ON A MULTIPLE-SCALES ANALYSIS OF MULTILATERAL PHENOMENA IN SEMICONDUCTOR LASERS*

BENJAMIN P. COX[†] AND WARREN R. SMITH[‡]

Abstract. A mathematical model describing the coupling of electrical and optical effects in the active region of a realistic semiconductor laser medium is introduced. The weakly nonlinear analysis which follows gives rise to a leading-order problem describing three lateral modes. At the next order, the secularity conditions exhibit competition for photons and modal interaction. By making further assumptions, a partially lumped model is deduced which has no counterpart in the existing literature; this simplified system consists of one parabolic and six first-order hyperbolic partial differential equations. Predictions of this partially lumped model are compared with experimental observations.

Key words. semiconductor lasers, multilateral phenomena, asymptotics

1. Introduction.

Two different approaches are followed by the laser community when modeling multimode effects in semiconductor lasers. The first approach describes M longitudinal modes by M rate equations (see, for example, [1], [2], and [11]). However, rate equations for the lateral modes have not been determined despite being required to model broad-area lasers. The second approach attempts to incorporate all possible effects (including sophisticated quantum mechanical models) into large numerical codes using the Maxwell–Bloch equations (see, for example, [7] and [10]). In this article, an alternative approach is proposed to determine simplified models based on a systematic asymptotic analysis of Maxwell's equations. Moreover, we derive traveling-wave rate equations for the lateral modes in a broad-area semiconductor laser.

A schematic cross-section of a typical semiconductor laser is shown in Figure 1. The current, assumed unidirectional in this paper, passes between the metal contact on the substrate and the heat sink. Electrons are injected into the active layer where they recombine with holes through both radiative and nonradiative mechanisms. During radiative recombination the energy released by an electron-hole pair appears in the form of a photon. This can happen through spontaneous emission, in which the photons are emitted in random directions, or stimulated emission, in which recombination is initiated by an existing photon. In the latter case the emitted photon matches the original photon in wavelength, phase, and direction. As long as the end faces of the semiconductor possess a suitable reflectivity and the current exceeds a given threshold value, the semiconductor is excited through stimulated emission into laser operation.

The purpose of this paper is to investigate the multilateral effects in semiconductor lasers by extending the weakly nonlinear analysis presented in [12]. The semiconductor laser is split into two regions—the active layer, in which the electrical-optical effects

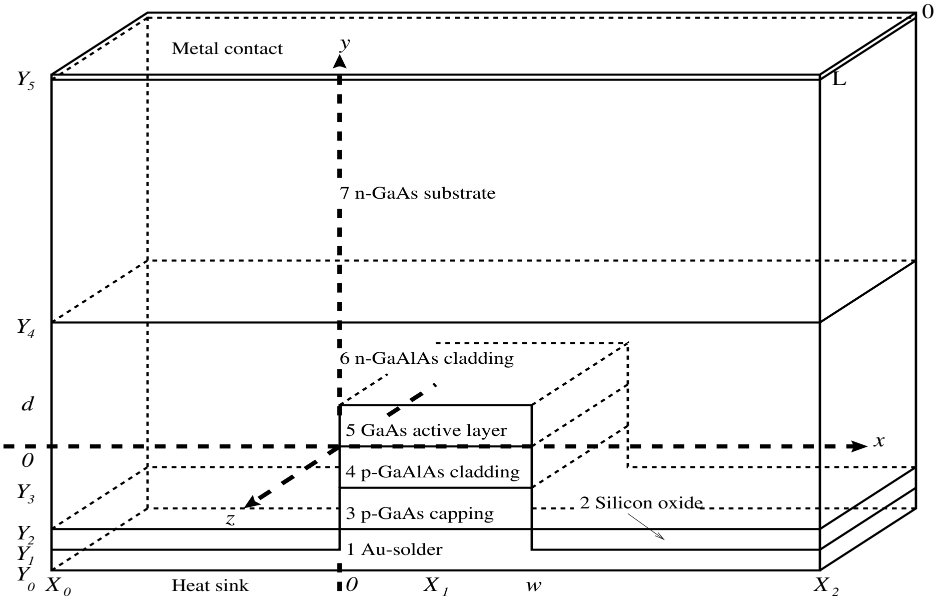

FIG. 1. *Typical layered structure of a double-heterostructure semiconductor laser. The lateral direction is denoted by x, the transverse direction by y, and the longitudinal (or axial) direction by z. The battery potential is applied in the transverse direction, with mirrors located at $z = 0$ and $z = L$.*

take place and lasing occurs, and the surrounding material. This work is concerned with the first of these regions. The analysis in [12], which assumes one dominant lateral mode, is extended to the case of three such modes. As multilateral mode operation is generally undesirable, we also investigate a bifurcation condition to quantify the onset of multilateral behavior.

We take Maxwell's equations as the starting point and add models for the polarization and current density. We assume that the whole device is maintained at a constant ambient temperature and that the gain takes place at a single frequency associated with the band gap of the active region. Each of the modes must satisfy the periodicity condition $\lambda_r = 2nL/q_r$, where n and q_r are positive integers, λ_r is the wavelength of the rth lateral mode, and L is the longitudinal cavity length. We assume that each lasing mode is confined to the active layer, noting that in certain devices, such as quantum well lasers, this is true of only a tenth of the lasing mode—the analysis in this paper will not be valid in such circumstances. We are primarily concerned with the steady-state behavior which is insensitive to spontaneous emission. Hence the contribution due to this process is omitted in the derivation of the models below.

Based on the above assumptions, the mathematical model is summarized in section 2. The problem is nondimensionalized in section 3, where the key small parameters are identified. Section 4 deals with a multiple-scale asymptotic analysis, whereby the governing equations are reduced to one parabolic partial differential equation and twelve first-order wave equations. In section 5, further simplifications lead to a time-dependent partially lumped model whose bifurcations are investigated. Numerical solutions to the steady-state system are presented in section 6. We split the results into two cases, prescribing a different lateral current density profile in each case, and compare the physical effects predicted by the model with experimental observations. The final section briefly draws some conclusions.

2. Theoretical background. The model formulation in the active region will now be outlined. We write down Maxwell's equations for a semiconductor medium in the form

$$\boldsymbol{\nabla}\cdot\boldsymbol{D} = \rho, \tag{1}$$

$$\boldsymbol{\nabla}\times\boldsymbol{E} = -\frac{\partial \boldsymbol{B}}{\partial t}, \tag{2}$$

$$\boldsymbol{\nabla}\cdot\boldsymbol{B} = 0, \tag{3}$$

$$\boldsymbol{\nabla}\times\boldsymbol{H} = \frac{\partial \boldsymbol{D}}{\partial t} + \boldsymbol{J}, \tag{4}$$

where $\boldsymbol{E}$ is the electric field, $\boldsymbol{D}$ is the electric displacement, $\boldsymbol{H}$ is the magnetic field, $\boldsymbol{B}$ is the magnetic induction, $\boldsymbol{J}$ is the current density, ρ is the charge density, t is time, and the differential operator $\boldsymbol{\nabla} = (\partial/\partial x, \partial/\partial y, \partial/\partial z)$, where x, y, and z are indicated in Figure 1. The constitutive equations are given by $\boldsymbol{D} = \epsilon_0\boldsymbol{E} + \boldsymbol{P}$ and $\boldsymbol{B} = \mu_0\boldsymbol{H}$, where ϵ_0 is the permittivity of free space, $\boldsymbol{P}$ is the polarization, and μ_0 is the permeability of free space. The speed of light in a vacuum is given by $c_0 = 1/\sqrt{\epsilon_0\mu_0}$.

We write the polarization as a sum,

$$\boldsymbol{P} = (\epsilon - \epsilon_0)\boldsymbol{E} + \boldsymbol{P}^{(R)}, \tag{5}$$

where the permittivity ϵ is assumed to be independent of changes in the carrier concentration (and self-focusing is neglected as a result). The time-periodic component $\boldsymbol{P}^{(R)}$ represents resonant coupling, which occurs when the frequency of the electric field closely matches a natural frequency of the semiconductor. As in [12] we adopt a simple model for this resonant interaction,

$$\frac{\partial^2\boldsymbol{P}^{(R)}}{\partial t^2} = -\frac{\partial}{\partial t}(\epsilon a(\min(n,p) - n_t)\boldsymbol{E}), \tag{6}$$

where n and p are the electron and hole concentrations, respectively, $\epsilon a n_t$ represents the absorption of photons, $-\epsilon a \min(n,p)$ is the stimulated gain, a is the linear gain rate, and n_t is the electron density at transparency (that is, the electron concentration at which the stimulated gain and absorption balance). Equation (6) is consistent with the corresponding constitutive equations adopted elsewhere (see [1]) and can be regarded as an approximation to the more sophisticated theories of polarization (see, for example, [3] and [10]).

The charge density and current density are split up as follows:

$$\rho = e(N + p - n), \qquad \boldsymbol{J} = \boldsymbol{J}_{\boldsymbol{n}} + \boldsymbol{J}_{\boldsymbol{p}}, \tag{7}$$

where e is the charge on an electron, N is the net impurity density in the active region, and $\boldsymbol{J}_{\boldsymbol{n}}$ and $\boldsymbol{J}_{\boldsymbol{p}}$ are the components of the current density carried by electrons and holes, respectively. If we let D_n and D_p represent the active region diffusivities of electrons and holes, respectively, and use μ_n and μ_p to represent their respective mobilities, then the components of the current density are written in the form (see [12])

$$\boldsymbol{J}_{\boldsymbol{n}} = e\,(D_n\boldsymbol{\nabla} n + \mu_n n\boldsymbol{E}), \qquad \boldsymbol{J}_{\boldsymbol{p}} = e\,(-D_p\boldsymbol{\nabla} p + \mu_p p\boldsymbol{E}). \tag{8}$$

Defining k to be Boltzmann's constant and T to be the temperature of the device (assumed constant here), the Einstein relations between the diffusivities and mobilities are $D_n = U_T \mu_n$ and $D_p = U_T \mu_p$, where the thermal voltage is given by $U_T = kT/e$. The continuity equations for electrons and holes are derived by taking the divergence of (4) and can be written in the form

$$e\frac{\partial n}{\partial t} = e(G - R) + \boldsymbol{\nabla}\boldsymbol{\cdot}\boldsymbol{J_n}, \qquad e\frac{\partial p}{\partial t} = e(G - R) - \boldsymbol{\nabla}\boldsymbol{\cdot}\boldsymbol{J_p}. \tag{9}$$

The net recombination rate of electron-hole pairs, $R - G$, is given by

$$\begin{aligned} R - G = {} & \frac{(np - n_i^2)}{A_p(n + n_i) + A_n(p + n_i)} + B(np - n_i^2) \\ & + (C_n n + C_p p)(np - n_i^2) - \frac{1}{E_g}\boldsymbol{E}\cdot\frac{\partial \boldsymbol{P}^{(R)}}{\partial t}. \end{aligned} \tag{10}$$

The terms on the right-hand side of (10) correspond respectively to Shockley–Read–Hall recombination (with reciprocal rate constants A_n and A_p), radiative recombination (with rate constant B), Auger recombination (with rate constants C_n and C_p), and recombination due to stimulated emission. We denote the intrinsic carrier density by n_i, while the constant E_g corresponds to the band-gap energy in the active region. We assume that the laser operates at a single angular frequency $\omega = 2\pi E_g/h$, where h represents Planck's constant.

Equations (1)–(4) can be simplified by the introduction of scalar and vector potentials. We satisfy (2) and (3) by writing $\boldsymbol{E} = -\boldsymbol{\nabla}\phi - \partial \boldsymbol{A}/\partial t$ and $\boldsymbol{B} = \boldsymbol{\nabla} \times \boldsymbol{A}$ in which ϕ is the scalar potential and $\boldsymbol{A}$ is the vector potential. We specify $\boldsymbol{A}$ uniquely via the gauge condition (see [14])

$$\boldsymbol{\nabla}\boldsymbol{\cdot}\boldsymbol{A} + \mu_0 \epsilon \frac{\partial \phi}{\partial t} = 0 \tag{11}$$

so that ϕ and $\boldsymbol{A}$ satisfy

$$\begin{aligned} \boldsymbol{\nabla}^2 \phi - \mu_0 \epsilon \frac{\partial^2 \phi}{\partial t^2} &= \frac{1}{\epsilon}\Big(\boldsymbol{\nabla}\boldsymbol{\cdot}\boldsymbol{P}^{(R)} - e(N + p - n)\Big), \\ \boldsymbol{\nabla}^2 \boldsymbol{A} - \mu_0 \epsilon \frac{\partial^2 \boldsymbol{A}}{\partial t^2} &= -\mu_0 \frac{\partial \boldsymbol{P}^{(R)}}{\partial t} - \mu_0 \boldsymbol{J}. \end{aligned} \tag{12}$$

The mathematical model comprises (6), (9), and (11)–(12) along with appropriate boundary conditions (see [12]).

3. The dimensionless mathematical model. In the nondimensionalization which follows, the quantities ϕ_e and A_e (defined in [12]) represent typical magnitudes of the scalar and vector potentials, respectively. We define n_e to be a representative value of the electron concentration (defined in [12]). Let w be the lateral width of the active region, d be the transverse width of the active region, λ be a typical wavelength of the lasing radiation, and $\tau_e = \lambda/c_0$ be the time-scale. We transform to dimensionless variables via $n = n_e \hat{n}$, $p = n_e \hat{p}$, $\phi = \phi_e \hat{\phi}$, $\boldsymbol{A} = A_e \hat{\boldsymbol{A}}$, $\boldsymbol{P}^{(R)} = n_e \lambda e \delta \nu \hat{\boldsymbol{P}}^{(R)}$, $x = w\hat{x}$, $y = d\hat{y}$, $z = \lambda \hat{z}$, and $t = \tau_e \hat{t}$, where the dimensionless constants δ and ν are defined in Table 1.

The model consists of continuity equations for the electron and hole densities $\hat{n}$ and $\hat{p}$, two second-order wave equations modeling the electric field components $\hat{\phi}$ and

$\hat{\boldsymbol{A}}$, the gauge condition, and an equation for the polarization component $\hat{\boldsymbol{P}}^{(R)}$:

$$\begin{aligned}\frac{\partial\hat{n}}{\partial\hat{t}} &= -\frac{\delta\nu(\hat{n}\hat{p}-\mathcal{N}^2)}{\mathcal{A}_p(\hat{n}+\mathcal{N})+\mathcal{A}_n(\hat{p}+\mathcal{N})} - \delta\nu\mathcal{B}(\hat{n}\hat{p}-\mathcal{N}^2) - \delta\nu(\mathcal{C}_n\hat{n}+\mathcal{C}_p\hat{p})(\hat{n}\hat{p}-\mathcal{N}^2)\\ &\quad - \delta\nu\mathcal{F}\frac{\partial\hat{\boldsymbol{P}}^{(R)}}{\partial\hat{t}}\cdot\left(\hat{\boldsymbol{\nabla}}\hat{\phi}+\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right) + \delta\nu\hat{\boldsymbol{\nabla}}\cdot\left(\mathcal{D}_n\hat{\boldsymbol{\nabla}}\hat{n} - \hat{n}\mathcal{V}_n\left\{\hat{\boldsymbol{\nabla}}\hat{\phi}+\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right\}\right),\end{aligned}\tag{13}$$

$$\begin{aligned}\frac{\partial\hat{p}}{\partial\hat{t}} &= -\frac{\delta\nu(\hat{n}\hat{p}-\mathcal{N}^2)}{\mathcal{A}_p(\hat{n}+\mathcal{N})+\mathcal{A}_n(\hat{p}+\mathcal{N})} - \delta\nu\mathcal{B}(\hat{n}\hat{p}-\mathcal{N}^2) - \delta\nu(\mathcal{C}_n\hat{n}+\mathcal{C}_p\hat{p})(\hat{n}\hat{p}-\mathcal{N}^2)\\ &\quad - \delta\nu\mathcal{F}\frac{\partial\hat{\boldsymbol{P}}^{(R)}}{\partial\hat{t}}\cdot\left(\hat{\boldsymbol{\nabla}}\hat{\phi}+\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right) + \delta\nu\hat{\boldsymbol{\nabla}}\cdot\left(\mathcal{D}_p\hat{\boldsymbol{\nabla}}\hat{p} + \hat{p}\mathcal{V}_p\left\{\hat{\boldsymbol{\nabla}}\hat{\phi}+\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right\}\right),\end{aligned}\tag{14}$$

$$\nu\epsilon_R\mathcal{G}\left(\hat{\boldsymbol{\nabla}}^2\hat{\phi}-\epsilon_R\frac{\partial^2\hat{\phi}}{\partial\hat{t}^2}\right) = \delta\nu\hat{\boldsymbol{\nabla}}\cdot\hat{\boldsymbol{P}}^{(R)} - (N^*+\hat{p}-\hat{n}),\tag{15}$$

$$\begin{aligned}\hat{\boldsymbol{\nabla}}^2\hat{\boldsymbol{A}} - \epsilon_R\frac{\partial^2\hat{\boldsymbol{A}}}{\partial\hat{t}^2} &= -\delta\mathcal{L}\left(\frac{\partial\hat{\boldsymbol{P}}^{(R)}}{\partial\hat{t}} + \mathcal{D}_n\hat{\boldsymbol{\nabla}}\hat{n} - \mathcal{D}_p\hat{\boldsymbol{\nabla}}\hat{p} - \mathcal{V}_n\hat{n}\hat{\boldsymbol{\nabla}}\hat{\phi} - \mathcal{V}_p\hat{p}\hat{\boldsymbol{\nabla}}\hat{\phi}\right.\\ &\qquad\left. - \mathcal{V}_n\hat{n}\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}} - \mathcal{V}_p\hat{p}\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right),\end{aligned}\tag{16}$$

$$\hat{\boldsymbol{\nabla}}\cdot\hat{\boldsymbol{A}} + \epsilon_R\frac{\partial\hat{\phi}}{\partial\hat{t}} = 0,\tag{17}$$

$$\frac{\partial^2\hat{\boldsymbol{P}}^{(R)}}{\partial\hat{t}^2} = \frac{\partial}{\partial\hat{t}}\left(\epsilon_R\hat{g}(\hat{n},\hat{p})\left(\hat{\boldsymbol{\nabla}}\hat{\phi}+\frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right)\right),\tag{18}$$

where the linear gain term in (18) is given by $\hat{g}(\hat{n},\hat{p}) = \mathcal{H}(\min(\hat{n},\hat{p}) - n^*)$. We define $A_x = \lambda/w$ and $A_y = \lambda/d$ whereby $\hat{\boldsymbol{\nabla}} = (A_x\partial/\partial\hat{x}, A_y\partial/\partial\hat{y}, \partial/\partial\hat{z})$. The relative permittivity, approximated by a constant in this weakly nonlinear analysis, is typically of $O(1)$ and $\epsilon_R = \epsilon/\epsilon_0$ (see Table 1). The dimensionless constants $\delta^{-1}\nu^{-1}\mathcal{A}_n$, $\delta^{-1}\nu^{-1}\mathcal{A}_p$, $\delta\nu\mathcal{B}$, $\delta\nu\mathcal{C}_n$, $\delta\nu\mathcal{C}_p$, $\delta\nu\mathcal{D}_n$, $\delta\nu\mathcal{D}_p$, $\delta\nu\mathcal{V}_n$, $\delta\nu\mathcal{V}_p$, $\mathcal{F}$, $\nu\mathcal{G}$, $\delta\nu\mathcal{H}$, $\nu^{-1}\mathcal{L}$, $\mathcal{N}$, n^*, and N^* are defined in Table 1; the constraints $\nu \ll \delta \ll 1$, $\mathcal{N} \ll 1$, and $N^* \ll 1$ typically hold in practice. The problem is regularly perturbed in $\mathcal{N}$ and N^*, and thus the terms that are multiplied by these are henceforth neglected. The former is the ratio of the intrinsic carrier density to a typical free carrier concentration. The latter represents the (low) doping concentration in the active region relative to the free carrier concentration. The problem is singularly perturbed in δ and ν. The first of these, δ, corresponds to the ratio of wavelength to cavity length; the second, ν, is the ratio of L/c to the time-scale on which the electron concentration varies (c is the speed of an electromagnetic wave in the active region medium). In the next section we will pursue a multiple-scale asymptotic analysis based around these key small parameters. Further discussion of the physical mechanisms and details that appear in the derivation of (13)–(18) may be found in [12].

We now outline the boundary conditions that accompany equations (13)–(18). In the following $\hat{\boldsymbol{n}}$ denotes the unit normal to the boundary of the lasing region. The normal components of the electron and hole current densities are assumed to be zero at the lateral boundaries, in which case

$$\left(\mathcal{D}_n\hat{\boldsymbol{\nabla}}\hat{n} - \mathcal{V}_n\hat{n}\left(\hat{\boldsymbol{\nabla}}\hat{\phi} + \frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right)\right)\cdot\hat{\boldsymbol{n}} = 0 \quad \text{at } \hat{x} = 0, 1, \tag{19}$$

together with a similar expression for holes. We prescribe the normal components of the electron and hole current densities at the transverse boundaries, that is,

$$\left(\mathcal{D}_n\hat{\boldsymbol{\nabla}}\hat{n} - \mathcal{V}_n\hat{n}\left(\hat{\boldsymbol{\nabla}}\hat{\phi} + \frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right)\right)\cdot\hat{\boldsymbol{n}} = \begin{cases} G_1(\hat{x},\hat{z},\hat{t}) & \text{at } \hat{y} = 0, \\ G_2(\hat{x},\hat{z},\hat{t}) & \text{at } \hat{y} = 1, \end{cases} \tag{20}$$

together with a similar expression for holes. At each mirror the normal fluxes of electrons and holes, denoted by $\partial\hat{n}/\partial\hat{z}$ and $\partial\hat{p}/\partial\hat{z}$, respectively, are assumed to be zero. The tangential component of the electric field and the normal component of the magnetic induction are assumed to be zero at the interfaces between lasing and nonlasing regions, and so

$$\hat{\boldsymbol{n}} \times \left(-\hat{\boldsymbol{\nabla}}\hat{\phi} - \frac{\partial\hat{\boldsymbol{A}}}{\partial\hat{t}}\right) = \boldsymbol{0} \quad \text{at } \ \hat{x} = 0, 1 \ \text{ and at } \ \hat{y} = 0, 1, \tag{21}$$

$$(\hat{\boldsymbol{\nabla}} \times \hat{\boldsymbol{A}})\cdot\hat{\boldsymbol{n}} = 0 \quad \text{at } \ \hat{x} = 0, 1 \ \text{ and at } \ \hat{y} = 0, 1. \tag{22}$$

In the models derived below it is possible to employ boundary conditions at the mirrors which approximate the reflected wave as a fraction of the incident wave (see (37)–(38)); this avoids the additional complication of modeling the transmitted electromagnetic wave.

4. Asymptotic analysis.

4.1. Periodicity. We require an important assumption concerning the multilateral mode case. The conjecture is that there exists an integer number of round trips on which the system is periodic (see section 1). Thus, when three lateral modes are operating within the laser's active region, we have

$$q_1\left(\frac{2\pi}{\hat{k}_1}\right) = q_2\left(\frac{2\pi}{\hat{k}_2}\right) = q_3\left(\frac{2\pi}{\hat{k}_3}\right),$$

where q_1, q_2, and q_3 are positive integers, while $\hat{k}_1$, $\hat{k}_2$, and $\hat{k}_3$ are the dimensionless wave numbers associated with the three modes. The corresponding dimensionless wavelengths are given by $\hat{\lambda}_r = 2\pi/\hat{k}_r$, where $\hat{\lambda}_r = \lambda_r/\lambda$. We will use r to differentiate between these lateral modes throughout the remainder of the paper.

4.2. Multiple scales. A multiple-scale asymptotic expansion is appropriate since there are two relevant longitudinal length-scales in the laser. These are wavelength ($\lambda \sim 10^{-6}$m) and cavity length ($L \sim 250 \times 10^{-6}$m). There are three physical time-scales to identify: the time-scale for carrier variations ($\sim 10^{-8}$s), that for an electromagnetic wave to traverse the longitudinal cavity length ($\sim 10^{-12}$s), and the reciprocal of the frequency ($\sim 10^{-15}$s). We shall employ a total of seven independent variables. Four of these describe space: the lateral length-scale $\hat{x}$, the transverse length-scale $\hat{y}$, the smaller axial length-scale $\hat{z}$, and the longer axial length-scale Z, where $Z = \delta\hat{z}$; the third variable corresponds to wavelength and the fourth to cavity length. The other three variables describe time: the shortest time-scale $\hat{t} = O(1)$, corresponding to the time-scale for a wave to travel a wavelength; the intermediate time-scale $T = \delta\hat{t} = O(1)$, the time-scale for traversing the cavity; and the longest time-scale $\tau = \delta\nu\hat{t} = O(1)$, that for carrier variations. At leading order the solution will be periodic in $\hat{t}$ with period $2\pi/\hat{\omega}$ ($\hat{\omega} = \omega\tau_e$ is the (known) dimensionless angular frequency) and in T with period $2q_2q_3\hat{k}_1/\hat{\omega}$. We note from Table 1 that $\nu \ll \delta$, and so we introduce expansions of the form $\hat{n} \sim n_0 + \delta n_1 + \nu n_2 + \delta^2 n_3 + \delta\nu n_4$, $\hat{p} \sim p_0 + \delta p_1$, $\hat{\boldsymbol{A}} \sim \boldsymbol{A_0} + \delta\boldsymbol{A_1}$, $\hat{\boldsymbol{P}}^{(R)} \sim \boldsymbol{P_0}$, and $\hat{\phi} \sim \phi_0 + \delta\phi_1$ as $\delta, \nu \to 0$. We seek solutions of the form $\phi_0 = \phi_0(\hat{x}, \hat{y}, \hat{z}, Z, \tau)$ and $\phi_1 = \phi_1(\hat{x}, \hat{y}, \hat{z}, Z, T, \tau)$ and consider only the y-component of the lasing mode to be nonzero at leading order, the dominance of the transverse electric mode being observed experimentally [16]. Hence we write $\boldsymbol{A_0} = (0, A_0^{(2)}, 0)$ and $\boldsymbol{A_1} = (0, A_1^{(2)}, 0)$.

Evaluating (13)–(14) at $O(1)$ and $O(\delta)$ implies that $n_0 = n_0(\hat{x}, \hat{y}, \hat{z}, Z, \tau)$ and $p_0 = p_0(\hat{x}, \hat{y}, \hat{z}, Z, \tau)$ with $n_0 = p_0$ given, at leading order, by (15). Since periodicity in $\hat{t}$ requires

$$\int_{\hat{t}=0}^{2\pi/\hat{\omega}} \frac{\partial n_4}{\partial \hat{t}}\, d\hat{t} = 0,$$

from (13) we have

$$\frac{\partial n_0}{\partial \tau} + \frac{\partial n_2}{\partial T} = -\frac{n_0}{\mathcal{A}_n + \mathcal{A}_p} - \mathcal{B}n_0^2 - (\mathcal{C}_n + \mathcal{C}_p)n_0^3 + \mathcal{D}_n\hat{\boldsymbol{\nabla}}^2 n_0 - \mathcal{V}_n\hat{\boldsymbol{\nabla}}\cdot(n_0\hat{\boldsymbol{\nabla}}\phi_0)$$
$$- \epsilon_R\mathcal{F}g(n_0)\,\frac{\hat{\omega}}{2\pi}\int_{\hat{t}=0}^{2\pi/\hat{\omega}}\left(\frac{\partial A_0^{(2)}}{\partial \hat{t}}\right)^2 d\hat{t},$$

where $g(n_0) = \mathcal{H}(n_0 - n^*)$ and we have assumed that $\partial\boldsymbol{P_0}/\partial\hat{t}$ is time-harmonic [12]. Periodicity in T demands that

$$\int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}} \frac{\partial n_2}{\partial T}\, dT = 0,$$

and so we obtain

$$\begin{aligned}\frac{\partial n_0}{\partial \tau} &= -\frac{n_0}{\mathcal{A}_n + \mathcal{A}_p} - \mathcal{B} n_0^2 - (\mathcal{C}_n + \mathcal{C}_p) n_0^3 + \mathcal{D}_n \hat{\boldsymbol{\nabla}}^2 n_0 - \mathcal{V}_n \hat{\boldsymbol{\nabla}} \boldsymbol{\cdot} (n_0 \hat{\boldsymbol{\nabla}} \phi_0) \\ &\quad - \epsilon_R \mathcal{F} g(n_0)\, \frac{\hat{\omega}^2}{4\pi q_2 q_3 \hat{k}_1} \int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}} \int_{\hat{t}=0}^{2\pi/\hat{\omega}} \left(\frac{\partial A_0^{(2)}}{\partial \hat{t}}\right)^2 d\hat{t}\, dT.\end{aligned} \tag{23}$$

A similar equation for $\partial p_0/\partial \tau$ is derived from (14). Subtracting this from (23) yields

$$\hat{\boldsymbol{\nabla}} \boldsymbol{\cdot} (n_0 \hat{\boldsymbol{\nabla}} \phi_0) = \left(\frac{\mathcal{D}_n - \mathcal{D}_p}{\mathcal{V}_n + \mathcal{V}_p}\right) \hat{\boldsymbol{\nabla}}^2 n_0,$$

which allows us to eliminate ϕ_0 from (23):

$$\begin{aligned}\frac{\partial n_0}{\partial \tau} &= -\frac{n_0}{\mathcal{A}_n + \mathcal{A}_p} - \mathcal{B} n_0^2 - (\mathcal{C}_n + \mathcal{C}_p) n_0^3 + \frac{\mathcal{D}_n \mathcal{V}_p + \mathcal{D}_p \mathcal{V}_n}{\mathcal{V}_n + \mathcal{V}_p} \hat{\boldsymbol{\nabla}}^2 n_0 \\ &\quad - \epsilon_R \mathcal{F} g(n_0)\, \frac{\hat{\omega}^2}{4\pi q_2 q_3 \hat{k}_1} \int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}} \int_{\hat{t}=0}^{2\pi/\hat{\omega}} \left(\frac{\partial A_0^{(2)}}{\partial \hat{t}}\right)^2 d\hat{t}\, dT.\end{aligned} \tag{24}$$

The first, second, third, and fifth terms on the right-hand side of (24) correspond to the electron-hole recombination mechanisms described in (10). The local reduction of electrons and holes due to spatial-hole burning (the integral term on the right-hand side of (24)) thus competes with the smoothing action of diffusion (fourth term on the right-hand side of (24)). The latter is the source of the current density term which will be introduced in section 5.

The following leading-order problem for the electric field is posed by (16)–(17):

$$\Box\, A_0^{(2)} = 0, \tag{25}$$

where the d'Alembertian operator is defined by

$$\Box = \epsilon_R \frac{\partial^2}{\partial \hat{t}^2} - A_x^2 \frac{\partial^2}{\partial \hat{x}^2} - \frac{\partial^2}{\partial \hat{z}^2}.$$

It follows from (21) that

$$A_0^{(2)} = 0 \quad \text{on} \quad \hat{x} = 0, 1. \tag{26}$$

We apply the method of separation of variables to (25)–(26). The solution is expressed in the form of an infinite sum in which each term corresponds to a lateral mode contained by the waveguide. For the remainder of this paper we consider three such modes which are distinguished using $r = 1, 2, 3$; their respective lateral profiles are $\sin(\pi\hat{x})$, $\sin(2\pi\hat{x})$, and $\sin(3\pi\hat{x})$. In this case

$$\begin{aligned}A_0^{(2)} = \sum_{r=1}^{3} \Big(& A_r^+ \cos(\hat{\omega}\hat{t} - \hat{k}_r\hat{z}) + B_r^+ \sin(\hat{\omega}\hat{t} - \hat{k}_r\hat{z}) \\ & + A_r^- \cos(\hat{\omega}\hat{t} + \hat{k}_r\hat{z}) + B_r^- \sin(\hat{\omega}\hat{t} + \hat{k}_r\hat{z})\Big) \sin(r\pi\hat{x}).\end{aligned} \tag{27}$$

The dispersion relation associated with (25) takes the form $\hat{k}_r^2 = \hat{\omega}^2\epsilon_R - (r\pi A_x)^2$. Evaluating (16)–(17) at $O(\delta)$ implies

$$\begin{aligned}\Box\, A_1^{(2)} &= 2\,\frac{\partial^2 A_0^{(2)}}{\partial\hat{z}\partial Z} - 2\epsilon_R\frac{\partial^2 A_0^{(2)}}{\partial\hat{t}\partial T} + \epsilon_R\mathcal{L}g(n_0)\frac{\partial A_0^{(2)}}{\partial\hat{t}} \\ &\quad + \mathcal{L}\left((\mathcal{D}_n - \mathcal{D}_p)A_y\frac{\partial n_0}{\partial\hat{y}} - (\mathcal{V}_n + \mathcal{V}_p)n_0A_y\frac{\partial\phi_0}{\partial\hat{y}} - (\mathcal{V}_n + \mathcal{V}_p)n_0\frac{\partial A_0^{(2)}}{\partial\hat{t}}\right),\end{aligned} \tag{28}$$

from which we deduce twelve secularity conditions governing the twelve unknown amplitude envelopes $A_r^{\pm}(Z,T,\tau)$ and $B_r^{\pm}(Z,T,\tau)$. Each condition takes the form of a first-order wave equation and can been verified using two different approaches. The first technique involves applying the Fredholm alternative to (28), and the second makes use of several trigonometric substitutions in order to directly eliminate the secular terms. We present the equations for A_1^+, A_2^+, and A_3^+ below; the equations for B_1^+, B_2^+, and B_3^+ are given in Appendix A. By symmetry in the direction of propagation, the equations for A_1^-, A_2^-, A_3^-, B_1^-, B_2^-, and B_3^- may be derived from (29)–(31) and (48)–(50) by replacing the quantities $\hat{k}_r$, A_r^+, B_r^+, A_r^-, and B_r^- with $-\hat{k}_r$, A_r^-, B_r^-, A_r^+, and B_r^+, respectively. We have

$$\begin{aligned}&\frac{2\pi q_1}{\hat{k}_1}\left(\epsilon_R\hat{\omega}\frac{\partial A_1^+}{\partial T} + \hat{k}_1\frac{\partial A_1^+}{\partial Z}\right) = A_1^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1-\alpha_2\big)\,d\hat{z} \\ &+ B_1^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1-\alpha_2\big)\sin\big(2\hat{k}_1\hat{z}\big)\,d\hat{z} + A_1^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1-\alpha_2\big)\cos\big(2\hat{k}_1\hat{z}\big)\,d\hat{z} \\ &+ B_3^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z} + A_3^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z} \\ &+ B_3^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z} + A_3^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z},\end{aligned} \tag{29}$$

$$\begin{aligned}&\frac{2\pi q_2}{\hat{k}_2}\left(\epsilon_R\hat{\omega}\frac{\partial A_2^+}{\partial T} + \hat{k}_2\frac{\partial A_2^+}{\partial Z}\right) = A_2^+\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\,d\hat{z} \\ &+ B_2^-\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\sin\big(2\hat{k}_2\hat{z}\big)\,d\hat{z} + A_2^-\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\cos\big(2\hat{k}_2\hat{z}\big)\,d\hat{z},\end{aligned} \tag{30}$$

$$\begin{aligned}&\frac{2\pi q_3}{\hat{k}_3}\left(\epsilon_R\hat{\omega}\frac{\partial A_3^+}{\partial T} + \hat{k}_3\frac{\partial A_3^+}{\partial Z}\right) = A_3^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\,d\hat{z} \\ &+ B_3^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\sin\big(2\hat{k}_3\hat{z}\big)\,d\hat{z} + A_3^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\cos\big(2\hat{k}_3\hat{z}\big)\,d\hat{z} \\ &- B_1^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z} + A_1^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z} \\ &+ B_1^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z} + A_1^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z},\end{aligned} \tag{31}$$

where the integral coefficients are defined by

$$\alpha_1 = \int_{\hat{x}=0}^{1} \hat{\omega}\epsilon_R \mathcal{L} g(n_0)\sin^2(\pi\hat{x})\,d\hat{x}, \quad \alpha_2 = \int_{\hat{x}=0}^{1} \hat{\omega}\mathcal{L}(\mathcal{V}_n+\mathcal{V}_p)n_0\sin^2(\pi\hat{x})\,d\hat{x}, \tag{32a}$$

$$\beta_1 = \int_{\hat{x}=0}^{1} \hat{\omega}\epsilon_R \mathcal{L} g(n_0)\sin(\pi\hat{x})\sin(3\pi\hat{x})\,d\hat{x}, \quad \beta_2 = \int_{\hat{x}=0}^{1} \hat{\omega}\mathcal{L}(\mathcal{V}_n+\mathcal{V}_p)n_0\sin(\pi\hat{x})\sin(3\pi\hat{x})\,d\hat{x}, \tag{32b}$$

$$\gamma_1 = \int_{\hat{x}=0}^{1} \hat{\omega}\epsilon_R \mathcal{L} g(n_0)\sin^2(2\pi\hat{x})\,d\hat{x}, \quad \gamma_2 = \int_{\hat{x}=0}^{1} \hat{\omega}\mathcal{L}(\mathcal{V}_n+\mathcal{V}_p)n_0\sin^2(2\pi\hat{x})\,d\hat{x}, \tag{32c}$$

$$\delta_1 = \int_{\hat{x}=0}^{1} \hat{\omega}\epsilon_R \mathcal{L} g(n_0)\sin^2(3\pi\hat{x})\,d\hat{x}, \quad \delta_2 = \int_{\hat{x}=0}^{1} \hat{\omega}\mathcal{L}(\mathcal{V}_n+\mathcal{V}_p)n_0\sin^2(3\pi\hat{x})\,d\hat{x}. \tag{32d}$$

The emergence of terms coupling $\sin(\pi\hat{x})$ and $\sin(3\pi\hat{x})$ profiles provides evidence of modal interaction. It has also been noted that no cross-coupling terms exist involving the $\sin(2\pi\hat{x})$ profile. This trend has been generalized to demonstrate that direct interaction is limited to any pair of $\sin(r_{odd}\pi\hat{x})$ modes, these related by their symmetry about $\hat{x}=0.5$, and any pair of $\sin(r_{even}\pi\hat{x})$ modes, the latter related by their antisymmetry about $\hat{x}=0.5$. For each lateral mode, those waves traveling along $\mathrm{O}\hat{z}$ in opposite directions also interact, this feature being described by the $\sin(2\hat{k}_r\hat{z})$ and $\cos(2\hat{k}_r\hat{z})$ integral terms above. The integrals α_1, β_1, γ_1, and δ_1 are associated with gain and absorption, while the integrals α_2, β_2, γ_2, and δ_2 describe the interaction between the electric field and charge carriers. We substitute (27) into (24) and evaluate the integral in $\hat{t}$ to obtain the second-order diffusion equation

$$\begin{aligned}\frac{\partial n_0}{\partial \tau} &= -\frac{n_0}{\mathcal{A}_n+\mathcal{A}_p} - \mathcal{B}n_0^2 - (\mathcal{C}_n+\mathcal{C}_p)n_0^3 + \frac{\mathcal{D}_n\mathcal{V}_p+\mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n+\mathcal{V}_p}\hat{\boldsymbol{\nabla}}^2 n_0 \\ &\quad - \epsilon_R\mathcal{F}g(n_0)\frac{\hat{\omega}^3}{4q_2q_3\hat{k}_1}\int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}}\left(\sum_{i=1}^{3}\sum_{j=1}^{3}\Gamma_{ij}\sin(i\pi\hat{x})\sin(j\pi\hat{x})\right)dT,\end{aligned} \tag{33}$$

where we have

$$\begin{aligned}\Gamma_{ij} &= \cos\big((\hat{k}_i-\hat{k}_j)\hat{z}\big)\Big(A_i^+A_j^+ + B_i^+B_j^+ + A_i^-A_j^- + B_i^-B_j^-\Big) \\ &\quad + \cos\big((\hat{k}_i+\hat{k}_j)\hat{z}\big)\Big(A_i^+A_j^- + B_i^+B_j^- + A_i^-A_j^+ + B_i^-B_j^+\Big) \\ &\quad + \sin\big((\hat{k}_i-\hat{k}_j)\hat{z}\big)\Big(A_i^+B_j^+ - B_i^+A_j^+ - A_i^-B_j^- + B_i^-A_j^-\Big) \\ &\quad + \sin\big((\hat{k}_i+\hat{k}_j)\hat{z}\big)\Big(A_i^+B_j^- - B_i^+A_j^- - A_i^-B_j^+ + B_i^-A_j^+\Big).\end{aligned}$$

Before examining a partially lumped model, we present the boundary conditions and periodicity conditions that accompany (33) and the twelve secularity conditions represented by (29)–(31) and (48)–(50). Using (19) we obtain

$$\frac{\partial n_0}{\partial \hat{x}}(0,\hat{y},\hat{z},Z,\tau) = \frac{\partial n_0}{\partial \hat{x}}(1,\hat{y},\hat{z},Z,\tau) = 0. \tag{34}$$

The supply of current through the boundary of the lasing region is prescribed, where, making use of (20), we have

$$\frac{\partial n_0}{\partial \hat{y}} = \begin{cases} g_1(\hat{x},\hat{z},Z,\tau) & \text{at } \hat{y}=0, \\ g_2(\hat{x},\hat{z},Z,\tau) & \text{at } \hat{y}=1. \end{cases} \tag{35}$$

The $\hat{x}$ dependence of functions g_1 and g_2 defines a lateral current density profile which is illustrated in section 6 for two different cases. The assumption of zero normal fluxes of electrons and holes at the mirrors gives

$$\frac{\partial n_0}{\partial \hat{z}}(\hat{x},\hat{y},\hat{z},0,\tau) = \frac{\partial n_0}{\partial \hat{z}}(\hat{x},\hat{y},\hat{z},1,\tau) = 0. \tag{36}$$

As indicated in section 3, we shall approximate the imperfect mirrors in terms of the reflectivities $R^{(1)}$ at $Z = 0$ and $R^{(2)}$ at $Z = 1$. The boundary conditions for the amplitude envelopes are then given by

$$\left(A_r^+(0,T,\tau)\right)^2 = R^{(1)}\left(A_r^-(0,T,\tau)\right)^2, \quad \left(B_r^+(0,T,\tau)\right)^2 = R^{(1)}\left(B_r^-(0,T,\tau)\right)^2, \tag{37}$$

$$\left(A_r^-(1,T,\tau)\right)^2 = R^{(2)}\left(A_r^+(1,T,\tau)\right)^2, \quad \left(B_r^-(1,T,\tau)\right)^2 = R^{(2)}\left(B_r^+(1,T,\tau)\right)^2. \tag{38}$$

In addition to this the amplitude envelopes must be periodic in T such that

$$A_r^{\pm}(Z,T,\tau) = A_r^{\pm}(Z,T+2q_2q_3\hat{k}_1/\hat{\omega},\tau), \quad B_r^{\pm}(Z,T,\tau) = B_r^{\pm}(Z,T+2q_2q_3\hat{k}_1/\hat{\omega},\tau). \tag{39}$$

In conclusion, the asymptotic analysis with three lateral modes has led to a system of thirteen unknowns, comprising twelve amplitude envelopes together with the carrier density.

5. Partially lumped model.

Unlike the preceeding analysis, the partially lumped model which follows requires ad hoc averaging procedures; nevertheless, it retains lateral spatial-hole burning effects and the lateral diffusion of carriers and provides a mathematical interpretation of some of the multilateral effects that are observed in experiments.

5.1. Time-dependent equations.

We take (33) and integrate with respect to $\hat{y}$ and $\hat{z}$, giving

$$\begin{aligned}\hat{J}_y = \frac{\hat{k}_1}{2\pi q_1}\int_{\hat{y}=0}^{1}\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\Bigg(&\frac{\partial n_0}{\partial \tau} + \frac{n_0}{\mathcal{A}_n+\mathcal{A}_p} + \mathcal{B}n_0^2 + (\mathcal{C}_n+\mathcal{C}_p)n_0^3\\ &- A_x^2\,\frac{\mathcal{D}_n\mathcal{V}_p+\mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n+\mathcal{V}_p}\,\frac{\partial^2 n_0}{\partial \hat{x}^2}\\ &+ \frac{\epsilon_R\mathcal{F}\hat{\omega}^3}{4q_2q_3\hat{k}_1}\int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}}\left(g(n_0)\sum_{i=1}^{3}\sum_{j=1}^{3}\Gamma_{ij}\sin(i\pi\hat{x})\sin(j\pi\hat{x})\right)dT\Bigg)\,d\hat{z}\,d\hat{y}.\end{aligned} \tag{40}$$

The (known) current flowing through the transverse boundaries is represented by

$$\begin{aligned}\hat{J}_y &= \frac{\hat{k}_1}{2\pi q_1}\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\left[A_y^2\,\frac{\mathcal{D}_n\mathcal{V}_p+\mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n+\mathcal{V}_p}\,\frac{\partial n_0}{\partial \hat{y}}\right]_{\hat{y}=0}^{\hat{y}=1}d\hat{z}\\ &= \frac{\hat{k}_1}{2\pi q_1}\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}A_y^2\,\frac{\mathcal{D}_n\mathcal{V}_p+\mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n+\mathcal{V}_p}\left(g_2-g_1\right)d\hat{z}\end{aligned}$$

when we apply (35). We now expand n_0 in a Fourier expansion for the physically significant modes dependent on $\hat{x}$, $\hat{y}$, and $\hat{z}$ as follows:

$$\begin{aligned}n_0 = {}& N_0(\hat{x},Z,\tau) + N_1(\hat{x},Z,\tau)\cos(\hat{k}_1\hat{z}) + N_2(\hat{x},Z,\tau)\sin(\hat{k}_1\hat{z}) + N_3(\hat{x},Z,\tau)\cos(\hat{k}_2\hat{z})\\ &+ N_4(\hat{x},Z,\tau)\sin(\hat{k}_2\hat{z}) + N_5(\hat{x},Z,\tau)\cos(\hat{k}_3\hat{z}) + N_6(\hat{x},Z,\tau)\sin(\hat{k}_3\hat{z}) + \dots,\end{aligned}$$

terms in $\hat{y}$ not being listed here. We will satisfy the equations in an averaged sense, effectively making the simplifying assumption that the electron concentration is independent of $\hat{y}$ and $\hat{z}$. To achieve this aim, we truncate the Fourier series after one term. Writing $n_0 = N_0(\hat{x}, Z, \tau)$, we automatically satisfy condition (36) and obtain the electron concentration rate equation,

$$\begin{aligned}\frac{\partial N_0}{\partial \tau} &= \hat{J}_y - \frac{N_0}{\mathcal{A}_n + \mathcal{A}_p} - \mathcal{B}N_0^2 - (\mathcal{C}_n + \mathcal{C}_p)N_0^3 + A_x^2 \frac{\mathcal{D}_n\mathcal{V}_p + \mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n + \mathcal{V}_p} \frac{\partial^2 N_0}{\partial \hat{x}^2} \\ &\quad - \frac{\epsilon_R \mathcal{F}\hat{\omega}\mathcal{H}(N_0 - n^*)}{q_2 q_3 \hat{k}_1} \int_{T=0}^{2q_2q_3\hat{k}_1/\hat{\omega}} \sum_{r=1}^{3} \left(\hat{I}_r^+ + \hat{I}_r^-\right) \sin^2(r\pi\hat{x})\, dT,\end{aligned} \tag{41}$$

where we define the forward (+) and backward (−) intensities of the lasing modes to be

$$\hat{I}_r^\pm = \frac{\hat{\omega}^2}{4}\left(\left(A_r^\pm\right)^2 + \left(B_r^\pm\right)^2\right).$$

The superscript + (−) denotes those waves traveling in the direction of increasing (decreasing) $\hat{z}$. We introduce the definition of optical intensity in order to secure unique solutions: conditions (37) and (38) do not permit us to calculate a unique phase shift associated with the amplitude envelopes. Taking the secularity conditions, we obtain the photon concentration rate equations

$$\epsilon_R \hat{\omega} \frac{\partial \hat{I}_r^\pm}{\partial T} \pm \hat{k}_r \frac{\partial \hat{I}_r^\pm}{\partial Z} = 2Q_r(Z,\tau)\hat{I}_r^\pm, \tag{42}$$

in which

$$Q_r(Z,\tau) = \hat{\omega}\mathcal{L}(\epsilon_R\mathcal{H} - \mathcal{V}_n - \mathcal{V}_p) \int_{\hat{x}=0}^{1} N_0(\hat{x}, Z, \tau)\sin^2(r\pi\hat{x})\, d\hat{x} - \frac{1}{2}\hat{\omega}\mathcal{L}\epsilon_R\mathcal{H}n^*.$$

The boundary conditions are $\partial N_0/\partial\hat{x} = 0$ at $\hat{x} = 0$ and $\hat{x} = 1$ along with $\hat{I}_r^+(0, T, \tau) = R^{(1)}\hat{I}_r^-(0, T, \tau)$ and $\hat{I}_r^-(1, T, \tau) = R^{(2)}\hat{I}_r^+(1, T, \tau)$. The intensities must also satisfy $\hat{I}_r^\pm(Z, T, \tau) = \hat{I}_r^\pm(Z, T + 2q_2q_3\hat{k}_1/\hat{\omega}, \tau)$. The model has thus been simplified such that N_0 and $\hat{I}_r^\pm$ are solutions to one partial differential equation and six first-order wave equations. A dimensional form of this system, generalized for M lateral modes, is presented in Appendix B. This partially lumped model is the generalization of the traveling-wave rate equations [15] to incorporate the multilateral mode effects in Maxwell's equations. In the next subsection, we study the bifurcations associated with (41)–(42) and use these to predict the onset of multilateral mode laser operation.

5.2. Bifurcation conditions. At steady state, (42) forms a system of six first-order separable differential equations. These are solved subject to the boundary conditions $\hat{I}_r^+(0) = R^{(1)}\hat{I}_r^-(0)$ and $\hat{I}_r^-(1) = R^{(2)}\hat{I}_r^+(1)$. As a consequence, we obtain three integral conditions that correspond to each of the three lateral modes,

$$\begin{aligned}&\frac{1}{4}\hat{k}_r \ln\left(R^{(1)}R^{(2)}\right) \\ &\qquad = \frac{1}{2}\hat{\omega}\mathcal{L}\epsilon_R\mathcal{H}n^* - \hat{\omega}\mathcal{L}(\epsilon_R\mathcal{H} - \mathcal{V}_n - \mathcal{V}_p) \int_0^1 \int_0^1 N_0(\hat{x}, Z)\sin^2(r\pi\hat{x})\, d\hat{x}\, dZ.\end{aligned} \tag{43}$$

Substituting the solutions for the forward and backward intensities into the steady-state problem from (41) leaves us with the following nonlinear ordinary differential equation to be solved numerically:

$$\begin{aligned} A_x^2\,\frac{\mathcal{D}_n\mathcal{V}_p+\mathcal{D}_p\mathcal{V}_n}{\mathcal{V}_n+\mathcal{V}_p}\frac{\partial^2 N_0}{\partial\hat{x}^2}-\frac{N_0}{\mathcal{A}_n+\mathcal{A}_p}-\mathcal{B}N_0^2-(\mathcal{C}_n+\mathcal{C}_p)N_0^3+\hat{J}_y \\ =\frac{1}{2}\,\epsilon_R\hat{\omega}^2\mathcal{F}\mathcal{H}(N_0-n^*)\sum_{r=1}^{3}\sin^2(r\pi\hat{x})f_r(Z), \end{aligned}\tag{44}$$

in which the functions $f_r(Z)=4\big(\hat{I}_r^+(Z)+\hat{I}_r^-(Z)\big)/\hat{\omega}^2$ are written in the form

$$\begin{aligned} C_r\Bigg(\exp\left\{\frac{2\hat{\omega}\mathcal{L}(\epsilon_R\mathcal{H}-\mathcal{V}_n-\mathcal{V}_p)}{\hat{k}_r}\int_{Z'=0}^{Z}G(Z')\,dZ'-\frac{\hat{\omega}\mathcal{L}\epsilon_R\mathcal{H}n^*Z}{\hat{k}_r}\right\} \\ +\sqrt{\frac{R^{(2)}}{R^{(1)}}}\exp\left\{\frac{2\hat{\omega}\mathcal{L}(\epsilon_R\mathcal{H}-\mathcal{V}_n-\mathcal{V}_p)}{\hat{k}_r}\int_{Z'=Z}^{1}G(Z')\,dZ'+\frac{\hat{\omega}\mathcal{L}\epsilon_R\mathcal{H}n^*(Z-1)}{\hat{k}_r}\right\}\Bigg), \end{aligned}$$

where

$$G(Z')=\int_{\hat{x}=0}^{1}N_0(\hat{x},Z')\sin^2(r\pi\hat{x})\,d\hat{x}.$$

From (34) we have the no flux boundary conditions

$$\frac{\partial N_0}{\partial\hat{x}}=0\qquad\text{at}\quad\hat{x}=0,1.\tag{45}$$

The additional unknowns, C_r, are constants of integration that emerge when calculating the intensities and are determinable through solving the electrical-optical problem (43)–(45) with prescribed current density $\hat{J}_y$.

Experiments suggest that the fundamental mode reaches threshold first, since it couples most effectively to the injected carrier distribution. The current is then increased until the gain distribution begins to couple effectively to the next mode. At such a threshold current the next mode begins to share power with the fundamental mode [6]. A series of bifurcation conditions arising from (43)–(45) describe this phenomenon, allowing us to calculate the threshold current density at which each mode begins lasing (note that the corresponding current is given by the integral of the current density, $\hat{J}_y$, over the area $0\le Z\le 1$, $0\le\hat{x}\le 1$):

(i) *First threshold.* For both forms of $\hat{J}_y$ considered below, we ascertain numerically that the $r=1$ lateral mode is activated first. At a current equal to the first threshold there is zero leading-order intensity, that is, $C_1=C_2=C_3=0$. The unknown threshold current density $\hat{J}_y$ and threshold electron concentration N_0 satisfy (43) with $r=1$ and (44)–(45). This constitutes the first bifurcation condition and determines the threshold current at which the dominant ($\sin(\pi\hat{x})$) mode is switched on.

(ii) *Next threshold.* As the $\sin(\pi\hat{x})$ mode is already activated, we take $C_2=C_3=0$ and include the unknown C_1 in (44). Either the $\sin(2\pi\hat{x})$ mode or the $\sin(3\pi\hat{x})$ mode may be switched on next, depending on which of the criteria below results in the lowest threshold current:

(a) $\sin(2\pi\hat{x})$. The unknown threshold current density $\hat{J}_y$, the threshold electron concentration N_0, and C_1 satisfy (43) with $r=1$ and $r=2$ and (44)–(45).

(b) $\sin(3\pi\hat{x})$. The unknown threshold current density $\hat{J}_y$, the threshold electron concentration N_0, and C_1 satisfy (43) with $r = 1$ and $r = 3$ and (44)–(45).

System (a) or (b) constitutes the second bifurcation condition. We thus have a physical criterion for the onset of multilateral mode operation, a dimensional form of which is presented in Appendix C. A final bifurcation condition, of the same ilk as the two described above, determines the threshold current density at which the remaining lateral mode begins lasing.

One consequence of this multimode formulation is a changing near-field lateral intensity envelope. Experiments demonstrate that this evolution varies depending on the form of the semiconductor laser and in particular on the lateral width of the active region. For narrow lateral widths, the single peak that exists at the center of the interval becomes far more pronounced with increased current [1, p. 66]. The 10–20μm stripe lasers measured in [13, p. 377] have an associated near-field distribution which broadens and then splits into two individual peaks as a new mode is activated. This particular observation compares closely to the results obtained in the following section. In broad-area semiconductor lasers a rippled profile has been observed, this being interpreted as the superposition of several lateral mode profiles [9]. As the pumped current increases, the near-field patterns exhibit a greater number of lobes, suggesting that more and more lateral modes are being activated. This model, albeit dealing with a relatively simple case, predicts this effect, enabling us to calculate the current density at which each lateral mode becomes operational.

6. Numerical results.

6.1. Introduction. Solutions to the steady-state electrical-optical problem (43)–(45) are split into two cases. The current density varies on the lateral length-scale and is expressed in the form $\hat{J}_y = J_{AMP}F(\hat{x})$ for $0 \leq Z \leq 1$, where J_{AMP} and $F(\hat{x})$ specify the current density amplitude and profile, respectively. We consider applications A and B which deal with two different current density distributions (see Figure 2), labeled $F_A(\hat{x})$ and $F_B(\hat{x})$, respectively. The latter case deals with a comparatively broader distribution. Varying $F(\hat{x})$ is found to impact the order in which the three lateral modes are activated. The closed problem (43)–(45) is solved using a finite-difference scheme. All of the results presented below are based on the parameter values given in Table 1.

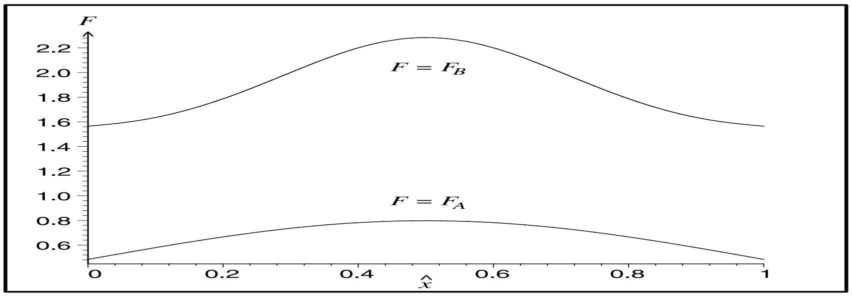

FIG. 2. *Graph displaying the two current density distributions used with $F(\hat{x}) = F_A(\hat{x})$ and $F(\hat{x}) = F_B(\hat{x})$ explored in cases A and B, respectively.*

6.2. Case study A: $\boldsymbol{F = F_A(\hat{x})}$. In this first case, the $\sin(r\pi\hat{x})$ lateral modes are activated in the order $r = 1, 2, 3$ as the pumped current increases. The corresponding threshold values of J_{AMP} are $t_1 \sim 26$, $t_2 \sim 34$, and $t_3 \sim 36$, respectively.

6.2.1. Stable and unstable steady states. In this section, a measure of the power, P_r, attributed to each lateral mode is found by averaging the backward intensity over the longitudinal length,

$$P_r = \int_{Z=0}^{1} \hat{I}_r^-(Z)\,dZ. \tag{46}$$

Time-independent numerical simulations determine a number of steady-state solutions, not all of which are stable. To demonstrate this, we analyze the power-current graphs belonging to the $r = 1$ and $r = 2$ lateral modes. In particular, there are transcritical bifurcations at those J_{AMP} values at which each lateral mode is switched on (see Figure 3). Prior to the first current threshold, the stable steady state has zero power (see branches A and D for $0 \leq J_{AMP} < t_1$ in Figure 3). At the first threshold, a continuation of zero power remains a valid solution of the equations. However, this solution is unstable following the activation of the $\sin(\pi\hat{x})$ mode. Thus, for $t_1 < J_{AMP} < t_2$, branches B and D represent the stable solution. An identical situation arises when the second threshold current is encountered. Here the $\sin(2\pi\hat{x})$ mode becomes operational. Beyond this point it is possible for the solution to continue along branches B and D; however, at the second threshold this solution too becomes unstable. A new stable solution exists due to the presence of the second lateral mode (see branches C and E for $J_{AMP} > t_2$ in Figure 3). The drop in gradient about $J_{AMP} = t_2$ in the top graph in Figure 3 symbolizes a reduction in the efficiency of the $\sin(\pi\hat{x})$ mode due to the onset of competition for photons (see subsection 6.2.2). These trends continue as the third, $\sin(3\pi\hat{x})$, mode is activated.

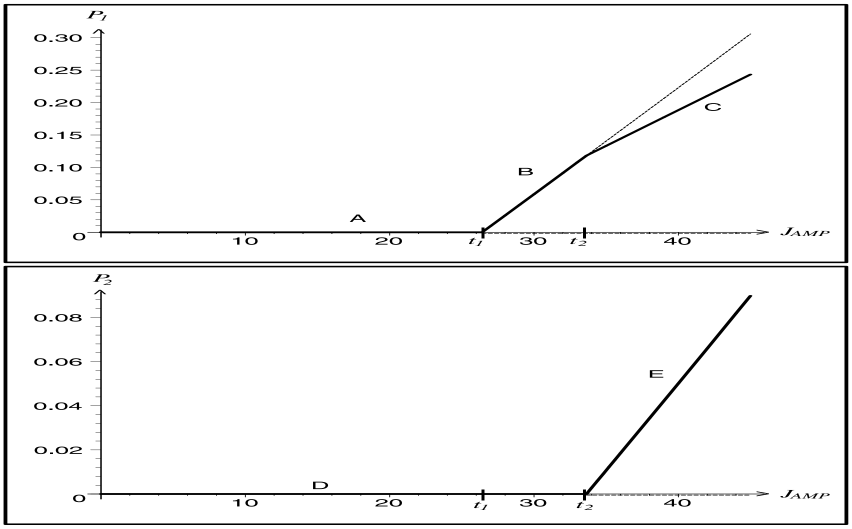

FIG. 3. *Power-current graphs for the $r = 1$ (top) and $r = 2$ (bottom) lateral modes. Solid and dashed lines indicate the stable and unstable steady states, respectively. The displayed quantities are dimensionless.*

6.2.2. Competition for photons. Hence, using (46) we are able to track the power associated with each of the three modes as the current density amplitude rises beyond each calculated threshold (see Figure 4). At the second and third threshold currents (corresponding to the broken vertical lines) there is a drop in gradient asso-

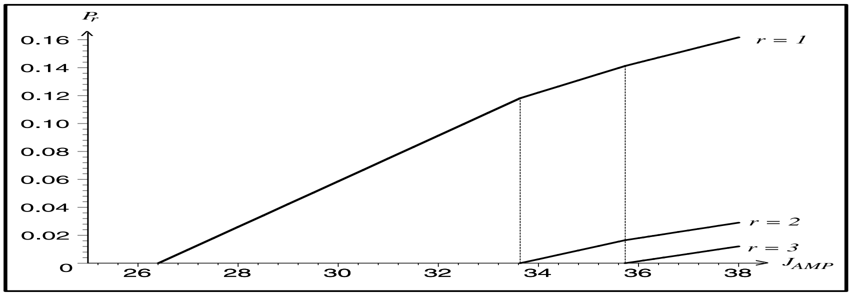

FIG. 4. *Graph showing the relationship between power and current with* $r = 1, 2, 3$ *representing the* $\sin(\pi\hat{x})$, $\sin(2\pi\hat{x})$, *and* $\sin(3\pi\hat{x})$ *modes, respectively. The values plotted are dimensionless.*

ciated with those modes already operating. This reduction in efficiency is caused by the competition for photons and the subsequent sharing of the available gain.

6.2.3. Lateral spatial-hole burning and changing near-field patterns. The lateral near-field intensity profile evolves following the activation of each mode, due to the superposition of the three $\sin(r\pi\hat{x})$ curves. The former is defined by

$$L^2(\hat{x}) = \left(\sum_{r=1}^{3} \sqrt{\left(\hat{I}_r^+(0) + \hat{I}_r^-(0)\right)}\,\sin(r\pi\hat{x})\right)^2 \tag{47}$$

and has been plotted in Figure 5 for case A. As the current increases, there is a shift in the peak of the optical distribution to one side, an effect observed in some of the stripe lasers studied in [13, p. 377]. This case does not generate a multilobed lateral near-field profile. Instead, the onset of the third ($\sin(3\pi\hat{x})$) mode creates a single ripple (top curve in Figure 5), this feature also appearing within the near-field scans in [1, p. 66]. The lateral intensity of the $\sin(\pi\hat{x})$ mode produces the high local rate of stimulated recombination at the center of the active region (bottom curve in Figure 5). After a sufficient increase in current, this causes the curvature at the peak of the carrier distribution to become inverted, forming a dip in the profile [13, p. 380]. This is seen in Figure 6, where we have plotted the lateral variation of N_0 at $Z = 0.5$. Note that the evolution of the lateral carrier profile at higher currents reflects a pattern of optical modes [8, p. 585], which is further illustrated in case B. The phenomenon described here is known as spatial-hole burning and takes place in the lateral direction in this particular problem. Note that longitudinal spatial-hole burning properties have been neglected due to the omission from N_0 of $\hat{z}$ dependence.

6.3. Case study B: $\boldsymbol{F = F_B(\hat{x})}$. In this second case, the sequence of activation of the $\sin(r\pi\hat{x})$ modes is given by $r = 1, 3, 2$; the respective threshold current density amplitudes are given by $J_{AMP} \sim 9.5$, 12.6, and 13.1. It follows that the physical behavior differs as a result of this revised sequence (or lateral mode hop). In particular, the near-field profile ($L^2(\hat{x})$) develops a lobed effect that is similar to that presented in [13, p. 377]. The distribution of light gradually focuses around two particular points along the active layer's lateral length (see Figure 7). The spatial-hole burning mechanism affects the lateral carrier profile quite dramatically, as indicated in Figure 8, where N_0 is plotted for $Z = 0.5$. At higher currents, a series of peaks and troughs like that in Figure 8 is typical of broad-area semiconductor lasers (see,

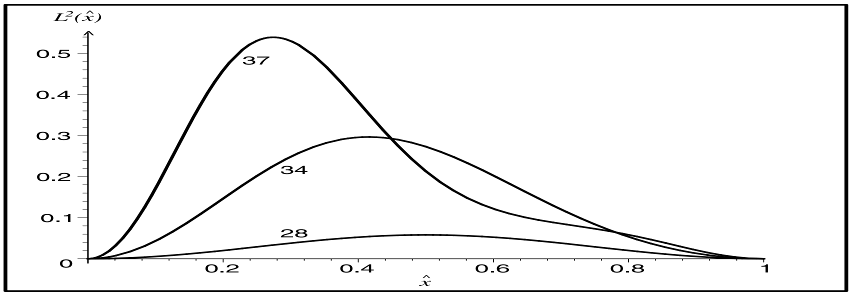

FIG. 5. *Tracing the near-field lateral intensity profile with increasing current in case A. The labels correspond to the values of J_{AMP} taken in each computation. All values used are nondimensional.*

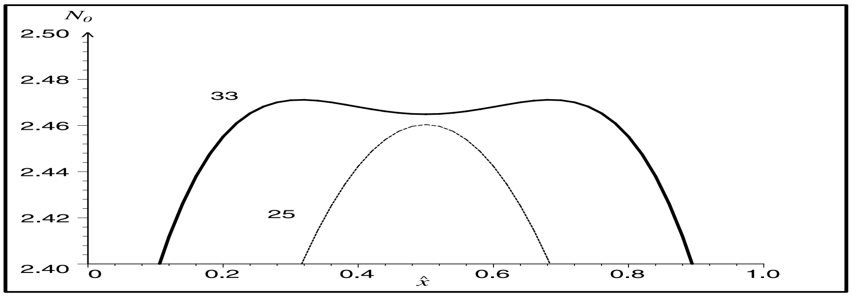

FIG. 6. *Zooming in on the center of the lateral carrier profile at $Z = 0.5$ to highlight the onset of lateral spatial-hole burning. The labels on each curve refer to the increasing dimensionless current density amplitude J_{AMP}.*

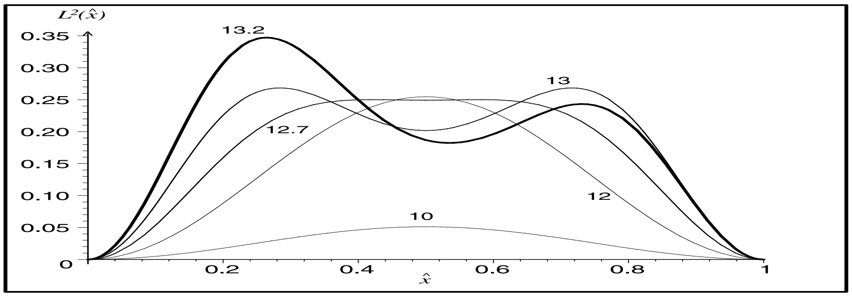

FIG. 7. *Tracing the near-field lateral intensity profile with increasing current in case B. Again the labels correspond to the increasing J_{AMP}. All values used are nondimensional.*

for example, [13, pp. 380–381]). Note that the increased levels of stimulated gain, which occur at the peaks in Figure 7, coincide with a local reduction in the electron concentration. As the $\sin(3\pi\hat{x})$ lateral mode is activated, the electron concentration can be seen to exhibit a $\cos(6\pi\hat{x})$ mode.

7. Conclusions. The models discussed in this paper have been employed to simulate electrical-optical effects in the active region of a multilateral mode semiconductor laser. The starting point was a system based on Maxwell's equations together with models for the polarization, charge density, and current density (which represent a realistic semiconductor medium). A multiple-scale asymptotic expansion resulted

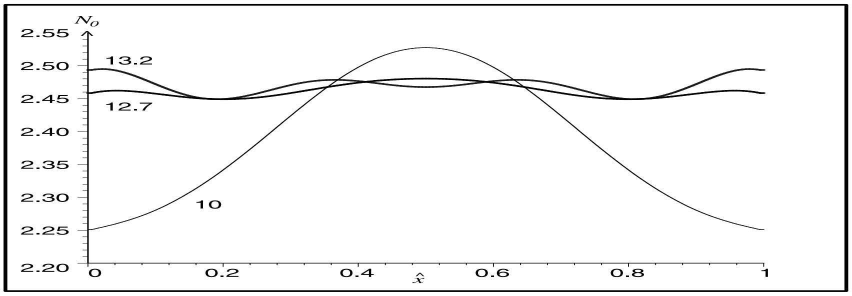

FIG. 8. *Lateral variation of the electron density at* $Z = 0.5$ *when one (*$J_{AMP} \sim 10$*), two (*$J_{AMP} \sim 12.7$*), and then three (*$J_{AMP} \sim 13.2$*) modes are operating in case B.*

in a leading-order problem in which the linear equations for the lasing mode can be viewed as representing a waveguide. The infinite number of possible lateral mode shapes in the waveguide has been truncated to the three most commonly observed in experiments. At the next order, a set of twelve nonlinear secularity conditions model the lasing mode envelopes. The original system has been reduced to twelve first-order wave equations for the envelope of the lasing mode and one second-order diffusion equation for the electron concentration.

Averaging over the transverse and short longitudinal length-scales led to the partially lumped model, which consists of six first-order wave equations and one nonlinear (lateral) diffusion equation for the electron concentration. The traveling-wave rate equations form a counterpart to the single lateral mode version of this partially lumped model. However, in the existing literature, there are no counterparts to the multilateral partially lumped model or criterion for the onset of multimode operation, these representing the most important aspects of the current paper.

We conclude by noting that the simplified models provide a basis for the study of broad-area lasers. Ongoing research incorporates a pair of two-dimensional heat equations into the partially lumped model in order to simulate thermal hot-spots in high-power lasers (see, for example, [4] and [5]).

Appendix A. Secularity conditions for amplitude envelopes $B_r^+(Z,T,\tau)$. The first-order wave equations associated with B_1^+, B_2^+, and B_3^+ are presented with the integral terms α_1, α_2, β_1, β_2, γ_1, γ_2, δ_1, and δ_2 as defined in (32a)–(32d):

(48)

$$\frac{2\pi q_1}{\hat{k}_1}\left(\epsilon_R\hat{\omega}\frac{\partial B_1^+}{\partial T} + \hat{k}_1\frac{\partial B_1^+}{\partial Z}\right) = B_1^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1 - \alpha_2\big)\,d\hat{z}$$

$$- A_1^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1-\alpha_2\big)\sin\big(2\hat{k}_1\hat{z}\big)\,d\hat{z} + B_1^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\alpha_1-\alpha_2\big)\cos\big(2\hat{k}_1\hat{z}\big)\,d\hat{z}$$

$$- A_3^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z} + B_3^+\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z}$$

$$- A_3^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z} + B_3^-\int_{\hat{z}=0}^{2\pi q_1/\hat{k}_1}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z},$$

$$\begin{aligned}(49)\quad &\frac{2\pi q_2}{\hat{k}_2}\left(\epsilon_R\hat{\omega}\frac{\partial B_2^+}{\partial T}+\hat{k}_2\frac{\partial B_2^+}{\partial Z}\right)=B_2^+\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\,d\hat{z}\\ &-A_2^-\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\sin\big(2\hat{k}_2\hat{z}\big)\,d\hat{z}+B_2^-\int_{\hat{z}=0}^{2\pi q_2/\hat{k}_2}\big(\gamma_1-\gamma_2\big)\cos\big(2\hat{k}_2\hat{z}\big)\,d\hat{z},\end{aligned}$$

(50)

$$\begin{aligned}&\frac{2\pi q_3}{\hat{k}_3}\left(\epsilon_R\hat{\omega}\frac{\partial B_3^+}{\partial T}+\hat{k}_3\frac{\partial B_3^+}{\partial Z}\right)=B_3^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\,d\hat{z}\\ &-A_3^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\sin\big(2\hat{k}_3\hat{z}\big)\,d\hat{z}+B_3^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\delta_1-\delta_2\big)\cos\big(2\hat{k}_3\hat{z}\big)\,d\hat{z}\\ &+A_1^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z}+B_1^+\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1-\hat{k}_3)\hat{z}\big)\,d\hat{z}\\ &-A_1^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\sin\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z}+B_1^-\int_{\hat{z}=0}^{2\pi q_3/\hat{k}_3}\big(\beta_1-\beta_2\big)\cos\big((\hat{k}_1+\hat{k}_3)\hat{z}\big)\,d\hat{z}.\end{aligned}$$

Appendix B. Dimensional traveling-wave rate equations for multilateral mode lasers. This appendix presents the traveling-wave rate equations for a broad-area semiconductor laser with M lateral modes. Letting k_r represent the dimensional wave number associated with the $\sin(r\pi x/w)$ lateral mode, the dimensional dispersion relation is given by $k_r^2=\omega^2\epsilon\mu_0-(r\pi/w)^2$. The current density profile is denoted by $J(x)$ below. After transforming to dimensional variables in (41)–(42), we arrive at the following diffusion equation for the electron concentration $n(x,z,t)$:

$$\begin{aligned}(51)\quad &\frac{\partial n}{\partial t}=\frac{J(x)}{ed}-\frac{n}{A_n+A_p}-Bn^2-(C_n+C_p)n^3+\left(\frac{D_n\mu_p+D_p\mu_n}{\mu_n+\mu_p}\right)\frac{\partial^2 n}{\partial x^2}\\ &-2a(n-n_t)\sum_{r=1}^{M}\left(I_r^++I_r^-\right)\sin^2\!\left(\frac{r\pi x}{w}\right).\end{aligned}$$

We deduce that the optical intensities, $I_r^\pm(z,t)$, satisfy

$$(52)\quad \epsilon\omega\frac{\partial I_r^\pm}{\partial t}\pm\frac{k_r}{\mu_0}\frac{\partial I_r^\pm}{\partial z}=\left(\frac{2\omega e}{w}\left(\frac{\epsilon a}{e}-\mu_n-\mu_p\right)\int_0^w n\sin^2\!\left(\frac{r\pi x}{w}\right)dx-\omega\epsilon a n_t\right)I_r^\pm,$$

where $r=1,2,\dots,M$. The boundary conditions are $I_r^+(0,t)=R^{(1)}I_r^-(0,t)$ and $I_r^-(L,t)=R^{(2)}I_r^+(L,t)$ along with $\partial n/\partial x=0$ at $x=0$ and $x=w$.

Appendix C. A dimensional criterion for multimode operation. This appendix presents a dimensional criterion that corresponds to the onset of multimode laser operation. The fundamental mode, characterized by the lateral profile $\sin(\pi x/w)$, is activated at the first threshold current. At the second threshold current density amplitude, J_P, the $\sin(p\pi x/w)$ lateral mode is switched on and multimode lasing is established. Note that the particular mode to be activated next (where $p\geq 2$) depends upon the lateral current density profile, $\bar{F}(x)$, and the bifurcation condition, as seen in section 6. The bifurcation condition thus consists of (53)–(54) and (55) for $r=1$ and $r=p$, where we solve for the threshold electron concentration $n(x,z)$, the constant of integration $\bar{C}_1$ (this corresponding to the dominant mode), and J_P. The dimensional ordinary differential equation for the threshold carrier density takes the form

$$\frac{D_n\mu_p + D_p\mu_n}{\mu_n+\mu_p}\frac{\partial^2 n}{\partial x^2} + J_P\bar{F}(x) = \frac{n}{A_n+A_p} + Bn^2 + (C_n+C_p)n^3 + 2a(n-n_t)\sin^2\Big(\frac{\pi x}{w}\Big)\bar{f}_1(z), \tag{53}$$

where the sum of the forward and backward intensities of the $\sin(\pi x/w)$ lateral mode is represented by

$$\bar{f}_1(z) = \bar{C}_1\left(\exp\left\{\frac{2\omega\mu_0 e}{wk_1}\Big(\frac{\epsilon a}{e}-\mu_n-\mu_p\Big)\int_{z'=0}^{z}\bar{G}(z')\,dz' - \frac{\omega\mu_0\epsilon a n_t}{k_1}\,z\right\} + \sqrt{\frac{R^{(2)}}{R^{(1)}}}\exp\left\{\frac{2\omega\mu_0 e}{wk_1}\Big(\frac{\epsilon a}{e}-\mu_n-\mu_p\Big)\int_{z'=z}^{L}\bar{G}(z')\,dz' - \frac{\omega\mu_0\epsilon a n_t}{k_1}\,(L-z)\right\}\right),$$

in which

$$\bar{G}(z') = \int_{x=0}^{w} n(x,z')\sin^2\Big(\frac{\pi x}{w}\Big)\,dx.$$

We apply the no flux condition

$$\frac{\partial n}{\partial x} = 0 \quad \text{at } x = 0, w. \tag{54}$$

The criterion is completed by the following integral condition:

$$\frac{1}{4}k_r\ln\Big(R^{(1)}R^{(2)}\Big) = \frac{1}{2}\omega\mu_0\epsilon a n_t L - \frac{\omega\mu_0 e}{w}\Big(\frac{\epsilon a}{e}-\mu_n-\mu_p\Big)\int_0^L\int_0^w n\sin^2\Big(\frac{r\pi x}{w}\Big)\,dx\,dz. \tag{55}$$

MULTIFREQUENCY TRANS-ADMITTANCE SCANNER: MATHEMATICAL FRAMEWORK AND FEASIBILITY[*]

SUNGWHAN KIM[†], JEEHYUN LEE[‡], JIN KEUN SEO[‡], EUNG JE WOO[§], AND HABIB ZRIBI[§]

Abstract. A trans-admittance scanner (TAS) is a device for breast cancer diagnosis based on numerous experimental findings that complex conductivities of breast tumors significantly differ from those of surrounding normal tissues. In TAS, we apply a sinusoidal voltage between a hand-held electrode and a scanning probe placed on the breast skin to make current travel through the breast. The scanning probe has an array of electrodes at zero voltage. We measure exit currents (Neumann data) through the electrodes that provide a map of trans-admittance data over the breast surface. The inverse problem of TAS is to detect a suspicious abnormality underneath the breast skin from the measured Neumann data. Previous anomaly detection methods used the difference between the measured Neumann data and a reference Neumann data obtained beforehand in the absence of anomaly. However, in practice, the reference data is not available and its computation is not possible since the inhomogeneous complex conductivity of the normal breast is unknown. To deal with this problem, we propose a frequency-difference TAS (fdTAS), in which a weighted frequency difference of the trans-admittance data measured at a certain moment is used for anomaly detection. This paper provides a mathematical framework and the feasibility of fdTAS by showing the relationship between the anomaly information and the weighted frequency difference of the Neumann data.

1. Introduction.

A trans-admittance scanner (TAS) is a device for breast cancer diagnosis that is based on the consensus that complex conductivity values of breast tumors significantly differ from those of surrounding normal tissues [4, 18, 22, 35, 37]. For example, T-Scan is a commercially available TAS system that has been suggested for adjunctive clinical uses with X-ray mammography to decrease equivocal findings and thereby reduce unnecessary biopsies [4]. In TAS, a patient holds a reference electrode with one hand through which a sinusoidal voltage $V_0 \sin \omega t$ is applied, while a scanning probe at the ground potential is placed on the surface of the breast. The voltage difference $V_0 \sin \omega t$ produces electric current flowing through the breast region. See Figure 1. The resulting electric potential at a position $x = (x_1, x_2, x_3)$ and time t can be expressed as the real part of $u(x)e^{i\omega t}$, where the complex potential $u(x)$ is governed by the equation $\nabla \cdot ((\sigma + i\omega\epsilon)\nabla u(x)) = 0$ in the subject, where σ and ϵ denote the conductivity and permittivity, respectively. The scanning probe is equipped with a planar array of electrodes, and we measure exit currents (Neumann

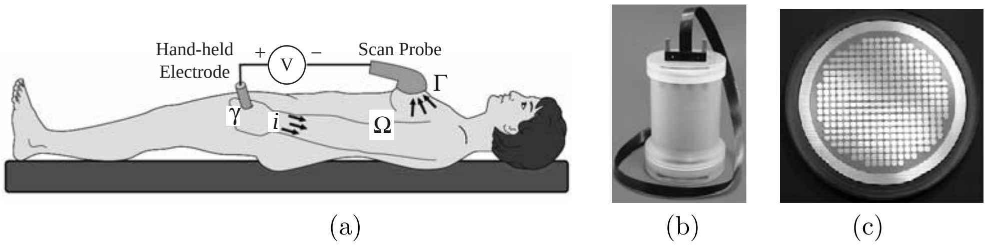

FIG. 1. *TAS setup.* (a) *Voltage is applied between the hand-held electrode and the planar array of electrodes in the scan probe. Exit currents through the scan probe are measured to provide trans-admittance data.* (b) *Picture of a scan probe and* (c) *its electrode array.*

data) $g = -(\sigma + i\omega\epsilon)\frac{\partial u}{\partial \mathbf{n}}$ which reflect electrical properties of tissues under the scan probe. Here, $\frac{\partial u}{\partial \mathbf{n}}$ is the normal derivative of u.

The inverse problem of TAS is to detect a suspicious abnormality in a breast region underneath the probe from measured Neumann data g. All previous anomaly detection methods utilize a difference $g - g^*$, where g^* is a reference Neumann data measured beforehand without any anomaly inside the breast region [1, 34]. This difference $g - g^*$ can be viewed as a kind of background subtraction so that it makes the anomaly apparently visible. However, in practice, it is not available in most cases, and calculating g^* is not possible since the inhomogeneous complex conductivity of a specific normal breast is unknown. In order for TAS to be more practical, we should avoid using this background difference data $g - g^*$. Therefore, we propose a frequency difference TAS method which uses a frequency difference of trans-admittance data measured at a certain moment.

To be precise, let the human body occupy a three-dimensional domain Ω with a smooth boundary $\partial\Omega$. Let Γ and γ be portions of $\partial\Omega$, denoting the probe plane placed on the breast and the surface of the metallic reference electrode, respectively. Through γ, we apply a sinusoidal voltage of $V_0 \sin \omega t$ with its frequency $f = \omega/2\pi$ in a range of 50 Hz to 500 kHz. Then the corresponding complex potential u_ω at ω satisfies the following mixed boundary value problem:

$$(1) \qquad \begin{cases} \nabla \cdot ((\sigma + i\omega\epsilon)\nabla u_\omega(x)) = 0 \quad \text{in } \Omega, \\ u_\omega(x) = 0, \quad x \in \Gamma, \\ u_\omega(x) = V_0, \quad x \in \gamma, \\ (\sigma + i\omega\epsilon)\nabla u_\omega(x) \cdot \mathbf{n}(x) = 0, \quad x \in \partial\Omega \setminus (\Gamma \cup \gamma), \end{cases}$$

where $\mathbf{n}$ is the unit outward normal vector to the boundary $\partial\Omega$. Note that both $\sigma = \sigma(x, \omega)$ and $\epsilon = \epsilon(x, \omega)$ depend on ω. The scan probe Γ consists of a planar array of electrodes $\mathcal{E}_1, \ldots, \mathcal{E}_m$, and we measure exit current $g_\omega(j)$ through each electrode $\mathcal{E}_j$:

$$g_\omega(j) := -\int_{\mathcal{E}_j} (\sigma + i\omega\epsilon)\, \nabla u_\omega \cdot \mathbf{n}\, ds \qquad (j = 1, \ldots, m),$$

where ds is the area element.

In the frequency-difference TAS (fdTAS), we apply voltage with two different frequencies $f_1 = \omega_1/2\pi$ and $f_2 = \omega_2/2\pi$ with 50 Hz $\leq f_1 < f_2 \leq$ 500 kHz and measure two sets of corresponding Neumann data g_{ω_1} and g_{ω_2} through Γ at the same time. We assume that there exists a region of breast tumor D beneath the probe Γ so that $\sigma + i\omega\epsilon$ changes abruptly across ∂D. (See Remark 2.1.) The inverse problem of fdTAS is to detect the anomaly D beneath Γ from a difference between g_{ω_1} and g_{ω_2}.

In order for any detection algorithm to be practical, we must take into account the following limitations:

(a) Since Ω differs for each subject, the algorithm should be robust against any change in the geometry of Ω and also any change in the complex conductivity distribution outside the breast region.

(b) The Neumann data g_ω is available only on a small surface Γ instead of the whole surface $\partial\Omega$.

(c) Since the inhomogeneous complex conductivity of the normal breast without D is unknown, it is difficult to obtain the reference Neumann data g^*_ω in the absence of D.

These limitations are indispensable to a TAS model in practical situations, and these are the reasons why we try to improve the previous techniques [1, 2, 3, 6, 7, 8, 9, 10, 11, 13, 17, 21, 24, 25, 26, 27, 28, 31, 34] by using frequency difference.

In the fdTAS model, we use a weighted frequency difference of Neumann data $g_{\omega_2} - \alpha g_{\omega_1}$ instead of $g_{\omega_2} - g_{\omega_1}$. The weight constant α is approximately $\alpha \approx \frac{\int_\Gamma g_{\omega_2} ds}{\int_\Gamma g_{\omega_1} ds}$, and the weight is a crucial factor in the anomaly detection. We should note that the simple difference $g_{\omega_2} - g_{\omega_1}$ may fail to extract the anomaly due to the complicated structure of the solution of the complex conductivity equation. See Remark 3.3. In Theorem 3.2, we explain how $g_{\omega_2} - \alpha g_{\omega_1}$ reflects a contrast in complex conductivity values between the anomaly D and surrounding normal tissues. The approximate representation formula is given in Remark 3.4.

Recently, we published a preliminary experimental validation study of fdTAS in [32]. However, this previous work lacks a mathematical analysis of the method. We therefore describe a rigorous mathematical framework of the fdTAS method in this paper.

2. Mathematical model and the feasibility of fdTAS.

We assume that σ and ϵ are isotropic, positive, and piecewise smooth functions in $\overline{\Omega}$. Let u_ω be the $H^1(\Omega)$-solution of (1). Denoting the real and imaginary parts of u_ω by $v_\omega = \Re u_\omega$ and $h_\omega = \Im u_\omega$, the mixed boundary value problem (1) can be expressed as the following coupled system:

$$(2)\qquad \begin{cases} \nabla\cdot(\sigma\nabla v_\omega) - \nabla\cdot(\omega\epsilon\nabla h_\omega) = 0 & \text{in} \quad \Omega, \\ \nabla\cdot(\omega\epsilon\nabla v_\omega) + \nabla\cdot(\sigma\nabla h_\omega) = 0 & \text{in} \quad \Omega, \\ \quad v_\omega = 0 \quad \text{and} \quad h_\omega = 0 & \text{on} \quad \Gamma, \\ \quad v_\omega = V_0 \quad \text{and} \quad h_\omega = 0 & \text{on} \quad \gamma, \\ \mathbf{n}\cdot\nabla v_\omega = 0 \quad \text{and} \quad \mathbf{n}\cdot\nabla h_\omega = 0 & \text{on} \partial\Omega \setminus (\Gamma\cup\gamma). \end{cases}$$

The measured Neumann data g_ω can be decomposed into

$$g_\omega(x) := \underbrace{\mathbf{n}\cdot(-\sigma\nabla v_\omega(x) + \omega\epsilon\nabla h_\omega(x))}_{\text{real part}} + i\ \underbrace{\mathbf{n}\cdot(-\sigma\nabla h_\omega(x) - \omega\epsilon\nabla v_\omega(x))}_{\text{imaginary part}}, \qquad x\in\Gamma.$$

The solution of the coupled system (2) is a kind of saddle point [5, 12], and we have the following relations:

$$(3)\qquad V_0\int_\Gamma \Re(g_\omega)ds = \min_{v\in\mathcal{H}_{re}}\max_{h\in\mathcal{H}_{im}}\int_\Omega \left[\sigma|\nabla v|^2 - 2\omega\epsilon\nabla v\cdot\nabla h - \sigma|\nabla h|^2\right]dx$$

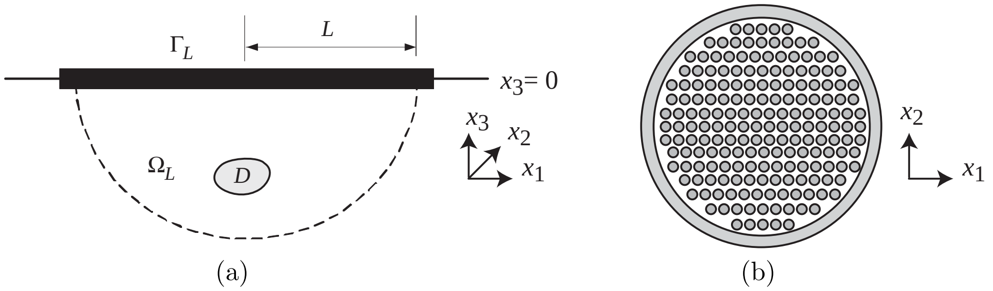

FIG. 2. (a) *Simplified model of the breast region with a cancerous lesion D under the scan probe.* (b) *Schematic of the scan probe in the (x_1, x_2)-plane.*

and

$$V_0 \int_\Gamma \Im(g_\omega) ds = \min_{v\in\mathcal{H}_{re}} \max_{h\in\mathcal{H}_{im}} \int_\Omega \left[\omega\epsilon|\nabla v|^2 + 2\sigma\nabla v\cdot\nabla h - \omega\epsilon|\nabla h|^2\right] dx, \tag{4}$$

where $\mathcal{H}_{re} := \{v \in H^1(\Omega) : v|_\Gamma = 0,\ v|_\gamma = V_0,\ \frac{\partial v}{\partial \mathbf{n}}|_{\partial\Omega\setminus(\Gamma\cup\gamma)} = 0\}$ and $\mathcal{H}_{im} := \{h \in H^1(\Omega) : h|_{\Gamma\cup\gamma} = 0,\ \frac{\partial h}{\partial \mathbf{n}}|_{\partial\Omega\setminus(\Gamma\cup\gamma)} = 0\}$.

In order to detect a lesion D underneath the scan probe Γ, we define a local region of interest under the probe plane Γ as shown in Figure 2. For simplicity, we let x_3 be the axis normal to Γ and let the center of Γ be the origin. Hence, the probe region Γ can be approximated as a two-dimensional region $\Gamma = \{(x_1, x_2, 0) : \sqrt{x_1^2 + x_2^2} < L\}$, where L is the radius of the scan probe. We set the region of interest inside the breast as a half ball $\Omega_L = \Omega \cap B_L$ shown in Figure 2, where B_L is a ball with a radius L and its center at the origin.

Remark 2.1. We summarize conductivity and permittivity values of normal and tumor tissues in the breast. Both σ and $\omega\epsilon$ have a unit of S/m and $\sigma + i\omega\epsilon = \sigma + i2\pi f\epsilon_0\epsilon_r$, where $\epsilon_0 \approx 8.854 \times 10^{-12}$ [F/m] is the permittivity of the free space and ϵ_r is a relative permittivity. Note that $\frac{\omega\epsilon_n}{\sigma_n} \le \frac{1}{50}$ for a frequency $f = \omega/2\pi \ge$50 kHz [37].

$f = \omega/2\pi$, [Hz]	σ_n, [S/m]	σ_c, [S/m]	$\omega\epsilon_n$, [S/m]	$\omega\epsilon_c$, [S/m]
≤ 500	0.03	0.2	$\ll \sigma_n$	$\ll \sigma_c$
50×10^3	0.03	0.2	5.6×10^{-4}	1.7×10^{-2}
100×10^3	0.03	0.2	2.8×10^{-4}	2.2×10^{-2}
500×10^3	0.03	0.2	1.1×10^{-3}	5.6×10^{-2}

For a successful anomaly detection, we should carefully choose two frequencies ω_1 and ω_2. In our TAS system, we choose $f_1 = \omega_1/2\pi$ and $f_2 = \omega_2/2\pi$ such that

$$50 \text{ Hz} \le f_1 \le 500 \text{ Hz} \quad \text{and} \quad 50 \text{ kHz} \le f_2 \le 500 \text{ kHz}. \tag{5}$$

We denote by $u_1 = v_1 + ih_1$ and $u_2 = v_2 + ih_2$ the complex potentials satisfying (2) at ω_1 and ω_2, respectively, and let $g_1 = g_{\omega_1}$ and $g_2 = g_{\omega_2}$. The fdTAS aims to detect D from a weighted difference between g_1 and g_2.

Now, let us investigate the connection between u_1 and u_2 and whether the frequency-difference Neumann data $g_2 - \alpha g_1$ has any information of D. Since both σ and ϵ depend on ω and x, $\sigma(x, \omega_1) \ne \sigma(x, \omega_2)$ and $\epsilon(x, \omega_1) \ne \epsilon(x, \omega_2)$. For simplicity, we denote

$$\sigma_j(x) = \sigma(x, \omega_j) \qquad \text{and} \qquad \epsilon_j(x) = \epsilon(x, \omega_j), \qquad j = 1, 2.$$

There is a cancerous lesion D inside Ω_L, and the complex conductivity $\sigma_j + i\omega_j\epsilon_j$ changes abruptly across ∂D as in the table in Remark 2.1. To distinguish them, we denote

$$(6)\qquad \sigma_j = \begin{cases} \sigma_{j,n} & \text{in } \Omega_L \setminus \overline{D}, \\ \sigma_{j,c} & \text{in } D, \end{cases} \qquad \text{and} \qquad \epsilon_j = \begin{cases} \epsilon_{j,n} & \text{in } \Omega_L \setminus \overline{D}, \\ \epsilon_{j,c} & \text{in } D. \end{cases}$$

With the use of this notation, u_1 and u_2 satisfy

$$(7) \begin{cases} \nabla \cdot ((\sigma_1 + i\omega_1\epsilon_1)\nabla u_1) = 0 \quad \text{in } \Omega, \\ u_1|_\Gamma = 0, \quad u_1|_\gamma = V_0, \\ (\sigma_1 + i\omega_1\epsilon_1)\frac{\partial u_1}{\partial \mathbf{n}}|_{\partial\Omega\setminus(\Gamma\cup\gamma)} = 0, \end{cases} \text{and} \begin{cases} \nabla \cdot ((\sigma_2 + i\omega_2\epsilon_2)\nabla u_2) = 0 \quad \text{in } \Omega, \\ u_2|_\Gamma = 0, \quad u_2|_\gamma = V_0, \\ (\sigma_2 + i\omega_2\epsilon_2)\frac{\partial u_2}{\partial \mathbf{n}}|_{\partial\Omega\setminus(\Gamma\cup\gamma)} = 0. \end{cases}$$

Remark 2.2. Due to the complicated structure of (3) and (4) for the solution u_ω, it is quite difficult to analyze the interrelation between the complex conductivity contrast $\nabla(\sigma + i\omega\epsilon)$ and the Neumann data g_ω. In [1], the authors briefly mentioned that the multifrequency TAS method can be regarded as a straightforward extension of their single-frequency TAS algorithm (Remark 2.3 in [1]). However, the simple frequency-difference data $g_2 - g_1$ on Γ may fail to extract the anomaly for more general cases of complex conductivity distributions in Ω due to the complicated structure of the solution of (2). To be precise, the use of the weighted difference is essential when the background comprises biological materials with nonnegligible frequency-dependent complex conductivity values. To explain it clearly, consider a homogeneous complex conductivity distribution in Ω where $\sigma(x,\omega)+i\omega\epsilon(x,\omega)$ depends only on ω. Due to the frequency dependency, the simple difference $g_2 - g_1$ is not zero, while $g_2 - \alpha g_1 = 0$. Hence, any reconstruction method using $g_2 - g_1$ always produces artifacts because $g_2 - g_1$ does not eliminate modeling errors. See (26) for an approximation of $g_2 - g_1$ in the presence of an anomaly D.

Remark 2.3. In this work, we do not consider effects of contact impedances along electrode-skin interfaces. For details about the contact impedance, please see [20, 36] and other publications cited therein. In TAS, we may adopt a skin preparation procedure and electrode gels to reduce contact impedances. Since we cannot expect complete removal of contact impedances, however, we need to investigate how exit currents are affected by contact impedances of a planner array of electrodes that are kept at the grounded potential. The contact impedance of each electrode leads to a voltage drop across it, and therefore the voltage underneath the electrode-skin interface layer would be slightly different than zero. In other words, when contact impedances are not negligible, the surface area in contact with Γ cannot be regarded as an equipotential surface anymore, and this will result in some changes in exit currents. Future studies are needed to estimate how the contact impedance affects the weighted difference of the Neumann data. We should also investigate experimental techniques, including choice of frequencies, to minimize their effects.

The next observation explains why we should use a weighted difference $g_2 - \alpha g_1$ instead of $g_2 - g_1$.

Observation 2.4. Denoting $\eta := \frac{\sigma_2 + i\omega_2\epsilon_2}{\sigma_1 + i\omega_1\epsilon_1}$, it follows from a direct computation that $u_2 - u_1$ satisfies

$$(8)\qquad \begin{cases} \nabla \cdot ((\sigma_1 + i\omega_1\epsilon_1)\nabla(u_2 - u_1)) = -(\sigma_1 + i\omega_1\epsilon_1)\nabla \log\eta \cdot \nabla u_2 \quad \text{in } \Omega, \\ (u_2 - u_1)|_{\Gamma\cup\gamma} = 0, \\ (\sigma_1 + i\omega_1\epsilon_1)\frac{\partial(u_2 - u_1)}{\partial \mathbf{n}}|_{\partial\Omega\setminus(\Gamma\cup\gamma)} = 0. \end{cases}$$

For the detection of D, we use the following weighted difference:

$$g_2 - \alpha g_1 = \eta\ (\sigma_1 + i\omega_1\epsilon_1)\ \mathbf{n} \cdot \nabla(u_2 - u_1) \qquad \text{on } \Gamma,$$

where $\alpha = \eta|_\Gamma$. If $\nabla \log \eta = 0$ in (8), $u_1 = u_2$ in Ω and $g_2 - \alpha g_1 = 0$ on Γ. In other words, if $\nabla \log \eta = 0$ in Ω_L, it is impossible to detect D from $g_2 - \alpha g_1 = 0$ regardless of contrasts in σ and ϵ across ∂D. Any useful information on D could be found from nonzero $g_2 - \alpha g_1$ on Γ when $|\nabla \log \eta|$ is large along ∂D.

For chosen frequencies ω_1 and ω_2, we can assume that σ and ϵ are approximately constant in the normal breast region $\Omega_L \setminus \overline{D}$ and also in the cancerous region D. Hence, if η changes abruptly across ∂D, we roughly have

$$\nabla \log \eta \approx 0 \quad \text{in } \Omega_L \setminus \bar{D} \quad \text{and} \quad |\nabla \log \eta| = \infty \quad \text{on } \partial D,$$

and therefore the term $(\sigma_1 + i\omega_1\epsilon_1)\nabla \log \eta \cdot \nabla u_2$ in (8) is supported on ∂D in the breast region Ω_L. This explains that the difference $g_2 - \alpha g_1$ on Γ can provide the information of ∂D. Take note that the inner product $\nabla \log \eta \cdot \nabla u_2$ is to be interpreted in a suitable distributional sense if the coefficients jump at ∂D.

3. Mathematical analysis for fdTAS.

3.1. Representation formula. Observation 2.4 in the previous section roughly explains how D is related to $g_2 - \alpha g_1$. In this section, the observation will be justified rigorously in a simplified model. We assume that $\sigma_{j,n}$, $\sigma_{j,c}$, $\epsilon_{j,n}$, and $\epsilon_{j,c}$ are constants. According to the table in Remark 2.1, the change of the conductivity due to the change of frequency is small, so we assume that

$$\sigma_{1,n} = \sigma_{2,n} := \sigma_n \quad \text{and} \quad \sigma_{1,c} = \sigma_{2,c} := \sigma_c. \tag{9}$$

Since the breast region of interest is relatively small compared with the entire body Ω, we may assume that Ω is the lower half space $\Omega = \mathbb{R}^3_- := \{\mathbf{x} = (x_1, x_2, x_3) \mid x_3 < 0\}$ and $\gamma = \infty$.

Suppose that v_j and h_j are H^1-solutions of the following coupled system for j =1 and 2:

$$\begin{cases} \nabla \cdot (\sigma \nabla v_j) - \nabla \cdot (\omega_j \epsilon_j \nabla h_j) = 0 & \text{in} \quad \Omega = \mathbb{R}^3_-, \\ \nabla \cdot (\omega_j \epsilon_j \nabla v_j) + \nabla \cdot (\sigma \nabla h_j) = 0 & \text{in} \quad \Omega = \mathbb{R}^3_-, \\ \quad v_j = 1 \quad \text{and} \quad h_j = 0 & \text{on} \quad \Gamma, \\ \mathbf{n} \cdot \nabla v_j = 0 \quad \text{and} \quad \mathbf{n} \cdot \nabla h_j = 0 & \text{on} \quad \partial\Omega \setminus \Gamma. \end{cases} \tag{10}$$

Let $u_j = v_j + ih_j$. Then $V_0(1 - u_j)$ can be viewed as a solution of (7) with $\Omega = \mathbb{R}^3_-$ and $\gamma = \infty$.

Let us introduce a key representation formula explaining the relationship between D and the weighted difference $g_2 - \alpha g_1$. For each $x \in \mathbb{R}^3 \backslash \Gamma$, we define

$$\Psi(x, y) = \Phi(x, y) + \Phi(x, y^+) + \varphi(x, y),$$

where $y^+ = (y_1, y_2, -y_3)$ is the reflection point of y with respect to the plane $\{y_3 = 0\}$ and $\varphi(x, \cdot)$ is the $H^1(\mathbb{R}^3 \backslash \Gamma)$-solution of the following PDE:

$$\begin{cases} \Delta_y \varphi(x, y) = 0, \quad y \in \mathbb{R}^3 \setminus \Gamma, \\ \varphi(x, y) = \frac{1}{2\pi|x-y|}, \quad y \in \Gamma, \\ \varphi(x, y) = 0 \quad \text{as } |y| \to \infty. \end{cases}$$

The following theorem explains an explicit relation between D and $\Im(g_2 - \alpha g_1)$.

THEOREM 3.1. *The imaginary part of the weighted difference $g_2 - \alpha g_1$ satisfies the following formula:*

$$\frac{1}{2\sigma_n}\Im(g_2-\alpha g_1)(x) = \int_D \nabla_y \frac{\partial\Phi(x,y)}{\partial x_3}\cdot\Theta(y)dy + \frac{\partial}{\partial x_3}\int_{\partial\Omega\setminus\Gamma}\frac{\partial\Phi(x,y)}{\partial y_3}\left[\int_D \nabla_z\Psi(y,z)\cdot\Theta(z)dz\right]ds,\ x\in\Gamma, \tag{11}$$

where

$$\Theta(y) = \frac{\sigma_n-\sigma_c}{\sigma_n}\nabla(h_2-h_1)(y) + \frac{\omega_2(\epsilon_{2,n}-\epsilon_{2,c})}{\sigma_n}\nabla(v_2-v_1)(y) - \Im(\beta\nabla u_1(y))$$

and

$$\beta = \frac{i}{1+i\frac{\omega_1\epsilon_{1,n}}{\sigma_n}} \cdot\left[\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\left(\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\right) - \frac{\omega_1\epsilon_{1,n}}{\sigma_n}\left(\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\sigma_c}{\sigma_n}\right) - i\frac{\omega_1\omega_2\epsilon_{1,n}\epsilon_{2,n}}{\sigma_n^2}\left(\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\epsilon_{2,c}}{\epsilon_{2,n}}\right)\right].$$

Proof. Due to Green's identity, $(\sigma_n+i\omega_2\epsilon_{2,n})(u_2-u_1)$ has integral representation: for each $x\in\Omega$,

$$\begin{aligned}&(\sigma_n+i\omega_2\epsilon_{2,n})(u_2-u_1)(x)\\ &= (\sigma_n+i\omega_2\epsilon_{2,n})\int_{\partial\Omega\setminus\Gamma}\frac{\partial\Phi(x,y)}{\partial\mathbf{n}}(u_2-u_1)(y)ds + \int_\Gamma \Phi(x,y)(g_2-\alpha g_1)(y)\ ds\\ &+ \int_{\partial D}\Phi(x,y)(\sigma_n+i\omega_2\epsilon_{2,n})\left(\frac{\partial(u_2-u_1)}{\partial\mathbf{n}}|_+ - \frac{\partial(u_2-u_1)}{\partial\mathbf{n}}|_-\right)(y)\ ds.\end{aligned} \tag{12}$$

Here, we denote $\frac{\partial u_j}{\partial\mathbf{n}}|_\pm = \mathbf{n}\cdot\nabla u_j^\pm|_{\partial D}$, where $u_j^+ = u_j|_{\Omega\setminus\bar D}$ and $u_j^- = u_j|_D$. From the transmission condition,

$$(\sigma_n+i\omega_j\epsilon_{j,n})\frac{\partial u_j}{\partial\mathbf{n}}|_+ = (\sigma_c+i\omega_j\epsilon_{j,c})\frac{\partial u_j}{\partial\mathbf{n}}|_-,\quad j=1,2 \qquad \text{on } \partial D.$$

It follows that

$$\frac{\sigma_n+i\omega_2\epsilon_{2,n}}{\sigma_n}\frac{\partial(u_2-u_1)}{\partial\mathbf{n}}|_+ = \frac{\sigma_c+i\omega_2\epsilon_{2,c}}{\sigma_n}\frac{\partial(u_2-u_1)}{\partial\mathbf{n}}|_- + \beta\frac{\partial u_1}{\partial\mathbf{n}}|_- \quad \text{on } \partial D. \tag{13}$$

Putting (13) into (12) and then applying $-\frac{\partial}{\partial x_3}$ to both sides of (12) yield for each $x\in\Gamma$

$$\frac{1}{2\sigma_n}\Im(g_2-\alpha g_1)(x) = \int_D \nabla_y\frac{\partial\Phi(x,y)}{\partial x_3}\cdot\left[\frac{\sigma_n-\sigma_c}{\sigma_n}\nabla(h_2-h_1) + \frac{\omega_2(\epsilon_{2,n}-\epsilon_{2,c})}{\sigma_n}\nabla(v_2-v_1) - \Im(\beta\nabla u_1)\right]dy + \Xi(x), \tag{14}$$

where

$$\Xi(x) = -\frac{\partial}{\partial x_3}\int_{\partial\Omega\setminus\Gamma}\frac{\partial\Phi(x,y)}{\partial y_3}\left((h_2-h_1)(y) + \frac{\omega_2\epsilon_{2,n}}{\sigma_n}(v_2-v_1)(y)\right)ds.$$

From the definition of $\Psi(x,y)$, it is easy to see that $\Psi(x,y)$ satisfies

$$\begin{cases} \triangle_x \Psi(x,y) = \delta(x-y), \quad x,\ y \in \mathbb{R}^3_-, \\ \Psi(x,y) = 0, \quad x \in \Gamma,\ y \in \mathbb{R}^3_-, \\ \frac{\partial \Psi(x,y)}{\partial x_3} = 0, \quad x \in \partial\Omega \setminus \Gamma,\ y \in \mathbb{R}^3_-, \\ \Psi(x,y) = 0 \quad \text{as } |x-y| \to \infty. \end{cases}$$

In order to relate $\Xi(x)$ with D, we repeat the argument in (12) with Φ replaced by Ψ:

$$(h_2 - h_1)(y) + \frac{\omega_2 \epsilon_{2,n}}{\sigma_n}(v_2 - v_1)(y) = \frac{1}{\sigma_n} \Im \left\{ (\sigma_n + i\omega_2\epsilon_{2,n})(u_2 - u_1)(y) \right\}$$

$$= \Im \left\{ \int_{\partial D} \Psi(y,z) \frac{\sigma_n + i\omega_2\epsilon_{2,n}}{\sigma_n} \left(\frac{\partial(u_2 - u_1)}{\partial \mathbf{n}}|_+ - \frac{\partial(u_2 - u_1)}{\partial \mathbf{n}}|_- \right)(z)\ ds \right\},\ y \in \partial\Omega \setminus \Gamma.$$

The above identity and the jump condition (13) lead to

$$(h_2 - h_1)(y) + \frac{\omega_2 \epsilon_{2,n}}{\sigma_n}(v_2 - v_1)(y) = -\int_D \nabla_z \Psi(y,z) \cdot \Theta(z) dz, \quad y \in \partial\Omega \setminus \Gamma.$$

This completes the proof. □

Now, let us derive a constructive formula extracting D from the representation formula (11) under some reasonable assumptions. We assume that

$$\text{(15)} \qquad \bar{D} \subset \Omega_{L/2}, \qquad D = B_\delta(\xi), \qquad \text{and} \qquad \delta \le \operatorname{dist}(D,\Gamma) \le C_1\delta,$$

where C_1 is a positive constant, B_δ is a ball with the radius δ and the center ξ, and $\frac{\delta}{L} \le \frac{1}{10}$. Suppose we choose $\frac{\omega_1}{2\pi} \approx 50$ Hz and $\frac{\omega_2}{2\pi} \approx 100$ kHz. Then the experimental data in Remark 2.1 shows $\frac{\omega_2\epsilon_{2,n}}{\sigma_n} \approx \frac{1}{100}$ and $\frac{\omega_1\epsilon_{1,n}}{\sigma_n} \le \frac{1}{10000}$. Hence, in practice, we can view

$$\text{(16)} \qquad \frac{\omega_1\epsilon_{1,n}}{\sigma_n} \approx 0, \quad (\delta/L)^3 \approx 0, \quad \left(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\right)^2 \approx 0.$$

Based on the experimental data in Remark 2.1, we assume that

$$\text{(17)} \qquad \max\left\{\frac{\epsilon_{j,n}}{\epsilon_{j,c}}, \frac{\sigma_n}{\sigma_c}\right\} \le \kappa_1, \quad \frac{\omega_2\epsilon_{2,n}}{\sigma_n} \le \kappa_2\frac{\sigma_n}{\sigma_c}, \quad \frac{\sigma_c}{\sigma_n} \le \kappa_3,$$

where κ_1 and κ_2 are positive constants less than $\frac{1}{2}$ and κ_3 is a positive constant less than 10. Taking advantage of these, we can simplify the representation formula (11).

THEOREM 3.2. *Under the assumptions* (15) *and* (17), *the imaginary part of the weighted frequency difference* $g_2 - \alpha g_1$ *can be expressed as*

$$\text{(18)} \quad \frac{1}{2\sigma_n}\Im\left(g_2 - \alpha g_1\right)(x) = \int_D \frac{\partial}{\partial x_3}\frac{(x-y)\cdot\tilde{\Theta}(y)}{4\pi|x-y|^3}dy + \mathit{Error}(x), \quad x \in \Gamma_{L/2},$$

where

$$\tilde{\Theta} = \frac{\sigma_n - \sigma_c}{\sigma_n}\nabla h_2 - \frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big(\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n}\Big)\nabla v_1$$

and the error term $Error(x)$ is estimated by

$$|Error(x)| \leq \Bigg[\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\mathcal{P}_1\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\frac{\delta^3}{L^3}$$

$$+\left(\frac{\omega_1\epsilon_{1,n}}{\sigma_n}\mathcal{P}_1\Big(\Big|\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)+\Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\right)\frac{\delta^3}{|x-\xi|^3}\Bigg].$$

Here, $\mathcal{P}_n(\lambda)$ is a polynomial function of order n such that $\mathcal{P}_n(0)=0$ and its coefficients depend only on $\kappa_j, j=1,2,3$.

Proof. From the transmission conditions of u_ω across ∂D, we have

$$\frac{\partial h_\omega}{\partial \mathbf{n}}\Big|_+ - \frac{\sigma_c}{\sigma_n}\frac{\partial h_\omega}{\partial \mathbf{n}}\Big|_- = \frac{\frac{\omega\epsilon_n}{\sigma_n}}{1+(\frac{\omega\epsilon_n}{\sigma_n})^2}\Big(\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big)\frac{\partial v_\omega}{\partial \mathbf{n}}\Big|_- + \frac{(\frac{\omega\epsilon_n}{\sigma_n})^2}{1+(\frac{\omega\epsilon_n}{\sigma_n})^2}\Big(\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big)\frac{\partial h_\omega}{\partial \mathbf{n}}\Big|_-.$$

Since h_ω satisfies the mixed boundary condition with $h_\omega|_\Gamma = 0$ and $\frac{\partial h_\omega}{\partial \mathbf{n}}|_{\partial\Omega\setminus\Gamma}=0$, we have the following estimate:

$$\int_\Omega \Big(\chi_{\Omega\setminus\bar{D}}+\frac{\sigma_c}{\sigma_n}\chi_D\Big)|\nabla h_\omega|^2 \leq \frac{\omega\epsilon_n}{\sigma_n}\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\|\nabla v_\omega\|_{L^2(D)}\|\nabla h_\omega\|_{L^2(D)} + \Big(\frac{\omega\epsilon_n}{\sigma_n}\Big)^2\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\|\nabla h_\omega\|^2_{L^2(D)}. \tag{19}$$

This gives

$$\|\nabla h_\omega\|_{L^2(D)} \leq \left(\frac{\sigma_c}{\sigma_n}-\Big(\frac{\omega\epsilon_n}{\sigma_n}\Big)^2\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\right)^{-1}\Big(\frac{\omega\epsilon_n}{\sigma_n}\Big)\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\|\nabla v_\omega\|_{L^2(D)}. \tag{20}$$

Since $\|\nabla v_\omega\|_{L^2(D)} \leq C\sqrt{|D|}$, where C depends only on κ_3, we obtain

$$\|\nabla h_\omega\|_{L^2(D)} \leq \Big(\frac{\omega\epsilon_n}{\sigma_n}\Big)\mathcal{P}_1\Big(\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\sqrt{|D|}. \tag{21}$$

We also use the jump condition for v_ω:

$$\frac{\partial v_\omega}{\partial \mathbf{n}}\Big|_+ - \frac{\sigma_c}{\sigma_n}\frac{\partial v_\omega}{\partial \mathbf{n}}\Big|_- = \frac{(\frac{\omega\epsilon_n}{\sigma_n})^2}{1+(\frac{\omega\epsilon_n}{\sigma_n})^2}\Big(\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big)\frac{\partial v_\omega}{\partial \mathbf{n}}\Big|_- + \frac{\frac{\omega\epsilon_n}{\sigma_n}}{1+(\frac{\omega\epsilon_n}{\sigma_n})^2}\Big(\frac{\sigma_c}{\sigma_n}-\frac{\epsilon_c}{\epsilon_n}\Big)\frac{\partial h_\omega}{\partial \mathbf{n}}\Big|_-.$$

Applying the same process as in (19), we obtain

$$\|\nabla v_\omega - \nabla u_0\|_{L^2(D)} \leq \left(\frac{\omega\epsilon_n}{\sigma_n}\right)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_c}{\epsilon_n}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\sqrt{|D|}, \tag{22}$$

where $u_0 = u_\omega$ with $\omega = 0$. From (22), we get

$$\|\nabla v_2 - \nabla v_1\|_{L^2(D)} \leq \|\nabla v_2 - \nabla u_0\|_{L^2(D)} + \|\nabla v_1 - \nabla u_0\|_{L^2(D)}$$

$$\leq \left(\Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)+\Big(\frac{\omega_1\epsilon_{1,n}}{\sigma_n}\Big)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\right)\sqrt{|D|}. \tag{23}$$

Hence, it follows from (20) and (23) that

$$\|\Theta - \tilde{\Theta}\|_{L^2(D)} \leq \left(\frac{\omega_1\epsilon_{1,n}}{\sigma_n}\mathcal{P}_1\Big(\Big|\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)+\Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\right)\sqrt{|D|}.$$

From the Schwarz inequality,

$$\left|\int_D \frac{\partial}{\partial x_3}\frac{(x-y)}{4\pi|x-y|^4}\cdot\Big(\Theta(y)-\tilde{\Theta}(y)\Big)dy\right| \le \frac{C\sqrt{|D|}}{|x-\xi|^3}\|\Theta-\tilde{\Theta}\|_{L^2(D)}$$

$$\le \left(\frac{\omega_1\epsilon_{1,n}}{\sigma_n}\mathcal{P}_1\Big(\Big|\frac{\epsilon_{1,c}}{\epsilon_{1,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)+\Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)^2\mathcal{P}_2\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\Big|\Big)\right)\frac{\delta^3}{|x-\xi|^3}.$$

Now, it remains to study the last term in (11). Using the Schwarz inequality, it is easy to see that

$$\left|\frac{\partial}{\partial x_3}\int_{\partial\Omega\setminus\Gamma}\frac{\partial\Phi(x,y)}{\partial y_3}\int_D \nabla_z\Psi(y,z)\cdot\Theta(z)dz\right| \le \frac{\delta^{\frac{3}{2}}}{L^3}\|\Theta\|_{L^2(D)}. \tag{24}$$

This completes the proof. □

Remark 3.3. According to Theorem 3.2, (21), and (23),

$$\frac{1}{2\sigma_n}\Im\left(g_2-\alpha g_1\right)=0 \quad\text{when}\quad \left|\frac{\epsilon_{j,c}}{\epsilon_{j,n}}-\frac{\sigma_c}{\sigma_n}\right|=0,\quad j=1,2.$$

Hence, even if $\epsilon_{2,c}$ and $\epsilon_{1,c}$ are quite different, we cannot extract any information of D when $|\frac{\epsilon_{j,c}}{\epsilon_{j,n}}-\frac{\sigma_c}{\sigma_n}|=0, j=1,2$. On the other hand, even if $\epsilon_{2,c}=\epsilon_{1,c}$, we can extract the information of D whenever $|\frac{\epsilon_{j,c}}{\epsilon_{j,n}}-\frac{\sigma_c}{\sigma_n}|\neq 0, j=1,2$.

Remark 3.4. Based on (18), we can derive the following simple approximate formula for the reconstruction of D:

$$\begin{aligned}\frac{1}{2\sigma_n}\Im\left(g_2-\alpha g_1\right)(x) \approx{}& \frac{\omega_2\epsilon_{2,n}}{\sigma_n}\frac{(3\sigma_n)^2}{(2\sigma_n+\sigma_c)^2}\left(\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\right)\partial_{x_3}U(\xi)\\ &\times|D|\frac{2\xi_3^2-(x_1-\xi_1)^2-(x_2-\xi_2)^2}{4\pi|x-\xi|^5},\quad x\in\Gamma_{L/2},\end{aligned} \tag{25}$$

where U is the solution of (10) in the absence of anomaly at $\omega=0$. Note that the difference g_2-g_1 can be approximated by

$$\begin{aligned}\frac{1}{2\sigma_n}\left(g_2-g_1\right)(x) \approx{}& i\frac{\omega_2\epsilon_{2,n}}{2\sigma_n^2}g_1(x)+i\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\frac{(3\sigma_n)^2}{(2\sigma_n+\sigma_c)^2}\left(\frac{\epsilon_{2,c}}{\epsilon_{2,n}}-\frac{\sigma_c}{\sigma_n}\right)\partial_{x_3}U(\xi)\\ &\times|D|\frac{2\xi_3^2-(x_1-\xi_1)^2-(x_2-\xi_2)^2}{4\pi|x-\xi|^5},\quad x\in\Gamma_{L/2},\end{aligned} \tag{26}$$

and therefore any detection algorithm using the above approximation will be disturbed by the term $\frac{\omega_2\epsilon_{2,n}}{2\sigma_n^2}g_1$.

We will prove the approximation (25) roughly. From [1], we have

$$\Big|\nabla U(y)-\partial_{x_3}U(\xi)\mathbf{e}_3\Big| \le C\frac{\delta}{L}\sqrt{|D|},\quad y\in D, \tag{27}$$

where $\mathbf{e}_3=(0,0,1)$. Now let V be the H^1-solution of the following PDE:

$$\begin{cases}\Delta V=0 \quad \text{in } \Omega\setminus\partial D,\\ \frac{\sigma_n}{\sigma_c}\frac{\partial V}{\partial\mathbf{n}}|_+-\frac{\partial V}{\partial\mathbf{n}}|_- = -\mathbf{n}\cdot\mathbf{e}_3 \quad \text{on } \partial D,\\ V|_\Gamma=0 \quad\text{and}\quad \frac{\partial V}{\partial\mathbf{n}}|_{\partial\Omega\setminus\Gamma}=0.\end{cases} \tag{28}$$

Using the same process as in (19) and (27), we obtain

$$\left\|\nabla u_0 - \nabla U(y) - \partial_{x_3} U(\xi)\Big(\frac{\sigma_n}{\sigma_c} - 1\Big)\nabla V\right\|_{L^2(D)} \le C\frac{\delta}{L}\sqrt{|D|}, \tag{29}$$

where C depends only on κ_3. From (22), (27), and (29), we have

$$\begin{aligned}&\left\|\nabla v_\omega - \partial_{x_3} U(\xi)\Big(\mathbf{e}_3 + \Big(\frac{\sigma_n}{\sigma_c} - 1\Big)\nabla V\Big)\right\|_{L^2(D)} \\ &\qquad \le \left(\Big(\frac{\omega\epsilon_n}{\sigma_n}\Big)^2 \mathcal{P}_2\Big(\Big|\frac{\epsilon_c}{\epsilon_n} - \frac{\sigma_c}{\sigma_n}\Big|\Big) + C\frac{\delta}{L}\right)\sqrt{|D|}.\end{aligned} \tag{30}$$

Applying the same process as in (19) and the identities (20) and (29), we obtain

$$\begin{aligned}&\left\|\nabla h_2 - \frac{\omega_2\epsilon_{2,n}}{\sigma_n}\frac{\sigma_n}{\sigma_c}\Big(\frac{\sigma_c}{\sigma_n} - \frac{\epsilon_{2,c}}{\epsilon_{2,n}}\Big)\partial_{x_3}U(\xi)\Big(1 + \Big(\frac{\sigma_n}{\sigma_c} - 1\Big)\partial_{x_3}V(\xi)\Big)\nabla V\right\|_{L^2(D)} \\ &\le \Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)\mathcal{P}_1\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n}\Big|\Big)\left\|\nabla v_2 - \partial_{x_3}U(\xi)\Big(\mathbf{e}_3 + \Big(\frac{\sigma_n}{\sigma_c} - 1\Big)\partial_{x_3}V(\xi)\mathbf{e}_3\Big)\right\|_{L^2(D)}.\end{aligned}$$

From (30), we get

$$\begin{aligned}&\left\|\nabla h_2 - \frac{\omega_2\epsilon_{2,n}}{\sigma_n}\frac{\sigma_n}{\sigma_c}\Big(\frac{\sigma_c}{\sigma_n} - \frac{\epsilon_{2,c}}{\epsilon_{2,n}}\Big)\partial_{x_3}U(\xi)\Big(\mathbf{e}_3 + \Big(\frac{\sigma_n}{\sigma_c} - 1\Big)\nabla V(\xi)\Big)\nabla V\right\|_{L^2(D)} \\ &\qquad \le \left(\Big(\frac{\omega_2\epsilon_{2,n}}{\sigma_n}\Big)^3\mathcal{P}_3\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n}\Big|\Big) + \frac{\omega_2\epsilon_{2,n}}{\sigma_n}\mathcal{P}_1\Big(\Big|\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n}\Big|\Big)\frac{\delta}{L}\right)\sqrt{|D|}.\end{aligned} \tag{31}$$

From [1], ∇V in D is approximated by

$$\nabla V|_D \approx \frac{\sigma_c}{2\sigma_n + \sigma_c}\Big(1 - \frac{r^3}{16\pi|\xi_3|^3}\Big)\mathbf{e}_3 \approx \frac{\sigma_c}{2\sigma_n + \sigma_c}\mathbf{e}_3. \tag{32}$$

The approximation (25) follows immediately from Theorem 3.2, (30), (31), and (32).

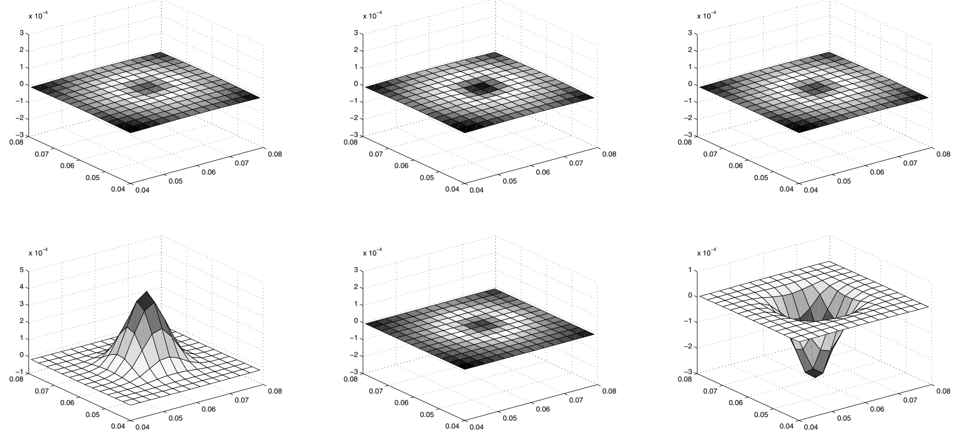
Remark 3.5. Our reconstruction algorithm is based on the approximation formula (25). In practice, we may not have a priori knowledge of the background conductivities. In that case, α is unknown. But α can be evaluated approximately by the ratio of the measured Neumann data as follows:

$$\alpha \;=\; \frac{\int_\Gamma g_{\omega_2} ds}{\int_\Gamma g_{\omega_1} ds} \;+\; \frac{\int_D \left((1-\alpha)\sigma_c + i(\omega_2\epsilon_{2,c} - \alpha\omega_1\epsilon_{1,c})\right)\nabla u_2 \cdot \nabla u_1 dx}{\int_\Omega (\sigma + i\omega_1\epsilon_1)|\nabla u_1|^2 dx}. \tag{33}$$

Hence, we may choose $\alpha \approx \frac{\int_\Gamma g_{\omega_2} ds}{\int_\Gamma g_{\omega_1} ds}$.

We can prove the identity (33) for a bounded domain Ω. Using $u_1|_\gamma = u_2|_\gamma = V_0$, we have

$$\begin{aligned}\textstyle\int_\Gamma (g_2 - \alpha g_1) ds \quad &= -\textstyle\int_\gamma (g_2 - \alpha g_1)\, ds = -\frac{1}{V_0}\int_\gamma (g_2 u_1 - \alpha g_1 u_1) ds \\ &= -\tfrac{1}{V_0}\textstyle\int_{\partial\Omega}(g_2 - \alpha g_1) u_1 ds \\ &= \tfrac{1}{V_0}\textstyle\int_\Omega \left((\sigma + i\omega_1\epsilon_2)\nabla u_2 - \alpha(\sigma + i\omega_1\epsilon_1)\nabla u_1\right)\cdot\nabla u_1 dx \\ &= \tfrac{1}{V_0}\textstyle\int_\Omega \Big[\alpha(\sigma + i\omega_1\epsilon_1)\left(\nabla u_2 - \nabla u_1\right)\cdot\nabla u_1 \\ &\qquad\qquad + \left((1-\alpha)\sigma + i(\omega_2\epsilon_2 - \alpha\omega_1\epsilon_1)\right)\nabla u_2 \cdot \nabla u_1\Big] dx \\ &= \tfrac{1}{V_0}\textstyle\int_D \left((1-\alpha)\sigma_c + i(\omega_2\epsilon_{2,c} - \alpha\omega_1\epsilon_{1,c})\right)\nabla u_2 \cdot \nabla u_1 dx.\end{aligned}$$



(a) (b) (c)

FIG. 3. *Frequency-difference trans-admittance map: Real and imaginary parts of* $g_2 - \alpha g_1$ *with three different values of* $\omega_2 \epsilon_{2,c}$ *such that* μ *is* (a) *positive,* (b) *zero, and* (c) *negative. All the plots are shown in the region* $[\,0.04,\, 0.08\,] \times [\,0.04,\, 0.08\,]$ *m*^{3} *by using the same scale of* 10^{-4}.

The identity (33) follows from the fact that

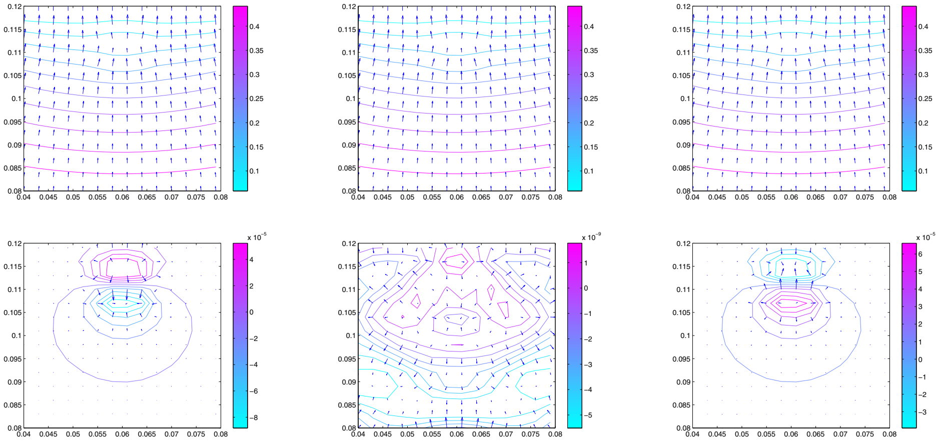
$$V_0 \int_\Gamma g_{\omega_1} ds = \int_\Omega (\sigma + i\omega_1 \epsilon_1) |\nabla u_1|^2 dx.$$

3.2. Numerical simulations. In fdTAS [32], we use a weighted frequency difference of Neumann data $g_2 - \alpha g_1$ instead of the simple difference $g_2 - g_1$. Theorems 3.1 and 3.2 show that the weight α and the difference $(\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n})$ are important factors in detecting anomaly D.

In order to test the observations in Theorem 3.2 and Remark 3.3, we consider a cubic model $\Omega := [\,0,\, 0.12\,] \times [\,0,\, 0.12\,] \times [\,0,\, 0.12\,]$ m^3 with the probe region $\Gamma := \{(x, y, 0.12) : \sqrt{x^2 + y^2} < 0.03\}$ and the reference electrode $\gamma := \{(x, y, z) \in \Omega : z = 0\}$. We assume that $\Omega \setminus D$ and D are homogeneous with frequency-independent conductivity values $\sigma_n = 0.03$ S/m and $\sigma_c = 0.2$ S/m. For permittivity values, we set $\omega_1 \epsilon_{1,n} = \omega_1 \epsilon_{1,c} = 0$ and $\omega_2 \epsilon_{2,n} = 3 \times 10^{-4}$ S/m. Numerical simulations are performed for a cube-shaped anomaly D centered at $(0.06, 0.06, 0.12 - 0.009)$ in meters with its side length of 0.006 m.

Figure 3 shows the images of $g_2 - \alpha g_1$ with three different values of $\omega_2 \epsilon_{2,c}$ that are chosen so that the corresponding $\mu = (\frac{\epsilon_{2,c}}{\epsilon_{2,n}} - \frac{\sigma_c}{\sigma_n})$ is positive, zero, or negative, respectively. This setup allows us to observe that $g_2 - \alpha g_1$ is influenced by μ and there is an interesting relation between them. As we discussed in Remark 3.3, $\mu = 0$ implies $g_2 - \alpha g_1$ providing no information on D even if ϵ_c changes a lot with respect to frequency. On the other hand, even if the permittivities ϵ_n and ϵ_c do not change with frequency, we can extract information on the anomaly from $g_2 - \alpha g_1$ as far as $\mu \neq 0$.

Figure 4 shows the vector fields of complex potential ∇u_2 corresponding to three different values of $\omega_2 \epsilon_{2,c}$ as before. In the plots, solid lines are equipotential lines of u_2, and arrows indicate the direction and magnitude of electric field $-\nabla u_2$. Figure 4



(a) (b) (c)

FIG. 4. *Equipotential lines and electric field streamlines in the slice* $\{(0.06, y, z) : 0.04 < y < 0.08, 0.08 < z < 0.12\}$*: Real and imaginary parts of the complex potential* u_2 *with three different values of* $\omega_2\epsilon_{2,c}$ *as above. Imaginary part plots are individually scaled as* (a) 10^{-5}, (b) 10^{-9}, (c) 10^{-5} *and real part plots are shown by using the same scale.*

illustrates that the electric field direction of the imaginary part changes as the sign of μ changes. We believe that the nonzero vector field is due to computational errors when $\mu = 0$.

ASYMPTOTIC AND NUMERICAL TECHNIQUES FOR RESONANCES OF THIN PHOTONIC STRUCTURES[*]

J. GOPALAKRISHNAN[†], S. MOSKOW[‡], AND F. SANTOSA[§]

Abstract. We consider the problem of calculating resonance frequencies and radiative losses of an optical resonator. The optical resonator is in the form of a thin membrane with variable dielectric properties. This work provides two very different approaches for doing such calculations. The first is an asymptotic method which exploits the small thickness and high index of the membrane. We derive a limiting resonance problem as the thickness goes to zero, and for the case of a simple resonance, find a first order correction. The limiting problem and the correction are in one less space dimension, which can make the approach very efficient. Convergence estimates are proved for the asymptotics. The second approach, based on the finite element method with a truncated perfectly matched layer, is not restricted to thin structures. We demonstrate the use of these methods in numerical calculations which further illustrate their differences. The asymptotic method finds resonance by solving a dense, but small, nonlinear eigenvalue problem, whereas the finite element method yields a large but linear and sparse generalized eigenvalue problem. Both methods reproduce a localized defect mode found previously by finite difference time domain methods.

Key words. photonic band gap structure, time harmonic wave equation, thin membrane structure, resonance phenomena, nonlinear eigenvalue, asymptotic analysis, finite element method, FEM, perfectly matched layer, PML, Lippman–Schwinger equation

1. Introduction.

This paper deals with the calculation of resonances of thin high contrast dielectric structures. Specifically, we are motivated by recent developments in photonic band gap (PBG) devices. PBG materials are artificially created structures having a refraction index which is spatially periodic, often on the nanoscale. As the name suggests, electromagnetic waves of frequencies in a “band gap” cannot propagate within PBG materials. These materials thus offer interesting possibilities for radical manipulation of light through introduction of defects, hence the increasing interest in them.

While the existence of band gaps has been definitively demonstrated for certain infinite periodic structures, practical PBG devices are of finite extent. When a band gap exists in a medium of infinite extent, it is possible to create a so-called defect mode, which is a standing wave of frequency in the band gap, by introducing a localized defect into the medium [6]. Such a mode corresponds to an eigenfunction of the partial differential equation governing the system. However, when the medium is of finite extent, such an eigenvalue no longer exists, but instead we may have a localized resonance mode.

A particularly interesting class of PBG structures are high index thin film devices where light is confined to the film by total internal reflection, and the PBG effect is achieved by drilling an array of air holes. Examples of such thin film devices can be found in [5, 19, 20]. The present work is aimed at calculating resonances for such structures. The dielectric properties of these structures are the restrictions of a periodic function to a bounded thin region in $\mathbb{R}^3$. Additionally they have a local "defect," i.e., a break in the periodic pattern. We want to identify resonance modes that are localized near the defect region, if any.

To model such structures, we consider the simplest equation for time harmonic wave propagation, namely, the Helmholtz equation

$$\Delta u + k^2 \varepsilon(\boldsymbol{x})\, u = 0, \qquad \boldsymbol{x} \in \mathbb{R}^n, \tag{1.1}$$

where $n = 2$ or 3, and u and ε are functions of $\boldsymbol{x}$ in $\mathbb{R}^n$. By an abuse in terminology we will call $\varepsilon(\boldsymbol{x})$ the dielectric constant. The geometry is captured by the variable coefficient $\varepsilon(\boldsymbol{x})$ which is set to unity in the background (air). The function $\varepsilon(\boldsymbol{x}) - 1$ is assumed to have compact support. To find resonances, we must find a nontrivial "radiating" mode u and a complex number $\lambda \equiv k^2$ such that

$$-\Delta u = \lambda \varepsilon(\boldsymbol{x}) u \qquad \text{in } \mathbb{R}^n. \tag{1.2}$$

When k is real, a mathematically precise form of the condition that u is "radiating" (or "outgoing") is the well-known Sommerfeld radiation condition at infinity. Writing (1.2) together with the Sommerfeld condition as $Au = \lambda Bu$, the resolvent $(A - \lambda B)^{-1}$ is well defined for λ in the positive real axis, because the Sommerfeld condition gives uniqueness of Helmholtz solutions. When k (or λ) is complex, one way to make the "outgoing" condition precise is by analytic continuation from the positive real axis. For instance, for a slightly different scattering problem studied in [13], the resolvent was proved to be a meromorphic function of λ and resonances were characterized as its poles occurring in the lower half of the complex plane.

The resonance modes u satisfying equations like (1.2) are sometimes also known as *quasi-normal modes* [12]. They are nonphysical and grow exponentially when k is in the fourth quadrant. To give a physical interpretation of resonance, we must go to the time domain and consider

$$\Delta U - \varepsilon(\boldsymbol{x})\, U_{tt} = 0, \qquad \boldsymbol{x} \in \mathbb{R}^n.$$

Resonance in this context is a time-dependent solution of the equation that resembles a standing wave except for the amplitude decay. Such a solution, especially when the decay is slow, is well captured by a superposition of quasi-normal modes with e^{ikt} modulation [12]. Generally these slowly decaying resonance modes are computed by using finite difference time domain (FDTD) methods, which are computationally intensive. In this work we propose two other ways to calculate resonances.

For thin devices, we propose a direct approach based on the Lippman–Schwinger reformulation. We assume a structure which fits into the following high contrast model, namely, the dielectric occupies the region $\Omega \times (-h/2, h/2)$. In three dimensions, Ω is a bounded planar domain, while in two space dimensions, Ω is bounded domain on the real line. Thus, in either case, Ω is of one space dimension less than n. Let $\boldsymbol{x} = (x, z)$ for $x \in \mathbb{R}^2$ and $z \in \mathbb{R}$. We assume that

$$\varepsilon(x, z) = \begin{cases} \dfrac{\varepsilon_0(x)}{h} & \text{if } |z| < h/2 \text{ and } x \in \Omega, \\ 1 & \text{otherwise.} \end{cases} \tag{1.3}$$

Note that whenever we have a membrane whose dielectric properties vary negligibly across its thickness h, we can satisfy this assumption by setting ε_0 to $h\varepsilon$. In [14], we studied scattering by this type of structure and found a limiting (i.e., effective) problem as $h \to 0$, with a correction term that improved the approximation. In this paper, we study the related resonance problem.

We *define* the resonant frequency k as a number in the complex plane for which there is a nontrivial resonance mode u satisfying

$$u(x,z) = \lambda \int_\Omega \int_{-h/2}^{h/2} \left(1 - \frac{\varepsilon_0(x')}{h}\right) G_\lambda(x,z,x',z') u(x',z')\, dz' dx'. \tag{1.4}$$

Here $\lambda \equiv k^2$ (which we will call the resonance value) and G is the Helmholtz fundamental solution (in two or three dimensions). One can show by variational arguments that such a λ must necessarily be in the lower half plane, and hence k must be in the fourth quadrant. This integral equation is arrived at from (1.1) by the same standard manipulations used in deriving the Lippman–Schwinger equation for scattering problems (see Theorem 8.3 of [4]). However, since λ has negative imaginary part, the solutions to (1.4) are exponentially growing at infinity, and such manipulations are only formal. Nevertheless this suggests that the definition of resonances using (1.4) is equivalent to (1.2). As another way to see why this is the case [8], consider the operator

$$(\Delta + k^2\epsilon)$$

for real k. One can then write the outgoing Green's function to characterize the inverse of this operator with Sommerfeld radiation conditions,

$$R(k) = (\Delta + k^2\epsilon)^{-1}.$$

If one continues this operator to negative complex k, the classical definition of resonance is its poles. Now we can rewrite this operator as

$$\begin{aligned} R(k) &= (\Delta + k^2 + k^2(\epsilon - 1))^{-1} \\ &= \left[(\Delta + k^2)(I + (\Delta + k^2)^{-1}k^2(\epsilon - 1))\right]^{-1} \\ &= \left[I + (\Delta + k^2)^{-1}k^2(\epsilon - 1)\right]^{-1} (\Delta + k^2)^{-1}. \end{aligned}$$

Since the term $(\Delta + k^2)^{-1}$ is characterized by the free space Green's function, it has no poles. So, the poles of $R(k)$ are exactly where

$$I + (\Delta + k^2)^{-1}k^2(\epsilon - 1)$$

has a null space, i.e., where (1.4) has a solution. Note that our theoretical analysis neither refers to nor deals with this equivalence. Indeed, our analysis takes (1.4) as the definition of resonances and proceeds to examine how such resonance values vary with h. Since G depends on λ, (1.4) is a *nonlinear* eigenvalue problem.

Another approach for numerical approximation of resonances is to directly approximate the eigenvalue problem in (1.1) with an outgoing boundary condition. A standard technique to handle outgoing boundary conditions at infinity is by introducing a perfectly matched layer (PML) [1] away from all inhomogeneities and eventually truncating the layer to obtain a finite computational domain. This suggests the use of PML for computing resonances by solving a linear eigenvalue problem in a truncated domain. We investigate this approach numerically, comparing the results with an exact solution as well as with approximations from the asymptotic approach. For the case of thin structures we can use both approaches to validate one another. A significant finding of this paper is that with both the asymptotic method and the PML calculations we can reproduce the high quality factor (low loss) resonance mode found in [5] by FDTD methods.

The next section contains a derivation and analysis of an asymptotic approximation to resonance solutions of (1.4) with respect to the thickness parameter h. Within this section, we prove convergence of the related operators, prove convergence of the resonance values, and then finally derive a correction term for the resonances utilizing an eigenvalue approximation theorem of Osborn [16]. Section 3 contains a numerical study of both asymptotic/nonlinear eigenvalue and PML approaches to find the resonance solutions. In section 3.1, we find exact solutions for the resonances of a disk and use them to analyze the convergence of PML solutions. In section 3.2 we return to a thin, high contrast structure. We compute resonances with both PML and asymptotics for the same problem and compare the results. In section 3.3 we study a thin periodic structure with a defect from [5], which was previously found to exhibit a localized low loss mode. The concluding section summarizes our results.

2. An asymptotic limit. In this section we develop an asymptotic approach to the resonance approximation for these thin, high contrast structures. The resonance problem is then formulated in terms of operator equations, and we prove operator convergence, that is, we show that the operators depend continuously on the thickness and frequency parameters. In the subsections that follow, we show that the resonance values converge and prove an error estimate. In the case of a simple resonance value, we introduce a correction term that increases the accuracy of the asymptotic approximation.

Assume that we have a dielectric with geometry defined by (1.3). A resonance value λ_h is a complex number for which there is a nontrivial function u_h satisfying

$$u_h(x,z) = \lambda_h \int_\Omega \int_{-h/2}^{h/2} \left(1 - \frac{\varepsilon_0(x')}{h}\right) G_{\lambda_h}(x,z,x',z') u_h(x',z') dz' dx', \tag{2.1}$$

where ε_0 is assumed to be piecewise continuous and G is the Helmholtz fundamental solution (in two or three dimensions) with complex $\lambda_h = k^2$. That is, when $n = 3$,

$$G_\lambda(x,z,x',z') = -\frac{1}{4\pi} \frac{e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+|z-z'|^2}}}{\sqrt{|x-x'|^2+|z-z'|^2}},$$

and when $n = 2$,

$$G_\lambda(x,z,x',z') = -\frac{i}{4} H_0^{(1)}(\sqrt{\lambda}\sqrt{|x-x'|^2+|z-z'|^2}),$$

where $H_0^{(1)}$ is a Hankel function of the first kind. We note that we are taking the branch of the square root in the complex plane for which the cut is on the negative real axis, and hence there is analyticity away from this cut. With the scaling in the z direction, $z = h\zeta$, let

$$\tilde{u}_h(x,\zeta) = u_h(x,z)$$

to obtain

$$\tilde{u}_h(x,\zeta) = \lambda_h \int_\Omega \int_{-1/2}^{1/2} (h - \varepsilon_0(x')) \, G_{\lambda_h}(x,h\zeta,x',h\zeta') \tilde{u}_h(x',\zeta') d\zeta' dx'. \tag{2.2}$$

Now, if we let $h \to 0$, this leads us to guess the limiting resonance problem: Find nontrivial solutions (u_0, λ_0) to

$$u_0(x) = -\lambda_0 \int_\Omega \varepsilon_0(x') G_{\lambda_0}(x, 0, x', 0) u_0(x') dx'. \tag{2.3}$$

Although still a nonlinear eigenvalue problem, this has one dimension less than we started with.

In order to analyze the validity of this asymptotic limit, it is useful to express these problems in operator form. Let S be the scaled, fixed domain

$$S = \Omega \times [-1/2, 1/2].$$

Consider, for $v \in L^2(S)$, the operators $T_h(\lambda)$ and $T_0(\lambda)$, with complex parameter λ, are defined by

$$T_h(\lambda)v = \int_{-1/2}^{1/2} \int_\Omega (h - \varepsilon_0(x')) G_\lambda(x, h\zeta, x', h\zeta') v(x', \zeta') dx' d\zeta'$$

and

$$T_0(\lambda)v = -\int_{-1/2}^{1/2} \int_\Omega \varepsilon_0(x') G_\lambda(x, 0, x', 0) v(x', \zeta') dx' d\zeta'.$$

The operators $T_h(\lambda)$ and $T_0(\lambda)$ are both compact from $L^2(S)$ to $L^2(S)$ by the proof of [14, Lemma 2]. (Unlike in that lemma, since here λ is not necessarily real, we are not ensured the invertibility of $(I - \lambda T_h(\lambda))$ or $(I - \lambda T_0(\lambda))$, hence the presence of resonance values.) We say that λ_h is a resonance value of T_h if there exists nontrivial $u_h \in L^2(S)$ such that

$$u_h = \lambda_h T_h(\lambda_h) u_h.$$

Similarly, λ_0 is a resonance value of T_0 if there exists nontrivial u_0 such that

$$u_0 = \lambda_0 T_0(\lambda_0) u_0.$$

The operators T_h, T_0 are compact on $C^0(S)$ as well as $L^2(S)$, but here we will use $L^2(S)$ for its Hilbert space structure. We use $\langle , \rangle$ to denote the standard $L^2(S)$ inner product over $\mathbb{C}$:

$$\langle u, v \rangle := \int_S u\overline{v},$$

where $\overline{v}$ is the complex conjugate of v.

2.1. Operator convergence. We first prove a lemma showing convergence of the fundamental solutions when $n = 3$. The same result also holds for $n = 2$. This is an extension of [14, Lemma 1] to complex λ. Here we also give the explicit dependence of the constant on λ. Recall the definition of the scaled domain

$$S = \Omega \times (-1/2, 1/2).$$

LEMMA 2.1. *There exists a constant C independent of h, ζ', and λ, such that*

$$\sup_{(x,\zeta)\in S} \int_\Omega |G_\lambda(x, 0, x', 0) - G_\lambda(x, h\zeta, x', h\zeta')| dx' \le Ch(1 + |\sqrt{\lambda}|) e^{|\mathcal{I}m\sqrt{\lambda}| diam(\Omega_h)}.$$

Proof. The difference of these fundamental solutions can be written as

$$\begin{aligned}
&G(x, h\zeta, x', h\zeta') - G(x, 0, x', 0)\\
&= \frac{1}{4\pi}\frac{e^{i\sqrt{\lambda}|x-x'|}}{|x-x'|} - \frac{1}{4\pi}\frac{e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\\
&= \frac{1}{4\pi}e^{i\sqrt{\lambda}|x-x'|}\left[\frac{1}{|x-x'|} - \frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right]\\
&\quad + \frac{1}{4\pi}\frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\left[e^{i\sqrt{\lambda}|x-x'|} - e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right]. \qquad (2.4)
\end{aligned}$$

We first work on the second term on the right-hand side of (2.4). By a standard Taylor expansion,

$$e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}} = e^{i\sqrt{\lambda}|x-x'|} + i\sqrt{\lambda}\left(\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2} - |x-x'|\right)e^{i\sqrt{\lambda}\xi}$$

for some ξ between $|x-x'|$ and $\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}$. Since we know that for $(x,\zeta) \in S$,

$$\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2} - |x-x'| \le h,$$

we obtain

$$\begin{aligned}
\left|e^{i\sqrt{\lambda}|x-x'|} - e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right| &\le |\sqrt{\lambda}|he^{|\mathcal{I}m\sqrt{\lambda}|\xi}\\
&\le |\sqrt{\lambda}|he^{|\mathcal{I}m\sqrt{\lambda}|\operatorname{diam}(\Omega_h)}. \qquad (2.5)
\end{aligned}$$

Also,

$$\frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}} \le \frac{1}{|x-x'|},$$

which is integrable with respect to x' on Ω, and we have that

$$\int_\Omega \frac{dx'}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}$$

is bounded independently of h, ζ', λ, and $(x,z) \in S$. This along with (2.5) gives that we can choose C independent of h, ζ' and $(x,\zeta) \in S$ such that

$$\int_\Omega \frac{1}{4\pi}\frac{|e^{i\sqrt{\lambda}|x-x'|} - e^{i\sqrt{\lambda}\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}|}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}dx' \le Ch|\sqrt{\lambda}|e^{|\mathcal{I}m\sqrt{\lambda}|\operatorname{diam}(\Omega_h)}. \qquad (2.6)$$

The integral of the first term on the right-hand side of (2.4) can be bounded,

$$\begin{aligned}
&\int_\Omega \left|\frac{1}{4\pi}e^{i\sqrt{\lambda}|x-x'|}\left[\frac{1}{|x-x'|} - \frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right]\right|dx'\\
&\le \frac{1}{4\pi}e^{|\mathcal{I}m\sqrt{\lambda}|\operatorname{diam}(\Omega_h)}\int_\Omega\left|\frac{1}{|x-x'|} - \frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right|dx'\\
&= \frac{1}{4\pi}e^{|\mathcal{I}m\sqrt{\lambda}|\operatorname{diam}(\Omega_h)}\int_\Omega\left(\frac{1}{|x-x'|} - \frac{1}{\sqrt{|x-x'|^2+h^2|\zeta-\zeta'|^2}}\right)dx',
\end{aligned}$$

since the integrand is nonnegative. Now choose R large enough so that if $B_R(x)$ is the ball of radius R centered at x in $\mathbb{R}^2$,

$$\Omega \subset B_R(x)$$

for all $x \in \Omega$. Then the integral over Ω above is bounded by

$$\leq \int_{B_R(x)} \left(\frac{1}{|x-x'|} - \frac{1}{\sqrt{|x-x'|^2 + h^2|\zeta - \zeta'|^2}} \right) dx'.$$

Change to polar coordinates centered at x with

$$r = |x - x'|.$$

The integral transforms to

$$\begin{aligned} &= 2\pi \int_0^R \left(\frac{1}{r} - \frac{1}{\sqrt{r^2 + h^2|\zeta-\zeta'|^2}} \right) \\ &= 2\pi \left[R - \sqrt{R^2 + h^2|\zeta - \zeta'|^2} + h|\zeta - \zeta'| \right] \end{aligned}$$

by direct calculation. One can see clearly that this quantity is then $O(h)$, where the constant is independent of $(x, \zeta) \in S$, λ, and $\zeta' \in (-1/2, 1/2)$. This, combined with (2.4) and the estimate (2.6), proves the lemma. □

Next we show that the operators depend continuously on the parameters h and λ.

PROPOSITION 2.1. *Assume we have a sequence of pairs* $\{h_j, \lambda_j\}$, *where* $h_j \in \mathbb{R}$, *the* λ_j *are in the complex plane with the negative real axis and the origin removed, i.e.,* $\lambda_j \in \mathbb{C} \setminus \{\mathbb{R}^- \cup \{0\}\}$, *and for which* $\lambda_j \to \lambda_0$ *for some* $\lambda_0 \in \mathbb{C} \setminus \{\mathbb{R}^- \cup \{0\}\}$, *and* $h_j \to 0$ *as* $j \to \infty$. *Then*

$$T_{h_j}(\lambda_j) \to T_0(\lambda_0)$$

in the operator norm on $L^2(S)$ *as* $j \to \infty$. *Furthermore, for* j *large enough there exists* C *independent of* j *such that*

$$\|T_{h_j}(\lambda_j) - T_0(\lambda_0)\| \leq C\left(h_j + |\lambda_j - \lambda_0|\right).$$

Proof. Consider, for $v \in L^2(S)$,

$$\left(T_{h_j}(\lambda_j) - T_0(\lambda_0)\right) v = \left(T_{h_j}(\lambda_j) - T_0(\lambda_j)\right) v + \left(T_0(\lambda_j) - T_0(\lambda_0)\right) v.$$

We will expand out the second term on the right-hand side:

$$\left(T_0(\lambda_j) - T_0(\lambda_0)\right) v = \int_{-1/2}^{1/2} \int_\Omega \varepsilon_0(x')(G_{\lambda_0}(x,0,x',0) - G_{\lambda_j}(x,0,x',0)) v(x',\zeta') dx' d\zeta'.$$

We can use the mean value theorem; for $|x - x'| \neq 0$,

$$\begin{aligned} G_{\lambda_j}(x,0,x',0) - G_{\lambda_0}(x,0,x',0) &= \frac{1}{4\pi} \frac{e^{i\sqrt{\lambda_0}|x-x'|}}{|x-x'|} - \frac{1}{4\pi} \frac{e^{i\sqrt{\lambda_j}|x-x'|}}{|x-x'|} \\ &= (\lambda_0 - \lambda_j) \frac{i}{8\pi\sqrt{\eta}} e^{i\sqrt{\eta}|x-x'|} \end{aligned}$$

for some η on the line in $\mathbb{C}$ joining λ_0 and λ_j. So, since λ_0 is bounded away from the negative real axis, for large enough j we have

$$\|G_{\lambda_0}(x,0,x',0) - G_{\lambda_j}(x,0,x',0)\|_\infty \le C|\lambda_0 - \lambda_j|$$

for some C independent of j. From this we easily obtain

$$\|\,(T_0(\lambda_j) - T_0(\lambda_0))\,v\|_{L^2(S)} \le C|\lambda_0 - \lambda_j|\|v\|_{L^2(S)}. \tag{2.7}$$

Now, for the other term,

$$\begin{aligned}(T_{h_j}(\lambda_j) - T_0(\lambda_j))v = h_j \int_S G_{\lambda_j}(x, h_j\zeta, x', h_j\zeta')v(x',\zeta')dx'd\zeta' \\ - \int_S \varepsilon_0(x')\left[G_{\lambda_j}(x,h_j\zeta,x',h_j\zeta') - G_{\lambda_j}(x,0,x',0)\right] v(x'\zeta')dx'd\zeta'.\end{aligned} \tag{2.8}$$

Now, since G_{λ_j} is a kernel which is bounded in L^1 independently of h, it follows from the generalized Young inequality [7] that the function

$$w(x,\zeta) = \int_S G_{\lambda_j}(x,h_j\zeta,x',h_j\zeta')v(x',\zeta')dx'd\zeta'$$

satisfies

$$\|w\|_{L^2(S)} \le C\|v\|_{L^2(S)},$$

which shows that the first term in (2.8) is $O(h_j)$. For the second term, we appeal to Lemma 2.1, which tells us that the kernel difference can be bounded:

$$\|G_{\lambda_j}(x,h_j\zeta,x',h_j\zeta') - G_{\lambda_j}(x,0,x',0)\|_{L^1(S)} \le Ch_j,$$

where C is independent of j. Since ε_0 is bounded in L^∞, again using the generalized Young and triangle inequalities in (2.8), we obtain

$$\|(T_{h_j}(\lambda_j) - T_0(\lambda_j))v\|_{L^2(S)} \le Ch_j\|v\|_{L^2(S)}.$$

Combining this with (2.7), the result follows. □

2.2. Convergence of the resonance values. Define the modified resolvent type operator-valued functions on $\mathbb{C}$

$$R_h(\lambda) = (I - \lambda T_h(\lambda))^{-1}$$

and

$$R_0(\lambda) = (I - \lambda T_0(\lambda))^{-1}.$$

An important note is that if $R_h(\lambda)$ does not exist as a bounded linear operator from $L^2(S)$ to itself, then λ is a resonance value of T_h. This is because if $R_h(\lambda)$ does not exist, then $1/\lambda$ is in the spectrum of the compact operator $T_h(\lambda)$. Hence $1/\lambda$ must be an eigenvalue, and $(I - \lambda T_h(\lambda))$ must have a nontrivial and finite-dimensional null space. The same holds for the limiting operator $R_0(\lambda)$.

In the following theorem, we show that, with an assumption of nonzero residue, the resonance values converge.

THEOREM 2.2. *Assume that λ_0 is a resonance value of T_0, and that R_0 and R_h are meromorphic in some region of $\mathbb{C}$ containing λ_0. Assume also that R_0 has nonzero residue at λ_0. Then for any ball B around λ_0, there exists $h_0 > 0$ such that T_h has a resonance in B for all $h < h_0$. Conversely, if $\{\lambda_h\}$ is a sequence of resonance values of T_h that converges as $h \to 0$, the limit is a resonance value of T_0.*

Proof. We first note that we know from [14] that $\lambda_0 \notin \mathbb{R}$. So, we can choose B, a ball around λ_0 which does not intersect the negative real axis $\mathbb{R}^-$, and such that T_0 has no other resonance values in $\overline{B}$.

We will also use a well-known result about the inverses of perturbed operators (see, for example, [10, p. 31]): If $S - T = A$ and T^{-1} exists, then for $\|A\| < \frac{1}{\|T^{-1}\|}$, S^{-1} exists and

$$\|S^{-1} - T^{-1}\| \leq \frac{\|A\|\|T^{-1}\|^2}{1 - \|A\|\|T^{-1}\|}. \tag{2.9}$$

Apply this, with

$$S = I - \lambda T_h(\lambda),$$

$$T = I - \lambda T_0(\lambda),$$

to get

$$\|R_h(\lambda) - R_0(\lambda)\| \leq \frac{\|\lambda(T_0(\lambda) - T_h(\lambda))\|\|R_0(\lambda)\|^2}{1 - \|\lambda(T_0(\lambda) - T_h(\lambda))\|\|R_0(\lambda)\|},$$

which, from Proposition 2.1, yields

$$\|R_h(\lambda) - R_0(\lambda)\| \leq \frac{Ch\|R_0(\lambda)\|^2}{1 - Ch\|R_0(\lambda)\|} \tag{2.10}$$

for C independent of h, for h small enough. The constant C does in general depend on λ, but for λ on a compact subset of $\mathbb{C}$ bounded away from the real line, C can be chosen independent of λ.

Let $\Gamma = \partial B$, positively oriented. By the choice of B, Γ does not intersect with $\mathbb{R}^-$, and λ_0 is the only pole of R_0 in the closed disk. Then $R_0(\lambda)$ is continuous with respect to λ on Γ, and hence $\|R_0(\lambda)\|$ is uniformly bounded for λ on Γ. Using (2.10), we have that

$$R_h(\lambda) \to R_0(\lambda)$$

in norm as $h \to 0$, uniformly for $\lambda \in \Gamma$. This implies that the operator-valued integral

$$\frac{1}{2\pi i}\int_\Gamma R_h(\lambda) d\lambda \to \frac{1}{2\pi i}\int_\Gamma R_0(\lambda) d\lambda$$

in norm as $h \to 0$. From the residue theorem, the integral

$$\frac{1}{2\pi i}\int_\Gamma R_0(\lambda) d\lambda$$

gives us the coefficient of the $(\lambda - \lambda_0)^{-1}$ term in the Laurent series expansion for $R_0(\lambda)$, which by assumption is nonzero. Hence the integrals must all be nonzero for

h small enough. This means that all R_h must have at least one pole in B for h small enough. That is, for h small enough, all T_h have a resonance value in B. This proves the first part of the statement of the proposition. For the converse, if λ_0 is not a resonance value of T_0, then $R_0(\lambda)$ exists in some neighborhood of λ_0. The formula (2.10) implies that $R_h(\lambda)$ also exists in that neighborhood for h small enough. Hence the resonance values of T_h are bounded away from λ_0 for h small enough. □

Some remarks about the assumptions in this theorem:

- The operator functions $I - \lambda T_h(\lambda)$ and $I - \lambda T_0(\lambda)$ are analytic with respect to λ away from the negative real axis. This, combined with the fact that the T's are compact, means that the inverses are meromorphic.
- If λ_0 is a resonance of T_0, then the classical resolvent of $T_0(\lambda_0)$, given by $(zI - T_0(\lambda_0))^{-1}$, automatically has nonzero residue at $z = \frac{1}{\lambda_0}$; its residue is the projection onto the generalized eigenspace [10]. It is not clear how the residue of R_0 relates to the nonlinear eigenspace. However, if λ_0 is a simple pole, this is a special case of nonzero residue.
- We do not need the assumption about nonzero residue for the converse.

2.3. A higher order correction. Once we know that we have a convergent sequence of resonance values as $h \to 0$, we can use standard eigenvalue perturbation theorems. In the resonance value expansion, we employ a result of Osborn [16] which is valid for nonself-adjoint operators and also yields a correction term. The actual result in [16] is more general, but we state it here for the case of norm convergence on a Hilbert space.

Suppose X is a Hilbert space and $T_n : X \to X$ is a sequence of compact linear operators such that $T_n \to T$ in norm. It then follows that the adjoint operators also converge in norm. Let μ be a nonzero eigenvalue of T of algebraic multiplicity m. It is well known that for n large enough there exist m eigenvalues of T_n, $\mu_1^n, \ldots, \mu_m^n$ (counted according to algebraic multiplicity) such that $\mu_j^n \to \mu$ as $n \to \infty$ for each $1 \le j \le m$.

Let E be the spectral projection onto the generalized eigenspace of T corresponding to eigenvalue μ. The space X can be decomposed in terms of the range and null space of E: $X = R(E) \oplus N(E)$.

THEOREM 2.3 (Osborn). *Let $\phi_1, \phi_2, \ldots, \phi_m$ be a normalized basis for $R(E)$. Then there exists a constant C such that*

$$\left| \mu - \frac{1}{m}\sum_{j=1}^{m} \mu_j^n - \frac{1}{m}\sum_{j=1}^{m} \langle (T - T_n)\phi_j, \phi_j\rangle \right| \le C \|(T - T_n)|_{R(E)}\| \cdot \|(T^* - T_n^*)|_{R(E^*)}\|.$$

To simplify the statement of the following theorem, we define the lower-dimensional operator $DT_0(\lambda)$ by

$$DT_0(\lambda)v = -\int_\Omega \varepsilon_0(x') \frac{\partial G}{\partial \lambda}(x, 0, x', 0) v(x') dx', \tag{2.11}$$

and we leave off the subscripts j for the sequence $\{h_j\}$ of values of h going to zero.

THEOREM 2.4. *Assume we have a sequence $\{\lambda_h\} \in \mathbb{C}$ of resonance values of T_h for which $\lambda_h \to \lambda_0$ as $h \to 0$, where $\lambda_0 \in \mathbb{C}$ is a simple resonance value of T_0 with normalized resonance function u_0 satisfying $\lambda_0 T_0(\lambda_0)u_0 = u_0$. Assume also that*

$$\lambda_0^2 \langle DT_0(\lambda_0)u_0, u_0\rangle \ne -1. \tag{2.12}$$

Then there exists C independent of h such that

$$|\lambda_h - \lambda_0| \leq Ch,$$

and furthermore

$$\lambda_h = \lambda_0 + \lambda_0^2 \frac{\langle (T_0(\lambda_0) - T_h(\lambda_0))u_0, u_0\rangle}{1 + \lambda_0^2 \langle DT_0(\lambda_0)u_0, u_0\rangle} + O(h^2). \tag{2.13}$$

Proof. Note that

$$\lambda_h T_h(\lambda_h) u_h = u_h$$

and

$$\lambda_0 T_0(\lambda_0) u_0 = u_0;$$

that is, $\frac{1}{\lambda_h}$ is an eigenvalue of $T_h(\lambda_h)$ and $\frac{1}{\lambda_0}$ is an eigenvalue of $T_0(\lambda_0)$. Also, from Proposition 2.1, we know that

$$T_h(\lambda_h) \to T_0(\lambda_0)$$

in the operator norm. So, what we have are the eigenvalues of a convergent sequence of compact operators. These operators, $\{T_h(\lambda_h), T_0(\lambda_0)\}$, are not self-adjoint, but it follows from the norm convergence that the adjoints also converge:

$$T_h^*(\lambda_h) \to T_0^*(\lambda_0)$$

in the operator norm, with the same norm error. Since we assume that $\frac{1}{\lambda_0}$ is a simple eigenvalue of $T_0(\lambda_0)$, Theorem 2.3 yields

$$\begin{aligned} &\left| \frac{1}{\lambda_0} - \frac{1}{\lambda_h} - \langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle \right| \\ &\qquad \leq \|(T_0(\lambda_0) - T_h(\lambda_h))u_0\| \cdot \|(T_0^*(\lambda_0) - T_h^*(\lambda_h))u_0\|. \end{aligned} \tag{2.14}$$

Since

$$\|T_0^*(\lambda_0) - T_h^*(\lambda_h)\| = \|T_0(\lambda_0) - T_h(\lambda_h)\|,$$

we have from Proposition 2.1

$$\left| \frac{1}{\lambda_0} - \frac{1}{\lambda_h} - \langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle \right| \leq C\left(h + |\lambda_0 - \lambda_h|\right)^2.$$

If we multiply everything by $\lambda_0\lambda_h$,

$$|\lambda_h - \lambda_0 - \lambda_0\lambda_h \langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle| \leq C\left(h + |\lambda_0 - \lambda_h|\right)^2,$$

which we manipulate to get

$$\begin{aligned} \lambda_h = \lambda_0 &+ \lambda_0^2 \langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle \\ &+ \lambda_0(\lambda_h - \lambda_0)\langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle + O\left((h + |\lambda_h - \lambda_0|)^2\right). \end{aligned}$$

Again using Proposition 2.1,

$$\lambda_h = \lambda_0 + \lambda_0^2 \langle (T_0(\lambda_0) - T_h(\lambda_h))u_0, u_0\rangle + O\left((h + |\lambda_h - \lambda_0|)^2\right). \tag{2.15}$$

Now, since the correction term above depends on λ_h, we need to expand the term further. We can write

$$T_0(\lambda_0) - T_h(\lambda_h) = (T_0(\lambda_0) - T_h(\lambda_0)) + (T_h(\lambda_0) - T_h(\lambda_h)) \tag{2.16}$$

and compute

$$(T_h(\lambda_0) - T_h(\lambda_h)) = \int_S (h - \varepsilon_0(x'))(G_{\lambda_0} - G_{\lambda_h})(x, h\zeta, x', h\zeta')u_0(x')d\zeta' dx'.$$

Note that since the range of T_0 contains only functions that are independent of ζ, u_0 must be independent of ζ. Since we are bounded away from the negative real axis, G is analytic with respect to λ, and so by standard Taylor expansion we obtain

$$\begin{aligned}(T_h(\lambda_0) - T_h(\lambda_h)) = &\int_S (h - \varepsilon_0(x'))(\lambda_0 - \lambda_h)\frac{\partial G}{\partial \lambda}\Big|_{\lambda=\lambda_0}(x, h\zeta, x', h\zeta')u_0(x')dx'd\zeta' \\ &+ O(|\lambda_0 - \lambda_h|^2).\end{aligned}$$

Note that the integrand is now continuous. This yields, after expanding the exponential or Hankel function about $h = 0$,

$$\begin{aligned}(T_h(\lambda_0) - T_h(\lambda_h)) = &\int_S \varepsilon_0(x')(\lambda_h - \lambda_0)\frac{\partial G}{\partial \lambda}\Big|_{\lambda=\lambda_0}(x, 0, x', 0)u_0(x')dx'd\zeta' \\ &+ O\left((h + |\lambda_0 - \lambda_h|)^2\right).\end{aligned} \tag{2.17}$$

Note the above integrand is independent of ζ'. Combining (2.17), (2.16), and (2.15),

$$\lambda_h = \lambda_0 + \lambda_0^2\langle (T_0(\lambda_0) - T_h(\lambda_0))u_0, u_0\rangle - \lambda_0^2(\lambda_h - \lambda_0)\langle DT_0(\lambda_0)u_0, u_0\rangle + O\left((h + |\lambda_0 - \lambda_h|)^2\right),$$

where DT_0 is defined by (2.11). We now collect terms for $(\lambda_h - \lambda_0)$ to get

$$(\lambda_h - \lambda_0)\left(1 + \lambda_0^2\langle DT_0(\lambda_0)u_0, u_0\rangle\right) = \lambda_0^2\langle (T_0(\lambda_0) - T_h(\lambda_0))u_0, u_0\rangle + O\left((h + |\lambda_0 - \lambda_h|)^2\right).$$

At this point we need to use the assumption (2.12) to obtain

$$\lambda_h = \lambda_0 + \frac{\lambda_0^2\langle (T_0(\lambda_0) - T_h(\lambda_0))u_0, u_0\rangle}{1 + \lambda_0^2\langle DT_0(\lambda_0)u_0, u_0\rangle} + O\left((h + |\lambda_0 - \lambda_h|)^2\right).$$

Recall that by the proof of Proposition 2.1,

$$\|T_0(\lambda_0) - T_h(\lambda_0)\| = O(h)$$

in the operator norm, and so we have

$$\lambda_h - \lambda_0 = O(h) + O\left((h + |\lambda_0 - \lambda_h|)^2\right).$$

Since we assume that $\lambda_h - \lambda_0 \to 0$, this can only hold if

$$\lambda_h - \lambda_0 = O(h).$$

This completes the proof. □

Remark 2.1. It is possible that the hypothesis (2.12) is related to the residue of the generalized resolvent $R_0(\lambda)$. In particular, we conjecture that for a simple resonance value, (2.12) holds if and only if the residue is nonzero, i.e., the requirement for convergence in Theorem 2.2.

The correction term above is not difficult to compute since it involves only applying integral operators to the limiting resonance function u_0. However, one may want to have an expression of the form

$$\lambda_h \approx \lambda_0 + h\lambda^{(1)}$$

in which $\lambda^{(1)}$ is independent of h. We had studied the numerator of the correction exactly in [14] for the case when λ_0 was real. By that same analysis,

$$\begin{aligned}(T_0(\lambda_0) - T_h(\lambda_0))u_0 &= -h\int_\Omega\int_{-1/2}^{1/2} G_{\lambda_0}(x, h\zeta, x', h\zeta')u_0 d\zeta' dx' \\ &+ \int_\Omega\int_{-1/2}^{1/2} \varepsilon_0(x')(G_{\lambda_0}(x, h\zeta, x', h\zeta') - G_{\lambda_0}(x, 0, x', 0))u_0(x')d\zeta' dx' \\ &= -h\int_\Omega G_{\lambda_0}(x, 0, x', 0)u_0(x')dx' \\ &\qquad + h\frac{\varepsilon_0(x)u_0(x)}{2}\left(\zeta^2 + \frac{1}{4}\right) + o(h).\end{aligned} \tag{2.18}$$

This yields the following corollary.

Corollary 2.5. *Assume the hypotheses as in Theorem* 2.4. *Then*

$$\lambda_h = \lambda_0 + h\lambda_0^2\frac{\langle g, u_0\rangle}{1 + \lambda_0^2\langle DT_0(\lambda_0)u_0, u_0\rangle} + o(h),$$

where

$$g(x) = -\int_\Omega G_{\lambda_0}(x, 0, x', 0)u_0(x')dx' + \frac{\varepsilon_0(x)u_0(x)}{2}\left(\zeta^2 + \frac{1}{4}\right).$$

Note, however, that here the error is no longer guaranteed to be $O(h^2)$.

3. Numerical techniques. In this section, we investigate two numerical approaches for the computation of resonances of thin membranes. The first is via Berenger's perfectly matched layer (PML) [1]. The second is a collocation discretization of the integral equation formulation combined with the asymptotics developed in the previous section. The numerical analyses of both of these approaches for resonance computation are presently open. Nonetheless, considerable insight into these computational approaches can be gained by comparing them with each other.

First, we will exhibit an example with a disk where we can compute resonances exactly. We will compute the approximations to these exact resonances using the PML approach and compare. Since no error analysis is known for the PML eigenvalue approximations, this will serve as validation of our first approach. Note that although PML has been increasingly used for computation of open resonances [9, 11, 17], we have not been able to locate a comparison of approximate and exact resonances in the literature—another reason for including such a comparison here.

Next, we will examine thin, high contrast homogeneous structures. Here will investigate the asymptotic integral equation approach along with PML. While the PML approach reduces to a *large sparse generalized eigenvalue computation*, the second approach yields a *small dense nonlinear eigenvalue problem.* We will establish that the asymptotics are sound by testing the results against the ones obtained from PML.

Finally, we will use both the PML approach and asymptotics to compute a resonance mode found in [5] for a periodic structure with a defect. The mode is localized near the defect; that is, it exhibits photonic band gap–type behavior. Also, it has a high quality factor, indicating that in the time domain its decay is slow. In [5] the mode was computed using an FDTD (finite difference time domain) method, as is typically the case.

3.1. A disk: Exact resonances and PML validation. We will now calculate the first few resonance modes of a circular homogeneous dielectric disk of radius a having (constant) permittivity ε_d placed in an infinite vacuum. If the mode is written in the form

$$U(\boldsymbol{x},t) = e^{-ikt}u(\boldsymbol{x}) = \begin{cases} e^{-ikt}u^+(\boldsymbol{x}), & |\boldsymbol{x}| > a, \\ e^{-ikt}u^-(\boldsymbol{x}), & |\boldsymbol{x}| \le a, \end{cases}$$

the governing equations are

$$\Delta u^+ + k^2 u^+ = 0, \qquad \text{when } r > a \text{ (in a vacuum)}, \tag{3.1}$$

$$\Delta u^- + k^2 \varepsilon_d u^- = 0, \qquad \text{when } r \le a \text{ (in the dielectric)}, \tag{3.2}$$

$$(u^+ - u^-)\big|_{r=a} = \frac{\partial}{\partial r}(u^+ - u^-)\bigg|_{r=a} = 0 \qquad \text{(compatibility conditions)}. \tag{3.3}$$

In addition, u^+ must be an outgoing wave at infinity. We use separation of variables. Substituting $u = R(r)\Theta(\theta)$ above and proceeding in the standard way, we conclude that

$$u^+ = H^{(1)}_{\tilde{n}}(kr)(\tilde{A}e^{i\tilde{n}\theta} + \tilde{B}e^{-i\tilde{n}\theta}) \qquad \text{in a vacuum}, \tag{3.4}$$

$$u^- = J_n(k\sqrt{\varepsilon_d}r)(Ae^{in\theta} + Be^{-in\theta})n \qquad \text{in the dielectric} \tag{3.5}$$

for some integers $n, \tilde{n} = 0, 1, 2, \ldots$. Here we have picked solutions that are outgoing in the vacuum region and bounded inside the dielectric.

Now, the first transmission condition of (3.3) implies $n = \tilde{n}$,

$$\tilde{A} = A\frac{J_n(k\sqrt{\varepsilon_d}a)}{H^{(1)}_n(ka)}, \qquad \text{and} \qquad \tilde{B} = B\frac{J_n(k\sqrt{\varepsilon_d}a)}{H^{(1)}_n(ka)}, \tag{3.6}$$

and the second condition of (3.3) further yields

$$(R^-)'(a)\Theta^-(\theta) = (R^+)'(a)\Theta^+(\theta),$$

where the $-$ and $+$ signify the interior and exterior of the disk, respectively. This implies that for each n, the values of k must satisfy

$$\sqrt{\varepsilon_d}\, J_n'(k\sqrt{\varepsilon_d}a)\, H^{(1)}_n(ka) = \ (H^{(1)}_n)'(ka)\ J_n(k\sqrt{\varepsilon_d}a). \tag{3.7}$$

We have not been able to analytically solve this equation for k. However, we can obtain numerical approximations to high precision by finding the roots of the function

$$f_n = k\bigg(\sqrt{\varepsilon_d}\, J_n'(k\sqrt{\varepsilon_d}a)\, H^{(1)}_n(ka) - (H^{(1)}_n)'(ka)\ J_n(k\sqrt{\varepsilon_d}a)\bigg), \tag{3.8}$$

where we have multiplied by k to remove a singularity.

TABLE 1
A few exact resonance values $k_{n,m}$.

$k_{n,m}$	$n = 0$	$n = 1$	$n = 2$	$n = 3$
$m = 1$	$0.436676 - 0.303945i$	$1.115540 - 0.239628i$	$1.756263 - 0.174352i$	$2.384047 - 0.121696i$
$m = 2$	$1.977701 - 0.279097i$	$2.716779 - 0.266504i$	$3.404368 - 0.245056i$	$4.064044 - 0.220085i$
$m = 3$	$3.542742 - 0.276273i$	$4.298557 - 0.271174i$	$5.013898 - 0.260996i$	$5.702569 - 0.248231i$

We enumerate the exact resonance values of this problem as $k_{n,m}$, as for each n, we have a sequence of roots for (3.8), indexed by m. A few exact resonance values obtained for the case

$$a = 1 \quad \text{and} \quad \varepsilon_d = 4$$

are displayed in Table 1. Note that for $n > 0$, each resonance value $k_{n,m}$ is of multiplicity two (both A and B in (3.5) are degrees of freedom), while for $n = 0$ the resonance values $k_{0,m}$ are simple.

Now we report on some discrete approximations to these exact resonances for the disk. These approximations are computed using finite elements and PMLs. The exact problem can be cast as the eigenvalue problem of finding complex numbers $\lambda \equiv k^2$ and nontrivial eigenfunctions u satisfying

$$-\Delta u = \lambda\, \varepsilon(\boldsymbol{x}) u \qquad \text{on } \mathbb{R}^2, \qquad \text{where } \varepsilon(\boldsymbol{x}) = \begin{cases} 4 \text{ if } |\boldsymbol{x}| \le 1, \\ 1 \text{ if } |\boldsymbol{x}| > 1, \end{cases}$$

with the additional condition that u is an outgoing wave at infinity. (Note that the dielectric parameters are the same as that used to obtain Table 1.) We will use PML as an absorbing layer to exponentially damp the solution outside a fixed radius r_1, and then truncate the computational domain for some $r_3 r_1$. In the truncated finite domain, we use the finite elements as the discretization method. This is a well-known technique used for source problems [1, 2, 3] with outgoing solutions, although its applicability to eigenvalue problems is less studied.

We first briefly describe the truncated PML and its finite element approximation. Our PML parameters are closer to [2, 3] than the original ones of Berenger [1]. In the region $r < 1$, we set the actual coefficients given by our ε. The artificial coefficients forming PML are set outside radius $r = r_1 \ge 1$. In the region $r_1 < r < r_2$ we have a transitional variable coefficient, and in the region $r_2 < r < r_3$ we have a constant artificial coefficient. Define

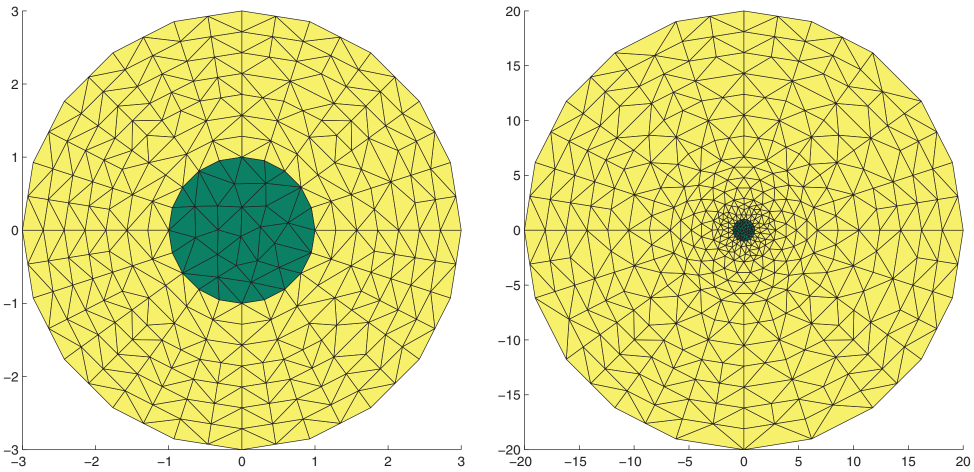
$$\text{(3.9)} \quad \tilde\sigma(r) = \begin{cases} 0 & \text{if } r < r_1, \\ \dfrac{s(r)}{s(r_2)} & \text{if } r_1 < r < r_2, \\ 1 & \text{if } r > r_2, \end{cases} \qquad \sigma(r) = \begin{cases} 0 & \text{if } r < r_1, \\ \dfrac{d}{dr}(r\tilde\sigma(r)) & \text{if } r_1 < r < r_2, \\ 1 & \text{if } r > r_2, \end{cases}$$

where

$$s(r) = \int_{r_1}^{r} (t - r_1)^2 (t - r_2)^2 \, dt.$$

Set $\gamma = 1 + i\sigma$ and $\tilde\gamma = 1 + i\tilde\sigma$. Then, with the coefficient matrices set to

$$\mathcal{A}(\boldsymbol{x}) = \frac{1}{r^2} \begin{pmatrix} \gamma x^2 + \tilde\gamma y^2 & xy(\gamma - \tilde\gamma) \\ xy(\gamma - \tilde\gamma) & \gamma y^2 + \tilde\gamma x^2 \end{pmatrix}, \qquad \mathcal{B}(\boldsymbol{x}) = \varepsilon(\boldsymbol{x})\gamma\tilde\gamma \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$



(a) The case $r_3 = 3$. (b) The case $r_3 = 20$.

FIG. 1. *Finite element meshes (the dielectric is in darker shade).*

the weak formulation of the truncated PML resonance problem is to find eigenvalues $\lambda \equiv k^2$ satisfying

$$\langle \mathcal{A}\nabla u, \nabla v\rangle = \lambda \langle \mathcal{B}u, v\rangle \quad \text{for all } v \in H_0^1(B_{r_3}) \tag{3.10}$$

for some nontrivial eigenfunction u in $H_0^1(B_{r_3})$. Here $B_{r_3} = \{\boldsymbol{x} \in \mathbb{R}^2 : |\boldsymbol{x}| < r_3\}$, and $\langle\cdot,\cdot\rangle$ denotes the $L^2(B_{r_3})$ inner product. To discretize (3.10), we used Lagrange finite elements of degree one on the meshes shown in Figure 1(a) and 1(b). The two meshes correspond to the two values of r_3 that we will investigate.

The discretization results in a large sparse generalized eigenvalue problem

$$\mathsf{A}\mathsf{x} = \lambda\, \mathsf{B}\mathsf{x}, \tag{3.11}$$

where $\mathsf{A}_{ij} = \langle \mathcal{A}\nabla\phi_j, \nabla\phi_j\rangle$, $\mathsf{B}_{ij} = \langle \mathcal{B}\phi_j, \phi_i\rangle$, and ϕ_i's are the usual nodal finite element basis. Note that this is a standard linear eigenvalue problem, because we have used PML coefficients that do *not* depend on frequency (unlike the ones in the original paper of Berenger [1]). We shall see that in the asymptotic integral equation approach in the next subsection, we will get a nonlinear eigenproblem. Now, recall the exact resonant k values calculated in Table 1. We compare the square roots of the eigenvalues computed by (3.11) with the exact values of Table 1.

The square root of the full spectrum of (3.11) in the case of the mesh in Figure 1(a) (the $r_3 = 3$ case), together with the first few exact resonance values, is shown in Figure 2. As marked in the figure, a number of points in the computed spectrum lie far away from the exact resonances and must clearly be considered spurious.

Next, we systematically investigate the convergence of the first ten nonspurious resonance values to the exact value with respect to the discretization meshsize. Starting with the mesh in Figure 1(a), we perform a series of successive refinements. The mesh at refinement level J is obtained by joining the midpoint of the edges of each triangle of the previous level $J-1$. At each refinement, the coordinates of the newly created vertices on the dielectric-air interface are adjusted so that they lie exactly on the unit circle. Let us denote by k_ℓ^J the ℓth resonance value computed at refinement level J, where the ordering in ℓ is with respect to increasing real part, considering

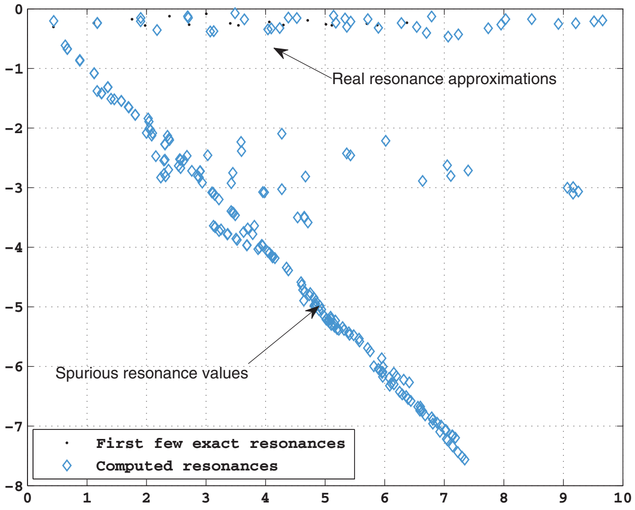


FIG. 2. *Computed resonances for the case* $r_3 = 3$.

only the nonspurious values. The results are tabulated in Table 2. The definitions of mean orders of convergence in the table are as follows:

$$\text{apparent mean order of convergence for } \ell\text{th resonance} := \frac{1}{3}\sum_{J=2}^{4}\log_2\left(\frac{|k_\ell^J - k_\ell^{J-1}|}{|k_\ell^J - k_\ell^{J+1}|}\right);$$

$$\text{actual mean order of convergence for } \ell\text{th resonance} := \frac{1}{3}\sum_{J=2}^{4}\log_2\left(\frac{e_\ell^J}{e_\ell^{J+1}}\right),$$

where for each ℓ, the true error e_ℓ^J is defined by $e_\ell^J = |k_\ell^J - k_{n,m}|$ for the n, m values indicated in the first column of the table (under the title "Compare with $k_{n,m}$"). The "apparent" rate quantifies the order of difference of approximations from successive refinements and is a standard way to measure convergence rate in cases where we have no knowledge of the exact solution.

It is important to note the difference between the apparent and actual rates of convergence in the case of some resonance values (see rows with $\ell = 1, 2, 3$ in Table 2). These suggest that although the computed resonances appear to converge at a second order rate, they converge to the wrong limit. We conjecture that this is due to the spectral changes caused by the truncation of PML at radius r_3. Consider the results in Table 3, where we report the resonance values obtained using the mesh in Figure 1(b), with $r_3 = 20$. Clearly there is a marked improvement in the actual convergence rates, supporting the conjecture that r_3 needs to be sufficiently large.

To summarize, we note the following difficulties encountered with the PML approach:

- It is necessary to separate the true eigenvalues from the spurious eigenvalues.
- Although eigenvalues may appear to converge, they can converge to the wrong value if the domain is not large enough.

These problems were readily identified in this validation experiment because we know the exact solution. However, in a situation without any a priori knowledge of the exact solution, it is important to keep in mind that such difficulties can occur.

Table 2
Apparent and actual convergence of computed resonance values.

Case $r_3 = 3$					
$\ell \backslash J$	Computed resonance approximations k_ℓ^J (displayed up to 3 digits)				
	Level 1	Level 2	Level 3	Level 4	Level 5
1	$0.441 - 0.202i$	$0.432 - 0.207i$	$0.430 - 0.208i$	$0.429 - 0.209i$	$0.429 - 0.209i$
2	$1.173 - 0.239i$	$1.129 - 0.240i$	$1.118 - 0.241i$	$1.115 - 0.241i$	$1.114 - 0.241i$
3	$1.175 - 0.236i$	$1.129 - 0.239i$	$1.118 - 0.241i$	$1.115 - 0.241i$	$1.114 - 0.241i$

For instance, in our experiments with PML in cases when an exact solution is unknown (reported in later subsections), we needed to separate the true eigenvalues from the spurious eigenvalues. To identify the true eigenvalues, we used the following techniques: (i) We compared the variations in the computed spectrum when PML parameters were varied. (ii) We also compared the spectrum computed with the standard rectangular (tensor product–type [3]) PML with the results from the circular PML in (3.9). The spectral points that persisted across these changes were considered to be the real eigenvalues. (We shall not report these details here for the sake

of brevity.) It is more difficult to overcome the discrepancy between the apparent and actual convergence. We typically experiment with an increasing set of r_3 values, holding meshsize (approximately) fixed, until the variation in the eigenvalues of interest becomes negligible. This often requires meshes with a large number of degrees of freedom and hence entails expensive computations.

3.2. A homogeneous thin membrane. In this subsection, we will describe the integral equation approach to the computation of resonances and compare the results from it to those obtained with PML. The resonating object is a thin homogeneous dielectric membrane occupying the rectangular region $[-0.5, 0.5] \times [-h/2, h/2]$. The dielectric constant is set to the following function:

$$\varepsilon(x, z) = \begin{cases} 6/h & \text{if } |z| < h/2, \quad x \in [-0.5, 0.5], \\ 1 & \text{otherwise;} \end{cases} \tag{3.12}$$

i.e., we choose $\varepsilon_0(x) \equiv 6$. For our numerical experiments here, we choose a geometrically decreasing sequence of values for h.

Let us first describe the collocation discretization of the asymptotic integral equation derived in section 2. The computational domain, which is now $[-0.5, 0.5]$, is meshed by a grid of evenly spaced points set at a distance δ apart. Discrete approximations to resonance modes are now in the space V_δ of continuous functions which are linear in between adjacent grid points. Define the matrix-valued function $\mathsf{S} : \mathbb{C} \mapsto \mathbb{C}^{N\times N}$ by $\mathsf{S}(\lambda) = \mathsf{I} - \lambda\,\mathsf{T}(\lambda)$, where I denotes the identity matrix, and the entries of the matrix $\mathsf{T}(\lambda)$ are defined by

$$[\mathsf{T}(\lambda)]_{ij} = -\int_{-1/2}^{1/2} \varepsilon_0(x')\, G_\lambda(x_i, 0, x', 0)\, \psi_j(x') \; dx'. \tag{3.13}$$

Here ψ_j is the unique function in V_δ, which is one at the jth grid point and zero at all other grid points. With these notations, the discrete problem is the dense *nonlinear eigenvalue problem* of finding complex numbers λ and corresponding nontrivial vectors x satisfying

$$\mathsf{S}(\lambda)\,\mathsf{x} = 0. \tag{3.14}$$

This can be rewritten as a nonlinear system for λ and x, to which Newton's method or its variants can be applied. To compute the matrix entries defined by (3.13) we split the integral into integrals over each mesh interval (of length δ). On those intervals where the integrand is smooth, the integrals are approximated by high order Gaussian quadratures. We must be more careful in the intervals containing the singularity of G_λ. On such elements, we use an expansion of the integrand to approximate the integral. In all cases, our integral approximations are at least $O(\delta^7)$ accurate.

To solve (3.14), we use the residual inverse iteration analyzed by Neumaier [15].

Algorithm 3.1 (residual inverse iterations).

```
1. Input an initial approximation $\lambda_0$ close to the eigenvalue of interest. If $\mathsf{S}(\lambda_0)$ is invertible, continue.
2. Set (Wilkinson) initial guess $\mathsf{x}_0$ for the eigenvector:
   (a) Perform the QR-factorization $\mathsf{QR} = \mathsf{S}(\lambda_0)$.
   (b) Let $\mathsf{b} = \mathsf{Q}\,\mathsf{n}$, where $\mathsf{n}$ is the vector whose components are 1.
   (c) Solve the linear system $\mathsf{S}(\lambda_0)\tilde{\mathsf{x}}_0 = \mathsf{b}$, by $\tilde{\mathsf{x}}_0 = \mathsf{R}^{-1}\mathsf{n}$.
   (d) Normalize by $\mathsf{x}_0 = \tilde{\mathsf{x}}_0/\mathsf{e}^*\tilde{\mathsf{x}}_0$, where $\mathsf{e}$ is the unit vector with one in the position of the largest entry of $\tilde{\mathsf{x}}_0$.
   (e) Set $\mathsf{y}^* = \mathsf{e}^*\mathsf{R}^{-1}\mathsf{Q}^*$ for use later.
3. For $l = 0, 1, 2, \ldots$ (until a stopping criteria is met) do:
   (a) $\lambda_{l+1} = \lambda_l - \frac{\mathsf{y}^*\mathsf{S}(\lambda_l)\mathsf{x}_l}{\mathsf{y}^*\mathsf{S}'(\lambda_l)\mathsf{x}_l}$, where $[\mathsf{S}'(z)]_{ij} = \frac{d}{dz}[\mathsf{S}(z)]_{ij}$.
   (b) $\tilde{\mathsf{x}}_{l+1} = \mathsf{x}_l - \mathsf{R}^{-1}\mathsf{Q}^*\mathsf{S}(\lambda_{l+1})\mathsf{x}_l$.
   (c) Normalize by $\mathsf{x}_{l+1} = \tilde{\mathsf{x}}_{l+1}/\|\tilde{\mathsf{x}}_{l+1}\|_2$.
```

These iterations can be stopped once $|\lambda_{l+1} - \lambda_l|$ is smaller than a prescribed tolerance. In step 3(a) of the algorithm, we have used one step of a one-dimensional Newton iteration. We can substitute this step with multiple Newton iterations or other nonlinear solvers.

This algorithm works well in our application *if* good initial approximations λ_0 are given. In order to find good initial guesses, we borrowed a technique used for plotting the pseudospectra [18] of matrices. Namely, if $\sigma_{\min}(\mathsf{S})$ denotes the smallest singular value of S, then it is easy to see that

$$\sigma_{\min}(\mathsf{S}(\lambda)) < \delta \quad \text{if and only if} \quad \|\mathsf{S}(\lambda)^{-1}\|_2 > 1/\delta. \tag{3.15}$$

Motivated by this, before launching the residual inverse iterations for fine meshes, we first use a coarse mesh to obtain an inexpensive matrix approximation $\mathsf{S}(\lambda)$. We then compute the minimum singular value $\sigma_{\min}(\mathsf{S}(\lambda))$ on a grid of λ in the complex plane. For coarse meshes, $\mathsf{S}(\lambda)$ is a small matrix, so this computation is fast. Because of (3.15), the plot of the minimum singular values locates regions where the resolvent $\mathsf{S}(\lambda)$ is nearly singular, thus providing good initial guesses for Algorithm 3.1. For our current example of the homogeneous thin membrane, a coarse mesh resulting in a 20×20 matrix function $\mathsf{S}(\lambda)$ yields the contour plot of $\sigma_{\min}$ shown in Figure 3. Note that since $k = \sqrt{\lambda}$ is what we shall report, Figure 3 shows $\sigma_{\min}$ as a function of k (rather than λ).

Next, we report the first few resonance values computed using Algorithm 3.1 applied to (3.14). We mesh the interval $[-0.5, 0.5]$ uniformly with a mesh of meshsize $\delta_0 = 1/20$. To perform a study of convergence with respect to meshsize, we refine this coarse mesh by splitting each grid element into two equal elements, so the meshsize at the refinement level J is $\delta_J = 2^{-(J-1)}/20$. Denoting the ℓth resonance value computed using the mesh at refinement level J as $k_\ell^{J,\infty}$, the differences in the computed resonance values at successive refinements are collected in Table 4. Examining these differences,

we conjecture that the convergence rate of collocation discretization for the resonance values is $O(\delta^2)$, where δ is the meshsize. The last column of Table 4 lists the resonance values computed using the finest mesh.

We now compare these resonance values with those obtained using the PML approach. We enclose the dielectric in $[-0.5, 0.5] \times [-h/2, h/2]$ by circles of radius r_1, r_2, and r_3 and set the PML parameters as described in section 3.1. We experimented with a number of r_3 values and concluded that selecting $r_3 = 20$ seems appropriate to get good approximations in this example. We also needed to isolate the spurious eigenvalues from the interesting ones (see remarks at the end of section 3.1). We shall consider the following geometrically decreasing sequence of membrane thicknesses:

$$h = \frac{0.25}{2^{L-1}}, \qquad L = 1, 2, \ldots, 7.$$

For each L value, we mesh the domain (B_{r_3}) such that mesh aligns with the dielectric boundaries. Furthermore, the meshes are such that for all values of h considered, the dielectric region will always have four layers of elements. The meshsize inside the dielectric is thus maintained approximately at $h/4$ by constraining the angles of

Table 5
Difference between the asymptotic and PML resonance approximations.

the mesh triangles to never deteriorate below 25 degrees. With $\varepsilon(x, y)$ as in (3.12), we then solve the resulting finite element eigenproblem (3.11) for the first few eigenvalues and compare them with the resonance approximations previously displayed in the last column of Table 4.

One of our aims in this comparison is the verification of the theoretically predicted asymptotic convergence rate of $O(h)$ of Theorem 2.4. To realize this goal, we must avoid discretization errors as much as we can, but without going to prohibitively expensive meshsizes. Note that the first six resonance values in Table 4 have stabilized up to four digits at the seventh level of refinement, so we denote these six values by $k_\ell^{*,\infty}$, $\ell = 1, 2, \ldots, 6$, and use them for the comparison with the corresponding first six resonance approximations from PML. In order to avoid finite element discretization errors in the comparable PML resonance approximations, we perform multiple refinements of the finite element mesh until their first six resonance approximations have no variation in at least the first two significant digits. Denoting these approximations by $k_\ell^{\text{pml},L}$ for the case of membrane thickness $h = 0.25/2^{L-1}$, we display in Table 5 the distance of these approximations to the asymptotic ones. The linear asymptotic convergence rate is clearly apparent.

Next we apply Corollary 2.5 to attempt to improve the asymptotic resonance approximations from the problem in the previous subsection. Recall that from the residual correction procedure described there, we have limiting resonance value λ_0 and a discrete approximation to the corresponding resonance function $u_0(x)$. We will apply these values to calculate

$$\lambda_0 + h\lambda_1$$

to get what should be a better approximation to the resonance value λ_h for a given total slab thickness h. Note that the correction

$$\lambda_1 = \lambda_0^2 \frac{\langle g, u_0\rangle}{1 + \lambda_0^2 \langle DT_0(\lambda_0)u_0, u_0\rangle},$$

where

$$g(x) = -\int_\Omega G_{\lambda_0}(x, 0, x', 0)u_0(x')dx' + \frac{\varepsilon_0(x)u_0(x)}{2}\left(\zeta^2 + \frac{1}{4}\right),$$

involves merely double integrations over Ω, in this case a one-dimensional domain. In the second term in the numerator the integration in ζ can be calculated exactly. The integral in the denominator is

$$\langle DT_0(\lambda_0)u_0, u_0\rangle = -\int_{-.5}^{.5}\int_{-.5}^{.5} \frac{i\varepsilon_0(x')}{8\sqrt{\lambda_0}} H_1^{(1)}\left(\sqrt{\lambda_0}|x - x'|\right)|x - x'|u_0(x')\overline{u_0}(x)dx'dx.$$

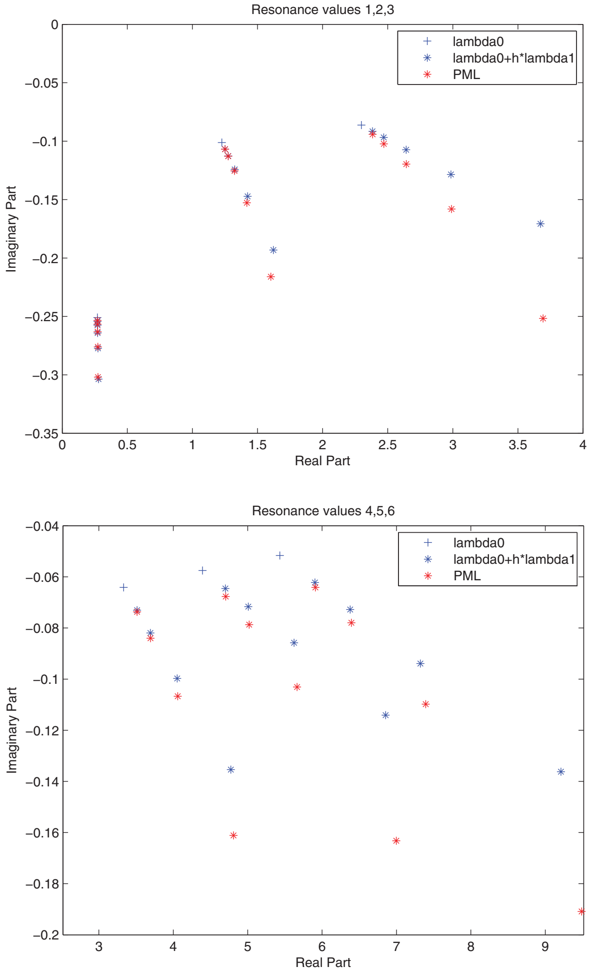

FIG. 4. *The first six computed resonance values λ in the complex plane for varying slab thicknesses.*

For both of the double integrals, we compute the inner integral using the piecewise linear basis functions for u_0, and for the outer integral we use the trapezoid rule. In all computations that follow the meshsize was $\delta = 1/640$, the sixth refinement level, for which we believe the calculations of the first six limiting resonance values λ_0 are accurate up to about four significant digits. Recall that the PML values used from the previous section are accurate to about two significant digits.

Figure 4 shows all of the computed values plotted on the complex plane, and Figure 5 gives a log-log plot of the errors. For the first resonance, the corrected asymptotic values are within the presumed accuracy of the PML approximation for all values of h, and hence we see the convergence flattening in the log-log plot. For the third resonance, the convergence appears only slightly more than linear, but all of the other values exhibit the significantly better than linear convergence expected from Corollary 2.5.

Remark 3.1. The approximation from [14] used to obtain Corollary 2.5 deteriorates for larger frequencies, and we therefore expect that for the higher-numbered

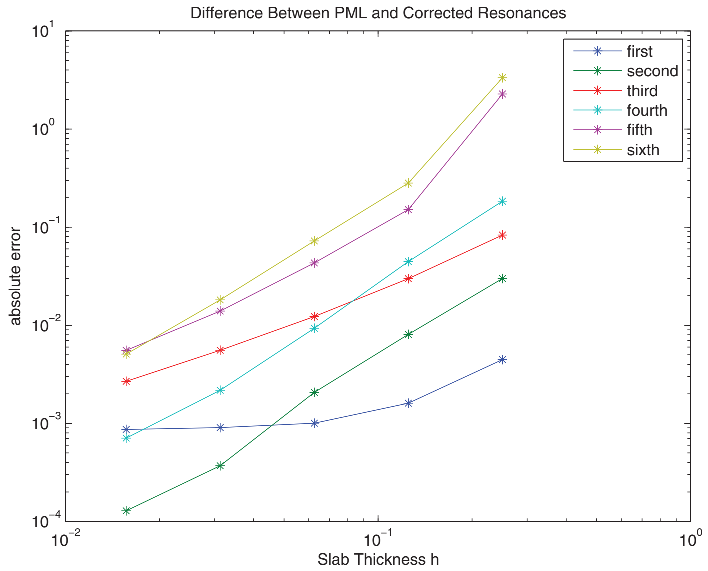

FIG. 5. *Log-log plot of the absolute error between the PML computed and corrected asymptotic resonance values.*

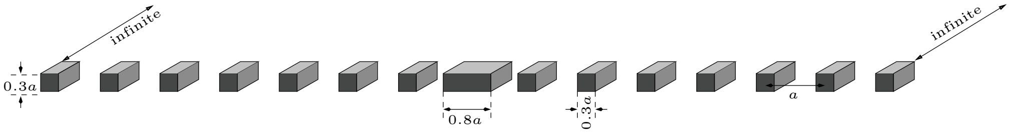

FIG. 6. *The photonic dielectric structure.*

resonances, the formula from Theorem 2.4 will be far superior. The computation of this more accurate correction will involve computing the application of the higher dimensional integral operator T_h, but will not require any inversion.

3.3. A photonic membrane. In this subsection, we will describe the results of computation from a thin photonic membrane having a periodic dielectric pattern with a defect. The structure is shown in Figure 6 and was previously investigated in [5] by time domain methods. We will give results from both the PML and the asymptotic integral equation approaches. Unlike the previous subsections, our purpose here is not a convergence study, but rather a comparison with the results in [5]. The structure in Figure 6 is invariant in the third direction, so the model is reduced to one in the xz plane perpendicular to the symmetry direction. Note that while fully periodic structures have band gaps, this structure is not periodic in that it has a defect in the center and has finite extent in the plane. Hence instead of defect eigenvalues, we seek resonances.

We choose the dielectric constant as in [5]; namely, in the central defect column and the fourteen off-center columns, $\varepsilon(\boldsymbol{x})$ is 13, while in the remaining region it equals 1. We set the scaling parameter a in Figure 6 to $1/14.3$ so that the xz cross section fits into $[-0.5, 0.5] \times [-h/2, h/2]$ with $h = 0.3a$. Since this h is small, it is reasonable to attempt the asymptotic approach.

