise, from which we can easily determine which eigenvalues can reliably be used to perform the range test. Figure 6.8 shows the corresponding reconstructions, which are quite reasonable even with 1% noise (bottom reconstruction).

7. The two-dimensional case. In this section we briefly comment on the modifications of our theory in two space dimensions; as a general reference we refer the reader to [25]. In two dimensions, solutions of the boundary value problem

$$\nabla \cdot \sigma \nabla u = 0 \quad \text{in } \mathbb{R}^2_+, \qquad -\sigma \frac{\partial u}{\partial e_2} = f \quad \text{on } \mathbb{R}, \tag{7.1}$$

are unique (up to additive constants) within the space $H^{1,0+}(\mathbb{R}^2_+)$ which is obtained by closing either $C^\infty(\mathbb{R}^2_+)$ or $C_0^\infty(\mathbb{R}^2_+)$ with respect to the inner product (2.6) for any $\alpha > 0$ (replacing the integrals by integrals over $\mathbb{R}^2_+$, of course). These spaces all contain the same functions, independent of the choice of $\alpha > 0$, including in particular the constant functions. We can get rid of these constants by turning to the quotient space $H(\mathbb{R}^2_+) = H^{1,0+}(\mathbb{R}^2_+)/\operatorname{span}\{\mathbf{1}\}$, for which we can use the H^1-seminorm as an equivalent norm.

Investigating the weak formulation of (7.1), the existence of a solution in $H^{1,0+}(\mathbb{R}^2_+)$ is guaranteed provided that the imposed current f belongs to

$$L^{2,-1-\alpha}_\diamond(\mathbb{R}) = \left\{ f : (1+|y|^2)^{1/2+\alpha/2} f \in L^2(\mathbb{R}) : \int_T f \,\mathrm{d}y = 0 \right\}$$

for some $\alpha > 0$; note that the normalization condition $\int_T f \,\mathrm{d}y = 0$ has not been required in the three-dimensional case.

Since the solution u of (7.1) is unique only up to additive constants, it is necessary to normalize the trace of u to set up a well-defined associated Neumann-to-Dirichlet operator. Accordingly, the general framework developed in section 4 requires some obvious changes for two space dimensions; in particular, a similar normalization is required in the definition of the operator L of (4.4). With these modifications, however, the result of Theorem 4.1 remains true, and a valid test function to be used in Theorem 5.1 (again, up to a suitable additive constant) is given by

$$g_{z,d}(x) = \frac{d \cdot (x-z)}{|x-z|^2}, \qquad x \in T. \tag{7.2}$$

We refer the reader to [25] for several numerical reconstructions in two space dimensions; preliminary results had been published in [14] and [24].

Appendix. In this appendix we prove that the weighted Sobolev space $H_{1/2+}(\mathbb{R}^3_+)$ introduced in Remark 2.3 is the direct sum

$$H_{1/2+}(\mathbb{R}^3_+) = H(\mathbb{R}^3_+) \oplus \operatorname{span}\{\mathbf{1}\}.$$

In the proof of this result we use the following Liouville-type theorem on bounded harmonic functions in the entire space, which appears to be of independent interest.

THEOREM A.1. *Every harmonic function u over $\mathbb{R}^3$ which satisfies*

$$\int_{\mathbb{R}^3} \frac{|u(x)|^2}{(1+|x|^2)^{5/2}} \,\mathrm{d}x < \infty \tag{A.1}$$

is a constant.

Proof. Our proof makes use of an appropriate modification of the argument given in Axler, Bourdon, and Ramey [1], which starts with the mean-value property of harmonic functions, to write

$$\begin{aligned}|u(x^*)-u(0)| &= \frac{3}{4\pi r^3}\left|\int_{B_r(x^*)} u(x)\,\mathrm{d}x - \int_{B_r(0)} u(x)\,\mathrm{d}x\right| \\ &= \frac{3}{4\pi r^3}\left|\int_{D_r} s(x)u(x)\,\mathrm{d}x\right|\end{aligned}$$

for any fixed $x^* \in \mathbb{R}^3$. In this equation $B_r(y)$ denotes the ball of radius r around y, $D_r = B_r(x) \cup B_r(0) \setminus (B_r(x) \cap B_r(0))$ is the symmetric difference of the two balls, and s is a sign function that attains the two values ± 1 in the respective components of D_r. We denote $|x^*|$ by r^* and restrict r to be larger than $r_0 \geq 2r^* + 1$ in what follows. Then D_r is contained in the annulus

$$A_r = \{x \in \mathbb{R}^3 : r - r^* < |x| < r + r^*\},$$

and we can estimate

$$|u(x^*)-u(0)| \leq \frac{3}{4\pi r^3}\int_{A_r} |u(x)|\,\mathrm{d}x \leq c\int_{A_r} \frac{|u(x)|}{(1+|x|^2)^{3/2}}\,\mathrm{d}x,$$

where, from now on, we use c to denote a generic positive constant, depending only on x^*. Integrating the above inequality from $r = r_0$ to some $R > r_0$, we obtain

$$\begin{aligned}|u(x^*)-u(0)| &\leq \frac{c}{R-r_0}\int_{r_0}^{R}\int_{A_r} \frac{|u(x)|}{(1+|x|^2)^{3/2}}\,\mathrm{d}x\,\mathrm{d}r \\ &\leq \frac{2r^*c}{R-r_0}\int_{r_0-r^*<|x|<R+r^*} \frac{|u(x)|}{(1+|x|^2)^{3/2}}\,\mathrm{d}x.\end{aligned}$$

Thus, the Cauchy–Schwarz inequality yields

$$\begin{aligned}|u(x^*)-u(0)|^2 &\leq \frac{c}{(R-r_0)^2}\int_{|x|>r_0-r^*} \frac{|u(x)|^2}{(1+|x|^2)^{5/2}}\,\mathrm{d}x \int_{|x|<R+r^*} \frac{1}{(1+|x|^2)^{1/2}}\,\mathrm{d}x \\ &\leq \frac{c}{(R-r_0)^2}\int_{|x|>r_0-r^*} \frac{|u(x)|^2}{(1+|x|^2)^{5/2}}\,\mathrm{d}x \int_0^{R+r^*} (1+r^2)^{1/2}\,\mathrm{d}r \\ &\leq c\left(\frac{R+r^*+1}{R-r_0}\right)^2 \int_{|x|>r_0-r^*} \frac{|u(x)|^2}{(1+|x|^2)^{5/2}}\,\mathrm{d}x.\end{aligned}$$

Now, if R is sufficiently large, then we can choose $r_0 = R/2$ and thus obtain

$$|u(x^*)-u(0)|^2 \leq c\int_{|x|>R/2-r^*} \frac{|u(x)|^2}{(1+|x|^2)^{5/2}}\,\mathrm{d}x = o(1)$$

as $R \to \infty$. It follows that $u(x^*) = u(0)$, i.e., that u is a constant. □

We mention that this result is sharp in that all polynomials u in x of exact degree one are harmonic in $\mathbb{R}^3$ and satisfy (A.1) for any exponent in the denominator bigger than 5/2.

Now we turn to verify (2.7). Let $w \in H_{1/2+}(\mathbb{R}^3_+)$, and consider the variational problem

$$\int_{\mathbb{R}^3_+} \nabla w_0(x) \cdot \nabla v(x)\,\mathrm{d}x = \int_{\mathbb{R}^3_+} \nabla w(x) \cdot \nabla v(x)\,\mathrm{d}x \qquad \text{for all } v \in H(\mathbb{R}^3_+).$$

This problem has a unique solution $w_0 \in H(\mathbb{R}^3_+)$, and it follows that $u = w - w_0 \in H_{1/2+}(\mathbb{R}^3_+)$ satisfies

$$\int_{\mathbb{R}^3_+} \nabla u(x) \cdot \nabla v(x)\,\mathrm{d}x = 0$$

for all $v \in C_0^\infty(\overline{\mathbb{R}^3_+})$, and hence, according to Weyl's lemma, u is a harmonic function in $\mathbb{R}^3_+$ with vanishing Neumann boundary values on the boundary of this half-space. Thus, u can be extended by reflection to an even harmonic function $\tilde{u}$ over the entire space $\mathbb{R}^3$; cf., e.g., [1]. As $u \in H_{1/2+}(\mathbb{R}^3_+)$ and hence has finite norm (2.6) for any $\alpha > 1/2$, it follows that $\tilde{u}$ satisfies (A.1). Thus $\tilde{u}$ and u are constant functions by virtue of Theorem A.1, and we have shown that any function $w \in H_{1/2+}(\mathbb{R}^3_+)$ can be decomposed in a unique way as $w = w_0 + c$, where $w_0 \in H(\mathbb{R}^3_+)$ and c is some constant. This proves (2.7).

A VARIATIONAL APPROACH TO REMOVING MULTIPLICATIVE NOISE[*]

GILLES AUBERT[†] AND JEAN-FRANÇOIS AUJOL[‡]

Abstract. This paper focuses on the problem of multiplicative noise removal. We draw our inspiration from the modeling of speckle noise. By using a MAP estimator, we can derive a functional whose minimizer corresponds to the denoised image we want to recover. Although the functional is not convex, we prove the existence of a minimizer and we show the capability of our model on some numerical examples. We study the associated evolution problem, for which we derive existence and uniqueness results for the solution. We prove the convergence of an implicit scheme to compute the solution.

Key words. calculus of variation, functional analysis, BV, variational approach, multiplicative noise, speckle noise, image restoration

1. Introduction.

Image denoising is a widely studied problem in the applied mathematics community. We refer the reader to [4, 14] and references therein for an overview of the subject. Most of the literature deals with the additive noise model: given an original image u, it is assumed that it has been corrupted by some additive noise v. The problem is then to recover u from the data $f = u + v$. Many approaches have been proposed. Among the most famous are wavelet approaches [17], stochastic approaches [21], and variational approaches [37, 30].

In this paper, we are concerned with a different denoising problem. The assumption is that the original image u has been corrupted by some multiplicative noise v: the goal is then to recover u from the data $f = uv$. Multiplicative noise occurs as soon as one deals with active imaging systems: laser images, microscope images, synthetic aperture radar (SAR) images, etc. As far as we know, the only variational approach devoted to multiplicative noise is the one by Rudin, Lions, and Osher [36] as used, for instance, in [33, 28, 29, 38]. The goal of this paper is to go further and to propose a functional that is well adapted to removing multiplicative noise. Inspired from the modeling of active imaging systems, this functional is

$$E(u) = \int |Du| + \int \left(\log u + \frac{f}{u} \right),$$

where f is the original corrupted image and $\int |Du|$ stands for the total variation of u.

From a mathematical point of view, part of the difficulty comes from the fact that, contrary to the additive case, the proposed model is nonconvex, which causes uniqueness problems, as well as the issue of convergence of the algorithms. Another mathematical issue comes from the fact that we deal with a linear growth functional.

The natural space in which we compute a solution is BV, the space of functions with bounded variations. But contrary to what happens with classical Sobolev spaces, the minimum of the functional does not verify an associated Euler–Lagrange equation (see [3] and [2] where this problem is studied) but a differential inclusion involving the subdifferential of the energy.

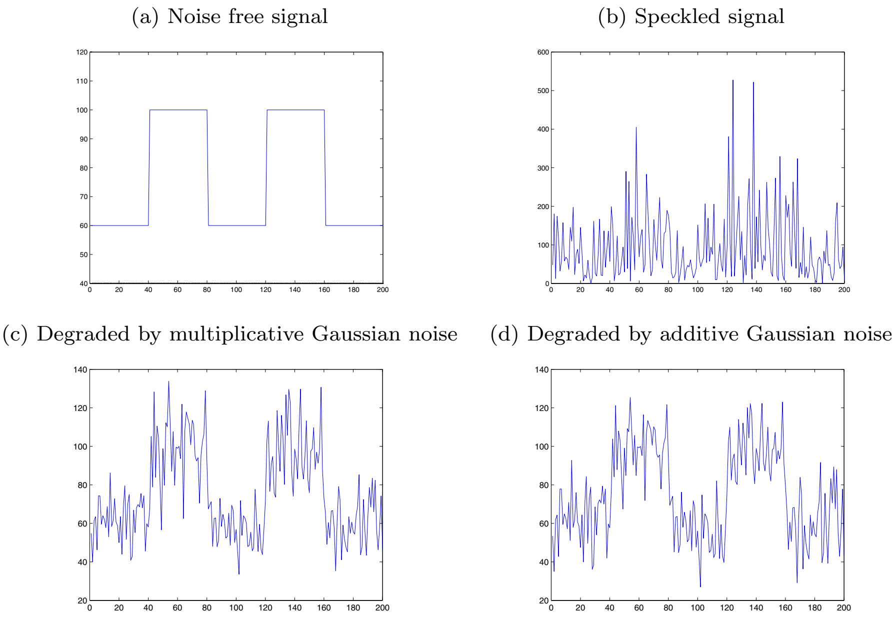
The paper is organized as follows. We draw our inspiration from the modeling of active imaging systems, which we describe to the reader in section 2. We use the classical MAP estimator to derive a new model to denoise nontextured SAR images in section 3. We then consider this model from a variational point of view in section 4 and we carry out the mathematical analysis of the functional in the continuous setting. In section 5 we illustrate our model by displaying some numerical examples. We also compare it with other models. Then in section 6 we study the evolution equation associated to the problem. To prove the existence and the uniqueness of a solution to the evolution problem we first consider a semi-implicit discretization scheme and then we let the discretization time step go to zero. The proofs are rather technical, and we give them in the appendix.

2. Speckle noise modeling. SAR images are strongly corrupted by a noise called speckle. A radar sends a coherent wave which is reflected on the ground and then registered by the radar sensor [26, 31]. If the coherent wave is reflected on a coarse surface (compared to the radar wavelength), then the image processed by the radar is degraded by a noise with large amplitude: this gives a speckled aspect to the image, and this is the reason such a noise is called speckle [24]. To illustrate the difficulty of speckle noise removal, Figure 1 shows a 1-dimensional (1D) noise free signal and the corresponding speckled signal (the noise free signal has been multiplied by a speckle noise of mean 1). It can be seen that almost all the information has disappeared (notice in particular that the vertical scale goes from 40 to 120 for the noise free signal presented in Figure 1(a), whereas it goes from 0 to 600 on the speckled signal presented in Figure 1(b)). As a comparison, Figure 1(c) shows the 1D signal of Figure 1(a) once it has been multiplied by a Gaussian noise of mean 1 and standard deviation 0.2 (as used, for instance, in [36]), and Figure 1(d) shows the 1D signal of Figure 1(a) with the addition of a Gaussian noise of zero mean and standard deviation $\sigma = 15$ (notice that for both Figures 1(c) and (d), the vertical scale goes from 20 to 140).

If we denote by I the image intensity considered as a random variable, then I follows a negative exponential law. The density function is $g_I(x) = \frac{1}{\mu_I} e^{-\frac{x}{\mu_I}} \mathbf{1}_{\{x \geq 0\}}$, where μ_I is both the mean and the standard deviation of I. In general the image is obtained as the summation of L different images (this is very classical with satellite images). If we assume that the variables I_k, $1 \leq k \leq L$, are independent and have the same mean μ_I, then the intensity $J = \frac{1}{L} \sum_{k=1}^{L} I_k$ follows a gamma law, with density function $g_J(x) = \left(\frac{L}{\mu_I}\right)^L \frac{1}{\Gamma(L)} x^{L-1} \exp\left(-\frac{Lx}{\mu_I}\right) \mathbf{1}_{\{x \geq 0\}}$, where $\Gamma(L) = (L-1)!$. Moreover, μ_I is the mean of J, and $\frac{\mu_I}{\sqrt{L}}$ is its standard deviation.

The classical modeling [41] for SAR images is $I = RS$, where I is the intensity of the observed image, R the reflectance of the scene (which is to be recovered), and S the speckle noise. S is assumed to follow a gamma law with mean equal to 1: $g_S(s) = \frac{L^L}{\Gamma(L)} s^{L-1} \exp(-Ls) \mathbf{1}_{\{s \geq 0\}}$. In the rest of the paper, we will assume that the image to recover has been corrupted by some multiplicative gamma noise.

Speckle removal methods have been proposed in the literature. There are geometric filters, such as the Crimmins filter [15] based on the application of convex hull



(a) Noise free signal

(b) Speckled signal

(c) Degraded by multiplicative Gaussian noise

(d) Degraded by additive Gaussian noise

Fig. 1. *Speckle noise in one dimension: notice that the vertical scale is not the same on the different images (scale between* 40 *and* 120 *on* (a)*,* 0 *and* 600 *on* (b)*,* 20 *and* 140 *on* (c)*,* 20 *and* 140 *on* (d)*).* (a) $1D$ *signal* f*;* (b) f *degraded by speckle noise of mean* 1*;* (c) f *degraded by a multiplicative Gaussian noise* ($\sigma = 0.2$)*;* (d) f *degraded by an additive Gaussian noise* ($\sigma = 15$)*. Speckle noise is much stronger than classical additive Gaussian noise* [37] *or classical multiplicative Gaussian noise* [36].

algorithms. There are adaptive filters, such as the Lee filter, the Kuan filter, or its improvement proposed by Wu and Maitre [42]: first and second order statistics computed in local windows are incorporated in the filtering process. Adaptive filters with some modeling of the scene, such as the Frost filter, have been proposed. The criterion is based on a MAP estimator, and Markov random fields can be used as in [40, 16]. Another class of filters are multitemporal, such as the Bruniquel filter [10]: by computing barycentric means, the standard deviation of the noise can be reduced (provided that several different images of the same scene are available). A last class of methods are variational methods as in [37, 36, 6], where the solution is computed with PDEs.

3. A variational multiplicative denoising model. The goal of this section is to propose a new variational model for denoising images corrupted by multiplicative noise and in particular for SAR images. We start from the following multiplicative model: $f = uv$, where f is the observed image, $u > 0$ the image to recover, and v the noise. We consider that f, u, and v are instances of some random variables F, U, and V. In the following, if X is a random variable, we denote by g_X its density function. We refer the interested reader to [25] for further details about random variables. In this section, we consider discretized images. We denote by $\mathcal{S}$ the set of the pixels of the image. Moreover, we assume that the samples of the noise on each pixel $s \in S$ are mutually independent and identically distributed (i.i.d.) with density function g_V.

3.1. Density laws with a multiplicative model. Our goal is to maximize $P(U|F)$, and thus thanks to the Bayes rule we need to know $P(F|U)$ and $g_{F|U}$.

PROPOSITION 3.1. *Assume that U and V are independent random variables, with continuous density functions g_U and g_V. Let us set $F = UV$. Then we have for $u > 0$*

$$g_V\left(\frac{f}{u}\right)\frac{1}{u} = g_{F|U}(f|u). \tag{3.1}$$

Proof. The proof is a standard result (see [25], for instance). We give the proof here for the sake of completeness.

Let $\mathcal{A}$ be an open subset in $\mathbb{R}$. We have

$$\int_{\mathbb{R}} g_{F|U}(f|u)\mathbf{1}_{\{f\in\mathcal{A}\}} = P(F\in\mathcal{A}|U) = \frac{P(F\in\mathcal{A},U)}{P(U)} = \frac{P\left(\left(V=\frac{F}{U}\right)\in\frac{\mathcal{A}}{U},U\right)}{P(U)}.$$

Using the fact that U and V are independent, we have

$$\begin{aligned}\frac{P\left(\left(V=\frac{F}{U}\right)\in\frac{\mathcal{A}}{U},U\right)}{P(U)} = P\left(\left(V=\frac{F}{U}\right)\in\frac{\mathcal{A}}{U}\right) &= \int_{\mathbb{R}} g_V(v)\mathbf{1}_{\{v\in\frac{\mathcal{A}}{u}\}}\,dv\\ &= \int_{\mathbb{R}} g_V(f/u)\mathbf{1}_{\{f\in\mathcal{A}\}}\,\frac{df}{u}.\end{aligned}$$ □

3.2. Our model via the MAP estimator. We assume the following multiplicative model: $f = uv$, where f is the observed image, u the image to recover, and v the noise. We assume that v follows a gamma law with mean 1 and with density function

$$g_V(v) = \frac{L^L}{\Gamma(L)}v^{L-1}e^{-Lv}\,\mathbf{1}_{\{v\geq 0\}}. \tag{3.2}$$

Using Proposition 3.1, we therefore get

$$g_{F|U}(f|u) = \frac{L^L}{u^L\Gamma(L)}f^{L-1}e^{-\frac{Lf}{u}}. \tag{3.3}$$

We also assume that U follows a Gibbs prior,

$$g_U(u) = \frac{1}{Z}\exp(-\gamma\phi(u)), \tag{3.4}$$

where Z is a normalizing constant and ϕ is a nonnegative given function. We aim to maximize $P(U|F)$. This will lead us to the classical MAP estimator. From the Bayes rule, we have $P(U|F) = \frac{P(F|U)\,P(U)}{P(F)}$. Maximizing $P(U|F)$ amounts to minimizing the log-likelihood:

$$-\log(P(U|F)) = -\log(P(F|U)) - \log(P(U)) + \log(P(F)). \tag{3.5}$$

We remind the reader that the image is discretized. We denote by $\mathcal{S}$ the set of the pixels of the image. Moreover, we assume that the samples of the noise on each pixel $s\in\mathcal{S}$ are mutually i.i.d. with density g_V. We therefore have $P(F|U) = \prod_{s\in\mathcal{S}} P(F(s)|U(s))$, where $F(s)$ (resp., $U(s)$) is the instance of the variable F (resp., U) at pixel s. Since $\log(P(F))$ is a constant, we just need to minimize:

$$-\log(P(F|U)) - \log(P(U)) = -\sum_{s\in\mathcal{S}}\left(\log(P(F(s)|U(s))) - \log(P(U(s)))\right). \tag{3.6}$$

Using (3.3), and since Z is a constant, we eventually see that minimizing $-\log(P(F|U))$ amounts to minimizing

$$\sum_{s\in\mathcal{S}}\left(L\left(\log U(s)+\frac{F(s)}{U(s)}\right)+\gamma\phi(U(s))\right). \tag{3.7}$$

The previous computation leads us to propose the following functional for restoring images corrupted with gamma noise:

$$\int\left(\log u+\frac{f}{u}\right)dx+\frac{\gamma}{L}\int\phi(u)\,dx. \tag{3.8}$$

Remarks. (1) It is easy to check that the function $u\rightarrow\log u+\frac{f}{u}$ reaches its minimum value $1+\log f$ over $\mathbb{R}_*^+$ for $u=f$.

(2) Multiplicative Gaussian noise: in the additive noise case, the most classical assumption is to assume that the noise is a white Gaussian noise. However, this can no longer be the case when dealing with multiplicative noise, except in the case of tiny noise. Indeed, if the model is $f=uv$, where v is a Gaussian noise with mean 1, then some instances of v are negative. Since the data f is assumed positive, this implies that the restored image u has some negative values, which is, of course, impossible. Nevertheless, numerically, if the standard deviation of the noise is smaller than 0.2 (i.e., in the case of tiny noise), then it is very unlikely that v takes some negative values. See also [32] where some limitations of the Bayesian estimator approach are investigated.

4. Mathematical study of the variational model.

In this section, we propose a nonconvex model for removing multiplicative noise, for which we prove the existence of a solution.

4.1. Preliminaries.

Throughout our study, we will use the following classical distributional spaces. $\Omega\subset\mathbb{R}^2$ will denote an open bounded set with Lipschitz boundary.

- $\mathcal{D}(\Omega)=C_0^\infty(\Omega)$ is the set of functions in $C^\infty(\Omega)$ with compact support in Ω. We denote by $\mathcal{D}'(\Omega)$ the dual space of $\mathcal{D}(\Omega)$, i.e., the space of distributions on Ω.
- $W^{m,p}(\Omega)$ denotes the space of functions in $L^p(\Omega)$ whose distributional derivatives $D^\alpha u$ are in $L^p(\Omega)$, $p\in[1,+\infty)$, $m\geq 1$, $m\in\mathbb{N}$, $|\alpha|\leq m$. For further details on these spaces, we refer the reader to [19, 20].
- $BV(\Omega)$ is the subspace of functions $u\in L^1(\Omega)$ such that the following quantity is finite:

$$J(u)=\sup\left\{\int_\Omega u(x)\operatorname{div}(\xi(x))\,dx\ /\ \xi\in C_0^\infty(\Omega,\mathbb{R}^2),\ \|\xi\|_{L^\infty(\Omega,\mathbb{R}^N)}\leq 1\right\}. \tag{4.1}$$

$BV(\Omega)$ endowed with the norm $\|u\|_{BV}=\|u\|_{L^1}+J(u)$ is a Banach space. If $u\in BV(\Omega)$, the distributional derivative Du is a bounded Radon measure, and (4.1) corresponds to the total variation, i.e., $J(u)=\int_\Omega|Du|$.

For $\Omega\subset\mathbb{R}^2$, if $1\leq p\leq 2$, we have $BV(\Omega)\subset L^p(\Omega)$. Moreover, for $1\leq p<2$, this embedding is compact. For further details on $BV(\Omega)$, we refer the reader to [1].

- Since $BV(\Omega)\subset L^2(\Omega)$, we can extend the functional J (which we still denote by J) over $L^2(\Omega)$:

$$J(u)=\begin{cases}\int_\Omega|Du| & \text{if } u\in BV(\Omega),\\ +\infty & \text{if } u\in L^2(\Omega)\backslash BV(\Omega).\end{cases} \tag{4.2}$$

We can then define the subdifferential ∂J of J [35]: $v \in \partial J(u)$ if and only if for all $w \in L^2(\Omega)$, we have $J(u+w) \geq J(u) + \langle v, w\rangle_{L^2(\Omega)}$, where $\langle ., .\rangle_{L^2(\Omega)}$ denotes the usual inner product in $L^2(\Omega)$.

- *Decomposability of $BV(\Omega)$.* If u in $BV(\Omega)$, then $Du = \nabla u\, dx + D_s u$, where $\nabla u \in L^1(\Omega)$ and $D_s u \perp dx$. ∇u is called the regular part of Du.
- *Weak * topology on $BV(\Omega)$.* If (u_n) is a bounded sequence in $BV(\Omega)$, then up to a subsequence, there exists $u \in BV(\Omega)$ such that $u_n \to u$ in $L^1(\Omega)$ strong, and $Du_n \to Du$ in the sense of measure; i.e., $\langle Du_n, \phi\rangle \to \langle Du, \phi\rangle$ for all ϕ in $(C_0^\infty(\Omega))^2$.
- *Approximation by smooth functions.* If u belongs to $BV(\Omega)$, then there exists a sequence u_n in $C^\infty(\Omega) \bigcap BV(\Omega)$ such that $u_n \to u$ in $L^1(\Omega)$ and $J(u_n) \to J(u)$ as $n \to +\infty$.
- In this paper, if a function f belongs to $L^\infty(\Omega)$, we denote by $\sup_\Omega f$ (resp., $\inf_\Omega f$) the sup ess of f (resp., the inf ess of f). We recall that $\operatorname{sup\,ess} f = \inf\{C \in \mathbb{R};\ f(x) \leq C \text{ a.e.}\}$ and $\operatorname{inf\,ess} f = \sup\{C \in \mathbb{R};\ f(x) \geq C \text{ a.e.}\}$.

4.2. The variational model. The application we have in mind is the denoising of nontextured SAR images. Inspired by the works of Rudin et al. [37, 36], we decide to choose $\phi(u) = J(u)$.

We thus propose the following restoration model (λ being a regularization parameter):

$$\inf_{u\in S(\Omega)} J(u) + \lambda \int_\Omega \left(\log u + \frac{f}{u}\right), \tag{4.3}$$

where $S(\Omega) = \{u \in BV(\Omega),\ u > 0\}$ and $f > 0$ in $L^\infty(\Omega)$ is the given data.

From now on, without loss of generality, we assume that $\lambda = 1$.

4.3. Existence of a minimizer. In this subsection, we show that problem (4.3) has at least one solution.

Theorem 4.1. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$; then problem* (4.3) *has at least one solution u in $BV(\Omega)$ satisfying*

$$0 < \inf_\Omega f \leq u \leq \sup_\Omega f \tag{4.4}$$

Proof. Let us denote $\inf f$ by α and $\sup f$ by β. Let us consider a minimizing sequence $(u_n) \in S(\Omega)$ for problem (4.3). Let us set

$$E(u) = J(u) + \int_\Omega \left(\log u + \frac{f}{u}\right). \tag{4.5}$$

We split the proof into two parts.

Part 1. We first show that we can assume without restriction that $\alpha \leq u_n \leq \beta$.

We remark that $x \mapsto \log x + \frac{f}{x}$ is decreasing if $x \in (0, f)$ and increasing if $x \in (f, +\infty)$. Therefore, if $M \geq f$, one always has

$$\left(\log(\min(x, M)) + \frac{f}{\min(x, M)}\right) \leq \log x + \frac{f}{x}. \tag{4.6}$$

Hence, if we let $M = \beta = \sup f$, we find that

$$\int_\Omega \left(\log \inf(u, \beta) + \frac{f}{\inf(u, \beta)}\right) \leq \int_\Omega \left(\log u + \frac{f}{u}\right). \tag{4.7}$$

Moreover, we have that (see Lemma 1 in section 4.3 of [27], for instance)

$$J(\inf(u,\beta)) \leq J(u).$$

We thus deduce that

$$E(\inf(u,\beta)) \leq E(u). \tag{4.8}$$

And in the same way we get that $E(\sup(u,\alpha)) \leq E(u)$, where $\alpha = \inf f$.

Part 2. From the first part of the proof, we know that we can assume that $\alpha \leq u_n \leq \beta$. This implies in particular that u_n is bounded in $L^1(\Omega)$.

By definition of (u_n), the sequence $E(u_n)$ is bounded; i.e., there exists a constant C such that $J(u_n) + \int_\Omega \left(\log u_n + \frac{f}{u_n}\right) \leq C$. Moreover, standard computations show that $\int_\Omega \left(\log u_n + \frac{f}{u_n}\right)$ reaches its minimum value $\int_\Omega (1 + \log f)$ when $u = f$, and thus we deduce that $J(u_n)$ is bounded.

Therefore we get that u_n is bounded in $BV(\Omega)$ and there exists u in $BV(\Omega)$ such that up to a subsequence, $u_n \to u$ in $BV(\Omega)$ weak * and $u_n \to u$ in $L^1(\Omega)$ strong. Necessarily, we have $0 \leq \alpha \leq u \leq \beta$, and thanks to the lower semicontinuity of the total variation and Fatou's lemma, we get that u is a solution of problem (4.3). □

4.4. Uniqueness and comparison principle. In this subsection, we address the problem of the uniqueness of a solution of problem (4.3). The question remains open in general, but we prove two results: we give a sufficient condition ensuring uniqueness and we show that a comparison principle holds.

PROPOSITION 4.2. *Let $f > 0$ be in $L^\infty(\Omega)$; then problem* (4.3) *has at most one solution $\hat{u}$ such that* $0 < \hat{u} < 2f$.

Proof. Let us set

$$h(u) = \log u + \frac{f}{u}. \tag{4.9}$$

We have $h'(u) = \frac{1}{u} - \frac{f}{u^2} = \frac{u-f}{u^2}$ and $h''(u) = -\frac{1}{u^2} + 2\frac{f}{u^3} = \frac{2f-u}{u^3}$. We deduce that if $0 < u < 2f$, then h is strictly convex, implying the uniqueness of a minimizer. □

We now state a comparison principle.

PROPOSITION 4.3. *Let f_1 and f_2 be in $L^\infty(\Omega)$ with $\inf_\Omega f_1 > 0$ and $\inf_\Omega f_2 > 0$. Let us assume that $f_1 < f_2$. We denote by u_1 (resp., u_2) a solution of* (4.3) *for $f = f_1$ (resp., $f = f_2$). Then we have $u_1 \leq u_2$.*

Proof. We use here the following classical notation: $u \vee v = \sup(u,v)$, and $u \wedge v = \inf(u,v)$.

From Theorem 4.1, we know that u_1 and u_2 do exist. We have, since u_i is a minimizer with data f_i,

$$J(u_1 \wedge u_2) + \int_\Omega \left(\log(u_1 \wedge u_2) + \frac{f_1}{u_1 \wedge u_2}\right) \geq J(u_1) + \int_\Omega \left(\log u_1 + \frac{f_1}{u_1}\right) \tag{4.10}$$

and

$$J(u_1 \vee u_2) + \int_\Omega \left(\log(u_1 \vee u_2) + \frac{f_2}{u_1 \vee u_2}\right) \geq J(u_2) + \int_\Omega \left(\log u_2 + \frac{f_2}{u_2}\right). \tag{4.11}$$

Adding these two inequalities and using the fact that $J(u_1 \wedge u_2) + J(u_1 \vee u_2) \leq J(u_1) + J(u_2)$ [12, 23], we get

$$\int_\Omega \left(\log(u_1 \wedge u_2) + \frac{f_1}{u_1 \wedge u_2} - \log u_1 - \frac{f_1}{u_1} + \log(u_1 \vee u_2) + \frac{f_2}{u_1 \vee u_2} - \log u_2 - \frac{f_2}{u_2}\right) \geq 0. \tag{4.12}$$

Writing $\Omega = \{u_1 > u_2\} \cup \{u_1 \leq u_2\}$, we easily deduce that

$$\int_{\{u_1>u_2\}} (f_1 - f_2)\frac{u_1 - u_2}{u_1 u_2} \geq 0. \tag{4.13}$$

Since $f_1 < f_2$, we thus deduce that $\{u_1 > u_2\}$ has a zero Lebesgue measure; i.e., $u_1 \leq u_2$ a.e. in Ω. □

4.5. Euler–Lagrange equation associated to problem (4.3). Let us now write an "Euler–Lagrange" equation for any solution of problem (4.3), the difficulty being that the ambient space is $BV(\Omega)$.

PROPOSITION 4.4. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$. If u in $BV(\Omega)$ is a solution of problem* (4.3)*, then we have*

$$-h'(u) \in \partial J(u). \tag{4.14}$$

Proof. This is a consequence of the maximum principle (4.4) of Theorem 4.1. Indeed, h can be replaced below the value $\inf_\Omega f$ by its C^1-quadratic extension, and this change does not alter the set of minimizers. The new functional has a Lipschitz derivative, and then standard results can be used to get (4.14). □

To give more insight into (4.14), we state the following result (see Proposition 1.10 in [2] for further details).

PROPOSITION 4.5. *Let (u, v) be in $L^2(\Omega)$ with u in $BV(\Omega)$. The following assertions are equivalent:*

(i) $v \in \partial J(u)$.

(ii) *Denoting by $X(\Omega)_2 = \{z \in L^\infty(\Omega, \mathbb{R}^2) : \mathrm{div}(z) \in L^2(\Omega)\}$, we have*

$$\int_\Omega vu\, dx = J(u) \tag{4.15}$$

and

$$\begin{array}{l}\exists z \in X(\Omega)_2,\ \|z\|_\infty \leq 1,\ z.N = 0 \textit{ on } \partial\Omega \\ \textit{such that } v = -\mathrm{div}(z) \textit{ in } \mathcal{D}'(\Omega).\end{array} \tag{4.16}$$

(iii) (4.16) *holds, and*

$$\int_\Omega (z, Du) = \int_\Omega |Du|. \tag{4.17}$$

From this proposition, we see that (4.14) means that $-h'(u) = \mathrm{div}\, z$, with z satisfying (4.16) and (4.17). This is a rigorous way to write $-\mathrm{div}\left(\frac{\nabla u}{|\nabla u|}\right) + h'(u) = 0$.

5. Numerical results.

We present in this section some numerical examples illustrating the capability of our model. We also compare it with some other existing models.

5.1. Algorithm. To numerically compute a solution to problem (4.3), we use the equation $-\mathrm{div}\left(\frac{\nabla u}{|\nabla u|}\right) + h'(u) = 0$ and, as it is classically done in image analysis, we embed it into a dynamical equation which we drive to a steady state:

$$\frac{\partial u}{\partial t} = \mathrm{div}\left(\frac{\nabla u}{|\nabla u|}\right) + \lambda\frac{f - u}{u^2} \tag{5.1}$$

with initial data $u(x,0) = \frac{1}{|\Omega|}\int_\Omega f$. We denote this model as the AA model. We use the following explicit scheme, with finite differences (we have checked numerically that for $\delta t > 0$ small enough, the sequence (u_n) satisfies a maximum principle):

$$\frac{u_{n+1} - u_n}{\delta t} = \left(\operatorname{div}\left(\frac{\nabla u_n}{\sqrt{|\nabla u_n|^2 + \beta^2}} \right) - \lambda h'(u_n) \right) \tag{5.2}$$

with β a small fixed parameter.

5.2. Other models. We have compared our results with some other classical variational denoising models.

*Additive model (*log*).* A natural way to turn a multiplicative model into an additive one is to use the logarithm transform (see [5, 22], for instance). Nevertheless, as can be seen on the numerical results, such a straightforward method does not produce satisfactory results. In the numerical results presented in this paper, we refer to this model as the log model. We first take the logarithm of the original image f. We then denoise $\log(f)$ by using the Rudin–Osher–Fatemi (ROF) model [37, 13], with the functional $\inf_y \left(J(y) + \frac{1}{2\lambda}\|x - z\|^2_{L^2} \right)$. We finally take the exponential to obtain the restored image. As can be seen in Figures 2 and 3, there is no maximum principle for this algorithm. In particular, the mean of the restored image is much smaller than that of the original image. In fact, in such an approach, the assumptions are not consistent with the modeling, as explained hereafter.

The original considered model is the following: $f = uv$, under the assumptions that u and v are independent, and $E(v) = 1$ (i.e., v is of mean 1). Hence $E(f) = E(u)$.

Now, if we take the logarithm, denoting by $x = \log(f)$, $y = \log(u)$, and $z = \log(v)$, we get the additive model $x = y + z$. To recover y from x, the classical assumption is $E(z) = 0$: this is the basic assumption in all the classical additive image restoration methods [11, 4] (total variation minimization, nonlinear diffusion, wavelet shrinkage, nonlocal means, heat equation, etc.).

But, from Jensen's inequality, we have $\exp(E(z)) \leq E(\exp(z))$, i.e., $1 \leq E(v)$. As soon as there is some noise, we are no longer in the case of equality in Jensen's inequality, which implies $E(v) > 1$. As a consequence, $E(u) < E(f)$ (in the numerical examples presented in Figures 2 and 3, we obtain $E(u) \approx E(f)/2$).

As a conclusion, if one wants to use the logarithm to get an additive model, then one cannot directly apply a standard additive noise removal algorithm. One needs to be more careful.

RLO model. The second model we use is a multiplicative version of the ROF model: it is a constrained minimization problem proposed by Rudin, Lions, and Osher in [36, 34], and we will call it the RLO model. In this approach, the model considered is $f = uv$, under the constraints that $\int_\Omega v = 1$ (mean 1) and $\int_\Omega (v-1)^2 = \sigma^2$ (given variance). The goal is then to minimize $\int_\Omega |Du|$ under the two previous constraints. The gradient projection method leads to

$$\frac{\partial u}{\partial t} = \operatorname{div}\left(\frac{\nabla u}{|\nabla u|} \right) - \lambda \frac{f^2}{u^3} - \mu \frac{f}{u^2}. \tag{5.3}$$

The two Lagrange multipliers λ and μ are dynamically updated to satisfy the constraints (as explained in [36]). With this algorithm, there is no regularization parameter to tune: the parameter to tune here is the number of iterations (since the considered flow is not associated to any functional). In practice, it appears that the Lagrange multipliers λ and μ are almost always of opposite signs.

Notice that the model proposed in this paper (AA) is specifically devoted to the denoising of images corrupted by gamma noise. The RLO model does not make such an assumption on the noise and therefore cannot be expected to perform as well as the AA model for speckle removal. Notice also that in the case of small Gaussian multplicative noise, both the RLO and AA models give very good results, as can be seen in Figure 5.

5.3. Deblurring. It is possible to modify our model to incorporate a linear blurring operator K. With u being the image to recover, we assume that the observed image f is obtained as $f = (Ku).v$. The functional to minimize in this case becomes

$$\inf_u \left(J(u) + \lambda \int_\Omega \left(\frac{f}{Ku} + \log(Ku) \right) \right). \tag{5.4}$$

The associated Euler–Lagrange equation is (denoting by K^T the transpose of K)

$$0 \in \partial J(u) + \lambda K^T \left(\frac{-f}{(Ku)^2} + \frac{1}{Ku} \right). \tag{5.5}$$

Numerically, we use a steepest gradient descent approach by solving

$$\frac{\partial u}{\partial t} = \operatorname{div}\left(\frac{\nabla u}{|\nabla u|} \right) + \lambda K^T \left(\frac{f - Ku}{(Ku)^2} \right). \tag{5.6}$$

5.4. Results. In Figure 2, we show a first example. The original synthetic image is corrupted by some multiplicative noise with gamma law of mean 1 (see (3.2)). We display the denoising results obtained by our approach (AA), as well as with the RLO model. Due to the very strong noise, the RLO model experiences some difficulties in bringing back in the range of the image some isolated points (white and black points on the denoised image) and at the same time keeping sharp edges: to remove these artifacts, one needs to regularize more, and therefore some part of the edges are lost. Moreover, the mean of the original image is not preserved (the mean of the restored image is quite larger than that of the original image): this is the reason why the signal-to-noise ratio (SNR) is not much improved, and also why the restored image with the RLO model looks lighter. We also display the results obtained with the log model: as explained before, this model gives bad results, due to the fact that the mean is not preserved (with the log model, the mean is much reduced). This is the reason why the restored image with the log model is much darker.

In Figure 3, we show how our model behaves with a complicated geometrical image. We also give the results with the RLO model and the log model (which have the same drawbacks as in Figure 2).

In Figure 4, we show the result we get on a SAR image provided by the CNES (French space agency). The reference image (also furnished by the CNES) has been obtained by amplitude summation.

In Figure 5, we show how our model behaves with multiplicative Gaussian noise. We have used the same parameters for the Gaussian noise as in [36], i.e., a standard deviation of 0.2 (and a mean equal to 1). The original image is displayed in Figure 3. In this case, we see that we get a very good restoration result. Notice that such a multiplicative Gaussian noise is much easier to handle than the speckle noise which was tackled in Figures 2–4. But, as far as we know, this is the type of multiplicative noise which was considered in all the variational approaches inspired by [36] (as used,

for instance, in [33, 28, 29, 38]). We also show the results with the RLO model and the log model. Notice that in this case all the models perform very well, even the log model: indeed, since the noise is small, Jensen's inequality is almost an equality.

In Figure 6, we finally show a deblurring example with our model (5.4). The original image (displayed in Figure 3) has been convolved with a Gaussian kernel of standard deviation $\sqrt{2}$ and then multiplied by a Gaussian noise of standard deviation 0.2 and mean 1 (we use the same parameters as in [36]). Even though the restored

image is not as good as in the denoising case presented in Figure 5, we see that our model works well for deblurring.

6. Evolution equation. In this section we study the evolution equation associated to (4.14). The motivation is that when searching for a numerical solution of (4.14) it is, in general, easier to compute a solution of the associated evolution equation (by using, for example, explicit or semi-implicit schemes) and then studying the asymptotic behavior of the process to get a solution of the stationary equation.

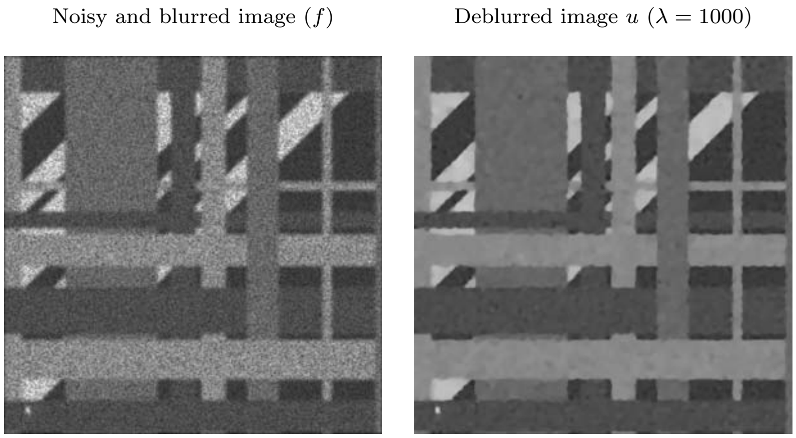
FIG. 5. *Denoising of a synthetic image degraded by multiplicative Gaussian noise with* $\sigma = 0.2$. *The original noise free image is shown in Figure* 3.

We first consider a semidiscrete version of the problem: the space Ω is still included in R^2, but we discretize the time variable. We consider the case of a regular time discretization, (t_n), with t_0 given and $t_{n+1} - t_n = \delta t$ in $\mathbb{R}_+^*$ (in this section, δt is fixed). We define $u_n = u(.,t_n)$, and we consider the following implicit scheme:

$$0 \in \frac{u_{n+1} - u_n}{\delta t} + \partial J(u_{n+1}) + h'(u_{n+1}), \tag{6.1}$$

where J is the extended total variation as defined in (4.2). We first need to check that



Noisy and blurred image (f)

FIG. 6. *Deblurring of the synthetic image of Figure* 3 *(the original image, which is shown in Figure* 3*, was first convolved with a Gaussian kernel of standard deviation $\sigma = \sqrt{2}$ and then multiplied by some Gaussian noise of mean* 1 *and standard deviation $\sigma = 0.2$).*

(6.1) indeed defines a sequence (u_n). To this end, we intend to study the following functional:

$$\inf_{u \in BV(\Omega),\, u>0} F(u, u_n) \tag{6.2}$$

with

$$F(u, u_n) = \int_\Omega \frac{u^2}{2}\, dx - \int_\Omega u_n u \, dx + \delta t \left(J(u) + \int_\Omega h(u)\, dx \right). \tag{6.3}$$

We want to define u_{n+1} as

$$u_{n+1} = \underset{\{u \in BV(\Omega),\, u>0\}}{\operatorname{argmin}} F(u, u_n). \tag{6.4}$$

6.1. Existence and uniqueness of the sequence (u_n). We first need to check that the sequence (u_n) is indeed well defined.

PROPOSITION 6.1. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$. Let (u_n) be in $BV(\Omega)$ such that $\inf_\Omega f \leq u_n \leq \sup_\Omega f$. If $\delta t < 27(\inf_\Omega f)^2$, then there exists a unique u_{n+1} in $BV(\Omega)$ satisfying* (6.4)*. Moreover, we have*

$$\inf\left(\inf_\Omega f \,,\, \inf_\Omega u_0\right) \leq u_n \leq \sup\left(\sup_\Omega f \,,\, \sup_\Omega u_0\right). \tag{6.5}$$

Proof. We split the proof into two parts.

Part 1. We first show the existence and uniqueness of u^{n+1}. We consider: $g(u) = \delta t h(u) + u^2/2 - u_n u$. We have $g''(u) = 1 + \delta t \frac{f-u}{u^2} = \frac{u^3 - \delta t u + 2\delta t f}{u^3}$. A simple computation shows that if $\delta t < 27(\inf_\Omega f)^2$, then $g''(u) > 0$ for all $u > 0$, i.e., g strictly convex on $\mathbb{R}_+^*$. It is then standard to deduce the existence and uniqueness of u^{n+1}.

Part 2. As in the proof of Theorem 4.1, we have

$$\int_\Omega \left(\log \inf(u, \beta) + \frac{f}{\inf(u, \beta)} \right) \leq \int_\Omega \left(\log u + \frac{f}{u} \right) \tag{6.6}$$

and $J(\inf(u,\beta)) \leq J(u)$.

We remark that $x \mapsto x^2/2 - xu_n$ is decreasing if $x \in (0, u_n)$ and increasing if $x \in (u_n, +\infty)$. Therefore, proceeding as in the proof of Theorem 4.1, we get

$$\int_\Omega \frac{\left(\inf\left(u\,,\,\sup u_n\right)\right)^2}{2} - u_n \inf\left(u\,,\,\sup u_n\right) \leq \int_\Omega \frac{u^2}{2} - uu_n. \tag{6.7}$$

Thus the truncation procedure decreases the energy, and we deduce the right-hand side inequality in (6.5). We get the other one in the same way. □

We can thus derive the following theorem.

Theorem 6.2. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$, and u_0 in $L^\infty(\Omega) \bigcap BV(\Omega)$ with $\inf_\Omega u_0 > 0$ be given. If $\delta t < 27(\inf_\Omega f)^2$, then there exists a unique sequence (u_n) in $BV(\Omega)$ satisfying* (6.4). *Moreover, the following estimates hold:*

$$\inf\left(\inf_\Omega f\,,\, \inf_\Omega u_0\right) = \alpha \leq u_n \leq \beta = \sup\left(\sup_\Omega f\,,\, \sup_\Omega u_0\right) \tag{6.8}$$

and

$$J(u_n) \leq J(u_0) + \int_\Omega h(u_0)\,dx - \int_\Omega (1 + \log f). \tag{6.9}$$

Proof. This theorem is just a consequence (by induction) of Proposition 6.1, except for estimate (6.9) which we prove now.

From (6.4), we have $F(u_{n+1}, u_n) \leq F(u_n, u_n)$, which means

$$\begin{aligned} &\delta t \left(J(u_{n+1}) - J(u_n) + \int_\Omega h(u_{n+1}) - \int_\Omega h(u_n) \right) \\ &+ \frac{1}{2} \int_\Omega (u_{n+1} - u_n)^2 \leq 0. \end{aligned} \tag{6.10}$$

This implies

$$J(u_{n+1}) - J(u_n) + \int_\Omega h(u_{n+1}) - \int_\Omega h(u_n) \leq 0. \tag{6.11}$$

By summation, we obtain

$$J(u_{n+1}) \leq -\int_\Omega h(u_{n+1}) + \int_\Omega h(u_0) + J(u_0). \tag{6.12}$$

Standard computations show that $\int_\Omega h(u_{n+1}) \geq \int_\Omega (1 + \log f)\,dx$, from which we deduce (6.9). □

6.2. Euler–Lagrange equation. We have the following "Euler–Lagrange" equation.

Proposition 6.3. *The sequence (u_n) satisfying* (6.4) *is such that*

$$0 \in \frac{u_{n+1} - u_n}{\delta t} + \left(\partial J(u_{n+1}) + h'(u_{n+1}) \right). \tag{6.13}$$

Proof. The proof is similar to that of Proposition 4.4. □

6.3. Convergence of the sequence u_n. The following convergence result holds.

PROPOSITION 6.4. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$, and u_0 in $L^\infty(\Omega)\bigcap BV(\Omega)$ with $\inf_\Omega u_0 > 0$ be fixed. Let $\delta t < 27(\inf_\Omega f)^2$. The sequence (u_n) defined by (6.1) is such that there exists u in $BV(\Omega)$ with $u_n \rightharpoonup u$ (up to a subsequence) for the $BV(\Omega)$ weak * topology, and u is solution of*

$$0 \in \partial J(u) + h'(u) \tag{6.14}$$

in the distributional sense.

Proof. As in the proof of Theorem 6.2, we get the same kind of equation as (6.10):

$$\frac{1}{2}\int_\Omega (u_{n+1}-u_n)^2 \leq \delta t \left(J(u_n) - J(u_{n+1}) + \int_\Omega h(u_n) - \int_\Omega h(u_{n+1}) \right). \tag{6.15}$$

By summation, we obtain

$$\begin{aligned}\frac{1}{2}\sum_{n=0}^{N-1}\int_\Omega (u_{n+1}-u_n)^2 &\leq \delta t \left(J(u_0) - J(u_N) + \int_\Omega h(u_0) - \int_\Omega h(u_N) \right)\\ &\leq \delta t \left(J(u_0) + \int_\Omega h(u_0) - \int_\Omega h(f) \right) < +\infty\end{aligned}$$

(since $\int_\Omega h(u_N \geq \int_\Omega h(f))$. In particular, this implies that $u_{n+1} - u_n \to 0$ in $L^2(\Omega)$ strong.

From estimate (6.9), we know that there exists u in $BV(\Omega)$ such that up to a subsequence $u_n \rightharpoonup u$ for the $BV(\Omega)$ weak * topology. Moreover, $u_n \to u$ in $L^1(\Omega)$ strong. Let $v \in L^2(\Omega)$. From (6.13), we have

$$J(v) \geq J(u_{n+1}) + \left\langle v - u_{n+1}, -\frac{u_{n+1}-u_n}{\delta t} - h'(u_{n+1}) \right\rangle_{L^2(\Omega)}. \tag{6.16}$$

Using estimate (6.8) and the fact that $u_n \to u$ in $L^1(\Omega)$ strong, we deduce from Lebesgue's dominated convergence theorem that (up to a subsequence) $u_n \to u$ in $L^2(\Omega)$ strong. Moreover, since $u_{n+1} - u_n \to 0$ in $L^2(\Omega)$ strong, and thanks to the lower semicontinuity of the total variation, we get $J(v) \geq J(u) + \langle v-u, -h'(u)\rangle_{L^2(\Omega)}$. Hence (6.14) holds. □

6.4. Continuous setting. Let us consider the evolution equation

$$\frac{\partial u}{\partial t} \in -\partial J(u) - h'(u) \tag{6.17}$$

with the initial condition $u(0) = u_0$ and with $h(u) = \frac{f}{u} + \log u$, i.e., $h'(u) = \frac{u-f}{u^2}$. $J(u)$ still denotes the extended total variation of u with respect to the space variable x.

To show the existence and uniqueness of a solution for (6.17), we could apply the theory of maximal monotone operator [9, 8, 2]. This theory works provided that h' is Lipschitz. One need only replace h by its C^1-quadratic extension below $\inf_\Omega$. This would yield a solution in $L^2(\Omega)$. Here, we derive sharper bounds with the next result, whose proof is given in Appendix A.

THEOREM 6.5. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$, and u_0 in $L^\infty(\Omega) \bigcap BV(\Omega)$ with $\inf_\Omega u_0 > 0$. Then problem (6.17) has exactly one solution u in $L^\infty_w((0,T);BV(\Omega))$ $\bigcap W^{1,2}((0,T);L^2(\Omega))$.*

Remark. u belongs to $L^\infty_w((0,T);BV(\Omega))$ means that u belongs to $L^\infty((0,T)\times\Omega)$ and Du belongs to $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$. $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ is the space of equivalent classes of weak * measurable mappings μ that are essentially bounded; i.e., $\sup\operatorname{ess}_{x\in\Omega}\|\mu(x)\| < +\infty$ (we say that μ is weak * measurable if $\langle\mu(x),f\rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega;\mathbb{R}^2)}$ is measurable with respect to x for every f in $C_0(\Omega;\mathbb{R}^2)$; see Lemma A.5 and [7] for further details).

Appendix A. Evolution equation: Continuous setting.

To show that problem (6.17) has a solution, we start from the semidiscrete problem we have studied in the previous section. We therefore consider a sequence (u_n) satisfying (6.4). From Proposition 6.3, we know that (u_n) satisfies

$$0 \in \frac{u_{n+1}-u_n}{\delta t} + \Big(\partial J(u_{n+1}) + h'(u_{n+1})\Big) \tag{A.1}$$

and u_{n+1} satisfies Neumann boundary conditions $\frac{\partial u_{n+1}}{\partial N} = 0$ on the boundary of Ω. From Theorem 6.2, we know that the sequence (u_n) exists and is unique provided that $\delta t < 27(\inf_\Omega f)^2$.

A.1. Definitions of interpolate functions.

We classically introduce two functions defined on $\Omega\times\mathbb{R}^+$. We assume that $t_0 = 0$ and $t_n = n\delta t$. Then

$$\tilde{u}_{\delta t}(t,x) = u_{[t/\delta t]+1}(x) = u_{n+1}(x) \text{ if } t_n < t \leq t_{n+1}, \tag{A.2}$$

where $[t/\delta t]$ is the integer part of $t/\delta t$. $\tilde{u}_{\delta t}(.,x)$ is thus piecewise constant. We also introduce

$$\hat{u}_{\delta t}(t,x) = (t-t_n)\frac{u_{n+1}(x)-u_n(x)}{\delta t} + u_n(x) \tag{A.3}$$

with $n = [t/\delta t]$. $\hat{u}_{\delta t}(.,x)$ is piecewise affine and continuous, and we have

$$\frac{\partial \hat{u}_{\delta t}}{\partial t}(t,x) = \frac{u_{n+1}(x)-u_n(x)}{\delta t}, \quad t_n < t < t_{n+1}. \tag{A.4}$$

With this notation, we can rewrite (A.1) as

$$\frac{\tilde{u}_{\delta t}(t,x) - \tilde{u}_{\delta t}(t-\delta t,x)}{\delta t} \in -\partial J(\tilde{u}_{\delta t}(t,x)) - h'(\tilde{u}_{\delta t}(t,x)), \tag{A.5}$$

i.e.,

$$\frac{\partial \hat{u}_{\delta t}}{\partial t}(t,x) \in -\partial J(\tilde{u}_{\delta t}(t,x)) - h'(\tilde{u}_{\delta t}(t,x)). \tag{A.6}$$

A.2. A priori estimates.

We first need to show some a priori estimates.

Proposition A.1. *Let $T>0$ be fixed, f in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$, and u_0 in $L^\infty(\Omega)\bigcap BV(\Omega)$ with $\inf_\Omega u_0 > 0$. Then if $0\leq t\leq T$,*

$$\inf\Big(\inf_\Omega f\,,\,\inf_\Omega u_0\Big) = \alpha \leq \tilde{u}_{\delta t}, \hat{u}_{\delta t} \leq \beta = \sup\Big(\sup_\Omega f\,,\,\sup_\Omega u_0\Big) \tag{A.7}$$

and

$$\sup_{t\in(0,T)}\{J(\tilde{u}_{\delta t}), J(\hat{u}_{\delta t})\} \leq J(u_0) + \int_\Omega h(u_0) - \int_\Omega h(f). \tag{A.8}$$

Proof. (A.7) for $\tilde{u}_{\delta t}$ comes from (6.8) in Theorem 6.2, and (A.8) comes from (6.9). We then get the estimates for $\hat{u}_{\delta t}$ from (A.3). □

PROPOSITION A.2. *Let $T > 0$ be fixed. There exists a constant $C > 0$, which does not depend on δt, such that*

$$\int_0^T \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} \leq C. \tag{A.9}$$

Proof. Let us denote $[t/\delta t]$ by N. We have

$$\int_{t_n}^{t_{n+1}} \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} = \delta t \int_\Omega \left| \frac{u_{n+1}(x) - u_n(x)}{\delta t} \right|^2 dx. \tag{A.10}$$

By using (6.15), we get

$$\int_{t_n}^{t_{n+1}} \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} \leq 2 \left(J(u_n) - J(u_{n+1}) + \int_\Omega h(u_n) - \int_\Omega h(u_{n+1}) \right). \tag{A.11}$$

Hence,

$$\begin{aligned} \sum_{n=0}^{N-1} \int_{t_n}^{t_{n+1}} \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} &\leq 2 \left(J(u_0) - J(u_N) + \int_\Omega h(u_0) - \int_\Omega h(u_N) \right) \\ &\leq 2 \left(J(u_0) + \int_\Omega h(u_0) - \int_\Omega h(f) \right). \end{aligned}$$

We thus deduce that

$$\int_0^T \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} dt \leq 2T \left(J(u_0) + \int_\Omega h(u_0) - \int_\Omega h(f) \right) + \int_{t_N}^T \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} dt. \tag{A.12}$$

But, by using (6.15), we have

$$\begin{aligned} \int_{t_N}^T \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} dt &\leq 2 \frac{T - t_n}{\delta t} \left(J(u_N) - J(u_{N+1}) + \int_\Omega h(u_N) - \int_\Omega h(u_{N+1}) \right) \\ &\leq 2 \left(J(u_0) - J(u_{N+1}) + \int_\Omega h(u_N) - \int_\Omega h(u_{N+1}) \right). \end{aligned}$$

We then get from (6.9) and (6.8) that there exists $B > 0$ which does not depend on N and δt such that $\int_{t_N}^T \left\| \frac{\partial \hat{u}_{\delta t}}{\partial t} \right\|^2_{L^2(\Omega)} dt \leq B$. We then conclude the proof thanks to (A.12). □

COROLLARY A.3. *Let $T > 0$ be fixed. Then*

$$\lim_{\delta t \to 0} \int_0^T \| \hat{u}_{\delta t} - \tilde{u}_{\delta t} \|^2_{L^2(\Omega)} dt = 0. \tag{A.13}$$

Proof. Let us denote $[t/\delta t]$ by N. We have

$$\int_0^T \| \hat{u}_{\delta t} - \tilde{u}_{\delta t} \|^2_{L^2(\Omega)} dt = \sum_{n=0}^{N-1} \int_{t_n}^{t_{n+1}} \| \hat{u}_{\delta t} - \tilde{u}_{\delta t} \|^2_{L^2(\Omega)} dt + \int_{t_N}^T \| \hat{u}_{\delta t} - \tilde{u}_{\delta t} \|^2_{L^2(\Omega)} dt. \tag{A.14}$$

But

$$\text{(A.15)}\quad \sum_{n=0}^{N-1}\int_{t_n}^{t_{n+1}}\|\hat{u}_{\delta t}-\tilde{u}_{\delta t}\|^2_{L^2(\Omega)}\,dt=\sum_{n=0}^{N-1}\int_{t_n}^{t_{n+1}}\|(t-t_n-\delta t)(u_{n+1}-u_n)\|^2_{L^2(\Omega)}\,dt.$$

We then deduce from (A.4) that

$$\begin{aligned}\sum_{n=0}^{N-1}\int_{t_n}^{t_{n+1}}\|\hat{u}_{\delta t}-\tilde{u}_{\delta t}\|^2_{L^2(\Omega)}\,dt &\le \sum_{n=0}^{N-1}\int_{t_n}^{t_{n+1}}\left\|\delta t\frac{\partial\hat{u}_{\delta t}}{\partial t}\right\|_{L^2(\Omega)}dt\\ &\le \underbrace{(\delta t)^2\int_0^T\left\|\frac{\partial\hat{u}_{\delta t}}{\partial t}\right\|^2_{L^2(\Omega)}dt\,.}_{\to 0\text{ as }\delta t\to 0}\end{aligned}$$

And

$$\text{(A.16)}\qquad \int_{t_N}^{T}\|\hat{u}_{\delta t}-\tilde{u}_{\delta t}\|^2_{L^2(\Omega)}\,dt\le\underbrace{(\delta t)^3\left\|\frac{u_{N+1}-u_N}{\delta t}\right\|^2_{L^2(\Omega)}dt\,.}_{\to 0\text{ as }\delta t\to 0}\qquad\square$$

We summarize the a priori estimates we have proved in the following corollary.

COROLLARY A.4. *Let $T>0$ be fixed. There exists a constant $C>0$ such that*

$$\text{(A.17)}\qquad \sup\left\{\sup_{t\in(0,T)}\|\tilde{u}_{\delta t}\|_{L^\infty(\Omega)}\,,\ \sup_{t\in(0,T)}\|\hat{u}_{\delta t}\|_{L^\infty(\Omega)}\right\}\le C,$$

$$\text{(A.18)}\qquad \sup\left\{\sup_{t\in(0,T)}J(\tilde{u}_{\delta t})\,,\ \sup_{t\in(0,T)}J(\hat{u}_{\delta t})\right\}\le C,$$

$$\text{(A.19)}\qquad \int_0^T\left\|\frac{\partial\hat{u}_{\delta t}}{\partial t}\right\|^2_{L^2(\Omega)}\le C,$$

$$\text{(A.20)}\qquad \lim_{\delta t\to 0}\int_0^T\|\hat{u}_{\delta t}-\tilde{u}_{\delta t}\|^2_{L^2(\Omega)}\,dt=0.$$

A.3. Existence of a solution. We can now prove Theorem 6.5.

Proof. The uniqueness of u will come from Proposition A.6. Here we just show the existence of u.

We first remark that, from inequalities (A.17) and (A.19), $\hat{u}_{\delta t}$ is uniformly bounded in $W^{1,2}((0,T);L^2(\Omega))$. Thus, up to a subsequence, there exists u in $W^{1,2}((0,T);L^2(\Omega))$ such that $\hat{u}_{\delta t}\rightharpoonup u$ in $W^{1,2}((0,T);L^2(\Omega))$ weak. Since $W^{1,2}((0,T);L^2(\Omega))$ is compactly embedded in $L^2((0,T);L^2(\Omega))$ (see [39, Theorem 2.1, Chapter 3]), $\hat{u}_{\delta t}\to u$ strongly in $L^2((0,T);L^2(\Omega))$.

Since (A.17) and (A.18) hold, we can apply Lemma A.5 (stated below) with $(\tilde{u}_{\delta t})$. Thus, up to a subsequence, there exists $\tilde{u}$ in $L^\infty_w((0,T);BV(\Omega))$ such that $\tilde{u}_{\delta t}\rightharpoonup\tilde{u}$ in $L^\infty(\Omega\times(0,T))$ weak * and $D_x\tilde{u}_{\delta t}\rightharpoonup D_x\tilde{u}$ in $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ weak *. From (A.20), we have that $\tilde{u}_{\delta t}\to u$ strongly in $L^2((0,T);L^2(\Omega))$, and we thus deduce that $\tilde{u}=u$.

The semidiscrete implicit scheme writes for a.e. $t \in (0,T)$

$$-\frac{\partial \hat{u}_{\delta t}}{\partial t} - h'(\tilde{u}_{\delta t}) \in \partial J(\tilde{u}_{\delta t}); \tag{A.21}$$

i.e., for all v in $BV(\Omega)$, $v > 0$, and a.e. $t \in (0,T)$,

$$J(v) \geq J(\tilde{u}_{\delta t}) + \left\langle v - \tilde{u}_{\delta t}, -\frac{\partial \hat{u}_{\delta t}}{\partial t} - h'(\tilde{u}_{\delta t}) \right\rangle_{L^2(\Omega)\times L^2(\Omega)}. \tag{A.22}$$

Let ϕ in $C_c^0(0,T)$ be a test function, $\phi \geq 0$. We multiply (A.22) by ϕ and integrate on $(0,T)$:

$$\int_0^T J(v)\phi(t)\,dt \geq \int_0^T J(\tilde{u}_{\delta t})\phi(t)\,dt + \int_0^T \int_\Omega (v - \tilde{u}_{\delta t}) \left(-\frac{\partial \hat{u}_{\delta t}}{\partial t} - h'(\tilde{u}_{\delta t}) \right) \phi(t)\,dt\,dx. \tag{A.23}$$

We want to let $\delta t \to 0$ in (A.23). By convexity, we have

$$\liminf \int_0^T J(\tilde{u}_{\delta t})\phi(t)\,dt \geq \int_0^T J(u)\phi(t)\,dt. \tag{A.24}$$

Now, since $\tilde{u}_{\delta t} \to u$ strongly in $L^2((0,T);L^2(\Omega))$, $\frac{\partial \hat{u}_{\delta t}}{\partial t} \rightharpoonup \frac{\partial u}{\partial t}$ in $L^2((0,T);L^2(\Omega))$ weak, and h' is bounded on the interval $[\alpha,\beta]$, the second term on the right-hand side of (A.23) tends to

$$\int_0^T \int_\Omega (v-u) \left(-\frac{\partial u}{\partial t} - h'(u) \right) \phi(t)\,dt\,dx.$$

We thus get

$$\int_0^T J(v)\phi(t)\,dt \geq \int_0^T J(u)\phi(t)\,dt + \int_0^T \int_\Omega (v-u) \left(-\frac{\partial u}{\partial t} - h'(u) \right) \phi(t)\,dt\,dx. \tag{A.25}$$

This inequality holds for all $\phi \geq 0$, and we deduce that for a.e. t in $(0,T)$

$$J(v) \geq J(u) + \int_\Omega (v-u) \left(-\frac{\partial u}{\partial t} - h'(u) \right) dx; \tag{A.26}$$

i.e., $-\frac{\partial u}{\partial t} \in \partial J(u) + h'(u)$. Hence we deduce that u is a solution of (6.17) in the distributional sense. □

In the above proof, we have used the following lemma.

LEMMA A.5. *Let (u_n) be a bounded sequence in $L^\infty_w(\Omega\times(0,T))$, such that $(D_x u_n)$ is a bounded sequence in $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$. Then, up to a subsequence, there exists u in $L^\infty_w((0,T);BV(\Omega))$ such that $u_n \rightharpoonup u$ in $L^\infty(\Omega\times(0,T))$ weak * and $D_x u_n \rightharpoonup D_x u$ in $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ weak *; i.e., for all ψ in $L^1((0,T);C_0(\Omega))$,*

$$\int_0^T \langle Du_n, \psi\rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega;\mathbb{R}^2)}\,dt \to \int_0^T \langle Du, \psi\rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega;\mathbb{R}^2)}\,dt, \tag{A.27}$$

where $\langle .,. \rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega)}$ denotes the duality product between bounded measures on Ω and $C_0(\Omega;\mathbb{R}^2)$ denotes the space of functions continuous on Ω and vanishing in $\partial\Omega$.

Proof. From the Riesz representation theorem [1, 20], there is an isometric isomorphism between $\mathcal{M}_b(\Omega)$ and the dual space of $C_0(\Omega)$. Moreover, since $C_0(\Omega)$ is separable, there is an isometric isomorphism between $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ and the dual space of $L^1((0,T);C_0(\Omega))$ (see [7] or [18, page 588]). Up to a subsequence, there exist u in $L^\infty(\Omega\times(0,T))$ and v in $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ such that $u_n \rightharpoonup u$ in $L^\infty(\Omega\times(0,T))$ weak *, and $D_x u_n \rightharpoonup v$ in $L^\infty_w((0,T);\mathcal{M}_b(\Omega))$ weak *. We therefore have for all ψ in $L^1((0,T);C_0(\Omega))$

$$\int_0^T \langle Du_n,\psi\rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega;\mathbb{R}^2)}\,dt \to \int_0^T \langle v,\psi\rangle_{\mathcal{M}_b(\Omega)\times C_0(\Omega;\mathbb{R}^2)}\,dt. \tag{A.28}$$

Moreover, we have $D_x u_n \to D_x u$ in $\mathcal{D}'(\Omega\times(0,T))$ and $D_x u_n \to v$ in $\mathcal{D}'(\Omega\times(0,T))$: this implies that $D_x u = v$. □

A.4. Uniqueness of the solution. A uniqueness result holds.

PROPOSITION A.6. *Let f be in $L^\infty(\Omega)$ with $\inf_\Omega f > 0$, and let u_0 be in $L^\infty(\Omega)\bigcap BV(\Omega)$ with $\inf_\Omega u_0 > 0$. Then problem* (6.17) *has at most one solution u such that $0<\alpha\le u\le\beta$.*

Proof. This is a standard result. It is based on the convexity of J, the fact that h' is Lipschitz on $[\inf_\Omega f, +\infty)$, and the Gronwall inequality. □

Acknowledgments. We would like to thank one of the anonymous referees for his very interesting comments about this paper (in particular for shortening the proof of Theorem 4.1 and suggesting the result of Proposition 4.3). We also would like to thank Professor Antonin Chambolle and Professor Vicent Caselles for fruitful discussions.

HILL'S EQUATION WITH RANDOM FORCING TERMS*

FRED C. ADAMS† AND ANTHONY M. BLOCH‡

Abstract. Motivated by a class of orbit problems in astrophysics, this paper considers solutions to Hill's equation with forcing strength parameters that vary from cycle to cycle. The results are generalized to include period variations from cycle to cycle. The development of the solutions to the differential equation is governed by a discrete map. For the general case of Hill's equation in the unstable limit, we consider separately the cases of purely positive matrix elements and those with mixed signs; we then find exact expressions, bounds, and estimates for the growth rates. We also find exact expressions, estimates, and bounds for the infinite products of several 2×2 matrices with random variables in the matrix elements. In the limit of sharply spiked forcing terms (the delta function limit), we find analytic solutions for each cycle and for the discrete map that matches solutions from cycle to cycle; for this case we find the growth rates and the condition for instability in the limit of large forcing strength, as well as the widths of the stable/unstable zones.

Key words. Hill's equation, random matrices, orbit problems

DOI. 10.1137/070689322

1. Introduction.

This paper presents new results concerning Hill's equation of the form

$$\frac{d^2y}{dt^2} + [\lambda_k + q_k \hat{Q}(t)]y = 0, \tag{1}$$

where the function $\hat{Q}(t)$ is periodic, so that $\hat{Q}(t+\pi) = \hat{Q}(t)$, and normalized, so that $\int_0^\pi \hat{Q} dt = 1$. The parameter q_k is denoted here as the forcing strength, which we consider to be a random variable that takes on a new value every cycle (the index k determines the cycle). The parameter λ_k, which determines the oscillation frequency in the absence of forcing, also varies from cycle to cycle. In principal, the duration of the cycle could also vary; our first result (see Theorem 1) shows that this generalized case can be reduced to the problem of (1).

Hill's equations [HI] arise in a wide variety of contexts [MW], and hence the consideration of random variations in the parameters (q_k, λ_k) is a natural generalization of previous work. This particular form of Hill's equation was motivated by a class of orbit problems in astrophysics [AB]. In many astrophysical systems, orbits take place in extended mass distributions with triaxial forms. Examples include dark matter halos that envelop galaxies and galaxy clusters, stellar bulges found at the centers of spiral galaxies, elliptical galaxies, and young embedded star clusters. These systems thus occur over an enormous range of scales, spanning factors of millions in size and

factors of trillions in mass. Nonetheless, the basic form of the potential is similar [NF, BE, AB] for all of these systems, and the corresponding orbit problem represents a sizable fraction of the orbital motion that takes place in our universe. In this context, when a test particle (e.g., a star or a dark matter particle) orbits within the triaxial potential, motion that is initially confined to a particular orbital plane can be unstable to motion in the perpendicular direction [AB]. The equation that describes the development of this instability takes the form of (1). Further, the motion in the original orbital plane often displays chaotic behavior, which becomes more extreme as the axis ratios of the potential increase [BT]. In this application, the motion in the original orbit plane—in particular, the distance to the center of the coordinate system—determines the magnitude of the forcing strength q_k that appears in Hill's equation. The crossing time, which varies from orbit to orbit, determines the value of the oscillation parameter λ_k. As a result, the chaotic behavior in the original orbital plane leads to random forcing effects in the differential equation that determines instability of motion out of the plane (see Appendix A for further discussion).

Given that Hill's equations arise in a wide variety of physical problems [MW], we expect that applications with random forcing terms will be common. Although the literature on stochastic differential equations is vast (e.g., see the review of [BL]), specific results regarding Hill's equations with random forcing terms are relatively rare.

In this application, Hill's equation is periodic or nearly periodic (we generalize to the case of varying periods for the basic cycles), and the forcing strength q_k varies from cycle to cycle. Since the forcing strength is fixed over a given cycle, one can solve the Hill's equation for each cycle using previously developed methods [MW], and then match the solutions from cycle to cycle using a discrete map. As shown below, the long-time solution can be developed by repeated multiplication of 2×2 matrices that contain a random component in their matrix elements.

The subject of random matrices, including the long term behavior of their products, is also the subject of a great deal of previous work [BL, DE, BD, FK, FU, LR, ME, VI]. In this application, however, Hill's equation determines the form of the random matrices, and the repeated multiplication of this type of matrix represents a new and specific application. Given that instances where analytic results can be obtained are relatively rare, this set of solutions adds new examples to the list of known cases.

This paper is organized as follows. In section 2, we present the basic formulation of the problem, define relevant quantities, and show that aperiodic generalizations of the problem can be reduced to random Hill's equations. The following section (section 3) presents the main results of the paper: We find specific results regarding the growth rates of instability for random Hill's equations in the limit of large forcing strengths (i.e., in the limit where the equations are robustly unstable). These results are presented for purely positive and for mixed signs in the 2×2 matrix map. We also find limiting forms and constraints on the growth rates. Finally, we find bounds and estimates for the errors incurred by working in the limit of large forcing strengths. This work is related to the general existence results of [FU] but provides much more detailed information in our setting. In the next section (section 4) we consider the limit where the forcing terms are Dirac delta functions; this case allows for analytic solutions to the original differential equation. We note that the growth rates calculated here (section 3) depend on the distribution of the ratios of the principal solutions to (1), rather than (directly) on the distributions of the parameters (λ_k, q_k). Using the analytic solutions for the delta function limit (section 4), we thus gain insight into the transformation between the distributions of the input parameters (λ_k, q_k) and the parameters that specify the growth rates. Finally, we conclude, in section 5, with a summary and discussion of our results.

2. Formulation.

Definition. *A* random Hill's equation *is defined here to be of the form given by* (1)*, where the forcing strength q_k and oscillation parameter λ_k vary from cycle to cycle. Specifically, the parameters q_k and λ_k are stochastic variables that take on new values every cycle $0 \leq [t] \leq \pi$, and the values are sampled from known probability distributions $P_q(q)$ and $P_\lambda(\lambda)$.*

2.1. Hill's equation with fixed parameters.

Over a single given cycle, a random Hill's equation is equivalent to an ordinary Hill's equation and can be solved using known methods [MW].

Definition. *The* growth factor f_c *per cycle (the Floquet multiplier) is given by the solution to the characteristic equation and can be written as*

$$f_c = \frac{\Delta + (\Delta^2 - 4)^{1/2}}{2}, \tag{2}$$

where the discriminant $\Delta = \Delta(q, \lambda)$ is defined by

$$\Delta \equiv y_1(\pi) + \frac{dy_2}{dt}(\pi), \tag{3}$$

and where y_1 and y_2 are the principal solutions [MW].

It follows from Floquet's theorem that $|\Delta| > 2$ is a sufficient condition for instability [MW, AS]. In addition, periodic solutions exist when $|\Delta| = 2$.

2.2. Random variations in forcing strength.

We now generalize to the case where the forcing strength q_k and oscillation parameter λ_k vary from cycle to cycle. In other words, we consider each period from $t = 0$ to $t = \pi$ as a cycle and consider the effects of successive cycles with varying values of (q_k, λ_k).

During any given cycle, the solution can be written as a linear combination of the two principal solutions y_1 and y_2. Consider two successive cycles. The first cycle has parameters (q_a, λ_a) and solution

$$f_a(t) = \alpha_a y_{1a}(t) + \beta_a y_{2a}(t), \tag{4}$$

where the solutions $y_{1a}(t)$ and $y_{2a}(t)$ correspond to those for an ordinary Hill's equation when evaluated using the values (q_a, λ_a). Similarly, for the second cycle with parameters (q_b, λ_b) the solution has the form

$$f_b(t) = \alpha_b y_{1b}(t) + \beta_b y_{2b}(t). \tag{5}$$

Next we note that the new coefficients α_b and β_b are related to those of the previous cycle through the relations

$$\alpha_b = \alpha_a y_{1a}(\pi) + \beta_a y_{2a}(\pi) \qquad \text{and} \qquad \beta_b = \alpha_a \frac{dy_{1a}}{dt}(\pi) + \beta_a \frac{dy_{2a}}{dt}(\pi). \tag{6}$$

The new coefficients can thus be considered as a two dimensional vector, and the transformation between the coefficients in one cycle and the next cycle is a 2 × 2 matrix. Here we consider the case in which the equation is symmetric with respect to the midpoint $t = \pi/2$. This case arises in the original orbit problem that motivated this study—the forcing function is determined by the orbit as it passes near the center of the potential and this passage is symmetric (or very nearly so). It also makes sense to consider the symmetric case, which is easier, first. Since the Wronskian of the original differential equation is unity, the number of independent matrix coefficients is reduced further, from four to two. We thus have the following result.

PROPOSITION 1. *The transformation between the coefficients α_a, β_a of one cycle and the coefficients α_b, β_b of the next may be written in the form*

$$\begin{bmatrix}\alpha_b\\ \beta_b\end{bmatrix} = \begin{bmatrix} h & (h^2-1)/g \\ g & h\end{bmatrix}\begin{bmatrix}\alpha_a\\ \beta_a\end{bmatrix} \equiv \mathbf{M}(q_a)\begin{bmatrix}\alpha_a\\ \beta_a\end{bmatrix}, \tag{7}$$

where the matrix $\mathbf{M}$ *(defined in the second equality) depends on the values* (q_a, λ_a) *and* $h = y_1(\pi)$ *and* $g = \dot{y}_1(\pi)$ *for a given cycle.*

Proof. This result can be verified by standard matrix multiplication, which yields (6) above. □

After N cycles with varying values of (q_k, λ_k), the solution retains the general form given above, where the coefficients are determined by the product of matrices according to

$$\begin{bmatrix}\alpha_N\\ \beta_N\end{bmatrix} = \mathbf{M}^{(N)}\begin{bmatrix}\alpha_0\\ \beta_0\end{bmatrix}, \qquad \text{where} \qquad \mathbf{M}^{(N)} \equiv \prod_{k=1}^{N}\mathbf{M}_k(q_k,\lambda_k). \tag{8}$$

This formulation thus transforms the original differential equation (with a random element) into a discrete map. The properties of the product matrix $\mathbf{M}^{(N)}$ determine whether the solution is unstable and the corresponding growth rate.

DEFINITION. *The* asymptotic growth rate γ_∞ *is that experienced by the system when each cycle amplifies the growing solution by the growth factor appropriate for the given value of the forcing strength for that cycle, i.e.,*

$$\gamma_\infty \equiv \lim_{N\to\infty}\frac{1}{\pi N}\log\left[\prod_{k=1}^{N}\frac{1}{2}\left\{\Delta_k + \sqrt{\Delta_k^2-4}\right\}\right], \tag{9}$$

where $\Delta_k = \Delta(q_k, \lambda_k)$ *is defined by* (3), *and where this expression is evaluated in the limit* $N \to \infty$. *In this definition, it is understood that if* $|\Delta_k| < 2$ *for a particular cycle, then the growth factor is unity for that cycle, resulting in no net contribution to the product (for that cycle).*

Notice that the factor of π appears in this definition of the growth rate because the original Hill's equation is taken to be π-periodic [MW, AS]. As we show below, the growth rates of the differential equation are determined by the growth rates resulting from matrix multiplication. In many cases, however, the growth rates for matrix multiplication are given without the factor of π [BL, FK], so there is a mismatch of convention (by a factor of π) between growth rates of Hill's equations and growth rates of matrix multiplication.

Notice that this expression for the asymptotic growth rate takes the form

$$\gamma_\infty = \lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}\gamma(q_k,\lambda_k) \to \langle\gamma\rangle, \tag{10}$$

where $\gamma(q_k, \lambda_k)$ is the growth rate for a given cycle. The asymptotic growth rate is thus given by the expectation value of the growth rate per cycle for a given probability distribution for the parameters q_k and λ_k.

We note that a given system does not necessarily experience growth at the rate γ_∞ because the solutions must remain continuous across the boundaries between subsequent cycles. This requirement implies that the solutions during every cycle will contain an admixture of both the growing solution and the decaying solution for that cycle, thereby leading to the possibility of slower growth. In some cases, however, the growth rate is larger than γ_∞; i.e., the stochastic component of the problem aids and abets the instability. One could also call γ_∞ the direct growth rate.

2.3. Generalization to aperiodic variations.

THEOREM 1. *Consider a generalization of Hill's equation so that the cycles are no longer exactly π-periodic. Instead, each cycle has period $\mu_k\pi$, where μ_k is a random variable that averages to unity. Then variations in period are equivalent to variations in (q,λ); i.e., the problem with three stochastic variables (q_k,λ_k,μ_k) reduces to a π-periodic problem with only two stochastic variables (q_k,λ_k).*

Proof. With this generalization, the equation of motion takes the form

$$\frac{d^2y}{dt^2}+\left[\lambda_k+q_k\hat{Q}(\mu_k t)\right]y=0, \tag{11}$$

where we have normalized the forcing frequency to have unit amplitude ($\hat{Q}=Q/q_k$). Since $\hat{Q}$ (and Q) are π-periodic, the jth cycle is defined over the time interval $0\le\mu_k t\le\pi$, or $0\le t\le\pi/\mu_k$. We can rescale both the time variable and the "constants" according to

$$t\to\mu_k t\,,\qquad \lambda_k\to\lambda_k/\mu_k^2=\widetilde{\lambda}_j\,,\qquad\text{and}\qquad q_k\to q_k/\mu_k^2=\widetilde{q}_j, \tag{12}$$

so the equation of motion reduces to the familiar form

$$\frac{d^2y}{dt^2}+\left[\widetilde{\lambda}_j+\widetilde{q}_j\hat{Q}(t)\right]y=0. \tag{13}$$

Thus, the effects of varying period can be incorporated into variations in the forcing strength q_k and oscillation parameter λ_k. □

3. Hill's equation in the unstable limit. In this section we consider Hill's equation in the general form (for the delta function limit see section 4) but restrict our analysis to the case of symmetric potentials so that $y_1(\pi)=h=\dot{y}_2(\pi)$. We also consider the *highly unstable limit*, where we define this limit to correspond to large $h\gg 1$. Since the 2×2 matrix of the discrete map must have its determinant equal to unity, the matrix of the map has the form given by (7), where the values of h and g depend on the form of the forcing potential.

The discrete map can be rewritten in the general form

$$\mathbf{M}=h\begin{bmatrix}1 & x\\ 1/x & 1\end{bmatrix}+\begin{bmatrix}0 & -1/g\\ 0 & 0\end{bmatrix}. \tag{14}$$

In the highly unstable limit $h\to\infty$, the matrix simplifies to the approximate form

$$\mathbf{M}\approx h\begin{bmatrix}1 & x\\ 1/x & 1\end{bmatrix}\equiv h\mathbf{C}, \tag{15}$$

where we have defined $x\equiv h/g$, and where the second equality defines the matrix $\mathbf{C}$.

In this problem we are concerned with both the long-time limit $N\to\infty$ and the "unstable" limit $h\to\infty$. In the first instance considered here we take the unstable limit first, but below we analyze precisely the difference between taking the long time limit first and then the unstable limit.

3.1. Fixed matrix of the discrete map. The simplest case occurs when the stochastic component can be separated from the matrix, i.e., when the matrix $\mathbf{C}$ does not vary from cycle to cycle. This case arises when the Hill's equation does not contain a random component; it also arises when the random component can be factored out so that x does not vary from cycle to cycle, although the leading factors h_k can vary. In either case, the matrix $\mathbf{C}$ is fixed. Repeated multiplications of the matrix $\mathbf{C}$ are then given by

$$\mathbf{C}^N = 2^{N-1}\mathbf{C}. \tag{16}$$

With this result, after N cycles the Floquet multiplier (eigenvalue) of the product matrix and the corresponding growth rate take the form

$$\Lambda = \prod_{k=1}^{N} (2h_k) \qquad \text{and} \qquad \gamma = \lim_{N\to\infty} \frac{1}{\pi N} \sum_{k=1}^{N} \log(2h_k). \tag{17}$$

Note that this result applies to the particular case of Hill's equation in the delta function limit (section 4), where the forcing strength q_k varies from cycle to cycle but the frequency parameter λ_k is constant. The growth rate in (17) is equal to the asymptotic growth rate γ_∞ (see (9)) for this case.

3.2. General results in the unstable limit. We now generalize to the case where the parameters of the differential equation vary from cycle to cycle. For a given cycle, the discrete map is specified by a matrix of the form specified by (15), where $x = x_k = h_k/g_k$, with varying values from cycle to cycle. The values of x_k depend on the parameters (q_k, λ_k) through the original differential equation. After N cycles, the product matrix $\mathbf{M}^{(N)}$ takes the form

$$\mathbf{M}^{(N)} = \prod_{k=1}^{N} h_k \, \prod_{k=1}^{N} \mathbf{C}_k, \tag{18}$$

where we have separated the two parts of the problem. One can show (by induction) that the product of N matrices $\mathbf{C}_k$ has the form

$$\mathbf{C}^{(N)} = \prod_{k=1}^{N} \mathbf{C}_k = \begin{bmatrix} \Sigma_{T(N)} & x_1 \Sigma_{T(N)} \\ \Sigma_{B(N)}/x_1 & \Sigma_{B(N)} \end{bmatrix}, \tag{19}$$

where x_1 is the value of the variable for the first cycle and where the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ are given by

$$\Sigma_{T(N)} = \sum_{j=1}^{2^{N-1}} r_j \qquad \text{and} \qquad \Sigma_{B(N)} = \sum_{j=1}^{2^{N-1}} \frac{1}{r_j}, \tag{20}$$

where the variables r_j are ratios of the form

$$r_j = \frac{x_{a_1} x_{a_2} \dots x_{a_n}}{x_{b_1} x_{b_2} \dots x_{b_n}}. \tag{21}$$

The ratios r_j arise from repeated multiplication of the matrices $\mathbf{C}_k$, and hence the indices lie in the range $1 \le a_i, b_i \le N$. The r_j always have the same number of factors in the numerator and the denominator, but the number of factors (n) varies from 0 (where $r_j = 1$) up to $N/2$. This upper limit arises because each composite ratio r_j has $2n$ values of x_j, which must all be different, and because the total number of possible values is N.

Next we define a composite variable

$$\widetilde{S} \equiv \frac{1}{2^N}\left[\Sigma_{T(N)} + \Sigma_{B(N)}\right] = \frac{1}{2^N}\sum_{j=1}^{2^{N-1}}\left(r_j + \frac{1}{r_j}\right). \tag{22}$$

With this definition, the (growing) eigenvalue Λ of the product matrix $\mathbf{M}^{(N)}$ takes the form

$$\Lambda = \widetilde{S}\prod_{k=1}^{N}(2h_k) \tag{23}$$

and the corresponding growth rate of the instability has the form

$$\gamma = \lim_{N\to\infty}\left[\frac{1}{\pi N}\sum_{k=1}^{N}\log(2h_k) + \frac{1}{N\pi}\log\widetilde{S}\right]. \tag{24}$$

The first term is the asymptotic growth rate γ_∞ defined by (9) and is thus an average of the growth rates for the individual cycles. All of the additional information regarding the stochastic nature of the differential equation is encapsulated in the second term through the variable $\widetilde{S}$. For example, if the composite variable $\widetilde{S}$ is finite in the limit $N \to \infty$, then the second term would vanish. As shown below, however, the stochastic component can provide a significant contribution to the growth rate and can provide either a stabilizing or destabilizing influence. In the limit $N \to \infty$, we can thus write the growth rate in the from

$$\gamma = \gamma_\infty + \Delta\gamma, \tag{25}$$

where we have defined the correction term $\Delta\gamma$,

$$\Delta\gamma \equiv \lim_{N\to\infty}\frac{1}{N\pi}\log\widetilde{S}. \tag{26}$$

Since the asymptotic growth rate γ_∞ is straightforward to evaluate, the remainder of this section focuses on evaluating $\Delta\gamma$ as well as finding corresponding estimates and constraints. This correction term $\Delta\gamma$ is determined by the discrete map $\mathbf{C}$, whose matrix elements are given by the ratios $x = h/g$, where h and g are determined by the solutions to Hill's equation over one cycle. One should keep in mind that the parameters in the original differential equation are (λ_k, q_k). The distribution of these parameters determines the distributions of the principal solutions (the distributions of h_k and g_k), whereas the distribution of the ratios x_k of these latter quantities determines the correction $\Delta\gamma$ to the growth rate. The problem thus separates into two parts: (1) the transformation between the distributions of the parameters (λ_k, q_k) and the resulting distribution of the ratios x_k that define the discrete map, and (2) the growth rate of the discrete map for a given distribution of x_k. The following analysis focuses on the latter issue (whereas section 4 provides an example of the former issue).

3.3. Growth rates for positive matrix elements. This subsection addresses the cases where the ratios x_k that define the discrete map $\mathbf{C}$ all have the same sign. For this case, the analysis is simplified, and a number of useful results can be obtained.

THEOREM 2. *Consider the general form of Hill's equation in the unstable limit so that $h = y_1(\pi) = \dot{y}_2(\pi) \gg 1$. For the case of positive matrix elements, $r_j > 0$, the growth rate is given by* (25), *where the correction term $\Delta\gamma$ is given by*

$$\Delta\gamma = \lim_{N\to\infty} \frac{1}{\pi N} \sum_{j=1}^{N} \log(1 + x_{j1}/x_{j2}) - \frac{\log 2}{\pi}, \tag{27}$$

where x_{j1} and x_{j2} represent two different (independent) samples of the x_j variable.[1]

Proof. Using the same induction argument that led to (19), one finds that from one cycle to the next the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ vary according to

$$\Sigma_{T(N+1)} = \Sigma_{T(N)} + \frac{x}{x_0}\Sigma_{B(N)} \tag{28}$$

and

$$\Sigma_{B(N+1)} = \Sigma_{B(N)} + \frac{x_0}{x}\Sigma_{T(N)}. \tag{29}$$

In this notation, the variable x (no subscript) represents the value of the x variable at the current cycle, whereas x_0 represents the value at the initial cycle. The growing eigenvalue of the product matrix of (19) is given by $\Lambda = \Sigma_{T(N)} + \Sigma_{B(N)}$. As a result, the eigenvalue (growth factor) varies from cycle to cycle according to

$$\Lambda^{(N+1)} = \Lambda^{(N)} + \frac{x}{x_0}\Sigma_{B(N)} + \frac{x_0}{x}\Sigma_{T(N)} = \Lambda^{(N)}\left[1 + \frac{(x/x_0)\Sigma_{B(N)} + (x_0/x)\Sigma_{T(N)}}{\Sigma_{B(N)} + \Sigma_{T(N)}}\right]. \tag{30}$$

The overall growth factor is then determined by the product

$$\Lambda^{(N)} = \prod_{j=1}^{N}\left[1 + \frac{(x/x_0)\Sigma_{B(N)} + (x_0/x)\Sigma_{T(N)}}{\Sigma_{B(N)} + \Sigma_{T(N)}}\right]. \tag{31}$$

The growth rate of matrix multiplication is determined by setting the above product equal to $\exp[N\pi\gamma]$. The growth rate $\Delta\gamma$ also includes the factor of 2 per cycle that is included in the definition of the asymptotic growth rate γ_∞. We thus find that

$$\Delta\gamma \approx \frac{1}{N\pi}\sum_{j=1}^{N}\log\left[1 + \frac{(x_{j1}/x_{j2})\Sigma_{B(N)} + (x_{j2}/x_{j1})\Sigma_{T(N)}}{\Sigma_{B(N)} + \Sigma_{T(N)}}\right] - \frac{\log 2}{\pi}. \tag{32}$$

Note that this expression provides the correction $\Delta\gamma$ to the growth rate. The full growth rate is given by $\gamma = \gamma_\infty + \Delta\gamma$ (where γ_∞ is specified by (9) and $\Delta\gamma$ is specified by (27)). In the limit of large N, the ratio of the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ approaches unity, almost surely, so that

$$\frac{\Sigma_{T(N)}}{\Sigma_{B(N)}} \to 1 \qquad \text{as} \qquad N \to \infty. \tag{33}$$

[1] Specifically, the index j labels the cycle number, and the indices $j1$ and $j2$ label two successive samples of the x variable; since the stochastic parameters of the differential equations are assumed to be independent from cycle to cycle, however, the variables x_{j1} and x_{j2} can be any independent samples.

This result follows from the definition of $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$: The terms in each of these two sums are the product of ratios x_a/x_b, and the terms r_j in the first sum $\Sigma_{T(N)}$ are the inverse of those $(1/r_j)$ in the second sum $\Sigma_{B(N)}$. Since the fundamental variables x_k that make up these ratios, and the products of these ratios, are drawn from the same distribution, the above condition (33) must hold. As a consequence, the expression for the growth rate given by (32) approaches that of (27). □

COROLLARY 2.1. *Let σ_0 be the variance of the composite variable* $\log(x_{j1}/x_{j2})$ *(see Theorem* 2*). The correction to the growth rate is positive semidefinite; specifically, $\Delta\gamma \geq 0$ and $\Delta\gamma \to 0$ in the limit $\sigma_0 \to 0$. Further, in the limit of small variance, the growth rate approaches the asymptotic form $\Delta\gamma \to \sigma_0^2/(8\pi)$.*

Proof. In the limit of small σ_0, we can write $x_j = 1 + \delta_j$, where $|\delta_j| \ll 1$. In this limit, (27) for the growth rate becomes

$$\Delta\gamma = \lim_{N\to\infty} \frac{1}{\pi N} \sum_{j=1}^{N} \log\big[2 + \delta_{j1} - \delta_{j2} + \delta_{j2}^2 - \delta_{j1}\delta_{j2} + \mathcal{O}(\delta^3)\big] - \frac{\log 2}{\pi}. \tag{34}$$

In the limit $|\delta_j| \ll 1$, we can expand the logarithm, and the above expression simplifies to the form

$$\Delta\gamma = \lim_{N\to\infty} \frac{1}{2\pi N} \sum_{j=1}^{N} \big[\delta_{j1} - \delta_{j2} + \delta_{j2}^2 - \delta_{j1}\delta_{j2} - (\delta_{j1} - \delta_{j2})^2/4 + \mathcal{O}(\delta^3)\big]. \tag{35}$$

Evaluation of the above expression shows that

$$\Delta\gamma = \frac{1}{2\pi}\left[\langle\delta_{j2}^2\rangle - \frac{1}{4}\langle(\delta_{j1} - \delta_{j2})^2\rangle + \mathcal{O}(\delta^3)\right] \to \frac{\sigma_0^2}{8\pi}. \tag{36}$$

As a result, $\Delta\gamma \geq 0$. In the limit $\sigma_0 \to 0$, all of the x_j approach unity and $\delta_j \to 0$; therefore, $\Delta\gamma \to 0$ as $\sigma_0 \to 0$. □

Although (27) is exact, the computation of the expectation value can be difficult in practice. As a result, it is useful to have simple constraints on the growth rate in terms of the variance of the probability distribution for the variables x_k. In particular, a simple bound can be derived.

THEOREM 3. *Consider the general form of Hill's equation in the unstable limit so that $h = y_1(\pi) = \dot{y}_2(\pi) \gg 1$. Take the variables $r_j > 0$. Then the growth rate is given by* (25) *and the correction term $\Delta\gamma$ obeys the constraint*

$$\Delta\gamma \leq \frac{\sigma_0^2}{4\pi}, \tag{37}$$

where σ_0^2 is the variance of the distribution of the variable $\xi = \log(x_{j1}/x_{j2})$, and where x_j are independent samplings of the ratios $x_j = h_j/g_j$.

Proof. First we define the variable $\xi_j = \log r_j$, where r_j is given by (21) above with a fixed value of n. In the limit of large n, the variable ξ_j has zero mean and will be normally distributed. If the variables x_j are independent, the variance of the composite variable ξ_j will be given by

$$\sigma_\xi^2 = n\sigma_0^2. \tag{38}$$

As shown below, in order to obtain 2^N terms in the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$, almost all of the variables r_j will fall in the large n limit; in addition, $n \to \infty$ in the limit $N \to \infty$.

As a result, we can consider the large n limit to be valid for purposes of evaluating the correction term $\Delta\gamma$. In practice, the variables will not be completely independent, so the actual variance will be smaller than that given by (38); nonetheless, this form can be used to find the desired upper limit.

Given the large n limit and a log-normal distribution of r_j, the expectation values $\langle r_j \rangle$ and $\langle 1/r_j \rangle$ are given by

$$\langle r_j \rangle = \exp\big[n\sigma_0^2/2\big] = \langle 1/r_j \rangle. \tag{39}$$

Note that the variable ξ_j is normally distributed, and we are taking the expectation value of $r_j = \exp \xi_j$; since the mean of the exponential is not necessarily equal to the exponential of the mean, the above expression contains the (perhaps counterintuitive) factor of 2. As expected, larger values of n allow for a wider possible distribution and result in larger expectation values. The maximum expectation values thus occur for the largest values of n. Since $n < N/2$, these results, in conjunction with (22), imply that $\widetilde{S}$ obeys the constraint

$$\widetilde{S} < \exp\big[N\sigma_0^2/4\big]. \tag{40}$$

The constraint claimed in (37) then follows immediately.

Combinatorics. To complete the argument, we must show that most of the variables r_j have a large number n of factors (in the limit of large N). The number of terms in the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ is large, namely, 2^{N-1}. Further, the ratios r_j must contain $2n$ different values of the variables x_k. The number $P(n|N)$ of different ways to choose the $2n$ variables for N cycles (and hence N possible values of x_k) is given by the expression

$$P(n|N) = \frac{N!}{(N-2n)!(n!)^2}. \tag{41}$$

Notice that this expression differs from the more familiar binomial coefficient because the values of r_j depend on whether or not the x_k factors are in the numerator or denominator of the ratio r_j. Next we note that if $n \ll N$, then the following chain of inequalities holds for large N:

$$P(n|N) < \frac{N^{2n}}{(n!)^2} \ll 2^{N-1}. \tag{42}$$

For large N and $n \ll N$, the central expression increases like a power of N, whereas the right-hand expression increases exponentially with N. As a result, for $n \ll N$, there are not enough different ways to choose the x_k values to make the required number of composite ratios r_j. In order to allow for enough different r_j, the number n of factors must be large (namely, large enough so that $n \ll N$ does not hold) for most of the r_j. This conclusion thus justifies our use of the large n limit in the proof of Theorem 3 (where we used a log-normal form for the composite distribution to evaluate the expectation values $\langle r_j \rangle$ and $\langle 1/r_j \rangle$). □

Estimate. Theorem 3 provides an upper bound on the contribution of the correction term $\Delta\gamma$ to the overall growth rate. This bound depends on the value of n, which determines the magnitude of the expectation value $\langle r_j \rangle$. It is useful to have an estimate of the "typical" size of n. In rough terms, the value of n must be large enough so that the number of possible combinations is large enough to account for the 2^{N-1} terms in the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$. For each n, we have $P(n|N)$ combinations.

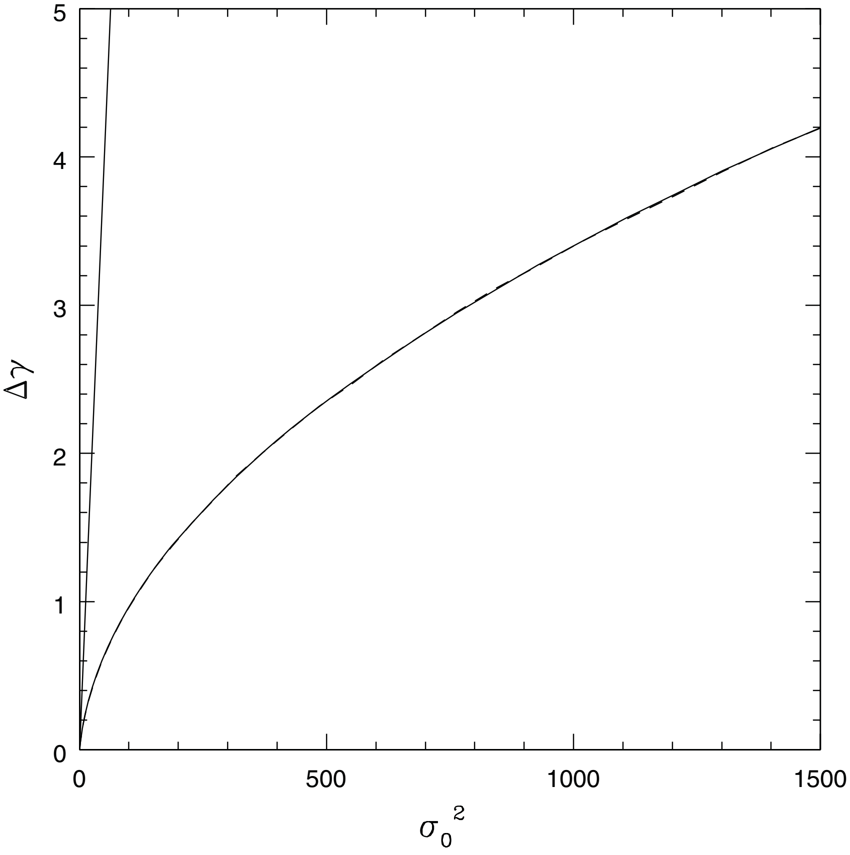

FIG. 1. *Comparison of the bound of Theorem* 3 *and the prediction of Theorem* 2 *with results from numerical experiments. All cases use matrices* $\mathbf{C}_k$ *of the form given by* (15)*, where the variables* x_k *are chosen according to distributions with variance* σ_0^2*. For each distribution, the growth rate* $\Delta\gamma$ *due to matrix multiplication is plotted versus the variance of the distribution of the composite variable* $\xi = \log(x_j/x_k)$*, where* $x_k = y_{1k}(\pi)/\dot{y}_{1k}(\pi)$ *and, similarly,* $x_j = y_{1j}(\pi)/\dot{y}_{1j}(\pi)$*. The solid curve shows the results obtained by averaging* 1000 *realizations of the numerical experiments; the overlying dashed curve shows the prediction of Theorem* 2*. The straight solid line shows the upper bound of Theorem* 3*, i.e.,* $\Delta\gamma \le \sigma_0^2/(4\pi)$*.*

As a rough approximation, $nP(n|N)$ accounts for all of the combinations of size less than n. If we set $nP(n|N) = 2^N$, we can solve for the ratio n/N required to have enough terms and find $n/N \approx 0.11354\cdots \approx 1/9$. As a result, we expect the ratio n/N to lie in the range

$$\frac{1}{9} < \frac{n}{N} < \frac{1}{2}. \tag{43}$$

If we use this range of n/N to evaluate the expectation value using (39) and estimate the growth rate, the upper end of this range provides a rigorous upper bound (Theorem 3). The lower end of the range represents only a rough guideline, however, since the variables are not fully independent. Nonetheless, it can be used to estimate the expectation values $\langle r_j \rangle$.

Notice that the upper bound is conservative. Figure 1 shows a comparison of the actual growth rate (from Theorem 2) and the bound (Theorem 3). At large variance, the actual growth rate is much less than our bound. In fact, as shown in the following section, in the limit of large variance, the growth rate $\Delta\gamma \propto \sigma_0$ (rather than $\propto \sigma_0^2$).

For this numerical experiment, we used a particular form for the x_k variables, namely, $x_k = 0.01 + (10a\xi_k)^a$, where ξ_k is a random variable in the range $0 \le \xi_k \le 1$ and a is a parameter that is chosen to attain varying values of σ_0^2. The exact form of the curve $\Delta\gamma(\sigma_0^2)$ depends on the distribution of the x_k. However, all of the distributions studied result in the general form shown in Figure 1, and all of the cases show the same agreement between numerical experiments and the predictions of Theorem 2.

3.4. Error bounds and estimates. The analysis presented thus far is valid in the highly unstable limit, as defined at the beginning of this section. In other words, we have found an exact solution to the reduced problem, as encapsulated in (15). In this problem we are taking two limits—the long-time limit $N \to \infty$ and the "unstable" limit $h \to \infty$. In the reduced problem, as analyzed above, we take the limit $h \to \infty$ first and then consider the long-time limit $N \to \infty$. In this subsection, we consider the accuracy of this approach by finding bounds (and estimates) for the errors in the growth rates incurred from working in the highly unstable limit. In other words, we find bounds on the difference between the results for the full problem (with large but finite h_k) and the reduced problem.

To assess the error budget, we write the general matrix (for the full problem) in the form

$$\mathbf{M} = h\mathbf{B}, \qquad \text{where} \qquad \mathbf{B} \equiv \begin{bmatrix} 1 & x\phi \\ 1/x & 1 \end{bmatrix}. \tag{44}$$

This form is the same as the matrix of the reduced problem (in the unstable limit) except for the correction factor ϕ in the (1,2) matrix element, where $\phi \equiv (1 - 1/h^2)$.

Let $(\Delta\gamma)_B$ denote the growth rate for the matrix $\mathbf{B}$ for the full problem defined in (44). Similarly, let $(\Delta\gamma)_C$ denote the growth rate found previously for the reduced problem using the matrix $\mathbf{C}$ defined in (15). Through repeated matrix multiplications, the product of matrices $\mathbf{B}_k$ will be almost the same as for the product of matrices $\mathbf{C}_k$, where the difference is due to the continued accumulation of factors ϕ_k. Note that the index k, as introduced here, denotes the cycle number, and that all of these quantities vary from cycle to cycle.

Proposition 2. *The error $\varepsilon_{BC} = (\Delta\gamma)_C - (\Delta\gamma)_B$ introduced by using the reduced form of the problem (the matrices $\mathbf{C}_k$) instead of the full problem (the matrices $\mathbf{B}_k$) is bounded by*

$$0 < \varepsilon_{BC} < -\frac{1}{\pi}\langle \log \phi_k \rangle. \tag{45}$$

Proof. Since $\phi_k < 1$, by definition, we see immediately that the growth rate for the full problem is bounded from above by that of the reduced problem, i.e.,

$$(\Delta\gamma)_B < (\Delta\gamma)_C. \tag{46}$$

Next we construct a new matrix of the form

$$\mathbf{A} \equiv \phi \begin{bmatrix} 1 & x \\ 1/x & 1 \end{bmatrix} = \phi\mathbf{C}. \tag{47}$$

The products of the matrices $\mathbf{A}_k$ will be almost the same as those for the matrices $\mathbf{B}_k$, where the difference is again due to the inclusion of additional factors of ϕ_k. Since the $\phi_k < 1$, we find that the growth rate for this benchmark problem is less than (or equal to) that of the full problem, i.e., $(\Delta\gamma)_A < (\Delta\gamma)_B$. Further, the growth rate $(\Delta\gamma)_A$ for this new matrix can be found explicitly and is given by

$$(48)\qquad (\Delta\gamma)_A = (\Delta\gamma)_C + \lim_{N\to\infty} \frac{1}{\pi N} \log \left[\prod_{k=1}^{N} \phi_k\right] = (\Delta\gamma)_C + \lim_{N\to\infty} \frac{1}{\pi N} \sum_{k=1}^{N} \log \phi_k .$$

Combining (46) and (48) shows that the growth rate for the full problem $(\Delta\gamma)_B$ is bounded on both sides and obeys the constraint

$$(49)\qquad (\Delta\gamma)_C + \frac{1}{\pi}\langle \log \phi_k \rangle < (\Delta\gamma)_B < (\Delta\gamma)_C .$$

Notice that the expectation value $\langle \log \phi_k \rangle < 0$ since $\phi_k < 1$. The error ε_{BC} introduced by using the reduced form of the problem (the matrices $\mathbf{C}_k$) instead of the full problem (the matrices $\mathbf{B}_k$) is thus bounded by

$$(50)\qquad 0 < \varepsilon_{BC} < -\frac{1}{\pi}\langle \log \phi_k \rangle .$$

This bound can be made tighter by a factor of 2. Note that the product of two matrices of the full problem has the form

$$(51)\qquad \mathbf{B}_2\mathbf{B}_1 = \begin{bmatrix} 1 + (x_2/x_1)\phi_2 & x_1\phi_1 + x_2\phi_2 \\ 1/x_1 + 1/x_2 & 1 + (x_1/x_2)\phi_1 \end{bmatrix} .$$

Thus, the product of two matrices contains only linear factors of ϕ_k. As a result, we can define a new reference matrix $\widetilde{\mathbf{A}} = \phi^{1/2}\mathbf{C}$ that accumulates factors of ϕ_k only half as quickly as the original matrix $\mathbf{A}$ in the above argument, so that

$$(52)\qquad \widetilde{\mathbf{A}}_2\widetilde{\mathbf{A}}_1 = \phi_1^{1/2}\phi_2^{1/2} \begin{bmatrix} 1 + x_2/x_1 & x_1 + x_2 \\ 1/x_1 + 1/x_2 & 1 + x_1/x_2 \end{bmatrix} = \phi_1^{1/2}\phi_2^{1/2}\mathbf{C}_2\mathbf{C}_1 .$$

The new reference matrix still grows more slowly than the matrix $\mathbf{B}$ of the full problem, but the product of N such matrices accumulates only N extra factors of $\phi_k^{1/2}$. Using this reference matrix in the above argument results in the tighter bound

$$(53)\qquad 0 < \varepsilon_{BC} < -\frac{1}{2\pi}\langle \log \phi_k \rangle .$$

In the limit where all of the $h_k \gg 1$, $\log \phi_k \approx -1/h_k^2$, and the above bound approaches the approximate form

$$(54)\qquad 0 < \varepsilon_{BC} < \frac{1}{2\pi}\langle h_k^{-2} \rangle .$$

This expression shows that the errors are well controlled. For large but finite h_k, the departure of the growth rates from those obtained in the highly unstable limit (Theorem 2) are $\mathcal{O}(h_k^{-2})$. □

Given the above considerations, we can write the growth rate $(\Delta\gamma)_B$ for the full problem in the form

$$(55)\qquad (\Delta\gamma)_B = (\Delta\gamma)_C - \frac{K_\varepsilon}{\pi}\langle h_k^{-2} \rangle ,$$

where $(\Delta\gamma)_C$ is the growth rate for the reduced problem and where K_ε is a constant of order unity. In the limit of large h_k (specifically for $\log\phi_k \approx 1/h_k^2$), the constant is bounded and lies in the range $0 < K_\varepsilon < 1/2$. Our numerical exploration of parameter space suggests that $K_\varepsilon \approx 1/4$ provides a good estimate for the correction term. In any case, however, the correction term depends on h_k through the quantity $\langle h_k^{-2}\rangle$ and decreases with the size of this expectation value.

3.5. Matrix elements with varying signs. We now consider the case in which the signs of the variables r_j can be either positive or negative. Suppose that the system has equal probability of attaining positive and negative factors. In the limit $N \to \infty$, one expects the sums $\Sigma_{T(N)}, \Sigma_{B(N)} \to 0$, which would seem to imply no growth. However, two effects counteract this tendency. First, the other factor that arises in the repeated matrix multiplication diverges in the same limit, i.e.,

$$\prod_k^N (2h_k) \to \infty \qquad \text{as} \qquad N \to \infty. \tag{56}$$

Second, the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ can random walk away from zero with an increasing number N of cycles, where the effective step length is determined by the variance σ_0 defined previously. If the random walk is fast enough, the system can be unstable even without considering the diverging product of (56). In order to determine the stability (or instability) of the Hill's equation in this case, we must thus determine how the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ behave with increasing N.

Theorem 4. *Consider the case of Hill's equation in the unstable limit with both positive and negative signs for the matrix elements. Let positive signs occur with probability p and negative signs occur with probability $1-p$. Then the general form of the growth rate is given by*

$$\Delta\gamma = \lim_{N\to\infty} \frac{1}{\pi N} \left\{ \left[p^2 + (1-p)^2\right] \sum_{j=1}^N \log\Big(1 + \Big|\frac{x_{j1}}{x_{j2}}\Big|\Big) + 2p(1-p) \sum_{k=1}^N \log\Big|1 - \Big|\frac{x_{k1}}{x_{k2}}\Big|\Big| \right\} - \frac{\log 2}{\pi}. \tag{57}$$

Proof. The same arguments leading to (32) in the proof of Theorem 2 can be used, where the signs of the ratios x_{j1}/x_{j2} must be taken into account. If p is the probability of the x_j variables being positive, the probability of the ratio of two variables being positive will be given by $p^2 + (1-p)^2$, i.e., the probability of getting either two positive signs or two negative signs. The probability of the ratio being negative is then $2p(1-p)$. With this consideration of signs, the intermediate form of (32) is modified to take the form

$$\Delta\gamma + \frac{\log 2}{\pi} \approx \frac{1}{N\pi} \sum_{j=1}^{N_P} \log\left[1 + \frac{|x_{j1}/x_{j2}|\Sigma_{B(N)} + |x_{j2}/x_{j1}|\Sigma_{T(N)}}{\Sigma_{B(N)} + \Sigma_{T(N)}}\right] + \frac{1}{N\pi} \sum_{j=1}^{N_Q} \log\left[1 - \frac{|x_{j1}/x_{j2}|\Sigma_{B(N)} + |x_{j2}/x_{j1}|\Sigma_{T(N)}}{\Sigma_{B(N)} + \Sigma_{T(N)}}\right], \tag{58}$$

where N_P is the number of terms where the ratios have positive signs and N_Q is the number of terms where the ratios have negative signs. In the limit $N \to \infty$, we argue (as before) that the sums $\Sigma_{B(N)}$ and $\Sigma_{T(N)}$ approach the same value. Notice also that the two sums can be either positive or negative, but they will both have the same sign (by construction). As a result, we can divide the sums out of the expression as before. In the limit $N \to \infty$, the fraction $N_P/N \to p^2 + (1-p)^2$ and the fraction $N_Q/N \to 2p(1-p)$. After some rearrangement, we obtain the form of (57). □

COROLLARY 4.1. *Let $P(\xi)$ denote the probability distribution of the composite variable $\xi = x_k/x_j$, and assume that the integral $\int d\xi (dP/d\xi) \log|\xi|$ exists. Then for Hill's equation in the unstable limit, and for the case of the variables x_k having mixed signs, in the limit of small variance the correction to the growth rate $\Delta\gamma$ approaches the following limiting form:*

$$\lim_{\sigma_0 \to 0} \Delta\gamma = \frac{2p(1-p)}{\pi} \left[\log \sigma_0 + C_0 - \log 2 \right], \tag{59}$$

where C_0 is a constant that depends on the probability distribution of the variables x_k.

Proof. In the limit of small σ_0, the variables x_k can be written in the form $x_k = 1 + \delta_k$, where $|\delta_k| \ll 1$. To leading order, the expression of (57) for the growth rate becomes

$$\begin{aligned} \Delta\gamma + \frac{\log 2}{\pi} = \lim_{N \to \infty} \frac{1}{\pi N} \Bigg\{ & [p^2 + (p-1)^2] \sum_{j=1}^{N} \log(2 + \delta_{j1} - \delta_{j2}) \\ & + 2p(1-p) \sum_{k=1}^{N} \log \left| \delta_{k1} - \delta_{k2} \right| \Bigg\}. \end{aligned} \tag{60}$$

In the limit of small variance $\sigma_0 \to 0$, the variables $\delta_k \to 0$, and the above expression reduces to the form

$$\Delta\gamma = \frac{2p(1-p)}{\pi} \left[\langle \log|\delta_{k1} - \delta_{k2}| \rangle - \log 2 \right]. \tag{61}$$

We thus need to evaluate the expectation value given by

$$\langle \log|\delta_k - \delta_j| \rangle = \int d\xi \log|\xi| \frac{dP}{d\xi}, \tag{62}$$

where we have defined the composite variable $\xi = \delta_k - \delta_j$. Notice that in the limit $|\delta| \ll 1$, the variance of ξ is σ_0^2. Next we define a dimensionless variable $z \equiv \xi/\sigma_0$ so that the integral becomes

$$I = \int dz \frac{dP}{dz} \log(\sigma_0 z) = \log \sigma_0 \int dz \frac{dP}{dz} + \int dz \frac{dP}{dz} \log z = \log \sigma_0 + \int dz \frac{dP}{dz} \log z. \tag{63}$$

As long as the differential probability distribution dP/dz allows the integral in the final expression to converge, then $I = \log \sigma_0 + C_0$, where C_0 is some fixed number that depends only on the shape of the probability distribution. This convergence requirement is given by the statement of the corollary, so that Corollary 4.1 holds. Notice also that in the limit of small σ_0, the $\log \sigma_0$ term dominates for any fixed C_0 so that $\Delta\gamma \sim 2p(1-p)(\log \sigma_0)/\pi$. □

Figure 2 shows the growth rates as a function of the variance σ_0 for the case of mixed signs. For the case of positive signs only, $p = 1$, the correction $\Delta\gamma$ to the growth rate goes to zero as $\sigma_0 \to 0$. For the case of mixed signs, the correction to the growth rate has the form $\Delta\gamma \propto \log \sigma_0$ as implied by Corollary 4.1.

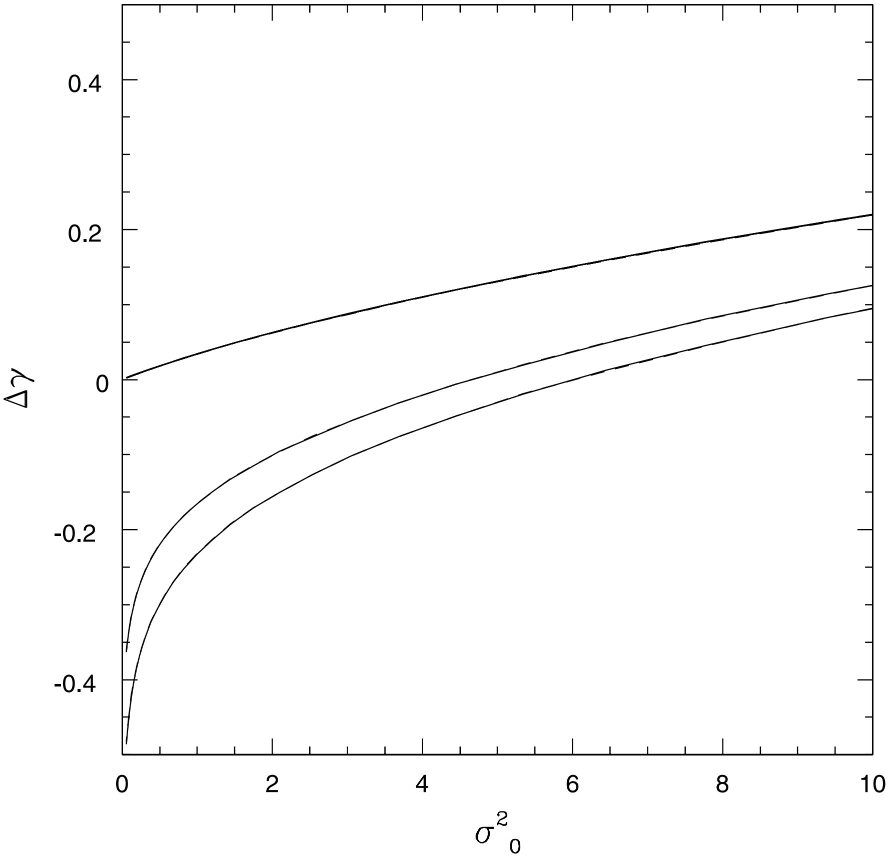

FIG. 2. *Correction $\Delta\gamma$ to the growth rate for the case in which the signs of the random variables x_k are both positive and negative. The three curves show the results for a* 50/50 *distribution (bottom),* 75/25 *(center), and the case of all positive signs (top). For all three cases, the solid curves show the results of numerical matrix multiplication, where* 1000 *realizations of each product are averaged. The overlying dashed curves, which are virtually indistinguishable, show the exact results from Theorem* 4.

Sometimes it is useful to explicitly denote when the growth rates under consideration are the result of purely positive signs or mixed signs for the variables x_k. Here, we use the notation $\Delta\gamma_p$ to specify the growth rate when all the signs are positive. Similarly, $\Delta\gamma_q$ denotes growth rates for the case of mixed signs.

COROLLARY 4.2. *In the limit of large variance, $\sigma_0 \to \infty$, the growth rates for the case of positive signs only and for the case of mixed signs converge, i.e.,*

$$\lim_{\sigma_0\to\infty} \Delta\gamma_q = \Delta\gamma_p, \tag{64}$$

where $\Delta\gamma_p$ denotes the case of all positive signs and $\Delta\gamma_q$ denotes the case of mixed signs.

Proof. The difference in the growth rates for two cases is given by

$$\Delta\gamma_p - \Delta\gamma_q = \frac{2p(1-p)}{\pi} \lim_{N\to\infty} \frac{1}{N} \sum_{j=1}^{N} \Big[\log(1 + |x_{j1}/x_{j2}|) - \log \Big| 1 - |x_{j1}/x_{j2}| \Big| \Big], \tag{65}$$

where p is the probability for the sign of x_k being positive. In the limit of large variance $\sigma_0^2 \to \infty$, the ratios $|x_j/x_k|$ are almost always far from unity. Only the cases with $|x_j/x_k| \gg 1$ have a significant contribution to the sums. For those cases, however, both of the logarithms in the sums reduce to the same form, $\log|x_j/x_k|$, and hence (65) becomes

$$\lim_{\sigma_0\to\infty} \Delta\gamma_p - \Delta\gamma_q = \frac{2p(1-p)}{\pi}\left[\langle\log|x_j/x_k|\rangle - \langle\log|x_j/x_k|\rangle\right] \to 0. \tag{66}$$

As a result, (64) is valid. □

COROLLARY 4.3. *In the limit of large variance $\sigma_0 \to \infty$, the growth rate $\Delta\gamma$ approaches the form given by*

$$\lim_{\sigma_0\to\infty} \Delta\gamma = \frac{\sigma_0}{\pi} C_\infty, \tag{67}$$

where C_∞ is a constant that depends on the form of the probability distribution for the variables x_k. In general, $C_\infty \le 1/2$.

Proof. Let the composite variable $\xi = \log(x_k/x_j)$ have a probability distribution $dP/d\xi$. Since the growth rate for the case of mixed signs converges to that for all positive signs in the limit of interest (from Corollary 4.2), we need only to consider the latter case (from Theorem 2). The growth rate is then given by the expectation value

$$\Delta\gamma = \frac{1}{\pi}\int_{-\infty}^{\infty} d\xi \frac{dP}{d\xi}\log(1+\mathrm{e}^{\xi}). \tag{68}$$

The integral can be separated into the domains $\xi < 0$ and $\xi > 0$. For the positive integral, we expand the integrand into two terms; for the negative domain, we change the variables of integration so that $\xi \to -\xi$. We thus obtain the three terms

$$\Delta\gamma = \frac{1}{\pi}\int_0^\infty d\xi\frac{dP}{d\xi}\xi + \frac{1}{\pi}\int_0^\infty d\xi\frac{dP}{d\xi}\log(1+\mathrm{e}^{-\xi}) + \frac{1}{\pi}\int_0^\infty d\xi\frac{d\widetilde{P}}{d\xi}\log(1+\mathrm{e}^{-\xi}). \tag{69}$$

In the third integral, the probability distribution $(d\widetilde{P}/d\xi)(\xi) = (dP/d\xi)(-\xi)$; the second and third terms will thus be the same since the distribution is symmetric (by construction, the composite variable ξ is the difference between two variables $\log x_k$ drawn from the same distribution). The sum of the second two integrals is bounded from above by $\log 2$ and can be neglected in the limit of interest. In the first integral, we change variables according to $z = \xi/\sigma$, so that

$$\Delta\gamma \to \frac{\sigma_0}{\pi}\langle z\rangle_{(\xi\ge0)}, \qquad \text{where} \qquad \langle z\rangle_{(\xi\ge0)} \equiv \int_0^\infty dz\frac{dP}{dz}z. \tag{70}$$

Since $\langle 1\rangle = 1$ and $\langle z^2\rangle = 1$, by definition, we expect the quantity $\langle z\rangle_{(\xi\ge0)} = C_\infty$ to be of order unity. Further, one can show that C_∞ as defined here is bounded from above by $1/2$. As a result, in this limit, we obtain a bound of the form $\pi(\Delta\gamma) \le \sigma_0/2 + \log 2$. We note that the constant C_∞ cannot be bounded from below (in the absence of further constraints placed on the probability distribution $dP/d\xi$). □

COROLLARY 4.4. *In the limit of large variance $\sigma_0^2 \gg 1$, the difference $\Delta(\Delta\gamma)$ between the growth rate for strictly positive signs and that for mixed signs takes the form*

$$\lim_{\sigma_0\to\infty} \Delta(\Delta\gamma) = \frac{8p(1-p)}{\pi\sigma_0} C_\Delta, \tag{71}$$

where C_Δ is a constant that depends on the form of probability distribution, and where p is the probability of positive matrix elements for the case of mixed signs.

Proof. Using the results from Theorems 2 and 4 to specify the growth rates for the cases of positive signs and mixed signs, respectively, the difference can be written in the form

$$\Delta(\Delta\gamma) = \frac{2p(1-p)}{\pi}\int_{-\infty}^{\infty} d\xi \, \frac{dP}{d\xi}\left[\log(1+\mathrm{e}^{\xi}) - \log\left|1-\mathrm{e}^{\xi}\right|\right]. \tag{72}$$

Next we separate the integrals into positive and negative domains and change the integration variable for the negative domain ($\xi \to -\xi$). The integral (I) then becomes

$$I = \int_0^{\infty} d\xi \frac{dP}{d\xi}\log\left(\frac{1+\mathrm{e}^{-\xi}}{1-\mathrm{e}^{-\xi}}\right) + \int_0^{\infty} d\xi \frac{d\widetilde{P}}{d\xi}\left(\frac{1+\mathrm{e}^{-\xi}}{1-\mathrm{e}^{-\xi}}\right), \tag{73}$$

where $\widetilde{P}(\xi) = P(-\xi)$. Since we are working in the large σ_0 limit, the variable ξ will be large over most of the domain where the integrals have support, so we can expand, using $\mathrm{e}^{-\xi}$ as a small parameter. In this case, the integral I becomes

$$I = 2\int_{-\infty}^{\infty} d\xi \, \frac{dP}{d\xi}\mathrm{e}^{-|\xi|} \; = \; 2\int_{-\infty}^{\infty} dz \frac{dP}{dz}\mathrm{e}^{-\sigma_0|z|}, \tag{74}$$

where we have made the substitution $z = \xi/\sigma$. For large σ_0, the decaying exponential dominates the behavior of the integrand. In the limit $\sigma \to \infty$, the exponential term decays to zero before the probability dP/dz changes so that $dP/dz \to C_\Delta$, where C_Δ is a constant. The integral thus becomes $I = 4C_\Delta/\sigma_0$, and the difference between the growth rates becomes

$$\Delta(\Delta\gamma) = \frac{8p(1-p)}{\pi\sigma_0}C_\Delta, \tag{75}$$

as claimed by Corollary 4.4. □

Figure 3 illustrates the behavior implied by the last three corollaries. In the limit of large variance, the growth rates for mixed signs and positive signs converge only (Corollary 4.2). Further, growth rates for both cases approach the form $\Delta\gamma \propto \sigma_0$ (as in Corollary 4.3). Finally, the difference between the growth rates for the two cases has the characteristic form $\Delta(\Delta\gamma) \propto 1/\sigma_0$ (from Corollary 4.4).

Corollary 4.5. *For the case of mixed signs, the crossover point between growing solutions and decaying solutions is given by the condition*

$$[p^2 + (1-p)^2]\langle\log\left|1 + |x_j/x_k|\right|\rangle + 2p(1-p)\langle\log\left|1 - |x_j/x_k|\right|\rangle \; = \log 2. \tag{76}$$

Proof. This result follows from Theorem 4 by inspection. □

Estimate for the crossover condition. Equation (76) is difficult to evaluate in practice. In order to obtain a rough estimate of the threshold for instability, we can consider the r_j to be independent variables and use elementary methods to estimate the conditions necessary for systems with mixed signs to be unstable. We first note that the sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ add up the composite variables r_j, which are made up of the variables x_j (which in turn are set by the form of the original differential equation). If the signs of the variables x_j are symmetrically distributed, then the signs of the composite variables r_j are also symmetrically distributed. We can thus focus on the variables r_j.

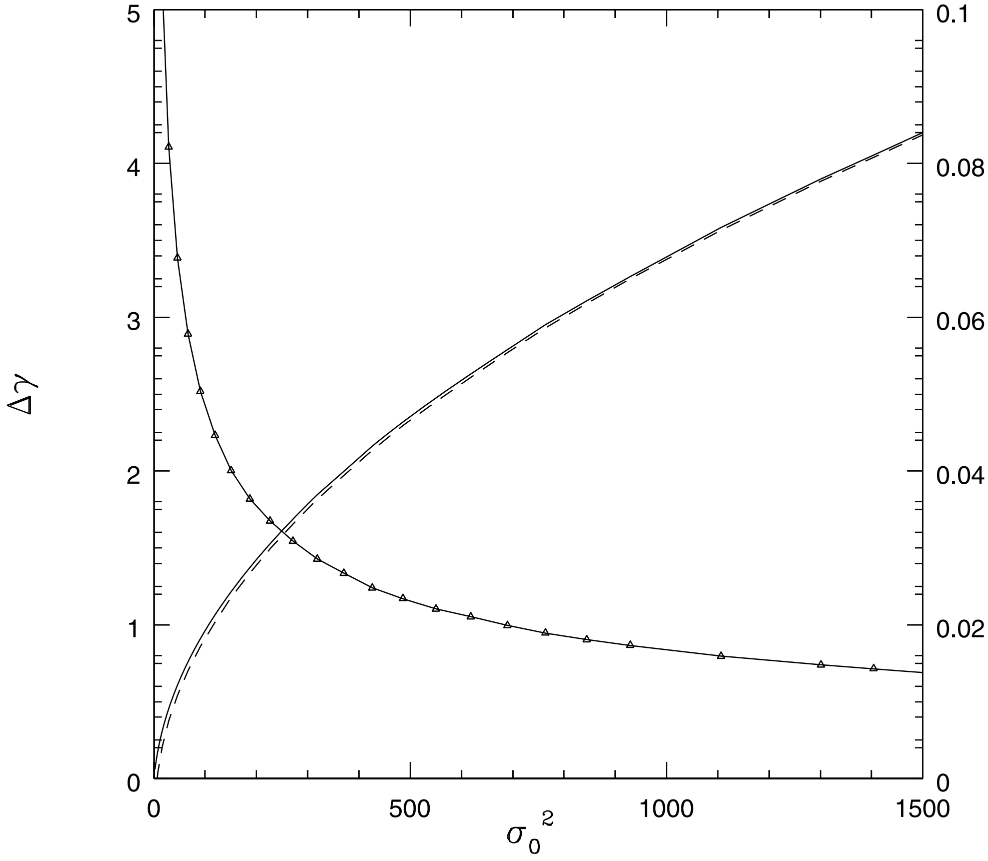

FIG. 3. *Convergence of growth rates in the limit of large variance. The increasing solid curve shows the growth rate as a function of variance for the case of all positive signs. The dashed curve shows the growth rate for the cased of mixed signs with a* 50/50 *sign distribution, i.e.,* $p = 1/2$. *The decreasing curve marked by triangles shows the difference between the two curves (where the axis on the right applies).*

Since the signs can be either positive or negative, the probability of a net excess of positive (or negative) terms is governed by the binomial distribution (which has a Gaussian form in the limit of large N). The probability P of having a net excess of m signs is given by the distribution

$$P(m) = (\pi N_S/2)^{-1/2} \exp\big[-m^2/2N_S\big], \tag{77}$$

where N_S is the number of steps in the random walk. The sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ have $N_S = 2^N$ steps, where N is the number of cycles of the Hill's equation.

If the net excess of signs of one type is m, the sums are reduced (from those obtained with purely positive variables) so that

$$\widetilde{S} = \widetilde{S}_0 \frac{m}{N_S}, \tag{78}$$

where $\widetilde{S}_0$ is the value of the composite sum obtained when the variables x_j have only one sign.

The probability of a growing solution is given by

$$P_G = \int_{m_*}^{\infty} P(m) dm, \tag{79}$$

where m_* is the minimum number of steps needed for instability. We can write m_* in the form

$$m_* = N_S \mathrm{e}^{-N\pi\Delta\gamma_0} = \exp\bigl[N(\log(2) - \pi\Delta\gamma_0)\bigr], \tag{80}$$

where $\Delta\gamma_0$ is the correction to the growth rate for the case of positive signs only.

The integral can be written in terms of the variable $\xi = m/(2N_S)^{1/2}$ so that

$$P_G = \frac{2}{\sqrt{\pi}} \int_{z_*}^{\infty} \mathrm{e}^{-z^2} dz, \tag{81}$$

where

$$z_* = \exp\left[N\left(\frac{1}{2}\log 2 - \pi\Delta\gamma_0\right)\right]. \tag{82}$$

Thus, the crossover for growth occurs under the condition

$$\Delta\gamma_0 \approx \log 2/(2\pi)\ . \tag{83}$$

Keep in mind that this result was derived under the assumption that the variables in the random walk are completely independent. We can derive the above approximate result from a simpler argument: The sums $\Sigma_{T(N)}$ and $\Sigma_{B(N)}$ random walk away from zero according to $\ell\sqrt{N_S} = \langle r_j^2\rangle^{1/2} 2^{N/2} = \exp[n\sigma_0^2 + (N/2)\log 2]$. As a result, $\widetilde{S} \approx \exp[n\sigma_0^2 - (N/2)\log 2]$ and hence $\Delta\gamma \approx (n/N)(\sigma_0^2/\pi) - (\log 2)/2\pi$.

3.6. Specific results for a normal distribution. In this section we consider the particular case where the composite variable $\xi = \log(x_k/x_j)$ has a normal distribution. Specifically, we let the differential probability distribution take the form

$$\frac{dP}{d\xi} = \frac{1}{\sqrt{2\pi}\sigma_0} \mathrm{e}^{-\xi^2/2\sigma_0^2}, \tag{84}$$

so that σ_0^2 is the variance of the distribution. In order to determine the growth rates, we must evaluate the integrals

$$J_{\pm} = \frac{1}{\sqrt{2\pi}\sigma_0} \int_{-\infty}^{\infty} d\xi\, \mathrm{e}^{-\xi^2/2\sigma_0^2} \log\left|1 \pm \mathrm{e}^{\xi}\right|. \tag{85}$$

In the limit $\sigma_0 \to 0$, the correction part of the growth rate ($\Delta\gamma$) can be evaluated and has the form

$$\lim_{\sigma_0 \to 0} \Delta\gamma = \frac{1}{\pi}\left\{\left[p^2 + (1-p)^2\right]\frac{\sigma_0^2}{8} + 2p(1-p)\left[\log\sigma_0 - \frac{\gamma_{\mathrm{em}}}{2}\right] - 3p(1-p)\log 2\right\}, \tag{86}$$

where $\gamma_{\mathrm{em}} = 0.577215665\ldots$ is the Euler–Mascheroni constant. Note that for the case of positive signs only ($p = 1$), this expression reduces to the form $\Delta\gamma = \sigma_0^2/(8\pi)$ as in Corollary 2.1. For the case of mixed signs, this expression reduces to the form $\Delta\gamma \propto \log\sigma_0$ from Corollary 4.1.

We can also evaluate the growth rate in the limit of large σ_0, and find the asymptotic form

$$\lim_{\sigma_0 \to \infty} \Delta\gamma = \frac{\sigma_0}{\sqrt{2}\pi^{3/2}}. \tag{87}$$

As a result, the constant C_∞ from Corollary 4.3 is given by $C_\infty = 1/\sqrt{2\pi}$. Note that in this limit, the growth rate is independent of the probabilities p and $(1-p)$ for the variables x_k to have positive and negative signs, consistent with Corollary 4.2. In this limit, we can also evaluate the difference between the cases of positive signs and mixed signs, i.e.,

$$\Delta\gamma_p - \Delta\gamma_q = \frac{8p(1-p)}{\sqrt{2}\pi^{3/2}\sigma_0}. \tag{88}$$

Thus, the constant C_Δ from Corollary 4.4 is given by $C_\Delta = 1/\sqrt{2\pi}$ for the case of a normal distribution. Note that although $C_\Delta = C_\infty$ for this particular example, these constants will not be the same in general.

Finally, for the case of purely positive signs, we can connect the limiting forms for small variance and large variance to construct a rough approximation for the whole range of σ_0, i.e.,

$$\Delta\gamma \approx \frac{\sigma_0^2/\pi}{8 + \sqrt{2\pi}\sigma_0}. \tag{89}$$

This simple expression, which is exact in the limits $\sigma_0 \to 0$ and $\sigma_0 \to \infty$, has a maximum error of about 18% over the entire range of σ_0.

3.7. Matrix decomposition for small variance. For completeness, and as a consistency check, we can study the growth rates by breaking the transformation matrix into separate parts. In this section we consider the case of small variance (see Appendix B for an alternate, more general, separation). In the limit of small variance, $\sigma_0^2 \ll 1$, the variables x_k have only small departures from unity and can be written in the form

$$x_k = 1 + \delta_k, \tag{90}$$

where $|\delta_k| \ll 1$. The matrices of the discrete map can then be decomposed into two parts so that

$$\mathbf{C}_k = \mathbf{A}_k + s_k\delta_k\mathbf{B}_k, \tag{91}$$

where $s_k = \pm 1$ is the sign of the kth term, and where

$$\mathbf{A}_k = \begin{bmatrix} 1 & s_k \\ s_k & 1 \end{bmatrix} \qquad \text{and} \qquad \mathbf{B}_k = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \tag{92}$$

The matrices $\mathbf{A}_k$ and $\mathbf{B}_k$ have simple multiplicative properties. In particular,

$$\mathbf{A}_j\mathbf{A}_k = 2\mathbf{A}_j \quad \text{if } s_j = s_k\,, \qquad \text{but} \qquad \mathbf{A}_j\mathbf{A}_k = 0 \quad \text{if } s_j \neq s_k, \tag{93}$$

and

$$\mathbf{B}_k^2 = -\mathbf{I}\,, \qquad \mathbf{B}_k^3 = -\mathbf{B}_k\,, \qquad \text{and} \qquad \mathbf{B}_k^4 = \mathbf{I}. \tag{94}$$

The product matrix $\prod \mathbf{C}_k$ will contain long strings of matrices $\mathbf{A}_k$ and $\mathbf{B}_k$ multiplied by each other. If any two matrices $\mathbf{A}_k$ have opposite signs in such a multiplication string, then the product of the two matrices will be zero and the entire string will vanish. As a result, after a large number N of cycles, the only matrices that are guaranteed to survive in the product are those with only $\mathbf{B}_k$ factors and those with only one $\mathbf{A}_k$ factor. Although it is possible for strings with larger numbers of $\mathbf{A}_k$ to survive, it becomes increasingly unlikely (exponentially) as the number of factors increases. To a good approximation, the eigenvalue of the resulting product matrix will be given by the product

$$\Lambda^{(N)} \approx \prod_{k=1}^{N} \delta_k . \tag{95}$$

We could correct for the possibility of longer surviving strings of $\mathbf{A}_k$ by multiplying by a factor of order unity; however, such a factor would have a vanishing contribution to the growth rate. The corresponding growth rate thus takes the form

$$\Delta\gamma = \lim_{N\to\infty} \frac{2p(1-p)}{N\pi} \sum_{k=1}^{N} \log|\delta_k| , \tag{96}$$

where the factor $2p(1-p)$ arises because the matrices with all positive signs lead to a zero growth rate in the limit $\sigma_0 \to 0$, so only the fraction of the cases with mixed signs contribute. Next we note that the sum converges to an expectation value

$$\langle|\delta_k|\rangle = \int d\delta \frac{dP}{d\delta} \log|\delta| . \tag{97}$$

Next we make the substitution $z = \delta/\sigma_0$ and rewrite the integral in the form

$$\langle|\delta_k|\rangle = \sigma_0 \int dz \frac{dP}{dz} + \int dz \frac{dP}{dz} \log z . \tag{98}$$

In the limit of interest, $\sigma_0 \to 0$, the first term dominates and the growth rate (to leading order) approaches the form

$$\Delta\gamma = \frac{2p(1-p)}{\pi} \log\sigma_0 . \tag{99}$$

This form agrees with the leading order expression found earlier in Corollary 4.1 (see also Figure 2, which shows the growth rate as a function of the variance).

4. Hill's equation in the delta function limit. In many physical applications, including the astrophysical orbit problem that motivated this analysis, we can consider the forcing potential to be sufficiently sharp so that $\hat{Q}(t)$ can be considered as a Dirac delta function. For this limit, we specify the main equation considered in this section.

Definition. Hill's equation in the delta function limit *is defined to have the form*

$$\frac{d^2y}{dt^2} + [\lambda + q\delta([t] - \pi/2)]y = 0 , \tag{100}$$

where q measures the strength of the forcing potential and where $\delta(t)$ is the Dirac delta function. In this form, the time variable is scaled so that the period of one cycle is

π. The argument of the delta function is written in terms of $[t]$, which corresponds to the time variable mod-π, so that the forcing potential is π-periodic.

This form of Hill's equation allows for analytic solutions, as outlined below, which can be used to further elucidate the instability for random Hill's equations. In particular, in this case, we can solve for the transformation between the variables (λ_k, q_k) that appear in Hill's equation and the derived composite variables x_k that determine the growth rates.

4.1. Principal solutions. To start the analysis, we first construct the principal solutions to (100) for a particular cycle with given values of forcing strength q and oscillation parameter λ. The equation has two linearly independent solutions $y_1(t)$ and $y_2(t)$, which are defined through their initial conditions

$$y_1(0) = 1, \quad \frac{dy_1}{dt}(0) = 0, \qquad \text{and} \qquad y_2(0) = 0, \quad \frac{dy_2}{dt}(0) = 1. \tag{101}$$

The first solution y_1 has the generic form

$$y_1(t) = \cos\sqrt{\lambda}t \qquad \text{for} \quad 0 \le t < \pi/2, \tag{102}$$

and

$$y_1(t) = A\cos\sqrt{\lambda}t + B\sin\sqrt{\lambda}t \qquad \text{for} \quad \pi/2 < t \le \pi, \tag{103}$$

where A and B are constants that are determined by matching the solutions across the delta function at $t = \pi/2$. We define $\theta \equiv \sqrt{\lambda}\pi/2$ and find

$$A = 1 + (q/\sqrt{\lambda})\sin\theta\cos\theta \qquad \text{and} \qquad B = -(q/\sqrt{\lambda})\cos^2\theta. \tag{104}$$

Similarly, the second solution y_2 has the form

$$y_2(t) = \sin\sqrt{\lambda}t \qquad \text{for} \quad 0 < t < \pi/2, \tag{105}$$

and

$$y_2(t) = C\cos\sqrt{\lambda}t + D\sin\sqrt{\lambda}t \qquad \text{for} \quad \pi/2 < t \le \pi, \tag{106}$$

where

$$C = (q/\lambda)\sin^2\theta \qquad \text{and} \qquad D = \frac{1}{\sqrt{\lambda}} - (q/\lambda)\sin\theta\cos\theta. \tag{107}$$

For the case of constant parameters (q, λ), we can find the criterion for instability and the growth rate for unstable solutions. Since the forcing potential is symmetric, $y_1(\pi) = dy_2/dt(\pi)$, from Theorem 1.1 of [MW]. The resulting criterion for instability reduces to the form

$$H \equiv \left| \frac{q}{2\sqrt{\lambda}}\sin(\sqrt{\lambda}\pi) - \cos(\sqrt{\lambda}\pi) \right| > 1, \tag{108}$$

and the growth rate γ is given by

$$\gamma = \frac{1}{\pi}\log[H + \sqrt{H^2 - 1}]. \tag{109}$$

In the delta function limit, the solution to Hill's equation is thus specified by two parameters—the frequency parameter λ and the forcing strength q. Figure 4 shows the plane of possible parameter space for Hill's equation in this limit, with the unstable regions shaded. Note that a large fraction of the plane is unstable.

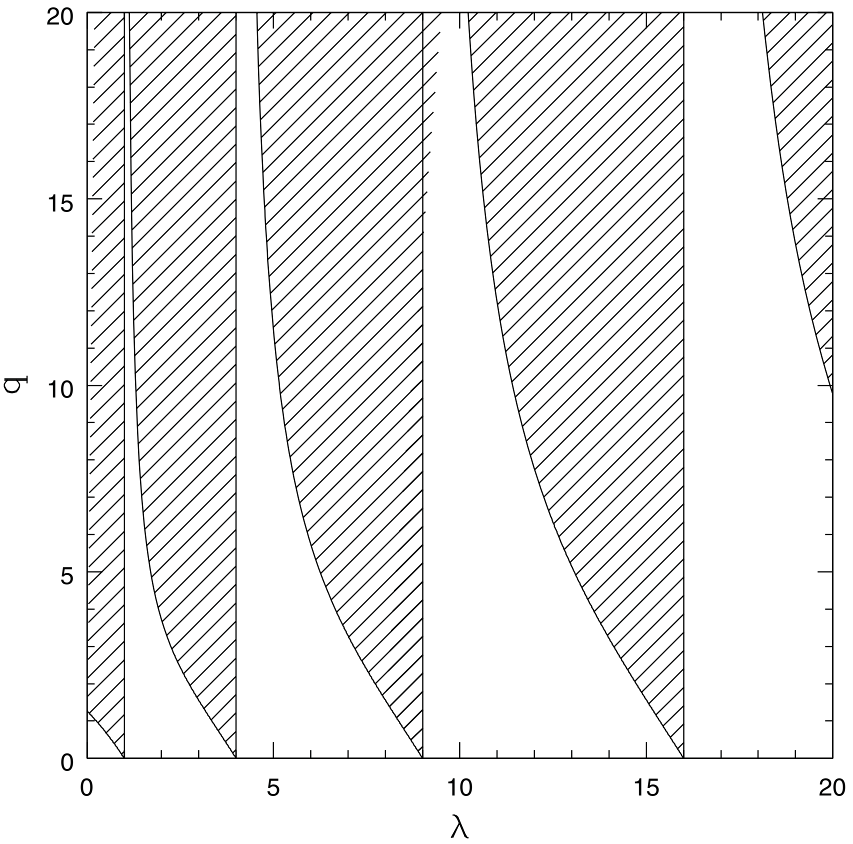

FIG. 4. *Regions of instability for Hill's equation in the delta function limit. The shaded regions show the values of (λ, q) that correspond to exponentially growing (unstable) solutions, which represent unstable growth of the perpendicular coordinate for orbits in our triaxial potential that are initially confined to one of the principal planes.*

4.2. Random variations in the forcing strength. We now generalize to the case where the forcing strength q varies from cycle to cycle, but the oscillation parameter λ is fixed. This version of the problem describes orbits in triaxial, extended mass distributions [AB] and is thus of interest in astrophysics. As outlined in section 2.2, the solutions from cycle to cycle are connected by the transformation matrix given by (7). Here, the matrix elements are given by

$$h = \cos(\sqrt{\lambda}\pi) - \frac{q}{2\sqrt{\lambda}}\sin(\sqrt{\lambda}\pi) \qquad \text{and} \qquad g = -\sqrt{\lambda}\sin(\sqrt{\lambda}\pi) - q\cos^2(\sqrt{\lambda}\pi/2). \tag{110}$$

THEOREM 5. *Consider a random Hill's equation in the delta function limit. For the case of fixed λ, the growth rate of instability approaches the asymptotic growth rate γ_∞ in the highly unstable limit $q/\sqrt{\lambda} \gg 1$, where the correction term has the following order:*

$$\gamma \to \gamma_\infty \left\{ 1 + \mathcal{O}\Big(\lambda/q^2\Big) \right\}. \tag{111}$$

Corollary 5.1. *In the delta function limit, the random Hill's equation with fixed λ is unstable when the asymptotic growth rate $\gamma_\infty > 0$.*

Remark 5.2. *Note that $\gamma_\infty > 0$ requires only that a nonvanishing fraction of the cycles be unstable.*

Proof. For this version of the problem, the matrix $\mathbf{M}$ represents the transition from one cycle to the next, where the solutions are written as linear combinations of y_1 and y_2 for the given cycle. In other words, this transformation operates in the (y_1, y_2) basis of solutions. However, one can also consider the purely growing and decaying solutions, which we denote here as f_+ and f_-.

For a given cycle, the eigenvectors $V_\pm$ of the matrix $\mathbf{M}$ take the form

$$V_\pm = \begin{bmatrix} 1 \\ \pm g/k \end{bmatrix}, \tag{112}$$

where the + (−) sign refers to the growing (decaying) solution. The eigenvalues have the form $\Lambda_\pm = h \pm k$, where $k \equiv (h^2 - 1)^{1/2}$. Keep in mind that $h = y_1(\pi)$ and $g = \dot{y}_2(\pi)$, and that $\Lambda_- = 1/\Lambda_+$. We can write any general solution in the form

$$f = AV_+ + BV_-, \tag{113}$$

where the coefficients (A, B) are related to the coefficients (α, β) in the first basis through the transformation

$$\begin{bmatrix} A \\ B \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & k/g \\ 1 & -k/g \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix}. \tag{114}$$

In the basis of eigenvectors, the action of the differential equation over any cycle is to amplify the growing solution (eigenvector) and attenuate the decaying solution, and this action can be written as the matrix transformation

$$\begin{bmatrix} A' \\ B' \end{bmatrix} = \begin{bmatrix} \Lambda_+ & 0 \\ 0 & \Lambda_- \end{bmatrix} \begin{bmatrix} A \\ B \end{bmatrix}. \tag{115}$$

At the end of the cycle, we can transform back to the original basis through the inverse of the transformation (114). As a result, the original matrix $\mathbf{M}$ can be decomposed into three components so that

$$\mathbf{M}(q, \lambda) = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ g/k & -g/k \end{bmatrix} \begin{bmatrix} \Lambda_+ & 0 \\ 0 & \Lambda_- \end{bmatrix} \begin{bmatrix} 1 & k/g \\ 1 & -k/g \end{bmatrix}. \tag{116}$$

For each cycle, the values of (q, λ) can vary. The next cycle will have a new matrix of the same general form, with the matrix elements specified by (q', λ').

We now shift our view to the basis of eigenvectors, so that each cycle amplifies the growing solution. Between the applications of the amplification factors, the action of successive cycles "rotates" the solution according to a transition matrix of the form

$$\mathbf{T}(q, \lambda; q', \lambda') = \frac{1}{2} \begin{bmatrix} 1 & k'/g' \\ 1 & -k'/g' \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 \\ g/k & -g/k \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 + \mathcal{R} & 1 - \mathcal{R} \\ 1 - \mathcal{R} & 1 + \mathcal{R} \end{bmatrix}, \tag{117}$$

where the primes denote the second cycle and where we have defined $\mathcal{R} \equiv k'g/(kg')$. For the case in which successive cycles have the same values of the original parameters (q, λ), the transition matrix $\mathbf{T}$ becomes the identity matrix (as expected).

For simplicity, we now specialize to the case where λ is held constant from cycle to cycle, but the forcing strength q varies. We can evaluate the transition matrix for the case in which Hill's equation lies in the delta function limit and where we also take the limit $q/\sqrt{\lambda} \gg 1$. In this regime,

$$\mathcal{R} = 1 + \frac{q-q'}{q'}\,\frac{2\sqrt{\lambda}}{q}\,\frac{1-2\cos(\sqrt{\lambda}\pi)}{\sin(\sqrt{\lambda}\pi)} + \mathcal{O}\Big(\frac{\lambda}{q^2}\Big) \equiv 1+2\delta. \tag{118}$$

Note that $\mathcal{R} = 1+2\delta$ to leading order, where δ (defined through the above relation) is small compared to unity and the sign of δ can be both positive and negative. Thus, not only is the parameter δ small, but it can average to zero. Repeated iterations of the mapping lead to the (1,1) matrix element growing according to the product

$$M_{(1,1)} = \prod_{k=1}^{N}\left[\Lambda_k(1+\delta_k)\right] \approx \left[\prod_{k=1}^{N}\Lambda_k\right]\left[1+\sum_{k=1}^{N}\delta_k + \sum_{k=1}^{N}\mathcal{O}(\delta_k^2)\right]. \tag{119}$$

The other matrix elements are of lower order (in powers of $1/q$) so that to leading order the growing eigenvalue of the product matrix is equal to the (1,1) matrix element. Further, for sufficiently well-behaved distributions of the parameter q, the sum of δ_k averages to zero as $N \to \infty$. The growth rate is thus given by

$$\gamma = \frac{1}{\pi N}\sum_{k=1}^{N}\log(\Lambda_k) + \frac{1}{\pi N}\sum_{k=1}^{N}\log(1+\delta_k) = \gamma_\infty + \mathcal{O}\Big(\frac{\lambda}{q^2}\Big). \tag{120}$$

The condition required for the δ_k to average to zero can be expressed in the form

$$\lim_{N\to\infty}\frac{1}{N}\sum_{k=1}^{N}\frac{q'-q}{qq'} = \Big\langle\frac{1}{q}\Big\rangle - \Big\langle\frac{1}{q'}\Big\rangle = 0, \tag{121}$$

which will hold provided that the expectation value $\langle 1/q\rangle$ exists. This constraint is nontrivial in that a uniform probability distribution $P(q) =$ *constant* that extends to $q = 0$ will produce a divergent expectation value for $\langle 1/q\rangle$. Fortunately, in the physical application that motivated this analysis, the value of q is determined by the distance to the center of an orbit (appropriately weighted) so that the minimum value of q corresponds to the maximum value of the distance. Since physical orbits have a maximum outer turning point (due to conservation of energy), physical orbit problems will satisfy the required constraint on the probability distribution. □

4.3. Second matrix decomposition. Another way to decompose the transformation matrix is to separate it into two separate rotations, one part that is independent of the forcing strength q, and another that is proportional to q. We can thus write the matrix in the form

$$\mathbf{M}(q,\lambda) = \mathbf{A} - \frac{q}{2\sqrt{\lambda}}\mathbf{B} \equiv \begin{bmatrix}\cos 2\theta & (\sin 2\theta)/\sqrt{\lambda}\\ -\sqrt{\lambda}\sin 2\theta & \cos 2\theta\end{bmatrix} - \frac{q}{2\sqrt{\lambda}}\begin{bmatrix}\sin 2\theta & (2\sin^2\theta)/\sqrt{\lambda}\\ 2\sqrt{\lambda}\cos^2\theta & \sin 2\theta\end{bmatrix}, \tag{122}$$

where the second equality defines the matrices $\mathbf{A}$ and $\mathbf{B}$. With these definitions, one finds that

$$\mathbf{A}^N(\theta) = \mathbf{A}(N\theta) \qquad \text{and} \qquad \mathbf{B}^N(\theta) = (2\sin 2\theta)^{N-1}\mathbf{B}(\theta), \tag{123}$$

where we again take λ to be constant from cycle to cycle. As a result, after N cycles, the effective transformation matrix can be written in the form

$$\mathbf{M}^{(N)} = \prod_{k=1}^{N} \Big(\mathbf{A} - \frac{q_k}{2\sqrt{\lambda}} \mathbf{B} \Big). \tag{124}$$

In the asymptotic limit $q/\sqrt{\lambda} \to \infty$, the matrix approaches the form

$$\mathbf{M}^{(N)} = (-1)^N \left[\prod_{k=1}^{N} \frac{q_k}{2\sqrt{\lambda}} \right] (2 \sin 2\theta)^{N-1} \mathbf{B}(\theta). \tag{125}$$

The condition for stability takes the form $|\mathrm{Tr}\mathbf{M}^{(N)}| \geq 2$, i.e.,

$$\left[\prod_{k=1}^{N} q_k \right] \left[\frac{\sin 2\theta}{\sqrt{\lambda}} \right]^N \geq 1. \tag{126}$$

When the system is unstable, the factor on the left-hand side of this equation represents the growth factor over the entire set of N cycles. The growth rate γ is thus given by

$$\gamma = \lim_{N\to\infty} \frac{1}{\pi N} \log \left[\prod_{k=1}^{N} \Big(q_k \frac{\sin 2\theta}{\sqrt{\lambda}} \Big) \right] = \lim_{N\to\infty} \frac{1}{\pi N} \sum_{k=1}^{N} \log \Big(q_k \frac{\sin 2\theta}{\sqrt{\lambda}} \Big). \tag{127}$$

Since $H_k = q_k(\sin 2\theta)/\sqrt{\lambda}$ in this asymptotic limit, the above expression for the growth rate can be rewritten in the form

$$\gamma = \lim_{N\to\infty} \frac{1}{\pi N} \sum_{k=1}^{N} \log(2H_k) = \lim_{N\to\infty} \frac{1}{N} \sum_{k=1}^{N} \gamma_k = \gamma_\infty, \tag{128}$$

in agreement with Theorem 5.

4.4. Width of stable and unstable zones. In the plane of parameters (e.g., Figure 4), the width of the stable and unstable zones can be found for the delta function limit. In this case, the leading edge of the zone of stability is given by the condition

$$\theta = \sqrt{\lambda}\pi = n\pi, \tag{129}$$

where n is an integer that can be used to label the zone in question. The beginning of the next unstable zone is given by the condition $|h| = 1$. In the limit of large $q \gg 1$, the width of the stable regime is narrow, and the boundary will fall at $\theta = n\pi + \varphi$, where φ is small. In particular, φ will be smaller than $\pi/2$, so that the angle θ will lie in either the first or the third quadrant, which in turn implies that $\sin\theta$ and $\cos\theta$ have the same sign. As a result, the condition at the boundary takes the form

$$\frac{q}{2\sqrt{\lambda}} = \frac{1+\cos\varphi}{\sin\varphi} \approx \frac{2}{\varphi}. \tag{130}$$

If we solve this expression for φ and use the definition $\varphi = \theta - n\pi$, we can solve for the value of λ at the boundary of the zone, i.e.,

$$\lambda \approx \frac{n^2}{(1-4/q\pi)^2} \approx n^2 \left[1 + \frac{8}{q\pi} + \mathcal{O}(q^{-2}) \right]. \tag{131}$$

The width of the stable zone can then be expressed in the form

$$\Delta\lambda = \frac{8n^2}{\pi q}. \tag{132}$$

For any finite q, there exists a zone number n such that $n^2 > q$ and the width of the zone becomes wide. In the limit $q \to \infty$, the zones are narrow for all finite n.

Note that when the forcing strength q_k varies from cycle to cycle, we can define the expectation value of the zone widths:

$$\langle \Delta\lambda \rangle = \frac{8n^2}{\pi} \left\langle \frac{1}{q_k} \right\rangle. \tag{133}$$

This expectation value exists under the same conditions required for Theorem 5 to be valid.

4.5. Variations in $(\boldsymbol{\lambda_k, q_k})$ and connection to the general case. As outlined earlier, the growth rates $\Delta\gamma$ depend on the ratios of the principal solutions, rather than on the input parameters (λ_k, q_k) that appear in the original differential equation (1). Since we have analytic expressions for the principal solutions in the delta function limit, we can study the relationship between the distributions of the fundamental parameters (λ_k, q_k) and the distribution of the composite variable $\xi = \log(x_k/x_j)$ that appears in the theorems of this paper.

As a starting point, we first consider the limiting case where $q_k \to \infty$ and the parameter λ_k is allowed to vary. We also focus the discussion on the correction $\Delta\gamma$ to the growth rate, which depends on the ratios x_k. In this limit, using (110), we see the variables x_k reduce to the simple form

$$x_k = \frac{\pi}{\theta_k} \frac{\sin\theta_k}{1+\cos\theta_k}, \tag{134}$$

where $\theta_k \equiv \sqrt{\lambda}\pi$. In this case the distribution of $\xi = \log(x_k/x_j)$ depends only on the distribution of the angles θ_k, which is equivalent to the distribution of λ_k. Since the x_j and x_k are drawn independently from the same distribution (of θ_k), the variance of the composite variable $\sigma_0^2 = 2\sigma_x^2$, where σ_x^2 is the variance of $\log x_k$.

As a benchmark case, we consider the distribution of θ to be uniformly distributed over the interval $[0, 2\pi]$. For this example,

$$\sigma_x^2 = \int_0^{2\pi} \frac{d\theta}{2\pi} \left[\log\left(\frac{\pi}{\theta} \frac{\sin\theta}{1+\cos\theta} \right) \right]^2 - \left[\int_0^{2\pi} \frac{d\theta}{2\pi} \log\left(\frac{\pi}{\theta} \frac{\sin\theta}{1+\cos\theta} \right) \right]^2. \tag{135}$$

Numerical evaluation indicates that $\sigma_0 \approx 2.159$. Further, the correction to the growth rate is bounded by $\Delta\gamma \le \sigma_0^2/(4\pi) \approx 0.371$ and is expected to be given approximately by $\Delta\gamma \sim 0.13$. In this limit we expect the asymptotic growth rate to dominate. For example, if $q_k \sim 1000$, a typical value for one class of astrophysical orbits [AB], then $\gamma_\infty \approx 2$, which is an order of magnitude greater than $\Delta\gamma$. Note that in the limit of large (but finite) q_k, the corrections to (134) are of order $\mathcal{O}(1/q_k)$, which will be small, so that the variance σ_0^2 of the composite variable ξ will be nearly independent of the distribution of q_k in this limit.

As another way to illustrate the transformation between the (λ_k, q_k) and the matrix elements x_k, we consider the case of fixed λ_k and large but finite (and varying) values of q_k. We are thus confining the parameter space in Figure 4 to a particular vertical line, which is chosen to be in an unstable band. We thus define $\theta = \sqrt{\lambda}\pi$, and the x_k take the form

$$x_k = \frac{q_k(\pi/\theta)\sin\theta - 2\cos\theta}{q_k(1+\cos\theta)/2 + (\theta/\pi)\sin\theta}. \tag{136}$$

For purposes of illustration, we can make a further simplification by taking θ to have a particular value; for example, if $\theta = \pi/2$, the x_k are given by

$$x_k = \frac{2q_k}{q_k+1}. \tag{137}$$

For this case, the relevant composite variable ξ is given by

$$\xi = \log\left[\frac{q_k}{q_j}\frac{q_j+1}{q_k+1}\right], \tag{138}$$

where q_j and q_k are the values for two successive cycles. In the limit of large $q_j, q_k \gg 1$, the composite variable takes the approximate form $\xi \approx (q_k - q_j)/(q_k q_j)$, which illustrates the relationship between the original variables (only the q_k in this example) and the x_k, or the composite variable ξ, that appear in the growth rates.

Before leaving this section, we note that the more general case of Hill's equation with a square barrier of finite width can also be solved analytically (e.g., let $\hat{Q}(t) = 1/w$ for a finite time interval of width $\Delta t = w$, with $\hat{Q}(t) = 0$ otherwise). For this case, in the limit of large q_k, the solution for h_k takes the form

$$|h_k| \propto \sin(wq_k)^{1/2}\left(\frac{q_k}{w\lambda_k}\right)^{1/2}. \tag{139}$$

In the limit of large but finite q_k and vanishing width $w \to 0$, we recover the result from the delta function limit; i.e., the dependence on the width w drops out and $|h_k| \propto q_k$. In the limit of finite w and large q_k (specifically, when $(wq_k) \ll 1$ does *not* hold); then $|h_k| \propto \sqrt{q_k}$. This example vindicates our expectation that large q_k should lead to large h_k, but the dependence depends on the shape of the barrier $\hat{Q}(t)$. An interesting problem for further study is to place constraints on the behavior of the matrix elements h_k (and g_k) as a function of the forcing strengths q_k for general $\hat{Q}(t)$.

5. Discussion and conclusion.

This paper has considered Hill's equation with forcing strengths and oscillation parameters that vary from cycle to cycle. We denote such cases as random Hill's equations. Our first result is that Hill-like equations where the period is not constant, but rather varies from cycle to cycle, can be reduced to a random Hill's equation (Theorem 1). The rest of the paper thus focuses on random Hill's equations, specifically, general equations in the unstable limit (section 3) and the particular cases of the delta function limit (section 4), where the solutions can be determined in terms of elementary functions.

For a general Hill's equation in the limit of a large forcing parameter, we have found general results governing instability. In all cases, the growth rates depend on the distribution of values for the elements of the transition matrix that maps the solution for one cycle onto the next. The relevant composite variable ξ is determined by the principal solutions via the relation $\xi = \log[y_{1k}(\pi)\dot{y}_{1j}(\pi)/\dot{y}_{1k}(\pi)y_{1j}(\pi)]$, where k and j denote two successive cycles; our results are then presented in terms of the variance σ_0 of the distribution of ξ. The growth rate can be separated into two parts—the asymptotic growth rate γ_∞ that would result if each cycle grew at the rate appropriate for an ordinary Hill's equation, and the correction term $\Delta\gamma$ that results from matching the solutions across cycles. The asymptotic growth rate γ_∞ is determined by the appropriate average of the growth rates for individual cycles (see (9) and (10)). In contrast, the correction term $\Delta\gamma$ results from a type of random walk behavior and depends on the variance of the distribution of the composite variable ξ defined above.

For the case of purely positive matrix elements, the correction term $\Delta\gamma$ has a simple form (Theorem 2) and is positive semidefinite and bounded from above and below. In the limit of small variance, the correction term $\Delta\gamma \propto \sigma_0^2$, whereas in the limit of large variance, $\Delta\gamma \propto \sigma_0$. For all σ_0, the correction term to the growth rate is bounded by $\Delta\gamma \le \sigma_0^2/4\pi$ (Theorem 3). A sharper bound could be obtained in the future.

For the case of matrix elements with varying signs, we have found the growth rate of instability (Theorem 4), where the results depend on the probability p of the matrix elements having a positive sign. In the limit of small variance, the correction term $\Delta\gamma$ is always negative and approaches the form $\Delta\gamma \propto \log\sigma_0$ (unless $p = 1$, where $\Delta\gamma \to 0$ in this limit). As a result, the total growth rate $\gamma = \gamma_\infty + \Delta\gamma$ will always be negative—and hence the system will be stable—for sufficiently small variance σ_0 and any admixture of mixed signs. In the opposite limit of large variance, the growth rate for mixed signs and that for purely positive signs converge, with both cases approaching the form $\Delta\gamma \propto \sigma$; the difference between the growth rates for the two cases decreases as $\Delta(\Delta\gamma) \propto 1/\sigma_0$.

For the delta function limit, we can find the solution explicitly for each cycle and thus analytically define the matrix elements of the discrete map that develops the solution (see (7) and (110)). For the case in which only the forcing strength varies, the growth rate of the general solution approaches the asymptotic growth rate (see (9)), which represents the growth the solution would have if every cycle grows at the rate appropriate for a standard (nonstochastic) Hill's equation. We have calculated the widths of the stable and unstable zones for Hill's equation in the limit of delta function forcing and large growth rates, which represents a specific case of the results presented in [WK], where this specific case includes random forcing terms. Finally, we have used the analytic solutions for the delta function limit to illustrate the transformation between the original variables (λ_k, q_k) that appear in Hill's equation and the variables x_k that determine the growth rates (section 4.5).

Although this paper takes a step forward in our understanding of Hill's equation (in particular, generalizing it to include random forcing terms) and the multiplication of random matrices (of the particular form motivated by Hill's equation), additional work along these lines can be carried out. The analysis presented herein works primarily in the limit of large q_k, where the solutions are highly unstable, although we have bounded the errors incurred by working in this limit. Nonetheless, the case in which some cycles have stable solutions, while others have unstable solutions, should be considered in greater detail. This paper presents bounds on the correction term $\Delta\gamma$ to the growth rate, but a sharper bound could be found. In the treatment of this paper, we considered the probability distribution of the composite variable $\xi = \log(x_k/x_j)$ to be symmetric, which implies that x_k and x_j are independently drawn from their distribution. In future work, correlations between successive cycles can be considered and would lead to asymmetric probability distributions. Most of the results of this paper are presented in terms of the distributions of the composite variables x_k, rather than the original parameters that appear in Hill's equation; the transformation between the distributions of the (λ_k, q_k) and the x_k thus represents another interesting problem for future study. Another case of interest we intend to consider is the case where $\hat{Q}(t)$ takes the form of a finite Fourier series. Finally, the relationship between solutions to random Hill's equations and the multiplication of random matrices should be explored in greater generality.

Random Hill's equations, and the properties of their solutions, have a wide variety of applications. The original motivation for this work was a class of orbit problems in astrophysics. In that context, many astrophysical systems—young embedded star clusters, galactic bulges, and dark matter halos—are essentially triaxial extended mass distributions. Orbits within these mass distributions are often chaotic; further, when motion is initially confined to a plane, the equation of motion for the perpendicular direction is described by a random Hill's equation. The instability explored here thus determines how quickly an orbiting body will explore the perpendicular direction. For example, this class of behavior occurs in young embedded star clusters, which begin in highly flattened configurations but quickly become rounder, in part due to the instability described here. Dark matter halos are found (numerically) to display nearly universal forms for their density distributions [NF, BE], but an a priori explanation for this form remains lacking. Since the orbits of dark matter particles will be subject to the instability studied herein, random Hill's equations must play a role in the explanation. As yet another example, galactic bulges often harbor supermassive black holes at their centers; the resulting stellar orbits, including the instability considered here, play a role in feeding stars into the central black hole. Finally, we note that in addition to astrophysical applications, random Hill's equations are likely to arise in a number of other settings.

Appendix A: Astrophysical motivation. This appendix outlines the original astrophysical problem that motivated this study of Hill's equation with random forcing. In the initial setting, the goal was to understand orbits in potentials resulting from a density profile of the form

$$\rho = \rho_0 \frac{f(m)}{m}, \tag{A1}$$

where ρ_0 is a density scale. This form arises in many different astrophysical contexts, including dark matter halos, galactic bulges, and young embedded star clusters. The density field is constant on ellipsoids and the variable m has a triaxial form

$$m^2 = \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2}, \tag{A2}$$

where, without loss of generality, $a > b > c > 0$. The radial coordinate ξ is given by $\xi^2 = x^2 + y^2 + z^2$. The function $f(m)$ is assumed to approach unity as $m \to 0$ so that the density profile approaches the form $\rho \sim 1/m$. For this inner limit, one can find an analytic form for both the potential and the force terms [AB]. For purposes of illustration, we write the force terms for the three spatial directions in the form

$$\mathcal{F}_x = -\frac{2x}{F(a)} \ln \left| \frac{2F(a)\sqrt{\Gamma} + 2\Gamma - \Lambda a^2}{a^2\left[2F(a)\xi + \Lambda - 2a^2\xi^2\right]} \right|, \tag{A3}$$

$$\mathcal{F}_y = -\frac{2y}{|F(b)|} \left[\sin^{-1}\left(\frac{\Lambda - 2b^2\xi^2}{\sqrt{\Lambda^2 - 4\xi^2\Gamma}} \right) - \sin^{-1}\left(\frac{2\Gamma/b^2 - \Lambda}{\sqrt{\Lambda^2 - 4\xi^2\Gamma}} \right) \right], \tag{A4}$$

(A5)
$$\mathcal{F}_z = -\frac{2z}{F(c)} \ln \left| \frac{2F(c)\sqrt{\Gamma} + 2\Gamma - \Lambda c^2}{c^2 \left[2F(c)\xi + \Lambda - 2c^2\xi^2 \right]} \right| .$$

The coefficients in the numerators are given by the following quadratic functions of the coordinates:

(A6)
$$\Lambda \equiv (b^2 + c^2)x^2 + (a^2 + c^2)y^2 + (a^2 + b^2)z^2 \qquad \text{and} \qquad \Gamma \equiv b^2c^2x^2 + a^2c^2y^2 + a^2b^2z^2 .$$

The remaining function F is defined by

(A7)
$$F(\alpha) \equiv \left[\xi^2\alpha^4 - \Lambda\alpha^2 + \Gamma \right]^{1/2} .$$

Equations (A3)–(A7) define the force terms that determine the orbital motion of a test particle moving in the potential under consideration (i.e., that resulting from a triaxial density distribution of the form (A1)). The work of [AB] shows that when the orbit begins in any of the three principal planes, the motion is (usually) highly unstable to perturbations in the perpendicular direction. For example, for an orbit initially confined to the $x - z$ plane, the amplitude of the y coordinate will (usually) grow exponentially with time. In the limit of small y, the equation of motion for the perpendicular coordinate simplifies to the form

(A8)
$$\frac{d^2y}{dt^2} + \omega_y^2 y = 0, \qquad \text{where} \qquad \omega_y^2 = \frac{4/b}{\sqrt{c^2x^2 + a^2z^2} + b\sqrt{x^2 + z^2}} .$$

Here, the time evolution of the coordinates (x, z) is determined by the orbit in the original $x - z$ plane. Since the orbital motion is nearly periodic, the (x, z) dependence of ω_y^2 represents a periodic forcing term. The forcing strengths, and hence the parameters q_k appearing in Hill's equation (1), are thus determined by the inner turning points of the orbit (with appropriate weighting from the axis parameters $[a, b, c]$). Further, since the orbit in the initial plane often exhibits chaotic behavior, the distance of closest approach of the orbit, and hence the strength q_k of the forcing, varies from cycle to cycle. The orbit also has outer turning points, which provide a minimum value of ω_y^2, which defines the unforced oscillation frequency λ_k appearing in Hill's equation (1). As a result, the equation of motion (A8) for the perpendicular coordinate has the form of Hill's equation, where the period, the forcing strength, and the oscillation frequency generally vary from cycle to cycle.

Appendix B: Growth rate for an ancillary matrix. In this appendix, we separate the transformation matrix for the general case (not in the limit of small variance) and find the growth rate for one of the matrices. We include this result because examples where one can explicitly find the growth rates (Lyapunov exponents) for random matrices are rare. Specifically, the transition matrix can be written in the form given by (91), where the second term in the sum has the form

(B1)
$$s_k(x_k - 1)\mathbf{B}_k, \qquad \text{where} \qquad \mathbf{B}_k = \begin{bmatrix} 0 & 1 \\ -1/x_k & 0 \end{bmatrix} .$$

Note that any pair of matrices $\mathbf{A}_k$ with opposite signs will vanish, and so will all subsequent products.

The products of the second term (the matrices $\mathbf{B}_k$ along with the leading factor) have a well-defined growth rate.

Proposition 3. *The growth rate of matrix multiplication for the matrix* $\mathbf{M}_k = (x_k - 1)\mathbf{B}_k$ *is given by*

$$\gamma_B = \lim_{N\to\infty} \frac{1}{2\pi N} \left\{ \sum_{k=1}^{N} \log|x_k - 1| + \sum_{j=1}^{N} \log|1/x_j - 1| \right\}. \tag{B2}$$

Proof. The products of the matrices $\mathbf{B}_k$ follow cycles as shown by the first three nontrivial cases:

$$\mathbf{B}_2\mathbf{B}_1 = \begin{bmatrix} -1/x_1 & 0 \\ 0 & -1/x_2 \end{bmatrix}, \qquad \mathbf{B}_3\mathbf{B}_2\mathbf{B}_1 = \begin{bmatrix} 0 & -1/x_2 \\ 1/(x_1x_3) & 0 \end{bmatrix}, \tag{B3}$$

and

$$\mathbf{B}_4\mathbf{B}_3\mathbf{B}_2\mathbf{B}_1 = \begin{bmatrix} 1/(x_1x_3) & 0 \\ 0 & 1/(x_2x_4) \end{bmatrix}. \tag{B4}$$

Thus, the even products of the matrices are diagonal matrices, whereas the odd products produce matrices with only off-diagonal elements. As a result, the product matrix will approach the form

$$\begin{aligned} \mathbf{M}^{(N)} &\sim \left(\prod_{k=1}^{N}(x_k - 1)\right) \begin{bmatrix} P_{\text{odd}} & 0 \\ 0 & P_{\text{even}} \end{bmatrix} \qquad \text{or} \\ \mathbf{M}^{(N)} &\sim \left(\prod_{k=1}^{N}(x_k - 1)\right) \begin{bmatrix} 0 & -P_{\text{even}} \\ P_{\text{odd}} & 0 \end{bmatrix}, \end{aligned} \tag{B5}$$

where we have defined

$$P_{\text{odd}} \equiv \prod_{k=1,odd}^{N} \frac{1}{x_k} \qquad \text{and} \qquad P_{\text{even}} \equiv \prod_{k=2,even}^{N} \frac{1}{x_k}. \tag{B6}$$

For N even (odd), the eigenvalues are $\Lambda = P_{\text{even}}, P_{\text{odd}}$ ($\Lambda = \pm i\sqrt{P_{\text{even}}P_{\text{odd}}}$). Since $|P_{\text{even}}| = |P_{\text{odd}}|$ in the limit $N \to \infty$, the eigenvalues (and hence the growth rates) have the same magnitudes in either case. To compute the growth rate γ_B, we need to account for the fact that only half of the factors (either the even or the odd terms) appear in the products P_{odd} and P_{even}. After some rearrangement, we obtain equation (B2). ◻

Acknowledgments. We would like to thank Charlie Doering, Gus Evrard, Divakar Vishwanath, and Michael Weinstein for many useful conversations, and research students Michael Busha, Suzanne Butler, Jeff Druce, Jake Ketchum, and Eva Proszkow for performing numerical calculations that guided the initial formulation of this project. We also thank an anonymous referee for many useful comments and criticisms that improved the paper.

A FLUID DYNAMIC MODEL FOR TELECOMMUNICATION NETWORKS WITH SOURCES AND DESTINATIONS*

CIRO D'APICE[†], ROSANNA MANZO[†], AND BENEDETTO PICCOLI[‡]

Abstract. This paper proposes a macroscopic fluid dynamic model dealing with the flows of information on a telecommunication network with sources and destinations. The model consists of a conservation law for the packet density and a semilinear equation for traffic distribution functions, i.e., functions describing packet paths. We describe methods to solve Riemann problems at junctions assigning different traffic distribution functions and two "routing algorithms." Moreover, we prove the existence of solutions to Cauchy problems for small perturbations of network equilibria.

Key words. data flows on telecommunication networks, sources and destinations, conservation laws, fluid dynamic models

1. Introduction.

This paper is concerned with the description and analysis of a macroscopic fluid dynamic model dealing with flows of information on a telecommunication network with sources and destinations. The latter are, respectively, areas from which packets start their travels on the network and areas where they end.

There are various approaches to telecommunication and data networks (see, for example, [1], [3], [4], [15], [21], [22]). A first model for telecommunication networks, similar to that introduced recently for car traffic, has been proposed in [10], where two algorithms for dynamics at nodes were considered and the existence of solutions to Cauchy problems was proved. The idea is to follow the approach used in [12] for road networks (see also [7], [9], [11], [14], [16], [17], [18]), introducing sources and destinations in the telecommunication model described in [10] and thus taking care of the paths of the packets inside the network.

A telecommunication network consists of a finite collection of transmission lines, modelled by closed intervals of $\mathbb{R}$ connected together by nodes (routers, hubs, switches, etc.). We assume that each node receives and sends information encoded in packets, which can be seen as particles travelling on the network. Taking the Internet network as a model, we assume the following:

(1) Each packet travels on the network with a fixed speed and with an assigned final destination.
(2) Nodes receive, process, and then forward packets. Packets may be lost with a probability increasing with the number of packets to be processed. Each lost packet is sent again.

Since each lost packet is sent again until it reaches the next node, looking at the macroscopic level, it is assumed that the number of packets is conserved. This leads

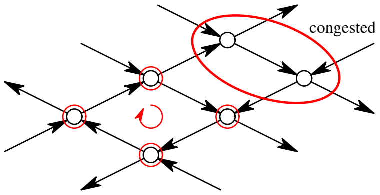

Fig. 1.1. *A possible cycling effect of* (RA2).

to a conservation law for the packet density ρ on each line:

$$\rho_t + f(\rho)_x = 0. \tag{1.1}$$

The flux $f(\rho)$ is given by $v \cdot \rho$, where v is the average speed of packets among nodes, derived considering the amount of packets that may be lost.

Recently, a conservation law model was obtained in [2] for supply chains, which have a dynamics somehow related to our case.

On each transmission line we also consider a vector π describing the traffic types, i.e., the percentage of packets going from a fixed source to a fixed destination. Assuming that packet velocity is independent from the source and the destination, the evolution of π follows a semilinear equation,

$$\pi_t + v(\rho)\pi_x = 0; \tag{1.2}$$

hence inside transmission lines the evolution of π is influenced by the average speed of packets.

The aim is then to consider networks in which many lines intersect. Riemann problems at junctions were solved in [10] proposing two different routing algorithms:

(RA1) Packets from incoming lines are sent to outgoing ones according to their final destination (without taking into account possible high loads of outgoing lines).

(RA2) Packets are sent to outgoing lines in order to maximize the flux through the node.

The main differences of the two algorithms are the following. The first one simply sends each packet to the outgoing line which is naturally chosen according to the final destination of the packet itself. The algorithm is blind to possible overloads of some outgoing lines and, by some abuse of notation, is similar to the behavior of a "switch." The second algorithm, on the contrary, send packets to outgoing lines taking into account the loads and thus possibly redirecting packets. Again by some abuse of notation, this is similar to a "router" behavior.

One of the drawbacks of the second algorithm is that it does not take into account the global path of packets, therefore leading to possible cycling. For example consider a telecommunication network in which some nodes are congested: if we use (RA2) alone, the packets are not routed towards the congested nodes, and so they can enter in loops (see Figure 1.1). These cyclings are avoided if we consider that the packets originated from a source and with an assigned destination have precise paths inside the network. Such paths are determined by the behavior at junctions via the coefficients π.

In this paper different distribution traffic functions describing different routing strategies have been considered:

- at a junction the traffic started at source s and with d as the final destination, coming from the transmission line i, is routed on an assigned line j;

- at a junction the traffic started at source s and with d as the final destination, coming from the transmission line i, is routed on every outgoing line or on some of them.

The first distribution traffic function has already been analyzed in [12] for road networks using algorithm (RA1); thus we focus on the second one. In particular, we define two ways according to which the traffic at a junction is split towards the outgoing lines.

Let us now comment further on the differences with the results of [12]. In that paper, only the routing algorithm (RA1) was considered, together with the first choice of distribution traffic functions (which can be seen as a particular case of the second choice). Since the algorithm (RA1) produces discontinuities in the map from traffic types to fluxes (and densities), a new Riemann solver was introduced, which considers the maximization of a quadratic cost. The latter produces as a drawback more difficulties in analysis and numerics. Finally, the present paper presents a more general approach and, using (RA2), the possibility of solving dynamics at nodes using linear functionals.

Starting from the distribution traffic function, and using the vector π, we assign the traffic distribution matrix, which describes the percentage of packets from an incoming line that are addressed to an outgoing one. Then we propose methods to solve Riemann problems considering the routing algorithms (RA1) and (RA2). The key point to construct a solution on the whole network, using a way-front tracking method, is to derive some BV estimates on the piecewise constant approximate solutions in order to pass to the limit. In the case in which the traffic at junctions is distributed on outgoing lines according to some probabilistic coefficients, estimates on packet density function and on traffic-type functions are derived for the algorithm (RA2) in order to prove the existence of solutions to Cauchy problems. More precisely, we prove the existence of solutions, locally in time, for perturbations of equilibria.

The paper is organized as follows. Section 2 gives a general definition of the network. Then, in section 3, we discuss possible choices of the traffic distribution functions and how to compute the traffic distribution matrix from the latter functions and the traffic-type function. We describe two routing algorithms in section 4, giving explicit unique solutions to Riemann problems. Finally, section 5 provides the needed estimates for constructing solutions to Cauchy problems.

2. Basic definitions.

We consider a telecommunication network that is a finite collection of transmission lines connected together by nodes, some of which are sources and destinations. Formally we introduce the following definition.

DEFINITION 2.1. *A telecommunication network is given by a 7-tuple* $(N, \mathcal{I}, \mathcal{F}, \mathcal{J}, \mathcal{S}, \mathcal{D}, \mathcal{R})$, *where we have the following:*

Cardinality. *N is the cardinality of the network, i.e., the number of lines in the network.*

Lines. *$\mathcal{I}$ is the collection of lines, modelled by intervals $I_i = [a_i, b_i] \subseteq \mathbb{R}$, $i = 1, \dots, N$.*

Fluxes. *$\mathcal{F}$ is the collection of flux functions $f_i : [0, \rho_i^{\max}] \mapsto \mathbb{R}$, $i = 1, \dots, N$.*

Nodes. *$\mathcal{J}$ is a collection of subsets of $\{\pm 1, \dots, \pm N\}$ representing nodes. If $j \in J \in \mathcal{J}$, then the transmission line $I_{|j|}$ is crossing at J as an incoming line (i.e., at point b_i) if $j > 0$ and as an outgoing line (i.e., at point a_i) if $j < 0$. For each junction $J \in \mathcal{J}$, we indicate by $\mathrm{Inc}(J)$ the set of incoming lines, which are I_i's such that $i \in J$, while by $\mathrm{Out}(J)$ the set of outgoing lines, which are I_i's such that $-i \in J$. We assume that each line is incoming for (at most) one node and outgoing for (at most) one node.*

Sources. *$\mathcal{S}$ is the subset of $\{1,\dots,N\}$ representing lines starting from traffic sources. Thus, $j \in \mathcal{S}$ if and only if j is not outgoing for any node. We assume that $\mathcal{S} \neq \emptyset$.*

Destinations. *$\mathcal{D}$ is the subset of $\{1,\dots,N\}$ representing lines leading to traffic destinations. Thus, $j \in \mathcal{D}$ if and only if j is not incoming for any node. We assume that $\mathcal{D} \neq \emptyset$.*

Traffic distribution functions. *$\mathcal{R}$ is a finite collection of functions $r_J : \mathrm{Inc}(J) \times \mathcal{S} \times \mathcal{D} \to \mathrm{Out}(J)$. For every J, $r_J(i,s,d)$ indicates the outgoing direction of traffic that started at source s, has d as the final destination, and reached J from the incoming road i. (We will also consider the case of r_J multivalued.)*

One usually assumes that the network is connected. However, this is not strictly necessary to develop our theory.

2.1. Dynamics on lines. Following [10], we recall the model used to define the dynamics of packet densities along lines. We make the following hypotheses:

(H1) Lines are composed of consecutive processors N_k, which receive and send packets. The number of packets at N_k is indicated by $R_k \in [0, R_{max}]$.

(H2) There are two time scales: Δt_0 represents the physical travel time of a single packet from node to node (assumed to be independent of the node for simplicity); T represents the processing time, during which each processor tries to operate the transmission of a given packet.

(H3) Each processor N_k tries to send all packets R_k at the same time. Packets are lost according to a loss probability function $p : [0, R_{max}] \to [0,1]$, computed at R_{k+1}, and lost packets are sent again for a time slot of length T.

The aim is to determine the fluxes on the network. Since the packet transmission velocity on the line is assumed constant, it is possible to compute an average velocity function and thus an average flux function.

Let us focus on two consecutive nodes N_k and N_{k+1}, assume a static situation, i.e., R_k and R_{k+1} are constant, and call δ the distance between the nodes. During a processing time slot of length T the following happens. All packets R_k are sent a first time: $(1 - p(R_{k+1}))\,R_k$ are sent successfully and $p(R_{k+1})\,R_k$ are lost. At the second attempt, among the lost packets $p(R_{k+1})\,R_k$, $(1-p(R_{k+1})\,p(R_{k+1})\,R_k$ are sent successfully and $p^2(R_{k+1})\,R_k$ are lost, and so on.

Let us indicate by Δt_{av} the average transmission time of packets, by $\bar{v} = \frac{\delta}{\Delta t_0}$ the packet velocity without losses, and by $v = \frac{\delta}{\Delta t_{av}}$ the average packet velocity. Then we can compute

$$\Delta t_{av} = \sum_{n=1}^{M} n \Delta t_0 (1 - p(R_{k+1})) p^{n-1}(R_{k+1}),$$

where $M = [T/\Delta t_0]$ (here $[\cdot]$ indicates the floor function) represents the number of attempts of sending a packet. We make a further assumption:

(H4) The number of packets not transmitted for a whole processing time slot is negligible.

Hypothesis (H4) corresponds to assuming that $\Delta t_0 \ll T$ or, equivalently, $M \sim +\infty$. Making the identification, $M = +\infty$, we get

$$\Delta t_{av} = \sum_{n=1}^{+\infty} n \Delta t_0 (1 - p(R_{k+1})) p^{n-1}(R_{k+1}) = \frac{\Delta t_0}{1 - p(R_{k+1})},$$

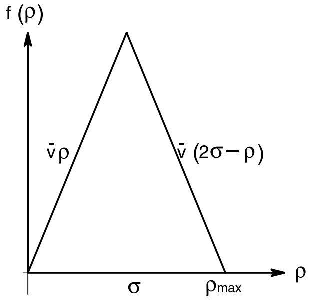

FIG. 2.1. *Example of flux function.*

and

$$v = \frac{\delta}{\Delta t_{av}} = \frac{\delta}{\Delta t_0}(1 - p(R_{k+1})) = \bar{v}(1 - p(R_{k+1})). \tag{2.1}$$

Let us now call ρ the averaged density and ρ_{max} its maximum. We can interpret the function p as a function of ρ and, using (2.1), determine the corresponding flux function, given by the averaged density times the average velocity. It is reasonable to assume that the probability loss function is null for some interval, which is a right neighborhood of zero. This means that at low densities no packet is lost. Then p should be increasing, reaching the value 1 at the maximal density, the situation of being completely stuck. A possible choice of the probability loss function is the following:

$$p\left(\rho\right) = \begin{cases} 0, & 0 \le \rho \le \sigma, \\ \frac{\rho_{max}\left(\rho - \sigma\right)}{\rho\left(\rho_{max} - \sigma\right)}, & \sigma \le \rho \le \rho_{\max}; \end{cases}$$

then it follows that

$$f\left(\rho\right) = \begin{cases} \bar{v}\rho, & 0 \le \rho \le \sigma, \\ \frac{\bar{v}\sigma(\rho_{max} - \rho)}{\rho_{max} - \sigma}, & \sigma \le \rho \le \rho_{\max}. \end{cases} \tag{2.2}$$

Setting, for simplicity, $\rho_{max} = 1$ and $\sigma = \frac{1}{2}$, we get the simple "tent" function of Figure 2.1. To simplify the treatment of the corresponding conservation laws, we will assume the following:

(F) Setting $\rho_{max} = 1$, on each line the flux $f_i : [0, 1] \to R$ is concave, $f(0) = f(1) = 0$, and there exists a unique maximum point $\sigma \in\,]0, 1[$.

Notice that the flux of Figure 2.1 or, more generally, the flux given in (2.2) satisfies assumption (F).

2.2. Dynamics on the network. On each transmission line I_i we consider the evolution equation

$$\partial_t \rho_i + \partial_x f_i\left(\rho_i\right) = 0, \tag{2.3}$$

where we use assumption (F). Therefore, the network load evolution is described by a finite set of functions $\rho_i : [0, +\infty[\, \times I_i \mapsto [0, \rho_i^{\max}]$.

On each transmission line I_i we want ρ_i to be a weak entropic solution of (2.3); that is, for every function $\varphi : [0, +\infty[\times I_i \to \mathbb{R}$ smooth, positive with compact support on $]0, +\infty[\times]a_i, b_i[$,

$$\int_0^{+\infty} \int_{a_i}^{b_i} \left(\rho_i \frac{\partial \varphi}{\partial t} + f_i(\rho_i) \frac{\partial \varphi}{\partial x} \right) dxdt = 0, \tag{2.4}$$

and for every $k \in \mathbb{R}$ and every $\tilde{\varphi} : [0, +\infty[\times I_i \to \mathbb{R}$ smooth, positive with compact support on $]0, +\infty[\times]a_i, b_i[$,

$$\int_0^{+\infty} \int_{a_i}^{b_i} \left(|\rho_i - k| \frac{\partial \tilde{\varphi}}{\partial t} + sgn(\rho_i - k) \left(f_i(\rho_i) - f_i(k) \right) \frac{\partial \tilde{\varphi}}{\partial x} \right) dxdt \geq 0. \tag{2.5}$$

For each $i \in \mathcal{S}$ (resp., $i \in \mathcal{D}$) we need an inflow function (resp., outflow) and thus consider measurable functions $\psi_i : [0, +\infty[\to [0, \rho_i^{\max}]$. Then the corresponding functions ρ_i must verify the boundary condition $\rho_i(t, a_i) = \psi_i(t)$ (resp., $\rho_i(t, b_i) = \psi_i(t)$) in the sense of [5].

Moreover, inside each line I_i we define a traffic-type function π_i, which measures the portion of the whole density coming from each source and travelling towards each destination.

Definition 2.2. *A traffic-type function on a line I_i is a function*

$$\pi_i : [0, \infty[\times [a_i, b_i] \times \mathcal{S} \times \mathcal{D} \mapsto [0, 1]$$

such that, for every $t \in [0, \infty[$ and $x \in [a_i, b_i]$,

$$\sum_{s \in \mathcal{S}, d \in \mathcal{D}} \pi_i(t, x, s, d) = 1.$$

In other words, $\pi_i(t, x, s, d)$ specifies the fraction of the density $\rho_i(t, x)$ that started from source s and is moving towards the final destination d.

We assumed, on the discrete model, that a FIFO policy is used at nodes. Then it is natural that the averaged velocity, obtained in the limit procedure, is independent from the original sources of packets and their final destinations. In other words, we make the following hypothesis:

(H5) On each line I_i, the average velocity of packets depends only on the value of the density ρ_i and not on the values of the traffic-type function π_i.

As a consequence of hypothesis (H5), we have the following. If $x(t)$ denotes a trajectory of a packet inside the line I_i, then we get

$$\pi_i(t, x(t), s, d) = \text{const.} \tag{2.6}$$

In fact, consider the packets that at time t are in position $x(t)$. All such packets have the same velocity by (H5); thus their trajectories coincide, independently of their sources and destinations. In other words, at a time $t' > t$ all packets will be in position $x(t')$. Then the fractions of the density, expressed by π, are the same at $(t, x(t))$ and at $(t', x(t'))$.

Taking the total differential with respect to the time of (2.6), we deduce the semilinear equation

$$\partial_t \pi_i(t, x, s, d) + \partial_x \pi_i(t, x, s, d) \cdot v_i(\rho_i(t, x)) = 0. \tag{2.7}$$

This equation is coupled with (2.3) on each line I_i. More precisely, (2.7) depends on the solution of (2.3), while in turn at junctions the values of π_i will determine the traffic distribution on outgoing lines as explained below.

For simplicity and without loss of generality, we assume from now on that the fluxes f_i are all the same, and we indicate them with f. Thus, the model for a single transmission line consists of the system of equations

$$\begin{cases} \rho_t + f(\rho)_x = 0, \\ \pi_t + \pi_x \cdot v(\rho) = 0. \end{cases}$$

To treat the evolution at a junction, let us introduce some notation. Fix a junction J with n incoming transmission lines, say $I_1, \dots, I_n$, and m outgoing transmission lines, say $I_{n+1}, \dots, I_{n+m}$. A weak solution at J is a collection of functions $\rho_l : [0, +\infty[\times I_l \mapsto \mathbb{R}$, $l = 1, \dots, n+m$, such that

$$\sum_{l=1}^{n+m} \left(\int_0^{+\infty} \int_{a_l}^{b_l} \left(\rho_l \frac{\partial \varphi_l}{\partial t} + f(\rho_l) \frac{\partial \varphi_l}{\partial x} \right) dx dt \right) = 0, \tag{2.8}$$

for every φ_l, $l = 1, \dots, n+m$, smooth having compact support in $]0, +\infty[\times]a_l, b_l]$ for $l = 1, \dots, n$ (incoming transmission lines) and in $]0, +\infty[\times [a_l, b_l[$ for $l = n+1, \dots, n+m$ (outgoing transmission lines), that are also smooth across the junction, i.e.,

$$\varphi_i(\cdot, b_i) = \varphi_j(\cdot, a_j), \quad \frac{\partial \varphi_i}{\partial x}(\cdot, b_i) = \frac{\partial \varphi_j}{\partial x}(\cdot, a_j), \quad i = 1, \dots, n, j = n+1, \dots, n+m.$$

REMARK 2.3. *Let $\rho = (\rho_1, \dots, \rho_{n+m})$ be a weak solution at the junction J such that each $x \to \rho_i(t, x)$ has bounded variation. We can deduce that ρ satisfies the Rankine–Hugoniot condition at J, namely*

$$\sum_{i=1}^{n} f(\rho_i(t, b_i-)) = \sum_{j=n+1}^{n+m} f(\rho_j(t, a_j+)),$$

for almost every $t > 0$.

For a scalar conservation law a Riemann problem is a Cauchy problem for an initial data of Heaviside type, that is, piecewise constant with only one discontinuity. One looks for centered solutions, i.e., $\rho(t, x) = \phi(\frac{x}{t})$ formed by simple waves, which are the building blocks to construct solutions to the Cauchy problem via a wave-front tracking algorithm. These solutions are formed by continuous waves called rarefactions and by travelling discontinuities called shocks. The speed of waves is related to the values of f'; see [6], [8], [19], [20].

Analogously, we call the Riemann problem for a junction the Cauchy problem corresponding to initial data $\rho_{1,0}, \dots, \rho_{n+m,0} \in [0, 1]$, and $\pi_1^{s,d}, \dots, \pi_{n+m}^{s,d} \in [0, 1]$, which are constant on each transmission line.

DEFINITION 2.4. *A Riemann solver (RS) for the junction J is a map that associates with Riemann data $\rho_0 = (\rho_{1,0}, \dots, \rho_{n+m,0})$ and $\Pi_0 = (\pi_{1,0}, \dots, \pi_{n+m,0})$ at J the vectors $\hat{\rho} = (\hat{\rho}_1, \dots, \hat{\rho}_{n+m})$ and $\hat{\Pi} = (\hat{\pi}_1, \dots, \hat{\pi}_{n+m})$ so that the solution on an incoming transmission line I_i, $i = 1, \dots, n$, is given by the wave $(\rho_{i,0}, \hat{\rho}_i)$ and on an outgoing one I_j, $j = n+1, \dots, n+m$, is given by the waves $(\hat{\rho}_j, \rho_{j,0})$ and $(\hat{\pi}_j, \pi_{j,0})$. We require the following consistency condition:*

(CC) $RS(RS(\rho_0, \Pi_0)) = RS(\rho_0, \Pi_0)$.

We will define an RS at a junction in the next sections. Once an RS is defined and the solution of the Riemann problem is obtained, we can define admissible solutions at junctions.

DEFINITION 2.5. *Assume an RS is assigned. Let $\rho = (\rho_1, \ldots, \rho_{n+m})$ and $\Pi = (\pi_1, \ldots, \pi_{n+m})$ be such that $\rho_i(t, \cdot)$ and $\pi_i(t, \cdot)$ are of bounded variation for every $t \geq 0$. Then (ρ, Π) is an admissible weak solution of* (1.1) *related to the RS at the junction J if and only if the following properties hold:*

1. *ρ is a weak solution at junction J;*
2. *Π is a weak solution at junction J;*
3. *for almost every t setting*

$$\rho_J(t) = (\rho_1(\cdot, b_1-), \ldots, \rho_n(\cdot, b_n-), \rho_{n+1}(\cdot, a_{n+1}+), \ldots, \rho_{n+m}(\cdot, a_{n+m}+)),$$
$$\Pi_J(t) = (\pi_1(\cdot, b_1-), \ldots, \pi_n(\cdot, b_n-), \pi_{n+1}(\cdot, a_{n+1}+), \ldots, \pi_{n+m}(\cdot, a_{n+m}+))$$

we have

$$RS(\rho_J(t), \Pi_J(t)) = (\rho_J(t), \Pi_J(t)).$$

Given an admissible network (see [12]) we have to specify how to define a solution.

DEFINITION 2.6. *Consider an admissible network $(N, \mathcal{I}, \mathcal{F}, \mathcal{J}, \mathcal{S}, \mathcal{D}, \mathcal{R})$. A set of initial-boundary conditions (IBC) is given assigning measurable functions $\bar{\rho}_i : I_i \mapsto [0, \rho_i^{\max}]$, $\bar{\pi}_i : [a_i, b_i] \times \mathcal{S} \times \mathcal{D} \mapsto [0, 1]$, $i = 1, \ldots, N$, and measurable functions $\psi_i : [0, +\infty[\mapsto [0, \rho_i^{\max}]$, $i \in \mathcal{S} \cup \mathcal{D}$, and $\vartheta_{i,j} : [0, +\infty[\mapsto [0, 1]$, $i \in \mathcal{S}$, $j \in \mathcal{D}$, with the property that $\sum_j \vartheta_{i,j}(t) = 1$.*

DEFINITION 2.7. *Consider an admissible network $(N, \mathcal{I}, \mathcal{F}, \mathcal{J}, \mathcal{S}, \mathcal{D}, \mathcal{R})$ and a set of IBC. A set of functions $\rho = (\rho_1, \ldots, \rho_N)$ with $\rho_i : [0, +\infty[\times I_i \mapsto [0, \rho_i^{\max}]$ continuous as functions from $[0, +\infty[$ into L^1, and $\Pi = (\pi_1, \ldots, \pi_N)$ with $\pi_i : [0, +\infty[\times I_i \times \mathcal{S} \times \mathcal{D} \mapsto [0, 1]$ continuous as functions from $[0, +\infty[$ into L^1 for every $s \in \mathcal{S}$, $d \in \mathcal{D}$, is an admissible solution if the following holds. Each ρ_i is a weak entropic solution to* (2.3) *on I_i, $\rho_i(0, x) = \bar{\rho}_i(x)$ for almost every $x \in [a_i, b_i]$, $\rho_i(t, a_i) = \psi_i(t)$ if $i \in S$ and $\rho_i(t, b_i) = \psi_i(t)$ if $i \in \mathcal{D}$ in the sense of* [5]. *Each π_i is a weak solution to the corresponding equation* (2.7), *$\pi_i(0, x) = \bar{\pi}_i(x)$ for almost every $x \in [a_i, b_i]$, and for every $i \in \mathcal{S}$, $j \in \mathcal{D}$ $\pi_i^{i,j}(t, a_i) = \vartheta_{i,j}$ in the sense of* [5]. *Finally, at each junction (ρ, Π) is a weak solution and is an admissible weak solution in the case of bounded variation.*

3. Traffic distribution at junctions.

3. Traffic distribution at junctions. Consider a junction J in which there are n transmission lines with incoming traffic and m transmission lines with outgoing traffic.

We denote by $\rho_i(t, x)$, $i = 1, \ldots, n$, and $\rho_j(t, x)$, $j = n+1, \ldots, n+m$, the traffic densities, respectively, on the incoming transmission lines and on the outgoing ones and by $(\rho_{1,0}, \ldots, \rho_{n+m,0})$ the initial datum.

Define $\gamma_i^{\max}$ and $\gamma_j^{\max}$ as follows:

$$\gamma_i^{\max} = \begin{cases} f(\rho_{i,0}) & \text{if } \rho_{i,0} \in [0, \sigma], \\ f(\sigma) & \text{if } \rho_{i,0} \in]\sigma, 1], \end{cases} \quad i = 1, \ldots, n, \tag{3.1}$$

and

$$\gamma_j^{\max} = \begin{cases} f(\sigma) & \text{if } \rho_{j,0} \in [0, \sigma], \\ f(\rho_{j,0}) & \text{if } \rho_{j,0} \in]\sigma, 1], \end{cases} \quad j = n+1, \ldots, n+m. \tag{3.2}$$

The quantities $\gamma_i^{\max}$ and $\gamma_j^{\max}$ represent the maximum flux that can be obtained by a single wave solution on each transmission line. Finally, denote by

$$\begin{aligned}\Omega_i &= [0, \gamma_i^{\max}], \quad i = 1, \dots, n,\\ \Omega_j &= [0, \gamma_j^{\max}], \quad j = n+1, \dots, n+m,\end{aligned}$$

and by $\hat{\gamma}_{inc} = (f(\hat{\rho}_i), \dots, f(\hat{\rho}_n))$, $\hat{\gamma}_{out} = (f(\hat{\rho}_{n+1}), \dots, f(\hat{\rho}_{n+m}))$, where $\hat{\rho} = (\hat{\rho}_1, \dots, \hat{\rho}_{n+m})$ is the solution of the Riemann problem at the junction.

Now, we discuss some possible choices for the traffic distribution function:

(1) $r_J : \mathrm{Inc}(J) \times \mathcal{S} \times \mathcal{D} \to \mathrm{Out}(J)$.

(2) $r_J : \mathrm{Inc}(J) \times \mathcal{S} \times \mathcal{D} \hookrightarrow \mathrm{Out}(J)$; i.e., r_J is a multifunction.

If r_J is of type (1), then each packet has a deterministic route; this means that, at the junction J, the traffic that started at source s and has d as the final destination, coming from the transmission line i, is routed on an assigned line j ($r_J(i, s, d) = j$).

Instead, if r_J is of type (2), at the junction J, the traffic with source s and destination d, coming from a line i, is routed on every line $I_j \in \mathrm{Out}(J)$ or on some lines $I_j \in \mathrm{Out}(J)$. We can define $r_J(i, s, d)$ in two different ways:

(2a) $r_J : \mathrm{Inc}(J) \times \mathcal{S} \times \mathcal{D} \hookrightarrow \mathrm{Out}(J)$,
$r_j(i, s, d) \subseteq \mathrm{Out}(J)$;

(2b) $r_J : \mathrm{Inc}(J) \times \mathcal{S} \times \mathcal{D} \to [0, 1]^{\mathrm{Out}(J)}$,
$r_J(i, s, d) = (\alpha_J^{i,s,d,n+1}, \dots, \alpha_J^{i,s,d,n+m})$
with $0 \le \alpha_J^{i,s,d,j} \le 1$, $j \in \{n+1, \dots, n+m\}$, $\sum_{j=n+1}^{n+m} \alpha_J^{i,s,d,j} = 1$.

In case (2a) we have to specify in which way the traffic at junction J is split towards the outgoing lines.

The definition (2b) means that, at the junction J, the traffic with source s and destination d, coming from line I_i, is routed on the outgoing line j, $j = n+1, \dots, n+m$, with probability $\alpha_J^{i,s,d,j}$.

Let us analyze how the distribution matrix A is constructed using π and r_J.

Definition 3.1. *A distribution matrix is a matrix*

$$A \doteq \{\alpha_{j,i}\}_{j=n+1,\dots,n+m, i=1,\dots,n} \in \mathbb{R}^{m \times n}$$

such that

$$0 < \alpha_{j,i} < 1, \qquad \sum_{j=n+1}^{n+m} \alpha_{j,i} = 1,$$

for each $i = 1, \dots, n$ and $j = n+1, \dots, n+m$, where $\alpha_{j,i}$ is the percentage of packets arriving from the ith incoming transmission line that take the jth outgoing transmission line.

In case (1) we can define the matrix A in the following way. Fix a time t, and assume that for all $i \in \mathrm{Inc}(J)$, $s \in \mathcal{S}$, and $d \in \mathcal{D}$, $\pi_i(t, \cdot, s, d)$ admits a limit at the junction J, i.e., the left limit at b_i. For $i \in \{1, \dots, n\}$, $j \in \{n+1, \dots, n+m\}$, we set

$$\alpha_{j,i} = \sum_{\substack{s \in \mathcal{S}, d \in \mathcal{D},\\ r_J(i,s,d) = j}} \pi_i(t, b_i-, s, d).$$

The fluxes $f_i(\rho_i)$ to be consistent with the traffic-type functions must satisfy the following relation:

$$f_j(\rho_j(\cdot, a_j+)) = \sum_{i=1}^{n} \alpha_{j,i} f_i(\rho_i(\cdot, b_i-))$$

for each $j = n+1, \dots, n+m$.

Let us analyze how to define the matrix A in case (2a). We may assign $\varphi(i,s,d) \in r_J(i,s,d)$ and set

$$\alpha_{j,i} = \sum_{\substack{s\in\mathcal{S},d\in\mathcal{D},\\ i:\varphi(i,s,d)=j}} \pi_i(t,b_i-,s,d),$$
$$\alpha_{j,i} = 0 \text{ if } j \notin r_J(i,s,d).$$

Example 3.2. *Fix a junction J with two incoming lines $\{1,2\}$ and two outgoing lines $\{3,4\}$, and suppose that $r_J(1,s,d) = \{3,4\}$ and $r_J(2,s,d) = \{3\}$. Since $\alpha_{4,2} = 0$, we have $\alpha_{3,2} = 1$. The coefficients $\alpha_{3,1}$ and $\alpha_{4,1}$ can assume the following values:*

$$\begin{cases} \alpha_{3,1} = 0, \\ \alpha_{4,1} = 1, \end{cases} \quad or \quad \begin{cases} \alpha_{3,1} = 1, \\ \alpha_{4,1} = 0. \end{cases}$$

We get a finite number of possible distribution matrices A:

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \qquad A = \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}.$$

Remark 3.3. *This model proposes an exclusive strategy; in fact all packet flow at the junction is routed from line 1 to line 3 or to line 4.*

However, it is more natural to assign a flexible strategy defining a set of admissible matrices A in the following way:

$$\mathcal{A} = \left\{ \begin{array}{c} A : \exists \alpha_J^{i,s,d,j} \in [0,1], \displaystyle\sum_{j=n+1}^{n+m} \alpha_J^{i,s,d,j} = 1, \alpha_J^{i,s,d,j} = 0 \text{ if } j \notin r_J(i,s,d) : \\ \alpha_{j,i} = \displaystyle\sum_{\substack{s\in\mathcal{S},d\in\mathcal{D},\\ j\in r_J(i,s,d)}} \pi_i(t,b_i-,s,d)\alpha_J^{i,s,d,j} \end{array} \right\}.$$

Finally, we now treat case (2b).

In this case the matrix A is unique and is defined by

$$\alpha_{j,i} = \sum_{s\in\mathcal{S},d\in\mathcal{D}} \pi_i(t,b_i-,s,d)\alpha_J^{i,s,d,j}. \tag{3.3}$$

4. Riemann solvers at junctions. In this section we define solutions to Riemann problems at junctions, since this is the basic ingredient to construct solutions to Cauchy problems via a wave-front tracking algorithm.

We describe two different Riemann solvers at a junction that represent two different routing algorithms:

(RA1) We assume that
  (A) the traffic from incoming transmission lines is distributed on outgoing transmission lines according to fixed coefficients;
  (B) respecting (A) the router chooses to send packets in order to maximize fluxes (i.e., the number of packets which are processed).

(RA2) We assume that the number of packets through the junction is maximized both over incoming and outgoing lines.

Remark 4.1. *In what follows we analyze the case in which the traffic distribution function is of type (2). Case (1) has been considered in [12] using the following rule:*

(RGP) *We assume that*

(A) *the traffic from incoming transmission lines is distributed on outgoing transmission lines according to fixed coefficients;*

(B) *respecting* (A) *the router chooses to send packets in order to maximize*

$$c_2 \sum_{i=1}^{n} f_i(\rho_i(\cdot, b_i-)) - c_1[dist((f_1(\rho_1(\cdot, b_1-)), \ldots, f_n(\rho_n(\cdot, b_n-))), r)]^2$$

subject to

$$f_j(\rho_j(\cdot, a_j+)) = \sum_{i=1}^{n} \alpha_{j,i} f_i(\rho_i(\cdot, b_i-)) \quad \textit{for each } j = n+1, \ldots, n+m,$$

where c_1 and c_2 are strictly positive constants, and $dist(\cdot, r)$ denotes the Euclidean distance in $\mathbb{R}^n$ from the line r, which is given by

$$\begin{cases} \gamma_2 = p_1\gamma_1, \\ \vdots \\ \gamma_n = p_{n-1}\gamma_{n-1}, \end{cases}$$

and $(p_1, \ldots, p_{n-1})$ determine a "level of priority" at the junctions of incoming lines. This maximization procedure takes into account priorities over incoming roads and ensures continuity of solutions with respect to the coefficients π.

4.1. Algorithm (RA1). We have to distinguish cases (2a) and (2b).

In case (2a) in order to solve the Riemann problem at the junction we have to prove that the admissible region is convex. First we prove the following lemma.

Lemma 4.2. *The set $\mathcal{A}$ is convex.*

Proof. Let us consider a convex combination $\lambda A_1 + (1-\lambda)A_2$ with $\lambda \in [0,1], A_1, A_2 \in \mathcal{A}$. We have

$$\begin{aligned}(\lambda A_1 + (1-\lambda)\mathcal{A}_2)_{i,j} &= \lambda \sum_{\substack{s\in\mathcal{S}, d\in\mathcal{D},\\ j\in r_J(i,s,d)}} \pi_i \alpha_{J,1}^{i,s,d,j} + (1-\lambda) \sum_{\substack{s\in\mathcal{S}, d\in\mathcal{D},\\ j\in r_J(i,s,d)}} \pi_i \alpha_{J,2}^{i,s,d,j} \\ &= \sum_{\substack{s\in\mathcal{S}, d\in\mathcal{D},\\ j\in r_J(i,s,d)}} \pi_i(\lambda\alpha_{J,1}^{i,s,d,j} + (1-\lambda)\alpha_{J,2}^{i,s,d,j}) = \sum_{\substack{s\in\mathcal{S}, d\in\mathcal{D},\\ j\in r_J(i,s,d)}} \pi_i \hat{\alpha}_J^{i,s,d,j},\end{aligned}$$

with $\hat{\alpha}_J^{i,s,d,j} \in [0,1]$. Moreover,

$$\sum_{j=n+1}^{n+m} \hat{\alpha}_J^{i,s,d,j} = \sum_{j=n+1}^{n+m} (\lambda\alpha_{J,1}^{i,s,d,j} + (1-\lambda)\alpha_{J,2}^{i,s,d,j}) = \lambda \sum_{j=n+1}^{n+m} \alpha_{J,1}^{i,s,d,j} + (1-\lambda) \sum_{j=n+1}^{n+m} \alpha_{J,2}^{i,s,d,j} = 1;$$

then $\lambda A_1 + (1-\lambda)A_2 \in \mathcal{A}$. □

Now recall that the admissible region is given by

$$\Omega_{adm} = \{\hat{\gamma} : \hat{\gamma} \in \Omega_1 \times \cdots \times \Omega_n, \exists A \in \mathcal{A}\ t.c. A\hat{\gamma} \in \Omega_{n+1} \times \cdots \times \Omega_{n+m}\}.$$

We can prove that this region is convex at least for the case of junctions with two incoming and two outgoing lines; more precisely, we have the following lemma.

Lemma 4.3. *Fix a junction J with $n = 2$ incoming lines and $m = 2$ outgoing ones, and assume that there is a unique source and a unique destination. Then the set Ω_{adm} is convex.*

Proof. We have to consider the following cases:

(i) $r_J(1,s,d)=3$ and $r_J(2,s,d)=3$;
(ii) $r_J(1,s,d)=3$ and $r_J(2,s,d)=4$;
(iii) $r_J(1,s,d)=\{3,4\}$ and $r_J(2,s,d)=4$;
(iv) $r_J(1,s,d)=\{3,4\}$ and $r_J(2,s,d)=\{3,4\}$.

All other cases can be obtained by relabelling lines. Cases (i) and (ii) are immediate, since $\hat\gamma\in\Omega_1\times\Omega_2$ satisfies $\hat\gamma\in\Omega_{adm}$ if and only if $\hat\gamma_1+\hat\gamma_2\le\gamma_3^{max}$ (case i) or $\hat\gamma_1\le\gamma_3^{max}$ and $\hat\gamma_2\le\gamma_4^{max}$ (case ii).

Now consider case (iii). Then $A\hat\gamma$, $A\in\mathcal{A}$, is the segment joining the point $(\hat\gamma_1,\hat\gamma_2)$ to the point $(0,\hat\gamma_1+\hat\gamma_2)$. Thus $\hat\gamma\in\Omega_1\times\Omega_2$ satisfies $\hat\gamma\in\Omega_{adm}$ if and only if $\hat\gamma_1+\hat\gamma_2\le\gamma_3^{max}+\gamma_4^{max}$ and $\hat\gamma_2\le\gamma_3^{max}$.

Finally, assume case (iv) holds true. Then $A\hat\gamma$, $A\in\mathcal{A}$, is the segment joining the point $(\hat\gamma_1+\hat\gamma_2,0)$ to the point $(0,\hat\gamma_1+\hat\gamma_2)$. Thus $\hat\gamma\in\Omega_1\times\Omega_2$ satisfies $\hat\gamma\in\Omega_{adm}$ if and only if $\hat\gamma_1+\hat\gamma_2\le\gamma_3^{max}+\gamma_4^{max}$. □

If the region Ω_{adm} is convex, then rules (A) and (B) amount to the linear programming problem:

$$\max_{\hat\gamma\in\Omega_{adm}}(\hat\gamma_1+\hat\gamma_2).$$

This problem clearly has a solution, which may not be unique.

Let us consider case (2b). We need some more notation.

Definition 4.4. *Let $\tau:[0,1]\to[0,1]$ be the map such that*

1. *$f(\tau(\rho))=f(\rho)$ for every $\rho\in[0,1]$;*
2. *$\tau(\rho)\neq\rho$ for every $\rho\in[0,1]\backslash\{\sigma\}$.*

Clearly, τ is well defined and satisfies

$$0\le\rho\le\sigma\Leftrightarrow\sigma\le\tau(\rho)\le1,$$
$$\sigma\le\rho\le1\Leftrightarrow0\le\tau(\rho)\le\sigma.$$

To state the main result of this section we need some assumption on the matrix A (satisfied under generic conditions for $m=n$). Let $\{e_1,\dots,e_n\}$ be the canonical basis of $\mathbb{R}^n$, and for every subset $V\subset\mathbb{R}^n$ indicate by $V^\perp$ its orthogonal. Define for every $i=1,\dots,n$, $H_i=\{e_i\}^\perp$, i.e., the coordinate hyperplane orthogonal to e_i, and for every $j=n+1,\dots,n+m$ let $\alpha_j=\{\alpha_{j1},\dots,\alpha_{jn}\}\in\mathbb{R}^n$, and define $H_j=\{\alpha_j\}^\perp$. Let $\mathcal{K}$ be the set of indices $k=(k_1,\dots,k_l)$, $1\le l\le n-1$, such that $0\le k_1<k_2<\dots<k_l\le n+m$, and for every $k\in\mathcal{K}$ set $H_k=\bigcap_{h=1}^{l}H_h$. Letting $\mathbf{1}=(1,\dots,1)\in\mathbb{R}^n$, we assume that

(C) for every $k\in\mathcal{K}$, $\mathbf{1}\notin H_k^\perp$.

In case (2b) the following result holds.

Theorem 4.5 (Theorem 3.1 in [7] and 3.2 in [12]). *Let $(N,\mathcal{I},\mathcal{F},\mathcal{J},\mathcal{S},\mathcal{D},\mathcal{R})$ be an admissible network and J a junction with n incoming lines and m outgoing ones. Assume that the flux $f:[0,1]\to\mathbb{R}$ satisfies* (F) *and the matrix A satisfies condition* (C). *For every $\rho_{1,0},\dots,\rho_{n+m,0}\in[0,1]$, and for every $\pi_1^{s,d},\dots,\pi_{n+m}^{s,d}\in[0,1]$, there exist densities $\hat\rho_1,\dots,\hat\rho_{n+m}$ and a unique admissible centered weak solution, $\rho=(\rho_1,\dots,\rho_{n+m})$, at the junction J such that*

$$\rho_1(0,\cdot)\equiv\rho_{1,0},\dots,\rho_{n+m}(0,\cdot)\equiv\rho_{n+m,0},$$
$$\pi^1(0,\cdot,s,d)=\pi_1^{s,d},\dots,\pi^{n+m}(0,\cdot,s,d)=\pi_{n+m}^{s,d}(s\in\mathcal{S},d\in\mathcal{D}).$$

We have

$$\hat{\rho}_i \in \left\{ \begin{array}{ll} \{\rho_{i,0}\} \cup]\tau(\rho_{i,0}), 1] & \text{if } 0 \le \rho_{i,0} \le \sigma, \\ [\sigma, 1] & \text{if } \sigma \le \rho_{i,0} \le 1, \end{array} \right. \quad i = 1, \dots, n, \tag{4.1}$$

$$\hat{\rho}_j \in \left\{ \begin{array}{ll} [0, \sigma] & \text{if } 0 \le \rho_{j,0} \le \sigma, \\ \{\rho_{j,0}\} \cup [0, \tau(\rho_{j,0})[& \text{if } \sigma \le \rho_{j,0} \le 1, \end{array} \right. \quad j = n+1, \dots, n+m, \tag{4.2}$$

and on each incoming line I_i, $i = 1, \dots, n$, the solution consists of the single wave $(\rho_{i,0}, \hat{\rho}_i)$, while on each outgoing line I_j, $j = n+1, \dots, n+m$, the solution consists of the single wave $(\hat{\rho}_j, \rho_{j,0})$. Moreover, $\hat{\pi}_i(t, \cdot, s, d) = \pi_i^{s,d}$ for every $t \ge 0$, $i \in \{1, \dots, n\}$, $s \in \mathcal{S}$, $d \in \mathcal{D}$, and

$$\hat{\pi}_j(t, a_j+, s, d) = \frac{\sum_{i=1}^n \alpha_J^{i,s,d,j} \pi_i^{s,d}(t, b_i-, s, d) f(\hat{\rho}_i)}{f(\hat{\rho}_j)}$$

for every $t \ge 0$, $j \in \{n+1, \dots, n+m\}$, $s \in \mathcal{S}$, $d \in \mathcal{D}$.

4.2. Algorithm (RA2). To solve Riemann problems according to (RA2) we need some additional parameters called priority and traffic distribution parameters. For simplicity of exposition, consider first a junction J in which there are two transmission lines with incoming traffic and two transmission lines with outgoing traffic. In this case we have only one priority parameter $q \in]0, 1[$ and one traffic distribution parameter $\alpha \in]0, 1[$. We denote by $(\rho_{1,0}, \rho_{2,0}, \rho_{3,0}, \rho_{4,0})$ and $(\pi_{1,0}^{s,d}, \pi_{2,0}^{s,d}, \pi_{3,0}^{s,d}, \pi_{4,0}^{s,d})$ the initial data.

In order to maximize the number of packets through the junction over incoming and outgoing lines we define

$$\Gamma = \min \{\Gamma_{in}^{\max}, \Gamma_{out}^{\max}\},$$

where $\Gamma_{in}^{\max} = \gamma_1^{\max} + \gamma_2^{\max}$ and $\Gamma_{out}^{\max} = \gamma_3^{\max} + \gamma_4^{\max}$. Thus we want to have Γ as the flux through the junction.

One easily sees that to solve the Riemann problem, it is enough to determine the fluxes $\hat{\gamma}_i = f(\hat{\rho}_i)$, $i = 1, 2$. In fact, to have simple waves with the appropriate velocities, i.e., negative on incoming lines and positive on outgoing ones, we get the constraints (4.1), (4.2). Observe that we compute $\hat{\gamma}_i = f(\hat{\rho}_i)$, $i = 1, 2$, without taking into account the type of traffic distribution function.

We have to distinguish two cases:

I. $\Gamma_{in}^{\max} = \Gamma$;

II. $\Gamma_{in}^{\max} > \Gamma$.

In the first case we set $\hat{\gamma}_i = \gamma_i^{\max}$, $i = 1, 2$.

Let us analyze the second case in which we use the priority parameter q. Not all packets can enter the junction, and so let C be the amount of packets that can go through. Then qC packets come from the first incoming line and $(1 - q)C$ packets from the second. Consider the space (γ_1, γ_2), and define the following lines:

$$r_q : \gamma_2 = \frac{1 - q}{q} \gamma_1,$$
$$r_\Gamma : \gamma_1 + \gamma_2 = \Gamma.$$

Define P to be the point of intersection of the lines r_q and r_Γ. Recall that the final fluxes should belong to the region (see Figure 4.1):

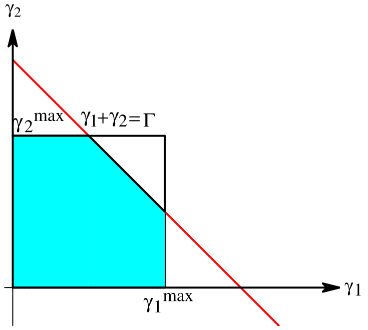

FIG. 4.1. *Case* $\Gamma_{in}^{\max} > \Gamma$.

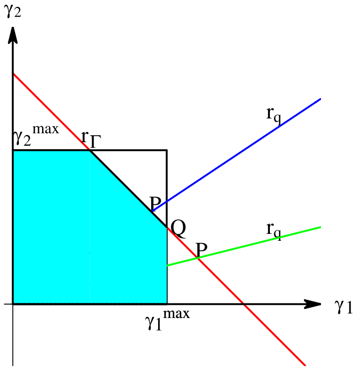

FIG. 4.2. *P belongs to* Ω, *and P is outside* Ω.

$$\Omega = \{(\gamma_1, \gamma_2) : 0 \leq \gamma_i \leq \gamma_i^{\max}, i = 1, 2\}.$$

We distinguish two cases:

(a) P belongs to Ω;

(b) P is outside Ω.

In the first case we set $(\hat{\gamma}_1, \hat{\gamma}_2) = P$, while in the second case we set $(\hat{\gamma}_1, \hat{\gamma}_2) = Q$, with $Q = proj_{\Omega \cap r_\Gamma}(P)$, where $proj$ is the usual projection on a convex set; see Figure 4.2.

The reasoning can be repeated also in the case of n incoming lines. In $\mathbb{R}^n$ the line r_q is given by $r_q = tv_q$, $t \in \mathbb{R}$, with $v_q \in \Delta_{n-1}$, where

$$\Delta_{n-1} = \left\{(\gamma_1, \dots, \gamma_n) : \gamma_i \geq 0, i = 1, \dots, n, \sum_{i=1}^{n} \gamma_i = 1\right\}$$

is the $(n-1)$ dimensional simplex and

$$H_\Gamma = \left\{(\gamma_1, \dots, \gamma_n) : \sum_{i=1}^{n} \gamma_i = \Gamma\right\}$$

is a hyperplane where $\Gamma = \min\{\sum_{in} \gamma_i^{\max}, \sum_{out} \gamma_j^{\max}\}$. Since $v_q \in \Delta_{n-1}$, there exists a unique point $P = r_q \cap H_\Gamma$. If $P \in \Omega$, then we set $(\hat{\gamma}_1, \dots, \hat{\gamma}_n) = P$. If $P \notin \Omega$, then we set $(\hat{\gamma}_1, \ldots, \hat{\gamma}_n) = Q = proj_{\Omega \cap H_\Gamma}(P)$, the projection over the subset $\Omega \cap H_\Gamma$. Observe that the projection is unique since $\Omega \cap H_\Gamma$ is a closed convex subset of H_Γ.

Remark 4.6. *A possible alternative definition in the case $P \notin \Omega$ is to set $(\hat{\gamma}_1, \ldots, \hat{\gamma}_n)$ as one of the vertices of $\Omega \cap H_\Gamma$.*

As for algorithm (RA1) $\hat{\pi}_i^{s,d} = \pi_{i,0}^{s,d}$, $i = 1, 2$.

Let us now determine $\hat{\gamma}_j$, $j = 3, 4$.

As for the incoming transmission lines we have to distinguish two cases:

I. $\Gamma_{out}^{\max} = \Gamma$;

II. $\Gamma_{out}^{\max} > \Gamma$.

In the first case $\hat{\gamma}_j = \gamma_j^{\max}$, $j = 3, 4$. Let us determine $\hat{\gamma}_j$ in the second case.

Recall α, the traffic distribution parameter. Since not all packets can go on the outgoing transmission lines, we let C be the amount that goes through. Then αC packets go on the outgoing line I_3 and $(1-\alpha)C$ on the outgoing line I_4. Consider the space (γ_3, γ_4), and define the following lines:

$$r_\alpha : \gamma_4 = \frac{1-\alpha}{\alpha}\gamma_3,$$
$$r_\Gamma : \gamma_3 + \gamma_4 = \Gamma.$$

The line r_α can be computed from the matrix A. In fact, if we assume that a traffic distribution matrix A is assigned, then we compute $\hat{\gamma}_1, \ldots, \hat{\gamma}_n$ and choose $v_\alpha \in \Delta_{m-1}$ by

$$v_\alpha = \Delta_{m-1} \cap \{tA(\hat{\gamma}_1, \ldots, \hat{\gamma}_n) : t \in \mathbb{R}\},$$

where

$$\Delta_{m-1} = \left\{(\gamma_{n+1}, \ldots, \gamma_{m+n}) : \gamma_{n+i} \geq 0, i = 1, \ldots, m, \sum_{i=1}^{n} \gamma_{n+i} = 1\right\}$$

is the $(m-1)$ dimensional simplex.

We have to distinguish cases (2a) and (2b) for the traffic distribution function.

Case (2a). Let us introduce the set

$$\mathcal{G} = \left\{A\hat{\gamma}_{inc}^T : A \in \mathcal{A}\right\}.$$

Lemma 4.7. *The set $\mathcal{G}$ is connected.*

Proof. The set $\mathcal{G}$ is the image of a connected set through a continuous map. With fixed $(\hat{\gamma}_1, \hat{\gamma}_2)$ the map is defined by

$$(\tilde{\alpha}_J^{1,s,d,3}, \tilde{\alpha}_J^{2,s,d,3}) \in [0,1] \times [0,1] \to (\Sigma, \hat{\gamma}_1 + \hat{\gamma}_2 - \Sigma),$$

where $\Sigma = \sum_{s,d}(\hat{\gamma}_1 \pi_1^{s,d} \tilde{\alpha}_J^{1,s,d,3} + \hat{\gamma}_2 \pi_2^{s,d} \tilde{\alpha}_J^{2,s,d,3})$. □

Let us denote with G_1 and G_2 the endpoints of this set. Since in case (2a) we have an infinite number of matrices A, each one determining a line r_α, we choose the most “natural” line r_α, i.e., the one nearest to the statistic line determined by measurements on the network.

Recall that the final fluxes should belong to the region:

$$\Omega = \left\{(\gamma_3, \gamma_4) : 0 \leq \gamma_j \leq \gamma_j^{\max}, j = 3, 4\right\}.$$

Define $P = r_\alpha \cap r_\Gamma$, $R = (\Gamma - \gamma_4^{\max}, \gamma_4^{\max})$, $Q = (\gamma_3^{\max}, \Gamma - \gamma_3^{\max})$. We distinguish three cases:

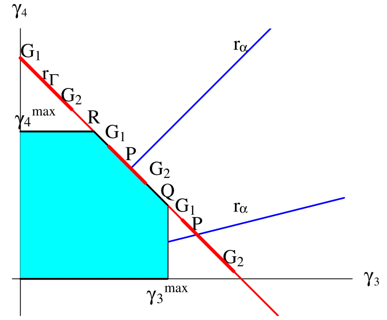

Fig. 4.3. *Traffic distribution function of type* (2a).

(a) $\mathcal{G} \cap \Omega \cap r_\Gamma \neq \varnothing$;
(b) $\mathcal{G} \cap \Omega \cap r_\Gamma = \varnothing$ and $\gamma_3(G_1) < \gamma_3(R)$;
(c) $\mathcal{G} \cap \Omega \cap r_\Gamma = \varnothing$ and $\gamma_3(G_1) > \gamma_3^{\max}$.

If the set $\mathcal{G}$ has a priority over the line r_Γ, we set $(\hat{\gamma}_3, \hat{\gamma}_4)$ in the following way. In case (a) we define $(\hat{\gamma}_3, \hat{\gamma}_4) = proj_{\mathcal{G}\cap\Omega\cap r_\Gamma}(P)$, in case (b) $(\hat{\gamma}_3, \hat{\gamma}_4) = R$, and finally in case (c) $(\hat{\gamma}_3, \hat{\gamma}_4) = Q$. The three cases are shown in Figure 4.3.

Otherwise, if r_Γ has a priority over $\mathcal{G}$, we set $(\hat{\gamma}_3, \hat{\gamma}_4) = \min_{\gamma\in\Omega} \mathcal{F}(\gamma, r_\alpha, \mathcal{G})$, where $\mathcal{F}$ is a convex functional which depends on γ, r_α, and the set $\mathcal{G}$ of the routing standards. A possible choice of $\mathcal{F}$ is $\mathcal{F} = d(\gamma, B)$, where $B = w_1 r_\alpha + w_2 \int_{\mathcal{G}} r dr$ with w_1, w_2 real numbers and d denotes a distance.

The reasoning can also be repeated in the case of m outgoing lines.

The vector $\hat{\pi}_i^{s,d}$, $j = 3, 4$, is computed in the same way as for algorithm (RA1).

Case (2b). In case (2b) we have a unique matrix A and a unique vector v_α, and so the fluxes on outgoing lines are computed as in the case without sources and destinations.

We distinguish two cases:
(a) P belongs to Ω;
(b) P is outside Ω.

In the first case we set $(\hat{\gamma}_3, \hat{\gamma}_4) = P$, while in the second case we set $(\hat{\gamma}_3, \hat{\gamma}_4) = Q$, where $Q = proj_{\Omega_{adm}}(P)$. Again, we can extend to the case of m outgoing lines as for the incoming lines defining the hyperplane $H_\Gamma = \{(\gamma_{n+1}, \ldots, \gamma_{n+m}) : \sum_{j=n+1}^{n+m} \gamma_j = \Gamma\}$ and choosing a vector $v_\alpha \in \Delta_{m-1}$.

Finally, we define $\hat{\pi}_i^{s,d}$, $j = 3, 4$, as in case (2a):

$$\hat{\pi}_j(t, a_j+, s, d) = \frac{\sum_{i=1}^{n} \alpha_J^{i,s,d,j} \pi_i^{s,d}(t, b_i-, s, d) f(\hat{\rho}_i)}{f(\hat{\rho}_j)}$$

for every $t \geq 0$, $j \in \{n+1, \ldots, n+m\}$, $s \in \mathcal{S}$, $d \in \mathcal{D}$.

Remark 4.8. *Note that in the case of algorithm* (RA2) *we find, separately, a solution on incoming and outgoing lines.*

Remark 4.9. *If* $\Gamma_{out}^{\max} < \Gamma_{in}^{\max}$*, we can define a different Riemann solver, considering a priority order of sending packets:* $(s_{k_1}, d_{l_1}) = c_1$, $(s_{k_2}, d_{l_2}) = c_2$, $(s_{k_3}, d_{l_3}) = c_3, \ldots$*. Packets are sent until the quantity of packets that has been sent is equal to*

$$\sum_{\iota=1}^{\bar{\iota}} \sum_{i=1}^{n} \pi_i^{c_\iota} \gamma_{i0},$$

where $\bar{\iota}$ is the minimum such that

$$\sum_{\iota=1}^{\bar{\iota}} \sum_{i=1}^{n} \pi_i^{c_\iota} \gamma_{i0} > \Gamma.$$

Let us define $d = \Gamma - \sum_{\iota=1}^{\bar{\iota}} \sum_{i=1}^{n} \pi_i^{c_\iota} \gamma_{i0}$*; then*

$$\hat{\gamma}_1 = \sum_{\iota=1}^{\bar{\iota}-1} \pi_1^{c_\iota} \gamma_{10} + d/2,$$

$$\hat{\gamma}_2 = \sum_{\iota=1}^{\bar{\iota}-1} \pi_2^{c_\iota} \gamma_{20} + d/2.$$

Once solutions to Riemann problems are given, one can use a wave-front tracking algorithm to construct a sequence of approximate solutions. To pass to the limit one has to bound the number of waves and the BV norm of approximate solutions; see [6, 7]. In the next section we prove a BV bound on the density for the case of junctions with two incoming and two outgoing transmission lines for both of the routing algorithms.

5. Estimates on density variation. In this section we derive estimates on the total variation of the densities along a wave-front tracking approximate solution (constructed as in [7]) for algorithm (RA2) with the traffic distribution function of type (2b). This allows us to construct the solutions to the Cauchy problem in the standard way; see [6].

Let us consider an admissible network $(N, \mathcal{I}, \mathcal{F}, \mathcal{J}, \mathcal{S}, \mathcal{D}, \mathcal{R})$. We assume that

(A1) every junction has at most two incoming and at most two outgoing lines.

This hypothesis is crucial, because the presence of more complicated junctions may provoke additional increases of the total variation of the flux and thus of the density. The case where junctions have at most two incoming transmission lines and at most two outgoing ones can be treated in the same way.

From now on we fix a telecommunication network $(\mathcal{I}, \mathcal{J})$, with each node having at most two incoming and at most two outgoing lines, and a wave-front tracking approximate solution ρ, Π, defined on the telecommunication network.

Our aim is to prove an existence result for a solution (ρ, Π) in the case of a small perturbation of the equilibrium $(\bar{\rho}, \bar{\Pi})$. We have to analyze the following types of interactions:

I1. interaction of ρ-waves with ρ-waves on lines;

I2. interaction of ρ-waves with Π-waves on lines;

I3. interaction of Π-waves with Π-waves on lines;

I4. interaction of ρ-waves with junctions;

I5. interaction of Π-waves with junctions.

Observe that interaction of type I1 is classical and the total variation of the density decreases. Interaction of type I3 cannot happen since Π-waves travel with speed depending only on the value of ρ.

5.1. Interaction of type I2. Let us consider a line I_i. We report some results proved in [12]. First we note that the characteristic speed of the density is smaller than the speed of a Π-wave, as follows from the next lemma.

Lemma 5.1. *Let $\rho \in [0, 1]$ be a density, and let $\lambda(\rho)$ be its characteristic speed. Then $\lambda(\rho) \leq v(\rho)$, and the equality holds if and only if $\rho = 0$.*

Lemma 5.2. *Let us consider a shock wave connecting ρ^- and ρ^+. Then*

1. $\lambda(\rho^-, \rho^+) < v(\rho^-)$;
2. $\lambda(\rho^-, \rho^+) \le v(\rho^+)$ *and the equality holds if and only if* $\rho^- = 0$.

LEMMA 5.3. *Let us consider a rarefaction shock fan connecting* ρ^- *and* ρ^+. *Then* $v(\rho^+) > v(\rho^-) > f'(\rho^-)$.

Putting together the previous lemmas we obtain the following result.

PROPOSITION 5.4. *An interaction of a* ρ*-wave with a* Π*-wave can happen only if the* Π*-wave interacts from the left with respect to the* ρ*-wave. Moreover, if this happens, then the* ρ*-wave does not change, while the* Π*-wave changes only its speed.*

5.2. Interaction of type I4.

We consider interactions of ρ-waves with the junctions. In general these interactions produce an increment of the total variation of the flux and of the density in all the lines and a variation of the values of traffic-type functions on outgoing lines.

Fix a junction J with two incoming transmission lines I_1 and I_2 and two outgoing ones I_3 and I_4. Suppose that at some time $\bar{t}$ a wave interacts with the junction J, and let $(\rho_1^-, \rho_2^-, \rho_3^-, \rho_4^-)$ and $(\rho_1^+, \rho_2^+, \rho_3^+, \rho_4^+)$ indicate the equilibrium configurations at the junction J before and after the interaction, respectively. Introduce the following notation:

$$\gamma_i^{\pm} = f(\rho_i^{\pm}), \quad \Gamma_{in}^{\pm} = \gamma_{1,\max}^{\pm} + \gamma_{2,\max}^{\pm}, \quad \Gamma_{out}^{\pm} = \gamma_{3,\max}^{\pm} + \gamma_{4,\max}^{\pm},$$
$$\Gamma^{\pm} = \min\{\Gamma_{in}^{\pm}, \Gamma_{out}^{\pm}\},$$

where $\gamma_{i,\max}^{\pm}$, $i = 1, 2$, and $\gamma_{j,\max}^{\pm}$, $j = 3, 4$, are defined as in (3.1) and (3.2). In general $-$ and $+$ denote the values before and after the interaction, while by Δ we indicate the variation, i.e., the value after the interaction minus the value before. For example $\Delta\Gamma = \Gamma^+ - \Gamma^-$. Let us denote by $TV(f)^{\pm} = TV(f(\rho(\bar{t}\pm, \cdot)))$ the flux variation of waves before and after the interaction, and

$$TV(f)_{in}^{\pm} = TV(f(\rho_1(\bar{t}\pm, \cdot))) + TV(f(\rho_2(\bar{t}\pm, \cdot))),$$
$$TV(f)_{out}^{\pm} = TV(f(\rho_3(\bar{t}\pm, \cdot))) + TV(f(\rho_4(\bar{t}\pm, \cdot))),$$

the flux variation of waves before and after the interaction, respectively, on incoming and outgoing lines.

Let us prove some estimates which are used later to control the total variation of the density function. For simplicity, from now on we assume that

(A2) the wave interacting at time $\bar{t}$ with J comes from line 1, and we let ρ_1 be the value on the left of the wave.

The case of a wave from an outgoing line can be treated similarly.

LEMMA 5.5. *We have*

$$sgn\,(\Delta\gamma_3) \cdot sgn\,(\Delta\gamma_4) \ge 0.$$

LEMMA 5.6. *We have*

$$sgn(\gamma_1^+ - \gamma_1) \cdot sgn(\Delta\gamma_2) \ge 0,$$

where $\gamma_1 = f(\rho_1)$.

LEMMA 5.7. *It holds that*

$$TV(f)_{out}^{+} = |\Delta\Gamma|.$$

Lemma 5.8. *We have*

$$TV(f)^-_{in} = TV(f)^+_{in} + |\Delta\Gamma|. \tag{5.1}$$

From Lemmas 5.7 and 5.8, we are ready to state the following.

Lemma 5.9. *It holds that*

$$TV(f)^+ = CTV(f)^-.$$

A ρ-wave produces a Π-wave, but the following lemma holds.

Lemma 5.10. *Let J be a junction with at most two incoming lines and two outgoing ones. Suppose that a ρ-wave (ρ_1, ρ_{10}) approaches the junction J. If there exists $\delta > 0$ such that $f(\rho_1) > \delta > 0$, $f(\rho_{1,0}) > \delta > 0$, then there exists $C > 0$, such that the variation of the traffic-type functions in outgoing lines is bounded by C times the flux variation of the interacting wave, i.e.,*

$$TV(\Pi)^+ \leq \frac{C}{\delta} TV(f)^-.$$

Proof. Fix a source $s \in \mathcal{S}$ and a destination $d \in \mathcal{D}$. We denote by $\pi_{i,0}, \rho_{i,0}$ and $\hat{\pi}_i, \hat{\rho}_i$ $(i \in \{1,2,3,4\})$ the values of the densities and of the traffic-type functions for s and d at J, respectively, before and after the interaction of the ρ-wave with J. We have for $j \in \{3,4\}$

$$\begin{aligned}
&|\pi^{s,d}_{j,0} - \hat{\pi}^{s,d}_j| \\
&= \left| \frac{\alpha_J^{1,s,d,j} \pi^{s,d}_{1,0} f(\rho_{1,0})}{f(\rho_{j,0})} + \frac{\alpha_J^{2,s,d,j} \pi^{s,d}_{2,0} f(\rho_{2,0})}{f(\rho_{j,0})} - \frac{\alpha_J^{1,s,d,j} \pi^{s,d}_{2,0} f(\hat{\rho}_1)}{f(\hat{\rho}_j)} - \frac{\alpha_J^{2,s,d,j} \pi^{s,d}_{2,0} f(\hat{\rho}_2)}{f(\hat{\rho}_j)} \right| \\
&\leq \frac{\alpha_J^{1,s,d,j} \pi^{s,d}_{1,0}}{f(\rho_{j,0}) f(\hat{\rho}_j)} |f(\rho_{1,0}) f(\hat{\rho}_j) - f(\hat{\rho}_1) f(\rho_{j,0})| + \frac{\alpha_J^{2,s,d,j} \pi^{s,d}_{2,0}}{f(\rho_{j,0}) f(\hat{\rho}_j)} |f(\rho_{2,0}) f(\hat{\rho}_j) - f(\hat{\rho}_2) f(\rho_{j,0})| \\
&\qquad \leq \frac{C'}{\delta^2} |f(\rho_{1,0})(f(\hat{\rho}_j) - f(\rho_{j,0})) + f(\rho_{j,0})(f(\rho_{1,0}) - f(\hat{\rho}_1))| \\
&\qquad\quad + \frac{C'}{\delta^2} |f(\rho_{2,0})(f(\hat{\rho}_j) - f(\rho_{j,0})) + f(\rho_{j,0})(f(\rho_{2,0}) - f(\hat{\rho}_2))| \\
&\qquad \leq \frac{C'}{\delta^2} f(\rho_{1,0}) |f(\hat{\rho}_j) - f(\rho_{j,0})| + \frac{C'}{\delta^2} f(\rho_{j,0}) |f(\rho_{1,0}) - f(\hat{\rho}_1)| \\
&\qquad\quad + \frac{C'}{\delta^2} f(\rho_{2,0}) |f(\hat{\rho}_j) - f(\rho_{j,0})| + \frac{C'}{\delta^2} f(\rho_{j,0}) |f(\rho_{2,0}) - f(\hat{\rho}_2)| \\
&\qquad\qquad = \frac{C'}{\delta} |f(\hat{\rho}_j) - f(\rho_{j,0})| + \frac{C'}{\delta} |f(\rho_{1,0}) - f(\hat{\rho}_1)| \\
&\qquad\qquad\quad + \frac{C'}{\delta} |f(\hat{\rho}_j) - f(\rho_{j,0})| + \frac{C'}{\delta} |f(\rho_{2,0}) - f(\hat{\rho}_2)| \\
&= \frac{C'}{\delta} (|f(\hat{\rho}_j) - f(\rho_{j,0})| + |f(\rho_{1,0}) - f(\hat{\rho}_1)| + |f(\rho_{2,0}) - f(\hat{\rho}_2)|) \leq 2 \frac{C'}{\delta} TV(f)^-
\end{aligned}$$

with a suitable constant C'. Set $C = 2C'$. □

5.3. Interaction of type I5. We consider interactions of Π-waves with the junctions. Since Π-waves always have positive speed, they can interact with the junction only from an incoming line.

Lemma 5.11. *Let us consider a junction J and a Π-wave on an incoming line I_i interacting with J. If A is the distributional matrix for J, whose entries are given by*

(3.3)*, then the interaction of the* Π*-wave with* J *modifies only the* i*th column of* A*. Moreover, the variation of the* i*th column is bounded by the* Π*-wave variation.*

Proof. For each $s \in \mathcal{S}$ and a destination $d \in \mathcal{D}$, we denote by $\pi_i^{s,d}$ and $\pi_{i,0}^{s,d}$, respectively, the left and the right states of the Π-wave. Moreover, for every $j \in \{3,4\}$, we denote by $\alpha_{j,i}^-$ and $\alpha_{j,i}^+$, respectively, the entries of the matrix A before and after the interaction of the Π-wave with J. By (3.3), it is clear that if $l \neq i$, then the entries $\alpha_{j,l}$ are not modified. For $l = i$, we have

$$\begin{aligned}|\alpha_{j,i}^+ - \alpha_{j,i}^-| &= \left| \sum_{s\in\mathcal{S},d\in\mathcal{D}} \pi_i^{s,d}\alpha_J^{i,s,d,j} - \sum_{s\in\mathcal{S},d\in\mathcal{D}} \pi_{i,0}^{s,d}\alpha_J^{i,s,d,j} \right| \\ &\leq \sum_{s\in\mathcal{S},d\in\mathcal{D}} |\pi_i^{s,d} - \pi_{i,0}^{s,d}|\alpha_J^{i,s,d,j}.\end{aligned}$$

This completes the proof. □

LEMMA 5.12. *Let us consider a junction* J *and a* Π*-wave on an incoming line* I_i *interacting with* J*. Then there exists* $C > 0$*, such that the variation of the fluxes is bounded by* C *times the* Π*-wave variation, i.e.,*

$$TV(f)^+ \leq CTV(\Pi)^-.$$

Proof. For simplicity let us consider the case $P \in \Omega$, where

$$\Omega = \left\{(\gamma_1,\gamma_2) \in \Omega_1 \times \Omega_2 : A(\gamma_1,\gamma_2)^T \in \Omega_3 \times \Omega_4\right\}.$$

Since the solution of the Riemann problem depends on the position of the traffic distribution line r_α we consider

$$\begin{aligned}|A(\pi)\gamma_{inc}^T - A(\hat{\pi})\gamma_{inc}^T| &= |(A(\pi) - A(\hat{\pi}))\gamma_{inc}^T| \\ &= \left|\begin{pmatrix} \alpha_{3,1}(\pi) - \alpha_{3,1}(\hat{\pi}) & \alpha_{3,2}(\pi) - \alpha_{3,2}(\hat{\pi}) \\ \alpha_{4,1}(\pi) - \alpha_{4,1}(\hat{\pi}) & \alpha_{4,2}(\pi) - \alpha_{4,2}(\hat{\pi}) \end{pmatrix}\begin{pmatrix}\gamma_1 \\ \gamma_2\end{pmatrix}\right| \\ &= |(\alpha_{3,1}(\pi) - \alpha_{3,1}(\hat{\pi}))\gamma_1 + (\alpha_{3,2}(\pi) - \alpha_{3,2}(\hat{\pi}))\gamma_2, \\ &\quad (\alpha_{4,1}(\pi) - \alpha_{4,1}(\hat{\pi}))\gamma_1 + (\alpha_{4,2}(\pi) - \alpha_{4,2}(\hat{\pi}))\gamma_2|\end{aligned}$$

$$= |(\alpha_{3,1}(\pi) - \alpha_{3,1}(\hat{\pi}), \alpha_{4,1}(\pi) - \alpha_{4,1}(\hat{\pi}))\gamma_1 + (\alpha_{3,2}(\pi) - \alpha_{3,2}(\hat{\pi}), \alpha_{4,2}(\pi) - \alpha_{4,2}(\hat{\pi}))\gamma_2|$$

$$\leq \gamma_1|(\alpha_{3,1}(\pi) - \alpha_{3,1}(\hat{\pi}), \alpha_{4,1}(\pi) - \alpha_{4,1}(\hat{\pi}))| + \gamma_2|(\alpha_{3,2}(\pi) - \alpha_{3,2}(\hat{\pi}), \alpha_{4,2}(\pi) - \alpha_{4,2}(\hat{\pi}))|$$

$$\begin{aligned}&= \gamma_1\left|\left(\sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d})\alpha_J^{1,s,d,3}, \sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d})\alpha_J^{1,s,d,4}\right)\right| \\ &\quad + \gamma_2\left|\left(\sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d})\alpha_J^{2,s,d,3}, \sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d})\alpha_J^{2,s,d,4}\right)\right| \\ &= \gamma_1\left|\sum_{s\in\mathcal{S},d\in\mathcal{D}} \left((\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d})\alpha_J^{1,s,d,3}, (\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d})\alpha_J^{1,s,d,4}\right)\right| \\ &\quad + \gamma_2\left|\sum_{s\in\mathcal{S},d\in\mathcal{D}} \left((\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d})\alpha_J^{2,s,d,3}, (\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d})\alpha_J^{2,s,d,4}\right)\right|\end{aligned}$$

$$\begin{aligned}
&\gamma_1 \left| \sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d})(\alpha_J^{1,s,d,3}, \alpha_J^{1,s,d,4}) \right| \\
&+\gamma_2 \left| \sum_{s\in\mathcal{S},d\in\mathcal{D}} (\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d})(\alpha_J^{2,s,d,3}, \alpha_J^{2,s,d,4}) \right| \\
\le \gamma_1 & \sum_{s\in\mathcal{S},d\in\mathcal{D}} |\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d}||(\alpha_J^{1,s,d,3}, \alpha_J^{1,s,d,4})| + \gamma_2 \sum_{s\in\mathcal{S},d\in\mathcal{D}} |\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d}||(\alpha_J^{2,s,d,3}, \alpha_J^{2,s,d,4})| \\
= & \sum_{s\in\mathcal{S},d\in\mathcal{D}} (\gamma_1 |\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d}||(\alpha_J^{1,s,d,3}, \alpha_J^{1,s,d,4})| + \gamma_2 |\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d}||(\alpha_J^{2,s,d,3}, \alpha_J^{2,s,d,4})|) \\
&\le C \sum_{s\in\mathcal{S},d\in\mathcal{D}} (|\pi_{1,0}^{s,d} - \hat{\pi}_1^{s,d}| + |\pi_{2,0}^{s,d} - \hat{\pi}_2^{s,d}|)
\end{aligned}$$

for some constant C. □

5.4. Existence of solutions for equilibria perturbations. Let us consider an admissible network $(N, \mathcal{I}, \mathcal{F}, \mathcal{J}, \mathcal{S}, \mathcal{D}, \mathcal{R})$. We have the following proposition.

PROPOSITION 5.13. *Let $(\bar{\rho}, \bar{\Pi})$ be an equilibrium on the whole network such that $f(\bar{\rho}) > \delta > 0$. Define $\hat{\lambda} = \max\{f'(0), -f'(1)\}$ and*

$$\Delta t = \frac{\min_i(b_i - a_i)}{\hat{\lambda}},$$

which represents the minimum time for a wave to go from one junction to another. For $0 < \varepsilon < \delta/\hat{\lambda}$ there exists $\tilde{t} = \tilde{t}(\delta, \varepsilon)$ such that the following holds. For every perturbation $(\tilde{\rho}, \tilde{\Pi})$ of the equilibrium with

$$\|\tilde{\rho}\|_{BV} \le \varepsilon, \left\|\tilde{\Pi}\right\|_{BV} \le \varepsilon$$

and

$$\|\tilde{\rho} - \bar{\rho}\|_\infty \le \varepsilon, \left\|\tilde{\Pi} - \bar{\Pi}\right\|_\infty \le \varepsilon$$

there exists an admissible solution (ρ, Π) defined for every $t \in [0, \tilde{t}]$ with initial datum $(\tilde{\rho}, \tilde{\Pi})$.

Proof. Denote with (ρ_ν, Π_ν) a sequence of approximate wave-front tracking solutions with initial data approximating $(\tilde{\rho}, \tilde{\Pi})$. Let us introduce the following notation:

$$\begin{aligned}
TV(f(\rho_\nu(k\Delta t, \cdot))) &= Tf_k, \\
TV(\Pi_\nu(k\Delta t, \cdot)) &= T\Pi_k.
\end{aligned}$$

For every interaction of a wave with a junction we have the estimates of Lemmas 5.9, 5.10, and 5.12; therefore

$$\begin{aligned}
Tf_k &\le Tf_{k-1} + CT\Pi_{k-1}, \\
T\Pi_k &\le T\Pi_{k-1} + \frac{C}{\delta_k} Tf_{k-1},
\end{aligned}$$

where $\delta_k = \delta_{k-1} - TVf_{k-1}$ and δ_0 is such that $f(\tilde{\rho}) > \delta_0 > 0$ (notice that $\delta_0 > \delta - \hat{\lambda}\epsilon$). Setting

$$\begin{aligned}
T_k &= \max_k(Tf_k, T\Pi_k), \\
\delta_k &= \delta_{k-1} - T_k,
\end{aligned}$$

we obtain

$$T_k \leq \left(\frac{C}{\delta_k}+1\right) T_{k-1}.$$

The exact computation of the existence time interval $[0,\tilde{t}]$ is a bit involved, thus we assume, for simplicity, that δ is small, and consider a continuous evolution. Defining $\delta(t)=\delta_0-T(t)$ we obtain

$$\dot{T}(t) \leq \frac{C}{\delta}T(t)=\frac{CT(t)}{\delta_0-T(t)},$$

from which we get $\delta_0 \ln(T)-T=\delta_0\ln(T_0)+CT-T_0$, which implicitly defines $T=T(t,\delta_0,T_0)$. Define $\hat{t}$ such that $T(\hat{t},\delta_0,T_0)=+\infty$; then for $t\leq\tilde{t}=\hat{t}/2$ there exists a constant $C_1>0$ such that

$$TV(f(\rho_\nu(t,\cdot)))\leq C_1$$
$$TV(\Pi_\nu(t,\cdot))\leq C_1$$

uniformly in ν.

Now, by the Helly theorem, Π_ν and $f(\rho_\nu)$ converge by subsequences strongly in L^1. Moreover, again by subsequences, ρ_ν converges weakly in L^1_{loc}. We then can complete the proof as in [7]. □

STATIONARY SOLUTIONS OF A MODEL FOR THE GROWTH OF TUMORS AND A CONNECTION BETWEEN THE NONNECROTIC AND NECROTIC PHASES*

H. BUENO†, G. ERCOLE†, AND A. ZUMPANO†

Abstract. Results of existence of stationary solutions are proved for a problem modeling the growth of a spheroid tumor in absence of inhibitor agents, for both the nonnecrotic and necrotic cases. The results obtained for the nonnecrotic case are used to prove the existence of stationary solutions for the necrotic case, thus clarifying the connection between both cases. Some bounds for the inner and external radii of the necrotic tumor are given. We also discuss the critical nutrient concentration that determines the necrotic phase.

Key words. necrotic and nonnecrotic tumors, stationary solution

1. Introduction.

In contrast to the exceptional development in the modeling aspects of tumor growth observed in recent years, rigorous mathematical analysis of the behavior of the models considered is rare in the literature. This is by no means surprising: the more the interrelated processes presented in cancer growth are taken into account by the model, the harder the mathematical analysis of the model becomes. (For a historical development of mathematical cancer modeling, see the review article by Araujo and McElwain [2].)

The aim of this paper is to present a rigorous study of a variation on an early model proposed by Byrne and Chaplain, introduced in [5] for the nonnecrotic case and then in [6] for its necrotic version. Here we investigate the transition from the nonnecrotic phase to the necrotic phase of the tumor and show how the stationary solutions of the nonnecrotic model impart information about the stationary solutions of the necrotic model.

In order to better situate the aim and scope of this paper, we describe briefly the model we consider. It consists of a spherical mass of cells of radius $R(t)$ (growing with time t), whose center, or necrotic core, contains only dead cells and is bounded by an inner sphere of radius $\rho(t) \geq 0$, while its surrounding symmetric annulus is composed of proliferating cells. In radial coordinates with $r = |x|$, this intermediary region $\rho(t) < r < R(t)$ receives nutrients not only by diffusion, but also through a developed network of capillary vessels, which is typical of in vivo cancer growth.

The *first equation* of the model is a reaction-diffusion equation for the nutrient concentration $\sigma(r, t)$, which we present in dimensionless form:

$$\epsilon\sigma_t = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\sigma}{\partial r}\right) - f(\sigma)H(r-\rho(t)); \quad 0 < r < R(t), \quad t > 0. \tag{1.1}$$

The coefficient $\epsilon = T_d/T_g$ is the ratio between the time necessary for the diffusion of nutrients T_d and the time elapsed until the tumor doubles its size. Typical values for T_d and T_g are, respectively, on the order of minutes and days. Thus, $\epsilon \approx 0$. Since we suppose that there is no blood supply within the necrotic core, the reaction term has the form $f(\sigma)H(r-\rho(t))$, where H is the Heaviside function (that is, $H(\xi) = 0$ for all $\xi \leq 0$ and $H(\xi) = 1$ for all $\xi > 0$). The function $f(\sigma) = C(\sigma) - V(\sigma)$ is the difference between the consumption of nutrients by the cells of the tumor, which is given by $C(\sigma)$, and the transference of nutrients $V(\sigma)$ between the tumor and the vasculature. This transference usually occurs from the vasculature to the tumor; that is, the tumor receives an extra supply of nutrients. (A detailed discussion on the absorption rate can be found, e.g., in [4]. Our hypotheses and further discussion on f are at the end of this section.)

In order to present the initial and boundary data for (1.1), we distinguish two cases. The first one, $\rho(t) \equiv 0$, corresponds to the *nonnecrotic* phase of the tumor, when there is no necrotic core. In this case, the initial conditions for the unknowns $R(t)$ and $\sigma(r,t)$ are, respectively,

$$R(0) = R_0 \quad \text{and} \quad \sigma(r,0) = \sigma_0(r), \quad 0 < r < R_0, \tag{1.2}$$

which describe the initial radius of the tumor and the initial concentration of nutrients on the tumor; the boundary conditions for σ are

$$\sigma_r(0,t) = 0 \quad \text{and} \quad \sigma(R(t),t) \equiv \bar{\sigma}, \quad t > 0. \tag{1.3}$$

Since $\sigma = \sigma(r,t)$ with $r = |x|$, $\nabla_x \sigma = \frac{\partial \sigma}{\partial r}\frac{x}{|x|}$, the boundary condition $\sigma_r(0,t) = 0$ is natural, meaning that the radial component σ_r of the field σ is null at the center of the tumor; mathematically, this condition is necessary to guarantee differentiability at the origin. We also make the natural supposition that the concentration of nutrients external to the tumor is constant, denoted by $\bar{\sigma}$. For compatibility, the initial data must satisfy $\sigma_0'(0) = 0$ and $\sigma_0(R_0) = \bar{\sigma}$.

The second case describes the *necrotic* phase of the tumor: we suppose that $\rho(0) > 0$. Aggressive tumors usually pass from the nonnecrotic phase to the necrotic phase. There are several causes for this behavior: we will suppose that the local concentration of nutrients is insufficient to sustain an individual cell.

The initial and boundary conditions for the necrotic phase of the tumor are

$$\begin{cases} 0 \leq \rho(0) < R(0), \\ \sigma(r,0) = \sigma_{\text{nec}} \ \text{ if } \ 0 \leq r \leq \rho(0), \\ \sigma(R(0),0) = \bar{\sigma}, \\ \sigma(r,t) \equiv \sigma_{\text{nec}} \ \text{ if } \ 0 \leq r \leq \rho(t), \\ \sigma_r(\rho(t),t) = 0, \ \sigma(\rho(t),t) \equiv \sigma_{\text{nec}}, \ \sigma(R(t),t) \equiv \bar{\sigma} \ \text{ for } \ t > 0. \end{cases} \tag{1.4}$$

Since all the cells in the necrotic core are dead, we admit that there is no absorption of nutrients in that region and that, on its border, the concentration of nutrients satisfies $\sigma(\rho(t),t) = \sigma_{\text{nec}} < \bar{\sigma}$. The experimentally obtained constant σ_{nec} is a threshold level below which the cells cannot survive. So, necrosis occurs when $\sigma(r,t) < \sigma_{\text{nec}}$ and cell proliferation is possible only if $\sigma(r,t) > \sigma_{\text{nec}}$. Because the initial data is constant, from the maximum principle we infer that $\sigma(r,t) = \sigma_{\text{nec}}$ for all $0 \leq r \leq \rho(t)$, $t \geq 0$.

The *second equation* of the model

$$\begin{aligned} R^2\frac{dR}{dt} &= \int_0^{R(t)} \big[S\big(\sigma(r,t)\big)H\big(r-\rho(t)\big) - N\big(\sigma(r,t)\big)H\big(\rho(t)-r\big)\big]r^2dr \\ &= \int_{\rho(t)}^{R(t)} S\big(\sigma(r,t)\big)r^2dr - \int_0^{\rho(t)} N\big(\sigma(r,t)\big)r^2dr \\ &= \int_{\rho(t)}^{R(t)} S\big(\sigma(r,t)\big)r^2dr - \mu\frac{\rho^3(t)}{3} \end{aligned} \tag{1.5}$$

describes the evolution of the tumor radius $R(t)$ and is obtained by applying mass balance equations with adequate constitutive laws and simplifying hypotheses to obtain a closed system (see [1] for a detailed deduction). It incorporates two terms: the *proliferation rate* $S(\sigma)$, which is the balance between birth (mitosis) and natural death rates of the cells (in the region $\rho(t) < r < R(t)$), and the term $N(\sigma)$, which measures necrosis and hypoxic apoptosis, i.e., death rates caused by deficiency of nutrients in the necrotic core. Since we have $\sigma \equiv \sigma_{\rm nec}$ on the necrotic core, it is natural to assume that $N(\sigma) \equiv \mu$, where μ stands for a constant. (Other types of necrosis and apoptosis are not taken into account by the model.) Of course, in the nonnecrotic phase of the tumor, we have $\rho(t) \equiv 0$. (In the nonnecrotic case, a broader discussion on the proliferation rate can be found in [4]. Our hypotheses on S are at the end of this section.)

A *quasi-stationary* solution of both problems (nonnecrotic and necrotic) is a solution of the respective problem in the case $\epsilon = 0$, maintaining dependence on time t (see [4]).

In the nonnecrotic phase of the tumor ($\rho(t) \equiv 0$), an *evolutionary solution* is a C^2-function $\sigma(r,t)$ that satisfies (1.1)–(1.3), (1.5). On its turn, a *stationary solution* is an equilibrium configuration in which the radius of the tumor stabilizes; it is obtained as a pair $(\sigma_R(r), R)$ such that both the concentration of nutrients $\sigma_R(r)$ and the stabilizing radius R do not depend on the time t.

A triple $(\sigma(r,t), \rho(t), R(t))$ is an evolutionary solution in the necrotic phase if $\sigma(r,t)$ is a C^2-function in each region (necrotic and nonnecrotic) which satisfies (1.1), (1.4), and (1.5) and has a C^1-contact on the boundary $r = \rho(t)$; as before, a stationary solution is a triple $(\sigma(r), \rho_{\rm nec}, R_{\rm nec})$ such that the concentration of nutrients $\sigma(r)$ and both the inner and the outer radii $\rho_{\rm nec}$ and $R_{\rm nec}$ do not depend on time.

In this paper we deal only with stationary solutions. Initially, our approach consists in establishing realistic hypotheses on the absorption rate $f(\sigma)$ and on the proliferation rate $S(\sigma)$ that imply the existence of a stationary solution. Then, we obtain bounds for the outer and inner radii of the tumor. In the nonnecrotic case, our investigation deals with rather general nonlinear absorption and proliferation rates, and we focus our analysis on different types of proliferation rates. In the necrotic case, for simplicity, we assume that the proliferation rate $S(\sigma)$ is a generic, continuous, and increasing function. As mentioned before, our ultimate intention is to investigate how the stationary solutions of the nonnecrotic model give information about the stationary solutions of the necrotic model. In both the nonnecrotic and necrotic cases, our approach naturally induces a simple numerical analysis of the problem, conjugating an iterative process with a finite difference method.

In spite of the simplicity of the model considered here, its mathematical analysis is interesting for various reasons: (a) detailed examination of phenomena not yet considered in tumor growth often start with this model [9, 13], which is, in a certain sense, generic to the area; (b) more elaborated models reduce to it under appropriate hypotheses [1, 7, 8, 11]; (c) the nonnecrotic model reproduces patterns observed in tumors cultured in vitro; (d) since no explicit stationary solution is available in the case of general absorption and proliferation rates, a rigorous proof of the existence of stationary solutions is an open question.

The outline of the article is as follows. The initial phase of the tumor (i.e., nonnecrotic) is considered in section 2. In the case of *linear* absorption and proliferation rates, the first theoretical results about the nonnecrotic model treated here were pointed out by Byrne and Chaplain [5] and rigorously proved by Friedman and Reitich [14]. However, for linear absorption and proliferation rates, the existence of a stationary solution is not a problem in itself, since an explicit stationary solution is available. (We stress that [14] is mainly devoted to the stability of the stationary solution.) The first subsection of section 2 establishes results of existence, uniqueness, and localization of stationary solutions for more realistic absorption and proliferation rates. Subsection 2.2 comments on some results obtained by Byrne and Chaplain [5], and subsection 2.3 compares our outcomes, by means of a numerical implementation, with those in [14].

This section poses, however, a simple question: Is the stationary solution (when it exists) a limit of solutions of the evolutionary problem? It is proved in [4] that solutions $\sigma(r,t)$ of the quasi-stationary problem (i.e., if we consider $\epsilon = 0$) converge monotonically to the stationary solution, which is also presented in this paper. This result gives insight about what can be expected for small $\epsilon > 0$ (a condition satisfied by real data). For example, let us consider a nonnecrotic tumor which has stabilizing radius R^* (a value that can be numerically computed, when the absorption and proliferation rates are known). If ϵ is small enough, this would imply that, if the tumor has radii $R_0 = R(t_0) < R_*$ for some time $t = t_0$ and $R_1 = R(t_1) > R_*$ for $t = t_1 > t_0$, then either no stationary solution will be achieved or the tumor will pass to the necrotic phase.

Section 3 studies the relationship between the stationary solutions of the nonnecrotic and necrotic models. This connection has been set aside in the mathematical handling of tumor growth. However, it turns out that this relationship allows us to predict if it is possible to achieve a stationary solution for the necrotic tumor. We show the existence of a value σ_*, which determines the existence of stationary solutions. Consequently, if the tumor is in the necrotic phase, the stationary solution exists if and only if $\sigma_* < \sigma_{\text{nec}} < \bar{\sigma}$; it exists in the nonnecrotic phase if and only if $\sigma_0 < \sigma_{\text{nec}} \leq \sigma_*$, where σ_0 stands for the zero of the absorption rate. In other words, if the phase of the tumor and the value of σ_{nec} are known, we can say whether it is possible to achieve a stationary solution. In both cases these solutions are unique. Under additional conditions on the behavior of the proliferation rate, we also present some estimates on the radii of the stabilizing tumor. (We emphasize that the value σ_{nec} can be empirically established.)

Our conclusions are presented in section 4, while most of the proofs of our results are deferred to section 5.

We now describe succinctly our hypotheses on the absorption rate $f(\sigma)$ and on the proliferation rate $S(\sigma)$. A more detailed discussion of these functions can be found in [4].

In the majority of works, the functions f and S depend linearly on σ. Under these hypotheses, existence and global stability of the nontrivial stationary solutions are proved, respectively, in [14] and [10] for the nonnecrotic and the necrotic cases. The approach used there rests on the existence of an explicit form for the stationary solution. Here our assumptions on both f and S are more general, and such an explicit solution is not available.

In this work we consider nonlinear absorption and proliferation rates. This was done not merely for generality reasons. Linearization of the absorption rate is just an approximation of real data, while the choice of an adequate proliferation rate is necessary for the evaluation of the mathematical model considered. Furthermore, nonlinearities of both functions might be considered as indirect effects of inhibitors on the absorption and proliferation rates if we are not able to mathematically describe their action; a hypothesis now in discussion concerns the inhibitory effects of certain nutrients on cancer growth.

We assume that the function $f(\sigma) = C(\sigma) - V(\sigma)$ is such that the consumption of nutrients by the tumor is an increasing function of σ, while the transference rate, as mentioned before, is a positive function. It is natural to assume that $V'(\sigma) \leq 0$, because the diminution of the concentration of nutrients in the tumor increases the transference rate as a compensation mechanism. We also assume that $f(\sigma) \geq 0$, which means that $C(\sigma) \geq V(\sigma)$, and we accept that $f(\sigma) = 0$ happens at a single value σ_0. So, we suppose that the absorption rate is increasing for $\sigma \in (\sigma_0, \bar{\sigma}]$. Therefore, if $\sigma > \sigma_0$, the consumption rate is greater than the transference rate, and the difference between these rates decreases when the concentration of nutrients decreases. Our assumptions on f appear to be natural and are similar to those of [3] if one considers only proliferating cells.

In the nonnecrotic phase, we acknowledge that S is continuous and either that it is monotonic on the interval $[\sigma_0, \bar{\sigma}]$ or that it assumes only one local extreme on this interval. But, supposing that the number of cells is growing when the nutrient concentration is $\bar{\sigma}$, it follows that $S(\bar{\sigma}) > 0$. And assuming that S increases in a neighborhood of $\bar{\sigma}$, our analysis is done when $S(\sigma)$ is either increasing on $[\sigma_0, \bar{\sigma}]$ or decreasing on $[\sigma_0, \Lambda]$ and increasing on $[\Lambda, \bar{\sigma}]$, Λ denoting the local minimum of S. These hypotheses include those made in the papers already cited (in some cases, if one considers only proliferating cells).

In the necrotic case, to render the presentation less complex, we assume that S is continuous and increasing on the interval $[\sigma_0, \bar{\sigma}]$.

2. The nonnecrotic problem. Putting $\lambda := R^2$, the change of variables $\sigma_\lambda(r) = \sigma_R(rR)$ transforms the system (1.1)–(1.3), (1.5) into the boundary value problem (BVP)

$$\begin{cases} (r^2\sigma_\lambda')' = \lambda r^2 f(\sigma_\lambda), \quad 0 < r < 1, \\ \sigma_\lambda'(0) = 0, \quad \sigma_\lambda(1) = \bar{\sigma}, \end{cases} \tag{2.1}$$

and the integral equation

$$\lambda \int_0^1 S(\sigma_\lambda(r)) r^2 dr = 0. \tag{2.2}$$

Hence, a stationary solution for the system (1.1)–(1.3), (1.5) is equivalent to a pair $(\sigma_\lambda, \lambda)$ satisfying (2.1)–(2.2). We note that $(\bar{\sigma}, 0)$ is a trivial stationary solution.

We will first solve (2.1) for all $\lambda > 0$ and then consider λ as a parameter in order to find a solution for (2.2).

Remark 1. Since σ_{nec} is an experimentally obtained value, the relation between σ_0 and σ_{nec} is unclear: it may be, for example, $\sigma_0 < \sigma_{\text{nec}} < \bar{\sigma}$. Let the pair $(\sigma_{\lambda_*}, \lambda_*)$

denote a solution of the problem (2.1)–(2.2). Since (2.1) and (2.2) are handled separately, the stationary solution for the nonnecrotic model makes sense only when $\sigma_{\lambda_*}(r)$ is above σ_{nec}. This condition is fulfilled, for instance, if $\sigma_{\text{nec}} \le \sigma_0 < \bar{\sigma}$; as we shall see, $\sigma_\lambda(r) > \sigma_0$ for all $\lambda \ge 0$.

2.1. Stationary solutions for the nonnecrotic model. In this subsection we collect some properties of the solution of (2.1)–(2.2) and present some estimates on the stabilizing radius. The technical proofs are found in section 5.

PROPOSITION 2.1. *Suppose that* $f(\sigma) \in C^1([\sigma_0, \bar{\sigma}])$ *is increasing and vanishes only at* $\sigma = \sigma_0$. *Then, for each* $\lambda \ge 0$, *there exists exactly one solution* σ_λ *of the BVP* (2.1), *which satisfies*

$$\sigma_0 < \sigma_\lambda(r) \le \bar{\sigma} \quad \textit{for all } r \in [0,1]. \tag{2.3}$$

Furthermore,

(i) σ_λ *is strictly increasing;*

(ii) σ_λ *is strictly convex, and*

$$\sigma''_\lambda(r) \ge \frac{\sigma'_\lambda(r)}{r} > 0 \quad \textit{for all } r \in (0,1]; \tag{2.4}$$

(iii) *if* $0 \le \lambda_1 < \lambda_2$, *then* $\sigma_{\lambda_2}(r) \le \sigma_{\lambda_1}(r)$ *for all* $r \in [0,1]$*;*

(iv) *the map* $\lambda \mapsto \sigma_\lambda$ *is continuous; and*

(v) $\lim_{\lambda\to\infty} \sigma_\lambda(r) = 0$ *pointwise in* $[0,1)$ *and uniformly in closed intervals contained in* $[0,1)$.

The properties of u_λ (monotonicity with respect to r and λ, convexity, and convergence to σ_0) are displayed in Figure 2.1.

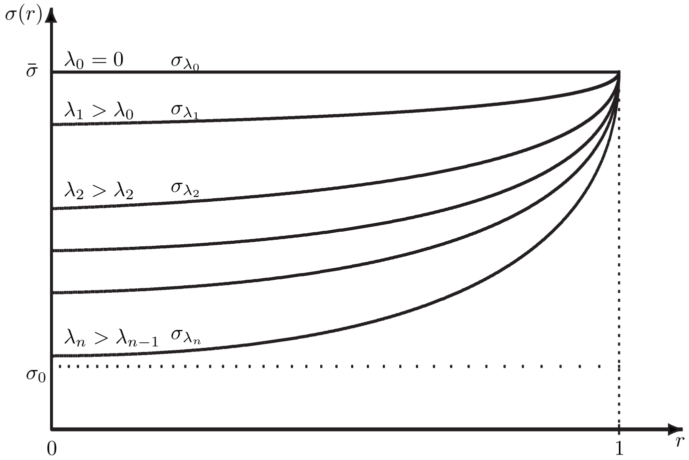

FIG. 2.1. *For each* $\lambda \ge 0$, *the functions* σ_λ *are convex and increasing. The sequence* $\{\sigma_{\lambda_n}\}$ *converges uniformly to* σ_0 *in compact subsets of* $[0,1)$ *when* $\lambda_n \to \infty$.

The uniqueness assertion in Proposition 2.1 rests on a form of the maximum principle (see section 5), while existence is based on the method of sub- and supersolutions. A numerical implementation of this method is very simple (see the remark below and subsection 2.3). The convexity of the solutions u_λ makes it possible to handle nonmonotonic proliferation rates.

Remark 2. The method of sub- and supersolutions (see [12]) is valid under more general hypotheses on f—for example, if $f \in C([\sigma_0, \bar{\sigma}])$ and if there exists a constant k such that $f(\sigma) - k\sigma$ is decreasing (a condition fulfilled by Lipschitz continuous f). Its numerical implementation is simple (see also subsection 2.3): the method produces solutions of (2.1) given as limits of two iterative sequences of the form $\{\sigma_n\}_{n=1}^{\infty}$, where

$$\begin{aligned} &(r^2\sigma'_{n+1})' - k\lambda r^2 \sigma_{n+1} = \lambda r^2 \left(f(\sigma_n) - k\sigma_n\right), \\ &\sigma'_{n+1}(0) = 0, \qquad \sigma_{n+1}(1) = \bar{\sigma}, \end{aligned}$$

starting at $\sigma_1(r) \equiv \sigma_0$ and $\sigma_1(r) = \bar{\sigma}$, respectively. (Taking into account the uniqueness of solutions, both sequences have the same limit.)

Let the pair $(\sigma_{\lambda_*}, \lambda_*)$ denote a solution of the problem (2.1)–(2.2) such that $\lambda_* > 0$. Then λ_* is obtained as a zero of the equation $I(\lambda) = 0$, where the continuous function $I : [0, \infty) \to \mathbb{R}$ is defined by

$$I(\lambda) = \int_0^1 S(\sigma_\lambda(r)) r^2 dr \tag{2.5}$$

and σ_λ is given by Proposition 2.1.

In this case, the pair (σ_{R_*}, R_*) is a stationary solution for the system (1.1)–(1.3), (1.5), where $R_* = \sqrt{\lambda_*}$ is the stabilizing radius and $\sigma_{R_*}(r) = \sigma_{\lambda_*}(r/R_*)$ for all $r \in [0, R_*]$.

The simplest way to ensure the existence of a zero for $I(\lambda)$ is given by the following theorem.

THEOREM 2.2. *If the continuous function $S(\sigma)$ satisfies the condition*

$$S(\sigma_0)S(\bar{\sigma}) < 0, \tag{2.6}$$

then there exists at least one positive value λ_* such that $I(\lambda_*) = 0$. Moreover, if $S(\sigma)$ is also monotonic, then λ_* is unique.

Proof. Since

$$I(0) = \int_0^1 S(\bar{\sigma}) r^2 dr = \frac{S(\bar{\sigma})}{3}$$

and

$$\lim_{\lambda \to \infty} I(\lambda) = \int_0^1 S\left(\lim_{\lambda \to \infty} \sigma_\lambda(r)\right) r^2 dr = \frac{S(\sigma_0)}{3},$$

the existence of λ_* is a consequence of the continuity of the function $I(\lambda)$. Uniqueness follows from the monotonicity of $I(\lambda)$. □

We now handle more general cases. The proof of the next result is based on a geometrical construction that strongly depends on the convexity of σ_λ. (See section 5.)

THEOREM 2.3. *Suppose that, for some $\alpha \in (\sigma_0, \bar{\sigma})$, S is nondecreasing on $[\alpha, \bar{\sigma}]$ and*

$$\int_\alpha^{\bar{\sigma}} S(\sigma)(\sigma - \alpha)^2 d\sigma = 0. \tag{2.7}$$

Then there exists $\lambda_* > 0$ such that $I(\lambda_*) = 0$. Moreover,

$$3\frac{(\bar{\sigma} - \alpha)}{f(\bar{\sigma})} \le \lambda_* \le 6\frac{(\bar{\sigma} - \alpha)}{f(\alpha)}. \tag{2.8}$$

Remark 3. Theorem 2.3 is also valid if $S \in C([\sigma_0, \bar{\sigma}])$ attains a minimum value at $\sigma = \Lambda \in (\sigma_0, \bar{\sigma})$, decreasing if $\sigma \in [\sigma_0, \Lambda]$ and increasing if $\sigma \in [\Lambda, \bar{\sigma}]$. In this situation, if $S(\sigma_0) \leq 0 < S(\bar{\sigma})$, we change (2.7) to

$$\int_{\Lambda}^{\bar{\sigma}} S(\sigma)(\sigma - \Lambda)^2 d\sigma \leq 0.$$

The technique applied in the proof of Theorem 2.3 may also be used to obtain bounds for λ_*, even when S does not satisfy (2.7). As an example we mention the following proposition

PROPOSITION 2.4. *Suppose that the continuous function $S(\sigma)$ is increasing and satisfies $S(\sigma_0) < 0 < S(\bar{\sigma})$. Then*

$$\lambda_* \geq \max\left\{\frac{3(\bar{\sigma} - \alpha)}{f(\bar{\sigma})}, \frac{6(\bar{\sigma} - \beta)}{f(\bar{\sigma})}\right\}, \tag{2.9}$$

where

$$\alpha = \min\left\{\xi \in [\sigma_0, \bar{\sigma}] : \int_{\xi}^{\bar{\sigma}} S(\sigma)(\sigma - \xi)^2 d\sigma \geq 0\right\} \tag{2.10}$$

and

$$\beta = \min\left\{\eta \in [\sigma_0, \bar{\sigma}] : \int_{\eta}^{\bar{\sigma}} S(\sigma)\sqrt{\sigma - \eta} d\sigma \geq 0\right\}. \tag{2.11}$$

Now we state the existence of solutions for (2.1)–(2.2) when neither (2.6) nor (2.7) is satisfied. From now on we assume that the proliferation rate $S \in C([\sigma_0, \bar{\sigma}])$ attains a minimum value at $\sigma = \Lambda \in (\sigma_0, \bar{\sigma})$, decreasing if $\sigma \in [\sigma_0, \Lambda]$ and increasing if $\sigma \in [\Lambda, \bar{\sigma}]$. The proof of the result below is obtained by refining the technique used to demonstrate Theorem 2.3. (See section 5.)

THEOREM 2.5. *Let S be as above. In addition, suppose that $S(\sigma_0) = 0 < S(\bar{\sigma})$ and*

$$\int_{\sigma_0}^{\bar{\sigma}} S(\sigma) d\sigma \leq 0.$$

Then there exists at least one λ_* such that $I(\lambda_*) = 0$. Moreover,

$$\lambda_* \geq 6\frac{(\bar{\sigma} - \Lambda)}{f(\bar{\sigma})}. \tag{2.12}$$

Remark 4. In the last theorem, we can exchange S for a function that increases from σ_0 to a maximum value Λ and then decreases from Λ to $\bar{\sigma}$. But the form of S stated in the theorem appears to be more natural under the model considered. (See the comments below.)

2.2. Comments. If $\widetilde{\sigma}$ stands for a constant, the logistic form

$$S(\sigma) = s\sigma(1 - \sigma/\widetilde{\sigma}) \tag{2.13}$$

was suggested by Byrne and Chaplain [5], the terms $s\sigma$ ($s > 0$) and $s\sigma^2/\widetilde{\sigma}$ meaning the birth and death rates, respectively.

In this case we have $S(\sigma) > 0$ if $\sigma \in (0, \widetilde{\sigma})$ and $S(\sigma) < 0$ if $\sigma > \bar{\sigma}$. If we have $0 < \sigma_0 < \widetilde{\sigma} < \bar{\sigma}$, there exists a stationary solution, since (2.6) is fulfilled. Assuming that $\sigma_0 = 0$ (which corresponds to an avascular tumor in [5]) and $\bar{\sigma} > \widetilde{\sigma}$, Remark 4 leads to the existence of λ_*, provided that $\int_{\sigma_0}^{\bar{\sigma}} S(\sigma) d\sigma > 0$.

The proliferation rate (2.13) was not analytically studied in [5], but some numerical implementations were done just for comparison with the linear case. In one of these implementations Byrne and Chaplain considered $f(\sigma) = 2\sigma - 1.2$ and $\sigma_0 = \widetilde{\sigma} = 0.6$ and obtained that the evolutionary solutions do not converge to any stationary solution. (See Figure 3 in that paper.)

According to our analysis,

$$0 \leq \sigma_0 < \widetilde{\sigma} < \bar{\sigma} \tag{2.14}$$

is a necessary condition for the existence of stationary solutions, since $\sigma_\lambda(r) \in (\sigma_0, \bar{\sigma}]$ for all $\lambda \geq 0$ and $r \in [0, 1]$. So, our results show that it was predictable that no stationary solution was to be found as a limit of the evolutionary solutions in the numerical implementation done in [5].

But (2.13)–(2.14) does not appear to be natural: it implies that $S(\bar{\sigma}) < 0$, that is, that the proliferation rate is negative when the concentration of nutrients is maximal, and $S(\sigma)$ grows when this concentration decreases, until it reaches the maximum value $S(\widetilde{\sigma}/2)$.

On the other hand, if we suppose a proliferation rate of the form

$$S(\sigma) = s\sigma \left(\frac{\sigma}{\widetilde{\sigma}} - 1 \right),$$

then (2.14) is still a necessary condition for the existence of a stationary solution. Remark 3 then implies the existence of at least one stationary solution if

$$0 < \sigma_0 < \widetilde{\sigma} < \bar{\sigma} \quad \text{and} \quad \int_{\widetilde{\sigma}/2}^{\bar{\sigma}} \sigma \left(\frac{\sigma}{\widetilde{\sigma}} - 1 \right) \left(\sigma - \frac{\widetilde{\sigma}}{2} \right)^2 d\sigma \leq 0$$

or

$$\sigma_0 = 0 < \widetilde{\sigma} < \bar{\sigma} \quad \text{and} \quad \int_{\sigma_0}^{\bar{\sigma}} \sigma \left(\frac{\sigma}{\widetilde{\sigma}} - 1 \right) d\sigma \leq 0.$$

In the first case, we obtain from Theorem 2.3 the estimates

$$3 \frac{(\bar{\sigma} - \alpha)}{f(\bar{\sigma})} < \lambda_* < 6 \frac{(\bar{\sigma} - \alpha)}{f(\alpha)}$$

if $\alpha \in (0, \bar{\sigma})$ is such that

$$\int_{\alpha}^{\bar{\sigma}} \sigma \left(\frac{\sigma}{\widetilde{\sigma}} - 1 \right) (\sigma - \alpha)^2 d\sigma = 0. \tag{2.15}$$

In the second case, we obtain from Theorem 2.5 the lower bound

$$\lambda_* > 6 \frac{(\bar{\sigma} - \widetilde{\sigma}/2)}{f(\bar{\sigma})}.$$

2.3. Numerical implementation. The approach used to solve problem (2.1)–(2.2) naturally induces a numerical method to deal with the problem. The numerical procedure described below was first intended to test our approach and to compare our outputs with results given in other papers for linear rates. Since they were coherent, we have in mind a rigorous analysis of our numerical method.

To exemplify how our theoretical approach leads to a numerical treatment of (2.1)–(2.2), we take $\bar{\sigma} = 1$ and consider quadratic absorption and proliferation rates:

$$f(\sigma) = (\sigma - 0.3)(\sigma + 0.5), \qquad S(\sigma) = 4\sigma \left(\frac{\sigma}{\widetilde{\sigma}} - 1 \right).$$

The values of $\widetilde{\sigma}$ are calculated from the given values of α by the equation

$$\widetilde{\sigma} = \frac{2(\alpha^2 + 3\alpha + 6)}{5(\alpha + 3)}, \quad 0 \le \alpha \le 1,$$

which is equivalent to (2.15). So, to each $\alpha \in [0, 1)$ corresponds a unique $\widetilde{\sigma} \in [0.8, 1)$.

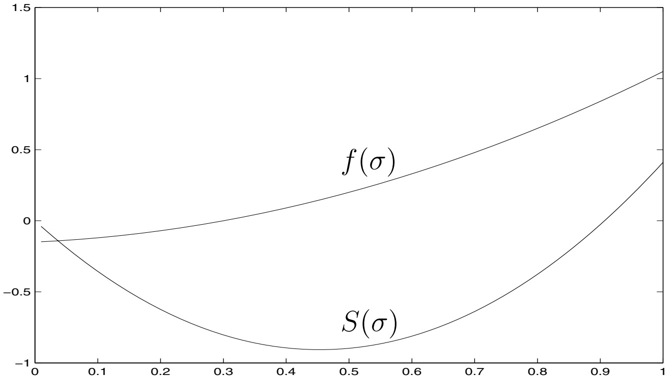

FIG. 2.2. *In the case of $\widetilde{\sigma}$ corresponding to $\alpha = 0.6$, the graphs of $f(\sigma)$ and $S(\sigma)$ are displayed.*

In Figure 2.2, the graphs of $f(\sigma)$ and $S(\sigma)$ are shown, while Figure 2.3 displays $I(\lambda)$ for $\alpha = 0.6$, in the interval $[\lambda_1, \lambda_2]$, where

$$\lambda_1 = \frac{3(\bar{\sigma} - \alpha)}{f(\bar{\sigma})} = \frac{3(1 - \alpha)}{1.05}$$

and

$$\lambda_2 = \frac{6(\bar{\sigma} - \alpha)}{f(\alpha)} = \frac{6(1 - \alpha)}{(\alpha - 0.3)(\alpha + 0.5)}.$$

The zero λ_* of $I(\lambda)$ is to be found in this interval, according to Theorem 2.3, and is confirmed by our numerical outputs. The same coherent behavior was observed for various values of α we have tested.

To approximate the functions $\sigma_* = \sigma_{\lambda_*}$ we have used an iterative method based on super- and subsolutions (see Remark 2), where two numerical sequences are generated, one departing from the subsolution and the other from the supersolution. Both sequences converge to the unique stationary solution (see Proposition 2.1). One

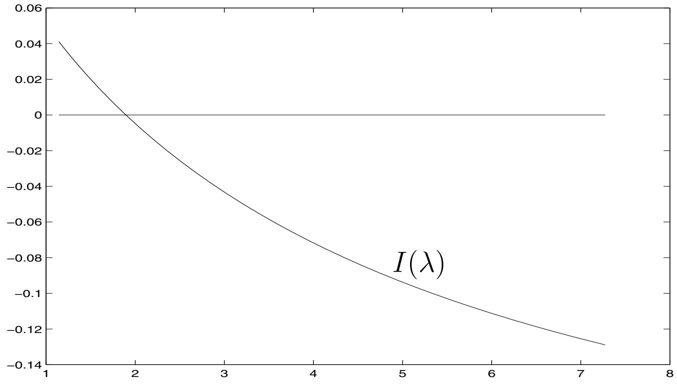

FIG. 2.3. *For $\widetilde{\sigma}$ corresponding to $\alpha = 0.6$, the graph of $I(\lambda)$ is displayed in the interval* $[\lambda_1, \lambda_2]$, *with $\lambda_1 \approx 1.1428$, $\lambda_2 \approx 7.2727$, and $\lambda_* \approx 1.8967$.*

function of these sequences was chosen to represent the solution, when the distance between the functions of each individual sequence and also between correspondent elements of both sequences was less than 10^{-3}. In each iteration, centered finite difference was used in a uniform 100-point grid. A maximum of 9 iterations was necessary in the "critical case" corresponding to the least possible value for α. We point out, however, that we have made no rigorous error analysis for this iterative method.

A simple method was chosen to evaluate $I(\lambda)$—the trapezoidal rule in a 100-point uniform grid. To find the zero λ_* of $I(\lambda)$, the bisection method with approximation of the order of 10^{-3} was used.

We now compare our results with those obtained in [14]. In order to do that, we consider, as in that paper, a linear case:

$$f(\sigma) = \sigma \quad \text{and} \quad S(\sigma) = \sigma - \widetilde{\sigma},$$

with $\sigma_0 = 0$, $\bar{\sigma} = 1$, and $0 \leq \widetilde{\sigma} < 1$. It holds that

$$\alpha = 4\widetilde{\sigma} - 3, \quad \lambda_1 = 12(1 - \widetilde{\sigma}), \quad \text{and} \quad \lambda_2 = \frac{24(1 - \widetilde{\sigma})}{4\widetilde{\sigma} - 3} \quad \text{for} \quad 0.75 < \widetilde{\sigma} < 1.$$

Theorem 2.3 ensures that

$$2.64 \leq \lambda_* \leq 44 \quad \text{if} \quad \widetilde{\sigma} = 0.78$$

and

$$0.48 \leq \lambda_* \leq 1.1429 \quad \text{if} \quad \widetilde{\sigma} = 0.96.$$

Using the numerical approach described above, we find

$$\lambda_* \approx 4.7697 \quad \text{if} \quad \widetilde{\sigma} = 0.78 \tag{2.16}$$

and

$$\lambda_* \approx 0.6363 \quad \text{if} \quad \widetilde{\sigma} = 0.96. \tag{2.17}$$

The value $\eta = \sqrt{\lambda_*}$ is obtained as a solution of an algebraic equation (see [14]), namely,

$$\tanh(\eta) = \frac{\eta}{1+\Lambda\eta^2}, \tag{2.18}$$

where $\Lambda = \widetilde{\sigma}/3 \in (0, 1/3)$. The approximate solutions of (2.18) are

$$\lambda_* = \eta^2 \approx 4.7681 \quad \text{if} \quad \widetilde{\sigma} = 0.78$$

and

$$\lambda_* = \eta^2 \approx 0.6362 \quad \text{if} \quad \widetilde{\sigma} = 0.96,$$

which are very close to our results, given by (2.16) and (2.17).

Friedman and Reitich [14] observed that the constant $\Lambda_{\text{crit}} = 0.2727\ldots$ satisfies

$$\eta(\Lambda) < \frac{1}{\sqrt{\Lambda}} \quad \text{if} \quad \Lambda_{\text{crit}} < \Lambda < 1/3, \tag{2.19}$$

where $\eta(\Lambda)$ denotes the solution of (2.18) for $\Lambda \in (0, 1/3)$. The estimate we have obtained is

$$\eta(\Lambda) \leq 2\sqrt{\frac{3(1-3\Lambda)}{4\Lambda - 1}} \quad \text{if} \quad 0.25 < \Lambda < \frac{1}{3}.$$

Our estimate is not only valid in a larger interval than that described in (2.19) but also better when Λ is very close to $1/3$. For example, when $\Lambda = 0.32$, we have

$$2\sqrt{\frac{3(1-3\Lambda)}{4\Lambda - 1}} \approx 1.3093 < \frac{1}{\sqrt{\Lambda}} \approx 1.76781.$$

3. The necrotic model. In the analysis of the necrotic phase of the tumor, as in the nonnecrotic phase, we suppose that $f(\sigma) > 0$ for $\sigma \in [\sigma_{\text{nec}}, \bar{\sigma}]$. (This means that the rate of consumption overcomes the rate of transference of nutrients from vasculature in that region.) Furthermore, we also assume that f vanishes only at $\sigma_0 \in [0, \sigma_{\text{nec}})$ and is nondecreasing on the interval $[\sigma_0, \bar{\sigma}]$. For simplicity, we assume here that the proliferation rate $S(\sigma)$ is continuous and *increasing* on the interval $[\sigma_0, \bar{\sigma}]$.

A stationary solution for the necrotic model is a triple $(\sigma, \rho_{\text{nec}}, R_{\text{nec}})$ such that $\sigma \in C^1[0,1] \cap C^2[0,\rho] \cap C^2[\rho, 1]$ satisfies $\sigma(r) \equiv \sigma_{\text{nec}}$ for all $r \in (0, \rho)$ and

$$\begin{cases} (r^2\sigma')' = r^2 f(\sigma), \ \rho_{\text{nec}} < r < R_{\text{nec}}, \\ \sigma'(\rho_{\text{nec}}) = 0, \ \sigma(\rho_{\text{nec}}) = \sigma_{\text{nec}}, \ \sigma(R_{\text{nec}}) = \bar{\sigma}, \\ \int_{\rho_{\text{nec}}}^{R_{\text{nec}}} S(\sigma(r)) r^2 dr = \mu(\rho_{\text{nec}})^3. \end{cases} \tag{3.1}$$

(We assume $\sigma_0 < \sigma_{\text{nec}} \leq \bar{\sigma}$; see Remark 1.)

As before, by making the change of variables $r \to rR_{\text{nec}}$, we transform (3.1) into the equivalent boundary value problem

$$\begin{cases} (r^2\sigma')' = \lambda r^2 f(\sigma), \ \rho < r < 1, \\ \sigma'(\rho) = 0, \ \sigma(\rho) = \sigma_{\text{nec}}, \ \sigma(1) = \bar{\sigma}, \end{cases} \tag{3.2}$$

and the integral equation

$$\int_{\rho}^{1} S(\sigma(r))r^2 = \mu\rho^3, \tag{3.3}$$

where $\lambda = R_{\text{nec}}^2$ and $\rho = \rho_{\text{nec}}/R_{\text{nec}} < 1$. Therefore, a stationary solution is still given by a triple $(\sigma(r), \rho, \lambda)$, which solves (3.2)–(3.3).

3.1. Stationary solutions for the necrotic model. In this subsection we give conditions for the existence of solutions of (3.2). Our approach is basically the one used to handle the nonnecrotic case, but now we treat both λ and the inner radius ρ as parameters. The proofs of the next two results are similar to that of Proposition 2.1.

LEMMA 3.1. *Let $\rho \in [0, 1)$ be fixed. Then the following hold:*

(i) *For each $\lambda \in (0, \infty)$, there exists a unique $\sigma_\lambda \in C^2[\rho, 1]$ satisfying*

$$\begin{cases} (r^2\sigma_\lambda')' = \lambda r^2 f(\sigma_\lambda), & \rho < r < 1, \\ \sigma_\lambda'(\rho) = 0, \ \sigma_\lambda(1) = \bar{\sigma}. \end{cases} \tag{3.4}$$

Furthermore, if $\lambda > 0$, then σ_λ is (strictly) increasing and strictly convex and satisfies

$$\sigma_0 < \sigma_\lambda(r) \leq \bar{\sigma} \text{ for all } r \in [\rho, 1]. \tag{3.5}$$

(ii) *The application $\lambda \longmapsto \sigma_\lambda$ from $[0, \infty)$ to $C[\rho, 1]$ is continuous and nonincreasing; that is, $\sigma_{\lambda_1} \geq \sigma_{\lambda_2}$ if $0 \leq \lambda_1 < \lambda_2$.*

(iii) $\lim_{\lambda\to\infty} \sigma_\lambda = \sigma_0$ *uniformly on each closed interval contained in $[\rho, 1)$.*

Since $\sigma_0 < \sigma_{\text{nec}} \leq \bar{\sigma}$, property (iii) of Lemma 3.1 associates each $\rho \in [0, 1)$ to a unique $\lambda = \lambda_\rho$ so that $\sigma_{\lambda_\rho}(\rho) := \sigma_\rho(\rho) = \sigma_{\text{nec}}$. We stress that the localization of the zero σ_0 of the function f is critical for the existence of a stationary solution: it is impossible to find a solution satisfying $\sigma(\rho) = \sigma_{\text{nec}}$, if $\sigma_{\text{nec}} \leq \sigma_0$.

THEOREM 3.2. *For each $\rho \in [0, 1)$ there exist a unique $\lambda_\rho > 0$ and a unique function $\sigma_\rho \in C^2[0, 1] \cap C^2[0, \rho] \cap C^2[\rho, 1]$ such that $\sigma_\rho(r) := \sigma_{\text{nec}}$ for all $r \in [0, \rho)$ and*

$$\begin{cases} (r^2\sigma_\rho')' = \lambda_\rho r^2 f(\sigma_\rho), & \rho < r < 1, \\ \sigma_\rho'(\rho) = 0, \ \sigma_\rho(\rho) = \sigma_{\text{nec}}, \ \sigma_\rho(1) = \bar{\sigma}. \end{cases} \tag{3.6}$$

Furthermore, the maps

$$\rho \in [0, 1) \mapsto \sigma_\rho \in C[0, 1] \quad \textit{and} \quad \rho \in [0, 1) \mapsto \lambda_\rho \in (0, \infty)$$

are continuous and satisfy the following:

(i) *$\rho \mapsto \sigma_\rho$ is nonincreasing:*

$$0 \leq \rho_1 < \rho_2 \quad \Rightarrow \quad \sigma_{\rho_1}(r) \geq \sigma_{\rho_2}(r) \quad \textit{for all } r \in [0, 1].$$

(ii) *$\rho \mapsto \lambda_\rho$ is (strictly) increasing and*

$$\lim_{\rho\to 1} \lambda_\rho = \infty. \tag{3.7}$$

Remark 5. When $\rho = 0$, we will denote λ_ρ by λ_{nec} and the corresponding solution σ_ρ by $\sigma_{\lambda_{\text{nec}}}$. So,

$$(r^2\sigma_{\lambda_{\text{nec}}}')' = \lambda_{\text{nec}} r^2 f(\sigma_{\lambda_{\text{nec}}}), \quad 0 < r < 1,$$
$$\sigma_{\lambda_{\text{nec}}}'(0) = 0, \ \sigma_{\lambda_{\text{nec}}}(0) = \sigma_{\text{nec}}, \ \sigma_{\lambda_{\text{nec}}}(1) = \bar{\sigma}.$$

We stress that $\sigma_{\lambda_{\mathrm{nec}}}$ is also a solution of the boundary value problem (2.1) for $\lambda = \lambda_{\mathrm{nec}}$.

Since the differential equation (3.2) is solved, let us now consider the integral equation (3.3). For this, we define

$$J(\rho) = \int_\rho^1 S(\sigma_\rho(r))r^2 dr - \mu\rho^3 \text{ for } \rho \in [0,1).$$

We will show how the nonnecrotic model brings information to the necrotic model. For this, we assume[1] that the proliferation rate $S(\sigma)$ is a *continuous, nondecreasing function* of the nutrient concentration σ.

Theorem 3.2 implies that the function J is continuous and nonincreasing. The existence of a uniform bound for $S(\sigma_\rho)$ with respect to ρ implies that

$$\lim_{\rho\to 1^-} J(\rho) = -\mu < 0. \tag{3.8}$$

According to Remark 5, we have

$$J(0) = I(\lambda_{\mathrm{nec}}), \tag{3.9}$$

where the function I is defined by (2.5). So, (3.2)–(3.3) has a solution $(\sigma(r), \rho, \lambda)$ with $\rho > 0$ if and only if $I(\lambda_{\mathrm{nec}}) > 0$ (since λ_{nec} corresponds to $\rho = 0$, a nonnecrotic solution).

As a consequence, we have the following result on the existence and uniqueness of stationary solutions.

THEOREM 3.3. *Suppose that* $(\sigma_{\lambda_*}, \lambda_*)$ *is a solution of* (2.1)–(2.2). *Denote* $\sigma_{\lambda_*}(0)$ *by* σ_*. *There exists a (unique) solution of* (3.2)–(3.3) *if and only if* $\sigma_* < \sigma_{\mathrm{nec}}$.

Proof. We have $J(0) = I(\lambda_{\mathrm{nec}}) > 0 = I(\lambda_*)$ if and only if $\lambda_{\mathrm{nec}} < \lambda_*$, an inequality that is equivalent to $\sigma_* < \sigma_{\mathrm{nec}}$. □

Theorem 3.3 depends on the solution of (2.1)–(2.2), which can be numerically obtained. A more intrinsic criterion is given by the following proposition.

PROPOSITION 3.4. *Suppose that* $S(\sigma_0) < 0 < S(\bar\sigma)$. *Let* $\widetilde\sigma$ *denote the zero of the function* S *(that is, the value of the nutrient concentration at which the rates of birth and death are equal). If* $\sigma_{\mathrm{nec}} \geq \widetilde\sigma$, *then there exists a unique solution of* (3.2)–(3.3).

Proof. Theorem 2.2 ensures the existence of a (unique) pair $(\sigma_{\lambda_*}, \lambda_*)$ that solves (2.1)–(2.2). The inequality $S(\sigma) \geq 0$ for all $\sigma \in [\widetilde\sigma, \bar\sigma]$ implies $I(\lambda) > 0$ for all λ such that $\sigma_\lambda(0) \geq \widetilde\sigma$. Therefore, $I(\lambda_{\mathrm{nec}}) > 0$. □

Remark 6. Comparing Proposition 3.4 with Theorem 3.3, we see that existence of stationary solutions is possible even when $\sigma_{\mathrm{nec}} < \widetilde\sigma$.

(a) Imitating the proof of Theorem 2.3, it can be shown that if there exists $\alpha \in (\sigma_0, \bar\sigma)$ such that

$$\int_\alpha^{\bar\sigma} S(\sigma)(\sigma - \alpha)^2 d\sigma = 0, \tag{3.10}$$

then $\alpha \leq \sigma_*$ (thus there is no stationary solution for the necrotic model if $\sigma_{\mathrm{nec}} \leq \alpha$) and there is a (unique) stationary solution when $\sigma_{\mathrm{nec}} \geq k_\alpha := \bar\sigma - \frac{(\bar\sigma-\alpha)}{2}\frac{f(\alpha)}{f(\bar\sigma)}$. Moreover, we obtain a lower bound for the outer radius

[1] The same technique also copes with more general proliferation rates.

$R_{\rm nec} = \sqrt{\lambda_{\rho_*}}$ of the stationary solution in terms of the parameters $\sigma_{\rm nec}$ and $\bar{\sigma}$, which are intrinsic to the tumor:

$$\lambda_{\rho_*} \geq \frac{6(\bar{\sigma} - \sigma_{\rm nec})}{f(\bar{\sigma})}.$$

In addition, if the constant μ in (3.3) fulfills the condition

$$\mu \geq \frac{1}{(\sigma_{\rm nec} - \alpha)^3} \int_\alpha^{\sigma_{\rm nec}} |S(\sigma)|(\sigma - \alpha)^2 d\sigma,$$

the following bounds for the inner and outer radii are true:

$$\rho_* \leq \rho_\alpha := \frac{\sigma_{\rm nec} - \alpha}{\bar{\sigma} - \alpha}$$

and

$$\lambda_{\rho_*} \leq \frac{6(\bar{\sigma} - \alpha)}{f(\alpha)(1 - \rho_\alpha^3)}.$$

Let us now consider the linear case $f(\sigma) = \sigma$ and $S(\sigma) = \sigma - \widetilde{\sigma}$, as studied in [6, 10]. Then k_α is an improvement on the result given by Proposition 3.4. More precisely, if

$$\widetilde{\sigma} \in \left(\frac{7\bar{\sigma}}{8}, \bar{\sigma}\right),$$

then $k_\alpha < \widetilde{\sigma}$ and we still have existence of stationary solutions for $\sigma_{\rm nec} \geq k_\alpha$. A result of this type was obtained in [10].

(b) We can also improve Proposition 3.4 by following closely the proofs of Theorem 2.3 and Proposition 2.4. In fact, suppose that $S(\sigma_0) < 0 < S(\bar{\sigma})$. Let us denote

$$\bar{\lambda} := \max\left\{\frac{3(\bar{\sigma} - \alpha)}{f(\bar{\sigma})}, \frac{6(\bar{\sigma} - \beta)}{f(\bar{\sigma})}\right\},$$

where α and β are given by (2.10) and (2.11), respectively. If we define $\gamma \in [\sigma_0, \bar{\sigma}]$ as the unique solution of

$$\gamma + \frac{\bar{\lambda}}{6} f(\gamma) = \bar{\sigma},$$

it can be shown that there exists a (unique) stationary solution if $\sigma_{\rm nec} \geq \gamma$. Besides, the outer radius is bounded by

$$\lambda_{\rho_*} \geq \frac{6(\bar{\sigma} - \sigma_{\rm nec})}{f(\bar{\sigma})}.$$

If the constant μ is such that

$$\mu \geq \frac{1}{(\sigma_{\rm nec} - \gamma)^3} \int_{\sigma_{\rm nec}}^{\bar{\sigma}} S(\sigma)(\sigma - \gamma)^2 d\sigma,$$

then

$$\rho_* \leq \rho_\gamma := \frac{\sigma_{\rm nec} - \gamma}{\bar{\sigma} - \gamma}$$

and

$$\lambda_{\rho_*} \leq \frac{\bar{\lambda}}{6(1-\rho_\gamma)^2}.$$

Considering, as before, $f(\sigma) = \sigma$ and $S(\sigma) = \sigma - \widetilde{\sigma}$, this constant γ is an enhancement in Proposition 3.4 if $\widetilde{\sigma} \in \left(\frac{3}{5}\bar{\sigma}, \bar{\sigma}\right)$.

4. Conclusions.

Rigorous analysis of the model given by the system (1.1)–(1.3), (1.5) was made considering only its stationary solutions. A realistic class of nonlinear absorption and proliferations rates has also been regarded. Our procedure also takes into account the results proved in this work and seems to be justified.

Dealing with nonlinear absorption and proliferation rates is not a simple task: even the existence of stationary solutions for the model is questionable, while an explicit stationary solution is available for its linear version.

Considering the nonnecrotic model, the chosen approach proved to be effective. It was shown that a stationary solution is possible in many situations, and bounds for the stabilizing radius were obtained. Comparing our result with that in other papers, where only linear absorption and proliferations rates were considered, our bounds are noteworthy.

Studying a nonnecrotic tumor, Byrne and Chaplain [5] considered a linear absorption rate and a nonlinear proliferation rate in a numerical implementation and looked for a stationary solution as a limit of evolutionary solutions. Taking into account the bounds for the stabilizing radius given in this paper, we easily concluded that the numerical implementation done in that paper was destined to fail. This shows that prior knowledge of the possibility of a stationary solution has practical implications. Of course, similar circumstances are plausible in the mathematical analysis of a situation in biomedical praxis.

On the nonnecrotic model, however, the principal contribution of our paper is given by the ease of its computational implementation, as exemplified in section 2.3.

The major contribution of this paper involves the stationary solutions of the necrotic model (3.2)–(3.3). It concerns the analysis of the intertwining of the nonnecrotic and necrotic models. Results from the nonnecrotic model are decisive for the study of the necrotic model: the (numerically obtainable) constant σ_* conclusively settles the possibility of existence of a stationary solution. Once more, the biomedical consequences of this result are remarkable.

Of course, since the evolution equation has not been considered for nonlinear rates, the results of this paper are given as possibilities and not as predictions. However, in [4] we prove the stability of the stationary solution in the quasi-stationary case. This shows that the outcomes of this paper are most likely valid in praxis.

5. Proofs.

For the convenience of the reader, we state the following form of the maximum principle, which is a fundamental tool in the demonstration of our results. Its proof is a simple exercise.

LEMMA 5.1. *Suppose that* $w \in C^2([\rho,1],\mathbb{R})$ *satisfies*

$$(r^2w')' = \phi(r) + h(r)w, \quad \rho < r < 1, \qquad w'(\rho) \geq 0, \tag{5.1}$$

where ϕ *and* h *are continuous functions, with* $h \geq 0$ *on* $[\rho,1]$.

(i) *If* $w(1) \leq 0$ *and* $\phi \geq 0$ *on* $[\rho,1]$*, then* $\max w \leq 0$*;*

(ii) *if* $w(\rho) \geq 0$ *and* $\phi > 0$ *on* $[\rho,1]$*, then* $\min w = w(\rho) \geq 0$.

Proof of Proposition 2.1. For each $\lambda \geq 0$, the constant functions $\underline{\sigma} \equiv \sigma_0$ and $\overline{\sigma} \equiv \bar{\sigma}$ are sub- and supersolutions of the BVP (2.1), respectively. Hence, there exists at least one solution $\sigma_\lambda \in C^2([0,1])$ for this problem, satisfying

$$\sigma_0 \leq \sigma_\lambda(r) \leq \bar{\sigma} \quad \text{for all } r \in [0,1].$$

Lemma 5.1 brings in the uniqueness of σ_λ. In fact, if $\sigma_1, \sigma_2 \in C^2([0,1])$ are two solutions of this problem, $w := \sigma_1 - \sigma_2$ and $-w$ satisfy

$$\begin{aligned} &(r^2 w')' = h(r) w, \quad 0 < r < 1, \\ &w'(0) = 0 = w(1), \end{aligned}$$

where

$$h(r) = \lambda r^2 \int_0^1 f'(\xi \sigma_1(r) + (1-\xi)\sigma_2(r)) d\xi \geq 0.$$

By integrating (2.1) once, we obtain (i). Uniqueness for the initial value problem implies that $\sigma_0 < \sigma_\lambda(0)$. Combining this with (i), we obtain $\sigma_0 < \sigma_\lambda(r)$ for all $r \in [0,1]$. Inequality (ii) results by substituting (i) into (2.1).

We obtain (iii) by using again Lemma 5.1. The continuity of the map $\lambda \mapsto u_\lambda$ is proved by integrating (2.1) twice and then considering an increasing sequence (λ_n) in $[0,\infty)$ such that $\lambda_n \nearrow \lambda_\infty \in [0,\infty]$. We define

$$\sigma_\infty(r) = \lim_{n\to\infty} \sigma_n(r) = \inf_{\lambda \geq 0} \sigma_\lambda(r) \quad \text{for all } r \in [0,1].$$

Application of the Arzela–Ascoli theorem produces the result if $\lambda_\infty < \infty$ (considering also a decreasing subsequence). If $\lambda_\infty = \infty$, the dominated convergence theorem shows that $\sigma_\infty = \sigma_0$ almost everywhere in $[0,1]$. A simple argument proves then that the convergence is uniform on each closed interval of $[0,1)$. □

Proof of Theorem 2.3. Taking into account Proposition 2.1, the function $\psi(\lambda) = \sigma_\lambda(0)$ is continuous and nonincreasing. It follows easily that ψ is onto $(\sigma_0, \bar{\sigma}]$. Therefore, there exists at least one $\lambda_\alpha > 0$ such that $\psi(\lambda_\alpha) = \alpha$.