For the PML calculations, we enclose the xz cross section of the photonic structure by disks of radius $r_1 = 0.6$, $r_2 = 2$, and $r_3 = 10$ and set the PML parameters as in the previous sections. This domain is meshed such that there are at least four layers

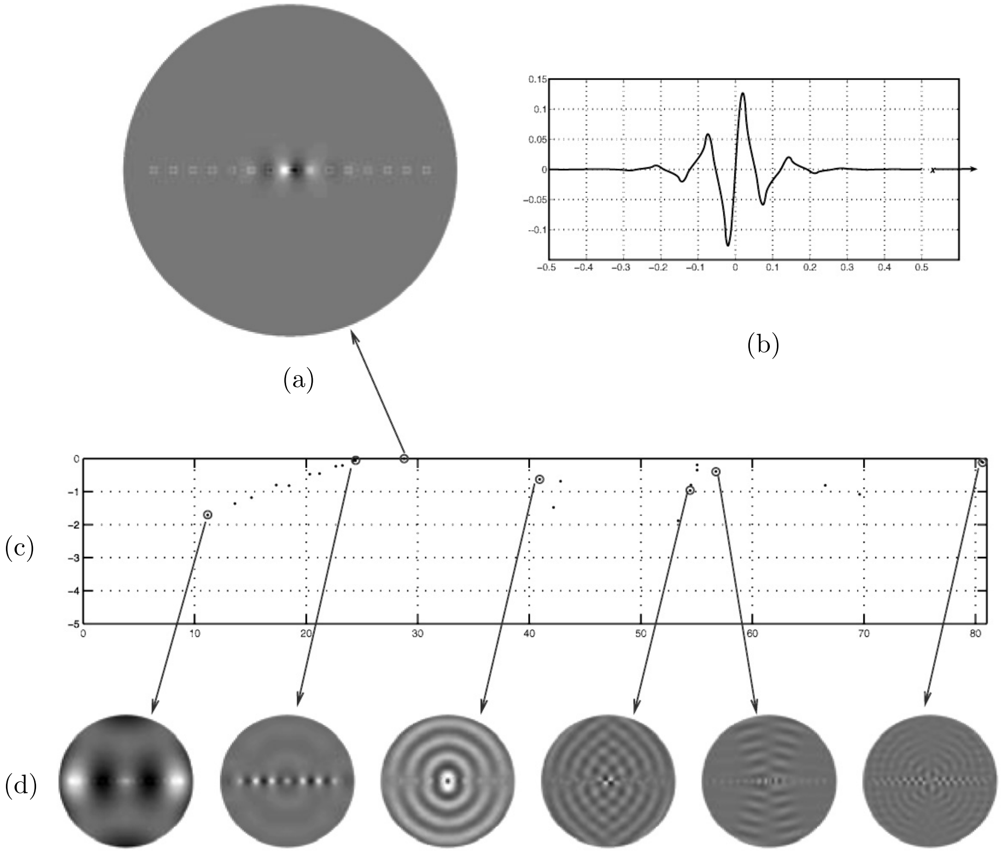

Fig. 7. *A few resonances of the photonic membrane.* (a) *The highly localized resonance mode corresponding to $k \approx 28.7878 - 0.0017i$ obtained using PML.* (b) *The corresponding mode obtained using the asymptotic approach, plotted on the limiting domain* $[-0.5, 0.5]$. of elements across the membrane thickness (and the mesh coarsens away from the dielectric). The computations then proceed similarly, except that to obtain higher accuracy, we now use Lagrange finite elements of degree five. The results are shown in Figure 7. The mode shown in Figure 7(a) is qualitatively similar to the one in [5, Fig. 5]. Furthermore, its corresponding resonance value is such that $ka/2\pi \approx 0.321$, a number close to the frequency of 0.313 reported in [5]. As seen from Figure 7(a), this mode is highly localized near the defect. Although there are many other resonances, as seen from Figure 7(d), localization near the defect or even near the membrane seems to be uncommon. (One other mode that is somewhat localized within the membrane is seen in the second plot of Figure 7(d).)

For the asymptotic approach, we set $\varepsilon_0 = \varepsilon h$ with the ε and h as described above and solve the resulting one-dimensional nonlinear eigenproblem on $\Omega = [-0.5, 0.5]$. The initial guesses for the nonlinear eigenvalue solver were obtained using the pseudospectrum-like plot in Figure 8 (computed as described previously; see Figure 3).

Values from PML	Asymptotic values	Corrected asymptotic values
$20.3154 - 0.4704i$	$17.8719 - 0.2655i$	$19.9420 - 0.4049i$
$22.6512 - 0.2292i$	$19.7458 - 0.1116i$	$22.7624 - 0.1228i$
$24.2375 - 0.0658i$	$20.3675 - 0.0348i$	$23.7018 - 0.0493i$
$28.7878 - 0.0017i$	$23.0690 - 0.0006i$	$28.0236 - 0.0005i$
$40.9258 - 0.6283i$	$29.7120 - 0.1592i$	$39.1908 - 0.4074i$

A few resonance values obtained using Algorithm 3.1 are reported in Table 6. The table also gives the corresponding resonance approximations from the PML calculations. There is good agreement between the PML and asymptotic values, especially after the correction. The most interesting mode is of course the one localized in the defect. The limiting, uncorrected resonance value for this mode is such that $ka/2\pi \approx 0.257$, and produced the nonlinear eigenfunction in Figure 7(b). This qualitatively resembles not only the mode plot in [5, Fig. 5], but also the trace of the corresponding mode obtained from PML (Figure 7(a)) on the x-axis (the centerline of the dielectric). The corrected asymptotic resonance value is such that $ka/2\pi \approx 0.311$, very close to the value 0.313 reported in [5].

Considering that the PML eigenvalue problem we solved is of size 221201×221201, while the asymptotic problem is only of size 2289×2289, the advantages of the asymptotic approach are clearly evident for this particular geometry.

4. Discussion. We propose two methods for calculating resonance associated with the scalar wave equation. The first method is suited for thin, high index structures which are gaining popularity in the photonic band gap community. It is an asymptotic method that exploits the specifics of the problem and allows for the calculation of resonance to be carried out in one dimension less than the spatial dimension of the problem. The second method, based on the finite element method with the PML, is a general approach which is not restricted to thin structures. In this work, we examine the convergence properties of the finite element approach and use it to verify the approximation properties of the asymptotic method. A final set of calculations with both methods reproduces a photonic band gap resonance calculation reported in the literature.

For a thin membrane structure with high index, we find that the asymptotic method (2.3) is particularly effective. When discretized, it leads to a dense, but small, nonlinear eigenvalue problem. While we established approximation properties of the method, the numerical evidence is quite convincing. A higher order correction, which is easy to implement, provides more accuracy at a low cost. In comparison with the PML approach, the asymptotic method has the clear advantage of a smaller system, brought about by the dimensional reduction. Its disadvantage lies in the complications involved in solving a dense nonlinear eigenproblem.

The finite element PML approach is attractive because the matrices involved are sparse and the eigenvalue problem to find resonance is linear. It is also more widely applicable. One challenge in using this method is the presence of spurious modes. Our experience is that it is possible to identify spurious modes. Another unattractive feature of the PML approach is that the resonance values may appear to converge under refinement, but to incorrect limits. Our experience with this method, while limited, does gives us hope that it is possible to deal with these difficulties, and that it is possible to develop a robust finite element–based method for calculating resonance. It remains to be seen, however, if it is a viable alternative to simple FDTD calculations.

Acknowledgment. The authors thank Joseph Pasciak for several enlightening discussions on exterior eigenvalue approximations.

A LEVEL SET APPROACH TO ANISOTROPIC SURFACE EVOLUTION WITH FREE ADATOMS*

CHRISTINA STÖCKER† AND AXEL VOIGT‡

Abstract. We variationally derive a thermodynamically consistent model for surface evolution under the influence of free adatoms. The resulting system of nonlinear partial differential equations couples a diffusion equation on a surface to the evolution of the surface. A numerical approach based on a finite element discretization of a level set equation is described for an anisotropic evolution, with nonconvex anisotropy functions. Various simulation examples in two and three dimensions demonstrate the applicability of the method.

Key words. thin film growth, anisotropic evolution, PDEs on surfaces, higher order evolution equations, level set method, finite elements, adaptivity

1. Introduction.

Evolving interfaces are a key ingredient in many problems in materials science. As smaller and smaller length scales become of interest, the importance of interfaces compared with phenomena in the bulk phases increases and therefore requires more detailed considerations than in classical, more macroscopic models. To model grain boundaries, solid-vapor interfaces, or coherent phase transitions, various geometric evolution laws have been proposed. Mean curvature flow and surface diffusion are two prominent examples. In its basic form these laws have been derived by Mullins [14, 15]. The equations follow from a surface free energy

$$E[\Gamma] = \int_\Gamma \gamma \, d\Gamma,$$

with $\Gamma = \Gamma(t)$ a compact smooth connected and oriented hypersurface in $\mathbb{R}^{d+1}$ ($d = 1, 2$) and $\gamma = \gamma(\mathbf{n})$ the surface free energy density, possibly depending on the normal to the surface $\mathbf{n}$. The geometric evolution laws are defined as gradient flows of the energy and read, e.g.,

$$V = -kH_\gamma, \tag{1.1}$$

$$bV = -(H_\gamma - c), \tag{1.2}$$

$$V = \nabla_\Gamma \cdot \big(\nu \nabla_\Gamma H_\gamma\big). \tag{1.3}$$

Here $k = k(\mathbf{n})$ is the evaporation modulus, $b = b(\mathbf{n})$ is a kinetic coefficient, $\nu = \nu(\mathbf{n})$ denotes the surface mobility, V is the normal velocity, H_γ is weighted mean curvature

$$H_\gamma = \sum_{i=1}^{d-1} \partial_{p_i p_i} \gamma(\mathbf{n}) \kappa_i,$$

which is $\frac{\delta E}{\delta \Gamma} \cdot \mathbf{n}$, the variational derivative with respect to variations in Γ in normal direction. Here $\partial_{p_i p_i}$ denotes the second derivative of the one-homogeneous extension of $\gamma : S^d \subset \mathbb{R}^{d+1} \to \mathbb{R}$ with respect to $\mathbf{n}$ in the ith principal direction, and κ_i, $i = 1, \dots, d$, are the principal curvatures. The coefficient $c = \int_\Gamma b^{-1} H_\gamma \, d\Gamma \,/\, \int_\Gamma b^{-1} \, d\Gamma$ is the averaged weighted mean curvature. Equation (1.1) models motion by evaporation-condensation, (1.2) describes the kinetics associated with the rearrangement of atoms on the surface, and (1.3) accounts for diffusion of atoms along the surface. Equation (1.1) is known as curvature flow, (1.2) as volume conserved curvature flow, and (1.3) as motion by surface diffusion. A more general geometric evolution law combining the three effects has been discussed by Fried and Gurtin [9]:

$$V = \nabla_\Gamma \cdot \big(\nu \nabla_\Gamma (H_\gamma + bV)\big) - k(H_\gamma + bV). \tag{1.4}$$

This equation incorporates surface diffusion, evaporation-condensation, and kinetics. We obtain the individual laws discussed above as follows:

- $\nu = 0$, $b = 0 \Rightarrow$ evaporation-condensation (1.1).
- $\nu = \infty$, $k = 0 \Rightarrow$ kinetic (1.2).
- $b = 0$, $k = 0 \Rightarrow$ surface diffusion (1.3).

The special case $k = 0$ has been considered by Cahn and Taylor [6] and can also be written as

$$V = -\big(\nabla_\Gamma \cdot (\nu \nabla_\Gamma)\big) \left(\nabla \cdot (\nu \nabla_\Gamma) - \frac{1}{b} \right)^{-1} \left(\frac{1}{b} H_\gamma \right). \tag{1.5}$$

Another special case is obtained for $\nu = 0$. The resulting equation reads

$$\left(\frac{1}{k} + b \right) V = -H_\gamma, \tag{1.6}$$

which again is a curvature flow equation, but with a modified kinetic coefficient.

More recently Fried and Gurtin [9] introduced a refined model of (1.4) which includes free adatoms. Adatoms are mobile atoms on the surface. They diffuse along the surface and attach and detach from surface defects, which contributes to the evolution of the surface. Especially in the case of solid-vapor interfaces such adatoms are assumed to play an important role in the dynamics of the surface evolution. The model reads

$$\partial_t u + V + uHV = \nabla_\Gamma \cdot (\nu \nabla_\Gamma \mu) - k\mu, \tag{1.7}$$

$$\mu = \partial_u \gamma, \tag{1.8}$$

$$bV + H_{\gamma_1} + \gamma_2 H - \mu - uH\mu = 0, \tag{1.9}$$

with u the adatom density, H the mean curvature, and μ the surface chemical potential, which is defined as the partial derivative of the surface free energy density $\gamma(\mathbf{n}, u) = \gamma_1(\mathbf{n}) + \gamma_2(u)$ with respect to u, and H_{γ_1} again the weighted mean curvature, given as the normal component of the variational derivative of γ_1 with respect to variations in Γ. If u is set to zero, the classic law (1.4) is obtained again with $\gamma = \gamma_1$ and $\mu = H_\gamma + bV$. The model is derived within the framework of configurational forces. Burger [3] used the principle of minimal work to derive the model and analyzed it with $k = 0$ in detail and numerically solved the isotropic case within a graph formulation. A phase-field approximation in this situation is considered by Rätz and Voigt [17].

We will show that the model can also be derived variationally from an energy

$$E[\Gamma, u] = \int_\Gamma \gamma \, d\Gamma,$$

with $\gamma = \gamma(\mathbf{n}, u) = \gamma_1(\mathbf{n}) + \gamma_2(u)$. The more general case, in which the dependency on $\mathbf{n}$ and u cannot be split, will lead to an even more complicated model in which also the adatom energy will be anisotropic. The functional form of such a dependency, however, is not known for any material. We therefore restrict our treatment to the separable case, which leads to the model introduced in [9]. We will introduce a numerical approach based on a level set method and allow for various anisotropies.

The outline of the paper is as follows: In section 2 we derive the model and show its thermodynamic consistency. In section 3 we describe a level set algorithm to solve the adatom surface diffusion model. In section 4 we give some details on the implementation in AMDiS [20] and show numerical results on the evolution towards the equilibrium shape.

2. Model derivation. In order to define a thermodynamically consistent dynamic model for the evolution of the surface we need $\frac{d}{dt}E \leq 0$, with $E = E[\Gamma, u]$. The time derivative of E implies

$$\frac{d}{dt}E = \int_\Gamma \partial_t u \frac{\delta E}{\delta u} \, d\Gamma + \int_\Gamma \mathbf{v} \cdot \frac{\delta E}{\delta \Gamma} \, d\Gamma, \tag{2.1}$$

with $\frac{\delta E}{\delta u}$ the variational derivative of E with respect to u and $\frac{\delta E}{\delta \Gamma}$ the variational derivative of E with respect to Γ, given by

$$\frac{\delta E}{\delta u} = \mu, \tag{2.2}$$

$$\frac{\delta E}{\delta \Gamma} = H_{\gamma_1}\mathbf{n} + \gamma_2 H \mathbf{n}, \tag{2.3}$$

with the chemical potential $\mu = \partial_u \gamma$ and the weighted mean curvature defined above. We decompose the velocity $\mathbf{v}$ into normal and tangential components through $\mathbf{v} = V\mathbf{n} + \mathbf{T}$. This decomposition might be used to obtain the identities

$$\nabla_\Gamma \cdot \mathbf{v} = \nabla_\Gamma \cdot (V\mathbf{n} + \mathbf{T}) = V\nabla_\Gamma \cdot \mathbf{n} + \nabla_\Gamma \cdot \mathbf{T} = VH + \nabla_\Gamma \cdot \mathbf{T}, \tag{2.4}$$

where $H = \nabla_\Gamma \cdot \mathbf{n}$ is used, and

$$\mathbf{v} \cdot \nabla u = (V\mathbf{n} + \mathbf{T}) \cdot \nabla u = V\frac{\partial u}{\partial \mathbf{n}} + \mathbf{T} \cdot \nabla_\Gamma u, \tag{2.5}$$

which will be needed in the following derivation.

A basic conservation law we wish to establish is the invariance of mass in time. The mass in the system is given by

$$m = \int_{\Omega_s} 1 \, d\Omega + \int_\Gamma u \, d\Gamma,$$

with $\Omega_s = \Omega_s(t)$ being the solid domain. Defining an arbitrary portion Σ of Γ and Λ of Ω_s, such that $\Sigma \subset \partial\Lambda$ and ignoring bulk diffusion, we have

$$\frac{d}{dt}m_{|\Sigma} = -\int_{\partial\Sigma} \mathbf{q} \cdot \mathbf{m} \, ds + \int_\Sigma f \, ds, \tag{2.6}$$

with $\partial\Sigma$ the boundary of Σ, $\mathbf{m}$ the conormal on $\partial\Sigma$, $\mathbf{q}$ a tangent surface flux, and f the supply from the vapor. The transport theorems (see, e.g., [1]) imply

$$\begin{aligned} \frac{d}{dt} m_{|\Sigma} = \frac{d}{dt}\left(\int_\Lambda 1\, d\Omega + \int_\Sigma u\, d\Gamma\right) &= \int_\Sigma V\, d\Gamma + \int_\Sigma \dot{u} + u\nabla_\Gamma \cdot \mathbf{v}\, d\Gamma \\ &= \int_\Sigma V + \dot{u} + uVH + u\nabla_\Gamma \cdot \mathbf{T}. \end{aligned} \tag{2.7}$$

$\dot{u}$ denotes the normal time derivative of the interfacial field u (see, e.g., [9])

$$\dot{u} = \partial_t u + \mathbf{T} \cdot \nabla_\Gamma u, \tag{2.8}$$

where we assume that u is constant in a normal direction. Together with the formula for integration by parts on Σ,

$$\int_{\partial\Sigma} \mathbf{q} \cdot \mathbf{m}\, ds = \int_\Sigma \nabla_\Gamma \cdot \mathbf{q}\, d\Gamma,$$

this implies

$$V + \dot{u} + uVH + u\nabla_\Gamma \cdot \mathbf{T} = -\nabla_\Gamma \cdot \mathbf{q} + f, \tag{2.9}$$

which we can rewrite, by using (2.5), as

$$\partial_t u + \nabla_\Gamma \cdot (u\mathbf{T}) + uVH + V = -\nabla_\Gamma \cdot \mathbf{q} + f. \tag{2.10}$$

We now use (2.10) in (2.1) and obtain

$$\begin{aligned} \frac{d}{dt}E &= -\int_\Gamma (\nabla_\Gamma \cdot (u\mathbf{T}) + uVH + V + \nabla_\Gamma \cdot \mathbf{q} - f)\frac{\delta E}{\delta u}\, d\Gamma + \int_\Gamma \mathbf{v} \cdot \frac{\delta E}{\delta \Gamma}\, d\Gamma \\ &= -\int_\Gamma \nabla_\Gamma \cdot (\mathbf{q} + u\mathbf{T})\frac{\delta E}{\delta u}\, d\Gamma + \int_\Gamma f\frac{\delta E}{\delta u} + \int_\Gamma V\mathbf{n} \cdot \frac{\delta E}{\delta \Gamma} - (uHV + V)\frac{\delta E}{\delta u}\, d\Gamma, \end{aligned}$$

where we have used $\mathbf{T} \cdot \frac{\delta E}{\delta \Gamma} = 0$. We now define

$$\mathbf{q} + u\mathbf{T} = -\nu\nabla_\Gamma \frac{\delta E}{\delta u}, \tag{2.11}$$

$$f = -k\frac{\delta E}{\delta u}, \tag{2.12}$$

$$bV = -\left(\mathbf{n} \cdot \frac{\delta E}{\delta \Gamma} - (uH + 1)\frac{\delta E}{\delta u}\right), \tag{2.13}$$

with ν, k, and b positive coefficients. In a general setting these coefficients might depend on $\mathbf{n}$ and/or u. These definitions imply

$$\frac{d}{dt}E = -\int_\Gamma \frac{1}{\nu}(\mathbf{q} - u\mathbf{T})^2\, d\Gamma - \int_\Gamma \frac{1}{k} f^2\, d\Gamma - \int_\Gamma bV^2\, d\Gamma \leq 0 \tag{2.14}$$

and thus energy dissipation, and with it consistency with the second law of thermodynamics.

We now use (2.10) and (2.11)–(2.13) to obtain the desired evolution law,

$$\partial_t u + uVH + V = \nabla_\Gamma \cdot (\nu\nabla_\Gamma \mu) - k\mu, \tag{2.15}$$

$$\mu = \partial_u \gamma, \tag{2.16}$$

$$bV + H_{\gamma_1} + \gamma_2 H - \mu - uH\mu = 0, \tag{2.17}$$

which is exactly (1.7)–(1.9).

In the same way as the equations are derived from the energy $E[\Gamma, u] = \int_\Gamma \gamma \, d\Gamma$, with $\gamma = \gamma(\mathbf{n}, u)$, more general surface free energies can be used. One example would be a curvature regularized free energy, as originally proposed for the evolution of curves in [7] to deal with strong anisotropies with missing orientations, which lead to backward parabolic behavior of the evolution laws. An extension to surfaces is discussed in [10, 16]. Combined with the adatoms the energy reads

$$E[\Gamma, u] = \int_\Gamma \gamma + \epsilon^2 \frac{1}{2} H^2 \, d\Gamma,$$

with $\gamma = \gamma(\mathbf{n}, u)$. Here ϵ sets a new length scale over which corners and edges in the surface are smeared out. The corners and edges result from the nonconvexity of γ with respect to $\mathbf{n}$. Thus the energy can be seen as a geometric generalization of a Ginzburg–Landau-type energy, where the curvature H plays the role of the gradient term. The variational derivatives now read

$$\frac{\delta E}{\delta u} = \mu, \tag{2.18}$$

$$\frac{\delta E}{\delta \Gamma} = H_{\gamma_1} \mathbf{n} + \gamma_2 H \mathbf{n} - \epsilon^2 \left(\Delta_\Gamma H + H \left(\|S\|^2 - \frac{1}{2} H^2 \right) \right) \mathbf{n}, \tag{2.19}$$

with $S = \nabla_\Gamma \mathbf{n}$ being the shape operator and $\|S\| = \sqrt{\mathrm{trace}(SS^T)}$ its Frobenius norm. The resulting equations read

$$\partial_t u + uVH + V = \nabla_\Gamma \cdot (\nu \nabla_\Gamma \mu) - k\mu, \tag{2.20}$$

$$\mu = \partial_u \gamma, \tag{2.21}$$

$$bV + H_{\gamma_1} + \gamma_2 H - \epsilon^2 \left(\Delta_\Gamma H + H \left(\|S\|^2 - \frac{1}{2} H^2 \right) \right) = \mu + uH\mu. \tag{2.22}$$

If we consider (2.17) with given u and μ, we see that the equation can become backward parabolic if $H_{\gamma_1} + \gamma_2 H - uH\mu < 0$. This has already been discussed in the isotropic case in [3], where this situation might occur for large adatom densities and special choices for γ. In the anisotropic case this situation is much more likely, because H might be large in situations where H_γ is small. Thus even for weak anisotropies the discussed regularization might be necessary to deal with the resulting backward parabolic equation.

3. Numerical approach.

The system (2.15)–(2.17) with $H_{\gamma_1} = H$ and $k = 0$ has been numerically treated in a graph formulation by Burger [3] and in a phase field approach by Rätz and Voigt [17]. Here we will consider a different numerical approach and allow for anisotropies, including strong anisotropies. Thus we will solve the system (2.20)–(2.22). We will use an operator splitting ansatz and consider (2.20) as a diffusion equation on an evolving surface Γ, with Γ given, and (2.22) as the geometric equation which determines the normal velocity, with the interfacial quantities u and μ given.

3.1. Diffusion equations on evolving surface.

The systems (2.15)–(2.17) and (2.20)–(2.22) include the problem of solving a diffusion equation on an evolving surface. Such problems can be found in various applications, e.g., in materials science, biophysics, image processing, and computer graphics. Theoretical results for such problems are rare and also numerical methods are much less developed then for equations defined in $\mathbb{R}^d$. Only recently various numerical approaches are introduced. Dziuk and Elliott [8] introduced a direct approach by parametric finite elements, which allows one to solve a diffusion equation on an evolving surface. The evolution of the surface in their approach is given and for complicated movements severe problems in maintaining the regularity of the surface mesh have to be overcome. A different approach in which the surface is described implicitly, and thus problems with the regularity of surface meshes circumvented, was used by Xu and Zhao [21]. In Lowengrub, Xu, and Voigt [13] this approach is extended to solve a Cahn–Hilliard equation on an evolving surface. In both approaches the evolution of the surface is described through a level set function and results from the interaction with a surrounding flow field. Both implementations, however, are restricted to curves. A different approach in which the surface is described implicitly is used in Rätz and Voigt [17]. Here a phase field function is used to describe the evolving surface and the evolution is governed by a modified Allen–Cahn equation.

3.2. Level set approximation. We are going to use the level set method to solve diffusion equations on a stationary surface, introduced by Bertalmio et al. [2], and extend it to evolving surfaces. The interface is described implicitly through a level set function. Equation (2.20) is thereby approximated by the diffusion equation on the time-independent domain Ω, with $\Gamma(t) \subset \Omega$ for all $t \in (0, T)$,

$$\partial_t u - u\frac{\partial_t \psi}{\|\nabla\psi\|}\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|} - \frac{\partial_t\psi}{\|\nabla\psi\|} = \frac{1}{\|\nabla\psi\|}\nabla\cdot\big(\nu\|\nabla\psi\|P_{\nabla\psi}\nabla\mu\big) - k\mu, \tag{3.1}$$

where now u and μ denote the extended variable, defined on Ω, and $P_{\nabla\psi}$ is the projection operator on the tangential space of $\Gamma(t)$ defined through

$$P_{\nabla\psi} = id - \frac{\nabla\psi}{\|\nabla\psi\|}\otimes\frac{\nabla\psi}{\|\nabla\psi\|}.$$

The first terms on the left and right sides of (3.1) are shown to represent $\partial_t u = \nabla_\Gamma\cdot(\nu\nabla_\Gamma\mu)$; see [2]. In the second and third terms on the left side we use the level set equation $\partial_t\psi + V\|\nabla\psi\| = 0$ to obtain V and the definition of H in level set form. We obtain

$$V = -\frac{\partial_t\psi}{\|\nabla\psi\|},$$

$$H = \nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|}.$$

The second term on the left side can be rewritten as

$$u\partial_t\psi\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|} = \nabla\cdot\left(u\partial_t\psi\frac{\nabla\psi}{\|\nabla\psi\|}\right) - \partial_t\psi\nabla u\cdot\frac{\nabla\psi}{\|\nabla\psi\|} - u\nabla(\partial_t\psi)\cdot\frac{\nabla\psi}{\|\nabla\psi\|}.$$

For (2.22) we follow the level set representation for curvature regularized anisotropic mean curvature flow introduced by Burger et al. [5] and obtain

$$\begin{aligned}-\partial_t\psi + \frac{1}{b}\Bigg[\nabla\cdot\gamma_{1_z}\left(\frac{\nabla\psi}{\|\nabla\psi\|}\right) + \gamma_2(u)\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|} - \epsilon^2\left(\Delta_\Gamma H + H\left(\|S\|^2 - \frac{1}{2}H^2\right)\right)\\ - \mu - u\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|}\mu\Bigg]\|\nabla\psi\| = 0,\end{aligned} \tag{3.2}$$

with $\gamma_{1_z}\big(\frac{\nabla\psi}{\|\nabla\psi\|}\big) = D\gamma_1(\mathbf{n})$, where $D\gamma_1$ is the differential of the one-homogeneous function γ_1. H and S need to be replaced by their level set definitions, which will be done in the following weak formulation. The last term in (3.2) can be rewritten as

$$u\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|}\mu = \nabla\cdot\left(u\mu\frac{\nabla\psi}{\|\nabla\psi\|}\right) - \mu\nabla u\cdot\frac{\nabla\psi}{\|\nabla\psi\|} - u\nabla\mu\cdot\frac{\nabla\psi}{\|\nabla\psi\|},$$

and with (1.8) we have $\mu = \gamma_2'(u)$, which gives

$$\gamma_2(u)\nabla\cdot\frac{\nabla\psi}{\|\nabla\psi\|} = \nabla\cdot\left(\gamma_2(u)\frac{\nabla\psi}{\|\nabla\psi\|}\right) - \mu\nabla u\frac{\nabla\psi}{\|\nabla\psi\|}.$$

A weak form of (3.1) and (3.2) thus reads

$$\begin{aligned}
&\int_\Omega \|\nabla\psi\|\partial_t u\eta\,dx + \int_\Omega u\partial_t\psi\frac{\nabla\psi}{\|\nabla\psi\|}\cdot\nabla\eta\,dx + \int_\Omega \partial_t\psi\nabla u\cdot\frac{\nabla\psi}{\|\nabla\psi\|}\eta\,dx\\
&\qquad + \int_\Omega u\nabla(\partial_t\psi)\cdot\frac{\nabla\psi}{\|\nabla\psi\|}\eta\,dx - \int_\Omega \partial_t\psi\eta\,dx\\
&\quad = -\int_\Omega \nu\|\nabla\psi\|P_{\nabla\psi}\nabla\mu\cdot\nabla\eta\,dx - \int_\Omega k\|\nabla\psi\|\mu\eta\,dx,\\
&\int_\Omega \frac{b}{\|\nabla\psi\|}\partial_t\psi\xi\,dx + \int_\Omega \gamma_{1_z}\left(\frac{\nabla\psi}{\|\nabla\psi\|}\right)\cdot\nabla\xi\,dx + \int_\Omega \gamma_2(u)\frac{\nabla\psi}{\|\nabla\psi\|}\cdot\nabla\xi\,dx\\
&\qquad + \frac{\epsilon^2}{2}\int_\Omega \frac{\omega^2}{\|\nabla\psi\|^3}\nabla\psi\cdot\nabla\xi\,dx\\
&\qquad + \epsilon^2\int_\Omega \frac{P_{\nabla\psi}\nabla\omega}{\|\nabla\psi\|}\cdot\nabla\xi\,dx + \int_\Omega \mu\xi\,dx - \int_\Omega u\mu\frac{\nabla\psi}{\|\nabla\psi\|}\cdot\nabla\xi\,dx\\
&\qquad - \int_\Omega u\nabla\mu\cdot\frac{\nabla\psi}{\|\nabla\psi\|}\xi\,dx = 0,\\
&\int_\Omega \frac{\omega}{\|\nabla\psi\|}\varphi\,dx = \int_\Omega \frac{\nabla\psi}{\|\nabla\psi\|}\cdot\nabla\varphi\,dx,
\end{aligned}$$

with appropriate test functions η, ξ, and ϕ. The third equation results from setting $\omega = -\|\nabla\psi\|H$ in (3.2). To discretize in time we use an operator splitting approach, starting with the second and third equations, to obtain ψ^{n+1} by given ψ^n, u^n, and μ^n. We apply a convex splitting ansatz derived in [5] for the treatment of the nonlinear anisotropy term and obtain

$$\begin{aligned}
&\int_\Omega \frac{b}{\|\nabla\psi^n\|}\frac{\psi^{n+1}-\psi^n}{\tau^n}\xi\,dx + \int_\Omega \gamma_z\left(\frac{\nabla\psi^n}{\|\nabla\psi^n\|}\right)\cdot\nabla\xi\,dx + \int_\Omega \gamma_2(u^n)\frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\cdot\nabla\xi\,dx\\
&\qquad + \int_\Omega \frac{\lambda}{\|\nabla\psi^n\|}\gamma\left(\frac{\nabla\psi^n}{\|\nabla\psi^n\|}\right)(\nabla\psi^{n+1}-\nabla\psi^n)\cdot\nabla\xi\,dx\\
&\qquad + \frac{\epsilon^2}{2}\int_\Omega \frac{(\omega^n)^2}{\|\nabla\psi^n\|}\nabla\psi^{n+1}\cdot\nabla\xi\,dx + \epsilon^2\int_\Omega \frac{\omega^{n+1}}{\|\nabla\psi^n\|}\cdot\nabla\xi\,dx\\
&\qquad - \epsilon^2\int_\Omega \frac{\big(\mathrm{id}-P_{\nabla\psi^n}\big)\nabla\omega^n}{\|\nabla\psi^n\|}\cdot\nabla\xi\,dx + \int_\Omega \mu^n\xi\,dx - \int_\Omega u^n\mu^n\frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\cdot\nabla\xi\,dx
\end{aligned}$$

$$-\int_\Omega u^n\nabla\mu^n\cdot\frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\xi\,dx = 0, \tag{3.3}$$

$$\int_\Omega \frac{\omega^{n+1}}{\|\nabla\psi^n\|}\varphi\, dx = \int_\Omega \frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\cdot\nabla\varphi\, dx, \tag{3.4}$$

with λ an appropriate parameter. ψ^{n+1} is then used in the first equation to determine u^{n+1} by given u^n, ψ^n, and ψ^{n+1}:

$$\begin{aligned}
&\int_\Omega \|\nabla\psi^{n+1}\|\frac{u^{n+1}-u^n}{\tau^n}\, dx + \int_\Omega u^{n+1}\frac{\psi^{n+1}-\psi^n}{\tau^n}\frac{\nabla\psi^{n+1}}{\|\nabla\psi^{n+1}\|}\cdot\nabla\eta\, dx\\
&\quad + \int_\Omega \frac{\psi^{n+1}-\psi^n}{\tau^n}\nabla u^{n+1}\cdot\frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\eta\, dx + \int_\Omega u^{n+1}\frac{\nabla\big(\psi^{n+1}-\psi^n\big)}{\tau^n}\cdot\frac{\nabla\psi^{n+1}}{\|\nabla\psi^n\|}\eta\, dx\\
&\quad - \int_\Omega \frac{\psi^{n+1}-\psi^n}{\tau^n}\eta\, dx\\
&= -\int_\Omega \nu\|\nabla\psi^{n+1}\|P_{\nabla\psi}\nabla\mu^{n+1}\cdot\nabla\eta\, dx - \int_\Omega k\|\nabla\psi^{n+1}\|\mu^{n+1}\eta\, dx. \qquad (3.5)
\end{aligned}$$

For the calculation of u^{n+1} the adatom density u^n of the last timestep is needed at the new interface ψ^{n+1}. The interface moves in a normal direction. So to ensure that u^n has adequate values at the new interface, we extend the adatom density in direction normal to the interface after each timestep. The extension is done by an adaption of the redistancing algorithm introduced in [19] and described in detail in [4]. The approach uses the Hopf–Lax formula and offers an efficient alternative to fast marching or fast sweeping algorithms, which works also on unstructured grids.

The equations resulting from (3.3)–(3.5) are linear and are discretized in space by linear finite elements. To describe the linear system to be solved we use the following weighted mass, first order, and stiffness matrices:

$$M[f] := \left(\int_\Omega f\,\varphi_i\,\varphi_j\, dx\right)_{i,j}, \qquad F[v] := \left(\int_\Omega v\cdot\nabla\varphi_i\,\varphi_j\, dx\right)_{i,j},$$

$$L[f] := \left(\int_\Omega f\,\nabla\varphi_i\,\nabla\varphi_j\, dx\right)_{i,j}, \qquad L[A] := \left(\int_\Omega A\,\nabla\varphi_i\,\nabla\varphi_j\, dx\right)_{i,j},$$

with functions $f:\Omega\to\mathbb{R}$, $v:\Omega\to\mathbb{R}^d$ and $A:\Omega\to\mathbb{R}^{d\times d}$ and basis functions φ_i of the finite element space $\mathcal{V}^h$ defined through

$$\mathcal{V}^h = \{v\in C(\Omega)\mid v|_T \text{ is linear polynomial for } T\in\mathcal{T}\},$$

with $\mathcal{T}$ a decomposition of the polygonal domain Ω into triangles or tetrahedra and $\mathcal{V}_h\subset\mathcal{V}=H^1(\Omega)$. In the case of periodic boundary conditions on part of the boundary $\Gamma_{per}\subset\partial\Omega$, the corresponding periodic subspaces of $\mathcal{V}$ and $\mathcal{V}_h$ are used. Moreover we assume natural boundary conditions for all variables on the boundary $\partial\Omega\backslash\Gamma_{per}$. We make use of a norm regularization $\|\nabla\psi^n\|_\delta = (\|\nabla\psi^n\|^2+\delta^2)^{1/2}$, δ about the grid size, for small norm values $\|\nabla\psi^n\|$. With the matrices and right-hand side vectors

$$\begin{aligned}
M_1 &:= M[\|\nabla\psi^n\|_\delta^{-1}], & M_2 &:= M[1],\\
M_3 &:= M[b\,\|\nabla\psi^n\|_\delta^{-1}], & M_4 &:= M[k\,\|\nabla\psi^n\|_\delta],\\
M_5 &:= M[\|\nabla\psi^{n+1}\|_\delta], & M_6 &:= M[\|\nabla\psi^{n+1}\|_\delta^{-1}\,\nabla\psi^{n+1}\cdot\nabla\big(\psi^{n+1}-\psi^n\big)],\\
F_1 &:= F[u^n\,\nabla\mu^n\,\|\nabla\psi^n\|_\delta^{-1}], & F_2 &:= F[\big(\psi^{n+1}-\psi^n\big)\,\|\nabla\psi^{n+1}\|_\delta^{-1}\,\nabla\psi^{n+1}],\\
L_1 &:= L[(W^n)^2\,\|\nabla\psi^n\|_\delta^{-3}], & L_3 &:= L[\|\nabla\psi^n\|_\delta^{-1}],\\
L_4 &:= L[(id-P_{\nabla\psi^n})\,\|\nabla\psi^n\|_\delta^{-1}], & L_5 &:= L\left[\gamma\left(\frac{\nabla\psi^n}{\|\nabla\psi^n\|_\delta}\right)\,\|\nabla\psi^n\|_\delta^{-1}\right],\\
L_6 &:= L[\nu\,P_{\nabla\psi^n}\,\|\nabla\psi^n\|_\delta], & L_7 &:= L[u^n\,\mu^n\,\|\nabla\psi^n\|_\delta^{-1}],\\
L_8 &:= L[(u^n)^2\,\|\nabla\psi^n\|_\delta^{-1}], & G &:= \left(\int_\Omega \gamma_z\left(\frac{\nabla\psi^n}{\|\nabla\psi^n\|_\delta}\right)\cdot\nabla\varphi_j\,dx\right)_j,
\end{aligned}$$

and the linear expansions

$$\psi^{n+1}=\sum_{i=1}^{L}\Psi_i^{n+1}\varphi_i,\qquad \omega^{n+1}=\sum_{i=1}^{L}W_i^{n+1}\varphi_i,$$
$$\mu^{n+1}=\sum_{i=1}^{L}\Upsilon_i^{n+1}\varphi_i,\qquad u^{n+1}=\sum_{i=1}^{L}U_i^{n+1}\varphi_i,$$

with L the dimension of the finite element space $\mathcal{V}^h$, the linear system for (3.3) and (3.4) then reads

$$\begin{pmatrix} \begin{array}{c} M_3+\tau\frac{\epsilon^2}{2}L_1+\tau\lambda L_5\\ -\tau L_7+\tau\frac{\alpha}{2}L_8-\tau F_1\end{array} & \tau\epsilon^2 L_3\\ -L_3 & M_1\end{pmatrix}\begin{pmatrix}\Psi^{n+1}\\ W^{n+1}\end{pmatrix}=\begin{pmatrix}\begin{array}{c} -\tau M_2\Upsilon^n+M_3\Psi^n+\tau\epsilon^2L_4W^n\\ +\tau\lambda L_5\Psi^n-\tau G\end{array}\\ 0\end{pmatrix}.$$

We use a Schur complement approach to solve the system for the unknown ψ^{n+1}, which gives

$$\begin{aligned}
&\left(M_3+\tau\frac{\epsilon^2}{2}L_1+\tau\lambda L_5-\tau L_7+\tau\frac{\alpha}{2}L_8-\tau F_1+\tau\epsilon^2L_3M_1^{-1}L_3\right)\Psi^{n+1}\\
&\qquad=-\tau M_2\Upsilon^n+M_3\Psi^n+\tau\epsilon^2L_4W^n+\tau\lambda L_5\Psi^n-\tau G,
\end{aligned}$$

where W^n is calculated via $W^n=M_1^{-1}L_3\psi^n$ and the inverse M_1^{-1} is obtained with mass lumping. The Schur complement system is solved by a GMRES solver, as the system matrix might not be positive definite for the timesteps used. Within the special case of a free energy γ such that $\mu=\alpha u$, with α a positive parameter, the system for (3.5) reads

$$\big[M_5+\big(F_2+F_2^T\big)+M_6+\tau\alpha L_6+\tau\alpha M_4\big]\,U^{n+1}=M_5U^k+M_2\big(\Psi^{k+1}-\Psi^k\big)$$

and is solved by a GMRES solver.

4. Simulation results. The derived numerical scheme is implemented in the adaptive finite element toolbox AMDiS [20]. The toolbox provides a framework for the efficient solution of systems of partial differential equations by adaptive finite

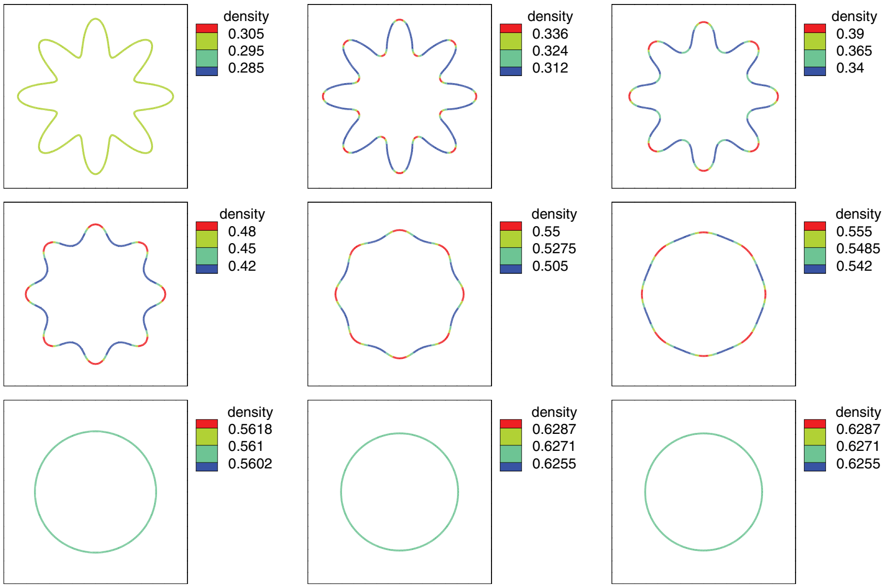

FIG. 4.1. *Isotropic evolution of interface and adatom density. Simulation parameters:* $[0,4] \times [0,4]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.3$*. From top left to bottom right:* $t = 0.0$, 0.002, 0.01, 0.03, 0.06, 0.09, 0.2, 2.5, 3.0.

elements. In the following examples linear finite elements are used on unstructured simplicial meshes, and the refinement is based on bisection. The criteria for refinement/coarsening is heuristic and based on the distance to the zero level set. This reduces the computational overhead by allowing for coarse meshes away from the zero level set. The computational cost is therefore comparable to a narrow band approach or a phase-field approximation with adaptive refinement at the diffuse interface.

The examples are chosen such that the influence of the adatom density is highlighted. For that purpose we compare the results with the corresponding model (1.5) in which the adatom density is neglected. The numerical approach used to solve (1.5) is described in [18]. In all simulations we use either the isotropic function $\gamma_1(\mathbf{n}) = 1$ or the anisotropic function

$$\gamma_1(\mathbf{n}) = 1 + a \sum_{k=1}^{d} n_k^4, \quad d = 2, 3,$$

with n_k denoting the kth spatial component of the normal. If not stated otherwise, we choose $a = 2.0$ (i.e., γ_1 is nonconvex), $\alpha = 1.0$ (i.e., $\mu = u$), the regularization parameter $\epsilon = 0.1$, the evaporation modulus $k = 0$, the kinetic coefficient $b = 1.0$, and the surface mobility $\nu = 1.0$. The relation between grid size h at the interface and timestep Δt is $\Delta t \leq h^4/\epsilon^2$. As ϵ has to be resolved by h we obtain with $h \sim \epsilon$ a timestep restriction of approximately $\Delta t \leq h^2$, which justifies the use of a semi-implicit discretization, as the restriction for an explicit strategy would be $\Delta t \leq h^6$ for the underlying sixth order problem.

Figure 4.1 shows the evolution of a perturbed circle with initial constant adatom concentration to the Wulff shape under isotropic conditions. The results are in agreement with the phase-field simulations for the same problem considered in [17]. The

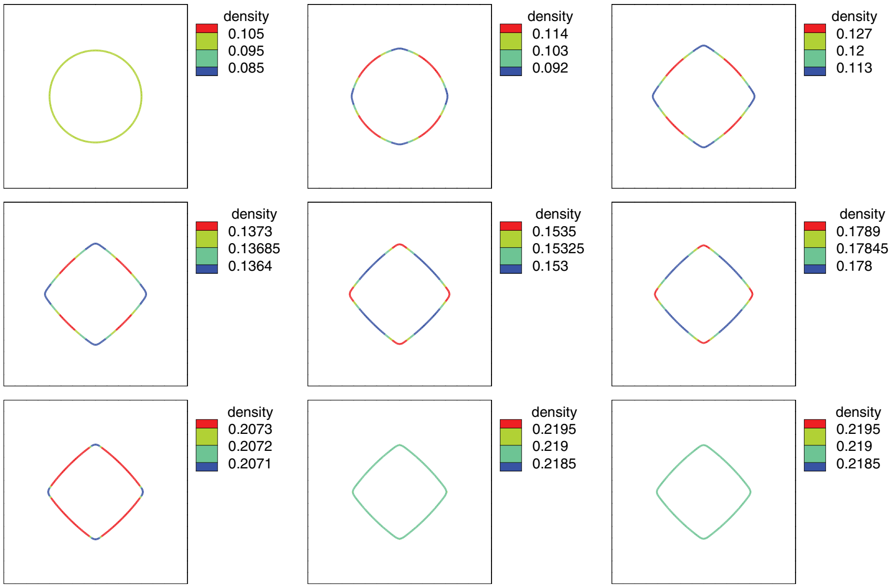

FIG. 4.2. *Anisotropic evolution of interface and adatom density. Simulation parameters:* $[0,4] \times [0,4]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.1$*,* $\alpha = 10.0$*. From top left to bottom right:* $t = 0.0$, 0.005, 0.02, 0.04, 0.06, 0.1, 0.2, 0.5, 1.0.

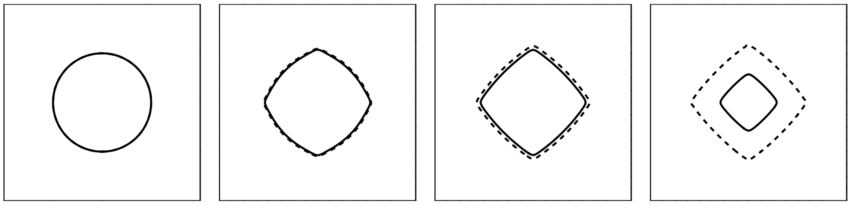

FIG. 4.3. *Anisotropic evolution: comparison of adatom model (solid) and kinetic model (dashed). Simulation parameters:* $[0,4] \times [0,4]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$ *(adatom model), and* $\Delta t = 5 \times 10^{-6}$ *(kinetic model). In adatom model:* $u_0 = 0.1$*. From left to right:* $t = 0.0$, 0.01, 0.03, 0.2.

perturbations smooth out and influence the adatom concentration, which adjusts to the local curvature and velocity. After a circle is obtained the adatom concentration becomes constant and converges to an equilibrium value, which is determined through the initial conditions.

Figure 4.2 shows the evolution of a circle with a constant initial adatom concentration to its Wulff shape under anisotropic conditions. Again the adatom concentration adjusts during the evolution to the local curvature and velocity, but if the Wulff shape is reached the adatom concentration becomes constant and converges towards its equilibrium value, which again depends on the initial conditions. Thus in equilibrium the adatom concentration is constant, independent on the local curvature.

If we compare this evolution with the kinetic surface diffusion model in which adatoms are neglected, we obtain similar results on the dynamics and the equilibrium shape; see Figure 4.3. The only difference is the size of the final shape, as in the kinetic surface diffusion model conservation in mass results in conservation in area, which is

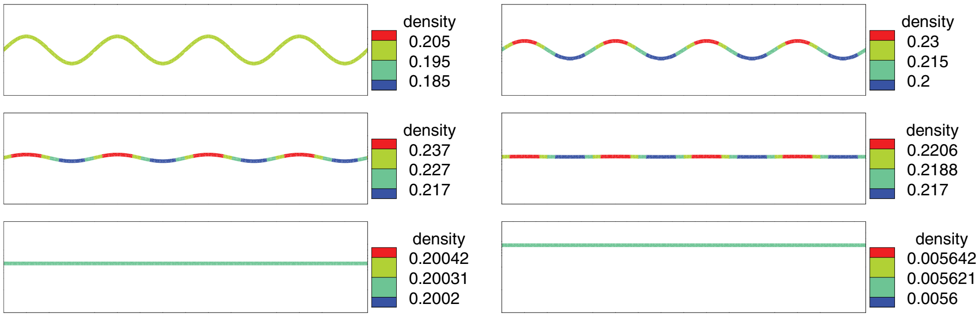

FIG. 4.4. *Isotropic evolution of interface and adatom density. Simulation parameters:* $[0,4] \times [-0.5,0.5]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0$, 0.01, 0.03, 0.09, 0.2, 7.0.

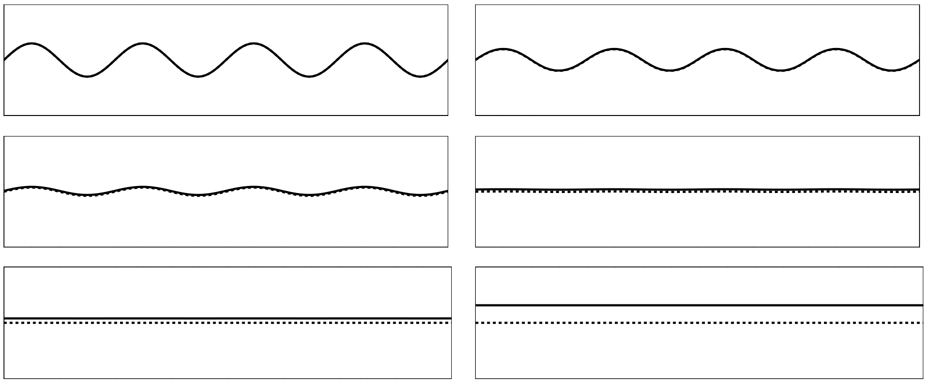

FIG. 4.5. *Isotropic evolution: comparison of adatom model (solid) and kinetic model (dashed). Simulation parameters:* $[0,4] \times [-0.5,0.5]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$ *(adatom model), and* $\Delta t = 5 \times 10^{-6}$ *(kinetic model). In adatom model:* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0$, 0.01, 0.03, 0.09, 0.2, 1.3.

not the case in the adatom model. Here the area can be reduced by increasing the adatom density. From a numerical point of view an additional difference is observed. The timesteps in the adatom model can be chosen larger than for the kinetic surface diffusion model. This results from the diffusion character of the adatom model and has already been speculated in [9].

The following examples are devoted to curves, which are not closed. Figure 4.4 shows the evolution of a perturbed straight line with a constant initial adatom concentration under isotropic conditions. In agreement with the results obtained by a graph formulation [3] and a phase-field formulation [17] the perturbations smooth out and the adatom concentration adjusts to the local curvature and velocity. After a straight line is formed the adatom concentration converges to zero.

In Figure 4.5 the evolution is compared with the kinetic surface diffusion model in which adatoms are neglected. Again the results agree, with the only difference being that the height in the adatom model is higher, which results from the additional mass from the adatoms, which become incorporated during the evolution. Numerically we again can use larger timesteps in the adatom model.

Figure 4.6 shows the evolution of a perturbed straight line with a constant initial

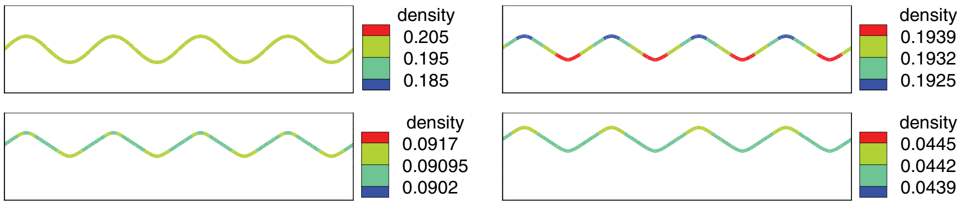

FIG. 4.6. *Anisotropic evolution of interface and adatom density. Simulation parameters:* $[0,4]\times[-1.0,1.0]$ *grid (shown here:* $[0,4]\times[-0.5,0.5]$*), grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0$, 0.001, 1.0, 2.0.

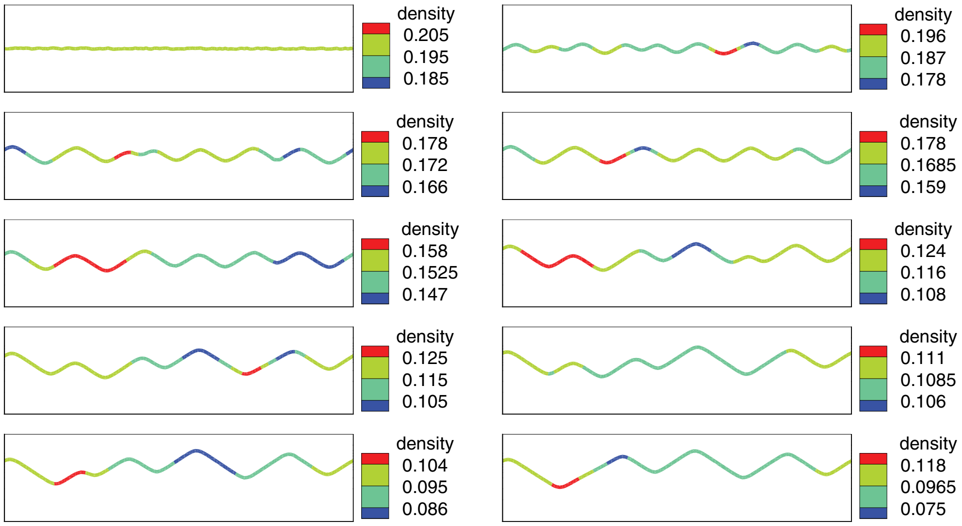

FIG. 4.7. *Anisotropic evolution of interface and adatom density. Simulation parameters:* $[0,4]\times[-1.0,1.0]$ *grid (shown here:* $[0,4]\times[-0.5,0.5]$*), grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0$, 0.02, 0.04, 0.06, 0.07, 0.2, 0.76, 0.8, 1.2, 2.6.

adatom concentration under anisotropic conditions. We observe the facet formation and the adjustment of the adatom concentration to the local curvature and velocity. After the facets are formed the adatom concentration is reduced. The structure, however, is not stable, due to the corner energy resulting from the regularization. Thus coarsening is expected, which will reduce the number of corners.

To further study the coarsening, we now start from an initially unstable orientation with an initially constant adatom concentration. Figures 4.7 and 4.8 show the spinodal decomposition into allowed orientations and the subsequent coarsening of the structure. The influence of the coarsening event on the adatom concentration can clearly be observed. During coarsening the interface moves fast. High velocities in the coarsening areas result in a smaller adatom concentration where the interface moves in a positive normal direction and a higher adatom concentration where the interface moves in a negative normal direction.

Again we compare this evolution with the kinetic surface diffusion model. Figure 4.9 shows the qualitative agreement. Numerically we again can use larger timesteps in the adatom model.

Finally we show results in three dimensions. We start with a cube and a constant

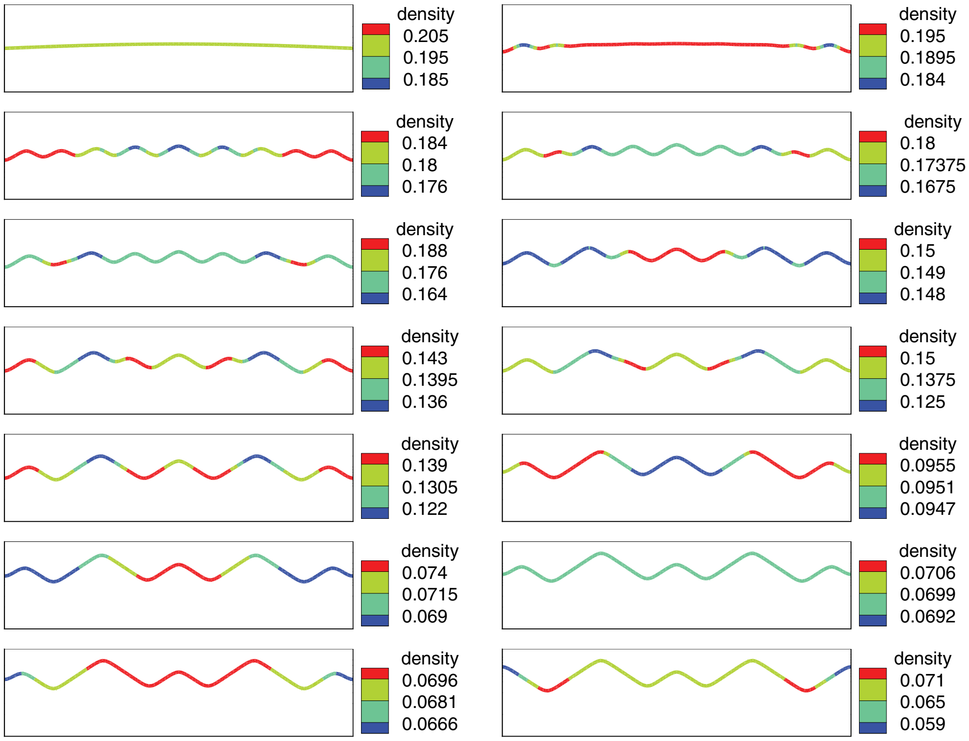

FIG. 4.8. *Anisotropic evolution of interface and adatom density. Simulation parameters:* $[0, 4] \times [-1.0, 1.0]$ *grid (shown here:* $[0, 4] \times [-0.5, 0.5]$*), grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$*,* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0, 0.008, 0.02, 0.07, 0.08, 0.3, 0.4, 0.42, 0.43, 0.9, 1.4, 2.4, 2.5, 2.6$.

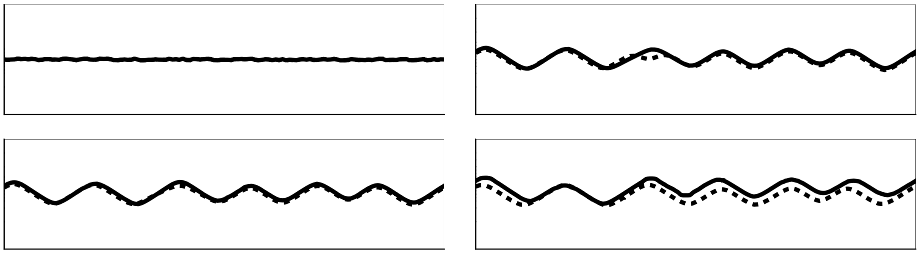

FIG. 4.9. *Anisotropic evolution: comparison of adatom model (solid) and kinetic model (dashed). Simulation parameters:* $[0, 4] \times [-0.5, 0.5]$ *grid, grid size* $h = 0.03125$*, timestep* $\Delta t = 10^{-5}$ *(adatom model), and* $\Delta t = 5 \times 10^{-6}$ *(kinetic model). adatom density, which relaxes to sphere. The adatom density adjusts to local curvature and velocity during evolution and saturates at a constant value; see Figure 4.10. Figure 4.11 shows the evolution of a randomly perturbed initial surface within an unstable orientation and a constant initial adatom concentration. Again the facet formation and the subsequent coarsening of the surface morphology can be observed. The adatom concentration adjusts to the local curvature and velocity. If we start with a periodic structure and a constant initial adatom concentration, we observe a sym-

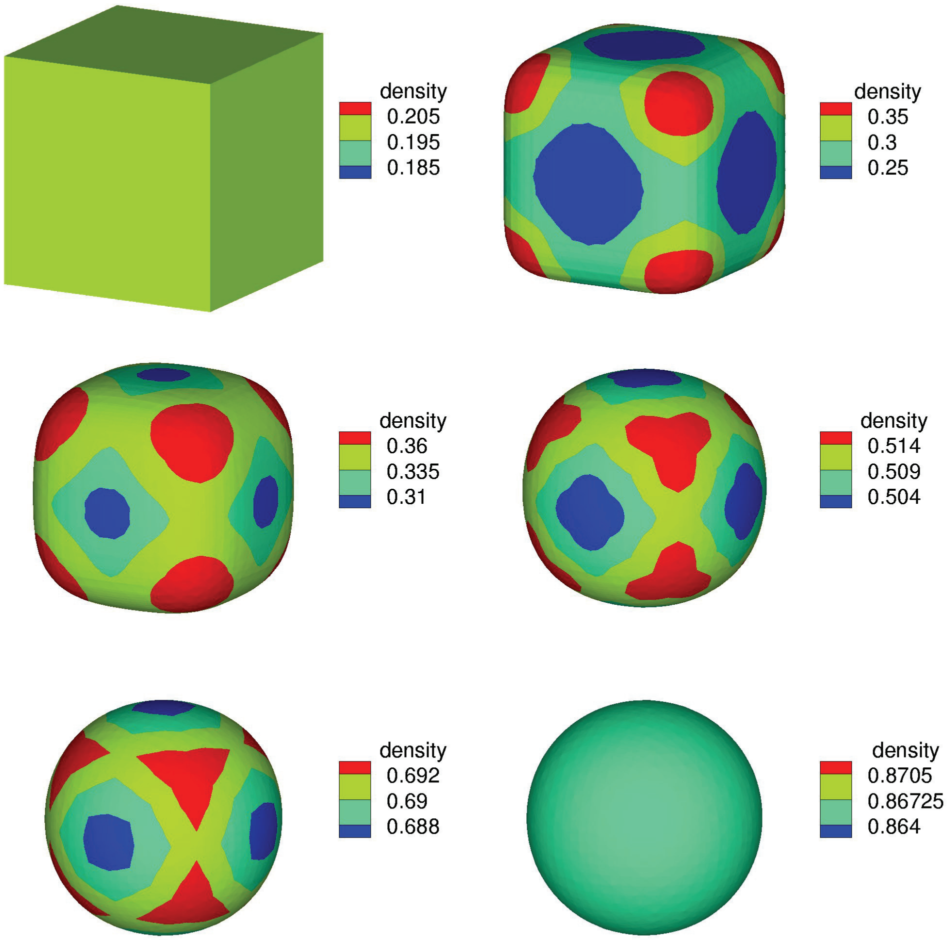

FIG. 4.10. *Isotropic evolution of interface and adatom density. Simulation parameters:* $[0.0, 4.0] \times [0.0, 4.0] \times [0.0, 4.0]$ *grid, grid size* $h = 0.0625$*, timestep* $\Delta t = 10^{-5}$*,* $\epsilon = 0.0$*,* $u_0 = 0.2$*. From top left to bottom right:* $t = 0.0$, 0.02, 0.05, 0.1, 0.15, 0.2.

metric coarsening in which four mounds collapse to form one mound; see Figure 4.12. This symmetry is probably a result of the 4-fold symmetry of the anisotropy function. A further example in Figure 4.10 shows the evolution of a cube with initial constant adatom concentration under isotropic conditions.

A more detailed study on the coarsening with more realistic physical parameters also under growth will be done elsewhere. Of interest is the influence of the adatom density on coarsening laws, as derived by Haußer and Voigt [11, 12]. The simulations in this paper are depicted to show the applicability of the algorithm. It has been shown that the introduced level set approach can be used to efficiently solve evolution equations on evolving surfaces. The approach is not restricted to diffusion problems on evolving surfaces but can be generalized to other equations as well.

Acknowledgment. The authors thank Martin Burger for helpful discussions.

INVERSE SOURCE PROBLEM IN NONHOMOGENEOUS BACKGROUND MEDIA. PART II: VECTOR FORMULATION AND ANTENNA SUBSTRATE PERFORMANCE CHARACTERIZATION[*]

EDWIN A. MARENGO[†], MOHAMED R. KHODJA[†], AND ABDELKADER BOUCHERIF[‡]

Abstract. This paper solves analytically and illustrates numerically the full-vector, electromagnetic inverse source problem of synthesizing an unknown source embedded in a given substrate medium of volume V and radiating a prescribed exterior field. The derived formulation and results generalize previous work on the scalar version of the problem, especially the recent Part I of this paper [A. J. Devaney, E. A. Marengo, and M. Li, *SIAM J. Appl. Math.*, 67 (2007), pp. 1353–1378]. Emphasis is put on substrates having constant constitutive properties within the source volume V, which, for formal tractability, is taken to be of spherical shape. The adopted approach is one of constrained optimization which also relies on spherical wavefunction theory. We find that the observed peaks in the spectrum of the singular values are primarily due to the phenomenon of Mie resonance. Therefore, for a given antenna radiating at a prescribed frequency, the set of solutions to the Mie resonance conditions corresponds to a set of constitutive parameters that maximize the radiated electromagnetic fields. The derived theory and associated implications for antenna substrates are illustrated numerically.

1. Introduction.

In this paper we investigate the full-vector, electromagnetic inverse source problem of reconstructing an unknown source (antenna) that is embedded, within a spherical region $V \equiv \left\{\mathbf{r} \in \mathbb{R}^3 : r \equiv |\mathbf{r}| \leq a\right\}$, in a given material or metamaterial substrate, and that radiates a given exterior field outside V. The derived formulation and results of this *inverse source problem in substrate media* generalize, within the full-vector formulation, previous work on the inverse source problem in free space (cf. [32] and the references therein), as well as previous work on the scalar version of the problem for nonhomogeneous backgrounds [13, 43], particularly Part I of this paper [12], coauthored by one of the authors of the present paper (Marengo). The formulation is based on constrained optimization. Two solution constraints are emphasized in the paper, in particular, the minimizing of the source L^2-norm or functional energy characterizing the "current level," with and without tuning to resonance, the former case corresponding to zero source reactive power. The ability of an antenna to radiate a prescribed power with reduced current levels as characterized by this norm is an indication of efficiency which has been adopted as a constraint in the antenna synthesis problem [5, 9]. Fundamental radiation limits related to the realizability of given fields or radiation performance with given source resources (antenna size, current level as measured by the source energy, reactive power, and so on)

or, alternatively, of the minimal resources needed for a given performance, are also elucidated as a by-product of the derived inverse source theory.

Motivation for this research is provided by the possibility of embedding an antenna in a substrate of a given size, where the original antenna plus the substrate are treated as the total antenna, so as to generate a given field or performance level which could not be achieved under the same physical constraints by another antenna in free space (i.e., without the substrate medium). This possibility has attracted interest from time to time in the antenna community; of particular interest have been a variety of antenna-embedding materials, including plasmas [37], nonmagnetic dielectrics [24, 25, 27, 26, 22, 2], magneto-dielectrics [18, 10, 36, 29], and, more recently, double-negative and single-negative metamaterials, which are receiving much attention as antenna performance-enhancing substrates by a number of groups [41, 40, 16, 3, 48, 42, 17, 28, 47]. The envisaged property is miniaturization of antennas by controlling electric size, via larger wavenumber, but other effects are involved, particularly when metamaterials are used. (A review of the pertinent state-of-the-art can be found in [15].)

For instance, it is well known [31, 34] that in the free-space case the source energy increases exponentially, for a given radiation pattern, with decreasing k_0a, where k_0 is the free-space wavenumber of the field. This increase occurs below a critical point determined by the fine detail that is desired in the radiation pattern, specifically, the antenna directivity. The question then is whether the critical source size in question can be made smaller by embedding the source in a properly selected substrate which becomes integral to the antenna. For small antennas (whose dimensions are smaller than about 1/3 of the wavelength [45, 46]) one is particularly interested in achieving radiation of an elemental dipolar mode, using minimal resources. Can antenna substrates help toward this goal? Alternatively, in certain applications using larger, resonant antennas whose dimensions are comparable to or larger than the wavelength, one can dispose of some “extra space” to accommodate a substrate, and the question is, Does antenna embedding yield enhancement of antenna directivity? Which values of the constitutive parameters give better performance?

We address these and related questions aided by the formalism of the inverse source problem, paying particular attention to lossless piecewise-constant radially symmetric backgrounds having electric permittivity ϵ_s and permeability μ_s. In particular, the total permittivity distribution is of the form

$$\epsilon(\mathbf{r}) = \epsilon_s\Theta(a-r) + \epsilon_0\Theta(r-a), \tag{1.1}$$

where Θ denotes Heaviside's unit step function ($\Theta(x) = 1$ for $x \geqslant 1$; otherwise $\Theta(x) = 0$), and the total permeability distribution is of the form

$$\mu(\mathbf{r}) = \mu_s\Theta(a-r) + \mu_0\Theta(r-a). \tag{1.2}$$

All the results are derived for time-harmonic fields, and thus the values of the constitutive parameters, which generally vary with frequency, are considered in this work for a given central frequency only.

Our results reveal the performance improvements due to antenna-embedding substrates from a fundamental inverse antenna theory point of view which is different from and complementary to efforts by other groups in this fruitful area. The observed peaks in the spectrum of the singular values of the source-to-exterior field mapping are primarily due to the phenomenon of Mie resonance, and maximum enhancement conditions are effectively summarized by the Mie resonance conditions (4.2) and (4.3).

Therefore, for a given antenna radiating at a prescribed frequency, the set of solutions to (4.2) and (4.3) corresponds to a set of constitutive parameters that maximize the radiated electromagnetic fields. As their amplitudes increase these radiated fields draw energy from the embedding medium. But because this medium is of finite extent the energy extraction process saturates, ultimately, and as a result of this saturation the fields fall short of effectively "blowing up."

2. The forward problem.

2.1. Electromagnetic generalities. Our starting point is provided by the frequency-domain Maxwell equations for a generally lossless, nonhomogeneous medium, in particular [7, 11],

$$\nabla \times \mathbf{E}(\mathbf{r}) = i\omega\mu(\mathbf{r})\mathbf{H}(\mathbf{r}), \tag{2.1}$$

$$\nabla \times \mathbf{H}(\mathbf{r}) = \mathbf{J}(\mathbf{r}) - i\omega\epsilon(\mathbf{r})\mathbf{E}(\mathbf{r}), \tag{2.2}$$

where $\mathbf{J}(\mathbf{r})$ represents an impressed current density (i.e., the source) confined within the spherical volume V, and $\mathbf{E}(\mathbf{r})$ and $\mathbf{H}(\mathbf{r})$ are, respectively, the electric and magnetic fields it generates. (These fields are subject to the radiation condition [38].) Substituting $\mathbf{H}(\mathbf{r})$ from (2.1) into (2.2) yields the vector wave equation

$$\nabla \times \left(\frac{\nabla \times \mathbf{E}(\mathbf{r})}{\mu(\mathbf{r})} \right) - \omega^2\epsilon(\mathbf{r})\mathbf{E}(\mathbf{r}) = i\omega\mathbf{J}(\mathbf{r}). \tag{2.3}$$

The partial differential operator in (2.3) admits an outgoing-wave dyadic Green's function $\bar{\mathbf{G}}(\mathbf{r}, \mathbf{r}')$ which, along with the radiation condition, obeys

$$\nabla \times \left(\frac{\nabla \times \bar{\mathbf{G}}(\mathbf{r}, \mathbf{r}')}{\mu(\mathbf{r})} \right) - \omega^2\epsilon(\mathbf{r})\bar{\mathbf{G}}(\mathbf{r}, \mathbf{r}') = i\omega\delta(\mathbf{r} - \mathbf{r}')\bar{\mathbf{I}}, \tag{2.4}$$

where $\bar{\mathbf{I}}$ denotes the identity dyadic and δ the Dirac delta.

For future convenience we define the weighted inner product

$$(\mathbf{f}, \mathbf{f}') = \int d\mathbf{r} M(\mathbf{r}) \mathbf{f}^*(\mathbf{r}) \cdot \mathbf{f}'(\mathbf{r}), \tag{2.5}$$

where $\mathbf{f}$ and $\mathbf{f}'$ are any two functions of position and the asterisk $*$ denotes the complex conjugate; $M(\mathbf{r})$ is a characteristic (indicator or masking) function defined as

$$M(\mathbf{r}) = \begin{cases} 1, & \mathbf{r} \in V, \\ 0, & \mathbf{r} \notin V. \end{cases} \tag{2.6}$$

Using this inner product, we express the source energy $\mathcal{E}$ as

$$\mathcal{E} \equiv (\mathbf{J}, \mathbf{J}), \tag{2.7}$$

and the complex interaction power $\mathcal{P}$ (cf. [7]) as

$$\mathcal{P} = -\frac{1}{2}(\mathbf{J}, \widetilde{\mathbf{G}}\mathbf{J}), \tag{2.8}$$

where we have introduced the linear mapping $\widetilde{\mathbf{G}}$ defined by

$$[\widetilde{\mathbf{G}}\mathbf{J}](\mathbf{r}) \equiv \int d\mathbf{r}' \bar{\mathbf{G}}(\mathbf{r}, \mathbf{r}') \cdot \mathbf{J}(\mathbf{r}'). \tag{2.9}$$

The real part of $\mathcal{P}$, i.e., $\Re\,[\mathcal{P}]$, represents the radiated power which is determined by the multipole moments $a_{l,m}^{(j)}$ via [14, 21, 30]

$$\Re\,[\mathcal{P}] = \frac{1}{2\eta_0}\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} l(l+1)|a_{l,m}^{(j)}|^2, \tag{2.10}$$

where $\eta_0 = \sqrt{\mu_0/\epsilon_0}$ is the free-space wave impedance.

On the other hand, the imaginary part of $\mathcal{P}$, i.e., $\Im\,[\mathcal{P}]$, corresponds to the energy-storage reactive power [7]. It can have a prescribed value, say, zero (as was shown in [32, 34]), which corresponds to a tuned antenna and is one of the solution constraints to be employed in the formulation to follow. We note that the reactive power can be expressed as

$$\Im\,[\mathcal{P}] = -\frac{1}{2}\int_V d\mathbf{r}\mathbf{J}^*(\mathbf{r})\cdot\int_V d\mathbf{r}'\bar{\mathbf{G}}_S(\mathbf{r},\mathbf{r}')\cdot\mathbf{J}(\mathbf{r}') \equiv -\frac{1}{2}(\mathbf{J},\widetilde{\mathbf{G}}_S\mathbf{J}), \tag{2.11}$$

where

$$\bar{\mathbf{G}}_S(\mathbf{r},\mathbf{r}') \equiv \Im\left[\bar{\mathbf{G}}(\mathbf{r},\mathbf{r}')\right] = \frac{1}{2i}\left[\bar{\mathbf{G}}(\mathbf{r},\mathbf{r}') - \bar{\mathbf{G}}^*(\mathbf{r},\mathbf{r}')\right], \tag{2.12}$$

and where we have introduced the linear mapping $\widetilde{\mathbf{G}}_S$ defined by (2.9) after the substitutions $\widetilde{\mathbf{G}} \to \widetilde{\mathbf{G}}_S$ and $\bar{\mathbf{G}} \to \bar{\mathbf{G}}_S$.

2.2. Source-to-multipole-moment mapping. To formulate the inverse problem for the cases described in (1.1) and (1.2) it is necessary to first have at our disposal the solution of the associated forward or radiation problem. To accomplish this, we note that, for these cases, the electric field $\mathbf{E}(\mathbf{r})$ generated by the most general source of support V can be represented, outside V, by the multipole expansion [14]

$$\mathbf{E}(\mathbf{r}) = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} a_{l,m}^{(j)}\mathbf{\Lambda}_{l,m}^{(j)}(\mathbf{r}), \quad \mathbf{r}\notin V, \tag{2.13}$$

where the complex-valued expansion coefficients $a_{l,m}^{(j)}$ are the multipole moments of the field, and where the multipole fields are

$$\mathbf{\Lambda}_{l,m}^{(j)}(\mathbf{r}) = \begin{cases} \mathbf{\nabla}\times[h_l^{(+)}(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], & j=1, \\ \\ ik_0 h_l^{(+)}(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & j=2, \end{cases} \tag{2.14}$$

where $\hat{\mathbf{r}} \equiv \mathbf{r}/r$; $h_l^{(+)}$ denotes the spherical Hankel function of the first kind and order l (as defined in [6]), corresponding to outgoing spherical waves in the far zone; $\mathbf{Y}_{l,m}$ is the vector spherical harmonic of degree l and order m (as defined in [14, equations (4.7) and (4.8)]); and $j=1$ and $j=2$ correspond to electric and magnetic multipole fields, respectively. The scalar spherical harmonics $Y_{l,m}(\hat{\mathbf{r}})$ and the vector spherical harmonics $\mathbf{Y}_{l,m}(\hat{\mathbf{r}})$ satisfy the analytic continuation properties $Y_{l,m}^*(\hat{\mathbf{r}}) = (-1)^m Y_{l,-m}(\hat{\mathbf{r}})$ and $\mathbf{Y}_{l,m}^*(\hat{\mathbf{r}}) = (-1)^{m+1}\mathbf{Y}_{l,-m}(\hat{\mathbf{r}})$ along with well-known orthogonality properties that can be found, e.g., in [14] (see [20] for further details). We will employ these properties in the following.

At this point it is important to note that the multipole moments $a^{(j)}_{l,m}$ are *uniquely* determined by the tangential component of the electric field $\mathbf{E}(\mathbf{r})$ on a sphere of radius $R > a$, in particular,

$$a^{(j)}_{l,m} = \begin{cases} -\frac{i}{l(l+1)k_0 h_l^{(+)}(k_0R)} \int \mathbf{Y}^*_{l,m}(\hat{\mathbf{r}}) \cdot \mathbf{E}(R\hat{\mathbf{r}})d\hat{\mathbf{r}}, & j = 1, \\ \frac{1}{l(l+1)k_0 V_l(k_0R)} \int \hat{\mathbf{r}} \times \mathbf{Y}^*_{l,m}(\hat{\mathbf{r}}) \cdot \mathbf{E}(R\hat{\mathbf{r}})d\hat{\mathbf{r}}, & j = 2. \end{cases} \tag{2.15}$$

(This follows by expanding (2.13) using [33]

$$\boldsymbol{\nabla} \times [\phi_l(r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})] = \hat{\mathbf{r}}\frac{il(l+1)}{r}\phi_l(r)Y_{l,m}(\hat{\mathbf{r}}) + \frac{1}{r}\frac{d}{dr}[r\phi_l(r)]\hat{\mathbf{r}} \times \mathbf{Y}_{l,m}(\hat{\mathbf{r}}), \tag{2.16}$$

and then invoking the orthogonality properties of the vector spherical harmonics and the associated vector functions $\hat{\mathbf{r}} \times \mathbf{Y}_{l,m}(\hat{\mathbf{r}})$.)

The electric and magnetic multipole moments, $a^{(1)}_{l,m}$ and $a^{(2)}_{l,m}$, respectively, are related to the current distribution $\mathbf{J}$ by

$$a^{(j)}_{l,m} = (\boldsymbol{\mathfrak{B}}^{(j)}_{l,m}, \mathbf{J}), \quad j = 1, 2; \tag{2.17}$$

i.e., they are the projections of the current distribution $\mathbf{J}$ onto the set of source-free vector fields $\boldsymbol{\mathfrak{B}}^{(j)}_{l,m}$ which need to be determined for the particular antenna background medium. For the special free-space case where $\mu(\mathbf{r})/\mu_0 = 1 = \epsilon(\mathbf{r})/\epsilon_0$ the latter fields are the familiar source-free multipole fields, in particular (cf. [19] and [11]),

$$\mathbf{B}^{(j)}_{l,m}(\mathbf{r}) \equiv \begin{cases} -\frac{\eta_0}{l(l+1)}\boldsymbol{\nabla} \times [j_l(k_0r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], & j = 1, \\ -i\frac{k_0\eta_0}{l(l+1)} j_l(k_0r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & j = 2, \end{cases} \tag{2.18}$$

where j_l is the spherical Bessel function of the first kind and order l (as defined in [6], for instance). On the other hand, it is shown in Appendix A that, for piecewise-constant radially symmetric backgrounds whose permittivity and permeability are given by (1.1) and (1.2),

$$\boldsymbol{\mathfrak{B}}^{(j)}_{l,m}(\mathbf{r}) \equiv \begin{cases} \frac{-\eta_0}{l(l+1)} F_l^{*(1)}(k_0a, ka, \epsilon_r, \mu_r)\boldsymbol{\nabla} \times [j_l(k^*r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], & j = 1, \\ \frac{-ik_0\eta_0}{l(l+1)} F_l^{*(2)}(k_0a, ka, \epsilon_r, \mu_r) j_l(k^*r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & j = 2, \end{cases} \tag{2.19}$$

where the substrate wavenumber $k = \omega\sqrt{\mu_s\epsilon_s}$, the relative permittivity $\epsilon_r = \epsilon_s/\epsilon_0$, the relative permeability $\mu_r = \mu_s/\mu_0$, and where we have defined the complex amplitudes

$$F_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r) \equiv \begin{cases} \frac{i/\left(k_0ka^2\right)}{(\epsilon_r/\mu_r)^{1/2} j_l(ka)V_l(k_0a) - h_l^{(+)}(k_0a)U_l(ka)}, & j = 1, \\ \frac{i\mu_r/\left(k_0ka^2\right)}{(\mu_r/\epsilon_r)^{1/2} j_l(ka)V_l(k_0a) - h_l^{(+)}(k_0a)U_l(ka)}, & j = 2, \end{cases} \tag{2.20}$$

where

$$U_l\,(\lambda a) \equiv U_l\,(\lambda r)|_{r=a} \equiv \left[\frac{dj_l(\lambda r)}{d\,(\lambda r)} + \frac{j_l(\lambda r)}{\lambda r}\right]\Bigg|_{r=a} \tag{2.21}$$

and

$$V_l\left(\lambda a\right) \equiv V_l\left(\lambda r\right)\big|_{r=a} \equiv \left[\frac{dh_l^{(+)}(\lambda r)}{d\left(\lambda r\right)} + \frac{h_l^{(+)}(\lambda r)}{\lambda r}\right]\Bigg|_{r=a} . \tag{2.22}$$

Because of the self-imposed restriction to the study of lossless substrates, the relative constitutive parameters μ_r and ϵ_r admit only real values. Consequently, the wavenumber k can assume only real values (positive for double-positive materials and negative for double-negative metamaterials) or purely imaginary values (for single-negative metamaterials). When k is purely imaginary, i.e., $k = i\alpha$, $\alpha \in \mathbb{R}$, the arguments of the spherical Bessel functions involving k in (2.20)–(2.22) are, accordingly, purely imaginary. In this case one notes that the regular spherical Bessel functions j_l and $h_l^{(+)}$ are replaced, respectively, with the modified spherical Bessel functions i_l and k_l such that (cf., for instance, [6])

$$j_l\left(ka\right) \equiv i^l i_l(\alpha a) \tag{2.23}$$

and

$$h_l^{(+)}\left(ka\right) \equiv -i^{-l} k_l(\alpha a). \tag{2.24}$$

(There shall be no confusion between the modified spherical Bessel functions i_l and k_l and the imaginary unit i and the wavenumber k since the latter do not carry a subscript.)

We draw the attention of the reader to the fact that $F_l^{(j)}$, $j = 1, 2$, represent the Mie amplitudes due to the scattering of a plane electromagnetic wave off a sphere of radius a and wavenumber k embedded in an infinite homogeneous medium of wavenumber k_0, $F_l^{(1)}$ being the amplitudes of the electric oscillations and $F_l^{(2)}$ those of the magnetic oscillations. This should not come as a surprise in view of the physics of the problem as well as the formulation itself.

3. Inverse source theory based on constrained optimization.

The inverse source problem of deducing the source $\mathbf{J}(\mathbf{r})$, confined within V from knowledge of the exterior field $\mathbf{E}(\mathbf{r})$, is seen from (2.13) to be equivalent to that of determining the source from knowledge of the multipole moments, i.e., to that of inverting (2.17). The respective inversion is addressed next via a generalization of the free-space optimization theory in [32] to nonhomogeneous backgrounds. Emphasis is given to the particular case of piecewise-constant radially symmetric backgrounds, but most of the derived expressions apply to more general cases including that of spherically symmetric backgrounds.

3.1. Minimum energy solution by constrained optimization.

We start by addressing the problem of determining the minimum energy source $\mathbf{J}_{ME}$ embedded in a substrate of volume V with *fixed* constitutive parameters ϵ_r, μ_r and generating a given exterior field. The problem can be cast as

$$\min_{\mathbf{J}\in S} \mathcal{E}\left(\mathbf{J}\right), \tag{3.1}$$

where

$$S \equiv \left\{\mathbf{J} \in L^2\left(V; \mathbb{C}^3\right) : a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}, \mathbf{J}) = 0\right\}. \tag{3.2}$$

Note that the constraint set S is convex; also, the objective functional $\mathcal{E}$ is coercive and strictly convex.

If a minimizer $\mathbf{J}_{ME}$ exists, then its uniqueness and global minimality are ensured by the strict convexity of $\mathcal{E}$ and the convexity of S [4]. But what guarantees the existence of at least one such minimizer? We note that, since S is closed and since $\mathcal{E}$ is weakly sequentially lower semicontinuous, problem (3.1), (3.2) admits only one global solution.

It is well known [4] that difficulties related to the definition of linearity of the Fréchet differentiation operator would be encountered when f maps a complex Banach space (in our case $L^2(V;\mathbb{C}^3)$) into a real Banach space (in our case $\mathbb{R}$). This is in particular the case for $\mathcal{E}$ and $(\mathbf{J}, \widetilde{\mathbf{G}}_S\mathbf{J})$. In such cases one considers $L^2(V;\mathbb{C}^3)$ as a Hilbert space over $\mathbb{R}$ instead of $\mathbb{C}$ [4]. It is then easy to show that the Fréchet derivatives of $\mathcal{E}$ and the constraints are given by $\boldsymbol{\nabla}_\mathbf{J}\mathcal{E}(\mathbf{J}) = 2\mathbf{J}$ and that $\boldsymbol{\nabla}_\mathbf{J}\,[a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}, \mathbf{J})] = -\mathfrak{B}_{l,m}^{(j)}$, respectively. Due to the continuity of these derivatives and the fact that $\boldsymbol{\nabla}_\mathbf{J}\,[a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}, \mathbf{J})]|_{\mathbf{J}=\mathbf{J}_{ME}}$ maps $L^2(V;\mathbb{C}^3)$ onto $\mathbb{C}$, there exist [23] Lagrange multipliers $c_{l,m}^{(j)} \in \mathbb{C}$ such that the generalized Lagrangian

$$\mathcal{L}\left(\mathbf{J}, c_{l,m}^{(j)}\right) \equiv \mathcal{E} + 2\Re\left[\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)}\left(a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}\,,\, \mathbf{J})\right)\right] \tag{3.3}$$

is stationary at $\mathbf{J}_{ME}$.

To compute the solution we require that

$$\delta\mathcal{L} = 2\Re\left[\left(\delta\mathbf{J}\,,\,\mathbf{J} - \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)*}\mathfrak{B}_{l,m}^{(j)}\right)\right] = 0. \tag{3.4}$$

From the Du Bois-Raymond lemma, (3.4), and the forward mapping relations (2.17), (2.19), (2.20), one finds that for piecewise-constant radially symmetric backgrounds, the minimum-energy source is given by

$$\mathbf{J}_{ME}(\mathbf{r}) = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} \frac{a_{l,m}^{(j)}}{\left[\sigma_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r)\right]^2}\mathfrak{B}_{l,m}^{(j)}(\mathbf{r}), \tag{3.5}$$

where we have introduced the positive-definite "singular values"

$$[\sigma_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r)]^2 \equiv (\mathfrak{B}_{l,m}^{(j)}, \mathfrak{B}_{l,m}^{(j)}), \tag{3.6}$$

specifically,

$$\left[\sigma_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r)\right]^2 = |F_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r)|^2\left[\kappa_l^{(j)}(k_0a, ka)\right]^2, \tag{3.7}$$

where

$$\left[\kappa_l^{(j)}(k_0a, ka)\right]^2 \equiv \begin{cases} \eta_0^2\int_0^a dr\left[|j_l(kr)|^2 + \frac{|kr|^2}{l(l+1)}\,|U_l(kr)|^2\right], & j = 1, \\ \\ \frac{\eta_0^2 k_0{}^2}{l(l+1)}\int_0^a dr\, r^2\,|j_l(kr)|^2\,, & j = 2. \end{cases} \tag{3.8}$$

For real k^2 the integral associated with the $j = 2$ case is calculable through the use of the second Lommel integral (see, for instance, [6]) and the recurrence relations of the Bessel functions along lines similar to those employed in [31] to evaluate similar inner products. Afterwards, the recurrence relations are also used to express the integral associated with the $j = 1$ case in terms of the calculated integral associated with the $j = 2$ case. Consequently, equations (3.8) reduce to

$$\left[\kappa_l^{(j)}\right]^2 = \begin{cases} \frac{\eta_0^2 a|ka|^2}{l(l+1)(2l+1)}\left[(l+1)\gamma_{l-1}^2(ka) + \ l\gamma_{l+1}^2(ka)\right], & j=1, \\ \frac{\eta_0^2 a(k_0a)^2}{l(l+1)}\gamma_l^2(ka), \quad j=2, \end{cases} \tag{3.9}$$

where we have introduced the unitless quantity (cf. [31, equation (17)])

$$\begin{aligned} \gamma_l^2(ka) &\equiv \frac{1}{a^3}\int_0^a dr\, r^2 j_l^2(kr) \\ &= \frac{1}{2}\left[j_l^2(ka) - j_{l-1}(ka)j_{l+1}(ka)\right]. \end{aligned} \tag{3.10}$$

For $k = i\alpha$, $\alpha \in \mathbb{R}$, as is the case for single-negative metamaterials, one uses definition (2.23) to express (3.9) and (3.10) in terms of i_l. (Note that the lone appearance of the size parameter a in (3.9), i.e., its appearance decoupled from the wavenumbers, is a direct consequence of the fact that the multipole moments $a_{l,m}^{(j)}$ are dimensioned quantities. It is, as well, a reminder of the boundedness of the enclosing volume V, i.e., of the embedding sphere of substrate material.)

Furthermore, the minimum source energy

$$\mathcal{E}_{ME} \equiv (\mathbf{J}_{ME}, \mathbf{J}_{ME}) = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} \frac{|a_{l,m}^{(j)}|^2}{[\sigma_l^{(j)}]^2}. \tag{3.11}$$

As expected, these developments reduce, for $\epsilon_r = 1 = \mu_r$, to the free-space result ((13) and (14) in [32]) since $F_l^{(j)}(k_0a, ka, \epsilon_r, \mu_r) = 1$; that is, the free-space minimum energy solution is given by (3.5) with $\mathfrak{B}_{l,m}^{(j)}$ given by (2.18) and $[\sigma_l^{(j)}]^2$ substituted by $[\kappa_l^{(j)}(k_0a = ka)]^2$.

3.2. Minimum energy source having zero reactive power. Next we consider the constrained optimization problem of minimizing the functional energy of the source subject to the additional constraint that the reactive power of the source has a prescribed value. The results for this problem will be elaborated next for the particular and important case of zero reactive power, i.e., $\Im[\mathcal{P}] = 0$. This corresponds to the minimizing of the antenna currents (the physical resources) while simultaneously enforcing perfect antenna reactance tuning inside the antenna.

The problem can be cast as

$$\min_{\mathbf{J}\in X} \mathcal{E}(\mathbf{J}), \tag{3.12}$$

where

$$X \equiv \left\{\mathbf{J} \in L^2\left(V; \mathbb{C}^3\right) : a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}, \mathbf{J}) \ = 0, \ (\mathbf{J}, \widetilde{\mathbf{G}}_S\mathbf{J}) = 0\right\}. \tag{3.13}$$

The constraint set X is closed, unbounded, and nonconvex. Its nonconvexity stems from that of the newly introduced constraint $(\mathbf{J}, \widetilde{\mathbf{G}}_S\mathbf{J}) = 0$. The set X is assumed to be nonempty. (If it turns out to be empty, this would mean that it is not possible for an antenna having a substrate medium of constitutive parameters ϵ_r, μ_r to produce the prescribed external field and at the same time have a vanishing reactive power.)

It is clear that problem (3.12), (3.13) is an inherently difficult nonconvex programming problem. Not only do we seek to minimize an objective functional under nonconvex functional constraints, but we also have to do that on an unbounded set. Proving, for instance, the existence of a solution to problem (3.12), (3.13) would have been easier if X were convex, but it is straightforward to show that the only way for X to become convex is to have $\Re[(\mathbf{J}_1, \widetilde{\mathbf{G}}_S\mathbf{J}_2)] \leq 0$ for all $\mathbf{J}_1, \mathbf{J}_2 \in L^2\left(V; \mathbb{C}^3\right)$. This would amount to imposing a new constraint which appears not to correspond to anything meaningful, physically speaking.

Now let us try to establish the existence of a solution to problem (3.12), (3.13) in the absence of the convexity and boundedness of the constraint set X. Since X is a closed subset of a normed vector space and since $\mathcal{E}$ is a coercive functional, there exist [23] $\mathbf{J}_0 \in X$ and $\Gamma > 0$ such that

$$\inf_{\mathbf{J}\in X} \mathcal{E}\left(\mathbf{J}\right) = \inf\left\{\mathcal{E}\left(\mathbf{J}\right) : \mathbf{J} \in X \cap \overline{B_\Gamma\left(\mathbf{J}_0\right)}\right\}, \tag{3.14}$$

where $\overline{B_\Gamma\left(\mathbf{J}_0\right)}$ is the closed (and bounded) ball of radius Γ and center $\mathbf{J}_0$. This is a powerful result. What this tells us is that minimizing $\mathcal{E}$ over the unbounded set X can be reduced to minimizing $\mathcal{E}$ over a bounded subset in X that could be much smaller than X. All that remains to complete the proof of existence of a solution to problem (3.12), (3.13) is to demonstrate the existence of a solution to the auxiliary problem

$$\min_{\mathbf{J}\in X\cap\overline{B_\Gamma(\mathbf{J}_0)}} \mathcal{E}\left(\mathbf{J}\right). \tag{3.15}$$

A useful variant of the generalized Weierstrass theorem stipulates that for a weakly sequentially lower semicontinuous functional defined on a weakly sequentially compact subset of a Hilbert space there exists at least one solution to the minimization problem [4]. But we have already shown that $\mathcal{E}$ is a weakly sequentially lower semicontinuous functional (see the discussion of problem (3.1), (3.2)). Consequently, the existence of a solution to problem (3.15), (3.13) depends entirely on the demonstration that $X \cap \overline{B_\Gamma\left(\mathbf{J}_0\right)}$ is a weakly sequentially compact subset. But this, too, is true because any bounded subset of a reflexive Banach space (e.g., a Hilbert space) is also weakly sequentially compact [8]. Hence, assuming that $X \cap \overline{B_\Gamma\left(\mathbf{J}_0\right)}$ is nonempty, we are, from the preceding discussion, in a position to affirm the existence of at least one global minimizer $\mathbf{J}_{\mathcal{E},\mathcal{P}} \in X \cap \overline{B_\Gamma\left(\mathbf{J}_0\right)}$ for the auxiliary problem (3.15), (3.13). However, by virtue of (3.14), this point $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ is also the sought solution of problem (3.12), (3.13), which completes our proof.

Unfortunately, though, we have yet to guarantee the uniqueness of this solution or even write down a minimality condition that would yield this solution. We shall now focus on trying to write down a necessary minimality condition whose solution would, at least in principle, yield a candidate $\mathbf{J}_{\mathcal{E},\mathcal{P}}$. The Fréchet derivative of the nonconvex constraints is given by $\boldsymbol{\nabla}_{\mathbf{J}}(\mathbf{J}, \widetilde{\mathbf{G}}_S\mathbf{J}) = 2\widetilde{\mathbf{G}}_S\mathbf{J}$. Now, let $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ be a minimizer. In view of the noted Fréchet differentiability of the objective functional and the constraints, the continuity of their Fréchet derivatives, and the fact that $\boldsymbol{\nabla}_{\mathbf{J}}\,[a_{l,m}^{(j)} - (\mathfrak{B}_{l,m}^{(j)}, \mathbf{J})]|_{\mathbf{J}=\mathbf{J}_{\mathcal{E},\mathcal{P}}}$ is surjective and the range of $\boldsymbol{\nabla}_{\mathbf{J}}(\mathbf{J}, \widetilde{\mathbf{G}}_S\mathbf{J})|_{\mathbf{J}=\mathbf{J}_{\mathcal{E},\mathcal{P}}}$ is closed, there exist Lagrange multipliers $\chi \in \mathbb{R}$ and $c_{l,m}^{(j)} \in \mathbb{C}$ such that [23]

$$\Re\left[\left(\boldsymbol{\nabla}_{\mathbf{J}}\mathcal{L}\left(\mathbf{J}_{\mathcal{E},\mathcal{P}},\chi,c_{l,m}^{(j)}\right)\ ,\ \mathbf{J}-\mathbf{J}_{\mathcal{E},\mathcal{P}}\right)\right]\geq 0\quad\forall\,\mathbf{J}\in L^{2}\left(V;\mathbb{C}^{3}\right), \tag{3.16}$$

where the generalized Lagrangian functional is given by

$$\begin{aligned}\mathcal{L}\left(\mathbf{J},\chi,c_{l,m}^{(j)}\right)&\equiv\mathcal{E}\left(\mathbf{J}\right)+\chi\left(\mathbf{J},\widetilde{\mathbf{G}}_{S}\mathbf{J}\right)\\&\quad+2\Re\left\{\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}c_{l,m}^{(j)}\left[a_{l,m}^{(j)}-(\mathfrak{B}_{l,m}^{(j)},\mathbf{J})\right]\right\}.\end{aligned} \tag{3.17}$$

Condition (3.16), (3.17) reduces to

$$\Re\left[\left(\mathbf{J}_{\mathcal{E},\mathcal{P}}+\chi\widetilde{\mathbf{G}}_{S}\mathbf{J}_{\mathcal{E},\mathcal{P}}-\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}c_{l,m}^{(j)}\mathfrak{B}_{l,m}^{(j)}\ ,\ \mathbf{J}-\mathbf{J}_{\mathcal{E},\mathcal{P}}\right)\right]\geq 0\quad\forall\,\mathbf{J}\in L^{2}\left(V;\mathbb{C}^{3}\right). \tag{3.18}$$

According to (3.18), to determine $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ one needs to solve an infinite number of equations with an infinite number of unknowns. That, of course, is not the case in practical situations. For any real problem the radiation emitted by the source has a maximum multipolarity $l_{\max}\sim ka$ $(<\infty)$. Thus for real problems one would need to solve $2l_{\max}\left(l_{\max}+2\right)+4$ integral equations with $2l_{\max}\left(l_{\max}+2\right)+4$ unknowns. By all standards this is a tedious task, even for small values of $l_{\max}$. One should try to find a more clever way of determining what the solution is. For instance, one could resort to numerical techniques and algorithms available in the literature (see, e.g., [44] and the references therein). In what follows we plan on adopting a similar approach that combines analytical and numerical methods.

We shall *assume* that $X\neq\emptyset$ and adopt partly analytical, partly numerical strategies to find a candidate $\mathbf{J}_{\mathcal{E},\mathcal{P}}$, which we proved exists, without having to solve a large number of complicated equations. The "hybrid" approach below is very much in line with the spirit of those adopted for this kind of problem. We shall also try to explore some of the properties of the solution. Once a feasible point $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ is found by means of the technique below, one would substitute it into the derived minimality conditions to check whether it satisfies these conditions.

Now let $\mathcal{L}$ be the generalized Lagrangian defined as

$$\begin{aligned}\mathcal{L}\left(\mathbf{J},\chi,c_{l,m}^{(j)}\right)&\equiv\mathcal{E}\left(\mathbf{J}\right)+\chi\left\{(\mathbf{J},\widetilde{\mathbf{G}}_{S}\mathbf{J})+2\Im[\mathcal{P}]\right\}\\&\quad+2\Re\left\{\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}c_{l,m}^{(j)}\left[a_{l,m}^{(j)}-(\mathfrak{B}_{l,m}^{(j)},\mathbf{J})\right]\right\},\end{aligned} \tag{3.19}$$

wherein the constraint on the reactive power is now written in such a way that it permits the latter to have an arbitrary value $\Im[P]$ that is not necessarily zero.

The first variation of the last term in (3.19) is found from (2.11) and (2.12) to be

$$\chi\delta(\mathbf{J},\widetilde{\mathbf{G}}_{S}\mathbf{J})=2\Re\left[\chi(\delta\mathbf{J},\widetilde{\mathbf{G}}_{S}\mathbf{J})\right]. \tag{3.20}$$

It follows from (3.3), (3.4), and (3.20) that the first variation of the Lagrangian in (3.19) is

$$\delta\mathcal{L} = 2\Re\left[(\delta\mathbf{J},\mathbf{J}) + \chi(\delta\mathbf{J},\widetilde{\mathbf{G}}_S\mathbf{J}) - \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)*}(\delta\mathbf{J},\mathfrak{B}_{l,m}^{(j)})\right]. \tag{3.21}$$

By equating the variation in (3.21) to zero, one deduces that the sought solution, to be denoted as $\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r})$, must obey, within its support V, the relation

$$\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) + \chi\widetilde{\mathbf{G}}_S\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)*}\mathfrak{B}_{l,m}^{(j)}(\mathbf{r}). \tag{3.22}$$

If $\chi = 0$, then this approach coincides with the one given earlier, leading to the minimum energy source in (3.5) (in such a situation, that source generates zero reactive power), while for the more general case $\chi \neq 0$ the two formulations (and their solutions) differ. However, we note that for certain peculiar constitutive-parameter values the constraint is not active and therefore $\chi = 0$. In that peculiar case the minimum-energy sources are intrinsically resonant.

By letting the vector wave equation operator $(\nabla\times\nabla\times - (k^*)^2) = (\nabla\times\nabla\times - k^2)$ (the equality stems from the requirement that the substrate be lossless) act on both sides of (3.22) and with the aid of the fact that the fields $\mathfrak{B}_{l,m}^{(j)}$ are solutions of the homogeneous wave equation associated to the same operator, one concludes that the source $\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r})$ obeys the homogeneous wave equation

$$\nabla\times\nabla\times\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) - K^2\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) = \mathbf{0} \tag{3.23}$$

in the interior of the source region V; the quantity K which appears in (3.23) is a modified wavenumber defined by

$$K^2 \equiv k^2 - \chi\mu_s\omega. \tag{3.24}$$

(Note that K quickly becomes purely imaginary as χ becomes large and positive.)

Now, the most general source that is confined within the spherical source volume V and is a solution of (3.23) in the interior of V must admit the representation

$$\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} v_{l,m}^{(j)}\mathfrak{D}_{l,m}^{(j)}(\mathbf{r}), \tag{3.25}$$

where $v_{l,m}^{(j)}$ are expansion coefficients that need to be determined (for the constraints of the problem) and where

$$\mathfrak{D}_{l,m}^{(j)}(\mathbf{r}) = \begin{cases} -\frac{\eta_0}{l(l+1)}\nabla\times[j_l(Kr)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], & j=1, \\ -\frac{i\eta_0 K}{l(l+1)} j_l(Kr)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & j=2. \end{cases} \tag{3.26}$$

From the formal similarity of $\mathfrak{B}_{l,m}^{(j)}$ and $\mathfrak{D}_{l,m}^{(j)}$ (cf. (2.19)) it follows at once from (3.6), (3.7), (3.9), and (3.10) that the inner product

$$\left(\mathfrak{D}_{l,m}^{(j)},\mathfrak{D}_{l,m}^{(j)}\right) = p^{(j)}\left[\kappa_l^{(j)}(k_0a,Ka)\right]^2, \tag{3.27}$$

where

$$p^{(j)} = \begin{cases} 1, \quad j = 1, \\ \\ |K|^2/k_0^2, \quad j = 2. \end{cases} \tag{3.28}$$

By substituting from (3.25) and (3.26) into (2.17) while using well-known orthogonality properties of the vector spherical harmonics $\mathbf{Y}_{l,m}(\hat{\mathbf{r}})$ and the associated vector functions $\hat{\mathbf{r}} \times \mathbf{Y}_{l,m}(\hat{\mathbf{r}})$ one obtains

$$\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) = \sum_{j=1}^{2} \sum_{l=1}^{\infty} \sum_{m=-l}^{l} \frac{a_{l,m}^{(j)}}{(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)})} \mathfrak{D}_{l,m}^{(j)}(\mathbf{r}), \tag{3.29}$$

where

$$(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}) = \begin{cases} \eta_0^2 F_l^{(1)} \int_0^a dr \left[j_l(kr) j_l(Kr) + \frac{kKr^2}{l(l+1)} U_l\,(kr)\, U_l\,(Kr) \right], \\ \hfill j = 1, \\ \\ \eta_0^2 F_l^{(2)} \frac{k_0 K}{l(l+1)} \int_0^a drr^2 j_l(kr) j_l(Kr), \quad j = 2. \end{cases} \tag{3.30}$$

Similarly to the integrals in (3.8), the integral associated with the $j = 2$ case in (3.30) is calculable through the use of the first Lommel integral (cf., for instance, [6]). The above inner product takes the form

$$(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}) = \begin{cases} \frac{\eta_0^2 kKa^3 F_l^{(1)}}{l(l+1)(2l+1)} \left[(l+1)\psi_{l-1}\,(ka, Ka) + \; l\psi_{l+1}\,(ka, Ka) \right], \\ \hfill j = 1, \\ \\ \frac{\eta_0^2 k_0 Ka^3 F_l^{(2)}}{l(l+1)} \psi_l\,(ka, Ka)\,, \quad j = 2, \end{cases} \tag{3.31}$$

where we have introduced the unitless quantity

$$\begin{aligned} \psi_l\,(ka, Ka) &\equiv \frac{1}{a^3} \int_0^a drr^2 j_l(kr) j_l(Kr) \\ &= \frac{1}{a\,(k^2 - K^2)} \left[Kj_l(ka) j_{l-1}(Ka) - kj_{l-1}(ka) j_l(Ka) \right]. \end{aligned} \tag{3.32}$$

(Note that (3.32) is valid only for $k \neq K$, i.e., for $\chi \neq 0$. The case $k = K$, i.e., for $\chi = 0$, has already been discussed.)

The source energy corresponding to (3.29) is of the form

$$\mathcal{E}_{\mathcal{E},\mathcal{P}} \equiv (\mathbf{J}_{\mathcal{E},\mathcal{P}}, \mathbf{J}_{\mathcal{E},\mathcal{P}}) = \sum_{j=1}^{2} \sum_{l=1}^{\infty} \sum_{m=-l}^{l} \frac{(\mathfrak{D}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)})}{|(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)})|^2} |a_{l,m}^{(j)}|^2. \tag{3.33}$$

Note that the above results (3.29) and (3.33) do not assume any particular value for $\Im\,[\mathcal{P}]$.

We need to incorporate the reactive power constraint, i.e., (2.11), which defines the value of the remaining Lagrange multiplier χ. Since the desired reactive power is specified to be zero, the problem now is to find an expression for the reactive power in terms of χ from which one can deduce the value of χ which minimizes the source energy under the constraint $\Im\left[\mathcal{P}\right] = 0$. This value of χ will be called χ_0. A number of partly analytical, partly numerical strategies can be implemented to accomplish this step.

One such approach, which generalizes the development for the free-space case in [32], consists of determining the field $\mathbf{E}(\mathbf{r})$ generated by the source $\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r})$ in the interior of the source region V. In particular, after evaluating the field, one can compute the interaction power via (2.8) and (2.9) and require that its imaginary part vanish. In particular, plotting $\Im\left[\mathcal{P}\right]$ and $\mathcal{E}_{\mathcal{E},\mathcal{P}}$ versus χ one can finally select the value of χ which yields minimum $\mathcal{E}_{\mathcal{E},\mathcal{P}}$ out of all values of χ for which $\Im\left[\mathcal{P}\right] = 0$. We adopt this approach next.

By rewriting (3.23) as

$$\left(\boldsymbol{\nabla} \times \boldsymbol{\nabla} \times -k^2\right)\left[\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) - i\chi\mathbf{E}(\mathbf{r})\right] = \mathbf{0}, \tag{3.34}$$

where we have borrowed from (2.3), one concludes that the field $\mathbf{E}(\mathbf{r})$ must admit in the interior of the source region V an expansion of the form

$$\mathbf{E}(\mathbf{r}) = \frac{1}{i\chi}\left[\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r}) + \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} u_{l,m}^{(j)}\mathfrak{B}_{l,m}^{(j)}(\mathbf{r})\right], \quad \mathbf{r} \in V, \tag{3.35}$$

where the expansion coefficients $u_{l,m}^{(j)}$ need to be determined taking into account continuity of the tangential components of the field on the boundary $\partial V \equiv \{\mathbf{r} \in \mathbb{R}^3 : r = a\}$ of V. Continuing with this idea, it is not hard to show from these developments, and by straightforward generalization of the discussion of the free-space version of the problem in [32], equations (30)–(42), that the complex interaction power can be expressed as

$$\mathcal{P} = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} q_l^{(j)}|a_{l,m}^{(j)}|^2, \tag{3.36}$$

where

$$q_l^{(j)} = \frac{i}{2\chi}\left[\frac{\left(\mathfrak{D}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}\right)}{\left|\left(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}\right)\right|^2} + \frac{u_{l,m}^{(j)}}{a_{l,m}^{(j)}}\right], \tag{3.37}$$

where the quantity $u_{l,m}^{(j)}/a_{l,m}^{(j)}$ is given by

$$\frac{u_{l,m}^{(j)}}{a_{l,m}^{(j)}} = \begin{cases} \frac{1}{F_l^{*(1)}k^*U_l(k^*a)}\left[-i\frac{k_0}{\eta_0}\chi l(l+1)V_l(k_0a) - \frac{KU_l(Ka)}{\left(\mathfrak{B}_{l,m}^{(1)}, \mathfrak{D}_{l,m}^{(1)}\right)}\right], \\ \hfill j = 1, \\ \\ \frac{1}{F_l^{*(2)}k_0j_l(k^*a)}\left[-i\frac{k_0}{\eta_0}\chi l(l+1)h_l^{(+)}(k_0a) - \frac{Kj_l(Ka)}{\left(\mathfrak{B}_{l,m}^{(2)}, \mathfrak{D}_{l,m}^{(2)}\right)}\right], \\ \hfill j = 2, \end{cases} \tag{3.38}$$

where the radial functions U_l and V_l have already been defined in (2.21) and (2.22), respectively.

Thus the reactive power of the source $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ is given by

$$\Im\left[\mathcal{P}\right] = \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} g_l^{(j)} |a_{l,m}^{(j)}|^2, \tag{3.39}$$

where

$$g_l^{(j)} = \frac{1}{2\chi}\left\{ \frac{\left(\mathfrak{D}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}\right)}{\left|\left(\mathfrak{B}_{l,m}^{(j)}, \mathfrak{D}_{l,m}^{(j)}\right)\right|^2} + \Re\left[\frac{u_{l,m}^{(j)}}{a_{l,m}^{(j)}}\right]\right\}. \tag{3.40}$$

By taking the real part of the complex interaction power, as given by (3.36)–(3.38), one also recovers (2.10), which is the well-known expression for the radiated power in terms of the multipole moments.

Equations (3.38)–(3.40) relate χ directly to $\Im\left[\mathcal{P}\right]$, as desired. For a certain problem, where $a_{l,m}^{(j)}$ and $\Im\left[\mathcal{P}\right]$ are given, one can compute the values of χ for which $\Im\left[\mathcal{P}\right] = 0$ by using these expressions, and pick, out of those values, the one which minimizes the functional energy in (3.33). By substituting that value of χ (i.e., χ_0) into (3.24), (3.26), and (3.29) one arrives at the desired solution.

Let

$$\Xi \equiv \left\{\chi \in \mathbb{R} : \Im\left[\mathcal{P}\left(\chi\right)\right] = 0\right\}. \tag{3.41}$$

It is found, numerically, that (see section 4) the minimum source energy is achieved for the value of χ that is closest to $\chi = 0$, i.e.,

$$|\chi_0| = \inf_{\chi\in\Xi}\left\{|\chi|\right\}. \tag{3.42}$$

It appears only natural to assume that an increase in the source energy from $\mathcal{E}_{ME}$ should correspond to χ_0 (and any other value of $\chi \in \Xi$ for that matter). This would be understood, intuitively, as a cost that one would have to pay to realize a tuned antenna. The numerical simulations suggest that this, in fact, is the case: Substituting any nonzero value $\chi \in \Xi$ in the expression for $\mathcal{E}_{\mathcal{E},\mathcal{P}}$ yields a value that is larger than $\mathcal{E}_{\mathcal{E},\mathcal{P}}|_{\chi=0} = \mathcal{E}_{ME}$. Does this mean that $\mathcal{E}_{ME}$ is a lower bound of $\mathcal{E}_{\mathcal{E},\mathcal{P}}$ and that $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ is a global minimum? Before we examine this question we note that the above observations remind us of (3.14). Indeed, a convenient way of viewing these observations is to think of the origin of the sphere $\overline{B_\Gamma\left(\mathbf{J}_0\right)} \ni \mathbf{J}_{\mathcal{E},\mathcal{P}}$ as the point $\mathbf{J}_0 = \mathbf{J}_{ME}$ and to think of its radius as $\Gamma \geq |\chi_0|$.

Supposing that $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ corresponds to a feasible point, let us try to derive a condition for it to be a global minimum. By definition, $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ is said to be a global minimum when

$$\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi\right) \geq \mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right) \quad \forall\chi \in \Xi. \tag{3.43}$$

If the inequality is strict, then the global minimum is also unique.

It follows from (2.17), (2.11), and (3.22) that

$$\begin{aligned}\mathcal{E}_{\mathcal{E},\mathcal{P}} - 2\chi\Im[\mathcal{P}] &= \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)*}(\mathbf{J}_{\mathcal{E},\mathcal{P}}, \mathfrak{B}_{l,m}^{(j)})\\ &= \sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l} c_{l,m}^{(j)*}a_{l,m}^{(j)*}.\end{aligned} \tag{3.44}$$

Thus if we require $\Im\left[\mathcal{P}\left(\chi\right)\right]=0$, (3.44) yields

$$\mathcal{E}_{\mathcal{E},\mathcal{P}}=\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}c_{l,m}^{(j)*}a_{l,m}^{(j)*}. \tag{3.45}$$

Furthermore, by projecting both sides of (3.22) onto the functions $\mathfrak{B}_{l,m}^{(j)}$ while recalling (2.17) and (3.6), one obtains

$$a_{l,m}^{(j)}+\chi(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathbf{J}_{\mathcal{E},\mathcal{P}})=c_{l,m}^{(j)*}[\sigma_l^{(j)}]^2. \tag{3.46}$$

By substituting from this result into (3.45), one obtains

$$\mathcal{E}_{\mathcal{E},\mathcal{P}}=\mathcal{E}_{ME}+\chi\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\frac{(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathbf{J}_{\mathcal{E},\mathcal{P}})a_{l,m}^{(j)*}}{[\sigma_l^{(j)}]^2}, \tag{3.47}$$

where $\chi\in\Xi$. Upon substituting $\mathbf{J}_{\mathcal{E},\mathcal{P}}(\mathbf{r})$ from (3.29) into (3.47) and using standard orthogonality properties of the spherical harmonics, one obtains

$$\mathcal{E}_{\mathcal{E},\mathcal{P}}=\mathcal{E}_{ME}+\chi\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\frac{(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathfrak{D}_{l,m}^{(j)}\left(\chi\right))}{(\mathfrak{B}_{l,m}^{(j)},\mathfrak{D}_{l,m}^{(j)}\left(\chi\right))}\frac{|a_{l,m}^{(j)}|^2}{[\sigma_l^{(j)}]^2}. \tag{3.48}$$

Expression (3.48) for the source energy directly assumes that $\Im\left[\mathcal{P}\right]=0$, while expression (3.33) holds for any value of the reactive power $\Im\left[\mathcal{P}\right]$.

It follows from (3.43) and (3.48) that the condition for $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ to be a global minimum is given by

$$\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\left\{\chi\frac{(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathfrak{D}_{l,m}^{(j)}\left(\chi\right))}{(\mathfrak{B}_{l,m}^{(j)},\mathfrak{D}_{l,m}^{(j)}\left(\chi\right))}-\chi_0\frac{(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathfrak{D}_{l,m}^{(j)}\left(\chi_0\right))}{(\mathfrak{B}_{l,m}^{(j)},\mathfrak{D}_{l,m}^{(j)}\left(\chi_0\right))}\right\}\frac{|a_{l,m}^{(j)}|^2}{[\sigma_l^{(j)}]^2}\geq 0 \tag{3.49}$$

for any value of $\chi\in\Xi$. Condition (3.49) is a necessary and sufficient condition for $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ to be a global minimum. The way it should be used is as follows. For a given substrate, solve $\Im\left[\mathcal{P}\left(\chi\right)\right]=0$ for χ (where $\Im\left[\mathcal{P}\left(\chi\right)\right]$ is given by (3.38)–(3.40)). If condition (3.49) is satisfied for *all* values of $\chi\in\Xi$, then $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ is a global minimum. If it is not satisfied for at least one value of $\chi\in\Xi$, then $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\right)$ is not a global minimum (but it may still be a local minimum).

Condition (3.49) was written based on the presumption that $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0\neq 0\right)$ was a global minimum. For $\mathcal{E}_{\mathcal{E},\mathcal{P}}\left(\chi_0=0\right)=\mathcal{E}_{ME}$, condition (3.49) reduces to

$$\chi\sum_{j=1}^{2}\sum_{l=1}^{\infty}\sum_{m=-l}^{l}\frac{(\mathfrak{B}_{l,m}^{(j)},\widetilde{\mathbf{G}}_S\mathfrak{D}_{l,m}^{(j)})}{(\mathfrak{B}_{l,m}^{(j)},\mathfrak{D}_{l,m}^{(j)})}\frac{|a_{l,m}^{(j)}|^2}{[\sigma_l^{(j)}]^2}\geq 0\quad\forall\chi\in\Xi. \tag{3.50}$$

4. Computer simulation study. The previous theory and algorithms are applied next to elucidate the effect of the antenna-embedding medium on radiation performance for two classes of antennas: electrically small and larger (resonant) antennas.

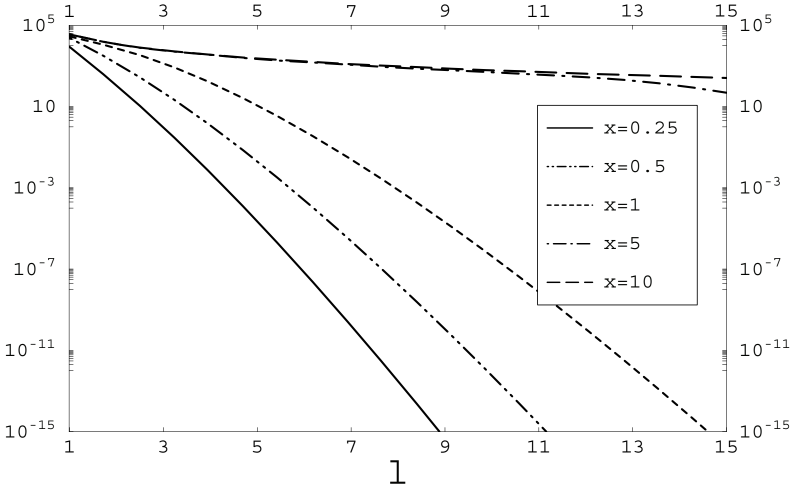

FIG. 4.1. *Free-space singular values* $[\sigma_l^{(1)}\ (x = x_0,\ \epsilon_r = +1 = \mu_r)]^2$ *versus* l *for a few representative values of* $x_0 \equiv k_0 a/\pi$. *(The unit of the singular values is* $V^2 m/A^2$*.)*

4.1. Minimum energy sources. It follows from (3.11) that, generally, the larger the singular values $[\sigma_l^{(j)}]^2$, the smaller the minimum source energy $\mathcal{E}_{ME}$ required for the launching of a given radiation pattern with a source of a given size. The singular values $[\sigma_l^{(j)}(k_0 = k,\ \epsilon_r = +1 = \mu_r)]^2$ correspond to the source in free space, that is, without the substrate. Thus, the larger the singular values $[\sigma_l^{(j)}]^2$ for a given substrate wavenumber ka relative to the corresponding free-space values, the greater the associated enhancement, due to the substrate, of radiation of the lth multipole order field with given resources. It is thus important to understand the dependence of the singular values $[\sigma_l^{(j)}(k_0 a, ka, \epsilon_r, \mu_r)]^2$ on $k_0 a$, ka, ϵ_r, μ_r, and l, for both the electric ($j = 1$) and the magnetic ($j = 2$) cases. Large singular values, such as resonances or peaks in the plots of the singular values versus these variables, will indicate enhanced radiation for such operational modes or conditions, with the given resources. This aspect is investigated numerically next.

Before engaging in the numerical illustrations we make some remarks: (1) the multipolarity l is handled in the plots as a continuous variable to facilitate understanding of the curves, yet the meaningful results correspond solely to the discrete values of l; (2) in the simulations the size parameter (radius) a of the antenna including the substrate has been set to unity, i.e., $a = 1$ meter; and (3) in the plots and associated discussion we consider the normalized wavenumbers defined by $x \equiv ka/\pi$ and $x_0 \equiv k_0 a/\pi$. The normalized wavenumber x represents the wavenumber of the field in the material, hence, the effective electric size in the material, while the normalized wavenumber x_0 measures the respective size in free space.

4.1.1. Behavior of the singular values $[\sigma_l^{(j)}]^2$. Figure 4.1 shows, for different antenna sizes, the free-space singular values $[\sigma_l^{(1)}(x_0 = x, , \epsilon_r = 1 = \mu_r)]^2$. No local maxima or resonances are seen for the free-space cases; in particular, in those cases the singular value spectrum decays exponentially. Figure 4.2 shows, for an antenna whose size corresponds to that of a quarter-wave antenna in free space ($x_0 = 1/4$), plots of the normalized electric singular values $[\varrho_l^{(1)}(x_0, x, \epsilon_r, \mu_r)]^2 \equiv [\sigma_l^{(1)}(x_0 = 1/4,\ x, , \epsilon_r =$

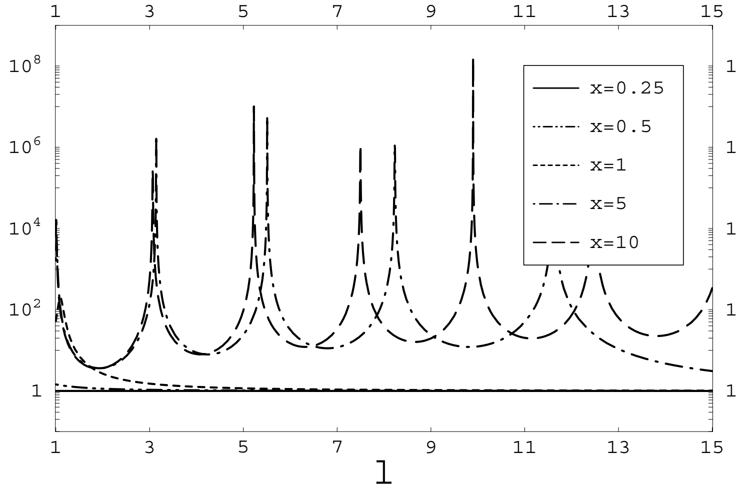

FIG. 4.2. *Normalized singular values* $[\varrho_l^{(1)}]^2$ *versus* l *for* $x_0 = 1/4$ *(quarter-wave case),* $\epsilon_r = +1$, *and a few representative values of* x.

$1)]^2 \,/\, [\sigma_l^{(1)}(x_0 = 1/4 = x, \, , \, \epsilon_r = 1 = \mu_r)]^2$ versus l, parameterized by the normalized wavenumber in the substrate x. From now on, the normalized singular values $[\varrho_l^{(j)}(x_0, x, \epsilon_r, \mu_r)]^2$ defined as

$$\left[\varrho_l^{(j)}(x_0, x, \epsilon_r, \mu_r)\right]^2 \equiv \frac{\left[\sigma_l^{(j)}(x_0, x, \epsilon_r, \mu_r)\right]^2}{\left[\sigma_l^{(j)}(x_0 = x, , \epsilon_r = 1 = \mu_r)\right]^2} \tag{4.1}$$

will be referred to simply as singular values, unless otherwise specified. The singular value spectrum plots for the larger x values considered ($x = 5$ and 10) reveal well-defined resonances (local peaks). The dominant resonances for these larger x values occur around $l \sim \pi$. In fact, the resonances in question appear to arise only when $x \gtrsim 1$. Overall, it is seen that as the material becomes electromagnetically denser, i.e., as the substrate normalized wavenumber x increases, the magnitudes of the singular values become accordingly larger. Since electrically small antennas such as the one considered here can effectively radiate only the lowest multipole orders (such as the dipolar mode), then of particular interest for small antenna applications is the antenna substrate-induced enhancement for low multipolarity l. The plots reveal that the dipolar-mode ($l = 1$) singular values can be significantly higher for the embedding substrate case than for the free-space case. The improvement for $x = 5$ and 10 relative to the free-space case is of more than 3 orders of magnitude (decades). This means that the magnitude of the exciting current or source required for launching of the given dipolar field can be made correspondingly smaller than in free space by embedding the antenna in a high wavenumber or electromagnetically dense substrate. Alternatively, for fixed source energy, the antenna size parameter a can be reduced relative to its value without the embedding substrate. The improvement for $l = 2$ and 3 associated to the larger wavenumber cases ($x = 5$ and 10) is also noticeable.

The respective plot for the case of a resonant or electrically large $x_0 = 10$ antenna is shown in Figure 4.3. The respective magnetic singular value spectra are shown in Figures 4.4–4.5. Many of the key features outlined above in the explanation of the

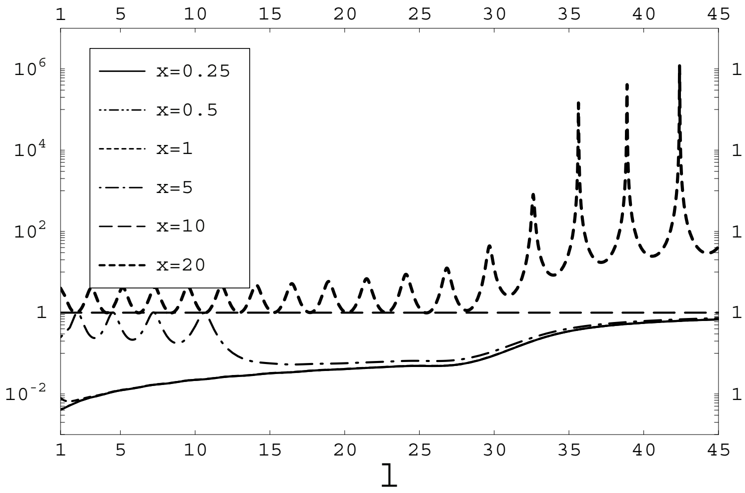

FIG. 4.3. *Normalized singular values* $[\varrho_l^{(1)}]^2$ *versus* l *for* $x_0 = 10$ *(resonant or electrically large antenna),* $\epsilon_r = +1$*, and a few representative values of* x*.*

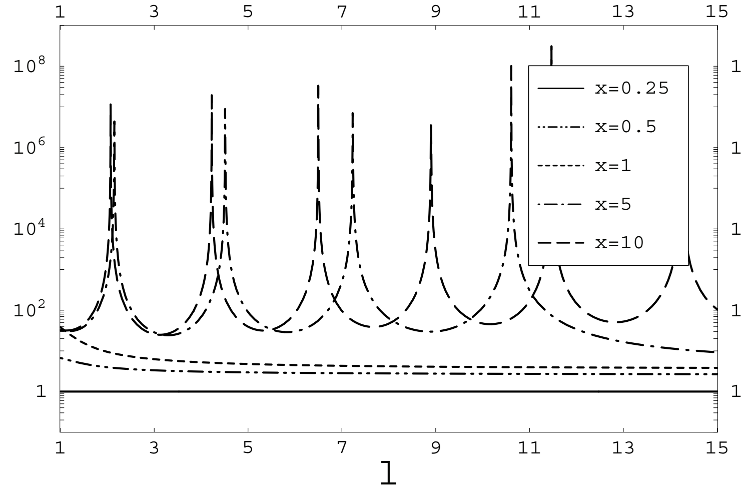

FIG. 4.4. *Normalized singular values* $[\varrho_l^{(2)}]^2$ *versus* l *for* $x_0 = 1/4$ *(quarter-wave case),* $\epsilon_r = +1$*, and a few representative values of* x*.*

particular electric quarter-wave antenna case also arise for these other cases. Yet other aspects become salient. A summary of the main results is given next, along with some of the former observations, as general conclusions learned from these simulations as a whole.

It is seen that, for sufficiently large multipolarity l (i.e., for $l \gtrsim 6$), and for the values of x_0 considered which comprise both small and large or resonant antennas, the singular values are consistently higher for the denser substrates (larger x) than for the less dense substrates including the free-space ($x = x_0$) case. This is true for both electric ($j = 1$) and magnetic ($j = 2$) modes. As we had indicated for the particular electric quarter-wave antenna case, generally for $x = x_0$ (no embedding medium or free-space case), the singular value spectrum decays exponentially with

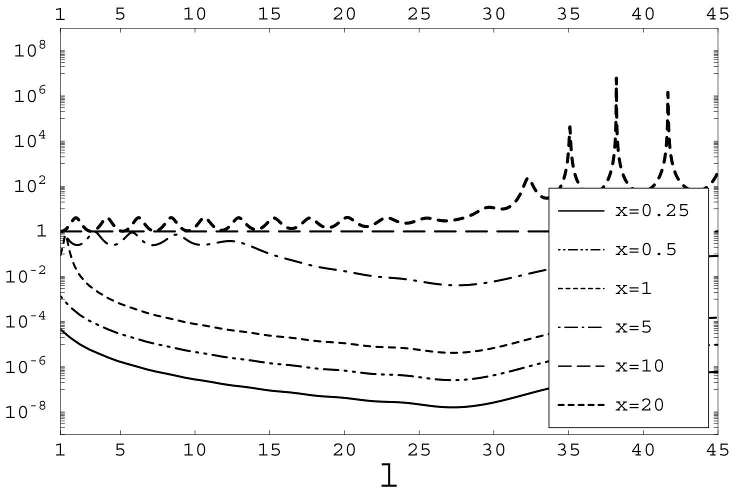

FIG. 4.5. *Normalized singular values $[\varrho_l^{(2)}]^2$ versus l for $x_0 = 10$ (resonant or electrically large antenna), $\epsilon_r = +1$, and a few representative values of x.*

l, i.e., without resonances. This decay is more or less exponential for the smaller antenna cases. For larger antennas the singular values remain more or less within a given order of magnitude until about the cutoff $l \sim k_0 a$ (this value approximately corresponds to the inflection point in the singular value spectrum curve for the free-space case), but this cutoff is clearly higher (includes higher order multipoles) for the large wavenumber cases. (Note that in order to see this visually one would need to plot not the normalized singular values $[\varrho_l^{(j)}]^2$ but the singular values $[\sigma_l^{(j)}]^2$ themselves. Yet a careful comparison of normalized values in Figures 4.2–4.5 and the illustrative free-space values in Figure 4.1 leads to the same conclusion.) This further shows performance enhancement via larger wavenumber or electromagnetically denser substrates since higher multipoles represent higher antenna directivity (higher level of details or narrower width in the radiation pattern). It is also important to note that the enhancement in the singular values due to larger substrate wavenumber k holds for both small and large multipolarities l.

Having shown some of the radiation enhancing possibilities offered by electromagnetically denser substrates, we discuss next the question of local optimal selection of the wavenumber x. Consider, for example, a half-wave antenna (so that $x_0 = 1/2$) embedded in a substrate with $\epsilon_r = 1$ and launching purely magnetic modes ($j = 2$). Local maxima of the respective normalized singular values $[\varrho_l^{(2)}(x_0 = 1/2,\, x,\, \epsilon_r = 1,\, \mu_r)]^2$ for $l = 1$, 2, and 3 were found to occur as follows: for the emission of dipole radiation ($l = 1$) at $x \simeq 1.430$, with an enhancement or gain $[\varrho_l^{(2)}(x_0 = 1/2,\, x = 1.430,\, \epsilon_r = 1,\, \mu_r)]^2 \simeq 3.110 \times 10^5$, relative to free space; for the emission of quadrupole radiation ($l = 2$) at $x \simeq 1.833$, with a gain relative to free space of 1.925×10^7; and for the emission of octupole radiation ($l = 3$) at $x \simeq 2.224$, with a gain of 10^{10}. For antennas embedded in denser substrates the numerical study indicates, however, that the improvement attained is comparatively marginal. For example, the gain associated to going from the aforementioned values of x to the local maxima at $x \sim 10$ is only 44.03, 23.86, and 5.55 for the dipole, quadrupole, and octupole radiation cases, respectively. Conversely, a half-wave antenna radiating purely electric modes instead displays a significantly different behavior in this regard, and the overall improvements of the substrate are also more significant. Thus for modest values of x, a locally maximum improvement in the radiation ability of the half-wave antenna can be attained for the following values: for electric dipole radiation at $x \simeq 0.946$ with a gain $[\varrho_1^{(1)}(x_0 = 1/2,\, x = 0.946,\, \epsilon_r,\, \mu_r)]^2 \simeq 5.36$; for quadrupole radiation at $x \simeq 1.362$ with a gain relative to free space of 163.6; for octupole radiation at $x \simeq 1.800$ with a gain of 2.952×10^4. For denser materials the enhancement relative to free space can be significantly larger. Thus numerical maximization of $[\varrho_l^{(1)}(x_0, x, \epsilon_r, \mu_r)]^2$ yields the following gains associated to going from the aforementioned values of x to the local maxima at $x \sim 10$: 126, 70.81, and 33.56 for the dipole, quadrupole, and octupole radiation cases, respectively. The first two of those numbers are relatively significant enhancements, yet for much denser materials the enhancements are less dramatic, though still meaningful.

A legitimate question arises as to the physical reason behind the appearance of these resonances in the spectra of the non–free-space singular values. As noted earlier, a careful examination of the quantities $F_l^{(j)}$ defined in (2.20) shows that these quantities are essentially the Mie amplitudes, $F_l^{(1)}$ being the amplitudes of the electric modes and $F_l^{(2)}$ those of the magnetic modes [35, 38]. The question that arises now is, Are those resonant peaks, which correspond to local maximum enhancement, related to Mie resonances? Before answering this question we review very briefly the features of Mie resonance that are most relevant to our results. Mie resonances are characterized by the vanishing of the denominators of the amplitudes $F_l^{(j)}$, or, more realistically, by the requirement that those denominators be minimum [38]. Thus the resonance conditions can be cast in the form of approximate transcendental equations, viz.,

$$\sqrt{\epsilon_r}\frac{V_l(x_0)}{h_l^{(+)}(x_0)} \simeq \sqrt{\mu_r}\frac{U_l(x)}{j_l(x)} \tag{4.2}$$

for the electric modes, and

$$\sqrt{\mu_r}\frac{V_l(x_0)}{h_l^{(+)}(x_0)} \simeq \sqrt{\epsilon_r}\frac{U_l(x)}{j_l(x)} \tag{4.3}$$

for the magnetic modes, where U_l and V_l are the functions defined in (2.21) and (2.22). Because of the presence of Bessel functions, (4.2) and (4.3) admit a discrete, albeit infinite, set of solutions. These solutions correspond to the so-called Mie resonances.

Now we can go back to the question of how the observed resonant peaks which correspond to local maximum enhancement relate to Mie resonances. Singular values $[\varrho_l^{(j)}(x_0, x, \epsilon_r, \mu_r)]^2$, defined by (4.1), (3.7), and (3.8), are composed not only of the quantities $|F_l^{(j)}|^2$, defined in (2.20), but also of another term, viz., $[\kappa_l^{(j)}(x_0, x)]^2$, defined in (3.8), and unless these latter quantities are sufficiently well behaved, one cannot conclude anything as to the relationship of the resonant values of $[\varrho_l^{(j)}(x_0, x, \epsilon_r, \mu_r)]^2$ to Mie resonances. Incidentally, the quantities $[\kappa_l^{(j)}(x_0, x)]^2$, where $x \in \mathbb{R}$, are essentially nonpathological combinations of the spherical Bessel functions $j_l(\lambda a)$ which are well behaved for all integer values of l and $\lambda \in \mathbb{R}$ [1] (which represent the most general cases considered in this work). Hence, one can confidently claim that the observed peaks in the spectrum of the singular values are primarily due to the phenomenon of Mie resonance and maximum enhancement conditions are effectively summarized by the two conditions (4.2) and (4.3). Therefore, for a given antenna radiating at a prescribed frequency, the discrete set of solutions x corresponds to a

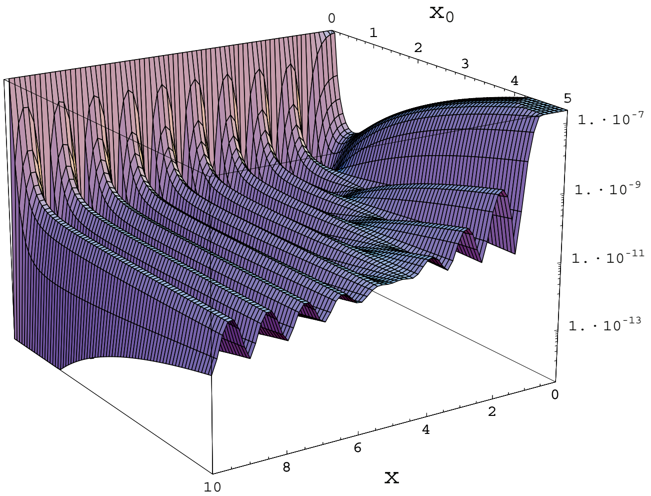

FIG. 4.6. *Logarithmic mesh plot of the source energy $\mathcal{E}_{ME}^{(j=1=l)}$ versus x_0 and x for a double-positive material with $\epsilon_r = +1$.*

set of constitutive parameters ϵ_s and μ_s that maximize the radiated electromagnetic fields. As their amplitudes increase, these radiated fields draw energy from the embedding medium. But because this medium is of finite extent, the energy extraction process saturates, ultimately, and as a result of this saturation the fields fall short of effectively "blowing up."

4.1.2. Further details: Electric dipole radiation. This part examines in greater detail the fundamental electric dipole radiation case, in particular, the multipole moment $a_{l,m}^{(j)} = 1$ if $j = 1 = l$ and $m = 0$, and $a_{l,m}^{(j)} = 0$ otherwise. The minimum source energy reduces in this case to $\mathcal{E}_{ME}^{(j=1=l)}(x_0, x, \epsilon_r, \mu_r) = [\sigma_1^{(1)}(x_0, x, \epsilon_r, \mu_r)]^{-2}$. Figure 4.6 shows a mesh plot of the minimum source energy $\mathcal{E}_{ME}^{(j=1=l)}$ versus the normalized wavenumbers x_0 and x for a double-positive substrate material with $\epsilon_r = 1$. For a double-negative substrate material having $\epsilon_r = -1$, the numerical study shows (plots not shown) that the minimum source energy displays a very similar, though not completely symmetrical, behavior when x changes sign, for a given x_0. Consequently, source energy $\mathcal{E}_{ME}^{(j=1=l)}$ is not an even function of x, and hence distinguishes between double-positive and double-negative embedding substrates. Figure 4.7 shows slices or cross-sections of the mesh plot in Figure 4.6 for particular values of the free-space normalized wavenumber x_0. Similar plots (results not shown) were obtained for $\epsilon_r = -1$ and negative x. Figure 4.6 also shows that, in general terms, source energy tends to decrease as the size of the antenna increases; this is also true when x is negative. Thus as the antenna size increases it tends to be easier to distribute the source currents in a more efficient way. As shown in Figure 4.7, for small antennas the source energy exhibits its first local minima at $|x| \sim 1$. In particular, for $x_0 = 1/4$ (quarter-wave antenna case) and $x_0 = 1/2$ (half-wave case) the first local minimum of $\mathcal{E}_{ME}^{(j=1=l)}$ appears for positive x at $x \simeq 0.960$ and $x \simeq 0.946$, respectively, and for negative x at $x = -0.760$ and $x = -0.860$, respectively. For $x_0 = 1$ (full-wave antenna case) the first local minimum of $\mathcal{E}_{ME}^{(j=1=l)}$ appears for positive x at $x \simeq 1.155$ and for negative x at $x \simeq -1.200$. However, for large antennas a slightly more subtle behavior is observed.

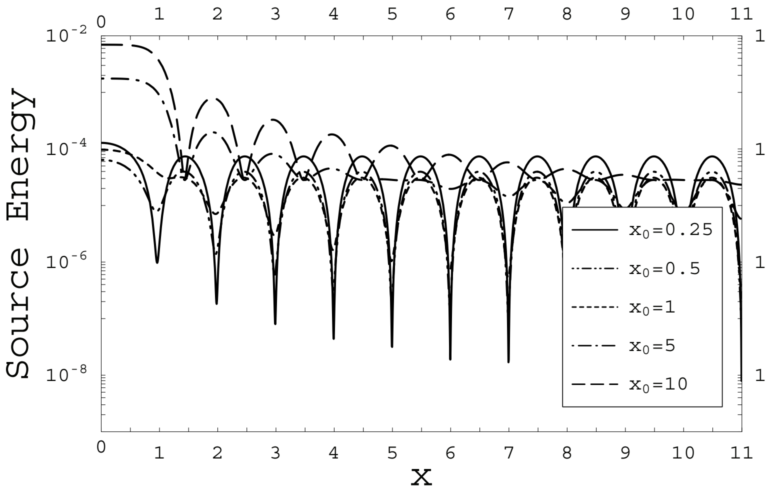

FIG. 4.7. *Logarithmic plot of the source energy $\mathcal{E}_{ME}^{(j=1=l)}$ versus x for $\epsilon_r = +1$ and some representative values of x_0 for a double-positive medium.*

If $|x| < x_0$, the local minima of $\mathcal{E}_{ME}^{(j=1=l)}$ appear at $|x| \sim (2n+1)/2$, $n = 1, 2, 3, \dots$, while if $|x| > x_0$, the minima appear at $|x| \sim n$, $n = 1, 2, 3, \dots$, with the least minimum still belonging to the smallest antenna (cf. Figure 4.7). These rules of thumb depend on the particular combination of constitutive parameters ϵ_r and μ_r under investigation. For example, it was found that for a double-positive material with $\mu_r = 1$ the rules are interchanged; i.e., now, if $x < x_0$, the local minima of $\mathcal{E}_{ME}^{(j=1=l)}$ appear at $x \sim n$, $n = 1, 2, 3, \dots$, while if $x > x_0$, the minima appear at $x \sim (2n+1)/2$, $n = 1, 2, 3, \dots$.

Finally, to further illustrate the possibility of reducing radiator size while achieving a given radiation pattern with prescribed source resources, specifically, source energy, we considered the free-space wavenumber $k_0 = \pi/4$ and sought values of the size parameter a for which the minimum source energy of a source embedded in a medium having $k = 10\pi$ renders the same source energy as a unit-valued a embedded in free space, for which $k = k_0 = \pi/4$. For an embedding substrate with $\epsilon_r = 1$ the first such values of a are $0.098, 0.101, 0.196, 0.204, \dots$ (units of meter), which are seen to occur in pairs around 0.1, 0.2, 0.3, etc. This is not surprising in light of the formula introduced earlier; in particular, the locally optimal values of ka are $ka \sim n\pi$, $n = 1, 2, 3, \dots$, that is, $a \sim 1/10, 2/10, 3/10, \dots$. The values of the size parameter a for which the source energy in question coincides with the free-space case source energy for a larger source having unit-valued radius then occur in pairs around these optimal values, which completes the picture.

4.2. Tuned minimum energy sources: Additional zero reactive power constraint. Next we consider minimum energy sources subjected to the additional zero reactive power constraint. In particular, we require the reactive power to vanish, that is, $\Im[\mathcal{P}] = 0$. As in the preceding subsection, the focus is the fundamental case of an electric dipole radiator (specifically, $a_{l,m}^{(j)} = 1$ if $j = 1 = l$ and $m = 0$, and $a_{l,m}^{(j)} = 0$ otherwise). Particular attention is given to the quarter-wave and the half-wave antenna cases, though some results related to larger antennas are also presented.

As in [32], we define the normalized reactive power

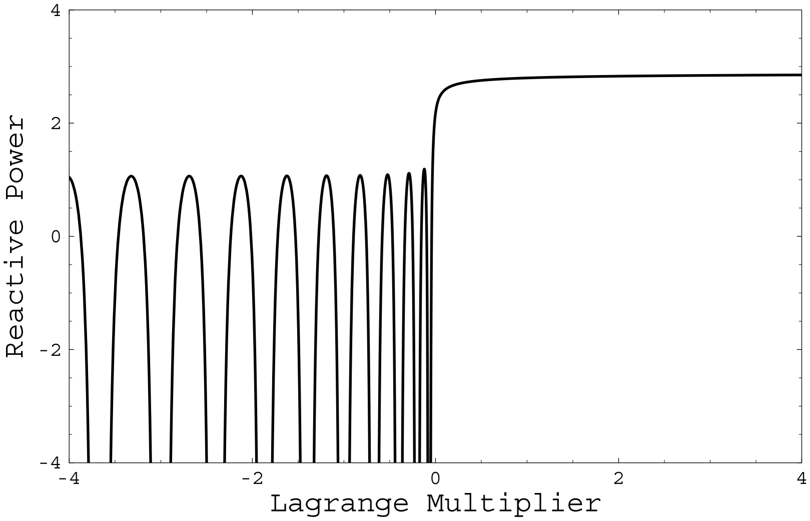

FIG. 4.8. *Plot of the normalized reactive power* $\overline{g}_1^{(1)}$ *versus* χ *for* $x_0 = 1/4 = x$ *and* $\epsilon_r = +1$.

$$\overline{g}_1^{(1)} \equiv \frac{g_1^{(1)}}{\Re\left[\mathcal{P}\right]} = \eta_0 g_1^{(1)}, \tag{4.4}$$

where $\Re\left[\mathcal{P}\right] = 1/2\eta_0$ is the radiated power and where the free-space wave impedance $\eta_0 = \sqrt{\mu_0/\epsilon_0} \simeq 120\pi\,\Omega$. We define χ_0 as the Lagrange multiplier value χ which annuls the normalized reactive power $\overline{g}_1^{(1)}$, i.e., $\overline{g}_1^{(1)}(\chi)\,|_{\chi=\chi_0} = 0$, and for which the resulting source energy is minimal among all such zero reactive power Lagrange multiplier values. The value in question was consistently found to occur in the vicinity of $\chi = 0$. This is not surprising since the absolute or unconstrained minimum energy source and its energy $\mathcal{E}_{ME}^{(j=1=l)}$ correspond to $\chi = 0$; that is, the minimum energy source is $\min \mathcal{E}_{\mathcal{E}\mathcal{P}}^{(j=1=l)} \equiv \lim_{\chi\to 0} \mathcal{E}_{\mathcal{E}\mathcal{P}}^{(j=1=l)}(x_0, x, \epsilon_r, \mu_r, \chi) = \mathcal{E}_{ME}^{(j=1=l)}$ (see section 3).

Figure 4.8 is a plot of the normalized reactive power $\overline{g}_1^{(1)}$ versus the Lagrange multiplier χ for a quarter-wavelength antenna, embedded in substrates with $\epsilon_r = 1$ and $x = 1/4$. The Lagrange multiplier value χ_0 is sought for which the respective source energy (shown in Figure 4.9) is minimized among all χ values rendering zero reactive power. Tables 4.1, 4.2, 4.3, and 4.4 summarize the values of χ_0, source energy for $\chi = \chi_0$ (i.e., $\mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}$), and absolute minimum energy $\mathcal{E}_{ME}^{(j=1=l)}$ for the case addressed in these plots, as well as for other cases.

One notes, from these results and other plots not shown due to space constraints, that the minimum energy solution $\mathbf{J}_{ME}^{(j=1=l)}$ yields minimum source energy $\mathcal{E}_{ME}^{(j=1=l)}$ or current level, but its reactive power is comparable to the maximum, saturated value corresponding to $\chi \gg 1$ for the double-positive materials and to $\chi \ll -1$ for double-negative materials (cf. Figure 4.8). On the other hand, the new solution $\mathbf{J}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}$ corresponding to χ_0 yields zero reactive power at the expense of a raised source energy or current level (cf. Tables 4.1, 4.2, 4.3, and 4.4). The difference between the source energies $\mathcal{E}_{\mathcal{E}\mathcal{P}}^{(j=1=l)}$ and $\mathcal{E}_{ME}^{(j=1=l)}$ of the two sources $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ and $\mathbf{J}_{ME}$, respectively, is the source energy of the additional nonradiating part contained in $\mathbf{J}_{\mathcal{E},\mathcal{P}}$ whose role in the new source is to counteract the reactive power of the minimum energy source alone. It decreases as the electromagnetic density of the substrate in-

creases, this being true for both double-positive and double-negative substrates. We found that, for $x_0 = 1/4$ and $1/2$, performances better than those of the free-space cases (i.e., for which $k = k_0$ and $\epsilon_r = 1 = \mu_r$) can be achieved (cf. Tables 4.1, 4.2, 4.3, and 4.4, though for the sake of space the energy difference $\mathcal{E}_{\mathcal{EP}}^{(j=1=l)}(\chi_0) - \min \mathcal{E}_{\mathcal{EP}}^{(j=1=l)}$ is not explicitly displayed in the tables). Superior performance can also be obtained by means of a judicious choice of the substrate constitutive properties, as we explain below. In addition to this, we note that the minimum of the energy decreases as the electromagnetic density of the substrate increases, whether the substrate is double-positive or double-negative. In Figure 4.9 it is clear that as $\chi \to 0$ the source energy

$\mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}$ reaches an absolute minimum $\min \mathcal{E}_{\mathcal{E}\mathcal{P}}^{(j=1=l)}$, as expected. This minimum is not the same for double-positive materials and double-negative metamaterials (cf. Tables 4.1, 4.2, 4.3, and 4.4), as we discussed earlier. Interestingly, the cancellation of the reactive power is not always possible. For instance, for a quarter-wave antenna and for $\epsilon_r = 1$, the equation $\overline{g}_1^{(1)}(\chi)\,|_{\chi=\chi_0} = 0$ admits no solutions if $x = -1/4$ or $-1/2$. (This is also true for $x_0 = 1/2$ and 1.)

Furthermore, it also follows that, if one allows the electromagnetic properties of the embedding substrate (i.e., ϵ_r and μ_r) to vary, then one could make the reactive power vanish for $\chi_0 = 0$, this being a *matching condition* under which the minimum energy sources are not only of local minimum energy (see below) but also self-matched to resonance. Let us illustrate this for a quarter-wavelength antenna. For a given positive relative electric permittivity, for instance, $\epsilon_r = 1$, we find that the matching condition mentioned above is satisfied for $x \simeq 0.511$, i.e., in this case $\epsilon_r = 1$ and $\mu_r \simeq 4.18$. Now, for a given negative relative electric permittivity, for instance, $\epsilon_r = -1$, we find that the matching condition is satisfied for $x \simeq -1.338$, i.e., in this case $\epsilon_r = -1$ and $\mu_r = -28.64$. A word of caution is necessary at this point. From the definition itself of the abovementioned matching, for $\chi_0 = 0$ one obtains $\mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)} = \min \mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}$ (cf. Tables 4.1 and 4.3). Yet one must not be lured into thinking that the substrate constitutive properties ϵ_r and μ_r associated to the matching cases must correspond to global minima for $\mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}$, i.e., that they represent the best substrate values. This is very clearly illustrated in Tables 4.1 and 4.3 where for $x = 1$, 5, and 10 in Table 4.1 and for $x = -1$, -5, and -10 in Table 4.3 one has $\mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}|_{\chi_0 \neq 0} < \mathcal{E}_{\mathcal{E},\mathcal{P}}^{(j=1=l)}|_{\chi_0 = 0}$. In other words a quarter-wavelength antenna embedded in substrates having those values of x as their electromagnetic densities exhibits source energies smaller than those exhibited by the antenna when it is embedded in a substrate whose constitutive parameters satisfy the matching condition.

Appendix A. Wavefunctions $\mathfrak{B}^{(j)}_{l,m}$ for piecewise-constant radially symmetric backgrounds. The aim of this appendix is to show that the multipole moments $a^{(j)}_{l,m}$ are given by (2.17) with the wavefunctions $\mathfrak{B}^{(j)}_{l,m}$ given by (2.19) and (2.20). The manipulations below rely on (2.13) and (2.14) and the concept of reciprocity. The latter can be stated as follows [7]: The reaction (coupling) $\mathcal{R}_{\mathbf{E}\to\mathbf{J}_0}$ of the field $\mathbf{E}$ produced by a source $\mathbf{J}$ on another source $\mathbf{J}_0$, given by

$$\mathcal{R}_{\mathbf{E}\to\mathbf{J}_0} = \int d\mathbf{r}\mathbf{E}(\mathbf{r})\cdot\mathbf{J}_0(\mathbf{r}), \tag{A.1}$$

is equal to the reaction of the field $\mathbf{E}_0$ produced by the source $\mathbf{J}_0$ on the source $\mathbf{J}$, in particular,

$$\mathcal{R}_{\mathbf{E}_0\to\mathbf{J}} = \int d\mathbf{r}\mathbf{E}_0(\mathbf{r})\cdot\mathbf{J}(\mathbf{r}) = \mathcal{R}_{\mathbf{E}\to\mathbf{J}_0}. \tag{A.2}$$

To evaluate the field due to a current distribution $\mathbf{J}(\mathbf{r})$ that is embedded in the piecewise-constant radially symmetric background of interest, we consider, without loss of generality, the following two classes of canonical sources:

$$\left[\mathbf{J}^{(1)}_{l,m}\right]_0(\mathbf{r}) = \delta(r-R)\hat{\mathbf{r}}\times\mathbf{Y}_{l,m}(\hat{\mathbf{r}}) \tag{A.3}$$

and

$$\left[\mathbf{J}^{(2)}_{l,m}\right]_0(\mathbf{r}) = \delta(r-R)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), \tag{A.4}$$

where in both expressions $R > a$ represents the radius of the helper source centered around the origin. (Ultimately, the multipole moments $a^{(j)}_{l,m}$ are expected to, and in fact will, turn out to be independent of R.) The justification for the above considerations relies on two results: (1) the transverse component of an arbitrary vector field on the spherical surface of radius $R > a$ centered about the origin is *uniquely* characterized by its expansion in terms of the vector spherical harmonics $\mathbf{Y}_{l,m}(\hat{\mathbf{r}})$ and their associated vector functions $\hat{\mathbf{r}}\times\mathbf{Y}_{l,m}(\hat{\mathbf{r}})$, and (2) the multipole moments characterizing any electric field outside the support of the emitting sources is *uniquely* determined by the tangential component of this field on a sphere totally enclosing the support of the emitting sources (as noted in section 2).

The field $[\mathbf{E}^{(j)}_{l,m}]_{inc}$ that would be produced by the source $[\mathbf{J}^{(j)}_{l,m}]_0$ in (A.4) if it were in free space (this will be the incident field in the following) is given by

$$\left[\mathbf{E}^{(j)}_{l,m}\right]_{inc} = \int d\mathbf{r}\bar{\mathbf{G}}_0(\mathbf{r},\mathbf{r}')\cdot\left[\mathbf{J}^{(j)}_{l,m}\right]_0,$$

where $\bar{\mathbf{G}}_0(\mathbf{r},\mathbf{r}')$ is the multipole representation of the free-space electric dyadic Green's function [39], viz.,

$$\begin{aligned}\bar{\mathbf{G}}_0(\mathbf{r},\mathbf{r}') = \sum_{l=1}^{\infty}\sum_{m=-l}^{l}\frac{-\omega\mu_0}{k_0 l\,(l+1)}&\Big\{k_0^2\left[j_l(k_0r_<)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}_<)\right]\left[h_l^{(+)}(k_0r_>)\mathbf{Y}^*_{l,m}(\hat{\mathbf{r}}_>)\right]\\ &+\boldsymbol{\nabla}\times\left[j_l(k_0r_<)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}_<)\right]\boldsymbol{\nabla}\times\left[h_l^{(+)}(k_0r_>)\mathbf{Y}^*_{l,m}(\hat{\mathbf{r}}_>)\right]\Big\}\\ &+\frac{i}{\omega\epsilon_0}\hat{\mathbf{r}}\hat{\mathbf{r}}\delta\left(\mathbf{r}-\mathbf{r}'\right).\end{aligned} \tag{A.5}$$

The $<$ ($>$) subscript designates the smaller (larger) of r and r'.

For $r < R$ the field $[\mathbf{E}^{(1)}_{l,m}]_{inc}$ is found to be given by

$$\left[\mathbf{E}^{(1)}_{l,m}\right]_{inc}(\mathbf{r}) = \tau_l(k_0, R)\boldsymbol{\nabla} \times [j_l(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], \tag{A.6}$$

where we have defined

$$\tau_l(k_0, R) \equiv -\eta_0 k_0 R^2 V_l\,(k_0 R)\,. \tag{A.7}$$

Along analogous lines, the (incident) field $[\mathbf{E}^{(2)}_{l,m}]_{inc}$ produced by the source $[\mathbf{J}^{(1)}_{l,m}]_0$ in (A.3) in free space is found, for $r < R$, to be given by

$$\left[\mathbf{E}^{(2)}_{l,m}\right]_{inc}(\mathbf{r}) = \zeta_l(k_0 R) j_l(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), \tag{A.8}$$

where we have introduced

$$\zeta_l(k_0 R) \equiv -\eta_0\,(k_0 R)^2\, h_l^{(+)}(k_0 R). \tag{A.9}$$

The obtainment of the above results requires the use of orthogonality properties of the vector spherical harmonics $\mathbf{Y}_{l,m}(\hat{\mathbf{r}})$ and the associated vector functions $\hat{\mathbf{r}} \times \mathbf{Y}_{l,m}(\hat{\mathbf{r}})$.

Introducing the index of refraction $n = \sqrt{\mu_s\epsilon_s}/\sqrt{\mu_0\epsilon_0} = \sqrt{\mu_r\epsilon_r}$, the evaluation of the total fields $[\mathbf{E}^{(j)}_{l,m}]_0$, $j = 1, 2$, associated with these sources for $r < R$ is seen from (1.1), (1.2), (2.1)–(2.3) to correspond to the solution of the forward scattering problem associated for $r < R$ with the equation

$$\left[\boldsymbol{\nabla}^2 + k_0^2\Theta(r-a) + n^2 k_0^2\Theta(a-r)\right]\left[\mathbf{E}^{(j)}_{l,m}\right]_0(\mathbf{r}) = \mathbf{0} \tag{A.10}$$

upon excitation by the incident fields $[\mathbf{E}^{(j)}_{l,m}]_{inc}$.

The total (incident plus scattered) field $[\mathbf{E}^{(1)}_{l,m}]_0$ must be, due to considerations of causality (in the scattered field) and well-behavedness of the interior field for $r < a$, of the form

$$\left[\mathbf{E}^{(1)}_{l,m}\right]_0(\mathbf{r}) = \begin{cases} \boldsymbol{\nabla} \times \left[\tau_l(k_0, R) j_l(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}) + D_1 h_l^{(+)}(k_0 r)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})\right], & r > a, \\ A_1\boldsymbol{\nabla} \times [j_l(kr)\mathbf{Y}_{l,m}(\hat{\mathbf{r}})], \quad r \le a, \end{cases} \tag{A.11}$$

where $k = nk_0$ is the wavenumber of the field in the background material confined within the source volume V and A_1 and D_1 are coefficients that are to be determined by imposing continuity of the tangential components of the electric and magnetic fields on the boundary $\partial V \equiv \{\mathbf{r} \in \mathbb{R}^3 : r = a\}$. Analogously, the total field $[\mathbf{E}^{(2)}_{l,m}]_0$ must be of the form

$$\left[\mathbf{E}^{(2)}_{l,m}\right]_0(\mathbf{r}) = \begin{cases} \left[\zeta_l(k_0 R) j_l(k_0 r) + D_2 h_l^{(+)}(k_0 r)\right] \times \mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & r > a, \\ A_2 j_l(kr)\mathbf{Y}_{l,m}(\hat{\mathbf{r}}), & r \le a, \end{cases} \tag{A.12}$$

where A_2 and D_2 are coefficients that need to be determined from the boundary conditions on ∂V.

By imposing the continuity requirements on the boundary ∂V and using the Wronskian relation for spherical Bessel functions [6], one obtains (for $j = 1$)

$$\begin{aligned}\frac{A_1}{\tau_l(k_0, R)} &= \frac{i/\,(k_0 a)\,(ka)}{(\epsilon_r/\mu_r)^{1/2}\, j_l(ka) V_l(k_0 a) - h_l^{(+)}(k_0 a) U_l(ka)} \\ &\equiv F_l^{(1)}\left(k_0 a, ka, \epsilon_r, \mu_r\right), \qquad \text{(A.13)}\end{aligned}$$

where U_l and V_l have already been defined in (2.21) and (2.22). The coefficient A_2 associated with the field $[\mathbf{E}_{l,m}^{(2)}]_0$ can be obtained by an analogous procedure which yields

$$\begin{aligned}\frac{A_2}{\zeta_l(k_0 R)} &= \frac{i\mu_r/\,(k_0 a)\,(ka)}{(\mu_r/\epsilon_r)^{1/2}\, j_l(ka) V_l(k_0 a) - h_l^{(+)}(k_0 a) U_l(ka)} \\ &\equiv F_l^{(2)}\left(k_0 a, ka, \epsilon_r, \mu_r\right). \qquad \text{(A.14)}\end{aligned}$$

Along with (A.11) and (A.12) the above results define the fields $[\mathbf{E}_{l,m}^{(1)}]_0$ and $[\mathbf{E}_{l,m}^{(2)}]_0$ in the region V.

By applying the reciprocity relation equation (A.2) to the preceding results (in particular, (A.3), (A.4), (A.7), (A.9), (A.11)–(A.14)), one finds that the multipole moments $a_{l,m}^{(j)}$ are indeed independent of R and are given by (2.17) with the source-free wavefunctions $\mathfrak{B}_{l,m}^{(j)}(\mathbf{r})$ given by (2.19)–(2.22). In obtaining these results we have also recalled the multipole expansion for the electric field $\mathbf{E}(\mathbf{r})$, i.e., (2.13) and (2.14), along with the orthogonality and analytic continuation properties of the vector spherical harmonics, and the analytic continuation property of the spherical Bessel functions of the first kind, viz., $j_l^*(ka) = j_l(k^* a)$.

Acknowledgments. E.A.M. gratefully acknowledges enlightening conversations with Prof. Anthony Devaney, Dr. Arthur Yaghjian, and Dr. Arje Nachman that were pertinent to the research reported here. Also, the authors would like to express their gratitude to the referees for their interesting comments and suggestions.

BOUNDARY DRIVEN WAVEGUIDE ARRAYS: SUPRATRANSMISSION AND SADDLE-NODE BIFURCATION[*]

HADI SUSANTO[†]

Abstract. In this paper, we consider a semi-infinite discrete nonlinear Schrödinger equation driven at one edge by a driving force. The equation models the dynamics of coupled waveguide arrays. When the frequency of the forcing is in the allowed band of the system, there will be a linear transmission of energy through the lattice. Yet, if the frequency is in the upper forbidden band, then there is a critical driving amplitude for a nonlinear tunneling, which is called supratransmission, of energy to occur. Here, we discuss mathematically the mechanism and the source of the supratransmission. By analyzing the existence and the stability of the rapidly decaying static discrete solitons of the system, we show rigorously that two of the static solitons emerge and disappear in a saddle-node bifurcation at a critical driving amplitude. One of the emerging solitons is always stable in its existence region and the other is always unstable. We argue that the critical amplitude for supratransmission is then the same as the critical driving amplitude of the saddle-node bifurcation. We consider as well the case of the forcing frequency in the lower forbidden band. It is discussed briefly that there is no supratransmission because in this case there is only one rapidly decaying static soliton that exists and is stable for any driving amplitude.

Key words. supratransmission, nonlinear tunneling, saddle-node bifurcations

1. Introduction.

An exotic nonlinear phenomenon has been discovered recently by Geniet and Leon [1] in a semi-infinite chain of coupled oscillators driven at one edge by a time periodic forcing. Energy excitations will propagate through the chain if the driving frequency is in the allowed band of the discrete system. It is natural because of the system's dispersion relation. In contrast, it would be expected that if the forcing frequency is in the band gap, then there would be no energy flow. Yet, Geniet and Leon [1] show theoretically and experimentally that there is a definite driving amplitude threshold above which a sudden energy flow takes place. This phenomenon is called nonlinear supratransmission [1]. An exciting independent work on a modified Klein–Gordon equation describing the Josephson phase of layered high-$\mathrm{T_c}$ superconductors shows the presence of the same phenomenon [2]. Promising technological applications employing supratransmission have been proposed accompanying these findings, such as binary signal transmissions of information [3] and terahertz frequency selection devices [4].

In [5] Khomeriki considers boundary driven coupled optical focusing waveguide arrays described by

$$i\frac{\partial\psi_n}{\partial z} = -\psi_{n+1} - \psi_{n-1} - \gamma|\psi_n|^2\psi_n, \quad \psi_0 = Ae^{i\Delta z}, \tag{1.1}$$

with $\gamma > 0$ and $n = 1, 2, \ldots$. Here, ψ_n is the electromagnetic wave amplitude in the nth guiding core, z is the propagation variable, Δ is the propagation constant or the driving frequency, and γ represents the nonlinearity coefficient, which is taken

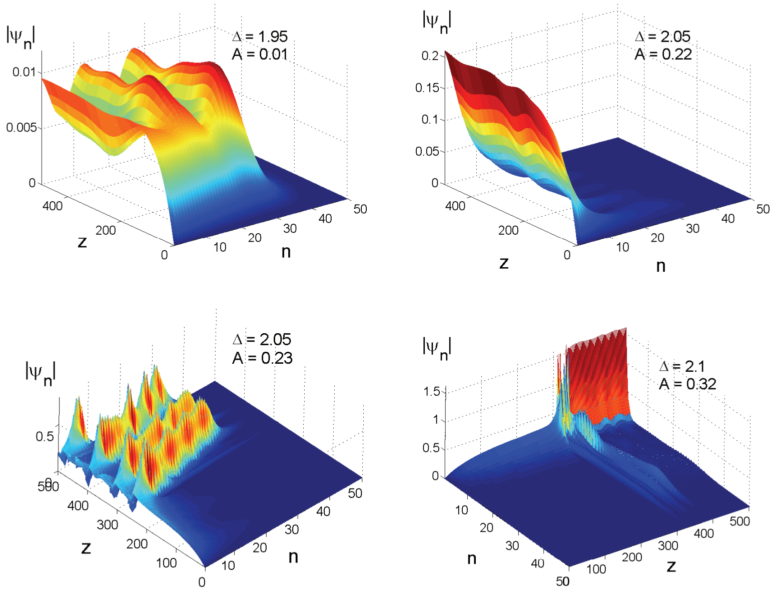

FIG. 1.1. *Three-dimensional plots of time evolution of the boundary driven waveguide arrays of* (1.1). *When the driving frequency $-2 < \Delta < 2$ is in the allowed band, any driving amplitude will lead to an energy flow to remote sites (top left panel). If Δ is in the upper forbidden band and A is small enough, the boundary will excite a couple of arrays only (top right panel). Yet, there is a critical threshold amplitude $A_{\text{th}}(\Delta)$ above which there is a nonlinear forbidden band tunneling indicated by the released of a train of discrete solitons (bottom left panel). A quantitatively different behavior of supratransmission occurs when the driving frequency is large enough, as is shown in the bottom right panel.*

to be $\gamma = 2$ in this report. This model can also be considered as a slow modulation wave approximation to the discrete sine-Gordon equation [6]. Similar to the nonlinear band-gap tunneling observed by Geniet and Leon [1], it is reported that there is a critical threshold $A_{\text{th}}(\Delta)$ for supratransmission when the propagation constant Δ is in the forbidden band $\Delta > 2$ [5].

In Figure 1.1, we present numerical simulations of the dynamics of (1.1). Following [5], the driving is turned on adiabatically to avoid the appearance of an initial shock by assuming the form

$$A = \breve{A}(1 - \exp(-z/\tau)),$$

where we omit the breve symbol henceforth. In the following figures, we take $\tau = 50$ and apply a linearly increasing damping to the last 20 sites to suppress edge reflection.

Presented in the top left panel of Figure 1.1 is a three-dimensional plot of time evolution of (1.1) when the driving frequency is in the allowed band $-2 < \Delta < 2$. A small driving amplitude will excite all the sites. On the other hand, if the driving frequency is in the upper band $\Delta > 2$, a small A will only excite several neighboring sites, as is shown in the top right panel of Figure 1.1. Yet, if the driving amplitude is large enough, then a train of "traveling" discrete solitons can be released [5] (see bottom left panel of the same figure). This flow of energy is the so-called supratransmission or nonlinear forbidden band tunneling, and we call the minimum A for supratransmission to occur a critical threshold A_{th}. The word *traveling* is in quotes because (1.1) does not admit a genuine one (see [7] and the references therein). If one waits long enough, the gap solitons will be trapped by the lattice. Khomeriki [5] also notices an immediate trapping when the driving frequency Δ is relatively large, as is shown in the bottom right panel of Figure 1.1. In this regime, the corresponding discrete gap solitons are highly localized.

An analytical approximation of $A_{\mathrm{th}}(\Delta)$ in the limit $0 < \Delta - 2 \ll 1$ is given by [5]

$$A_{\mathrm{th}}(\Delta) = \sqrt{\Delta - 2}. \tag{1.2}$$

Remark 1.1. Equation (1.1) is symmetric with respect to the transformation $A \to -A$ and $\psi_n \to -\psi_n$. This means that there is also a critical amplitude $-A_{\mathrm{th}}(\Delta)$ if one applies $A < 0$ such that for $A < -A_{\mathrm{th}}(\Delta) < 0$, a nonlinear forbidden band tunneling will occur. Equation (1.1) is also symmetric with respect to the transformation $\Delta \to -\Delta$, $\psi_n \to (-1)^n \psi_n$, and $\gamma \to -\gamma$. Therefore, the same phenomenon can be observed in defocusing waveguide arrays $\gamma < 0$. Due to the transformation, the only difference of defocusing arrays from the self-focusing ones is that there will be a π phase difference between neighboring lattices.

It is presented in [5] that the numerical result for the threshold amplitude deviates rapidly from the approximation (1.2). It is because (1.2) is actually the amplitude-temporal frequency relation of the continuous nonlinear Schrödinger (NLS) equation's solitons. The relation has been phase-shifted properly due to some transformation, i.e., $\psi_n \to \psi_n \exp(2iz)$. Applying the transformation to (1.1) will take it to a normalized standard finite difference approximation of the continuous NLS equation.

Remembering the aforementioned promising applications of nonlinear tunneling, it is therefore of interest to obtain an approximation of the threshold amplitude in the other limit $\Delta - 2 \gg 1$. This is one of the aims of the present report. The other aim is to understand mathematically the mechanism of the nonlinear tunneling. It is mentioned but not rigorously proved [8] that the supratransmission happens because of the emergence of two solutions at the critical driving amplitude, i.e., a saddle-node bifurcation. If this is the case, then this means that supratranmissions correspond to an existence issue, as opposed to a stability phenomenon [9], and the threshold amplitude is not necessarily the amplitude of the corresponding fundamental soliton (1.2). Understanding the source of supratransmission also will allow us to explain, for example, the reason why there is no threshold amplitude for nonlinear tunneling when the driving frequency is in the lower forbidden band $\Delta < -2$.

Nonetheless, one may question the relevance of our first aim, as supratransmission is quickly trapped by the lattices for large Δ. Even though our analysis may not be immediately applicable to the present case, the aim is still of relevance. There are several experimentally realizable discrete equations that support "traveling" solitons in a parameter region where the gap solitons are highly localized. One particular example is the discrete Schrödinger equation with saturable nonlinearity in the large nonlinearity coefficient regime [10]. We have observed supratransmission in this equation and have successfully applied our analysis presented herein to obtain an approximation to the threshold amplitude [11]. Later on in this paper, we also conjecture that our analytically obtained approximation, presented in terms of a power series expansion, may well be convergent uniformly in the region of interest, i.e., $\Delta > 2$. Moreover, the mathematical procedure presented herein can also be applied as an alternative method to analyze the bistability effect considered, e.g., in [12]. We might even consider it simpler and more appropriate as the analysis can then be done solely in its discrete setup, with no need for approximating the problem with its continuous counterpart [12].

In this study, we will show that the supratransmission is indeed related to saddle-node bifurcations. To mathematically prove this, our strategy is as follows. We will first prove the existence of a mode bifurcating from the constant solution $\psi_n \equiv 0$ due to the driving site. We will also show that there is a singular mode bifurcating from infinity. We will then demonstrate that these two modes collide in a saddle-node bifurcation by developing an asymptotic analysis in the range of Δ large. Such an analysis is doable in that regime because the modes are highly localized. The final step to show that the critical amplitude is the same as the threshold amplitude for supratransmission is to prove that the mode bifurcating from the zero state is stable, all the way on its existence region. Using this result, then we can derive an approximation of the threshold amplitude in terms of a power series expansion that can be calculated to any order. Numerical computations will be presented as well to compare our analytical results.

Our paper is outlined as follows. In subsection 2.1, we present our asymptotic analysis for the existence of monotonically decaying static solutions of (1.1). The next subsection will contain our study on the stability analysis of solutions discussed in the preceding subsection. Using the same procedures, we then briefly discuss in subsection 2.3 that there is no supratransmission in the case of $\Delta < -2$ as there is no bifurcation occurring in this regime. Then we compare our analytical findings with the results of numerical computations in subsection 2.4. Finally, we summarize our findings and present our conclusions in the last section.

2. Existence and stability analysis of rapidly decaying discrete solitons.

2.1. Existence analysis. Stationary solutions of (1.1) are sought in the form of $\psi_n(z) = \phi_n e^{i\Delta z}$, where ϕ_n is a real-valued function. This ansatz can be applied, as one would naturally expect that all the sites will be excited with the same frequency as the driving frequency. Since we are interested in the large propagation constant Δ, we scale $\Delta \to 1$ and define $\epsilon = 1/\Delta$. Hence, we consider $|\epsilon| \ll 1$. A static equation of (1.1) is then given by

$$F(\phi, \epsilon) := -\phi_n + \epsilon \left(\phi_{n+1} + \phi_{n-1} + \gamma {\phi_n}^3\right) = 0, \tag{2.1}$$

with $\phi_0 = A$.

When $|\epsilon|$ is small enough, apart from the boundary, the leading order solution of ϕ_n would formally satisfy

$$\phi_n \left(-1 + \epsilon\gamma {\phi_n}^2\right) \approx 0, \tag{2.2}$$

from which we obtain that $\phi_n \approx 0$ and $\phi_n \approx \pm 1/\sqrt{\epsilon\gamma}$. It physically means that the arrays are almost uncoupled and indicates that solutions of (2.1) can be expressed in terms of an asymptotic or a perturbation expansion in ϵ. It also says that when we consider finitely long waveguide arrays, i.e., $n = 1, 2, \ldots, N$, (2.1) can have at most 3^N solutions. Yet, only some of them are related to the nonlinear tunneling phenomenon presented in Figure 1.1. We are especially interested in solutions with a magnitude that is monotonically decaying with the property $|\phi_n| \to 0$ as $n \to \infty$. This consideration is based on the fact that when the driving frequency is in the forbidden band and the driving amplitude is below the critical threshold, the solution profile is monotonically decaying as $n \to \infty$ (see the top right panel of Figure 1.1). Moreover, we only need to consider particularly a family of *rapidly decaying discrete solitons*, which is defined as follows.

Definition 2.1. *Let $\phi_n = \sum_{k=0}^{\infty} a_{n,k}\vartheta_k(\epsilon)$ be a solution of* (2.1)*, where $n \in \mathbb{Z}^+$, $\vartheta_k(\epsilon)$ is an asymptotic sequence, and $\vartheta_k(\epsilon) = o\left(\vartheta_{k-1}(\epsilon)\right)$ for $\epsilon \to 0$. ϕ_n is a rapidly decaying discrete soliton of* (2.1) *if $|\phi_n|$ is a monotonically decreasing function to* 0 *as $n \to \infty$ with a property that to the leading order $\mathcal{O}(\vartheta_0)$ only the first lattice site is nonzero, i.e., $a_{1,0} \neq 0$ and $a_{n,0} = 0$, $n \neq 1$.*

As an example of this definition, let us consider the following solution of (2.1):

$$\Phi_0(n, A) = \begin{cases} -\dfrac{1}{\sqrt{\gamma}}\left(\dfrac{1}{\sqrt{\epsilon}} + \dfrac{\sqrt{\epsilon}}{2}\right) - A\dfrac{\epsilon}{2} + \mathcal{O}(\epsilon^{3/2}),\ n = 1, \\ \dfrac{1}{\sqrt{\gamma}}\left(\dfrac{1}{\sqrt{\epsilon}} + \dfrac{\sqrt{\epsilon}}{2}\right) + \mathcal{O}(\epsilon^{3/2}),\ n = 2, \\ \mathcal{O}(\sqrt{\epsilon}) \quad \text{otherwise.} \end{cases} \tag{2.3}$$

This solution is obtained from the expansion: $\phi_1 = -1/\sqrt{\epsilon\gamma} + a_{1,1}\sqrt{\epsilon} + a_{1,2}\epsilon + \cdots$, $\phi_2 = 1/\sqrt{\epsilon\gamma} + a_{2,1}\sqrt{\epsilon} + a_{2,2}\epsilon + \cdots$, $\phi_3 = 0 + a_{3,1}\sqrt{\epsilon}+$, and $\phi_n = 0 + \cdots$ for $n > 3$. Substituting the ansatz to (2.1) will yield polynomials in ϵ. Equating the coefficients of the polynomials for all orders of ϵ to zero will yield equations for $a_{k,l}$ that have to be solved simultaneously to obtain (2.3).

It is clear that the profile of $|\Phi_0(n, A)|$ (2.3) is monotonically decaying in n. However, this solution is not rapidly decaying as to the leading order, i.e., $\mathcal{O}(1/\sqrt{\epsilon})$, $|\Phi_0(2, A)| = |\Phi_0(1, A)| \neq 0$.

The existence of rapidly decaying solutions of (2.1) when $A = \mathcal{O}(1)$ is guaranteed by the following theorem.

Theorem 2.2. *Let A be of $\mathcal{O}(1)$. Then for ϵ positive and small there are three rapidly decaying discrete solitons of the static equation* (2.1)*. Denoted by Φ_j, $j = 1, 2, 3$, the solitons are given by*

$$\Phi_1(n, A) = \begin{cases} \dfrac{1}{\sqrt{\epsilon\gamma}} - A\dfrac{\epsilon}{2} - \dfrac{\epsilon^{3/2}}{2\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 1, \\ \dfrac{\sqrt{\epsilon}}{\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 2, \\ \dfrac{\epsilon^{3/2}}{\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 3, \\ 0 + \mathcal{O}(\epsilon^2) \quad \textit{otherwise,} \end{cases} \tag{2.4}$$

$$\Phi_2(n, A) = \begin{cases} A\epsilon + A\epsilon^3 + \mathcal{O}(\epsilon^5),\ n = 1, \\ A\epsilon^2 + \mathcal{O}(\epsilon^4),\ n = 2, \\ A\epsilon^3 + \mathcal{O}(\epsilon^5),\ n = 3, \\ 0 + \mathcal{O}(\epsilon^4) \quad \textit{otherwise,} \end{cases} \tag{2.5}$$

$$\Phi_3(n, A) = \begin{cases} -\dfrac{1}{\sqrt{\epsilon\gamma}} - A\dfrac{\epsilon}{2} + \dfrac{\epsilon^{3/2}}{2\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 1, \\ -\dfrac{\sqrt{\epsilon}}{\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 2, \\ -\dfrac{\epsilon^{3/2}}{\sqrt{\gamma}} + \mathcal{O}(\epsilon^2),\ n = 3, \\ 0 + \mathcal{O}(\epsilon^2) \quad \textit{otherwise.} \end{cases} \tag{2.6}$$

Proof. Because we are looking for rapidly decaying solitons, to the leading order (2.1) can be represented by

$$-\phi_1 + \epsilon A + \gamma\epsilon{\phi_1}^3 = 0. \tag{2.7}$$

Equation (2.7) is a cubic equation similar to (2.2), also with three roots. However, as $\epsilon \to 0$, (2.7) reduces to a linear equation $\phi_1 = 0$ with only a single root. Therefore, finding the roots of the equation is a singular perturbation problem. Following, e.g., [13] (see Example 3 of sections 2.1 and 2.2), one will obtain the roots of (2.7), i.e., $\phi_1 = A\epsilon + \cdots$ and $\phi_1 = \pm 1/\sqrt{\gamma\epsilon} + \cdots$. This concludes that there are three rapidly decaying solutions of (2.1). In the following, let us name the solitons $\Phi_j(n, A)$, $j = 1, 2, 3$, with $\Phi_1(1, A) = 1/\sqrt{\epsilon\gamma} + \cdots$, $\Phi_2(1, A) = \epsilon A + \cdots$, and $\Phi_3(1, A) = -1/\sqrt{\epsilon\gamma} + \cdots$. The existence of $\Phi_j(n, A)$ for (2.1) follows immediately from the implicit function theorem (see, e.g., [14]) since F is differentiable and the Jacobian matrix of problem (2.1) $DF(\phi, 0)$ is invertible. Explicit calculations to obtain (2.4)–(2.6) can be done similarly following the derivation of (2.3). □

If one compares the above theorem and the top right panel of Figure 1.1, it can be recognized immediately that the solution observed in the panel in the limit $z \to \infty$ is nothing else but $|\Phi_2(n, A)|$.

One still can obtain the existence of the above rapidly decaying solutions even when $A \gg 1$, as stated in the following theorem.

THEOREM 2.3. *Let A be scaled to $A = \tilde{A}/\epsilon^{3/2}$, $\tilde{A} < 2/\sqrt{27\gamma}$.*

$$\Phi_j(n, A) = \begin{cases} \dfrac{\Phi_j^0}{\sqrt{\epsilon}} + \dfrac{\tilde{A}}{3\gamma{\Phi_j^0}^2 - 1}\left(\sqrt{\epsilon} - \epsilon\right) + \mathcal{O}(\epsilon^{3/2}), \ n = 1, \\ \Phi_j^0\sqrt{\epsilon} + \mathcal{O}(\epsilon^{3/2}), \ n = 2, \\ 0 + \mathcal{O}(\epsilon^{3/2}) \quad \textit{otherwise,} \end{cases} \tag{2.8}$$

with Φ_j^0 given by

$$\Phi_j^0 = \begin{cases} \dfrac{2}{\sqrt{3\gamma}}\cos\left(\dfrac{1}{3}\arccos\left(\dfrac{-\tilde{A}\sqrt{27\gamma}}{2}\right)\right), & j = 1, \\ \dfrac{2}{\sqrt{3\gamma}}\cos\left(\dfrac{4\pi}{3} + \dfrac{1}{3}\arccos\left(\dfrac{-\tilde{A}\sqrt{27\gamma}}{2}\right)\right), & j = 2, \\ \dfrac{2}{\sqrt{3\gamma}}\cos\left(\dfrac{2\pi}{3} + \dfrac{1}{3}\arccos\left(\dfrac{-\tilde{A}\sqrt{27\gamma}}{2}\right)\right), & j = 3. \end{cases} \tag{2.9}$$

Moreover, if we write $A = 2/\sqrt{(27\gamma\epsilon^3)} - \widehat{A}\sqrt{\epsilon}$, with $\widehat{A} > 1/\sqrt{3\gamma}$, then Φ_j, $j = 1, 2$, can be written as

$$\Phi_{1,2} = \begin{cases} \dfrac{1}{\sqrt{3\gamma}\sqrt{\epsilon}} \mp \sqrt{\dfrac{\widehat{A}}{\sqrt{3\gamma}} - \dfrac{1}{3\gamma}}\sqrt{\epsilon} + \mathcal{O}(\epsilon^{3/2}), \ n = 1, \\ \dfrac{\sqrt{\epsilon}}{\sqrt{3\gamma}} + \mathcal{O}(\epsilon^{3/2}), \ n = 2, \\ \mathcal{O}(\epsilon^{3/2}) \quad \textit{otherwise.} \end{cases} \tag{2.10}$$

Proof. As we are interested in the case of $A \gg 1$, we first scale $A = \tilde{A}/\epsilon^{3/2}$ and correspondingly write $\Phi_j(n, A) = \Phi_j^0(n, A)/\sqrt{\epsilon} + \cdots$, $j = 1, 2, 3$, with $\Phi_j^0(n, A) = 0$

for all $1 < n \in \mathbb{Z}^+$. Substituting the expansion to (2.1) and identifying coefficients for power series of $\mathcal{O}(1/\sqrt{\epsilon})$ yields the following cubic equation for $\Phi_j^0(1, A) = \Phi_j^0$:

$$G\left(\Phi_j^0\right) := -\Phi_j^0 + \tilde{A} + \gamma\left(\Phi_j^0\right)^3 = 0. \tag{2.11}$$

Equation (2.11) cannot be solved perturbatively to obtain the roots Φ_j^0 as before since all the terms in (2.11) are of the same order. Therefore, we need the following lemma on cubic equations.

LEMMA 2.4. *Consider the following polynomial equation:*

$$g(x) = ax^3 + bx^2 + cx + d, \quad a, b, c, d \in \mathbb{R}.$$

Let

$$X = \frac{-b}{3a}, \quad Y = g(X), \quad h = 2av^3,$$
$$v^2 = \frac{b^2 - 3ac}{9a^2}, \quad \theta = \frac{1}{3}\arccos\left(\frac{-Y}{h}\right).$$

If $Y^2 < h^2$, then the cubic equation has three distinct real roots given by

$$x_1 = X + 2v\cos\theta, \tag{2.12}$$
$$x_2 = X + 2v\cos(4\pi/3 + \theta), \tag{2.13}$$
$$x_3 = X + 2v\cos(2\pi/3 + \theta), \tag{2.14}$$

where

$$x_1 > x_2 > x_3.$$

When $Y^2 = h^2$, two of the roots which are neighbors to each other, i.e., x_1 and x_2 or x_2 and x_3, will collide in a saddle-node bifurcation and disappear when $Y^2 > h^2$, i.e., the cubic equation then has only a single real root.

Proof. There is an enormous number of textbooks and online references on cubic equations; see, e.g., http://mathworld.wolfram.com/CubicFormula.html. The expression of the cubic polynomial roots (2.12)–(2.14) is using Nickalls's geometric representation [15]. □

According to Lemma 2.4, (2.11) has geometric representation parameters:

$$X = 0, \quad Y = \tilde{A}, \quad v = \frac{1}{\sqrt{3\gamma}}, \quad h = \frac{2}{\sqrt{27\gamma}}, \quad \theta = \frac{1}{3}\arccos\left(\frac{-Y}{h}\right),$$

from which we can conclude that (2.11) has three real roots when $\tilde{A} < 2/\sqrt{27\gamma}$. The roots of (2.11), i.e., (2.9), are obtained using (2.12)–(2.13). Then the continuation of Φ_j^0 can be obtained immediately using the implicit function theorem.

It is then straightforward to calculate that when $\tilde{A} = 2/\sqrt{27\gamma}$, $\Phi_{1,2}^0 = 1/\sqrt{3\gamma}$ as $2\cos\theta = 2\cos(4\pi/3 + \theta) = 1$. Hence, we know that $\Phi_1(n, A)$ collides with $\Phi_2(n, A)$ in a saddle-node bifurcation.

For the value of A close to the occurrence of the saddle-node bifurcation, we write $A = 2/\sqrt{27\gamma\epsilon^3} - \widehat{A}\sqrt{\epsilon}$. In this case, the implicit function theorem cannot be immediately employed to prove the existence of Φ_1 and Φ_2 as we need a bound for $\widehat{A}$.

First, we substitute $\Phi_j = \Phi_j^0(n,A)/\sqrt{\epsilon} + \sqrt{\epsilon}\Phi_j^1(n,A)$, $j = 1,2$, in the steady state equation (2.1) with $\Phi_j^0(n,A) = 1/\sqrt{3\gamma}$ for $n = 1$ and 0 otherwise. This then gives the following equations:

$$\begin{aligned}
&\tilde{G}_1(\Phi_j^1,\epsilon) := \Phi_j^1(2,A) - \widehat{A} + \sqrt{3\gamma}\left(\Phi_j^1(1,A)\right)^2 + \epsilon\gamma\left(\Phi_j^1(1,A)\right)^3 = 0,\\
&\tilde{G}_2(\Phi_j^1,\epsilon) := -\Phi_j^1(2,A) + \epsilon\Phi_j^1(3,A) + \frac{1}{\sqrt{3\gamma}} + \epsilon\Phi_j^1(1,A) + \epsilon^2\gamma\left(\Phi_j^1(1,A)\right)^3 = 0,\\
&\tilde{G}_n(\Phi_j^1,\epsilon) := \Phi_j^1(n,A) + \epsilon\left(\Phi_j^1(n+1,A) + \Phi_j^1(n-1,A) + \epsilon\gamma\Phi_j^1(n,A)^3\right) = 0, \quad n \neq 1,2.
\end{aligned}$$

Taking $\epsilon = 0$, the above equations give us

$$\begin{aligned}
\Phi_j^1(1,A) &= \pm\sqrt{\frac{\widehat{A}}{\sqrt{3\gamma}} - \frac{1}{3\gamma}},\\
\Phi_j^1(2,A) &= \frac{1}{\sqrt{3\gamma}},\\
\Phi_j^1(n,A) &= 0, \quad n \neq 1,2.
\end{aligned}$$

Note that the $\pm$-solutions collide for $\widehat{A} = 1/\sqrt{3\gamma}$. Because the linearization $D\tilde{G}(\Phi_j^1,0)$ is invertible for $\widehat{A} > 1/\sqrt{3\gamma}$, the implicit function theorem can be applied again and we have the existence of rapidly decaying solitons $\Phi_j = \Phi_j^0(n,A)/\sqrt{\epsilon} + \sqrt{\epsilon}\Phi_j^1(n,A)$, $j = 1,2$. □

With this theorem, we then have shown that Φ_1 collides in a saddle-node bifurcation with Φ_2. Yet, we cannot directly claim that this is the source of the supratransmission observed in Figure 1.1 before we show and discuss the stability of the two solitons.

2.2. Stability analysis. After discussing the existence of rapidly decaying solitons of (2.1), we study their stability. If ϕ_n, $n = 1,2,\ldots$, is a solution of (2.1), then the linear spectral stability of ϕ_n can be obtained by substituting the ansatz $\psi_n = (\phi_n + \delta[v_n e^{i\lambda z} + \overline{w_n}e^{-i\overline{\lambda}z}])e^{i\Delta z}$ with $\lambda \in \mathbb{C}$, $(v_n,w_n) \in \mathbb{C}^2$, and $n \in \mathbb{Z}^+$ into (1.1). Linearizing the equation to $\mathcal{O}(\delta)$, we obtain the eigenvalue problem

$$\lambda\epsilon\begin{pmatrix} v_n \\ w_n \end{pmatrix} = \epsilon\sigma\begin{pmatrix} v_{n-1} \\ w_{n-1} \end{pmatrix} + \mathcal{L}\begin{pmatrix} v_n \\ w_n \end{pmatrix} + \epsilon\sigma\begin{pmatrix} v_{n+1} \\ w_{n+1} \end{pmatrix}, \tag{2.15}$$

with

$$\begin{aligned}
\begin{pmatrix} v_0 \\ w_0 \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad \sigma = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\\
\mathcal{L} &= \begin{pmatrix} -1 + 2\epsilon\gamma|\phi_n|^2 & \epsilon\gamma{\phi_n}^2 \\ -\epsilon\gamma{\phi_n}^2 & 1 - 2\epsilon\gamma|\phi_n|^2 \end{pmatrix}, \quad n \in \mathbb{Z}^+,
\end{aligned}$$

where we have scaled $\Delta \to 1$.

The natural domain for $\tilde{\mathcal{L}} = (\epsilon\sigma \quad \mathcal{L} \quad \epsilon\sigma)$ is $L^2(\mathbb{C})$. We call λ an eigenvalue of $\tilde{\mathcal{L}}$ if there is a function $\{v_n\}_{n\in\mathbb{Z}^+}, \{w_n\}_{n\in\mathbb{Z}^+} \in L^2(\mathbb{C})$ which satisfies (2.15). Since $\tilde{\mathcal{L}}$ depends smoothly on A, the eigenvalues of $\tilde{\mathcal{L}}$ will depend smoothly on A, too. ϕ_n is linearly stable if the imaginary part of λ is zero, i.e., $\mathrm{Im}(\lambda) = 0$.

The continuous spectrum is obtained by substituting

$$v_n = Ae^{ikn}, \quad w_n = Be^{ikn}, \quad \phi_n = 0$$

in (2.15), from which we will obtain

$$\epsilon\lambda = \pm 2\epsilon \cos k \mp 1.$$

Thus, the continuous spectrum of solutions under investigation is the range

$$\lambda \in \left(-\frac{1}{\epsilon} - 2, -\frac{1}{\epsilon} + 2\right) \quad \text{and} \quad \lambda \in \left(\frac{1}{\epsilon} - 2, \frac{1}{\epsilon} + 2\right). \tag{2.16}$$

As the continuous spectrum lies in the real axis, the stability of the solutions is determined only by the discrete spectrum, i.e., eigenvalues. For the solutions given in Theorems 2.2 and 2.3, we have the following stability results.

THEOREM 2.5. *For small driving amplitude $A = \mathcal{O}(1)$, the various rapidly decaying discrete solitons have the following properties:*

1. *The discrete soliton Φ_1 is unstable. It has a single imaginary eigenvalue.*
2. *The soliton Φ_2 is strictly stable as the soliton has no discrete eigenvalues.*
3. *The discrete soliton Φ_3 is stable. It has a single real eigenvalue.*

Proof. We are looking for eigenvectors that are also rapidly decaying. Therefore, the eigenvalue problem (2.15) to the leading order can be approximated by the linear eigenvalue problem

$$\lambda\epsilon \begin{pmatrix} v_1 \\ w_1 \end{pmatrix} = \mathcal{L} \begin{pmatrix} v_1 \\ w_1 \end{pmatrix},$$

which gives the following approximate eigenvalues:

$$\lambda = \pm\frac{1}{\epsilon}\sqrt{3\left(\epsilon\gamma{\phi_n}^2\right)^2 - 4\epsilon\gamma{\phi_n}^2 + 1}. \tag{2.17}$$

In the above expression, we have taken into account the fact that $\phi_n \in \mathbb{R}$.

For the stability of Φ_1 and Φ_3, substitute $\phi_1 = \Phi_j(1, A)$, $j = 1, 3$, into (2.17). Taking the series expansion of the expression gives the following eigenvalue λ for $\Phi_j(n, A)$:

$$\lambda = \begin{cases} \epsilon^{-1/4}\sqrt{2A\sqrt{\gamma}}i + \mathcal{O}(\epsilon^{1/4}), & j = 1, \\ \epsilon^{-1/4}\sqrt{2A\sqrt{\gamma}} + \mathcal{O}(\epsilon^{1/4}), & j = 3. \end{cases} \tag{2.18}$$

Because the eigenvalue of $\Phi_1(n, A)$ has a nonzero imaginary part, we conclude that to the leading order Φ_1 is unstable, as opposed to Φ_3.

As for $\phi_1 = \Phi_2(1, A)$, the series expansion of (2.17) gives

$$\lambda = 1/\epsilon + \mathcal{O}(\epsilon^2). \tag{2.19}$$

Because λ is inside the continuous spectrum (2.16), our assumption that the eigenfunction is rapidly decaying is not justified. Nonetheless, we know that Φ_2 bifurcates from a uniform solution $\phi_n \equiv 0$, which is stable. Because L depends smoothly on A, we then can conclude that Φ_1 has no eigenvalue. □

When the driving amplitude is large, we also have the following theorem.

THEOREM 2.6. *For large driving amplitude $A = \tilde{A}\epsilon^{-3/2}$, the various rapidly decaying discrete solitons have the following properties:*

1. *The discrete soliton Φ_1 is unstable with a single imaginary eigenvalue.*
2. *The soliton Φ_2 is strictly stable with a single real eigenvalue.*

3. *The discrete soliton Φ_3 is in general stable with a single eigenvalue, except in a finite interval, where our asymptotic analysis is inconclusive.*

To the leading order, the eigenvalue of the three solitons is given by

$$\lambda = K/\epsilon + \frac{\tilde{A}}{\Phi_j^0\left(3\gamma\left(\Phi_j^0\right)^2 - 1\right)}\left(\frac{\left(3\gamma^2\left(\Phi_j^0\right)^4 - 1\right)}{K} + K\right) + \mathcal{O}(\sqrt{\epsilon}), \tag{2.20}$$

with $K = \sqrt{3(\gamma{\Phi_j^0}^2)^2 - 4\gamma{\Phi_j^0}^2 + 1}$. Moreover, by writing $A = 2/\sqrt{27\gamma e^3} - \widehat{A}\sqrt{\epsilon}$, the eigenvalue of $\Phi_{1,2}$ is given by

$$\lambda = \frac{2}{3^{1/4}\sqrt{\epsilon}}\sqrt{\mp\sqrt{\widehat{A}\sqrt{\frac{\gamma}{3}} - \frac{1}{3}}} + \mathcal{O}(\sqrt{\epsilon}), \tag{2.21}$$

with the minus sign for the eigenvalue of Φ_1 and the plus sign for Φ_2.

Proof. The proof of Theorem 2.6 is similar to the proof of Theorem 2.5. The stability result of Φ_3 cannot be deduced immediately because the expression of Φ_3 is not trivial. The presence of a finite interval where our asymptotic analysis is inconclusive cannot be seen clearly. It is inconclusive because there is a range of A in which λ is in the domain of the continuous spectrum (2.16). A numerical proof will be presented in the following section. □

2.3. Analysis for the case of $\Delta < -2$. We omit the details and the rigorous proof, but it can be shown that for $\Delta < -2$, there is only one rapidly decaying soliton which is stable for any driving amplitude. The idea is as follows.

Instead of (2.1), consider

$$\phi_n = -\epsilon(\phi_{n+1} + \phi_{n-1}) - \gamma\epsilon{\phi_n}^3, \quad \phi_0 = A, \tag{2.22}$$

where we again have scaled $0 > \Delta \to 1$ and define $\epsilon = 1/|\Delta|$. For a rapidly decaying solution, the leading order equation of (2.22) is then given by

$$f := \phi_1 + \epsilon\left(A + \gamma{\phi_1}^3\right) = 0. \tag{2.23}$$

It is clear that $f \to \pm\infty$ as $\phi \to \pm\infty$. Yet, f has no critical point, i.e., $df/d\phi_1 > 0$. Therefore, one can conclude that f is a monotonically increasing function which intersects the horizontal axis once, i.e., f has one real root. The stability of this rapidly decaying solution might be determined immediately following Theorems 2.5 and 2.6. Our numerics, which are not presented here, show that when $A = \mathcal{O}(1)$ the solution is stable with no discrete spectrum, and when $A = \mathcal{O}(1/\epsilon^{3/2})$ there is an eigenvalue bifurcating from the upper edge of the continuous spectrum. Hence, the soliton is stable all the way to $A \to \infty$, which explains why there is no supratransmission for $\Delta < -2$.

2.4. Numerical results. To accompany our analytical results, we have used numerical calculations. For that purpose, we have made a continuation program based on a Newton iteration technique to obtain stationary rapidly decaying discrete solitons of (2.1) and an eigenvalue problem solver to solve (2.15) in MATLAB. Throughout the subsection, we consider in particular $\Delta = 10$. Even though there is no prominent supratransmission of energy for this value of Δ, it is taken solely as an example to show that especially in the regime of Δ large, our asymptotic analysis explains the

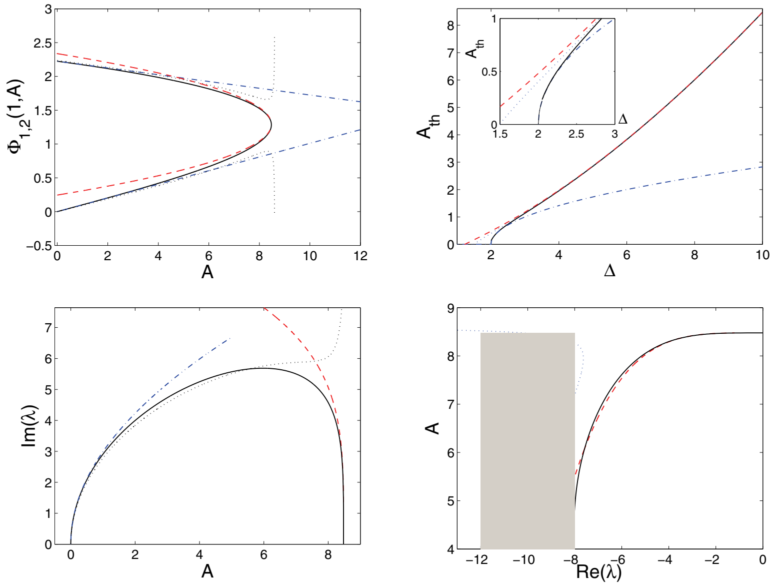

FIG. 2.1. *Presented is the comparison between the numerically obtained results and the analytical calculations presented in section* 2. *Top left panel: the existence curve of* Φ_1 *and* Φ_2 *represented by the solution of the first site, where the upper and lower branches correspond to the existence curve of* Φ_1 *and* Φ_2*, respectively. problem well. It will be shown below that, e.g., even using the first two terms of the approximate threshold amplitude, our analytical result is already relatively in agreement with the numerical results.

We summarize our results and discussions for the existence and the stability of Φ_1 and Φ_2 in Figure 2.1. At the top left panel of the figure, we present the existence of Φ_j, $j = 1, 2$, represented by the solution of the first site, where the upper and lower branches correspond to the existence curve of Φ_1 and Φ_2, respectively. Numerical results are represented by the solid lines. Our analytical result as given by (2.4) and (2.5) which is supposed to be valid when $A = \mathcal{O}(1)$ is depicted by dash-dotted lines. As for the analytical approximations for $A = \mathcal{O}(1/\epsilon^{3/2})$, i.e., (2.8) and (2.10), they are presented as dotted and dashed lines, respectively. It is interesting to note that Figure 2.1 shows clearly a good agreement between our analytical and the numerical results.

Top right panel of Figure 2.1 presents the comparison between the critical amplitude $A_{\mathrm{th}}(\Delta)$ calculated numerically from (2.1) and our approximation $A_{\mathrm{th}}(\Delta) = 2/\sqrt{27\gamma\epsilon^{3/2}} - \sqrt{\epsilon}/\sqrt{3\gamma}$ (see Theorem 2.3), which are presented in solid and dashed lines, respectively. The numerical results were also checked against the full dynamics of the original problem (1.1), where an agreement is obtained as it should be provided that τ is large enough. Note the good agreement when $\Delta \gg 1$. As a comparison with the analytical approximation obtained by Khomeriki [5], we also present $A_{\mathrm{th}}(\Delta) = \sqrt{\Delta - 2}$ as a dash-dotted line.

It is interesting to note that in the limit $\Delta \to 2$ our analytical approximation does not diverge. As is shown in the inset of the top right panel, the difference of the approximate value of the threshold amplitude and the numerical result at $\Delta = 2$ is about 50%. Using the same method presented in the preceding sections, we obtain that the first three terms of the approximation of $A_{\text{th}}(\Delta)$ are actually given by

$$A_{\text{th}}(\Delta) = \frac{2}{\sqrt{27\gamma\epsilon^{3/2}}} - \frac{\sqrt{\epsilon}}{\sqrt{3\gamma}} - \frac{13\sqrt{3}}{36\sqrt{\gamma}}\epsilon^{5/2}. \tag{2.24}$$

The plot of this curve is depicted in the same panel as a dotted line, where one can see that the difference now has decreased by about 10%. This then motivates us to question whether the infinite power series of the approximate threshold amplitude $A_{\text{th}}(\Delta)$ is actually convergent uniformly to the critical amplitude curve. Considering the fact that the region of interest is on $0 < \epsilon \leq 1/2$ and the coefficients of the power series are so far bounded, the answer might well be affirmative. Yet, this question is out of the scope of the present paper and will therefore be addressed in future investigations.

After presenting the numerical and the analytical results for the existence of Φ_1 and Φ_3, next we consider the stability of the solitons. The bottom panels of Figure 2.1 present the comparison between the results. The left panel shows the imaginary part of the critical eigenvalue of Φ_1 as a function of A in its existence region. It is clear that the soliton is always unstable. The right panel presents the eigenvalue of Φ_2 as a function of the driving amplitude, where one can see that the soliton is always stable, as opposed to Φ_1. Our analytical approximations (2.18), (2.20), and (2.21) are presented as well in the two panels as dash-dotted, dotted, and dashed lines, respectively. It is also interesting to note that, as is predicted by Theorem 2.2, Φ_2 has no eigenvalue when A is small. Our analytical approximation (2.21) predicts very well the appearance of the eigenvalue of Φ_2.

Because it is known that Φ_1 is unstable in its entire existence region, it is of interest to see the dynamics with regards to instability. In Figure 2.2 we present the evolution of Φ_1 for a parameter value $A \equiv 8.46$ (A is already at this value from the beginning $z = 0$, as opposed to Figure 1.1, where A is 0 in the beginning and gradually increases to a constant). The top left panel presents the dynamics of Φ_1 with the initial condition $\psi_n(z = 0) = \Phi_1(n, A) - 10^{-4}$. The initial condition $\Phi_1(n, A)$ is obtained numerically from (2.1). The top right panel depicts the behavior of the first site in time, where one can see that the instability manifests in the form of the soliton's oscillations. Interestingly, if we start with an initial condition of the form $\psi_n(z = 0) = \Phi_1(n, A) + 10^{-4}$, the solution has a similar instability behavior but with a different oscillation maximum. The dynamics are presented in the bottom panels of Figure 2.2. It is important to note that with such a small change, the dynamics can be significantly different. This duality therefore might be employed as a small intensity light detector similar to the proposal of [12].

We have numerically analyzed as well the existence and the stability of the soliton Φ_3. We summarize our results in Figure 2.3. The numerical result for the existence of the soliton is shown in the top left panel of the figure. Our analytical approximations (2.6) and (2.8) are shown in dash-dotted and dotted lines, respectively, where one can see the good agreement between the numerical and the analytical results.