The graph of the function

$$v(r) = \alpha + (\bar{\sigma} - \alpha) r$$

is the straight line through the points $(0,\alpha)$ and $(1,\bar{\sigma})$. Since σ_{λ_α} is strictly convex, for all $r \in [0,1]$ we have

$$\alpha \leq \sigma_{\lambda_\alpha}(r) \leq v(r) \leq \bar{\sigma}. \tag{5.2}$$

Now, let us consider the auxiliary function $\phi(\lambda) = \sigma'_\lambda(1)$ for $\lambda \geq 0$. The continuous function ϕ clearly satisfies $\phi(0) = 0$. We claim that $\phi(\infty) = \infty$. In fact, from (2.4) we obtain

$$r \sigma'_\lambda(1) \geq \sigma'_\lambda(r) \quad \text{for all} \quad 0 < r < 1.$$

Integration of the last inequality produces

$$\sigma'_\lambda(1) \left(\frac{1 - r^2}{2} \right) \geq \bar{\sigma} - \sigma_\lambda(r), \quad 0 < r < 1. \tag{5.3}$$

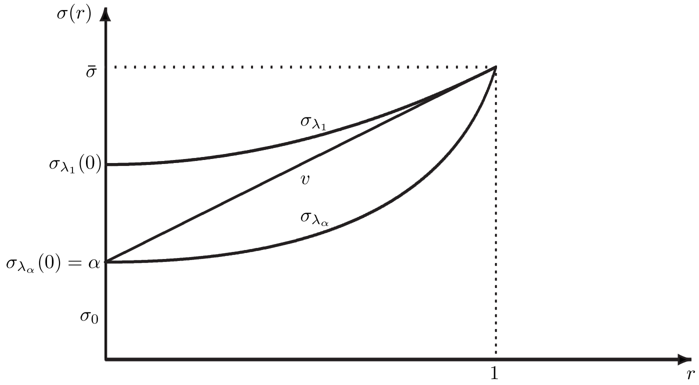

FIG. 5.1. *The geometrical construction in Theorem* 2.3: $\alpha \le \sigma_{\lambda_\alpha}(r) \le v(r) \le \sigma_{\lambda_1}(r) \le \bar{\sigma}$.

Consequently,

$$\lim_{\lambda\to\infty} \phi(\lambda) \ge \lim_{\lambda\to\infty} \frac{2(\bar{\sigma}-\sigma_\lambda(r))}{1-r^2} = \frac{2(\bar{\sigma}-\sigma_0)}{1-r^2} \quad \text{for each } r \in [0,1).$$

The claim results by making $r \to 1^-$.

Ergo, there exists $\lambda_1 > 0$ such that $\phi(\lambda_1) = \bar{\sigma} - \alpha$. The convexity of σ_{λ_1} implies that

$$\sigma_{\lambda_1}(r) \ge (\bar{\sigma}-\alpha)r + \alpha = v(r), \quad r \in [0,1]. \tag{5.4}$$

Combining (5.2) and (5.4) yields (see Figure 5.1)

$$\alpha \le \sigma_{\lambda_\alpha}(r) \le v(r) \le \sigma_{\lambda_1}(r) \le \bar{\sigma} \quad \text{for all } r \in [0,1].$$

Hence,

$$\int_0^1 S(\sigma_{\lambda_\alpha}(r))r^2 dr \le \int_0^1 S(v(r))r^2 dr \le \int_0^1 S(\sigma_{\lambda_1}(r))r^2 dr. \tag{5.5}$$

Since

$$\int_0^1 S(v(r))r^2 dr = \frac{1}{(\bar{\sigma}-\alpha)^3} \int_\alpha^{\bar{\sigma}} S(\sigma)(\sigma-\alpha)^2 d\sigma = 0,$$

inequality (5.5) means that

$$I(\lambda_\alpha) \le 0 \le I(\lambda_1).$$

The existence of $\lambda_* \in [\lambda_1, \lambda_\alpha]$ such that $I(\lambda_*) = 0$ follows then by continuity.

Now we obtain the estimates (2.8). Since $\alpha = \sigma_{\lambda_\alpha}(0) \le \sigma_{\lambda_\alpha}(r)$ and

$$\sigma_{\lambda_\alpha}(0) = \bar{\sigma} - \lambda_\alpha \int_0^1 \int_0^\theta \left(\frac{s}{\theta}\right)^2 f(\sigma_{\lambda_\alpha}(s)) ds d\theta,$$

we have

$$\alpha \le \bar{\sigma} - \frac{\lambda_\alpha}{6} f(\alpha) \le \bar{\sigma} - \frac{\lambda_*}{6} f(\alpha),$$

thus showing the upper bound for λ_*.

On the other hand, since

$$\sigma'_{\lambda_1}(0) = \phi(\lambda_1) = \bar{\sigma} - \alpha = \lambda_1 \int_0^1 s^2 f(\sigma_{\lambda_1}(s))ds,$$

we find

$$\bar{\sigma} - \alpha \leq \lambda_1 f(\bar{\sigma}) \int_0^1 s^2 ds < \frac{\lambda_*}{3} f(\bar{\sigma}),$$

from which we obtain the lower bound. □

Proof of Proposition 2.4. Proposition 2.2 brings in existence and uniqueness of λ_*. Since $S(\bar{\sigma}) > 0$,

$$\int_\xi^{\bar{\sigma}} S(\sigma)(\sigma - \xi)^2 d\sigma \geq 0 \quad \text{for all } \xi \text{ near } \bar{\sigma}. \tag{5.6}$$

So, for each ξ as above, we repeat the construction of the last proof to find

$$I(\lambda_1) \geq \int_0^1 S(v(r))r^2 dr = \frac{1}{(\bar{\sigma} - \xi)^3} \int_\xi^{\bar{\sigma}} S(\sigma)(\sigma - \xi)^2 dt \geq 0,$$

showing that $\lambda_1 \leq \lambda_*$. Because of that,

$$\bar{\sigma} - \xi \leq \lambda_1 f(\bar{\sigma}) \int_0^1 s^2 ds \leq \frac{\lambda_*}{3} f(\bar{\sigma})$$

implies the lower bound

$$\lambda_* \geq 3 \frac{(\bar{\sigma} - \xi)}{f(\bar{\sigma})}.$$

But the same function S also satisfies

$$\int_\eta^{\bar{\sigma}} S(\sigma)\sqrt{\sigma - \eta} d\sigma \geq 0 \quad \text{for all } \eta \text{ near } \bar{\sigma}. \tag{5.7}$$

Let $\lambda_\eta > 0$ be such that $\sigma'_{\lambda_\eta}(1) = 2(\bar{\sigma} - \eta)$. From (5.3) we obtain

$$\sigma_{\lambda_\eta}(r) \geq \bar{\sigma} - \frac{\sigma'_{\lambda_\eta}(1)}{2}(1 - r^2) = \eta + (\bar{\sigma} - \eta)r^2,$$

and, since $S(\sigma)$ is increasing and

$$\int_0^1 S(\eta + (\bar{\sigma} - \eta)r^2)r^2 dr = \frac{1}{2\,(\bar{\sigma} - \eta)^{3/2}} \int_\eta^{\bar{\sigma}} S(\sigma)\sqrt{\sigma - \eta} d\sigma \geq 0,$$

we conclude that $I(\lambda_\eta) \geq 0$. The monotonicity of S then implies that $\lambda_* \geq \lambda_\eta$. Accordingly,

$$2(\bar{\sigma} - \eta) = \sigma'_{\lambda_\eta}(1) = \lambda_\eta \int_0^1 s^2 f(\sigma_{\lambda_\eta}(s))ds \leq \frac{\lambda_* f(\bar{\sigma})}{3}$$

implies the bound

$$\lambda_* \geq \frac{6(\bar{\sigma}-\eta)}{f(\bar{\sigma})}.$$

Collecting the two estimates, we obtain (2.9). □

Proof of Theorem 2.5. Since $I(0) = S(\bar{\sigma})/3 > 0$ and $\lim_{\lambda\to\infty} I(\lambda) = \int_0^1 S(\sigma_0)r^2 dr = 0$, it suffices to verify that $I(\lambda)$ tends to zero by negative values.

Fix $\lambda_\Lambda > 0$ such that $\sigma_{\lambda_\Lambda}(0) = \Lambda$. The monotonicity of $\sigma_\lambda(r)$ with respect to λ and to r ensures the existence of a unique $r_\lambda \in (0,1)$ such that $\sigma_\lambda(r_\lambda) = \Lambda$ for all $\lambda \geq \lambda_\Lambda$. Denote by Γ the function whose graph is the straight line through the points (r_λ, Λ) and $(1, \bar{\sigma})$. Since the functions σ_λ are strictly convex, $\Gamma(r) > \sigma_\lambda(r)$ if $r > r_\lambda$ and $\Gamma(r) < \sigma_\lambda(r)$ if $r < r_\lambda$. Now, for each $\lambda \geq \lambda_\Lambda$, let $(s_\lambda, \sigma_\lambda(0))$ be the point where the horizontal line $\sigma = \sigma_\lambda(0) \leq \Lambda$ intersects Γ (see Figure 5.2).

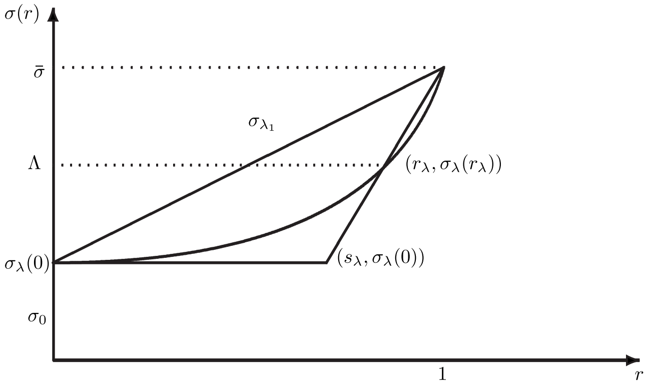

FIG. 5.2. *The geometrical construction in Theorem* 2.5*:* $s_\lambda = \frac{\bar{\sigma}-\sigma_\lambda(0)}{\bar{\sigma}-\Lambda} r_\lambda - \frac{\Lambda-\sigma_\lambda(0)}{\bar{\sigma}-\Lambda} < r_\lambda$.

So, Γ is given by

$$\Gamma(r) = \sigma_\lambda(0) + \frac{\bar{\sigma}-\sigma_\lambda(0)}{1-s_\lambda}(r - s_\lambda),$$

where

$$s_\lambda = \frac{\bar{\sigma}-\sigma_\lambda(0)}{\bar{\sigma}-\Lambda} r_\lambda - \frac{\Lambda-\sigma_\lambda(0)}{\bar{\sigma}-\Lambda} < r_\lambda.$$

From Proposition 2.1 we deduce that

$$\lim_{\lambda\to\infty} s_\lambda = \lim_{\lambda\to\infty} r_\lambda = 1.$$

Let us define the auxiliary function

$$v_\lambda(r) = \begin{cases} \sigma_\lambda(0) & \text{if } 0 \leq r \leq s_\lambda, \\ \sigma_\lambda(0) + \frac{\bar{\sigma}-\sigma_\lambda(0)}{1-s_\lambda}(r - s_\lambda) & \text{if } s_\lambda \leq r \leq 1. \end{cases} \tag{5.8}$$

Thus, v_λ coincides with the horizontal line $\sigma = \sigma_\lambda(0)$ for $0 \leq r \leq s_\lambda$ and with Γ for $s_\lambda \leq r \leq 1$.

For $0 \leq r \leq r_\lambda$ we have $v_\lambda(r) \leq \sigma_\lambda(r)$. Since S is decreasing in $[0, \Lambda]$, we have $S(\sigma_\lambda(r)) < S(v_\lambda(r))$ for all $r \in [0, r_\lambda]$. On the other hand, we have $v_\lambda(r) \geq \sigma_\lambda(r)$ if $r_\lambda \leq r \leq 1$. Since S is increasing in the interval $[\Lambda, \bar{\sigma}]$, we have that $S(\sigma_\lambda(r)) \leq S(v_\lambda(r))$ for all $r \in [r_\lambda, 1]$. We deduce that

$$S(\sigma_\lambda) \leq S(v_\lambda) \text{ on } [0,1].$$

For all $\lambda \geq \lambda_\Lambda$, it follows that

$$\begin{aligned} I(\lambda) &\leq \int_0^1 S(v_\lambda(r))r^2 dr \\ &= \int_0^{s_\lambda} S(v_\lambda(r))r^2 dr + \int_{s_\lambda}^1 S(v_\lambda(r))r^2 dr \\ &= S(\sigma_\lambda(0))\frac{s_\lambda^3}{3} + \int_{s_\lambda}^1 S(v_\lambda(r))r^2 dr. \end{aligned}$$

Since S is decreasing for $[\sigma_0, \sigma_\lambda(0)] \subset [\sigma_0, \Lambda]$ and $S(\sigma_0) = 0$, we have

$$S(\sigma_\lambda(0))s_\lambda^3/3 \leq 0 \quad \text{for all } \lambda \geq \lambda_\Lambda.$$

Therefore,

$$I(\lambda) \leq \int_{s_\lambda}^1 S(v_\lambda(r))r^2 dr \quad \text{for all } \lambda \geq \lambda_\Lambda.$$

Making use of (5.8), we obtain

$$\int_{s_\lambda}^1 S(v_\lambda(r))r^2 dr = (1 - s_\lambda)p(\lambda),$$

where

$$p(\lambda) = \frac{1}{(\bar{\sigma} - \sigma_\lambda(0))^3} \int_{\sigma_\lambda(0)}^{\bar{\sigma}} S(\sigma)[(1 - s_\lambda)\,\sigma + \bar{\sigma} s_\lambda - \sigma_\lambda(0)^2] d\sigma.$$

Since $s_\lambda \to 1$ and $\sigma_\lambda(0) \to \sigma_0^+$ when $\lambda \to \infty$, we have

$$\lim_{\lambda \to \infty} p(\lambda) = \frac{1}{\bar{\sigma} - \sigma_0} \int_{\sigma_0}^{\bar{\sigma}} S(\sigma) d\sigma \leq 0.$$

Consequently,

$$I(\lambda) \leq (1 - s_\lambda)p(\lambda) \leq 0$$

for all $\lambda \geq \lambda_\Lambda$ large enough, since $(1 - s_\lambda) > 0$ for all $\lambda \geq \lambda_\Lambda$. This shows the existence of $\lambda_* > \lambda_\Lambda$ such that $I(\lambda_*) = 0$.

Furthermore, since $\Lambda = \sigma_{\lambda_\Lambda}(0)$ and

$$\Lambda = \sigma_{\lambda_\Lambda}(0) = \bar{\sigma} - \lambda_\Lambda \int_0^1 \int_0^\theta (s/\theta)^2 f(\sigma_{\lambda_\Lambda}(s)) ds d\theta \geq \bar{\sigma} - \frac{\lambda_*}{6} f(\bar{\sigma}),$$

we obtain the lower bound (2.12) for λ_*. □

RECONSTRUCTING DISCONTINUITIES USING COMPLEX GEOMETRICAL OPTICS SOLUTIONS[*]

GUNTHER UHLMANN[†] AND JENN-NAN WANG[‡]

Abstract. In this paper we provide a framework for constructing general complex geometrical optics solutions for several systems of two variables that can be reduced to a system with the Laplacian as the leading order term. We apply these special solutions to the problem of reconstructing inclusions inside a domain filled with known conductivity from local boundary measurements. Computational results demonstrate the versatility of these solutions to determine electrical inclusions.

Key words. geometrical optics, inclusions, numerical algorithm

AMS subject classifications. 35R30, 65N21

1. Introduction.

Inverse boundary value problems are a class of inverse problems where one attempts to determine the internal parameters of body by making measurements only at the surface of the body. A prototypical example that has received a lot of attention is electrical impedance tomography (EIT). In this inverse method one would like to determine the conductivity distribution inside a body by making voltage and current measurements at the boundary.

There are many applications of EIT ranging from early breast cancer detection [32] to geophysical sensing for underground objects; see [18], [24], [25], [27]. The article [28] and the ones reviewed in [29] assume that the measurements are made on the whole boundary. However, it is often possible to make the measurements only on part of the boundary; this is the partial data problem. This is the case for the applications in breast cancer detection and geophysical sensing mentioned above.

The boundary information is encoded into the Dirichlet-to-Neumann map associated with the conductivity equation. More precisely, let Ω be an open bounded domain with smooth boundary in $\mathbb{R}^d$ with $d = 2$ or 3. Assume that $\gamma(x) > 0$ in Ω possesses a suitable regularity. The conductivity equation is described by the following elliptic equation:

$$\nabla \cdot (\gamma(x)\nabla u) = 0 \quad \text{in} \quad \Omega. \tag{1.1}$$

For an appropriate function f defined on $\partial\Omega$, there exists a unique solution $u(x)$ to the boundary value problem for (1.1) with Dirichlet condition $u|_{\partial\Omega} = f$. Thus, one can define a map Λ_γ sending the Dirichlet data to the Neumann data by

$$\Lambda_\gamma(f) = \gamma\frac{\partial u}{\partial \nu}\Big|_{\partial\Omega}.$$

The map Λ_γ is the Dirichlet-to-Neumann map associated with the conductivity equation (1.1). It is worth mentioning that even though (1.1) is linear, the map Λ_γ depends nonlinearly on γ. The famous Calderón problem is to determine γ from the knowledge of Λ_γ.

In [3], Calderón studied this inverse problem by linearizing the fully nonlinear problem around a constant conductivity function. To attack this linearized problem, Calderón introduced harmonic functions of the form $e^{x\cdot\rho}$ with $\rho \in \mathbb{C}^n$ and $\rho\cdot\rho = 0$, which is the genesis of *complex geometrical optics* (CGO) *solutions* since the phase function $x\cdot\rho$ is complex-valued. Inspired by Calderón's approach, Sylvester and Uhlmann [28] solved the uniqueness question of Calderón's problem for smooth conductivities by constructing CGO solutions for (1.1). Since the conductivity equation (1.1) is closely related to the Schrödinger equation (see (2.2)), it suffices to construct CGO solutions for the Schrödinger which are of the form $u(x) = e^{x\cdot\rho}(1 + r(x,\rho))$, where r is decaying in $|\rho|$. To motivate the name of the solution, we write

$$u(x) = e^{ih^{-1}x\cdot(\omega_1+i\omega_2)}(1 + h\tilde{r}), \tag{1.2}$$

where $h = |\rho|^{-1}$, $i(\omega_1 + i\omega_2) = |\rho|^{-1}(\mathrm{Re}\rho + i\mathrm{Im}\rho)$, and $\tilde{r} = h^{-1}r = |\rho|r$. The form (1.2) is analogous to the geometrical optics solution for the wave propagation equation in which the phase function is real-valued. Here the phase function in (1.2) is complex-valued. Nevertheless, it is linear. CGO solutions have been used in EIT and have been instrumental in solving several inverse problems. We will not review these developments in detail here; see [30] and [29] for references; other reviews in EIT are [1], [2], and [4].

Recently, new CGO solutions that are useful for the partial data problem were constructed in [20] for the conductivity equation and zeroth order perturbations of the Laplacian. The real parts of the phase of these solutions are limiting Carleman weights. They have been generalized to first order perturbation of the Laplacian for scalar equations or systems in [5], [9], [26], and [31]. Constructions of CGO solutions for the conductivity equation and zeroth order perturbations of the Laplacian using hyperbolic geometry can be found in [16], [17]; these have been applied to determine electrical inclusions in [10].

In two dimensions, when the underlying equation has the Laplacian as the leading part, due to the rich conformal structure, we have more freedom of choosing the complex phases for the CGO solutions. In particular any harmonic function is a limiting Carleman weight and can be the real part of a CGO solution. The aim of the paper is to provide a framework for constructing these solutions for several systems of two variables that can be reduced to a system with the Laplacian as the leading term. We apply these special solutions to the problem of reconstructing inclusions inside a domain filled with known conductivity from local boundary measurements. We also provide numerical results to demonstrate the applicability and flexibility of these special solutions.

From now on, we consider the case $d = 2$, i.e., the $\mathbb{R}^2$ plane. Let $n \in \mathbb{N}$ and denote $U(x) = (u_1(x_1,x_2),\ldots,u_n(x_1,x_2))^\top$. We consider the following system of equations:

$$PU := \Delta_x U + A_1(x)\partial_{x_1}U + A_2(x)\partial_{x_2}U + Q(x)U = 0 \quad \text{in} \quad \Omega, \tag{1.3}$$

where $\Delta_x = \partial_{x_1}^2 + \partial_{x_2}^2$ and A_1, A_2, Q are $n\times n$ matrices whose regularities will be specified later. The system (1.3) contains all scalar or two-dimensional physical systems that can be reduced to a system with the Laplacian as the leading part. Those systems include the conductivity equation, the magnetic Schrödinger equation, the two-dimensional isotropic elasticity system, the two-dimensional Stokes system, etc. In this paper we first study CGO solutions with special phase functions for (1.3).

In the papers [20], [5], [9], [10], [17], [26], and [31], the real parts of the phase functions are radial functions. These can be used to probe the region with spherical fronts, the so-called complex spherical waves. Even though these solutions are better suited for the local data problem than the usual CGO solutions with linear phase functions, they are still quite restrictive. Fortunately, in the two-dimensional case, we have many more choices of phase functions. For example, let $\varphi(x)$ be a harmonic function with nonvanishing gradient in Ω; then $\varphi + i\psi$ can be the phase function of the CGO solutions when ψ is a harmonic conjugate of φ. In other words, $\rho(x) := \varphi(x) + i\psi(x)$ is holomorphic in Ω. Our method in this paper is developed based on this idea.

Using the CGO solutions, we can consider the problem of finding embedded inclusions in a known medium. This is the object identification problem. The method developed here shares the same spirit as Ikehata's *enclosure method* [11], [12]. For the two-dimensional problem, we would like to mention a very interesting result by Ikehata in [14], where he introduced the Mittag–Leffler function in the object identification problem. This has the property that its modulus grows exponentially in some cone and decays to zero algebraically outside the same cone. Using the Mittag–Leffler function and shrinking the opening angle of the cone, one can reconstruct precisely the shapes of some embedded objects such as star-shaped objects. The numerical implementation of the Mittag–Leffler functions was carried out by Ikehata and Siltanen in [15]. The main restriction of the method using the Mittag–Leffler function is that it can be applied only to scalar equations with a homogeneous background. That is, they probe the region with harmonic functions. The novelty of our method is its flexibility in treating scalar equations, or even two-dimensional *systems*, with an *inhomogeneous background*. Furthermore, for the object identification problem in such general systems, using our special CGO solutions, we are able to reconstruct the precise information of some embedded objects including star-shaped regions by boundary measurements. This identification result is similar to that in [14] and [15], where only the Laplace equation is treated. So, in theory, our reconstruction method with these CGO solutions is in greater generality. In this paper, we are developing the foundational work to treat the case of an inhomogeneous background and also to deal with the case of systems. Moreover, we give numerical evidence that the method works in the homogeneous case.

Before going further, we also would like to compare our method with that in [10]. As we have pointed out above, the real parts of the phase functions of CGO solutions in [10] are radially symmetric. So their probing fronts are circles or spheres. Moreover, the construction of CGO solutions in [10] is based on the hyperbolic geometry. It has not been developed for studying more general equations or systems. The advantage of our method lies in the freedom of choosing the phase functions of CGO solutions. One useful example is to take $\rho(x)$ as a polynomial. By increasing the degree of the polynomial, we can narrow our probing fronts. Consequently, we are able to determine more information in the object identification problem in the two-dimensional case than [10] does. On the other hand, since the real parts of the phase functions in our CGO solutions are not necessarily radially symmetric, we can create different probing fronts by simply rotating the phase functions. Like [10], we can also localize the measurements in an arbitrarily small region on the boundary. Here the local data means that the Dirichlet condition is nonzero only on a small part of the boundary.

On the same region, we measure the Neumann condition. In theory, the nonzero part of the Dirichlet data can be taken as small as we wish.

Our construction of CGO solutions with more general phases is rather elementary. The main idea is to transform CGO solutions with linear phases by suitable conformal mappings. The construction of CGO solutions with linear phases for (1.3) was first given by Nakamura and Uhlmann in [21], [22], where they introduced the intertwining technique in handling the first order terms (also see [7] for similar results). Here we shall use Carleman's technique to construct CGO solutions with linear phases for (1.3).

This paper is organized a follows. In section 2, we give concrete examples of (1.3). In section 3, we review of the construction of CGO solutions with linear phases for (1.3). CGO solutions with more general phases will be discussed in section 4. For an application of CGO solutions with general phases, we consider the problem of reconstructing inclusions embedded into a domain with known conductivity by boundary measurements. Numerical experiments of our method are presented in section 6.

2. Physical examples of (1.3).

2.1. Conductivity equation. Our first example is the well-known conductivity equation already given in the previous section. Let $\gamma(x) \in C^2(\bar{\Omega})$ and $\gamma(x) > 0$ for all $x \in \bar{\Omega}$. We consider the equation

$$\nabla \cdot (\gamma \nabla u) = 0 \quad \text{in} \quad \Omega. \tag{2.1}$$

Introducing the new variable $v = \gamma^{1/2} u$, (2.1) is equivalent to

$$(\Delta + q)v = 0 \quad \text{in} \quad \Omega \tag{2.2}$$

with $q = -\Delta\gamma^{1/2}/\gamma^{1/2} \in L^\infty(\Omega)$. Equation (2.2) is a Schrödinger-type equation. We can also consider a more general Schrödinger-type equation with a convection term:

$$(\Delta + a(x) \cdot \nabla + q)v = 0 \quad \text{in} \quad \Omega, \tag{2.3}$$

where $a = (a_1, a_2)$.

2.2. Isotropic elasticity. The domain Ω is now modeled as an inhomogeneous, isotropic, elastic medium characterized by the Lamé parameters $\lambda(x)$ and $\mu(x)$. Assume that $\lambda(x) \in C^2(\overline{\Omega})$, $\mu(x) \in C^4(\overline{\Omega})$, and the following inequalities hold:

$$\mu(x) > 0 \quad \text{and} \quad \lambda(x) + 2\mu(x) > 0 \quad \forall\, x \in \overline{\Omega} \quad \text{(strong ellipticity).} \tag{2.4}$$

We consider the static isotropic elasticity system without sources

$$\nabla \cdot (\lambda(\nabla \cdot u)I + 2\mu S(\nabla u)) = 0 \quad \text{in} \quad \Omega. \tag{2.5}$$

Here and below, $S(A) = (A + A^T)/2$ denotes the symmetric part of the matrix $A \in \mathbb{C}^{2\times 2}$. Equivalently, if we denote $\sigma(u) = \lambda(\nabla \cdot u)I + 2\mu S(\nabla u)$ the stress tensor, then (2.5) becomes

$$\nabla \cdot \sigma = 0 \quad \text{in} \quad \Omega.$$

On the other hand, since the Lamé parameters are differentiable, we can also write (2.5) in the nondivergence form

$$\mu\Delta u + (\lambda + \mu)\nabla(\nabla \cdot u) + \nabla\lambda\nabla \cdot u + 2S(\nabla u)\nabla\mu = 0 \quad \text{in} \quad \Omega. \tag{2.6}$$

We will use the reduced system derived by Ikehata [13]. This reduction was also mentioned in [29]. Let $\binom{w}{g}$ satisfy

$$\Delta\begin{pmatrix} w\\ g\end{pmatrix}+A(x)\begin{pmatrix}\nabla g\\ \nabla\cdot w\end{pmatrix}+Q(x)\begin{pmatrix} w\\ g\end{pmatrix}=0, \tag{2.7}$$

where

$$A(x)=\begin{pmatrix}2\mu^{-1/2}(-\nabla^2+\Delta)\mu^{-1} & -\nabla\log\mu\\ 0 & \frac{\lambda+\mu}{\lambda+2\mu}\mu^{1/2}\end{pmatrix}$$

and

$$Q(x)=\begin{pmatrix}-\mu^{-1/2}(2\nabla^2+\Delta)\mu^{1/2} & 2\mu^{-5/2}(\nabla^2-\Delta)\mu\ \nabla\mu\\ -\frac{\lambda-\mu}{\lambda+2\mu}(\nabla\mu^{1/2})^T & -\mu\Delta\mu^{-1}\end{pmatrix}.$$

Here $\nabla^2 f$ is the Hessian of the scalar function f. Then

$$u:=\mu^{-1/2}w+\mu^{-1}\nabla g-g\nabla\mu^{-1}$$

satisfies (2.6). A similar form was also used in [7] for studying the inverse boundary value problem for the isotropic elasticity system.

2.3. Stokes system. Let $\mu(x)\in C^4(\bar\Omega)$ and $\mu(x)>0$ for all $x\in\bar\Omega$. Here μ is called the viscosity function. Suppose that $u=(u_1,u_2)$ and p satisfy the Stokes system

$$\begin{cases}\nabla\cdot(\mu S(\nabla u))-\nabla p=0 \quad \text{in} \quad \Omega,\\ \nabla\cdot u=0 \quad \text{in} \quad \Omega.\end{cases} \tag{2.8}$$

Here u and p represent the velocity field and the pressure, respectively. Motivated by the isotropic elasticity, we set $u=\mu^{-1/2}w+\mu^{-1}\nabla g-(\nabla\mu^{-1})g$ and

$$p=\nabla\mu^{1/2}\cdot w+\mu^{1/2}\nabla\cdot w+2\Delta g=\nabla\cdot(\mu^{1/2}w)+2\Delta g; \tag{2.9}$$

then (u,p) is a solution of (2.8), provided $\binom{w}{g}$ satisfies

$$\Delta\begin{pmatrix} w\\ g\end{pmatrix}+A(x)\begin{pmatrix}\nabla g\\ \nabla\cdot w\end{pmatrix}+Q(x)\begin{pmatrix} w\\ g\end{pmatrix}=0 \tag{2.10}$$

with

$$A(x)=\begin{pmatrix}-2\mu^{1/2}\nabla^2\mu^{-1} & -\mu^{-1}\nabla\mu\\ 0 & \mu^{1/2}\end{pmatrix}$$

and

$$Q=\begin{pmatrix}-2\mu^{-1/2}\nabla^2\mu^{1/2}-\mu^{-1/2}\Delta\mu^{1/2} & -4\nabla^2\mu^{-1}\nabla\mu^{1/2}-2\mu^{1/2}\nabla\cdot(\nabla\mu^{-1})\\ \mu(\nabla\mu^{-1/2})^T & -\mu\Delta\mu^{-1}\end{pmatrix}.$$

3. CGO solutions with linear phases. In this section we review the method of constructing CGO solutions with linear phases using Carleman estimates. We consider a slightly different system here. Let $\tilde{\Omega}$ be an open bounded domain in $\mathbb{R}^2$. Let $V(y) = V(y_1, y_2)$ satisfy

$$\Delta_y V + \tilde{A}_1 \partial_{y_1} V + \tilde{A}_2 \partial_{y_2} V + \tilde{Q} V = 0 \quad \text{in} \quad \tilde{\Omega}. \tag{3.1}$$

Assume that $\tilde{A}_1, \tilde{A}_2 \in C^2(\bar{\tilde{\Omega}})$ and $\tilde{Q} \in L^\infty(\tilde{\Omega})$. Given $\omega \in \mathbb{R}^2$ with $|\omega| = 1$, we look for $V(y)$ of (3.1) having the form

$$V(y) = e^{y\cdot(\omega+i\omega^\perp)/h}(\tilde{L} + \tilde{R}), \tag{3.2}$$

where $\tilde{L}$ is independent of h and $\tilde{R}$ satisfies

$$\|\partial^\alpha \tilde{R}\|_{L^2(\tilde{\Omega})} \le Ch^{1-\alpha} \quad \forall\ |\alpha| \le 2. \tag{3.3}$$

To construct V having the form (3.2), (3.3), we follow the approach in [9] and [31], which are based on [5] and [20]. Note that the real part of the phase function $y \cdot \omega$ is a limiting Carleman estimate. So if we define the semiclassical operator

$$P_h = h^2\Delta + h\tilde{A}_1(h\partial_{y_1}) + h\tilde{A}_2(h\partial_{y_2}) + h^2\tilde{Q},$$

then we can derive, by combining a Carleman estimate and the Hahn–Banach theorem, the following.

THEOREM 3.1 (see [9], [31]). *For h sufficiently small, for any $F \in L^2(\tilde{\Omega})$, there exists $W \in H^2_h(\tilde{\Omega})$ such that*

$$e^{-y\cdot\omega/h}P_h(e^{y\cdot\omega/h}W) = F$$

and $h\|W\|_{H^2_h(\tilde{\Omega})} \le C\|F\|_{L^2(\tilde{\Omega})}$, where $\|W\|^2_{H^2_h(\tilde{\Omega})} = \sum_{|\alpha|\le 2} \|(h\partial)^\alpha W\|^2_{L^2(\tilde{\Omega})}$ is the semiclassical H^2 norm.

This theorem will be needed below. Finding V of the form (3.2) is equivalent to solving

$$e^{-y\cdot(\omega+i\omega^\perp)/h}P_h(e^{y\cdot(\omega+i\omega^\perp)/h}(\tilde{L}+\tilde{R})) = 0 \quad \text{in} \quad \tilde{\Omega}.$$

We can compute that

$$e^{-y\cdot(\omega+i\omega^\perp)/h}P_h e^{y\cdot(\omega+i\omega^\perp)/h} = hT_\omega + P_h,$$

where $T_\omega = 2(\omega+i\omega^\perp)\cdot\nabla + (\omega+i\omega^\perp)\cdot(\tilde{A}_1, \tilde{A}_2)$. Hence we want to find $\tilde{L}$, independent of h, so that

$$T_\omega \tilde{L} = 0 \quad \text{in} \quad \tilde{\Omega}. \tag{3.4}$$

Equation (3.4) is a system of Cauchy–Riemann type. In fact, introducing the new variable $z = (z_1, z_2) = (\omega + i\omega^\perp) \cdot y$ and setting $\tilde{A}(\omega, z) = (\omega + i\omega^\perp) \cdot (\tilde{A}_1, \tilde{A}_2)$, (3.4) becomes

$$(4\partial_{\bar{z}} + \tilde{A})\tilde{L} = 0, \tag{3.5}$$

where $\partial_{\bar{z}} = (\partial_{z_1} + i\partial_{z_2})/2$. The existence of nontrivial $\tilde{L}$ can be found in, for example, [6], [8], and [23]. Having found $\tilde{L}$, $\tilde{R}$ is required to satisfy

$$e^{-y\cdot\omega/h}P_h(e^{y\cdot(\omega+i\omega^\perp)/h}\tilde{R}) = -e^{iy\cdot\omega^\perp/h}P_h\tilde{L}. \tag{3.6}$$

Note that $\|e^{iy\cdot\omega^\perp/h}P_h\tilde{L}\|_{L^2(\tilde{\Omega})}=O(h^2)$. Thus Theorem 3.1 implies that

$$\|e^{iy\cdot\omega^\perp/h}\tilde{R}\|_{H^2_h(\tilde{\Omega})}\le Ch, \tag{3.7}$$

which leads to

$$\|\partial^\alpha\tilde{R}\|_{L^2(\tilde{\Omega})}\le Ch^{1-|\alpha|}\quad\text{for}\quad|\alpha|\le 2. \tag{3.8}$$

Remark 3.2. *The leading term $\tilde{L}$ of the CGO solution* (3.2) *is obtained by solving* (3.5). *It is possible to solve* (3.5) *by an iteration scheme, which is numerically feasible. Theorem* 3.1 *is a general theorem to guarantee the existence of the remainder term $\tilde{R}$ in* (3.2). *It may be a nontrivial task to actually find $\tilde{R}$ for general systems. However, since $\tilde{R}$ is $O(h)$ for small h, it could be omitted in numerical computations.*

4. CGO solutions with general phases. In this section we will construct CGO solutions with more general phases for (1.3) from CGO solutions with linear phases given in the previous section. Without loss of generality, we choose $\omega=(1,0)$ and $\omega^\perp=(0,1)$, i.e., $y\cdot(\omega+i\omega^\perp)=y_1+iy_2$. Denote $y=y_1+iy_2$ and $x=x_1+ix_2$. Let Ω_0 be an open subdomain of Ω. Suppose that $A_1,A_2\in C^2(\bar{\Omega}_0)$ and $Q\in L^\infty(\Omega_0)$. Let $y=\rho(x)=y_1(x_1,x_2)+iy_2(x_1,x_2)$ be a conformal map in Ω_0, i.e., $\rho'(x)\neq 0$ for all $x\in\Omega_0$. Define $U(x)=V(y(x))$ and $\tilde{\Omega}=\rho(\Omega_0)$. By straightforward computations, we have

$$\begin{pmatrix}\partial_{x_1}\\ \partial_{x_2}\end{pmatrix}U=J(x)\begin{pmatrix}\partial_{y_1}\\ \partial_{y_2}\end{pmatrix}V\Big|_{y=\rho(x)}\quad\text{and}\quad\Delta_xU=\Delta_yV|\rho'(x)|^2,$$

where

$$J(x)=\begin{pmatrix}\partial_{x_1}y_1 & \partial_{x_1}y_2\\ \partial_{x_2}y_1 & \partial_{x_2}y_2\end{pmatrix}.$$

Suppose that ρ^{-1} exists on $\tilde{\Omega}$. Let $\hat{A}_1(y)=(A_1\partial_{x_1}y_1+A_2\partial_{x_2}y_1)\circ\rho^{-1}(y)$, $\hat{A}_2(y)=(A_1\partial_{x_1}y_2+A_2\partial_{x_2}y_2)\circ\rho^{-1}(y)$, and $\hat{Q}(y)=(Q\circ\rho^{-1})(y)$ and $g(y)=|(\rho'\circ\rho^{-1})(y)|^2$. Now if we choose $V(y)$ satisfying

$$\Delta_yV+g(y)^{-1}\hat{A}_1(y)\partial_{y_1}V+g(y)^{-1}\hat{A}_2(y)\partial_{y_2}V+g(y)^{-1}\hat{Q}V=0\quad\text{in }\tilde{\Omega}, \tag{4.1}$$

then $U(x)$ satisfies (1.3) in Ω_0. According to the construction given previously, let $V(y)$ be a solution of (4.1) having the form

$$V(y)=e^{(y_1+iy_2)/h}(\tilde{L}+\tilde{R}),$$

where

$$\|\partial^\alpha\tilde{R}\|_{L^2(\tilde{\Omega})}\le Ch^{1-\alpha}\quad\forall\ |\alpha|\le 2.$$

Denote $y_1(x_1,x_2)=\varphi(x_1,x_2)$ and $y_2(x_1,x_2)=\psi(x_1,x_2)$. We then obtain CGO solutions for (1.3) in Ω_0:

$$U(x)=e^{(\varphi+i\psi)/h}(L+R)$$

with $L=\tilde{L}\circ\rho$, $R=\tilde{R}\circ\rho$, and

$$\|\partial^\alpha R\|_{L^2(\Omega_0)}\le Ch^{1-\alpha}\quad\forall\ |\alpha|\le 2. \tag{4.2}$$

Due to the conformality of ρ, φ and ψ are harmonic functions in Ω_0. Conversely, given any φ harmonic in Ω_0 with $\nabla\varphi \neq 0$ in Ω_0, we can find a harmonic conjugate ψ of φ in Ω_0 so that $\rho = \varphi + i\psi$ is conformal in Ω_0. The freedom of choosing φ plays a key role in our reconstruction method for the object identification problem. Actually, we will mainly focus on the level curves of φ. We give some concrete examples here.

Pick a point $x_0 \notin \bar{\Omega}$. It is no restriction to assume that $x_0 = 0$. We now consider $\varphi_N = \mathrm{Re}(c_N x^N)$ for $N \geq 2$, where $c_N \in \mathbb{C}$ with $|c_N| = 1$. In the polar coordinates, $\varphi_N(r, \theta) = r^N \cos N(\theta - \theta_N)$ for some θ_N determined by c_N. We observe that $\varphi_N > 0$ in some open cone Γ_N with an opening angle π/N. The freedom of choosing θ_N (or, equivalently, c_N) allows us to "sweep" the domain Ω by Γ_N without moving the point x_0. This is quite useful in practice. Now assume that $\Gamma_N \cap \Omega \neq \emptyset$. The complex function $\rho_N(x) = c_N x^N = \varphi_N + i\psi_N$ is clearly conformal in Ω, where $\psi_N = \mathrm{Im}(c_N x^N)$. In order to apply to the inverse problem, we want to shrink the opening angle of Γ_N by taking $N \to \infty$. However, there are two serious problems in doing so. On one hand, φ_N is periodic in the angular variable, which means that it is positive in some other cones with the same opening angle which also intersect Ω when N is large. Some level curves of φ_N for different N's are shown in Figure 4.1. This property of φ_N prohibits us from using corresponding CGO solutions with large N to the object identification problem. On the other hand, the complex function $\rho_N(x)$ fails to be injective in the whole domain Ω when N is large. To overcome those difficulties and construct useful CGO solutions in the whole domain Ω, we shall carry out the construction described above in a suitable Ω_0 and extend the constructed solutions to Ω by cut-off functions.

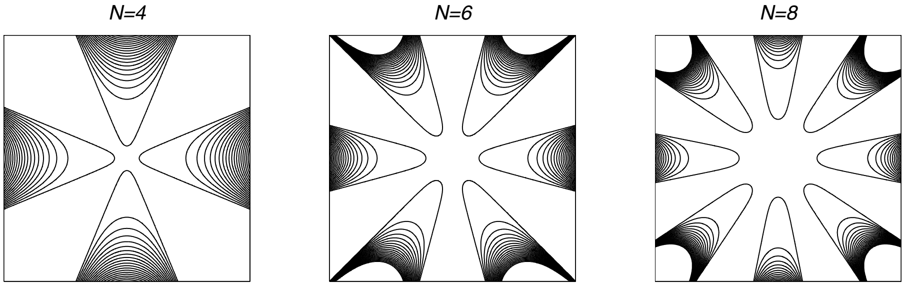

FIG. 4.1. *Some level curves of ϕ_N.*

We now set

$$\Omega_0 := \Gamma_N \cap \Omega.$$

Then ρ_N is conformal in Ω_0 and is bijective from Ω_0 onto $\rho_N(\Omega_0)$. Therefore, we can find CGO solutions for (1.3) in Ω_0,

$$U_{N,h}(x) = e^{(\varphi_N + i\psi_N)/h}(L + R),$$

and the estimate (4.2) holds. So far we have constructed only special solutions for (1.3) in some particular subdomain of Ω. To get solutions in the whole domain Ω, we use a cut-off technique. For $s > 0$, let $\ell_s = \{x \in \Gamma_N : \varphi_N = s^{-1}\}$. This is the level curve of φ_N in Γ_N. Let $0 < t < t_0$ such that

$$\left(\bigcup_{s\in(0,t)} \ell_s\right) \cap \Omega \neq \emptyset$$

and choose a small $\varepsilon > 0$. Define a cut-off function $\phi_{N,t}(x) \in C^\infty(\mathbb{R}^2)$ so that $\phi_{N,t}(x) = 1$ for $x \in \overline{(\cup_{s\in(0,t+\varepsilon/2)}\ell_s) \cap \Omega}$ and is zero for $x \in \bar{\Omega} \setminus (\cup_{s\in(0,t+\varepsilon)}\ell_s)$. We now define

$$U_{N,t,h}(x) = \phi_{N,t}e^{-t^{-1}/h}U_N = \phi_{N,t}e^{(\varphi_N - t^{-1}+i\psi_N)/h}(L+R)$$

for $x \in (\cup_{s\in(0,t+\varepsilon)}\ell_s) \cap \Omega$. So $U_{N,t,h}$ can be regarded as a function in Ω which is zero outside of Ω_0. We now take $f_{N,t,h} = U_{N,t,h}|_{\partial\Omega}$. We remark that $f_{N,t,h}$ can be used as the boundary data in the inverse problem. An obvious reason for using $f_{N,t,h}$ is that they are local.

Now we define a function $W := W_{N,t,h}$ satisfying

$$\begin{cases} \Delta W + A_1(x)\partial_{x_1}W + A_2(x)\partial_{x_2}W + Q(x)W = 0 \quad \text{in} \quad \Omega, \\ W = f_{N,t,h} \quad \text{on} \quad \partial\Omega. \end{cases} \tag{4.3}$$

We would like to compare $W_{N,t,h}$ with $U_{N,t,h}$. It turns out they differ only by an exponentially small term under some minor condition. This property plays an essential role in our method for the inverse problem.

Lemma 4.1. *Assume that the boundary value problem*

$$\begin{cases} PU = 0 \quad \textit{in} \quad \Omega, \\ U = 0 \quad \textit{on} \quad \partial\Omega \end{cases} \tag{4.4}$$

has only a trivial solution. Then there exist $C > 0$ and $\varepsilon' > 0$ such that

$$\|W_{N,t,h} - U_{N,t,h}\|_{H^2(\Omega)} \le Ce^{-\varepsilon'/h} \tag{4.5}$$

for $h \ll 1$.

Proof. By setting $G := W_{N,t,h} - U_{N,t,h}$, we get that

$$\begin{aligned} PG &= P(W_{N,t,h} - U_{N,t,h}) \\ &= -\phi_{N,t}e^{-t^{-1}/h}PU_N + [\phi_{N,t}, P]e^{-t^{-1}/h}U_N \\ &= [\phi_{N,t}, P]e^{-t^{-1}/h}U_N \\ &= [\phi_{N,t}, P]e^{(\varphi_N - t^{-1}+i\psi_N)/h}(L+R) \end{aligned}$$

since $PU_N = 0$ in $(\cup_{s\in(0,t_0)}\ell_s) \cap \Omega$. Now we observe that $[\phi_{N,t}, P]$, the commutator of $\phi_{N,t}$ and P, is a first order differential operator with coefficients supported in

$$\overline{\left(\bigcup_{s\in(t+\varepsilon/2,t+\varepsilon)} \ell_s\right) \cap \Omega}.$$

So we have that

$$\|[\phi_{N,t}, P]e^{(\varphi_N - t^{-1}+i\psi_N)/h}(L+R)\|_{L^2(\Omega)} \le C'e^{-\varepsilon'/h} \tag{4.6}$$

for some $C' > 0$ and $\varepsilon' > 0$. Note that $G = 0$ on $\partial\Omega$. Combining the regularity theorem, the triviality of (4.4), and (4.6) yields (4.5). □

Even though the solutions $W_{N,t,h}$ of (1.3) are not exactly in the form of complex geometrical optics, with the help of Lemma 4.1, they are exponentially close to $U_{N,t,h}$. Now we describe how to construct special solutions for some concrete systems given in section 2 from $W_{N,t,h}$. For the conductivity equation (2.1), (1.3) is reduced to (2.2). For (2.2), we denote the corresponding $U_{N,t,h} = u_{N,t,h}$ and

$$u_{N,t,h} = \phi_{N,t} e^{(\varphi_N - t^{-1} + i\psi_N)/h}(1 + r),$$

where r satisfies (4.2). With $u_{N,t,h}$, we can solve for $w_{N,t,h}$ satisfying

$$\begin{cases} (\Delta + q)w = 0 \quad \text{in} \quad \Omega, \\ w = u_{N,t,h} \quad \text{on} \quad \partial\Omega. \end{cases} \tag{4.7}$$

The problem (4.7) has a unique solution since the boundary value problem for the corresponding conductivity equation has a unique solution. So Lemma 4.1 implies that

$$\|w_{N,t,h} - u_{N,t,h}\|_{H^1(\Omega)} \le Ce^{-\varepsilon'/h}. \tag{4.8}$$

Returning to the conductivity equation, we see that $\gamma^{-1/2} w_{N,t,h}$ are solutions of (2.1).

For the isotropic elasticity and the Stokes system, we have that $n = 3$ and (1.3) become, respectively, (2.7) and (2.10). We discuss only the isotropic elasticity here. The Stokes system can be treated similarly. Assume that the homogeneous boundary value problem (4.4) associated with (2.7) has only the trivial solution. Thus Lemma 4.1 yields

$$\|W_{N,t,h} - U_{N,t,h}\|_{H^2(\Omega)} \le Ce^{-\varepsilon'/h}.$$

We now express $U_{N,t,h} = \binom{v_{N,t,h}}{b_{N,t,h}}$ and $W_{N,t,h} = \binom{w_{N,t,h}}{g_{N,t,h}}$, where $v_{N,t,h}$, $w_{N,t,h}$ are two-dimensional vectors and $b_{N,t,h}$, $g_{N,t,h}$ are scalars. Hence, we obtain that

$$u_{N,t,h} = \mu^{-1/2} w_{N,t,h} + \mu^{-1}\nabla g_{N,t,h} - g_{N,t,h}\nabla\mu^{-1}$$

are solutions of (2.6) or (2.5) and $u_{N,t,h}$ satisfies

$$\|u_{N,t,h} - (\mu^{-1/2} v_{N,t,h} + \mu^{-1}\nabla b_{N,t,h} - b_{N,t,h}\nabla\mu^{-1})\|_{H^1(\Omega)} \le Ce^{-\varepsilon'/h}.$$

5. Inverse problems. In this section we demonstrate how to use CGO solutions constructed previously in the object identification problem. To simplify our presentation, we will discuss only the case of identifying inclusions inside of the domain Ω filled with known conductivity. This inverse problem has been extensively studied both theoretically and numerically. We refer the reader to [10] for related references. Using our method, we can also treat the object identification problem for other systems. We shall report the results elsewhere.

Let D be an open bounded domain with C^1 boundary such that $\bar{D} \subset \Omega$ and $\Omega \setminus \bar{D}$ is connected. Assume $\gamma(x) \in C^2(\bar{\Omega})$ with $\gamma(x) > 0$ for all $x \in \bar{\Omega}$. The conductivity $\tilde{\gamma}(x)$ is a perturbation of γ described by $\tilde{\gamma}(x) = \gamma + \chi_D\gamma_1$, where χ_D is the characteristic function of D and $\gamma_1 \in C(\bar{D})$. We suppose that

$$\gamma_1 \ge 0 \quad \text{in} \quad D \quad \text{and} \quad \gamma_1 > 0 \quad \text{on} \quad \partial D. \tag{5.1}$$

Then we have $\tilde{\gamma}(x) \ge c > 0$ almost everywhere in Ω. Let v be the solution of

$$\begin{cases} \nabla \cdot (\tilde{\gamma}\nabla v) = 0 \quad \text{in} \quad \Omega, \\ v = f \quad \text{on} \quad \partial\Omega. \end{cases} \tag{5.2}$$

The meaning of the solution to (5.2) is understood in the following way. Define

$$[w]_{\partial D} = \mathrm{tr}^+ w - \mathrm{tr}^- w,$$

the jump of the function across ∂D, where tr^+ and tr^- denote, respectively, the trace of w on ∂D from inside and outside of D. For $f \in H^{3/2}(\partial\Omega)$, we define

$$\mathcal{V}_f = \left\{ w \in H^2(D) \oplus H^2(\Omega \setminus \bar{D}) : w|_{\partial\Omega} = f, [w]_{\partial D} = 0, \left[\tilde{\gamma}\frac{\partial w}{\partial \nu}\right]_{\partial D} = 0 \right\}.$$

We say that v is the solution of (5.2) if $v \in \mathcal{V}_f$ and $\nabla \cdot (\tilde{\gamma} v) = 0$ in D and $\Omega \setminus \bar{D}$. The Dirichlet-to-Neumann map is given as

$$\Lambda_D : f \to \tilde{\gamma}\frac{\partial v}{\partial \nu}\Big|_{\partial\Omega},$$

where ν is the unit outer normal of $\partial\Omega$. The inverse problem is to determine the inclusion D from Λ_D. Here we are interested in the reconstruction question.

Since our method shares the same spirit as Ikehata's enclosure method [11], [12], we will briefly describe Ikehata's ideas to motivate our method. Here we take $\gamma \equiv 1$, i.e., $\tilde{\gamma} = 1 + \chi_D \gamma_1$. Denote

$$f_\omega(x, \tau, t) = \exp\{\tau(x \cdot \omega - t) + i\tau x \cdot \omega^\perp\}$$

and

$$I_\omega(\tau, t) = \langle (\Lambda_D - \Lambda_0) f_\omega(\cdot, \tau, t), \overline{f_\omega(\cdot, \tau, t)} \rangle,$$

where Λ_0 is the Dirichlet-to-Neumann map associated with $\Delta u = 0$ in Ω. Let us define

$$h_D(\omega) = \sup_{x \in D} x \cdot \omega.$$

Then the following formulas hold:

$$\left\{ t \in \mathbb{R} : \lim_{\tau \to 0} I_\omega(\tau, t) = 0 \right\} = (h_D(\omega), \infty)$$

and

$$\lim_{\tau \to \infty} \frac{\log |\tau_\omega(\tau, t)|}{2\tau} = h_D(\omega) - t \quad \forall\, t \in \mathbb{R}$$

(see [11], [12]).

To describe our method, we begin with the following integral inequalities given in [19] (also see [10] for a proof).

Lemma 5.1. *Assume that* (5.6) *holds. Let $f \in H^{3/2}(\partial\Omega)$ and u be the unique solution of*

$$\begin{cases} \nabla \cdot (\gamma \nabla u) = 0 & in \quad \Omega, \\ u = f & on \quad \partial\Omega. \end{cases} \tag{5.3}$$

Define $\Lambda_0 : f \to \gamma \frac{\partial u}{\partial \nu}|_{\partial\Omega}$. Then we have

$$\int_{\partial\Omega} (\Lambda_D - \Lambda_0)\bar{f} \cdot f ds \le \int_D \gamma_1 |\nabla u|^2 dx \tag{5.4}$$

and

$$\int_{\partial\Omega}(\Lambda_D - \Lambda_0)\bar{f}\cdot f ds \geq \int_D \frac{\gamma_1\gamma}{\gamma+\gamma_1}|\nabla u|^2 dx. \tag{5.5}$$

It follows from (5.1) that for any $p \in \partial D$, there exists an $\epsilon > 0$ such that

$$\gamma_1 \geq \epsilon \quad \forall\ x \in D \cap B_\epsilon(p). \tag{5.6}$$

Let $x_0 \notin \bar{\Omega}$ and define the open cone Γ_N with $\Gamma_N \cap \Omega \neq \emptyset$ in terms of $\varphi_N = \mathrm{Re}(c_N(x-x_0)^N)$ $(\rho_N = c_N(x-x_0)^N)$ as in Figure 4.1. Likewise, we denote the level curve $\ell_s = \{x \in \Gamma_N : \varphi_N = s^{-1}\}$ for $s > 0$. For $\varepsilon > 0$ and $t > 0$, we take

$$f = f_{N,t,h} = \gamma^{-1/2} w_{N,t,h}|_{\partial\Omega} = \gamma^{-1/2} u_{N,t,h}|_{\partial\Omega}, \tag{5.7}$$

where $w_{N,t,h}$ and $u_{N,t,h}$ are constructed previously. Note that $\gamma^{-1/2}w_{N,t,h}$ is the solution of (5.3). It should be noted that the Dirichlet condition f is localized in $\Gamma_N \cap \partial\Omega$ and supp (f) becomes narrower as N gets bigger. This property is very useful in actual applications.

To construct the inclusion D, we rely on the quantity

$$E(N,t,h) := \int_{\partial\Omega}(\Lambda_D - \Lambda_0)\bar{f}_{N,t,h}\cdot f_{N,t,h} ds. \tag{5.8}$$

Clearly, this quantity is completely determined by the boundary data. From (5.1) and (5.5) we see that

$$E(N,t,h) \geq \int_D \frac{\gamma_1\gamma}{\gamma+\gamma_1}|\nabla(\gamma^{-1/2}w_{N,t,h})|^2 dx \geq 0$$

for all N, t, h. We now prove the following important behavior of $E(N,t,h)$.

THEOREM 5.2. *Let $t > 0$ and $\mathcal{L}_t = \{x \in \Gamma_N : \varphi_N \geq t^{-1}\}$. Then we have the following:*

(i) *if $\mathcal{L}_t \cap \bar{D} = \emptyset$, then there exist $C_1 > 0$, $\varepsilon_1 > 0$, and $h_1 > 0$ such that $E(N,t,h) \leq C_1 e^{-\varepsilon_1/h}$ for all $h \leq h_1$;*

(ii) *if $\mathcal{L}_t \cap D \neq \emptyset$, then there exist $C_2 > 0$, $\varepsilon_2 > 0$, and $h_2 > 0$ such that $E(N,t,h) \geq C_2 e^{\varepsilon_2/h}$ for all $h \leq h_2$.*

Proof. To prove (i), we use the inequality (5.4) to obtain

$$E(N,t,h) \leq \int_D \gamma_1|\nabla(\gamma^{-1/2}w_{N,t,h})|^2 dx \leq C\|w_{N,t,h}\|^2_{H^1(D)}. \tag{5.9}$$

With the help of (4.8), we can replace $w_{N,t,h}$ in (5.9) by $u_{N,t,h}$ with an error $O(e^{-\varepsilon'/h})$. Since $\mathcal{L}_t \cap \bar{D} = \emptyset$, we have $\varphi_N - t^{-1} < 0$ for all $x \in \bar{D} \cap \Gamma_N$. Also, note that $u_{N,t,h} \equiv 0$ in $\Omega \setminus \Gamma_N$. Therefore, by the form of $u_{N,t,h}$ we immediately derive that

$$E(N,t,h) \leq Ce^{-\varepsilon_1/h}$$

for $h \leq h_1$.

To establish (ii), in view of $\mathcal{L}_t \cap D \neq \emptyset$, there exist $z \in \partial D$ and $\epsilon > 0$ such that the jump condition (5.6) holds and

$$\varphi_N - t^{-1} \geq \epsilon \quad \forall\ B_\epsilon(z) \cap D. \tag{5.10}$$

From (5.5) we get

$$\begin{aligned}E(N,t,h) &\geq \int_D \frac{\gamma_1\gamma}{\gamma+\gamma_1}|\nabla(\gamma^{-1/2}w_{N,t,h})|^2dx\\ &\geq C\epsilon\int_{D\cap B_\epsilon(z)}(|\nabla w_{N,t,h}|^2+|w_{N,t,h}|^2)dx\\ &\geq C'\int_{D\cap B_\epsilon(z)}(|\nabla u_{N,t,h}|^2+|u_{N,t,h}|^2)dx - C''e^{-\varepsilon'/h}. \qquad (5.11)\end{aligned}$$

Substituting the form of $u_{N,t,h}$ with the estimate (5.10) into (5.11) implies the statement of (ii). □

THEOREM 5.3. *With the same notation as in Theorem* 5.2*, if* $\ell_t \cap \partial D \neq \emptyset$ *and* $\mathcal{L}_t \cap D = \emptyset$*, then*

$$\liminf_{h\to 0} E(N,t,h) > 0.$$

Recall that $\ell_t = \{x \in \Gamma_N : \varphi_N = t^{-1}\}$.

Proof. In view of (5.6), we pick a sufficiently small $\epsilon > 0$ such that (5.6) is satisfied in $B_\epsilon(p)\cap D$ and $B_\epsilon(p)\cap D \subset (\cup_{s\in(t,t+\varepsilon/2)}\ell_s)\cap D$. So the cut-off function $\phi_{N,t} = 1$ on $B_\epsilon(p)\cap D$. We now introduce a new coordinate system $\Psi(x) = (y_1(x), y_2(x))$ near p with $y_2(x) = \varphi_N - t^{-1}$ such that ℓ_t becomes $y_2 = 0$ near p and $\tilde{D}_\epsilon := \Psi(B_\epsilon(p)\cap D)$ lies in $\{y_2 < 0\}$. We can choose a small cone C_p in $\tilde{D}_\epsilon$ with vertex p and the length of the axis being δ. Denote $J(y)$ the Jacobian of $\Psi^{-1}(y)$. Therefore, using (5.11) we can estimate

$$\begin{aligned}&E(N,t,h)\\ &\geq C'\int_{D\cap B_\epsilon(p)}(|\nabla u_{N,t,h}|^2+|u_{N,t,h}|^2)dx - C''e^{-\varepsilon'/h}\\ &\geq C'\int_{D\cap B_\epsilon(p)}(|\nabla(e^{(\varphi_N-t^{-1}+i\psi_N)/h}(1+r))|^2+|e^{(\varphi_N-t^{-1}+i\psi_N)/h}(1+r)|^2)dx\\ &\quad - C''e^{-\varepsilon'/h}\\ &\geq \frac{\tilde{C}}{h^2}\int_{C_p} e^{2y_2/h}|J|dy_1dy_2 - C''e^{-\varepsilon'/h}\\ &\geq \frac{\tilde{C}'}{h^2}\int_{-\delta}^0 e^{2y_2/h}y_2dy_2 - C''e^{-\varepsilon'/h}\\ &> 0 \quad \text{as} \quad h\to 0. \qquad \square\end{aligned}$$

In view of Theorems 5.2 and 5.3, we are able to reconstruct some part of ∂D by looking into the asymptotic behavior of $E(N,t,h)$ for various t's. More precisely, let

$$t_{D,N} := \sup\left\{t\in(0,\infty) : \lim_{h\to 0}E(N,h,t) = 0\right\};$$

then if $t_{D,N} = \infty$, we have $\Gamma_N \cap D = \emptyset$. On the other hand, if $t_{D,N} < \infty$, then there exists a $p_{D,N} \in \ell_{t_{D,N}} \cap \partial D$.

By taking N arbitrarily large (the opening angle of Γ_N becomes arbitrarily small), we can reconstruct even more information of ∂D. A point p on ∂D is said to be *detectable* if there exists a half-line l starting from p such that l does not intersect ∂D except at p. For example, if D is star-shaped, every point of ∂D is detectable.

COROLLARY 5.4. *Every detectable point of ∂D can be reconstructed from Λ_D.*

Proof. Let p be a detectable point and l be the corresponding half-line. We can choose l which is not tangent to ∂D at p since if the chosen half-line, say l', is tangent to ∂D at p, we can always choose a desired l by perturbing l' a little bit. Assume that $z_0 \in l$ and $z_0 \neq p$. Let L be the straight line containing l. Pick a point $x_0 \in L$ with $\frac{x_0-p}{|x_0-p|} = -\frac{z_0-p}{|z_0-p|}$ and $x_0 \notin \bar{\Omega}$. Let Γ_N be the cone with axis L and vertex x_0 whose opening angle is π/N. For any $N \in \mathbb{N}$, we construct $w_{N,t,h}$, $u_{N,t,h}$, and $f_{N,t,h}$ as above. So we can determine $E(N,t,h)$ from the measurement $\Lambda_D f_{N,t,h}$. Applying Theorems 5.2 and 5.3, we can determine $t_{D,N}$ so that $\ell_{t_{D,N}} \cap \partial D \neq \emptyset$. Then there exists $p_N \in \Gamma_N$, and $\ell_{t_{D,N}} \cap \partial D = p_N$. By taking $N \to \infty$, we can see that $p_N \to p$. □

To end this section, we give an algorithm of our reconstruction method based on Theorem 5.2.

Step 1. Pick a point $x_0 \notin \bar{\Omega}$ (but close to $\bar{\Omega}$). Given $N \in \mathbb{N}$, choose the cone Γ_N which intersects Ω. [Γ_N is defined in section 4]

Step 2. Start with $t > 0$ such that $\ell_t \cap \Omega \neq \emptyset$. Construct $u_{N,t,h}$ and determine the Dirichlet data $f_{N,t,h} = \gamma^{-1/2} u_{N,t,h}|_{\partial\Omega}$. [(5.7)]

Step 3. Compute $E(N,t,h) = \int_{\text{supp }(f_{N,t,h})} (\Lambda_D - \Lambda_0)\bar{f}_{N,t,h} \cdot f_{N,t,h} ds$. [(5.8)]

Step 4. If $E(N,t,h)$ is arbitrarily small, then increase t and repeat Steps 2 and 3; if $E(N,t,h)$ is arbitrarily large, then decrease t and repeat Steps 2 and 3. [Theorem 5.2]

Step 5. Repeat Step 4 to get a good approximation of ∂D in Γ_N. [Theorem 5.2]

Step 6. Move the cone Γ_N around x_0 by taking a different c_N in $\varphi_N = \text{Re}(c_N x^N)$. Repeat Steps 2–5.

Step 7. Choose a larger N and a new cone Γ_N. Repeat Steps 2–6.

Step 8. Pick a different x_0 and repeat Steps 1–7.

6. Numerical results.

We demonstrate some numerical results of our method in this section. Assume that the domain Ω is given by

$$\Omega = \{(x_1, x_2) : -1 < x_1 < 1, -1.01 < x_2 < -0.1\}.$$

We shall use the Dirichlet data localized on $\{(x_1, -1.01) : -1 < x < 1\}$. To set up $\rho_N(x)$, we consider $N = 4$; i.e., the phase function of the CGO solution is $\rho(x) := \rho_4(x)$. In our numerical computations, we use two sweeping schemes. In the first scheme, we fix the reference point x_0 and rotate the "probing cone" (the cone with the vertex at x_0 and the opening angle $\pi/4$). For the second one, we do not rotate the probing cone but move the reference points along the x-axis. More precisely, let the reference point $x_0 = (x_{0,1}, 0)$ for $-1 < x_{0,1} < 1$. In our first scheme, we fix $x_0 = (0,0)$ and rotate the probing cone determined by the shifted angle θ; in the second scheme, we consider different x_0's and choose $\theta = 0$. In other words, for both schemes, we have

$$\rho(x, x_0, \theta) := c(\theta)(x_1 - x_{0,1} + ix_2)^4 = e^{-i4\theta}(x_1 - x_{0,1} + ix_2)^4.$$

Thus, the probing fronts are level curves of $\varphi(x, x_0, \theta) := \text{Re}(\rho(x, x_0, \theta))$. Figure 6.1 shows some probing fronts of $\varphi(x, x_0, \theta)$ with three different θ's and three x_0's, respectively.

We take the background conductivity $\gamma = 1$, and the conductivity inside the inclusion is 4, i.e, $\gamma_1 = 3$. For numerical experiments, we ignore the cut-off function and take

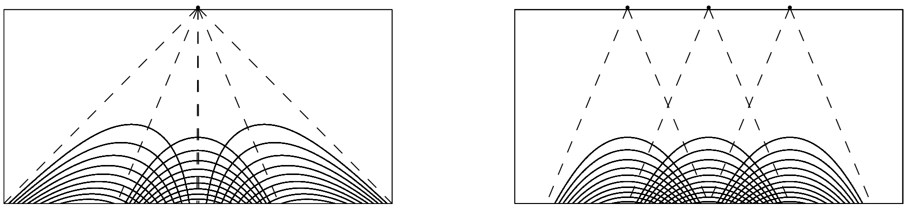

Fig. 6.1. *Probing fronts of our numerical method. In the first column, we consider the probing cone in three different angles. In the second column, we move the probing cone by taking three reference points. In our numerical method, we use* 10 *different probing cones.*

$$g_{x_0,h}|_{\partial\Omega} = \begin{cases} e^{\rho(x,x_0,\theta)/h} & \text{for } (x_1,x_2) \in \partial\Omega_{\text{obs}}, \\ 0, & \partial\Omega \setminus \partial\Omega_{\text{obs}}, \end{cases}$$

where $\partial\Omega_{\text{obs}}$ is determined by x_0 and θ. For example, for $x_0 = (0,0)$ and $\theta = 0$,

$$\partial\Omega_{\text{obs}} = \left\{(x_1,x_2) : -1.01 \times \tan\left(\frac{\pi}{8}\right) < x_1 < 1.01 \times \tan\left(\frac{\pi}{8}\right),\ x_2 = -1.01\right\}.$$

Then for $t > 0$ the required Dirichlet data is given by $f = f_{t,h,x_0} = e^{-t^{-1}/h} g_{x_0,h}$. To get the synthetic data $\Lambda_0 f$ and $\Lambda_D f$, we need to solve the boundary value problems (5.2) and (5.3) with the Dirichlet condition f. To solve these forward problems, we use the PDE Toolbox with the finite element method in MATLAB 7.0. Since we need to collect data on the bottom boundary of Ω, we refine the mesh there; see Figure 6.2.

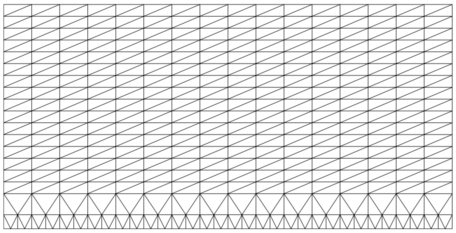

Fig. 6.2. *Example of our finite element method meshes. The mesh has* $2^m + 1$ *nodes on the top boundary and* $2^n + 1$ *nodes on the lower boundary. This example is created with* $m = 4$, $n = 6$. *In solving our forward problems, we choose* $m = 6$, $n = 12$.

To show the effect of noise to our method, we add appropriate noise to the synthetic data. We consider the form of noise given in [10]. To be precise, let $\eta : [-1,1] \mapsto \mathbb{C}$ be a random function defined by

$$\eta(s) = \sum_{k=-32}^{32} (a_k + ib_k) e^{iks\pi/2},$$

where $a_k, b_k \sim \mathcal{N}(0,1)$ are normally distributed random numbers. The number 32 in η is chosen to roughly model a collection of 32 electrodes on the bottom boundary of Ω. Measurement noise is modeled by $\Lambda_D f$ by $\Lambda_D f + c\eta$ with

$$c = \frac{A\|\Lambda_D f\|_\infty}{\|\eta\|_\infty},$$

where $A > 0$.

Our strategy of reconstructing the inclusion is described as follows. We first design M probing cones which are forms by taking either M different vertex points or M different rotating angles. Recall that each cone is congruent to the cone with its vertex at the origin and opening angle $\pi/4$. We then take appropriate h_1 and h_2 with $h_1 > h_2$ and choose a suitable number of probing fronts determined by t_j for $j = 1, \dots, J$ with $t_j < t_{j+1}$. In each probing cone Γ_m $(m = 1, \dots, M)$ given above, we construct the Dirichlet data f supported in the intersection of Γ_m and the bottom boundary of $\partial\Omega$ for every h_k and t_j, $k = 1, 2$, $j = 1, \dots, J$. We now evaluate $E_{j,k} := E(N, t_j, h_k)$ and determine t_n such that

$$E_{n+1,2} > E_{n+1,1}. \tag{6.1}$$

Then the region R_m defined by

$$R_m = \{x \in \Gamma_m : \varphi(x, x_0, \theta) \leq t_n^{-1}\}$$

is the estimated largest region in Γ_m which does not contain the inclusion. So the region $R := \cup_{m=1}^{M} R_m$ is the estimated largest region with the absence of the inclusion with a given sweeping scheme. We would like to point out that condition (6.1) is our rule of thumb in determining whether the level curve $\varphi(x, x_0, \theta) = t^{-1}$ intersects the inclusion in our numerical experiments. It is not equivalent to Theorem 5.2 but is based on the reasoning that $E(N, t, h)$ is *exponentially decaying* when $\varphi(x, x_0, \theta) = t^{-1}$ stays away from the inclusion and *exponentially growing* when $\varphi(x, x_0, \theta) = t^{-1}$ intersects the inclusion. A similar idea was also used in [10].

Our numerical results for each sweeping scheme are shown in Figures 6.3 and 6.4. To save computational time, we show only numerical results obtained from probing

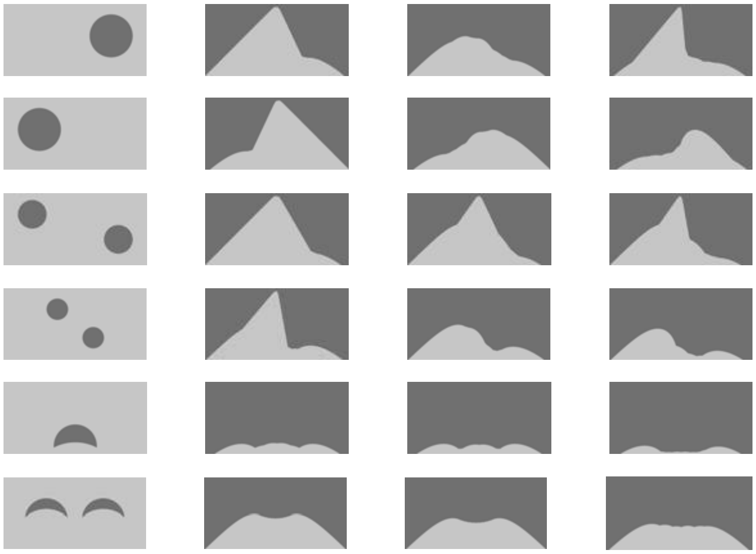

FIG. 6.3. *Numerical results of the first sweeping scheme. All black regions have the conductivity* 4, *and all gray regions have conductivity* 1. *So the gray regions represent the inclusion-free regions. The first column represents the actual location of inclusions. The second column is the theoretical reconstruction when we probe the region only from the bottom. The third column represents the numerical reconstruction from noiseless synthetic data. The fourth column is the numerical reconstruction from data with* 0.01% *noise. To see the effectiveness of our method, we can compare the images in the third column or in the fourth column with those in the second column.*

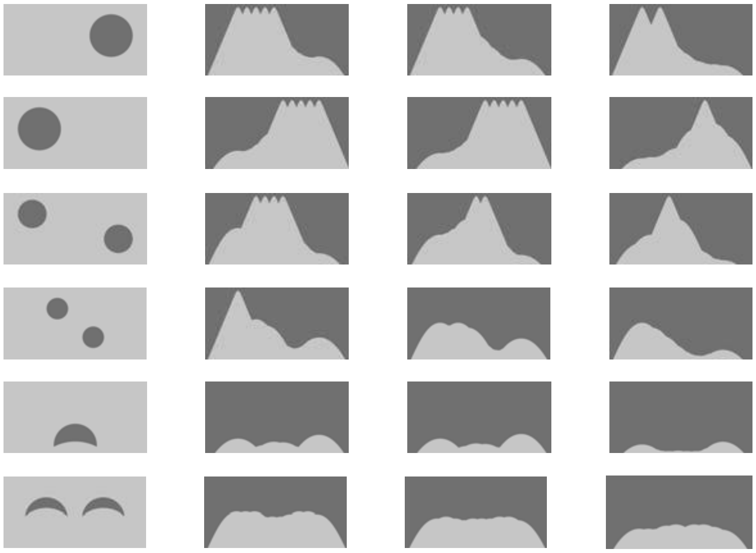

FIG. 6.4. *Numerical results of the second sweeping scheme. All black regions have the conductivity* 4*, and all gray regions have conductivity* 1*. So the gray regions represent the inclusion-free regions. The first column represents the actual location of inclusions. The second column is the theoretical reconstruction when we probe the region only from the bottom. The third column represents the numerical reconstruction from noiseless synthetic data. The fourth column is the numerical reconstruction from data with* 0.01% *noise. To see the effectiveness of our method, we can compare the images in the third column or in the fourth column with those in the second column.*

the region from one side (the bottom part of the boundary). Therefore, the inclusion-free region (with gray color) is near the bottom of the boundary. Since our domain is a rectangle, we can expect to obtain similar results when we probe the region from other sides. We believe that these numerical results are sufficient to demonstrate the applicability of our method.

7. Conclusion.

In this work we present a framework of constructing special complex geometrical optics solutions for several systems of two variables that can be reduced to a system with the Laplacian as the leading term. Here we choose complex polynomials as phase functions. Using these special solutions, we design a novel algorithm to identify embedded objects with boundary measurements. One distinctive feature of our method is that we can probe the region using cones with as small an opening angle as we wish. Theoretically, we are able to reconstruct the exact geometry of the embedded object whose boundary points are all detectable. One typical example is the star-shaped object.

In the numerical experiments, we consider the case of inclusion embedded into a domain with homogeneous conductivity. The numerical results show that our method detects the location of inclusion quite well and is stable under measurements with (small) noise. For computational reasons, we consider only $N = 4$ and use two sweeping schemes separately. It is quite natural to consider higher N's and also combine two sweeping schemes into one. Of course, by doing so, we need to pay the price of increasing computational time.

Our method can be applied to classes of equations or even systems in two dimensions that can be reduced to the Laplacian on the top order part. Its flexibility and effectiveness gives us another technique that can potentially be used in real applications such as medical imaging or nondestructive evaluation.

Acknowledgments. The program codes used in this work are modified from those used in [10]. We would like to thank H. Isozaki, T. Ide, S. Nakata, and S. Siltanen for generously sharing the codes with us. In completing the numerical results of this paper, the second author benefited from conversations with Z. Li, R. LeVeque, G. Nakamura, K. M. Shyue, and C. T. Wu. We also thank the referees and the editor for carefully reading the manuscript and for many valuable suggestions.

BIFURCATION ANALYSIS OF A GENERAL CLASS OF NONLINEAR INTEGRATE-AND-FIRE NEURONS*

JONATHAN TOUBOUL†

Abstract. In this paper we define a class of formal neuron models being computationally efficient and biologically plausible, i.e., able to reproduce a wide range of behaviors observed in in vivo or in vitro recordings of cortical neurons. This class includes, for instance, two models widely used in computational neuroscience, the Izhikevich and the Brette–Gerstner models. These models consist of a 4-parameter dynamical system. We provide the full local bifurcation diagram of the members of this class and show that they all present the same bifurcations: an Andronov–Hopf bifurcation manifold, a saddle-node bifurcation manifold, a Bogdanov–Takens bifurcation, and possibly a Bautin bifurcation, i.e., all codimension two local bifurcations in a two-dimensional phase space except the cusp. Among other global bifurcations, this system shows a saddle homoclinic bifurcation curve. We show how this bifurcation diagram generates the most prominent cortical neuron behaviors. This study leads us to introduce a new neuron model, the *quartic model*, able to reproduce among all the behaviors of the Izhikevich and Brette–Gerstner models self-sustained subthreshold oscillations, which are of great interest in neuroscience.

Key words. neuron models, dynamical system analysis, nonlinear dynamics, Hopf bifurcation, saddle-node bifurcation, Bogdanov–Takens bifurcation, Bautin bifurcation, saddle homoclinic bifurcation, subthreshold neuron oscillations

DOI. 10.1137/070687268

Introduction. During the past few years, in the neurocomputing community, the problem of finding a computationally simple and biologically realistic model of neuron has been widely studied, in order to be able to compare experimental recordings with numerical simulations of large-scale brain models. The key problem is to find a model of neuron realizing a compromise between its simulation efficiency and its ability to reproduce what is observed at the cell level, often considering in-vitro experiments [15, 18, 24].

Among the numerous neuron models, from the detailed Hodgkin–Huxley model [11] still considered as the reference, but unfortunately computationally intractable when considering neuronal networks, down to the simplest integrate-and-fire model [8] very effective computationally, but unrealistically simple and unable to reproduce many behaviors observed, two models seem to stand out [15]: the adaptive quadratic (Izhikevich [14] and related models such as the theta model with adaptation [6, 10]) and exponential (Brette and Gerstner [5]) neuron models. These two models are computationally almost as efficient as the integrate-and-fire model. The Brette–Gerstner model involves an exponential function, which needs to be tabulated if we want the algorithm to be efficient. They are also biologically plausible, and reproduce several important neuronal regimes with a good adequacy with biological data, especially in high-conductance states, typical of cortical in vivo activity. Nevertheless, they fail in reproducing deterministic self-sustained subthreshold oscillations, a behavior of particular interest in cortical neurons for the precision and robustness of spike generation

patterns, for instance in the inferior olive nucleus [4, 22, 23], in the stellate cells of the entorhinal cortex [1, 2, 17], and in the dorsal root ganglia (DRG) [3, 20, 21]. Some models have been introduced to study from a theoretical point of view the currents involved in the generation of self-sustained subthreshold oscillations [25], but the model failed in reproducing lots of other neuronal behaviors.

The aim of this paper is to define and study a general class of neuron models, containing the Izhikevich and Brette–Gerstner models, from a dynamical systems point of view. We characterize the local bifurcations of these models and show how their bifurcations are linked with different biological behaviors observed in the cortex. This formal study will lead us to define a new model of neuron, whose behaviors include those of the Izhikevich–Brette–Gerstner (IBG) models but also self-sustained subthreshold oscillations.

In the first section of this paper, we introduce a general class of nonlinear neuron models which contains the IBG models. We study the fixed-point bifurcation diagram of the elements of this class, and show that they present the same local bifurcation diagram, with a saddle-node bifurcation curve, an Andronov–Hopf bifurcation curve, a Bogdanov–Takens bifurcation point, and possibly a Bautin bifurcation, i.e., all codimension two bifurcations in dimension two except the cusp. This analysis is applied in the second section to the Izhikevich and the Brette–Gerstner models. We derive their bifurcation diagrams and prove that none of them shows the Bautin bifurcation. In the third section, we introduce a new simple model—the *quartic model*—presenting, in addition to common properties of the dynamical system of this class, a Bautin bifurcation, which can produce self-sustained oscillations. Last, the fourth section is dedicated to numerical experiments. We show that the quartic model is able to reproduce some of the prominent features of biological spiking neurons. We give qualitative interpretations of those different neuronal regimes from the dynamical systems point of view, in order to give a grasp of how the bifurcations generate biologically plausible behaviors. We also show that the new quartic model, presenting supercritical Hopf bifurcations, is able to reproduce the oscillatory/spiking behavior presented, for instance, in the DRG. Finally, we show that numerical simulation results of the quartic model show a good agreement with biological intracellular recordings in the DRG.

1. Bifurcation analysis of a class of nonlinear neuron models.

In this section we introduce a large class of formal neurons which are able to reproduce a wide range of neuronal behaviors observed in cortical neurons. This class of models is inspired by the review made by Izhikevich [15]. He found that the quadratic adaptive integrate-and-fire model was able to simulate efficiently a lot of interesting behaviors. Brette and Gerstner [5] defined a similar model of neuron which presented a good adequacy between simulations and biological recordings.

We generalize these models, and define a new class of neuron models, wide but specific enough to keep the diversity of behaviors of the IBG models.

1.1. The general class of nonlinear models.

In this paper, we are interested in neurons defined by a dynamical system of the type

$$\begin{cases} \frac{\mathrm{d}v}{\mathrm{d}t} = F(v) - w + I, \\ \frac{\mathrm{d}w}{\mathrm{d}t} = a(bv - w), \end{cases}$$

where a, b, and I are real parameters and F is a real function.[1]

In this equation, v represents the membrane potential of the neuron, w is the adaptation variable, I represents the input intensity of the neuron, $1/a$ is the characteristic time of the adaptation variable, and b accounts for the interaction between the membrane potential and the adaptation variable.[2]

This equation is a very general model of neuron. For instance when F is a polynomial of degree three, we obtain a FitzHugh–Nagumo model, when F is a polynomial of degree two the Izhikevich neuron model [14], and when F is an exponential function the Brette–Gerstner model [5]. However, in contrast with continuous models like the FitzHugh–Nagumo model [8], the two latter cases diverge when spiking, and an external reset mechanism is used after a spike is emitted.

In this paper, we want this class of models to have common properties with the IBG neuron models. To this purpose, let us make some assumptions on the function F. The first assumption is a regularity assumption.

Assumption (A1). F is at least three times continuously differentiable.

A second assumption is necessary to ensure us that the system would have the same number of fixed points as the IBG models.

Assumption (A2). The function F is strictly convex.

DEFINITION 1.1 (convex neuron model). *We consider the two-dimensional model defined by the equations*

$$\begin{cases} \frac{dv}{dt} = F(v) - w + I, \\ \frac{dw}{dt} = a(bv - w), \end{cases} \tag{1.1}$$

where F satisfies Assumptions (A1) *and* (A2) *and characterizes the passive properties of the membrane potential.*

Many neurons of this class blow up in finite time. These neurons are the ones we are interested in.

REMARK. *Note that all the neurons of this class do not blow up in finite time. For instance if $F(v) = v\log(v)$, it will not. For F functions such that $F(v) = (v^{1+\alpha})R(v)$ for some $\alpha > 0$, where $\lim_{v\to\infty} R(v) > 0$ (possibly ∞), the dynamical system will possibly blow up in finite time.*

If the solution blows up at time t^*, a spike is emitted, and subsequently we have the following reset process:

$$\begin{cases} v(t^*) = v_r, \\ w(t^*) = w(t^{*-}) + d, \end{cases} \tag{1.2}$$

where v_r is the reset membrane potential and $d > 0$ a real parameter. Equations (1.1) and (1.2), together with initial conditions (v_0, w_0), give us the existence and uniqueness of a solution on $\mathbb{R}^+$.

The two parameters v_r and d are important to understand the repetitive spiking properties of the system. Nevertheless, the bifurcation study with respect to these

[1] The same study can be done for a parameter-dependent function. More precisely, let $E \subset \mathbb{R}^n$ be a parameter space (for a given n) and $F : E \times \mathbb{R} \to \mathbb{R}$ a parameter-dependent real function. All the properties shown in this section are valid for any fixed value of the parameter p. Further p-bifurcations studies can be done for specific $F(p, \cdot)$. The first equation can be derived from the general I-V relation in neuronal models: $C\frac{\mathrm{d}V}{\mathrm{d}t} = I - I_0(V) - g(V - E_K)$, where $I_0(V)$ is the instantaneous I-V curve.

[2] See, for instance, section 2.2, where the parameters of the initial equation (2.2) are related to biological constants and where we proceed to a dimensionless reduction.

parameters is outside the scope of this paper, and we focus here on the bifurcations of the system with respect to (a, b, I), in order to characterize the subthreshold behavior of the neuron.

1.2. Fixed points of the system. To understand the qualitative behavior of the dynamical system defined by (1.1) before the blow up (i.e., between two spikes), we begin by studying the fixed points and analyze their stability. The linear stability of a fixed point is governed by the Jacobian matrix of the system, which we define in the following proposition.

PROPOSITION 1.2. *The Jacobian of the dynamical system* (1.1) *can be written*

$$L := v \mapsto \begin{pmatrix} F'(v) & -1 \\ ab & -a \end{pmatrix}. \tag{1.3}$$

The fixed points of the system satisfy the equations

$$\begin{cases} F(v) - bv + I = 0, \\ bv = w. \end{cases} \tag{1.4}$$

Let $G_b(v) := F(v) - bv$. From (A1) and (A2), we know that the function G_b is strictly convex and has the same regularity as F. To have the same behavior as the IBG models, we want the system to have the same number of fixed points. To this purpose, it is necessary that G_b has a minimum for all $b > 0$. Otherwise, the *convex* function G_b would have no more than one fixed point, since a fixed point of the system is the intersection of an horizontal curve and G_b.

This means for the function F that $\inf_{x\in\mathbb{R}} F'(x) \leq 0$ and $\sup_{x\in\mathbb{R}} F'(x) = +\infty$. Using the monotony property of F', we write Assumption (A3).

Assumption (A3).

$$\begin{cases} \lim\limits_{x\to-\infty} F'(x) \leq 0, \\ \lim\limits_{x\to+\infty} F'(x) = +\infty. \end{cases}$$

Assumptions (A1), (A2), and (A3) ensure us that for all $b \in \mathbb{R}_+^*$, G_b has a unique minimum, denoted $m(b)$, which is reached. Let $v^*(b)$ be the point where this minimum is reached.

This point is the solution of the equation

$$F'(v^*(b)) = b. \tag{1.5}$$

PROPOSITION 1.3. *The point $v^*(b)$ and the value $m(b)$ are continuously differentiable with respect to b.*

Proof. We know that F' is a bijection. The point $v^*(b)$ is defined implicitly by the equation $H(b, v) = 0$, where $H(b, v) = F'(v) - b$. H is a C^1-diffeomorphism with respect to b, and the differential with respect to b never vanishes. The implicit function theorem (see, for instance, [7, Annex C.6]) ensures us that $v^*(b)$ solution of $H(b, v^*(b)) = 0$ is continuously differentiable with respect to b, and so does $m(b) = G(v^*(b)) - bv^*(b)$. □

THEOREM 1.4. *The parameter curve defined by $\{(I, b);\ I = -m(b)\}$ separates three behaviors of the system (see Figure* 1.1*):*

(i) *If $I > -m(b)$, then the system has no fixed point.*

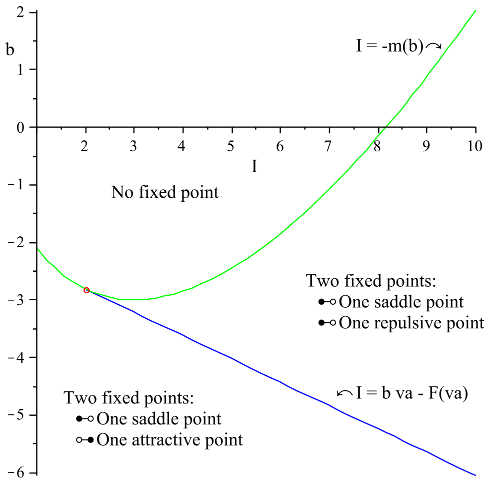

FIG. 1.1. *Number of fixed points and their stability in the plane (I, b) for the exponential adaptive model.*

(ii) *If $I = -m(b)$, then the system has a unique fixed point, $(v^*(b), w^*(b))$, which is nonhyperbolic. It is unstable if $b > a$.*

(iii) *If $I < -m(b)$, then the dynamical system has two fixed points $(v_-(I, b)$, $v_+(I, b))$ such that*

$$v_-(I, b) < v^*(b) < v_+(I, b).$$

The fixed point $v_+(I, b)$ is a saddle fixed point, and the stability of the fixed point $v_-(I, b)$ depends on I and on the sign of $(b - a)$:

(a) *If $b < a$, the fixed point $v_-(I, b)$ is attractive.*

(b) *If $b > a$, there is a unique smooth curve $I^*(a, b)$ defined by the implicit equation $F'(v_-(I^*(a, b), b)) = a$. This curve reads $I^*(a, b) = bv_a - F(v_a)$, where v_a is the unique solution of $F'(v_a) = a$.*

(b.1) *If $I < I^*(a, b)$, the fixed point is attractive.*

(b.2) *If $I > I^*(a, b)$, the fixed point is repulsive.*

Proof.

(i) We have $F(v) - bv \geq m(b)$ by definition of $m(b)$. If $I > -m(b)$, then for all $v \in \mathbb{R}$ we have $F(v) - bv + I > 0$ and the system has no fixed point.

(ii) Let $I = -m(b)$. We have already seen that G_b is strictly convex and continuously differentiable and for $b > 0$ reaches its unique minimum at the point $v^*(b)$. This point is such that $G_b(v^*(b)) = m(b)$, and so it is the only point satisfying $F(v^*(b)) - bv^*(b) - m(b) = 0$.

Furthermore, this point satisfies $F'(v^*(b)) = b$. The Jacobian of the system at this point reads

$$L(v^*(b)) = \begin{pmatrix} b & -1 \\ ab & -a \end{pmatrix}.$$

Its determinant is 0, and so the fixed point is nonhyperbolic (0 is eigenvalue of the Jacobian matrix). The trace of this matrix is $b - a$. So the fixed point $v^*(b)$ is attractive when $b > a$ and repulsive when $b > a$. The case $a = b$,

$I = -m(b)$ is a degenerate case which we will study more precisely in section 1.3.3.

(iii) Let $I < -m(b)$. By the strict convexity assumption, Assumption (A2), of the function G together with Assumption (A3), we know that there are only two intersections of the curve G to a level $-I$ higher than its minimum. These two intersections define our two fixed points. At the point v^* the function is strictly lower than $-I$, and so the two solutions satisfy $v_-(I,b) < v^*(b) < v_+(I,b)$.

Let us now study the stability of these two fixed points. To this end, we have to characterize the eigenvalues of the Jacobian matrix of the system at these points.

We can see from formula (1.3) and the convexity assumption, Assumption (A2), that the Jacobian determinant, equal to $-aF'(v) + ab$, is a decreasing function of v and vanishes at $v^*(b)$, and so $\det(L(v_+(I,b))) < 0$ and the fixed point is a saddle point (the Jacobian matrix has a positive and a negative eigenvalue).

For the other fixed point $v_-(I,b)$, the determinant of the Jacobian matrix is strictly positive. So the stability of the fixed point depends on the trace of the Jacobian. This trace reads $F'\big(v_-(I,b)\big) - a$.

(a) When $b < a$, we have a stable fixed point. Indeed, the function F' is an increasing function equal to b at $v^*(b)$, and so $\text{Trace}\big(L(v_-(I,b))\big) \leq F'(v^*(b)) - a = b - a < 0$ and the fixed point is attractive.

(b) If $b > a$, then the type of dynamics around the fixed point v_- depends on the input current (parameter I). Indeed, the trace reads

$$T(I,b,a) := F'\big(v_-(I,b)\big) - a,$$

which is continuous and continuously differentiable with respect to I and b, and which is defined for $I < -m(b)$. We have

$$\begin{cases} \lim\limits_{I \to -m(b)} T(I,b,a) = b - a > 0, \\ \lim\limits_{I \to -\infty} T(I,b,a) = \lim\limits_{x \to -\infty} F'(x) - a < 0. \end{cases}$$

So there exists a curve $I^*(a,b)$ defined by $T(I,b,a) = 0$ and such that

- for $I^*(b) < I < -m(b)$, the fixed point $v_-(I,b)$ is repulsive;
- for $I < I^*(b)$, the fixed point v_- is attractive.

To compute the equation of this curve, we use the fact that point $v_-(I^*(b),b)$ is such that $F'(v_-(I^*(b),b)) = a$. We know from the properties of F that there is a unique point v_a satisfying this equation. Since $F'(v^*(b)) = b$, $a < b$, and F' is increasing, the condition $a < b$ implies that $v_a < v^*(b)$.

The associated input current satisfies fixed points equation $F(v_a) - bv_a + I^*(a,b) = 0$, or equivalently

$$I^*(a,b) = bv_a - F(v_a).$$

The point $I = I^*(a,b)$ will be studied in detail in the next section, since it is a bifurcation point of the system. □

Figure 1.1 represents the different zones enumerated in Theorem 1.4 and their stability in the parameter plane (I,b).

Remark. *In this proof, we used the fact that F' is invertible on* $[0,\infty)$. *Assumption* (A3) *ensures us that it will be the case and that F has a unique minimum. Assumption* (A3) *is the weakest possible to have this property.*

1.3. Bifurcations of the system. In the study of the fixed points and their stability, we identified two bifurcation curves where the stability of the fixed points changes. The first curve $I = -m(b)$ corresponds to a saddle-node bifurcation and the curve $I = I^*(a,b)$ to an Andronov–Hopf bifurcation. These two curves meet in a specific point, $b = a$ and $I = -m(a)$. This point has a double 0 eigenvalue, and we show that it is a Bogdanov–Takens bifurcation point.

Let us show that the system undergoes these bifurcations with no other assumption than (A1), (A2), and (A3) on F. We also prove that the system can undergo only one other codimension two bifurcation, a Bautin bifurcation.

1.3.1. Saddle-node bifurcation curve. In this section we characterize the behavior of the dynamical system along the curve of equation $I = -m(b)$, and we prove the following theorem.

Theorem 1.5. *The dynamical system* (1.1) *undergoes a saddle-node bifurcation along the parameter curve:*

$$(SN) : \{(b, I) \; ; \; I = -m(b)\}, \tag{1.6}$$

when $F''(v^*(b)) \neq 0$.

Proof. We derive the normal form of the system at this bifurcation point. Following the works of Guckenheimer and Holmes [9] and Kuznetsov [19], we check only the transversality conditions to be sure that the normal form at the bifurcation point will have the expected form.

Let $b \in \mathbb{R}^+$ and $I = -m(b)$. Let $v^*(b)$ be the unique fixed point of the system for these parameters. The point $v^*(b)$ is the unique solution of $F'(v^*(b)) = b$. At this point, the Jacobian matrix (1.3) reads

$$L(v^*(b)) = \begin{pmatrix} b & -1 \\ ab & -a \end{pmatrix}.$$

This matrix has two eigenvalues 0 and $b - a$. The pairs of right eigenvalues and right eigenvectors are

$$0, U := \begin{pmatrix} 1/b \\ 1 \end{pmatrix} \quad \text{and} \quad b - a, \begin{pmatrix} 1/a \\ 1 \end{pmatrix}.$$

Its pairs of left eigenvalues and left eigenvectors are

$$0, V := (-a, 1) \quad \text{and} \quad b - a, (-b, 1).$$

Let $f_{b,I}$ be the vector field

$$f_{b,I}(v, w) = \begin{pmatrix} F(v) - w + I \\ a(bv - w) \end{pmatrix}.$$

The vector field satisfies

$$\begin{aligned} V\left(\frac{\partial}{\partial I} f_{b,I}(v^*(b), w^*(b))\right) &= (-a, 1) \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ &= -a < 0. \end{aligned}$$

So the coefficient of the normal form corresponding to the Taylor expansion along the parameter I does not vanish.

Finally, let us show that the quadratic terms of the Taylor expansion in the normal form does not vanish. With our notations, this condition reads

$$V\Big(D_x^2 f_{b,-m(b)}(v^*(b), w^*(b))(U,U)\Big) \neq 0.$$

This property is satisfied in our framework. Indeed,

$$\begin{aligned}
V\Big(D_x^2 f_{b,-m(b)}(v^*(b), w^*(b))(U,U)\Big) &= V\left(\begin{pmatrix} U_1^2 \dfrac{\partial^2 f_1}{\partial v^2} + 2U_1U_2 \dfrac{\partial^2 f_1}{\partial v \partial w} + U_2^2 \dfrac{\partial^2 f_1}{\partial w^2} \\ U_1^2 \dfrac{\partial^2 f_2}{\partial v^2} + 2U_1U_2 \dfrac{\partial^2 f_2}{\partial v \partial w} + U_2^2 \dfrac{\partial^2 f_2}{\partial w^2} \end{pmatrix}\right)\\
&= V\left(\begin{pmatrix} \frac{1}{b^2} F''(v^*) \\ 0 \end{pmatrix}\right)\\
&= (-a, 1) \cdot \begin{pmatrix} \frac{1}{b^2} F''(v^*) \\ 0 \end{pmatrix}\\
&= -\frac{a}{b^2} F''(v^*) < 0.
\end{aligned}$$

So the system undergoes a saddle-node bifurcation along the manifold $I = -m(b)$. □

Remark. *Note that $F''(v^*(b))$ can vanish only countably many times since F is strictly convex.*

1.3.2. Andronov–Hopf bifurcation curve. In this section we consider the behavior of the dynamical system along the parameter curve $I = I^*(b)$, and we consider the fixed point v_-.

Theorem 1.6. *Let $b > a$, v_a be the unique point such that $F'(v_a) = a$ and $A(a,b)$ be defined by the formula*

$$A(a,b) := F'''(v_a) + \frac{1}{b-a}\left(F''(v_a)\right)^2. \tag{1.7}$$

If $F''(v_a) \neq 0$ and $A(a,b) \neq 0$, then the system undergoes an Andronov–Hopf bifurcation at the point v_a, along the parameter line

$$(AH) := \Big\{(b, I)\ ;\ b > a \ \text{ and } \ I = bv_a - F(v_a)\Big\}. \tag{1.8}$$

This bifurcation is subcritical if $A(a,b) > 0$ and supercritical if $A(a,b) < 0$.

Proof. The Jacobian matrix at the point v_a reads

$$L(v_a) = \begin{pmatrix} a & -1 \\ ab & -a \end{pmatrix}.$$

Its trace is 0 and its determinant is $a(b-a) > 0$, and so the matrix at this point has a pair of pure imaginary eigenvalues $(i\omega, -i\omega)$, where $\omega = \sqrt{a(b-a)}$. Along the curve of equilibria when I varies, the eigenvalues are complex conjugates with real part $\mu(I) = \frac{1}{2}\operatorname{Tr}\big(L(v_-(I,b))\big)$ which vanishes at $I = I^*(a,b)$.

We recall that from Proposition 1.3, this trace varies smoothly with I. Indeed, $v_-(b,I)$ satisfies $F(v_-(I,b)) - bv_-(I,b) + I = 0$ and is differentiable with respect to I. We have

$$\frac{\partial v_-(I,b)}{\partial I}(F'(v_-(I,b)) - b) = -1.$$

At the point $v_-(I^*(b), b) = v_a$, we have $F'(v_a) = a < b$, and so for I close to this equilibrium point, we have

$$\frac{\partial v_-(I,b)}{\partial I} > 0.$$

Now let us check that the transversality condition of an Andronov–Hopf bifurcation is satisfied (see [9, Theorem 3.4.2]). There are two conditions to be satisfied: the transversality condition $\frac{\mathrm{d}\mu(I)}{\mathrm{d}I} \neq 0$ and the nondegeneracy condition $l_1 \neq 0$, where l_1 is the first Lyapunov coefficient at the bifurcation point.

First of all, we prove that the transversality condition is satisfied:

$$\begin{aligned}\mu(I) &= \frac{1}{2}\mathrm{Tr}(L(v_-(I,b)))\\ &= \frac{1}{2}(F'(v_-(I,b)) - a),\\ \frac{\mathrm{d}\mu(I)}{\mathrm{d}I} &= \frac{1}{2}F''(v_-(I,b))\frac{\mathrm{d}v_-(I,b)}{\mathrm{d}I}\\ &> 0.\end{aligned}$$

Let us now write the normal form at this point. To this purpose, we change variables:

$$\begin{cases} v - v_a = x,\\ w - w_a = ax + \omega y.\end{cases}$$

The (x, y) equation reads

$$\text{(1.9)} \qquad \begin{cases} \dot{x} = -\omega y + (F(x + v_a) - ax - w_a) =: -\omega y + f(x),\\ \dot{y} = \omega x + \frac{a}{\omega}(ax - F(x + v_a) + w_a - I) =: \omega x + g(x).\end{cases}$$

According to Guckenheimer in [9], we state that the Lyapunov coefficient of the system at this point has the same sign as B, where B is defined by

$$B := \frac{1}{16}[f_{xxx}+f_{xyy}+g_{xxy}+g_{yyy}]+\frac{1}{16\omega}[f_{xy}(f_{xx}+f_{yy})-g_{xy}(g_{xx}+g_{yy})-f_{xx}g_{xx}+f_{yy}g_{yy}].$$

Replacing f and g by the expressions found in (1.9), we obtain the expression of A:

$$\begin{aligned}B &= \frac{1}{16}F'''(v_a) + \frac{a}{16\omega^2}(F''(v_a))^2\\ &= \frac{1}{16}F'''(v_a) + \frac{1}{16(b-a)}(F''(v_a))^2\\ &= \frac{1}{16}A(a,b).\end{aligned}$$

Hence when $A(a, b) \neq 0$, the system undergoes an Andronov–Hopf bifurcation. When $A(a, b) > 0$, the bifurcation is subcritical and the periodic orbits generated by the Hopf bifurcation are repelling, and when $A(a, b) < 0$, the bifurcation is supercritical and the periodic orbits are attractive (the formula of A has also been introduced by Izhikevich in [16, eq. (15), p. 213]). □

Remark. *The case $A(a,b) = 0$ is not treated in the theorem and is a little bit more intricate. We fully treat it in section* 1.3.4 *and show that a Bautin (generalized Hopf) bifurcation can occur if the A-coefficient vanishes. Since the third derivative is a priori unconstrained, this case can occur, and we prove in section* 3 *that this is the case for a simple (quartic) model.*

1.3.3. Bogdanov–Takens bifurcation.

We have seen in the study that this formal model presents an interesting point in the parameter space, corresponding to the intersection of the saddle-node bifurcation curve and the Andronov–Hopf bifurcation curve. At this point, we show that the system undergoes a Bogdanov–Takens bifurcation.

Theorem 1.7. *Let F be a real function satisfying Assumptions* (A1), (A2), *and* (A3). *Let $a \in \mathbb{R}_+^*$ and $b = a$, and let v_a be the only point such that $F'(v_a) = a$. Assume again that $F''(v_a) \neq 0$.*

Then at this point and with these parameters, the dynamical system (1.1) *undergoes a subcritical Bogdanov–Takens bifurcation of normal form:*

$$\begin{cases} \dot\eta_1 = \eta_2, \\ \dot\eta_2 = \left(\frac{8F''(v_a)\,a\,I_1}{(a+b_1)^3}\right) - \left(\frac{2(2\,b_1\,a+I_1\,F''(v_a))}{(a+b_1)^2}\right)\eta_1 + \eta_1^2 + \eta_1\eta_2 + \mathcal{O}(\|\eta\|^3), \end{cases} \tag{1.10}$$

where $b_1 := b - a$ and $I_1 = I + m(a)$.

Proof. The Jacobian matrix (1.3) at this point reads

$$L(v_a) = \begin{pmatrix} a & -1 \\ a^2 & -a \end{pmatrix}.$$

This matrix is nonzero and has two 0 eigenvalues (its determinant and trace are 0). The matrix $Q := \left(\begin{smallmatrix} a & 1 \\ a^2 & -a \end{smallmatrix}\right)$ is the passage matrix to the Jordan form of the Jacobian matrix:

$$Q^{-1} \cdot L(v_a) \cdot Q = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

To prove that the system undergoes a Bogdanov–Takens bifurcation, we show that the normal form reads

$$\begin{cases} \dot\eta_1 = \eta_2, \\ \dot\eta_2 = \beta_1 + \beta_2\eta_1 + \eta_1^2 + \sigma\eta_1\eta_2 + \mathcal{O}(\|\eta\|^3) \end{cases} \tag{1.11}$$

with $\sigma = \pm 1$. The proof of this theorem consists of (i) proving that the system undergoes a Bogdanov–Takens bifurcation, (ii) finding a closed-form expression for the variables β_1 and β_2, and (iii) proving that $\sigma = 1$.

First of all, let us prove that the normal form can be written in the form of (1.11). This is equivalent to showing some transversality conditions on the system (see, for instance, [19, Theorem 8.4]).

To this end, we center the equation at this point and write the system in the coordinates given by the Jordan form of the matrix. Let $\binom{y_1}{y_2} = Q^{-1}\binom{v-v_a}{w-w_a}$ at the point $b = a + b_1$, $I = -m(a) + I_1$. We get

$$\begin{cases} \dot y_1 = y_2 + \frac{b_1}{a}(ay_1 + y_2), \\ \dot y_2 = F(ay_1 + y_2 + v_a) - w_a - m(a) + I_1 - a^2 y_1 - ay_2 - b_1(ay_1 + y_2). \end{cases} \tag{1.12}$$

Let us denote $v_1 = ay_1 + y_2$. The Taylor expansion on the second equation gives us

$$\begin{aligned}
\dot{y}_2 &= F(v_1 + v_a) - w_a - m(a) + I_1 - a^2 y_1 - a y_2 - b_1(ay_1 + y_2)\\
&= F(v_a) + F'(v_a)v_1 + \frac{1}{2}F''(v_a)v_1^2 - w_a - m(a)\\
&+ I_1 - a^2 y_1 - a y_2 - b_1(ay_1 + y_2) + \mathcal{O}(\|v_1\|^3)\\
&= (F(v_a) - w_a - m(a)) + I_1 + (F'(v_a) - a)v_1 - b_1 v_1 + \frac{1}{2}F''(v_a)v_1^2\\
&+ \mathcal{O}(\|v_1\|^3)\\
&= I_1 - b_1(ay_1 + y_2) + \frac{1}{2}F''(v_a)(ay_1 + y_2)^2 + \mathcal{O}(\|y\|^3). \qquad (1.13)
\end{aligned}$$

Let us denote for the sake of clarity $\alpha = (b_1, I_1)$ and write (1.12) as

$$\begin{cases} \dot{y}_1 = y_2 + a_{00}(\alpha) + a_{10}(\alpha)y_1 + a_{01}(\alpha)y_2,\\ \dot{y}_2 = b_{00}(\alpha) + b_{10}(\alpha)y_1 + b_{01}(\alpha)y_2 + \frac{1}{2}b_{20}(\alpha)y_1^2 + b_{11}(\alpha)y_1y_2 + \frac{1}{2}b_{02}(\alpha)y_2^2 + \mathcal{O}(\|y\|^3). \end{cases} \qquad (1.14)$$

From (1.12) and (1.13), it is straightforward to identify the expressions for the coefficients $a_{ij}(\alpha)$ and $b_{ij}(\alpha)$.

Let us now use the change of variables:

$$\begin{cases} u_1 = y_1,\\ u_2 = y_2 + \frac{b_1}{a}(ay_1 + y_2). \end{cases}$$

The dynamical system governing (u_1, u_2) reads

$$\begin{cases} \dot{u}_1 = u_2,\\ \dot{u}_2 = (1 + \frac{b_1}{a}) - b_1\, a\, u_1 + \frac{1}{2}\frac{a^3F''(v_a)}{a+b_1}u_1^2 + \frac{a^2F''(v_a)}{a+b_1}u_1\, u_2 + \frac{1}{2}\frac{aF''(v_a)}{a+b_1}u_2^2. \end{cases}$$

The transversality conditions of a Bogdanov–Takens bifurcation [9, 19] can easily be verified from this expression:

(BT.1) The Jacobian matrix is not 0.

(BT.2) With the notations of (1.14), we have $a_{20} = 0$ and $b_{11}(0) = aF''(v_a) > 0$, and so $a_{20}(0) + b_{11}(0) = aF''(v_a) > 0$.

(BT.3) $b_{20} = a^2F''(v_a) > 0$.

(BT.4) We show that the map

$$\left(x := \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}, \alpha := \begin{pmatrix} I_1 \\ b_1 \end{pmatrix}\right) \mapsto \Big[f(x, \alpha), \mathrm{Tr}\big(D_x f(x, \alpha)\big), \mathrm{Det}\big(Dxf(x, \alpha)\big)\Big]$$

is regular at the point of interest.

From the two first assumptions, we know that the system can be put in the form of (1.11). Guckenheimer in [9] proves that this condition can be reduced to the nondegeneracy of the differential with respect to (I_1, b_1) of the vector $\binom{\beta_1}{\beta_2}$ of (1.11).

In our case, we can compute these variables β_1 and β_2 following the calculation steps of [19], and we get

$$\begin{cases} \beta_1 = \frac{8F''(v_a)\, a\, I_1}{(a+b_1)^3},\\ \beta_2 = -\frac{2(2\, b_1\, a + I_1\, F''(v_a))}{(a+b_1)^2}. \end{cases} \qquad (1.15)$$

Hence the differential of the vector $\binom{\beta_1}{\beta_2}$ with respect to the parameters (I_1, b_1) at the point $(0,0)$ reads

$$D_\alpha \beta|_{(0,0)} = \begin{pmatrix} \frac{8F''(v_a)}{a^2} & 0 \\ -2\frac{F''(v_a)}{a^2} & -4/a \end{pmatrix}.$$

This matrix has a nonzero determinant if and only if $F''(v_a) \neq 0$.

Therefore we have proved the existence of a Bogdanov–Takens bifurcation under the condition $F''(v_a) \neq 0$.

Let us now show that $\sigma = 1$. Indeed, this coefficient is given by the sign of $b_{20}(0)\big(a_{20}(0) + b_{11}(0)\big)$ which in our case is equal to $a^3 F''(v_a)^2 > 0$, and so the bifurcation is always of the type (1.10) (generation of an unstable limit cycle) for all the members of our class of models. □

The existence of a Bogdanov–Takens bifurcation point implies the existence of a smooth curve corresponding to a saddle homoclinic bifurcation in the system (see [19, Lemma 8.7]).

Corollary 1.8. *There is a unique smooth curve (P) corresponding to a saddle homoclinic bifurcation in the system (1.1) originating at the parameter point $b = a$ and $I = -m(a)$ defined by the implicit equation:*

$$(P) := \Bigg\{ (I = -m(a) + I_1,\, b = a + b_1)\ ;$$

$$I_1 = \frac{\left(-\frac{25}{6}\, a - \frac{37}{6}\, b_1 + \frac{5}{6}\sqrt{25\, a^2 + 74\, b_1\, a + 49\, {b_1}^2}\right) a}{F''(v_a)} + o(|\, b_1\,| + |\, I_1\,|) \tag{1.16}$$

$$\textit{and } b_1 > -\frac{I_1 F''(v_a)}{2a} \Bigg\}.$$

Moreover, for (b, I) in a neighborhood of $(a, -m(a))$, the system has a unique and hyperbolic unstable cycle for parameter values inside the region bounded by the Hopf bifurcation curve and the homoclinic bifurcation curve (P), and it has no cycle outside this region.

Proof. As noticed, from the Bogdanov–Takens bifurcation point, we have the existence of this saddle homoclinic bifurcation curve. Let us now compute the equation of this curve in the neighborhood of the Bogdanov–Takens point. To this purpose we use the normal form we derived in Theorem 1.7 and use the local characterization given, for instance, in [19, Lemma 8.7] for the saddle homoclinic curve:

$$(P) := \left\{ (\beta_1, \beta_2)\ ;\ \beta_1 = -\frac{6}{25}\beta_2^2 + o(\beta_2^2),\, \beta_2 < 0 \right\}.$$

Using the expressions (1.15) yields

$$(P) := \Bigg\{ (I = -m(a) + I_1,\, b = a + b_1)\ ;$$

$$\frac{8F''(v_a) a I_1}{(a+b_1)^3} = \frac{24}{25}\frac{(2\, b_1\, a + I_1\, F''(v_a))^2}{(a+b_1)^4} + o(|\, b_1\,| + |\, I_1\,|)$$

$$\text{and } b_1 > -\frac{I_1 F''(v_a)}{2a} \Bigg\}.$$

We can solve this equation. There are two solutions but only one satisfying $I_1 = 0$ when $b_1 = 0$. This solution is the curve of saddle homoclinic bifurcations. $\square$

1.3.4. Formal conditions for a Bautin bifurcation. In the study of the Andronov–Hopf bifurcation, we showed that the sub- or supercritical type of bifurcation depended on the variable $A(a, b)$ defined by (1.7). If this variable changes sign when b varies, then the stability of the limit cycle along Hopf bifurcation changes stability. This can occur if the point v_a satisfies the following condition.

Assumption (A4). For v_a such that $F'(v_a) = a$, we have

$$F'''(v_a) < 0.$$

Indeed, if this happens, the type of Andronov–Hopf bifurcation changes, since we have

$$\begin{cases} \lim\limits_{b \to a^-} A(a, b) = +\infty, \\ \lim\limits_{b \to +\infty} A(a, b) = F'''(v_a) < 0. \end{cases}$$

In this case the first Lyapunov exponent vanishes for

$$b = a - \frac{(F''(v_a))^2}{F'''(v_a)}.$$

At this point, the system has the characteristics of a Bautin (generalized Hopf) bifurcation. Nevertheless, we still have to check two nondegeneracy conditions to ensure that the system actually undergoes a Bautin bifurcation:

(BGH.1) The second Lyapunov coefficient of the dynamical system l_2 does not vanish at this equilibrium point.

(BGH.2) Let $l_1(I, b)$ be the first Lyapunov exponent of this system and $\mu(I, b)$ the real part of the eigenvalues of the Jacobian matrix. The map

$$(I, b) \mapsto (\mu(I, b), l_1(I, b))$$

is regular at this point.

In this case the system would be locally topologically equivalent to the normal form:

$$\begin{cases} \dot{y}_1 = \beta_1 y_1 - y_2 + \beta_2 y_1(y_1^2 + y_2^2) + \sigma y_1(y_1^2 + y_2^2)^2, \\ \dot{y}_2 = \beta_1 y_2 - y_1 + \beta_2 y_2(y_1^2 + y_2^2) + \sigma y_2(y_1^2 + y_2^2)^2. \end{cases}$$

We reduce the problem to the point that checking the two conditions of a BGH bifurcation becomes straightforward.

Let (v_a, w_a) be the point where the system undergoes the Bautin bifurcation (when it exists). Since we already computed the eigenvalues and eigenvectors of the Jacobian matrix along the Andronov–Hopf bifurcation curve, we can use it to reduce the problem. The basis where we express the system is given by

$$\begin{cases} Q := \begin{pmatrix} \frac{1}{b} & \frac{\omega}{ab} \\ 1 & 0 \end{pmatrix}, \\ \binom{x}{y} := Q^{-1} \binom{v - v_a}{w - w_a}. \end{cases}$$

Let us write the dynamical equations satisfied by (x, y):

$$\begin{cases} \dot{x} = \omega y, \\ \dot{y} = \frac{ab}{\omega}\left(F\big(v_a + \frac{1}{b}x + \frac{\omega}{ab}y\big) - w_a - x + I_a - ay\right). \end{cases}$$

To ensure that we have a Bautin bifurcation at this point we will need to perform a Taylor expansion up to the fifth order, and so we need to make the following assumption.

Assumption (A5). The function F is six times continuously differentiable at (v_a, w_a).

First, let us denote $v_1(x, y) = \frac{1}{b}x + \frac{\omega}{ab}y$; the Taylor expansion reads

$$\begin{aligned} \dot{y} = {} & \frac{ab}{\omega}\big(F(v_a) - w_a + I\big) + \frac{ab}{\omega}\left[F'(v_a)v_1(x, y) - ay\right] + \frac{1}{2}\frac{ab}{\omega}\left[F''(v_a)v_1(x, y)^2\right] \\ & + \frac{1}{6}\frac{ab}{\omega}F'''(v_a)v_1(x, y)^3 + \frac{1}{4!}\frac{ab}{\omega}F^{(4)}(v_a)v_1(x, y)^4 \\ & + \frac{1}{5!}\frac{ab}{\omega}F^{(5)}(v_a)v_1(x, y)^5 + \mathcal{O}\left(\left\|\begin{pmatrix} x \\ y \end{pmatrix}\right\|^6\right). \end{aligned}$$

This expression, together with the complex left and right eigenvectors of the Jacobian matrix, allows us to compute the first and second Lyapunov coefficients and to check the existence of a Bautin bifurcation.

Nevertheless, we cannot push the computation any further at this level of generality, but, for a given function F presenting a change in the sign of $A(a, b)$, this can easily be done through the use of a symbolic computation package. The interested reader is referred to Appendix A for checking the Bautin bifurcation transversality conditions, where calculations are given for the quartic neuron model.

1.4. Conclusion: The full bifurcation diagram. We now summarize the results obtained in this section in the two following theorems.

THEOREM 1.9. *Let us consider the formal dynamical system*

$$\begin{cases} \dot{v} = F(v) - w + I, \\ \dot{w} = a(bv - w), \end{cases} \tag{1.17}$$

where a is a fixed real, b and I bifurcation parameters, and $F : \mathbb{R} \mapsto \mathbb{R}$ a real function. If the function F satisfies the assumptions that

(A.1) *the function F is three times continuously differentiable,*

(A.2) *F is strictly convex, and*

(A.3) *F' satisfies the conditions*

$$\begin{cases} \lim\limits_{x \to -\infty} F'(x) \leq 0, \\ \lim\limits_{x \to \infty} F'(x) = \infty, \end{cases}$$

then the dynamical system (1.17) *shows the following bifurcations:*

(B1) *A saddle-node bifurcation curve:*

$$(SN) : \{(b, I)\ ;\ I = -m(b)\},$$

where $m(b)$ is the minimum of the function $F(v) - bv$ (if the second derivative of F does not vanish at this point).

(B2) *An Andronov–Hopf bifurcation line:*

$$(AH) := \Big\{(b, I)\ ;\ b > a \ \ and\ \ I = bv_a - F(v_a)\Big\},$$

where v_a is the unique solution of $F'(v_a) = a$ (if $F''(v_a) \neq 0$). This type of Andronov–Hopf bifurcation is given by the sign of the variable

$$A(a, b) = F'''(v_a) + \frac{1}{b-a} F''(v_a)^2.$$

If $A(a, b) > 0$, then the bifurcation is subcritical, and if $A(a, b) < 0$, then the bifurcation is supercritical.

(B3) *A Bogdanov–Takens bifurcation point at the point $b = a$ and $I = -m(a)$ if $F''(v_a) \neq 0$.*

(B4) *A saddle homoclinic bifurcation curve characterized in the neighborhood of the Bogdanov–Takens point by*

$$(P) := \Bigg\{(I = -m(a) + I_1,\ b = a + b_1)\ ;$$
$$I_1 = \frac{\left(-\frac{25}{6}\,a - \frac{37}{6}\,b_1 + \frac{5}{6}\sqrt{25\,a^2 + 74\,b_1\,a + 49\,{b_1}^2}\right) a}{F''(v_a)} + o(|\,b_1\,| + |\,I_1\,|)$$
$$and\ b_1 > -\frac{I_1 F''(v_a)}{2a}\Bigg\}.$$

Theorem 1.10. *Consider the system* (1.1)*, where a is a given real number, b and I are real bifurcation parameters, and $F : E \times \mathbb{R} \mapsto \mathbb{R}$ is a function satisfying the following assumptions:*

(A.5) *The function F is six times continuously differentiable.*

(A.2) *F is strictly convex.*

(A.3) *F' satisfies the conditions*

$$\begin{cases} \lim_{x\to-\infty} F'(x) \leq 0, \\ \lim_{x\to\infty} F'(x) = \infty. \end{cases}$$

(A.4) *Let v_a be the unique real such that $F'(v_a) = a$. We have*

$$F'''(v_a) < 0.$$

Furthermore, consider the following conditions:

(BGH.1) *The second Lyapunov coefficient of the dynamical system $l_2(v_a) \neq 0$.*

(BGH.2) *Let $l_1(v)$ denote the first Lyapunov exponent and $\lambda(I, b) = \mu(I, b) \pm i\omega(I, b)$ the eigenvalues of the Jacobian matrix in the neighborhood of the point of interest. The map $(I, b) \to (\mu(I, b), l_1(I, b))$ is regular at this point.*

Having these, the system undergoes a Bautin bifurcation at the point v_a for the parameters $b = a - \frac{F''(v_a)^2}{F'''(v_a)}$ and $I = bv_a - F(v_a)$.

Remark. *Theorem* 1.9 *enumerates some of the bifurcations that any dynamical system of the class* (1.1) *will always undergo. Together with Theorem* 1.10*, they summarize all the local bifurcations the system can undergo, and no other fixed-point bifurcation is possible. In section* 3 *we introduce a model actually showing all these local bifurcations.*

2. Applications: Izhikevich and Brette–Gerstner models. In this section we show that the neuron models proposed by Izhikevich in [14] and Brette and Gerstner in [5] are part of the class studied in section 1. Using the results of the latter section, we derive their bifurcation diagram and obtain that they show exactly the same types of bifurcations.

2.1. Izhikevich quadratic adaptive model. We produce here a complete description of the bifurcation diagram of the adaptive quadratic integrate-and-fire model proposed by Izhikevich in [14] and [16, Chapter 8]. We use here the dimensionless equivalent version of this model with the fewest parameters:

$$\begin{cases} \dot{v} = v^2 - w + I, \\ \dot{w} = a(bv - w). \end{cases} \tag{2.1}$$

Equation (2.1) is clearly a particular case of (1.1) with

$$F(v) = v^2.$$

F is clearly strictly convex and C^∞. $F'(v) = 2v$, and so it also satisfies Assumption (A3). Furthermore, the second derivative never vanishes, and so the system undergoes the three bifurcations stated in Theorem 1.9.

(Izh.B1) A saddle-node bifurcation curve defined by

$$\left\{ (b, I) \; ; \; I = \frac{b^2}{4} \right\}.$$

For $(I, b) \in \mathbb{R}^2$, the fixed point is given by $(v^*(b) = \frac{1}{2}b, \; w^*(b) = \frac{1}{2}b^2)$.
For $I < \frac{b^2}{4}$, the fixed point(s) are

$$v_\pm(b, I) = \frac{1}{2}\big(b \pm \sqrt{b^2 - 4I}\big).$$

(Izh.B2) An Andronov–Hopf bifurcation line:

$$\left\{ (I, b) \; ; \; b > a \;\text{ and }\; I = \frac{a}{2}\left(b - \frac{a}{2}\right) \right\},$$

whose type is given by the sign of the variable

$$A(a, b) = \frac{4}{b - a}.$$

This value is always strictly positive, and so the bifurcation is always subcritical.

(Izh.B3) A Bogdanov–Takens bifurcation point for $b = a$ and $I = \frac{a^2}{4}$, $v_a = \frac{a}{2}$.

(Izh.B4) A saddle homoclinic bifurcation curve satisfying the quadratic equation near the Bogdanov–Takens point:

$$\begin{aligned} (P) := \Bigg\{ & \left(I = \frac{a^2}{2} + I_1, \, b = a + b_1 \right) \; ; \\ & I_1 = \frac{a}{2}\left(-\frac{25}{6}\, a - \frac{37}{6}\, b_1 + \frac{5}{6} \sqrt{25\, a^2 + 74\, b_1\, a + 49\, {b_1}^2} \right) + o(|\, b_1 \,| + |\, I_1 \,|) \\ & \text{and } b_1 > -\frac{I_1}{a} \Bigg\}. \end{aligned}$$

Figure 2.1 represents the fixed points of this dynamical system, and their stability, together with the bifurcation curves.

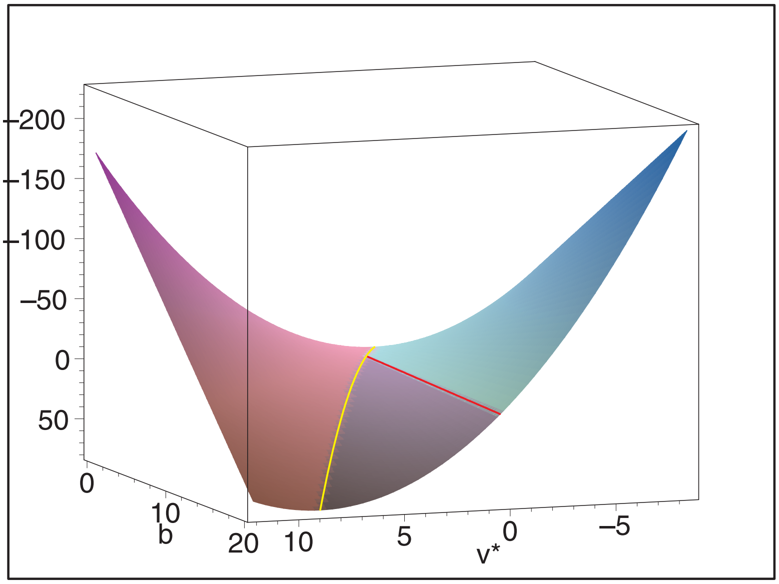

Fig. 2.1. *Representation of the v fixed point with respect to the parameters I and b in the Izhikevich model. The reddish component is the surface of saddle fixed points, the purplish one corresponds to the repulsive fixed points, and the greenish/bluish one corresponds to the attractive fixed points The yellow curve corresponds to a saddle-node bifurcation and the red one to an Andronov–Hopf bifurcation.*

2.2. Brette–Gerstner exponential adaptative integrate-and-fire neuron. In this section we study the bifurcation diagram of the adaptive exponential neuron. This model has been introduced by Brette and Gerstner in [5]. This model, inspired by the Izhikevich adaptive quadratic model, can be fitted to biological values, takes into account the adaptation phenomenon, and is able to reproduce many behaviors observed in cortical neurons. The bifurcation analysis we derived in section 1 allows us to understand how the parameters of the model can affect the behavior of this neuron. We show that this model is part of the general class studied in section 1, and we obtain the fixed-point bifurcation diagram of the model.

2.2.1. Reduction of the original model. This original model is based on biological constants and is expressed with a lot of parameters. We first reduce this model to a simpler form with the fewest number of parameters.

The basic equations proposed in the original paper [5] read

$$\begin{cases} C\frac{\mathrm{d}V}{\mathrm{d}t} = -g_L(V-E_L) + g_L\Delta_T \exp\left(\frac{V-V_T}{\Delta_T}\right) \\ \qquad\qquad -g_e(t)(V-E_e) - g_i(t)(V-E_i) - W + I_m, \\ \tau_W\frac{\mathrm{d}W}{\mathrm{d}t} = \kappa(V-E_L) - W. \end{cases} \tag{2.2}$$

First, we do not assume that the reversal potential of the w equation is the same as the leakage potential E_L, and we write the equation for the adaptation variable by

$$\tau_W\frac{\mathrm{d}W}{\mathrm{d}t} = a(V-\bar{V}) - W.$$

Next we assume that $g_e(\cdot)$ and $g_i(\cdot)$ are constant (in the original paper it was assumed that the two conductances were null).

After some straightforward algebra, we eventually get the following dimensionless equation equivalent to (2.2):

$$\begin{cases} \dot{v} = -v + e^v - w + I, \\ \dot{w} = a(bv - w), \end{cases} \tag{2.3}$$

where we denoted

$$\begin{cases} \tilde{g} := g_L + g_e + g_i, \\ \tau_m := \frac{C}{\tilde{g}}, \\ B := \frac{\kappa}{\tilde{g}} \left(\frac{E_L}{\Delta_T} + \log(\frac{g_L}{\tilde{g}} e^{-V_T/\Delta_T}) \right), \\ v(\tau) := \frac{V(\tau\tau_m)}{\Delta_T} + \log\left(\frac{g_L}{\tilde{g}} e^{-V_T/\Delta_T} \right), \\ w(\tau) := \frac{W(\tau\tau_m)}{\tilde{g}\Delta_T} + B, \\ a := \frac{\tau_m}{\tau_W}, \\ b := \frac{\kappa}{\tilde{g}}, \\ I := \frac{I_m + g_L E_L + g_e E_e + g_i E_i}{\tilde{g}\Delta_T} + \log(\frac{g_l}{\tilde{g}} e^{-V_T/\Delta_T}) + B \end{cases} \tag{2.4}$$

and where the dot denotes the derivative with respect to τ.

Remark. *These expressions confirm the qualitative interpretation of the parameters a, b, and I of the model* (1.1). *Indeed,* $a = \frac{\tau_m}{\tau_w}$ *accounts for the time scale of the adaptation (with the membrane time scale as reference), and the parameter* $b = \frac{\kappa}{\tilde{g}}$ *is proportional to the interaction between the membrane potential and the adaptation variable and inversely proportional to the total conductivity of the membrane potential. Eventually, I is an affine function of the input current* I_m *and models the input current of the neurons.*

2.2.2. Bifurcation diagram. From (2.3) we can clearly see that the Brette–Gerstner model is included in the formal class studied in the paper with

$$F(v) = e^v - v.$$

This function satisfies Assumptions (A1), (A2), and (A3). Furthermore, its second order derivative never vanishes.

Theorem 1.9 shows that the system undergoes the following bifurcations:

(BG.B1) A saddle-node bifurcation curve defined by

$$\{(b, I) \; ; \; I = (1+b)(1 - \log(1+b))\}.$$

So $v^*(b) = \log(1+b)$. For $I \leq (1+b)(1-\log(1+b))$, the system has the fixed points

$$\begin{cases} v_-(I,b) := -W_0\left(-\frac{1}{1+b} e^{\frac{I}{1+b}}\right) + \frac{I}{1+b}, \\ v_+(I,b) := -W_{-1}\left(-\frac{1}{1+b} e^{\frac{I}{1+b}}\right) + \frac{I}{1+b}, \end{cases} \tag{2.5}$$

where W_0 is the principal branch of Lambert's W function[3] and W_{-1} the real branch of Lambert's W function such that $W_{-1}(x) \leq -1$, defined for $-e^{-1} \leq x < 1$.

[3] The Lambert W function is the inverse function of $x \mapsto xe^x$.

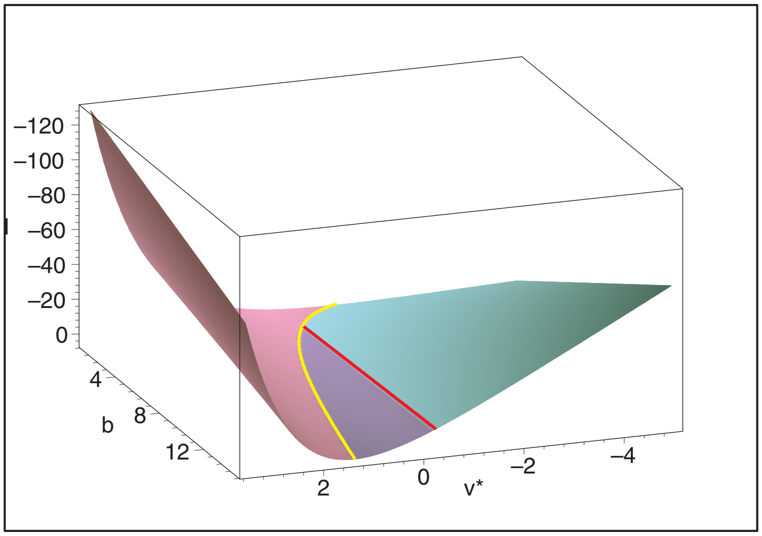

FIG. 2.2. *Representation of the v fixed point of the Brette–Gerstner model with respect to the parameters I and b. The reddish/pinkish component is the surface of saddle fixed points, the purplish one corresponds to the repulsive fixed points, and the bluish/greenish one corresponds to the attractive fixed points The yellow curve corresponds to a saddle-node bifurcation and the red one to an Andronov–Hopf bifurcation.*

(BG.B2) An Andronov–Hopf bifurcation line for

$$\{(b, I)\ ;\ b > a \text{ and } I = I^*(a, b) = (1 + b)\log(1 + a) - (1 + a)\}$$

at the equilibrium point ($v_a = \log(1+a)$, $w_a = bv_a$). This type of Andronov–Hopf bifurcation is given by the sign of the variable

$$A(a, b) = F'''(v_a) + \frac{1}{b - a}F''(v_a)^2 = (1 + a) + \frac{4}{b - a}(1 + a)^2 > 0.$$

So the bifurcation is always subcritical, and there is not any Bautin bifurcation.

(BG.B3) A Bogdanov–Takens bifurcation point at the point $b = a$ and $I = \log(1 + a)$.

(BG.B4) A saddle homoclinic bifurcation curve satisfying, near the Bogdanov–Takens point, the equation

$$(P) := \Bigg\{ (I = (1 + a)(\log(1 + a) - 1) + I_1,\ b = a + b_1)\ ;$$

$$I_1 = \frac{\left(-\frac{25}{6}\,a - \frac{37}{6}\,b_1 + \frac{5}{6}\,\sqrt{25\,a^2 + 74\,b_1\,a + 49\,{b_1}^2}\right) a}{(1 + a)} + o(|\,b_1\,| + |\,I_1\,|)$$

$$\text{and } b_1 > -\left(1 + \frac{1}{a}\right) I_1 \Bigg\}.$$

In Figure 2.2 we represent the fixed points of the exponential model and their stability, together with the bifurcation curves, in the space (I, b, v).

3. The richer quartic model.

In this section, we introduce a new specific model having a richer bifurcation diagram than the two models studied in section 2. It is as simple as the two previous models from the mathematical and computational points of view. To this end, we define a model which is part of the class studied in section 1 by specifying the function F.

3.1. The quartic model: Definition and bifurcation map.

Let $a > 0$ be a fixed real and $\alpha > a$. We instantiate the model (1.1) with the function F a quartic polynomial:

$$F(v) = v^4 + 2av.$$

REMARK. *The choice of the function F here is just an example where all the formulas are rather simple. Exactly the same analysis can be done with any F function satisfying $F'''(v_a) < 0$ and the transversality conditions given in Theorem* 1.10. *This would be the case, for instance, for any quartic polynomial $F(v) = v^4 + \alpha v$ for $\alpha > a$.*

The function F satisfies Assumptions (A1), (A2), and (A5). $F'(v) = 4v^3 + 2a$ satisfies Assumption (A3).

Nevertheless, we have to bear in mind that the second order derivative vanishes at $v = 0$:

$$\begin{cases} \dot{v} = v^4 + 2av - w + I, \\ \dot{w} = a(bv - w). \end{cases} \tag{3.1}$$

Theorem 1.9 shows that the quartic model undergoes the following bifurcations:

(B1) A saddle-node bifurcation curve defined by

$$(SN) := \left\{ (b, I) \ ; \ I = 3\left(\frac{b-2a}{4}\right)^{(4/3)} \right\}.$$

Proof. Indeed, the function G reads $G(v) = v^4 + (2a - b)v$ and reaches its minimum at the point $v = (\frac{b-2a}{4})^{(1/3)}$. So the minimum of G is $m(b) = -3\,(\frac{b-2a}{4})^{(4/3)}$. □

The point $v^*(b)$ is $(\frac{b-2a}{4})^{(1/3)}$, and we have closed-form expressions (but rather complicated) for the two fixed points for $I < 3\,(\frac{b-2a}{4})^{(4/3)}$ since the quartic equation is solvable in radicals. The closed form expression can be obtained using a symbolic computation package like Maple using the command

```
S:=allvalues( solve( x^4 + (2*a - b) * x + I0 = 0,x));
```

(B2) An Andronov–Hopf bifurcation curve for $b > a$ along the straight line

$$(AH) := \left\{ (I, b) \ ; \ b > a \text{ and } I = -\left(\frac{a}{4}\right)^{1/3} b - \left(\frac{a}{4}\right)^{4/3} \right\}.$$

The fixed point where the system undergoes this bifurcation is $v_a = -(\frac{a}{4})^{1/3}$. The kind of Andronov–Hopf bifurcation we have is governed by the sign of

$$\alpha = -24\left(\frac{a}{4}\right)^{1/3} + \frac{144}{b-a}\left(\frac{a}{4}\right)^{4/3}.$$

Finally, the type of bifurcation changes when b varies.

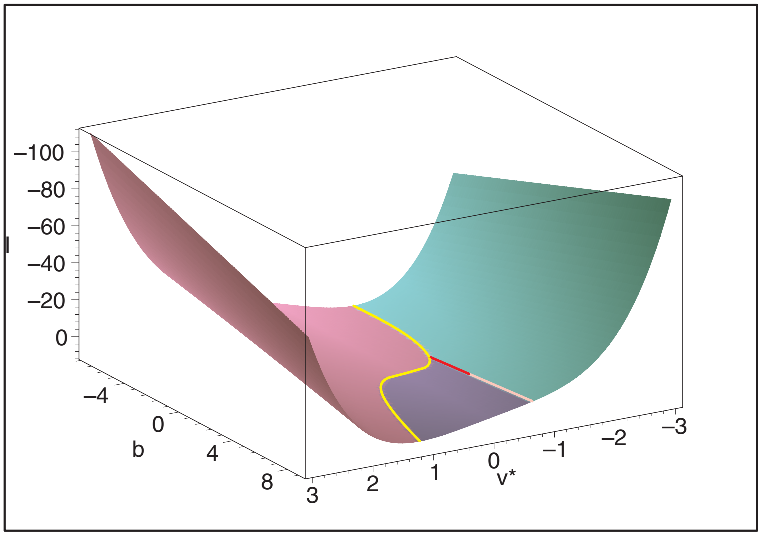

FIG. 3.1. *v fixed points and their stability in function of I and b. The reddish/pinkish component is the surface of saddle fixed points, the purplish one corresponds to the repulsive fixed points, and the bluish/greenish one corresponds to the attractive fixed points. The yellow curve corresponds to a saddle-node bifurcation, the red curve to a subcritical Andronov–Hopf bifurcation, and the greyish one to the supercritical Andronov–Hopf bifurcation. The intersection point between the yellow and the red curve is the Bogdanov–Takens bifurcation point, and the intersection point of the red and greyish curves is the Bautin bifurcation point.*

- When $b < \frac{5}{2}a$, then $\alpha > 0$, hence $l_1 > 0$, and the Andronov–Hopf bifurcation is subcritical.
- When $b > \frac{5}{2}a$, then $\alpha < 0$, hence $l_1 < 0$, and the Andronov–Hopf bifurcation is supercritical.

We prove below that the change in the type of Hopf bifurcation is obtained via a Bautin bifurcation.

(B3) A Bogdanov–Takens bifurcation point is located at $b = a$ and $I = -3\,(\frac{a}{4})^{(4/3)}$.

(B4) A saddle homoclinic bifurcation curve satisfying, near the Bogdanov–Takens point, the equation

$$\begin{aligned}(P) := \Bigg\{ &\left(I = -3\left(\frac{a}{4}\right)^{(4/3)} + I_1,\, b = a + b_1\right)\ ;\\ &I_1 = \frac{1}{12}\left(-\frac{25}{6}\,a - \frac{37}{6}\,b_1 + \frac{5}{6}\sqrt{25\,a^2 + 74\,b_1\,a + 49\,{b_1}^2}\right)a^{1/3}\\ &+ o(|\,b_1\,| + |\,I_1\,|)\\ &\text{and } b_1 > -6 I_1 a^{-1/3} \Bigg\}.\end{aligned}$$

(B5) A Bautin bifurcation at the point $\big(b = \frac{5}{2}a,\ I = -3(\frac{a}{4})^{4/3}\,(2\,a - 1)\big)$ and a saddle node bifurcation of periodic orbits coming along (see section 3.2).

Figure 3.1 represents the bifurcation curves and the fixed point of the quartic model in the space (I, b, v).

3.2. The Bautin bifurcation. As we have seen in the last section, at the point

$$\begin{cases} v_a = -\left(\frac{a}{4}\right)^{1/3}, \\ I = -3\left(\frac{a}{4}\right)^{4/3}(2\,a-1), \\ b = \frac{5}{2}a \end{cases} \tag{3.2}$$

the Jacobian matrix of the system has a pair of purely conjugate imaginary eigenvalues and a vanishing first Lyapunov exponent.

To prove the existence of a Bautin bifurcation, we start our computations from the point of section 1.3.4. In this case the calculations can be led until the end, but the expressions are very intricate, and we do not reproduce it here. In Appendix A we show the calculations to perform. We prove that the system actually undergoes a Bautin bifurcation except for two particular values of the parameter a.[4]

With this method we obtain a closed-form expression for the second Lyapunov exponent. We show that this second Lyapunov exponent vanishes for two values of a, whose expressions are complicated. These calculations are rigorous, but nevertheless, the interested reader can find numerical expressions of this exponent to get a grasp on its behavior in the appendix (see (A.7)) and of the two numerical values of a such that $l_2(a)$ vanishes.

Things are even more involved when we are interested in the regularity of the map $(I, b) \mapsto (\mu(I, b), l_1(I, b))$. Nevertheless, we obtain that this determinant never vanishes.

Eventually, for all a different from the critical values where the second Lyapunov exponent vanishes, the system undergoes a Bautin bifurcation.

Note finally that the Bautin bifurcation point separates two branches of sub- and supercritical Hopf bifurcations. For nearby parameter values, the system has two coexisting limit cycles, an attractive one and a repelling one, which collide and disappear via a saddle-node bifurcation of periodic orbits.

4. Numerical simulations.

In the previous sections we emphasized the fact that the class of models we defined in section 1 was able to reproduce the behaviors observed by Izhikevich in [15]. In this section, first we show that the quartic model indeed reproduces the behaviors observed by Izhikevich and which correspond to cortical neuron behaviors observed experimentally. We also produce some simulations of self-sustained subthreshold oscillations which occur only when the dynamical system has attracting periodic orbits, which is not the case in the IBG models.

Izhikevich in [15] explains the main features we obtain in numerical simulations from the neurocomputational point of view. In this paper, we comment on these same features from the dynamical systems point of view. This analysis also gives us a systematic way of finding the parameters associated with one of the possible behaviors.

4.1. Simulation results. We now provide simulation results of the quartic model introduced in section 3. In the simulated model, the spike is not represented by the blow up of the potential membrane v, but we consider that the neuron emits a spike when its membrane potential crosses a constant threshold.[5]

[4] All the computations have been performed using Maple, but the expressions are very involved and are not reproduced here.

[5] Note that the numerical simulations are very robust with respect to the choice of the threshold, if taken large enough, since the underlying equation blows up in finite time.

Let θ be our threshold. The simulated model considered in this section is the solution of the equations

$$\begin{cases} \dot{v} = v^4 + 2av - w + I, \\ \dot{w} = a(bv - w) \end{cases} \tag{4.1}$$

together with the spike-and-reset condition

$$\text{If } v(t^-) > \theta \Rightarrow \begin{cases} v(t) = v_r, \\ w(t) = w(t^-) + d. \end{cases} \tag{4.2}$$

Simulations have been done using an Euler numerical scheme, with a time step ranging from 10^{-1} to 10^{-2} depending on the precision needed, and with time intervals ranging from 10 to 500. This method is very efficient numerically and remains precise. Other integration methods could be used, and the qualitative results we obtained do not depend on the integration scheme, as soon as the time step is small enough.

Remark (on Figure 4.1). *Note that we did not reproduce the last three behaviors presented by Izhikevich in* [15, *Figs.* 1.(R), 1.(S), *and* 1.(T)]. *Indeed, these behaviors are not in the scope of the present paper and do not correspond to the model we studied.*

More precisely, in the study of the general model (1.1), *we considered for phenomenological reasons $a > 0$, modelling the leak of the adaptation variable: the adaptation would converge to its rest value if it was not influenced by the membrane potential v. If we considered $a < 0$, this adaptation variable would diverge exponentially from this rest value if it was not controlled by the membrane potential v. The inhibition-induced behaviors* [15, *Figs.* 1.(S) *and* 1.(T)] *require a to be strictly negative, and so we will not comment on these behaviors any further.*

Similarly, the accommodation behavior presented by Izhikevich in [15, *Fig.* 1.(R)] *is a limit case when w is very slow and the adaptation efficiency b very high. Mathematically speaking, it corresponds to a case where $a \to 0$ and $ab \to \lambda \neq 0$. This case is not taken into account in our study and amounts to replacing* (1.1) *by an equation of the type*

$$\begin{cases} \frac{dv}{dt} = F(v) - w + I, \\ \frac{dw}{dt} = ab(v - v_0), \end{cases} \tag{4.3}$$

and the study of this equation is not in the scope of the present paper.

The simulated behaviors we obtained in Figure 4.1 have been obtained playing with the bifurcation parameters in the phase plane. The way the parameters were set was based on a qualitative reasoning on the phase plane and the bifurcation diagram in a way we now describe.

4.2. Bifurcations and neuronal dynamics. In this section we link the neuronal behaviors shown in Figure 4.1 with the bifurcations of the system.

- (i) *Tonic spiking*: This behavior corresponds to the saddle-node bifurcation. The system starts from a (stable) equilibrium point near the saddle-node bifurcation curve (see Figure 4.2). Then we apply a greater constant current I, and the new dynamical system has no fixed point (we "cross" the saddle-node bifurcation curve). So the neuron begins spiking. The stabilization of the spiking frequency is linked with the existence of what we will call a *limit spiking cycle*. Indeed, we can see that the phase plane trajectory

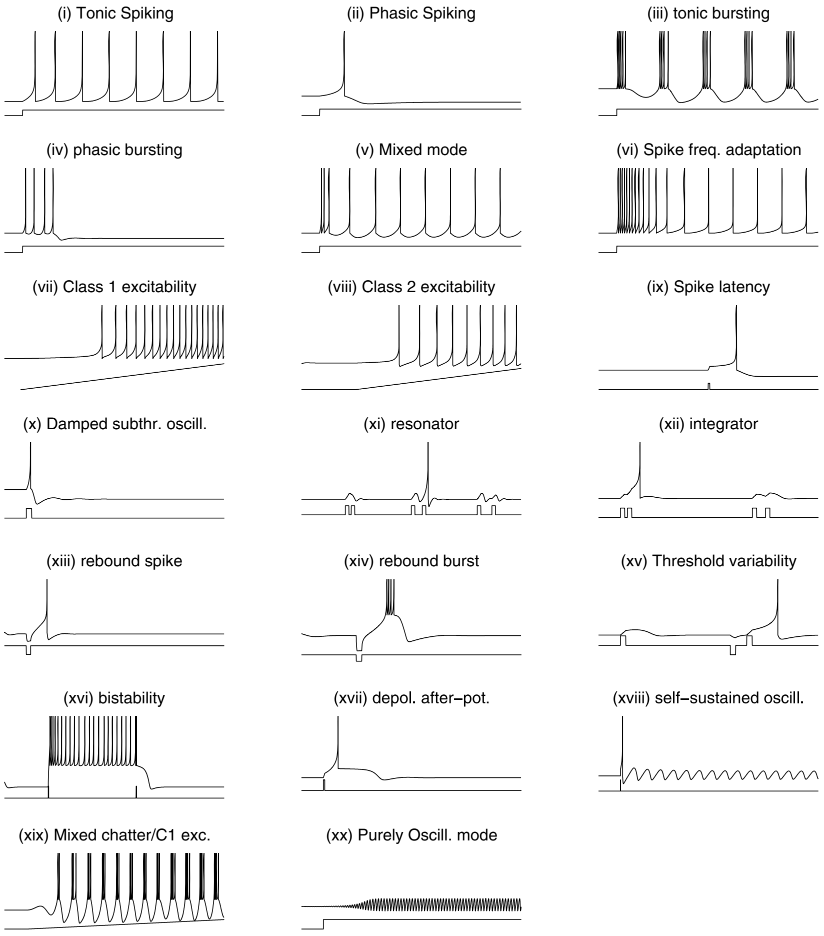

FIG. 4.1. *Different remarkable neurocomputational interesting behaviors of the neuron model* (4.1) *with the reset condition* (4.2) *for different choices of the parameters* (a, b, I, v_r, d). *The higher curve represents the membrane potential* v *and the lower one the input current* I *(see Appendix* B *for the numerical values of each simulations).*

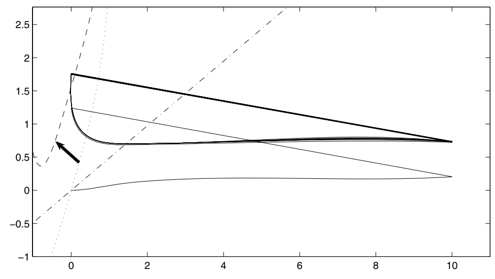

FIG. 4.2. *Tonic spiking: phase plane trajectory. The dotted curve is the* v *nullcline at the initial time. It is shifted to the dashed one when applying a constant input current. The new dynamical system has no fixed point and spikes regularly. We can see the* spiking cycle *appearing.*

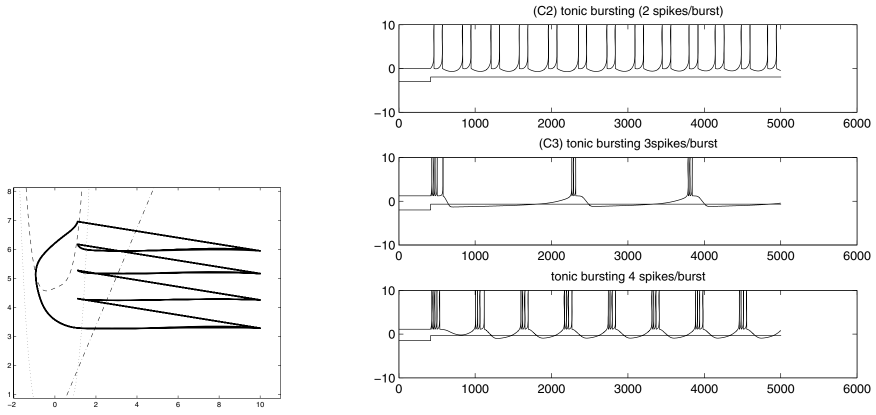


(a) Phase plane of the tonic spiking (without the transient phase)

(b) Controlling the number of spikes per burst

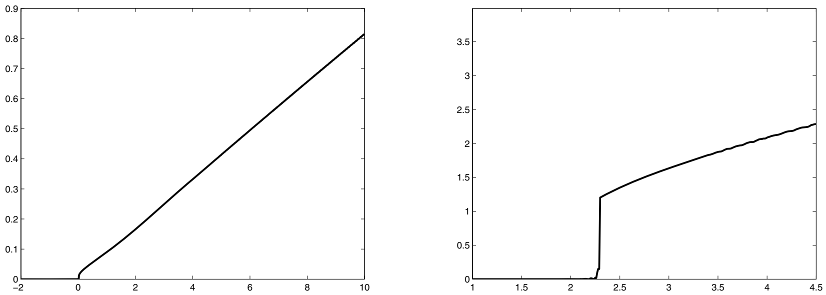
FIG. 4.3. *Tonic bursting: phase plane trajectory. The dotted curve is the v nullcline at the initial time. It is shifted to the dashed one when applying a constant input current. The new dynamical system has no fixed point. We can see the* multiple spike limit cycle *here.*

converges to a kind of cycle. This cycle includes a spike point ($v = \infty$, or $v =$ threshold in the numerical case), and so it is not a classical limit cycle. The v is always reset to the same value, and we can see that the adaptation variable w converges to an attracting stable value w_{spike}. This value satisfies $w_s(t_{\text{spike}}) + b = w_{\text{spike}}$, where $w_s(\cdot)$ is solution of (4.1) with the initial conditions

$$\begin{cases} v(0) = v_r, \\ w(0) = w_{\text{spike}} \end{cases}$$

and where t_{spike} denotes the time of the spike.

- (ii) *Phasic spiking*: This behavior occurs on the stable fixed point portion of the phase plane. The system starts at a fixed point. Then we apply a constant current to the neuron greater than the initial current but lower than the current associated with the saddle-node bifurcation. This stimulation forces the neuron to spike. Nevertheless, the reset point falls in the attraction basin of the new fixed point, and the trajectory converges to this point.
- (iii) *Tonic bursting*: This behavior is also linked to the saddle-node bifurcation. The system starts at a (stable) fixed point, and when we apply a constant current, we cross this bifurcation. The new dynamical system has no fixed point and is in a spiking behavior. The only difference with the tonic spiking behavior is that the point (v_r, w_{spike}) is in the zone $\{(v, w);\ \dot{v} < 0\}$. So the system emits quickly a precise number of spikes and then crosses the v nullcline. At this point, the membrane potential decays before spiking. We can see numerically that the system converges to a stable *spiking cycle* (see Figure 4.3(a)) containing a given number of spikes, a decay, and then the same sequence of spikes again. So the two-dimensional system is able to reproduce the diagrams presented by Izhikevich in [13] in an (at least) three-dimensional space. This is possible in two dimensions because of the



(a) Class 1 excitability

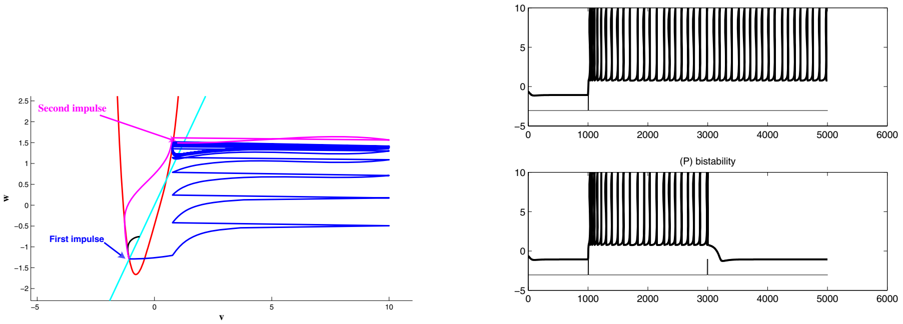
(b) Class 2 excitability

Fig. 4.4. *Spiking frequency vs. input current I for different choices of b. These curves have been obtained running simulations for different values of the input current, computing the frequency of the emitted spikes in a time range $T = 10000$.*

singularity of the model (explosion or threshold/reinitialization). If the system was regular, this behavior would not have been possible because it would have contradicted the Cauchy–Lipschitz theorem of existence and uniqueness of a solution.

Note that we can choose exactly the number of spikes per burst by changing the adaptation parameter d and that the bursting can be of parabolic or square-wave type as defined in Hoppensteadt and Izhikevich [12] (see Figure 4.3(b)).

- (iv) *Phasic bursting*: This behavior is linked with what we discussed in (ii) and (iii): the system starts at a stable fixed point. When the input current is turned on, the nullcline is shifted and the initial point is now in the spiking zone, and so a spike is emitted. Nevertheless, in contrast with (ii), the reset does not fall in the attraction basin of the new stable fixed point, but the point (v_0, w_{spike}) is inside this attraction basin. So a certain number of spikes are emitted before returning to the new fixed point. Here again we are able to control the number of spikes in the initial burst.
- (v) *Mixed mode*: The dynamical system interpretation is mixed between the phasic bursting and the tonic spiking. A certain number of spikes are necessary to converge to the spiking cycle.
- (vi) *Spike frequency adaptation*: This behavior is a particular case of tonic bursting where the convergence to the stable spiking cycle is slow.
- (vii)/(viii) *Class one/two excitability*: Figure 4.4(a) and (b) represents the spiking frequency of the neurons as a function of the input current. We can see that for the first choice of parameter, the frequency can be very small and increases regularly, and for the second choice of parameter, we can see that the system cannot spike in a given range of frequency (this frequency cannot be lower than 1.2Hz). Those simulations show that, depending on the chosen parameters, the system can be class 1 or class 2 excitable.
- (ix)/(xvii) *Spike latency/DAP*: It is a particular case of phasic spiking when the equilibrium v^* or the reset point v_r is near a point such that $F(v) = F'(v) = 0$. The membrane potential dynamics is very slow around this point. In the spike latency behavior, the initial point is close to this point, which generates the observed latency. In our case, it is around the minimum of



(a) Bistability: return to equilibrium via the same impulse

(b) Bistability

FIG. 4.5. *Bistability phenomenon: The first impulse induces a self-sustained tonic spiking behavior while the system has a stable fixed point. The second impulse perturbs this regular spiking behavior, and the system falls in the attraction basin of the stable fixed point.*

the function F (see Figure 4.6(ix)). In the depolarized after-potential (DAP) case, the reset occurs near this point, which is also in the attraction basin of the stable fixed point.

- (x) *Damped subthreshold oscillations*: This behavior occurs in the neighborhood of the stable fixed point: the stimulation evokes a spike, and the reset falls in the attraction basin of the stable fixed point, which has complex eigenvalues with negative real parts. This generates damped subthreshold oscillations.
- (xi) *Resonator*: This behavior occurs at the stable fixed point when the Jacobian matrix has complex eigenvalues. The first spike induces damped subthreshold oscillations. The spike is emitted if the second spike is given at the period of those oscillations, which is given by the argument of the complex eigenvalue. If it occurs before or after, then no spike is emitted.
- (xii) *Integrator*: This behavior occurs when we stimulate the system from the stable fixed point when the Jacobian matrix has real (negative) eigenvalues. If the first stimulation is not sufficient to make the neuron spike, then the stimulation is damped. Nevertheless, the membrane potential returns to equilibrium slowly, and if the same stimulation arrives to the "destabilized" neuron, it can generate a spike. The closer the second stimulation is to the first one, the more probable the omission of the spike.
- (xiii)/(xiv) *Rebound spike or burst*: The input impulse makes the neuron spike, and the reset (or the second, third, nth reset) falls in the attraction basin of the stable fixed point.
- (xv) *Threshold variability*: This phenomenon is exactly the same as the integrator, but instead of destabilizing the variable v we play on the adaptation variable.
- (xvi) *Bistability*: This behavior starts from the stable fixed point. The *attracting reset* (v_r, w_{spike}) is outside the attraction basin of the fixed point but still close to this zone. The first impulse generates a spike and initiates a tonic spiking mode. Nevertheless, it is possible via a small perturbation of the trajectory to fall into the attraction basin of the fixed point (see Figure 4.5).

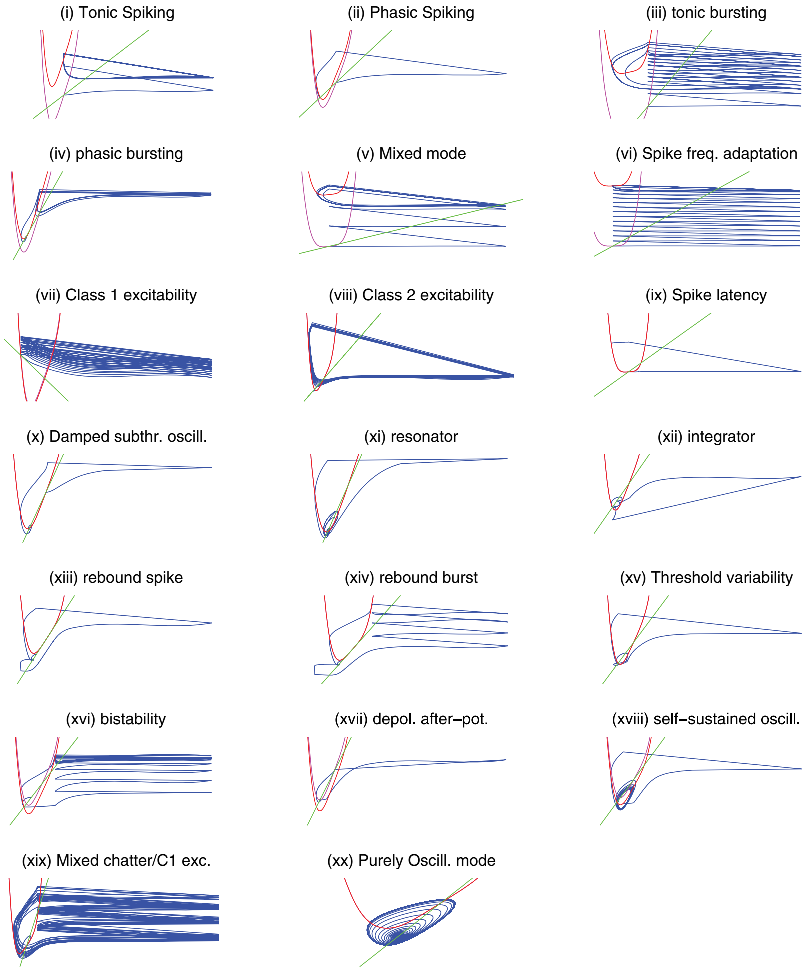


FIG. 4.6. *Phase diagrams corresponding to the behaviors presented in Figure* 4.1.

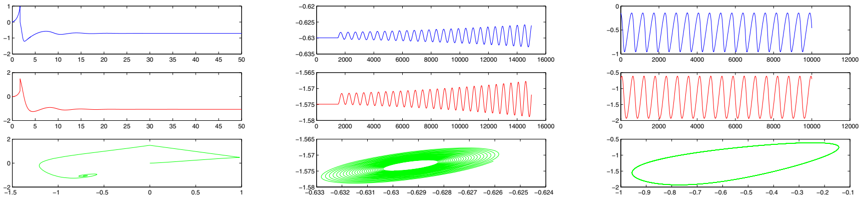
- (xviii)/(xx) *Self-sustained subthreshold oscillations and purely oscillating mode*: They are linked with the supercritical Hopf bifurcation and its stable periodic orbit. These two behaviors cannot be obtained in the IBG models since the Hopf bifurcations are always subcritical.

4.3. Self-sustained subthreshold oscillations in cortical neurons. In this study we gave a set of sufficient conditions to obtain an IBG-like model of neuron. In this framework we proposed a model that displays a Bautin bifurcation the IBG neurons lack; as a consequence our model can produce subthreshold oscillations. In this section, we explain from a biological point of view the origin and the role of those oscillations and reproduce in vivo recordings.

In the IBG models, the Andronov–Hopf bifurcation is always subcritical. The only oscillations created in these models are damped (see Figure 4.7(a)) and correspond in the phase plane to the convergence to a fixed point where the Jacobian matrix has complex eigenvalues. Our quartic model undergoes supercritical Andronov–Hopf bifurcations, and so there are attracting periodic solutions. This means that the



(a) Damped oscillations

(b) Transient phase towards the self-sustained oscillations

(c) Self-sustained oscillations (stationary state)

FIG. 4.7. *The quartic model shows damped subthreshold oscillations like the IBG models (Figure* 4.7(a)*): the trajectory collapses to a fixed point (parameters: $a = 1$, $b = 1.5$, $I = 0.1$, $T_{max} = 100$, $dt = 0.01$). The upper (blue) curve represents the solution in v, the middle (red) one w, and the lower one (green) the trajectory in the plane (v, w). Self-sustained subthreshold oscillations of the quartic model (Figures* 4.7(b) *and* 4.7(c)*): the trajectory is attracted towards a limit cycle (parameters: $a = 1$, $b = 5/2$, $I = -3(a/4)^{4/3}(2a-1)$, $T_{max} = 150000$, $dt = 0.01$, $I = (-3(a/4)^{4/3}(2a-1)+0.001)$.*

neurons can show self-sustained subthreshold oscillations (Figures 4.7(b) and 4.7(c)), which is of particular importance in neuroscience.

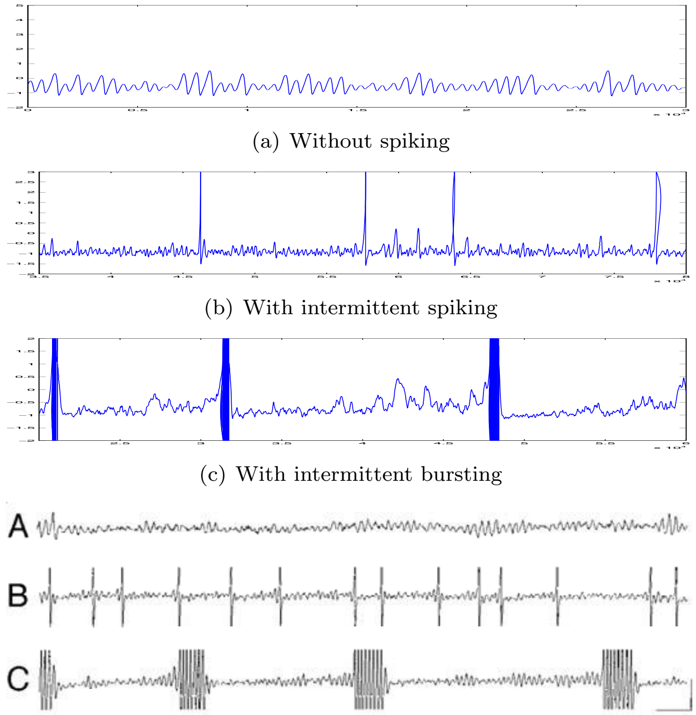
Most biological neurons show a sharp transition from silence to a spiking behavior, which is reproduced in all the models of class (1.1). However, experimental studies suggest that some neurons may experience a regime of small oscillations [21]. These subthreshold oscillations can facilitate the generation of spike oscillations when the membrane gets depolarized or hyperpolarized [22, 23]. They also play an important role in shaping specific forms of rhythmic activity that are vulnerable to the noise in the network dynamics.

For instance, the inferior olive nucleus, a part of the brain that sends sensory information to the cerebellum, is composed of neurons able to support oscillations around the rest potential. It has been shown by Llinás and Yarom [22, 23] that the precision and robustness of these oscillations are important for the precision and the robustness of spike generation patterns. The quartic model is able to reproduce the main features of the inferior olive neuron dynamics:

i. autonomous subthreshold periodic and regular oscillations (see intracellular recordings of inferior olive neurons in brain stem slices in [23]),
ii. rhythmic generation of action potentials.

The robust subthreshold oscillations shown by in vivo recordings [4, 21, 23] correspond in our quartic model to the stable limit cycle coming from the supercritical Hopf bifurcation. The oscillations generated by this cycle are stable, and they have a definite amplitude and frequency. This oscillation occurs at the same time as the rhythmic spike generation in the presence of noisy or varying input. Note that other neuron models such as those studied above, even if they do not undergo a supercritical Hopf bifurcation, can also exhibit oscillations in the presence of noise, for instance near a subcritical Hopf bifurcation. Nevertheless, these oscillations do not have the regularity in the amplitude and the frequency linked with the presence of an attracting limit cycle. The results we obtain simulating the quartic model are very similar to those obtained by in vivo recordings (see Figure 4.8).

But the inferior olive neurons are not the only neurons to present subthreshold membrane potential oscillations. For instance, stellate cells in the enthorhinal cortex demonstrate theta frequency subthreshold oscillations [1, 2, 17], linked with the persistent Na$^+$ current I_{NaP}.



(a) Without spiking

(b) With intermittent spiking

(c) With intermittent bursting

(d) Biological recordings

FIG. 4.8. *Subthreshold membrane oscillations, qualitatively reproducing the recordings from* [20] *in DRG neurons. Traces illustrate (*4.8(a)*) oscillations without spiking, (*4.8(b)*) oscillations with intermittent spiking, and (*4.8(c)*) oscillations with intermittent bursting (in the figures, spikes are truncated). The noisy input is an Ornstein–Ulhenbeck process. The biological recordings* 4.8(d) *are reproduced from* [20, *Fig.* 1] *and used with permission.*

We now conclude this section on the specific example of subthreshold self-sustained oscillations given by the dorsal root ganglia (DRG) neuron. This neuron presents subthreshold membrane potential oscillations coupled with repetitive spike discharge or burst, for instance in the case of a nerve injury [20, 3]. Figure 4.8(d) shows biological in vivo intracellular recordings performed by Liu et al. [20] from a DRG neuron of an adult male rat. The recorded membrane potentials exhibit high frequency subthreshold oscillation in the presence of noise, combined with a repetitive spiking or bursting. These behaviors can be reproduced by the quartic model, as we can see in Figure 4.8, around a point where the system undergoes a supercritical Hopf bifurcation.[6]

Conclusion. In this paper we defined a general class of neuron models able to reproduce a wide range of neuronal behaviors observed in experiments on cortical neurons. This class includes the Izhikevich and the Brette–Gerstner models, which are widely used. We derived the bifurcation diagram of the neurons of this class and proved that they all undergo the same types of bifurcations: a saddle-node bifurcation curve, an Andronov–Hopf bifurcation curve, and a codimension two Bogdanov–Takens

[6] The amplitude and frequency of the subthreshold oscillations can be controlled choosing a point on the supercritical Hopf bifurcation curve.

bifurcation. We proved that there was only one other possible fixed-point bifurcation, a Bautin bifurcation. Then using those theoretical results we proved that the Izhikevich and the Brette–Gerstner models had the same bifurcation diagram.

This theoretical study allows us to search for interesting models in this class of neurons. Indeed, Theorem 1.9 ensures us that the bifurcation diagram will present at least the bifurcations stated. This information is of great interest if we want to control the subthreshold behavior of the neuron of interest.

Following these ideas, we introduced a new neuron model of our global class undergoing the Bautin bifurcation. This model, called the *quartic model*, is computationally and mathematically as simple as the IBG models and able to reproduce some cortical neuron behaviors which the IBG models cannot reproduce.

This study focused on the subthreshold properties of this class of neurons. The adaptative reset of the model is of great interest and is a key parameter in the repetitive spiking properties of the neuron. Its mathematical study is very rich and is still an ongoing work.

Appendix A. Bautin bifurcation. In this appendix we prove that the quartic model undergoes a Bautin bifurcation at the point

$$\text{(A.1)} \qquad \begin{cases} b = \frac{5}{2}\,a, \\ I = -3\left(\frac{a}{4}\right)^{4/3}(2\,a-1)\,, \\ v_a = -\left(\frac{a}{4}\right)^{1/3}. \end{cases}$$

A.1. The first Lyapunov exponent. Indeed, using a suitable affine change of coordinates, the system at this point reads

$$\text{(A.2)} \qquad \begin{cases} \dot{x} = \omega y, \\ \dot{y} = \frac{ab}{\omega}\left(6v_a^2 v_1(x,y)^2 + 4v_a v_1(x,y)^3 + v_1(x,y)^4\right) \\ \quad = \frac{1}{2}F_2\left(\binom{x}{y},\binom{x}{y}\right) + \frac{1}{6}F_3\left(\binom{x}{y},\binom{x}{y},\binom{x}{y}\right) + \frac{1}{24}F_3\left(\binom{x}{y},\binom{x}{y},\binom{x}{y},\binom{x}{y}\right), \end{cases}$$

where $v_1(x,y) = \frac{1}{b}x + \frac{\omega}{ab}y$. We also denote $F_2(X,Y)$, $F_3(X,Y,Z)$, and $F_4(X,Y,Z,T)$ the multilinear symmetric vector functions of (A.2) ($X,Y,Z,T \in \mathbb{R}^2$):

$$\begin{cases} F_2\left(\binom{x}{y},\binom{z}{t}\right) = \binom{0}{12\frac{ab}{\omega}v_a^2 v_1(x,y) v_1(z,t)}, \\ \dots \end{cases}$$

To compute the two first Lyapunov exponents of the system, we follow Kuznetsov's method [19]. In this method we need to compute some specific right and left complex eigenvectors, which can be chosen in our case to be

$$\text{(A.3)} \qquad \begin{cases} p = \begin{pmatrix} \frac{1}{-i\sqrt{a\,b-a^2}+a} \\ 1 \end{pmatrix}, \\ q = \begin{pmatrix} \frac{1}{2}\,\frac{(i\sqrt{a(b-a)}+a)b}{b-a-i\sqrt{a(b-a)}} \\ 1/2\,\frac{(i\sqrt{a(b-a)}+a)^2}{a\,(b-a-i\sqrt{a(b-a)})} \end{pmatrix}. \end{cases}$$

We now put the system in a complex form letting $z = x + iy$.

We can now compute the complex Taylor coefficients g_{ij}:

$$\tag{A.4} \begin{cases} g_{20} = \langle p, F_2(q,q)\rangle, \\ g_{11} = \langle p, F_2(q,\bar{q})\rangle, \\ g_{02} = \langle p, F_2(\bar{q},\bar{q})\rangle, \\ \\ g_{30} = \langle p, F_3(q,q,q)\rangle, \\ g_{21} = \langle p, F_3(q,q,\bar{q})\rangle, \\ g_{12} = \langle p, F_3(\bar{q},\bar{q},\bar{q})\rangle, \\ g_{03} = \langle p, F_3(\bar{q},\bar{q},\bar{q})\rangle, \\ \dots \end{cases}$$

So the Taylor coefficients (A.4) read

$$\tag{A.5} \begin{cases} g_{20} = 12\frac{ab}{\omega} v_a^2 v_1 \left(\frac{1}{2}\frac{(i\sqrt{a(b-a)}+a)b}{b-a-i\sqrt{a(b-a)}}, \frac{1}{2}\frac{(i\sqrt{a(b-a)}+a)^2}{a\,(b-a-i\sqrt{a(b-a)})} \right)^2, \\ g_{11} = 12\frac{ab}{\omega} v_a^2 v_1(q) v_1(\bar{q}), \\ g_{02} = 12\frac{ab}{\omega} v_a^2 v_1(\bar{q}) v_1(\bar{q}), \\ \\ \dots \end{cases}$$

Now let $S(I,b) := F'(v_-(I,b))$ be the value of the derivative of the function F, defined around the bifurcation point we are interested in.

The Jacobian matrix in the neighborhood of the point (A.1) reads

$$L(v) = \begin{pmatrix} S(I,b) & 1 \\ ab & -a \end{pmatrix}.$$

Let us denote $\alpha = \binom{I}{b}$ the parameter vector and $\lambda(\alpha) = \mu(\alpha) \pm i\omega(\alpha)$ the eigenvalues of the Jacobian matrix. We have

$$\begin{cases} \mu(\alpha) = \frac{1}{2}\left(S(\alpha) - a\right), \\ \omega(\alpha) = \frac{1}{2}\sqrt{-(S(\alpha)-a)^2 + 4ab}. \end{cases}$$

With these notations, let $c_1(\alpha)$ be the complex defined by

$$c_1(\alpha) = \frac{g_{20}g_{11}(2\lambda+\bar{\lambda})}{2|\lambda|^2} + \frac{|g_{11}|^2}{\lambda} + \frac{|g_{02}|^2}{2(2\lambda-\bar{\lambda})} + \frac{g_{21}}{2}$$

(in this formula we omit the dependence in α of λ for the sake of clarity).

The first Lyapunov exponent $l_1(\alpha)$ eventually reads

$$\tag{A.6} \boxed{l_1(\alpha) = \frac{Re(c_1(\alpha))}{\omega(\alpha)} - \frac{\mu(\alpha)}{\omega(\alpha)^2}\mathrm{Im}(c_1(\alpha))}$$

A.2. The second Lyapunov exponent. The method to compute the second Lyapunov exponent is the same as the one we described in the previous section. The expression is given by the following formula:

$$\begin{aligned} 2l_2(0) = {}& \frac{1}{\omega(0)}\,\mathrm{Re}[g_{32}] \\ & + \frac{1}{\omega(0)^2}\,\mathrm{Im}\left[g_{20}\,\bar{g_{31}} - g_{11}\,(4\,g_{31} + 3\,\bar{g_{22}}) - \frac{1}{3}g_{02}\,(g_{40} + \bar{g_{13}}) - g_{30}\,g_{12}\right] \\ & + \frac{1}{\omega(0)^3}\left\{\mathrm{Re}\left[g_{20}\left(\bar{g_{11}}(3\,g_{12} - \bar{g_{30}}) + g_{02}\,(\bar{g_{12}} - 1/3\,g_{30}) + \frac{1}{3}\bar{g_{02}}g_{03}\right)\right.\right. \\ & \left. + g_{11}\left(\bar{g_{02}}\left(\frac{5}{3}\bar{g_{30}} + 3\,g_{12}\right) + \frac{1}{3}g_{02}\,\bar{g_{03}} - 4\,g_{11}\,g_{30}\right)\right] \\ & \left. + 3\,\mathrm{Im}[g_{20}\,g_{11}]\,\mathrm{Im}[g_{21}]\right\} \\ & + \frac{1}{\omega(0)^4}\left\{\mathrm{Im}\left[g_{11}\bar{g_{02}}\left(\bar{g_{20}}^2 - 3\,\bar{g_{20}}g_{11} - 4\,g_{11}^2\right)\right]\right. \\ & \left. + \mathrm{Im}[g_{20}\,g_{11}]\left(3\,\mathrm{Re}(g_{20}\,g_{11}) - 2\,|g_{02}|^2\right)\right\}. \end{aligned}$$

This expression is quite intricate in our case. Nevertheless, we have a closed-form expression depending on the parameter a, vanishing for two values of the parameter a. We evaluate numerically this second Lyapunov exponent. We get the following expression:

$$\begin{aligned} l_2(a) \approx {}& -0.003165\,a^{-\frac{28}{3}} - 0.1898\,a^{-\frac{22}{3}} + 0.3194\,a^{-16/3} \\ & - 0.05392\,a^{-\frac{25}{3}} + 0.1400\,a^{-\frac{19}{3}} - 0.3880\,a^{-7/3} + 0.5530\,a^{-10/3} \\ & + 0.7450\,a^{-13/3}. \end{aligned} \tag{A.7}$$

We can see that this numerical exponent vanishes only for two values of the parameter a which are

$$\{0.5304, 2.385\}.$$

The expression of the determinant of the matrix $D_{I,b}\,(\mu(I,b), l_1(I,b))$ is even more involved, and so we do not reproduce it here (it would take pages to write down its numerical expression!). Nevertheless, we proceed exactly as we did for the second Lyapunov exponent and obtain again the rigorous result that this determinant never vanishes for all $a > 0$.

Appendix B. Numerical values for the simulations. In this annex we give the numerical values used to generate Figure 4.1.

(i) Tonic Spiking $a = 1$; $b = 0.49$; $v_r = 0$; $I(t) = 1.56\mathbb{1}_{t>1}(t)$; $d = 1$; $T = 10$; $dt = 0.01$; $\theta = 10$;	(ii) Phasic Spiking $a = 1$; $b = 0.76$; $v_r = 0.2$; $I = 0.37\mathbb{1}_{t>1}(t)$; $d = 1$; $T = 10$; $dt = 0.01$; $\theta = 10$;	(iii) Tonic Bursting $a = 0.15$; $b = 1.68$; $v_r = (-2a + b)^{\frac{1}{3}}$; $I = 4.67\mathbb{1}_{t>1}(t)$; $d = 1$; $T = 30$; $dt = 0.01$; $\theta = 10$;
(iv) Phasic Bursting $a =1.58$; $b =1.70$; $v_r =-\frac{a}{4}^{\frac{1}{3}}$; $I(t) =0.73\mathbb{1}_{t>1}(t)$; $d = 0.01$; $T =50$; $dt =0.01$; $\theta =10$.	(v) Mixed Mode $a =0.07$; $b =0.32$; $v_r =0$; $I(t) =3.84\mathbb{1}_{t>1}(t)$; $d = 1.50$; $T =50$; $dt =0.01$; $\theta =10$.	(vi) Spike Freq. Adaptation $a =0.02$; $b =0.74$; $v_r =0$; $I(t) =4.33\mathbb{1}_{t>1}(t)$; $d = 0.36$; $T =50$; $dt =0.01$; $\theta =10$.
(vii) Class 1 Excitability $a =4$; $b =0.67$; $v_r =-1.3$; $I(t) =-0.1 + 0.23t$; $d = 1$; $T =30$; $dt =0.01$; $\theta =10$.	(viii) Class 2 Excitability $a =1$; $b =1.09$; $v_r =-1.2$; $I(t) =0.06t$; $d = 5$; $T =50$; $dt =0.01$; $\theta =20$.	(ix) Spike Latency $a =0.02$; $b =0.42$; $v_r =0$; $I(t) =5\delta_{7.5}(t)$; $d = 1$; $T =15$; $dt =0.01$; $\theta =10$.
(x) Damped Subthr. Oscill. $a =2.58$; $b =4.16$; $v_r =0.1$; $I(t) =2\delta_2(t)$; $d = 0.05$; $T =20$; $dt =0.01$; $\theta =10$. METHODS FOR SOLVING ELLIPTIC PDEs IN SPHERICAL COORDINATES*

G. DASSIOS† AND A. S. FOKAS‡

Abstract. A new method for investigating boundary value problems in two dimensions has recently been introduced by one of the authors. The main achievement of this method is that it yields explicit *integral* (as oppose to series) representations for a variety of boundary value problems. In addition, this method also provides an alternative, apparently simpler, approach for deriving those solution representations that are traditionally constructed by the method of images and of classical integral transforms. Here, we implement this latter approach to boundary value problems formulated in spherical coordinates. In particular, we do the following: (a) We derive the classical Poisson integral formula for the solutions of the Dirichlet problem for the Poisson equation in the interior of a sphere, the analogous formula for the Neumann problem, and the generalizations of these formulae in n dimensions. (b) We derive the solutions of various boundary value problems for the inhomogeneous Helmholtz equation in the interior of a sphere. (c) We solve the Dirichlet problem for the Laplace equation in the interior of a spherical sector.

Key words. elliptic partial differential equations, boundary value problems, spectral methods, Fourier expansions

1. Introduction.

By using Green's identity and the associated fundamental solutions, it is straightforward to obtain integral representations for the solution of the Poisson and the inhomogeneous Helmholtz equations in an arbitrary three dimensional domain. These representations involve a volume integral of the forcing term as well as surface integrals of the Dirichlet and of the Neumann boundary values. This classical formulation provides the starting point for proving certain rigorous results and for constructing efficient numerical approximations. However, it does *not* provide an analytic representation of the solution, since depending on the given problem, either the Dirichlet or the Neumann boundary values are unknown. For the Poisson equation with simple boundary conditions (such as Dirichlet) formulated on simple domains (such as spheres), this difficulty can be bypassed by employing the *method of images*. More complicated boundary value problems can be solved by the *method of integral transforms*.

A new method for solving boundary value problems for linear and for integrable nonlinear PDEs in two dimensions has been introduced by one of the authors [7, 8] and implemented for a large class of problems; see [9]. For linear PDEs this method does the following: (i) It yields analytic solutions to a variety of boundary value problems, for which classical techniques are apparently ineffective. (ii) It expresses the solutions of classical problems in terms of *integrals* as opposed to the traditional *series*

representations; these novel representations have analytical and numerical advantages. (iii) It provides an alternative, apparently simpler, approach for solving those problems that can be solved by the methods of images and of integral transforms.

The aim of this paper is to implement the approach (iii) above to boundary value problems formulated in spherical coordinates. Although the approach (iii) is the least novel among the approaches (i)–(iii), the implementation of the classical method of integral transforms increases in complexity as the number of dimensions increases; thus perhaps the approach (iii) becomes more useful as the number of dimensions increases.

Notation.

- The symbol "ˆ" on the top of a vector indicates that this vector has unit length.
- $\mathrm{ds}(\boldsymbol{\rho})$ and $\mathrm{dv}(\boldsymbol{\rho})$ denote surface and volume elements, respectively, at the point $\boldsymbol{\rho}$.
- $\hat{\boldsymbol{n}}$ denotes the outward unit normal on the boundary $\partial\Omega$ of a smooth domain Ω.
- $\frac{\partial}{\partial n} = \hat{\boldsymbol{n}} \cdot \nabla$ denotes the outward normal differentiation on $\partial\Omega$.

1.1. An alternative to the method of images. Let the scalar valued function $u(\boldsymbol{r})$ satisfy a linear PDE in a smooth domain Ω. The alternative to the method of images proposed here consists of the following three steps:

(a) Supplement the classical representation of the solution obtained by Green's identity and the relevant fundamental solution with an equation which is valid in the complement of the domain Ω, which will be denoted by Ω^c.

(b) Use an appropriate transformation to map the equation valid in Ω^c to an equation valid in Ω.

(c) Manipulate the *two* above equations valid in Ω to eliminate either the Neumann or the Dirichlet boundary values.

Example 1.1. Let $u(\boldsymbol{r})$ satisfy the Poisson equation in the interior of a sphere of radius α,

$$\Delta u(\boldsymbol{r}) = f(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \tag{1}$$

where the function f has sufficient smoothness. Then

$$u(\boldsymbol{r}) = u_p(\boldsymbol{r}) + u_0(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \tag{2}$$

where u_p is defined by

$$u_p(\boldsymbol{r}) = -\frac{1}{4\pi}\int_{|\boldsymbol{\rho}|<\alpha} \frac{f(\boldsymbol{\rho})}{|\boldsymbol{\rho}-\boldsymbol{r}|}\mathrm{dv}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{3}$$

and u_0 is the following harmonic function:

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi}\oint_{|\boldsymbol{\rho}|=\alpha}\left[\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|}\frac{\partial}{\partial\rho}u_0(\boldsymbol{\rho}) - u_0(\boldsymbol{\rho})\frac{\partial}{\partial\rho}\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|}\right]\mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha. \tag{4}$$

We will now use steps (a)–(c) above to determine u_0.

(a) Using

$$\frac{\partial}{\partial\rho}\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|} = -\frac{\hat{\boldsymbol{\rho}}\cdot(\boldsymbol{\rho}-\boldsymbol{r})}{|\boldsymbol{\rho}-\boldsymbol{r}|^3}$$

(4) becomes

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi} \oint_{|\boldsymbol{\rho}|=\alpha} \left[\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|} \frac{\partial}{\partial \rho} u_0(\boldsymbol{\rho}) + \frac{\alpha^2 - \boldsymbol{\rho}\cdot\boldsymbol{r}}{\alpha|\boldsymbol{\rho}-\boldsymbol{r}|^3} u_0(\boldsymbol{\rho}) \right] \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha. \tag{5}$$

The left-hand side of (5) vanishes if $|\boldsymbol{r}| > \alpha$; thus we supplement (5) with the equation

$$0 = \frac{1}{4\pi} \oint_{|\boldsymbol{\rho}|=\alpha} \left[\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|} \frac{\partial}{\partial \rho} u_0(\boldsymbol{\rho}) + \frac{\alpha^2 - \boldsymbol{\rho}\cdot\boldsymbol{r}}{\alpha|\boldsymbol{\rho}-\boldsymbol{r}|^3} u_0(\boldsymbol{\rho}) \right] \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| > \alpha. \tag{6}$$

(b) Kelvin's inversion, i.e., the transformation

$$\boldsymbol{r} \to \frac{\alpha^2}{r^2}\boldsymbol{r}, \tag{7}$$

maps the exterior to the sphere of radius α to its interior, and vice versa [11]. Furthermore, under this transformation, if $|\boldsymbol{\rho}| = \alpha$, then

$$|\boldsymbol{\rho}-\boldsymbol{r}| = \sqrt{\alpha^2 - 2\alpha r \hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}} + r^2} \to \sqrt{\alpha^2 - 2\alpha\frac{\alpha^2}{r}\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}} + \frac{\alpha^4}{r^2}} = \frac{\alpha}{r}|\boldsymbol{\rho}-\boldsymbol{r}|. \tag{8}$$

Consequently, using the transformation (7) and dropping the multiplicative factor r/α, (6) becomes

$$0 = \frac{1}{4\pi} \oint_{|\boldsymbol{\rho}|=\alpha} \left[\frac{1}{|\boldsymbol{\rho}-\boldsymbol{r}|} \frac{\partial}{\partial \rho} u_0(\boldsymbol{\rho}) + \frac{r^2 - \boldsymbol{\rho}\cdot\boldsymbol{r}}{\alpha|\boldsymbol{\rho}-\boldsymbol{r}|^3} u_0(\boldsymbol{\rho}) \right] \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{9}$$

which now holds in the interior of the sphere.

(c) Equations (5) and (9) are both valid for $|\boldsymbol{r}| < \alpha$; thus by subtracting these equations we can eliminate the Neumann boundary values $\partial_\rho u_0(\boldsymbol{\rho})$ and obtain

$$u_0(\boldsymbol{r}) = \frac{\alpha^2 - r^2}{4\pi\alpha} \oint_{|\boldsymbol{\rho}|=\alpha} \frac{u_0(\boldsymbol{\rho})}{|\boldsymbol{\rho}-\boldsymbol{r}|^3} \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha. \tag{10}$$

Equation (10) is the well-known Poisson integral formula for the solution of the Dirichlet problem [1, 2, 11, 16].

It is shown in section 2 that by further manipulating (5) and (9) we can eliminate the Dirichlet boundary value $u_0(\boldsymbol{\rho})$ and obtain

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi\alpha} \oint_{|\boldsymbol{\rho}|=\alpha} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \left[\frac{2\alpha}{|\boldsymbol{\rho}-\boldsymbol{r}|} - \ln\left(|\boldsymbol{\rho}-\boldsymbol{r}| + \frac{\boldsymbol{\rho}\cdot(\boldsymbol{\rho}-\boldsymbol{r})}{\alpha} \right) \right] \mathrm{ds}(\boldsymbol{\rho}). \tag{11}$$

Equation (2), with $u_p(\boldsymbol{r})$ and $u_0(\boldsymbol{r})$ given by (3) and (9), respectively, provides the analogue of the Poisson integral formula for the solution of the Neumann problem [1, 2, 11, 16].

The extension of these formulae to n dimensions is given in section 2.

1.2. An alternative to the method of integral transforms. If u satisfies either the Poisson or the inhomogeneous Helmholtz equations with a forcing term f in a smooth domain Ω, then Green's third identity implies the relation

$$\int_D w(\boldsymbol{\rho}) f(\boldsymbol{\rho}) \mathrm{dv}(\boldsymbol{\rho}) = \oint_{\partial D} \left[w(\boldsymbol{\rho}) \frac{\partial}{\partial n} u(\boldsymbol{\rho}) - u(\boldsymbol{\rho}) \frac{\partial}{\partial n} w(\boldsymbol{\rho}) \right] \mathrm{ds}(\boldsymbol{\rho}), \tag{12}$$

where $D \subset \Omega$ is *any* smooth subdomain of Ω and w is *any* solution of the Laplace or the Helmholtz equation, respectively. We will refer to this well-known equation as the *global relation* [9], since it connects the Dirichlet and the Neumann values on the boundary in a global sense.

1.2.1. The Dirichlet-to-Neumann map. The use of the global relation apparently provides the most effective approach for constructing the Dirichlet-to-Neumann map, i.e., computing the Neumann boundary values in terms of the Dirichlet data *directly*, without constructing the solution in the interior of the domain. This approach consists of the following steps:

(a) Apply the global relation in the domain Ω for a suitable function w.

(b) Eliminate the unknown boundary values by choosing appropriately the parameters occurring in w. This procedure yields an integral transform for the Neumann boundary values in terms of the Dirichlet data.

(c) Invert the above integral transform by using standard Sturm–Liouville techniques.

Example 1.2. Let u satisfy the Laplace equation in the spherical sector Ω:

$$\Omega = \{(\rho, \theta, \varphi) \mid 0 < \rho < \alpha,\ 0 \leqslant \theta < \theta_0,\ 0 \leqslant \varphi < 2\pi\}, \quad 0 < \theta_0 < \pi. \tag{13}$$

It is shown in section 4 that steps (a) and (b) above yield the following integral transform for the Neumann boundary values on the spherical cap $\{\rho = \alpha,\ 0 \leqslant \theta < \theta_0,\ 0 \leqslant \varphi < 2\pi\}$:

$$\int_0^{2\pi}\int_0^{\theta_0} \frac{\partial u(\alpha,\theta,\varphi)}{\partial r} P_{l_n}^m(\cos\theta) e^{im\varphi} \sin\theta \,\mathrm{d}\theta\,\mathrm{d}\varphi = M_n^m(\alpha,\theta_0), \tag{14}$$

where the constants $M_n^m(\alpha,\theta_0)$ are given in terms of the Dirichlet data in (66), $P_{l_n}^m$ denote the usual Legendre functions, and $\{l_n\}_{n=0}^\infty$ is a sequence of nonnegative real numbers defined by

$$P_{l_n}^m(\cos\theta_0) = 0, \quad n = 0, 1, 2, \dots, \quad m \in \mathbb{Z}. \tag{15}$$

1.2.2. A representation of the solution. The appropriate use of the global relation also yields the solutions in the interior. However, step (a) above is now replaced by the following:

(a′) By choosing appropriate subdomains D and appropriate solutions w, obtain a *set* of global relations.

Example 1.3. For Example 1.2, it is shown in section 4 that steps (a′) and (b) above yield the following integral transform for the solution of the Dirichlet problem in Ω:

$$\int_0^{2\pi}\int_0^{\theta_0} u(r,\theta,\varphi) P_{l_n}^m(\cos\theta) e^{im\varphi} \sin\theta \,\mathrm{d}\theta\,\mathrm{d}\varphi = K_n^m(r,\theta_0), \quad n = 0, 1, 2, \dots, \quad m \in \mathbb{Z}, \tag{16}$$

where the functions $K_n^m(r,\theta_0)$ are defined in terms of the known Dirichlet data in (70).

It is emphasized that the derivation of (14) and (16) involves only *algebraic* manipulations. The only analysis needed is the inversion of the integrals on the left-hand side of (14) and (16); see section 4.

1.2.3. A hybrid method using the fundamental solution and the global relation. For very simple boundary value problems, it is possible to obtain the solution in the interior of the domain by applying the global relation to the domain Ω instead of using a set of subdomains. For such problems our approach consists of the following three steps:

(a) Formulate the global relation in Ω.

(b) Expand the fundamental solution in terms of the functions w appearing in the global relation (12).

(c) Use the algebraic manipulation of the global relation and of the equation obtain by replacing in the classical integral representation of u the fundamental solution in terms of the expansion obtained in (b) to eliminate the unknown boundary values.

This approach has the disadvantage that it requires knowledge of the expansion described in (b), but it has the advantage that the remaining steps are entirely algebraic.

Example 1.4. Let u satisfy the inhomogeneous Helmholtz equation in the interior of a sphere of radius α,

$$(\Delta + \lambda^2)u(\boldsymbol{r}) = f(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \tag{17}$$

where the function f has sufficient smoothness and λ is a positive constant. Then u is given by (2), where u_p and u_0 are defined by

$$u_p(\boldsymbol{r}) = -\frac{1}{4\pi}\int_{|\boldsymbol{\rho}|<\alpha} f(\boldsymbol{\rho})\frac{e^{i\lambda|\boldsymbol{\rho}-\boldsymbol{r}|}}{|\boldsymbol{\rho}-\boldsymbol{r}|}\mathrm{dv}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{18}$$

and

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi}\oint_{|\boldsymbol{\rho}|=\alpha}\left[\frac{e^{i\lambda|\boldsymbol{\rho}-\boldsymbol{r}|}}{|\boldsymbol{\rho}-\boldsymbol{r}|}\frac{\partial}{\partial\rho}u_0(\boldsymbol{\rho}) - u_0(\boldsymbol{\rho})\frac{\partial}{\partial\rho}\frac{e^{i\lambda|\boldsymbol{\rho}-\boldsymbol{r}|}}{|\boldsymbol{\rho}-\boldsymbol{r}|}\right]\mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha. \tag{19}$$

We will now solve the Dirichlet boundary value problem using steps (a)–(c) above.

(a) Letting $w(\boldsymbol{\rho}) = j_n(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})$ in the global relation (12), where j_n is the spherical Bessel function of the first kind and P_n is the Legendre polynomial, we find the following equation, which is valid for any unit vector $\hat{\boldsymbol{k}}$ and any $n \in \mathbb{Z}$:

$$\begin{aligned}&\int_{|\boldsymbol{\rho}|<\alpha} f(\boldsymbol{\rho})j_n(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})\mathrm{dv}(\boldsymbol{\rho})\\ &= \oint_{|\boldsymbol{\rho}|=\alpha}\left[j_n(\lambda\rho)\frac{\partial}{\partial\rho}u(\boldsymbol{\rho}) - u(\boldsymbol{\rho})\frac{\partial}{\partial\rho}j_n(\lambda\rho)\right]P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})\mathrm{ds}(\boldsymbol{\rho})\\ &= j_n(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}\frac{\partial u(\boldsymbol{\rho})}{\partial\rho}P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})\mathrm{ds}(\boldsymbol{\rho}) - \lambda j_n'(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}u(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})\mathrm{ds}(\boldsymbol{\rho}),\end{aligned} \tag{20}$$

where for the second equality we have used that on the boundary $\rho = \alpha$.

(b) The fundamental solution for the Helmholtz equation admits the following expansion [14, 15]:

$$\frac{1}{4\pi}\frac{e^{i\lambda|\boldsymbol{\rho}-\boldsymbol{r}|}}{|\boldsymbol{\rho}-\boldsymbol{r}|} = \frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)h_n^{(1)}(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}}), \quad r < \rho, \tag{21}$$

where $h_n^{(1)}$ is the spherical Hankel function of the first kind.

(c) Using the representation (21) and (2) in (19) we find that for $r < \alpha$

$$\begin{aligned}u_0(\boldsymbol{r}) = &-\frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)\\ &\times\left[\lambda h_n^{(1)'}(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}(u(\boldsymbol{\rho}) - u_p(\boldsymbol{\rho}))P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho})\right.\\ &\left.- h_n^{(1)}(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}\frac{\partial(u(\boldsymbol{\rho}) - u_p(\boldsymbol{\rho}))}{\partial\rho}P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho})\right],\end{aligned} \tag{22}$$

where u_p is given by (18).

In order to eliminate the Neumann boundary values $\partial_\rho u(\boldsymbol{\rho})$ from (22) we let $\hat{\boldsymbol{k}} = \hat{\boldsymbol{r}}$ in (20), we multiply the resulting equation by the expression

$$-\frac{i\lambda}{4\pi}(2n+1)\frac{h_n^{(1)}(\lambda\alpha)}{j_n(\lambda\alpha)}j_n(\lambda r),$$

we use the Wronskian relation

$$n_n'(x)j_n(x) - n_n(x)j_n'(x) = \frac{1}{x^2}, \tag{23}$$

we sum over n, and we add the resulting equation to (22). This yields

$$\begin{aligned} u_0(\boldsymbol{r}) = \frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)\Bigg[&\frac{-i}{\lambda\alpha^2 j_n(\lambda\alpha)}\oint_{|\boldsymbol{\rho}|=\alpha} u(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho}) \\ &+ \lambda h_n^{(1)\prime}(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha} u_p(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho}) \\ &- h_n^{(1)}(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}\frac{\partial u_p(\boldsymbol{\rho})}{\partial\rho}P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho}) \\ &+ \frac{h_n^{(1)}(\lambda\alpha)}{j_n(\lambda\alpha)}\int_{|\boldsymbol{\rho}|<\alpha} f(\boldsymbol{\rho})j_n(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{dv}(\boldsymbol{\rho})\Bigg], \end{aligned} \tag{24}$$

where the right-hand side of (24) involves only known quantities. Equation (2), with u_p and u_0 given by (18) and (24), respectively, provides the solution of the Dirichlet boundary value problem. The Neumann and the Robin problems are solved in section 3.

2. The Poisson integral formula and its analogue for the Neumann problem in *n* dimensions.

PROPOSITION 2.1. *Let u satisfy the Poisson equation in the interior of an n dimensional sphere of radius α,*

$$\Delta u(\boldsymbol{r}) = f(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \quad \boldsymbol{r} \in \mathbb{R}^n, \quad n \geqslant 3, \tag{25}$$

with either Dirichlet

$$u(\boldsymbol{r}) = D(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \tag{26}$$

or Neumann

$$\frac{\partial u(\boldsymbol{r})}{\partial r} = N(\boldsymbol{r}), \quad |\boldsymbol{r}| < \alpha, \tag{27}$$

boundary conditions, where the functions f, D, N have sufficient smoothness. Then

$$\begin{aligned} u(\boldsymbol{r}) &= u_0(\boldsymbol{r}) - \frac{1}{(n-2)\omega_n}\int_{|\boldsymbol{\rho}|<\alpha}\frac{f(\boldsymbol{\rho})}{|\boldsymbol{\rho}-\boldsymbol{r}|^{n-2}}\mathrm{dv}(\boldsymbol{\rho}) \\ &= u_0(\boldsymbol{r}) - u_p(\boldsymbol{r}), \end{aligned} \tag{28}$$

where

$$\omega_n = \frac{2\pi^{n/2}}{\Gamma(n/2)}, \tag{29}$$

Γ *denotes the Euler Gamma function, and* u_0 *is given by the following expressions:*

For the Dirichlet problem,

$$u_0(\boldsymbol{r}) = \frac{\alpha^2 - r^2}{\alpha\omega_n} \oint_{|\boldsymbol{\rho}|=\alpha} \frac{D_0(\boldsymbol{\rho})}{|\boldsymbol{\rho} - \boldsymbol{r}|^n} \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{30}$$

where $D_0 = D - u_p$ *on the boundary.*

For the Neumann problem,

$$r\frac{\partial u_0(\boldsymbol{r})}{\partial r} = \frac{\alpha^2 - r^2}{\omega_n} \oint_{|\boldsymbol{\rho}|=\alpha} \frac{N_0(\boldsymbol{\rho})}{|\boldsymbol{\rho} - \boldsymbol{r}|^n} \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{31}$$

where $N_0 = N - u_p$ *on the boundary, or equivalently,*

$$u_0(\boldsymbol{r}) = \frac{1}{\alpha\omega_n} \oint_{|\boldsymbol{\rho}|=\alpha} I(\boldsymbol{\rho}, \boldsymbol{r}) N_0(\boldsymbol{\rho}) \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{32}$$

with

$$\begin{aligned} I(\boldsymbol{\rho}, \boldsymbol{r}) &= \int_\alpha^r \frac{\alpha(\alpha^2 - t^2)}{t|\boldsymbol{\rho} - t\hat{\boldsymbol{r}}|^n} dt \\ &= \frac{\ln(ra)}{\alpha^{n-3}} + \frac{1}{\alpha^{n-3}} \sum_{\kappa=0}^{\infty} \left[\frac{1}{\kappa} \left(\frac{r}{\alpha}\right)^{\kappa} - \frac{1}{\kappa+2} \left(\frac{r}{\alpha}\right)^{\kappa+2} \right] C_\kappa^{n/2}(\hat{\boldsymbol{\rho}} \cdot \hat{\boldsymbol{r}}), \end{aligned} \tag{33}$$

where $C_\kappa^{n/2}$ *is the Gegenbauer polynomial of degree* κ *and order* $n/2$.

For $n = 3$, (28), (30), and (32) reduce to (2), (10), and (11), respectively.

Proof. We first concentrate on the particular case of $n = 3$. It is straightforward to show that $r\partial_r u_0$ is a harmonic function. Then (10) implies

$$r\frac{\partial u_0(\boldsymbol{r})}{\partial r} = \frac{\alpha^2 - r^2}{4\pi} \oint_{|\boldsymbol{\rho}|=\alpha} \frac{1}{|\boldsymbol{\rho} - \boldsymbol{r}|^3} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \mathrm{ds}(\boldsymbol{\rho}). \tag{34}$$

Alternatively, this equation can be obtained as follows: Adding (5) and (9) we find that

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi\alpha} \oint_{|\boldsymbol{\rho}|=\alpha} \left[2\alpha \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} + u_0(\boldsymbol{\rho}) \right] \frac{1}{|\boldsymbol{\rho} - \boldsymbol{r}|} \mathrm{ds}(\boldsymbol{\rho}). \tag{35}$$

Differentiating this equation and using (9) we find (34). Integrating (34) with respect to r we obtain

$$u_0(\boldsymbol{r}) = \frac{1}{4\pi\alpha} \oint_{|\boldsymbol{\rho}|=\alpha} I(\boldsymbol{\rho}, \boldsymbol{r}) \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{36}$$

where the kernel I is given by

$$\begin{aligned} I(\boldsymbol{\rho}, \boldsymbol{r}) &= \int \frac{\alpha(\alpha^2 - r^2)}{r|\boldsymbol{\rho} - \boldsymbol{r}|^3} \mathrm{d}r \\ &= \frac{2\alpha}{|\boldsymbol{\rho} - \boldsymbol{r}|} - \ln \frac{\alpha - \boldsymbol{\rho} \cdot \hat{\boldsymbol{r}} + |\boldsymbol{\rho} - \boldsymbol{r}|}{2r}. \end{aligned} \tag{37}$$

The Gauss theorem implies

$$\oint_{|\boldsymbol{\rho}|=\alpha} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \mathrm{ds}(\boldsymbol{\rho}) = 0; \tag{38}$$

hence, we actually define the *Neumann kernel* as

$$N(\boldsymbol{\rho}, \boldsymbol{r}) = \frac{2\rho}{|\boldsymbol{\rho} - \boldsymbol{r}|} - \ln\left(|\boldsymbol{\rho} - \boldsymbol{r}| + \frac{\boldsymbol{\rho} \cdot (\boldsymbol{\rho} - \boldsymbol{r})}{\alpha}\right). \tag{39}$$

Therefore, the analogue of formula (10) for the Neumann problem is recovered.

The fundamental solution of the Laplace equation in n dimensions is given by

$$G(\boldsymbol{\rho}, \boldsymbol{r}) = -\frac{1}{(n-2)\omega_n} \frac{1}{|\boldsymbol{\rho} - \boldsymbol{r}|^{n-2}}, \quad n \geqslant 3, \tag{40}$$

where ω_n is given by (29). Using Green's third identity,

$$\begin{aligned} &\int_{|\boldsymbol{\rho}|<\alpha} [u(\boldsymbol{\rho}) \Delta_{\boldsymbol{\rho}} G(\boldsymbol{\rho}, \boldsymbol{r}) - G(\boldsymbol{\rho}, \boldsymbol{r}) \Delta_{\boldsymbol{\rho}} u(\boldsymbol{\rho})] \mathrm{dv}(\boldsymbol{\rho}) \\ &= \oint_{|\boldsymbol{\rho}|=\alpha} [u(\boldsymbol{\rho}) \partial_\rho G(\boldsymbol{\rho}, \boldsymbol{r}) - G(\boldsymbol{\rho}, \boldsymbol{r}) \partial_\rho u(\boldsymbol{\rho})] \mathrm{ds}(\boldsymbol{\rho}), \end{aligned} \tag{41}$$

we find (28), where u_0 satisfies Laplace's equation. In view of the identity

$$\frac{\partial}{\partial \rho} \frac{1}{|\boldsymbol{\rho} - \boldsymbol{r}|^{n-2}} = (2-n) \frac{\boldsymbol{\rho} \cdot (\boldsymbol{\rho} - \boldsymbol{r})}{\rho |\boldsymbol{\rho} - \boldsymbol{r}|^n}, \tag{42}$$

(40) implies

$$\oint_{|\boldsymbol{\rho}|=\alpha} \left[u_0(\boldsymbol{\rho}) \frac{\boldsymbol{\rho} \cdot (\boldsymbol{\rho} - \boldsymbol{r})}{\alpha |\boldsymbol{\rho} - \boldsymbol{r}|^n} + \frac{1}{(n-2)|\boldsymbol{\rho} - \boldsymbol{r}|^{n-2}} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \right] \mathrm{ds}(\boldsymbol{\rho}) = \begin{cases} \omega_n u_0(\boldsymbol{r}), & |\boldsymbol{r}| < \alpha, \\ 0, & |\boldsymbol{r}| > \alpha. \end{cases} \tag{43}$$

Applying Kelvin's inversion (7), (8) to (43) we obtain

$$\oint_{|\boldsymbol{\rho}|=\alpha} \left[u_0(\boldsymbol{\rho}) \frac{r^2 - \boldsymbol{\rho} \cdot \boldsymbol{r}}{\alpha |\boldsymbol{\rho} - \boldsymbol{r}|^n} + \frac{1}{(n-2)|\boldsymbol{\rho} - \boldsymbol{r}|^{n-2}} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} \right] \mathrm{ds}(\boldsymbol{\rho}) = 0, \quad |\boldsymbol{r}| < \alpha. \tag{44}$$

Subtracting (44) from the first of (43) we obtain Poisson's integral formula (30).

On the other hand, adding the first of (43) and (44) we obtain

$$\omega_n u_0(\boldsymbol{r}) = \oint_{|\boldsymbol{\rho}|=\alpha} \left[\frac{2}{n-2} \frac{\partial u_0(\boldsymbol{\rho})}{\partial \rho} + \frac{1}{\alpha} u_0(\boldsymbol{\rho}) \right] \frac{1}{|\boldsymbol{\rho} - \boldsymbol{r}|^{n-2}} \mathrm{ds}(\boldsymbol{\rho}). \tag{45}$$

Dividing (31) by r and integrating with respect to r we obtain

$$u_0(\boldsymbol{r}) = \frac{1}{\alpha \omega_n} \oint_{|\boldsymbol{\rho}|=\alpha} I(\boldsymbol{\rho}, \boldsymbol{r}) N_0(\boldsymbol{\rho}) \mathrm{ds}(\boldsymbol{\rho}), \quad |\boldsymbol{r}| < \alpha, \tag{46}$$

where

$$\begin{aligned} I(\boldsymbol{\rho}, \boldsymbol{r})|_{|\boldsymbol{\rho}|=\alpha} &= \int \frac{\alpha(\alpha^2 - r^2)}{r |\boldsymbol{\rho} - \boldsymbol{r}|^n} \mathrm{d}r \\ &= \int \frac{\alpha(\alpha^2 - r^2)}{r(\alpha^2 - 2\alpha r \hat{\boldsymbol{\rho}} \cdot \hat{\boldsymbol{r}} + r^2)^{n/2}} \mathrm{d}r. \end{aligned} \tag{47}$$

The Gauss theorem

$$\oint_{|\boldsymbol{\rho}|=\alpha} N_0(\boldsymbol{\rho}) \mathrm{ds}(\boldsymbol{\rho}) = 0 \tag{48}$$

implies that $I(\boldsymbol{\rho}, \boldsymbol{r})$ is well defined independent of the constant of integration. For any specific value of n the integral in (47) can be evaluated explicitly. Alternatively, it can be expanded in terms of Gegenbauer polynomials of order $n/2$ [12]. Indeed, the Gegenbauer polynomials $C_\kappa^{n/2}(\gamma)$, $\gamma = \hat{\boldsymbol{\rho}} \cdot \hat{\boldsymbol{r}}$, $\kappa = 0, 1, 2, \ldots$, are generated as follows:

$$(1 - 2\gamma z + z^2)^{-n/2} = \sum_{\kappa=0}^{\infty} C_\kappa^{n/2}(\gamma) z^\kappa, \qquad |z| < 1. \tag{49}$$

Hence

$$|\boldsymbol{\rho} - \boldsymbol{r}|^{-n}|_{|\boldsymbol{\rho}|=\alpha} = \frac{1}{\alpha^n} \sum_{\kappa=0}^{\infty} C_\kappa^{n/2}(\gamma) \left(\frac{r}{\alpha}\right)^\kappa, \qquad |z| < \alpha, \tag{50}$$

and

$$\begin{aligned} I(\boldsymbol{\rho}, \boldsymbol{r})|_{|\boldsymbol{\rho}|=\alpha} &= \frac{1}{\alpha^{n-1}} \sum_{\kappa=0}^{\infty} C_\kappa^{n/2}(\gamma) \frac{1}{\alpha^\kappa} \int (\alpha^2 - r^2) r^{\kappa-1} \mathrm{d}r \\ &= \frac{\ln r}{\alpha^{n-3}} + \frac{1}{\alpha^{n-3}} \sum_{\kappa=1}^{\infty} C_\kappa^{n/2}(\gamma) \frac{1}{\kappa} \left(\frac{r}{\alpha}\right)^\kappa - \frac{1}{\alpha^{n-3}} \sum_{\kappa=0}^{\infty} C_\kappa^{n/2}(\gamma) \frac{1}{\kappa+2} \left(\frac{r}{\alpha}\right)^{\kappa+2}. \end{aligned} \tag{51}$$

This completes the proof of Proposition 2.1. □

Remark 1. Equation (45) with $n = 3$ provides a new integral representation for the solution of the Dirichlet problem involving only $|\boldsymbol{\rho} - \boldsymbol{r}|$, as opposed to $|\boldsymbol{\rho} - \boldsymbol{r}|^3$.

Remark 2. For the corresponding exterior problems [5], one needs to impose the far-field behavior

$$u_0(\boldsymbol{r}) = O\left(\frac{1}{r^{n-2}}\right), \quad r \to \infty, \tag{52}$$

and to change the sign of every surface integral.

3. The inhomogeneous Helmholtz equation. We first recall the derivation of the well-known global relation (12). Let u satisfy the inhomogeneous Helmholtz equation (17) and let w satisfy the Helmholtz equation. Manipulating the two equations we find that

$$\nabla \cdot [w(\boldsymbol{r}) \nabla u(\boldsymbol{r}) - u(\boldsymbol{r}) \nabla w(\boldsymbol{r})] = w(\boldsymbol{r}) f(\boldsymbol{r}) \tag{53}$$

and the Gauss theorem yields (12).

PROPOSITION 3.1. *Suppose that the function u satisfies the inhomogeneous equation* (17) *in $\mathbb{R}^3$ together with any of the three boundary conditions*

$$u(\boldsymbol{r}) = D(\boldsymbol{r}), \quad |\boldsymbol{r}| = \alpha, \tag{54}$$

$$\frac{\partial u(\boldsymbol{r})}{\partial r} = N(\boldsymbol{r}), \quad |\boldsymbol{r}| = \alpha, \tag{55}$$

$$\frac{\partial u(\boldsymbol{r})}{\partial r} + \nu u(\boldsymbol{r}) = R(\boldsymbol{r}), \quad |\boldsymbol{r}| = \alpha, \tag{56}$$

where the given functions D, N, R have sufficient smoothness and ν is a constant such that $n+\alpha\nu \neq 0$, $n = 0, 1, 2, \ldots$. Then u is given by (2)*, where u_p is defined by* (18)*, and u_0 for the Dirichlet, the Neumann, and the Robin conditions is given by the following expressions:*

$$\begin{aligned} u_0^D(\boldsymbol{r}) = \frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)\Bigg[&T(\hat{\boldsymbol{r}}) + \frac{h_n^{(1)}(\lambda\alpha)}{j_n(\lambda\alpha)}S(\hat{\boldsymbol{r}}) \\ &- \frac{i}{\lambda\alpha^2 j_n(\lambda\alpha)}\oint_{|\boldsymbol{\rho}|=\alpha} D(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho})\Bigg], \end{aligned} \tag{57}$$

$$\begin{aligned} u_0^N(\boldsymbol{r}) = \frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)\Bigg[&T(\hat{\boldsymbol{r}}) - \frac{h_n^{(1)'}(\lambda\alpha)}{j_n'(\lambda\alpha)}S(\hat{\boldsymbol{r}}) \\ &+ \frac{i}{\lambda^2\alpha^2 j_n'(\lambda\alpha)}\oint_{|\boldsymbol{\rho}|=\alpha} N(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho})\Bigg], \end{aligned} \tag{58}$$

$$\begin{aligned} u_0^R(\boldsymbol{r}) = \frac{i\lambda}{4\pi}\sum_{n=0}^{\infty}(2n+1)j_n(\lambda r)\Bigg[&T(\hat{\boldsymbol{r}}) + \frac{\lambda h_n^{(1)'}(\lambda\alpha) + \nu h_n^{(1)}(\lambda\alpha)}{\lambda j_n'(\lambda\alpha) + j_n(\lambda\alpha)}S(\hat{\boldsymbol{r}}) \\ &- \frac{i}{\lambda\alpha^2(\lambda j_n'(\lambda\alpha) + j_n(\lambda\alpha))}\oint_{|\boldsymbol{\rho}|=\alpha} R(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho})\Bigg], \end{aligned} \tag{59}$$

where the direction dependent functions T and S are defined by

$$\begin{aligned} T(\hat{\boldsymbol{r}}) = \lambda h_n^{(1)'}(\lambda\alpha)&\oint_{|\boldsymbol{\rho}|=\alpha} u_p(\boldsymbol{\rho})P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho}) \\ &- h_n^{(1)}(\lambda\alpha)\oint_{|\boldsymbol{\rho}|=\alpha}(\partial_\rho u_p(\boldsymbol{\rho}))P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{ds}(\boldsymbol{\rho}) \end{aligned} \tag{60}$$

and

$$S(\hat{\boldsymbol{r}}) = \int_{|\boldsymbol{\rho}|<\alpha} f(\boldsymbol{\rho})j_n(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{r}})\mathrm{dv}(\boldsymbol{\rho}). \tag{61}$$

In the formulae above we have used the notation

$$\left[\frac{\partial}{\partial\rho}j_n(\lambda\rho)\right]_{\rho=\alpha} = \lambda j_n'(\lambda\alpha) \tag{62}$$

and similarly for $h_n^{(1)}$.

Proof. The derivation of u_0^D was demonstrated in the introduction (Example 1.4). For the derivation of u_0^N and u_0^R we follow similar arguments. □

Remark 3. It is straightforward to solve the analogous problem in the exterior of the sphere. In fact, for exterior problems the following modifications are required: First, one needs to specify the appropriate asymptotic behavior of the solution at infinity. For a compactly supported source function f, the solution of the inhomogeneous Helmholtz equation has to satisfy the radiation condition [5]

$$u(\boldsymbol{r}) = g(\hat{\boldsymbol{r}})\frac{\mathrm{e}^{i\lambda r}}{r} + O(r^{-2}), \quad r \to \infty, \tag{63}$$

where g is the far-field pattern.

Second, the terms in the surface integral representation involving the normal differentiation on the boundary must change sign.

Third, one must choose an appropriate set of eigenfunctions. In particular, for the sphere the interior eigenfunctions have to be replaced by the radiative functions $w(\boldsymbol{\rho}) = h_n^{(1)}(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})$, where $n = 0, 1, 2, \dots$ and $\hat{\boldsymbol{k}}$ is a unit vector. We note that the above choice of exterior eigenfunctions is dictated by the radiation condition (63). If the radiation condition is taken in the form

$$u(\boldsymbol{r}) = g(\hat{\boldsymbol{r}})\frac{\mathrm{e}^{-i\lambda r}}{r} + O(r^{-2}), \quad r \to \infty, \tag{64}$$

then the proper choice of exterior eigenfunctions is $w(\boldsymbol{\rho}) = h_n^{(2)}(\lambda\rho)P_n(\hat{\boldsymbol{\rho}}\cdot\hat{\boldsymbol{k}})$. For scattering problems these choices will ensure that as we approach infinity, the solutions tend to outgoing spherical waves having the appropriate geometrical attenuation [5].

4. Laplace's equation in a spherical sector.

Separation of variables, for the Laplace equation in spherical coordinates, yields the following solutions:

$$w_1^{\pm}(\boldsymbol{r}) = r^l P_l^k(\cos\theta)e^{\pm ik\varphi} \quad \text{and} \quad w_2^{\pm}(\boldsymbol{r}) = r^{-(l+1)}P_l^k(\cos\theta)e^{\pm ik\varphi}, \tag{65}$$

where l and k are arbitrary complex constants.

4.1. The Dirichlet-to-Neumann map.

PROPOSITION 4.1. *Let u satisfy Laplace's equation in the spherical sector Ω defined in* (13). *Then the Neumann boundary values on the spherical cap $\{\rho = \alpha, 0 \leqslant \theta < \theta_0, 0 \leqslant \varphi < 2\pi\}$ can be expressed in terms of the Dirichlet boundary values by* (14)*, where l_n is defined by* (15) *and M_n^m are given by*

$$\begin{aligned} M_n^m(\alpha,\theta_0) = {} & \frac{\sin\theta_0}{\alpha^{l_n+2}}\frac{\partial P_{l_n}^m(\cos\theta_0)}{\partial\theta}\int_0^{2\pi}\int_0^{\alpha} u(r',\theta_0,\varphi)(r')^{l_n+1}e^{im\varphi}\,\mathrm{d}r'\,\mathrm{d}\varphi \\ & - \frac{l_n}{\alpha}\int_0^{2\pi}\int_0^{\theta_0} u(\alpha,\theta,\varphi)P_{l_n}^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi. \end{aligned} \tag{66}$$

Proof. We will derive (14) by applying steps (a) and (b) of section 1.2.1. Applying the global relation (12) in Ω (see Figure 1) with $w = w_1^+$ defined in (65), we find that

$$\begin{aligned} & \int_0^{2\pi}\int_0^{\alpha}\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}\rho^{l+1}P_l^k(\cos\theta_0)e^{ik\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ & + \int_0^{2\pi}\int_0^{\theta_0}\frac{\partial u(\alpha,\theta,\varphi)}{\partial r}\alpha^{l+2}P_l^k(\cos\theta)e^{ik\varphi}\sin\theta\mathrm{d}\theta\,\mathrm{d}\varphi \\ & + \int_0^{\theta_0}\int_0^{\alpha}\left(iku(\rho,\theta,0) - \frac{\partial u(\rho,\theta,0)}{\partial\varphi}\right)\rho^{l-1}P_l^k(\cos\theta)\,\mathrm{d}\rho\,\mathrm{d}\theta \\ & = \int_0^{2\pi}\int_0^{\alpha} u(\rho,\theta_0,\varphi)\rho^{l+1}\frac{\partial P_l^k(\cos\theta_0)}{\partial\theta}e^{ik\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ & + \int_0^{2\pi}\int_0^{\theta_0} u(\alpha,\theta,\varphi)l\alpha^{l+1}\sin\theta\,P_l^k(\cos\theta)e^{ik\varphi}\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ & + \int_0^{\theta_0}\int_0^{\alpha}\left(iku(\rho,\theta,2\pi) - \frac{\partial u(\rho,\theta,2\pi)}{\partial\varphi}\right)\rho^{l-1}P_l^k(\cos\theta)e^{i2k\pi}\,\mathrm{d}\rho\,\mathrm{d}\theta, \end{aligned} \tag{67}$$

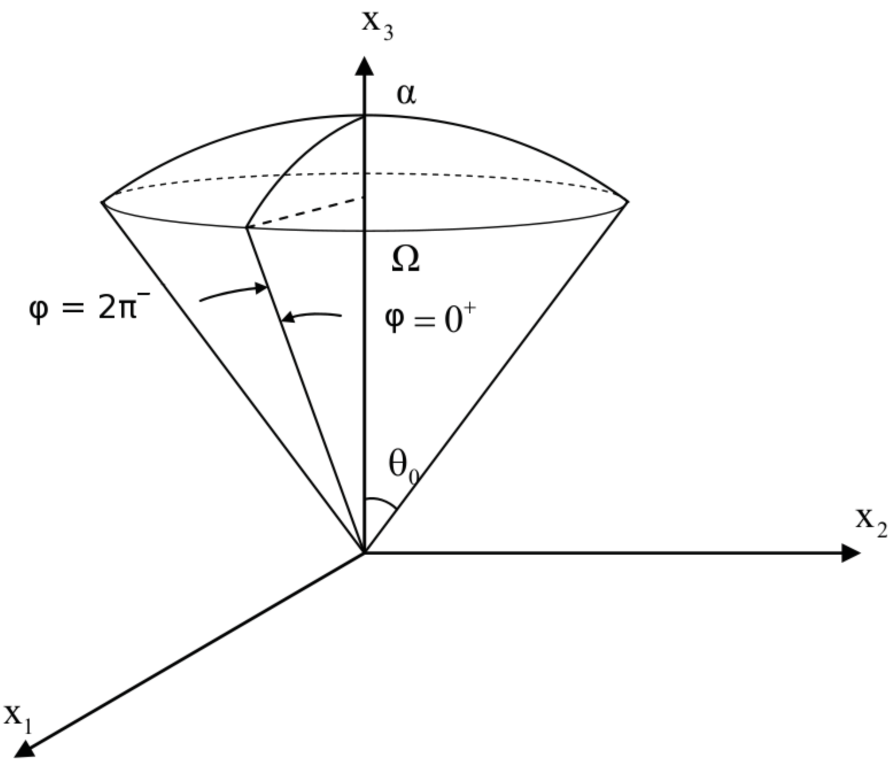

FIG. 1.

where the angular normal derivatives are given by

$$\hat{\boldsymbol{\theta}}\cdot\nabla = \frac{1}{r}\frac{\partial}{\partial\theta} \qquad \text{and} \qquad \hat{\boldsymbol{\varphi}}\cdot\nabla = \frac{1}{r\sin\theta}\frac{\partial}{\partial\varphi}. \tag{68}$$

The third integral on the left-hand side and the third integral on the right-hand side of (67) cancel each other if we choose $k = m \in \mathbb{Z}$. Then (67) becomes

$$\begin{aligned} &\int_0^{2\pi}\int_0^{\alpha} \frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}\rho^{l+1}P_l^m(\cos\theta_0)e^{im\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ &+\int_0^{2\pi}\int_0^{\theta_0} \frac{\partial u(\alpha,\theta,\varphi)}{\partial r}\alpha^{l+2}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ &=\int_0^{2\pi}\int_0^{\alpha} u(\rho,\theta_0,\varphi)\rho^{l+1}\frac{\partial P_l^m(\cos\theta_0)}{\partial\theta}e^{im\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ &+\int_0^{2\pi}\int_0^{\theta_0} u(\alpha,\theta,\varphi)l\alpha^{l+1}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi. \end{aligned} \tag{69}$$

By choosing $l = l_n$, as defined by (15), (69) becomes (15) with M_n^m given by (66). ▯

4.2. The spherical sector problem. We will now derive (16) by applying step (a′) of section 1.2.2 and step (b) of section 1.2.1.

PROPOSITION 4.2. *Let u be as in Proposition* 4.1. *Then the solution u of the Dirichlet problem satisfies* (16), *where l_n are defined by* (15) *and K_n^m are given in terms of the known Dirichlet values by*

$$\begin{aligned} K_n^m(r,\theta_0) &= \left(\frac{r}{\alpha}\right)^{l_n+1}\int_0^{2\pi}\int_0^{\theta_0} u(\alpha,\theta,\varphi)P_{l_n}^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ &\quad -\left(\frac{r}{\alpha}\right)^{l_n+1}\frac{\sin\theta_0}{2l_n+1}\frac{\partial P_{l_n}^m(\cos\theta_0)}{\partial\theta} \\ &\quad\times\left\{\int_0^{2\pi}\int_0^{r} u(\rho,\theta_0,\varphi)\left[\left(\frac{\alpha}{r}\right)^{2l_n+1}-1\right]\left(\frac{\rho}{\alpha}\right)^{l_n+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi\right. \\ &\quad\left.+\int_0^{2\pi}\int_r^{\alpha} u(\rho,\theta_0,\varphi)\left[\left(\frac{\alpha}{\rho}\right)^{2l_n+1}-1\right]\left(\frac{\rho}{\alpha}\right)^{l_n+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi\right\}. \end{aligned} \tag{70}$$

Proof. We apply the global relation (12) (with $f=0$) in the subdomain Ω_1 defined by

$$\Omega_1 = \{(\rho,\theta,\varphi)\mid 0<\rho<r,\ 0\leqslant\theta<\theta_0,\ 0\leqslant\varphi<2\pi\},\quad 0<\theta_0<\pi, \tag{71}$$

and depicted in Figure 2, with $w=w_1^+$ defined in (65). This yields the following equation, which is valid for $k\in\mathbb{C}$ and $\operatorname{Re} l\geqslant 0$:

$$\begin{aligned} &\int_0^{2\pi}\int_0^{r}\left[\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}P_l^k(\cos\theta_0)-u(\rho,\theta_0,\varphi)\frac{\partial P_l^k(\cos\theta_0)}{\partial\theta}\right]\rho^{l+1}e^{ik\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ &+\int_0^{2\pi}\int_0^{\theta_0}\left[r\frac{\partial u(r,\theta,\varphi)}{\partial r}-lu(r,\theta,\varphi)\right]r^{l+1}P_l^k(\cos\theta)e^{ik\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ &+\int_0^{\theta_0}\int_0^{r}\left(iku(\rho,\theta,0)-\frac{\partial u(\rho,\theta,0)}{\partial\varphi}\right)\rho^{l-1}P_l^k(\cos\theta)\,\mathrm{d}\rho\,\mathrm{d}\theta \\ &-\int_0^{\theta_0}\int_0^{r}\left(iku(\rho,\theta,2\pi)-\frac{\partial u(\rho,\theta,2\pi)}{\partial\varphi}\right)\rho^{l-1}P_l^k(\cos\theta)e^{i2k\pi}\,\mathrm{d}\rho\,\mathrm{d}\theta \\ &=0. \end{aligned} \tag{72}$$

The requirement $\operatorname{Re} l\geqslant 0$ is needed in order for the integrals to make sense near $r=0$. The last two integrals in (72) involve the Neumann boundary values $\partial_\varphi u(\rho,\theta,0)$ and $\partial_\varphi u(\rho,\theta,2\pi)$. However, these unknown functions can be eliminated by choosing $k=m\in\mathbb{Z}$.

We next apply the global relation (12) (with $f=0$) in the domain $\Omega_2=\Omega-\Omega_1$ with $w=w_1^+$ and with $w=w_2^+$ defined in (65), where $\operatorname{Re} l\geqslant 0$ and $k=m\in\mathbb{Z}$. This yields the following two equations, which are valid for $\operatorname{Re} l\geqslant 0$ and $m\in\mathbb{Z}$:

$$\begin{aligned} &\int_0^{2\pi}\int_r^{\alpha}\left[\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}P_l^m(\cos\theta_0)-u(\rho,\theta_0,\varphi)\frac{\partial P_l^m(\cos\theta_0)}{\partial\theta}\right]\rho^{l+1}e^{im\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi \\ &+\int_0^{2\pi}\int_0^{\theta_0}\left[\alpha\frac{\partial u(\alpha,\theta,\varphi)}{\partial r}+lu(\alpha,\theta,\varphi)\right]\alpha^{l+1}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ &-\int_0^{2\pi}\int_0^{\theta_0}\left[r\frac{\partial u(r,\theta,\varphi)}{\partial r}-lu(r,\theta,\varphi)\right]r^{l+1}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\ &=0 \end{aligned} \tag{73}$$

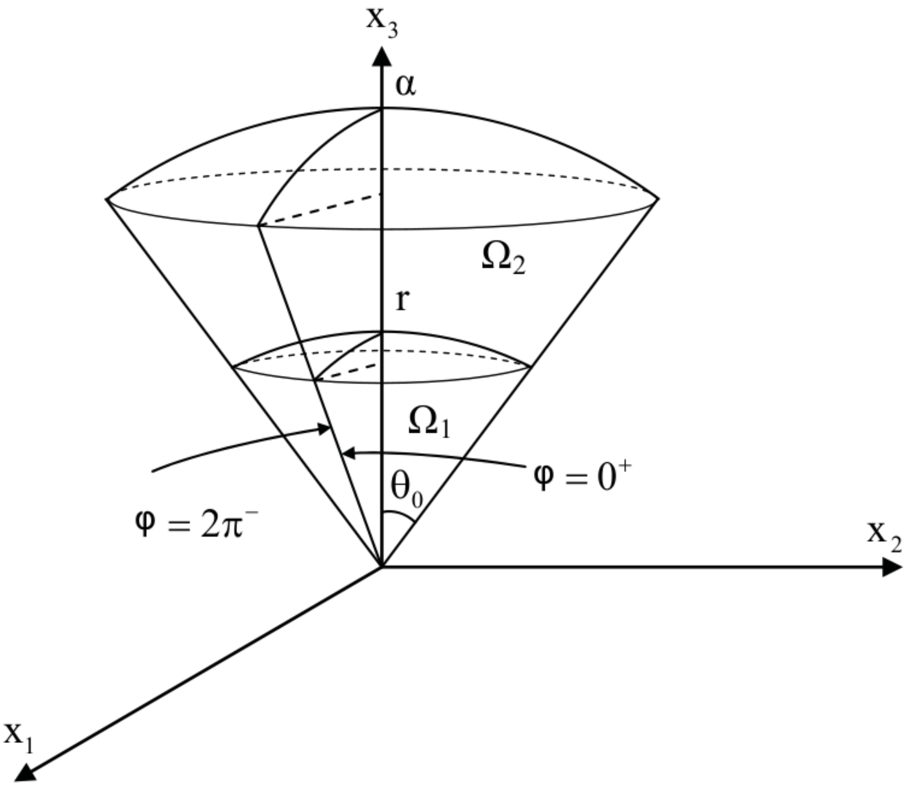

FIG. 2.

and

$$(74)\quad \int_0^{2\pi}\int_r^{\alpha}\left[\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}P_l^m(\cos\theta_0)-u(\rho,\theta_0,\varphi)\frac{\partial P_l^m(\cos\theta_0)}{\partial\theta}\right]\frac{1}{\rho^l}e^{im\varphi}\sin\theta_0\,\mathrm{d}\rho\,\mathrm{d}\varphi$$
$$+\int_0^{2\pi}\int_0^{\theta_0}\left[\alpha\frac{\partial u(\alpha,\theta,\varphi)}{\partial r}+(l+1)u(\alpha,\theta,\varphi)\right]\frac{1}{\alpha^l}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi$$
$$-\int_0^{2\pi}\int_0^{\theta_0}\left[r\frac{\partial u(r,\theta,\varphi)}{\partial r}+(l+1)u(r,\theta,\varphi)\right]\frac{1}{r^l}P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi$$
$$=0.$$

Multiplying (74) by α^{2l+1} and subtracting the resulting equation from (73) we obtain an equation that involves only the integral over the spherical cap of the unknown function $\partial_r u(r,\theta,\varphi)$. But this unknown integral can be eliminated with the use of (72). These steps yield

$$(75)\qquad P_l^m(\cos\theta_0)\sin\theta_0\int_0^{2\pi}\int_0^{r}\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}\left(\frac{\alpha^{2l+1}}{r^{2l+1}}-1\right)\rho^{l+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi$$
$$+P_l^m(\cos\theta_0)\sin\theta_0\int_0^{2\pi}\int_r^{\alpha}\frac{\partial u(\rho,\theta_0,\varphi)}{\partial\theta}\left(\frac{\alpha^{2l+1}}{\rho^{2l+1}}-1\right)\rho^{l+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi$$
$$-\frac{\partial P_l^m(\cos\theta_0)}{\partial\theta}\sin\theta_0\int_0^{2\pi}\int_0^{r}u(\rho,\theta_0,\varphi)\left(\frac{\alpha^{2l+1}}{r^{2l+1}}-1\right)\rho^{l+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi$$

$$
\begin{aligned}
&- \frac{\partial P_l^m(\cos\theta_0)}{\partial\theta}\sin\theta_0 \int_0^{2\pi}\int_r^{\alpha} u(\rho,\theta_0,\varphi)\left(\frac{\alpha^{2l+1}}{\rho^{2l+1}}-1\right)\rho^{l+1}e^{im\varphi}\,\mathrm{d}\rho\,\mathrm{d}\varphi \\
&+ (2l+1)\alpha^{l+1}\int_0^{2\pi}\int_0^{\theta_0}\left(u(\alpha,\theta,\varphi)-\frac{\alpha^l}{r^l}u(r,\theta,\varphi)\right)P_l^m(\cos\theta)e^{im\varphi}\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\varphi \\
&= 0.
\end{aligned}
$$

In order to eliminate the unknown boundary values $\partial_\theta u(\rho,\theta_0,\varphi)$ we choose l such that

$$P_{l_n}^m(\cos\theta_0) = 0, \quad n = 0,1,2,\dots, \quad m \in \mathbb{Z}. \tag{76}$$

It is known that, for every order m and every angle $\theta_0 \in (0,\pi)$, there exists a sequence $\{l_n\}_{n=0}^{\infty}$ of nonnegative real numbers such that (76) holds; see [10, page 408]. With the above choice of k and l, (75) implies (16) with K_n^m defined by (70). □

Remark 4. The formal inversion of (16) yields

$$u(r,\theta,\varphi) = \frac{1}{2\pi}\sum_{n=0}^{\infty}\sum_{m\in\mathbb{Z}}\frac{1}{c_n^2}K_n^m(r,\theta_0)P_{l_n}^m(\cos\theta)e^{-im\varphi}. \tag{77}$$

Indeed, the inversion with respect to φ is elementary and gives

$$\int_0^{\theta_0} u(r,\theta,\varphi)P_{l_n}^m(\cos\theta)\sin\theta\,\mathrm{d}\theta = \frac{1}{2\pi}\sum_{m\in\mathbb{Z}}K_n^m(\boldsymbol{r})e^{-im\varphi}. \tag{78}$$

In order to invert the left-hand side of (78) we use the following standard Sturm–Liouville technique. We set $x=\cos\theta$ and write the Legendre equation for l_n and $l_{n'}$:

$$\frac{d}{dx}\left[(1-x^2)\frac{d}{dx}P_{l_n}^m(x)\right] + \left[l_n(l_n+1)-\frac{m^2}{1-x^2}\right]P_{l_n}^m(x) = 0 \tag{79}$$

and

$$\frac{d}{dx}\left[(1-x^2)\frac{d}{dx}P_{l_{n'}}^m(x)\right] + \left[l_{n'}(l_{n'}+1)-\frac{m^2}{1-x^2}\right]P_{l_{n'}}^m(x) = 0. \tag{80}$$

Multiplying (79) by $P_{l_{n'}}^m(x)$, (80) by $P_{l_n}^m(x)$, and subtracting the resulting equations we obtain

$$
\begin{aligned}
&\frac{d}{dx}\left[(1-x^2)P_{l_{n'}}^m(x)\frac{d}{dx}P_{l_n}^m(x) - (1-x^2)P_{l_n}^m(x)\frac{d}{dx}P_{l_{n'}}^m(x)\right] \\
&= (l_{n'}-l_n)(l_{n'}+l_n+1)P_{l_n}^m(x)P_{l_{n'}}^m(x).
\end{aligned} \tag{81}
$$

Integrating (81) from $\cos 0 = 1$ to $\cos\theta_0 = x_0$ and using (76) we find that

$$\int_1^{x_0} P_{l_n}^m(x)P_{l_{n'}}^m(x)dx = \begin{cases} 0, & n \neq n', \\ c_n^2, & n = n', \end{cases} \tag{82}$$

where the normalization constants c_n^2 can be evaluated by using L'Hôpital's rule,

(83)

$$
\begin{aligned}
c_n^2 &= \lim_{l\to l_n}\frac{1}{(l-l_n)(l+l_n+1)}\left[(1-x^2)\left(P_l^m(x)\frac{d}{dx}P_{l_n}^m(x) - P_{l_n}^m(x)\frac{d}{dx}P_l^m(x)\right)\right]\Bigg|_{x=1}^{x=x_0} \\
&= \frac{1-x_0^2}{2l_n+1}\left[\frac{d}{dl}P_l^m(x_0)\right]\Bigg|_{l=l_n}\left[\frac{d}{dx}P_{l_n}^m(x)\right]\Bigg|_{x=x_0}.
\end{aligned}
$$

We note that the series in (77) converges due to the factors $(r/\alpha)^{l_n}$, with $r < \alpha$ and $\operatorname{Re} l_n > 0$, which enter the functions K_n^m defined in (70). This result is valid, provided that the set $\{P_{l_n}^m(x)\}$ with l_n defined by (76) forms a complete set. We will not pursue further the question of completeness because in a future work we will present an alternative derivation of this result which bypasses this difficulty (see the discussion in section 5).

Remark 5. As with the previous cases, the extension of this result to the solution of the Dirichlet problem in the exterior of the spherical sector

$$\Omega^c = \{(r, \theta, \varphi) \mid \alpha < r < \infty,\, 0 \leqslant \theta < \theta_0,\, 0 \leqslant \varphi < 2\pi\} \tag{84}$$

is straightforward.

5. Conclusions.

We have presented alternative, apparently simpler, approaches to the classical methods of images and integral transforms for boundary value problems formulated in spherical coordinates.

Regarding the alternative to the method of images presented here, we also note that the formulae for the solution of the Neumann problem in the interior of an n dimensional sphere, $n \geqslant 3$, presented in section 2, are to our knowledge new.

Regarding the alternative to the method of integral transforms presented here, we note that the solution of certain PDEs depends on the *global form* of the boundary values; namely, it depends on certain integrals of the boundary values. The advantage of the global relation is that it yields *directly* these global forms, and in this sense the term *global relation* is justified.

The employment of the global relation in the domain Ω provides the most efficient way of constructing the Dirichlet-to-Neumann map [6]. For example, it is shown in section 4.1 that it is possible, using *only algebraic manipulations*, to obtain a certain *integral* of the Neumann boundary values on a spherical cap in terms of the given Dirichlet data; see (14). Then it is straightforward to obtain the Dirichlet boundary value itself by inverting this integral. It is well known that for a variety of physical applications, one is interested only in the unknown Neumann values on the boundary and *not* on the actual solution in the interior of the domain. For such problems, the approach presented here provides, in our opinion, the most direct and simple way of obtaining the unknown boundary values.

The analysis of the global relation, in addition to constructing the Dirichlet-to-Neumann map, can also yield the solution in Ω. This requires formulating the global relation in appropriate *subdomains* of Ω; see section 4.2.

The new, almost algebraic, alternative to the method of classical transforms should be compared with the latter method, which involves the following steps: (a) Derive the proper transform. (b) Use integration by parts to obtain the PDE satisfied by this transform. (c) Solve the resulting PDE by an integral transform, which in fact involves (c_1) deriving the proper transform, (c_2) using integration by part to obtain the ODE satisfied by this transform, and (c_3) using Green's function techniques to solve this ODE.

It should be noted that integral representations obtained by Green's identity and the appropriate fundamental solution have been used extensively in the literature; see [1, 2, 3, 4, 5, 11, 13, 14, 15]. In most of these approaches, one first characterizes the unknown boundary values by evaluating the integral representation on the boundary and solving the resulting integral equation, and then one inserts the density function for the single or double potential in the integral representation. Our approach has certain conceptual similarities with the method of Waterman and with the null-field method [13] used in scattering theory.

It was mentioned in the introduction that the most important achievement of the method reviewed in [9] is the construction of integral, as opposed to series representations in the spectral domain. The problem of constructing such representations for the problems solved in sections 3 and 4 is under investigation.

THE FACTORIZATION METHOD APPLIED TO THE COMPLETE ELECTRODE MODEL OF IMPEDANCE TOMOGRAPHY*

ARMIN LECHLEITER[†], NUUTTI HYVÖNEN[‡], and HARRI HAKULA[‡]

Abstract. The factorization method is a tool for recovering inclusions inside a body when the Neumann-to-Dirichlet operator, which maps applied currents to measured voltages, is known. In practice this information is never at hand due to the discreteness and physical properties of the measurement devices. The complete electrode model of impedance tomography includes these physical characteristics but leads to a finite-dimensional data set, called the resistivity matrix. The main result of this work is an approximation link relating the resistivity matrix to the Neumann-to-Dirichlet operator in the L^2-operator norm. This result allows us to extend the factorization method to the framework of real-life electrode measurements using a regularized series criterion which is easy to implement in practice. The truncation index of the sequence criterion, which represents the stopping index of the regularization scheme, can be computed solely from the measured, perturbed, and finite-dimensional data. The functionality of the method is demonstrated through numerical experiments.

Key words. impedance tomography, complete electrode model, finite-dimensional approximation, boundary elements, factorization method, perturbation theory

1. Introduction.

Electrical impedance tomography (EIT) is an imaging technique which has attracted a vast amount of research during the last 20 years, starting with the fundamental paper of Calderón [7]. The nonlinearity and ill-posedness of the problem make it particularly challenging to tackle. The factorization method is one of the rare tools for the inverse EIT problem that is both theoretically founded and suitable for practical application. It stems from the linear sampling method for inverse scattering problems (see Colton and Kirsch [9] and Kirsch [19, 20]) and has been applied to impedance tomography by Brühl and Hanke [3, 5, 4, 14] and by Hyvönen [16, 15]. For an extension to more general inverse elliptic problems we refer the reader to Kirsch [21] and Gebauer [11].

The impedance tomography problem consists of reconstruction of the admittance tensor γ in the elliptic equation

$$\nabla.(\gamma\nabla u) = 0 \quad \text{in } \Omega$$

from boundary measurements of the electric potential u and the corresponding current on the boundary of the bounded domain $\Omega \subset \mathbb{R}^n$, $n = 2$ or 3. Mathematically, this information is given by the Neumann-to-Dirichlet operator that maps the used current pattern on the measured potential. Various imaging problems of practical importance

deal with locating embedded inhomogeneities in an object with known background admittance. In [3] Brühl applied the factorization method to such a situation and provided explicit characterization of the inclusions under suitable conditions on the inhomogeneities and the background admittance. His results have been generalized in [21, 16].

In [3, 21, 16] the physical characteristics of impedance tomography were modeled using the *continuum model* [8]. This is in practice a poor choice because it does not predict experimental results with satisfactory precision. Especially for medical applications the *complete electrode model* is a much better choice [27]. A main feature of this model is the introduction of a contact impedance z on the boundary between the discrete electrodes and the investigated object. From the viewpoint of the factorization method, the complete model has the fundamental drawback that there are only a limited number of feasible linearly independent electrode current and voltage patterns. This results in a finite-dimensional boundary measurement map, called the resistivity matrix, which makes characterization results like those in [3, 21, 16] unattainable.

Within the continuum model, let us denote by Λ the Neumann-to-Dirichlet map corresponding to the admittance contaminated with inhomogeneities and by Λ_0 the map corresponding to the known background admittance. The main result of this paper (see Theorem 7.1) is that $\Lambda - \Lambda_0$ and the corresponding difference of the finite-dimensional resistivity matrices related to the complete model are arbitrarily close to each other if a large enough number of electrodes is used in the measuring process and the gaps between the electrodes are small enough. This closeness is measured in the operator norm of $L^2(\partial\Omega)$. We give explicit expressions for the rate of convergence in terms of the geometry of the measurement configuration. Having obtained norm estimates in $L^2(\partial\Omega)$, we can apply the perturbation analysis from [22] to construct a factorization method for the complete model; see Theorem 8.2. We emphasize that the difficult and technical norm estimates between the two electrode models are necessary to be able to use results from [22]; compare these with Theorem 2.3. The factorization method we obtain is easy to implement and numerical examples in the last section underline the quality of its reconstructions. However, one has to pay the price that the method requires the knowledge of the resistivity matrix with and without inclusions and the contact impedance of the electrodes (which is for simplicity assumed to be constant). Since we are doing asymptotic analysis in the number of electrodes, a sufficiently large number of them is required to obtain reasonable results. However, our numerical examples indicate that already 16 seems to be an adequate number.

An earlier result concerning the factorization method within the complete model was obtained by Hyvönen in [15], where a Tikhonov regularization approach is used to treat the finite-dimensional situation in the limit case when the electrode configuration gets infinitesimally fine. However, [15] does not treat the numerically simpler series criterion of [21], and it proves only pointwise convergence of the resistivity matrices toward the Neumann-to-Dirichlet maps. It is the sharpness of our estimates that permits us to work here with the series criterion in a manner which is attractive from the viewpoint of practical computations. Numerical experiments with the method developed in [15] have recently been presented in [17], and reference [14] also considers the numerics of the factorization method in the framework of certain simplified electrode models and, to some extent, with real-world data. However, [14] lacks the asymptotic analysis as the number of electrodes is increased. Compared to [17], our method has the advantage that the regularization parameter for regularization by spectral cut-off of the series criterion can, in principle, be chosen in a systematic way by looking at the measurement configuration; in our numerical experiments, we use a substantially simplified way of choosing the spectral cut-off, which results in relatively good reconstructions.

We briefly outline the structure of this paper. In the next section we introduce the factorization method within the continuum model of EIT and state a regularization result [22] which is used as a basic ingredient in what follows. Section 3 recalls some basics of boundary triangulations, used in sections 4 and 5 to introduce the complete electrode model as a perturbation of the continuum model. In section 6 we prove two technical lemmas before the main approximation result of the work is announced in section 7. This result permits us to construct a factorization method using a truncated sequence criterion for the complete electrode model in section 8. Numerical experiments in section 9 confirm the validity of our theoretical findings.

2. Factorization method and its regularization.

Let us consider the factorization method in the framework of the continuum model of EIT, i.e., assuming that there is no contact impedance, that the current can be applied, and that the potential can be measured everywhere on the object boundary. We will follow the presentation of [21]; in particular, we will assume, overly cautiously, that all boundaries are of the class C^2 if not stated otherwise.

Consider admittance tensors $\gamma : \overline{\Omega} \to \mathbb{C}^{n\times n}$ of the form

$$\gamma = \begin{cases} \gamma_0 + \gamma_1 & \text{in } \Omega_{\rm c} \Subset \Omega, \\ \gamma_0 & \text{in } \Omega \setminus \overline{\Omega_{\rm c}}, \end{cases} \tag{2.1}$$

where $\Omega \setminus \overline{\Omega_{\rm c}}$ is connected and the known background admittance tensor $\gamma_0 \in C^{2,\alpha}(\overline{\Omega})$, $\alpha \in (0,1)$, is real, symmetric, and uniformly positive definite. The matrix $\gamma_1 \in L^\infty(\Omega_{\rm c})$ is symmetric with strictly positive definite and negative semidefinite real and imaginary parts, respectively,

$$\operatorname{Re}(\xi^*\gamma_1\xi) \geq c_0|\xi|^2 \quad \text{and} \quad \operatorname{Im}(\xi^*\gamma_1\xi) \leq 0 \quad \text{for } \xi \in \mathbb{C}^n \text{ and some } c_0 > 0. \tag{2.2}$$

Here and in what follows, we denote by $\xi^* = \overline{\xi}^\top$ the transpose conjugate of a vector or a matrix. Notice that for alternating currents with the harmonic time dependence $\exp(-i\omega\cdot)$, $\omega \geq 0$, the admittance γ can be considered to be of the form $\sigma - i\omega\varepsilon$, where σ is the electric conductivity, ε is the electric permittivity, and ω is the angular frequency of the applied current; compare with [8]. As a consequence, if σ and ε are real and symmetric and the angular frequency of the input is not zero, the condition (2.2) is equivalent to saying that the conductivity inside the inclusion is strictly higher than in the background (in the sense of positive definiteness) and the permittivity of the inclusion is positive semidefinite. On the other hand, the conditions set on γ_0 mean that in the background the conductivity is positive and the permittivity vanishes. If $\omega = 0$, i.e., direct current is used, ε does not contribute to the measurements, and so the conditions on the permittivity can be ignored. Also take note that the factorization method retains its functionality also if the conductivity drops in $\Omega_{\rm c}$ [6].

The admittance tensor γ gives rise to a Neumann-to-Dirichlet operator Λ, defined between the $L^2(\partial\Omega)$-based Sobolev spaces $H_\diamond^{\pm 1/2}(\partial\Omega)$ with differentiability index $\pm 1/2$; see [24, 21]. Here, $H_\diamond^{\pm 1/2}(\partial\Omega)$ denotes the closed subspace of zero mean functions in $H^{\pm 1/2}(\partial\Omega)$, i.e., $\int_{\partial\Omega} f \, \mathrm{d}S = 0$ for $f \in H_\diamond^{\pm 1/2}(\partial\Omega)$, and the integral is a shorthand notation for the duality pairing between $H_\diamond^{\pm 1/2}(\partial\Omega)$ in the Gelfand triple $H_\diamond^{1/2}(\partial\Omega) \subset L_\diamond^2(\partial\Omega) \subset H_\diamond^{-1/2}(\partial\Omega)$. We define

$$\Lambda : \ H_\diamond^{-1/2}(\partial\Omega) \to H_\diamond^{1/2}(\partial\Omega), \quad f \mapsto u|_{\partial\Omega},$$

where u is the unique (weak) solution of

$$\begin{cases} \nabla.(\gamma\nabla u) = 0 & \text{in } \Omega, \\ \mathcal{B}_\nu u = f & \text{on } \partial\Omega, \end{cases} \tag{2.3}$$

in $H^1_\diamond(\Omega) = \{v \in H^1(\Omega) \mid \int_{\partial\Omega} v\,\mathrm{d}S = 0\}$. Here $\mathcal{B}_\nu u := (\gamma\nabla u).\nu$ denotes the conormal derivative with respect to the exterior unit normal field ν. Analogously, one defines Λ_0 using γ_0 instead of γ in (2.3). Compactness of the embeddings $H^{1/2}_\diamond(\partial\Omega) \hookrightarrow L^2_\diamond(\partial\Omega) \hookrightarrow H^{-1/2}_\diamond(\partial\Omega)$ implies that Λ and Λ_0 are compact when acting on $L^2_\diamond(\partial\Omega)$.

The inverse problem we consider is to locate Ω_c from measurements of current and voltage on the boundary $\partial\Omega$. This information is within the continuum model given by the Neumann-to-Dirichlet operator Λ. The factorization method solves the inverse problem using the spectral data of the "square root" of the difference $\Lambda - \Lambda_0$. In its original formulation the method required Λ to be self-adjoint. However, Grinberg and Kirsch [13, 21] showed that decomposition of a non–self-adjoint operator into its real and imaginary parts allows us to set up factorization methods for some non–self-adjoint Neumann-to-Dirichlet operators which arise, for instance, when alternating current is used [2].

In brief, the factorization method for EIT works as follows. Let $\mathcal{N}$ be the Neumann function of the differential operator $\nabla.(\gamma_0\nabla\cdot)$ in Ω, i.e., $\mathcal{N}$ satisfies the boundary value problem

$$\nabla.(\gamma_0\nabla\mathcal{N}(\cdot,y)) = \delta_y \quad \text{in } \Omega, \quad \mathcal{B}_\nu\mathcal{N}(\cdot,y) = \frac{1}{|\partial\Omega|} \quad \text{on } \partial\Omega,$$

where δ_y is the Dirac distribution at $y \in \Omega$ and the ground level of potential is chosen so that $\mathcal{N}(\cdot,y)$ integrates to zero over $\partial\Omega$. One constructs test functions $\varphi_y \in L^2_\diamond(\partial\Omega)$ for each point $y \in \Omega$ by

$$\varphi_y(x) = \varphi_{y,a}(x) = a^\top\nabla_y\mathcal{N}(x,y), \quad x \in \partial\Omega, \tag{2.4}$$

where $a \in \mathbb{R}^3$ is the dipole moment. Notice that φ_y can be computed without any information on the inclusion Ω_c. Furthermore, we introduce the—physically meaningless—positive self-adjoint operator

$$(\Lambda - \Lambda_0)_\sharp = |\mathrm{Re}\,(\Lambda - \Lambda_0)| + \mathrm{Im}\,(\Lambda - \Lambda_0) \in \mathcal{L}(L^2_\diamond(\partial\Omega)), \tag{2.5}$$

where the absolute value and the real and imaginary parts are defined as in [21].

Theorem 2.1 (characterization of the inclusion). *Let $(\lambda_j, \psi_j)_{j\in\mathbb{N}}$ be an eigensystem of the compact self-adjoint operator $(\Lambda - \Lambda_0)_\sharp$. Then the sequence*

$$M \mapsto \sum_{j=1}^{M} \frac{|\langle\varphi_y, \psi_j\rangle_{L^2}|^2}{\lambda_j} \tag{2.6}$$

is bounded if and only if $y \in \Omega_\mathrm{c}$.

Let us next consider how the above characterization result can be regularized in case we are given only a noisy incomplete version of $\Lambda - \Lambda_0$. We first recall a perturbation theorem concerning the spectrum of a self-adjoint operator [18, Theorem V.4.10, section 4.3, p. 291], where we denote the spectrum of a linear operator A by $\sigma(A)$.

Theorem 2.2 (continuity of the spectrum). *Let A and B be bounded self-adjoint operators on a Hilbert space H. Then* $\operatorname{dist}(\sigma(A),\sigma(B)) \le \|A-B\|$*; that is,*

$$\sup_{\lambda\in\sigma(B)} \operatorname{dist}(\lambda,\sigma(A)) \le \|A-B\| \quad \textit{and} \quad \sup_{\mu\in\sigma(A)} \operatorname{dist}(\mu,\sigma(B)) \le \|A-B\|.$$

Hence, there is some hope that a measured approximation of the Neumann-to-Dirichlet operator yields good approximations for the eigenvalues of Λ. Due to Rellich's lemma [24, Theorem 3.27], Λ and Λ_0 are compact when acting on $L^2_\diamond(\partial\Omega)$, and hence $(\Lambda-\Lambda_0)_\sharp$ is compact as well; in fact, $(\Lambda-\Lambda_0)_\sharp$ is smoothing if $\partial\Omega$ and the admittances are smooth. Therefore, even a small perturbation of the eigenvalues λ_j of $(\Lambda-\Lambda_0)_\sharp$ might completely destroy the behavior of the sequence $M\mapsto\sum_{j=1}^M |\langle\varphi_y,\psi_j\rangle|^2/\lambda_j$, which characterizes $\Omega_\mathrm{c}\Subset\Omega$ in (2.6). Actually, if $\lambda'_j\approx\lambda_j$, the sequence $M\mapsto\sum_{j=1}^M |\langle\varphi_y,\psi_j\rangle|^2/\lambda'_j$ does not even need to be well defined. Here enters the ill-posedness of the problem. It is quite natural to use a spectral cut-off as a regularization technique or, equivalently, truncate the perturbed Picard series in (2.6). A perturbation analysis of the problem has to deal not only with the perturbed eigenvalues of $(\Lambda-\Lambda_0)_\sharp$ but also with the perturbed eigenvectors which enter the series criterion in (2.6), but above we have neglected this question for simplicity. Interested readers are referred to [22].

For regularization of the Picard series (2.6) in the case of perturbed data, we define a truncation index which depends on two arbitrary, but fixed, parameters $\omega\in(0,1/2)$ and $C>0$. Assume that we have been given the operators $B_M, B_{0M}\in\mathcal{L}(L^2_\diamond(\partial\Omega))$ with the property

$$\|(\Lambda-\Lambda_0)_\sharp-(B_M-B_{0M})_\sharp\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))}=\varepsilon_M\to 0 \quad \text{as } M\to\infty. \tag{2.7}$$

For an eigenvalue $\lambda_j^{(M)}$ of the self-adjoint operator $(B_M-B_{0M})_\sharp$, we define its cluster to be the set of all eigenvalues closer to $\lambda_j^{(M)}$ than $2\varepsilon_M$:

$$\operatorname{clu}(\lambda_j^{(M)}) := \left\{\lambda_l^{(M)}\in\sigma\left((B_M-B_{0M})_\sharp\right) \,\middle|\, \left|\lambda_j^{(M)}-\lambda_l^{(M)}\right|\le 2\varepsilon_M\right\}.$$

Roughly speaking, $\operatorname{clu}(\lambda_j^{(M)})$ contains the eigenvalues of $(B_M-B_{0M})_\sharp$ that might converge to $\lim_{M\to\infty}\lambda_j^{(M)}$ as $M\to\infty$. Now we can define the cut-off index as

$$R(M) := \max\{k\in\mathbb{N} \mid \lambda_k^{(M)}\ge 3\varepsilon_M^\omega,\ \rho_k^{(M)}\ge 8\varepsilon_M^\omega,\ k\varepsilon_M^{1-2\omega}\le C\}, \tag{2.8}$$

where $\rho_k^{(M)}=\min\left\{\left|\lambda_k^{(M)}-\lambda_j^{(M)}\right| \,\middle|\, \operatorname{clu}(\lambda_k^{(M)})\ne\operatorname{clu}(\lambda_j^{(M)})\right\}$. The definition of $R(M)$ has no other motivation than cutting off as many terms in the series criterion as necessary to be able to prove the theorem below. For this asymptotic result it is naturally crucial that $R(M)\to\infty$ as $M\to\infty$. Note that the truncation index prevents, for instance, eigenvalues too close to zero to be investigated in the regularized sequence criterion and that (2.8) implies the more complicated condition (35) of [22].

Theorem 2.3. *Let $\omega\in(0,1/2)$ and $C>0$ be arbitrary, but fixed, parameters, and let the compact operators $B_M, B_{0M}\in\mathcal{L}(L^2_\diamond(\partial\Omega))$, $M\in\mathbb{N}$, be the given data and such that* (2.7) *holds. Let $(\lambda_j^{(M)},\psi_j^{(M)})_{j\in\mathbb{N}}$ be an eigensystem of the compact self-adjoint operator $(B_M-B_{0M})_\sharp$. Then the sequence*

$$M\mapsto\sum_{j=1}^{R(M)}\frac{|\langle\varphi_y,\psi_j^{(M)}\rangle|^2}{\lambda_j^{(M)}}, \quad M\in\mathbb{N},$$

is bounded if and only if $y\in\Omega_\mathrm{c}$.

3. Boundary elements and local projections. Approximation of Neumann-to-Dirichlet operators in a finite-dimensional space motivates us to subdivide the boundary $\partial\Omega$ using a mesh and to consider piecewise polynomial functions on the elements. Such techniques are well known in finite element theory. Our approach is slightly different because we need triangulations (more precisely, quadrangulations) of the boundary and thus curved elements or *panels*. The construction of such meshes is standard in boundary element methods. For completeness we recall some basic results following Sauter and Schwab [25, Kapitel 4]. To be able to reference to this text, we need to make the additional assumption that the boundary $\partial\Omega$ is of the class C^∞ and introduce the reference element

$$\hat{Q} = (0,1) \times (0,1) \subset \mathbb{R}^2.$$

Moreover, we denote the Euclidean norm by $|\cdot|$.

Definition 3.1 (triangulation of $\partial\Omega$). *A triangulation $\mathcal{T}$ of $\partial\Omega$ is a subdivision of $\partial\Omega$ into relatively open disjoint elements such that the following hold:*

1. *$\mathcal{T}$ covers $\partial\Omega$, i.e., $\partial\Omega = \bigcup_{T\in\mathcal{T}} \overline{T}$.*
2. *Each element $T \in \mathcal{T}$ is the image of the reference element $\hat{Q}$ under a diffeomorphism χ_T and there exist constants $C_{\min}$ and $C_{\max}$ such that*

$$0 < C_{\min} < \inf_{x\in\hat{Q}} \inf_{v\in\mathbb{S}^1} |D\chi_T(x)v|^2 \leq \sup_{x\in\hat{Q}} \sup_{v\in\mathbb{S}^1} |D\chi_T(x)v|^2 < C_{\max} < \infty,$$

where $D\chi_T$ denotes the Jacobian of χ_T.

3. *For each reference mapping $\chi_T : \hat{Q} \to T$ there exists an affine mapping $\chi_T^{\mathrm{af}} : \mathbb{R}^2 \to \mathbb{R}^3$ and a smooth map $\chi_{\partial\Omega} : \mathbb{R}^3 \to \mathbb{R}^3$ independent of T such that $\chi_T = \chi_{\partial\Omega} \circ \chi_T^{\mathrm{af}}$ and $\chi_{\partial\Omega} : \chi_T^{\mathrm{af}}(\hat{Q}) \to T$ is a diffeomorphism for all $T \in \mathcal{T}$.*

Finally, $\mathcal{T}$ is a regular triangulation if any two elements contact each other either not at all or in exactly one point or on an entire side. The number of elements of the triangulation is called the size of $\mathcal{T}$.

Any initial mesh $\mathcal{T}$ of $\partial\Omega$ can be refined using a subdivision of the reference element if this subdivision is transported to $\partial\Omega$ via the mapping χ_T. Consecutively refined triangulations lead to a family of triangulations.

Definition 3.2 (family of triangulations). *A set $(\mathcal{T}_M)_{M\in\mathbb{N}}$ is called a family of triangulations if each $\mathcal{T}_M$ is a triangulation of $\partial\Omega$ of size M such that the mesh size δ_M tends to zero:*

$$\delta_M := \max_{T\in\mathcal{T}_M} \sup_{s,s'\in T} |s - s'| \to 0 \quad \textit{as } M \to \infty. \tag{3.1}$$

The family of triangulations $(\mathcal{T}_M)_{M\in\mathbb{N}}$ is shape regular if the quotient of the diameter and the in-circle diameter of $T \in \mathcal{T}_M$ is bounded by some constant κ independent of M [25, *Kapitel* 4.1] *and quasiuniform if*

$$\sup_{M\in\mathbb{N}} \left[\frac{\max_{T\in\mathcal{T}_M} \sup_{s,s'\in T} |s - s'|}{\min_{T\in\mathcal{T}_M} \sup_{s,s'\in T} |s - s'|} \right] < \infty.$$

In what follows, all triangulations are assumed to be regular and all families of triangulations shape regular. It appears later on that quasiuniformity of a family of triangulations is a serious hindrance when dealing with the complete electrode model: Our convergence proof of the finite-dimensional complete model toward the infinite-dimensional continuum model requires the technical assumption that the gaps between the electrodes shrink faster than the electrodes and therefore nonquasiuniform meshes arise naturally. The choice of discontinuous elements makes this special feature no drawback; see [12, 25].

With the help of triangulations it is possible to approximate functions on $\partial\Omega$ in finite-dimensional spaces. We consider polynomial spaces on the reference element and transport them onto $\partial\Omega$ by $\chi_T = \chi_{\partial\Omega} \circ \chi_T^{\mathrm{af}}$. Therefore, we define

$$\hat{\mathcal{P}}^k := \operatorname{span}\{x^\mu \mid \mu \in \mathbb{N}_0^2,\ |\mu_1| + |\mu_2| \leq k\}$$

to be the space of polynomials of degree less than or equal to k in two variables.

Definition 3.3. *Let $\mathcal{T}$ be a triangulation of $\partial\Omega$. Then*

$$\mathcal{P}^k := \{\psi : \partial\Omega \to \mathbb{C} \mid \textit{for all } T \in \mathcal{T} : \psi \circ \chi_T \in \hat{\mathcal{P}}^k\}.$$

Observe that, in general, $f \in \mathcal{P}^k$ is a polynomial not on $\partial\Omega$ but on the reference element $\hat{Q}$ after backtransport with χ_T. Moreover, f does not need to be continuous over the edges of the elements (discontinuous elements).

The *local L^2-projection* is now constructed by lifting the orthogonal projection from $L^2(\hat{Q})$ to $\hat{\mathcal{P}}^k$ to the boundary $\partial\Omega$: For $\psi \in L^2(\hat{Q})$ one defines $\hat{P}^k$ via

$$\hat{P}^k\psi \in \hat{\mathcal{P}}^k \quad \text{and} \quad (\hat{P}^k\psi - \psi) \perp v \quad \text{for all } v \in \hat{\mathcal{P}}^k,$$

where the orthogonality is in the sense of the inner product of $L^2(\hat{Q})$. Furthermore, for $\psi \in H^s(\partial\Omega)$, $s \geq 0$, and a triangulation $\mathcal{T}$ of $\partial\Omega$ we set

$$P^k\psi\big|_T := (\hat{P}^k(\psi|_T \circ \chi_T)) \circ \chi_T^{-1}, \quad T \in \mathcal{T}. \tag{3.2}$$

The lifting of $\hat{P}^k$ to the curved boundary makes the L^2-projector P^k, in general, nonorthogonal on $L^2(\partial\Omega)$. The approximation quality of P^k depends in principal on the magnitude of the Sobolev index of the space $H^s(\partial\Omega)$ [25, Satz 4.3.18].

Theorem 3.4. *Let $(\mathcal{T}_M)_{M\in\mathbb{N}}$ be a shape regular family of triangulations of the boundary of the smooth domain $\Omega \subset \mathbb{R}^3$, $s > 0$, and P_M^k the L^2-projection on $\mathcal{T}_M$. Then*

$$\|\psi - P_M^k\psi\|_{L^2(\partial\Omega)} \leq C\delta_M^{\min(k+1,s)}\|\psi\|_{H^s(\partial\Omega)} \qquad \textit{for } \psi \in H^s(\partial\Omega), \tag{3.3}$$

where C depends on the constant of shape regularity κ and on $\partial\Omega$.

In this work we make use only of the case $k = 0$ (piecewise constant interpolation) since this is the relevant case in impedance tomography when dealing with perfectly conducting electrodes. Thus, we drop the index k in what follows.

4. The complete electrode model. In practice, the current is injected through electrodes attached to the surface of the investigated body Ω. The complete electrode model [8, 27] is now the standard model for this procedure. It takes into account the following four properties of the setup.

First, the electrodes are a discrete set denoted by $E_1, \ldots, E_p$. Each E_j is considered to be a relatively open subset of the boundary $\partial\Omega$ with positive surface measure: $|E_j| > 0$. We assume, furthermore, that the electrodes are connected and well separated, i.e., $\operatorname{dist}(E_k, E_j) > 0$ for $k \neq j$. The set $\{E_1, \ldots, E_p\}$ is called an *electrode configuration.*

Second, the net current through E_j equals the total flux through the surface patch underneath the electrode. Let $I_j \in \mathbb{C}$ be the mean current flux applied to E_j, i.e., $I_j|E_j|$ is the net current, and define $I = (I_1, \ldots, I_p)^\top$. It holds that

$$\frac{1}{|E_j|}\int_{E_j} \mathcal{B}_\nu u \, \mathrm{d}S = I_j \quad \text{for } j = 1, \ldots, p,$$

where $\mathcal{B}_\nu$ is defined as in (2.3). Due to the principle of conservation of charge, we require that $\sum_j I_j\,|E_j| = 0$. The vector I is called a *current pattern* or a *current vector*. For convenience, we denote the space of current patterns of length p by

$$\mathbb{C}^p_E = \left\{ I \in \mathbb{C}^p \;\Big|\; \sum\nolimits_{j=1}^p I_j\,|E_j| = 0 \right\}, \tag{4.1}$$

with the weighted norm $|\cdot|_E$ defined through

$$|I|_E^2 := \sum_{j=1}^p |E_j|\,|I_j|^2\,. \tag{4.2}$$

We remark that $\mathbb{C}^p_E$ can be identified as a subspace of $L^2_\diamond(\partial\Omega)$ via $C^p_E \ni I \mapsto f$, where $f(x) = I_j$ on E_j, $j = 1, \ldots, p$, and 0 elsewhere.

Third, we model the electrodes as perfect conductors; that is, we assume that the potential along an electrode is constant. This is the so-called shunting effect. The set of electrode voltages is denoted by $U = (U_1, \ldots, U_p)^\top$ and assumed to belong to $\mathbb{C}^p_E$. This condition can be seen as a grounding of potential.

Fourth, the complete electrode model includes the effect of contact impedance at the electrodes: When EIT is used in a medical context, a thin layer with high resistivity is formed at the boundary between the electrodes and the skin due to dermal moisture. We incorporate this effect by introducing the surface impedance function $z \in C^\infty(\partial\Omega)$, which denotes the resistivity of the contact layer at the boundary. The real part of z is assumed to be positive. According to Ohm's law, the potential u at E_j drops by $z\mathcal{B}_\nu u|_{E_j}$ over the contact layer.

The complete electrode model gives rise to the following (weak) formulation of the forward problem: Given a current vector $I = (I_1, \ldots, I_p)^\top \in \mathbb{C}^p_E$, an admittance tensor γ, and a contact impedance z, find the potential $u \in H^1(\Omega)$ and the set of electrode voltages $U \in \mathbb{C}^p_E$ that satisfy

$$\nabla.\big(\gamma\nabla u\big) = 0 \quad \text{in } \Omega, \tag{4.3}$$

$$u + z\mathcal{B}_\nu u = U_j \quad \text{on } E_j \quad \text{for } j = 1, \ldots, p, \tag{4.4}$$

$$\frac{1}{|E_j|}\int_{E_j} \mathcal{B}_\nu u \, \mathrm{d}S = I_j \quad \text{for } j = 1, \ldots, p, \tag{4.5}$$

$$\mathcal{B}_\nu u = 0 \quad \text{on } \partial\Omega \setminus \cup_{j=1}^p \overline{E}_j. \tag{4.6}$$

Notice that without the grounding of potential, i.e., the condition $U \in \mathbb{C}^p_E$, the above problem would not have a unique solution. According to [27], the accuracy of this model corresponds to the measurement precision of the physical experiment.

The measurement map, i.e., the resistivity matrix, associated to the complete electrode model is given by

$$\Sigma : \mathbb{C}^p_E \to \mathbb{C}^p_E, \quad I \mapsto U,$$

where U is the second part of the solution to (4.3)–(4.6) corresponding to the current pattern I. The resistivity matrix corresponding to the background admittance is defined by this very same equation when γ is replaced by γ_0 in (4.3).

The existence and uniqueness of the solution $(u, U) \in H^1(\Omega) \oplus \mathbb{C}^p_E$ can be shown using the Lax–Milgram lemma. One starts to look for the solution in the quotient space $(H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C}$ and chooses afterward the unique representative in $H^1(\Omega) \oplus \mathbb{C}^p_E$. In [27, 15] it is shown that $(u, U) \in (H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C}$ satisfies (4.3)–(4.6) if and only if

$$b((u,U),(v,V)) = f(v,V) \quad \text{for all } (v,V) \in (H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C}, \tag{4.7}$$

where the elliptic sesquilinear form $b = b_{\gamma,z}$ is defined by

$$b((u,U),(v,V)) := \int_\Omega \nabla v^* \gamma \nabla u \,\mathrm{d}x + \sum_{j=1}^p \int_{E_j} \frac{1}{z}(u - U_j)(\overline{v} - \overline{V}_j)\,\mathrm{d}S,$$

and

$$f(v,V) := \sum_{j=1}^p |E_j| I_j \overline{V}_j.$$

As in [15], we use the inner product

$$\langle (u,U),(v,V)\rangle_* = \int_\Omega \nabla v^* \nabla u \,\mathrm{d}x + \sum_{j=1}^p \int_{E_j} (U - u)(\overline{V} - \overline{v})\,\mathrm{d}S$$

on $(H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C}$. The associated norm is equivalent to the quotient norm

$$\|(u,U)\|^2_{(H^1(\Omega)\oplus\mathbb{C}^p)/\mathbb{C}} := \inf_{c\in\mathbb{C}} \left\{ \|u + c\|^2_{H^1(\Omega)} + |U + c|^2_E \right\},$$

independently of the number and size of the electrodes [15, Lemma 2.5, Corollary 2.6]. It follows from the conditions set on γ and z that there is a constant of ellipticity $c = c(z,\gamma) > 0$ such that

$$\operatorname{Re} b((u,U),(u,U)) \geq c\|(u,U)\|^2_* \quad \text{for all } (u,U) \in (H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C} \tag{4.8}$$

and for any electrode configuration $\{E_1, \ldots, E_p\}$, $p \in \mathbb{N}$ [15, Corollary 2.6]. Moreover, there exists C independent of the geometry of the electrodes such that

(4.9)
$$|b((u,U),(v,V))| \leq C\|(u,U)\|_*\|(v,V)\|_* \quad \text{for all } (u,U),(v,V) \in (H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C}.$$

Since the functional $f : (H^1(\Omega) \oplus \mathbb{C}^p)/\mathbb{C} \to \mathbb{C}$ is well defined, continuous, and antilinear, the existence and uniqueness of the solution to (4.3)–(4.6) follow now by combining (4.8) and (4.9) with the Lax–Milgram lemma.

5. Electrode configurations and discretization. Let $\mathcal{T} = (T_j)$ be a triangulation of $\partial\Omega$, as introduced in section 3. We choose a subset $\mathcal{E} = (E_j)_{j=1}^p \subset \mathcal{T}$ that we call the electrodes and write $E = \cup_{j=1}^p E_j$. The complementing elements $\mathcal{G} := \mathcal{T} \smallsetminus \mathcal{E}$, $G := \cup_{G_j \notin \mathcal{E}} G_j$, play the role of the gaps between the electrodes. For simplicity, we denote

$$h_T = \sup_{s,s'\in T} |s - s'|, \quad h_\mathcal{E} = \max_{T\in\mathcal{E}} h_T, \quad h_\mathcal{G} = \max_{T\in\mathcal{G}} h_T, \quad h_\mathcal{T} = \max_{T\in\mathcal{T}} h_T.$$

Motivated by the EIT experiment, we assume that between any two electrodes there is a gap (the electrodes are separated)

$$\operatorname{dist}(E_k, E_j) > 0 \quad \text{for all } j, k = 1, \dots, p,\ j \neq k.$$

The space of piecewise polynomials of degree 0 on the electrodes is denoted by $\mathcal{P}^E$,

$$\mathcal{P}^E = \{u : \partial\Omega \to \mathbb{C} \,|\, \text{for all } E_j : u|_{E_j} \equiv \text{const. and } u|_G \equiv 0\},$$

and we write P^E for the local L^2-projector on this space; i.e., P^E acts on the electrodes like a usual L^2-projector (3.2) but vanishes on the gaps. In the same way we define the space $\mathcal{P}^G$ of piecewise constant functions vanishing on the electrodes and associate the projector P^G. Observe that $P^{E+G} := P^E + P^G = P^0_{\mathcal{T}}$ is the piecewise constant L^2-projector on $\mathcal{T}$. In particular, Theorem 3.4 holds for P^{E+G}.

Since $\mathcal{P}^E$ is finite-dimensional, the following vector notation is sometimes useful:

$$\psi = (\psi_j)_{j=1}^p, \quad \psi_j := \psi|_{E_j} \quad \text{for } \psi \in \mathcal{P}^E.$$

That is, we identify a function in $\mathcal{P}^E$ with the associated vector of function values on the electrodes. Likewise, we identify functions in $\mathcal{P}^G$ and $\mathcal{P}^{E+G}$ with their coordinate representation. The $L^2(\partial\Omega)$ norm on $\mathcal{P}^E$ can then be written as

$$\|\psi\|^2_{L^2(\partial\Omega)} = \|\psi\|^2_{L^2(E)} = \sum_{j=1}^p |\psi_j|^2 |E_j| = \left|(\psi_j)_{j=1}^p\right|^2_E \quad \text{for } \psi \in \mathcal{P}^E.$$

Let now $f \in L^2_\diamond(\partial\Omega)$ be the Neumann boundary data for the continuum model problem (2.3). We try to approximate the solution of (2.3) by the solution of the complete electrode model forward problem. Since $P^E f$ does not, in general, belong to $\mathbb{C}^p_E$, it cannot be used as an input of (4.5), and so we are forced to define yet another projector:

$$\tilde{P}^E f = P^E f - K_f \quad \text{for } f \in L^2(\partial\Omega), \tag{5.1}$$

where

$$K_f = \frac{\sum_j (P^E f)_j |E_j|}{\sum_j |E_j|}. \tag{5.2}$$

It is easy to check that $\tilde{P}^E$ maps $L^2(\partial\Omega)$ to $\mathbb{C}^p_E$. In the following two sections we will investigate how well the mapping

$$(\Sigma - \Sigma_0)\tilde{P}^E : L^2_\diamond(\partial\Omega) \to \mathbb{C}^p_E \subset L^2_\diamond(\partial\Omega)$$

approximates the difference $\Lambda - \Lambda_0$ in the L^2-operator norm.

The projection operator $\frac{1}{|E_j|}\int_{E_j}(\cdot)\,\mathrm{d}S$ which appears in the formulation of the complete model (4.5), is abbreviated to $⨍_E(\cdot)$, i.e.,

$$\left[⨍_E f\right](s) = \begin{cases} \frac{1}{|E_j|}\int_{E_j} f\,\mathrm{d}S & \text{if } s \in E_j \in \mathcal{E}, \\ 0 & \text{else,} \end{cases} \qquad \text{for } f \in L^2(\partial\Omega). \tag{5.3}$$

This projection is orthogonal in $L^2(\partial\Omega)$ and it plays a crucial role in our analysis, as does its counterpart on the gaps, namely,

$$\left[⨍_G f\right](s) = \begin{cases} \frac{1}{|G_j|}\int_{G_j} f\,\mathrm{d}S & \text{if } s \in G_j \in \mathcal{G}, \\ 0 & \text{else,} \end{cases} \qquad \text{for } f \in L^2(\partial\Omega).$$

6. Two technical lemmas on projection operators. The aim of this work is to prove that $\Sigma - \Sigma_0$ is an approximation of $\Lambda - \Lambda_0$. The key for this perturbation lemma turns out to be the comparison of the two projection operators P^E and $\fint(\cdot)$ in $L^2(\partial\Omega)$. The two projectors are close to each other if the mesh size is small, as the following technical lemma shows. This statement is by no means surprising since for a polyhedral surface the projectors agree.

Lemma 6.1. *Let Ω be of class C^∞ and $\mathcal{T} = \mathcal{E} \cup \mathcal{G}$ a triangulation of $\partial\Omega$. Then there exists a constant $C(\Omega)$ such that*

$$\left\| \fint_E u - P^E u \right\|_{L^2(E)} \leq C(\Omega)\, h_{\mathcal{E}}^2 \|u\|_{L^2(\partial\Omega)} \quad \textit{for } u \in L^2(\partial\Omega).$$

For simplicity we restrict ourselves in this lemma to smooth domains, although the proof shows that a domain of class C^2 is sufficient.

Proof. 1. The projector P^E has been defined as the L^2-projector on the reference element $\hat{Q} = (0,1)^2$, transported onto the electrodes E_j. Since P^E projects onto constant functions, for $f \in L^2(\partial\Omega)$, $P^E f$ has the form

$$P^E f\big|_{E_j} = \frac{1}{|\hat{Q}|}\int_{\hat{Q}} f \circ \chi_{E_j}\,\mathrm{d}x = \int_{\hat{Q}} f \circ \chi_{E_j}\,\mathrm{d}x, \quad j = 1, \ldots, p,$$

and $P^E f \equiv 0$ between the electrodes. On the other hand, the transformation theorem shows that

$$\fint_E u\bigg|_{E_j} = \frac{1}{|E_j|}\int_{\hat{Q}} f \circ \chi_{E_j} \sqrt{\det\Big(\left(D\chi_{E_j}\right)^* D\chi_{E_j}\Big)}\,\mathrm{d}x, \quad j = 1, \ldots, p.$$

Hence, we have to estimate an expression of the form

$$\frac{1}{|E_j|}\int_{\hat{Q}} f \circ \chi_{E_j} \sqrt{\det\Big(\left(D\chi_{E_j}\right)^* D\chi_{E_j}\Big)}\,\mathrm{d}x - \int_{\hat{Q}} f \circ \chi_{E_j}\,\mathrm{d}x.$$

Our strategy is to exploit the smoothness of $\partial\Omega$.

2. Let us introduce auxiliary quadrilaterals $\hat{E}_j \subset \mathbb{R}^3$ such that $\hat{E}_j$ touches E_j in some point $\xi_j \subset E_j$; i.e., $\hat{E}_j$ lies in the tangential hyperplane $T_{\xi_j}(\partial\Omega)$ (compare with Figure 6.1). In addition, the four corner points of $\hat{E}_j$ are orthogonal projections of the four corner points of E_j onto $T_{\xi_j}(\partial\Omega)$. Without loss of generality we can assume (using a rigid motion) that $T_{\xi_j}(\partial\Omega) = \{x_1 = x_2 = 0\}$ and denote the diameter of $\hat{E}_j$ by

$$h_{\hat{E}_j} = \sup_{\xi,\xi' \in \hat{E}_j} |\xi - \xi'|\,. \tag{6.1}$$

By choosing $h_{\mathcal{E}}$ small enough we can assume that there exists a C^∞ function $\zeta_j : \mathbb{R}^2 \to \mathbb{R}$ such that ζ_j "transports $\hat{E}_j$ onto E_j"; i.e.,

$$\hat{\chi}_{E_j} : \hat{E}_j \ni \xi \mapsto (\xi, \zeta_j(\xi)) \in \mathbb{R}^3 \tag{6.2}$$

is a C^∞ diffeomorphism that maps $\hat{E}_j$ onto E_j. By the compactness of $\partial\Omega$, our smoothness assumption on $\partial\Omega$ implies that there exists $C(\Omega)$ such that

$$\|\hat{\chi}_{E_j}\|_{C^2(\hat{E}_j)} \leq C(\Omega) \quad \text{and} \quad \|\hat{\chi}_{E_j}^{-1}\|_{C^2(E_j)} \leq C(\Omega) \quad \text{for all } j = 1, \ldots, p. \tag{6.3}$$

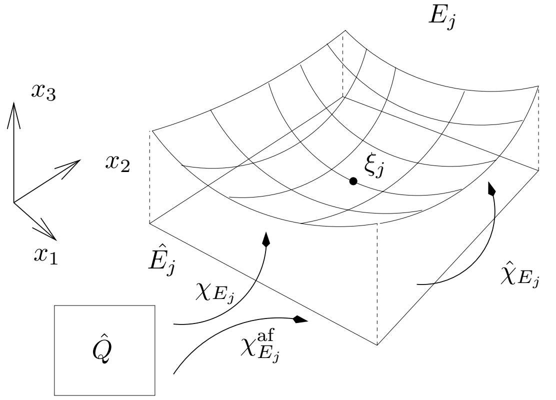

FIG. 6.1. *The quadrilaterals E_j and $\hat{E}_j$. E_j is a C^∞ surface in $\mathbb{R}^3$ with diameter h_{E_j} and $\hat{E}_j \subset \mathbb{R}^2$ with diameter $h_{\hat{E}_j}$. The diffeomorphism $\hat{\chi}_{E_j}$ transports $\hat{E}_j$ onto E_j. The reference element $\hat{Q}$ is transported by χ_{E_j} onto E_j and by $\chi_{E_j}^{\mathrm{af}}$ onto $\hat{E}_j$. We have $\chi_{E_j} = \hat{\chi}_{E_j} \circ \chi_{E_j}^{\mathrm{af}}$.*

Finally, we denote by $\chi_{E_j}^{\mathrm{af}}$ the affine mapping that transports $\hat{Q}$ onto $\hat{E}_j$.

3. As a side computation, we estimate the difference of the surface measures of E_j and $\hat{E}_j$. By the transformation theorem,

$$\begin{aligned}\left||E_j| - |\hat{E}_j|\right| &= \left|\int_{E_j} \mathrm{d}S - \int_{\hat{E}_j} \mathrm{d}\xi\right| \\ &\leq \int_{\hat{E}_j} \left|\sqrt{\det\left(\left(D\hat{\chi}_{E_j}\right)^* D\hat{\chi}_{E_j}\right)} - 1\right| \mathrm{d}\xi \\ &= \int_{\hat{E}_j} \left|\sqrt{1 + |\nabla\zeta_j|^2} - 1\right| \mathrm{d}\xi = \int_{\hat{E}_j} \sqrt{1 + |\nabla\zeta_j|^2} - 1 \, \mathrm{d}\xi.\end{aligned}$$

Recall that we constructed $\hat{E}_j$ so that $\nabla\zeta_j(\xi_j) = 0$ since $\hat{E}_j$ is tangential to E_j at ξ_j. Hence, by the mean value theorem,

$$|\nabla\zeta_j(\xi)| = |\nabla\zeta_j(\xi) - \nabla\zeta_j(\xi_j)| \leq \|\hat{\chi}_{E_j}\|_{C^2(\Omega)} \sup_{\xi \in \hat{E}_j} |\xi - \xi_j| \leq C(\Omega) h_{\hat{E}_j}, \tag{6.4}$$

where $C(\Omega)$ was defined in (6.3) and $h_{\hat{E}_j}$ in (6.1). As a consequence, the mean value theorem for $\sqrt{\cdot}$ implies that

$$\sqrt{1 + |\nabla\zeta_j|^2} - 1 \leq \frac{1}{2}|\nabla\zeta_j|^2 \leq C(\Omega) h_{\hat{E}_j}^2$$

and, in particular, that

$$\int_{\hat{E}_j} \sqrt{1 + |\nabla\zeta_j|^2} - 1 \, \mathrm{d}\xi \leq C(\Omega) h_{\hat{E}_j}^2 \left|\hat{E}_j\right|. \tag{6.5}$$

4. The preceding side computation enables us to estimate as follows:

$$\begin{aligned}
&\left|\frac{1}{|E_j|}\int_{E_j} f\,\mathrm{d}S-(P^E f)_j\right| = \left|\frac{1}{|E_j|}\int_{\hat{E}_j}\left(f\circ\hat{\chi}_{E_j}\right)\sqrt{\det\left(\left(D\hat{\chi}_{E_j}\right)^* D\hat{\chi}_{E_j}\right)}\,\mathrm{d}\xi-(P^E f)_j\right|\\
&=\left|\frac{1}{|E_j|}\int_{\hat{E}_j}\left(f\circ\hat{\chi}_{E_j}\right)\sqrt{1+|\nabla\zeta_j|^2}\,\mathrm{d}\xi-\frac{1}{|\hat{E}_j|}\int_{\hat{E}_j} f\circ\hat{\chi}_{E_j}\,\mathrm{d}\xi\right|\\
&\le\frac{1}{|E_j|}\int_{\hat{E}_j}\left|f\circ\hat{\chi}_{E_j}\right|\left(\sqrt{1+|\nabla\zeta_j|^2}-1\right)\mathrm{d}\xi+\frac{\left||\hat{E}_j|-|E_j|\right|}{|\hat{E}_j|\,|E_j|}\int_{\hat{E}_j}\left|f\circ\hat{\chi}_{E_j}\right|\mathrm{d}\xi\\
&\le\frac{1}{|E_j|}\int_{\hat{E}_j}\left|f\circ\hat{\chi}_{E_j}\right|\left(C(\Omega)h_{\hat{E}_j}^2\right)\mathrm{d}\xi+C(\Omega)\frac{h_{\hat{E}_j}^2}{|E_j|}\int_{\hat{E}_j}\left|f\circ\hat{\chi}_{E_j}\right|\mathrm{d}\xi\\
&\le\frac{C(\Omega)}{|E_j|}h_{\hat{E}_j}^2\sqrt{|\hat{E}_j|}\,\|f\circ\hat{\chi}_{E_j}\|_{L^2(\hat{E}_j)},
\end{aligned}$$

where we used the Cauchy–Schwarz inequality. Note that

$$\|f\circ\hat{\chi}_{E_j}\|_{L^2(\hat{E}_j)}\le C(\Omega)\|f\|_{L^2(E_j)},\qquad h_{\hat{E}_j}\le C(\Omega)h_{E_j},\quad\text{and}\quad|\hat{E}_j|\le|E_j|,$$

where $C(\Omega)$ depends on the curvature of $\partial\Omega$.

5. We are ready for the final estimate of this proof. The preceding parts and the Cauchy–Schwarz inequality allow us to estimate as follows:

$$\begin{aligned}
\left\|\fint_E f\,\mathrm{d}S-P^E f\right\|_{L^2(E)}^2&=\sum_{j=1}^{p}\left\|\frac{1}{|E_j|}\int_{E_j} f\,\mathrm{d}S-(P^E f)_j\right\|_{L^2(E_j)}^2\\
&=\sum_{j=1}^{p}\left|\frac{1}{|E_j|}\int_{E_j} f\,\mathrm{d}S-(P^E f)_j\right|^2|E_j|\\
&\le C(\Omega)\sum_{j=1}^{p}\left[\frac{1}{|E_j|}h_{\hat{E}_j}^2\sqrt{|\hat{E}_j|}\|f\|_{L^2(E_j)}\right]^2|E_j|\\
&\le C(\Omega)\sum_{j=1}^{p}h_{\hat{E}_j}^4\|f\|_{L^2(E_j)}^2\le C(\Omega)h_{\mathcal{E}}^4\|f\|_{L^2(E)}^2.
\end{aligned}\tag{6.6}$$

□

By using the above lemma, we can extend the result of Theorem 3.4.

Corollary 6.2. *Suppose that the assumptions of Theorem* 3.4 *hold. Then*

$$\|\psi-P_M\psi\|_{H^{-1/2}(\partial\Omega)}\le C\delta_M^{1/2}\|\psi\|_{L^2(\partial\Omega)}\qquad\textit{for }\psi\in L^2(\partial\Omega),$$

where C depends on the constant of shape regularity κ and on $\partial\Omega$ and $P_M=P_M^0$.

Proof. Let us introduce the L^2-orthogonal projectors

$$\fint_{\mathcal{T}_M}:L^2(\partial\Omega)\to\mathcal{P}_M\subset L^2(\partial\Omega),\quad M\in\mathbb{N},$$

that are defined in accordance with (5.3) but on the whole triangulations $\mathcal{T}_M$, $M\in\mathbb{N}$, respectively. Here $\mathcal{P}_M$ denotes the space of piecewise constant functions on the triangulation $\mathcal{T}_M$. In the rest of this proof, we will denote by $\psi_M^0\in\mathcal{P}_M$ the image of $\psi\in L^2(\partial\Omega)$ under the Mth of the above-defined projections.

Application of Lemma 6.1 to the whole triangulation $\mathcal{T}_M$ instead of the subset $\mathcal{E}$ shows that

$$\left|\left\langle \psi_M^0 - P_M\psi, \phi\right\rangle_{L^2(\partial\Omega)}\right| \leq C\delta_M^2 \|\psi\|_{L^2(\partial\Omega)}\|\phi\|_{L^2(\partial\Omega)} \quad \text{for } \psi, \phi \in L^2(\partial\Omega),$$

where we used the Cauchy–Schwarz inequality and the notation of Theorem 3.4. In particular, it holds that

$$\begin{aligned}\left|\langle \psi, P_M\phi\rangle_{L^2(\partial\Omega)} - \langle P_M\psi, \phi\rangle_{L^2(\partial\Omega)}\right| &= \left|\left\langle \psi, P_M\phi - \phi_M^0\right\rangle_{L^2(\partial\Omega)} - \left\langle P_M\psi - \psi_M^0, \phi\right\rangle_{L^2(\partial\Omega)}\right| \\ &\leq C\delta_M^2 \|\psi\|_{L^2(\partial\Omega)}\|\phi\|_{L^2(\partial\Omega)}.\end{aligned}$$

As a consequence, it follows from the triangle and Cauchy–Schwarz inequalities and Theorem 3.4 that

$$\begin{aligned}\left|\langle \psi - P_M\psi, \phi\rangle_{L^2(\partial\Omega)}\right| &\leq \left|\langle \psi, \phi - P_M\phi\rangle_{L^2(\partial\Omega)}\right| + \left|\langle \psi, P_M\phi\rangle_{L^2(\partial\Omega)} - \langle P_M\psi, \phi\rangle_{L^2(\partial\Omega)}\right| \\ &\leq C\delta_M^{1/2}\|\psi\|_{L^2(\partial\Omega)}\|\phi\|_{H^{1/2}(\partial\Omega)}\end{aligned}$$

for all $\psi \in L^2(\partial\Omega)$ and $\phi \in H^{1/2}(\partial\Omega)$. Now we can argue by duality as follows:

$$\|\psi - P_M\psi\|_{H^{-1/2}(\partial\Omega)} \leq \sup_{\phi\in H^{1/2}(\partial\Omega),\phi\neq 0} \frac{\left|\langle \psi - P_M\psi, \phi\rangle_{L^2(\partial\Omega)}\right|}{\|\phi\|_{H^{1/2}(\partial\Omega)}} \leq C\delta_M^{1/2}\|\psi\|_{L^2(\partial\Omega)}$$

for all $\psi \in L^2(\partial\Omega)$. This completes the proof. □

When we discretized the boundary current $f \in L^2_\diamond(\partial\Omega)$ of the continuum model to obtain input data for the discrete complete model, we needed to introduce a constant K_f; see (5.2). This constant appeared since for the zero mean current $f \in L^2_\diamond(\partial\Omega)$ the projection $P^E f$ fails to possess zero mean value in general. The following lemma shows that K_f is small for thin gaps and small electrodes.

LEMMA 6.3. *Let $f \in L^2_\diamond(\partial\Omega)$, suppose that the assumptions of Lemma* 6.1 *hold, and define K_f as in* (5.2). *Then there exists $C(\Omega)$ such that*

$$|K_f| \leq \left[|E|^{-1}|G|^{1/2} + C(\Omega)|E|^{-1/2}h_{\mathcal{E}}^2\right]\|f\|_{L^2(\partial\Omega)}. \tag{6.7}$$

Since $|E| + |G| = |\partial\Omega|$ we observe that if the gaps are small, i.e., $|G|$ is small, then $|E| \approx |\partial\Omega|$. If, moreover, the electrodes are thin, i.e., $h_{\mathcal{E}}$ is small, then K_f is small due to (6.7).

Proof. 1. Using techniques similar to those in the proof of Lemma 6.1, one computes that

$$\begin{aligned}\left|\int_E P^E f - f \,\mathrm{d}S\right| &= \left|\sum_{j=1}^{p} |E_j| \left[(P^E f)_j - \frac{1}{|E_j|}\int_{E_j} f \,\mathrm{d}S\right]\right| \\ &\leq \sqrt{|E|}\left\|P^E f - \fint_E f\right\|_{L^2(E)} \\ &\overset{(6.6)}{\leq} C(\Omega)\sqrt{|E|}h_{\mathcal{E}}^2\|f\|_{L^2(\partial\Omega)}.\end{aligned}$$

2. The definition of K_f and part 1 of the proof imply that

$$\begin{aligned}
|K_f| &= \left| \frac{\sum_j (P^E f)_j |E_j|}{\sum_j |E_j|} \right| = \frac{1}{|E|} \left| \int_E P^E f \, \mathrm{d}S \right| \\
&\le \frac{1}{|E|} \left| \int_E f \, \mathrm{d}S \right| + \frac{1}{|E|} \left| \int_E P^E f - f \, \mathrm{d}S \right| \\
&\le \frac{1}{|E|} \left| \int_G f \, \mathrm{d}S \right| + C(\Omega)|E|^{-1/2} h_{\mathcal{E}}^2 \|f\|_{L^2(\partial\Omega)} \\
&\le \left[|E|^{-1} |G|^{1/2} + C(\Omega)|E|^{-1/2} h_{\mathcal{E}}^2 \right] \|f\|_{L^2(\partial\Omega)},
\end{aligned}$$

where we used the zero mean property of f in the second to last intermediate phase. □

7. Approximation of the continuum model by the complete electrode model. We have now collected all tools we require to prove our main theorem. It shows that the complete model approximates the continuum model in the operator norm if the electrodes covering $\partial\Omega$ are fine enough. Moreover, the surface area of the gaps needs to be small. All required geometric assumptions appear quite explicitly in the estimates. Concerning notation, recall that Λ and Λ_0 denote the Neumann-to-Dirichlet operators associated to the admittances γ and γ_0, respectively, whereas Σ and Σ_0 denote the corresponding resistivity matrices. The projection $\tilde{P}^E$ is defined by (5.1). For simplicity, we assume that the contact impedance z is just a complex constant with positive real part. This technical assumption is used to ease the proof of Lemma 7.3.

THEOREM 7.1. *Let $\mathcal{T}$ be a triangulation of the boundary of the smooth bounded domain Ω. We denote as usual by $h_{\mathcal{E}} = \max_j h_{E_j}$, $h_{\mathcal{G}} = \max_j h_{G_j}$, and $h_{\mathcal{T}} = \max(h_{\mathcal{E}}, h_{\mathcal{G}})$ the element size of the electrodes, the gaps, and the triangulation, respectively. Then*

$$\begin{aligned}
&\|(\Lambda - \Lambda_0) - (\Sigma - \Sigma_0)\, \tilde{P}^E\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} \\
&\qquad \le C(\Omega, \gamma, \gamma_0, \kappa_{\mathcal{T}}, z) \left[h_{\mathcal{T}}^{1/2} + \left(\sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1} \right)^{1/2} + |E|^{-1/2} h_{\mathcal{T}}^2 + |E|^{-1} |G|^{1/2} \right]
\end{aligned} \tag{7.1}$$

for $\theta^* \in (4/3, 2)$.

It is crucial that the constant in the above estimate does not depend on the electrode configuration.

Proof. 1. Let us denote by $u \in H^1_\diamond(\Omega)$ the unique solution of the Neumann problem (2.3) for $f \in L^2_\diamond(\partial\Omega)$ and by $(\tilde{u}, U) \in H^1(\Omega) \oplus \mathbb{C}^p_E$ the unique solution to the complete model forward problem (4.3)–(4.6) with the input current $\tilde{P}^E f = P^E f - K_f$; see (5.1). Analogously, we set u_0 and $\tilde{u}_0$ to be the solutions of the same problems for the admittance γ_0 and introduce the constant $c = \int_{\partial\Omega} \tilde{u} \, \mathrm{d}S$ such that $\tilde{u} - c \in H^1_\diamond(\Omega)$. We first observe that there exists a constant $C(\Omega, \gamma)$ such that

$$\begin{aligned}
\|u - \tilde{u} + c\|_{L^2(\partial\Omega)} &\le C(\Omega)\|u - \tilde{u} + c\|_{H^{1/2}(\partial\Omega)} \le C(\Omega)\|u - \tilde{u} + c\|_{H^1(\Omega)} \\
&\le C(\Omega, \gamma)\|\mathcal{B}_\nu u - \mathcal{B}_\nu \tilde{u}\|_{H^{-1/2}(\partial\Omega)}.
\end{aligned} \tag{7.2}$$

This inequality relies on well-posedness of the Neumann problem (2.3) in $H^1_\diamond(\Omega)$: The difference $u - \tilde{u} + c$ solves (2.3) with the Neumann boundary values $\mathcal{B}_\nu u - \mathcal{B}_\nu \tilde{u} \in H^{-1/2}(\partial\Omega)$. Hence, (7.2) follows from the trace theorem and the continuous embedding $H^{1/2}(\partial\Omega) \subset L^2(\partial\Omega)$. An analogous inequality holds of course for $u_0 - \tilde{u}_0$.

Since $\Lambda f = u|_{\partial\Omega}$, $\Sigma\tilde{P}^E f = \tilde{u}|_{\partial\Omega} + z\mathcal{B}_\nu\, \tilde{u}|_{\partial\Omega}$ on the electrodes and $\Sigma\tilde{P}^E f = 0$ in between the electrodes, the triangle inequality implies that

$$\begin{aligned}
&\left\| \left((\Lambda - \Lambda_0) - (\Sigma - \Sigma_0)\, \tilde{P}^E \right) f \right\|^2_{L^2(\partial\Omega)} \\
&\quad = \|u - u_0 - \tilde{u} - z\mathcal{B}_\nu\tilde{u} + \tilde{u}_0 + z\mathcal{B}_\nu\tilde{u}_0\|^2_{L^2(E)} + \|u - u_0\|^2_{L^2(G)} \\
&\quad \le 3\|u - \tilde{u}\|^2_{L^2(E)} + 3\|u_0 - \tilde{u}_0\|^2_{L^2(E)} \\
&\qquad + 3\,\|z\|^2_\infty \|\mathcal{B}_\nu\tilde{u} - \mathcal{B}_\nu\tilde{u}_0\|^2_{L^2(E)} + \|u - u_0\|^2_{L^2(G)}\,.
\end{aligned} \tag{7.3}$$

The terms $\|u - \tilde{u}\|_{L^2(E)}$ and $\|u_0 - \tilde{u}_0\|_{L^2(E)}$ can be estimated in exactly the same manner and we will treat only the first of the two in the following. We set again $c = \int_{\partial\Omega} \tilde{u}\ \mathrm{d}S$ and estimate

$$\begin{aligned}
\|u - \tilde{u}\|_{L^2(E)} &\le \|u - \tilde{u} + c\|_{L^2(E)} + |c||E|^{1/2} \\
&\le C(\Omega, \gamma, z)\|\mathcal{B}_\nu u - \mathcal{B}_\nu\tilde{u}\|_{H^{-1/2}(\partial\Omega)} + |c||E|^{1/2} \\
&\le C(\Omega, \gamma, z) \left(\underbrace{\|f - P^E f\|_{H^{-1/2}(\partial\Omega)}}_{\text{I}} + \underbrace{\|P^E f - \mathcal{B}_\nu\tilde{u}\|_{L^2(\partial\Omega)}}_{\text{II}} \right) + |c||E|^{1/2}.
\end{aligned} \tag{7.4}$$

The absolute value of c can be easily controlled, since

$$\begin{aligned}
c &= \int_{\partial\Omega} \tilde{u}\ \mathrm{d}S = \int_E \tilde{u}\,\mathrm{d}S + \int_G \tilde{u}\,\mathrm{d}S \\
&= \sum_{E_j \in \mathcal{E}} \int_{E_j} (U_j - z\mathcal{B}_\nu u)\ \mathrm{d}S + \int_G \tilde{u}\,\mathrm{d}S \\
&= \sum_{E_j \in \mathcal{E}} U_j|E_j|\ - z \sum_{E_j \in \mathcal{E}} I_j|E_j| + \int_G \tilde{u}\,\mathrm{d}S = \int_G \tilde{u}\,\mathrm{d}S
\end{aligned}$$

and hence $|c| \le \|\tilde{u}\|_{L^2(\partial\Omega)}|G|^{1/2} \le C(\Omega, \gamma)\|f\|_{L^2(\partial\Omega)}|G|^{1/2}$. Note that

$$\|\mathcal{B}_\nu\tilde{u} - \mathcal{B}_\nu\tilde{u}_0\|_{L^2(E)} \le \|\mathcal{B}_\nu\tilde{u} - P^E f\|_{L^2(\Omega)} + \|P^E f - \mathcal{B}_\nu\tilde{u}_0\|_{L^2(\Omega)},$$

and both of the latter terms correspond to the term II of (7.4). Terms I and II of (7.4) will be estimated in parts 2 and 3 of the proof. The only remaining term $\|u - u_0\|_{L^2(G)}$, appearing at the end of (7.3), will be treated in the fourth part.

2. We bound term I using the approximation property of $P^{E+G} = P^0_{\mathcal{T}}$ on $L^2(\partial\Omega)$; see Theorem 3.4. For convenience, we formulate this result as a lemma.

LEMMA 7.2. *Under the assumptions of Theorem* 7.1*, it holds that*

$$\|f - P^E f\|_{H^{-1/2}(\partial\Omega)} \le C(\Omega, \kappa_{\mathcal{T}}) \left(h^{1/2}_{\mathcal{T}} + \sqrt{\sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1}} \right) \|f\|_{L^2(\partial\Omega)}.$$

We estimate as follows:

$$\begin{aligned}
\mathrm{I} &= \|f - (P^E + P^G)f + P^G f\|_{H^{-1/2}(\partial\Omega)} \\
&\leq \|f - P^{E+G} f\|_{H^{-1/2}(\partial\Omega)} + \left\|P^G f - \textstyle⨍_G f \,\mathrm{d}S\right\|_{H^{-1/2}(\partial\Omega)} + \left\|\textstyle⨍_G f \,\mathrm{d}S\right\|_{H^{-1/2}(\partial\Omega)} \\
&\leq C(\Omega, \kappa_{\mathcal{T}})\, h_{\mathcal{T}}^{1/2} \|f\|_{L^2(\partial\Omega)} + C(\Omega) \left\|P^G f - \textstyle⨍_G f \,\mathrm{d}S\right\|_{L^2(G)} + \left\|\textstyle⨍_G f \,\mathrm{d}S\right\|_{H^{-1/2}(\partial\Omega)} \\
&\leq C(\Omega, \kappa_{\mathcal{T}})\, h_{\mathcal{T}}^{1/2} \|f\|_{L^2(\partial\Omega)} + C(\Omega)\, h_{\mathcal{G}}^2 \|f\|_{L^2(\partial\Omega)} + \left\|\textstyle⨍_G f \,\mathrm{d}S\right\|_{H^{-1/2}(\partial\Omega)},
\end{aligned}$$

where we used Corollary 6.2 and Lemma 6.1 for the gaps instead of the electrodes. The constant $C(\Omega, \kappa_{\mathcal{T}})$ depends on the curvature of $\partial\Omega$ and the shape regularity of the triangulation $\mathcal{T}$.

The last term on the right will be estimated using a duality argument, and so we start with the "dual" case $\phi \in H^{1/2}(\partial\Omega)$. Due to a Sobolev embedding theorem, we know that for $v \in W^{1,p}(\Omega)$, $p < n$, the trace $v|_{\partial\Omega}$ belongs to $L^\theta(\partial\Omega)$ for $1 \leq \theta < (n-1)p/(n-p)$; see [26, Abschnitt 117, Satz 4; Abschnitt 118] or [1, Theorem 7.43]. In our case, $p = 2$ and $n = 3$ and we find that $H^{1/2}(\partial\Omega) = H^1(\Omega)\big|_{\partial\Omega} \subset L^\theta(\partial\Omega)$ for $1 \leq \theta < 4$, with continuous embedding.[1] We fix $2 < \theta < 4$ and define the conjugate exponent θ^* in $(4/3, 2)$ by $1/\theta + 1/\theta^* = 1$. Then we estimate as follows:

$$\begin{aligned}
\left\|⨍_G \phi\right\|^2_{L^2(\partial\Omega)} &\leq \sum_{G_j \in \mathcal{G}} \left|\frac{1}{|G_j|} \int_{G_j} \phi \,\mathrm{d}S\right|^2 |G_j| \\
&\leq \sum_{G_j \in \mathcal{G}} \frac{1}{|G_j|} \|1\|^2_{L^{\theta^*}(G_j)} \|\phi\|^2_{L^\theta(G_j)} \qquad (7.5)\\
&\leq C(\Omega) \|\phi\|^2_{H^{1/2}(\partial\Omega)} \sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1} \quad \text{for } \phi \in H^{1/2}(\partial\Omega).
\end{aligned}$$

A duality argument is now used to bound the $L^2(\partial\Omega)$-orthogonal mean value projection $⨍(\cdot)$ on G in $H^{-1/2}(\partial\Omega)$:

$$\begin{aligned}
\left\|⨍_G f\right\|_{H^{-1/2}(\partial\Omega)} &= \sup_{\phi \in H^{1/2}(\partial\Omega), \phi \neq 0} \frac{\left|\langle ⨍ f, \phi\rangle_{L^2(\partial\Omega)}\right|}{\|\phi\|_{H^{1/2}(\partial\Omega)}} \\
&= \sup_{\phi \in H^{1/2}(\partial\Omega), \phi \neq 0} \frac{\left|\langle f, ⨍ \phi\rangle_{L^2(\partial\Omega)}\right|}{\|\phi\|_{H^{1/2}(\partial\Omega)}} \\
&\leq \sup_{\phi \in H^{1/2}(\partial\Omega), \phi \neq 0} \frac{\|f\|_{L^2(\partial\Omega)} \|⨍ \phi\|_{L^2(\partial\Omega)}}{\|\phi\|_{H^{1/2}(\partial\Omega)}} \\
&\overset{(7.5)}{\leq} C(\Omega) \sqrt{\sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1}} \|f\|_{L^2(\partial\Omega)}. \qquad \square
\end{aligned}$$

3. In this part of the proof we estimate term II of (7.4). Again, we announce the bound in a lemma.

Lemma 7.3. *Under the assumptions of Theorem* 7.1, *it holds that*

$$\|P^E f - \mathcal{B}_\nu \tilde{u}\|_{L^2(\partial\Omega)} \leq C(\Omega, \kappa_{\mathcal{T}}, z, c) \left(h_{\mathcal{T}}^{1/2} + |E|^{-1/2} h_{\mathcal{T}}^2 + |E|^{-1} |G|^{1/2}\right) \|f\|_{L^2(\partial\Omega)}.$$

[1] At this point, an extension to the two-dimensional case is not obvious without suitable modification, but see Remark 7.7.

We first observe that both $\mathcal{B}_\nu \tilde{u}$ and $P^E f$ are identically zero on G. Thus,

$$\begin{aligned}
\mathrm{II}^2 &= \|P^E f - \mathcal{B}_\nu \tilde{u}\|^2_{L^2(\partial\Omega)} \\
&\overset{(4.5),(5.1)}{=} \sum_{E_j \in \mathcal{E}} \left\| \left(\frac{1}{|E_j|} \int_{E_j} \mathcal{B}_\nu \tilde{u} \, \mathrm{d}S + K_f \right) - \mathcal{B}_\nu \tilde{u} \right\|^2_{L^2(E_j)} \\
&\le \underbrace{2 \sum_{E_j \in \mathcal{E}} \left\| \frac{1}{|E_j|} \int_{E_j} \mathcal{B}_\nu \tilde{u} \, \mathrm{d}S - \mathcal{B}_\nu \tilde{u} \right\|^2_{L^2(E_j)}}_{\mathrm{III}^2} + 2|\partial\Omega| \, |K_f|^2.
\end{aligned}$$

Lemma 6.3 gives a bound for the latter term on the right side of this inequality.