After studying the existence of the discrete soliton, we next present our stability analysis of the soliton. Shown in the bottom panels of Figure 2.3 is the numerically obtained critical eigenvalue of Φ_3 as a function of A. In the bottom left panel is the real part of the critical eigenvalue. It is clear that when $A = 0$, the eigenvalue is a double

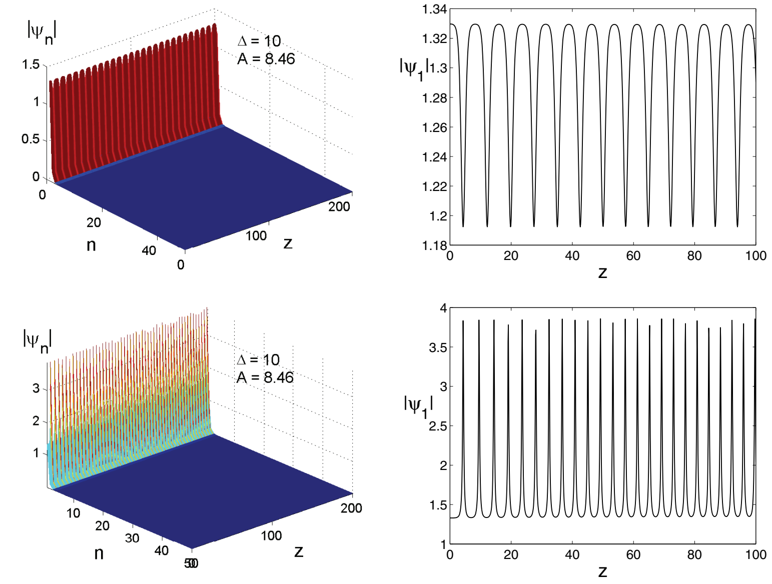

FIG. 2.2. *The instability dynamics of Φ_1 for $A = 8.46$ and $\Delta = 10$. It is presented that even with a tiny change in perturbation the dynamics can be significantly different (see the text).*

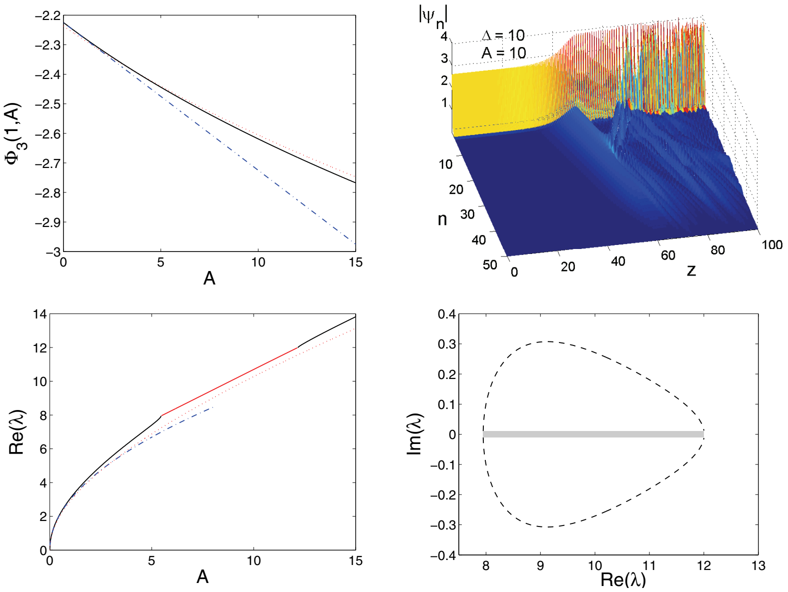

FIG. 2.3. *Similar to Figure 2.1 but for the soliton Φ_3. Top left panel shows the numerical results for the existence of Φ_3 versus the driving amplitude A (solid line). Presented is the value of the solution at the first site, i.e., $\Phi_3(1, A)$. The bottom left panel presents the stability of the soliton. The red solid line that separates the black solid line indicates that the soliton is unstable in this region. The behavior of the critical eigenvalue in the complex plane is depicted in the bottom right panel. In the panel, the parametric variable is the driving parameter A. The top right panel shows the dynamics of the soliton when it is unstable. See the text for the analytical approximation curves. (For interpretation of the references to color in this figure legend, the reader is referred to the online version of this article.)*

eigenvalue at zero. As soon as A is increased, the zero eigenvalue bifurcates along the real line. At a critical driving amplitude, the eigenvalue collides with the lower boundary of the continuous spectrum. The result of the collision is the bifurcation of the eigenvalue into the complex plane resulting in an eigenvalue with nonzero imaginary part. In the bottom right panel, we present the trajectory of the eigenvalue in the complex plane as A is increased. One can then see that there is also another critical amplitude above which the eigenvalue becomes real again, i.e., the soliton becomes stable. In the region where the imaginary part is nonzero, we depict the curve in the bottom left panel of Figure 2.3 in solid red line. We also compare it with our analytical approximations, (2.18) and (2.20), which are shown as dash-dotted and dotted lines, respectively. In Theorem 2.6, it is stated that our analytical approximation is inconclusive for the case of A large. As can be seen from Figure 2.3, our analytical approximation equation (2.20) is always real. This is because when the real part of the eigenvalue is in the region of the continuous spectrum, our assumption that the eigenfunction is rapidly decreasing is not justified.

It is then interesting to see the dynamics of the instability. In the top right panel, we depict the evolution of an unstable discrete soliton of type Φ_3. The parameter values are depicted in the figure. The setup for the driving amplitude is similar to the setup of Figure 2.2.

Regarding the involvement of Φ_3 in the dynamics of the driven boundary waveguides (1.1) (see Figure 1.1), it is not clear, when Φ_2 disappears, whether it evolves into Φ_3.

3. Conclusions. We have analyzed mathematically the mechanism of supratransmissions observed in a boundary driven discrete nonlinear Schrödinger equation describing electromagnetic fields in waveguide arrays. We have shown that the source of the phenomenon is the presence of a saddle-node bifurcation between a stable discrete soliton and an unstable one. We have shown as well numerically that the unstable one can exhibit a different dynamics, sensitive to the perturbation. We therefore argue that it might be possible to propose it as a weak signal light detector.

Acknowledgments. The author wishes to thank Panayotis Kevrekidis and Ramaz Khomeriki for numerous useful interactions and discussions. The manuscript has greatly benefited from the constructive comments and suggestions of two anonymous reviewers.

THE SHAPE OF CHARGED DROPS OVER A SOLID SURFACE AND SYMMETRY-BREAKING INSTABILITIES[*]

M. A. FONTELOS[†] AND U. KINDELÁN[‡]

Abstract. We study the static shape of charged drops of a conducting fluid placed over a solid substrate, surrounded by a gas, and in absence of gravitational forces. The question can be formulated as a variational problem where a certain energy involving the areas of the solid-liquid interface and of the liquid-gas interface, as well as the electric capacity of the drop, has to be minimized. As a function of two parameters, Young's angle θ_Y and the potential at the drop's surface V_0, we find the axisymmetric minimizers of the energy and describe their shape. We also discuss the existence of symmetry-breaking bifurcations such that, for given values of θ_Y and V_0, configurations for which the axial symmetry is lost are energetically more favorable than axially symmetric configurations. We prove the existence of such bifurcations in the limits of very flat and almost spherical equilibrium shapes. All other cases are studied numerically with a boundary integral method. One conclusion of this study is that axisymmetric drops cannot spread indefinitely by introducing sufficient amount of electric charges, but can reach only a limiting (saturation) size, after which the axial symmetry would be lost and finger-like shapes energetically preferred.

1. Introduction.

The determination of the stationary shapes of liquid drops surrounded by a vapor phase and in contact with a solid surface is an old problem both in fluid mechanics and in the theory of partial differential equations (see [7] and the references therein). The problem can be posed, since Gauss, in a variational setting consisting of obtaining the configurations of a given mass of fluid that minimize (or in general make extremal) an energy defined by

$$E = \gamma_{lv} A_{lv} - (\gamma_{sv} - \gamma_{sl}) A_{sl} + E_F, \tag{1.1}$$

where γ_{lv}, γ_{sv}, and γ_{sl} denote the liquid-vapor, solid-vapor, and solid-liquid surface tensions, respectively; A_{lv} and A_{sl} denote the area of the liquid-vapor and solid-liquid interfaces, respectively (see Figure 1.1). E_F is the contribution of external forces to the total energy. If the drop is affected by gravity, then $E_F = \int_\Omega \mathbf{g} \cdot \mathbf{x} dx$, where $\mathbf{g}$ is the gravitational force and Ω the domain occupied by the fluid. In absence of external forces, the configurations that minimize the energy (1.1) are spherical caps such that the contact angle θ_Y, called Young's angle, between the liquid-vapor and solid-liquid interfaces satisfies

$$\cos\theta_Y = \frac{\gamma_{sv} - \gamma_{sl}}{\gamma_{lv}}.$$

When the volume of fluid under consideration is sufficiently small, the contribution of gravitational forces to the energy is negligible in comparison with interfacial

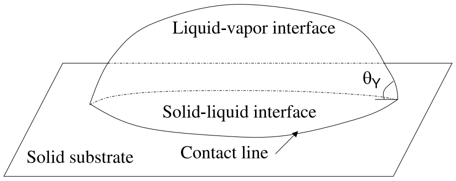

Fig. 1.1. *Sketch of the problem.*

energies. A consistent approximation is then to ignore gravity in (1.1), as it is done systematically in the study of multiphase flows in microfluidic applications, for instance (see [18]). It is precisely in connection with such microfluidic applications that electric fields are incorporated with the purpose of controlling the shape and motion of small masses of fluid. This is the case, for instance, of electrowetting applications in which the shape of a mass of electrically conducting fluid is controlled via the addition of electric charges and application of external electric fields (see [12] and the references therein).

The simplest situation corresponds to a drop of perfectly conducting fluid with a total charge Q. In this case, the energy would be given (cf. [12]) by

$$E = \gamma_{lv}\left[A_{lv} - (\cos\theta_Y)A_{sl}\right] - \frac{1}{2}\varepsilon_0 \int_{\mathbb{R}^3\setminus\Omega} |\mathbf{E}|^2\, dx, \tag{1.2}$$

where $\mathbf{E} = -\nabla V$ is the electric field (V is the electric potential) created by the charges, concentrated in $\partial\Omega$ with a density $\sigma = -\varepsilon_0 \frac{\partial V}{\partial n}$ in a perfect conductor. ε_0 is the dielectric constant of the medium surrounding the drop. The potential V at the surface of a conductor is constant and, in absence of charges in $\mathbb{R}^3 \setminus \Omega$, is harmonic in the exterior of Ω. Hence, V is solution of the boundary value problem

$$\Delta V = 0 \quad \text{at } \mathbb{R}^3 \setminus \Omega, \tag{1.3}$$

$$V = V_0 \quad \text{at } \partial\Omega, \tag{1.4}$$

$$V = O(|\mathbf{r}|^{-1}) \quad \text{as } |\mathbf{r}| \to \infty. \tag{1.5}$$

The electrical energy term in (1.2) can be written, after integration by parts, in the equivalent forms

$$\frac{1}{2}\varepsilon_0 \int_{\mathbb{R}^3\setminus\Omega} |\mathbf{E}|^2\, dx = \frac{1}{2}\varepsilon_0 \int_{\partial\Omega} V\frac{\partial V}{\partial n} dS = \frac{1}{2}\int_{\partial\Omega} V_0\sigma dS = \frac{1}{2}QV_0 = \frac{1}{2}CV_0^2,$$

where C is the capacity of Ω defined as

$$C = -\frac{\varepsilon_0}{V_0}\int_{\Omega} \frac{\partial V}{\partial n} dS.$$

The determination of the capacity of a given set is, in general, a difficult problem. There are explicit expressions for only a few configurations, such as spheres and discs (see [10]). The best source concerning estimation of the capacity of arbitrary sets is [14] and the related article [15]. More complex configurations, such as spherical caps, have a capacity that can be estimated from above and below but no explicit formulae. This is the main difficulty in the deduction of minimizers of (1.2).

A particular case of the problem corresponds to $\theta_Y = 2\pi$, which would correspond to absence of contact with solids. This is the case of levitating droplets, in which the energy is, instead of (1.2),

$$E = \gamma_{lv} A_{lv} - \frac{1}{2} C V_0^2,$$

and extremal values are reached by spheres, as Lord Rayleigh showed in 1882 [17]. This particular situation points to the possibility of appearance of instabilities breaking the axial symmetry and leading to singularities at the drop's surface. When the electric charge (and V_0 therefore) is large enough, those spheres cannot be stable. Two scenarios are possible then: evolution towards nonspherical stationary configurations that accommodate such amount of charge, or destabilization leading to singularities at the interface in finite time. The existence of nonspherical equilibrium configurations in the form of spheroids was proved in [8], and they were characterized as branches of solutions bifurcating, via the Crandall–Rabinowitz theorem, from the branch of spherical solutions. The appearance of singularities in the evolution of initially spherical levitating drops with large charge was shown in [3]. The drop evolves initially into a prolate spheroid with its poles increasing in curvature and becoming conical tips in finite time.

By computing the first variation of the functional (1.2) one arrives at the following equation:

$$\gamma\kappa - \frac{\sigma^2}{2\varepsilon_0} = -p, \tag{1.6}$$

where $\gamma = \gamma_{lv}$, κ is the mean curvature (sum of the principal curvatures) of the liquid-vapor interface at a point $\mathbf{x}$, $\sigma = -\varepsilon_0 \frac{\partial V}{\partial n}$ is the surface charge density at the same point $\mathbf{x}$, and p is a constant to be determined through the constraint that the drop has a given volume. In the fluid dynamics context, p is the difference of pressure across the interface. Equation (1.6) has to be complemented with the boundary condition stating that the normal vector to the interface forms a constant angle with the normal to the solid substrate at any point of the contact line Γ, the set where the liquid-vapor and the solid-liquid interfaces meet. This angle has to be, exactly, θ_Y (cf. [13]). Finally, we introduce characteristic length $(\mathit{Vol.})^{\frac{1}{3}}$, where *Vol.* is the volume of the drop, characteristic potential $(\mathit{Vol.})^{\frac{1}{6}}(\gamma\varepsilon_0^{-1})^{\frac{1}{2}}$, characteristic surface charge density $(\mathit{Vol.})^{-\frac{1}{6}}(\gamma\varepsilon_0)^{\frac{1}{2}}$, and characteristic pressure $\gamma(\mathit{Vol.})^{-\frac{1}{3}}$. Accordingly, we change variables and unknowns in the form $\mathbf{x} \to (\mathit{Vol.})^{\frac{1}{3}}\mathbf{x}$, $V \to (\mathit{Vol.})^{\frac{1}{6}}(\gamma\varepsilon_0^{-1})^{\frac{1}{2}}V$, $\sigma \to (\mathit{Vol.})^{-\frac{1}{6}}(\gamma\varepsilon_0)^{\frac{1}{2}}\sigma$, $p \to \gamma(\mathit{Vol.})^{-\frac{1}{3}}p$ so that space coordinates, potential, surface charge density, and pressure are now dimensionless. We end up with the following dimensionless version of (1.6):

$$\kappa - \frac{\sigma^2}{2} = -p, \tag{1.7}$$

and the variational problem associated to the functional

$$E = [A_{lv} - (\cos\theta_Y)A_{sl}] - \frac{1}{2} C V_0^2, \tag{1.8}$$

where $C = -\frac{1}{V_0}\int_\Omega \frac{\partial V}{\partial n} dS$, V being the solution to (1.3)–(1.5), and Ω is now a domain of unit volume.

One important motivation for this work is its relation with the phenomenon of electrowetting. This consists in the control of the wetting properties of fluids by means of electric fields. The simplest situation is that of a drop of conducting fluid connected to a battery and, therefore, kept at a given difference of potential with respect to an electrode placed at some distance below the solid substrate. In the situation studied in the present paper, such an electrode would be placed at infinity, so that we establish a given potential on the drop's surface and assume the potential to decay at infinity. The simplest theories on electrowetting follow the original ideas of Lippmann, who developed a formula (cf. [11]) that predicts an unlimited spreading of droplets through application of sufficiently strong electrostatic potentials. Nevertheless, the physical observation is that drops do not spread infinitely but reach a saturation regime such that an increase of the potential does not produce any additional spreading but rather the appearance of instabilities at the contact line with subsequent emission of a varying number of satellite filaments (see [12] and the references therein). The demonstration of such facts, also appearing when the electrode is at a fixed distance to the drop, requires a somewhat different analysis and will be published elsewhere.

In this paper we shall study, as a function θ_Y and V_0, the equilibrium configurations. We will present explicit formulae for the geometry of axially symmetric profiles in certain limits of θ_Y and V_0. We will deduce a first constraint to indefinite spreading due to the fact that static solutions develop dewetted cores with the fluid concentrated in a rim around these cores. The second constraint concerns stability. By analyzing the energy functional (1.8) we will conclude that axially symmetric solutions must become unstable under nonaxisymmetric perturbations with n undulations ($n = 2, 3, \ldots$), provided V_0 is large enough. We shall determine numerically (and analytically in some limiting cases) for what values of V_0 such instabilities do develop as a function of θ_Y. This offers a possible explanation to the saturation effect explained above and the contact line instabilities observed in experiments.

The paper is organized as follows. In section 2 we study the radially symmetric configurations. We perform an analysis in the limiting cases of almost spherical drops and almost flat drops and then develop a numerical code to compute the profiles in all intermediate cases. This allows us to represent in a phase diagram the radius of spreading of a drop as a function of V_0 for arbitrary θ_Y. In section 3 we study the stability of the radially symmetric solutions under symmetry-breaking perturbations. Again, we focus the theoretical discussion in the limiting cases of almost spherical and flat drops, but end with a numerical study of all cases. Finally, section 4 is devoted to the study of the capacity of axially symmetric configurations perturbed in the radial direction and it also includes the proof of several results used in previous sections.

2. Radially symmetric configurations. These are solutions of (1.6) which are invariant under rotations about an axis normal to the solid surface. We can describe the height of each point of the fluid-vapor interface by a function $h(r)$, where r is the radial coordinate in a cylindrical coordinate system about the axis of symmetry. The mean curvature is then (see [7])

$$\kappa = -\frac{1}{r}\frac{d}{dr}\left(r\frac{h_r}{(1+h_r^2)^{\frac{1}{2}}}\right) = -\frac{1}{r}(r\sin\psi)_r, \tag{2.1}$$

where ψ is the angle of inclination of the solution curve $h(r)$ with respect to the r-axis. Notice that $\tan\psi = \frac{dh}{dr}$. We shall study in this section the radially symmetric profiles in two limits for which the analysis simplifies: (1) the limit of small potential V_0 at $\partial\Omega$ so that drops are almost spherical caps, and (2) the limit of large potential V_0 at

$\partial\Omega$ or small contact angle so that drops are almost flat discs. The profiles between these two situations will be found numerically.

2.1. Almost spherical shapes. If we assume $\partial\Omega$ to be continuously differentiable except for the contact line, which we consider located at $r = L$, where $h(r)$ is only Lipschitz continuous (due to the existence of a corner of opening angle θ_Y), then by the classical theory of Dirichlet problems for elliptic linear partial differential equations (cf. [6], for instance) we will have a continuous solution V of problem (1.3)–(1.5) such that $\frac{\partial V}{\partial n}$ will be continuous everywhere except for the contact line. There $\frac{\partial V}{\partial n}$ will be singular since V has the asymptotic behavior

$$V = V_0 + A\rho^{\alpha}\sin(\alpha\theta),$$

where (ρ, θ) are polar coordinates about $(r, z) = (L, 0)$ and α is such that $\sin(\alpha 0) = \sin(\alpha(2\pi - \theta_Y)) = 0$ and $\frac{\partial V}{\partial \rho}$ is square integrable in the neighborhood of the contact line. Hence $\alpha = \frac{1}{2-\theta_Y/\pi}$ and

$$\sigma = -\frac{\partial V}{\partial n} \sim A'\rho^{\frac{1}{2-\theta_Y/\pi}-1} \quad \text{as } \rho \to 0.$$

Notice that σ^2 is integrable with respect to ρ, provided $\theta_Y > 0$, and therefore is integrable over the whole $\partial\Omega$.

Let us assume that $V_0 = \varepsilon \ll 1$ so that we can write the surface charge distribution of a unit volume spherical cap with contact angle θ_Y as $\varepsilon\Sigma$. Then (1.7) and (2.1) yield the equation

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{h_r}{(1+h_r^2)^{\frac{1}{2}}}\right) = -\varepsilon^2\frac{\Sigma^2}{2} + p.$$

By integrating once we get

$$\sin\psi = \frac{1}{2}pr - \varepsilon^2 a_1(r),$$

where

$$a_1(r) = \frac{1}{r}\int_0^r \frac{\Sigma^2}{2}r'dr'.$$

Notice that

$$-\sin\theta_Y = \frac{1}{2}pL - \varepsilon^2 a_1(L). \tag{2.2}$$

In order to find the profile we use

$$\begin{aligned} h_r = \tan\psi &= \frac{\frac{1}{2}pr - \varepsilon^2 a_1(r)}{\sqrt{1-\left(\frac{1}{2}pr - \varepsilon^2 a_1(r)\right)^2}} \\ &= \frac{\frac{1}{2}pr}{\sqrt{1-\frac{1}{4}p^2r^2}} - \frac{1}{\left(1-\frac{1}{4}p^2r^2\right)^{\frac{3}{2}}}\varepsilon^2 a_1(r) + O(\varepsilon^4), \end{aligned}$$

and then

$$h(r) = h_0 + \frac{2}{p} - \frac{2}{p}\sqrt{1-\frac{1}{4}p^2r^2} - \varepsilon^2 a_2(r, p),$$

where

$$a_2(r,p) = \int_0^r \frac{1}{\left(1-\frac{1}{4}p^2r'^2\right)^{\frac{3}{2}}}a_1(r')dr.$$

The parameters h_0, p, and L are chosen so that (2.2) is satisfied, the volume is 1, and $h(L) = 0$. Hence we impose (2.2) together with the condition

$$\begin{aligned} &2\pi\int_0^L \left(h_0 + \frac{2}{p} - \frac{2}{p}\sqrt{1-\frac{1}{4}p^2r^2}\right) rdr - \varepsilon^2 a_3(L,p) \\ &= \pi L^2\left(h_0 + \frac{2}{p}\right) - \frac{16\pi}{3p^3}\left(1-\left(1-\frac{1}{4}p^2L^2\right)^{\frac{3}{2}}\right) - \varepsilon^2 a_3(L,p) = 1, \end{aligned} \tag{2.3}$$

where

$$a_3(r,p) = 2\pi\int_0^r a_2(r',p)r'dr'$$

and

$$0 = h_0 + \frac{2}{p} - \frac{2}{p}\sqrt{1-\frac{1}{4}p^2L^2} - \varepsilon^2 a_2(L,p). \tag{2.4}$$

We write now $p = p_0 + \varepsilon^2 p_1$, $h_0 = h_{0,0} + \varepsilon^2 h_{\prime 0,1}$, $L = L_0 + \varepsilon^2 L_1$ and obtain the following solution at order zero in ε from (2.2), (2.3), (2.4):

$$L_0 = \left[\frac{3}{\pi}\frac{\sin^3\theta_Y}{(\cos\theta_Y - 1)^2(\cos\theta_Y + 2)}\right]^{\frac{1}{3}}, \tag{2.5}$$

$$p_0 = -2\left[\frac{\pi}{3}(\cos\theta_Y - 1)^2(\cos\theta_Y + 2)\right]^{\frac{1}{3}}, \tag{2.6}$$

$$h_{0,0} = \left(\frac{3}{\pi}\frac{1-\cos\theta_Y}{2+\cos\theta_Y}\right)^{\frac{1}{3}}; \tag{2.7}$$

and we obtain the following solutions at $O(\varepsilon^2)$:

$$\begin{aligned} p_1 &= \frac{-a_3p_0^3\cos\theta_Y + 8\pi a_1\sin^3\theta_Y - 8\pi a_2p_0\cos\theta_Y\sin^2\theta_Y}{3p_0^2\cos\theta_Y}, \\ L_1 &= \frac{2}{p_0}\left(-\frac{a_1}{\cos\theta_Y(\cos\theta_Y+2)} + \frac{1}{6}\frac{L_0\left(a_3p_0^3\cos\theta_Y + 8\pi a_2p_0\cos\theta_Y\sin^2\theta_Y\right)}{p_0^2\cos\theta_Y}\right), \\ h_{0,1} &= \frac{2(1-\cos\theta_Y)\left(a_3p_0^3\cos\theta_Y + 8\pi a_2p_0\sin^2\theta_Y\cos\theta_Y\right)}{3p_0^4\cos\theta_Y} + \frac{2a_1\sin\theta_Y}{p_0(\cos\theta_Y+2)} - a_2, \end{aligned}$$

where $a_1 = a_1(L)$, $a_2 = a_2(L,p)$, $a_3 = a_3(L,p)$. Notice that, since $a_i > 0$ for $i = 1,2,3$ and $p_0 < 0$, it follows that $L_1 > 0$ and $h_{0,1} < 0$. Therefore, the drops spread a length $\varepsilon^2 L_1 + O(\varepsilon^4)$.

2.2. Almost flat shapes. In the limit of large values of the potential, or in case $\theta_Y \ll 1$, the drop's configurations are so that the aspect ratio of its height to its radius is a very small number and we can approximate the drop by a flat disc. An advantage to this approximation lies in the fact that the charge distribution in a flat conducting disc has an explicit closed form formula (see [9]) given by

$$\sigma(r) = \frac{Q/(2\pi a)}{\sqrt{a^2 - r^2}}, \tag{2.8}$$

where Q is the total charge stored by the disc and a is its radius. Here we consider the disc to be two-sided and the distribution on each side will be 1/2 of the density $\sigma(r)$ in (2.8). Therefore, (1.7) can be approximated by

$$\kappa - \frac{Q^2/(4\pi a)^2}{2(a^2 - r^2)} = -p,$$

or, in terms of the potential V_0 at the surface of the drop and using the value of the capacity of a flat disc $C = 8a$, by

$$-\frac{1}{r}\frac{d}{dr}\left(r\frac{h_r}{(1+h_r^2)^{\frac{1}{2}}}\right) - \frac{2}{\pi^2}\frac{V_0^2}{(a^2 - r^2)} = -p. \tag{2.9}$$

We introduce now the change of variables in (2.9),

$$p = \frac{V_0^2}{a^2}k, \quad r = ar', \quad h = V_0^2 H,$$

to arrive at

$$\frac{1}{r'}\frac{d}{dr'}\left(r'\frac{H_{r'}}{(1+\frac{V_0^2}{a^2}H_{r'}^2)^{\frac{1}{2}}}\right) + \frac{2}{\pi^2}\frac{1}{(1 - r'^2)} = k$$

and assume $\frac{V_0^2}{a^2} \ll 1$ so that we can finally deduce the equation

$$\frac{1}{r'}\frac{d}{dr'}(r'H_{r'}) + \frac{2}{\pi^2}\frac{1}{(1 - r'^2)} = k,$$

with solution

$$H(r') = -\frac{1}{4}k + \frac{1}{12} + \frac{1}{4\pi^2}(4\,\mathrm{dilog}(1 - r') + 4\,\mathrm{dilog}(1 + r') + \pi^2 k r'^2), \tag{2.10}$$

such that $H(1) = 0$. A few profiles $H(r')$ for various values of k are represented in Figure 2.1. The fact that the drop's center touches the solid substrate when $k = \frac{1}{3}$, as one can easily compute from (2.10), implies that these solutions cannot be constructed for arbitrary values of a and V. If we compute the volume associated to these drops, we find

$$2\pi\int_0^1 H(r')r'dr' = \frac{Vol.}{V_0^2 a^2},$$

or, using (2.10),

$$\frac{0.6366}{4}\cdots - \frac{1}{8}\pi k = \frac{Vol.}{V_0^2 a^2},$$

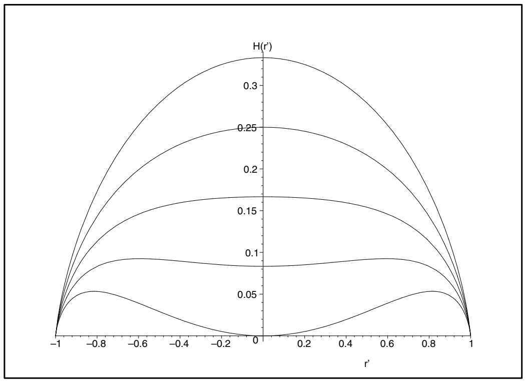

FIG. 2.1. *Profiles $H(r')$ for $k = 0, 1/8, 1/6, 1/4, 1/3$.*

implying, since $k < \frac{1}{3}$,

$$V_0^2 a^2/4 < 8.847\ldots. \tag{2.11}$$

The immediate implication of this formula is that one cannot spread the drop indefinitely even when it is strongly charged.

2.3. The calculation of shapes for moderate values of $\boldsymbol{V_0}$ and $\boldsymbol{\theta_Y}$. We have implemented a numerical method in order to calculate stationary shapes of drops. For a given value of the potential V_0 we find the shapes for varying values of the base radius a and compute their energy. This will allow us to compute the solid-liquid interface radius of the equilibrium shapes for given values V_0 and θ_Y by minimization of the energy (1.8) as a function of a. The way to approach the problem is by finding solutions of (1.7) as stationary solutions of the evolution problem

$$h_t - \Delta\left(\kappa - \frac{\sigma^2}{2}\right) = 0, \tag{2.12}$$

with boundary conditions

$$h(a) = \left.\frac{\partial(\kappa - \frac{\sigma^2}{2})}{\partial n}\right|_{r=a} = 0. \tag{2.13}$$

As the initial condition we take a spherical cap with base radius a. We compute numerically the solutions to problem (2.12), (2.13) and observe that $\kappa - \frac{\sigma^2}{2}$ converges to a constant value $-p$ and stop the calculation when the difference between the maximum and minimum values of $\kappa - \frac{\sigma^2}{2}$ lies below some tolerance threshold fixed a priori. At each time-step we compute σ by solving the integral equation

$$V_0 = \frac{1}{4\pi}\int_{\partial\Omega} \frac{\sigma(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} dS \tag{2.14}$$

with a boundary element technique for axisymmetric profiles (cf. [16]).

We compute, for these profiles, the energy as the sum of two contributions,

$$\begin{aligned} E &= E_1 - \cos\theta_Y E_2, \\ E_1 &= A_{lv} - \frac{1}{2}CV_0^2, \quad E_2 = A_{sl} = \pi a^2. \end{aligned}$$

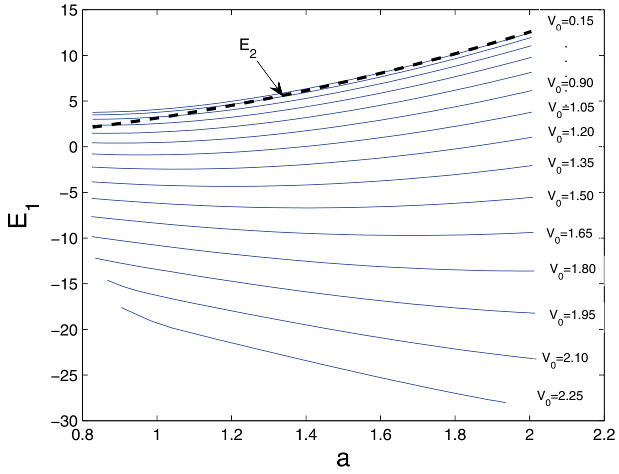

FIG. 2.2. *Energies as a function of the radius of the circular base* (a) *for different potentials* V_0. *The potentials run from* 0.15 *up to* 2.25 *at intervals of* 0.15.

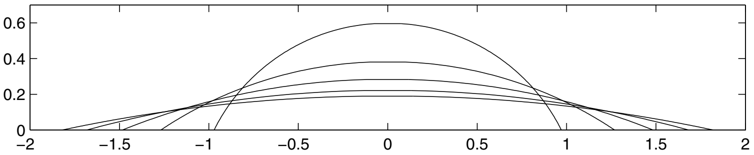

FIG. 2.3. *Shapes of the profiles for various values of the radius of the circular base* (a) *and* $V_0 = 0.15$.

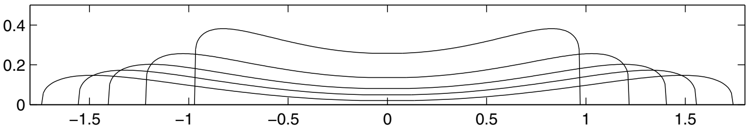

FIG. 2.4. *Shapes of the profiles for various values of the radius of the circular base* (a) *and* $V_0 = 2.25$.

In Figure 2.2 we represent the computed values of E_1 for various values of V_0. The profiles for $V_0 = 0.15$ and 2.25 are represented in Figures 2.3 and 2.4, respectively. For a given value of θ_Y one can compute the equilibrium shapes for each value of V_0 by minimizing E as a function of a, that is, by finding the solutions to

$$\frac{dE}{da} = \frac{dE_1}{da} - \cos\theta_Y \frac{dE_2}{da} = 0,$$

leading to the relation

$$\theta_Y = \arccos\left(\frac{\frac{dE_1}{da}}{\frac{dE_2}{da}}\right).$$

In Figure 2.5 we represent θ_Y as a function of a for various V_0. The intersection of the horizontal line corresponding to a given θ_Y with the curves of constant V_0 gives the

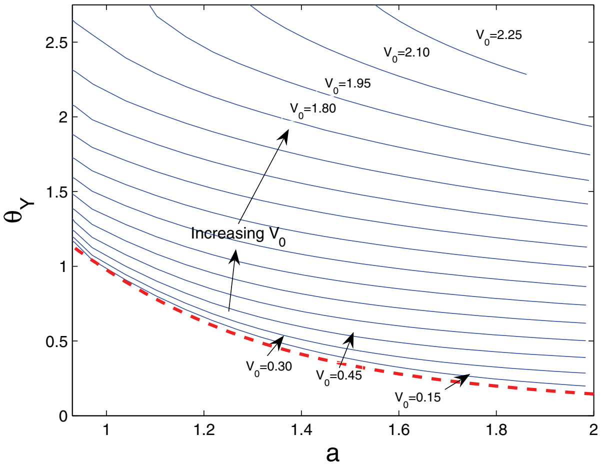

FIG. 2.5. *θ_Y as a function of the radius of the circular base (a) for different values of the potential V_0. The potentials run from 0.15 up to 2.25 at intervals of 0.15. The dashed line is the explicit curve, at $V_0 = 0$, of L_0 $(= a)$ as a function of θ_Y given by* (2.5).

values of a as a function of V_0. Notice that we are representing level lines of constant V_0 at intervals of 0.15 and that the level lines increase their separation with increasing V_0. This implies a superlinear growth of a with V_0 for a given value of θ_Y. As we saw in section 2.1, this increase is exactly quadratic for sufficiently small V_0.

2.4. The approximation with ellipsoids. When $V_0 = 0$, the axially symmetric minimizers of (1.8) are spherical caps. In the case of levitating droplets ($\theta_Y = \pi$) the minimizers are spheres if $V_0 < 1.575\ldots$ and approximately oblate ellipsoids (cf. [8], [4], and section 3.1 below) if $V_0 > 1.575\ldots$. Moreover, we have observed that for moderate values of the potential the profiles can be approximated by truncated oblate ellipsoids (ellipsoidal caps) with a very high degree of accuracy. These observations lead us to study the variational problem (1.8) restricted to the class of ellipsoidal caps in the neighborhood of $\theta_Y = \pi$. We shall see below that the resulting $a - \theta_Y$ diagram is consistent with Figure 2.5 and that both overlap smoothly in the common region.

The family of profiles we consider is

$$\frac{1}{c^2}(z - \alpha c)^2 + \beta^2 r^2 = 1$$

for $z \geq 0$ only. These are ellipsoidal caps resulting from the truncation of an axially symmetric ellipsoid with the center at αc and semiaxis c and β^{-1}. Written in this form, it is simple to compute c such that the volume of the drop is 1. Hence we have to consider a two-parameter family of profiles with parameters $-1 \leq \alpha \leq 1$ and $\beta \leq \frac{1}{c}$. The areas A_{lv} and A_{sl} and the capacity C are then functions of α and β, and the minimization problem is simply the one of finding the minima of a function of two variables. We can show that $A_{sl} = \pi \frac{1-\alpha^2}{\beta^2}$. The main difficulty is the lack of explicit expressions (except for just a few cases) for A_{lv} and C. We compute these values numerically for (α, β) in a grid with $O(10^5)$ nodes. The capacity is determined as the total charge from a surface charge distribution σ that we evaluate by solving the integral equation (2.14) with a boundary element method. Then, for given values of

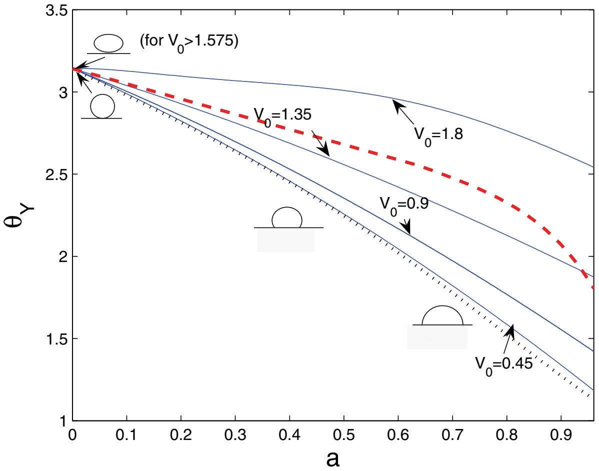

Fig. 2.6. *θ_Y as a function of the radius of the circular base (a) for different values of the potential V_0 using the approximation with truncated ellipsoids. The dotted line is the explicit curve at $V_0 = 0$. The dashed line represents the line of symmetry breaking bifurcations to be discussed in section* 3.

V_0, we compute for each θ_Y the values of α and β in the grid that minimize the energy (1.8), and with these values we compute a. The result is represented in Figure 2.6. In the range of values of a and θ_Y for which Figures 2.5 and 2.6 overlap, the ellipsoidal approximation is very accurate. Nevertheless, it degrades for larger values of a, and one can only apply it safely in the parametric region of Figure 2.6.

3. Instabilities of radially symmetric solutions. In this section we shall proceed to study the stability of the radially symmetric solutions deduced above. We approach the problem in a spirit very similar to Rayleigh's in [17], that is, by computing the energy associated to charged axially symmetric droplets and looking at situations where the breaking of axial symmetry via a small perturbation is more favorable energetically. The existence of these energetically preferred nonsymmetric configurations in the neighborhood of a symmetric configuration indicates that in a dynamic situation, such as, for instance, a gradient flow associated to this energy or a thin-film-type equation [2], symmetric solutions might become unstable. Once a symmetric solution destabilizes there are essentially two possibilities: evolving towards a different equilibrium configuration with broken symmetry, or evolving in time up to the formation of some kind of singularity in the solution of the system of evolution partial differential equations (such as Navier–Stokes for fluids). We are not going to study the evolution problem here, but our discussion will show when instabilities happen and which kind of perturbation modes make the energy decrease most so that one can expect them to be the dominant ones in the early-time evolution of the system and somehow determine the shape of the asymmetric drop. As in the previous section, we start with two limiting cases: the spherical drops and the flat drops, where analytical calculations are feasible, and study all other cases numerically.

3.1. Almost spherical shapes. When $\theta_Y = \pi$, there are equilibrium configurations which are perfectly spherical independent of the potential at their boundary V_0. These configurations are certainly stable when V_0 is sufficiently small, but eventually will become unstable if they store a large charge (and have a large V_0 consequently). In what follows, we will compute the energy of nearby spheroidal configurations and deduce a formula for the value of V_0 at which spheroidal shapes are preferred to spherical shapes. This analysis can easily be extended to drops with different, but close to π, values of θ_Y.

For an oblate ellipsoid with semiaxis a and c such that $c < a$, the volume, area, and capacity (see [14] and [15]) are given by

$$\begin{aligned} Vol. &= \frac{4}{3}\pi a^2 c, \\ A &= 2\pi \left(a^2 + c^2 \frac{\operatorname{arctanh}(\sin\alpha)}{\sin\alpha} \right), \\ C &= 4\pi \frac{a\beta}{\arcsin\beta}, \end{aligned}$$

where

$$\alpha = \arccos(c/a), \tag{3.1a}$$

$$\beta = \sqrt{1 - \frac{c^2}{a^2}}. \tag{3.1b}$$

For a prolate ellipsoid with semiaxis a and c such that $a < c$,

$$\begin{aligned} Vol. &= \frac{4}{3}\pi a^2 c, \\ A &= 2\pi \left(a^2 + c^2 \frac{\alpha}{\tan\alpha} \right), \\ C &= 8\pi \frac{a\beta}{\log\frac{1+\beta}{1-\beta}}, \end{aligned}$$

with α and β given by (3.1a), (3.1b). Hence, the energy associated to both oblate and prolate spheroids is, respectively,

$$\begin{aligned} E_{oblate} &= 2\pi \left(a^2 + c^2 \frac{\operatorname{arctanh}(\sin\alpha)}{\sin\alpha} \right) - \frac{1}{2}\left(4\pi \frac{a\beta}{\arcsin\beta} \right) V_0^2, \\ E_{prolate} &= 2\pi \left(a^2 + c^2 \frac{\alpha}{\tan\alpha} \right) - \frac{1}{2}\left(8\pi \frac{a\beta}{\log\frac{1+\beta}{1-\beta}} \right) V_0^2. \end{aligned}$$

If $a = c = R$, the case of a sphere, then

$$E_{oblate} = E_{prolate} = 4\pi R^2 - 2\pi R V_0^2.$$

If we perturb the sphere to be an ellipsoid (with the same volume) by considering

$$\begin{aligned} a &= R(1+\varepsilon), \quad c = \frac{R}{(1+\varepsilon)^2} \quad \text{in the oblate case,} \\ a &= \frac{R}{(1+\varepsilon)}, \quad c = R(1+\varepsilon)^2 \quad \text{in the prolate case} \end{aligned}$$

($0 < \varepsilon \ll 1$), we get the following energies:

$$\begin{aligned} E_{oblate} &= (4\pi R^2 - 2\pi R V_0^2) + \left(-\frac{8}{5}\pi R V_0^2 + \frac{32}{5}\pi R^2 \right)\varepsilon^2 + O(\varepsilon^3), \\ E_{prolate} &= (4\pi R^2 - 2\pi R V_0^2) + (8\pi R^2 - 2\pi R V_0^2)\varepsilon + O(\varepsilon^2). \end{aligned}$$

In both types of perturbations, the ellipsoidal shapes are more favorable energetically when

$$V_0^2 > 4R. \tag{3.2}$$

In fact, since $\varepsilon \ll 1$, the prolate shape should be more favorable. A spherical drop such that (3.2) is satisfied shall become unstable, and preferably start its evolution by deforming into a prolate spheroid. This is, in fact, what is observed in experiments done on levitating droplets [5] and in the numerical simulations in [3].

For a sphere of unit volume, (3.2) holds when

$$V_0 > 2\left(\frac{3}{4\pi}\right)^{\frac{1}{6}} = 1.575\ldots. \tag{3.3}$$

3.2. Almost flat shapes. We consider now very extended drops such that the radius of their base is $a \gg 1$ and their height $h_0 = h(0) \ll 1$. When $V_0 = 0$ these drops are spherical caps and they appear when $\theta_Y \ll 1$. If the volume, given by

$$Vol. = \frac{1}{6}\pi h_0(3a^2 + h_0^2), \tag{3.4}$$

is equal to 1, then it follows from a direct calculation that, for $V_0 = 0$, a and h_0 are given by

$$h_0 = \left(\frac{3}{\pi}\frac{1-\cos\theta_Y}{2+\cos\theta_Y}\right)^{\frac{1}{3}}, \quad a = \left(\frac{3}{\pi}\right)^{\frac{1}{3}}\left(\frac{1-\cos\theta_Y}{2+\cos\theta_Y}\right)^{-\frac{1}{6}}\left(\frac{1+\cos\theta_Y}{2+\cos\theta_Y}\right)^{\frac{1}{2}}, \tag{3.5}$$

which coincide with the expression we obtained for $h_{0,0}$ and L_0 in (2.7) and (2.5), respectively.

The capacity of a flat disc is $C = 8a$ and the area of a spherical cap is $\pi(a^2 + h_0^2)$. Hence, the total energy of the charged drop is

$$E = \pi(a^2 + h_0^2) - (\cos\theta_Y)\,\pi a^2 - \frac{1}{2}CV_0^2 = \pi(a^2 + h_0^2) - (\cos\theta_Y)\,\pi a^2 - V_0^2 4a,$$

or keeping in mind the relation between a and h_0, from (3.4) and the constraint $Vol. = 1$,

$$E(h_0) = \pi\left(\frac{2}{\pi h_0} - \frac{h_0^2}{3} + h_0^2\right) - (\cos\theta_Y)\,\pi\left(\frac{2}{\pi h_0} - \frac{h_0^2}{3}\right) - V_0^2 4\sqrt{\frac{2}{\pi h_0} - \frac{h_0^2}{3}}.$$

For small h_0,

$$E'(h_0) \simeq (1-\cos\theta_Y)\left(\frac{-2}{h_0^2}\right) + 2\frac{V_0^2}{h_0^{\frac{3}{2}}}\sqrt{\frac{2}{\pi}} + O(h_0) = 0,$$

and hence

$$h_0 \sim \frac{\pi}{2V_0^4}\left(1-\cos\theta_Y\right)^2, \tag{3.6}$$

$$a = \frac{1}{h_0}\left(\frac{2}{\pi} - \frac{h_0^3}{3}\right) \sim \frac{4V_0^4}{\pi^2\left(1-\cos\theta_Y\right)^2}, \tag{3.7}$$

which gives an estimate of the radius of the drop's base as a function of V_0 and θ_Y, provided V_0 is small enough for (2.11) to be verified and θ_Y is sufficiently close to zero in order to have almost flat drops.

Next we will discuss whether or not almost flat configurations which are not discs can be more favorable energetically than the axially symmetric configurations. This is not surprising due to the important result of Pólya and Szegö (cf. [14]) on the effect of Schwarz symmetrization on capacity. They proved that the process of Schwarz symmetrization of a three-dimensional body diminishes (or leaves unchanged) the capacity of a body. Schwarz symmetrization about an axis e replaces each cross section of the body orthogonal to e by a circular section of the same area centered at e. This leads to a body of revolution. In the case of a disc, one can conclude that the capacity of a perturbed disc is larger than or equal to the capacity of the disc of the same area. Therefore, the energy functional decreases or remains equal when deforming a disc. We will show below that the energy, in fact, decreases.

The energy of the almost flat droplet can be approximated by

$$E \sim (1 - \cos\theta_Y)\, A_{sl} - \frac{1}{2} C_b V_0^2,$$

where we have assumed $h_r(r) \ll 1$ so that one can assume that the liquid-vapor interface has an area similar to the liquid-solid interface and the capacity of the drop is similar to the capacity of the planar region consisting of the liquid-solid interface, denoted by C_b.

When changing the geometry of the liquid-solid interface, the energy will experience a variation given by

$$\delta E = (1 - \cos\theta_Y)\, \delta A_{sl} - \frac{1}{2} V_0^2 \delta C_b.$$

A flat ellipsoid has capacity (cf. [14]) and area given by

$$C_b = 2\pi \frac{b' + b}{K\left(\frac{b'-b}{b'+b}\right)}, \quad A_{sl} = \pi b' b,$$

where b and b' are the length of the semiaxis of the ellipse and $K(x)$ is the complete elliptic integral of the first kind. If we perturb the disc into an ellipse, in such a way that the area is preserved, by writing

$$b = a(1+\varepsilon), \quad b' = \frac{a}{1+\varepsilon},$$

we will have

$$\delta A_{sl} = 0, \quad \delta C_b = \frac{2a + a\varepsilon^2}{K\left(\varepsilon - \frac{1}{2}\varepsilon^2\right)} - 8a2\pi \sim 2\pi \frac{2a + a\varepsilon^2}{\frac{\pi}{2} + \frac{\pi}{8}\varepsilon^2} - 8a \sim 8a\varepsilon^2,$$

and this implies $\delta E < 0$. Therefore, the flat ellipsoid is energetically favorable with respect to a flat disc. The same result will hold true for nonplanar bodies which are almost flat in the sense that h_0 given by (3.6) is much smaller than a, given by (3.7).

Notice that (3.7) has to be combined with (2.11) in order to have consistent almost-flat droplets. This condition requires, in addition to a given by (3.7) being large, that

$$V_0 a = \frac{4V_0^5}{\pi^2 \left(1 - \cos\theta_Y\right)^2} < 2\sqrt{8.848\ldots},$$

which is only true if V_0 is sufficiently small.

Finally, we introduce general perturbations of the flat disc in the form

$$r(\theta) = a\frac{1}{1+\frac{\varepsilon^2}{2}}(1+\varepsilon\cos(n\theta)),$$

with θ and r polar coordinates about the axis, so that

$$A_{sl} = \frac{1}{2}\int r^2(\theta)d\theta = a^2. \tag{3.8}$$

When $n = 2$, we recover, at first order in ε, the perturbation into an ellipsoid. For $n > 2$ we obtain a shape with n undulations of the disc's boundary. Such perturbations do not change the area by (3.8) but do change the capacity in the sense of increasing it with increasing n, provided $n\varepsilon \ll 1$. This implies that the larger n is, the more favorable energetically is a configuration with n undulations in its boundary.

3.3. Symmetry-breaking instabilities for intermediate values of $\boldsymbol{V_0}$ and $\boldsymbol{\theta_Y}$. We identify values of the potential at which nonaxisymmetric solutions are energetically more favorable than the axially symmetric configurations $r = a(z)$. We perturb the profiles radially in the form

$$r(\theta, z) = \frac{a(z)}{\sqrt{1+\frac{\varepsilon^2}{2}}}(1+\varepsilon\cos(n\theta)); \quad z\in[0,H], \quad \theta\in[0,2\pi). \tag{3.9}$$

In the last section, we will show that this kind of perturbation leads, for $\varepsilon \ll 1$ and provided $n\varepsilon \ll 1$, to an increase of the capacity which is a nondecreasing function of n. Since this fact follows from a lengthy calculation we postpone its proof and use it here to conclude the existence of symmetry-breaking bifurcations.

The volume of the drop does not change, since

$$Vol. = \int_0^H z\left[\int_0^{2\pi}\left(\int_0^{\frac{a(z)}{\sqrt{1+\frac{\varepsilon^2}{2}}}(1+\varepsilon\cos(n\theta))} rdr\right)d\theta\right]dz$$

$$= \int_0^H z\left[\frac{1}{2}\int_0^{2\pi}\frac{a^2(z)}{1+\frac{\varepsilon^2}{2}}(1+\varepsilon\cos(n\theta))^2 d\theta\right]dz = \pi\int_0^H za^2(z)dz.$$

The lateral area (area of the liquid-vapor interface) has a value

$$\begin{aligned}
A_{lv}(\varepsilon) &= \int_0^H\int_0^{2\pi}\sqrt{r^2+r_\theta^2+r^2r_z^2}d\theta dz \\
&= \int_0^H\int_0^{2\pi}\left(a^2\left(1+2\varepsilon\cos n\theta+\frac{\varepsilon^2}{2}\cos 2n\theta\right)+a^2n^2\varepsilon^2\sin^2(n\theta)\right. \\
&\qquad \left. +a^2a_z^2(1+4\varepsilon\cos n\theta+\varepsilon^2(3\cos 2n\theta+2))\right)^{\frac{1}{2}}dz+O(\varepsilon^3) \\
&= A_{lv}(0)+\varepsilon^2\pi\int_0^H\frac{\frac{n^2}{2}+2a_z^2}{\sqrt{1+a_z^2}}adz+O(\varepsilon^3) \\
&= A_{lv}(0)+\varepsilon^2(c_1n^2+c_2)+O(\varepsilon^3),
\end{aligned}$$

while the area of the solid-liquid interface remains unchanged. Hence, we can estimate the variation of the energy under a radial perturbation:

$$\begin{aligned}\delta E &= \delta A_{lv} - \cos\theta_Y \delta A_{sl} - \frac{1}{2}\delta C V_0^2\\ &= \varepsilon^2\left[(c_1 n^2 + c_2) - \frac{1}{2}\left(\delta C/\varepsilon^2\right) V_0^2\right] + O(\varepsilon^3).\end{aligned}$$

Since $\delta C/\varepsilon^2$ is always positive and $O(1)$ for $n > 2$, as we prove in the next section, one should always have, for

$$V_0 > V_{0,n} = \sqrt{\frac{2(c_1 n^2 + c_2)}{(\delta C/\varepsilon^2)}},$$

instabilities with a given n. For profiles close to a sphere $V_{0,n}$ is increasing with n, but this is not the case for profiles close to a disc. Given the strict monotonicity of the capacity with n (even for profiles that are close to discs), again as we prove in the next section, and given the fact that c_1 and c_2 can be made arbitrarily small for sufficiently flat profiles (when $H \ll 1$), we can make the combination $\left[(c_1 n^2 + c_2) - \frac{1}{2}\left(\delta C/\varepsilon^2\right) V_0^2\right]$ to decrease monotonically with n for configurations close to a disc. This would imply that perturbations with large n are more unstable than perturbations with a small n. Hence, one can expect the boundary to destabilize first with multiple oscillations. In the next subsection we implement a numerical method to compute the energy of radially perturbed equilibrium shapes and determine, for given θ_Y, the values of the radius of the solid-liquid interface and V_0 for which instabilities with various n appear.

3.4. Numerical results.

Numerical approximation in the radially perturbed case. When dealing with radially perturbed equilibrium shapes we lose the axially symmetric properties and need to do a full three-dimensional (3D) approximation in order to compute area and capacity and hence the energy given in (1.8). We use a boundary element method that we have already implemented in [3] to compute the surface charge density by solving the integral equation (2.14) in the profiles given by (3.9) with a unit potential at the boundary. From the surface charge density we can obtain the total charge integrating over the surface and that will be the capacity of the body.

Validation. In order to validate the numerical method described above we have done two tests:

1. Comparison with the exact capacity of a perfectly conducting thin spherical shell. The exact capacity can be obtained through

$$C = 4a(\sin\beta + \beta),$$

where a is the radius of the sphere and β is the zenithal angle of the shell; see [1].

We have compared in Figure 3.1 the capacity obtained numerically for values of β from 0 up to $\pi/2$ (a hemispherical shell) and with two different meshes (mesh 1 and mesh 2; see Figure 3.2), with the exact capacity. We found with mesh 1 a maximum relative error of 0.011 and with mesh 2 a maximum relative error of 0.0058. In both cases, the relative error is below 2%.

2. Comparison with the exact capacity of a hemisphere (a spherical cap with $\beta = \pi/2$ and a lower tap representing the liquid-solid interface). The exact capacity

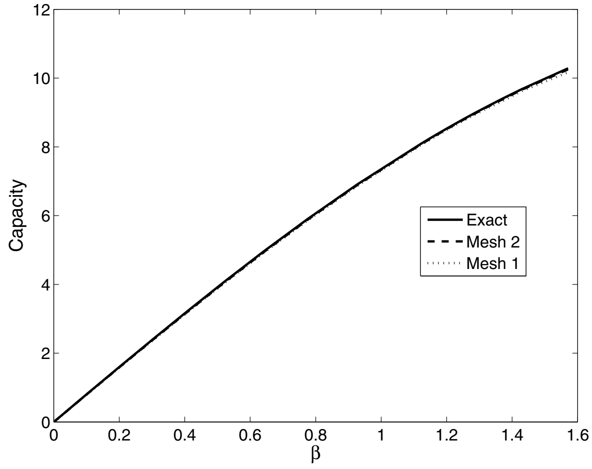

FIG. 3.1. *Capacity versus zenithal angle in an axisymmetric drop.*

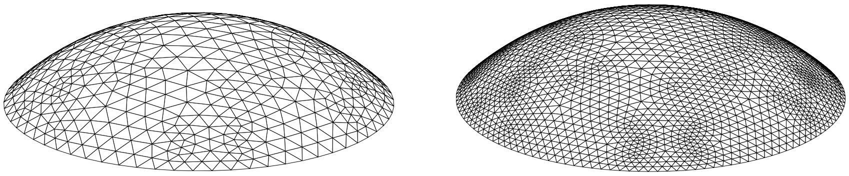

FIG. 3.2. *Two* 3*D meshes of a spherical cap (*$a = 0.7$*,* $\beta = 0.7754$*). On the left, mesh* 1 *(*541 *nodes and* 1016 *elements), and on the right, mesh* 2 *(*2097 *nodes and* 4064 *elements).*

of a hemisphere of radius a is (see [10])

$$4\pi a\left(1-\frac{1}{\sqrt{3}}\right).$$

In this case we compare again the results obtained with meshes 1 and 2. We obtained a relative error of 0.00997 with mesh 1 and a relative error of 0.00253 with mesh 2.

Results and discussion. We have used the numerical method described above to compute the energy of profiles perturbed in the form (3.9) and compare it with the energy of the axisymmetric profile $a(z)$. We use mesh 2 for the numerical simulations. In Figure 3.3 we show the perturbed drops with $n = 0$, 2, 3, and 4 for the case corresponding to $V = 0.6$ and $a = 1.16$.

In Figure 3.4 we represent, together with the curves of θ_Y as a function of a for all axisymmetric profiles at a given potential, the approximate "bifurcation curves" for $n = 2$, 3, and 4. Each of these curves, with a given value of n, delimits the regions where the configurations of the type (3.9) with $\varepsilon \ll 1$ (that we took equal to 0.025 for our numerical computations) are energetically more favorable than configurations with smaller value of n (including the axisymmetric profiles). Notice the tendency of the curves to intersect for large values of a. This is in agreement with the discussion on profiles close to a disc in the previous section.

From Figure 3.4 we can obtain two important conclusions:

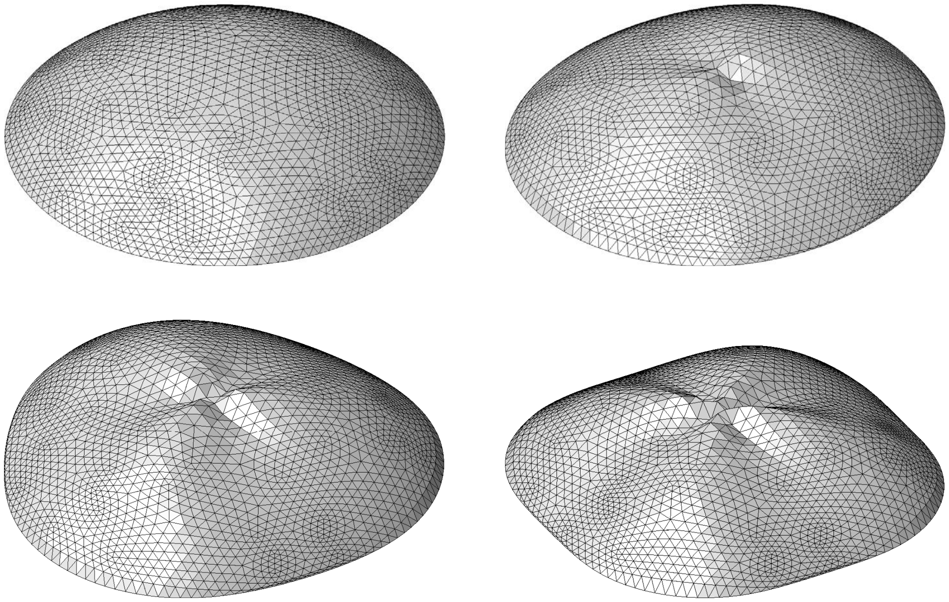

Fig. 3.3. *Shape of a radially symmetric droplet with a bottom tap of radius $a = 1.16$ under a potential $V = 0.6$ (top left). The same drop perturbed radially with $n = 2$ (top right), $n = 3$ (bottom left), and $n = 4$ (bottom right).*

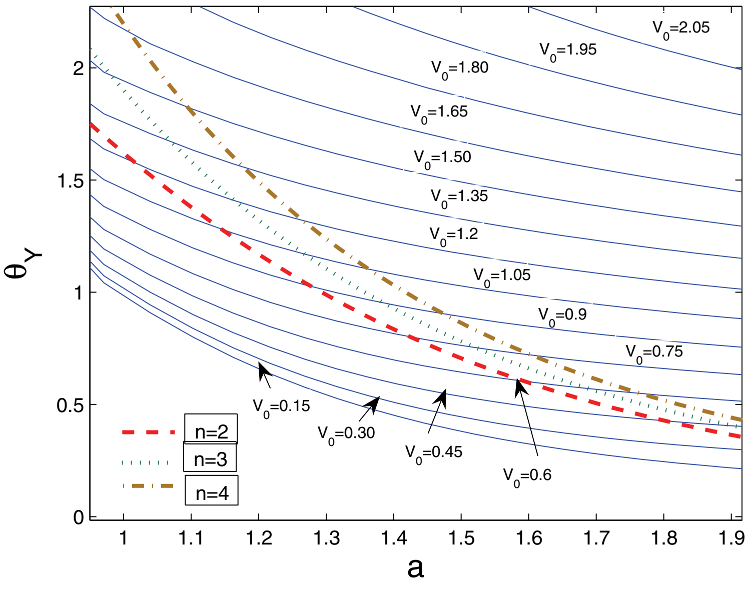

Fig. 3.4. *Bifurcation branches in the $a - \theta_Y$ plane. The bifurcations with $n = 2$ are represented with dashed line, $n = 3$ with dotted line, and $n = 4$ with dash-dot line.*

1. Drops cannot be spread indefinitely by increasing the potential V_0. If we trace a horizontal line in Figure 3.4 for a given value of θ_Y, we find that a increases with the potential in a superlinear manner, but only up to some limiting value where

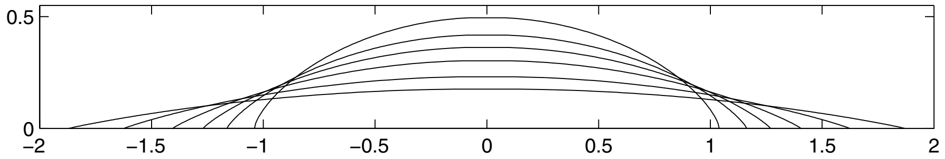

FIG. 3.5. *Axisymmetric profiles at the bifurcation curve $n = 2$ for $\theta_Y = 1.55$, 1.26, 1.03, 0.81, 0.59, 0.43.*

we meet the first bifurcation curve $n = 2$. At this point, an axisymmetric drop is no longer the most favorable configuration, and drops with elliptic cross sections will be preferred. A further increase of V_0 leads to an intersection with the curves $n = 3, 4, \ldots$ and configurations with a higher number of undulations would be more favorable energetically. The intersection with the first bifurcation curve takes place for relatively small values of a (in comparison with the maximum values that a may take from the constraint established in (2.11)). In Figure 3.5 we represent the axisymmetric profiles at the $n = 2$ bifurcation curve for different values of θ_Y. Observe that all the profiles are concave. Hence, the profiles changing concavity, like those represented in Figure 2.4, are probably not observable in nature since nonaxisymmetric perturbations lead to configurations which are energetically more favorable. Once a bifurcation curve has been crossed, axisymmetric drops should destabilize. This provides an explanation to the saturation effect in electrowetting.

2. For a given value of θ_Y, the transition between bifurcation curves occurs relatively fast: if we take, for instance, $\theta_Y = \frac{\pi}{4}$, we can see that a only changes approximately from 1.4 to 1.6 while crossing the bifurcation curves $n = 2$, 3, and 4. This fast transition is more remarkable the smaller θ_Y is, and for sufficiently small values of θ_Y the transition takes place for very flat shapes; for those shapes (see the previous section) the first bifurcation curve we cross when increasing a may correspond to $n > 2$. The quick transition between bifurcation curves provides an explanation of the characteristic multiple-finger patterns observed in electrowetting once saturation is reached and potential is slowly increased.

4. The capacity of radially perturbed bodies of revolution. In this section we deduce some important results used in this paper concerning the capacity of a radially perturbed body of revolution (including drops as a particular case). We shall show how the breaking of axial symmetry leads to an increase in the capacity, and we estimate this increase. By Dirichlet's principle, the capacity of Ω can be evaluated as (cf. [14])

$$C = \int_{\mathbb{R}^3 \setminus \Omega_0} |\nabla V|^2 \, d\mathbf{x}.$$

We will consider here the case of Ω being a small axial perturbation of an axisymmetric domain Ω_0. More precisely, we shall consider a domain described in cylindrical coordinates (r, θ, z) by

$$r(\theta, z) = \frac{a(z)}{\sqrt{1 + \frac{\varepsilon^2}{2}}}(1 + \varepsilon \cos(n\theta)); \quad z \in [0, H], \quad \theta \in [0, 2\pi),$$

where $r = a(z)$ describes the generatrix of Ω_0; together with the upper and lower taps $r < \{a(H)(1 + \varepsilon \cos(n\theta)),\, z = H\}$ and $r < \{a(0)(1 + \varepsilon \cos(n\theta)),\, z = 0\}$. Notice that

$a(H) = 0$ in the particular case of a drop, which is the one considered in the present paper. Then, assuming $a(z) = 0$ for $z < 0$ and $z > H$, one can write

$$\int_{\mathbb{R}^3 \setminus \Omega_0} |\nabla V|^2 \, d\mathbf{x} = \int_0^{2\pi} \int_{-\infty}^{\infty} \int_{\frac{a(z)}{\sqrt{1+\frac{\varepsilon^2}{2}}}(1+\varepsilon\cos(n\theta))}^{\infty} |\nabla V|^2 \, r dr d\theta dz.$$

We change variables to a new system $r' = \sqrt{1+\frac{\varepsilon^2}{2}}\, r/(1+\varepsilon\cos(n\theta))$, $\theta' = \theta$, $z' = z$, so that

$$\frac{\partial V}{\partial r} = \frac{\partial V}{\partial r'} \frac{1}{1+\varepsilon\cos(n\theta')},$$
$$\frac{\partial V}{\partial \theta} = \frac{\partial V}{\partial \theta'} + \frac{\partial V}{\partial r'} r' \frac{\varepsilon n \sin(n\theta')}{1+\varepsilon\cos(n\theta')},$$

and hence

$$\begin{aligned} C = \int_{\mathbb{R}^3 \setminus \Omega_0} \Bigg\{ & \frac{1}{(1+\varepsilon\cos(n\theta'))^2} \left| \frac{\partial V}{\partial r'} \right|^2 + \frac{1}{r'^2 (1+\varepsilon\cos(n\theta'))^2} \left| \frac{\partial V}{\partial \theta'} + \frac{\partial V}{\partial r'} \frac{r' \varepsilon n \sin(n\theta')}{1+\varepsilon\cos(n\theta')} \right|^2 \\ & + \frac{1}{1+\frac{\varepsilon^2}{2}} \left| \frac{\partial V}{\partial z'} \right|^2 \Bigg\} (1+\varepsilon\cos(n\theta'))^2 \, r' dr' d\theta' dz' \\ = \int_{\mathbb{R}^3 \setminus \Omega_0} & \left\{ \left| \frac{\partial V}{\partial r'} \right|^2 + \frac{1}{r'^2} \left| \frac{\partial V}{\partial \theta'} \right|^2 + \left| \frac{\partial V}{\partial z'} \right|^2 \right\} r' dr' d\theta' dz' \\ + \int_{\mathbb{R}^3 \setminus \Omega_0} & \Bigg\{ \frac{2}{r'} \frac{\partial V}{\partial \theta'} \frac{\partial V}{\partial r'} \frac{\varepsilon n \sin(n\theta')}{(1+\varepsilon\cos(n\theta'))} + \frac{1}{r'^2} \left| \frac{\partial V}{\partial r'} r' \frac{\varepsilon n \sin(n\theta')}{1+\varepsilon\cos(n\theta')} \right|^2 \\ & + \left(2\varepsilon\cos(n\theta') + \varepsilon^2 \cos^2(n\theta') - \frac{\varepsilon^2}{2} \right) \left| \frac{\partial V}{\partial z'} \right|^2 \Bigg\} r' dr' d\theta' dz' + O(\varepsilon^3). \end{aligned}$$

Let $V_0(r,z)$ be the potential outside Ω_0 such that $V_0 = 1$ at $\partial\Omega_0$, with C_0 the capacity of Ω_0, and write

$$V(r', \theta', z') = V_0(r', z') + \varepsilon^2 V_1(r', \theta', z').$$

Then, as long as $n\varepsilon \ll 1$, we can expand

$$\begin{aligned} C = & \int_{\mathbb{R}^3 \setminus \Omega_0} |\nabla V_0|^2 \, d\mathbf{x}' + 2\varepsilon \int_{\mathbb{R}^3 \setminus \Omega_0} \nabla V_0 \cdot \nabla V_1 d\mathbf{x}' + \varepsilon^2 \int_{\mathbb{R}^3 \setminus \Omega_0} |\nabla V_1|^2 \, d\mathbf{x}' \\ & + \varepsilon^2 \int_{\mathbb{R}^3 \setminus \Omega_0} \Bigg\{ \frac{2}{r'} \frac{\partial V_1}{\partial \theta'} \frac{\partial V_0}{\partial r'} n \sin(n\theta') + \left(\frac{\partial V_0}{\partial r'} \right)^2 n^2 \sin^2(n\theta') \\ & \qquad + \frac{1}{2} \cos(2n\theta') \left(\frac{\partial V_0}{\partial z'} \right)^2 + 4\cos(n\theta') \frac{\partial V_1}{\partial z'} \frac{\partial V_0}{\partial z'} \Bigg\} r' dr' d\theta' dz' + O(\varepsilon^3), \end{aligned}$$

and since $\int_{\mathbb{R}^3 \setminus \Omega_0} \nabla V_0 \cdot \nabla V_1 d\mathbf{x}' = 0$ (as one can show after integration by parts and using $\Delta V_0 = 0$ outside Ω_0 and $V_1 = 0$ at $\partial\Omega_0$) we can write

$$C = C_0 + \varepsilon^2 C_{n,1} + O(\varepsilon^3),$$

where

$$C_{n,1} = \int_{\mathbb{R}^3 \diagdown \Omega_0} |\nabla V_1|^2 \, d\mathbf{x}' + \int_{\mathbb{R}^3 \diagdown \Omega_0} \Bigg\{ \left(\frac{\partial V_0}{\partial r'} \right)^2 n^2 \sin^2(n\theta') \\ + \frac{2}{r'} \frac{\partial V_1}{\partial \theta'} \frac{\partial V_0}{\partial r'} n \sin(n\theta') + 4 \cos(n\theta') \frac{\partial V_1}{\partial z'} \frac{\partial V_0}{\partial z'} \Bigg\} r' dr' d\theta' dz'.$$

By Dirichlet's principle, V_1 can also be characterized as the function W for which the minimum of

$$\int_{\mathbb{R}^3 \diagdown \Omega_0} \left(|\nabla W|^2 + \frac{2}{r'} \frac{\partial W}{\partial \theta'} \frac{\partial V_0}{\partial r'} n \sin(n\theta') + 4 \cos(n\theta') \frac{\partial W}{\partial z'} \frac{\partial V_0}{\partial z'} \right) d\mathbf{x}'$$

is achieved or, equivalently, the solution to the boundary value problem

$$\begin{aligned} 2\Delta V_1 &= -\frac{2}{r'} \frac{\partial V_0}{\partial r'} n^2 \cos(n\theta') - 4 \frac{\partial^2 V_0}{\partial z'^2} \cos(n\theta') \quad \text{in } \mathbb{R}^3 \diagdown \Omega_0, \\ V_1 &= 0 \quad \text{at } \partial\Omega_0. \end{aligned}$$

We can find the solution to this problem in the form

$$V_1 = \cos(n\theta') \Phi(r', z'),$$

which leads to

$$C_{n,1} = \int_{-\infty}^{+\infty} \int_{a(z')}^{+\infty} \left(\frac{n^2}{2} \left| \frac{\partial V_0}{\partial r'} \right|^2 \right) r' dr' dz'$$

$$+ \int_{-\infty}^{+\infty} \int_{a(z')}^{+\infty} \left(\frac{1}{2} \left| \frac{\partial \Phi}{\partial r'} \right|^2 + \frac{1}{2} \left| \frac{\partial \Phi}{\partial z'} \right|^2 + \frac{n^2}{2r'^2} \Phi^2 - \frac{n^2}{r'} \Phi \frac{\partial V_0}{\partial r'} + 2 \frac{\partial \Phi}{\partial z'} \frac{\partial V_0}{\partial z'} \right) r' dr' dz'.$$

Hence, using $\Delta V_0 = 0$, one finds

$$-\Delta_{(r',z')} \Phi + \frac{n^2}{r'^2} \Phi = \frac{n^2}{r'} \frac{\partial V_0}{\partial r'} - \frac{2}{r'} \frac{\partial}{\partial r'} \left(r' \frac{\partial V_0}{\partial r'} \right) \quad \text{in } \mathbb{R}^3 \diagdown \Omega_0, \tag{4.1}$$

$$\Phi = 0 \quad \text{at } \partial\Omega_0. \tag{4.2}$$

We are going to show two important facts: (1) $C_{n,1}$ is strictly positive, and (2) $C_{n,1}$ is increasing with n. The first fact follows from the following calculations:

$$\begin{aligned} C_{n,1} &= \int_{-\infty}^{+\infty} \int_{a(z')}^{+\infty} \left(\frac{n^2}{2} \left| \frac{\partial V_0}{\partial r'} \right|^2 \right) r' dr' dz' + \int_{-\infty}^{+\infty} \int_{a(z')}^{+\infty} \left(\frac{1}{2} \left| \frac{\partial \Phi}{\partial z'} \right|^2 \right) r' dr' dz' \\ &\quad + \int_{-\infty}^{+\infty} \int_{a(z')}^{+\infty} \left(\frac{1}{2} \left| \frac{\partial \Phi}{\partial r'} \right|^2 + \frac{n^2}{2r'^2} \Phi^2 - \frac{n^2}{r'} \Phi \frac{\partial V_0}{\partial r'} + 2 \frac{\partial \Phi}{\partial z'} \frac{\partial V_0}{\partial z'} \right) r' dr' dz' \\ &> \int_0^H \int_{a(z')}^{+\infty} \left\{ \frac{n^2}{2} \left| \frac{\partial V_0}{\partial r'} \right|^2 + \frac{1}{2} \left| \frac{\partial \Phi}{\partial r'} \right|^2 + \frac{n^2}{2r'^2} \Phi^2 - \frac{n^2}{r'} \Phi \frac{\partial V_0}{\partial r'} - 2 \frac{\partial \Phi}{\partial r'} \frac{\partial V_0}{\partial r'} \right\} r' dr' dz' \\ &\underset{u=\log r}{=} \int_0^H \left[\int_{\log a(z')}^{+\infty} \left\{ \frac{n^2}{2} \left| \frac{\partial V_0}{\partial u} \right|^2 + \frac{1}{2} \left| \frac{\partial \Phi}{\partial u} \right|^2 + \frac{n^2}{2} \Phi^2 - n^2 \Phi \frac{\partial V_0}{\partial u} - 2 \frac{\partial \Phi}{\partial u} \frac{\partial V_0}{\partial u} \right\} du \right] dz'. \end{aligned}$$

By performing Fourier transform in u of this last expression we get

$$\begin{aligned}
&\int_0^H \left[\int_{-\infty}^{+\infty} \left\{\frac{n^2}{2}k^2 \left|\widehat{V_0}\right|^2 + \frac{1}{2}k^2 \left|\widehat{\Phi}\right|^2 + \frac{n^2}{2}\left|\widehat{\Phi}\right|^2 - ikn^2\overline{\widehat{\Phi}}\widehat{V_0} + 2k^2\overline{\widehat{\Phi}}\widehat{V_0}\right\} dk\right] dz' \\
&= \int_0^H \left\{\int_{-\infty}^{+\infty} \left[\frac{n^2}{2}k^2 \left|\widehat{V_0}\right|^2 + \left(\frac{1}{2}k^2 + n^2\right)\left|\widehat{\Phi}\right|^2\right.\right. \\
&\qquad \left.\left. + n^2k^2(\Im\widehat{V_0}\Re\widehat{\Phi} - \Im\widehat{\Phi}\Re\widehat{V_0}) + 2k^2((\Re\widehat{V_0}\Re\widehat{\Phi} + \Im\widehat{V_0}\Im\widehat{\Phi}))\right] dk\right\} dz. \qquad (4.3)
\end{aligned}$$

Let

$$\mathbf{a} = (\Re\widehat{\Phi}, \Im\widehat{\Phi}, \Re\widehat{V_0}, \Im\widehat{V_0}).$$

Then the integrand in (4.3) is $\mathbf{a}T(n,k)\mathbf{a}^t$ with

$$T(n,k) = \begin{pmatrix} \frac{k^2+n^2}{2} & 0 & k^2 & \frac{n^2k}{2} \\ 0 & \frac{k^2+n^2}{2} & -\frac{n^2k}{2} & k^2 \\ k^2 & -\frac{n^2k}{2} & \frac{k^2n^2}{2} & 0 \\ \frac{n^2k}{2} & k^2 & 0 & \frac{k^2n^2}{2} \end{pmatrix}$$

possessing the following two double eigenvalues:

$$\lambda_\pm = \frac{1}{4}k^2n^2 + \frac{1}{4}k^2 + \frac{1}{4}n^2 \pm \frac{1}{4}\sqrt{k^4n^4 - 2k^4n^2 + 17k^4 + 2k^2n^4 + 2k^2n^2 + n^4}.$$

Notice that

$$\lambda_- = \frac{k^4\left(n^2-4\right)}{k^2n^2 + k^2 + n^2 + \sqrt{k^4n^4 - 2k^4n^2 + 17k^4 + 2k^2n^4 + 2k^2n^2 + n^4}} > \frac{k^4/2}{1+k^2}\frac{n^2-4}{n^2+1}$$

so that

$$C_{n,1} > \frac{n^2-4}{n^2+1}\int_0^H \left[\int_{-\infty}^{+\infty} \frac{1}{2}\frac{k^4}{1+k^2}\left|\widehat{V_0}\right|^2 dk\right] dz = c'\frac{n^2-4}{n^2+1}.$$

The capacity is increasing with n:

$$\begin{aligned}
C_{n,1} &= \int_{-\infty}^{+\infty}\int_{a(z')}^{+\infty} \left(\frac{1}{2}\left|\frac{\partial\Phi}{\partial r'}\right|^2 + \frac{1}{2}\left|\frac{\partial\Phi}{\partial z'}\right|^2 + \frac{n^2}{2}\left|\frac{\Phi}{r'} - \frac{\partial V_0}{\partial r'}\right|^2 + 2\frac{\partial\Phi}{\partial z'}\frac{\partial V_0}{\partial z'}\right) r'dr'dz' \\
&\geq \int_{-\infty}^{+\infty}\int_{a(z')}^{+\infty} \left(\frac{1}{2}\left|\frac{\partial\Phi}{\partial r'}\right|^2 + \frac{1}{2}\left|\frac{\partial\Phi}{\partial z'}\right|^2 + \frac{(n-1)^2}{2}\left|\frac{\Phi}{r'} - \frac{\partial V_0}{\partial r'}\right|^2 + 2\frac{\partial\Phi}{\partial z'}\frac{\partial V_0}{\partial z'}\right) r'dr'dz' \\
&\geq \frac{1}{2}\min_{\Psi}\int_{-\infty}^{+\infty}\int_{a(z')}^{+\infty} \left(\left|\frac{\partial\Psi}{\partial r'}\right|^2 + \left|\frac{\partial\Psi}{\partial z'}\right|^2 + (n-1)^2\left|\frac{\Psi}{r'} - \frac{\partial V_0}{\partial r'}\right|^2 + 4\frac{\partial\Psi}{\partial z'}\frac{\partial V_0}{\partial z'}\right) r'dr'dz' \\
&= C_{n-1,1},
\end{aligned}$$

with equality if and only if

$$\Phi = r'\frac{\partial V_0}{\partial r'}, \qquad (4.4)$$

which would imply, by (4.1),

$$-\Delta_{(r',z')}\Phi + \frac{2}{r'}\frac{\partial \Phi}{\partial r'} = 0. \tag{4.5}$$

Multiplying (4.5) by Φ and integrating by parts using $\Phi = 0$ at $\partial\Omega$, we get

$$\int |\nabla \Phi|^2 \, d\mathbf{x}' = 0,$$

which would imply $\Phi = 0$ at almost every point, a fact that is incompatible with (4.4). Therefore the capacity is strictly increasing with n.

The fact that the capacity is strictly increasing with n is crucial to the proof of existence of symmetry-breaking bifurcations in section 3.3. Another important consequence of the result proved in this section, discussed in section 3.3, is the fact that perturbations with high order modes (large value of n) may be the most favorable energetically if the body of revolution that we perturb is sufficiently flat. This may lead to instabilities of the contact line in the form of numerous fingers.

MATHEMATICS AND MONUMENT CONSERVATION: FREE BOUNDARY MODELS OF MARBLE SULFATION[*]

FABRIZIO CLARELLI[†], ANTONIO FASANO[‡], AND ROBERTO NATALINI[†]

Abstract. We introduce some free boundary problems which describe the evolution of calcium carbonate stones under the attack of atmospheric SO_2, taking into account both swelling of the external gypsum layer and the influence of humidity. Different behaviors are described according to the relative humidity of the environment, and in all cases reliable explicit quasi-steady approximations are introduced under reasonable assumptions on the data. Some numerical simulations are also performed to describe gypsum formation using experimental data, which show a good agreement with the quasi-steady solutions. The influence of the cleaning the crust and of the change in concentration of pollution is evaluated and discussed.

Key words. free boundary problems, chemical damage, porous media, swelling, influence of humidity, damage of cultural heritage

1. Introduction.

Deterioration of stones is a complex problem and one of the main concerns for people working in the field of conservation and restoration of cultural heritage. It is extremely difficult to isolate a single factor in these kinds of processes, which are the results of the interaction of various mechanisms, many of which also occur in natural weathering; however, atmospheric pollution can certainly be considered as one of the most important factor of damage. In this paper we shall introduce some free boundary models to describe damage induced by pollution.

Although in recent years air pollution in European urban areas has decreased considerably, there still remain concentrations of pollutants such as sulfur dioxide (SO_2) from combustion of fossil fuels, and nitrogen oxides (NO_x) from combustion engines, the former being the most important factor in the deterioration of stones. Indeed SO_2 can react with any calcareous component in the stone, producing an external layer of gypsum, which may be drained away by rain or form crusts that eventually exfoliate. This process greatly depends on the nature of the stone and on the presence of moisture. Since the stone is a porous material, condensation of moisture may occur deep within the pores of the material, and it is critical to its reactivity to pollutant. Despite the intense experimental research performed in this area (see [5] for a large review), further studies are necessary in order to provide a predictive tool.

The present paper will be concerned with the so-called dry deposition of SO_2 on calcium carbonate stones. Many experimental investigations (see, for instance, [7, 5]) have shown that this process, which is mainly influenced by short-range transport of pollutants from local sources, is the main source of damage in stones, and more precisely in very compact stones like high-quality marbles. Wet deposition, in which

pollutants are dissolved in moisture droplets and rain, is actually considered as secondary, even if, as in areas where buildings and monuments remain wet for a long time, it may become important.

For dry deposition the path of reaction of SO_2 with calcium carbonate is revealed by the x-ray diffraction counts, which suggest that the reaction can be approximated by the following simplified one-step reaction [2, 7]:

$$CaCO_3 + SO_2 + \frac{1}{2}O_2 + 2H_2O \to CaSO_4 \cdot 2H_2O + CO_2. \tag{1.1}$$

Namely, one mole of calcium carbonate and one mole of sulfur dioxide, combined with two moles of water, produce one mole of calcium sulfate dihydrate (gypsum) $CaSO_4 \cdot 2H_2O$ and one of carbon dioxide CO_2. In the following we will use the fact that, on the typical time scale of the whole process, which will be one year, not only can we neglect the intermediate steps leading to (1.1), but we may also consider this reaction instantaneous, thus producing a sharp free boundary between gypsum and the unreacted calcium carbonate. In stones with very low porosity, the appearance of a sharp gypsum-marble interface has been experimentally observed in [7, 4, 8]. Moreover, according to the results in [9], this is an excellent approximation of the finite rate regime.

In our model we will consider only a one-dimensional geometry. Actually, since the typical thickness of the gypsum layer produced in one year in standard conditions is 20 [μm], if the gypsum layer is not removed, then for surfaces without too high a curvature a one-dimensional model is fully appropriate. However, a peculiar feature of the process is that the advancement of the sulfation front depends on factors that can change several hundreds of times during the same time scale. Such factors may be influenced very much by local conditions, with the consequence that monuments made of the same material, having the same age, and located in the same city not far from each other can have a very different state of preservation. Thus, even if we consider a small number of influencing factors, the resulting picture is not simple and requires a rather detailed knowledge of data concerning not only the regional climatic conditions, but also the local environment.

An additional comment about reaction (1.1) is in order. As a matter of fact, in real processes, calcium sulfate is also produced, according to the reaction path

$$CaCO_3 + SO_2 + \frac{1}{2}H_2O \to CaSO_3 \cdot \frac{1}{2}H_2O + CO_2.$$

In this regard, it has been shown that the proportion of $CaSO_4$ and $CaSO_3$ in a sulfation process can be affected to a great extent not only by relative humidity, but also by the presence of other substances like $CaCl_2$, $MnCl_2$, $CuCl_2$, and $FeCl_3$ acting as catalysts which favor one of the two reactions [7, 11]. The two reactions generally occur simultaneously and the resulting mixed layer can have properties (e.g., porosity, permeability, etc.) depending on the volume fractions of the two substances, and calcium sulfite may be converted to calcium sulfate, so that the process, including the two reactions, is considerably more complicated. However, even if laboratory tests show that calcium sulfite is the primary product of the reaction, in situ analysis reveals only the presence of calcium sulfate, which can be considered as the final state reached by the whole reaction.

In this paper we present some free boundary models, which include important phenomena not considered in the previous mathematical papers on the subject [3, 1]:

swelling and relative humidity. As we can see in the following, these two factors have a deep influence in the evolution of sulfation and require specific consideration. Using dimensional scaling we are able to build almost explicit approximations of these models, which will be very useful in their calibration and qualitative study. Different regimes are determined, according to the presence of relative humidity near the stones. We also introduce some finite difference schemes to compare the results of our asymptotic analysis and the real behavior of the solutions. A good agreement is found in all cases, even if on the scale of 10 years the numerical schemes should be preferred. Finally, some simulations are performed utilizing real data, which were kindly provided by Arpalazio, the Rome regional authority for monitoring pollution. Useful indications are derived by our elaboration of these data.

2. Swelling. The transformation of marble into gypsum is accompanied by a volume change. The swelling rate can be calculated easily because the molar ratio in (1.1) between $CaCO_3$ and $CaSO_4$ is 1 : 1. Thus, on the unit surface of the reaction front the consumption rate of $CaCO_3$ moles equals the production rate of $CaSO_4$ moles. If $x = \sigma(t)$ denotes the sulfation front and $x = \sigma_0(t)$ is the gypsum surface exposed to air (the frame of reference is chosen so that unreacted marble is at rest), we have the relation

$$\dot{\sigma}_0 = -\omega\dot{\sigma}, \tag{2.1}$$

where $\omega = \frac{\mu_m}{\mu_s} - 1$, μ_m and μ_s being the molar density (# mol/cm^3) of $CaCO_3$ in the marble and of $CaSO_4$ in the gypsum, respectively. We are supposing that μ_m is constant (i.e., the marble is a homogeneous material) and that μ_s is also constant, meaning that gypsum is formed with some standard structure, independently of its production rate. Under this assumption, if $\sigma_0(0) = \sigma(0) = 0$, we may conclude that

$$\sigma_0(t) = -\omega\sigma(t), \tag{2.2}$$

so that the thickness of the gypsum layer at time t is

$$h(t) = (1 + \omega)\sigma(t). \tag{2.3}$$

Otherwise if $\sigma(0) > 0$ and $\sigma_0(0) > 0$, we obtain

$$\sigma_0(t) - \sigma_0(0) = -\omega\left(\sigma(t) - \sigma(0)\right). \tag{2.4}$$

Swelling is an important phenomenon. First of all *it is not small*. Although the determination of μ_s is not easy, it is reasonable to say that the swelling rate ω can approach 2. The motion of gypsum influences the flow of the air and of the other gaseous components present in the pores. We concentrate our attention on SO_2 and water vapor. On the length and time scales typical of the process, air can be considered to move with the same speed as gypsum, i.e.,

$$v_a = \dot{\sigma}_0. \tag{2.5}$$

This approximation will be completely justified in the appendix.

3. Sulfation: A two-regime process. Experimental researchers know that relative humidity has a key role in regulating the speed of marble sulfation. One could think that since SO_2 is by far the most diluted among the reactants in (1.1), it has to play a limiting role. On the contrary, this role is taken up by H_2O. Indeed it is observed that when relative humidity exceeds some threshold, then SO_2 reacts completely. Below that threshold (which is around 75%) there is another range (down to 45%) in which the reaction slows down and stops completely for even lower values; see [5, 7] and the references therein. We can interpret this phenomenon as follows.

According to (1.1) a molecule of SO_2 coming in contact with $CaCO_3$ reacts if two molecules of H_2O are available at the same point (we suppose that there is always enough O_2). Such a multiple encounter has a negligibly small probability to occur if H_2O is just in the gaseous form. To make the reaction proceed at full speed it is necessary that H_2O is permanently available. This is true only if vapor condenses on the unreacted marble surface forming a liquid film.

Condensation is made possible by the fact that marble is hygroscopic and will be the result of a sorption-desorption process, which we assume to go through equilibrium states. Therefore, we may interpret the limiting role of H_2O by saying that the liquid film is present if the relative humidity is above the 75% threshold, while in the range 45%–75% there will be just humid spots on which the reaction takes place. Accordingly only a fraction of the SO_2 arriving to the front will be employed in the reaction. For relative humidity below 45% no liquid water is present and the reaction stops.

The two sulfation regimes (full and reduced speed) have different boundary conditions on the unreacted marble surface. We will examine them separately.

4. Full sulfation speed. If temperature T and pressure p are prescribed, the condition for full reaction speed is that the concentration of H_2O in air exceeds some value $w_0(T,p)$.

Let s denote the concentration of SO_2 in the pores of gypsum. The flow of SO_2 relative to air is governed by Fick's law. Thus in the frame of reference where marble is at rest the SO_2 flux has the expression

$$j_s = n_g\Big(-d_s\frac{\partial s}{\partial x} - s\omega\dot{\sigma}\Big), \tag{4.1}$$

n_g denoting gypsum porosity and d_s the diffusivity of SO_2 in air.

We have used (2.5) and (2.1). Consistently with the assumption $\mu_s =$ constant, we suppose also $n_g =$ constant.

Thus the SO_2 mass balance in the gypsum layer $\sigma_0(t) < x < \sigma(t)$ is expressed by

$$\frac{\partial s}{\partial t} - d_s\frac{\partial^2 s}{\partial x^2} - \omega\dot{\sigma}\frac{\partial s}{\partial x} = 0. \tag{4.2}$$

The value of s at the external boundary is some known function of time

$$s(\sigma_0(t), t) = s_a(t). \tag{4.3}$$

When SO_2 reacts totally at the front we have

$$s(\sigma(t), t) = 0, \tag{4.4}$$

implying that the flux of SO_2 at the front is purely diffusive. Hence the mass balance in the reaction is

$$-n_g\frac{d_s}{M_s}\frac{\partial s}{\partial x}(\sigma(t), t) = \frac{\rho_m}{M_m}\dot{\sigma}, \tag{4.5}$$

where M_s, M_m are the molar weights of SO_2 and of $CaCO_3$, respectively, and ρ_m is the density of the pristine marble (the ratio $\frac{\rho_m}{M_m}$ is nothing but the molar density μ_m we have already introduced).

Thus in this region the problem for the pair (s, σ) can be formulated independently of the evolution of other quantities.

Although the water vapor concentration w plays no role during this time, it is important to monitor its evolution in view of the possible transition to the other regime, since the constraint

$$w(\sigma(t), t) \geq w_0(T, p) \tag{4.6}$$

must be satisfied during this stage.

The water vapor flux is

$$j_w = n_g \Big(-d_w \frac{\partial w}{\partial x} - w\omega\dot{\sigma} \Big) \tag{4.7}$$

(d_w is the diffusivity of H_2O in air), thus the H_2O mass balance is

$$\frac{\partial w}{\partial t} - d_w \frac{\partial^2 w}{\partial x^2} - \omega\dot{\sigma} \frac{\partial w}{\partial x} = 0. \tag{4.8}$$

At the outer surface w equals the external concentration (see the comment about (4.3)).

$$w(\sigma_0(t), t) = w_a(t). \tag{4.9}$$

On the free boundary

$$-n_g \frac{d_w}{M_w} \frac{\partial w}{\partial x} = 2 \frac{\rho_m}{M_m} \dot{\sigma} + n_g (1 + \omega) \frac{w}{M_w} \dot{\sigma} \tag{4.10}$$

(M_w molar weight of H_2O), since two moles of H_2O react with one mole of $CaCO_3$.

The validity of (4.6) must be checked at all times. The system (4.2)–(4.5) can be reduced to a standard Stefan problem, as we shall see, and once $\sigma(t)$ is known, problem (4.8)–(4.10) presents no difficulties.

Remark 4.1. The balance in (4.10) contains some implicit assumptions. As we have stated, in order to trigger the reaction, water must condense as a liquid film. The production of $CaSO_4$ is the result of intermediate reactions occurring in the film and producing H_2SO_4, which eventually reacts with $CaCO_3$. In writing (4.10) we neglected the film thickness and also the moisture content in the pristine marble. Strictly speaking, the left-hand side (l.h.s.) in (4.10) must be interpreted as the feeding rate of the water film, whose thickness we suppose to be very small in comparison with the typical scale length of the process and constant. The first term on the right-hand side (r.h.s.) of (4.10) is the water moles consumption rate in the reaction per unit surface. However, if the pores of the pristine marble contain some water, this would enter the balance with a term $n_m \dot{\sigma} \frac{w_m}{M_w}$ (n_m marble porosity, w_m water concentration in marble pores).

If by chance marble is saturated by liquid water ($w_m =$ liquid water density), this term may not be negligible. Moreover, the water within the marble may contribute to keep a sufficiently high relative humidity in the gypsum for some time, even when the relative humidity in air drops below the full speed threshold. In any case the fact that marble is hygroscopic is going to affect the water vapor flow within the marble. However, in the case of stones having a very low porosity, the mass fraction of the water possibly stored in the pores is not enough to maintain a liquid film at the reaction front when air humidity is below threshold. In any case, the threshold values (45% and 75%) are currently found in the literature (with some fluctuation), but the state of the stone to which they refer is never specified. So they may already include the effect of stored water.

5. Reduced sulfation speed. We have now w between two thresholds:

$$w_1(T,p) \le w(\sigma(t),t) \le w_0(T,p). \tag{5.1}$$

The governing differential equations for s, w remain unchanged (i.e., (4.2), (4.8)), as do the conditions on the external boundary (4.3), (4.9). A deep modification intervenes on the free boundary, since the $CaCO_3$ front is not coated by a continuous water film, but rather covered by humid spots. We can define an efficiency factor $\alpha(w,T,p)$ (which for simplicity we denote $\alpha(w) = \frac{1}{w_0-w} - \frac{1}{w_0-w_1}$) for the chemical reaction, which increases from 0 to ∞ as w goes from w_1 (the no-reaction threshold) to w_0 (the full reaction threshold). The two free boundary conditions (4.4), (4.5) are now replaced by

$$\frac{j_s}{M_s} = \frac{\rho_m}{M_m}\dot\sigma + n_g \frac{s}{M_s}\dot\sigma, \tag{5.2}$$

$$\frac{\rho_m}{M_m}\dot\sigma = n_g \alpha(w) \frac{s}{M_s}. \tag{5.3}$$

The first equation expresses the total molar balance of SO_2, including the loss rate due to the reaction and the advective flux due to the transport of the residual SO_2 by the moving front. The second condition contains the factor $\alpha(w)$ specifying the reaction efficiency (α is dimensionally a velocity). When α goes to $+\infty$, $s(\sigma(t),t)$ is forced to tend to zero and we are back to the full speed regime. When α vanishes the front stops and the SO_2 flux vanishes too, yielding $\frac{\partial s}{\partial x} = 0$.

6. Lagrangian coordinate. Before we deal with the flow of air, it is convenient to adopt a frame of reference (ξ,t) moving with the gypsum. In the frame (x,t) we have used so far the marble is at rest. Let us consider a gypsum particle which is formed at the point $x=\xi$ at a time $\tau(\xi)$. Following its motion up to the time t, we find it at the location

$$x = \xi + \int_{\tau(\xi)}^{t} \dot\sigma_0(\vartheta)d\vartheta = \xi - \omega[\sigma(t) - \sigma(\tau(\xi))] = (1+\omega)\xi - \omega\sigma(t), \tag{6.1}$$

since by definition $\sigma(\tau(\xi)) = \xi$. Thus ξ plays the role of a Lagrangian coordinate. Inverting (6.1) we find

$$\xi = \frac{1}{1+\omega}x + \frac{\omega}{1+\omega}\sigma(t) \tag{6.2}$$

and of course $x = \xi = \sigma(t)$ on the free boundary. We define

$$s(\xi,t) = s(x,t), \tag{6.3}$$

so that the domain $\sigma_0(t) < x < \sigma(t)$, $t > 0$, is mapped to $0 < \xi < \sigma(t)$, $t > 0$, and (4.2)–(4.5) transform to

$$\frac{\partial s}{\partial t} - \frac{d_s}{(1+\omega)^2}\frac{\partial^2 s}{\partial \xi^2} = 0, \tag{6.4}$$

$$s(0,t) = s_a(t), \tag{6.5}$$

$$s(\sigma(t),t) = 0, \tag{6.6}$$

$$-n_g \frac{d_s}{M_s}\frac{1}{1+\omega}\frac{\partial s}{\partial \xi} = \frac{\rho_m}{M_m}\dot{\sigma}. \tag{6.7}$$

Similarly, we introduce

$$w(\xi,t) = w(x,t) \tag{6.8}$$

and (4.8)–(4.10) become

$$\frac{\partial w}{\partial t} - \frac{d_w}{(1+\omega)^2}\frac{\partial^2 w}{\partial \xi^2} = 0, \tag{6.9}$$

$$w(0,t) = w_a(t), \tag{6.10}$$

$$-n_g \frac{d_w}{M_w}\frac{1}{1+\omega}\frac{\partial w}{\partial \xi} = 2\frac{\rho_m}{M_m}\dot{\sigma} + n_g(1+\omega)\frac{w}{M_w}\dot{\sigma}. \tag{6.11}$$

The free boundary conditions (5.2), (5.3) for the reduced speed regime take the form

$$-\frac{1}{M_s}\Big(\frac{d_s}{1+\omega}\frac{\partial s}{\partial \xi} + n_g\omega\dot{\sigma}s\Big) = \Big(\frac{\rho_m}{M_m} + n_g\frac{s}{M_s}\Big)\dot{\sigma}, \tag{6.12}$$

$$\frac{\rho_m}{M_m}\dot{\sigma} = n_g\alpha(w)\frac{s}{M_s}. \tag{6.13}$$

7. Rescaling. Let σ^*, t^* be suitable length and time scales. Set $\eta = \xi/\sigma^*$, $\vartheta = t/t^*$, $\delta(\vartheta) = \sigma(t^*\vartheta)/\sigma^*$, and define

$$\widehat{s}(\eta,\vartheta) = s(\xi,t)/s^*, \qquad \widehat{w}(\eta,\vartheta) = w(\xi,t)/w^*.$$

To be specific, we take $t^* = 1$ year $\simeq 3.15 \cdot 10^7$ sec and $\sigma^* = 2 \cdot 10^{-3}$ cm. Then we take $s^* = 14.3 \cdot 10^{-12}\mathrm{g}\cdot\mathrm{cm}^{-3}$ as a typical yearly average of SO_2 concentration in air, and $w^* = 13 \cdot 10^{-6}\mathrm{g}\cdot\mathrm{cm}^{-3}$ as the H_2O concentration coinciding with the threshold w_0 corresponding to P_0 and to a fixed temperature $T = 20°$ Celsius.

7.1. Rescaling the SO_2 flow problem. The system (6.4)–(6.7) rescales to

$$\frac{\partial \widehat{s}}{\partial \vartheta} - \frac{1}{(1+\omega)^2}K_s\frac{\partial^2 \widehat{s}}{\partial \eta^2} = 0, \tag{7.1}$$

$$\widehat{s}(0,\vartheta) = \widehat{s}_a(\vartheta), \tag{7.2}$$

$$\widehat{s}(\delta(\vartheta),\vartheta) = 0, \tag{7.3}$$

$$-n_g K_s\frac{1}{1+\omega}\frac{s^*}{M_s}\frac{M_m}{\rho_m}\frac{\partial \widehat{s}}{\partial \eta} = \frac{d\delta}{d\vartheta}, \tag{7.4}$$

where $\widehat{s}_a(\vartheta) = s_a(t^*\sigma)/s^*$, $K_s = \frac{t^* d_s}{\sigma^{*2}}$, and $d_s = 0.1$ cm^{2}sec^{-1}. With $\omega \simeq 2$ we have $\frac{K_s}{(1+\omega)^2} \simeq 9 \cdot 10^{10} \gg 1$ and here too (7.1) simplifies to $\frac{\partial^2 \widehat{s}}{\partial \eta^2} \simeq 0$. With $n_g = 0.3$, the coefficient of $\frac{\partial \widehat{s}}{\partial \eta}$ in (7.4) is

$$\Omega_s = \frac{n_g}{1+\omega} \frac{s^* M_m}{M_s \rho_m} K_s \simeq 0.286. \tag{7.5}$$

Thus we may say that at each time $\widehat{s}(\eta, \vartheta)$ is very well approximated by a linear function of η,

$$\widehat{s}(\eta, \vartheta) = \widehat{s}_a(\vartheta) - \gamma(\vartheta)\eta, \tag{7.6}$$

satisfying the conditions

$$\gamma(\vartheta)\delta(\vartheta) = \widehat{s}_a(\vartheta), \qquad \Omega_s \gamma(\vartheta) = \dot{\delta}(\vartheta).$$

Hence we obtain

$$\delta(\vartheta) = \Big[2\Omega_s \int_0^\vartheta \widehat{s}_a(\tau) d\tau\Big]^{1/2}, \qquad \widehat{s}(\eta, \vartheta) = \widehat{s}_a(\vartheta)\Big[1 - \frac{\eta}{\delta(\vartheta)}\Big]. \tag{7.7}$$

The procedure of approximating $\widehat{s}$ as in (7.6) is justified as long as $\frac{\partial \widehat{s}}{\partial \vartheta}$ is not singular, or more precisely as long as

$$\frac{\partial \widehat{s}}{\partial \vartheta} \cdot 10^{-11} \ll 1 \tag{7.8}$$

in our setting. However, if $\widehat{s}_a(0)$ is not zero, we know that (7.1)–(7.4) has an explicit solution with $\frac{d\delta}{d\vartheta} \approx \frac{1}{\sqrt{\vartheta}}$ and $\frac{\partial \widehat{s}}{\partial \vartheta} \approx \frac{1}{\vartheta}$, which could make approximation not applicable. Let us investigate these points more carefully. Let us consider the case $\widehat{s}_a(\vartheta) = \widehat{s}_0 > 0$. Set $A = \frac{K_s}{(1+\omega)^2}$. The explicit solution of (7.1)–(7.4) is

$$\widehat{s}(\eta, \vartheta) = \frac{A}{\Omega_s} 2\gamma e^{\gamma^2} \int_{\frac{\eta}{2\sqrt{A\vartheta}}}^{\gamma} e^{-\xi^2} d\xi, \qquad \delta(\vartheta) = 2\gamma\sqrt{A\vartheta}, \tag{7.9}$$

where γ is the unique solution of

$$\frac{\Omega_s}{A} \widehat{s}_0 = 2\gamma e^{\gamma^2} \int_0^\gamma e^{-\xi^2} d\xi. \tag{7.10}$$

Now, we notice that $\Omega_s / A \approx 3 \cdot 10^{-11}$, implying that $\gamma \ll 1$. Therefore, setting $F(\gamma) = 2\gamma e^{\gamma^2} \int_0^\gamma e^{-\xi^2} d\xi$, since $F(0) = \partial_\gamma F(0) = 0$ and $\partial_{\gamma\gamma} F(0) = 4$, we may approximate the r.h.s. of (7.10) as $F(\gamma) \simeq 2\gamma^2$, and hence

$$\gamma \simeq \left(\widehat{s}_0 \frac{\Omega_s}{2A}\right)^{1/2} \quad \left[\simeq 4 \cdot 10^{-6}\right], \tag{7.11}$$

concluding that

$$\delta(\vartheta) \simeq \sqrt{2\Omega_s \widehat{s}_0 \vartheta}. \tag{7.12}$$

This is precisely formula (7.7), which is therefore justified even for small ϑ. At the same time we conclude that

$$\widehat{s}(\eta, \vartheta) = \widehat{s}_0 \left(1 - \frac{\eta}{\sqrt{2\Omega_s \vartheta \widehat{s}_0}}\right), \quad 0 < \eta < \sqrt{2\Omega_s \vartheta \widehat{s}_0}. \tag{7.13}$$

7.2. Rescaling the $\mathbf{H_2O}$ flow problem. The system (6.9)–(6.11) rescales to

$$\frac{\partial \widehat{w}}{\partial \vartheta} - \frac{K_w}{(1+\omega)^2}\frac{\partial^2 \widehat{w}}{\partial \eta^2} = 0, \qquad K_w = \frac{t^* d_w}{\sigma^{*2}} = K_s \frac{d_w}{d_s} \gg 1, \tag{7.14}$$

$$\widehat{w}(0,\vartheta) = \widehat{w}_a(\vartheta) = w_a(t^*\vartheta)/w^*, \tag{7.15}$$

$$-\Omega_w \frac{\partial \widehat{w}}{\partial \eta} = \Big[1 + \frac{1}{2} n_g (1+\omega) \frac{w^* M_m \widehat{w}}{M_w \rho_m}\Big] \frac{d\delta}{d\vartheta}, \tag{7.16}$$

with

$$\begin{aligned}\Omega_w &= \frac{1}{2}\frac{n_g}{1+\omega}\frac{d_w w^* t^*}{M_w \sigma^{*2}}\frac{M_m}{\rho_m}\\ &= \frac{1}{2}\frac{n_g}{1+\omega}\frac{w^* M_m}{M_w \rho_m} K_w = \frac{1}{2}\frac{w^*}{s^*}\frac{M_s}{M_w}\frac{d_w}{d_s}\Omega_s.\end{aligned}$$

Due to the smallness of the ratio $\frac{w^*}{\rho_m}$, condition (7.16) can be simplified to

$$-\Omega_w \frac{\partial \widehat{w}}{\partial \eta} = \frac{d\delta}{d\vartheta}. \tag{7.17}$$

Then, according to the approximation $\widehat{w}_{\eta\eta} = 0$,

$$\widehat{w}(\eta,\vartheta) = \widehat{w}_a(\vartheta) - \beta(\vartheta)\eta, \tag{7.18}$$

where $\beta = -\widehat{w}_\eta = \dot{\delta}/\Omega_w = \frac{\Omega_s}{\Omega_w}\frac{\widehat{s}_a(\vartheta)}{\delta(\vartheta)}$. Then

$$\widehat{w}(\eta,\vartheta) = \widehat{w}_a(\vartheta) - \frac{\Omega_s}{\Omega_w}\frac{\widehat{s}_a(\vartheta)}{\delta(\vartheta)}\eta. \tag{7.19}$$

All the coefficients used in (7.1), (7.4), (7.14), (7.16) are displayed in Table 1. In addition, Table 2 shows the reference values of the parameters used in our considerations as well as in the numerical simulations in the following sections.

It is useful to observe that the different order of magnitude of $\Omega_s = 0.286$ and $\Omega_w \simeq 3 \cdot 10^6$, related to the ratio $\frac{w^*}{s^*}$, yields a strong qualitative difference between the transport of SO_2 and H_2O within gypsum.

TABLE 1
Rescaling.

$K_s = \frac{t^* d_s}{\sigma^{*2}}$
$K_w = K_s \frac{d_w}{d_s}$
$\Omega_s = \frac{n_g}{1+\omega}\frac{s^* M_m}{M_s \rho_m} K_s$
$\Omega_w = \frac{1}{2}\frac{n_g}{1+\omega}\frac{d_w M_m w^* t^*}{M_w \rho_m \sigma^{*2}}$

TABLE 2
Values of parameters.

Parameter	Meaning	Dimensions	value
n_g	Gypsum porosity	nondimensional	0.3
n_m	Marble porosity	nondimensional	0.005–0.015
M_w	Molar weight (water)	[g/mol]	18.0153
M_m	Molar weight (marble)	[g/mol]	100.087
M_m	Molar weight (gypsum)	[g/mol]	172.166
d_s	Diffusivity in gypsum (SO_2)	[cm^2/sec]	0.1
d_w	Diffusivity in gypsum (H_2O)	[cm^2/sec]	0.2178
ρ_m	mass density of marble	[g/cm^3]	2.83
ρ_w	mass density of water	[g/cm^3]	1
ρ_g	mass density of gypsum	[g/cm^3]	1.6
ω	molar density ratio	nondimensional	≈ 2
σ^*	reference layer in 1 year	[cm]	$2 \cdot 10^{-3}$
t^*	reference time (1 year)	[sec]	$3.15 \cdot 10^{7}$
s^*	reference density (SO_2)	[g/cm^3]	$14.3 \cdot 10^{-12}$
w^*	reference density (H_2O)	[g/cm^3]	$17.3 \cdot 10^{-6}$

7.3. Rescaling the SO_2 and H_2O flow in the reduced speed regime. The rescaled version of (6.12), (6.13) is

$$-\Omega_s \frac{\partial \widehat{s}}{\partial \eta} = \frac{d\delta}{d\vartheta}\Big[1 + n_g \frac{s^* M_m \widehat{s}}{\rho_m M_s}(1+\omega)\Big], \tag{7.20}$$

$$\frac{d\delta}{d\vartheta} = n_g \frac{s^* M_m}{M_s \rho_m}\widehat{\alpha}(\widehat{w})\widehat{s} = \lambda_1 \widehat{\alpha}(\widehat{w})\widehat{s}, \qquad \widehat{\alpha} = \frac{\alpha}{v^*}. \tag{7.21}$$

Again we may simplify (7.20) to

$$-\Omega_s \frac{\partial \widehat{s}}{\partial \eta} = \frac{d\delta}{d\vartheta}. \tag{7.22}$$

The solution (7.6) on the boundary $\eta = \delta(\vartheta)$ is

$$\widehat{s}(\delta, \vartheta) = \widehat{s}_a(\vartheta) - \frac{d\delta}{d\vartheta}\frac{\delta(\vartheta)}{\Omega_s}; \tag{7.23}$$

substituting (7.21) in (7.23), we get

$$\widehat{s}(\delta, \vartheta) = \frac{\widehat{s}_a(\vartheta)}{\left(1 + \dfrac{\lambda_1}{\Omega_s}\widehat{\alpha}\delta(\vartheta)\right)}. \tag{7.24}$$

Then, using (7.24) in (7.21), we have

$$\frac{d\delta}{d\vartheta} = \lambda_1 \widehat{\alpha} \frac{\widehat{s}_a(\vartheta)}{\left(1 + \dfrac{\lambda_1}{\Omega_s}\widehat{\alpha}\delta(\vartheta)\right)}; \tag{7.25}$$

finally, from (7.6) and (7.18)

$$\widehat{s}(\eta,\vartheta)=\widehat{s}_a(\vartheta)-\frac{d\delta}{d\vartheta}\frac{\eta}{\Omega_s}, \tag{7.26}$$

$$\widehat{w}(\eta,\vartheta)=\widehat{w}_a(\vartheta)-\frac{d\delta}{d\vartheta}\frac{\eta}{\Omega_w}. \tag{7.27}$$

The initial condition depends on when the reduced speed regime is started. Note that when $\widehat{\alpha}$ becomes large, (7.25) reduces to $\dot{\delta}\delta=\Omega_s\widehat{s}_a(\vartheta)$, i.e., the full speed law of advancement.

Remark 7.1. A possible variation in time of the water film thickness would imply an additional term. This is not a trivial change. Suppose, for instance, that the water film thickness is $\varepsilon(w)$ with $\varepsilon=0$ below the lower threshold, $\varepsilon=\varepsilon_{\max}$ above the upper threshold, and $\frac{d\varepsilon}{dt}>0$ in between. In the range of w where ε varies the additional water molar flux created by the variation of the water film thickness is $n_g\frac{d\varepsilon}{dt}\frac{\rho_w}{M_w}$, where ρ_w is the density of liquid water. This means that the term to be added on the r.h.s. of (4.10) is

$$n_g\frac{\rho_w}{M_w}\frac{d\varepsilon}{dt}\Big(\frac{\partial w}{\partial t}+\dot{\sigma}\frac{\partial w}{\partial x}\Big),$$

which makes the problem of finding w much more difficult. However, we point out that performing the rescaling so far adopted, the influence of this effect can be neglected.

Remark 7.2. We remark that in (7.1) and (7.14), the coefficients K_s and K_w play the same role as the nondimensional number $(Ste)^{-1}$ in phase change problems. With *Ste* we indicate the Stefan number; see, for instance, [6]. Our approximation corresponds to the case $Ste\ll 1$ (latent heat dominant with respect to the so-called sensible heat) and makes the quasi-steady approach feasible. We refer to [6] for some results for small and large Stefan numbers.

8. Numerical schemes. As we have seen, the quasi-steady approximations provide a simple way of constructing solutions; however, it is advisable to set up a numerical scheme capable of dealing with the complete equations (i.e., including the inertia terms). The reason is twofold:

1. Although we have limited our attention to a one-year period (which is the time for which data were available to us), in practical cases one could be interested in predictions extended over a period of ten years or more. We will see that for the cases here examined the discrepancy between the full model and the quasi-steady approximation ranges between 2%–4%, but errors may accumulate over the years. Also, if we used data with higher frequency and amplitude, we could obtain a greater relative error.
2. It may happen that the SO_2 concentration and/or relative humidity undergo sudden changes (for instance, due to a massive air replacement in the region where the monument is situated). This event may not be correctly described on the basis of the quasi-steady approximation.

These arguments motivate the numerical scheme we are going to present in this section. The quasi-steady approximation will be useful anyway in providing a reliable starting point.

Consider equations (7.1), (7.2), (7.3), (7.4), (7.14), (7.15), (7.17), and (7.21). This is a problem with a moving boundary given by $\delta(\vartheta)$. We prefer to change coordinates, and so obtain a fixed boundary. To this purpose, we introduce (y,τ)

such that $y = \eta/\delta(\vartheta)$ and $\tau = \vartheta$, the domain changes to $0 \le y \le 1$, supposing $\delta(0) > 0$.

Equations change to

$$\frac{\partial \widehat{s}}{\partial \tau} - \frac{y\dot{\delta}(\tau)}{\delta(\tau)}\frac{\partial \widehat{s}}{\partial y} - \frac{1}{(1+\omega)^2(\delta(\tau))^2}K_s\frac{\partial^2 \widehat{s}}{\partial y^2} = 0, \tag{8.1}$$

$$\widehat{s}(y=0,\tau) = \widehat{s}_a(\tau), \tag{8.2}$$

$$-\Omega_s\frac{1}{\delta(\tau)}\frac{\partial \widehat{s}}{\partial y} = \frac{d\delta}{d\tau} \qquad \text{at} \quad y=1, \tag{8.3}$$

$$\widehat{s}(y=1,\tau) = 0 \quad \text{(full speed)}, \tag{8.4}$$

or

$$\frac{d\delta}{d\tau} = n_g\frac{s^* M_m}{M_s\rho_m}\widehat{\alpha}(\widehat{w})\widehat{s}, \qquad \widehat{\alpha} = \frac{\alpha}{v^*} \quad \text{(reduced speed)}, \tag{8.5}$$

$$\frac{\partial \widehat{w}}{\partial \tau} - \frac{y\dot{\delta}(\tau)}{(\delta(\tau))^2}\frac{\partial \widehat{w}}{\partial y} - \frac{K_w}{(1+\omega)^2\delta(\tau)^2}\frac{\partial^2 \widehat{w}}{\partial y^2} = 0, \tag{8.6}$$

$$\widehat{w}(y=0,\tau) = \widehat{w}_a(\tau), \tag{8.7}$$

$$-\frac{\Omega_w}{\delta(\tau)}\frac{\partial \widehat{w}}{\partial y} = \left[1 + \frac{1}{2}n_g(1+\omega)\frac{w^* M_m \widehat{w}}{M_w\rho_m}\right]\frac{d\delta}{d\tau} \approx \frac{d\delta}{d\tau}. \tag{8.8}$$

8.1. Finite difference scheme. From now on, for the sake of simplicity, we write all the notation without the hat symbol.

Consider (8.1) and (8.6). We note that the diffusion coefficients are $K_i/(1+\omega)^2 \approx 10^{11}$, where $i = s, w$ and $\delta \approx 1$. For this reason we use an implicit numerical scheme—which is stable, monotone, and even uses large time steps—to solve our system.

8.1.1. Full speed case. We assume that $j = 1, \dots, J$ (space index) and $n = 1, \dots, N$ (time index), and we indicate $w(x,t)$ and $s(x,t)$ by the numerical approximations W_i^n and S_j^n. We discretize (8.3) by

$$\frac{\delta^{n+1} - \delta^n}{\Delta\tau} = -\frac{\Omega_s}{\delta^n}\frac{3S_J^n - 4S_{J-1}^n + S_{J-2}^n}{2\Delta y}, \tag{8.9}$$

and (8.1) by

$$\frac{S_j^{n+1} - S_j^n}{\Delta\tau} = y_j\frac{\dot{\delta}^n}{\delta^n}\frac{S_{j+1}^n - S_{j-1}^n}{2\Delta y} + \frac{K_s}{(1+\omega)^2(\delta^{n+1})^2}\frac{S_{j+1}^{n+1} - 2S_j^{n+1} + S_{j-1}^{n+1}}{(\Delta y)^2}, \tag{8.10}$$

where $y_j = \Delta y(j-1)$. Boundary conditions are given by

$$S_1^n = S_a^n, \quad S_J^n = 0.$$

The first system is explicit. System (8.10) is implicit but driven by a standard tridiagonal matrix, and then it is solved by standard methods.

In the same way we solve problem (8.6) by the scheme

$$\frac{W_j^{n+1} - W_j^n}{\Delta\tau} = y_j\frac{\dot{\delta}^n}{\delta^n}\frac{W_{j+1}^n - W_{j-1}^n}{2\Delta y} + \frac{K_w}{(1+\omega)^2(\delta^{n+1})^2}\frac{W_{j+1}^{n+1} - 2W_j^{n+1} + W_{j-1}^{n+1}}{(\Delta y)^2},$$

with the boundary conditions given by

$$W_1^{n+1} = W_a^n, \quad W_J^{n+1} = \frac{4}{3}W_{J-1}^{n+1} - \frac{1}{3}W_{J-2}^{n+1} + \frac{\Omega_s}{\Omega_w}\left(3S_J^{n+1} - 4S_{J-1}^{n+1} + S_{J-2}^{n+1}\right).$$

This yields another algebraic system, based on a tridiagonal matrix, and hence solvable with a low computational cost.

8.1.2. Reduced speed case. If we are in the reduced speed case, we have different boundary conditions for S; see (8.3) and (8.5). This means that we set

$$\alpha = \frac{t^*}{\sigma^*}\left(\frac{1}{W_0 - W_J^n} - \frac{1}{W_0 - W_1}\right), \tag{8.11}$$

and we first compute

$$\delta^{n+1} = \delta^n + \Delta\tau n_g \frac{M_m s^*}{\rho_m M_s}\alpha S_J^n. \tag{8.12}$$

Now, we again have to solve a system like (8.10). However, to obtain the unknown boundary value S_J^{n+1}, we first observe that (8.12) and (8.5) yield

$$-\Omega_s \frac{1}{\delta(\tau)}\frac{\partial s}{\partial y} = n_g \frac{M_m s^*}{\rho_m M_s}\alpha\left(w\right)s. \tag{8.13}$$

Therefore, we can discretize this equation, preserving the second order accuracy, by the relation

$$-\Omega_s \frac{1}{\delta^{n+1}}\frac{\left(3S_J^{n+1} - 4S_{J-1}^{n+1} + S_{J-2}^{n+1}\right)}{2\Delta y} = n_g \frac{M_m s^*}{\rho_m M_s}\alpha S_J^{n+1}. \tag{8.14}$$

8.2. Initial conditions. Our numerical procedure requires $\delta(0) \neq 0$. If we have to deal with the case $\delta(0) = 0$, then we can obtain a quite reasonable guess of the location of the interface and of the SO_2 distribution in the gypsum at some sufficiently small time Δt proceedings as follows. We distinguish two cases: (a) $s_a(0) > 0$; (b) $s_a(0) = s_a^0 = 0$.

(a) From formulas (7.12), (7.13) we know that $\delta(\Delta t) = \sqrt{2\Omega_s s_a^0 \Delta t}$, $s(\eta, \Delta t) = s_a\left(1 - \frac{\eta}{\Delta t}\right)$.

(b) Here we assume that $\dot{s}_a(0) = c > 0$. Then the slope of the free boundary will be finite and can be obtained from the continuity of s_η, s_ϑ in the origin and the equations

$$-\Omega_s s_\eta(\delta, t) = \dot{\delta}, \quad s_\eta \dot{\delta} + s_\vartheta = 0.$$

For $t \downarrow 0$ and $s_\vartheta \to c$ we derive

$$\dot{\delta}(0) = \sqrt{\Omega_s c}.$$

Hence we may take

$$\delta(\Delta t) \simeq \sqrt{\Omega_s c}\Delta t,$$

$$s(\eta, \Delta t) \simeq c\left(1 - \frac{\eta}{\delta(\Delta t)}\right)\Delta t.$$

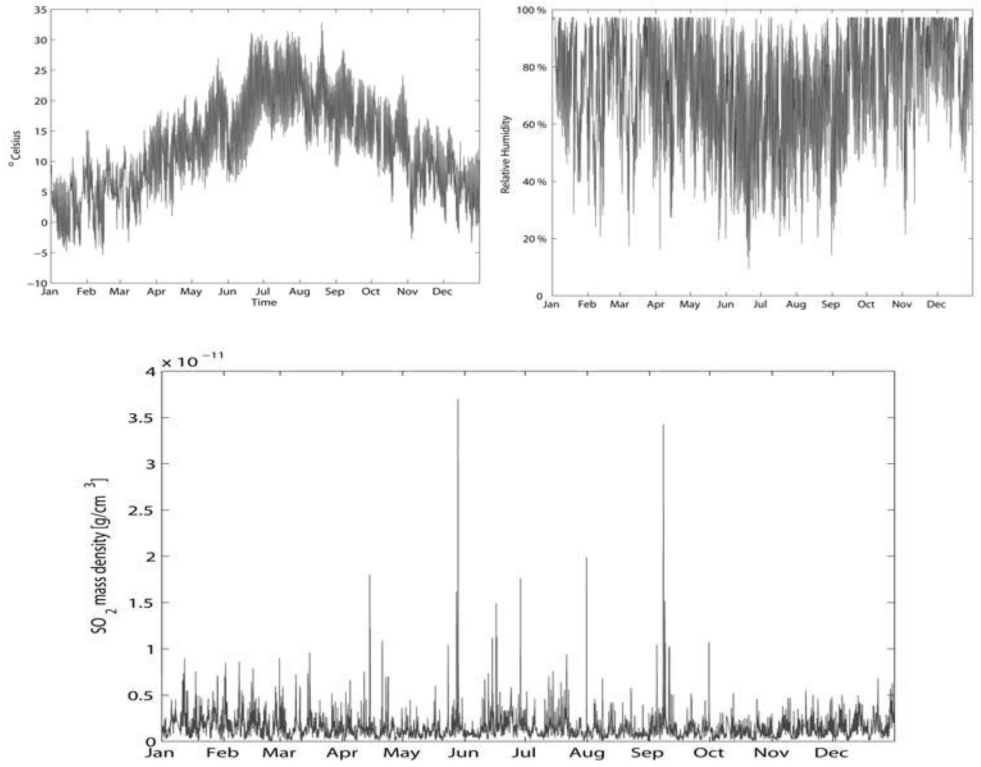

FIG. 1. *Temperature (upper left), relative humidity (upper right), and SO_2 concentration (lower) during* 2006 *at Villa Ada.*

In a realistic situation case (a) is the one of interest. Then we use as initial conditions the solutions of quasi-steady case (7.7) and (7.19) obtained for a time period of one day.

We can note that for each initial condition $s(x, 0)$ and $w(x, 0)$ chosen, these conditions have a completely negligible influence on our solutions after one year of simulations.

9. Numerical simulations. In this section we present some simulations which have been performed using SO_2, humidity, and temperature experimental data detected by Arpalazio, the Roman Regional Authority for air monitoring, every hour during 2006 at Villa Ada in Rome, Italy, a public park with a low level of pollution. Let us also notice that although we simulated the growth of the gypsum crust by our model, we have no experimental data on the real behavior of marble in the same time and under the same conditions. This comparison is beyond the aims of the present work and will be the object of a future work. However, we do have a full agreement between our results and the laboratory tests in [4, 8, 7].

In Figure 1 are shown the temperature (upper left), the relative humidity (upper right), and the distribution of pollutant SO_2 detected at Villa Ada. We get the saturated vapor density (SVD in [g/m^3]) as function of temperature T [°C] using the following relation [10]:

$$SVD(T) = 5.018 + 0.32321T + 8.184710^{-3}T^2 + 3.1243 * 10^{-4}T^3, \tag{9.1}$$

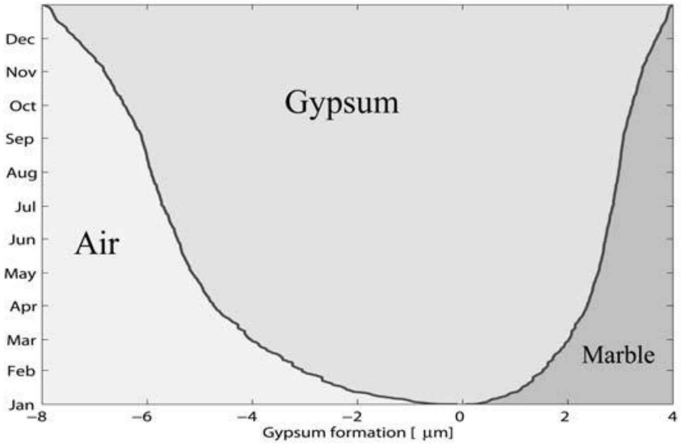

FIG. 2. *Simulated gypsum evolution at Villa Ada.*

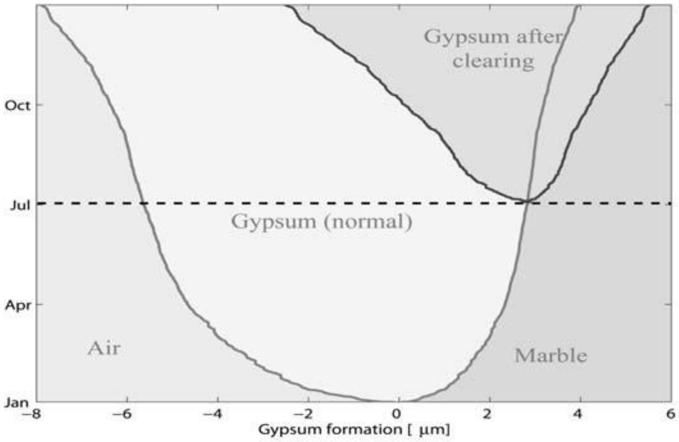

FIG. 3. *Simulated gypsum formation, with and without clearing.*

from which we can obtain the density of vapor in [g/cm^3].

Now, under the conditions detected during 2006 at Villa Ada, we compute marble degradation, starting with $\sigma_0 = 0$. Using our mathematical model with $\Delta t = 10^{-5}$ and $\Delta x = 10^{-1}$, we show in Figure 2 the simulated total thickness of gypsum at the end of 2006. To understand the effect of restoration techniques, let us suppose the gypsum is removed on July 2. We obtain the following simulated gypsum development with and without clearing, shown in Figure 3.

10. Comparison with the quasi-steady solutions. Here, we want to see what happens using quasi-steady solutions, motivated by the fact that the coefficients K_s, K_w are very large. If we assume to have $s(0,t) = s_a =$ const. and $w(0,t) = w_a =$ const., we can observe that the solutions $s(x,t)$ and $w(x,t)$ can be approximated very well by a function linear in x. For this reason, if the fluctuations of boundary values are sufficiently slow, then we can approximate our model by stationary solutions. Here, we want to estimate the error between numerical solutions of the full model and

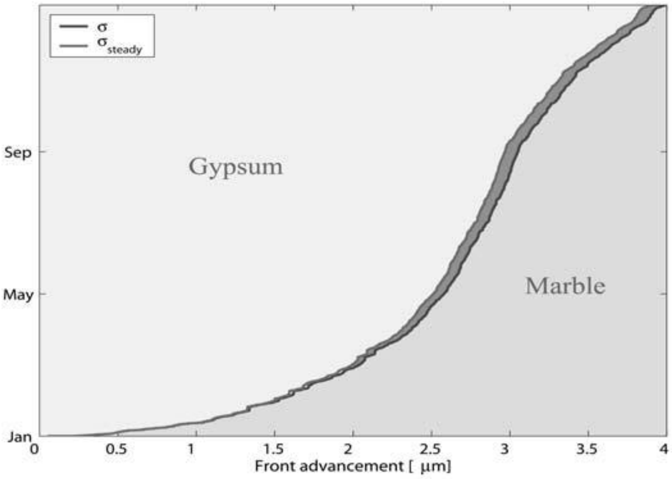

FIG. 4. *Comparison between steady state and numerical solutions at Villa Ada.*

the quasi-steady approximations.

In the full speed case, the system is given by (7.3), (7.7), (7.17), and (7.19). We introduce a new space variable $y = \eta/\delta$, where $y \in [0,1]$, and obtain

$$\dot{\delta} = s_a(\vartheta)\frac{\Omega_s}{\delta(\vartheta)}, \quad s(\eta,\vartheta) = s_a(\vartheta)\,(1-y)\,, \quad w(\eta,\vartheta) = w_a(\vartheta) - \frac{\Omega_s}{\Omega_w}s_a(\vartheta)y.$$

In the reduced speed case, we obtain the analogous equations

$$\dot{\delta}(\tau) = \lambda_1\alpha\frac{s_a(\tau)}{\left(1+\dfrac{\lambda_1}{\Omega_s}\alpha\delta(\tau)\right)},\ s(y,\tau) = s_a(\tau) - \frac{\dot{\delta}(\tau)}{\Omega_s}y\delta(\tau),\ w(y,\tau) = w_a(\tau) - \frac{\dot{\delta}(\tau)}{\Omega_w}y\delta(\tau).$$

To have a quantitative idea of the difference between stationary solutions and numerical solutions, we use the experimental data of Villa Ada. We obtain the behavior of the two fronts of advancement (full model and quasi-stationary solutions), shown on the left of Figure 4. We note that the maximum relative error $\left(\frac{\sigma-\sigma_{steady}}{\sigma}\right)$ obtained is about 2.2%. Therefore this is a case in which it would have been safe to use directly the quasi-steady approximation.

11. Contributions to the front advancement.

11.1. Front advancement as a function of SO$_2$. In the wake of the latter calculation we decided to investigate the influence of SO$_2$ by a factor c, that is to say, we replace $s(0,t)$ by $c \cdot s(0,t)$, where c is a given constant. We used the Villa Ada data and multiplied the SO$_2$ concentration by $c = 1/9$, $1/4$, 1, 2, 4, 6, 9. We can see the result in Figure 5. The results obtained show that the thickness of the front σ, after one year, varies as $\sqrt{c}$. In order to better visualize this fact, in Figure 6 we have reported $\sigma = \sigma(\sqrt{c})$, obtaining a clearly linear graph, consistently with the nature of the quasi-steady approximation.

11.2. Front advancement as a function of time. For the same reason the average growth of σ is close to a $\sqrt{t}$ behavior, strengthening the conclusion reported

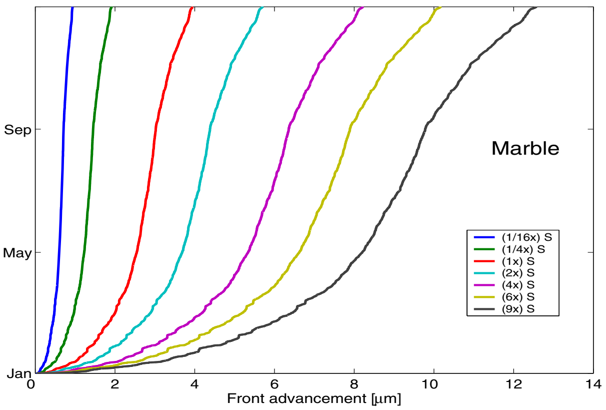

FIG. 5. *Front advancement as a function of SO_2 data.*

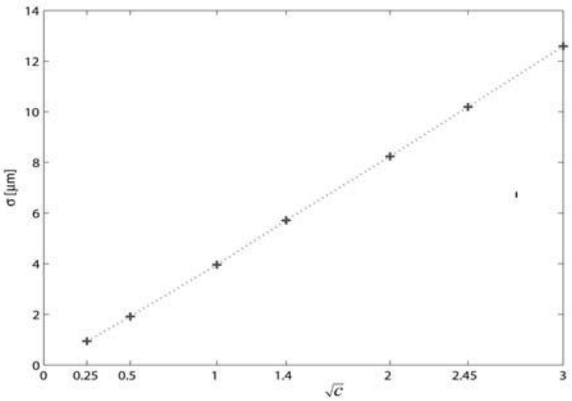

FIG. 6. *Marble wasted after one year for different values of $\sqrt{c}$.*

in [3]. We used the Villa Ada data, and we have repeated the experimental data of the first year (2006) for the next 8 years. This way, we obtained $\sigma(1 \text{ year}) \approx 4\ \mu$m, after 4 years $\sigma(4 \text{ years}) \approx 8.2\ \mu$m, and after 9 years $\sigma(9 \text{ years}) \approx 12.5\ \mu$m. Figure 7 show oscillations around a parabolic behavior.

11.3. Order of accuracy of numerical schemes and extrapolation results. Since we do not have the exact solution of the problem, we give an approximate estimate of the order of the numerical method using the following standard relations:

1. accuracy in L^1 norm:

$$\gamma_1 = \log_2\left(\frac{\|u(h) - u(h/2)\|_1}{\|u(h/2) - u(h/4)\|_1}\right); \tag{11.1}$$

2. accuracy in L^∞ norm:

$$\gamma_\infty = \log_2\left(\frac{\max_x |u(h) - u(h/2)|}{\max_x |u(h/2) - u(h/4)|}\right). \tag{11.2}$$

Using the simulations of the Villa Ada case, with $h = 0.1$, we obtain the results shown in Table 3, which are in good agreement with the formal truncation error of the implicit

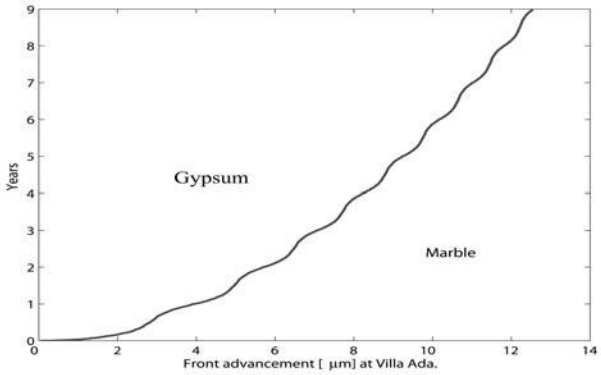

FIG. 7. *Front advancement in* 9 *years at Villa Ada.*

TABLE 3
Approximate order of accuracy of the numerical schemes.

Norm	γ_s	γ_w
L^1	0.89	0.84
L^∞	0.90	0.84

scheme, which is just order 1. Finally further consideration can be done regarding σ obtained after 1 year at Villa Ada. Using $h^* = 0.1$ we found $\sigma_{h^*} = 3.960$ μm, with $h^*/2$, $\sigma_{h^*/2} = 3.971$ μm, and with $h^*/4$, $\sigma_{h^*/4} = 3.977$ μm. Making an extrapolation as $h \to 0$, we obtained an estimate for the real value, namely, $\sigma_{exact} = 3.983$. This way we can estimate that our numerical relative error, in terms of the gypsum front, is about 0.5%.

12. Conclusions.

We have proposed a quantitative model to predict the growth of the gypsum crust on marble stones by using environmental data, i.e., temperature, relative humidity, and pollution concentration. For this model we have identified a quasi-steady asymptotic regime, in good agreement with laboratory data [4, 8, 7] and numerical simulations. Thanks to this model we are now able to quantify how the influence of the evolution of local conditions, or even the cleaning of the stone surface, can change the thickness of the crust, and so the total waste of marble. These results will be useful in the optimal design of future conservation strategies.

Appendix. The flow of air.

So far we have used the approximation (2.5), which has yet to be justified, studying the flow of air through gypsum. In this appendix, we use directly the Lagrangian coordinates, introduced in section 6, to deal with the air pressure $p(x,t) = P(\xi,t)$. In isothermal conditions the air density $\rho_a(\xi,t)$ is a known function of pressure that we can linearize around a reference pressure P_0 (typically 1 Atm.):

$$\rho_a = \rho_0 + \lambda(P - P_0) \tag{A.1}$$

($\rho_0 = \rho_a(P_0)$). The *volumetric* flow of air relative to gypsum can be described by Darcy's law,

$$n_g v_a^R = -k_a \frac{1}{1+\omega}\frac{\partial P}{\partial \xi}, \tag{A.2}$$

where v_a^R is the average molecular velocity in the Lagrangian reference frame, and for hydraulic conductivity of air we take the linear approximation $k_a = k_0 + \chi(P - P_0)$.

In this same frame the air mass balance can be written as

$$\frac{\partial \rho_a}{\partial t} + \frac{1}{1+\omega}\frac{\partial}{\partial \xi}(v_a^R \rho_a) = 0, \tag{A.3}$$

yielding the equation governing the evolution of pressure

$$\begin{aligned} &\lambda \frac{\partial P}{\partial t} - \frac{1}{(1+\omega)^2}[k_0\rho_0 + (k_0\lambda + \rho_0\chi)(P - P_0)]\frac{\partial^2 P}{\partial \xi^2} \\ &- \frac{1}{(1+\omega)^2}\{\lambda[k_0 + \chi(P - P_0)] + \chi[\rho_0 + \lambda(P - P_0)]\}\Big(\frac{\partial P}{\partial \xi}\Big)^2 = 0, \end{aligned} \tag{A.4}$$

where we have neglected the terms with $(P - P_0)^2$, consistently with the linearization already performed.

In conditions of still external air the value of P at $\xi = 0$ can be set equal to the value in the atmosphere (the wind can alter the air pressure at the gypsum surface):

$$P(0, t) = P_a(t). \tag{A.5}$$

In order to write down the mass balance of air on the reaction front $\xi = \sigma(t)$, we suppose that marble pores are filled with air having a prescribed density ρ^0 (for instance, $\rho^0 = \rho_0$), and we impose that the air flux supplies the amount of air $(n_g\rho_a - n_m\rho^0)\dot{\sigma}$ per unit time and unit surface of the front (n_m is the marble porosity). Performing the usual linearization we obtain

$$\begin{aligned} &-\frac{1}{1+\omega}[k_0\rho_0 + (k_0\lambda + \rho_0\chi)(P - P_0)]\frac{\partial P}{\partial \xi} \\ &= n_g[\rho_0 + \lambda(P - P_0)](1+\omega)\dot{\sigma} - n_m\rho^0\dot{\sigma}. \end{aligned} \tag{A.6}$$

The justification of (2.5) now comes from rescaling, as we shall see next.

Rescaling the air flow problem. Rescaling P, following the indications in section 7, we get $\widehat{P}(\eta, \vartheta) = P(\xi, t)/P_0$. In the new variables (A.4) is written as

$$\frac{\partial \widehat{P}}{\partial \vartheta} - \frac{[1 + (A+B)(\widehat{P} - 1)]}{(1+\omega)^2}K_a\frac{\partial^2 \widehat{P}}{\partial \eta^2} = \frac{[A + B + 2AB(\widehat{P} - 1)]}{(1+\omega)^2}K_a\Big(\frac{\partial \widehat{P}}{\partial \eta}\Big)^2, \tag{A.7}$$

containing the nondimensional coefficients $A = P_0\frac{\lambda}{\rho_0}$, $B = P_0\frac{\chi}{k_0}$, $K_a = \frac{t^* k_0\rho_0}{\lambda\sigma^{*2}}$. We remark that $t_0 = k_0\rho_0$ has the dimension of time and that $\lambda^{-1/2} = v_\lambda$ is the reference value of the speed of sound in air (340 m/sec). Thus the constant K_a can be written as

$$K_a = \frac{v_\lambda^2}{v^{*2}}\frac{t_0}{t^*}, \tag{A.8}$$

with $v^* = \frac{\sigma^*}{t^*}$ representing a typical mean velocity of the reaction front.

Let us derive the nondimensional version of the balance equation (A.6), noting that $\dot{\sigma} = \frac{\sigma^*}{t^*}\frac{d\delta}{d\vartheta} = v^*\frac{d\delta}{d\vartheta}$ and that $\frac{P_0 t_0}{\rho_0 v^* \sigma^*} = AK_a$:

$$-\frac{[1 + (A+B)(\widehat{P} - 1)]}{(1+\omega)^2}AK_a\frac{\partial \widehat{P}}{\partial \eta} = n_g\frac{d\delta}{d\vartheta}\Big[1 + A(\widehat{P} - 1) - \frac{1}{1+\omega}\frac{n_m}{n_g}\frac{\rho^0}{\rho_0}\Big]. \tag{A.9}$$

Since $A \simeq 1$, if $K_a \gg 1$ the air motion is quasi steady and $Q = \frac{\partial \widehat{P}}{\partial \eta}$ obeys

$$[1 + (A + B)(\widehat{P} - 1)]\frac{\partial Q}{\partial \eta} + [A + B + 2AB(\widehat{P} - 1)]Q^2 = 0,$$

with the condition $Q(\delta(\vartheta)) \simeq 0$, implying $\frac{\partial \widehat{P}}{\partial \eta} \simeq 0$ throughout the gypsum.

Therefore, if $K_a \gg 1$, the pressure field is flat. To check this property, we observe that $v_\lambda^2 \simeq (3.4 \cdot 10^4 \text{cm} \cdot \text{sec}^{-1})^2$, $v^{*2} = \left(\frac{2 \cdot 10^{-3}\text{cm}}{3.15 \cdot 10^7 \text{sec}}\right)^2$, and hence $\frac{v_\lambda^2}{v^{*2}} \simeq 2.5 \cdot 10^{28}$, $t_0 \simeq 10^{-13}$sec since $k_0 \simeq 10^{-10}\text{g}^{-1}\text{cm}^3\text{sec}$ and $\rho_0 \simeq 10^{-3}\text{g}\cdot\text{cm}^{-3}$, and thus $\frac{t_0}{t^*} \simeq \frac{10^{-20}}{3}$. So finally $K_a \simeq 10^8$ and formula (2.5) is largely justified.

Acknowledgments. The authors thank the Roman Regional Authority for environment, Arpalazio (http://www.arpalazio.it/), Agenzia Regionale per la Protezione Ambientale del Lazio, for all the in situ data used in this paper. They also wish to thank Deepika Ghai for the work done on this problem during her summer internship in 2006 at Istituto per le Applicazioni del Calcolo in Rome.

NEURAL ASSOCIATIVE MEMORY AND THE WILLSHAW–PALM PROBABILITY DISTRIBUTION*

ANDREAS KNOBLAUCH†

Abstract. Previous asymptotic analyses of binary neural associative networks of Willshaw or Steinbuch type relied on a binomial approximation of the neurons' dendritic potentials. This approximation has been proven to be good only if the stored patterns are extremely sparse, for example, when the mean number of active units k per pattern vector scales with the logarithm of the vector size n. Recent promising results concerning storage capacity and retrieval efficiency for larger pattern activities $k > \log n$ have been doubted because here the binomial approximation can lead to a massive overestimation of performance. In this work I compute and characterize the exact Willshaw–Palm distribution of the dendritic potentials for hetero-association, auto-association, and fixed and random pattern activity. Comparing the raw and central moments of the Willshaw–Palm distribution to the moments of the corresponding binomial probability reveals that, asymptotically, the binomial approximation becomes exact for almost any sublinear pattern activity, including $k = O(n/\log^2 n)$. This verifies, for large networks, the existence of a wide high-performance parameter range as predicted by the approximative theory.

1. Introduction.

Associative memories are systems that contain information about a finite set of associations between pattern vector pairs $\{(\mathbf{u}^\mu \mapsto \mathbf{v}^\mu) : \mu = 1, \ldots, M\}$, where $\mathbf{u}^\mu$ and $\mathbf{v}^\mu$ are called *address* and *content* patterns, respectively [28]. Given a possibly noisy address pattern $\tilde{\mathbf{u}}$ the problem is to find a content pattern $\mathbf{v}^\mu$ for which the corresponding address pattern $\mathbf{u}^\mu$ is most similar to $\tilde{\mathbf{u}}$. This is a variant of the *best match problem* in [31], and efficient solutions have widespread applications, including object recognition and information retrieval [28, 36, 40, 3, 13, 20, 32, 42].

In *neural network implementations* the information about the associations is stored in the synaptic connectivity of one or more neuron populations [46, 16, 17, 37]. Besides the potential for technical applications, neural associative memories also play an important role in many *brain theories* (e.g., [14, 30, 5, 35, 16, 17, 11, 12, 27, 10, 15]), where the patterns correspond to attractors in the brain's neuronal state space.

One of the most efficient networks is the so-called Willshaw or Steinbuch model with binary neurons and synapses [44, 46, 34, 33, 8, 43]. In particular, it has been shown that the Willshaw model has a very high asymptotic storage capacity of $C = 0.7$ bits per synapse which exceeds the capacity of most alternative models. For example, the original Hopfield model achieves only $C = 0.14$ bits per synapse [16, 1, 2]. In general the classical work points out that high capacities can be obtained only if the stored patterns are extremely sparse, for example, when the mean number of active units k per pattern vector scales logarithmic with the vector size n.

For a number of reasons, a regime of larger pattern activity with $k/\log n \to \infty$ has recently gained increased attention: First, logarithmic $k = \log n$ is simply too sparse

for many applications of distributed representations [41, 45, 42]. Second, activity patterns with extremely sparse activity $k \sim \log n$ appear inconsistent with neurophysiology because they are difficult to stabilize in a noisy regime where neurons have high rates of spontaneous activity [29]. Third, it has been argued that $k/\log n \to \infty$ can actually lead to a massive increase in storage capacity and retrieval efficiency if the network structures are adequately compressed ([22]; see also [18, 19, 20]). Fourth, $k/\log n \to \infty$ allows an efficient inhibitory implementation of the Willshaw model which implies new interpretations for inhibitory circuits in the brain [22, 24].

However, the viability of this regime with moderately sparse patterns, $k/\log n \to \infty$, has been doubted. On the one hand, here the established theories on Willshaw- or Steinbuch-type networks with fixed connectivity structure predict only a very low performance, for example, zero storage capacity per synapse, such that both technical applicability and biological relevance seem unlikely. On the other hand, the extended theory considering structural changes and inhibitory implementations predicts high performance but, similar to the established theories, relied on a *binomial approximation* of the neurons' dendritic potentials (e.g., [46, 34, 37, 33, 4, 43, 20]). This approximation may be inaccurate for large pattern activities $k \gg \log n$ and thus the corresponding high-performance regime illusory. Indeed, the convergence of the binomial approximation to the true potential distribution and thus the asymptotic correctness of the theory has been demonstrated only for some special cases involving very sparse activity patterns, where a binary pattern vector of n neurons contains only $k = \log n$ or $k \leq n^{1/3}$ active units [34, 38]. Another analysis showed that the binomial approximation becomes very inaccurate for linear $k \sim n$ [19, 21]. However, it remained unclear for precisely which $k(n)$ the binomial approximation converges to the true potential distribution.

In this work I have solved this problem. Section 2 gives an overview of the Willshaw model and the analysis employing the binomial approximation of the dendritic potentials. Section 3 then defines and computes the exact Willshaw–Palm distribution of the dendritic potentials which can be used to determine exact retrieval error probabilities and storage capacity. Section 4 characterizes the Willshaw–Palm probability by computing the raw and central moments. Finally, section 5 compares the Willshaw–Palm probability to the binomial probability and determines asymptotic conditions when the two probability distributions become identical.

2. Binary associative networks.

2.1. Learning and retrieving patterns.

An attractive model of neural associative memory both for biological modeling and applications is the so-called Willshaw or Steinbuch model with binary neurons and synapses [46, 44, 34, 33, 37, 7, 4, 43, 20] illustrated in Figure 2.1. Each address pattern $\mathbf{u}^\mu$ is a binary vector of length m containing k one-entries and $m-k$ zero-entries. Similarly, each content pattern $\mathbf{v}^\mu$ is a binary vector of length n containing l one-entries and $n-l$ zero-entries. Typically, the patterns are sparse, i.e., $k \ll m$ and $l \ll n$. For our analysis of storage capacity we will further assume that each pattern is randomly drawn from the sets of the $\binom{m}{k}$ potential address patterns and the $\binom{n}{l}$ potential content patterns.

The M pattern pairs are stored *hetero-associatively* in a binary *memory matrix* $\mathbf{A} \in \{0,1\}^{m \times n}$ with

$$A_{ij} = \min\left(1, \tilde{A}_{ij} + \sum_{\mu=1}^{M} u_i^\mu \cdot v_j^\mu\right) \in \{0,1\}, \tag{2.1}$$

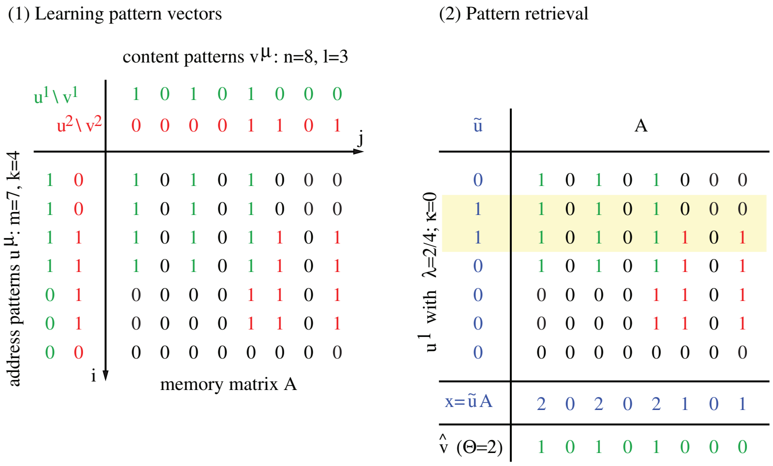

FIG. 2.1. *Example of the binary Willshaw associative memory for hetero-association. Left: During learning, M associations between address patterns $\mathbf{u}^\mu$ and content patterns $\mathbf{v}^\mu$ are stored in the binary memory matrix $\mathbf{A}$ representing binary synaptic weights of the connection from neuron population u to v. Initially all synapses are inactive ($\tilde{p}_1 = 0$). During learning of pattern associations, the synapses are activated according to Hebbian coincidence learning (equation (2.1)). Right: For retrieval an address pattern $\tilde{\mathbf{u}}$ is propagated through the network. Vector-matrix multiplication yields the dendritic potentials $\mathbf{x} = \tilde{\mathbf{u}}\mathbf{A}$. To obtain the retrieval result $\hat{\mathbf{v}}$ (here equal to $\mathbf{v}^1$) a threshold Θ is applied. For pattern part retrieval with $\tilde{\mathbf{u}} \subseteq \mathbf{u}^\mu$ we can simply choose the Willshaw threshold $\Theta = |\tilde{\mathbf{u}}|$. Then the retrieval output is a superset of the original pattern, $\hat{\mathbf{v}} \supseteq \mathbf{v}^\mu$, which means $\hat{\mathbf{v}}$ contains no miss-errors.*

where $\tilde{\mathbf{A}}$ is a binary noise matrix with each component being active independently with probability $\tilde{p}_1$.

The *neural interpretation* is that of two neuron populations, an address population u consisting of m neurons and a content population v consisting of n neurons. The patterns $\mathbf{u}^\mu$ and $\mathbf{v}^\mu$ describe the activity states of the two populations at time μ, and A_{ij} is the strength of the Hebbian learned synaptic connection from neuron u_i to neuron v_j. Positive $\tilde{p}_1$ can be used to model noisy synaptic potentiation (e.g., the synapses that are already active before learning starts), noisy synaptic transmission, or incomplete connectivity [22, 23, 24].

Besides the feed-forward interpretation, the Willshaw model can also be used to model *auto-association* or pattern completion where address population content population are identical, $u = v$, and consequently also $\mathbf{u}^\mu = \mathbf{v}^\mu$. Here the memory matrix $\mathbf{A}$ describes the recurrent synaptic connectivity within the neuron population.

For independently generated random patterns, there is a simple relation between the number M of stored associations and the so-called *memory load* p_1 defined as the fraction of one-entries in the memory matrix. The probability that a synapse is *not* activated by the association of one pattern pair is $1 - kl/mn$; therefore, after learning M pattern associations,

$$p_1 = 1 - (1 - \tilde{p}_1)\left(1 - \frac{kl}{mn}\right)^M \geq \tilde{p}_1, \tag{2.2}$$

$$M = \frac{\ln \frac{1-p_1}{1-\tilde{p}_1}}{\ln(1 - kl/mn)} \approx -\frac{mn}{kl} \ln \frac{1 - p_1}{1 - \tilde{p}_1}, \tag{2.3}$$

where the approximation is valid for $kl \ll mn$. As we will see, the memory load p_1

will play an important role both for the exact analysis of the Willshaw model and for the binomial approximative analysis.

After learning, the stored information can be retrieved by applying an address pattern $\tilde{\mathbf{u}}$. Vector-matrix multiplication yields the dendritic potentials $\mathbf{x} = \tilde{\mathbf{u}}\mathbf{A}$ of the content neurons, and imposing a threshold Θ gives the (one-step) retrieval result $\hat{\mathbf{v}}$,

$$\hat{v}_j = \begin{cases} 1, & x_j = (\sum_{i=1}^{m} \tilde{u}_i A_{ij}) \geq \Theta, \\ 0 & \text{otherwise.} \end{cases} \tag{2.4}$$

Choosing $\Theta = z := \sum_{i=1}^{m} \tilde{u}_i$ will be referred to as the *Willshaw threshold* and plays an important role both for more realistic *spiking* neuron networks [26, 19] and also for pattern part retrieval with $\tilde{\mathbf{u}} \subseteq \mathbf{u}^\mu$ as analyzed in section 2.3.

2.2. Retrieval errors and storage capacity. We have retrieval errors if the retrieval result $\hat{\mathbf{v}}^\mu$ is not identical to the originally learned pattern $\mathbf{v}^\mu$. For a closer analysis we can divide the neurons of the content population into two groups: The *lo-units*, which correspond to the $n - l$ zero-entries of $\mathbf{v}^\mu$, and the *hi-units*, which correspond to the l one-entries of $\mathbf{v}^\mu$. For an error-free retrieval result $\hat{\mathbf{v}}^\mu$ the potentials $\mathbf{x}$ of lo- and hi-units must be separable; i.e., the largest potential of a lo-unit must be smaller than the smallest potential of a hi-unit. If the two potential distributions have overlap, two kinds of retrieval errors can occur. An *add-error* occurs if the potential of a lo-unit is above threshold Θ, and a *miss-error* occurs if the potential of a hi-unit is below threshold. If the probability distribution of a lo-unit i is known, we can compute the probability p_{01} of an *add-error*. Similarly, for a hi-unit j we can compute the probability p_{10} of a *miss-error*. With $z = |\tilde{\mathbf{u}}|$ being the activity of the address pattern, we have

$$p_{01} = \mathrm{pr}(\hat{v}_i = 1 | v_i^\mu = 0) = \sum_{x=\Theta}^{z} \mathrm{pr}[x_i = x], \tag{2.5}$$

$$p_{10} = \mathrm{pr}(\hat{v}_j = 0 | v_j^\mu = 1) = \sum_{x=0}^{\Theta-1} \mathrm{pr}[x_j = x]. \tag{2.6}$$

Thus, the expected *Hamming distance* $h(\mathbf{v}^\mu, \hat{\mathbf{v}}^\mu) := \sum_{j=1}^{n} |v_j^\mu - \hat{v}_j^\mu|$ between learned and retrieved patterns is

$$Eh(\mathbf{v}^\mu, \hat{\mathbf{v}}^\mu) = (n - l)p_{01} + lp_{10}. \tag{2.7}$$

To enforce retrieval quality we bound the expected Hamming distance to be no more than a fraction ϵ of the content pattern activity l. Thus, we require

$$(n - l)p_{01} + lp_{10} \leq \epsilon l, \tag{2.8}$$

where retrieval quality parameter ϵ is typically a small positive constant (e.g., $\epsilon = 0.01$). Because the minimal Hamming distance (optimizing Θ) is obviously increasing with M, we can finally define the *pattern capacity* M_ϵ,

$$M_\epsilon := \max\{M : (n - l)p_{01} + lp_{10} \leq \epsilon l\}, \tag{2.9}$$

being the maximal number of storable pattern associations fulfilling the retrieval quality requirement (2.8). Considering the Shannon information of individual content patterns, we get the normalized *network storage capacity* in bits per synapse,

$$C_\epsilon := \frac{M_\epsilon T(\mathbf{v}^\mu; \hat{\mathbf{v}}^\mu)}{mn}, \tag{2.10}$$

where $T(\mathbf{v}^\mu;\hat{\mathbf{v}}^\mu)$ is the transinformation (or mutual information) between learned and retrieved content patterns [9]. From the network capacity we can derive further performance measures such as *information capacity* C^I and *synaptic capacity* C^S, making use of the compressibility of the memory matrix for a memory load $p_1 \neq 0.5$ (see section 2.4; for more details see [18, 19, 20, 22]).

2.3. Sketch of the binomial approximative analysis for random patterns. The approximative analysis of the Willshaw model relies on the assumption that the one-entries in the memory matrix are generated independently of each other. Although obviously not true for distributed patterns, this assumptions leads to seminal insights into the Willshaw model and, at least for certain parameter ranges, quite good approximations of the actual storage capacity (see section 3 and [22]).

Let us again assume that the retrieval address pattern $\tilde{u}$ contains $c = \lambda k$ correct and $f = \kappa k$ false one-entries of address pattern u^μ previously used for learning $(0 < \lambda \leq 1,\ \kappa \geq 0)$. Assuming $\mathrm{pr}[A_{ij} = 1] = p_1$ independently of i, j, the dendritic potentials x_{lo} of a lo-unit and x_{hi} of a hi-unit are binomially distributed (equation (A.2)),

$$\mathrm{pr}[x_{\mathrm{lo}} = x] = p_B(x; c+f, p_1), \quad x = 0, 1, \ldots, c+f, \tag{2.11}$$

$$\mathrm{pr}[x_{\mathrm{hi}} = x] = p_B(x-c; f, p_1), \quad x = c, c+1, \ldots, c+f. \tag{2.12}$$

For purposes of clarity, in the following we restrict the analysis to the case of *pattern part retrieval* where the address pattern contains no add-noise, that is, $f = 0$. For the general analysis see [43]. Here one can apply the Willshaw threshold $\Theta = c$, which will limit the retrieval errors to add-noise. Thus, the retrieval error probabilities are

$$p_{01} = p(\hat{v}_i = 1 | v_i^\mu = 0) \approx {p_1}^{\lambda k} \tag{2.13}$$

and $p_{10} = 0$. To enforce retrieval quality as described above (see (2.8)) we have to bound the error probability p_{01} by $p_{01\epsilon}$,

$$p_{01} \leq p_{01\epsilon} := \frac{\epsilon l}{n-l}. \tag{2.14}$$

The number of patterns that can be stored is limited to the point where $p_{01} = p_{01\epsilon}$ or, equivalently, where the memory load reaches

$$p_{1\epsilon} \approx \left(\frac{\epsilon l}{n-l}\right)^{\frac{1}{\lambda \cdot k}} \qquad \left(\Leftrightarrow k \approx \frac{\mathrm{ld}\,\frac{\epsilon l}{n-l}}{\lambda\,\mathrm{ld}\,p_{1\epsilon}}\right). \tag{2.15}$$

From (2.3) we obtain the maximal number of stored patterns or *pattern capacity*

$$M_\epsilon \approx -\lambda^2 \cdot (\mathrm{ld}\,p_{1\epsilon})^2 \cdot \ln\frac{1-p_{1\epsilon}}{1-\tilde{p}_1} \cdot \frac{k}{l} \cdot \frac{mn}{(\mathrm{ld}\,\frac{n-l}{\epsilon \cdot l})^2}. \tag{2.16}$$

With this result we can also estimate the network capacity (equation (2.10))

$$C_\epsilon = \frac{M_\epsilon T(l/n, p_{01\epsilon}, 0)}{m} \approx \lambda \cdot \mathrm{ld}\,p_{1\epsilon} \cdot \ln\frac{1-p_{1\epsilon}}{1-\tilde{p}_1} \cdot \eta, \tag{2.17}$$

where $T(p, p_{01}, p_{10})$ is the transinformation (or mutual information) of a binary channel (see (A.1), [9]) and

$$\eta := \frac{T\left(\frac{l}{n}, \frac{\epsilon l}{n-l}, 0\right)}{-\frac{l}{n}\,\mathrm{ld}\,\frac{\epsilon l}{n-l}} \approx \frac{1}{1 + \frac{\ln \epsilon}{\ln(l/n)}}. \tag{2.18}$$

The approximation is valid for small $\epsilon, l/n \ll 1$ when $T \approx -(l/n)\,\mathrm{ld}(l/n)$: In that case $\eta \to 1$ for large $n \to \infty$. For $p_{1\epsilon} = 0.5$ and $\tilde{p}_1 = 0$ we therefore have $C_\epsilon \to \ln 2 \approx 0.69$ bits per synapse, the asymptotic storage capacity of the Willshaw model [46, 34, 43, 22]. Note that C_ϵ increases by factor $1/(1-\tilde{p}_1)$ if $1-\tilde{p}_1$ is interpreted as network connectivity (i.e., the chance that a potential synapse is actually realized; see [22, 8, 4]).

2.4. The asymptotic regimes of sparse and dense potentiation. The main conclusions from the binomial approximative analysis are that a very high storage capacity of almost 0.7 bits per synapse can be achieved for sparse patterns with $k \sim \log n$ and memory load $p_1 = 0.5$. Then we can store on the order of $M \sim mn/(\log n)^2$ pattern associations with high retrieval quality. From (2.15), (2.17) it is easy to see that asymptotically

$$C_\epsilon > 0 \Leftrightarrow k \sim \log n \Leftrightarrow 0 < p_{1\epsilon} < 1. \tag{2.19}$$

Thus, the analysis suggests that neural associative memory is efficient ($C_\epsilon > 0$) only for logarithmically sparse patterns. For sublogarithmic sparse patterns with $k/\log n \to 0$ we have $p_{1\epsilon} \to 0$, and for supralogarithmic sparseness with $k/\log n \to \infty$ we have $p_{1\epsilon} \to 1$, both cases implying vanishing network storage capacity $C_\epsilon \to 0$. These results bear importance for both technical and biological applications, in particular with respect to the sparseness of postulated Hebbian cell assemblies in the brain [14, 5, 35]. In the following we will refer to the three cases $p_{1\epsilon} \to 0/c/1$ as sparse, balanced, and dense synaptic potentiation, respectively.

I have argued elsewhere that these conclusions may be biased by the definition of network storage capacity, and that alternative definitions of storage capacity considering the compressibility of the network lead to different conclusions [18, 19, 20, 22]. For example, in technical implementations of the Willshaw model the memory matrix can be compressed for $p_1 \to 0/1$ and the storage capacity improves by factor $I(p_1) := -p_1\,\mathrm{ld}\,p_1 - (1-p_1)\,\mathrm{ld}(1-p_1)$. Similar arguments hold for biological networks where “compression” could be realized by synaptic pruning and structural plasticity (see [22] for more details). This has led to the definition of information capacity $C_\epsilon^I := C_\epsilon/I(p_{1\epsilon})$ and synaptic capacity $C_\epsilon^S := C_\epsilon/\min(p_{1\epsilon}, 1-p_{1\epsilon})$. Interestingly, and in contrast to network capacity C_ϵ, optimizing C_ϵ^I and C_ϵ^S reveals highest capacities for $p_{1\epsilon} \to 0$ and $p_{1\epsilon} \to 1$. Here, presuming the validity of the binomial theory, technical implementations could fully exploit the physical memory by storing $C_\epsilon^I \to 1$ bit information per memory bit. Similarly, biological networks could improve storage capacity to arbitrary large values $C_\epsilon^S \sim \log n \to \infty$ bits per synapse. By these results, the regimes with ultrasparse and moderately sparse patterns (or cell assemblies) have gained increased attention. However, the convergence of the binomial approximations towards the exact values is questionable since this has been strictly proven only for some special conditions including $k \sim \log n$ [34, 38]. In particular, for dense potentiation with $p_{0\epsilon} = 1 - p_{1\epsilon} \to 0$, supralogarithmic sparseness, $k/\log n \to \infty$, and

$$p_{1\epsilon} = \left(\frac{\epsilon l}{n-l}\right)^{1/\lambda k} = e^{\frac{\ln(\epsilon l/(n-l))}{\lambda k}} \approx 1 - \frac{\ln \frac{n-l}{\epsilon l}}{\lambda k}, \tag{2.20}$$

numerical simulations of the Willshaw model reveal that the real capacities can be massively overestimated by the binomial approximative analysis [22]. Therefore, in the following we conduct an exact analysis of the Willshaw model based on the exact potential distributions, and investigate conditions when the binomial probability distribution becomes a good approximation of the Willshaw–Palm distribution.

3. The Willshaw–Palm distribution of the dendritic potentials.

For an exact analysis of the Willshaw model we have to compute the distribution of the neurons' dendritic potentials, i.e., the probability $\mathrm{pr}[X = x]$ that the potential X of a given hi- or lo-unit equals a certain value x (see (2.5), (2.6)). This probability distribution is also called *Willshaw–Palm distribution* for random pattern associations and random retrieval address pattern. In the following more formal definition we take into account different ways to generate random patterns.

Definition 3.1 (Willshaw–Palm probability). *Let A be the memory matrix of a Willshaw associative memory after learning M random pattern associations and with synaptic noise $\tilde{p}_1$ as described in section* 2.1. *The associations are between address patterns u^μ with size m and mean activity k, and content patterns v^μ with size n and mean activity l ($\mu = 1, 2, \ldots, M$). Further let $\tilde{u}$ be a binary random address pattern with activity $z = |\tilde{u}|$. Then we define the* Willshaw–Palm probability *as the probability* $\mathrm{pr}[(\tilde{u}A)_j = x]$ *that a given content neuron v_j has potential x when retrieving with $\tilde{u}$. We distinguish between four relevant versions of the Willshaw–Palm probability depending on the generation of the random patterns:*

1. $p_{\mathrm{Ph}}(x; k, l, m, n, M, \tilde{p}_1, z)$ *for* fixed *address activity and* hetero-association.
2. $p_{\mathrm{Pa}}(x; k, n, M, \tilde{p}_1, z, \sigma)$ *for* fixed *address activity and* auto-association.
3. $p_{\mathrm{Wh}}(x; k, l, m, n, M, \tilde{p}_1, z)$ *for* random *address activity and* hetero-association.
4. $p_{\mathrm{Wa}}(x; k, n, M, \tilde{p}_1, z, \sigma)$ *for* random *address activity and* auto-association.

Auto-association *means that address patterns and content patterns are identical, $u^\mu = v^\mu$.* Fixed *address activity means that each address pattern has exactly k active units.* Random *address activity means that a component of an address pattern is active, $u_i^\mu = 1$, with probability k/m independently of other components. For the hetero-associative cases, the* content *patterns can have either fixed activity l or random activity with mean l. The auto-associative cases require an additional parameter $\sigma := \mathrm{pr}[j \in \tilde{u}]$ denoting the probability that neuron j is among the z active address units.*

We sometimes denote p_{W} briefly as the *Willshaw probability* since p_{Wh} has first been determined by Buckingham and Willshaw [7, 6]. Similarly, we denote p_{P} briefly as the *Palm probability* since some special cases of p_{Ph} have first been determined by Palm [34]. Note that the difference between the two variants is that the Palm model has address patterns with fixed activity and the Willshaw model has address patterns with fixed mean.

Theorem 3.2. *The four Willshaw–Palm probabilities p_{Ph}, p_{Pa}, p_{Wh}, p_{Wa} are given by* (3.22), (3.34), (3.39), (3.41), *respectively.*

The proof of the theorem follows in the next four subsections, each determining one version of the Willshaw–Palm probability and the corresponding retrieval error probabilities.

3.1. Fixed pattern activity and hetero-association.

Here we will determine the Willshaw–Palm probability $p_{\mathrm{Ph}}(x; k, l, m, n, M, z)$ of Definition 3.1. For brevity we identify patterns with sets of one-entries, e.g., $\mathbf{u} = 011001$ is identified with the index set $\mathbf{u} = \{2, 3, 6\}$. Generalizing Palm's definition of a predicate or condition C (see appendix 1 in [34]) for index sets Y, N ("yes!" and "no!") let

$$C(Y, N, j) := [\forall i \in Y : A_{ij} = 1] \cap [\forall i \in N : A_{ij} = 0]; \tag{3.1}$$

i.e., condition $C(Y, N, j)$ means that content neuron j receives inputs from the subset Y of address pattern $\tilde{\mathbf{u}}$, but no input from subset N. We further assume that Y and N are disjunct random sets unrelated to the M stored pattern pairs. For Y equal to a further $(M+1)$th address pattern, i.e., $Y = \mathbf{u}^{M+1}$, the condition $C(Y, \emptyset, j)$ would coincide with the definition of C in the appendix of [34]. Then C would be equivalent to the occurrence of an add-error at lo-unit j for retrieval with the noise-free address pattern $\tilde{\mathbf{u}} = \mathbf{u}^{M+1}$. We first compute the probability that $C(Y, \emptyset, j)$ holds after storing M pattern associations. Contrary to [34] we assume that $Y \subseteq \{1, \dots, m\}$ is an arbitrary *subset* of address units unrelated to the M stored pattern associations.

$$\operatorname{pr}(C(Y,\emptyset,j)) = \operatorname{pr}([\forall i \in Y : A_{ij} = 1]) = 1 - \operatorname{pr}([\exists i \in Y : A_{ij} = 0]) \tag{3.2}$$

$$= 1 - \operatorname{pr}\left(\bigcup_{i \in Y} [A_{ij} = 0] \right) = 1 - \operatorname{pr}\left(\bigcup_{i=1}^{|Y|} [A_{ij} = 0] \right) \tag{3.3}$$

$$= 1 - \sum_{s=1}^{|Y|} (-1)^{s+1} \sum_{1 \le i_1 < \dots < i_s \le |Y|} \operatorname{pr}\left(\bigcap_{h=1}^{s} [A_{i_h j} = 0] \right) \tag{3.4}$$

$$= 1 - \sum_{s=1}^{|Y|} (-1)^{s+1} \binom{|Y|}{s} \operatorname{pr}\left(\bigcap_{i=1}^{s} [A_{ij} = 0] \right). \tag{3.5}$$

For (3.4) we used the formula of Sylvester–Poincaré equation (A.6). Note that for random patterns the probabilities that a given subcolumn of $\mathbf{A}$ has at least one zero-entry (equation (3.3)) or only zero-entries (see (3.5)) depend only on the subcolumn's size, but not on the specific indices. The latter probability is written as

$$\operatorname{pr}\left(\bigcap_{i=1}^{s} [A_{ij} = 0] \right) = \operatorname{pr}\left(\bigcap_{i=1}^{s} [\tilde{A}_{ij} = 0] \cap \bigcap_{\mu=1}^{M} [1, \dots, s \notin \mathbf{u}^{\mu} \vee j \notin \mathbf{v}^{\mu}] \right) \tag{3.6}$$

$$= (1 - \tilde{p}_1)^s (\operatorname{pr}[1, \dots, s \notin \mathbf{u}^1 \vee j \notin \mathbf{v}^1])^M, \tag{3.7}$$

where we used the facts that the entries of the noise matrix $\tilde{\mathbf{A}}$ and the address patterns are generated independently of each other, and the probability that all entries of a subcolumn remain zero during learning of the μth pattern pair is independent of μ. The latter probability is written as

$$\operatorname{pr}[1, \dots, s \notin \mathbf{u}^1 \vee j \notin \mathbf{v}^1] \tag{3.8}$$

$$= \operatorname{pr}([1, \dots, s \notin \mathbf{u}^1]) + \operatorname{pr}([j \notin \mathbf{v}^1]) - \operatorname{pr}([1, \dots, s \notin \mathbf{u}^1 \wedge j \notin \mathbf{v}^1]) \tag{3.9}$$

$$= \frac{\binom{m-s}{k}}{\binom{m}{k}} + \frac{\binom{n-1}{l}}{\binom{n}{l}} - \frac{\binom{m-s}{k}\binom{n-1}{l}}{\binom{m}{k}\binom{n}{l}} \tag{3.10}$$

$$= B(m,k,s) + B(n,l,1) - B(m,k,s)B(n,l,1) = 1 - \frac{l(1 - B(m,k,s))}{n}, \tag{3.11}$$

where $B(a,b,c) := \binom{a-b}{c} / \binom{a}{c} = \prod_{i=0}^{c-1} (a-b-i)/(a-i) = B(a,c,b)$; see [34] and (A.8) in the appendix. Thus

$$\operatorname{pr}(C(Y,\emptyset,j)) = \sum_{s=0}^{|Y|} (\tilde{p}_1 - 1)^s \binom{|Y|}{s} \left(1 - \frac{l}{n}(1 - B(m,k,s)) \right)^M. \tag{3.12}$$

With this result we can finally compute the general case with arbitrary, but disjunct, $Y, N = \{N_1, N_2, \ldots\} \subseteq \{1, \ldots, m\}$, $Y \cap N = \emptyset$:

$$\operatorname{pr}(C(Y,N,j)) = \operatorname{pr}(C(Y,\emptyset,j)) - \operatorname{pr}\left(\bigcup_{i=1}^{|N|} C(Y \cup \{N_i\}, \emptyset, j)\right) \tag{3.13}$$

$$= \operatorname{pr}(C(Y,\emptyset,j)) - \sum_{t=1}^{|N|} (-1)^{t+1} \sum_{1 \le i_1 < \cdots < i_t \le |N|} \operatorname{pr}\left(\bigcap_{h=1}^{t} C(Y \cup \{N_{i_h}\}, \emptyset, j)\right) \tag{3.14}$$

$$= \operatorname{pr}(C(Y,\emptyset,j)) - \sum_{t=1}^{|N|} (-1)^{t+1} \binom{|N|}{t} \operatorname{pr}(C(Y \cup \{N_1, \ldots, N_t\}, \emptyset, j)) \tag{3.15}$$

$$= \sum_{t=0}^{|N|} (-1)^t \binom{|N|}{t} \sum_{s=0}^{|Y|+t} (-1)^s \binom{|Y|+t}{s} (1-\tilde{p}_1)^s \left(1 - \frac{l}{n}(1 - B(m,k,s))\right)^M \tag{3.16}$$

$$= \sum_{s=0}^{|Y|+|N|} (1-\tilde{p}_1)^s \left(1 - \frac{l(1-B(m,k,s))}{n}\right)^M \sum_{\substack{t=\max(0,\\ s-|Y|)}}^{|N|} (-1)^{s+t} \binom{|Y|+t}{s} \binom{|N|}{t} \tag{3.17}$$

$$= \sum_{s=|N|}^{|Y|+|N|} (-1)^{s-|N|} \binom{|Y|}{s-|N|} (1-\tilde{p}_1)^s \left(1 - \frac{l}{n}(1 - B(m,k,s))\right)^M, \tag{3.18}$$

where for (3.14) we used again (A.6) (Sylvester–Poincaré), and for the last equation we used (A.7). Thus, the (Willshaw–)Palm probability for hetero-association is

$$p_{\text{Ph}}(x; k, l, m, n, M, z) = \operatorname{pr}\left(\bigcup_{Y \subseteq \tilde{u},\, |Y|=x,\, N=\tilde{u}-Y} C(Y,N,j)\right) \tag{3.19}$$

$$= \binom{z}{x} \operatorname{pr}(C(\{1,\ldots,x\}, \{x+1,\ldots,z\}, j)) \tag{3.20}$$

$$= \binom{z}{x} \sum_{s=z-x}^{z} (-1)^{s-z+x} \binom{x}{s-z+x} (1-\tilde{p}_1)^s \left(1 - \frac{l}{n}(1 - B(m,k,s))\right)^M \tag{3.21}$$

$$= \binom{z}{x} \sum_{s=0}^{x} (-1)^s \binom{x}{s} (1-\tilde{p}_1)^{s+z-x} \left(1 - \frac{l}{n}(1 - B(m,k,s+z-x))\right)^M \tag{3.22}$$

for $0 \le x \le z$ and B as defined below (3.11).

Now we are able to compute exact retrieval error probabilities when addressing with noisy patterns. For example, when addressing with a single address pattern containing c correct and f false one-entries and retrieving with threshold Θ, then the exact retrieval error probabilities p_{01} of a false one-entry and p_{10} of a missing one-entry are

$$p_{01}(\Theta) = \sum_{x=\Theta}^{c+f} p_{\text{Ph}}(x; k, l, m, n, M-1, \tilde{p}_1, c+f), \tag{3.23}$$

$$p_{10}(\Theta) = \sum_{x=c}^{\Theta-1} p_{\text{Ph}}(x-c; k, l, m, n, M-1, \tilde{p}_1, f). \tag{3.24}$$

Note that the situation is as if only $M-1$ patterns were stored since, as a precondition, the pattern to be retrieved affects neither any of the synapses of a 0-neuron nor any of the synapses connecting add-noise to a 1-neuron.

3.2. Fixed pattern activity and auto-association. The analysis for hetero-association in section 3.1 can be extended to auto-association where address and content population are identical, i.e., $m=n$, $k=l$, and $u^\mu = v^\mu$ (see also appendix 1 in [34]). Here the diagonal matrix elements A_{jj} have a much higher probability,

$$\bar{p}_1 = 1-(1-\tilde{p}_1)(1-k/n)^M, \tag{3.25}$$

of being activated than nondiagonal elements (cf. (2.2)). We use again $C(Y,N,j)$ as defined in (3.1), but now we have to care whether j is contained in Y or N. We first compute the special case $N=\emptyset$ and $j \notin Y$. The analysis for $\mathrm{pr}(C(Y,\emptyset,j\notin Y))$ starts the same way as for the hetero-associative case (see (3.2)–(3.7)). Instead of (3.8)–(3.11) we have to write $\mathrm{pr}([1,\dots,s\notin u^1 \vee j\notin u^1]) = \mathrm{pr}([1,\dots,s\notin u^1]) + \mathrm{pr}([j\notin u^1]) - \mathrm{pr}([1,\dots,s,j\notin u^1]) = B(n,k,s)+B(n,k,1)-B(n,k,s+1) = 1-\frac{k}{n}(1-\frac{n}{n-s}B(n,k,s))$ and therefore

$$\mathrm{pr}(C(Y,\emptyset,j\notin Y)) = \sum_{s=0}^{|Y|}(\tilde{p}_1-1)^s\binom{|Y|}{s}\left(1-\frac{k}{n}\left(1-\frac{n}{n-s}B(n,k,s)\right)\right)^M. \tag{3.26}$$

With this result we can again compute the general case with arbitrary, but disjunct, $Y, N=\{N_1,N_2,\dots\}\subseteq\{1,\dots,m\}$, $Y\cap N=\emptyset$, but $j\notin Y\cup N$ (cf. (3.13)–(3.18)):

$$\begin{aligned}&\mathrm{pr}(C(Y,N,j\notin Y\cup N))\\ &\quad=\sum_{s=|N|}^{|Y|+|N|}(-1)^{s-|N|}\binom{|Y|}{s-|N|}(1-\tilde{p}_1)^s\left(1-\frac{k}{n}\left(1-\frac{nB(n,k,s)}{n-s}\right)\right)^M.\end{aligned} \tag{3.27}$$

If we presume $N=\emptyset$ and $j\in Y$, then (3.3) becomes $\mathrm{pr}(C(Y,\emptyset,j\in Y)) = 1-\mathrm{pr}(\bigcup_{i=1}^{|Y|-1}[A_{ij}=0]) - \mathrm{pr}[A_{jj}=0](1-\mathrm{pr}(\bigcup_{i=1}^{|Y|-1}[A_{ij}=0]|[A_{jj}=0]))$. Here the first probability on the right side evolves as before except for replacing $|Y|$ by $|Y|-1$. The conditional probability is $1-\mathrm{pr}(\bigcap_{i=1}^{|Y|-1}[A_{ij}=1]|[A_{jj}=0]) = 1-\tilde{p}_1^{|Y|-1}$ because $A_{jj}=0$ implies that the other synapses of neuron j can be activated only by noise. Thus with $\mathrm{pr}[A_{jj}=0]=1-\bar{p}_1$ we obtain

$$\mathrm{pr}(C(Y,\emptyset,j\in Y)) = \mathrm{pr}(C(Y-\{j\},\emptyset,j)) - (1-\bar{p}_1)\tilde{p}_1^{|Y|-1}. \tag{3.28}$$

This can be generalized to $N\neq\emptyset$ analogously to (3.13)–(3.18). Equation (3.15) becomes

$$\mathrm{pr}(C(Y,N,j\in Y)) = \sum_{t=0}^{|N|}(-1)^t\binom{|N|}{t}\mathrm{pr}(C(Y\cup\{N_1,\dots,N_t\},\emptyset,j\in Y)). \tag{3.29}$$

Inserting (3.28) yields two components. The first component equals (3.27) except for replacing $|Y|$ by $|Y|-1$. The second component is $\sum_{t=0}^{|N|}(-1)^t\binom{|N|}{t}(1-\bar{p}_1)\tilde{p}_1^{|Y|-1+t} = (1-\bar{p}_1)\tilde{p}_1^{|Y|-1}(1-\tilde{p}_1)^{|N|}$ and therefore

$$\begin{aligned}&\mathrm{pr}(C(Y,N,j\in Y)) = -(1-\bar{p}_1)\tilde{p}_1^{|Y|-1}(1-\tilde{p}_1)^{|N|}\\ &\quad+\sum_{s=|N|}^{|Y|+|N|-1}(-1)^{s-|N|}\binom{|Y|-1}{s-|N|}(1-\tilde{p}_1)^s\left(1-\frac{k}{n}\left(1-\frac{nB(n,k,s)}{n-s}\right)\right)^M.\end{aligned} \tag{3.30}$$

We will also need the case $j \in N$. This case implies $A_{jj} = 0$, and therefore any other synapse of neuron j can only be activated by noise. Thus simply

$$\mathrm{pr}(C(Y, N, j \in N)) = (1 - \bar{p}_1)\tilde{p}_1^{|Y|}(1 - \tilde{p}_1)^{|N|-1}. \tag{3.31}$$

With this we can finally determine the Palm probability for auto-association. If neuron j does not belong to the z address units, then we can proceed as in (3.19)–(3.22) and obtain

$$\begin{aligned} &p_{\mathrm{Pa}}(x; k, n, M, z, 0) \\ &= \binom{z}{x} \sum_{s=0}^{x} (-1)^s \binom{x}{s} (1 - \tilde{p}_1)^{s+z-x} \left(1 - \frac{k}{n}\left(1 - \frac{nB(n, k, s+z-x)}{n - z + x - s}\right)\right)^M . \end{aligned} \tag{3.32}$$

If neuron j is among the z address units, we have to split the union of (3.19) into two disjunct components, $\bigcup_{Y \subseteq \tilde{u},\, |Y|=x,\, N=\tilde{u}-Y,\, j \in Y} C$ and $\bigcup_{Y \subseteq \tilde{u},\, |Y|=x,\, N=\tilde{u}-Y,\, j \in N} C$. Then we can proceed again with transformations similar to (3.19)–(3.22). With (3.30), the first union corresponds to $p_{\mathrm{Pa}}(x-1; k, n, M, z-1, 0) - \binom{z-1}{x-1}(1-\bar{p}_1)\tilde{p}_1^{x-1}(1-\tilde{p}_1)^{z-x}$. With (3.31), the second union becomes $\binom{z-1}{x}(1-\bar{p}_1)\tilde{p}_1^{x}(1-\tilde{p}_1)^{z-x-1}$. Adding the two components yields

$$\begin{aligned} p_{\mathrm{Pa}}(x; k, n, M, \tilde{p}_1, z, 1) &= p_{\mathrm{Pa}}(x-1; k, n, M, \tilde{p}_1, z-1, 0) \\ &\quad + (1 - \bar{p}_1)\left(p_B(x; z-1, \tilde{p}_1) - p_B(x-1; z-1, \tilde{p}_1)\right), \end{aligned} \tag{3.33}$$

and thus the general Palm probability for auto-association is

$$\begin{aligned} &p_{\mathrm{Pa}}(x; k, n, M, \tilde{p}_1, z, \sigma) \\ &= (1 - \sigma)p_{\mathrm{Pa}}(x; k, n, M, \tilde{p}_1, z, 0) + \sigma p_{\mathrm{Pa}}(x; k, n, M, \tilde{p}_1, z, 1). \end{aligned} \tag{3.34}$$

When addressing with a single address pattern containing c correct and f false one-entries then $\sigma = f/(n-k)$ for a lo-unit, while $\sigma = 0$ for the f noisy inputs to the hi-units. Thus, retrieving with threshold Θ, the exact retrieval error probabilities p_{01} of a false one-entry and p_{10} of a missing one-entry are

$$p_{01}(\Theta) = \sum_{x=\Theta}^{c+f} p_{\mathrm{Pa}}(x; k, n, M-1, \tilde{p}_1, c+f, f/(n-k)), \tag{3.35}$$

$$p_{10}(\Theta) = \sum_{x=c}^{\Theta-1} p_{\mathrm{Pa}}(x-c; k, n, M-1, \tilde{p}_1, f, 0). \tag{3.36}$$

3.3. Random pattern activity and hetero-association. For technical applications, the patterns to be stored have often fixed pattern activities k and l (e.g., see [34, 41, 17, 42]). However, for the biological interpretation we identify the pattern activities with the size of cell assemblies [14, 5, 35], and it seems not very plausible to assume that all cell assemblies have exactly the same size. Here it might be more realistic to assume that an address pattern component is 1 with probability k/m independently of each other (and similarly l/n for the content patterns). Then the mean assembly sizes are still k and l, but the size of a given cell assemblies is a binomially distributed random variable.

The analysis can be conducted in analogy to section 3.1. Due to independently generated pattern components, (3.8) simplifies to

$$\mathrm{pr}[1,\ldots,s \notin \mathbf{u}^1 \vee j \notin \mathbf{v}^1] = 1 - \frac{l}{n} + \left(\frac{l}{n}\right)\left(1-\frac{k}{m}\right)^s \tag{3.37}$$

$$= 1 - \frac{l}{n}\left(1-\left(1-\frac{k}{m}\right)^s\right). \tag{3.38}$$

Thus in the further analysis of section 3.1 we can simply replace $B(m,k,s)$ by $(1-k/m)^s$. From (3.22) we finally obtain the *Willshaw probability* for hetero-association:

$$p_{\mathrm{Wh}}(x;k,l,m,n,M,\tilde{p}_1,z)$$

$$= \binom{z}{x}\sum_{s=0}^{x}(-1)^s\binom{x}{s}(1-\tilde{p}_1)^{s+z-x}\left(1-\frac{l}{n}\left(1-\left(1-\frac{k}{m}\right)^{s+z-x}\right)\right)^M \tag{3.39}$$

$$= \sum_{i=0}^{M} p_B(i;M,l/n)\,p_B\left(x;z,1-(1-\tilde{p}_1)\left(1-\frac{k}{m}\right)^i\right) \tag{3.40}$$

for $0 \le x \le z$. The retrieval error probabilities p_{01} and p_{10} are as in (3.23), (3.24), replacing p_{Ph} by p_{Wh}. The second formula, (3.40), results from an alternative approach to obtain the Willshaw probability for random pattern activities (see [7, 6]). Here the first binomial is the probability that the considered content neuron has unit-usage i, i.e., that it has been activated i times during the learning of the M associations. Given unit usage i the term $1-(1-\tilde{p}_1)(1-k/m)^i$ is the probability that a given synapse on the content neuron has been potentiated or activated by noise. Thus, the second binomial is the probability that a content neuron receives x out of the z random inputs given a unit usage of i.

Equation (3.40) for $\tilde{p}_1 = 0$ was found in 1991 by Buckingham and Willshaw [7, 6], while (3.39) for $\tilde{p}_1 = 0$ was derived from (3.40) in 1999 by Sommer and Palm [43]. For numerical evaluations (3.39) is particularly useful if z is small and M is large, while evaluating (3.40) is more efficient for small M and large z. In cases where both M and z are large, evaluating the Willshaw probability can be computationally very expensive [22, 23].

Unfortunately, we do not know a formula for the exact Palm probability (3.22) that is analogous to (3.40). Thus, evaluating the exact error probabilities for the model variant with fixed assembly size is computationally cheap only for cases with small z. However, numerical investigations suggest that p_{W} quickly converges to p_{P} for large m, n, and z and that the resulting retrieval error probabilities for fixed assembly sizes are smaller than for random assembly size [22].

3.4. Random pattern activity and auto-association. In analogy to the previous sections we can also investigate the auto-associative case with binomially distributed pattern activities where each pattern component is active with probability k/n independently of other components. Here $\mathrm{pr}(C(Y,N,j \notin Y \cup N))$ can be obtained in the same way as done in section 3.3 for hetero-association with $k = l$ and $m = n$. This corresponds to $\sigma = 0$ and leads to $p_{\mathrm{Wa}}(x;k,n,M,\tilde{p}_1,z,0) = p_{\mathrm{Wh}}(x;k,n,k,n,M,\tilde{p}_1,z)$. The remaining subtleties concerning autapses having a much higher activation probability $\bar{p}_1$ than other synapses (see (3.25)) can be handled in the same way as done in section 3.2 for fixed pattern activity. Thus, simply replacing $p_{\mathrm{Pa}}(x;k,n,M,\tilde{p}_1,z,0)$ by $p_{\mathrm{Wh}}(x;k,n,k,n,M,\tilde{p}_1,z)$ we obtain from (3.34)

$$\begin{aligned} p_{\mathrm{Wa}}(x;k,n,M,\tilde{p}_1,z,\sigma) &= (1-\sigma)p_{\mathrm{Wh}}(x;k,n,k,n,M,\tilde{p}_1,z) \\ &\quad + \sigma p_{\mathrm{Wh}}(x-1;k,n,k,n,M,\tilde{p}_1,z-1) \\ &\quad + \sigma(1-\bar{p}_1)\left(p_B(x;z-1,\tilde{p}_1) - p_B(x-1;z-1,\tilde{p}_1)\right). \end{aligned} \tag{3.41}$$

When addressing with a single address pattern containing c correct and f false one-entries then the error probabilities for threshold Θ can be computed similarly as in section 3.2,

$$p_{01}(\Theta) = \sum_{x=\Theta}^{c+f} p_{\mathrm{Wa}}(x;k,n,M-1,\tilde{p}_1,c+f,\bar{\sigma}), \tag{3.42}$$

$$p_{10}(\Theta) = \sum_{x=c}^{\Theta-1} p_{\mathrm{Wa}}(x-c;k,n,M-1,\tilde{p}_1,f,0) \tag{3.43}$$

for $0 \leq x \leq z$. For the lo-units σ has to be averaged over the constrained range of possible pattern activities k' with $c \leq k' \leq n-f$; thus, $\bar{\sigma} := (\sum_{k'=c}^{n-f} p_B(k';n,k/n)f/(n-k'))/(\sum_{k'=c}^{n-f} p_B(k';n,k/n))$. Note that computing the expected Hamming distance (see (2.8)) requires a similar adjustment. Note also that p_{10} is the same as for hetero-association with the corresponding parameters (see section 3.3).

3.5. Probabilities of add-errors for pattern part retrieval. For the particular case of pattern part retrieval, $c = \lambda k$ and $f = 0$ with $0 < \lambda \leq 1$, we can use the Willshaw threshold $\Theta = \lambda k$. Then the probability of miss-errors in the retrieval outputs is generally $p_{10} = 0$. For fixed pattern activity the probability of an add-error is

$$p_{01,\mathrm{Ph}} = \sum_{s=0}^{\lambda k} (\tilde{p}_1 - 1)^s \binom{\lambda k}{s} \left[1 - \frac{l}{n}(1 - B(m,k,s))\right]^{M-1}, \tag{3.44}$$

$$p_{01,\mathrm{Pa}} = \sum_{s=0}^{\lambda k} (\tilde{p}_1 - 1)^s \binom{\lambda k}{s} \left[1 - \frac{k}{n}\left(1 - \frac{n}{n-s}B(n,k,s)\right)\right]^{M-1} \tag{3.45}$$

for hetero-association and auto-association, respectively. For random pattern activity, the corresponding error probabilities are

$$p_{01,\mathrm{Wh}} = \sum_{s=0}^{\lambda k} (\tilde{p}_1 - 1)^s \binom{\lambda k}{s} \left[1 - \frac{l}{n}(1 - (1-k/m)^s)\right]^{M-1} \tag{3.46}$$

$$= \sum_{i=0}^{M-1} p_B(i;M-1,l/n)(1 - (1-\tilde{p}_1)(1-k/m)^i)^{\lambda k} \tag{3.47}$$

$$\geq [1 - (1-\tilde{p}_1)(1-kl/mn)^{M-1}]^{\lambda k} = p_1^{\lambda k}, \tag{3.48}$$

$$p_{01,\mathrm{Wa}} = p_{01,\mathrm{Wh}}|_{l=k,\, m=n}, \tag{3.49}$$

where p_B is again the binomial probability (see below (2.12)). Here the error probabilities are essentially the same for auto-association and hetero-association with $k = l$, $m = n$. Equation (3.48) corresponds to the binomial approximation equation (2.13) as used in section 2.3. The bound can be obtained from Jensen's inequality

$Ef(y) \geq f(Ey)$ (see, e.g., [9]) for convex $f(y) := (1-y)^{\lambda k}$ with random variable $y := (1-\tilde{p}_1)(1-k/m)^i$. Here the expectation $Ey = 1 - p_1$ can be computed from (A.9) using $J = 1$.

Although I could not prove this strictly, numerical experiments suggest $p_{01,\mathrm{Pa}} \leq p_{01,\mathrm{Ph}} \leq p_{01,\mathrm{Wh}} = p_{01,\mathrm{Wa}}$ [22]. The binomial approximation equation (3.48) can strongly underestimate p_{01}. Palm and Sommer [34, 38] give some asymptotic conditions when the true potential distribution converges to the corresponding binomial distribution, but only for relatively small $k \sim \log n$ and $k \leq n^{1/3}$, respectively. In section 5 we will see that the parameter range of convergence is actually much larger.

3.6. Numerical evaluations. Theorem 3.2 and the resulting retrieval error probabilities have been verified by extensive numerical simulations of the Willshaw model [22]. Some data are shown in Table 3.1.

TABLE 3.1

Results from numerical simulations of retrieval in the Willshaw model with $m = 10$, $k = 3$, $M = 5$, $\tilde{p}_1 = 0.1$ when addressing with patterns containing $c = 2$ correct and $f = 2$ false one-entries. Upper rows (S) show results for "symmetric" networks with $n = m$ and $l = k$ (cf. Figure 3.1, *left panel). Lower rows (A) show results for "asymmetric" networks with $n = 11$ and $l = 2$. The columns show optimal retrieval threshold Θ, output noise ϵ, and the error probabilities p_{01} and p_{10} for add-noise and miss-noise as well as the corresponding average values (mean) and standard errors (s.e.) from the simulation experiments (evaluating $N \approx 10^8$ retrievals in each case). The experimental values closely match the theoretical values and thus verify Theorem* 3.2.

	Θ	ϵ	p_{01}	mean	s.e.	p_{10}	mean	s.e.

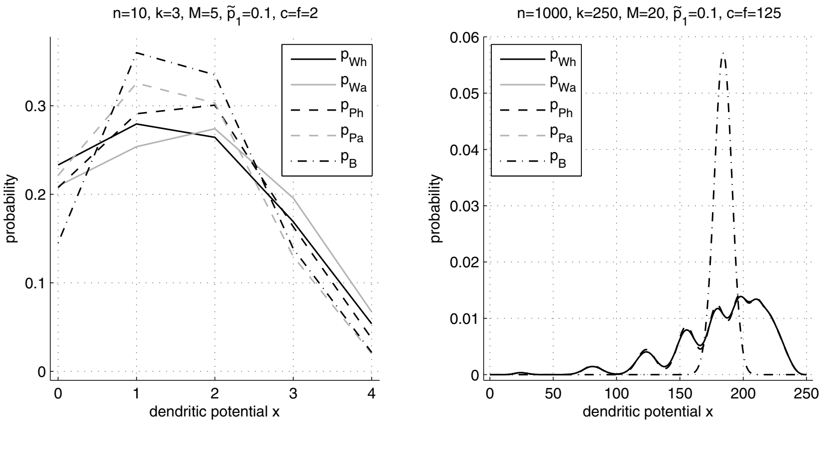

FIG. 3.1. *Examples of the Willshaw–Palm distributions (see Theorem* 3.2*) and the corresponding binomial approximation (equation* (2.11)*) for a small network (left panel) and a larger network (right panel). The plots show the distribution of the lo-units when addressing with c correct and f false units in symmetric networks ($m = n$ and $k = l$). The plots indicate that the binomial approximation can be very inaccurate.*

Figure 3.1 gives examples for the Willshaw–Palm distribution illustrating the differences between the four probability versions and the binomial approximation. For small networks the difference between the four versions of the Willshaw–Palm distribution is significant. In comparison to the binomial approximation the Willshaw–Palm probability can have a much *larger variance* and *oscillatory modulations* [19, 21]. The difference in variance is computed in section 5.2 (see (5.5)), and conditions where the variances and higher-order moments become identical are computed in section 5.4. The oscillatory modulations can be understood from (3.40) writing p_{Wh} as a superposition of $M+1$ binomials. They occur if the binomials $p_B(x;z,1-(1-\tilde{p}_1)(1-k/m)^i)$ around mean unit usage $i \approx Ml/n$ have a small standard deviation $\sqrt{z(1-\tilde{p}_1)(1-k/m)^i(1-(1-\tilde{p}_1)(1-k/m)^i)}$ compared to the mean distance $z(1-\tilde{p}_1)((1-k/m)^i-(1-k/m)^{i+1})$ between two neighboring binomials, i.e., if

$$(1-\tilde{p}_1)\frac{zk^2}{m^2}\left(1-\frac{k}{m}\right)^{Ml/n} \gg 1. \tag{3.50}$$

4. Expectation, variance, and higher-order moments of the Willshaw–Palm distribution. In this section we investigate the moments of the Willshaw–Palm probability distribution. Here we will focus on the more simple case of random pattern activity, i.e., on the Willshaw probabilities p_{Wh} and p_{Wa} (see Definition 3.1 and Theorem 3.2). The analysis for fixed pattern activity is more difficult, but it is plausible to assume that the basic (asymptotic) properties for the Palm probabilities p_{Ph}, p_{Pa} are similar to p_{Wh}, p_{Wa}. At least the expectation values of Willshaw and Palm probabilities are the same: Because the dendritic potential is $x_j = \sum_{i\in\tilde{u}} A_{ij}$, the expectation for hetero-association is identical to the corresponding binomial expectation (see section 2.3),

$$E_{p_{\mathrm{Wh}}}(x_j) = E_{p_{\mathrm{Ph}}}(x_j) = E_{p_B}(x_j) = zp_1, \tag{4.1}$$

$$E_{p_{\mathrm{Wa}}}(x_j) = E_{p_{\mathrm{Pa}}}(x_j) = zp_1 + \sigma(\bar{p}_1 - p_1), \tag{4.2}$$

where p_1 is the memory load equation (2.2). The expectation for auto-association follows similarly from $E_{p_{\mathrm{Wa}}}(x_j) = (z-1)p_1 + \sigma\bar{p}_1 + (1-\sigma)p_1$, where σ is the probability that j is among the z active units of address pattern $\tilde{u}$, and $\bar{p}_1$ is the probability that A_{jj} is active (see (3.25)).

In the following text we will sometimes write $p_0 := 1-p_1$, $\bar{p}_0 := 1-\bar{p}_1$, and $\tilde{p}_0 := 1-\tilde{p}_1$ for the sake of brevity.

4.1. Moment generating functions. The moment generating function of a random variable X with probability function p is defined by $G_p(t) := E_p(e^{tX})$ (e.g., see [39]). The following theorem shows that the moment generating functions of the Willshaw–Palm probabilities for *random* pattern activity k can be obtained from the generating function of the binomial probability (equation (A.3)).

THEOREM 4.1. *The moment generating functions* $G_{p_{\mathrm{Wh}}}(t;k,l,m,n,M,\tilde{p}_1,z)$ *and* $G_{p_{\mathrm{Wa}}}(t;k,n,M,\tilde{p}_1,z,\sigma)$ *of the Willshaw probability functions* p_{Wh} *for hetero-association (equation* (3.39)*) and* p_{Wa} *for auto-association (equation* (3.41)*) are*

$$G_{p_{\mathrm{Wh}}}(t) = \sum_{i=0}^{M} p_B(i;M,l/n)G_{p_B}(t;z,1-\tilde{p}_0(1-k/m)^i), \tag{4.3}$$

$$\begin{aligned} G_{p_{\mathrm{Wa}}}(t;\ldots,z,\sigma) &= (1-\sigma)G_{p_{\mathrm{Wh}}}(t;\ldots,z) + \sigma e^t G_{p_{\mathrm{Wh}}}(t;\ldots,z-1) \\ &\quad + \sigma\bar{p}_0(1-e^t)G_{p_B}(t;z-1,\tilde{p}_1). \end{aligned} \tag{4.4}$$

Proof. By definition it is $G_{p_{\mathrm{Wh}}}(t) := E_{p_{\mathrm{Wh}}} e^{tX} = \sum_{x=0}^{z} e^{tx} \sum_{i=0}^{M} p_B(i; M, l/n) \cdot p_B(x; z, 1-\tilde{p}_0(1-k/m)^i) = \sum_{i=0}^{M} p_B(i; M, l/n) \sum_{x=0}^{z} e^{tx} p_B(x; z, 1-\tilde{p}_0(1-k/m)^i)$. Here the second sum is the moment generating function of a binomial equation (A.3) with $N = z$ and $P = 1-(1-k/m)^i$. This shows (4.3). Similarly, the auto-associative moment generating function $G_{p_{\mathrm{Wa}}}(t)$ follows with (3.41) because moment generating functions $G_{p(x)}(t)$ are linear in $p(x)$ and have the shifting property $G_{p(x-1)}(t) = \sum_x p(x-1)e^{tx} = \sum_x p(x)e^{t(x+1)} = e^t G_{p(x)}(t)$. □

4.2. Higher order moments. The dth *raw moment* of a random variable X with probability function p is defined by the expectation $E_p X^d$ and can be computed from the moment generating function $G_p(t) := E_p(e^{tX})$, where the dth derivative $G_p^{(d)}(t)$ at $t = 0$ yields the dth moment (see, e.g., [39]). Then the dth *central moment* (or moment about the mean) is defined by the expectation $E_p(X-\mu)^d$, where $\mu := E_p X$ is the mean value. The following theorem computes the moments of the Willshaw probabilities from the moments of the binomial probability.

THEOREM 4.2. *Let $p_{\mathrm{Wh}}(x; k, l, m, n, M, \tilde{p}_1, z)$ be the Willshaw probability for hetero-association (equation* (3.39)*) and $p_B(x; z, 1-p_0)$ the corresponding binomial approximation with $p_0 := 1 - p_1$ (see* (A.2), (2.2)*). Then the raw and central moments of the Willshaw probability can be computed from the binomial moments (see* (A.4)–(A.5)*) by formally substituting powers p_0^j by numbers $p_0^{(j)}$ defined as*

$$p_0^{(j)} := \tilde{p}_0^j \left(1 - \frac{l}{n}\left(1 - \left(1 - \frac{k}{m}\right)^j\right)\right)^M, \tag{4.5}$$

where $\tilde{p}_0 := 1 - \tilde{p}_1$. For example, the raw and central Willshaw moments for hetero-association*, $\mathfrak{m}_{r,p_{\mathrm{Wh}}}(d; k, l, m, n, M, \tilde{p}_1, z)$ and $\mathfrak{m}_{c,p_{\mathrm{Wh}}}(d; k, l, m, n, M, \tilde{p}_1, z)$, can be obtained from*

$$E_{p_{\mathrm{Wh}}}(X-\mu)^d = \sum_{j=0}^{d} p_0^{(j)} (-1)^j \binom{z}{j} \sum_{i=0}^{j} (-1)^i \binom{j}{i} (z-\mu-i)^d, \tag{4.6}$$

which is true for an arbitrary offset μ. The raw and central moments follow with $\mu = 0$ and $\mu = zp_1$, respectively.

Similarly, the raw and central Willshaw moments for the auto-associative probability p_{Wa} (see (3.41)*), $\mathfrak{m}_{r,p_{\mathrm{Wa}}}(d; k, n, M, \tilde{p}_1, z, \sigma)$ and $\mathfrak{m}_{c,p_{\mathrm{Wa}}}(d; k, n, M, \tilde{p}_1, z, \sigma)$, follow from*

$$\begin{aligned} E_{p_{\mathrm{Wa}}}(X-\mu)^d &= \sum_{j=0}^{d} p_0^{(j)} (-1)^j \binom{z}{j} \left(1 - \frac{\sigma j}{z}\right) \sum_{i=0}^{j} (-1)^i \binom{j}{i} (z-\mu-i)^d \\ &+ \sigma \bar{p}_0 \sum_{j=0}^{d} \tilde{p}_0^j (-1)^j \binom{z-1}{j} \sum_{i=0}^{j} (-1)^i \binom{j}{i} ((z-\mu-i-1)^d - (z-\mu-i)^d)) \end{aligned} \tag{4.7}$$

using $\mu = 0$ and $\mu = zp_1 - \sigma(\bar{p}_1 - p_1)$, respectively.

Proof. The dth *raw moment* $E_{p_{\mathrm{Wh}}} X^d$ equals the dth derivative $G_{p_{\mathrm{Wh}}}^{(d)}(t)$ at $t = 0$. From (4.3) we obtain

$$G_{p_{\mathrm{Wh}}}^{(d)}(0) = \sum_{i=0}^{M} p_B(i; M, l/n) G_{p_B}^{(d)}(0; z, 1-\tilde{p}_0(1-k/m)^i),$$

where $G^{(d)}_{p_B}(0;N,1-Q) = \mathfrak{m}_{r,p_B}(d,N,1-Q) = \sum_{j=0}^{d} c_j^{(d)}(N)Q^j$ is the dth raw moment of the binomial probability (see (A.5)). For brevity we have defined coefficients $c_j^{(d)}(N) := (-1)^j\binom{N}{j}\sum_{k=0}^{j}(-1)^k\binom{j}{k}(N-k)^d$. Applying (A.9) we obtain

$$\begin{aligned} E_{p_{\mathrm{Wa}}}X^d &= \sum_{i=0}^{M} p_B(i;M,l/n)\sum_{j=0}^{d} c_j^{(d)}(z)\tilde{p}_0^j(1-k/m)^{ij} \\ &= \sum_{j=0}^{d} c_j^{(d)}(z)\tilde{p}_0^j\sum_{i=0}^{M} p_B(i;M,l/n)(1-k/m)^{ij} = \sum_{j=0}^{d} c_j^{(d)}(z)p_0^{(j)}. \end{aligned}$$

This proves the formulae for the raw moments $\mathfrak{m}_{r,p_{\mathrm{Wh}}}$, for example, (4.6) for $\mu = 0$. The general moment equation (4.6) with arbitrary offset μ follows then from inserting the raw moments into $E(X-\mu)^d = \sum_{i=0}^{d}\binom{d}{i}(-\mu)^{d-i}EX^i$, where we used the binomial sum (see below (A.9)) and the linearity of the expectation operator. Inserting $\mu = zp_1$ (see (4.1)) finally yields the central moments $\mathfrak{m}_{c,p_{\mathrm{Wh}}}$ for the hetero-associative Willshaw probability (see also (A.5); cf. [25]).

Similarly, the general moment equation (4.7) for auto-association follows with (3.41) because moments $E_{p(x)}(X-\mu)^d$ are linear in $p(x)$ and have the shifting property $E_{p(x-1)}(X-\mu)^d = \sum_x p(x-1)(x-\mu)^d = \sum_x p(x)(x-\mu+1)^d = E_{p(x)}(X-(\mu-1))^d$. In particular, summing the two Willshaw terms in (3.41) leads to the factor $(1-\sigma)\binom{z}{j} + \sigma\binom{z-1}{j} = \binom{z}{j}(1-\frac{\sigma j}{z})$ in (4.7). The raw and central moments $\mathfrak{m}_{r,p_{\mathrm{Wa}}}$ and $\mathfrak{m}_{c,p_{\mathrm{Wa}}}$ then follow from inserting $\mu = 0$ and $\mu = E_{p_{\mathrm{Wa}}}X$ (see (4.2)). □

The following lemma gives a more detailed characterization of the numbers $p_0^{(j)}$ that have been used to compute the moments of the Willshaw probability.

Lemma 4.3. *Let $p_0^{(j)}$ be as defined in Theorem 4.2. For $0 < P < 1$ we have*

$$R_j(P) := \frac{1}{P}\sum_{i=2}^{j}\binom{j}{i}(-P)^i = \frac{(1-P)^j - 1 + Pj}{P} \geq 0, \tag{4.8}$$

$$p_0 := 1 - p_1 = \tilde{p}_0\left(1 - \frac{kl}{mn}\right)^M, \tag{4.9}$$

$$p_0^{(j)} := \tilde{p}_0^j\left(1 - \frac{l}{n}\left(1 - \left(1 - \frac{k}{m}\right)^j\right)\right)^M = \tilde{p}_0^j\left(1 - \frac{kl}{mn}\left(j - R_j\left(\frac{k}{m}\right)\right)\right)^M \approx p_0^j. \tag{4.10}$$

For $j = 0, 1$ we have $R_j(P) = 0$ and $p_0^{(j)} = p_0^j$. For $j \geq 2$ we have $R_j(P) > 0$. For sufficiently small $P \to 0$ the bound $R_j(P) < \binom{j}{2}P$ becomes true. Furthermore, for $j \geq 2$ we have the bounds

$$p_0^j < p_0^{(j)} < p_0^{j-R_j(k/m)}, \tag{4.11}$$

$$0 < \frac{p_0^{(j)} - p_0^j}{p_0^j} < p_0^{-R_j(k/m)} - 1 < -(e-1)R_j(k/m)\ln p_0, \tag{4.12}$$

where the latter bound in (4.12) *is true only for $-R_j(k/m)\ln p_0 < 1$. In particular, the relative difference between $p_0^{(j)}$ and p_0^j vanishes for $R_j(k/m)\ln p_0 \to 0$. Finally, let $p := k/m \to 0$, $q := l/n$, $M = \ln p_0/\ln(1-pq)$ (see* (2.3)*). Then for $j^2p(1-\ln p_0) \to 0$,* *fixed* $\tilde{p}_1$*, and using the asymptotic* Θ *notation as defined in the appendix, we have*

$$p_0^{(j)} - p_0^j = -\binom{j}{2} p(1-q) p_0^j \ln p_0 + \Theta(j^3 p^2 p_0^j (1 - j \ln p_0) \ln p_0). \tag{4.13}$$

Proof. Equation (4.8) follows from the binomial sum (see below (A.9)). Equation (4.9) is simply rewriting (2.2) with $\tilde{p}_0 := 1 - \tilde{p}_1$ for the sake of completeness. Equation (4.10) follows from simple transformations of the definitions (4.5), (4.8). The claims for $j = 0, 1$ follow trivially. $R_j(P) > 0$ for $j \geq 2$ follows from $(1-P)^j > (1 - Pj)$ (see (A.11)). $R_j(P) < \binom{j}{2} P$ for $P \to 0$ follows directly from the definition of R_j. The lower bound in (4.11) follows from $(1 - kl/mn)^j = 1 - (kl/mn)(j - R_j(kl/mn))$ because $R_j(P)$ is monotonically increasing for $0 < P < 1$. The upper bound in (4.11) follows from $(1 - pq(j - R_j)) < (1-pq)^{j - R_j}$ (see (A.11) with $j - R_j > j - R_j(1) = 1$). Equation (4.12) follows from (4.11) and (A.12). We finally prove the asymptotic approximation equation (4.13): For $p \to 0$, $M = \ln p_0 / \ln(1 - pq)$ (see (2.3)) we have with (A.13)–(A.14)

$$M = \frac{-\ln p_0}{pq + \Theta(p^2 q^2)} = \frac{-\ln p_0}{pq} \frac{1}{1 + \Theta(pq)} = \frac{-\ln p_0}{pq}(1 + \Theta(pq)), \tag{4.14}$$

$$Mpq = -\ln p_0 + \Theta(pq \ln p_0), \tag{4.15}$$

$$R_j(p) = \binom{j}{2} p - \binom{j}{3} p^2 + \cdots = \binom{j}{2} p + \Theta(j^3 p^2) \to 0 \text{ for } j^2 p \to 0. \tag{4.16}$$

The final purpose of this is to find a close approximation for

$$p_0^{(j)} - p_0^j = p_0^j \left(\frac{p_0^{(j)}}{p_0^j} - 1 \right) \quad \text{with} \quad \frac{p_0^{(j)}}{p_0^j} = e^{M(\ln(1 - pq(j - R_j)) - j \ln(1 - pq))}. \tag{4.17}$$

For $R_j \to 0$ the term in the outer brackets of the exponential is written as $\ln(1 - pq(j - R_j)) - j \ln(1 - pq) = -pq(j - R_j) - \frac{p^2 q^2 (j - R_j)^2}{2} + \Theta(p^3 q^3 j^3) - j(-pq - \frac{p^2 q^2}{2} + \Theta(p^3 q^3)) = pqR_j - \frac{p^2 q^2}{2} \left((j - R_j)^2 - j \right) + \Theta(p^3 q^3 j^3)$. Here we have $(j - R_j)^2 - j = j^2 - j + \Theta(j R_j) = j^2 - j + \Theta(j^3 p)$ and therefore

$$\frac{p_0^{(j)}}{p_0^j} = e^{M(pqR_j - 0.5 p^2 q^2 (j^2 - j) + \Theta(p^3 q^2 j^3))} \tag{4.18}$$

$$= e^{M(p^2 q \binom{j}{2}(1-q) + \Theta(p^3 q j^3))} = e^{Mpq(p\binom{j}{2}(1-q) + \Theta(p^2 j^3))} \tag{4.19}$$

$$= e^{(-\ln p_0 + \Theta(pq \ln p_0))(p\binom{j}{2}(1-q) + \Theta(p^2 j^3))} = e^{-\binom{j}{2} p(1-q) \ln p_0 + \Theta(j^3 p^2 \ln p_0)} \tag{4.20}$$

$$= 1 - \binom{j}{2} p(1-q) \ln p_0 + \Theta(j^4 p^2 \ln^2 p_0 - j^3 p^2 \ln p_0) \tag{4.21}$$

$$= 1 - \binom{j}{2} p(1-q) \ln p_0 + \Theta(j^3 p^2 \ln p_0 (1 - j \ln p_0)). \qquad \square \tag{4.22}$$

4.3. Variance. Applying Theorem 4.2, we can easily compute the second raw and central moments of the Willshaw probability from the well-known second moments of the corresponding binomial probability $p_B(x; z, 1 - p_0)$ (see also (A.4)–(A.5)). Thus, replacing p_0^j by $p_0^{(j)}$ in

$$E_{p_{B(x;z,1-p_0)}} X^2 = z p_0 (1 - p_0) + z^2 (1 - p_0)^2 = z^2 + p_0 (z - 2z^2) + p_0^2 (z^2 - z) \tag{4.23}$$

gives us immediately the second moment and variance of the Willshaw probability p_{Wh} for *hetero-association*,

$$\begin{align} E_{p_{\mathrm{Wh}}} X^2 &= z^2 + p_0(z - 2z^2) + p_0^{(2)}(z^2 - z) \tag{4.24}\\ &= z^2(1 - 2p_0 + p_0^{(2)}) + z(p_0 - p_0^{(2)}), \tag{4.25}\\ \mathrm{Var}_{p_{\mathrm{Wh}}} X = E_{p_{\mathrm{Wh}}} X^2 - E^2_{p_{\mathrm{Wh}}} X &= z^2(p_0^{(2)} - p_0^2) + z(p_0 - p_0^{(2)}), \tag{4.26}\end{align}$$

where $p_0^{(2)} = \tilde{p}_0^2(1-(kl/mn)(2-k/m))^M$. Note that in (4.25), (4.26) all coefficients of z are positive since with (4.11) we have $p_0 > p_0^{2-k/m} > p_0^{(2)} > p_0^2$ and $1 - 2p_0 + p_0^{(2)} > (1 - p_0)^2 > 0$ for $0 < k/m, l/n < 1$. Thus, the variance increases monotonically with z. Indeed, the variance of the Willshaw probability scales with z^2, while the corresponding binomial variance scales only with z [21]. Applying (4.7) with $d = 2$, we easily obtain the second moments of the Willshaw probability p_{Wa} for *auto-association*,

$$\begin{align} E_{p_{\mathrm{Wa}}}(X - \mu)^2 = (z - \mu)^2 &- (2(z - \mu) - 1)(zp_0 - \sigma(p_0 - \bar{p}_0)) \nonumber\\ &+ (z - 1)((z - 2\sigma)p_0^{(2)} + 2\sigma\bar{p}_0\tilde{p}_0), \tag{4.27}\end{align}$$

$$\begin{align} \mathrm{Var}_{p_{\mathrm{Wa}}} X &= z^2(p_0^{(2)} - p_0^2) + z(p_0 - p_0^{(2)} - 2\sigma(p_0^{(2)} - p_0^2 - \bar{p}_0(\tilde{p}_0 - p_0))) \nonumber\\ &\qquad - \sigma(p_0 - 2p_0^{(2)} + \sigma(p_0 - \bar{p}_0)^2 + \bar{p}_0(2\tilde{p}_0 - 1)), \tag{4.28}\\ &= \mathrm{Var}_{p_{\mathrm{Wh}}} X - 2\sigma z(p_0^{(2)} - p_0^2 - \bar{p}_0(\tilde{p}_0 - p_0)) \nonumber\\ &\qquad - \sigma(p_0 - 2p_0^{(2)} + \sigma(p_0 - \bar{p}_0)^2 + \bar{p}_0(2\tilde{p}_0 - 1)). \tag{4.29}\end{align}$$

Here (4.27) is true for any offset μ. In particular, the second raw moment follows with $\mu = 0$, and the variance equation (4.28) follows with $\mu = E_{p_{\mathrm{Wa}}} X = z - zp_0 + \sigma(p_0 - \bar{p}_0)$ (see (4.2)).

4.4. Auto-association vs. hetero-association. As long as the dendritic potential distribution has a Gaussian shape, the variance determines retrieval quality, i.e., the larger the variance, the larger the error probabilities (e.g., see (3.42)). Thus, in order to answer the question whether retrieval quality is better for auto-association or hetero-association (with $k = l$ and $m = n$), the following lemma investigates the asymptotic behavior of the variances difference $\delta_{\mathrm{Var_{WaWh}}} := \mathrm{Var}_{p_{\mathrm{Wa}}} X - \mathrm{Var}_{p_{\mathrm{Wh}}} X$. To obtain general results, we fix the memory load $p_1 = p_{1\epsilon}$ to its maximum under quality constraint ϵ, as discussed in section 2.3 (see (2.15)).

Lemma 4.4. *For $p = k/n \to 0$, $\sigma/p \sim 1$, $z \sim k$, $p \ln p \ln k \to 0$, $z \sim k$, fixed $\tilde{p}_1$, and "hifi" memory load $1 - p_0 = p_{1\epsilon} = (\epsilon p)^{1/z}$ as in* (2.15), *we have*

$$\begin{align} \delta_{\mathrm{Var_{WaWh}}} &\approx 2\sigma z p p_0^2 \ln p_0 - \sigma(p_0 - 2p_0^2) \tag{4.30}\\ &\approx \begin{cases} +\sigma, & p_0 \to 1, \\ -\sigma p_0, & p_0 \to 0. \end{cases} \tag{4.31}\end{align}$$

Proof. We can apply (4.13) because $p \ln p \ln k \to 0$ implies $p \ln p_0 \to 0$ even for $p_0 \to 0$ with $p_0 \approx -\ln(\epsilon p)/z$ (see (2.20)). Thus, (4.30) follows from (4.29) because $p_0 - 2p_0^{(2)} \sim -pp_0^2 \ln p_0$ dominates over $\bar{p}_0 \sim e^{-Mp} = e^{(\ln p_0)/p} = p_0^{n/k}$ even for sparse potentiation with $p_0 \to 1$ and $\bar{p}_0 \sim (1 - (\epsilon k/n)^{1/z})^{n/k} \sim \exp(-(\epsilon k/n)^{1/z}(n/k))$, and similarly, $p_0 - 2p_0^{(2)} \approx p_0 - 2p_0^2$ dominates over $\sigma(p_0 - \bar{p}_0)^2 + \bar{p}_0(2\tilde{p}_0 - 1)$.

Equation (4.31) follows because for sparse potentiation with $p_0 \to 1$ we have $p_0^2 \ln p_0 \to 0$ and $zp \sim k^2/n \to 0$ (see (2.19)). Similarly, for dense potentiation with

$p_0 \to 0$ we have $-\sigma(p_0 - 2p_0^2) \approx -\sigma p_0$, and for $p_0 \approx -\ln(\epsilon p)/z$ (see (2.20)) we have $0 > 2\sigma z p p_0^2 \ln p_0 \approx 2\sigma p_0(-p\ln(\epsilon p)\ln z)$. $\square$

Thus, the auto-associative variance $\mathrm{Var}_{p_{\mathrm{Wa}}}X$ becomes larger than $\mathrm{Var}_{p_{\mathrm{Wh}}}X$ for sparse potentiation with $p_1 \to 0$, but smaller for dense potentiation with $p_1 \to 1$. However, remember from sections 3.4 and 3.2 that pattern part retrieval with $f = 0$ (i.e., no add-errors in the address pattern) implies $\sigma = 0$ and thus identical distributions for auto-association and hetero-association. Also, the following lemma shows that in general the differences between hetero-associative and auto-associative moments vanish asymptotically.

LEMMA 4.5. *For fixed d, $p = k/n \to 0$, $\sigma/p \sim 1$, $z \sim k$, $zp_1 \leq \mu \leq z$, $p\ln p_0 \to 0$, and "hifi" memory load $1 - p_0 = p_{1\epsilon} = (\epsilon p)^{1/z}$ as in* (2.15), *we have*

$$E_{p_{\mathrm{Wh}}}(X-\mu)^d - E_{p_{\mathrm{Wa}}}(X-\mu)^d \to 0. \tag{4.32}$$

Proof. The difference is identical to (4.7) (cf. (4.6)) except that the factor $(1-\frac{\sigma j}{z})$ in the first double sum becomes simply $\frac{\sigma j}{z} \sim \frac{j}{n}$. Thus, with (A.10) the absolute value of the first double sum becomes zero because

$$\left| \sum_{j=0}^{d} p_0^{(j)} (-1)^j \frac{\sigma j}{z} z^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} b_{di} (z-\mu-j)^{\underline{i-j}} \right|$$
$$\leq \sum_{j=0}^{d} p_0^{(j)} \frac{\sigma j}{z} z^j \sum_{i=j}^{d} \binom{i}{j} S_{di} (zp_0)^{i-j} \sim \frac{(zp_0)^d}{n} \to 0.$$

The inequality is true for large enough z with $d < z-\mu \leq z - zp_1 = zp_0$. The asymptotic approximations remain true even for small constant z where we used $p_0^{(j)} \sim p_0^j$ (see (4.12)). Note here that $z = O(\log n)$ implies sparse or balanced potentiation with $1 \geq p_0 \not\to 0$, while larger z implies dense potentiation with $p_0 \to 0$ and $zp_0 = O(\log n)$ (see (2.19), (2.20)). We still have to show that also the second double sum in (4.7) becomes zero:

$$\left| \sigma \bar{p}_0 \sum_{j=0}^{d} \tilde{p}_0^j (-1)^j \binom{z-1}{j} \sum_{i=0}^{j} (-1)^i \binom{j}{i} ((z-\mu-i-1)^d - (z-\mu-i)^d) \right|$$
$$\sim O\left(\frac{\bar{p}_0 z^{2d+1}}{n}\right) \to 0.$$

This is obvious for sparse and balanced potentiation when $z \sim k \sim O(\log n)$ (see (2.19)), but follows also for dense potentiation ($p_0 = O((\log n)/z) \to 0$; see (2.20)) since here $\bar{p}_0 \sim e^{-Mp} = e^{(\ln p_0)/p} = p_0^{n/k}$ quickly approaches zero. $\square$

5. Comparison of Willshaw–Palm to binomial distribution. In this section we compare the Willshaw–Palm probability distribution of the dendritic potentials (see Definition 3.1) to the corresponding binomial approximation $p_B(x; z, p_1)$, which assumes independently generated memory matrix entries (see section 2.3). In particular, we are interested in asymptotic conditions when the two probability distributions, as judged by their moments, become identical for maximal memory load (i.e., $p_1 = p_{1\epsilon}$ and $M = M_\epsilon$ as estimated by (2.15), (2.16)). This corresponds to correctness conditions for many previous results that rely on the binomial approximation equation (2.13) (see, e.g., [46, 34, 33, 37, 7, 38, 4, 43, 20]).

5.1. Difference in moments. For the difference $\Delta^{(d)}_{\mathrm{Wh}}$ between the dth moments of the *hetero-associative* Willshaw probability p_{Wh} and the corresponding binomial probability $p_B(x; z, 1-p_0)$ (see section 2.3), we obtain from (4.6), (A.5), (A.10)

$$\Delta^{(d)}_{\mathrm{Wh}}(\mu) := E_{p_{\mathrm{Wh}}}(X-\mu)^d - E_{p_B(x;z,1-p_0)}(X-\mu)^d \tag{5.1}$$

$$= \sum_{j=2}^{d} (p_0^{(j)} - p_0^j)(-1)^j \binom{z}{j} \sum_{i=0}^{j} (-1)^i \binom{j}{i} (z-\mu-i)^d \tag{5.2}$$

$$= \sum_{j=2}^{d} (p_0^{(j)} - p_0^j)(-1)^j z^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} S_{di} (z-\mu-j)^{\underline{i-j}}, \tag{5.3}$$

where μ is again an arbitrary offset (e.g., $\mu = 0$ for the raw moments and $\mu = zp_1$ for the central moments). Thus, $\Delta^{(d)}_{\mathrm{Wh}}$ has the same form as the dth binomial moment, written as a polynomial in p_0, but where powers p_0^j have been replaced by $p_0^{(j)} - p_0^j$ (see Theorem 4.2). Also note that $p_0^{(j)} = p_0^j$ for $j = 0, 1$ (see Lemma 4.3). The corresponding difference $\Delta^{(d)}_{\mathrm{Wa}}(\mu) := E_{p_{\mathrm{Wa}}}(X-\mu)^d - E_{p_{\mathrm{B}}(x;z,1-p_0)}(X-\mu)^d$ for the *auto-associative* Willshaw probability p_{Wa} can be obtained in a similar way from (4.7).

5.2. Difference in variance. A particularly interesting case is variance ($d = 2$): As long as the overall distribution of dendritic potentials resembles a Gaussian (which is often true, but see [19, 21, 23]), the retrieval error probabilities are essentially determined by the first two moments, i.e., expectation ($d = 1$) and variance ($d = 2$). Thus, it seems plausible to assume that a necessary condition for convergence of the Willshaw–Palm distribution towards a binomial is that expectation and variance become identical. For hetero-association, the expectations are already identical (equation (4.1)). Thus, it is sufficient to investigate conditions when the difference $\delta_{\mathrm{Wh}B}$ between the two variances vanishes. From (4.26), (4.23) we obtain for hetero-association

$$\delta_{\mathrm{Wh}B} := \mathrm{Var}_{p_{\mathrm{Wh}}} X - \mathrm{Var}_{p_B} X = z^2(p_0^{(2)} - p_0^2) + z(p_0 - p_0^{(2)}) - zp_0(1-p_0) \tag{5.4}$$

$$= (z^2 - z)(p_0^{(2)} - p_0^2) > 0. \tag{5.5}$$

Note that $\delta_{\mathrm{Wh}B}$ is always positive (see (4.11)). Thus, the binomial approximation always underestimates the variance of the dendritic potentials. Therefore the binomial approximation generally underestimates the probabilities of retrieval errors and overestimates storage capacity, at least if the Willshaw distribution comes close to a Gaussian, which is often true (cf. (3.48) for pattern part retrieval; but see [19, 21, 23]). With (4.12), (4.13) we obtain

$$\delta_{\mathrm{Wh}B} \le (z^2 - z)p_0^2(p_0^{-k/m} - 1) \approx -(z^2 - z)\frac{k}{m}\left(1 - \frac{l}{n}\right) p_0^2 \ln p_0, \tag{5.6}$$

where the approximation is true for $(k/m)(1 - \ln p_0) \to 0$ (see also (2.20)). Note that (5.6) can become zero for a very large parameter range under maximal memory load (see (2.19), (2.20)).

The analysis for auto-association is similar. The difference $\delta_{\mathrm{Wa}B} := \mathrm{Var}_{p_{\mathrm{Wa}}}(X) - \mathrm{Var}_{p_B}(X)$ can be obtained from (5.5) and (4.29). It is easy to see from (4.32) that in general $\delta_{\mathrm{Wa}B}$ vanishes asymptotically with $\delta_{\mathrm{Wh}B}$. In the following two sections we generalize our asymptotic considerations to higher-order moments.

5.3. Convergence of the raw moments. The following lemma determines asymptotic conditions when the dth raw moment of the Willshaw–Palm probability p_{Wh} becomes identical to the dth raw moment of the corresponding binomial probability $p_B(x;z,1-p_0)$, i.e., conditions when the difference $\Delta^{(d)}_{\mathrm{Wh}}(0) := E_{p_{\mathrm{Wh}}}X^d - E_{p_B(x;z,1-p_0)}X^d$ becomes zero.

LEMMA 5.1. *For fixed d and $(k/m)\ln p_0 \to 0$ the following bounds become asymptotically true:*

$$|\Delta^{(d)}_{\mathrm{Wh}}(0)| \le \sum_{j=2}^{d} (p_0^{(j)} - p_0^j) z^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} S_{di} (z-j)^{\underline{i-j}} \tag{5.7}$$

$$\le -(e-1)\frac{k}{m}\sum_{j=2}^{d}\binom{j}{2} z^{\underline{j}} p_0^j \ln p_0 \sum_{i=j}^{d}\binom{i}{j} S_{di}(z-j)^{\underline{i-j}} \tag{5.8}$$

$$\le -d^2\frac{k}{m} z^d p_0^2 \ln p_0 \sum_{j=2}^{d}\sum_{i=j}^{d}\binom{i}{j} S_{di} \sim \frac{k}{m} z^d p_0^2 \ln p_0 \le \frac{kz^d}{m}. \tag{5.9}$$

Proof. The lemma follows from (5.3), (4.12), and $R_j(k/m) < \binom{j}{2}(k/m)$ (see Lemma 4.3). □

Thus, the raw moments of the Willshaw–Palm probability p_{Wh} and the corresponding binomial probability $p_B(x;z,1-p_0)$ become identical if the address pattern activities $k := |\mathbf{u}^\mu|$ and $z := |\tilde{\mathbf{u}}|$ grow at most polynomial in the logarithm $\log m$ of the address population size m.

In the following section we will see that even for larger $k(m)$ the two probability distributions can still become essentially identical as judged by the difference of the *central* moments. The reason for this effect can be easily explained: Consider two probability distributions p_A and p_B with zero mean values and $\delta(x) := p_A(x) - p_B(x) \to 0$ and also $\delta(x)/p_A(x) \to 0$ and $\delta(x)/p_A(x) \to 0$ for any x. Then assume that the dth (central) moments converge, i.e., $\sum x^d \epsilon(x) \to 0$. Then it is still possible that the corresponding distributions p'_A and p'_B with mean $\mu > 0$ have diverging moments because $\sum (x+\mu)^d \epsilon(x)$ can grow arbitrarily with μ. This is the motivation to have a closer look at the convergence of the central moments in the following section.

5.4. Convergence of the central moments. Here we determine asymptotic conditions when the dth *central* moments of the Willshaw–Palm probabilities p_{Wh} and p_{Wa} become identical to the dth central moment of the corresponding binomial probability $p_B(x;z,1-p_0)$, i.e., conditions when $\Delta^{(d)}_{\mathrm{Wh}}(\mu)$ and $\Delta^{(d)}_{\mathrm{Wa}}(\mu)$ become zero (see section 5.1).

LEMMA 5.2. *For fixed d, $(k/m)\ln p_0 \to 0$, and $d < z - \mu \le z - zp_1 = zp_0$ the following bounds become asymptotically true:*

$$|\Delta^{(d)}_{\mathrm{Wh}}(\mu)| \le \sum_{j=2}^{d} (p_0^{(j)} - p_0^j) z^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} S_{di} (z-\mu-j)^{\underline{i-j}} \tag{5.10}$$

$$\le -(e-1)\frac{k}{m}\sum_{j=2}^{d}\binom{j}{2} z^{\underline{j}} p_0^j \ln p_0 \sum_{i=j}^{d}\binom{i}{j} S_{di}(zp_0)^{\underline{i-j}} \tag{5.11}$$

$$\le -(e-1)\frac{k}{m}\sum_{j=2}^{d}\binom{j}{2} \ln p_0 \sum_{i=j}^{d}\binom{i}{j} S_{di}(zp_0)^{i} \tag{5.12}$$

$$(5.13) \qquad \leq -d^2 \frac{k}{m}(zp_0)^d \ln p_0 \sum_{j=2}^{d} \sum_{i=j}^{d} \binom{i}{j} S_{di} \sim \frac{-k(zp_0)^d \ln p_0}{m}.$$

Proof. The lemma follows from (5.3), (4.12), and $R_j(k/m) < \binom{j}{2}(k/m)$ (see Lemma 4.3). □

With this we can easily find asymptotic convergence conditions for maximal memory load as approximately analyzed in section 2.3.

THEOREM 5.3. *For maximal memory load as estimated by the binomial approximation* (2.13)*, i.e., for $p_1 = p_{1\epsilon}$ and $M = M_\epsilon$ as estimated by* (2.15), (2.16)*, the dth central moment of the Willshaw–Palm probability p_{Wh} becomes identical to the dth central moment of the corresponding binomial probability $p_B(x; z, p_{1\epsilon})$, i.e.,*

$$(5.14) \qquad \Delta_{\mathrm{Wh}}^{(d)}(zp_{1\epsilon}) \to 0 \quad \textit{if} \quad \frac{k(\ln \frac{n}{\epsilon l})^d \ln z}{m} \to 0.$$

Thus, for n polynomial in m the dth central moments converge at least for $k = O(m/\log^{d+2} m)$. In particular, the variances converge at least for $k = O(m/\log^4 m)$. Moreover, all *central moments converge, and therefore the Willshaw probability p_{Wh} becomes identical to the binomial approximation, at least for $k = O(m^P)$ with fixed $P < 1$.*

Proof. For $zp_{0\epsilon} \to \infty$ with $p_{0\epsilon} := 1 - p_{1\epsilon}$, the theorem follows from Lemma 5.2 by using $zp_{0\epsilon} \sim \log(n/(\epsilon l))$ (see (2.20)). For smaller (e.g., constant) z the convergence of the central moments follows already from the convergence of the raw moments (see Lemma 5.1). □

A particular case are "symmetric" networks with $m = n$ and $k = l$, for example, for auto-association. It turns out that for such networks the range of convergence is even larger: Assume $k = n/\ln^P n$. Then the convergence condition in (5.14) becomes $(k/n)(\ln((\ln^P n)/\epsilon))^d \ln n \to 0$. Thus, here the central moments converge at least for $k = O(n/\log^2 n)$. Note that the results for hetero-association apply also to auto-association due to Lemma 4.5. Together these considerations suggest that the theoretical results on neural associative networks apply to a much larger range than assumed previously [34, 38, 19]. This includes large portions of the dense potentiation regime with $k/\log n \to \infty$ (see section 2.4). Here previous analyses relying on the binomial approximation have suggested the potential for very efficient computer implementations and new biological hypotheses about the roles of structural plasticity and inhibitory neurons [22, 24].

5.5. Numerical evaluations. The results of this section are verified by Figure 5.1, which shows data from numerical experiments testing how well the binomial theory approximates exact values. In fact, the reliability of the binomial approximation depends both on the network size (n) and the pattern activity (k). In general, the binomial theory becomes better for larger n and smaller k. The approximations of pattern capacity M_ϵ (equation (2.16)) and network capacity C_ϵ (equation (2.17)) are comparably reliable and, even for linear $k = n/2$ and small n, overestimate the true values by less than a factor of two (Figure 5.1a).

However, the derived "compression capacities" C^I and C^S depend on the maximal memory load $p_{1\epsilon}$ (or $1 - p_{1\epsilon}$; see sections 2.2 and 2.4), which can be strongly overestimated by the binomial theory (Figure 5.1b). For linear $k \sim n$ the relative error seems to grow without bound, implying $C^I \to 0$ and possibly $C^S \to 0$. Nevertheless, for smaller k the binomial approximation is much better already for realistic

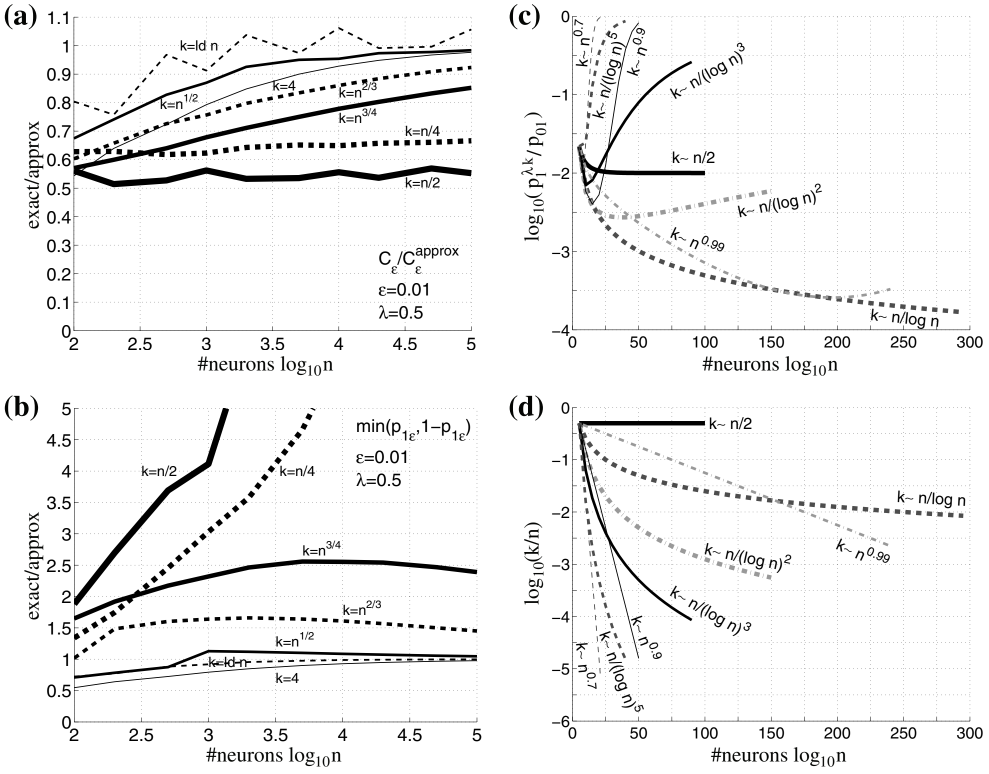

FIG. 5.1. *Numerical experiments comparing the binomial approximative analysis to the exact theory for $m = n$, $k = l$, $\tilde{p}_1 = 0$, $\epsilon = 0.01$, and pattern part retrieval with half addresses ($\lambda = 0.5$).* (a) *Relative approximation error for network storage capacity, $C_\epsilon/C_\epsilon^{\text{approx}}$ (see* (2.10), (2.17)*). Each curve corresponds to a particular pattern activity function $k(n)$ growing with the neuron number n (log-scale) as indicated in the plots. Relative errors for pattern capacity M_ϵ are virtually identical.* (b) *Relative approximation error for the memory load $p_{1\epsilon}$ at maximal pattern load M_ϵ (see* (2.9), (2.2)*), similar to panel* (a)*. More exactly, the plots show* $\min(p_{1\epsilon}, 1-p_{1\epsilon})/\min(p_{1\epsilon}^{\text{approx}}, 1-p_{1\epsilon}^{\text{approx}})$, *where $p_{1\epsilon}^{\text{approx}}$ is the approximation* (2.15)*. The corresponding approximation errors for the related compression capacities C_ϵ^I and C_ϵ^S (see section* 2.4*) look qualitatively very similar (cf.* [23]*).* (c) *Relative approximation error (log-scale) for the retrieval error probability* p_{01} *(see* (2.13), (3.47)*) when storing M_ϵ patterns approximated by* (2.16)*. Each curve corresponds to a particular function $k(n)$ with $k(10^5) = 50000$. Each case was evaluated for increasing n until a maximal computation time was reached (about* 50*h per data point on a* 2.4*GHz AMD Opteron processor evaluating relevant summands of* (3.47) *with computing precision* 1000*bit (see* [23] *for further details). The plots indicate convergence $p_1^{\lambda k}/p_{01} \to 1$ for $k = O(n/\log^2 n)$, but divergence for $k \sim n/\log n$, thus verifying the theoretical results of section* 5.4. (d) *Actual pattern activities k/n (log-scale) corresponding to panel* (c).

network sizes. For example, for $n = 10^5$ the information capacity C^I is about 100% of the binomial estimate for constant $k = 4$, 95% for $k = n^{1/2}$, 70% for $k = n^{2/3}$, and still 40% for $k = n^{3/4}$ (similar values for C^S; data not shown). Interestingly, the binomial approximations first become worse with growing n until a turning point is reached (e.g., $n = 10^4$ for $k = n^{3/4}$), and only then approach finally the exact values.

Figure 5.1c, d shows results for very large network size n and comparably large pattern activities $k(n)$. For near linear $k(n)$ the turning points are reached only for n too large to be useful for applications or relevant for biology. Nevertheless, for smaller pattern activities, for example, $k = O(n^{0.8})$, the convergence is much faster. Turning points as described above are still visible for $k = O(n/\log^2 n)$, but seem absent for

$k \sim n/\log n$. Thus, the numerical experiments are consistent with the theoretical bound derived at the end of section 5.4.

6. Conclusions.

Theories on neural associative networks with binary synapses often use a binomial approximation of the dendritic potential distribution to estimate retrieval error probabilities and performance measures such as storage capacity or retrieval speed [46, 34, 37, 33, 4, 43, 20]. However, for finite network size n or patterns with a relatively large number of active units k this approximation can be very inaccurate. So far, the convergence of the binomial approximation to the true potential distribution and thus the asymptotic correctness of the classical theory has been demonstrated only for some special cases involving very sparse activity patterns, where a binary pattern vector of n neurons contains on average only $k = \log n$ or $k \leq n^{1/3}$ active units [34, 38]. This appeared sufficient because it was believed that neural associative networks would be efficient only for extreme sparseness anyway [34, 43]. In contrast, recent applications of the theory to problems requiring less sparse patterns has gained increased attention for a number of reasons described in the introduction. For example, theoretical analyses based on the binomial approximation suggest that associative networks can operate very efficiently for large pattern activities with $k/\log n \to \infty$ (or equivalently "dense potentiation" with memory load $p_1 \to 1$) if the synaptic matrix is adequately compressed [18, 19, 20, 22]. However, the correctness of these results has been doubted because it remained unclear whether the binomial approximation is sufficiently good for large pattern activity $k(n)$.

Here I have solved this problem. For this it was necessary to compute general expressions for the true potential distribution by defining different versions of the Willshaw–Palm probability including hetero-association, auto-association, and fixed and random pattern activities (see section 3). I then focused on the characterization of the probability distributions for random pattern activities. This involved computation of the raw and central moments of the Willshaw–Palm probability (section 4) from the corresponding moments of the binomial probability [25]. Finally, I have investigated the convergence of the two probabilities by determining conditions when the moments become identical. The analysis reveals that the moments become identical for almost any sublinear sparseness, for example, $k = O(n/(\log n)^2)$ (see section 5.4), and thus verifies the theory on associative networks for large pattern activities.

Appendix. Lemmas.

The following lemmas are required to prove the claims in this work. Proofs of the lemmas can be found in a technical report [23, 25] or in the standard literature of information theory, combinatorics, analysis, and probability theory (see, e.g., [9, 39]).

Let $X \in \{0, 1\}$ be a *binary* random variable with $p := \mathrm{pr}[X = 1]$ and information $I(p) := -p \,\mathrm{ld}\, p - (1 - p) \,\mathrm{ld}(1 - p)$. Further let Y be the result of transmitting X over a binary memoryless channel with transmission error probabilities $p_{01} := \mathrm{pr}[Y = 1|X = 0]$ and $p_{10} := \mathrm{pr}[Y = 0|X = 1]$. Then the *transinformation* between X and Y is

$$T(X;Y) = T(p, p_{01}, p_{10}) := I_Y(p, p_{01}, p_{10}) - I_{Y|X}(p, p_{01}, p_{10}), \tag{A.1}$$

where $I_Y(p, p_{01}, p_{10}) := I\left(p\,(1 - p_{10}) + (1 - p)\,p_{01}\right)$ is the information (or entropy) of Y and $I_{Y|X}(p, p_{01}, p_{10}) := p \cdot I(p_{10}) + (1 - p) \cdot I(p_{01})$ is the information of Y given X.

Now let $X \in \{0, 1, \ldots, N\}$ be a *binomially* distributed random variable with parameters N and P. Then X has expectation $E_{p_B} X = NP$, and the probability and moment generating functions are

$$\mathrm{pr}[X = x] = p_B(x; N, P) := \binom{N}{x} P^x (1-P)^{N-x}, \tag{A.2}$$

$$G_{p_B}(t; N, P) := E_{p_B} e^{tX} = (Pe^t + (1-P))^N. \tag{A.3}$$

Furthermore, substituting $Q := 1 - P$, it has been proven in [25] that the dth raw and central moments of X can be written as polynomials in Q,

$$\mathfrak{m}_{r,p_B}(d, N, P) := E_{p_B} X^d = \sum_{j=0}^{d} (-Q)^j \sum_{i=j}^{d} \binom{i}{j} S_{di} N^{\underline{i}} \quad \text{with} \tag{A.4}$$

$$E_{p_B}(X-\mu)^d = \sum_{j=0}^{d} (-Q)^j \binom{N}{j} \sum_{k=0}^{j} (-1)^k \binom{j}{k} (N-\mu-k)^d, \tag{A.5}$$

where $N^{\underline{i}} := N(N-1)\cdots(N-i+1)$ denotes a falling factorial, $S_{di} \geq 0$ are Stirling numbers of the second kind, and μ is an arbitrary offset. For $\mu = NP$, (A.5) yields the dth central moment $\mathfrak{m}_{c,p_B}(d, N, P)$ of the binomial probability. For $\mu = 0$, (A.5) becomes identical to the raw moment equation (A.4) [25]. The following lemma is the sieve formula of Sylvester and Poincaré:

$$\mathrm{pr}\left(\bigcup_{k=1}^{n} A_i\right) = \sum_{k=1}^{n} (-1)^{k+1} \sum_{1 \leq i_1 < \cdots < i_k \leq n} \mathrm{pr}\left(\bigcap_{h=1}^{k} A_{i_h}\right). \tag{A.6}$$

The following combinatorial equations are true:

$$\binom{Y}{s-N} = \sum_{t=0}^{N} (-1)^{N+t} \binom{Y+t}{s} \binom{N}{t}, \tag{A.7}$$

$$\binom{n}{m}\binom{m}{p} = \binom{n}{p}\binom{n-p}{m-p} = \binom{n}{m-p}\binom{n-m+p}{p}, \tag{A.8}$$

$$\sum_{i=0}^{M} p_B(i; M, Q) \cdot (1-P)^{Ji} = (1 - Q(1-(1-P)^J))^M, \tag{A.9}$$

$$\binom{N}{j} \sum_{i=0}^{j} (-1)^i \binom{j}{i} (n-\mu-i)^d = N^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} S_{di} (N-\mu-j)^{\underline{i-j}}\ . \tag{A.10}$$

Equation (A.8) implies $B(a,b,c) = B(a,c,b)$ or $\binom{a}{b}\binom{a-b}{c} = \binom{a}{c}\binom{a-c}{b}$. Equation (A.9) is a variant of the binomial sum $(A+B)^M = \sum_{i=0}^{M} \binom{M}{i} A^i B^{M-i}$. For a proof of (A.10) see Lemma 3.1 in [25]. Here $N^{\underline{i}}$ denotes again a falling factorial, and $S_{di} \geq 0$ denotes Stirling numbers of the second kind.

Then we have used the bounds

$$(1-pq) \gtrless (1-p)^q \quad \text{for} \quad p \in (0;1) \quad \text{and} \quad q \substack{\in \\ \notin} (0;1), \tag{A.11}$$

$$1 + x \leq e^x \leq 1 + (e-1)x \quad \text{for} \quad 0 \leq x \leq 1, \tag{A.12}$$

where the first bound in (A.12) is true for any x. Finally, the following asymptotic equations are true for $n \to \infty$ with $|x(n)|, |y(n)| \to 0$:

$$e^x = 1 + x + \Theta(x^2), \qquad \ln(1+x) = x + \Theta(x^2), \tag{A.13}$$

$$e^{x+\Theta(y)} = 1 + x + \Theta(x^2) + \Theta(y), \qquad \frac{1}{1+x} = 1 - x + \Theta(x^2), \tag{A.14}$$

where for a function $f(n)$ we write $f(n) = \Theta(g(n))$ iff there are constants c_1, c_2, n_0 such that for any $n > n_0$ we have $c_1 g(n) < f(n) < c_2 g(n)$.

Acknowledgments. The author is grateful to Edgar Körner and Marc-Oliver Gewaltig for providing the opportunity to do this work at the Honda Research Institute, and also to Friedrich Sommer and Günther Palm for helpful discussions and comments.

CLOSED-FORM EXPRESSIONS FOR THE MOMENTS OF THE BINOMIAL PROBABILITY DISTRIBUTION[*]

ANDREAS KNOBLAUCH[†]

Abstract. This work develops closed-form expressions for the raw and central moments of the binomial probability distribution. For this I first derive a recursive formula for the raw moments from the moment generating function. Then it is shown that the recursion involved is essentially the same as for the Stirling numbers of the second kind. From this fact it is then possible to derive the closed formulae. Finally, I discuss an application of these formulae to the analysis of neural associative memory.

Key words. Stirling numbers, Pochhammer polynomial, neural associative memory, storage capacity, retrieval errors

1. The binomial probability and its moments. A random variable X is called *binomially distributed* with parameters n and p if the random variable takes value $x \in \{0, 1, 2, \ldots, n\}$ with probability

$$p_B(x; n, p) = \binom{n}{x} p^x (1-p)^{n-x}. \tag{1.1}$$

The *moment generating function* $G_B(s) := E_{p_B} e^{sX}$ of the binomial probability can then be computed using the binomial sum $(a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k}$,

$$G_B(s; n, p) = \sum_{x=0}^{n} \binom{n}{x} (pe^s)^x (1-p)^{n-x} = (pe^s + 1 - p)^n. \tag{1.2}$$

The dth *raw moment* $E_{p_B} X^d$ equals the dth derivative of the generating function $G_B(s)$ at $s = 0$ (e.g., [14]). For example, the mean value is $\mu := E_{p_B} X = n(pe^s + 1 - p)^{n-1} pe^s|_{s=0} = np$ and the second raw moment is $E_{p_B} X^2 = np((n-1)(pe^s + 1 - p)^{n-2} pe^s + (pe^s + 1 - p)^{n-1} e^s)|_{s=0} = np(np + 1 - p)$. Higher-order moments for larger d can be computed, in principle, by continuing this procedure, but computing higher-order derivatives of $G_B(s)$ becomes tedious with increasing d. In the following, we aim to find a recursive formula without referring to higher-order derivatives of $G_B(s)$ (see also [2] for a related approach).

2. Recursive formulae. To compute the higher-order derivatives of the moment generating function $G_B(s)$ for larger d, we can define auxiliary functions

$$H_d(s) := (pe^s)^d \text{ with derivative } H'_d(s) = dH_d(s), \tag{2.1}$$

$$F_d(s) := n^{\underline{d}} G_B(s; n-d, p) \text{ with derivative} \tag{2.2}$$

$$F'_d(s) = n^{\underline{d+1}} (pe^s + 1 - p)^{n-d-1} H_1(s) = F_{d+1}(s) H_1(s), \text{ and} \tag{2.3}$$

$$K_d(s) := F_d(s) H_d(s) \text{ with derivative} \tag{2.4}$$

$$K'_d(s) = F'_d(s) H_d(s) + dF_d(s) H_d(s) = K_{d+1}(s) + dK_d(s), \tag{2.5}$$

where $n^{\underline{d}} = n(n-1)\cdots(n-d+1)$ denotes a falling factorial or Pochhammer symbol. Since $G_B(s) = K_0(s)$, we can obtain the higher-order derivatives of the moment generating function $G_B(s)$ recursively from (2.5), for example, $G_{p_B}^{(0)} = K_0$, $G_{p_B}^{(1)} = K_1$, $G_{p_B}^{(2)} = K_2 + K_1$, $G_{p_B}^{(3)} = K_3 + 2K_2 + K_2 + K_1 = K_3 + 3K_2 + K_1$. Thus, we can prove the following.

Lemma 2.1. *The dth derivative $G_B^{(d)}$ of the moment generating function $G_B(s)$ of the binomial probability $p_B(x; n, p)$ can be written as a weighted sum of functions $K_i(s)$:*

$$G_{p_B}^{(d)}(s) = \sum_{i=0}^{d} b_{di} K_i(s) \tag{2.6}$$

for appropriate coefficients b_{di}. The coefficients can be computed recursively from

$$b_{0i} = \delta_{i0}, \tag{2.7}$$

$$b_{di} = i b_{d-1,i} + b_{d-1,i-1}, \tag{2.8}$$

where δ_{ij} is the usual Kronecker symbol (1 for $i = j$, and 0 otherwise). For convenience, we further define $b_{di} = 0$ for $d < 0$, $i < 0$, or $i > d$.

Proof. Equation (2.7) follows from $G_B^{(0)} = K_0$ (see (2.4)). Equation (2.8) can then be shown inductively using (2.6) with (2.5):

$$\begin{aligned} G_{p_B}^{(d+1)}(s) &= \sum_{i=0}^{d} b_{di}(K_{i+1} + iK_i) = \sum_{i=1}^{d+1} b_{d,i-1} K_i + \sum_{i=0}^{d} b_{di} i K_i \\ &= \sum_{i=0}^{d+1} (i b_{di} + b_{d,i-1}) K_i. \qquad \square \end{aligned}$$

From this lemma and $K_i(0) = n^{\underline{i}} p^i$, we can give recursive formulae for the raw and central moments as summarized by the following theorem.

Theorem 2.2. *The dth raw and central moment of a binomially distributed random variable X with $\mathrm{pr}[X = x] = p_B(x; n, p)$, expectation $\mu := np$, and $q := 1 - p$ are*

$$E_{p_B} X^d = \sum_{i=0}^{d} b_{di} p^i n^{\underline{i}} \tag{2.9}$$

$$= \sum_{j=0}^{d} (-q)^j \sum_{i=j}^{d} \binom{i}{j} b_{di} n^{\underline{i}}, \tag{2.10}$$

$$E_{p_B}(X - \mu)^d = \sum_{i=0}^{d} \binom{d}{i} (-\mu)^{d-i} E_{p_B} X^i. \tag{2.11}$$

Equations (2.10), (2.11) can be obtained from the binomial sum (see section 1). Equation (2.10) is written as polynomial in q, which is useful for some applications (see section 5). The first few values of the coefficients b_{di} are shown in Table 2.1.

Table 2.1

Values of the binomial moment coefficients b_{di} for $0 \le d, i \le 10$. These coefficients can be used to compute the moments of the binomial probability (see (2.9)*) and are identical to the Stirling numbers of the second kind (see section* 3*).*

b_{di}	$i=0$	1	2	3	4	5	6	7	8	9	10
$d=0$	1	0	0	0	0	0	0	0	0	0	0

3. Relation to Stirling numbers of the second kind. The coefficients b_{di} for computing the binomial moments (2.9) are actually Stirling numbers of the second kind: The Stirling number of the second kind $S(d,i)$ is defined as the number of ways of partitioning a set of d elements into i nonempty sets, and one can show that $S(d,i)$ obeys the same recurrence relations (2.7), (2.8) as b_{di} (e.g., [1, 17, 9]). Closed formulae for the Stirling numbers of the second kind are well known, for example,

$$b_{di} = S(d,i) = \frac{(-1)^i}{i!} \sum_{k=0}^{i} (-1)^k \binom{i}{k} k^d. \tag{3.1}$$

Thus, inserting this into the formulae of Theorem 2.2 gives us already closed-form expressions for the moments of the binomial probability. However, these formulae can still be simplified using a generalization of the following generating function (e.g., see [17]):

$$n^d = \sum_{i=0}^{d} b_{di} n^{\underline{i}}. \tag{3.2}$$

The generalization is given by the following lemma.

Lemma 3.1.

$$\sum_{i=j}^{d} \binom{i}{j} b_{di} n^{\underline{i}} = \binom{n}{j} \sum_{k=0}^{j} (-1)^k \binom{j}{k} (n-k)^d. \tag{3.3}$$

Proof. Instead of (3.3), we prove the equivalent equation

$$C(d,j,n) := \sum_{i=j}^{d} i^{\underline{j}} b_{di} n^{\underline{i}} = n^{\underline{j}} \sum_{k=0}^{j} (-1)^k \binom{j}{k} (n-k)^d \tag{3.4}$$

by induction over j. For $j=0$, the lemma is identical to (3.2). For larger j, we compute, using $ib_{di} = b_{d+1,i} - b_{d,i-1}$ (see (2.8)),

$$\begin{aligned} C(d,j+1,n) &= \sum_{i=j+1}^{d} i^{\underline{j+1}} b_{di} n^{\underline{i}} = \sum_{i=j+1}^{d} i^{\underline{j}} i b_{di} n^{\underline{i}} - j \sum_{i=j+1}^{d} i^{\underline{j}} b_{di} n^{\underline{i}} \\ &= \sum_{i=j+1}^{d} i^{\underline{j}} b_{d+1,i} n^{\underline{i}} - \sum_{i=j+1}^{d} i^{\underline{j}} b_{d,i-1} n^{\underline{i}} - j \sum_{i=j+1}^{d} i^{\underline{j}} b_{di} n^{\underline{i}}. \end{aligned}$$

The three sums can be written individually:

$$\begin{aligned}
S_1 &:= \sum_{i=j+1}^{d} i^{\underline{j}} b_{d+1,i} n^{\underline{i}} = C(d+1,j,n) - j! b_{d+1,j} n^{\underline{j}} - (d+1)^{\underline{j}} n^{\underline{d+1}},\\
S_2 &:= \sum_{i=j+1}^{d} i^{\underline{j}} b_{d,i-1} n^{\underline{i}}\\
&= n \sum_{i=j+1}^{d} (i-1)^{\underline{j}} b_{d,i-1} (n-1)^{\underline{i-1}} + jn \sum_{i=j+1}^{d} (i-1)^{\underline{j-1}} b_{d,i-1} (n-1)^{\underline{i-1}}\\
&= n \sum_{i=j}^{d-1} i^{\underline{j}} b_{d,i} (n-1)^{\underline{i}} + jn \sum_{i=j}^{d-1} i^{\underline{j-1}} b_{d,i} (n-1)^{\underline{i}}\\
&= nC(d,j,n-1) - nd^{\underline{j}}(n-1)^{\underline{d}}\\
&\quad + jnC(d,j-1,n-1) - jn(j-1)^{\underline{j-1}} b_{d,j-1}(n-1)^{\underline{j-1}} - jnd^{\underline{j-1}}(n-1)^{\underline{d}},\\
S_3 &:= j \sum_{i=j+1}^{d} i^{\underline{j}} b_{di} n^{\underline{i}} = jC(d,j,n) - jj^{\underline{j}} b_{dj} n^{\underline{j}},
\end{aligned}$$

where we used $b_{dd} = 1$ for $d \geq 0$. For the second sum, S_2, we used $i^{\underline{j}} = ((i-j)+j)(i-1)^{\underline{j-1}}$. Fortunately, in $S_1 - S_2 - S_3$ all the non-C terms cancel out: The b terms cancel out because with $b_{d+1,j} = jb_{d,j} + b_{d,j-1}$ from (2.8), we have

$$-j!n^{\underline{j}} b_{d+1,j} + j!n^{\underline{j}} b_{d,j-1} + jj!n^{\underline{j}} b_{dj} = j!n^{\underline{j}}(-b_{d+1,j} + b_{d,j-1} + jb_{dj}) = 0.$$

The remaining non-C and non-b terms cancel out because

$$-(d+1)^{\underline{j}} n^{\underline{d+1}} + d^{\underline{j}} n^{\underline{d+1}} + jd^{\underline{j-1}} n^{\underline{d+1}} = n^{\underline{d+1}} d^{\underline{j-1}}(-(d+1) + (d-j+1) + j) = 0.$$

Thus, using the induction hypothesis, we have simply

$$\begin{aligned}
C(d,j+1,n) &= C(d+1,j,n) - nC(d,j,n-1) - jnC(d,j-1,n-1) - jC(d,j,n)\\
&= n^{\underline{j}} \sum_{k=0}^{j} \binom{j}{k} (-1)^k (n-k)^{d+1}\\
&\quad - n(n-1)^{\underline{j}} \sum_{k=0}^{j} \binom{j}{k} (-1)^k (n-(k+1))^d\\
&\quad - jn(n-1)^{\underline{j-1}} \sum_{k=0}^{j-1} \binom{j-1}{k} (-1)^k (n-(k+1))^d\\
&\quad - jn^{\underline{j}} \sum_{k=0}^{j} \binom{j}{k} (-1)^k (n-k)^d\\
&= \sum_{k=0}^{j+1} a_k (n-k)^d.
\end{aligned}$$

In the last line we have simply summed over the $(n-k)^d$ terms. Thus, our proof is finished if we can show that $a_k = n^{\underline{j+1}}\binom{j+1}{k}(-1)^k$ for $k = 0, 1, \ldots, j+1$. The highest coefficient a_{j+1} gets contributions only from the second sum:

$$a_{j+1} = -n^{\underline{j+1}}(-1)^j(n-(j+1))^d = n^{\underline{j+1}}\binom{j+1}{j+1}(-1)^k.$$

The lowest coefficient a_0 gets contributions only from the first and fourth sums:

$$a_0 = n^{\underline{j}}n - jn^{\underline{j}} = n^{\underline{j+1}} = n^{\underline{j+1}}\binom{j+1}{0}(-1)^0.$$

The remaining intermediary coefficients a_k for $k = 1, 2, \dots, j$ get contributions from all four sums:

$$\begin{aligned} a_k &= n^{\underline{j}}\binom{j}{k}(-1)^k(n-k) - n^{\underline{j+1}}\binom{j}{k-1}(-1)^{k-1} \\ &\quad - jn^{\underline{j}}\binom{j-1}{k-1}(-1)^{k-1} - jn^{\underline{j}}\binom{j}{k}(-1)^k \\ &= (-1)^k n^{\underline{j}}\binom{j}{k}\left((n-k)+(n-j)\frac{k}{j-k+1}+j\frac{k}{j}-j\right) \\ &= (-1)^k n^{\underline{j}}\binom{j}{k}\frac{(n-j)(j+1)}{j-k+1} = n^{\underline{j+1}}\binom{j+1}{k}(-1)^k. \end{aligned}$$

Thus, we have proven (3.4). □

A useful variant of Lemma 3.1, including an offset μ, is

$$\binom{n}{j}\sum_{k=0}^{j}(-1)^k\binom{j}{k}(n-\mu-k)^d = n^{\underline{j}}\sum_{i=j}^{d}\binom{i}{j}b_{di}(n-\mu-j)^{\underline{i-j}}. \tag{3.5}$$

4. Closed formulae. The following theorem summarizes the main results of this work.

THEOREM 4.1. *Let X be a binomially distributed random variable with probability function $p_B(x; n, p)$ (see* (1.1)*). Further, let $q := 1 - p$ and let b_{di} be Stirling numbers of the second kind (see Table* 2.1 *and* (2.7), (2.8), *and* (3.1)*). Then the dth raw moment of the binomial probability p_B can be written as*

$$E_{p_B}X^d = \sum_{i=0}^{d} b_{di}p^i n^{\underline{i}} \tag{4.1}$$

$$= \sum_{i=0}^{d}(-p)^i\binom{n}{i}\sum_{k=0}^{i}(-1)^k\binom{i}{k}k^d \tag{4.2}$$

$$= \sum_{j=0}^{d}(-q)^j\sum_{i=j}^{d}\binom{i}{j}b_{di}n^{\underline{i}} \tag{4.3}$$

$$= \sum_{j=0}^{d}(-q)^j\binom{n}{j}\sum_{k=0}^{j}(-1)^k\binom{j}{k}(n-k)^d. \tag{4.4}$$

For the dth raw moment, the following bounds are true:

$$(np)^d \le E_{p_B}X^d \le n^d. \tag{4.5}$$

For an arbitrary offset μ, we have

$$E_{p_B}(X-\mu)^d = \sum_{i=0}^{d} \binom{d}{i} (-\mu)^{d-i} E_{p_B} X^i \tag{4.6}$$

$$= \sum_{j=0}^{d} (-p)^j \binom{n}{j} \sum_{k=0}^{j} (-1)^k \binom{j}{k} (k-\mu)^d \tag{4.7}$$

$$= \sum_{j=0}^{d} (-q)^j n^{\underline{j}} \sum_{i=j}^{d} \binom{i}{j} b_{di} (n-\mu-j)^{\underline{i-j}} \tag{4.8}$$

$$= \sum_{j=0}^{d} (-q)^j \binom{n}{j} \sum_{k=0}^{j} (-1)^k \binom{j}{k} (n-\mu-k)^d. \tag{4.9}$$

In particular, for $\mu = E_{p_B}X = np$, we obtain the dth central moment of the binomial probability p_B. For $z - d \geq \mu \geq E_{p_B}X$, the following bound is true:

$$|E_{p_B}(X-\mu)^d| \leq \sum_{j=0}^{d} \sum_{i=j}^{d} \binom{i}{j} b_{di} (nq)^i \quad (\sim (nq)^d \; for \; fixed \; d \; and \; nq \to \infty). \tag{4.10}$$

Proof. Equations (4.1), (4.2) follow from (2.9), (3.1). Equations (4.3), (4.4) follow from (2.10), (3.3). The bounds of (4.5) follow simply from $p^d \leq p^i \leq 1$ and (3.2) because (4.1) is obviously a sum of nonnegative numbers. Equation (4.6) is (2.11). Equation (4.7) follows by inserting (4.2) into (4.6) and applying the binomial sum (see section 1). Similarly, (4.9) follows from inserting (4.4) into (4.6). Equation (4.8) follows from (4.9) with (3.5). Equation (4.10) follows from (4.8) because $n^{\underline{j}} \leq n^j$ and $(n-\mu-j)^{\underline{i-j}} \leq (nq)^{i-j}$ for $n \geq \mu + d$ and $\mu \geq E_{p_B}X = np$. □

5. Related work and application to the analysis of neural associative networks. Computing the higher-order moments of a binomially distributed random variable is rarely emphasized. Standard textbooks give expressions for the moment generating function (1.2) and some lower-order moments such as mean, variance, and, perhaps, skewness and kurtosis, but higher-order moments are usually neglected (e.g., see [14, 16]). For some applications it may be sufficient to approximate a binomial random variable by either a Gaussian or a Poissonian where closed-form expressions for higher-order moments are known. For example, for large variance $np(1-p) \to \infty$, according to the DeMoivre–Laplace theorem, the binomial probability becomes similar to a Gaussian with the same mean and variance. Likewise, for $n \to \infty$ and finite $np \to \lambda < \infty$, the binomial becomes Poissonian. However, for applications as described below, these approximations are not appropriate, and it is necessary to find an exact formula.

A previous attempt [2] to compute the higher-order moments of the binomial distribution revealed recursive expressions similar to those developed in section 2, but was restricted to the special case $p = 0.5$. Moreover, the recursive form was not appropriate for efficient computation or application in further analyses. In contrast to [2], this work provides general recursive and nonrecursive (or closed-form) expressions for the higher-order moments of the binomial distribution.

My main motivation to obtain a closed formula for the binomial moments comes from analyzing storage capacity and retrieval error probabilities in neural associative memory networks [21, 12, 4, 18, 6]. *Associative memories* are systems that contain information about a finite set of associations between pattern vector pairs $\{(\mathbf{u}^{\mu} \mapsto \mathbf{v}^{\mu}) : \mu = 1, \ldots, M\}$ [10]. Given a possibly noisy address pattern $\tilde{\mathbf{u}}$, the problem is to find a target pattern $\mathbf{v}^{\mu}$ for which the corresponding address pattern $\mathbf{u}^{\mu}$ is most similar to $\tilde{\mathbf{u}}$.

Neural associative networks have wide applications for both artificial intelligence (e.g., visual object recognition [10, 15]) and modeling the brain (e.g., [13, 6, 22, 5, 19, 20]). In neural implementations the associations are stored in a matrix $\mathbf{A}$ describing the synaptic connections between two cell populations u and v. Here the retrieval result $\hat{\mathbf{v}}^{\mu}$ may differ from the original pattern $\mathbf{v}^{\mu}$. This is due to retrieval noise being an increasing function of the memory load or the number of stored associations. In general, the probability of a retrieval error can be computed from the neuron potential distribution as obtained by propagating the address pattern $\tilde{\mathbf{u}}$ through the synaptic matrix $\mathbf{A}$.

One of the most efficient models is the so-called *Willshaw network* with binary neurons and synapses [21]. Here the synaptic matrix is simply $\mathbf{A} = \vee_{\mu=1}^{M} \mathbf{u}^{\mu,\mathbf{T}} \mathbf{v}^{\mu}$, and the retrieval error probabilities can be computed from the so-called Willshaw–Palm distribution of neuron potentials $\mathbf{x} = \tilde{\mathbf{u}}^{\mathbf{T}} \mathbf{A}$. Since the Willshaw–Palm distribution is more difficult to formulate, many analyses of neural associative memory actually rely on a binomial approximation (e.g., [21, 12, 11, 3, 18]). However, it is unclear for which network parameters this approximation is sufficiently accurate. In a further paper [8] (see also [7]), I will compute the moments of the Willshaw–Palm distribution from the binomial moments. For this it is sufficient to replace q^j in (4.4), (4.9) by some more complex term $q^{(j)}$. With this it will be possible to compare the exact potential distribution to the binomial approximation and determine asymptotic conditions when they become identical.

Acknowledgments. I am grateful to Edgar Körner and Marc-Oliver Gewaltig for providing the opportunity to do this work at the Honda Research Institute. I am also grateful to Günther Palm and Friedrich Sommer for helpful discussions and comments.

ABSOLUTE STABILITY AND COMPLETE SYNCHRONIZATION IN A CLASS OF NEURAL FIELDS MODELS*

OLIVIER FAUGERAS†, FRANÇOIS GRIMBERT†, AND JEAN-JACQUES SLOTINE‡

Abstract. Neural fields are an interesting option for modeling macroscopic parts of the cortex involving several populations of neurons, like cortical areas. Two classes of neural field equations are considered: voltage- and activity-based. The spatio-temporal behavior of these fields is described by nonlinear integro-differential equations. The integral term, computed over a compact subset of $\mathbb{R}^q$, $q = 1, 2, 3$, involves space and time varying, possibly nonsymmetric, intracortical connectivity kernels. Contributions from white matter afferents are represented as external input. Sigmoidal nonlinearities arise from the relation between average membrane potentials and instantaneous firing rates. Using methods of functional analysis, we characterize the existence and uniqueness of a solution of these equations for general, homogeneous (i.e., independent of the spatial variable), and spatially locally homogeneous inputs. In all cases we give sufficient conditions on the connectivity functions for the solutions to be absolutely stable, that is to say, asymptotically independent of the initial state of the field. These conditions bear on some compact operators defined from the connectivity kernels, the maximal slope of the sigmoids, and the time constants used in describing the temporal shape of the postsynaptic potentials. Numerical experiments are presented to illustrate the theory. To our knowledge this is the first time that such a complete analysis of the problem of the existence and uniqueness of a solution of these equations has been obtained. Another important contribution is the analysis of the absolute stability of these solutions—more difficult but more general than the linear stability analysis which it implies. The reason we have been able to complete this work is our use of the functional analysis framework and the theory of compact operators in a Hilbert space which has allowed us to provide simple mathematical answers to some of the questions raised by modelers in neuroscience.

Key words. neural fields, integro-differential equations, compact operators, Hilbert space, absolute stability, complete synchronization, Lyapunov function, neural masses, cortical columns

1. Introduction.

We model neural fields as continuous networks of cortical units and investigate the ability of these units to completely synchronize, i.e., to produce the same output when receiving the same input independently of their initial state. We therefore emphasize the dynamics and the spatio-temporal behavior of these networks.

Cortical units are built from a local description of the dynamics of a number of interacting neuron populations, called *neural masses* [15], where the spatial structure of the connections is neglected. These “vertically” built units can be thought of as *cortical columns* [29, 30, 3]. Probably the most well-known neural mass–based column model is that of Jansen and Rit [21] based on the original work of da Silva, Van Rotterdam, and colleagues [25, 26, 38]. A complete analysis of the bifurcations of this model can be found in [18]. More realistic models can be derived from experimental connectivity studies, such as the one shown in Figure 1. This figure, adapted

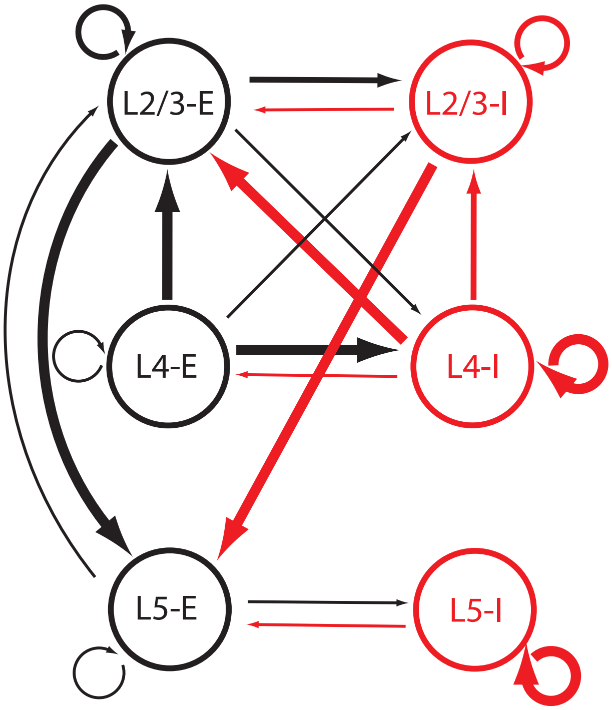

Fig. 1. *A simplified model of local cortical interactions based on six neuron populations. This local connectivity graph can be seen as a model of a cortical column composed of six interacting neural masses. There are three layers corresponding to cortical layers* II/III, IV, *and* V *and two types of neurons (excitatory ones in black and inhibitory ones in red) in each of these layers. The size of the arrows gives an idea of the average strength of the postsynaptic potentials elicited by the presynaptic neurons; see section* 2.1.1. *This figure is adapted from* [19].

from [19], is based on the work of Thomson and Bannister [37]. It shows the local connectivity graph of six populations of neurons and can be thought of as a model of a column comprising six interacting neural masses.

Such columns are then assembled spatially to form the neural field, which is meant to represent a macroscopic part of the neocortex, e.g., a visual area such as V1. Connections between columns are intracortical (gray matter) connections. Connections made via white matter with, e.g., such visual areas as the LGN or V2 are also considered in our models but are treated as input/output quantities.

There are at least three reasons why we think this is the relevant granularity to do modeling:

- Realistic modeling of a macroscopic part of the brain at the scale of the neuron is still difficult for obvious complexity reasons. Starting from mesoscopic building blocks like neural masses, described by the average activity of their neurons, is therefore a reasonable choice.
- While MEG and scalp EEG recordings mostly give a bulk signal of a cortical area, multielectrode recordings, in vitro experiments on pharmacologically treated brain slices, and new imaging techniques like extrinsic optical imaging can provide a spatially detailed description of neural masses dynamics in a macroscopic part of the brain like an area.
- The column/area scales correspond to available local connectivity data. In-

deed, these are obtained by averaging over local populations of neurons we can think of as neural masses. Besides, local (intracolumnar) connectivity is supposed to be spatially invariant within an area.

We now present a general mathematical framework for neural field modeling that agrees with the ideas of using average descriptions of neuronal activity and spatial invariance of the local connectivity across the field. This framework uses the elegant tools of functional analysis with the advantage of providing simple characterizations of some important properties of neural field equations.

In section 2 we describe the local and spatial models of neural masses and derive the equations that govern their spatio-temporal variations. In section 3 we analyze the problem of the existence and uniqueness of the smooth general and homogeneous solutions of these equations. In section 4 we study the absolute stability of these solutions, i.e., their robustness to arbitrary perturbations caused by changes of the initial conditions. In section 5 we extend this analysis to the absolute stability of the homogeneous, i.e., independent of space, solutions when they exist. A consequence of the absolute stability is the ability of the network to completely synchronize. In section 6 we revisit the functional framework of our analysis and extend our results to nonsmooth functions with the effect that we can discuss the existence and absolute stability of locally homogeneous solutions. We also propose another extension of the model by generalizing the previous results to higher order synaptic responses. In section 7 we present a number of numerical experiments to illustrate the theory and conclude in section 8.

2. The models.

We discuss local and spatial models.

2.1. The local models.

We consider n interacting populations of neurons such as those shown in Figure 1. The following derivation is built after Ermentrout's review [10]. We consider that each neural population i is described by its average membrane potential $V_i(t)$ or by its average instantaneous firing rate $\nu_i(t)$, the relation between the two quantities being of the form $\nu_i(t) = S_i(V_i(t))$ [16, 8], where S_i is sigmoidal. The functions S_i, $i = 1, \dots, n$, satisfy the properties introduced in the following definition.

DEFINITION 2.1. *For all $i = 1, \dots, n$, S_i and S_i' are positive and bounded (S_i' is the derivative of the function S_i). We note $S_{im} = \sup_x S_i(x)$, $S_m = \max_i S_{im}$, $S_{im}' = \sup_x S_i'(x)$, and $DS_m = \max_i S_{im}'$. Finally, we define $D\mathbf{S}_m$ as the diagonal matrix* $\mathrm{diag}(S_{im}')$.

Neurons in population j are connected to neurons in population i. A single action potential from neurons in population j is seen as a postsynaptic potential $PSP_{ij}(t-s)$ by neurons in population i, where s is the time of the spike hitting the synapse and t the time after the spike. We neglect the delays due to the distance traveled down the axon by the spikes.

Assuming that the postsynaptic potentials sum linearly, the average membrane potential of population i is

$$V_i(t) = \sum_{j,k} PSP_{ij}(t - t_k),$$

where the sum is taken over the arrival times of the spikes produced by the neurons in population j. The number of spikes arriving between t and $t+dt$ is $\nu_j(t)dt$. Therefore, we have

$$V_i(t) = \sum_j \int_{t_0}^{t} PSP_{ij}(t-s)\nu_j(s)\,ds = \sum_j \int_{t_0}^{t} PSP_{ij}(t-s)S_j(V_j(s))\,ds$$

or, equivalently,

$$\nu_i(t) = S_i\left(\sum_j \int_{t_0}^{t} PSP_{ij}(t-s)\nu_j(s)\,ds\right). \tag{2.1}$$

The PSP_{ij}s can depend on several variables in order to account for adaptation, learning, etc.

There are two main simplifying assumptions that appear in the literature [10], and they yield two different models.

2.1.1. The voltage-based model. The assumption, made in [20], is that the postsynaptic potential has the same shape no matter which presynaptic population caused it; the sign and amplitude may vary, though. This leads to the relation

$$PSP_{ij}(t) = W_{ij}PSP_i(t).$$

PSP_i represents the unweighted shape of the postsynaptic potentials and W_{ij} is the average strength of the postsynaptic potentials elicited by neurons of type j on neurons of type i. In biophysical connectivity models, like the one presented in Figure 1, the W_{ij}s should be chosen proportionally to the number of presynaptic cells, the average amplitude of postsynaptic potentials, and the probability of connection between the considered neuron species [17, 13]. In particular, if $W_{ij} > 0$, the population j excites population i, whereas it inhibits it when $W_{ij} < 0$.

Finally, if we assume that $PSP_i(t) = e^{-t/\tau_i}Y(t)$ (where Y is the Heaviside distribution) or, equivalently, that

$$\tau_i \frac{dPSP_i(t)}{dt} + PSP_i(t) = \tau_i\delta(t), \tag{2.2}$$

we end up with the system of ordinary first order differential equations

$$\frac{dV_i(t)}{dt} + \frac{V_i(t)}{\tau_i} = \sum_j W_{ij}S_j(V_j(t)) + I^i_{\mathrm{ext}}(t), \tag{2.3}$$

which describes the dynamic behavior of a cortical column. We have added an external current $I_{\mathrm{ext}}(t)$ to model the nonlocal connections of population i.

The approach developed in this article generalizes easily to the case of more sophisticated postsynaptic potentials models resulting in higher order differential equations, as shown in section 6.3.

We introduce the $n \times n$ matrix $\mathbf{W} = (W_{ij})_{i,j}$ and the function $\mathbf{S}$: $\mathbb{R}^n \to \mathbb{R}^n$ such that $\mathbf{S}(\mathbf{x})$ is the vector of coordinates $S_i(x_i)$. We rewrite (2.3) in vector form and obtain the system of n ordinary differential equations

$$\mathbf{V}' = -\mathbf{L}\mathbf{V} + \mathbf{W}\mathbf{S}(\mathbf{V}) + \mathbf{I}_{\mathrm{ext}}, \tag{2.4}$$

where $\mathbf{L}$ is the diagonal matrix $\mathbf{L} = \mathrm{diag}(1/\tau_{\mathrm{i}})$.

2.1.2. The activity-based model.

The assumption is that the shape of a postsynaptic potential depends only on the nature of the presynaptic cell, that is,

$$PSP_{ij}(t) = W_{ij} PSP_j(t).$$

As above, we suppose that $PSP_i(t)$ satisfies the differential equation (2.2) and define the activity to be

$$A_j(t) = \int_{t_0}^{t} PSP_j(t-s)\nu_j(s)\, ds.$$

A similar derivation yields the following set of n ordinary differential equations:

$$\frac{dA_i(t)}{dt} + \frac{A_i(t)}{\tau_i} = S_i\left(\sum_j W_{ij} A_j(t) + I^i_{\text{ext}}(t)\right), \quad i = 1, \dots, n.$$

We rewrite this in vector form as

$$\mathbf{A}' = -\mathbf{L}\mathbf{A} + \mathbf{S}(\mathbf{W}\mathbf{A} + \mathbf{I}_{\text{ext}}). \tag{2.5}$$

We introduce the following definition.

Definition 2.2. *We denote $\tau_{\max}$ the maximum of the decay time constants τ_i, $i = 1, \dots, n$:*

$$\tau_{\max} = \max_i \tau_i.$$

2.2. Neural fields models.

We now combine these local models to form a continuum of columns, e.g., in the case of a model of a significant part Ω of the cortex. From now on we consider a compact subset Ω of $\mathbb{R}^q$, $q = 1, 2, 3$. This encompasses several cases of interest.

When $q = 1$ we deal with one-dimensional neural fields. Even though this appears to be of limited biological interest, it is one of the most widely studied cases because of its relative mathematical simplicity and because of the insights one can gain on the more realistic situations.

When $q = 2$ we discuss properties of two-dimensional neural fields. This is perhaps more interesting from a biological point of view since Ω can be viewed as a piece of cortex where the third dimension, its thickness, is neglected. This case has received far less attention than the previous one, probably because of the increased mathematical difficulty.

Finally, $q = 3$ allows us to discuss properties of volumes of neural masses, e.g., cortical sheets where their thickness is taken into account [22, 4].

The results that are presented in this paper are independent of q. Nevertheless, we have a good first approximation of a real cortical area with $q = 2$, and cortical depth given by the index $i = 1, \dots, n$ of the considered cortical population, following the idea of a field composed of columns or, equivalently, of interconnected cortical layers.

We denote $\mathbf{V}(\mathbf{r}, t)$ (resp., $\mathbf{A}(\mathbf{r}, t)$) the n-dimensional state vector at the point $\mathbf{r}$ of the continuum and at time t. We introduce the $n \times n$ matrix function $\mathbf{W}(\mathbf{r}, \mathbf{r}', t)$, which describes how the neural mass at point $\mathbf{r}'$ influences that at point $\mathbf{r}$ at time t. More precisely, $W_{ij}(\mathbf{r}, \mathbf{r}', t)$ describes how population j at point $\mathbf{r}'$ influences population i at point $\mathbf{r}$ at time t. We call $\mathbf{W}$ the connectivity matrix function. Neglecting, as in the local case above, the delays due to the distance between the neural masses, we extend (2.4) to

$$\mathbf{V}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{V}(\mathbf{r},t) + \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{S}(\mathbf{V}(\mathbf{r}',t))\,d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t) \tag{2.6}$$

and (2.5) to

$$\mathbf{A}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{A}(\mathbf{r},t) + \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{A}(\mathbf{r}',t)\,d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t)\right). \tag{2.7}$$

$\mathbf{V}_t$ (resp., $\mathbf{A}_t$) stands for the partial derivative of the vector $\mathbf{V}$ (resp., $\mathbf{A}$) with respect to the time variable t. A special case which will be considered later is when $\mathbf{W}$ is translation invariant: $\mathbf{W}(\mathbf{r},\mathbf{r}',t) = \mathbf{W}(\mathbf{r}-\mathbf{r}',t)$. We give below sufficient conditions on $\mathbf{W}$ and $\mathbf{I}_{\text{ext}}$ for (2.6) and (2.7) to be well defined and study their solutions.

3. Existence and uniqueness of a solution. In this section we deal with the problem of the existence and uniqueness of a solution to (2.6) and (2.7) for a given set of initial conditions. Unlike previous authors [12, 5, 28], we consider the case of a neural field with the effect that we have to use the tools of functional analysis to characterize their properties.

We start with the assumption that the state vectors $\mathbf{V}$ and $\mathbf{A}$ are differentiable (resp., continuous) functions of the time (resp., the space) variable. This is certainly reasonable in terms of the temporal variations because we are essentially modeling large populations of neurons and do not expect to be able to represent time transients. It is far less reasonable in terms of the spatial dependency since one should allow neural mass activity to be spatially distributed in a locally nonsmooth fashion with areas of homogeneous cortical activity separated by smooth boundaries. A more general assumption is proposed in section 6. But it turns out that most of the groundwork can be done in the setting of continuous functions.

Let $\mathcal{F}$ be the set $\mathbf{C}_n(\Omega)$ of the continuous functions from Ω to $\mathbb{R}^n$. This is a Banach space for the norm $\|\mathbf{V}\|_{n,\infty} = \max_{1\le i\le n}\sup_{\mathbf{r}\in\Omega}|\mathbf{V}_i(\mathbf{r})|$; see section A.1. We denote by J a closed interval of the real line containing 0.

We will need the following lemma several times.

Lemma 3.1. *We have the following inequalities for all* $\mathbf{x},\mathbf{y}\in\mathcal{F}$ *and* $\mathbf{r}'\in\Omega$*:*

$$\|\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{S}(\mathbf{y}(\mathbf{r}'))\|_\infty \le DS_m\|\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')\|_\infty \quad \text{and}$$
$$\|\mathbf{S}(\mathbf{x}) - \mathbf{S}(\mathbf{y})\|_{n,\infty} \le DS_m\|\mathbf{x}-\mathbf{y}\|_{n,\infty}.$$

Proof. $\mathbf{S}$ is smooth so we can perform a zeroth-order Taylor expansion with integral remainder [9] and write

$$\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{S}(\mathbf{y}(\mathbf{r}')) = \left(\int_0^1 D\mathbf{S}(\mathbf{y}(\mathbf{r}') + \zeta(\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')))\,d\zeta\right)(\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')),$$

and, because of Lemma A.1 and Definition 2.1

$$\begin{aligned}\|\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{S}(\mathbf{y}(\mathbf{r}'))\|_\infty &\le \int_0^1 \|D\mathbf{S}(\mathbf{y}(\mathbf{r}') + \zeta(\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')))\|_\infty\,d\zeta\,\|\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')\|_\infty \\ &\le DS_m\|\mathbf{x}(\mathbf{r}')-\mathbf{y}(\mathbf{r}')\|_\infty.\end{aligned}$$

This proves the first inequality. The second follows immediately. □

3.1. General solution. A function $\mathbf{V}(t)$ is thought of as a mapping $\mathbf{V} : \mathrm{J} \rightarrow \mathcal{F}$. This means that $\mathbf{V}(t)$ is now a function defined in Ω. Equations (2.6) and (2.7) are formally recast as an initial value problem (see, e.g., [11]):

$$\left\{ \begin{array}{rcl} \mathbf{V}'(t) &=& f(t, \mathbf{V}(t)), \\ \mathbf{V}(0) &=& \mathbf{V}_0, \end{array} \right. \tag{3.1}$$

where $\mathbf{V}_0$ is an element of $\mathcal{F}$ and the function f from $\mathrm{J} \times \mathcal{F}$ is equal to f_v defined by the right-hand side of (2.6):

$$f_v(t, \mathbf{x})(\mathbf{r}) = -\mathbf{L}\mathbf{x}(\mathbf{r}) + \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{S}(\mathbf{x}(\mathbf{r}'))\, d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(\mathbf{r}, t) \quad \forall \mathbf{x} \in \mathcal{F}, \tag{3.2}$$

or to f_a defined by the right-hand side of (2.7):

$$f_a(t, \mathbf{x})(\mathbf{r}) = -\mathbf{L}\mathbf{x}(\mathbf{r}) + \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{x}(\mathbf{r}')\, d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(\mathbf{r}, t)\right) \quad \forall \mathbf{x} \in \mathcal{F}. \tag{3.3}$$

We have the following proposition.

PROPOSITION 3.2. *If the following two hypotheses are satisfied:*

1. *the connectivity function* $\mathbf{W}$ *is in* $C(\mathrm{J}; \mathbf{C}_{\mathrm{n}\times\mathrm{n}}(\Omega \times \Omega))$ *(see section* A.2*),*
2. *the external current* $\mathbf{I}_{\mathrm{ext}}$ *is in* $C(\mathrm{J}; \mathbf{C}_{\mathrm{n}}(\Omega))$*,*

then the mappings f_v *and* f_a *are from* $\mathrm{J}\times\mathcal{F}$ *to* $\mathcal{F}$*, continuous, and Lipschitz continuous with respect to their second argument, uniformly with respect to the first (*$\mathbf{C}_{n\times n}(\Omega\times\Omega)$ *and* $\mathbf{C}_n(\Omega)$ *are defined in section* A.1*).*

Proof. Let $t \in \mathrm{J}$ and $\mathbf{x} \in \mathcal{F}$. We introduce the mapping

$$F_v : (t, \mathbf{x}) \rightarrow F_v(t, \mathbf{x}) \quad \text{such that} \quad F_v(t, \mathbf{x})(\mathbf{r}) = \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{S}(\mathbf{x}(\mathbf{r}'))\, d\mathbf{r}'. \tag{3.4}$$

$F_v(t, \mathbf{x})$ is well defined for all $\mathbf{r} \in \Omega$ because, thanks to the first hypothesis, it is the integral of the continuous function $\mathbf{W}(\mathbf{r}, ., t)\mathbf{S}(\mathbf{x}(.))$ on a compact domain. For all $\mathbf{r}' \in \Omega$, $\mathbf{W}(., \mathbf{r}', t)\mathbf{S}(\mathbf{x}(\mathbf{r}'))$ is continuous (first hypothesis again) and we have (Lemma A.1)

$$\|\mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{S}(\mathbf{x}(\mathbf{r}'))\|_\infty \le \|\mathbf{W}(., ., t)\|_{n\times n,\infty} \|\mathbf{S}(\mathbf{x}(\mathbf{r}'))\|_\infty.$$

Since $\|\mathbf{S}(\mathbf{x}(.))\|_\infty$ is bounded, it is integrable in Ω, and we conclude that $F_v(t, \mathbf{x})$ is continuous on Ω. Then it is easy to see that $f_v(t, \mathbf{x})$ is well defined and belongs to $\mathcal{F}$.

Let us prove that f_v is continuous:

$$\begin{aligned} f_v(t, \mathbf{x}) - f_v(s, \mathbf{y}) = -\mathbf{L}(\mathbf{x} - \mathbf{y}) &+ \int_\Omega \left(\mathbf{W}(\cdot, \mathbf{r}', t)\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{W}(\cdot, \mathbf{r}', s)\mathbf{S}(\mathbf{y}(\mathbf{r}'))\right)\, d\mathbf{r}' \\ &+ \mathbf{I}_{\mathrm{ext}}(\cdot, t) - \mathbf{I}_{\mathrm{ext}}(\cdot, s) \\ = -\mathbf{L}(\mathbf{x} - \mathbf{y}) &+ \int_\Omega (\mathbf{W}(\cdot, \mathbf{r}', t) - \mathbf{W}(\cdot, \mathbf{r}', s))\mathbf{S}(\mathbf{x}(\mathbf{r}'))\, d\mathbf{r}' \\ &+ \int_\Omega \mathbf{W}(\cdot, \mathbf{r}', s)(\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{S}(\mathbf{y}(\mathbf{r}')))\, d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(\cdot, t) - \mathbf{I}_{\mathrm{ext}}(\cdot, s). \end{aligned}$$

It follows from Lemma 3.1 that

$$\begin{aligned} \|f_v(t, \mathbf{x}) - f_v(s, \mathbf{y})\|_{n,\infty} \le{} & \|\mathbf{L}\|_\infty \, \|\mathbf{x} - \mathbf{y}\|_{n,\infty} + |\Omega|\, S_m \|\mathbf{W}(\cdot, \cdot, t) - \mathbf{W}(\cdot, \cdot, s)\|_{n\times n,\infty} \\ & + |\Omega|\, \|\mathbf{W}(\cdot, \cdot, s)\|_{n\times n,\infty} DS_m \, \|\mathbf{x} - \mathbf{y}\|_{n,\infty} + \|\mathbf{I}_{\mathrm{ext}}(\cdot, t) - \mathbf{I}_{\mathrm{ext}}(\cdot, s)\|_{n,\infty}. \end{aligned}$$

Because of the hypotheses we can choose $|t - s|$ small enough so that $\|\mathbf{W}(\cdot, \cdot, t) - \mathbf{W}(\cdot, \cdot, s)\|_{n\times n,\infty}$ and $\|\mathbf{I}_{\mathrm{ext}}(\cdot, t) - \mathbf{I}_{\mathrm{ext}}(\cdot, s)\|_{n,\infty}$ are arbitrarily small. Similarly, since $\mathbf{W}$ is continuous on the compact interval J, it is bounded there and $\|\mathbf{W}(\cdot, \cdot, s)\|_{n\times n,\infty} \le w > 0$ for all $s \in \mathrm{J}$. This proves the continuity of f_v.

It follows from the previous inequality that

$$\|f_v(t,\mathbf{x}) - f_v(t,\mathbf{y})\|_{n,\infty} \le \|\mathbf{L}\|_\infty \, \|\mathbf{x}-\mathbf{y}\|_{n,\infty} + |\Omega| \, \|\mathbf{W}(\cdot,\cdot,t)\|_{n\times n,\infty} DS_m \, \|\mathbf{x}-\mathbf{y}\|_{n,\infty},$$

and because $\|\mathbf{W}(\cdot,\cdot,t)\|_{n\times n,\infty} \le w > 0$ for all ts in J, this proves the Lipschitz continuity of f_v with respect to its second argument, uniformly with respect to the first.

A very similar proof applies to f_a. □

We continue with the proof that there exists a unique solution to the abstract initial value problem (3.1) in the two cases of interest.

Proposition 3.3. *Subject to the hypotheses of Proposition* 3.2 *for any element* $\mathbf{V}_0$ *(resp.,* $\mathbf{A}_0$*) of* $\mathcal{F}$ *there is a unique solution* $\mathbf{V}$ *(resp.,* $\mathbf{A}$*), defined on a subinterval of* J *containing* 0 *and continuously differentiable, of the abstract initial value problem* (3.1) *for* $f = f_v$ *(resp.,* $f = f_a$*).*

Proof. All conditions of the Picard–Lindelöf theorem on differential equations in Banach spaces [9, 2] are satisfied; hence the proposition is proved. □

This solution, defined on the subinterval J of $\mathbb{R}$ can in fact be extended to the whole real line, and we have the following proposition.

Proposition 3.4. *If the following two hypotheses are satisfied:*

1. *the connectivity function* $\mathbf{W}$ *is in* $C(\mathbb{R};\mathbf{C}_{\mathrm{n\times n}}(\Omega\times\Omega))$*,*
2. *the external current* $\mathbf{I}_{\mathrm{ext}}$ *is in* $C(\mathbb{R};\mathbf{C}_{\mathrm{n}}(\Omega))$*,*

then for any function $\mathbf{V}_0$ *(resp.,* $\mathbf{A}_0$*) in* $\mathcal{F}$ *there is a unique solution* $\mathbf{V}$ *(resp.,* $\mathbf{A}$*), defined on* $\mathbb{R}$ *and continuously differentiable, of the abstract initial value problem* (3.1) *for* $f = f_v$ *(resp.,* $f = f_a$*).*

Proof. In Theorem B.1, we prove the existence of a constant $\tau > 0$ such that for any initial condition $(t_0, \mathbf{V}_0) \in \mathbb{R}\times\mathcal{F}$, there is a unique solution defined on the closed interval $[t_0-\tau,\, t_0+\tau]$. We can then cover the real line with such intervals and finally obtain the global existence and uniqueness of the solution of the initial value problem. □

3.2. Homogeneous solution. A homogeneous solution to (2.6) or (2.7) is a solution $\mathbf{U}$ that does not depend upon the space variable $\mathbf{r}$ for a given homogeneous input $\mathbf{I}_{\mathrm{ext}}(t)$ and a constant initial condition $\mathbf{U}_0$. If such a solution $\mathbf{U}(t)$ exists, then it satisfies

$$\mathbf{U}'(t) = -\mathbf{L}\mathbf{U}(t) + \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{S}(\mathbf{U}(t))\,d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(t)$$

in the case of (2.6) and

$$\mathbf{U}'(t) = -\mathbf{L}\mathbf{U}(t) + \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{U}(t)\,d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(t)\right)$$

in the case of (2.7). The integral $\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{S}(\mathbf{U}(t))\,d\mathbf{r}'$ is equal to $\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\,d\mathbf{r}'\right)$ $\cdot\mathbf{S}(\mathbf{U}(t))$. The integral $\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{U}(t)\,d\mathbf{r}'$ is equal to $\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\,d\mathbf{r}'\right)\mathbf{U}(t)$. They must be independent of the position $\mathbf{r}$. Hence a necessary condition for the existence of a homogeneous solution is that

$$\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\,d\mathbf{r}' = \overline{\mathbf{W}}(t), \tag{3.5}$$

where the $n\times n$ matrix $\overline{\mathbf{W}}(t)$ does not depend on the spatial coordinate $\mathbf{r}$.

In the special case where $\mathbf{W}(\mathbf{r}, \mathbf{r}', t)$ is translation invariant, $\mathbf{W}(\mathbf{r}, \mathbf{r}', t) \equiv \mathbf{W}(\mathbf{r} - \mathbf{r}', t)$, the condition is not satisfied in general because of the border of Ω. In all cases, the homogeneous solutions satisfy the differential equation

$$\mathbf{U}'(t) = -\mathbf{L}\mathbf{U}(t) + \overline{\mathbf{W}}(t)\mathbf{S}(\mathbf{U}(t)) + \mathbf{I}_{\text{ext}}(t) \tag{3.6}$$

for (2.6) and

$$\mathbf{U}'(t) = -\mathbf{L}\mathbf{U}(t) + \mathbf{S}\left(\overline{\mathbf{W}}(t)\mathbf{U}(t)) + \mathbf{I}_{\text{ext}}(t)\right) \tag{3.7}$$

for (2.7), with initial condition $\mathbf{U}(0) = \mathbf{U}_0$, a vector of $\mathbb{R}^n$. The following theorem gives a sufficient condition for the existence of a homogeneous solution.

Theorem 3.5. *If the external current $\mathbf{I}_{\text{ext}}(t)$ and the connectivity matrix $\overline{\mathbf{W}}(t)$ are continuous on some closed interval* J *containing* 0*, then for all vectors $\mathbf{U}_0$ of $\mathbb{R}^n$, there exists a unique solution $\mathbf{U}(t)$ of* (3.6) *or* (3.7) *defined on a subinterval* J_0 *of* J *containing* 0 *such that $\mathbf{U}(0) = \mathbf{U}_0$.*

Proof. The proof is an application of Cauchy's theorem on differential equations. Consider the mapping $f_{hv} : \mathbb{R}^n \times \mathrm{J} \to \mathbb{R}^n$ defined by

$$f_{hv}(\mathbf{x}, t) = -\mathbf{L}\mathbf{x} + \overline{\mathbf{W}}(t)\mathbf{S}(\mathbf{x}) + \mathbf{I}_{\text{ext}}(t).$$

We have

$$\|f_{hv}(\mathbf{x}, t) - f_{hv}(\mathbf{y}, t)\|_\infty \leq \|\mathbf{L}\|_\infty \|\mathbf{x} - \mathbf{y}\|_\infty + \|\overline{\mathbf{W}}(t)\|_\infty \|\mathbf{S}(\mathbf{x}) - \mathbf{S}(\mathbf{y})\|_\infty.$$

It follows from Lemma 3.1 that $\|\mathbf{S}(\mathbf{x}) - \mathbf{S}(\mathbf{y})\|_\infty \leq DS_m \|\mathbf{x} - \mathbf{y}\|_\infty$, and, since $\overline{\mathbf{W}}$ is continuous on the compact interval J, it is bounded there by $w > 0$ and

$$\|f_{hv}(\mathbf{x}, t) - f_{hv}(\mathbf{y}, t)\|_\infty \leq (\|\mathbf{L}\|_\infty + wDS_m)\|\mathbf{x} - \mathbf{y}\|_\infty$$

for all $\mathbf{x}, \mathbf{y}$ of $\mathbb{R}^n$ and all $t \in \mathrm{J}$. A similar proof applies to (3.7), and the conclusion of the proposition follows. □

As in Proposition 3.4, this existence and uniqueness result extends to the whole time real line if $\mathbf{I}$ and $\overline{\mathbf{W}}$ are continuous on $\mathbb{R}$.

This homogeneous solution can be seen as describing a state where the columns of the continuum are synchronized: they receive the same input $\mathbf{I}_{\text{ext}}(t)$ and produce the same output $\mathbf{U}(t)$.

3.3. Some remarks about the case $\boldsymbol{\Omega} = \mathbb{R}^q$. A significant amount of work has been done on equations of the type (2.6) or (2.7) in the case of a one-dimensional infinite continuum, $\Omega = \mathbb{R}$, or a two-dimensional infinite continuum, $\Omega = \mathbb{R}^2$. The reader is referred to the review papers by Ermentrout [10] and by Coombes [6] as well as to [33, 14, 35].

Aside from the fact that an infinite cortex is unrealistic, the case $\Omega = \mathbb{R}^q$ raises some mathematical questions. Indeed, the choice of the functional space $\mathcal{F}$ is problematic. A natural idea would be to choose $\mathcal{F} = \mathbf{L}^2_n(\mathbb{R}^q)$, the space of square-integrable functions with values in $\mathbb{R}^n$; see section A.1. If we make this choice, we immediately encounter the problem that the homogeneous solutions (constant with respect to the space variable) do not belong to that space. A further difficulty is that $\mathbf{S}(\mathbf{x})$ does not in general belong to $\mathcal{F}$ if $\mathbf{x}$ does. As shown in this article, these difficulties vanish if Ω is compact.

4. Absolute stability of the general solution. We investigate the absolute stability of a solution to (2.6) and (2.7) for a given input $\mathbf{I}_{\text{ext}}$. Proposition 3.4 guarantees that for a given initial condition there exists a unique solution to (2.6) or (2.7) defined for all times.

In order to investigate its absolute stability we choose a different initial condition, which is a way to perturb the solution (in effect the only way because of the existence uniqueness proposition, Proposition 3.4), and look for sufficient conditions for the new solution to converge toward the original one. Absolute stability implies linear stability, which is studied by perturbing the solution by adding to it a small function and performing a first-order Taylor expansion of the equations, thereby obtaining a perturbed equation. One then usually has to make some assumptions about the spatio-temporal form of the perturbation, e.g., that it is separable in time and space, ending up with a nontrivial eigenvalue problem which has to be solved in order to find sufficient conditions for the perturbation to converge to 0, up to first-order [6, 10, 12, 14, 28, 33, 34, 24, 35].

This is also the case of [1] and [7]; those authors study the convolution case for $n = q = 1$ but incorporate propagation delays. Linear stability is local because it is derived for a particular solution. The functional analysis approach that we use in this paper allows us to find simple sufficient conditions for the absolute stability of the system, and hence for all its solutions, regardless of the initial condition or input. In this sense it is a global approach. This is achieved by constructing a Lyapunov function measuring some distance between two state vectors at each time instant. This function has a single minimum corresponding to the equality of the states. One then finds sufficient conditions for the time derivative of this function to be strictly negative, thereby guaranteeing the asymptotic equality of the states. This approach has been followed by fewer people. In [23] the authors study the case where $\mathbf{W}(\mathbf{r}, \mathbf{r}')$ is symmetric with respect to the space variables $\mathbf{r}$ and $\mathbf{r}'$ for $n = q = 1$ for a finite interval and add the translation invariance assumption when the interval is infinite. They do not study the case of general time-varying input currents.

Absolute stability is a relevant concept for systems of neurons. Indeed, absolutely stable systems forget their initial state exponentially fast but do not forget their input. Hence such systems can differentiate distinct stimuli by converging to the corresponding states without being influenced by their initial state. This property is desirable, for example, in modeling visual perception: different forms elicit different percepts, but the percepts should not depend on the initial state of the visual system. We first look at the general case and then at the convolution case.

4.1. The general case. We define a number of matrices and linear operators that are useful in what follows.

Definition 4.1. *Let*

$$\mathbf{W}_{cm} = \mathbf{W} D\mathbf{S}_m, \quad \mathbf{W}_{mc} = D\mathbf{S}_m\mathbf{W}.$$

Consider also the linear operators, noted g, g_m, and h_m, defined on $\mathcal{F}$:

$$g(\mathbf{x})(\mathbf{r}, t) = \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{x}(\mathbf{r}')\, d\mathbf{r}' \quad \forall \mathbf{x} \in \mathcal{F},$$

$$g_m(\mathbf{x})(\mathbf{r}, t) = \int_\Omega \mathbf{W}_{cm}(\mathbf{r}, \mathbf{r}', t)\mathbf{x}(\mathbf{r}')\, d\mathbf{r}' \quad \forall \mathbf{x} \in \mathcal{F},$$

and

$$h_m(\mathbf{x})(\mathbf{r},t) = \int_\Omega \mathbf{W}_{mc}(\mathbf{r},\mathbf{r}',t)\mathbf{x}(\mathbf{r}')\,d\mathbf{r}' \quad \forall \mathbf{x} \in \mathcal{F}.$$

We start with a lemma.

LEMMA 4.2. *With the hypotheses of Proposition* 3.2, *the operators* g, g_m, *and* h_m *are compact operators from* $\mathcal{F}$ *to* $\mathcal{F}$ *for each time* $t \in \mathrm{J}$.

Proof. This is a direct application of the theory of Fredholm's integral equations [9]. We prove it for g.

Because of hypothesis 1 in Proposition 3.2, at each time instant t in J, $\mathbf{W}$ is continuous on the compact set $\Omega \times \Omega$; therefore, it is uniformly continuous. Hence, for each $\varepsilon > 0$ there exists $\eta(t) > 0$ such that $\|\mathbf{r}_1 - \mathbf{r}_2\| \le \eta(t)$ implies that $\|\mathbf{W}(\mathbf{r}_1,\mathbf{r}',t) - \mathbf{W}(\mathbf{r}_2,\mathbf{r}',t)\|_\infty \le \varepsilon$ for all $\mathbf{r}' \in \Omega$, and, for all $\mathbf{x} \in \mathcal{F}$,

$$\|g(\mathbf{x})(\mathbf{r}_1,t) - g(\mathbf{x})(\mathbf{r}_2,t)\|_\infty \le \varepsilon|\Omega|\|\mathbf{x}\|_{n,\infty}.$$

This shows that the image $g(B)$ of any bounded subset B of $\mathcal{F}$ is equicontinuous.

Similarly, if we set $w(t) = \|\mathbf{W}(.,.,t)\|_{n\times n,\infty}$, we have $\|g(\mathbf{x})(\mathbf{r},t)\|_\infty \le w(t)|\Omega|\|\mathbf{x}\|_{n,\infty}$. This shows that for every $\mathbf{r} \in \Omega$, the set $\{\mathbf{y}(\mathbf{r}),\, \mathbf{y} \in g(B)\}$ is bounded in $\mathbb{R}^n$ and hence relatively compact. From the Arzelà–Ascoli theorem, we conclude that the subset $g(B)$ of $\mathcal{F}$ is relatively compact for all $t \in \mathrm{J}$. And so the operator is compact.

The same proof applies to g_m and h_m. □

To study the absolute stability of the solutions of (2.6) and (2.7), it is convenient to use an inner product on $\mathcal{F}$. It turns out that the natural inner product will pave the way for the generalization in section 6. We therefore consider the pre-Hilbert space $\mathcal{G}$ defined on $\mathcal{F}$ by the usual inner product

$$\langle \mathbf{x},\, \mathbf{y}\rangle = \int_\Omega \mathbf{x}(\mathbf{r})^T\mathbf{y}(\mathbf{r})\,d\mathbf{r}.$$

We denote $\|\mathbf{x}\|_{n,2}$ as the corresponding norm to distinguish it from $\|\mathbf{x}\|_{n,\infty}$; see section A.1. It is easy to show that all previously defined operators are also compact operators from $\mathcal{G}$ to $\mathcal{G}$. We have the following lemma.

LEMMA 4.3. g, g_m, *and* h_m *are compact operators from* $\mathcal{G}$ *to* $\mathcal{G}$ *for each time* $t \in \mathrm{J}$.

Proof. We give the proof for g.

The identity mapping $\mathbf{x} \to \mathbf{x}$ from $\mathcal{F}$ to $\mathcal{G}$ is continuous since $\|\mathbf{x}\|_{n,2} \le \sqrt{n|\Omega|}\,\|\mathbf{x}\|_{n,\infty}$. Consider now g as a mapping from $\mathcal{G}$ to $\mathcal{F}$. As in the proof of Lemma 4.2, for each $\varepsilon > 0$ there exists $\eta(t) > 0$ such that $\|\mathbf{r}_1 - \mathbf{r}_2\| \le \eta(t)$ implies $\|\mathbf{W}(\mathbf{r}_1,\mathbf{r}',t) - \mathbf{W}(\mathbf{r}_2,\mathbf{r}',t)\|_\infty \le \varepsilon$ for all $\mathbf{r}' \in \Omega$. Therefore, the ith coordinate $g^i(\mathbf{x})(\mathbf{r}_1,t) - g^i(\mathbf{x})(\mathbf{r}_2,t)$ satisfies (Cauchy–Schwarz inequalities)

$$\begin{aligned}|g^i(\mathbf{x})(\mathbf{r}_1,t) - g^i(\mathbf{x})(\mathbf{r}_2,t)| &\le \sum_j \int_\Omega |W_{ij}(\mathbf{r}_1,\mathbf{r}',t) - W_{ij}(\mathbf{r}_2,\mathbf{r}',t)|\,|x_j(\mathbf{r}')|\,d\mathbf{r}' \\ &\le \varepsilon \sum_j \int_\Omega |x_j(\mathbf{r}')|\,d\mathbf{r}' \le \varepsilon\sqrt{|\Omega|}\sum_j \left(\int_\Omega |x_j(\mathbf{r}')|^2\,d\mathbf{r}'\right)^{1/2} \le \varepsilon\sqrt{n\,|\Omega|}\|\mathbf{x}\|_{n,2},\end{aligned}$$

and the image $g(B)$ of any bounded set B of $\mathcal{G}$ is equicontinuous. Similarly, if we set $w(t) = \|\mathbf{W}(.,.,t)\|_{n\times n,\infty}$ in $\Omega \times \Omega$, we have $|g^i(\mathbf{x})(\mathbf{r},t)| \le w(t)\sqrt{n\,|\Omega|}\,\|\mathbf{x}\|_{n,2}$. The same reasoning as in Lemma 4.2 shows that the operator $\mathbf{x} \to g(\mathbf{x})$ from $\mathcal{G}$ to $\mathcal{F}$ is compact, and since the identity from $\mathcal{F}$ to $\mathcal{G}$ is continuous, $\mathbf{x} \to g(\mathbf{x})$ is compact from $\mathcal{G}$ to $\mathcal{G}$.

The same proof applies to g_m and h_m. □

We proceed with the following lemma.

LEMMA 4.4. *The adjoint g^* of the operator g of $\mathcal{G}$ is the operator defined by*

$$g^*(\mathbf{x})(\mathbf{r}, t) = \int_\Omega \mathbf{W}^T(\mathbf{r}', \mathbf{r}, t)\mathbf{x}(\mathbf{r}')\, d\mathbf{r}'.$$

It is a compact operator. Similar results apply to g_m^* and h_m^*.

Proof. The adjoint, if it exists, is defined by the condition $\langle g(\mathbf{x}), \mathbf{y}\rangle = \langle \mathbf{x}, g^*(\mathbf{y})\rangle$ for all $\mathbf{x}, \mathbf{y}$ in $\mathcal{G}$. We have

$$\begin{aligned}\langle g(\mathbf{x}),\, \mathbf{y}\rangle &= \int_\Omega \mathbf{y}(\mathbf{r})^T \left(\int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{x}(\mathbf{r}')\, d\mathbf{r}'\right) d\mathbf{r} \\ &= \int_\Omega \mathbf{x}(\mathbf{r}')^T \left(\int_\Omega \mathbf{W}^T(\mathbf{r}, \mathbf{r}', t)\mathbf{y}(\mathbf{r})\, d\mathbf{r}\right) d\mathbf{r}',\end{aligned}$$

from which the conclusion follows. Since $\mathcal{G}$ is not a Hilbert space, the adjoint of a compact operator is not necessarily compact. But the proof of compactness of g in Lemma 4.3 extends easily to g^*. □

We finally prove two useful lemmas that will complete our toolbox for the proof of the main results of this section.

LEMMA 4.5. *Given a diagonal matrix $\mathbf{D} = \operatorname{diag}(d_1, \ldots, d_n)$, with $d_1, \ldots, d_n \in \mathbf{L}^\infty(\Omega)$ and a function $\mathbf{x} \in \mathcal{G}$, we have*

$$\|\mathbf{D}\mathbf{x}\|_{n,2} \le \max_i(\|d_i\|_\infty)\|\mathbf{x}\|_{n,2}.$$

Proof.

$$\|\mathbf{D}\mathbf{x}\|_{n,2}^2 = \int_\Omega \mathbf{x}(\mathbf{r})^T\mathbf{D}^2(\mathbf{r})\mathbf{x}(\mathbf{r})\, d\mathbf{r} = \sum_i \int_\Omega d_i^2(\mathbf{r})\mathbf{x}_i^2(\mathbf{r})\, d\mathbf{r} \le \sum_i \|d_i\|_\infty^2 \int_\Omega \mathbf{x}_i^2(\mathbf{r})\, d\mathbf{r},$$

from which the result follows. □

LEMMA 4.6. *$\|g\|_\mathcal{G}$, $\|g_m\|_\mathcal{G}$, and $\|h_m\|_\mathcal{G}$ satisfy the inequalities*

$$\|g_m\|_\mathcal{G} \le DS_m\, \|g\|_\mathcal{G} \quad \textit{and} \quad \|h_m\|_\mathcal{G} \le DS_m\, \|g\|_\mathcal{G}\,,$$

where DS_m is defined in Definition 2.1.

Proof. By definition

$$\|g_m\|_\mathcal{G} = \sup_{\|\mathbf{x}\|_{n,2}\le 1} \frac{\|g_m(\mathbf{x})\|_{n,2}}{\|\mathbf{x}\|_{n,2}} = \sup_{\|\mathbf{x}\|_{n,2}\le 1} \frac{\|g(D\mathbf{S}_m\mathbf{x})\|_{n,2}}{\|\mathbf{x}\|_{n,2}}.$$

Let $\mathbf{y} = D\mathbf{S}_m\mathbf{x}$. Since $\{\mathbf{x} \in \mathcal{G},\ \|\mathbf{x}\|_{n,2} \le 1\} \subset \{\mathbf{x} \in \mathcal{G},\ \|D\mathbf{S}_m\mathbf{x}\|_{n,2} \le DS_m\}$ (Lemma 4.5),

$$\begin{aligned}\|g_m\|_\mathcal{G} &\le \sup_{\|\mathbf{y}\|_{n,2}\le DS_m} \frac{\|g(\mathbf{y})\|_{n,2}}{\|D\mathbf{S}_m^{-1}\mathbf{y}\|_{n,2}} = \sup_{\|\mathbf{y}\|_{n,2}\le 1} \frac{\|g(\mathbf{y})\|_{n,2}}{\|D\mathbf{S}_m^{-1}\mathbf{y}\|_{n,2}} \\ &\le \sup_{\|\mathbf{y}\|_{n,2}\le 1} \frac{\|g(\mathbf{y})\|_{n,2}}{\|\mathbf{y}\|_{n,2}} \cdot \sup_{\|\mathbf{y}\|_{n,2}\le 1} \frac{\|\mathbf{y}\|_{n,2}}{\|D\mathbf{S}_m^{-1}\mathbf{y}\|_{n,2}} \le \|g\|_\mathcal{G}\, DS_m.\end{aligned}$$

The last inequality is also obtained from Lemma 4.5, which is used again to prove the inequality for h_m: $h_m = D\mathbf{S}_m g$ and $\|D\mathbf{S}_m g(\mathbf{x})\|_{n,2} \leq DS_m \|g(\mathbf{x})\|_{n,2}$ for all $\mathbf{x} \in \mathcal{G}$, from which the result follows. □

We show in Appendix D a table summarizing the main notation introduced so far for future reference.

We now state an important result of this section.

THEOREM 4.7. *A sufficient condition for the absolute stability of a solution to* (2.6) *is*

$$DS_m \tau_{\max} \|g\|_{\mathcal{G}} < 1, \tag{4.1}$$

where $\|.\|_{\mathcal{G}}$ *is the operator norm.*

Proof. Let us denote $\underline{\mathbf{S}}$ as the function $D\mathbf{S}_m^{-1}\mathbf{S}$ and rewrite (2.6) as

$$\mathbf{V}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{V}(\mathbf{r},t) + \int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)\,\underline{\mathbf{S}}(\mathbf{V}(\mathbf{r}',t))\,d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t).$$

Let $\mathbf{U}$ be its unique solution with initial conditions $\mathbf{U}(0) = \mathbf{U}_0$, an element of $\mathcal{G}$. Let also $\mathbf{V}$ be the unique solution of the same equation with different initial conditions $\mathbf{V}(0) = \mathbf{V}_0$, another element of $\mathcal{G}$. We introduce the new function $\mathbf{X} = \mathbf{V} - \mathbf{U}$ which satisfies

$$\begin{aligned}\mathbf{X}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{X}(\mathbf{r},t) + \int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)\,\mathbf{H}(\mathbf{X},\mathbf{U})(\mathbf{r}',t)\,d\mathbf{r}'\\ = -\mathbf{L}\mathbf{X}(\mathbf{r},t) + g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))(\mathbf{r},t),\end{aligned} \tag{4.2}$$

where the vector $\mathbf{H}(\mathbf{X},\mathbf{U})$ is given by $\mathbf{H}(\mathbf{X},\mathbf{U})(\mathbf{r},t)) = \underline{\mathbf{S}}(\mathbf{V}(\mathbf{r},t)) - \underline{\mathbf{S}}(\mathbf{U}(\mathbf{r},t)) = \underline{\mathbf{S}}(\mathbf{X}(\mathbf{r},t) + \mathbf{U}(\mathbf{r},t)) - \underline{\mathbf{S}}(\mathbf{U}(\mathbf{r},t))$. Consider now the functional (Lyapunov function)

$$V(\mathbf{X}) = \frac{1}{2}\left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathbf{X} \right\rangle,$$

where the symmetric positive definite matrix $\mathbf{L}$ can be seen as defining a metric on the state space. Its time derivative is $\left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathbf{X}_t \right\rangle$. We replace $\mathbf{X}_t$ by its value from (4.2) in this expression to obtain

$$\frac{dV(\mathbf{X})}{dt} = -\left\langle \mathbf{X},\, \mathbf{X} \right\rangle + \left\langle \mathbf{X},\, \mathbf{L}^{-1} g_m(\mathbf{H}(\mathbf{X},\mathbf{U})) \right\rangle.$$

We consider the second term on the right-hand side of this equation:

$$\begin{aligned}\left| \left\langle \mathbf{X},\, \mathbf{L}^{-1} g_m(\mathbf{H}(\mathbf{X},\mathbf{U})) \right\rangle \right| &\leq \|\mathbf{X}\|_{n,2}\, \|\mathbf{L}^{-1} g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\|_{n,2}\\ &\leq \tau_{\max}\|\mathbf{X}\|_{n,2}\, \|g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\|_{n,2} \leq \tau_{\max}\|\mathbf{X}\|_{n,2}\, \|g_m\|_{\mathcal{G}} \|\mathbf{H}(\mathbf{X},\mathbf{U})\|_{n,2}.\end{aligned} \tag{4.3}$$

Using a zeroth-order Taylor expansion with integral remainder, as in the proof of Lemma 3.1, we write $\mathbf{H}(\mathbf{X},\mathbf{U}) = \mathcal{D}_m\mathbf{X}$, where $\mathcal{D}_m$ is a diagonal matrix whose diagonal elements are continuous functions with values between 0 and 1:

$$\mathcal{D}_m(\mathbf{r},t) = \int_0^1 D\underline{\mathbf{S}}(\mathbf{U}(\mathbf{r},t) + \zeta(\mathbf{V}(\mathbf{r},t) - \mathbf{U}(\mathbf{r},t)))\,d\zeta.$$

Hence, according to Lemma 4.5,

$$\|\mathbf{H}(\mathbf{X},\mathbf{U})\|_{n,2} = \|\mathcal{D}_m\mathbf{X}\|_{n,2} \leq \|\mathbf{X}\|_{n,2}.$$

We use this result and Lemma 4.6 in (4.3) to obtain

$$| \left\langle \mathbf{X},\, \mathbf{L}^{-1} g_m(\mathbf{H}(\mathbf{X},\mathbf{U})) \right\rangle | \leq \tau_{\max} DS_m \, \|g\|_{\mathcal{G}} \, \|\mathbf{X}\|_{n,2}^2,$$

and the conclusion follows. □

An identical sufficient condition holds for the stability of a solution to (2.7).

Theorem 4.8. *A sufficient condition for the absolute stability of a solution to* (2.7) *is*

$$DS_m \tau_{\max} \, \|g\|_{\mathcal{G}} < 1.$$

Proof. Let $\mathbf{U}$ be the unique solution of (2.7) with an external current $\mathbf{I}_{\text{ext}}(\mathbf{r},t)$ and initial conditions $\mathbf{U}(0) = \mathbf{U}_0$. As in the proof of Theorem 4.7, we introduce the new function $\mathbf{X} = \mathbf{V} - \mathbf{U}$, where $\mathbf{V}$ is the unique solution of the same equation with different initial conditions. We have

$$\begin{aligned} \mathbf{X}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{X}(\mathbf{r},t) &+ \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{V}(\mathbf{r}',t)\, d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t) \right) \\ &- \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{U}(\mathbf{r}',t)\, d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t) \right). \end{aligned} \tag{4.4}$$

Using a zeroth-order Taylor expansion, as in the proof of Lemma 3.1, this equation can be rewritten as

$$\begin{aligned} \mathbf{X}_t(\mathbf{r},t) = -\mathbf{L}\mathbf{X}(\mathbf{r},t) + \Bigg(\int_0^1 D\mathbf{S}\Bigg(&\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{U}(\mathbf{r}'t)\, d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t) \\ &+ \zeta \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{X}(\mathbf{r}',t)\, d\mathbf{r}' \Bigg) d\zeta \Bigg) \left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{X}(\mathbf{r}',t)\, d\mathbf{r}' \right). \end{aligned}$$

We use the same functional as in the proof of Theorem 4.7:

$$V(\mathbf{X}) = \frac{1}{2} \left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathbf{X} \right\rangle.$$

Its time derivative is readily obtained with the help of (4.4),

$$\frac{dV(\mathbf{X})}{dt} = -\left\langle \mathbf{X},\, \mathbf{X} \right\rangle + \left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathcal{D}_m h_m(\mathbf{X}) \right\rangle, \tag{4.5}$$

where $\mathcal{D}_m$ is defined by

$$\begin{aligned} &\mathcal{D}_m(\mathbf{U},\mathbf{X},\mathbf{r},t) \\ &= \int_0^1 D\mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{U}(t)\, d\mathbf{r}' + \mathbf{I}_{\text{ext}}(\mathbf{r},t) + \zeta \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\mathbf{X}(\mathbf{r}',t)\, d\mathbf{r}' \right) D\mathbf{S}_m^{-1}\, d\zeta, \end{aligned}$$

a diagonal matrix whose diagonal elements are continuous functions with values between 0 and 1. We consider the second term on the right-hand side of (4.5) and use the property of matrix $\mathcal{D}_m$ and Lemma 4.6 to obtain

$$\begin{aligned} | \left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathcal{D}_m h_m(\mathbf{X}) \right\rangle | &\leq \|\mathbf{X}\|_{n,2} \|\mathbf{L}^{-1}\mathcal{D}_m h_m(\mathbf{X})\|_{n,2} \\ &\leq \tau_{\max} \|\mathbf{X}\|_{n,2} \, \|h_m(\mathbf{X})\|_{n,2} \leq \tau_{\max}\, DS_m \, \|g\|_{\mathcal{G}} \, \|\mathbf{X}\|_{n,2}^2, \end{aligned}$$

from which the result follows. □

Note that $\|g\|_{\mathcal{G}} = \|g\|_{\mathbf{L}^2}$ by density of $\mathcal{G}$ in $\mathbf{L}^2$ (see section 6). In Appendix A, we show how to compute such operator norms.

4.2. The convolution case. In the case where $\mathbf{W}$ is translation invariant, we can obtain a slightly easier to exploit sufficient condition for the stability of the solutions than in Theorems 4.7 and 4.8. We first consider the case of a general compact Ω and then the case where Ω is an interval. Translation invariance means that $\mathbf{W}(\mathbf{r}+\mathbf{a},\ \mathbf{r}'+\mathbf{a},\ t) = \mathbf{W}(\mathbf{r},\mathbf{r}',t)$ for all $\mathbf{a}$ such that $\mathbf{a}+\mathbf{r} \in \Omega$ and $\mathbf{a}+\mathbf{r}' \in \Omega$, so we can write $\mathbf{W}(\mathbf{r},\mathbf{r}',t) = \mathbf{W}(\mathbf{r}-\mathbf{r}',t)$. Hence $\mathbf{W}(\mathbf{r},t)$ must be defined for all $\mathbf{r} \in \widehat{\Omega} = \{\mathbf{r}-\mathbf{r}', \text{ with } \mathbf{r},\mathbf{r}' \in \Omega\}$, and we suppose it to be continuous on $\widehat{\Omega}$ for each t. $\widehat{\Omega}$ is a symmetric with respect to the origin, compact subset of $\mathbb{R}^q$.

4.2.1. General $\boldsymbol{\Omega}$. We denote $\mathbf{1}_A$ as the characteristic function of the subset A of $\mathbb{R}^q$ and $\mathbf{M}^* = \overline{\mathbf{M}}^T$ as the conjugate transpose of the complex matrix $\mathbf{M}$.

We prove the following theorem.

THEOREM 4.9. *If the eigenvalues of the Hermitian matrix*

$$\widetilde{\mathbf{W}}^*(\mathbf{f},t)\,\widetilde{\mathbf{W}}(\mathbf{f},t) \tag{4.6}$$

are strictly less than $(\tau_{\max} DS_m)^{-2}$ for almost all $\mathbf{f} \in \mathbb{R}^q$ and $t \in \mathrm{J}$, then the system (2.6) *is absolutely stable.*[1] *$\widetilde{\mathbf{W}}(\mathbf{f},t)$ is the Fourier transform with respect to the space variable $\mathbf{r}$ of $\mathbf{1}_{\widehat{\Omega}}(\mathbf{r})\,\mathbf{W}(\mathbf{r},t)$,*

$$\widetilde{\mathbf{W}}(\mathbf{f},t) = \int_{\widehat{\Omega}} \mathbf{W}(\mathbf{r},t) e^{-2i\pi \mathbf{r}\cdot\mathbf{f}}\, d\mathbf{r}.$$

Proof. We recall that

$$\|g\|_{\mathcal{G}}^2 = \sup_{\|\mathbf{x}\|_{n,2} \le 1} \frac{\|g(\mathbf{x})\|_{n,2}^2}{\|\mathbf{x}\|_{n,2}^2}.$$

We then note that, by definition,

$$\|g(\mathbf{x})\|_{n,2} = \|(\mathbf{1}_{\widehat{\Omega}}\mathbf{W}) \otimes (\mathbf{1}_\Omega \mathbf{x})\|_{\mathbb{R}^q,\,n,\,2},$$

where $\otimes$ indicates the convolution over $\mathbb{R}^q$. Parseval's theorem gives

$$\|(\mathbf{1}_{\widehat{\Omega}}\mathbf{W}) \otimes (\mathbf{1}_\Omega \mathbf{x})\|_{\mathbb{R}^q,\,n,\,2}^2 = \int_{\mathbb{R}^q} \widetilde{\mathbf{x}}^*(\mathbf{f},t)\widetilde{\mathbf{W}}^*(\mathbf{f},t)\widetilde{\mathbf{W}}(\mathbf{f},t)\widetilde{\mathbf{x}}(\mathbf{f},t)\, d\mathbf{f},$$

where $\widetilde{\mathbf{x}}$ is the Fourier transform of $\mathbf{1}_\Omega \mathbf{x}$.

As a Hermitian matrix, $\widetilde{\mathbf{W}}^*(\mathbf{f},t)\widetilde{\mathbf{W}}(\mathbf{f},t)$ can be rewritten as $\mathbf{U}^*(\mathbf{f},t)\mathbf{D}(\mathbf{f},t)\mathbf{U}(\mathbf{f},t)$, with $\mathbf{U}^*\mathbf{U} = \mathrm{Id_n}$ and $\mathbf{D}$ real and diagonal. In particular, $\mathbf{U}$ preserves length ($\|\mathbf{U}\mathbf{v}\|_2 = \|\mathbf{v}\|_2$). Besides, $\widetilde{\mathbf{W}}^*\widetilde{\mathbf{W}}$ is positive because for any complex vector $\mathbf{v}$,

$$\mathbf{v}^*\widetilde{\mathbf{W}}^*\widetilde{\mathbf{W}}\mathbf{v} = \|\widetilde{\mathbf{W}}\mathbf{v}\|_2^2 \ge 0.$$

So, all values of $\mathbf{D}$ are positive, and if the hypothesis of the theorem is satisfied, Lemma 4.5 yields

$$\begin{aligned}&\int_{\mathbb{R}^q} \widetilde{\mathbf{x}}^*(\mathbf{f},t)\widetilde{\mathbf{W}}^*(\mathbf{f},t)\widetilde{\mathbf{W}}(\mathbf{f},t)\widetilde{\mathbf{x}}(\mathbf{f},t)\, d\mathbf{f} = \|\sqrt{\mathbf{D}}\mathbf{U}\widetilde{\mathbf{x}}\|_{\mathbb{R}^q,\,n,\,2}^2 \\ &\quad\le (\tau_{\max} DS_m)^{-2}\|\mathbf{U}\widetilde{\mathbf{x}}\|_{\mathbb{R}^q,\,n,\,2}^2 = (\tau_{\max} DS_m)^{-2}\|\widetilde{\mathbf{x}}\|_{\mathbb{R}^q,\,n,\,2}^2 = (\tau_{\max} DS_m)^{-2}\|\mathbf{x}\|_{n,2}^2;\end{aligned}$$

[1] Note that since $\widetilde{\mathbf{W}}$ is continuous with respect to $\mathbf{f}$, some eigenvalues of the Hermitian matrix may be equal to $(\tau_{\max} DS_m)^{-2}$ on a domain of measure 0 of the $\mathbf{f}$-plane.

hence $\|g\|_{\mathcal{G}} < (\tau_{\max} D S_m)^{-1}$, and Theorem 4.7 applies. □

Since the sufficient condition for the absolute stability of the solution of the activation-based model is identical, we have the following theorem.

THEOREM 4.10. *If the eigenvalues of the Hermitian matrix*

$$\widetilde{\mathbf{W}}^*(\mathbf{f},t)\,\widetilde{\mathbf{W}}(\mathbf{f},t)$$

are strictly less than $(\tau_{\max} D S_m)^{-2}$ *for almost all* $\mathbf{f}$ *and* $t \in \mathrm{J}$, *then the system* (2.7) *is absolutely stable.* $\widetilde{\mathbf{W}}(\mathbf{f},t)$ *is the Fourier transform of* $\mathbf{1}_{\widehat{\Omega}}(\mathbf{r})\mathbf{W}(\mathbf{r},t)$ *with respect to the space variable* $\mathbf{r}$.

These two theorems are somewhat unsatisfactory since they replace a condition that must be satisfied over a countable set, the spectrum of a compact operator, as in Theorems 4.7 and 4.8, by a condition that must be satisfied over a continuum, i.e., $\mathbb{R}^q$. Nonetheless, one may consider that the computation of the Fourier transforms of the matrix $\mathbf{W}$, extended by zeros outside $\widehat{\Omega}$, is easier than that of the spectrum of the operator g, for which a method is given in section A.3.

4.2.2. Ω is an interval. In the case where Ω is an interval, i.e., an interval of $\mathbb{R}$ ($q = 1$), a parallelogram ($q = 2$), or a parallelepiped ($q = 3$), we can state different sufficient conditions. We can always assume that Ω is the q-dimensional interval $[0,1]^q$ by applying an affine change of coordinates. The connectivity matrix $\mathbf{W}$ is defined on $\mathrm{J} \times [-1,1]^{\mathrm{q}}$ and extended to a q-periodic function of periods 2 on $\mathrm{J} \times \mathbb{R}^{\mathrm{q}}$, reflecting periodic boundary conditions. Similarly, the state vectors $\mathbf{V}$ and $\mathbf{A}$ as well as the external current $\mathbf{I}_{\mathrm{ext}}$ defined on $\mathrm{J} \times [0,1]^{\mathrm{q}}$ are extended to q-periodic functions of the same periods over $\mathrm{J} \times \mathbb{R}^{\mathrm{q}}$ by padding them with zeros in the complement in the interval $[-1,1]^q$ of the interval $[0,1]^q$. $\mathcal{G}$ is now the space $\mathbf{L}^2_n(2)$ of the square-integrable q-periodic functions of periods 2 with values in $\mathbb{R}^n$.

We define the functions $\psi_{\mathbf{m}}(\mathbf{r}) \equiv e^{-\pi i(r_1 m_1 + \cdots + r_q m_q)}$ for $\mathbf{m} \in \mathbb{Z}^q$ and consider the matrix $\widetilde{\mathbf{W}}(\mathbf{m},t)$ whose elements are given by

$$\widetilde{W}_{ij}(\mathbf{m},t) = \int_{[0,2]^q} W_{ij}(\mathbf{r},t)\psi_{\mathbf{m}}(\mathbf{r})\,d\mathbf{r}, \quad 1 \le i,\, j \le n.$$

We recall the following definition.

DEFINITION 4.11. *The matrix* $\widetilde{\mathbf{W}}(\mathbf{m})$ *is the* $\mathbf{m}$*th element of the Fourier series of the periodic matrix function* $\mathbf{W}(\mathbf{r})$.

Theorems 4.9 and 4.10 can be stated in this framework.

THEOREM 4.12. *If the eigenvalues of the Hermitian matrix*

$$\widetilde{\mathbf{W}}^*(\mathbf{m},t)\,\widetilde{\mathbf{W}}(\mathbf{m},t) \tag{4.7}$$

are strictly less than $(\tau_{\max} D S_m)^{-2}$ *for all* $\mathbf{m} \in \mathbb{Z}^q$ *and all* $t \in \mathrm{J}$, *then the system* (2.6) *(resp.,* (2.7)*) is absolutely stable.* $\widetilde{\mathbf{W}}(\mathbf{m},t)$ *is the* $\mathbf{m}$*th element of the Fourier series of the q-periodic matrix function* $\mathbf{W}(\mathbf{r},t)$ *with periods* 2 *at time* t.

5. Absolute stability of the homogeneous solution.

We next investigate the absolute stability of a homogeneous solution to (2.6) and (2.7). As in the previous section, we distinguish the general and convolution cases.

5.1. The general case. The homogeneous solutions are characterized by the fact that they are spatially constant at each time instant. We consider the subspace $\mathcal{G}_c$ of $\mathcal{G}$ of the constant functions. We have the following lemma.

LEMMA 5.1. *$\mathcal{G}_c$ is a complete linear subspace of $\mathcal{G}$. The orthogonal projection operator $\mathcal{P}_{\mathcal{G}_c}$ from $\mathcal{G}$ to $\mathcal{G}_c$ is defined by*

$$\mathcal{P}_{\mathcal{G}_c}(\mathbf{x}) = \overline{\mathbf{x}} = \frac{1}{|\Omega|}\int_\Omega \mathbf{x}(\mathbf{r})\,d\mathbf{r}.$$

The orthogonal complement $\mathcal{G}_c^\perp$ of $\mathcal{G}_c$ is the subset of functions of $\mathcal{G}$ that have a zero average. The orthogonal projection[2] *operator $\mathcal{P}_{\mathcal{G}_c^\perp}$ is equal to $\mathrm{Id} - \mathcal{P}_{\mathcal{G}_c}$. We also have*

$$\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{M}\mathbf{x} = \mathbf{M}\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{x} \quad \forall\,\mathbf{x}\in\mathcal{G},\,\mathbf{M}\in\mathcal{M}_{n\times n}. \tag{5.1}$$

Proof. The constant functions are clearly in $\mathcal{G}$. Any Cauchy sequence of constants is converging to a constant; hence $\mathcal{G}_c$ is closed in the pre-Hilbert space $\mathcal{G}$. Therefore, there exists an orthogonal projection operator from $\mathcal{G}$ to $\mathcal{G}_c$ which is linear, continuous, of unit norm, positive, and self-adjoint. $\mathcal{P}_{\mathcal{G}_c}(\mathbf{x})$ is the minimum with respect to the constant vector $\mathbf{a}$ of the integral $\int_\Omega \|\mathbf{x}(\mathbf{r})-\mathbf{a}\|^2\,d\mathbf{r}$. Taking the derivative with respect to $\mathbf{a}$, we obtain the necessary condition

$$\int_\Omega (\mathbf{x}(\mathbf{r})-\mathbf{a})\,d\mathbf{r} = 0$$

and hence $\mathbf{a}_{min} = \overline{\mathbf{x}}$. Conversely, $\mathbf{x}-\mathbf{a}_{min}$ is orthogonal to $\mathcal{G}_c$ since $\int_\Omega(\mathbf{x}(\mathbf{r}) - \mathbf{a}_{min})\mathbf{b}\,d\mathbf{r} = 0$ for all $\mathbf{b}\in\mathcal{G}_c$.

Let $\mathbf{y}\in\mathcal{G}$, $\int_\Omega \mathbf{x}\,\mathbf{y}(\mathbf{r})\,d\mathbf{r} = \mathbf{x}\int_\Omega \mathbf{y}(\mathbf{r})\,d\mathbf{r} = 0$ for all $\mathbf{x}\in\mathcal{G}_c$ if and only if $\mathbf{y}\in\mathcal{G}_c^\perp$.

Finally,

$$\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{M}\mathbf{x} = \mathbf{M}\mathbf{x} - \overline{\mathbf{M}\mathbf{x}} = \mathbf{M}\mathbf{x} - \mathbf{M}\overline{\mathbf{x}} = \mathbf{M}(\mathbf{x}-\overline{\mathbf{x}}) = \mathbf{M}\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{x}. \qquad \square$$

We are now ready to prove the theorem on the absolute stability of the homogeneous solutions to (2.6).

THEOREM 5.2. *If $\mathbf{W}$ satisfies* (3.5)*, a sufficient condition for the absolute stability of a homogeneous solution to* (2.6) *is that the norm $\|g^*\|_{\mathcal{G}_c^\perp}$ of the restriction to $\mathcal{G}_c^\perp$ of the compact operator g^* be less than $(\tau_{\max}DS_m)^{-1}$ for all $t\in$* J.

Proof. This proof is inspired by [31]. Note that $\mathcal{G}_c^\perp$ is invariant by g^* and hence by g_m^*. Indeed, from Lemma 4.4 and (3.5) we have

$$\overline{g^*(\mathbf{x})} = \overline{\mathbf{W}^T}(t)\overline{\mathbf{x}} = 0 \quad \forall\mathbf{x}\in\mathcal{G}_c^\perp.$$

Let $\mathbf{V}_p$ be the unique solution of (2.6) with homogeneous input $\mathbf{I}_{\mathrm{ext}}(t)$ and initial conditions $\mathbf{V}_p(0) = \mathbf{V}_{p0}\in\mathcal{G}$, and consider the initial value problem

$$\left\{\begin{array}{rcl} \mathbf{X}'(t) & = & \mathcal{P}_{\mathcal{G}_c^\perp}\left(f_v(t, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X} + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p)\right), \\ \mathbf{X}(0) & = & \mathbf{X}_0. \end{array}\right. \tag{5.2}$$

$\mathbf{X} = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{V}_p$ is a solution with initial condition $\mathbf{X}_0 = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{V}_{p0}$, since $\mathcal{P}_{\mathcal{G}_c^\perp}^2 = \mathcal{P}_{\mathcal{G}_c^\perp}$, and $\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{V}_p + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p = \mathbf{V}_p$. But $\mathbf{X} = 0$ is also a solution with initial condition $\mathbf{X}_0 = 0$. Indeed $\mathcal{G}_c$ is flow-invariant because of (3.5), that is, $f_v(t,\mathcal{G}_c)\subset\mathcal{G}_c$, and hence $\mathcal{P}_{\mathcal{G}_c^\perp}(f_v(t,\mathcal{G}_c)) = 0$. We therefore look for a sufficient condition for the system (5.2) to be absolutely stable at $\mathbf{X} = 0$.

[2] To be accurate, this is the projection on the closure of $\mathcal{G}_c^\perp$ in the closure of $\mathcal{G}$, which is the Hilbert space $\mathbf{L}_n^2(\Omega)$.

We consider again the functional $V(\mathbf{X}) = \frac{1}{2}\left\langle \mathbf{X},\, \mathbf{L}^{-1}\mathbf{X}\right\rangle$ with time derivative $\frac{dV(\mathbf{X})}{dt} = \left\langle\, \mathbf{X},\, \mathbf{L}^{-1}\mathbf{X}_t \,\right\rangle$. We substitute $\mathbf{X}_t$ with its value from (5.2) which can be rewritten as

$$\mathbf{X}_t = \mathcal{P}_{\mathcal{G}_c^\perp}\left(-\mathbf{L}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X} + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p) + \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}',t)\,\mathbf{S}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t) + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t))\,d\mathbf{r}'\right).$$

Because of Lemma 5.1 this yields

$$\mathbf{X}_t = -\mathbf{L}\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X} + \mathcal{P}_{\mathcal{G}_c^\perp}\left(\int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)\,\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t) + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t))\,d\mathbf{r}'\right).$$

Using a zeroth-order Taylor expansion, as in the proof of Lemma 3.1, we write

$$\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X} + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p) = \underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p) + \left(\int_0^1 D\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p + \zeta\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X})\,d\zeta\right)\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X},$$

and since $\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p) \in \mathcal{G}_c$, and because of (3.5),

$$\begin{aligned}&\mathcal{P}_{\mathcal{G}_c^\perp}\left(\int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)\,\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t) + \mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t))\,d\mathbf{r}'\right)\\ &= \mathcal{P}_{\mathcal{G}_c^\perp}\left(\int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)\left(\int_0^1 D\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t)+\zeta\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t))\,d\zeta\right)\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t)\,d\mathbf{r}'\right).\end{aligned}$$

We use (5.1) and the fact that $\mathcal{P}_{\mathcal{G}_c^\perp}$ is self-adjoint and idempotent to write

$$\begin{aligned}\frac{dV(\mathbf{X})}{dt} = -\langle\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X},\, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}\rangle + \Bigg\langle \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X},\, \mathbf{L}^{-1}\int_\Omega \mathbf{W}_{cm}(\mathbf{r},\mathbf{r}',t)&\\ \cdot\left(\int_0^1 D\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t) + \zeta\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t))\,d\zeta\right)\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t)\,d\mathbf{r}'\Bigg\rangle&.\end{aligned}$$

Let us denote by $\mathcal{D}_v(\mathbf{r}',t)$ the diagonal matrix $\int_0^1 D\underline{\mathbf{S}}(\mathcal{P}_{\mathcal{G}_c}\mathbf{V}_p(\mathbf{r}',t)+\zeta\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}(\mathbf{r}',t))\,d\zeta$. Its diagonal elements are continuous functions with values between 0 and 1. Letting $\mathbf{Y} = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{X}$, we rewrite the previous equation in operator form, introducing the operator g_m (Definition 4.1), as

$$\frac{dV(\mathbf{X})}{dt} = -\langle\mathbf{Y},\, \mathbf{Y}\rangle + \left\langle\mathbf{Y},\, \mathbf{L}^{-1}g_m(\mathcal{D}_v\,\mathbf{Y})\right\rangle.$$

By definition of the adjoint

$$\left\langle\mathbf{Y},\, \mathbf{L}^{-1}g_m(\mathcal{D}_v\,\mathbf{Y})\right\rangle = \left\langle g_m^*\left(\mathbf{L}^{-1}\mathbf{Y}\right),\, \mathcal{D}_v\,\mathbf{Y}\right\rangle.$$

Using the Cauchy–Schwarz inequality and Lemma 4.5

$$\left|\left\langle g_m^*\left(\mathbf{L}^{-1}\mathbf{Y}\right),\, \mathcal{D}_v\,\mathbf{Y}\right\rangle\right| \le \left\|g_m^*\left(\mathbf{L}^{-1}\mathbf{Y}\right)\right\|_{n,2}\|\mathcal{D}_v\,\mathbf{Y}\|_{n,2} \le \left\|g_m^*\left(\mathbf{L}^{-1}\mathbf{Y}\right)\right\|_{n,2}\|\mathbf{Y}\|_{n,2},$$

and since

$$\left\|g_m^*\left(\mathbf{L}^{-1}\mathbf{Y}\right)\right\|_{n,2} \le \|g_m^*\|_{\mathcal{G}_c^\perp}\left\|\mathbf{L}^{-1}\mathbf{Y}\right\|_{n,2} \le \tau_{\max}DS_m\|g^*\|_{\mathcal{G}_c^\perp}\|\mathbf{Y}\|_{n,2},$$

the conclusion follows. □

Note that $\|g^*\|_{\mathcal{G}_c^\perp} = \|g^*\|_{\mathbf{L}_0^2}$ by density of $\mathcal{G}_c^\perp$ in $\mathbf{L}_0^2$, where $\mathbf{L}_0^2$ is the subspace of $\mathbf{L}^2$ of zero mean functions. We show in Appendix A how to compute this norm.

We prove a similar theorem in the case of (2.7).

THEOREM 5.3. *If* $\mathbf{W}$ *satisfies* (3.5), *a sufficient condition for the stability of a homogeneous solution to* (2.7) *is that the norm* $\|g\|_{\mathcal{G}_c^\perp}$ *of the restriction to* $\mathcal{G}_c^\perp$ *of the compact operator* g *be less than* $(\tau_{\max} DS_m)^{-1}$ *for all* $t \in \mathrm{J}$.

Proof. The proof is similar to that of Theorem 5.2. We consider $\mathbf{A}_p$ the unique solution to (2.7) with homogeneous input $\mathbf{I}_{\text{ext}}(t)$ and initial conditions $\mathbf{A}_p(0) = \mathbf{A}_{p0}$, and we consider the initial value problem

$$\left\{ \begin{array}{lcl} \mathbf{A}'(t) & = & \mathcal{P}_{\mathcal{G}_c^\perp}\left(f_a(t, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A} + \mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p)\right), \\ \mathbf{A}(0) & = & \mathbf{A}_0. \end{array} \right. \tag{5.3}$$

$\mathbf{A} = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}_p$ is a solution with initial conditions $\mathbf{A}_0 = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}_{p0}$ since $\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}_p + \mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p = \mathbf{A}_p$. But $\mathbf{A} = 0$ is also a solution with initial conditions $\mathbf{A}_0 = 0$. Indeed, $\mathcal{G}_c$ is flow-invariant because of (3.5), that is, $f_a(t, \mathcal{G}_c) \subset \mathcal{G}_c$, and hence $\mathcal{P}_{\mathcal{G}_c^\perp}(f_a(t, \mathcal{G}_c)) = 0$. We therefore look for a sufficient condition for the system (5.3) to be absolutely stable at $\mathbf{A} = 0$.

Consider again the functional $V(\mathbf{A}) = \frac{1}{2}\left\langle \mathbf{A}, \mathbf{L}^{-1}\mathbf{A} \right\rangle$ with time derivative $\frac{dV(\mathbf{A})}{dt} = \left\langle \mathbf{A}, \mathbf{L}^{-1}\mathbf{A}_t \right\rangle$. We substitute $\mathbf{A}_t$ with its value from (5.3) which, using (3.5), can be rewritten as

$$\mathbf{A}_t = \mathcal{P}_{\mathcal{G}_c^\perp}\Bigg(-\mathbf{L}(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A} + \mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p) + \mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}(\mathbf{r}', t)\, d\mathbf{r}' + \overline{\mathbf{W}}(t)\mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p + \mathbf{I}_{\text{ext}}(t) \right) \Bigg).$$

We perform a first-order Taylor expansion with integral remainder of the $\mathbf{S}$ term and introduce the operator h_m (Definition 4.1):

$$\begin{aligned} &\mathbf{S}\left(\int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}(\mathbf{r}', t)\, d\mathbf{r}' + \overline{\mathbf{W}}(t)\mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p + \mathbf{I}_{\text{ext}}(t) \right) = \\ &\qquad \mathbf{S}\left(\overline{\mathbf{W}}(t)\mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p + \mathbf{I}_{\text{ext}}(t) \right) \\ &+ \left(\int_0^1 D\underline{\mathbf{S}}\left(\overline{\mathbf{W}}(t)\mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p + \mathbf{I}_{\text{ext}}(t) + \zeta \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}(\mathbf{r}', t)\, d\mathbf{r}' \right) d\zeta \right) h_m(\mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A})(\mathbf{r}, t). \end{aligned}$$

Let us define

$$\mathcal{D}_a(\mathbf{r}, t) = \int_0^1 D\underline{\mathbf{S}}\left(\overline{\mathbf{W}}(t)\mathcal{P}_{\mathcal{G}_c}\mathbf{A}_p + \mathbf{I}_{\text{ext}}(t) + \zeta \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\, \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}(\mathbf{r}', t)\, d\mathbf{r}' \right) d\zeta,$$

a diagonal matrix whose diagonal elements are continuous functions with values between 0 and 1. Letting $\mathbf{Y} = \mathcal{P}_{\mathcal{G}_c^\perp}\mathbf{A}$, we write

$$\frac{dV(\mathbf{A})}{dt} = -\langle \mathbf{Y}, \mathbf{Y} \rangle + \left\langle \mathbf{Y}, \mathbf{L}^{-1}\mathcal{D}_a\, h_m(\mathbf{Y}) \right\rangle,$$

and the conclusion follows from the Cauchy–Schwarz inequality and Lemmas 4.5 and 4.6:

$$\begin{aligned}\left|\left\langle \mathbf{Y},\, \mathbf{L}^{-1}\mathcal{D}_a\, h_m(\mathbf{Y})\right\rangle\right| &\leq\leq \|\mathbf{Y}\|_{n,2}\, \left\|\mathbf{L}^{-1}\mathcal{D}_a\, h_m(\mathbf{Y})\right\|_{n,2} \\ &\leq \tau_{\max}\, \|\mathbf{Y}\|_{n,2}\, \|h_m(\mathbf{Y})\|_{n,2} \leq \tau_{\max} DS_m\, \|g\|_{\mathcal{G}_c^{\perp}}\, \|\mathbf{Y}\|_{n,2}^{2}. \qquad \square\end{aligned}$$

5.2. The convolution case. As $\mathbf{W}$ is translation-invariant, $\int_\Omega \mathbf{W}(\mathbf{r}-\mathbf{r}',t)\,d\mathbf{r}'$ is in general a function of $\mathbf{r}$, unless Ω has no border. In our framework, this case occurs only when Ω is an interval with periodic conditions and we have the following theorem.

THEOREM 5.4. *A sufficient condition for the stability of a homogeneous solution to* (2.6) *(resp.,* (2.7)*) is that the eigenvalues of the Hermitian matrices*

$$\widetilde{\mathbf{W}}^*(\mathbf{m},t)\widetilde{\mathbf{W}}(\mathbf{m},t)$$

are strictly less than $(\tau_{\max}\, DS_m)^{-2}$ *for all* $\mathbf{m} \neq \mathbf{0} \in \mathbb{Z}^q$ *and all* $t \in \mathrm{J}$. $\widetilde{\mathbf{W}}(\mathbf{m},t)$ *is the* $\mathbf{m}$*th element of the Fourier series of the q-periodic matrix function* $\mathbf{W}(\mathbf{r},t)$ *with respect to the space variable* $\mathbf{r}$.

The only difference from Theorem 4.12 is that there are no constraints on the Fourier coefficient $\mathbf{m} = 0$. This is due to the fact that we "look" only at the subspace of $\mathcal{G}$ of functions with zero spatial average.

5.3. Complete synchronization. The property of absolute stability of the solution that is characterized in Theorems 5.2, 5.3, and 5.4 can be seen as the ability for the neural masses in the continuum to synchronize. By synchronization we mean that the state vectors at all points in the continuum converge to a unique state vector that is a function only of the common input $\mathbf{I}_{\text{ext}}$ and not of the initial states of the neural masses. The state vector is the homogeneous solution of (2.6) and (2.7). This effect is called complete synchronization [32].

6. Extending the theory. We have developed our analysis of (2.6) and (2.7) in the Banach space $\mathcal{F}$ of continuous functions of the spatial coordinate $\mathbf{r}$ even though we have used a structure of pre-Hilbert space $\mathcal{G}$ on top of it. But there remains the fact that the solutions that we have been discussing are smooth, i.e., continuous with respect to the space variable. It may be interesting to also consider nonsmooth solutions, e.g., piecewise continuous solutions that can be discontinuous along curves of Ω. A natural setting, given the fact that we are interested in having a structure of Hilbert space, is $\mathbf{L}^2_n(\Omega)$, the space of square-integrable functions from Ω to $\mathbb{R}^n$; see Appendix A. It is a Hilbert space and $\mathcal{G}$ is a dense subspace, $\overline{\mathcal{G}} = \mathbf{L}^2_n(\Omega)$, where $\overline{A}$ indicates the topological closure of the set A.

6.1. Existence, uniqueness, and stability of a solution. The theory developed in the previous sections can be readily extended to $\mathbf{L}^2_n(\Omega)$: the analysis of the stability of the general and homogeneous solutions has been done using the pre-Hilbert space structure of $\mathcal{G}$, and all the operators that have been shown to be compact in $\mathcal{G}$ are also compact in its closure $\mathbf{L}^2_n(\Omega)$ [9]. The only point that has to be reworked is the problem of existence and uniqueness of a solution addressed in Propositions 3.2 and 3.3. This allows us to *relax* the rather stringent spatial smoothness hypotheses imposed on the connectivity function $\mathbf{W}$ and the external current $\mathbf{I}_{\text{ext}}$, thereby bringing in more flexibility to the model. We have the following proposition.

PROPOSITION 6.1. *If the following two hypotheses are satisfied:*

1. *the mapping* $\mathbf{W}$ *is in* $C(\mathrm{J}; \mathbf{L}^2_{\mathrm{n}\times\mathrm{n}}(\Omega \times \Omega))$*,*
2. *the external current* $\mathbf{I}_{\mathrm{ext}}$ *is in* $C(\mathrm{J}; \mathbf{L}^2_{\mathrm{n}}(\Omega))$*,*

then the mappings f_v *and* f_a *are from* $\mathrm{J} \times \mathbf{L}^2_{\mathrm{n}}(\Omega)$ *to* $\mathbf{L}^2_n(\Omega)$*, continuous, and Lipschitz continuous with respect to their second argument, uniformly with respect to the first.*

Proof. Because of the first hypothesis, the fact that $\mathbf{S}(\mathbf{x})$ is in $\mathbf{L}^2_n(\Omega)$ for all $\mathbf{x} \in \mathbf{L}^2_n(\Omega)$, and because of Lemma A.2, f_v is well defined. Let us prove that it is continuous. As in the proof of Proposition 3.2, we write

$$f_v(t,\mathbf{x}) - f_v(s,\mathbf{y}) = -\mathbf{L}(\mathbf{x}-\mathbf{y}) + \int_\Omega (\mathbf{W}(\cdot,\mathbf{r}',t) - \mathbf{W}(\cdot,\mathbf{r}',s))\mathbf{S}(\mathbf{x}(\mathbf{r}'))\,d\mathbf{r}'$$
$$+ \int_\Omega \mathbf{W}(\cdot,\mathbf{r}',s)(\mathbf{S}(\mathbf{x}(\mathbf{r}')) - \mathbf{S}(\mathbf{y}(\mathbf{r}')))\,d\mathbf{r}' + \mathbf{I}_{\mathrm{ext}}(\cdot,t) - \mathbf{I}_{\mathrm{ext}}(\cdot,s),$$

from which we obtain, using Lemma A.2,

$$\|f_v(t,\mathbf{x}) - f_v(s,\mathbf{y})\|_{n,2} \le \|\mathbf{L}\|_F\|\mathbf{x}-\mathbf{y}\|_{n,2} + \sqrt{n|\Omega|}S_m\|\mathbf{W}(\cdot,\cdot,t) - \mathbf{W}(\cdot,\cdot,s)\|_F$$
$$+ DS_m\|\mathbf{W}(\cdot,\cdot,s)\|_F\|\mathbf{x}-\mathbf{y}\|_{n,2} + \|\mathbf{I}_{\mathrm{ext}}(\cdot,t) - \mathbf{I}_{\mathrm{ext}}(\cdot,s)\|_{n,2},$$

and the continuity follows from the hypotheses. $\|\ \|_F$ is the Frobenius norm; see Appendix A. Note that since $\mathbf{W}$ is continuous on the compact interval J, it is bounded and $\|\mathbf{W}(\cdot,\cdot,t)\|_F \le w$ for all $t \in \mathrm{J}$ for some positive constant w. The Lipschitz continuity with respect to the second argument uniformly with respect to the first one follows from the previous inequality by choosing $s = t$.

The proof for f_a is similar. □

From this proposition we deduce the existence and uniqueness of a solution over a subinterval of $\mathbb{R}$.

PROPOSITION 6.2. *Subject to the hypotheses of Proposition* 6.1 *for any element* $\mathbf{V}_0$ *of* $\mathbf{L}^2_n(\Omega)$ *there is a unique solution* $\mathbf{V}$*, defined on a subinterval of* J *containing* 0 *and continuously differentiable, of the abstract initial value problem* (3.1) *for* $f = f_v$ *and* $f = f_a$ *such that* $\mathbf{V}(0) = \mathbf{V}_0$*.*

Proof. All conditions of the Picard–Lindelöf theorem on differential equations in Banach spaces (here a Hilbert space) [9, 2] are satisfied; hence the proposition is proved. □

We can also prove that this solution exists for all times, as in Proposition 3.4.

PROPOSITION 6.3. *If the following two hypotheses are satisfied:*

1. *the connectivity function* $\mathbf{W}$ *is in* $C(\mathbb{R}; \mathbf{L}^2_{\mathrm{n}\times\mathrm{n}}(\Omega \times \Omega))$*,*
2. *the external current* $\mathbf{I}_{\mathrm{ext}}$ *is in* $C(\mathbb{R}; \mathbf{L}^2_{\mathrm{n}}(\Omega))$*,*

then for any function $\mathbf{V}_0$ *in* $\mathbf{L}^2_n(\Omega)$ *there is a unique solution* $\mathbf{V}$*, defined on* $\mathbb{R}$ *and continuously differentiable, of the abstract initial value problem* (3.1) *for* $f = f_v$ *and* $f = f_a$*.*

Proof. The proof is similar to that of Proposition 3.4. □

The absolute stability of the solution can be studied exactly as in Theorems 4.7 and 4.8. Since $\mathcal{G}$ is dense in $\mathbf{L}^2_n(\Omega)$, we have $\|g\|_{\mathcal{G}} = \|g\|_{\mathbf{L}^2_n(\Omega)}$ and similar relations for all the other operators. We have the following theorem.

THEOREM 6.4. *If the compact operator* g *satisfies the condition of Theorem* 4.7*, the solution of the abstract initial value problem* (3.1) *for* $f = f_v$ *and* $f = f_a$ *is absolutely stable.*

6.2. Locally homogeneous solutions. An application of the previous extension is the following. Consider a partition of Ω into P subregions Ω_i, $i = 1, \ldots, P$.

We assume that the Ω_is are closed, hence compact, subsets of Ω intersecting along finitely many piecewise regular curves. These curves form a set of 0 Lebesgue measure of Ω. We consider locally homogeneous input current functions

$$\mathbf{I}_{\text{ext}}(\mathbf{r},t) = \sum_{k=1}^{P} \mathbf{1}_{\Omega_k}(\mathbf{r})\mathbf{I}_{\text{ext}}^k(t), \tag{6.1}$$

where the P functions $\mathbf{I}_{\text{ext}}^k(t)$ are continuous on some closed interval J containing 0. On the border between two adjacent regions, the value of $\mathbf{I}_{\text{ext}}(\mathbf{r},t)$ is undefined. Since this set of borders is of 0 measure, the functions defined by (6.1) are in $\mathbf{L}_n^2(\Omega)$ at each time instant.

6.2.1. Existence and uniqueness. We are interested in the existence of solutions to the abstract initial value problem (3.1) that are homogeneous in each subregion Ω_i, $i = 1, \ldots, P$. We call them locally homogeneous solutions.

We assume that the connectivity matrix $\mathbf{W}$ satisfies the following conditions:

$$\int_{\Omega_k} \mathbf{W}(\mathbf{r},\mathbf{r}',t)\, d\mathbf{r}' = \sum_{i=1}^{P} \mathbf{1}_{\Omega_i}(\mathbf{r})\mathbf{W}_{ik}(t), \quad k = 1, \ldots, P. \tag{6.2}$$

These conditions are analogous to (3.5). A locally homogeneous solution of (2.6) or (2.7) can be written as

$$\mathbf{V}(\mathbf{r},t) = \sum_{i=1}^{P} \mathbf{1}_{\Omega_i}(\mathbf{r})\mathbf{V}_i(t),$$

where the functions $\mathbf{V}_i$ satisfy the system of ordinary differential equations

$$\mathbf{V}_i'(t) = -\mathbf{L}\mathbf{V}_i(t) + \sum_{k=1}^{P} \mathbf{W}_{ik}(t)\mathbf{S}(\mathbf{V}_k(t)) + \mathbf{I}_{\text{ext}}^i(t) \tag{6.3}$$

for the voltage-based model and

$$\mathbf{V}_i'(t) = -\mathbf{L}\mathbf{V}_i(t) + \mathbf{S}\left(\sum_{k=1}^{P} \mathbf{W}_{ik}(t)\mathbf{V}_k(t) + \mathbf{I}_{\text{ext}}^i(t)\right) \tag{6.4}$$

for the activity-based model. The conditions for the existence and uniqueness of a locally homogeneous solution are given in the following theorem, analogous to Theorem 3.5.

THEOREM 6.5. *If the external currents $\mathbf{I}_{\text{ext}}^k(t)$, $k = 1, \ldots, P$, and the connectivity matrices $\mathbf{W}_{ik}(t)$, $i, k = 1, \ldots, P$, are continuous on some closed interval* J *containing* 0*, then for all sets of P vectors $\mathbf{U}_0^k$, $k = 1, \ldots, P$, of $\mathbb{R}^n$, there exists a unique solution $(\mathbf{U}_1(t), \ldots, \mathbf{U}_P(t))$ of* (6.3) *or* (6.4) *defined on a subinterval* J_0 *of* J *containing* 0 *such that $\mathbf{U}_k(0) = \mathbf{U}_0^k$, $k = 1, \ldots, P$.*

Proof. The system (6.3) can be written in the form

$$\mathcal{V}'(t) = -\mathcal{L}\mathcal{V}(t) + \mathcal{W}(t)\mathcal{S}(\mathcal{V}(t)) + \mathcal{I}_{\text{ext}}(t), \tag{6.5}$$

where $\mathcal{V}$ is the nP-dimensional vector

$$\begin{pmatrix} \mathbf{V}_1 \\ \vdots \\ \mathbf{V}_P \end{pmatrix}, \mathcal{I}_{\text{ext}} = \begin{pmatrix} \mathbf{I}_{\text{ext}}^1 \\ \vdots \\ \mathbf{I}_{\text{ext}}^P \end{pmatrix}, \mathcal{S}(\mathcal{X}) = \begin{pmatrix} \mathbf{S}(\mathbf{X}_1) \\ \vdots \\ \mathbf{S}(\mathbf{X}_P) \end{pmatrix},$$

$\mathcal{W}$ is the block matrix $(\mathbf{W}_{ik})_{i,k}$, and $\mathcal{L}$ is the block diagonal matrix whose diagonal elements are all equal to $\mathbf{L}$. Then we are dealing with a classical initial value problem of dimension nP, and the proof of existence and uniqueness is similar to that of Theorem 3.5. A similar proof can be written in the case of system (6.4). $\square$

Again, if $\mathcal{I}_{\text{ext}}$ and $\mathcal{W}$ are continuous on $\mathbb{R}$, the existence and uniqueness result extends to the whole time line $\mathbb{R}$.

6.2.2. Absolute stability. Having proved the existence and uniqueness of a locally homogeneous solution, we consider the problem of characterizing its absolute stability. The method is the same as in section 5. We consider the subset, noted $\mathcal{G}_c^P$, of the functions that are constant in the interior $\overset{\circ}{\Omega}_i$ of each region $\Omega_i, i = 1, \dots, P$ (the interior $\overset{\circ}{A}$ of a subset A is defined as the biggest open subset included in A). We have the following lemma that echoes Lemma 5.1.

Lemma 6.6. *$\mathcal{G}_c^P$ is a complete linear subspace of $\mathbf{L}_n^2(\Omega)$. The orthogonal projection operator $\mathcal{P}_{\mathcal{G}_c^P}$ from $\mathbf{L}_n^2(\Omega)$ to $\mathcal{G}_c^P$ is defined by*

$$\mathcal{P}_{\mathcal{G}_c^P}(\mathbf{x})(\mathbf{r}) = \overline{\mathbf{x}}^P = \sum_{k=1}^{P} \mathbf{1}_{\Omega_k}(\mathbf{r}) \frac{1}{|\Omega_k|} \int_{\Omega_k} \mathbf{x}(\mathbf{r}')\, d\mathbf{r}'.$$

The orthogonal complement $\mathcal{G}_c^{P\,\perp}$ of $\mathcal{G}_c^P$ is the subset of functions of $\mathbf{L}_n^2(\Omega)$ that have a zero average in each Ω_i, $i = 1, \dots, P$. The orthogonal projection operator $\mathcal{P}_{\mathcal{G}_c^{P\,\perp}}$ is equal to $\mathrm{Id} - \mathcal{P}_{\mathcal{G}_c^{\mathrm{P}}}$. *We also have*

$$\mathcal{P}_{\mathcal{G}_c^{P\,\perp}} \mathbf{M}\mathbf{x} = \mathbf{M}\mathcal{P}_{\mathcal{G}_c^{P\,\perp}}\mathbf{x} \quad \forall\, \mathbf{x} \in \mathbf{L}_n^2(\Omega),\, \mathbf{M} \in \mathcal{M}_{n\times n}. \tag{6.6}$$

Proof. The proof of this lemma is similar to that of Lemma 5.1. $\square$

We have the following theorem, corresponding to Theorems 5.2 and 5.3.

Theorem 6.7. *If $\mathbf{W}$ satisfies* (6.2)*, a sufficient condition for the absolute stability of a locally homogeneous solution to* (2.6) *(resp.,* (2.7)*) is that the norm $\|g^*\|_{\mathcal{G}_c^{P\,\perp}}$ (resp., $\|g\|_{\mathcal{G}_c^{P\,\perp}}$) of the restriction to $\mathcal{G}_c^{P\,\perp}$ of the compact operator g^* (resp., g) be less than $(\tau_{\max} DS_m)^{-1}$ for all $t \in \mathrm{J}$.*

Proof. The proof strictly follows the lines of the ones of Theorems 5.2 and 5.3. $\square$

Note that the condition on the operator norm in Theorems 4.7 and 4.8 is stronger than the one of Theorems 5.2 and 5.3 which is in turn stronger than the one of Theorem 6.7; therefore, we have the following proposition.

Proposition 6.8. *If the operator g satisfies the condition of Theorem* 4.7 *or if $g*$ (resp., g) satisfies the condition of Theorem* 5.2 *(resp., of Theorem* 5.3*), then for every partition of Ω, corresponding locally homogeneous current, and $\mathbf{W}$ satisfying* (6.2)*, the locally homogeneous solution of* (2.6) *(resp.,*(2.7)*) is absolutely stable.*

Proof. Since all spaces are contained in $\mathbf{L}_n^2(\Omega)$, the first part of the proposition is proved. Next, it is clear that $\mathcal{G}_c \subset \mathcal{G}_c^P$; therefore, $\mathcal{G}_c^{P\,\perp} \subset \mathcal{G}_c^{\perp}$ and $\|g^*\|_{\mathcal{G}_c^{P\,\perp}} \le \|g^*\|_{\mathcal{G}_c^{\perp}}$ (resp., $\|g\|_{\mathcal{G}_c^{P\,\perp}} \le \|g\|_{\mathcal{G}_c^{\perp}}$). $\square$

Condition (6.2) depends on the partition of Ω. It is therefore unrealistic since one expects this partition to change over time with the external currents. In this context it is interesting to define the notion of a *pseudo–locally homogeneous* solution.

Definition 6.9. *A pseudo–locally homogeneous solution of* (2.6) *(resp.,* (2.7)*) corresponds to a locally homogeneous input current (verifying* (6.1)*) when the connectivity function satisfies the condition of Proposition* 6.3 *(existence and uniqueness of a solution) but not necessarily conditions* (6.2).

How much a pseudo–locally homogeneous solution differs from a locally homogeneous solution obviously depends upon how poorly the connectivity function satisfies the conditions (6.2). But since pseudo–locally homogeneous solutions are solutions, they enjoy the following property.

PROPOSITION 6.10. *If the operator g satisfies the condition of Theorem* 4.7*, the unique pseudo–locally homogeneous solution of* (2.6) *(resp., of* (2.7)*) corresponding to a locally homogeneous input current is absolutely stable.*

A numerical example of pseudo–locally homogeneous solution is given in section 7 (Figures 17 and 18).

6.2.3. Complete local synchronization. The property of absolute stability of the solution that is characterized in Theorem 6.7 can be seen as the ability for the neural masses in the continuum to synchronize locally within each region Ω_i, $i = 1, \dots, P$. By local synchronization we mean that the state vectors at all points of each region Ω_i converge to a unique state vector that is a function only of the common input $\mathbf{I}^i_{\text{ext}}$ within Ω_i and not of the initial states of the neural masses. The state vector is the locally homogeneous solution of (2.6) and (2.7). This effect is called complete local synchronization.

6.3. Higher order postsynaptic potentials. We now show how the theory developed so far can be extended to accomodate more complicated time variations of the postsynaptic potentials than the decaying exponential that we adopted so far with the advantage that we had only to deal with a first-order differential equation. We show how to proceed only in the case of a second-order differential equation; going to a higher order does not bring in new difficulties. We also treat only the case of the voltage-based model, the case of the activity-based model being similar.

We therefore assume that, with the notation of section 2.1.1, we have $PSP_i(t) = te^{-t/\tau_i}Y(t)$ or, equivalently, that

$$\frac{d^2 PSP_i(t)}{dt^2} + \frac{2}{\tau_i}\frac{dPSP_i(t)}{dt} + \frac{1}{\tau_i^2} = \delta(t).$$

The analogue of (2.4) is

$$\mathbf{V}'' = -2\mathbf{L}\mathbf{V}' - \mathbf{L}^2\mathbf{V} + \mathbf{W}\,\mathbf{S}(\mathbf{V}) + \mathbf{I}_{\text{ext}}. \tag{6.7}$$

We rewrite this as a first order system of differential equations by introducing the vector $\boldsymbol{\mathcal{V}} = \left[\begin{smallmatrix}\mathbf{V}\\ \mathbf{V}'\end{smallmatrix}\right]$:

$$\boldsymbol{\mathcal{V}}' = -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{V}} + \begin{bmatrix}\mathbf{0}\\ \mathbf{W}\,\mathbf{S}(\mathbf{V})\end{bmatrix} + \begin{bmatrix}\mathbf{0}\\ \mathbf{I}_{\text{ext}}\end{bmatrix}, \quad \boldsymbol{\mathcal{L}} = \begin{bmatrix}\mathbf{0} & -\text{Id}\\ \mathbf{L}^2 & 2\mathbf{L}\end{bmatrix}.$$

The dynamic system $\boldsymbol{\mathcal{V}}' = -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{V}}$ is globally asymptotically stable since all the eigenvalues of the $2n \times 2n$ matrix $\boldsymbol{\mathcal{L}}$ have a strictly positive real part, as can be easily verified.[3] This has the following consequence [36, 27] that is used below and that we cite without proof.

THEOREM 6.11 (Lyapunov). *The symmetric positive definite matrix*

$$\boldsymbol{\mathcal{M}} = \int_0^\infty e^{-\boldsymbol{\mathcal{L}}^T t}\, e^{-\boldsymbol{\mathcal{L}} t}\, dt$$

[3] In fact, the eigenvalues of $\boldsymbol{\mathcal{L}}$ are those of $\mathbf{L}$, $1/\tau_i$s, with multiplicity 2.

satisfies

$$\boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{L}} + \boldsymbol{\mathcal{L}}^T\boldsymbol{\mathcal{M}} = \mathrm{Id}_{2n}, \tag{6.8}$$

where Id_{2n} *is the* $2n \times 2n$ *identity matrix.*

The analogue of (2.6) is readily found to be

$$\boldsymbol{\mathcal{V}}_t(\mathbf{r}, t) = -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{V}}(\mathbf{r}, t) + \left[\begin{array}{c} \mathbf{0} \\ \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}', t)\mathbf{S}(\mathbf{V}(\mathbf{r}', t))\, d\mathbf{r}' \end{array} \right] . + \left[\begin{array}{c} \mathbf{0} \\ \mathbf{I}_{\mathrm{ext}} \end{array} \right]. \tag{6.9}$$

The state is now $2n$-dimensional, the corresponding functional space is $\mathbf{L}^2_{2n}(\Omega)$, and the operator g is defined on the subspace $\mathbf{L}^2_n(\Omega)$ of $\mathbf{L}^2_{2n}(\Omega)$. It keeps all its previous properties. All proofs of the existence and uniqueness of a solution to (2.6) extend mutatis mutandis to this new setting.

Let us now examine the problem of the absolute stability of the solution, the analogue of Theorem 4.7.

Theorem 6.12. *A sufficient condition for the solution of* (2.6) *to be absolutely stable is*

$$2\, \lambda_{\max}\, DS_m\, \|g\|_{\mathbf{L}^2_n(\Omega)} < 1,$$

where $\lambda_{\max}$ *is the largest eigenvalue of the* $2n \times 2n$ *matrix* $\boldsymbol{\mathcal{M}}$ *defined in Theorem* 6.11.

Proof. We consider the equation

$$\boldsymbol{\mathcal{V}}_t(\mathbf{r}, t) = -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{V}}(\mathbf{r}, t) + \left[\begin{array}{c} \mathbf{0} \\ \int_\Omega \mathbf{W}_{cm}(\mathbf{r}, \mathbf{r}', t)\underline{\mathbf{S}}(\mathbf{V}(\mathbf{r}', t))\, d\mathbf{r}' \end{array} \right] + \left[\begin{array}{c} \mathbf{0} \\ \mathbf{I}_{\mathrm{ext}} \end{array} \right],$$

where $\mathbf{V}$ is the vector composed of the first n components of vector $\boldsymbol{\mathcal{V}}$ (the same convention will be used in the following for subvectors of $\boldsymbol{\mathcal{U}}$ and $\boldsymbol{\mathcal{X}}$). Let $\boldsymbol{\mathcal{U}}$ be its unique solution with initial condition $\boldsymbol{\mathcal{U}}(0) = \boldsymbol{\mathcal{U}}_0$, an element of $\mathbf{L}^2_{2n}(\Omega)$. Let also $\boldsymbol{\mathcal{V}}$ be the unique solution of the same equation with different initial conditions $\boldsymbol{\mathcal{V}}(0) = \boldsymbol{\mathcal{V}}_0$, another element of $\mathbf{L}^2_{2n}(\Omega)$. We introduce the new function $\boldsymbol{\mathcal{X}} = \boldsymbol{\mathcal{V}} - \boldsymbol{\mathcal{U}}$ which satisfies

$$\begin{aligned} \boldsymbol{\mathcal{X}}_t(\mathbf{r}, t) &= -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{X}}(\mathbf{r}, t) + \left[\begin{array}{c} \mathbf{0} \\ \int_\Omega \mathbf{W}_{cm}(\mathbf{r}, \mathbf{r}', t)\, \mathbf{H}(\mathbf{X}, \mathbf{U})(\mathbf{r}', t)\, d\mathbf{r}' \end{array} \right] \\ &= -\boldsymbol{\mathcal{L}}\boldsymbol{\mathcal{X}}(\mathbf{r}, t) + \left[\begin{array}{c} \mathbf{0} \\ g_m(\mathbf{H}(\mathbf{X}, \mathbf{U}))(\mathbf{r}, t) \end{array} \right], \end{aligned} \tag{6.10}$$

where the vector $\mathbf{H}(\mathbf{X}, \mathbf{U})$ is given by $\mathbf{H}(\mathbf{X}, \mathbf{U})(\mathbf{r}, t) = \underline{\mathbf{S}}(\mathbf{V}(\mathbf{r}, t)) - \underline{\mathbf{S}}(\mathbf{U}(\mathbf{r}, t)) = \underline{\mathbf{S}}(\mathbf{X}(\mathbf{r}, t) + \mathbf{U}(\mathbf{r}, t)) - \underline{\mathbf{S}}(\mathbf{U}(\mathbf{r}, t))$. Consider now the functional

$$V(\boldsymbol{\mathcal{X}}) = \frac{1}{2}\, \langle\, \boldsymbol{\mathcal{X}},\, \boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{X}}\, \rangle,$$

where the symmetric positive definite matrix $\boldsymbol{\mathcal{M}}$ can be seen as defining a metric on the state space. Its time derivative is $\langle\, \boldsymbol{\mathcal{X}},\, \boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{X}}_t\, \rangle$. We replace $\boldsymbol{\mathcal{X}}_t$ by its value from (6.10) in this expression to obtain

$$\frac{dV(\boldsymbol{\mathcal{X}})}{dt} = -\frac{1}{2} \left\langle \boldsymbol{\mathcal{X}},\, (\boldsymbol{\mathcal{L}}^T\boldsymbol{\mathcal{M}} + \boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{L}})\boldsymbol{\mathcal{X}} \right\rangle + \left\langle \boldsymbol{\mathcal{X}},\, \boldsymbol{\mathcal{M}} \left[\begin{array}{c} \mathbf{0} \\ g_m(\mathbf{H}(\mathbf{X}, \mathbf{U})) \end{array} \right] \right\rangle.$$

Using the property (6.8) of $\boldsymbol{\mathcal{M}}$, we obtain

$$\frac{dV(\boldsymbol{\mathcal{X}})}{dt} = -\frac{1}{2}\, \langle\, \boldsymbol{\mathcal{X}},\, \boldsymbol{\mathcal{X}}\, \rangle + \left\langle \boldsymbol{\mathcal{X}},\, \boldsymbol{\mathcal{M}} \left[\begin{array}{c} \mathbf{0} \\ g_m(\mathbf{H}(\mathbf{X}, \mathbf{U})) \end{array} \right] \right\rangle.$$

We consider the second term on the right-hand side of this equation. Since $\boldsymbol{\mathcal{M}}$ is symmetric,

$$\begin{aligned}(6.11)\quad \left|\left\langle \boldsymbol{\mathcal{X}}, \boldsymbol{\mathcal{M}}\begin{bmatrix}\mathbf{0}\\ g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\end{bmatrix}\right\rangle\right| &= \left|\left\langle \boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{X}}, \begin{bmatrix}\mathbf{0}\\ g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\end{bmatrix}\right\rangle\right|\\ &\leq \|\boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{X}}\|_{2n,2}\,\|g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\|_{n,2} \leq \lambda_{\max}\|\boldsymbol{\mathcal{X}}\|_{2n,2}\,\|g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\|_{n,2}\\ &\leq \lambda_{\max}\,\|\boldsymbol{\mathcal{X}}\|_{2n,2}\,\|g_m\|_{\mathbf{L}^2_n}\|\mathbf{H}(\mathbf{X},\mathbf{U})\|_{n,2}.\end{aligned}$$

The inequality $\|\boldsymbol{\mathcal{M}}\boldsymbol{\mathcal{X}}\|_{2n,2} \leq \lambda_{\max}\|\boldsymbol{\mathcal{X}}\|_{2n,2}$ is obtained using the spectral properties of the symmetric positive definite matrix $\boldsymbol{\mathcal{M}}$ and Lemma 4.5.

Using the idea in the proof of Lemma 3.1, we write $\mathbf{H}(\mathbf{X},\mathbf{U}) = \mathcal{D}_m\mathbf{X}$, where $\mathcal{D}_m$ is a diagonal matrix whose diagonal elements are continuous functions with values between 0 and 1. Hence, because of Lemma 4.5,

$$\|\mathbf{H}(\mathbf{X},\mathbf{U})\|_{n,2} = \|\mathcal{D}_m\mathbf{X}\|_{n,2} \leq \|\mathbf{X}\|_{n,2} \leq \|\boldsymbol{\mathcal{X}}\|_{2n,2}.$$

We use this result and Lemma 4.6 in (6.11) to obtain

$$\left|\left\langle \boldsymbol{\mathcal{X}}, \boldsymbol{\mathcal{M}}\begin{bmatrix}\mathbf{0}\\ g_m(\mathbf{H}(\mathbf{X},\mathbf{U}))\end{bmatrix}\right\rangle\right| \leq \lambda_{\max}\,DS_m\,\|g\|_{\mathbf{L}^2_n}\,\|\boldsymbol{\mathcal{X}}\|^2_{2n,2},$$

and the conclusion follows. □

All other theorems in sections 4, 5, and 6 and in this section can be similarly extended to this more general setting. More information about $\boldsymbol{\mathcal{M}}$ and $\lambda_{\max}$ can be found in Appendix C.

7. Numerical examples. We consider two ($n = 2$) one-dimensional ($q = 1$) populations of neurons, population 1 being excitatory and population 2 inhibitory. The set Ω is the closed interval $[0, 1]$. We denote x as the spatial variable and f as the spatial frequency variable. We consider Gaussian functions, denoted $G_{ij}(x)$, $i, j = 1, 2$, from which we define the connectivity functions. Hence we have $G_{ij} = \mathcal{G}(0, \sigma_{ij})$. We consider three cases. In the first case, section 7.1, we assume that the connectivity matrix is translation invariant (see sections 4.2 and 5.2). In the second case, section 7.2, we relax this assumption and study the stability of the homogeneous solutions. The third case, finally, section 7.3, covers the case of the locally homogeneous solutions and their stability. In this section we have $S_1(x) = S_2(x) = 1/(1 + e^{-x})$. Therefore,

$$D\mathbf{S}_m = \begin{bmatrix}\frac{1}{4} & 0\\ 0 & \frac{1}{4}\end{bmatrix};$$

hence $DS_m = 1/4$. We also choose $\tau_1 = \tau_2 = 4$; therefore, $\tau_{\max} = 4$, and the product $DS_m\,\tau_{\max}$ is equal to 1.

7.1. The convolution case. We define $W_{ij}(x, x') = \pm\alpha_{ij}\,G_{ij}(x - x')$, where the α_{ij}'s are positive weights and the sign determines whether population j excites (+) or inhibits (−) population i. As explained in section 4.2, $\mathbf{W}(\mathbf{r})$ is defined on the closed interval $\widehat{\Omega} = [-1, 1]$. For simplicity we use the approach described in section 4.2.1 and approximate the Fourier transform of $\mathbf{1}_{\widehat{\Omega}}(x)\mathbf{W}(x)$ by that of $\mathbf{W}(x)$ for which we have an analytical formula. This approximation is good as long as the σ_{ij}'s are small with respect to 1.

The connectivity functions and their Fourier transforms are then given by

$$W_{ij}(x) = \pm \frac{\alpha_{ij}}{\sqrt{2\pi\sigma_{ij}^2}} e^{-\frac{x^2}{2\sigma_{ij}^2}}, \quad \widetilde{W}_{ij}(f) = \pm\alpha_{ij} e^{-2\pi^2 f^2 \sigma_{ij}^2}.$$

The matrices $\mathbf{W}(x)$ and $\widetilde{\mathbf{W}}(f)$ can be written

$$\mathbf{W}(x) = \begin{bmatrix} \frac{\alpha_{11}}{\sqrt{2\pi\sigma_{11}^2}} e^{-\frac{x^2}{2\sigma_{11}^2}} & -\frac{\alpha_{12}}{\sqrt{2\pi\sigma_{12}^2}} e^{-\frac{x^2}{2\sigma_{12}^2}} \\ \frac{\alpha_{21}}{\sqrt{2\pi\sigma_{21}^2}} e^{-\frac{x^2}{2\sigma_{21}^2}} & -\frac{\alpha_{22}}{\sqrt{2\pi\sigma_{22}^2}} e^{-\frac{x^2}{2\sigma_{22}^2}} \end{bmatrix},$$

$$\widetilde{\mathbf{W}}(f) = \begin{bmatrix} \alpha_{11} e^{-2\pi^2 f^2 \sigma_{11}^2} & -\alpha_{12} e^{-2\pi^2 f^2 \sigma_{12}^2} \\ \alpha_{21} e^{-2\pi^2 f^2 \sigma_{21}^2} & -\alpha_{22} e^{-2\pi^2 f^2 \sigma_{22}^2} \end{bmatrix}.$$

Therefore, we have, with the notation of Theorem 4.9,

$$\widetilde{\mathbf{W}}^*(f)\widetilde{\mathbf{W}}(f) \overset{def}{=} \mathbf{X}(f) = \begin{bmatrix} A & C \\ C & B \end{bmatrix}.$$

It can be easily verified that

$$A = \tau_1 \left(\alpha_{11}^2 \tau_1 e^{-4\pi^2 \sigma_{11}^2 f^2} + \alpha_{21}^2 \tau_2 e^{-4\pi^2 \sigma_{21}^2 f^2} \right),$$
$$B = \tau_2 \left(\alpha_{22}^2 \tau_2 e^{-4\pi^2 \sigma_{22}^2 f^2} + \alpha_{12}^2 \tau_1 e^{-4\pi^2 \sigma_{12}^2 f^2} \right),$$

and

$$C = -\sqrt{\tau_1\tau_2} \left(\alpha_{21}\alpha_{22}\tau_2 e^{-2\pi^2(\sigma_{21}^2+\sigma_{22}^2)f^2} + \alpha_{12}\alpha_{11}\tau_1 e^{-2\pi^2(\sigma_{12}^2+\sigma_{11}^2)f^2} \right).$$

By construction the eigenvalues of the matrix $\mathbf{X}$ are positive (it is Hermitian), the largest one, $\lambda_{\max}$, being given by

$$\lambda_{\max} = \frac{1}{2}\left(A + B + \sqrt{(A-B)^2 + 4C^2} \right).$$

Introducing the parameters $A_1 = (\tau_1\alpha_{11})^2$, $A_2 = (\tau_2\alpha_{22})^2$, $r = \tau_1/\tau_2$, $x_1 = \alpha_{21}/\alpha_{11}$, and $x_2 = \alpha_{12}/\alpha_{22}$, we can rewrite A, B, and C as

$$A = A_1 \left(e^{-4\pi^2\sigma_{11}^2 f^2} + \frac{x_1^2}{r} e^{-4\pi^2\sigma_{21}^2 f^2} \right), \quad B = A_2 \left(e^{-4\pi^2\sigma_{22}^2 f^2} + r x_2^2 e^{-4\pi^2\sigma_{12}^2 f^2} \right),$$

and

$$C = -\sqrt{A_1 A_2} \left(\frac{x_1}{\sqrt{r}} e^{-2\pi^2(\sigma_{21}^2+\sigma_{22}^2)f^2} + x_2\sqrt{r} e^{-2\pi^2(\sigma_{12}^2+\sigma_{11}^2)f^2} \right).$$

The necessary and sufficient condition that the two eigenvalues are less than 1 for all f is therefore $\lambda_{\max} < 1$ or

$$c(f) \overset{def}{=} 2 - A - B - \sqrt{(A-B)^2 + 4C^2} > 0 \quad \forall f. \tag{7.1}$$

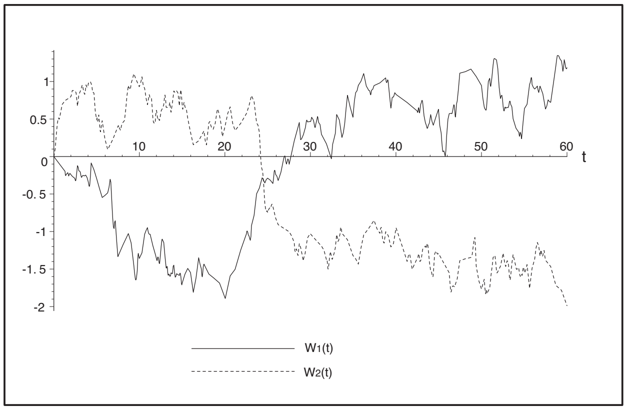

FIG. 2. *The two coordinates of the input* $\mathbf{I}_{\text{ext}}(t)$ *are realizations of independent standard Brownian/Wiener processes. Time runs along the horizontal axis.*

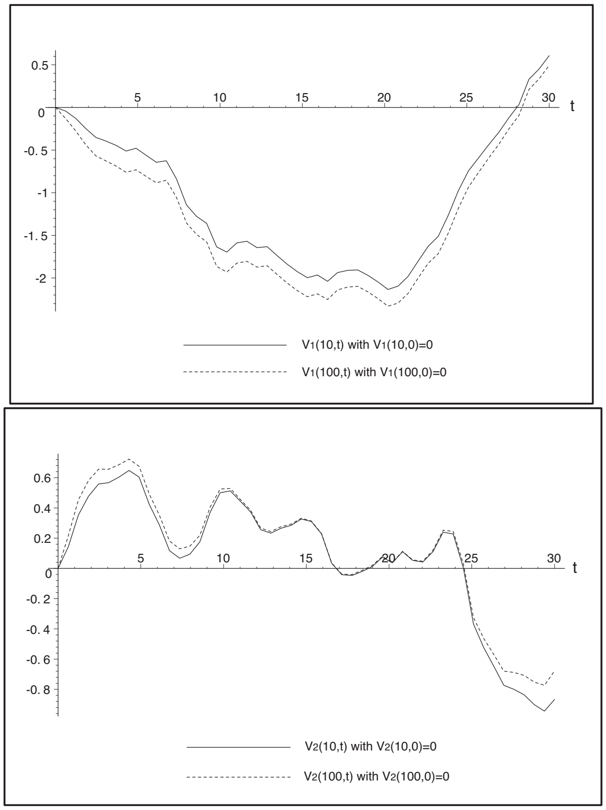

FIG. 3. *An illustration of the fact that when the connectivity matrix is translation invariant there does not exist in general a homogeneous solution: The state vectors of different neural masses follow different trajectories even when the input and the initial condition are homogeneous (independent of the location* x*). Top graph: The time variation of the first coordinate of the solution at points of coordinates* 0.1 *(continuous line) and* 1 *(dotted line) of the interval* $[0, 1]$*. Bottom graph: Same for the second coordinate. The initial condition is* 0 *in both cases.*

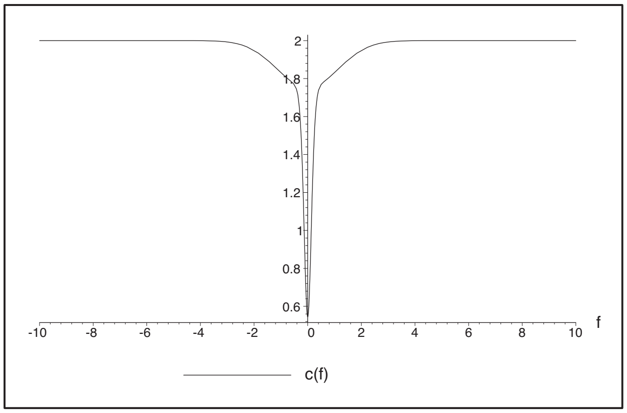

FIG. 4. *The function $c(f)$ defined in* (7.1) *is positive for all spatial frequencies f: The system is absolutely stable.*

The function $c(f)$ depends on the spatial frequency f and the nine parameters A_1, A_2, x_1, x_2, r, and $\boldsymbol{\sigma}$, the 2×2 matrix σ_{ij}, $i, j = 1, 2$.

We have solved (2.6) on $\Omega = [0, 1]$. We have sampled the interval with 100 points corresponding to 100 neural masses. The input $\mathbf{I}_{\text{ext}}$ is equal to $[W_1(t), W_2(t)]^T$, where the $W_i(t)$'s, $i = 1, 2$, are realizations of independent standard Brownian/Wiener processes shown in Figure 2. We know that the solution is not homogeneous because $\mathbf{W}$ is translation-invariant. This is illustrated in Figure 3. The initial conditions are homogeneous and equal to $(0, 0)$ for all neural mass state vectors $\mathbf{V}$.

7.1.1. Absolute stability of the solution. Let us now study the absolute stability of the solutions. According to Theorem 4.9 and the previous analysis, a sufficient condition for absolute stability is that $c(f) > 0$ for all frequencies f. As shown in Figure 4, the following choice of the parameters $\boldsymbol{\alpha}$ and $\boldsymbol{\sigma}$ produces a curve $c(f)$ that is positive for all frequencies:

$$\boldsymbol{\alpha} = \begin{bmatrix} 2 & 1.414 \\ 1.414 & 2 \end{bmatrix}, \quad \boldsymbol{\sigma} = \begin{bmatrix} 1 & 0.1 \\ 0.1 & 1 \end{bmatrix}.$$

We can check that this is indeed the case in Figure 5, which shows the absolute stability of the solution at the point of coordinate 0.5 of the interval $[0, 1]$.

7.1.2. Loss of absolute stability. The following choice of the parameters $\boldsymbol{\alpha}$ and $\boldsymbol{\sigma}$ produces a curve $c(f)$ that is not positive for all frequencies (see Figure 6):

$$\boldsymbol{\alpha} = \begin{bmatrix} 565.7 & 565.7 \\ 565.7 & 565.7 \end{bmatrix}, \quad \boldsymbol{\sigma} = \begin{bmatrix} 0.01 & 0.01 \\ 0.1 & 0.1 \end{bmatrix}.$$

Therefore, absolute stability is not guaranteed. We show in Figure 7 that this is indeed the case.

7.2. Homogeneous solutions. In the previous case the translation invariance of the connectivity matrix forbids the existence of homogeneous solutions. We can obtain a connectivity matrix satisfying condition (3.5) by defining

$$W_{ij}(x, x') = \pm \alpha \alpha_{ij} \frac{G_{ij}(x - x')}{\int_0^1 G_{ij}(x - y)\, dy}, \quad i, j = 1, 2,$$

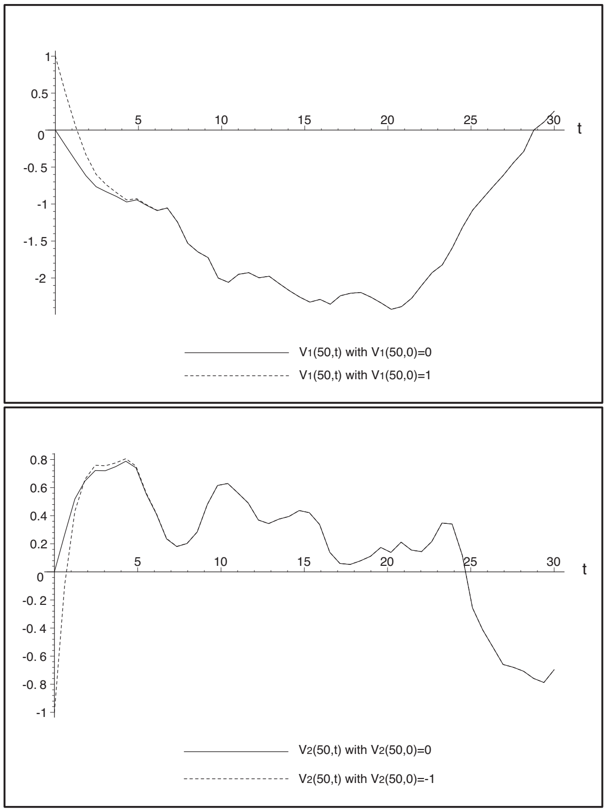

Fig. 5. *An illustration of the absolute stability of the solution: Independently of the choice of the initial condition, the trajectories of the state vector converge to a single trajectory. where α and the α_{ij}'s are connectivity weights. These functions are well defined since the denominator is never equal to 0 and the resulting connectivity matrix is in $\mathbf{L}^2_{2\times 2}([0, 1] \times [0, 1])$. It is shown in Figure 8. The values of the parameters are given in (7.2). Proposition 6.3 guarantees the existence and uniqueness of a homogeneous solution for an initial condition in $\mathbf{L}^2_2(\Omega)$. According to Theorem 5.2 and our choice for the values of $\tau_{\max}$ and DS_m, a sufficient condition for this solution to be absolutely stable is that $\|g*\|_{\mathcal{G}_c^\perp} < 1$.

7.2.1. Absolute stability. The values of the parameters

$$\boldsymbol{\alpha} = \begin{bmatrix} 5.20 & 5.20 \\ 2.09 & 2.09 \end{bmatrix}, \quad \boldsymbol{\sigma} = \begin{bmatrix} 0.1 & 0.1 \\ 1 & 1 \end{bmatrix}, \quad \tau_1 = \tau_2 = 1, \quad \alpha = 1/20 \tag{7.2}$$

yield $\|g^*\|_{\mathcal{G}_c^\perp} \simeq 0.01$; hence the homogeneous solutions are absolutely stable. All operator norms have been computed using the method described in section A.3.

The initial conditions are drawn randomly and independently from the uniform distribution on $[-2, 2]$. The input $\mathbf{I}_{\text{ext}}(t)$ is equal to $[W_1(t), W_2(t)]^T$, where the $W_i(t)$'s, $i = 1, 2$, are realizations of independent standard Brownian/Wiener processes shown in Figure 2.

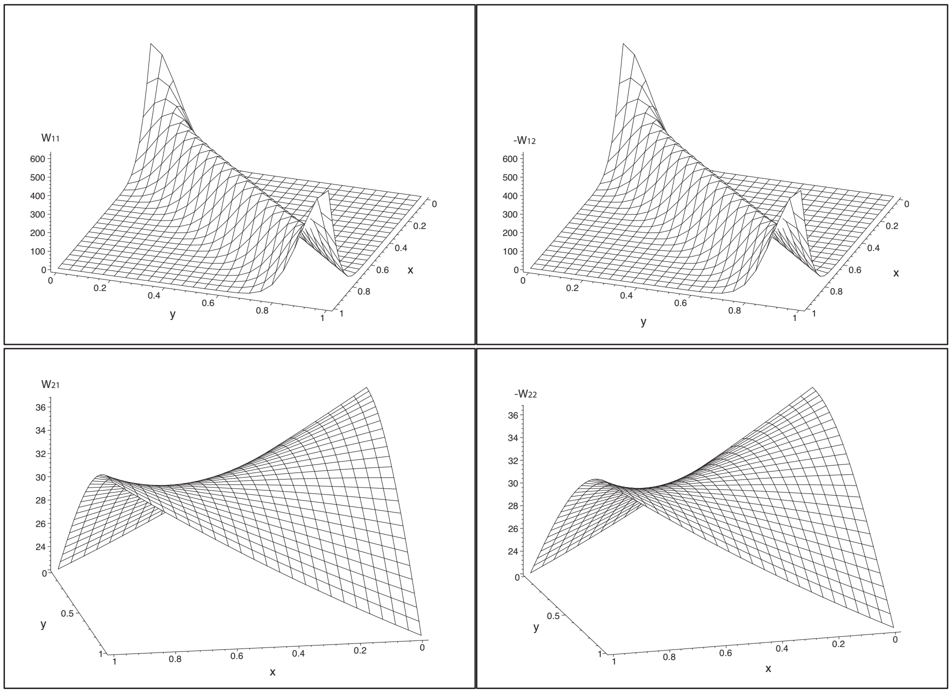

FIG. 8. *The four elements of the matrix* $\mathbf{W}(x,y)$ *in the homogeneous case. Upper left:* $W_{11}(x,y)$*. Upper right:* $-W_{12}(x,y)$*. Lower left:* $W_{21}(x,y)$*. Lower right:* $-W_{22}(x,y)$*.*

We show in Figure 9 the complete synchronization of four (numbers 10, 36, 63, and 90) of the hundred neural masses that results from the absolute stability of the homogeneous solution.

7.2.2. Loss of absolute stability. If we increase the value of α, it has the effect of increasing $\|g^*\|_{\mathcal{G}_c^\perp}$. The sufficient condition will eventually not be satisfied, and we may lose the absolute stability of the homogeneous solution and hence the complete synchronization of the solution. Such a case is shown in Figure 10 for $\alpha = 15$, corresponding to an operator norm $\|g^*\|_{\mathcal{G}_c^\perp} \simeq 2.62$.

7.3. Locally homogeneous solutions. We partition $\Omega = [0,1]$ into $\Omega_1 = [0,1/2[$ and $\Omega_2 = [1/2,1]$; hence with the notation of section 6.2, $P = 2$. We can obtain a connectivity matrix satisfying condition (6.2) by defining

$$W_{ij}(x,x') = \begin{cases} \pm\alpha\alpha_{ij}(x,x')\dfrac{G_{ij}(x-x')}{\displaystyle\int_0^{1/2} G_{ij}(x-y)\,dy}, \ x' \in \Omega_1, \\ \pm\alpha\alpha_{ij}(x,x')\dfrac{G_{ij}(x-x')}{\displaystyle\int_{1/2}^{1} G_{ij}(x-y)\,dy}, \ x' \in \Omega_2, \end{cases}$$

with $\alpha_{ij}(x,x') = \alpha_{ij}^{kl}$, $x \in \Omega_k$, $x' \in \Omega_l$, $k,l = 1,2$.

The resulting connectivity matrix is in $\mathbf{L}^2_{2\times 2}([0,1]\times[0,1])$. It is shown in Figure 11. The input $\mathbf{I}_{\rm ext}(t)$ is equal to $[W_1(t), W_2(t)]^T$ in Ω_1 and to $[W_3(t), W_4(t)]^T$ in Ω_2, where the $W_i(t)$'s, $i = 1,\dots,4$, are realizations of independent standard Brownian/Wiener

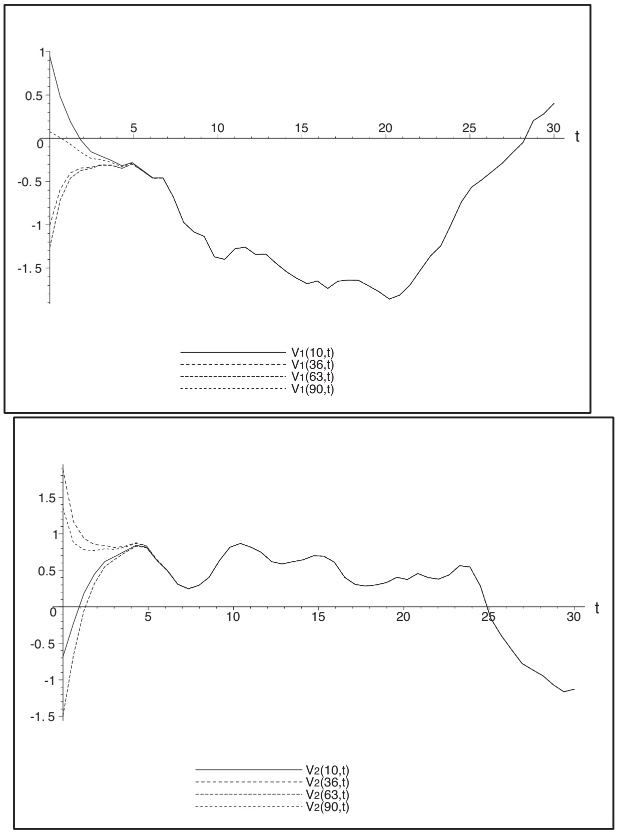

FIG. 9. *The absolute stability of the homogeneous solution results in the complete synchronization of the neural masses. This is shown for four out of the hundred (coordinates* 0.1, 0.36, 0.63, *and* 0.9*). The input is shown in Figure* 2. *The initial conditions are drawn independently from the uniform distribution on* $[-2, 2]$. *Top: The first components of the four state vectors. Bottom: The second components.*

processes shown in Figure 12. Hence it is homogeneous in Ω_1 (resp., in Ω_2) but not in $\Omega = \Omega_2 \cup \Omega_2$. According to Proposition 6.3, there exists a unique solution to (2.6) for a given initial condition in $\mathbf{L}_2^2(\Omega)$. This solution is locally homogeneous if the initial condition is locally homogeneous (Theorem 6.5), given the fact that the input is locally homogeneous.

7.3.1. Absolute stability. The parameters

$$\boldsymbol{\alpha}^{11} = \begin{bmatrix} 5.21 & 0.23 \\ 0.23 & 5.21 \end{bmatrix}, \quad \boldsymbol{\alpha}^{12} = \begin{bmatrix} 4.98 & 0.34 \\ 0.34 & 4.98 \end{bmatrix}, \quad \boldsymbol{\sigma} = \begin{bmatrix} 0.05 & 0.075 \\ 0.1 & 0.03 \end{bmatrix}$$
$$\boldsymbol{\alpha}^{21} = \begin{bmatrix} 4.75 & 0.45 \\ 0.45 & 4.75 \end{bmatrix}, \quad \boldsymbol{\alpha}^{22} = \begin{bmatrix} 5.39 & 0.13 \\ 0.13 & 5.39 \end{bmatrix},$$

result in an operator norm $\|g^*\|_{\mathcal{G}_c^2 \perp} \simeq 0.23$. Therefore, according to Theorem 6.7, the locally homogeneous solutions are absolutely stable, resulting in the complete local synchronization of the neural masses (within Ω_1 and Ω_2).

We show in Figure 13 (resp., Figure 14) the complete synchronization of two neural masses (numbers 10 and 36) in Ω_1 (resp., two neural masses (numbers 63

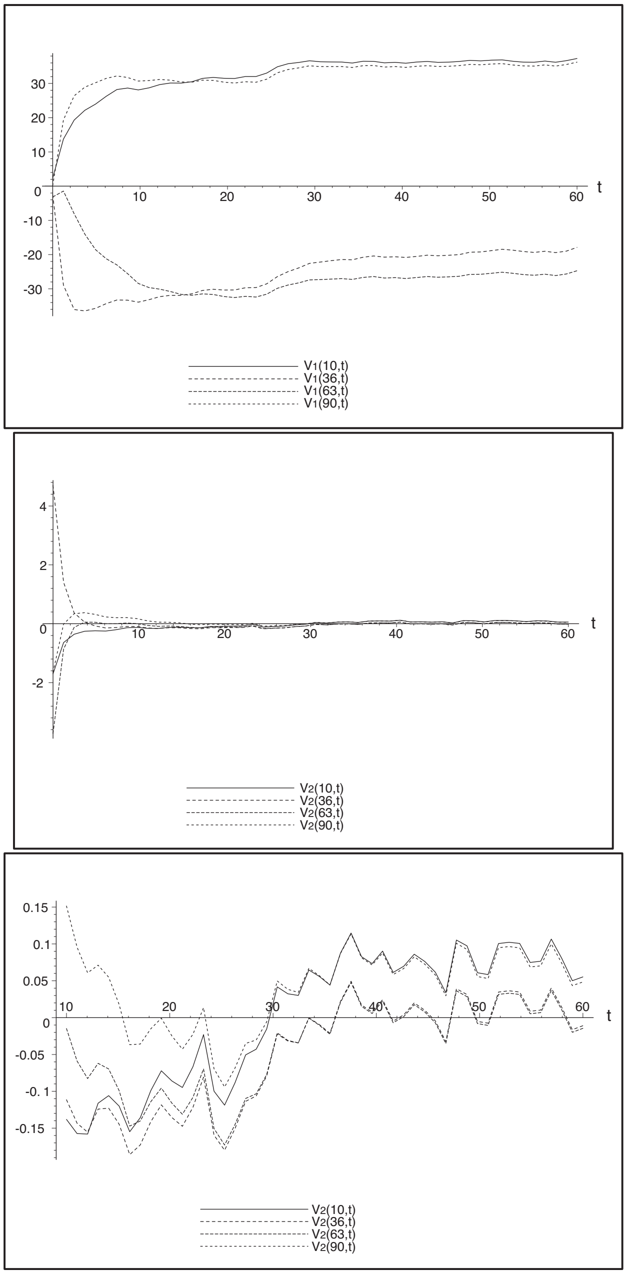

Fig. 10. *The loss of the absolute stability of the homogeneous solution results in the loss of the complete synchronization of neural masses when the sufficient condition of Theorem* 5.2 *is not satisfied. This is shown for four out of the hundred (coordinates* 0.1, 0.36, 0.63, *and* 0.9*). The input is the same as in the previous example. Top: The first components of the four state vectors. and 90) in Ω_2). The initial conditions are drawn randomly and independently from the uniform distribution on $[-10, 10]$ and $[-2, 2]$ for Ω_1 and on $[-20, 20]$ and $[-2, 2]$

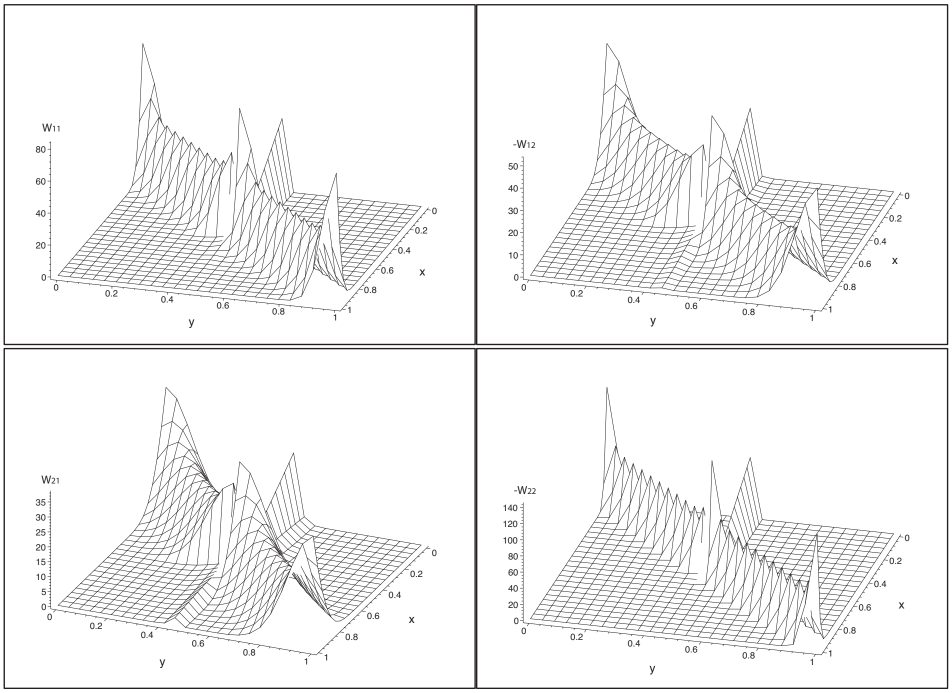

FIG. 11. *The four elements of the matrix* $\mathbf{W}(x,y)$ *in the locally homogeneous case. Upper left:* $W_{11}(x,y)$*. Upper right:* $-W_{12}(x,y)$*. Lower left:* $W_{21}(x,y)$*. Lower right:* $-W_{22}(x,y)$*.*

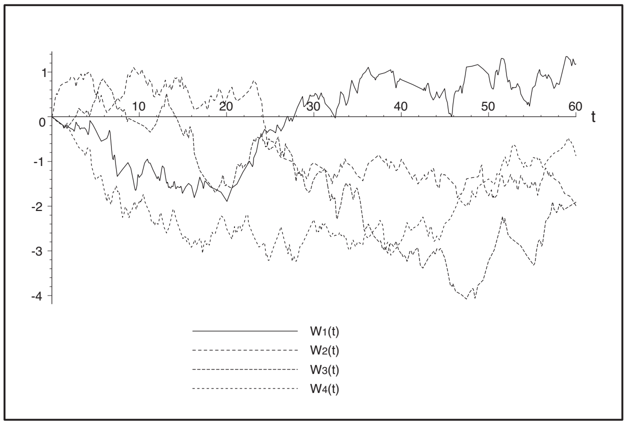

FIG. 12. *The two coordinates of the input* $\mathbf{I}_{\text{ext}}(t)$ *in* Ω_1 *and* Ω_2 *are realizations of four independent Wiener processes (*W_1 *and* W_2 *are identical to those shown in Figure* 2*).*

for Ω_2.