The term III can be bounded using the formulation of the complete electrode model. The following estimate is very strong, since we start with Neumann boundary values and end up with Dirichlet ones. Additionally, we obtain a factor $\sqrt{h_\mathcal{E}}$.

$$\begin{aligned}
\mathrm{III}^2 &= \sum_{E_j \in \mathcal{E}} \left\| \frac{1}{|E_j|} \int_{E_j} \left(\frac{U_j - \tilde{u}}{z} \right) \mathrm{d}S - \left(\frac{U_j - \tilde{u}|_{E_j}}{z} \right) \right\|^2_{L^2(E_j)} \qquad \text{by (4.4)} \\
&\le C(z) \sum_{E_j \in \mathcal{E}} \left\| \frac{1}{|E_j|} \int_{E_j} \tilde{u} \, \mathrm{d}S - \tilde{u} \right\|^2_{L^2(E_j)} \qquad \text{since } U_j/z \text{ constant} \\
&\le 2C(z) \left[\left\| \fint_E \tilde{u} - P^E \tilde{u} \right\|^2_{L^2(E)} + \|P^E \tilde{u} - \tilde{u}\|^2_{L^2(E)} \right] \\
&\le 2C(\Omega, \kappa_\mathcal{T}, z) \left[h^2_\mathcal{E} \|\tilde{u}\|^2_{L^2(E)} + h_\mathcal{E} \|\tilde{u}\|^2_{H^{1/2}(E)} \right] \quad \text{due to Theorems 3.4, 6.1} \\
&\le 2C(\Omega, \kappa_\mathcal{T}, z) h_\mathcal{E} \|\tilde{u}\|^2_{H^{1/2}(\partial\Omega)} \le 2C(\Omega, \kappa_\mathcal{T}, z) h_\mathcal{E} \|\tilde{u}\|^2_{H^1(\Omega)}
\end{aligned}$$

for $h_\mathcal{E}$ small enough, due to the boundedness of the trace mapping. The first inequality in the above chain of estimates is the only reason why we assumed that z is a constant in the beginning of this section. It is crucial to observe that this estimate remains valid if $\tilde{u}$ on the right-hand side is replaced by any $\tilde{u} + d$, $d \in \mathbb{C}$. This follows, for example, by noticing that the value of the term following the first of the above inequalities is not affected if we write $\tilde{u} + d$ in the place of $\tilde{u}$. As a consequence, with the help of Theorem 2.3 of [15] and (5.1), we see that

$$\begin{aligned}
\mathrm{III} &\le C(\Omega, \kappa_\mathcal{T}, z) h^{1/2}_\mathcal{E} \inf_{d \in \mathbb{C}} \|\tilde{u} + d\|_{H^1(\Omega)} \\
&\le C(\Omega, \kappa_\mathcal{T}, \gamma, z) h^{1/2}_\mathcal{E} \|\tilde{P}^E f\|_{L^2(\partial\Omega)} \\
&\le C(\Omega, \kappa_\mathcal{T}, \gamma, z) h^{1/2}_\mathcal{E} \left(\|f\|_{L^2(\partial\Omega)} + \|K_f\|_{L^2(\partial\Omega)} \right),
\end{aligned}$$

the last step being valid because $P^E : L^2(\partial\Omega) \to L^2(\partial\Omega)$ is bounded. Once again, we can bound the latter term on the right-hand side of the last inequality with the help of Lemma 6.3. □

4. In order to complete the proof, we still need to estimate the term $\|u - u_0\|_{L^2(G)}$ in (7.3). By the triangle inequality, it is sufficient to bound $\|u\|_{L^2(G)}$ and $\|u_0\|_{L^2(G)}$ separately. Again, we restrict ourselves to the first of these two terms. Using the approximation properties of different projections and the second part of this proof,

we find that

$$\begin{aligned}\|u\|_{L^2(G)} &\leq \|u - P^G u\|_{L^2(G)} + \left\|P^G u - \fint_G u\right\|_{L^2(G)} + \left\|\fint_G u\right\|_{L^2(G)} \\ &\leq C(\Omega, \kappa_{\mathcal{T}}) \left(h_{\mathcal{T}}^{1/2} + h_{\mathcal{T}}^2\right) \|u\|_{H^{1/2}(\partial\Omega)} + C(\Omega) \sqrt{\sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1}} \|u\|_{H^{1/2}(\partial\Omega)} \\ &\leq C(\Omega, \kappa_{\mathcal{T}}, \gamma) \left[h_{\mathcal{T}}^{1/2} + \sqrt{\sum_{G_j \in \mathcal{G}} |G_j|^{2/\theta^* - 1}} \right] \|f\|_{L^2(\partial\Omega)}.\end{aligned}$$

5. Now, the initial claim follows by combining part 4 and Lemmas 7.2 and 7.3 with the considerations in the beginning of this proof. □

REMARK 7.4. *Theorem* 7.1 *provides an approximation result suitable for the factorization method as the differences* $\Lambda - \Lambda_0$ *and* $(\Sigma - \Sigma_0)\tilde{P}^E$ *are considered. If one merely considers the difference between* Λ *and* $\Sigma\tilde{P}^E$, *the analogous approximation result fails. The reason for this is that the resistivity matrix does not approximate the Neumann-to-Dirichlet operator but the Neumann-to-Robin operator, defined as*

$$\Upsilon : H^s_\diamond(\partial\Omega) \to H^s_\diamond(\partial\Omega), \quad f \mapsto u|_{\partial\Omega} + zf \qquad \textit{for } s \in [-1/2, 1/2],$$

with a suitable grounding of the potential. This operator "of the second kind" does not share the smoothing properties of Λ. *However, if one considers the difference* $\|\Upsilon - \Sigma P^E\|_{\mathcal{L}(L^2_\diamond(\partial\Omega), H^s_\diamond(\partial\Omega))}$ *in weaker norms, i.e., for* $s < 0$, *then a similar bound as given in Theorem* 7.1 *holds.*

REMARK 7.5. *By taking advantage of Lemma* 6.1 *and the continuity of the mappings* $\Sigma, \Sigma_0 : \mathbb{C}^p_E \to \mathbb{C}^p_E$, *Theorem* 7.1 *could also be formulated using the projection that is related to* $\fint_E$ *in the same way as* $\tilde{P}_E$ *is related to* P_E. *This observation can be useful in practical considerations since constructing* $\fint_E$ *does not necessarily require construction of the diffeomorphisms* $(\chi_T)_{T \in \mathcal{E}}$.

REMARK 7.6. *Although we formulated Theorem* 7.1 *for the admittance* γ, *defined by* (2.1), *and the background admittance* γ_0, *the result holds true for any other two smooth enough admittances as well. In particular, the two admittances do not need to be related in the same way as the ones we used above.*

REMARK 7.7. *The crucial point for extension of the last theorem to two dimensions is the Sobolev embedding theorem used in the proof of Lemma* 7.2. *All other steps are independent of dimension. As proven in* [23, *section* 8.5], $H^{1/2}(\mathbb{R}) \hookrightarrow L^\theta(\mathbb{R})$ *for any* $\theta \in [2, \infty)$. *Using standard localization techniques this embedding can be transported to* $\partial\Omega$ *and serves, in two dimensions, as a replacement of the Sobolev embeddings used in* (7.5).

Let us now consider a family of triangulations $(\mathcal{T}_M)_{M \in \mathbb{N}}$ of $\partial\Omega$ and denote the electrodes of $\mathcal{T}_M$ by $\mathcal{E}^M$ and the gaps by $\mathcal{G}^M$. The spaces of constant functions on the electrodes and on the gaps are denoted $\mathcal{P}^E_M$ and $\mathcal{P}^G_M$, respectively, and the local L^2-projection operators by P^E_M and P^G_M. Furthermore, the auxiliary projection operator $\tilde{P}^E_M$ is defined in accordance with (5.1). By the definition of a family of triangulations the mesh size of $\mathcal{T}_M$ tends to zero as M tends to infinity. This implies that the mesh size of the electrodes, as well as the mesh size of the gaps, tends to zero. In view of our aim to prove that $(\Sigma_M - \Sigma_{0M})\tilde{P}^E_M$ approximates $\Lambda - \Lambda_0$, we need to require that the surface measure of the gaps tends to zero as M tends to infinity. Such a condition can be set up as

$$(7.6)\qquad \sum_{G_j^M \in \mathcal{G}^M} \left|G_j^M\right| = \left|\partial\Omega \setminus \bigcup_{E_j^M \in \mathcal{E}^M} E_j^M\right| \to 0 \quad \text{as } M \to \infty$$

and is inspired by Hyvönen's notion of a sequence of electrode configurations [15]. However, in view of (7.1), we are forced to set up a stronger assumption, namely,

$$(7.7)\qquad \sum_{G_j \in \mathcal{G}_M} \left|G_j^M\right|^{2/\theta^* - 1} \to 0 \quad \text{as } M \to \infty.$$

For $\theta^* = 1$ this condition is equivalent to (7.6), but the proof of Theorem 7.1 requires that $\theta^* \in (4/3, 2)$. Hence, fast shrinking of the gaps is assumed. If (7.7) is satisfied, we have norm convergence of the difference of the two resistivity matrices toward the difference of the corresponding Neumann-to-Dirichlet operators.

Theorem 7.8. *Let $(\mathcal{T}_M)_{M\in\mathbb{N}}$ be a family of triangulations of $\partial\Omega$ satisfying condition* (7.7)*. Then*

$$\|(\Lambda - \Lambda_0) - (\Sigma_M - \Sigma_{0M})\tilde{P}_M^E\|_{\mathcal{L}\left(L^2_\diamond(\partial\Omega)\right)} =: \delta_M \to 0 \quad \textit{as } M \to \infty.$$

Proof. Since $(\mathcal{T}_M)_{M\in\mathbb{N}}$ is shape regular, we can bound $\kappa_{\mathcal{T}_M}$ by a common constant κ. Hence, the constant in (7.1) is uniformly bounded for all $M \in \mathbb{N}$. Condition (7.7) implies, in particular, that the surface area of the gaps $|G| = \sum |G_j|$ tends to zero. Consequently, $|E| = \sum |E_j| \to |\partial\Omega|$, and the claim follows from (7.1). □

The rest of this work concentrates on using the above result in building a factorization algorithm for the complete electrode model of EIT; thorough numerical testing of the approximation link provided by Theorems 7.1 and 7.8 is left for future articles.

8. A factorization method for the complete electrode model. In this section we combine the approximation result of Theorem 7.8 with the perturbation result of Theorem 2.3. In view of the series criterion (2.6) of the factorization method, we need to consider the self-adjoint operator $(\Lambda - \Lambda_0)_\sharp$ instead of $\Lambda - \Lambda_0$. However, if $(\Sigma_M - \Sigma_{0M})\tilde{P}_M^E$ approaches $\Lambda - \Lambda_0$ in $\mathcal{L}(L^2_\diamond(\partial\Omega))$, then $((\Sigma_M - \Sigma_{0M})\tilde{P}_M^E)_\sharp$ approaches $(\Lambda - \Lambda_0)_\sharp$ in $\mathcal{L}(L^2_\diamond(\partial\Omega))$, as the following result shows.

Proposition 8.1. *Under the assumptions and notation of Theorem* 7.8*,*

$$\left\|(\Lambda - \Lambda_0)_\sharp - \big((\Sigma_M - \Sigma_{0M})P_M^E\big)_\sharp\right\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} \le C(2 + |\ln\delta_M|)\delta_M \to 0 \quad \textit{as } M \to \infty.$$

Proof. The proof uses the following estimate of Vainikko [28]. If $A, B \in \mathcal{L}(H)$ are bounded operators on a Hilbert space H and $\|A - B\| \le \varepsilon$, then

$$(8.1)\qquad \||A|^p - |B|^p\| \le C_p(1 + |\ln\varepsilon|)\varepsilon^{\min(1,p)} \quad \text{for any real } p > 0.$$

We abbreviate $A = \Lambda - \Lambda_0$ and $B_M = (\Sigma_M - \Sigma_{0M})\tilde{P}_M^E$ and observe that

$$\begin{aligned}\|\operatorname{Re} A - \operatorname{Re} B_M\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} &= \frac{1}{2}\|A + A^* - (B_M + B_M^*)\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))}\\ &\le \|A - B_M\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} \le \delta_M,\end{aligned}$$

and the same estimate also holds for $\operatorname{Im} A - \operatorname{Im} B_M$. Therefore, we can use (8.1) with $p = 1$ to estimate as follows:

$$\begin{aligned}\|A_\sharp - B_{M\sharp}\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} &\le \||\operatorname{Re} A| - |\operatorname{Re} B_M|\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} + \|\operatorname{Im}(A - B_M)\|_{\mathcal{L}(L^2_\diamond(\partial\Omega))} \\ &\le C_1(1 + |\ln(\delta_M)|)\delta_M + \delta_M \le \max(C_1, 1)\,(2 + |\ln(\delta_M)|)\delta_M.\end{aligned}$$

It holds that $|\ln(\delta_M)|\delta_M \to 0$ as $M \to \infty$ since δ_M is a zero sequence. Hence, $B_{M\sharp}$ approximates $A_\sharp$ if B_M approximates A. □

The $L^2_\diamond(\partial\Omega)$ estimate of the preceding proposition enables to us to use the material from section 2 to construct a factorization method for the complete electrode model. The idea is to approximate the infinite series (2.6) using the eigenvalues λ_j^M and eigenvectors ψ_j^M of $((\Sigma_M - \Sigma_{0M})\tilde{P}_M^E)_\sharp$.

THEOREM 8.2. *Let $\omega \in (0, 1/2)$ and $C > 0$ be arbitrary, but fixed, parameters, and consider the finite-dimensional operators $(\Sigma_M - \Sigma_{0M})\tilde{P}_M^E \in \mathcal{L}(L^2_\diamond(\partial\Omega))$, $M \in \mathbb{N}$. We denote by $(\lambda_j^{(M)}, \psi_j^{(M)})_{j\in\mathbb{N}}$ an eigensystem of $((\Sigma_M - \Sigma_{0M})\tilde{P}_M^E)_\sharp$ and define the truncation index $R(M)$ according to* (2.8), *with the noise level ε_M set as*

$$\varepsilon_M := C(2 + |\ln \delta_M|)\delta_M, \quad M \in \mathbb{N},$$

where C is the constant from Proposition 8.1 *and δ_M is defined as in Theorem* 7.8. *Then the sequence*

$$M \mapsto \sum_{j=1}^{R(M)} \frac{|\langle \varphi_y, \psi_j^{(M)}\rangle|^2}{\lambda_j^{(M)}}, \quad M \in \mathbb{N},$$

is bounded if and only if $y \in \Omega_c$.

In the following section, we will demonstrate that Theorem 8.2 is not only of theoretical interest; it can also lead to practical reconstruction algorithms.

9. Numerical experiments.

In this section, we present numerical experiments that implement a simplified version of the series criterion of Theorem 8.2 with simulated electrode data. Although the theoretical results of this paper have been formulated in three spatial dimensions (but note Remark 7.7), the numerical tests are carried out in two dimensions: Our object of interest Ω is an isotropic unit square characterized by unit background admittance and unit contact impedance. Moreover, there are sixteen electrodes that cover 44 percent of $\partial\Omega$. We consider two different inclusion geometries: Ω is contaminated in the first test by one kite-shaped inclusion and, in the second test, by a kite-shaped inclusion and a circular inhomogeneity. The admittance inside the inclusions is two. Our experimental settings are exactly the ones used in the third and the fourth numerical tests of [17], where the reader can find the precise details on the measurement geometry, the computation of the forward data, and the simulation of the measurement noise. This arrangement also gives the reader an opportunity to compare the series criterion and the factorization-type algorithm of [17] in a straightforward manner. More extensive studies on numerical implementation of factorization-type algorithms for different electrode models can be found in [14, 17].

The test functions φ_y, defined on the boundary of the unit square, are computed with the help of a suitable analytic map and the known functional form of the test functions in the unit disk [3, 5, 17]. To be more precise, we introduce

$$\tilde{\varphi}_y(x) = \tilde{\varphi}_{y,b}(x) := \frac{1}{\pi}\frac{(y - x)\cdot b}{|y - x|^2}, \quad |x| = 1,\ |y| < 1,\ b \in \mathbb{R}^2, \tag{9.1}$$

and let $\eta : \Omega \to \{z \in \mathbb{R}^2 \mid |z| < 1\}$ be a bijective analytic function whose derivative does not vanish anywhere on Ω. We set

$$\varphi_y = \tilde{\varphi}_{\eta(y)} \circ \eta + c,$$

where the constant c is chosen in such a way that φ_y integrates to zero over $\partial\Omega$. We compute the auxiliary test functions $\tilde{\varphi}_{y,b}$, $|y| < 1$, with a fixed dipole moment b, which results in $\varphi_y = \varphi_{y,a}$, where the dipole moment $a \in \mathbb{R}^2$ (see (2.4)) depends on the probe location $y \in \Omega$ through η (cf. [3, 17]). The analytic mapping η needed above is provided by the Schwarz–Christoffel toolbox for MATLAB [10].

Using the notation of Theorem 8.2, we define a preliminary indicator function through

$$\alpha_{R,b}(y) = \sum_{j=1}^{R} \frac{|\langle \varphi_y, \psi_j \rangle|^2}{\lambda_j} \Big/ \sum_{j=1}^{R} |\langle \varphi_y, \psi_j \rangle|^2, \quad y \in \Omega, \ 1 \leq R \leq 15, \tag{9.2}$$

where b is the dipole moment in the unit disk (see (9.1)) and we have left out the parameter M appearing in the formulae of Theorem 8.2 since the electrode configuration is fixed. Take note that we have introduced the normalizing factor $\sum_{j=1}^{R} |\langle \varphi_y, \psi_j \rangle|^2$ in the denominator of (9.2) since one is ultimately interested in the shape of the test function φ_y and not in its magnitude; it is easy to check that all above theoretical results remain valid if φ_y is replaced by $\varphi_y / \|\varphi_y\|_{L^2(\partial\Omega)}$. In order to average out artifacts, we take the mean of $\alpha_{R,b}(y)$ over three dipole moments:

$$\alpha_R(y) = \frac{1}{3} \sum_{k=0}^{2} \alpha_{R,b_k}(y), \quad y \in \Omega,$$

where $b_k = (\cos(2\pi k/3), \sin(2\pi k/3))$.

For visualization purposes, i.e., to obtain better contrast, we introduce one more indicator function, namely,

$$\operatorname{ind}(y) = \frac{1}{\alpha_R(y)}, \quad y \in \Omega.$$

The reconstructions of Figures 9.1 and 9.2 were obtained by plotting ind over Ω. Theorem 8.2 suggests that $\alpha_R(y)$ is probably larger when $y \in \Omega \setminus D$ than when $y \in D$ if $1 \leq R \leq 15$ is chosen suitably. Hence, $\operatorname{ind}(y)$ should be larger when $y \in D$ than when $y \in \Omega \setminus D$.

In both tests, we use three different noise levels: $\varepsilon = 0$, 2×10^{-4}, and 2×10^{-3} (cf. [17]). For the noiseless cases the cut-off parameter is chosen to be $R = 12$. When working with noisy resistivity matrices, we use a significantly simplified and less conservative version of (2.8): Since the admittances are real and the inclusions are more conductive than the background, the operator $\Sigma - \Sigma_0$ is self-adjoint and negative definite [15]. In particular, it holds that $((\Sigma - \Sigma_0)\tilde{P}^E)_\sharp = (\Sigma_0 - \Sigma)\tilde{P}^E$. When noise is added to Σ (cf. [17]), some eigenvalues of $\Sigma_0 - \Sigma$ may become negative. We choose the cut-off parameter R and rearrange the eigenvalues if necessary, so that the eigenvectors corresponding to the negative eigenvalues of the noisy $\Sigma_0 - \Sigma$ do not contribute to (9.2). In the first experiment, this approach produced the cut-off parameters $R = 11$ and 8 for the noise levels $\varepsilon = 2 \times 10^{-4}$ and 2×10^{-3}, respectively. In the second test, the corresponding values were $R = 10$ and 9. Notice that different realizations of measurement noise produce different cut-off parameters.

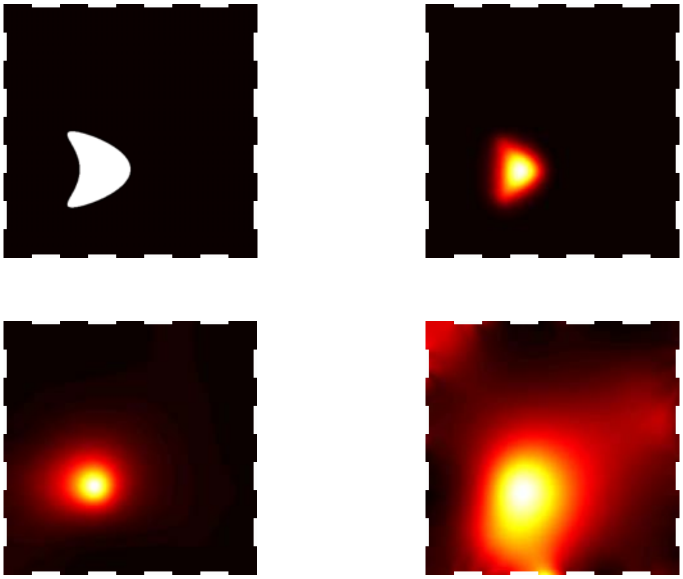

Fig. 9.1. *The first experiment. The parameters ε and R represent the noise level and the spectral cut-off, respectively. Top left: The inclusion support. Top right: $\varepsilon = 0$ and $R = 12$. Bottom left: $\varepsilon = 2 \times 10^{-4}$ and $R = 11$. Bottom right: $\varepsilon = 2 \times 10^{-3}$ and $R = 8$.*

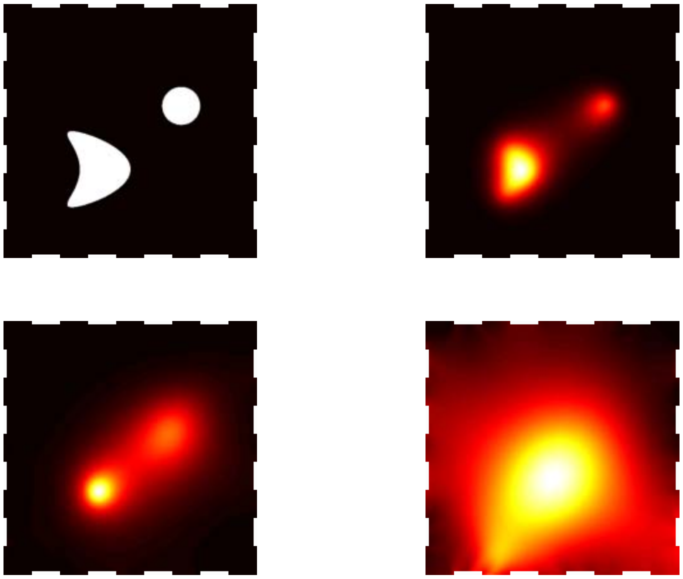

Fig. 9.2. *The second experiment. The parameters ε and R represent the noise level and the spectral cut-off, respectively. Top left: The inclusion support. Top right: $\varepsilon = 0$ and $R = 12$. Bottom left: $\varepsilon = 2 \times 10^{-4}$ and $R = 10$. Bottom right: $\varepsilon = 2 \times 10^{-3}$ and $R = 9$.*

The findings of the first numerical experiment, where Ω contains one kite-shaped inclusion, are presented in Figure 9.1, and the reconstructions of the second experiment, where Ω is contaminated by a kite-shaped inclusion and a circular inhomogeneity, are shown in Figure 9.2. As the figures illustrate, the noiseless reconstructions capture the shapes and the locations of the inclusions quite well. When $\varepsilon = 2 \times 10^{-4}$, the function ind : $\Omega \to \mathbb{R}$ still provides information on the whereabouts of the inhomogeneities. Unfortunately, with the highest noise level $\varepsilon = 2 \times 10^{-3}$, the reconstructions are badly blurred and their information content is rather low. We conclude that the above-described simplified version of the method implicated by Theorem 8.2 provides useful information on the inclusions if the signal to noise ratio of the measurements is not too low.

The quality of our reconstructions is approximately the same as of those obtained by a factorization-type algorithm in [17]. However, the above-introduced algorithm has a slight advantage in the noisy case: Its regularization parameter, i.e., the spectral cut-off R, is chosen in a systematic way by looking at the measurement data. The algorithm used in [14], even more notably, has this advantageous property but lacks the asymptotic analysis, which is provided for the series criterion by this work, and it has not been properly studied within the complete electrode model.

FINGERING FROM IONIZATION FRONTS IN PLASMAS*

MANUEL ARRAYÁS†, SANTIAGO BETELÚ‡, MARCO A. FONTELOS§, AND JOSÉ L. TRUEBA†

Abstract. In this paper we describe the formation of fingers from ionization fronts for a hydrodynamic plasma model. The fingers result from a balance between the destabilizing effect of impact ionization and the stabilizing effect of electron diffusion on ionization fronts. We show that electron diffusion acts as an effective surface tension on moving fronts and we estimate analytically the size of the fingers and its dependence on both the electric field and electron diffusion coefficient. We perform direct numerical simulation of the model and compute finger-like traveling waves analogous to structures such as Saffman–Taylor fingers and Ivantsov paraboloid in the context of Hele–Shaw and Stefan problems, respectively.

Key words. ionization fronts, fingering instabilities, plasmas, pattern formation

1. Introduction.

Lightning is a stream of electrified air, known as plasma. Charged particles are bound in the air by powerful electric forces to form electrically neutral atoms and molecules. As a result, the air is an excellent insulator. This means that if we apply an electric field to a volume filled with neutral particles, electric currents will not flow. However, if a very strong electric field is applied to matter of low conductivity and some electrons or ions are created, then the few mobile charges can generate an avalanche of more charges by impact ionization. A low temperature plasma is created, resulting in an electric discharge. The change in the properties of a dielectric that causes it to become conductive is known as electric breakdown. Breakdown is a threshold process: no changes in the state of the medium are noticeable while the electric field across a discharge gap is gradually increased but, suddenly, at a certain value of the electric field, a current is detected.

Discharges can assume different appearances depending on the characteristics of the electric field and the properties of the medium. Phenomenologically, discharges can be classified into stationary ones, such as arc, glow, or dark discharges, and transient ones, such as sparks and leaders [18].

At atmospheric pressure and at distances over 1 cm between anode and cathode, the discharge channels are sharp and narrow, and we have a streamer discharge. A streamer is a sharp ionization wave that propagates into a nonionized gas, leaving a nonequilibrium plasma behind. Streamers have been also reported in early stages of atmospheric discharges [15, 17]. They can split into branches spontaneously, but how this branching is determined by the underlying physics is one of the greatest unsolved problems in the physics of electric discharges. The pattern of this branching resembles

the ones observed in the propagation of cracks, dendritic growth and viscous fingering. Those phenomena are known to be governed by deterministic equations rather than by stochastic events. In this paper, we extend and generalize the results announced in [8] and implement direct numerical simulations of these deterministic models.

1.1. The minimal model for streamers. We consider a fluid description of a low-ionized plasma. The electron density N_e^d varies in time as

$$\frac{\partial N_e^d}{\partial \tau^d} + \nabla_{\mathbf{R}}^d \cdot \mathbf{J}_e^d = S_e^d. \tag{1.1}$$

In this expression, the superscript d means that the quantity has physical dimensions so that τ^d is the physical time, $\nabla_{\mathbf{R}}^d$ is the gradient operator, S_e^d is the source term, i.e., the net creation rate of electrons per unit volume, and

$$\mathbf{J}_e^d(\mathbf{R}^d, \tau^d) = N_e^d(\mathbf{R}^d, \tau^d)\, \mathbf{U}_e^d(\mathbf{R}^d, \tau^d)$$

is the electron current density, with $\mathbf{U}_e^d$ being the average velocity of electrons. Similar expressions can be obtained for positive N_p^d and negative N_n^d ion densities. On timescales of interest for the case of negative streamers, the ion currents can be neglected because they are more than two orders of magnitude smaller than the electron one, so we will take

$$\frac{\partial N_p^d}{\partial \tau^d} = S_p^d, \tag{1.2}$$

$$\frac{\partial N_n^d}{\partial \tau^d} = S_n^d, \tag{1.3}$$

with $S_{p,n}^d$ being source terms for positive and negative ions. Conservation of charge has to be imposed in all processes so that the condition $S_p^d = S_e^d + S_n^d$ holds.

A usual procedure is to approximate the electron current $\mathbf{J}_e^d$ as the sum of a drift (electric force) and a diffusion term

$$\mathbf{J}_e^d = -\mu_e \boldsymbol{\mathcal{E}}^d N_e^d - D_e^d \nabla_{\mathbf{R}}^d N_e^d, \tag{1.4}$$

where $\boldsymbol{\mathcal{E}}^d$ is the total electric field (the sum of the external electric field applied to initiate the propagation of a ionization wave and the electric field created by the local point charges) and μ_e^d and D_e^d are the mobility and diffusion coefficients of the electrons. Note that, as the initial charge density is low and there is no applied magnetic field, the magnetic effects in (1.4) are neglected. In principle, the diffusion coefficient is not completely determined but, in the case of equilibrium, diffusion is linked to mobility through the Einstein relation $D_e^d/\mu_e = kT/e$, with k being the Boltzmann constant, T the temperature, and e the absolute value of the electron charge.

Several physical processes can be considered to give rise to the source terms $S_{e,p,n}^d$. The most important of them are impact ionization (an accelerated electron collides with a neutral molecule and ionizes it), attachment (an electron may become attached when it collides with a neutral gas atom or molecule, forming a negative ion), recombination (of a free electron with a positive ion or a negative ion with a positive ion), and photoionization (when photons created by recombination or scattering processes interact with a neutral atom or molecule, producing a free electron and a positive ion; see [7] and references therein).

A model to describe streamers is obtained when explicit expressions for the source terms, the electron mobility μ_e, and the diffusion coefficient D_e^d are provided. It is also necessary to impose equations for the evolution of the electric field $\boldsymbol{\mathcal{E}}^d$. It is usual to consider that this evolution is given by Poisson's law,

$$\nabla_{\mathbf{R}}^d \cdot \boldsymbol{\mathcal{E}}^d = \frac{e}{\varepsilon_0} \left(N_p^d - N_n^d - N_e^d \right), \tag{1.5}$$

where ε_0 is the permittivity of the gas and we are assuming that the absolute value of the charge of positive and negative ions is e.

A simplification occurs when the streamer development out of a macroscopic initial ionization seed is considered in a nonattaching gas such as argon or nitrogen [12]. In this case, attachment, recombination, and photoionization processes can be neglected. As a consequence, the negative ion density N_n^d can be considered constant. The balance equations turn out to be

$$\frac{\partial N_e^d}{\partial \tau^d} = \nabla_{\mathbf{R}}^d \cdot \left(\mu_e \boldsymbol{\mathcal{E}}^d N_e^d + D_e^d \nabla_{\mathbf{R}}^d N_e^d \right) + \nu_i N_e^d, \tag{1.6}$$

$$\frac{\partial N_p^d}{\partial \tau^d} = \nu_i N_e^d. \tag{1.7}$$

This is called the minimal streamer model for a nonattaching gas. In these equations, $\nu_i N_e^d$ is a model for the impact ionization source term, in which the ionization coefficient ν_i is given by the phenomenological Townsend's approximation,

$$\nu_i = \mu_e |\boldsymbol{\mathcal{E}}^d| \alpha_0 e^{-\mathcal{E}_0 / |\boldsymbol{\mathcal{E}}^d|}, \tag{1.8}$$

where α_0 is the inverse of ionization length. The ionization length is the distance, on average, that a free electron travels before ionizing a molecule. The value of α_0 is proportional to the pressure of the ambient gas according to Townsend's theory [9]. $\mathcal{E}_0$ is the characteristic impact ionization electric field.

Townsend's approximation provides physical scales and intrinsic parameters for the model as long as only impact ionization is present in the gas. It is then convenient to reduce the equations to a dimensionless form. The natural units for nitrogen are functions of the gas pressure p (in bars). These units are the ionization length

$$R_0 = \frac{1}{\alpha_0} = 2.3 \times 10^{-6}\,\mathrm{m} \left(\frac{p}{1\,bar} \right)^{-1}, \tag{1.9}$$

as a length unit, the characteristic impact ionization field

$$\mathcal{E}_0 = 2 \times 10^7\,\mathrm{V/m} \left(\frac{p}{1\,bar} \right), \tag{1.10}$$

as an electric field unit, and the electron mobility

$$\mu_e = 3.8 \times 10^{-2}\,\mathrm{m}^2/(\mathrm{V} \cdot \mathrm{s}) \left(\frac{p}{1\,bar} \right)^{-1}, \tag{1.11}$$

as a unit of velocity divided by electric field. These natural units lead to the velocity scale

$$U_0 = \mu_e \mathcal{E}_0 = 7.6 \times 10^5\,\mathrm{m/s}, \tag{1.12}$$

the time scale

$$\tau_0 = \frac{R_0}{U_0} = 3 \times 10^{-12}\,\mathrm{s}\,\left(\frac{p}{1\,bar}\right)^{-1}, \tag{1.13}$$

the particle density scale

$$N_0 = \frac{\varepsilon_0 \mathcal{E}_0}{eR_0} = 4.7 \times 10^{20}\,\mathrm{m}^{-3}\,\left(\frac{p}{1\,bar}\right)^{2}, \tag{1.14}$$

and the electron diffusion scale

$$D_0 = R_0 U_0 = 1.8\,\mathrm{m}^2/\mathrm{s}\,\left(\frac{p}{1\,bar}\right)^{-1}. \tag{1.15}$$

We introduce the dimensionless variables $\mathbf{r} = \mathbf{R}^d/R_0$, $\tau = \tau^d/\tau_0$, the dimensionless field $\boldsymbol{\mathcal{E}} = \boldsymbol{\mathcal{E}}^d/\mathcal{E}_0$, the dimensionless electron and positive ion particle densities $N_e = N_e^d/N_0$ and $N_p = N_p^d/N_0$, and the dimensionless diffusion constant $D_e = D_e^d/D_0$.

The dimensionless minimal model reads

$$\frac{\partial N_e}{\partial \tau} = \nabla \cdot (N_e \boldsymbol{\mathcal{E}} + D_e\,\nabla N_e) + N_e |\boldsymbol{\mathcal{E}}| e^{-1/|\boldsymbol{\mathcal{E}}|}, \tag{1.16}$$

$$\frac{\partial N_p}{\partial \tau} = N_e |\boldsymbol{\mathcal{E}}| e^{-1/|\boldsymbol{\mathcal{E}}|}, \tag{1.17}$$

$$N_p - N_e = \nabla \cdot \boldsymbol{\mathcal{E}}. \tag{1.18}$$

This model exhibits spontaneous branching of the streamers, as indicated by numerical simulations [4], in agreement with experimental situations [17]. In order to understand this branching, Arrayás and Ebert [5] derived the dispersion relation for transversal Fourier-modes of planar negative shock fronts without diffusion (D_e). For perturbations of small wave number k, the planar shock front becomes unstable with a linear growth rate proportional to k. It has been also shown that all the modes with large enough wave number k (small wave length perturbations) grow at the same rate (the growth rate does not depend on k when k is large). However, it could be expected from the physics of the problem that a particular mode would be selected. To address this problem, we consider in this paper the effect of diffusion.

1.2. Outline of this paper. Our analysis will show that the electron density N_e may develop sharp fronts of thickness $O(\sqrt{D_e})$. Moreover, it satisfies an equation analogous to the Fisher equation, which is a well-known model in some biological contexts (see [14]). A surprising fact established during the last 30 years is that the combination of sharp interfaces with small diffusive effects may result in asymptotic limits (for $D_e \ll 1$) in which the motion of the interface is described by equations involving solely geometrical properties such as its mean curvature. A pioneer attempt to achieve such a description is due to Allen and Cahn [2] and concerns a model, today known as the Allen–Cahn equation, for the kinetics of melted Fe-Al alloys. Subsequent work by Rubinstein, Sternberg, and Keller [19] showed that the points of the interface separating both species move along the normal direction with a velocity proportional to its mean curvature. This kind of dynamics is termed "mean curvature flow." Many mathematicians have contributed to providing a rigorous proof of the convergence of the Allen–Cahn model to motion by mean curvature. These ideas have also been extended to some other, rather different, contexts. An improvement of the above model is the so-called Cahn–Hilliard model [10], described by a fourth order differential equation. This model leads to an asymptotic limit given by the motion of sharp interfaces in the Hele–Shaw (or Mullins–Sekerka) problem for the evolution of a fluid between two plates separated by a small distance [1]. A biological model consisting of reaction-diffusion equations [11] for competing species separated by a sharp interface gives rise to a limiting problem similar to the Stefan problem for phase transformation (for example, ice solidifying water). Remarkably, some of these limiting models have solutions that develop branch-like patterns, such as fingers in Hele–Shaw or dendrites in the Stefan problem.

In this paper we exploit some of the ideas introduced in the references above in order to study the motion of ionization fronts. We will show that a planar front separating a partly ionized region from a region without charge is affected by two opposing effects: electrostatic repulsion of electrons and electron diffusion. The first effect tends to destabilize the front, while the second acts effectively as a mean curvature contribution to the velocity of the front that stabilizes it. The net result is the appearance of fingers with a characteristic thickness determined by the balance of these two opposing actions. The common underlying mathematical structure among the minimal streamer model and other pattern-forming systems such as the Hele–Shaw and Stefan problems strongly suggests that the basic mechanisms governing important phenomena such as the development of complex patterns through branching of single "fingers" should be very similar.

2. Streamer evolution in strong electric fields. In order to study the evolution and branching of ionization fronts, we consider the following experimental situation. The space between two plates is filled with a nonattaching gas such as nitrogen. A stationary potential difference is applied to these plates so that an electric field is produced in the gas. The electric field is directed from the anode to the cathode. To initiate the avalanche, an initial seed of ionization is set near the cathode. We study the evolution of negative ionization fronts towards the anode.

We will assume that the distance between the cathode and the anode is much larger than the space scale R_0 (in experiments, this distance is more than one thousand times larger than R_0) so that we can consider the anode to be at an infinite distance from the initial seed of ionization. Moreover, we will concentrate on the study of the dynamics under the effect of strong external electric fields, which are larger than the electric field unit $\mathcal{E}_0$. This means that the modulus of the dimensionless electric field $|\boldsymbol{\mathcal{E}}|$ is larger than 1. Strictly speaking, if we denote by $\mathcal{E}_\infty$ the modulus of the dimensionless electric field at large distance from the cathode, we will assume that $\mathcal{E}_\infty \gg 1$. Under these circumstances, it is natural to rescale the dimensionless quantities in the minimal model as

$$\boldsymbol{\mathcal{E}} = \mathcal{E}_\infty \, \mathbf{E}, \tag{2.1}$$

$$N_e = \mathcal{E}_\infty \, n_e, \tag{2.2}$$

$$N_p = \mathcal{E}_\infty \, n_p, \tag{2.3}$$

$$\tau = \frac{t}{\mathcal{E}_\infty}, \tag{2.4}$$

so that we have

$$\frac{\partial n_e}{\partial t} - \nabla \cdot (n_e \mathbf{E} + D \, \nabla n_e) = n_e |\mathbf{E}| e^{-1/(\mathcal{E}_\infty |\mathbf{E}|)}, \tag{2.5}$$

$$\frac{\partial n_p}{\partial t} = n_e |\mathbf{E}| e^{-1/(\mathcal{E}_\infty |\mathbf{E}|)}, \tag{2.6}$$

$$\nabla \cdot \mathbf{E} = n_p - n_e, \tag{2.7}$$

where

$$D = \frac{D_e}{\mathcal{E}_\infty} \tag{2.8}$$

is, in general, a small parameter. For $\mathcal{E}_\infty \gg 1$, this system can be approximated by

$$\frac{\partial n_e}{\partial t} - \nabla \cdot (n_e \mathbf{E} + D \, \nabla n_e) = n_e |\mathbf{E}|, \tag{2.9}$$

$$\frac{\partial n_p}{\partial t} = n_e |\mathbf{E}|, \tag{2.10}$$

$$\nabla \cdot \mathbf{E} = n_p - n_e. \tag{2.11}$$

Our approximation will be valid in all regions where $\mathcal{E}_\infty |\mathbf{E}| \gg 1$. These are the regions of interest in the situations studied in this paper since by (2.11) the intensity of the electric field varies continuously as long as n_e and n_p are bounded, and hence should not vary much in the neighborhood of the ionization front. We will show that this is indeed the case and it is in this region that the mechanisms leading to branching occur.

3. Planar fronts.

We will concentrate on the planar case. Experimentally, this means that we have two large planar plates situated at $x = 0$ (cathode) and $x = d$ (anode), respectively (x is the horizontal axis and we suppose that $d \gg 1$). The space between the plates is filled with a nonattaching gas such as nitrogen. A stationary electric potential difference is applied to the plates so that an electric field is produced in the gas. The initial electric field is directed from the anode to the cathode and is uniform in the space between the plates with a value $\mathcal{E}_\infty \gg 1$. As in this section we are interested in the evolution of the ionization wave along the x axis, the rescaled electric field can be written as $\mathbf{E} = E\mathbf{u}_x$, where $E < 0$ so that $|\mathbf{E}| = |E| = -E$, and $\mathbf{u}_x$ is a unitary vector in the x direction. We are left then with the following system:

$$\frac{\partial n_e}{\partial t} = \frac{\partial}{\partial x}\left(n_e E + D \frac{\partial n_e}{\partial x} \right) + n_e |E|, \tag{3.1}$$

$$\frac{\partial n_p}{\partial t} = n_e |E|, \tag{3.2}$$

$$\frac{\partial E}{\partial x} = n_p - n_e. \tag{3.3}$$

3.1. The traveling waves with $D = 0$.

It is very simple to compute traveling wave solutions when $D = 0$. In this case, the equation for the evolution of the electron density is

$$\frac{\partial n_e}{\partial t} = \frac{\partial (n_e E)}{\partial x} - n_e E. \tag{3.4}$$

Subtracting (3.1) from (3.2) with $D = 0$, and taking the time derivative of (3.3), we obtain the equation

$$\frac{\partial^2 E}{\partial x \partial t} + \frac{\partial}{\partial x}(n_e E) = 0. \tag{3.5}$$

Integrating this expression once in x, one obtains

$$\frac{\partial E}{\partial t} + n_e E = C(t), \tag{3.6}$$

where $C(t)$ can be fixed by the boundary conditions at infinity, $E \to -1$ and $n_e \to 0$. This implies $C(t) = 0$ so that

$$\frac{\partial E}{\partial t} = -n_e E. \tag{3.7}$$

In physical terms, the left-hand side of (3.6), due to Ampére's law, is the curl of the magnetic field which is zero because the magnetic effects are neglected in the framework of the minimal model.

We look for traveling wave solutions of the system (3.4)–(3.7), introducing the ansatz

$$n_e = f(x-ct), \; E = -g(x-ct) \tag{3.8}$$

into the above system. The minus sign in the electric field is due to the fact that the electric field is negative, so g is a positive function. Introducing (3.8) into (3.4) and (3.7), we obtain

$$-c\frac{df}{d\xi} = \frac{d}{d\xi}(fg) + fg, \tag{3.9}$$

$$c\frac{dg}{d\xi} = fg. \tag{3.10}$$

Introducing $dg/d\xi$ given by (3.10) into (3.9), we obtain an equation for $df/d\xi$, and hence we obtain the following system of ODEs:

$$\frac{df}{d\xi} = \frac{-fg + \frac{1}{c}f^2 g}{c-g}, \tag{3.11}$$

$$\frac{dg}{d\xi} = \frac{1}{c}fg, \tag{3.12}$$

where $\xi = x - ct$. This system can be explicitly solved by noticing that

$$\frac{df}{dg} = -\frac{c-f}{c-g} \tag{3.13}$$

so that

$$(c-f)(c-g) = c(c-1), \tag{3.14}$$

with the constant $c(c-1)$ being given by conditions at $\xi \to \infty$, namely, that the electron density vanishes and the electric field is equal to -1 there. Therefore,

$$\frac{dg}{d\xi} = \frac{g(1-g)}{c-g}, \tag{3.15}$$

allowing direct integration to yield the implicit solution (up to translations in ξ),

$$c\log g + (1-c)\log(1-g) = \xi. \tag{3.16}$$

This expression yields solutions for any $c \geq 1$. We will be interested in the limit $c \to 1$ since it is well known [6] that compactly supported initial data (representing a seed

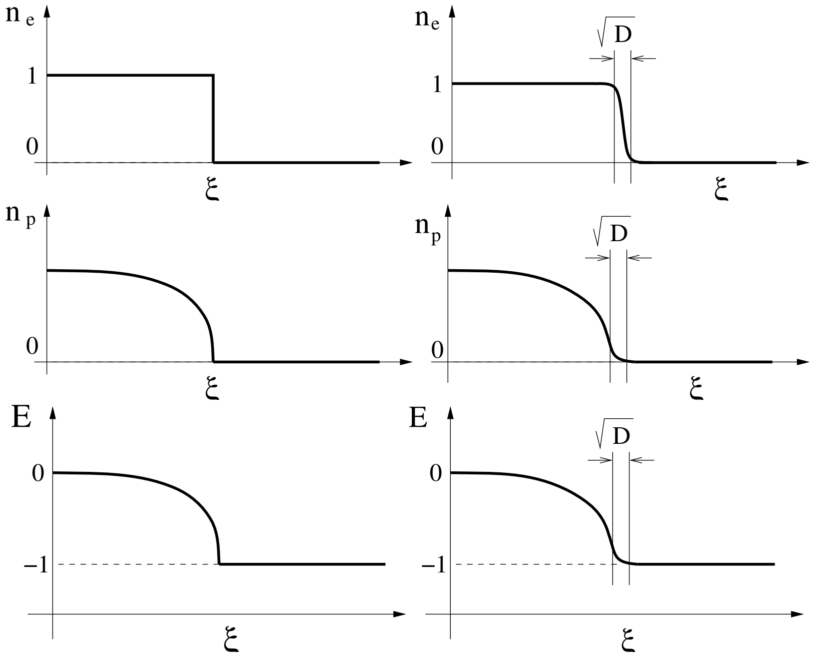

FIG. 1. *The moving fronts with $D = 0$ and $c = 1$. The moving fronts when $0 < D \ll 1$ and $c = 1 + 2\sqrt{D}$.*

of ionization located in some region) develop fronts traveling with this velocity. In the case $c = 1$ the solution can be obtained straightforwardly, giving

$$g(\xi) = \begin{cases} e^{\xi}, & \text{for } \xi < 0, \\ 1, & \text{for } \xi \geq 0, \end{cases} \quad f(\xi) = \begin{cases} 1, & \text{for } \xi < 0, \\ 0, & \text{for } \xi \geq 0. \end{cases} \tag{3.17}$$

We can also find the solution for the positive ion density n_p in the case $c = 1$. Taking $n_p = h(x - t)$, we have

$$h(\xi) = \begin{cases} 1 - e^{\xi} \text{ for } \xi < 0, \\ 0 \text{ for } \xi \geq 0. \end{cases} \tag{3.18}$$

This solution for n_e represents a shock front moving with velocity $c = 1$ (see Figure 1).

3.2. The traveling waves with $D \neq 0$. We proceed now to investigate the traveling waves for $0 < D \ll 1$. As D is a small parameter, the traveling wave solutions for the electron and positive ion densities and the electric field are expected to be not very different to that corresponding to $D = 0$ found in the previous subsection. Consequently, we look for solutions such that n_e and n_p decay exponentially at infinity and E is also an exponentially small correction of -1 at infinity. This means that we can take

$$n_e = Ae^{-\lambda(x-ct)}, \tag{3.19}$$

$$n_p = Be^{-\lambda(x-ct)}, \tag{3.20}$$

$$E = -1 + Ce^{-\lambda(x-ct)} \tag{3.21}$$

asymptotically far behind the wave. If we introduce these expressions into (3.1) we obtain, for $x - ct \to \infty$, the relation

$$-c\lambda + \lambda + D\lambda^2 = -1, \tag{3.22}$$

which has real solutions if and only if $(c-1)^2 - 4D \geq 0$. Therefore,

$$c \geq 1 + 2\sqrt{D}. \tag{3.23}$$

All initial data decaying at infinity faster than $Ae^{-\lambda^* x}$, with $\lambda^* = 1/\sqrt{D}$, will develop traveling waves [12] with velocity $c = 1 + 2\sqrt{D}$. If $D \ll 1$, the profiles for n_p and E will vary very little from the profiles with $D = 0$. On the other hand, n_e will develop a boundary layer at the front, smoothing the jump from $n_e = 1$ to $n_e = 0$. If we write the equation for the traveling wave $n_e = f(x - (1 + 2\sqrt{D})t)$ into the expression

$$\frac{\partial n_e}{\partial t} - n_e \frac{\partial E}{\partial x} - E\frac{\partial n_e}{\partial x} - D\frac{\partial^2 n_e}{\partial x^2} = n_e|E|, \tag{3.24}$$

and we take, from (3.3), $\partial_x E = n_p - n_e$, approximating at the boundary layer $n_p = 0$, $E = -1$, we obtain the equation

$$-2\sqrt{D}\frac{\partial f}{\partial \xi} - D\frac{\partial^2 f}{\partial \xi^2} = f(1-f), \tag{3.25}$$

where $\xi = x - (1 + 2\sqrt{D})t$. Defining $\chi = \xi/\sqrt{D}$, we obtain an equation for the boundary layer,

$$-2\frac{\partial f}{\partial \chi} - \frac{\partial^2 f}{\partial \chi^2} = f(1-f), \tag{3.26}$$

together with the matching conditions,

$$f(-\infty) = 1, \; f(+\infty) = 0. \tag{3.27}$$

Expression (3.26) is the well-known equation for traveling waves of Fisher's equation. It appears in the context of mathematical biology [16] and is known to have solutions subject to (3.27). This means that we have a boundary layer of width $\sqrt{D}$ at $\xi = 0$ in which (3.26) gives the solution for the electron density n_e. Before this layer, we have $n_e \approx 1$, and after the layer, $n_e \approx 0$. When $D = 0$, this is the shock front found in the previous subsection. It will be useful to analyze the structure of n_p at the boundary layer. Introducing

$$n_p = \sqrt{D}h(\chi), \tag{3.28}$$

one obtains from (3.2) the following formula at zero order in D, with $\chi = [x - (1 + 2\sqrt{D})t]/\sqrt{D}$:

$$\frac{dh(\chi)}{d\chi} = f(\chi) \tag{3.29}$$

so that

$$h(\chi) = -\int_{\chi}^{\infty} f(z)dz. \tag{3.30}$$

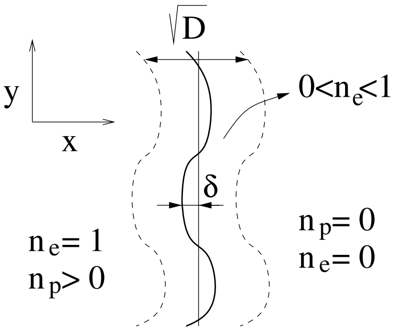

FIG. 2. *Schematic representation of the perturbed front.*

Notice that we now have

$$\frac{\partial n_p}{\partial x} = f(\chi) = O(1) \text{ at the boundary layer.} \tag{3.31}$$

Analogously, from Poisson's equation $\partial_x E = n_p - n_e$, we can deduce $E = -1 + O(\sqrt{D})$ across the boundary layer. We will write this solution as

$$E = -1 + \sqrt{D} E_{bl} + O(D). \tag{3.32}$$

These solutions can be seen in Figure 1.

4. The dispersion relation.

The planar front studied in the previous sections may be unstable with respect to perturbations on the boundary layer, which then forms "ripples" or "corrugations." Consequently, we are interested in obtaining the dispersion relation to find which transversal mode will grow faster and eventually determine the characteristic shape of the streamer. So we let the planar front that propagates in the x-direction receive a small perturbation with an initial arbitrary dependence on the transversal coordinates.

Next we introduce a perturbation in the transversal direction y (see Figure 2). We will do it by introducing a new system of coordinates in the form

$$\bar{t} = t, \tag{4.1}$$

$$\overline{y} = y, \tag{4.2}$$

$$\overline{x} = x - \delta\,\varphi(x, y, t) \tag{4.3}$$

so that, at $t = 0$, $n_e^{(0)}(\overline{x})$ and $E^{(0)}(\overline{x})$ correspond to the profiles of a traveling wave computed in the previous section, and δ is a sufficiently small parameter compared to $\sqrt{D}$. By doing this, we follow a strategy analogous to the one used in [19] to deduce the asymptotic approximation of the Allen–Cahn equation by mean curvature flow.

We can compute straightforwardly the relations between derivatives up to order δ^2,

$$\frac{\partial}{\partial x} = \frac{\partial}{\partial \overline{x}} - \delta\, \frac{\partial \varphi}{\partial x} \frac{\partial}{\partial \overline{x}}, \tag{4.4}$$

$$\frac{\partial}{\partial y} = \frac{\partial}{\partial \overline{y}} - \delta\, \frac{\partial \varphi}{\partial y} \frac{\partial}{\partial \overline{x}}, \tag{4.5}$$

$$\frac{\partial}{\partial t} = \frac{\partial}{\partial \overline{t}} - \delta\, \frac{\partial \varphi}{\partial t} \frac{\partial}{\partial \overline{x}}, \tag{4.6}$$

$$\frac{\partial^2}{\partial x^2} = \frac{\partial^2}{\partial \overline{x}^2} - \delta\, \frac{\partial^2 \varphi}{\partial x^2} \frac{\partial}{\partial \overline{x}} - 2\delta\, \frac{\partial \varphi}{\partial x} \frac{\partial^2}{\partial \overline{x}^2} + O(\delta^2), \tag{4.7}$$

$$\frac{\partial^2}{\partial y^2} = \frac{\partial^2}{\partial \overline{y}^2} - \delta\, \frac{\partial^2 \varphi}{\partial y^2} \frac{\partial}{\partial \overline{x}} - 2\delta\, \frac{\partial \varphi}{\partial y} \frac{\partial^2}{\partial \overline{x} \partial \overline{y}} + O(\delta^2). \tag{4.8}$$

We introduce the perturbed electric field and electron density as

$$\mathbf{E} = E^{(0)}\, \mathbf{u}_x + \delta \left(E_x^{(1)}\, \mathbf{u}_x + E_y^{(1)} \mathbf{u}_y \right), \tag{4.9}$$

$$n_e = n_e^{(0)} + \delta\, n_e^{(1)}, \tag{4.10}$$

$$n_p = n_p^{(0)} + \delta\, n_p^{(1)}. \tag{4.11}$$

For example, the perturbed electron density (4.10) reads

$$n_e = n_e^{(0)} \left(x - \delta \varphi(x, y, t) \right) + \delta\, n_e^{(1)}, \tag{4.12}$$

where $\varphi(x, y, t)$ is a purely geometrical perturbation and $\delta\, n_e^{(1)}$ is a perturbation of the electron density behind the front. Note that, in this sense, the kind of perturbation we are introducing is similar to the perturbations that are usually introduced in the study of the stability of other pattern-forming systems. This is the case, for instance, of the propagation of solidification fronts [13]. The difference here with respect to those other systems is the fact that our interface is not sharp but a boundary layer of thickness $\sqrt{D}$.

We shall assume here that $\varphi(x, y, 0)$ is an initial perturbation independent of x. Note, at this point, that an x-dependence of the perturbation to the electron density is allowed in the term $n_e^{(1)}$.

4.1. Equations for the corrections at first order. Inserting these expressions into (2.9), we obtain

$$\begin{aligned}
\frac{\partial n_e^{(0)}}{\partial \overline{t}} - E^{(0)} \frac{\partial n_e^{(0)}}{\partial \overline{x}} &= n_e^{(0)} |E^{(0)}| + n_e^{(0)} \left(n_p^{(0)} - n_e^{(0)} \right) \\
&\quad + D \left(1 - 2\delta\, \frac{\partial \varphi}{\partial x} \right) \frac{\partial^2 n_e^{(0)}}{\partial \overline{x}^2} \\
&\quad + \delta \left[\frac{\partial \varphi}{\partial t} + E_x^{(1)} - E^{(0)} \frac{\partial \varphi}{\partial x} - D\, \Delta_{(x,y)} \varphi \right] \frac{\partial n_e^{(0)}}{\partial \overline{x}} \\
&\quad + \delta \left(|E_x^{(1)}| + \left(n_p^{(1)} - n_e^{(1)} \right) \right) n_e^{(0)} \\
&\quad + \delta \left(- \frac{\partial n_e^{(1)}}{\partial \overline{t}} + n_e^{(1)} \left(n_p^{(0)} - n_e^{(0)} \right) + E^{(0)} \frac{\partial n_e^{(1)}}{\partial \overline{x}} + n_e^{(1)} |E^{(0)}| \right) \\
&\quad + \delta\, D\, \Delta_{(\overline{x}, \overline{y})} n_e^{(1)} + O(\delta^2),
\end{aligned} \tag{4.13}$$

where $\Delta_{(x,y)} = \partial^2/\partial x^2 + \partial^2/\partial y^2$ and $\Delta_{(\overline{x},\overline{y})} = \partial^2/\partial \overline{x}^2 + \partial^2/\partial \overline{y}^2$. From (2.10) we obtain

$$\frac{\partial n_p^{(0)}}{\partial \overline{t}} + \delta\,\frac{\partial n_p^{(1)}}{\partial \overline{t}} = n_e^{(0)}|E^{(0)}| + \delta\,\frac{\partial \varphi}{\partial t}\frac{\partial n_p^{(0)}}{\partial \overline{x}} + \delta\,|E_x^{(1)}|n_e^{(0)} + \delta\,|E^{(0)}|n_e^{(1)} + O(\delta^2), \tag{4.14}$$

and from (2.11),

$$\frac{\partial E^{(0)}}{\partial \overline{x}} + \delta\left(\frac{\partial E_x^{(1)}}{\partial \overline{x}} + \frac{\partial E_y^{(1)}}{\partial \overline{y}}\right) = n_p^{(0)} - n_e^{(0)} + \delta\left(n_p^{(1)} - n_e^{(1)}\right) + \delta\,\frac{\partial \varphi}{\partial x}\frac{\partial E^{(0)}}{\partial \overline{x}} + O(\delta^2). \tag{4.15}$$

We can construct a solution up to $O(\delta^2)$ by imposing that $O(\delta^0)$ terms and $O(\delta^1)$ terms in (4.13), (4.14), and (4.15) vanish. The $O(\delta^0)$ terms give

$$\frac{\partial n_e^{(0)}}{\partial \overline{t}} = E^{(0)}\frac{\partial n_e^{(0)}}{\partial \overline{x}} + n_e^{(0)}|E^{(0)}| + n_e^{(0)}\left(n_p^{(0)} - n_e^{(0)}\right) + D\,\frac{\partial^2 n_e^{(0)}}{\partial \overline{x}^2}, \tag{4.16}$$

$$\frac{\partial n_p^{(0)}}{\partial \overline{t}} = n_e^{(0)}|E^{(0)}|, \tag{4.17}$$

$$\frac{\partial E^{(0)}}{\partial \overline{x}} = n_p^{(0)} - n_e^{(0)}, \tag{4.18}$$

and the $O(\delta^1)$ terms give

$$\begin{aligned} 0 = {} & \left[\frac{\partial \varphi}{\partial \overline{t}} + E_x^{(1)} - E^{(0)}\frac{\partial \varphi}{\partial \overline{x}} - D\,\Delta_{(\overline{x},\overline{y})}\varphi\right]\frac{\partial n_e^{(0)}}{\partial \overline{x}} \\ & -2D\,\frac{\partial \varphi}{\partial \overline{x}}\frac{\partial^2 n_e^{(0)}}{\partial \overline{x}^2} + \left(|E_x^{(1)}| + n_p^{(1)} - n_e^{(1)}\right)n_e^{(0)} \\ & -\frac{\partial n_e^{(1)}}{\partial \overline{t}} + n_e^{(1)}\left(n_p^{(0)} - n_e^{(0)}\right) + E^{(0)}\frac{\partial n_e^{(1)}}{\partial \overline{x}} + n_e^{(1)}|E^{(0)}| \\ & +D\,\Delta_{(\overline{x},\overline{y})}n_e^{(1)}, \end{aligned} \tag{4.19}$$

$$0 = \frac{\partial n_p^{(1)}}{\partial \overline{t}} + \frac{1}{1+2\sqrt{D}}\frac{\partial \varphi}{\partial \overline{t}}n_e^{(0)} - |E_x^{(1)}|n_e^{(0)} - |E^{(0)}|n_e^{(1)}, \tag{4.20}$$

$$0 = \frac{\partial E_x^{(1)}}{\partial \overline{x}} + \frac{\partial E_y^{(1)}}{\partial \overline{y}} - \left(n_p^{(1)} - n_e^{(1)}\right) - \frac{\partial \varphi}{\partial \overline{x}}\left(n_p^{(0)} - n_e^{(0)}\right), \tag{4.21}$$

in which we have replaced, at order δ, derivatives with respect to x by derivatives with respect to $\overline{x}$, used (4.18) to replace $\partial E^{(0)}/\partial \overline{x}$ by $n_p^{(0)} - n_e^{(0)}$, and used (4.17), (3.29), and (3.30) to replace $\partial n_p^{(0)}/\partial \overline{x}$ by

$$\frac{\partial n_p^{(0)}}{\partial \overline{x}} = \frac{-1}{1+2\sqrt{D}}\frac{\partial n_p^{(0)}}{\partial \overline{t}} = \frac{-1}{1+2\sqrt{D}}n_e^{(0)}. \tag{4.22}$$

The solution of the system given by (4.16), (4.17), and (4.18) is the traveling wave found in the previous section so that

$$n_e^{(0)} = f(\overline{\xi}), \tag{4.23}$$

where $\overline{\xi} = \overline{x} - c\overline{t}$.

In order to analyze the system (4.19)–(4.21), we introduce changes of coordinates in two stages: first, we change coordinates into a frame in which the planar front remains stationary and, second, we rescale coordinates in the boundary layer in order to make it of $O(1)$ size.

The first change of coordinates is of the form

$$x' = \overline{x} - c\overline{t},\ y' = \overline{y},\ t' = \overline{t}, \tag{4.24}$$

where $c = 1 + 2\sqrt{D}$. Hence, the system (4.19)–(4.21) transforms into

$$\begin{aligned} 0 = &\left[\frac{\partial \varphi}{\partial t'} + E_x^{(1)} - D\,\Delta_{(x',y')}\varphi\right]\frac{\partial n_e^{(0)}}{\partial x'} - (E^{(0)}+c)\frac{\partial \varphi}{\partial x'}\frac{\partial n_e^{(0)}}{\partial x'} \\ &-2D\,\frac{\partial \varphi}{\partial x'}\frac{\partial^2 n_e^{(0)}}{\partial x'^2} + \left(|E_x^{(1)}| + n_p^{(1)}\right)n_e^{(0)} - \frac{\partial n_e^{(1)}}{\partial t'} + (E^{(0)}+c)\frac{\partial n_e^{(1)}}{\partial x'} \\ &+\left(|E^{(0)}| + n_p^{(0)} - 2n_e^{(0)}\right)n_e^{(1)} + D\,\Delta_{(x',y')}n_e^{(1)}, \end{aligned} \tag{4.25}$$

$$\begin{aligned} 0 = &\left(\frac{\partial}{\partial t'} - c\frac{\partial}{\partial x'}\right)n_p^{(1)} + \frac{1}{1+2\sqrt{D}}\left[\left(\frac{\partial}{\partial t'} - c\frac{\partial}{\partial x'}\right)\varphi\right]n_e^{(0)} \\ &-|E_x^{(1)}|n_e^{(0)} - |E^{(0)}|n_e^{(1)}, \end{aligned} \tag{4.26}$$

$$0 = \frac{\partial E_x^{(1)}}{\partial x'} + \frac{\partial E_y^{(1)}}{\partial y'} - \left(n_p^{(1)} - n_e^{(1)}\right) - \frac{\partial \varphi}{\partial x'}\left(n_p^{(0)} - n_e^{(0)}\right). \tag{4.27}$$

Second, noticing that x' is of order $\sqrt{D}$ at the boundary layer, as we saw in the previous section, we write

$$x' = \sqrt{D}\,\tilde{x},\ y' = \sqrt{D}\,\tilde{y},\ t' = \tilde{t} \tag{4.28}$$

to obtain the rescaled system

$$\begin{aligned} 0 = &\left[\frac{\partial \varphi}{\partial \tilde{t}} + E_x^{(1)} - \Delta_{(\tilde{x},\tilde{y})}\varphi\right]\frac{\partial n_e^{(0)}}{\partial \tilde{x}} - 2\frac{\partial \varphi}{\partial \tilde{x}}\frac{\partial^2 n_e^{(0)}}{\partial \tilde{x}^2} \\ &-(E_{bl}+2)\frac{\partial \varphi}{\partial \tilde{x}}\frac{\partial n_e^{(0)}}{\partial \tilde{x}} + \sqrt{D}\left(|E_x^{(1)}| + n_p^{(1)}\right)n_e^{(0)} \\ &-\sqrt{D}\frac{\partial n_e^{(1)}}{\partial \tilde{t}} + \sqrt{D}(E_{bl}+2)\frac{\partial n_e^{(1)}}{\partial \tilde{x}} \\ &+\sqrt{D}\left(|E^{(0)}| + n_p^{(0)} - 2n_e^{(0)}\right)n_e^{(1)} + \sqrt{D}\,\Delta_{(\tilde{x},\tilde{y})}n_e^{(1)}, \end{aligned} \tag{4.29}$$

$$\begin{aligned} 0 = &\left(\frac{\partial}{\partial \tilde{t}} - \frac{c}{\sqrt{D}}\frac{\partial}{\partial \tilde{x}}\right)n_p^{(1)} \\ &+\frac{1}{1+2\sqrt{D}}\left[\left(\frac{\partial}{\partial \tilde{t}} - \frac{c}{\sqrt{D}}\frac{\partial}{\partial \tilde{x}}\right)\varphi\right]n_e^{(0)} - |E_x^{(1)}|n_e^{(0)} - |E^{(0)}|n_e^{(1)}, \end{aligned} \tag{4.30}$$

$$0 = \frac{\partial E_x^{(1)}}{\partial \tilde{x}} + \frac{\partial E_y^{(1)}}{\partial \tilde{y}} - \sqrt{D}\left(n_p^{(1)} - n_e^{(1)}\right) - \frac{\partial \varphi}{\partial \tilde{x}}\left(n_p^{(0)} - n_e^{(0)}\right), \tag{4.31}$$

where we have used that, at the boundary layer, by (3.32), $(E^{(0)} + c)/\sqrt{D} = E_{bl} + 2 + O(\sqrt{D})$.

The terms in (4.29) involving $n_e^{(1)}$ lead to a PDE for $n_e^{(1)}$. Namely,

$$\frac{\partial n_e^{(1)}}{\partial \tilde{t}} - (E_{bl}+2)\frac{\partial n_e^{(1)}}{\partial \tilde{x}} - \Delta_{(\tilde{x},\tilde{y})}n_e^{(1)} = \left(|E^{(0)}| + n_p^{(0)} - 2n_e^{(0)}\right)n_e^{(1)}. \tag{4.32}$$

Notice that (4.32) is an advection-diffusion equation with a source term of the form $(|E^{(0)}| + n_p^{(0)} - 2n_e^{(0)})\,n_e^{(1)}$. Since the source term is, from the expression for the traveling waves found in subsection 3.2, negative behind the front, $n_e^{(1)}$ will decay exponentially fast, provided it lays in the ionized region, which is a basic assumption for our perturbation.

Hence, at leading order in (4.29), when $D \ll 1$, one obtains the equation

$$0 = \left[\frac{\partial\varphi}{\partial\tilde{t}} + E_x^{(1)} - \Delta_{(\tilde{x},\tilde{y})}\varphi\right]\frac{\partial n_e^{(0)}}{\partial\tilde{x}} - 2\frac{\partial\varphi}{\partial\tilde{x}}\frac{\partial^2 n_e^{(0)}}{\partial\tilde{x}^2} - (E_{bl}+2)\frac{\partial\varphi}{\partial\tilde{x}}\frac{\partial n_e^{(0)}}{\partial\tilde{x}}. \tag{4.33}$$

Equation (4.31) is, at leading order in D,

$$0 = \frac{\partial E_x^{(1)}}{\partial\tilde{x}} + \frac{\partial E_y^{(1)}}{\partial\tilde{y}} - \frac{\partial\varphi}{\partial\tilde{x}}\left(n_p^{(0)} - n_e^{(0)}\right), \tag{4.34}$$

so that (4.33) and (4.34) are independent of $n_p^{(1)}$, and we can describe the evolution of the perturbed system as

$$0 = \frac{\partial\varphi}{\partial\tilde{t}} + E_x^{(1)} - \Delta_{(\tilde{x},\tilde{y})}\varphi - 2\frac{\partial\varphi}{\partial\tilde{x}}\frac{\partial^2 n_e^{(0)}/\partial\tilde{x}^2}{\partial n_e^{(0)}/\partial\tilde{x}} - (E_{bl}+2)\frac{\partial\varphi}{\partial\tilde{x}}, \tag{4.35}$$

$$0 = \frac{\partial E_x^{(1)}}{\partial\tilde{x}} + \frac{\partial E_y^{(1)}}{\partial\tilde{y}} - \frac{\partial\varphi}{\partial\tilde{x}}\left(n_p^{(0)} - n_e^{(0)}\right). \tag{4.36}$$

It will be more convenient for us to formulate (4.36) in terms of the electric potential in the next subsection.

4.2. The first order correction to the electric field. To establish conditions for the behavior of the perturbation of the electric field, we first note that the total electric field has to be irrotational since the magnetic field is negligible. So we will write $\mathbf{E} = -\nabla V$, where V is an electric potential. Then, (2.11) can be written as

$$-\Delta_{(x,y)}V = n_p^{(0)} - n_e^{(0)} + \delta\, n_p^{(1)} + O(\delta^2). \tag{4.37}$$

Changing variables, we have

$$\begin{aligned} &- \Delta_{(\overline{x},\overline{y})}V + \delta\,\Delta_{(x,y)}\varphi\frac{\partial V}{\partial\overline{x}} + 2\delta\left(\frac{\partial\varphi}{\partial\overline{y}}\frac{\partial^2 V}{\partial\overline{x}\partial\overline{y}} + \frac{\partial\varphi}{\partial\overline{x}}\frac{\partial^2 V}{\partial\overline{x}^2}\right)\\ &\qquad = n_p^{(0)} - n_e^{(0)} + \delta\, n_p^{(1)} + O(\delta^2). \end{aligned} \tag{4.38}$$

We write the electric potential as

$$V(\overline{x},\overline{y}) = V^{(0)}(\overline{x}) + \delta\, V^{(1)}(\overline{x},\overline{y}), \tag{4.39}$$

so that (4.38) can be written, at the first two orders in δ, as

$$-\frac{\partial^2 V^{(0)}(\overline{x})}{\partial\overline{x}^2} = n_p^{(0)} - n_e^{(0)}, \tag{4.40}$$

$$-\Delta_{(\overline{x},\overline{y})}V^{(1)}(\overline{x},\overline{y}) = -\Delta_{(\overline{x},\overline{y})}\varphi\frac{\partial V^{(0)}(\overline{x})}{\partial\overline{x}} - 2\frac{\partial\varphi}{\partial\overline{x}}\frac{\partial^2 V^{(0)}(\overline{x})}{\partial\overline{x}^2} + n_p^{(1)}. \tag{4.41}$$

Expression (4.40) implies that $V^{(0)}(\overline{x})$ is an electric potential associated with the electric field $E^{(0)}(\overline{x})$. The electric potential $V^{(1)}$ satisfies (4.41) with the condition of decaying at $|\overline{x}| \to \infty$. Using (4.40) and (4.41), and the relation $E^{(0)} = -\partial V^{(0)}/\partial \overline{x}$, we arrive at

$$-\Delta_{(\overline{x},\overline{y})} V^{(1)}(\overline{x},\overline{y}) = \Delta_{(\overline{x},\overline{y})}\varphi E^{(0)} + 2\frac{\partial \varphi}{\partial \overline{x}}\left(n_p^{(0)} - n_e^{(0)}\right) + n_p^{(1)}. \tag{4.42}$$

Changing coordinates as in (4.24) and (4.28), in terms of $(\tilde{x},\tilde{y})$ coordinates that are $O(1)$ at the diffusion boundary layer, we obtain

$$\begin{aligned} - \Delta_{(\tilde{x},\tilde{y})} V^{(1)} &= \left(\Delta_{(\tilde{x},\tilde{y})}\varphi\right) E^{(0)}(\sqrt{D}\tilde{x}) \\ &+2\sqrt{D}\,\frac{\partial \varphi}{\partial \tilde{x}}\left(n_p^{(0)}(\sqrt{D}\tilde{x}) - n_e^{(0)}(\sqrt{D}\tilde{x})\right) + D\, n_p^{(1)}. \end{aligned} \tag{4.43}$$

Neglecting $O(\sqrt{D})$ and $O(D)$ terms, and using (4.35), we can finally describe the evolution of the perturbed system as

$$0 = \frac{\partial \varphi}{\partial \tilde{t}} + E_x^{(1)} - \Delta_{(\tilde{x},\tilde{y})}\varphi - 2\frac{\partial \varphi}{\partial \tilde{x}}\frac{\partial^2 n_e^{(0)}/\partial \tilde{x}^2}{\partial n_e^{(0)}/\partial \tilde{x}} - (E_{bl}+2)\frac{\partial \varphi}{\partial \tilde{x}}, \tag{4.44}$$

$$0 = \Delta_{(\tilde{x},\tilde{y})} V^{(1)} + \left(\Delta_{(\tilde{x},\tilde{y})}\varphi\right) E^{(0)}(\sqrt{D}\tilde{x}). \tag{4.45}$$

In the following subsections we shall analyze the system (4.44)–(4.45).

4.3. Analysis of the perturbed system. It proves convenient, since the system (4.44)–(4.45) is linear, to use Fourier transforms in the coordinate $\tilde{y}$ (associated with the wave number k). Denoting the Fourier transform of function f as $\hat{f}$, we find

$$0 = \frac{\partial \hat{\varphi}}{\partial \tilde{t}} + \hat{E}_x^{(1)} - \left(\frac{\partial^2 \hat{\varphi}}{\partial \tilde{x}^2} - k^2\hat{\varphi}\right) - 2\frac{\partial \hat{\varphi}}{\partial \tilde{x}}\frac{\partial^2 n_e^{(0)}/\partial \tilde{x}^2}{\partial n_e^{(0)}/\partial \tilde{x}} - (E_{bl}+2)\frac{\partial \hat{\varphi}}{\partial \tilde{x}}, \tag{4.46}$$

$$0 = \frac{\partial^2 \hat{V}^{(1)}}{\partial \tilde{x}^2} - k^2\hat{V}^{(1)} + \left(\frac{\partial^2 \hat{\varphi}}{\partial \tilde{x}^2} - k^2\hat{\varphi}\right) E^{(0)}(\sqrt{D}\tilde{x}), \tag{4.47}$$

a linear system that can be represented symbolically by

$$\mathcal{L}(\hat{\varphi}, \hat{V}^{(1)}) = 0. \tag{4.48}$$

In principle, once $\hat{V}^{(1)}$ has been calculated from (4.47), we can calculate $\hat{E}_x^{(1)}$ as

$$\frac{\partial \hat{V}^{(1)}}{\partial \overline{x}} = -\hat{E}_x^{(1)}, \tag{4.49}$$

insert it into (4.46), and obtain an equation for $\hat{\varphi}$. Since $\hat{\varphi}$ is initially independent of $\tilde{x}$, we shall write

$$\hat{\varphi} = \hat{\varphi}_0(k,t) + \hat{\varphi}_1(x,k,t), \tag{4.50}$$

with $\hat{\varphi}_1(x,k,t=0) = 0$ and, accordingly,

$$\hat{V}^{(1)} = \hat{V}_0^{(1)}(x,k,t) + \hat{V}_1^{(1)}(x,k,t). \tag{4.51}$$

We will require the following equations to be fulfilled: (i) for $\hat{\varphi}_0$ and $\hat{V}_0^{(1)}$,

$$0 = \frac{\partial \hat{\varphi}_0}{\partial \tilde{t}} + \hat{E}_{0x}^{(1)}(\tilde{x}=0) + k^2\hat{\varphi}_0, \tag{4.52}$$

$$0 = \frac{\partial^2 \hat{V}_0^{(1)}}{\partial \tilde{x}^2} - k^2\hat{V}_0^{(1)} - k^2\hat{\varphi}_0 E^{(0)}(\sqrt{D}\tilde{x}), \tag{4.53}$$

where

$$\hat{E}^{(1)}_{0x} = -\frac{\partial \hat{V}^{(1)}_0}{\partial \overline{x}}; \tag{4.54}$$

and (ii)

$$\mathcal{L}(\hat{\varphi}_1, \hat{V}^{(1)}_1) = \begin{pmatrix} \hat{E}^{(1)}_{0x}(\tilde{x}=0,k,t) - \hat{E}^{(1)}_{0x}(\tilde{x},k,t) \\ 0 \end{pmatrix} \tag{4.55}$$

for $\hat{\varphi}_1$ and $\hat{V}^{(1)}_1$. We shall solve first (4.52)–(4.53) and proceed later to show that the φ_1 solution of (4.55) is merely a small perturbation of φ_0.

If we take the derivative of (4.53) with respect to $\overline{x}$, taking into account (4.49) and the relation between $E^{(0)} = -\partial V^{(0)}/\partial \overline{x}$ and $n^{(0)}_p - n^{(0)}_e$ given by (4.40), we find

$$\frac{\partial^2 \hat{E}^{(1)}_{0x}}{\partial \tilde{x}^2} - k^2 \hat{E}^{(1)}_{0x} = -k^2 \hat{\varphi}_0 \left(n^{(0)}_p(\sqrt{D}\tilde{x}) - n^{(0)}_e(\sqrt{D}\tilde{x}) \right). \tag{4.56}$$

Taking the Fourier transform in $\tilde{x}$ (associated with the wave number ω) and denoting the double Fourier transform as $\hat{\hat{f}}$, one obtains

$$(k^2+\omega^2)\hat{\hat{E}}^{(1)}_{0x}(\omega,k) = \frac{k^2\hat{\varphi}_0(k)}{\sqrt{2\pi}} \int_{-\infty}^{\infty} ds\, e^{-i\omega s} q(\sqrt{D}s), \tag{4.57}$$

where we have defined the net charge density as $q(\sqrt{D}\tilde{x}) = n^{(0)}_p(\sqrt{D}\tilde{x}) - n^{(0)}_e(\sqrt{D}\tilde{x})$. Taking the inverse Fourier transform in ω of (4.57), it follows that

$$\begin{aligned} \hat{E}^{(1)}_{0x}(\tilde{x},k) &= \frac{1}{2\pi}\int_{-\infty}^{\infty} d\omega\, e^{i\omega\tilde{x}} \frac{k^2\hat{\varphi}_0(k)}{k^2+\omega^2} \int_{-\infty}^{\infty} ds\, e^{-i\omega s} q(\sqrt{D}s) \\ &= \frac{1}{2\pi} k^2 \hat{\varphi}_0(k) \int_{-\infty}^{\infty} ds\, q(\sqrt{D}s) \int_{-\infty}^{\infty} d\omega\, \frac{e^{i\omega(\tilde{x}-s)}}{k^2+\omega^2}. \end{aligned} \tag{4.58}$$

The integral in ω can be done by deforming the integration contour in the complex plane. The result is

$$\hat{E}^{(1)}_{0x}(\tilde{x},k) = \frac{|k|\hat{\varphi}_0(k)}{2} \int_{-\infty}^{\infty} ds\, q(\sqrt{D}s) e^{-|k|\,|\tilde{x}-s|}. \tag{4.59}$$

Since the value of $q = n^{(0)}_p - n^{(0)}_e$ in the case $D \ll 1$ differs from the same quantity in the case $D = 0$ only in the region of the boundary layer, that is, $O(D^{1/2})$, we can approximate the profile for the net charge density $q(\sqrt{D}\tilde{x})$ by the profile for the diffusionless traveling waves calculated in the previous section, i.e.,

$$q(\sqrt{D}\tilde{x}) = \begin{cases} -e^{\sqrt{D}\tilde{x}} \text{ for } \tilde{x} < 0, \\ \quad 0 \text{ for } \tilde{x} > 0. \end{cases} \tag{4.60}$$

With this approximation, (4.59) reads

$$\hat{E}^{(1)}_{0x}(\tilde{x},k) = -\frac{|k|\hat{\varphi}_0(k)}{2} \int_{-\infty}^{0} ds\, e^{\sqrt{D}s} e^{-|k|\,|\tilde{x}-s|}. \tag{4.61}$$

The integral in (4.61) can be computed for both $\tilde{x} < 0$ and $\tilde{x} > 0$. The result is

$$\hat{E}^{(1)}_{0x}(\tilde{x}, k) = -\frac{|k|\hat{\varphi}_0(k)}{2\sqrt{D}} \times \begin{cases} \frac{1}{1+|k|/\sqrt{D}} e^{-|k|\tilde{x}} \text{ for } \tilde{x} \geq 0, \\ \frac{-2|k|/\sqrt{D}}{1-|k|^2/D} e^{\sqrt{D}\tilde{x}} + \frac{1}{1-|k|/\sqrt{D}} e^{|k|\tilde{x}} \text{ for } \tilde{x} \leq 0. \end{cases} \tag{4.62}$$

Therefore,

$$\hat{E}^{(1)}_{0x}(0, k) = -\frac{|k|\hat{\varphi}_0(k)}{2(\sqrt{D} + |k|)}, \tag{4.63}$$

and

$$R \equiv |\hat{E}^{(1)}_{0x}(\tilde{x} = 0, k, t) - \hat{E}^{(1)}_{0x}(\tilde{x}, k, t)| = O(e^{-|k|\tilde{x}} - 1)|\hat{\varphi}_0|. \tag{4.64}$$

Notice that

$$R \leq |k\tilde{x}||\hat{\varphi}_0|, \tag{4.65}$$

a fact that we shall use below.

Let us remark that considering the profile of q with diffusion would change the integral in (4.61) by only an $O(1)$ amount, which is negligible in comparison with $1/(\sqrt{D} + |k|)$, provided $|k| \ll 1$.

4.4. The dispersion relation.

Inserting the result (4.63) into (4.52), we find

$$\frac{\partial \hat{\varphi}_0(k)}{\partial \tilde{t}} - \frac{|k|\hat{\varphi}_0(k)}{2(\sqrt{D} + |k|)} + |k|^2 \hat{\varphi}_0(k) = 0. \tag{4.66}$$

Let us write the following ansatz for $\hat{\varphi}_0$:

$$\hat{\varphi}_0(k, \tilde{t}) = e^{m\tilde{t}} \hat{\phi}(k). \tag{4.67}$$

Introducing this expression into (4.66), we obtain the relation

$$m = \frac{|k|}{2(\sqrt{D} + |k|)} - |k|^2, \tag{4.68}$$

that is, the dispersion relation of the perturbations of the fronts. Note that there exists a maximum of $m(|k|)$ that selects the wavelength of the perturbation. It is easy to obtain the following expansion (in D) for the location of the maximum of m:

$$k_{max} = \frac{1}{2^{2/3}} D^{1/6} - \frac{2}{3} D^{1/2} + \frac{2^{2/3}}{9} D^{5/6} + \frac{2^{7/3}}{81} D^{7/6} + O(D^{3/2}). \tag{4.69}$$

When D is a small parameter, this maximum is approximately located at

$$k_{max} \approx \frac{D^{1/6}}{2^{2/3}}. \tag{4.70}$$

Notice that k_{max} is $O(D^{1/6})$ so that in the front, and for the fastest growing mode, where $\tilde{x} = O(1)$, we will have R defined in (4.64) of order $O(D^{1/6})|\hat{\varphi}_0|$.

Hence the solution to (4.55), with initial condition $\hat{\varphi}_1(\tilde{x}, k, 0) = 0$, will be such that $|\hat{\varphi}_1| = O(D^{1/6})t$ and will constitute merely a small perturbation of the leading order $\hat{\varphi}_0$. In fact, $\hat{\varphi}_1$ will be a small perturbation of $\hat{\varphi}_0$ whenever $|k| \ll 1$ and not only in the neighborhood of the fastest growing mode.

The value of k_{max} in (4.70) corresponds to a typical spacing between fingers in the coordinate y given by

$$\lambda_{max} = \frac{2\pi D^{1/2}}{k_{max}} \approx 10\, D^{1/3}. \tag{4.71}$$

In the original nondimensional quantities, this is

$$\lambda_{max} \approx 10 \left(\frac{D_e}{\mathcal{E}_\infty}\right)^{1/3}. \tag{4.72}$$

The typical spacing can be put into physical quantities for nitrogen using the relations (1.9), (1.10), and (1.15). In this way, we can give the dependence of the physical spacing λ^d between consecutive fingers in terms of the gas pressure p (in bars), the physical external electric field $\mathcal{E}^d_\infty$, and the diffusion coefficient D^d_e. We obtain

$$\begin{aligned} \lambda^d_{max} &\approx 10 R_0 \left(\frac{\mathcal{E}_0}{D_0}\right)^{1/3} \left(\frac{D^d_e}{\mathcal{E}^d_\infty}\right)^{1/3} \\ &\approx 2.3 \times 10^{-5}\,\mathrm{m} \left(\frac{2 \times 10^7\,\mathrm{V} \cdot \mathit{bar}/\mathrm{m}}{1.8\,\mathrm{m}^2/\mathrm{s}}\right)^{1/3} \left(\frac{D^d_e}{p\,\mathcal{E}^d_\infty}\right)^{1/3} \end{aligned} \tag{4.73}$$

so that the spacing decreases as the gas pressure or the external electric field increases, and increases as the diffusion coefficient increases. This expression shows the possibility of validating the main results of this work through experiments of electric discharges in nitrogen.

5. Numerical studies of stability of planar fronts and nonplanar waves.

The theory developed in the previous sections applies solely to waves traveling at velocity $c = 1$ in the nondiffusive case and $c = 1 + 2\sqrt{D}$ when $D \neq 0$. These traveling waves appear only for a certain class of initial data, namely, those for which n_e is identically zero beyond a certain point in space. From the numerical point of view, solutions tend to develop traveling waves which do not propagate exactly with that velocity. Nevertheless, we will show in this numerical section that the main stability/instability features of our theoretical results remain valid in general. Specifically, we show the existence of traveling waves in the form of fingers when the diffusion coefficient is small enough, and show that for a given diffusion coefficient, stability of planar fronts depends critically on the wavelength of the perturbations.

We developed a numerical code to solve the initial value problem and study the evolution of nonplanar traveling waves. We discretized the equations with finite differences on a domain of size $L_x \times L_y$ with a uniform square grid of spacing h. For the temporal integration we used an improved Euler scheme. We first compute an approximation for the solution of the system (2.9)–(2.11) at $t + \delta t/2$ as

$$\Delta_a \phi^{(k)} = -\left(n_p - n_e\right)^{(k)}, \tag{5.1}$$

$$n_e^{(k+1/2)} = n_e^{(k)} + \frac{\delta t}{2}\left(\mathbf{E} \cdot \nabla_u n_e + n_e(n_p - n_e) + D + \Delta_a n_e + n_e|\mathbf{E}|\right)^{(k)}, \tag{5.2}$$

$$n_p^{(k+1/2)} = n_p^{(k)} + \frac{\delta t}{2}\left(n_e|\mathbf{E}|\right)^{(k)}, \tag{5.3}$$

and then we obtain a second order approximation by using the derivatives at the center of the interval $(t, t + \delta t)$,

$$\Delta_a \phi^{(k+1/2)} = -\left(n_p - n_e\right)^{(k+1/2)}, \tag{5.4}$$

$$n_e^{(k+1)} = n_e^{(k)} + \delta t \left(\mathbf{E} \cdot \nabla_c n_e + n_e(n_p - n_e) + D\Delta_a n_e + n_e|\mathbf{E}|\right)^{(k+1/2)}, \tag{5.5}$$

$$n_p^{(k+1)} = n_p^{(k)} + \delta t \left(n_e|\mathbf{E}|\right)^{(k+1/2)}, \tag{5.6}$$

where the superscript (k) denotes the time step at time $k\delta t$, $\mathbf{E} = -\nabla_c \phi$, and

$$\begin{aligned}\Delta_a \phi = \frac{1}{6h^2}[&\phi_{i+1,j+1} + \phi_{i+1,j-1} + \phi_{i-1,j+1} + \phi_{i-1,j-1} \\ &+4(\phi_{i+1,j}\phi_{i-1,j} + \phi_{i,j+1} + \phi_{i,j-1}) - 20\phi_{ij}]\end{aligned} \tag{5.7}$$

is the second order accurate approximation of the Laplacian that is symmetrical up to third order. In (5.2) and (5.5), ∇_u is the upwind gradient with respect to the electric field, and ∇_c is the centered second order accurate gradient. In order to solve the Poisson equations (5.1) and (5.4), we used successive overrelaxations (SOR) [3], which in our case is convenient because at each time step we have a good approximation of the solution from the previous step.

We found empirically that the scheme is stable, provided we satisfy the following CFL-like condition:

$$\delta t < \min(h/(2E_m), h^2/4D), \tag{5.8}$$

where E_m is the maximum value of the absolute value of the electric field in the domain of integration (which in our equations plays the role of velocity).

We enforce the following boundary conditions:

$$\frac{\partial \phi}{\partial x}(L_x, y) = 1, \qquad \phi(0, y) = 0, \qquad \frac{\partial \phi}{\partial y}(x, L_y) = \frac{\partial \phi}{\partial y}(x, 0) = 0, \tag{5.9}$$

$$n_e(L_x, y) = \frac{\partial n_e}{\partial x}(0, y) = 0, \qquad \frac{\partial n_e}{\partial y}(x, L_y) = \frac{\partial n_e}{\partial y}(x, 0) = 0, \tag{5.10}$$

$$n_p(L_x, y) = \frac{\partial n_p}{\partial x}(0, y) = 0, \qquad \frac{\partial n_p}{\partial y}(x, L_y) = \frac{\partial n_p}{\partial y}(x, 0) = 0, \tag{5.11}$$

which correspond to a constant electric field on the top end of the domain and zero-flux conditions on the sides.

5.1. Validation with traveling waves. We validated the scheme by comparing the numerical solution with the following exact solutions for the traveling waves without diffusion:

$$n_e^{ex}(\zeta) = 1 - \frac{e^\zeta}{\sqrt{e^\zeta(4 + e^\zeta)}}, \tag{5.12}$$

$$\begin{aligned}n_p^{ex}(\zeta) = 1 &+ \frac{e^\zeta}{2} - \frac{e^{\zeta/2}\sqrt{4 + e^\zeta}}{2} + \frac{\log 2}{2} \\ &- \log\left(e^{\zeta/2} + \sqrt{4 + e^\zeta}\right) + \frac{1}{2}\log\left(2 + e^\zeta + e^{\zeta/2}\sqrt{4 + e^\zeta}\right),\end{aligned} \tag{5.13}$$

where $\zeta = x - 2t$. This solution is convenient for the validation because it is smooth, and our numerical scheme is best suited to calculating differentiable solutions. We

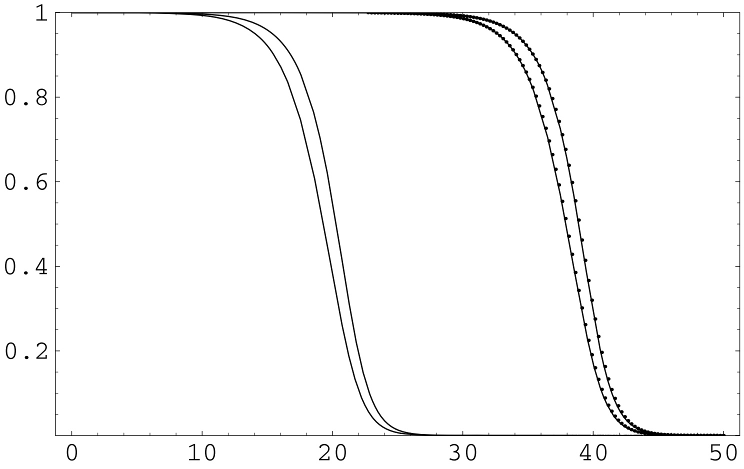

FIG. 3. *Validation with an explicit solution for $c = 2$ and $D = 0$. The size of the domain is $L_x = 50$ and we used 200 gridpoints. The curves on the left indicate the initial condition for n_e (upper line) and n_p (lower line), and the curves on the right show the comparison between the numerical calculation and the exact solution at $t = t_q$.*

first set as an initial condition the exact solution at $t = 0$ and then we compute the numerical solution at $t_q = 9.5$. In Figure 3 we show the comparison between both solutions. In Figure 4 we show the total error calculated as

$$\text{error} = \int_0^{L_x} \left(n_e(x, t_q) - n_e^{ex}(x, t_q)\right)^2 dx. \tag{5.14}$$

This measure of error takes into account the accumulation of all arithmetic and truncation errors on the time interval $(0, t_q)$. Figure 4 shows that the error is proportional to the square of the interspacing h, indicating that the scheme is second order accurate.

5.2. Computing two-dimensional traveling waves. One difficulty that arises with a finite computational domain is that traveling waves eventually arrive at the end of the domain of integration. This is a problem because, given an arbitrary initial condition, sometimes it takes a long time for traveling waves to converge to a steady state.

We solve this difficulty by making use of a displacement technique that keeps the waves near the center of the domain at all times. Each time that the position of the front of a wave (defined, for example, as the point where $n_e = 0.1$) is beyond the middle of the domain, we then translate the solution backwards by exactly one gridpoint,

$$n_{ei,j} \leftarrow n_{ei+1,j}, \qquad n_{p_{i,j}} \leftarrow n_{p_{i+1,j}}. \tag{5.15}$$

At the end of the domain ($i = n_x$) we set zero values for the charge densities. Using this procedure, we can compute two-dimensional traveling waves. In the following calculations, we have $\lambda = 10$, $L_y = 2\lambda$, $L_x = 3L_y$ and the domain is discretized by 300×100 points. The initial condition has a plane front perturbed with a cosenoidal perturbation of wavelength λ and amplitude $\lambda/40$.

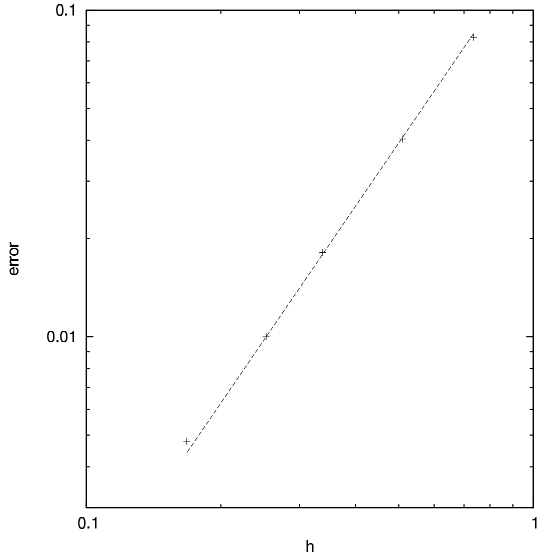

FIG. 4. *Errors integrated along the domain of integration for $D = 0$ at time $t_q = 9.5$. The size of the domain is $L = 50$ and we used 200 gridpoints. The points indicate the resulting numerical errors, and the line is a power with exponent 2, indicating that the scheme is second order accurate.*

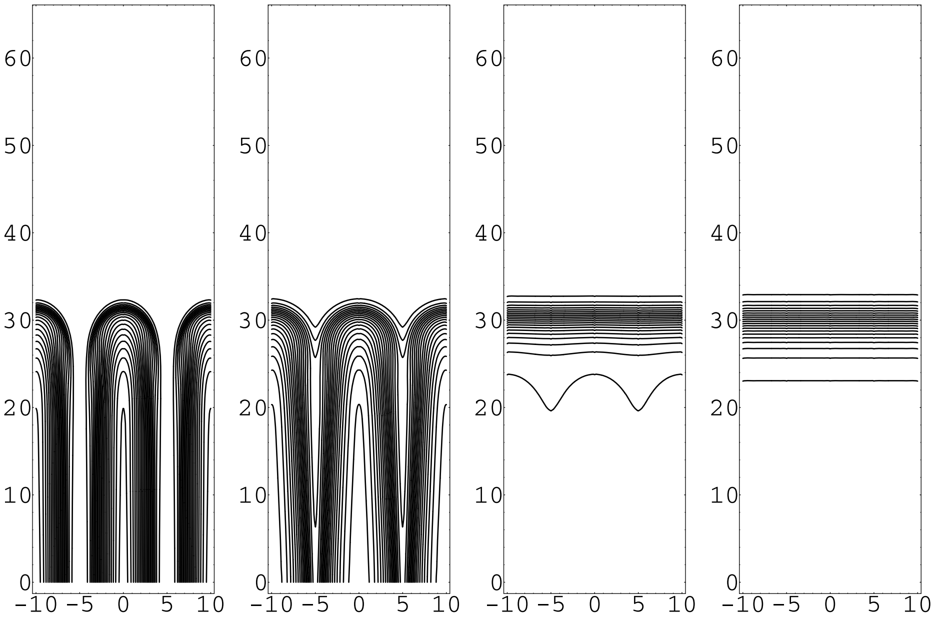

FIG. 5. *Two-dimensional contour plots for the electronic charge density for the traveling waves with $D = 0$, 0.1, 0.2, and 0.3. The x-axis is in the vertical direction.*

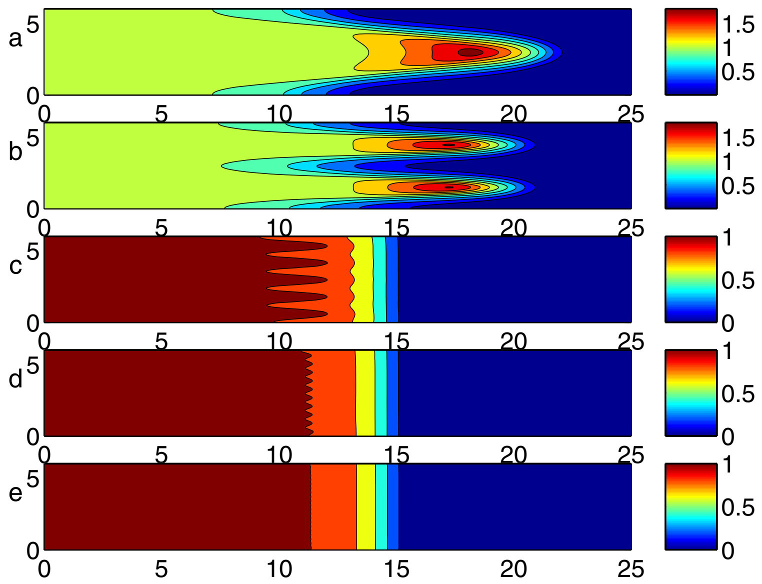

Fig. 6. *Level curves of the electron density n_e with diffusion coefficient $D = 0.1$ and time interval* 2. *The wavelength of the perturbation is, in each case,* (a) $\lambda = 6$, (b) $\lambda = 3$, (c) $\lambda = 5/6$, (d) $\lambda = 10/6$, *and* (e) $\lambda = 20/6$. *These values correspond to wave numbers $k = 2\pi/\lambda$.*

We observed that after the wave travels a distance equivalent to ten times the length of the computational domain, the numerical solution reaches a steady state, which is insensitive to the initial conditions. In Figure 5 we show traveling waves with $D = 0$, 0.1, 0.2, and 0.3. Notice that the aspect of the traveling waves is very sensitive to the value of the diffusion coefficient. In particular, when D is close to zero, well-developed fingers do appear, while the fronts remain essentially planar when D is large enough.

In Figure 6 we perturb a planar traveling wave, which was found with the displacement procedure described above. The perturbation was introduced by translating all the contour lines a distance $\cos(2\pi y/\lambda)$ on the x-direction. Then we evolved the solution on a time interval of length 2. In all cases $D = 0.1$, and we take several wavelengths λ. It is evident from the figures that there is a tendency to form fingers when the wavelength is above some critical value while the perturbation decays and disappears for small enough wavelengths. In Figure 7, the cases (b) and (c) of Figure 6 have been plotted in perspective. This confirms the results obtained in previous sections concerning stability.

6. Conclusions. In this paper we have used a fluid approximation to describe the process of electric breakdown in nonattaching gases such as nitrogen. We have shown that a planar negative front separating an ionized region from a region without charge may become unstable under the combined action of the external electric field and the electron diffusion. The common underlying mathematical structure allows us to exploit some of the ideas developed for other pattern-forming systems such as the Hele–Shaw and Stefan problems.

We have calculated the dispersion relation for a perturbation in the transversal direction of a planar traveling wave in the limit of small diffusion. An analytical expression for the typical spacing between fingers is obtained.

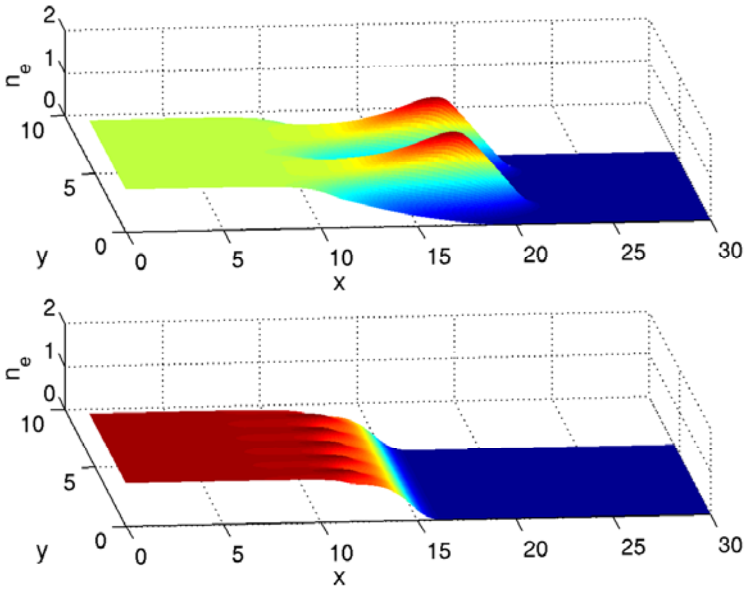

Fig. 7. *Representations in perspective of the electron density in the cases* (b) *and* (c) *of Figure* 6*, respectively.*

In order to test the analytical results, we have developed a numerical code to study the evolution of planar traveling waves. The traveling waves are then perturbed and we follow the evolution after that. Under some circumstances the solutions converge to traveling waves in the form of fingers that we have computed numerically for several diffusion coefficients. Our numerical results clearly support the conclusions on the branching and stability developed analytically.

EFFECTIVE MOTION OF A VIRUS TRAFFICKING INSIDE A BIOLOGICAL CELL[*]

THIBAULT LAGACHE[†] AND DAVID HOLCMAN[‡]

Abstract. Virus trafficking is fundamental for infection success, and plasmid cytosolic trafficking is a key step of gene delivery. Based on the main physical properties of the cellular transport machinery such as microtubules and motor proteins, our goal here is to derive a mathematical model to study cytoplasmic trafficking. Because experimental results reveal that both active and passive movements are necessary for a virus to reach the cell nucleus, by taking into account the complex interactions of the virus with the microtubules, we derive here an estimate of the mean time a virus reaches the nucleus. In particular, we present a mathematical procedure in which the complex viral movement, oscillating between pure diffusion and a deterministic movement along microtubules, can be approximated by a steady state stochastic equation with a constant effective drift. An explicit expression for the drift amplitude is given as a function of the real drift, the density of microtubules, and other physical parameters. The present approach can be used to model viral trafficking inside the cytoplasm, which is a fundamental step of viral infection, leading to viral replication and, in some cases, to cell damage.

Key words. virus trafficking, cytoplasmic transport, mean first passage time, exit points distribution, stochastic processes, wedge geometry

1. Introduction.

Because cytosolic transport has been identified as a critical barrier for synthetic gene delivery [1], the delivery of plasmids or viral DNAs from the cell membrane to the nuclear pores has attracted the attention of many biologists. The cell cytosol contains many types of organelles, actin filaments, microtubules, etc., so that to reach the nucleus, a viral DNA has to travel through a crowded and risky environment. We are interested here in studying the efficiency of the delivery process and we present a mathematical model of virus trafficking inside the cell cytoplasm. We model the viral movement as a Brownian motion. However, the density of actin filaments and microtubules inside the cell can hinder diffusion, as demonstrated experimentally [2]. In a crowded environment, we will model the virus as a material point. This reduction is simplistic for several reasons: an actin filament network can trap a diffusing object that is beyond a certain size, and, as observed experimentally, a DNA fragment cannot find its way across the actin filaments [2]. Active directional transport along microtubules or actin filaments seems then the only way to deliver a plasmid to the nucleus. The active transport of the virus generally involves motor proteins, such as kinesin (to travel in the direction of the cell membrane) or dynein (to travel toward the nucleus). Once a virus is attached to a dynein protein, its movement can be modeled as a deterministic drift toward the nucleus.

Recently, a macroscopic model has been developed to describe the dynamics of

adenovirus concentration inside the cell cytoplasm [3]. This approach offers very interesting results about the effect of microtubules, but neglects the complexity of the geometry and cannot be used to describe the movement of a single virus, which might be enough to cause cellular infection. Modeling virus trafficking requires the use of a stochastic description. We model here the motion of a virus as that of a material point, so the probability of it being trapped by actin filaments or microtubules is neglected. In the present approximation, the viral movement has two main components: a Brownian one, which accounts for its free movement, and a drift directed toward the centrosome or MTOC (microtubules organization center), an organelle located near the nucleus. The magnitude of the drift along microtubules depends on many parameters such as the binding and unbinding rates and the velocity of the motor proteins [4].

In the present approach, we present a method to approximate a time-dependent dynamics of virus trafficking by an effective stochastic equation with a radial steady state drift. The main difficulties we have to overcome arise from the time-dependent nature of the trajectories which consists of intermittent epochs of drifts and free diffusion. We propose to derive an explicit expression for the steady state drift amplitude. In this approximation, the effective drift will gather the mean properties of the cytoplasmic organization such as the density of microtubules and its off binding rate.

Our method for finding the effective drift can be described as follows. First, we approximate the cell geometry as a two-dimensional disk and use a pure Brownian description to approximate the virus diffusion step. This geometrical approximation is valid for any two-dimensional cell such as the *in vitro* flat skin fibroblast culture cells [3]: indeed, due to their adhesion to the substrate, the thickness of these cells can be neglected in first approximation. Second, when the distribution of the initial viral position is uniform on the cell surface, we will estimate, during the diffusing period, the hitting position on a microtubule. By solving a partial differential equation, inside a sliced shape domain, delimited by two neighboring microtubules, we will provide an estimate of the mean time to the most likely hitting point. Finally, the amplitude of the radial steady state drift will be obtained by an iterative method which assumes that, after a virus has moved a certain distance along a microtubule, it is released at a point uniformly distributed on the final radial distance from the nucleus, ready for a new random walk. This scenario repeats until the virus reaches the nucleus surface. Finally, we will compute the mean time, the mean number of steps before a virus reaches the nucleus, and the amplitude of the effective drift by using the following criteria: The mean first passage time (MFPT) to the nucleus of the iterative approximation is equal to the MFPT obtained by directly solving an Ornstein–Uhlenbeck stochastic equation. The explicit computation of the effective drift is a key result in the estimation of the probability and the mean time a single virus or DNA molecule takes to reach a small nuclear pore [5].

2. Modeling stochastic viral movement inside a biological cell.

We approximate the cell as a two-dimensional geometrical domain Ω, which is here a disk of radius R, and the nucleus located inside is a concentric disk of much smaller radius $\delta \ll R$. We model the motion of an unattached DNA fragment as a material point so that the probability of it being trapped by actin filaments or microtubules is neglected. The motion of a (DNA) molecule of mass m is described by the overdamped limit of the Langevin equation (Smoluchowski's limit) [6] for the position $\mathbf{X}(t)$ of the molecule at time t. When the particle is not bound to a microtubule filament, its movement is described as pure Brownian with a diffusion constant D. When the particle hits

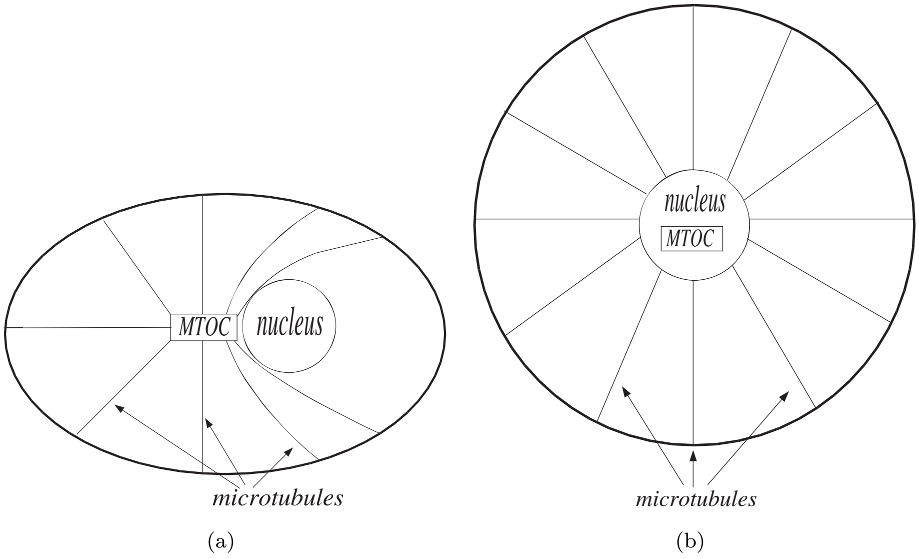

FIG. 2.1. *Cell geometry.* (a) *Cell's microtubules network. All microtubules starting from the cell membrane converge to the MTOC, located near the nucleus.* (b) *Simplified cell's microtubules network organization. The MTOC coincides with the nucleus.*

a filament, it binds for a certain random time and moves along with a deterministic drift. We take into account only the movement toward the nucleus, which coincides here with the MTOC, an organelle in which all microtubules converge (see Figure 2.1). For $\delta < |\mathbf{X}(t)| < R$, we describe the overall movement by the stochastic rule

$$\dot{\mathbf{X}} = \begin{cases} \sqrt{2D}\dot{\mathbf{w}} & \text{for} \quad \mathbf{X}(t) \quad \text{free}, \\ V\frac{\mathbf{r}}{|\mathbf{r}|} & \text{for} \quad \mathbf{X}(t) \quad \text{bound}, \end{cases} \tag{2.1}$$

where V is a constant velocity, $\dot{\mathbf{w}}$ a δ-correlated standard white noise, and $\mathbf{r}$ the $\mathbf{X}$ radial coordinate, the origin of which is the center of the cell. We assume that all filaments starting from the cell surface end on the nuclear surface. The binding time corresponds to a chemical reaction event; we assume that it is exponentially distributed, and for simplicity we approximate it by a constant t_m.

Once a virus enters the cell membrane, it moves according to the rule (2.1) until it hits a nuclear pore. Although nuclear pores occupy a small portion of the nuclear surface, we consider only the virus movement until it hits the nuclear surface $D(\delta)$. In this article, our goal is to replace (2.1) by a steady state stochastic equation

$$\dot{\mathbf{X}} = \mathbf{b}(\mathbf{X}) + \sqrt{2D}\dot{\mathbf{w}}, \tag{2.2}$$

where the drift $\mathbf{b}$ is radially symmetric. In a first approximation, we consider a constant radial drift $\mathbf{b}(\mathbf{X}) = -B\frac{\mathbf{r}}{|\mathbf{r}|}$ and compute hereafter the value of the constant amplitude B such that the MFPTs of the processes (2.2) and (2.1) to the nucleus are equal.

2.1. Modeling viral dynamics in the cytoplasm. Inside the cytosol, microtubules are distributed on the cell surface and converge radially to the MTOC. In the present analysis, we do not take into account the effect of organelle crowding due

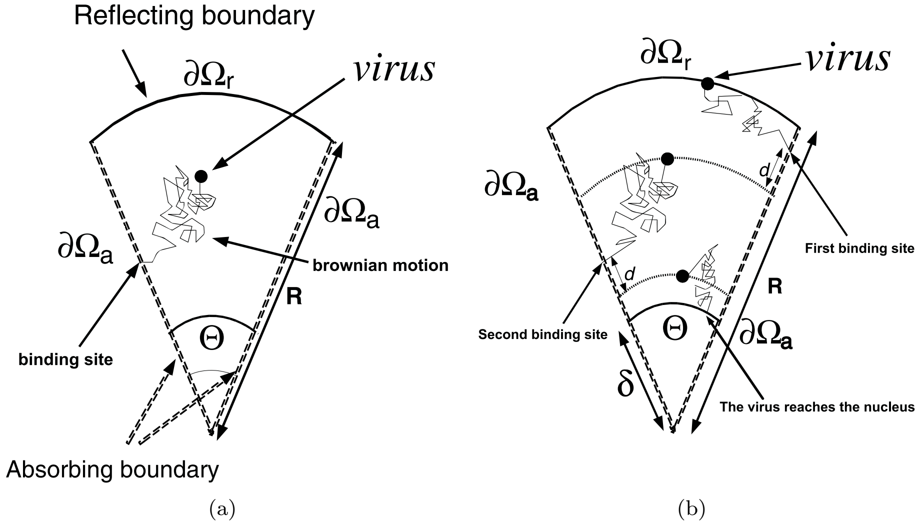

FIG. 2.2. *Virus trafficking inside a cell.* (a) *Representation of the cell portion between two microtubules.* (b) *Transport along microtubules: Two fundamental steps are represented. A fundamental step is made of the two intermediate steps which are first the diffusion inside the domain and then the directed motion along the microtubule.*

to the endoplasmic reticulum, the Golgi apparatus, etc. However, it is always possible to include them indirectly by using an apparent diffusion constant. We consider the fundamental domain $\tilde{\Omega}$ defined as the two-dimensional slice of angle Θ between two neighboring microtubules. We consider here that microtubules are uniformly distributed, and thus $\Theta = \frac{2\pi}{N}$, where N is the total number of microtubules.

Although a virus can drift along microtubules in both directions by using dynein (resp., kinesin) motor proteins for the inward (resp., outward) movement, we only take into account the drift toward the nucleus [7]. It is still unclear what is the precise mechanism used by a virus to select a direction of motion. Attached to a dynein molecule, the virus transport consists of several steps of few nanometers: the length of each step depends on the load of the transported cargo and adenosine tryphosphate (ATP) concentration [8]. We neglect here the complexity of this process, assuming that ATP molecules are abundant, uniformly distributed over the cell, and not a limiting factor. We thus assume the bound particle moves toward the nucleus with the mean constant velocity V. When the particle is released from the microtubule, inside the domain, the process can start afresh and the particle diffuses freely. Because the Smoluchowski limit of the Langevin equation does not account for the change in velocity, we release the particle at a certain distance away from the microtubule, but at a fixed distance from the nucleus (at an angle chosen uniformly distributed); see Figure 2.2.

Because microtubules are taken uniformly distributed, we can always release the virus inside the slice $\tilde{\Omega}$, between two neighboring microtubules. Thus the movement of the virus will be studied in $\tilde{\Omega}$: inside the cytosol, the viral movement is purely Brownian until it hits a microtubule, which is now the lateral boundary of $\tilde{\Omega}$ (see Figure 2.2). We assume that once a virus hits a microtubule, with probability one, the dynamics switches from diffusion to a deterministic motion with a constant drift. A virus spends on a microtubule a time that we consider to be exponentially distributed, since this time is the sum of escape time from deep potential wells. We approximate the total time on a microtubule by the mean time t_m. Thus a virus moves at a distance $d_m = Vt_m$ along a microtubule, which depends only on the characteristic of the virus–microtubule interactions. To summarize, the virus trajectory is a succession of diffusion steps mixed with some periods of attaching and detaching to microtubules. This scenario repeats until the virus hits the nuclear surface (Figure 2.2).

2.2. Computing the MFPT to reach the nucleus. We define the *mean time to infection* as the MFPT a virus reaches the surface of the disk $D(\delta)$ inside the domain $\tilde{\Omega}$ (see Figure 2.2).

To estimate the mean time to infection, we note that we can decompose the overall motion as a repeated fundamental step. This step consists of the free diffusion of the particle inside the domain followed by the motion along the microtubule. The total time of infection τ_i is then the sum of times the particle spends in each step. Although the time on a microtubule is deterministically equal to t_m, the diffusing time is not easy to compute and depends on the initial condition. Ultimately τ_i depends on the number of times the fundamental step repeats before the particle reaches the nucleus.

Let us now describe each step. The first step starts when the virus enters the cell at the periphery $r = R = R_0$ (at a random angle $\theta \in [0;\Theta]$) and ends when the virus hits either the lateral boundary or the nucleus. We now consider the first passage time $u(R_0)$ to the absorbing boundary and denote by $r(R_0)$ the hitting position. To account for the deterministic drift, during a deterministic time t_m we move the virus from a distance d_m along the microtubule. In that case, the initial random position for the next step is given by $r = R_1 = r(R_0) - d_m$ and the total time in step 1 is $u(R_0) + t_m$.

We iterate the process as follows and consider in each step k the distance $R_k = r(R_{k-1}) - d_m$ from which the particle starts and the time $u(R_k) + t_m$ it spends inside the step. If we denote by n_s the random number of steps necessary to reach the nucleus $r = \delta$, the time to infection τ_i is given by

$$\tau_i = \sum_{k=0}^{n_s-1} u(R_k) + n_s t_m + t_r, \tag{2.3}$$

where t_r is a residual time, which is the time to reach the nucleus before a full step is completed.

We are interested in estimating the MFPT τ of τ_i, given by

$$\tau = E(\tau_i) = E\left(\sum_{k=0}^{n_s-1} u(R_k)\right) + \langle n_s\rangle t_m + \langle t_r\rangle, \tag{2.4}$$

where $\langle n_s\rangle$ is the mean number of steps and $\langle t_r\rangle$ is the mean residual time. If we introduce the probability distribution $p_m = \Pr\{n_s = m\}$, which states that the number of steps is exactly equal to m, we can write

$$\tau = E(\tau_i) = \sum_{m=1}^{\infty} E\left(\sum_{k=0}^{n_s-1} u(R_k)|n_s = m\right) p_m + \langle n_s\rangle t_m + \langle t_r\rangle. \tag{2.5}$$

To estimate the MFPT τ, we shall approximate the previous sum by using the MFPT $\bar{u}(R_k)$ in each step k. To estimate $\bar{u}(R_k)$, we will solve (in the next paragraph) the Dynkin's equation with the following boundary conditions: Inside $\tilde{\Omega}$, the particle is reflected at the periphery $r = R$ and absorbed at the nucleus $\partial\tilde{\Omega}_a$ and at $\theta = 0$ and $\theta = \Theta$. We will also estimate the mean distance $\bar{d}_k$ covered during step k. For that purpose we will estimate the mean exit position $r_m(R_k)$, conditioned on the initial position $r = R_k$. Indeed, we will thus get $\bar{d}_k = R_k - r_m(R_k) - d_m$. The estimates of the mean distances covered for each fundamental step will ultimately lead to an approximation of the mean number of steps $n = \langle n_s \rangle$: n will be computed such that $R_n \geq \delta$ and $R_{n+1} < \delta$ (where $R_n = r_m(R_{n-1}) - d_m$ is defined recursively). Finally, we will obtain the following approximation for the infection time:

$$\tau \approx \sum_{k=0}^{n-1} \bar{u}(R_k) + nt_m + \langle t_r \rangle. \tag{2.6}$$

The mean residual time $\langle t_r \rangle$ can be equal either to $\bar{u}(R_n) + \alpha t_m$, where $0 \leq \alpha < 1$ if the virus binds to a microtubule in the last step and travels a distance αd_m on the microtubule, or to the MFPT to the nuclear boundary if $r_m(R_n) < \delta$.

3. MFPT and exit point distribution.

In a first approximation, under the assumptions of a sufficiently small radius $\delta \ll R$ and an angle $\Theta \ll 1$ for the computation of the MFPT and the distribution of exit points, we neglect the nuclear area. We define the full pie wedge Ω^R domain of angle Θ. Inside Ω^R, we use the boundary conditions described above. Consequently, the MFPT to a microtubule $u = u(r, \theta)$ of a virus starting initially at position (r, θ) is a solution of the Dynkin's equations [6]

$$\begin{aligned} D\Delta u(\boldsymbol{x}) &= -1 \text{ for } \boldsymbol{x} \in \Omega^R, \\ u(\boldsymbol{x}) &= 0 \text{ for } \boldsymbol{x} \in \partial\Omega^R_a, \\ \frac{\partial u}{\partial \boldsymbol{n}} &= 0 \text{ for } \boldsymbol{x} \in \partial\Omega^R_r, \end{aligned} \tag{3.1}$$

where $\partial\Omega^R_a = \{\theta = 0\} \cup \{\theta = \Theta\}$ and $\Omega^R_r = \{r = R\}$.

3.1. The general solution for the MFPT.

In this paragraph only we reparametrize the domain by $-\Theta/2 \leq \theta \leq \Theta/2$. By writing (3.1) in polar coordinates and using the separation of variables, the general solution of equation

$$\left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} \right)(r, \theta) = -1 \text{ for } (r, \theta) \in \Omega^R, \tag{3.2}$$

$$u(r, \theta) = 0 \text{ for } (r, \theta) \in \partial\Omega^R_a, \tag{3.3}$$

is given by [9],

$$u(r, \theta) = \frac{r^2}{4D}\left(\frac{\cos(2\theta)}{\cos(\Theta)} - 1 \right) + \sum_{n=0}^{\infty} A_n r^{\lambda_n} \cos(\lambda_n \theta) \text{ for } \frac{-\Theta}{2} \leq \theta \leq \frac{\Theta}{2}, \tag{3.4}$$

where the edge boundary is here located at position $\theta = \pm\Theta/2$. The sum in the right-hand side is the general solution of the homogeneous problem $\Delta u = 0$ in Ω^R. The boundary conditions on the sides of the wedge impose that

$$\lambda_n = (2n+1)\frac{\pi}{\Theta}, \tag{3.5}$$

while the reflecting condition for $r = R$ reads

$$\frac{\partial u}{\partial r}(R, \theta) = 0 \text{ for all } \theta \in \left[-\frac{\Theta}{2}, \frac{\Theta}{2} \right]. \tag{3.6}$$

Using the uniqueness of Fourier decomposition and the boundary condition (3.6), we obtain that

$$A_n = \frac{(-1)^{n+1} 8R^{2-\lambda_n}}{D\Theta\lambda_n^2 \left(\lambda_n^2 - 4\right)}. \tag{3.7}$$

By averaging formula (3.4) over an initial uniform distribution, the MFPT to one of the absorbing edges of the wedge is given by

$$\bar{u}(r) = \frac{1}{\Theta}\int_{\theta=0}^{\theta=\Theta} u(r,\theta)\,d\theta = \frac{r^2}{4D}\left(\frac{\tan(\Theta)}{\Theta} - 1\right) - \sum_{n=0}^{\infty} \frac{16R^{2-\lambda_n} r^{\lambda_n}}{D\Theta^2\lambda_n^3\left(\lambda_n^2 - 4\right)}, \tag{3.8}$$

where $\lambda_n = (2n+1)\frac{\pi}{\Theta}$. For Θ small, (3.8) can be approximated by

$$\bar{u}(r) = \frac{r^2}{4D}\left(\frac{\tan(\Theta)}{\Theta} - 1\right) - \frac{16\Theta R^2 (r/R)^{\pi/\Theta}}{D\pi^3\left((\pi/\Theta)^2 - 4\right)}. \tag{3.9}$$

3.2. Exit points distribution. To estimate the position at which a virus will attach preferentially to the microtubule, we determine the distribution of exit points, when the viral particle initially started at a certain radial distance from the nucleus. We recall that the probability density function (pdf) $p(\mathbf{r}, t|\mathbf{r_0})$ for finding a diffusing particle in a volume element $d\mathbf{r}$ at time t inside the wedge $\tilde{\Omega}$, conditioned on the initial position $\mathbf{r} = \mathbf{r_0}$, is a solution of the diffusion equation

$$\begin{aligned}\frac{\partial p(\mathbf{r}, t|\mathbf{r_0})}{\partial t} &= D\Delta p(\mathbf{r}, t|\mathbf{r_0}) \text{ for } \mathbf{r} \in \Omega^R,\\ p(\mathbf{r}, t|\mathbf{r_0}) &= 0 \text{ for } \mathbf{r} \in \partial\Omega_a^R,\\ \frac{\partial p(\mathbf{r}, t|\mathbf{r_0})}{\partial n} &= 0 \text{ for } \mathbf{r} \in \partial\Omega_r^R,\end{aligned}$$

where the initial condition is $p(\mathbf{r}, 0|\mathbf{r_0}) = \delta(\mathbf{r} - \mathbf{r_0})$. The distribution of exit points $\epsilon(\boldsymbol{y})$ is given by

$$\epsilon(\boldsymbol{y}) = \int_0^\infty j(\boldsymbol{y}, t)\,dt, \tag{3.10}$$

where the flux j is defined by

$$j(\boldsymbol{y}, t) = -D\frac{\partial p(\mathbf{r}, t)}{\partial \boldsymbol{n}}_{|\mathbf{r} = \boldsymbol{y}}.$$

If we denote $C(\mathbf{r_0}, \mathbf{r}) = \int_0^\infty p(\mathbf{r}, t|\mathbf{r_0})\,dt$, then C is a solution of

$$-D\Delta C(\mathbf{r_0}, \mathbf{r}) = \delta(\mathbf{r} - \mathbf{r_0}), \tag{3.11}$$

and we have

$$\epsilon(\mathbf{y}) = -D\frac{\partial C}{\partial n}(\mathbf{r_0}, \mathbf{y}) \text{ for } \mathbf{y} \in \Omega_a^R. \tag{3.12}$$

Consequently, to obtain the pdf of exit points ϵ, we use the Green function in the wedge domain Ω^R. By using a conformal transformation, we hereafter solve a simplified case of an open wedge (i.e., without a reflecting boundary at $r = R$). This computation could be compared with the general one that will be derived in the next section.

To compute the exit points distribution, we consider the solution of (3.11), obtained by the image method and a conformal transformation from the open wedge to the upper complex half-plane. The Green function, solution of (3.11) in the upper complex half-plane, is given by

$$C(z) = \frac{1}{2\pi D} \ln \frac{z - z_0}{z - z_0^*}, \tag{3.13}$$

where z_0^* is the complex conjugate of z_0. Using the conformal transformation $\omega = f(z) = z^{\frac{\pi}{\Theta}}$ [10] that maps the interior of the wedge of opening angle Θ to the upper half-plane, the Green function in the wedge is given by

$$C(z) = \frac{1}{2\pi D} \ln \left(\frac{z^{\frac{\pi}{\Theta}} - z_0^{\frac{\pi}{\Theta}}}{z^{\frac{\pi}{\Theta}} - (z_0^*)^{\frac{\pi}{\Theta}}} \right). \tag{3.14}$$

The flux to the line θ is given by

$$\begin{aligned}
\epsilon_\theta(r) = -\frac{D}{r}\frac{\partial C}{\partial \theta}\left(re^{i\theta}\right) &= \frac{1}{2\pi r} \frac{i\nu \left(re^{i\theta}\right)^\nu . (k_0 - k_0^*)}{\left(\left(re^{i\theta}\right)^\nu - k_0\right)\left(\left(re^{i\theta}\right)^\nu - k_0^*\right)} \\
&= \frac{1}{2\pi r} \frac{-2\nu \left(re^{i\theta}\right)^\nu r_0^\nu \sin(\nu\theta_0)}{\left(re^{i\theta}\right)^{2\nu} + r_0^{2\nu} - 2\left(re^{i\theta}\right)^\nu r_0^\nu \cos(\nu\theta_0)},
\end{aligned}$$

where $\nu = \frac{\pi}{\Theta}$, $k_0 = z_0^\nu = \left(r_0 e^{i\theta_0}\right)^\nu$. Finally, the exit point distribution for $\theta = \Theta$ is given by

$$\epsilon_\Theta(r) = \frac{r_0}{\Theta} \frac{(rr_0)^{(\nu-1)} \sin(\nu\theta_0)}{r^{2\nu} + r_0^{2\nu} + 2(rr_0)^\nu \cos(\nu\theta_0)}, \tag{3.15}$$

while for $\theta = 0$ it is given by

$$\epsilon_0(r) = \frac{r_0}{\Theta} \frac{(rr_0)^{(\nu-1)} \sin(\nu\theta_0)}{r^{2\nu} + r_0^{2\nu} - 2(rr_0)^\nu \cos(\nu\theta_0)}. \tag{3.16}$$

A MATLAB check guarantees that

$$\int_0^\infty \{\epsilon_\Theta(r) + \epsilon_0(r)\} dr = 1. \tag{3.17}$$

This simple computation is instructive and shall be compared to the full one given in section 3.3.

3.3. Exit pdf in a pie wedge. To compute the exit points distribution in a pie wedge with a reflecting boundary at $r = R$, we search for an explicit solution of the diffusion equation in polar coordinates inside the pie wedge. We first consider the general diffusion equation

$$\begin{aligned}
\frac{\partial p}{\partial t}(\boldsymbol{x}, t|\boldsymbol{y}) &= D\left(\frac{\partial^2 p}{\partial r^2} + \frac{1}{r}\frac{\partial p}{\partial r} + \frac{1}{r^2}\frac{\partial^2 p}{\partial \theta^2}\right)(\boldsymbol{x}, t|\boldsymbol{y}), \\
p(\boldsymbol{x}, 0|\boldsymbol{y}) &= \delta(\boldsymbol{x} - \boldsymbol{y}),
\end{aligned} \tag{3.18}$$

where the boundary conditions are given in (3.1). We may often use the change of variable for all $n \in \mathbf{N}^*$:

$$k = \frac{n\pi}{\Theta}.$$

The initial condition is given by

$$p(\boldsymbol{x}, 0|\boldsymbol{y}) = p(r, \theta, 0|r_0, \theta_0) = \frac{2}{\Theta r_0}\delta(r - r_0)\sum_k \sin(k\theta)\sin(k\theta_0)$$

for $\theta < \theta_0$ (if $\theta > \theta_0$, θ_0 must be replaced by $\Theta - \theta_0$). To compute the solution of (3.18), we consider the Laplace transform $\hat{p}$ of the probability p,

$$\begin{aligned} s\hat{p}(r, \theta, s|r_0, \theta_0) - \frac{2}{\Theta r_0}\delta(r - r_0)\sum_k \sin(k\theta)\sin(k\theta_0) \\ = D\left(\frac{\partial^2 \hat{p}}{\partial r^2} + \frac{1}{r}\frac{\partial \hat{p}}{\partial r} + \frac{1}{r^2}\frac{\partial^2 \hat{p}}{\partial \theta^2}\right)(r, \theta, s|r_0, \theta_0). \end{aligned}$$

Using the separation of variables, we have

$$\hat{p}(r, \theta, s|r_0, \theta_0) = \sum_k R_k(r, s)\sin(k\theta)\sin(k\theta_0).$$

Using the change of variable, $x(s) = r\sqrt{\frac{s}{D}}$ and $x_0(s) = r_0\sqrt{\frac{s}{D}}$, we get for all k that

$$\begin{aligned} R_k^{''}(x(s), s) + \frac{1}{x(s)}R_k^{'}(x(s), s) - \left(1 + \frac{k^2}{x(s)^2}\right)R_k(x(s), s) \\ = -\frac{2}{\Theta D x_0(s)}\delta(x(s) - x_0(s)). \end{aligned} \tag{3.19}$$

$R_k(x(s), s)$ is a superposition of modified Bessel functions of order k: $I_k(x(s))$ and $K_k(x(s))$. Thus, for $x(s) \neq x_0(s)$ we obtain that

$$R_k(x(s), s) = A_k I_k(x(s)) + B_k K_k(x(s)),$$

where A_k and B_k are real constants. Since K_k diverges as $x(s) \to 0$, the interior solution for $(x(s) < x_0(s))$ depends only on I_k. We denote by D_k the exterior solution for $(x(s) > x_0(s))$. We use the general notation $x \wedge y = \min(x, y)$ and $x \vee y = \max(x, y)$; thus

$$R_k(x(s), s) = A_k I_k(x(s) \wedge x_0(s)) D_k(x(s) \vee x_0(s)).$$

To determine $D_k = a_k I_k + b_k K_k$, we use the reflecting condition at $x(s) = x_+(s) = R\sqrt{\frac{s}{D}}$ and we get that

$$A_k I_k(x_0(s)).\left(a_k I_k^{'}(x_+(s)) + b_k K_k^{'}(x_+(s))\right) = 0.$$

We choose

$$a_k = -K_k^{'}(x_+(s)) \text{ and } b_k = I_k^{'}(x_+(s)).$$

Thus

$$R_k\left(x\left(s\right),s\right)=A_kI_k\left(x\left(s\right)\wedge x_0\left(s\right)\right)\left(I_k^{'}\left(x_+\left(s\right)\right)K_k-K_k^{'}\left(x_+\left(s\right)\right)I_k\right)\left(x\left(s\right)\vee x_0\left(s\right)\right).$$

The constants A_k are determined by integrating (3.19) over an infinitesimal interval that includes r_0. Using the continuity of R_k, we get

$$\left(R_k\right)_{x(s)>x_0(s)}^{'}|_{x(s)=x_0(s)}-\left(R_k\right)_{x(s)<x_0(s)}^{'}|_{x(s)=x_0(s)}=-\frac{2}{\Theta Dx_0\left(s\right)},$$

that is,

$$A_k\left(I_k\left(I_k^{'}\left(x_+\left(s\right)\right)K_k^{'}-K_k^{'}\left(x_+\left(s\right)\right)I_k^{'}\right)-I_k^{'}\left(I_k^{'}\left(x_+\left(s\right)\right)K_k-K_k^{'}\left(x_+\left(s\right)\right)I_k\right)\right)\left(x_0\left(s\right)\right)$$
$$=-\frac{2}{\Theta Dx_0\left(s\right)}.$$

After some simplifications, we get

$$A_kI_k^{'}\left(x_+\left(s\right)\right)\left(I_kK_k^{'}-I_k^{'}K_k\right)\left(x_0\left(s\right)\right)=-\frac{2}{\Theta Dx_0\left(s\right)}.$$

Using the recurrent relation between modified Bessel functions (see [11] or [12, p. 489]),

$$I_k^{'}\left(x_0\left(s\right)\right)=\left(I_{k-1}-\frac{k}{x_0\left(s\right)}I_k\right)\left(x_0\left(s\right)\right)\text{ and }K_k^{'}\left(x_0\left(s\right)\right)=\left(-K_{k-1}-\frac{k}{x_0\left(s\right)}K_k\right)\left(x_0\left(s\right)\right),$$

we get

$$A_kI_k^{'}\left(x_+\left(s\right)\right)\left(I_k\left(-K_{k-1}-\frac{k}{x_0\left(s\right)}K_k\right)-\left(I_{k-1}-\frac{k}{x_0\left(s\right)}I_k\right)K_k\right)\left(x_0\left(s\right)\right)=-\frac{2}{\Theta Dx_0\left(s\right)},$$

that is

$$A_kI_k^{'}\left(x_+\left(s\right)\right)\left(I_kK_{k-1}+I_{k-1}K_k\right)\left(x_0\left(s\right)\right)=\frac{2}{\Theta Dx_0\left(s\right)}.$$

Finally, using this relation and the following Wronskian relation [12, p. 489]:

$$\left(I_kK_{k-1}+I_{k-1}K_k\right)\left(x_0\left(s\right)\right)=\frac{1}{x_0\left(s\right)},$$

we obtain that

$$A_k=\frac{2}{\Theta DI_k^{'}\left(x_+\left(s\right)\right)}.$$

Thus

$$R_k\left(x\left(s\right),s\right)$$
$$=\frac{2}{\Theta DI_k^{'}\left(x_+\left(s\right)\right)}I_k\left(x\left(s\right)\wedge x_0\left(s\right)\right)\left(I_k^{'}\left(x_+\left(s\right)\right)K_k-K_k^{'}\left(x_+\left(s\right)\right)I_k\right)\left(x\left(s\right)\vee x_0\left(s\right)\right).$$

We can now express the solution $\hat{p}$ for $\theta<\theta_0$ by

$$\hat{p}\left(r,\theta,s\right)=\frac{2}{\Theta D}\sum_k\frac{I_k\left(x\left(s\right)\wedge x_0\left(s\right)\right)\left(I_k^{'}\left(x_+\left(s\right)\right)K_k-K_k^{'}\left(x_+\left(s\right)\right)I_k\right)\left(x\left(s\right)\vee x_0\left(s\right)\right)}{I_k^{'}\left(x_+\left(s\right)\right)}\sin\left(k\theta\right)\sin\left(k\theta_0\right).$$

The exit point distribution $\epsilon^0(r)$ is given by

$$\epsilon^0(r) = -\left(\frac{D}{r}\frac{\partial}{\partial\theta}\left(\int_0^\infty p(r,\theta,t)\,dt\right)\right)(\theta = 0). \tag{3.20}$$

To obtain an analytical expression for expression (3.20), we use the Laplace relation

$$\mathcal{L}\left(\int_0^t f(u)\,du\right) = \frac{F(z)}{z},$$

where $F = \mathcal{L}(f)$ is the Laplace transform of the function f. We have

$$\int_0^t p(r,\theta,u)\,du = \mathcal{L}^{-1}\left(\frac{\hat{p}(r,\theta,s)}{s}\right)$$

$$= \mathcal{L}^{-1}\left(\frac{2}{\Theta D}\sum_k \sin(k\theta)\sin(k\theta_0)\frac{I_k(x(s)\wedge x_0(s))\left(I_k'(x_+(s))K_k - K_k'(x_+(s))I_k\right)(x(s)\vee x_0(s))}{sI_k'(x_+(s))}\right).$$

The computation of the integral

$$\begin{aligned}&I(r,\theta,t)\\ &= \frac{1}{\Theta\pi Di}\sum_k \sin(k\theta)\sin(k\theta_0)\int_{-i\infty}^{+i\infty}\frac{I_k(x(s)\wedge x_0(s))(I_k'(x_+(s))K_k - K_k'(x_+(s))I_k)(x(s)\vee x_0(s))}{sI_k'(x_+(s))}e^{st}ds\end{aligned} \tag{3.21}$$

uses the residue theorem, and the details are given in the appendix. We have

$$I(r,\theta,t) = \int_0^t p(r,\theta,u)\,du = \frac{2}{\Theta D}\left(S_1(r,\theta,t) + S_2(r,\theta,t)\right),$$

where

$$S_1(r,\theta,t) = \sum_k \sin(k\theta)\sin(k\theta_0)\frac{r^k\left(r_0^{2k} + R^{2k}\right)}{2kR^{2k}r_0^k},$$

$$S_2(r,\theta,t) = -2\sum_k \sin(k\theta)\sin(k\theta_0)\sum_{j=1}^\infty e^{-D\alpha_{j,k}^2 t}\frac{J_k(r\alpha_{j,k})J_k(r_0\alpha_{j,k})}{\left(R^2\alpha_{j,k}^2 - k^2\right)J_k^2(R\alpha_{j,k})},$$

and J_k are the k-order Bessel functions and $\alpha_{j,k}$ are the roots of the equation:

$$J_k'(R\alpha) = 0.$$

Consequently, for $r < r_0$, using (3.20), we get the following exit distribution (for $\Theta = 0$):

$$\epsilon^0(r) = \frac{2}{\Theta}\frac{\partial}{r\partial\theta}\left(\lim_{t\to\infty}\left(S_1(r,\theta,t) + S_2(r,\theta,t)\right)\right)_{\theta=0}.$$

Because

$$\lim_{t\to\infty} S_1(r,\theta,t) = S_1(r,\theta) \text{ and } \lim_{t\to\infty} S_2(r,\theta,t) = 0,$$

we finally obtain that

$$\epsilon^0(r) = \frac{1}{\Theta}\sum_k \sin(k\theta_0)\frac{r^{k-1}\left(r_0^{2k} + R^{2k}\right)}{R^{2k}r_0^k}, \tag{3.22}$$

and, for $r > r_0$, a similar computation leads to

$$\epsilon^0(r) = \frac{1}{\Theta}\sum_k \sin(k\theta_0)\frac{r_0^k\left(r^{2k}+R^{2k}\right)}{R^{2k}r^{k+1}}. \tag{3.23}$$

These expressions can be further simplified. Indeed, we rewrite them as follows (for $r < r_0$):

$$\epsilon^0(r) = \frac{1}{\Theta r}\sum_k \sin(k\theta_0)\left(\frac{r}{r_0}\right)^k\left(1+\left(\frac{r_0}{R}\right)^{2k}\right).$$

Thus,

$$\epsilon^0(r) = \frac{1}{\Theta r}\Im m\left(\sum_{n\geq 1} e^{in\nu\theta_0}\left(\frac{r}{r_0}\right)^{n\nu}\left(1+\left(\frac{r_0}{R}\right)^{2n\nu}\right)\right),$$

where $\Im m$ denotes the imaginary part of the expression. We obtain two geometrical series that can be summed. We get

$$\epsilon^0(r) = \frac{1}{\Theta r}\Im m\left(\frac{e^{i\nu\theta_0}\left(\frac{r}{r_0}\right)^\nu}{1-e^{i\nu\theta_0}\left(\frac{r}{r_0}\right)^\nu}+\frac{e^{i\nu\theta_0}\left(\frac{r}{r_0}\right)^\nu\left(\frac{r_0}{R}\right)^{2\nu}}{1-e^{i\nu\theta_0}\left(\frac{r}{r_0}\right)^\nu\left(\frac{r_0}{R}\right)^{2\nu}}\right),$$

that is,

$$\epsilon^0(r) = \frac{1}{\Theta r}\Im m\left(e^{i\nu\theta_0}\left(\frac{\left(\frac{r}{r_0}\right)^\nu}{1-e^{i\nu\theta_0}\left(\frac{r}{r_0}\right)^\nu}+\frac{\left(\frac{rr_0}{R^2}\right)^\nu}{1-e^{i\nu\theta_0}\left(\frac{rr_0}{R^2}\right)^\nu}\right)\right).$$

After some rearrangements, we obtain the following exit point distribution on $\theta = 0$, conditioned on the initial position (r_0, θ_0):

$$\begin{aligned}\epsilon^0(r) &= \epsilon^0(r|r_0,\theta_0)\\ &= \frac{1}{\Theta r}\left(\frac{(rr_0)^\nu\sin(\nu\theta_0)}{r^{2\nu}+r_0^{2\nu}-2(rr_0)^\nu\cos(\nu\theta_0)}+\frac{\left(rr_0R^2\right)^\nu\sin(\nu\theta_0)}{(rr_0)^{2\nu}+R^{4\nu}-2\left(rr_0R^2\right)^\nu\cos(\nu\theta_0)}\right),\end{aligned} \tag{3.24}$$

for $0 \leq r \leq R$. Similarly, for $\theta = \Theta$, we obtain

$$\begin{aligned}\epsilon^\Theta(r) &= \epsilon^\Theta(r|r_0,\theta_0)\\ &= \frac{1}{\Theta r}\left(\frac{(rr_0)^\nu\sin(\nu\theta_0)}{r^{2\nu}+r_0^{2\nu}+2(rr_0)^\nu\cos(\nu\theta_0)}+\frac{\left(rr_0R^2\right)^\nu\sin(\nu\theta_0)}{(rr_0)^{2\nu}+R^{4\nu}+2\left(rr_0R^2\right)^\nu\cos(\nu\theta_0)}\right).\end{aligned} \tag{3.25}$$

We notice that by letting R tend to ∞, we recover the expressions computed in the open wedge case ((3.15) and (3.16)).

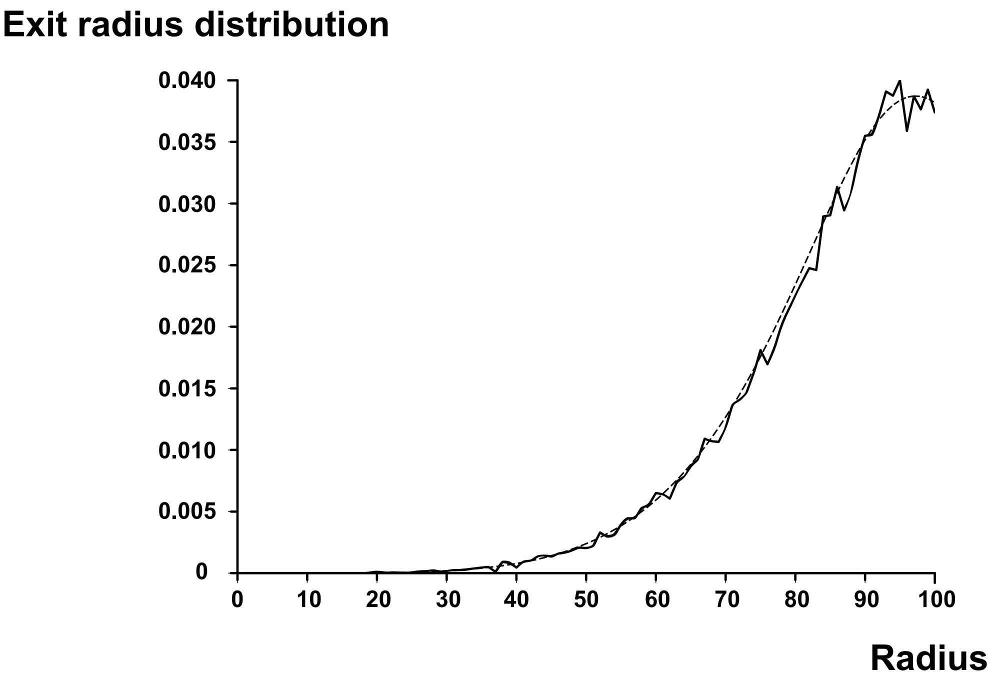

FIG. 3.1. *Mean exit points distribution. The theoretical distribution (dashed line) is tested against the empirical one (solid line) obtained by running a simulation of* 20,000 *Brownian particles, starting on the wedge bisectrix* ($\theta_0 = \frac{\Theta}{2}$ *at* $r_0 = R = 100$ *for* $\Theta = \frac{\pi}{6}$)*. Because the starting point is located on the bisectrix,* $\epsilon^0(x) = \epsilon^\Theta(x)$*, and thus the analytical curve is given by* $\epsilon(r) = \epsilon^0(r) + \epsilon^\Theta(r) = \frac{2}{\Theta r}\left(\frac{(rr_0)^{(\nu)}}{r^{2\nu}+r_0^{2\nu}} + \frac{(rr_0R^2)^{(\nu)}}{(rr_0)^{2\nu}+R^{4\nu}}\right)$*. In that case, the maximum of the function* $\epsilon(r)$ *is achieved at* $r = r_0 e^{\frac{1}{2\nu}\ln\left(\frac{\nu-1}{\nu+1}\right)}$.

3.4. The mean exit radius. To determine the mean exit distribution radius $\overline{\epsilon}(r|r_0)$ for a viral particle starting initially at position r_0, θ_0, where θ_0 is uniformly distributed between 0 and Θ, we consider $\epsilon(r|r_0,\theta_0) = \epsilon^0(r|r_0,\theta_0) + \epsilon^\Theta(r|r_0,\theta_0)$ and estimate the integral

$$\overline{\epsilon}(r|r_0) = \frac{1}{\Theta}\int_{\Theta_0=0}^{\Theta} \epsilon(r|r_0,\theta_0)\, d\theta_0. \tag{3.26}$$

Integrating expressions (3.24) and (3.25), we get

$$\overline{\epsilon}(r|r_0) = \frac{2}{\Theta\pi r}\left(\ln\left(\frac{r^\nu + r_0^\nu}{|r^\nu - r_0^\nu|}\right) + \ln\left(\frac{R^{2\nu} + (rr_0)^\nu}{R^{2\nu} - (rr_0)^\nu}\right)\right).$$

We define the mean exit point as $r_m(r_0) = \mathbf{E}(r|r_0)$ conditioned on the initial radius r_0. Thus,

$$r_m(r_0) = \mathbf{E}(r|r_0) = \int_0^R r\overline{\epsilon}(r|r_0)\, dr. \tag{3.27}$$

Using the expansion $\ln(1+x) = \sum_{n\geq 1}(-1)^{n+1}\frac{x^n}{n}$ for $x < 1$, we obtain by a direct integration that

$$r_m\left(r_0\right) = \frac{8}{\pi^2}\left(r_0\left(\sum_{n=0}^{\infty}\frac{1}{\left(2n+1\right)^2}\left(\frac{1}{1-\frac{1}{(2n+1)^2\left(\frac{\pi}{\Theta}\right)^2}}\right)\right)\right.$$
$$\left. - R\left(\sum_{n=0}^{\infty}\frac{\left(\frac{r_0}{R}\right)^{(2n+1)\frac{\pi}{\Theta}}\frac{\pi}{\Theta}}{\left(2n+1\right)\left(\left(\left(2n+1\right)\frac{\pi}{\Theta}\right)^2-1\right)}\right)\right). \tag{3.28}$$

Using the expansion in the first part,

$$\frac{1}{1-\frac{1}{(2n+1)^2\left(\frac{\pi}{\Theta}\right)^2}} = \sum_{p=0}^{\infty}\left(\frac{\Theta}{\left(2n+1\right)\pi}\right)^{2p}, \tag{3.29}$$

and the approximation $\Theta \ll 1$, by using the value of the Riemann ζ-function, $\zeta\left(2\right) = \frac{\pi^2}{6}$ and $\zeta\left(4\right) = \frac{\pi^4}{90}$, we obtain that

$$r_m\left(r_0\right) \approx r_0\left(1+\frac{\Theta^2}{12}\right) - \frac{8R}{\pi^2}\left(\frac{r_0}{R}\right)^{\pi/\Theta}\frac{\pi/\Theta}{\left(\pi/\Theta\right)^2-1}. \tag{3.30}$$

For Θ small, the second term in the right-hand side of (3.30) is exponentially small.

4. Approximation of a virus motion by an effective Markovian stochastic equation.

We replace the successive steps of viral dynamics with an effective stochastic equation containing a constant steady state drift.

4.1. Methodology.

Virus motion described in subsection 2.2 consists of a succession of drift and diffusing periods. We start with the stochastic equation

$$\dot{\mathbf{X}} = -B\frac{\mathbf{r}}{|\mathbf{r}|} + \sqrt{2D}\dot{\mathbf{w}}, \tag{4.1}$$

where $\boldsymbol{r}$ is the radial component of $\mathbf{X}$ and B is the amplitude of the drift. The MFPT of the process (4.1) to the nucleus, which is located at $r = \delta$, when the initial position is located on the cell surface $r = R$, is solution of

$$\begin{aligned} D\left(\frac{d^2t}{dr^2}+\frac{1}{r}\frac{dt}{dr}\right)\left(r,\theta\right) - B\frac{dt}{dr}\left(r,\theta\right) &= -1 \text{ for } \left(r,\theta\right)\in\Omega,\\ t\left(r,\theta\right) &= 0 \text{ for } r=\delta,\\ \frac{dt}{dr}\left(r,\theta\right) &= 0 \text{ for } r=R. \end{aligned}$$

A similar equation can be written in the domain $\tilde{\Omega}$ with reflective boundary conditions of the wedge. Both processes in the full domain or in $\tilde{\Omega}$ lead to the same MFPT. The solution $t(B,r)$ is given by

$$t\left(B,r\right) = C - \int_r^R\left(\int_v^R\frac{ue^{-\alpha(u-v)}}{Dv}du\right)dv, \tag{4.2}$$

where $\alpha = \frac{B}{D}$ and

$$t\left(B,R\right) = C = \int_\delta^R\left(\int_v^R\frac{ue^{-\alpha(u-v)}}{Dv}du\right)dv. \tag{4.3}$$

For a fixed radius R, the derivative of the function $t(B,R)$ with respect to B is strictly negative, which shows that $B \to t(B,R)$ is strictly decreasing. To determine the value of the amplitude B, we match the mean time $t(B,R)$ with the MFPT to reach the nucleus within the iterative procedure, as described in subsection 2.2: at time zero, the virus starts at position $r = R = R_0$ and reaches the edge boundary in mean time $\bar{u}(R_0)$ and at mean position $r_m(R_0)$. The viral particle is then transported toward the nucleus over a distance d_m during time t_m. Either the particle reaches the nucleus before time t_m and then the algorithm is terminated, or in a second step it starts at position $R_1 = r_m(R_0) - d_m$. The process iterates until the particle reaches the nucleus. We consider the mean number of fundamental steps (diffusion step and directed motion along a microtubule step) that the virus needs to reach the nucleus to be equal to $n \geq 0$. Thus the mean time to reach the nucleus computed by (4.2) has to be equal to the mean time $\tau = \sum_{k=0}^{n-1} \bar{u}(R_k) + nt_m + \langle t_r \rangle$ of the iterative trajectory. In a first approximation, we neglect the mean residual time $\langle t_r \rangle$ and we thus get the equality

$$t(B,R) = \tau = \sum_{k=0}^{n-1} \bar{u}(R_k) + nt_m, \tag{4.4}$$

$$R_{k+1} = r_m(R_k) - d_m, \tag{4.5}$$

$$R_0 = R. \tag{4.6}$$

For a fixed radius R, equation (4.4) has a unique solution B, which can be found in practice by any standard numerical method.

Remark. The MFPT of a particle in which the trajectory consists of alternating drift (traveling along microtubules) and diffusion periods can be either higher or lower than the MFPT of a pure Brownian particle. Indeed, when $B < 0$, the drift effect is less efficient than pure diffusion. For example, for $\Theta = \frac{\pi}{6}$, $R = 100\mu m$, and $\delta = \frac{R}{4} = 25\mu m$, a large diffusion constant $D = 10\mu m^2 s^{-1}$ with the dynamical parameters $t_m = 1s$ and $d_m = 1\mu m$ leads to a negative mean drift

$$B \approx -0.14\mu m s^{-1}. \tag{4.7}$$

On the other hand, for a small diffusion constant $D = 1\mu m^2 s^{-1}$, an efficient microtubule transport obtained for $t_m = 1s$ and $d_m = 5\mu m$ leads to a mean positive drift

$$B \approx 0.13\mu m s^{-1}. \tag{4.8}$$

4.2. Explicit expression of the drift in the limit of $\Theta \ll 1$.

When the number of microtubules is large enough, the condition $\Theta \ll 1$ is satisfied. Moreover, because a virus entering a cell surface has a deterministic motion, we can assume that the initial position satisfies $R_0 < R$ so that we can neglect any boundary effects and use the open wedge approximation, which consists of using formula (3.30) without the boundary layer term. Actually, this approximation is not that restrictive because after the first iteration process (movement along the microtubule followed by the particle release), the boundary layer term is negligible compared to the other term.

To obtain an explicit expression for the amplitude B, we consider the successive approximations

$$r_m(R_0) \approx R_0 \left(1 + \frac{\Theta^2}{12}\right) \tag{4.9}$$

and

$$\begin{aligned}
&R_0 = R_0;\\
&R_1 \simeq R_0\left(1+\frac{\Theta^2}{12}\right) - d_m;\\
&R_2 \simeq R_0\left(1+\frac{\Theta^2}{12}\right)^2 - d_m\left(1+\left(1+\frac{\Theta^2}{12}\right)\right);\\
&\quad\vdots\\
&R_i \simeq R_0\left(1+\frac{\Theta^2}{12}\right)^i - d_m\left(\sum_{k=0}^{i-1}\left(1+\frac{\Theta^2}{12}\right)^k\right);
\end{aligned}$$

that is,

$$R_i \simeq \left(R_0 - \frac{12d_m}{\Theta^2}\right)\left(1+\frac{\Theta^2}{12}\right)^i + \frac{12d_m}{\Theta^2}. \tag{4.10}$$

Thus the particle reaches the nucleus after n iteration steps which approximatively satisfies $R_n = \delta$,

$$n \simeq \frac{\ln\left(\frac{1-\frac{\delta\Theta^2}{12d_m}}{1-\frac{R_0\Theta^2}{12d_m}}\right)}{\ln\left(1+\frac{\Theta^2}{12}\right)} \approx \frac{R_0-\delta}{d_m} + o\left(1\right). \tag{4.11}$$

If T_n denotes the mean time a viral particle takes to reach the nucleus, then using formula (3.9), we obtain

$$T_n \simeq n.t_m + \frac{\left(\frac{\tan(\Theta)}{\Theta}-1\right)}{4D}\sum_{i=0}^{n-1} R_i^2, \tag{4.12}$$

that is,

$$\begin{aligned}
t \simeq n.t_m + &\frac{\left(\frac{\tan(\Theta)}{\Theta}-1\right)}{4D}\\
&\times\sum_{i=0}^{n-1}\left(\left(\frac{12d_m}{\Theta^2}\right)^2 + 2\left(\frac{12d_m}{\Theta^2}\right)\left(R_0-\frac{12d_m}{\Theta^2}\right)\left(1+\frac{\Theta^2}{12}\right)^i\right.\\
&\qquad\left. + \left(R_0-\frac{12d_m}{\Theta^2}\right)^2\left(1+\frac{\Theta^2}{12}\right)^{2i}\right),
\end{aligned}$$

$$\begin{aligned}
T_n \simeq nt_m + &\frac{\left(\frac{\tan(\Theta)}{\Theta}-1\right)}{4D}\\
&\times\left(n\left(\frac{12d_m}{\Theta^2}\right)^2 - \left(\frac{24d_m}{\Theta^2}\right)\left(R_0-\frac{12d_m}{\Theta^2}\right)\frac{1-\left(1+\frac{\Theta^2}{12}\right)^n}{\frac{\Theta^2}{12}}\right.\\
&\qquad\left. + \left(R_0-\frac{12d_m}{\Theta^2}\right)^2\frac{1-\left(1+\frac{\Theta^2}{12}\right)^{2n}}{1-\left(1+\frac{\Theta^2}{12}\right)^2}\right).
\end{aligned}$$

For $\Theta \ll 1$, a Taylor expansion gives that

$$T_n \simeq \left(\frac{R_0-\delta}{d_m}\right) t_m + \frac{t_m\left(R_0-\delta\right)}{24 d_m}\left(1+\frac{R_0+\delta}{d_m}\right)\Theta^2 + \frac{\left(R_0-\delta\right)}{72D}\left(d_m + 3\left(R_0+\delta\right) + \frac{2\left(R_0^2+R_0\delta+\delta^2\right)}{d_m}\right)\Theta^4 + o\left(\Theta^4\right).$$

In small diffusion limit $D \ll 1$, $\Theta \ll 1$, the velocity is $B \simeq \frac{R_0-\delta}{T_n}$, and consequently we obtain for $R_0 \approx R$ a second order approximation,

$$B \approx \frac{\frac{d_m}{t_m}}{1+\left(1+\frac{R+\delta}{d_m}\right)\frac{\Theta^2}{24}+O\left(\Theta^4\right)}, \tag{4.13}$$

where d_m, t_m are the mean distance and the mean time a virus stays on the microtubule, R (resp., δ) is the radius of the cell (resp., nucleus) and $\Theta = \frac{2\pi}{N}$, where N is the total number of microtubules.

4.3. Justification of the MFPT criteria. To justify the use of the MFPT criteria to estimate the steady state drift, we run numerical simulations of 1,000 viruses inside a two-dimensional domain Ω ($\delta < r < R$) with intermittent dynamics, alternating between epochs of free diffusion and directed motion along microtubules, and compare the steady state distribution with the one obtained by solving the Fokker–Planck equation for viruses whose trajectories are described by the effective stochastic equation (2.2) with our computed constant drift

$$\mathbf{b}\left(\mathbf{X}\right) = -\frac{\frac{d_m}{t_m}}{1+\left(1+\frac{R+\delta}{d_m}\right)\frac{\Theta^2}{24}}\frac{\mathbf{r}}{|\mathbf{r}|} = -B\frac{\mathbf{r}}{|\mathbf{r}|}. \tag{4.14}$$

We imposed reflecting boundary conditions at the nuclear and the external membrane. The theoretical normalized steady state distribution ρ satisfies

$$D\Delta\rho - \nabla.[\mathbf{b}\rho] = 0 \text{ in } \Omega,$$
$$\frac{d\rho}{dr}\left(R\right) = \frac{d\rho}{dr}\left(\delta\right) = 0,$$

and the solution ρ is given by

$$\rho(r) = \frac{e^{-\frac{Br}{D}}}{\int_\delta^R e^{-\frac{Br}{D}} 2\pi r dr} = \frac{e^{-\frac{Br}{D}}}{2\pi\frac{D}{B}(\delta e^{-\frac{B\delta}{D}} - Re^{-\frac{BR}{D}} + \frac{D}{B}(e^{-\frac{B\delta}{D}} - e^{-\frac{BR}{D}}))}. \tag{4.15}$$

The result of both distributions is presented in Figure 4.1, where we can observe that both curves match very nicely. This result shows that the criteria we have used is at least enough to recover the distribution. For the simulations, we consider that the directed run of the virus along a microtubule (loaded by dynein) lasts $t_m = 1s$ and covers a mean distance $d_m = 0.7\mu m$ [13]. The diffusion constant is $D = 1.3\mu m^2 s^{-1}$, as observed for the adeno-associated virus [14]. The two curves in Figure 4.1 fit very nicely except at the neighborhood of the nuclear membrane, where the simulation of the empirical distribution is plagued with a possible boundary layer. Another source of discrepancy comes from the difference of behavior of viruses far from and close to the nucleus: viruses far from the nucleus do not bind as often as those located in its neighborhood. Consequently, a constant effective drift cannot account for the radial geometry near the nucleus. A theory for radius-dependent effective drift has been derived in [15].