7.3.2. Loss of absolute stability. If we increase the value of α, it has the effect of increasing $\|g^*\|_{\mathcal{G}_c^{2},\perp}$. The sufficient condition for absolute stability will eventually not be satisfied, and we may lose the absolute stability of the locally homogeneous solution and hence the complete local synchronization of the solution. This is shown in Figures 15 and 16 for $\alpha = 10$, corresponding to an operator norm $\|g_m^{L\,*}\|_{\mathcal{G}_c^2\perp} \simeq 2.3$.

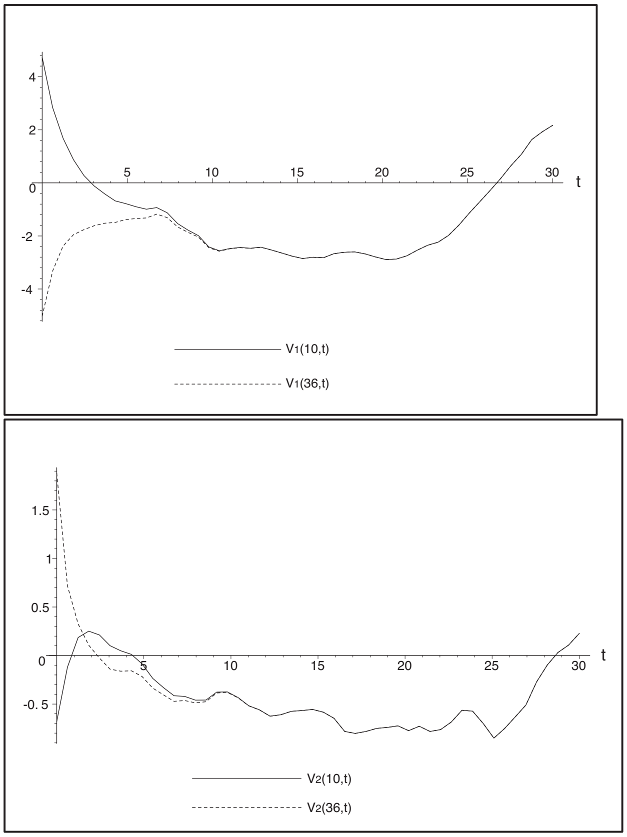

FIG. 13. *The complete synchronization of two neural masses in Ω_1 of coordinates* 0.1 *and* 0.36. *The input is shown in Figure* 12. *Top: The first components of the two state vectors. Bottom: The second components of the two state vectors.*

7.4. Pseudo–locally homogeneous solutions and their absolute stability. As mentioned at the end of section 6.2.2, even if the connectivity function does not satisfy condition (6.2) and the operator g^* satisfies only the condition of Theorem 4.7 but not that of Theorem 6.7, the existence of locally homogeneous solutions is not guaranteed, but the absolute stability of the solution is, because of Proposition 6.8. As shown in Figures 17 and 18, these solutions can be very close to being locally homogeneous and thus enjoy the property of complete local synchronization. This is potentially very interesting from the application viewpoint since one may say that if the system admits homogeneous solutions and if they are absolutely stable, it can have locally homogeneous solutions without "knowing" the partition, and they are absolutely stable.

8. Conclusion. We have studied the existence, uniqueness, and absolute stability of a solution of two examples of nonlinear integro-differential equations that describe the spatio-temporal activity of sets of neural masses. These equations involve space- and time-varying, possibly nonsymmetric, intracortical connectivity kernels. The time dependency of the connectivity kernels opens the door to the study, in this framework, of plasticity and learning. Contributions from white matter afferents are represented by external inputs. Sigmoidal nonlinearities arise from the relation

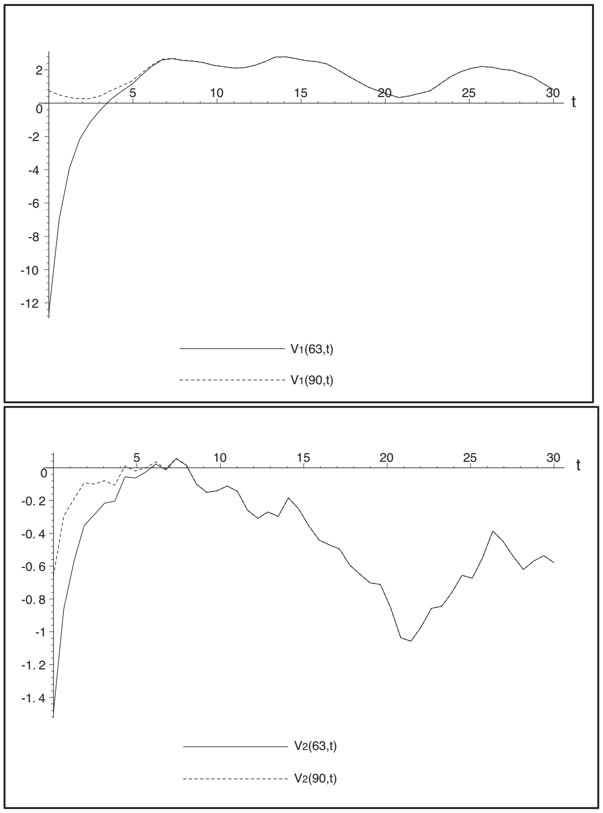

Fig. 14. *The complete synchronization of two neural masses in* Ω_2 *of coordinates* 0.63 *and* 0.9. *The input is shown in Figure* 12. *Top: The first components of the two state vectors. Bottom: The second components of the two state vectors.*

between average membrane potentials and instantaneous firing rates.

The intracortical connectivity functions have been shown to naturally define compact operators of the functional space of interest. Using methods of functional analysis, we have given sufficient conditions for the existence and uniqueness of a solution of these equations for general, homogeneous (i.e., independent of the spatial variable), and locally homogeneous inputs. In all cases we have provided sufficient conditions for the solutions to be absolutely stable, that is to say, independent of the initial state of the neural field. These conditions involve the connectivity functions and the maximum slopes of the sigmoids as well as the time constants used to described the time variation of the postsynaptic potentials. They are very relevant to neuroscience, where dynamical neuronal systems that "recognize" a given input regardless of their initial state are quite common.

To our knowledge this is the first time that such a complete analysis of the problem of the existence and uniqueness of a solution of these equations has been obtained. An important contribution also is the analysis of the absolute stability of these solutions which had been considered as much more difficult to perform than the linear stability analysis which it implies.

The reason we have been able to complete this work is our use of the functional analysis framework and the theory of compact operators in a Hilbert space with the

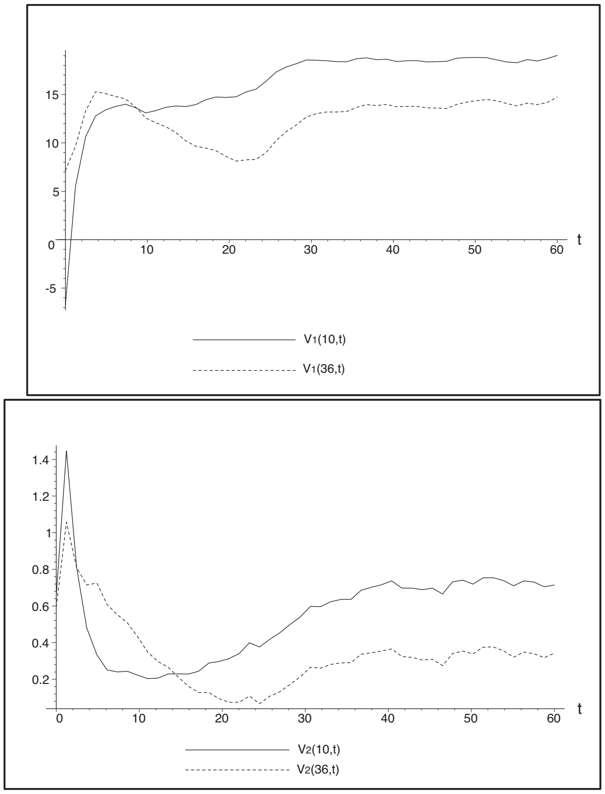

FIG. 15. *The loss of the absolute stability of the locally homogeneous solution results in the loss of the complete local synchronization of neural masses when the sufficient condition of Theorem* 6.7 *is not satisfied. effect of providing simple mathematical answers to some of the questions raised by modelers in neuroscience.

Future work includes adding delays to account for the distance traveled by the spikes down the axons and taking into account specific forms of the time variation of the connectivity matrices in the context of neural plasticity.

Appendix A. Notation and background material.

A.1. Matrix norms and spaces of functions. We denote $\mathcal{M}_{n\times n}$ as the set of $n \times n$ real matrices. We consider the matrix norm

$$\|\mathbf{M}\|_\infty = \max_i \sum_j |M_{ij}|.$$

We denote $\mathbf{C}_{n\times n}(\Omega)$ as the set of continuous functions from Ω to $\mathcal{M}_{n\times n}$ with the infinity norm. This is a Banach space for the norm induced by the infinity norm on $\mathcal{M}_{n\times n}$. Let $\mathbf{M}$ be an element of $\mathbf{C}_{n\times n}(\Omega)$; we denote and define $\|\mathbf{M}\|_{n\times n,\infty}$ as

$$\|\mathbf{M}\|_{n\times n,\infty} = \sup_{\mathbf{r}\in\Omega} \max_i \sum_j |M_{ij}(\mathbf{r})| = \max_i \sup_{\mathbf{r}\in\Omega} \sum_j |M_{ij}(\mathbf{r})|.$$

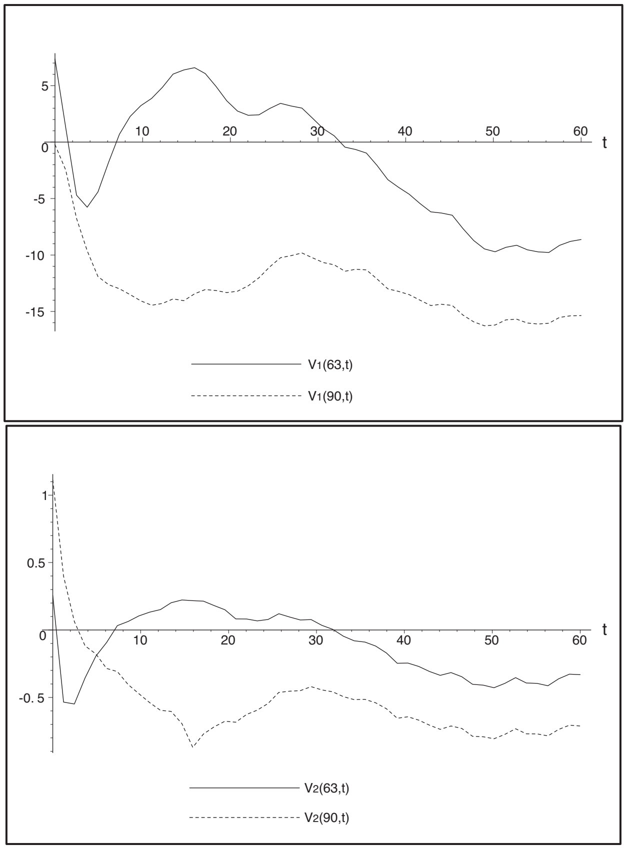

FIG. 16. *The loss of the absolute stability of the locally homogeneous solution results in the loss of the complete local synchronization of neural masses when the sufficient condition of Theorem* 6.7 *is not satisfied. This is shown for two out of the fifty (coordinates* 0.63, 0.9*) neural masses in* Ω_2. *The input is the same as in the previous example. Top: The first components of the two state vectors. Bottom: The second components of the two state vectors.*

We also denote $\mathbf{C}_n(\Omega)$ as the set of continuous functions from Ω to $\mathbb{R}^n$ with the infinity norm. This is also a Banach space for the norm induced by the infinity norm of $\mathbb{R}^n$. Let $\mathbf{x}$ be an element of $\mathbf{C}_n(\Omega)$; we denote and define $\|\mathbf{x}\|_{n,\infty}$ as

$$\|\mathbf{x}\|_{n,\infty} = \sup_{\mathbf{r}\in\Omega} \|\mathbf{x}(\mathbf{r})\|_\infty = \sup_{\mathbf{r}\in\Omega} \max_i |x_i(\mathbf{r})| = \max_i \sup_{\mathbf{r}\in\Omega} |x_i(\mathbf{r})|.$$

We can similarly define the norm $\|.\|_{n\times n,\infty}$ (resp., $\|.\|_{n,\infty}$) for the space $\mathbf{C}_{n\times n}(\Omega\times\Omega)$ (resp., $\mathbf{C}_n(\Omega\times\Omega)$).

We have the following lemma.

LEMMA A.1. *Given* $\mathbf{x}\in\mathbf{C}_n(\Omega)$ *and* $\mathbf{M}\in\mathbf{C}_{n\times n}(\Omega)$, *we have*

$$\|\mathbf{M}\,\mathbf{x}\|_{n,\infty} \le \|\mathbf{M}\|_{n\times n,\infty}\,\|\mathbf{x}\|_{n,\infty}.$$

More precisely, we have for all $\mathbf{r}\in\Omega$

$$\|\mathbf{M}(\mathbf{r})\,\mathbf{x}(\mathbf{r})\|_\infty \le \|\mathbf{M}(\mathbf{r})\|_\infty \|\mathbf{x}(\mathbf{r})\|_\infty.$$

The same results hold for $\Omega\times\Omega$ *instead of* Ω.

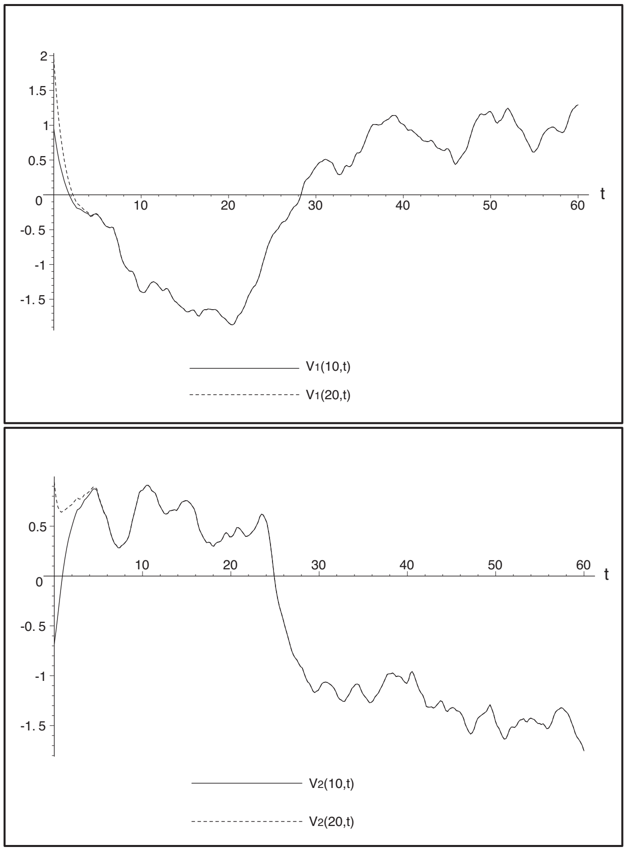

FIG. 17. *The connectivity function satisfies condition* (3.5) *but not condition* (6.2)*, and the operator g^* satisfies the condition of Theorem* 5.2 *but not that of Theorem* 6.7*. The input is locally homogeneous, as in Figures* 13 *and* 14*. The solution is absolutely stable, because of Theorem* 5.2*, and almost locally homogeneous. Something very close to complete local synchronization is observed. This is shown for two out of the fifty (coordinates* 0.1*,* 0.2*) neural masses in Ω_1. Top: The first components of the two state vectors. Bottom: The second components of the two state vectors.*

Proof. Letting $\mathbf{y} = \mathbf{M}\,\mathbf{x}$, we have

$$y_i(\mathbf{r}) = \sum_j M_{ij}(\mathbf{r}) x_j(\mathbf{r}),$$

and therefore

$$|y_i(\mathbf{r})| \leq \sum_j |M_{ij}(\mathbf{r})|\,|x_j(\mathbf{r})| \leq \sum_j |M_{ij}(\mathbf{r})|\,\|\mathbf{x}(\mathbf{r})\|_\infty,$$

so, taking the $\max_i$,

$$\|\mathbf{y}(\mathbf{r})\|_\infty \leq \|\mathbf{M}(\mathbf{r})\|_\infty\,\|\mathbf{x}(\mathbf{r})\|_\infty,$$

from which the first statement easily comes. □

We also consider the Frobenius norm on $\mathcal{M}_{n\times n}$

$$\|\mathbf{M}\|_F = \sqrt{\sum_{i,j=1}^{n} M_{ij}^2}$$

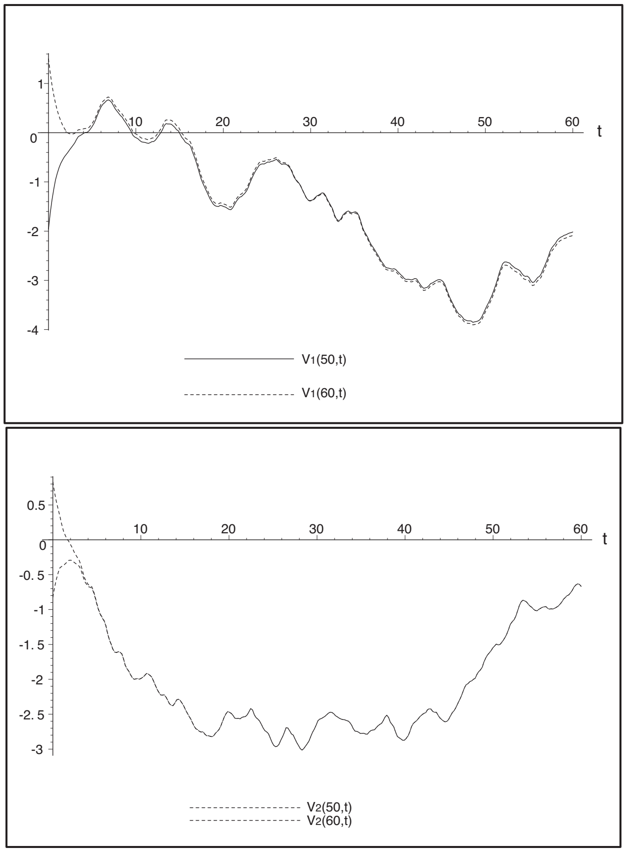

FIG. 18. *Same as in Figure* 17*. The complete local synchronization is shown for two out of the fifty (coordinates* 0.5, 0.6*) neural masses in* Ω_2.

and consider the space $\mathbf{L}^2_{n\times n}(\Omega\times\Omega)$ of the functions from $\Omega\times\Omega$ to $\mathcal{M}_{n\times n}$, whose Frobenius norm is in $L^2(\Omega\times\Omega)$. If $\mathbf{W}\in\mathbf{L}^2_{n\times n}(\Omega\times\Omega)$, we denote $\|\mathbf{W}\|^2_F = \int_{\Omega\times\Omega}\|\mathbf{W}(\mathbf{r},\mathbf{r}')\|^2_F\,d\mathbf{r}\,d\mathbf{r}'$. Note that this implies that each element w_{ij}, $i,j=1,\dots,n$ is in $L^2(\Omega\times\Omega)$. We denote $\mathbf{L}^2_n(\Omega)$ as the set of square-integrable mappings from Ω to $\mathbb{R}^n$ and $\|\mathbf{x}\|_{n,2} = (\sum_j \|x_j\|^2_2)^{1/2}$ as the corresponding norm. We have the following lemma.

LEMMA A.2. *Given* $\mathbf{x}\in\mathbf{L}^2_n(\Omega)$ *and* $\mathbf{W}\in\mathbf{L}^2_{n\times n}(\Omega\times\Omega)$*, we define* $\mathbf{y}(\mathbf{r}) = \int_\Omega \mathbf{W}(\mathbf{r},\mathbf{r}')\mathbf{x}(\mathbf{r}')\,d\mathbf{r}'$*. This integral is well defined for almost all* $\mathbf{r}$*,* $\mathbf{y}$ *is in* $\mathbf{L}^2_n(\Omega)$*, and we have*

$$\|\mathbf{y}\|_{n,2}\le\|\mathbf{W}\|_F\,\|\mathbf{x}\|_{n,2}.$$

Proof. Since each w_{ij} is in $L^2(\Omega\times\Omega)$, $w_{ij}(\mathbf{r},.)$ is in $L^2(\Omega)$ for almost all $\mathbf{r}$, thanks to Fubini's theorem. So $w_{ij}(\mathbf{r},.)x_j(.)$ is integrable for almost all $\mathbf{r}$ from our deduction that $\mathbf{y}$ is well defined for almost all $\mathbf{r}$. Next, we have

$$|y_i(\mathbf{r})|\le\sum_j\left|\int_\Omega w_{ij}(\mathbf{r},\mathbf{r}')\,x_j(\mathbf{r}')\,d\mathbf{r}'\right|$$

and (Cauchy–Schwarz)

$$|y_i(\mathbf{r})| \le \sum_j \left(\int_\Omega w_{ij}^2(\mathbf{r}, \mathbf{r}')\, d\mathbf{r}' \right)^{1/2} \|x_j\|_2,$$

from which it follows that (Cauchy–Schwarz again, discrete version)

$$\begin{aligned} |y_i(\mathbf{r})| &\le \left(\sum_j \|x_j\|_2^2 \right)^{1/2} \left(\sum_j \int_\Omega w_{ij}^2(\mathbf{r}, \mathbf{r}')\, d\mathbf{r}' \right)^{1/2} \\ &= \|\mathbf{x}\|_{n,2} \left(\sum_j \int_\Omega w_{ij}^2(\mathbf{r}, \mathbf{r}')\, d\mathbf{r}' \right)^{1/2}, \end{aligned}$$

from which it follows that $\mathbf{y}$ is in $\mathbf{L}_n^2(\Omega)$ (thanks again to Fubini's theorem) and

$$\|\mathbf{y}\|_{n,2}^2 \le \|\mathbf{x}\|_{n,2}^2 \sum_{i,j} \int_{\Omega\times\Omega} w_{ij}^2(\mathbf{r}, \mathbf{r}')\, d\mathbf{r}'\, d\mathbf{r} = \|\mathbf{x}\|_{n,2}^2 \, \|\mathbf{W}\|_F^2. \qquad \square$$

A.2. Banach space-valued functions. A useful viewpoint that is used in this article is to consider the state vector of the neural field as a mapping from a closed time interval J containing the origin 0 into one of the spaces discussed in the previous section. We denote $C(\mathrm{J}; \mathbf{C}_{\mathrm{n}}(\Omega))$ as the set of continuous mappings from J to the Banach space $\mathbf{C}_n(\Omega)$ and $C(\mathrm{J}; \mathbf{L}_{\mathrm{n}}^2(\Omega))$ as the set of continuous mappings from J to the Hilbert (hence Banach) space $\mathbf{L}_n^2(\Omega)$; see, e.g., [11].

A.3. Computation of operator norms. We give a method to compute the norms $\|g\|_{\mathcal{G}}$ and $\|g^*\|_{\mathcal{G}_c^\perp}$ for an operator g of the form

$$g(\mathbf{x})(\mathbf{r}) = \int_\Omega \mathbf{W}(\mathbf{r}, \mathbf{r}')\, \mathbf{x}(\mathbf{r}')\, d\mathbf{r}'.$$

Since $\mathcal{G}$ (resp., $\mathcal{G}_c^\perp$) is dense in the Hilbert space $\mathbf{L}^2(\Omega)$ (resp., $\mathbf{L}_0^2(\Omega)$, the subspace of $\mathbf{L}^2(\Omega)$ of functions with zero mean), we have $\|g\|_{\mathcal{G}} = \|g\|_{\mathbf{L}^2}$ and $\|g^*\|_{\mathcal{G}_c^\perp} = \|g^*\|_{\mathbf{L}_0^2}$. We consider the compact self-adjoint operators

$$G = g^* g : \mathbf{L}^2 \to \mathbf{L}^2$$

and

$$G_c^\perp = g^* \mathcal{P} g : \mathbf{L}_0^2 \to \mathbf{L}_0^2,$$

where $\mathcal{P}$ is the orthogonal projection on $\mathbf{L}_0^2$. We compute the norms of the two self-adjoint positive operators G and $G_c^\perp$ and use the relations

$$\|G\|_{\mathbf{L}^2} = \|g\|_{\mathbf{L}^2}^2$$

and

$$\|G_c^\perp\|_{\mathbf{L}_0^2} = \|g^* \mathcal{P}^* \mathcal{P} g\|_{\mathbf{L}_0^2} = \|g^* \mathcal{P}^*\|_{\mathbf{L}_0^2}^2 = \|g^*\|_{\mathbf{L}_0^2}^2.$$

Let T be a compact self-adjoint positive operator on a Hilbert space $\mathcal{H}$. Its largest eigenvalue is $\lambda = \|T\|_{\mathcal{H}}$. Let $x \in \mathcal{H}$. If $x \notin \mathrm{Ker}(\lambda \mathrm{Id} - T)^{\perp}$, then, according to, e.g., [9],

$$\lim_{n \to \infty} \|T^n x\|_{\mathcal{H}} / \|T^{n-1} x\|_{\mathcal{H}} = \lambda.$$

This method can be applied to g_m and h_m and generalized to the computation of the $\|.\|_{\mathcal{G}_c^{P\,\perp}}$ norm.

Appendix B. Global existence of solutions. In this appendix, we complete the proof of Proposition 3.4 by computing the constant $\tau > 0$ such that for any initial condition $(t_0, \mathbf{V}_0) \in \mathbb{R} \times \mathcal{F}$, the existence and uniqueness of the solution $\mathbf{V}$ are guaranteed on the closed interval $[t_0 - \tau,\, t_0 + \tau]$.

We refer the reader to [2] and exploit the following theorem.

THEOREM B.1. *Let $\mathcal{F}$ be a Banach space and $c > 0$. We consider the initial value problem*

$$\begin{cases} \mathbf{V}'(t) &= f(t, \mathbf{V}(t)), \\ \mathbf{V}(t_0) &= \mathbf{V}_0 \end{cases}$$

for $|t - t_0| < c$, where $\mathbf{V}_0$ is an element of $\mathcal{F}$ and $f : [t_0 - c,\, t_0 + c] \times \mathcal{F} \to \mathcal{F}$ is continuous. Let $b > 0$. We define the set $Q_{b,c} \equiv \{(t, \mathbf{X}) \in \mathbb{R} \times \mathcal{F},\ |t - t_0| \leq c$ and $\|\mathbf{X} - \mathbf{V}_0\| \leq b\}$. Assume the function $f : Q_{b,c} \to \mathcal{F}$ is continuous and uniformly Lipschitz continuous with respect to its second argument, i.e.,

$$\|f(t, \mathbf{X}) - f(t, \mathbf{Y})\| \leq K_{b,c} \|\mathbf{X} - \mathbf{Y}\|,$$

where $K_{b,c}$ is a constant independent of t.

Let $M_{b,c} = \sup_{Q_{b,c}} \|f(t, \mathbf{X})\|$ and $\tau_{b,c} = \min\{b/M_{b,c}, c\}$.

Then the initial value problem has a unique continuously differentiable solution $\mathbf{V}(.)$ defined on the interval $[t_0 - \tau_{b,c},\, t_0 + \tau_{b,c}]$.

In our case, $f = f_v$ and all the hypotheses of the theorem hold, thanks to Proposition 3.2 and the hypotheses of Proposition 3.4, with

$$K_{b,c} = \|\mathbf{L}\|_{\infty} + |\Omega|\, D S_m \sup_{|t - t_0| \leq c} \|\mathbf{W}(\cdot, \cdot, t)\|_{n \times n, \infty},$$

where the sup is well defined (continuous function on a compact domain).

We have

$$M_{b,c} \leq \|\mathbf{L}\|_{\infty} \left(\|\mathbf{V}_0\|_{n,\infty} + b \right) + |\Omega|\, S_m\, W + I,$$

where $W = \sup_{|t - t_0| \leq c} \|\mathbf{W}(\cdot, \cdot, t)\|_{n \times n, \infty}$ and $I = \sup_{|t - t_0| \leq c} \|\mathbf{I}_{\mathrm{ext}}(\cdot, t)\|_{n, \infty}$.

So

$$b/M_{b,c} \geq \frac{1}{\|\mathbf{L}\|_{\infty} + \frac{\|\mathbf{L}\|_{\infty} \|\mathbf{V}_0\|_{n,\infty} + |\Omega|\, S_m\, W + I}{b}}.$$

Hence, for $c \geq \frac{1}{2\|\mathbf{L}\|_{\infty}}$ and b big enough, we have $\tau_{b,c} \geq \frac{1}{2\|\mathbf{L}\|_{\infty}}$, and we can set $\tau = \frac{1}{2\|\mathbf{L}\|_{\infty}}$.

A similar proof applies to the case $f = f_a$ and that of Proposition 6.3.

Appendix C. More on $\boldsymbol{\mathcal{M}}$ and $\boldsymbol{\lambda}_{\mathbf{max}}$. Expressing the exponential as a power series in the definition of $\boldsymbol{\mathcal{M}}$ and computing the powers of the block matrix $\boldsymbol{\mathcal{L}}$, we easily find a block expression of $\boldsymbol{\mathcal{M}}$ depending on $\mathbf{L}$:

$$\boldsymbol{\mathcal{M}} = \begin{pmatrix} \mathbf{L}/4 + 5\mathbf{L}^{-1}/4 & \mathbf{L}^{-2}/2 \\ \mathbf{L}^{-2}/2 & \mathbf{L}^{-1}/4 + \mathbf{L}^{-3}/4 \end{pmatrix}.$$

$\boldsymbol{\mathcal{M}}$ is diagonalizable, as a symmetric positive definite matrix, and has at most $2n$ distinct eigenvalues. More precisely, these eigenvalues are the roots of the second-order polynomials

$$\lambda^2 - \left(\frac{1}{4\,\tau_i} + \frac{3\,\tau_i}{2} + \frac{\tau_i^3}{4}\right)\lambda + \frac{1}{16} + \frac{3\,\tau_i^2}{8} + \frac{\tau_i^4}{16}, \quad 1 \le i \le n.$$

The largest eigenvalue of each of these polynomials is

$$\lambda(\tau_i) = \frac{1}{8\,\tau_i}\left(1 + 6\,\tau_i^2 + \tau_i^4 + \sqrt{1 + 8\,\tau_i^2 + 14\,\tau_i^4 + 8\,\tau_i^6 + \tau_i^8}\right),$$

so that $\lambda_{\max}$ is simply $\max_i \lambda(\tau_i)$. Note that since the function $\lambda(\tau)$ is not monotonous, $\lambda_{\max}$ is not necessarily equal to $\lambda(\tau_{\max})$.

Appendix D. Summary of important notation. Table D.1 summarizes some notation which is introduced in the article and is used in several places.

TABLE D.1
Summary of some important definitions.

Matrix functions	Definition (if applicable)	Where defined	Operators (if applicable)
$\mathbf{L}$	diagonal matrix of the inverse synaptic time constants	(2.4)	
$\tau_{\max}$	largest time constant	Definition 2.2	
$D\mathbf{S}_m$		Definition 2.1	
$\mathbf{W}$		(3.2), (3.3), (3.4)	f_v, f_a, g_v
$\mathbf{W}_{cm}$	$\mathbf{W}D\mathbf{S}_m$	Definition 4.1	g_m
$\mathbf{W}_{mc}$	$D\mathbf{S}_m\mathbf{W}$	Definition 4.1	h_m

TURING PATTERN FORMATION IN THE BRUSSELATOR MODEL WITH SUPERDIFFUSION[*]

A. A. GOLOVIN[†], B. J. MATKOWSKY[†], AND V. A. VOLPERT[‡]

Abstract. The effect of superdiffusion on pattern formation and pattern selection in the Brusselator model is studied. Our linear stability analysis shows, in particular, that, unlike the case of normal diffusion, the Turing instability can occur even when diffusion of the inhibitor is slower than that of the initiator. A weakly nonlinear analysis yields a system of amplitude equations, analysis of which predicts parameter regimes where hexagons, stripes, and their coexistence are expected. Numerical computations of the original Brusselator model near the stability boundaries confirm the results of the analysis. In addition, further from the stability boundaries, we find a regime of self-replicating spots.

Key words. pattern formation, Brusselator, anomalous diffusion, superdiffusion, Turing instability

1. Introduction.

Reaction-diffusion systems are ubiquitous in many branches of science and engineering and have attracted the attention of scientists, engineers, and mathematicians for decades; see, e.g., [4, 9]. Since the groundbreaking discoveries of Turing [49], who showed that diffusion in a mixture of chemically reacting species could cause instability of a spatially uniform state leading to the formation of spatial patterns, and Belousov and Zhabotinskii [61, 62], who discovered oscillating chemical reactions, reaction-diffusion systems have become paradigms for spatio-temporal pattern formation in systems far from thermodynamic equilibrium [11, 31, 54], including living organisms [33]. Experimental observations of such fascinating structures as spiral waves [58], spatially regular, stationary patterns with different symmetries (hexagonal, striped, etc.) [21, 22, 39], as well as the theoretical description of chemical turbulence [19], have made reaction-diffusion systems the subject of numerous ongoing investigations.

A characteristic feature of most of the reaction-diffusion systems that have been studied to date is that diffusion is normal, i.e., at the molecular level it is the result of independent random jumps, e.g., nearest neighbor jumps, at regularly spaced time increments. In fact, the molecules can wait between successive jumps and can also execute not just nearest neighbor jumps, but rather long jumps. However, both the waiting time distribution and jump size distribution must have finite moments. In some cases, however, these conditions are not met, in that the molecules may undergo *anomalous diffusion* [3, 13, 16, 29, 30, 45]. Unlike normal diffusion, which is characterized by the dependence of the mean square displacement of a randomly walking particle on time $\langle(\Delta\mathbf{r})^2\rangle \sim t$, anomalous diffusion is characterized by the

more general dependence

$$\langle(\Delta\mathbf{r})^2\rangle = 2dK_\gamma t^\gamma, \tag{1}$$

where d is the (embedding) spatial dimension, K_γ is a generalized diffusion constant, and the exponent γ is not necessarily an integer. For $\gamma = 1$, anomalous diffusion reduces to normal diffusion, with $K_1 = D$ being the ordinary diffusion coefficient. For $\gamma < 1$ ($\gamma > 1$), the diffusion process is slower (faster) than normal diffusion and is called "subdiffusive" (resp., "superdiffusive"). Both types of anomalous diffusion processes have been recognized as playing important roles in various physical, chemical, biological, and geological processes. For example, subdiffusion, which corresponds to molecules waiting for long times before jumping, i.e., with a waiting time distribution having infinite moments, often occurs in gels (especially bio-gels [53, 55]), porous media [8], and polymers [1]. An important limiting case of superdiffusion corresponds to *Lévy flights* [30], which occur in systems in which there are *long jumps* of particles, i.e., with a jump size distribution having infinite moments. It is typical of some processes in plasmas and turbulent flows [6, 12, 47], surface diffusion [25, 42], diffusion in porous media with flow [8], surfactant diffusion along polymer chains [2], cosmic ray propagation [57], charge carrier transfer in semiconductors [43], motion of animals [44, 48, 52], as well as in geophysical and geological processes, including the dispersion of nuclear waste in soil [37] (see also [3, 13, 16, 29, 30, 45] for reviews and numerous other examples).

An important property of Lévy flights is that in the continuum limit, in one dimension, they are described by means of a partial differential equation with a *fractional derivative*, which is, in fact, defined as a nonlocal, integrodifferential equation,

$$u_t = K^\mu \frac{\partial^\mu}{\partial|x|^\mu}u, \tag{2}$$

where (for $1 < \mu < 2$)

$$\frac{d^\mu u}{d|x|^\mu} = -\frac{1}{2\cos(\pi\mu/2)}(\mathbf{D}_+^\mu u + \mathbf{D}_-^\mu u), \tag{3a}$$

$$\mathbf{D}_+^\mu u = \frac{1}{\Gamma(2-\mu)}\frac{d^2}{dx^2}\int_{-\infty}^{x}\frac{u(\xi,t)\,d\xi}{(x-\xi)^{\mu-1}}, \tag{3b}$$

$$\mathbf{D}_-^\mu u = \frac{1}{\Gamma(2-\mu)}\frac{d^2}{dx^2}\int_{x}^{\infty}\frac{u(\xi,t)\,d\xi}{(\xi-x)^{\mu-1}}, \tag{3c}$$

or in a form defined by its action in Fourier space, $\mathcal{F}[\partial^\mu u/\partial|x|^\mu](k) = -|k|^\mu\mathcal{F}[u](k)$. For $\mu = 1$, (3) reduces to the derivative of the Hilbert transform of u. In higher dimensions, the Laplacian is replaced by the operator $\nabla^\beta \equiv -(-\nabla^2)^{\beta/2}(1 < \beta < 2)$, defined by its action in Fourier space, $\mathcal{F}[\nabla^\beta u](\mathbf{k}) = -|\mathbf{k}|^\beta\mathcal{F}[u](\mathbf{k})$. The derivation of this macroscopic description from an appropriate continuous time random walk model at the microscopic (i.e., molecular) level can be found in [29].

Although many aspects of anomalous diffusion have been extensively studied (see [30] for the most recent review), nonlinear dynamic and pattern formation aspects were the subject of only a very limited number of works. The propagation of reaction-diffusion fronts governed by anomalous diffusion and nonlinear kinetics (similar to the Kolmogorov–Petrovsky–Piskunov problem [18]) was investigated both for the subdiffusive case [27, 59] and the superdiffusive case [7, 26]. It was shown that superdiffusion leads to a significant increase of the front speed. It was also shown that the effects of fluctuations could be important [5].

Several papers study pattern formation in reaction-diffusion systems with anomalous diffusion [10, 14, 15, 20, 56]. The formation of Turing patterns in the subdiffusive case was studied in [56], where it was shown that subdiffusion suppresses pattern formation. In [23] it was also shown that, in one-dimensional systems, anomalous diffusion leads to anomalous heat conduction that may be very important for reaction-diffusion dynamics coupled to heat release, as in combustion. In [14,15], linear stability analysis that predicts Turing instabilities is performed, and the results are supported by numerical simulations. The nonlinear dynamics of oscillating reaction-diffusion patterns that can lead to the formation of spiral waves and chemical turbulence in systems with Levy flights has been recently studied in [34]. At the same time, important aspects of nonlinear dynamics and pattern formation in reaction-diffusion systems, such as *pattern selection* in the presence of anomalous diffusion, have not been studied.

It is well known that the diffusivities in systems of reaction-diffusion equations with normal diffusion play a decisive role in the development of instabilities leading to spatio-temporal pattern formation. For example, this is the case if the diffusivities differ significantly from one another. How much more so is this expected to be the case when one or more of the diffusivities is anomalous, where the diffusivities differ not only quantitatively, but qualitatively as well. In experiments, an efficient way to control the nature of diffusion and the dynamical regimes of chemical reactions in a liquid phase, including those generated by instabilities, is by stirring [17, 24, 28, 35, 36, 38, 41, 51, 63]. In catalytic systems with surface chemical reactions, the anomaly of the reactant surface diffusion can be controlled, for example, by turbulent flow in the adjacent gas phase.

The Brusselator is a well-known paradigm for the study of nonlinear reaction-diffusion systems. In this paper we study Turing pattern formation in the Brusselator model with superdiffusion, namely, Lévy flights. We focus on pattern selection in the formation of hexagons and stripes and compare the cases of normal and superdiffusion. In section 2 we formulate the mathematical model that we consider. It exhibits a solution corresponding to a homogeneous, stationary state. In section 3 we consider the linear stability of this state, while in section 4 we present a weakly nonlinear analysis to derive a set of coupled amplitude equations. These equations are analyzed in section 5, where we describe hexagonal and striped patterns and their stability. In section 6 we present the results of numerical computations of the original model. In addition to verifying the results of our analysis by computing hexagonal and striped patterns near the neutral stability boundaries, we also present new patterns, not described by our analysis, corresponding to the regions where hexagons and stripes are unstable. Specifically, we compute solutions corresponding to self-replicating spots. Finally, in section 7 we present conclusions of our analysis.

2. Mathematical model. The mathematical model that we consider is the standard Brusselator model (see, e.g., [50] and the references therein),

$$\frac{\partial X}{\partial \tau} = D_X \nabla^\alpha X + A - (B+1)X + X^2 Y, \tag{4a}$$

$$\frac{\partial Y}{\partial \tau} = D_Y \nabla^\beta Y + BX - X^2 Y, \tag{4b}$$

with the only exception that the Laplacians with respect to the spatial variables are replaced by ∇^α and ∇^β, the operators that represent superdiffusion as discussed earlier. The system is considered in the entire plane $-\infty < \xi, \zeta < \infty$, and we are interested in bounded solutions. We do not impose initial conditions in the analysis, as we are interested in stable steady solutions of the problem rather than in transient behaviors. We remark that the reaction terms in the equations are taken to be "normal," i.e., the same as in the normal diffusion Brusselator model. This does not have to be the case—anomalous diffusion may affect the form of the reaction terms [20, 46, 59, 60].

The critical point of the system (4), corresponding to a homogeneous stationary solution, is

$$X = A, \quad Y = \frac{B}{A}.$$

It is convenient to rewrite the system of equations in terms of the deviation of the solution from the critical point by introducing

$$U = X - A, \quad V = Y - \frac{B}{A},$$

which yields

$$\frac{\partial U}{\partial \tau} = D_X \nabla^\alpha U + (B-1)U + A^2 V + \frac{B}{A}U^2 + 2AUV + U^2 V, \tag{5a}$$

$$\frac{\partial V}{\partial \tau} = D_Y \nabla^\beta V - BU - A^2 V - \frac{B}{A}U^2 - 2AUV - U^2 V. \tag{5b}$$

Finally, we rescale (5), using

$$U = u_* u, \quad V = v_* v, \quad \tau = t_* t, \quad \xi = \ell_* x, \quad \zeta = \ell_* y$$

with

$$u_* = \sqrt{D_Y/(D_X)^{\beta/\alpha}}, \quad v_* = 1/u_*, \quad \ell_* = D_X^{1/\alpha}, \quad t_* = 1$$

to obtain

$$\frac{\partial u}{\partial t} = \nabla^\alpha u + (B-1)u + Q^2 v + \frac{B}{Q}u^2 + 2Quv + u^2 v, \tag{6a}$$

$$\eta^2 \frac{\partial v}{\partial t} = \nabla^\beta v - Bu - Q^2 v - \frac{B}{Q}u^2 - 2Quv - u^2 v, \tag{6b}$$

where

$$\eta = \sqrt{(D_X)^{\beta/\alpha}/D_Y}, \quad Q = A\eta. \tag{7}$$

The critical point is now given by $u = v = 0$.

3. Linear stability analysis. To study the linear stability of the solution $u = v = 0$, we substitute the normal mode solution

$$\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix} e^{\sigma t + ik_x x + ik_y y},$$

where σ is the growth rate of the perturbation and (k_x, k_y) is its wave vector, into (6) to obtain the dispersion relation

$$\eta^2\sigma^2 + M_1\sigma + M_2 = 0, \tag{8}$$

$$M_1 = Q^2 + k^\beta - \eta^2(B - 1 - k^\alpha), \quad M_2 = BQ^2 - (B - 1 - k^\alpha)(Q^2 + k^\beta),$$

where k is the wavenumber of the perturbation, $k = (k_x^2 + k_y^2)^{1/2}$. The problem exhibits both Turing and oscillatory instabilities. We are particularly interested in the Turing stability boundary, which corresponds to $\sigma = 0$. The neutral stability curve, which can be written in the form

$$B = \frac{1}{k^\beta}(1 + k^\alpha)(Q^2 + k^\beta),$$

has a single minimum (k_{cr}, B_{cr}) which depends on the value of Q. It can be found parametrically as

$$B_{cr} = \frac{(1+x)^2}{1 + (1-s)x}, \quad Q^2 = \frac{sx^{1+1/s}}{1 + (1-s)x}, \quad k_{cr} = x^{1/\alpha}, \tag{9}$$

where $s = \alpha/\beta$. The quantity s varies between $1/2$ and 2 since both α and β are between 1 and 2. The range of variation of the parameter x depends on s:

$$0 < x < \infty \;\text{ if }\; \frac{1}{2} < s \le 1, \quad 0 < x < \frac{1}{s-1} \;\text{ if }\; 1 < s < 2,$$

so that B_{cr} and Q^2 are positive in (9). Figure 1 demonstrates stability regions in the (Q^2, B) plane for selected values of the parameter s that are parametrically given by (9). Instability regions are located above the respective curves. We see that, except for very small Q, the general trend is that increasing s broadens the stability regions. In the weakly nonlinear analysis of the next section we will need the eigenvector (a, b) for $\sigma = 0$, $k = k_{cr}$, and $B = B_{cr}$. It is given by

$$\begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} x^{1/s} \\ -(1+x) \end{pmatrix}.$$

The trivial steady state is unstable for $B > B_{cr}$. Whether it is stable for $B < B_{cr}$ depends on the location of the oscillatory instability boundary. This boundary is obtained by setting the coefficient M_1 in the dispersion relation (8) equal to zero under the condition that the coefficient M_2 is positive. Thus, oscillatory instability occurs at

$$B = 1 + \frac{Q^2}{\eta^2} \;\text{ if }\; 1 + \frac{Q^2}{\eta^2} < B_{cr}.$$

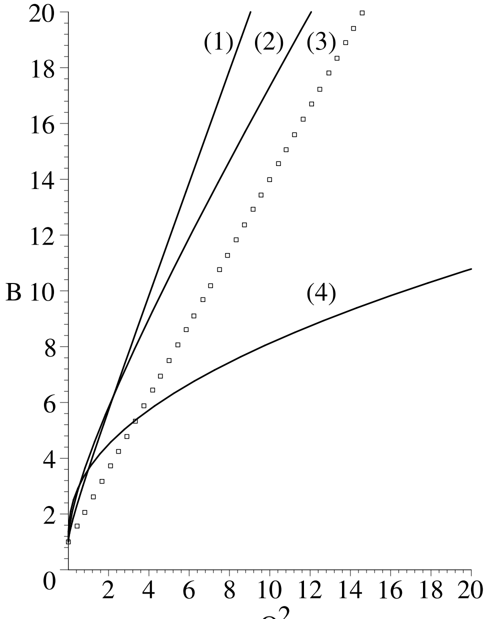

FIG. 1. *Stability boundaries in the* (Q^2, B) *plane. The instability region lies above the curve. Curve* (1) *Turing stability boundary for* $s = 2$*; curve* (2) *Turing stability boundary for* $s = 1$*; curve* (3) *oscillatory stability boundary,* $\eta = 0.877$*; curve* (4) *Turing stability boundary for* $s = 0.5$.

In order for Turing instability to occur prior to oscillatory instability as B increases, we need $B_{cr} < 1 + Q^2/\eta^2$, which can be interpreted as a condition on η,

$$\eta^2 < \frac{Q^2}{B_{cr} - 1} = \frac{s x^{1/s}}{x + 1 + s}. \tag{10}$$

The Turing mechanism of pattern formation, which is due to diffusion-induced instability of the homogeneous steady state, requires that the ratio of the diffusion coefficient of the inhibitor (in our problem, the inhibitor is Y) to that of the activator (X) be sufficiently large in "normal" reaction-diffusion systems. This corresponds to D_Y being sufficiently greater than D_X or, equivalently, η being sufficiently small. Based on this result obtained for the Brusselator problem with normal diffusion, one might expect that if the fractional derivative order β for the inhibitor Y is larger than α, the fractional derivative order for the activator X, i.e., if the inhibitor diffuses slower than the activator, $s < 1$, then no Turing instability will be observed. As can be seen from the above results, this is not necessarily true. Indeed, let us first discuss in greater detail the case of normal diffusion, in which $s = 1$. It is convenient to return to the original parameters A and B instead of Q and B. From (10), using (7) and (9), we get

$$A\eta^2 + 2\eta - A < 0,$$

so that

$$\eta = \sqrt{\frac{D_X}{D_Y}} < \sqrt{\frac{1}{A^2} + 1} - \frac{1}{A} \equiv F_1(A). \tag{11}$$

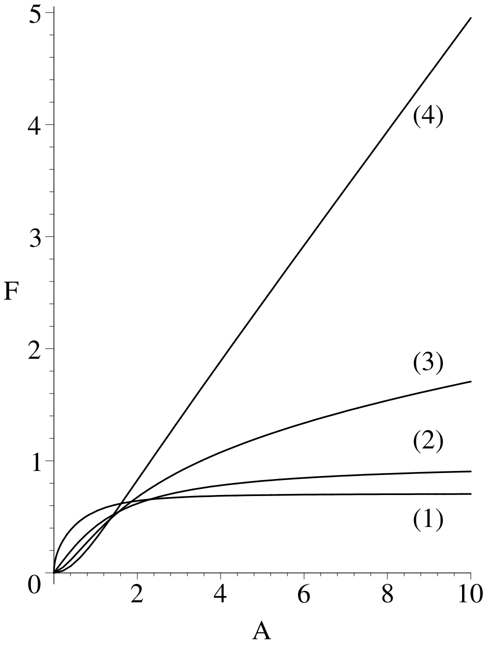

FIG. 2. *The function* $F(A)$ *for selected values of* s. *Curve* (1) $s = 2$; *curve* (2) $s = 1$; *curve* (3) $s = 0.7$; *curve* (4) $s = 0.5$.

The function $F_1(A)$ is a monotonically increasing function that is zero at $A = 0$ and goes to one as A goes to infinity. This means that if η is greater than one, i.e., the diffusion coefficient of the inhibitor is too small, then Turing instability of the homogeneous stationary solution cannot occur because it is always preceded by the oscillatory instability. If $\eta < 1$, then for the supply rate A sufficiently large, specifically, for $A > 2\eta/(1-\eta^2)$, Turing instability does occur as B increases.

In the general case of s not necessarily equal to one, condition (11) is replaced by

$$\eta^2 = \frac{D_X^{1/s}}{D_Y} < 2^{1-1/s} s \frac{[\sqrt{[A^2(s-1)+(s+1)]^2+4A^2} - A^2(s-1) - (s+1)]^{1/s}}{\sqrt{[A^2(s-1)+(s+1)]^2+4A^2} - A^2(s-1) + (s+1)} \equiv F(A), \tag{12}$$

the derivation of which also uses (7), (9), and (10). If this condition is satisfied, then by increasing B we reach the Turing instability boundary. If this condition is not satisfied, then increasing B results in oscillatory instability. We remark that increasing B necessarily results in an instability because the term without σ in the dispersion relation (8) becomes negative for B sufficiently large, so that the dispersion relation has a positive root. The function $F(A)$ in (12) is a monotonically increasing function of A with $F(0) = 0$ for any s of interest, i.e., for $1/2 \leq s \leq 2$. The behavior of this function is, however, different for $1/2 \leq s < 1$ and $1 \leq s \leq 2$. In the first case the function increases without bound as $A \to \infty$, while in the second case it remains finite with

$$\lim_{A\to\infty} F(A) = \frac{1}{s}(s-1)^{1-1/s}.$$

The behavior of this function is illustrated in Figure 2. These results are somewhat counterintuitive because not only can Turing instability occur in the case $s < 1$, when it is not expected because diffusion of the inhibitor in this case is slower than diffusion of the initiator, but it may also occur for any value of η provided that A is sufficiently large, while the case of normal diffusion carries the restriction $\eta < 1$.

4. Weakly nonlinear analysis: Stripes and hexagons. We now perform a weakly nonlinear analysis of the system (6) near the instability threshold in order to study pattern formation. Specifically, we are interested in the formation of hexagons and stripes.

We introduce the slow time $T = \varepsilon^2 t$ and expand both unknowns u and v as well as the bifurcation parameter B as

$$\begin{aligned} u &\sim \varepsilon u_1 + \varepsilon^2 u_2 + \varepsilon^3 u_3 + \cdots , \\ v &\sim \varepsilon v_1 + \varepsilon^2 v_2 + \varepsilon^3 v_3 + \cdots , \\ B &= B_{cr} + \varepsilon^2 \mu. \end{aligned} \tag{13}$$

Here u_j and v_j $(j = 1, 2, 3)$, which correspond to the long time solution behavior after all transients have decayed, are functions of T, x, and y.

Substituting the expansions (13) into the system of equations (6) and collecting like powers of ε, we obtain at orders ε^j $(j = 1, 2, 3)$ the sequence of problems

$$\begin{aligned} O(\varepsilon):\quad & L_u(u_1, v_1) \equiv \nabla^\alpha u_1 + (B_{cr} - 1)u_1 + Q^2 v_1 = 0, \\ & L_v(u_1, v_1) \equiv \nabla^\beta v_1 - B_{cr} u_1 - Q^2 v_1 = 0, \end{aligned} \tag{14}$$

$$O(\varepsilon^2):\quad L_u(u_2, v_2) = -R_2, \quad L_v(u_2, v_2) = R_2, \tag{15}$$

$$O(\varepsilon^3):\quad L_u(u_3, v_3) = \frac{\partial u_1}{\partial T} - R_3, \quad L_v(u_3, v_3) = \eta^2 \frac{\partial v_1}{\partial T} + R_3, \tag{16}$$

where

$$R_2 = \frac{B_{cr}}{Q} u_1^2 + 2Q u_1 v_1, \quad R_3 = 2\frac{B_{cr}}{Q} u_1 u_2 + 2Q(u_1 v_2 + u_2 v_1) + u_1^2 v_1 + \mu u_1.$$

As before, the problems are considered in the entire plane $-\infty < x, y < \infty$.

We wish to describe the appearance of both hexagons and stripes as well as their interactions. Therefore, at $O(\varepsilon)$ we seek solutions of the linearized system in the form

$$\begin{pmatrix} u_1 \\ v_1 \end{pmatrix} = \begin{pmatrix} a \\ b \end{pmatrix} E, \tag{17}$$

where

$$E = L_1 e_1 + L_2 e_2 + L_3 e_3 + c.c.,$$

$$e_1 = \exp(ik_{cr} x), \quad e_{2,3} = \exp\left[ik_{cr}\left(-\frac{x}{2} \pm \frac{\sqrt{3}}{2} y\right)\right], \tag{18}$$

and *c.c.* denotes complex conjugate terms. Here, the amplitudes L_1, L_2, L_3 are functions of the slow time T.

Next, we turn to the $O(\varepsilon^2)$ problem. The right-hand side R_2 can be written in the form

$$R_2 = PE^2, \quad P \equiv \frac{B_{cr}}{Q}a^2 + 2Qab,$$

and can be represented as

$$R_2 = (E_1 + E_2 + 2E_3 + 2E_4)P,$$

where

$$E_1 = L_1^2 e_1^2 + L_2^2 e_2^2 + L_3^2 e_3^2 + c.c.,$$

$$E_2 = 2(|L_1|^2 + |L_2|^2 + |L_3|^2),$$

$$E_3 = L_1 L_2^* e_1 e_2^* + L_1 L_3^* e_1 e_3^* + L_2 L_3^* e_2 e_3^* + c.c.,$$

$$E_4 = L_1 L_2 e_3^* + L_1 L_3 e_2^* + L_2 L_3 e_1^* + c.c.,$$

and the asterisk denotes the complex conjugate. We remark that the terms proportional to E_4 are secular terms that appear in the $O(\varepsilon^2)$ problem due to the resonant interaction of the modes (18). As in [54] these secular terms are considered to be small, so that they contribute to the solvability condition at $O(\varepsilon^3)$.

Then the solution of the $O(\varepsilon^2)$ problem is given by

$$\begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \left[E_1 \begin{pmatrix} u_{21} \\ v_{21} \end{pmatrix} + E_2 \begin{pmatrix} u_{22} \\ v_{22} \end{pmatrix} + 2E_3 \begin{pmatrix} u_{23} \\ v_{23} \end{pmatrix} \right] P,$$

where the coefficients u_{2j}, v_{2j} are

$$u_{21} = \frac{2^\beta k_{cr}^\beta}{(1 + 2^\alpha k_{cr}^\alpha)(Q^2 + 2^\beta k_{cr}^\beta) - 2^\beta k_{cr}^\beta B_{cr}},$$

$$v_{21} = \frac{-1 - 2^\alpha k_{cr}^\alpha}{(1 + 2^\alpha k_{cr}^\alpha)(Q^2 + 2^\beta k_{cr}^\beta) - 2^\beta k_{cr}^\beta B_{cr}},$$

$$u_{22} = 0,$$

$$v_{22} = -\frac{1}{Q^2},$$

$$u_{23} = \frac{3^{\beta/2} k_{cr}^\beta}{(1 + 3^{\alpha/2} k_{cr}^\alpha)(Q^2 + 3^{\beta/2} k_{cr}^\beta) - 3^{\beta/2} k_{cr}^\beta B_{cr}},$$

$$v_{23} = \frac{-1 - 3^{\alpha/2} k_{cr}^\alpha}{(1 + 3^{\alpha/2} k_{cr}^\alpha)(Q^2 + 3^{\beta/2} k_{cr}^\beta) - 3^{\beta/2} k_{cr}^\beta B_{cr}}.$$

We now turn to the $O(\varepsilon^3)$ problem. Substituting the solutions u_1, u_2, v_1, v_2 into R_3 yields

$$R_3 = 2PK_1EE_1 + 2PK_2EE_2 + 4PK_3EE_3 + a^2bE^3 + \mu aE,$$

where

$$K_1 = \frac{B_{cr}}{Q}au_{21} + Qav_{21} + Qbu_{21},$$

$$K_2 = \frac{B_{cr}}{Q}au_{22} + Qav_{22} + Qbu_{22},$$

$$K_3 = \frac{B_{cr}}{Q}au_{23} + Qav_{23} + Qbu_{23}.$$

The secular terms in the above products EE_1, EE_2, and so on are given as follows:

$$\text{in } EE_1: \qquad L_1|L_1|^2e_1 + L_2|L_2|^2e_2 + L_3|L_3|^2e_3 + c.c. \equiv E_0,$$

$$\text{in } EE_2: \qquad 2EF, \quad F = |L_1|^2 + |L_2|^2 + |L_3|^2,$$

$$\text{in } EE_3: \qquad EF - E_0,$$

$$\text{in } E^3: \qquad 6EF - 3E_0.$$

Thus, the secular terms in R_3 are

$$\mu aE + a\frac{\partial E}{\partial T} + E_0(2PK_1 + 4PK_2 + 3a^2b) + (EF - E_0)(4PK_2 + 4PK_3 + 6a^2b).$$

Elimination of secular terms in the $O(\varepsilon^3)$ problem results in the following system of equations for the leading order amplitudes L_1, L_2, L_3:

$$C_0\frac{dL_1}{dT} = \mu C_1L_1 + C_2L_2^*L_3^* + C_3L_1|L_1|^2 + C_4L_1(|L_2|^2 + |L_3|^2), \tag{19a}$$

$$C_0\frac{dL_2}{dT} = \mu C_1L_2 + C_2L_1^*L_3^* + C_3L_2|L_2|^2 + C_4L_2(|L_1|^2 + |L_3|^2), \tag{19b}$$

$$C_0\frac{dL_3}{dT} = \mu C_1L_3 + C_2L_1^*L_2^* + C_3L_3|L_3|^2 + C_4L_3(|L_1|^2 + |L_2|^2). \tag{19c}$$

The coefficients C_k, $k = 0, 1, 2, 3, 4$, are given by

$$C_0 = \frac{a(1+x) + \eta^2bsx}{1 + (1-s)x} = \frac{(1+x)(x^{1/s} - \eta^2sx)}{1 + (1-s)x},$$

$$C_1 = a = x^{1/s} > 0,$$

$$C_2 = 2P = \frac{2(1+x)[1+(1-2s)x]x^{2/s}}{\big[s[1+(1-s)x]x^{1+1/s}\big]^{1/2}}, \tag{20}$$

$$C_3 = 2PK_1 + 4PK_2 + 3a^2b = \frac{(1+x)x^{2/s}}{s\,x^2}\,\frac{C_{3\,n}}{C_{3\,d}},$$

$$C_4 = 4PK_2 + 4PK_3 + 6a^2b = \frac{(1+x)x^{2/s}}{s\,x^2}\,\frac{C_{4\,n}}{C_{4\,d}},$$

where

$$C_{3\,n} = \big[(-6+11s-4s^2)2^{\beta} + (6s-9s^2)2^{\alpha} + (4-9s+5s^2)2^{\alpha+\beta}\big]\,x^3$$

$$+\big[(-14+13s+s^2)2^{\beta} + 6\,s\,2^{\alpha} + (8-9s)\,2^{\alpha+\beta} + 6s - 9s^2\big]\,x^2$$

$$+\big[(-10+2s)2^{\beta} + 4\cdot 2^{\alpha+\beta} + 6s\big]\,x - 2^{1+\beta},$$

$$C_{3\,d} = \big[2^{\beta} + (s-1)2^{\alpha+\beta} - s\,2^{\alpha}\big]\,x + (1+s)2^{\beta} - 2^{\alpha+\beta} - s,$$

$$C_{4\,n} = \Big[(-8+14s-8s^2)\,3^{\beta/2} + (4-6s+2s^2)\,3^{(\alpha+\beta)/2} + (8s-10s^2)\,3^{\alpha/2}\Big]\,x^3$$

$$+\Big[(-20+22s-6s^2)\cdot 3^{\beta/2} + (8-6s)3^{(\alpha+\beta)/2} + 8\,s\,3^{\alpha/2} + 8s - 10s^2\Big]\,x^2$$

$$+\Big[(8s-16)3^{\beta/2} + 4\cdot 3^{(\alpha+\beta)/2} + 8\,s\Big]\,x - 4\cdot 3^{\beta/2},$$

$$C_{4\,d} = \Big[(-1+s)3^{(\alpha+\beta)/2} + 3^{\beta/2} - s\,3^{\alpha/2}\Big]\,x - 3^{(\alpha+\beta)/2} + (s+1)3^{\beta/2} - s.$$

We note that both C_0 and C_1 are positive. Indeed, upon simple manipulations that use (10), we obtain

$$C_0 = \frac{(1+x)sx}{1+(1-s)x}\left[\frac{x^{1/s}}{sx} - \eta^2\right]$$

$$> \frac{(1+x)sx}{1+(1-s)x}\left[\frac{x^{1/s}}{sx} - \frac{sx^{1/s}}{x+1+s}\right] = \frac{x^{1/s}(1+s)(1+x)}{1+x+s} > 0.$$

The fact that C_0 and C_1 are positive will be used in the next section.

5. Analysis of the amplitude equations: Stripes and hexagons. We consider steady states of the system (19); specifically, we are interested in the steady states that describe hexagons and stripes in the original system. We briefly list below well-known general results concerning these patterns [54] and then relate these results to the problem at hand. Hexagonal patterns correspond to

$$L_1 = L_2 = L_3 = L_h,$$

where L_h is a solution of the quadratic equation

$$(C_3 + 2C_4)L_h^2 + C_2 L_h + \mu C_1 = 0. \tag{21}$$

Stripes parallel to the y-axis correspond to

$$L_1 = L_s, \quad L_2 = L_3 = 0, \quad L_s = \sqrt{-\frac{\mu C_1}{C_3}}.$$

We first discuss the stripes. The linear stability analysis of the system (19) in the case of stripes results in the following values for the growth rate σ of perturbations:

$$C_0\sigma_1 = -2\mu C_1, \quad \sigma_2 = 0, \quad C_0\sigma_{3,4} = C_2 L_s - (C_3 - C_4)L_s^2,$$

$$C_0\sigma_{5,6} = -C_2 L_s - (C_3 - C_4)L_s^2.$$

Since the coefficients C_0 and C_1 are always positive, we conclude that supercritical stripes exist if $C_3 < 0$. They are stable if $C_3 - C_4 > 0$ and the amplitude L_s is sufficiently large, $L_s > |C_2|/(C_3 - C_4)$.

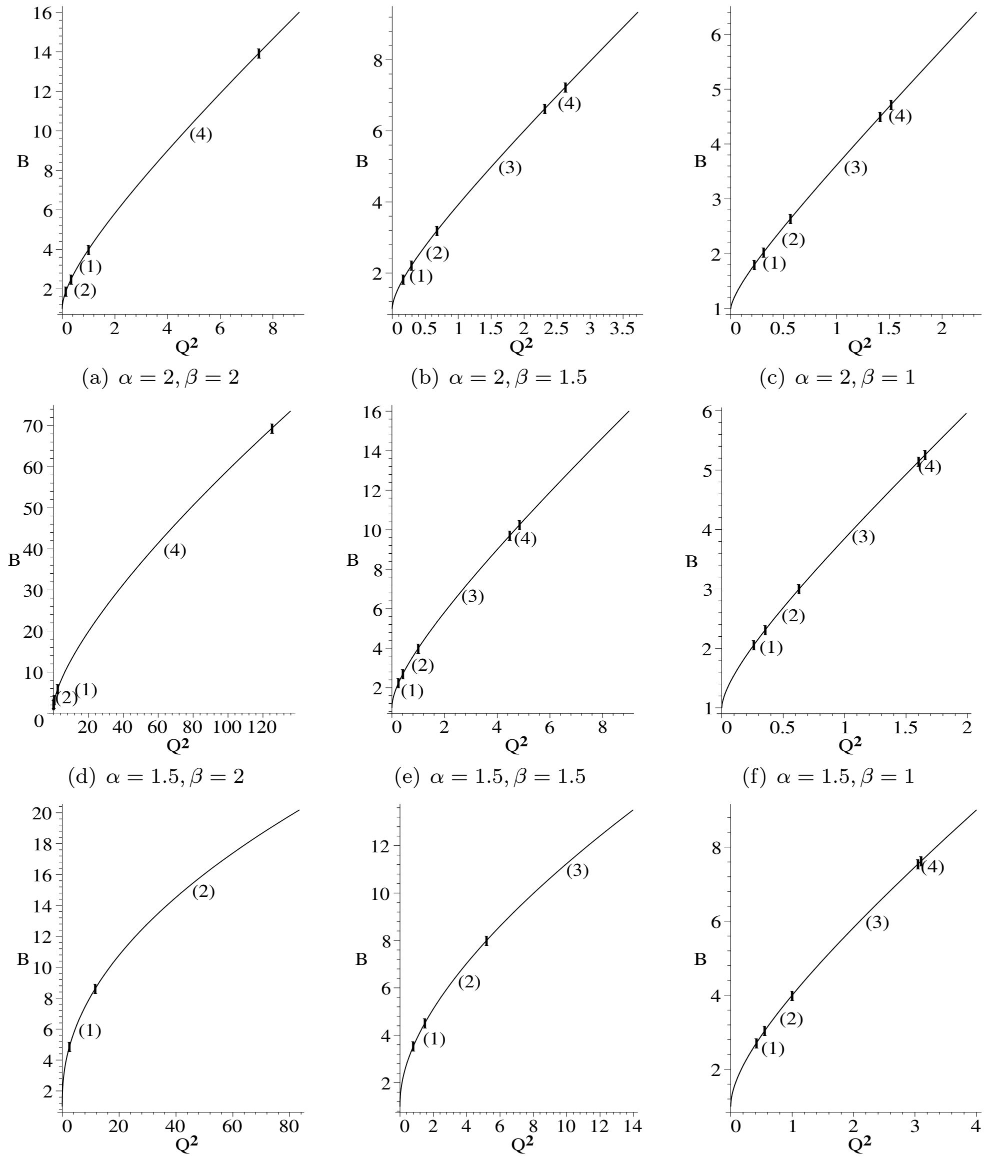
The linear stability analysis of the system (19) in the case of hexagons results in the following values for the growth rate σ of perturbations:

$$C_0\sigma_1 = C_2 L_h + 2(C_3 + 2C_4)L_h^2, \quad C_0\sigma_{2,3} = 2[-C_2 L_h + (C_3 - C_4)L_h^2],$$

$$C_0\sigma_4 = -3C_2 L_h, \quad \sigma_{5,6} = 0.$$

Again, keeping in mind that $C_0 > 0$, $C_1 > 0$, we conclude that a necessary condition for stable hexagons to exist is $C_3 + 2C_4 < 0$. This condition is not sufficient. If, in addition to this condition, $C_3 - C_4 < 0$, then the entire increasing branch of hexagons is stable. If the necessary condition is satisfied but $C_3 - C_4 > 0$, hexagons can still be stable. Specifically, they are stable if $C_3 + C_4 < 0$, but in this case only part of the increasing hexagon branch is stable. The hexagons in this case will coexist with stripes if $C_3 < 0$. Finally, we remark that in all of the above cases the hexagons may be either positive, which corresponds to $L_h > 0$ and is the case when $C_2 > 0$, or negative, which corresponds to $L_h < 0$ (for $C_2 < 0$).

In order to illustrate the effect of superdiffusion on Turing pattern formation, we consider three values of the superdiffusion exponents α and β, namely, 1, 3/2, and 2, and consider all possible combinations. In each case we plot the Turing instability boundary in the (Q^2, B) parameter plane and mark different parts of the boundary according to the different scenarios predicted by the weakly nonlinear analysis. The results are presented in Figure 3. Different parts of the stability boundaries are marked by different numbers in the figure. Crossing the boundary corresponding to different numbers as B increases leads to the appearance of different spatial patterns.



(a) $\alpha = 2, \beta = 2$

(b) $\alpha = 2, \beta = 1.5$

(c) $\alpha = 2, \beta = 1$

(d) $\alpha = 1.5, \beta = 2$

(e) $\alpha = 1.5, \beta = 1.5$

(f) $\alpha = 1.5, \beta = 1$

(g) $\alpha = 1, \beta = 2$

(h) $\alpha = 1, \beta = 1.5$

(i) $\alpha = 1, \beta = 1$

FIG. 3. *Stability boundaries in the* (Q^2, B) *plane; see text.*

Positive hexagons bifurcate when the part of the boundary marked by (1) is crossed; (2) indicates coexistence of positive hexagons and stripes, (3) shows the coexistence of negative hexagons and stripes; and finally, (4) corresponds to negative hexagons. There are parts of the boundaries that are not marked, which means that neither hexagons nor stripes are observed as these boundaries are crossed. This may occur, e.g., when both hexagons and stripes are unstable.

As Figure 3 illustrates, most of the differences between the normal diffusion and superdiffusion cases are quantitative rather than qualitative. This can be explained by the fact that in the case of a shortwave instability, the local structure of the dispersion

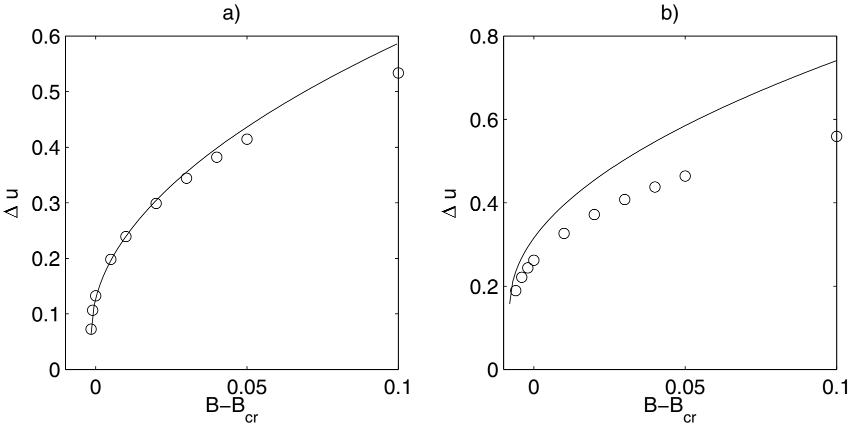


FIG. 4. *Bifurcation diagrams for hexagonal patterns. In both figures* $\alpha = \beta = 1$*;* $x = 0.9$ *in* (a), $x = 0.8$ *in* (b). *See text.*

curve near the instability threshold (parabola) remains the same as in the case of the normal diffusion. Therefore, the effect of the anomalous diffusion reduces to changing characteristic diffusion times, which leads to the renormalization of the coefficients in the amplitude equations. All types of bifurcating regimes are present in the three cases when $\beta = 1$, while larger β, e.g., $\beta = 2$, demonstrates the presence of "preferred" regimes. Another observation is that for $\alpha > \beta$ the bifurcations occur in the range of Q significantly smaller than in the case $\alpha < \beta$.

We now return to the discussion of the quadratic terms in the amplitude equations. The way the terms were treated, though commonly used [54], can by no means be claimed systematic. There is, however, a systematic way to deal with the quadratic terms. Indeed, if we consider the distinguished limit in which

$$x - \frac{1}{2s-1} = O(\varepsilon), \tag{22}$$

then $C_2 = O(\varepsilon)$ (see the expression (20) for C_2). In this case the quadratic terms become $O(\varepsilon^3)$, so that they are shifted to the $O(\varepsilon^3)$ problem, and the amplitude equations (19) arise in a systematic way due to solvability conditions applied to the $O(\varepsilon^3)$ problem. Not only is this approach more systematic, but also the results obtained under the condition (22) are expected to be more accurate. This is illustrated by comparing numerical and analytical bifurcation curves in Figure 4. Shown are numerically (circles) and analytically (solid lines) computed amplitude of u, denoted by Δu, as a function of supercriticality $B - B_{cr}$. The numerical solution was obtained for the original nondimensional problem (6) with parameter values given by (9) (details of our numerical approach are in the next section), with

$$\Delta u = \max_{(x,y)} u - \min_{(x,y)} u.$$

To obtain the analytical amplitude Δu, we used the leading order analytical solution, so that

$$\Delta u = L_h a \left[\max_{(x,y)} (e_1 + e_2 + e_3 + c.c.) - \min_{(x,y)} (e_1 + e_2 + e_3 + c.c.) \right],$$

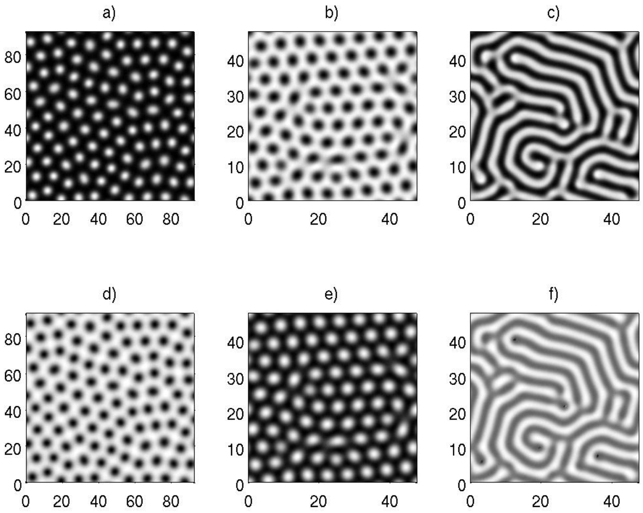

FIG. 5. *Numerical solutions of the system* (6) *in the case of superdiffusion* ($\alpha = \beta = 1.5$, $\eta = 0.2$) *showing positive hexagons* ((a) *shows* u, (d) *shows* v, $x = 0.55$, $\epsilon = 0.1$), *negative hexagons* ((b) *shows* u, (e) *shows* v, $x = 1.5$, $\epsilon = 0.1$), *and stripes* ((c) *shows* u, (f) *shows* v, $x = 1.5$, $\epsilon = 1.0$).

with L_h computed from the quadratic equation (21) as

$$L_h = \frac{1}{2(C_3 + 2C_4)} \left(-C_2 - \sqrt{C_2^2 - 4(C_3 + 2C_4)(B - B_{cr})} \right).$$

Since $\alpha = \beta = 1$ is used for the calculations shown in the figure, (22) reduces to $x - 1 = O(\varepsilon)$. For $x = 0.9$ the figure illustrates almost perfect agreement between the analytical and numerical results. For $x = 0.8$ the accuracy is acceptable. For x farther away from 1, the difference between the numerical and analytical calculations increases. However, there still is a qualitative agreement between the two, and this is why the amplitude equations (19) may be useful even if (22) is not satisfied.

6. Numerical computation of patterns. We have performed numerical computations of the system (6) by means of a pseudospectral method, with time integration in Fourier space, using a Crank–Nicolson scheme for the linear operator and an Adams–Bashforth scheme for the nonlinear operator. Periodic boundary conditions and small-amplitude random initial data have been used.

Our numerical computations confirmed the results of the weakly nonlinear analysis summarized in Figure 3. Figure 5 shows examples of positive hexagons (Figure 5(a),(d)), negative hexagons (Figure 5(b),(e)), and stripes (Figure 5(c),(f)) for the anomalous diffusion case. Note that in the hexagonal patterns several penta-hepta defects are clearly visible, while in the stripe patterns typical defects such as dislocations and disclinations are present. The defects can be described analytically as solutions of equations which generalize our equations (19) to the case when spatial modulations are present, i.e., Ginzburg–Landau equations. These defects gradually disappear as time goes on, so that the resulting final patterns will be perfect hexagons or stripes.

We also performed numerical computations of a regime where neither hexagons nor stripes are stable. The most interesting is a regime of self-replicating spots, first

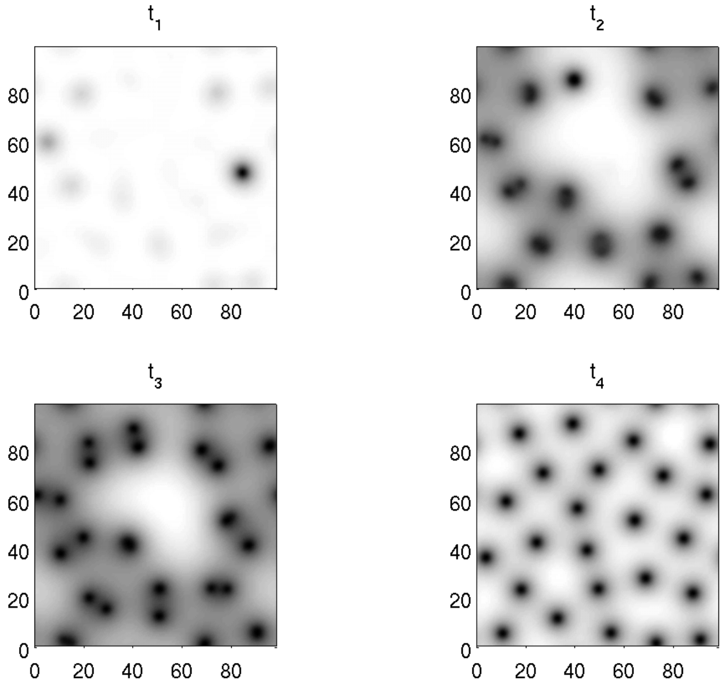

Fig. 6. *Numerical solutions of the system* (6) *in the case of normal diffusion* ($\alpha = \beta = 2.0$, $\eta = 0.2$, $x = 0.1$, $\epsilon = 0.1$) *showing the formation of self-replicating spots for the v-component. Different figures correspond to different moments of time.*

discovered in [40] for the case of normal diffusion. Figure 6 shows this regime for the case of normal diffusion. One can see that the spots appear from small perturbations of the homogeneous state and then start self-replicating until the average distance between the spots reaches a particular value. After that the spots move slowly, repelling each other, until they form a hexagonal pattern corresponding to a "Wigner crystal" [40] (not shown here).

In the case of anomalous diffusion, this regime exhibits slightly different dynamics. Namely, a single spot that appears from a small fluctuation first forms a *ring* which in turn becomes unstable and disintegrates into spots that continue to self-replicate. The ring radius at which it becomes unstable and the instability mode depend on the Lévy flight exponents α and β. Figure 7 shows the formation of a ring and its subsequent disintegration into localized spots in the case of Lévy flights with $\alpha = \beta = 1.5$. One can see that the instability occurs when the ring radius is still quite small, and the instability mode corresponds to the superposition of two modes with azimuthal numbers $m = 2$ and $m = 4$. As a result each ring produces four spots.

We have observed that the number of spots resulting from the instability of a ring depends on the anomalous diffusion exponents. The farther the anomalous diffusion exponents are from the normal diffusion case, the more spots are produced from each ring. Figure 8 shows the results of the corresponding numerical simulations for different values of α and β. One can see that for $\alpha = \beta = 1.8$ there are two rings that disintegrate into two and three spots. For $\alpha = \beta = 1.35$ the rings develop into four and five spots. Disintegration into five and seven spots can be seen for $\alpha = \beta = 1.3$.

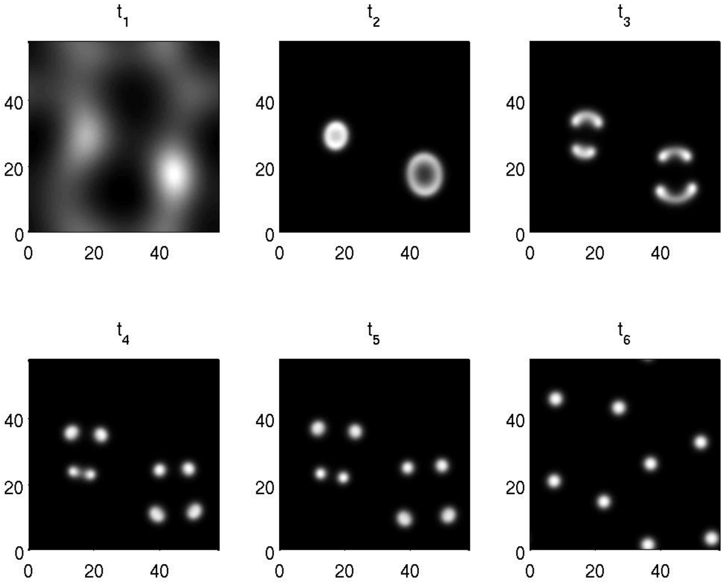

FIG. 7. *Numerical solutions of the system* (6) *in the case of superdiffusion (*$\alpha = \beta = 1.5$*,* $\eta = 0.2$*,* $x = 0.1$*,* $\epsilon = 0.1$*) showing the formation of rings that decay into localized spots. The component* u *is shown. Different figures correspond to different moments of time.*

For $\alpha = \beta = 1.2$ the ring instability results in the formation of 13 spots. This behavior may be attributed to the nonlocal character of Lévy flights: with the decrease of the anomalous exponents, different parts of the ring are "communicating" with each other more easily, which causes the ring to disintegrate into a larger number of spots.

Figure 9 shows the same type of instability in the case $\alpha = \beta = 1.0$. One can see that the ring radius at which instability occurs is much larger, and the instability mode number is much larger as well. Note too that the spots that result from the ring instability self-replicate at a later time. Finally, we note that the ring formation can be observed not only for equal Lévy exponents, as shown in Figures 7–9, but also when α and β are different but sufficiently smaller than 2.0.

7. Conclusion. The Turing mechanism of pattern formation, which is due to diffusion-induced instability of the homogeneous steady state, requires that the ratio of the diffusion coefficient of the inhibitor to that of the activator be sufficiently large in "normal" reaction-diffusion systems. One might expect, based on this result for the Brusselator problem with normal diffusion, that if the fractional derivative order β for the inhibitor Y is larger than α, the fractional derivative order for the activator (i.e., the inhibitor diffuses slower than the activator, $s < 1$), then no Turing instability can be observed. In fact, the result is quite the opposite. Not only can Turing instability occur in the case $s < 1$, which is unexpected because diffusion of the inhibitor in this case is slower than diffusion of the initiator, but it may also occur for any values of the diffusion coefficients provided that the "supply" parameter A is sufficiently large. These are the most striking qualitative differences between normal and anomalous diffusion.

The remaining results derived from the weakly nonlinear analysis indicate that

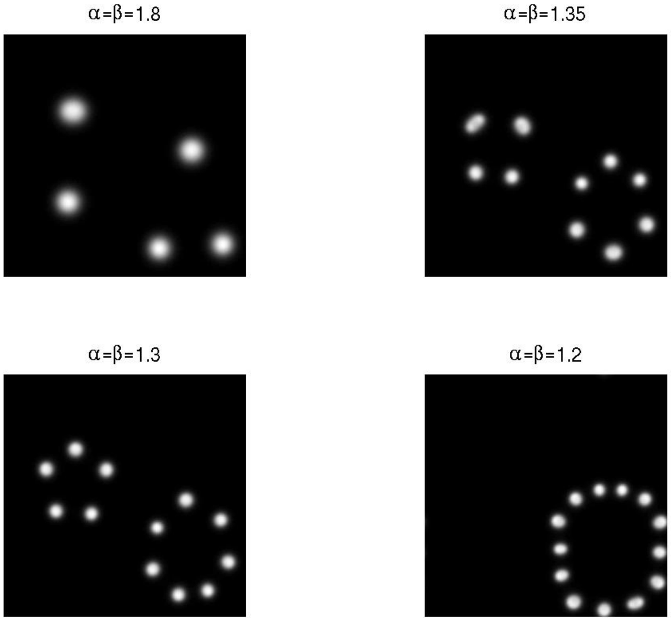

FIG. 8. *Numerical solutions of the system* (6) *in the case of superdiffusion* ($\eta = 0.2$, $x = 0.1$, $\epsilon = 0.1$) *for different values of* α *and* β *showing the result of a ring instability leading to different numbers of localized spots. The component* u *is shown.*

most of the differences between normal diffusion and superdiffusion are quantitative rather than qualitative. That is, the value of the transition point changes as normal diffusion is replaced by anomalous diffusion. This can be explained by the fact that in the case of a short-wave instability the local structure of the dispersion curve near the instability threshold is the same in both cases of normal and anomalous diffusion. The anomalous diffusion in this case just leads to the change in coefficients characterizing the parabolic character of the dispersion curve due to the change of the characteristic diffusion times. A more profound, qualitative effect of the anomalous diffusion can be expected in the case of a long-wave instability when the anomalous diffusion qualitatively changes the relation between characteristic slow spatial and time scales [34]. The analysis of this case is, however, beyond the scope of the present paper. All types of bifurcating regimes, i.e., positive and negative hexagons and regions of coexistence of these hexagons and stripes, are present when $\beta = 1$, while larger β, e.g., $\beta = 2$, demonstrates the presence of "preferred" regimes. Another observation is that for $\alpha > \beta$ the bifurcations occur in the range of A significantly smaller than in the case $\alpha < \beta$.

Our numerical computations confirmed the results of the weakly nonlinear analysis. In addition, a regime of localized, self-replicating spots has been found. We have observed that, unlike the case of normal diffusion, in the case of Lévy flights, the spots result from the instability of *localized rings.* We have exhibited the initial breakup of the rings into different numbers of spots depending on the anomalous diffusion exponents. The spots resulting from a ring instability may later self-replicate. We have observed that the number of spots resulting from the ring instability increases with the decrease of the Lévy flight exponent. This can be attributed to the increase of the nonlocal character of the superdiffusion in this case, i.e., the increase of the

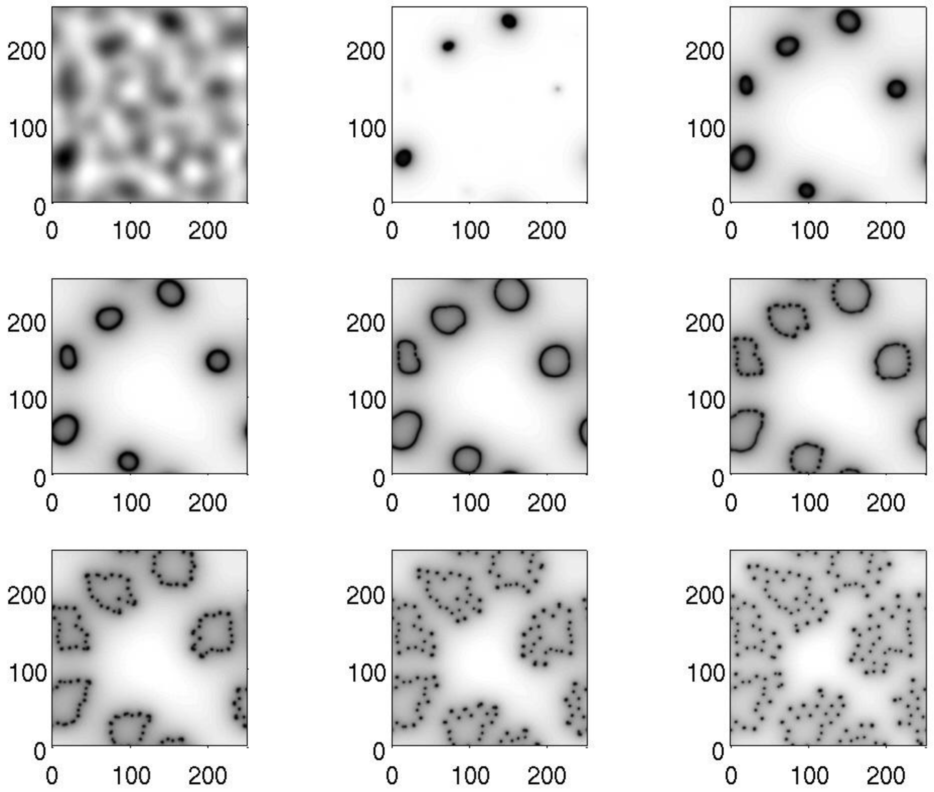

Fig. 9. *Numerical solutions of the system* (6) *in the case of superdiffusion (*$\alpha = \beta = 1.0$*,* $\eta = 0.2$*,* $x = 0.1$*,* $\epsilon = 0.1$*) showing the formation of rings that decay into localized spots. Six rings are clearly seen. The component* v *is shown. Different figures correspond to different moments of time increasing from left to right and from top to bottom.*

characteristic "communication" distance between the structures.

Finally, we note that it would be interesting to investigate the means to experimentally control the anomalous diffusion exponents in superdiffusive reaction-diffusion systems. In a system where superdiffusion is caused by, say, turbulent mixing, a possible way to control the anomalous exponents would be to vary the mixing intensity [63]. For a reaction-diffusion system in a porous medium, the control can be achieved by changing the velocity of the gas flowing through the medium. For, say, a catalytic system governed by surface diffusion and reactions, when the reactants can perform long jumps along the catalytic surface, the parameters of the surface diffusion could possibly be controlled by irradiation of the catalyst. Note that feedback control of catalytic patterns by light has been attracting a great deal of attention [32]. Another possibility would be to affect the characteristics of the anomalous surface diffusion by changing the parameters of a turbulent gas flow in the adjacent gas phase. The investigation of ways to control reaction-diffusion systems with anomalous diffusion, as well as possible feedback control mechanisms to stabilize certain desired patterns, will be considered in future studies.

PROPAGATION OF LOCAL DISTURBANCES IN REACTION DIFFUSION SYSTEMS MODELING QUADRATIC AUTOCATALYSIS[*]

XINFU CHEN[†] AND YUANWEI QI[‡]

Abstract. This article studies the propagation of initial disturbance in a quadratic autocatalytic chemical reaction in one-dimensional slab geometry, where two chemical species A, called the reactant, and B, called the autocatalyst, are involved in the simple scheme $A + B \to 2B$. Experiments demonstrate that chemical systems for which quadratic or cubic catalysis forms a key step can support propagating chemical wavefronts. When the autocatalyst is introduced locally into an expanse of the reactant, which is initially at uniform concentration, the developing reaction is often observed to generate two wavefronts, which propagate outward from the initial reaction zone. We show rigorously that with such an initial setting the spatial region is divided into three regions by the two wavefronts. In the middle expanding region, the reactant is almost consumed so that $A \approx 0$, whereas in the other two regions there is basically no reaction so that $B \approx 0$. Most of the chemical reaction takes place near the wavefronts. The detailed characterization of the concentrations is given for each of the three zones.

Key words. quadratic autocatalysis, traveling wave, propagation of local disturbance, reaction-diffusion

1. Introduction.

In this paper we consider an isothermal autocatalytic chemical reaction step governed by the quadratic reaction relation

$$A + B \to 2B \quad \text{with rate} \quad kab.$$

Here, $k > 0$ is the reaction rate, and a and b are the concentrations of reactant A and autocatalyst B, respectively.

Well documented in the literature, the quadratic reaction relation has appeared in several important models of real chemical reactions, e.g., the Belousor–Zhabotinskii reaction and also gas-phase radical chain branching, oxidation reactions, such as the carbon-monoxide-oxygen reaction, and hydrogen-oxygen systems [13].

Experimental observations demonstrate the existence of propagating chemical wave fronts in unstirred chemical systems for which quadratic or cubic catalysis forms a key step [15], [25]. These wavefronts, or travelling waves, arise due to the interaction of reaction and diffusion. Quite often when a quantity of autocatalyst is added locally into an expanse of reactant, which is initially at uniform concentration, the ensuing reaction is observed to generate wavefronts which propagate outward from the initial reaction zone, consuming fresh reactant ahead of the wavefront as it propagates. This is the phenomenon to be addressed in this paper.

We study the following system for $u = u(x,t), v = v(x,t)$:

$$(1.1) \qquad \begin{cases} u_t - Du_{xx} = -uv & \text{in } \mathbb{R} \times (0,\infty), \\ v_t - v_{xx} = uv & \text{in } \mathbb{R} \times (0,\infty), \\ u(\cdot,0) = u_0(\cdot), \quad v(\cdot,0) = v_0(\cdot) & \text{on } \mathbb{R} \times \{0\}. \end{cases}$$

It is the result of simple scaling of the standard system

$$a_t = D_A a_{xx} - kab, \qquad b_t = D_B b_{xx} + kab,$$

with $D = D_A/D_B$.

Our basic assumptions are the following:

(A1) $D \in (0,1]$;

(A2) $u_0(x) = 1$ for all $x \in \mathbb{R}$; and

(A3) v_0 is a continuous nonnegative function having compact support, $v_0(0) > 0$.

Our main result is the following.

Theorem 1.1. *Assume* (A1)–(A3) *and let* (u,v) *be the solution of* (1.1). *Set*

$$(1.2) \qquad m(t) = 2t - 3(\log[3+t] - \log 3).$$

Then for each $t > 0$ *and* $x \in [-m(t), m(t)]$, *we have* $(u,v) \approx (0,1)$ *in the following sense:*

$$(1.3) \qquad u(x,t) \le e^{-\mu[m(t)-|x|]}, \qquad \Big|1 - v(x,t)\Big| \le \frac{C}{\sqrt{1 + m(t) - |x|}}.$$

On the other hand, when $x \in (-\infty, -m(t)] \cup [m(t), \infty)$, *we have* $(u,v) \approx (1,0)$ *in the sense that*

$$(1.4) \qquad \Big|1 - u(x,t)\Big| + v(x,t) \le C\Big\{1 + |x| - m(t)\Big\} e^{m(t)-|x|}.$$

A result somewhat similar to ours is obtained by Billingham and Needham [7] using formal asymptotic and numerical computation. There, instead of a Cauchy initial problem, an initial-boundary value problem on $(0,\infty)$ is considered, with a homogenous Newmann condition at $x = 0$. The proof we give here is rigorous.

It will be interesting to see how to generalize our result to the cubic autocatalysis reaction with nonlinear reaction term uv^2. But a number of technical difficulties need to be overcome, not least of which is a result similar to that of Bramson on the traveling speed of a scalar equation with nonlinearity $u(1-u)^2$.

The organization of this paper is as follows. Section 2 contains the analysis of u behind the reaction front. In section 3 the estimate of the front location is provided. The behavior of (u,v) after the reaction has taken place is shown in section 4.

We note in passing that unlike the single equation case, of which many excellent results have been proved in the last 30 years as exemplified by the works of Aronson and Weinberger [2], Fife and McLeod [10], Sattinger [21], and Chen and Guo [8] (the survey paper of Xin [24] provides a more detailed account on recent progress), there are very limited results on the study of traveling waves and their effect on global dynamics for parabolic systems. With the recent progress of proving the existence of traveling waves in [9] and [20], we hope to spur interest in such problems since many mathematical models in biology, most of which are reaction-diffusion systems, are deeply linked to traveling wave phenomena. We also note that systems similar to ours appear in the study of thermal-diffusive flows with advection; see [4], [16], [17], [18], [19], and [23].

2. Exponential decay of a reactant behind a reaction front. Whenever an autocatalyst presents, the chemical reaction takes place very fast; as a result, the reactant is consumed quickly and therefore experiences an exponential decay (in time). The central issue here is to find the spreading speed of the autocatalyst. Mathematically, by assuming $D \in (0, 1]$ (i.e., the reactant diffuses no faster than the autocatalyst does), we are able to find a good comparison to pin down the autocatalyst's spreading speed.

2.1. A comparison.

LEMMA 2.1. *Assume that $D \in (0, 1]$ and $u_0(x) \geq 0$, $v_0(x) \geq 0$, $u_0(x) + v_0(x) \geq 1$ for every $x \in \mathbb{R}$. Then the solution of (1.1) satisfies*

$$v(x, t) \geq \sqrt{D}\, \Phi(x, t) \quad \forall (x, t) \in \mathbb{R} \times (0, \infty),$$

where Φ is the solution of the initial value problem of the Fisher KPP (Kolmogorov–Petrovskii–Piskuno) equation

$$\Phi_t - \Phi_{xx} = \Phi - \Phi^2 \text{ in } \mathbb{R} \times (0, \infty), \qquad \Phi(\cdot, 0) = v_0(\cdot) \textit{ on } \mathbb{R} \times \{0\}. \tag{2.1}$$

Proof. Denote by $K(x, t)$ the fundamental solution to the heat operator,

$$K(x, t) := (4\pi t)^{-1/2} e^{-x^2/(4t)}.$$

Then the solution of (1.1) can be decomposed as

$$u = u^0 - u^1, \qquad v = v^0 + v^1,$$

where

$$\begin{aligned} u^0(x, t) &= \int_{\mathbb{R}} K(x - y, D\,t)\; u_0(y)\, dy, \\ v^0(x, t) &= \int_{\mathbb{R}} K(x - y, t)\; v_0(y)\, dy, \\ u^1(x, t) &= \int_0^t \int_{\mathbb{R}} K(x, y, D(t - s)\,)\; f(y, s)\, dyds, \\ v^1(x, t) &= \int_0^t \int_{\mathbb{R}} K(x - y, t - s)\; f(y, s)\, dyds, \\ f(x, t) &= u(x, t)\; v(x, t). \end{aligned}$$

Here u^0 and v^0 are the concentrations of the reactant and the autocatalyst, respectively, before chemical reaction is initiated. The quantity u^1 is the amount of reactant consumed and v^1 is the amount of autocatalyst produced in the reaction.

By the maximum principle, we know that $u \geq 0$ and $v \geq 0$, and so $f := uv \geq 0$. Upon noticing that

$$K(x, Dt) := (4\pi Dt)^{-1/2} e^{-x^2/(4Dt)} \leq (4\pi Dt)^{-1/2} e^{-x^2/(4t)} = D^{-1/2} K(x, t),$$

we see that

$$u^1(x, t) \leq D^{-1/2}\; v^1(x, t) \quad \forall\, (x, t) \in \mathbb{R} \times [0, \infty).$$

This implies that

$$u = u^0 - u^1 \geq u^0 - \frac{v^1}{\sqrt{D}} = u^0 - \frac{v - v^0}{\sqrt{D}} = \left(u^0 + \frac{v^0}{\sqrt{D}} \right) - \frac{v}{\sqrt{D}}\,.$$

Note that

$$\begin{aligned}
u^0(x,t)+\frac{v^0(x,t)}{\sqrt{D}} &= \int_{\mathbb{R}} K(y,Dt)u_0(x-y)dy + \frac{1}{\sqrt{D}}\int_{\mathbb{R}} K(y,t)v_0(x-y)dy\\
&= \frac{1}{\sqrt{\pi}}\int_{\mathbb{R}}\Big\{e^{-\eta^2}u_0(x-2\eta\sqrt{Dt}\,)+e^{-D\eta^2}v_0(x-2\eta\sqrt{Dt}\,)\Big\}d\eta\\
&\geq \frac{1}{\sqrt{\pi}}\int_{\mathbb{R}} e^{-\eta^2}\Big\{u_0(x-2\eta\sqrt{Dt}\,)+v_0(x-2\eta\sqrt{Dt}\,)\Big\}d\eta\\
&\geq \frac{1}{\sqrt{\pi}}\int_{\mathbb{R}} e^{-\eta^2}d\eta = 1.
\end{aligned}$$

Thus,

$$\left(\frac{v}{\sqrt{D}}\right)_t - \left(\frac{v}{\sqrt{D}}\right)_{xx} = u\frac{v}{\sqrt{D}} \geq \left(1-\frac{v}{\sqrt{D}}\right)\frac{v}{\sqrt{D}}.$$

A simple comparison then gives $\Phi \leq v/\sqrt{D}$. □

2.2. Bramson's result. We denote by W the minimum speed traveling wave profile of the Fisher equation

$$\begin{gathered}
2W' + W'' + W - W^2 = 0 \quad \text{on } \mathbb{R},\\
W(-\infty)=1, \quad W(0)=1/2, \quad W(\infty)=0.
\end{gathered}$$

The following result can be derived from Bramson's work [3].

LEMMA 2.2. *Assume that v_0 is a nonnegative continuous function on $\mathbb{R}$ with compact support and $v_0(0) > 0$. Let Φ be the solution of* (2.1). *Then there exist constants z_+ and z_- such that*

$$\begin{aligned}
&\lim_{t\to\infty}\ \sup_{x>0}\Big|\Phi(x,t)-W([x-z_+-m(t)])\Big| = 0,\\
&\lim_{t\to\infty}\ \sup_{x<0}\Big|\Phi(x,t)-W([m(t)+z_--x])\Big| = 0,
\end{aligned}$$

where

$$m(t) := 2t - 3[\log(3+t)-\log 3] \quad \forall\, t>0.$$

2.3. The exponential decay of *u* in the reaction zone.

THEOREM 2.3. *Assume that $D\in(0,1]$, $u_0\geq 0, v_0\geq 0, u_0+v_0\geq 1$, and $v_0(0)>0$. Let (u,v) be the solution of* (1.1). *Then there exists a positive constant k such that*

$$v > k \quad \textit{in} \;\; Q := \{(x,t) \mid t>0, |x|<m(t)\}. \tag{2.2}$$

Consequently, with $\mu = [\sqrt{1+kD}-1]/D$, there holds

$$u(x,t) \leq \bar{u}(x,t) := e^{\mu[x-m(t)]} + e^{-\mu[m(t)+x]} \quad \forall\ t\geq 0,\ x\in\mathbb{R}.$$

Proof. First, applying the comparison lemma, Lemma 2.1, and Bramson's result, Lemma 2.2, we see that $v>k$ in Q.

Since $u \le 1$, we need only consider the function u in the set Q. When $(x,t) \in Q$, we use $v \ge k$ to calculate

$$\begin{aligned}\bar{u}_t - D\bar{u}_{xx} + v\bar{u} &\ge \bar{u}_t - D\bar{u}_{xx} + k\bar{u} \\ &= \bar{u}\left\{k - D\mu^2 - 2\mu + \frac{3\mu}{3+t}\right\} \ge \bar{u}[k - D\mu^2 - 2\mu] = 0.\end{aligned}$$

Since $\bar{u} > 1 \ge u$ on the parabolic boundary of Q, the assertion of the lemma thus follows from the parabolic comparison principle. □

3. Location of the reaction front. The comparison of v with the solution of the Fisher equation shows that the reaction front is at least as far as $\pm(2t - 3\log t)$ from the origin for large t. Here we show that the reaction front is located exactly in a vicinity of $\pm(2t - 3\log t)$.

For this, we denote

$$\hat{u}(x,t) = \min\left\{1, e^{\mu[x-m(t)]} + e^{-\mu[m(t)+x]}\right\}.$$

Then $u \le \hat{u}$. Consequently,

$$v_t - v_{xx} = uv \le \hat{u}v \quad \text{in } \mathbb{R} \times (0,\infty).$$

Hence, by Green's formula,

$$0 \le v(x,t) \le \int_{\mathbb{R}} G(x,t;y,0)\, v_0(y)\, dy,$$

where for each $(x,t) \in \mathbb{R} \times (0,\infty)$, $G(x,t;\cdot,\cdot)$ is the fundamental solution of

$$\begin{aligned} G_s + G_{yy} &= \hat{u}(y,s)\, G(x,t,y,s) \quad && \forall\, y \in \mathbb{R},\ s \in [0,t), \\ G(x,t;y,t) &= \delta(x-y) && \forall\, y \in \mathbb{R}.\end{aligned}$$

Here δ is the Dirac measure. Using Bramson's technique [3, Chapters 6 and 7], one can derive that

$$G(x,y,t,0) \le \frac{C(\mu)\, e^{t-|x-y|^2/(4t)}}{\sqrt{4\pi t}} (1 - e^{-|y|\, [|x|-m(t)+1]/t}).$$

Since v_0 has compact support, by following calculations illustrated in [3] we obtain the following.

LEMMA 3.1. *There exists a positive constant C_1 such that*

$$v(\pm[m(t)+z],t) \le C_1[1+|z|]e^{-z} \quad \forall z \in \mathbb{R},\ t > 0.$$

Note that when $u_0 \equiv 1$, we have $u^0 \equiv 1$ so that

$$|u-1| = u^1 \le D^{-1/2}v^1 \le D^{-1/2}v.$$

The estimate (1.4) thus follows from the above lemma.

4. Autocatalyst generated after reaction. We know that the two reaction fronts are near $m(t)$ and $-m(t)$. In the reaction zone $[-m(t), m(t)]$, the reactant is consumed very quickly. As the autocatalyst is assumed to diffuse no slower than the reactant, it is expected that $v \approx 1$ inside the reaction zone when reaction is completed. This section is devoted to proving this expectation.

4.1. An L^∞ estimate of v.

LEMMA 4.1. *There exists a positive constant C_2 such that*

$$v(x,t) \le C_2, \qquad |u_x| \le C_2 e^{-\mu||x|-m(t)|]} \quad \forall\, x \in \mathbb{R}, t > 0.$$

Proof. Set

$$K = \max\left\{\frac{1}{4}, \frac{1}{(\mu^2+2\mu)}\right\}.$$

Let t_0 be the constant such that

$$Ke^{-m(t_0)} = \frac{1}{4}.$$

Consider the function

$$\bar{v}(x,t) = 1 - K\bar{u} = 1 - Ke^{\mu[x-m(t)]} - Ke^{-\mu[x+m(t)]} \tag{4.1}$$

in the set

$$Q(t_0) := \{(x,t) \mid t > t_0, |x| < m(t) - m(t_0)\}.$$

Since $u < \bar{u}$ in $Q(t_0)$, we have

$$\bar{v}_t - \bar{v}_{xx} - u\bar{v} \ge \bar{v}_t - \bar{v}_{xx} - \bar{u}\bar{v} \ge K\bar{u}^2 > 0.$$

Then we have $\bar{v} \ge 1/2$ on the parabolic boundary of $Q(t_0)$. Hence, by comparison,

$$v \le M\ \bar{v} \ \text{ in } \ Q(t_0), \qquad M := \sup_{\partial Q(t_0)} v \le C_1[1 + m(t_0)]e^{m(t_0)}.$$

This estimate, together with Lemma 3.1, implies that v is uniformly bounded.

Once we know the boundedness of v, we can obtain the estimate for u_x by applying the local parabolic estimate. For each $x \in \mathbb{R}$ and $t \ge 2$,

$$\|u_x\|_{L^\infty(Q_1)} \le C(D)\Big\{\|f\|_{L^\infty(Q_2)} + \min\{\|u\|_{L^\infty(Q_2)}, \|u-1\|_{L^\infty(Q_2)}\}\Big\},$$

where

$$Q_1 = (x-1, x+1) \times (\max\{t-1, 0\}, t], \qquad Q_2 := (x-2, x+2) \times (\max\{t-2, 0\}, t].$$

Here we used, for simplicity, the assumption that $u_0 \equiv 1$ is a smooth function. □

4.2. The equilibrium state after reaction. Now we show that $v \approx 1$ in $(-m(t), m(t))$ for large t. For this purpose, we consider the function

$$w = u + v - u^0 - v^0.$$

Note that $u^0 \equiv 1$; then

$$\|v^0(\cdot,t)\|_{L^\infty(\mathbb{R})} = \left\|\int_{\mathbb{R}} K(\cdot - y, t)v_0(y)dy\right\|_{L^\infty(\mathbb{R})} = O\left(\frac{1}{\sqrt{t}}\right),$$

$$|u(x,t)| \le e^{-\mu|m(t)-x|} + e^{-\mu[x+m(t)]}.$$

We see that

$$|v-1| \le |w| + |u| + |v^0|.$$

The assertion (1.3) thus follows from the following.

LEMMA 4.2. *There exists a constant $C_2 > 0$ such that*

$$|w(x,t)| \le \frac{C_2}{\sqrt{m(t)-|x|}} \quad \forall\, x \in (-m(t), m(t)),\ t>0.$$

Proof. Note that w satisfies

$$w_t - w_{xx} = (D-1)u_{xx} \quad \text{in} \ \ \mathbb{R}\times(0,\infty), \qquad w(\cdot,0)=0.$$

Hence,

$$\begin{aligned} w(x,t) &= (D-1)\int_0^t \int_{\mathbb{R}} K(x-y,t-s)u_{yy}(y,s)dyds \\ &= (D-1)\int_0^t \int_{\mathbb{R}} K_x(x-y,t-s)u_y(y,s)dyds. \end{aligned}$$

It then follows that

$$|w(x,t)| \le C(1-D)\Big\{J(x,t)+J(-x,t)\Big\},$$

where

$$\begin{aligned} J(x,t) &= \int_0^t \int_{\mathbb{R}} |K_x(x-y,t-s)|e^{-\mu|y-m(s)|}dyds \\ &= \int_0^t \int_{\mathbb{R}} |K_x(x-y-m(t-s),s)|\ e^{-\mu|y|}dyds. \end{aligned}$$

To complete the proof, it suffices to show the following:

$$J(m(t)-z,t) \le \frac{C}{\sqrt{z}} \quad \forall\, z>0.$$

Let $z>0$ and $t>0$ be arbitrary. Note that

$$\begin{aligned} J(m(t)-z,t) &= \int_0^t \int_{\mathbb{R}} |K_x(m(t)-m(t-s)-z-y,s)|\ e^{-\mu|y|}dyds, \\ K_x(x,s) &= -\frac{xe^{-x^2/(4s)}}{4\sqrt{\pi}s^{3/2}}\ . \end{aligned}$$

We divide the integral in s into the following three intervals.

(i) $s\in[z/4,2z]$. For each fixed $y\in\mathbb{R}$, we have

$$\begin{aligned} &\int_{z/4}^{2z} |K_x(m(t)-m(s)-z-y,s)|ds \\ &\le \int_{z/4}^{2z} \frac{|m(t)-m(t-s)-y-z|}{4\sqrt{\pi}[z/4]^{3/2}} e^{-|m(t)-m(t-s)-y-z|^2/(4z)}ds. \end{aligned}$$

We use the change of variable from s to η defined by

$$\eta = \frac{m(t) - m(t-s) - z - y}{z}, \qquad d\eta = \frac{m'(t-s)}{z} ds = \frac{2 - \frac{3}{3+(t-s)}}{z} ds \geq \frac{ds}{z}.$$

We find that

$$\int_{z/4}^{\min\{2z,t\}} |K_x(m(t) - m(t-s) - z - y, s)| ds \leq \frac{2}{\sqrt{\pi z}} \int_{\mathbb{R}} \eta e^{-\eta^2} d\eta = \frac{2}{\sqrt{\pi z}}.$$

It then follows that

$$\int_{z/4}^{\min\{2z,t\}} \int_{\mathbb{R}} |K_x(m(t) - m(t-s) - z - y, s)| e^{-\mu|y|} ds dy \leq \frac{2}{\sqrt{\pi z}} \int_{\mathbb{R}} e^{-\mu|y|} dy \leq \frac{4}{\mu\sqrt{\pi z}}.$$

(ii) $s > 2z$. We write

$$\int_{\mathbb{R}} |K_x(m(t) - m(t-s) - z - y, s)| e^{-\mu|y|} dy = \int_{|y|>s/6} + \int_{|y|<s/6}.$$

For the first integral,

$$\begin{aligned} \int_{|y|>s/6} &\leq e^{-\mu s/6} \int_{\mathbb{R}} |K_x(m(t) - m(t-s) - z - y, s| dy \\ &= 2e^{-\mu s/6} K(0,s) = \frac{e^{-\mu s/6}}{\sqrt{\pi s}}. \end{aligned}$$

For the second integral, we first notice that $|m(t) - m(t-s)| \geq s$ (since $1 \leq m' < 2$ on $[0,\infty)$). Hence, when $|y| < s/6$,

$$|m(t) - m(t-s) - z - y| \geq |m(t) - m(t-s)| - z - y \geq s - \frac{s}{2} - \frac{s}{6} = \frac{s}{3}.$$

Consequently,

$$\int_{|y|<s/6} |K_x| e^{-\mu|y|} dy \leq \int_{|x|>s/3} |K_x(x,s)| dx = 2K\Big(\frac{s}{3}, s\Big) = \frac{\sqrt{3}e^{-s/36}}{\sqrt{\pi s}}.$$

Thus,

$$\begin{aligned} &\int_z^t \int_{\mathbb{R}} |K_x(m(t) - m(t-s) - z - y, s)|\ e^{-\mu|y|} dy ds \\ &\qquad \leq \int_z^\infty \left(\frac{e^{-\mu s/6}}{\sqrt{\pi s}} + \frac{\sqrt{3}e^{-s/36}}{\sqrt{\pi s}} \right) ds = O(e^{-z/36}) + O(e^{-\mu z/6}). \end{aligned}$$

(iii) $0 < s < z/4$. We write

$$\int_{\mathbb{R}} |K_x(m(t) - m(t-s) - z - y, s)| e^{-\mu|y|} dy = \int_{|y|>z/4} + \int_{|y|<z/4}.$$

The first integral is easy to estimate:

$$\int_{|y|>z/4} \leq e^{-\mu z/4} \int_{\mathbb{R}} |K_x| dy = \frac{e^{-\mu z/4}}{\sqrt{\pi s}}.$$

For the second integral, we notice that $|m(t)-m(t-s)| \le 2s \le z/2$, so that when $|y| \le z/4$, we have

$$|m(t)-m(t-s)-z-y| \ge z-|m(t)-m(t-s)|-|y| \ge z-z/2-z/4 = z/4.$$

Also, $|m(t)-m(t-s)-z-y| < 2z$. Hence,

$$|K_x(m(t)-m(t-s)-z-y,s)| \le \frac{ze^{-z^2/(64s)}}{2\sqrt{\pi}s^{3/2}}.$$

It follows that

$$\int_{|y|<z/4} |K_x|e^{-\mu|y|}dy \le \frac{ze^{-z^2/(64s)}}{2\sqrt{\pi}s^{3/2}} \int_{\mathbb{R}} e^{-\mu|y|} = \frac{ze^{-z^2/(64s)}}{\mu\sqrt{\pi}s^{3/2}}.$$

Thus,

$$\begin{aligned}\int_0^{\min\{z/4,t\}} \int_{\mathbb{R}} |K_x|e^{-\mu|y|}dy &\le \int_0^{z/4} \frac{ze^{-z^2/(64s)}ds}{\mu\sqrt{\pi}s^{3/2}} + \int_0^z \frac{e^{-\mu z/4}ds}{\sqrt{\pi s}} \\ &= \int_{\sqrt{z/8}}^{\infty} \frac{4}{\mu\sqrt{\pi}}e^{-\eta^2}d\eta + \frac{\sqrt{z}e^{-\mu z/4}}{\sqrt{\pi}} = O(e^{-\mu z/8}).\end{aligned}$$

Combining all these estimate, we then obtain the assertion of the lemma. □

Proof of Theorem 1.1. The theorem follows directly from the results of Theorem 2.3 and Lemmas 4.1 and 4.2.

A THERMAL ELASTIC MODEL FOR DIRECTIONAL CRYSTAL GROWTH WITH WEAK ANISOTROPY[*]

JINBIAO WU[†], C. SEAN BOHUN[‡], AND HUAXIONG HUANG[§]

Abstract. In this paper we present a semi-analytical thermal stress solution for directional growth of type III–V compounds with small lateral heat flux and weak anisotropy. Both geometric and material anisotropy are considered, and our solution can be applied to crystals grown by various growth techniques such as the Czochralski (Cz) method. The semi-analytical nature of the solution allows us to compute thermal stress in crystals with weak anisotropic effects much more efficiently, compared to a full 3D simulation. Examples are given for crystals pulled in a variety of seed orientations. Our results show that the geometric effect is the dominant one while the effect of material anisotropy on thermal stress is secondary.

Key words. crystal growth, asymptotic expansion, anisotropy, facet formation, thermal stress, Czochralski technique

1. Introduction.

Directional growth techniques such as the Czochralski (Cz) method are frequently used to produce high quality single crystals. By dipping a small seed crystal into a pool of molten material in the crucible and carefully controlling the heat balance inside the grower, a large crystal can be grown by pulling the crystal away from the melt in a slow and steady fashion. The pulling rod and the crucible are normally rotated in opposite directions during the growth period. For a more detailed account of the Cz and other techniques, we refer the readers to the extremely informative handbooks by Hurle [5]. Almost perfectly cylindrical crystals are grown for silicon and other semiconductor materials despite their internal structure and material anisotropy. For these crystals, the effect of material anisotropy on thermal stress has been investigated by assuming an axisymmetric cylindrical shape [3, 9, 11, 12]. On the other hand, anisotropic effects such as facets are often visible on the surface of binary compound semiconductor crystals grown by these methods [8]. The effect of a noncylindrical shape on the thermal stress is therefore of practical interest.

In a previous paper, we developed a thermal stress model for directional growth of crystals with facets [13]. For constrained growth such as that of the Cz method, a lateral growth model consistent with the lattice structure of type III–V crystals was proposed. This model is capable of predicting facet formation on the lateral surface, which qualitatively resembles experimental observations [8] of indium antimonide (InSb) crystals. Furthermore, under the assumptions of weak lateral heat flux, we have derived perturbation solutions for temperature and related thermal stress for faceted crystals by neglecting material anisotropy.

The effect of material anisotropy on thermal stress, on the other hand, could be significant for cylindrical crystals with an underlying cubic lattice structure, as shown in [11, 12]. It is, however, not clear whether the conclusions in [11, 12] hold for InSb crystals grown in a noncylindrical shape, especially those with facets forming on the lateral surface. The purpose of this paper is to investigate the combined effect of the geometric and material anisotropy on thermal stress inside the conic crystals considered in [13]. We start with the description of the mathematical model and the thermal problem in section 2. Since the growth model and temperature solution are identical to those in [13], they are presented without detailed derivation.

The main results of this paper are given in section 3, where the detailed derivation of the thermal stress with anisotropic elastic constants is presented. We show that the thermal stress can be expanded into an asymptotic series with respect to ω, a measure of the material anisotropy, and in Appendix A we prove that the series converges. As a result, a systematic approach can be devised to compute thermal stress to arbitrary order with the zeroth order solution corresponding to the case of isotropic material constants. In section 4, we present computational results for crystals pulled in a variety of seeding orientations. The results show that the effect of material anisotropy could be significant when the geometric effect is absent. The geometric effect, when it is present, usually dominates.

2. Model.

The basic assumptions of our model are that the lateral heat flux is small and the material and geometric anisotropic effects are weak, following [1, 13]. To simplify the discussion, we assume that lateral heat transfer from the crystal to the background is known. We also assume that the heat flux from the melt is fixed while the pull rate can be adjusted in order to grow a crystal with a desirable lateral profile, e.g., a conic crystal. In principle, we could incorporate the effect of the melt flow by coupling the heat transfer process in the crystal with that in the melt. However, to focus on the thermal stress in the crystal, we neglect the effect of the melt flow and assume that the axial heat flux from the melt at the crystal/melt interface does not vary in the cross-sectional (radial and circumferential) directions.

2.1. Thermal problem.

Within the crystal Ω, the temperature $T(\mathbf{x},t)$ satisfies the heat equation,

$$\rho_s c_s \frac{\partial T}{\partial t} = \nabla \cdot (\kappa_s \nabla T), \qquad \mathbf{x} \in \Omega,\ t > 0, \tag{2.1a}$$

where ρ_s, c_s, and κ_s are the density, specific heat, and thermal conductivity of the crystal, respectively. The boundary conditions on the crystal/gas interface Γ_g, and the chuck (holding the seed), are,

$$-\kappa_s \frac{\partial T}{\partial \mathbf{n}} = h_{\mathrm{gs}}(T - T_g) + h_F(T^4 - T_b^4), \qquad \mathbf{x} \in \Gamma_g, \tag{2.1b}$$

$$\kappa_s \frac{\partial T}{\partial z} = h_{\mathrm{ch}}(T - T_{\mathrm{ch}}), \qquad z = 0, \tag{2.1c}$$

where h_{gs} and h_{ch} represent the heat transfer coefficients of the crystal/gas and crystal/chuck interfaces; h_F is the radiation heat transfer coefficient; and T_g, T_{ch}, and T_b denote the ambient gas temperature, the chuck temperature, and background temperature, respectively.

The crystal/melt interface is denoted Γ_S and is where $T = T_m$, which is the melting temperature. Explicitly we denote the melting isotherm by

$$z - S(\mathbf{x},t) = 0, \qquad \mathbf{x} \in \Gamma_S, \tag{2.1d}$$

with S denoting the crystal/melt interface. The motion of the interface of the phase transition is governed by the Stefan condition,

$$\rho_s L|\mathbf{v}_n| = \kappa_s \left.\frac{\partial T}{\partial \mathbf{n}}\right|_{z\to S^-} - q_{l,n}, \qquad |\mathbf{v}_n| = v_n = \frac{\partial S}{\partial t}\mathbf{k}\cdot\mathbf{n}, \tag{2.1e}$$

where L is the latent heat, $|\mathbf{v}_n|$ is the speed of the interface in the direction of its outward normal $\mathbf{n}$, $q_{l,n}$ is the heat flux from the melt normal to the interface, and $\partial S/\partial t$ is the speed of the interface S in the $\mathbf{k}$ direction.

2.2. Crystal shape. For the purpose of computing thermal stress, we assume that the shape of the crystal is self-similar in that the crystal radius $R(\phi, z)$ scales with its angular average $\bar{R}(z)$. Such crystals are indeed seen experimentally [8], and representing the angular dependence with a truncated Fourier series gives

$$R(\phi, z) = \bar{R}(z)\left(1 + \epsilon\sum_{k=1}^{m}\beta_k \cos(n_k\phi + \delta_k)\right) = \bar{R}(z)\left(1 + \epsilon\lambda(\phi)\right). \tag{2.2a}$$

In this expression $2\pi\bar{R}(z) = \int_{-\pi}^{\pi} R(\phi, z)\,d\phi$, m, $n_1 < n_2 < \cdots < n_m$ are positive integers ($m = 1$, $n_1 = 4$ for fourfold symmetry); the $\delta_k \in [0, 2\pi)$ are chosen to ensure that $\beta_k > 0$. Note that only those n_k corresponding to $\beta_k > 0$ are represented in the series. The parameter $\epsilon \geq 0$ is a measure of the anisotropy, and choosing the β_k so that $\sum_{k=1}^{m}\beta_k^2 = 1$ yields the expression

$$\epsilon^2 = \frac{1}{\pi\bar{R}(z)^2}\int_{-\pi}^{\pi}\left(R(\phi, z) - \bar{R}(z)\right)^2 d\phi. \tag{2.2b}$$

We will assume that $\epsilon < 1$, which will certainly[1] be the case if $\max_\phi R(\phi, z) < \frac{3}{2}\bar{R}(z)$. The β_k, δ_k, and ϵ values for the cross sections used in section 4 can be found in [13].

Of particular interest are the angular integrals

$$I_{i,j}(\epsilon) = \int_0^{2\pi}(1+\epsilon\lambda)^i\left((1+\epsilon\lambda)^2 + (\epsilon\lambda')^2\right)^{j/2} \mathrm{d}\phi \tag{2.2c}$$

$$= 2\pi + \frac{\pi}{2}\left[(i+j)(i+j-1) + j\sum_{k=1}^{m} n_k^2\beta_k^2\right]\epsilon^2 + O(\epsilon^3), \tag{2.2d}$$

where $i, j \in \mathbb{Z}$ and $\lambda' = d\lambda/d\phi$. Both the enclosed area (A) and circumference (s) of R will be utilized in what follows. For any fixed z it is an easy exercise to verify $A(z) = \bar{R}^2 I_{2,0}/2$ and $s(z) = \bar{R}I_{0,1}$.

2.3. Nondimensionalization. For simplicity, we assume that the gas temperature T_g is constant. Defining the Biot number by

$$\mathrm{Bi} = \frac{\bar{h}_{\mathrm{gs}}\tilde{R}}{\kappa_s}, \tag{2.3}$$

where $\tilde{R}$ is a characteristic radius of the crystal and $\bar{h}_{\mathrm{gs}}$ is the mean value of h_{gs}, we adopt the following scalings:

$$r = \tilde{R}\hat{r}, \quad R(\phi, z) = \tilde{R}\hat{R}(\hat{\phi}, \hat{z}), \quad \mathrm{Bi}^{1/2}\, z = \tilde{R}\hat{z}, \quad \mathrm{Bi}^{1/2}\, S(r, \phi, t) = \tilde{R}\hat{S}(\hat{r}, \hat{\phi}, \hat{t}),$$

$$\mathrm{St} = \frac{L}{c_s\Delta T}, \quad \Delta T = T_m - T_g, \quad T = T_g + \Delta T\Theta, \quad t = \frac{\mathrm{St}\,\tilde{R}^2\rho_s c_s}{\kappa_s\,\mathrm{Bi}}\hat{t},$$

[1] This is simply a consequence of the positivity of R and the mean value theorem applied to (2.2b).

with $\phi = \hat{\phi}$. Here variables with hats ($\hat{}$) are the nondimensional ones. In terms of these variables, the heat equation (2.1a) becomes (after dropping hats)

$$\frac{\mathrm{Bi}}{\mathrm{St}}\Theta_t = \frac{1}{r}(r\Theta_r)_r + \frac{1}{r^2}\Theta_{\phi\phi} + \mathrm{Bi}\,\Theta_{zz}, \qquad \mathbf{x} \in \Omega,\ t > 0, \tag{2.4a}$$

and boundary conditions (2.1b)–(2.1d) under the nondimensional scaling become

$$-\Theta_r + \frac{1}{R^2}R_\phi\Theta_\phi + \mathrm{Bi}\,R_z\Theta_z = \mathrm{Bi}\,F(\Theta)\left(1 + \frac{R_\phi^2}{R^2} + \mathrm{Bi}\,R_z^2\right)^{1/2}, \qquad \mathbf{x} \in \Gamma_g, \tag{2.4b}$$

$$\Theta_z(0,\phi,t) = \delta\left(\Theta(0,\phi,t) - \Theta_{\mathrm{ch}}\right), \tag{2.4c}$$

$$\Theta = 1, \qquad \mathbf{x} \in \Gamma_S, \tag{2.4d}$$

where $\Theta_{\mathrm{ch}} = (T_{\mathrm{ch}} - T_g)/\Delta T$ and

$$F(\Theta) = \frac{h_F(T_g^4 - T_b^4)}{\bar{h}_{\mathrm{gs}}\Delta T} + \left(\beta(z) + \frac{4h_F}{\bar{h}_{\mathrm{gs}}}T_g^3\right)\Theta + \frac{h_F}{\bar{h}_{\mathrm{gs}}}\Delta T(6T_g^2 + 4T_g\Delta T\Theta + \Delta T^2\Theta^2)\Theta^2,$$

$\beta(z) = h_{\mathrm{gs}}/\bar{h}_{\mathrm{gs}}$, and $\delta = \mathrm{Bi}^{1/2}\,h_{\mathrm{ch}}/\bar{h}_{\mathrm{gs}}$. The crystal/melt interface advances according to the Stefan condition (2.1e), which in nondimensional coordinates becomes

$$\Theta_z - \frac{1}{\mathrm{Bi}}S_r\Theta_r - \frac{1}{\mathrm{Bi}\,r^2}S_\phi\Theta_\phi = \gamma + S_t, \qquad \gamma = \frac{q_l\tilde{R}}{\mathrm{Bi}^{1/2}\,\kappa_s\Delta T}, \tag{2.4e}$$

where γ (q_l) is the nondimensional (resp., dimensional) heat flux in the liquid across the crystal/melt interface in the axial direction.

2.4. Temperature solution. Equations (2.4a) and (2.4b) strongly suggest that the temperature Θ is independent of r and ϕ to leading order. If true, then the crystal/melt interface S is also independent of r and ϕ to leading order. These observations motivate the following approximates:

$$\begin{aligned} \Theta &\sim \Theta_0(z,t) + \mathrm{Bi}\,\Theta_1(r,\phi,z,t) + \mathrm{Bi}^2\,\Theta_2(r,\phi,z,t) + \cdots, \\ S &\sim S_0(t) + \mathrm{Bi}\,S_1(r,\phi,t) + \mathrm{Bi}^2\,S_2(r,\phi,t) + \cdots. \end{aligned} \tag{2.5}$$

We substitute them into the scaled model, expand in powers of Bi, and simplify and collect terms of the same orders.

The zeroth order problem is given by[2]

$$\frac{1}{\mathrm{St}}\Theta_{0,t} - \Theta_{0,zz} = \frac{2}{\bar{R}}\left(\bar{R}'\Theta_{0,z} - \frac{I_{0,1}}{I_{2,0}}F(\Theta_0)\right), \qquad 0 < z < S_0(t),\ t > 0, \tag{2.6a}$$

$$\Theta_{0,z}(0,t) = \delta(\Theta_0(0,t) - \Theta_{\mathrm{ch}}), \qquad t \geq 0, \tag{2.6b}$$

$$\Theta_0(S_0(t),t) = 1, \qquad t \geq 0, \tag{2.6c}$$

$$S_0'(t) = \Theta_{0,z}(S_0(t),t) - \gamma, \qquad S_0(0) = Z_0,\ t > 0. \tag{2.6d}$$

The first order solution is given by

$$\Theta_1(r,\phi,z,t) = \Theta_1^a(z,t) + r^2\Theta_1^b(z,t) + \epsilon\Theta_1^c(r,\phi,z,t) + O(\epsilon^2), \tag{2.7a}$$

[2] For weak anisotropy, $I_{0,1}/I_{2,0} = 1 + O(\epsilon^2)$.

where, keeping only those terms to $O(\epsilon)$,

$$\Theta_1^b(z,t) = \frac{1}{2\bar{R}}\left(\bar{R}'\Theta_{0,z} - F(\Theta_0)\right), \tag{2.7b}$$

$$\Theta_1^c(r,\phi,z,t) = \bar{R}F(\Theta_0)\sum_{k=1}^{m}\frac{\beta_k}{n_k}\left(\frac{r}{\bar{R}}\right)^{n_k}\cos(n_k\phi+\delta_k). \tag{2.7c}$$

These last two terms are completely determined by Θ_0 and $\bar{R}$. The first term $\Theta_1^a(z,t)$ can be found in [13] and is not repeated here since it is not relevant to the stress computation.

3. Thermal stress. We now turn our attention to thermal stress. In the following, the general case in 3D space is discussed first, followed by a more detailed discussion using the plane-strain assumption.

3.1. Thermoelasticity equations for solids with cubic anisotropy. We consider a 3D elasticity problem for a crystal with cubic symmetry as in [6]. In this case the stresses $\boldsymbol{\sigma} = (\sigma_{xx}, \sigma_{yy}, \sigma_{zz}, \sigma_{yz}, \sigma_{xz}, \sigma_{xy})^{\mathrm{T}}$ and strains $\mathbf{e} = (e_{xx}, e_{yy}, e_{zz}, 2e_{yz}, 2e_{xz}, 2e_{xy})^{\mathrm{T}}$ are related through

$$\boldsymbol{\sigma} = C\mathbf{e}, \qquad C = \begin{pmatrix} C_{11} & C_{12} & C_{12} & & & \\ C_{12} & C_{11} & C_{12} & & & \\ C_{12} & C_{12} & C_{11} & & & \\ & & & C_{44} & & \\ & & & & C_{44} & \\ & & & & & C_{44} \end{pmatrix}. \tag{3.1}$$

We denote the displacement vector by $\mathbf{w}$ and the related strain by $\mathbf{e} = \mathbf{S}(\mathbf{w})$ so that the related stress tensor is given by $\boldsymbol{\sigma} = \mathcal{D}\mathbf{S}(\mathbf{w})$. For an anisotropic material, the quantity $H = 2C_{44} - C_{11} + C_{12} \neq 0$. By defining $C = C^0 - C^a$, where $C^a = H/4 \times \operatorname{diag}(2,2,2,-1,-1,-1)$, the matrix

$$C^0 = \begin{pmatrix} C^0_{11} & C^0_{12} & C^0_{12} & & & \\ C^0_{12} & C^0_{11} & C^0_{12} & & & \\ C^0_{12} & C^0_{12} & C^0_{11} & & & \\ & & & C^0_{44} & & \\ & & & & C^0_{44} & \\ & & & & & C^0_{44} \end{pmatrix} \tag{3.2a}$$

is isotropic and the quantities E and ν in terms of C^0_{ij} are given by [10]

$$E = \frac{(C^0_{11} + 2C^0_{12})(C^0_{11} - C^0_{12})}{C^0_{11} + C^0_{12}}, \qquad \nu = \frac{C^0_{12}}{C^0_{11} + C^0_{12}}. \tag{3.2b}$$

By adopting the scaling in section 2.3 for r and T in addition to (α is the thermal expansion coefficient)

$$\mathbf{w} = \tilde{R}\alpha\Delta T\hat{\mathbf{w}}, \quad \sigma_{ij} = \frac{\alpha\Delta TE}{1-\nu}\hat{\sigma}_{\hat{i}\hat{j}}, \quad e_{ij} = \alpha\Delta T\hat{e}_{\hat{i}\hat{j}},$$

we set

$$C_{ij} = \frac{E}{1-\nu}\hat{C}_{\hat{i}\hat{j}}, \qquad H = \frac{E}{1-\nu}\hat{H}$$

and obtain (after dropping hats)

$$C_{11}^0 = \frac{(1-\nu)^2}{(1+\nu)(1-2\nu)}, \quad C_{12}^0 = \frac{\nu(1-\nu)}{(1+\nu)(1-2\nu)}, \quad C_{44}^0 = \frac{1}{2}(C_{11}^0 - C_{12}^0), \tag{3.2c}$$

$$C_{11} + 2C_{12} = \frac{1-\nu}{1-2\nu} - \frac{H}{2}. \tag{3.2d}$$

According to $C = C^0 - C^a$, we have the splitting of the operator $\mathcal{D}$, $\mathcal{D} = \mathcal{D}^0 - \mathcal{D}^a$. With this notation, the linear operators $\nabla \cdot \sigma$ and $\sigma \cdot \mathbf{n}$ take the form

$$\begin{aligned} \mathcal{L} &:= \nabla \cdot (\mathcal{D}\mathbf{S}) = \nabla \cdot (\mathcal{D}^0\mathbf{S}) - \nabla \cdot (\mathcal{D}^a\mathbf{S}) = \mathcal{L}^0 - \mathcal{L}^a, \\ \mathcal{B} &:= (\mathcal{D}\mathbf{S}) \cdot \mathbf{n} = (\mathcal{D}^0\mathbf{S}) \cdot \mathbf{n} - (\mathcal{D}^a\mathbf{S}) \cdot \mathbf{n} = \mathcal{B}^0 - \mathcal{B}^a, \end{aligned}$$

and the thermoelastic boundary value problem can be stated in the form

$$\mathcal{L}(\mathbf{w}) = \mathbf{F}, \qquad \mathbf{x} \in \Omega, \ t > 0, \tag{3.3a}$$

$$\mathcal{B}(\mathbf{w}) = \mathbf{g}, \qquad r = R(\phi, z), \tag{3.3b}$$

where

$$\mathbf{F} = (C_{11} + 2C_{12})\nabla\Theta = \left(\frac{1-\nu}{1-2\nu} - \frac{H}{2}\right)\nabla\Theta, \qquad \mathbf{g} = \left(\frac{1-\nu}{1-2\nu} - \frac{H}{2}\right)\Theta\mathbf{n},$$

with $\mathbf{n}$ denoting the outward normal of the surface $r = R(\phi, z)$. The total stress contains an extra diagonal term related to the scaling with respect to the isotropic quantities E and ν so that

$$\sigma_{ij}^{\text{tot,aniso}} = \sigma_{ij} - \left(\frac{1-\nu}{1-2\nu} - \frac{H}{2}\right)\Theta\delta_{ij}. \tag{3.4}$$

We assume that the displacement $\mathbf{w}$ can be written as $\sum_{k=0}^{n} \mathbf{w}_k$. The following procedure defines the $\mathbf{w}_k$ under the assumption that $\mathbf{w}_{k+1} = \mathcal{N}\mathbf{w}_k$ for some linear operator $\mathcal{N}$. To solve for $\mathbf{w}(\mathbf{x})$ in (3.1) we begin by finding the displacement $\mathbf{w}_0$ given by

$$\mathcal{L}^0(\mathbf{w}_0) = \mathbf{F}, \qquad \mathbf{x} \in \Omega, \ t > 0, \tag{3.5a}$$

$$\mathcal{B}^0(\mathbf{w}_0) \ = \mathbf{g}, \qquad r = R(\phi, z), \tag{3.5b}$$

which is the displacement found in [13], multiplied by a factor of $\mu = 1 - \frac{H}{2}\frac{1-2\nu}{1-\nu}$. Having defined $\mathbf{w}_0$, we denote by $\mathbf{w}_{k+1} = \mathcal{N}\mathbf{w}_k$, with $k \geq 0$, the solution to

$$\mathcal{L}^0(\mathbf{w}_{k+1}) = \mathcal{L}^a(\mathbf{w}_k), \qquad \mathbf{x} \in \Omega, \ t > 0, \tag{3.6a}$$

$$\mathcal{B}^0(\mathbf{w}_{k+1}) \ = \mathcal{B}^a(\mathbf{w}_k), \qquad r = R(\phi, z). \tag{3.6b}$$

Continuing this process, we have for $\mathbf{w}(\mathbf{x})$ in (3.1)

$$\mathbf{w} = \mathbf{w}_0 + \mathcal{N}\mathbf{w}_0 + \mathcal{N}^2\mathbf{w}_0 + \cdots + \mathcal{N}^n\mathbf{w}_0 + \cdots . \tag{3.7}$$

Since $\|\mathcal{N}\| \leq \omega$ in a suitable norm, where $\omega = \frac{|H|/2}{C_{11}-C_{12}+H/2} = \frac{|2C_{44}-C_{11}+C_{12}|}{2C_{44}+C_{11}-C_{12}} < 1$ is an anisotropic factor, the series converges and an error can be estimated when (3.7) is replaced by a finite sum; cf. Appendix A. For typical cubic anisotropic materials, $\omega \approx 1/3$ [2].

Vigdergauz and Givoli [11, 12] have discussed the fourfold symmetry case (corresponding to the [001] pulling direction in our case) for a given symmetric temperature field. However, their splitting is not optimal and is valid only for crystals with weak cubic anisotropy. Our procedure can be applied to elastic stress computations with cubic anisotropy under a relatively general setting for a wide variety of materials.

Converting the stress-strain relationship to polar coordinates, we note that C^0 will not change, so we will concern ourselves only with C^a. Corresponding to (3.1) we let $\boldsymbol{\sigma}_{\text{cyc}} = (\sigma_{rr}, \sigma_{\phi\phi}, \sigma_{zz}, \sigma_{\phi z}, \sigma_{rz}, \sigma_{r\phi})^{\text{T}}$, $\mathbf{e}_{\text{cyc}} = (e_{rr}, e_{\phi\phi}, e_{zz}, 2e_{\phi z}, 2e_{rz}, 2e_{r\phi})^{\text{T}}$. The components of C_{cyc} are given by

$$\begin{aligned} C_{\text{cyc},ijkl} = {} & \frac{H}{2}(a_{i1}a_{j1}a_{k1}a_{l1} + a_{i2}a_{j2}a_{k2}a_{l2} + a_{i3}a_{j3}a_{k3}a_{l3}) - \frac{H}{4}(a_{i2}a_{j3}a_{k2}a_{l3} \\ & + a_{i2}a_{j3}a_{k3}a_{l2} + a_{i3}a_{j2}a_{k2}a_{l3} + a_{i3}a_{j2}a_{k3}a_{l2} + a_{i1}a_{j3}a_{k1}a_{l3} + a_{i1}a_{j3}a_{k3}a_{l1} \\ & + a_{i3}a_{j1}a_{k1}a_{l3} + a_{i3}a_{j1}a_{k3}a_{l1} + a_{i1}a_{j2}a_{k1}a_{l2} + a_{i1}a_{j2}a_{k2}a_{l1} + a_{i2}a_{j1}a_{k1}a_{l2} \\ & + a_{i2}a_{j1}a_{k2}a_{l1}) \end{aligned}$$

with a_{ij} the cosine of the angle between x'_i (new axes) and x_j (old axes) [10]. Furthermore, the first two and last two suffixes are abbreviated into a single suffix according to the scheme $11 \to 1$; $22 \to 2$; $33 \to 3$; $23, 32 \to 4$; $13, 31 \to 5$; $12, 21 \to 6$. For example, $C_{\text{cyc},1111} \equiv C_{\text{cyc},11}$ and $C_{\text{cyc},1231} \equiv C_{\text{cyc},65}$.

For the [001] pulling direction, we choose the z-direction as [001], and the directions [100] and [010] correspond to $\phi = 0$ and $\phi = \pi/2$, respectively, so that

$$a_{ij}^{[001]} = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

For the $[\bar{1}\bar{1}\bar{1}]$ pulling direction, the z-direction is $[\bar{1}\bar{1}\bar{1}]$ and we choose $\phi = 0$ and $\phi = \pi/2$ to correspond to $[2\bar{1}\bar{1}]$ and $[0\bar{1}1]$, respectively. In this case,

$$a_{ij}^{[\bar{1}\bar{1}\bar{1}]} = \begin{pmatrix} \frac{2}{\sqrt{6}}\cos\phi & -\frac{1}{\sqrt{6}}\cos\phi - \frac{1}{\sqrt{2}}\sin\phi & -\frac{1}{\sqrt{6}}\cos\phi + \frac{1}{\sqrt{2}}\sin\phi \\ -\frac{2}{\sqrt{6}}\sin\phi & \frac{1}{\sqrt{6}}\sin\phi - \frac{1}{\sqrt{2}}\cos\phi & \frac{1}{\sqrt{6}}\sin\phi + \frac{1}{\sqrt{2}}\cos\phi \\ -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} & -\frac{1}{\sqrt{3}} \end{pmatrix}.$$

Finally, for the $[\bar{2}11]$ pulling direction, the z-direction is $[\bar{2}11]$, $\phi = 0$ corresponds to [111], and $\phi = \pi/2$ corresponds to $[01\bar{1}]$ yielding

$$a_{ij}^{[\bar{2}11]} = \begin{pmatrix} \frac{1}{\sqrt{3}}\cos\phi & \frac{1}{\sqrt{3}}\cos\phi + \frac{1}{\sqrt{2}}\sin\phi & \frac{1}{\sqrt{3}}\cos\phi - \frac{1}{\sqrt{2}}\sin\phi \\ -\frac{1}{\sqrt{3}}\sin\phi & -\frac{1}{\sqrt{3}}\sin\phi + \frac{1}{\sqrt{2}}\cos\phi & -\frac{1}{\sqrt{3}}\sin\phi - \frac{1}{\sqrt{2}}\cos\phi \\ -\frac{2}{\sqrt{6}} & \frac{1}{\sqrt{6}} & \frac{1}{\sqrt{6}} \end{pmatrix}.$$

Each of these transformations changes the form of C_{cyc}, and in general we have the form $C_{\text{cyc}} = \sum_k C_{\text{cyc,k}}$, where each matrix with subscript k consists of only elements $c_k = \cos(k\phi)$, $s_k = \sin(k\phi)$ and zero. The detailed expressions are given in Appendix B. Since the anisotropic part of the constitutive relation C^a_{cyc} can be decomposed into components $C^a_{\text{cyc},k}$ consisting of only s_k and c_k, we can systematically construct higher order approximations. This is accomplished by first determining the solution for a generic $C^a_{\text{cyc},k}$, and then computing an appropriate linear combination of all the solutions for a particular pulling direction. To illustrate the procedure, we now discuss a simpler problem, where we use the plane-strain assumption.

3.2. Plane-strain thermal stress for solids with cubic anisotropy. As in [13], we assume that the displacement is only in the (r, ϕ) plane so that $\mathbf{e}_{\mathrm{cyc}} = (e_{rr}, e_{\phi\phi}, 0, 0, 0, 2e_{r\phi})^{\mathrm{T}}$. We will also reintroduce the notation $(\mathcal{C}_k, \mathcal{S}_k) = (\cos(n_k\phi + \delta_k), \sin(n_k\phi + \delta_k))$ and its generalizations $(\mathcal{C}, \mathcal{S})$ and $(\tilde{\mathcal{C}}_k, \tilde{\mathcal{S}}_k)$ with the k suffix suppressed, and $\tilde{n}_k$ replacing n_k, respectively.

Starting with the isotropic case, where $\mathbf{w}_0$ is the solution of (3.5), when ϵ is small it is shown in [13] that $\mathbf{w}_0$ can be approximated by

$$\mathbf{w}_0 \sim \begin{pmatrix} rD_r^{(1)} + r^3 D_r^{(3)} \\ 0 \end{pmatrix} + r^{n_k - 1} \begin{pmatrix} D_r^- \mathcal{C}_k \\ D_\phi^- \mathcal{S}_k \end{pmatrix} + r^{n_k + 1} \begin{pmatrix} D_r^+ \mathcal{C}_k \\ D_\phi^+ \mathcal{S}_k \end{pmatrix}, \tag{3.8}$$

where

$$D_r^{(1)} = \mu \left(\frac{1+\nu}{1-\nu}\right) C_1(1-2\nu), \qquad D_r^{(3)} = \mu \left(\frac{1+\nu}{1-\nu}\right) \frac{C_1}{\bar{R}^2}, \tag{3.9a}$$

$$D_r^- = \mu \left(\frac{1+\nu}{1-\nu}\right) \frac{C_1 \epsilon \beta_k}{\bar{R}^{n_k - 2}} n_k, \qquad D_\phi^- = -\mu \left(\frac{1+\nu}{1-\nu}\right) \frac{C_1 \epsilon \beta_k}{\bar{R}^{n_k - 2}} n_k, \tag{3.9b}$$

$$D_r^+ = \mu \left(\frac{1+\nu}{1-\nu}\right) \frac{C_1 \epsilon \beta_k}{\bar{R}^{n_k}} (2 - 4\nu - n_k) + \frac{4\mu(1+\nu)}{n_k(n_k+1)} \frac{C_2 \epsilon \beta_k}{\bar{R}^{n_k}}, \tag{3.9c}$$

$$D_\phi^+ = \mu \left(\frac{1+\nu}{1-\nu}\right) \frac{C_1 \epsilon \beta_k}{\bar{R}^{n_k}} (4 - 4\nu + n_k) + \frac{4\mu(1+\nu)}{n_k(n_k+1)} \frac{C_2 \epsilon \beta_k}{\bar{R}^{n_k}}, \tag{3.9d}$$

where $\mu = 1 - \frac{H}{2} \frac{1-2\nu}{1-\nu}$ (see section 3.1).

Having determined $\mathbf{w}_0$, $\mathbf{w}$ is given by the expansion (3.7). Each of the terms in the expansion is a solution of the boundary value problem (3.6). To illustrate the procedure, in the following we construct $\mathbf{w}_1 = \mathcal{N}\mathbf{w}_0$.

Due to the linearity of the equilibrium equation, we can pick a representative $\mathbf{v} = (D_r r^k \cos(n\phi + \delta), D_\phi r^k \sin(n\phi + \delta))^{\mathrm{T}}$ with $n \geq 0$, $k \geq 1$. From this $\mathbf{v}$, the strain

$$\mathbf{S}(\mathbf{v}) = \begin{pmatrix} e_{rr} \\ e_{\phi\phi} \\ 2e_{r\phi} \end{pmatrix} = \begin{pmatrix} kD_r r^{k-1} \mathcal{C} \\ (D_r + nD_\phi) r^{k-1} \mathcal{C} \\ (kD_\phi - D_\phi - nD_r) r^{k-1} \mathcal{S} \end{pmatrix},$$

and the stress due to the anisotropy in the material parameters is given by $C_{\mathrm{cyc}}^a \mathbf{S}(\mathbf{v})$, where the exact form of C_{cyc}^a depends on the orientation of the crystal. Expressions (B.1)–(B.3) show that C_{cyc}^a is a sum of terms, $C_{\mathrm{cyc},m}^a$, characterized by $\cos m\phi$ and $\sin m\phi$. Therefore, $C_{\mathrm{cyc},m}^a \mathbf{S}(\mathbf{v})$ can be expressed as a sum with terms of the form $r^{k-1}(\cos(\tilde{n}\phi + \delta), \cos(\tilde{n}\phi + \delta), \sin(\tilde{n}\phi + \delta))^{\mathrm{T}}$, $\tilde{n} = n \pm m$. So, we need only consider the problem

$$\frac{\partial \sigma_{rr}}{\partial r} + \frac{1}{r} \frac{\partial \sigma_{r\phi}}{\partial \phi} + \frac{\sigma_{rr} - \sigma_{\phi\phi}}{r} = f_r r^{k-2} \tilde{\mathcal{C}}, \qquad r < \bar{R}(z), \tag{3.10a}$$

$$\frac{\partial \sigma_{r\phi}}{\partial r} + \frac{1}{r} \frac{\partial \sigma_{\phi\phi}}{\partial \phi} + \frac{2\sigma_{r\phi}}{r} = f_\phi r^{k-2} \tilde{\mathcal{S}}, \qquad r < \bar{R}(z), \tag{3.10b}$$

with integers $\tilde{n} \geq 0$, $k \geq 1$, and

$$\sigma_{rr} = g_r r^{k-1} \tilde{\mathcal{C}}, \qquad r = \bar{R}(z), \tag{3.11a}$$

$$\sigma_{r\phi} = g_\phi r^{k-1} \tilde{\mathcal{S}}, \qquad r = \bar{R}(z), \tag{3.11b}$$

corresponding to (3.6) with the higher order terms omitted.

To determine the solution to (3.10)–(3.11) we take a two-step approach. We begin by finding a particular solution $\mathbf{w}_p$ which satisfies (3.10) but not necessarily (3.11). Next, we find $\mathbf{w}_h$ which solves the homogeneous version of (3.10) and the modified boundary condition

$$\sigma^h_{rr} = g_r r^{k-1}\tilde{\mathcal{C}} - \sigma^p_{rr} := \tilde{g}_r r^{k-1}\tilde{\mathcal{C}}, \qquad r = \bar{R}(z), \tag{3.12a}$$

$$\sigma^h_{r\phi} = g_\phi r^{k-1}\tilde{\mathcal{S}} - \sigma^p_{r\phi} := \tilde{g}_\phi r^{k-1}\tilde{\mathcal{S}}, \qquad r = \bar{R}(z), \tag{3.12b}$$

where σ^p_{rr} and $\sigma^p_{r\phi}$ are stress components corresponding to $\mathbf{w}_p$. Accordingly, we find

$$\mathbf{w}_p = \begin{cases} \frac{1+\nu}{(1-\nu)^2}\begin{pmatrix} a_r r^k\tilde{\mathcal{C}} \\ a_\phi r^k \tilde{\mathcal{S}}\end{pmatrix}, & (k\pm\tilde{n})^2 \neq 1, \\ \frac{1+\nu}{(1-\nu)^2}\begin{pmatrix} (b_r + b_\phi\zeta\ln r)r^k\tilde{\mathcal{C}} \\ (b_\phi r^k \ln r\tilde{\mathcal{S}})\end{pmatrix}, & (k\pm\tilde{n})^2 = 1, \end{cases} \tag{3.13a}$$

where

$$a_r = \frac{((1-2\nu)(k^2-1) - 2\tilde{n}^2(1-\nu))f_r + \tilde{n}(3-4\nu-k)f_\phi}{((k-\tilde{n})^2-1)((k+\tilde{n})^2-1)}, \tag{3.13b}$$

$$a_\phi = \frac{\tilde{n}(3-4\nu+k)f_r + (2(1-\nu)(k^2-1) - (1-2\nu)\tilde{n}^2)f_\phi}{((k-\tilde{n})^2-1)((k+\tilde{n})^2-1)}, \tag{3.13c}$$

$$b_r = \begin{cases} -\frac{(3-4\nu)(\tilde{n}-1)(f_r+f_\phi)+(f_r-f_\phi)}{8\tilde{n}(\tilde{n}-1)}, & k = \tilde{n}-1, \\ \frac{(3-4\nu)\tilde{n}^2(f_r+f_\phi)+8(1-\nu)(1-2\nu)(\tilde{n}+1)(f_r-f_\phi)}{8\tilde{n}(\tilde{n}+1)(\tilde{n}+4-4\nu)}, & k = \tilde{n}+1, \end{cases} \tag{3.13d}$$

$$b_\phi = \begin{cases} -\frac{(\tilde{n}-1)(f_r+f_\phi)+(3-4\nu)(f_r-f_\phi)}{8(\tilde{n}-1)}, & k = \tilde{n}-1, \\ \frac{(\tilde{n}+4-4\nu)(f_r+f_\phi)}{8(\tilde{n}+1)}, & k = \tilde{n}+1, \end{cases} \tag{3.13e}$$

$$\zeta = \begin{cases} -1, & k = \tilde{n}-1, \\ -\frac{\tilde{n}-2+4\nu}{\tilde{n}+4-4\nu}, & k = \tilde{n}+1. \end{cases} \tag{3.13f}$$

The special case when $\tilde{n} = 0$ and $k = 1$ takes the form $\mathbf{w}_p = \frac{1+\nu}{2(1-\nu)^2} r\ln r \times ((1-2\nu)f_r\cos\delta,\, 2(1-\nu)f_\phi\sin\delta)^{\mathrm{T}}$. Corresponding to $\mathbf{w}_p$ are the stress components

$$\begin{pmatrix} \sigma^p_{rr} \\ \sigma^p_{\phi\phi} \\ \sigma^p_{r\phi} \end{pmatrix} = \begin{pmatrix} \frac{1-\nu}{(1+\nu)(1-2\nu)}((k-k\nu+\nu)a_r + \nu\tilde{n}a_\phi)r^{k-1}\tilde{\mathcal{C}} \\ \frac{1-\nu}{(1+\nu)(1-2\nu)}((1-\nu+k\nu)a_r + (1-\nu)\tilde{n}a_\phi)r^{k-1}\tilde{\mathcal{C}} \\ \frac{1-\nu}{2(1+\nu)}(-\tilde{n}a_r + (k-1)a_\phi)r^{k-1}\tilde{\mathcal{S}} \end{pmatrix} \tag{3.14a}$$

for $(k\pm\tilde{n})^2 \neq 1$ and

$$\begin{pmatrix} \sigma^p_{rr} \\ \sigma^p_{\phi\phi} \\ \sigma^p_{r\phi} \end{pmatrix} = \begin{pmatrix} \frac{1}{(1-\nu)(1-2\nu)}c_{rr}r^{k-1}\tilde{\mathcal{C}} \\ \frac{1}{(1-\nu)(1-2\nu)}c_{\phi\phi}r^{k-1}\tilde{\mathcal{C}} \\ \frac{1}{2(1-\nu)}c_{r\phi}r^{k-1}\tilde{\mathcal{S}} \end{pmatrix} \tag{3.14b}$$

for $(k \pm \tilde{n})^2 = 1$, where

$$c_{rr} = (k - k\nu + \nu)(b_r + b_\phi \zeta \ln r) + b_\phi((1-\nu)\zeta + \nu \tilde{n} \ln(r)), \tag{3.14c}$$

$$c_{\phi\phi} = (1 - \nu + k\nu)(b_r + b_\phi \zeta \ln r) + b_\phi(\nu\zeta + (1-\nu)\tilde{n} \ln(r)), \tag{3.14d}$$

$$c_{r\phi} = -\tilde{n}(b_r + b_\phi \zeta \ln r) + b_\phi(1 + (k-1)\ln r). \tag{3.14e}$$

For the special case when $\tilde{n} = 0$ and $k = 1$, we have

$$(\sigma^p_{rr}, \sigma^p_{\phi\phi}, \sigma^p_{r\phi})^{\mathrm{T}} = \frac{1}{2(1-\nu)}(f_r(\ln r + 1 - \nu)\cos\delta, f_r(\ln r + \nu)\cos\delta, f_\phi(1-\nu)\sin\delta)^{\mathrm{T}}.$$

Using the technique described in [13], we can find $\mathbf{w}_h$ which solves the homogeneous version of (3.10) and the boundary condition (3.12),

$$\mathbf{w}_h = \frac{1+\nu}{2(1-\nu)} \begin{pmatrix} \left(\frac{(2-\tilde{n}-4\nu)(\tilde{g}_r+\tilde{g}_\phi)r^{\tilde{n}+1}}{(\tilde{n}+1)\bar{R}^{\tilde{n}}} + \frac{(\tilde{n}\tilde{g}_r+(\tilde{n}-2)\tilde{g}_\phi)r^{\tilde{n}-1}}{(\tilde{n}-1)\bar{R}^{\tilde{n}-2}}\right)\tilde{\mathcal{C}} \\ \left(\frac{(4+\tilde{n}-4\nu)(\tilde{g}_r+\tilde{g}_\phi)r^{\tilde{n}+1}}{(\tilde{n}+1)\bar{R}^{\tilde{n}}} - \frac{(\tilde{n}\tilde{g}_r+(\tilde{n}-2)\tilde{g}_\phi)r^{\tilde{n}-1}}{(\tilde{n}-1)\bar{R}^{\tilde{n}-2}}\right)\tilde{\mathcal{S}} \end{pmatrix}. \tag{3.15}$$

The corresponding stress components are given by

$$\begin{pmatrix} \sigma^h_{rr} \\ \sigma^h_{\phi\phi} \\ \sigma^h_{r\phi} \end{pmatrix} = \begin{pmatrix} \left(\frac{(2-\tilde{n})(\tilde{g}_r+\tilde{g}_\phi)r^{\tilde{n}}}{2\bar{R}^{\tilde{n}}} + \frac{(\tilde{n}\tilde{g}_r+(\tilde{n}-2)\tilde{g}_\phi)r^{\tilde{n}-2}}{2\bar{R}^{\tilde{n}-2}}\right)\tilde{\mathcal{C}} \\ \left(\frac{(2+\tilde{n})(\tilde{g}_r+\tilde{g}_\phi)r^{\tilde{n}}}{2\bar{R}^{\tilde{n}}} - \frac{(\tilde{n}\tilde{g}_r+(\tilde{n}-2)\tilde{g}_\phi)r^{\tilde{n}-2}}{2\bar{R}^{\tilde{n}-2}}\right)\tilde{\mathcal{C}} \\ \left(\frac{\tilde{n}(\tilde{g}_r+\tilde{g}_\phi)r^{\tilde{n}}}{2\bar{R}^{\tilde{n}}} - \frac{(\tilde{n}\tilde{g}_r+(\tilde{n}-2)\tilde{g}_\phi)r^{\tilde{n}-2}}{2\bar{R}^{\tilde{n}-2}}\right)\tilde{\mathcal{S}} \end{pmatrix}. \tag{3.16}$$

In the special case when $\tilde{n} = 0$ (or $\tilde{n} = 1$), we require $\tilde{g}_\phi = 0$ (or $\tilde{g}_r = \tilde{g}_\phi$) for the homogeneous elasticity problem to be well-posed. The solution and the corresponding stress components are given by (3.15) and (3.16) without the term related to $r^{\tilde{n}-1}$ and $r^{\tilde{n}-2}$, respectively.

In the following we find the explicit form of the expression $\mathbf{w}_1 = \mathcal{N}\mathbf{w}_0$ for the $[\bar{1}\bar{1}\bar{1}]$ pulling direction. This expression generates the first order corrections to the stress of an anisotropic cubic crystal. The outline of the procedure is also given for the [001] and $[\bar{2}11]$ seeding orientations.

3.2.1. $[\bar{1}\bar{1}\bar{1}]$ pulling direction. To treat this case systematically we decompose $\mathbf{w}_0$ into five separate quantities given by

$$\mathbf{w}_{0,A} = \begin{pmatrix} D^{(1)}_r r \\ 0 \end{pmatrix}, \quad \mathbf{w}_{0,B} = \begin{pmatrix} D^{(3)}_r r^3 \\ 0 \end{pmatrix}, \quad \mathbf{w}_{0,C} = D^-_r r^k \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix},$$
$$\mathbf{w}_{0,D} = \frac{D^+_r + D^+_\phi}{2} r^k \begin{pmatrix} \mathcal{C}_k \\ \mathcal{S}_k \end{pmatrix}, \quad \mathbf{w}_{0,E} = \frac{D^+_r - D^+_\phi}{2} r^k \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix}.$$

For $\mathbf{w}_{0,C}$, $k = n_k - 1$, while for both $\mathbf{w}_{0,D}$ and $\mathbf{w}_{0,E}$, $k = n_k + 1$. What characterizes the $[\bar{1}\bar{1}\bar{1}]$ direction is the anisotropic stiffness given by C^a. From (B.1), we have in the case of plane-strain $C^a = C^a_0$, where

$$C^{a,[\bar{1}\bar{1}\bar{1}]} = \frac{H}{12} \begin{pmatrix} 0 & 2 & 0 \\ 2 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

and as a result $\tilde{n} = n$ for the $[\bar{1}\bar{1}\bar{1}]$ direction.

For the first component, $\mathbf{w}_{0,A}$, we find from (3.6a) and (3.10) that

$$\mathcal{L}^a(\mathbf{w}_{0,A}) = \nabla \cdot C^{a,[\bar{1}\bar{1}\bar{1}]}\mathbf{S}(\mathbf{w}_{0,A}) = \begin{pmatrix} 0 \\ 0 \end{pmatrix} = r^{k-2}\begin{pmatrix} f_r\mathcal{C} \\ f_\phi\mathcal{S} \end{pmatrix}, \tag{3.17a}$$

and for the boundary condition, (3.6b) and (3.11) give

$$\mathcal{B}^a(\mathbf{w}_{0,A}) = C^{a,[\bar{1}\bar{1}\bar{1}]}\mathbf{S}(\mathbf{w}_{0,A}) \cdot \mathbf{n} = \frac{H}{6}\begin{pmatrix} D_r^{(1)} \\ 0 \end{pmatrix} = \bar{R}^{k-1}\begin{pmatrix} g_r\mathcal{C} \\ g_\phi\mathcal{S} \end{pmatrix}, \tag{3.17b}$$

where $k = 1$, $\delta = 0$, and $n = \tilde{n} = n_k = 0$. Setting $\Lambda_A = \frac{H}{6}D_r^{(1)}$ we identify $f_r = f_\phi = 0$, $g_r = \Lambda_A$, and $g_\phi = 0$. The quantities f_r and f_ϕ applied to (3.13)–(3.14) give the particular solution for the stress as $\sigma^p_{ij,A} = 0$, which through (3.12) indicates that $\tilde{g}_r = \Lambda_A$ and $\tilde{g}_\phi = 0$. For the homogeneous solution, we solve $\mathcal{L}^0(\mathbf{w}_{1,A}) = \mathcal{L}^a(\mathbf{w}_{0,A})$ with the boundary condition $\mathcal{B}^0(\mathbf{w}_{1,A}) = \mathcal{B}^a(\mathbf{w}_{0,A})$ and by using (3.16) to determine the stress, which gives

$$\begin{pmatrix} \sigma^h_{rr,A} \\ \sigma^h_{\phi\phi,A} \\ \sigma^h_{r\phi,A} \end{pmatrix} = \Lambda_A \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}. \tag{3.17c}$$

For $\mathbf{w}_{0,B}$, we have $k = 3$, $\delta = 0$, and $n = \tilde{n} = n_k = 0$, and continuing in an analogous fashion we find that

$$\mathcal{L}^a(\mathbf{w}_{0,B}) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \qquad \mathcal{B}^a(\mathbf{w}_{0,B}) = \bar{R}^2\begin{pmatrix} g_r \\ g_\phi \end{pmatrix} = \frac{H}{6}\bar{R}^2\begin{pmatrix} D_r^{(3)} \\ 0 \end{pmatrix}. \tag{3.18a}$$

As with the previous case, we find $\sigma^p_{ij,B} = 0$, and defining $\Lambda_B = \frac{H}{6}D_r^{(3)}$ we identify $\tilde{g}_r = g_r = \Lambda_B$, and $\tilde{g}_\phi = g_\phi = f_r = f_\phi = 0$. From (3.16) we have

$$\begin{pmatrix} \sigma^h_{rr,B} \\ \sigma^h_{\phi\phi,B} \\ \sigma^h_{r\phi,B} \end{pmatrix} = \Lambda_B\bar{R}^2 \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}. \tag{3.18b}$$

For $\mathbf{w}_{0,C}$, $k = n_k - 1$, $n = \tilde{n} = n_k$, and defining $\Lambda_C = \frac{H}{6}(1 - n_k)D_r^-$ we determine

$$\mathcal{L}^a(\mathbf{w}_{0,C}) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \qquad \mathcal{B}^a(\mathbf{w}_{0,C}) = \Lambda_C\bar{R}^{n_k-2}\begin{pmatrix} \mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix}$$

so that $f_r = f_\phi = 0$, $\sigma^p_{ij,C} = 0$, $g_r = \tilde{g}_r = \Lambda_C$, and $g_\phi = \tilde{g}_\phi = -\Lambda_C$. Applying (3.16) we obtain

$$\begin{pmatrix} \sigma^h_{rr,C} \\ \sigma^h_{\phi\phi,C} \\ \sigma^h_{r\phi,C} \end{pmatrix} = \Lambda_C r^{n_k-2} \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix}. \tag{3.19}$$

The fourth component is $\mathbf{w}_{0,D}$ and $k = n_k + 1$, $n = \tilde{n} = n_k$. By defining $\Lambda_D = \frac{H}{12}(n_k + 1)(D_r^+ + D_\phi^+)$ one has

$$\mathcal{L}^a(\mathbf{w}_{0,D}) = n_k \Lambda_D r^{n_k - 1} \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix}, \qquad \mathcal{B}^a(\mathbf{w}_{0,D}) = \Lambda_D \bar{R}^{n_k} \begin{pmatrix} \mathcal{C}_k \\ 0 \end{pmatrix}$$

so that $f_r = -f_\phi = n_k \Lambda_D$, $g_r = \Lambda_D$, and $g_\phi = 0$. In this case the particular solution for the stress is

$$\begin{pmatrix} \sigma^p_{rr,D} \\ \sigma^p_{\phi\phi,D} \\ \sigma^p_{r\phi,D} \end{pmatrix} = \frac{\Lambda_D r^{n_k}}{n_k + 4 - 4\nu} \begin{pmatrix} 2(n_k + 1 - \nu n_k)\mathcal{C}_k \\ 2(1 + \nu n_k)\mathcal{C}_k \\ -n_k(1 - 2\nu)\mathcal{S}_k \end{pmatrix} \tag{3.20a}$$

so that

$$\begin{pmatrix} \tilde{g}_r \\ \tilde{g}_\phi \end{pmatrix} = \frac{(1 - 2\nu)\Lambda_D}{n_k + 4 - 4\nu} \begin{pmatrix} 2 - n_k \\ n_k \end{pmatrix},$$

and from (3.16)

$$\begin{pmatrix} \sigma^h_{rr,D} \\ \sigma^h_{\phi\phi,D} \\ \sigma^h_{r\phi,D} \end{pmatrix} = \frac{(1 - 2\nu)\Lambda_D r^{n_k}}{n_k + 4 - 4\nu} \begin{pmatrix} (2 - n_k)\mathcal{C}_k \\ (n_k + 2)\mathcal{C}_k \\ n_k \mathcal{S}_k \end{pmatrix}. \tag{3.20b}$$

The last component, $\mathbf{w}_{0,E}$, has $k = n_k + 1$ and $n = \tilde{n} = n_k$. For this case we choose $\Lambda_E = \frac{H}{12}(D_\phi^+ - D_r^+)$ and find

$$\mathcal{L}^a(\mathbf{w}_{0,E}) = n_k \Lambda_E r^{n_k - 1} \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix}, \qquad \mathcal{B}^a(\mathbf{w}_{0,E}) = \Lambda_E \bar{R}^{n_k} \begin{pmatrix} (n_k - 1)\mathcal{C}_k \\ -n_k \mathcal{S}_k \end{pmatrix}$$

so that $f_r = -f_\phi = n_k \Lambda_E$, $g_r = (n_k - 1)\Lambda_E$, and $g_\phi = -n_k \Lambda_E$. Continuing,

$$\begin{pmatrix} \sigma^p_{rr,E} \\ \sigma^p_{\phi\phi,E} \\ \sigma^p_{r\phi,E} \end{pmatrix} = \frac{\Lambda_E r^{n_k}}{n_k + 4 - 4\nu} \begin{pmatrix} 2(n_k + 1 - \nu n_k)\mathcal{C}_k \\ 2(1 + \nu n_k)\mathcal{C}_k \\ -n_k(1 - 2\nu)\mathcal{S}_k \end{pmatrix}, \tag{3.21a}$$

yielding

$$\begin{pmatrix} \tilde{g}_r \\ \tilde{g}_\phi \end{pmatrix} = \frac{(n_k + 3 - 2\nu)\Lambda_E}{n_k + 4 - 4\nu} \begin{pmatrix} n_k - 2 \\ -n_k \end{pmatrix}$$

and

$$\begin{pmatrix} \sigma^h_{rr,E} \\ \sigma^h_{\phi\phi,E} \\ \sigma^h_{r\phi,E} \end{pmatrix} = -\frac{(n_k + 3 - 2\nu)\Lambda_E r^{n_k}}{n_k + 4 - 4\nu} \begin{pmatrix} (2 - n_k)\mathcal{C}_k \\ (n_k + 2)\mathcal{C}_k \\ n_k \mathcal{S}_k \end{pmatrix}. \tag{3.21b}$$

Combining (3.17)–(3.21) and using both (3.9) and (3.4), we find the first order correction to the total stress in the $[\bar{1}\bar{1}\bar{1}]$ direction accounting for cubic anisotropy as

$$\begin{aligned}
\begin{pmatrix} \sigma_{rr}^{\mathrm{tot}} \\ \sigma_{\phi\phi}^{\mathrm{tot}} \\ \sigma_{zz}^{\mathrm{tot}} \\ \sigma_{r\phi}^{\mathrm{tot}} \end{pmatrix}_{[\bar{1}\bar{1}\bar{1}]}
&= \frac{2(1-\nu)\omega C_1}{3} \begin{pmatrix} 1 \\ 1 \\ 2\nu \\ 0 \end{pmatrix} - \frac{4(1-\nu)^2 \omega C_1 r^2}{(1+\nu)(1-2\nu)\bar{R}^2} \begin{pmatrix} 1 \\ 1 \\ 1+\nu \\ 0 \end{pmatrix} \\
&\quad - \frac{4(1-\nu)\epsilon\omega C_2}{3(1-2\nu)} \frac{\beta_k}{n_k} \left(\frac{r}{\bar{R}}\right)^{n_k} \mathcal{C}_k \begin{pmatrix} 2\frac{1-\nu+\nu^2}{1+\nu} \\ 2\frac{1-\nu+\nu^2}{1+\nu} \\ 3-5\nu+4\nu^2 \\ 0 \end{pmatrix} \\
&\quad + \frac{\epsilon\omega C_1}{3} \beta_k (n_k+1) \left(\frac{r}{\bar{R}}\right)^{n_k} \begin{pmatrix} (n_k+2-4\nu)\mathcal{C}_k \\ (2-n_k-4\nu)\mathcal{C}_k \\ 4\nu(1-2\nu)\mathcal{C}_k \\ -n_k\mathcal{S}_k \end{pmatrix} \\
&\quad - \frac{\epsilon\omega C_1}{3} \beta_k n_k (n_k-1) \left(\frac{r}{\bar{R}}\right)^{n_k-2} \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{C}_k \\ 0 \\ -\mathcal{S}_k \end{pmatrix}
\end{aligned} \tag{3.22}$$

with $\omega = \frac{1+\nu}{1-\nu}\frac{|H|}{2}$ using the scaled version of H.

This procedure can of course be followed for any pulling direction provided the form of C^a is known. It can also be applied to finding higher order corrections provided that the solution (3.13) to (3.10) is generalized to allow a multiplicative factor of $(\ln r)^l$ for some integer $l \geq 1$. In the following we simply state $\mathcal{L}^a$ and $\mathcal{B}^a$ for the [001] and $[\bar{2}11]$ seeding orientations for each of the five components of the displacement (3.8).

3.2.2. [001] pulling direction. From (B.2) we have $C^a = C_0^a + C_4^a$ with

$$C_0^a = \frac{H}{4}\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \qquad C_4^a = \frac{H}{4}\begin{pmatrix} c_4 & -c_4 & -s_4 \\ -c_4 & c_4 & s_4 \\ -s_4 & s_4 & -c_4 \end{pmatrix}.$$

Accordingly one finds that

$$\begin{aligned}
\mathcal{L}^a(\mathbf{w}_{0,A}) &= \begin{pmatrix} 0 \\ 0 \end{pmatrix}, & \mathcal{B}^a(\mathbf{w}_{0,A}) &= 3\Lambda_A \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \\
\mathcal{L}^a(\mathbf{w}_{0,B}) &= 12\Lambda_B r \begin{pmatrix} 1 \\ 0 \end{pmatrix}, & \mathcal{B}^a(\mathbf{w}_{0,B}), &= 3\Lambda_B \bar{R}^2 \begin{pmatrix} 2+c_4 \\ -s_4 \end{pmatrix}.
\end{aligned}$$

The composite form of $\mathcal{B}^a(\mathbf{w}_{0,B})$ shows that the condition (3.11) can generate more than one term of a particular solution for a fixed version of (3.10). For the rest of the terms we extend the notation $\{\mathcal{C}_k, \mathcal{S}_k\}$ to $\{\mathcal{C}_{k,m}, \mathcal{S}_{k,m}\}$, where $\mathcal{C}_{k,m} = \cos((n_k - m)\phi + \delta_k)$, and $\mathcal{S}_{k,m}$ is updated similarly. In this notation, one has

$$\mathcal{L}^a(\mathbf{w}_{0,C}) = 6(2-n_k)\Lambda_C r^{n_k-3}\begin{pmatrix}\mathcal{C}_{k,4}\\ \mathcal{S}_{k,4}\end{pmatrix}, \quad \mathcal{B}^a(\mathbf{w}_{0,C}) = -3\Lambda_C \bar{R}^{n_k-2}\begin{pmatrix}\mathcal{C}_{k,4}\\ \mathcal{S}_{k,4}\end{pmatrix},$$

$$\mathcal{L}^a(\mathbf{w}_{0,D}) = 3n_k\Lambda_D r^{n_k-1}\begin{pmatrix}\mathcal{C}_{k}\\ -\mathcal{S}_{k}\end{pmatrix}, \quad \mathcal{B}^a(\mathbf{w}_{0,D}) = 3\Lambda_D \bar{R}^{n_k}\begin{pmatrix}\mathcal{C}_{k}\\ 0\end{pmatrix},$$

$$\mathcal{L}^a(\mathbf{w}_{0,E}) = 3n_k\Lambda_E r^{n_k-1}\begin{pmatrix}2(1-n_k)\mathcal{C}_{k,4} - \mathcal{C}_k\\ 2(1-n_k)\mathcal{S}_{k,4} + \mathcal{S}_k\end{pmatrix},$$

$$\mathcal{B}^a(\mathbf{w}_{0,E}) = -3\Lambda_E \bar{R}^{n_k}\begin{pmatrix}n_k\mathcal{C}_{k,4} + \mathcal{C}_k\\ n_k\mathcal{S}_{k,4}\end{pmatrix}.$$

3.2.3. $[\bar{2}11]$ pulling direction. From (B.3),

$$C^{a,[\bar{2}11]} = \frac{H}{48}\begin{pmatrix}3-4c_2-7c_4 & 9+7c_4 & 2s_2+7s_4\\ 9+7c_4 & 3+4c_2-7c_4 & 2s_2-7s_4\\ 2s_2+7s_4 & 2s_2-7s_4 & -3+7c_4\end{pmatrix}.$$

In the case for $[\bar{2}11]$, C^a is decoupled into C^a_0, C^a_2, C^a_4, which is analogous to the [001] case. Repeating the calculation we find

$$\begin{aligned}
\mathcal{L}^a(\mathbf{w}_{0,A}) &= \begin{pmatrix}0\\0\end{pmatrix},\\
\mathcal{B}^a(\mathbf{w}_{0,A}) &= \frac{1}{2}\Lambda_A\begin{pmatrix}3-c_2\\ s_2\end{pmatrix},\\
\mathcal{L}^a(\mathbf{w}_{0,B}) &= 3\Lambda_B r\begin{pmatrix}1-c_2\\ s_2\end{pmatrix},\\
\mathcal{B}^a(\mathbf{w}_{0,B}) &= \frac{1}{4}\Lambda_B\bar{R}^2\begin{pmatrix}-7c_4-6c_2+9\\ 7s_4+4s_2\end{pmatrix},\\
\mathcal{L}^a(\mathbf{w}_{0,C}) &= \frac{1}{2}(n_k-2)\Lambda_C r^{n_k-3}\begin{pmatrix}7\mathcal{C}_{k,4}+\mathcal{C}_{k,2}\\ 7\mathcal{S}_{k,4}-\mathcal{S}_{k,2}\end{pmatrix},\\
\mathcal{B}^a(\mathbf{w}_{0,C}) &= \frac{1}{4}\Lambda_C\bar{R}^{n_k-2}\begin{pmatrix}7\mathcal{C}_{k,4}+2\mathcal{C}_{k,2}+3\mathcal{C}_k\\ 7\mathcal{S}_{k,4}-3\mathcal{S}_k\end{pmatrix},\\
\mathcal{L}^a(\mathbf{w}_{0,D}) &= \frac{1}{2}n_k\Lambda_D r^{n_k-1}\begin{pmatrix}-\mathcal{C}_{k,2}+3\mathcal{C}_k\\ -\mathcal{S}_{k,2}-3\mathcal{S}_k\end{pmatrix},\\
\mathcal{B}^a(\mathbf{w}_{0,D}) &= \frac{1}{4}\Lambda_D\bar{R}^{n_k}\begin{pmatrix}-\mathcal{C}_{k,2}-\mathcal{C}_{k,-2}+6\mathcal{C}_k\\ -\mathcal{S}_{k,2}+\mathcal{S}_{k,-2}\end{pmatrix},\\
\mathcal{L}^a(\mathbf{w}_{0,E}) &= \frac{1}{2}n_k\Lambda_E r^{n_k-1}\begin{pmatrix}7(n_k-1)\mathcal{C}_{k,4}+(n_k+1)\mathcal{C}_{k,2}\\ 7(n_k-1)\mathcal{S}_{k,4}+(3-n_k)\mathcal{S}_{k,2}\end{pmatrix},\\
\mathcal{B}^a(\mathbf{w}_{0,E}) &= \frac{1}{4}\Lambda_E\bar{R}^{n_k}\begin{pmatrix}7n_k\mathcal{C}_{k,4}+(2n_k+1)\mathcal{C}_{k,2}+\mathcal{C}_{k,-2}+3(n_k-2)\mathcal{C}_k\\ 7n_k\mathcal{S}_{k,4}+\mathcal{S}_{k,2}-\mathcal{S}_{k,-2}-3n_k\mathcal{S}_k\end{pmatrix}.
\end{aligned}$$

In summary, the total stress is the sum of the stress components due to anisotropy in the elastic constants obtained above, plus the sum for isotropic solids given in [13] multiplied by $\mu = 1 - \frac{H}{2}\frac{1-2\nu}{1-\nu}$, which is reproduced as follows for completeness:

$$\begin{aligned}
\text{(3.23a)}\quad \begin{pmatrix} \sigma_{rr}^{\text{tot,iso}} \\ \sigma_{\phi\phi}^{\text{tot,iso}} \\ \sigma_{r\phi}^{\text{tot,iso}} \end{pmatrix} &= \mu C_1 \begin{pmatrix} 1 - \left(\frac{r}{\bar{R}}\right)^2 \\ 1 - 3\left(\frac{r}{\bar{R}}\right)^2 \\ 0 \end{pmatrix} + \mu\epsilon C_1 \beta_k n_k (n_k - 1) \left(\frac{r}{\bar{R}}\right)^{n_k - 2} \begin{pmatrix} \mathcal{C}_k \\ -\mathcal{C}_k \\ -\mathcal{S}_k \end{pmatrix} \\
&\quad + \mu\epsilon C_1 \beta_k (n_k + 1) \left(\frac{r}{\bar{R}}\right)^{n_k} \begin{pmatrix} (2 - n_k)\mathcal{C}_k \\ (n_k + 2)\mathcal{C}_k \\ n_k \mathcal{S}_k \end{pmatrix}
\end{aligned}$$

and

$$\text{(3.23b)}\quad \sigma_{zz}^{\text{tot,iso}} = 2\mu C_1 \left(1 - 2\left(\frac{r}{\bar{R}}\right)^2\right) + 4\mu\epsilon\beta_k \left(\nu(n_k + 1)C_1 - \frac{1-\nu}{n_k} C_2\right) \left(\frac{r}{\bar{R}}\right)^{n_k} \mathcal{C}_k.$$

3.3. The von Mises and total resolved stresses. A characteristic amount of stress can be assigned to each point with the von Mises stress, which satisfies

$$\text{(3.24)}\qquad 2\sigma_{\text{vm}}^2 = (\sigma_{rr} - \sigma_{\phi\phi})^2 + (\sigma_{rr} - \sigma_{zz})^2 + (\sigma_{\phi\phi} - \sigma_{zz})^2 + 6\sigma_{r\phi}^2$$

for a cubic material, where the σ_{ij} are given by (3.23) and the corrections due to material anisotropy, such as that given by (3.22).

The preferred method of dislocation generation in all III–V semiconductors is through the generation of slip defects, in particular the $\{111\}$, $\langle 1\bar{1}0\rangle$ slip system [1], which consists of four glide planes within which atoms can slip in one of three directions. The resolved stress σ_{rs}, in a particular slip direction $\mathbf{d}$ within the glide plane with normal $\mathbf{n}$, is given by

$$\sigma_{\text{rs}} = \mathbf{d}^{\text{T}} U_{\mathbf{p}}^{\text{T}} Q^{\text{T}} \sigma^{\text{tot}} Q U_{\mathbf{p}} \mathbf{n}.$$

The matrix $U_{\mathbf{p}}$ rotates vectors from the crystallographic frame to the solidification frame. If the stress tensor σ^{tot} is expressed in the (r, ϕ, z) coordinates, Q is the coordinate transformation matrix that takes $(x, y, z) \to (r, \phi, z)$.

Plastic deformation of the crystal occurs if the stress in any of the 12 slip directions exceeds a maximum value known as the critical resolved shear stress, σ_{crss}. To leading order, the actual density of dislocations suffered by the crystal is proportional to the total excess stress at any given point within the crystal. In this sense, an estimation of where dislocations are likely to occur is given by the distribution of the total absolute resolved stress

$$\text{(3.25)}\qquad |\sigma_{\text{rs}}^{\text{tot}}| = \sum_{i=1}^{12} \left| \mathbf{d}_i^T U_{\mathbf{p}}^T Q^T \sigma^{\text{tot}} Q U_{\mathbf{p}} \mathbf{n}_i \right|.$$

4. Numerical results. The physical parameters used for the simulations correspond to InSb grown with the Cz method can be found in [1]. Numerical results are obtained for a conic crystal with a half opening angle of $\varphi_{\text{cone}} = 5°$ so that in nondimensional coordinates $\bar{R}(z) = \bar{R}(Z_0) + \hat{\theta}_{\text{cone}} z$. The initial seed length is $Z_0 = 0.054$ and the radius is $\bar{R}(Z_0) = 1/6$, corresponding to an initial dimensional radius and length of 0.005 m and 0.01 m, respectively. Here we have taken $h_{\text{gs}} = \bar{h}_{\text{gs}} = 4$ so that by using the characteristic radius $\tilde{R} = 0.03$ m and thermal conductivity of

TABLE 1

The maximum von Mises and resolved stress values for the three seed orientations using j correction terms.

	Maximum von Mises stress		
j	$\mathbf{p} = [001]$	$\mathbf{p} = [\bar{1}\bar{1}\bar{1}]$	$\mathbf{p} = [\bar{2}11]$
0	3.32×10^{-3}	7.23×10^{-3}	3.83×10^{-3}
1	2.75×10^{-3}	6.80×10^{-3}	3.89×10^{-3}
12	2.85×10^{-3}	6.89×10^{-3}	4.04×10^{-3}

	Maximum resolved stress		
j	$\mathbf{p} = [001]$	$\mathbf{p} = [\bar{1}\bar{1}\bar{1}]$	$\mathbf{p} = [\bar{2}11]$
0	9.23×10^{-3}	1.34×10^{-2}	8.78×10^{-3}
1	7.66×10^{-3}	1.20×10^{-2}	8.78×10^{-3}
12	8.15×10^{-3}	1.21×10^{-2}	8.84×10^{-3}

4.57 $\mathrm{W\,m^{-1}K^{-1}}$ we find $\mathrm{Bi} = 0.026$. The final radius and length (not including the seed) are 0.03 m and 0.286 m or 1 and 1.537, respectively, in scaled units. This gives a value of $\hat{\theta}_{\text{cone}} = 0.542$.

Θ_0 is the solution of (2.6) in the pseudosteady case ($1/\mathrm{St} = 0$) with $\delta = \gamma = 0$ and $I_{0,1}/I_{2,0} = 1$. Θ_1 is given by (2.7) with $h_F = 0$ so that $F(\Theta) = \beta\Theta = \Theta$. Since the stiffness constants for InSb are $C_{11} = 6.70 \times 10^4$, $C_{12} = 3.65 \times 10^4$, $C_{44} = 3.02 \times 10^4$ MPa, one has $H = 2C_{44} - C_{11} + C_{12} = 2.99 \times 10^4$ MPa and $\omega = 0.329$. In addition, the values of E and ν used in the calculation are represented by (3.2b),

$$E = \frac{(C_{11} + 2C_{12} + H/2)(C_{11} - C_{12} + H/2)}{C_{11} + C_{12} + H/2} = 5.95 \times 10^4 \text{ MPa}, \tag{4.1a}$$

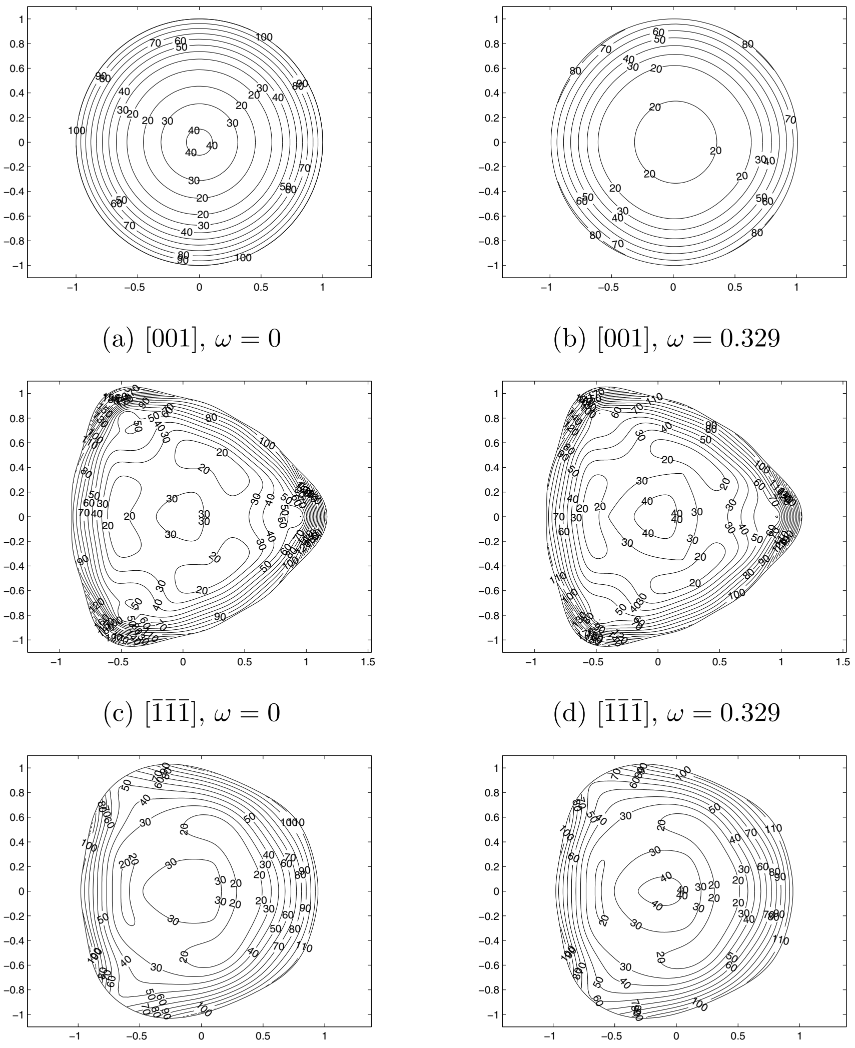
$$\nu = \frac{C_{12}}{C_{11} + C_{12} + H/2} = 0.308. \tag{4.1b}$$

When combined with the parameters above, the dimensional constant for the stress calculations is $\alpha \Delta T E/(1 - \nu) \sim 93.8$ MPa, where $\alpha = 5.5 \times 10^{-6}\mathrm{K}^{-1}$ and $\Delta T = 198.4$ K [1].

We start with the expression for the displacement (3.8), which defines $D^{(1)}$, $D^{(3)}$, $D^{\pm}$, k, and n for the $\mathcal{L}^a(\mathbf{w}_0)$ and $\mathcal{B}^a(\mathbf{w}_0)$ expressions found in sections 3.2.1, 3.2.2, and 3.2.3. The $\mathcal{L}^a(\mathbf{w}_0)$ defines f_r, f_ϕ, k, and $\tilde{n}$ in (3.10), which gives σ^p_{ij}, and $\mathcal{B}^a(\mathbf{w}_0)$ defines g_r, g_ϕ, k, and $\tilde{n}$ in (3.11), which gives σ^h_{ij} with $\tilde{g}_r$ and $\tilde{g}_\phi$ given by g_r, g_ϕ, and σ^p_{ij}.

Figure 1 shows the von Mises stress for the three seeding orientation: [001], $[\bar{1}\bar{1}\bar{1}]$ and $[\bar{2}11]$. To the left of each pair is the isotropic case corresponding to the material in [13], and to the right is the anisotropic case corresponding to one correction term, namely, $\mathbf{w} \sim \mathbf{w}_0 + \mathbf{w}_1$. Reported stress values are given in percentages with 100% corresponding to the outer edge of a cylindrical crystal ($\alpha = 0$) grown in the [001] direction or $|\sigma_{\text{vm}}| = 3.32 \times 10^{-3}$. In the [001] pulling direction the von Mises stress retains its axial symmetry even when anisotropic stiffness coefficients are included. For the $[\bar{1}\bar{1}\bar{1}]$ and $[\bar{2}11]$ seeding orientations the geometric effect dominates the amount of stress. Table 1 lists the maximum value of the von Mises stress for the three orientations using zero (isotropic, $\omega = 0$), one, and twelve correction terms for the total stress. It can be seen that the von Mises stress can either decrease or increase when material anisotropy is considered, depending on seed orientation.

Figure 2 shows the corresponding resolved stress $\sigma^{\text{tot}}_{\text{rs}}$ as given by (3.25), which is relevant to dislocation generation. The computed peak values for the total resolved stress are listed in Table 1 and once again we conclude that the effect of the material



(a) [001], $\omega = 0$

(b) [001], $\omega = 0.329$

(c) $[\bar{1}\bar{1}\bar{1}]$, $\omega = 0$

(d) $[\bar{1}\bar{1}\bar{1}]$, $\omega = 0.329$

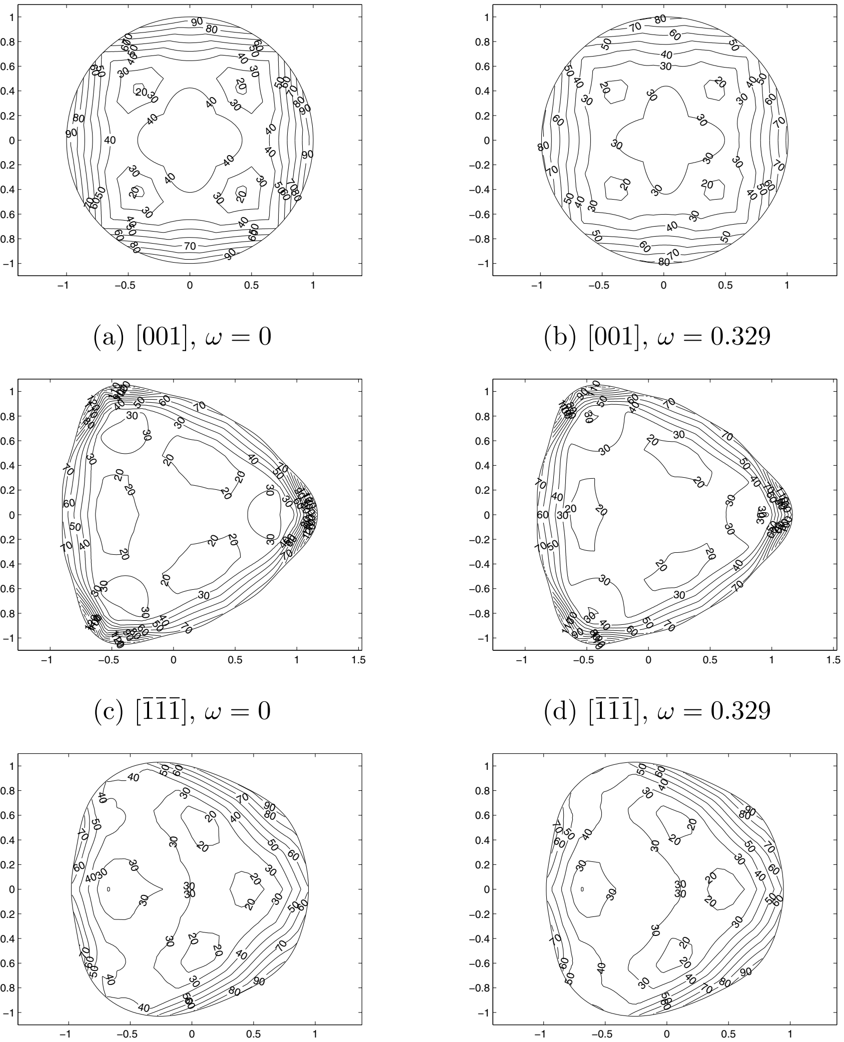
(e) $[\bar{2}11]$, $\omega = 0$

(f) $[\bar{2}11]$, $\omega = 0.329$

FIG. 1. *The von Mises stress computed using* (3.24) *at the indicated orientation, just inside the crystal/melt interface at the end of the growth. The* $\omega = 0.329$ *case utilizes one correction term.*

anisotropy is more significant for the [001] orientation since there is no geometric effect in that case. For the other two directions, the geometric effect dominates and the material anisotropy has a limited effect.

5. Conclusion. In this paper we have discussed the effect of material anisotropy on the thermal stress and compared it with that of geometric anisotropy due to facet formation. We have presented a systematic procedure which computes the stress iteratively, using an asymptotic series. We have also shown that the series converges for any anisotropic cubic material. Numerical results are obtained for InSb crystals



(a) [001], $\omega = 0$

(b) [001], $\omega = 0.329$

(c) $[\bar{1}\bar{1}\bar{1}]$, $\omega = 0$

grown by the Cz method in three pulling directions. When the seed orientation is in the [001] direction, since no facet forms and no geometric anisotropy is present, the material anisotropy has a visible effect on both the von Mises and the total resolved stresses. For the $[\bar{1}\bar{1}\bar{1}]$ and $[\bar{2}11]$ seeding orientations, however, the material anisotropy has only a limited effect, while the geometric (facet formation) has a much stronger effect. Our results suggest that for faceted crystals, it is much more important to take the geometric effect into account, while neglecting the material anisotropy is justified. Finally, the methodology used in this paper is not limited to the case of Cz crystals.

It can be applied to other elastic problems, such as the ones investigated in [7, 14], by including the effect of an anisotropic material property.

Appendix A. Proof of (3.7). We begin by introducing the weighted direct sum Hilbert space

$$\overset{\circ}{\mathcal{H}} = \left\{ \mathbf{w} \in \left(H^1(\Omega)\right)^3 : \int_\Omega \mathbf{w} \,\mathrm{d}V = \mathbf{0}, \int_\Omega \operatorname{rot}(\mathbf{w}) \,\mathrm{d}V = \mathbf{0}, \|\mathbf{w}\|^2_{\overset{\circ}{\mathcal{H}}} = \sum_{i=1}^{6} \lambda_i \|e_i(\mathbf{w})\|_0^2 \right\}$$

on the bounded domain Ω. $\|\cdot\|_0$ denotes the standard L^2 norm, and the quantity $\mathbf{e}(\mathbf{w})$ consists of elements of the strain tensor associated with the displacement $\mathbf{w}$. The weights λ_i take on the value $C_{11}-C_{12}+H/2$ for $i=1,2,3$ and $C_{44}-H/4$ for $i=4,5,6$ with $H = 2C_{44} - C_{11} + C_{12} \neq 0$ for an anisotropic, cubic material. In Cartesian coordinates, $\mathbf{e}(\mathbf{w}) = (e_{xx}, e_{yy}, e_{zz}, 2e_{yz}, 2e_{xz}, 2e_{xy})^{\mathrm{T}}$, where $e_{ij} = (w_{i,j} + w_{j,i})/2$, the comma denoting partial differentiation.

For the uniqueness of (3.3), (3.5), and (3.6), we assume that the displacement solutions to these equations belong to $\overset{\circ}{\mathcal{H}}$.

Lemma A.1. *For an anisotropic cubic material characterized by the stiffness values* $\{C_{11}, C_{12}, C_{44}\}$*, the quantity*

$$\omega = \frac{|2C_{44} - C_{11} + C_{12}|}{2C_{44} + C_{11} - C_{12}}$$

satisfies $0 < \omega < 1$.

Proof. The eigenvalues of the stiffness matrix $C_{11}+2C_{12}$, $C_{11}-C_{12}$, and C_{44} must be positive, for otherwise the crystal would be unstable [10]. Due to the positivity constraint, we have the strict inequalities

$$-2C_{44} - C_{11} + C_{12} < 2C_{44} - C_{11} + C_{12} < 2C_{44} + C_{11} - C_{12}$$

so that $|2C_{44} - C_{11} + C_{12}| < 2C_{44} + C_{11} - C_{12}$ or $\omega < 1$. The case $\omega = 0$ corresponds to an isotropic crystal. □

The space $\overset{\circ}{\mathcal{H}}$ is the natural choice for an anisotropic cubic crystal. The next lemma states that convergence in $\overset{\circ}{\mathcal{H}}$ is equivalent to convergence in $(H^1)^3$.

Lemma A.2. $\|\cdot\|_{\overset{\circ}{\mathcal{H}}}$ *is equivalent to* $\|\cdot\|_1$ *(the* $(H^1)^3$ *norm) in* $\overset{\circ}{\mathcal{H}}$.

Proof. This is a direct consequence of the Korn inequality [4],

$$\|\mathbf{w}\|_1^2 \le C(\Omega) \left(\sum_{i=1}^{6} \|e_i(\mathbf{w})\|_0^2 \right) \quad \forall \mathbf{w} \in \overset{\circ}{\mathcal{H}},$$

where $C(\Omega)$ is a constant depending only on the domain Ω. □

Next we illustrate that the operator $\mathcal{N}$ is a contraction mapping on $\overset{\circ}{\mathcal{H}}$.

Lemma A.3. *The operator* $\mathcal{N}$ *in* (3.7) *satisfies* $\|\mathcal{N}\|_{\overset{\circ}{\mathcal{H}} \mapsto \overset{\circ}{\mathcal{H}}} \le \omega < 1$.