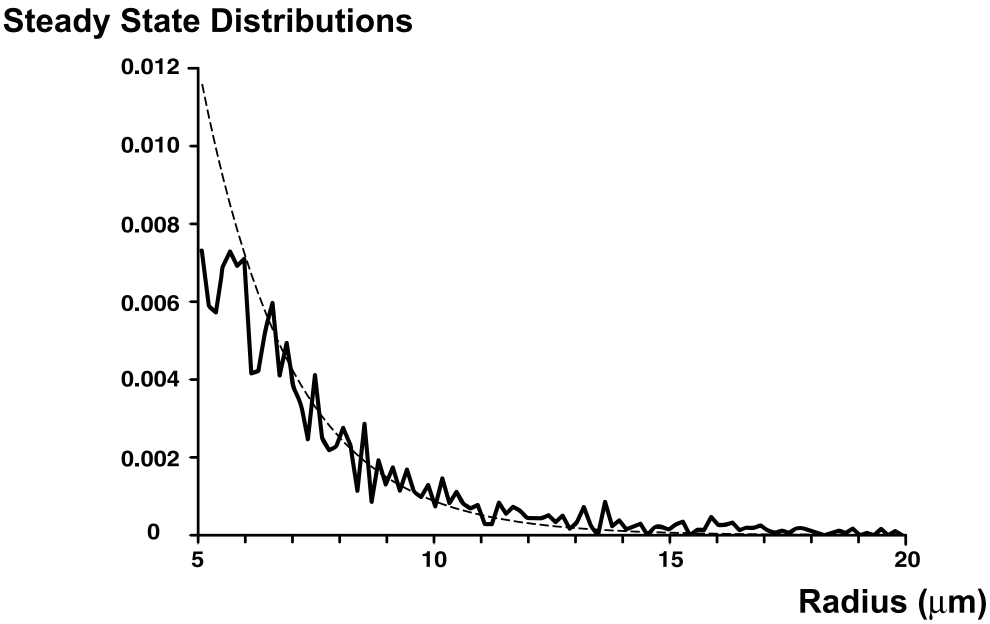

FIG. 4.1. *Steady state distributions. We show the empirical steady state distribution for* 1,000 *viral trajectories with an intermittent dynamic (solid line). The theoretical distribution of viruses whose trajectories are described by the stochastic equation* (2.2) *is shown by the dashed line. Geometrical parameters are* $R = 20\mu m$, $\delta = 5\mu m$, *and* $\Theta = \frac{\pi}{24}$.

5. Conclusion. For the limit of a cell containing an excess of microtubules, we have presented here a model to describe the motion of biological particles such as viruses, vesicles, and many others moving inside the cell cytoplasm by a complex combination of Brownian motion and deterministic drift. Our procedure consists mainly of approximating an alternative switching mode between diffusion and deterministic drift epochs by a steady state stochastic equation; it also consists of estimating the amplitude of the effective drift and is based on the criteria that the MFPTs to the nucleus computed in both cases are equal. In that case, this amplitude accounts for the directed transport along microtubules, the cell geometry, and the binding constants. The model has, however, several limitations. First, we do not take into account directly the backward movement of the virus along the microtubules [16, 17], which can affect the mean time and the amplitude of the drift. Second, the present computations are given only for two-dimensional cell geometry. It can still be applied to many in vitro culture cells; however, it is not clear how to generalize our approach to a three-dimensional cell geometry. For example, to study the trafficking inside cylindrical axons or dendrites of neuronal cells, a different approach should include these geometrical features. However, despite these real difficulties, the present model may be used to analyze plasmid transport in a host cell, at the molecular level, which is one of the fundamental limitations of gene delivery [18, 19, 20, 21].

Appendix. In this appendix, we provide an explicit computation of integral (3.21) using the method of the residues. This method was previously used in a similar context in [12, p. 386]. We denote by $\left(p_j^k\right)_{j\geq 0}$ the poles of the function

$$\Phi : s \to \frac{I_k\left(x\left(s\right) \wedge x_0\left(s\right)\right)\left(I_k^{'}\left(x_+\left(s\right)\right)K_k - K_k^{'}\left(x_+\left(s\right)\right)I_k\right)\left(x\left(s\right) \vee x_0\left(s\right)\right)}{sI_k^{'}\left(x_+\left(s\right)\right)}e^{st},$$

where ($x(s) = r\sqrt{\frac{s}{D}}$, $x_0(s) = r_0\sqrt{\frac{s}{D}}$, and $x_+(s) = R\sqrt{\frac{s}{D}}$). The associated residues are $\left(r_j^k\right)_{j\geq 0}$. We now compute the residues explicitly.

To identify the poles, we recall the relation between the k-order Bessel function J_k (that is true for z such that $-\pi < \arg(z) < \frac{\pi}{2}$) and the modified Bessel functions I_k [11, p. 375]:

$$I_k(z) = e^{-\frac{1}{2}k\pi i} J_k\left(z e^{\frac{1}{2}\pi i}\right). \tag{5.1}$$

All roots $\alpha_{j,k}$ of the equations

$$J_k^{'}(R\alpha) = 0$$

are real, simple, and strictly positive [11, p. 370] because k is real and

$$k \leq \alpha_{1,k} < \alpha_{2,k} \ldots .$$

Thus,

$$I_k^{'}(-iR\alpha_{j,k}) = 0.$$

Finally, the poles of Φ are simple, given by $p_0^k = 0$ and that for all $j \geq 1$, $p_j^k = -D\alpha_{j,k}^2$. Consequently the associated residues are given for each k for all $j \geq 0$ by

$$r_j^k = \lim_{s\to p_j^k} \left(s - p_j^k\right)\Phi(s). \tag{5.2}$$

Then using the residues, integral (3.21) is given by

$$I(r,\theta,t) = \frac{1}{\Theta\pi Di}\sum_k \sin(k\theta)\sin(k\theta_0)(2\pi i)\sum_{j\geq 0} r_j^k = \frac{2}{\Theta D}\sum_k \sin(k\theta)\sin(k\theta_0)\sum_{j\geq 0} r_j^k.$$

We now compute the residues r_j^k. The residue r_0^k is associated with the pole $p_0^k = 0$ and given by

$$r_0^k = \lim_{s\to 0} s\Phi(s).$$

Using the following identities on the modified Bessel functions [12, p. 489],

$$I_k^{'}(z) = I_{k+1}(z) + \frac{k}{z}I_k(z) \text{ and } K_k^{'}(z) = -K_{k-1}(z) - \frac{k}{z}K_k(z),$$

and substituting the derivatives $I_k^{'}$ and $K_k^{'}$ in the expression of Φ, we get

$$\begin{aligned} r_0^k = \lim_{s\to 0} & \frac{I_k(x(s)\wedge x_0(s))}{\left(I_{k+1} + \frac{k}{x_+(s)}I_k\right)(x_+(s))} \\ & \times\left(\left(\left(I_{k+1} + \frac{k}{x_+(s)}I_k\right)(x_+(s))K_k\right)\right. \\ & \left. + \left(\left(K_{k-1} + \frac{k}{x_+(s)}K_k\right)(x_+(s))I_k\right)\right)(x(s)\vee x_0(s)). \end{aligned}$$

Taking into account only the dominant terms, we get

$$r_0^k = \lim_{s \to 0} \frac{I_k\left(x\left(s\right) \wedge x_0\left(s\right)\right)\left(I_k\left(x_+\left(s\right)\right)K_k + K_k\left(x_+\left(s\right)\right)I_k\right)\left(x\left(s\right) \vee x_0\left(s\right)\right)}{I_k\left(x_+\left(s\right)\right)}.$$

To further compute this limit, we use the Taylor expansions of I_k and K_k [11, p. 375] expressed in terms of the Γ function:

$$I_k\left(z\right) \approx \frac{\left(\frac{1}{2}z\right)^k}{\Gamma\left(k+1\right)} \text{ and } K_k\left(z\right) \approx \frac{1}{2}\Gamma\left(k\right)\left(\frac{1}{2}z\right)^{-k}.$$

For $r < r_0$, we get

$$r_0^k = \lim_{s \to 0} \frac{\frac{\left(\frac{1}{2}\left(x\left(s\right)\right)\right)^k}{\Gamma(k+1)}\left(\frac{\left(\frac{1}{2}\left(x_+\left(s\right)\right)\right)^k}{\Gamma(k+1)}\frac{1}{2}\Gamma\left(k\right)\left(\frac{1}{2}\left(x_0\left(s\right)\right)\right)^{-k} + \frac{1}{2}\Gamma\left(k\right)\left(\frac{1}{2}\left(x_+\left(s\right)\right)\right)^{-k}\frac{\left(\frac{1}{2}\left(x_0\left(s\right)\right)\right)^k}{\Gamma(k+1)}\right)}{\frac{\left(\frac{1}{2}\left(x_+\left(s\right)\right)\right)^k}{\Gamma(k+1)}}.$$

Finally, using the relation $\Gamma\left(k+1\right) = k\Gamma\left(k\right)$ and the expressions of $x(s)$, $x_0(s)$, and $x_+(s)$, we get

$$r_0^k = \frac{r^k\left(r_0^{2k} + R^{2k}\right)}{2kR^{2k}r_0^k}.$$

The computation of the other residues $\left(r_j^k\right)_{j \geq 1}$ is slightly different,

$$r_j^k = \lim_{s \to p_j^k}\left(s - p_j^k\right)\Phi(s),$$

where $p_j^k = -D\alpha_{j,k}^2$. Using the Wronskian relation [12, p. 489],

$$I_k\left(z\right)K_k'\left(z\right) - K_k\left(z\right)I_k'\left(z\right) = -\frac{1}{z},$$

we now substitute

$$K_k^{'}\left(z\right) = \frac{-\frac{1}{z} + K_k\left(z\right)I_k^{'}\left(z\right)}{I_k\left(z\right)}.$$

In the expression of Φ, we get

$$r_j^k = \lim_{s \to p_j^k}\frac{\left(s - p_j^k\right)e^{st}}{s}\frac{I_k\left(x\left(s\right)\right)\left(I_k^{'}\left(x_+\left(s\right)\right)K_k - \left(\frac{-\frac{1}{x_+(s)} + K_k I_k^{'}}{I_k}\right)\left(x_+\left(s\right)\right)I_k\right)\left(x_0\left(s\right)\right)}{I_k^{'}\left(x_+\left(s\right)\right)}.$$

Because

$$\lim_{s \to p_j^k} I_k^{'}\left(x_+\left(s\right)\right) = I_k^{'}\left(x_+\left(p_j^k\right)\right) = 0,$$

we obtain the expression for the residues:

$$r_j^k = \frac{e^{p_j^k t}}{p_j^k}\frac{I_k\left(x\left(p_j^k\right)\right)I_k\left(x_0\left(p_j^k\right)\right)}{I_k\left(x_+\left(p_j^k\right)\right)x_+\left(p_j^k\right)}\lim_{s \to p_j^k}\frac{\left(s - p_j^k\right)}{I_k^{'}\left(x_+\left(s\right)\right)}.$$

Finally, since

$$\lim_{s\to p_j^k} \frac{\left(s-p_j^k\right)}{I_k^{'}\left(x_+(s)\right)} = \frac{2\sqrt{Dp_j^k}}{R} \lim_{s\to p_j^k} \frac{x_+(s)-x_+\left(p_j^k\right)}{I_k^{'}\left(x_+(s)\right)-I_k^{'}\left(x_+\left(p_j^k\right)\right)} = \frac{2\sqrt{Dp_j^k}}{RI_k^{''}\left(x_+\left(p_j^k\right)\right)},$$

we obtain

$$r_j^k = \frac{e^{p_j^k t}}{p_j^k} \frac{I_k\left(x\left(p_j^k\right)\right) I_k\left(x_0\left(p_j^k\right)\right)}{I_k\left(x_+\left(p_j^k\right)\right) x_+\left(p_j^k\right)} \frac{2\sqrt{Dp_j^k}}{RI_k^{''}\left(x_+\left(p_j^k\right)\right)}.$$

To simplify this expression, we use that I_k satisfies the differential equation [11, p. 374]

$$I_k^{''}(z) + \frac{1}{z} I_k^{'}(z) - \left(1 + \frac{k^2}{z^2}\right) I_k(z) = 0.$$

Thus for $z = x_+\left(p_j^k\right)$,

$$I_k^{''}\left(x_+\left(p_j^k\right)\right) = \frac{p_j^k R^2 + Dk^2}{p_j^k R^2} I_k\left(x_+\left(p_j^k\right)\right).$$

We get

$$r_j^k = \frac{2De^{p_j^k t}}{R^2 p_j^k + Dk^2} \frac{I_k\left(x\left(p_j^k\right)\right) I_k\left(x_0\left(p_j^k\right)\right)}{I_k^2\left(x_+\left(p_j^k\right)\right)},$$

and finally, using (5.1), we get

$$r_j^k = \frac{2e^{-D\alpha_{j,k}^2 t}}{-R^2\alpha_{j,k}^2 + k^2} \frac{J_k\left(r\alpha_{j,k}\right) J_k\left(r_0\alpha_{j,k}\right)}{J_k^2\left(R\alpha_{j,k}\right)}.$$

Integral (3.21) is given by

$$I(r,\theta,t) = \frac{2}{\Theta D} \sum_k \sin(k\theta)\sin(k\theta_0) \sum_{j\geq 0} r_j^k = \frac{2}{\Theta D}\left(S_1(r,\theta,t) + S_2(r,\theta,t)\right), \tag{5.3}$$

where

$$S_1(r,\theta,t) = \sum_k \sin(k\theta)\sin(k\theta_0) \frac{r^k\left(r_0^{2k} + R^{2k}\right)}{2kR^{2k}r_0^k},$$

$$S_2(r,\theta,t) = -2\sum_k \sin(k\theta)\sin(k\theta_0) \sum_{j=1}^{\infty} e^{-D\alpha_{j,k}^2 t} \frac{J_k\left(r\alpha_{j,k}\right) J_k\left(r_0\alpha_{j,k}\right)}{\left(R^2\alpha_{j,k}^2 - k^2\right) J_k^2\left(R\alpha_{j,k}\right)}.$$

OPTIMAL LIQUIDATION BY A LARGE INVESTOR*

AJAY SUBRAMANIAN†

Abstract. We develop a partial equilibrium model to investigate the problem of optimal liquidation over a finite or infinite time horizon for an investor with large holdings in a risky asset. The imperfect liquidity in the market for the asset leads to a nonlinear path dependent feedback on the underlying asset price process due to the large investor's trades and his holdings in the asset. We use probabilistic techniques to prove verification and existence results for optimal liquidation policies for the utility-maximizing investor under broad assumptions. In particular, our results imply the existence of optimal policies if the investor has power utility functions. We provide analytical expressions for the optimal policy when the large investor has logarithmic preferences. We use these results to characterize the "liquidity discount," which is a measure of the liquidity risk of the large investor's position in the risky asset.

1. Introduction.

Traditional finance theory is based on the competitive market paradigm which assumes that markets are perfectly elastic, that is, that all investors are price-takers who can buy or sell as many shares of a security as they want without affecting its price and purchases/sales have immediate execution. The absence of these conditions is sometimes labeled *liquidity risk*. Liquidity risk is particularly important for thinly traded securities or in scenarios in which investors with comparatively large positions in a security wish to liquidate their holdings in a short period of time. Examples of such investors are insurance firms who face regulatory minimum capital requirements, financial institutions who face "value at risk" constraints, mutual or hedge fund managers who must make large trades in a short period of time in the face of redemptions by investors, and financially distressed firms who must liquidate large asset holdings to meet contractual debt obligations.[1]

Motivated by the above considerations, several studies attempt to provide characterizations of liquidity risk through the investigation of the optimal liquidation problem for an investor in an illiquid underlying asset market (see, for example, Bertsimas and Lo [3], Almgren and Chriss [1], Duffie and Ziegler [8], and Subramanian and Jarrow [30]). These studies use different frameworks to examine the optimal liquidation policy of a large investor with holdings in a single illiquid asset or a portfolio of such assets where trades by the investor may affect the underlying asset price processes. The liquidity risk is characterized in terms of the value (or utility) the investor derives from liquidating her portfolio over a finite time horizon.

In this article, we contribute to this aspect of the literature by examining the optimal liquidation problem over a finite or infinite time horizon for an investor with large holdings in a single risky asset where the investor's trades and holdings in the

[1] The importance of liquidity risk is highlighted by the turmoil in global capital markets in the late 1990's when Long Term Capital Management (LTCM) was forced to unwind its large positions in several securities in a very short period of time in the aftermath of the Asian currency crisis.

asset may have a *nonlinear and path dependent* feedback on the underlying asset price process. We consider the situation where there are no execution lags for trade orders and the investor trades continuously, as in the continuous auction models of Kyle [21] and Back [2]. The investor's liquidation policy is characterized by a *liquidation rate* process, which is a mathematically tractable representation of the effect of insider trading restrictions that prevent the investor from making large trades on a single date. The absence of execution lags makes this a viable continuous time extension of a more realistic model where investors trade only at discrete, but "closely spaced," instants of time. There could be a nonlinear path dependent feedback on the underlying asset price process due to the investor's holdings in the asset as well as her liquidation rate. In particular, this general formulation allows for both permanent and temporary price impacts. The underlying asset price process is continuous and, similar to the models of Kyle [21], Back [2], and Cuoco and Cvitanic [5], the investor's liquidation policy affects only the expected return of the asset. As in these studies, the volatility of the asset is due to the presence of "small" or "liquidity" traders.

We adopt a *partial equilibrium* approach where the impact of the large investor's trades on the asset price is exogenously specified as opposed to the general equilibrium framework adopted in Kyle [21], where the impact is derived endogenously through equilibrium considerations. This facilitates the investigation of a much broader class of models of the effect of large investors on financial markets.

We use probabilistic "martingale" techniques to prove verification and existence results for optimal liquidation policies for the investor. Our analysis leads to an explicit characterization of sufficient conditions on the investor's preferences and the feedback function describing the impact of the large investor's trades on the asset price, under which optimal liquidation policies exist. The identification of such conditions that ensure the existence of an optimal policy and, therefore, a partial equilibrium, is important from an economic standpoint since it establishes the *viability* of the class of partial equilibrium models we propose as an appropriate description of large investor behavior. We use the results of our analysis to derive explicit analytical expressions for the investor's optimal liquidation policy and his value function when he has logarithmic preferences. We then characterize the *liquidity discount*, which is a measure proposed by Subramanian and Jarrow [30] to quantify the liquidity risk of a large investor's position in a risky asset. As they discuss, the liquidity discount could be used to modify value at risk measures to also incorporate liquidity risk.

From a mathematical standpoint, the probabilistic methodology we employ is similar to that adopted in earlier papers that examine optimal consumption/investment or pricing/hedging problems in incomplete markets within frameworks where dynamic programming techniques may be difficult to apply.[2] In particular, we show the existence of optimal liquidation policies by establishing the duality between the investor's liquidation problem and a dual control problem.

Apart from the fact that the problem we consider is different from those examined by previous studies in this area, there are some important aspects of our framework that make the application of the duality methodology significantly different from the analyses in these studies. Since we examine the optimal liquidation problem of an investor with holdings in a single risky asset, the only feasible trades are *sales* of

[2] See, for example, He and Pearson [14], Cvitanic and Karatzas [6], Cvitanic and Ma [7], Karatzas and Kou [16], El Karoui, Peng, and Quenez [11], Buckdahn and Hu [4], Cuoco and Cvitanic [5], El Karoui and Jeanblanc [10], Kramkov and Schachermayer [20], Ma and Yong [22], Follmer and Leukert [12], and Mnif and Pham [25]. See Pritsker [27], He and Mamaysky [15], and Polimenis [26] for frameworks with large traders where dynamic programming techniques are employed.

the asset. As we will see later, this feature causes the set of feasible dual processes to be *unbounded*. This leads to nontrivial complications in the demonstration of verification and existence results for solutions to the dual control problem and hence the primal one. Further, the investor derives utility from the periodic liquidation of her holdings in the asset, but her liquidation rate affects the underlying asset price process. Finally, the "wealth process" of the investor that is the market value of her holdings in the asset is always nonnegative. Therefore, our study also contributes to the existing literature from a mathematical standpoint by illustrating the application of the convex duality methodology to a stochastic control problem where the typical assumptions and features of the frameworks examined by prior studies do not hold.

We analyze the optimal liquidation problem of a large investor over a finite as well as an infinite time horizon. The finite time horizon formulation is particularly relevant in the context of the motivating examples discussed earlier in which large investors such as insurance firms, financial institutions, mutual and hedge funds, and financially distressed firms have to liquidate large asset holdings over short periods of time. Insurance firms have to liquidate large holdings in risky assets to make liability payments in the aftermath of catastrophic events such as the September 11th terrorist attack and Hurricane Katrina. Given the time taken to file and process liability claims, the liquidation horizon for such firms would be expected to be of the order of 6 months to a year. For financial services firms who face minimum capital requirements or "value at risk" constraints, the relevant liquidation horizon could be much shorter (10 days to a month).[3] Mutual funds and hedge funds that face redemptions by investors, especially in bear markets, typically have to liquidate large holdings over a period of one to two months. Finally, financially distressed firms often have to liquidate large asset holdings over short periods of time (3–6 months) to meet contractual debt obligations.

In the infinite time horizon version of the model, the investor does not self-impose a possibly suboptimal liquidation horizon, but optimally liquidates his asset holdings until they fall to zero. The theoretical advantages of the infinite time horizon formulation are, however, mitigated to some extent by two important observations. First, as discussed above, the choice of liquidation horizon may not always be at the discretion of the investor and could be a consequence of regulatory requirements or market considerations. Second, it follows from standard convergence arguments that one can choose a sufficiently large finite liquidation horizon such that the investor's optimal value function in the finite time horizon model is arbitrarily close to the optimal value function in the infinite time horizon model. In our view, therefore, the finite time horizon and infinite time horizon analyses are complementary.

The plan for the paper is as follows. Section 2 presents the model in which a large investor liquidates his holdings over a finite time horizon. In section 3, we formulate the large investor's dual control problem. In section 4, we prove verification and existence theorems for optimal liquidation policies. In section 5, we explicitly derive the optimal policies for an investor with logarithmic preferences and characterize the liquidity discount. In section 6, we analyze two extensions of the model: the scenario in which the investor could incur costs from holding nonzero wealth in the asset at the terminal date, and the scenario in which the liquidation horizon is infinite and the investor liquidates his shares until they fall to zero. Section 7 concludes the paper. Detailed proofs are in the appendix.

2. The model. We consider a time horizon $[0, T]$ and a probability space (Ω, F, P) with a complete and augmented filtration $\{F_t\}$ generated by a Brownian

[3] In fact, standard "value at risk" measures presume a liquidation horizon of ten days.

motion B_t with $F_T \equiv F$. The number of shares of the asset that the large investor holds at any date is represented by the nonnegative F_t-adapted process $N(.)$. The large investor's intertemporal liquidation process is absolutely continuous; that is, the large investor liquidates at the rate $n(.)$ so that $n(t)\,dt$ shares of the asset are liquidated over the time interval $[t, t+dt]$. We examine the scenario where there are no execution lags and transaction costs are insignificant (see Almgren and Chriss [1] or Subramanian and Jarrow [30] for models that incorporate execution lags and transaction costs). The process $n(.)$ may be random but is assumed to be $\{F_t\}$-progressively measurable, reflecting the assumption that the large investor's choice trade at a certain time depends on his information at that time and cannot anticipate the future. Thus,

$$N(t) = N(0) - \int_0^t n(s)\,ds.$$

The presence of insider trading restrictions and imperfect liquidity in financial markets prevents investors from making large trades on a single date. The assumption of an absolutely continuous liquidation process is a mathematically tractable representation of the effect of such restrictions. Hence, the investor may only liquidate his large position in the risky asset over an extended time horizon. Further, the fact that we examine the scenario where execution lags are insignificant implies that this is a viable continuous time extension of a more realistic model where the investor trades at discrete, but closely spaced, instants of time.

The asset price process $S(.)$ satisfies the following stochastic differential equation:

$$dS(t,\omega) = S(t,\omega)(\overline{\mu}(t,\omega) + \overline{\overline{\mu}}(W(t,\omega), c(t,\omega), t, \omega))\,dt + S(t,\omega)\sigma(t,\omega)\,dB_t, \tag{2.1}$$

where $W(t,\omega) = N(t,\omega)S(t,\omega)$ represents the *market value* of the large investor's holdings in the asset and $c(t,\omega) = n(t,\omega)S(t,\omega)\,dt$ is the large investor's cash flow from liquidating $n(t,\omega)$ shares at time t. Equation (2.1) implies that the asset price process $S(.)$ may be affected by the large investor's liquidation rate $n(.)$ as well as his wealth in the asset. The feedback function $\overline{\overline{\mu}}$ may depend explicitly on time and the probability space parameter ω and is therefore, in general, path dependent. Therefore, the large investor's past liquidation policy may affect his present and future cash flows from liquidation. This formulation allows us to incorporate both permanent and transient price impacts of the large investor's trades. The restrictions on $\overline{\mu}, \overline{\overline{\mu}}, \sigma$ that ensure the existence of a unique strong solution to (2.1) are specified later. We refer to the process $c(.)$ as the *liquidation rate* process and the process $W(.)$ as the *wealth process.*

ASSUMPTION 1. *We assume that* $\overline{\mu}(t,\omega)$ *is uniformly bounded and* F_t*-progressively measurable and* $\sigma(.)$ *and* $\sigma^{-1}(.)$ *are uniformly bounded and* F_t*-progressively measurable. In the following, we shall occasionally drop the explicit dependence on the probability space parameter* ω *wherever there is no danger of confusion. From* (2.1)*, we see that the process* $W(.)$ *evolves as follows:*

$$dW(t) = W(t)[\overline{\mu}(t) + \overline{\overline{\mu}}(W(t), c(t), t)]\,dt + W(t)\sigma(t)\,dB(t) - c(t)\,dt. \tag{2.2}$$

ASSUMPTION 2. *A feasible liquidation strategy is a nonnegative process* $(W(.), c(.))$ *satisfying*

$$\begin{aligned} &\int_0^T |W(t)(\overline{\mu}(t) + \overline{\overline{\mu}}(W(t), c(t), t))\mid dt + \int_0^T \left|(W(t)\sigma(t))^2\right| dt < \infty \ \textit{a.s.},\\ &\int_0^T c(t)\,dt < \infty \ \textit{a.s.} \end{aligned} \tag{2.3}$$

The conditions in (2.3) *basically ensure that the process* $W(.)$ *described by* (2.2) *is well defined. Alternatively, we say that the terminal wealth-liquidation rate process* $(W, c(.))$ *is feasible if* $W(T) = W$*, where* $W(.)$ *is the wealth process corresponding to the liquidation rate process* $c(.)$ *and* $(W(.), c(.))$ *is feasible. We denote the set of feasible liquidation strategies* $(W(.), c(.))$ *by* Θ.

ASSUMPTION 3. *The large investor has a time-additive utility function for intertemporal cash flows and a utility of terminal wealth defined by*

$$U(c, W) = E\left[\int_0^T u_1(c(t), t))\, dt\right] + E[u_2(W, T)]. \tag{2.4}$$

Remark 1. We allow for the possibility that the investor may derive nonzero utility from terminal wealth for the sake of generality. As we discuss in Remark 4 in section 4, all our results hold even when the investor derives no utility from remaining holdings in the asset at date T so that he liquidates his entire position over the interval $[0, T)$. The explicit time dependence of u_1, u_2 allows for the incorporation of costs borne by the investor from delaying liquidation of his holdings. In section 6.2, we analyze the scenario in which the time horizon $T = \infty$.

The objective function (2.4) is well defined for liquidation rate–terminal wealth processes satisfying

$$E\left[\int_0^T u_1(c(t), t)^-\, dt\right] < \infty; \quad E[u_2(W, T)^-] < \infty. \tag{2.5}$$

We assume that the large investor's liquidation rate process and the terminal wealth are *admissible* if they satisfy the above condition.

Note. If $u_1(c, t) \geq 0, u_2(W, T) \geq 0$ for all (c, t) and W, then (2.5) is trivially satisfied.

The investor's objective function (2.4), which implies that he has a concave, Von Neumann–Morgenstern utility function over his intertemporal liquidation rate $c(.)$ and terminal wealth $W(.)$, is justified as follows.

First, recall that the investor's cash flow from liquidating shares at date t is $c(t)\, dt$. This cash flow could be used for current consumption as well as to finance future consumption. If the cash flow is used for current consumption, then the investor's utility payoff is $u_1(c(t), t)$. If a portion of the cash flow is used to finance future consumption (by possibly trading in other securities), then, like the terminal utility function$u_2(W, T)$, the function $u_1(c(t), t)$ should be viewed as an "indirect" utility function over cash flows as in Chapter 6 of Mas-Colell, Whinston, and Green [23].

Second, as discussed in Mas-Colell, Whinston, and Green [23], the objective function (2.4) could more generally be viewed as corresponding to the scenario in which the investor has convex preferences over *monetary lotteries*; that is, the investor's preferences are directly defined over cash flow streams.

Third, the concavity of the function u_1 also incorporates the possible presence of "direct" liquidation/transaction costs that are convex in the size of the trade (recall that the model incorporates "indirect" costs through the effects of trades on the asset price process—see (2.1)). In the absence of friction due to illiquidity, the payoff to a risk-neutral investor would be $c(t)\, dt$. In an illiquid market, the payoff would be $c(t)\, dt$ less liquidation/transaction costs that are convex in the size of the trade, which implies that the *net* payoff to the investor is concave. Hence, even if the investor were risk-neutral, his payoffs from liquidation would be concave.

Fourth, the objective function (2.4) incorporates precautionary motives of the investor to smooth liquidation proceeds over time and across states in order to lower the direct and indirect costs he faces due to the illiquidity of the underlying asset.

A possible alternative objective function is one in which the investor maximizes an increasing, concave function of his discounted "cumulative" liquidation proceeds; that is, the investor maximizes

$$Eu\left[\int_0^T e^{-lt}c(t)\,dt\right],$$

where l is a discount rate and u is increasing and concave. The investor, therefore, derives the same utility from liquidation proceeds that have the same discounted present value; that is, the *timing* of intertemporal liquidation cash flows along a particular sample path does not matter. Adapting the arguments in Fudenberg, Holmstrom, and Milgrom [13] to our setting, such an objective function is, in general, justified from a decision-theoretic standpoint when the investor has unlimited access to credit markets from which he can borrow against future liquidation proceeds. As discussed earlier, however, liquidity risk is particularly relevant precisely when the investor is credit- or liquidity-constrained and does not have easy access to outside credit. Further, in contrast with (2.4), the above objective function does not incorporate the fact that the *timing* of intertemporal proceeds from liquidation often matters to liquidity-constrained investors such as insurance firms faced with large liability claims, mutual or hedge funds faced with rapid redemptions by investors, and financially distressed firms who must meet contractual debt obligations. Finally, the objective function above precludes the possibility of precautionary motives for the investor to smooth liquidation proceeds over time that are potentially important, especially in highly illiquid markets with large costs arising from the price impact of trades.

ASSUMPTION 4. *In the following, the symbol $u(.)$ generically refers to the utility functions u_1 and u_2 above. The utility function $u(.,t)$ is increasing, strictly concave, and continuously differentiable on $(0,\infty)$ for all $t \in [0,T]$. It satisfies $\lim_{c\uparrow\infty} u(c,t) = \infty$ for all $t \in [0,T]$. Moreover, it satisfies*

$$\lim_{c\downarrow 0} u_c(c,t) = \infty \text{ and } \lim_{c\uparrow\infty} u_c(c,t) = 0, \tag{2.6}$$

and there exist constants $\delta \in (0,1)$ and $\gamma \in (0,\infty)$ such that

$$\delta u_c(c,t) \geq u_c(\gamma c,t) \quad \forall (c,t) \in (0,\infty)\times[0,T]. \tag{2.7}$$

Finally, $u(c,.)$ is continuous and decreasing on $[0,T]$ for all $c \geq 0$. The above conditions ensure that the function $u_c(.,t)$ has a continuous and strictly decreasing inverse $f(.,t)$ mapping $(0,\infty)$ onto itself which also satisfies the property

$$\forall\delta \in (0,\infty), \exists\,\gamma \in (0,\infty)$$

such that

$$f(\delta y,t) \leq \gamma f(y,t) \quad \forall (y,t) \in (0,\infty)\times[0,T]. \tag{2.8}$$

Remark 2. In section 6, we analyze the scenario in which the investor could incur costs from any remaining wealth in the asset at date T. In this case, the function $u_2(.,T)$ could be a general, concave, possibly *nonmonotonic* function taking both positive and negative values.

We define the function

$$h(W,c,t,\omega)=W\overline{\overline{\mu}}(W,c,t,\omega) \text{ for } (W,c)\in R_+\times R_+. \tag{2.9}$$

Assumption 5. *We assume that $h(.)$ is concave and upper semicontinuous in (W,c) for each $(t,\omega)$and uniformly bounded above. We also assume that $h(W,.,t,\omega)$ is monotonically decreasing for each (W,t,ω) and $h(0,0,t,\omega)=0$ so that there is no feedback on the asset price process if the large investor's asset holdings and liquidation rate are zero.*

From (2.2), we see that Assumption 5 implies that the expected increase in the wealth process $W(.)$ of the large investor decreases with the liquidation rate. The concavity of the function h implies that liquidating at a higher rate *relative* to his holdings has a disproportionately greater impact on the investor's wealth process. For mathematical reasons that will become clear later, we extend the definition of $h(.)$ to *negative* values of W. More precisely, we define $h(W',c,t,\omega)$ for $W'<0$ to be *any* nonpositive, concave, upper semicontinuous extension of $h(W,c,t,\omega)$ for $W>0$ (such an extension always exists by recalling that $h(0,0,t,\omega)=0$). Therefore,

$$\begin{gathered} h(.,.,t,\omega): R\times R_+\to R \text{ is concave and upper semicontinuous with} \\ h(W,c,t,\omega)\le 0 \text{ for } W\le 0. \end{gathered} \tag{2.10}$$

For convenience of notation, we also denote this extension by $h(.)$.

We now introduce some additional notation that we will need subsequently and some technical assumptions. For $(\mu_1,\nu)\in R^2$, define

$$\overrightarrow{h}(\mu_1,\nu,t,\omega)=\sup_{(W,c)\in R^\times R_+} h(W,c,t,\omega)-\mu_1 W-\nu c. \tag{2.11}$$

Let

$$M_t(\omega)=\left\{(\mu_1,\nu)\in R^2:\overrightarrow{h}(\mu_1,\nu,t,\omega)<\infty\right\}. \tag{2.12}$$

$M_t(\omega)$ is the *effective domain* of $\overrightarrow{h}$. It is well known that $\overrightarrow{h}$ is a nonnegative, convex, lower semicontinuous function and $M_t(\omega)$ is a nonempty, closed convex set with $0\in M_t(\omega)$ for all (t,ω) (see, e.g., Ekeland and Temam [9]). We assume that $h(.,.,t,\omega)$ is such that the sets $M_t(\omega)$ are *uniformly bounded* in the first coordinate and *uniformly bounded below* in the second coordinate. A sufficient, but not necessary, condition for this to hold is that $h(W,c,t,\omega)$ be uniformly Lipschitz in (W,c) (see, for example, El Karoui, Peng and Quenez [11]). Denote by M the family of two-dimensional progressively measurable processes $(\mu_1(t,\omega),\nu(t,\omega))$ such that $\chi(t,\omega)\in M_t(\omega)$ for all $(t,\omega)\in[0,T]\times\Omega$, $\nu(.)$ is *uniformly bounded*, and

$$E\left[\int_0^T \|\chi(t,\omega)\|^2\,dt\right]<\infty. \tag{2.13}$$

For later use, we define the sets

$$N_t(\omega)=R\times M_t(\omega) \tag{2.14}$$

and denote by N the family of three-dimensional progressively measurable processes $(\mu_0(t,\omega),\mu_1(t,\omega),\nu(t,\omega))$ such that $(\mu_0(t,\omega),\mu_1(t,\omega),\nu(t,\omega))\in N_t(\omega)$ for all $(t,\omega)\in$

$[0,T] \times \Omega$, $\nu(.)$ is uniformly bounded, and $E[\int_0^T [\|\mu_0(t,\omega)\|^2 + \|\mu_1(t,\omega)\|^2]\, dt] < \infty$. For subsequent notational convenience, we define the function $\overrightarrow{g}$ by

$$\overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \nu(t,\omega), t, \omega) = \overrightarrow{h}(\mu_1(t,\omega), \nu(t,\omega), t, \omega). \tag{2.15}$$

Assumption 6. *The function $\overrightarrow{h}$ is continuous and bounded on its effective domain.*

It follows from Theorem 12.2 in Rockafellar [28] that

$$h(W, c, t, \omega) = \inf_{((\mu_1,\nu)\in M_t(\omega))} \left[\overrightarrow{h}(\mu_1, \nu, t, \omega) + W\mu_1 + c\nu\right]. \tag{2.16}$$

In section 5, we present an example of a feedback function h that satisfies all the assumptions above, and we explicitly solve the optimal liquidation problem for an investor with logarithmic preferences. We now state an approximation lemma whose proof we omit for the sake of brevity since it follows using standard arguments.

Lemma 2.1. *For any $(W, c) \in \Theta$, there exists a sequence $\{\chi^n() \equiv (\mu_1(), \nu^n()) \in M\}$ and an F_t-progressively measurable process$\nu^*(.)$ such that a.e.*

$$\begin{aligned} &h(W(t), c(t), t) = \lim\nolimits_{n\to\infty} \left[\overrightarrow{h}(\chi^n(t), t) + W(t)\mu_1(t) + c(t)\nu^n(t)\right], \\ &\nu^*(t,\omega) = \lim\nolimits_{n\to\infty} \nu^n(t,\omega), \end{aligned} \tag{2.17}$$

and

$$\int_0^T |\nu^*(t,\omega)c(t,\omega)|\, dt < \infty \quad a.s.$$

3. Feasible liquidation policies. We now establish the duality between the primal problem ((2.4) and (2.5)) of maximizing the large investor's expected utility with a *dual problem* for which it is easier to verify optimal policies and to show their existence under broad assumptions. The space of dual processes $\chi(.)$ is

$$\{\chi(t) \equiv (\mu_0(t), \mu_1(t), \nu(t)), \chi \in N\},$$

where N is defined in the paragraph following (2.14).

Remark 3. The space of dual processes is *unbounded*, unlike in Cuoco and Cvitanic [5]. This makes our framework and analysis significantly different. Mathematically, this feature complicates the demonstration of verification and existence results of solutions to the dual control problem.

For an arbitrary process $\chi \in N$, define the exponential local martingale

$$\xi_\chi(t) = \exp\left(\int_0^t \kappa_\chi(s)\, dB(s) - \frac{1}{2}\int_0^t |\kappa_\chi(s)|^2\, ds\right) \tag{3.1}$$

and the discount factor

$$\beta_\chi(t) = \exp\left(-\int_0^t \mu_0(s)\, ds\right), \tag{3.2}$$

where

$$\kappa_\chi(t) = -\sigma(t)^{-1}(\overline{\mu}(t) + \mu_1(t) - \mu_0(t)), \tag{3.3}$$

and let

$$\pi_\chi(t) = \beta_\chi(t)\xi_\chi(t). \tag{3.4a}$$

Note. Although $\pi_\chi(.)$ does not depend on $\nu(.)$, we retain the notation above to simplify subsequent exposition. Throughout the paper, the notation $\pi_\chi(.)$ should be taken to represent $\pi_{(\mu_0(.),\mu_1(.))}(.)$ to indicate that it depends only on $(\mu_0(.), \mu_1(.))$. From (3.4a), it follows that

$$\pi_\chi(t) = 1 - \int_0^t \pi_\chi(s)\mu_0(s)\,ds - \int_0^t \pi_\chi(s)\sigma(s)^{-1}(\overline{\mu}(s) + \mu_1(s) - \mu_0(s))\,dB_s. \tag{3.4b}$$

The following proposition establishes the fundamental relationship between *feasible* liquidation policies and the space of dual processes.

Proposition 3.1. *If $(W(.), c(.))$ is a feasible liquidation policy and W is the terminal wealth, then*

$$E\left[\int_0^T \pi_\chi(t)(1-\nu(t))c(t)\,dt + \pi_\chi(T)W\right] \leq W_0 + E\left[\int_0^T \pi_\chi(t)\overrightarrow{g}(\chi(t),t)\,dt\right] \tag{3.5}$$

for all $\chi \in N$ with $\nu(.) \leq 1$.

Proof. The proof is in the appendix. □

Equation (3.5) is a *necessary condition* for feasibility of the policy $(c(.), W(.))$ and therefore represents a constraint on the arguments of the large investor's optimization problem (2.4).

4. Verification and existence of optimal liquidation policies.

In this section, we first prove a verification theorem for the optimal liquidation policy for the large investor in terms of the solution to a dual optimization problem. We then prove the existence of optimal liquidation policies for the large investor under fairly broad assumptions by proving the existence of a solution to the dual problem satisfying the conditions of the verification theorem. We thereby provide broad sufficient conditions for the existence of optimal liquidation policies.

Suppose the large investor's optimal liquidation/terminal wealth policy exists and is denoted by (c^*, W^*). By the result of Proposition 3.1, there should exist a Lagrange multiplier $\lambda^* > 0$ such that $(c^*, W^*, \lambda^*, \chi^*)$ is a saddle point of the map

$$\begin{aligned}L(c, W, \lambda, \chi) = U(c, W) - \lambda \\ \times \left(E\left[\int_0^T \pi_\chi(t)((1-\nu(t))c(t) - \overrightarrow{g}(\chi(t),t))\,dt + \pi_\chi(T)W\right] - W_0\right),\end{aligned} \tag{4.1}$$

where we maximize with respect to c, W and minimize with respect to (λ, χ). Let

$$\begin{aligned}\overline{u_1}(y,t) &= \sup_{c\geq 0}[u_1(c,t) - yc] = u_1(f_1(y,t),t) - yf_1(y,t),\\ \overline{u_2}(y,t) &= \sup_{W\geq 0}[u_2(W,T) - yW] = u_2(f_2(y,T),T) - yf_2(y,T).\end{aligned} \tag{4.2}$$

We have the following well-known lemma (see Karatzas et al. [17, p. 707]).

Lemma 4.1. *The function $\overline{u}(.,t) : (0,\infty) \to R$ is strictly decreasing and strictly convex for all $t \in [0,T]$, with $\frac{\partial}{\partial y}\overline{u}(y,t) = -f(y,t)$. Moreover, $\overline{u}(0+,t) = u(\infty,t)$ and $\overline{u}(\infty,t) = u(0+,t)$, where the symbol u refers generically to the functions u_1 and u_2.*

If we maximize (4.1) with respect to c, we obtain

$$\begin{aligned}(4.3)\quad & J(\lambda,\chi)\\ &= E\left[\int_0^T \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t),t)\,dt + \lambda\int_0^T \pi_\chi(t)\overrightarrow{g}(\chi(t),t)\,dt + \overline{u_2}(\lambda\pi_\chi(T),T)\right] + \lambda W_0.\end{aligned}$$

We see that the functional above is well defined for all $\chi \in N$ if and only if

$$E\left[\int_0^T \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t),t)^- dt\right] < \infty \quad \text{and} \quad E\left[\overline{u_2}(\lambda\pi_\chi(T),T)^-\right] < \infty \text{ for all } \chi \in N.$$

By Lemma 4.1 and the continuity of $\overline{u_1}(0,t)$ for $t \in [0,T]$, which follows from Assumption 4, $\overline{u_1}(.,t)$ is uniformly bounded below for all $t \in [0,T]$ and $\overline{u_2}(.,T)$ is bounded below. Therefore, both the inequalities above hold and $J : (0,\infty) \times N \to R \cup \{\infty\}$ is well defined. We note that $J(\lambda,\chi) = \infty$ if $1-\nu(t) \leq 0$ on a set of positive measure in $[0,T]\times\Omega$ (since $\overline{u_1}(y,t) = \infty$ for $y \leq 0$). Therefore, it suffices to consider the problem

$$(4.4)\qquad \inf_{(\lambda,\chi)\in(0,\infty)\times N'} J(\lambda,\chi),$$

where

$$N' = \{\chi(.) \in N : \nu(t) \leq 1 \text{ on } [0,T]\times\Omega\}.$$

We can then prove the following *verification theorem* for the optimal liquidation policy.

PROPOSITION 4.1. *If* $(\lambda^*,\chi^*) \in (0,\infty)\times N'$ *solves problem* (4.4) *and*

$$(4.5)\qquad \begin{aligned} &E\left[\int_0^T \pi_{\chi^*}(t) f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt + \pi_{\chi^*}(T) f_2(\lambda^*\pi_{\chi^*}(T),T)\right] < \infty,\\ &E\left[\int_0^T \pi_{\chi^*}(t)\,dt\right] < \infty, E[\pi_{\chi^*}(T)] < \infty,\end{aligned}$$

then the policy

$$(4.6)\qquad \begin{aligned} c_{\chi^*}(t) &= f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t),\\ W_{\chi^*} &= f_2(\lambda^*\pi_{\chi^*}(T),T)\end{aligned}$$

is optimal, and the optimal wealth process is given by

$$\begin{aligned}(4.7)\quad & W_{\chi^*}(t)\\ &= \pi_{\chi^*}(t)^{-1} E\left[\int_t^T \pi_{\chi^*}(s)((1-\nu^*(s))c_{\chi^*}(s) - \overrightarrow{g}(\chi^*(s),s))\,ds + \pi_{\chi^*}(T)W_{\chi^*}\,|F_t\right].\end{aligned}$$

Proof. The proof is in the appendix. □

We now use the previous results to show that optimal liquidation policies for the large investor exist under fairly broad assumptions on the large investor's preferences and the feedback function $h(.)$. Before proceeding, we need to introduce some notation. Let $(\mu_0(.),\mu_1(.))$ be a fixed, square integrable, progressively measurable process such that the set of processes $\nu(.)$ (denoted by$D_{(\mu_0(.),\mu_1(.))}$), for which

$(\mu_0(.), \mu_1(.), \nu(.)) \in N'$, is nonempty. The (t, ω)-section of the set $D_{(\mu_0(.),\mu_1(.))}$ is denoted by $D_{(\mu_0(.),\mu_1(.))}(t, \omega)$, i.e.,

$$D_{(\mu_0(.),\mu_1(.))}(t, \omega) = \left\{\nu(t, \omega) : \nu(.) \in D_{(\mu_0(.),\mu_1(.))}\right\}.$$

By Assumption 5, the set $D_{(\mu_0(.),\mu_1(.))}(t, \omega)$ is closed, convex, uniformly bounded below, and uniformly bounded above (by the definition of the set N').

Lemma 4.2. *For a fixed, square integrable, progressively measurable process $(\mu_0(.), \mu_1(.))$ and a fixed $\lambda \in (0, \infty)$, such that $D_{(\mu_0(.),\mu_1(.))}$ is nonempty, if*

$$\inf_{\nu(.) \in D_{(\mu_0(.),\mu_1(.))}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.))$$

exists, then it is uniquely attained. Moreover, $\inf_{\nu(.) \in D_{(\mu_0(.),\mu_1(.))}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.))$ is a convex functional of $\pi_\chi \equiv \pi_{(\mu_0(.),\mu_1(.))}$.

Proof. The proof is in the appendix. □

Assumption 7. *$D_{(\mu_0(.),\mu_1(.))}(t, \omega) = [-\Gamma_{(t,\omega)}, 1]$ for all square integrable, progressively measurable $(\mu_0(.), \mu_1(.))$ for which $D_{(\mu_0(.),\mu_1(.))}$ is nonempty. Here $0 \leq \Gamma_{(t,\omega)} < \infty$ is a fixed constant for each (t, ω).*

It is easy to see that a sufficient, but not necessary, condition for this to hold is that $h(.)$ be separable, i.e., that it have the form

$$h(\theta, c, t, \omega) = g_1(\theta, t, \omega) + g_2(c, t, \omega),$$

where $g_1(., t, \omega)$ and $g_2(., t, \omega)$ are concave, upper semicontinuous, and uniformly bounded above.

Proposition 4.2. *In the following, the symbol u generically refers to the functions u_1 and u_2. An optimal liquidation policy for the large investor exists if, in addition to Assumptions 1–7,*

(a) *$u(\infty, t) = \infty$ for all $t \in [0, T]$ and $0 \leq u(c, t) \leq k(1 + c^{1-b})$ on $(0, \infty) \times [0, T]$ for some $k \geq 0, 0 < b < 1$;*

(b) *$c \to cu'(c, t)$ is increasing on $(0, \infty)$ for each $t \in [0, T]$ so that $x \to \overline{u}(\exp(x), t)$ is convex on R;*

(c) *for all, there exists $\chi \in N'$ such that $J(\lambda, \chi) < \infty$;*

(d) *the functions $\overline{u}(., t) : R_+ \to R$ and $\overrightarrow{g}(., t, \omega) : N_t(\omega) \to R$ are strictly convex and continuously differentiable on the interior of their domains for each (t, ω); and*

(e) *$cu_c(c, t) \leq a + (1 - b)u(c, t)$ on $(0, \infty) \times [0, T]$ for some $a, b \geq 0$.*

Note. Assumption (c) above actually follows from assumption (a). (see Remark 11.9 in Karatzas et al. [17]).

Proof. The proof is in the appendix. □

It is easily checked that the assumptions of the above proposition hold if $u(c, t) = \beta(t)c^\gamma, 0 < \gamma < 1$, for some nonnegative uniformly bounded measurable function $\beta(.)$, where $u(.)$ refers generically to the utility functions $u_1(.)$ and $u_2(.)$. Therefore, the result of Proposition 4.2 implies that an optimal policy exists for a large investor with power utility functions.

Remark 4. All our results hold if the investor derives no utility from wealth at the terminal date, that is, $u_2 \equiv 0$. Under the hypotheses of Proposition 4.2, the investor's optimal liquidation policy is given by (4.6) with the terminal wealth W_{χ^*} equal to zero. Hence, the investor liquidates his entire position in the asset prior to date T. In section 6, we analyze the scenario in which the terminal payoff function u_2 could be nonmonotonic and take on positive and negative values.

5. Optimal liquidation with logarithmic utility and the liquidity discount. We now use the results of the previous section to explicitly derive the optimal liquidation policy for the large investor in the situation where his utility functions are logarithmic. Specifically,

$$\begin{aligned} u_1(c,t) &= \exp(-\rho t)\log(c), \\ u_2(W,T) &= \exp(-\rho T)\log(W). \end{aligned} \tag{5.1}$$

From (4.2), we see that

$$\begin{aligned} \overline{u_1}(y,t) &= -\exp(-\rho t)(1+\rho t+\log(y)), \\ \overline{u_2}(y,T) &= -\exp(-\rho T)(1+\rho T+\log(y)). \end{aligned} \tag{5.2}$$

We also assume that

$$h(W,c,t,\omega) = -\alpha(c,t,\omega), \tag{5.3}$$

where $\alpha(.,t,\omega)$ is a differentiable (with a bounded derivative), nonnegative, convex function with $\alpha(0)=0$ so that $h(.,.,t,\omega)$ is concave, uniformly Lipschitz, and nonpositive. Therefore,

$$\overrightarrow{g}(\chi(t),t,\omega) = \overrightarrow{h}(\chi(t),t,\omega) = \sup_{c(t)\geq 0}[-\alpha(c(t),t,\omega)-\nu(t)c(t)].$$

We assume that the function $\alpha(.)$ is such that $\overrightarrow{g}(\chi(t),t)$ is zero on its effective domain. It is easily seen that an example of such a function is the linear function $\alpha(c,t,\omega) = \Gamma(t,\omega)c$, where $\Gamma(t,\omega)>0$.

Equation (5.3) implies that $\mu_1(t,\omega)\equiv 0$. We also note that $\nu(t,\omega)\in[-\Gamma(t,\omega),\infty)$, where $\Gamma(t,\omega)>0$. Therefore, the effective domain is given by

$$N_t(\omega) = R\times\{0\}\times[-\Gamma(t,\omega),\infty).$$

The dual problem (4.4) can now be expressed as

$$\begin{aligned} &\inf_{(\lambda,\chi)\in(0,\infty)\times N'} E\Bigg[-\int_0^T \exp(-\rho t)(1+\rho t+\log(1-\nu(t))+\log(\lambda\pi_\chi(t)))\,dt \\ &\qquad\qquad - \exp(-\rho T)(1+\rho T+\log(\lambda\pi_\chi(T)))\Bigg] + \lambda W_0 \\ &\quad = (T(1-\rho)-1)\exp(-\rho T) - 2\frac{1-\exp(-\rho t)}{\rho} \\ &\qquad + \inf_{\lambda>0}\left[\lambda W_0 - \frac{1-(1-\rho)\exp(-\rho T)}{\rho}\log(\lambda)\right] \\ &\qquad + \inf_{\nu} E\left[-\int_0^T \exp(-\rho t)\log(1-\nu(t))\,dt\right] \\ &\qquad + \inf_{\mu_0,\mu_1} E\Bigg[\int_0^T \exp(-\rho t)\left(\int_0^t\left(\mu_0(s)+\frac{1}{2}\left|\kappa_\chi(s)^2\right|\right)ds\right)dt \\ &\qquad\qquad + \exp(-\rho T)\left(\int_0^T\left(\mu_0(s)+\frac{1}{2}\left|\kappa_\chi(s)\right|^2\right)ds\right)\Bigg]. \end{aligned}$$

From the above, we obtain

$$\lambda^* = \frac{1-(1-\rho)e^{-\rho T}}{\rho W_0}, \tag{5.4}$$

$$\nu^*(t,\omega) = -\Gamma(t,\omega), \tag{5.5}$$

$$\mu_1^*(t,\omega) = 0, \tag{5.6}$$

$$\begin{aligned} \mu_0^*(t,\omega) &= \arg \min_{\mu_0(t)\in R} \left(\mu_0(t) + \frac{1}{2}\sigma(t,\omega)^{-2}(\overline{\mu}(t,\omega) - \mu_0(t,\omega))^2\right) \\ &= \overline{\mu}(t,\omega) - \sigma(t,\omega)^2. \end{aligned} \tag{5.7}$$

Since $\sigma(.)$ is uniformly bounded, we see that $\mu_0^*(.)$ is uniformly bounded, and consequently we easily see that condition (4.5) of Proposition 4.1 is satisfied. By Proposition 4.1, (4.7), and (5.4)–(5.7), the optimal liquidation rate and wealth processes are given by

$$\begin{aligned} c_{\chi^*}(t) &= W_0 \frac{\rho e^{-\rho T}}{(1+\Gamma(t,\omega))(1-(1-\rho)e^{-\rho T})} \pi_{\chi^*}(t)^{-1}, \\ W_{\chi^*}(t) &= W_0 \pi_{\chi^*}(t)^{-1} \frac{\rho e^{-\rho T}(T+1-t)}{(1-(1-\rho)e^{-\rho T})}. \end{aligned} \tag{5.8}$$

In the above, the process $\pi_{\chi^*}(.)$ may be derived from (3.1)–(3.4). From (5.8), we see that

$$\frac{c_{\chi^*}(t)}{W_{\chi^*}(t)} = \frac{T+1-t}{1+\Gamma(t,\omega)}. \tag{5.9}$$

Since $\Gamma(t,\omega) > 0$ and is uniformly bounded, (5.9) implies that $\frac{c_{\chi^*}(t)}{W_{\chi^*}(t)}$ is also uniformly bounded. Hence, the feedback on the stock price drift $\overline{\overline{\mu}}(W_{\chi^*}, c_{\chi^*}, t, \omega) = \frac{h(W_{\chi^*}, c_{\chi^*}, t,\omega)}{W_{\chi^*}} = -\frac{\Gamma(t,\omega)c_{\chi^*}}{W_{\chi^*}}$ is also uniformly bounded. If $\Gamma(t,\omega)$ is deterministic, then (5.9) implies that the investor liquidates a deterministic proportion of his holdings at each date; that is, the proportion liquidated does not depend on the stock price process. Moreover, if $\Gamma(t,\omega)$ is a constant, then (5.9) implies that the investor liquidates a decreasing proportion of his holdings in the risky asset over time.

We can use (5.4)–(5.8) to derive the optimal value function of the large investor, which is

$$\begin{aligned} U &= E\left[\int_0^T e^{-\rho t}\log(c_{\chi^*}(t))\,dt + e^{-\rho T}\log(W_{\chi^*}(T))\right] \\ &= E\left[\int_0^T e^{-\rho t}\left\{\log(N(0)S(0)) + \int_0^t \left(\overline{\mu}(s) - \frac{1}{2}\sigma(s)^2\right) ds \right.\right. \\ &\qquad \left. + \log\left(\frac{\rho e^{-\rho T}}{(1+\Gamma(t,\omega))(1-(1-\rho)e^{-\rho T})}\right)\right\} dt \\ &\qquad + e^{-\rho T}\left\{\log(S(0)) + \log(N(0)) + \int_0^T \left(\overline{\mu}(s) - \frac{1}{2}\sigma(s)^2\right) ds \right. \\ &\qquad \left.\left. + \log\left(\frac{\rho e^{-\rho T}}{(1-(1-\rho)e^{-\rho T})}\right)\right\}\right]. \end{aligned} \tag{5.10}$$

The liquidity discount. Subramanian and Jarrow [30] characterize the liquidity risk of a large investor's position in a risky asset in terms of the *liquidity discount.* The liquidity discount is defined in terms of the value functions of the large investor's optimal liquidation problem, and an "equivalent" hypothetical price-taker's optimal liquidation problem. The "equivalent" hypothetical price-taker has the same preferences and holdings in the risky asset, but his trades have no effect on the stock price. Specifically, the liquidity discount is defined as follows:

$$\text{liquidity discount} \;=\; S(0) - S(0)\prime, \tag{5.11}$$

where

$$U(S(0), N(0)) = U_{price\text{-}taker}(S(0)\prime, N(0)). \tag{5.12}$$

As discussed in Subramanian and Jarrow [30], the liquidity discount is the difference between the actual asset price and the asset price that would provide an equivalent price-taker with the same optimal expected utility. In (5.12), we explicitly indicate the dependence of the value functions on the initial stock price and holdings in the risky asset. The equivalent price-taker's value function is given by (5.10) with $\Gamma(t,\omega) \equiv 0$. Therefore, from (5.10) and (5.12), $S(0)\prime$ solves the equation

$$\begin{aligned}&\frac{1-(1-\rho)e^{-\rho T}}{\rho}\log(S(0)) + E\left[\int_0^T e^{-\rho t}\log\left(\frac{\rho e^{-\rho T}}{(1+\Gamma(t,\omega))(1-(1-\rho)e^{-\rho T})}\right)dt\right]\\ &\quad = \frac{1-(1-\rho)e^{-\rho T}}{\rho}\log(S(0)') + E\left[\int_0^T e^{-\rho t}\log\left(\frac{\rho e^{-\rho T}}{(1-(1-\rho)e^{-\rho T})}\right)dt\right].\end{aligned} \tag{5.13}$$

Hence,

$$S(0) = S(0)'\exp\left[\frac{\rho}{1-(1-\rho)e^{-\rho T}}E\left[\int_0^T e^{-\rho t}\log(1+\Gamma(t,\omega))\,dt\right]\right]. \tag{5.14}$$

Finally, from the definition (5.11), we have

$$\begin{aligned}&\text{liquidity discount}\\ &\quad = S(0)\left(1-\exp\left[-\frac{\rho}{1-(1-\rho)e^{-\rho T}}E\left[\int_0^T e^{-\rho t}\log(1+\Gamma(t,\omega))\,dt\right]\right]\right).\end{aligned} \tag{5.15}$$

6. Extensions.

In this section, we analyze two extensions of the model developed in the previous sections.[4]

6.1. Optimal liquidation with costs of residual terminal wealth.

Thus far, our analysis has focused on the case where the investor derives utility $u_2(W,T)$ from wealth W at date T, where $u_2(.,T)$ is increasing and concave (all the results presented thus far hold if u_2 is identically equal to zero—see Remark 4). Given that the investor wishes to liquidate his asset holdings, it is interesting to consider the scenario in which the investor actually bears *costs* from retaining nonzero wealth in the asset at the terminal date T. The interaction of these costs with the positive

[4] We thank an anonymous referee for suggesting these extensions.

(indirect) utility that the investor gains from the fact that residual wealth could be used to finance future consumption could lead to *nonmonotonicity* in the function $u_2(.,T)$. An example of such a function is

$$u_2(W,T) = A(W) - B(W), \tag{6.1}$$

where $A(.)$ is an increasing concave function and $B(.)$ is a nonnegative, increasing, and convex function.

We now modify our previous analysis by considering the class of functions $u_2(.,T)$ that are concave and possibly nonmonotonic and could take positive and negative values. It follows from the concavity of $u_2(.,T)$ that it is *either* monotonically decreasing *or* strongly unimodal (hump-shaped) and has a single local (therefore, global) maximum in $(0,\infty)$. A general hump-shaped function $u_2(.,T)$ (see the functional form (6.1)) has the economically intuitive features that, for low wealth levels, the benefits outweigh the costs so that the function increases, while for wealth levels above a threshold, the costs outweigh the benefits so that the function decreases. We make the following additional technical assumptions on $u_2(.,T)$ that modify Assumption 4.

ASSUMPTION 4. *The function $u_2(.,T)$ is strictly concave and continuously differentiable on $(0,\infty)$. If it is nonmonotonic, it satisfies*

$$\lim_{c\downarrow 0}(u_2)_c(c,T) = \infty. \tag{6.2}$$

Let $\hat{c}$ be the point at which $u_2(c,T)$ attains its unique local (therefore, global) maximum for $c \in [0,\infty)$. There exist constants $\delta \in (0,1)$ and $\gamma \in (0,\infty)$ such that

$$\delta(u_2)_c(c,T) \geq (u_2)_c(\gamma c,T) \quad \forall c \in (0,\hat{c}). \tag{6.3}$$

The above conditions ensure that the function $(u_2)_c(.,T)$ has a continuous and strictly decreasing inverse $f_2(.,T)$, which also satisfies the property

$$\forall \delta \in (0,\infty), \exists \gamma \in (0,\infty) \tag{6.4}$$

such that

$$f_2(\delta y,T) \leq \gamma f_2(y,T) \quad \forall\ y \in (0,\infty).$$

The function u_1 satisfies Assumption 4 *and Assumptions* 1–3, 5, *and* 6 *remain unaltered.*

Proposition 3.1, which characterizes the feasible liquidation policies of the investor, does not depend on the function u_2 and, therefore, continues to hold. Since $u_2(.,T)$ is concave, (4.1) defines the Lagrangian $L(c,W,\lambda,\chi)$ associated with the investor's optimal liquidation problem. In particular, if (c^*,W^*) is the investor's optimal liquidation/terminal wealth policy, there exists a Lagrange multiplier $\lambda^* > 0$ such that $(c^*,W^*,\lambda^*,\chi^*)$ is a saddle point of the map $L(c,W,\lambda,\chi)$ defined in (4.1).

We define the conjugate function $\overline{u_2}(y,T)$ as in (4.2). The following lemma describes the properties of this function that we will need in what follows.

LEMMA 6.1. *We have*

$$\overline{u_2}(y,T) = u_2(l_2(y,T),T) - yl_2(y,T) \text{ for } y \in [0,\infty), \tag{6.5}$$

where

$$l_2(y,T) = 0 \quad \forall y \in [0,\infty) \tag{6.6}$$

if $u_2(.,T)$ is monotonically decreasing, and

$$l_2(y,T) = (u_2')^{-1}(y,T) = f_2(y,T) \in [0,\hat{c}] \quad \forall y \in [0,\infty) \tag{6.7}$$

if $u_2(.,T)$ is nonmonotonic. In the above, $\hat{c}$ is as defined in Assumption 4.

Proof. The proof is in the appendix. □

To simplify the notation in the subsequent discussion, we combine the scenario in which $u_2(.,T)$ is strictly decreasing with the scenario in which it is nonmonotonic by setting $\hat{c} = 0$ in the former case. We can now proceed as in section 4 to consider the dual problem (4.4) and arrive at the following verification theorem for the optimal liquidation policy of the investor.

Proposition 6.1. *If $(\lambda^*, \chi^*) \in (0,\infty) \times N'$ solves problem* (4.4) *and*

$$\begin{aligned} &E\left[\int_0^T \pi_{\chi^*}(t) f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt + \pi_{\chi^*}(T) l_2(\lambda^*\pi_{\chi^*}(T),T)\right] < \infty,\\ &E\left[\int_0^T \pi_{\chi^*}(t)\,dt\right] < \infty, E[\pi_{\chi^*}(T)] < \infty, \end{aligned} \tag{6.8}$$

then the policy

$$\begin{aligned} c_{\chi^*}(t) &= f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t),\\ W_{\chi^*} &= l_2(\lambda^*\pi_{\chi^*}(T),T) \end{aligned} \tag{6.9}$$

is optimal, and the optimal wealth process is given by

$$\begin{aligned} &(6.10)\ W_{\chi^*}(t) =\\ &\pi_{\chi^*}(t)^{-1} E\left[\int_t^T \pi_{\chi^*}(s)((1-\nu^*(s))c_{\chi^*}(s) - \overrightarrow{g}(\chi^*(s),s))\,ds + \pi_{\chi^*}(T) W_{\chi^*}\,|F_t\right]. \end{aligned}$$

Proof. The proof is in the appendix. □

Lemma 6.1 and Proposition 6.1 ((6.6), (6.7), and (6.9)) lead to the following result.

Corollary 6.1. (a) *If the function $u_2(.,T)$ is decreasing, then the optimal terminal wealth is zero; that is, it is optimal for the investor to liquidate his entire holdings prior to the date T.*

(b) *If the function $u_2(.,T)$ is nonmonotonic, then the optimal terminal wealth $W_{\chi^*} \in [0,\hat{c}]$; that is, the terminal wealth lies in the increasing region of the function $u_2(.,T)$.*

The above results follow from the duality between the investor's primal problem (2.4) and the dual problem (4.4). For a given pair of dual control parameters (λ,χ), the liquidation rate process and the terminal wealth solve separate optimization problems. Proposition 4.1 (which depends on the martingale representation theorem for Brownian motion) shows that there exist an optimal liquidation policy that gives rise to the liquidation rate and terminal wealth that solve these two separate optimization problems. Because of the separability of the investor's problem of optimizing his terminal wealth level, it is suboptimal for the investor to retain nonzero terminal wealth in the region in which $u_2(.,T)$ is decreasing. It then follows that the optimal terminal wealth is zero when the function $u_2(.,T)$ is decreasing and lies in the increasing region of the function when it is nonmonotonic.

Corollary 6.1 immediately implies that the large investor's optimal liquidation policy is completely determined by the *increasing* part of the function $u_2(.,T)$. In other words, two concave terminal payoff functions with identical increasing parts are associated with the same optimal liquidation policies. This result is not transparent from an examination of the primal problem (2.4) but is immediately apparent from the dual problem (4.4). The duality approach, therefore, facilitates the characterization of optimal liquidation policies under more general terminal payoff functions.

Note. In the context of example (6.1), the increasing part of the function $u_2(.,T)$ is, in general, affected by *both* the "benefit" function $A(.)$ and the "cost" function $B(.)$. Hence, the investor's optimal liquidation policy is influenced by both these functions.

We now derive an existence result for optimal liquidation policies. We define the set $D_{(\mu_0(.),\mu_1(.))}$ as in the discussion following Proposition 4.1. An examination of the proof of Lemma 4.2 shows that it continues to hold.

PROPOSITION 6.2. *Suppose that conditions* (a), (b), (d), *and* (e) *of Proposition* 4.2 *hold for the functions* u_1 *and* $\overline{u_1}$. *An optimal liquidation policy for the large investor exists if the following conditions hold:*

(a) $0 \leq u_2(W,T) \leq k(1+W^{1-b})$ *for* $W \in [0,\hat{c}]$ *for some* $k \geq 0, 0 < b < 1$.

(b) $W \rightarrow W(u_2)'(W,T)$ *is increasing for* $W \in [0,\hat{c}]$ *so that* $x \rightarrow \overline{u_2}(\exp(x),T)$ *is convex on* R.

(c) *For all* $\lambda \in (0,\infty)$, *there exists* $\chi \in N'$ *such that* $J(\lambda,\chi) < \infty$.

(d) *The function* $\overline{u_2}(.,T)$ *is strictly convex and continuously differentiable on* R_+, *and the function* $\overrightarrow{g}(.,t,\omega) : N_t(\omega) \rightarrow R$ *is strictly convex and continuously differentiable on the interior of its domain for each* (t,ω).

(e) $W(u_2)_W(W,T) \leq a + (1-b)u_2(W,T)$ *for* $W \in [0,\hat{c}]$ *and some* $a, b \geq 0$.

Proof. The proof is in the appendix. □

6.2. Infinite liquidation horizon. In this section, we analyze the scenario in which the investor's liquidation horizon is $[0,\infty)$. Our presentation is brief because it closely follows the discussion in sections 3 and 4. A feasible liquidation strategy is a nonnegative process $(W(.),c(.))$ satisfying (2.3) with the time horizon $T=\infty$. A liquidation rate process $c(.)$ is admissible if it satisfies the first condition in (2.5) with $T=\infty$. The investor's objective is to choose an admissible liquidation strategy to maximize

$$U(c) = E\left[\int_0^\infty u_1(c(t),t))\,dt\right]. \tag{6.11}$$

The investor, therefore, optimally liquidates his holdings in the asset until they fall to zero.

We impose Assumptions 1, 4, 5, and 6 as in section 2 with $T=\infty$ and define the space of dual processes as in section 3. The following proposition is the analogue of Proposition 3.1.

PROPOSITION 6.3. *If* $(W(.),c(.))$ *is a feasible liquidation policy, then*

$$E\left[\int_0^\infty \pi_\chi(t)(1-\nu(t))c(t)\,dt\right] \leq W_0 + E\left[\int_0^\infty \pi_\chi(t)\overrightarrow{g}(\chi(t),t)\,dt\right] \tag{6.12}$$

for all $\chi \in N$ *with* $\nu(.) \leq 1$.

Proof. The proof proceeds exactly as the proof of Proposition 3.1 with $T=\infty$. □

The Lagrangian for the investor's optimal liquidation problem is

$$L(c,\lambda,\chi) = U(c) - \lambda\left(E\left[\int_0^\infty \pi_\chi(t)((1-\nu(t))c(t) - \overrightarrow{g}(\chi(t),t))\,dt\right] - W_0\right). \tag{6.13}$$

If an optimal liquidation policy $c^*(.)$ exists, then there exists a Lagrange multiplier $\lambda^* > 0$ and a dual process χ^* such that (c^*, λ^*, χ^*) is a saddle point of the above map where we maximize with respect to c and minimize with respect to (λ, χ). We define the conjugate function $\overline{u_1}$ as in (4.2). The investor's dual problem is defined by (4.4), where

$$J(\lambda, \chi) = E\left[\int_0^\infty \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t), t)\, dt + \lambda \int_0^\infty \pi_\chi(t) \overrightarrow{g}(\chi(t), t)\, dt\right] + \lambda W_0. \tag{6.14}$$

The following proposition is the analogue of the verification Proposition 4.1.

PROPOSITION 6.4. *If* $(\lambda^*, \chi^*) \in (0, \infty) \times N'$ *solves the problem* (4.4) *and*

$$E\left[\int_0^\infty \pi_{\chi^*}(t) f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t), t)\, dt < \infty, \quad E\left[\int_0^\infty \pi_{\chi^*}(t)\, dt\right]\right] < \infty, \tag{6.15}$$

then the policy

$$c_{\chi^*}(t) = f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t), t) \tag{6.16}$$

is optimal, and the optimal wealth process is given by

$$W_{\chi^*}(t) = \pi_{\chi^*}(t)^{-1} E\left[\int_t^\infty \pi_{\chi^*}(s)((1-\nu^*(s))c_{\chi^*}(s) - \overrightarrow{g}(\chi^*(s), s))\, ds \,|F_t\right]. \tag{6.17}$$

Proof. The proof proceeds exactly as the proof of Proposition 4.1 setting $T = \infty, u_2 \equiv 0, f_2 \equiv 0$, and $W^* = 0$. □

The analysis now proceeds along the lines of the analysis following Proposition 4.1. Lemma 4.2 holds in this setting, and we impose Assumption 7. The existence result Proposition 4.2 holds as stated in this setting with $T = \infty, u_2 \equiv 0, f_2 \equiv 0$, and $W^* = 0$.

7. Conclusions. We study the optimal liquidation problem for an investor with a large holding in a risky asset where there may be a nonlinear path dependent feedback on the asset price process due to his liquidation policy. Under broad and general assumptions on the large investor's preferences, and the parameters of the asset price process, we establish the duality between the investor's optimal liquidation problem and a dual optimization problem. We prove verification and existence results for optimal liquidation policies for the large investor. In particular, our results imply the existence of optimal policies if the investor has power utility functions. We explicitly derive the optimal policy when the large investor's utility functions are logarithmic. We use our results to characterize the *liquidity discount*, which is a measure of the *liquidity risk* of the investor's position in the risky asset. The derivation of conditions under which optimal liquidation policies for the large investor exist is important from an economic standpoint since it identifies a class of *viable* partial equilibrium models of large investor behavior. In future research, it would be interesting and important to construct a general equilibrium model of large investor behavior.

Appendix.

Proof of Proposition 3.1. Recall that, by definition (2.15), $\overrightarrow{g}(\chi(t), t) = \overrightarrow{h}(\mu_1(t), \nu(t), t)$. Using (2.2) and Itǒ's lemma,

$$\begin{aligned}\pi_\chi(t)W(t) &+ \int_0^t \pi_\chi(s)c(s)\, ds - \int_0^t \pi_\chi(s)[W(s)\sigma(s) + W(s)\kappa_\chi(s)]\, dB(s) \\ &= W_0 + \int_0^t \pi_\chi(s)(h(W(s), c(s), s) - W(s)\mu_1(s))\, ds.\end{aligned}$$

Since $\nu(.) \leq 1$ by hypothesis, $\int_0^T c(s)\,ds < \infty$ by the definition of the feasibility of the liquidation policy, and $\pi_\chi(.)$ has continuous paths a.s., we see that $\int_0^t \pi_\chi(s)\nu(s)c(s)\,ds$ exists a.s. for each $t \in [0,T]$. Subtracting the term $\int_0^t \pi_\chi(s)\nu(s)c(s)\,ds$ from both sides, we see that for all $\chi \in N$,

(A.1)

$$\begin{aligned}\pi_\chi(t)W(t) &+ \int_0^t \pi_\chi(s)(1-\nu(s))c(s)\,ds - \int_0^t \pi_\chi(s)[W(s)\sigma(s) + W(s)\kappa_\chi(s)]\,dB(s)\\ &= W_0 + \int_0^t \pi_\chi(s)(h(W(s),c(s),s) - W(s)\mu_1(s) - c(s)\nu(s))\,ds\\ &\leq W_0 + \int_0^t \pi_\chi(s)\overrightarrow{h}(\chi(s),s)\,ds\end{aligned}$$

from the definition (2.11) of $\overrightarrow{h}(.)$. For each positive integer n, let

$$\begin{aligned}\tau_n = T \wedge \inf\Bigg\{t \in [0,T] : \int_0^t &[|\pi_\chi(s)(W(s)\sigma(s) + W(s)\kappa_\chi(s))|^2\\ &+ \pi_\chi(s)(1-\nu(s))c(s)]\,ds \geq n\Bigg\}.\end{aligned}$$

Since the stochastic integral in (A.1) is a martingale on $[0,\tau_n]$, taking expectations gives

(A.2)

$$E[\pi_\chi(\tau_n)W(\tau_n)] + E\left[\int_0^{\tau_n} \pi_\chi(t)(1-\nu(t))c(t)\,dt\right] \leq W_0 + E\left[\int_0^{\tau_n} \pi_\chi(t)\overrightarrow{h}(\chi(t),t)\,dt\right].$$

Since $W(\tau_n) \geq 0$ a.s. (by the definition of feasibility of the liquidation strategy), $\tau_n \uparrow T$, $\overrightarrow{h}(.)$ is nonnegative and bounded on its effective domain, and $\nu(.) \leq 1$, we see from (A.2) and the monotone convergence theorem that

$$\lim_{n\to\infty} E\left[\int_0^{\tau_n} \pi_\chi(t)(1-\nu(t))c(t)\,dt\right] = E\left[\int_0^T \pi_\chi(t)(1-\nu(t))c(t)\,dt\right].$$

An application of the monotone convergence theorem and Fatou's lemma implies that

$$\begin{aligned}E&\left[\int_0^T \pi_\chi(t)(1-\nu(t))c(t)\,dt + \pi_\chi(T)W\right]\\ &\leq W_0 + E\left[\int_0^T \pi_\chi(t)\overrightarrow{h}(\chi(t),t)\,dt\right] \text{ for all } \chi \in N \text{ with } \nu(.) \leq 1.\end{aligned}$$

This completes the proof. □

Proof of Proposition 4.1. Let the liquidation process be defined by $c^* = c_{\chi^*}$ and the terminal wealth level by $W^* = W_{\chi^*}$.

Step 1. *Optimality of* $(c^*(.), W^*)$ *given feasibility.* We shall first show that the policy $(c^*(.), W^*)$ is optimal *provided it is feasible.* Since $u_1(1,t) - y \leq \sup_{c>0}[u_1(c,t) - yc] = u_1(f_1(y,t),t) - yf_1(y,t)$, we have

$$E\left[\int_0^T u_1(c^*(t),t)^- dt\right] \leq \int_0^T u_1(1,t)^- dt + \lambda^* E\left[\int_0^T (1-\nu^*(t))\pi_{\chi^*}(t)\,dt\right] < \infty.$$

The last inequality follows from the fact that $E[\int_0^T (1-\nu^*(t))\pi_{\chi^*}(t)\,dt] < \infty$ as $\nu^*(.)$ is uniformly bounded and $E[\int_0^T \pi_{\chi^*}(t)\,dt] < \infty$ by assumption. Therefore, the process $c^*(.)$(and similarly the random variable W^*) satisfies (2.5). We shall now prove that $U(c^*, W^*) \geq U(c, W)$ for all *feasible* liquidation and terminal wealth processes $(c(.), W)$. By (2.7), we see that (4.5) implies that

$$\text{(A.3)}\quad E\left[\int_0^T \pi_{\chi^*}(t) f_1(\lambda(1-\nu^*(t))\pi_{\chi^*}(t), t)\,dt\right] + E\left[\pi_{\chi^*}(T) f_2(\lambda\pi_{\chi^*}(T), T)\right] < \infty$$

holds for all $\lambda \in (0, \infty)$. Since λ^* is optimal by assumption, we have

$$\begin{aligned}
0 &= \lim_{\varepsilon\to 0}\frac{J(\lambda^*+\varepsilon, \chi^*) - J(\lambda^*, \chi^*)}{\varepsilon} \\
&= E\left[\int_0^T \lim_{\varepsilon\to 0}\frac{\overline{u}_1((\lambda^*+\varepsilon)(1-\nu^*(t))\pi_{\chi^*}(t), t) - \overline{u_1}(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t), t)}{\varepsilon}\right. \\
&\qquad \left. + \int_0^T \pi_{\chi^*}(t)\overrightarrow{g}(\chi^*(t), t)\,dt + \frac{\overline{u}_2((\lambda^*+\varepsilon)\pi_{\chi^*}(T), T) - \overline{u_2}(\lambda^*\pi_{\chi^*}(T), T)}{\varepsilon} + W_0\right] \\
&= W_0 - E\left[\int_0^T \pi_{\chi^*}(t)[(1-\nu^*(t))c^*(t) - \overrightarrow{g}(\chi^*(t), t)]\,dt + \pi_{\chi^*}(T)W^*\right],
\end{aligned}$$

where the second and third equalities above follow from the dominated convergence theorem and (A.3). It follows that

$$W_0 = E\left[\int_0^T \pi_{\chi^*}(t)[(1-\nu^*(t))c^*(t) - \overrightarrow{g}(\chi^*(t), t)]\,dt + \pi_{\chi^*}(T)W^*\right].$$

Let $(c(.), W)$ be any feasible liquidation and terminal wealth process. Since

$$\begin{aligned}
&u_1(f_1(y,t),t) - u_1(c,t) \geq y[f_1(y,t) - c] \quad \forall c > 0, y > 0, \\
&u_2(f_2(y,T),T) - u_2(W,T) \geq y[f_2(y,T) - W] \quad \forall W > 0, y > 0,
\end{aligned}$$

(3.5) leads to

$$\begin{aligned}
U(c^*, W^*) - U(c, W) &= E\left[\int_0^T (u_1(c^*(t), t) - u_1(c(t), t))\,dt + u_2(W^*, T) - u_2(W, T)\right] \\
&\geq \lambda^* E\left[\int_0^T \pi_{\chi^*}(t)(1-\nu^*(t))(c^*(t) - c(t))\,dt\right] + \lambda^* E[\pi_{\chi^*}(T)(W^* - W)] \geq 0.
\end{aligned}$$

Therefore, $(c^*(.), W^*)$ is optimal *provided it is feasible.*

Step 2: *Feasibility of* $(c^*(.), W^*)$. From (4.7), we see that

$$\pi_{\chi^*}(t)W_{\chi^*}(t) + \int_0^t \pi_{\chi^*}(s)((1-\nu^*(s))c^*(s) - \overrightarrow{g}(\chi^*(s), s))\,ds$$

is a P-martingale. By the martingale representation theorem, there exists a predictable process $\phi(.)$ with $\int_0^T \phi(t)^2 dt < \infty$ a.s. such that

$$\pi_{\chi^*}(t)W_{\chi^*}(t) + \int_0^t \pi_{\chi^*}(s)((1-\nu^*(s))c^*(s) - \overrightarrow{g}(\chi^*(s), s))\,ds = W_0 + \int_0^t \phi(s)\,dB(s).$$

Define the pair (α, θ) by

$$\pi_{\chi^*}(t)(\sigma(t)\theta(t) + W_{\chi^*}(t)\kappa_{\chi^*}(t)) = \phi(t),$$
$$\alpha(t) = W_{\chi^*}(t) - \theta(t).$$

By Itŏ's lemma, we easily see that

$$W_{\chi^*}(t) = W_0 + \int_0^t [\alpha(s)\mu_0^*(s) + \theta(s)(\overline{\mu}(s) + \mu_1^*(s)) + c^*(s)\nu^*(s) + \overrightarrow{g}(\chi^*(s), s)]\, ds$$
$$+ \int_0^t \theta(s)\sigma(s)\, dB(s) - \int_0^t c^*(s)\, ds.$$

Therefore, in order to prove that $(c^*(.), W^*)$ is feasible, we need to show, from (2.2) and the definition of the feedback function $h(.)$, that

$$\alpha(.) \equiv 0,$$
$$h(\theta(t), c^*(t), t) = \overrightarrow{g}(\chi^*(t), t) + \theta(t)\mu_1^*(t) + c^*(t)\nu^*(t),$$

and $W_{\chi^*}(t) \geq 0$ a.s. for $t \in [0, T]$ with $W_{\chi^*}(T) = W^*$. We shall now prove these assertions. By the result of Lemma 2.1, there exist processes $(\mu_1(.), \nu^{n'}(.)) \in M$ such that

$$h(\theta(t), c^*(t), t) = \lim_{n' \to \infty} \left[\overrightarrow{h}(\mu_1(t), \nu^{n'}(t), t) + \theta(t)\mu_1(t) + c^*(t)\nu^{n'}(t)\right] \tag{A.4}$$

and a process $\nu(.)$ with $\int_0^T \nu(t)c^*(t)\, dt < \infty$ a.s. such that $\nu^{n'}(.) \uparrow \nu(.)$ a.e. Define a process $\mu_0^n(.)$ by

$$\mu_0^n(t) = (\mu_0^*(t) - n)1_{\alpha(t)>0} + (\mu_0^*(t) + n)1_{\alpha(t)<0}. \tag{A.5}$$

Define the two-dimensional sequence of processes $\chi^{n,n'}(.)$ by

$$\chi^{n,n'}(t) = (\mu_0^n(t), \mu_1(t), \nu^{n'}(t)). \tag{A.6}$$

By Assumption 6 and (2.15), (2.16), (A.4), and (A.5), we easily see that

$$-\infty 1_{\alpha(t)\neq 0} + h(\theta(t), c^*(t), t)1_{\alpha(t)=0} = \lim_{n,n' \to \infty} \overrightarrow{h}(\mu_1(t), \nu^{n'}(t), t) + \alpha(t)\mu_0^n(t)$$
$$+ \theta(t)\mu_1(t) + c^*(t)\nu^{n'}(t) = \lim_{n,n' \to \infty} \overrightarrow{g}(\chi^{n,n'}(t), t) + \alpha(t)\mu_0^n(t) + \theta(t)\mu_1(t) + c^*(t)\nu^{n'}(t)$$

since $\overrightarrow{h}(\mu_1(t), \nu^{n'}(t), t) = \overrightarrow{g}(\chi^{n,n'}(t), t)$ by (2.15). Define the processes

$$\zeta^n(t) = \int_0^t (\mu_0^n(s) - \mu_0^*(s))\, ds$$
$$+ \int_0^t \sigma(s)^{-1}(\mu_1(s) - \mu_1^*(s) - (\mu_0^n(s) - \mu_0^*(s)))(dB(s) - \kappa_{\chi^*}(s)\, ds)$$

and the sequence of stopping times (for each n)

$$\tau_m^n = T \wedge \inf \left\{ \begin{array}{l} t \in [0, T] : |\zeta^n(t)| + |\pi_{\chi^*}(t)| + |W_{\chi^*}(t)| \geq m, \quad \text{or} \\ \displaystyle\int_0^t \left[|\sigma(s)\theta(s) + W_{\chi^*}(s)\kappa_{\chi^*}(s)|^2 + |\ \nu(s)c^*(s)\ |\right] ds \geq m \end{array} \right\}.$$

Then $\tau_m^n \uparrow T$ a.s. for each n. Denoting

$$\chi_{\varepsilon,m}^{n,n'}(t) = \chi^*(t) + \varepsilon[\chi^{n,n'}(t) - \chi^*(t)]1_{t\le\tau_m^n}$$

for $\varepsilon \in (0,1)$, we have $\chi_{\varepsilon,m}^{n,n'} \in N$ (since the sets N_t are convex). We now see that

(A.7)

$$\begin{aligned}
&\lim_{\varepsilon\downarrow 0} \frac{J(\lambda^*, \chi_{\varepsilon,m}^{n,n'}) - J(\lambda^*, \chi^*)}{\varepsilon} \\
&\quad = \lim_{\varepsilon\downarrow 0} E\left[\int_0^T \frac{\overline{u_1}(\lambda^*(1-\nu_{\varepsilon,m}^{n'}(t))\pi_{\chi_{\varepsilon,m}^{n,n'}}(t),t) - \overline{u_1}(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)}{\varepsilon}\,dt\right] \\
&\qquad\qquad - \lambda^*\int_0^T \pi_{\chi^*}(t)\frac{\overrightarrow{g}(\chi^*(t),t)}{\varepsilon}\left(1 - \frac{\pi_{\chi_{\varepsilon,m}^{n,n'}}(t)}{\pi_{\chi^*}(t)}\right)dt \\
&\qquad\qquad + \lambda^*\int_0^T \pi_{\chi_{\varepsilon,m}^{n,n'}}(t)\frac{\overrightarrow{g}(\chi_{\varepsilon,m}^{n,n'}(t),t) - \overrightarrow{g}(\chi^*(t),t)}{\varepsilon}\,dt \\
&\qquad\qquad + \frac{\overline{u_2}(\lambda^*\pi_{\chi_{\varepsilon,m}^{n,n'}}(T),T) - \overline{u_2}(\lambda^*\pi_{\chi^*}(T),T)}{\varepsilon} \\
&\quad \le \lambda^* E\left[\int_0^T \zeta^n(t\wedge\tau_m^n)\pi_{\chi^*}(t)((1-\nu^*(t))c^*(t) - \overrightarrow{g}(\chi^*(t),t))\,dt\right. \\
&\qquad\qquad + \int_0^{\tau_m^n} \pi_{\chi^*}(t)(\nu^{n'}(t) - \nu^*(t))c^*(t)\,dt \\
&\qquad\qquad + \int_0^{\tau_m^n} \pi_{\chi^*}(t)(\overrightarrow{g}(\chi^{n,n'}(t),t) - \overrightarrow{g}(\chi^*(t),t))\,dt \\
&\qquad\qquad \left. + \zeta^n(\tau_m^n)\pi_{\chi^*}(T)W^*\right] \\
&\quad = E\left[\int_0^{\tau_m^n} \zeta^n(t)\pi_{\chi^*}(t)((1-\nu^*(t))c^*(t) - \overrightarrow{g}(\chi^*(t),t))\,dt + \zeta^n(\tau_m^n)\pi_{\chi^*}(\tau_m^n)W_{\chi^*}(\tau_m^n)\right. \\
&\qquad\qquad \left. + \int_0^{\tau_m^n} \pi_{\chi^*}(t)(\overrightarrow{g(}\chi^{n,n'}(t),t) + \nu^{n'}(t)c^*(t) - \overrightarrow{g}(\chi^*(t),t) - \nu^*(t)c^*(t))\,dt\right],
\end{aligned}$$

where the first inequality above follows from the convexity of $\overrightarrow{g}$ and the dominated convergence theorem and the last equality follows from the definition (4.7) of W_{χ^*}. The first term in the sequence of expressions above $\lim_{\varepsilon\downarrow 0}\frac{J(\lambda^*,\chi_{\varepsilon,m}^{n,n'})-J(\lambda^*,\chi^*)}{\varepsilon}$ is nonnegative for all n, n', m since $J(\lambda^*, \chi_{\varepsilon,m}^{n,n'})$ attains a minimum at $\varepsilon = 0$ as χ^* is optimal by hypothesis. By an application of Itŏ's lemma, we can easily show that

$$\begin{aligned}
&E\left[\int_0^{\tau_m^n} \zeta^n(t)\pi_{\chi^*}(t)[(1-\nu^*(t))c^*(t) - \overrightarrow{g}(\chi^*(t),t)]\,dt + \zeta^n(\tau_m^n)\pi_{\chi^*}(\tau_m^n)W_{\chi^*}(\tau_m^n)\right] \\
&\qquad = E\left[\int_0^{\tau_m^n} \pi_{\chi^*}(t)[\alpha(t)(\mu_0^n(t) - \mu_0^*(t)) + \theta(t)(\mu_1(t) - \mu_1^*(t))]\,dt\right].
\end{aligned}$$

Substituting the above into (A.7), we see that

(A.8)

$$\begin{aligned}&\lim_{\varepsilon\downarrow 0}\frac{J(\lambda^*,\chi^{n,n'}_{\varepsilon,m})-J(\lambda^*,\chi^*)}{\varepsilon}\\ &\quad\le E\left[\int_0^{\tau^n_m}\pi_{\chi^*}(t)(\alpha(t)(\mu^n_0(t)-\mu^*_0(t))+\theta(t)(\mu_1(t)-\mu^*_1(t))+c^*(t)(\nu^{n'}(t)-\nu^*(t))\right.\\ &\qquad\qquad\left.+\ \overrightarrow{g}(\chi^{n,n'}(t),t)-\overrightarrow{g}(\chi^*(t),t))\,dt\right].\end{aligned}$$

The left-hand side of the equation above is nonnegative by hypothesis for all n, n', m. If Λ denotes Lebesgue measure on $[0,T]$, and if $\Lambda\times P((t,\omega):\alpha(t,\omega)\neq 0)>0$, then (A.5) and (A.6) imply that

$$\lim_{n\to\infty}E\left[\int_0^T\pi_{\chi^*}(t)\alpha(t)(\mu^n_0(t)-\mu^*_0(t))\,dt\right]=-\infty.$$

Since $\overrightarrow{g}(\chi^{n,n'}(t),t)=\overrightarrow{h}(\mu_1(t),\nu^{n'}(t),t)$ does not depend on $\mu^n_0()$, we easily see that the right-hand side of (A.8) is strictly negative for sufficiently large n and m, which contradicts the fact that the left-hand side of (A.8) is nonnegative by hypothesis for every n, n' and m. Hence, $\alpha(t)=0$, $\Lambda\times P$ a.s. on $[0,T]\times\Omega$. Therefore, we have

(A.9)

$$\begin{aligned}&\lim_{\varepsilon\downarrow 0}\frac{J(\lambda^*,\chi^{n,n'}_{\varepsilon,m})-J(\lambda^*,\chi^*)}{\varepsilon}\\ &\le E\left[\int_0^{\tau^n_m}\pi_{\chi^*}(t)(\theta(t)(\mu_1(t)-\mu^*_1(t))+c^*(t)(\nu^{n'}(t)-\nu^*(t))\right.\\ &\qquad\left.+\ \overrightarrow{g}(\chi^{n,n'}(t),t)-\overrightarrow{g}(\chi^*(t),t))\,dt\right]\\ &=E\left[\int_0^{\tau^n_m}\pi_{\chi^*}(t)(\theta(t)(\mu_1(t)-\mu^*_1(t))+c^*(t)(\nu^{n'}(t)-\nu^*(t))\right.\\ &\qquad\left.+\ \overrightarrow{h}(\mu_1(t),\nu^{n'}(t),t)-\overrightarrow{h}(\mu^*_1(t),\nu^*(t),t))\,dt\right]\\ &=E\left[\int_0^{\tau^n_m}\pi_{\chi^*}(t)[(-\theta(t)\mu^*_1(t))-c^*(t)(\nu^*(t))+h(\theta(t),c^*(t),t)-\overrightarrow{h}(\mu^*_1(t),\nu^*(t),t)\right.\\ &\qquad\left.+\ \overrightarrow{h}(\mu_1(t),\nu^{n'}(t),t)+\theta(t)\mu_1(t)+c^*(t)\nu^{n'}(t)-h(\theta(t),c^*(t),t)]\,dt\right].\end{aligned}$$

Since

$$h(\theta(t),c^*(t),t)=\lim_{n'\to\infty}[\overrightarrow{h}(\mu_1(t),\nu^{n'}(t),t)+\theta(t)\mu_1(t)+c^*(t)\nu^{n'}(t)]$$

and

$$\overrightarrow{h}(\mu^*_1(t),\nu^*(t),t)\ge h(\theta(t),c^*(t),t)-\theta(t)\mu^*_1(t)-c^*(t)\nu^*(t)$$

and the first expression in (A.9) is nonnegative by hypothesis, we see that equality must in fact hold in the expression above by applying the dominated convergence theorem and using the fact that $h(.,t,\omega)$ is uniformly Lipschitz and $\overrightarrow{h}$ is uniformly bounded by assumption. Since $\alpha(t) = 0$, and $\overrightarrow{g}(\chi^*(t),t) = \overrightarrow{h}(\mu_1^*(t), \nu^*(t), t)$ by (2.15), we see that

$$h(\theta(t), c^*(t), t) = \overrightarrow{g}(\chi^*(t),t) + \theta(t)\mu_1^*(t) + c^*(t)\nu^*(t).$$

We have therefore shown that $\alpha(.) \equiv 0$ and

$$h(\theta(t), c^*(t), t) = \overrightarrow{h}(\mu_1^*(t), \nu^*(t), t) + \theta(t)\mu_1^*(t) + c^*(t)\nu^*(t).$$

Clearly, $W_{\chi^*}(T) = W$ by (4.7). Therefore, it remains only to show that $W_{\chi^*}(t) \geq 0$ a.s. for all $t \in [0,T]$. *We prove this by contradiction.*

Since $\alpha(s) = W_{\chi^*}(s) - \theta(s)$ by definition, we see that $\alpha(s) = 0$ implies that $\theta(s) = W_{\chi^*}(s)$. Therefore, we have

$$\begin{aligned} W_{\chi^*}(t) = W_0 &+ \int_0^t [W_{\chi^*}(s)\overline{\mu}(s) + h(W_{\chi^*}(s), c^*(s), s)]\, ds \\ &+ \int_0^t W_{\chi^*}(s)\sigma(s)\, dB(s) - \int_0^t c^*(s)\, ds. \end{aligned}$$

Suppose, *to the contrary*, that $P(W_{\chi^*}(t) < 0) > 0$ for some $t \in [0,T]$. Let $\tau_\varepsilon = \inf\{t : W_{\chi^*}(t) < -\varepsilon\} \wedge T$. Clearly, $P[\tau_\varepsilon < T] > 0$ for some $\varepsilon > 0$. Clearly, $W_{\chi^*}(\tau) \leq 0$ on $\tau_\varepsilon < T$. On $[\tau_\varepsilon, T]$, we have

$$\begin{aligned} W_{\chi^*}(t) = W_{\chi^*}(\tau_\varepsilon) &+ \int_{\tau_\varepsilon}^t [W_{\chi^*}(s)\overline{\mu}(s) + h(W_{\chi^*}(s), c^*(s), s)]\, ds \\ &+ \int_0^t W_{\chi^*}(s)\sigma(s)\, dB(s) - \int_0^t c^*(s)\, ds. \end{aligned}$$

Since $h(W,c) \leq 0$ for $W \leq 0$ from the definition (2.10) of $h(.)$ and Assumption 5, we can compare the above equation with the equation

$$\widehat{W}(t) = W_{\chi^*}(\tau_\varepsilon) + \int_{\tau_\varepsilon}^t [\widehat{W}(s)\overline{\mu}(s)]\, ds + \int_{\tau_\varepsilon}^t \widehat{W}(s)\sigma(s)\, dB(s).$$

By the comparison theorem for stochastic differential equations (see Proposition 2.18 in Karatzas and Shreve [19]), we see that on $[\tau_\varepsilon, T]$, $P[W_{\chi^*}(t) \leq \widehat{W}(t)] = 1$. Since $\widehat{W}(T) < 0$ on the set $\{\tau_\varepsilon < T\}$ as $W_{\chi^*}(\tau) \leq 0$ on$\tau_\varepsilon < T$, we have $P[W_{\chi^*}(T) \leq \widehat{W}(T) < 0] > 0$, which *contradicts* the fact that $W_{\chi^*}(T) = W \geq 0$ a.s. This contradiction allows us to conclude that $W_{\chi^*}(t) \geq 0$ a.s. This completes the proof. □

Proof of Lemma 4.2. By Lemma 4.1 and Assumption 4, $\overline{u_1}(.,t), \overline{u_2}(.,T)$ are both bounded below. For a fixed process $(\mu_0(.), \mu_1(.))$ and a fixed λ as in the statement of the lemma, we note that

$$\overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) + \lambda\pi_\chi(t,\omega)\overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)$$

is a strictly convex, lower semicontinuous function of $\eta \in D_{(\mu_0(.),\mu_1(.))}(t,\omega)$ that is uniformly bounded below. Since $D_{(\mu_0(.),\mu_1(.))}(t,\omega)$ is closed, convex, and bounded for each (t,ω), we see that

$$\inf_{\eta \in D_{(\mu_0(.),\mu_1(.))}(t,\omega)} \overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) + \lambda\pi_\chi(t,\omega)\overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)$$

exists and is uniquely attained by some $\eta^*_{(t,\omega)}$. Moreover, by measurable selection theorems of the Dubins–Savage type, the process $\nu^*(.)$ defined by $\nu^*(t,\omega) = \eta^*_{(t,\omega)}$ is bounded and progressively measurable. By an application of Fatou's lemma, we see that if

$$\begin{aligned}&\inf_{\nu(.)\in D_{(\mu_0(.),\mu_1(.))}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.))\\ &\quad = E\left[\int_0^T \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t), t)\,dt + \lambda\int_0^T \pi_\chi(t)\overrightarrow{g}(\chi(t),t)\,dt + \overline{u_2}(\lambda\pi_\chi(T),T)\right] + \lambda W_0\end{aligned}$$

exists, it is uniquely attained by the process $\nu^*(.)$. From (3.4b), it follows easily that $\{(\pi_\chi, \pi_\chi\mu_0, \pi_\chi\mu_1) : \chi \in N\}$ is a convex set and that $\pi_\chi$is uniquely determined by $(\mu_0(.), \mu_1(.))$. It clearly suffices to consider the case where the infimum above is attained. Let

$$\begin{aligned}&\inf_{\nu(.)\in D_{(\mu_0^1(.),\mu_1^1(.))}} J(\lambda, \mu_0^1(.), \mu_1^1(.), \nu(.)) = J(\lambda, \mu_0^1(.), \mu_1^1(.), \nu^1(.)),\\ &\inf_{\nu(.)\in D_{(\mu_0^2(.),\mu_1^2(.))}} J(\lambda, \mu_0^2(.), \mu_1^2(.), \nu(.)) = J(\lambda, \mu_0^2(.), \mu_1^2(.), \nu^2(.)).\end{aligned}$$

By the convexity of $\overline{u_1}(.), \overline{u_2}, \overrightarrow{g}(.)$, we have (with $0 < q < 1$)

$$\begin{aligned}&(1-q)J(\lambda, \mu_0^1(.), \mu_1^1(.), \nu^1(.)) + qJ(\lambda, \mu_0^2(.), \mu_1^2(.), \nu^2(.))\\ &\quad > E\Bigg[\int_0^T \overline{u_1}((1-q)\lambda(1-\nu^1(t))\pi_{\chi^1}(t) + q\lambda(1-\nu^2(t))\pi_{\chi^2}(t), t)\,dt\\ &\qquad + \lambda\int_0^T [(1-q)\pi_{\chi^1}(t)\overrightarrow{g}(\chi^1(t),t) + q\pi_{\chi^2}(t)\overrightarrow{g}(\chi^2(t),t)]\,dt\\ &\qquad + \overline{u_2}(\lambda(1-q)\pi_{\chi^1}(T) + \lambda q\pi_{\chi^2}(T), T)\Bigg] + \lambda W_0.\end{aligned}$$

If we define

$$\begin{aligned}\pi_{\chi^*}(t) &= (1-q)\pi_{\chi^1}(t) + q\pi_{\chi^2}(t),\\ (1-\nu^*(t)) &= \frac{(1-q)\pi_{\chi^1}(t)(1-\nu^1(t)) + q\pi_{\chi^2}(t)(1-\nu^2(t))}{\pi_{\chi^*}(t)},\\ \mu_0^*(t) &= \frac{(1-q)\pi_{\chi^1}(t)\mu_0^1(t) + q\pi_{\chi^2}(t)\mu_0^2(t)}{\pi_{\chi^*}(t)},\\ \mu_1^*(t) &= \frac{(1-q)\pi_{\chi^1}(t)\mu_1^1(t) + q\pi_{\chi^2}(t)\mu_1^2(t)}{\pi_{\chi^*}(t)},\end{aligned}$$

we see that

$$\begin{aligned}&(1-q)J(\lambda, \mu_0^1(.), \mu_1^1(.), \nu^1(.)) + qJ(\lambda, \mu_0^2(.), \mu_1^2(.), \nu^2(.))\\ &\quad > E\Bigg[\int_0^T \overline{u_1}(\lambda(1-\nu^*(t))\pi_{\chi^*}(t), t) + \int_0^T \lambda\pi_{\chi^*}(t)\overrightarrow{g}(\chi^*(t),t)\,dt + \overline{u_2}(\lambda\pi_{\chi^*}(T),T)\\ &\qquad + \lambda W_0\Bigg] \geq \inf_{\nu(.)} J(\lambda, \mu_0^*(.), \mu_1^*(.), \nu(.)).\end{aligned}$$

Note. In the inequalities above, we have used the fact that the set $\{(\pi_\chi, \pi_\chi\mu_0, \pi_\chi\mu_1)\colon \chi \in N'\}$ is a convex set, which follows from relation (3.4b), and that $\overline{u_1}(.), \overline{u_2}(.), \overrightarrow{g}(.)$ are convex functions of their arguments. It follows that $\inf_{\nu(.)\in D_{(\mu_0(.),\mu_1(.))}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.))$ is a convex functional of π_χ.

This completes the proof. □

Proof of Proposition 4.2. Since the proof of this proposition is rather involved, we will split it into several steps. We shall first prove that for each $\lambda \in (0, \infty)$, the problem

$$V(\lambda) = \inf_{\chi \in N'} J(\lambda, \chi) \tag{A.10}$$

has a solution. By hypothesis (c) of the proposition, $V(\lambda)$ exists for each λ.

Step 1. By the result of Lemma 4.2, if

$$\inf_{\nu(.)\in D_{(\mu_0(.),\mu_1(.))}} J(\lambda, \chi)$$

exists, it is attained uniquely by some bounded, progressively measurable process $\nu^*()$ for each fixed λ and square-integrable, progressively measurable process $(\mu_0(.), \mu_1(.))$ for which the set $D_{(\mu_0(.),\mu_1(.))}$ is nonempty.

Step 2. The problem (A.10) can be rewritten as

$$V(\lambda) = \inf_{(\mu_0(.),\mu_1(.))} \inf_{\nu(.)\in D_{\mu_0(.),\mu_1(.)}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.)).$$

Since $V(\lambda)$ exists by hypothesis (c) of the proposition, $\inf_{\nu(.)\in D_{\mu_0(.),\mu_1(.)}} \overline{J}(\lambda, \pi_\chi, \nu(.))$ exists and is attained uniquely by some bounded, progressively measurable process $\nu^*()$ for each fixed λ and square integrable, progressively measurable process $(\mu_0(.), \mu_1(.))$ for which the set $D_{(\mu_0(.),\mu_1(.))}$ is nonempty. By arguments analogous to those used in the proof of Theorem 3 in Cuoco and Cvitanic [5], the problem above can be rewritten as

$$V(\lambda) = \inf_{(\pi_\chi:\chi\in N')} \inf_{\nu(.)\in D_{\mu_0(.),\mu_1(.)}} \overline{J}(\lambda, \pi_\chi, \nu(.)),$$

where $\overline{J}(\lambda, \pi_\chi, \nu(.)) = J(\lambda, \mu_0(.), \mu_1(.), \nu(.))$.

Note. In the above, we have used the fact that π_χ (defined in (3.4a)) does not depend on $\nu(.)$.

Moreover, by arguments identical to those in the proof of Theorem 3 in Cuoco and Cvitanic [5], the set $\Pi = (\pi_\chi : \chi \in N')$ is a convex subset of $L^2([0,T] \times \Omega)$ and the functional $\overline{J}(\lambda, ., \nu(.))$ is convex on Π. By the result of Lemma 4.2, the functional

$$T(\lambda, .) = \inf_{\nu(.)} \overline{J}(\lambda, \dots, \nu(.)) \text{ is also convex on } \Pi.$$

We can now write

$$V(\lambda) = \inf_{(\pi_\chi:\chi\in N')} T(\lambda, \pi_\chi), \tag{A.11}$$

where $T(\lambda, .)$ is convex on Π.

Step 3. We shall now prove that in the problem (A.11) above, it is enough to consider the set of processes π_χ defined by processes $(\mu_0(.), \mu_1(.))$ for which $\|\mu_0\|_2$ is uniformly bounded by some constant Λ. By Assumption 4 and Lemma 4.1, $\overline{u_1}(c, t)$

is uniformly bounded below for all $(c,t) \in [0,\infty) \times [0,T]$. By hypothesis (c) of the proposition, for each $\lambda \in (0,\infty)$, there exists $\chi^* \in N'$ such that $J(\lambda,\chi^*) = \mathrm{A}(\lambda) < \infty$. We have

(A.12)

$$\begin{aligned}
T(\lambda,\pi_\chi) = &\inf_{\nu(.)\in D_{\mu_0(.),\mu_1(.)}} E\left[\int_0^T \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t),t)\,dt \right.\\
&\qquad\left. + \lambda\int_0^T \pi_\chi(t)\overrightarrow{g}(\chi(t),t)\,dt + \overline{u_2}(\lambda\pi_\chi(T),T)\right] + \lambda W_0\\
\geq{}& \Psi + \overline{u_2}\left(\lambda\left(\left[\exp\left(-E\int_0^T \mu_0(s)\,ds - \frac{1}{2}E\int_0^T \kappa_\chi(s)^2\,ds\right)\right]\right),T\right) + \lambda W_0\\
={}& \Psi + \overline{u_2}\left(\lambda\left(\left[\exp\left(-E\int_0^T \mu_0(s)\,ds - \frac{1}{2}E\right.\right.\right.\right.\\
&\qquad\left.\left.\left.\left. \times\int_0^T(\sigma(s)^{-1}(\overline{\mu}(s)+\mu_1(s)-\mu_0(s)))^2\,ds\right)\right]\right),T\right) + \lambda W_0\\
={}& \Psi + \overline{u_2}\left(\lambda\left(\left[\exp\left(-\frac{1}{2}E\int_0^T \sigma(s)^{-2}\mu_0(s)^2\,ds - E\right.\right.\right.\right.\\
&\qquad \int_0^T\left[\sigma(s)^{-1}\mu_0(s)(\overline{\mu}(s)+\mu_1(s)+\sigma(s))\right.\\
&\qquad\left.\left.\left.\left.\left. -\frac{1}{2}\sigma(s)^{-2}(\overline{\mu}(s)+\mu_1(s))^2\right]ds\right)\right]\right),T\right) + \lambda W_0\\
\geq{}& \Psi + \overline{u_2}\left(\lambda\left(\exp\left(-\frac{1}{2}E\int_0^T \sigma(s)^{-2}\mu_0(s)^2\,ds + ME\int_0^T |\mu_0(s)|\,ds\right)\right),T\right),
\end{aligned}$$

where Ψ is a lower bound on the integral $\int_0^T \overline{u_1}(\lambda(1-\nu(t))\pi_\chi(t),t)\,dt$. The first inequality in (A.12) follows from Jensen's inequality, condition (b) of the proposition, and the fact that $\overrightarrow{g}(.)$ is nonnegative and independent of $\mu_0(.)$ by (2.16). The last inequality follows from the fact that $\overline{u_2}(.)$ is decreasing. The constant M in the last inequality above is the uniform bound on $|\sigma(s)^{-1}(\overline{\mu}(s)+\mu_1(s))+1|$ which exists by Assumption 1.

Since $J(\lambda,\chi^*) = \mathrm{A}(\lambda) < \infty$ for some $\chi^* \in N'$, it is clearly enough in problem (A.11) to consider $\chi \in N'$ for which

$$\begin{aligned}
&\overline{u_2}\left(\lambda\left(\exp\left(-\frac{1}{2}E\int_0^T \sigma(s)^{-2}\mu_0(s)^2\,ds + ME\int_0^T |\mu_0(s)|\,ds\right)\right),T\right) \leq A(\lambda) \quad \text{or}\\
&\exp\left(-\frac{1}{2}E\int_0^T \sigma(s)^{-2}\mu_0(s)^2\,ds + ME\int_0^T |\mu_0(s)|\,ds\right) \geq \frac{1}{\lambda}\overline{u_2}^{-1}(A(\lambda),T)
\end{aligned}$$

(since $\overline{u_2}$ is decreasing), or

$$E\int_0^T \sigma(s)^{-2}\mu_0(s)^2\,ds - ME\int_0^T |\mu_0(s)|\,ds$$

is uniformly bounded above, which in turn implies that $\|\mu_0\|_2$ is uniformly bounded by some constant Λ since $\sigma(.)$ and $\sigma^{-1}(.)$ are uniformly bounded by assumption. Let us denote $\Pi_\Lambda = \{\pi_\chi : \chi \in N'; \|\mu_0\|_2 \leq \Lambda\}$. Then, we can rewrite problem (A.11) as

$$V(\lambda) = \inf_{(\pi_\chi : \pi_\chi \in \Pi_\Lambda)} T(\lambda, \pi_\chi). \tag{A.13}$$

Step 4. Let $\Pi_\Lambda^l = \Pi_\Lambda \cap \{\pi_\chi : \chi \in N'; \|\mu_0\|_\infty \leq l\}$ for each $l \in Z_{++}$; i.e., Π_Λ^l is the subset of Π_Λ consisting of those processes π_χ for which $|\mu_0|$ is uniformly bounded by l. Clearly, for each $\pi_\chi \in \Pi_\Lambda$, there exists a sequence $\pi_{\chi^n} \in \Pi_\Lambda^n$ such that

$$\lim_{n\to\infty} \pi_{\chi^n}(t,\omega) = \pi_\chi(t,\omega) \text{ a.e. on } [0,T] \times \Omega. \tag{A.14}$$

In this step, we prove that the problem

$$V^l(\lambda) = \inf_{(\pi_\chi : \pi_\chi \in \Pi_\Lambda^l)} T(\lambda, \pi_\chi)$$

has a solution; i.e., the minimum above *exists and is attained*. Since $\chi \in N' \Rightarrow |\mu_1|$ is uniformly bounded (Assumption 6) , we can use arguments identical to those used in the proof of Theorem 3 in Cuoco and Cvitanic [5] to show that Π_Λ^l is convex, uniformly bounded, and closed in $L^2([0,T] \times \Omega)$.

We now prove that $T(\lambda, .)$ is lower semicontinuous on Π_Λ^l. *Suppose this is not the case.* Then, there is an $\alpha > 0$, $\pi_\chi \in \Pi_\Lambda^l$, and a sequence $\{\pi_{\chi^n}\}$ converging to π_χ in $L^2([0,T] \times \Omega)$ such that $T(\lambda, \pi_{\chi^n}) \leq \alpha < T(\lambda, \pi_\chi)$. Since Π_Λ^l is convex, uniformly bounded, and closed in $L^2([0,T] \times \Omega)$, there exists a subsequence $\{\pi_{\overline{\chi^n}}\} \subset co(\{\pi_{\chi^n}\})$ such that $(\pi_{\overline{\chi^n}}, \overline{\mu_0^n}, \overline{\mu_1^n}) \to (\pi_\chi, \mu_0, \mu_1)$ a.e. and it follows from the convexity of $T(\lambda, .)$ that $T(\lambda, \pi_{\overline{\chi^n}}) \leq \alpha$ for all n. By the result of Step 1, there exist processes $\overline{\nu^n}$ and ν such that $(\overline{\mu_0^n}, \overline{\mu_1^n}, \overline{\nu^n}) \in N'$ and $(\mu_0, \mu_1, \nu) \in N'$ satisfying

$$T(\lambda, \pi_{\overline{\chi^n}}) = \overline{J}(\lambda, \pi_{\overline{\chi^n}}, \overline{\nu^n}),$$
$$T(\lambda, \pi_\chi) = \overline{J}(\lambda, \pi_\chi, \nu).$$

Moreover, it is proved in Lemma A.1 following this proposition that $\overline{\nu^n} \to \nu$ a.e. Due to the continuity of $\overline{u_1}(., t), \overline{u_2}$, and $\overrightarrow{g}(.)$ and the fact that they are uniformly bounded below, we can apply Fatou's lemma to conclude that

$$\alpha < T(\lambda, \pi_\chi) = \overline{J}(\lambda, \pi_\chi, \nu) \leq \liminf_{n\to\infty} \overline{J}(\lambda, \pi_{\overline{\chi^n}}, \overline{\nu^n}) = \liminf_{n\to\infty} T(\lambda, \pi_{\overline{\chi^n}}) \leq \alpha,$$

which is a contradiction. Therefore, $T(\lambda, .)$ *is lower semicontinuous on* Π_Λ^l. We have therefore shown that Π_Λ^l is *convex, uniformly bounded, and closed* in $L^2([0,T] \times \Omega)$ and that $T(\lambda, .)$ is *convex and lower semicontinuous* on Π_Λ^l. We can now apply the results of Proposition 2.1.2 in Ekeland and Temam [9] to conclude that

$$V^l(\lambda) = \inf_{(\pi_\chi : \pi_\chi \in \Pi_\Lambda^l)} T(\lambda, \pi_\chi) \tag{A.15}$$

exists and is attained. Moreover, by (A.13), (A.14), Lemma A.1, and Fatou's lemma,

$$\lim_{l\to\infty} V^l(\lambda) = V(\lambda) \text{ and } V^l(\lambda) \text{ decreases with } l.$$

Step 5. We now show that the minimum in the definition (A.10) of $V(\lambda)$ is attained. By the results of the previous steps, we have for each l $V^l(\lambda) = J(\lambda, \mu_0^l(.),$

$\mu_1^l(.), \nu^l(.))$ for some sequence of processes $\{(\mu_0^l(.), \mu_1^l(.), \nu^l(.))\}$ which is uniformly bounded in $L_3^2([0,T] \times \Omega)$; i.e., $\{\|\mu_0^l\|_2 + \|\mu_1^l\|_2 + \|\nu^l\|_2\}$ is uniformly bounded (using the result of Step 3).

Since the space $L_3^2([0,T] \times \Omega)$ is locally convex and meterizable, it follows that there is a subsequence, again denoted by $\{(\mu_0^l(.), \mu_1^l(.), \nu^l(.))\}$ for notational simplicity, converging weakly to some process $(\mu_0(.), \mu_1(.), \nu(.)) \in N'$. Therefore, there exists a further sequence $\{(\mu_0^{l'}(.), \mu_1^{l'}(.), \nu^{l'}(.))\} \subset co\{(\mu_0^l(.), \mu_1^l(.), \nu^l(.))\}$ that converges a.e. to $(\mu_0(.), \mu_1(.), \nu(.))$. By the continuity and convexity of $\overline{u_1}(., t), \overline{u_2}(., t)$ and $\overrightarrow{g}(., t, \omega)$ and the fact that they are uniformly bounded below, we can use Fatou's lemma to see that

$$J(\lambda, \mu_0(.), \mu_1(.), \nu(.)) \leq \liminf_{l\to\infty} J(\lambda, \mu_0^l(.), \mu_1^l(.), \nu^l(.)) = \liminf_{l\to\infty} V^l(\lambda) = V(\lambda).$$

Therefore, $J(\lambda, \mu_0(.), \mu_1(.), \nu(.)) = V(\lambda)$ and $(\mu_0(.), \mu_1(.), \nu(.))$ is an optimal solution.

Step 6. We now prove that the function $V(\lambda)$ is strictly convex and coercive for $\varepsilon(0, \infty)$, which would imply that

$$\inf_{\lambda \in (0,\infty)} V(\lambda)$$

exists and is attained. Let $\chi^1_, \chi^2$ be the optimal solutions derived in *Step 5* corresponding to λ_1, λ_2, respectively, and let $\lambda = (1-q)\lambda_1 + q\lambda_2$, where $0 < q < 1$. Therefore,

$$V(\lambda_i) = J(\lambda_i, \chi^i) = E\left[\int_0^T \overline{u_1}(\lambda_i(1-\nu^i(t))\pi_{\chi^i}(t), t)\,dt \right.$$
$$\left. + \lambda_i \int_0^T \pi_{\chi^i}(t) \overrightarrow{g}(\chi^i(t), t)\,dt + \overline{u_2}(\lambda_i \pi_{\chi^i}(T), T)\right] + \lambda_i W_0; i = 1, 2.$$

By the strict convexity of $\overline{u_1}, \overline{u_2}$ and the convexity of $\overrightarrow{g}$, we have

$$(1-q)V(\lambda_1) + qV(\lambda_2)$$
$$> E\left[\int_0^T \overline{u_1}((1-q)\lambda_1(1-\nu^1(t))\pi_{\chi^1}(t) + q\lambda_2(1-\nu^2(t))\pi_{\chi^2}(t), t) \right.$$
$$+ (1-q)\lambda_1 \int_0^T \pi_{\chi^1}(t)\overrightarrow{g}(\chi^1(t), t)\,dt + q\lambda_2 \int_0^T \pi_{\chi^2}(t)\overrightarrow{g}(\chi^2(t), t)\,dt$$
$$\left. + \overline{u_2}((1-q)\lambda_1\pi_{\chi^1}(T) + q\lambda_2\pi_{\chi^2}(T), T) + \lambda W_0\right].$$

If we define

$$\pi_{\chi^*}(t) = \frac{(1-q)\lambda_1\pi_{\chi^1}(t) + q\lambda_2\pi_{\chi^2}(t)}{\lambda},$$

$$(1-\nu^*(t)) = \frac{(1-q)\lambda_1\pi_{\chi^1}(t)(1-\nu^1(t)) + q\lambda_2\pi_{\chi^2}(t)(1-\nu^2(t))}{\lambda\pi_{\chi^*}(t)},$$

$$\mu_0^*(t) = \frac{(1-q)\lambda_1\pi_{\chi^1}(t)\mu_0^1(t) + q\lambda_2\pi_{\chi^2}(t)\mu_0^2(t)}{\lambda\pi_{\chi^*}(t)},$$

$$\mu_1^*(t) = \frac{(1-q)\lambda_1\pi_{\chi^1}(t)\mu_1^1(t) + q\lambda_2\pi_{\chi^2}(t)\mu_1^2(t)}{\lambda\pi_{\chi^*}(t)},$$

we easily see that

$$\begin{aligned}&(1-q)V(\lambda_1)+qV(\lambda_2)\\&\quad> E\left[\int_0^T \overline{u_1}(\lambda(1-\nu^*(t))\pi_{\chi^*}(t),t)\right.\\&\qquad\left.+\int_0^T \lambda\pi_{\chi^*}(t)\overrightarrow{g}(\chi^*(t),t)\,dt+\overline{u_2}(\lambda\pi_{\chi^*}(T),T)+\lambda W_0\right]\geq V(\lambda).\end{aligned}$$

Note. In the inequalities above, we have used the fact that the set $\{(\pi_\chi,\pi_\chi\mu_0,\pi_\chi\mu_1):\chi\in N'\}$ is a convex set, which follows from relation (3.4b).

This proves the strict convexity of $V(.)$. Since $W_0>0$ by assumption and $\overline{u_1},\overline{u_2},\overrightarrow{g}$ are uniformly bounded below,

$$\lim_{\lambda\to\infty} J(\lambda,\chi)=\infty \text{ uniformly in } \chi(.).$$

From (A.12),

$$\begin{aligned}J(\lambda,\chi)&\geq\overline{u_2}\left(\lambda\left(\exp\left(-\frac{1}{2}E\int_0^T\sigma(s)^{-2}\mu_0(s)^2\,ds+ME\int_0^T|\mu_0(s)|\,ds\right)\right),T\right)\\&\geq\overline{u_2}\left(\lambda\exp\left(\frac{1}{2}E\int_0^T M^2\sigma(s)^2\,ds\right),T\right)\geq\overline{u_2}\left(\lambda\exp\left(\frac{1}{2}M^2K^2T\right),T\right),\end{aligned}$$

where K is the uniform upper bound on $\sigma(.)$. By Lemma 4.1, we therefore have

$$\lim_{\lambda\to 0} J(\lambda,\chi)=\infty \textit{ uniformly} \text{ in } \chi(.).$$

Therefore, $\lim_{\lambda\to 0}V(\lambda)=\lim_{\lambda\to\infty}V(\lambda)=\infty$. Hence, $V(.)$ is strictly convex and coercive on $(0,\infty)$. This completes the proof of the existence of an optimal solution to the dual problem. Let the optimal solution be denoted by $(\lambda^*,\mu_0^*(.),\mu_1^*(.),\nu^*(.))$.

Step 7. It remains only to verify that condition (4.5) of the verification Proposition 4.1 is satisfied. By condition (e) of the proposition, we have

$$\begin{aligned}yf_1(y,t)&\leq a+(1-b)u_1(f_1(y,t),t),\\yf_2(y,T)&\leq a+(1-b)u_2(f_2(y,T),T).\end{aligned}$$

Therefore,

$$\begin{aligned}&E\left[\int_0^T\pi_{\chi^*}(t)f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt+\pi_{\chi^*}(T)f_2(\lambda^*\pi_{\chi^*}(T),T)\right]\\&\qquad\leq\frac{2a}{b\lambda^*}+\frac{1-b}{b\lambda^*}E\left[\int_0^T\overline{u_1}(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt+\overline{u_2}(\lambda^*\pi_{\chi^*}(T),T)\right]<\infty\end{aligned}$$

since $|J(\lambda^*,\chi^*)|<\infty$ from assumption (c) of the proposition. By an examination of the proof of Proposition 4.1, we see that the conditions $E[\int_0^T\pi_{\chi^*}(t)\,dt]<\infty$ and $E[\pi_{\chi^*}(T)]<\infty$ are required only to ensure that $E[\int_0^T u_1(c^*(t),t)^-dt]<\infty$ and $E[u_2(W^*,T)^-]<\infty$, which are trivially satisfied since $u_1(.)$ and $u_2(.)$ are assumed to be nonnegative by hypothesis (a) of the proposition. Therefore, by the result of Proposition 4.1, an optimal liquidation policy for the large investor exists. □

LEMMA A.1. *Assume the conditions of Proposition* 4.2. *In the notation of the proof of Proposition* 4.2, *if*

$$T(\lambda, \pi_{\chi^n}) = \inf_{\nu \in D_{(\mu_0^n(.),\mu_1^n(.))}} \overline{J}(\lambda, \pi_{\chi^n}, \nu) = \inf_{\nu \in D_{(\mu_0^n(.),\mu_1^n(.))}} J(\lambda, \mu_0^n(.), \mu_1^n(.), \nu(.))$$

and

$$\begin{aligned} &= J(\lambda, \mu_0^n(.), \mu_1^n(.), \nu^n(.)) < \infty \\ &T(\lambda, \pi_\chi) = \inf_{\nu \in D_{(\mu_{0(.)},\mu_{1(.)})}} \overline{J}(\lambda, \pi_\chi, \nu) = \inf_{\nu \in D_{\mu_0(.),\mu_1(.)}} J(\lambda, \mu_0(.), \mu_1(.), \nu(.)) \\ &= J(\lambda, \mu_0(.), \mu_1(.), \nu^*(.)) < \infty \end{aligned}$$

and $\mu_0^n(.) \to \mu_0(.)$ *a.e.,* $\mu_1^n(.) \to \mu_1(.)$ *a.e., and* $\pi_{\chi^n}(.) \to \pi_\chi(.)$ *a.e., then* $\nu^n(.) \to \nu^*(.)$ *a.e.*

Proof. By the arguments in the proof of Lemma 4.2 we have

$$\begin{aligned} \nu^n(t,\omega) = \arg\min\nolimits_{\eta \in D_{\mu_0^n(.),\mu_1^n(.)}(t,\omega)} [&\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega), t) \\ &+ \lambda \pi_{\chi^n}(t,\omega) \overrightarrow{g}(\mu_0^n(t,\omega), \mu_1^n(t,\omega), \eta, t, \omega)] \end{aligned}$$

and

$$\begin{aligned} \nu^*(t,\omega) = \arg\min\nolimits_{\eta \in D_{\mu_0(.),\mu_1(.)}(t,\omega)} [&\overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) \\ &+ \lambda \pi_\chi(t,\omega) \overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)]. \end{aligned}$$

By condition (a) of Proposition 4.2, the functions being minimized in both equations above are strictly convex functions of η. It follows that $\nu^n(t,\omega)$ and $\nu^*(t,\omega)$ are uniquely defined. By Assumption 7, the sets $D_{\mu_0^n(.),\mu_1^n(.)}(t,\omega)$ and $D_{\mu_0(.),\mu_1(.)}(t,\omega)$ are equal and have the form $[-\Gamma_{(t,\omega)}, 1]$, where $0 \leq \Gamma_{(t,\omega)} < \infty$. Since we cannot have $\nu^*(t,\omega) = 1$ (as $\overline{u_1}(0,t) = \infty$), we can distinguish two cases.

Case 1. $-\Gamma_{(t,\omega)} < \nu^*(t,\omega) < 1$; i.e., $\nu^*(t,\omega)$ is an interior minimum.

Since $\overline{u_1}(.)$ and $\overrightarrow{g}(.)$ are continuously differentiable functions by hypothesis (d) of Proposition 4.2,

$$\frac{\partial}{\partial \eta}[\overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) + \lambda \pi_\chi(t,\omega) \overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)]|_{\eta = \nu^*(t,\omega)} = 0.$$

Since the function inside the parentheses above is a strictly convex function of η, the first partial derivative above is strictly increasing as a function of η. Therefore, for $\nu_l < \nu^*(t,\omega) < \nu_h$, we have

$$\begin{aligned} &\frac{\partial}{\partial \eta}[\overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) + \lambda \pi_\chi(t,\omega) \overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)]|_{\eta = \nu_l} < 0 \\ &\quad < \frac{\partial}{\partial \eta}[\overline{u_1}(\lambda(1-\eta)\pi_\chi(t,\omega), t) + \lambda \pi_\chi(t,\omega) \overrightarrow{g}(\mu_0(t,\omega), \mu_1(t,\omega), \eta, t, \omega)]|_{\eta = \nu_h}. \end{aligned}$$

Since $\mu_0^n(t,\omega) \to \mu_0(t,\omega)$, $\mu_1^n(t,\omega) \to \mu_1(t,\omega)$, $\pi_{\chi^n}(t,\omega) \to \pi_\chi(t,\omega)$, and the first partial derivatives above are continuous functions of their arguments, it is easy to see that for n sufficiently large

$$\begin{aligned} &\frac{\partial}{\partial \eta}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega), t) + \lambda \pi_{\chi^n}(t,\omega) \overrightarrow{g}(\mu_0^n(t,\omega), \mu_1^n(t,\omega), \eta, t, \omega)] \,|_{\eta = \nu_l} < 0 \\ &\quad < \frac{\partial}{\partial \eta}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega), t) + \lambda \pi_{\chi^n}(t,\omega) \overrightarrow{g}(\mu_0^n(t,\omega), \mu_1^n(t,\omega), \eta, t, \omega)] \,|_{\eta = \nu_h}. \end{aligned}$$

It follows that

$$\nu_l < \nu^n(t,\omega) = \arg\min_{\eta \in D_{\mu_0^n(.),\mu_1^n(.)}(t,\omega)}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega),t) \\ + \lambda\pi_{\chi^n}(t,\omega)\overrightarrow{g}(\mu_0^n(t,\omega),\mu_1^n(t,\omega),\eta,t,\omega)] < \nu_h.$$

Since $\nu_h - \nu_l$ can be chosen to be arbitrarily small, we easily see that $\nu^n(t,\omega) \to \nu^*(t,\omega)$.

Case 2. $\nu^*(t,\omega) = -\Gamma_{(t,\omega)}$; i.e., $\nu^*(t,\omega)$ is an extreme point.

In this case, we have

$$\frac{\partial}{\partial\eta}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi}(t,\omega),t) + \lambda\pi_{\chi}(t,\omega)\overrightarrow{g}(\mu_0(t,\omega),\mu_1(t,\omega),\eta,t,\omega)]\mid_{\eta=\nu^*(t,\omega)} \geq 0.$$

Since the first partial derivative above is strictly increasing as a function of η, we have

$$\frac{\partial}{\partial\eta}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi}(t,\omega),t) + \lambda\pi_{\chi}(t,\omega)\overrightarrow{g}(\mu_0(t,\omega),\mu_1(t,\omega),\eta,t,\omega)]\mid_{\eta=\eta_h} > 0$$

for $\eta_h > \nu^*(t,\omega) = -\Gamma^*(t,\omega)$. It follows that for n sufficiently large

$$\frac{\partial}{\partial\eta}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega),t) + \lambda\pi_{\chi^n}(t,\omega)\overrightarrow{g}(\mu_0^n(t,\omega),\mu_1^n(t,\omega),\eta,t,\omega)]\mid_{\eta=\eta_h} > 0.$$

It follows that

$$-\Gamma(t,\omega) \leq \nu^n(t,\omega) = \arg\min_{\eta \in D_{\mu_0^n(.),\mu_1^n(.)}(t,\omega)}[\overline{u_1}(\lambda(1-\eta)\pi_{\chi^n}(t,\omega),t) \\ + \lambda\pi_{\chi^n}(t,\omega)\overrightarrow{g}(\mu_0^n(t,\omega),\mu_1^n(t,\omega),\eta,t,\omega)] < \eta_h.$$

Since η_h can be chosen arbitrarily close to $-\Gamma(t,\omega)$, it follows that

$$\nu^n(t,\omega) \to -\Gamma(t,\omega) = \nu^*(t,\omega).$$

This completes the proof of the lemma. □

Proof of Lemma 6.1. If $u_2(.,T)$ is monotonically decreasing, then the maximization problem on the right-hand side of the definition (4.2) of the function $\overline{u_2}$ is solved by $W = 0$ if $y \geq 0$. This implies (6.6). If $u_2(.,T)$ is nonmonotonic, Assumption 4 implies that, for $y \in [0,\infty)$, $f_2(y,T)$ must satisfy $u_2'(f_2(y,T),T) = y$. Since $u_2(.,T)$ is strictly increasing on $[0,\hat{c}]$, attains a maximum at $\hat{c}$ (so that its derivative is zero), and satisfies (6.2), it follows that (6.7) holds. □

Proof of Proposition 6.1. The proof proceeds along the lines of the proof of Proposition 4.1. Let the liquidation process be defined by $c^* = c_{\chi^*}$ and the terminal wealth level by $W^* = W_{\chi^*}$. The consumption process c^* satisfies (2.5) using exactly the same arguments used in Step 1 of the proof of Proposition 4.1. By (6.6), (6.7), and (6.9), the terminal wealth W^* is uniformly bounded so that it satisfies (2.5). The rest of the proof follows the proof of Proposition 4.1. □

Proof of Proposition 6.2. The proof proceeds exactly as the proof of Proposition 4.2 until Step 7, which establishes that condition (6.8) of the verification Proposition 6.1 is satisfied. By condition (e) of the proposition,

$$yl_2(y,T) \leq a + (1-b)u_2(l_2(y,T),T) \text{ for } y \geq 0.$$

Since $\lambda^*\pi_{\chi^*}(T) > 0$, we have

$$E\left[\int_0^T \pi_{\chi^*}(t)f_1(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt + \pi_{\chi^*}(T)l_2(\lambda^*\pi_{\chi^*}(T),T)\right] \\ \leq \frac{2a}{b\lambda^*} + \frac{1-b}{b\lambda^*}E\left[\int_0^T \overline{u_1}(\lambda^*(1-\nu^*(t))\pi_{\chi^*}(t),t)\,dt + \overline{u_2}(\lambda^*\pi_{\chi^*}(T),T)\right] < \infty,$$

since $|J(\lambda^*, \chi^*)| < \infty$ from assumption (c) of the proposition. The conditions $E[\int_0^T \pi_{\chi^*}(t)\, dt] < \infty$ and $E[\pi_{\chi^*}(T)] < \infty$ are required only to ensure that $E[\int_0^T u_1(c^*(t), t)^- dt] < \infty$ and $E[u_2(W^*, T)^-] < \infty$. These conditions are trivially satisfied since, by hypothesis (a) of the proposition and Lemma 6.1, $u_1(.)$ is nonnegative, $u_2(.)$ is nonnegative for $W \in [0, \hat{c}]$, and $W^* \in [0, \hat{c}]$. Therefore, by the result of Proposition 6.1, an optimal liquidation policy for the large investor exists. □

CORRIGENDUM: SUPPRESSION OF THE DIRICHLET EIGENVALUES OF A COATED BODY[*]

STEVE ROSENCRANS[†] AND XUEFENG WANG[†]

Abstract. In our paper [*SIAM J. Appl. Math.*, 66 (2006), pp. 1895–1916] there are several mistakes in signs in the statements of Theorems 3 and 6.

Key words. nanocomposite, Dirichlet eigenvalue, anisotropic heat conduction, thermal tensor, thermal management, insulation, reinforcement

AMS subject classifications. 35J05, 35J20, 80A20, 80M30, 80M40

DOI. 10.1137/070705404

In the upper bounds on $\lambda_1(\Omega)$ stated in Theorems 3 and 6, there should be "$-$" signs in front of π and $\overline{H}$.

On page 1905 all "$-$" signs in front of the principal curvatures k_1 and k_2 should be changed to "$+$" signs. This leads to some obvious minor changes in the rest of the proof of Theorem 3 and the statement and proof of Lemma 5. The speed of the curves of principal curvature are 1 only at q, and so the six equations following "speed equal to 1" hold only at q.

These corrections necessitate *only* the above-mentioned changes in the statements of Theorems 3 and 6. The statements of all the other theorems remain unchanged.

SOLUTE TRANSPORT IN POROUS MEDIA. MEDIA WITH CAPILLARIES AS VOIDS[*]

GUILLERMO H. GOLDSZTEIN[†]

Abstract. We study solute transport in porous media with periodic microstructures consisting of interconnected thin channels. We discuss a local physical mechanism that occurs at the intersections of channels and promotes mixing of the solute with the solvent (i.e., the host liquid). We identify the parameter regime, where this mechanism is the dominant cause of dispersion, and obtain the effective or macroscopic transport equation that the concentration of solute satisfies when the medium is subjected to a time periodic applied pressure gradient. We conclude with illustrative examples.

Key words. porous media, solute transport, hydrodynamic dispersion, network approximation, macroscopic behavior, homogenization

DOI. 10.1137/070695228

1. Introduction.

A porous medium is a material that contains relatively small spaces filled with fluid (such as a gas, a liquid, or a mixture of different fluids) embedded in a solid matrix. These fluid filled spaces are called pores or voids. With the exception of metals, some dense rocks, and some plastics, virtually all solid materials are porous to varying degrees.

Solutes are materials that dissolve in liquids forming solutions. An example is salt (not at very large concentrations) in water. The host liquid, such as water in the mentioned example, is called the solvent. The transport of a solute in porous media depends on several factors, including the solvent and solute properties, the fluid velocity field within the porous medium, and the *microgeometry*, i.e., shape, size, and location of the solid part of the medium and the voids. The objective of this paper is to provide new tools for the study of the influence of these factors on solute transport.

Solute transport in liquid filled porous media plays a significant role in several phenomena of scientific and technological importance including the transport of contaminants in soils [17, 32], the transport of nutrients in bones [50, 45, 43, 44, 65, 39], the intrusion of salt in fresh water in soils near ocean coasts, movement of minerals (e.g., fertilizers) in soils, secondary recovery techniques in oil reservoirs (where the injected fluid dissolves the reservoir's oil), the use of tracers in petroleum engineering and hydrology research projects, etc. (see more about these and other examples in [14, 6, 9, 19, 30, 58]).

Several theoretical methods are used to study solute transport in porous media [23]. These include the use of numerical experiments on networks of channels with varying widths forming regular grids [2, 15, 16, 20, 27, 58, 59], percolation methods [2, 7, 8, 10, 47, 55, 56, 57, 59, 62], numerical experiments on media with fractal geometry [2, 16, 59, 64], assuming periodic media and calculating the effective transport equation by means of the method of moments [2, 11, 12, 13, 14, 31]

or homogenization techniques [42, 48, 49, 51], and the calculation of effective transport equations by means of the method of moments on periodic networks of channels [2, 1, 29] (see also [38] for a study of diffusion in periodic networks with no flow). The most well-known early theoretical works are studies of solute transport in single straight tubes [63, 3]. We also mention the work on random networks of thin channels [52, 53, 54], the work on media with trapped fluid in dead-end pores [21], the early work using the method of moments [41], and the work on solute transport in a dilute suspension of spheres [46] and in parallel channels [18]. Further discussions can be found in [10, 36, 60, 5, 24, 25, 9, 26]. Experimentally, these phenomena have also been extensively studied (see summaries in [37, 30, 22]; see also [40, 28]).

The local phenomenon that motivates our work is simple and described next. Consider the three interconnected channels of Figure 1.1(a). We labeled the channels 1, 2, and 3. The arrows indicate the direction of the fluid velocity field within each channel. The channels are thin. More precisely, assume that the lengths of the channels are $O(\ell)$, their diameters are $O(\delta)$, the fluid velocities within the channels are $O(v)$, and these parameters satisfy $\delta^2/D \ll \ell/v \ll \ell^2/D$, where D is the diffusion coefficient of the solute in the solvent under consideration. In this parameter regime, the concentration of solute in each channel is homogeneous in slices perpendicular to the channel and is convected with the average fluid velocity within the channel (see [63, 3] and our section 2.1).

In Figure 1.1(b) we display the initial solute concentration, i.e., at time $t = 0$. The darker the regions, the larger the solute concentration. Only channel 2 has solute at $t = 0$. Let t_1 be the time when solute first reaches the intersection of the channels. The solute concentration at time $t = t_1$ is shown in Figure 1.1(c). Let $t_2 > t_1$. In the absence of diffusion, fluid from channel 2 with solute and fluid from channel 3 without solute would be convected next to each other along channel 1 during the time interval (t_1, t_2), and the distribution of solute concentration at $t = t_2$ would look as displayed in Figure 1.1(d). This is in contradiction with the fact that solute concentration is homogeneous in slices perpendicular to the channels. In fact, as discussed in section 2.1, diffusion homogenizes the concentration of solute in slices perpendicular to the channels, and thus the distribution of solute at $t = t_2$ is as illustrated in Figure 1.1(e). During the time interval (t_1, t_2), liquid with solute from channel 2 enters channel 1 and mixes with liquid without solute that enters channel 1 from channel 3.

In this paper we consider porous media with periodic microstructures and void spaces consisting of interconnected thin channels. The local effect described in the above paragraph (that corresponds to Figure 1.1(e)) occurs throughout the porous media and promotes solute transport. In this paper we study this phenomenon.

In section 2 we describe our mathematical model. This model is the asymptotic limit of the Navier–Stokes equations within the void with nonslip boundary condition coupled with the convection-diffusion equation for the transport of solute. In section 3 we obtain the *macroscopic* transport equation which the solute concentration satisfies. We assume that the medium is subjected to a time periodic applied pressure gradient and obtain, by means of homogenization techniques on the model of section 2, that the solute concentration satisfies a macroscopic convection-diffusion equation. As expected, it is convected with the average fluid velocity. We obtain a relatively simple mean to compute the diffusion tensor, known in the literature as the dispersion tensor. In section 4 we provide some examples and in section 5 conclude with some discussions.

As previously mentioned, there are several methods for studying solute transport in porous media. Each method has its strengths and weaknesses. The most computational economical methods are those that compute the macroscopic properties with the use of periodic networks. This class of methods is essentially limited to [1] and its generalizations [2, 29]. The authors of [1, 2, 29] use the method of moments instead of homogenization or asymptotic techniques, as we do here. However, this is not the essential difference between those methods and the technique developed in this paper. The models in [1, 2, 29] use ad hoc rules that correspond to assuming that the volume of the channels is much smaller than the volume of the intersections, and some ad hoc mixing rules are given at the intersections. As a consequence, the physical effect that motivated our work (that of Figure 1.1(e)) is not captured well by the existing models [1, 2, 29] (see also our section 4). We believe our method is an ideal tool for studying the dependence of the dispersion tensor on the microgeometry and will prove to be very useful.

2. Mathematical model.

2.1. Preliminaries. Fluid flow and solute transport in channels.

Figure 2.1 shows a two-dimensional channel with length ℓ and width δ filled with a Newtonian incompressible fluid that is subjected to pressures $p = p_a$ and $p = p_b$ at the ends of the channel. Let $\hat{\mathbf{e}}$ be the vector of unit length parallel to the channel displayed in Figure 2.1. Let y be the coordinate in the direction perpendicular to the channel. At low Reynolds numbers (low velocities), the fluid velocity of the steady state flow is of the form $u(y)\hat{\mathbf{e}}$ with u satisfying $(p_b - p_a)/\ell = \mu u''$, where μ is the fluid viscosity and u'' is the second derivative of u. In addition, the fluid velocity satisfies nonslip boundary conditions at the channel walls, i.e., $u = 0$ at the walls. Simple calculations show that the velocity has a parabolic profile (see Figure 2.1) and its spatial average across the channel is

$$\mathbf{v} = \frac{\delta^2}{12\mu\ell}(p_a - p_b)\hat{\mathbf{e}} \tag{2.1}$$

(see [4]). This type of flow is known as Poiseuille flow.

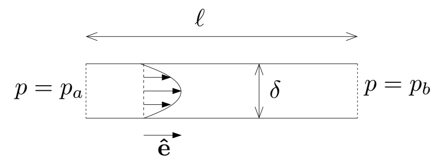

FIG. 2.1. *Velocity profile of a Poseuille flow within a straight channel (indicated by arrows).*

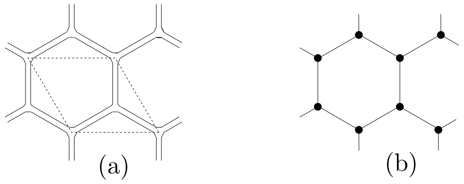

FIG. 2.2. (a) *Example of a periodic network of interconnected channels. The period cell is shown by dashed lines.* (b) *Associated graph. The lines are the edges and the solid circles the nodes.*

Taylor studied solute transport in channels at low Reynolds numbers [63]; see also Aris [3]. The result relevant to us is the following. Let D be the coefficient of diffusion of the solute in the host liquid, ℓ the length of the channel, δ its diameter, and v the spatial average of the norm of the fluid velocity. If

$$\frac{\delta^2}{D} \ll \frac{\ell}{v} \ll \frac{\ell^2}{D}, \tag{2.2}$$

the evolution of solute concentration is described by these two rules:

(2.3)
Rule 1: The concentration of solute is homogeneous in slices (of infinitesimal thickness) perpendicular to the channel.
Rule 2: The solute concentration is convected (or advected) with the average fluid velocity within the channel.

The validity of these two rules can be easily understood as follows. The time required by diffusion to homogenize the solute concentration in slices perpendicular to the channel is of order $O(\delta^2/D)$. Since the time required for solute to be convected from one end to the opposite end of the channel is $O(\ell/v)$, the validity of Rule 1 results from $\delta^2/D \ll \ell/v$. On the other hand, Taylor showed that, in the direction of the tube, the time for solute to disperse distances of $O(\ell)$ is $O(\ell^2/D^\star)$, where $D^\star = O(D + v^2\delta^2/D)$. Thus, the validity of Rule 2 results if $\ell/v \ll \ell^2/D^\star$. Simple algebra shows that, in fact, the two conditions $\delta^2/D \ll \ell/v$ and $\ell/v \ll \ell^2/D^\star$ are equivalent to (2.2).

2.2. Microgeometry. We consider two-dimensional porous media with periodic microstructures. We denote the void or pore space (i.e., the space filled by fluid) by Ω_p. Note that $\Omega_p \subseteq \mathbb{R}^2$. Since the microstructures are periodic, there exist two linearly independent vectors $\mathbf{w}$ and $\mathbf{q}$ such that

$$\Omega_p = \Omega_p + n\mathbf{w} + m\mathbf{q} \tag{2.4}$$

for all pairs of integers n and m. We assume that Ω_p is a collection interconnected thin channels (see Figure 2.2(a)). We assume that exactly three channels merge at each intersection. We associate a periodic graph with the microstructure of the medium in a natural way, as illustrated in Figure 2.2(b); the edges are the channels and the nodes the intersection of channels. We denote by $\mathcal{N}$ the set of nodes. We identify the nodes with their location, and thus $\mathcal{N} \subset \mathbb{R}^2$. We denote by $\mathcal{E}$ the set of edges. Given an edge e, its width (i.e., the width of the channel that corresponds to e) is denoted by δ_e and its length by ℓ_e. We assume that the widths of the channels are much smaller than their lengths. We also assume that the void space Ω_p is a connected set.

2.3. Fluid flow. Microscopic description. The fluid that fills Ω_p is an incompressible Newtonian fluid with constant density ρ and constant viscosity μ and satisfies nonslip boundary conditions, i.e., the fluid velocity vanishes at the channels walls (i.e., at the boundary of Ω_p).

For each node $\mathbf{a} \in \mathcal{N}$, we denote by $p_{\mathbf{a}}$ the pressure at $\mathbf{a}$. Note that $p_{\mathbf{a}} = p_{\mathbf{a}}(t)$ is a function of time t. We assume that the medium is subjected to an applied pressure gradient $\mathbf{G} = \mathbf{G}(t)$ that is periodic in t with period t_0. Thus, the pressures at the nodes satisfy the condition

$$p_{\mathbf{a}+n\mathbf{w}+m\mathbf{q}} = p_{\mathbf{a}} + \mathbf{G} \cdot (n\mathbf{w} + m\mathbf{q}) \tag{2.5}$$

for all integers n and m and all nodes $\mathbf{a}$, where, as described above, $\mathbf{w}$ and $\mathbf{q}$ are the vectors that determine the periodicity of the microgeometry, and we use the notation $\mathbf{r} \cdot \mathbf{s} = r_1 s_1 + r_2 s_2$ for all vectors $\mathbf{r}, \mathbf{s}$, and r_i is the ith component of the vector $\mathbf{r}$.

If e is an edge, we denote by $\mathbf{v}_e$ the average of the velocity field within the channel e. We assume that the variation of $\mathbf{G}(t)$ in time is slow enough that the pressure difference between the two ends of a channel creates a Poiseuille flow within that channel, and thus, for each edge e, according to our review (equation (2.1)), we have

$$\mathbf{v}_e = -\frac{\delta_e^2}{12\mu\ell_e}\,(p_{\mathbf{b}} - p_{\mathbf{a}})\,\frac{\mathbf{b}-\mathbf{a}}{\|\mathbf{b}-\mathbf{a}\|}, \text{ where } \mathbf{a} \text{ and } \mathbf{b} \text{ are the endpoints of } e, \tag{2.6}$$

and we use the standard notation for the Euclidean norm $\|\mathbf{r}\| = \sqrt{r_1^2 + r_2^2}$.

The rate at which the volume of fluid enters an intersection is equal to the rate at which it leaves the intersection, i.e., conservation of mass. This implies that, for each node $\mathbf{a}$, we have

$$\sum_{\{e \in \mathcal{E} : \mathbf{a} \text{ is an endpoint of } e\}} \delta_e \mathbf{v}_e \cdot \frac{\mathbf{b}-\mathbf{a}}{\|\mathbf{b}-\mathbf{a}\|} = 0, \text{ where } \mathbf{b} \text{ is the endpoint of } e \text{ not equal to } \mathbf{a}. \tag{2.7}$$

The velocities within all the channels are uniquely determined by the system (2.5)–(2.7). This well-known system (similar models were used as early as [33, 34, 35]; see also [61, 30]) is the asymptotics of the Navier–Stokes equations within the void with nonslip boundary conditions in the limit when the widths of the channels are much smaller than their lengths, and the time variations of the applied pressure gradient $\mathbf{G}(t)$ are slow enough. Note that the resultant velocity field is periodic in space with the same period as the microstructure.

In practice, we first solve for the pressure at the nodes and then for the velocities within the channels. More precisely, using the expression for the velocities in (2.6), we reduce (2.7) into

$$\sum_{\{\mathbf{b} \in \mathcal{N} : \mathbf{b} \text{ is connected to } \mathbf{a} \text{ by an edge}\}} \frac{\delta_e^3}{12\mu\ell_e}\,(p_{\mathbf{b}} - p_{\mathbf{a}}) = 0 \text{ for all } \mathbf{a} \in \mathcal{N}, \tag{2.8}$$

which together with condition (2.5) reduce, for each fixed t, to a system of linear equations, where the number of unknowns is equal to the number of nodes in a single period cell minus one. Once the pressure at the nodes is obtained, the velocities in the edges are easily computed with (2.6).

2.4. Solute transport. Microscopic description. For each $e \in \mathcal{E}$ we use the notation $v_e = \|\mathbf{v}_e\|$. We assume that

$$v_e = O(v),\ \ell_e = O(\ell),\ \delta_e = O(\delta) \text{ for all } e \in \mathcal{E}, \tag{2.9}$$

where v, ℓ, and δ are parameters that satisfy (2.2), and thus the transport of solute concentration within each channel is given by Rules 1 and 2 (see (2.3)).

Given an edge e, its endpoint with smallest pressure will be called its head and will be denoted by $\mathbf{h}(e)$. Analogously, $\mathbf{k}(e)$, the tail of the edge e, is the endpoint of e with largest pressure. Thus, fluid within an edge e (or channel) flows from its tail $\mathbf{k}(e)$ to its head $\mathbf{h}(e)$. Note that, since the fluid flow is time dependent, an endpoint of an edge may be its head for some period of time and its tail for other times.

We parametrize each edge e (more precisely, the segment joining the tail and head of e) by

$$\mathbf{x}_e(s) = \mathbf{k}(e) + s\frac{\mathbf{h}(e) - \mathbf{k}(e)}{\|\mathbf{h}(e) - \mathbf{k}(e)\|} \tag{2.10}$$

and we denote by $u_e(s,t)$ the solute concentration in the channel e at the point $\mathbf{x}_e(s)$ and time t. Note that $\mathbf{x}_e(0) = \mathbf{k}(e)$ and $\mathbf{x}_e(\ell_e) = \mathbf{h}(e)$ because $\ell_e = \|\mathbf{h}(e) - \mathbf{k}(e)\|$. Thus, the channel is parametrized by $\mathbf{x}_e(s)$ with $0 \leq s \leq \ell_e$. The fact that solute concentration in a channel is convected with the average fluid velocity within the channel translates into

$$\frac{\partial u_e}{\partial t} + v_e\frac{\partial u_e}{\partial s} = 0 \text{ for } 0 \leq s \leq \ell_e,\ t \geq 0, \text{ and all } e \in \mathcal{E}. \tag{2.11}$$

Let e be an edge and $\mathbf{k}(e)$ its tail (at a fixed time t). One of two cases is possible: $\mathbf{k}(e)$ is the head of two other edges, or $\mathbf{k}(e)$ is the head of only one other edge. Assume first that $\mathbf{k}(e)$ is the head of two other edges, say, β_1 and β_2, i.e., $\mathbf{h}(\beta_1) = \mathbf{h}(\beta_2) = \mathbf{k}(e)$. Conservation of solute implies that solute enters $\mathbf{k}(e)$ at the same rate that it leaves $\mathbf{k}(e)$, and thus $\delta_e v_e u_e(0,t) = \delta_{\beta_1} v_{\beta_1} u_{\beta_1}(\ell_{\beta_1}, t) + \delta_{\beta_2} v_{\beta_2} u_{\beta_2}(\ell_{\beta_2}, t)$. This condition can be written as

$$u_e(0,t) = \frac{\sum_{\{\beta:\mathbf{h}(\beta)=\mathbf{k}(e)\}} \delta_\beta v_\beta u_\beta(\ell_\beta, t)}{\sum_{\{\beta:\mathbf{h}(\beta)=\mathbf{k}(e)\}} \delta_\beta v_\beta} \tag{2.12}$$

once we note that (2.7) at $\mathbf{k}(e)$ is $\delta_e v_e = \delta_{\beta_1} v_{\beta_1} + \delta_{\beta_2} v_{\beta_2}$. We have just shown that (2.12) is valid for edges e for which its tail $\mathbf{k}(e)$ is the head of two other edges. We next show that, in fact, (2.12) is valid for all edges e. To that end, assume now that $\mathbf{k}(e)$ is the head of only one edge, say β. In other words, fluid flows into $\mathbf{k}(e)$ from only channel β. Thus, the concentration of solute going into e should be equal to the concentration of solute entering $\mathbf{k}(e)$ from β, i.e., $u_e(0,t) = u_\beta(\ell_\beta, t)$. This condition is, in fact, (2.12) in this case, i.e., when $\mathbf{k}(e)$ is the head of only one edge.

The system (2.11)–(2.12) uniquely determines the time evolution of the solute concentration within the channels once initial conditions and appropriate boundary conditions are given. We mention that the system (2.11)–(2.12) is not ad hoc; it is the asymptotic limit of the convection-diffusion equation for the transport of solute within the network in the parameter regime in which we work (i.e., (2.9) and (2.2)).

3. Macroscopic transport equation. We say that two edges are equivalent if one is the translation of the other by a vector of the form $n\mathbf{w} + m\mathbf{q}$, where $\mathbf{w}$ and $\mathbf{q}$ are the vectors that determine the periodicity of the microstructure (see (2.4)) and n and m are integers. Thus, two edges e_1 and e_2 are equivalent if there exist n and m integers such that $\mathbf{h}(e_2) = \mathbf{h}(e_1) + n\mathbf{w} + m\mathbf{q}$ and $\mathbf{k}(e_2) = \mathbf{k}(e_1) + n\mathbf{w} + m\mathbf{q}$ (we recall that $\mathbf{h}(e)$ denotes the head of the edge e and $\mathbf{k}(e)$ denotes its tail). This defines an equivalence relation in the set of edges. Note that the widths, lengths, and velocities of equivalent edges are equal, i.e., $\delta_{e_1} = \delta_{e_2}$, $\ell_{e_1} = \ell_{e_2}$, and $\mathbf{v}_{e_1} = \mathbf{v}_{e_2}$ if e_1 and e_2 are equivalent. In what follows we will take spatial average of quantities. Thus, we need to be able to select exactly one edge per equivalence class. We denote by $\mathcal{F}$ a set of edges that contains exactly one edge per equivalent class. For example, $\mathcal{F}$ could be all the edges whose heads are in the period cell

$$Q = \{s\mathbf{w} + r\mathbf{q} : 0 \leq s, r < 1\} \tag{3.1}$$

at a certain time.