Proof. For any given $\mathbf{u} \in \overset{\circ}{\mathcal{H}}$, let $\mathbf{w} = \mathcal{N}\mathbf{u}$. Using the boundary condition in the definition of $\mathcal{N}$, we see that $\mathbf{w}$ satisfies

$$\int_\Omega C^0_{ij} e_i(\mathbf{w}) e_j(\mathbf{v}) \,\mathrm{d}V = \int_\Omega C^a_{ij} e_i(\mathbf{u}) e_j(\mathbf{v}) \,\mathrm{d}V \quad \forall \mathbf{v} \in \overset{\circ}{\mathcal{H}},$$

and in particular for $\mathbf{v} = \mathbf{w}$,

$$\int_\Omega C^0_{ij} e_i(\mathbf{w}) e_j(\mathbf{w})\, \mathrm{d}V = \int_\Omega C^a_{ij} e_i(\mathbf{u}) e_j(\mathbf{w})\, \mathrm{d}V. \tag{A.1}$$

Taking only the diagonal terms of the left-hand side of (A.1) yields

$$\int_\Omega C^0_{ij} e_i(\mathbf{w}) e_j(\mathbf{w})\, \mathrm{d}V \geq \int_\Omega \sum_{k=1}^{6} \lambda_k e_k^2(\mathbf{w})\, \mathrm{d}V = \|\mathbf{w}\|^2_{\overset{\circ}{\mathcal{H}}}, \tag{A.2}$$

while noting that C^a is itself diagonal gives

$$\int_\Omega C^a_{ij} e_i(\mathbf{u}) e_j(\mathbf{w})\, \mathrm{d}V \leq \int_\Omega \left(\sum_{k=1}^{3} \left| \frac{H}{2} e_k(\mathbf{u}) e_k(\mathbf{w}) \right| + \sum_{k=4}^{6} \left| \frac{H}{4} e_k(\mathbf{u}) e_k(\mathbf{w}) \right| \right) \mathrm{d}V. \tag{A.3}$$

Using the definitions of ω and H, one has

$$\omega = \frac{|H/2|}{C_{11} - C_{12} + H/2} = \frac{|H/4|}{C_{44} - H/4}$$

so that estimates (A.2) and (A.3) with (A.1) allow us to conclude, with Hölder's inequality, that

$$\|\mathbf{w}\|^2_{\overset{\circ}{\mathcal{H}}} \leq \omega \|\mathbf{w}\|_{\overset{\circ}{\mathcal{H}}} \|\mathbf{u}\|_{\overset{\circ}{\mathcal{H}}}$$

or $\|\mathbf{w}\|_{\overset{\circ}{\mathcal{H}}} \leq \omega \|\mathbf{u}\|_{\overset{\circ}{\mathcal{H}}}$ for any given $\mathbf{u} \in \overset{\circ}{\mathcal{H}}$. Using Lemma A.1, $\|\mathcal{N}\|_{\overset{\circ}{\mathcal{H}} \mapsto \overset{\circ}{\mathcal{H}}} \leq \omega < 1$. □

PROPOSITION A.4. *Let* $\mathbf{s}_n = \mathbf{w}_0 + \mathcal{N}\mathbf{w}_0 + \mathcal{N}^2\mathbf{w}_0 + \cdots + \mathcal{N}^n\mathbf{w}_0$, *with* $\mathbf{s}_0 = \mathbf{w}_0$. *Expression* (3.7) *converges to* $\mathbf{w}$ *in* $\overset{\circ}{\mathcal{H}}$, *and*

$$\|\mathbf{w} - \mathbf{s}_n\|_{\overset{\circ}{\mathcal{H}}} \leq \omega^{n+1} \|\mathbf{w}\|_{\overset{\circ}{\mathcal{H}}}.$$

Proof. Lemma A.3 implies that the right-hand side of (3.7) converges. What remains is to show that $\mathbf{w}$ is in fact the limit. We note that

$$\begin{aligned} \mathcal{L}^0(\mathbf{w} - \mathbf{w}_0) &= \mathcal{L}(\mathbf{w}) + \mathcal{L}^a(\mathbf{w}) - \mathbf{F} = \mathcal{L}^a(\mathbf{w}), && \mathbf{x} \in \Omega, \quad t > 0, \\ \mathcal{B}^0(\mathbf{w} - \mathbf{w}_0) &= \mathcal{B}(\mathbf{w}) + \mathcal{B}^a(\mathbf{w}) - \mathbf{g} = \mathcal{B}^a(\mathbf{w}), && r = R(\phi, z). \end{aligned}$$

By the definition of $\mathcal{N}$, one has $\mathbf{w} - \mathbf{w}_0 = \mathcal{N}\mathbf{w}$ and $\|\mathbf{w} - \mathbf{w}_0\| = \|\mathcal{N}\mathbf{w}\| \leq \omega \|\mathbf{w}\|$. $\mathbf{w} - \mathbf{s}_n = \mathcal{N}(\mathbf{w} - \mathbf{s}_{n-1})$ gives $\|\mathbf{w} - \mathbf{s}_n\| \leq \omega \|\mathbf{w} - \mathbf{s}_{n-1}\|$ with all norms taken in $\overset{\circ}{\mathcal{H}}$. By induction on n

$$\|\mathbf{w} - \mathbf{s}_n\|_{\overset{\circ}{\mathcal{H}}} \leq \omega^{n+1} \|\mathbf{w}\|_{\overset{\circ}{\mathcal{H}}} \quad \forall n \geq 0$$

so that letting $n \to \infty$ and using Lemma A.3 gives the result. □

Appendix B. Detailed form of $C_{\mathbf{cyc}}$. For the $[\bar{1}\bar{1}\bar{1}]$ pulling direction we obtain $C^{a,[\bar{1}\bar{1}\bar{1}]}_{\text{cyc}} = C^{a,[\bar{1}\bar{1}\bar{1}]}_{\text{cyc},0} + C^{a,[\bar{1}\bar{1}\bar{1}]}_{\text{cyc},3}$, where

$$C^{a,[\bar{1}\bar{1}\bar{1}]}_{\text{cyc},0} = \frac{H}{12}\begin{pmatrix} 0 & 2 & 4 & 0 & 0 & 0 \\ 2 & 0 & 4 & 0 & 0 & 0 \\ 4 & 4 & -2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \end{pmatrix}, \tag{B.1a}$$

$$C^{a,[\bar{1}\bar{1}\bar{1}]}_{\text{cyc},3} = \frac{\sqrt{2}H}{6}\begin{pmatrix} 0 & 0 & 0 & s_3 & -c_3 & 0 \\ 0 & 0 & 0 & -s_3 & c_3 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ s_3 & -s_3 & 0 & 0 & 0 & c_3 \\ -c_3 & c_3 & 0 & 0 & 0 & s_3 \\ 0 & 0 & 0 & c_3 & s_3 & 0 \end{pmatrix}. \tag{B.1b}$$

For the [001] pulling direction, $C^{a,[001]}_{\text{cyc}} = C^{a,[001]}_{\text{cyc},0} + C^{a,[001]}_{\text{cyc},4}$, where

$$C^{a,[001]}_{\text{cyc},0} = \frac{H}{4}\begin{pmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{B.2a}$$

$$C^{a,[001]}_{\text{cyc},4} = \frac{H}{4}\begin{pmatrix} c_4 & -c_4 & 0 & 0 & 0 & -s_4 \\ -c_4 & c_4 & 0 & 0 & 0 & s_4 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ -s_4 & s_4 & 0 & 0 & 0 & -c_4 \end{pmatrix}. \tag{B.2b}$$

Finally, for the $[\bar{2}11]$ pulling direction, $C^{a,[\bar{2}11]}_{\text{cyc}} = C^{a,[\bar{2}11]}_{\text{cyc},0} + C^{a,[\bar{2}11]}_{\text{cyc},1} + C^{a,[\bar{2}11]}_{\text{cyc},2} + C^{a,[\bar{2}11]}_{\text{cyc},3} + C^{a,[\bar{2}11]}_{\text{cyc},4}$, where

$$C^{a,[\bar{2}11]}_{\text{cyc},0} = \frac{H}{16}\begin{pmatrix} 1 & 3 & 4 & 0 & 0 & 0 \\ 3 & 1 & 4 & 0 & 0 & 0 \\ 4 & 4 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 \end{pmatrix}, \tag{B.3a}$$

$$C^{a,[\bar{2}11]}_{\text{cyc},1} = \frac{\sqrt{2}H}{24}\begin{pmatrix} 0 & 0 & 0 & -s_1 & 3c_1 & 0 \\ 0 & 0 & 0 & -3s_1 & c_1 & 0 \\ 0 & 0 & 0 & 4s_1 & -4c_1 & 0 \\ -s_1 & -3s_1 & 4s_1 & 0 & 0 & c_1 \\ 3c_1 & c_1 & -4c_1 & 0 & 0 & -s_1 \\ 0 & 0 & 0 & c_1 & -s_1 & 0 \end{pmatrix}, \tag{B.3b}$$

$$C^{a,[\bar{2}11]}_{\mathrm{cyc},2} = \frac{H}{24}\begin{pmatrix} -2c_2 & 0 & 2c_2 & 0 & 0 & s_2 \\ 0 & 2c_2 & -2c_2 & 0 & 0 & s_2 \\ 2c_2 & -2c_2 & 0 & 0 & 0 & -2s_2 \\ 0 & 0 & 0 & -2c_2 & -2s_2 & 0 \\ 0 & 0 & 0 & -2s_2 & 2c_2 & 0 \\ s_2 & s_2 & -2s_2 & 0 & 0 & 0 \end{pmatrix}, \tag{B.3c}$$

A CONTINUUM MODEL FOR A CHUTE FLOW OF GRAINS*

A. S. ELLIS† AND F. T. SMITH†

Abstract. This paper is motivated by a problem from the food-sorting industry and is concerned with the development of a continuum model for a chute flow of grains, based on analogies with the Lighthill–Whitham model of traffic flow. A fundamental relationship between the density and the flux is proposed which is multivalued due to the fact that grains can move leftwards and rightwards across the chute. The subsequent implications are discussed in detail. Results are presented first by solving with a method of characteristics and second by solving analytically and numerically after including a viscous dissipation term to smooth out discontinuities. The fundamental diagram is revisited in view of the viscous dissipation term and a substantial modification at the cusps is found necessary to allow physically sensible solutions to emerge. If the viscous dissipation is small, then in general the viscous effects also are small. Exceptions, however, are shocks, where the viscosity has a smoothing effect, as is well known, and two new features/observations: crossovers, which allow two-way solutions, and steady states, which can exist only in the viscous case and appear over a long time scale.

Key words. wave equation, shocks and related discontinuities, granular flows

1. Introduction.

The aim of this paper is to define and explore a mathematical model for the nearly two-dimensional (2D), gravity-driven, rapid flow of a monolayer of grains down an inclined chute. This is directly motivated by a problem from the food-sorting industry, in particular from a company that manufactures machines for the sorting of food, Sortex Ltd.

In the particular food-sorting process developed by Sortex, grains fall from a hopper and are subsequently moved along by a vibrator tray. At the end of the tray the grains fall onto an inclined chute, down which they are accelerated due to gravity. They quickly form an apparent 2D monolayer upon the chute. Shortly after the grains have fallen from the bottom of the chute they pass an optical system that can detect defective grains. A grain is considered to be defective if it is, for example, of the wrong size, shape, or color. Foreign bodies, such as small shards of glass, can also be detected. If a defective grain or foreign body is detected, a powerful jet of air is fired from at least one ejector in an array of ejectors, and the grain is knocked into a reject bucket by the force of the impact. A schematic diagram of the process is shown in Figure 1.1. Studies of the ejector and jet properties are in theses by Westwood [16] and Wilson [18].

The chute is approximately 30cm wide and a meter in length, and its angle of inclination from the vertical is 30°. The grains exit the chute with a vertical velocity of the order of 4–5ms^{-1}. A typical grain of rice has a width of 1–3mm and a length of 5–7mm. The mass has a magnitude of roughly 10^{-5}kg.

Particular difficulties arise as the grains fall off the chute, since they are not uniformly distributed but typically clustered and inhomogeneous. As a consequence, the air jet can, and usually does, remove other grains of rice surrounding the target

grain which may not themselves be defective. This is a source of inefficiency in the food-sorting process; the grains in the reject bucket sometimes must be sorted through again to reduce waste. Currently, the optical system can be configured to yield an increased sorting performance, but if a high level of sorting is required a chute with channels must be used; these align the grains with the ejectors and improve the uniformity of the product feed. There is, however, a concomitant reduction in the mass of grains that can be sorted in a given time (known as the "throughput"). The main goal is to increase uniformity of "product feed" as much as possible while maintaining a high throughput of grains. In the current work we therefore try to find a suitable mathematical model for a chute flow of grains so that the above issue regarding ejection can be better treated.

As there is no general theory applicable to chute flows of grains, we necessarily develop a theory from modeling the process from first principles. Other attempts have been made, notably the approach of Jenkins and Savage [9], who describe a *kinetic theory* of the particle motion, whereas after consideration we choose to develop a *continuum description* of the chute flow. It may seem unusual to model an inherently discrete process with a continuum model, but there is a strong and successful history of doing so in other particulate flow problems. For example, continuum models have been used to model traffic and pedestrian flows [7], [8], [10], [11], [12] and many aspects of granular flows; see, for example, the review by Rajchenbach [14] and the works of Aranson and Tsimring [1], [2] and Grossman, Zhou, and Ben-Naim [6] and the references therein, to name but a few. The particulate nature of the problem can be essentially overlooked by addressing larger macroscale behavior and assuming that quantities such as density are continuous. It is then possible to write hydrodynamic-like equations that govern the overall particulate motion. For example, Hughes [7] used a continuum theory of pedestrian flows to suggest a method of safely placing barriers to prevent tragic events as pilgrims cross the bridge of Jamarat in Mecca, and Lighthill and Whitham [11] used a continuum theory of kinematic waves to describe traffic flow. Their results explain well-observed phenomena such as traffic jams at traffic lights and density waves in moving vehicular flow. In this paper we extend the Lighthill–Whitham theory of traffic flow to produce a description of a chute flow.

The structure of the paper is as follows. Basic modeling and simple analytic solutions are dealt with first in sections 2 and 3, including descriptions of separating grains and clashing grains. Next in section 4 more general solutions are sought numerically, and we shall see that this necessitates the introduction of a viscous dissipation term into the governing equations, and that these solutions compare well to those found from the inviscid theory. In section 5 it is demonstrated that in principle two-way solutions can exist for the viscous model in which the grains move both left and right across the chute. Steady states are discussed in section 6 before concluding remarks are made in section 7.

2. Continuum modeling. The continuum model below is based on an argument for extending the Lighthill–Whitham model of traffic flow to cover aspects of the chute flow. Strengths and weaknesses of the argument are described. In particular, the continuum model we propose requires the introduction of a fundamental relation between the nondimensional flux q and the nondimensional density ρ, and the underlying physical mechanism requires discussion. The variables are nondimensionalized as follows: $x^* = a^*x$, $y^* = L^*y$, $v^* = V^*v$, $u^* = U^*u$, $t^* = (a^*/U^*)t$, $\rho^* = (M^*/a^*)\rho$, and $q^* = (M^*U^*/a^*)q$. Here variables with an asterisk are dimensional and variables without an asterisk are nondimensional. The parameters are defined so that a^* is the distance across the chute; L^* is the distance down the chute; V^* is a typical vertical velocity given by $\sqrt{g^*h^*}$, say, where h^* is distance fallen down the chute and g^* is the acceleration due to gravity; finally U^* is a typical velocity across the chute. We follow through the implications of the proposed flux-density relation in detail and an appraisal is given in the conclusion. We cannot deny that the model omits many factors, and as such is incomplete, as would be any first model. In a sense, the approach is an empirical one, and we shall examine whether the model can describe some special situations seen on chutes in reality, although the original physical arguments per se may remain open to question.

We make the assumption that the density of rice grains, ρ, forms a continuum and that the grains move along a horizontal line (the x axis) with a flow rate q. The lines are considered to fall down the chute with increasing time t, their vertical displacement being given by $y^* = -g^*{t^*}^2$ (the grains are assumed to have a vertical speed $v^* = 0$ at the top of the chute where $y^* = 0$). Although the assumption of grain motion occurring only in horizontal lines appears simplistic, because in reality vertical interactions could be expected to be an important mechanism of the flow, as noted below, computations with this assumption achieve physically reasonable results as qualitatively they show the development of clusters and voids which are seen in experiments [5]. Moreover, the one-dimensional (1D) model itself is found to contain some rich and complex behavior suggesting that to try to start immediately with a 2D model might be premature.

In addition to the a posteriori motivation for modeling grain motion along a horizontal line, mentioned above, there exists a priori justification for doing so which is as follows. We shall see shortly that the spatially 2D extension, which includes vertical grain motion, reduces to the 1D model of present interest *at large distances* *down the chute* (see (2.4) below). Primarily we are interested in obtaining the density profile *at the bottom of the chute*, where the ejection issue occurs. Given that the 2D model reduces to the 1D model in the lower portion of the chute, then it seems appropriate to use the 1D equation, at least as a first approximation. In fact, the interest and novelty in this work lie in the perhaps surprising result that the horizontal grain motion is seen to dominate the flow behavior, rather than the vertical motion of grains down the chute. The reason for the existence of horizontal grain motion is described later, but briefly it is due to the action of the vibrator tray.

A continuum model for this discrete process is believed justifiable since in reality a state can evolve on the chute where the grains form into large coalesced masses, each one moving as if it is one body with a particular velocity distribution and each one containing a large number of grains. The density of these masses may be different in each case and as there are large numbers of grains the density could take any value. When the flow is in this state there are sudden jumps in density between each cluster and there can also be voids. We shall see that this can be modeled by the shocks and expansion fans in the continuum model and thus the model provides qualitative agreement with experiments, which do indeed indicate the formation of clusters and voids.

By conservation of mass the continuity equation is

$$\rho_t + q_x = 0. \tag{2.1}$$

Taking q to depend only on ρ keeps the wave problem simple as a first approximation and may also be justified on physical grounds, and if $q_\rho \equiv \frac{dx}{dt}$, then the total derivative $\frac{d\rho}{dt} = 0$. Defining the wavespeed $q_\rho \equiv c\,(\rho)$, the density is constant along straight characteristics given by

$$x = c\,(\rho)\,t + x_0, \tag{2.2}$$

where x_0 is a constant of integration representing an initial position for x. The resultant equation for the flow is

$$\rho_t + c\,(\rho)\,\rho_x = 0. \tag{2.3}$$

Therefore an initial density distribution $\rho = f\,(x)$ at $t = 0$ determines in principle the density evolution with time via the characteristics.

To determine $c\,(\rho)$ we argue that the flux q is related to the density ρ by $q = Q\,(\rho)$ say and then $c\,(\rho) = Q'\,(\rho)$, where the prime denotes differentiation with respect to the argument. (We shall discuss shortly the validity of choosing a particular $q = Q(\rho)$ relation.) We must also initially specify q along each characteristic. The values (ρ, q) in the initial condition thus determine a unique value of c which in turn determines the gradient of the characteristic. The flux and the density are then constant along the characteristic, i.e., both q and ρ are propagated along the characteristics. The initial conditions in the current section are piecewise-constant as these provide a basic starting point for the analysis.

An important point concerning improvement and extension is to make the model spatially 2D, the 2D equation being

$$\rho_t + c_1(\rho)\rho_x + c_2(\rho)\rho_y = 0, \tag{2.4}$$

where y is the vertical distance down the chute. Seeking a solution independent of y as $y \to \infty$ leads back to the 1D model of (2.3), however. Thus the 1D model of

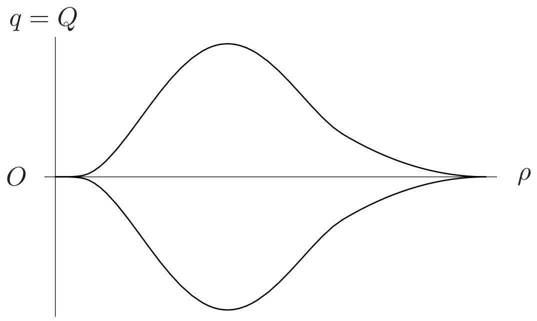

Fig. 2.1. *Sketch of the fundamental diagram, including the cusps at $q = \rho = 0$ and at $q = 0$, $\rho = \rho_M$ and the inflexion points relatively nearby.*

present interest evolves directly from the 2D case at large times or sufficiently large distances down the chute. This justifies a priori the assumption of horizontal grain motion.

We propose below a particular $Q(\rho)$ relation for the chute flow (see Figure 2.1); the validity of the proposition is discussed shortly. Note that, borrowing from traffic flow theories, the $Q(\rho)$ curve is known as the fundamental diagram or fundamental curve. If $\rho = 0$, there can be no flow, so then $q = 0$ trivially. Further, it is argued that there is no flow for a maximum value ρ_M of the density, corresponding to a "jamming" of grains across the chute where each grain is touching the neighboring grain or wall and hence, within some interval of at least x, there is no room for any grain to move relatively across the chute. In between q takes a single maximum at some value of the density ρ_F. However, the rice can travel in both directions (unlike the traffic flow case) and hence q can also take negative values (of the same magnitude by virtue of symmetry) for each value of ρ. The reason for this bidirectional grain motion is as follows. Before the grains fall down the chute, they are transported along a vibrator tray. As they fall off the vibrator tray, its motion induces horizontal velocity fluctuations. Hence, as they travel down the chute, grains can collide, which induces further horizontal velocity fluctuations, or they can separate. Thus there are two branches of the fundamental diagram, one which describes leftward-moving grains and the other rightward-moving grains, and so the flux-density relation is necessarily double-valued.

Finally here, the $Q\,(\rho)$ curve on each branch is expected to pass through inflexion points relatively near the cusps, which lie at the zero-q end of the branches. The two branches meet at cusps so that the wavespeed remains finite and smooth as the solution passes through the endpoints and switches branches; they also allow mass-conserving shock-fan structures, as we shall see later, which enable physically acceptable descriptions of clashing and separating regions to develop. In more detail, the cusps must behave locally as

$$q \propto \pm\rho^{\frac{3}{2}} \text{ near } \rho = 0 \tag{2.5a}$$

or

$$q \propto \pm(\rho_M - \rho)^{\frac{3}{2}} \text{ near } \rho = \rho_M. \tag{2.5b}$$

To see this consider putting $\rho = f(\mu)$, where $\mu = \frac{x}{t}$ is a similarity variable. The governing equation is then satisfied provided that

$$(c - \mu)f' = 0; \tag{2.6}$$

so $\mu = c$ is allowed, which produces expansion fans. Next, at the high-density endpoint (the reasoning applies equally to the zero-density endpoint) consider having locally

$$q = \pm\beta(\rho_M - \rho)^n \tag{2.7}$$

with the unknown power $n > 0$ and the constant β being nonzero. Via the definition of c we obtain from (2.7) the local behavior

$$\rho = \rho_M - \left(\frac{|\mu|}{\beta n}\right)^{\frac{1}{n-1}}. \tag{2.8}$$

Consequently the relation $\frac{1}{n-1} = M$ must hold with M an even integer in order that the wavespeed varies smoothly as the density passes through its maximum. Hence $n = 1 + \frac{1}{M}$. In particular, the value

$$n = \frac{3}{2} \tag{2.9}$$

corresponds to $M = 2$ and the density $\rho = \rho_M - (\frac{|\mu|}{\beta n})^2$, which would be expected to be the most general case. Similar reasoning for a cusp also applies at the low-density end. The fundamental curve's upper branch must therefore be concave upwards at its endpoints. It follows also that for there to be a maximum q in between, *inflexion points* must be produced between the maximum and the endpoints. The only alternative to having cusps, while retaining a smooth wavespeed as the solution switches branches, would be to have an infinite wavespeed at the endpoints, which is physically unacceptable. Flux functions with inflexion points also arise in traffic flow theory; see, for example, Lebacque and Khoshyaran [10] or Morgan [12].

Concerning strengths and weaknesses of the present proposed fundamental diagram, in pedestrian and traffic flows there are obvious physical reasons why people or cars slow down with increased density (overcrowding, driver nervousness, and so on), whereas it is difficult to provide a comprehensive argument as to why, for example, a densely packed region of grains may move more slowly than a sparser region as in the cases here. This difficulty could be countered by arguing that, when the densities are low, grains may have small horizontal velocities because there is a smaller probability of velocities being induced impulsively by a collision. At large densities, however, collisions are likely to be very numerous and thus grain speeds would reduce as energy would be lost repeatedly at each collision. At moderate densities the probability of a collision lies somewhere in between these two extremes and so horizontal velocities may be induced impulsively by a collision, but there may not be so many repeated collisions as to cause a continual reduction in the velocity component via restitution, so that the magnitude of the horizontal velocities may be larger. In the extreme case of a blockage the grains would come to a complete stop and may become packed at the jammed density. Thus a situation arises in which the density influences the flux, or vice versa, and the view that $q = Q(\rho)$ appears to be justified (at least as a first approximation). Further, owing to these simple arguments, a shape of such a fundamental curve similar to the one proposed above seems to be suggested. Alternatively, we could argue that such a choice of fundamental diagram is appropriate for certain physical situations, such as with colliding or separating grains on a chute. It may be of significance here that at a collision the grains can be considered to instantaneously change velocity at the point of touching, and so the flux of the grains is zero when the density is maximal, exactly as in the proposed fundamental diagram. Other situations, such as with a highly dense region moving rapidly on an otherwise empty chute, should be covered by another fundamental diagram, but such a situation may be unlikely to develop in practice because high densities seem more likely to arise when grain speeds are slow. It is also worth mentioning that as clusters and voids are the key feature of the computational results [5] and as collisions and separations are believed to be the crucial mechanism behind the formation of clusters and voids, then this aspect of the flow may be the most pertinent part to consider in an initial model. Some of the above criticisms may also hold for the theory when it is applied to traffic flow: for example, a densely packed region of cars on an otherwise empty highway will not in reality have $q = 0$; they may accelerate away and diffuse.

Given the above setting, we continue with the present 1D formulation and, in brief, examine the outcome.

3. Inviscid solutions. Interesting aspects arise in the model because $Q(\rho)$ is smoothly varying on each branch and so the characteristics generally intersect or diverge within a finite time if ρ and q vary on each characteristic. Intersections are a significant feature since the density is implied as multivalued. Such an apparent contradiction is resolved by the formation of a “shock” (see Whitham [17]) which travels with velocity

$$U = \frac{q_2 - q_1}{\rho_2 - \rho_1}, \tag{3.1}$$

which is the gradient of the chord between (ρ_1, q_1) and (ρ_2, q_2) on the fundamental curve. Diverging characteristics potentially create an area devoid of information about the density but lead to an “expansion fan.” The aim in what follows is to employ the shock wave and expansion fan structures as mechanisms to obtain inhomogeneous density distributions upon the chute and provide some further explanation of clusters and voids when grains are colliding or separating.

A number of simple analytical solutions are illustrated here. We shall see that it is possible to build increasingly complex solutions to the continuum model. In theory, it is possible to determine any solution analytically by examining the characteristics, together with the shocks and fans. The approach is much the same as that of Morgan [12], the difference here being the multivalued fundamental diagram.

Let us first define ρ_F as the value of the density for which q is maximum; ρ_{IR} as the value of the density at the right-hand inflexion point; and ρ_{IL} as the value of the density at the left-hand inflexion point.

3.1. Example solution one. We start simply with a classical example [4] in which a shock must occur. Consider two adjacent regions of constant density, one with density ρ_1 and the other with density ρ_2, and allow $\rho_1 < \rho_2 < \rho_F$. The corresponding values of the flux are q_1 and q_2, respectively, with $0 < q_1 < q_2 < q_F$. It is possible to choose this arrangement such that $c_1 > c_2$; see Figure 3.1 for clarity.

Furthermore, if the region of density ρ_1 is assumed to lie to the left of the region of density ρ_2, as depicted in Figure 3.2(a), then the characteristics are seen to intersect in the $x - t$ plane. As has already been stated, the density at first glance would be multivalued at such an intersection since the density is a different constant along each intersecting characteristic. This would be physically unacceptable.

The resolution is well known, namely, to replace the intersecting points with a shock, i.e., a sudden jump in the density. In this way, we see that the correct $x - t$

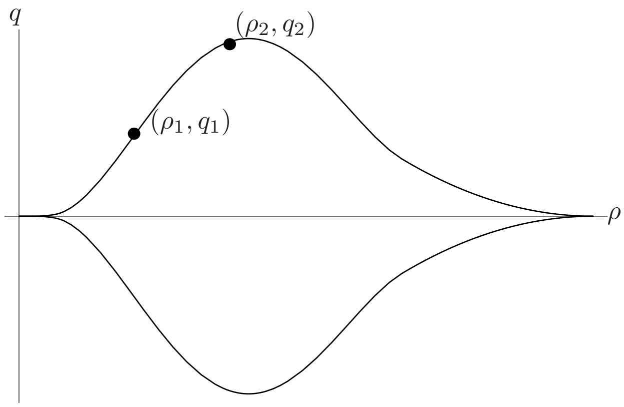

FIG. 3.1. *Illustration highlighting the values of* (ρ_1, q_1), (ρ_2, q_2) *for the case producing a shock outlined in section* 3.1. *The respective slopes of the tangents at* (ρ_1, q_1) *and* (ρ_2, q_2) *are* c_1 *and* c_2.

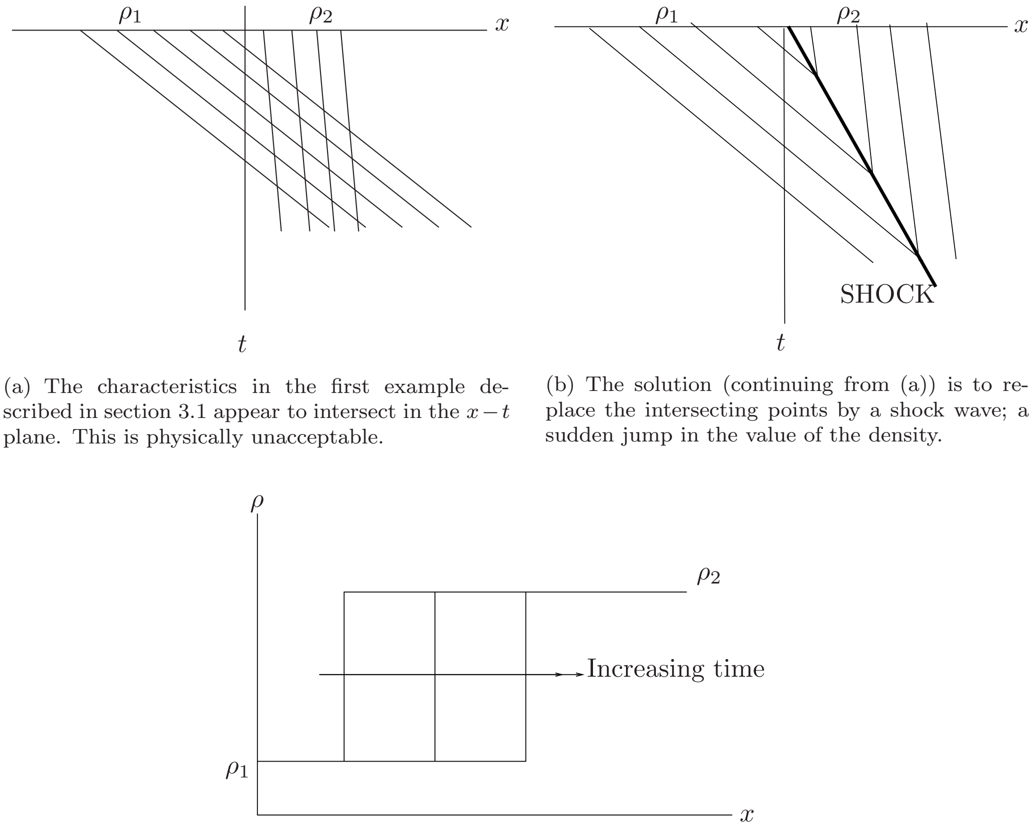

(a) The characteristics in the first example described in section 3.1 appear to intersect in the $x - t$ plane. This is physically unacceptable.

(b) The solution (continuing from (a)) is to replace the intersecting points by a shock wave; a sudden jump in the value of the density.

(c) The corresponding density profile is shown above as it evolves over time. The two regions translate rightwards, separated by a shock.

FIG. 3.2. *Shock formation.*

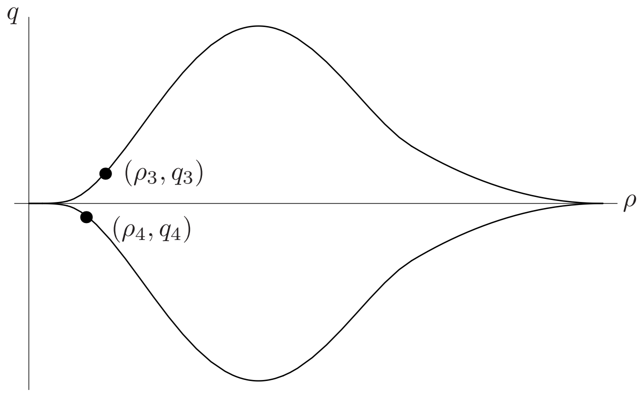

FIG. 3.3. *Illustration highlighting the values of* (ρ_3, q_3), (ρ_4, q_4) *for the case of the "fan" outlined in section* 3.2.

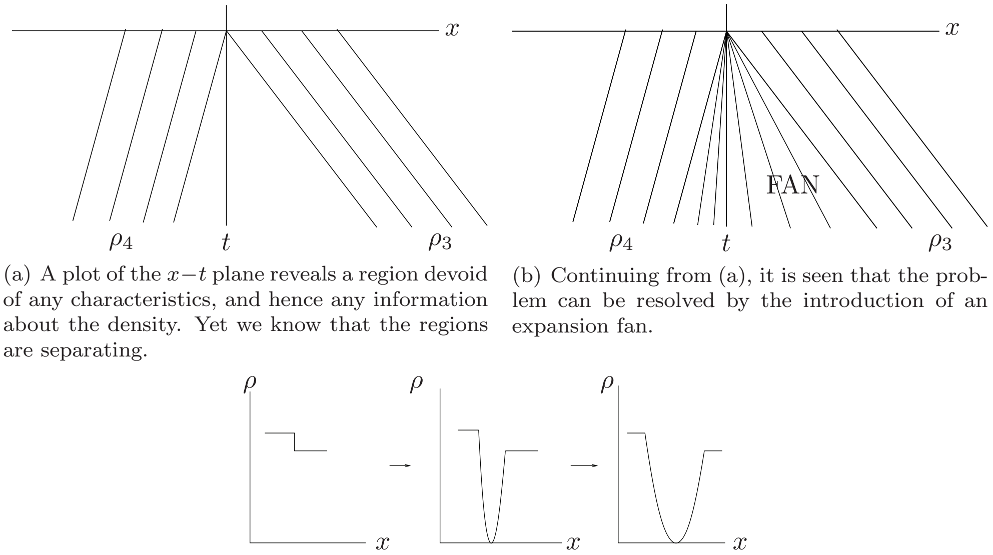
diagram for this case is as in Figure 3.2(b), in which two regions of constant density are separated by a shock.

The corresponding evolution of the density profile is as in Figure 3.2(c). Both regions are moving rightward (as $q > 0$) and there is a translating shock between the two regions.

3.2. Example solution two. Similarly, a scenario which involves an expansion fan is as follows. Again consider two adjacent regions of constant density, one with density ρ_3 and the other with density ρ_4, where the corresponding values of the flux are q_3 and q_4, respectively. However, now suppose that $q_3 > 0$, $q_4 < 0$, and $\rho_4 < \rho_3 < \rho_{IL}$. Thus $c_3 > 0$, $c_4 < 0$, and $|c_3| > |c_4|$; see Figure 3.3. (If $\rho_{IL} < \rho_3 < \rho_4 < \rho_F$, then the solution is a little more complex, as we shall see in a later example.) The region with density ρ_3 is assumed to lie to the right of the region with density ρ_4, as in Figure 3.4(a). Such an arrangement corresponds to the two regions moving apart since $q > 0$ in the right-hand region and $q < 0$ in the left-hand region, and in the $x - t$ diagram there is seen to be a region devoid of characteristics. Consequently, there appears to be no information about the density evolution here, yet we know that the regions are separating. The problem can be resolved by the introduction of an expansion fan.

An expansion fan is a region of characteristics which all start from the same point, but their gradient continuously changes from the value of the gradient of the characteristic in the right-hand region to the gradient of the characteristic in the left-hand region. Hence the void region is now replaced by a "fan" of characteristics whose gradients decrease monotonically. As the gradient varies through this fan, so must the density. See Figure 3.4(b). The continual change in the gradient corresponds to moving from the point (ρ_3, q_3) on the upper branch of the $q(\rho)$ curve to the point (ρ_4, q_4) via the cusp at $(0, 0)$. Notice that the characteristic at the center of the fan has zero slope and thus the point of zero density is stationary. Therefore the fan in this case corresponds to a gradual decrease in the density and a reduction in flux to a stationary central point with zero density. This is followed by a gradual increase in the density accompanied by an increase in magnitude of the flux, which is now negative. The expansion fan has allowed the density to *switch* branches. The physical interpretation of this is indeed a separation of the two regions. Figure 3.4(c) illustrates the evolution of the corresponding density profile to highlight the physics.



(a) A plot of the $x-t$ plane reveals a region devoid of any characteristics, and hence any information about the density. Yet we know that the regions are separating.

(b) Continuing from (a), it is seen that the problem can be resolved by the introduction of an expansion fan.

(c) The evolution of the density profile corresponding to the preceding figure shows that the expansion fan captures the physical process of separation.

Fig. 3.4. *The expansion fan solution of the example in section* 3.2.

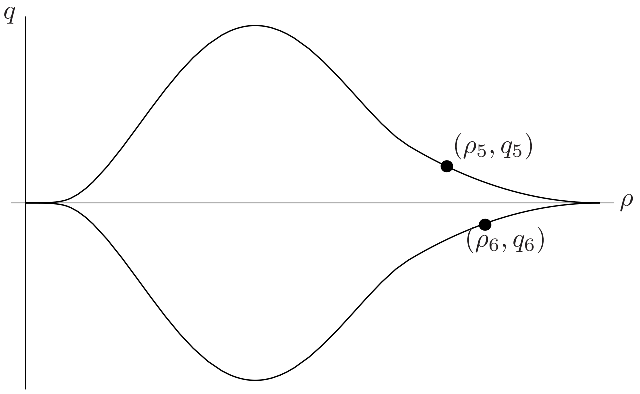


Fig. 3.5. *Illustration highlighting the values of* (ρ_5, q_5), (ρ_6, q_6) *for the example of a fan in a colliding region.*

3.3. Example solution three. This again is a classical problem [4] in which expansion fans arise, this time describing regions of colliding grains. Consider two regions of constant density with $\rho_6 > \rho_5 > \rho_{IR}$ and $q_5 > 0$ and $q_6 < 0$. Now $c_5 < 0$ and $c_6 > 0$ since ρ_5 and ρ_6 lie toward the large density end of the fundamental diagram, as in Figure 3.5. Assuming that the ρ_5 region lies to the left of the ρ_6 region will result in an $x - t$ plot of the characteristics that is qualitatively similar to that in the example above in Figure 3.4. Such an arrangement now corresponds to clashing of grains. Again there will be a region devoid of characteristics where an expansion fan can be introduced. However, in this example, the monotonically decreasing gradient of the characteristics in the fan corresponds to moving along the

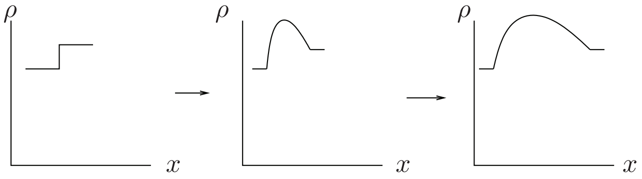

FIG. 3.6. *The corresponding evolution of the density profile for Figure* 3.5 *illustrates the expansion fan capturing the physical process of collision.*

fundamental diagram from (ρ_6, q_6) to (ρ_5, q_5) via the cusp located at $(\rho_M, 0)$. Observe that the characteristic at the center of the fan has zero slope and thus the point of maximal density is stationary.

Thus, moving through the fan from ρ_6 to ρ_5 allows the density to switch branches from the lower branch to the upper branch while passing through a point of maximum density. The fan describes a "hump" of large density at the location where we know that grains are colliding. Figure 3.6 shows the evolution of the density profile to highlight this point.

The expansion fan structures can be described analytically [17]. The characteristics satisfy (2.2) and each characteristic in the fan crosses the x axis at the same point, hence x_0 is the same constant for each one. Therefore we can rearrange (2.2) to find the gradient of each characteristic in the fan as

$$c(\rho) = \frac{x - x_0}{t}. \tag{3.2}$$

Therefore the complete solution for the wavespeed is

$$c = \begin{cases} c_5, & c_5 < \frac{x-x_0}{t}, \\ \frac{x-x_0}{t}, & c_6 < \frac{x-x_0}{t} < c_5, \\ c_6, & \frac{x-x_0}{t} < c_6. \end{cases} \tag{3.3}$$

3.4. Example solution four. A more complex case is illustrated here. Consider two regions of constant density: the right-hand region with $\rho_F < \rho_7 < \rho_{IR}$ and $q_7 < 0$ and the left-hand region with $\rho_F < \rho_8 < \rho_{IR}$ and $q_8 > 0$; see Figure 3.7. Thus $c_7 > 0$ and $c_8 < 0$. If the characteristics are plotted in the $x - t$ plane, there will again be a region devoid of characteristics which we intuitively expect to describe a clashing region.

One simply might expect the solution of this problem to be an expansion fan between (ρ_7, q_7) and (ρ_8, q_8), but it is actually a little more involved, as follows. Since ρ_7 and ρ_8 are to the left of the inflexion point ρ_{IR} the characteristics in an expansion fan would not monotonically decrease from c_7 to c_8. Hence an expansion fan cannot be immediately plotted.

Instead, consideration indicates that there must be a shock from ρ_7 to ρ_{T-} and a shock from ρ_8 to ρ_{T+}, where ρ_{T-} is the point where a chord drawn from (ρ_7, q_7) is tangent to the fundamental curve. Similarly, ρ_{T+} is the point where a chord drawn from (ρ_8, q_8) is tangent to the fundamental curve. This is similar to the approach of Morgan [12]. Both ρ_{T-}, $\rho_{T+} > \rho_{IR}$, clearly. See Figure 3.7. An expansion fan which passes through the cusp at $(\rho_M, 0)$ can now be drawn between ρ_{T-} and ρ_{T+}. Such a "shock-fan-shock" structure will still conserve mass.

Figure 3.8(a) shows the plot of the characteristics in the $x - t$ diagram for this situation, and Figure 3.8(b) depicts the time evolution of the density profile. There

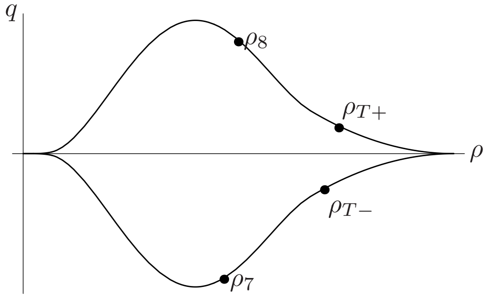

FIG. 3.7. *The values of* (ρ_7, q_7), (ρ_8, q_8), (ρ_{T-}, q_{T-}), (ρ_{T+}, q_{T+}) *for a case including a mix of shocks and fan(s) in a colliding region.*

(b) The corresponding evolution of the density profile is shown for (a).

FIG. 3.8. *The shock-fan-shock structure of the solution in the example in section* 3.4.

is a region of constant density moving leftward, then a shock to a fan where there is a high density region, then a shock down to a region of constant density moving rightward. Thus the characteristics appear to give a solution where a high-density cluster develops, as might be anticipated for a clashing region.

3.5. Example solution five. Shock-fan-shock structures can arise in other situations. Consider $\rho_9 = \rho_7$, $\rho_{10} = \rho_8$ given as in the above case, but now with ρ_{10} lying in the right-hand region and ρ_9 lying in the left-hand region, so that the regions are separating. At first sight, it seems that the characteristics are intersecting and so the solution ought to be a shock. However, if a line were drawn through the intersecting points, the gradient would not be equal to the gradient of the chord between (ρ_9, q_9) and (ρ_{10}, q_{10}); the chord would not have the required speed U (hence such a shock would not conserve mass and moreover, by violating the Rankine–Hugoniot condition, it would not be a weak solution to the conservation law).

The problem is avoided by the introduction of two shocks: one from ρ_9 to ρ_{T2-}, and the other from ρ_{10} to ρ_{T2+}. The point ρ_{T2-} is the place on the fundamental curve where the gradient c_{T2-} is tangent to a chord drawn from ρ_9 such that $\rho_{T2-} < \rho_{IL}$.

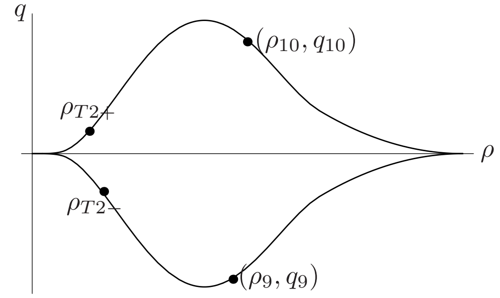

FIG. 3.9. *The values of* (ρ_9, q_9), (ρ_{10}, q_{10}), (ρ_{T2-}, q_{T2-}), (ρ_{T2+}, q_{T2+}) *for a case including a mix of shocks and fan in a separating region.*

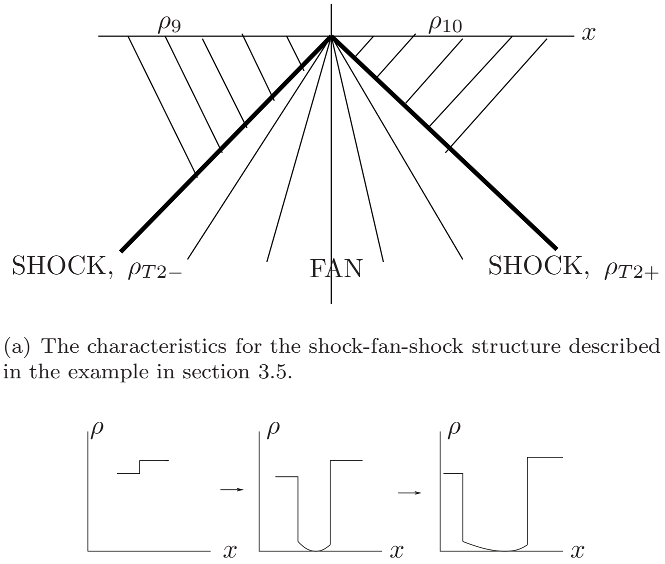

(a) The characteristics for the shock-fan-shock structure described in the example in section 3.5.

(b) A sketch of the time evolution of the density profile for the example of a shock-fan-shock structure when grains are separating.

FIG. 3.10. *The shock-fan-shock structure of the solution in the example in section* 3.5.

Similarly, the point ρ_{T2+} is the place on the fundamental curve where the gradient c_{T2+} is tangent to a chord drawn from ρ_9 such that $\rho_{T2+} < \rho_{IL}$. See Figure 3.9 for details. An expansion fan can now be drawn between ρ_{T2-} and ρ_{T2+} that switches branches through the cusp at zero density. Thus there is a region of constant density moving leftward adjacent to a leftward-translating shock down to small densities. Then there is a fan through zero density that is next to a rightward-moving shock that jumps to large densities; see Figure 3.10. Hence the characteristics here appear to give a solution in which a void develops, as might be anticipated for a separating region.

3.6. Example solution six. It is useful to consider an example with three discontinuous density regions to show the complexity of possible solutions. Thus consider three regions of density ρ_{11}, ρ_{12}, and ρ_{13} as given in Figure 3.11. These are chosen such that $\rho_{IL} < \rho_{11} < \rho_F$ with corresponding $q_{11} > 0$; $\rho_{12} > \rho_{IR}$ with

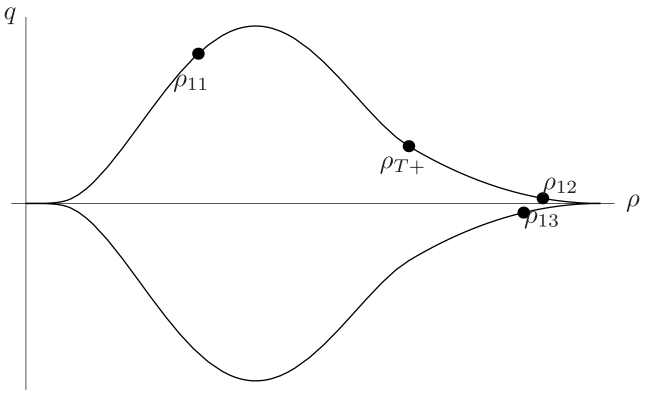

FIG. 3.11. *The important values of ρ_{11}, ρ_{12}, etc., are shown on the fundamental diagram for the example in section* 3.6*, which has three regions of different density.*

corresponding $q_{12} > 0$; and $\rho_{13} > \rho_{IR}$ with corresponding $q_{13} < 0$. We also draw attention to the point ρ_{T+}, which is the point where a chord drawn from (ρ_{11}, q_{11}) is tangent to the fundamental curve on the upper branch. Observe that $\rho_{IL} < \rho_{T+} < \rho_{IR}$ and the chord is the shock s_1.

These three regions are assumed to lie in the $x - t$ plane such that the region of density ρ_{13} lies to the right of the region of density ρ_{12}, which in turn lies to the right of the region of density ρ_{11}. Thus we observe that there is an area of colliding grains between ρ_{13} and ρ_{12}, and consequently an expansion fan is required here. Further consideration shows that a fan is also required at the bottom of the ρ_{12} region to a density with value ρ_{T+}. The characteristic with density ρ_{T+} coincides with the shock s_1 where there is a jump down to density ρ_{11}. Consequently the $x - t$ plane is as shown in Figure 3.12(a), and a schematic representing the evolution of the density profile is shown in Figure 3.12(b).

These examples illustrate how shocks and fans can be used to model clusters and voids. We wish to highlight here that we have observed that there might be cases, for example, where waves of negative speed and positive velocity occur and where waves of positive speed but negative velocity occur. The physical interpretation of this, as in the example in section 3.3, is when two regions collide, causing grains to “pile up” and form a blockage. This is analogous, say, to a traffic jam in a unidirectional traffic flow model. The transition between positive and negative velocities is either grains colliding and hence reversing velocities or grains which are separating due to the initial velocities induced by the vibrator tray. More complex solutions can be constructed in a similar fashion for any number of colliding or separating regions, and interactions with walls may be included. We also remark here that in general a steady state behavior does not set in at, say, large times for the inviscid model, except for ρ, q constant.

A further point for discussion is that the model above could instead be written as

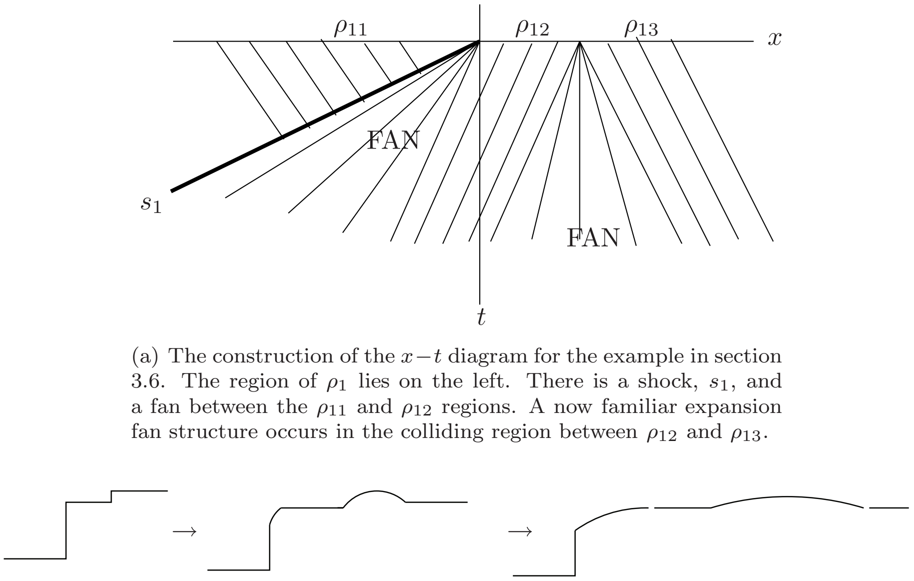
$$\rho_t + Q(q, \rho)_x = 0 \tag{3.4a}$$

and

$$q_t = 0, \tag{3.4b}$$

where

$$Q(q, \rho) = \mathrm{sgn}(\rho) f(\rho), \tag{3.4c}$$



(a) The construction of the $x - t$ diagram for the example in section 3.6. The region of ρ_1 lies on the left. There is a shock, s_1, and a fan between the ρ_{11} and ρ_{12} regions. A now familiar expansion fan structure occurs in the colliding region between ρ_{12} and ρ_{13}.

(b) A sketch of the the evolution of the density profile corresponding to (a). Density is on the vertical axis, and the position across the chute is along the horizontal axis. A shock exists between ρ_{11}, on the left of the chute, and the small fan to the region of density ρ_{12}. A "hump" of high density exists in the colliding region between ρ_{12} and ρ_{13}. As time increases the two fans spread out. The shock on the left persists for all time.

FIG. 3.12. *The solution from the example in section* 3.6*, which involves three regions of different density.*

where f is a classical flux function. The six examples above could be examined in the realm of the above system, which yields a 2×2 conservation law whose Riemann problems can be analyzed. This could form the scope of future work, and we are grateful to a referee for making this observation.

4. Viscous effects. Only examples that have discontinuous initial conditions have so far been investigated. Obviously we would wish to find the long-term density distributions for an arbitrary set of initial conditions, and in particular we would like to solve for problems with continuous initial density distributions. However, owing to the shock wave and expansion fan structures, it is difficult to do this in general, both analytically and computationally.

We now attempt to find such generalized solutions, but in this section we consider only those which *remain always on one branch* of the fundamental diagram, that is, only those situations in which *grain movement is unidirectional* and especially those which are not near the chute walls. (Solutions which require a branch switch, in which grains move to and fro, are dealt with in the following section.)

One standard way to compute general solutions to equations of the above form is to add an artificial viscous dissipation term $\nu\rho_{xx}$, so all discontinuities can be "smoothed out" in principle, as the equation is now parabolic. Indeed, this is the conventional method used in traffic flow problems [13], [17]. Whitham [17] discusses at length the validity of such an approach and shows that in the limit of the viscosity ν tending to zero the solutions do in fact asymptote toward the familiar shock and fan structures seen for the inviscid equation.

A strong physical argument for including viscous dissipation in our case is the inclusion of air effects. As grains approach each other in collisions, effects of air cushioning can reduce the importance of impacts in the model for certain flow rates [5], [15] and thus make the density distribution more homogeneous. Another line of argument is that including a viscous dissipation term is comparable to including the next term in a Taylor expansion of the flux, in the sense that now the flux $q = Q(\rho) - \nu\rho_x$, where ν is a small positive constant; see Whitham [17]. Equation (2.3) is therefore modified to

$$\rho_t + c\rho_x = \nu\rho_{xx}. \tag{4.1}$$

This admits some general solutions for the density in a one-way flow, which we investigate below. Equation (4.1) is of central importance here and is referred to frequently hereafter as the "continuum equation."

The continuum equation (4.1) is solved numerically by a finite difference scheme. In the examples below, $\nu = 0.0001$. Upwind or downwind differencing is used for the spatial first derivative, depending on the sign of $c(\rho)$ at each cell in the numerical grid. Although this method of solution is standard and well known, we wish to briefly examine two problems in the new context of the chute flow.

An appropriate flux-density relation must first be specified for the continuum model. We take

$$q = \begin{cases} \pm\rho^4, & 0 \le \rho < 1, \\ \pm\left(c_1\rho^4 + c_2\rho^3 + c_3\rho^2 + c_4\rho + c_5\right) & 1 \le \rho < 10, \\ \pm\left(\rho_M - \rho\right)^2, & 10 \le \rho < \rho_M, \end{cases} \tag{4.2}$$

where for now $\rho_M = 15$; $c_1, c_2, \dots, c_5$ are constants chosen to ensure that the function matches smoothly, and ± obtains the upper or lower branch, respectively. Equation (4.2) captures the main features required of the fundamental diagram that were elucidated earlier. As we consider only unidirectional grain movement we choose the positive branch without loss of generality.

We illustrate two solutions here. Recall that in section 3 solutions were for discrete, discontinuous input, as these formed a basic starting point for the analysis. We attempt to approximate such initial conditions in the code, although of course it is not particularly desirable to start the computation with discontinuous input.

For the first case here we find a solution which mimics the translating shock type of solution.

The initial condition used for this case is

$$\rho(x,0) = \begin{cases} 2 + e^{-25}, & x \le 4, \\ e^{-25(x-5)^2} + 2, & 4 < x \le 5, \\ 3, & x > 5, \end{cases} \tag{4.3}$$

and the boundary conditions are

$$\rho(0,t) = 2 + e^{-25}, \tag{4.4a}$$

$$\rho(15,t) = 3. \tag{4.4b}$$

Hence there are two regions of constant density, both with $q > 0$ (i.e., the density is fixed on the upper branch), and there is a smooth transition between the two

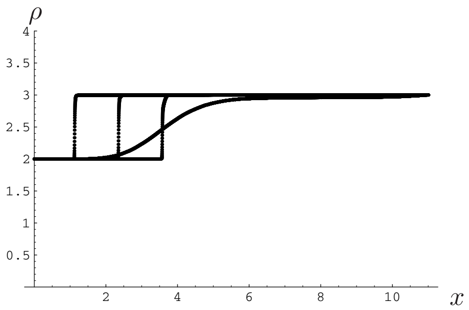


FIG. 4.1. *The initial condition together with solutions at $t = 0.5,\ 1,$ and 1.5. The initial condition is the smoothest thick black line. As time increases, the "jump" between the two near-constant regions steepens considerably and translates leftward, mimicking a translating shock. The solution is shown at times $t = 0.5,\ 1,$ and 1.5.*

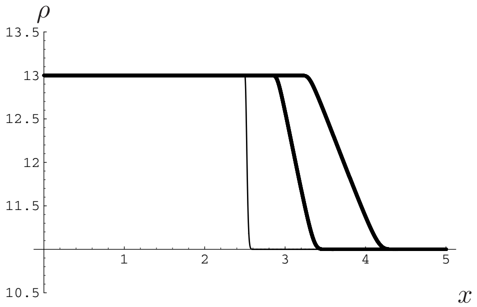

FIG. 4.2. *The initial condition and two solutions, one at $t = 0.1$ and the other at $t = 0.2$. As time increases, the "jump" between the two near-constant regions flattens considerably and spreads rightward across the chute, mirroring well an expansion fan.*

regions; this approximates the discontinuous input leading to a translating shock type of solution in the $\nu = 0$ "inviscid" case.

Figure 4.1 shows the initial condition together with solutions obtained at times $t = 0.5,\ 1,$ and 1.5. As time increases, the "jump" between the two near-constant regions steepens considerably and translates leftward, mimicking well a translating shock.

For the second case here an expansion fan type of solution is replicated. The initial condition is

$$\rho(x,0) = \begin{cases} 13, & x \le 2.5, \\ 2e^{-1000(x-2.5)^2} + 11, & 2.5 < x \le 3, \\ 11 + 2e^{-250}, & x > 3. \end{cases} \tag{4.5}$$

The boundary conditions are

$$\rho(0,t) = 13 + 2e^{-250}, \tag{4.6a}$$

$$\rho(5,t) = 11. \tag{4.6b}$$

Hence initially there are two regions of constant density, and a smooth, yet steep, transition between the two regions.

Figure 4.2 shows the initial condition and the solution obtained at times $t = 0.1$ and 0.2. As time increases, the "jump" between the two near-constant regions flattens considerably and spreads rightward across the chute, resembling an expansion fan, as hoped. Other solutions can similarly be found.

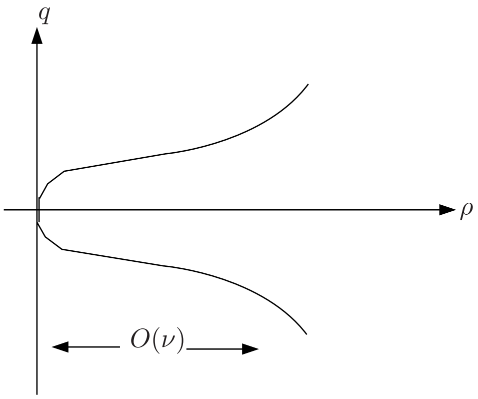

FIG. 5.1. *A sketch of the new fundamental diagram in the neighborhood of $\rho = q = 0$.*

5. Viscous two-way flows. In this section, we demonstrate that in principle valid solutions can be obtained for the continuum equation in which grains can move to and fro across the chute; i.e., there exist valid solutions for "viscous" two-way flows. Such solutions, however, require a modification to the fundamental diagram at the endpoints. In particular, we stated in section 2 that the two branches of the fundamental diagram must meet at cusps at the endpoints. Such geometry is required if the wavespeed is to change smoothly during the branch switch *in the inviscid model*, but in the viscous parabolic governing equation such discontinuities are found to be incompatible with the viscous dissipation term. Consequently, the local inviscid $q \sim \rho^{\frac{3}{2}}$ relation should be altered for the viscous case.

On changing the fundamental diagram locally near the endpoints, we show below that the local behavior near the origin (or maximum) must in general be

$$q \propto \rho^{\frac{1}{2}} \text{ near } \rho = 0 \tag{5.1a}$$

or

$$q \propto (\rho_M - \rho)^{\frac{1}{2}} \text{ near } \rho = \rho_M, \tag{5.1b}$$

and then we examine if a valid solution exists. The suggested behavior above is required by the following reasoning. As the solution passes through a minimum, as it must do in separating regions, $\rho \propto x^2$ is clearly the most general case. This, in answer to a referee's query, is because we expect ρ to be small and positive as the solution passes through a minimum. As x is also small (since ρ is expected to be zero in the center of a separating region) the higher order terms x^4, x^6, etc., give only an asymptotically small correction, in general. Balancing terms in (4.1) thus reveals immediately that $q \sim x$, i.e., $q \propto \rho^{\frac{1}{2}}$ as just above. A similar relation applies near a maximum. The consequences of this new law in the vicinity of $\rho = 0$ are considered next, where we aim to find a similarity solution valid at *small time*. Figure 5.1 shows a sketch of the new fundamental diagram in the neighborhood of $\rho = q = 0$. Note that the size of the viscous region is $O(\nu)$.

Locally $q \sim 2c_0\rho^{\frac{1}{2}}$, say, with c_0 a constant, so $c \sim c_0\rho^{-\frac{1}{2}}$ and substitution into (4.1) yields the ordering

$$\frac{\rho}{t} \pm c_0\rho^{-\frac{1}{2}}\frac{\rho}{x} \sim \frac{\rho}{x^2}.$$

Balancing terms in ρ we see that, in terms of orders, $x \sim t^{\frac{1}{2}}$ and hence $\rho \sim t$. This is acceptable since the density is small in a separating region. Therefore the similarity variable $\eta = \frac{x}{t^{\frac{1}{2}}}$ and the form $\rho = tf\left(\eta\right)$ hold locally.

It is also clear that application of this local argument is actually quite wide-ranging because of the parameters c_0, ν. Their inclusion gives the representative size of x as $(\nu t)^{\frac{1}{2}}$ and hence the size of ρ as $\frac{c_0^2 t}{\nu}$, implying formally that the small-density law continues to apply provided that $t \ll \frac{\nu}{c_0^2}$. The time range could therefore be small or large, depending on the parameters.

The solutions for the current revised model thus have regions which are governed by the new viscous behavior when $\rho \approx 0$ or $\rho \approx \rho_M$, and regions governed by the inviscid behavior away from $\rho \approx 0$ or $\rho \approx \rho_M$, where the fundamental diagram is unchanged. As $\nu \to 0$ the viscous regions effectively vanish and the fully inviscid solutions are regained. In this way, the solutions from the inviscid model and the current viscous model are correlated.

Substituting into the continuum equation (4.1) and choosing $+c_0$ with c_0 positive when the flux q is greater than zero, where locally $f' > 0$, and choosing $-c_0$ with c_0 positive when the flux q is less than zero, where $f' < 0$ locally, we obtain the nonlinear ordinary differential equation

$$\nu f'' - \left(\pm\frac{c_0}{f^{\frac{1}{2}}} - \frac{\eta}{2}\right) f' - f = 0 \tag{5.2}$$

as the nominal small-time equation near the density extremum. It is shown in the coming analysis that f is necessarily zero at a minimum, a physically sensible result for the density in the center of a separating region. Thus (5.2) is to be solved subject to $f(k) = f'(k) = 0$, where $\eta = k$ is the location of the minimum. Also f is expected to be a smooth function for all η and to grow proportionally to η^2 at large $|\eta|$.

As a check, approximating the behavior away from the extremum, in the core, we put $c \sim \pm c_0 \rho^{-\frac{1}{2}}$ and expand

$$\rho = \rho_0\left(x\right) + t\rho_1\left(x\right) + t^2\rho_2\left(x\right) + \cdots . \tag{5.3}$$

Now if we assume that, for some positive constant λ, $\rho_0 \approx \lambda x^2$, which is the most general form for a minimum (separating grains) local to the origin, then on substitution into (4.1) we obtain

$$\rho = \lambda x^2 + 2t\lambda^{\frac{1}{2}}\left(\lambda^{\frac{1}{2}}\nu \mp c_0\right) - t^2\frac{c_0^2 \mp c_0\nu\lambda^{\frac{1}{2}}}{x^2} + O(t^3). \tag{5.4}$$

Hence if $x^2 \sim t$, then the three leading terms become $O\left(t\right)$ and the series is no longer asymptotic. This reinforces the earlier similarity variable $\eta = xt^{-\frac{1}{2}}$. Moreover, if $\lambda = c_0^2\nu^{-2}$, then the $O\left(t\right)$ and the $O\left(t^2\right)$ terms are zero and so the expansion may still be valid. Therefore a simple crossover between branches is possible with $\lambda = c_0^2\nu^{-2}$.

Indeed, turning to (5.2) we observe that

$$f = \Gamma\eta^2 \tag{5.5}$$

is an exact solution if $\Gamma = \left(\frac{c_0}{\nu}\right)^2$. All other solutions fall into one of two categories. One is where the minimum of f is zero, in which case a series solution through the minimum is required so the numerical scheme does not blow up. The second category is where the minimum has f nonzero: the series in this case is not regular. The latter might be dismissed by a physical argument (the density must be zero at the center of a separating region) but an analysis is presented for completeness. The series are helpful in the subsequent numerical study.

First we put $f = F^2$; so (5.2) becomes

$$\nu F F'' + F' \left(\nu F' \mp c_0 + \frac{1}{2} (k + s) F \right) - \frac{1}{2} F^2 = 0, \tag{5.6}$$

where we have defined $s \equiv \eta - k$ and $f' = 0$ at $\eta = k$, a prime denoting differentiation with respect to s.

We mention here that having k nonzero allows the minimum, which cannot then be at the origin, to move with speed $\dot{x} = \frac{k}{2} t^{-\frac{1}{2}}$. Thus the solution has a fixed minimum point at $x = 0$ only if $k = 0$ (we shall see later that this corresponds to the exact solution $f = \Gamma \eta^2$). We are free to choose k in the local problem; it is actually determined by the global solution across the whole chute. Since $t \ll 1$ slower movements correspond to $k \to 0$, in effect, and faster movements can be roughly approximated by $|k|$ becoming large.

We must find a series solution through the minimum point, in order that a Runge–Kutta scheme can start away from the minimum point, where (5.2) has a singularity. We therefore write an expansion for F near the minimum point:

$$F = F_0 + s F_1 + s^2 F_2 + \cdots . \tag{5.7}$$

Since $f' = 0$ at $\eta = k$ then $2FF' = 0$ at $s = 0$, implying that $F_0 F_1 = 0$. In the first instance we choose $F_1 = 0$ and hence

$$F = F_0 + s^2 F_2 + s^3 F_3 + O(s^4). \tag{5.8}$$

Substituting (5.8) into (5.6) reveals that at leading order

$$F_0 = 0 \qquad \text{or} \qquad F_2 = \frac{F_0}{4\nu}. \tag{5.9}$$

So this leads to either $f = 0$ at the minimum or to a series for the case when $f = F_0$ at the minimum. If the former case is chosen, then we can re-expand

$$F = s F_1 + s^2 F_2 + s^3 F_3 + s^4 F_4 + O(s^5) \tag{5.10}$$

about $s = 0$, since the condition $F_0 F_1 = 0$ is automatically satisfied (we shall return shortly to the case $F_0 \neq 0$, $F_1 = 0$, $F_2 = \frac{F_0}{4\nu}$). Expansion (5.10) ultimately results in

$$F = \frac{c_0}{\nu} \left(s - s^2 \frac{k}{8\nu} + s^3 \frac{k^2}{96\nu^2} - s^4 \frac{1}{256} \left(\frac{k^3}{6\nu^3} - \frac{k}{\nu^2} \right) + \cdots \right) \tag{5.11}$$

to the right of the minimum, and

$$F = -\frac{c_0}{\nu} \left(s + s^2 \frac{k}{8\nu} + s^3 \frac{k^2}{96\nu^2} + s^4 \frac{1}{256} \left(\frac{k^3}{6\nu^3} - \frac{k}{\nu^2} \right) + \cdots \right) \tag{5.12}$$

to the left of the minimum. In fact, any number of terms in the series can be deduced.

We can now use the series in (5.11) to march from the minimum to the right to some positive value $s = a$, say (i.e., $\eta = k + a$) to obtain f and f' there. Similarly we can use the series in (5.12) to find the values of f and its first derivative at some $s = -b$, $b > 0$, which is to the left of the minimum ($\eta = k - b$). Hence we have the starting conditions for two Runge–Kutta schemes: one starting at $\eta = k + a$ and solving (5.2) shooting forward to some large positive η, and the other starting at $\eta = k - b$ and solving (5.2) shooting backward to some large negative η. In the following solutions we have also normalized both c_0, ν to one.

Before examining these solutions, however, we return to the option where the minimum $f \neq 0$, i.e., $F_0 \neq 0$ and $F_1 = 0$, giving the alternative result that $F_2 = \frac{F_0}{4\nu}$ at leading order (5.9). In this case the expansion to the right of the minimum is

$$F = F_0\left(1 + \frac{s^2}{4\nu} + s^3\left(-\frac{k}{24\nu^2} + \frac{c_0}{12\nu^2 F_0}\right)\right) \tag{5.13}$$

and the expansion to the left of the minimum is

$$F = F_0\left(1 + \frac{s^2}{4\nu} + s^3\left(-\frac{k}{24\nu^2} - \frac{c_0}{12\nu^2 F_0}\right)\right). \tag{5.14}$$

The central point here is that the third term in (5.13) differs from the third term in (5.14) in the sign of c_0. The series about the minimum is therefore not regular if $F_0 \neq 0$, which is unacceptable as we are seeking a smooth solution. An inner-inner region would be required if the series solution were nonregular, within which more knowledge of the local physics would be required, possibly concerning "jump conditions," for example. Hence it turns out that the series with this choice is not regular and furthermore it results in the unphysical condition that $f \neq 0$ at the center of a separating region, and this option is therefore ultimately dismissed. Altogether, therefore, the minimum must occur with $f = 0$, and so series (5.11) and (5.12) can be used in conjunction with a Runge–Kutta method to find solutions of (5.2). These correspond to the density being zero at the center of a separating region, agreeing with physical intuition.

The first solution we find is for the values $a = b = 0.1$ and $k = 1$, corresponding to the minimum being located at $(\eta, f) = (1, 0)$. A series expansion is used to find the solution between $\eta = [0.9, 1.1]$, and then two Runge–Kutta schemes are used to shoot forwards or backwards from the endpoints of the series. Figure 5.2 shows that the density increases relatively rapidly to large values to the left of the minimum yet increases to a smaller value to the right of the minimum: the density distribution is asymmetric either side of the minimum. Four terms have been used in the series expansion in this case. Although this may seem a surprisingly small number, when the number of terms in the series is changed to check the numerical accuracy the solution remains virtually the same.

The numerical accuracy of the above solution was further checked. The step-length was made shorter or longer to check the grid-dependence of the solution. Also the number of terms in the series expansion was changed, and the interval of η in which the series is applied, to make sure the solution is not dependent on either. Finally, the length of the series can be changed to further ensure the result has no dependence on this as well. The solution is found to be robust to the above changes, and we can conclude that the numerical scheme is indeed sufficiently accurate.

Other solutions can be found where the minimum is located at different points. These solutions have quantitatively different behavior from the one found above. For example, the solution shown in Figure 5.3 has the minimum placed at $(\eta, f) = (0, 0)$. Again, a four-term series expansion is used to find the solution through the minimum,

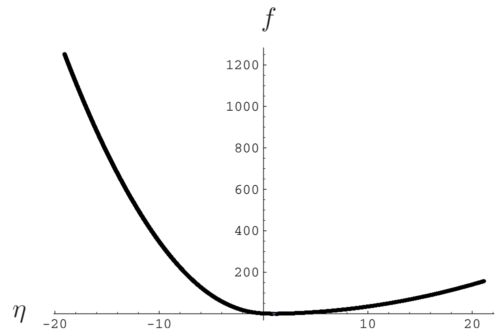

FIG. 5.2. *A solution to* (5.2) *where the minimum occurs at* $(\eta, f) = (1, 0)$. *A series solution has been used to enable passage through the minimum. The step size in this example is* $h = 0.001$. *The grains separate into regions of differing density.*

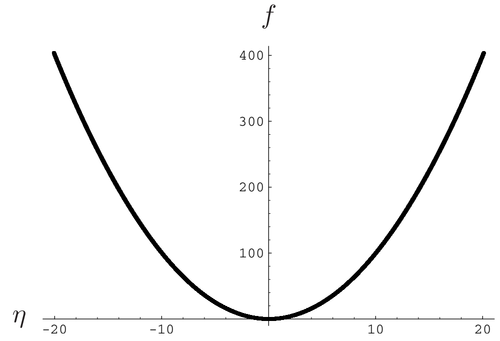

FIG. 5.3. *The solution to* (5.2) *for when the minimum is located at the origin. A step size of* $h = 0.001$ *was used and a four-term series expansion was used to find the solution through the minimum. The grains separate into two regions of equal density.*

and then the Runge–Kutta scheme is used to find the solutions from the endpoints of the series which are located at $\eta = -0.1$ and $\eta = 0.1$. In this case, the analytical solution is exactly $f = \Gamma\eta^2$ with $\Gamma = c_0^2\nu^{-2}$, which is symmetric about the origin. Therefore this case corresponds to the situation where grains separate into regions of equal density.

Another example is to find the solution when the minimum is placed at $(\eta, f) = (-2, 0)$, as shown in Figure 5.4. Again we see an asymmetric solution: to the left of the minimum f increases only to relatively small values, whereas to the right of the minimum the solution increases relatively rapidly to large values of f. We pay particular note to the way in which the curve seems to tend to a small constant for a large distance to the left of the minimum before beginning to increase.

In summary, by modifying the fundamental diagram to include a self-consistent local viscous law we indeed find that physically sensible solutions are obtained for the case of separating grains at low density, for small times and order-one viscosity, or for order-one times and small viscosity, depending on the parameters. In the solutions presented above the condition $f = 0$ (i.e., density is zero) must be satisfied at the center of the separating region. This agrees with physical intuition and also fits well with results from the idealized inviscid case. Furthermore, the solutions can be asymmetric about the origin. This corresponds to grains moving apart, possibly at different speeds, into regions of differing density. It is important that the con-

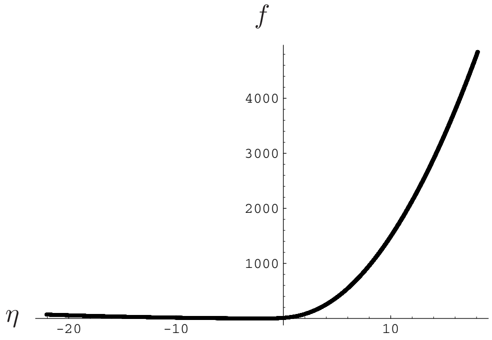

FIG. 5.4. *The solution to* (5.2) *when the minimum is located at* $(\eta, f) = (-2, 0)$*. Again we see an asymmetric solution: to the left of the minimum* f *increases only to relatively small values, whereas to the right the solution rapidly increases to large values of* f*. The solution appears to have a large region where* f *remains constant. For the above solution a step size of* $h = 0.001$ *was again used, as was a four-term series expansion through the minimum. Thus the creation of a void in a separating region seems to be described.*

tinuum model allows this kind of solution as regions of differing density are seen in direct numerical simulations of the chute flow, where clusters of different sizes develop [5]. We also found above that a large region of low density can evolve between two separating regions; see Figure 5.4. Again, one would expect this to occur for some cases of separating regions, and we also mention that numerical simulations have some large regions that are devoid of grains [5]. Finally, an origin shift of the center of the separating region is possible; i.e., the grains do not have to separate about a fixed point, which is also a physically sensible result. Consequently, it seems reasonable to conclude for cases of separating grains that the $q \sim \rho^{\frac{3}{2}}$ law from the inviscid case should be changed locally to a viscous $q \sim \rho^{\frac{1}{2}}$ law. Similar results describing clashing of grains apply at the high-density cusp $\rho \to \rho_M$ [5]. Although this fundamental diagram cannot yet be entirely supported by physical arguments, physically sensible results are nevertheless obtained. The modifications therefore appear to be admissible.

6. Remarks on steady states. We noted at the end of section 3 that general steady states do not exist for the inviscid model, except for ρ, q constant. This is not the case for the viscous model, where steady states are possible in the sense of being a large-time limit. The steady continuum equation is, from (4.1),

$$q_x = \nu \rho_{xx}. \tag{6.1}$$

Hence

$$\frac{x - c_2}{\nu} = \int_{\rho_1}^{\rho} \frac{d\rho}{q + c_1}, \tag{6.2}$$

where c_1, c_2 are constants of integration. Here for a finite integral we must choose $c_1 = 0$, and then the local behavior $q \sim \pm\rho^{\frac{1}{2}}$ from section 5 results in $\rho \sim (x - c_2)^2$ on integration of (6.2). This confirms (5.1a), which allows for a maximum or a minimum near crossover at $x = c_2$. Thus steady viscous states exist with two-way viscous flow.

The contrasting predictions from inviscid theory and viscous theory concerning steady states are due to there being a long viscous time scale in the viscous regime for small ν; evolution over times t of order $\frac{1}{\nu}$ is inferred directly from (4.1) for x

remaining of order unity. This conclusion is reinforced by the case of near-uniform density flow where $\rho = \bar{\rho} + \tilde{\rho}$, with $\bar{\rho}$ being a constant and $\tilde{\rho}$ being small. For then $c \approx \bar{c}$ is near-uniform and (4.1) reduces to

$$\tilde{\rho}_t + \bar{c}\tilde{\rho}_x = \nu\tilde{\rho}_{xx}, \tag{6.3}$$

admitting a solution of the form $\tilde{\rho} = \tilde{f}\,(x - \bar{c}t, t)$, where $\tilde{f}$ is controlled by the diffusion equation acting over the time scale of order $\frac{1}{\nu}$.

7. Further comments. If the fundamental diagram proposed in the present paper is taken to give the flux-density law for a chute flow of grains, the previous sections show that the inherent discontinuities in the model can apparently describe the formation of clusters, voids, and sudden jumps in the density during collisions and separations. Hence we can construct descriptions of significant parts of a chute flow including regions of colliding or separating grains. However, we do not claim that the fundamental diagram must describe the *entire* chute flow. The approach has also been an empirical one: we have seen that the results can describe some situations seen on chutes in reality, although the original physical arguments per se may remain open to question.

In section 3 on the inviscid model, solutions with discontinuous input were found, these being cases that yield relatively easily to analysis. Several examples of increasing complexity illustrated how shocks and fans can be used to model clusters and voids. It was noted that steady state solutions in general do not exist, except for ρ, q constant. In the future, it may be possible to include an analysis of the effects of the chute wall in an inviscid case.

In section 4, the number of solutions was extended to other cases. To obviate problems associated with the discontinuities present in the model, an artificial viscous dissipation term was added so that the governing equation is parabolic. We focused there solely on problems in which grain movement is unidirectional so that no branch-switching occurred. Hence a finite difference scheme was used to obtain numerical solutions that imitate those found in the inviscid model.

Finally, in sections 5 and 6, we showed that the work can be extended further to encompass a two-way flow in which grains can move to and fro. In order to find such solutions, the fundamental diagram has to be modified so its curvature is convex outwards at the endpoints. It was determined that such an alteration allows physically reasonable descriptions of separating and clashing grains to develop. Again, it is interesting, as section 6 pointed out, that steady state solutions do exist for the viscous model.

If the viscosity ν is small, then in general the viscous effects also are small. Exceptions are (a) shocks, where ν has a smoothing effect, as is well known [17]; (b) crossovers, which allow two-way solutions, and which are a new feature; and (c) steady states, which can exist only if $\nu \neq 0$ and appear over a long time scale, which is also a new observation.

It may be possible in future work to determine the fundamental diagram more rigorously from a direct numerical simulation. A small control volume can be considered in the computational domain and at random times a measurement of the grain density and flux within the control volume could be taken. This would be repeated for many computational runs and a distribution of points of q versus ρ produced. These points could then be collapsed onto a curve by an appropriate statistical method and a fundamental diagram would be produced. This is similar to the recent approach of Armbruster et al. [3].

We also aim to obtain two-way viscous solutions across the entire chute, involving the whole multivalued fundamental diagram. We hope to include such solutions, alongside aspects addressing other mathematical properties of the viscous system, in a future paper.

OPTICAL FIBER DRAWING AND DOPANT TRANSPORT[*]

H. HUANG[†], R. M. MIURA[‡], AND J. J. WYLIE[§]

Abstract. Optical fibers are made of glass with different refractive indices in the (inner) core and the (outer) cladding regions. The difference in refractive indices arises due to a rapid transition in the concentration of a dopant across the boundary between these two regions. Fibers are normally drawn from a heated glass preform, and the different dopant concentrations in the two regions will change due to dopant diffusion and convective transport induced by the flow. In this paper, we analyze a mathematical model for the dynamics of dopant concentration changes during the fiber drawing process. Using a long-wave approximation, we show that the governing equations can be reduced to a simple diffusion equation. As a result, we are able to identify key dimensionless parameters that contribute to the diffusion process. We also derive asymptotic solutions for the temperature, cross-sectional area, and effective diffusion coefficient when there are strong temperature dependencies in the viscosity and the diffusion coefficient. Our simplified model and asymptotic solutions reduce the need for extensive numerical simulations and can be used to devise control strategies to limit excess dopant diffusion.

Key words. dopant diffusion, optical fiber drawing, incompressible viscous flow, long-wave approximation, asymptotic approximation

1. Introduction. Optical fibers are drawn from a heated glass preform using mechanical pullers. The glass preform is fabricated so that there is a difference in the refractive index between the fiber core and the outer cladding region. This refractive index difference is achieved normally by adding a dopant to the inner core region [4]. Typically, dopant materials, such as oxides of germanium, phosphorus, and boron, are deposited in pure silica in the perform. However, during drawing, splicing, and fusion, the refractive index may change due to diffusion of the dopant in the glass [7, 11].

Compared to dopant concentration changes due to splicing and fusion of these fibers, dopant concentration changes during fiber drawing would appear to be more complicated since dopant diffusion depends not only on temperature, but also on a number of other factors, including the mechanics of the drawing process. In Lyytikäinen et al. [5], numerical simulations and an experimental study of specialized fibers have been carried out. For relatively low drawing speeds, it was shown that diffusion can cause a small but visible spreading of the dopant. It also was shown that larger drawing speeds and lower furnace temperatures both reduce the diffusion of dopant. Their simulations ignored advection of dopant by the flow and were based

on a simple diffusion equation with only a radial component. Their experiments and simulations compare favorably, which indicates that the key mechanism is captured by simple radial diffusion; however, it is not clear why this is the case and whether this assumption will hold for other parameter values. On the other hand, Yan and Pitchumani [11] carried out a full numerical simulation of the drawing process, including dopant diffusion. Although the fiber surface is a free boundary, they simplified their computations by using a prescribed surface boundary based on previous numerical studies of the drawing process by Lee and Jaluria [6]. Contrary to the conclusion in Lyytikäinen et al. [5], the numerical simulations by Yan and Pitchumani [11] show that a significant amount of diffusion occurs during the drawing process, in spite of a similar drawing environment and higher drawing speeds, which should reduce the amount of diffusion.

In this paper, we analyze a mathematical model for dopant concentration changes during optical fiber drawing. The main objective of the paper is to understand the mechanism of dopant transport during drawing. We also are interested in exploring different ways to control dopant diffusion since from a practical point of view it is desirable to minimize its effect. Based on an asymptotic analysis of this model, we are able to show that the diffusion of dopant is governed by a simple diffusion equation with only a radial component, as used by Lyytikäinen et al. [5]. However, the molecular diffusion coefficient used in [5] must be replaced by an effective diffusion coefficient, which includes a “history” factor. For typical parameter values, we show that the effective diffusion coefficient is determined mainly by two dimensionless parameters, namely, the Péclet number based on the diffusion coefficient for dopant, and a parameter that quantifies the heating strength. For large changes in viscosity, we derive analytical expressions that are uniformly valid asymptotic expansions for velocity, radius, and temperature. This allows us to find simple expressions for the effective diffusion coefficient that clearly show the way in which all of the parameters affect the diffusion process and hence reduces the need for extensive numerical simulations.

The paper is organized as follows. In section 2, the mathematical model for glass optical fiber drawing is given and subsequently simplified. We derive explicit approximations for the temperature and cross-sectional area in section 3. For these approximations, we considered two cases, one with cooling and one without cooling. In section 4, we derive asymptotic approximations for the effective diffusion in the case of no cooling.

2. Problem description. In a typical setup for glass optical fiber drawing, a cylindrical preform with radius R_0 and temperature T_0 is extruded from an input nozzle into a heating and cooling device with speed u_0; see Figure 1. At a distance L from the input nozzle, the fiber is pulled out of the device by a roller. Between the input nozzle and a distance $L_f < L$, the fiber is inside a furnace and is subjected to heating. This heating causes the viscosity of the glass to dramatically decrease, and thus facilitates rapid stretching of the fiber with moderate forces. Between the end of the furnace and the roller, the fiber is cooled by natural and forced cooling. At the nozzle input, the dopant concentration $c = c_0(r)$ will be assumed to be a given function of the radial distance from the fiber axis, r. The aim of this study is to understand how the heating, cooling, and the stretching process, as well as the diffusion and advection of the dopant, affect the dopant concentration profile when the fiber exits the device. We note that throughout this paper, subscripts 0, f, and c refer to quantities associated with the input nozzle, furnace heating, and cooling, respectively.

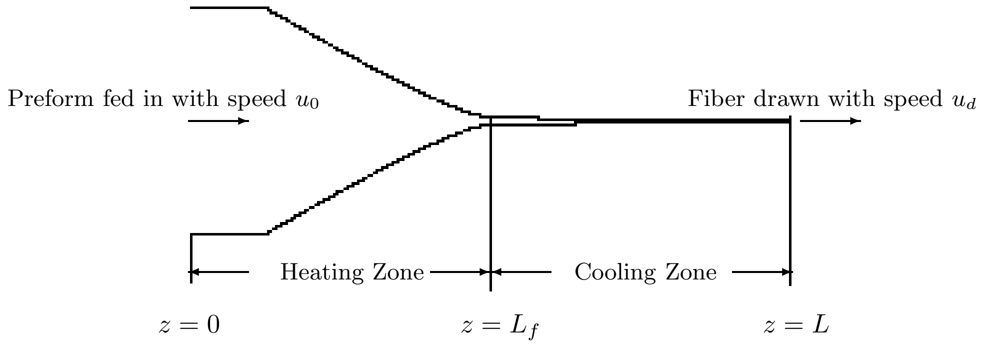

FIG. 1. *Schematic of heating and cooling zones.*

2.1. Mathematical model. We assume that the glass fiber is an incompressible fluid with temperature-dependent viscosity. Also, we assume that the dopant concentration has a negligible effect on the density, viscosity, and conductivity of the glass, the fiber remains axisymmetric, and the drawing conditions are in a steady state. Under these assumptions, the governing equations for mass, momentum, energy, and dopant concentration are given by [11]

$$\frac{\partial(\rho u)}{\partial z} + \frac{1}{r}\frac{\partial(r\rho v)}{\partial r} = 0, \tag{2.1}$$

$$\frac{\partial(\rho u^2)}{\partial z} + \frac{1}{r}\frac{\partial(r\rho uv)}{\partial r} = -\frac{\partial p}{\partial z} + 2\frac{\partial}{\partial z}\left(\mu\frac{\partial u}{\partial z}\right) + \frac{1}{r}\frac{\partial}{\partial r}\left[r\mu\left(\frac{\partial u}{\partial r} + \frac{\partial v}{\partial z}\right)\right], \tag{2.2}$$

$$\frac{\partial(\rho uv)}{\partial z} + \frac{1}{r}\frac{\partial(r\rho v^2)}{\partial r} = -\frac{\partial p}{\partial r} + \frac{\partial}{\partial z}\left[\mu\left(\frac{\partial u}{\partial r} + \frac{\partial v}{\partial z}\right)\right] + \frac{2}{r}\frac{\partial}{\partial r}\left(r\mu\frac{\partial v}{\partial r}\right) - \frac{2\mu v}{r^2}, \tag{2.3}$$

$$\frac{\partial(\rho c_p uT)}{\partial z} + \frac{1}{r}\frac{\partial(r\rho c_p vT)}{\partial r} = \frac{\partial}{\partial z}\left(k\frac{\partial T}{\partial z}\right) + \frac{1}{r}\frac{\partial}{\partial r}\left(rk\frac{\partial T}{\partial r}\right), \tag{2.4}$$

$$\frac{\partial(uc)}{\partial z} + \frac{1}{r}\frac{\partial(rvc)}{\partial r} = \frac{\partial}{\partial z}\left(D\frac{\partial c}{\partial z}\right) + \frac{1}{r}\frac{\partial}{\partial r}\left(rD\frac{\partial c}{\partial r}\right), \tag{2.5}$$

where z is the distance from the input nozzle measured along the axis of the fiber, u and v are the velocity components in the axial and radial directions, respectively, p is the pressure, T is the temperature, c is the dopant concentration, ρ is the density, μ is the viscosity, c_p is the specific heat, $k = k_T + k_R$ is the effective conductivity [11] where k_T is the (molecular) thermal conductivity and k_R is the radiative conductivity, and D is the molecular diffusivity of the dopant. We observe that the mass, momentum, and energy equations decouple from the dopant equation.

The boundary conditions at the inlet of the furnace are

$$u = u_0,\ v = 0,\ T = T_0,\ c = c_0(r),\ 0 \le r \le R_0, \quad \text{at} \quad z = 0. \tag{2.6}$$

At a fixed downstream location, we assume the velocity is known:

$$u = u_d \quad \text{at} \quad z = L. \tag{2.7}$$

At this downstream location, boundary conditions also are needed for the radial component of the velocity v, the temperature T, and the dopant concentration c. However, we will show that in the asymptotic limit of the long-wave approximation, such boundary conditions do not play a significant role outside of a thin region near this boundary. The lateral fiber surface $r = R(z)$ is a free boundary at which the following dynamic and kinematic conditions must be applied:

$$\mathbf{n}^T \cdot \sigma \cdot \mathbf{n} = \Gamma\kappa, \; \mathbf{t}^T \cdot \sigma \cdot \mathbf{t} = 0, \; v = R'u \tag{2.8}$$

where the prime denotes differentiation with respect to z, σ is the stress tensor, $\mathbf{n} = [(1 + R'^2)^{-1/2}, \; R'(1 + R'^2)^{-1/2}]^T$ is the outward normal vector to the glass surface, $\mathbf{t} = [-R'(1 + R'^2)^{-1/2}, \; (1 + R'^2)^{-1/2}]^T$ is the corresponding vector in the tangential direction, κ is the mean curvature, and Γ is the surface tension coefficient.

The boundary condition for temperature at the fiber surface depends on whether the fiber is inside or outside of the furnace. In Lee and Jaluria [6], the heat flux q is specified when the fiber is inside the furnace. In general, q depends on many factors, such as the furnace wall temperature profile, inert gas flow, and the dimensions of the furnace, as well as the fiber temperature. Here, as in previous studies [6], we have adopted the standard Newton's cooling law[1]

$$-k\frac{\partial T}{\partial n} = q := \begin{cases} h_f(T_f - T), & 0 \le z < L_f, \\ -h_c(T - T_c), & L_f \le z \le L, \end{cases} \tag{2.9}$$

where T_f and T_c are the furnace and background temperatures, respectively, and h_f and h_c are the heat transfer coefficients for the heating from the furnace and cooling to the background, respectively. For simplicity, we will assume that the background temperature is the same as the temperature at the nozzle input, that is, $T_c = T_0$, although generalization is straightforward.

Finally, the dopant concentration satisfies the no-flux boundary condition

$$D\frac{\partial c}{\partial n} = 0 \tag{2.10}$$

at the fiber surface $r = R(z)$ and the regularity condition

$$\frac{\partial c}{\partial r} = 0 \tag{2.11}$$

at the axis of the fiber $r = 0$.

For the glass fibers used in typical optical fiber fabrication, the viscosity of the fiber varies rapidly with temperature. This rapid variation plays a fundamental role in controlling the dynamics. Empirical data for glass (see [8, 3] and the references therein) show that the viscosity can be well approximated by an Arrhenius formula or an exponential law. In this paper, we will use the exponential law in the form

$$\mu(T) = \mu_0 \exp\left(-G_\mu(T - T_0)\right) \tag{2.12}$$

where μ_0 is the viscosity of the fiber at T_0 and G_μ is a constant. The diffusion coefficient for the dopant also is normally assumed to follow the Arrhenius formula

$$D(T) = D_\infty \exp\left(-\frac{G_D}{T}\right) \tag{2.13}$$

where G_D is the activation energy divided by the universal gas constant and D_∞ is the diffusion coefficient at high temperatures.

[1] Within the furnace, there is a complicated balance between radiative and convective heat processes, but it is straightforward to generalize our approach, as outlined in this paper, to heating laws for these processes, e.g., for radiative heat transfer; see [3].

TABLE 1
List of the physical parameter values.

ρ	c_p	k_T	k_R	Γ	h_f	h_c
kg/m^3	J/(K kg)	W/(m K)	W/(m K)	kg/s	W/(m^2 K)	W/(m^2 K)
2.23×10^3	7.538×10^2	1.130	1.2×10^1	3×10^{-1}	200	20

u_0	u_d	L	L_f	R_0	T_0	T_f	μ_0	G_μ	D_∞	G_D
m/s	m/s	m	m	m	K	K	kg/(m s)	K^{-1}	m$^2/s$	K
10^{-4}	1	0.5	0.1	6×10^{-3}	300	2300	10^8	2×10^{-2}	2.4×10^{-6}	3.73×10^4

2.2. Dimensional analysis. We nondimensionalize the governing equations using the following scalings:

$$\hat{z} = \frac{z}{L},\ \hat{r} = \frac{r}{R_0},\ \hat{R} = \frac{R}{R_0},\ \hat{u} = \frac{u}{u_0},\ \hat{v} = \frac{Lv}{R_0 u_0},\ \hat{p} = \frac{R_0^2 p}{\mu_0 u_0 L},$$

$$\hat{\mu} = \frac{\mu}{\mu_0},\ \theta = \frac{T - T_0}{T_f - T_0},\ \hat{c_0} = \frac{c_0}{c_0(0)},\ \hat{c} = \frac{c}{c_0(0)},\ \hat{D} = \frac{D}{D_\infty}.$$

Substitution of these scalings into (2.1)–(2.4) yields the following dimensionless parameters, which we list along with their order of magnitude estimates based on the typical parameter values [5, 6, 11] that are listed in Table 1:

$$D_r = \frac{u_d}{u_0} \approx 10^4,\ \delta = \frac{R_0}{L} \approx 10^{-2},\ \mathrm{Re} = \frac{\rho u_0 L}{3\mu_0} \approx 10^{-9},\ \lambda = \frac{\Gamma L}{3\mu_0 u_0 R_0} \approx 10^{-3},$$

$$\mathrm{Bi} = \frac{h_f R_0}{k} \approx 10^{-1},\ \alpha_\mu = G_\mu(T_f - T_0) \approx 40,\ \alpha_D = \frac{G_D}{T_f - T_0} \approx 20,$$

$$\Theta = \frac{T_0}{T_f - T_0} \approx 0.15,\ \mathcal{P} = \frac{u_0 R_0^2}{L D_\infty} \approx 3 \times 10^{-3},$$

and

$$\mathcal{H}_f = \frac{2\sqrt{\pi} h_f L}{\rho c_p u_0 R_0} \approx 350,\ \mathcal{H}_c = \frac{2\sqrt{\pi} h_c L}{\rho c_p u_0 R_0} \approx 35,\ \ell = \frac{L_f}{L} \approx 0.2.$$

Here D_r is the draw ratio, δ is the aspect ratio, Re is the Reynolds number, λ is the ratio of surface tension forces to viscous forces, and Bi is the Biot number. The parameters α_μ and α_D measure the changes in the viscosity and the diffusion coefficient as the temperature varies between its initial value and the heater temperature, respectively, Θ is the ratio of the initial temperature to the difference between the heater and initial temperatures, $\mathcal{P}$ is the Péclet number for the dopant, $\mathcal{H}_f$ and $\mathcal{H}_c$ represent the dimensionless strengths of the heating and cooling, respectively, and ℓ represents the proportion of the length of the device that is heated by the furnace. We note that the Biot number estimated here is consistent with the value cited in [6], where the heat transfer is estimated based on an estimate for the heat flux.

2.2.1. Flow and temperature equations: Simplifications. The mass, momentum, and temperature equations clearly decouple from the dopant equation, and we begin by simplifying these equations. Based on the parameter values given in Table 1, we see that δ, Re, λ, and Bi are small. Since $\delta \ll 1$, we can use the long-wave approximation. Furthermore, since $\lambda \ll 1$ and $\mathrm{Re} \ll 1$, we can ignore the inertia and surface tension terms in the momentum equations. Finally, assuming that Bi $\ll 1$, equations (2.1)–(2.4) become (dropping the hats)

$$\frac{\partial}{\partial z}(us) = 0, \tag{2.14}$$

$$\frac{1}{s}\frac{\partial}{\partial z}\left(\mu s \frac{\partial u}{\partial z}\right) = 0, \tag{2.15}$$

$$u\frac{\partial \theta}{\partial z} = \frac{\mathcal{H}_f(1-\theta)H(\ell - z) - \mathcal{H}_c \theta H(z-\ell)}{s^{1/2}}, \tag{2.16}$$

where $s = R^2,\ \mu = \exp(-\alpha_\mu \theta)$, and H is the Heaviside step function. The derivation of these equations follows the derivation of similar equations in previous work (cf. [1, 2, 9, 10]).

The boundary conditions (2.6) and (2.7) become

$$s = 1,\ u = 1,\ \theta = 0 \quad \text{at} \quad z = 0 \tag{2.17}$$

and

$$u = D_r \quad \text{at} \quad z = 1. \tag{2.18}$$

2.2.2. Dopant equation: Long-wave approximation. The long-wave approximation of the dopant concentration equation (2.5) is

$$\mathcal{P}\left(u\frac{\partial c}{\partial z} - \frac{r}{2}\frac{\partial u}{\partial z}\frac{\partial c}{\partial r}\right) = \frac{1}{r}\frac{\partial}{\partial r}\left(rD\frac{\partial c}{\partial r}\right) \tag{2.19}$$

where

$$D = \exp\left(-\frac{\alpha_D}{\theta + \Theta}\right). \tag{2.20}$$

The boundary conditions are

$$c = c_0(r),\ 0 \le r \le R_0, \quad \text{at} \quad z = 0 \tag{2.21}$$

and

$$c_r = 0 \quad \text{at} \quad r = 0 \quad \text{and} \quad r = \sqrt{s}. \tag{2.22}$$

2.2.3. Flow and temperature equations: Reduced system. From (2.14), (2.15), and the boundary conditions on u and s in (2.17) and (2.18), it is easy to verify that

$$su = 1 \quad \text{and} \quad \mu s u_z = 2F \tag{2.23}$$

where

$$F = \frac{\ln D_r}{2\int_0^1 \mu^{-1} dz}$$

is the effective pulling force that will be obtained by using the boundary condition at $z = 1$. Using the first equation in (2.23) to eliminate u in the temperature equation

(2.16) and u_z in the second equation in (2.23), we obtain a system of two coupled first-order ordinary differential equations for s and θ:

$$s_z = -\frac{2Fs}{\mu}, \tag{2.24}$$

$$\theta_z = s^{1/2}\left[\mathcal{H}_f(1-\theta)H(\ell - z) - \mathcal{H}_c\theta H(z-\ell)\right], \tag{2.25}$$

which must be solved subject to the following boundary conditions:

$$s=1,\ \theta=0 \quad \text{at} \quad z=0 \quad \text{and} \quad s=D_r^{-1} \quad \text{at} \quad z=1. \tag{2.26}$$

2.2.4. Dopant equation: Simplification. We can further simplify the equation for dopant concentration changes by defining

$$\phi(z) \equiv \int_0^z D[\theta(z')]dz' \quad \text{and} \quad \bar{\phi} \equiv \phi(1) \tag{2.27}$$

and using the coordinate transformations $\xi = r/R$ and $\tau = \phi(z)/\bar{\phi}$. The quantity

$$\mathcal{D} = \frac{\bar{\phi}}{\mathcal{P}} \tag{2.28}$$

will be called the effective diffusion coefficient, and we obtain

$$c_\tau = \frac{\mathcal{D}}{\xi}\frac{\partial}{\partial \xi}\left(\xi\frac{\partial c}{\partial \xi}\right) \tag{2.29}$$

subject to

$$c = c_0(\xi) \quad \text{at} \quad \tau = 0 \tag{2.30}$$

and

$$c_\xi = 0 \quad \text{at} \quad \xi = 0 \quad \text{and} \quad \xi = 1. \tag{2.31}$$

The exit of the entire heating and cooling device is located at $\tau = 1$.

To summarize, we have shown that dopant transport during fiber drawing is governed by a diffusion equation in the coordinates (ξ, τ), which has the form for diffusion in cylindrically symmetric heat flow. The amount of diffusion is characterized by the effective diffusion coefficient, $\mathcal{D}$, which depends on the temperature distribution inside the fiber. In principle, the fiber temperature can be obtained by solving two coupled first-order ordinary differential equations (2.24) and (2.25) numerically. The effective diffusion coefficient can then be evaluated numerically using (2.27).

Since the range of temperature variation is large, the value of the molecular diffusion coefficient varies over several orders of magnitude and the effective diffusion coefficient is mainly determined by the portion of the fiber where the temperature is high. It can be seen that if the temperature is uniformly high, i.e., $\theta =$ constant, then $\bar{\phi} = D(\theta)$ and $\mathcal{D} = D(\theta)/\mathcal{P}$. Therefore, to estimate the value of the effective diffusion coefficient, it is important to obtain an estimate of the temperature inside the fiber. In the next two sections, we show that due to special features of the setup and parameter values used in practice, approximate solutions could be obtained for the fiber temperature. In the case without cooling, solutions also can be obtained for the effective diffusion coefficient. When compared with numerical solutions, such asymptotic solutions provide valuable insights for understanding the dopant transport mechanism.

3. Asymptotic solution for θ and s. We consider two cases: first without cooling ($\ell = 1$), in which the furnace heats the entire fiber, followed by the case with cooling ($\ell < 1$), in which the furnace heats the initial portion of the fiber, whereas the remaining portion is subjected to cooling.

3.1. $\ell = 1$. Introducing the scaled effective force $\mathcal{F} = 2Fe^{\alpha_\mu}/\ln D_r$, we can rewrite the system (2.24) and (2.25) as

$$s_z = -\mathcal{F}\ln D_r s e^{-\alpha_\mu(1-\theta)}, \tag{3.1}$$

$$\theta_z = \mathcal{H}_f\sqrt{s}(1-\theta), \tag{3.2}$$

subject to the boundary conditions $s(0) = 1$ and $\theta(0) = 0$. From the above two equations, we obtain

$$\frac{ds}{d\theta} = -\frac{\mathcal{F}\ln D_r}{\mathcal{H}_f}\frac{\sqrt{s}e^{-\alpha_\mu(1-\theta)}}{1-\theta}. \tag{3.3}$$

Integrating and using the boundary conditions, we obtain

$$s = \left(1 - \frac{\mathcal{F}\ln D_r}{2\mathcal{H}_f}\left\{E_1[\alpha_\mu(1-\theta)] - E_1[\alpha_\mu]\right\}\right)^2 \tag{3.4}$$

where

$$E_1[\eta] = \int_\eta^\infty \frac{e^{-x}}{x}dx$$

is the exponential integral. Note that up to this point no approximation has been made to (3.1) and (3.2). To proceed further, we exploit the fact that viscosity varies rapidly with temperature, that is, $\alpha_\mu \gg 1$. Note that the exponential integral has the following asymptotic approximations:

$$E_1[\eta] \sim \frac{e^{-\eta}}{\eta} \text{ as } \eta \to \infty, \qquad E_1[\eta] \sim -\ln(\eta) - \gamma \text{ as } \eta \to 0$$

where $\gamma = 0.5772\ldots$ is Euler's constant.

From (3.2), we have

$$\theta_z = \mathcal{H}_f\left(1 - \frac{\mathcal{F}\ln D_r}{2\mathcal{H}_f}\left\{E_1[\alpha_\mu(1-\theta)] - E_1[\alpha_\mu]\right\}\right)(1-\theta). \tag{3.5}$$

Since $\alpha_\mu \approx 30 \gg 1$, we have that $E_1[\alpha_\mu]$ is small. Also, $E_1[\alpha_\mu(1-\theta)]$ will be small if $1-\theta \gg \alpha_\mu^{-1}$. Therefore,

$$\theta_z = \mathcal{H}_f(1-\theta), \tag{3.6}$$

which can be solved to give

$$\theta = 1 - e^{-\mathcal{H}_f z}. \tag{3.7}$$

Clearly, $1-\theta \to 0$ as z increases to 1 for $\mathcal{H}_f \gg 1$. Thus, for $z \gg \mathcal{H}_f^{-1}$, we have

$$\theta_z = \mathcal{H}_f\left(1 + \frac{\mathcal{F}\ln D_r}{2\mathcal{H}_f}\left\{\ln[\alpha_\mu(1-\theta)] + \gamma\right\}\right)(1-\theta). \tag{3.8}$$

Letting

$$\alpha_\mu(1-\theta) = e^{-\frac{2\mathcal{H}_f}{\mathcal{F}\ln D_r}}\hat{\theta},$$

we have

$$\hat{\theta}_z = -\frac{\mathcal{F}\ln D_r}{2}\left(\ln\hat{\theta}+\gamma\right)\hat{\theta}, \tag{3.9}$$

which can be integrated to obtain

$$\ln\hat{\theta} = -\gamma + C_1 e^{-\frac{\mathcal{F}\ln D_r}{2}z} \tag{3.10}$$

where C_1 is an integration constant.

Next, we match the above solution with (3.6) to obtain

$$C_1 = \gamma + \ln\alpha_\mu + \frac{2\mathcal{H}_f}{\mathcal{F}\ln D_r}. \tag{3.11}$$

Thus,

$$\hat{\theta} = \exp\left[-\gamma + \left(\gamma + \ln\alpha_\mu + \frac{2\mathcal{H}_f}{\mathcal{F}\ln D_r}\right)e^{-\frac{\mathcal{F}\ln D_r}{2}z}\right], \tag{3.12}$$

or returning to the original variable,

$$\theta = 1 - \exp\left[-\left(\gamma + \ln\alpha_\mu + \frac{2\mathcal{H}_f}{\mathcal{F}\ln D_r}\right)\left(1 - e^{-\frac{\mathcal{F}\ln D_r}{2}z}\right)\right]. \tag{3.13}$$

Given θ, we can find s using (3.4).

The scaled pulling force $\mathcal{F}$ can be obtained by substituting $z = 1$ into (3.13) and (3.4) and using the condition $s(1) = D_r^{-1}$. Using the fact that $\alpha_\mu \gg 1$ and the asymptotic properties of E_1, we obtain

$$\mathcal{F} = 1 + \frac{2}{\ln D_r}\ln\left[1 + \frac{\mathcal{F}(\ln\alpha_\mu+\gamma)\ln D_r}{2\mathcal{H}_f}\right]. \tag{3.14}$$

In general, to obtain $\mathcal{F}$, this equation must be solved numerically. But for typical parameter values, we have

$$\frac{(\ln\alpha_\mu+\gamma)\ln D_r}{2\mathcal{H}_f} \sim 10^{-1} \ll 1, \tag{3.15}$$

and so we can obtain an asymptotic estimate for $\mathcal{F}$ in closed form:

$$\mathcal{F} = 1 + \frac{\ln\alpha_\mu+\gamma}{\mathcal{H}_f}. \tag{3.16}$$

In Figure 2, we plot the asymptotic and numerical solutions, and it can be seen that the agreement between the two solutions is excellent.

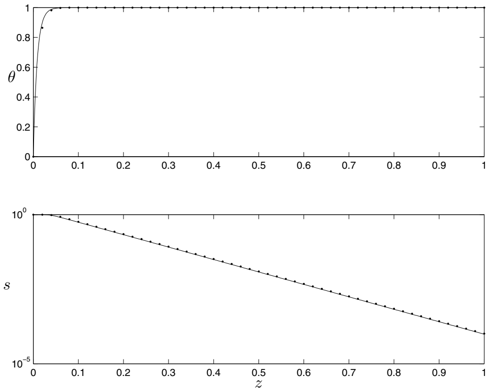

FIG. 2. *Numerical (dots) vs. asymptotic (lines) solutions. The parameter values are* $\mathcal{H}_f = 100$, $\alpha_\mu = 30$, *and* $D_r = 10^4$.

3.2. $\boldsymbol{\ell < 1}$. When there is cooling, the previous solution is valid up to the location $z = \ell$, but for $z > \ell$, the area and temperature are determined from (2.24) and (2.25):

$$s_z = -\mathcal{F} \ln(D_r) e^{\alpha_\mu(\theta-1)} s, \tag{3.17}$$

$$\theta_z = -\mathcal{H}_c \sqrt{s}\theta, \tag{3.18}$$

subject to the boundary conditions $s(\ell) = s_\ell$ and $\theta(\ell) = \theta_\ell$.

We rescale the variables using

$$\vartheta = \alpha_\mu(\theta_\ell - \theta), \quad \mathfrak{s} = \sqrt{\frac{s}{s_\ell}}, \quad y = \frac{\mathcal{F}\ln(D_r)e^{\alpha_\mu(\theta_\ell-1)}}{2}(z-\ell),$$

and (3.17) and (3.18) become

$$\mathfrak{s}_y = -\mathfrak{s}e^{-\vartheta}, \tag{3.19}$$

$$\vartheta_y = \mathcal{A}\mathfrak{s}(1-\epsilon\vartheta) \tag{3.20}$$

where

$$\mathcal{A} = \frac{2\sqrt{s_\ell}\mathcal{H}_c\alpha_\mu\theta_\ell e^{\alpha_\mu(1-\theta_\ell)}}{\mathcal{F}\ln(D_r)}, \quad \epsilon = \frac{1}{\alpha_\mu\theta_\ell} \ll 1,$$

and subject to $\vartheta(0) = 0$ and $\mathfrak{s}(0) = 1$.

From (3.19) and (3.20), we obtain

$$\frac{d\vartheta}{d\mathfrak{s}} = -\mathcal{A}(1-\epsilon\vartheta)e^{\vartheta}. \tag{3.21}$$

Using $\vartheta(0) = 0$, $\mathfrak{s}(0) = 1$, and integration by parts, we obtain

$$\mathfrak{s} = 1 - \frac{1}{\mathcal{A}}\int_0^{\vartheta}\frac{e^{-w}}{1-\epsilon w}dw = 1 + \frac{1}{\mathcal{A}}\left(\frac{e^{-\vartheta}}{1-\epsilon\vartheta} - 1\right) - \frac{\epsilon}{\mathcal{A}}\int_0^{\vartheta}\frac{e^{-w}}{(1-\epsilon w)^2}dw. \tag{3.22}$$

Given typical parameter values, one can readily see that the scaled temperature ϑ at the exit is much greater than ϵ^{-1}. Therefore, $\epsilon/(1-\epsilon\vartheta) \ll 1$, and (3.22) can be approximated as

$$\mathfrak{s} = 1 + \frac{1}{\mathcal{A}}\left(\frac{e^{-\vartheta}}{1-\epsilon\vartheta} - 1\right). \tag{3.23}$$

We now proceed with three different cases: $\mathcal{A} = 1$, $\mathcal{A} < 1$, and $\mathcal{A} > 1$.

Case 1. $\boldsymbol{\mathcal{A} = 1}$. In this case, we have

$$\mathfrak{s} = e^{-\vartheta} \tag{3.24}$$

and the equation for ϑ becomes

$$\vartheta_y = e^{-\vartheta}, \tag{3.25}$$

which can be solved as

$$\vartheta = \ln(y+1) \tag{3.26}$$

using the boundary condition $\vartheta(0) = 0$. Thus, the leading-order solution for $\mathfrak{s}$ is

$$\mathfrak{s} = \frac{1}{(y+1)}. \tag{3.27}$$

Case 2. $\boldsymbol{\mathcal{A} < 1}$. Note that $\mathcal{A}$ is the scaled cooling strength, and when $\mathcal{A} < 1$, we expect that the temperature is bounded below by $\mathcal{A} = 1$. Using the solution in Case 1, we note that ϑ is a monotonically increasing function with a maximum value

$$\vartheta_{max} = \ln\left(\frac{\mathcal{F}\ln(D_r)e^{\alpha_\mu(\theta_\ell-1)}}{2}(1-\ell) + 1\right). \tag{3.28}$$

The quantity ϑ_{max} is an order one quantity as long as $\ln(\ln(D_r)) \ll \epsilon^{-1}$, so we conclude that ϑ also will be an order one quantity.

Having established that $\vartheta = O(1)$, we can approximate (3.23) by

$$\mathfrak{s} = 1 + \frac{1}{\mathcal{A}}\left(e^{-\vartheta} - 1\right). \tag{3.29}$$

From (3.20), we obtain

$$\vartheta_y = \mathcal{A}\mathfrak{s} = e^{-\vartheta} + \mathcal{A} - 1, \tag{3.30}$$

which can be integrated to give

$$\vartheta = \ln\frac{\mathcal{A}e^{(\mathcal{A}-1)y} - 1}{\mathcal{A} - 1} \tag{3.31}$$

after applying the condition $\vartheta(0) = 0$. Note that this solution also applies to the case of $\mathcal{A} = 1$ by taking the limit $\mathcal{A} \to 1$, which yields (3.26). The solution for $\mathfrak{s}$ can be obtained as

$$\mathfrak{s} = \frac{\mathcal{A} - 1}{A - e^{-(\mathcal{A}-1)y}}. \tag{3.32}$$

Case 3. $\mathcal{A} > 1$. In this case, we need to consider two scenarios: when $\vartheta = O(1)$ and when ϑ is large.

(i) $\vartheta = O(1)$. When $\vartheta = O(1)$, the analysis is identical to the case for $A < 1$, yielding the same formulas (3.31) and (3.32).

(ii) *Large* ϑ. When $1 \ll \vartheta \ll \epsilon^{-1}$ and $\mathcal{A} > 1$, the approximation of (3.23), neglecting exponentially small terms, is given by

$$\mathfrak{s} = 1 - \frac{1}{\mathcal{A}}, \tag{3.33}$$

which can be combined with (3.20) to yield

$$\vartheta_y = (\mathcal{A} - 1)(1 - \epsilon\vartheta). \tag{3.34}$$

This equation can be solved as

$$\vartheta = \frac{1 - C_2 e^{-\epsilon(\mathcal{A}-1)y}}{\epsilon} \tag{3.35}$$

where C_2 is an integration constant. Since we obtained the solution based on the assumption that ϑ is not small, we cannot use the boundary condition $\vartheta(0) = 0$. To determine C_2, we need to match the small ϑ solution given by (3.31) with that for large ϑ given by (3.35). Taking the limit of $\vartheta \to 0$ from (3.35), we obtain

$$\vartheta \sim \frac{1 - C_2(1 - \epsilon(\mathcal{A} - 1)y)}{\epsilon}.$$

For large ϑ, i.e., $y \to 0$, (3.31) gives

$$\vartheta \sim (\mathcal{A} - 1)y + \ln \frac{\mathcal{A}}{\mathcal{A} - 1}.$$

Comparing the two expressions, the only choice we have is

$$C_2 = 1 - \epsilon \ln \frac{\mathcal{A}}{\mathcal{A} - 1},$$

and the solution becomes

$$\vartheta = \frac{1 - e^{-\epsilon(\mathcal{A}-1)y}}{\epsilon} + \left(\ln \frac{\mathcal{A}}{\mathcal{A} - 1}\right) e^{-\epsilon(\mathcal{A}-1)y}. \tag{3.36}$$

Note that when $\mathcal{A} \gg 1$, $C_2 \sim 1$ and ϑ can be approximated by

$$\vartheta = \frac{1 - e^{-\epsilon(\mathcal{A}-1)y}}{\epsilon}. \tag{3.37}$$

(iii) *Uniformly valid solution.* The uniformly valid solution for ϑ obtained by combining the solutions for small and large values of ϑ is given by

$$\begin{aligned}\vartheta = \ln \frac{\mathcal{A}e^{(\mathcal{A}-1)y} - 1}{\mathcal{A} - 1} + \frac{1 - e^{-\epsilon(\mathcal{A}-1)y}}{\epsilon} + \ln \frac{\mathcal{A}}{\mathcal{A} - 1} e^{-\epsilon(\mathcal{A}-1)y} \\ - (\mathcal{A} - 1)y - \ln \frac{\mathcal{A}}{\mathcal{A} - 1}.\end{aligned} \tag{3.38}$$

The solution for $\mathfrak{s}$ can be obtained using (3.23).

Solutions in original variables. Using the original variables and $\theta = \theta_\ell - \alpha_\mu^{-1}\vartheta$, the temperature solution is given by

$$\theta = \theta_\ell - \frac{1}{\alpha_\mu} \ln \frac{\mathcal{A} \exp\left[(\mathcal{A}-1)\mathcal{B}(z-\ell)\right] - 1}{\mathcal{A}-1} \tag{3.39}$$

for $\mathcal{A} \leq 1$ and

$$\begin{aligned}\theta = \theta_\ell &- \frac{1}{\alpha_\mu} \ln \frac{\mathcal{A} \exp\left[(\mathcal{A}-1)\mathcal{B}(z-\ell)\right] - 1}{\mathcal{A}-1} \\ &- \left(\theta_\ell - \frac{1}{\alpha_\mu} \ln \frac{\mathcal{A}}{\mathcal{A}-1}\right)\left(1 - \exp\left[-\frac{(\mathcal{A}-1)\mathcal{B}}{\alpha_\mu \theta_\ell}(z-\ell)\right]\right) + \frac{1}{\alpha_\mu}(\mathcal{A}-1)\mathcal{B}(z-\ell)\end{aligned} \tag{3.40}$$

for $\mathcal{A} > 1$. Here $\mathcal{B} = \mathcal{F} \ln(D_r) e^{\alpha_\mu(\theta_\ell - 1)}/2$.

In both cases, the solution for the cross-sectional area in the original variables is obtained using (3.23):

$$s = s_\ell \left(1 - \frac{1}{\mathcal{A}} + \frac{\theta_\ell \exp[\alpha_\mu(\theta - \theta_\ell)]}{\mathcal{A}\theta}\right)^2. \tag{3.41}$$

Using $s(1) = D_r^{-1}$, we can obtain $\mathcal{F}$ (and F) by solving the following equation numerically:

$$D_r^{-1} = s_\ell \left(1 - \frac{1}{\mathcal{A}} + \frac{\theta_\ell \exp[\alpha_\mu(\theta(1) - \theta_\ell)]}{\mathcal{A}\theta(1)}\right)^2 \tag{3.42}$$

where $\theta(1)$ is evaluated at $z = 1$ using (3.39) or (3.40), depending on the value of $\mathcal{A}$.

In Figures 3 and 4, we have plotted both the numerical and the asymptotic solutions for various values of the draw ratio D_r and for two different values of the cooling parameter $\mathcal{H}_c$, respectively. It can be seen that the solutions agree very well with each other. Therefore, instead of relying on numerical solutions, one can use (3.39) and (3.40) to evaluate the effective diffusion coefficient for the dopant. This will be shown in the next section.

4. Dopant diffusion.

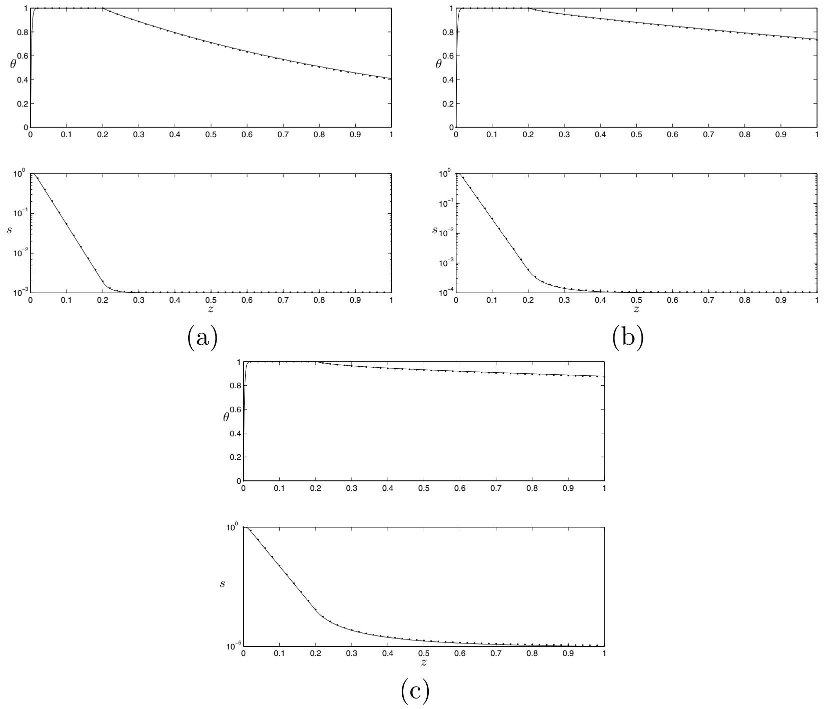
Since dopant transport follows a standard diffusion equation, the solution is completely determined by the effective diffusion coefficient. When the diffusion coefficient is small (as in the case of dopant diffusion), the effect of the boundary on the dopant distribution is also small. Therefore, we can ignore the boundary and solve (2.29) on an infinite domain as an approximation.[2] In this case, the solution for the dopant concentration can be written as

$$c(\tau, \xi) = 2\pi \int_0^1 G(\tau, \xi; \eta) c_0(\eta) \eta d\eta. \tag{4.1}$$

[2] If we consider the boundary effect, we can use the series solution given by

$$c(\tau, \xi) = 2\left[1 + \frac{r_*}{R} \sum_{m=1}^{\infty} e^{-\lambda_m^2 \mathcal{D}\tau} \frac{J_0(\lambda_m \xi) J_1(\lambda_m r_* R^{-1})}{\lambda_m J_0(\lambda_m)^2}\right]$$

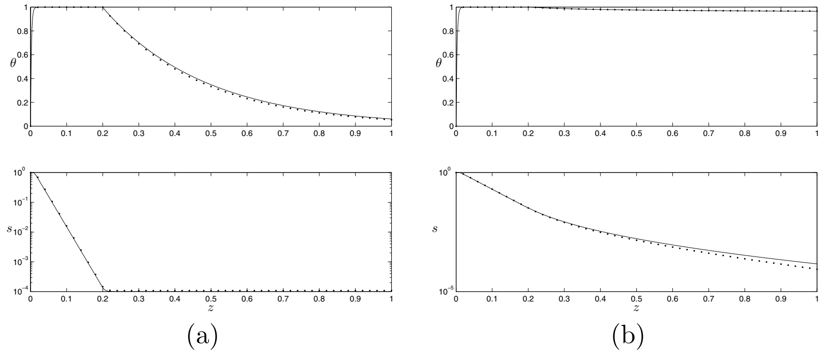
where λ_m are the zeros of $J_1(\lambda)$. As long as the diffusion is not too small, only a small number of terms is needed. For small diffusion coefficient values, convergence becomes slow, and we can switch to the solution based on the infinite domain Green's function.



(a) (b)

(c)

FIG. 3. *Numerical (dots) vs. asymptotic solutions (solid line) given by* (3.40) *and* (3.41)*:* (a) $D_r = 10^3$ *($\mathcal{A} = 3.67$);* (b) $D_r = 10^4$ *($\mathcal{A} = 1.71$); and* (c) $D_r = 10^5$ *($\mathcal{A} = 1.20$). Values of the other parameters are $\mathcal{H} = 350$, $\mathcal{H}_c = 35$, $\alpha_\mu = 40$, $\ell = 0.2$.*



(a) (b)

FIG. 4. *Numerical (dots) vs. asymptotic solutions (solid line) given by* (3.39), (3.40)*, and* (3.41)*:* (a) $\mathcal{H}_c = 350$ *($\mathcal{A} = 6.96$); and* (b) $\mathcal{H}_c = 1$ *($\mathcal{A} = 0.78$). Values of the other parameters are $\mathcal{H} = 350$, $D_r = 10^4$, $\alpha_\mu = 40$, $\ell = 0.2$.*

If we know the value of $\mathcal{D}$, then the Green's function is given by

$$G(\tau, \xi; \eta) = \frac{1}{4\pi \mathcal{D}\tau} \exp\left(-\frac{\xi^2 + \eta^2}{4\mathcal{D}\tau}\right) I_0\left(\frac{\xi\eta}{2\mathcal{D}\tau}\right) \tag{4.2}$$

where I_0 is the modified Bessel function of the first kind.

In order to illustrate how the effective diffusion coefficient $\mathcal{D}$ is affected by various parameter values, we obtain an asymptotic approximation for the case with no cooling

($\ell = 1$). Recall that in this case, the temperature is given by (3.13):

$$\theta = 1 - \exp\left[-C_1\left(1 - e^{-\frac{\mathcal{F}\ln D_r}{2}z}\right)\right],$$

with C_1 given by (3.11) and the effective diffusion coefficient is given by $\mathcal{D} = \bar{\phi}/\mathcal{P}$ where $\bar{\phi}$ is given by (2.27) with D given by (2.20).

Introducing new variables $\zeta = 1 - \exp\left(-\frac{\mathcal{F}\ln D_r}{2}z\right)$ and $\varphi(\zeta) \equiv \phi(z)$, we have

$$d\zeta = \frac{\mathcal{F}\ln D_r}{2}(1-\zeta)dz$$

and

$$\varphi_\zeta = \frac{2}{\mathcal{F}\ln D_r}\frac{\exp\left(-\frac{\alpha_D}{\Theta+1-\exp(-C_1\zeta)}\right)}{1-\zeta}, \quad \varphi(0) = 0. \tag{4.3}$$

Since $C_1 \gg 1$, the solution can be found for two cases: $\zeta \sim C_1^{-1}$ and $\zeta \sim 1$.

Case I. $\boldsymbol{\zeta \sim C_1^{-1} \ll 1}$. In this case, we use a new variable $\hat{\zeta} = C_1\zeta$ and denote the solution by $\varphi^{(i)}$ (inner solution) which satisfies

$$\varphi^{(i)}_{\hat{\zeta}} = \frac{2\exp\left(-\frac{\alpha_D}{\Theta+1-\exp(-\hat{\zeta})}\right)}{C_1\mathcal{F}\ln D_r}, \quad \varphi^{(i)}(0) = 0. \tag{4.4}$$

The inner solution can be obtained as

$$\varphi^{(i)}(\hat{\zeta}) = -\frac{2}{C_1\mathcal{F}\ln D_r}\left[E_1(x) - \exp\left(-\frac{\alpha_D}{\Theta+1}\right)E_1\left(x - \frac{\alpha_D}{\Theta+1}\right)\right]_{x=\alpha_D/\Theta}^{x=\alpha_D/(\Theta+1-\exp(-\hat{\zeta}))}. \tag{4.5}$$

Case II. $\boldsymbol{\zeta \sim 1}$. In this case, we denote the solution by $\varphi^{(o)}$ (outer solution) which satisfies

$$\varphi^{(o)}_\zeta = \frac{2}{\mathcal{F}\ln D_r}\frac{\exp(-\frac{\alpha_D}{\Theta+1})}{1-\zeta}. \tag{4.6}$$

The solution can be obtained as

$$\varphi^{(o)}(\zeta) = -\frac{2\exp(-\frac{\alpha_D}{\Theta+1})}{\mathcal{F}\ln D_r}\ln(1-\zeta) + C_3 \tag{4.7}$$

where C_3 is an integration constant.

Matching. To determine the integration constant C_3 and the outer solution, $\varphi^{(o)}$, we need to match the two solutions as follows:

$$\lim_{\hat{\zeta}\to\infty}\varphi^{(i)}(\hat{\zeta}) = \lim_{\zeta\to 0}\varphi^{(o)}(\zeta).$$

Since

$$\varphi^{(o)}(\zeta) \sim C_3 + \frac{2\exp(-\frac{\alpha_D}{\Theta+1})}{\mathcal{F}\ln D_r}\zeta \quad \text{as} \quad \zeta \to 0 \tag{4.8}$$

and $E_1[z] \sim -\gamma - \ln(z)$ for small z, we have

$$\begin{aligned}
\varphi^{(i)}(\hat{\zeta}) \sim & -\frac{2}{C_1 \mathcal{F} \ln D_r} \Bigg\{ E_1\left(\frac{\alpha_D}{\Theta+1}\right) - E_1\left(\frac{\alpha_D}{\Theta}\right) - \exp\left(-\frac{\alpha_D}{\Theta+1}\right) \\
& \times \left[-\gamma - \ln\left(\frac{\alpha_D}{\Theta+1-\exp\left(-\hat{\zeta}\right)} - \frac{\alpha_D}{\Theta+1}\right)\right] \\
& + \exp\left(-\frac{\alpha_D}{\Theta+1}\right) E_1\left(\frac{\alpha_D}{\Theta} - \frac{\alpha_D}{\Theta+1}\right) \Bigg\} \\
\approx & -\frac{2}{C_1 \mathcal{F} \ln D_r} \left\{ E_1\left(\frac{\alpha_D}{\Theta+1}\right) - E_1\left(\frac{\alpha_D}{\Theta}\right) - \exp\left(-\frac{\alpha_D}{\Theta+1}\right) \right. \\
& \left. \times \left[-\gamma - \ln\alpha_D + \hat{\zeta} + 2\ln(\Theta+1)\right] + \exp\left(-\frac{\alpha_D}{\Theta+1}\right) E_1\left(\frac{\alpha_D}{\Theta(\Theta+1)}\right) \right\} \\
\approx & -\frac{2}{C_1 \mathcal{F} \ln D_r} \left\{ E_1\left(\frac{\alpha_D}{\Theta+1}\right) - E_1\left(\frac{\alpha_D}{\Theta}\right) - \exp\left(-\frac{\alpha_D}{\Theta+1}\right) \right. \\
& \left. \times [-\gamma - \ln\alpha_D + 2\ln(\Theta+1)] + \exp\left(-\frac{\alpha_D}{\Theta+1}\right) E_1\left(\frac{\alpha_D}{\Theta(\Theta+1)}\right) \right\} \\
& + \frac{2\exp\left(-\frac{\alpha_D}{\Theta+1}\right)}{\mathcal{F}\ln D_r} \frac{\hat{\zeta}}{C_1} \quad \text{as} \quad \hat{\zeta} \to \infty.
\end{aligned} \tag{4.9}$$

We obtain

$$\begin{aligned}
C_3 = & -\frac{2}{C_1 \mathcal{F} \ln D_r} \left\{ E_1\left(\frac{\alpha_D}{\Theta+1}\right) - E_1\left(\frac{\alpha_D}{\Theta}\right) - \exp\left(-\frac{\alpha_D}{\Theta+1}\right) \right. \\
& \left. \times [-\gamma - \ln\alpha_D + 2\ln(\Theta+1)] + \exp\left(-\frac{\alpha_D}{\Theta+1}\right) E_1\left(\frac{\alpha_D}{\Theta(\Theta+1)}\right) \right\}.
\end{aligned} \tag{4.10}$$

Using the original variable, we have

$$\phi^{(o)}(z) = \exp\left(-\frac{\alpha_D}{\Theta+1}\right) z + C_3, \tag{4.11}$$

from which we obtain the effective diffusion coefficient as

$$\mathcal{D} = \frac{\exp\left(-\frac{\alpha_D}{\Theta+1}\right) + C_3}{\mathcal{P}}. \tag{4.12}$$

First, we observe that the first term on the right-hand side of $\mathcal{D}$ is given by $\mathcal{P}^{-1}\exp\left(-\frac{\alpha_D}{\Theta+1}\right)$, which is the value of the effective diffusion coefficient when $\theta = \Theta$ for all z, i.e., uniform temperature. The correction term C_3 is inversely proportional to

$$2\mathcal{H}_f + (\ln\alpha_\mu + \gamma)\left(1 + \frac{\ln\alpha_\mu + \gamma}{\mathcal{H}_f}\right)\ln D_r.$$

The parameter $\mathcal{H}_f$ is typically much larger than the other parameters. Therefore, the above asymptotic analysis clearly shows that the effective diffusion is extremely weakly dependent on the draw ratio D_r.

On the other hand, $\mathcal{D}$ is strongly affected by the Péclet number $\mathcal{P}$. Therefore, the most effective way to control excessive diffusion is to increase $\mathcal{P}$, which can be achieved by using a relatively large feeding speed. We note that the diffusion coefficient given here is for the scaled fiber radius. Thus, the absolute length of diffusion is proportional to the initial fiber radius R_0. For illustrative purposes, we have evaluated the effective diffusion coefficient given in (4.12) using the parameter values listed in Table 1 and keeping the feeding speed as a free parameter, yielding

$$\mathcal{D} \approx \frac{3.02 \times 10^{-9}}{u_0} - \frac{1.44 \times 10^{-11}}{4.27u_0^2 + 5.10 \times 10^{-5}} \text{ m}^2/\text{s}.$$

Here the second term comes from the correction term $C_3/\mathcal{P}$. Taking the value of $u_0 = 10^{-4}$ m/s (cf. [6]), we obtain $\mathcal{D} \approx 2.99 \times 10^{-5}$ m^2/s with the correction term and 3.02×10^{-5} m^2/s without the correction term. Next we compute the effective diffusion coefficient using numerical quadrature, based on (2.27), (2.28), and (3.13), which yields $\mathcal{D} = 2.99 \times 10^{-5}$ m^2/s. For a higher feeding speed, e.g., $u_0 = 3 \times 10^{-3}$ m/s, the asymptotic solution is $\mathcal{D} \approx 8.45 \times 10^{-7}$ m^2/s with the correction term and 1.01×10^{-6} m^2/s without the correction term, while the numerical solution is $\mathcal{D} = 8.5 \times 10^{-7}$ m^2/s. In both cases the asymptotic solution is a very good approximation when it is compared with the numerical solution, especially when the correction term is included.

Finally, to find $\mathcal{D}$ for the case with cooling, we could solve for the temperature from (2.24)–(2.25) with boundary condition (2.26). The effective diffusion coefficient could be computed using the integral $\int_0^1 D(\theta)dz$. In general, we can apply numerical methods, e.g., finite difference to solve the flow and temperature equations (2.24) and (2.25) and numerical quadrature to the integral to find an approximation of $\mathcal{D}$. However, since we already obtained an asymptotic solution for the temperature, $\mathcal{D}$ can be computed easily by evaluating the integral using numerical quadrature.

5. Conclusion. In this paper, we have shown that the long-wave approximation can be used to dramatically simplify the governing equations for dopant transport in optical fiber drawing. The viscosity and diffusion coefficient vary rapidly with temperature, which makes direct numerical simulations difficult. However, we take advantage of these rapid changes to derive asymptotic approximations of the solution. We show that the transport of dopant satisfies a simple diffusion equation with an effective diffusion coefficient that can be computed easily using our asymptotic solution. Our solution shows that the feeding speed is the most effective way to control dopant diffusion from the core into the cladding region. Using our asymptotic solution, other control strategies can also be developed. For example, one can use an optimal control framework based on a cost function that maximizes fiber production and minimizes dopant diffusion and which uses the feeding and drawing speeds or the heating and cooling rates as control variables. However, such a study is beyond the scope of this paper and will be pursued in future work.

STATIONARY SOLUTIONS OF DRIVEN FOURTH- AND SIXTH-ORDER CAHN–HILLIARD-TYPE EQUATIONS[*]

M. D. KORZEC[†], P. L. EVANS[‡], A. MÜNCH[§], AND B. WAGNER[¶]

Abstract. New types of stationary solutions of a one-dimensional driven sixth-order Cahn–Hilliard-type equation that arises as a model for epitaxially growing nanostructures, such as quantum dots, are derived by an extension of the method of matched asymptotic expansions that retains exponentially small terms. This method yields analytical expressions for far-field behavior as well as the widths of the humps of these spatially nonmonotone solutions in the limit of small driving force strength, which is the deposition rate in case of epitaxial growth. These solutions extend the family of the monotone kink and antikink solutions. The hump spacing is related to solutions of the Lambert W function. Using phase-space analysis for the corresponding fifth-order dynamical system, we use a numerical technique that enables the efficient and accurate tracking of the solution branches, where the asymptotic solutions are used as initial input. Additionally, our approach is first demonstrated for the related but simpler driven fourth-order Cahn–Hilliard equation, also known as the convective Cahn–Hilliard equation.

1. Introduction.

A paradigm for phase separating systems such as binary alloys is the Cahn–Hilliard equation for the phase fraction u,

$$u_t + \left(Q(u) + \varepsilon^2 u_{xx}\right)_{xx} = 0, \tag{1.1}$$

where $Q(u)$ is the negative derivative of the double-well potential $-\mathcal{F}$, typically

$$Q(u) = \mathcal{F}'(u) = u - u^3. \tag{1.2}$$

The long-time dynamics are characterized by the logarithmically slow coarsening process of phases, corresponding to local minima of the potential, separated by interfaces of width ε. This process is described well by the motion of equidistantly spaced smoothed shock solutions or *kinks* ("positive kinks") and *antikinks* ("negative kinks") which connect the local minimum of $\mathcal{F}(u)$ at $u = -1$ to that at $u = 1$ and vice versa.

In recent years, an extension of this model has been studied for the case when the phase separating system is driven by an external field [16, 27]. In one space dimension it can be written as

$$u_t - \nu u u_x + \left(Q(u) + \varepsilon^2 u_{xx}\right)_{xx} = 0, \tag{1.3}$$

where ν denotes the strength of the external field. This equation, the convective Cahn–Hilliard (CCH) equation, also arises as a model for the evolution of the morphology of steps on crystal surfaces [21], and the growth of thermodynamically unstable crystal surfaces into a melt with kinetic undercooling and strongly anisotropic surface tension [17, 11, 9].

The dynamics of this model as $\nu \to 0$ are characterized by coarsening, as is typical for the Cahn–Hilliard equation ($\nu = 0$) [7, 26]. If $\nu \to \infty$, using the transformation $u \mapsto u/\nu$ in (1.3) one obtains the Kuramoto–Sivashinski equation, which is a well-known model for spatiotemporal chaotic dynamics (see, e.g., [10] and references therein). Recently, Eden and Kalantarov [6] also established the existence of a finite-dimensional inertial manifold for the CCH equation, viewed as an infinite-dimensional dynamical system.

A related higher order evolution equation arises in the context of epitaxially growing thin films (for a review on self-ordered nanostructures on crystal surfaces see Shchukin and Bimberg [24]). Here, the formation of *quantum dots* and their faceting has been described by the sixth-order equation

$$u_t - \nu u u_x - \big(Q(u) + \varepsilon^2 u_{xx}\big)_{xxxx} = 0, \tag{1.4}$$

where u denotes the surface slope, ν is proportional to the deposition rate [22], and $Q(u)$ is given with (1.2); it is assumed to have this form from now on throughout the paper. The high order derivatives are a result of the additional regularization energy which is required to form an edge between two plane surfaces with different orientations. This implies that the crystal surface tension also depends on curvature, which becomes very high at edges as the parameter ε goes to zero. In analogy to the Cahn–Hilliard equation, here the phases are the orientations of the facets. This *higher order convective* Cahn–Hilliard (HCCH) equation shares many properties with the CCH equation. In both cases the dynamics are described by conserved order parameters if $\nu = 0$. They also share characteristic coarsening dynamics as $\nu \to 0$ and chaotic dynamics as ν becomes large. To understand the complicated structure of the solutions it is instructive to study first the stationary solutions and their stability, as has been done for the CCH equation [28, 16]. For small ν, the stationary solutions for both equations have been characterized by the monotone *kink* and *antikink* solutions [16, 22]. Recently new spatially nonmonotone solutions were found for the lower order equation [28]. In this study we establish that the HCCH equation also possesses such nonmonotone solutions. We show this by using phase-space methods for the corresponding fifth-order boundary value problem. We use the expression "simple" or "monotone" for a solution that connects the maximal value of $u(x)$ to the minimal value without any humps on the way down, although these extrema exist and lead to nonmonotonicity even for simple (anti-)kink solutions of the HCCH equation.

Since the treatment of this high order problem is not straightforward, one part of this study is concerned with the development of an approach that accurately locates the heteroclinic connections in the five-dimensional phase space. We find that these stationary solutions develop oscillations whose width and amplitude increase as $\nu \to 0$.

In the second part of this study we derive an analytic expression for the width and amplitude within the asymptotic regime of small external field strength. For the CCH equation we find that the width has a logarithmic dependency on the strength of the external field, while for the HCCH equation our analysis yields a dependency in terms of the Lambert W function. In order to arrive at these expressions we solve the fifth-order equation by a combination of the method of matched asymptotic expansions and exponential asymptotics. We first demonstrate our approach for the third-order boundary value problem arising from the CCH equation. Our approach generalizes the work by Lange [15] to higher order singularly perturbed nonlinear boundary value problems, where standard application of matched asymptotics is not able to locate the position of interior layers that delimit the oscillations of the nonmonotone solutions.

Reyna and Ward [19] previously developed an approach to resolve the internal layer structure of the solutions to the boundary value problem for the related Cahn–Hilliard and viscous Cahn–Hilliard equations. The approach is based on a method due to Ward [25], who uses a "near" solvability condition for the corresponding linearized problem in his asymptotic analysis, and who was inspired by an earlier variational method [13] and work by O'Malley [18] and Rosenblat and Szeto [20], who investigated the problem of spurious solutions to singular perturbation problems of second-order nonlinear boundary value problems [3]. Moreover, for the related Kuramoto–Sivashinsky equation, a multiple-scales analysis of the corresponding third-order nonlinear boundary value problem by Adams, King, and Tew [1] shows that the derivation of monotone and oscillating traveling-wave solutions involve exponentially small terms; their method is based on an analysis of the *Stokes phenomenon* of the corresponding problem in the complex plane (see Howls, Kawai, and Takei [12] for an introduction).

In what follows we begin with the phase-space analysis for the CCH equation in section 2, followed by the asymptotic treatment for $\nu \ll 1$. The asymptotic ideas used for the CCH equation are then applied to the HCCH equation in section 3. The solutions obtained there are useful to serve as initial input for the numerical investigations of the branches of nonmonotone solutions in section 4. In this part we develop our numerical approach and then use it to identify new stationary solutions of the HCCH equation; these agree with the asymptotic theory. Finally, we briefly sum up the results together with concluding remarks in section 5.

2. Stationary solutions of the CCH equation.

The high order term in the CCH equation represents the regularization of the internal layers of the solutions. For most of our investigations we consider the problem in the scaling of the internal layers, or *inner* scaling, where the x-coordinate is stretched around the location $x = \bar{x}$ of a layer according to

$$x^* = \frac{x - \bar{x}}{\varepsilon}. \tag{2.1}$$

In this scaling the CCH equation becomes (after dropping the "$*$")

$$\varepsilon^2 u_t - \frac{\delta}{2}(u^2)_x + (Q(u) + u_{xx})_{xx} = 0, \tag{2.2}$$

where $\delta = \varepsilon\nu$. The stationary problem obtained by setting u_t to zero can be integrated once, requiring that the solutions approach the constants $\pm\sqrt{A}$ as $x \to \mp\infty$, where A is a constant of integration. That is, we consider the boundary value problem

$$\frac{\delta}{2}\left(u^2 - A\right) = (Q(u) + u_{xx})_x \tag{2.3}$$

together with the far-field conditions

$$\lim_{x \to \pm\infty} u = \mp\sqrt{A} \tag{2.4}$$

and vanishing derivatives in the same spatial limit. We refer to solutions of this system as antikinks. Monotone antikinks are known analytically [16], while recently, nonmonotone connections were computed numerically by Zaks et al. [28]. We now briefly discuss the numerical approach for obtaining these solutions. Here we concentrate on the regime where $0 < \delta \ll 1$ in order to compare the results with the asymptotic solutions derived later on. For a bifurcation analysis for larger δ we refer the reader to [28].

2.1. Numerical solutions. For the numerical solutions, we will work with a rescaled version, where we set $u = \sqrt{A}c$ so that the equilibrium points do not depend on A, and for $Q(u)$ given by (1.2), (2.3) and (2.4) become

$$(1 - c^2) = -\frac{2}{\delta\sqrt{A}}(c_{xx} + c - Ac^3)_x\,, \quad \lim_{x\to\pm\infty} c = \mp 1. \tag{2.5}$$

This differential equation could be reduced to second order by the transformation $g(c) = c_x$ at the expense of making it nonautonomous. However, for this problem we find it most convenient to present a shooting method, which enables us to track solution branches in the (A, δ) parameter plane. We transform (2.5) into a first-order system $U' = F(U)$, where $F : \mathrm{R}^3 \to \mathrm{R}^3$ is the function

$$F_1(U) = U_2, \quad F_2(U) = U_3, \quad F_3(U) = (3A(U_1)^2 - 1)U_2 + \frac{\delta\sqrt{A}}{2}((U_1)^2 - 1)\,. \tag{2.6}$$

We work in a three-dimensional phase space and denote either vectors or whole trajectories therein with capital U's. We use the same notation for two different objects because it will be clear from the context what is meant. Subscripts indicate the components.

The characteristic polynomials at the equilibrium points $U^{\pm} = (\pm 1, 0, 0)^T$ are

$$\mathcal{P}^{\pm}(\lambda) = \left|\frac{dF}{dU}(U^{\pm}) - \lambda I\right| = \lambda^3 + \lambda(1 - 3A) \mp \delta\sqrt{A}. \tag{2.7}$$

The signs of the real parts of the roots determine the dimension of the stable and unstable manifolds $W^u(U^+)$, $W^s(U^-)$, $W^s(U^+)$, $W^u(U^-)$ of the equilibrium points. The latter two are two-dimensional and so the existence of a kink is generic, while this is not the case for the antikinks. The dimension of $W^u(U^+)$ and $W^s(U^-)$ is one, so that the heteroclinic connections from the positive to the negative equilibrium arise from a codimension two intersection. This means that with the two parameters A and δ, we can expect only separated solutions when the manifolds intersect, but due to the reversibility properties, which are discussed below, the codimension reduces to one and we can expect separated solutions for the free parameter A and a fixed δ, and hence one or several whole branches in the (A, δ) parameter plane. An example of a nonmonotone connection is sketched in Figure 2.1, where the trajectories wind themselves in the phase space with a solution that exhibits 15 humps.

Reversibility and computations . It is instructive to note that the solution of (2.5) is translation invariant, $c(x) \to c(x + L)$, and that (2.6) forms a reversible dynamical system; hence it is invariant with respect to the transformation $x \to -x, U \to -U$, as has also been noted by Zaks et al. [28].

Let us consider generally a k-dimensional phase space, since the following discussion will be also useful in section 4, where we analyze the HCCH equation with its higher order system. The linear transformation

$$R : \mathrm{R}^k \to \mathrm{R}^k, \quad R(U_j) = (-1)^j U_j, \quad j = 1, \ldots, k, \tag{2.8}$$

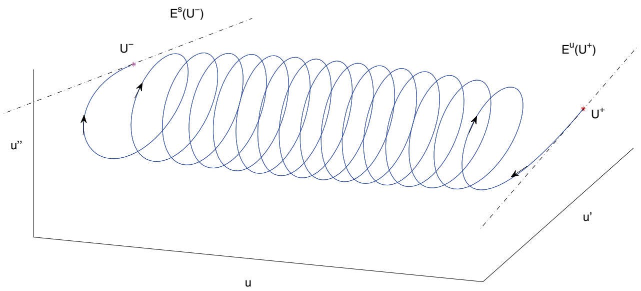

FIG. 2.1. *CCH: Antikink solutions connecting the hyperbolic equilibrium points U^+ and U^- are sought in a three-dimensional phase space. The unstable manifold emerging from U^+, $W^u(U^+)$ is one-dimensional, as is the stable manifold $W^s(U^-)$. The approximating linearized spaces $E^u(U^+)$ and $E^s(U^-)$ are drawn as dash-dotted lines and are used in the computations.*

fulfills $R^2 = Id$ and $RF(U) = -F(RU)$ for $k = 3$ and (2.6) and represents the reversibility in the phase space. It is an involution (or a reflection), and its set of fixed points is the symmetric section of the reversibility; these are zero at odd components, $U_i = 0$ for odd i. A solution that crosses such a point is necessarily symmetric under R, and for each point U on the connection there exists a corresponding transformed point RU somewhere on the branch. In fact there is an equivalence here since odd solutions necessarily cross a point in the symmetric section. It holds that c and its even derivatives have to vanish in the point of symmetry L because of the fulfilled equations $\frac{d^{2m}}{dx^{2m}}c(x+L) = -\frac{d^{2m}}{dx^{2m}}c(-x+L), m = 0, 1, \ldots, \lfloor k/2 \rfloor$, and continuity of the solution and its derivatives.

From the above we conclude that with a shooting method we can stop integrating when we find a point with zero odd components, since the second half of the solution is then given by the set of transformed points under R. Hence we define the following distance function for a trajectory U over the interval of integration which helps to find these points,

$$d_A(U) = \min_x \sqrt{\sum_{i \text{ odd}} U_i(x)^2} \ . \tag{2.9}$$

The minimization of $d_A(U)$ over the free parameter, $\min_A d_A(U)$, must result in the value zero for an antisymmetric heteroclinic solution. We can use this condition for shooting and boundary value problem formulations, for the CCH and later for the HCCH equation in section 4.

For a fixed value of δ and a range of different A we follow the relevant branch of $W^u(U^+)$ by shooting from an initial point $U^+ \pm \epsilon v$ near U^+, where v is a unit eigenvector corresponding to the positive eigenvalue of $dF/dU_{|U=U^+}$ and $\epsilon \ll 1$. We stop the integration if a certain threshold value for $|U_1|$ is crossed. Figure 2.2 shows $d_A(U)$ as a function of A for $\delta = 0.05$.

At this point we have heteroclinic connections for one fixed value of δ, which we denote by $het_k, k = 0, 1, \ldots$ (using the notation in Zaks et al. [28]). het_0 is the analytical, monotone tanh solution, while het_k has k humps on the way down from

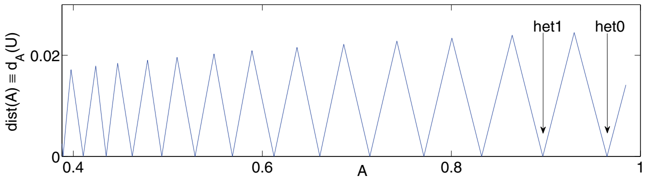

FIG. 2.2. *Distance function d_A defined by* (2.9) *depending on A with fixed $\delta = 0.05$, showing the first* 14 *zeros corresponding to het_0 to het_{13}.*

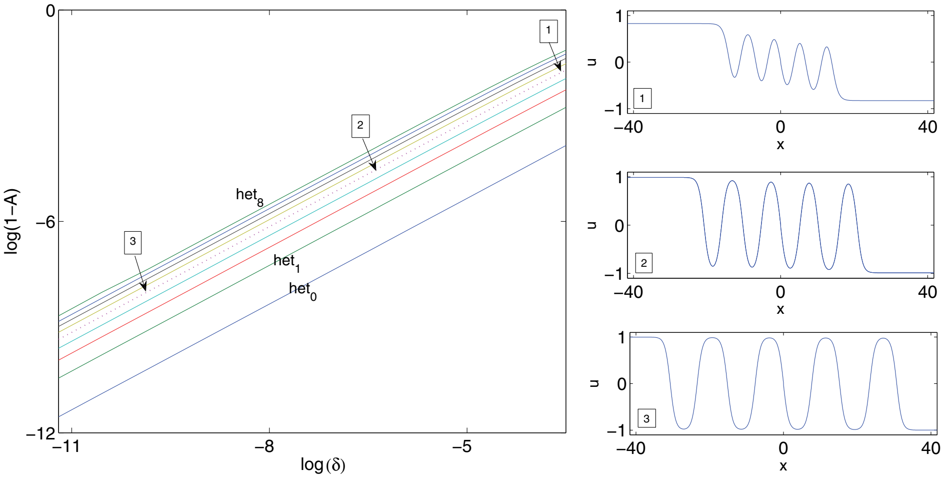

FIG. 2.3. *Parameter plane,* $\log(\delta)$ *for the x-axis and* $\log(1 - A)$ *for the y-axis, for the CCH equation for the first nine antikink solutions $het_k, k = 0, 1, \dots, 8$. The graphs on the right show the shapes of representative het_4 solutions, and hence those on the fifth line from below, for the approximate (A, δ) tuples* $(0.8259, 0.0289)$, $(0.9893, 0.0017)$, *and* $(0.9998, 2.6457 \cdot 10^{-5})$.

$\sqrt{A}$ to $-\sqrt{A}$. We will use the same terminology for the solution structure of the stationary HCCH problem in section 4. Here, a het_k solution corresponds to the kth zero from the right in Figure 2.2. We then follow the roots of the distance function by linearly extrapolating to a new guess for A and use a bisection algorithm to quickly converge to the next root. Figure 2.3 shows a portion of the (A, δ) parameter plane, where we concentrate on very small values of δ or, differently interpreted, on the bifurcation of the various spiraling CCH orbits from the heteroclinic connections of the Cahn–Hilliard equation in its one dimension smaller phase space.

2.2. Asymptotic internal layer analysis. For the asymptotic analysis we use a slightly different scaling than for the numerical treatment. Here, we let

$$x^* = \frac{x - \bar{x}}{\sqrt{2}\,\varepsilon} \tag{2.10}$$

denote the *inner* variable about a layer located at $x = \bar{x}$. For the stationary problem we then obtain

$$\left(u'' + 2\,Q(u)\right)' = \delta\sqrt{2}\left(u^2 - A\right) \tag{2.11}$$

instead of (2.3), where $' = d/dx^*$. For later comparisons of the numerical and asymptotic results we have to keep in mind that the spatial scales differ by a factor of $\sqrt{2}$.

We point out that the problem considered here shares the internal layer structure of the singular perturbation problems discussed by Lange [15], and we will make use of and extend this ansatz for our situation. This will also prove useful for understanding the approach taken for the HCCH problem in section 3.1, since there we have to carefully combine the exponential matching with the conventional matching procedure when matching the two regions. For both problems the asymptotic analysis can be conveniently carried out in terms of the small parameter δ.

In the following analysis we consider the simplest case of a nonmonotone solution with only one hump, as illustrated in Figure 2.4; we note that nonmonotone solutions with more oscillations can be treated similarly.

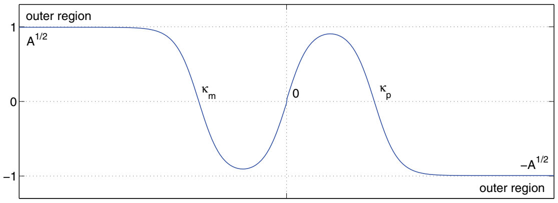

FIG. 2.4. *Sketch of a* 1*-hump, or het*$_1$*, solution showing the general setup for the matching procedure for the CCH and HCCH equations.*

2.2.1. The 1-hump solution. We observe that the 1-hump solution has three internal layers, one at $\kappa_m < 0$, one at κ_p, and one at the symmetry point in between. Since the solution is point symmetric, we can choose this point to be $x = 0$, and it will be enough to discuss only the two layers at κ_m and zero and then match them to the *outer* solution.

Internal layer near κ_m. For the first internal layer at κ_m we let

$$x_m = \frac{x}{\sqrt{2}\,\varepsilon} - \frac{\bar{\kappa}_m}{\sqrt{2}}, \tag{2.12}$$

where $\bar{\kappa}_m < 0$, and set

$$\kappa_m = \bar{\kappa}_m + \sqrt{2}\sum_{k=1}^{\infty} \delta^k \kappa_{mk}, \tag{2.13}$$

so that to leading order the location where the solution crosses zero is $\bar{\kappa}_m$ and the additional terms account for the corrections due to the higher order problems.

With $u_m(x_m) = u(\varepsilon(\bar{\kappa}_m + \sqrt{2}\,x_m))$ the governing equation becomes

$$u_m''' + 2\,Q'(u_m) = \delta\,\sqrt{2}\,(u_m^2 - A)\,, \quad \text{where} \quad ' = \frac{d}{dx_m}. \tag{2.14}$$

For the boundary condition where u_m crosses zero, we have

$$u_m\left(\frac{\kappa_m - \bar{\kappa}_m}{\sqrt{2}}\right) = 0, \tag{2.15}$$

and the condition towards $-\infty$ is

$$\lim_{x_m \to -\infty} u_m(x_m) = \sqrt{A}. \tag{2.16}$$

We now assume $u_m(x_m)$ can be written as the following asymptotic expansion, valid near κ_m:

$$u_\alpha(x_\alpha) = u_{\alpha 0}(x_\alpha) + \sum_{k=1}^{\infty} \delta^k \, u_{\alpha k}(x_\alpha)\,, \tag{2.17}$$

with $\alpha = m$ here. Additionally, we assume A has the asymptotic expansion

$$A = 1 + \delta A_1 + O(\delta^2). \tag{2.18}$$

Observe that from (2.16) and (2.18),

$$\lim_{x_m \to -\infty} u_m(x_m) = \lim_{x_m \to -\infty} u_{m0}(x_m) + \sum_{k=1}^{\infty} \delta^k \, u_{mk}(x_m) = 1 + \frac{1}{2} \sum_{k=1}^{\infty} \delta^k A_k\,. \tag{2.19}$$

To leading order in δ we get the following problem for the Cahn–Hilliard equation:

$$u_{m0}''' + 2\,Q'(u_{m0}) = 0, \tag{2.20a}$$

$$u_{m0}(0) = 0 \quad \text{and} \quad \lim_{x_m \to -\infty} u_{m0}(x_m) = 1 \tag{2.20b}$$

with the unique solution $u_{m0}(x_m) = -\tanh(x_m)$. Next, the problem of order δ is

$$\Big(\mathcal{L}\left(u_{m1}, x_m\right)\Big)' = \sqrt{2}\,\left(\tanh^2(x_m) - 1\right), \tag{2.21a}$$

$$u_{m1}(0) = \kappa_{m1} \quad \text{and} \quad \lim_{x_m \to -\infty} u_{m1}(x_m) = \frac{A_1}{2}\,, \tag{2.21b}$$

where κ_{m1} and A_1 are constants to be exponentially matched and the operator $\mathcal{L}$ is defined by

$$\mathcal{L}(v, z) = v'' + 2\left(1 - 3\,\tanh^2(z)\right)\,v\,, \tag{2.22}$$

and $z = x_m$, $v = u_{m1}$, and $\prime = d/dx_m$. Note that the first boundary condition is obtained by expanding (2.15),

$$\begin{aligned} u_m\left(\sum_{k=1}^{\infty} \delta^k \kappa_{mk}\right) &= u_m\Big(\,\delta\kappa_{m1} + \delta^2\kappa_{m2} + O(\delta^3)\,\Big) \\ &= u_{m0}(0) + \delta\big(\,\kappa_{m1}u_{m0}'(0) + u_{m1}(0)\big) + O(\delta^2), \end{aligned} \tag{2.23}$$

so that collecting the terms of order δ gives

$$u_{m1}(0) = -\kappa_{m1}\,u_{m0}'(0) = \kappa_{m1}\,.$$

Next, we integrate (2.21) once to obtain

$$\mathcal{L}\left(u_{m1}, x_m\right) = f_m(x_m)\,, \tag{2.24}$$

where $f_m(x_m) = -\sqrt{2}\tanh(x_m) + c_m$. Taking the limit of this equation to $-\infty$ yields $c_m = -\sqrt{2} - 2A_1$ so that

$$f_m(x_m) = -\sqrt{2}\,(\tanh(x_m) + 1) - 2A_1\,. \tag{2.25}$$

The homogeneous solutions of (2.24) are

$$\phi_m(x_m) = -u'_{m0}(x_m) = 1 - \tanh^2(x_m)\,, \tag{2.26}$$

$$\psi_m(x_m) = \left(\int_0^{x_m} \frac{dz}{\phi_m^2(z)}\right)\phi_m(x_m)\,. \tag{2.27}$$

Also note that $\lim_{x_m\to-\infty}\phi_m(x_m) = 0$ and $\psi_m(0) = 0$. At this stage it is convenient to choose the inhomogeneous solution that remains bounded as $x_m \to -\infty$ and vanishes at $x_m = 0$, which is satisfied by

$$\varphi_\alpha(x_\alpha) = \psi_\alpha(x_\alpha)\int_{-\infty}^{x_\alpha} \phi_\alpha\, f_\alpha\, dz - \phi_\alpha(x_\alpha)\int_0^{x_\alpha} \psi_\alpha\, f_\alpha\, dz \tag{2.28}$$

with $\alpha = m$. Hence, the unique solution for (2.21) is the linear combination

$$u_{m1}(x_m) = -\kappa_{m1}\phi_m(x_m) + \varphi_m(x_m)\,. \tag{2.29}$$

Internal layer near $x = 0$. For the internal layer near the origin we proceed as above. Here, we stretch the independent variable as

$$x_0 = \frac{x}{\sqrt{2}\varepsilon} \tag{2.30}$$

and construct an asymptotic expansion (2.17) near $x = 0$ with $\alpha = 0$ for the solution of the problem

$$u_0''' + 2\,Q'(u_0) = \delta\,\sqrt{2}\,(u_0^2 - A)\,, \quad \text{where} \quad ' = \frac{d}{dx_0}. \tag{2.31}$$

We note that the point $x = 0$ is assumed to be the symmetry point of the complete solution; hence here we require

$$u_0(0) = 0 \quad \text{and} \quad u_0''(0) = 0\,. \tag{2.32}$$

In anticipation of the exponential matching we also require that $\lim_{x_0\to-\infty} u_{00}(x_0) = -1$, so that the solution to the leading order problem is $u_{00}(x_0) = \tanh(x_0)$. For the solution to $O(\delta)$ we find

$$u_{01}(x_0) = b_0\,\psi_0(x_0) + \varphi_0(x_0), \tag{2.33}$$

where b_0 is a further constant to be exponentially matched. Here, the homogeneous solutions are

$$\phi_0(x_0) = -u'_{00}(x_0) \quad \text{and} \quad \psi_0(x_0) = \left(\int_0^{x_0} \frac{dz}{\phi_0^2(z)}\right)\phi_0(x_0), \tag{2.34}$$

and the inhomogeneous solution is defined by (2.28), where $\alpha = 0$ and $f_0(x_0) = -\sqrt{2}\tanh(x_0)$. They are chosen such that $\varphi_0(0) = 0$ and $\varphi_0''(0) = 0$; in fact we have $\lim_{x_0\to\pm\infty}\varphi_0(x_0) = \pm\sqrt{2}/4$.

2.2.2. Exponential matching. Exponential matching requires that all exponentially small and exponentially growing terms have to be accounted for and matched. This means that first we have to express the variable x_0 in terms of x_m (or vice versa). From the definitions of these variables it follows that

$$x_0 = x_m + \frac{\bar{\kappa}_m}{\sqrt{2}}\,. \tag{2.35}$$

In particular, exponential terms in the solution $u_0(x_0)$ transform as $e^{2x_0} = e^{\sqrt{2}\bar{\kappa}_m}\, e^{2x_m}$ and so forth for higher order exponential terms e^{2nx_0} or terms with different signs in the exponent.

Now note that as $x_0 \to -\infty$, the leading and $O(\delta)$ solutions can be written as

$$u_{00}(x_0) = -1 + 2e^{2x_0} - O(e^{4x_0}), \tag{2.36}$$

and with $\bar{\mu} = \left(\frac{3}{2}b_0 + \sqrt{2}\right)$,

$$u_{01}(x_0) = -\frac{1}{4}\bar{\mu} - \frac{b_0}{16}e^{-2x_0} + \left(\frac{13}{16}b_0 + \frac{1}{\sqrt{2}} + \bar{\mu}x_0\right)e^{2x_0} + O(e^{4x_0})\,. \tag{2.37}$$

Written in x_m variables, the solution

$$\begin{aligned} u_0(x_m) &= -1 + 2e^{2x_m}e^{\sqrt{2}\bar{\kappa}_m} + O(e^{2\sqrt{2}\bar{\kappa}_m}) \\ &\quad + \delta\left(-\frac{1}{4}\bar{\mu} - \frac{b_0}{16}e^{-2x_m}e^{-\sqrt{2}\bar{\kappa}_m} + \left(\frac{13}{16}b_0 + \frac{1}{\sqrt{2}} + \bar{\mu}\left(x_m + \frac{\bar{\kappa}_m}{\sqrt{2}\varepsilon}\right)\right)e^{2x_m}e^{\sqrt{2}\bar{\kappa}_m} \right. \\ &\qquad \left. + O(e^{2\sqrt{2}\bar{\kappa}_m})\right) + O(\delta^2) \end{aligned} \tag{2.38}$$

has to be exponentially matched to

$$\begin{aligned} u_m(x_m) &= -1 + 2e^{-2x_m} + O(e^{-4x_m}) \\ &\quad + \delta\left(-\left(A_1 + \frac{\sqrt{2}}{4}\right) - \frac{1}{4}\left(A_1 + \frac{1}{\sqrt{2}}\right)e^{2x_m} + \left(\frac{7}{2}A_1 + \frac{5}{4}\sqrt{2} + 4\kappa_{m1}\right)e^{-2x_m} \right. \\ &\qquad \left. - \left(3A_1 + \frac{1}{\sqrt{2}}\right)x_m e^{-2x_m} + O\big(e^{-4x_m}\big)\right) + O(\delta^2) \end{aligned} \tag{2.39}$$

as $x_m \to \infty$. While we have already anticipated matching of the constants during the derivation of the leading order solutions, the constant terms of the $O(\delta)$ solutions are first to be matched. Matching to the exponential terms in (2.39) entails a rearranging of terms of different orders of magnitude in the expansion (2.38). In particular, the first exponential term to leading order in (2.39) matches the second term of $O(\delta)$ in (2.38), the second and largest exponential term of $O(\delta)$ in (2.39) matches the second term of the leading order in (2.38), and so forth. Summarizing, we obtain

$$\frac{1}{4}\left(\frac{3}{2}b_0 + \sqrt{2}\right) = A_1 + \frac{\sqrt{2}}{4}, \quad -\rho\frac{b_0}{16} = 2, \quad -\frac{\rho}{4}\left(A_1 + \frac{1}{\sqrt{2}}\right) = 2\,, \tag{2.40}$$

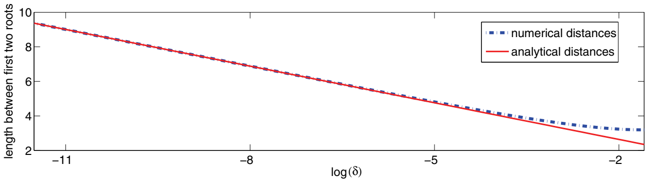

FIG. 2.5. *Distances between the first two roots of the* het_1 *solutions versus* $\log(\delta)$ *together with the width predicted by the asymptotic formula* (2.43).

where we denote $\rho = \delta\, e^{-\sqrt{2}\bar{\kappa}_m}$. Solving yields

$$\rho = 4\sqrt{2}, \quad A_1 = -\frac{3}{\sqrt{2}}, \quad \text{and} \quad b_0 = -\frac{8}{\sqrt{2}}\,. \tag{2.41}$$

We observe that we have determined the $O(\delta)$ correction A_1. Additionally, we now know that $\delta\, e^{-\sqrt{2}\bar{\kappa}_m} = 4\sqrt{2}$, hence

$$\bar{\kappa}_m = \frac{\ln(\delta)}{\sqrt{2}} - \frac{\ln\left(4\sqrt{2}\right)}{\sqrt{2}}, \tag{2.42}$$

and if we recall (2.13) and $\kappa_m < 0$, then the width of the hump is $-\kappa_m$, where

$$\kappa_m = \frac{\ln(\delta)}{\sqrt{2}} - \frac{\ln\left(4\sqrt{2}\right)}{\sqrt{2}} + O(\delta)\ . \tag{2.43}$$

Further constants, such as κ_{m1}, are found by including higher exponential terms and expansions of the higher order problems. Finally, we note that by making use of the symmetry of the solution about the point $x = 0$, the exponential matching of the solution near zero to the one near κ_p proceeds analogously.

2.2.3. Comparison of numerical and asymptotic solution.

For the comparison with the asymptotic solution we are interested mainly in the het_1 solution which we derived in section 2.2.1. By numerical continuation of the shooting method, one obtains N tuples $(A^{(j)}, \delta^{(j)})$, $j = 1, \ldots, N$, in the parameter plane that give a het_1-branch when being connected. We use two vectors of parameters which we abbreviate $\mathbf{A} = (A^{(j)})_{j=1,\ldots,N}$ and $\boldsymbol{\delta} = (\delta^{(j)})_{j=1,\ldots,N}$ to confirm the formulas we obtained in the previous section. Further we make use of a distance vector $\mathbf{K} = (K^{(j)})_{j=1,\ldots,N}$. $\mathbf{K}$ contains the distances between the zero crossings of the solutions, or in context of the asymptotics section (see Figure 2.4) $K^{(j)} \approx |\kappa_m(\delta^{(j)})|$. To obtain the relation between A and δ and the evolution of the distances we solve the least squares problems

$$\min_{\mu_1} \|(\mathbf{1} - \mu_1\boldsymbol{\delta}) - \mathbf{A}\|_2^2 \quad \text{and} \quad \min_{\eta_1,\eta_2} \|\eta_1 \log(\boldsymbol{\delta}\eta_2) - \mathbf{K}\|_2^2,$$

and hence we assume a linear law for the A-values in δ and a general logarithmic law for the distances. We obtain

$$A \approx 1 - 2.12\delta \approx 1 - \frac{3}{\sqrt{2}}\delta \quad \text{and} \quad K \approx -0.71\log(0.18\delta), \tag{2.44}$$

which confirms the results from the analysis, (2.41) and (2.43). We see the good match in the distance plot in Figure 2.5.

These results motivated us to obtain a general rule for the relation between the two parameters of the CCH equation for different stationary solutions. The numerically computed branches in Figure 2.3 show that the slopes of the het_k branches are one when plotting $\log(\delta)$ against $\log(1-A)$, so that the relation $\log(\delta)+\text{const} = \log(1-A)$ shows the linear dependence $A(k) = 1+A_1(k)\delta$, where $A(k)$ is the A value for the het_k solution and $A_1(k)$ its linear coefficient. We see that the magnitude of A_1 increases linearly with the order k of the heteroclinic connection, and we obtain a general expression for the squared far-field value for nonmonotone het_k solutions, namely,

$$A_1(k) = -\frac{2k+1}{\sqrt{2}}\,. \tag{2.45}$$

3. Matched and exponential asymptotics for the stationary HCCH equation. As we did for the CCH equation, we will perform our analysis of the internal layers in the inner scaling (2.10). From the stationary form of (1.4) we obtain the equation

$$\left(u'' + 2\,Q(u)\right)''' = -\delta\; 2^{3/2}\left(u^2 - A\right) \tag{3.1}$$

after integrating once and requiring that for an antikink $\lim_{x\to\pm\infty} u = \mp\sqrt{A}$ and setting $\delta = \epsilon^3\nu$ here. We consider the het_1 (1-hump) solution and again make use of the point symmetry of the problem. Now, however, unlike for the CCH equation, the solutions in the *outer* region are not just constants. Here, we have to introduce an *outer* layer to the left of the *inner* layer about κ_m; see also Figure 2.4 for the case of a 1-hump solution. In the following subsections we first briefly derive the solution to this *outer* problem and match it to the solution to the *inner* problem near κ_m. The remaining degrees of freedom are then used to exponentially match it to a second inner layer near $x = 0$.

It has been demonstrated in [22] for monotone antikink solutions of the HCCH equation that it is necessary to match terms up to order δ in order to obtain the correction A_1, given the asymptotic expansion of A,

$$A = 1 + \sum_{k=1}^{\infty} \delta^{k/3}\, A_k\,. \tag{3.2}$$

Here, for the nonmonotone antikinks we have to match *inner* and *outer* solutions and then also exponentially match the *inner* layers. This has to be carried through iteratively up to three orders of magnitude in order to obtain not only the correction A_1 but also the expression for the width of the humps.

3.1. The 1-hump solution for the HCCH equation. We start by shifting to the inner coordinates that describe the region near κ_m, which is to be matched to the outer region. Again defining x_m by (2.12), the governing equation in this inner region is

$$\Big(u_m'' + 2\,Q(u_m)\Big)''' = -\,2^{3/2}\,\delta\,(u_m^2 - A), \quad \text{where} \quad {}' = \frac{d}{dx_m}. \tag{3.3}$$

For the boundary conditions we again place κ_m near the point where u_m crosses zero, i.e.,

$$u_m\left(\frac{\kappa_m - \bar{\kappa}_m}{\sqrt{2}}\right) = 0\,. \tag{3.4}$$

The condition towards $-\infty$ is not as trivial as for the CCH equation but needs to be matched to the outer solution in the region to the left of κ_m (or to the right of κ_p, taking account of symmetry).

For the *outer* region (see Figure 2.4), where x_m becomes very large, we use the ansatz

$$\xi = \delta^{1/3}\, x_m \quad \text{and} \quad Y(\xi;\delta) = u_m(x_m;\delta) \tag{3.5}$$

and obtain the *outer* problem

$$\Big(\delta^{2/3}\, Y_{\xi\xi} + 2\, Q\,(Y)\Big)_{\xi\xi\xi} = -\,2^{3/2}\,\left(Y^2 - A\right) \tag{3.6}$$

with the far-field condition

$$\lim_{\xi\to-\infty} Y(\xi) = \sqrt{A}\,. \tag{3.7}$$

The region near $x = 0$, for which we use the variable x_0 from (2.30), is described by the problem

$$\Big(u_0'' + 2\, Q(u_0)\Big)''' = -\,2^{3/2}\,\delta\,(u_0^2 - A) \quad \text{where} \quad {}' = \frac{d}{dx_0}. \tag{3.8}$$

The point $x = 0$ is the point of symmetry of the solution. Here we require

$$u_0(0) = 0, \quad u_0''(0) = 0, \quad \text{and} \quad u_0''''(0) = 0\,, \tag{3.9}$$

plus additional conditions from the exponential matching to the internal layer near κ_m as $x_0 \to -\infty$, as we have shown for the CCH equation.

Here we assume that the solutions to these three problems for Y, u_m, and u_0 can be represented by asymptotic expansions

$$u_\alpha(x_\alpha;\varepsilon) = u_{\alpha 0}(x_\alpha) + \sum_{k=1}^{\infty} \delta^{k/3}\, u_{\alpha k}(x_\alpha), \quad \text{where} \quad \alpha = 0, m, \tag{3.10}$$

valid near κ_m and $x = 0$, respectively, and

$$Y(\xi;\delta) = Y_0(\xi) + \sum_{k=1}^{\infty} \delta^{k/3}\, Y_k(\xi)\,, \tag{3.11}$$

valid in the outer region, where we let

$$\kappa_m = \bar{\kappa}_m + \sqrt{2}\sum_{k=1}^{\infty} \delta^{k/3}\kappa_{mk}\,. \tag{3.12}$$

Obtaining solutions to the outer problem is straightforward [22], but in order to be more comprehensible we include the results in Appendix A. The solutions to the other regions are discussed now.

3.1.1. Leading order. To leading order in δ we get the problem

$$(u''_{m0} + 2\,Q(u_{m0}))''' = 0, \tag{3.13a}$$

$$u_{m0}(0) = 0. \tag{3.13b}$$

Matching to the leading order outer solution (A.2) $Y_0 = 1$ we find

$$u_{m0}(x_m) = -\tanh(x_m)\,. \tag{3.14}$$

Its representation towards the internal layer about $x = 0$ is given by

$$u_{m0} = -1 + 2e^{-2x_m} - 2e^{-4x_m} + O(e^{-6x_m}) \tag{3.15}$$

as $x_m \to \infty$. The leading order problem for this region is

$$(u''_{00} + 2\,Q(u_{00}))''' = 0, \tag{3.16a}$$

$$u_{00}(0) = 0, \quad u''_{00}(0) = 0, \quad \text{and} \quad u''''_{00}(0) = 0, \tag{3.16b}$$

and its solution is

$$u_{00}(x_0) = \tanh(x_0)\,. \tag{3.17}$$

As $x_0 \to -\infty$, its behavior is given by

$$u_{00} = -1 + 2e^{2x_0} - 2e^{4x_0} + O(e^{6x_0})\,. \tag{3.18}$$

3.1.2. $\mathbf{O(\delta^{1/3})}$.

Internal layer near $x = \kappa_m$. The expansion of (3.3) and (3.4) to order $\delta^{1/3}$ yields

$$\mathcal{L}(u_{m1}, x_m) = f_{m1}(x_m), \tag{3.19a}$$

$$u_{m1}(0) = -u'_{m0}(0)\,\kappa_{m1} = \kappa_{m1}, \tag{3.19b}$$

where $\mathcal{L}$ is defined by (2.22) as for the CCH equation and

$$f_{m1}(x_m) := c_{1m}x_m^2 + c_{2m}x_m + c_{3m}\,. \tag{3.20}$$

The homogenous solutions are therefore (2.26) and (2.27). The constants c_{1m}, c_{2m}, c_{3m} are obtained by three successive integrations of the ODE for u_{m1} obtained at this order. We choose the inhomogeneous solution so that it grows only algebraically as $x_m \to -\infty$ and vanishes at $x_m = 0$. Particular solutions to (3.19b) are of the form

$$\varphi_{\alpha j}(x_\alpha) = \psi_\alpha(x_\alpha) \int_0^{x_\alpha} \phi_\alpha\, f_{\alpha j}\, dz - \phi_\alpha(x_\alpha) \int_0^{x_\alpha} \psi_\alpha\, f_{\alpha j}\, dz + \gamma_{\alpha j}\psi_\alpha(x_\alpha)\,, \tag{3.21}$$

so that now we obtain φ_{m1} for $\alpha = m, j = 1$ in (3.21) and

$$\gamma_{m1} = -\frac{\pi^2}{12}c_{1m} + \ln(2)c_{2m} - c_{3m}\,. \tag{3.22}$$

Hence the solution is

$$u_{m1}(x_m) = -\kappa_{m1}\phi_m(x_m) + \varphi_{m1}(x_m)\,. \tag{3.23}$$

We evaluate ψ_α, ϕ_α, etc. and subsequent functions with the assistance of *Maple*. As $x_m \to -\infty$, the limiting behavior of u_{m1} is

(3.24)
$$\begin{aligned} u_{m1}(x_m) =& -\frac{1}{8}(c_{1m}+2c_{3m}) - \frac{1}{4}c_{2m}x_m - \frac{1}{4}c_{1m}x_m^2 \\ &+ \left(\frac{1}{64}(-7c_{1m} - 8c_{3m} + 256\kappa_{m1} + 30c_{2m} + 4c_{2m}\pi^2 - 72c_{1m}\zeta(3))\right. \\ &\left.+\frac{1}{16}(-6c_{2m}+15c_{1m}+24c_{3m})x_m + \frac{1}{8}(6c_{2m}-3c_{1m})x_m^2 + \frac{1}{2}c_{1m}x_m^3\right) e^{2x_m} \\ &+O(\,e^{4x_m}), \end{aligned}$$

where ζ is the Riemann zeta function, and u_{m1} must match the outer solution, which is given in the appendix by (A.10) and has only constant terms to this order. Hence we require $c_{2m} = 0$ and $c_{1m} = 0$. The matched solution is now

$$\begin{aligned} u_{m1}^{(m)}(x_m) &= (1-\tanh^2(x_m))\,\kappa_{m1} \\ &\quad -\frac{c_{3m}}{16}\Big(-2e^{6x_m} + 4 + 10e^{2x_m} - 12e^{4x_m} - 24x_m e^{2x_m}\Big)\frac{e^{-2x_m}}{(e^{2x_m}+1)^2}\,, \end{aligned} \tag{3.25}$$

where we denote by $u_{m1}^{(m)}$ the solution that is obtained by matching to the outer solution Y. As we will see later, exponential matching to the inner solution u_0, i.e., as $x_m \to \infty$, where we find

$$\begin{aligned} u_{m1}^{(m)}(x_m) = \frac{1}{8}c_{3m}e^{2x_m} + \frac{1}{2}c_{3m} + \left(-\frac{7}{4}c_{3m} + 4\kappa_{m1} + \frac{3}{2}c_{3m}x_m\right)e^{-2x_m} \\ + \left(\frac{11}{4}c_{3m} - 8\kappa_{m1} - 3c_{3m}x_m\right)e^{-4x_m} + O(e^{-6x_m})\,, \end{aligned}$$

requires also $c_{3m} = 0$. Hence, denoting by $u_{m1}^{(e)}$ the solution that has been exponentially matched to the inner solution u_0 near $x = 0$, we obtain

$$u_{m1}^{(e)}(x_m) = \big(1-\tanh^2(x_m)\big)\;\kappa_{m1}\,. \tag{3.26}$$

Internal layer near $x = 0$. The $O(\delta^{1/3})$ problem is

$$\mathcal{L}(u_{01}, x_0) = f_{01}(x_0)\,, \tag{3.27a}$$
$$u_{01}(0) = 0, \quad u_{01}''(0) = 0, \quad \text{and} \quad u_{01}''''(0) = 0\,, \tag{3.27b}$$

with

$$f_{01}(x_0) := c_{10}x_0^2 + c_{20}x_0 + c_{30}\,. \tag{3.28}$$

Its general solution reads

$$u_{01}(x_0) = \varphi_{01}(x_0) + g_1\,\psi_0(x_0)\,, \tag{3.29}$$

where the homogeneous solutions are as before and the inhomogeneous solution is given by (3.21) with $\alpha = 0, j = 1$, and

$$\gamma_0 = -\frac{\pi^2}{12}c_{10} + \ln(2)\,c_{20} - c_{30}\,, \tag{3.30}$$

so that $\varphi_{01}(0)=0$ and φ_{01} grows algebraically as $x_0 \to -\infty$. Furthermore, symmetry requires $\varphi''_{01}(0)=0$ and $\varphi''''_{01}(0)=0$, which implies $c_{10}=0$ and $c_{30}=0$, leading to

$$\begin{aligned}\varphi_{01}(x_0) = {}& \frac{c_{20}}{16(1+e^{-2x_0})^2}\Big(1-4x_0+12\,\mathrm{dilog}(e^{2x_0}+1)e^{-2x_0}-e^{-4x_0}+12x_0^2e^{-2x_0}\\ &+\pi^2e^{-2x_0}+12x_0e^{-4x_0}-14x_0e^{-2x_0}-\ln(1+e^{-2x_0})e^{2x_0}+8e^{-4x_0}\ln(1+e^{-2x_0})\\ &-8\ln(1+e^{-2x_0})+e^{-6x_0}\ln(1+e^{-2x_0})+2e^{-6x_0}x_0\Big)\,,\end{aligned} \tag{3.31}$$

where dilog denotes the dilogarithm function. The remaining free parameters of u_{01} to be matched are c_{20} and g_1. As will be demonstrated later, exponential matching to u_m requires an expression for u_{01} as $x_0 \to -\infty$,

$$\begin{aligned}u_{01}(x_0) = {}& -\frac{g_1}{16}e^{-2x_0}-\frac{1}{4}c_{20}x_0-\frac{3}{8}g_1\\ &+\frac{1}{32}\Big(2c_{20}\pi^2+15c_{20}+26g_1+(48g_1-12c_{20})x_0+24c_{20}x_0^2\Big)e^{2x_0}\\ &+\frac{1}{48}\Big(-36g_1-89c_{20}-6c_{20}\pi^2+(84c_{20}-144g_1)x_0-72c_{20}x_0^2\Big)e^{4x_0}+O(e^{6x_0}),\end{aligned} \tag{3.32}$$

and then re-expanding u_0 in the variable x_m. This shows that also $c_{20}=0$, $g_1=0$ and $c_{3m}=0$. Any other choice leads to a system for the parameters having no solution. Hence, only κ_m remains as a free constant in the two regions. The exponentially matched solution is therefore simply

$$u_{01}^{(e)}(x_0)=0\,. \tag{3.33}$$

3.1.3. O($\delta^{2/3}$).

Internal layer near κ_m. The problem of order $\delta^{2/3}$ is

$$\mathcal{L}(u_{m2},x_m)=f_{m2}(x_m)\,, \tag{3.34a}$$

$$u_{m2}(0)=-u'_{m0}(0)\,\kappa_{m2}-\frac{1}{2}u''_{m0}\kappa_{m1}^2-u'_{m1}(0)\kappa_{m1}=\kappa_{m2}-u'_{m1}(0)\,\kappa_{m1}\,, \tag{3.34b}$$

where

$$f_{m2}(x_m):=d_{1m}x_m^2+d_{2m}x_m+d_{3m}+6\,u_{m0}\,(u_{m1}^{(e)})^2\,. \tag{3.35}$$

Note that $u_{m1}^{(m)'}(0)=0$. Again we choose the inhomogeneous solution so that it grows only algebraically as $x_m \to -\infty$ and vanishes at $x_m=0$ to obtain (3.21) with $\alpha=m, j=2$, and

$$\gamma_{m2}=-\frac{\pi^2}{12}d_{1m}+\ln(2)\,d_{2m}-d_{3m}-\kappa_{m1}^2\,, \tag{3.36}$$

so that the general solution is represented as

$$u_{m2}(x_m)=-\kappa_{m2}\phi_m(x_m)+\varphi_{m2}(x_m)\,. \tag{3.37}$$

As $x_m \to -\infty$, we have to compare

$$\begin{aligned} u_{m2}(x_m) = & -\frac{1}{8}(d_{1m} + 2d_{3m}) - \frac{1}{4}d_{2m}x_m - \frac{1}{4}d_{1m}x_m^2 \\ & + e^{2x_m}\Bigg(\frac{1}{64}[(-7 - 72\zeta(3))d_{1m} - 8d_{3m} + 256(\kappa_{m2} - \kappa_{m1}^2) + (30 + 4\pi^2)d_{2m}] \\ & + \frac{3}{16}(5d_{1m} - 2d_{2m} + 8d_{3m})x_m + \frac{3}{8}(2d_{2m} - d_{1m})x_m^2 + \frac{1}{2}d_{1m}x_m^3\Bigg) + O(e^{4x_m}) \end{aligned}$$

with the outer solution. Matching the constant and the linear terms in x_m yields

$$-\frac{1}{4}d_{3m} = \frac{1}{2}A_1 - \frac{1}{8}A_1^2 + \frac{1}{3}C_1A_1 + \frac{23}{14}C_1^2 + D_1\,, \tag{3.38}$$

$$-\frac{1}{4}d_{2m} = 2^{1/6}C_1\,. \tag{3.39}$$

There is no quadratic term in the outer solution (A.10); hence $d_{1m} = 0$. There are further matching conditions, but they do not simplify the problem structurally at this point and will be enforced later, so that d_{2m}, d_{3m}, and κ_{m2} remain to be determined via exponential matching. As $x_m \to \infty$, the expansion to this order can be written as

(3.40)

$$\begin{aligned} u_{m2}^{(m)} = & \frac{1}{2}d_{3m} - \frac{1}{4}d_{2m}x_m + \frac{1}{8}d_{3m}e^{2x_m} + \frac{e^{-2x_m}}{32}\Big(- 56d_{3m} - 15d_{2m} \\ & - 2d_{2m}\pi^2 + 128(\kappa_{m1}^2 + \kappa_{m2}) + (48d_{3m} - 12d_{2m})x_m - 24d_{2m}x_m^2\Big) + O(e^{-4x_m})\,. \end{aligned}$$

Internal layer near $x = 0$. As for the $O(\delta^{1/3})$ problem, at $O(\delta^{2/3})$ we have

$$\mathcal{L}(u_{02}, x_0) = f_{02}(x_0)\,, \tag{3.41a}$$

$$u_{02}(0) = 0, \quad u_{02}''(0) = 0, \quad \text{and} \quad u_{02}''''(0) = 0\,, \tag{3.41b}$$

with

$$f_{02}(x_0) := d_{10}x_0^2 + d_{20}x_0 + d_{30}\,. \tag{3.42}$$

The general solution is

$$u_{02}(x_0) = \varphi_{02}(x_0) + g_2\,\psi_0(x_0)\,, \tag{3.43}$$

where the homogeneous component is as before and the inhomogeneous part is obtained by setting $\alpha = 0$, $j = 2$, and $\gamma_{02} = 0$ in (3.21), so that $\varphi_{02}(0) = 0$ and φ_{02} grows algebraically as $x_0 \to -\infty$. Symmetry requires $\varphi_{02}''(0) = 0$, $\varphi_{02}''''(0) = 0$, which implies $d_{10} = 0$ and $d_{30} = 0$. The remaining free parameters to be matched are d_{20} and g_2. In order to exponentially match to u_m to $O(\delta^{2/3})$ and obtain $u_{m2}^{(e)}$, we again have to expand $u_{02}(x_0)$ as $x_0 \to -\infty$, giving

(3.44)

$$\begin{aligned} u_{02}(x_0) = & -\frac{\hat{\mu}}{16}e^{-2x_0} - \frac{1}{4}d_{20}x_0 - \frac{3}{8}\hat{\mu} \\ & + \frac{1}{32}\Big((15 + 2\pi^2 + 2\ln(2))d_{20} + 26g_2 + (48\hat{\mu} - 12d_{20})x_0 + 24d_{20}x_0^2\Big)e^{2x_0} \\ & + \frac{1}{48}\Big(- (89 + 6\pi^2)d_{20} - 36\hat{\mu} + (84d_{20} - 144\hat{\mu})x_0 - 72d_{20}x_0^2\Big)e^{4x_0} + O(e^{6x_0})\,, \end{aligned}$$

and re-express in terms of x_m, where we have used the abbreviation $\hat{\mu} = d_{20}\ln(2) + g_2$.

3.1.4. O(δ).

Internal layer near κ_m. The problem to be solved at order $O(\delta)$ is

$$\mathcal{L}(u_{m3}, x_m) = f_{m3}(x_m)\,, \tag{3.45a}$$

$$\begin{aligned} u_{m3}(0) = {} & -u'_{m2}(0)\kappa_{m1} - u''_{m0}(0)\kappa_{m1}\kappa_{m2} - u'_{m0}(0)\kappa_{m3} \\ & - \frac{1}{6}u'''_{m0}(0)\kappa_{m1}^3 - u'_{m1}(0)\kappa_{m2} - \frac{1}{2}u''_{m1}(0)\kappa_{m2}^2\,, \end{aligned} \tag{3.45b}$$

with

$$\begin{aligned} f_{m3}(x_m) := {} & 2\left((u_{m1}^{(e)})^3 + 6\,u_{m0}\,u_{m1}^{(e)}\,u_{m2}^{(e)}\right) \\ & -2^{3/2}\left[\frac{1}{2}\mathrm{dilog}(e^{2x_m}+1) + \frac{1}{2}(1+k_{1m})x_m^2 + (\ln(2)+k_{2m})x_m + k_{3m}\right]. \end{aligned} \tag{3.46}$$

Again we choose the inhomogeneous solution so that it grows only algebraically as $x_m \to -\infty$ and vanishes at $x_m = 0$ and so that we obtain $\varphi_{m3}(x_m)$ by using formula (3.21) with $\alpha = m$, $j = 3$, and $\gamma_{m3} = 0$. The solution is

$$u_{m3}(x_m) = -u_{m3}(0)\phi_m(x_m) + \varphi_{m3}(x_m)\,, \tag{3.47}$$

where k_{1m}, k_{2m}, k_{3m}, and κ_{m3} remain to be determined via matching. In order to exclude exponential growth as $x_m \to -\infty$ we obtain the relation

$$\begin{aligned} k_{2m} = \frac{\sqrt{2}}{48\ln(2)}\Big(& \kappa_{m1}\left(-(12+9\pi^2)d_{2m} + 12d_{3m} - 24\kappa_{m2}\right). \\ & +\sqrt{2}(24k_{3m} - 12\ln(2)^2 + k_{1m}\pi^2)\Big)\,, \end{aligned} \tag{3.48}$$

so that the expansion obtained as $x_m \to -\infty$ is

$$\begin{aligned} u_{m3}(x_m) = {} & \frac{1}{4\sqrt{2}}(1+k_{1m}+4k_{3m}) + \frac{1}{\sqrt{2}}(\ln(2)+k_{2m})x_m \\ & + (k_{1m}+1)\frac{\sqrt{2}}{4}x_m^2 + O(e^{2x_m})\,. \end{aligned} \tag{3.49}$$

Comparing this with the outer solution to $O(\delta)$, equation (A.10), yields the matching conditions

$$\begin{aligned} \frac{1}{4\sqrt{2}}(1+k_{1m}+4k_{3m}) = {} & \left(-\frac{1}{4}A_1 + \frac{1}{3}C_1\right)A_2 + \left(\frac{7}{12}C_1^2 + \frac{1}{3}D_1\right)A_1 \\ & +\frac{1}{2}A_3 - \frac{59}{216}C_1A_1^2 - \frac{1}{12}2^{1/3}C_1 + K_1 - \frac{23}{7}C_1D_1 + \frac{1}{16}A_1^3 + \frac{127}{28}C_1^3 \end{aligned} \tag{3.50}$$

for the constant terms,

$$\frac{1}{\sqrt{2}}(\ln(2)+k_{2m}) = \left(D_1 - \frac{23}{7}C_1^2\right)2^{1/6} \quad \text{and} \quad (k_{1m}+1)\frac{\sqrt{2}}{4} = 2^{-2/3}C_1 \tag{3.51}$$

for the linear and the quadratic terms, respectively.

Expanding the solution as $x_m \to \infty$, we find

$$
\begin{aligned}
u_{m3}(x_m) = {} & \frac{1}{192}\Big(\kappa_{m1} d_{2m}(9\pi^2+24) - 48\kappa_{m1} d_{3m} + 2\sqrt{2}\pi^2(1-k_{1m}) - 48\sqrt{2}k_{3m}\Big)e^{2x_m} \\
& + \frac{1}{96}\left(\kappa_{m1} d_{2m}(27\pi^2+72) + \sqrt{2}(k_{1m}(12-6\pi^2) - 96k_{3m} - 12 + 2\pi^2)\right) \\
& + \frac{1}{\sqrt{2}}(\ln(2)+k_{2m})x_m + (k_{1m}+1)\frac{\sqrt{2}}{4}x_m^2 + O(e^{-2x_m})\,,
\end{aligned}
\tag{3.52}
$$

and we will exponentially match it to the solution near $x = 0$, which we construct next.

Internal layer near $x = 0$. The general solution to the $O(\delta)$ problem

$$\mathcal{L}(u_{03}, x_0) = f_{03}(x_0)\,, \tag{3.53a}$$

$$u_{03}(0) = 0, \quad u_{03}''(0) = 0, \quad \text{and} \quad u_{03}''''(0) = 0\,, \tag{3.53b}$$

with

$$f_{03}(x_0) := -2^{1/2}\left[\operatorname{dilog}(e^{2x_0}+1) - \operatorname{dilog}(2) + 2\mu_2 x_0 + (1+k_{10})x_0^2\right] \tag{3.54}$$

and the abbreviation $\mu_2 = \ln(2) + k_{20}$, reads

$$u_{03}(x_0) = \varphi_{03}(x_0) + g_3\,\psi_0(x_0)\,, \tag{3.55}$$

where we have required that $u_{03}(0) = 0$ and $u_{03}''(0) = 0$. If we also enforce $u_{03}''''(0) = 0$, then $k_{10} = 0$. Again we take an inhomogeneous solution $\varphi_{03}(x_0)$, which satisfies the above conditions, so that the general solution is obtained with

$$\mu_1 = \sqrt{2}(\ln(2)^2 + 2k_{20}\ln(2)) - g_3 \quad \text{and} \quad \omega = \int_0^1 \frac{1}{z}\ln\left(\frac{z^2+1}{2z}\right)^2 - \frac{\ln(2z)^2}{z}dz \approx 0.3094\,,$$

as

$$
\begin{aligned}
u_{03} = {} & \frac{12\mu_1 - \pi^2\sqrt{2}}{192}e^{-2x_0} + \frac{1}{96}(36\mu_1 + \sqrt{2}(12-\pi^2)) + \frac{\mu_2}{\sqrt{2}}x_0 + \frac{\sqrt{2}}{4}x_0^2 \\
& + \left[\frac{1}{192}\left(156\mu_1 + \sqrt{2}[(19-24k_{20})\pi^2 - 15 - 288\omega - 180\mu_2]\right)\right. \\
& \left. + \frac{1}{16}\Big(-24\mu_1 + \sqrt{2}(12\mu_2 - 11)\Big)\,x_0 + \frac{\sqrt{2}}{8}\,(3 - 12\mu_2)\,x_0^2 - \frac{1}{\sqrt{2}}x_0^3\right]e^{2x_0} + O(e^{4x_0})\,.
\end{aligned}
\tag{3.56}
$$

For exponentially matching to u_m this again has to be re-expressed in x_m and combined with the corresponding expressions for u_{00}, u_{01}, and u_{02} . This will be done in the next section.

3.2. Exponential matching. Now we have to match the rest of the solution $u_m(x_m)$ to the rest of the solution $u_0(x_0)$. This requires matching the exponential terms in addition to the algebraic terms, similarly to the procedure for the CCH equation; i.e., matching of the solution describing the internal layer near $x = \kappa_m$ to the solution near $x = 0$ requires expressing the variable x_0 in terms of x_m (or vice versa). Recall again that $x_0 = x_m + \bar{\kappa}_m/\sqrt{2}$ and that $\bar{\kappa}_m < 0$; the e^{2x_0} terms in the u_0 expansion will produce e^{2x_m} terms with a factor $e^{\sqrt{2}\bar{\kappa}_m}$ (and analogously for e^{-2x_0} terms) and so we will find their corresponding matching partner at a different order in δ in the u_m expansion, as we have shown for the CCH equation. The somewhat subtle difference here is that additionally we need to determine the relationship between $e^{\sqrt{2}\bar{\kappa}_m}$ and δ, and we have in principle several choices, only one of which allows a consistent matching of both expansions. One can observe that the choice $e^{\sqrt{2}\bar{\kappa}_m} = \rho\,\delta^{1/3}$, where ρ is some constant, quickly leads to a contradiction. However, setting

$$e^{\sqrt{2}\bar{\kappa}_m} = \rho\,\delta^{2/3} \tag{3.57}$$

will lead to an $O(\delta^{2/3})$ shift of terms, so that, e.g.,

$$e^{2x_0} \quad \text{will shift to a term} \quad \delta^{2/3}\,e^{2x_m}\,, \tag{3.58}$$

$$e^{-2x_0} \quad \text{will end up as a term} \quad \delta^{-2/3}\,e^{-2x_m}\,, \tag{3.59}$$

and so forth, so that, e.g., a term e^{2x_0} in the leading order part of the u_0 expansion will have to match an e^{2x_m} term in the $O(\delta^{2/3})$ part of the u_m expansion, or an e^{-2x_0} term in the $O(\delta)$ part of the u_0 expansion will have to match an e^{-2x_m} term in the $O(\delta^{1/3})$ part of the u_m expansion. This will also produce terms that will have no partner term in the transformed expansion. Their coefficients must then be set to zero. If we now sum the expansions for $u_{01}(x_0)$, $u_{02}(x_0)$, and $u_{03}(x_0)$ and re-expand using (3.57), we obtain

$$\begin{aligned} u_0(x_m) = {}& -1 - \frac{1}{16}\Big(d_{20}\ln(2) + g_2\Big)e^{-2x_m}\rho + \frac{1}{192}\Big(12\mu_1 - \sqrt{2}\pi^2\Big)e^{-2x_m}\,\rho\,\delta^{1/3} \\ & + \frac{1}{24}\Big(d_{20}(3\ln(\rho) - 9\ln(2) - 2\ln(\delta)) - 9g_2 - 6d_{20}x_m + 48e^{2x_m}/\rho\Big)\delta^{2/3} \\ & + \Bigg[\frac{1}{96}\Bigg(36\mu_1 + \sqrt{2}\Big[12 + (16\ln(\delta) - 24\ln(\rho))\mu_2 \\ & \qquad + 6\left(\ln(\rho) - \frac{2}{3}\ln(\delta)\right)^2 - \pi^2\Big]\Bigg) \\ & + \frac{\sqrt{2}}{12}\,(2\ln(\delta) + 6\mu_2 - 3\ln(\rho))\,x_m + \frac{\sqrt{2}}{4}x_m^2\Bigg]\delta\,, \end{aligned} \tag{3.60}$$

which has to match $u_{m1}(x_m)$, $u_{m2}(x_m)$, and $u_{m3}(x_m)$ to each order, respectively. From this we obtain further conditions for the parameters in addition to those we have already found. Solving the complete system of equations then yields the solutions for the width of the hump

$$\Delta = \frac{\sqrt{2}}{6}\ln\left(\frac{\beta}{W(\beta^{1/3})^3}\right)\,, \tag{3.61}$$

with $\beta = 2^{11}/(27\delta^2)$, where W is the Lambert W function (so $W(x)$ is the solution of $x = W\exp(W)$). The expressions for the remaining matching constants C_1, D_1, etc. are omitted. The first correction in (3.2) has the coefficient

$$A_1 = -3\,2^{1/6}\,. \tag{3.62}$$

Note that not only the transformed expansions but also the expressions for the parameters contain so-called *logarithmic switch-back* terms.

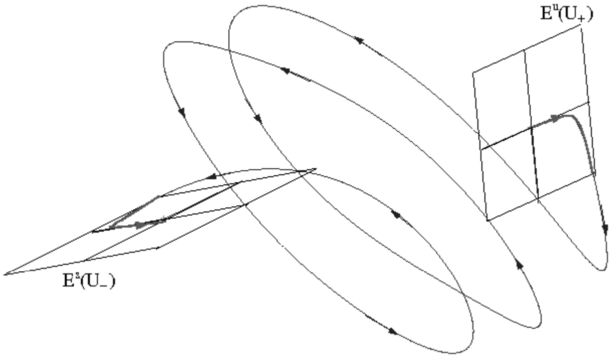

FIG. 4.1. *HCCH: Heteroclinic orbits between the equilibrium points are sought in a five-dimensional phase space that is indicated here in three dimensions. The manifolds $W^u(U^+)$ and $W^s(U^-)$ are two-dimensional, which is suggested by the two planes in the picture.*

4. Numerical method for the fifth-order phase space.

For the numerical stationary solutions of the HCCH equation (3.1) we apply the same scaling for u that we used for the CCH equation to obtain equilibrium points at ±1,

$$(1-c^2)=\frac{2}{\delta\sqrt{A}}(c_{xx}+c-Ac^3)_{xxx}\,,\qquad \lim_{x\to\pm\infty} c=\mp 1, \tag{4.1}$$

again assuming that derivatives vanish in the far field. Reduction to a first-order system $U'=F(U)$, with $F:\mathrm{R}^5\to\mathrm{R}^5$, gives a five-dimensional phase space, where the first four components of $F_i(U)$ are equal to U_{i+1} and the fifth is

$$F_5(U)=6A(U_2)^3+18AU_1U_2U_3+(3A(U_1)^2-1)U_4+\delta\sqrt{A}(1-(U_1)^2)/2\,. \tag{4.2}$$

The equilibrium points are $U^\pm=\pm(1,0,0,0,0)^T$, and at these points the characteristic polynomials are

$$\mathcal{P}^\pm(\lambda)=\lambda^5+\lambda^3(1-3A)\pm\delta\sqrt{A}\,. \tag{4.3}$$

For small δ the manifolds $W^u(U^+)$ and $W^s(U^-)$ are both two-dimensional, resulting in a codimension two event when searching for heteroclinic solutions connecting the two hyperbolic fixed points U^+ and U^-. The HCCH equation exhibits the same reversibility properties as its lower order version. This reversibility is again given by the transformation (2.8) from the CCH section, which also here fulfills $RF(U)=-F(RU)$. The codimension reduces by one and again we deal with a codimension one problem and two parameters; hence we may expect solution branches in the (A,δ) parameter plane. Section 2.1 showed that a condition for the existence of heteroclinic orbits is a value where the distance function (2.9) reaches zero, and the same condition holds for the HCCH equation. The phase space is sketched in Figure 4.1, indicating the linearizations of the intersecting manifolds in the equilibrium points. For this problem a shooting method will be very slow and may lead to inaccuracy since the additional parameter, say $\varphi\in[0,2\pi)$, an angle defining points on a circle close to the equilibrium point on the linearization of the two-dimensional manifold, requires a very fine resolution to obtain heteroclinic solutions.

4.1. Boundary value problem formulation. There exist several possibilities for setting up equations for finding heteroclinic connections in a boundary value problem framework. Generally one crucial stumbling block is the choice of a suitable phase condition that picks out a certain solution from the infinitely many available ones due to phase shifts [8, 2]. We choose to incorporate one phase condition, proposed by Beyn [2], for which we use an approximation of the solution, V, typically given by a previous solution for slightly different parameter values. Equation (4.1) contains two parameters, A, δ, and in addition the truncated domain length L. As discussed by Doedel and Friedman [5], one of the free parameters can be replaced by L to find a connection. For a nearby chosen and fixed δ, we treat L and A as free parameters. We extrapolate in the (A, δ) plane to get an approximate value of A and solve for the exact data. Rescaling the domain to $[0, 1]$ yields, with the phase condition variable U_{ph} introduced by Beyn [2], the first-order system

$$\text{(4.4a)} \qquad U_i' = LU_{i+1}, \quad i = 1, 2, 3, 4,$$

$$\text{(4.4b)} \qquad U_5' = L\left(6A(U_2)^3 + 18AU_1U_2U_3 + (3A(U_1)^2 - 1)U_4 + \delta\sqrt{A}\frac{(1-(U_1)^2)}{2}\right),$$

$$\text{(4.4c)} \qquad U_{ph}' = L(V')^T U,$$

$$\text{(4.4d)} \qquad L' = 0,\ A' = 0.$$

Hence, we obtain one equation for the phase condition and two for the parameters in addition to the five given by the original ODE; i.e., we have an overall system of eight equations, which have to be supplemented by the same number of boundary conditions. At the edges of the domain we utilize *projected boundary conditions* [4, 2], which make use of eigenvectors in the equilibrium points and can be incorporated by computing V_0, the matrix whose columns are composed of the eigenvectors which correspond to the eigenvalues at the upper equilibrium point U^+ with negative real part, and by forming the counterpart V_1 containing those eigenvectors given by the unstable directions at the lower stationary point U^-. Hence, we consider the eight boundary conditions

$$\text{(4.5)} \qquad U_{ph}(0) = 0, \quad U_{ph}(1) = 0, \quad V_0^T(U(0) - U^+) = 0, \quad V_1^T(U(1) - U^-) = 0\,.$$

For initial estimates we can use solutions obtained from the asymptotic analysis of section 3.1, i.e., the leading order solution tanh profiles

$$V(x) = -\tanh(x - K) + \tanh(x) - \tanh(x + K),$$

for the het_1 solution with guessed root-distance K.

The boundary value solvers we use are based on mono-implicit Runge–Kutta formulae [23, 14]. As for the CCH problem, efficiency can be improved by making use of the theory from section 2.1, which holds analogously for the HCCH equation, to obtain a boundary condition at the fixed point of a point-symmetric solution. We can use half of the previous domain length, and phase conditions become redundant because the phase is already fixed. We replace the projected boundary conditions by

$$U_1(0) = 1, \quad U_2(0)^2 + U_3(0)^2 = 0, \quad U_4(0)^2 + U_5(0)^2 = 0$$

so that together with the self-reversibility condition on the right interval end $U_1(1) = U_3(1) = U_5(1) = 0$ we have six conditions which match the five equations together with the free parameter A. Final solutions are obtained by reflecting the solution and its derivatives around zero and changing the signs of the first, third, and fifth components. Examples of branches of different solutions are shown in Figure 4.2.

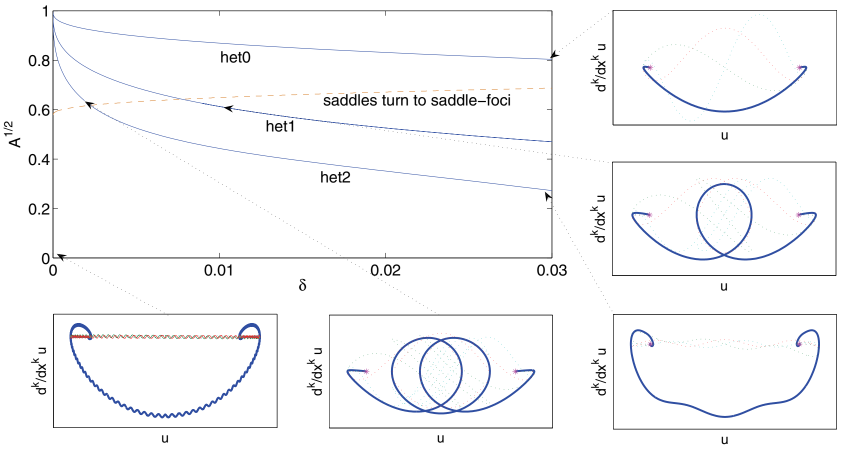

FIG. 4.2. *$(\sqrt{A}, \delta)$-plane with curves for the first three heteroclinic connection branches for the HCCH equation. The dashed line in the parameter plane indicates the position where the positive roots of the characteristic polynomial in U^+ have nonzero imaginary parts. Below and to the right we see five phase-space diagrams (tuples $(U_1, U_2), (U_1, U_3), \dots$) for selected solutions pointed out with arrows marking the corresponding parameters. The first pair (U_1, U_2) is plotted as a bold solid curve.*

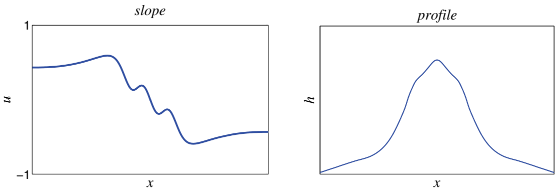

FIG. 4.3. *het_2 solution for $\delta = 0.01$ and $A = 0.443$ and the corresponding profile obtained by integration.*

4.2. Solutions and comparison to analytical results. With the boundary value formulation we are able to compute new HCCH stationary solutions. In Figure 4.3 we see a particular het_2 solution and the profile of the growing structure.

Up to three dimensions one can nicely visualize heteroclinic orbits in the corresponding phase space, while when the dimension is four or higher and the derivatives vanish in the far field one can still plot the two-dimensional phase spaces $(U_1, U_2), (U_1, U_3), \dots$ and demand connections between the equilibrium tuples $(\pm\sqrt{A}, 0)$ as a necessary condition for heteroclinic orbits in the higher order space. Several such projections onto two dimensions are shown in Figure 4.2, where we also see a very rapidly oscillating heteroclinic curve in the bottom left plot, which was found by a shooting approach with a minimization procedure that used the two parameters and an angle as free parameters and the distance function (2.9) as an objective function, depending on those parameters. It indicates that, as shown for the CCH equation, we can in fact find many more het_k branches than those presented for $k = 0, 1, 2$, all emerging from $(A, \delta) = (1, 0)$, which corresponds to the Cahn–Hilliard equation.

In Figure 4.4 we see the change in appearance of solutions on the het_2 branch as δ is increased. The shape varies from a solution with two pronounced humps to a monotone one, similar to the het_0 solution, although associated with different,

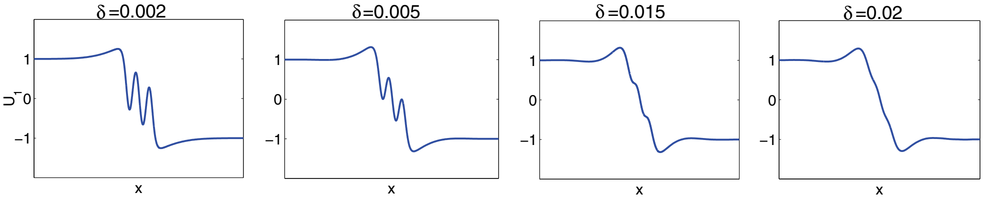

Fig. 4.4. *Structural change of the scaled het$_2$ solution as δ is increased.*

smaller values of A. This is crucial if one wants to compute solutions for bigger δ with a boundary value solver. It easily happens that the solver switches between solution branches; however, this can be prevented by starting continuation in a parameter regime where the high-slope parts of the solutions are nonmonotone, and continuing with small steps. A characteristic of the HCCH solutions is the overshoot from the equilibrium value before the solutions tend into the direction of the negative equilibrium point. This is not observed for the CCH equation, where the shape is similar at these regions to hyperbolic tangent functions.

In light of the expansion (3.2) we try to estimate the $\mathcal{O}(\delta^{1/3})$ terms A_1 for the different heteroclinic connections in a range of very small δ. As we see in Figure 4.5 on the left, the numerically obtained values for A behave like $A = 1 - 2^{1/6}\delta^{1/3}$ in the case of the het_0 solutions, so that $A_1 = -2^{1/6}$, which is consistent with the result in Savina et al. [22]. The numerical result for het_1 is in line with the analytical value (3.62), and since for het_2 we see the agreement $A_1 \approx -5\,2^{1/6}$, we propose for higher order trajectories that for het_k we have the general approximation $A_1 \approx -(2k+1)\,2^{1/6}$, which is reminiscent of the CCH expression (2.45). Hence this formula is used in Figure 4.5 to plot the *analytical values.*

We measure the distance between the first and second roots for the het_1 and het_2 solutions, as seen in Figure 4.5 on the right. We compare this to the analytical expression (3.61) for the 1-hump solutions in the same figure and see that for small δ the agreement is good. For both het_1 and het_2 solutions the distance is seen to increase logarithmically as δ decreases.

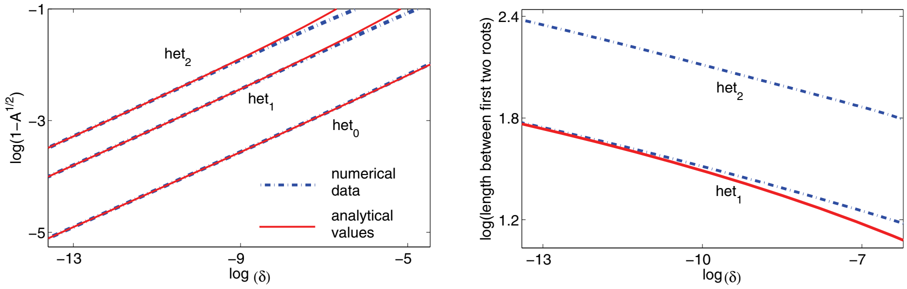

Fig. 4.5. *Left figure: Logarithmic version of the* $(\sqrt{A}, \delta)$ *plot for very small* δ*. The solid lines give the analytical values, and the dash-dotted lines give those computed with the BVP solver. On the right we see the distances between the first two roots of the het*$_1$ *and het*$_2$ *solutions numerically and for het*$_1$ *via the analytical expression* (3.61) *(solid line).*

5. Conclusion.

We have demonstrated that a sixth-order generalization of the CCH equation admits multiple stationary solutions connecting constant values. As for the fourth-order CCH solution, these include a simple base solution, which is monotone for the CCH and "almost" monotone for the HCCH equation. More complex solutions, containing multiple humps, are also possible for each value of the forcing parameter δ, given particular values of the integration constant $A(\delta)$. These nonmonotone stationary solutions constitute an essential part of the solution structure for this higher order Cahn–Hilliard type of equation. We have demonstrated this via a numerical investigation of the phase space in which we are able to follow solution branches. For the simplest of the multi-humped solutions, the het_1 branch, careful use of matched asymptotics that accounts for exponentially small terms allows us to find a solution which yields both the length scale for the solution (the "hump length") and the parameter value $A(\delta)$, at which it occurs, in the limit of small δ. Extension of the analysis to higher branches appears feasible. Our numerical evidence suggests that similarly simple asymptotic expressions hold for these branches for both the CCH and HCCH equations.

Various issues, such as the stability of these solutions, are presently being considered in light of applications of the HCCH equation as a model for the morphology and dynamics of quantum dots. In particular, how do adjacent internal layers derived from these solutions interact, and what is their effect on the coarsening behavior in large spatial domains? Savina et al. [22] have begun an investigation of these questions by numerical simulation of (1.4); it is likely that asymptotics can yield further insights.

Physically, further interesting questions relate to the extension of the HCCH model to richer models for the energetics of faceted surfaces, and analyzing the three-dimensional extension of the model.

Appendix A. Outer problem. For the solution to the outer problem (3.6), (3.7) it is easy to observe that to leading order in δ the solution of

$$Q\left(Y_0\right)_{\xi\xi\xi} = -\sqrt{2}\left(Y_0^2 - 1\right) \quad \text{with} \quad \lim_{\xi\to-\infty} Y_0(\xi) = 1 \tag{A.1}$$

is

$$Y_0(\xi) = 1\,. \tag{A.2}$$

To $O(\delta^{1/3})$ the general solution to the problem

$$Y_{1_{\xi\xi\xi}} - \sqrt{2}\,Y_1 = -\frac{A_1}{\sqrt{2}} \quad \text{with} \quad \lim_{\xi\to-\infty} Y_1(\xi) = \frac{A_1}{2} \tag{A.3}$$

is

$$Y_1(\xi) = \frac{A_1}{2} + C_1 e^{2^{1/6}\xi} + e^{-\xi/2^{5/6}}\left[C_2\cos\left(\sqrt{3}\,\xi/2^{5/6}\right) + C_3\sin\left(\sqrt{3}\,\xi/2^{5/6}\right)\right], \tag{A.4}$$

with C_1, C_2, and C_3 being constants of integration. The far-field condition requires that Y_1 remains bounded as $\xi \to -\infty$. Hence, $C_2 = C_3 = 0$ and

$$Y_1(\xi) = \frac{A_1}{2} + C_1 e^{2^{1/6}\xi}. \tag{A.5}$$

Using this and the far-field conditions, the solution to the $O(\delta^{2/3})$ problem

$$Y_{2_{\xi\xi\xi}} - \sqrt{2}\,Y_2 = -\frac{A_2}{\sqrt{2}} - \frac{1}{2}\left(3\left(Y_1^2\right)_{\xi\xi\xi} - \sqrt{2}\,Y_1^2\right) \quad \text{with} \quad \lim_{\xi\to-\infty} Y_2(\xi) = \frac{A_2}{2} - \frac{A_1^2}{8} \tag{A.6}$$

is

$$Y_2(\xi) = \frac{A_2}{2} - \frac{A_1^2}{8} + D_1 e^{2^{1/6}\xi} + \frac{A_1 C_1}{3} e^{2^{1/6}\xi}\left(1 - 2^{1/6}\xi\right) - \frac{23}{14} C_1^2 e^{2^{7/6}\xi}, \tag{A.7}$$

and the solution to the $O(\delta)$ problem

$$Y_{3_{\xi\xi\xi}} - \sqrt{2}\,Y_3 = -\frac{A_2}{\sqrt{2}} + \frac{Y_{1_{\xi\xi\xi\xi}}}{4} + \sqrt{2}\,Y_1 Y_2 - \frac{1}{2}\left(Y_1^3 + 6\,Y_1 Y_2\right)_{\xi\xi\xi}$$
$$\text{with} \quad \lim_{\xi\to-\infty} Y_3(\xi) = \frac{A_3}{2} - \frac{A_1 A_2}{4} + \frac{A_1^3}{16} \tag{A.8}$$

is

(A.9)
$$\begin{aligned} Y_3(\xi) = {} & \frac{A_3}{2} - \frac{A_1 A_2}{4} + \frac{A_1^3}{16} \\ & + \Bigg[K_1 - \frac{2^{1/3}}{12} C_1 + \frac{1}{3}\left(A_1 D_1 + A_2 C_1\right) - \frac{59}{216} C_1 A_1^2 \\ & + \left(\frac{\sqrt{2}}{12} C_1 - \frac{2^{1/6}}{3}\left(A_1 D_1 + A_2 C_1\right) + \frac{17}{72} 2^{1/6} A_1^2 C_1 \right)\xi + \frac{2^{1/3}}{18} A_1^2 C_1\,\xi^2 \Bigg] e^{2^{1/6}\xi} \\ & + \left[-\frac{23}{7} C_1 D_1 + \left(\frac{7}{12} + \frac{23}{21} 2^{1/6}\xi\right) A_1 C_1^2 \right] e^{2^{7/6}\xi} + \frac{127}{28} C_1^3 e^{2^{1/6} 3\xi}\,, \end{aligned}$$

with another integration constant K_1. Finally, we obtain the asymptotic representation in terms of x_m:

(A.10)
$$\begin{aligned} Y(x_m) = 1 & + \left[C_1 + \frac{1}{2} A_1 \right] \delta^{1/3} \\ & + \left[C_1\, 2^{1/6}\, x_m - \frac{1}{8}\, A_1^2 + \frac{1}{3}\, C_1\, A_1 + D_1 - \frac{23}{14} C_1^2 + \frac{1}{2}\, A_2 \right] \delta^{2/3} \\ & + \Bigg[-\frac{23}{7} C_1^2\, 2^{1/6} x_m + D_1\, 2^{1/6} x_m + \frac{1}{2}\, C_1\, 2^{1/3} x_m^2 + \left(-\frac{1}{4}\, A_1 + \frac{1}{3}\, C_1 \right) A_2 \\ & \quad + \left(\frac{7}{12} C_1^2 + \frac{1}{3}\, D_1 \right) A_1 + \frac{1}{2}\, A_3 - \frac{59}{216} C_1\, A_1^2 - \frac{1}{12}\, 2^{1/3}\, C_1 \\ & \quad + K_1 - \frac{23}{7} C_1\, D_1 + \frac{1}{16} A_1^3 + \frac{127}{28} C_1^3 \Bigg]\ \delta. \end{aligned}$$

MESENCHYMAL MOTION MODELS IN ONE DIMENSION[*]

ZHI-AN WANG[†], THOMAS HILLEN[‡], AND MICHAEL LI[‡]

Abstract. Mesenchymal motion denotes a form of cell movement through tissue which can be observed for certain cancer metastases. In [T. Hillen, *J. Math. Biol.*, 53 (2006), pp. 585–616], a mathematical model for this form of movement was introduced. In the current paper we present a comprehensive analysis of the one-dimensional mesenchymal motion model. We establish the global existence of classical solutions and rigorously carry out the parabolic limit of the model. We discuss the stationary solutions, prove the existence of traveling wave solutions, and use numerical simulations to illustrate the results. Finally, we discuss the biological implications of the results.

Key words. mesenchymal motion, stationary solutions, global existence, macroscopic limits, traveling waves, hyperbolic systems

1. Introduction.

Mesenchymal motion is a form of cellular movement through tissue which is formed from fiber networks. An example is the invasion of tumor metastases through collagen networks [7]. Cells migrate in fiber networks and change their directions according to the orientational distribution of fibers. Moreover, cells actively remodel the matrix by excreting a matrix degrading enzyme (e.g., protease) to generate sufficient space in which to migrate.

The motion of mesenchymal cells in a tissue matrix was reported in a review article by Friedl and Bröcker [7]. Mesoscopic and macroscopic mathematical models for mesenchymal motion were derived by Hillen [12] in a temporally varying network tissue. The mesoscopic models consist of a transport equation for the cell movement and an ordinary differential equation (ODE) for the dynamics of tissue fibers. The macroscopic models have the form of drift-diffusion equations, where the mean drift velocity is given by the mean orientation of the tissue, and the diffusion tensor is given by the variance-covariance matrix of the tissue orientation. The analysis in [12] is divided into the case of undirected and directed tissue according to the distribution of fiber orientation. In undirected tissue, the fibers are symmetrical along their axes and both fiber directions are identical. For example, collagen fibers are undirected and form the basis for many human and animal tissues. For directed tissue, the fibers are unsymmetrical and the two ends can be distinguished (such as microtubules and actin filaments). Branching collagen fiber networks can also be considered directional if the branching points are of significance for the movement of cells [12].

The model from [12] was extended in [3, 4] to include cell-cell interactions and chemotactic forces for the case of undirected fibers. Formal methods were used to derive the corresponding macroscopic models. Painter [21] numerically studied models for cell movement in fiber tissues and showed pattern formation in the form of

macroscopic networks.

In this paper, the one-dimensional mesenchymal motion model is fully analyzed. The global existence of solutions, macroscopic limits, traveling waves, and stationary solutions are investigated. The one-dimensional model is very instructive and we can gain much insight into the mechanisms involved in the model. For example, we find the existence of traveling pulse solutions for the cell population and identify some mechanisms for cell aggregation. We also identify some differences between undirected and directed tissue by analyzing the one-dimensional model. We restrict our attention to the model for directed tissue only and the analysis can be completely adopted to the study for undirected tissue from the mathematical point of view.

The paper is organized as follows. In the rest of this section, we will present the one-dimensional mesenchymal motion model derived in [12] and discuss the stationary solutions based on the telegraph process analysis. In section 2, we classify the one-dimensional model as a degenerated hyperbolic system and conclude that there is no shock solution. In section 3, the global existence of classical solutions is obtained along the characteristics using a fixed point argument and general regularity results for the semilinear hyperbolic system. In section 4, we rigorously carry out the parabolic limit of the one-dimensional mesenchymal transport model, where we show that solutions of the one-dimensional model converge to solutions of the corresponding drift-diffusion limit equation. In section 5, we study the traveling wave solutions and find traveling pulse solutions for the cell population and traveling front waves for fiber orientations. In the final section 6, we summarize and compare our results with the results obtained in [12]. Furthermore, we explain the findings in the context of the biological application of cell movement in tissue.

1.1. Models for mesenchymal motion in one dimension. In this paper, we are primarily interested in the one-dimensional mesenchymal motion model for the case of directed tissue, which reads as follows [12]:

$$
\begin{aligned}
p_t^+ + sp_x^+ &= -\mu p^+ + \mu q^+(p^+ + p^-),\\
p_t^- - sp_x^- &= -\mu p^- + \mu q^-(p^+ + p^-),\\
q_t^+ &= \kappa(p^+ - p^-)(q^- - q^+ + 1)q^+,\\
q_t^- &= \kappa(p^+ - p^-)(q^- - q^+ - 1)q^-.
\end{aligned}
\tag{1.1}
$$

The quantities p^+, p^- denote density of cells moving to the right or left, respectively, with a constant speed s. The functions q^+, q^- are distributions of fibers pointing to the right $(+)$ or left $(-)$. The constant $\mu \geq 0$ denotes the turning rate, and the constant $\kappa \geq 0$ represents the cutting efficiency (rate of fiber degradation). The transport term $sp_x^\pm$ in (1.1) accounts for the cell migration in either direction with speed s. The right-hand side of the first two equations describes the change of cell movement in the field of fibers. The third and fourth equations of (1.1) describe the changes of the fibers in either direction due to the interaction with cells. The derivation of the above model is omitted here for brevity and we refer interested readers to [12] for details. It is worthwhile to point out that the model for undirected tissue can be regarded as a special case of (1.1) for $\kappa = 0$ (see also [12]). In this paper, we focus on the model of directed tissue, and most of our results can be applied to the case of undirected tissue. The significant difference, when it appears, will be emphasized.

The system (1.1) is closely related to the Goldstein–Kac system [8, 17] which describes correlated random walk in one space dimension. With $p = p^+ + p^-$,

$j = s(p^+ - p^-)$, $q = q^+ + q^-$, and $\xi = q^+ - q^-$, system (1.1) becomes

$$\begin{aligned} p_t + j_x &= \mu(q-1)p, \\ j_t + s^2 p_x &= -\mu j + \mu s \xi p, \\ q_t &= (\kappa/s) j \xi (1-q), \\ \xi_t &= (\kappa/s) j (q - \xi^2). \end{aligned} \tag{1.2}$$

Since (q^+, q^-) denotes a distribution, $q^+ + q^- = 1$. Hence one is interested in solutions with $q = 1$. The set $q = 1$ is an invariant manifold of the system (1.2) which will be verified later in Lemma 3.1. On this manifold the system (1.2) reduces to

$$\begin{aligned} p_t + j_x &= 0, \\ j_t + s^2 p_x &= -\mu j + \mu s \xi p, \\ \xi_t &= (\kappa/s) j (1 - \xi^2). \end{aligned} \tag{1.3}$$

If q^+ is used instead of ξ, then the system becomes

$$\begin{aligned} p_t + j_x &= 0, \\ j_t + s^2 p_x &= -\mu j + \mu s (2q^+ - 1)p, \\ q_t^+ &= 2(\kappa/s) j q^+ (1 - q^+). \end{aligned} \tag{1.4}$$

Finally, if the Kac's trick is applied to the first two equations of the above equation, then a damped wave equation is obtained:

$$p_{tt} + \mu p_t = s^2 p_{xx} - \mu s((2q^+ - 1)p)_x. \tag{1.5}$$

Any of (1.1)–(1.5) will be used for a particular question as shown later.

Now we investigate the connections between the one-dimensional mesenchymal motion model and the well-known Goldstein–Kac model [8, 17]. We use the normalization condition $q^+ + q^- = 1$ to substitute $q^- = 1 - q^+$ into the first two equations of (1.1) and obtain

$$\begin{aligned} p_t^+ + s p_x^+ &= -\mu(1 - q^+)p^+ + \mu q^+ p^-, \\ p_t^- - s p_x^- &= \mu(1 - q^+)p^+ - \mu q^+ p^-. \end{aligned} \tag{1.6}$$

The model for the case of undirected tissue ($\kappa = 0$) possesses some very interesting properties. Undirected tissue fibers are symmetrical along their axes and both fiber directions are identical, which indicates that $q^+ = q^- = \frac{1}{2}$. Then the model (1.6) becomes the Goldstein–Kac model [8, 17]

$$\begin{aligned} p_t^+ + s p_x^+ &= \frac{\mu}{2}(p^- - p^+), \\ p_t^- - s p_x^- &= -\frac{\mu}{2}(p^- - p^+). \end{aligned} \tag{1.7}$$

The parabolic scaling for the Goldstein–Kac model, which leads to a parabolic equation, has been discussed in [9] and references therein.

For directed tissue, we define $\lambda^+ = \mu(1 - q^+), \lambda^- = \mu q^+$; then (1.6) is converted into

$$\begin{aligned} p_t^+ + s p_x^+ &= -\lambda^+ p^+ + \lambda^- p^-, \\ p_t^- - s p_x^- &= \lambda^+ p^+ - \lambda^- p^-, \end{aligned} \tag{1.8}$$

which is a modification of the Goldstein–Kac model. Extensions of the Goldstein–Kac model and local and global existence of the solution to the extended model have been extensively investigated in the literature [14, 15, 16]. The telegraph process of (1.8) has been briefly discussed recently by Erban and Othmer [5]. The results obtained in [14, 15, 16] can be applied to system (1.8) if the turning rates $\lambda^{\pm}(t,x)$ are given functions. The theory does not, however, apply to (1.1), since the turning rates are coupled with the $q^{\pm}$ equations.

In the next subsection, we will discuss stationary solutions for (1.1) based on the telegraph process examined in [12].

We supply the system (1.1) with the initial condition

$$p^{\pm}(0,x) = p_I^{\pm}(x), \quad q^{\pm}(0,x) = q_I^{\pm}(x), \quad x \in \Omega. \tag{1.9}$$

Due to the biological interest and normalization condition $q^+ + q^- = 1$, we make the following assumptions for the initial data and boundary conditions.

(ic) $p_I^{\pm} \geq 0$, $0 \leq q_I^+, q_I^- \leq 1$, and $q_I^+ + q_I^- = 1$. For undirected tissue, we assume that the initial data is symmetrical, i.e., $q_I^+ = q_I^- = \frac{1}{2}$.

Here we consider two types of boundary conditions.

(bc1) $\Omega = \mathbb{R}$ and $p_I^{\pm}(x), q_I^{\pm}(x)$ have compact support in Ω.

(bc2) $\Omega = [-l, l]$ and zero flux boundary condition, namely,

$$p^+(t, \pm l) = p^-(t, \pm l).$$

1.2. Stationary solutions. In this section we discuss stationary solutions of the mesenchymal transport model (1.1) using an argument similar to that in [6]. We first present a second-order telegraph equation which is derived from system (1.1). To this end, we add and subtract the first two equations of (1.1) and obtain equations for the total population $p = p^+ + p^-$ and the population flux $j = s(p^+ - p^-)$,

$$\begin{aligned} p_t + j_x &= 0, \\ j_t + s^2 p_x &= -\mu j + \mu(q^+ - q^-)sp, \end{aligned} \tag{1.10}$$

with initial conditions $p(0,x) = p_I(x)$ and $j(0,x) = j_I(x)$, where p_I and j_I are determined from the initial condition (1.9) of p^+ and p^-. We differentiate the first equation of (1.10) with respect to t and the second equation with respect to x. After that, we subtract the resulting equations and end up with a damped wave equation with drift term (see (1.5) or [12])

$$p_{tt} + \mu p_t + \mu(s\xi_q p)_x = s^2 p_{xx}, \tag{1.11}$$

where the drift velocity is given by the expectation of q denoted by $\xi_q = q^+ - q^-$. Equation (1.11) is a form of telegraph equation which describes electrical transmission in a telegraph cable when current leaks to the ground. A drift-diffusion equation can be approximated by taking the limit $\mu \to \infty, s \to \infty$ with diffusivity $D = s^2/\mu < \infty$ and drift velocity $s\xi_q < \infty$. The same drift-diffusion equation also can be obtained by multiscale methods (see [12]).

Suppose that equations (1.10) are defined in the interval $\Omega = [-l, l]$ and satisfy the boundary condition (bc2). In terms of cell population density, the zero flux boundary condition is equivalent to $p^+(\pm l) = p^-(\pm l) = \frac{1}{2}p(\pm l)$. We want to know under what conditions, if any, these equations have time-independent, space-dependent solutions for $p^{\pm}$. The steady state condition $j_x = 0$ of the first equation of (1.10) implies that

j is a constant, and the zero flux boundary condition $j(\pm l) = 0$ furthermore gives that $j = 0$. Consequently the second equation of (1.10) becomes

$$p_x = \frac{\mu}{s}(q^+ - q^-)p.$$

This is a first-order equation for p, whose solution can be easily found:

$$p(x) = p(-l)\exp\left(\frac{\mu}{s}\int_{-l}^{x}(q^+(y) - q^-(y))dy\right). \tag{1.12}$$

The vanishing flux $j = 0$ gives that $p^+ = p^-$, and hence

$$p^\pm(x) = \frac{p(-l)}{2}\exp\left(\frac{\mu}{s}\int_{-l}^{x}(q^+(y) - q^-(y))dy\right). \tag{1.13}$$

Note that the above integrals are bounded since q^+ and q^- are bounded by 1, which will be proved in section 3. From the above equations, one can see how the distribution of fiber orientations $q^\pm$ affects the distribution of cell populations p and $p^\pm$. In particular, if $\mu \neq 0$ and $q^+ \neq q^-$, then p and $p^\pm$ are nonconstants which correspond to the stationary solutions of the system (1.10).

Particularly in undirected tissue, $q^+ = q^- = \frac{1}{2}$ due to symmetry; then p and $p^\pm$ are constants and $p^+ = p^- = \frac{p(-l)}{2}$, which means that there is no aggregation of cells.

If $q^+ = 1, q^- = 0$, then

$$p^\pm(x) = \frac{p(-l)}{2}\exp\left(\frac{\mu}{s}(x + l)\right).$$

The cells accumulate at the end $x = l$. This is not surprising because all cells bias their movement to the right and eventually accumulate at the right end due to the zero flux boundary condition.

Similarly, if $q^+ = 0, q^- = 1$, then

$$p^\pm(x) = \frac{p(-l)}{2}\exp\left(-\frac{\mu}{s}(x + l)\right),$$

and $p^\pm$ attains the maximum at $x = -l$.

Therefore, here we identify a mechanism which can lead to aggregation, namely, $\mu \neq 0$, and the tissues are directed and cells have a probability 1 moving to the left or right.

2. Classification as hyperbolic system.

In this section we show that the system (1.1) is degenerately hyperbolic, and we discuss shock solutions. To this end, we rewrite (1.1) in a matrix form

$$u_t + \Theta u_x = H(u), \tag{2.1}$$

where u, Θ, and $H(u)$ are defined as

$$u = \begin{bmatrix} p^+ \\ p^- \\ q^+ \\ q^- \end{bmatrix}, \quad \Theta = \begin{bmatrix} s & 0 & 0 & 0 \\ 0 & -s & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad H(u) = \begin{bmatrix} -\mu p^+ + \mu q^+(p^+ + p^-) \\ -\mu p^- + \mu q^-(p^+ + p^-) \\ \kappa(p^+ - p^-)(q^- - q^+ + 1)q^+ \\ \kappa(p^+ - p^-)(q^- - q^+ - 1)q^- \end{bmatrix}.$$

The drift term is linear, and hence the system (2.1) cannot create shock solutions. The 4×4 matrix Θ has eigenvalues $\lambda_1 = -s < 0, \lambda_2 = \lambda_3 = 0, \lambda_4 = s$ satisfying $\lambda_1 < \lambda_2 = \lambda_3 < \lambda_4$ provided that $s > 0$. This implies that the system (2.1) and hence (1.1) are hyperbolic but not strictly hyperbolic since the two eigenvalues λ_2 and λ_3 are identical. The eigenvectors r_i corresponding to eigenvalues λ_i, $i = 1, 2, 3, 4$, are

$$r_1 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}, \ r_2 = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}, \ r_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}, \ r_4 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}.$$

It can be verified that $\nabla\lambda_i(u) \cdot r_i(u) = 0$ for $i = 1, 2, 3, 4$, where $\nabla\lambda_i(u) \cdot r_i(u)$ means the directional derivative of the eigenvalues λ_i in the direction of the eigenfunction r_i. Hence all characteristic fields (λ_i, r_i) are linearly degenerate [2, 19]. Thus a shock which separates intersecting characteristics defining a discontinuity does not exist. However, the solution might contain contact discontinuities if data are discontinuous (see [2]).

The characteristic slopes are determined from the eigenvalues of the 4×4 matrix Θ in (2.1) by $\frac{dx}{dt} = \lambda_i$, which is never infinite, so the line $t = 0$ is nowhere tangent to a characteristic. Therefore, if initial data for p^+, p^-, q^+, and q^- are given along the line $t = 0$, the resulting Cauchy problem should be well-posed, as shown in the subsequent section.

3. Global existence.

In this section, we will prove the global existence of solutions to the system (1.1) subject to the initial condition (ic) and boundary condition (bc1). For a bounded domain, the analysis for global existence will be a little bit more complicated than for an unbounded domain, due to the boundary conditions, and is left open here.

The system (1.1) is a coupling of two partial differential equations (PDEs) and two ODEs. To prove the global existence of solutions to the system (1.1), we first prove the nonnegativity of solutions.

Lemma 3.1. *Let $p_I^\pm \geq 0$ and $q_I^\pm \geq 0$ with $q_I^+ + q_I^- = 1$. Assume that $p^\pm, q^\pm \in L^\infty(0, T; L^\infty(\mathbb{R}))$ is a solution to system* (1.1) *for some $T > 0$; then $p^\pm \geq 0$ and $0 \leq q^\pm(t, x) \leq 1$ with $q^+ + q^- = 1$.*

Proof. We first show that $q^+ + q^- = 1$. Toward this end, we consider $q = q^+ + q^-$ and $\xi = q^+ - q^-$. Then we add and subtract the third and fourth equations of (1.1) to obtain equations for q and ξ as follows:

$$\begin{aligned} q_t &= -\kappa(p^+ - p^-)(q - 1)\xi, \\ \xi_t &= \kappa(p^+ - p^-)(q - \xi^2), \end{aligned} \tag{3.1}$$

which can be rewritten in vector form

$$Q_t = -\kappa(p^+ - p^-)F(Q), \tag{3.2}$$

where

$$Q = \begin{pmatrix} q \\ \xi \end{pmatrix}, \qquad F(Q) = \begin{pmatrix} (q-1)\xi \\ \xi^2 - q \end{pmatrix}.$$

The initial data of the system (3.1) is given by

$$q_I = q_I^+ + q_I^- = 1, \qquad \xi_I = q_I^+ - q_I^-. \tag{3.3}$$

It is straightforward to verify that the vector field $F(Q) \in C^1(\mathbb{R}^2)$, and hence it is locally Lipschitz continuous with respect to Q for a given $p^{\pm} \in L^\infty(0,T;L^\infty(\mathbb{R}))$. Then the Cauchy problem (3.1), (3.3) has a unique solution by the fundamental existence-uniqueness theorem. On the other hand, it is trivial to check that $q = 1$ is a solution of the first equation of (3.1) satisfying initial condition (3.3). Hence the system (3.1), (3.3) has a unique solution $(q = 1, \xi)$, where ξ is determined by the equation

$$\xi_t = \kappa(q^+ - q^-)(1 - \xi^2), \qquad \xi_I = q_I^+ - q_I^-.$$

It is worthwhile to point out that we provide an idea here for proving that $q = 1$ and for proving the (local) existence of q and ξ given that $p^{\pm} \in L^\infty(0,T;L^\infty(\mathbb{R}))$. This idea will be used later without repeating this procedure.

We proceed to show that solutions $q^{\pm}$ preserve the positivity. Substituting $q^- = 1 - q^+$ into the third equation of (1.1), we have

$$q_t^+ = 2\kappa(p^+ - p^-)(1 - q^+)q^+. \tag{3.4}$$

There are three cases to consider.

Case 1. $q_I^+ = 1$. Then we conclude that $q^+ = 1$ is a solution to (3.4) with initial condition $q_I^+ = 1$. Since the right-hand side of (3.4) is locally Lipschitz continuous with respect to q^+, the solution of (3.4) is unique. Hence $q^+(t,x) = 1$ for all t, x.

Case 2. $q_I^+ = 0$. Using an argument similar to Case 1 we can show that $q^+(t,x) = 0$ is a unique solution to (3.4).

Case 3. $0 < q_I^+ < 1$. Then integrating (3.4) with respect to t from 0 to t, one has

$$\frac{q^+}{1 - q^+} = \frac{q_I^+}{1 - q_I^+} \exp\left(\int_0^t 2\kappa(p^+(\tau,\cdot) - p^-(\tau,\cdot))d\tau\right).$$

Due to $0 < q_I^+ < 1$, we have

$$\frac{q^+}{1 - q^+} \geq 0.$$

It follows immediately from the above equality that $0 \leq q^+ \leq 1$. Combining Cases 1, 2, and 3, we get that $0 \leq q^+ \leq 1$ for $0 \leq q_I^+ \leq 1$. Applying $q^+ = 1 - q^-$ in the fourth equation of (1.1) and using the same approach, we can show that $0 \leq q^- \leq 1$.

Finally, we show the positivity of cell density $p^{\pm}(t,x)$. We use the theory of invariant principle from [11] for the hyperbolic random walk system to achieve this goal. To this end, we write the first two equations of the system (1.1) in a matrix form

$$\phi_t = G\phi + B\phi + \mathcal{F}(\phi), \tag{3.5}$$

where

$$\phi = \begin{pmatrix} p^+ \\ p^- \end{pmatrix}, \ G = \begin{pmatrix} -s\dfrac{\partial}{\partial x} & 0 \\ 0 & s\dfrac{\partial}{\partial x} \end{pmatrix}, \ B = \begin{pmatrix} -\mu & \mu \\ \mu & -\mu \end{pmatrix},$$

and

$$\mathcal{F}(\phi) = \begin{pmatrix} \mu q^+(p^+ + p^-) - \mu p^- \\ \mu q^-(p^+ + p^-) - \mu p^+ \end{pmatrix}.$$

Let $\Lambda = [0, \infty) \subset \mathbb{R}$. Then Λ is convex, and for each $z \in \partial\Lambda$, Λ has an outward normal vector. Moreover, define $\Sigma = \Lambda \times \Lambda$. Let $\phi \in \partial\Sigma$, and without loss of generality we assume that $\phi = (\vartheta, 0)$ with $\vartheta \geq 0$. Then for the outward normal vector $\eta(\phi) = (0, -1)$ of ϕ, we have

$$\eta(\phi) \cdot (B\phi + \mathcal{F}(\phi)) = -\mu q^- \vartheta \leq 0,$$

where we have used the positivity of q^-. Then by the theory in [11, Theorem 2], the set Σ is positively invariant for the system (3.5), which shows the positivity of $p^\pm$. The proof is completed. □

By Lemma 3.1, we obtain the following theorem.

Theorem 3.2. *The set* $\{\ (p^+, p^-, q^+, q^-) \mid p^\pm \geq 0, q^\pm \geq 0, q^+ + q^- = 1\}$ *is invariant to the system* (1.1) *provided that* $p^\pm, q^\pm \in L^\infty(0, T; L^\infty(\mathbb{R}))$ *for* $T > 0$.

Remark 1. For $p^+ > p^-$, the term $p^+ - p^- > 0$ and q^+ will increase while q^- decreases. Hence directionality is enhanced by the last two equations of (1.1).

Next, we prove the global existence of solutions to system (1.1) subject to initial condition (ic). Due to Theorem 3.2, we can reformulate the system (1.1) as

$$\begin{aligned} p_t^+ + sp_x^+ &= -\mu p^+ + \mu q^+(p^+ + p^-), \\ p_t^- - sp_x^- &= -\mu p^- + \mu q^-(p^+ + p^-), \\ \xi_t &= \kappa(p^+ - p^-)(1 - \xi^2), \end{aligned} \tag{3.6}$$

where q^+ and q^- are given by

$$q^+ = \frac{1+\xi}{2}, \qquad q^- = \frac{1-\xi}{2}. \tag{3.7}$$

It is worthwhile to note that here ξ represents the expectation of fiber orientation in one dimension subject to the initial condition $\xi_I := \xi(0) = q_I^+ - q_I^-$. Furthermore from initial condition (ic), we have

$$-1 \leq \xi_I \leq 1.$$

We seek the global solutions of the system (3.6) in the following space:

$$\mathbb{X}(0, T) := \{(p^+, p^-, \xi) |\ p^\pm, \xi \in L^\infty(0, T; L^1 \cap L^\infty(\mathbb{R}))\}.$$

We first give the local existence of solutions for the system (3.6).

Lemma 3.3 (local existence). *Let* $p_I^\pm, q_I^\pm(x) \geq 0$ *and* $q_I^+ + q_I^- = 1$. *Assume* $p_I^\pm \in L^1 \cap L^\infty(\mathbb{R})$ *and* $\xi_I \in L^1(\mathbb{R})$. *Then there exists a time* $T_0 > 0$ *such that the problem* (3.6) *with boundary condition* (bc1) *has a unique solution* $(p^+, p^-, \xi) \in \mathbb{X}(0, T_0)$ *satisfying* $-1 \leq \xi \leq 1$.

Proof. For short we denote $\eta = (p^+, p^-, \xi)^T$. The norm of the vector η is defined as

$$\begin{aligned} \|\eta\|_{L^\infty(\mathbb{R})} &= \max\{\|p^+\|_{L^\infty(\mathbb{R})}, \|p^-\|_{L^\infty(\mathbb{R})}, \|\xi\|_{L^\infty(\mathbb{R})}\}, \\ \|\eta\|_{L^1(\mathbb{R})} &= \max\{\|p^+\|_{L^1(\mathbb{R})}, \|p^-\|_{L^1(\mathbb{R})}, \|\xi\|_{L^1(\mathbb{R})}\}, \end{aligned}$$

Moreover, for the convenience of presentation we denote

$$\begin{aligned} f_1(p^+, p^-, \xi) &= -\mu p^+ + \frac{\mu}{2}(1 + \xi)(p^+ + p^-), \\ f_2(p^+, p^-, \xi) &= -\mu p^- + \frac{\mu}{2}(1 - \xi)(p^+ + p^-), \\ f_3(p^+, p^-, \xi) &= \kappa(p^+ - p^-)(1 - \xi^2). \end{aligned}$$

Clearly the function $f_i (i = 1, 2, 3)$ is differentiable with respect to its arguments and hence is locally Lipschitz continuous in any bounded subset of $L^1 \cap L^\infty(\mathbb{R})$.

It is straightforward to show that system (3.6) is strictly hyperbolic with three distinct uniform bounded eigenvalues λ_1, λ_2 satisfying $-s = \lambda_1 < \lambda_3 = 0 < \lambda_2 = s$. Then for each $i = 1, 2, 3$ and each point (t, x) in the $t - x$ plane, the characteristic equation of (3.6) defined by

$$\frac{d\mathbf{x}_i}{d\tau} = \lambda_i, \qquad \mathbf{x}_i(t) = x,$$

has a unique solution defined for all $t > 0$, describing the ith characteristic through point (t, x). We denote such a solution by $t \mapsto \mathbf{x}_i(\tau; t, x)$, where $\mathbf{x}_i(\tau; t, x) = x + \lambda_i(\tau - t)$ and in particular $\mathbf{x}_3(\tau; t, x) = x$ due to $\lambda_3 = 0$. Following the argument in [2], we define a set

$$\mathcal{D} = \left\{(t, x) \mid 0 \leq t < \ell/s, -\ell + st \leq x \leq l - st\right\}.$$

Note that ℓ can be arbitrarily large since the domain is unbounded. Then for every $(t, x) \in \mathcal{D}$ and every $i \in \{1, 2\}$, the characteristic curve $\{(t, x_i(\tau; t, x))| \ 0 \leq \tau \leq t\}$ is entirely contained inside $\mathcal{D}$ with $\mathbf{x}_i(0; t, x) \in [-\ell, \ell]$. Such a set $\mathcal{D}$ is called a domain of determinacy (see [2]).

The system (3.6) has two independent characteristics. We integrate the first equation of (3.6) along the second characteristic curve $\mathbf{x}_2(\tau; t, x)$, the second equation of (3.6) along the first characteristic $\mathbf{x}_1(\tau; t, x)$, and the third equation along $\mathbf{x}_3(\tau; t, x) = x$. Then (3.6) can be rewritten as an ODE system

$$\begin{aligned} p^+_\tau &= -\mu p^+(\tau, \mathbf{x}_2(\tau)) + \mu q^+(\tau, \mathbf{x}_2(\tau))(p^+(t, \mathbf{x}_2(\tau)) + p^-(\tau, \mathbf{x}_2(\tau))),\\ p^-_\tau &= -\mu p^-(\tau, \mathbf{x}_1(\tau)) + \mu q^-(\tau, \mathbf{x}_1(\tau))(p^+(\tau, \mathbf{x}_1(\tau)) + p^-(\tau, \mathbf{x}_1(\tau))),\\ \xi_\tau &= \kappa(p^+(\tau, x) - p^-(\tau, x))(1 - \xi^2(\tau, x)), \end{aligned} \tag{3.8}$$

where $\mathbf{x}_i(\tau) := \mathbf{x}_i(\tau; t, x)$ for $i = 1, 2$ and $\mathbf{x}_3(\tau) = x$.

In vector form, (3.8) can be reformulated as

$$u_\tau = f(u), \qquad u \in \mathbb{R}^3,$$

where

$$f(u) = \begin{pmatrix} f_1(u(\tau, \mathbf{x}_2(\tau))) \\ f_2(u(\tau, \mathbf{x}_1(\tau))) \\ f_3(u(\tau, x)) \end{pmatrix}.$$

Note that $\mathbf{x}_i(\tau) \in \mathbb{R}$ $(i = 1, 2)$. Then $f(u)$ is locally Lipschitz continuous in any bounded subset of $L^1 \cap L^\infty(\mathbb{R})$, and hence the local existence follows from the fundamental theorem of existence and uniqueness (e.g., see [22]). Due to Theorem 3.2 and the definition of ξ, we have that $-1 \leq \xi \leq 1$. Then the proof is finished. □

We proceed to derive a priori estimates in order to get global existence.

LEMMA 3.4 (a priori estimates). *Let the assumptions in Lemma* 3.3 *hold and let* (p^+, p^-, ξ) *be the solution obtained in Lemma* 3.3. *Then for any* $0 < t \leq T_0$, *there exist constants* $C > 0$ *and* $\widetilde{C} > 0$ *such that*

$$\|p^+(t)\|_{L^1 \cap L^\infty(\mathbb{R})} + \|p^-(t)\|_{L^1 \cap L^\infty(\mathbb{R})} + \|\xi(t)\|_{L^1 \cap L^\infty(\mathbb{R})} \leq C \exp(\widetilde{C} T),$$

and $-1 \leq \xi \leq 1$, *where* $\| \cdot \|_{L^1 \cap L^\infty(\mathbb{R})} = \| \cdot \|_{L^1(\mathbb{R})} + \| \cdot \|_{L^\infty(\mathbb{R})}$.

Proof. For each $(t,x) \in \mathcal{D}$ and $\mathbf{x}_i(0;t,x) \in [-\ell,\ell]$, we integrate the first two equations of (3.8) with respect to τ over $[0,t]$ and obtain that

$$\begin{aligned} &p^+(t,x) = p^+(\mathbf{x}_2(0)) + \int_0^t f_1\big(p^+(\tau,\mathbf{x}_2(\tau)), p^-(\tau,\mathbf{x}_2(\tau)), \xi(\tau,\mathbf{x}_2(\tau))\big)d\tau,\\ &p^-(t,x) = p^-(\mathbf{x}_1(0)) + \int_0^t f_2\big(p^+(\tau,\mathbf{x}_1(\tau)), p^-(\tau,\mathbf{x}_1(\tau)), \xi(\tau,\mathbf{x}_1(\tau))\big)d\tau,\\ &\xi(t,\xi) = \xi_I + \int_0^t (p^+(\tau,x) - p^-(\tau,x))(1-\xi^2(\tau,x))d\tau. \end{aligned} \tag{3.9}$$

Using the terminology from [2], we call (p^+,p^-,ξ) a *broad* solution for the Cauchy problem of (3.8) if (p^+,p^-,ξ) satisfies (3.9), at almost every point $(t,x)\in\mathcal{D}$. In the circumstance of semigroup theory, the broad solution defined above is called a mild solution if the transport operator in (3.6) generates a continuous semigroup (see [13] for details).

Taking the L^∞-norm on both sides of (3.9), using the fact that f_i is Lipschitz continuous, and taking into account $f_i(0,0,\xi)=0$ for $i=1,2$, we infer that

$$\begin{aligned} &\|p^+(t)\|_{L^\infty(\mathbb{R})} + \|p^-(t)\|_{L^\infty(\mathbb{R})} + \|\xi(t)\|_{L^\infty(\mathbb{R})}\\ &\quad \le C_1 + C_2\int_0^t (\|p^+(\tau)\|_{L^\infty(\mathbb{R})} + \|p^-(\tau)\|_{L^\infty(\mathbb{R})} + \|\xi(\tau)\|_{L^\infty(\mathbb{R})})d\tau, \end{aligned}$$

where C_1 is a constant such that $\|p_I^+\|_{L^\infty(\mathbb{R})} + \|p_I^-\|_{L^\infty(\mathbb{R})} + \|\xi_I\|_{L^\infty(\mathbb{R})} \le C_1$ and C_2 depends on the Lipschitz constants of the functions $f_i (i=1,2,3)$ and the turning rate μ.

The application of Gronwall's inequality to the above inequality gives

$$\|p^+(t)\|_{L^\infty(\mathbb{R})} + \|p^-(t)\|_{L^\infty(\mathbb{R})} + \|\xi(t)\|_{L^\infty(\mathbb{R})} \le C_1\exp(C_2 t).$$

Similarly, one can deduce that there exist constants $C_3, C_4 > 0$ such that

$$\|p^+(t)\|_{L^1(\mathbb{R})} + \|p^-(t)\|_{L^1(\mathbb{R})} + \|\xi(t)\|_{L^1(\mathbb{R})} \le C_3\exp(C_4 t).$$

The last two inequalities imply the first conclusion of the lemma. The second conclusion $-1\le\xi\le 1$ follows directly from Theorem 3.2 and the definition of ξ. ☐

By Lemmas 3.3 and 3.4, the existence theorem of global solutions is obtained.

THEOREM 3.5 (global existence). *Let initial condition* (ic) *hold. Assume* $p_I^\pm, \xi_I \in L^1\cap L^\infty(\mathbb{R})$. *Then the problem* (3.6) *with boundary condition* (bc1) *has a unique global solution* $(p^+,p^-,\xi)\in\mathbb{X}(0,\infty)$ *satisfying* $-1\le\xi\le 1$ *and* $p^\pm \ge 0$. *Consequently, the problem* (1.1) *with initial condition* (ic) *and boundary condition* (bc1) *has a unique global solution* (p^+,p^-,q^+,q^-) *such that* $p^\pm, q^\pm \in L^\infty(0,\infty; L^1\cap L^\infty(\mathbb{R}))$ *with* $p^\pm\ge 0$ *and* $0\le q^\pm\le 1$ *with* $q^+ + q^- = 1$.

Proof. We suppose that the maximal time $T_{\max}$ of existence for the solution of (3.6) is finite, namely, $T_{\max}<\infty$. From Lemma 3.4, we know that $-1\le\xi\le 1$ for any $0\le t\le T_{\max}$. Hence according to the well-known alternative results (e.g., see [20, 22]), one has that

$$\lim_{t\to T_{\max}} \|p^+(t)\|_{L^1\cap L^\infty(\mathbb{R})} = \infty \quad \text{or} \quad \lim_{t\to T_{\max}} \|p^-(t)\|_{L^1\cap L^\infty(\mathbb{R})} = \infty. \tag{3.10}$$

On the other hand, when $-1 \leq \xi \leq 1$, we have proven in Lemma 3.4 that for any $t \leq T_{\max}$, it holds that

$$\|p^+(t)\|_{L^1\cap L^\infty(\mathbb{R})} + \|p^-(t)\|_{L^1\cap L^\infty(\mathbb{R})} \leq C\exp(\widetilde{C}T_{\max}),$$

which contradicts (3.10) for $0 < T_{\max} < \infty$. This contradiction in turn shows that $T_{\max} = \infty$, and hence the global solution of (3.6) follows. Due to Theorem 3.1, the second conclusion is an immediate consequence. $\square$

Remark 2. Mathematically, when cutting efficiency $\kappa = 0$, the system (1.1) becomes the one-dimensional mesenchymal motion model for undirected tissue (see [12]). Due to the assumption $q^+(t,x) = q^-(t,x)$ for undirected tissue, we obtain the following global existence theorem for the model associated with undirected tissue.

THEOREM 3.6. *Suppose $\kappa = 0$. Let initial condition* (ic) *hold and let $q_I^+ = q_I^- = 1/2$. Assume $p_I^\pm \in L^1 \cap L^\infty(\mathbb{R})$. Then there exists a unique global solution to system* (3.6) *such that $(p^+, p^-, \xi) \in \mathbb{X}(0,\infty)$ with $\xi = 0$ and $p^\pm \geq 0$. Hence there is a unique global solution $(p^+, p^-, 1/2, 1/2)$ to* (1.1) *with initial condition* (ic) *and boundary condition* (bc1) *such that $p^\pm \in L^\infty(0,\infty; L^1 \cap L^\infty(\mathbb{R}))$ satisfying $p^\pm \geq 0$.*

Since the functions on the right-hand side of (1.1) are continuously differentiable with respect to p^+, p^-, q^+, and q^-, by a theory for semilinear hyperbolic systems in [2] (see Theorem 3.6 in [2]), the broad solution of Cauchy problem (1.1) obtained in Theorem 3.5 is indeed a classical solution provided that the initial data (1.9) are continuously differentiable, namely, we have the following results.

THEOREM 3.7. *Let the assumptions in Theorem* 3.5 *hold. In addition, we assume that the initial data in* (1.9) *are continuously differentiable. Then the broad solution $u : \mathcal{D} \to \mathbb{R}^2$ obtained in Theorem* 3.5 *provides a classical solution. Moreover, if initial data in* (1.9) *are nonnegative, the solution is nonnegative. Its partial derivatives u_t and u_x, respectively, are broad solutions of the following semilinear system:*

$$\begin{aligned}(u_t)_t &= H_u u_t - \Theta \cdot (u_t)_x,\\ (u_x)_t &= H_u u_x - \Theta \cdot (u_x)_x,\end{aligned}$$

where u, H, and Θ are defined as in section 2 *and H_u denotes the derivative of H with respect to u.*

Proof. The proof is similar to the argument in [2]. We omit the details. $\square$

4. Macroscopic limits. For the given fiber distribution $q^\pm(t,x)$, formal parabolic and hydrodynamic limits were derived in [12] for the mesenchymal motion models (1.1) in $n(n \geq 1)$ dimensions. In this section we rigorously carry out the parabolic limits for system (1.1) under some suitable assumptions.

To derive a limiting diffusion model for (1.1), we use the parabolic scaling of space and time, with $\bar{x} = \varepsilon x$ denoting a macroscopic space scale and $\bar{t} = \varepsilon^2 t$ a long time scale. Now we use the equivalent system (1.3) in a slightly different form using the flux $J = p^+ - p^-$. Upon substituting the above scaling variable into (1.3), and dropping the bar for convenience, we end up with the following equations:

$$\begin{aligned}\varepsilon^2\partial_t p_\varepsilon + \varepsilon s \partial_x J_\varepsilon &= 0,\\ \varepsilon^2\partial_t J_\varepsilon + \varepsilon s \partial_x p_\varepsilon &= \mu\xi_\varepsilon p_\varepsilon - \mu J_\varepsilon,\\ \varepsilon^2\partial_t \xi_\varepsilon &= \kappa(p_\varepsilon^+ - p_\varepsilon^-)(1-\xi_\varepsilon^2),\end{aligned} \tag{4.1}$$

with initial data $p_\varepsilon(0) = p_I = p_I^+ + p_I^-$, $J_\varepsilon(0) = J_I = p_I^+ - p_I^-$, $\xi_\varepsilon(0, \cdot) = q_I^+ - q_I^-$. The system (4.1) is equivalent to the following second-order damped hyperbolic equation (see (1.5) or [12]):

$$\frac{\varepsilon^4}{\mu}\partial_t^2 p_\varepsilon + \varepsilon^2 \partial_t p_\varepsilon + \varepsilon \partial_x (s\xi_\varepsilon p_\varepsilon) = \varepsilon^2 \frac{s^2}{\mu}\partial_x^2 p_\varepsilon, \tag{4.2}$$

which indicates that the drift term is a dominating term for ε small. As in [12], we assume that the expectation of fiber directions is small as to the order of ε:

$$\xi_q(t,x) = \lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\xi_\varepsilon\left(\frac{t}{\varepsilon^2}, \frac{x}{\varepsilon}\right) = \lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\left[q^+\left(\frac{t}{\varepsilon^2}, \frac{x}{\varepsilon}\right) - q^-\left(\frac{t}{\varepsilon^2}, \frac{x}{\varepsilon}\right)\right] < \infty. \tag{4.3}$$

Under the above assumption, we formally obtain a drift-diffusion model with diffusion coefficient $\frac{s^2}{\mu}$ and drift velocity $s\xi_q$ from (4.2) by sending $\varepsilon \to 0$ (see [12]),

$$\partial_t p + \partial_x(s\xi_q p) = \frac{s^2}{\mu}\partial_x^2 p, \tag{4.4}$$

where p is the limit of p_ε as $\varepsilon \to 0$. The goal of this section is to show that the solution of (4.2) is convergent to the solution of (4.4) in the weak sense as $\varepsilon \to 0$. To proceed we give the definition of weak solutions that we address here.

DEFINITION 4.1. *We say that a function $P \in L^\infty([0,T]; H^1(\mathbb{R}))$ is a weak solution of* (4.4) *if $P(t,x)$ satisfies the following:*

(a) *For any test function $\phi \in C_0^\infty([0,T) \times \mathbb{R})$, it holds that*

$$-\int_0^T \int_{\mathbb{R}} P\partial_t\phi dxdt - \int_0^T\int_{\mathbb{R}} (s\xi_q P)\partial_x\phi dxdt = \frac{s^2}{\mu}\int_0^T\int_{\mathbb{R}} P\partial_x^2\phi dxdt + \int_{\mathbb{R}} P(0)\phi(0)dx.$$

(b) $P(0) = p_I = p_I^+ + p_I^-$.

Next we establish the convergence properties of the solution $(p_\varepsilon,\ J_\varepsilon)$ as $\varepsilon \to 0$. It suffices to derive a uniform estimate for the solutions of system (4.1), which is given in the following lemma.

LEMMA 4.2. *Let $p_I^\pm \in H^1(\mathbb{R})$ and let the assumption* (4.3) *hold. Assume further that there exists a constant $C_1 > 0$, independent of ε, such that*

$$|\xi_\varepsilon|, |\partial_x\xi_\varepsilon| \le C_1\varepsilon. \tag{4.5}$$

Then there is a constant C_2, independent of ε, such that the solution $(p_\varepsilon, J_\varepsilon)$ of system (4.1) *satisfies, for any $0 \le t \le T$,*

$$\begin{aligned} &\|p_\varepsilon(t)\|_{H^1(\mathbb{R})} + \|J_\varepsilon(t)\|_{H^1(\mathbb{R})} + \|\varepsilon\partial_t p_\varepsilon\|_{L^2(\mathbb{R})} \\ &\quad \le C_2(C_1,\mu,T)(\|p_I\|_{H^1(\mathbb{R})} + \|J_I\|_{H^1(\mathbb{R})}), \end{aligned} \tag{4.6}$$

where the constant C_2 depends on C_1, μ, and T.

Proof. We use the energy method to prove the lemma. First, note that $p_\varepsilon(0) = p_I = p_I^+ + p_I^- \in H^1(\mathbb{R})$ and $J_\varepsilon(0) = J_I = p_I^+ - p_I^- \in H^1(\mathbb{R})$. Multiplying the first equation of (4.1) by p_ε and the second by J_ε, adding the resultant equations, and integrating over $[0,t) \times \mathbb{R}$, we end up with the following inequality:

$$\begin{aligned}
&\frac{1}{2}\int_{\mathbb{R}}(|p_\varepsilon|^2 + |J_\varepsilon|^2)dx + \int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}|J_\varepsilon|^2 dxd\tau \\
&\quad = \frac{1}{2}\int_{\mathbb{R}}(|p_I|^2 + |J_I|^2)dx + \int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}\xi_\varepsilon p_\varepsilon J_\varepsilon dxd\tau \\
&\quad \leq \frac{1}{2}\int_{\mathbb{R}}(|p_I|^2 + |J_I|^2)dx + \int_0^t \int_{\mathbb{R}} \mu C_1|\varepsilon^{-1}p_\varepsilon J_\varepsilon|dxd\tau,
\end{aligned} \tag{4.7}$$

where we have used the assumption (4.5). Applying Young's inequality $|C_1\varepsilon^{-1}p_\varepsilon J_\varepsilon| \leq \frac{1}{2}(\varepsilon^{-2}|J_\varepsilon|^2 + C_1^2|p_\varepsilon|^2)$ in (4.7), we have

$$\begin{aligned}
&\int_{\mathbb{R}}(|p_\varepsilon|^2 + |J_\varepsilon|^2)dx + \int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}|J_\varepsilon|^2 dxd\tau \\
&\qquad \leq \int_{\mathbb{R}}(|p_I|^2 + |J_I|^2)dx + \mu C_1^2 \int_0^t \int_{\mathbb{R}} |p_\varepsilon|^2 dxd\tau.
\end{aligned}$$

By Gronwall's inequality, we immediately get an L^2-estimate of p_ε and J_ε independent of ε such that for $0 \leq t < T$,

$$\|p_\varepsilon\|^2_{L^2(\mathbb{R})} + \|J_\varepsilon\|^2_{L^2(\mathbb{R})} \leq (\|p_I\|^2_{L^2(\mathbb{R})} + \|J_I\|^2_{L^2(\mathbb{R})})\exp(\mu C_1^2 T). \tag{4.8}$$

Next we go to the higher order estimates. To this end, we multiply the first equation of (4.1) by $-\partial_x^2 p_\varepsilon$ and the second by $-\partial_x^2 J_\varepsilon$. Then we end up with the following estimates using the same procedure as that deriving (4.7):

$$\begin{aligned}
&\frac{1}{2}\int_{\mathbb{R}}(|\partial_x p_\varepsilon|^2 + |\partial_x J_\varepsilon|^2)dx + \int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}|\partial_x J_\varepsilon|^2 dxd\tau \\
&= \frac{1}{2}\int_{\mathbb{R}}(|\partial_x p_I|^2 + |\partial_x J_I|^2)dx + \int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}\partial_x(\xi_\varepsilon p_\varepsilon)\partial_x J_\varepsilon dxd\tau \\
&\leq \frac{1}{2}\int_{\mathbb{R}}(|\partial_x p_I|^2 + |\partial_x J_I|^2)dx + \int_0^t \int_{\mathbb{R}} \mu C_1\varepsilon^{-1}(|p_\varepsilon| + |\partial_x p_\varepsilon|)|\partial_x J_\varepsilon|dxd\tau.
\end{aligned}$$

Using Young's inequality and the fact that $(a+b)^2 \leq 2(a^2+b^2)$ for $a, b \in \mathbb{R}$, we deduce that

$$\begin{aligned}
&\int_0^t \int_{\mathbb{R}} \mu C_1\varepsilon^{-1}(|p_\varepsilon| + \partial_x p_\varepsilon|)|\partial_x J_\varepsilon|dxd\tau \\
&\leq \frac{1}{2}\int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}|\partial_x J_\varepsilon|^2 dxd\tau + \frac{C_1^2}{2}\int_0^t \int_{\mathbb{R}} \mu(|p_\varepsilon| + |\partial_x p_\varepsilon|)^2 dxd\tau \\
&\leq \frac{1}{2}\int_0^t \int_{\mathbb{R}} \mu\varepsilon^{-2}|\partial_x J_\varepsilon|^2 dxd\tau + C_1^2\int_0^t \int_{\mathbb{R}} \mu|\partial_x p_\varepsilon|^2 dxd\tau + C(T, p_I, J_I),
\end{aligned} \tag{4.9}$$

where (4.8) has been used and

$$C(T, p_I, J_I) = \mu C_1^2 T(\|p_I\|^2_{L^2(\mathbb{R})} + \|J_I\|^2_{L^2(\mathbb{R})})\exp(\mu C_1^2 T).$$

Now substituting (4.9) into (4.7) and applying Gronwall's inequality to the resulting inequality, we infer that

$$\begin{aligned}
&\|\partial_x p_\varepsilon\|^2_{L^2(\mathbb{R})} + \|\partial_x J_\varepsilon\|^2_{L^2(\mathbb{R})} \\
&\quad \leq C(T, p_I, J_I)(\|\partial_x p_I\|^2_{L^2(\mathbb{R})} + \|\partial_x J_I\|^2_{L^2(\mathbb{R})})\exp(\mu C_1^2 T) \\
&\quad \leq \mu C_1^2 T(\|p_I\|_{H^1(\mathbb{R})} + \|J_I\|_{H^1(\mathbb{R})})^2 \exp(2\mu C_1^2 T).
\end{aligned} \tag{4.10}$$

Furthermore, by (4.1) we have

$$\|\varepsilon\partial_t p_\varepsilon\|_{L^2(\mathbb{R})} = \|\partial_x J_\varepsilon\|_{L^2(\mathbb{R})}. \tag{4.11}$$

Then the combination of (4.8), (4.10), and (4.11) gives (4.6) and completes the proof. □

THEOREM 4.3. *Let the assumptions in Lemma* 4.2 *hold and let* $p_\varepsilon(0) = p_I = p_I^+ + p_I^-$. *Then as* $\varepsilon \to 0$, *the solutions* p_ε *of* (4.2) *converge to a limit function* p_0, *which is a weak solution of* (4.4) *such that* $p_0(t = 0) = p_I$.

Proof. According to the energy estimates (4.6), we see that the solution sequence p_ε is uniformly bounded in $L^\infty_{\text{loc}}([0,\infty); H^1(\mathbb{R}))$ and $\varepsilon\partial_t p_\varepsilon$ is uniformly bounded in $L^\infty_{\text{loc}}([0,\infty); L^2(\mathbb{R}))$ for every $\varepsilon > 0$.

As a consequence of the Rellich–Kondrachov compactness theorem, there exist a subsequence of p_ε and $\varepsilon\partial_t p_\varepsilon$, still denoted by p_ε and $\varepsilon\partial_t p_\varepsilon$, and functions $p_0 \in L^\infty_{\text{loc}}([0,\infty); H^2(\mathbb{R}))$ and $p_1 \in L^\infty_{\text{loc}}([0,\infty); L^2(\mathbb{R}))$ such that

$$\begin{cases} p_\varepsilon \rightharpoonup p_0 \quad \text{weakly}^* \text{ in } \ L^\infty_{\text{loc}}([0,\infty); H^1(\mathbb{R})), \\ \varepsilon\partial_t p_\varepsilon \rightharpoonup p_1 \quad \text{weakly}^* \text{ in } \ L^\infty_{\text{loc}}([0,\infty); L^2(\mathbb{R})). \end{cases} \tag{4.12}$$

Next we show that p_0 is a weak solution of (4.4) subject to the given initial data. To this end we multiply (4.2) by a test function $\phi \in C_0^\infty([0,T) \times \mathbb{R})$ with $\phi(T) = 0$ and integrate the resultant equation to get

(4.13)
$$\begin{aligned} &\frac{\varepsilon^2}{\mu}\int_0^T\int_{\mathbb{R}} p_\varepsilon \partial_t^2\phi dxdt + \frac{\varepsilon^2}{\mu}\int_{\mathbb{R}}[p_\varepsilon(T)\partial_t\phi(T) - \partial_t p_\varepsilon(0)\phi(0)]dx \\ &\quad - \frac{\varepsilon^2}{\mu}\int_{\mathbb{R}}[\partial_t p_\varepsilon(T)\phi(T) - p_\varepsilon(0)\partial_t\phi(0)]dx - \int_0^T\int_{\mathbb{R}} p_\varepsilon\partial_t\phi dxdt + \int_{\mathbb{R}} p_\varepsilon(T)\phi(T)dx \\ &\quad - \frac{1}{\varepsilon}\int_0^T\int_{\mathbb{R}}(s\xi_\varepsilon p_\varepsilon)\partial_x\phi dxdt = \int_{\mathbb{R}} p_\varepsilon(0)\phi(0)dx + \frac{s^2}{\mu}\int_0^T\int_{\mathbb{R}} p_\varepsilon\partial_x^2\phi dxdt. \end{aligned}$$

Note that $p_\varepsilon(0) = p_I = p_I^+ + p_I^- \in H^1(\mathbb{R})$. Hence $J_\varepsilon(0) = J_I = p_I^+ - p_I^- \in H^1(\mathbb{R})$ and $\varepsilon\partial_t p_\varepsilon(0) = \partial_x J_\varepsilon(0) \in L^2(\mathbb{R})$ from (4.1). Thus the second, third, and fourth terms in (4.13) vanish as $\varepsilon \to 0$ by (4.12). Using assumption (4.3) and sending $\varepsilon \to 0$ in (4.13), we obtain from (4.12) that

$$\begin{aligned} &-\int_0^T\int_{\mathbb{R}} p_0\partial_t\phi dxdt - \int_0^T\int_{\mathbb{R}}(s\xi_q p_0)\partial_x\phi dxdt \\ &\quad = \int_{\mathbb{R}} p_I\phi(0)dx + \frac{s^2}{\mu}\int_0^T\int_{\mathbb{R}} p_0\partial_x^2\phi dxdt, \end{aligned} \tag{4.14}$$

which shows that p_0 is a weak solution of (4.4) satisfying the initial condition. □

Remark 3. It is worthwhile to note that assumptions (4.5) and (4.3) are automatically satisfied for the case of undirected tissue where $\xi_\varepsilon = 0$ (see also Remark 2). Then the limit equation for the case of undirected tissue is a pure diffusion equation without a drift term.

5. Traveling waves. Since the system (1.1) models the invasion of cells through tissue, it is of interest to look for traveling wave solutions for (1.1) and see what kinds of movement patterns are used by cells for invasion. To this end, we first use the invariant of motion $q^+ + q^- = 1$ and consider the equivalent system (1.4).

We introduce the wave variable

$$z = x - ct,$$

where $c \geq 0$ denotes the wave speed. Then we can define the wave profile by

$$\begin{aligned} p(z) &= p(t,x) = p(x-ct), \\ j(z) &= j(t,x) = j(x-ct), \\ q^+(z) &= q^+(t,x) = q^+(x-ct). \end{aligned} \tag{5.1}$$

Substituting (5.1) into (1.4), we convert (1.4) into an ODE system as follows:

$$\begin{aligned} -cp_z + j_z &= 0, \\ -cj_z + s^2 p_z &= -\mu j + \mu s(2q^+ - 1)p, \\ -cq_z^+ &= \frac{2\kappa}{s} j(1-q^+)q^+. \end{aligned} \tag{5.2}$$

We prescribe the boundary conditions by

$$\begin{aligned} p(-\infty) &= p(+\infty) = 0, \\ j(-\infty) &= j(+\infty) = 0, \\ q^+(-\infty) &= q_l^+,\ q^+(+\infty) = q_r^+, \end{aligned} \tag{5.3}$$

where q_l^- and q_r^+ are constants and satisfy $0 \leq q_l^-,\, q_r^+ \leq 1$, and $q_l^- > q_r^+$. That is, we look for the traveling pulse wave for p and decreasing traveling front wave for q^+.

From (5.2) and the boundary conditions (5.3), we obtain an invariant of motion for j and p such that

$$j = cp. \tag{5.4}$$

Then the system (5.2) is reduced to a two-dimensional system by the substitution of (5.4) into (5.2):

$$\begin{aligned} (c^2 - s^2)p_z &= \mu p[c - s(2q^+ - 1)], \\ q_z^+ &= -\frac{2\kappa}{s} p(1-q^+)q^+. \end{aligned} \tag{5.5}$$

It is clear that (5.5) becomes a singular problem when $c = s$ and that this singular problem has no solution satisfying the boundary conditions (5.3). Indeed if $c = s$, then $q^+ = 1$ due to $\mu \neq 0$, which biologically means cells continuously move to the right without changing movement direction. Also, $q^+ = 1$ does not agree with the boundary conditions (5.3). Thus we assume $c \neq s$ hereafter. We will see later that biologically meaningful waves exist only for $c < s$. However, for now, we just assume $c \neq s$, and system (5.5) can be rewritten as

$$\begin{aligned} p_z &= -\alpha p[c - s(2q^+ - 1)], \\ q_z^+ &= -\beta p(1-q^+)q^+, \end{aligned} \tag{5.6}$$

where $\alpha = -\frac{\mu}{c^2 - s^2}$, $\beta = \frac{2\kappa}{s} > 0$. Due to the biological interest, we consider only nonnegative solutions where $p \geq 0$ and $0 \leq q^\pm \leq 1$. In fact, the nonnegativity of solutions to the system (5.6) with boundary conditions (5.3) can be analogously obtained by following the argument used in section 3. Therefore we are interested only in those heteroclinic orbits that remain nonnegative.

5.1. Phase plane analysis. System (5.6) has a continuum of steady states $(0,\theta)$ with $0 \le \theta \le 1$. The Jacobian matrix linearized about the steady state $(0,\theta)$ is

$$J_s = \begin{bmatrix} -\alpha\big(c - s(2\theta - 1)\big) & 0 \\ -\beta(1-\theta)\theta & 0 \end{bmatrix}.$$

The eigenvalues of J_s are

$$\lambda_1 = -\alpha\big(c - s(2\theta - 1)\big), \qquad \lambda_2 = 0. \tag{5.7}$$

The corresponding eigenvectors are

$$r_1 = \begin{bmatrix} \lambda_1 \\ -\beta(1-\theta)\theta \end{bmatrix}, \qquad r_2 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}. \tag{5.8}$$

When $c \ne s$, we have two cases to consider corresponding to the sign of eigenvalue λ_1.

Case 1. If $c > s > 0$, then $\alpha < 0$. It is straightforward to check that $\lambda_1 > 0$, which indicates every steady state $(0,\theta)$ with $0 \le \theta \le 1$ is unstable, and consequently there is no nonnegative heteroclinic connection due to the lack of the stable manifold. We thus claim that $0 \le c < s$ is a necessary condition for the existence of a traveling wave and s is then a critical traveling speed. Thus we assume that $c < s$ hereafter.

Case 2. If $0 \le c < s$, then $\alpha > 0$. We first fix the traveling speed c and solve $c - s(2\theta^* - 1) = 0$ to get $\theta^* = \frac{c+s}{2s}$. Clearly we have that $0 < \theta^* < 1$. Furthermore the following properties hold:

$$\begin{aligned} &\theta < \theta^* \Rightarrow \lambda_1 < 0, \\ &\theta = \theta^* \Rightarrow \lambda_1 = 0, \\ &\theta > \theta^* \Rightarrow \lambda_1 > 0. \end{aligned} \tag{5.9}$$

Next, we show that there exists a pair of equilibria which generates a heteroclinic connection for each fixed c satisfying $0 \le c < s$. From (5.7), we see that every steady state $(0,\theta)$ of the system (5.6) with $0 \le \theta \le 1$ has two manifolds, one of which is a one-dimensional center manifold corresponding to zero eigenvalue λ_2. Since each center manifold is invariant under the flow of the system (5.6), and the set $\{(p,q^+) : p = 0, 0 \le q^+ \le 1\}$ consists of steady states only and hence is invariant, the center manifold is the q^+ axis where $0 \le q^+ \le 1$. So the heteroclinic connection is determined only by the stable and unstable manifolds corresponding to positive and negative eigenvalues given by λ_1, respectively. The existence of a heteroclinic orbit connecting the unstable manifold of one fixed point with the stable manifold of another fixed point corresponds to the existence of a traveling wave (heteroclinic orbit). Below we rigorously prove the existence of such a heteroclinic connection. Beyond this, we also shall prove the existence of a family of traveling waves since a continuum of steady state exists for the system (5.6). Before proceeding, we give a remark as follows.

Remark 4. The constants $q^+ = 0$ and $q^+ = 1$ are solutions of the second equation of (5.6), and furthermore it holds that

(a) if $q^+ = 0$, then $p \to +\infty$ as $z \to -\infty$;

(b) if $q^+ = 1$, then $p \to +\infty$ as $z \to +\infty$.

Therefore, neither the orbit $q^+ = 0$ nor $q^+ = 1$ can form a heteroclinic connection, although $\{q^+ = 1\}$ is the unstable manifold of the equilibrium $(0,1)$ and $\{q^+ = 0\}$ is the stable manifold of the equilibrium $(0,0)$. So hereafter we assume that $0 < q^+ < 1$ in order to obtain the existence of traveling waves.

5.2. Existence of traveling waves. To show that an unstable manifold can be connected by a stable manifold, we need to investigate the global structure of the original nonlinear system. Below we shall apply LaSalle's invariant principle (see [10, 18]) to study the asymptotic behavior of solutions of the system (5.6), which is described in the following lemma.

LEMMA 5.1. *Assume* $0 \le c < s$. *Let* (p, q^+) *be a solution of* (5.6) *subject to initial conditions* $p_I > 0$ *and* $0 < q_I^+ < 1$. *Then the* ω*-limit set of solutions to system* (5.6) *is contained in the following set:*

$$\mathbb{N} = \{(p, q^+) |\ p = 0,\ 0 < q^+ < \theta^*\}, \tag{5.10}$$

and the α*-limit set is contained in the set*

$$\mathbb{G} = \{(p, q^+) |\ p = 0,\ \theta^* < q^+ < 1\}, \tag{5.11}$$

where θ^* *is a constant between* 0 *and* 1 *determined by* $\theta^* = \frac{c+s}{2s}$.

Proof. Define a function $V(p, q^+)$ by $V(p, q^+) = q^+$. Then in the set $\{(p, q^+) |\ p \geq 0, 0 < q^+ < 1\}$, $V(p(z), q^+(z)) > 0$ and $\frac{dV}{dz} \le 0$ thanks to the second equation of (5.6). Given a number $L > 0$, we now define a set

$$\Omega_L = \{(p, q^+) |\ V(p, q^+) \le L, p > 0, 0 < q^+ < 1\}.$$

Since we restrict our attention to the case of $0 < q^+ < 1$, we let $0 < L < 1$. Hence it holds that

$$\Omega_L = \{(p, q^+) |\ p > 0, 0 < q^+ < L\}.$$

We now proceed to justify that the set Ω_L is bounded for given $0 < L < 1$. Toward this end, we divide the first equation of (5.6) by the second equation to obtain that

$$\frac{dp}{dq^+} = -\frac{\alpha(c+s)}{\beta}\frac{1}{(1-q^+)q^+} + \frac{2\alpha s}{\beta}\frac{1}{1-q^+}. \tag{5.12}$$

Integrating this equation and recovering α and β yield a first integral

$$p(q^+) = \frac{\mu s}{2\kappa}\left[\frac{\ln(1-q^+)}{c+s} - \frac{\ln q^+}{c-s}\right] + C, \tag{5.13}$$

where C is a constant of integration determined by the boundary condition of q^+ given in (5.3).

Then for any $q^+ = V(p, q^+) < L$, it is clear from (5.13) that p is bounded as a function of q^+. As a result, the set Ω_L defined above is bounded.

We now define another set

$$\mathbb{N}_1 = \left\{(p, q^+) \middle| \frac{dV}{dz} = 0, 0 < q^+ < 1\right\}.$$

From the second equation of (5.6), we know that

$$\frac{dV}{dz} = 0 \Longleftrightarrow p = 0 \text{ or } q^+ = 0 \text{ or } q^+ = 1.$$

Therefore, $\mathbb{N}_1 = \{(p, q^+) |\ p = 0, 0 < q^+ < 1\}$ and is invariant since it is composed of only steady states. With the help of LaSalle's invariant principle, the ω-limits set of

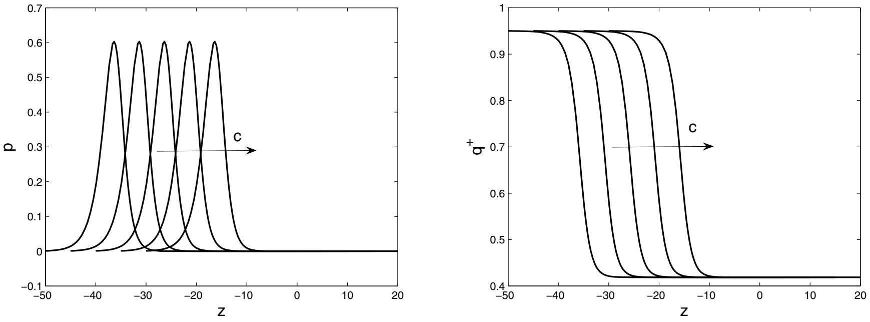

FIG. 1. *The traveling wave for the system* (5.6)*, where* $c = 1, s = 2, \mu = 2, \kappa = 1$*. The waves travel from the left to the right and* c *denotes the traveling speed and* $z = 0, 5, 10, 15, 20$*.*

any trajectories of the system starting in the set Ω_L for $0 < L < 1$ is contained in the set $\mathbb{N}_1$. Indeed, we can characterize the asymptotic behavior of the solution more precisely. From (5.9), we know that $\lambda_1 > 0$ for all $\theta^* < \theta < 1$. Then the equilibrium $(0, \theta)$ with $\theta^* < \theta < 1$ is unstable. If we define $\mathbb{N}_2 = \{(p, q^+)|\ p = 0, \theta^* < q^+ < 1\}$, then all solutions of the system (5.6) converge to the set as $z \to +\infty$:

$$\mathbb{N} = \mathbb{N}_1 \setminus \mathbb{N}_2 = \{(p, q^+)|\ p = 0,\ 0 < q^+ < \theta^*\}.$$

In a similar fashion, if we study the problem (5.6) backward on variable z, we can prove that all solutions of (5.6) converge to the set $\mathbb{G}$ when $z \to -\infty$, which completes the proof. □

Lemma 5.1 shows that any trajectory of the system (5.6) starting in a neighborhood of an equilibrium $(0, \theta)$ with $\theta^* < \theta < 1$ converges, as $z \to +\infty$, to another equilibrium $(0, \theta)$ with $0 < \theta < \theta^*$, which gives a nonnegative heteroclinic orbit (traveling wave) connecting these two equilibria. This heteroclinic orbit can be explicitly given by a level curve equation in the form of (5.13). It is worthwhile to point out that the traveling speed c can be 0 from our analysis, which corresponds to a standing wave. Hence we obtain the following existence theorem of traveling waves.

THEOREM 5.2. *Let us consider the system* (5.6) *given traveling speed* c *with* $0 \leq c < s$ *and* $\theta^* = \frac{c+s}{2s}$*. Then for any equilibrium* $(0, c_1)$ *with* $\theta^* < c_1 < 1$ *there exists another equilibrium* $(0, c_2)$ *with* $0 < c_2 < \theta^*$ *such that there is a bounded, nonnegative, heteroclinic orbit connecting* $(0, c_1)$ *to* $(0, c_2)$*. That is, there exists a traveling solution* (p, q^+) *of the system* (5.6) *connecting two equilibria. Particularly, the system* (5.6) *admits a standing wave for* $c = 0$*.*

Notice that in Lemma 5.3 we will give an explicit relation between c_1 and c_2.

An example of traveling solution (p, q^+) for system (5.6) is numerically plotted in Figure 1. From the definition of p and the relation (5.4), we can derive that

$$p^+ = \frac{s+c}{2s} p, \qquad p^- = \frac{s-c}{2s} p. \tag{5.14}$$

In addition to the relation

$$q^- = 1 - q^+, \qquad j = cp, \tag{5.15}$$

we find the traveling waves for p^+, p^-, q^-, and j in terms of p and q^+, as given above. The plots of the traveling structures of these quantities are given in Figure 2.

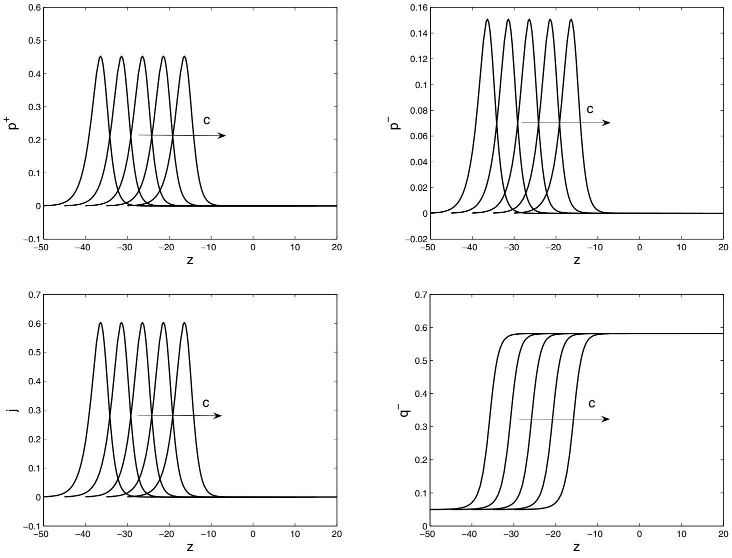

FIG. 2. *Numerical illustration of traveling waves for* p^+, p^-, j, *and* q^-, *where* $c = 1, s = 2, \mu = 2, \kappa = 1$. *The waves shift from the left to the right and* c *denotes the traveling speed and* $z = 0, 5, 10, 15, 20$.

A plot of all these quantities in a coordinate system is given in Figure 3 from which the transition properties between cell movement direction and fiber orientation are clearly indicated.

From the first equation of (1.4), we know that the total mass of cells is conserved and so traveling pulse waves are expected, as we found analytically and numerically above. The numerical simulation for p in Figure 1 indicates that individual cells can move to the left or the right, but the whole cell group will move to the right continuously. However, when the waves travel through, the fiber orientations are modified by cells, and alignment to cell movement direction is enhanced, which is indicated by the numerical simulation for q^+ in Figure 3.

5.3. Family of traveling waves. Note that for each left state q_l^+ with $\theta^* < q_l^+ < 1$ we find a corresponding right state $(0, q_r^+)$ connecting to $(0, q_l^+)$ which gives a traveling wave. Here we give an explicit formula which relates q_l^+ and q_r^+.

LEMMA 5.3. *Given a speed* c *satisfying* $0 \leq c < s$, *the left and right equilibria* $(0, q_l^+)$ *and* $(0, q_r^+)$ *are related as*

$$\left(\frac{1-q_r^+}{1-q_l^+}\right)^{s-c} = \left(\frac{q_l^+}{q_r^+}\right)^{s+c}, \qquad 0 \leq c < s. \tag{5.16}$$

Proof. An explicit heteroclinic connection has been given by (5.13). By Lemma 5.1, we infer that $p(q_l^+) = p(q_r^+) = 0$. Applying this condition to (5.13), one has that

$$\frac{\ln(1-q_l^+)}{c+s} - \frac{\ln q_l^+}{c-s} = \frac{\ln(1-q_r^+)}{c+s} - \frac{\ln q_r^+}{c-s}.$$

Rearranging the above identity yields (5.16). ▯

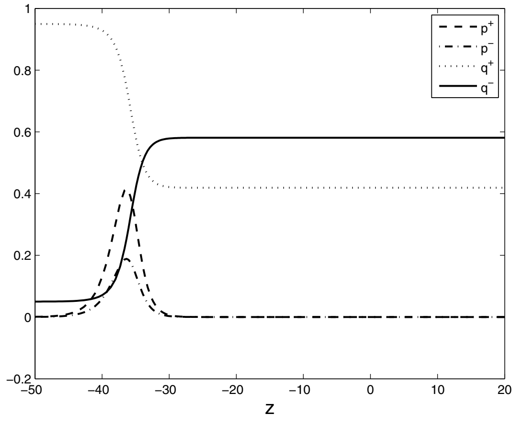

FIG. 3. *A plot of traveling solutions of system* (1.1) *in a coordinate system, where* $c = 1, s = 2, \mu = 2, \kappa = 1,$ *and* $z = 0, 5, 10, 15, 20$.

By Lemma 5.3 we identify a family of heteroclinic orbits as shown in Figure 4.

From (5.13) we see that p is bounded as a function of q^+ if $0 < q^+ < 1$. It would be of interest also to find the upper bound for each orbit and to see how the upper bound varies with respect to the right/left states of q^+. Indeed, by (5.12), we get a unique critical point $q^+ = \theta^*$ such that $\frac{dp}{dq^+}|_{q^+=\theta^*} = 0$. The second derivative of p with respect to q^+ is

$$\frac{d^2p}{dq^{+2}} = -\frac{\mu s}{2\kappa}\left[\frac{1}{(c+s)(1-q^+)^2} + \frac{1}{(s-c)q^{+2}}\right], \tag{5.17}$$

Noting that $0 \le c < s$, it is easy to verify that $\frac{d^2p}{dq^{+2}} < 0$ at $q^+ = \theta^*$. Moreover, we know that $p(q_l^+) = p(q_r^+) = 0$. Hence p attains the maximal value at $q^+ = \theta^*$ given by

$$p_{\max} = \frac{\mu s}{2\kappa}\left[\frac{\ln(1-\theta^*)}{c+s} - \frac{\ln\theta^*}{c-s}\right] + \sigma, \tag{5.18}$$

where

$$\sigma = -\frac{\mu s}{2\kappa}\left[\frac{\ln(1-q_l^+)}{c+s} - \frac{\ln q_l^+}{c-s}\right], \qquad \theta^* = \frac{c+s}{2s}. \tag{5.19}$$

Remark 5. From the above equation, we know that the upper bound $p_{\max}$ of p depends on the left states q_l^+ of q. Also, we can easily verify that upper bound $p_{\max}$ increases with respect to $q_l^+ > \theta^*$ (see Figure 4).

Remark 6. The results obtained above for traveling waves are valid only for the case of directed tissue. For undirected tissue, traveling waves with $c < s$ do not exist. Indeed, in the undirected case, we know that $q^+ = q^- = \frac{1}{2}$, and the system (5.6) is reduced to a scalar equation

$$p_z = \frac{\mu^2}{c^2 - s^2}cp. \tag{5.20}$$

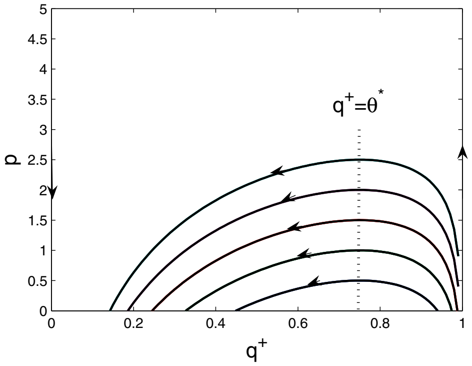

FIG. 4. *The illustration of a family of heteroclinic orbits for the system* (5.6)*, where* $c = 1, s = 2, \mu = 2, \kappa = 1,$ *and* $\theta^* = 0.75$*. The arrow denotes the orientation of trajectories to the system* (5.6)*.*

Clearly, equation (5.20) has no solution satisfying boundary conditions (5.3).

Remark 7. The situation of nested heteroclinic orbits which correspond to traveling waves is also known from other biological applications, for example, for an epidemic with moving infectives (see [24]).

6. Conclusions.

In this study, we analyze the one-dimensional mesenchymal motion model proposed by Hillen [12]. We establish the global existence of classical solutions for both cases of directed and undirected tissue. Particularly, we show that the model of undirected tissue ($\kappa = 0$) has a constant solution for fiber orientation distribution such that $q(t, x, +s) = q(t, x, -s) = \frac{1}{2}$, which means cells have no preference in choosing a particular movement direction and they have equal probability of moving to the right or left. We discuss the existence of inhomogeneous steady states for the case of directed tissue and identify a mechanism of cell aggregation. We rigorously show the convergence of macroscopic limits of the model; i.e., the solution of the mesoscopic model converges to that of the corresponding macroscopic continuum model. Moreover, we study the traveling wave solutions and establish the existence of a traveling pulse in total cell population $p(t, x)$ and traveling front waves in fiber orientation distribution $q^{\pm}(t, x)$. The standing wave ($c = 0$) is admitted in our analysis. This is not surprising considering the fact that cells can move in two directions (left and right) and two traveling waves with opposite direction can eliminate each other to result in a standing wave. All our results are fairly consistent with the biological relevance discussed in paper [12].

The one-dimensional model appears artificial when compared to the real three-dimensional process of cell movement in fiber tissue. The benefit of studying the one-dimensional model in detail is twofold. First of all, this model and its properties give good intuition into mechanisms that might be important in the higher dimensional case. For example, the existence of nonhomogeneous steady states will also be expected for higher dimensional models. Also, the model with directed fibers seems to have a richer behavior. Essentially we identify three distinctions between directed and undirected tissue which are hard to see from the three-dimensional model. We show that for the one-dimensional model, there is no aggregation for undirected tissue, whereas aggregation is possible for directed tissue. In addition, for the macroscopic limit, there are no constraints of convergence for the model of undirected tissue. However, some suitable restriction is needed for directed tissue. Moreover, the model of undirected tissue does not admit traveling waves and the model of directed tissue does. All these distinctions might be true for higher dimensional models.

Second, the model considered here can be used to describe cell movement in highly aligned tissue. In fact, many tissues show a predominant orientation; for example, the rapid spread of glioma cells across the *corpus callosum* results from the migration of individual glioma cells along the highly aligned white matter tracks inside brain tissue [1]. F-actin filaments in vascular smooth muscle cells (VSMCs) are highly aligned on textured polydimethylsiloxane (PDMS) scaffolds [23], and skeletal muscles have a highly organized structure which consists of parallel bundles of multinucleated myotubes that are formed by the fusion of myoblast satellite cells [25]. The model studied here can be used to describe spread and propagation of cells along those aligned tissues. In that case, the traveling pulse waves shown in section 5 correspond to an application of a "comb" to the tissue which is aligned positively or negatively in a common direction. If a brush is applied upstream, say, the fibers will be flipped and higher alignment to the right results, we call these waves *alignment waves*; see also our simulations in Figures 1–3.

For the application of these models to cancer invasion through collagen tissue, the undirected formalism is important. The result of no traveling pulses for that case does not preclude invasions. It precludes only invasion in a self-similar fashion. It is still possible that cells invade new areas, in particular if nonlinear proliferation terms are added. The existence of traveling waves under incorporation of cell proliferation is an interesting open question that comes out of the research done here.

Mathematically, the higher dimensional mesenchymal motion models show significant differences when compared to the one-dimensional case. In one dimension, fiber orientation $q(t, x, \theta)$ has only two directions and hence is bounded due to the normalization condition $q^+ + q^- = 1$. However, in higher dimensions, fibers have infinitely many directions, and highly aligned tissue corresponds to $q(t, x, \theta)$ being a Dirac delta function along that direction. Hence the function spaces have to be chosen to include nonintegrable distributions, and standard L^2 or L^∞ methods do not apply. In a forthcoming paper [13], we will study the existence of solutions for the high dimensional mesenchymal motion models in a Banach space of measurable functions using semigroup theory. If the existence theory stands, we can look into the interesting network formation dynamics, which were found numerically in Painter [21].

DIFFRACTION BY A NONCONVEX POLYGON*

BAIR V. BUDAEV[†] AND DAVID B. BOGY[†]

Abstract. The probabilistic approach to wave propagation and diffraction is applied to a typical problem of diffraction by a nonconvex polygon. The solution is obtained using a transparent technique that employs a floating coordinate system, and it combines ideas from ray theory, stochastic analysis, and complex analysis. The obtained solution is compatible with intuitive ideas about diffraction, and it admits simple implementations.

Key words. diffraction, scattering, ray theory, Feynman–Kac formula, wave propagation

1. Introduction.

It is widely known that the process of wave propagation may be conveniently separated into (a) propagation along the rays, which makes possible the long-range transport of energy, and (b) diffusion across the rays, which smooths the distribution of energy and spreads it to the shadow zones. These two processes correspond to different physical phenomena, and they are described by very different mathematical models. Thus, the ray theory [15], describing propagation along the rays, involves first-order partial differential equations, and it provides approximate solutions of the wave equation which have a clear mathematical structure as well as a simple physical meaning. In contrast, the process of diffraction (diffusion across the rays) is described by second-order partial differential equations which are difficult for analysis but, if solved, provide a correction of the ray theory approximation to the exact solution of the considered problem of wave propagation.

The difference in the mathematical foundations of ray and diffraction theories is reflected in the difference in the levels of their development. The ray approximation to the solutions of the wave equation can be computed by a canonical procedure which remains valid in very general settings, and it admits a clear interpretation in physically meaningful terms. However, computation of the diffracted fields remains a difficult problem which has to be studied by special methods tailored to each particular configuration. Moreover, in most cases for which the solutions of the problem of diffraction are known, they either present extremely complicated analytic expressions or rely on massive computations which do not mimic any physical processes and, therefore, do not extend the understanding of the wave propagation phenomena.

For more than one hundred years since the first problems of diffraction were formulated, exact descriptions of the diffracted fields have been obtained only for a small number of domains bounded by surfaces of simple shapes, such as a wedge, cylinder, sphere, or ellipsoid, and most of these solutions have been obtained either by the method of separation of variables or by integral transform methods leading to functional or integral equations solvable by the Wiener–Hopf or other analytic

methods [4, 12]. However, despite their limited areas of applicability, these exact solutions of particular problems of diffraction by simple objects play an important role in the further understanding of wave propagation, and they have also been used as building blocks for various iterative techniques [1, 2, 3, 14, 16] developed for the analysis of diffraction by more complex objects, such as polygons, for example.

The above-mentioned analytic approaches to the computation of diffracted fields were recently complemented by a probabilistic method which represents solutions of certain second-order partial differential equations by the Feynman–Kac formulas [11, 13], which are mathematical expectations of specific functionals depending on the trajectories of Brownian motions. This method has already been successfully applied to a number of recognized difficult problems, including the problems of diffraction by a finite segment [6], by a half-plane with piecewise constant impedance, and by an arbitrary convex polygon with sidewise constant surface impedance [8]. These problems do not have simple closed-form solutions, but their probabilistic solutions are transparent, simple to implement, and provide clear interpretation of diffraction in terms of diffusion across the rays. The probabilistic approach to wave propagation appears as an extension of the ray method approximation to the exact solutions, which suggests that the probabilistic solutions may be used not only at high frequencies but also at intermediate and low frequencies.

The probabilistic method presented in [8] made it possible to obtain theoretically exact representations for wave fields in the exterior of an arbitrary convex polygon, but due to some technical reasons it could not be directly applied to problems in the exterior of a nonconvex polygon. However, in a more recent development the probabilistic approach has been generalized and enhanced to the extent which makes it possible to use it for the description of wave fields in domains of general shape, including domains bounded by nonconvex polygons. This extension is discussed in [10] in a very general setting which may be excessive for a transparent presentation of its main ideas. For this reason, here we do not directly use the results from [10] but rederive them in a simplified form just sufficient for the analysis of a particular problem of diffraction by a nonconvex polygon. We hope that such an approach will be helpful for the further demonstration of the capabilities of the probabilistic approach to wave propagation.

This paper is organized as follows: two introductory sections, 2 and 3, are followed by the technical sections, 4–6, which lead to the solution of the main problem of diffraction in sections 7 and 8.

In section 2, we introduce notation for handling multiple systems of polar coordinates which are simultaneously used for the adequate description of wave fields in the exterior of a polygon. The lack of a coordinate system naturally associated with the exterior of a polygon seems to be a major obstacle for the description of wave fields in such domains, but the use of a floating coordinate system makes it possible to get around this obstacle by selecting different coordinate systems for different observation points. In section 3 the problem of diffraction by a nonconvex polygon is reduced to the fundamental Problem-1, the computation of wave fields that have specified jumps along rays originating from the vertices of the polygon.

The main technical tools of the paper are developed in section 4, which deals with the problem of radiation into a wedge with virtually arbitrary boundary conditions. The obtained representation generalizes the results from both [8] and [10], which are restricted to analytic boundary conditions and to wedges with angles smaller than 270°, respectively. The results of section 4 are then utilized in sections 5 and 6 as building blocks for the solutions of the radiation problems in the exterior of convex and nonconvex polygons, which are covered by sets of overlapping wedges. Finally, in section 7 we obtain the solution of Problem-W for a nonconvex polygon, and in section 8 the feasibility of the obtained expressions is confirmed by numerical examples.

2. Notation and coordinate systems. Let Γ be a nonconvex N-sided polygon with the vertices $O_0, O_1, \ldots, O_{N-1}$, shown in Figure 1 for the case when $N = 6$. The polygon Γ subdivides the plane into two domains, but our interest here is restricted to the exterior domain G.

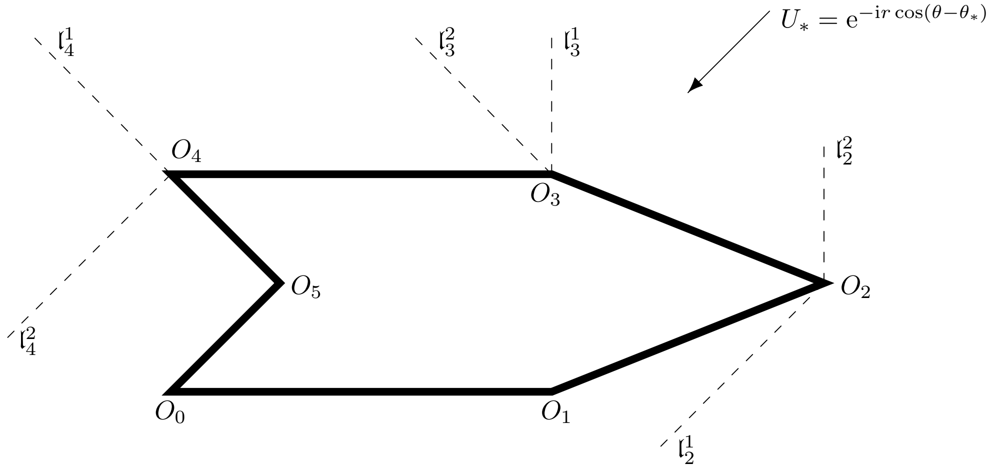

FIG. 1. *Geometry of the problem.*

To describe wave fields in the exterior of a polygon it is convenient to use several coordinate systems simultaneously. The standard polar coordinates (r, θ) are used as a universal reference system, but we also use polar coordinates (r_n, θ_n) centered at the vertices O_n and calibrated by the conditions

$$\theta_n(O_{n-1}) = 0, \tag{2.1}$$

which become meaningful for any integer n if we adopt the periodicity convention

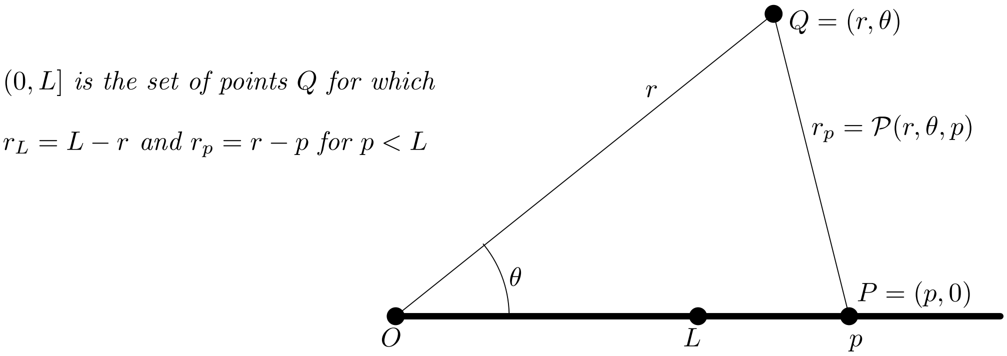
$$O_{n+N} \equiv O_n. \tag{2.2}$$

Similar conventions will also be applied to the exterior angle α_n at the vertex O_n, as well as the sides $\mathfrak{g}_n^\pm$ of the polygon and their lengths $L_n^\pm$ defined as

$$\mathfrak{g}_n^+ = \mathfrak{g}_{n+1}^- = O_n O_{n+1} \qquad \text{and} \qquad L_n^+ = L_{n+1}^- = |O_n O_{n+1}|, \tag{2.3}$$

respectively. It should be noted that although the use of the overlapping notations $\mathfrak{g}_n^+ = \mathfrak{g}_{n+1}^-$ and $L_n^+ = L_{n+1}^-$ may initially look confusing, it is justified by the duality of the position of the segment $O_n O_{n+1}$, which may be considered either as the side attached to the vertex O_n from the right or as the side attached to the vertex O_{n+1} from the left.

To eliminate the ambiguity caused by the use of several coordinate systems it is convenient to include reference to the coordinate system in the notation of the functions. Thus, a function in the domain G is denoted hereafter either as $F(r, \theta)$ or as $F(r, \theta; n)$. In the first case, the pair (r, θ) represents an observation point P in the



$(0,L]$ is the set of points Q for which
$r_L = L - r$ and $r_p = r - p$ for $p < L$
$Q = (r, \theta)$
r
$r_p = \mathcal{P}(r, \theta, p)$
θ
$P = (p, 0)$
O
L
p

FIG. 2. *Analytic description of the segment* $(0, L]$.

standard reference system. In the second case, the index n indicates that (r, θ) are the coordinates of P in the nth coordinate system.

When different coordinates (r_n, θ_n) refer to the same point of the plane there is a one-to-one correspondence between any pair of such coordinates. For example, applying the cosine theorem to the triangles $O_{n-1}PO_n$ and O_nPO_{n+1}, where P is the observation point, it is easy to show that the coordinates r_{n+1} and r_{n-1} are related to (r_n, θ_n) through the analytic expressions

$$r_{n-1} = \mathcal{P}(r_n, \theta_n, L_n^-), \qquad r_{n+1} = \mathcal{P}(r_n, \alpha_n - \theta_n, L_n^+), \tag{2.4}$$

$$\theta_{n-1} = \alpha_{n-1} - \mathcal{F}(r_n, \theta_n, L_n^-), \qquad \theta_{n+1} = \mathcal{F}(r_n, \alpha_n - \theta_n, L_n^+), \tag{2.5}$$

where

$$\mathcal{P}(r, \theta, L) = \sqrt{r^2 - 2rL\cos\theta + L^2} \equiv \sqrt{(r\mathrm{e}^{\mathrm{i}\theta} - L)(r\mathrm{e}^{-\mathrm{i}\theta} - L)} \tag{2.6}$$

and

$$\mathcal{F}(r, \theta, L) = \arcsin\left(\frac{r\sin\theta}{\mathcal{P}(r, \theta, L)}\right). \tag{2.7}$$

Functions $\mathcal{P}(r, \theta, L)$ and $\mathcal{F}(r, \theta, L)$ are also useful for analytical continuation of "real" geometric objects to the complex space. For example, let $I(\phi; 0, L)$ and $I(\phi; L, \infty)$, where

$$I(\phi, a, b) = \{r, \theta : \ \theta = \phi;\ a < r \leq b\}, \tag{2.8}$$

be a segment and a half-line which comprise the ray $r > 0$, $\theta = \phi$. Then, applying the cosine theorem to the triangle $\triangle OPQ$ shown in Figure 2, we conclude that if $Q \in (0, L]$, then $|QP| = p - r$ for all $p \geq L$, and therefore $I(\phi; 0, L)$ can be described by the formula

$$(r, \theta) \in I(\phi; 0, L) \iff \begin{cases} \mathcal{P}(r, \theta - \phi, p) = p - r & \text{if} \quad p = L, \\ \mathcal{P}(r, \theta - \phi, p) = r - p & \text{if} \quad p < L, \end{cases} \tag{2.9}$$

which provides analytic continuation of the intervals $I(\phi; 0, L)$ to a surface in the complex space formed by the pairs (r, θ).

3. The problem. Let a plane incident wave arriving from infinity in the domain G be defined as

$$U_*(r,\theta) = \mathrm{e}^{-\mathrm{i}kr\cos(\theta-\theta_*)}. \tag{3.1}$$

Then, the problem of diffraction of this wave by the perfectly reflecting polygon Γ can be formulated as the problem of computation of the total field U which is bounded in G and satisfies the Helmholtz equation

$$\nabla^2 U + k^2 U = 0 \qquad \text{in} \quad G, \tag{3.2}$$

complimented by the Dirichlet boundary conditions $U|_\Gamma = 0$, and by the requirement that $U(r,\theta)$ admit the decomposition

$$U = U_g + U_d \tag{3.3}$$

into the predefined piecewise continuous geometric component $U_g(r,\theta)$ and the unknown piecewise continuous scattered field $U_d(r,\theta)$, which has the following asymptote

$$U_d(r_\mu,\theta_\mu;\mu) = \frac{f(\theta)\mathrm{e}^{\mathrm{i}kr_\mu}}{\sqrt{kr_\mu}} + o(1/\sqrt{kr_\mu}), \qquad \theta_\mu \neq \phi_\mu^\nu, \tag{3.4}$$

everywhere in G, except for a finite number of predefined semiaxes

$$\mathfrak{l}_\mu^\nu : \qquad r_\mu \geq 0, \quad \theta_\mu = \phi_\mu^\nu, \tag{3.5}$$

along which the geometric field $U_g(r,\theta)$ has jumps. To keep track of these half-lines we use a double-index notation $\mathfrak{l}_\mu^\nu$, where the lower index corresponds to the vertex O_μ from which the ray originates and the upper index enumerates the rays originating from this vertex.

The geometric field $U_g(r,\theta)$ can be explicitly defined by a straightforward application of the laws of geometrical optics which, however, are easier to apply than to formalize. To keep focused on the principal issues we illustrate the structure of the geometric field for the simple but representative configuration shown in Figure 1. In this case the incident wave illuminates faces $\mathfrak{g}_2^+ = O_2O_3$ and $\mathfrak{g}_3^+ = O_3O_4$ of the polygon, and the waves reflected from these faces do not illuminate any other parts of the polygon, so that the geometric field $U_g(r,\theta)$ admits the decomposition

$$U = U_i + U_r^2 + U_r^3 \tag{3.6}$$

into the incident wave U_i and the waves U_r^2 and U_r^3 reflected by the sides $\mathfrak{g}_2^+$ and $\mathfrak{g}_3^+$, respectively. These waves have the following piecewise continuous structure:

$$U_i(r,\theta) = \begin{cases} \mathrm{e}^{-\mathrm{i}kr\cos(\theta-\theta_*)} & \text{between } \mathfrak{l}_2^1 \text{ and } \mathfrak{l}_4^2 \text{, counterclockwise,} \\ 0 & \text{everywhere else,} \end{cases} \tag{3.7}$$

and

$$U_r^\mu(r,\theta) = \begin{cases} K\mathrm{e}^{-\mathrm{i}kr\cos(\theta+\theta_*^\mu)-\mathrm{i}k\lambda_\mu} & \text{between } \mathfrak{l}_\mu^2 \text{ and } \mathfrak{l}_{\mu+1}^1 \text{, counterclockwise,} \\ 0 & \text{everywhere else,} \end{cases} \tag{3.8}$$

where $\mu = 2, 3$ are the indices of the sides illuminated by the incident wave,

$$K = -1 \tag{3.9}$$

is the reflection coefficient corresponding to the considered Dirichlet boundary conditions, and $\lambda_\mu = r(O_\mu)\cos[\theta(O_\mu) - \theta_*]$ is the phase of the incident wave at the vertex O_μ.

It is easy to see that the geometric field obeys all of the conditions of the problem of diffraction except that it is not continuous along a finite number of the rays $\mathfrak{l}_\mu^\nu$, which can be identified by an elementary geometric optical analysis. Accordingly, the scattered field U_d should admit the decomposition

$$U_d(r,\theta) = \sum_{\mu=1}^{N}\sum_{\nu=1}^{N_\mu} U_\mu^\nu(r,\theta;\phi_\mu^\nu), \tag{3.10}$$

into the sum of $\widetilde{N} = \sum N_\mu$ diffracted fields U_μ^ν each of which compensates the jump of the geometric field along one and only one semiaxis $\mathfrak{l}_\mu^\nu$. Next, assuming that every individual diffracted field is 2π-periodic with respect to the angular coordinate, we arrive at the decomposition

$$U_\mu^\nu(r,\theta;\phi) = K_\mu^\nu \mathrm{e}^{-\mathrm{i}k\lambda_\mu} \sum_{j=-\infty}^{\infty} U_{\mu,\phi}(r,\theta + 2\pi j), \tag{3.11}$$

where $U_{\mu,\phi}(r,\theta)$ is the solution of the following problem.

Problem-1. *Find a bounded solution $U_{\mu,\phi}(r,\theta)$ of the Helmholtz equation $\nabla^2 U_{\mu,\phi} + k^2 U_{\mu,\phi} = 0$ which is defined in the domain $r > 0$, $-\infty < \theta < \infty$, obeys the boundary conditions $U_{\mu,\phi}|_{\mathfrak{g}_m} = 0$ for all integers m, has an asymptote*

$$U_{\mu,\phi}(r_\mu,\theta_\mu;\mu)\mathrm{e}^{-\mathrm{i}kr_\mu} = o(1), \qquad r_\mu \to \infty, \quad \theta_\mu \neq \phi,$$

and satisfies the interface conditions

$$U_{\mu,\phi}(r_\mu,\phi + 0;\mu) - U_{\mu,\phi}(r_\mu,\phi - 0;\mu) = \mathrm{e}^{\mathrm{i}kr_\mu}, \qquad \left.\frac{\partial U_{\mu,\phi}}{\partial \theta_\mu}\right|_{\theta_m = \phi + 0} = \left.\frac{\partial U_{\mu,\phi}}{\partial \theta_\mu}\right|_{\theta_m = \phi - 0},$$

formulated in the μth coordinate system (r_μ,θ_μ).

As shown above, the formulas (3.10) and (3.11) reduce the problem of diffraction to the fundamental Problem-1, which is formulated in the domain $-\infty < \theta < \infty$ and has to be solved with several sets of the parameters μ and ϕ.

4. Radiation into a wedge. Our approach to Problem-1 is based on obtaining a simple representation of the solution of the following basic problem of wave radiation into a wedge.

Problem-*W*. *Find a solution $U(r,\theta)$ of the Helmholtz equation which is bounded in a wedge $r > 0$, $\alpha_1 < \theta < \alpha_2$, has the asymptote $\mathrm{e}^{-\mathrm{i}kr}U(r,\theta) = o(1)$ as $r \to \infty$, and satisfies the boundary conditions*

$$U(r,\alpha_1) = f(r,\alpha_1), \qquad U(r,\alpha_2) = f(r,\alpha_2), \tag{4.1}$$

where

$$f(r,\theta) = \begin{cases} f_1(r) & \text{if} \quad \theta = \alpha_1, \\ f_2(r) & \text{if} \quad \theta = \alpha_2, \end{cases} \tag{4.2}$$

is a "boundary function" defined only on the faces $\theta = \alpha_1$ and $\theta = \alpha_2$.

This problem was studied in detail in [8, 10], but since the results obtained there are not yet commonly known, we briefly reproduce them here in a form adapted to our current needs.

It is shown in [5] that if both $f_1(r)\mathrm{e}^{-\mathrm{i}kr}$ and $f_2(r)\mathrm{e}^{-\mathrm{i}kr}$ are analytic and bounded in the complex r-domain $0 < \arg(r) < \pi/2$, then $U(r, \theta)$ admits the probabilistic representation

$$U(r,\theta) = \mathrm{e}^{\mathrm{i}kr}\mathbf{E}\left\{f(\xi_\tau, \eta_\tau)\mathrm{e}^{\mathrm{i}k[S(\tau)-\xi_\tau]}\right\}, \qquad S(\tau) = \frac{1}{2}\int_0^\tau \xi_t \mathrm{d}t, \tag{4.3}$$

where $\mathbf{E}$ denotes the mathematical expectation computed over the trajectories of the radial and angular motions ξ_t and η_t that are controlled by the stochastic equations

$$\xi_0 = r, \qquad \mathrm{d}\xi_t = \xi_t \mathrm{d}w_t^1 + \xi_t\left(\frac{1}{2} + \mathrm{i}k\xi_t\right)\mathrm{d}t, \tag{4.4}$$

$$\eta_0 = \theta, \qquad \mathrm{d}\eta_t = \mathrm{d}w_t^2, \tag{4.5}$$

and stopped at the exit time $t = \tau$ defined as the first time when the angular motion η_t eventually hits one of the faces $\eta_t = \alpha_1$ or $\eta_t = \alpha_2$. Obviously, the angular motion η_t is contained in the segment $0 \leq \eta_t \leq \alpha$, while the radial motion ξ_t at any $t > 0$ runs inside the first quarter $0 \leq \arg(\xi_t) < \pi/2$ drifting to an unreachable point $\xi = \mathrm{i}/2k$.

Although solution (4.3) is very convenient, it is of limited use because it can only be applied to the cases when the function $f(\xi, \eta)$ is analytic with respect to the first argument ξ. However, using (4.3), it is possible derive a representation of the the field $U(r, \theta)$ in much less restrictive form,

$$U(r,\theta) = \mathrm{e}^{\mathrm{i}kr}\mathbf{E}\left\{f(\hat{\xi}_\tau, \eta_\tau)\mathrm{e}^{\mathrm{i}k[S(\hat{\xi}_\tau)-\hat{\xi}_\tau]}\right\}, \qquad S(\tau) = \frac{1}{2}\int_0^\tau \hat{\xi}_t \mathrm{d}t, \tag{4.6}$$

where the angular motion η_t runs exactly as in (4.3), while the radial motion $\hat{\xi}_t$ for most of the time runs as the radial motion ξ_t from (4.3) but at the exit time $t = \tau$ jumps to a certain point $\hat{\xi}_\tau \in (0, \infty)$ on the positive semiaxis where the boundary function $f(\xi, \eta)$ is defined so that no analytical continuation of $f(\xi, \eta)$ is required. More precisely, on the time interval $0 < t < \tau$ the motion $\hat{\xi}_t$ is controlled by the stochastic differential equation

$$\hat{\xi}_0 = r, \qquad \mathrm{d}\hat{\xi}_t = \hat{\xi}_t \mathrm{d}w_t^1 + \hat{\xi}_t\left(\frac{1}{2} + \mathrm{i}k\hat{\xi}_t\right)\mathrm{d}t \qquad \text{if} \quad 0 \leq t < \tau, \tag{4.7}$$

and then suddenly, at the exit time $t = \tau$, it moves to the final position

$$\hat{\xi}_\tau = \begin{cases} \inf\left\{\mathfrak{z}_+^1(r,\theta) \cup \mathfrak{z}_-^1(r,\theta)\right\} & \text{if} \quad \eta_\tau = \alpha_1, \\ \inf\left\{\mathfrak{z}_+^2(r,\theta) \cup \mathfrak{z}_-^2(r,\theta)\right\} & \text{if} \quad \eta_\tau = \alpha_2, \end{cases} \tag{4.8}$$

where $\mathfrak{z}_\pm^1(r, \theta)$ and $\mathfrak{z}_\pm^2(r, \theta)$ are the intersections of the trajectories of the auxiliary motions

$$\zeta_\pm^1(t) = \hat{\xi}_t \mathrm{e}^{\pm\mathrm{i}(\eta_t - \alpha_1)} \qquad \text{and} \qquad \zeta_\pm^2(t) = \hat{\xi}_t \mathrm{e}^{\pm\mathrm{i}(\alpha_2 - \eta_t)} \tag{4.9}$$

with the semiaxis $\zeta > 0$. It is clear that the final position $\hat{\xi}_\tau$ of the motion $\hat{\xi}_t$ is determined by the entire trajectory of both components of the two-dimensional motion

$(\hat{\xi}_t, \eta_t)$ launched at $t = 0$ from the point (r, θ) and stopped as soon as the angular motion η_t reaches at the exit time $t = \tau$ either of the endpoints $\eta_\tau = \alpha_1$ or $\eta_\tau = \alpha_2$.

To make the derivation of (4.6) more transparent we limit ourselves to the case when $\alpha_1 = 0$, $\alpha_2 \equiv \alpha \leq 2\pi$, and consider the problem with the special piecewise constant boundary function

$$f(r,\theta) = \begin{cases} a_0 & \text{if} \quad (r,\theta) \in I(0,0,L), \\ a_1 & \text{if} \quad (r,\theta) \in I(0;L,\infty), \\ a_2 \equiv 0 & \text{if} \quad (r,\theta) \in I(\alpha;0,\infty), \end{cases} \tag{4.10}$$

where a_ν and $L > 0$ are given constants. Then, the basic formula (4.3) leads to the representation

$$U(r,\theta) = \mathrm{e}^{\mathrm{i}kr}\mathbf{E}\left\{a_{\nu(\tau)} \exp\left(\frac{1}{2}\int_0^\tau \mathrm{i}k\xi_t \mathrm{d}t - \mathrm{i}k\xi_\tau\right)\right\}, \tag{4.11}$$

where the index

$$\nu(\tau) = \begin{cases} 0 & \text{if} \quad \eta_\tau = 0, \quad \mathcal{P}(\xi_\tau, \eta_\tau, p) = p - \xi_\tau \quad \forall p \geq L, \\ 1 & \text{if} \quad \eta_\tau = 0, \quad \mathcal{P}(\xi_\tau, \eta_\tau, p) \neq p - \xi_\tau \quad \forall p < L, \\ 2 & \text{if} \quad \eta_\tau = \alpha \end{cases} \tag{4.12}$$

depends on the entire trajectory of the motion (ξ_t, η_t) rather than on its final position (ξ_τ, η_τ).

To compute $\nu(\tau)$ by the formula (4.12) it is necessary to trace the value of the radical

$$\mathcal{P}(\xi_t, \eta_t, p) = \sqrt{(\xi_t \mathrm{e}^{\mathrm{i}\eta_t} - p)(\xi_t \mathrm{e}^{-\mathrm{i}\eta_t} - p)} \tag{4.13}$$

along the trajectory of the motion $P_t = (\xi_t, \eta_t)$. To proceed we represent this function as a product

$$\mathcal{P}(\xi_t, \eta_t, p) = \Xi_p(\zeta_+(t))\, \Xi_p(\zeta_-(t)), \qquad \zeta_\pm(t) = \xi_t \mathrm{e}^{\pm \mathrm{i}\eta_t}, \tag{4.14}$$

where $\Xi_p(\zeta) = \sqrt{\zeta - p}$ is the radical with the branch fixed by a slit along the half-line $\zeta > p$.

Let $\mathbb{C}_p^+$ and $\mathbb{C}_p^-$ be the two sheets of the Riemann surface of the radical $\Xi_p(\zeta)$, so that

$$\Xi_p(\zeta) = \pm\sqrt{|\zeta - p|}\mathrm{e}^{\mathrm{i}\,\mathrm{Arg}(\zeta - p)/2}, \qquad \zeta \in \mathbb{C}_p^\pm. \tag{4.15}$$

Since $\mathcal{P}(r, \theta, p)$ is the distance between the observation point (r, θ) and the point $(p, 0)$ on the main axis, we need to select the branches of the radical in such a way as to have $\mathcal{P}(r, \theta, p) \geq 0$. To guarantee this inequality the initial points $\zeta_\pm(0) = r\mathrm{e}^{\pm \mathrm{i}\theta}$ must be located on different sheets $\mathbb{C}_p^\pm$. For definiteness we assume that

$$\zeta_+(0) = r\mathrm{e}^{\mathrm{i}\theta} \in \mathbb{C}_p^+, \qquad \zeta_-(0) = r\mathrm{e}^{-\mathrm{i}\theta} \in \mathbb{C}_p^-, \tag{4.16}$$

which implies the identities

$$\Xi_p(\zeta_\pm(0)) = \sqrt{|r\mathrm{e}^{\pm\mathrm{i}\theta} - p|}\, \exp\left[\frac{\mathrm{i}}{2}\,\mathrm{Arg}(r\mathrm{e}^{\pm\mathrm{i}\theta} - p)\right], \tag{4.17}$$

leading to the required inequality $\mathcal{P}(r, \theta, p) \geq 0$.

To compute $\Xi(\zeta_+(\tau))$ we need to trace the trajectory of the point $\zeta_+(t) = \xi_t \mathrm{e}^{\mathrm{i}\eta_t}$, which starts from $\zeta_+(0) = r\mathrm{e}^{\mathrm{i}\theta} \in \mathbb{C}_p^+$ and stops at the point $\zeta_\tau^+ = \xi_\tau$ in the first quarter $0 < \arg(\zeta_\tau^-) < \pi/2$. The restraints $0 \le \arg(\xi_t) < \pi/2$ and $\eta_t > 0$ imply that $\zeta_-(t)$ never crosses the ray $\arg(\zeta) = 0$ but may cross any of the rays $\arg(\zeta) = 2\pi n$ with $n > 1$ an even number of times, so that the total number of intersections of the trajectory of ζ_t with the half-line $\zeta > 0$ is even, as illustrated in Figure 3.

FIG. 3. *Trajectory of* $\zeta_+(t) = \xi_t \mathrm{e}^{\mathrm{i}\eta_t}$ *on the sheet* $\mathbb{C}_p^+$.

Let $\mathfrak{Z}_+$ be the set of all points where the trajectory of $\zeta_+(t)$ intersects the ray $\zeta > 0$. Then, adopting the notation $N(\mathfrak{Z} > p)$ for the number of points of the set $\mathfrak{Z}$ located to the right of p, we conclude that the radical $\Xi_p(\zeta_+(\tau))$ has the value

$$\Xi_p(\zeta_+(\tau)) = \begin{cases} \sqrt{|\xi_\tau - p|}\, \mathrm{e}^{\mathrm{i}\,\mathrm{Arg}(\xi_\tau - p)/2} & \text{if } N(\mathfrak{Z}_+ > p) \text{ is even,} \\ -\sqrt{|\xi_\tau - p|}\, \mathrm{e}^{\mathrm{i}\,\mathrm{Arg}(\xi_\tau - p)/2} & \text{if } N(\mathfrak{Z}_+ > p) \text{ is odd,} \end{cases} \tag{4.18}$$

which is completely determined by the disposition of the parameter p with respect to the set $\mathfrak{Z}_+$ and does not depend on other details of the trajectory of $\zeta_+(t)$. It is interesting to note that if $\alpha < 3\pi/2$, then the set $\mathfrak{Z}_+$ is empty, and therefore the second option in (4.18) never occurs.

To compute $\Xi_p(\zeta_-(t))$ we need to trace the trajectory of the point $\zeta_-(t) = \xi_t \mathrm{e}^{-\mathrm{i}\eta_t}$, which starts from $\zeta_-(0) = r\mathrm{e}^{-\mathrm{i}\theta} \in \mathbb{C}_p^-$ and stops at the point $\zeta_\tau^- = \xi_\tau$ in the first quarter $0 < \arg(\zeta) < \pi/2$. The restraints $0 \le \arg(\xi_t) < \pi/2$ and $\eta_t > 0$ imply that $\zeta_-(t)$ crosses the half-line $\zeta > 0$ an odd number of times, as illustrated in Figure 4. Therefore, assuming that $\mathfrak{Z}_-$ is the set of all points where $\zeta_-(t)$ intersects this ray $\zeta > 0$, we conclude that the value of $\Xi_p(\zeta_-(\tau))$ is determined by the formula

$$\Xi_p(\zeta_-(\tau)) = \begin{cases} -\sqrt{|\xi_\tau - p|}\, \mathrm{e}^{\mathrm{i}\,\mathrm{Arg}(\xi_\tau - p)/2} & \text{if } N(\mathfrak{Z}_- > p) \text{ is even,} \\ \sqrt{|\xi_\tau - p|}\, \mathrm{e}^{\mathrm{i}\,\mathrm{Arg}(\xi_\tau - p)/2} & \text{if } N(\mathfrak{Z}_- > p) \text{ is odd,} \end{cases} \tag{4.19}$$

which is similar to (4.18).

Finally, combining (4.13) with (4.18) and (4.19), we see that

$$\mathcal{P}(\xi_\tau, \eta_\tau, p) = \begin{cases} \xi_\tau - p & \text{if } \eta_\tau = 0, \quad N(\mathfrak{Z}_- \cup \mathfrak{Z}_+ > p) \text{ is even,} \\ p - \xi_\tau & \text{if } \eta_\tau = 0, \quad N(\mathfrak{Z}_- \cup \mathfrak{Z}_+ > p) \text{ is odd,} \end{cases} \tag{4.20}$$

FIG. 4. *Trajectory of* $\zeta_-(t) = \xi_t \mathrm{e}^{-\mathrm{i}\eta_t}$ *on the sheet* $\mathbb{C}_p^-$.

and, combining (4.20) with (2.9), we arrive at the remarkable formula

$$\nu(\tau) = \begin{cases} 0 & \text{if} \quad \eta_\tau = 0, \quad \inf\{\mathfrak{Z}_+ \cup \mathfrak{Z}_-\} \geq L, \\ 1 & \text{if} \quad \eta_\tau = 0, \quad \inf\{\mathfrak{Z}_+ \cup \mathfrak{Z}_-\} < L, \\ 2 & \text{if} \quad \eta_\tau = \alpha, \end{cases} \tag{4.21}$$

which makes it possible to evaluate (4.11) by tracing the intersections of the trajectories of $\zeta_\pm(t) = \xi_t \mathrm{e}^{\pm \mathrm{i}\eta_t}$ with the positive semiaxis, but without tracing the radical (4.13).

Formulas (4.3) and (4.11) represent the field $U(r, \theta)$ in the special cases when the boundary function $f(r, \theta)$ is either analytic in the first quarter or a piecewise constant on $\theta = 0$ with only one jump. To obtain the representation of $U(r, \theta)$ corresponding to an arbitrary boundary function $f(r, \theta)$, we first assume that $f(r, \theta)$ has a piecewise constant structure

$$f(r, \theta) = \begin{cases} a_n & \text{if} \quad \theta = 0, \quad r \in I_n = (L_n, L_{n+1}], \qquad n \geq 0, \\ 0 & \text{if} \quad \theta = \alpha, \end{cases} \tag{4.22}$$

where $\{L_n\}$ is an increasing sequence with the first element $L_0 = 0$ and a_n are some constants.

To employ the technique from the previous subsection we observe that the interval I_n admits the representation $I_n = I(0; 0, L_{n+1}) \backslash I(0; 0, L_n)$, where $I(\phi; a, b)$ is the domain in the space (r, θ) defined by (2.9). Then Problem-W can be considered in the domain bounded by the junction $\bigcup I_n$, and its solution (4.6) takes the form

$$U(r, \theta) = \mathrm{e}^{\mathrm{i}kr} \mathbf{E} \left\{ f(L_{\nu(\tau)+1}, \eta_\tau) \exp\left(\frac{1}{2} \int_0^\tau \mathrm{i}k\xi_t \mathrm{d}t - \mathrm{i}k\xi_\tau \right) \right\}, \tag{4.23}$$

where the mathematical expectation is computed over the trajectories of the stochastic processes ξ_t and η_t, which are described by (4.4), (4.5) and are stopped at the exit time τ defined as the first time when $\eta_t = 0$ or $\eta_t = \alpha$. It is easy to see that if $\eta_\tau = 0$, then the exit point $P_\tau = (\xi_\tau, \eta_\tau)$ belongs to the interval $I_{\nu(\tau)}$ with the index

$$\nu(\tau) = n \quad \text{if} \quad L_n < \inf\{\mathfrak{Z}_+ \cup \mathfrak{Z}_-\} \leq L_{n+1}, \tag{4.24}$$

where $\mathfrak{Z}_\pm$ are the intersections of the trajectories of $\zeta_t^\pm = \xi_t \mathrm{e}^{\mathrm{i}\eta_t}$ with the ray $\zeta > 0$. Comparison of the last formula with (4.22) shows that if $\hat{\xi}_\tau = \inf\{\mathfrak{Z}_+ \cup \mathfrak{Z}_-\}$ belongs to the interval I_n, then $\nu_\tau = n$ and $f(\hat{\xi}_\tau, 0) = a_{\nu(\tau)}$. As a result, the solution (4.23) can be converted to the form (4.6), which does not rely on the piecewise structure of $f(r, 0)$, and which, therefore, can be straightforwardly extended to the case when $f(r, 0)$ has a virtually arbitrary structure, particularly to the cases when it is not analytic at all or when it is analytic but grows excessively fast in the first quarter of the complex plane, where the radial motion ξ_t runs.

It is worth noticing that although formulas (4.3) and (4.6) look similar, there is a significant difference between them. Thus, in (4.3) the exit position ξ_τ of the radial motion is always complex, while in (4.6) the exit value $\hat{\xi}_\tau$ is real, which is very important for our purposes.

In the above we considered only the case when the boundary values vanish on the face $\theta = \alpha$, but the case with nonzero boundary values on $\theta = \alpha$ can be considered similarly.

5. Radiation to the exterior of a convex polygon.

The solution of the boundary value problem for the Helmholtz equation in a wedge makes it possible to solve a similar problem of radiation to the exterior of a convex polygon.

Problem-C. *Find the solution $U(r, \theta)$ of the Helmholtz equation $\nabla^2 U + k^2 U = 0$ which is bounded in the exterior of the convex polygon Γ with sides $\mathfrak{g}_n^+$, has the asymptote*

$$U(r, \theta) = u(\theta)\frac{\mathrm{e}^{\mathrm{i}kr}}{\sqrt{kr}} + o\left(\frac{1}{\sqrt{kr}}\right), \qquad r \to \infty,$$

and obeys the boundary condition $U|_{\partial\Gamma} = f$, where $f(r, \theta) = f(r_n, \theta_n; n)$ is a function defined only on the sides $\mathfrak{g}_n^+$ of Γ.

To compute the solution of this problem at an observation point (r, θ) we select an exterior wedge $\mathfrak{O}_\mu$ which contains (r, θ). The boundary of this wedge consists of two sides $\mathfrak{g}_{\mu-1}^+ \equiv \mathfrak{g}_\mu^-$ and $\mathfrak{g}_{\mu+1}^- \equiv \mathfrak{g}_\mu^+$ of the polygon Γ, which are described by the equations

$$\mathfrak{g}_\mu^- = \{\theta_\mu = 0, \quad r_\mu < L_\mu^-\}, \qquad \mathfrak{g}_\mu^+ = \{\theta_\mu = \alpha_\mu, \quad r_\mu < L_\mu^+\}, \tag{5.1}$$

and of two half-lines $\mathfrak{a}_\mu^-$ and $\mathfrak{b}_\mu^+$, which are described by the equations

$$\mathfrak{a}_\mu^- = \{\theta_\mu = 0, \quad r_\mu > L_\mu^-\}, \qquad \mathfrak{a}_\mu^+ = \{\theta_\mu = \alpha, \quad r_\mu > L_\mu^+\}, \tag{5.2}$$

and are shown in Figure 5 by dashed lines.

On the sides described in (5.1) the values of the field $U(r_\mu, \theta_\mu; \mu)$ are preassigned by the boundary conditions, but on the half-lines (5.2) this field may not be known until the problem is solved. However, we assume that the values of $U(r_\mu, \theta_\mu; \mu)$ on the half-lines $\mathfrak{a}_\mu^-$ and $\mathfrak{a}_\mu^+$ are already known, and, using this information, we calculate $U(r_\mu, \theta_\mu; \mu)$ inside $\mathfrak{O}_\mu$ by the formula (4.6), which can be rearranged to the form

$$\begin{aligned} U(r_\mu, \theta_\mu; \mu) = \mathrm{e}^{\mathrm{i}kr_\mu}\mathbf{E}\Big\{&\chi(\tau, t_1) f(\hat{\xi}_\tau, \eta_\tau; \mu)\mathrm{e}^{\mathrm{i}k[S(\tau)-\hat{\xi}_\tau]} \\ &+ \chi_*(\tau, t_1) U(\hat{\xi}_{t_1}, \eta_{t_1}; \mu)\mathrm{e}^{\mathrm{i}k[S(t_1)-\hat{\xi}_{t_1}]}\Big\}, \qquad S(t) = \frac{1}{2}\int_0^t \hat{\xi}_t \mathrm{d}t, \end{aligned} \tag{5.3}$$

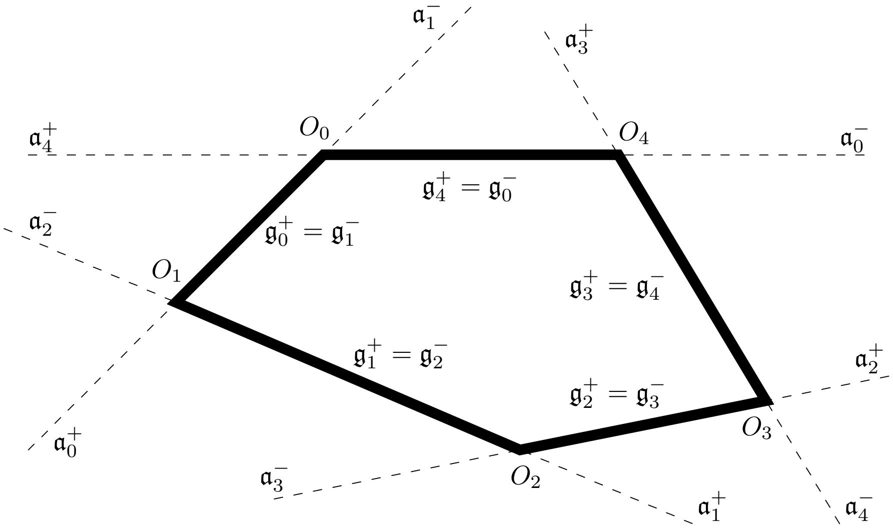

FIG. 5. *Geometry of a convex polygon.*

where

$$\chi(a,b) = \begin{cases} 1 & \text{if} \quad a \geq b, \\ 0 & \text{if} \quad a < b, \end{cases} \qquad \chi_*(a,b) = \begin{cases} 0 & \text{if} \quad a \geq b, \\ 1 & \text{if} \quad a < b, \end{cases} \tag{5.4}$$

and $P_t = (\hat{\xi}_t, \eta_t)$ is a random motion which starts from the point (r_μ, θ_μ) and runs inside $\mathfrak{O}_\mu$ controlled by (4.5) and (4.7)–(4.9) until the earlier of the times $t = \tau$ or $t = t_1$, when it hits either the "real" boundary $\mathfrak{g}_\mu^- \cup \mathfrak{g}_\mu^+$ or the "auxiliary" boundary $\mathfrak{a}_\mu^- \cup \mathfrak{a}_\mu^+$, respectively.

Expression (5.3) cannot be accepted as a solution of the problem because its right-hand side involves yet unknown values $U(\hat{\xi}_{t_1}, \eta_{t_1}; \mu)$ of the field $U(r,\theta)$ on the half-lines $\mathfrak{a}_\mu^\pm$. However, these values can be computed by analogues of the formula (5.3) applied to the neighboring wedges $\mathfrak{O}_{\mu-1}$ and $\mathfrak{O}_{\mu+1}$, the first of which contains $\mathfrak{a}_\mu^-$ while the latter contains $\mathfrak{a}_\mu^+$. To perform such evaluations we observe that the half-lines $\mathfrak{a}_\mu^-$ and $\mathfrak{a}_\mu^+$ are characterized by the equations

$$\mathfrak{a}_\mu^- : \quad r_\mu = r_{\mu-1} + L_\mu^-, \qquad \theta_\mu = \theta_{\mu-1} - \pi + \alpha_\mu^-, \tag{5.5}$$

$$\mathfrak{a}_\mu^+ : \quad r_\mu = r_{\mu+1} + L_\mu^+, \qquad \theta_\mu = \theta_{\mu+1} + \pi - \alpha_\mu^+, \tag{5.6}$$

which show that the ray $\mathfrak{a}_\mu^-$ is a good place for switching from the coordinates (r_μ, θ_μ) to the coordinates $(r_{\mu-1}, \theta_{\mu-1})$, and $\mathfrak{a}_\mu^+$ is good place for switching from (r_μ, θ_μ) to $(r_{\mu+1}, \theta_{\mu+1})$. Then, applying (5.5) and (5.6), we obtain the identities

$$U(\hat{\xi}_{t_1}, \eta_{t_1}; \mu) = U(\hat{\xi}_{t_1} - L_\mu^\pm,\, \eta_{t_1} \pm [\pi - \alpha_\mu^\pm];\, \mu \pm 1), \tag{5.7}$$

with right-hand sides that can be computed by the formula (5.3) adapted to the wedges $\mathfrak{O}_{\mu-1}$ and $\mathfrak{O}_{\mu+1}$. For example, the right-hand part of (5.7), determined by the choice "−," can be represented as the mathematical expectation

$$(5.8)\quad \begin{aligned} &U(\hat{\xi}_{t_1}-L_\mu^-,\, \eta_{t_1}+\alpha_\mu^- - \pi;\, \mu-1) \\ &\quad = \mathrm{e}^{\mathrm{i}k[\hat{\xi}_{t_1}-L_\mu^-]}\mathbf{E}\Big\{\chi(\tau,t_2)f(\hat{\xi}_\tau,\eta_\tau;\mu-1)\mathrm{e}^{\mathrm{i}k[S(\hat{\xi}_\tau)-\hat{\xi}_\tau]} \\ &\qquad\qquad + \chi_*(\tau,t_2)U(\hat{\xi}_{t_2},\eta_{t_2};\mu-1)\mathrm{e}^{\mathrm{i}k[S(\hat{\xi}_{t_2})-\hat{\xi}_{t_2}]}\Big\} \end{aligned}$$

computed over the trajectories of the stochastic process $P_t=(\hat{\xi}_t,\eta_t)$, which is launched at the time $t=t_1+0$ from the initial position

$$(5.9)\qquad \hat{\xi}_{t_1+0}=\hat{\xi}_{t_1}-L_\mu^-,\qquad \eta_{t_1+0}=\eta_{t_1}+\alpha_\mu^- - \pi$$

and runs in the wedge $\mathfrak{O}_{\mu-1}$ until the earlier of the exit times $t=\tau$ or $t=t_2$, when it hits one of the sides $\mathfrak{g}_{\mu-1}^\pm$ of the polygon or their continuations $\mathfrak{a}_{\mu-1}^\pm$.

It is obvious that the value of $U(\xi_{t_2},\eta_{t_2};\mu-1)$ that appears in the right-hand side of (5.8) can be evaluated by a formula similar to that in (5.8). Then, the recursion can be repeated infinitely many times, which eventually results in the expression

$$(5.10)\quad U(r,\theta;\mu)=\mathrm{e}^{\mathrm{i}kr_\mu}\mathbf{E}\Big\{f(\hat{\xi}_\tau,\eta_\tau;n_\tau)\mathrm{e}^{\mathrm{i}k[S(\tau)-\hat{\xi}_\tau]}\Big\},\qquad S(\tau)=\frac{1}{2}\int_0^\tau \hat{\xi}_t\mathrm{d}t-\Lambda_\tau,$$

where the mathematical expectation is computed over trajectories of the stochastic processes n_t, $P_t=(\hat{\xi}_t,\eta_t)$, and Λ_t, which evolve as described below.

The process n_t indicates the index of the currently used coordinate system. It takes integer values which change only at the times $t=t_1,t_2,\ldots$, when P_t reaches one of the rays $\mathfrak{a}_n^\pm$. More precisely, the evolution of n_t is described by the rules

$$(5.11)\qquad n_0=\mu,\qquad n_{t+\mathrm{d}t}=\begin{cases} n_t\pm 1 & \text{if}\quad P_t\in\mathfrak{a}_{n_t}^\pm, \\ n_t & \text{otherwise,}\end{cases}$$

where the initial index μ is not rigidly fixed but must be selected according to the condition that the observation point (r,θ) is located inside the wedge $\mathfrak{O}_\mu$.

The process n_t is closely related to another piecewise process Λ_t described by the equations

$$(5.12)\qquad \Lambda_0=0,\qquad \mathrm{d}\Lambda_t\equiv\Lambda_{t+\mathrm{d}t}-\Lambda_t=\begin{cases} L_{n_t}^\pm & \text{if}\quad P_t\in\mathfrak{a}_{n_t}^\pm, \\ 0 & \text{otherwise,}\end{cases}$$

which show that every time $t=t_\nu$ when the coordinate system is changed, Λ_t takes an increment equal to the distance between the centers of the old and new coordinate systems.

The changes of the coordinate systems at the times $t=t_1$, $t=t_2,\ldots$, affect both of the components of the motion $P_t=(\hat{\xi}_t,\eta_t)$, where η_t is controlled by the stochastic equations

$$(5.13)\qquad \eta_0=\theta,\qquad \eta_{t+\mathrm{d}t}=\eta_t+\mathrm{d}w_t^2+\begin{cases} \alpha_{n_t-1}-\pi & \text{if}\quad P_t\in\mathfrak{a}_{n_t}^-, \\ \pi-\alpha_{n_t} & \text{if}\quad P_t\in\mathfrak{a}_{n_t}^+, \\ 0 & \text{otherwise,}\end{cases}$$

which describe a standard Brownian motion w_t^2 modified by certain jumps at the times $t=t_\nu$. The radial motion $\hat{\xi}_t$ has a more complicated structure. In the intervals

$t \in [t_\nu, t_{\nu+1})$ between changes of the coordinate systems $\hat{\xi}_t$ is a continuous motion governed by the equations

$$\hat{\xi}_0 = r, \qquad \hat{\xi}_{t+\mathrm{d}t} = \hat{\xi}_t + \hat{\xi}_t \mathrm{d}w_t^1 + \hat{\xi}_t \left(\frac{1}{2} + \mathrm{i}k\hat{\xi}_t\right) \mathrm{d}t, \qquad t \leq t_\nu < t_{\nu+1}, \tag{5.14}$$

where w_t^1 is the standard Brownian motion. Then, at the time $t = t_{\nu+1}$ the point $\hat{\xi}_t$ jumps to the position

$$\hat{\xi}_{t_{\nu+1}} = -\mathrm{d}\Lambda_{t_{\nu+1}} + \begin{cases} \inf\left[\mathfrak{Z}^1_+(\hat{\xi}_{t_\nu}, \eta_{t_\nu}) \cup \mathfrak{Z}^1_-(\hat{\xi}_{t_\nu}, \eta_{t_\nu})\right] & \text{if} \quad \eta_t = 0, \\ \inf\left[\mathfrak{Z}^2_+(\hat{\xi}_{t_\nu}, \eta_{t_\nu}) \cup \mathfrak{Z}^2_-(\hat{\xi}_{t_\nu}, \eta_{t_\nu})\right] & \text{if} \quad \eta_t = \alpha_{n_{t-0}}, \end{cases} \tag{5.15}$$

where $\mathrm{d}\Lambda_{t_{\nu+1}}$ is defined by (5.12), while $\mathfrak{Z}^1(\hat{\xi}_{t_\nu}, \eta_{t_\nu})$ and $\mathfrak{Z}^2(\hat{\xi}_{t_\nu}, \eta_{t_\nu})$ are the sets of intersections of the trajectories of the motions

$$\zeta^1_\pm(t) = \hat{\xi}_t \exp[-\mathrm{i}\eta_t] \quad \text{and} \quad \zeta^2_\pm(t) = \hat{\xi}_t \exp[-\mathrm{i}(\alpha_{n_t} - \eta_t)] \qquad t_\nu < t < t_{\nu+1}, \tag{5.16}$$

with the semiaxis $\mathrm{Im}(\zeta) = 0$, $\mathrm{Re}(\zeta) > 0$.

It is important to note that the obtained solution remains valid in the case of an "infinite-sided" polygon Γ with the vertices O_n defined by the recursive process which starts from two initial vertices O_0, O_1 and continues in both directions $n > 1$ and $n < 0$ making steps

$$O_{n+1} = \{r_n = L_n^+,\ \theta_n = \alpha_n\}, \qquad O_{n-1} = \{r_n = L_{n-1}^+,\ \theta_n = \alpha_{n-1}\}, \tag{5.17}$$

determined by the sequences $\{\alpha_\nu\}$ and $\{L_\nu^+\}$, where $L_\nu > 0$, $\alpha_\nu > \pi$, and $\sum(\alpha_\nu - \pi) = \infty$. Assume first that there exists $N > 1$ for which $\sum_{\nu=0}^{N-1}(\alpha_\nu - \pi) = 2\pi$ and the boundary function $f(r, \theta; \nu)$ satisfies the periodicity condition $f(r, \theta; \nu) = f(r, \theta; \nu + N)$. In this case the vertices O_ν with $0 \leq \nu < N - 1$ form an N-sided convex polygon, and formulas (5.10)–(5.16) determine the field radiated into the exterior of this polygon. In the other case, when either of the mentioned conditions is not met, these formulas determine a field radiated to the spiral-like surface bounded by Γ.

6. Radiation to the exterior of a nonconvex polygon. In section 5 the problem of radiation to the exterior of a convex polygon was reduced to the problem of radiation into a wedge. Here a similar idea is employed to obtain the solution of the problem of radiation into the exterior of a nonconvex polygon by recursive applications of already known solutions of the problems of radiation from a convex polygon and from a wedge.

Let Γ be a "single-cavity" nonconvex polygon with the vertices $O_0, \ldots, O_{N-2}$, O_{N-1}, located in such a way that the first $\widetilde{N} \equiv (N-1)$ vertices form a convex polygon $\widetilde{\Gamma}$. This configuration is illustrated in Figure 6, which shows a nonconvex polygon Γ obtained by the addition of a vertex O_5 to the convex pentagon from Figure 5. To keep the notation consistent with the previous sections we reserve the symbols $\mathfrak{g}_n^\pm$ and $\mathfrak{a}_n^\pm$ for the sides $O_n O_{n\pm 1}$ of the polygon Γ and for their continuations beyond the vertices $O_{n\pm 1}$. Similarly, symbols $\widetilde{\mathfrak{g}}_n^\pm$ and $\widetilde{\mathfrak{a}}_n^\pm$ denote the sides and their continuations of the convex polygon $\widetilde{\Gamma}$. This notation is used in Figure 6, which, however, does not show $\widetilde{\Gamma}$-related symbols whenever a similar Γ-related notation can be used.

Looking back at the previous section, we see that the employed technique is built around the ability to represent the exterior G of the convex polygon Γ as a junction $G = \bigcup \mathfrak{O}_n$ of overlapping wedges $\mathfrak{O}_n$ defined as the exterior wedges of the polygon Γ.

FIG. 6. *Geometry of a nonconvex polygon.*

This representation is also used here for the analysis of radiation from the nonconvex polygon, but this time we say that $\mathfrak{D}_n$ is the maximal wedge which fits into the exterior of the polygon Γ and has a tip at the vertex O_n of Γ.

Obviously, in the case when Γ is convex, all of the newly defined wedges $\mathfrak{D}_n$ coincide with the corresponding exterior wedges of Γ, but in the case when Γ is nonconvex, this coincidence is no longer necessary. For example, in the configuration shown in Figure 6, the wedges $\mathfrak{D}_0$ and $\mathfrak{D}_4$ are smaller than the exterior wedges at the vertices O_0 and O_4.

To compute the field $U(r,\theta)$ that satisfies the Helmholtz equation in the exterior of Γ and has preassigned values on Γ we first assume that the values of $U(r,\theta)$ are already known on the segment O_0O_{N-2}, which can be considered as a side $\widetilde{\mathfrak{g}}_0^-$ of the convex polygon $\widetilde{\Gamma}$. Then, applying formula (5.10), we find that if (r,θ) is located outside $\widetilde{\Gamma}$, then the value of $U(r,\theta)$ can be represented as the mathematical expectation

$$\begin{aligned} U(r,\theta;\mu) = \mathrm{e}^{\mathrm{i}kr_\mu}\mathbf{E}\Big\{&\chi(\tau,t_1)f(\hat{\xi}_\tau,\eta_\tau;n_\tau)\mathrm{e}^{\mathrm{i}k[S(\tau)-\hat{\xi}_\tau]} \\ &+\chi_*(\tau,t_1)U(\hat{\xi}_{t_1},\eta_{t_1};n_{t_1})\mathrm{e}^{\mathrm{i}k[S(t_1)-\hat{\xi}_{t_1}]}\Big\}, \end{aligned} \tag{6.1}$$

where the averaging is extended over the stochastic processes $P_t = (\hat{\xi}_t,\eta_t)$, Λ_t, and n_t, which are controlled by the formulas (5.11)–(5.12) adapted to the polygon $\widetilde{\Gamma}$ and are stopped at the earlier of the exit times $t=\tau$ or $t=t_1$ defined, respectively, as the first times when P_t hits a side of the original polygon Γ or the side $\mathfrak{g}_0^- = O_0O_{N-2}$ of the auxiliary convex polygon $\widetilde{\Gamma}$.

The definition of the auxiliary exit time t_1 implies that P_{t_1} belongs to the segment O_0O_{N-2} which is located inside the wedge $\mathfrak{D}_{N-1}$ bounded by the half-lines $\mathfrak{a}_{N-1}^{\pm}$ and by the sides $\mathfrak{g}_{N-1}^{\pm}$ of the polygon Γ, where the values of $U(r,\theta)$ are assigned by the boundary conditions. This observation makes it possible to use the identities (2.4)–(2.5) and represent the unknown quantity $U(\hat{\xi}_{t_1},\eta_{t_1};n_{t_1})$ from the right-hand side of (6.1) as

$$U(\hat{\xi}_{t_1},\eta_{t_1};n_{t_1}) = U(r_{N-2},\theta_{N-2};N-2), \tag{6.2}$$

where r_{N-2} and θ_{N-2} are the $(N-2)$th coordinates computed by the formulas

$$r_{N-2} = \begin{cases} \mathcal{P}(\hat{\xi}_{t_1}, \eta_{t_1}, L_0^-) & \text{if} \quad n_{t_1-0} = j(N-1), \\ \mathcal{P}(\hat{\xi}_{t_1}, \alpha_{N-2} - \eta_{t_1}, L_0^-) & \text{if} \quad n_{t_1-0} = j(N-1) - 1, \end{cases} \tag{6.3}$$

and

$$\theta_{N-2} = \begin{cases} \alpha_{N-1} - \mathcal{F}(\hat{\xi}_{t_1}, \eta_{t_1}, L_0^-) & \text{if} \quad n_{t_1-0} = j(N-1) + 1, \\ \mathcal{F}(\hat{\xi}_{t_1}, \alpha_{N-2} - \eta_{t_1}, L_0^-) & \text{if} \quad n_{t_1-0} = j(N-1) - 1, \end{cases} \tag{6.4}$$

where j is an arbitrary integer. Then, evaluating the right-hand side of (6.2) by the formula (5.3) adjusted to the wedge $\mathfrak{D}_{N-1}$, we get a representation of $U(\hat{\xi}_{t_1}, \eta_{t_1}; n_{t_1})$ through yet unknown values of the field $U(r,\theta)$ on the half-lines $\mathfrak{a}_{N-1}^{\pm}$. Next, observing that both $\mathfrak{a}_{N-1}^{\pm}$ are located in the exterior of the convex polygon $\widetilde{\Gamma}$, we evaluate the new unknown quantities by another application of (6.1), and continuing recursively, we eventually come to the representation of $U(r,\theta)$ by the formulas

$$U(r,\theta;\mu) = \mathrm{e}^{\mathrm{i}kr_\mu} \mathbf{E} \left\{ f(\hat{\xi}_\tau, \eta_\tau; n_\tau) \mathrm{e}^{\mathrm{i}k[S(\tau) - \hat{\xi}_\tau]} \right\}, \qquad S(t) = \frac{1}{2} \int_0^\tau \hat{\xi}_t \mathrm{d}t - \Lambda_t, \tag{6.5}$$

where the stochastic processes n_t, $\hat{\xi}_t$, η_t, and Λ_t are defined by the transparent rules which are easier to understand than to formulate.

These processes start at the time $t = 0$ from initial positions defined by the formulas

$$\hat{\xi}_0 = r, \qquad \eta_0 = \theta, \qquad \Lambda_0 = 0, \qquad n_0 = \mu, \tag{6.6}$$

where, as in (5.11), the initial value $n_0 = \mu$ is not fixed but must be selected from the condition that $(r,\theta) \in \mathfrak{D}_\mu$. The further evolution of these processes is determined by their current position, which may be classified into the following distinct cases:

$$\begin{array}{lll} \text{Case } A_-: & P_t \in \widetilde{\mathfrak{a}}_{n_t}^-, & n_t = jN, \\ \text{Case } A_+: & P_t \in \widetilde{\mathfrak{a}}_{n_t}^+, & n_t = jN - 2, \\ \text{Case } B_-: & P_t \in \widetilde{\mathfrak{g}}_{n_t}^-, & n_t = jN, \\ \text{Case } B_+: & P_t \in \widetilde{\mathfrak{g}}_{n_t}^+, & n_t = jN - 2, \\ \text{Case } C_\pm: & P_t \in \mathfrak{a}_{n_t}^\pm, & \end{array}$$

where j may have any integer value. Then the processes n_t, Λ_t, and η_t are described by the following complicated but transparent rules:

$$n_{t+\mathrm{d}t} - n_t = \begin{cases} \pm 2 & \text{in Cases } A_\pm, \\ \pm 1 & \text{in Cases } B_\pm,\ C_\pm, \\ 0 & \text{otherwise}, \end{cases} \tag{6.7}$$

$$\Lambda_{t+\mathrm{d}t} - \Lambda_t = \begin{cases} |O_0 O_{N-2}| & \text{in Cases } A_\pm, \\ \rho_\pm & \text{in Cases } B_\pm, \\ L_{n_t}^\pm & \text{in Cases } C_\pm, \\ 0 & \text{otherwise}, \end{cases} \tag{6.8}$$

and

$$\eta_{t+\mathrm{d}t} - \eta_t = \mathrm{d}w_t^2 + \begin{cases} \widetilde{\alpha}_{n_t - 2} - \pi & \text{in Case } A_-, \\ \pi - \widetilde{\alpha}_{n_t} & \text{in Case } A_+, \\ \vartheta_\pm & \text{in Cases } B_\pm, \\ \alpha_{n_t - 1} - \pi & \text{in Case } C_-, \\ \pi - \alpha_{n_t} & \text{in Case } C_+, \\ 0 & \text{otherwise}, \end{cases} \tag{6.9}$$

where

$$\vartheta_- = \alpha_{N-1} - \mathcal{F}(\hat{\xi}_t, \eta_t, |O_0 O_{N-2}|), \qquad \vartheta_+ = \mathcal{F}(\hat{\xi}_t, \alpha_{N-1} - \eta_t, |O_0 O_{N-2}|), \tag{6.10}$$

$$\rho_- = \mathcal{P}(\hat{\xi}_t, \eta_t, |O_0 O_{N-2}|), \qquad \rho_+ = \mathcal{P}(\hat{\xi}_t, \alpha_{N-1} - \eta_t, |O_0 O_{N-2}|). \tag{6.11}$$

As for the radial motion $\hat{\xi}_t$, it is described by the same equations (5.14)–(5.16) as in the case of the convex polygon, but the term Λ_t involved there must get values from (6.8).

7. Solution of Problem-1. Results of the previous sections open the way to the solution of the fundamental Problem-1 identified in the end of section 3 as the principal part of the problem of diffraction by a polygon Γ.

Following the order established in the previous sections, we first consider the case when Γ is treated as a polygon with two infinite sides. More precisely, we start from the slightly more general problem formulated below, which includes nonvanishing boundary conditions on the faces of the wedge.

Problem-1w. Find a solution $U_\phi(r, \theta)$ of the Helmholtz equation that is bounded in a wedge $\mathfrak{O} : \alpha_1 < \theta < \alpha_2$, has the boundary values $U(r, \alpha_n) = f(r, \alpha_n)$ and the asymptote $\mathrm{e}^{-\mathrm{i}kr} U_\phi(r, \theta) = o(1)$ as $r \to \infty$, $\theta \neq \phi$, and satisfies the interface conditions

$$U_\phi(r, \phi + 0) - U_\phi(r, \phi - 0) = e^{\mathrm{i}kr}, \qquad \frac{\partial U_\phi(r, \phi + 0)}{\partial \theta} = \frac{\partial U_\phi(r, \phi - 0)}{\partial \theta}, \tag{7.1}$$

imposed on the ray $\theta = \phi$.

It is shown in [10] that to obtain the solution of this problem it suffices to split the wedge $\mathfrak{O}$ into two smaller wedges $\mathfrak{O}_-$ and $\mathfrak{O}_+$ defined by the inequalities $\alpha_1 < \theta < \phi$ and $\phi < \theta < \alpha_2$, respectively. Indeed, assuming that $U_\phi(r, \theta)$ is known on both sides of the ray $\theta = \phi$, we represent $U_\phi(r, \theta)$ in each of these wedges by formulas of the type (4.6). Then, matching these representations in order to enforce the interface conditions (7.1), we eventually arrive at the solution of the Problem-1w in the form

$$U_\phi(r, \theta) = \mathrm{e}^{\mathrm{i}kr} \mathbf{E} \left\{ f(\hat{\xi}_\tau, \eta_\tau) \mathrm{e}^{\mathrm{i}k[S(\tau) - \hat{\xi}_\tau]} + \sum_{\nu=1}^{t_\nu < \tau} \delta(t_\nu, \phi) \mathrm{e}^{\mathrm{i}kS(t_\nu)} \right\}, \quad S(t) = \frac{1}{2} \int_0^t \hat{\xi}_t \mathrm{d}t, \tag{7.2}$$

where $\hat{\xi}_t$ and η_t retain their meanings from (4.6); τ is the exit time defined as the first time when $\eta_t = \alpha_1$ or $\eta_t = \alpha_2$; the factor $\delta(t, \phi)$ is determined by the rule

$$\delta(t, \phi) = \begin{cases} 1 & \text{if} \quad \vartheta_{t-0} > \phi, \quad \vartheta_{t+0} < \phi, \\ -1 & \text{if} \quad \vartheta_{t-0} < \phi, \quad \vartheta_{t+0} > \phi, \\ 0 & \text{otherwise;} \end{cases} \tag{7.3}$$

and $\{t_n\}$, where $n \geq 1$, is a sequence of times when the angular motion η_t, running inside the interval $[\alpha_1, \alpha_2]$, touches the fixed point $\eta = \phi$.

With the solution of the auxiliary Problem-1w in hand we can now obtain the solution $U_{\mu,\phi}$ of Problem-1 for a nonconvex polygon Γ. Thus, assuming that this solution is already known on the entire faces of the wedge $\mathfrak{O}_\mu$, we can apply formula (7.2) and conclude that for any $(r, \theta) \in \mathfrak{O}_\mu$ the value of $U_{\mu,\phi}(r_\mu, \theta_\mu; \mu)$ can be evaluated as

$$U_{\mu,\phi}(r_\mu, \theta_\mu; \mu) = \mathrm{e}^{\mathrm{i}kr_\mu} \mathbf{E} \left\{ \sum_{\nu=1}^{t_\nu < \tau} \delta(t_\nu, \phi) \mathrm{e}^{\mathrm{i}kS(t_\nu)} + \chi(\hat{\xi}_\tau, \eta_\tau) U_{\mu,\phi}(\hat{\xi}_\tau, \eta_\tau; \mu) \mathrm{e}^{\mathrm{i}kS(\tau)} \right\}, \tag{7.4}$$

where

$$\chi(\hat{\xi},\eta) = \begin{cases} 0 & \text{if} \quad (\hat{\xi},\eta) \in \Gamma, \\ 1 & \text{otherwise.} \end{cases} \tag{7.5}$$

The right-hand side of (7.4) contains yet unknown values of the field $U_{\mu,\phi}(r_\mu, \theta_\mu; \mu)$ at the points $(\hat{\xi}_\tau, \eta_\tau)$ which belong to the boundary of the wedge $\mathfrak{O}_\mu$ but do not belong to the polygon Γ. These points, however, are located inside one of the wedges $\mathfrak{O}_{\mu\pm1}$, and therefore the field there can be computed by the formula (6.5) applied to the appropriate wedge $\mathfrak{O}_{\mu\pm1}$. Continuing the iterations, we eventually arrive at the expression

$$U_{\mu,\phi}(r,\theta) = \mathrm{e}^{\mathrm{i}kr_{\bar{\mu}}} \mathbf{E}\left\{\sum_{\nu=1}^{\infty} \delta(t_\nu, \phi; \mu) \mathrm{e}^{\mathrm{i}kS(t_\nu)}\right\}, \qquad S(t) = \frac{1}{2}\int_0^t \hat{\xi}_t \mathrm{d}t - \Lambda_t, \tag{7.6}$$

which is similar to (6.5)–(6.11) with the few exceptions described below.

Thus the mathematical expectation in (7.4) is computed over the stochastic processes n_t, $\hat{\xi}_t$, η_t, and Λ_t, which retain their meanings from (6.5)–(6.11), except that the integer-valued process n_t starts from the position (see Figure 7)

$$n_0 = \bar{\mu} = \begin{cases} \mu & \text{if} \quad 0 \le \theta_\mu \le \alpha_\mu, \\ \min\{m : \; P \in \mathfrak{O}_m\} & \text{if} \quad \theta_\mu > \alpha_\mu, \\ \max\{m : \; P \in \mathfrak{O}_m\} & \text{if} \quad \theta_\mu < 0, \end{cases} \tag{7.7}$$

which is the closest to the μ index of the wedge $\mathfrak{O}_{\bar{\mu}}$ containing the observation point $P = (r, \theta)$.

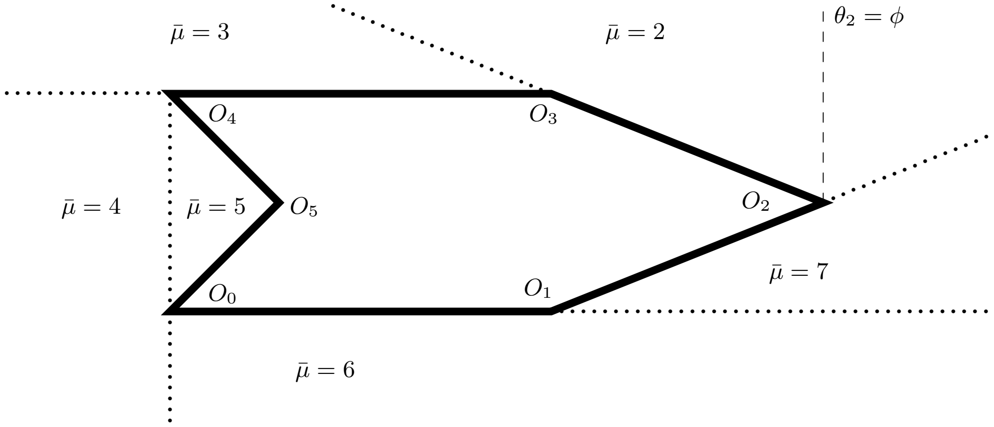

FIG. 7. *Selectionof $\bar{\mu}$ for $\theta_\mu > \phi$.*

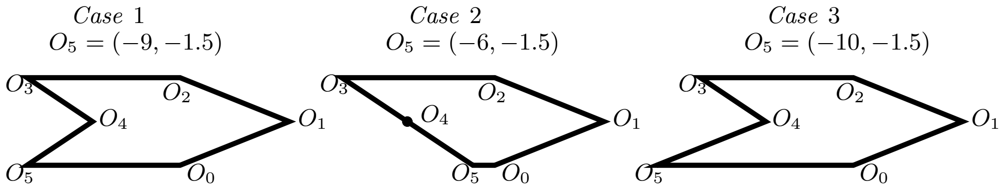
Another feature of (7.4) which does not appear in (6.5) is the presence of the factor $\delta(t, \phi)$ determined by the rule

$$\delta(t, \phi; \mu) = \begin{cases} 1 & \text{if} \quad \phi < \eta_{\tau_\nu - 0}, \quad \eta_{\tau_\nu + 0} < \phi, \quad n_t = \mu, \\ -1 & \text{if} \quad \phi > \eta_{\tau_\nu - 0}, \quad \eta_{\tau_\nu + 0} > \phi, \quad n_t = \mu, \\ 0 & \text{otherwise,} \end{cases} \tag{7.8}$$



Fixed vertices: $O_0 = (-3.5, -1.5)$, $O_1 = (0, 0)$, $O_2 = (-3.5, 1.5)$, $O_3 = (-9, 1.5)$ $O_4 = (-6, 0)$

FIG. 8. *Samples of nonconvex polygons.*

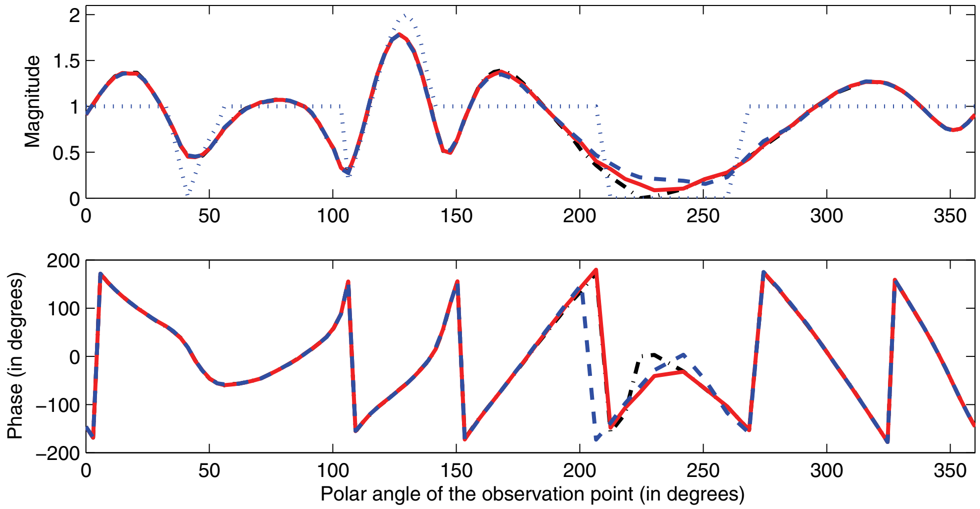


FIG. 9. *The total and geometric fields around the polygons from Figure* 8. *The wave fields were computed along circles of radius $R = 9$ with centers at the point $C = (-4.5, 0)$ in the middle of the polygons. In all of the diagrams the light dashed lines correspond to the geometric fields which comprise the incident and reflected plane waves, and the bold lines correspond to the total wave fields, which include the diffracted fields. The solid bold lines correspond to Case* 1, *the dash-dotted bold lines correspond to Case* 2, *and dashed bold lines correspond to Case* 3.

where ν enumerates the times $t = \tau_\nu$ when $n_t = \mu$ and the motion η_t touches the point $\eta = \phi$.

We don't provide here an extended derivation of (7.4)–(7.8) because it goes along the same lines as that discussed in section 6, and also because very similar formulas have actually been discussed in detail in the paper [8], devoted to diffraction by a convex polygon. The only difference between the solutions of Problem-1 obtained in that paper and here is that in [8] the analysis is based on the representation of the wave field in a wedge by the formulas (4.3)–(4.5), while the solution (7.4)–(7.8) is based on the more versatile formulas (4.6)–(4.9).

8. Example. To verify the feasibility of the obtained solution of the problem of diffraction by a nonconvex polygon, we conducted numerical simulations of the wave fields generated by an incident plane wave $U_* = \mathrm{e}^{-\mathrm{i}r\cos(\theta-\theta_*)}$, with $\theta_* = 60°$, from three short polygons shown in Figure 8. The vertices are located by standard Cartesian coordinates with the origin at O_1.

Figure 9 shows the magnitudes and the phases of the total and the geometric

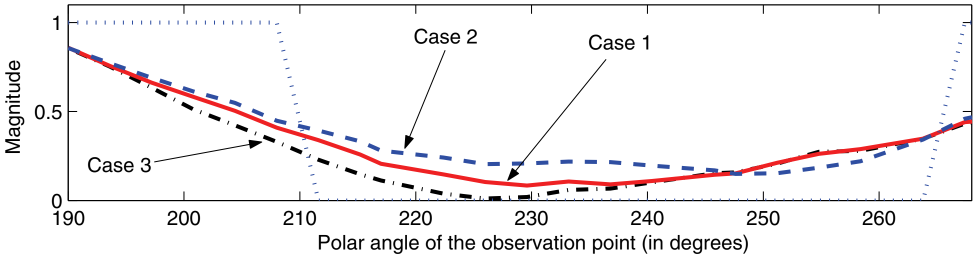

FIG. 10. *Zoomed view on magnitudes of the total fields from Figure* 9.

fields generated due to the scattering by the pentagons shown in Figure 8.

All of the numerical results were obtained by the approximation of the mathematical expectation (7.6) by the average of 1500 sample values of the functional depending on two standard one-dimensional Brownian motions w_t^1 and w_t^2. These Brownian motions are simulated by simple discreet random walks with jumps of distance $\Delta w = \pm\sqrt{\Delta t}$ following each other with the time increment $\Delta t = 0.01$. The standard deviation of the samples did not exceed the level $D = 0.5$, which suggests good convergence and stability of the solution. All computations were carried out using a MATLAB code of about 100 lines with no attempts at optimization. The code was run on a 900MHz notebook PC, and it required only a few seconds to calculate the results at each observation point.

The diagrams in Figure 9 clearly demonstrate the expected behavior of the simulated wave fields generated by the interaction of an incident plane wave with the polygon. Thus, in the absence of the scatter, the total wave field along the circles would have a unit magnitude and sinusoidal phase. In the presence of any of the scatterers from Figure 8, the laws of geometric optics predict a shadow zone around the ray $\theta = 235°$, and two zones illuminated by the waves reflected from the sides O_1O_2 and O_2O_3. It is also expected that the difference in the total fields should be most noticeable in the shadow zone where the magnitude of the total field should be highest in Case 2, medium in Case 1, and minimal in Case 3. These physically justified predictions are soundly confirmed by the presented graphs, which show that the total field in Case 3 almost vanishes around the ray $\theta \approx 225°$ located close to the vertex O_5 of the grounded polygon. At the same time the magnitude of the total field in Case 1 has a little variation in the domain between the rays $\theta = 220°$ and $\theta = 240°$, which is located on the approximately constant distance from the grounded polygon. These peculiarities of the wave fields are best seen in Figure 10, which reproduces in a larger scale the magnitudes of the total fields shown in Figure 9.

9. Conclusion. The probabilistic approach to wave propagation and diffraction made it possible to solve the problem of diffraction by a nonconvex polygon and, therefore, to expand the list of difficult problems of diffraction solved by this method.

In the past, the probabilistic random walk method led to explicit solutions of a number of nontrivial problems of diffraction, including the scalar problem of diffraction by a plane angular sector [6], the vector problem of diffraction of the electromagnetic wave by a wedge with anisotropic impedance faces [9], as well as problems of diffraction by a wedge with faces of variable impedance and by an arbitrary convex polygon. Although all of these problems are notoriously difficult for analysis by conventional methods, the obtained probabilistic solutions appear to be simple, transparent, compatible with intuitive ideas about diffraction, and easy for numerical implementation. The advantages of the random walk approach become even more apparent when it is applied to problems with several diffraction points. Thus, in [7, 8] we solved the problems of wave scattering in a half-plane with a piecewise constant impedance boundary condition, the problem of diffraction by a finite line segment with different impedance sides, and the problem of diffraction by an arbitrary convex polygon. Here we have taken the next step and extended the method to problems of diffraction by a nonconvex polygon. To make the presentation more transparent we limited ourselves to a perfectly reflecting nonconvex polygon of a specific shape, but, as shown in [10], the further extensions of the method to domains of virtually arbitrary shape with virtually arbitrary first-order impedance boundary conditions requires only routine modifications of the general method.

We hope that the presented results will stimulate further applications of the probabilistic methods and will extend the understanding of wave propagation and diffraction.

MUTUALLY EXCLUSIVE SPIKY PATTERN AND SEGMENTATION MODELED BY THE FIVE-COMPONENT MEINHARDT–GIERER SYSTEM[*]

JUNCHENG WEI[†] AND MATTHIAS WINTER[‡]

Abstract. We consider the five-component Meinhardt–Gierer model for mutually exclusive patterns and segmentation, which was proposed in [H. Meinhardt and A. Gierer, *J. Theoret. Biol.*, 85 (1980), pp. 429–450]. We prove rigorous results on the existence and stability of mutually exclusive spikes which are located in different positions for the two activators. Sufficient conditions for existence and stability are derived, which depend in particular on the relative size of the various diffusion constants. Our main analytical methods are the Liapunov–Schmidt reduction and nonlocal eigenvalue problems. The analytical results are confirmed by numerical simulations.

Key words. pattern formation, mutual exclusion, stability, steady states

1. Introduction.

We analyze the five-component Meinhardt–Gierer system whose components are two activators and one inhibitor as well as two lateral activators. It has been introduced and very successfully used in various modeling aspects by Meinhardt and Gierer [11]. In particular, it can explain the phenomenon of mutual exclusion and can handle segmentation in the simplest case of two different segments. This model has been reviewed and its many implications discussed in detail by Meinhardt in Chapter 12 of [10].

The most important features of this system can be highlighted as *lateral activation of mutually exclusive states*. To each of the local activators a lateral activator is associated in a spatially nonlocal and time-delayed way. The consequence of the presence of the two lateral activators in the system is the possibility of having stable patterns which for the two activators are mutually exclusive; in other words, the patterns for the two activators are located in different positions. It is clear that mutually exclusive patterns are not possible for a three-component system with only two activators and one inhibitor since mutually exclusive patterns for the two activators could destabilize each other in various ways. Therefore the lateral activators are needed.

Numerical simulations of mutually exclusive patterns have been performed in [11], [10]. Many interesting features have been discovered and explained, but those works do not give analytical solutions, and they are not mathematically rigorous. To obtain mathematically rigorous results, in this study we show the existence and stability of mutually exclusive spikes in such a system.

The overall feedback mechanism of the system can be summarized as follows: *Lateral activation is coupled with self-activation and overall inhibition.* We will explain this in more detail after the system has been formulated quantitatively.

A widespread pattern in biology is *segmentation.* The mutual exclusion effect described in this paper is a special case of segmentation where only two different segments are present. Examples for biological segmentation are the body segments of insects or the segments of insect legs. The segments usually resemble each other strongly, but, on the other hand, they are different from each other. Segments may, for example, have an internal polarity which is often visible by bristles or hairs. This internal pattern within a segment depends on the position of the segment within the sequence in its natural state. In some biological cases a good understanding of how segment position and internal structure are related has been obtained. One famous example is surgical experiments on insects, e.g., cockroach legs. Creating a discontinuity in the normal neighborhood of structures by cutting a leg and pasting one piece to the end of another partial leg creates a discontinuity in the segment structure as some segments are missing their natural neighbors. By a process called intercalary regeneration new stable patterns in the cockroach leg are formed such that all segments get back their natural neighbors. However, the resulting pattern can be very different from any naturally occurring pattern.

For example, for cockroach legs, if the normal sequence of structures within a segment is 123 . . . 9, a combination of a partial leg 12345678 to which the piece 456789 is added first leads to the structure 12345678456789. Note the presence of the jump discontinuity in this sequence between the numbers 8 and 4. Now segment regulation adds the piece 765, which removes the discontinuity and leads to the final structure, 12345678**765**456789. This is different from the original natural structure, but nevertheless each segment has the same neighbors as in the natural situation.

In this example, which was experimentally verified by Bohn [1], it is not the natural sequence but the normal neighborhood which is regulated. It is exactly this neighboring structure which can be modeled mathematically using the system from [11] which is considered here, and this paper can be the starting point to a rigorous understanding of more complex segmentation phenomena.

Now we give a sociological application of mutual exclusion (see [11]). Consider two families. They can hardly live in exactly the same house, as this would lead to undesirable overcrowding. But if they live in the same street or neighborhood they can support, nurture, and benefit each other. Thus this collaborative behavior can lead to a rather stable situation. Indeed, stable coexisting states with concentration peaks remaining close but keeping a certain characteristic distance from each other are typical phenomena which are observed in quantitative models of systems modeling mutual exclusion, and they obviously resemble real-world behavior in this example very well.

This feedback mechanism of lateral activation coupled with overall inhibition can be quantified by formulating the effects of "activation," "lateral activation," and "inhibition" using the language of molecular reactions and invoking the law of mass action. Now we are going to discuss this in a quantitative manner. We will introduce the resulting model system first and then explain how these feedback mechanisms are represented by the terms in the model.

The original system from [11] (after rescaling and some simplifications) can be stated as follows:

$$\begin{cases} g_{1,t} = \epsilon^2 g_{1,xx} - g_1 + \dfrac{cs_2 g_1^2}{r}, \quad g_{2,t} = \epsilon^2 g_{2,xx} - g_2 + \dfrac{cs_1 g_2^2}{r}, \\ \tau r_t = D_r r_{xx} - r + cs_2 g_1^2 + cs_1 g_2^2, \\ \tau s_{1,t} = D_s s_{1,xx} - s_1 + g_1, \quad \tau s_{2,t} = D_s s_{2,xx} - s_2 + g_2. \end{cases} \tag{1.1}$$

Here $0 < \epsilon \ll 1$, $D_r > 0$ and $D_s > 0$ are diffusion constants, c is a positive reaction constant, and τ is a nonnegative time-relaxation constant (in [11] the choice $\tau = 1$ was made).

The x-indices indicate spatial derivatives. We will derive results for the system (1.1) on a bounded interval $\Omega = (-L, L)$ for $L > 0$ with Neumann boundary conditions. Some results for the system on the real line ($L = \infty$) will also be established and will be compared with the bounded interval case.

The first two components, the *activators* g_1 and g_2, activate themselves locally is due to the terms g_1^2 and g_2^2, respectively, in the first two equations.

The *lateral activators* are introduced in (1.1) by the fourth and fifth components s_1 and s_2 as follows: For both the activators, g_i, $i = 1, 2$, there are nonlocal and delayed versions s_i. Now s_1 acts as an activator to g_2, and s_2 acts as in activator to g_1 due to the terms s_2 in the first and s_1 in the second equation which have a positive feedback. The expression lateral activation is used since g_i activates g_{3-i} laterally through its nonlocal counterpart s_i rather than locally through g_i itself.

Lateral activation is finally coupled with overall inhibition as follows: The third component r acts as an *inhibitor* to both g_1 and g_2 due to the term r in the first and second equations, which has a negative feedback. Note also that both the local and the nonlocal activators have a positive feedback on r due to the terms $s_2 g_1^2$ and $s_1 g_2^2$ in the third equation.

This feedback mechanism is a generalization of the well-known Gierer–Meinhardt system [6] which has one local activator coupled to an inhibitor. We recall that the classical Gierer–Meinhardt system as well as the five-component system considered here are both Turing systems [13], as they allow spatial patterns to arise out of a homogeneous steady state by the so-called Turing instability. (Some analytical results for the existence and stability of a spiky Turing pattern for the Gierer–Meinhardt system have been obtained, for example, in [3], [4], [5], [9], [12], [14], [17], [18], [19].)

Now we state our rigorous results on the existence and stability of stationary, mutually exclusive, spiky patterns for the system (1.1).

We prove the *existence* of a spiky pattern with one spike for g_1 and one spike for g_2, which are located in different positions under the following conditions:

(i) the diffusivities of the two lateral activators are large compared to the inhibitor diffusivity and

(ii) the inhibitor diffusivity is large compared to the diffusivities of the two (local) activators.

We summarize the two main conditions (i) and (ii), which guarantee the existence of mutually exclusive spike patterns for (1.1), in the following:

$$\text{We assume that} \quad \epsilon^2 \ll C_1 D_r \le D_s \quad \text{for some constant } C_1 > 0. \tag{1.2}$$

We also prove the *stability* of these mutually exclusive spiky patterns, provided that certain conditions are met, which are of the type (1.2) with C_1 replaced by some new constant C_2.

In this paper we consider a pattern displaying one spike for g_1 and one for g_2 which are located in different positions.

In particular, we prove the existence of a mutually exclusive two-spike solution to the system (1.1) if $D_s/D_r > 4$. We show that this solution is stable if (i) $D_s/D_r > 43.33$ for $L = \infty$, or in general if (5.3) holds (condition for $O(1)$ eigenvalues), and if (ii) $D_s/D_r > 4$ (condition for $o(1)$ eigenvalues).

The main results will be stated in Theorem 3.2 on the existence of solutions and in Theorems 5.1 and 6.7 on the large and small eigenvalues, respectively, of the linearized problem at the solutions.

What do these results tell us about segmentation? As a first step, we have proved that in the case of two segments, which we call 1 and 2, the sequence 12 can exist and be stable, and we have found sufficient conditions for this effect to happen.

The case of $n > 2$ components will lead to a system with $2n+1$ components, which is very large and not easy to handle. Even in the case $n = 2$ for the five-component system investigated in this paper the analysis becomes rather lengthy. We expect that, following our approach, we will be able to prove existence and stability of n spikes in n different locations. We do not see any major obstacle, only that the proofs become more technical. We are currently working on this issue.

The outline of the paper is as follows. In section 2, we compute the amplitudes of the spikes for g_1 and g_2. In section 3, we determine the positions of the spikes and show the existence of steady states with mutually exclusive spikes. In section 4, we first derive the eigenvalue problem. Then we compute the large (i.e., $O(1)$) eigenvalues and derive sufficient conditions for the stability of solutions with respect to these. In section 5, we solve a nonlocal eigenvalue problem which has been delayed from section 4. In section 6, we give the most important steps and state the main result on the stability of solutions with respect to small (i.e., $o(1)$) eigenvalues. Sufficient conditions for this stability are derived. The technical details of the analysis of small eigenvalues is delayed to the appendices. Finally, in section 7, our results are confirmed by numerical simulations.

2. Computing the amplitudes.

We construct steady states of the form

$$g_1(x) = t_1 w\left(\frac{x - x_1}{\epsilon}\right)(1 + O(\epsilon)), \quad g_2(x) = t_2 w\left(\frac{x - x_2}{\epsilon}\right)(1 + O(\epsilon)),$$

where $w(y)$ is the unique positive and even homoclinic solution of the equation

$$w_{yy} - w + w^2 = 0 \tag{2.1}$$

on the real line decaying to zero at $\pm\infty$. Here we assume that the spikes for g_1 and g_2 have the same amplitude, i.e., $t_1 = t_2$. We often use different notation for the two amplitudes, as this will be important later when we consider stability, since there could be an instability which breaks the symmetry of having the same amplitudes. The analysis will show that t_1, t_2 and x_1, x_2 depend on ϵ but to leading order and after suitable scaling are independent of ϵ. To keep notation simple we will not explicitly indicate this dependence.

All functions used throughout this paper belong to the Hilbert space $H^2(-L, L)$, and the error terms are taken in the norm $H^2(-L, L)$ unless otherwise stated. After integrating (2.1), we get the relation

$$\int_R w(y)\,dy = \int_R w^2(y)\,dy, \tag{2.2}$$

which will be used frequently, often without explicitly stating it. We denote

$$w_1(x) = w\left(\frac{x - x_1}{\epsilon}\right), \quad w_2(x) = w\left(\frac{x - x_2}{\epsilon}\right). \tag{2.3}$$

Note that g_1 and g_2 are small-scale variables, as $\epsilon \ll 1$, and r, s_1, and s_2 are large-scale (with respect to the spatial variable). For steady states, using Green functions, these slow variables, to leading order, can be expressed by an integral representation.

To get this representation, g_1 in the last three equations of (1.1) can be expanded as

$$g_1(x) = t_1\epsilon\left(\int_R w\right)\delta_{x_1}(x) + O(\epsilon^2), \quad g_1^2(x) = t_1^2\epsilon\left(\int_R w^2\right)\delta_{x_1}(x) + O(\epsilon^2),$$

where $\delta_{x_1}(x) = \delta(x - x_1)$ is the Dirac delta distribution located at x_1. Similarly, for g_2 we have

$$g_2(x) = t_2\epsilon\left(\int_R w\right)\delta_{x_2}(x) + O(\epsilon^2), \quad g_2^2(x) = t_2^2\epsilon\left(\int_R w^2\right)\delta_{x_2}(x) + O(\epsilon^2).$$

Using the Green function $G_D(x,y)$, which is defined as the unique solution of the equation

(2.4)

$$D\Delta G_D(x,y) - G_D(x,y) + \delta_y(x) = 0, \quad -L < x < L, \quad G_{D,x}(-L,y) = G_{D,x}(L,y) = 0,$$

we can represent $s_1(x)$ by using the fourth equation of (1.1) as

$$s_1(x) = t_1\epsilon\left(\int_R w\right)G_{D_s}(x,x_1) + O(\epsilon^2). \tag{2.5}$$

An elementary calculation gives

$$G_D(x,y) = \begin{cases} \frac{\theta}{\sinh(2\theta L)}\cosh\theta(L+x)\cosh\theta(L-y), & -L < x < y < L, \\ \frac{\theta}{\sinh(2\theta L)}\cosh\theta(L-x)\cosh\theta(L+y), & -L < y < x < L, \end{cases} \tag{2.6}$$

with $\theta = 1/\sqrt{D}$. Note that

$$G_D(x,y) = \frac{1}{2\sqrt{D}}e^{-|x-y|/\sqrt{D}} - H_D(x,y), \tag{2.7}$$

where H_D is the regular part of the Green function G_D. In particular, for $L = \infty$, we have

$$G_D(x_1,x_2) = \frac{1}{2\sqrt{D}}e^{-|x-y|/\sqrt{D}} =: K_D(x_1,x_2). \tag{2.8}$$

In the same way, we derive

$$s_2(x) = t_2\epsilon\left(\int_R w\right)G_{D_s}(x,x_2) + O(\epsilon). \tag{2.9}$$

Now we compute the last two terms on the right-hand side (r.h.s.) of the third equation of (1.1) as follows:

$$\begin{aligned} cs_2g_1^2(x) &= cs_2(x_1)t_1^2\epsilon\left(\int_R w\right)\delta_{x_1}(x) + O(\epsilon^2) \\ &= ct_1^2t_2\epsilon^2\left(\int_R w\right)^2\delta_{x_1}(x)G_{D_s}(x_1,x_2) + O(\epsilon^3) \end{aligned}$$

and, similarly,

$$cs_1g_2^2(x) = ct_1t_2^2\epsilon^2\left(\int_R w\right)^2\delta_{x_2}(x)G_{D_s}(x_1,x_2) + O(\epsilon^3).$$

Now, using the third equation of (1.1), we can represent $r(x)$ by the Green function G_{D_r},

$$r(x) = ct_1t_2\epsilon^2\left(\int_R w\right)^2 G_{D_s}(x_1,x_2)(t_1G_{D_r}(x,x_1)+t_2G_{D_r}(x,x_2))+O(\epsilon^3). \tag{2.10}$$

Going back to the first equation in (1.1), we get

$$\epsilon^2\Delta g_1 - g_1 + \frac{cs_2g_1^2}{r} = t_1(\epsilon^2\Delta w_1 - w_1) + \frac{cs_2t_1^2w_1^2}{r} + O(\epsilon) = t_1\left[\frac{cs_2t_1}{r}-1\right]w_1^2 + O(\epsilon). \tag{2.11}$$

To have the same amplitudes of the two contributions in (2.11), we require

$$\frac{cs_2(x_1)t_1}{r(x_1)} = 1 + O(\epsilon). \tag{2.12}$$

Now we rewrite (2.12), using (2.9) and (2.10):

$$\frac{cs_2(x_1)t_1}{r(x_1)} = \frac{1}{\epsilon(\int_R w)(t_1G_{D_r}(x_1,x_1)+t_2G_{D_r}(x_1,x_2))} + O(\epsilon). \tag{2.13}$$

Thus, (2.12) for $x = x_1$ gives

$$t_1G_{D_r}(x_1,x_1)+t_2G_{D_r}(x_1,x_2) = \frac{1}{\epsilon\int_R w} + O(1). \tag{2.14}$$

In the same way, from the second equation in (1.1) we get

$$t_1G_{D_r}(x_1,x_2)+t_2G_{D_r}(x_2,x_2) = \frac{1}{\epsilon\int_R w} + O(1). \tag{2.15}$$

The relations (2.14), (2.15) are a linear system for the amplitudes t_1, t_2 of the spikes if their positions state that the amplitudes x_1, x_2 are known. Note that the amplitudes depend on the positions in leading order, as also the Green function G_{D_r} depends on its arguments in leading order. We say that the amplitudes are strongly coupled to the positions.

Note that the system (2.14), (2.15) has a unique solution t_1, t_2 since by (2.6)

$$G_{D_r}(x_1,x_1)G_{D_r}(x_2,x_2) - (G_{D_r}(x_1,x_2))^2 = \frac{\theta_r^2}{\sinh^2(2\theta_rL)}\cosh\theta_r(L-x_1)\cosh\theta_r(L+x_2)$$
$$\times[\cosh\theta_r(L+x_1)\cosh\theta_r(L-x_2) - \cosh\theta_r(L-x_1)\cosh\theta_r(L+x_2)] > 0$$

for $-L < x_2 < x_1 < L$, where $\theta_r = 1/\sqrt{D_r}$.

By symmetry, for $x_1 = -x_2$ we have $t_1 = t_2$. This is the case we are interested in. However, we have not yet shown that there are such positions x_1, x_2. This will be done in the next section.

For the special case $L = \infty$, we have $G_{D_r}(x_1,x_2) = \frac{1}{2\sqrt{D_r}}e^{-|x-y|/\sqrt{D_r}}$, and (2.14), (2.15) in this case are given by

$$t_1 + t_2e^{-|x_1-x_2|/\sqrt{D_r}} = \frac{2\sqrt{D_r}}{\epsilon\int_R w}, \quad t_2 + t_1e^{-|x_1-x_2|/\sqrt{D_r}} = \frac{2\sqrt{D_r}}{\epsilon\int_R w}.$$

Finally, we summarize the main result of this section as follows.

LEMMA 2.1. *Assume that $\epsilon > 0$ is small enough. Then for spike-solutions of* (1.1) *of the type*

$$g_1(x) = t_1 w\left(\frac{x - x_1}{\epsilon}\right)(1 + O(\epsilon)), \quad g_2(x) = t_2 w\left(\frac{x - x_2}{\epsilon}\right)(1 + O(\epsilon)),$$

where $w(y)$ is the unique positive and even solution of the equation

$$w_{yy} - w + w^2 = 0$$

on the real line decaying to zero at $\pm\infty$, the amplitudes t_1 and t_2 are given as the unique solution of the system

$$t_1 G_{D_r}(x_1, x_1) + t_2 G_{D_r}(x_1, x_2) = \frac{1}{\epsilon \int_R w} + O(1),$$
$$t_1 G_{D_r}(x_1, x_2) + t_2 G_{D_r}(x_2, x_2) = \frac{1}{\epsilon \int_R w} + O(1),$$

where G_D is the Green function defined in (2.4).

3. Existence of mutually exclusive spikes. In this section, we use the Liapunov–Schmidt reduction method to rigorously prove the existence of mutually exclusive spikes. We will get a sufficient condition on the locations of the spikes.

The problem here is that the linearization of the r.h.s. of the first equation in (1.1) around w_1 has an approximate nontrivial kernel. This comes from the fact that a derivative of (2.1) with respect to y gives

$$(w_y)_{yy} - w_y + 2ww_y = 0.$$

Thus, w_y belongs to the kernel of the linearization of (2.1) around w. Note that the function w_y represents the translation mode. Therefore a direct application of the implicit function theorem is not possible; one has to deal with this kernel first. This is the goal in this section.

Recall that for given $g_1, g_2 \in H_N^2(\Omega_\epsilon)$, where $\Omega_\epsilon = (-L/\epsilon, L/\epsilon)$ and $H_N^2(\Omega_\epsilon)$ denotes the space of all functions in $H^2(\Omega_\epsilon)$ satisfying the Neumann boundary condition, by the fourth equation of (1.1) s_1 is uniquely determined, by the fifth equation s_2 is uniquely determined, and finally by the third equation r is uniquely determined. Therefore, the steady state problem is reduced to solving the first two equations.

We are looking for solutions which satisfy

$$g_1(x) = t_1 w\left(\frac{x - x_1}{\epsilon}\right)(1 + O(\epsilon)), \quad g_2(x) = t_1 w\left(\frac{x + x_1}{\epsilon}\right)(1 + O(\epsilon))$$

with $g_1(x) = g_2(-x)$ $(x_1 > 0)$. By this reflection symmetry the problem is reduced to determining just one function: $g_1(x) = t_1 w_1(x) + v$.

We are now going to determine this function in *two steps.* Denoting the r.h.s. of the first equation of (1.1) by $S_\epsilon[t_1 w_1 + v]$, which is well defined for steady states, our problem can be written as follows: $S_\epsilon[t_1 w_1 + v] = 0$, where $S_\epsilon : H_N^2(\Omega_\epsilon) \to L^2(\Omega_\epsilon)$.

First step. Determine a small $v \in H^2(\Omega_\epsilon)$ with $\int_\Omega v \frac{dw_1}{dx}\, dx = 0$ such that

$$S_\epsilon[t_1 w_1 + v] = \beta\epsilon \frac{dw_1}{dx}. \tag{3.1}$$

Second step. Choose x_1 such that

$$\beta = 0. \tag{3.2}$$

We begin with the *first* step. To this end, we need to study the linearized operator

$$\tilde{L}_{\epsilon,x_1} : H^2(\Omega_\epsilon) \to L^2(\Omega_\epsilon) \quad \text{defined by} \quad \tilde{L}_{\epsilon,x_1} := S_\epsilon^{'}[t_1 w_1]\phi,$$

where $S_\epsilon^{'}[t_1 w_1]$ denotes the Fréchet derivative of the operator S_ϵ at $t_1 w_1$.

We define the approximate kernel and cokernel, respectively, as follows:

$$\mathcal{K}_{\epsilon,x_1} := \text{span}\left\{\epsilon \frac{dw_1}{dx}\right\} \subset H^2(\Omega_\epsilon), \quad \mathcal{C}_{\epsilon,x_1} := \text{span}\left\{\epsilon \frac{dw_1}{dx}\right\} \subset L^2(\Omega_\epsilon).$$

By projection, we define the operator

$$L_{\epsilon,x_1} = \pi^\perp_{\epsilon,x_1} \circ \tilde{L}_{\epsilon,x_1} : \mathcal{K}^\perp_{\epsilon,x_1} \to \mathcal{C}^\perp_{\epsilon,x_1},$$

where $\pi^\perp_{\epsilon,x_1}$ is the orthogonal projection in $L^2(\Omega_\epsilon)$ onto $\mathcal{C}^\perp_{\epsilon,x_1}$.

Then we have the following key result for the Liapunov–Schmidt reduction.

PROPOSITION 3.1. *There exist positive constants* $\bar{\epsilon}, \bar{\delta}, \lambda$ *such that we have for all* $\epsilon \in (0, \bar{\epsilon})$, $x_1 \in \Omega$ *with* $\min(|L + x_1|, |L - x_1|) > \bar{\delta}$,

$$\|L_{\epsilon,x_1}\phi\|_{L^2(\Omega_\epsilon)} \geq \lambda \|\phi\|_{H^2(\Omega_\epsilon)} \quad \textit{for all} \quad \phi \in \mathcal{K}^\perp_{\epsilon,x_1}. \tag{3.3}$$

Further, the map L_{ϵ,x_1} *is surjective.*

Proof of Proposition 3.1. We proceed by deriving a contradiction.

Suppose that (3.3) is false. Then there exist sequences $\{\epsilon_k\}, \{{x_1}^k\}, \{\phi^k\}$ with $\epsilon_k \to 0$, ${x_1}^k \in \Omega$, $\min(|L + x_1^k|, |L - x_1^k|) > \bar{\delta}$, $\phi^k = \phi_{\epsilon_k} \in K^\perp_{\epsilon_k, x_1^k}$, $k = 1, 2, \ldots,$ such that

$$\|L_{\epsilon_k, {x_1}^k}\phi^k\|_{L^2(\Omega_{\epsilon_k})} \to 0 \quad \text{as } k \to \infty, \quad \|\phi^k\|_{H^2(\Omega_{\epsilon_k})} = 1, \quad k = 1, 2, \ldots. \tag{3.4}$$

At first (after rescaling) ϕ_ϵ is defined only on Ω_ϵ. However, by a standard result (compare [7]) it can be extended to R such that its norm in $H^2(R)$ is still bounded by a constant independent of ϵ and x_1 for ϵ small enough. It is then a standard procedure to show that this extension converges strongly in $H^2(\Omega_\epsilon)$ to some limit ϕ_1 with $\|\phi_1\|_{L^2(R)} = 1$. For the details of the argument, we refer to [8].

The same analysis is performed for w_2 and its perturbation $\phi_{\epsilon,2}$. Then $\Phi = (\phi_1, \phi_2)^T$ solves the system

$$\begin{aligned} L_0\phi_1 - \frac{1}{\int_R w\, dy}\Bigg[& 2\hat{t}_1 G_{D_r}(x_1, x_1)\left(\int_R w\phi_1\, dy\right) + 2\hat{t}_1 G_{D_r}(x_1, x_2)\left(\int_R w\phi_2\, dy\right) \\ & + \hat{t}_2 G_{D_r}(x_1, x_2)\left(\int \phi_1\, dy\right) - \hat{t}_1 G_{D_r}(x_1, x_2)\left(\int \phi_2\, dy\right)\Bigg] = 0, \end{aligned} \tag{3.5}$$

$$\begin{aligned} L_0\phi_2 - \frac{1}{\int_R w\, dy}\Bigg[& 2\hat{t}_2 G_{D_r}(x_2, x_2)\left(\int w\phi_2\, dy\right) + 2\hat{t}_2 G_{D_r}(x_1, x_2)\left(\int w\phi_1\, dy\right) \\ & + \hat{t}_1 G_{D_r}(x_1, x_2)\left(\int_R \phi_2\, dy\right) - \hat{t}_2 G_{D_r}(x_1, x_2)\left(\int_R \phi_1\, dy\right)\Bigg] = 0, \end{aligned} \tag{3.6}$$

where $L_0\phi = \epsilon^2\phi_{yy} - \phi + 2w\phi$ and

$$\alpha_\epsilon = \left(\frac{1}{\epsilon\int_R w\,dy}\right) \quad \text{and} \quad \hat{t}_i = (\alpha_\epsilon)^{-1}t_i. \tag{3.7}$$

This system is the special case with $\lambda = 0$ of (4.7), (4.8) derived in section 4. To avoid doing this computation twice we have delayed it to section 4, where the more general case is considered.

Now, adding (3.5) and (3.6), we obtain

$$L_0(\phi_1+\phi_2) - w^2\left(\frac{2\int_R w(\phi_1+\phi_2)\,dy}{\int_R w^2\,dy}\right) = 0.$$

This implies by Theorem 1.4 of [15] that $\phi_1 = -\phi_2$, and, setting $\phi := \phi_1$, for ϕ we must have

$$L_0\phi - \frac{4}{4-c_0}\frac{w^2}{\int w^2\,dy}\int w\phi\,dy = \lambda\phi, \tag{3.8}$$

where $0 < c_0 < 2$ (compare (5.1) for $\lambda = 0$). Now by Theorem 1.4 of [15] we must have $\phi = 0$. This contradicts $\|\phi\|_{L^2(R)} = 1$. Therefore, (3.3) must be true.

By the closed range theorem it follows that the map L_{ϵ,x_1} is surjective. (The details are given, for example, in [8].) □

Based on this key result for the Liapunov–Schmidt reduction it is now fairly standard (see, for example, the works [8] and [16]) to derive that there exists a small $v \in H^2(\Omega_\epsilon)$ with $\int_\Omega v\frac{dw_1}{dx}\,dx = 0$ such that

$$S[t_1w_1 + v] = \beta\epsilon\frac{dw_1}{dx}.$$

This completes the *first* step.

We now turn to the *second* step. We have to show that $\beta = 0$ for a certain x_1. This amounts to showing that

$$\int_\Omega S[t_1w_1+v](x)\epsilon\frac{dw_1}{dx}\,dx = 0$$

for a certain x_1. Note that computing x_1 in fact means determining the locations of the spikes. To this end, we have to expand $S[t_1w_1+v](x_1+\epsilon y)$.

We compute

$$S[t_1w_1+v](x_1+\epsilon y) = t_1\left[\frac{cs_2(x_1+\epsilon y)t_1}{r(x_1+\epsilon y)} - 1\right]w_1^2(x_1+\epsilon y) + O(\epsilon^2).$$

Using (2.9), (2.10) and the expansions

$$G_D(x_1+\epsilon y, x_2) = G_D(x_1,x_2) + G_{D,x_1}(x_1,x_2)\epsilon y + O(\epsilon^2|y|^2)$$

and

$$G_D(x_1+\epsilon y, x_1) = G_D(x_1,x_1) - \frac{1}{2D}\epsilon|y| - \frac{1}{2}H_{D,x_1}(x_1,x_1)\epsilon y + O(\epsilon^2|y|^2),$$

where we have used (2.7), we get

$$\frac{cs_2(x_1+\epsilon y)t_1}{r(x_1+\epsilon y)} = \frac{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)}{G_{D_s}(x_1,-x_1)} \tag{3.9}$$

$$\times \frac{G_{D_s}(x_1,-x_1)+\frac{1}{2}G_{D_s,x_1}(x_1,-x_1)\epsilon y+O(\epsilon^2|y|^2)}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)-\epsilon|y|/(2D)+\frac{1}{2}(-H_{D_r,x_1}(x_1,x_1)+G_{D_r,x_1}(x_1,-x_1))\epsilon y}$$

$$= 1+\frac{G_{D_s,x_1}(x_1,-x_1)}{2G_{D_s}(x_1,-x_1)}\epsilon y - \frac{G_{D_r,x_1}(x_1,-x_1)-H_{D_r,x_1}(x_1,x_1)}{2[G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)]}\epsilon y + O(\epsilon^2 y^2)$$
$$+\,\text{even term in } y.$$

This implies

$$\int_\Omega S[w_1+v](x)\epsilon\frac{dw_1}{dx}\,dx$$

$$= \frac{1}{2}\left[\frac{G_{D_s,x_1}(x_1,-x_1)}{G_{D_s}(x_1,-x_1)} - \frac{G_{D_r,x_1}(x_1,-x_1)-H_{D_r,x_1}(x_1,x_1)}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)}\right]\epsilon y\int_R yw^2\frac{dw}{dy}\,dy+\epsilon^2 W_\epsilon(x_1),$$

where $W_\epsilon(x_1)=O(\epsilon)$, uniformly for $0\le x_1\le L$.

Using (2.6), we further compute

$$F(x_1) := \frac{G_{D_s,x_1}(x_1,-x_1)}{G_{D_s}(x_1,-x_1)} - \frac{G_{D_r,x_1}(x_1,-x_1)-H_{D_r,x_1}(x_1,x_1)}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)}$$

$$= -\theta_s\frac{\sinh 2\theta_s(L-x_1)}{\cosh^2\theta_s(L-x_1)} - \theta_r\frac{\sinh 2\theta_r x_1-\sinh 2\theta_r(L-x_1)}{\cosh\theta_r(L-x_1)[\cosh\theta_r(L-x_1)+\cosh\theta_r(L+x_1)]},$$

where $\theta = 1/\sqrt{D}$. We have to determine x_1 such that $F(x_1)=0$. Note that

$$F(0) = -\theta_s\frac{\sinh 2\theta_s L}{\cosh^2\theta_s L}+\theta_r\frac{\sinh 2\theta_r L}{2\cosh^2\theta_r L} > 0$$

if

$$\frac{\theta_s}{\theta_r} < \frac{1}{2}\frac{\tanh\theta_r L}{\tanh\theta_s L}. \tag{3.10}$$

The inequality (3.10) is satisfied if, for fixed L, θ_r is large compared to θ_s.

In the limit $L\to 0$ the condition (3.10) converges to $\frac{\theta_s}{\theta_r} < 1/\sqrt{2}$. In the limit $L\to\infty$, (3.10) gives $\frac{\theta_s}{\theta_r} < 1/2$. For general $L\in(0,\infty)$ we can write (3.10) as follows: $\frac{\theta_s}{\theta_r} < \alpha(L)$ with $\frac{1}{2} < \alpha(L) < \frac{1}{\sqrt{2}}$.

Going back to the original diffusion constants, the inequality (3.10) is equivalent to

$$\frac{D_s}{D_r} > 4\frac{\tanh^2\theta_s L}{\tanh^2\theta_r L}. \tag{3.11}$$

In the limit $L\to 0$, (3.11) gives $\frac{D_s}{D_r} > 2$ and, in the limit $L\to\infty$, we can write (3.11) as follows: $\frac{D_s}{D_r} > 4$.

For all $L \in (0, \infty)$ we can write (3.11) as follows: $\frac{D_s}{D_r} > \beta(L)$ for some continuous function $\beta(L) \in (2, 4)$.

Note that (3.11) holds if

$$\frac{D_s}{D_r} > 4. \tag{3.12}$$

This is not the optimal condition, but it is rather handy and easy to check.

On the other hand,

$$F(L/2) = -\theta_s \frac{\sinh \theta_s L}{\cosh^2(\theta_s L/2)} < 0.$$

By the intermediate value theorem, under the condition (3.11), there exists an $x_1 \in (0, L/2)$ such that $F(x_1) = 0$. There exists no such $x_1 \in [L/2, L)$, since the function F is negative in that interval.

Note that $F(L/2) \to 0$ as $\theta_s \to 0$. This implies that $x_1 \to L/2$ as $\theta_s \to 0$.