We first observe that the area occupied by fluid within the period cell Q (i.e., the area of $\Omega_p \cap Q$) is

$$|\Omega_p \cap Q| = \sum_{e\in\mathcal{F}} \delta_e \ell_e. \tag{3.2}$$

We denote by $\mathbf{V}$ the spatial average fluid velocity, i.e.,

$$\mathbf{V} = \frac{\sum_{e\in\mathcal{F}} \delta_e \ell_e \mathbf{v}_e}{\sum_{e\in\mathcal{F}} \delta_e \ell_e} = \frac{\sum_{e\in\mathcal{F}} \delta_e \ell_e \mathbf{v}_e}{|\Omega_p \cap Q|}. \tag{3.3}$$

Note that assumption (2.9) implies that $\|\mathbf{V}\| = O(v)$. Assume that t_0, the period of the applied pressure gradient $\mathbf{G}$, satisfies

$$t_0 \gg \frac{\ell}{v} \qquad \text{(more precisely } t_0 \gg \max \ell_e/v_e \text{ most of the time);} \tag{3.4}$$

i.e., the time required for solute concentration to be convected across a channel is much smaller than the period of the applied pressure gradient. In Appendix A we show that, *macroscopically*, the solute concentration is convected with the average fluid velocity $\mathbf{V}$ and dispersed with dispersion tensor

$$D_{ij}^{\text{eff}} = \frac{1}{t_0} \int_0^{t_0} D_{ij}^\star(t) \mathrm{d}t, \tag{3.5}$$

where

$$D_{ij}^\star = \frac{1}{2|\Omega_p \cap Q|} \left\{ \sum_{e\in\mathcal{F}} \delta_e \ell_e \left(\frac{\ell_e}{v_e} \left[\mathbf{v}_e - \mathbf{V}\right]_i \left[\mathbf{v}_e - \mathbf{V}\right]_j \right.\right.$$
$$\left.\left. + \left[\mathbf{V} - \mathbf{v}_e\right]_i \left[\mathbf{f}_{\mathbf{k}(e)}\right]_j + \left[\mathbf{V} - \mathbf{v}_e\right]_j \left[\mathbf{f}_{\mathbf{k}(e)}\right]_i \right) \right\}, \tag{3.6}$$

$[\mathbf{y}]_i$ denotes the ith component of the vector $\mathbf{y}$, and the family of vectors $(\mathbf{f_a})_{\mathbf{a}\in\mathcal{N}}$ is a solution periodic in space and time (i.e., $\mathbf{f_a}(t) = \mathbf{f}_{\mathbf{a}+n\mathbf{w}+m\mathbf{q}}(t + pt_0)$ for all integers n, m, and p) of the following system:

$$\sum_{\{e:\mathbf{h}(e)=\mathbf{a}\}} \delta_e v_e (\mathbf{f}_{\mathbf{k}(e)} - \mathbf{f_a}) = \sum_{\{e:\mathbf{h}(e)=\mathbf{a}\}} \delta_e \ell_e \left(\mathbf{v}_e - \mathbf{V}\right) \text{ for all } \mathbf{a} \in \mathcal{N}. \tag{3.7}$$

More precisely, for each $\mathbf{a} \in \mathcal{N}$, let $u_{\mathbf{a}}(t)$ be the solute concentration that leaves the intersection $\mathbf{a}$ at time t, i.e.,

$$u_{\mathbf{a}}(t) = u_e(0,t) \text{ if } \mathbf{a} = \mathbf{k}(e) \text{ at time } t. \tag{3.8}$$

Note that $u_{\mathbf{a}}(t)$ is well defined because $u_{e_1}(0,t) = u_{e_2}(0,t)$ if e_1 and e_2 are two edges that have the same tail at time t, i.e., $\mathbf{k}(e_1) = \mathbf{k}(e_2)$. In Appendix A we show that

$$u_{\mathbf{a}}(t) \simeq u\left(\mathbf{a},t\right) \text{ for } t = O\left(t_0^2 \frac{v}{\ell}\right), \tag{3.9}$$

where $u(\mathbf{x},t)$ satisfies

$$\frac{\partial u}{\partial t} + \mathbf{V} \cdot \nabla u = \sum_{i,j} D_{ij}^{\text{eff}} \frac{\partial^2 u}{\partial x_i \partial x_j}, \tag{3.10}$$

where ∇u is the gradient of u with respect to $\mathbf{x}$ and u is subjected to appropriate boundary and initial conditions that depend on the particular problem under consideration. We note that $\mathbf{D}^{\text{eff}}$ is usually referred to as the dispersion tensor.

4. Examples and observations.

4.1. Constant applied pressure gradient. As a first general example, we consider the case when the applied pressure gradient $\mathbf{G}$ is time independent. In this case, the system for the pressure at the nodes (2.5) and (2.8) is time independent and so are the velocities within the channels (see (2.6)). The spatially periodic family of vectors $(\mathbf{f_a})_{\mathbf{a}\in\mathcal{N}}$, solution of system (3.7), is also time independent, and the expression for the dispersion tensor simplifies to

$$\begin{aligned} D_{ij}^{\text{eff}} = D_{ij}^{\star} = \frac{1}{2\sum_{e\in\mathcal{F}} \delta_e \ell_e} \sum_{e\in\mathcal{F}} \delta_e \ell_e \Bigg(& \frac{\ell_e}{v_e} \left[\mathbf{v}_e - \mathbf{V}\right]_i \left[\mathbf{v}_e - \mathbf{V}\right]_j \\ & + \left[\mathbf{V} - \mathbf{V}_e\right]_i \left[\mathbf{f}_{\mathbf{k}(e)}\right]_j + \left[\mathbf{V} - \mathbf{v}_e\right]_j \left[\mathbf{f}_{\mathbf{k}(e)}\right]_i \Bigg). \end{aligned} \tag{4.1}$$

4.2. Applied pressure gradient of the form $\mathbf{G}(t) = g(t)\mathbf{E}$ with $\mathbf{E}$ constant. As a second general example, we consider the case when the applied pressure gradient $\mathbf{G}$ is of the form $\mathbf{G}(t) = g(t)\mathbf{E}$ with $\mathbf{E}$ constant and $g(t)$ a real valued periodic function with period t_0. The evaluation of the dispersion tensor is also simple in this case. Let $\mathbf{D}_{\mathbf{E}}^{\text{eff}}$ be the dispersion tensor that corresponds to the applied pressure gradient $\mathbf{E}$. Then, the dispersion tensor that corresponds to the applied pressure gradient $\mathbf{G}(t) = g(t)\mathbf{E}$ is

$$\mathbf{D}^{\text{eff}} = \mathbf{D}_{\mathbf{E}}^{\text{eff}} \frac{1}{t_0} \int_0^{t_0} |g(t)| \mathrm{d}t. \tag{4.2}$$

The validity of the above equation results from simple calculation. Briefly, we first note that, if $\mathbf{v}_e^{\mathbf{E}}$ are the velocities within the channels when the applied pressure gradient is $\mathbf{E}$, then $\mathbf{v}_e = g(t)\mathbf{v}_e^{\mathbf{E}}$ are the velocities within the channels when the applied pressure gradient is $g(t)\mathbf{E}$. As a consequence, if the vectors $\mathbf{f}_a^{\mathbf{E}}$ solve system (3.7) when the applied pressure gradient is $\mathbf{E}$, then $\mathbf{f}_a = g(t)\mathbf{f}_a^{\mathbf{E}}$ is a solution of system (3.7) when the applied pressure gradient is $g(t)\mathbf{E}$. Thus, if $\mathbf{D}_{\mathbf{E}}^{\star}$ is the tensor of (3.6) when the applied pressure gradient is $\mathbf{E}$, then $\mathbf{D}^{\star} = |g(t)|\mathbf{D}_{\mathbf{E}}^{\star}$ is the tensor of (3.6) when the applied pressure gradient is $g(t)\mathbf{E}$. Note that $\mathbf{D}_{\mathbf{E}}^{\star}$ is time independent, and thus $\mathbf{D}_{\mathbf{E}}^{\text{eff}} = \mathbf{D}_{\mathbf{E}}^{\star}$ (see (3.6)). Finally, (4.2) results from (3.6).

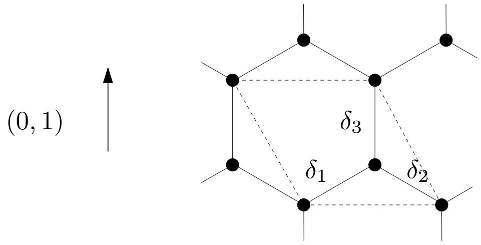

FIG. 4.1. *Graph corresponding to the microgeometry of our example. The period cell is enclosed by dashed lines. The widths of the channels are δ_1, δ_2, and δ_3.*

4.3. A concrete example. The graph that corresponds to the microgeometry of our example is shown in Figure 4.1. All the channels have the same length ℓ and form regular hexagons. The period cell is enclosed by dashed lines. The width of the channels in the period cell are, as displayed in the figure, δ_1, δ_2, and δ_3. We assume the applied pressure gradient to be of the form

$$\mathbf{G}(\mathbf{t}) = \left(0, \frac{g(t)}{\ell}\right), \tag{4.3}$$

where g is a periodic function with period t_0 and $(0,1)$ is the unit vector that points in the vertical direction (see Figure 4.1). Some algebra shows that, in this example, the use of our method leads to

$$\mathbf{V}_2(t) = -\frac{3}{16\mu\ell}\frac{\delta_3^3(\delta_1^3+\delta_2^3)}{(\delta_1^3+\delta_2^3+\delta_3^3)(\delta_1+\delta_2+\delta_3)}g(t) \tag{4.4}$$

and

$$\mathbf{D}_{22}^{\text{eff}} = \frac{9}{64\mu}\frac{\delta_3^3(\delta_1^3+\delta_2^3)(\delta_1+\delta_2)^2(\delta_1-\delta_2)^2}{\delta_1\delta_2(\delta_1^3+\delta_2^3+\delta_3^3)(\delta_1+\delta_2+\delta_3)^3}\frac{1}{t_0}\int_0^{t_0}|g(t)|\mathrm{d}t. \tag{4.5}$$

To discuss the above formulas in a more concrete context, assume that the material occupies the region $x_2 > 0$. Also assume that the material is attached to a reservoir of solute located at $x_2 < 0$ and that initially there is no solute within the material (for $x_2 > 0$). Due to symmetry, the solute concentration u, solution of (3.10), in this example depends only on x_2. Thus, we need only $\mathbf{V}_2$ and $\mathbf{D}_{22}^{\text{eff}}$, which are given by (4.4) and (4.5), respectively.

As a first observation, note that $\mathbf{D}_{22}^{\text{eff}} = 0$ if $\delta_1 = \delta_2$. Thus, after each period, solute is convected a distance $\int_0^{t_0}\mathbf{V}(t)\,\mathrm{d}t$ but is not dispersed in our asymptotic limit; there is a smaller order effective dispersion that results from an effect known as Taylor dispersion inside the channels [63, 3]. Note that this is in accordance with the physical effect described in the introduction as shown in Figure 1.1(e). The mixing of solute with the host liquid occurs when solute from two different channels and at different concentrations flows into the same intersection (in Figure 1.1(e) one of the channels had zero solute concentration). Due to symmetry in our example when $\delta_1 = \delta_2$, whenever solute from two channels flows into the same intersection, the concentration in both channels is the same. This is illustrated in Figure 4.2(a), where we show that solute reaches the upper ends of all the channels attached to the reservoir at the same time if $\delta_1 = \delta_2$.

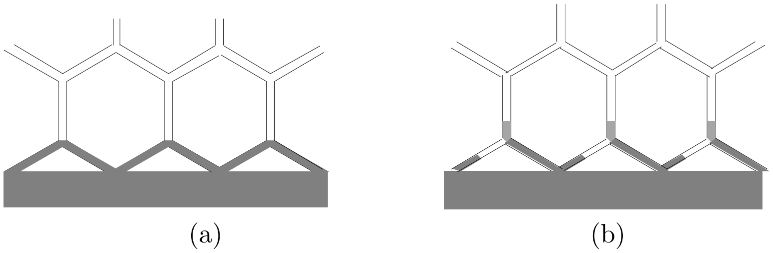

Fig. 4.2. *Microgeometry that corresponds to the graph of Figure* 4.1. *In* (a), $\delta_1 = \delta_2$. *In* (b), $\delta_1 < \delta_2$. *The shaded areas represent the solute concentration. The darker the shade, the larger the solute concentration.*

On the other hand, in Figure 4.2(b) we display an example where $\delta_1 < \delta_2$. As illustrated in that figure, the time required for solute from the reservoir to travel through the thinner channels is longer than the travel time through the thicker channels. Thus, the effect illustrated in Figure 1.1(e) does occur and, as (4.5) implies, we have that $D^{\text{eff}}_{22} \neq 0$. Note in particular that, in the case $\int_0^{t_0} g(t)\,\mathrm{d}t = 0$, there is no convection after a complete period. Thus, there will be much more transport of solute in our second example, where $D^{\text{eff}}_{22} \neq 0$, than in the example of the previous paragraph, where $D^{\text{eff}}_{22} = 0$.

At first glance, (4.5) seems to lead to the following contradiction. On one hand, (4.5) shows that $D^{\text{eff}}_{22} \to \infty$ as $\delta_1 \to 0$ while keeping δ_2 and δ_3 fixed. However, $\delta_1 = 0$ means not having the channels with width δ_1, and thus not having intersection of three channels. According to our discussions, we would expect $D^{\text{eff}}_{22} = 0$ in this case. This apparent contradiction is resolved by (3.4) and (3.9) which state that (4.5) is valid for $t = O(t_0^2 v/\ell)$ and $t_0 \gg \ell/v_1$, and thus we need $t \gg \ell/v_1$. Finally, we note that, since $v_1 \to 0$ as $\delta_1 \to 0$, this is a singular limit, which resolves this apparent contradiction. In other words, the smaller δ_1, the longer we have to wait for dispersion to occur and for our asymptotics to be valid. As $\delta_1 \to 0$, we would have to wait an infinitely long time.

5. Discussion. As mentioned in the introduction, there are several methods for studying solute transport in porous media. For their computational efficiency and their flexibility in modeling microstructures, methods that compute the macroscopic properties with the use of periodic networks are very useful. So far, this class of methods is essentially limited to [1] and its generalizations [2, 29]. Moreover, as mentioned in the introduction, the models in [1, 2, 29] use ad hoc rules that prevent them from accurately modeling the physical effect that motivated the present work, i.e., that of Figure 1.1(e).

Thus, while a large body of work exists in solute transport in porous media, the work introduced here is new and, we believe, will prove powerful in providing new understanding of the dependence of solute transport on the microgeometry. The strengths of our method include the following: (1) This method is exact to first order, i.e., has a small error. More precisely, it is the asymptotic limit of the well-established Navier–Stokes system for fluid flow and the convection-diffusion equation for solute transport (there are no ad hoc rules imposed). (2) The asymptotic limit used results from considering the simple but, we believe, fundamental effect of Figure 1.1(e). While this local effect has been identified and appears in standard texts on porous media [30], its global consequence (i.e., the combined effect of this phenomenon at all intersections) has not been well studied. This method is an ideal tool for those studies. (3) This method is relatively computationally inexpensive, essentially solving a linear system whose number of variables is equal to two times the number of nodes in a period cell. We mention that the extension of our method to three dimension is immediate.

Appendix A. Asymptotic approximation.

A.1. Dimensionless variables, parameters, and equations. We first define the small dimensionless parameter ε as

$$\varepsilon = \frac{\ell}{vt_0} \ll 1 \tag{A.1}$$

for each edge e, the dimensionless parameters as

$$\bar{\ell}_e = \frac{\ell_e}{\ell} \text{ and } \bar{\delta}_e = \frac{\delta_e}{\delta}, \tag{A.2}$$

the dimensionless velocities and their norms as

$$\bar{\mathbf{v}}_e = \frac{\mathbf{v}_e}{v} \text{ and } \bar{v}_e = \|\bar{\mathbf{v}}_e\|, \tag{A.3}$$

and the dimensionless average velocity as

$$\bar{\mathbf{V}} = \frac{\mathbf{V}}{v}. \tag{A.4}$$

The velocities will be periodic with the same period t_0 as the applied pressure gradient. This motivates the choice of the dimensionless time

$$\bar{t} = \frac{t}{t_0}. \tag{A.5}$$

We regard the dimensionless velocities as 1-periodic functions of the dimensionless time; i.e., $\bar{\mathbf{v}}_e = \bar{\mathbf{v}}_e(\bar{t})$ and $\bar{\mathbf{V}} = \bar{\mathbf{V}}(\bar{t})$ are periodic with period 1.

Since the velocities are of order v, distances traveled by convection in periods of times of order t_0 are of order vt_0. This motivates the use of the following space dimensionless variable:

$$\bar{\mathbf{x}} = \frac{\mathbf{x}}{vt_0}. \tag{A.6}$$

Accordingly, the dimensionless nodes are the set

$$\bar{\mathcal{N}} = \frac{\mathcal{N}}{vt_0}, \tag{A.7}$$

the dimensionless head and tail of each edge e are

$$\bar{\mathbf{h}}(e) = \frac{\mathbf{h}(e)}{vt_0} \text{ and } \bar{\mathbf{k}}(e) = \frac{\mathbf{k}(e)}{vt_0}, \tag{A.8}$$

respectively, and the dimensionless vectors that determine the periodicity of the microstructure are

$$\bar{\mathbf{w}} = \frac{\mathbf{w}}{vt_0} \text{ and } \bar{\mathbf{q}} = \frac{\mathbf{q}}{vt_0}. \tag{A.9}$$

Thus, parametrizing the segment joining $\bar{\mathbf{k}}(e)$ and $\bar{\mathbf{h}}(e)$ by

$$\bar{\mathbf{x}}_e(\bar{s}) = \bar{\mathbf{k}}(e) + \bar{s}\frac{\bar{\mathbf{h}}(e) - \bar{\mathbf{k}}(e)}{\|\bar{\mathbf{h}}(e) - \bar{\mathbf{k}}(e)\|}, \tag{A.10}$$

we have that (2.11) becomes

$$\frac{\partial \bar{u}_e}{\partial \bar{t}} + \bar{v}_e \frac{\partial \bar{u}_e}{\partial \bar{s}} = 0 \text{ for } 0 \leq \bar{s} \leq \varepsilon \bar{\ell}_e,\ \bar{t} \geq 0, \text{ and all } e \in \mathcal{E}, \tag{A.11}$$

where $\bar{u}_e(\bar{s}, \bar{t})$ is the solute concentration in the channel e at the point $vt_0\bar{\mathbf{x}}_e(\bar{s})$ and time $t_0\bar{t}$. Note that $\bar{\mathbf{k}}(e) = \bar{\mathbf{x}}_e(0)$ and $\bar{\mathbf{h}}(e) = \bar{\mathbf{x}}_e(\varepsilon\bar{\ell}_e)$.

On the other hand, (2.12) becomes

$$\bar{u}_e(0, \bar{t}) = \frac{\sum_{\{\beta : \bar{\mathbf{h}}(\beta) = \bar{\mathbf{k}}(e)\}} \bar{\delta}_\beta \bar{v}_\beta \bar{u}_\beta(\varepsilon\bar{\ell}_\beta, \bar{t})}{\sum_{\{\beta : \bar{\mathbf{h}}(\beta) = \bar{\mathbf{k}}(e)\}} \bar{\delta}_\beta \bar{v}_\beta}. \tag{A.12}$$

A.2. Solute transport within each channel. Let e be an edge. Solute is convected from $\bar{\mathbf{k}}(e)$, the tail of e, to $\bar{\mathbf{h}}(e)$, the head of e. Thus, the solute concentration at $\bar{\mathbf{h}}(e)$ at time $\bar{t}$ is equal to the solute concentration at $\bar{\mathbf{k}}(e)$ at an earlier time $\bar{t} - \Delta\bar{t}_e$, i.e.,

$$\bar{u}_e(0, \bar{t} - \Delta\bar{t}_e) = \bar{u}_e(\varepsilon\bar{\ell}_e, \bar{t}). \tag{A.13}$$

We next compute $\Delta\bar{t}_e$.

Let $S(\tau)$ be the solution of

$$S'(\tau) = \bar{v}_e(\tau) \text{ and } S(\bar{t}) = \varepsilon\bar{\ell}_e, \tag{A.14}$$

where S' is the derivative of S. We claim that $\Delta\bar{t}_e$ is the solution of

$$S(\bar{t} - \Delta\bar{t}_e) = 0. \tag{A.15}$$

This is due to the fact that $\bar{u}_e(S(\tau), \tau)$ is independent of τ, and thus $\bar{u}_e(0, \bar{t} - \Delta\bar{t}_e) = \bar{u}_e(S(\bar{t} - \Delta\bar{t}_e), \bar{t} - \Delta\bar{t}_e) = \bar{u}_e(S(\bar{t}), \bar{t}) = \bar{u}_e(\varepsilon\bar{\ell}_e, \bar{t})$.

From (A.14) and (A.15), we note that $\Delta\bar{t}_e = O(\varepsilon)$. Thus, we Taylor expand (A.15) to get

$$0 = S(\bar{t} - \Delta\bar{t}_e) \simeq S(\bar{t}) - S'(\bar{t})\Delta\bar{t}_e + \frac{S''(\bar{t})}{2}(\Delta\bar{t}_e)^2. \tag{A.16}$$

Next we note that $S(\bar{t}) = \varepsilon\bar{\ell}_e$ and $S'(\bar{t}) = \bar{v}_e(\bar{t})$ (see (A.14)). Thus, $S''(\bar{t}) = \bar{v}_e'(\bar{t})$, and we conclude from (A.16) that

$$0 \simeq \varepsilon\bar{\ell}_e - \bar{v}_e(\bar{t})\Delta\bar{t}_e + \frac{\bar{v}_e'(\bar{t})}{2}(\Delta\bar{t}_e)^2. \tag{A.17}$$

We now set $\Delta\bar{t}_e = \varepsilon\Delta\bar{t}_1 + \varepsilon^2\Delta\bar{t}_2$, plug this expression into (A.17), collect powers of ε to obtain equations for $\Delta\bar{t}_1$ and $\Delta\bar{t}_2$, and finally get

$$\Delta\bar{t}_e \simeq \varepsilon\frac{\bar{\ell}_e}{\bar{v}_e} + \varepsilon^2\frac{\bar{\ell}_e^2}{2}\frac{\bar{v}_e'}{\bar{v}_e^3}, \tag{A.18}$$

where $\bar{v}_e$ and $\bar{v}_e'$ are evaluated at $\bar{t}$. Note that $\Delta\bar{t}_e$ is a function of $\bar{t}$.

A.3. Continuum approximation. Using (A.13), (A.12) becomes

$$\bar{u}_e(0,\bar{t}) = \frac{\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{k}}(e)\}} \bar{\delta}_\beta \bar{v}_\beta \bar{u}_\beta(0,\bar{t}-\Delta\bar{t}_\beta)}{\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{k}}(e)\}} \bar{\delta}_\beta \bar{v}_\beta}, \tag{A.19}$$

where $\Delta\bar{t}_\beta$ is given by (A.18).

For each dimensionless node $\bar{\mathbf{a}} \in \bar{\mathcal{N}}$, let $\bar{u}_{\bar{\mathbf{a}}}(\bar{t})$ be the solute concentration that leaves the intersection $\bar{\mathbf{a}}$, i.e.,

$$\bar{u}_{\bar{\mathbf{a}}}(\bar{t}) = \bar{u}_e(0,\bar{t}) \text{ if } \bar{\mathbf{a}} = \bar{\mathbf{k}}(e) \text{ at time } \bar{t}. \tag{A.20}$$

With the notation introduced in (A.20), (A.19) becomes

$$\bar{u}_{\bar{\mathbf{a}}}(\bar{t}) = \frac{\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}} \bar{\delta}_\beta \bar{v}_\beta \bar{u}_{\bar{\mathbf{k}}(\beta)}(\bar{t}-\Delta\bar{t}_\beta)}{\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}} \bar{\delta}_\beta \bar{v}_\beta}. \tag{A.21}$$

A.3.1. Ansatz and expansions. We now use standard asymptotic techniques to obtain the macroscopic transport equation for the solute concentration. We propose the ansatz

$$\bar{u}_{\bar{\mathbf{a}}}(\bar{t}) = \rho(\bar{\mathbf{a}},\bar{t},\varepsilon\bar{t}) + \varepsilon f_{\hat{\mathbf{a}}}(\bar{\mathbf{a}},\bar{t},\varepsilon\bar{t}) + \varepsilon^2 g_{\hat{\mathbf{a}}}(\bar{\mathbf{a}},\bar{t},\varepsilon\bar{t}), \text{ where } \hat{\mathbf{a}} = \frac{\bar{\mathbf{a}}}{\varepsilon}, \tag{A.22}$$

$\rho(\bar{\mathbf{x}},\bar{t},\tau)$ is a smooth function of its variables periodic in $\bar{t}$ with period 1, and for each $\hat{\mathbf{a}} \in \bar{\mathcal{N}}/\varepsilon = \mathcal{N}/\ell$ the functions $f_{\hat{\mathbf{a}}}(\bar{\mathbf{x}},\bar{t},\tau)$ and $g_{\hat{\mathbf{a}}}(\bar{\mathbf{x}},\bar{t},\tau)$ are smooth functions of $\bar{\mathbf{x}}$, $\bar{t}$, and τ and are also periodic in $\bar{t}$ with period 1. The family of functions $f_{\hat{\mathbf{a}}}$ and $g_{\hat{\mathbf{a}}}$ are periodic in $\hat{\mathbf{a}}$ in the sense that $f_{\hat{\mathbf{a}}+(n\bar{\mathbf{w}}+m\bar{\mathbf{q}})/\varepsilon}(\bar{\mathbf{x}},\bar{t},\tau) = f_{\hat{\mathbf{a}}}(\bar{\mathbf{x}},\bar{t},\tau)$ and $g_{\hat{\mathbf{a}}+(n\bar{\mathbf{w}}+m\bar{\mathbf{q}})/\varepsilon}(\bar{\mathbf{x}},\bar{t},\tau) = g_{\hat{\mathbf{a}}}(\bar{\mathbf{x}},\bar{t},\tau)$ for all integers n and m and $\hat{\mathbf{a}} \in \bar{\mathcal{N}}/\varepsilon$.

Let $\bar{\mathbf{x}}$ be a point that we hold fixed for the moment. Let $\bar{\mathbf{a}}$ be a dimensionless node $\bar{\mathbf{a}} \in \bar{\mathcal{N}}$ such that $\|\bar{\mathbf{x}} - \bar{\mathbf{a}}\| = O(\varepsilon)$. We write

$$\bar{\mathbf{a}} = \bar{\mathbf{x}} + \varepsilon(\hat{\mathbf{a}} - \hat{\mathbf{x}}), \text{ where } \hat{\mathbf{a}} = \frac{\bar{\mathbf{a}}}{\varepsilon} \text{ and } \hat{\mathbf{x}} = \frac{\bar{\mathbf{x}}}{\varepsilon}. \tag{A.23}$$

We now plug this expression for $\bar{\mathbf{a}}$ into the right-hand side of (A.22) to get

$$\begin{aligned}\bar{u}_{\bar{\mathbf{a}}}(\bar{t}) = \rho(\bar{\mathbf{x}} + \varepsilon(\hat{\mathbf{a}} - \hat{\mathbf{x}}),\bar{t},\varepsilon\bar{t}) + \varepsilon f_{\hat{\mathbf{a}}}(\bar{\mathbf{x}} + \varepsilon(\hat{\mathbf{a}} - \hat{\mathbf{x}}),\bar{t},\varepsilon\bar{t})\\ +\varepsilon^2 g_{\hat{\mathbf{a}}}(\bar{\mathbf{x}} + \varepsilon(\hat{\mathbf{a}} - \hat{\mathbf{x}}),\bar{t},\varepsilon\bar{t}).\end{aligned} \tag{A.24}$$

We now Taylor expand the right-hand side of the above equality around the point $(\bar{\mathbf{x}},\bar{t},\varepsilon\bar{t})$ to get

$$\begin{aligned}\bar{u}_{\bar{\mathbf{a}}}(\bar{t}) \simeq \rho + \varepsilon\left\{\sum_i \frac{\partial\rho}{\partial\bar{x}_i}[\hat{\mathbf{a}} - \hat{\mathbf{x}}]_i + f_{\hat{\mathbf{a}}}\right\}\\ +\varepsilon^2\left\{\frac{1}{2}\sum_{i,j}\frac{\partial^2\rho}{\partial\bar{x}_i\partial\bar{x}_j}[\hat{\mathbf{a}} - \hat{\mathbf{x}}]_i[\hat{\mathbf{a}} - \hat{\mathbf{x}}]_j + \sum_i \frac{\partial f_{\hat{\mathbf{a}}}}{\partial\bar{x}_i}[\hat{\mathbf{a}} - \hat{\mathbf{x}}]_i + g_{\hat{\mathbf{a}}}\right\},\end{aligned} \tag{A.25}$$

where ρ, $f_{\hat{\mathbf{a}}}$, $g_{\hat{\mathbf{a}}}$ and their derivatives are evaluated at $(\bar{\mathbf{x}},\bar{t},\varepsilon\bar{t})$. In the above equation we neglected terms of order ε^3.

Now let β be an edge whose dimensionless head is $\bar{\mathbf{a}}$, i.e., $\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}$. Note that $\|\bar{\mathbf{k}}(\beta)-\bar{\mathbf{a}}\|=\varepsilon\bar{\ell}_\beta$. Thus, since $\|\bar{\mathbf{x}}-\bar{\mathbf{a}}\|=O(\varepsilon)$, we have $\|\bar{\mathbf{x}}-\bar{\mathbf{k}}(\beta)\|=O(\varepsilon)$. We write

$$\bar{\mathbf{k}}(\beta)=\bar{\mathbf{x}}+\varepsilon(\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}),\ \text{where } \hat{\mathbf{k}}(\beta)=\frac{\bar{\mathbf{k}}(\beta)}{\varepsilon} \text{ and } \hat{\mathbf{x}}=\frac{\bar{\mathbf{x}}}{\varepsilon}. \tag{A.26}$$

From (A.24), but replacing $\bar{\mathbf{a}}$ by $\bar{\mathbf{k}}(\beta)$ and $\bar{t}$ by $\bar{t}-\Delta\bar{t}_\beta$, we get

$$\begin{aligned}\bar{u}_{\bar{\mathbf{k}}(\beta)}(\bar{t}-\Delta\bar{t}_\beta)=&\rho(\bar{\mathbf{x}}+\varepsilon(\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}),\bar{t}-\Delta\bar{t}_\beta,\varepsilon\bar{t}-\varepsilon\Delta\bar{t}_\beta)\\ &+\varepsilon f_{\hat{\mathbf{k}}(\beta)}(\bar{\mathbf{x}}+\varepsilon(\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}),\bar{t}-\Delta\bar{t}_\beta,\varepsilon\bar{t}-\varepsilon\Delta\bar{t}_\beta)\\ &+\varepsilon^2 g_{\hat{\mathbf{k}}(\beta)}(\bar{\mathbf{x}}+\varepsilon(\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}),\bar{t}-\Delta\bar{t}_\beta,\varepsilon\bar{t}-\varepsilon\Delta\bar{t}_\beta).\end{aligned} \tag{A.27}$$

We now Taylor expand the right-hand side of the above equation around the point $(\bar{\mathbf{x}},\bar{t},\varepsilon\bar{t})$ and make use of the expression (A.18) (with e replaced by β) to get

$$\begin{aligned}\bar{u}_{\bar{\mathbf{k}}(\beta)}(\bar{t}-\Delta\bar{t}_\beta)\simeq\rho+\varepsilon\left\{\sum_i\frac{\partial\rho}{\partial\bar{x}_i}[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}]_i-\frac{\partial\rho}{\partial\bar{t}}\frac{\bar{\ell}_\beta}{\bar{v}_\beta}+f_{\hat{\mathbf{k}}(\beta)}\right\}\\ +\varepsilon^2\left\{\frac{1}{2}\sum_{i,j}\frac{\partial^2\rho}{\partial\bar{x}_i\partial\bar{x}_j}[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}]_i[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}]_j-\sum_i\frac{\partial^2\rho}{\partial\bar{t}\partial\bar{x}_i}[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}]_i\frac{\bar{\ell}_\beta}{\bar{v}_\beta}\right.\\ \left.+\frac{1}{2}\frac{\partial^2\rho}{\partial\bar{t}^2}\frac{\bar{\ell}_\beta^2}{\bar{v}_\beta^2}-\frac{\partial\rho}{\partial\bar{t}}\frac{\bar{\ell}_\beta^2}{2}\frac{\bar{v}'_\beta}{\bar{v}_\beta^3}-\frac{\partial\rho}{\partial\tau}\frac{\bar{\ell}_\beta}{\bar{v}_\beta}+\sum_i\frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial\bar{x}_i}[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}]_i-\frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial\bar{t}}\frac{\bar{\ell}_\beta}{\bar{v}_\beta}+g_{\hat{\mathbf{k}}(\beta)}\right\},\end{aligned} \tag{A.28}$$

where ρ, $f_{\hat{\mathbf{k}}(\beta)}$, $g_{\hat{\mathbf{k}}(\beta)}$ and their derivatives are evaluated in $(\bar{x},\bar{t},\varepsilon\bar{t})$, and $\bar{v}_\beta$ and its derivative are evaluated at $\bar{t}$. In the above equation we neglected terms of order ε^3.

Now we plug the expressions for $\bar{u}_{\hat{\mathbf{a}}}(\bar{t})$ and $\bar{u}_{\bar{\mathbf{k}}(\beta)}(\bar{t}-\Delta\bar{t}_\beta)$ given in (A.25) and (A.28) into (A.21), neglect terms of ε^2, and make simple algebraic manipulations (which include dividing by ε) to obtain

$$\sum_{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}}\bar{\delta}_\beta\bar{v}_\beta(f_{\hat{\mathbf{k}}(\beta)}-f_{\hat{\mathbf{a}}})=\left(\sum_{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}}\bar{\delta}_\beta\bar{\ell}_\beta\right)\frac{\partial\rho}{\partial\bar{t}}+\left(\sum_{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}}\bar{\delta}_\beta\bar{\ell}_\beta\bar{\mathbf{v}}_\beta\right)\cdot\bar{\nabla}\rho. \tag{A.29}$$

We require the above equation to be valid for all $(\bar{x},\bar{t},\tau)$, not just at $\tau=\varepsilon\bar{t}$.

A.3.2. Fredholm alternative. First equation for ρ. Convection with average velocity. We recall that two edges are equivalent if one is the translation of the other by a vector of the form $n\mathbf{w}+m\mathbf{q}$, where n and m are integers, and we denote by $\mathcal{F}$ a set of edges that contains exactly one edge per equivalent class (see section 3). Analogously, we also say that two dimensionless nodes $\bar{\mathbf{a}}$ and $\bar{\mathbf{b}}$ are equivalent if $\bar{\mathbf{b}}=\bar{\mathbf{a}}+n\bar{\mathbf{w}}+m\bar{\mathbf{q}}$ for some n and m integers, and we denote by $\bar{\mathcal{M}}$ a set of dimensionless nodes that contains exactly one dimensionless node per equivalent class. For example, $\bar{\mathcal{M}}$ could be all the dimensionless nodes included in the dimensionless period cell $\bar{Q}=\{s\bar{\mathbf{w}}+r\bar{\mathbf{q}}:0\le s,r<1\}$, i.e., $\bar{\mathcal{M}}=\bar{\mathcal{N}}\cap\bar{Q}$.

Let $y_{\hat{\mathbf{a}}}$ be defined for all $\hat{\mathbf{a}}\in\bar{\mathcal{N}}/\varepsilon$ and have the same periodicity as $f_{\hat{\mathbf{a}}}$, i.e., $y_{\hat{\mathbf{a}}+(n\bar{\mathbf{w}}+m\bar{\mathbf{q}})/\varepsilon}=y_{\hat{\mathbf{a}}}$ for all integers n and m and all $\hat{\mathbf{a}}\in\bar{\mathcal{N}}/\varepsilon$. Note that

$$\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}}y_{\hat{\mathbf{a}}}\sum_{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}}\bar{\delta}_\beta\bar{v}_\beta f_{\hat{\mathbf{k}}(\beta)}=\sum_{\beta\in\mathcal{F}}\bar{\delta}_\beta\bar{v}_\beta y_{\hat{\mathbf{h}}(\beta)}f_{\hat{\mathbf{k}}(\beta)}=\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}}f_{\hat{\mathbf{a}}}\sum_{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}}\bar{\delta}_\beta\bar{v}_\beta y_{\hat{\mathbf{h}}(\beta)}. \tag{A.30}$$

Thus,

$$\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}} y_{\hat{\mathbf{a}}} \sum_{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}} \bar{\delta}_\beta \bar{v}_\beta (f_{\hat{\mathbf{k}}(\beta)} - f_{\hat{\mathbf{a}}}) = \sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}} f_{\hat{\mathbf{a}}} \sum_{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}} \bar{\delta}_\beta \bar{v}_\beta (y_{\hat{\mathbf{h}}(\beta)} - y_{\hat{\mathbf{a}}}). \tag{A.31}$$

The above expression is equal to 0 for all periodic $f_{\hat{a}}$ if and only if

$$\sum_{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}} \bar{\delta}_\beta \bar{v}_\beta (y_{\hat{\mathbf{h}}(\beta)} - y_{\hat{\mathbf{a}}}) = 0 \text{ for all } \bar{\mathbf{a}} \in \bar{\mathcal{N}}. \tag{A.32}$$

A simple calculation shows that $y_{\hat{\mathbf{b}}} = y_{\hat{\mathbf{a}}}$ for all $\hat{\mathbf{a}}, \hat{\mathbf{b}} \in \bar{\mathcal{N}}/\varepsilon$ (if $\bar{v}_e \neq 0$ for all edges e. This is a generic condition that we assume is satisfied).

If we multiply the left-hand side of (A.29) by $y_{\hat{\mathbf{a}}}$ and add over all $\mathbf{a} \in \bar{\mathcal{M}}$, we obtain the expression in (A.31). Thus, the above discussion, the Fredholm alternative theory, and simple manipulations imply that there exists a solution $f_{\hat{\mathbf{a}}}$ (of (A.29)) that satisfies $f_{\hat{\mathbf{a}}+(n\bar{\mathbf{w}}+m\bar{\mathbf{z}})/\varepsilon} = f_{\hat{\mathbf{a}}}$ for all integers n and m if and only if

$$\frac{\partial \rho}{\partial \bar{t}} + \bar{\mathbf{V}} \cdot \bar{\nabla} \rho = 0, \tag{A.33}$$

where $\bar{\nabla}\rho$ is the gradient of ρ with respect to $\bar{\mathbf{x}}$.

A.3.3. Further expansions. Next we take derivatives of (A.33) with respect to $\bar{x}_i$ to obtain

$$\frac{\partial^2 \rho}{\partial \bar{t} \partial \bar{x}_i} = -\sum_j [\bar{\mathbf{V}}]_j \frac{\partial^2 \rho}{\partial \bar{x}_i \partial \bar{x}_j}. \tag{A.34}$$

Analogously, taking derivatives of (A.33) with respect to $\bar{t}$ and using (A.34), we obtain

$$\frac{\partial^2 \rho}{\partial \bar{t}^2} = -\sum_i [\bar{\mathbf{V}}']_i \frac{\partial \rho}{\partial \bar{x}_i} - \sum_i [\bar{\mathbf{V}}]_i \frac{\partial^2 \rho}{\partial \bar{x}_i \partial \bar{t}} = -\sum_i [\bar{\mathbf{V}}']_i \frac{\partial \rho}{\partial \bar{x}_i} + \sum_{i,j} [\bar{\mathbf{V}}]_i [\bar{\mathbf{V}}]_j \frac{\partial^2 \rho}{\partial \bar{x}_i \partial \bar{x}_j}. \tag{A.35}$$

Using the last three identities, (A.28) becomes

$$\begin{aligned} \bar{u}_{\bar{\mathbf{k}}(\beta)}(\bar{t} - \Delta \bar{t}_\beta) = \rho + \varepsilon \left\{ \sum_i \frac{\partial \rho}{\partial \bar{x}_i} \left[\hat{\mathbf{k}}(\beta) - \hat{\mathbf{x}} + \frac{\bar{\ell}_\beta}{\bar{v}_\beta} \bar{\mathbf{V}} \right]_i + f_{\hat{\mathbf{k}}(\beta)} \right\} \\ + \varepsilon^2 \left\{ \frac{1}{2} \sum_{i,j} \frac{\partial^2 \rho}{\partial \bar{x}_i \partial \bar{x}_j} \left[\hat{\mathbf{k}}(\beta) - \hat{\mathbf{x}} + \frac{\bar{\ell}_\beta}{\bar{v}_\beta} \bar{\mathbf{V}} \right]_i \left[\hat{\mathbf{k}}(\beta) - \hat{\mathbf{x}} + \frac{\bar{\ell}_\beta}{\bar{v}_\beta} \bar{\mathbf{V}} \right]_j \right. \\ \left. - \frac{1}{2} \frac{\bar{\ell}_\beta}{\bar{v}_\beta} \sum_i \left(\frac{\bar{\ell}_\beta}{\bar{v}_\beta} [\bar{\mathbf{V}}]_i \right)' \frac{\partial \rho}{\partial \bar{x}_i} - \frac{\partial \rho}{\partial \tau} \frac{\bar{\ell}_\beta}{\bar{v}_\beta} + \sum_i \frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial \bar{x}_i} [\hat{\mathbf{k}}(\beta) - \hat{\mathbf{x}}]_i - \frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial \bar{t}} \frac{\bar{\ell}_\beta}{\bar{v}_\beta} + g_{\hat{\mathbf{k}}(\beta)} \right\}. \end{aligned} \tag{A.36}$$

We now plug into (A.21) the expressions for $\bar{u}_{\hat{\mathbf{k}}(\beta)}(\bar{t} - \Delta \bar{t}_\beta)$ and $\bar{u}_a(\bar{t})$ given by (A.36) and (A.25), respectively, to obtain, after some algebraic manipulations and making use of (A.29), that

(A.37)
$$\left(\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\right)\frac{\partial\rho}{\partial\tau}+\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\left[\bar{\delta}_\beta\bar{v}_\beta\left(\bar{\nabla}f_{\hat{\mathbf{a}}}\cdot(\hat{\mathbf{a}}-\hat{\mathbf{x}})-\bar{\nabla}f_{\hat{\mathbf{k}}(\beta)}\cdot\left(\hat{\mathbf{k}}(\beta)-\hat{\mathbf{x}}\right)\right)\right.$$
$$\left.+\frac{\bar{\delta}_\beta}{2}\bar{\ell}_\beta^2\left(\frac{\bar{\mathbf{V}}}{\bar{v}_\beta}\right)'\cdot\bar{\nabla}\rho+\bar{\delta}_\beta\bar{\ell}_\beta\frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial\bar{t}}\right]$$
$$=\frac{1}{2}\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{v}_\beta\sum_{i,j}\frac{\partial^2\rho}{\partial\bar{x}_i\partial\bar{x}_j}\left(\left[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{a}}+\frac{\bar{\ell}_\beta}{\bar{v}_\beta}\bar{\mathbf{V}}\right]_i\left[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{a}}+\frac{\bar{\ell}_\beta}{\bar{v}_\beta}\bar{\mathbf{V}}\right]_j\right.$$
$$\left.2+[\hat{\mathbf{a}}-\hat{\mathbf{x}}]_i\left[\hat{\mathbf{k}}(\beta)-\hat{\mathbf{a}}+\frac{\bar{\ell}_\beta}{\bar{v}_\beta}\bar{\mathbf{V}}\right]_j\right)+\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{v}_\beta\left(g_{\hat{\mathbf{k}}(\beta)}-g_{\hat{\mathbf{a}}}\right).$$

Taking the gradient of (A.29), taking the dot product of the result with $(\hat{\mathbf{a}}-\hat{\mathbf{x}})$, making use of previous equations, performing some algebraic manipulations, and noting that $\bar{v}_\beta(\hat{\mathbf{a}}-\hat{\mathbf{k}}(\beta))=\bar{\ell}_\beta\bar{\mathbf{v}}_\beta$, (A.37) can be reduced to

(A.38)
$$\left(\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\right)\frac{\partial\rho}{\partial\tau}+\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\left[\bar{\nabla}f_{\hat{\mathbf{k}}(\beta)}\cdot\bar{\mathbf{v}}_\beta+\frac{\bar{\ell}_\beta}{2}\left(\frac{\bar{\mathbf{V}}}{\bar{v}_\beta}\right)'\cdot\bar{\nabla}\rho+\frac{\partial f_{\hat{\mathbf{k}}(\beta)}}{\partial\bar{t}}\right]$$
$$=\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{v}_\beta\left(g_{\hat{\mathbf{k}}(\beta)}-g_{\hat{\mathbf{a}}}\right)+\frac{1}{2}\sum_{i,j}\frac{\partial^2\rho}{\partial\bar{x}_i\partial\bar{x}_j}\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\frac{\bar{\delta}_\beta\bar{\ell}_\beta^2}{\bar{v}_\beta}\left[\bar{\mathbf{v}}_\beta-\bar{\mathbf{V}}\right]_i\left[\bar{\mathbf{v}}_\beta-\bar{\mathbf{V}}\right]_j.$$

A.4. Fredholm alternative. Long time equation for ρ. Dispersion tensor. Following the same arguments to obtain (A.33), we have that there exists a solution $g_{\hat{\mathbf{a}}}$ of (A.38) that is periodic in $\hat{\mathbf{a}}$ if and only if

$$\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}}\left\{\left(\sum_{\{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\right)\frac{\partial f_{\hat{\mathbf{a}}}}{\partial\bar{t}}+\left(\sum_{\{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\bar{\mathbf{v}}_\beta\right)\cdot\bar{\nabla}f_{\hat{\mathbf{a}}}\right\}$$
$$\text{(A.39)}\quad+\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}}\left\{\left(\sum_{\{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\right)\frac{\partial\rho}{\partial\tau}+\left(\sum_{\{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}\}}\frac{\bar{\delta}_\beta}{2}\bar{\ell}_\beta^2\left(\frac{\bar{\mathbf{V}}}{\bar{v}_\beta}\right)'\right)\cdot\bar{\nabla}\rho\right\}$$
$$=\frac{1}{2}\sum_{i,j}\frac{\partial^2\rho}{\partial\bar{x}_i\partial\bar{x}_j}\sum_{\bar{\mathbf{a}}\in\bar{\mathcal{M}}}\sum_{\{\beta:\bar{\mathbf{k}}(\beta)=\bar{\mathbf{a}}\}}\frac{\bar{\delta}_\beta\bar{\ell}_\beta^2}{\bar{v}_\beta}\left[\bar{\mathbf{v}}_\beta-\bar{\mathbf{V}}\right]_i\left[\bar{\mathbf{v}}_\beta-\bar{\mathbf{V}}\right]_j.$$

Let $\mathbf{F}_{\hat{\mathbf{a}}}=\mathbf{F}_{\hat{\mathbf{a}}}(\bar{t})$ be a solution of

$$\text{(A.40)}\qquad\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{v}_\beta\left(\mathbf{F}_{\hat{\mathbf{k}}(\beta)}-\mathbf{F}_{\hat{\mathbf{a}}}\right)=\sum_{\{\beta:\bar{\mathbf{h}}(\beta)=\bar{\mathbf{a}}\}}\bar{\delta}_\beta\bar{\ell}_\beta\left(\bar{\mathbf{v}}_\beta-\bar{\mathbf{V}}\right)$$

that is periodic in $\bar{t}$ and $\hat{\mathbf{a}}$, i.e., $\mathbf{F}_{\hat{\mathbf{a}}+(n\bar{\mathbf{w}}+m\bar{\mathbf{q}})/\varepsilon}(\bar{t}+p)=\mathbf{F}_{\hat{\mathbf{a}}}(\bar{t})$ for all integers n,m,p. A simple calculation shows that $f_{\hat{\mathbf{a}}}$ is a periodic (in $\hat{\mathbf{a}}$ and $\bar{t}$) solution of (A.29) if and only if

$$\text{(A.41)}\qquad f_{\hat{\mathbf{a}}}(\bar{\mathbf{x}},\bar{t},\tau)=\mathbf{F}_{\hat{\mathbf{a}}}(\bar{t})\cdot\bar{\nabla}\rho(\bar{x},\bar{t},\tau)+\psi(\bar{x},\bar{t},\tau),$$

where ψ is an arbitrary function that is periodic on $\bar{t}$.

Note that $\{\beta : \bar{\mathbf{k}}(\beta) = \bar{\mathbf{a}} \text{ and } \bar{\mathbf{a}} \in \bar{\mathcal{M}}\}$ is a set that contains exactly one edge per equivalent class. Thus, the sums in equation (A.39) are spatial averages, i.e., $\sum_{\bar{\mathbf{a}} \in \bar{\mathcal{M}}} \sum_{\{\beta : \bar{\mathbf{k}}(\beta) = \bar{\mathbf{a}}\}} = \sum_{\beta \in \mathcal{F}}$, where we recall that $\mathcal{F}$ is any set of edges that contains exactly one edge per equivalent class. Using this observation, (A.41), and some simple algebraic manipulations, we transform (A.39) in

$$\begin{aligned}
&\left(\sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta\right) \left(\frac{\partial \rho}{\partial \tau} + \frac{\partial \psi}{\partial \bar{t}} + \bar{\mathbf{V}} \cdot \bar{\nabla} \psi\right) + \left(\sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta \mathbf{F}'_{\hat{\mathbf{k}}(\beta)} + \frac{\bar{\delta}_\beta}{2} \bar{\ell}_\beta^2 \left(\frac{\bar{\mathbf{V}}}{\bar{v}_\beta}\right)'\right) \cdot \bar{\nabla} \rho \\
&= \frac{1}{2} \sum_{i,j} \frac{\partial^2 \rho}{\partial \bar{x}_i \partial \bar{x}_j} \sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta \left(\frac{\bar{\ell}_\beta}{\bar{v}_\beta} \left[\bar{\mathbf{v}}_\beta - \bar{\mathbf{V}}\right]_i \left[\bar{\mathbf{v}}_\beta - \bar{\mathbf{V}}\right]_j + 2 \left[\mathbf{F}_{\hat{\mathbf{k}}(\beta)}\right]_i \left[\bar{\mathbf{V}} - \bar{\mathbf{v}}_\beta\right]_j\right).
\end{aligned} \tag{A.42}$$

We now make the change of variables

$$\bar{\mathbf{y}} = \bar{\mathbf{x}} - \int_0^{\bar{t}} \bar{\mathbf{V}}(s)\, \mathrm{d}s. \tag{A.43}$$

To avoid confusion, we denote ρ by $\bar{\rho}$ when the new independent variables $(\bar{\mathbf{y}}, \bar{t}, \tau)$ are used. In these new variables, (A.33) becomes $\partial \bar{\rho}/(\partial \bar{t}) = 0$, from which we get that $\bar{\rho}$ is a function that depends only on $\bar{\mathbf{y}}$ and τ, i.e., $\bar{\rho} = \bar{\rho}(\bar{\mathbf{y}}, \tau)$.

Analogously, $\bar{\psi}$ is simply ψ, but only when the new independent variables $(\bar{\mathbf{y}}, \bar{t}, \tau)$ are used. The changes that occur in (A.42) when the new variables are used are the following: (1) The term $\bar{\mathbf{V}} \cdot \bar{\nabla} \psi$ is removed; (2) derivatives with respect to $\bar{\mathbf{x}}$ are replaced by derivatives with respect to $\bar{\mathbf{y}}$; and (3) ρ is replaced by $\bar{\rho}$ and ψ by $\bar{\psi}$. After making this change of variables, we integrate the resulting equation (A.42) with respect to $\bar{t}$ over a period, from $\bar{t} = \bar{t}_0$ to $\bar{t} = \bar{t}_0 + 1$, and divide by $\sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta$ to obtain

$$\frac{\partial \bar{\rho}}{\partial \tau}(\bar{\mathbf{y}}, \tau) + \bar{\psi}(\bar{\mathbf{y}}, \bar{t}_0 + 1, \tau) - \bar{\psi}(\bar{\mathbf{y}}, \bar{t}_0, \tau) = \sum_{i,j} \bar{D}_{ij} \frac{\partial^2 \bar{\rho}}{\partial y_i \partial y_j}(\bar{\mathbf{y}}, \tau), \tag{A.44}$$

where

$$\begin{aligned}
\bar{D}_{ij} = \frac{1}{2 \sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta} \sum_{\beta \in \mathcal{F}} \bar{\delta}_\beta \bar{\ell}_\beta \int_0^1 &\left(\frac{\bar{\ell}_\beta}{\bar{v}_\beta} \left[\bar{\mathbf{v}}_\beta - \bar{\mathbf{V}}\right]_i \left[\bar{\mathbf{v}}_\beta - \bar{\mathbf{V}}\right]_j \right. \\
&\left. + \left[\mathbf{F}_{\hat{\mathbf{k}}(\beta)}\right]_i \left[\bar{\mathbf{V}} - \bar{\mathbf{v}}_\beta\right]_j + \left[\mathbf{F}_{\hat{\mathbf{k}}(\beta)}\right]_j \left[\bar{\mathbf{V}} - \bar{\mathbf{v}}_\beta\right]_i\right) \mathrm{d}\bar{t}.
\end{aligned} \tag{A.45}$$

Finally, the dependence of $\bar{\rho}$ in τ is obtained by requiring $\bar{\psi}$ to be bounded. Given (A.44), we note that this occurs only if

$$\frac{\partial \bar{\rho}}{\partial \tau}(y, \tau) = \sum_{i,j} \bar{D}_{ij} \frac{\partial^2 \bar{\rho}}{\partial y_i \partial y_j}(y, \tau). \tag{A.46}$$

The result stated in section 3 is obtain by going back to the original dimensional variables.

DIFFUSION OF PROTEIN RECEPTORS ON A CYLINDRICAL DENDRITIC MEMBRANE WITH PARTIALLY ABSORBING TRAPS[*]

PAUL C. BRESSLOFF[†], BERTON A. EARNSHAW[†], AND MICHAEL J. WARD[‡]

Abstract. We present a model of protein receptor trafficking within the membrane of a cylindrical dendrite containing small protrusions called spines. Spines are the locus of most excitatory synapses in the central nervous system and act as localized traps for receptors diffusing within the dendritic membrane. We treat the transverse intersection of a spine and dendrite as a spatially extended, partially absorbing boundary and use singular perturbation theory to analyze the steady-state distribution of receptors. We compare the singular perturbation solutions with numerical solutions of the full model and with solutions of a reduced one-dimensional model and find good agreement between them all. We also derive a system of Fokker–Planck equations from our model and use it to exactly solve a mean first passage time (MFPT) problem for a single receptor traveling a fixed axial distance along the dendrite. This is then used to calculate an effective diffusion coefficient for receptors when spines are uniformly distributed along the length of the cable and to show how a nonuniform distribution of spines gives rise to anomalous subdiffusion.

Key words. protein receptor trafficking, diffusion-trapping, matched asymptotics, singular perturbation theory

1. Introduction.

Neurons are amongst the largest and most complex cells in biology. Their intricate geometry presents many challenges for cell function, in particular with regard to the efficient delivery of newly synthesized proteins from the cell body or soma to distant locations on the axon or dendrites. The axon contains ion channels for action potential propagation and presynaptic active zones for neurotransmitter release, whereas each dendrite contains postsynaptic domains (or densities) where receptors that bind neurotransmitter tend to cluster. At most excitatory synapses in the brain, the postsynaptic density is located within a dendritic spine, which is a small, submicrometer membranous extrusion that protrudes from a dendrite. Typically spines have a bulbous head which is connected to the parent dendrite through a thin spine neck. Given that hundreds or thousands of synapses and their associated spines are distributed along the entire length of a dendrite, it follows that neurons must traffic receptors and other postsynaptic proteins over long distances (several 100μm) from the soma. This can occur by two distinct mechanisms: either by lateral diffusion in the plasma membrane [8, 26, 1, 7] or by motor-driven intracellular transport along microtubules followed by local insertion into the surface membrane (exocytosis) [17, 20, 29]. It is likely that both forms of transport occur in dendrites, depending on the type of receptor and the developmental stage of the organism.

Recently, we constructed a one-dimensional diffusion-trapping model for the surface transport of AMPA (α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid) receptors along a dendrite [6]. AMPA receptors respond to the neurotransmitter glutamate and mediate the majority of fast excitatory synaptic transmission in the central nervous system. Moreover, there is a large body of experimental evidence suggesting that the fast trafficking of AMPA receptors into and out of spines contributes to activity-dependent, long-lasting changes in synaptic strength [21, 22, 4, 8, 9, 16]. Single-particle tracking experiments suggest that surface AMPA receptors diffuse freely within the dendritic membrane until they encounter a spine [13, 26]. If a receptor flows into a spine, then it is temporarily confined by the geometry of the spine and through interactions with scaffolding proteins and cytoskeletal elements [4, 8]. A surface receptor may also be internalized via endocytosis and stored within an intracellular pool, where it is either recycled to the surface via exocytosis or degraded [11]. Motivated by these experimental observations, we modeled the surface transport of receptors along a dendrite as a process of diffusion in the presence of spatially localized, partially absorbing traps [6]. One of the major simplifications of our model was to reduce the cylindrical like surface of a dendrite to a one-dimensional domain by neglecting variations in receptor concentration around the circumference of the cable relative to those along the cable. We also neglected the spatial extent of each spine by treating it as a homogeneous compartment that acts as a point-like source/sink for receptors on the dendrite. This was motivated by the observation that the spine neck, which forms the junction between a synapse and its parent dendrite, varies in radius from 0.02–0.2μm [23]. This is typically an order of magnitude smaller than the spacing between neighboring spines and the radius of the dendritic cable (around 1μm). In the one-dimensional case, the introduction of point-like spines does not lead to any singularities since the associated one-dimensional Green's function for diffusion is a pointwise bounded function. We were thus able to calculate explicitly the steady-state distribution of receptors along the dendrite and spines, as well as to determine the mean first passage time (MFPT) for a receptor to reach a certain distance from the soma. This allowed us to investigate the efficacy of diffusive transport as a function of various biophysical parameters such as surface diffusivity and the rates of exo/endocytosis within each spine.

In this paper we extend our diffusion-trapping model to the more realistic case of a two-dimensional cylindrical surface. However, since the two-dimensional Green's function has logarithmic singularities, we can no longer neglect the spatial extent of a spine. Therefore, we proceed by solving the steady-state diffusion equation on a finite cylindrical surface containing a set of small, partially absorbing holes, which represent the transverse intersections of the spines with the dendrite. The solution is constructed by matching appropriate "inner" and "outer" asymptotic expansions [27, 25, 28, 24]. This leads to a system of linear equations that determines the dendritic receptor concentration on the boundary between the dendrite and each spine. We numerically solve these equations and use this to construct the steady-state distribution of receptors along the dendrite. We compare our results with numerical solutions of the full model and with a reduced one-dimensional model.

A brief outline of this paper is as follows: In section 2 we formulate our diffusion-trapping model for receptor trafficking on the boundary of a cylindrical dendritic cable. In section 3 we construct the steady-state solution to this model using singular perturbation techniques in the limit of small spine radii. In section 4 we present some numerical experiments for realistic physiological parameter values that compare our asymptotic solution of section 3 with both full numerical solutions and with the solution of a one-dimensional approximation valid for a large aspect ratio dendritic cable. Finally, in section 5 we asymptotically calculate the MFPT for the diffusion of a single tagged receptor.

2. Diffusion-trapping model on a cylinder. Consider a population of N dendritic spines distributed along a cylindrical dendritic cable of length L and radius l as shown in Figure 2.1(A). Since protein receptors are much smaller than the length and circumference of the cylinder, we can neglect the extrinsic curvature of the membrane. Therefore, as shown in Figure 2.1(B), we represent the cylindrical surface of the dendrite as a long rectangular domain Ω_0 of width $2\pi l$ and length L so that

$$\Omega_0 \equiv \{(x,y) : 0 < x < L\,, |y| < \pi l\}.$$

The cylindrical topology is preserved by imposing periodic boundary conditions along the circumference of the cylinder, that is, at $y = \pm\pi l$. At one end of the cylinder $(x = 0)$ we impose a nonzero flux boundary condition, which represents a constant source of newly synthesized receptors from the soma, and at the other end $(x = L)$ we impose a no-flux boundary condition. Each spine neck is assumed to intersect the dendritic surface transversely such that the intersection is a circle of radius $\varepsilon\rho$ centered about the point $\mathbf{r}_j = (x_j, y_j) \in \Omega_0$, where $j = 1, \dots, N$ labels the jth spine. For simplicity, we take all spines to have the same radius. Since a dendrite is usually several hundred μm in length, we will assume the separation of length scales $\varepsilon\rho \ll 2\pi l \ll L$. We then fix the units of length by setting $\rho = 1$ such that $2\pi l = \mathcal{O}(1)$ and treat ε as a small dimensionless parameter. Finally, we denote the surface of the cylinder excluding the small discs arising from the spines by Ω_ε so that

$$\Omega_\varepsilon = \Omega_0 \setminus \bigcup_{j=1}^{N} \Omega_j, \quad \Omega_j = \{\mathbf{r} : |\mathbf{r} - \mathbf{r}_j| \le \varepsilon\}.$$

Let $U(\mathbf{r}, t)$ denote the concentration of surface receptors within the dendritic membrane at position $\mathbf{r} \in \Omega_\varepsilon$ at time $t \in \mathbf{R}_+$. As a result of the small area of each spine, we assume that the receptor concentrations within each spine are spatially homogeneous. We let $R_j(t)$ denote the concentration of surface receptors in the jth spine. The dendritic surface receptor concentration evolves according to the diffusion equation

$$\frac{\partial U}{\partial t} = D\nabla^2 U, \quad (\mathbf{r}, t) \in \Omega_\varepsilon \times \mathbf{R}_+ \tag{2.1}$$

for a homogeneous surface diffusivity D, with periodic boundary conditions at the ends $y = \pm\pi l$,

$$U(x, \pi l, t) = U(x, -\pi l, t), \quad \partial_y U(x, \pi l, t) = \partial_y U(x, -\pi l, t), \tag{2.2}$$

and nonzero or zero flux conditions at the ends $x = 0, L$,

$$\partial_x U(0, y, t) = -\sigma \equiv -\frac{\sigma_0}{2\pi l D}\,, \quad \partial_x U(L, y, t) = 0. \tag{2.3}$$

Here σ_0 denotes the number of receptors per unit time entering the surface of the cylinder from the soma. At each interior boundary $\partial\Omega_j$ we impose the mixed boundary condition

$$\varepsilon\partial_n U(\mathbf{r}, t) = -\frac{\omega_j}{2\pi D}(U(\mathbf{r}, t) - R_j), \quad \mathbf{r} \in \partial\Omega_j, \quad j = 1, \dots, N, \tag{2.4}$$

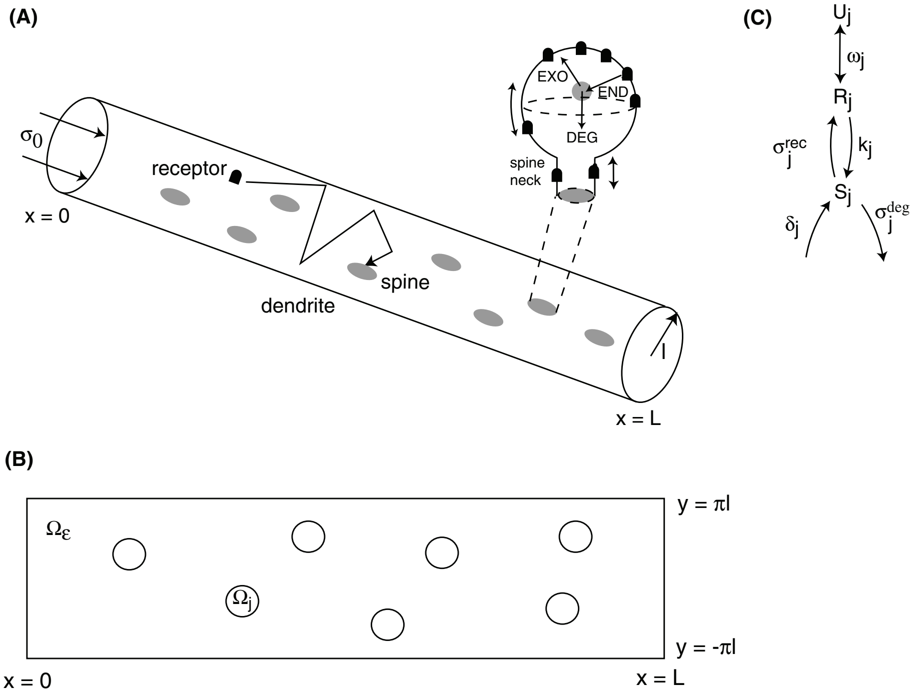

Fig. 2.1. *Diffusion-trapping model of receptor trafficking on a cylindrical dendritic cable (diagram not to scale).* (A) *A population of dendritic spines is distributed on the surface of a cylinder of length L and radius l. Each receptor diffuses freely until it encounters a spine where it may become trapped. Within a spine receptors may be internalized via endocytosis (END) and then either recycled to the surface via exocytosis (EXO) or degraded (DEG); see the inset. Synthesis of new receptors at the soma and insertion into the plasma membrane generates a surface flux σ_0 at one end of the cable.* (B) *Topologically equivalent rectangular domain with opposite sides $y = \pm\pi l$ identified.* (C) *State transition diagram for a simplified one-compartment model of a dendritic spine. Here R_j denotes the concentration of surface receptors inside the jth spine, U_j is the mean dendritic receptor concentration on the boundary between the spine neck and dendrite, and S_j is the number of receptors within the corresponding intracellular pool. Freely diffusing surface receptors can enter/exit the spine at a hopping rate ω_j, be endocytosed at a rate k_j, be exocytosed at a rate σ_j^{rec}, and be degraded at a rate σ_j^{deg}. New intracellular receptors are produced at a rate δ_j.*

where $\partial_n U$ is the outward normal derivative to Ω_ε. The flux of receptors across the boundary between the dendrite and jth spine is taken to depend on the difference in concentrations on either side of the boundary with ω_j an effective hopping rate. (This rate is determined by the detailed geometry of the spine [2].) It follows that the total number of receptors crossing the boundary per unit time is $\omega_j[U_j(t) - R_j(t)]$, where $U_j(t)$ is the mean dendritic receptor concentration on the boundary $\partial\Omega_j$ of the jth spine of length $2\pi\varepsilon$:

$$U_j = \frac{1}{2\pi\varepsilon}\int_{\partial\Omega_j} U(\mathbf{r}, t)\, d\mathbf{r}. \tag{2.5}$$

Surface receptors within the jth spine can be endocytosed at a rate k_j and stored in an intracellular pool. Intracellular receptors are either reinserted into the surface via exocytosis at a rate σ_j^{rec} or degraded at a rate σ_j^{deg}. We also allow for a local source of intracellular receptors with a production rate δ_j. Denoting the number of receptors in the jth intracellular pool by $S_j(t)$, we then have the pair of equations

$$\frac{dR_j}{dt} = \frac{\omega_j}{A_j}[U_j - R_j] - \frac{k_j}{A_j}R_j + \frac{\sigma_j^{rec}S_j}{A_j}\,, \tag{2.6}$$

$$\frac{dS_j}{dt} = -\sigma_j^{rec}S_j - \sigma_j^{deg}S_j + k_jR_j + \delta_j. \tag{2.7}$$

The first term on the right-hand side of (2.6) represents the exchange of surface receptors between the spine and parent dendrite. Since $\omega_j[U_j - R_j]$ is the number of receptors per unit time flowing across the junction between the dendritic cable and the spine, it is necessary to divide through by the surface area A_j of the spine in order to properly conserve receptor numbers. Note that in our previous one-dimensional model [6] we absorbed the factor of A_j into our definition of the rate of endocytosis k_j. (The precise variation of endocytic rate with spine area A_j will depend upon whether or not endocytosis is localized to certain hotspots within the spine [4].) The various processes described by (2.6) and (2.7) are summarized in Figure 2.1(C).

3. Steady-state analysis using asymptotic matching. In steady-state one can solve (2.6) and (2.7) for R_j in terms of the mean concentration U_j to get

$$R_j = \frac{\omega_jU_j}{\omega_j + k_j(1-\lambda_j)} + \frac{\lambda_j\delta_j}{\omega_j + k_j(1-\lambda_j)}, \tag{3.1}$$

where

$$\lambda_j \equiv \frac{\sigma_j^{rec}}{\sigma_j^{rec} + \sigma_j^{deg}}, \quad S_j = \frac{\lambda_j}{\sigma_j^{rec}}\left(k_jR_j + \delta_j\right). \tag{3.2}$$

Then U_j is determined from (2.5) and the steady-state version of (2.1):

$$\nabla^2 U = 0\,, \quad \mathbf{r} \in \Omega_\varepsilon, \tag{3.3}$$

with boundary conditions

$$U(x,\pi l) = U(x,-\pi l)\,, \quad \partial_y U(x,\pi l) = \partial_y U(x,-\pi l), \tag{3.4}$$

$$\partial_x U(0,y) = -\sigma, \quad \partial_x U(L,y) = 0, \tag{3.5}$$

where $\sigma = \sigma_0/(2\pi l D)$ from (2.3) and

$$\varepsilon\partial_n U(\mathbf{r}) = -\frac{\omega_j}{2\pi D}(U(\mathbf{r}) - R_j), \quad \mathbf{r} \in \partial\Omega_j\,, \quad j = 1,\ldots,N. \tag{3.6}$$

Since the radius of each spine is asymptotically small, we can make the simplification that $U(\mathbf{r}) = U_j$ on $\partial\Omega_j$. The substitution of (3.1) into (3.6) then yields the following reduced condition on the boundary of each spine:

$$\varepsilon\partial_n U(\mathbf{r}) = -\frac{\widehat{\omega}_j}{2\pi D}(U_j - \widehat{R}_j)\,, \quad \mathbf{r} \in \partial\Omega_j\,, \quad j = 1,\ldots,N, \tag{3.7}$$

where $\widehat{\omega}_j$ and $\widehat{R}_j$ are defined by

$$\widehat{\omega}_j \equiv \frac{\omega_j k_j(1-\lambda_j)}{\omega_j + k_j(1-\lambda_j)}\,, \qquad \widehat{R}_j \equiv \frac{\sigma_j^{rec}}{k_j}\frac{\delta_j}{\sigma_j^{deg}}. \tag{3.8}$$

Under steady-state conditions, one can view $\widehat{\omega}_j$ as an effective spine-neck hopping rate and $\widehat{R}_j$ as an effective receptor concentration within the spine.

Upon integrating the diffusion equation (3.3) over the domain Ω_ε and imposing the boundary conditions (3.4), (3.5), and (3.7), we obtain the solvability condition

$$\sigma_0 = \sum_{j=1}^{N} \widehat{\omega}_j \left[U_j - \widehat{R}_j\right]. \tag{3.9}$$

This expresses the condition that the rate at which receptors enter the dendrite from the soma is equal to the effective rate at which receptors exit the dendrite into spines and are degraded. Note that in the limit of negligible degradation of receptors in the intracellular pools so that $\sigma_j^{deg} \to 0$, it follows from (3.2) and (3.8) that $\lambda_j \to 1$, $\widehat{\omega}_j \to 0$, $\widehat{R}_j \to \infty$ with $\widehat{\omega}_j\widehat{R}_j \to -\delta_j$. Consequently, in the limit $\sigma_j^{deg} \to 0$, (3.9) reduces to $\sigma_0 \to -\sum_{j=1}\delta_j$, which has no solution for $\sigma_0 > 0$ and positive production rates $\delta_j > 0$. This shows that there is no steady-state solution when $\sigma_j^{deg} = 0$, as the number of receptors in the dendrite would grow without bound as time increases. A similar argument shows that there is also no steady-state solution in the limit of infinite spine-neck resistances such that $\omega_j \to 0$ for $j = 1, \ldots, N$. In this limit, newly synthesized receptors at the soma would not be able to diffuse from the dendrite to a spine and be degraded.

Our method of solution for the boundary value problem given by (3.3), (3.4), (3.5), and (3.7), which we denote by BVPI, proceeds in two steps. First, we solve a related problem, denoted by BVPII, in which the mixed boundary conditions (3.7) are replaced by the inhomogeneous Dirichlet conditions

$$U(\mathbf{r}) = U_j\,, \quad \mathbf{r} \in \partial\Omega_j, \quad j = 1, \ldots, N, \tag{3.10}$$

under the assumption that the U_j are known. In the singularly perturbed limit $\varepsilon \to 0$, the approximate solution for U valid away from each of the spines is shown below to be determined up to an arbitrary constant χ. Then, by substituting our asymptotic solution to BVPII into the N mixed boundary conditions (3.7) and upon satisfying the conservation equation (3.9), we obtain $N+1$ linear equations for the $N+1$ unknowns χ and $U_j, j = 1, \ldots, N$. This closed linear system of equations can be solved numerically to generate the full solution to the original boundary value problem BVPI. In order to solve BVPII asymptotically in the limit of small spine radii $\varepsilon \to 0$, we match appropriate "inner" and "outer" asymptotic expansions, following along similar lines to previous studies of boundary value problems in domains with small holes [27, 25, 28, 24].

3.1. Matching inner and outer solutions. Around each small circle $\partial\Omega_j$ we expect the solution of BVPII to develop a boundary layer where it changes rapidly from its value U_j on $\partial\Omega_j$ to another value that is required by the solution to the steady-state diffusion equation in the bulk of the domain. Therefore, Ω_ε may be decomposed into a set of $j = 1, \ldots, N$ "inner" regions, where $|\mathbf{r} - \mathbf{r}_j| = \mathcal{O}(\varepsilon)$, and an "outer" region, where $|\mathbf{r} - \mathbf{r}_j| \gg \mathcal{O}(\varepsilon)$ for all $j = 1, \ldots, N$. In the jth inner region, we introduce the stretched local variable $\mathbf{s} = \varepsilon^{-1}(\mathbf{r} - \mathbf{r}_j)$ and set $V(\mathbf{s};\varepsilon) = U(\mathbf{r}_j + \varepsilon\mathbf{s};\varepsilon)$ so that to leading order (omitting far-field boundary conditions)

$$\begin{aligned} \nabla_{\mathbf{s}}^2 V &= 0\,, \quad |\mathbf{s}| > 1, \\ V &= U_j\,, \quad |\mathbf{s}| = 1. \end{aligned} \tag{3.11}$$

This has an exact solution of the form $V = U_j + B_j \log|\mathbf{s}|$ with the unknown amplitude B_j determined by matching inner and outer solutions. This leads to an infinite logarithmic expansion of B_j in terms of the small parameter [27, 25, 28, 24]

$$\nu = -\frac{1}{\log(\varepsilon)}. \tag{3.12}$$

Since the outer solution is $\mathcal{O}(1)$ as $\nu \to 0$ and V grows logarithmically at infinity, we write $B_j = \nu A_j(\nu)$, where the function $A_j(\nu)$ is to be found. The inner solution becomes

$$V = U_j + \nu A_j(\nu) \log|\mathbf{s}|. \tag{3.13}$$

In terms of the outer variable $|\mathbf{r} - \mathbf{r}_j|$, we then obtain the following far-field behavior of the inner solution:

$$V \sim U_j + A_j(\nu) + \nu A_j(\nu) \log|\mathbf{r} - \mathbf{r}_j|. \tag{3.14}$$

This far-field behavior must then match with the near-field behavior of the asymptotic expansion of the solution in the outer region away from the N traps. The corresponding outer problem is given by

$$\nabla^2 U = 0, \quad \mathbf{r} \in \Omega_0 \backslash \{\mathbf{r}_1, \ldots, \mathbf{r}_N\}, \tag{3.15}$$

with boundary conditions

$$\begin{aligned} &U(x, \pi l) = U(x, -\pi l)\,, \quad \partial_y U(x, \pi l) = \partial_y U(x, -\pi l), \\ &\partial_x U(0, y) = -\sigma, \quad \partial_x U(L, y) = 0, \end{aligned}$$

together with the asymptotic singularity conditions

$$U \sim U_j + A_j(\nu) + \nu A_j(\nu) \log|\mathbf{r} - \mathbf{r}_j| \quad \text{as } \mathbf{r} \to \mathbf{r}_j\,, \quad j = 1, \ldots, N. \tag{3.16}$$

Equations (3.15) and (3.16) can be reformulated in terms of an outer problem with homogeneous boundary conditions and a constant forcing term by decomposing

$$U(\mathbf{r}) = \mathcal{U}(\mathbf{r}) + u(\mathbf{r})\,, \quad u(x, y) \equiv \frac{\sigma}{2L}(x - L)^2. \tag{3.17}$$

Then (3.15) becomes

$$\nabla^2 \mathcal{U} = -\frac{\sigma}{L}\,, \quad \mathbf{r} \in \Omega_0 \backslash \{\mathbf{r}_1, \ldots, \mathbf{r}_N\}\,, \tag{3.18}$$

with boundary conditions

$$\begin{aligned} &\mathcal{U}(x, \pi l) = \mathcal{U}(x, -\pi l)\,, \quad \partial_y \mathcal{U}(x, \pi l) = \partial_y \mathcal{U}(x, -\pi l), \\ &\partial_x \mathcal{U}(0, y) = 0, \quad \partial_x \mathcal{U}(L, y) = 0\,, \end{aligned}$$

and the asymptotic singularity conditions

$$\mathcal{U} \sim -u(\mathbf{r}_j) + U_j + A_j(\nu) + \nu A_j(\nu) \log|\mathbf{r} - \mathbf{r}_j| \quad \text{as } \mathbf{r} \to \mathbf{r}_j\,, \quad j = 1, \ldots, N. \tag{3.19}$$

In order to treat the logarithmic behavior of the outer solution at $\mathbf{r}_j$, we introduce the Neumann Green's function $G(\mathbf{r}; \mathbf{r}')$, defined as the unique solution to

$$\begin{gathered} \nabla^2 G = \frac{1}{|\Omega_0|} - \delta(\mathbf{r} - \mathbf{r}')\,, \quad \mathbf{r} \in \Omega_0\,, \\ G(x, \pi l; \mathbf{r}') = G(x, -\pi l; \mathbf{r}')\,, \quad \partial_y G(x, \pi l; \mathbf{r}') = \partial_y G(x, -\pi l; \mathbf{r}'), \\ \partial_x G(0, y; \mathbf{r}') = 0\,, \quad \partial_x G(L, y; \mathbf{r}') = 0\,, \\ \int_{\Omega_0} G(\mathbf{r}; \mathbf{r}')\, d\mathbf{r} = 0. \end{gathered} \tag{3.20}$$

Here $|\Omega_0| = 2\pi L l$ is the area of the rectangular domain Ω_0. This Green's function has a logarithmic singularity as $\mathbf{r} \to \mathbf{r}'$ so that we can decompose G as

$$G(\mathbf{r}; \mathbf{r}') = -\frac{1}{2\pi} \log|\mathbf{r} - \mathbf{r}'| + \mathcal{G}(\mathbf{r}; \mathbf{r}'), \tag{3.21}$$

where $\mathcal{G}$ is the regular part of G. We will calculate $\mathcal{G}$ explicitly in section 3.3. This property of G suggests that we replace (3.18) and (3.19) by the following single equation in Ω_0:

$$\nabla^2 \mathcal{U} = -\frac{\sigma}{L} + \sum_{j=1}^{N} 2\pi\nu A_j(\nu) \delta(\mathbf{r} - \mathbf{r}_j)\,, \quad \mathbf{r} \in \Omega_0. \tag{3.22}$$

Then, upon using the divergence theorem together with the homogeneous boundary conditions for $\mathcal{U}$, we obtain the solvability condition

$$\frac{\sigma}{L} |\Omega_0| = \sum_{j=1}^{N} 2\pi\nu A_j(\nu). \tag{3.23}$$

It readily follows that (3.22) has the solution

$$\mathcal{U}(\mathbf{r}) = -\sum_{j=1}^{N} 2\pi\nu A_j(\nu) G(\mathbf{r}; \mathbf{r}_j) + \chi, \tag{3.24}$$

where χ is a constant to be found. Since $\int_{\Omega_0} G\, d\mathbf{r} = 0$, it follows that χ can be interpreted as the spatial average of $\mathcal{U}$, defined by $\chi = |\Omega_0|^{-1} \int_{\Omega_0} \mathcal{U}\, d\mathbf{r}$. Then, as $\mathbf{r} \to \mathbf{r}_j$, the outer solution for $\mathcal{U}$ given in (3.24) has the near-field behavior

$$\mathcal{U} \sim -2\pi\nu A_j(\nu) \left[-\frac{1}{2\pi} \log|\mathbf{r} - \mathbf{r}_j| + \mathcal{G}(\mathbf{r}_j; \mathbf{r}_j) \right] - \sum_{i \neq j}^{N} 2\pi\nu A_i(\nu) G(\mathbf{r}_j; \mathbf{r}_i) + \chi \tag{3.25}$$

for each $j = 1, \ldots, N$. Upon comparing the nonsingular terms in this expression and that of (3.19), we obtain the following system of equations:

$$(1 + 2\pi\nu \mathcal{G}_{jj}) A_j + \sum_{i \neq j}^{N} 2\pi\nu G_{ji} A_i = u_j - U_j + \chi\,, \quad j = 1\,, \ldots, N\,, \tag{3.26}$$

where $u_j \equiv u(\mathbf{r}_j)$, $G_{ji} \equiv G(\mathbf{r}_j; \mathbf{r}_i)$, and $\mathcal{G}_{jj} \equiv \mathcal{G}(\mathbf{r}_j; \mathbf{r}_j)$.

3.2. Calculation of boundary concentrations U_j. Equations (3.13) and (3.24) are the inner and outer solutions of BVPII, respectively, where the $N+1$ coefficients χ and A_j for $j=1,\dots,N$ are determined from the N linear equations (3.26) together with the solvability condition (3.23). We can now generate the solution to the original problem BVPI by substituting the inner solution (3.13) into the mixed boundary conditions (3.7). This gives

$$2\pi\nu A_j(\nu) = \frac{\widehat{\omega}_j}{D}[U_j - \widehat{R}_j] \equiv V_j. \tag{3.27}$$

Substituting (3.27) into the solvability condition (3.23) shows that the latter is equivalent to the conservation equation (3.9). Furthermore, upon substituting (3.27) into (3.26) we obtain the system of linear equations

$$\left[(2\pi\nu)^{-1} + \mathcal{G}_{jj}\right]\frac{\widehat{\omega}_j}{D}[U_j - \widehat{R}_j] + \sum_{i\neq j}^{N} G_{ji}\frac{\widehat{\omega}_i}{D}[U_i - \widehat{R}_i] = u_j - U_j + \chi\,, \quad j=1,\dots,N. \tag{3.28}$$

This system, together with the conservation equation (3.9), gives $N+1$ equations for the $N+1$ unknowns χ and $U_j, j=1,\dots,N$. This system depends on the flux σ_0 of receptors from the soma, the number and the locations of the dendritic spines, and the aspect ratio of Ω_0. Upon solving this system for U_j and χ, the dendritic receptor concentration in the bulk of the dendritic membrane, obtained from (3.17), (3.24), and (3.27), is given by

$$U(\mathbf{r}) = u(\mathbf{r}) - \sum_{j=1}^{N}\frac{\widehat{\omega}_j}{D}[U_j - \widehat{R}_j]G(\mathbf{r};\mathbf{r}_j) + \chi. \tag{3.29}$$

This approximate solution for U is valid for distances larger than $\mathcal{O}(\varepsilon)$ away from the centers $\mathbf{r}_j$, for $j=1,\dots,N$, of the spines. Moreover, the distribution R_j of receptors within the spines is given in terms of U_j by (3.1).

There are two important remarks. First, we emphasize that the system (3.26) together with (3.23) contains all of the logarithmic correction terms in the asymptotic solution to BVPI. The error made in this approximation is transcendentally small of order $\mathcal{O}(\varepsilon)$, which is asymptotically smaller than any power of ν. A precise estimate of such transcendentally small terms for a related problem is given in Appendix A of [25]. Second, we remark that in [6] we have previously derived one-dimensional versions of (3.9), (3.28), and (3.29). In contrast to the two-dimensional case, the one-dimensional Neumann Green's function is nonsingular so that one can represent the spines as point sources/sinks on the dendrite, and singular perturbation theory is not needed.

It is convenient to introduce a matrix solution to (3.28). We first introduce the matrix $\mathbf{B}$ with elements

$$B_{jj} = 2\pi\left(\frac{D}{\widehat{\omega}_j} + \mathcal{G}_{jj}\right)\,, \quad B_{ji} = 2\pi G_{ji}\,,\ j\neq i. \tag{3.30}$$

Then (3.28) can be written in the compact form

$$\sum_{i=1}^{N}(\delta_{i,j} + \nu B_{ji})V_i = 2\pi\nu[u_j - \widehat{R}_j + \chi]\,,$$

where V_i is defined in (3.27). Defining $\mathbf{M} = (\mathbf{I} + \nu\mathbf{B})^{-1}$, where $\mathbf{I}$ is the $N \times N$ identity matrix, we have

$$V_j = 2\pi\nu \sum_{i=1}^{N} M_{ji}(u_i - \widehat{R}_i + \chi). \tag{3.31}$$

The constant χ is then determined by substituting (3.31) into the solvability condition (3.9). This yields

$$\frac{\sigma_0}{D} = \sum_{j=1}^{N} V_j = 2\pi\nu \sum_{i=1}^{N}\sum_{j=1}^{N} M_{ji}(u_i - \widehat{R}_i + \chi).$$

Upon solving this equation for χ we get

$$\chi = \frac{\frac{\sigma_0}{2\pi\nu D} - \sum_{i=1}^{N}\sum_{j=1}^{N} M_{ji}(u_i - \widehat{R}_i)}{\sum_{i=1}^{N}\sum_{j=1}^{N} M_{ji}}. \tag{3.32}$$

Since $M_{ji} = \delta_{i,j} + \mathcal{O}(\nu)$, it follows that to leading order in ν

$$\chi = \frac{\sigma_0}{2\pi N D\nu} + \mathcal{O}(1), \quad U_j = \widehat{R}_j + \frac{\sigma_0}{N\widehat{\omega}_j} + \mathcal{O}(\nu). \tag{3.33}$$

The singular nature of the constant χ as $\nu \to 0$, and hence the solution $U(\mathbf{r})$, reflects the fact that for fixed somatic flux σ_0, the flux in the neighborhood of each spine boundary $\partial\Omega_j$ diverges as $\varepsilon \to 0$. This is necessary in order to maintain the solvability condition (3.9). Note, in particular, that $\widehat{\omega}_j[U_j - \widehat{R}_j]$ gives the number of receptors flowing across the boundary per unit time, and its size essentially remains fixed as ε decreases. Thus, in this limit, the flux through the boundary increases, resulting in a steeper concentration gradient in a neighborhood of the spine boundary. If the hopping rate $\widehat{\omega}_j$ decreases as ε decreases, then the boundary concentration U_j will also diverge in order to maintain (3.9).

3.3. Evaluation of Green's function. To evaluate the Green's function G satisfying (3.20), we begin by writing its Fourier series representation,

$$\begin{aligned} G(\mathbf{r};\mathbf{r}') = {} & \frac{2}{|\Omega_0|}\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi n x}{L}\right)\cos\left(\frac{\pi n x'}{L}\right)}{\left(\frac{\pi n}{L}\right)^2} + \frac{2}{|\Omega_0|}\sum_{m=1}^{\infty} \frac{\cos\left(\frac{m(y-y')}{l}\right)}{\left(\frac{m}{l}\right)^2} \\ & + \frac{4}{|\Omega_0|}\sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{\cos\left(\frac{\pi n x}{L}\right)\cos\left(\frac{\pi n x'}{L}\right)\cos\left(\frac{m(y-y')}{l}\right)}{\left(\frac{\pi n}{L}\right)^2 + \left(\frac{m}{l}\right)^2}. \end{aligned} \tag{3.34}$$

Upon recalling the formula (cf. p. 46 of [12])

$$\sum_{k=1}^{\infty} \frac{\cos(k\theta)}{k^2 + b^2} = \frac{\pi}{2b}\frac{\cosh(b(\pi - |\theta|))}{\sinh(\pi b)} - \frac{1}{2b^2}, \quad |\theta| \leq 2\pi\,, \tag{3.35}$$

we can sum the third term of (3.34) over the index n to obtain

$$\frac{1}{2\pi}\sum_{m=1}^{\infty}\frac{\cos\left(\frac{m(y-y')}{l}\right)\left[\cosh\left(\frac{m(L-|x-x'|)}{l}\right)+\cosh\left(\frac{m(L-|x+x'|)}{l}\right)\right]}{m\sinh\left(\frac{Lm}{l}\right)} - \frac{2}{|\Omega_0|}\sum_{m=1}^{\infty}\frac{\cos\left(\frac{m(y-y')}{l}\right)}{\left(\frac{m}{l}\right)^2}. \tag{3.36}$$

Notice that the second sum of (3.36) cancels the second sum of (3.34). Then, using the angle addition formula for hyperbolic cosine and the relation $\cosh(x)-\sinh(x)=\mathrm{e}^{-x}$, we derive the following key identity for any constants a, b, and c:

$$\frac{\cosh(a-b)+\cosh(a-c)}{\sinh a} = \frac{1}{1-\mathrm{e}^{-2a}}\left[\mathrm{e}^{-b}+\mathrm{e}^{-c}+\mathrm{e}^{b-2a}+\mathrm{e}^{c-2a}\right]. \tag{3.37}$$

We use this identity to rewrite the first sum in (3.36) and then substitute the resulting expression into (3.34). This yields

$$G(\mathbf{r};\mathbf{r}') = \frac{H(x;x')}{2\pi l} + \sum_{m=1}^{\infty}\frac{\left(z_+^m+\overline{z_+}^m+z_-^m+\overline{z_-}^m+\zeta_+^m+\overline{\zeta_+}^m+\zeta_-^m+\overline{\zeta_-}^m\right)}{4\pi m(1-q^m)}, \tag{3.38}$$

where $q\equiv \mathrm{e}^{-2L/l}$. Here $z_\pm$ and $\zeta_\pm$ are defined by $z_\pm \equiv \mathrm{e}^{r_\pm/l}$ and $\zeta_\pm\equiv \mathrm{e}^{\rho_\pm/l}$, where

$$r_+ \equiv -|x+x'|+i(y-y'), \quad r_-\equiv -|x-x'|+i(y-y'), \tag{3.39}$$

$$\rho_+ \equiv |x+x'|-2L+i(y-y'), \quad \rho_-\equiv |x-x'|-2L+i(y-y'), \tag{3.40}$$

and $\bar{\cdot}$ denotes complex conjugate. Moreover, in (3.38), $H(x;x')$ is defined by

$$H(x;x') \equiv \frac{2}{L}\sum_{n=1}^{\infty}\frac{\cos\left(\frac{\pi n x}{L}\right)\cos\left(\frac{\pi n x'}{L}\right)}{\left(\frac{\pi n}{L}\right)^2} = \frac{L}{12}\left[h\left(\frac{x-x'}{L}\right)+h\left(\frac{x+x'}{L}\right)\right], \quad h(\theta)\equiv 3\theta^2-6|\theta|+2. \tag{3.41}$$

The function $H(x;x')$ is the one-dimensional Green's function in the x-direction.

Since $q=\mathrm{e}^{-2L/l}<1$, we can write $(1-q^m)^{-1}=\sum_{n=0}^{\infty}(q^m)^n$ for all $m\ge 1$. In this way, the sum in (3.38) can be written as

$$\sum_{m=1}^{\infty}\sum_{n=0}^{\infty}(q^n)^m\frac{\left(z_+^m+\overline{z_+}^m+z_-^m+\overline{z_-}^m+\zeta_+^m+\overline{\zeta_+}^m+\zeta_-^m+\overline{\zeta_-}^m\right)}{4\pi m}. \tag{3.42}$$

Notice that when $z_\pm\neq 1$ and $\zeta_\pm \neq 1$ (i.e., when $r_\pm\neq 0$ and $\rho_\pm\neq 0$) this double sum is absolutely convergent, so we can interchange the order of summation in (3.42) and then perform the sum over the index m, yielding

$$-\frac{1}{4\pi}\sum_{n=0}^{\infty}\left(\ln|1-q^n z_+|^2+\ln|1-q^n z_-|^2+\ln|1-q^n\zeta_+|^2+\ln|1-q^n\zeta_-|^2\right) = -\frac{1}{2\pi}\ln|1-z_+||1-z_-||1-\zeta_+||1-\zeta_-|+\mathcal{O}(q). \tag{3.43}$$

The only singularity exhibited by (3.43) in Ω_0 is at $(x, y) = (x', y')$, in which case $z_- = 1$ and $\ln|1 - z_-|$ diverges. Writing $\ln|1 - z_-| = \ln|r_-| + \ln(|1 - z_-|/|r_-|)$ and noting that $\ln|r_-| = \ln|\mathbf{r} - \mathbf{r}'|$ and $\ln(|1 - z_-|/|r_-|)$ is regular, we find that

$$G(\mathbf{r}; \mathbf{r}') = -\frac{1}{2\pi} \ln|\mathbf{r} - \mathbf{r}'| + \mathcal{G}(\mathbf{r}; \mathbf{r}'), \tag{3.44}$$

where the regular part $\mathcal{G}$ of G is given explicitly by

$$\mathcal{G}(\mathbf{r}; \mathbf{r}') = \frac{H(x; x')}{2\pi l} - \frac{1}{2\pi} \ln \frac{|1 - z_+||1 - z_-||1 - \zeta_+||1 - \zeta_-|}{|r_-|} + \mathcal{O}(q). \tag{3.45}$$

This expression for $\mathcal{G}$ is valid in the large aspect ratio limit $L/l \gg 1$ for which $q \ll 1$.

4. Numerics. In this section we compare the asymptotic solution U of (3.29) and (3.31) with the full solution obtained by numerically solving (3.3)–(3.6). In order to implement the boundary conditions (3.6) we use the steady-state solution of R_j given by (3.1), with the mean boundary concentration U_j identified with the corresponding solution of the singular perturbation problem as determined by (3.27) and (3.1). We then check that the resulting numerical solution is self-consistent; that is, the mean receptor concentration around the boundary is well approximated by the assumed value for U_j. The two-dimensional numerical solutions are generated by using the *Partial Differential Equation Toolbox* of MATLAB [30]. In Figure 4.1(A) we plot the steady-state concentration U given by (3.29) and (3.31) for a cable of length $L = 100\mu$m and radius $l = (2\pi)^{-1}\mu$m having 99 identical spines spaced 1μm apart along a single horizontal line ($y = 0\mu$m). In Figure 4.1(B) we plot the corresponding values of U_j, R_j, and S_j, with R_j, S_j given by (3.1) and (3.2). Here the diffusivity is $D = 0.1\mu\text{m}^2\text{s}^{-1}$ [13, 2], the somatic flux is $\sigma_0 = 0.1\mu\text{m}^{-1}\ \text{s}^{-1}$, and all spines are identical with radius $\varepsilon\rho = 0.1\mu$m, $A = 1\mu$m, $\omega = 10^{-3}\mu\text{m}^2\text{s}^{-1}$, $k = 10^{-3}\mu\text{m}^2\text{s}^{-1}$, $\sigma^{rec} = 10^{-3}\text{s}^{-1}$, $\sigma^{deg} = 10^{-4}\text{s}^{-1}$, and $\delta = 10^{-3}\text{s}^{-1}$. We set $\rho = 2\pi l = 1\mu$m so that $\varepsilon = 0.1$. While U decays significantly along the length of the cable, it varies very little around the circumference of the cable. In Figure 4.1(C) we show the results of numerically solving the original steady-state system for U described in (3.3)–(3.6). This numerical solution agrees almost perfectly with the perturbation solution shown in Figure 4.1(A).

We consider the parameter regime of Figure 4.1 physiological in the sense that parameter values were chosen from experimental data [2, 11, 13, 23] in conjunction with previous modeling studies [5, 6]. Our results suggest that in this parameter regime the dendrite can be treated as a quasi-one-dimensional system in which variations in receptor concentration around the circumference of the cable can be neglected. This is further reinforced by the observation that the solutions of the two-dimensional model shown in Figure 4.1(A)–(C) are virtually indistinguishable from the corresponding solution of the reduced one-dimensional model previously introduced in [6] (see Figure 4.1(D)). In the one-dimensional model, (2.1)–(2.4) are replaced by the inhomogeneous diffusion equation

$$\frac{\partial U}{\partial t} = D\frac{\partial^2 U}{\partial x^2} - \sum_{j=1}^{N} \frac{\omega_j}{2\pi l}[U_j - R_j]\delta(x - x_j), \tag{4.1}$$

with boundary conditions $U_j(t) = U(x_j, t)$ and

$$D\left.\frac{\partial U}{\partial x}\right|_{x=0} = -\frac{\sigma_0}{2\pi l D}, \quad D\left.\frac{\partial U}{\partial x}\right|_{x=L} = 0. \tag{4.2}$$

Cable and spine parameter values are given in the text.* (A) *Plot of bulk dendritic concentration U given by the outer solution* (3.29) *of the matched asymptotic expansion. Boundaries of spines are indicated by white lines. The dendritic cable is not drawn to scale.* (B) *Corresponding plots of U_j, R_j, and S_j obtained from* (3.27), (3.31), (3.1), *and* (3.2). *(Note that S_j is converted to a concentration by dividing through by the area A_j of a spine, which is taken to be* 1μm.*)* (C) *Numerical solution of* (3.3)–(3.6). (D) *Plots of U_j, R_j, and S_j obtained by solving the corresponding one-dimensional model* [6].

As in the two-dimensional model, R_j evolves according to (2.6) and (2.7). The steady-state solution of (4.1) can be obtained using the one-dimensional Green's function H such that

$$U(x) = \chi - \sum_{j=1}^{N} \frac{\widehat{\omega}_j [U_j - \widehat{R}_j]}{2\pi l D} H(x, x_j) + \frac{\sigma}{2\pi l D} H(x, 0)\,, \tag{4.3}$$

where the constant χ is determined from the self-consistency condition (3.9). The set of concentrations U_j can then be determined self-consistently by setting $x = x_i$ in (4.3) and solving the resulting matrix equation along analogous lines to (3.28) (cf. [6]). It is important to note that the excellent agreement between the two-dimensional and one-dimensional models is not a consequence of taking the spines to all lie along a one-dimensional line. This is illustrated in Figure 4.2 for a configuration of three staggered rows of 33 spines. The receptor concentrations are indistinguishable from the configuration consisting of a single row of 99 spines.

There is a simple heuristic argument to show why our original two-dimensional diffusion problem can be reduced to a corresponding one-dimensional problem, at

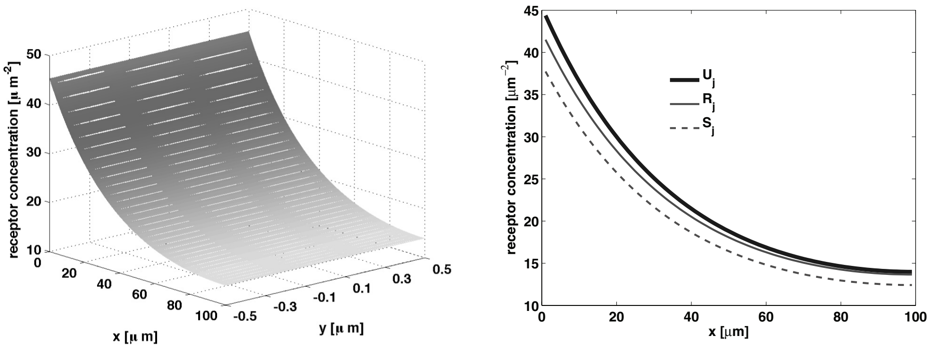

Fig. 4.2. *Plot of receptor concentration profiles along a dendritic cable with three staggered rows of spines. All other parameters are as in Figure* 4.1. *Left: Plot of bulk dendritic concentration U given by the outer solution* (3.29) *of the matched asymptotic expansion. Boundaries of spines are indicated by white lines. The dendritic cable is not drawn to scale. Right: Corresponding plots of U_j, R_j, and S_j obtained from* (3.27), (3.31), (3.1), *and* (3.2). *Concentration plots are indistinguishable from Figure* 4.1.

least in the parameter regime of Figure 4.1. Given a somatic flux $\sigma_0 = 0.1\mu\text{m}^{-1}\text{s}^{-1}$, a cable circumference of 1μm, and $N = 100$ spines, it follows that the mean number of receptors flowing through each spine boundary per second is 10^{-3}. Thus a rough estimate of the mean flux through each spine boundary of circumference $2\pi\varepsilon$ is $\bar{J} = 10^{-3}/(2\pi\varepsilon)\text{s}^{-1}\text{m}^{-1}$. Let ΔU represent the typical size of changes in receptor concentration needed to generate such a flux over a length scale Δx comparable to that of the dendritic circumference. Taking $\bar{J} \sim D\Delta U/\Delta x$ with $\Delta x = 2\pi l = 1\mu$m and $D = 0.1\mu\text{m}^2\text{s}^{-1}$ then gives $\Delta U \sim 10^{-2} l/\varepsilon \approx 1.6 \times 10^{-3}\mu\text{m}^{-2}$. Such a variation is negligible compared to the variation in receptor concentration along the length of the cable due to the source at the soma (see Figure 4.1), thus justifying a reduction to a one-dimensional model.

The above argument shows that the relatively small variation of receptor concentration around the circumference of the cable is a consequence of two factors: the large number of spines and the large aspect ratio ($l \ll L$) of the dendritic geometry; the length scales L, l put upper bounds on the maximum variation of the concentration in the x- and y-directions, respectively, for fixed σ_0. Thus we expect the two-dimensional nature of the spine's surface to become significant in the case of a few spines distributed on a short dendritic cable; such a situation could be relevant in the case of immature neurons. The solution for the receptor concentration will then be sensitive to the size of the spine radius ε. We illustrate this in Figure 4.3 in the case of a single spine centered at $(x, y) = (1, 0)$ on the surface of a dendrite of length $L = 2\mu$m. With this smaller value of L, the aspect ratio of the cable is now $L/l = 4\pi$. We also choose $\omega = k = 1\mu\text{m}^2\text{s}^{-1}$. In Figure 4.3(A)–(C) we show the singular perturbation solution for U when $\varepsilon = 0.01$, 0.1, and 0.4, respectively. In Figure 4.3(D)–(F) we show corresponding plots for the numerical solutions of U. It can be seen that the effect of the logarithmic singularity in the vicinity of the spine becomes prominent as ε decreases. Finally, in Figure 4.3(G) we plot the solution from the one-dimensional model. Although this model contains no information about the radius of the spine neck, and the aspect ratio of the system is now only moderately large, it still provides an approximate solution that agrees quite well with the full two-dimensional solutions.

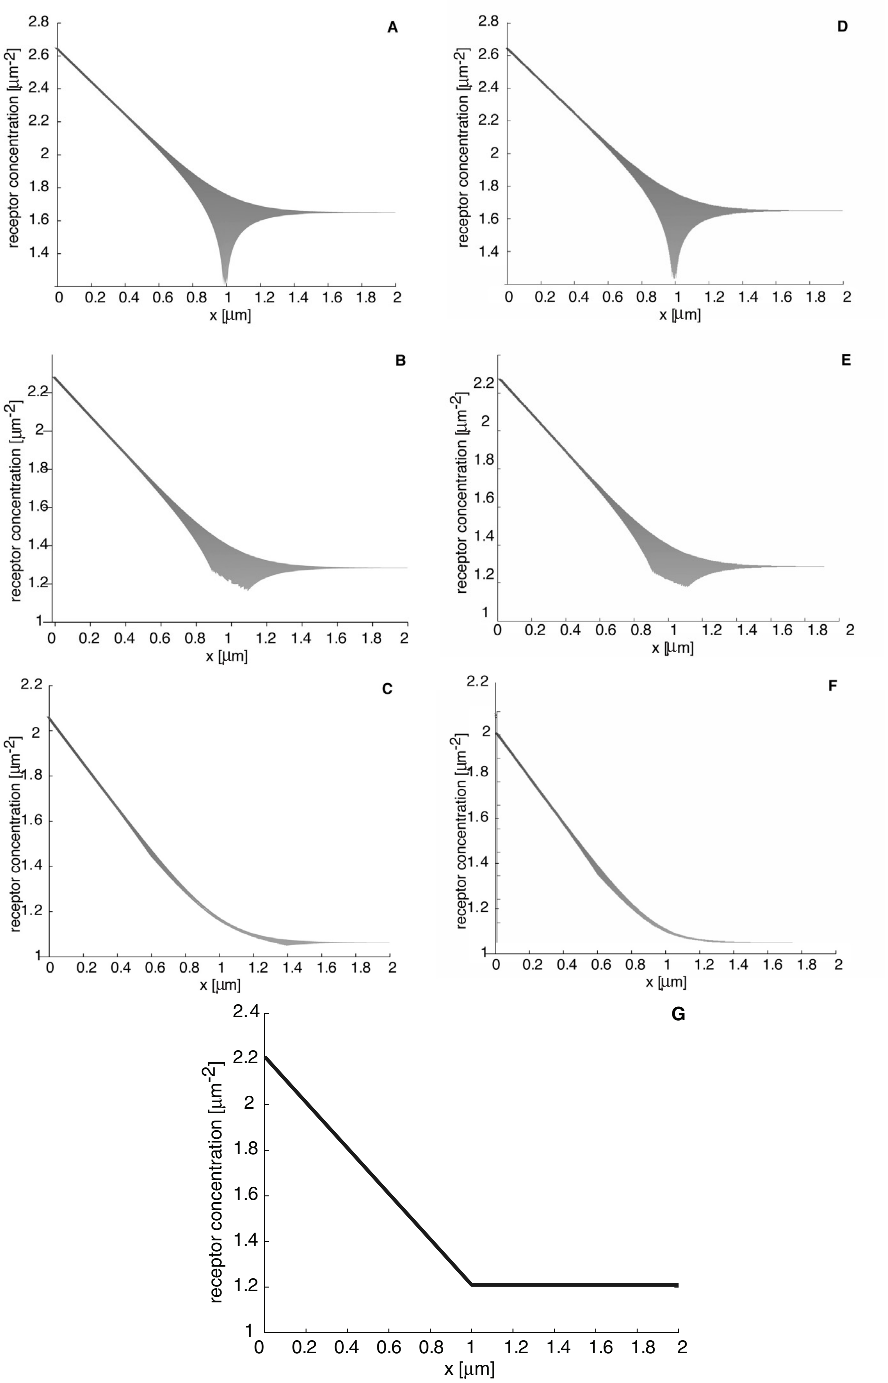

FIG. 4.3. *Effect of spine radius* ε *on the solution* U *for a single spine centered at* $x = 1\mu\mathrm{m}$, $y = 0$ *on a short dendritic cable of length* $L = 2\mu\mathrm{m}$. 5. Mean first passage time (MFPT) for a single receptor. In this section we calculate the MFPT for a single tagged receptor to travel an axial distance X from the soma, $X < L$, assuming that the receptor does not undergo degradation. We then use this to determine an effective diffusivity, which takes into account the effects of trapping at spines. We proceed by reinterpreting the dendritic receptor concentration as a probability density and the diffusion equation (2.1) as a Fokker–Planck (FP) equation. The FP equation is defined on a spatial domain Ω_ε^X, where

$$\Omega_\varepsilon^X = \Omega_X \setminus \bigcup_{j=1}^{N_X} \Omega_j, \quad \Omega_j = \{\mathbf{r} : |\mathbf{r} - \mathbf{r}_j| \leq \varepsilon\}.$$

Here $\Omega_X = \{(x, y); 0 < x < X, |y| < \pi l\}$ and N_X is the number of spines within the rectangular domain Ω_X. We impose an absorbing boundary condition at $x = X$ so that the receptor is immediately removed once it reaches this boundary; i.e., we are interested only in the time it takes for a receptor to first reach $x = X$ from the soma. Let $u(\mathbf{r}, t|\mathbf{r}_0, 0)$ denote the probability density that at time $t \geq 0$ the receptor is located at $\mathbf{r} \in \Omega_\varepsilon^X$, given that it started at the point $\mathbf{r}_0 = (0, y_0)$. The probability density u evolves according to the FP equation

$$\frac{\partial u}{\partial t} = D\nabla^2 u, \quad (\mathbf{r}, t) \in \Omega_\varepsilon^X \times \mathbf{R}_+ \,, \tag{5.1}$$

with periodic boundary conditions at the ends $y = \pm\pi l$,

$$u(x, \pi l, t|\mathbf{r}_0, 0) = u(x, -\pi l, t|\mathbf{r}_0, 0), \quad \partial_y u(x, \pi l, t|\mathbf{r}_0, 0) = \partial_y u(x, -\pi l, t|\mathbf{r}_0, 0) \,, \tag{5.2}$$

and with

$$\partial_x u(0, y, t|\mathbf{r}_0, 0) = 0 \,, \quad u(X, y, t|\mathbf{r}_0, 0) = 0. \tag{5.3}$$

At each interior boundary $\partial\Omega_j$ we impose the mixed boundary condition

$$\varepsilon \partial_n u(\mathbf{r}, t|\mathbf{r}_0, 0) = -\frac{\omega_j}{2D\pi}(u(\mathbf{r}, t|\mathbf{r}_0, 0) - r_j(t|\mathbf{r}_0, t)), \quad \mathbf{r} \in \partial\Omega_j \,, \quad j = 1, \ldots, N_X. \tag{5.4}$$

Here $A_j r_j(t|\mathbf{r}_0, t)$ denotes the probability that the receptor is located within the jth spine at time t. Defining $s_j(t|\mathbf{r}_0, t)$ to be the corresponding probability that the receptor is located within the jth intracellular pool, we have

$$A_j \frac{dr_j}{dt} = \omega_j[u_j - r_j] - k_j r_j + \sigma_j^{rec} s_j \,, \tag{5.5}$$

$$\frac{ds_j}{dt} = -\sigma_j^{rec} s_j + k_j r_j. \tag{5.6}$$

Since we are assuming that the tagged receptor has not been degraded over the time interval of interest, we have set $\sigma_j^{deg} = 0$ for all j. We also assume no production of intracellular receptors so that $\delta_j = 0$. The initial conditions are $u(\mathbf{r}, 0|\mathbf{r}_0, 0) = \delta(\mathbf{r} - \mathbf{r}_0)$ and $r_j(0|\mathbf{r}_0, 0) = s_j(0|\mathbf{r}_0, 0) = 0$ for all j.

5.1. MFPT. Let $\tau(X|\mathbf{r}_0)$ denote the time it takes for a receptor starting at $\mathbf{r}_0 = (0, y_0)$ to first reach the boundary $x = X$. The function

$$F(X, t|\mathbf{r}_0) \equiv \int_{\Omega_\varepsilon^X} u(\mathbf{r}, t|\mathbf{r}_0, 0)\, d\mathbf{r} + \sum_{j=1}^{N_X} [A_j r_j(t|\mathbf{r}_0, 0) + s_j(t|\mathbf{r}_0, 0)] \tag{5.7}$$

is the probability that $t < \tau(X|\mathbf{r}_0)$; i.e., the probability that a receptor which was initially at the origin has not yet reached $x = X$ in a time t. Notice that $1 - F$ is the cumulative density function for τ, and hence

$$\frac{\partial(1-F)}{\partial t} = -\frac{\partial F}{\partial t} \tag{5.8}$$

is its probability density function. Thus the MFPT, denoted by T, is

$$T = -\int_0^\infty t\frac{\partial F}{\partial t}\, dt = \int_0^\infty F\, dt. \tag{5.9}$$

The last equality in (5.9) follows by integrating the first integral by parts and recalling that F, being an L^1 function in time, decays more rapidly to zero than t^{-1} as t becomes large. Therefore, integrating (5.7) over time gives us the following expression for $T(X|\mathbf{r}_0)$:

$$T(X|\mathbf{r}_0) = \lim_{z\to 0}\left(\int_{\Omega_\varepsilon^X} \widehat{u}(\mathbf{r}, z|\mathbf{r}_0, 0) d\mathbf{r} + \sum_{j=1}^{N_X} [A_j \widehat{r}_j(z|\mathbf{r}_0, 0) + \widehat{s}_j(z|\mathbf{r}_0, 0)]\right), \tag{5.10}$$

where $\widehat{\cdot}$ denotes the Laplace transform,

$$\widehat{f}(z) \equiv \int_0^\infty \mathrm{e}^{-zt} f(t) dt. \tag{5.11}$$

Upon Laplace transforming (5.1)–(5.6) and using the initial conditions, we can take the limit $z \to 0$ to obtain

$$\widehat{u}_j(\mathbf{r}_0) = \widehat{r}_j(0|\mathbf{r}_0, 0) = \frac{\sigma_j^{rec}}{k_j}\widehat{s}_j(0|\mathbf{r}_0, 0), \tag{5.12}$$

where

$$\widehat{u}_j(\mathbf{r}_0) = \frac{1}{2\pi\varepsilon}\int_{\partial\Omega_j} \widehat{u}(\mathbf{r}; \mathbf{r}_0)\, d\mathbf{r}. \tag{5.13}$$

Here we have set $\widehat{u}(\mathbf{r}; \mathbf{r}_0) = \lim_{z\to 0} \widehat{u}(\mathbf{r}, z|\mathbf{r}_0, 0)$. Hence, we obtain the boundary value problem

$$D\nabla^2 \widehat{u}(\mathbf{r}; \mathbf{r}_0) = -\delta(\mathbf{r} - \mathbf{r}_0), \quad \mathbf{r} \in \Omega_\varepsilon^X, \tag{5.14}$$

with

$$\widehat{u}(x, \pi l; \mathbf{r}_0) = \widehat{u}(x, -\pi l; \mathbf{r}_0), \quad \partial_y \widehat{u}(x, \pi l; \mathbf{r}_0) = \partial_y \widehat{u}(x, -\pi l; \mathbf{r}_0), \tag{5.15}$$

$$\partial_x \widehat{u}(0, y; \mathbf{r}_0) = 0, \quad \widehat{u}(X, y; \mathbf{r}_0) = 0, \tag{5.16}$$

and the mixed boundary condition

$$\varepsilon \partial_n \widehat{u}(\mathbf{r};\mathbf{r}_0) = -\beta_j \left(\widehat{u} - \frac{1}{2\pi\varepsilon} \int_{\partial\Omega_j} \widehat{u}\, d\mathbf{r} \right), \quad j = 1, \ldots, N_X \,, \tag{5.17}$$

where β_j is defined in terms of the hopping rate by $\beta_j \equiv \omega_j/(2D\pi)$.

As in section 3, we have a singularly perturbed boundary value problem, although in a weaker sense than the previous case. Carrying out a matched asymptotic expansion, the details of which are presented in the appendix, we find that there are no logarithmic singularities and the dependence on the spine size is $\mathcal{O}(\varepsilon^2)$. More specifically, the outer solution has the asymptotic expansion

$$\widehat{u} \sim \frac{G_X(\mathbf{r};\mathbf{r}_0)}{D} + 2\pi\varepsilon^2 \sum_{j=1}^{N_X} \left(\frac{\beta_j - 1}{\beta_j + 1} \right) \mathbf{a}_j \cdot \nabla_j G_X(\mathbf{r};\mathbf{r}_j)\,, \tag{5.18}$$

where ∇_j denotes differentiation with respect to the source variable $\mathbf{r}_j$, and $\mathbf{a}_j$ is defined by

$$\mathbf{a}_j \equiv \frac{\nabla G_X(\mathbf{r}_j;\mathbf{r}_0)}{D}. \tag{5.19}$$

Here G_X is the Green's function on the rectangular domain Ω_X with periodic boundary conditions at the ends $y = \pm\pi l$, a reflecting boundary at $x = 0$, and an absorbing boundary at $x = X$. Thus,

$$G_X(\mathbf{r};\mathbf{r}') = \frac{2}{|\Omega_X|} \sum_{m=-\infty}^{\infty} \sum_{n=0}^{\infty} \frac{\cos\left(\frac{\pi(2n+1)x}{2X}\right) \cos\left(\frac{\pi(2n+1)x'}{2X}\right) \mathrm{e}^{im(y-y')/l}}{\left(\frac{\pi(2n+1)}{2X}\right)^2 + \left(\frac{m}{l}\right)^2}. \tag{5.20}$$

Since G_X has a logarithmic singularity, it follows that

$$\nabla_j G_X(\mathbf{r};\mathbf{r}_j) \sim -\frac{1}{2\pi} \frac{(\mathbf{r} - \mathbf{r}_j)}{|\mathbf{r} - \mathbf{r}_j|^2} + \nabla_j \mathcal{G}_X \quad \text{as} \quad \mathbf{r} \to \mathbf{r}_j\,, \tag{5.21}$$

where $\mathcal{G}_X$ is the regular part of G_X. The average concentration $\widehat{u}_j$ around the boundary of the jth spine is obtained from the corresponding inner solution given in the appendix; see (A.6) and (A.8). Thus

$$\widehat{u}_j = \frac{G_X(\mathbf{r}_j;\mathbf{r}_0)}{D} + \frac{\varepsilon}{2\pi} \sum_{k=1}^{N_X} \left(\frac{2}{\beta_j + 1} \right) \int_0^{2\pi} \mathbf{a}_j \cdot \mathbf{e}_\rho \, d\theta\,, \tag{5.22}$$

where $\mathbf{e}_\rho$ is the unit normal to the circular boundary $\partial\Omega_j$. Since $\mathbf{a}_j$ is a constant vector, it follows that $\int \mathbf{a}_j \cdot \mathbf{e}_\rho d\theta = 0$, and so the $\mathcal{O}(\varepsilon)$ term vanishes. Finally, substituting (5.12), (5.18), and (5.22) into (5.10) shows that

$$T(X|\mathbf{r}_0) = \int_{\Omega_X} \frac{G_X(\mathbf{r};\mathbf{r}_0)}{D} d\mathbf{r} + \sum_{j=1}^{N_X} \eta_j \frac{G_X(\mathbf{r}_j;\mathbf{r}_0)}{D} + \varepsilon^2 \mathcal{J} + \cdots\,, \tag{5.23}$$

where $\eta_j = A_j + k_j/\sigma_j^{rec}$ and

$$\mathcal{J} = -\pi \sum_{j=1}^{N_X} \frac{G_X(\mathbf{r}_j;\mathbf{r}_0)}{D} + 2\pi \sum_{j=1}^{N_X} \left(\frac{\beta_j - 1}{\beta_j + 1} \right) \mathbf{a}_j \cdot \nabla_j \int_{\Omega_X} G_X(\mathbf{r};\mathbf{r}_j)\, d\mathbf{r}. \tag{5.24}$$

In the following we will determine the zeroth-order expression for the MFPT by dropping the $\mathcal{O}(\varepsilon^2)$ terms.

5.2. Evaluation of Green's function. We wish to evaluate the Green's function G_X in (5.20). We begin by expressing the double sum as

$$G_X(\mathbf{r};\mathbf{r}') = \frac{2}{|\Omega_X|}\sum_{n=0}^{\infty}\frac{\cos\left(\frac{\pi(2n+1)x}{2X}\right)\cos\left(\frac{\pi(2n+1)x'}{2X}\right)}{\left(\frac{\pi(2n+1)}{2X}\right)^2} + \frac{4}{|\Omega_X|}\sum_{m=1}^{\infty}\sum_{n=0}^{\infty}\frac{\cos\left(\frac{\pi(2n+1)x}{2X}\right)\cos\left(\frac{\pi(2n+1)x'}{2X}\right)\cos\left(\frac{m(y-y')}{l}\right)}{\left(\frac{\pi(2n+1)}{2X}\right)^2+\left(\frac{m}{l}\right)^2}. \tag{5.25}$$

Upon using the identity (derived from p. 46 of [12])

$$\sum_{k=0}^{\infty}\frac{\cos((2k+1)\theta)}{(2k+1)^2+b^2} = \frac{\pi}{4b}\left[\frac{\cosh(b(\pi-|\theta|))}{\sinh(\pi b)} - \frac{\cosh(b|\theta|)}{\sinh(\pi b)}\right], \quad |\theta|\le\pi, \tag{5.26}$$

we can perform the sum over the index n in (5.25), yielding

$$\frac{1}{2\pi}\sum_{m=1}^{\infty}\frac{\cos\left(\frac{m(y-y')}{l}\right)\left[\cosh\left(\frac{m(2X-|x-x'|)}{l}\right)+\cosh\left(\frac{m(2X-|x+x'|)}{l}\right)\right]}{m\sinh\left(\frac{2Xm}{l}\right)} + \mathcal{E}\,, \tag{5.27}$$

where $\mathcal{E}$ is defined by

$$\mathcal{E} \equiv -\frac{1}{2\pi}\sum_{m=1}^{\infty}\frac{\cos\left(\frac{m(y-y')}{l}\right)\left[\cosh\left(\frac{m|x-x'|}{l}\right)+\cosh\left(\frac{m|x+x'|}{l}\right)\right]}{m\sinh\left(\frac{2Xm}{l}\right)}. \tag{5.28}$$

Following arguments similar to those used in section 3.3, together with the identity (3.37), the infinite sums in (5.27) and (5.28) can be represented as infinite sums of logarithmic terms. Our calculations are greatly simplified if X is not too small (e.g., by assuming that $X \gg l/2$). In this large aspect ratio limit, the identity (3.37) yields that

$$\frac{\cosh\left(\frac{m(2X-|x-x'|)}{l}\right)+\cosh\left(\frac{m(2X-|x+x'|)}{l}\right)}{\sinh\left(\frac{2Xm}{l}\right)} \approx \mathrm{e}^{-m|x-x'|/l}+\mathrm{e}^{-m|x+x'|/l}+\mathcal{O}(q_X)\,, \tag{5.29}$$

where $q_X \equiv \mathrm{e}^{-2X/l}$. In addition, $\mathcal{E}=\mathcal{O}(q_X)\ll 1$ and can be neglected to a first approximation. Using these approximations for the large aspect ratio limit, we readily derive that

$$G_X(\mathbf{r};\mathbf{r}') = \frac{H_X(x;x')}{2\pi l} - \frac{1}{2\pi}\ln|1-z_+||1-z_-| + \mathcal{O}(q_X)\,, \tag{5.30}$$

where (cf. p. 46 of [12])

$$H_X(x;x') = \frac{2}{X}\sum_{n=0}^{\infty}\frac{\cos\left(\frac{\pi(2n+1)x}{2X}\right)\cos\left(\frac{\pi(2n+1)x'}{2X}\right)}{\left(\frac{\pi(2n+1)}{2X}\right)^2} = \frac{X}{2}\left[h_X\left(\frac{x-x'}{X}\right)+h_X\left(\frac{x+x'}{X}\right)\right], \quad h_X(\theta)=1-|\theta|\,, \tag{5.31}$$

is the one-dimensional Green's function in the x-direction, and $z_{\pm}$ is as defined in (3.39).

Suppose that $\mathbf{r}' = \mathbf{r}_0 = (0, y_0)$. Since $x_0 = 0$,

$$G_X(\mathbf{r};\mathbf{r}_0) = \frac{X-x}{2\pi l} - \frac{1}{2\pi}\ln\left|1 - \mathrm{e}^{-x/l}\mathrm{e}^{i(y-y_0)/l}\right|^2 + \mathcal{O}(q_X). \tag{5.32}$$

If x is sufficiently large (e.g., $x \geq l$), then the contribution of the logarithmic term in (5.32) is of order $q_x = \mathrm{e}^{-2x/l}$, and hence

$$G_X(\mathbf{r};\mathbf{r}_0) = \frac{X-x}{2\pi l} + \mathcal{O}(q_x). \tag{5.33}$$

Since $\mathcal{O}(q_x)$ is exponentially small, this term can be dropped from (5.33), yielding the one-dimensional Green's function used in [6]. The fact that these results are effectively one-dimensional is again due to the large aspect ratio of our system.

5.3. Effective diffusivity and anomalous diffusion. Let us now evaluate the zeroth-order contributions to the MFPT $T(X|\mathbf{r}_0)$ given in (5.23). First, it follows from integrating (5.20) that $\int_{\Omega_X} G_X(\mathbf{r};\mathbf{r}_0)d\mathbf{r} = X^2/2$. Following the discussion of the previous paragraph, we will assume that all x_j are sufficiently large so that $G_X(\mathbf{r}_j;\mathbf{r}_0)$ is well approximated by the one-dimensional Green's function $(X - x_j)/(2\pi l)$. Since we are dropping any explicit dependence on y, y_0, we simply denote the MFPT $T(X|\mathbf{r}_0)$ by T. In the case of a large number of identical spines uniformly distributed along the length of the cable with spacing d (i.e., $N_X = X/d \gg 1$ and $x_j = jd$ for all j), we can compute an effective diffusivity D_{eff}. That is, substituting our one-dimensional approximation for G_X into (5.23) and dropping $\mathcal{O}(\varepsilon^2)$ terms gives

$$\begin{aligned} T &\approx \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\sum_{j=1}^{N_X}(X - jd) = \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\left(N_X X - \frac{(N_X+1)N_X d}{2}\right) \\ &\approx \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\left(N_X X - \frac{N_X^2 d}{2}\right) = \frac{X^2}{2D}\left(1 + \frac{\eta}{2\pi l d}\right) = \frac{X^2}{2D_{eff}}, \end{aligned} \tag{5.34}$$

where $\eta \equiv A + k/\sigma^{rec}$. In (5.34), the effective diffusivity D_{eff} is

$$D_{eff} = D\left(1 + \frac{\eta}{2\pi l d}\right)^{-1} = D\left(1 + \frac{A + k/\sigma^{rec}}{2\pi l d}\right)^{-1}. \tag{5.35}$$

As one would expect, the presence of traps reduces the effective diffusivity of a receptor. In particular, the diffusivity is reduced by increasing the ratio k/σ^{rec} of the rates of endocytosis and exocytosis, by increasing the surface area A of a spine, or by decreasing the spine spacing d. Interestingly, D_{eff} does not depend on the hopping rate ω, at least to lowest order in the spine size ε. At first sight this might seem counterintuitive, since a smaller ω implies that a receptor finds it more difficult to exit a spine. However, this is compensated by the fact that it is also more difficult for a receptor to enter a spine in the first place. (For a more detailed analysis of entry/exit times of receptors with respect to spines see [14, 15]).

In (5.34) the MFPT T is proportional to X^2. This relationship is the hallmark of Brownian diffusion, and here it is due to the fact that the spacing between spines is independent of the index j. Now suppose that the spacing varies with j according to $x_j = d(\ln(j)+1)$. In this case $N_X = \mathrm{e}^{X/d-1}$, and hence N_X grows exponentially with X [19]. Therefore, upon summing the series and using Stirling's formula, we get

(5.36)
$$\begin{aligned} T &\approx \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\sum_{j=1}^{N_X}(X - d(\ln(j)+1)) = \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\left(N_X X - d(\ln(N_X!) + N_X)\right) \\ &\approx \frac{X^2}{2D} + \frac{\eta}{2\pi l D}\left(N_X X - d N_X \ln(N_X)\right) = \frac{X^2}{2D} + \frac{\eta d}{2\pi l D}\mathrm{e}^{X/d-1} = \frac{X^2}{2D_{eff}(X)}, \end{aligned}$$

where the effective diffusivity is

$$D_{eff}(X) = D\left(1 + \frac{A + k/\sigma^{rec}}{2\pi l d}\frac{\mathrm{e}^{X/d-1}}{\frac{(X/d)^2}{2}}\right)^{-1}. \tag{5.37}$$

The fact that the effective diffusivity is a function of X indicates anomalous diffusion, which is to say that the relationship $T \propto X^2$ does not hold. Moreover, because $\mathrm{e}^{X/d-1}$ grows faster than $(X/d)^2$, the anomalous behavior is subdiffusive.

Note that the above analysis reproduces results obtained previously for a simplified one-dimensional model [6]. However, our asymptotic analysis shows that there are $\mathcal{O}(\varepsilon^2)$ corrections to the one-dimensional results given by (5.24). In particular, these higher-order corrections introduce a weak dependence of the MFPT on the size of the spines and the hopping rates ω_j via the parameters β_j.

6. Discussion.

In this paper we have used singular perturbation theory to determine the steady-state receptor concentration on the cylindrical surface of a dendritic cable in the presence of small dendritic spines, which act as partially absorbing traps. In the case of long, thin dendrites we have shown that the variation of the receptor concentration around the circumference of the cable is negligible so that the concentration profile along the cable can be determined using a simpler one-dimensional model [6]. We have also shown that the MFPT for a single tagged receptor to travel a certain distance along the cable is well approximated by considering a random walk along a one-dimensional cable. In both cases, our perturbation analysis provides details regarding corrections to the one-dimensional results that depend on the size ε of spines. Such corrections would be significant in the case of short dendrites with few spines, which may occur in immature neurons. An important extension of our work would be to consider a much more detailed model of receptor trafficking within each spine [10]. This would take into account the fact that the spine is not a homogeneous medium but contains a protein rich subregion known as the postsynaptic density where receptors can bind and unbind to various scaffolding proteins [4]. Interestingly, the coupling between the spine and the dendritic cable would not be affected by such details so that our solutions for the dendritic receptor concentration within the cable would carry over to more complex models.

The analysis presented in this paper provides a general mathematical framework for taking into account the effects of the size of spines on the surface diffusion of receptors (and other proteins) within the cell membrane. In the particular case of spiny dendrites it allows us to establish rigorously the validity of a one-dimensional reduction. This is important from a biological modeling perspective since the reduced model provides a relatively simple system in which to explore the role of diffusion in protein receptor trafficking along a dendrite. For example, one important biological issue is whether or not diffusion is sufficient as a mechanism for delivering protein receptors to distal parts of the dendrite [1]. If one ignores the effects of trapping in spines, then an estimate for the mean time a receptor takes to travel a distance X from the soma via surface diffusion along a uniform cable is $T = X^2/2D$. Even for a relatively large diffusivity $D = 0.45\mu\text{m}^2\text{s}^{-1}$, the mean time to reach a proximal synapse at 100μm from the soma is approximately 3 hrs., whereas the time to reach a distal synapse at 1mm from the soma is around 300 hrs. The latter is much longer than the average lifetime of a receptor, which is around 1 day. The one-dimensional formulae for the MFPT in the presence of traps (see section 5) establishes that trapping within spines increases the delivery time of receptors to synapses even further due to an effective reduction in the diffusivity. Indeed, if the density of spines grows sufficiently fast towards distal ends of the dendrite, then this increase in the MFPT could be significant due to the emergence of anomalous subdiffusive behavior. Interestingly, there is experimental evidence for an enhanced spine density at distal locations [18].

Finally, it would be interesting to consider protein receptor trafficking across a population of synapses with other geometric configurations. In this study we focused on synapses located within dendritic spines that are distributed along a dendritic cable, since most excitatory neurons in the central nervous system have such structures. However, there are some classes of neurons that have synapses located directly on the cell body or soma. One striking example is the chick ciliary ganglion, which supplies motor input to the iris of the eye; the ganglion has nicotinic receptors that are distributed across the surface of the cell body within somatic spines [3]. Thus the basic mathematical approach presented here could be extended to other biologically relevant examples of surface diffusion in the presence of partially absorbing traps, including diffusion on the surface of a spherical cell body, where a reduction to a one-dimensional problem would not be possible.

Appendix. In this appendix we present the singular perturbation analysis used to obtain the outer solution (5.18). First, let $\widehat{u}_0$ be the solution to the boundary value problem without traps given by (5.14), (5.15), and (5.16). Then

$$\widehat{u}_0(\mathbf{r}) = \frac{G_X(\mathbf{r};\mathbf{r}_0)}{D}\,, \tag{A.1}$$

where G_X is the Green's function of (5.20). For the problem with traps, we write the outer expansion as

$$\widehat{u} = \frac{G_X(\mathbf{r};\mathbf{r}_0)}{D} + \sigma(\varepsilon)\widehat{u}_1 + \cdots\,, \tag{A.2}$$

where $\sigma(\varepsilon)$ is to be found. In order to determine the inner solution near the jth hole, we introduce the scaled coordinates $\mathbf{s} = \varepsilon^{-1}(\mathbf{r} - \mathbf{r}_j)$ and set $V(\mathbf{s}) = \widehat{u}(\mathbf{r}_j + \varepsilon\mathbf{s})$. Then V satisfies (omitting the far-field condition)

$$\nabla_{\mathbf{s}}^2 V = 0\,, \quad s \equiv |\mathbf{s}| \geq 1\,, \tag{A.3}$$

$$\partial_s V = \beta_j \left(V - \frac{1}{2\pi}\int_0^{2\pi} V\, d\theta \right) \quad \text{on} \quad s \equiv |\mathbf{s}| = 1. \tag{A.4}$$

Notice that any constant V_0 satisfies this problem. We therefore write $V = V_0 + \mu(\varepsilon)V_1 + \cdots$. The inner and outer solutions must satisfy the matching condition

$$\frac{1}{D}\left[G_X(\mathbf{r}_j;\mathbf{r}_0) + \nabla G_X(\mathbf{r}_j;\mathbf{r}_0)\cdot(\mathbf{r}_j - \mathbf{r}) + \cdots\right] + \sigma(\varepsilon)\widehat{u}_1 \sim V_0 + \mu(\varepsilon)V_1 + \cdots\,. \tag{A.5}$$

This implies that $\mu(\varepsilon) = \varepsilon$ and that the constant V_0 is given by

$$V_0 = \frac{G_X(\mathbf{r}_j; \mathbf{r}_0)}{D}. \tag{A.6}$$

In addition, V_1 is the solution to the inner problem (A.3) and (A.4) with the far-field behavior

$$V_1 \sim \mathbf{a}_j \cdot \mathbf{s}\,, \qquad \mathbf{a}_j \equiv \frac{\nabla G_X(\mathbf{r}_j; \mathbf{r}_0)}{D}. \tag{A.7}$$

A simple separation of variables calculation gives the exact solution

$$V_1 = \mathbf{a}_j \cdot \mathbf{s} - \left(\frac{\beta_j - 1}{\beta_j + 1}\right) \mathbf{a}_j \cdot \frac{\mathbf{s}}{|\mathbf{s}|^2}. \tag{A.8}$$

Substituting this into the matching condition (A.5) gives $\sigma(\varepsilon) = \varepsilon^2$ and that $\widehat{u}_1$ satisfies the asymptotic singularity conditions

$$\widehat{u}_1 \sim -\left(\frac{\beta_j - 1}{\beta_j + 1}\right) \mathbf{a}_j \cdot \frac{(\mathbf{r} - \mathbf{r}_j)}{|\mathbf{r} - \mathbf{r}_j|^2} \quad \text{as} \quad \mathbf{r} \to \mathbf{r}_j. \tag{A.9}$$

The function $\widehat{u}_1$ is to satisfy Laplace's equation, the boundary conditions (5.15) and (5.16), and the singularity conditions (A.9) for $j = 1, \dots, N$.

Since the two-dimensional Green's function G_X has the logarithmic singularity $\frac{1}{2\pi} \log |\mathbf{r} - \mathbf{r}_j|$ for $\mathbf{r} \to \mathbf{r}_j$, it follows that $\nabla G_X(\mathbf{r}; \mathbf{r}_j)$ has the dipole singularity

$$\frac{1}{2\pi} \frac{(\mathbf{r} - \mathbf{r}_j)}{|\mathbf{r} - \mathbf{r}_j|^2} \quad \text{as} \quad \mathbf{r} \to \mathbf{r}_j. \tag{A.10}$$

Unfortunately, $\nabla G_X(\mathbf{r}; \mathbf{r}_j)$ does not satisfy the boundary conditions (5.15) and (5.16), so it cannot be used to construct an outer solution with the correct near-field behavior. On the other hand, we can construct a solution using $\nabla_j G_X(\mathbf{r}; \mathbf{r}_j)$, where ∇_j is the gradient operator with respect to the singular point $\mathbf{r}_j$. That is, $-\nabla_j G_X(\mathbf{r}; \mathbf{r}_j)$ has the same singular behavior as $\nabla G_X(\mathbf{r}; \mathbf{r}_j)$ and also satisfies the boundary conditions (5.15) and (5.16). The latter follows from the observation that the boundary conditions for G_X do not involve $\mathbf{r}_j$ so that the boundary and Laplace operators commute with ∇_j. Finally, using linearity and superposition over the N_X holes, we readily obtain that the outer approximation is given explicitly by

$$\widehat{u} \sim \frac{G_X(\mathbf{r}; \mathbf{r}_0)}{D} + 2\pi\varepsilon^2 \sum_{j=1}^{N_X} \left(\frac{\beta_j - 1}{\beta_j + 1}\right) \mathbf{a}_j \cdot \nabla_j G_X(\mathbf{r}; \mathbf{r}_j). \tag{A.11}$$

CONVERGENCE OF DUAL ALGORITHM WITH ARBITRARY COMMUNICATION DELAYS[*]

RICHARD J. LA[†] AND PRIYA RANJAN[‡]

Abstract. We study the issue of convergence of user rates and resource prices under a family of rate control schemes called dual algorithms with arbitrary communication delays. We first consider a case where a single resource is shared by many users. Then we study a general network shared by heterogeneous users and derive sufficient conditions for convergence. We show that in the case of a single user utilizing a single resource, our condition is also necessary. Using our results we derive a sufficient condition for convergence with a family of popular utility and resource price functions. We present numerical examples to validate our analysis.

1. Introduction.

A communication network, e.g., the Internet or a telephone network, comprises networking equipment that enables exchange of information between multiple parties or end user equipment (e.g., personal computers or laptops). Networking equipment includes switches, routers, and links (e.g., fiber optics or twisted copper wires) that connect switches and routers and have finite bandwidth or capacity, i.e., the number of bits that can be transmitted by a link per unit time. This networking equipment, which we call network elements in this paper, communicates using a set of rules called *network protocols*.

Since the links in the Internet have finite capacity, excessive demands brought on by the users can cause severe congestion or even a collapse of the Internet (e.g., the congestion collapse of 1986). Hence, in order to prevent any unexpected collapse of the Internet from severe congestion, it is imperative to control the congestion level inside the network by regulating the rates at which packets are injected into the network by the users, called the packet transmission rates or simply rates of the users. With the increasing size and complexity of the Internet, the problem of computing a fair share of network bandwidth for every user and allocating their rates is becoming a challenging task. To this end, in his seminal work [13] Kelly suggested that the problem of allocating fair shares of available network bandwidth to elastic traffic users,[1] which we call a *rate allocation* problem, can be posed as an optimization problem.

Under the proposed optimization framework each user receives a utility as a function of its rate, i.e., its share of bandwidth. The utility of a user can represent either the true utility or benefit the user receives or a utility function enforced by the end user protocol that adjusts the packet transmission rate on behalf of the user. An

[1] A user or a connection created by the user for information exchange is said to be *elastic* if its packet transmission rate can be adjusted based on feedback from the network (e.g., packet losses).

example of such a protocol is transmission control protocol (TCP), which is the most popular congestion or rate control protocol in the Internet today. In the latter case the selection of the utility function determines the behavior of the end user protocol and the desired rate allocation [14, 18, 20]. The objective of the optimization problem is to maximize the aggregate utility, i.e., the sum of the utilities of the users, subject to the link capacity constraints. Using the proposed framework Kelly and his colleagues proposed two classes of *distributed* rate control algorithms—primal and dual algorithms [14] (described in subsections 2.1 and 2.2)—and established their convergence to the desired rate allocation in the absence of delays.

In reality signals take time to travel from one end of a link connecting two network elements to the other end. This introduces a communication delay, which equals the length of the link divided by the speed at which the signal travels the medium, when a signal is transmitted over a link. Modeling communication delays over links between network elements is important when the delays are nonnegligible (e.g., intercontinental links) or widely varying with uncertainty; i.e., the delays are not known in advance. An example of such an environment is multihop wireless networks, which are wireless networks formed and maintained by (mobile) users without any infrastructure including physical links [27].

Recently, the convergence of user rates to the desired allocation under the primal algorithm in the presence of communication delays has been studied extensively [4, 12, 24, 30, 33]. The authors of [4, 12, 24] provided sufficient conditions on the gain parameters of the users[2] and communication delays for convergence, whereas Ranjan, La, and Abed [30] studied the case with arbitrary communication delays and provided sufficient conditions on user utility functions and resource price functions for convergence. Throughout this paper a resource refers to a link that connects two network elements. In addition, the authors of [30, 33] provided sufficient conditions for convergence with popular utility and resource price functions [2].

The convergence of user rates and resource prices under the dual algorithm in the presence of communication delays, however, has not been studied as much. Maulloo [23] studied the local convergence of the dual algorithm using a linearized model and provided sufficient conditions on the delay and resource gain parameters for local convergence. Low et al. introduced a family of dual algorithms, which are variants of those proposed by Kelly, Maulloo, and Tan [14], and studied the convergence in the presence of communication delays [1, 26].

In this paper we study the convergence property of the dual algorithm proposed by Kelly, Maulloo, and Tan [14] and derive sufficient conditions for convergence with *arbitrary* communication delays. We use the same technique we employed in [30] for the primal algorithm and demonstrate that the same framework can be used to investigate both the primal algorithm and the dual algorithm. We first consider a simpler scenario where a single resource is shared by a large number of users with heterogeneous round-trip delays. We model the dispersion or spread of heterogeneous round-trip delays of many users utilizing the resource using a family of probability distributions known as gamma kernels. This family of distributions has been used to model delay dispersion in other disciplines (see, e.g., [3, 32]). Then, using MacDonald's linear chain technique [21] we write the system dynamics as higher-order differential equations [7]. We derive a sufficient condition for convergence of user rates and resource prices. We also study the case where the users have the same round-trip delay (i.e., a discrete

[2] The gain parameter of a user or a resource determines how fast the user changes its rate or the resource updates its price in response to a change in network congestion level and is explained in subsections 2.1 and 2.2.

delay). We show that when the derived sufficient condition is violated, the system becomes unstable for sufficiently large delays and exhibits oscillatory behavior. Using a linear analysis we provide an upper bound on the delay for local convergence.

We extend the above results to general network cases where a set of resources is shared by heterogeneous users and derive sufficient conditions for convergence in the presence of arbitrary communication delays. These sufficient conditions are derived based on a simple discrete time map that emerges from the intrinsic market structure that underlies the rate control system and captures the interaction between the demands of the users and supplies of the network resources. We note that a similar approach has been used [10, 11, 22] in the past to study the behavior of delay differential systems. We apply our results to derive (necessary and) sufficient conditions with the same utility and resource price functions studied in [30, 33]. We show that the derived conditions for the dual algorithm are less restrictive than those for the primal algorithm in [30, 33]. In other words, for some choices of users' utility and resource price functions the dual algorithm converges irrespective of the communication delays, while the convergence of the primal algorithm with the same utility and resource price functions can be ensured only for small delays.

The main contributions of this paper can be briefly summarized as follows:

- We provide sufficient conditions for convergence of the dual algorithm, which are robust against the variations in the communication delays and resource gain parameters. This result can be used to provide a guideline and to simplify the design of the rate control system for a communication network that constantly evolves and changes (e.g., the Internet).
- We demonstrate that when the dispersion of round-trip delays can be modeled by a gamma kernel, the effects of the heterogeneous delays can be studied using the model of Hale and Ivanov [7] and are similar to those of introducing low pass filters in the feedback control loop [19].

This paper is organized as follows: Section 2 describes the optimization framework for rate allocation and the primal and dual algorithms proposed by Kelly [13] and Kelly, Maulloo, and Tan [14]. We study the simpler case of a single resource in section 3. This is followed by a study of general network cases in section 4. We apply our results to example utility and resource price functions and derive (necessary and) sufficient conditions for convergence with arbitrary communication delays in section 5. Simulation results are provided in section 6. We conclude in section 7.

2. Background. In this section we briefly describe the rate allocation problem in the proposed optimization framework. Consider a network with a set $\mathcal{L}$ of resources and a set $\mathcal{I}$ of users. Let C_l denote the finite capacity of resource $l \in \mathcal{L}$. Each user $i \in \mathcal{I}$ has a fixed route r_i, which is a set of resources traversed by user i's packets. We define a zero-one matrix A, where $A_{i,l} = 1$ if $l \in r_i$ and $A_{i,l} = 0$ otherwise. When its rate is x_i, user i receives utility $U_i(x_i)$. We take the view that the utility functions of the users are used to select the desired rate allocation among the users. The utility $U_i(x_i)$ is an increasing, strictly concave, and continuously differentiable function of x_i over the range $x_i \geq 0$. Under this setting, the rate allocation problem of interest can be formulated as the following optimization problem [13]:
SYSTEM(U,A,C):

$$\begin{aligned} &\text{maximize} \quad \sum_{i \in \mathcal{I}} U_i(x_i) \\ &\text{subject to} \quad A^T x \leq C, \qquad x \geq 0, \end{aligned} \tag{2.1}$$

where $C = (C_l,\, l \in \mathcal{L})$.[3] The first constraint is the capacity constraint, which states that the sum of the rates of all users utilizing resource l should not exceed its capacity C_l.

With the goal of solving this optimization problem in a *distributed* manner, Kelly, Maulloo, and Tan proposed two classes of rate-based algorithms [14]: Suppose that every user adopts rate-based congestion control in that it adjusts its rate based on the feedback from the network in the form of resource prices. Let $w_i(t)$ and $x_i(t)$ denote the amount user i is willing to pay, which we call its willingness to pay, per unit time and its rate at time t, respectively.[4] At time t each resource $l \in \mathcal{L}$ charges a price per unit flow of $\mu_l(t)$.

2.1. Primal algorithm. In a primal algorithm the end users adjust their rates based on the (shadow) prices per unit time of the resources given by

$$\mu_l(t) = p_l\Big(\sum_{i:l\in r_i} x_i(t)\Big), \qquad l \in \mathcal{L}, \tag{2.2}$$

where $p_l(\cdot)$ is an increasing function of the aggregate rate of the users going through it. Based on the resource prices, each user i adjusts its rate according to the following differential equation:

$$\frac{d}{dt}x_i(t) = \kappa_i\Big(w_i(t) - x_i(t)\sum_{l\in r_i}\mu_l(t)\Big), \qquad i \in \mathcal{I}, \tag{2.3}$$

where $w_i(t) = x_i(t) \cdot U_i'(x_i(t))$ and the user gain parameter $\kappa_i > 0$. The basic idea in (2.3) is to provide a market-based rate control mechanism; each user i constantly attempts to reach a market equilibrium where its willingness to pay $w_i(t)$ equals its total price per unit time charged by the resources given by $x_i(t)\sum_{l\in r_i}\mu_l(t)$. Note that the prices charged by the resources in (2.2) depend on the rates of the users, which can be viewed as users' current demands.

Under (2.3) one can see that both users' utility functions and resource price functions can be utilized to decide a desired allocation of network bandwidth to the end users. Therefore, the design of rate control algorithms is equivalent to selecting users' utility functions and the price functions of the resources that appear in (2.2) and (2.3).

Kelly, Maulloo, and Tan [14] have shown that, under some conditions on $p_l(\cdot)$, $l \in \mathcal{L}$, the user rates $x(t) = (x_i(t),\, i \in \mathcal{I})$ converge to a rate vector that maximizes the following expression:

$$\mathcal{U}(x) = \sum_i U_i(x_i) - \sum_l \int_0^{\sum_{i:l\in r_i} x_i} p_l(y)\,dy. \tag{2.4}$$

The first term in (2.4) is the aggregate utility of the users in our *SYSTEM(U,A,C)* problem in (2.1) which we want to maximize. Thus, the primal algorithm proposed by Kelly, Maulloo, and Tan in (2.3) solves a variation of the *SYSTEM(U,A,C)* problem in that it maximizes (2.4) instead of the aggregate utility in the original *SYSTEM(U,A,C)* problem.

[3] All vectors are assumed to be column vectors.

[4] Throughout the rest of the paper we refer to the willingness to pay per unit time as simply willingness to pay.

2.2. Dual algorithm. In a dual algorithm each resource $l \in \mathcal{L}$ updates its price, $\mu_l(t)$, based on the difference between the observed aggregate rate of the users and its *expected* rate $q_l(\mu_l(t))$ according to

$$\frac{d}{dt}\mu_l(t) = \kappa_l\Big(\sum_{j:l\in r_j} x_j(t) - q_l(\mu_l(t))\Big), \tag{2.5}$$

where the resource gain parameter $\kappa_l > 0$. The user rates are set to

$$x_j(t) = \frac{w_j(t)}{\sum_{l\in r_j}\mu_l(t)} =: D_j\Big(\sum_{l\in r_j}\mu_l(t)\Big), \tag{2.6}$$

where $D_j(\lambda)$ is the solution to $\lambda = U_j'(x)$ with $D_j(\lambda) = 0$ if $\lambda \geq U_j'(0)$ and $D_j(\lambda) = \infty$ if $\lambda \leq U_j'(\infty)$.[5] In other words, $D_j(\lambda)$ denotes the demand of user j as a function of the price per unit flow λ, which is the solution to the user optimization problem $\max_{x\geq 0} U_j(x) - x \cdot \lambda$ (called the USER$(U_j; \lambda)$ problem [13]). We call D_j the demand function of user j throughout the paper. It is easy to see that if $(U_j')^{-1}$ exists, then $D_j(\lambda) = (U_j')^{-1}(\lambda)$.

Here the function q_l can be viewed as the inverse function of the resource price function p_l in the primal algorithm. Hence, $q_l(\mu_l(t))$ gives the expected rate of resource l, given its current price $\mu_l(t)$. From (2.5)–(2.6) one can see that each resource adjusts its price according to the difference between the user demand (given by aggregate rate $\sum_{j:l\in r_j} x_j(t)$) and its desired supply at the current price (given by $q_l(\mu_l(t))$) [14, 31].

Kelly, Maulloo, and Tan [14] have proved that under mild technical conditions on the functions q_l, $l \in \mathcal{L}$, the expression

$$\mathcal{V}(\mu) = \sum_{i\in\mathcal{I}} \int_0^{\sum_{l\in r_i}\mu_l} D_i(\xi)\, d\xi - \sum_{l\in\mathcal{L}} \int_0^{\mu_l} q_l(\eta)\, d\eta \tag{2.7}$$

provides a Lyapunov function for the system of differential equations (2.5)–(2.6). We call a resource price vector μ that maximizes (2.7) a solution to (2.7) in the rest of the paper. Similarly, we call a rate vector x that maximizes (2.4) a solution to (2.4).

It is a simple exercise to show that if $q_l(\cdot) = p_l^{-1}(\cdot)$, at the solution to (2.7) denoted by $\overline{\mu}^\star = (\mu_l^\star,\ l \in \mathcal{L})$, (i) the solutions to USER$(U_i; \sum_{l\in r_i}\mu_l^\star)$ problems are the solution to (2.4), $\overline{x}^\star = (x_i^\star,\ i \in \mathcal{L})$, and (ii) $p_l(\sum_{i:l\in r_i} x_i^\star) = \mu_l^\star$ for all $l \in \mathcal{L}$. In other words, the user rates and resource prices at the equilibrium are the same under both the dual algorithm and the primal algorithm.

3. Single resource case. In this section we first study a simpler case where a single resource is shared by users with the same utility function. This is similar to the model used in [9] for studying the interaction of TCP connections with a random early detection (RED) gateway.[6] However, unlike in [9] we do not assume that the round-trip delays of the users are the same. General network cases will be studied in the following section.

[5] One should interpret $U_j'(\infty)$ to be $\lim_{x\to\infty} U_j'(x)$.

[6] A RED gateway is a queue management scheme that attempts to regulate the rates of the users by either dropping or marking packets with some probability to signal to the users impending congestion. The drop or mark probability is a function of the average number of packets queued at the gateway over a period.

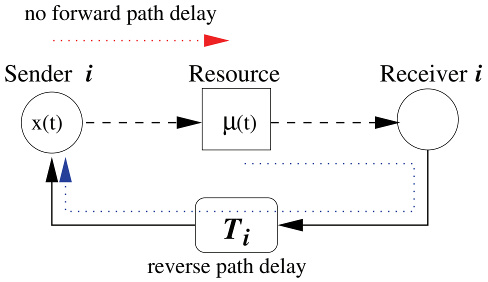

FIG. 3.1. *Network model for a single resource case.*

We assume that there is no forward delay from senders to the resource, and all of user i's round-trip delay, denoted by T_i, lies in the reverse path from the resource back to the sender. This is shown in Figure 3.1. Under this assumption the resource price update rule in (2.5) is given by

$$\frac{d}{dt}\mu(t) = \kappa\Big(\sum_{i\in\mathcal{I}} \frac{w_i(t)}{\mu(t-T_i)} - q(\mu(t))\Big). \tag{3.1}$$

We first focus on the case where users' willingness to pay is fixed, i.e., $w_i(t) = w$, $w > 0$, for all $i \in \mathcal{I}$. The case with user adaptation is discussed in subsection 3.3.

Here we are interested in the case where the resource is shared by a large number of users, e.g., an intercontinental link. In order to facilitate the analysis we assume that we can model the dispersion of heterogeneous round-trip delays of the users using some distribution function $\bar{K}$ as follows: Suppose $T \geq 0$ is the minimum round-trip delay of the users. For every $u \in [0,\infty)$, let $\bar{K}(u)$ be the *fraction* of users whose round-trip delays are less than or equal to $u + T$. We assume $\bar{K}$ is differentiable and yields a density function K, i.e., $K(u) = \bar{K}^{(1)}(u)$. This is reasonable when the number of users is large. Under this assumption, we can approximate the *average* rate of the users seen at the resource at time t using

$$\frac{1}{|\mathcal{I}|}\sum_{i\in\mathcal{I}} \frac{w}{\mu(t-T_i)} \approx \int_0^\infty \frac{w}{\mu(t-T-s)} K(s)\, ds, \tag{3.2}$$

where $|\mathcal{I}|$ is the cardinality of $\mathcal{I}$.

In the rest of this section we normalize both the aggregate rate of the users at the resource and the expected rate of the resource in (3.1) by the number of users $|\mathcal{I}|$, and we replace these terms with (3.2) and the expected rate per user of the resource, respectively:

$$\begin{aligned} \frac{d}{dt}\mu(t) &= \overline{\kappa}\left(\int_0^\infty \frac{w}{\mu(t-T-s)}\, K(s)\, ds - q_N(\mu(t))\right) \\ &= \overline{\kappa}\left(\int_0^\infty f(\mu(t-T-s))\, K(s)\, ds - q_N(\mu(t))\right), \end{aligned} \tag{3.3}$$

where $\overline{\kappa} = \kappa \cdot |\mathcal{I}|$, $q_N(\mu) = q(\mu)/|\mathcal{I}|$, and $f(\mu) = \frac{w}{\mu}$. Hence, the resource adjusts its price based on the average rate of the users and its expected (average) user rate based on the current price $\mu(t)$.

In this paper we consider the case where the delay density function K can be modeled by a family of generic delay kernels also known as gamma kernels, which have the following form:

$$K(u) = \begin{cases} \frac{\alpha^{r+1} u^r}{r!} \exp(-\alpha u) & \text{if } u \geq 0, \\ 0 & \text{otherwise,} \end{cases} \tag{3.4}$$

where $\alpha > 0$ is a constant, and $r \in \{0, 1, 2, \ldots\}$. The kernel K with different parameters is plotted in Figure 3.2.

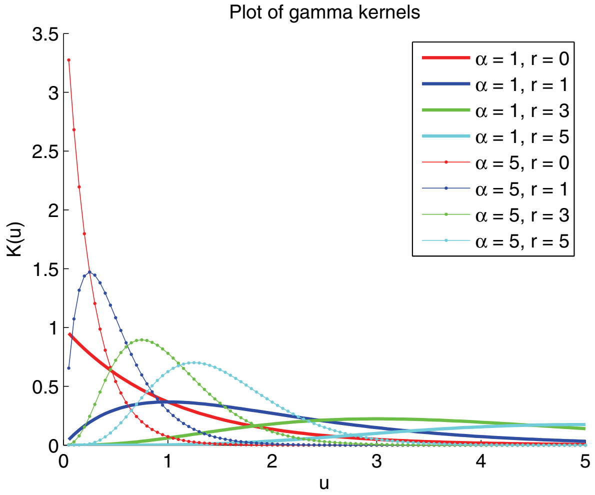

FIG. 3.2. *Gamma kernels for different parameters.*

The parameter r is called the order of gamma kernel K [21], and the mean of K for fixed (α, r) is given by

$$\mathbf{E}[K] = \int_0^\infty u \frac{\alpha^{r+1} u^r}{r!} \exp(-\alpha u)\, du = \frac{r+1}{\alpha}.$$

The kernel K with $r = 0$ and $r = 1$ is called the weak and strong kernel, respectively, and is frequently used to model distributed delay in different disciplines including population biology [3, 32]. These gamma kernels can be used to model a whole class of delay distributions (see, e.g., Figure 3.2), including an exponential distribution (i.e., the weak kernel). The case of discrete delay can be realized by letting r and α go to infinity simultaneously while keeping the mean delay $\frac{r+1}{\alpha}$ fixed.

In the remainder of this section we study the asymptotic behavior of the system in (3.3) under a set of reasonable assumptions on function q. In particular, we adopt the gamma kernels in (3.4) and apply *MacDonald's linear chain technique* to derive sufficient conditions for convergence of the dual algorithm [21].

Define $\mathbb{R}_+ := (0, \infty)$ and $\overline{\mathbb{R}}_+ := [0, \infty)$. The resource price function p is a strictly increasing function that maps $\overline{\mathbb{R}}_+$ to $\overline{\mathbb{R}}_+$. We first introduce the following assumption.

Assumption 1. (i) The function $q : \overline{\mathbb{R}}_+ \to \overline{\mathbb{R}}_+$ is strictly increasing with $q(0) = 0$.

(ii) The function q is Lipschitz continuous on any bounded interval $[\mu_{min}, \mu_{max}] \subset \mathbb{R}_+$.

(iii) There exists a unique point $\mu^\star \in \mathbb{R}_+$ such that $f(\mu^\star) = q(\mu^\star)/|\mathcal{I}| = q_N(\mu^\star)$.

It is clear from (3.3) that $\mu^\star$ is the unique equilibrium of the dual algorithm in (2.5), at which the total demand of the users equals the expected rate of the resource given by $q(\mu^\star)$. Note that under Assumption 1, if the initial function is nonnegative, i.e., $\mu(s) \geq 0$ for all $s \in (-\infty, 0)$, the resource price $\mu(t)$ remains nonnegative because when $\mu(t) = 0$, the right-hand side of (3.3) is nonnegative if $\mu(t') \geq 0$ for all $t' < t$.

The existence of a unique solution of (3.3) is guaranteed by Theorem 2.3 in [8, p. 44] under Assumption 1 if there exist bounds μ_{min} and μ_{max}, where $0 < \mu_{min} < \mu_{max} < \infty$, such that $\mu(t)$ remains in $[\mu_{min}, \mu_{max}]$ for all $t \geq 0$, starting with an appropriate initial function that lies in $[\mu_{min}, \mu_{max}]$. In the following section we assume the existence of a unique positive solution of (3.3) and the bounds μ_{min} and μ_{max} such that $\mu_{min} \leq \mu(t) \leq \mu_{max}$ for all $t \geq 0$. We will provide an assumption under which this is true in subsection 3.2.

3.1. MacDonald's linear chain technique. Let $\mu(t)$ be a positive solution of (3.3) with some positive initial function $\mu(s)$ for all $s < 0$. We define

$$\begin{aligned} \omega_i(t) &= \int_0^\infty \frac{w}{\mu(t-T-s)}\, G^i(s)\, ds \\ &= \int_{-\infty}^t f(\mu(\theta - T))\, G^i(t-\theta)\, d\theta, \qquad i = 0, 1, \ldots, r, \end{aligned} \tag{3.5}$$

where $\theta = t - s$, $d\theta = -ds$, and $G^i(u) = \frac{\alpha^{i+1} u^i}{i!} \exp(-\alpha u)$, $u \geq 0$. Note that for any $i \in \{1, 2, \ldots\}$,

$$\frac{d}{du} G^i(u) = -\alpha G^i(u) + \alpha G^{i-1}(u) \quad \text{and} \quad \frac{d}{du} G^0(u) = -\alpha G^0(u). \tag{3.6}$$

Suppose that the delay kernel K is given by G^r for some $\alpha > 0$ and $r \in \{0, 1, \ldots\}$. From (3.6) we see that $(\mu(t), \omega_r(t), \omega_{r-1}(t), \ldots, \omega_0(t))$ satisfies

$$\frac{d}{dt}\mu(t) = \overline{\kappa}\left(\omega_r(t) - q_N(\mu(t))\right), \tag{3.7}$$

$$\frac{d}{dt}\omega_i(t) = -\alpha\left(\omega_i(t) - \omega_{i-1}(t)\right), \qquad i = 1, \ldots, r, \tag{3.8}$$

$$\frac{d}{dt}\omega_0(t) = -\alpha\left(\omega_0(t) - f(\mu(t-T))\right). \tag{3.9}$$

Define $\eta(t) := q_N(\mu(t))$. We have

$$\frac{d}{dt}\eta(t) = q_N'(q_N^{-1}(\eta(t)))\frac{d}{dt}\mu(t) \quad \text{and, hence,} \quad \frac{d}{dt}\mu(t) = \frac{1}{q_N'(q_N^{-1}(\eta(t)))}\frac{d}{dt}\eta(t),$$

where the inverse q_N^{-1} exists from Assumption 1. Note that, from Assumption 1, if $\mu(t)$ is positive for all $t \geq 0$, so is $\eta(t)$.

We can rewrite (3.7) in terms of $\eta(t)$ and $\omega_r(t)$ defined in (3.5):

$$\frac{1}{\overline{\kappa} \cdot q_N'(q_N^{-1}(\eta(t)))}\frac{d}{dt}\eta(t) = \omega_r(t) - \eta(t). \tag{3.10}$$

Using the definition of $\eta(t)$, we can rewrite (3.9) as

$$\begin{aligned} \frac{d}{dt}\omega_0(t) &= -\alpha\,\omega_0(t) + \alpha\, f(q_N^{-1}(\eta(t-T))) \\ &= -\alpha\,\omega_0(t) + \alpha\, \check{F}(\eta(t-T)), \end{aligned}$$

where the map $\check{F} : \overline{\mathbb{R}}_+ \to \mathbb{R}_+ \cup \{\infty\}$ is defined by

$$\check{F}(\eta) := f(q_N^{-1}(\eta)) = \frac{w}{q_N^{-1}(\eta)} \quad \forall\, \eta \in \overline{\mathbb{R}}_+. \tag{3.11}$$

Therefore, we have the following set of differential equations for describing the dynamics of the rate control system:

$$\begin{aligned} &\frac{1}{\kappa \cdot q_N'(q_N^{-1}(\eta(t)))} \frac{d}{dt}\eta(t) = -\eta(t) + \omega_r(t), \\ &\frac{d}{dt}\omega_i(t) = -\alpha\, \omega_i(t) + \alpha\, \omega_{i-1}(t), \qquad i = 1, \ldots, r, \\ &\frac{d}{dt}\omega_0(t) = -\alpha\, \omega_0(t) + \alpha\, \check{F}(\eta(t-T)). \end{aligned} \tag{3.12}$$

We note that the delay differential system in (3.12) is similar to that in [19] for a variant of the primal algorithm where the price charged by a resource is a function of the averaged or low pass filtered version of the aggregate rate of the users through the resource, as opposed to the users' instantaneous rates in the original primal algorithm. Hence, this suggests that the dynamical effect of heterogeneous delays in the dual algorithm, summarized by the averaging in (3.2), is similar to that of low pass filtering (or averaging) of the rate seen by the resource in the primal algorithm [19].

In the rest of this section we will show that, similarly as in the primal algorithm case [30], the convergence of the dual algorithm in (3.3) (or in (3.12)) can be studied using the map $\check{F}$ defined in (3.11).

3.2. Convergence. We denote by $C([-T, 0], A)$ the set of continuous functions from the interval $[-T, 0]$ to some interval $A \subset \mathbb{R}_+$ with topology of uniform convergence [8]. Suppose that there exists an interval $J := [a, b] \subset \mathbb{R}_+$, which is invariant under the map $\check{F}$, i.e., $\check{F}(J) \subset J$. Let $Y_J := C([-T, 0], J)$, and the initial function of $\eta(s)$, $s \in [-T, 0]$, is given by ϕ.

THEOREM 3.1. *If the initial function $\phi \in Y_J$ and $\omega_0(0), \ldots, \omega_r(0) \in J$, then for all $t \geq 0$ we have $(\eta(t; \phi), \omega_0(t), \ldots, \omega_r(t)) \in J^{r+2}$.*

Proof. A proof is provided in Appendix A. □

Theorem 3.1 implies that, under the assumption stated in the theorem, since $\eta(t; \phi)$ remains in J, from the definition of $\eta(t)$ and Assumption 1 the resource price $\mu(t)$ lies in a compact interval not including zero and, hence, stays away from zero for all $t \geq 0$. Therefore, the existence of a unique solution is guaranteed by Theorem 2.3 in [8, p. 44] under the assumption, as mentioned earlier.

For any interval A let $\mathrm{int}(A)$ denote its interior. We establish the convergence of (3.12) under the following assumption.

Assumption 2. There is a sequence of closed intervals $J_k \subset \mathbb{R}_+$, $k = 0, 1, \ldots$, such that (i) $\check{F}(J_k) \subset \mathrm{int}(J_{k+1}) \subset J_{k+1} \subset \mathrm{int}(J_k)$ for all $k = 0, 1, \ldots$, and (ii) $\cap_{k \geq 0} J_k = \{q_N(\mu^\star)\}$, where $\mu^\star$ is the unique point that satisfies $f(\mu^\star) = q_N(\mu^\star)$ in Assumption 1.

An example of utility and resource price functions that satisfy this assumption will be given in section 5.

THEOREM 3.2. *Suppose that Assumption 2 holds. If $\phi \in Y_{J_0}$ and $\omega_i(0) \in J_0$ for all $i = 0, 1, \ldots, r$, then $(\eta(t; \phi), \omega_0(t), \ldots, \omega_r(t)) \to (q_N(\mu^\star), \ldots, q_N(\mu^\star))$ as $t \to \infty$.*

Proof. A proof is given in Appendix B. □

3.3. User adaptation. In the previous subsection we have assumed that the willingness of the users to pay is fixed at w. This describes a case where the users' utility function is given by $w \cdot \log(x)$ [12, 14]. Suppose that the users' utility function is not of the form $w \cdot \log(x)$. If the user can accurately track the price per unit flow $\mu(t)$ and solve the USER$(U; \mu(t))$ problem, it should select a rate $x^\star(\mu(t))$ that satisfies $U'(x) = \mu(t)$ and set its willingness to pay to $w(t) = \mu(t) \cdot x^\star(\mu(t))$. This rate $x^\star(\mu(t))$ is given by the demand function D of the user defined in subsection 2.2.

We assume that the demand function D is (i) strictly decreasing in μ on the interval $[U'(\infty), U'(0))$, (ii) differentiable on $(U'(\infty), U'(0))$, and (iii) Lipschitz continuous on every bounded interval $[U'(\mu_{max}), U'(\mu_{min})]$, where $[\mu_{min}, \mu_{max}] \subset \mathbb{R}_+$. An example of utility functions that satisfy these assumptions is provided in section 5. Under these assumptions one can show that if there exists a unique $\mu^\star$ such that $D(\mu^\star) = q_N(\mu^\star)$ and the map $\check{F}(\eta) := D(q_N^{-1}(\eta))$ satisfies Assumption 2, then the theorems in subsection 3.2 hold with the same proofs [17]. Note that the function $f(\mu) = w/\mu$ plays the role of the demand function D when the willingness to pay w is constant.

3.4. Local stability with a homogeneous delay. In this subsection we consider the case where the resource is utilized by a single user with a fixed delay T. This user can be viewed as the aggregate of many users with the same round-trip delay T [9]. Recall that the case of discrete delay T can be modeled by gamma kernels by letting r and α go to ∞ simultaneously with a fixed mean delay $\frac{r+1}{\alpha} = T$. Using a linear analysis, we study the local stability of the system around the equilibrium $\mu^\star$.

When a single user utilizes the resource, the resource price is updated according to

$$\frac{d}{dt}\mu(t) = \kappa \left(x(t) - q(\mu(t))\right) = \kappa \left(D(\mu(t-T)) - q(\mu(t))\right). \tag{3.13}$$

We rewrite (3.13) in terms of $\eta(t) = q(\mu(t))$ as

$$\begin{aligned} \frac{d}{dt}\eta(t) &= \kappa \cdot q'(q^{-1}(\eta(t))) \left(D(q^{-1}(\eta(t-T))) - \eta(t)\right) \\ &= \zeta(\eta(t)) \left(\check{F}(\eta(t-T)) - \eta(t)\right), \end{aligned} \tag{3.14}$$

where $\zeta(\eta(t)) := \kappa \cdot q'(q^{-1}(\eta(t)))$ and $\check{F}(\eta) = D(q^{-1}(\eta))$. Note that $\zeta(\eta(t)) > 0$ from the assumptions on function q. Following the similar steps in the proof of Theorem 3.2 one can show that the resource price generated by (3.14) converges if Assumption 2 holds and $\phi \in Y_{J_0}$.

Assuming that the map $\check{F}$ is locally smooth around $\eta^\star = q(\mu^\star)$, one can find the conditions for local stability of the fixed point $\eta^\star$ for the delay differential equation in (3.14). Proposition 4 in [25, p. 17] tells us that the linearized system

$$\begin{aligned} \frac{d}{dt}Z(t) \; &= \; \zeta(\eta(t))\check{F}'(\eta(t-T))\Big|_{\eta=\eta^\star} Z(t-T) \\ &\quad + \left(\zeta'(\eta(t)) \left[\check{F}(\eta(t-T)) - \eta(t)\right] - \zeta(\eta(t))\right)\Big|_{\eta=\eta^\star} Z(t) \\ &= \; \zeta(\eta^\star)\check{F}'(\eta^\star)Z(t-T) - \zeta(\eta^\star)Z(t) \\ &:= -B \cdot Z(t-T) - A \cdot Z(t), \end{aligned} \tag{3.15}$$

where $A = \zeta(\eta^\star)$ and $B = -\zeta(\eta^\star)\check{F}'(\eta^\star)$,[7] is stable *if and only if*

[7] This is because $\eta^\star$ is a fixed point of the map $\check{F}$, i.e., $\check{F}(\eta^\star) = \eta^\star$.

(i) $A + B > 0$ and $A \geq |B|$, or

(ii) $B > |A|$ and $T \leq T^\star := \cos^{-1}(-A/B)/\sqrt{B^2 - A^2}$.

Note that in our problem the above conditions tell us that the linearized system in (3.15) is stable if and only if (i) the map $\check{F}$ is locally stable, i.e., $|\check{F}'(\eta^\star)| < 1$, or (ii) $\check{F}'(\eta^\star) < -1$ and

$$T \leq \frac{\cos^{-1}\left((\check{F}'(\eta^\star))^{-1}\right)}{\zeta(\eta^\star)\sqrt{\left(\check{F}'(\eta^\star)\right)^2 - 1}}.$$

Since local stability is required for global stability, these conditions tell us that the local stability of the map $\check{F}$ is both *necessary* and *sufficient* for convergence of the dual algorithm in (3.13) with an arbitrary delay in the neighborhood of the equilibrium point $\mu^\star$. We use these conditions to establish a *necessary* and *sufficient* condition for convergence with example utility and resource price functions in section 5.

4. General network cases.

In the previous section we studied the case where a single resource is shared by many users. Using MacDonald's linear chain technique we demonstrated that the effects of heterogeneous delays of the users are similar to introducing low pass filters in the feedback loop (see (3.12)). Then we showed that the asymptotic stability of the discrete time map $\check{F}$ is sufficient for convergence of the dual algorithm. In this section we extend these results to the case of a general network shared by multiple heterogeneous users with different delays. We first describe the model used for our analysis and then derive sufficient conditions for convergence of the resource prices and user rates with a general network topology.

4.1. General network model with delays.

In this subsection we describe the network model that captures the communication delays between network elements and end users under the assumption that the delays are *constant.* Recall from section 2 that $\mathcal{I} = \{1, \ldots, N\}$ is the set of users sharing a network consisting of a set $\mathcal{L} = \{1, \ldots, L\}$ of resources. Define $I_l = \{i \in \mathcal{I} \mid l \in r_i\}$ to be the set of users utilizing resource $l \in \mathcal{L}$. For all $i \in \mathcal{I}$ and $l \in r_i$ let $T^r_{i,l}$ and $T^f_{i,l}$ denote the delay of the feedback signal from resource l to sender i and the delay from sender i to resource l, respectively. This is shown in Figure 4.1. If user i packets do not traverse resource l, i.e., $l \notin r_i$, we assume that $T^r_{i,l} = T^f_{i,l} = 0$. Suppose that the resources in $r_i = \{l_{i,1}, \ldots, l_{i,R_i}\}$ are arranged in the order user i packets visit, where $R_i = |r_i|$. Define $T_i = T^f_{i,l_{i,k}} + T^r_{i,l_{i,k}}$, $k = 1, \ldots, R_i$, to be the round-trip delay of user i.

Similarly as in the single resource case, we introduce the following assumptions on the demand functions $D_i(\cdot)$ and $q_l(\cdot)$.

Assumption 3. (i) The demand functions $D_i(\mu)$ are strictly decreasing in price per unit flow μ on the interval $[U'_i(\infty), U'_i(0))$ and differentiable on $(U'_i(\infty), U'_i(0))$. In addition, they are Lipschitz continuous on any bounded interval $A \subset (U'_i(\infty), U'_i(0))$.

(ii) The function $q_l : [0, \infty) \to [0, \infty)$ is strictly increasing with $q_l(0) = 0$ for all $l \in \mathcal{L}$. Moreover, the function q_l is Lipschitz continuous on any bounded interval $[\mu_{l,min}, \mu_{l,max}] \subset \mathbb{R}_+$.

Assumption 3(ii) simply says that the equilibrium price of a resource increases with the aggregate rate traversing the resource, i.e., the total demand from the users. Note that Assumption 3(ii) also ensures that the inverse functions q_l^{-1} exist.

With the communication delays defined above, under Assumption 3, the differential equations in (2.5) and (2.6) become[8]

[8] As explained in the single resource case, under Assumption 3, the resource prices $\mu_l(t)$ remain nonnegative if the initial functions are nonnegative.

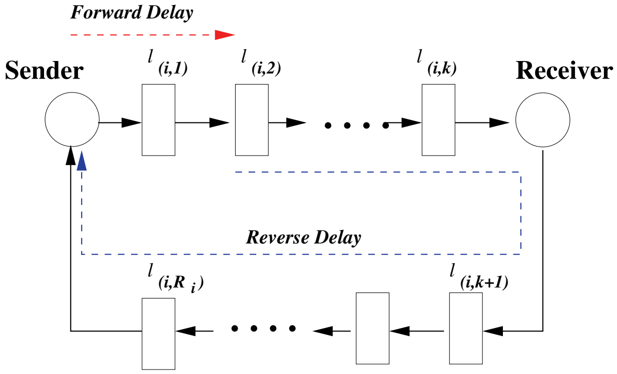

FIG. 4.1. *Network model with delays.*

$$\frac{d}{dt}\mu_l(t) = \kappa_l \left(\sum_{i\in I_l} D_i\Big(\sum_{j\in r_i} \mu_j(t-(T^r_{i,j}+T^f_{i,l}))\Big) - q_l(\mu_l(t))\right) \qquad \forall\, l\in\mathcal{L}. \tag{4.1}$$

We can show that a unique solution of (4.1) exists under an assumption to be stated shortly (i.e., Assumption 4) together with Assumption 3. We will revisit this issue after stating the assumption in subsection 4.2.

Similarly as in the previous section we define $\eta_l(t) := q_l(\mu_l(t))$. Recall that $\eta_l(t)$ denotes the expected rate of resource l at time t as a function of its price $\mu_l(t)$. We rewrite (4.1) in terms of $\eta_l(t)$ as

$$\frac{d}{dt}\eta_l(t) = \kappa_l q_l'(q_l^{-1}(\eta_l(t))) \left(\sum_{i\in I_l} D_i\Big(\sum_{j\in r_i} q_j^{-1}(\eta_j(t-T^r_{i,j}-T^f_{i,l}))\Big) - \eta_l(t)\right). \tag{4.2}$$

This can be put in the following matrix form:

$$\frac{d}{dt}\overline{\eta}(t) = \overline{\zeta}(t)\left[F(\tilde{\eta}(t)) - \overline{\eta}(t)\right], \tag{4.3}$$

where $\overline{\eta}(t) = (\eta_l(t);\ l\in\mathcal{L})$, $\overline{\zeta}(t) = \mathrm{diag}(\kappa_l \cdot q_l'(q_l^{-1}(\eta_l(t)));\ l\in\mathcal{L})$, $\tilde{\eta}(t) = (\eta_{(i,l)}(t);\ l\in\mathcal{L},\ i\in I_l)$, and $\eta_{(i,l)}(t) = (\eta_j(t-T^r_{i,j}-T^f_{i,l});\ j\in\mathcal{L})$. The lth element of the multidimensional map $F : \overline{\mathbb{R}}_+^{L\cdot\Xi} \to \overrightarrow{\mathbb{R}}_+^L$, where $\Xi := \sum_{l\in\mathcal{L}}|I_l|$ and $\overrightarrow{\mathbb{R}}_+ = \overline{\mathbb{R}}_+\cup\{\infty\}$, is defined by

$$F_l(\tilde{\eta}(t)) = \sum_{i\in I_l} D_i\Big(\sum_{j\in r_i} q_j^{-1}(\eta_j(t-T^r_{i,j}-T^f_{i,l}))\Big), \qquad l\in\mathcal{L}. \tag{4.4}$$

Note that Assumption 3 guarantees that the gain matrix $\overline{\zeta}(t)$ is positive definite.

4.2. Convergence. In this subsection we investigate the convergence of resource prices and aggregate rates at the resources generated by (4.3). More specifically, we will provide sufficient conditions for their convergence regardless of the delays $T^f_{i,j}$ and $T^r_{i,j}$.

DEFINITION 1. *A set $D\subset\mathbb{R}^L_+$ is said to be invariant under the map F if $F(\tilde{\eta})\in D$ for all $\tilde{\eta}\in D^\Xi$, i.e., $\tilde{\eta} = (\eta_{(i,l)};\ l\in\mathcal{L},\ i\in I_l)$ and $\eta_{(i,l)}\in D$ for all $l\in\mathcal{L}$ and $i\in I_l$. A vector $\overline{\eta}^\star\in\mathbb{R}^L_+$ is said to be a fixed point of F if $F(\overline{\eta}^\star,\ldots,\overline{\eta}^\star) = \overline{\eta}^\star$.*

The invariance of the map F can be interpreted as follows. Suppose that expected rates $\overline{\eta}(t)$ of the resources based on their current prices at time t as well as time delayed values $\eta_{(i,l)}(t)$, $l \in \mathcal{L}$ and $i \in I_l$, belong to the set D. Then the invariance of the set D implies that $F(\tilde{\eta}(t))$ lies in the set D. Similarly, a fixed point $\overline{\eta}^\star$ means that if $\overline{\eta}(t) = \overline{\eta}^\star$, $\eta_{(i,l)}(t) = \overline{\eta}^\star$ for all $l \in \mathcal{L}$ and $i \in I_l$, then $F(\tilde{\eta}(t)) = \overline{\eta}^\star$. In other words, $\overline{\eta}(t)$ and hence resource prices $\overline{\mu}(t)$ remain constant. One can verify that if $\overline{\eta}^\star$ is a fixed point of F, then $\overline{q}^{-1}(\overline{\eta}^\star) = (q_1^{-1}(\eta_1^\star), \ldots, q_L^{-1}(\eta_L^\star))$ is a solution to (2.7) from (4.3), i.e., $\overline{\eta}^\star = \overline{q}(\overline{\mu}^\star)$, where $\overline{\mu}^\star$ is a solution to (2.7).

We now state the assumption under which the convergence of (4.3) is established.

Assumption 4. Suppose that $\overline{\eta}^\star \in \mathbb{R}_+^L$ is a fixed point of the multidimensional map F. There is a sequence of compact, convex sets $E_k = \times_{l \in \mathcal{L}} E_{k,l} \subset \mathbb{R}_+^L$, $k \geq 0$, such that $F(E_k^\Xi) \subset \text{int}(E_{k+1}) \subset E_{k+1} \subset \text{int}(E_k)$ and $\cap_{k \geq 0} E_k = \{\overline{\eta}^\star\}$.

Define $T_{max} = \max_{l \in \mathcal{L},\, i \in I_l}(\max_{j \in r_i}(T_{i,j}^r + T_{i,l}^f))$. We denote by $C([-T_{max}, 0], E)$ the set of continuous functions mapping the interval $[-T_{max}, 0]$ into E with topology of uniform convergence [8]. Let $Y_{E_0} = C([-T_{max}, 0], E_0)$ be a subset of initial functions. When the initial function ϕ lies in Y_{E_0}, Theorem 2.3 in [8, p. 44] guarantees the existence of a unique solution of (4.3) under Assumptions 3 and 4. Denote by $\overline{\eta}(t;\phi)$ the solution of (4.3) constructed using an initial function $\phi \in Y_{E_0}$.

THEOREM 4.1. *All solutions $\overline{\eta}(t;\phi)$ starting with an initial function $\phi \in Y_{E_0}$ remain in E_0 for all $t \geq 0$ and converge to $\overline{\eta}^\star$ as $t \to \infty$ for all $T_{i,j}^r, T_{i,j}^f \in \mathbb{R}_+$.*

Proof. The basic idea of the proof of the theorem is similar to that of Theorem 4 in [30], and a proof is provided in [17], which is omitted in this paper due to a space constraint. □

Theorem 4.1 tells us that the attracting fixed point of the map F is stable in the set E_0. Since $\overline{\mu}(t) = \overline{q}^{-1}(\overline{\eta}(t))$, this tells us that $\overline{\mu}(t) \to \overline{\mu}^\star$ as $t \to \infty$.

4.3. Comparison with a homogeneous delay system.

In this subsection we investigate how the convergence of the resource prices under the general delay differential system in (4.3) is related to that of a much simpler system where (i) there are no forward delays from the senders to the resources, and (ii) all users have the same homogeneous round-trip delay. In other words, $T_{i,l}^f = 0$ and $T_{i,l}^r = T$ for all $i \in \mathcal{I}$ and $l \in r_i$, where T is some positive constant. Under this assumption the delay differential equations in (4.2) simplify to

$$\text{(4.5)} \quad \frac{d}{dt}\eta_l(t) = \kappa_l q_l'(q_l^{-1}(\eta_l(t))) \left(\sum_{i \in I_l} D_i\Big(\sum_{j \in r_i} q_j^{-1}(\eta_j(t-T)) \Big) - \eta_l(t) \right) \qquad \forall\ l \in \mathcal{L},$$

and the matrix form is given by

$$\frac{d}{dt}\overline{\eta}(t) = \overline{\zeta}(t)\left[\hat{F}(\eta(t-T)) - \overline{\eta}(t)\right],$$

where the map $\hat{F} : \overline{\mathbb{R}}_+^L \to \overrightarrow{\mathbb{R}}_+^L$ is defined by

$$\text{(4.6)} \qquad \hat{F}_l(\overline{\eta}) = \sum_{i \in I_l} D_i\Big(\sum_{j \in r_i} q_j^{-1}(\eta_j) \Big), \qquad l \in \mathcal{L}.$$

Assumption 5. The multidimensional map $\hat{F}$ has a fixed point $\overline{\eta}^\star \in \mathbb{R}_+^L$. In addition, there is a sequence of compact, convex sets $\check{E}_k = \times_{l \in \mathcal{L}} \check{E}_{k,l} \subset \mathbb{R}_+^L$, $k \geq 0$, such that $\hat{F}(\check{E}_k) \subset \mathrm{int}(\check{E}_{k+1}) \subset \check{E}_{k+1} \subset \mathrm{int}(\check{E}_k)$ and $\cap_{k \geq 0} \check{E}_k = \{\overline{\eta}^\star\}$; i.e., the map $\hat{F}$ is stable with a domain of attraction $\check{E}_0$.

We state the following theorem. The proof is provided in [17] due to a space constraint. The basic idea of the proof is essentially identical to that of Theorem 4.1 and is a modification of the proof of Theorem 4 in [30].

THEOREM 4.2. *All solutions* $\overline{\eta}(t;\phi)$ *of* (4.5) *starting with initial function* $\phi \in Y_{\check{E}_0}$ *converge to* $\overline{\eta}^\star$ *as* $t \to \infty$ *for all* $T > 0$.

Theorem 4.2 tells us that if $\check{E}_0$ is a region of attraction of the map $\hat{F}$ in (4.6), then the resource prices under the delay differential system in (4.5) with a homogeneous delay converge, provided that the initial function lies in $\check{E}_0$. It is easy to show that the same sequence of closed, convex sets $\check{E}_k$, $k \geq 0$, in Assumption 5 also satisfies Assumption 4. This follows from the assumed monotonicity properties of the functions q_l and D_i stated in Assumption 3. This in turn implies that the resource prices under the delay differential system in (4.3) converge if the initial function lies in $\check{E}_0$. Hence, the stability of the map $\hat{F}$ is a *sufficient* condition for convergence of resource prices under (4.3) with arbitrary communication delays.

5. Example utility and resource price functions. In this section we adopt a family of well-known users' utility functions and resource price functions studied in [30, 33] and derive a condition for convergence with arbitrary gains κ_l and delays, making use of our results in sections 3 and 4. Users' utility functions are of the following form:

$$U_a(x) = \begin{cases} \frac{1}{a}x^a, & -\infty < a < 1,\ a \neq 0, \\ \log(x), & a = 0. \end{cases} \tag{5.1}$$

In particular, $a = -1$ has been found useful for modeling the utility function of TCP-like algorithms [15]. With the utility functions of the form in (5.1), user i's price elasticity of demand[9] is given by $-1/(1-a)$. Thus, one can see that users become more elastic or responsive with increasing value of a [30]; i.e., the sensitivity of user demand, $1/(1-a)$, increases with a. Since the utility function $U_a(x)$ is strictly concave with $\lim_{x \downarrow 0} U'_a(x) = \infty$ and $\lim_{x \uparrow \infty} U'_a(x) = 0$, the demand function $D_a(\mu)$ is well defined for all $\mu \in \mathbb{R}_+$ and is given by

$$D_a(\mu) = \mu^{-1/(1-a)}. \tag{5.2}$$

The class of resource price functions that we are interested in has the form

$$p(x) = q^{-1}(x) = c \cdot \left(\frac{x}{C}\right)^b, \qquad x \in \overline{\mathbb{R}}_+, \tag{5.3}$$

where $b > 0$, c is some positive constant, and C is the capacity of the resource. However, C can be replaced by a virtual capacity, typically smaller than the real capacity. The use of virtual capacity was first proposed in [6] to reduce packet losses due to buffer overflow at highly utilized resources, at the expense of slightly reduced utilization. Kunniyur and Srikant in [16] proposed dynamically adjusting the virtual capacity and consequently the resource price function, based on the current aggregate rate seen at the resource. The value of c does not affect our convergence results and is assumed to be one unless stated otherwise. From (5.3), the function q is given by

$$q(\mu) = C \cdot \mu^{1/b}, \qquad \mu \in \overline{\mathbb{R}}_+. \tag{5.4}$$

[9] Price elasticity of demand measures the sensitivity of a user's demand to price changes and is defined to be $\frac{\mu}{D(\mu)} \frac{dD(\mu)}{d\mu}$, where $D(\mu)$ is the demand of the user at the price μ.

The parameter b is used to change the shape of the price function. The larger b is, the more convex and responsive the price function is. It is easy to verify that user demand function D_a in (5.2) and resource expected rate function q in (5.4) satisfy the assumptions in sections 3 and 4.

5.1. A single user, single resource case. Suppose that the utility function of the user is given by $U_a(x)$, $a < 1$, and $q(\mu)$ is of the form in (5.4) for some parameter $b > 0$.

Assumption 6. Suppose that $a + b < 1$.

Let σ be a constant that satisfies $\frac{b}{1-a} < \sigma < 1$. Since $a + b < 1$, it is easy to see that one can find such an σ. Fix $\overline{\alpha} > 1$ and choose $\overline{\beta} < 1$ that satisfies

$$\overline{\alpha}^{-\frac{(1-a)}{b}} < \overline{\beta} < \overline{\alpha}^{-\frac{b}{1-a}}. \tag{5.5}$$

Again, the existence of such a $\overline{\beta}$ is guaranteed from the assumption that $\overline{\alpha} > 1$ and $\frac{b}{1-a} < 1$.

Define a sequence of compact intervals I_k, $k \geq 0$, given by

$$I_k = \begin{cases} [\overline{\beta}^{\sigma^k} \mu^\star,\ \overline{\alpha}^{\sigma^k} \mu^\star] & \text{if } k \text{ is even,} \\ [\overline{\alpha}^{-\sigma^k} \mu^\star,\ \overline{\beta}^{-\sigma^k} \mu^\star] & \text{if } k \text{ is odd,} \end{cases} \tag{5.6}$$

where $\mu^\star$ is the unique solution to (2.7) and is given by $C^{-b(1-a)/(1+b-a)}$. Note that since $0 < \sigma < 1$, $\sigma^k \to 0$ and the interval I_k decreases to $\{\mu^\star\}$ as $k \to \infty$.

We define a map $\overline{F} : \overline{\mathbb{R}}_+ \to \overline{\mathbb{R}}_+ \cup \{\infty\}$, where $\overline{F}(\mu) = q^{-1}(D_a(\mu))$.

LEMMA 5.1. *If Assumption* 6 *holds, then we have*

$$\overline{F}(I_k) \subset \text{int}(I_{k+1}) \subset I_{k+1} \subset \text{int}(I_k) \qquad \forall\ k \geq 0.$$

Proof. A proof is provided in Appendix C. □

THEOREM 5.2. *Suppose that $a + b < 1$ and the initial function $\phi \in C([-T, 0],$ $I_0 = [\overline{\beta}\mu^\star, \overline{\alpha}\mu^\star])$ with any $\overline{\alpha} > 1$ and $\overline{\beta} < 1$ satisfying* (5.5). *Then the solution $\mu(t; \phi)$ of* (3.13) *converges to $\mu^\star$ as $t \to \infty$.*

Proof. The theorem follows directly from Theorem 3.2 and Lemma 5.1. □

Note that as $\overline{\alpha} \uparrow \infty$, $\overline{\beta} \downarrow 0$. Since the above is true for any arbitrary $\overline{\alpha} > 1$ and $\overline{\beta}$ that satisfies (5.5), the resource price $\mu(t)$ converges to $\mu^\star$ starting from any arbitrary positive value because I_0 can be made large enough to contain the initial function.

We now show that if $a + b > 1$, then the system is unstable for sufficiently large T. Note that the map $\check{F}$ is given by

$$\check{F}(\eta) = D_a(q^{-1}(\eta)) = C^{b/(1-a)} \eta^{-b/(1-a)}.$$

Hence,

$$\check{F}'(\eta)\Big|_{\eta=\eta^\star} = \frac{-b \cdot C^{b/(1-a)}}{1-a} (\eta^\star)^{-(1+\frac{b}{1-a})}.$$

Here the fixed or equilibrium point $\eta^\star$ is given by $C^{b/(1+b-a)}$. Substituting this for $\eta^\star$ we obtain

$$\check{F}'(\eta)\Big|_{\eta=\eta^\star} = \frac{-b}{1-a}.$$

Therefore, if $a + b > 1$, then $\check{F}'(\eta^\star) < -1$ and the system is unstable for sufficiently large T from the linear stability analysis in subsection 3.4. A numerical example illustrating this is provided in subsection 6.2.

5.2. General network with multiple heterogeneous users case. Suppose that the utility functions of the users are of the form given by (5.1) and the resource price functions are of the type described by (5.3). The utility function of user i is parametrized by $a_i \in (-\infty, 1)$, and the price function of resource l has parameter $b_l > 0$. Making use of the fact stated in subsection 4.3 that the stability of the map $\hat{F}$ defined in (4.6) is sufficient for convergence with both a homogeneous delay and heterogeneous delays, we consider only the case described in subsection 4.3 with a homogeneous delay T in the reverse path only. In this case the map $\hat{F}$ is given by

$$\hat{F}_l(\overline{\eta}) = \sum_{i\in I_l} \left(\sum_{j \in r_i} \left(\frac{\eta_j}{C_j} \right)^{b_j} \right)^{-\frac{1}{1-a_i}}, \qquad l \in \mathcal{L}. \tag{5.7}$$

Note that $\hat{F}_l(\overline{\eta})$ is strictly decreasing in each of η_j, $j \in \cup_{i\in I_l} r_i$.

We define $b^i_{max} = \max_{l\in r_i} b_l$ for all $i \in \mathcal{I}$. Fix some finite positive constant $\overline{\alpha}$ larger than one. Suppose that $E_0 = \times_{l\in\mathcal{L}} E^l_0$, where $E^l_0 = [\overline{\beta}\eta^\star_l, \overline{\alpha}\eta^\star_l]$, with $\overline{\beta}$ being a positive constant that satisfies the following componentwise inequalities:

$$\hat{F}(\overline{\beta}\cdot\overline{\eta}^\star) < \overline{\alpha}\cdot\overline{\eta}^\star \quad \text{and} \quad \overline{\beta}\cdot\overline{\eta}^\star < \hat{F}(\overline{\alpha}\cdot\overline{\eta}^\star). \tag{5.8}$$

LEMMA 5.3. *Suppose that $a_i + b^i_{max} < 1$ for all $i \in \mathcal{I}$. Define $\sigma = -\max_{i\in\mathcal{I}} \left\{ \frac{b^i_{max}}{1-a_i} \right\} - \varepsilon$, where $0 < \varepsilon < 1 - \max_{i\in\mathcal{I}} \frac{b^i_{max}}{1-a_i}$. Then any $\overline{\beta}$ such that $\overline{\alpha}^{1/\sigma} < \overline{\beta} < \overline{\alpha}^\sigma$ satisfies* (5.8).

Proof. The proof is given in Appendix D of [17] due to a space constraint. □

We assume that $\overline{\beta}$ satisfies the condition in Lemma 5.3. Now, for $k = 1, 2, \ldots,$ we define

$$E_k = \begin{cases} \prod_{l\in\mathcal{L}} [\overline{\alpha}^{\sigma^k}\eta^\star_l \ , \ \overline{\beta}^{\sigma^k}\eta^\star_l], & k \text{ odd}, \\ \prod_{l\in\mathcal{L}} [\overline{\beta}^{\sigma^k}\eta^\star_i \ , \ \overline{\alpha}^{\sigma^k}\eta^\star_l], & k \text{ even}. \end{cases}$$

LEMMA 5.4. *Suppose that $a_i + b^i_{max} < 1$ for all $i \in \mathcal{I}$. Then $\hat{F}(E_{k-1}) \subset \text{int}(E_k) \subset E_k \subset \text{int}(E_{k-1})$, and $\cap_{k=0}^\infty E_k = \{\overline{\eta}^\star\}$.*

Proof. The proof is provided in Appendix E of [17] due to a space constraint. □

THEOREM 5.5. *Suppose that $a_i + b^i_{max} < 1$ for all $i \in \mathcal{I}$. If the initial function ϕ lies in $C([-T, 0], E_0)$, then $\overline{\eta}(t;\phi)$ produced by* (4.5) *converges to $\overline{\eta}^\star$ as $t \to \infty$ for all $T > 0$ and $\kappa_l > 0$, $l \in \mathcal{L}$.*

Proof. The theorem follows from Lemma 5.4 and Theorem 4.2. □

Now note that as $\overline{\alpha} \uparrow \infty$, $\hat{F}(\overline{\alpha}\cdot\overline{\eta}^\star) \to \underline{0} = [0, \ldots, 0]^T$. Hence, we can see that starting from any positive continuous initial function, the resource prices converge to $\overline{\mu}^\star$ as $t \to \infty$ from the above results because we can select a sufficiently large $E_0 \subset \mathbb{R}^L_+$ that contains the initial function.

5.3. Comparison with the primal algorithm. In this subsection we comment on the difference in the conditions for convergence under the primal algorithm [29, 30] and the dual algorithm studied in this paper. The convergence condition of the primal algorithm with a single user and a single resource is first studied in [29], and a necessary and sufficient condition for convergence with an arbitrary delay using the utility and resource price functions of (5.1) and (5.3) is provided. The derived convergence condition states that the user rate converges if and only if $a + b < -1$.[10]

[10] In [29] we considered only the utility functions with $a < 0$ because when $a \geq 0$ the system is unstable for sufficiently large delays.

Since $b > 0$, this implies that the parameter of the utility function needs to be strictly smaller than -1. Clearly, this is a more restrictive condition than the one provided for the dual algorithm in this paper (i.e., $(a + b < 1)$, which allows positive values of a for $b < 1$).

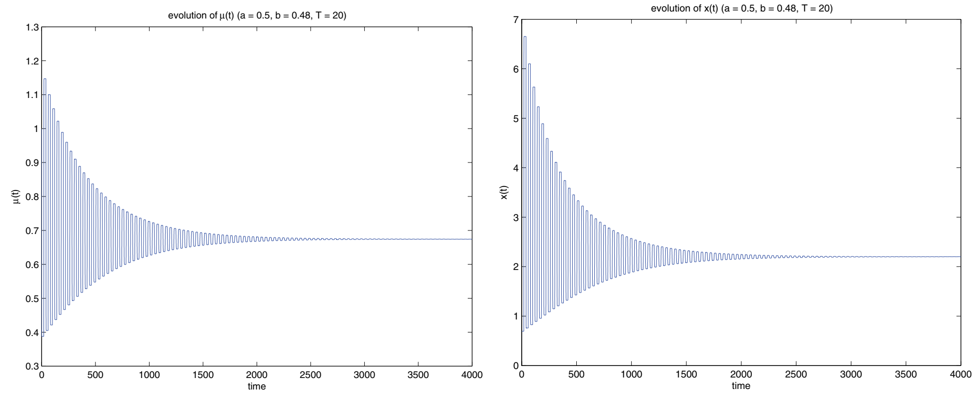
Similarly, in a general network case the sufficient conditions for convergence under the primal algorithm are given by $a_i + b^i_{max} < -1$ for all $i \in \mathcal{I}$ [30, 33], whereas the conditions that $a_i + b^i_{max} < 1$ for all $i \in \mathcal{I}$ suffice in the dual algorithm. Hence, the derived sufficient conditions for the primal algorithm in [30, 33] are more restrictive than those for the dual algorithm.

6. Numerical result.

In this section we present a numerical example to validate our results in the previous sections. We consider a single user, single resource case with the utility and resource price functions given in section 5 with $a = 0.5$. The capacity of the resource is set to $C = 5$. We vary the resource price function parameter b to create both a stable scenario and an unstable scenario according to our condition in Theorem 5.2.

6.1. Stable system.

In the first case we set $b = 0.49$. Since $a + b = 0.99 < 1$, Theorem 5.2 tells us that the resource price and user rate converge irrespective of the gain κ and the delay T. For the numerical example the delay is set to $T = 200$ and the gain is set to $\kappa = 1$. The initial value $\mu(t)$ is set to 1.2 for all $t \in [-T, 0]$. The evolution of $\mu(t)$ and $x(t)$ is plotted in Figure 6.1. As one can see both $\mu(t)$ and $x(t)$ converge to their equilibrium values of 0.6715 and 2.218, respectively.



(a) (b)

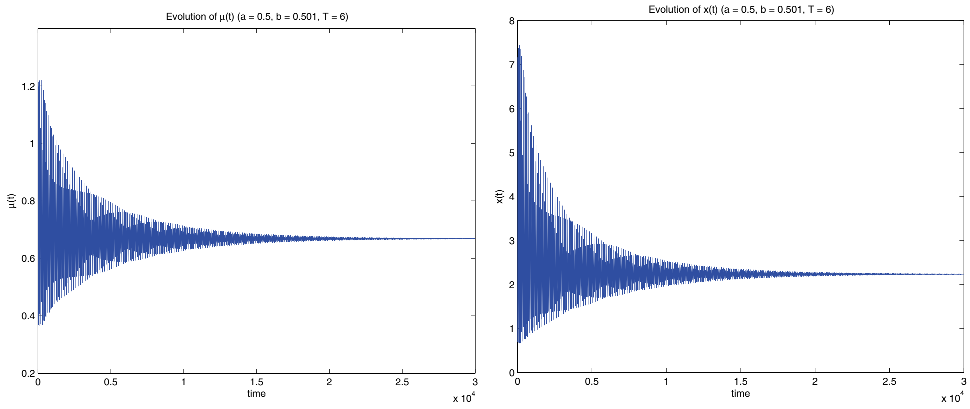
FIG. 6.1. *Evolution of $\mu(t)$ and $x(t)$ ($a = 0.5$, $b = 0.49$, $T = 200$).* (a) $\mu(t)$, (b) $x(t)$.

6.2. Unstable system.

In the second example we have increased the resource price function parameter b to 0.501. Since $a + b = 1.001 > 1$, the system loses its stability for sufficiently large delay T. The linear stability analysis provided in subsection 3.4 tells us that the linearized system in (3.14) is stable if and only if

$$T \leq \frac{\cos^{-1}\left((\check{F}'(\eta^\star))^{-1}\right)}{\zeta(\eta^\star)\sqrt{(\check{F}'(\eta^\star))^2 - 1}} = 7.28.$$

Figures 6.2 and 6.3 plot the evolution of $\mu(t)$ and $x(t)$ for $T = 6$ and $T = 10$, respectively, sampled at every 20 unit times. As one can easily see, the system with



(a) (b)

FIG. 6.3. *Evolution of* $\mu(t)$ *and* $x(t)$ *(*$a = 0.5$*,* $b = 0.501$*,* $T = 10$*).* (a) $\mu(t)$, (b) $x(t)$.

$T = 6$ is stable, and $\mu(t)$ and $x(t)$ converge to the equilibrium points of 0.6685 and 2.2379, respectively. However, when the delay T is increased to 10, the system loses stability and exhibits oscillatory behavior, as shown in Figure 6.3.

7. Conclusions.

We studied the issue of convergence of user rates and resource prices under a dual algorithm in the presence of communication delays. Using the same framework first employed in [30] for the primal algorithm, we derived sufficient conditions for convergence with arbitrary delays. In addition, we showed that these sufficient conditions can be obtained from a simple underlying discrete time system. We applied our result to an example of popular utility and resource price functions and derived sufficient conditions for convergence. In the simpler case of a single user utilizing a resource, we derived the necessary and sufficient condition for convergence. In addition, we studied the case when the convergence condition is violated and, using a linear stability analysis, provided an upper bound on the delay for convergence. Numerical examples are presented to validate our analysis. We believe that the framework used in this paper as well as in [30] is quite general and will prove to be useful for studying the convergence property of a variety of distributed control systems, in particular in the context of networking and networked control systems.

Appendix A. Proof of Theorem 3.1. The proof of the theorem is based on the following lemma.

Lemma A.1 (see [7, p. 507]). *Suppose that $I^\star = [a^\star, b^\star] \subset \mathbb{R}$, where $a^\star < b^\star$, is a compact interval and $\xi : \overline{\mathbb{R}}_+ \to I^\star$ is a continuous function. If $\sigma : \overline{\mathbb{R}}_+ \to \mathbb{R}_+$ is a bounded, continuous, strictly positive function and $u(t)$ is a solution of equation*

$$\sigma(t)\dot{u}(t) + u(t) = \xi(t), \tag{A.1}$$

with $u(0) \in I^\star$, then $u(t) \in I^\star$ for all $t \geq 0$.

Proof. The existence of a unique solution of (A.1) is guaranteed by the theorem in [28, p. 74]. We will prove this lemma by contradiction. Suppose that the lemma is not true. Define

$$t_0 = \inf\{t \geq 0 \mid u(t) \notin I^\star\}.$$

First, suppose that $u(t_0) = b^\star$. Then every interval $(t_0, t_0 + \delta)$, $\delta > 0$, contains a point τ such that $u(\tau) > b^\star$ and $\dot{u}(\tau) > 0$ under the assumption $a^\star < b^\star$ stated in the lemma. However, if $u(\tau) > b^\star$, (A.1) tells us that $\dot{u}(\tau) < 0$ because $\xi(t) \leq b^\star$, which is a contradiction. The case $u(t_0) = a^\star$ can be shown to lead to a similar contradiction. This completes the proof. □

We proceed with the proof of Theorem 3.1. Apply Lemma A.1 to $\frac{d}{dt}\omega_0(t) = -\alpha\omega_0(t) + \alpha\check{F}(\eta(t - T))$. Clearly, if $\omega_0(0) \in J$ and initial function $\phi \in Y_J$, then $\omega_0(t) \in J$ for all $0 \leq t \leq T$. By applying Lemma A.1 to $\frac{d}{dt}\omega_1(t) = -\alpha\omega_1(t) + \alpha\omega_0(t)$, we can argue that $\omega_1(t) \in J$ for all $0 \leq t \leq T$. Following this recursive argument, we can show that $\omega_i(t) \in J$ for $i = 0, \ldots, r$ and $\eta(t) \in J$ for all $0 \leq t \leq T$. Now by an induction argument on time (called the method of steps [5]) the same can be argued for all $t \geq 0$.

Appendix B. Proof of Theorem 3.2. The proof of the theorem is a simple application of the following lemma.

Lemma B.1. *Consider the same setup in Lemma* A.1. *Assume that $\bar{I} = [\bar{a}, \bar{b}]$ is a compact interval whose interior contains $I^\star$, i.e., $I^\star \subset \mathrm{int}(\bar{I})$. Then, for any $u(0) = u_0 \in \mathbb{R}_+$, there exists finite $t_0 := t_0(u_0, \bar{I})$ such that $u(t) \in \bar{I}$ for all $t \geq t_0$.*

Proof. First, note that if $u(t^*) \in \bar{I}$ for some $t^* \geq 0$, then from Lemma A.1 $u(t) \in \bar{I}$ for all $t \geq t^*$. Thus, we need only show that there exists some finite t_0 such that $u(t_0) \in \bar{I}$. Suppose that this is not true. First, assume that $u(t) > \bar{b}$ for all $t \geq 0$. Then from (A.1) we have $\dot{u}(t) = \frac{\xi(t) - u(t)}{\sigma(t)} \leq \frac{b^\star - \bar{b}}{\sigma(t)}$. Since $\sigma(t)$ is bounded, we can find a positive ε such that $\dot{u}(t) \leq -\varepsilon$ for all $t \geq 0$. However, this implies that $u(t) \downarrow -\infty$, which contradicts the assumption that $u(t) > \bar{b}$ for all $t \geq 0$. The other case, $u(t) < \bar{a}$ for all $t \geq 0$, can be shown to lead to a similar contradiction, and the lemma follows. □

We now proceed with the proof of the theorem. First, since $\check{F}(J_0) \subset \mathrm{int}(J_1)$, we can find a set of compact intervals $\{L_1^i,\, i = 0, \ldots, r\}$ such that

$$\check{F}(J_0) \subset \mathrm{int}(L_1^0) \subset L_1^0 \subset \mathrm{int}(L_1^1) \subset \cdots \subset \mathrm{int}(L_1^r) \subset L_1^r \subset \mathrm{int}(J_1). \tag{B.1}$$

Using the property in (B.1), we can repeatedly apply Lemma B.1, starting with the third equation in (3.12) for $\omega_0(t)$ and then the second equation with $\omega_i(t)$, $i = 1, \ldots, r$, to find finite t_1^i, $i = 0, \ldots, r$, where $0 \leq t_1^0 \leq t_1^1 \leq \cdots \leq t_1^r$, such that $\omega_i(t) \in L_1^i$ for all

$t \geq t_1^i$. Finally, applying Lemma B.1 to the first equation in (3.12) we can find finite $t_1^\star \geq t_1^r$ such that $\eta(t) \in J_1$ for all $t \geq t_1^\star$.

Now, by an induction argument for each $k = 2, 3, \dots$, one can find an increasing sequence $t_k^\star$, $k = 1, 2, \dots$, such that, for all $t \geq t_k^\star$, $\eta(t) \in J_k$ and $\omega_i(t) \in J_k$, $i = 0, 1, \dots, r$. Now the theorem follows from the assumption that $\mathrm{diam}(J_k) \to 0$ as $k \to \infty$ and $\cap_{k \geq 1} J_k = \{q_N(\mu^\star)\}$.

Appendix C. Proof of Lemma 5.1. In this proof we consider only the case of even k. Proof for the case with odd k follows in a similar manner. From the monotonicity of the map $\overline{F}(\mu) = C^{-b}\mu^{-b/(1-a)}$, it suffices to show that $\overline{F}(\overline{\beta}^{\sigma^k}\mu^\star) \in I_{k+1}$ and $\overline{F}(\overline{\alpha}^{\sigma^k}\mu^\star) \in I_{k+1}$.

First,

$$\begin{aligned}\overline{F}(\overline{\alpha}^{\sigma^k}\mu^\star) &= C^{-b}(\overline{\alpha}^{\sigma^k}\mu^\star)^{-b/(1-a)} = C^{-b}\mu^{\star -b/(1-a)}\overline{\alpha}^{\sigma^k(-b/(1-a))}\\ &= \mu^\star\overline{\alpha}^{\sigma^k(-b/(1-a))} > \mu^\star\overline{\alpha}^{-\sigma^{k+1}},\end{aligned}$$

where the last equality follows from the fact that $\mu^\star$ is a fixed point of the map $\overline{F}$, and the inequality follows from the assumption that $0 < \frac{b}{1-a} < \sigma < 1$ and $\overline{\alpha} > 1$. Clearly, $\mu^\star\overline{\alpha}^{\sigma^k(-b/(1-a))} < \mu^\star < \mu^\star\overline{\beta}^{-\sigma^{k+1}}$ because $\overline{\beta} < 1 < \overline{\alpha}$.

Similarly,

$$\begin{aligned}\overline{F}(\overline{\beta}^{\sigma^k}\mu^\star) &= C^{-b}(\overline{\beta}^{\sigma^k}\mu^\star)^{-b/(1-a)} = C^{-b}\mu^{\star -b/(1-a)}\overline{\beta}^{\sigma^k(-b/(1-a))}\\ &= \mu^\star\overline{\beta}^{\sigma^k(-b/(1-a))} < \mu^\star\overline{\beta}^{-\sigma^{k+1}}.\end{aligned}$$

Therefore, $\overline{F}(I_k) \subset \mathrm{int}(I_{k+1})$, and the lemma follows.

ANALYTICAL APPROXIMATION FOR THE GENERALIZED LAPLACE EQUATION WITH STEP FUNCTION COEFFICIENT[*]

R. F. SVIERCOSKI[†], C. L. WINTER[‡], AND A. W. WARRICK[§]

Abstract. Many problems in science and engineering require the solution of the steady-state diffusion equation with a highly oscillatory coefficient. In this paper, we propose an analytical approximation $\tilde{u}(x) \in L^p(\Omega)$, $1 \leq p \leq \infty$, for the generalized Laplace equation $\nabla \cdot (K(x) \nabla u(x)) = 0$ in $\Omega \subset R^n$, with prescribed boundary conditions and the coefficient function $K(x) \in L^p(\Omega)$ defined as a step function, not necessarily periodic. The proposed solution can be regarded as an approximation to the weak solution belonging to $W^{1,p}(\Omega)$, the Sobolev space. When the coefficient function describes inclusions in a main matrix, then $K(x)$ is a periodic function, and such formulation leads to an approximation, in $L^p(\Omega)$, to the solution of the periodic cell-problem, $\nabla \cdot (K(\varepsilon^{-1}x)\nabla \mathbf{w}(\varepsilon^{-1}x)) = \nabla \cdot (K(\varepsilon^{-1}x)\mathbf{1})$. The solution to the cell-problem is the key information needed to obtain the upscaled coefficient and therefore the zeroth-order approximation for a generalized elliptic equation with highly oscillating coefficient in $\Omega \subset R^n$. Our numerical computation of the error between the proposed analytical approximation for the cell-problem, $\tilde{w}(\varepsilon^{-1}x)$ in $L^p(\Omega)$, and the solution $w(\varepsilon^{-1}x)$ in $W^{1,2}(\Omega)$, demonstrates to converge in the L^2-norm, when the scale parameter ε approaches zero. The proposed approximation leads to the lower bound of the generalized Voigt–Reiss inequality, which is a more accurate two-sided estimate than the classical Voigt–Reiss inequality. As an application, we compute our approximate value for the homogenized coefficient when the heterogeneous coefficients are inclusions such as squares, circles, and lozenges, and we demonstrate that the results underestimate the effective coefficient with an error of 10% on average, when compared with published numerical results.

Key words. Laplace's equation, L^p-approximation, homogenization, cell-problem, generalized Voigt–Reiss inequality

1. Introduction.

A major problem in natural porous media is providing an accurate description of the flow's behavior, given the intrinsic heterogeneity of geological formations. By specifying the flow over the boundary of the given domain Ω, one way of quantifying the steady-state flow behavior in such a medium is by computing the solution $u(x) \in W^{1,p}(\Omega)$ of the generalized Laplace equation:

$$\nabla \cdot (K(x) \nabla u) = 0 \quad \text{in} \quad \Omega, \tag{1.1}$$

where the coefficient function $K(x)$ describes the heterogeneity of the medium over Ω. In this paper, we study the case when the coefficient belongs to $L^p(\Omega)$, $1 \leq p \leq \infty$, and can be described as the step function

$$K(x) = \begin{cases} \xi_1 & \text{if } x \in \Omega_c, \\ \xi_2 & \text{if } x \in \Omega \backslash \Omega_c \end{cases} \tag{1.2}$$

and when (1.1) has some particular prescribed boundary conditions, depending on whether Ω_c is defined such that $K(x)$ is either a nonperiodic or a periodic function.

The first goal of this paper is to develop an analytical approximation $\tilde{u}(x) \in L^p(\Omega)$, $1 \leq p \leq \infty$, to the weak solution $u(x) \in W^{1,p}(\Omega)$ of the boundary value problem (BVP) (1.1), when the coefficient $K(x)$ is given as (1.2). By considering (1.2) an ε-periodic function, $K\left(\varepsilon^{-1}x\right)$, and using $\tilde{u}(\varepsilon^{-1}x) \in L^p(\Omega)$, satisfying (1.1) almost everywhere (a.e.), the second goal is to propose an analytical approximate value for the homogenized coefficient, $\tilde{K}^0$, and therefore an approximation as $\varepsilon \to 0$, for the zeroth-order solution of the generalized BVP:

$$\left\{ \begin{aligned} \nabla \cdot \left(K\left(\varepsilon^{-1}x\right) \nabla u\left(\varepsilon^{-1}x\right)\right) &= f(x) \qquad \text{in} \quad \Omega, \\ u\left(\varepsilon^{-1}x\right) &= g(x), \qquad x \in \partial\Omega. \end{aligned} \right. \tag{1.3}$$

We present an approximation and its properties without discussing its uniqueness, as this is a subject that requires mathematical tools beyond the scope of this paper.

It is expected that a solution to (1.1) will depend on the type and smoothness of the coefficient function. In the n-dimensions, for particular types of coefficient and boundary conditions, analytical solutions for this problem are known. The solutions follow for the cases when $K(x)$ is a separable function $K(x) = \prod_{i=1}^n k_i\left(x_i\right)$ and when $K(x)$ describes a layered medium in one of the directions. By allowing the coefficient (1.2), it may happen that the solution and its gradient are not differentiable. Then one needs the definition of a weak solution, where (1.1) is replaced by its variational formulation, namely

$$\left\{ \begin{array}{c} \text{Find} \quad u \in W^{1,p} \quad \text{such that} \\ \int_\Omega K(x) \nabla u \nabla v dx = 0 \qquad \forall\, v \in W^{1,q}, \end{array} \right. \tag{1.4}$$

where $W^{1,p}$ is the appropriate Sobolev space taking into account the boundary conditions, and such that $1/p + 1/q = 1$. Existence and uniqueness of the weak solution, under the condition that $K(x)$ is an elliptic and bounded operator, follow from the Lax–Milgram theorem (see [6], for example).

Equations (1.1)–(1.4) have a wide application in mathematics, physics, and engineering. For example, in water flow systems, $u(x)$ is the hydraulic head, $K(x)$ is the hydraulic conductivity, and the flux is defined from Darcy's law $q = -K(x)\nabla u(x)$; for solute diffusion, Fick's law follows the same formulation with $u(x)$ a concentration and $K(x)$ the diffusion coefficient. Other analogous systems can be found, for example, in Warrick [18]. The reader can further refer to Gilbarg and Trudinger [6] for the mathematical formalism and the respective historical contributions. For the applications of (1.1)–(1.4) to flow and transport in porous media, one can consult references such as Bear [2] and Warrick [18].

The approximation to (1.3) is, on its own, a major problem in the subject of multiscale analysis and therefore in many areas of applied mathematics. In particular, this is so in porous media when $K^\varepsilon(x)$ characterizes a periodic inclusion, with size l, in a main matrix with size L and $\varepsilon = l/L$ defining the period. In such a case, the analysis follows by considering the coefficient defined in $\Omega = \bigcup \Omega^\varepsilon$ so that over each Ω^ε one has the step function

$$K\left(\varepsilon^{-1}x\right) = \left\{ \begin{array}{ll} \xi_1 & \text{if } x \in \Omega_c^\varepsilon, \\ \xi_2 & \text{if } x \in \Omega^\varepsilon \backslash \Omega_c^\varepsilon. \end{array} \right. \tag{1.5}$$

In such a context, one proposes that the solution to (1.3) can be approximated by the two-scale asymptotic expansion

$$u\left(\varepsilon^{-1}x\right) = u^0\left(x, \varepsilon^{-1}x\right) + \varepsilon u^1\left(x, \varepsilon^{-1}x\right) + \varepsilon^2 u^2\left(x, \varepsilon^{-1}x\right) + \cdots . \tag{1.6}$$

The question becomes how to obtain the terms in such an expansion and, in particular, the zeroth-order approximation $u^0\left(x, \varepsilon^{-1}x\right)$. The zeroth-order term describes the averaged or macroscopic behavior of the flow, whereas the other terms add microscopic features to the approximation. This is the main scope of homogenization theory. To find $u^0(x, \varepsilon^{-1}x)$ one needs to obtain the homogenized or effective coefficient K^0, which can be accomplished by solving, say for a given ε, the cell-problem

$$\left\{ \begin{array}{lr} \nabla \cdot (K\left(x\right) \nabla \mathbf{w}\left(x\right)) = -\nabla \cdot \left(K\left(x\right) \nabla \mathbf{x}\right) & \text{in} \quad \Omega = (0,1)^n, \\ \mathbf{w}(x) = \sum_{i=1}^n w_i(x), & x \in \partial\Omega, \end{array} \right. \tag{1.7}$$

where $\mathbf{x} = \sum_{i=1}^n x_i$ and $x_i = x \cdot e_i$, with $x = (x_1, x_2, \ldots, x_n)$.

Note that (1.7) is a particular case of (1.1), by setting $u = \mathbf{w} + \mathbf{x}$.

Historical works in homogenization theory include Tartar [17], Keller [8], [9], Bensoussan, Lions, and Papanicolau [3], and Sanchez-Palencia [13]. A complete review of homogenization theory and its application, including the cases of random coefficients, has been compiled in Jikov, Kozlov, and Oleinik [7]. There is also a vast literature on obtaining the effective coefficient by other methods; for example, in Milton [10] one can follow a thorough review and application to a variety of phenomena in composite media. The work by Renard and De Marsily [12] contains a review specifically for upscaling Darcy's law.

We follow the convention that the analytical approximations to (1.1) and (1.7) have the symbol $\tilde{u}$, in contrast to the true solution. In addition, an analytical approximation in L^p means that it solves the respective equation a.e. The results are constrained neither to the periodicity of the coefficient nor to $\Omega = [0,1]^n$, as can be verified shortly.

The presentation is outlined as follows: In section 2, we first look for the approximation $\tilde{w}(x) \in L^p(\Omega)$ to the BVP (1.7), which is obtained by the superposition of $\tilde{w}_i(x) \in L^p(\Omega)$ for each $i = 1, \ldots, n$ and $\partial\Omega = \bigcup_{i=1}^n \Gamma_i$, the approximate solution of the BVP

$$\left\{ \begin{array}{lr} \nabla \cdot \left(K\left(x\right) \nabla w_i\left(x\right)\right) = -\nabla \cdot \left(K\left(x\right) e_i\right) & \text{in} \quad \Omega, \\ w_i\left(x\right) = 0, & x \in \Gamma_i. \end{array} \right. \tag{1.8}$$

In section 3, we consider the case when $K(x)$ is periodic, leading (1.7) and (1.8) to be periodic BVPs. In this case, some properties of interest in homogenization theory are obtained. In section 4, we apply the results to the homogenization and analyze the numerical convergence between our solution in L^2 and the numerical solution in H_0^1 for particular shapes of interest in porous media applications. We also compute the approximate value for the effective coefficient and compare it with some numerical values reported in the literature for inclusions such as squares, circles, and lozenges. This comparison demonstrates an error of about 10% on average.

2. Approximate solutions.

Throughout this section, we consider the two-dimensional version of BVP (1.8), without loss of generality.

THEOREM 2.1. *Let $K(x)$ be defined as in* (1.2) *with e_1 the unit vector in R^2. If $\tilde{w}_1(x_1, x_2) \in L^p(\Omega)$, $i = 1, 2$, can be written as the product $\tilde{w}_1(x_1, x_2) = f_1(x_1, x_2) f_2(x_2)$ for $f_1(x)$, a linear function on x_1, and some $f_2(x_2)$, then the expression*

$$\tilde{w}_1\left(x\right) = \int_0^{x_1} \frac{d\tau}{K\left(\tau, x_2\right)} \left(\int_0^1 \frac{d\tau}{K\left(\tau, x_2\right)}\right)^{-1} - x_1 \tag{2.1}$$

satisfies the BVP

$$\begin{cases} \nabla \cdot (K(x)\, \nabla \tilde{w}_1(x)) = -\nabla \cdot (K(x)\, e_1) & \textit{in} \quad \Omega = (0,1)^2, \\ \tilde{w}_1(x) = 0, & x \in \Gamma_1, \end{cases} \tag{2.2}$$

a.e. in Ω.

Proof. ($\Rightarrow$) Suppose that $\tilde{w}_1(x)$ can be written as $\tilde{w}_1(x) = f_1(x_1, x_2)\, f_2(x_2)$. The boundary conditions on f_1 and f_2 on the $x_1 = 0$ and $x_1 = 1$ faces of Ω will be such that

$$\tilde{w}_1(0, x_2) = f_1(0, x_2)\, f_2(x_2) = \tilde{w}_1(1, x_2) = f_1(1, x_2)\, f_2(x_2) = 0$$

$$\Leftrightarrow f_1(0, x_2) = f_1(1, x_2) = 0$$

for all $f_2(x_2) \neq 0$. Now, we make the substitution of $\tilde{w}_1(x)$, and the equality

$$\nabla \cdot \left(K(x) \left(\frac{\partial f_1}{\partial x_1} f_2(x_2), \frac{\partial \tilde{w}_1}{\partial x_2} \right) \right) = -\nabla \cdot (K(x)\, e_1)$$

must be satisfied a.e. in Ω. The last relationship can be rearranged to give

$$\frac{\partial}{\partial x_1} \left(K(x)\, f_2(x_2) \left(\frac{\partial f_1}{\partial x_1} + \frac{1}{f_2(x_2)} \right) \right) + \frac{\partial}{\partial x_2} \left(K(x) \frac{\partial \tilde{w}_1}{\partial x_2} \right) = 0. \tag{2.3}$$

Setting the first term everywhere in Ω to zero, i.e.,

$$\frac{\partial}{\partial x_1} \left(K(x)\, f_2(x_2) \left(\frac{\partial f_1}{\partial x_1} + \frac{1}{f_2(x_2)} \right) \right) = 0, \tag{2.4}$$

and letting $v(x) = \frac{\partial f_1}{\partial x_1} + \frac{1}{f_2(x_2)}$, we have

$$\frac{\partial}{\partial x_1} (K(x)\, v(x)) = 0 \Rightarrow v(x) = \frac{h_1(x_2)}{K(x)}.$$

This implies the following:

$$\frac{\partial f_1}{\partial x_1} = \frac{h_1(x_2)}{K(x)} - \frac{1}{f_2(x_2)}. \tag{2.5}$$

Furthermore, integrating this last equation over x_1 gives

$$f_1(x_1, x_2) = \int_0^{x_1} \frac{h_1(x_2)\, d\tau}{K(\tau, x_2)} - \frac{x_1}{f_2(x_2)} + d.$$

In order to have $f_1(0, x_2) = 0$, d must be zero. Therefore

$$f_1(x_1, x_2) = \int_0^{x_1} \frac{h_1(x_2)\, d\tau}{K(\tau, x_2)} - \frac{x_1}{f_2(x_2)}. \tag{2.6}$$

The condition $f_1(1, x_2) = 0$ will be satisfied if

$$h_1(x_2) = \frac{1}{f_2(x_2) \int_0^1 \frac{1}{K(\tau, x_2)} d\tau}. \tag{2.7}$$

Now, going back to the expression for $f_1(x_1, x_2)$ above, one ends up with

$$(2.8)\quad f_1(x_1,x_2) = \frac{\int_0^{x_1} \frac{d\tau}{K(\tau,x_2)}}{f_2(x_2)\int_0^1 \frac{1}{K(\tau,x_2)}d\tau} - \frac{x_1}{f_2(x_2)} = \frac{1}{f_2(x_2)}\left[\frac{\int_0^{x_1}\frac{d\tau}{K_1(\tau,x_2)}}{\int_0^1 \frac{1}{K_1(\tau,x_2)}d\tau} - x_1\right].$$

The multiplication by $f_2(x_2)$, just now defined to be $f_2(x_2) = \left(\int_0^1 \frac{1}{K_1(\tau,x_2)}d\tau\right)^{-1}$, leads to $\tilde{w}_1(x_1,x_2)$ in (2.1), which can then be written as

$$(2.9)\quad \tilde{w}_1(x_1,x_2) = \left(\int_0^{x_1}\frac{d\tau}{K(\tau,x_2)} - x_1\int_0^1 \frac{1}{K_1(\tau,x_2)}d\tau\right)\left(\int_0^1 \frac{1}{K_1(\tau,x_2)}d\tau\right)^{-1}.$$

Note also that $f_1(x_1,x_2) = \left(\int_0^{x_1}\frac{d\tau}{K(\tau,x_2)} - x_1\int_0^1 \frac{1}{K_1(\tau,x_2)}d\tau\right)$ is indeed a linear function of x_1. To finalize, we look back at the sum (2.3), and since the first term is zero and the sum is zero a.e., it follows that the second term is zero a.e.

($\Leftarrow$) Let $\tilde{w}_1(x)$ as in (2.1) be given as

$$(2.10)\qquad \tilde{w}_1(x) = \frac{\int_0^{x_1}\frac{d\tau}{K(\tau,x_2)}}{\int_0^1 \frac{d\tau}{K(\tau,x_2)}} - x_1 = \tilde{u}_1(x) - x_1.$$

We make the substitution into (2.2) to get

$$\nabla\cdot(K(x)\nabla\tilde{w}_1(x)) = \nabla\cdot(K(x)\nabla\tilde{u}_1(x)) - \nabla\cdot(K(x)e_1) = -\nabla\cdot(K(x)e_1) \quad \text{a.e.}$$

This is true since the equation in the middle can be written as

$$(2.11)\quad \frac{\partial}{\partial x_1}\left(K(x)\frac{\partial\tilde{u}_1}{\partial x_1}\right) + \frac{\partial}{\partial x_2}\left(K(x)\frac{\partial\tilde{u}_1}{\partial x_2}\right) - \frac{\partial}{\partial x_1}(K(x)e_1) = -\frac{\partial}{\partial x_1}(K(x)e_1).$$

On the left-hand side, the first term is zero, and the second term may be extended continuously as zero, even though it is not zero at the discontinuity points of $K(x)$ in the x_2-direction, say x_2^*. The extension can be formalized as follows:

$$(2.12)\qquad \lim_{x_2\to x_2^*-}\frac{\partial\tilde{u}_1}{\partial x_2}(x) = \lim_{x_2\to x_2^*+}\frac{\partial\tilde{u}_1}{\partial x_2}(x) = 0.$$

Moreover, this is true since $K(x)$ is defined as in (1.2).

The same procedure applies to obtaining $\tilde{w}_2(x) = \tilde{u}_2(x) - x_2$, which corresponds to (2.2) in the e_2-direction. In two dimensions, one can think of $\tilde{w}_2(x)$ as the transpose of $\tilde{w}_1(x)$. □

A natural question regards the estimate of the error of this approximation, which requires us to analyze the properties of $\frac{\partial\tilde{u}_1}{\partial x_2}$, such as boundedness, and how it relates to $\frac{\partial u_1}{\partial x_2}$. One possible way to address this problem is to identify a mollifier or Green's function $\rho(x) = \rho(K(x)) \in C^\infty(\Omega)$ such that $\int_\Omega \rho(x)dx = 1$ and the convolution

$$(2.13)\qquad w_i^h(x) = h^{-n}\int_\Omega \rho_h(K(x-\zeta))\tilde{w}_i(\zeta)d\zeta$$

with $h < \text{dist}(x,\partial\Omega)$. Then $\tilde{w}_i$ converges to $w_i^h \in W^{1,p}(\Omega)$ in the sense of $L^p(\Omega)$, $p < \infty$ (see Lemma 7.2 of [6]).

However, finding $\rho(x)$ and proving (2.13) is a problem related to the uniqueness of the approximation and would require a deeper analysis beyond the present work. Instead, we present some interesting and relevant results that may be of help when addressing the problem in the future.

Illustrations of the approximation $\tilde{w}_1(x)$, comparing it with the numerical solution in $H_0^1(\Omega)$, are shown in Figures 1 and 2 by using $K(x)$ with square inclusions. Also, an illustration of the functions $\frac{\partial \tilde{u}_1}{\partial x_2}$ and $\frac{\partial \tilde{u}_2}{\partial x_1}$ is given in Figure 3 for the respective functions. Observe also that $\rho(x)$, from (2.13), would smooth out the sharp edges presented in the figures.

The generalization to $[0,1]^n \subset R^n$ follows by solving each subproblem as in (2.2). In such a case, the product form for the ith subproblem is given as $\tilde{w}_i(x) = f_i(x) f_j(x_j)$, where $f_i(x)$ is a function linear in x_i and $f_j(x_j)$ is a function of all the variables but x_i. Applying Theorem 2.1, we find that

(2.14)

$$\begin{aligned}\tilde{w}_i\left(x\right) &= \int_0^{x_i} \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)} \left(\int_0^1 \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)}\right)^{-1} - x_i = \tilde{u}_i(x) - x_i \\ &= \left[\int_0^{x_i} \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)} - x_i \int_0^1 \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)}\right] \\ &\quad \cdot \left(\int_0^1 \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)}\right)^{-1} \\ &= f_i(x) f_j(x_j)\end{aligned}$$

is the approximate solution in $L^p(\Omega)$ for $w_i(x)$, the solution to (1.8). Moreover, we have the following consequences relating the solutions of (1.8) to those of (1.7) and (1.1), for particular cases of prescribed boundary conditions.

Corollary 2.2. *Let $\tilde{w}_i(x)$ be given as* (2.14)*; then $\tilde{u}_i(x) \in L^p(\Omega)$ approximates the solution of the BVP*

$$\left\{ \begin{array}{rl} \nabla \cdot \left(K\left(x\right) \nabla u_i\left(x\right)\right) = 0 & \mathit{in} \quad \Omega = (0,1)^n, \\ u_i(x) = x_i, & x \in \partial\Omega. \end{array} \right. \tag{2.15}$$

The next results are derived by using the superposition principle.

Corollary 2.3. *Let $\tilde{w}_i(x)$ be given as* (2.14)*; then $\tilde{\mathbf{w}}(x) = \sum_{i=1}^n \tilde{w}_i(x) \in L^p(\Omega)$ approximates the solution to the BVP* (1.7).

Corollary 2.4. *Let $\tilde{w}_i(x)$ be given as* (2.14)*; then $\tilde{u}(x) = \sum_{i=1}^n \tilde{u}_i(x) \in L^p(\Omega)$ approximates the solution of the BVP*

$$\left\{ \begin{array}{rl} \nabla \cdot \left(K\left(x\right) \nabla u\left(x\right)\right) = 0 & \mathit{in} \quad \Omega = (0,1)^n, \\ u(x) = \sum_{i=1}^n x_i, & x \in \partial\Omega. \end{array} \right. \tag{2.16}$$

The integration procedure used to obtain (2.14) can be applied to general bounded rectangular domains. In particular, consider $\Omega_\varepsilon = [0,\varepsilon]^n$; then $h_1(x_j)$, $j \neq i$, in (2.7) becomes

$$h_1\left(x_j\right) = \frac{\varepsilon}{f_j\left(x_j\right) \int_0^\varepsilon \frac{1}{K(\tau, x_j)} d\tau}, \tag{2.17}$$

leading to

$$\tilde{w}_i\left(x\right) = \varepsilon \int_0^{x_i} \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)} \left(\int_0^\varepsilon \frac{d\tau}{K\left(x_1, \ldots, \tau, \ldots, x_n\right)}\right)^{-1} - x_i. \tag{2.18}$$

The x variable can be normalized to $\Omega = [0,1]^n$. The last equation then becomes

$$\tilde{w}_i^\varepsilon(x) = \varepsilon \left[\frac{\int_0^{\varepsilon^{-1}x_i} \frac{d\xi}{K(\varepsilon^{-1}x_1,\ldots,\xi,\ldots,\varepsilon^{-1}x_n)}}{\int_0^1 \frac{d\xi}{K(\varepsilon^{-1}x_1,\ldots,\xi,\ldots,\varepsilon^{-1}x_n)}} - \varepsilon^{-1}x_i \right], \tag{2.19}$$

where ε may represent the period of Ω_ε in the i-direction of Ω. One has the following result.

Corollary 2.5. *Let $\tilde{w}_i^\varepsilon(x)$ be as defined above; then*

$$\lim_{\varepsilon\to 0} \tilde{w}_i^\varepsilon(x) = 0 \quad in \quad L^p(\Omega). \tag{2.20}$$

Proof. The proof follows by the definition of $\tilde{w}_i^\varepsilon(x)$ and by noting that the ratio in brackets is a bounded function for all ε, since $x_i \le \varepsilon$. □

This result is also in agreement with the numerical $w_i(\varepsilon^{-1}x)$, as will be illustrated in section 4.1 (Tables 1 and 2) for particular cases of periodic inclusion.

The additional condition on the geometry of a periodic coefficient, outlined in the next corollary, allows one to obtain results that are relevant in homogenization theory presented in section 4.

3. Periodic coefficients.

By considering $K(x)$ a periodic function, it can be verified that the solutions to (1.7)–(1.8) are periodic. Moreover, if $K(x)$ is constant throughout the boundary, then the approximation to (1.8) leads to $w_i(x) = 0$, $x \in \partial\Omega$, and $\mathbf{w}(x) = 0$, $x \in \partial\Omega$, in (1.7). However, some additional properties are presented for the particular case when $K(x)$ has its center of mass at half of the period of the unit cell. This symmetry leads to properties of the functions $f_i(x)$ and $f_j(x)$ defined in (2.14).

Corollary 3.1. *Let $\Omega = [0,1]^n$. If $K(x)$ is periodic and has its center of mass at $x = \left(\frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{2}\right)$, then the following relationships are true:*

(i) $\int_\Omega \tilde{w}_i(x)\,dx = 0$.

(ii) $\int_\Omega \tilde{w}_i\tilde{w}_j dx = 0$ *for $j \ne i$, where $\tilde{w}_j(x)$ is the respective approximation to* (1.8) *in the jth direction.*

(iii) $\int_\Omega K(x) \frac{\partial \tilde{w}_i}{\partial x_j} dx = 0$ *for $j \ne i$.*

Proof. (i) There are two proofs (a) and (b) of this result. (a) First, this is true by defining an appropriate constant of integration c in (2.1). Moreover, if $N(x) = \frac{1}{K(x)}$ has its center of mass at $x_i = \frac{1}{2}$, then c is zero. Indeed, $\tilde{w}_i(x)$ in (2.14) becomes

$$\tilde{w}_i(x) = \frac{\int_0^{x_i} \frac{d\tau}{K(x_1,\ldots,\tau,\ldots,x_n)} - x_i \int_0^1 \frac{d\tau}{K(x_1,\ldots,\tau,\ldots,x_n)}}{\int_0^1 \frac{d\tau}{K(x_1,\ldots,\tau,\ldots,x_n)}} = \frac{\int_0^{x_i} N(\tau)d\tau - x_i \int_0^1 N(\tau)d\tau}{\int_0^1 N(\tau)d\tau}. \tag{3.1}$$

By exploiting the triangular domain of integration, recall that

$$\int_0^1 \int_0^{x_i} N(\tau)d\tau dx_i = \int_0^1 (1-\xi)N(\xi)d\xi.$$

In particular, $\int_0^1 x_i dx_i = \int_0^1\int_0^{x_i} d\tau dx_i = \int_0^1 (1-\xi)d\xi$. Therefore, computing the average of $\tilde{w}_i(x)$ and performing iterated integration in the numerator of (3.1), we solve the ith integral to give

$$\int_0^1 \tilde{w}_i\,(x)\,dx_i = \int_0^1 (1-\xi)N(\tau)d\tau - \int_0^1 (1-\xi)\int_0^1 N(\xi)d\xi d\xi \tag{3.2}$$
$$= \int_0^1 \left[(1-\xi)N(\xi) - (1-\xi)\int_0^1 N(\tau)d\tau\right] d\xi$$
$$= -\int_0^1 \xi N(\xi)d\xi + \int_0^1 \xi d\xi \int_0^1 N(\tau)d\tau,$$

and (3.2) is zero if and only if

$$\frac{\int_0^1 \xi N(\xi)d\xi}{\int_0^1 N(\tau)d\tau} = \frac{1}{2}.$$

Thus, in order for $\tilde{w}_i(x)$ to have zero mean, we need $N(x)$ to have its center of mass at half of the period in the x_i variable. Equivalently, $N(x)$ has its first moment at half of the period.

(b) Note that $\tilde{w}_i\,(x)$ is an odd function w.r.t. x_i and an even function w.r.t. the x_j variables. Indeed, considering $\tilde{w}_i\,(x) = f_i(x)f_j(x_j)$ in (2.14), we observe that $f_i(x)$ is odd and symmetric w.r.t. $x_i = 1/2$, and $f_j(x_j)$ is an even function because $K(x)$ is an even function.

(ii) By having $K(x)$ with its center of mass at $x = \frac{1}{2}$, it follows that $K(x)$ is an even function w.r.t. $x = \frac{1}{2}$. By using the argument from (b) applied to $\tilde{w}_j(x) = g_j(x)g_i(x_i)$, the approximation to the jth problem, $\tilde{w}_j(x)$ is an even function w.r.t. x_i. Thus $\tilde{w}_i(x)$ is orthogonal to $\tilde{w}_j(x)$.

(iii) The proof of (iii) follows since $\frac{\partial \tilde{w}_i}{\partial x_j}$ is an odd function and $K(x)$ is an even function. $\square$

Figures 1, 2, and 3 illustrate the properties (i)–(iii) proved in Corollary 3.1. It also illustrates that they are common properties between $\tilde{w}_1(x)$ and the numerical solution $w_1(x) \in H_0^1(\Omega)$. Another common property is discussed in section 4.2.

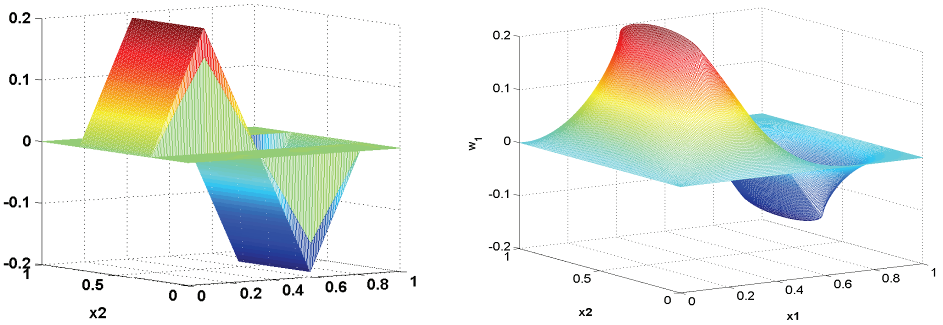

FIG. 1. $\tilde{w}_1\,(x)$ *(left) and numerical* $w_1\,(x)$ *(right), using* $K(x)$ *as in* (1.2)*, with* $\xi_1 = 10$ *and* $\xi_2 = 1$ *and one square inclusion, centered at* $(0.5, 0.5)$ *with an area equal to* $\frac{1}{4}$.

4. Application to homogenization theory. For the purpose of this section we constrain the analysis to L^2 and H^1 spaces and the properties and results obtained from Corollary 3.1 above. In order to illustrate the homogenization procedure, we consider composite materials as media with microstructures on a scale much smaller than the macroscopic scale of interest. The macroscopic length scale, L, is the dimension of a reservoir or a typical wavelength. The characteristic length of the medium

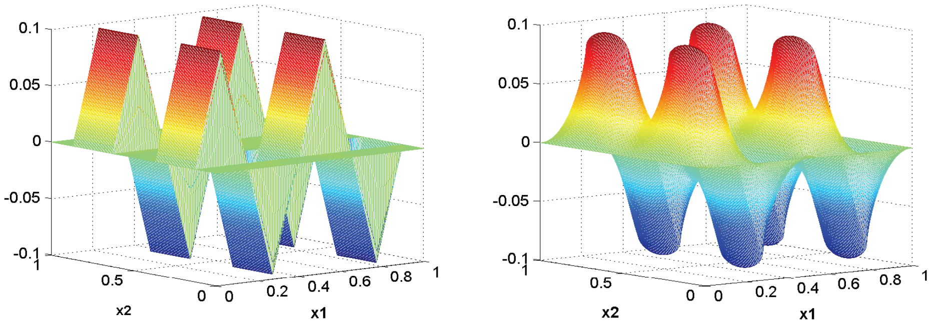

FIG. 2. *$\tilde{w}_1(x)$ (left) and numerical $w_1(x)$ (right), using $K(x)$ as in* (1.2)*, with $\xi_1 = 10$ and $\xi_2 = 1$ and four square inclusions, centered at* $(0.25, 0.25), (0.75, 0.25), (0.25, 0.75)$*, and* $(0.75, 0.75)$*, respectively, with total area equal to $\frac{1}{4}$.*

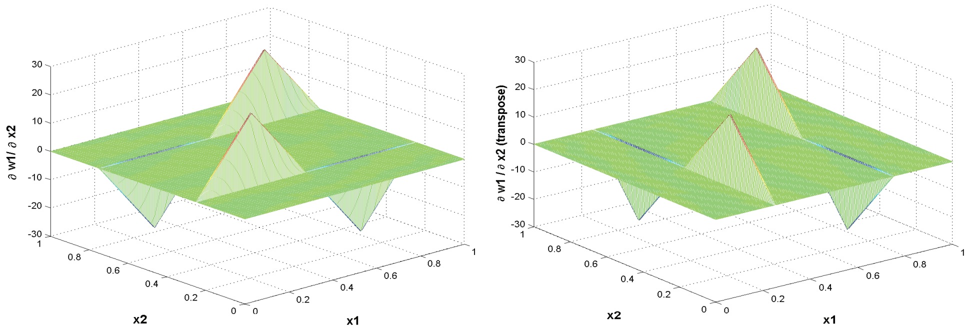

FIG. 3. $\frac{\partial \tilde{w}_1}{\partial x_2}$ *and its transpose, i.e.,* $\frac{\partial \tilde{w}_2}{\partial x_1}$ *from $\tilde{w}_1(x)$ in Figure* 1.

configuration is denoted by l, and the ratio between l and L is denoted by $\varepsilon = \frac{l}{L}$. In the study of physical processes in media with microstructure, known and unknown quantities are dependent on ε, and an asymptotic analysis is used to determine the unknown field quantities. To make precise the fact that the medium varies rapidly on the small scale l and may also vary slowly on the large scale L, we assume that the coefficient is of the form $K^{\varepsilon}(x) = K\left(\varepsilon^{-1}x\right) = K(y)$. One looks for a solution $u(x, y) = u^{\varepsilon}(x)$ given by the two-scale asymptotic expansion

$$u^{\varepsilon}(x) = u^0(x, y) + \varepsilon u^1(x, y) + \varepsilon^2 u^2(x, y) + \cdots, \tag{4.1}$$

where $x = (x_1, x_2, \ldots, x_n)$ is a vector in R^n called the global variable and $y = \varepsilon^{-1}x = (y_1, y_2, \ldots, y_n)$ is the local variable. The two-scale differentiation, $\nabla = \nabla_x + \varepsilon^{-1}\nabla_y$, used in the substitution of $u^{\varepsilon}(x)$ into the BVP,

$$\begin{cases} \nabla \cdot (K^{\varepsilon}(x) \nabla u^{\varepsilon}(x)) = f(x), & x \in \Omega, \\ u(x) = g(x), & x \in \partial\Omega, \end{cases} \tag{4.2}$$

leads to a rigorous deductive procedure for obtaining the macroscopic equations (in x) based upon solutions of local equations (in y) (examples are given in [3], [5], [7], among others). The equations in y are solvable if the microstructure is locally periodic and the terms $u^i(x, y)$ in the expansion are periodic in the y variable with the same period as the structure. By doing so, homogenization has two objectives:

(i) Determine what equation $u^0(x)$ satisfies, where $u^0(x)$ is

$$u^0(x) = \lim_{\varepsilon \to 0} u^\varepsilon(x).$$

(ii) Determine in what sense the last limit needs to be considered.
To address these questions one has the following definition (from [7]).

Definition 4.1 (H-convergence). *A constant matrix K^0 is said to be the homogenized limit of K^ε if and only if for any bounded domain $\Omega \subset R^n$ and for any $f \in H^{-1}(\Omega)$ the solutions $u^\varepsilon \in H^1(\Omega)$ of the BVP (4.2) possess the properties*

$$u^\varepsilon \rightharpoonup u^0 \quad in \quad H^1(\Omega), \tag{4.3}$$

$$K^\varepsilon(x)\nabla u^\varepsilon(x) \rightharpoonup K^0 \nabla u^0(x) \quad in \quad L^2(\Omega) \tag{4.4}$$

as $\varepsilon \to 0$, where $u^0 \in H^1(\Omega)$ is the solution of the BVP

$$\nabla \cdot \left(K^0 \nabla u^0(x)\right) + f(x) = 0. \tag{4.5}$$

Using the *Kronecker delta* δ_{ij}, the homogenized coefficient K^0 is defined by

$$K^0_{ij} = \int_Y K(y)\left(\delta_{ij} + \partial_{y_i} w_i(y)\right) dy, \tag{4.6}$$

where $w_i(y) \in H^1(\Omega)$ is the solution of the periodic cell-problem

$$\nabla \cdot \left(K(y)\nabla_y w_i(y)\right) = -\nabla \cdot \left(K(y)e_i\right) \quad \text{for} \quad y \in Y \tag{4.7}$$

and e_i is the unit vector in the i-direction. By using the approximation $\tilde{w_i}(y)$ from (2.1) in (4.7) and (iii) from Corollary 3.1, one computes an approximation to (4.6):

$$\tilde{K}^0 = \operatorname{diag} \int_Y (R_1, R_2, \ldots, R_i, \ldots, R_n)\, dY, \tag{4.8}$$

where $R_i = \left(\int_0^1 \frac{d\tau}{K(y_1,\ldots,\tau,\ldots,y_n)}\right)^{-1}$ is the harmonic average in the e_i-direction. Therefore, $\tilde{K}^0$ is the arithmetic average of the harmonic average. One important observation is that (4.8) reduces to three well-known results in the literature: the harmonic average in one dimension, the arithmetic and harmonic averages for layered media, and the arithmetic average of the harmonic average for the case when $K(y)$ is a separable function. Moreover, one has the following result.

Corollary 4.2. *$\tilde{K}^0$ is the lower bound of the generalized Voigt–Reiss inequality:*

$$\tilde{K}^0 \leq K^0 \leq K^u, \tag{4.9}$$

where $K^u = \left(\int_Y \frac{dy_j}{\int_Y K(y)dy_i}\right)^{-1}$, with $j \neq i$.

Proof. The same expression for $\tilde{K}^0$ was obtained in Jikov, Kozlov, and Oleinik [7, eq. (1.74)]; however, they had used a variational principle argument instead of the approximation (2.1). □

This shows how the proposed approximate solution fits into the classical framework of homogenization theory. Inequality (4.9) is a more accurate estimate than the classical Voigt–Reiss inequality, which states that K^0 lies between the harmonic and arithmetic averages of $K(y)$. As will be seen in the next section, $\tilde{K}^0$ indeed always underestimates the numerical values for K^0, and for completeness we also computed K^u. What is surprising, though, is that the error is about 10% on average (see [14] and section 4.2). A corrector is needed in order to obtain K^0, which may arise by finding the mollifier on (2.13) or other analytical means that can take advantage of the proposed approximation. This was proposed in Sviercoski, Travis, and Hyman [15], [16].

4.1. Convergence properties. We have proved in Corollary 2.5 that $\tilde{w}_1^\varepsilon(x) \to 0$ linearly. Tables 1 and 2 illustrate that this is another common property of $\tilde{w}_1^\varepsilon(x) \in L^2(\Omega)$, the approximation to the periodic cell-problem (1.8), and the numerical solution $w_1^\varepsilon(x) \in H^1(\Omega)$, in addition to the symmetries illustrated in Figures 1 and 2. The fact that each of them is going to zero implies that their difference is going to zero in the L^2-norm. The functions $\tilde{w}_1^\varepsilon(x)$ in the tables were obtained by setting up the cell-problem (1.8) considering the $K^\varepsilon(x)$ function as in (1.5) and constructing the sequence by taking its value as $(0.5)^n$, where $n = 1, 2, 3, 4, 5, 6$ and $\Omega = \bigcup \Omega^\varepsilon$ so that over each Ω^ε, Ω_c^ε are taken to be either square or circular inclusions. Furthermore, $K^{0.5}(x)$ refers to having one inclusion over the unit domain with a resulting area of (0.25); $K^{0.25}(x)$ has four inclusions, 2 × 2, in the unit domain with the same total area of (0.25), up to $K^{(0.5)^6}(x)$ with 64×64 inclusions and the same total area of the inclusions. The same is done to obtain the respective numerical solution $w_1^\varepsilon(x)$.

Table 1
Square inclusions with $\xi_1 = 100$ *and* $\xi_2 = 1$.

ε	$\|\|\tilde{w}_1^\varepsilon(x)\|\|_2$	$\|\|w_1^\varepsilon(x)\|\|_2$	$\|\|\tilde{w}_1^\varepsilon(x) - w_1^\varepsilon(x)\|\|_2$

4.2. Comparison between numerical results and $\tilde{K}^0$. We compute the approximate value (4.8) and compare it with some published numerical results. The numerical values have been taken from Bourgat [4], Amaziane, Bourgeat, and Koebbe [1], and Moulton, Dendy, and Hyman [11]. Note that in [1], the homogenization procedure has been applied to a nonlinear two-phase flow equation. For some particular cases of nonlinearity, the value of the effective coefficient can be computed as in the linear case.

4.2.1. Case 1. In [1], each function $K^\varepsilon(x)$ is defined as in (1.5), with values of ξ_1 being in the inclusion and ξ_2 in the main matrix. (Note that this is the opposite of the definition used elsewhere in this paper). The effective value $K^\#$ was obtained by numerically solving (1.3) for four tests:

Test 1. $K^\varepsilon(x)$ with $\xi_1 = 1$ and $\xi_2 = 10$.

Test 2. The same $K^\varepsilon(x)$ as in Test 1. However, a two-phase analysis was used with a change in the viscosity ratios.

Test 3. $K^\varepsilon(x)$ with $\xi_1 = 1$ and $\xi_2 = 100$.

Test 4. $K^\varepsilon(x)$ with $\xi_1 = 1$ and $\xi_2 = 10$, as illustrated in Figure 4 (right).

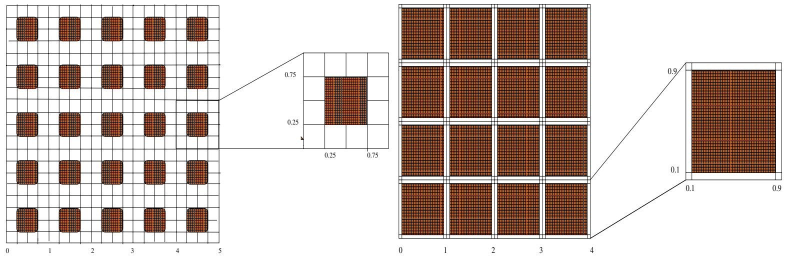

FIG. 4. *Left: Function $K(y)$ used in Tests 1, 2, and 3, respectively. Right: $K(y)$ used in Test 4.*

The results are presented in Table 3, where K^h is the harmonic average, $K^{\#}$ is numerical from [1], $\tilde{K}^0$ results from (4.8), and K^a is the arithmetic average. RD is the relative difference, $RD = \frac{|K^{\#}-\tilde{K}^0|}{\tilde{K}^0}$. The difference between the numerical and analytical results is about 10%, on average. Observe that in Test 4, the error is smaller compared to the others. This coincides with the fact that the medium is "less heterogeneous" than the others. An analogous argument applies for the "highly heterogeneous" Test 3, where the error is the largest.

TABLE 3
Comparison between (4.8) and numerical values from [1].

	K^h	$\tilde{K}^0$	$K^{\#}$	K^u	K^a	RD
Test 1	3.09	**5.91**	6.52	7.09	7.75	10.3 %
Test 2	3.09	**5.91**	6.52	7.09	7.75	10.3 %
Test 3	3.89	**51.0**	59.2	67	75.2	16 %
Test 4	1.48	**2.98**	3.106	3.271	4.24	4 %

4.2.2. Case 2. Table 4 shows the comparison between values of the effective coefficient, K^{bb}, obtained by the black box multigrid algorithm, from [11], the numerical asymptotic value, K^{num}, computed in [4], and the analytical form (4.8). The idea is also to show the dependence of the results on the shape of the inclusions. Three different inclusions are presented with an area equal to $\frac{1}{4}$, as in Figure 5 with $\xi_1 = 10$ and $\xi_2 = 1$, where RD is computed with K^{num} as it is more closely related to our procedure. Table 4 also indicates that $\tilde{K}^0$ is consistent with the others w.r.t. the correspondence between the order of the values and their respective shapes. Indeed, the circular shape renders the smallest effective value, whereas the lozenge gives the largest.

TABLE 4
Comparison between (4.8) and numerical values from [4] and [11].

Shape	K^h	$\tilde{K}^0$	K^{num}	K^{bb}	K^u	K^a	RD
Square	1.292	**1.409**	1.548	1.598	1.695	3.26	9 %
Circle	1.291	**1.403**	1.516	1.563	1.791	3.251	8 %
Lozenge	1.288	**1.417**	1.573	1.608	1.936	3.236	11 %

5. Discussions. The results presented in this paper are one step towards obtaining the solution of a generalized Laplace equation not only for the coefficient functions presented here but also for more general multiscaled geometries. They also provide

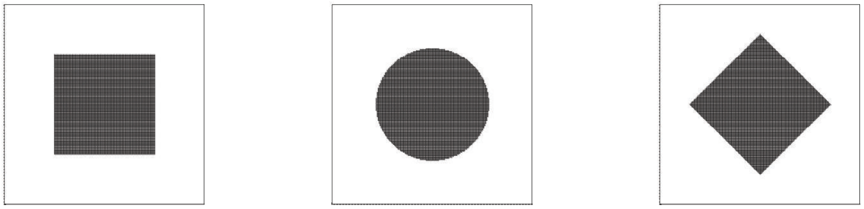

Fig. 5. *Different shape of inclusion.*

insight on deriving, by analytical means, the effective coefficient for the generalized flow equation with a rapidly oscillating coefficient. Other simulations, not presented here, indicate that when using (4.8) and the approximation in Definition 4.1, one gets the boundedness of the sequence, $\left|\left|u^{\varepsilon} - u^{0}\right|\right|_{2} \leq C$, that is, a strong convergence up to a subsequence of u^{ε}. It is possible that, by defining a mollifier in order to smooth out the various approximations presented, the numerical and analytical values for the effective coefficient will be closer. In this sense, we are proposing in Sviercoski, Travis, and Hyman [15], [16] an analytical corrector to (2.14) and (4.8) to overcome the demonstrated difference.

Acknowledgments. The authors are grateful to Mac Hyman, Bryan Travis, and Peter Popov for useful discussions.

LOCAL TOMOGRAPHY IN ELECTRON MICROSCOPY*

ERIC TODD QUINTO† AND OZAN ÖKTEM‡

Abstract. We present a new local tomographic algorithm applicable to electron microscope tomography. Our algorithm applies to the standard data acquisition method, single-axis tilting, as well as to more arbitrary acquisition methods including double axis and conical tilt. Using microlocal analysis we put the reconstructions in a mathematical context, explaining which singularities are stably visible from the limited data given by the data collection protocol in the electron microscope. Finally, we provide reconstructions of real specimens from electron tomography data.

Key words. X-ray transform, limited data tomography, microlocal analysis, Lambda tomography, electron tomography

1. Introduction.

Our goal is to show how singularity detection algorithms can be useful in *electron (microscope) tomography (ET)*. Briefly, given *transmission electron microscope (TEM)* data and using principles of tomography, the goal in ET is to reconstruct the scattering potential of the individual molecules in an in situ (in the cellular environment) or in vitro (in aqueous environment) specimen, each of which can be fairly arbitrary. Because the specimen extends far beyond the area exposed to the electrons, the exposed region covers only a small subregion, which is usually referred to as the *region of interest*. Again, because of the size of the whole specimen, one can rotate it only in a limited range of angles, so the reconstruction problem is a *limited angle* problem. These imply that one has *nonuniqueness* and *severe ill-posedness*. Nonuniqueness, as illustrated in Example 3.1, means that one cannot exactly reconstruct the scattering potential of the specimen even in cases when one assumes exact data (no measurement errors) and disregards the discretization of the set of lines (i.e., one deals with the corresponding continuous problem where data are given over a continuous set of lines). Furthermore, as discussed in section 2.2, the data are very noisy, in particular because of the dose problem—the dose needed to get low-noise data destroys the specimen. Since the limited angle problem leads to severe ill-posedness, the reconstruction problem is unstable and the noise in the data is amplified.

These issues, namely nonuniqueness and ill-posedness, point to using a reconstruction method that regularizes by reconstructing only some information about the specimen that can be stably retrieved, in our case the shape of the boundaries of the molecules in the specimen. Our method is a generalization of Lambda tomography [6, 28].

The article is organized as follows. In section 2, we give the background from physics and state the inverse problem. To provide perspective, we briefly describe

planar Lambda tomography in section 3. Next, we provide our general algorithm for arbitrary data sets in section 4. Then, in section 5 we give the specifics for single-axis tilt ET. In section 6, we describe which singularities of the specimen are stably recoverable from the limited data in ET. We put our results in the context of microlocal analysis as done by [20] for planar CT. This is based on the theory of Fourier integral operators, and the specific results are based on very general theorems in [8] or [2]. Finally, in section 7, we give reconstructions from real data to illustrate the efficiency of our algorithm and demonstrate our characterization of stably recoverable singularities. The appendix includes proofs of our technical theorems.

2. Electron (microscope) tomography (ET).

In what follows we will provide a very brief overview of ET, where our aim is to properly state the inverse problem and show how integral geometry can be used to solve it. The reader is referred to [4] and the references therein for a more detailed account.

2.1. Scientific application and experimental setting.

The problem of recovering the three-dimensional structure of an individual molecule (e.g., a protein or a macromolecular assembly) at the highest possible resolution in situ or in vitro plays a central role in understanding biological processes in time and space. Established approaches, such as X-ray crystallography and nuclear magnetic resonance (NMR), for dealing with this problem cannot recover the structure of an *individual* molecule in a sample. The publication of [3, 29, 11] in 1968 marked the beginning of ET, where the idea of recovering the structure of a sample from TEM data using principles of tomography was first outlined. ET is currently the *only* approach that allows one to reconstruct the three-dimensional structure of *individual* molecules in in situ/in vitro samples. The main drawback of ET when compared to NMR/X-ray crystallography, mentioned earlier, is that it provides only a low-resolution structure due to reasons explained in section 2.2. However, since the ability to study individual molecules is important in order to address many biological problems, ET is nowadays enjoying an increasing interest within life sciences as a technique for low- or medium-resolution structure determination of individual molecules.

A specimen that is to be imaged in a TEM must first be physically immobilized since it is imaged in a vacuum. It also needs to be thin (about 70–100 nm) if enough electrons are to pass through to form an image. The purpose of sample preparation is to achieve this *without interfering with the structure of the specimen.* Data collection in ET is done by mounting the specimen on a holder (goniometer) that allows one to change its positioning relative to the optical axis of the TEM. For a fixed position, the specimen is radiated with an electron beam, and the resulting data, referred to as a *micrograph*, is recorded by a detector. Hence, each fixed orientation of the specimen yields one micrograph, and the procedure is then repeated for a set of different positions. The most common data acquisition geometry is *single-axis tilting*, where the specimen plane is allowed only to rotate around a fixed single axis, called the *tilt axis*, which is orthogonal to the optical axis of the TEM. The rotation angle is called the *tilt angle*, and its angular range is usually contained in a subset of $[-60^\circ, 60^\circ]$.

2.2. Difficulties.

Limitations in instrumentation combined with the unfortunate combination of very noisy data and the severe ill-posedness of the inverse problem have been (and still are) responsible for the slow dissemination of ET as a reliable structure determination technique in life sciences. The former issue is partly addressed by the rapid technological development, so we focus on the latter, which is due to the following reasons.

The dose problem. This is *the* single most important problem in ET. It limits the total number of images that can be taken and arises due to specimen damage during electron exposure. A typical range of dose that can be tolerated by a biological specimen is about 2000–7000 $\mathrm{e}^-/\mathrm{nm}^2$, which translates into about a total of 500–1250 e^-/pixel (at 25000× magnification with pixel size of 14 μm) distributed over 60 or 120 micrographs, so each micrograph is very noisy, and the Poisson randomness of the data (shot noise) has to be accounted for.

Limited range of the tilt angle. Restrictions in the data acquisition geometry for ET, especially the restriction on the range of the tilt angle in single-axis tilting, lead to limited angle data and therefore imply that the conditions for stable reconstruction are not fulfilled.

Region of interest problem. For a given positioning of the specimen, only a subregion of it is subject to electron exposure. Thus, the region of interest then equals (or is a subset of) the intersection of all the exposed parts of the specimen from different positions. Since we have contribution from outside the region of interest,[1] we are dealing with the region of interest problem (local tomography), somewhat similar to the well-known "long object problem" in three-dimensional CT.

2.3. The inverse problem in ET. We therefore confine ourselves to presenting a very brief outline for how one arrives at the expression for the forward operator that occurs in the standard phase contrast model used by the ET community. The interested reader is referred to [4, 10, 23] for a more detailed exposition.

The starting point is to assume that we have perfect coherent imaging; i.e., the incoming electron wave is a monochromatic plane wave (coherent illumination), and electrons scatter only elastically. The scattering properties of the specimen are in this case given by the electrostatic potential, and the electron-specimen interaction is modeled by the scalar Schrödinger equation. The picture is completed by adding a description of the effects of the optics and the detector of the TEM, both modeled as convolution operators. However, inelastic scattering and incoherent illumination introduce partial incoherence, so the basic assumption of perfect coherent imaging must be relaxed. The incoherence that stems from inelastic scattering is accounted for within the coherent framework by introducing an imaginary part to the scattering potential, called the absorption potential. The incoherence that stems from incoherent illumination is modeled by modifying the convolution kernel that describes the effect of the optics. Next, as shown in [4, Theorem 9.5], taking the first order Born approximation and linearizing the intensity enables one to explicitly express the measured intensity in terms of the propagation operator (well known from diffraction tomography [18, p. 48]) acting on the scattering potential of the specimen convolved with point spread functions describing the optics and detector. The *standard phase contrast model* used by the ET community for the image formation in TEM is based on replacing the propagation operator by its high energy limit as the wave number tends to infinity. This yields a model for the image formation that is based on the parallel beam transform (see (2.3) for a definition).

The structure of the specimen is assumed to be fully described by the *scattering potential* $f\colon \mathbb{R}^3 \to \mathbb{C}$, which is defined as

$$f(\boldsymbol{x}) := -\frac{2m}{\hbar^2}\big(V(\boldsymbol{x}) + iV_{\mathrm{abs}}(\boldsymbol{x})\big), \tag{2.1}$$

[1] The exposed part of the specimen is larger than the region of interest.

where m denotes the electron mass at rest, $V\colon \mathbb{R}^3 \to \mathbb{R}^-$ is the potential energy[2] that models elastic interaction, and $V_{\text{abs}}\colon \mathbb{R}^3 \to \mathbb{R}^-$ is the absorption potential that models the decrease in the flux, due to inelastic scattering, of the nonscattered and elastically scattered electrons. Under the assumptions and approximations outlined in the previous paragraph, the expression for the *intensity generated by a single electron* is given as

$$(2.2)\quad \mathcal{I}(f)(\boldsymbol{z},\boldsymbol{\omega}) := \frac{1}{M^2}\Biggl(1-(2\pi)^{-2}\Biggl[\Bigl\{\mathrm{PSF}^{\mathrm{re}}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f^{\mathrm{re}})(\cdot,\boldsymbol{\omega})\Bigr\}\Bigl(\frac{\boldsymbol{z}}{M}\Bigr) + \Bigl\{\mathrm{PSF}^{\mathrm{im}}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f^{\mathrm{im}})(\cdot,\boldsymbol{\omega})\Bigr\}\Bigl(\frac{\boldsymbol{z}}{M}\Bigr)\Biggr]k^{-1}\Biggr)$$

for a unit vector $\boldsymbol{\omega} \in S^2$ and $\boldsymbol{z} \in \boldsymbol{\omega}^\perp$, where $\boldsymbol{\omega}^\perp := \{\boldsymbol{x} \in \mathbb{R}^n \mid \boldsymbol{x}\cdot\boldsymbol{\omega} = 0\}$. In the above expression, $f^{\mathrm{re}}, f^{\mathrm{im}}\colon \mathbb{R}^3 \to \mathbb{R}^+$ denotes the real and imaginary parts of f in (2.1) and $\mathcal{P}$ denotes the *parallel beam transform (X-ray transform)*, which is defined as the operator taking the line integral of a function, i.e.,

$$(2.3)\qquad \mathcal{P}(f)(\boldsymbol{y},\boldsymbol{\omega}) := \int_{t=-\infty}^{\infty} f(\boldsymbol{y}+t\boldsymbol{\omega})\,dt \quad \text{for } \boldsymbol{\omega} \in S^2 \text{ and } \boldsymbol{y} \in \boldsymbol{\omega}^\perp.$$

Moreover, $\circledast_{\boldsymbol{\omega}^\perp}$ denotes the two-dimensional convolution in the $\boldsymbol{\omega}^\perp$-plane, and the point spread functions $\mathrm{PSF}^{\mathrm{re}}$ and $\mathrm{PSF}^{\mathrm{im}}$ in (2.2) model the effect of the optics and incoherent illumination of the TEM. A precise expression for these can be found, e.g., in [4, section 9.1], [10, Chapter 65], or [23, section 3.3]. Finally, k is the particle wave number[3] w.r.t. the homogeneous background medium (which in our case is a vacuum) and M denotes the magnification.

As already mentioned, (2.2) yields the expression for the intensity generated by a single electron. The expression for the actual data measured on a micrograph needs to account for the detector point spread function (usually a slow-scan CCD camera) as well as the stochasticity in the data. Following [4, section 6.3], the stochasticity in the data is captured by assuming that the actual data delivered by the detector from a pixel should be modeled as a *sample of a random variable*, which in turn implies that the inverse problem in ET must be defined in a probabilistic setting.

Definition 2.1. *We have a fixed finite set S_0 of directions on a smooth curve $S \subset S^2$ that defines our parallel beam data collection geometry. The scattering properties of the specimen are assumed to be fully described by the complex valued scattering potential f defined in* (2.1). *For each direction $\boldsymbol{\omega} \in S_0$, the specimen is probed by a monochromatic wave, and the resulting data on the micrograph at pixel (i,j) is denoted by* $\mathrm{data}[f](\boldsymbol{\omega})_{i,j}$. *The* forward operator *in ET, denoted by $\mathcal{T}$, is defined as the expected value of* $\mathrm{data}[f](\boldsymbol{\omega})_{i,j}$, *i.e.,*

$$\mathcal{T}(f)(\boldsymbol{\omega})_{i,j} := \mathbf{E}\Bigl[\mathrm{data}[f](\boldsymbol{\omega})_{i,j}\Bigr] \quad \textit{for } \boldsymbol{\omega} \in S^2 \textit{ and pixel } (i,j).$$

The inverse problem *is to determine f when a sample of* $\mathrm{data}[f](\boldsymbol{\omega})_{i,j}$ *is known for $\boldsymbol{\omega} \in S_0$ and finitely many pixels (i,j).*

[2] The potential energy is related to the electrostatic potential $U\colon \mathbb{R}^3 \to \mathbb{R}^+$ by $V = -eU$, where e is the charge of the electron.

[3] We use the convention that the relation between the wave number k and the wavelength λ is given by $k = 2\pi/\lambda$.

The full expression for $\mathrm{data}[f](\boldsymbol{\omega})_{i,j}$ (and the corresponding forward operator $\mathcal{T}$) is given in [4, equation (29)]. We will settle for a simplified version, also given in [4, equation (30)], which yields the following expression for the forward operator:

$$\mathcal{T}(f)(\boldsymbol{\omega})_{i,j} = \mathrm{gain}_{i,j}\,|\triangle_{i,j}|\,\mathrm{Dose}(\boldsymbol{\omega})\Big\{\mathrm{PSF}_{\mathrm{det}} \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{I}(f)(\cdot,\boldsymbol{\omega})\Big\}(\boldsymbol{z}_{i,j}) + \epsilon_{i,j}. \tag{2.4}$$

In the above expression, $\mathrm{gain}_{i,j}$ is a detector constant, $|\triangle_{i,j}|$ is the area of the (i,j)th pixel, $\mathrm{Dose}(\boldsymbol{\omega})$ is the incoming dose which gives the number of electrons hitting the specimen per area unit, $\mathrm{PSF}_{\mathrm{det}}$ is the detector point spread function, and $\epsilon_{i,j}$ is the mean value of the stochastic variable representing the *additive noise introduced by the detector.*

2.4. Integral geometric approaches for solving the inverse problem. There are two main assumptions underlying all current integral geometric approaches for solving the inverse problem given in Definition 2.1. The first is to assume that *the forward operator yields the actual measured data*; i.e., the data in pixel (i,j) in the micrograph with tilt $\boldsymbol{\omega}$ equals the expected value of the random variable $\mathrm{data}[f](\boldsymbol{\omega})_{i,j}$. The second is to assume that *the forward operator is given by* (2.4). Next, we shall see that appropriate postprocessing of the measured data allows us to obtain an expression for the values of the parallel beam transform on $(\boldsymbol{z}_{i,j},\boldsymbol{\omega})$ with $\boldsymbol{\omega}\in S_0$ and $\boldsymbol{z}_{i,j}\in\Sigma\subset\boldsymbol{\omega}^\perp$, where Σ is a fixed finite set defined by the pixels in the detector. We have in this way recast the inverse problem in ET (given by Definition 2.1) as the problem of inverting the parallel beam transform.

2.4.1. Generate single electron intensity data. The first step is to generate *single electron intensity data* from the actual measured data. This can be done by deconvolving the effects of the detector point spread function $\mathrm{PSF}_{\mathrm{det}}$ and rescaling the measured data so that it corresponds to the intensity generated by a *single electron.* Let $\mathrm{I}(\boldsymbol{\omega})_{i,j}$ correspond to the intensity generated by a single electron at pixel (i,j). If the rescaling and deconvolution are appropriately[4] done, then we get

$$\mathrm{I}(\boldsymbol{\omega})_{i,j} \approx \mathcal{I}(f)(\boldsymbol{z}_{i,j},\boldsymbol{\omega}) \quad \text{for } \boldsymbol{\omega}\in S_0 \text{ and } \boldsymbol{z}_{i,j}\in\Sigma.$$

By (2.2), for $\boldsymbol{z}_{i,j}\in\Sigma$ we then get that

$$\begin{aligned}\Big\{\mathrm{PSF}^{\mathrm{re}}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f^{\mathrm{re}})(\cdot,\boldsymbol{\omega})\Big\}\Big(\frac{\boldsymbol{z}_{i,j}}{M}\Big)& \\ + \Big\{\mathrm{PSF}^{\mathrm{im}}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f^{\mathrm{im}})(\cdot,\boldsymbol{\omega})\Big\}\Big(\frac{\boldsymbol{z}_{i,j}}{M}\Big) &\approx (2\pi)^2 k\Big(1 - M^2\,\mathrm{I}(\boldsymbol{\omega})_{i,j}\Big).\end{aligned} \tag{2.5}$$

One can now proceed in a number of different ways in order to recast the inverse problem in Definition 2.1 as the problem of inverting the parallel beam transform.

2.4.2. Amplitude contrast only. The easiest approach is to assume that we have *perfect optics (no defocus and no spherical or chromatic aberration) and ignore all apertures.* These assumptions imply that $\mathrm{PSF}^{\mathrm{re}}\equiv 0$ and $\mathrm{PSF}^{\mathrm{im}} = \delta_{\boldsymbol{\omega}^\perp}$ (see, e.g., [4, section 9.3]), so (2.5) reduces to

$$\mathcal{P}(f^{\mathrm{im}})\Big(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\Big) \approx (2\pi)^2 k\Big(1 - M^2\,\mathrm{I}(\boldsymbol{\omega})_{i,j}\Big) \quad \text{for } \boldsymbol{z}_{i,j}\in\Sigma. \tag{2.6}$$

[4] The deconvolution of the detector point spread function $\mathrm{PSF}_{\mathrm{det}}$ needed to create $\mathrm{I}(\boldsymbol{\omega})$ is an ill-posed operation, and therefore it needs to be performed using a regularization scheme. However, the ill-posedness is not severe since the Fourier transform of $\mathrm{PSF}_{\mathrm{det}}$ is positive [4, Remark 6.3], so it should be fairly straightforward to perform this regularization as exemplified in [32].

The inverse problem in Definition 2.1 can now be reformulated as the problem of inverting the parallel beam transform of f^{im} when the data is given by the right-hand side of (2.6).

Note that the real part f^{re} of the scattering potential is absent in (2.6) and thus cannot be recovered. This is to be expected since the phase contrast is visible only due to the imperfections in the optics (with nonzero defocus and/or nonzero aberration). The inability to recover f^{re} is a serious deficiency with this approach since f^{re} is the part of the scattering potential that has a straightforward physical interpretation in terms of the molecular structure of the specimen, whereas f^{im} is a phenomenological construction that accounts for the decrease in the flux, due to inelastic scattering, of the nonscattered and elastically scattered electrons. Assuming only amplitude contrast therefore works well only with strongly scattering specimens where most of the contrast in the micrographs is from amplitude contrast.

2.4.3. Constant amplitude contrast ratio. This is the most common approach in ET. It is based on introducing an additional assumption, namely, that $f^{\mathrm{im}}(\boldsymbol{x}) = Qf^{\mathrm{re}}(\boldsymbol{x})$, where the constant Q is called the *amplitude contrast ratio.* Under this assumption (2.5) reduces to

$$\Big\{\mathrm{PSF}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^{\perp}}{\circledast} \mathcal{P}(f^{\mathrm{re}})(\cdot,\boldsymbol{\omega})\Big\}\Big(\frac{\boldsymbol{z}_{i,j}}{M}\Big) \approx (2\pi)^2 k\Big(1 - M^2\,\mathrm{I}(\boldsymbol{\omega})_{i,j}\Big) \quad \text{for } \boldsymbol{z}_{i,j} \in \Sigma, \tag{2.7}$$

where

$$\mathrm{PSF}(\boldsymbol{z},\boldsymbol{\omega}) := \Big\{\mathrm{PSF}^{\mathrm{re}}(\cdot,\boldsymbol{\omega}) + Q\,\mathrm{PSF}^{\mathrm{im}}(\cdot,\boldsymbol{\omega})\Big\}(\boldsymbol{z}).$$

An expression for $\mathcal{P}(f^{\mathrm{re}})\big(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\big)$ can now be obtained by deconvolving the point spread function PSF in the expression (2.7).

There are several problems with this above approach. The first is that it requires a priori knowledge of Q. Second, deconvolving PSF is an ill-posed operation. This ill-posedness is especially pronounced since the Fourier transform of the kernel PSF has multiple zeroes (see, e.g., [4, section 9.1]). Thus, if one wants to use (2.7) in order to retrieve f^{re} (and f^{im} with knowledge of Q), then one needs to regularize the deconvolution operation involved in the right-hand side of (2.7). The most common approach is to again assume perfect optics and ignore all apertures. However, in such a case the criticism raised against the amplitude contrast model (2.6) also applies to this case, and not much is gained.

2.4.4. Phase contrast model with low-resolution amplitude contrast. We now propose a novel approach that does circumvent some of the difficulties raised above. The idea is to recover f^{re} by a hybrid approach. Begin by assuming *perfect optics (no defocus and no spherical or chromatic aberration) and ignore all apertures.* Under these assumptions we know that (2.6) is valid, which gives an expression for $\mathcal{P}(f^{\mathrm{im}})\big(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\big)$ with $\boldsymbol{z}_{i,j} \in \Sigma$. Inserting this expression into (2.5) yields an expression for

$$\Big\{\mathrm{PSF}^{\mathrm{re}}(\cdot,\boldsymbol{\omega}) \underset{\boldsymbol{\omega}^{\perp}}{\circledast} \mathcal{P}(f^{\mathrm{re}})(\cdot,\boldsymbol{\omega})\Big\}\Big(\frac{\boldsymbol{z}_{i,j}}{M}\Big).$$

Finally, by deconvolving the point spread function $\mathrm{PSF}^{\mathrm{re}}$, we obtain the expression for $\mathcal{P}(f^{\mathrm{re}})\big(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\big)$ with $\boldsymbol{z}_{i,j} \in \Sigma$. This deconvolution operation is, however, ill-posed since the Fourier transform of the corresponding kernel $\mathrm{PSF}^{\mathrm{re}}$ has multiple zeroes. Hence, in order to use this approach, one needs to regularize this deconvolution operation.

2.4.5. Phase contrast model with higher order terms. The troublesome deconvolutions with the optics point spread functions can be avoided altogether if one makes an approximation based on the asymptotic expansion of the forward operator that includes higher order terms. More precisely, in [4, equation (40)] it is shown that

$$\begin{aligned}\mathcal{I}(f)(\boldsymbol{z},\boldsymbol{\omega}) = \frac{1}{M^2}\Biggl(1 &- (2\pi)^{-2}\mathcal{P}(f^{\mathrm{im}})\Bigl(\frac{\boldsymbol{z}}{M},\boldsymbol{\omega}\Bigr)k^{-1} \\ &+ (2\pi)^{-2}\biggl\{\Bigl(\frac{\triangle z}{2}+q\Bigr)\triangle_{\boldsymbol{\omega}^\perp}\Bigl[\mathcal{P}(f^{\mathrm{re}})(\cdot,\boldsymbol{\omega})\Bigr]\Bigl(\frac{\boldsymbol{z}}{M}\Bigr) \\ &\qquad + \triangle_{\boldsymbol{\omega}^\perp}\Bigl[\int_{\mathbb{R}} s f^{\mathrm{re}}(s\boldsymbol{\omega}+\cdot)\,ds\Bigr]\Bigl(\frac{\boldsymbol{z}}{M}\Bigr)\biggr\}k^{-2}\Biggr) + O(k^{-3}),\end{aligned}$$

where $\triangle_{\boldsymbol{\omega}^\perp}$ is the two-dimensional Laplacian in the $\boldsymbol{\omega}^\perp$-plane, $\triangle z$ is the defocus, and q is the shortest distance (considering all the tilts) between the specimen and the objective lens in the idealized optical system (the value of q is determined by the magnification M and focal length of the objective lens [4, section 8.5]). Now, note that

$$\int_{\mathbb{R}} s f^{\mathrm{re}}(s\boldsymbol{\omega}+\boldsymbol{z})\,ds \approx q\mathcal{P}(f^{\mathrm{re}})(\boldsymbol{z},\boldsymbol{\omega}),$$

which holds simply because q is much larger than the specimen thickness (where f^{re} has its support). Moreover, $\triangle_{\boldsymbol{\omega}^\perp}\bigl[\mathcal{P}(f^{\mathrm{re}})(\boldsymbol{z},\boldsymbol{\omega})\bigr] = \mathcal{P}(\triangle f^{\mathrm{re}})(\boldsymbol{z},\boldsymbol{\omega})$, where $\triangle$ is the Laplacian in $\mathbb{R}^3$, so we therefore end up with the following replacement of (2.5):

$$\begin{aligned}(2.8)\quad \mathcal{P}(f^{\mathrm{im}})\Bigl(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\Bigr) + \Bigl(\frac{\triangle z}{2}+2q\Bigr)k^{-1}\mathcal{P}(\triangle f^{\mathrm{re}})\Bigl(\frac{\boldsymbol{z}_{i,j}}{M},\boldsymbol{\omega}\Bigr)& \\ \approx (2\pi)^2 k\Bigl(1-M^2\,\mathrm{I}(\boldsymbol{\omega})_{i,j}\Bigr)&\end{aligned}$$

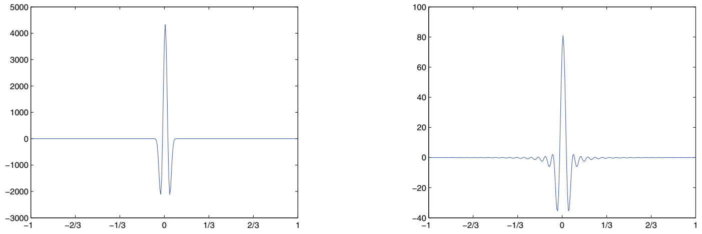
for $\boldsymbol{z}_{i,j}\in\Sigma$. One can now repeat the postprocessing approaches described in sections 2.4.3 and 2.4.4 but this time based on (2.8) instead of (2.5). This would yield postprocessing operations of data where one does not have to go through the ill-posed operation of deconvolving the optics.

2.4.6. Summary. As we have seen in the previous sections, performing a number of approximations allows us to recast the inverse problem in ET (given as in Definition 2.1) as the problem of solving (2.5) for f^{re} and f^{im}. This problem can then by additional assumptions be reduced to the problem of inverting the X-ray transform. Finally, bearing in mind the data collection scheme outlined in Definition 2.1, we are reduced to inverting the parallel beam transform since the line complex where the X-ray transform is sampled consists of lines parallel to a direction (which in turn varies on a curve in S^2).

3. Limited data local tomography.

To help the reader understand our three-dimensional local reconstruction methods, we will first outline planar Lambda tomography and then recall the parameterization of lines for the ET data set in $\mathbb{R}^3$.

Lambda tomography [6, 5, 28] is a very clever algorithm for parallel beam or fan beam tomography in the plane. It allows one to image a function $f(\boldsymbol{x})$ using only line integrals of f for lines near $\boldsymbol{x}$. It is a variant of the standard filtered backprojection inversion algorithm that replaces the standard filter (that has infinite support)



(a) Plot of the convolution kernel we use in place of $-D^2_{\boldsymbol{\sigma}}$ (see (5.8)). The kernel is local because it is zero off of the interval $[-0.1, 0.1]$.

(b) Plot of the standard filtered backprojection kernel with a comparable width.

FIG. 1. *Plot of kernels in Lambda tomography and in filtered backprojection. We see that the Lambda kernel illustrated in Figure* 1(a) *is local, whereas the standard filtered backprojection kernel shown in Figure* 1(b) *has infinite support.*

with a filter that takes a second derivative in the detector variable. Because the numerical derivative filter has small support, just near the line being evaluated, this reconstruction becomes local; see Figure 1.

The formula reads as follows:

$$\Lambda_\mu(f) = \frac{1}{4\pi}\mathcal{P}^*\big(\mu - \mathcal{D}^2_{\boldsymbol{\omega}^\perp}\big)\mathcal{P}(f). \tag{3.1}$$

In the above formula, $\mathcal{P}^*$ is the standard dual parallel beam transform integrating over all lines in the plane through the given point and $\mathcal{D}^2_{\boldsymbol{\omega}^\perp}$ is the second derivative in the $\boldsymbol{\omega}^\perp$ direction, i.e.,

$$\mathcal{D}^2_{\boldsymbol{\omega}^\perp}(g)(\boldsymbol{y}, \boldsymbol{\omega}) := \frac{d^2}{ds^2} g\big(\boldsymbol{y} + s\boldsymbol{\omega}^\perp, \boldsymbol{\omega}\big)\Big|_{s=0} \quad \text{for } \boldsymbol{y} \in \mathbb{R}^2$$

with $\boldsymbol{\omega} := (\sin\theta, \cos\theta)$ and $\boldsymbol{\omega}^\perp := (\cos\theta, -\sin\theta)$. In this section, $\boldsymbol{\omega}^\perp$ is a vector, and for the three-dimensional parallel beam transform, $\boldsymbol{\omega}^\perp$ is a plane. Note that $\boldsymbol{\omega}$ is the unit vector $\pi/2$ radians counterclockwise from $\boldsymbol{\omega}^\perp$.

We subtract $\mathcal{D}^2_{\boldsymbol{\omega}^\perp}$ in (3.1) so that the Fourier transform of the kernel of Λ_μ is positive. *The result is a reconstruction not of f but of a function $\Lambda_\mu(f)$ that has singularities at the same places as f but with the singularities accentuated.* As has been shown in numerous articles (e.g., [6, 16, 21]) and as we will try to show here, Lambda reconstructions can be as useful as reconstructions from filtered backprojection if one does not need actual density values or if one has only local data from which density values cannot be obtained. The constant $\mu \geq 0$ is included in (3.1), as suggested by Smith and coauthors [26, 6], to provide some contour to the reconstruction. That is, the backprojected second derivative

$$-\Delta\mathcal{P}^*\mathcal{P}(f) = \mathcal{P}^*\big(-\mathcal{D}^2_{\boldsymbol{\omega}^\perp}\mathcal{P}\big)(f) = \Lambda_0(f),$$

or "pure" Lambda, emphasizes density changes or boundaries. The μ factor provides "contours" from the smoothed version of the original function since it results in the convolution

$$\mu\mathcal{P}^*\mathcal{P}(f) = f * \frac{2\mu}{\|\cdot\|},$$

where $*$ denotes the convolution in $\mathbb{R}^3$. The sum, (3.1), provides a reconstruction including both contours of f and the boundaries. A more complete rationale and analysis are given in [6, 5].

We now recall the three-dimensional parallel beam complex for ET. Let $S \subset S^2$ be a smooth curve on the sphere, and for $\boldsymbol{\omega} \in S$ let $\boldsymbol{\omega}^{\perp}$ be the plane through the origin perpendicular[5] to $\boldsymbol{\omega}$. Then, following any of the approaches outlined in section 2.4, the inverse problem in ET as stated in Definition 2.1 can be recast as the problem of recovering f given values $\mathcal{P}(f)(\boldsymbol{y}, \boldsymbol{\omega})$, where $\mathcal{P}$ is given as in (2.3), $\boldsymbol{\omega} \in S$, and $\boldsymbol{y} \in \boldsymbol{\omega}^{\perp}$ (or for the local problem, $\boldsymbol{y}$ is in a proper subset of $\boldsymbol{\omega}^{\perp}$). The example below shows that this is an intrinsically ill-posed problem in the single-axis tilting case since the local transform is not injective even in the absence of noise. Thus, singularity detection algorithms such as Lambda tomography are natural methods since they regularize the problem by reconstructing only features that are stably visible (see, e.g., [20, 16, 21]).

Example 3.1. *Assume $f(x) = g(x_3)$, where the specimen is parallel to the (x_1, x_2)-plane. Then, only $\int_{-\infty}^{\infty} g(x_3)\, dx_3$ can be determined from single-axis tilt ET data with tilt angle less than $\pi/2$. This also is a counterexample for any set of lines, as in ET, without horizontal directions.*

4. The algorithm in general.

In this section, we describe our Lambda tomography algorithm for directions (or angles) on an arbitrary smooth curve $S \subset S^2$. Note that we follow an ET convention when we use the word "angle" to describe a point on S^2. This general setup will provide a general framework for the single-axis tilt geometry we use in ET, which will be described in section 5. The algorithm is general enough to take care of other tilting geometries such as dual-axis and conical tilting, which some of the newest electron microscopes can provide. A generalization of algorithm to slant-hole SPECT (with the same geometry as conical tilt) will be given in [22].

The planar Lambda tomography we described in section 3 has two important advantages: it solves the region of interest problem—it is local—and it is easily adaptable to other limited data sets in the plane [16, 21]. As noted in section 1, the inverse problem in ET (as given in Definition 2.1) can be rephrased as a three-dimensional limited angle region of interest reconstruction problem. It is therefore natural to consider a type of singularity detection algorithm related to Lambda tomography. Furthermore, as shown by Example 3.1, *inversion is not possible, so recovering singularities is an appropriate goal.* It also turns out that, despite the severe ill-posedness of the inverse problem, *those singularities that can be recovered are recovered stably* at least in range of Sobolev spaces.[6] Such an algorithm includes two pieces, a backprojection operator and a derivative along the lines.

Let S be a curve on the sphere. The backprojection operator is the *dual parallel beam transform* for directions on the curve S,

$$\mathcal{P}_S^*(g)(\boldsymbol{x}) := \int_{\boldsymbol{\omega} \in S} g\big(\boldsymbol{x} - (\boldsymbol{x} \cdot \boldsymbol{\omega})\boldsymbol{\omega}, \boldsymbol{\omega}\big)\, d\boldsymbol{\omega} \quad \text{for } \boldsymbol{x} \in \mathbb{R}^3, \tag{4.1}$$

where the measure $d\boldsymbol{\omega}$ is the arc length measure on the curve S and the point $\boldsymbol{x} - (x \cdot \boldsymbol{\omega})\boldsymbol{\omega}$ is the projection of $\boldsymbol{x}$ onto the plane $\boldsymbol{\omega}^{\perp}$.

[5] Note that $\boldsymbol{\omega}^{\perp}$ was a direction in S^1 perpendicular to $\boldsymbol{\omega}$ in the planar (two-dimensional) setting, whereas in the three-dimensional setting it is a plane perpendicular to $\boldsymbol{\omega}$.

[6] A stronger type of stability would be a microlocal inverse continuity estimate, and the authors are not aware of such a direct estimate for these operators.

The derivative along lines is defined as follows. Assume the curve S is parameterized by the differentiable function $\boldsymbol{\omega}(\theta)$ with derivative $\boldsymbol{\omega}'(\theta) \neq \mathbf{0}$, and let

$$\boldsymbol{\sigma}(\theta) := \frac{\boldsymbol{\omega}'(\theta)}{\|\boldsymbol{\omega}'(\theta)\|} \tag{4.2}$$

be a unit tangent to the curve S at $\boldsymbol{\omega}(\theta)$. Then, we denote the second derivative in direction $\boldsymbol{\sigma}$ by

$$\mathcal{D}^2_{\boldsymbol{\sigma}} g\big(\boldsymbol{y}, \boldsymbol{\omega}(\theta)\big) := \frac{d^2}{ds^2} g\big(\boldsymbol{y} + s\boldsymbol{\sigma}(\theta), \boldsymbol{\omega}(\theta)\big)\bigg|_{s=0}. \tag{4.3}$$

Our basic reconstruction operator is

$$\mathcal{L}(f) := \mathcal{P}^*_S\big((\mu - \mathcal{D}^2_{\boldsymbol{\sigma}})\mathcal{P}(f)\big). \tag{4.4}$$

This is a natural generalization of the two-dimensional Lambda operator (3.1) since it includes a second derivative along lines, a smoothing term, and a backprojection. We include the factor of μ, as is done for standard Lambda tomography, to provide contour to the reconstruction.

How $\mathcal{L}$ detects singularities can be understood using microlocal analysis, as we do in section 6. We will show that $\mathcal{L}$ is a pseudodifferential operator (PDO) with a mildly singular symbol (Theorem A.1). Moreover, ET data are very noisy, as discussed in section 2.2, so to cope with that we smooth in two ways. First, we evaluate the derivative $\mathcal{D}^2_{\boldsymbol{\sigma}}$ using a kernel that is a smoothed version of the second derivative. Second, we smooth by averaging nearby slices; that is, we also convolve in the $\boldsymbol{\omega}^{\perp}$-plane in the direction perpendicular to $\boldsymbol{\sigma}$. We will describe this smoothing explicitly in the case of single-axis tilting in the next section.

5. Single-axis tilt ET.

In this section, we will describe our algorithm for single-axis tilt ET. In *single-axis tilt* ET, one restricts the directions to a single tilt axis. We use a coordinate system where the electrons come in along the z-axis when $\boldsymbol{\omega} = (0, 0, 1)$, and we assume the *tilt axis* is the x-axis. Let us now write (4.4) in these coordinates.

Expression for S. Because the specimen cannot be fully rotated, this means that the curve of directions, S, is an arc of a circle in the (y, z)-plane and there is a limited angular range of $\pm\theta_{\max}$, where $\theta_{\max} \approx \pi/3$ radians. One appropriate parameterization for the curve S in this setting is

$$\boldsymbol{\omega}(\theta) := (0, \sin\theta, \cos\theta), \quad \theta \in \,]-\theta_{\max}, \theta_{\max}[\,, \tag{5.1}$$

and by (4.2) we get

$$\boldsymbol{\sigma}(\theta) = (0, \cos\theta, -\sin\theta). \tag{5.2}$$

Expression for $\mathcal{P}$. Now, $\boldsymbol{e}_1 := (1, 0, 0)$ and $\boldsymbol{\sigma}(\theta)$ form an orthonormal basis of the plane $\boldsymbol{\omega}(\theta)^{\perp}$ and thereby provide orthonormal coordinates on $\boldsymbol{\omega}(\theta)^{\perp}$:

$$\boldsymbol{y} = (y_1, y_{\boldsymbol{\sigma}}) \mapsto y_1\boldsymbol{e}_1 + y_{\boldsymbol{\sigma}}\boldsymbol{\sigma}(\theta) \in \boldsymbol{\omega}(\theta)^{\perp}. \tag{5.3}$$

In these coordinates the set of lines is parameterized by

$$\begin{aligned} &Y := \Big\{(\boldsymbol{y}, \theta) \;\Big|\; \boldsymbol{y} = (y_1, y_{\boldsymbol{\sigma}}) \in \mathbb{R}^2,\, \theta \in \,]-\theta_{\max}, \theta_{\max}[\,\Big\}, \\ &(\boldsymbol{y}, \theta) \mapsto \ell(\boldsymbol{y}, \theta) := \Big\{y_1\boldsymbol{e}_1 + y_{\boldsymbol{\sigma}}\boldsymbol{\sigma}(\theta) + t\boldsymbol{\omega}(\theta) \;\Big|\; t \in \mathbb{R}\Big\}, \end{aligned} \tag{5.4}$$

and functions on lines will be written $g(\boldsymbol{y},\theta) = g\big((y_1, y_{\boldsymbol{\sigma}}),\theta\big)$, so in particular $\mathcal{P}$ has parameterization

$$\mathcal{P}(f)(\boldsymbol{y},\theta) := \mathcal{P}(f)\big(y_1\boldsymbol{e}_1 + y_{\boldsymbol{\sigma}}\boldsymbol{\sigma}(\theta), \boldsymbol{\omega}(\theta)\big). \tag{5.5}$$

Expression for $\mathcal{P}^*_S$. Before expressing the dual operator $\mathcal{P}^*_S$ in (4.1) in these coordinates, we smooth it slightly in order to make it a classical Fourier integral operator (FIO) and in order to increase the accuracy in the numerical integration. This is done by choosing $0.9\,\theta_{\max} < \theta_{\text{cut}} < \theta_{\max}$ and defining the smooth function

$$\varphi : [-\pi/2, \pi/2] \to [0,1], \quad \operatorname{supp}\varphi = [-\theta_{\text{cut}}, \theta_{\text{cut}}], \tag{5.6}$$

where φ is nonzero on $]{-\theta_{\text{cut}}}, \theta_{\text{cut}}[$ and equal to one on most of this interval. φ is then extended $\mathbb{R}$ by making it π-periodic. The *smoothed limited angle dual parallel beam transform*, which is the version of $\mathcal{P}^*_S$ that we will be using, is

$$\mathcal{P}^*_{\theta_{\text{cut}}}(g)(\boldsymbol{x}) := \int_{-\theta_{\text{cut}}}^{\theta_{\text{cut}}} g\Big(\boldsymbol{x} - \big(\boldsymbol{x}\cdot\boldsymbol{\omega}(\theta)\big)\boldsymbol{\omega}(\theta), \boldsymbol{\omega}(\theta)\Big)\varphi(\theta)\,d\theta \quad \text{for } \boldsymbol{x} \in \mathbb{R}^3. \tag{5.7}$$

A simple trapezoidal rule integration, which corresponds to a specific choice of φ, works well in (5.7).

Expression for $\mathcal{D}^2_{\boldsymbol{\sigma}}$. In our coordinates $(\boldsymbol{y},\theta)$, $\mathcal{D}^2_{\boldsymbol{\sigma}}$ becomes

$$\mathcal{D}^2_{\boldsymbol{\sigma}}(g)(\boldsymbol{y},\theta) := \frac{d^2}{ds^2} g\big((y_1, s),\theta\big)\bigg|_{s=0}. \tag{5.8}$$

Expression for (4.4). Our expression for the Lambda operator $\mathcal{L}$ in (4.4) becomes

$$\mathcal{L}(f) = \mathcal{P}^*_{\theta_{\text{cut}}}\big((\mu - \mathcal{D}^2_{\boldsymbol{\sigma}})\mathcal{P}(f)\big). \tag{5.9}$$

This operator is a two-dimensional limited angle Lambda operator in each fixed plane $\boldsymbol{x} = \text{constant}$ (compare with (3.1)).

Further smoothing. We actually use a smoothed version of the derivative $\mathcal{D}^2_{\boldsymbol{\sigma}}$ in the $\boldsymbol{\sigma}$ direction, and we also smooth between slices in the $\boldsymbol{e}_1$ direction. This can be understood as either a convolution/smoothing of the data in the data plane, $\boldsymbol{\omega}^\perp$, or as a convolution/smoothing of the final reconstruction, as we now explain. Let $\phi_1 \in \mathscr{C}^\infty_c(\mathbb{R})$ be even with $\int_{\mathbb{R}} \phi_1 = 1$ and $\phi_2 \in \mathscr{C}^\infty_c(\mathbb{R}^2)$ be radial with $\int_{\mathbb{R}^2} \phi_2 = 1$. Moreover, let $\widetilde{\phi}_2$ be the two-dimensional parallel beam transform of ϕ_2, and note that $\widetilde{\phi}_2$ is radial and independent of direction. Let $(\phi_1 \otimes \widetilde{\phi}_2)(x_1,x_2,x_3) = \phi_1(x_1)\widetilde{\phi}_2(x_2,x_3)$. Then, for $(\boldsymbol{y},\theta) \in Y$ and data f with compact support,

$$(\phi_1 \otimes \widetilde{\phi}_2) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f)(\boldsymbol{y},\theta) = \mathcal{P}\big((\phi_1 \otimes \phi_2) * f\big)(\boldsymbol{y},\theta), \tag{5.10}$$

where $*$ denotes the convolution in $\mathbb{R}^3$ and $\circledast_{\boldsymbol{\omega}^\perp}$ is the convolution in the detector plane, $\boldsymbol{\omega}(\theta)^\perp$. Equation (5.10) is valid since $\mathcal{P}$ integrates only over lines perpendicular to $\boldsymbol{e}_1$ and ϕ_1 is a function only of x_1. Because $\mathcal{L}$ is a convolution operator (see Theorem A.1), it commutes with the convolution with $\phi_1 \otimes \phi_2$. This means that

$$\big(\phi_1 \otimes \phi_2\big) * \mathcal{L}(f) = \mathcal{P}^*_{\theta_{\text{cut}}}\Big[(\mu - \mathcal{D}^2_{\boldsymbol{\sigma}})\big((\phi_1 \otimes \widetilde{\phi}_2) \underset{\boldsymbol{\omega}^\perp}{\circledast} \mathcal{P}(f)\big)\Big] \tag{5.11}$$

$$= \mathcal{P}^*_{\theta_{\text{cut}}}\Big[\phi_1 \underset{\boldsymbol{e}_1}{\circledast} \big((\mu\widetilde{\phi}_2 - \mathcal{D}^2_{\boldsymbol{\sigma}}\widetilde{\phi}_2) \underset{\boldsymbol{\sigma}}{\circledast} \mathcal{P}(f)\big)\Big], \tag{5.12}$$

where $\circledast_{\boldsymbol{e}_1}$ and $\circledast_{\boldsymbol{\sigma}}$ are one-dimensional convolutions in the $\boldsymbol{\omega}^{\perp}$-plane in the respective directions $\boldsymbol{e}_1$ and $\boldsymbol{\sigma}(\theta)$. So, our algorithm can be viewed as a smoothed version of $\mathcal{L}(f)$ (left-hand side of (5.11)), a smoothing of the data before applying $\mathcal{L}$ (right-hand side of (5.11)), or averaging over slices (the $\circledast_{\boldsymbol{e}_1}$ convolution in (5.12)) of a smoothed derivative (the $\circledast_{\boldsymbol{\sigma}}$ convolution in (5.12)).

6. Microlocal analysis applied to ET. We will now use microlocal analysis to analyze which singularities of a specimen are stably visible from single-axis tilt ET data.

Microlocal analysis allows one to rigorously define singularities of functions such as object boundaries. This is made precise by the wavefront set whose definition is our first task. Next, the theory of FIOs describes which singularities of a function are visible from its ET data. This correspondence follows from general theorems of Greenleaf and Uhlmann [8] about geodesic Radon transforms on admissible complexes, and the microlocal properties of this specific transform were examined by Boman and Quinto [2]. Here we will give a basic version of the microlocal regularity theorem which will allow us to characterize visible singularities. The complete version of the theorem will be presented in the appendix along with characterizations of $\mathcal{L}$ as a convolution PDO. In the appendix, we also introduce a generalization, $\mathcal{L}_{\triangle}$ (A.14), of an operator of Louis and Maaß. Our characterization will show the trade-offs between the operators; $\mathcal{L}_{\triangle}$ can add stronger singularities than $\mathcal{L}$. At the end of the section, we give an example that illustrates the predictions.

Before stating the formal definition of the wavefront set we need to deal with a technicality.

REMARK 6.1. *The wavefront set is typically defined as a subset of the cotangent bundle, because in this way it is invariant under diffeomorphisms. Furthermore, this is a natural way to describe wavefronts in general. Here is the identification for* $\mathbb{R}^3$. *For* $\boldsymbol{x} \in \mathbb{R}^3$, *the cotangent space* $T^*_{\boldsymbol{x}}(\mathbb{R}^n)$ *is the set of linear functionals on the tangent space* $T_{\boldsymbol{x}}(\mathbb{R}^3)$, *and* $\boldsymbol{dx}_j$ *is the dual covector to* $\frac{\partial}{\partial x_j}$ $(j = 1, 2, 3)$. *This gives a canonical representation,*

$$\boldsymbol{\xi} \ni \mathbb{R}^3 \to \boldsymbol{\xi}\boldsymbol{dx} := \xi_1\boldsymbol{dx}_1 + \xi_2\boldsymbol{dx}_2 + \xi_3\boldsymbol{dx}_3.$$

The cotangent bundle, $T^*(\mathbb{R}^3)$, *is the set* $T^*(\mathbb{R}^3) := \big\{(\boldsymbol{x}, \boldsymbol{\xi}\boldsymbol{dx}) \;\big|\; \boldsymbol{x} \in \mathbb{R}^3,\ \boldsymbol{\xi} \in \mathbb{R}^3\big\}$, *where* $(\boldsymbol{x}; \boldsymbol{\xi}\boldsymbol{dx}) = (x_1, x_2, x_3; \xi_1\boldsymbol{dx}_1 + \xi_2\boldsymbol{dx}_2 + \xi_3\boldsymbol{dx}_3)$.

Recall that $\mathscr{D}'(\mathbb{R}^3)$ is the set of all distributions, $\mathscr{S}'(\mathbb{R}^3)$ is the set of tempered distributions (dual space of $\mathscr{S}(\mathbb{R}^3)$), and $\mathscr{E}'(\mathbb{R}^3)$ is the space of compactly supported distributions. We are now ready to define the concept of a wavefront set.

DEFINITION 6.2 (see [19, p. 259]). *Let* f *be a distribution,* $\boldsymbol{x}_0 \in \mathbb{R}^n$, *and* $\boldsymbol{\xi}_0 \in \mathbb{R}^n \setminus \{\boldsymbol{0}\}$. *We then define the following:*

1. f *is in* $\mathscr{C}^\infty$ microlocally near $(\boldsymbol{x}_0, \boldsymbol{\xi}_0\boldsymbol{dx})$ *if and only if there is a cut-off function* $\psi \in \mathscr{C}_c^\infty(\mathbb{R}^n)$ *with* $\psi(\boldsymbol{x}_0) \neq 0$ *and a function* u *homogeneous of degree zero that is smooth on* $\mathbb{R}^n \setminus \{\boldsymbol{0}\}$ *with* $u(\boldsymbol{\xi}_0) \neq 0$ *such that the product* $u(\cdot)\widehat{\psi f}(\cdot)$ *is rapidly decreasing at* ∞.[7] *The* $\mathscr{C}^\infty$ wavefront set of f, $\mathrm{WF}(f)$, *is the complement of the set of* $(\boldsymbol{x}_0; \boldsymbol{\xi}_0\boldsymbol{dx})$ *near which* f *is microlocally smooth.*
2. f *is in* $\mathscr{H}^\alpha$ microlocally near $(\boldsymbol{x}_0; \boldsymbol{\xi}_0\boldsymbol{dx})$ *if and only if there is a cut-off function* $\psi \in \mathscr{C}_c^\infty(\mathbb{R}^n)$ *with* $\psi(\boldsymbol{x}_0) \neq 0$ *and a function* u *homogeneous of*

[7] In our context, a function h is *rapidly decreasing at* ∞ if for each $k \in \mathbb{N}$ there is a $C > 0$ such that for all $\boldsymbol{x} \in \mathbb{R}^n$, $\big|h(\boldsymbol{x})\big| \leq C\big(1 + \|\boldsymbol{x}\|\big)^{-k}$. Sometimes one replaces the function u by an open cone U containing $\boldsymbol{\xi}_0$ on which $\widehat{\psi f}$ is rapidly decreasing at ∞.

degree zero and smooth on $\mathbb{R}^n \setminus \{\mathbf{0}\}$ *and with* $u(\boldsymbol{\xi}_0) \neq 0$ *such that the product* $u(\cdot)\widehat{\psi f}(\cdot) \in \mathscr{L}^2\big(\mathbb{R}^n, \big(1+|\boldsymbol{\xi}|^2\big)^\alpha\big)$*. The* $\mathscr{H}^\alpha$ wavefront set of f, $\mathrm{WF}^\alpha(f)$*, is the complement of the set of* $(\boldsymbol{x}_0, \boldsymbol{\xi}_0 \boldsymbol{dx})$ *near which* f *is microlocally in* $\mathscr{H}^\alpha$*.*

For example, if f is one inside the unit disk and zero outside, then $\mathrm{WF}(f) = \mathrm{WF}^1(f)$ and they both consist of the covectors conormal to the boundary of the disk. In general, if $f : \mathbb{R}^3 \to \mathbb{R}$ is $\mathscr{C}^\infty$ except for jump singularities along smooth surfaces, then the $\mathscr{C}^\infty$ wavefront set of f consists of all the conormals to these surfaces of discontinuity.

Having defined the necessary concept of a wavefront set, we now turn our attention to our main theorem, which characterizes the singularities that are visible from single-axis tilt ET data.

Theorem 6.3 (microlocal regularity theorem). *Let* $f \in \mathscr{E}'(\mathbb{R}^3)$*,* $(y_1, y_{\boldsymbol{\sigma}}, \theta_0) = \boldsymbol{y} \in Y$*, and let* $\boldsymbol{\xi}_0 \in \boldsymbol{\omega}(\theta)^\perp$ *be a nonzero vector where we write* $\boldsymbol{\xi}_0 = \xi_1 \boldsymbol{e}_1 + \xi_{\boldsymbol{\sigma}} \boldsymbol{\sigma}(\theta)$*. Finally, let* $\boldsymbol{x}_0 \in \ell(y_1, y_{\boldsymbol{\sigma}}, \theta)$*. If* $\xi_{\boldsymbol{\sigma}} \neq 0$*, then there is a corresponding covector in* $T^*_{\boldsymbol{y}}(Y)$ *such that* $(\boldsymbol{x}_0, \boldsymbol{\xi}_0 \boldsymbol{dx}) \in \mathrm{WF}(f)$ *if and only if this covector is in* $\mathrm{WF}\big(\mathcal{P}(f)\big)$ *(this correspondence is given in Theorem* A.6*). If we also assume that* $\mathcal{P}(f)$ *is* $\mathscr{C}^\infty$ *near* $\boldsymbol{y}$*, then* $(\boldsymbol{x}_0, \boldsymbol{\xi}_0 \boldsymbol{dx}) \notin \mathrm{WF}(f)$*.*

Note that $\boldsymbol{dx}_1$ is conormal to $\boldsymbol{\omega}(\theta)$ (and thus conormal to the line $\ell(\boldsymbol{y}, \theta)$ for all θ since $\boldsymbol{\omega}(\theta)$ is in the (y, z)-plane). So, the restriction $\xi_{\boldsymbol{\sigma}} \neq 0$ just means $\boldsymbol{\xi}_0 \boldsymbol{dx}$ defined in the theorem above is not a multiple of $\boldsymbol{dx}_1$ ($\boldsymbol{\xi}_0$ is not parallel to $\boldsymbol{e}_1$).

In general, Radon transforms (such as the parallel beam transform in this article) detect only singularities perpendicular to the sets of integration, so it is not surprising that the theorem provides information only about singularities of f conormal to $\boldsymbol{\omega}(\theta)$ since these are conormal to the corresponding lines in the data set. However, for this transform, there are two conormal directions that are excluded, $\boldsymbol{\xi}_0 = \pm\boldsymbol{e}_1$; these are *"bad" cotangent directions* because they "should" be visible (they are conormal to lines in the data set), but they cause problems. We will examine these problems in the appendix, and in particular we will show that $\mathcal{L}$ can add singularities in these directions.

Example 6.4. *We now illustrate the implications of Theorem* 6.3 *for ET. Let* D *be the unit disk in space, and let* f *be one inside* D *and zero outside. Assume the region of interest contains* D*, and assume that* φ *satisfies* (5.6)*. If* $\boldsymbol{x} \in \operatorname{bd} D$*, then* $\boldsymbol{x}$ *is normal to* $\operatorname{bd} D$ *at* $\boldsymbol{x}$*, so* $(\boldsymbol{x}; \boldsymbol{x}\boldsymbol{dx}) \in \mathrm{WF}(f)$*. No matter what* θ_{cut} *is, the wavefront* $\pm\boldsymbol{e}_1\boldsymbol{dx}$ *is problematic. This is a conormal at the points* $(\pm 1, 0, 0)$ *on the boundary. Singularities in other conormal directions are visible from the data as long as the direction is perpendicular to a line in the data set. Let* $\boldsymbol{x} = (x_1, x_2, x_3) \in \operatorname{bd} D$*. Because of the geometry of the single-axis tilt* (5.1)*, this means that* $|x_3/x_2| < \tan(\theta_{\mathrm{cut}})$ *in order for the wavefront at* $\boldsymbol{x}$ *to be visible. The part of the sphere that should be visible is illustrated in Figure* 2*. One would expect for numerical reasons that the boundary would get gradually less well defined near the edge of the visible part.*

7. Applications to real data.

We have tested the limited angle Lambda algorithm based on the Lambda operator (5.9) on both in vitro and in situ ET data. The Lambda reconstruction is obtained by applying the limited angle Lambda algorithm directly on the region of interest. This reconstruction is compared to a filtered back-projection (FBP) reconstruction that has been regularized by an additional low-pass filtering (low-pass FBP). This latter filtering, which in our case reduces the resolution to 10 nm, is necessary in order to gain stability, and the value for the low-pass filtering represents the best trade-off between stability and resolution if FBP is to be used on

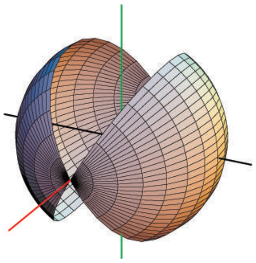


FIG. 2. *Part of sphere with normal vectors normal to lines in the data set with $\theta_{\text{cut}} = 60°$. The x_1-axis is facing out of the page.*

these particular examples. The low-pass FBP is applied to the entire reconstruction region, and the region of interest is then extracted for comparison against the limited angle Lambda reconstruction.

The first case, shown in Figure 3, is the reconstruction of in vitro monoclonal immunoglobulin G (IgG) molecules with a molecular weight of 150 kDa. The ET data was collected from single-axis tilting (see section 2.1) with a uniform sampling of the tilt angle in $[-60°, 60°]$ at 1° step. The pixel size is 0.5241 nm and the total dose is 1820 e^-/nm^2. A detailed account on the background for the study, the experimental setting, and the study objective is given in [24]. The reconstruction region is $256 \times 256 \times 256$ pixels in size, and the local region of interest is centered in the midpoint of the reconstruction region with a size of $128 \times 128 \times 128$ pixels.

Figure 3 shows how the limited angle Lambda reconstruction emphasizes boundaries better. It also seems to somewhat suppress the background noise outside the molecule, and the IgG molecule (which is in the center) is more visible than in the low-pass FBP reconstruction.

The next case, shown in Figure 4, is the reconstruction of an in situ tissue sample (could be a human, rat, or mouse kidney). The ET data was collected from single-axis tilting (see section 2.1) with a uniform sampling of the tilt angle in $[-60°, 60°]$ at 2° step. The pixel size is 0.5241 nm and the total dose is 1520 e^-/nm^2. A detailed account on the background for the study, the experimental setting, and the study objective is given in [30, 27]. The reconstruction region is $300 \times 300 \times 150$ pixels in size, and the local region of interest is centered in the midpoint of the reconstruction region and is of $200 \times 200 \times 140$ pixels size.

Since the object in Figure 4 is in situ, parts of the object outside the region of interest will affect the FBP reconstruction in the region of interest but not the Lambda reconstruction (since it does not require data from outside the region of interest). The reconstructions in Figure 4 clearly show that the limited angle Lambda reconstruction defines boundaries better since the "V" shaped region containing the slit diaphragm (in the upper right side of the object) is more clearly defined than in the low-pass FBP reconstruction. This also illustrates the microlocal principles of section 6 since the slabs are tangent to lines in the data set.

Appendix. The microlocal properties of $\mathcal{P}$ and $\mathcal{L}$. In this section, we will describe the microlocal properties of our transform $\mathcal{P}$ and the reconstruction operator $\mathcal{L}$ (5.9). We will use this information to explain how the transform detects singularities and show the relevance to ET. The properties of the more general operator (4.4) are similar, and the details will be given in a subsequent article [22].

The convolution operator in $\mathbb{R}^n$ is denoted by $*$. For the Fourier transform on