We now show that the zero $x_1 \in [0, L/2]$ of F is unique by proving that $F'(x_1) < 0$ for $x_1 \in (0, L/2)$ if

$$\frac{\theta_s}{\theta_r} < \frac{\tanh(\theta_r L/2)}{\sqrt{2}\tanh(\theta_s L/2)}. \tag{3.13}$$

We compute

$$F'(x_1) = 2\theta_s^2 \frac{1}{\cosh^2 \theta_s(L - x_1)} - \theta_r^2 \frac{1}{\cosh^2 \theta_r(L - x_1)}$$

$$- \theta_r^2 \frac{[\cosh \theta_r(L - x_1) + \cosh \theta_r(L + x_1)]^2 - [\sinh \theta_r(L - x_1) + \sinh \theta_r(L + x_1)]^2}{[\cosh \theta_r(L - x_1) + \cosh \theta_r(L + x_1)]^2}.$$

Therefore, taking into consideration only the first two terms and noting that the last term is negative, we have $F'(x_1) < 0$ if (3.13) holds, and in this case, the solution for x_1 is unique.

Note that (3.13) holds if $\frac{\theta_s}{\theta_r} < \frac{1}{\sqrt{2}}$ or, equivalently, $\frac{D_s}{D_r} > 2$.

Therefore (3.10) and (3.13) are both true if $\frac{\theta_s}{\theta_r} < \frac{1}{2}$ or, equivalently, $\frac{D_s}{D_r} > 4$.

Now for (3.13), since $F'(x_1) \neq 0$, a standard degree argument shows that for $\epsilon \ll 1$ there exists a unique x_1^ϵ depending on ϵ such that $\int_\Omega S[w_1 + v](x)\epsilon \frac{dw_1}{dx}\, dx = 0$. Further, $x_1^\epsilon \to x_1$ as $\epsilon \to 0$, where x_1 satisfies

$$\frac{G_{D_s, x_1}(x_1, -x_1)}{G_{D_s}(x_1, -x_1)} - \frac{G_{D_r, x_1}(x_1, -x_1) - H_{D_r, x_1}(x_1, x_1)}{G_{D_r}(x_1, x_1) + G_{D_r}(x_1, -x_1)} = 0.$$

Thus we have shown existence and at the same time located the positions of the spikes. We summarize this result in the following theorem.

Theorem 3.2. *There exist mutually exclusive, spiky steady states to* (1.1) *in* $(-L, L)$ *with Neumann boundary conditions such that*

$$g_1^\epsilon(x) = t_1^\epsilon w\left(\frac{x - x_1^\epsilon}{\epsilon}\right)(1 + O(\epsilon)), \quad g_2^\epsilon(x) = t_1^\epsilon w\left(\frac{x + x_1^\epsilon}{\epsilon}\right)(1 + O(\epsilon)) \tag{3.14}$$

with

$$t_1^\epsilon = \frac{1}{\epsilon \int_R w\, dy\, (G_{D_r}(x_1, x_1) + G_{D_r}(x_1, -x_1))} + O(1) \tag{3.15}$$

and $x_1^\epsilon \to x_1$ *as* $\epsilon \to 0$*, where*

$$\frac{G_{D_s,x_1}(x_1,-x_1)}{G_{D_s}(x_1,-x_1)} - \frac{G_{D_r,x_1}(x_1,-x_1) - H_{D_r,x_1}(x_1,x_1)}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,-x_1)} = 0. \tag{3.16}$$

If $D_s/D_r > 4$*, then* (3.16) *has a unique solution* $x_1 \in (0,L/2]$ *and no solution in* $(L/2,L]$*. Further,* $x_1 \to L/2$ *as* $\theta_s \to 0$*.*

Finally, we compute the equation for x_1 in the limit $L \to \infty$. In this limit, x_1 satisfies

$$\frac{\theta_s}{\theta_r} = \frac{e^{-2\theta_r x_1}}{1+e^{-2\theta_r x_1}} + O(e^{-CL})$$

for some $C > 0$ independent of x_1. This is equivalent to

$$e^{2|x_1|/\sqrt{D_r}} = \sqrt{\frac{D_s}{D_r}} - 1 + O(e^{-CL}). \tag{3.17}$$

This concludes our study of existence. In the following sections we consider the stability issue.

4. Stability I: The eigenvalue problem and the large eigenvalues. Now we study the (linearized) stability of this mutually exclusive steady state. To this end, we first derive the linearized operator around the steady state $(g_1^\epsilon, g_2^\epsilon, r^\epsilon, s_1^\epsilon, s_2^\epsilon)$ given in Theorem 3.2.

We perturb the steady state as follows:

$$g_1 = g_1^\epsilon + \phi_1^\epsilon e^{\lambda t}, \quad g_2 = g_2^\epsilon + \phi_2^\epsilon e^{\lambda t}, \quad r = r^\epsilon + \psi^\epsilon e^{\lambda t},$$

$$s_1 = s_1^\epsilon + \eta_1^\epsilon e^{\lambda t}, \quad s_2 = s_2^\epsilon + \eta_2^\epsilon e^{\lambda t}.$$

By linearization we obtain the following eigenvalue problem (dropping superscripts ϵ):

$$\begin{cases} \lambda_\epsilon \phi_1 = \epsilon^2 \phi_{1,xx} - \phi_1 + \dfrac{c\eta_2 g_1^2}{r} + \dfrac{2cs_2 g_1 \phi_1}{r} - \dfrac{cs_2 g_1^2 \psi}{r^2}, \\ \lambda_\epsilon \phi_2 = \epsilon^2 \phi_{2,xx} - \phi_2 + \dfrac{c\eta_1 g_2^2}{r} + \dfrac{2cs_1 g_2 \phi_2}{r} - \dfrac{cs_1 g_2^2 \psi}{r^2}, \\ \tau\lambda_\epsilon \psi = D_r \psi_{xx} - \psi + c\eta_2 g_1^2 + 2cs_2 g_1 \phi_1 + c\eta_1 g_2^2 + 2cs_1 g_2 \phi_2, \\ \tau\lambda_\epsilon \eta_1 = D_s \eta_{1,xx} - \eta_1 + \phi_1, \\ \tau\lambda_\epsilon \eta_2 = D_s \eta_{2,xx} - \eta_2 + \phi_2, \end{cases} \tag{4.1}$$

where all components belong to the space $H_N^2(\Omega)$.

We now analyze the case $\lambda_\epsilon \to \lambda_0 \neq 0$ (large eigenvalues). After rescaling and taking the limit $\epsilon \to 0$ in (4.1) and noting that ϕ_i converges locally in $H^2(-L/\epsilon, L/\epsilon)$, we get for the first two components, using the approximations of g_1 and g_2 given in Theorem 3.2:

$$\epsilon^2 \Delta \phi_1 - \phi_1 + \frac{2cs_2(x_1)t_1 w_1 \phi_1}{r(x_1)} - \frac{cs_2(x_1)t_1^2 w_1^2}{r^2(x_1)}\psi(x_1) + \frac{c\eta_2(x_1)t_1^2 w_1^2}{r(x_1)} = \lambda\phi_1, \tag{4.2}$$

$$\epsilon^2 \Delta \phi_2 - \phi_2 + \frac{2cs_1(x_2)t_2 w_2 \phi_2}{r(x_2)} - \frac{cs_1(x_2)t_2^2 w_2^2}{r^2(x_2)}\psi(x_2) + \frac{c\eta_2(x_2)t_2^2 w_2^2}{r(x_2)} = \lambda\phi_1. \tag{4.3}$$

Now, in (4.2) and (4.3) we calculate the terms $\psi(x)$ and $\eta_1(x)$ and $\eta_2(x)$, respectively. To get $\psi(x)$, using the Green function G_{D_r}, we solve the linear equation for ψ given by

$$D_r\psi_{xx} - \psi + 2cs_2t_1w_1\phi_1 + 2cs_1t_2w_2\phi_2 + c\eta_2t_1^2w_1^2 + c\eta_1t_2^2w_2^2 = 0,$$

where again for g_1 and g_2 we have used the asymptotic expansions of Theorem 3.2. For simplicity, we study the case $\tau = 0$. Then the stability result extends to small τ as well, since we know that $|\lambda_\epsilon| \le C$ for all eigenvalues such that $\lambda_\epsilon > -c_0$ for some small $c_0 > 0$, which can be shown by a simple argument based on quadratic forms. This gives

$$\begin{aligned}\psi(x) \sim &\left[2cs_2(x_1)t_1\epsilon\left(\int_R w\phi_1\,dy\right) + c\eta_2(x_1)t_1^2\epsilon\int_R w^2\,dy\right]G_{D_r}(x,x_1)\\ &+\left[2cs_1(x_2)t_2\epsilon\left(\int_R w\phi_2\,dy\right) + c\eta_1(x_2)t_2^2\epsilon\int_R w^2\,dy\right]G_{D_r}(x,x_2).\end{aligned} \tag{4.4}$$

Similarly, using G_{D_s}, we compute

$$\eta_1(x) \sim \epsilon G_{D_s}(x,x_1)\int_R \phi_1\,dy, \quad \eta_2(x) \sim \epsilon G_{D_s}(x,x_2)\int_R \phi_2\,dy. \tag{4.5}$$

Recalling from (2.5) and (2.9) that

$$s_1(x) \sim \epsilon t_1\left(\int_R w\,dy\right)G_{D_s}(x,x_1), \quad s_2(x) \sim \epsilon t_2\left(\int_R w\,dy\right)G_{D_s}(x,x_2),$$

we get from (4.4)

$$\begin{aligned}\psi(x)\sim&\left[2ct_1t_2\epsilon^2\left(\int_R w\,dy\right)\left(\int_R w\phi_1\,dy\right) + ct_1^2\epsilon^2\left(\int_R w\,dy\right)\int_R \phi_2\,dy\right]G_{D_s}(x_1,x_2)G_{D_r}(x,x_1)\\ &+\left[2ct_1t_2\epsilon^2\left(\int_R w\,dy\right)\left(\int_R w\phi_2\,dy\right) + ct_2^2\epsilon^2\left(\int_R w\,dy\right)\int_R \phi_1\,dy\right]G_{D_s}(x_1,x_2)G_{D_r}(x,x_2).\end{aligned} \tag{4.6}$$

Further, recall from (2.10) that

$$r(x) = ct_1t_2\epsilon^2\left(\int_R w\,dy\right)^2 G_{D_s}(x_1,x_2)(t_1G_{D_r}(x,x_1) + t_2G_{D_r}(x,x_2)) + O(\epsilon^3).$$

Substituting into (4.2), we get for the coefficient of $\int_R \phi_1\,dy$ on the r.h.s.

$$\begin{aligned}&-\frac{cs_2(x_1)t_1^2w_1^2}{r^2(x_1)}c\epsilon^2\left(\int_R w\,dy\right)t_2^2G_{D_s}(x_1,x_2)G_{D_r}(x_1,x_2) + O(\epsilon^2)\\ &= -\frac{w_1^2}{s_2(x_1)}\epsilon^2\left(\int_R w\,dy\right)t_2^2G_{D_s}(x_1,x_2)G_{D_r}(x_1,x_2) + O(\epsilon^2)\\ &= -\epsilon t_2w_1^2G_{D_r}(x_1,x_2) + O(\epsilon^2).\end{aligned}$$

Similarly, the coefficient for $\int_R \phi_2\,dy$ is calculated as

$$
\begin{aligned}
&-\frac{cs_2(x_1)t_1^2w_1^2}{r^2(x_1)}c\epsilon^2\left(\int_R w^2\,dy\right)t_1^2G_{D_s}(x_1,x_2)G_{D_r}(x_1,x_1)+\frac{c\epsilon G_{D_s}(x_1,x_2)t_1^2w_1^2}{r(x_1)}+O(\epsilon^2)\\
&=-\frac{w_1^2}{s_2(x_1)}\epsilon^2\left(\int_R w^2\,dy\right)t_1^2G_{D_s}(x_1,x_2)G_{D_r}(x_1,x_1)+\frac{w_1^2}{s_2(x_1)}\epsilon t_1G_{D_s}(x_1,x_2)+O(\epsilon^2)\\
&\quad=-\frac{\epsilon t_1^2w_1^2}{t_2}G_{D_r}(x_1,x_1)+\frac{t_1}{t_2\int_R w\,dy}w_1^2+O(\epsilon^2)=\epsilon t_1w_1^2G_{D_r}(x_1,x_2)+O(\epsilon^2).
\end{aligned}
$$

Here we have used (2.14). Then (4.2) gives the nonlocal eigenvalue problem (NLEP)

$$
\begin{aligned}
&L_0\phi_1-\frac{1}{\int_R w\,dy}\Bigg[2\hat{t}_1G_{D_r}(x_1,x_1)\left(\int_R w\phi_1\,dy\right)+2\hat{t}_1G_{D_r}(x_1,x_2)\left(\int_R w\phi_2\,dy\right)\\
&\qquad+\hat{t}_2G_{D_r}(x_1,x_2)\left(\int_R \phi_1\,dy\right)-\hat{t}_1G_{D_r}(x_1,x_2)\left(\int_R \phi_2\,dy\right)\Bigg]=\lambda\phi_1,
\end{aligned}
\tag{4.7}
$$

where $L_0\phi=\epsilon^2\phi_{yy}-\phi+2w\phi$ and $\hat{t}_i$ has been defined in (3.7). In the same way, for (4.3) we obtain

$$
\begin{aligned}
&L_0\phi_2-\frac{1}{\int_R w\,dy}\Bigg[2\hat{t}_2G_{D_r}(x_2,x_2)\left(\int_R w\phi_2\,dy\right)+2\hat{t}_2G_{D_r}(x_1,x_2)\left(\int_R w\phi_1\,dy\right)\\
&\qquad+\hat{t}_1G_{D_r}(x_1,x_2)\left(\int_R \phi_2\,dy\right)-\hat{t}_2G_{D_r}(x_1,x_2)\left(\int_R \phi_1\,dy\right)\Bigg]=\lambda\phi_2,
\end{aligned}
\tag{4.8}
$$

where $\phi_1,\phi_2\in H^2(R)$. Set $\phi=(\phi_1,\phi_2)$ and denote by $L\phi$ the left-hand sides (l.h.s.) of (4.7) and (4.8), respectively.

Then, writing (4.7) and (4.8) in matrix notation, we have following the vectorial NLEP:

$$
L\phi=\Delta\phi-\phi+2w\phi-\left[\mathcal{B}\int_R \phi\,dy+2\mathcal{C}\left(\int_R w\phi\,dy\right)\right]\left(\int_R w\,dy\right)^{-1}w^2,
$$

where

$$
\mathcal{B}=G_{D_r}(x_1,x_2)\begin{pmatrix}\hat{t}_2 & -\hat{t}_1\\ -\hat{t}_2 & \hat{t}_1\end{pmatrix}=\frac{G_{D_r}(x_1,x_2)}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,x_2)}\begin{pmatrix}1 & -1\\ -1 & 1\end{pmatrix}
\tag{4.9}
$$

and

$$
\begin{aligned}
\mathcal{C}&=\begin{pmatrix}\hat{t}_1G_{D_r}(x_1,x_1) & \hat{t}_1G_{D_r}(x_1,x_2)\\ \hat{t}_2G_{D_r}(x_1,x_2) & \hat{t}_2G_{D_r}(x_2,x_2)\end{pmatrix}\\
&=\frac{1}{G_{D_r}(x_1,x_1)+G_{D_r}(x_1,x_2)}\begin{pmatrix}G_{D_r}(x_1,x_1) & G_{D_r}(x_1,x_2)\\ G_{D_r}(x_1,x_2) & G_{D_r}(x_2,x_2)\end{pmatrix}.
\end{aligned}
\tag{4.10}
$$

Here we have used that (2.14), (2.15) imply

$$
\hat{t}_1G_{D_r}(x_1,x_1)+\hat{t}_2G_{D_r}(x_1,x_2)=1,\qquad \hat{t}_1G_{D_r}(x_1,x_2)+\hat{t}_2G_{D_r}(x_2,x_2)=1
\tag{4.11}
$$

and therefore

$$\hat{t}_i = \frac{G_{D_r}(x_{3-i}, x_{3-i}) - G_{D_r}(x_1, x_2)}{G_{D_r}(x_1, x_1)G_{D_r}(x_2, x_2) - (G_{D_r}(x_1, x_2))^2}, \quad i = 1, 2. \tag{4.12}$$

In the special case when $G_{D_r}(x_1, x_1) = G_{D_r}(x_2, x_2)$ we have

$$\hat{t}_1 = \hat{t}_2 = \frac{1}{G_{D_r}(x_1, x_1) + G_{D_r}(x_1, x_2)}. \tag{4.13}$$

Now, adding (4.7) and (4.8), we obtain

$$L_0(\phi_1 + \phi_2) - w^2 \left(\frac{2\int_R w(\phi_1 + \phi_2)\, dy}{\int_R w^2\, dy} \right) = \lambda(\phi_1 + \phi_2),$$

which implies by Theorem 1.4 of [15] that $\phi_1 + \phi_2 = 0$ if $\mathrm{Re}(\lambda_0) \geq 0$. So we set $\phi_2 = -\phi_1 = -\phi$.

From (4.7), we obtain a scalar NLEP for ϕ,

$$L_0\phi - \frac{w^2}{\int_R w^2\, dy} \left[c_0 \int_R w\phi\, dy + d_0 \int_R \phi\, dy \right] = \lambda\phi, \tag{4.14}$$

where

$$c_0 = \frac{2(G_{D_r}(x_1, x_1) - G_{D_r}(x_1, x_2))}{G_{D_r}(x_1, x_1) + G_{D_r}(x_1, x_2)}, \quad d_0 = \frac{2G_{D_r}(x_1, x_2)}{G_{D_r}(x_1, x_1) + G_{D_r}(x_1, x_2)}. \tag{4.15}$$

Note that $0 < c_0 < 2$ and $0 < d_0 < 1$.

In the following section we study the NLEP (4.14). It determines the stability or instability of the large eigenvalues of (4.1) if $0 < \epsilon < \epsilon_0$ for a suitably chosen ϵ_0. By our analysis, instabilities for small $\epsilon > 0$ imply instabilities for $\epsilon = 0$. On the other hand, by an argument of Dancer [2], an instability for $\epsilon = 0$ also gives an instability for small $\epsilon > 0$.

Note that the NLEP problem here is quite different from those studied in [4], [5], [14], and [15].

In the next section we study this eigenvalue problem and complete the investigation of $O(1)$ eigenvalues for (4.1).

5. Stability II: A nonlocal eigenvalue problem. In this section, we study the NLEP (4.14) to determine whether or not there are large eigenvalues, i.e., eigenvalues of the order $O(1)$ as $\epsilon \to 0$, which destabilize the mutually exclusive spiky pattern. Integrating (4.14), we have

$$\int_R \phi\, dy = \frac{2 - c_0}{\lambda + 1 + d_0} \int_R w\phi\, dy.$$

Substituting this back into (4.14), we can eliminate the term $\int_R \phi\, dy$. This gives

$$L_0\phi - \mu(\lambda) \frac{w^2}{\int_R w^2\, dy} \int_R w\phi\, dy = \lambda\phi, \quad \text{where} \quad \mu(\lambda) = \frac{c_0\lambda + 2}{\lambda + 2 - c_0/2}. \tag{5.1}$$

Here we have used that $c_0 + 2d_0 = 2$. Applying inequality (2.22) of [18], we get

$$\frac{\int_R w^3\, dy}{\int_R w^2\, dy} |\mu(\lambda_0) - 1|^2 + \mathrm{Re}(\overline{\lambda_0}(\mu(\lambda_0) - 1)) \leq 0 \quad \text{if } \mathrm{Re}(\lambda_0) \geq 0. \tag{5.2}$$

Observe that after multiplying (2.1) by w and by w', respectively, and integrating, we get

$$\int_R w^3\,dy = \frac{6}{5}\int_R w^2\,dy.$$

So, assuming without loss of generality that $\lambda_0 = +\sqrt{-1}\lambda_I$, we get for the l.h.s. in (5.2) the following:

$$\frac{6}{5}\left|\frac{c_0\lambda_0+2}{\lambda_0+1+d_0}-1\right|^2 + \mathrm{Re}\left(\overline{\lambda_0}\left(\frac{c_0\lambda_0+2}{\lambda_0+1+d_0}-1\right)\right)$$

$$= \frac{6}{5}\frac{(c_0-1)^2|\lambda_0|^2+(1-d_0)^2}{|\lambda_0+1+d_0|^2} + \mathrm{Re}\left(\frac{(c_0|\lambda_0|^2+2\overline{\lambda_0})(\overline{\lambda_0}+1+d_0)}{|\lambda_0+1+d_0|^2}\right)$$

$$= \frac{|\lambda_0|^2[1.2(1-c_0)^2+(1+d_0)c_0-2]+1.2(1-d_0)^2}{|\lambda_0+1+d_0|^2}.$$

Thus if $1.2(1-c_0)^2+(1+d_0)c_0-2>0$, we have stability by (5.2). Using $c_0+2d_0=2$, we calculate that this is equivalent to $7c_0^2-4c_0-8>0$, which is true if $c_0>\frac{2}{7}(1+\sqrt{15})\approx 1.3923$.

We compute, using (2.6),

$$c_0 = \frac{2(\cosh\theta_r(L+x_1)-\cosh\theta_r(L-x_1))}{\cosh\theta_r(L+x_1)+\cosh\theta_r(L-x_1)}, \quad d_0 = \frac{2\cosh\theta_r(L-x_1)}{\cosh\theta_r(L+x_1)+\cosh\theta_r(L-x_1)}.$$

Note that for $L=\infty$ we have

$$c_0 = \frac{2(e^{2\theta_r|x_1|}-1)}{e^{2\theta_r|x_1|}+1}, \quad d_0 = \frac{2}{e^{2\theta_r|x_1|}+1}.$$

By (3.17), this implies $\sqrt{\frac{D_s}{D_r}}-1 = e^{2\theta_r|x_1|} > 5.5822$ and $\frac{D_s}{D_r} > 43.33$. If the last condition is valid, we have stability.

We summarize the stability result for the $O(1)$ eigenvalues as follows.

Theorem 5.1. *The mutually exclusive, spiky steady state given in Theorem* 3.2 *is linearly stable with respect to large eigenvalues $\lambda_\epsilon = O(1)$ for $\tau \ge 0$ and $\epsilon>0$ small enough if*

$$\frac{\cosh\theta_r(L+x_1)-\cosh\theta_r(L-x_1)}{\cosh\theta_r(L+x_1)+\cosh\theta_r(L-x_1)} > \frac{1}{7}(1+\sqrt{15}). \tag{5.3}$$

For $L=\infty$, this corresponds to

$$\frac{D_s}{D_r} > 43.33.$$

Now the study of the large eigenvalues is complete. In the next section we study the small eigenvalues.

6. Stability III: The small eigenvalues. Now we study the small eigenvalues for (6.3), namely those with $\lambda_\epsilon \to 0$ as $\epsilon \to 0$. In this section we summarize the main steps and results in several lemmas. Their proofs are rather technical, and we therefore delay them to the appendices.

For given $f \in L^2(\Omega)$, let $T_r[f]$ be the unique solution in $H^2_N(\Omega)$ of the problem

$$D_r \Delta(T_r[f]) - T_r[f] + \alpha_\epsilon f = 0. \tag{6.1}$$

In the same way, the operator T_s is defined with D_r replaced by D_s.

Let

$$\bar{g}_{\epsilon,1} = \hat{t}_1 w_{\epsilon,x_1^\epsilon} + \phi_{\epsilon,x_1^\epsilon}, \quad \bar{g}_{\epsilon,2} = \hat{t}_2 w_{\epsilon,x_2^\epsilon} + \phi_{\epsilon,x_2^\epsilon},$$

$$\bar{r}_\epsilon = cT_r[T_s[\bar{g}_{\epsilon,2}]\bar{g}^2_{\epsilon,1} + T_s[\bar{g}_{\epsilon,1}]\bar{g}^2_{\epsilon,2}], \quad \bar{s}_{\epsilon,1} = T_s[\bar{g}_{\epsilon,1}], \quad \bar{s}_{\epsilon,2} = T_s[\bar{g}_{\epsilon,2}], \tag{6.2}$$

where $\hat{t}_i$ has been defined in (3.7) After rescaling, the eigenvalue problem (4.1) becomes

(6.3)

$$\begin{cases} \lambda_\epsilon \phi_{\epsilon,1} = \epsilon^2 \Delta \phi_{\epsilon,1} - \phi_{\epsilon,1} + \dfrac{c\eta_{\epsilon,2}\bar{g}^2_{\epsilon,1}}{\bar{r}_\epsilon} + \dfrac{2c\bar{s}_{\epsilon,2}\bar{g}_{\epsilon,1}\phi_{\epsilon,1}}{\bar{r}_\epsilon} - \dfrac{c\bar{s}_{\epsilon,2}\bar{g}^2_{\epsilon,1}\psi_\epsilon}{\bar{r}^2_\epsilon}, \\ \lambda_\epsilon \phi_{\epsilon,2} = \epsilon^2 \Delta \phi_{\epsilon,2} - \phi_{\epsilon,2} + \dfrac{c\eta_{\epsilon,1}\bar{g}^2_{\epsilon,2}}{\bar{r}_\epsilon} + \dfrac{2c\bar{s}_{\epsilon,1}\bar{g}_{\epsilon,2}\phi_{\epsilon,2}}{\bar{r}_\epsilon} - \dfrac{c\bar{s}_{\epsilon,1}\bar{g}^2_{\epsilon,2}\psi_\epsilon}{\bar{r}^2_\epsilon}, \\ \tau\lambda_\epsilon \psi_\epsilon = D_r \Delta \psi_\epsilon - \psi_\epsilon + c\alpha_\epsilon \eta_{\epsilon,2}\bar{g}^2_{\epsilon,1} + 2c\alpha_\epsilon \bar{s}_{\epsilon,2}\bar{g}_{\epsilon,1}\phi_{\epsilon,1} + c\alpha_\epsilon \eta_{\epsilon,1}\bar{g}^2_{\epsilon,2} + 2c\alpha_\epsilon \bar{s}_{\epsilon,1}\bar{g}_{\epsilon,2}\phi_{\epsilon,2}, \\ \tau\lambda_\epsilon \eta_{\epsilon,1} = D_s \Delta \eta_{\epsilon,1} - \eta_{\epsilon,1} + \alpha_\epsilon \phi_{\epsilon,1}, \\ \tau\lambda_\epsilon \eta_{\epsilon,2} = D_s \Delta \eta_{\epsilon,2} - \eta_{\epsilon,2} + \alpha_\epsilon \phi_{\epsilon,2}, \end{cases}$$

where all functions are in $H^2_N(\Omega)$ and α_ϵ has been defined in (3.7).

For simplicity, we set $\tau = 0$. Since $\tau\lambda_\epsilon \ll 1$ the results in this section are also valid for τ finite. The case of general $\tau > 0$ can be treated as in [18]. We will see that the small eigenvalues are of the order $O(\epsilon^2)$. To compute them, we will need to expand the eigenfunction up to the order $O(\epsilon)$ term.

Let us define

$$\tilde{g}_{\epsilon,j}(x) = \chi\left(\frac{x - x_j^\epsilon}{r_0}\right)\bar{g}_{\epsilon,j}(x), \quad j = 1, 2, \tag{6.4}$$

where $\chi(x)$ is a smooth cut-off function such that $\chi(x) = 1$ for $|x| < 1$ and $\chi(x) = 0$ for $|x| > 2$. Further,

$$r_0 = \frac{1}{10}\left(1 + x_2, 1 - x_1, \frac{1}{2}|x_1 - x_2|\right). \tag{6.5}$$

In a similar way as in section 3, we define approximate kernel and cokernel, but in contrast now we can use the exact solution given in Theorem 3.2:

$$\mathcal{K}^{new}_{\epsilon,\mathbf{x}^\epsilon} := \text{span}\left\{\epsilon\frac{d}{dx}\tilde{g}_{\epsilon,1}\right\} \oplus \text{span}\left\{\epsilon\frac{d}{dx}\tilde{g}_{\epsilon,2}\right\} \subset (H^2_N(\Omega_\epsilon))^2,$$

$$\mathcal{C}^{new}_{\epsilon,\mathbf{x}^\epsilon} := \text{span}\left\{\epsilon\frac{d}{dx}\tilde{g}_{\epsilon,1}\right\} \oplus \text{span}\left\{\epsilon\frac{d}{dx}\tilde{g}_{\epsilon,2}\right\} \subset (L^2(\Omega_\epsilon))^2,$$

where $\mathbf{x}^\epsilon = (x_1^\epsilon, x_2^\epsilon)$ and $\Omega_\epsilon = \left(-\frac{L}{\epsilon}, \frac{L}{\epsilon}\right)$.

Then it is easy to see that

$$\bar{g}_i(x) = \tilde{g}_{\epsilon,i}(x) + \text{e.s.t.}, \quad i = 1, 2, \tag{6.6}$$

where e.s.t. denotes exponentially small terms.

Note that, by Theorem 3.2, $\tilde{g}_{\epsilon,j}(x) \sim \hat{t}_j w\left(\frac{x-x_j^\epsilon}{\epsilon}\right)$ in $H^2_{loc}(\Omega_\epsilon)$ and $\tilde{g}_{\epsilon,j}$ satisfies

$$\epsilon^2 \Delta \tilde{g}_{\epsilon,j} - \tilde{g}_{\epsilon,j} + \frac{(\tilde{g}_{\epsilon,j})^2 \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} + \text{e.s.t.} = 0, \quad j = 1, 2.$$

Thus $\tilde{g}_{\epsilon,j}^{'} := \frac{d\tilde{g}_{\epsilon,j}}{dx}$ satisfies

$$\epsilon^2 \Delta \tilde{g}_{\epsilon,j}^{'} - \tilde{g}_{\epsilon,j}^{'} + \frac{2c\tilde{g}_{\epsilon,j}\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\tilde{g}_{\epsilon,j}^{'} + \frac{c\tilde{g}_{\epsilon,j}^2}{\bar{r}_\epsilon}\bar{s}_{\epsilon,3-j}^{'} - \frac{c\tilde{g}_{\epsilon,j}^2\bar{s}_{\epsilon,3-j}}{(\bar{r}_\epsilon)^2}\bar{r}_\epsilon^{'} + \text{e.s.t.} = 0. \tag{6.7}$$

Let us now decompose

$$\phi_{\epsilon,j} = \epsilon a_j^\epsilon \tilde{g}_{\epsilon,j}^{'} + \phi_{\epsilon,j}^\perp, \quad j = 1, 2, \tag{6.8}$$

with complex numbers a_j^ϵ, where the factor ϵ is for scaling purposes, to achieve that a_j^ϵ is of order $O(1)$, and

$$\phi_\epsilon^\perp = (\phi_{\epsilon,1}^\perp, \phi_{\epsilon,2}^\perp) \in (\mathcal{K}_{\epsilon,\mathbf{x}^\epsilon}^{new})^\perp,$$

where orthogonality is taken for the scalar product of the product space $(L^2(\Omega_\epsilon))^2$. Note that, by definition,

$$\phi_\epsilon = (\phi_{\epsilon,1}, \phi_{\epsilon,2}) \in \mathcal{K}_{\epsilon,\mathbf{x}^\epsilon}^{new}.$$

Suppose that $\|\phi_\epsilon\|_{H^2(\Omega_\epsilon)} = 1$. Then we need to have $|a_j^\epsilon| \leq C$.

Similarly, we decompose

$$\psi_\epsilon = \epsilon \sum_{j=1}^{2} a_j^\epsilon \psi_{\epsilon,j} + \psi_\epsilon^\perp, \quad \eta_{\epsilon,j} = \epsilon a_j^\epsilon \eta_{\epsilon,j}^0 + \eta_{\epsilon,j}^\perp, \quad j = 1, 2, \tag{6.9}$$

where $\psi_{\epsilon,j}$ satisfies

$$D_r \Delta \psi_{\epsilon,j} - \psi_{\epsilon,j} + 2\alpha_\epsilon c\tilde{g}_{\epsilon,j}\tilde{g}_{\epsilon,j}^{'}\bar{s}_{\epsilon,3-j} + \alpha_\epsilon c\tilde{g}_{\epsilon,3-j}^2 \eta_{\epsilon,j}^0 = 0, \tag{6.10}$$

$\eta_{\epsilon,i}^0$ is given by

$$D_s \Delta \eta_{\epsilon,i}^0 - \eta_{\epsilon,i}^0 + \alpha_\epsilon \tilde{g}_{\epsilon,i}^{'} = 0, \tag{6.11}$$

$\psi_\epsilon^\perp$ satisfies

$$D_r \Delta \psi_\epsilon^\perp - \psi_\epsilon^\perp + 2\alpha_\epsilon\, c\tilde{g}_{\epsilon,1}\bar{s}_{\epsilon,2}\phi_{\epsilon,1}^\perp + \alpha_\epsilon\, c\tilde{g}_{\epsilon,1}^2\eta_{\epsilon,2}^\perp + 2\alpha_\epsilon\, c\tilde{g}_{\epsilon,2}\bar{s}_{\epsilon,1}\phi_{\epsilon,2}^\perp + \alpha_\epsilon\, c\tilde{g}_{\epsilon,2}^2\eta_{\epsilon,1}^\perp = 0, \tag{6.12}$$

and, finally, $\eta_i^\perp$ is given by

$$D_s \Delta \eta_{\epsilon,i}^\perp - \eta_{\epsilon,i}^\perp + \alpha_\epsilon \phi_{\epsilon,i}^\perp = 0. \tag{6.13}$$

Substituting the decompositions of $\phi_{\epsilon,i}$, ψ_ϵ, and $\eta_{\epsilon,i}$ into (6.3), we have

$$\begin{aligned} &\epsilon c\left(a_j^\epsilon \frac{(\tilde{g}_{\epsilon,j})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon^2}\bar{r}_\epsilon^{'} - \sum_{k=1}^{2} a_k^\epsilon \frac{(\tilde{g}_{\epsilon,j})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon^2}\psi_{\epsilon,k}\right) \\ &- \epsilon c\left(a_j^\epsilon \frac{(\tilde{g}_{\epsilon,j})^2}{\bar{r}_\epsilon}\bar{s}_{\epsilon,3-j}^{'} - a_{3-j}^\epsilon \frac{(\tilde{g}_{\epsilon,j})^2}{\bar{r}_\epsilon}\eta_{\epsilon,3-j}^0\right) \\ &+ \epsilon^2 \Delta \phi_{\epsilon,j}^\perp - \phi_{\epsilon,j}^\perp + \frac{2c\tilde{g}_{\epsilon,j}\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\phi_{\epsilon,j}^\perp - \frac{c\tilde{g}_{\epsilon,j}^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon^2}\psi_\epsilon^\perp + \frac{c\tilde{g}_{\epsilon,j}^2}{\bar{r}_\epsilon}\eta_{\epsilon,3-j}^\perp - \lambda_\epsilon\phi_{\epsilon,j}^\perp + \text{e.s.t.} \\ &= \lambda_\epsilon \epsilon a_j^\epsilon \tilde{g}_{\epsilon,j}^{'}, \quad j = 1, 2, \end{aligned} \tag{6.14}$$

since

$$\epsilon^2\Delta\tilde{g}_{\epsilon,j}^{'} - \tilde{g}_{\epsilon,j}^{'} + \frac{2c\tilde{g}_{\epsilon,j}\bar{s}_{3-j,\epsilon}}{\bar{r}_\epsilon}\tilde{g}_{\epsilon,j}^{'} + \text{e.s.t.} = 0.$$

Multiplying both sides of (6.14) for $j = 1, 2$ by $\tilde{g}_{\epsilon,l}^{'}$ for $l = 1, 2$ and integrating over $(-L, L)$, we obtain

$$\text{r.h.s. of (6.14)} = \lambda_\epsilon a_j^\epsilon \epsilon \int_{-L}^{L} \tilde{g}_{\epsilon,j}^{'}\tilde{g}_{\epsilon,l}^{'}\,dx = \lambda_\epsilon \delta_{jl} a_l^\epsilon (\hat{t}_l)^2 \int_R (w^{'}(y))^2\,dy\,(1+o(1)) \tag{6.15}$$

and

$$\begin{aligned}
\text{l.h.s. of (6.14)} &= c\epsilon \sum_{k=1}^{2} a_k^\epsilon \delta_{jl} \int_{-L}^{L} \frac{(\tilde{g}_{\epsilon,j})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon^2}\left(\delta_{jk}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)\tilde{g}_{\epsilon,l}^{'}\,dx \\
&\quad + c\epsilon \sum_{k=1}^{2} a_k^\epsilon \delta_{jl} \int_{-L}^{L} \frac{(\tilde{g}_{\epsilon,j})^2}{\bar{r}_\epsilon}\left(\delta_{j,3-k}\eta_{\epsilon,3-j}^{0} - \delta_{j,k}\bar{s}_{\epsilon,3-j}^{'}\right)\tilde{g}_{\epsilon,l}^{'}\,dx \\
&\quad + c\delta_{jl} \int_{-L}^{L} \frac{(\tilde{g}_{\epsilon,l})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\left(\frac{\bar{r}_\epsilon^{'}}{\bar{r}_\epsilon} - \frac{\bar{s}_{\epsilon,3-j}^{'}}{\bar{s}_{\epsilon,3-j}}\right)\phi_{\epsilon,j}^{\perp}\,dx \\
&\quad + c\delta_{jl} \int_{-L}^{L} \frac{(\tilde{g}_{\epsilon,j})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\left(\frac{\eta_{\epsilon,3-j}^{\perp}}{\bar{s}_{\epsilon,3-j}} - \frac{\psi_\epsilon^{\perp}}{\bar{r}_\epsilon}\right)\tilde{g}_{\epsilon,l}^{'}\,dx + o(\epsilon^2)
\end{aligned}$$

$$= J_{1,l} + J_{2,l} + J_{3,l} + J_{4,l} := J_l, \tag{6.16}$$

where $J_{i,l}$, $i = 1, \ldots, 4$, are defined by the last equality. The following is the key lemma for the asymptotic behavior of the small eigenvalues.

Lemma 6.1. *We have*

$$\begin{aligned}
&J_l \\
&= -\epsilon^2\left(\int_R \frac{1}{3}w^3\,dy\right)\sum_{k=1}^{2} a_k^\epsilon \Bigg\{\Bigg\{-\hat{t}_l\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)\right) + \hat{t}_{3-l}\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon))\Bigg\} \\
&\qquad - \nabla_{x_l^\epsilon}\left(\frac{\delta_{k,3-l}\nabla_{x_{3-l}^\epsilon}G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}\right) \\
&\quad + \Bigg\{(\nabla_{x_k^\epsilon}\hat{t}_l(x_1^\epsilon, x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon, x_l^\epsilon) + (\nabla_{x_k^\epsilon}\hat{t}_{3-l}(x_1^\epsilon, x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\Bigg\}\Bigg\} + o(\epsilon^2).
\end{aligned} \tag{6.17}$$

Lemma 6.1 follows from the following series of lemmas.

Lemma 6.2. *We have*

$$\eta_{\epsilon,k}^{0}(x_{3-k}^\epsilon) = \hat{t}_k\nabla_{x_k^\epsilon}G_{D_s}(x_{3-k}^\epsilon, x_k^\epsilon) + O(\epsilon). \tag{6.18}$$

Lemma 6.3. *We have*

$$\bar{s}_{\epsilon,k}^{'}(x_{3-k}^\epsilon) = \hat{t}_k\nabla_{x_{3-k}^\epsilon}G_{D_s}(x_{3-k}^\epsilon, x_k^\epsilon) + O(\epsilon). \tag{6.19}$$

LEMMA 6.4. *For $k, l = 1, 2$ we have*

$$\begin{aligned}\left(\delta_{kl}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)(x_l^\epsilon) = c\hat{t}_1\hat{t}_2\Big\{ & -\hat{t}_l \nabla_{x_k^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) \\ & + \hat{t}_{3-l}\nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) \\ & + \frac{1}{2\sqrt{D_r}}\hat{t}_l \nabla_{x_k^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\Big\} + O(\epsilon).\end{aligned} \tag{6.20}$$

Similar to Lemma 6.4, we get the next claim.

LEMMA 6.5. *For $k, l = 1, 2$ we have*

$$\begin{aligned}& \left(\delta_{kl}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)(x_l^\epsilon + \epsilon y) - \left(\delta_{kl}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)(x_l^\epsilon) \\ & = \epsilon y c\hat{t}_1\hat{t}_2\Big\{ - \hat{t}_l \nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) \\ & \qquad + \hat{t}_{3-l}\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) \\ & \qquad + \frac{1}{2\sqrt{D_r}}\hat{t}_l \nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\Big\} + O(\epsilon^2).\end{aligned} \tag{6.21}$$

Lemma 6.1 will be shown in Appendix A, proving Lemmas 6.2–6.5 first.

After obtaining the asymptotic behavior of the small eigenvalues, our next goal is to study their stability.

Combining Lemma 6.1 with (6.15) and (6.16), the small eigenvalues λ^ϵ are given by the following two-dimensional eigenvalue problem, where $(a_1^\epsilon, a_2^\epsilon)$ are the corresponding eigenvectors:

$$\begin{aligned}& -\epsilon^2\hat{t}_l\left(\int_R \frac{1}{3}w^3\,dy\right)\sum_{k=1}^2 a_k^\epsilon\Bigg\{\Big\{-\hat{t}_l\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)\right) + \hat{t}_{3-l}\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\Big\} \\ & \qquad\qquad - \nabla_{x_l^\epsilon}\left(\frac{\delta_{k,3-l}\nabla_{x_{3-l}^\epsilon}G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}\right) \\ & + \Big\{(\nabla_{x_k^\epsilon}\hat{t}_l(x_1^\epsilon, x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon, x_l^\epsilon) + (\nabla_{x_k^\epsilon}\hat{t}_{3-l}(x_1^\epsilon, x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\Big\}\Bigg\} + o(\epsilon^2) \\ & \qquad = \lambda_\epsilon\delta_{jl}a_l^\epsilon(\hat{t}_l)^2\int_R (w^{'}(y))^2\,dy\,(1 + o(1)).\end{aligned} \tag{6.22}$$

From (6.22) it follows that the eigenvectors $(a_1^0, a_2^0) = \lim_{\epsilon\to 0}(a_1^\epsilon, a_2^\epsilon)$ satisfy $(a_1^0, a_2^0) = (1, -1)$ or $(a_1^0, a_2^0) = (1, 1)$, up to a constant factor.

For the eigenvector $(a_1^0, a_2^0) = (1, -1)$, the computations of the eigenvalue λ_1^ϵ are similar to those given in section 3. We get

$$\lambda_1^\epsilon = C_3\epsilon^2 M'(x_1^\epsilon) + o(\epsilon^2),$$

where

$$M(x) = -2\theta_s\tanh\theta_s(L - x) + \theta_r\tanh\theta_r(L - x) + \theta_r\frac{\sinh\theta_r(L - x) - \sinh\theta_r(L + x)}{\cosh\theta_r(L - x) + \cosh\theta_r(L + x)}$$

and

$$C_3 = \frac{1}{3\hat{t}_l} \frac{\int_R w^3\, dy}{\int_R (w')^2\, dy} > 0. \tag{6.23}$$

This implies

$$\begin{aligned} M^{'}(x) = {} & \frac{2\theta_s^2}{\cosh^2 \theta_s(L-x)} - \frac{\theta_r^2}{\cosh^2 \theta_r(L-x)} \\ & - \theta_r^2 \left(1 - \frac{[\sinh \theta_r(L-x) - \sinh \theta_r(L+x)]^2}{[\cosh \theta_r(L-x) - \cosh \theta_r(L+x)]^2} \right). \end{aligned}$$

Obviously, $M'(x) < 0$ if $\theta_s = 0$ or if θ_s is small compared to θ_r. A simple sufficient condition is obtained by taking into account the first two terms of $M'(x)$ which has been derived in section 3 and is given by (3.13). Recall that (3.13) holds if $D_s/D_r > 4$.

If $D_s/D_r > 4$, the eigenvalue λ_1^ϵ has negative real part.

Now we consider the eigenvalue λ_2^ϵ with eigenvector such that $\lim_{\epsilon\to 0}(a_1^\epsilon, a_2^\epsilon) = (1,1)$. We have the following result.

Lemma 6.6. *Suppose that* λ_2^ϵ *is the eigenvalue with eigenvector* $\lim_{\epsilon\to 0}(a_1^\epsilon, a_2^\epsilon) = (1,1)$. *Then we have*

$$\lambda_2^\epsilon = C_3 \epsilon^2 P(x_1^\epsilon, x_2^\epsilon) + o(\epsilon^2), \quad \textit{where } C_3 > 0 \textit{ has been defined in } (6.23), \tag{6.24}$$

and

$$\begin{aligned} P(x_1^\epsilon, x_2^\epsilon) = (\nabla_{x_1^\epsilon} + \nabla_{x_2^\epsilon}) \Bigg\{ & \frac{(\nabla_{x_1^\epsilon} - \nabla_{x_2^\epsilon}) G_{D_s}(x_1^\epsilon, x_2^\epsilon)}{G_{D_s}(x_1^\epsilon, x_2^\epsilon)} \\ & - \hat{t}_1^\epsilon(x_1^\epsilon, x_2^\epsilon)(\nabla_{x_1^\epsilon} - \nabla_{x_2^\epsilon}) H_{D_r}(x_1^\epsilon, x_1^\epsilon) - \hat{t}_2^\epsilon(x_1^\epsilon, x_2^\epsilon)(\nabla_{x_1^\epsilon} - \nabla_{x_2^\epsilon}) H_{D_r}(x_1^\epsilon, x_1^\epsilon) \Bigg\}. \end{aligned}$$

We have $P(x_1^\epsilon, x_2^\epsilon) \le 0$ *with equality if and only if* $x_1^\epsilon = x_2^\epsilon = 0$.

Lemma 6.6 will be proved in Appendix B.

By the argument of Dancer [2] the eigenvalue problem (6.22) captures all converging sequences of small eigenvalues λ^ϵ, and so λ_1^ϵ and λ_2^ϵ are all $o(1)$ eigenvalues for ϵ small enough. Therefore we have the following main result on $o(1)$ eigenvalues.

Theorem 6.7. *Suppose* $D_s/D_r > 4$ *and* $\lim_{\epsilon\to 0} x_1^\epsilon = x_1 \neq 0$. *The mutually exclusive, spiky steady state given in Theorem* 3.2 *is linearly stable with respect to small eigenvalues* $\lambda_\epsilon = o(1)$ *if* $\tau \ge 0$ *and* $\epsilon > 0$ *are both small enough. More precisely, we have* $Re(\lambda_\epsilon) \le c\epsilon^2$ *for some* $c > 0$ *independent of* ϵ *and* τ.

7. Numerical simulations. For the simulations we use the domain $\Omega = (-1, 1)$ and Neumann boundary conditions for all components. The constants in the five-component Meinhardt–Gierer system are chosen as follows:

$$\epsilon^2 = .001, \quad D_r = .1, \quad D_s = 1, \quad c = 1, \quad \tau = 1.$$

The graphs in Figure 1 show the numerically obtained long-term limit of the five components g_1, g_2, r, s_1, s_2, i.e., the state at $t = 3{,}000$. After that the solution is numerically stable and does not change anymore. This confirms the analytical result

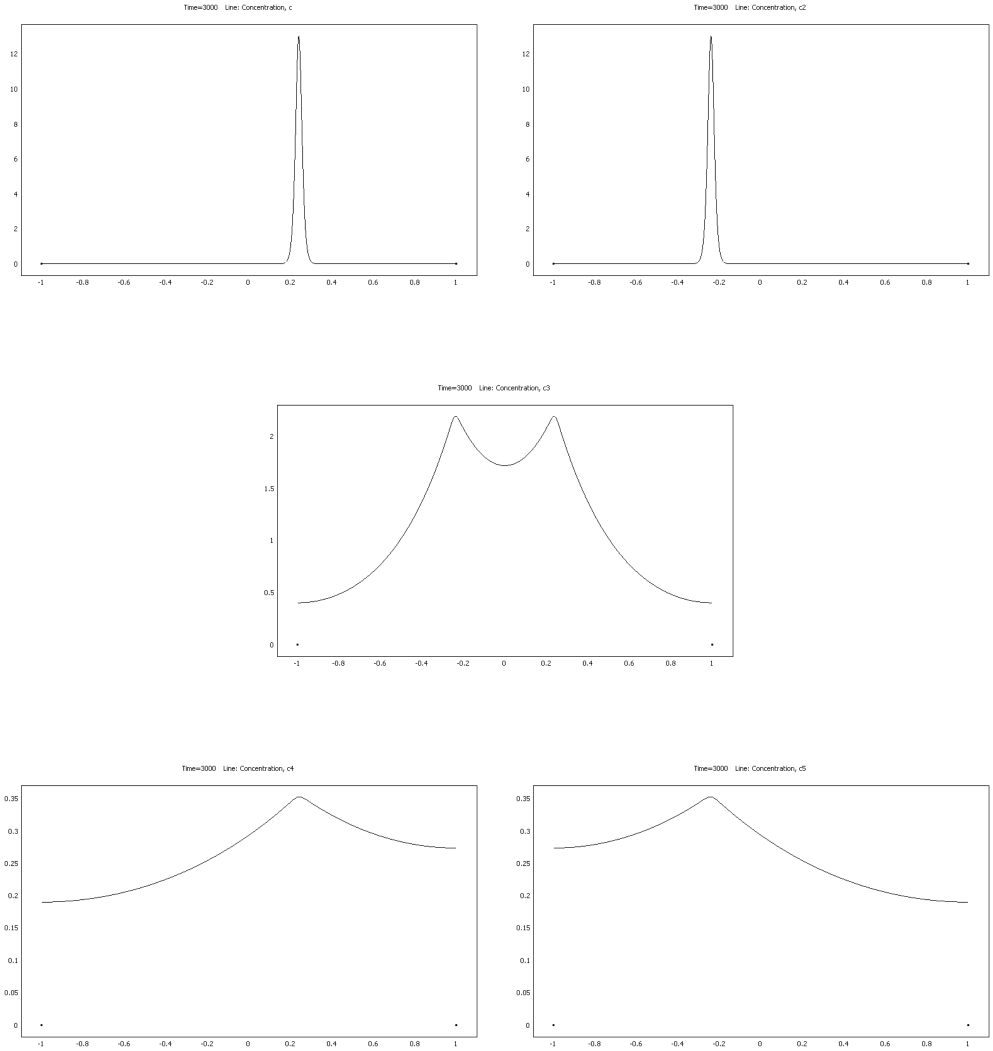

FIG. 1. *The stable, mutually exclusive, two-spike steady state. The five components g_1, g_2, r, s_1, s_2 have been plotted to highlight the interactions between them.*

that the steady state with two mutually exclusive spikes for the two activators which are located in different positions is stable.

Our simulations support the conjecture that the spikes are not only linearly stable as steady states but that, at least locally, they are also dynamically stable for the parabolic reaction-diffusion system.

The choice of constants for the numerical simulations has been motivated by the analysis. In particular, D_r has to be rather small compared to D_s by the stability result in section 4. On the other hand, D_r cannot be too small since otherwise by the results in section 3 the distance between the spikes becomes very large and there is no such solution on the interval $(-1, 1)$. So the parameters have to be chosen very carefully, and without any analytical results it would be very hard to find the parameter range for which stable mutually exclusive spikes exist.

Figure 1 shows that the inhibitor r has two peaks which are near the peaks of the local activators g_1 and g_2. The profile of the peaks of r is "smoother" than for those of the local activators. The lateral activator s_i has a peak near the peak of g_i, and its profile again is smoother than the latter.

We expect Hopf bifurcation and oscillating spikes to occur for sufficiently large tau. We analyzed only the case $\tau = 0$ and did not observe oscillations numerically for $\tau = 1$. The instabilities of the spikes which we encountered in the numerical calculations were (i) disappearance of spikes when their amplitudes becomes unstable (related to large eigenvalues)—this happens if the ratio of the diffusion constants $\frac{D_s}{D_r}$ is too small, and (ii) movement of the spikes to the boundary or towards each other when their positions became unstable (related to small eigenvalues)—this occurs if D_r is too small.

For numerical simulations with very large τ we expect oscillations to occur.

Appendix A. Proof of Lemma 6.1. In this appendix we prove Lemma 6.1 in a sequence of lemmas. First we introduce some notation.

Using the notation of (3.7), we introduce matrix notation

$$e = (1,1)^T, \quad t = \left(\hat{t}_1, \hat{t}_2\right)^T, \quad \nabla_{x_i}\hat{t} = \left(\nabla_{x_i}\hat{t}_1, \nabla_{x_i}\hat{t}_2\right)^T, \quad i = 1,2,$$

$$\mathcal{G}_{ij} = \left(\ G(x_i, x_j)\ \right), \quad i,j = 1,2, \quad \nabla_{x_i}\mathcal{G}_{kl} = \left(\ \nabla_{x_i} G(x_k, x_l)\ \right), \quad i,j,k = 1,2,$$

from which we get

$$\left\{\begin{array}{l} e = \mathcal{G}\hat{t}, \\ 0 = \left(\nabla_{x_1}\mathcal{G}\right)\hat{t} + \mathcal{G}\left(\nabla_{x_1}\hat{t}\right), \\ 0 = \left(\nabla_{x_2}\mathcal{G}\right)\hat{t} + \mathcal{G}\left(\nabla_{x_2}\hat{t}\right). \end{array}\right. \tag{A.1}$$

The system (A.1) has a unique solution $(\hat{t}, \nabla_{x_1}\hat{t}, \nabla_{x_2}\hat{t})$ since $\det(\mathcal{G}) \neq 0$, which can be written as follows:

$$\hat{t} = \mathcal{G}^{-1}e, \quad \nabla_{x_i}\hat{t} = -\mathcal{G}^{-1}\left(\nabla_{x_i}\mathcal{G}\right)\mathcal{G}^{-1}e, \quad i = 1,2. \tag{A.2}$$

Let us set

$$\tilde{L}_{\epsilon,j}\phi_\epsilon^\perp := \epsilon^2\Delta\phi_{\epsilon,j}^\perp - \phi_{\epsilon,j}^\perp + \frac{2c\tilde{g}_{\epsilon,j}\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\phi_{\epsilon,j}^\perp - \frac{c\tilde{g}_{\epsilon,j}^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon^2}\psi_\epsilon^\perp + \frac{c\tilde{g}_{\epsilon,j}^2}{\bar{r}_\epsilon}\eta_{\epsilon,3-j}^\perp \tag{A.3}$$

and $\mathbf{a}_\epsilon := (a_1^\epsilon, a_2^\epsilon)^T$.

We now prove the key lemma, Lemma 6.1, in a sequence of lemmas.

Proof of Lemma 6.2. Note that for $k = 3 - l$ we have

$$\begin{aligned} \eta_{\epsilon,k}^0(x_l^\epsilon) &= \alpha_\epsilon \int_{-L}^{L} G_{D_s}(x_l^\epsilon, z)\tilde{g}_{\epsilon,k}^{'}(z)\,dz + O(\epsilon) \\ &= \alpha_\epsilon\hat{t}_k\nabla_{x_k^\epsilon}G_{D_s}(x_l^\epsilon, x_k^\epsilon)\int_{-L}^{L} zw'\left(\frac{z-x_k}{\epsilon}\right)(z)\,dz \\ &= -\hat{t}_k\nabla_{x_k^\epsilon}G_{D_s}(x_l^\epsilon, x_k^\epsilon)\alpha_\epsilon\left(\epsilon\int_{-\infty}^{\infty} w(y)\,dy\right) + O(\epsilon) \\ &= -\hat{t}_k\nabla_{x_k^\epsilon}G_{D_s}(x_l^\epsilon, x_k^\epsilon) + O(\epsilon). \qquad \square \end{aligned} \tag{A.4}$$

Proof of Lemma 6.3. Note that for $k = 3 - l$ we have

$$
\begin{aligned}
\bar{s}'_{\epsilon,k}(x_l^\epsilon) &= \alpha_\epsilon \nabla_{x_l^\epsilon} \int_{-L}^{L} G_{D_s}(x_l^\epsilon, z)\tilde{g}_{\epsilon,k}(z)\,dz \\
&= \alpha_\epsilon \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_k^\epsilon) \int_{-L}^{L} \hat{t}_k w\left(\frac{z - x_k}{\epsilon}\right)(z)\,dz + O(\epsilon) \\
&= \alpha_\epsilon \hat{t}_k \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_k^\epsilon)\left(\epsilon \int_{-\infty}^{\infty} w(y)\,dy\right) + O(\epsilon) \\
&= \hat{t}_k \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_k^\epsilon) + O(\epsilon). \qquad \Box
\end{aligned}
\tag{A.5}
$$

Proof of Lemma 6.4. We first consider the case $k = l$ and compute $\psi_{\epsilon,l}(x_l^\epsilon)$ as follows:

$$
\begin{aligned}
\psi_{\epsilon,l}(x_l^\epsilon) &= c\alpha_\epsilon \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left(2\tilde{g}'_{\epsilon,l}\tilde{g}_{\epsilon,l}\bar{s}_{\epsilon,3-l} + \tilde{g}^2_{\epsilon,3-l}\eta^0_{\epsilon,l}\right)(z)\,dz + O(\epsilon) \\
&= c(\alpha_\epsilon)^2 \int_{-\infty}^{\infty} K_{D_r}(|z|)\left(2\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\tilde{g}'_{\epsilon,l}(x_l^\epsilon + z)\right)\int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\,dz \\
&\quad - c(\alpha_\epsilon)^2 \int_{-L}^{L} H_{D_r}(x_l^\epsilon, z)\left(\frac{d}{dz}(\tilde{g}_{\epsilon,l}(z))^2\right)\int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\,dz \\
&\quad + c(\alpha_\epsilon)^2 \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left(\tilde{g}_{\epsilon,3-l}(z)\right)^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}'_{\epsilon,l}(y)\,dy\,dz + O(\epsilon) \\
&= c(\alpha_\epsilon)^2 \int_{-\infty}^{\infty} K_{D_r}(|z|)\left(2\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\tilde{g}'_{\epsilon,l}(x_l^\epsilon + z)\right)\int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\,dz \\
&+ \frac{c}{2}\hat{t}_1\hat{t}_2\hat{t}_l\left(\left(\nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon)\right)G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) + c\hat{t}_1\hat{t}_2\hat{t}_l\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)\nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) \\
&\quad - c\hat{t}_1\hat{t}_2\hat{t}_{3-l}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\nabla_{x_l^\epsilon} G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) + O(\epsilon).
\end{aligned}
\tag{A.6}
$$

Next we consider the case $k = 3 - l$ and compute $\psi_{\epsilon,3-l}(x_l^\epsilon)$ as follows:

$$
\begin{aligned}
\psi_{\epsilon,3-l}(x_l^\epsilon) &= c\alpha_\epsilon \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left(2\tilde{g}'_{\epsilon,3-l}\tilde{g}_{\epsilon,3-l}\bar{s}_{\epsilon,l} + \tilde{g}^2_{\epsilon,l}\eta_{\epsilon,3-l}\right)(z)\,dz + O(\epsilon) \\
&= c(\alpha_\epsilon)^2 \int_{-\infty}^{\infty} K_{D_r}(|z|)\left(\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\right)^2 \int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}'_{\epsilon,3-l}(y)\,dy\,dz \\
&\quad + c(\alpha_\epsilon)^2 \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left(\frac{d}{dz}(\tilde{g}_{\epsilon,3-l}(z))^2\right)\int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,l}(y)\,dy\,dz \\
&\quad - c(\alpha_\epsilon)^2 \int_{-L}^{L} H_{D_r}(x_l^\epsilon, z)\left(\tilde{g}_{\epsilon,l}(z)\right)^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}'_{\epsilon,3-l}(y)\,dy\,dz + O(\epsilon) \\
&= c(\alpha_\epsilon)^2 \int_{-\infty}^{\infty} K_{D_r}(|z|)\left(\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\right)^2 \int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}'_{\epsilon,3-l}(y)\,dy\,dz \\
&\qquad + c\hat{t}_1\hat{t}_2\hat{t}_l\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)\nabla_{x_{3-l}^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) \\
&\qquad - c\hat{t}_1\hat{t}_2\hat{t}_{3-l}\left(\left(\nabla_{x_{3-l}^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\right)G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) \\
&\qquad - c\hat{t}_1\hat{t}_2\hat{t}_{3-l}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)\nabla_{x_{3-l}^\epsilon} G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) + O(\epsilon).
\end{aligned}
\tag{A.7}
$$

Next we compute $\bar{r}_\epsilon(x_l^\epsilon)$:

$$\begin{aligned}
\bar{r}_\epsilon(x_l^\epsilon) &= \alpha_\epsilon c \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left(\tilde{g}_{\epsilon,1}^2 \bar{s}_{\epsilon,2} + \tilde{g}_{\epsilon,2}^2 \bar{s}_{\epsilon,1}\right)(z)\,dz + O(\epsilon)\\
&= (\alpha_\epsilon)^2 c \int_{-\infty}^{\infty} K_{D_r}(|z|)\left\{(\tilde{g}_{\epsilon,l}(x_l^\epsilon + z))^2 \int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right\} dz\\
&\quad - (\alpha_\epsilon)^2 c \int_{-L}^{L} H_{D_r}(x_l^\epsilon, z)\left\{(\tilde{g}_{\epsilon,l}(z))^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right\} dz\\
&\quad + (\alpha_\epsilon)^2 c \int_{-L}^{L} G_{D_r}(x_l^\epsilon, z)\left\{(\tilde{g}_{\epsilon,3-l}(z))^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,l}(y)\,dy\right\} dz + O(\epsilon).
\end{aligned}$$

So we have

$$\begin{aligned}
\bar{r}_\epsilon^{'}(x_l^\epsilon) &= (\alpha_\epsilon)^2 c \int_{-\infty}^{\infty} K_{D_r}(|z|)\left\{\left(2\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\tilde{g}_{\epsilon,l}^{'}(x_l^\epsilon + z)\right) \int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right.\\
&\qquad\left. + (\tilde{g}_{\epsilon,l}(x_l^\epsilon + z))^2 \int_{-L}^{L} \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right\} dz\\
&\quad - (\alpha_\epsilon)^2 c \int_{-L}^{L} \nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, z)\,(\tilde{g}_{\epsilon,l}(z))^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\,dz\\
&\quad + (\alpha_\epsilon)^2 c \int_{-L}^{L} \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, z)\,(\tilde{g}_{\epsilon,3-l}(z))^2 \int_{-L}^{L} G_{D_s}(z, y)\tilde{g}_{\epsilon,l}(y)\,dy + O(\epsilon)\\
&= (\alpha_\epsilon)^2 c \int_{-\infty}^{\infty} K_{D_r}(|z|)\left\{\left(2\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\tilde{g}_{\epsilon,l}^{'}(x_l^\epsilon + z)\right) \int_{-L}^{L} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right.\\
&\qquad\left. + (\tilde{g}_{\epsilon,l}(x_l^\epsilon + z))^2 \int_{-L}^{L} \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\right\} dz\\
&\quad - \frac{c}{2}\hat{t}_1\hat{t}_2\hat{t}_l\left((\nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon))G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\\
&\quad + c\hat{t}_1\hat{t}_2\hat{t}_{3-l}\left((\nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon))G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) + O(\epsilon). \qquad \text{(A.8)}
\end{aligned}$$

Now we compute $\left(\delta_{kl}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)(x_l^\epsilon)$. Again we consider the two cases $k = l$ and $k \neq l$ separately.

First, for $k = l$, we get

$$\begin{aligned}
\left(\bar{r}_\epsilon^{'} - \psi_{\epsilon,l}\right)(x_l^\epsilon) &= -c\hat{t}_1\hat{t}_2\hat{t}_l \nabla_{x_l^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\\
&\quad + c\hat{t}_1\hat{t}_2\hat{t}_{3-l} \nabla_{x_l^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right)\\
&\quad + (\alpha_\epsilon)^2 c \int_{-\infty}^{\infty} K_{D_r}(|z|)\,(\tilde{g}_{\epsilon,l}(x_l^\epsilon + z))^2 \int_{-L}^{L} \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\,dy\,dz + O(\epsilon)\\
&= c\hat{t}_1\hat{t}_2\left\{-\hat{t}_l \nabla_{x_l^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon)G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right) + \hat{t}_{3-l} \nabla_{x_l^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon)G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right)\right.\\
&\qquad\left. + \frac{1}{2\sqrt{D_r}}\hat{t}_l \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right\} + O(\epsilon).
\end{aligned}$$

Next we consider the case $k = 3 - l$ and get

$$\begin{aligned}
-\psi_{\epsilon,3-l}(x_l^\epsilon) &= -c\hat{t}_1\hat{t}_2\hat{t}_l \nabla_{x_{3-l}^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\\
&\quad + \hat{t}_1\hat{t}_2\hat{t}_{3-l} \nabla_{x_{3-l}^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right)\\
&\quad + (\alpha_\epsilon)^2 c \int_{-\infty}^{\infty} K_{D_r}(|z|)\left(\tilde{g}_{\epsilon,l}(x_l^\epsilon + z)\right)^2 \int_{-L}^{L} \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon + z, y)\tilde{g}_{\epsilon,3-l}(y)\, dy\, dz + O(\epsilon)\\
&= c\hat{t}_1\hat{t}_2 \Big\{ -\hat{t}_l \nabla_{x_{3-l}^\epsilon}\left(H_{D_r}(x_l^\epsilon, x_l^\epsilon) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\\
&\quad + \hat{t}_{3-l} \nabla_{x_{3-l}^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right)\\
&\quad + \frac{1}{2\sqrt{D_r}} \hat{t}_l \nabla_{x_{3-l}^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} + O(\epsilon).
\end{aligned}$$

This implies (6.20). The proof of Lemma 6.4 is finished. □

Remark. Note that Lemma 6.4 can be written in the simpler way

$$\begin{aligned}
\left(\delta_{kl}\bar{r}_\epsilon^{'} - \psi_{\epsilon,k}\right)(x_l^\epsilon) &= c\hat{t}_1\hat{t}_2 \Big\{ \hat{t}_l \nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_l^\epsilon) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)\right)\\
&\quad + \hat{t}_{3-l} \nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon)\right) \Big\} + O(\epsilon),
\end{aligned} \tag{A.9}$$

with the understanding that at jump discontinuities the derivative is defined as the arithmetic mean of its left-hand and right-hand derivatives.

Proof of Lemma 6.5. The proof of Lemma 6.5 follows along the same lines as that for Lemma 6.4 and is therefore omitted. □

Before we can complete the proof of Lemma 6.1, we first need to study the asymptotic expansion of $\phi_\epsilon^\perp$ as $\epsilon \to 0$. Let us define

$$\begin{aligned}
\phi_\epsilon^1 &= \begin{pmatrix} \phi_{\epsilon,1}^1 \\ \phi_{\epsilon,2}^1 \end{pmatrix}\\
&:= \epsilon a_1^\epsilon \begin{pmatrix} (\nabla_{x_1} t_1) w_1 \\ (\nabla_{x_1} t_2) w_2 \end{pmatrix} + \epsilon a_2^\epsilon \begin{pmatrix} (\nabla_{x_2} t_1) w_1 \\ (\nabla_{x_2} t_2) w_2 \end{pmatrix} + \epsilon \frac{\mathcal{G}^{-1}\mathcal{W}\mathcal{A}_\epsilon^0 \nabla G_{D_s}(x_1, x_2)}{G_{D_s}(x_1, x_2)},
\end{aligned} \tag{A.10}$$

where w_i, $i = 1, 2$, have been defined in (2.3) and

$$\mathcal{A}_\epsilon^0 = \begin{pmatrix} 0 & a_2^\epsilon \\ a_1^\epsilon & 0 \end{pmatrix}, \quad \mathcal{W} = \begin{pmatrix} w_1 & 0 \\ 0 & w_2 \end{pmatrix}.$$

Then we have the following estimate.

Lemma A.1. *For ϵ sufficiently small, it holds that*

$$\|\phi_\epsilon^\perp - \phi_\epsilon^1\|_{(H^2(\Omega_\epsilon))^2} = O(\epsilon^2). \tag{A.11}$$

Proof. To prove Lemma A.1, we first need to derive a relation between $\phi_{\epsilon,j}^\perp$, $\eta_{\epsilon,j}^\perp$, and $\psi_{\epsilon,j}^\perp$. Note that, similarly to the proof of Proposition 3.1 in section 3, it follows that $\tilde{L}_\epsilon$ is uniformly invertible from $(\mathcal{K}^{new}_{\epsilon,\mathbf{x}^\epsilon})^\perp$ to $(\mathcal{C}^{new}_{\epsilon,\mathbf{x}^\epsilon})^\perp$. By this uniform invertibility, we deduce that

$$\|\phi^\perp_\epsilon\|_{(H^2(\Omega_\epsilon))^2} = O(\epsilon), \quad \text{where } \phi^\perp_\epsilon = \left(\phi^\perp_{\epsilon,1}, \phi^\perp_{\epsilon,2}\right)^T \in (\mathcal{K}^{new}_{\epsilon,\mathbf{x}^\epsilon})^\perp. \tag{A.12}$$

Let us cut off and rescale $\phi^\perp_{\epsilon,j}$ as follows: $\tilde{\phi}_{\epsilon,j} = \frac{\phi^\perp_{\epsilon,j}}{\epsilon}\chi\left(\frac{x-x^\epsilon_j}{r_0}\right)$. Then $\phi^\perp_{\epsilon,j} = \epsilon\tilde{\phi}_{\epsilon,j}$ +e.s.t.

Choose $\phi_{\epsilon,j}$ such that $\|\tilde{\phi}_{\epsilon,j}\|_{H^1(R)} = 1$. Then we have, possibly for a subsequence, that $\tilde{\phi}_{\epsilon,j} \to \phi_j$ in $H^1_{loc}(R)$.

By (6.12) and (6.13), $\psi^\perp_\epsilon$ can be represented as follows (the proof is similar to that of Lemma 6.4):

$$\begin{aligned}
\psi^\perp_\epsilon(x^\epsilon_j) &= \epsilon(\alpha_\epsilon)^2 c \sum_{k=1}^{2} \int_{-L}^{L} G_{D_r}(x^\epsilon_j, z)\Bigg\{2\tilde{g}_{\epsilon,k}(z)\tilde{\phi}_{\epsilon,k}(z)\int_{-L}^{L} G_{D_s}(z,y)\tilde{g}_{\epsilon,3-k}(y)\,dy \\
&\qquad + \tilde{g}^2_{\epsilon,k}(z)\int_{-L}^{L} G_{D_s}(z,y)\tilde{\phi}_{\epsilon,3-k}(y)\,dy\Bigg\}\,dz \qquad \text{(A.13)}\\
&= \epsilon\alpha_\epsilon c \sum_{k=1}^{2} G_{D_r}(x^\epsilon_j, x^\epsilon_k)G_{D_s}(x^\epsilon_k, x^\epsilon_{3-k})\left(2\hat{t}_{3-k}\int_{-L}^{L}\tilde{g}_{\epsilon,k}\tilde{\phi}_{\epsilon,k}\,dx + (\hat{t}_k)^2\int_{-L}^{L}\tilde{\phi}_{\epsilon,3-k}\,dx\right) + o(\epsilon) \\
&= \epsilon c \sum_{k=1}^{2} \hat{t}_k G_{D_r}(x^\epsilon_j, x^\epsilon_k)G_{D_s}(x^\epsilon_k, x^\epsilon_{3-k})\left(2\hat{t}_{3-k}\frac{\int_R w\phi_k\,dy}{\int_R w^2\,dy} + \hat{t}_k\frac{\int_R \phi_{3-k}\,dy}{\int_R w\,dy}\right) + o(\epsilon) \\
&= \frac{\epsilon c}{G_{D_r}(x^\epsilon_1, x^\epsilon_1) + G_{D_r}(x^\epsilon_1, x^\epsilon_2)}\Bigg\{G_{D_r}(x^\epsilon_j, x^\epsilon_j)G_{D_s}(x^\epsilon_j, x^\epsilon_{3-j})\left(2\hat{t}_{3-j}\frac{\int_R w\phi_j\,dy}{\int_R w^2\,dy} + \hat{t}_j\frac{\int_R\phi_{3-j}\,dy}{\int_R w\,dy}\right) \\
&\qquad + G_{D_r}(x^\epsilon_j, x^\epsilon_{3-j})G_{D_s}(x^\epsilon_{3-j}, x^\epsilon_j)\left(2\hat{t}_j\frac{\int_R w\phi_{3-j}\,dy}{\int_R w^2\,dy} + \hat{t}_{3-j}\frac{\int_R\phi_j\,dy}{\int_R w\,dy}\right)\Bigg\} + o(\epsilon).
\end{aligned}$$

In the same way, we calculate

$$\begin{aligned}
\eta^\perp_{\epsilon,3-j}(x^\epsilon_j) &= \epsilon\alpha_\epsilon\int_{-L}^{L} G_{D_s}(x^\epsilon_j, z)\tilde{\phi}_{\epsilon,3-j}(z)\,dz \\
&= \epsilon\alpha_\epsilon G_{D_s}(x^\epsilon_j, x^\epsilon_{3-j})\int_{-L}^{L}\tilde{\phi}_{\epsilon,3-j}\,dx + O(\epsilon^2) \\
&= \epsilon G_{D_s}(x^\epsilon_j, x^\epsilon_{3-j})\frac{\int_R\phi_{3-j}\,dy}{\int_R w\,dy} + o(\epsilon) \qquad \text{(A.14)}
\end{aligned}$$

and

$$\eta^\perp_{\epsilon,j}(x^\epsilon_j) = o(\epsilon). \tag{A.15}$$

Substituting (6.18), (6.19), (6.20), (A), and (A.14) into (6.14) and calculating the limit $\epsilon \to 0$ as we have done in section 4, it follows that $\phi = (\phi_1, \phi_2)^T$ satisfies

$$\begin{aligned}
L\phi &= \Delta\phi - \phi + 2w\phi - \left[\mathcal{B}\int\phi + 2\mathcal{C}\left(\int_R w\phi\right)\right]\left(\int_R w\right)^{-1} w^2 \\
&= \hat{t}_1(\mathbf{a}\cdot\nabla\mathcal{G})\mathcal{G}^{-1}ew^2 - \frac{\hat{t}_1\mathcal{A}^0\nabla G_{D_s}(x_1, x_2)}{G_{D_s}(x_1, x_2)}w^2. \qquad \text{(A.16)}
\end{aligned}$$

In the previous calculation we have used (4.9), (4.10), (A.2), the notation

$$\mathbf{a} = (a_1, a_2)^T = \lim_{\epsilon\longrightarrow 0} (a_1^\epsilon, a_2^\epsilon)^T, \quad \mathbf{a}\cdot\nabla = a_1\nabla_{x_1} + a_2\nabla_{x_2}, \quad x_j = \lim_{\epsilon\longrightarrow 0} x_j^\epsilon,\ j = 1, 2,$$

$$\mathcal{A}^0 = \begin{pmatrix} 0 & a_2 \\ a_1 & 0 \end{pmatrix}$$

and (compare section 2)

$$\bar{r}_\epsilon(x_j^\epsilon) = c\hat{t}_1\hat{t}_2 G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon) + O(\epsilon), \quad j = 1, 2, \tag{A.17}$$

$$\bar{s}_{\epsilon,3-j}(x_j^\epsilon) = \hat{t}_{3-j} G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon) + O(\epsilon), \quad j = 1, 2. \tag{A.18}$$

We compute

$$\mathrm{Id} - \mathcal{B} - 2\mathcal{C} = -\frac{1}{G_{D_r}(x_1,x_1) + G_{D_r}(x_1,x_2)} \begin{pmatrix} G_{D_r}(x_1,x_1) & G_{D_r}(x_1,x_2) \\ G_{D_r}(x_1,x_2) & G_{D_r}(x_2,x_2) \end{pmatrix} = -\hat{t}_1\mathcal{G}.$$

By the Fredholm alternative and since $\det(\mathcal{G}) \neq 0$, equation (A.16) has a unique solution ϕ which is given by

$$\phi = -\mathcal{G}^{-1}(\mathbf{a}\cdot\nabla\mathcal{G})\mathcal{G}^{-1}ew + \frac{\mathcal{G}^{-1}\mathcal{A}^0\nabla G_{D_s}(x_1,x_2)}{G_{D_s}(x_1,x_2)}w. \tag{A.19}$$

Now we compare ϕ with ϕ_ϵ^1. By definition and using (A.2), we get

$$\begin{aligned}\phi_\epsilon^1 &= \left(\epsilon\left(a_1^\epsilon\nabla_{x_1^\epsilon}\hat{t}_1 + a_2^\epsilon\nabla_{x_2^\epsilon}\hat{t}_1\right)\tilde{g}_{\epsilon,1},\ \epsilon\left(a_1^\epsilon\nabla_{x_1^\epsilon}\hat{t}_2 + a_2^\epsilon\nabla_{x_2^\epsilon}\hat{t}_2\right)\tilde{g}_{\epsilon,2}\right)^T \\ &\qquad + \epsilon\frac{\mathcal{G}^{-1}\mathcal{W}\mathcal{A}^0\nabla G_{D_s}(x_1,x_2)}{G_{D_s}(x_1,x_2)} \\ &= \epsilon(\mathbf{a}^\epsilon\cdot\nabla_{x^\epsilon}\hat{t})w + \epsilon\frac{\mathcal{G}^{-1}\mathcal{A}^0\nabla G_{D_s}(x_1,x_2)}{G_{D_s}(x_1,x_2)}w + o(\epsilon) \\ &= -\epsilon\mathcal{G}^{-1}(\mathbf{a}\cdot\nabla\mathcal{G})\mathcal{G}^{-1}ew + \epsilon\frac{\mathcal{G}^{-1}\mathcal{A}^0\nabla G_{D_s}(x_1,x_2)}{G_{D_s}(x_1,x_2)}w + o(\epsilon). \qquad \text{(A.20)}\end{aligned}$$

On the other hand, using (A.19) gives

$$\begin{aligned}\phi_\epsilon^\perp &= \epsilon\left(\tilde{\phi}_{\epsilon,1}, \tilde{\phi}_{\epsilon,2}\right)^T + \text{e.s.t.} = \epsilon\left(\phi_j\left(\frac{x - t_j^\epsilon}{\epsilon}\right)\right)_{j=1,2} + o(\epsilon) \\ &= -\epsilon\mathcal{G}^{-1}(\mathbf{a}\cdot\nabla\mathcal{G})\mathcal{G}^{-1}ew + \epsilon\frac{\mathcal{G}^{-1}\mathcal{A}^0\nabla G_{D_s}(x_1,x_2)}{G_{D_s}(x_1,x_2)}w + o(\epsilon). \qquad \text{(A.21)}\end{aligned}$$

From (A.20) and (A.21), it follows that $\phi_\epsilon = \phi_\epsilon^1 + o(1)$. □

Finally, we complete the proof of the key lemma, Lemma 6.1.

Proof of Lemma 6.1. The computation of J_1 follows from Lemmas 6.4 and 6.5 and from (A.17), (A.18). We get

$$J_{1,l} = c\epsilon\sum_{k=1}^{2} a_k^\epsilon\delta_{jl}\int_{-L}^{L}\frac{c(\tilde{g}_{\epsilon,j})^2\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}\left(\delta_{kl}\frac{\bar{r}_\epsilon'}{\bar{r}_\epsilon} - \frac{\psi_{\epsilon,k}}{\bar{r}_\epsilon}\right)\tilde{g}_{\epsilon,l}'\,dx$$

$$= \epsilon \sum_{k=1}^{2} a_k^\epsilon \delta_{jl} \int_{-L}^{L} c(\tilde{g}_{\epsilon,j})^2 \frac{\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}(x_l^\epsilon) \left(\delta_{kl} \frac{\bar{r}_\epsilon^{'}}{\bar{r}_\epsilon} - \frac{\psi_{\epsilon,k}}{\bar{r}_\epsilon} \right) \tilde{g}_{\epsilon,l}^{'} \, dx$$

$$+ \epsilon \sum_{k=1}^{2} a_k^\epsilon \delta_{jl} \int_{-L}^{L} \frac{c(\tilde{g}_{\epsilon,j})^2 \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} \left[\left(\delta_{kl} \frac{\bar{r}_\epsilon^{'}}{\bar{r}_\epsilon} - \frac{\psi_{\epsilon,k}}{\bar{r}_\epsilon} \right) (x_l^\epsilon) \right] \tilde{g}_{\epsilon,l}^{'} \, dx + o(\epsilon^2)$$

$$= -\epsilon^2 \hat{t}_l \left(\int_R \frac{1}{3} w^3 \, dy \right) \sum_{k=1}^{2} a_k^\epsilon \Bigg\{ \nabla_{x_l^\epsilon} \Bigg\{ -\hat{t}_l \nabla_{x_k^\epsilon} \left(H_{D_r}(x_l^\epsilon, x_l^\epsilon) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \right)$$

$$+ \hat{t}_{3-l} \nabla_{x_k^\epsilon} \left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon) \right) + \frac{1}{2\sqrt{D_r}} \hat{t}_l \nabla_{x_k^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\}$$

$$\times \left\{ \left(\hat{t}_l G_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \right) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \right\}^{-1}$$

$$- \Bigg\{ -\hat{t}_l \nabla_{x_k^\epsilon} \left(H_{D_r}(x_l^\epsilon, x_l^\epsilon) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \right)$$

$$+ \hat{t}_{3-l} \nabla_{x_k^\epsilon} \left(G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) G_{D_s}(x_{3-l}^\epsilon, x_l^\epsilon) \right) + \frac{1}{2\sqrt{D_r}} \hat{t}_l \nabla_{x_k^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\}$$

$$\times \Bigg\{ \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\} \Bigg\{ G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\}^{-2} \Bigg\} + o(\epsilon^2)$$

$$= -\epsilon^2 \hat{t}_l \left(\int_R \frac{1}{3} w^3 \, dy \right) \sum_{k=1}^{2} a_k^\epsilon \Bigg\{ \Bigg\{ -\hat{t}_l \nabla_{x_l^\epsilon} \nabla_{x_k^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_l^\epsilon} \nabla_{x_k^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\}$$

$$+ \nabla_{x_l^\epsilon} \left(\frac{\nabla_{x_k^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)} \right)$$

$$- \Bigg\{ -\hat{t}_l \nabla_{x_k^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_k^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\}$$

$$\times \Bigg\{ -\hat{t}_l \nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Bigg\} \Bigg\} + o(\epsilon^2).$$

In the previous computation of $J_{1,l}$ we have used the condition for the positions of the spikes given in the derivation of Theorem 3.2, which implies that $\frac{\bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon}(x_j^\epsilon) = O(\epsilon)$. More precisely, this condition implies that the second line in the previous computation has only a contribution which was included in the error terms. We will use the same condition in the computation of the other $J_{i,l}$ without explicitly mentioning it again.

Similarly, we compute $J_{2,l}$. We get

$$J_{2,l} = \epsilon \sum_{k=1}^{2} a_k^\epsilon \int_{-L}^{L} \frac{c(\tilde{g}_{\epsilon,j})^2 \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} \left(\delta_{3-j,k} \frac{\eta_{\epsilon,3-j}^0}{\bar{s}_{\epsilon,3-j}} - \delta_{jk} \frac{\bar{s}_{\epsilon,3-j}^{'}}{\bar{s}_{\epsilon,3-j}} \right) \tilde{g}_{\epsilon,l}^{'} \, dx$$

$$= -\epsilon \sum_{k=1}^{2} a_k^\epsilon \int_{-L}^{L} \frac{c(\tilde{g}_{\epsilon,j})^2 \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} \left(\frac{(\delta_{jk} \nabla_{x_j^\epsilon} + \delta_{3-j,k} \nabla_{x_{3-j}^\epsilon}) G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon)}{G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon)} \right) \tilde{g}_{\epsilon,l}^{'} \, dx + o(\epsilon^2)$$

$$= \epsilon^2 \hat{t}_l \left(\int_R \frac{1}{3} w^3(y) \, dy \right) \sum_{k=1}^{2} a_k^\epsilon \nabla_{x_l^\epsilon} \left(\frac{(\delta_{kl} \nabla_{x_l^\epsilon} + \delta_{k,3-l} \nabla_{x_{3-l}^\epsilon}) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)} \right) + o(\epsilon^2).$$

Note that we need to have $k = 3 - j$ and $j = l$; otherwise $J_{2,l}$ is of the order $o(\epsilon^2)$.

The estimate $J_{3,l} = o(\epsilon^2)$ follows by the fact that $\phi^{\perp}_{\epsilon,j} \perp \tilde{g}_{\epsilon,j}$.

Next we determine $J_{4,l}$. We compute, using (A), (A.14), and Lemma 7, that

$$
\begin{aligned}
J_{4,l} &= c\delta_{jl} \int_{-L}^{L} \frac{(\tilde{g}_{\epsilon,j})^2 \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} \left(\frac{\eta^{\perp}_{\epsilon,3-j}}{\bar{s}_{\epsilon,3-j}} - \frac{\psi^{\perp}_\epsilon}{\bar{r}_\epsilon} \right) \tilde{g}^{'}_{\epsilon,l}\, dx \\
&= -\epsilon^2 \hat{t}_l \left(\int_R \frac{1}{3} w^3\, dy \right) \sum_{k=1}^{2} a_k^\epsilon \Bigg\{ \Big\{ (\nabla_{x_k^\epsilon} \hat{t}_l(x_1^\epsilon, x_2^\epsilon)) \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_l^\epsilon) \\
&\qquad\qquad + (\nabla_{x_k^\epsilon} \hat{t}_{3-l}(x_1^\epsilon, x_2^\epsilon)) \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \\
&\quad - \Big\{ (\nabla_{x_k^\epsilon} \hat{t}_l(x_1^\epsilon, x_2^\epsilon)) G_{D_r}(x_l^\epsilon, x_l^\epsilon) + (\nabla_{x_k^\epsilon} \hat{t}_{3-l}(x_1^\epsilon, x_2^\epsilon)) G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \\
&\quad \times \Big\{ -\hat{t}_l \nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \Bigg\} + o(\epsilon^2).
\end{aligned}
$$

Here we have used the relation

$$
\int_{-L}^{L} \frac{c\tilde{g}^2_{\epsilon,j} \bar{s}_{\epsilon,3-j}}{\bar{r}_\epsilon} \frac{\eta^{\perp}_{\epsilon,3-j}}{\bar{s}_{\epsilon,3-j}} \epsilon \tilde{g}^{'}_{\epsilon,j}\, dx = o(\epsilon^2),
$$

which follows from the trivial identity

$$
\nabla_{x_l^\epsilon} \left(\frac{G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon)}{G_{D_s}(x_j^\epsilon, x_{3-j}^\epsilon)} \right) = 0.
$$

In a similar way, using the identity

$$
\nabla_{x_l^\epsilon} \left(\frac{\hat{t}_j G_{D_r}(x_j^\epsilon, x_j^\epsilon) + \hat{t}_{3-j} G_{D_r}(x_j^\epsilon, x_{3-j}^\epsilon)}{\hat{t}_j G_{D_r}(x_j^\epsilon, x_j^\epsilon) + \hat{t}_{3-j} G_{D_r}(x_j^\epsilon, x_{3-j}^\epsilon)} \right) = 0,
$$

it can be seen that the contribution of the term $-\epsilon \frac{\mathcal{G}^{-1}\mathcal{W}\mathcal{A}^0 \nabla G_{D_s}(x_1^\epsilon, x_2^\epsilon)}{G_{D_s}(x_1^\epsilon, x_2^\epsilon)}$ in $\psi^{\perp}_\epsilon$ to $J_{4,l}$ is of the order $o(\epsilon^2)$.

Adding $J_{1,l}$, $J_{2,l}$, and $J_{4,l}$, we get

$$
\begin{aligned}
J_l = -\epsilon^2 \hat{t}_l \left(\int_R \frac{1}{3} w^3\, dy \right) \sum_{k=1}^{2} a_k^\epsilon \Bigg\{ &\Big\{ -\hat{t}_l \nabla_{x_l^\epsilon} \nabla_{x_k^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_l^\epsilon} \nabla_{x_k^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \\
&+ \nabla_{x_l^\epsilon} \left(\frac{\delta_{kl} \nabla_{x_l^\epsilon} G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)} \right) \\
&- \Big\{ -\hat{t}_l \nabla_{x_k^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_k^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \\
&\times \Big\{ -\hat{t}_l \nabla_{x_l^\epsilon} H_{D_r}(x_l^\epsilon, x_l^\epsilon) + \hat{t}_{3-l} \nabla_{x_l^\epsilon} G_{D_r}(x_l^\epsilon, x_{3-l}^\epsilon) \Big\} \\
&- \nabla_{x_l^\epsilon} \left(\frac{(\delta_{kl} \nabla_{x_l^\epsilon} + \delta_{k,3-l} \nabla_{x_{3-l}^\epsilon}) G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon, x_{3-l}^\epsilon)} \right)
\end{aligned}
$$

$$+\Big\{\big(\nabla_{x_k^\epsilon}\hat{t}_l(x_1^\epsilon,x_2^\epsilon)\big)\,\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon,x_l^\epsilon)+\big(\nabla_{x_k^\epsilon}\hat{t}_{3-l}(x_1^\epsilon,x_2^\epsilon)\big)\,\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon,x_{3-l}^\epsilon)\Big\}$$

$$-\Big\{\big(\nabla_{x_k^\epsilon}\hat{t}_l(x_1^\epsilon,x_2^\epsilon)\big)\,G_{D_r}(x_l^\epsilon,x_l^\epsilon)+\big(\nabla_{x_k^\epsilon}\hat{t}_{3-l}(x_1^\epsilon,x_2^\epsilon)\big)\,G_{D_r}(x_l^\epsilon,x_{3-l}^\epsilon)\Big\}$$

$$\times\Big\{-\hat{t}_l\nabla_{x_l^\epsilon}H_{D_r}(x_l^\epsilon,x_l^\epsilon)+\hat{t}_{3-l}\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon,x_{3-l}^\epsilon)\Big\}\Bigg\}+o(\epsilon^2).$$

This expression consists of six parts, which are given in lines 1, 2, 3–4, 5, 6, 7–8, respectively. Part 3 is minus part 6 (up to $o(\epsilon^2)$) by (A.1), and they cancel. Part 2 and part 4 cancel partially.

Making these simplifications, we finally get

$$J_l=-\epsilon^2\hat{t}_l\left(\int_R\frac{1}{3}w^3\,dy\right)\sum_{k=1}^{2}a_k^\epsilon\Bigg\{\Big\{-\hat{t}_l\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(H_{D_r}(x_l^\epsilon,x_l^\epsilon)\right)$$

$$+\hat{t}_{3-l}\nabla_{x_l^\epsilon}\nabla_{x_k^\epsilon}\left(G_{D_r}(x_l^\epsilon,x_{3-l}^\epsilon)\right)\Big\}$$

$$-\nabla_{x_l^\epsilon}\left(\frac{\delta_{k,3-l}\nabla_{x_{3-l}^\epsilon}G_{D_s}(x_l^\epsilon,x_{3-l}^\epsilon)}{G_{D_s}(x_l^\epsilon,x_{3-l}^\epsilon)}\right)$$

$$+\Big\{(\nabla_{x_k^\epsilon}\hat{t}_l(x_1^\epsilon,x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon,x_l^\epsilon)+(\nabla_{x_k^\epsilon}\hat{t}_{3-l}(x_1^\epsilon,x_2^\epsilon))\nabla_{x_l^\epsilon}G_{D_r}(x_l^\epsilon,x_{3-l}^\epsilon)\Big\}\Bigg\}+o(\epsilon^2).$$

This finishes the proof of Lemma 6.1. $\square$

Appendix B. Proof of Lemma 6.6.

Proof of Lemma 6.6. We show that

$$P(x_1^\epsilon,x_2^\epsilon)=(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\Bigg\{\frac{(\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})G_{D_s}(x_1^\epsilon,x_2^\epsilon)}{G_{D_s}(x_1^\epsilon,x_2^\epsilon)}$$

$$-\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)(\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})H_{D_r}(x_1^\epsilon,x_1^\epsilon)-\hat{t}_2^\epsilon(x_1^\epsilon,x_2^\epsilon)(\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})H_{D_r}(x_1^\epsilon,x_1^\epsilon)\Bigg\}<0.$$

We compute

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})G_{D_s}(x_1^\epsilon,x_2^\epsilon)=0$$

and

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})(\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})G_{D_s}(x_1^\epsilon,x_2^\epsilon)=((\nabla_{x_1^\epsilon})^2-(\nabla_{x_2^\epsilon})^2)G_{D_s}(x_1^\epsilon,x_2^\epsilon)=0.$$

Therefore, the first term coming from G_{D_s} gives no contribution at all.

Further, we get

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)=\frac{\nabla_{x_2^\epsilon}G_{D_r}(x_2^\epsilon,x_2^\epsilon)}{\det\mathcal{G}}.$$

To simplify the previous expression, we use the identity

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})(\det\mathcal{G})=0, \tag{B.1}$$

which is easy to derive.

Using (B.1), we get

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)=\frac{\nabla_{x_2^\epsilon}G_{D_r}(x_2^\epsilon,x_2^\epsilon)}{\det\mathcal{G}}, \tag{B.2}$$

which gives

$$\begin{aligned}
&-[(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)](\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})G_{D_r}(x_1^\epsilon,x_1^\epsilon)\\
&\quad=-\frac{\nabla_{x_2^\epsilon}G_{D_r}(x_2^\epsilon,x_2^\epsilon)}{\det\mathcal{G}}\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1\epsilon)\\
&\quad=\frac{\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)}{\det\mathcal{G}}\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon).
\end{aligned} \tag{B.3}$$

In analogy to (B.2), we get

$$(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\hat{t}_2^\epsilon(x_1^\epsilon,x_2^\epsilon)=\frac{\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)}{\det\mathcal{G}}, \tag{B.4}$$

which implies

$$-[(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})\hat{t}_2^\epsilon(x_1^\epsilon,x_2^\epsilon)](\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})G_{D_r}(x_1^\epsilon,x_2^\epsilon)=-\frac{\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)}{\det\mathcal{G}}2\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_2^\epsilon). \tag{B.5}$$

Finally, we compute

$$\begin{aligned}
-\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)(\nabla_{x_1^\epsilon}+\nabla_{x_2^\epsilon})(\nabla_{x_1^\epsilon}-\nabla_{x_2^\epsilon})G_{D_r}(x_1^\epsilon,x_1^\epsilon)&=-\hat{t}_1^\epsilon(x_1^\epsilon,x_2^\epsilon)\nabla^2_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)\\
&=-\frac{G_{D_r}(x_2^\epsilon,x_2^\epsilon)-G_{D_r}(x_1^\epsilon,x_2^\epsilon)}{\det\mathcal{G}}\nabla^2_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon).
\end{aligned} \tag{B.6}$$

Now $P(x_1^\epsilon,x_2^\epsilon)$ is given by the sum of (B.3), (B.5), and (B.6).

Using the explicit expression of the Green's function (2.6), we get for the sum of (B.3) and (B.5)

$$\begin{aligned}
&\frac{\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)}{\det\mathcal{G}}\left[\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)-2\nabla_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_2^\epsilon)\right]\\
&\quad=\frac{\theta_r^4}{\sinh^2 2\theta_r L\det\mathcal{G}}\sinh(2\theta_r-x_1^\epsilon)\left[\sinh 2\theta_r x_1^\epsilon+\sinh 2\theta_r(L-x_1^\epsilon)\right].
\end{aligned}$$

For (B.6), we get

$$-\frac{G_{D_r}(x_2^\epsilon,x_2^\epsilon)-G_{D_r}(x_1^\epsilon,x_2^\epsilon)}{\det\mathcal{G}}\nabla^2_{x_1^\epsilon}G_{D_r}(x_1^\epsilon,x_1^\epsilon)$$

$$=-\frac{\theta_r^4}{\sinh^2 2\theta_r L\det\mathcal{G}}\cosh 2\theta_r(L+x_2^\epsilon)\left[\cosh\theta_r(L-x_2^\epsilon)-\cosh\theta_r(L-x_1^\epsilon)\right]2\cosh 2\theta_r x_1^\epsilon.$$

Adding this all up, we get

$$\begin{aligned} P(x_1^\epsilon, x_2^\epsilon) = \frac{\theta_r^4}{\sinh^2 2\theta_r L \det \mathcal{G}} \Bigg\{ & -2\cosh 2\theta_r(L+x_2^\epsilon)\,[\cosh\theta_r(L-x_2^\epsilon) \\ & - \cosh\theta_r(L-x_1^\epsilon)]\cosh 2\theta_r x_1^\epsilon \\ & + \sinh 2\theta_r x_1^\epsilon\,[\sinh 2\theta_r x_1^\epsilon + \sinh 2\theta_r(L-x_1^\epsilon)] \Bigg\} \\ = \frac{\theta_r^4}{\sinh^2 2\theta_r L \det \mathcal{G}} & \Bigg\{ \cosh 2\theta_r L \cdot [1-\cosh 2\theta_r x_1^\epsilon] \Bigg\}. \end{aligned}$$

Note that for $x_1 = \lim_{\epsilon\to 0} x_1^\epsilon$ we have

$$\cosh 2\theta_r L \cdot [1-\cosh 2\theta_r x_1] \leq 0$$

and

$$\cosh 2\theta_r L \cdot [1-\cosh 2\theta_r x_1] = 0 \quad \text{if and only if} \quad x_1 = 0.$$

Therefore, if $x_1 \neq 0$, then for ϵ small enough we have $P(x_1^\epsilon, x_2^\epsilon) < 0$.

This concludes the proof of Lemma 6.6. □

THERMOPHORESIS DUE TO STRONG TEMPERATURE GRADIENTS[*]

EHUD YARIV[†]

Abstract. We consider a standard thermophoretic configuration, wherein an insulating spherical particle is suspended within a gaseous domain which is bounded between two parallel walls. The walls are maintained at two different temperatures, thereby generating a nonuniform temperature field within the gas. Due to thermal slip, the particle drifts toward the cold wall. Conventional analyses of this problem, starting with the classical work of Epstein [*Z. Physik.*, 54 (1929), pp. 537–563], employ the small-temperature-difference limit. Then, if the particle is small enough, the problem becomes quasi-steady, and the animating effect of the two walls can be represented by a uniform far-field temperature gradient. The corresponding unbounded problem is identical to other slip-generated problems, such as electrophoresis. We focus here upon the general case where the temperature difference is not small. The dependence of the pertinent flow variables upon the absolute temperature prohibits a transformation to a quasi-steady description, whence the transport problem is governed by an unsteady nonlinear process. The small-particle limit is a singular one, wherein the walls cannot be represented by effective far-field conditions. Moreover, the unique structure of the thermal-slip condition implies that inertia and heat-convection effects are of comparable scaling to wall effects. The singular limit is analyzed using inner–outer expansions. In the outer domain, the temperature field is steady to leading-order, but is not described by a uniform gradient. In the inner particle-scale domain, the flow problem is governed by the steady Stokes equations only in the leading order. The transformation between the inner and outer coordinates involves the particle velocity, itself a dependent variable. Using symmetry arguments, we avoid the detailed calculation of the leading-order flow correction, and focus instead upon its effect on the particle thermophoretic velocity. Due to a fortuitous cancellation of terms, Epstein's result remains valid to leading-order analysis. It has been proposed by Kogan, Galkin, and Fridlender [*Sov. Phys. Usp.*, 19 (1976), pp. 420–428] that thermal stresses must be incorporated into all continuum descriptions which apply to flows driven by $O(1)$ temperature differences. Using symmetry arguments, we also analyze the effects of these stresses in the present configuration.

1. Introduction.

When solving continuum flows, the common approach is to postulate a no-slip boundary condition over all solid surfaces in contact with the fluid. Theoretical predictions based upon this condition, however, fail to explain two well-known gas experiments which involve nonisothermal solid surfaces. The first experiment was carried out by Tyndall [21], who observed that solid particles drift away from heated surfaces. (This motion is now known as thermophoresis.) Another deviation from the no-slip prediction was observed by Reynolds [19], who exposed closed gas capillaries to temperature gradients and noticed the establishment of a pressure difference between the capillary ends, with higher pressure at the hot end (see also [15, 2]). (This phenomenon was coined "thermal transpiration.")

These experiments have been performed in the continuum regime. According to "conventional" continuum theory, both describe pure heat conduction scenarios,

with no mechanism for flow generation (gravity being neglected). Indeed, both the governing balance equations and the boundary conditions (including the ubiquitous no-slip condition) are satisfied by a static solution. In the absence of flow, however, there is no mechanism to push the particle in Tyndall's experiment, and there can be no pressure variation in Reynolds's experiment.

Both phenomena were explained by Maxwell [16] using gas-kinetic theory. Maxwell analyzed the Knudsen layer which lies in at the gas–solid interface, wherein the gas is out of thermodynamic equilibrium, and showed that even if the layer thickness goes to zero, it results in a finite slip velocity $\boldsymbol{v}_S^*$ at its outer edge—where the continuum boundary conditions are prescribed:

$$\boldsymbol{v}_S^* = c_S \frac{\nu^*}{\theta^*} \frac{\partial \theta^*}{\partial \boldsymbol{x}_S^*}. \tag{1.1}$$

Here c_S is an $O(1)$ dimensionless coefficient, ν^* is the kinematic viscosity, θ^* is the temperature, and $\partial/\partial \boldsymbol{x}_S^*$ denotes surface gradient (dimensional variables are decorated with stars). Maxwell obtained the value $c_S = 3/4$ using the artificial-yet-simple model of central molecular interactions that decay with the sixth power of the intermolecular separation ("Maxwell molecules"). Other systematic analyses of this problem [20, 13] yield different values of c_S.[1] The predicted value of c_S depends upon the molecular model which is employed to solve Boltzmann's equation in the Knudsen layer. At present, there is no universally accepted value for c_S. Practically speaking, however, all molecular models predict $O(1)$ slip coefficients, in agreement with experimental results.

Given the relative slip of gases along nonisothermal solid surfaces, it becomes clear that a force-free solid particle will drift toward cold regions (thermophoresis). In the case of nonuniformly heated closed capillary, the thermal slip along the capillary walls tends to generate a uniform plug flow, directed from the cold end to the hot one. This flow generates a nonzero net mass flux; in a closed capillary, it must therefore be accompanied by a counter-balancing Poiseuillian velocity profile (which is the only nontrivial solution that satisfies the Navier–Stokes equations and a no-slip condition on the capillary walls). This profile, in turn, generates a longitudinal pressure gradient, which is directed toward the hot end of the capillary. This pressure gradient explains the thermal transpiration phenomenon.

In analyzing slip-driven flows, it is a common practice to assume that the temperature difference $\Delta\theta^*$ associated with the imposed wall- temperature distribution is small compared with a characteristic temperature, say θ_∞^*, of that distribution. Then, the gas density and transport coefficients are considered constant. This leads to two major simplifications: the temperature field is essentially governed by conduction (and therefore satisfies Laplace's equation), and the slip condition (1.1) adopts the approximated form

$$\boldsymbol{v}_S^* \approx c_S \frac{\nu_\infty^*}{\theta_\infty^*} \frac{\partial \theta^*}{\partial \boldsymbol{x}_S^*}$$

(where ν_∞^* is a characteristic viscosity value). Within this approximation, the thermal-slip condition is analogous to that appearing in a variety of other phoretic mecha-

[1] The structure (1.1) is valid for arbitrary temperature gradients [14]. The above-mentioned analyses were performed using a linearized version of the Boltzmann equation, valid for small gradients: Since the value of c_S is independent of the magnitude of the gradients, this linearized approach is legitimate.

nisms [1], where the slip velocity is proportional to the gradient of some harmonic field (electric potential, solute concentration, etc.).

The analogy breaks down when $\Delta\theta^*$ is comparable to θ^*_∞. Indeed, numerical simulations in the strong-gradient regime [18] exhibit rich phenomena, not all of which can be described by the linearized model. Despite its importance for a variety of applications (in Annis's experiments [2], for example, $\Delta\theta^* = 300\,\mathrm{K}$), this general case has not yet been systematically investigated. It is the goal of this paper to present an analytic investigation of flows driven by significant temperature differences, where the parameter

$$\zeta = \frac{\Delta\theta^*}{\theta^*_\infty} \tag{1.2}$$

is $O(1)$.

A fundamental property of such thermally-driven flows, identified by Kogan [13], has to do with the velocity scaling. According to the slip condition (1.1), slip-driven flows are quantified by the velocity scale

$$\mathscr{U} = \zeta \frac{\nu^*_\infty}{L}. \tag{1.3}$$

Here, ν^*_∞ is a characteristic viscosity and L is the length dimension associated with the temperature gradient. This scaling implies that the Reynolds number, $\mathscr{U} L/\nu^*_\infty$, is simply given by ζ. Thus, flows which are driven by strong temperature differences are characterized by inherently $O(1)$ Reynolds numbers. (Since the Prandtl number of a gas is $O(1)$, the same conclusion holds for the Péclet number.) This universal scaling contrasts with phoretic slip-driven mechanisms which are characterized by independent velocity scales.[2]

It becomes evident that flows driven by strong temperature differences are inherently nonlinear. The nonlinearity results from both the dependence of thermodynamic and transport properties upon the temperature and from the universal velocity scaling. In a previous work [23], the role of nonlinearity was investigated in the context of channel flows. In this paper we investigate its implications upon thermophoretic particle motion.

Conceptually, the simplest thermophoretic configuration consists of a gaseous domain which is bounded between two walls. The walls are separated distance $2L$ apart, and are held at two different temperatures, say $\theta^*_\infty \pm \Delta\theta^*$. A particle of dimension a is introduced into the gas domain, and drifts toward the cold wall. Practical interest often surrounds the small-particle case, $\epsilon = a/L \ll 1$.

This problem was solved by Epstein [8] in the limit $\zeta \to 0$. In that limit, the flow and heat transport are affected only by the temperature gradients, rather than the absolute temperature. In that case, it is possible to transform the bounded-fluid-domain problem into a comparable unbounded-fluid-domain problem, whereby the two walls are represented by a far-field "imposed gradient" condition. The resulting steady problem is identical to that describing electrophoresis of a constant zeta-potential particle under the action of a uniformly applied electric field [1], the temperature being analogous to the electric potential.

For $\zeta = O(1)$, however, the absolute temperature affects the flow and heat-transport processes. Accordingly, the spatial distribution of the pertinent fields depends upon the instantaneous position of the particle relative to the walls. This

[2] These reflect the dependence of phoretic slip upon dimensional physicochemical surface properties (e.g., surface charge density), which have no counterpart in the thermal-slip mechanism.

dependence implies that the $\zeta = O(1)$ regime is inherently unsteady. Moreover, even for small particles ($\epsilon \ll 1$) it is not possible to replace the two walls by a far-field condition. The limit $\epsilon \ll 1$ is a singular one.

The asymptotic limit $\epsilon \ll 1$ is addressed here via the use of matched asymptotic expansions. The transport processes are analyzed in two separate regions. An "outer" region, characterized by the large length scale L associated with the interwall separation, and an "inner" region, characterized by the particle dimension a. In both regions, each of the pertinent fields is expanded into an asymptotic series in terms of the aspect-ratio parameter ϵ.

The outer region is dominated by a pure heat conduction process. In a sense, this region constitutes the analog of the "far-field" in the linearized problem. In the present problem, however, the outer temperature field is affected by the gas conductivity and therefore is not harmonic; specifically, its longitudinal variation is nonlinear. A spatially-linear profile is attained only in the limit $\zeta \ll 1$, and only then does the outer solution conform to the "applied-gradient" notion.

The inner region is suitable for the description of the transport processes at the particle scale, which are governed by nonlinear and unsteady equations. In that scale, where the fluid domain appears unbounded, conditions at "infinity" are supplemented by the requirement of matching with the outer solution. The equations are closed by imposing Newton's second law on the particle motion, thereby relating the particle velocity to the flow field about it. In view of that dependence, the particle velocity must also be expressed as an asymptotic series in ϵ. Since the transformation between the inner and outer coordinates is performed using this velocity, Van Dyke's matching rules cannot be applied and we resort to the use of intermediate variables.

The leading-order inner flow problem is similar to the linearized $\zeta \ll 1$ problem analyzed by Epstein [8]. Due to the time-varying "applied gradient" appearing in the $\zeta = O(1)$ case, the similarity is not complete. Nevertheless, a fortuitous cancellation of terms reveals that the leading-order thermophoretic velocity is identical to that obtained by Epstein. Nonlinear effects in the flow problem appear only in the leading-order asymptotic correction. This correction is governed by a perturbation of the compressible Navier–Stokes equations. The mathematical problem governing that correction is transformed into a nonhomogeneous creeping-flow equation. Without solving the flow correction in detail, we employ symmetry arguments and show that it does not affect the particle velocity.

We also consider the role of Burnett stresses. In a formal small-Knudsen-number analysis of the Boltzmann equation [6], these stresses constitute a correction to the "conventional" Newtonian stress. Given their small magnitude in continuum flows, Burnett stresses can be ignored in most practical scenarios. Continuum flow in the presence of strong temperature gradients, however, may pose an exceptional case, since two of the Burnett terms (the "thermal stresses") are associated with temperature variations. Indeed, it was shown by Kogan and his coworkers [13, 14] that thermal stresses can actually *generate* flow if such variations are externally imposed. In that case, Burnett terms actually possess the same scaling as the Newtonian stress, and must therefore be superimposed upon the conventional Navier–Stokes equations. A systematic discussion of this asymptotic reordering appears in [4].

Flows driven by strong temperature variations through the action of thermal stresses were studied for a variety of idealized configurations [14], which are usually characterized by several isothermal surfaces (held at different temperatures). In such configurations, the only mechanism for flow generation are the thermal stresses, since no thermal slip is generated on the surfaces. Unfortunately, these idealized configurations are not encountered in practical devices. To this day, as a matter of fact, there is no available experimental evidence for the existence of thermal stresses.

Since the velocity scaling associated with thermal-stress-driven flows is the same as that of flows driven by thermal slip, thermal stresses may be pertinent to the present problem. We therefore revisit the thermophoretic analysis, incorporating the two Burnett thermal terms into the momentum balance. Symmetry arguments show that this incorporation does not affect the $O(\epsilon)$ correction to the particle velocity.

2. Problem formulation. Consider the simplest model of thermophoresis, taking place within an ideal gas domain (constant specific heats c_P and c_V) which is bounded between two parallel solid walls separated distance $2L$ apart. The two walls are maintained at two different temperatures, say $(1 \pm \zeta)\,\theta^*_\infty$ (where $0 < \zeta < 1$).

Neglecting gravity effects, the pressure field between the walls must be uniform; it is denoted by p^*_∞. Since the temperature field θ^* is nonuniform, so must be the density field ρ^*. The static pure-conduction state described here is compatible with the equations of fluid motion.

A spherical solid particle of radius a ($a < L$) is now introduced between the walls. For simplicity, we assume a thermally-insulating particle. The nonuniform temperature field along the particle surface, in conjunction with the slip condition (1.1), implies that the particle-free static state is perturbed: the slip animates a velocity field $\boldsymbol{v}^*$, and a consequent modification of the the uniform pressure p^*_∞ to a nonuniform distribution p^*; the fields θ^* and ρ^* are then modified from their respective static distributions. Since the particle is freely suspended, these fields may result in its motion relative to the ambient nonuniform temperature field. The problem is therefore inherently unsteady; in general, then, all fields depend upon both the position vector $\boldsymbol{x}^*$ and the time t^*.

Clearly, the problem is axi-symmetric about an axis (say z^*) which runs perpendicular to the walls and passes through the particle center. For convenience, we take the walls to be at $z^* = \pm L$. Symmetry implies that the particle velocity is given by $\boldsymbol{w}^* = \boldsymbol{e}_z\, w^*$, $\boldsymbol{e}_z$ being a unit vector pointing in the positive-z^* direction. The instantaneous configuration of the system is determined by the position $z^*_P\,(t^*)$ of the particle center, where $w^* = dz^*_P/dt^*$. A schematic of the problem is presented in Figure 2.1.

The pertinent fields ($\boldsymbol{v}^*$, p^*, ρ^*, and θ^*) involved in this unsteady transport

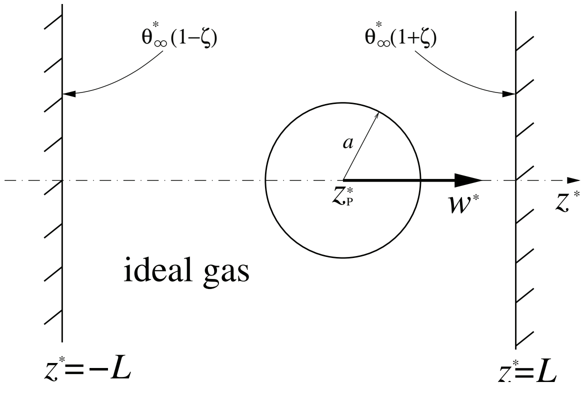

FIG. 2.1. *A schematic of the particle-walls configuration.*

process are governed by the standard set of balance equations [3], in which the viscosity μ^* and the heat conductivity k^* are both temperature dependent. The heat transport is described by the enthalpy-balance equation,

$$c_P \rho^* \frac{D\theta^*}{Dt^*} = \frac{\partial}{\partial \boldsymbol{x}^*} \cdot \left(k^* \frac{\partial \theta^*}{\partial \boldsymbol{x}^*} \right) + \frac{Dp^*}{Dt^*} + \Phi^*. \tag{2.1}$$

Here,

$$\frac{D}{Dt^*} = \frac{\partial}{\partial t^*} + \boldsymbol{v}^* \cdot \frac{\partial}{\partial \boldsymbol{x}^*}$$

is the material derivative operator, and

$$\Phi^* = 2\mu^* \mathsf{e}^* : \mathsf{e}^* \tag{2.2}$$

is the dissipation rate, wherein e^* is the rate-of-strain tensor:

$$\mathsf{e}^* = \frac{1}{2} \left[\left(\frac{\partial \boldsymbol{v}^*}{\partial \boldsymbol{x}^*} \right) + \left(\frac{\partial \boldsymbol{v}^*}{\partial \boldsymbol{x}^*} \right)^\dagger \right] - \frac{1}{3} \left(\frac{\partial}{\partial \boldsymbol{x}^*} \cdot \boldsymbol{v}^* \right) \mathsf{I}. \tag{2.3}$$

The flow is described by the mass-balance equation

$$\frac{D\rho^*}{Dt^*} + \rho^* \frac{\partial}{\partial \boldsymbol{x}^*} \cdot \boldsymbol{v}^* = 0 \tag{2.4}$$

and the momentum-balance equation

$$\rho^* \frac{D\boldsymbol{v}^*}{Dt^*} = -\frac{\partial p^*}{\partial \boldsymbol{x}^*} + 2 \frac{\partial}{\partial \boldsymbol{x}^*} \cdot (\mu^* \mathsf{e}^*). \tag{2.5}$$

The three thermodynamic fields are coupled by the ideal-gas equation of state,

$$p^* = \mathscr{R} \rho^* \theta^*. \tag{2.6}$$

Here, $\mathscr{R} = c_P - c_V$ is the gas constant. Also, the dependence of μ^* and k^* upon θ^* is provided by the functional relations:

$$\frac{\mu^*}{\mu^*_\infty} = f_\mu \left(\frac{\theta^*}{\theta^*_\infty} \right), \quad \frac{k^*}{k^*_\infty} = f_k \left(\frac{\theta^*}{\theta^*_\infty} \right), \tag{2.7}$$

where μ^*_∞ and k^*_∞ are the values of μ^* and k^* at the reference temperature θ^*_∞ (so that $f_\mu(1) = f_k(1) = 1$).

The differential equations are supplemented by the appropriate boundary conditions. On the two walls $z^* = \pm L$ the imposed thermal conditions are

$$\theta^* = \theta^*_\infty (1 \pm \zeta), \tag{2.8}$$

and the no-slip condition is

$$\boldsymbol{v}^* = \boldsymbol{0}. \tag{2.9}$$

The conditions on the particle surface are written using the relative position vector,

$$\boldsymbol{r}^* = \boldsymbol{x}^* - \boldsymbol{e}_z \, z^*_P \, (t^*) \, , \tag{2.10}$$

which is measured from the particle center. Thus, on $r^* = a$ the temperature field satisfies the no-flux condition,

$$\frac{\partial \theta^*}{\partial n} = 0, \tag{2.11}$$

and the velocity field satisfies the slip condition (cf. (1.1))[3]

$$\boldsymbol{v}^* - \boldsymbol{w}^* = c_S \frac{\nu^*}{\theta^*} \frac{\partial \theta^*}{\partial \boldsymbol{x}^*}. \tag{2.12}$$

At large distances from the particle, the flow-induced pressure disturbance attenuates, and the pressure approaches its quiescent value:

$$p^* \to p^*_\infty \quad \text{as} \quad {x^*}^2 + {y^*}^2 \to \infty. \tag{2.13}$$

The governing equations are closed by imposing Newton's second law on the particle motion:

$$\text{hydrodynamic force on particle} = \frac{4\pi}{3} \sigma \rho^*_\infty a^3 \frac{dw^*}{dt^*}. \tag{2.14}$$

Here, $\rho^*_\infty = p^*_\infty / \mathscr{R} \theta^*_\infty$ is a reference density value, and $\sigma \rho^*_\infty$ is the average particle density.

3. Dimensionless formulation. In what follows, it proves convenient to employ dimensionless variables, which appear without the star designation. The coordinates and gradient operator are normalized using the length L. The normalized density and pressure fields are given by the ratios

$$p = \frac{p^*}{p^*_\infty}, \quad \rho = \frac{\rho^*}{\rho^*_\infty}, \tag{3.1}$$

and the reduced temperature θ is defined by the relation

$$\frac{\theta^*}{\theta^*_\infty} = 1 + \zeta \theta. \tag{3.2}$$

Velocity variables are normalized using the velocity scale (see (1.3)):

$$\mathscr{U} = \zeta \frac{\mu^*_\infty}{\rho^*_\infty L}. \tag{3.3}$$

In the transition to dimensionless description, three parameters emerge: (i) the Prandtl number $\mathrm{Pr} = \mu^*_\infty c_P / k^*_\infty$; (ii) the ratio $\gamma = c_P / c_V$; and (iii) the Mach number $M = \mathscr{U} / c^*_\infty$, wherein c_∞ is the sound speed in the reference state:

$$c^2_\infty = \gamma \mathscr{R} \theta^*_\infty. \tag{3.4}$$

The dimensionless enthalpy equation adopts the form

$$\zeta \rho \frac{D\theta}{Dt} = \frac{2}{\mathrm{Pr}} \frac{\partial}{\partial \boldsymbol{x}} \cdot \left[f_k \left(1 + \zeta\theta\right) \frac{\partial \theta}{\partial \boldsymbol{x}} \right] + \frac{\gamma - 1}{\gamma} \frac{Dp}{Dt} + \frac{\gamma - 1}{\zeta} M^2 \Phi, \tag{3.5}$$

[3] In principle, (2.12) should be written using a surface gradient operator; (2.11), however, implies that the conventional gradient operator is equivalent here.

with $D/Dt = \partial/\partial t + \boldsymbol{v}\cdot\partial/\partial\boldsymbol{x}$. Here, the dimensionless dissipation is

$$\Phi = 2f_\mu\,(1+\zeta\theta)\,\mathsf{e}:\mathsf{e}, \tag{3.6}$$

where e is given by the dimensionless equivalent of (2.3). The dimensionless mass- and momentum-conservation equations are

$$\frac{D\rho}{Dt} + \rho\frac{\partial}{\partial\boldsymbol{x}}\cdot\boldsymbol{v} = 0 \tag{3.7}$$

and

$$\zeta\rho\frac{D\boldsymbol{v}}{Dt} = -\frac{\zeta}{\gamma}M^{-2}\frac{\partial p}{\partial\boldsymbol{x}} + 2\frac{\partial}{\partial\boldsymbol{x}}\cdot\left[f_\mu\,(1+\zeta\theta)\,\mathsf{e}\right]. \tag{3.8}$$

Last, the dimensionless equation of state appears as

$$p = \rho\,(1+\zeta\theta)\,. \tag{3.9}$$

Given the velocity scaling of thermal slip, it is not surprising that both the Reynolds and Péclet numbers are simply given by ζ.

The boundary conditions on the two walls are

$$\left.\begin{array}{c}\theta = \pm 1,\\ \boldsymbol{v} = \boldsymbol{0},\end{array}\right\} \quad \text{at} \quad z = \pm 1. \tag{3.10}$$

At the particle surface, the no-flux condition reads as

$$\frac{\partial\theta}{\partial r} = 0 \quad \text{at} \quad r = \epsilon \tag{3.11}$$

and the slip condition is

$$\boldsymbol{v} - \boldsymbol{w} = \frac{c_S}{\rho}\frac{f_\mu\,(1+\zeta\theta)}{1+\zeta\theta}\frac{\partial\theta}{\partial\boldsymbol{x}} \quad \text{at} \quad r = \epsilon. \tag{3.12}$$

At large distances from the particle, the pressure approaches the unperturbed value

$$p \to 1 \quad \text{as} \quad x^2 + y^2 \to \infty. \tag{3.13}$$

The equations are closed by the dimensionless version of (2.14).

4. The dynamic incompressibility limit. In continuum gas flows, the Knudsen number Kn must be small [6]. This number is proportional to the ratio of the Mach number to the Reynolds number. In the present context, the latter is given by the scaled temperature difference ζ, which is $O(1)$. Accordingly, the Mach number is small.

We therefore extract the leading-order limit of the preceding equations for $M \ll 1$. In that limit, the momentum-balance (3.8) and the far-field condition (3.13) imply the following distinguished limit for the pressure field:

$$p \to 1 + \frac{\gamma}{\zeta}M^2\tilde{p}. \tag{4.1}$$

The "dynamic pressure" $\tilde{p}$ actually represents a Stokes-type normalization using the viscous scale $\mu^*_\infty\mathscr{U}/L$ (cf. the "thermodynamic" normalization (3.1)):

$$\tilde{p} = \frac{p^* - p^*_\infty}{\mu^*_\infty\mathscr{U}/L}. \tag{4.2}$$

Since the pressure is constant to leading-order (the "hydrodynamic" pressure is unaffected by the flow), the equation-of-state (3.9) becomes

$$\rho = \frac{1}{1+\zeta\theta}. \tag{4.3}$$

This equation describes a "dynamically-incompressible" fluid [3], whose density is affected only by the temperature.

The density is therefore eliminated as an independent variable. Thus, the slip condition (3.12) becomes

$$\boldsymbol{v} - \boldsymbol{w} = c_S f_\mu \left(1+\zeta\theta\right) \frac{\partial\theta}{\partial\boldsymbol{x}} \quad \text{at} \quad r = \epsilon, \tag{4.4}$$

and the balance equations (3.5), (3.7), and (3.8) adopt the following continuum limits:

$$\frac{\zeta \,\mathrm{Pr}}{1+\zeta\theta}\frac{D\theta}{Dt} = \frac{\partial}{\partial\boldsymbol{x}} \cdot \left[f_k \left(1+\zeta\theta\right) \frac{\partial\theta}{\partial\boldsymbol{x}}\right], \tag{4.5}$$

$$\frac{\partial}{\partial\boldsymbol{x}} \cdot \boldsymbol{v} = \frac{\zeta}{1+\zeta\theta}\frac{D\theta}{Dt}, \tag{4.6}$$

$$\frac{\zeta}{1+\zeta\theta}\frac{D\boldsymbol{v}}{Dt} = -\frac{\partial\tilde{p}}{\partial\boldsymbol{x}} + 2\frac{\partial}{\partial\boldsymbol{x}} \cdot \left[f_\mu \left(1+\zeta\theta\right) \mathsf{e}\right]. \tag{4.7}$$

Note that both the pressure and dissipation terms disappear from the enthalpy equation, which adopts a standard convective–diffusive form. Also, because the fluid is dynamically incompressible, it is only the gradient of the dynamic pressure $\tilde{p}$ which affects the flow. Since the hydrodynamic force is insensitive to the addition of a constant pressure, the pressure $\tilde{p}$ is effectively defined up to an additive constant.

The preceding analysis resembles the Janzen–Rayleigh expansions for small Mach number inviscid flows. Similar analyses for thermodynamically-compressible flows in the limit of small Mach numbers were also performed in the context of forced convection [5, 10].

The present framework of strong-gradient thermophoresis introduces two new features which are absent in the linearized model: (i) the Péclet and Reynolds numbers are both $O\left(1\right)$—in principle, nonlinear convective terms are of the same order as the diffusive terms; (ii) since the absolute temperature affects the transport process, the flow depends upon the instantaneous location of the particle, and the problem is inherently unsteady.

For simplicity of subsequent analysis, we assume Maxwellian intermolecular interactions. Thus, $\mathrm{Pr} = 2/3$, and the transport coefficients are proportional to the temperature

$$f_\mu\left(\eta\right) = f_k\left(\eta\right) = \eta. \tag{4.8}$$

5. Small-particle limit. We now focus upon the small-particle case, $\epsilon = a/L \ll 1$. Since the flow is driven by a slip mechanism at the particle scale, the actual Reynolds and Péclet numbers that characterize the transport are modified from $O(1)$ to $O\left(\epsilon\right)$, whence the continuum domain is modified from $M \ll 1$ to $M \ll \epsilon$. Thus, it is still consistent to employ the preceding equations of a dynamically incompressible gas, obtained via neglecting $O\left(M^2\right)$ terms, while retaining both $O\left(\epsilon\right)$ and $O\left(\epsilon^2\right)$ corrections.

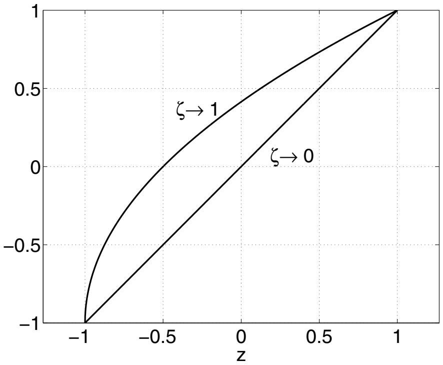

FIG. 5.1. *Variation of the outer temperature field for the limiting ζ values.*

The limit $\epsilon \to 0$ corresponds to the absence of a particle. Since the slip over the particle surface is the animating mechanism for the generation of flow, this limit represents a steady heat conduction process. Moreover, the transport problem becomes one-dimensional: $\theta = \tilde{\theta}(z)$. Thus, the energy equation adopts the form

$$\frac{d}{dz}\left[\left(1+\zeta\tilde{\theta}\right)\frac{d\tilde{\theta}}{dz}\right] = 0. \tag{5.1}$$

The solution to this equation, which satisfies the boundary conditions (3.10), is

$$\tilde{\theta}\left(z\right) = \frac{\sqrt{\zeta^2+2\zeta z+1}-1}{\zeta}. \tag{5.2}$$

For $\zeta \to 0$, $\tilde{\theta}\left(z\right) \sim z$; this is the linearized solution. For $\zeta \to 1^-$, $\tilde{\theta}\left(z\right) \sim \sqrt{2z+2}-1$. The dependence of $\tilde{\theta}$ upon ζ is depicted in Figure 5.1. Note that (5.2) implies that the temperature gradient is inversely proportional to the absolute temperature:

$$\frac{d\tilde{\theta}}{dz} = \frac{1}{1+\zeta\tilde{\theta}}. \tag{5.3}$$

Only in the limit $\zeta \to 0$ does the outer solution correspond to the notion of an "applied gradient."

Since the preceding solution does not satisfy the no-flux condition (3.11), it actually constitutes an outer solution of the limit $\epsilon \to 0$. Thus, the temperature distribution (5.2) (with vanishing $\boldsymbol{v}$ and $\tilde{p}$) needs to be supplemented by a comparable inner solution, which is valid for $r = O\left(\epsilon\right)$. When solving the thermophoretic problem using inner–outer expansions, separate asymptotic expansions in $\epsilon \ll 1$ are required in each separate region. These expansions must match in their common region of validity.

A solution comprised of a quiescent gas in the temperature profile (5.2) actually satisfies the exact governing equations. However, since it is not guaranteed to match the inner solution at all asymptotic orders, it constitutes only a leading-order outer solution. As will become evident in subsequent analysis, the leading-order inner solution consists of a temperature dipole and a velocity doublet. This solution "induces," through matching requirements, an $O\left(\epsilon^2\right)$ temperature correction and an $O\left(\epsilon^3\right)$ velocity correction in the outer solution. Luckily, the determination of such higher-order corrections proves unnecessary in the present investigation.

6. Inner problem. The inner problem is formulated in terms of the relative position vector. The rescaled variables of the inner problem are denoted by capital letters. Thus, the position and time variables are defined by $\boldsymbol{r} = \epsilon\boldsymbol{R}$ and $t = \epsilon T$, while the dependent variables are rescaled as

$$\Theta = \theta, \quad P = \epsilon\tilde{p}, \quad \boldsymbol{V} = \boldsymbol{v}, \quad \boldsymbol{W} = \boldsymbol{w}. \tag{6.1}$$

Note that the pressure rescaling is equivalent to normalization with the Stokes viscous scale $\mu_\infty\mathscr{U}/a$ (cf. (4.2)). The inner and outer coordinates are related via the relation

$$\boldsymbol{x} = \boldsymbol{x}_P(0) + \epsilon\int_0^T \boldsymbol{W}(\tau)\,d\tau + \epsilon\boldsymbol{R}, \tag{6.2}$$

and, specifically,

$$z = z_p(0) + \epsilon\int_0^T W(T')\,dT' + \epsilon R\cos\vartheta, \tag{6.3}$$

where $R = |\boldsymbol{R}|$ and with the polar angle ϑ measured from the z-axis. These two variables therefore constitute the radial and polar coordinates in a particle-fixed spherical reference system.

The inner temperature field is governed by the enthalpy equation (cf. (4.5))

$$\epsilon\frac{2\zeta}{3(1+\zeta\Theta)}\frac{D\Theta}{DT} = \nabla\cdot[(1+\zeta\Theta)\nabla\Theta], \tag{6.4}$$

together with the no-flux condition

$$\frac{\partial\Theta}{\partial R} = 0 \quad \text{at} \quad R = 1. \tag{6.5}$$

Here, $\nabla \equiv \partial/\partial\boldsymbol{R}$ is the inner gradient operator. The modified material derivative operator,

$$\frac{D}{DT} = \frac{\partial}{\partial T} + (\boldsymbol{V}-\boldsymbol{W})\cdot\nabla, \tag{6.6}$$

reflects the transformation (6.2) to a particle-fixed reference system. In addition to satisfying (6.4)–(6.5), Θ should also match the outer solution (5.2).

The inner flow field is governed by the differential equations (cf. (4.6)–(4.7)),

$$\nabla\cdot\boldsymbol{V} = \frac{\zeta}{1+\zeta\Theta}\frac{D\Theta}{DT}, \tag{6.7}$$

$$\epsilon\frac{\zeta}{1+\zeta\Theta}\frac{D\boldsymbol{V}}{DT} = -\nabla P + 2\nabla\cdot[(1+\zeta\Theta)\,\mathsf{E}], \tag{6.8}$$

where

$$\mathsf{E} = \frac{1}{2}\left[\nabla\boldsymbol{V} + (\nabla\boldsymbol{V})^\dagger\right] - \frac{1}{3}(\nabla\cdot\boldsymbol{V})\,\mathsf{I} \tag{6.9}$$

is the rescaled rate of strain tensor. It also satisfies the slip condition on the particle surface:

$$\boldsymbol{V} - \boldsymbol{W} = \epsilon^{-1}c_S(1+\zeta\Theta)\nabla\Theta \quad \text{at} \quad R = 1, \tag{6.10}$$

and is required to decay at large R. The flow problem is closed by the application of Newton's second law to the particle:

$$\oint d^2\boldsymbol{n}\,\boldsymbol{n}\cdot\left[-P\mathsf{I}+2\left(1+\zeta\Theta\right)\mathsf{E}\right]=\frac{4\pi}{3}\epsilon\zeta\sigma\frac{d\boldsymbol{W}}{dT}. \tag{6.11}$$

Here, $\boldsymbol{n}$ is an outward-pointing unit vector, normal to the particle surface, and $d^2\boldsymbol{n}$ is a differential solid angle about it.

7. Asymptotic matching.

A convenient procedure for performing inner–outer matching is provided by Van Dyke laws [22]:

(7.1) The m-term inner expansion of (the n-term outer expansion) =
The n-term outer expansion of (the m-term inner expansion).

Note that this is a statement of strict equality. Applying this law requires rewriting the left-hand side of (7.1) in terms of the outer variables (or, alternatively, rewriting the right-hand side of (7.1) in terms of the inner variables). The transformation between the inner and outer coordinates, however, involves the variable $\boldsymbol{W}$, which is itself expanded into an asymptotic series in ϵ. Thus, (7.1) cannot be satisfied unless one assumes a priori that the expansion of W terminates after a finite number of terms.

We therefore abandon Van Dyke's method in favor of the more general approach of intermediate variables [12]. We define the intermediate position vector $\boldsymbol{\xi}$:

$$\boldsymbol{r}=\epsilon^{\alpha}\boldsymbol{\xi}, \tag{7.2}$$

where $0<\alpha<1$. This vector is related to the inner coordinate through the relation $\boldsymbol{\xi}=\epsilon^{1-\alpha}\boldsymbol{R}$, and to the outer coordinate through the relation

$$\boldsymbol{X}=\boldsymbol{X}_p\left(0\right)+\epsilon\int_0^T\boldsymbol{W}\left(\tau\right)d\tau+\epsilon^{\alpha}\boldsymbol{\xi}. \tag{7.3}$$

The matching procedure requires that the inner and outer expansions possess a common domain of validity, in which ξ is $O(1)$. The more terms are required to be matched, the smaller this common domain becomes. It is therefore expected that matching of higher-order expansions would decrease the upper bound on α.

For future reference, we express the outer temperature field (5.2) in terms of the intermediate variable:

$$\begin{aligned}\tilde{\theta}\sim\tilde{\theta}_P&+\frac{\epsilon^{\alpha}}{1+\zeta\tilde{\theta}_P}\xi\cos\theta+\frac{\epsilon\int_0^T W\left(\tau\right)d\tau}{1+\zeta\tilde{\theta}_P}\\&-\frac{\epsilon^{2\alpha}\zeta}{2(1+\zeta\tilde{\theta}_P)^3}\xi^2\cos^2\vartheta-\frac{\epsilon^{1+\alpha}\zeta\int_0^T W\left(\tau\right)d\tau}{(1+\zeta\tilde{\theta}_P)^3}\xi\cos\vartheta+O\left(\epsilon^{3\alpha},\epsilon^2\right).\end{aligned} \tag{7.4}$$

Here,

$$\tilde{\theta}_P=\frac{\sqrt{\zeta^2+2\zeta z_P\left(0\right)+1}-1}{\zeta} \tag{7.5}$$

is the value of undisturbed temperature field (5.2) at the original position (at time $T=0$) of the particle center.

8. Asymptotic analysis in the inner region. We postulate the following asymptotic expansions: Inner solution

$$\Theta \sim \Theta_0 + \epsilon\Theta_1 + \epsilon^2\Theta + \cdots , \tag{8.1a}$$

$$\boldsymbol{V} \sim \boldsymbol{V}_0 + \epsilon\boldsymbol{V}_1 + \cdots , \tag{8.1b}$$

and

$$P \sim P_0 + \epsilon P_1 + \cdots , \tag{8.1c}$$

together with a comparable expansion E. In principle, these expansions induce the following expansion for $\boldsymbol{W} = \boldsymbol{e}_z W$:

$$W \sim W_0 + \epsilon W_1 + \cdots . \tag{8.1d}$$

8.1. Leading-order temperature field. The leading-order temperature field is governed by the equations

$$(1 + \zeta\Theta_0)\, \nabla^2\Theta_0 + \zeta\, (\nabla\Theta_0)^2 = 0, \tag{8.2a}$$

$$\frac{\partial\Theta_0}{\partial R} = 0 \quad \text{at} \quad R = 1, \tag{8.2b}$$

which possess a trivial constant solution. Matching with (7.4) readily yields

$$\Theta_0 \equiv \tilde{\theta}_P. \tag{8.3}$$

To calculate the leading-order velocity field the next term is also needed; see the slip condition (6.10). It is convenient to define

$$\bar{\Theta}_1 = (1 + \zeta\tilde{\theta}_P)\Theta_1. \tag{8.4a}$$

This scaled variable satisfies the following equations:

$$\nabla^2\bar{\Theta}_1 = 0, \tag{8.4b}$$

$$\frac{\partial\bar{\Theta}_1}{\partial R} = 0 \quad \text{at} \quad R = 1. \tag{8.4c}$$

Accordingly, it consists of spherical harmonics of the form

$$c^{(0)}\,(T) + \sum_{n=1}^{\infty} c^{(n)}\,(T) \left(R^n + \frac{n}{n+1} R^{-n-1} \right) P^{(n)}\,(\cos\vartheta)\,. \tag{8.5}$$

Here, $P^{(n)}$ is the Legendre Polynomial of degree n.[4] Note that the terms in (8.5) appear in pair-combinations which satisfy the no-flux condition (8.4c).

Matching with (7.4) reveals that Θ_1 does not possess any modes of $n > 1$. Accordingly,

$$\bar{\Theta}_1 = c_1^{(0)}\,(T) + c_1^{(1)}\,(T) \left(R + \frac{1}{2R^2} \right) \cos\vartheta. \tag{8.6}$$

[4] It is usually denoted by P_n; here we use an unconventional notation to avoid confusion with the various terms of the inner pressure expansion (8.1c).

In terms of the intermediate variable, the inner temperature field adopts the expansion

$$\Theta_0 + \epsilon\Theta_1 \sim \tilde{\theta}_P + \epsilon^{\alpha}\frac{c_1^{(1)}}{1+\zeta\tilde{\theta}_P}\xi\cos\theta + \epsilon\frac{c_1^{(0)}}{1+\zeta\tilde{\theta}_P} + O\left(\epsilon^{3-2\alpha}\right). \tag{8.7}$$

Matching with (7.4) then yields

$$c_1^{(1)} = 1, \quad c_1^{(0)} = \int_0^T W_0\left(\tau\right) d\tau. \tag{8.8}$$

The time-dependent term $c_1^{(0)}$ accounts for the slowly-varying temperature background observed in a particle-fixed reference system as the particle moves through the nonuniform temperature field.

8.2. Leading-order flow. The leading-order velocity field is governed by the following equation set:

$$\nabla\cdot\boldsymbol{V}_0 = 0, \tag{8.9a}$$

$$(1+\zeta\tilde{\theta}_P)\nabla^2\boldsymbol{V}_0 - \nabla P_0 = 0, \tag{8.9b}$$

$$\boldsymbol{V}_0 - \boldsymbol{W}_0 = c_S\nabla\bar{\Theta}_1 \quad \text{at} \quad R = 1, \tag{8.9c}$$

$$\boldsymbol{V}_1 \to \boldsymbol{0} \quad \text{as} \quad R\to\infty. \tag{8.9d}$$

In addition, (6.11) implies that the particle appears force-free at this asymptotic level.

Now, $\bar{\Theta}_1$ satisfies Laplace's equation, the no-flux condition, and the far-field behavior for large R:

$$\nabla\bar{\Theta}_1 \to \boldsymbol{e}_z. \tag{8.10}$$

Accordingly, it satisfies the same equations as would the electric potential in a thin-Debye-layer electrophoretic problem [1]. Moreover, the velocity field satisfies the same equations as those that apply to electrophoresis of a constant-zeta-potential particle. Thus, we can exploit Morrison's classical analysis [17] to obtain a solution to the present problem. The particle translates with the velocity

$$W_0 = -c_S \tag{8.11}$$

(corresponding to the Smoluchowski velocity in electrophoresis), the flow is irrotational,

$$\boldsymbol{V}_0 - \boldsymbol{W}_0 = c_S\nabla\bar{\Theta}_1, \tag{8.12}$$

and $P_0 = 0$. In view of (8.4b), it is readily verified that (8.12) trivially satisfies the flow equations (8.9a)–(8.9b). Moreover, using the Gauss theorem allows us to write the force delivered by $\boldsymbol{V}_0$ as an integral over any surface enclosing the particle, not necessarily its boundary. With the stress field decaying as R^{-4} (corresponding to the dipole term in (8.7)), it becomes evident that this force vanishes, as required.[5]

[5] These results actually hold for nonspherical particle shapes (in which case $\bar{\Theta}_1$ would not be given by (8.6), but would still decay as a dipole to leading order). When considering such particles, it is also necessary to demonstrate that they remain torque-free. This is again verified using the Gauss theorem and the fast decay of $\nabla\nabla\bar{\Theta}_1$.

The velocity (8.11) is the same as that obtained by Epstein [8]. This may appear surprising, since the outer temperature field deviates from the linear gradient of Epstein's small-ζ analysis. Indeed, the outer temperature field (5.2) appears at the particle-scale description (represented by (8.3) and (8.6)) as a uniform gradient superimposed upon a uniform temperature. This gradient is smaller by a factor $1+\zeta\tilde{\theta}_P$ from that appropriate to its $\zeta \to 0$ limit; see (5.3). Moreover, the absolute temperature is larger by that factor. Considering the slip condition (1.1), we then find that the direct effect of deviation from the small-ζ uniform gradient is to reduce the slip by the factor $(1+\zeta\tilde{\theta}_P)^2$. On the other hand, the kinematic viscosity increases by the same factor; see (4.3) and (4.8). Thus, Epstein's result is recovered due to a fortuitous cancellation of effects.

For future reference, we note that the leading-order rate-of-strain satisfies the relations

$$\mathsf{E}_0 = \nabla \boldsymbol{V}_0 = c_S \nabla\nabla\bar{\Theta}_1, \quad \nabla \cdot \mathsf{E}_0 = \mathbf{0}. \tag{8.13}$$

8.3. Convective-driven temperature correction. To analyze the perturbation to the leading-order flow, we need to evaluate Θ_2. It is convenient to define the variable

$$\bar{\Theta}_2 = \frac{(1+\zeta\tilde{\theta}_P)^3}{\zeta}\Theta_2, \tag{8.14a}$$

which is governed by the following equations:

$$\nabla^2\bar{\Theta}_2 = \left(\frac{2}{3}c_S - 1\right)(\nabla\Theta_1)^2 - \frac{2}{3}c_S, \tag{8.14b}$$

$$\frac{\partial\bar{\Theta}_2}{\partial R} = 0 \quad \text{at} \quad R = 1. \tag{8.14c}$$

A particular integral to (8.14b) is

$$\bar{\Theta}_{2,p} = -\frac{R^2}{6} + \left(\frac{2}{3}c_S - 1\right)\left[\frac{1}{24R^4} + \left(\frac{1}{3R} + \frac{1}{12R^4}\right)P^{(2)}(\cos\vartheta)\right]. \tag{8.15a}$$

This solution, however, does not satisfy the no-flux condition (8.14c). Thus, we add to (8.15a) the following terms, which, together with (8.15a), retain the condition

$$-\frac{1}{3R} - \left(\frac{2}{3}c_S - 1\right)\left[\frac{1}{6R} + \frac{2}{9R^3}P^{(2)}(\cos\vartheta)\right]. \tag{8.15b}$$

These terms satisfy the homogeneous counterpart of (8.14b).

The solution obtained is not unique: we can add to it an additional homogeneous solution, say $\bar{\Theta}_{2,h}$, consisting of spherical-harmonics pairs of the form (8.5) (recall that these pairs retain the no-flux condition). Since the inner solution must be matched with (7.4), only modes 0, 1, and 2 of the general solution (7.4) can be added. Thus, (8.15c)

$$\bar{\Theta}_{2,h} = c_2^{(0)}(T) + c_2^{(1)}(T)\left(R + \frac{1}{2R^2}\right)\cos\vartheta + c_2^{(2)}(T)\left(R^2 + \frac{2}{3R^3}\right)P^{(2)}(\cos\vartheta).$$

An asymptotic expansion for Θ in the intermediate domain is (cf. (8.7))

$$\tilde{\theta}_P + \epsilon^\alpha c_1^{(1)} \xi \cos\vartheta + \epsilon c_1^{(0)} + \frac{\epsilon^{2\alpha}\zeta}{(1+\zeta\tilde{\theta}_P)^3}\xi^2 \left[c_2^{(2)} P^{(2)}(\cos\vartheta) - \frac{1}{6}\right] + \frac{\epsilon^{1+\alpha}\zeta}{(1+\zeta\tilde{\theta}_P)^3} c_1^{(1)} \xi \cos\vartheta + O\left(\epsilon^{3-2\alpha}, \epsilon^2\right).$$

Matching with (7.4) in conjunction with (8.11) readily yields

$$c_2^{(2)} = -\frac{1}{3}, \quad c_2^{(1)} = c_S T. \tag{8.16}$$

(It is not necessary to obtain $c_2^{(0)}$.) For this matching process the intermediate domain must be modified to the range $0 < \alpha < 2/3$.

9. Leading-order flow correction. The leading-order flow correction $(\boldsymbol{V}_1, P_1)$ is governed by the mass equation

$$\nabla \cdot \boldsymbol{V}_1 = \frac{\zeta}{1+\zeta\tilde{\theta}_P}\frac{D\Theta_1}{DT} \tag{9.1a}$$

and momentum equation

$$\frac{\zeta}{1+\zeta\tilde{\theta}_P}\frac{D\boldsymbol{V}_0}{DT} = -\nabla P_1 + 2\nabla\cdot\left[(1+\zeta\tilde{\theta}_P)\mathsf{E}_1 + \zeta\Theta_1\mathsf{E}_0\right], \tag{9.1b}$$

together with the boundary conditions

$$\boldsymbol{V}_1 - \boldsymbol{W}_1 = c_S\left[(1+\zeta\tilde{\theta}_P)\nabla\Theta_2 + \zeta\Theta_1\nabla\Theta_1\right] \quad \text{at} \quad R = 1, \tag{9.1c}$$

$$\boldsymbol{V}_1 \to \boldsymbol{0} \quad \text{as} \quad R \to \infty. \tag{9.1d}$$

Since W_0 is constant, (6.11) implies that the particle is also force-free at the $O(\epsilon)$ asymptotic level:

$$\oint d^2\boldsymbol{n}\,\boldsymbol{n}\cdot\left\{-P_1\mathsf{I} + 2\left[(1+\zeta\tilde{\theta}_P)\mathsf{E}_1 + \zeta\Theta_1\mathsf{E}_0\right]\right\} = \boldsymbol{0}. \tag{9.1e}$$

9.1. A fictitious Stokes-type problem. Define

$$P_1 = (1+\zeta\tilde{\theta}_P)\bar{P}_1. \tag{9.2}$$

Making use of (8.12) and (8.13), the momentum-balance equation (9.1b) and the force-free condition (9.1e) are, respectively, rewritten as

$$\nabla^2\boldsymbol{V}_1 - \nabla\bar{P}_1 = -\zeta c_S(c_S - 2)\nabla\Theta_1\cdot\nabla\nabla\Theta_1 - \frac{1}{3}c_S\zeta\nabla\left[(\nabla\Theta_1)^2\right] \tag{9.3}$$

and

$$\oint d^2\boldsymbol{n}\,\boldsymbol{n}\cdot\left(-\bar{P}_1\mathsf{I} + 2\mathsf{E}_1\right) = -2c_S\zeta\oint d^2\boldsymbol{n}\,\boldsymbol{n}\cdot\Theta_1\nabla\nabla\Theta_1. \tag{9.4}$$

Note the Stokes operator appearing in (9.3) and the constant-viscosity structure of the stress-like object appearing in (9.4). Thus, we have transformed the flow problem for the variable-viscosity fluid into a comparable problem governing a fictitious constant-viscosity flow field $\big(\boldsymbol{V}_1, \bar{P}_1\big)$. The latter problem is driven by a mass-source distribution (the right-hand side of (9.1a)), velocity slip (the right-hand side of (9.1)), a body force distribution (the right-hand side of (9.3)), and an external force on the particle (the right-hand side of (9.4)).

The flow field $(\boldsymbol{V}_1, \bar{P}_1)$ is decomposed as follows:

$$\boldsymbol{V}_1 = \boldsymbol{V}_I + \boldsymbol{V}_{II} + \boldsymbol{V}_{III} + \boldsymbol{V}_{IV}, \tag{9.5a}$$

$$\bar{P}_1 = P_I + P_{II} + P_{III} + P_{IV}, \tag{9.5b}$$

wherein the subfields $\boldsymbol{V}_I$, $\boldsymbol{V}_{II}$, $\boldsymbol{V}_{III}$, and $\boldsymbol{V}_{IV}$ all decay at large R. The flow problem is, respectively, decomposed into four problems. The first problem satisfies

$$\nabla^2 \boldsymbol{V}_I = \text{right-hand side of (9.3)}, \tag{9.6a}$$

$$P_I = 0. \tag{9.6b}$$

The second problem satisfies

$$\nabla^2 \boldsymbol{V}_{II} = 0, \quad P_{II} = 0, \tag{9.7a}$$

$$\nabla \cdot \boldsymbol{V}_{II} = \text{right-hand side of (9.1a)} - \nabla \cdot \boldsymbol{V}_I. \tag{9.7b}$$

The third problem is governed by the Stokes equations, together with a slip-type boundary condition:

$$\nabla^2 \boldsymbol{V}_{III} - \nabla P_{III} = 0, \quad \nabla \cdot \boldsymbol{V}_{III} = 0, \tag{9.8a}$$

$$\boldsymbol{V}_{III} = \text{right-hand side of (9.1c)} - \boldsymbol{V}_I - \boldsymbol{V}_{II} \quad \text{at} \quad R = 1. \tag{9.8b}$$

The fourth problem is also governed by the Stokes equations, but with the boundary condition

$$\boldsymbol{V}_{IV} = \boldsymbol{W}_1 \quad \text{at} \quad R = 1. \tag{9.9}$$

It is identical to the problem governing the slow translation of a sphere at velocity $\boldsymbol{W}_1 = \boldsymbol{e}_z W_1$ relative to an otherwise quiescent fluid, wherein the no-slip boundary applies.

Our interest is not in the detailed fields, bur rather in their effect upon W_1. This velocity is determined from the condition that the total hydrodynamic force exerted upon the particle by the flow field $(\boldsymbol{V}_1, \bar{P}_1)$ is equal to the right-hand side of (9.4).

9.2. Symmetry arguments. It is convenient here to define a "flip-symmetry" property: We will say that a scalar field has this symmetry if it is invariant under the transformation $z \to -z$. Similarly, an axisymmetric vector field is flip-symmetric if its transverse component is flip-symmetric, while its axial component is antisymmetric. The latter definition can be equivalently stated using polar spherical coordinates: a vector field is flip-symmetric if its radial component is flip-symmetric, while its angular component is antisymmetric. It is readily verified that the Laplacian operator preserves flip-symmetry (or antisymmetry) when applied to either scalar or vector fields; the same is true for the divergence operator: the divergence of a flip-symmetric (antisymmetric) vector field is a flip-symmetric (antisymmetric) scalar field.

The right-hand side of (9.6a) is flip-symmetric; accordingly, so is $\boldsymbol{V}_I$. Clearly, then, $\boldsymbol{V}_I$ does not contribute to the hydrodynamic on the particle. Moreover, it is readily seen that the right-hand side of (9.7b) is flip-symmetric, whence so is $\boldsymbol{V}_{II}$, which then also does not contribute to the hydrodynamic force.

Consider now the slip-driven field $\boldsymbol{V}_{III}$. The slip-terms in the right-hand-side of (9.8b) which are contributed by $\boldsymbol{V}_I$ and $\boldsymbol{V}_{II}$ are flip-symmetric. They therefore contribute flip-symmetric components to $\boldsymbol{V}_{III}$; these components, obviously, do not generate any hydrodynamic force. Moreover, the antisymmetric terms in the right-hand side of (9.1c) cancel each other. We conclude that $\boldsymbol{V}_{III}$, too, does not contribute to the force.

The hydrodynamic force contributed by the fourth hydrodynamic subfield is simply the Stokes drag $-6\pi\boldsymbol{W}_1$. Thus, W_1 is determined by equating this force to the right-hand side of (9.4). Straightforward calculation shows that the latter vanishes. Accordingly, $W_1 = 0$.

10. Maxwell stresses. From the viewpoint of gas-kinetic theory, viscous stresses (and the heat-flux vector) constitute $O\left(\mathrm{Kn}\right)$ correction terms in the Chapman–Enskog expansion of the Boltzmann equation [6], wherein the ideal-fluid model emerges at the leading-order. Higher-order terms obtained in that expansion, such as the $O\left(\mathrm{Kn}^2\right)$ Burnett terms, are traditionally not included in conventional continuum descriptions.

The exclusion of Burnett stresses, however, has been shown to be inconsistent in flows driven by significant temperature differences [9, 13]. The inconsistency is related to only two of the six Burnett stress terms, which are provoked by temperature gradients. For Maxwell molecules, these two "thermal" terms adopt the dimensional form

$$-3\frac{\mu^{*2}}{\rho^*\theta^*}\frac{\partial^2\theta^*}{\partial\boldsymbol{x}^*\partial\boldsymbol{x}^*}, \quad -3\frac{\mu^{*2}}{\rho^*\theta^{*2}}\frac{\partial\theta^*}{\partial\boldsymbol{x}^*}\frac{\partial\theta^*}{\partial\boldsymbol{x}^*}. \tag{10.1}$$

In the presence of a single length scale L, these terms are of order $\zeta{\mu^*_\infty}^2/\rho^*_\infty L^2$. The ratio of these stresses to the $O\left(\mu^*_\infty\mathscr{U}/L\right)$ viscous terms (where $\mathscr{U}$ is a characteristic velocity of the flow) therefore scale as $\zeta\nu^*_\infty/L\mathscr{U}$. Since the kinematic viscosity ν^*_∞ is $O\left(\lambda c^*_\infty\right)$, where λ is the mean free path, this ratio is about $\zeta\,\mathrm{Kn}/M$, and is indeed $O\left(\mathrm{Kn}\right)$ small for "normal" ($M = O\left(1\right)$) situations considered in gas-kinetic theory.[6]

For slip-driven flows, however, the velocity $\mathscr{U}$ scales according to (1.3), and the above-mentioned ratio is actually $O\left(1\right)$: the thermal stresses are of comparable magnitude to the viscous (and inertial) terms. It was shown in [9] that the remaining Burnett terms are still $O\left(\mathrm{Kn}\right)$ small, and are therefore negligible.

In the present dimensionless momentum equation, the right-hand side of (4.7) is accordingly supplemented by the term

$$-3\frac{\partial}{\partial\boldsymbol{x}}\cdot\left[\left(1+\zeta\theta\right)^2\frac{\partial^2\theta}{\partial\boldsymbol{x}\,\partial\boldsymbol{x}} + \zeta\left(1+\zeta\theta\right)^2\frac{\partial\theta}{\partial\boldsymbol{x}}\frac{\partial\theta}{\partial\boldsymbol{x}}\right], \tag{10.2}$$

which corresponds to the divergence of the Maxwell stresses (10.1).

In principle, the existence of Maxwell stresses implies that classical pure-conduction situations may not be compatible with mechanical equilibrium. In the present investigations, it is therefore necessary to reexamine the validity of the outer solution. Fortunately, the one-dimensional temperature profile (5.2) generates Maxwell stresses which possess only an $\boldsymbol{e}_z\boldsymbol{e}_z$ component:

$$-3\left[\left(1+\zeta\theta\right)^2\frac{d^2\theta}{dz^2} + \zeta\left(1+\zeta\theta\right)^2\left(\frac{d\theta}{dz}\right)^2\right].$$

[6] Usually it is even smaller, since in the absence of *imposed* temperature differences, ζ is also small; if the temperature field is set by viscous dissipation, for example, it is $O\left(\mathrm{Kn}\right)$.

According to (5.3), this component vanishes.

Of course, the Maxwell stresses do modify the inner solution. It is readily verified that the right-hand side of the inner momentum equation (6.8) is supplemented by the term

$$-3\epsilon^{-1}\nabla\cdot\left[(1+\zeta\Theta)^2\,\nabla\nabla\Theta+\zeta\,(1+\zeta\Theta)\,\nabla\Theta\nabla\Theta\right]. \tag{10.3}$$

In the leading-order flow problem, the right-hand side of (8.9b) is supplemented by the term

$$-3\nabla\cdot\left[(1+\zeta\tilde{\theta}_P)^2\nabla\nabla\Theta_1\right].$$

Since Θ_1 is harmonic (see (8.4b)), this term vanishes. Consider now the leading-order flow correction: the right-hand side of (9.3) is supplemented by the term

$$-3\nabla\cdot\left[(1+\zeta\tilde{\theta}_P)\nabla\nabla\Theta_2+2\zeta\Theta_1\nabla\nabla\Theta_1+\zeta(1+\zeta\tilde{\theta}_P)\nabla\Theta_1\nabla\Theta_1\right].$$

It is easily verified that this term is flip-symmetric and does not contribute to the hydrodynamic force experienced by the particle.

11. Concluding remarks.

The drift of a spherical particle in a nonisothermal gaseous environment, provoked by a thermally-induced slip at the outer edge of a Knudsen layer, was investigated theoretically. The gas is bounded between two parallel walls maintained at uniform but unequal temperatures. Unlike previous studies, it was not assumed that the temperature difference is small compared with the mean absolute temperature. The problem is then inherently nonlinear, with a universal scaling for the Reynolds and Péclet numbers.

With the goal of obtaining qualitative understanding, we adopt the simple model of an insulating particle. (At the other extreme, when the particle conductivity is large compared with that of the gas, the slip model obviously predicts null thermophoretic velocity.) We also restrict the analysis to the continuum regime, the Knudsen number approaching zero.

The analysis is asymptotic, in the limit of a small particle. In view of the inherent nonlinearity, it is impossible to transform the problem into a steady one. The small-particle limit is singular and requires asymptotic matching between the particle-scale solution and the apparatus-scale nonlinear behavior. The transformation between the inner and outer descriptions employs the particle position, itself a dependent variable of the asymptotic problem.

Due to a fortuitous cancellation of terms, we found that Epstein's result [8] holds at leading order. Moreover, the symmetric leading-order $O(\epsilon)$ correction to the flow field does not affect Epstein's result. The inclusion of Burnett stresses modifies the flow field, but symmetry arguments show that this modification does not contribute to the thermophoretic velocity at the inspected asymptotic orders.

In view of the growing interest in the effect of walls upon thermophoretic motion [7, 11] and the $O(\epsilon^3)$ asymptotically small wall effects predicted by prevailing analyses of the linearized model [1], it is desirable to evaluate higher-order corrections to the flow. Unfortunately, we were unable to progress further with the present asymptotic scheme. Thorough understanding of the nonlinear thermophoretic mechanism may therefore require analysis of the nonlinear model in the future.

OSTWALD RIPENING IN THIN FILM EQUATIONS[*]

K. B. GLASNER[†]

Abstract. Fourth order thin film equations can have late stage dynamics that are analogous to the classical Cahn–Hilliard equation. We undertake a systematic asymptotic analysis of a class of equations that describe partial wetting with a stable precursor film introduced by intermolecular interactions. The limit of small precursor film thickness is considered, leading to explicit expressions for the late stage dynamics of droplets. Our main finding is that exchange of mass between droplets characteristic of traditional Ostwald ripening is a subdominant effect over a wide range of kinetic exponents. Instead, droplets migrate in response to variations of the precursor film. Timescales for these processes are computed using an effective medium approximation to the reduced free boundary problem, and dynamic scaling in the reduced system is demonstrated.

Key words. thin film equation, dewetting, coarsening, Ostwald ripening

1. Introduction.

Viscous liquid films have a rich set of dynamics that are still only partially understood [7, 28]. A large subset of phenomena involves dewetting instabilities that produce a diverse collection of patterns that have been studied experimentally [1, 13, 33, 34, 35, 42] as well as theoretically [2, 3, 19, 22, 27, 36, 37, 42]. These instabilities cause nearly uniform fluid layers to break up into arrays of large droplets connected by a remaining (very) thin film, which undergo an elaborate coarsening process characterized both by coalescence of droplets and exchange of fluid between droplets and the intervening film [11, 12, 15, 16].

The results we describe run parallel to other studies of dynamical coarsening processes, most notably phase separation phenomena described by the Cahn–Hilliard equation [5, 30]. At late times and small volume fractions, this equation describes the Ostwald ripening process [14, 24, 25, 38, 39]. Our purpose is to describe a similar limit for a class of thin film equations and to highlight the differences between our problem and classical Ostwald ripening.

The analogy between spinodal decomposition and liquid dewetting was first explored by Mitlin [19, 20, 21, 22]. Subsequent theoretical works have studied coarsening in thin film equations that results from other instabilities. Bestehorn, Pototsky, and Thiele [4] consider the evolution of a film destabilized by Marangoni effects and quantify coarsening rates through numerical experiments. Merkt et al. [18] obtain similar results for a two-layer film. There are, in fact, numerous other variations of dissipative fourth order equations that exhibit coarsening behavior, for example, the convective Cahn–Hilliard equation studied by Watson et al. [40].

This paper is a continuation of a body of work initiated by Glasner and Witelski [11, 12] on coarsening behavior of liquid droplets described by disjoining-pressure models. It was found there that the dewetting instability leads to the eventual development of droplets separated by a precursor film. The subsequent one-dimensional

dynamics of these droplets was computed, involving mass exchange between droplets and the precursor layer as well as motion of the droplets themselves. This results in a coarsening process characterized by both mass transfer and coalescence, and exhibits dynamic scaling with a nonstandard exponent. Rigorous bounds for dynamic scaling were subsequently obtained by Otto, Rump, and Slepčev [29]. In two dimensions, the interaction of droplets has been studied by Pismen and Pomeau [32]. Although not entirely dissimilar from the conclusions described here, their results are in both quantitative and qualitative disagreement with our calculations (see the concluding section for a comparison).

This work serves as a companion paper to the manuscript of Glasner et al. [9]. Instead of a matched asymptotics approach, that work utilizes a variational principle (the Rayleigh–Onsager notion of least dissipation [26]) to explain and quantify droplet migration effects. Both papers obtain comparable results, although a careful interpretation is needed to show their equivalence. Some comparison is provided in section 5.

This paper considers a class of fourth order parabolic equations which have the structure

$$\tau(\epsilon)h_t = \nabla\cdot(h^q\nabla p), \qquad p = \epsilon^{-1}U'\left(\frac{h}{\epsilon}\right) - \Delta h, \quad q > 0. \tag{1.1}$$

The physical domain is taken to be a two-dimensional, bounded, simply connected open set Ω, where Neumann and no-flux boundary conditions are imposed (although few of our results depend crucially on these assumptions). The timescale $\tau(\epsilon)$ is chosen to capture the slow dynamics associated with migration and mass exchange (i.e., ripening) of droplets. It depends on the mobility exponent as

$$\tau(\epsilon) = \begin{cases} \epsilon^q, & q \in (0,2), \\ \epsilon^2 \ln(\epsilon^{-1}), & q = 2, \\ \epsilon^2, & q \in (2,3), \\ \epsilon^2/\ln(\epsilon^{-1}), & q = 3, \\ \epsilon^{q-1}, & q > 3. \end{cases} \tag{1.2}$$

Our interest is in the limit of small ϵ, which corresponds to both thin precursor films and long timescales.

It is instructive to consider a range of mobility exponents to capture the crossover between different dynamical mechanisms. For liquid films, this exponent is a function of the solid-liquid boundary condition and the fluid rheology. The standard case of a Newtonian fluid with a no-slip boundary condition corresponds to $q = 3$. The Navier slip condition leads to $q = 2$ if particular limits are considered [8, 23], whereas Darcy's law can lead to $q = 1$ [6]. Models of non-Newtonian fluids may have a variety of exponents (see, e.g., [41]).

The class of potentials U considered here include those commonly employed to describe a combination of attractive and repulsive van der Waals forces [28]. The following assumptions are used:

1. U is scaled so that it has a minimum at 1 and $U(\infty) - U(1) = 2$.
2. U' has a unique maximum at $H^* > 1$.
3. The potential decays as

$$U'(H) = \mathcal{O}(H^{-\alpha}), \quad H \to \infty, \tag{1.3}$$

where

$$\alpha > \begin{cases} q+1, & q \in (0,2), \\ 3, & q \geq 2. \end{cases} \tag{1.4}$$

This will ensure that intermolecular interactions have a subdominant effect for macroscopic ($h \sim \mathcal{O}(1)$) films.

The structure of the paper is as follows. Section 2 describes the results of the lengthy calculation, whose details are given in sections 3 and 4. Section 5 goes on to propose an approximation procedure for the resulting free boundary problem, and timescales for the relevant dynamics are worked out. Section 6 gives example calculations and compares them to predictions of dynamic scaling.

2. Setup for matched asymptotics and a summary of results. There will be three regions in the matched asymptotic analysis (see Figure 2.1):

- Region I: This region corresponds to droplets and is composed of the union of disjoint disks $\{D_i\}$ which have the form $D = \{\mathbf{x} \,\big|\, |\mathbf{x} - X| < R\}$ so that X is the droplet center and R is its radius. Unit normals to ∂D will be denoted $\mathbf{n}$, and we will also utilize the coordinate unit vectors $\hat{\mathbf{x}}$, $\hat{\mathbf{y}}$, etc. In this region, h and x will both scale like $\mathcal{O}(1)$. It will be convenient to use the moving polar coordinates $r = |\mathbf{x} - X(t)|$, $\theta = \arg(\mathbf{x} - X(t))$.
  To be more precise about R and X, we define the contact line at finite ϵ to be the set $\{\mathbf{x} \mid h(\mathbf{x}) = \epsilon H^*\}$, where H^* is the global maximum of U'. This definition is somewhat arbitrary and is chosen merely for convenience. On the other hand, in the limit $\epsilon \to 0$ this set converges to the boundary of the support of h, i.e., the sharp-interface contact line. We suppose that for each droplet this curve is nearly circular and has the form $\mathbf{x} = X + R(\theta)\hat{\mathbf{r}}$. Properly speaking, R and X should also be expanded in ϵ, but to avoid

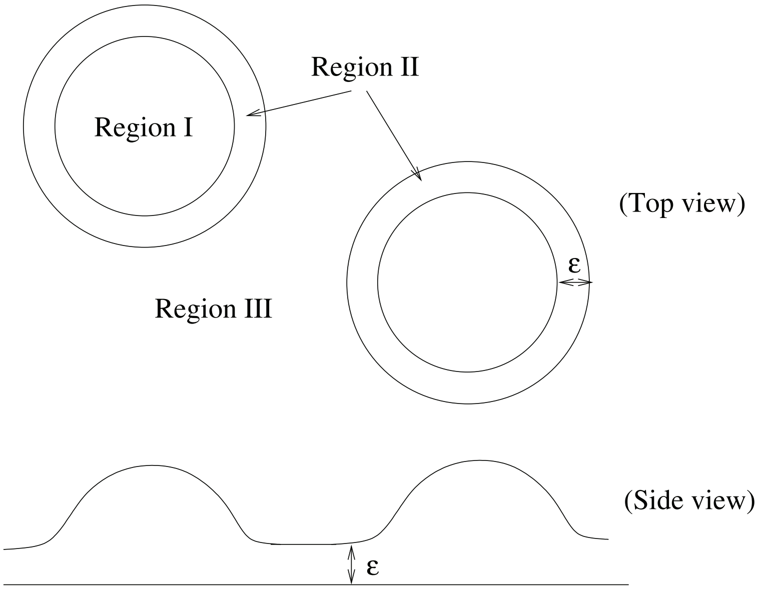

FIG. 2.1. *Three regions for the matched asymptotic calculation.*

excessive notation, these labels will simply denote the corresponding leading order solutions. In particular, we find that R is independent of θ at leading order.

- Region II is a microscopic internal layer near the contact line where h and x scale like ϵ. The moving rescaled radial coordinate

$$z = \frac{R(t) - r}{\epsilon} \tag{2.1}$$

will be employed. In light of the definition of R, the solution in this region must satisfy

$$h(z = 0) = h^*. \tag{2.2}$$

For reference, the Laplacian in z, θ coordinates expands as

$$\Delta h = \epsilon^{-2} h_{zz} - \epsilon^{-1} R^{-1} h_z - \Big(z R^{-2} h_z + R^{-2} h_{\theta\theta} \Big) + \mathcal{O}(\epsilon). \tag{2.3}$$

- Region III is the complement $\Omega / \cup D_i$ which contains the precursor film. In this region, h will scale like ϵ.

The overall strategy is to propose self-consistent asymptotic expansions in each region and to connect them via matching conditions. Less-standard matching conditions are derived when needed. Corrections to the leading order base solutions solve linear equations, and Fredholm-type solvability conditions will yield information about the dynamics.

The main goal is to determine the dynamic behavior of R and X, which will be shown to arise from a flux J which is determined by the elliptic problem

$$\Delta P = 0, \quad P|_{\partial D_i} = \frac{2}{R_i}, \quad J = -\nabla P, \tag{2.4}$$

solved in the exterior region $\Omega / \cup D_i$. Here P represents the first nontrivial correction to the pressure p. Equations (2.4) describe quasi-steady diffusion of material driven by a Gibbs–Thomson boundary condition. We find that, with respect to the timescale τ, the dynamics at leading order are

$$R_t = \begin{cases} -\frac{4}{3\pi R^2} \int_{\partial D} J \cdot \mathbf{n} \, ds, & q < 2, \\ 0, & q \geq 2, \end{cases} \tag{2.5}$$

and

$$X_t = -M(R) \int_{\partial D} \mathbf{n} J \cdot \mathbf{n} \, ds, \tag{2.6}$$

where the mobility factor $M(R)$ is

$$M = \frac{1}{\pi} \begin{cases} R^{-2} \Psi_1(1) \Big/ \int_0^1 \Psi_1(r) r^2 dr, & q < 2, \\ R^{-2} \Big/ \int_0^1 \Psi_1(r) r^2 dr, & q = 2, \\ R^{q-4} \int_{-\infty}^{\infty} [H_1^{1-q} - H_1^{-q}] dz \Big/ \int_0^1 \Psi_1(r) r^2 dr, & q \in (2,3), \\ R^{-1} \int_{-\infty}^{\infty} [H_1^{-2} - H_1^{-3}] dz, & q = 3, \\ R^{-1} \int_{-\infty}^{\infty} [H_1^{1-q} - H_1^{-q}] dz \Big/ \int_{-\infty}^{\infty} H_1^{2-q} - H_1^{1-q} dz, & q > 3. \end{cases} \tag{2.7}$$

H_1 is the leading order solution for the microscopic contact line region II. The function Ψ_1 arises from the solvability argument and is specified as the solution of the rescaled boundary value problem (4.5)–(4.7).

The point of writing $R_t = 0$ for $q \geq 2$ in (2.5) is to emphasize the crossover between radial and migration dynamics. This is to some extent an artifact of our choice of timescales (1.2). Had we chosen $\tau = \epsilon^q$ for all q instead, then the radial dynamics would just be given by the first nonzero formula in (2.5).

3. Base solutions.

This section summarizes the aspects of the analysis which are common to all mobility exponents $q > 0$. The rest is split into cases in the following section.

Region II. The solution is expanded as $h = \epsilon H_1 + \epsilon^2 H_2 + o(\epsilon^2)$. The leading order equation is

$$(H_1^q[-(H_1)_{zz} + U'(H_1)]_z)_z = 0. \tag{3.1}$$

Integrating twice and using the matching conditions $(H_1)_z \sim 0$ as $z \to -\infty$, we get

$$-(H_1)_{zz} + U'(H_0) = c_1. \tag{3.2}$$

The matching condition $(H_1)_{zz} \sim 0$ as $z \to +\infty$ means that $C = 0$ in light of (1.3). It follows that $H_1 \sim 1$ as $z \to -\infty$, and we can integrate again to obtain

$$\frac{1}{2}(H_1)_z^2 = U(H_1) - U(1), \tag{3.3}$$

from which the equilibrium contact angle is determined by

$$(H_1)_z = \sqrt{2[U(H_1) - U(1)]} \sim 1, \quad z \to +\infty. \tag{3.4}$$

Solving (3.3) gives the solution implicitly as

$$\int^{H_1} \frac{dH}{\sqrt{2[U(H) - U(1)]}} = z + c_2. \tag{3.5}$$

The constant of integration is determined uniquely by the condition (2.2).

The next order correction satisfies

$$(H_1^q[-(H_2)_{zz} - R^{-1}(H_1)_z + U''(H_1)H_2]_z)_z = 0. \tag{3.6}$$

Integrating and using the matching condition $(H_2)_{zzz} \to 0$ as $z \to \infty$ gives

$$[-(H_2)_{zz} - R^{-1}(H_1)_z + U''(H_1)H_2]_z = 0. \tag{3.7}$$

A further integration implies

$$-(H_2)_{zz} - R^{-1}(H_1)_z + U''(H_1)H_2 \equiv P = \text{constant}. \tag{3.8}$$

This says that (total) leading order pressure is constant through region II, and we can use this to match between regions I and III. We remark that both H_1 and H_2 are independent of θ. Later in the calculation, this will provide symmetry that is needed to make certain integrals vanish.

Region I. Expanding $h = h_0(\mathbf{x}, t) + o(1)$ for now, we obtain

$$\nabla\cdot(h_0^q \nabla \Delta h_0) = 0, \quad \mathbf{x} \in D. \tag{3.9}$$

Provided that h_0 is well behaved (bounded third derivatives), integration of (3.9) against Δh_0 gives

$$\int_D h_0^q |\nabla \Delta h_0|^2 dx = 0. \tag{3.10}$$

Since $h_0 \to 0$ on the boundary of D, it follows that Δh_0 is a constant. Using the matching conditions

$$h_0(R,\theta) = 0, \quad (h_0)_r(R,\theta) = -1 \tag{3.11}$$

gives the family of radially symmetric droplet solutions

$$h_0(\mathbf{x}; R(t), X(t)) = R(t) H\left(\frac{\mathbf{x} - X(t)}{R(t)}\right), \quad H(\eta) = \frac{1}{2}(1-\eta^2). \tag{3.12}$$

Using (3.8), (3.12) and the matching condition

$$(h_0)_{rr}(R,\theta) = \lim_{z\to\infty} (H_2)_{zz} \tag{3.13}$$

allows us to relate the pressure P and the droplet radius:

$$P = -\Delta h_0 = \frac{2}{R(t)}. \tag{3.14}$$

Region III. Here we expand $h = \epsilon h_1 + \epsilon^2 h_2 + o(\epsilon^2)$. Because of the scaling of $\tau(\epsilon)$, the leading order problem for all $q > 0$ is the elliptic equation

$$\nabla \cdot (h_1^q \nabla U'(h_1)) = 0. \tag{3.15}$$

Matching to region II implies $h_1 = 1$ on the boundary $\cup \partial D_i$; therefore $h_1 \equiv 1$. At order ϵ^2, the correction term satisfies the "quasi-steady" problem

$$\Delta h_2 = 0. \tag{3.16}$$

This equation is solved together with boundary conditions that are derived by matching. Using (3.8) and (3.14), we find that

$$U''(1) h_2 = \frac{2}{R(t)}, \quad \mathbf{x} \in \partial D. \tag{3.17}$$

It is convenient introduce the flux

$$J = -h^q \nabla p = -\epsilon^q U''(1) \nabla h_2 + o(\epsilon^q) \tag{3.18}$$

so that at leading order

$$J_q = -\nabla P, \quad P \equiv U''(1) \nabla h_2 \tag{3.19}$$

is therefore determined by solving the boundary value problem (3.16), (3.17). To avoid excessive notation, we also use J_q to denote the flux of order $\mathcal{O}(\epsilon^q)$ in regions I and II.

4. Mobility-dependent expansions.

4.1. Case $q \in (0, 2)$. The expansion of the equation in region II at order ϵ^q gives $0 = (J_q \cdot \hat{\mathbf{z}})_z$, which merely says that the z-component of J_q is constant through this layer. Thus the normal component of J_q to the boundary of D is that given by the solution in region III.

In region I, we expand $h = h_0(x,t) + \epsilon^q h_q + o(\epsilon^q)$, which means that leading order flux is $J_q = h_0^q \nabla \Delta h_q$. The first nontrivial correction to the equation in this region gives the linear problem

$$\mathcal{L} h_q = X_t \cdot \nabla h_0 - R_t \frac{\partial h_0}{\partial R}, \quad \mathcal{L} = \nabla \cdot [h_0^q \nabla \Delta \tag{4.1}$$

for $\mathbf{x} \in D$ (the mismatched bracket indicates that the divergence applies to everything to the right). We remark that a similar linear problem was encountered by Pismen [31]. The linear operator $\mathcal{L}$ (on a space endowed with suitable homogeneous boundary conditions) has the adjoint

$$\mathcal{L}^\dagger = \Delta \nabla \cdot [h_0^q \nabla. \tag{4.2}$$

Nullspace of $\mathcal{L}^\dagger$. To invoke a Fredholm solvability argument, we need to characterize its nullspace by finding orthogonal functions whose span is the same as $\{(h_0)_x, (h_0)_y, (h_0)_R\}$. Observe that if ψ is in the nullspace, then

$$\nabla \cdot \left[h_0^q \nabla \psi \right] = \phi, \quad \Delta \phi = 0. \tag{4.3}$$

We shall be interested in the particular harmonic functions $\phi = 0, -x, -y$, which ultimately correspond to changes in droplet size and translation in each direction, respectively. Since $x = r\cos\theta$, $y = r\sin\theta$, we look for a solution of (4.3a) of the form $\psi = \Psi(r)\cos\theta$ or $\psi = \Psi(r)\sin\theta$. In either case we are led to the differential equation

$$r(r h_0^q \Psi')' - h_0^q \Psi = -r^3 \tag{4.4}$$

together with the boundary conditions

$$h_0^q \Psi'(R) = 0, \quad \Psi(0) = 0. \tag{4.5}$$

Several observations about (4.4)–(4.5) are in order. First, the solution is unique, since multiplying the homogeneous version of this linear equation by Ψ/r and integrating leads to

$$\int_0^R \left[r h_0^q \Psi'^2 + \frac{h_0^q \Psi^2}{r} \right] dr = 0. \tag{4.6}$$

There is also a natural scale invariance for this problem: If Ψ_1 solves

$$r(r H^q \Psi_1')' - H^q \Psi_1 = r^3, \quad \Psi_1(0) = 0, \quad H^q \Psi_1(1) = 0, \tag{4.7}$$

then

$$\Psi = R^{3-q} \Psi_1(r/R) \tag{4.8}$$

solves (4.4). Finally, the regularity of solutions of the ordinary differential equation (4.4) and the first boundary condition (4.5) allow us to ascertain the asymptotics at

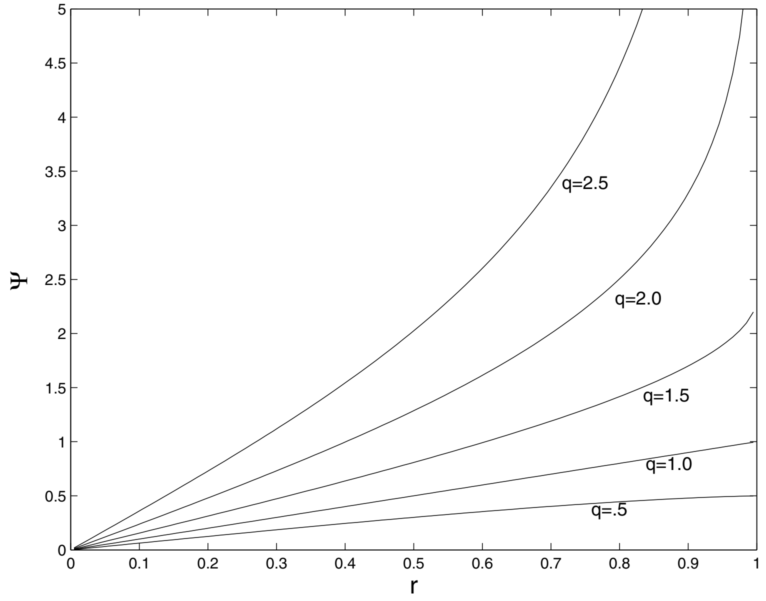

FIG. 4.1. *The function $\Psi(r)$ with $R = 1$, used in the solvability argument.*

$r = R$. In particular, we have $h_0^q\Psi'(R) = \mathcal{O}(|r - R|)$, and therefore one computes for $r \to R$

$$\Psi \sim \begin{cases} \mathcal{O}(1), & q < 2, \\ R\ln|r - R|, & q = 2, \\ \frac{R}{q-2}|r - R|^{2-q}, & q > 2. \end{cases} \tag{4.9}$$

In particular, Ψ is bounded for $q < 2$ and integrable for $q < 3$. Since $r = R$ is a regular singular point of (4.4), the first boundary condition in (4.5) implies

$$h_0^q\Psi'(r) = \mathcal{O}(|r - R|), \quad r \to R. \tag{4.10}$$

In practice, solutions to (4.4) can be obtained numerically (see Figure 4.1). To summarize, the desired functions for the solvability argument are

$$\psi_R = 1, \quad \psi_x = \Psi(r)\cos\theta, \quad \psi_y = \Psi(r)\sin\theta. \tag{4.11}$$

Solvability conditions. The inner product of ψ_R with (4.1) produces

$$R_t = -\frac{\int_{\partial D} h_0^q\nabla\Delta h_q \cdot \mathbf{n}\,ds}{\int_D \partial h_0/\partial R\,dx}. \tag{4.12}$$

Using the matching condition for flux,

$$R_t = -\frac{4}{3\pi R^2}\int_{\partial D} J_q \cdot \mathbf{n}\,ds. \tag{4.13}$$

This is just a statement about conservation of the droplet volume $V = \int h_0\,dx = \pi R^3/4$ since

$$V_t = -\int_{\partial D} J_q \cdot \mathbf{n}\,ds. \tag{4.14}$$

Inner products of (4.1) with $\psi_{x,y}$ determine the translation dynamics. Integration with ψ_x gives

$$
\begin{aligned}
X_t \cdot \hat{\mathbf{x}} \int_D \psi_x \frac{\partial h_0}{\partial x} d\mathbf{x} &= \int_{\partial D} \psi_x h_0^q \nabla \Delta h_q \cdot \mathbf{n}\, ds - \int_{\partial D} h_0^q (\Delta h_q) \nabla \psi_x \cdot \mathbf{n} ds \\
&\quad - \int_{\partial D} x \nabla h_q \cdot \mathbf{n} ds + \int_{\partial D} h_q \cos\theta \, ds \\
&\equiv \int_{\partial D} \psi_x J_q \cdot \mathbf{n}\, ds + B_1 + B_2 + B_3.
\end{aligned} \tag{4.15}
$$

In writing this, the inner products with $\partial h_0/\partial y$ and $\partial h_0/\partial R$ are zero by symmetry. We will argue that $B_1 = B_2 = B_3 = 0$.

First, since the leading order flux is constant across region II,

$$J_q \cdot \mathbf{n} = h_0^q \nabla \Delta h_q \cdot \mathbf{n} = \mathcal{O}(1), \quad r \to R. \tag{4.16}$$

Therefore

$$\nabla \Delta h_q \cdot \mathbf{n} = \mathcal{O}(|r-R|)^{-q}, \quad \Delta h_q = \mathcal{O}(|r-R|^{-q+1}), \quad r \to R. \tag{4.17}$$

Using (4.10), this means that

$$h_0^q (\psi_x)_z \Delta h_q = \mathcal{O}(|r-R|^{-q+2}), \quad r \to R, \tag{4.18}$$

so that integral $B_1 = 0$.

For the integrals B_2 and B_3, consider first the subcase $q = 1$. The relevant matching conditions are

$$h_1(R,\theta) = \lim_{z\to\infty} H_1(z), \quad (h_1)_r(R,\theta) = \lim_{z\to\infty} H_2'(z). \tag{4.19}$$

Since H_1 and H_2 are independent of θ, the integrals B_2 and B_3 vanish by symmetry.

For noninteger q, the terms in the region II expansion necessary for matching would be orders ϵ^q and ϵ^{q+1}. If such orders were included in the expansion, they would solve equations like

$$\Big(H_1^q [(H_n)_{zz} - U''(H_1) H_n]_z \Big)_z = 0, \tag{4.20}$$

where $1 < n < 3$. Since there is no flux of order $\epsilon^{q+n-3} > \epsilon^q$, integrating (4.20), one gets

$$(H_n)_{zz} - U''(H_1) H_n = \text{constant}. \tag{4.21}$$

From this it is seen that the solution H_n of *any* order $n < 3$ is independent of θ, and therefore the integrals B_2 and B_3 again vanish.

We now return to determining the migration dynamics. A similar argument as presented holds for the inner product with ψ_y. Using (4.11), (4.15) and $\mathbf{n} = (\cos\theta, \sin\theta)$ leads to

$$X_t = -\frac{1}{\pi} \frac{R\Psi(R)}{\int_0^R \Psi(r) r^2 dr} \left(\int_{\partial D} \mathbf{n} J_q \cdot \mathbf{n}\, ds \right). \tag{4.22}$$

Equations (4.13), (4.22) specify the droplet dynamics once the boundary value problem (3.16)–(3.18) is solved.

4.2. Case $q \in (2, 3)$. As for the case of $p \le 2$, in region II the flux of order ϵ^q involves the correction to H of order ϵ^3, which satisfies the linear equation

$$0 = (J_q \cdot \hat{\mathbf{z}})_z = \Big(H_1^q \Big[(H_3)_{zz} - R^{-1}(H_2)_z - zR^{-2}(H_1)_z + \frac{1}{2}U'''(H_1)H_2^2 + U''(H_1)H_3 \Big]_z \Big)_z . \tag{4.23}$$

The relevant solvability condition for the linear equation (4.23) is found by using the bounded function

$$\Phi(z) = -\int_z^\infty \frac{H_1 - 1}{H_1^q} dz', \tag{4.24}$$

which is in the adjoint nullspace of the linear operator in (4.23) and corresponds to translation. Taking an inner product with (4.23) gives

(4.25)
$$0 = \Big[(J_q \cdot \hat{\mathbf{z}})\, \Phi - (H_1 - 1)[(H_3)_{zz} - U''(H_1)H_3] + (H_1)_z(H_3)_z - (H_1)_{zz}(H_3) \Big]_{-\infty}^{\infty} + Q,$$
$$Q = \int_{-\infty}^{\infty} (H_1 - 1) \Big[R^{-1}(H_2)_z + zR^{-2}(H_1)_z + \frac{1}{2}U'''(H_1)H_2^2 \Big]_z dz.$$

Here $(J_q \cdot \hat{\mathbf{z}}) = -(J_q \cdot \mathbf{n})$ is just the flux matched to the region III solution at $z = -\infty$. Note that the term Q inherits radial symmetry from H_1, H_2 and therefore should be inconsequential for migration dynamics.

Applying the far field and matching conditions

$$\Phi \sim 0, \quad (H_1)_z \sim 1, \quad (H_3)_z \sim +\frac{\partial^2 h_1}{\partial r^2}(R,\theta)z - \frac{\partial h_2}{\partial r}(R,\theta), \quad z \to \infty, \tag{4.26}$$

$$H_1 \sim 1, \quad z \to -\infty, \tag{4.27}$$

to (4.25) gives

$$\Big(J_q \cdot \hat{\mathbf{z}} \Big) \int_{-\infty}^{\infty} \frac{H_1 - 1}{H_1^q} dz' = \frac{\partial h_2}{\partial r}(R, \theta) - Q. \tag{4.28}$$

In region I, we expand $h = h_0(x,t) + \epsilon h_1 + \epsilon^2 h_2 + o(\epsilon^2)$ and obtain the same as (4.1), except that it applies to the correction at order ϵ^2 instead of order ϵ^q:

$$\mathcal{L}h_2 = X_t \cdot \nabla h_0 - R_t \frac{\partial h_0}{\partial R}, \quad \mathcal{L} = \nabla\cdot[h_0^q \nabla\Delta, \quad \mathbf{x} \in D. \tag{4.29}$$

Solvability conditions are obtained as in case $q < 2$. An inner product with ψ_R gives

$$R_t = -\frac{\int_{\partial D} h_0^q \nabla\Delta h_2 \cdot \mathbf{n}\, ds}{\int_D \partial h_0/\partial R \, dx}. \tag{4.30}$$

Note that $h_0^q \nabla\Delta h_2$ would be the flux at order ϵ^2, but this is zero since the leading order flux scales like ϵ^q. This means that $R_t = 0$ on the timescale specified by $\tau(\epsilon)$. One could potentially obtain the slow dynamics for mass exchange by going further in the expansion, where a result like (4.13) should follow on a timescale ϵ^q instead of $\tau(\epsilon)$.

For exponents $q \geq 2$ the functions ψ_x, ψ_y are not bounded at $r = R$, but we can integrate over a smaller disk D_ρ of radius ρ and take $\rho \to R$. To avoid excessive notation, the integrals $\int_D, \int_{\partial D}$ which appear below should be interpreted as this limit. Integration with ψ_x yields

$$\begin{aligned} X_t \cdot \hat{\mathbf{x}} \int_D \psi_x (h_0)_x \, d\mathbf{x} &= \int_{\partial D} \psi_x h_0^q \nabla \Delta h_2 \cdot \mathbf{n} ds - \int_{\partial D} h_0^q (\Delta h_2) \nabla \psi_x \cdot \mathbf{n} ds \\ &\quad - \int_{\partial D} x \nabla h_2 \cdot \mathbf{n} ds + \int_{\partial D} h_2 \cos\theta \, ds \\ &\equiv B_1 + B_2 + B_3 + B_4. \end{aligned} \tag{4.31}$$

In contrast to $p < 2$, only the boundary term B_3 is not zero. In light of (4.9), one has the asymptotics

$$\psi_x = \mathcal{O}(|r-R|^{2-q}), \quad \nabla \psi_x \cdot \mathbf{n} = \mathcal{O}(|r-R|^{1-q}), \quad h_0^q = \mathcal{O}(|r-R|^q). \tag{4.32}$$

The boundedness of derivatives of h_2 then implies $B_1 = B_2 = 0$. For B_4, matching to region I implies $H_2 \sim \frac{1}{2}(h_0)_{rr}(R,\theta) z^2 - (h_1)_r(R,\theta) z + (h_2)(R,\theta)$ for large z. This means that h_2 is independent of θ, and symmetry gives $B_4 = 0$. It follows that

$$X_t \cdot \hat{\mathbf{x}} \int_D \psi_x (h_0)_x \, d\mathbf{x} = - \int_{\partial D} x \nabla h_2 \cdot \mathbf{n} ds. \tag{4.33}$$

A similar expression can be obtained using ϕ_y. Combining this with (4.28), the terms involving Q drop away by symmetry, leaving

$$X_t = -\frac{1}{\pi} \frac{R^2 \int_{-\infty}^{\infty} H_1^{1-q} - H_1^{-q} dz'}{\int_0^R \Psi(r) r^2 dr} \left(\int_{\partial D} \mathbf{n} J_q \cdot \mathbf{n} ds \right). \tag{4.34}$$

4.3. Case $q > 3$. The expansion in region II is now done as $H = \epsilon H_1 + \epsilon^2 H_2 + \epsilon^3 H^3 + \cdots$. At the level of the first nonzero flux J_q, we get the linear equation

$$\begin{aligned} -(X_t \cdot \mathbf{n})(H_1)_z = \Bigg(H_1^q \Bigg[& (H_3)_{zz} - R^{-1}(H_2)_z - z R^{-2} (H_1)_z \\ & + \frac{1}{2} U'''(H_1) H_2^2 + U''(H_1) H_3 \Bigg]_z \Bigg)_z . \end{aligned} \tag{4.35}$$

The solvability argument proceeds as for the case $2 < q < 3$ and uses the bounded function Φ defined in (4.24). The inner product with (4.35) gives the same result as for $2 < q < 3$ except that the left-hand side is nonzero:

$$(X_t \cdot \mathbf{n}) \int_{-\infty}^{\infty} \frac{H_1 - 1}{H_1^{q-1}} dz = -(J_q \cdot \mathbf{n}) \int_{-\infty}^{\infty} \frac{H_1 - 1}{H_1^q} dz - \frac{\partial h_2}{\partial r}(R,\theta) - Q. \tag{4.36}$$

Here $(J_q \cdot \mathbf{n}) = -(J_q \cdot \hat{\mathbf{z}})(z = -\infty)$ is the flux matched to region III.

The expansion in region I is $h = h_0 + \epsilon h_1 + \epsilon^2 h_2 + o(\epsilon^2)$, which means h_2 solves

$$\nabla \cdot (h_0^q \nabla \Delta h_2) = 0. \tag{4.37}$$

This is the homogeneous version of (4.29), and therefore the relevant solvability conditions (for each coordinate direction) are the same as (4.33) with the left-hand side suppressed:

$$\int_{\partial D} x \nabla h_2 \cdot \mathbf{n} ds = 0 = \int_{\partial D} y \nabla h_2 \cdot \mathbf{n} ds. \tag{4.38}$$

We can now multiply (4.36) by x or y and integrate over ∂D and use (4.38). Again the Q term drops away and we are left with

$$X_t = -\frac{1}{\pi}\frac{\int_{-\infty}^{\infty}[H_1^{1-q} - H_1^{-q}]dz'}{R\int_{-\infty}^{\infty}[H_1^{2-q} - H_1^{1-q}]dz'}\left(\int_{\partial D} \mathbf{n}J_q \cdot \mathbf{n} ds\right). \tag{4.39}$$

4.4. Case $q = 2$. This case is similar to $q \in (2, 3)$, but there are logarithmically diverging terms that require care. The flux of order ϵ^2 in region II satisfies the linear equation

$$\begin{aligned} 0 = (J_2 \cdot \hat{\mathbf{z}})_z = \Bigg(H_1^2 \Big[&(H_3)_{zz} - R^{-1}(H_2)_z - zR^{-2}(H_1)_z \\ &+ \frac{1}{2}U'''(H_1)H_2^2 + U''(H_1)H_3\Big]_z\Bigg)_z, \end{aligned} \tag{4.40}$$

which again says that the normal component of the flux is constant. The relevant solvability condition uses the function

$$\Phi = \int_{-\infty}^{z} \frac{H_1 - 1}{H_1^2} dz', \tag{4.41}$$

which diverges logarithmically:

$$\Phi = \ln(z) + O(1), \quad z \to \infty. \tag{4.42}$$

Multiplying Φ by (4.40) and integrating from $-\infty$ to some finite value $z = Z$ (since the result is unbounded as $Z \to \infty$) gives a result similar to (4.25):

$$\begin{aligned} &0 = \Big[(J_2 \cdot \hat{\mathbf{z}})\,\Phi - (H_1 - 1)[(H_3)_{zz} - U''(H_1)H_3] + (H_1)_z(H_3)_z - (H_1)_{zz}(H_3)\Big]_{-\infty}^{Z} + Q, \\ &Q = \int_{-\infty}^{Z} (H_1 - 1)\left[R^{-1}(H_2)_z + zR^{-2}(H_1)_z + \frac{1}{2}U'''(H_1)H_2^2\right]_z dz. \end{aligned} \tag{4.43}$$

Since the flux J_2 is nonzero, integrating (4.40) directly gives $(H_3)_{zzz} \sim 1/z^2$ for large z. Therefore H_3 is bounded and $(H_3)_z$ diverges logarithmically as $z \to +\infty$. The balance of logarithmically diverging terms in (4.43) gives

$$(H_3)_z = (J_2 \cdot \mathbf{n}) \ln(z) + O(1), \quad z \to \infty, \tag{4.44}$$

where $(J_q \cdot \mathbf{n}) = -(J_q \cdot \hat{\mathbf{z}})(z = -\infty)$ is the flux matched to region III.

In region I, we expand $h = h_0(x, t) + \epsilon h_1 + \epsilon^2 \ln(1/\epsilon)h_* + o(\epsilon^2 \ln(1/\epsilon))$. Then h_* solves the linear equation (4.1), and the solvability arguments proceed as before. Like the case $q \in (2, 3)$, $R_t = 0$ to leading order (albeit mass exchange is only logarithmically slower). The other solvability conditions are obtained by taking inner products with ψ_x, ψ_y, which produces a result analogous to (4.33):

$$X_t \cdot \hat{\mathbf{x}} \int_D \psi_x(h_0)_x \, d\mathbf{x} = -\int_{\partial D} x\nabla h_* \cdot \mathbf{n} ds. \tag{4.45}$$

Matching conditions that relate $(h_*)_x$ to $(H_3)_z$ are now derived. It is assumed that region I and II solutions describe the same solution on some overlapping region

$1 \ll z \ll [\epsilon \ln(1/\epsilon)]^{-1}$. Within this region, a Taylor expansion is justified for h_0, h_1 but not h_* so that

$$\begin{aligned}(4.46)\qquad &(H_1)_z + \epsilon(H_2)_z + \epsilon^2(H_3)_z + o(\epsilon^2)\\ &= -(h_0)_r - \epsilon(h_1)_r - \epsilon^2\ln(1/\epsilon)(h_*)_r + o(\epsilon^2\ln(1/\epsilon))\\ &= -(h_0)_r(R,\theta) - \epsilon\Big[(h_1)_r(R,\theta) + (h_0)_{rr}(R,\theta)z\Big]\\ &\quad - \epsilon^2\ln(1/\epsilon)(h_*)_r(R,\theta) + o(\epsilon^2\ln(1/\epsilon)).\end{aligned}$$

Equating terms at order 1 and ϵ gives the usual matching conditions for regular expansions. For the logarithmic terms, the procedure is to take $\epsilon \to 0$ and $z \sim [\epsilon\ln(1/\epsilon)]^{-1}$ simultaneously. Using (4.44), for large z we have

$$(4.47)\quad (H_3)_z = (J_2\cdot\mathbf{n})\ln\Big([\epsilon\ln(1/\epsilon)]^{-1}\Big) + O(1) = (J_2\cdot\mathbf{n})\ln(1/\epsilon) + \mathcal{O}\Big(\ln(\ln(1/\epsilon))\Big).$$

Inserting into (4.46) and equating terms of order $\epsilon^2\ln(1/\epsilon)$ gives

$$(4.48)\qquad (J_2\cdot\mathbf{n}) = -(h_*)_r(R,\theta).$$

This can be combined with (4.45) to yield

$$(4.49)\qquad X_t = -\frac{1}{\pi}\frac{R^2}{\int_0^R \Psi(r)r^2dr}\left(\int_{\partial D}\mathbf{n}J_q\cdot\mathbf{n}\,ds\right).$$

4.5. Case $q = 3$. This case is similar to both $q > 3$ and $q \in (2,3)$, but there are again logarithmically diverging terms. The flux of order ϵ^3 in region II satisfies the linear equation

$$\begin{aligned}0 = (J_3\cdot\hat{\mathbf{z}})_z = \Bigg(H_1^3\Bigg[&(H_3)_{zz} - R^{-1}(H_2)_z - zR^{-2}(H_1)_z\\ (4.50)\qquad &+ \frac{1}{2}U'''(H_1)H_2^2 + U''(H_1)H_3\Bigg]_z\Bigg)_z.\end{aligned}$$

A solvability argument identical to the case $q \in (2,3)$ produces

$$(4.51)\qquad (J_3\cdot\mathbf{n})\int_{-\infty}^{\infty}\frac{H_1-1}{H_1^3}dz' = (H_3)_z - Q.$$

In region I, we expand $h = h_0(x,t)+\epsilon h_1+\epsilon^2/\ln(1/\epsilon)h_*+o(\epsilon^2/\ln(1/\epsilon))$, so that h_* solves the linear equation (4.1) with $q = 3$, and the solvability arguments proceed as before. As for all cases $q \geq 2$, $R_t = 0$ to leading order. In this case, the inner products with ψ_x, ψ_y diverge logarithmically, so we integrate on a disk $D(\rho)$ with radius $\rho < R$ and consider the asymptotics as $\rho \to R$. Multiplying by ψ_x and integrating gives

(4.52)
$$\begin{aligned}(X_t\cdot\hat{\mathbf{x}})\int_{D(\rho)}\psi_x(h_0)_x\,d\mathbf{x} &= \int_{\partial D(\rho)}\psi_x h_0^3\nabla\Delta h_*\cdot\mathbf{n}ds - \int_{\partial D(\rho)}h_0^3(\Delta h_*)\nabla\psi_x\cdot\mathbf{n}ds\\ &- \int_{\partial D(\rho)}x\nabla h_*\cdot\mathbf{n}ds + \int_{\partial D(\rho)}h_*\cos\theta\,ds = B_1+B_2+B_3+B_4.\end{aligned}$$

The integral on the left-hand side has a logarithmic singularity as $\rho \to R$ because of (4.9); in particular,

$$\int_{D(\rho)} \psi_x (h_0)_x \, d\mathbf{x} = -\pi R^2 \ln |R-\rho| + \mathcal{O}(1), \quad \rho \to R. \tag{4.53}$$

Matching conditions (which are detailed below) require $\nabla h_* \sim C \ln |R-r|$. As a consequence, we find that h_* is bounded and

$$\nabla \Delta h_* \sim |R-r|^{-2}, \quad \Delta h_* \sim |R-r|^{-1} \tag{4.54}$$

as $r \to R$. All this implies that the integrals B_1, B_2, B_4 are bounded as $\rho \to R$ but B_3 diverges logarithmically. Using (4.52)–(4.53) gives

$$\int_{\partial D(\rho)} x \nabla h_* \cdot \mathbf{n} ds = \pi R^2 (X_t \cdot \hat{\mathbf{x}}) \ln |R-\rho| + \mathcal{O}(1), \quad \rho \to R. \tag{4.55}$$

The matching condition that relates $(h_*)_r$ to $(H_3)_z$ is derived as for $q = 2$. Equating expansions for h_r in regions I and II, then for $1 \ll z \ll \log(1/\epsilon)$,

$$\begin{aligned} &(H_1)_z + \epsilon (H_2)_z + \epsilon^2 (H_3)_z + o(\epsilon^2) \\ &= -(h_0)_r - \epsilon (h_1)_r - \epsilon^2 / \ln(1/\epsilon) (h_*)_r + o(\epsilon^2/\ln(1/\epsilon)) \\ &= -(h_0)_r (R,\theta) - \epsilon \Big[(h_1)_r (R,\theta) + (h_0)_{rr} (R,\theta) z \Big] \\ &\quad - \epsilon^2 (h_1)_{rr} (R,\theta) z - \epsilon^2/\ln(1/\epsilon)(h_*)_r + o(\epsilon^2/\ln(1/\epsilon)). \end{aligned} \tag{4.56}$$

Let $(h_*)_r \sim C \ln |R-r|$, $r \to R$, where C is to be determined. Taking $\epsilon \to 0$ with $z \sim \ln(1/\epsilon)$ simultaneously implies for large z

$$(h_*)_r = C \ln(\epsilon z) + \mathcal{O}(1) = C \ln(\epsilon) + \mathcal{O}(\ln(\ln(1/\epsilon))), \quad \epsilon \to 0. \tag{4.57}$$

Inserting into (4.56) and equating terms of order ϵ^2, we obtain

$$C = \lim_{z \to \infty} -(H_3)_z. \tag{4.58}$$

Finally, combining (4.51), (4.55), (4.58),

$$X_t = -\frac{1}{\pi} \frac{\int_{-\infty}^{\infty} [H_1^{-2} - H_1^{-3}] dz}{R} \left(\int_{\partial D} \mathbf{n} J_q \cdot \mathbf{n} \, ds \right). \tag{4.59}$$

5. Effective medium approximation and identification of timescales.

One potentially useful approximation to the free boundary problem described in section 2 utilizes Green's functions similar to the effective medium approximations for standard Ostwald ripening [38]. This is employed to determine timescales and study large systems of interacting droplets.

5.1. Reduced system.

Let X_k, R_k, $k = 1, \ldots, N$, be the droplet centers and radii. We want to solve $\Delta P = 0$ exterior to the droplets, i.e., for all $\mathbf{x}$, $|\mathbf{x} - X_k| > R_k$, subject to the boundary conditions

$$P(\mathbf{x}) = \frac{2}{R_k}, \quad |\mathbf{x} - X_k| = R_k. \tag{5.1}$$

The simplest approximation looks for a solution as a sum of Green's functions,

$$P(\mathbf{x}) = B_0 + \sum_{k=1}^{N} B_k \ln|\mathbf{x} - X_k|^2. \tag{5.2}$$

For each $j = 1, \dots, N$, the boundary condition which one wishes to satisfy is

$$\frac{2}{R_j} = B_0 + \sum_{k=1}^{N} B_k \ln|\mathbf{x} - X_k|^2 \quad \text{for} \;\; |\mathbf{x} - X_j| = R_j. \tag{5.3}$$

Assuming the droplets are well separated, the approximation $|\mathbf{x} - X_k| \approx |X_j - X_k|$ holds on the boundary of droplet $j \neq k$, giving

$$\frac{2}{R_j} = B_0 + B_j \ln(R_j^2) + \sum_{k \neq j} B_k \ln|X_j - X_k|^2, \quad j = 1, \dots, N. \tag{5.4}$$

The system is completed by the requirement that there be no flux at infinity:

$$\int_S \nabla P \cdot n \to 0, \tag{5.5}$$

as the curve S (take it to be a giant circle) is taken out to infinity. As $\mathbf{x} \to \infty$, $1/|\mathbf{x} - R_k| \approx 1/|\mathbf{x}|$, and therefore

$$\int_S \nabla P \cdot n \to \sum_{k=1}^{N} B_k \left(\int_S \frac{1}{|\mathbf{x}|} ds \right) = 2\pi \sum_{k=1}^{N} B_k. \tag{5.6}$$

This integral will be zero only if

$$\sum_{k=1}^{N} B_k = 0. \tag{5.7}$$

Equations (5.4) and (5.7) define an $(N+1) \times (N+1)$ linear problem to be solved.

The integral in (2.5) to be computed for each j is

$$\int_{\partial D_j} J \cdot \mathbf{n} \, ds = - \int_{\partial D_j} \nabla P \cdot \mathbf{n} \, ds = 4\pi B_j. \tag{5.8}$$

The integral in (2.6) to be evaluated for each j is

$$\begin{aligned} \int_{\partial D_j} (J \cdot \mathbf{n})\mathbf{n} \, ds &= - \int_{\partial D_j} \left(\sum_k B_k \frac{2(\mathbf{x} - X_k) \cdot \mathbf{n}}{|\mathbf{x} - X_k|^2} \right) ds(\mathbf{x}) \\ &\approx -2 \left(\sum_{k \neq j} B_k \frac{X_j - X_k}{|X_j - X_k|^2} \right) \cdot \left(\int_{\partial D_j} \mathbf{n} \otimes \mathbf{n} \, ds \right), \end{aligned} \tag{5.9}$$

where the same approximation $|\mathbf{x} - X_k| \approx |X_j - X_k|$ as before was used. Since

$$\int_{\partial D_j} \mathbf{n} \otimes \mathbf{n} \, ds = \pi R_j \mathbf{I}, \tag{5.10}$$

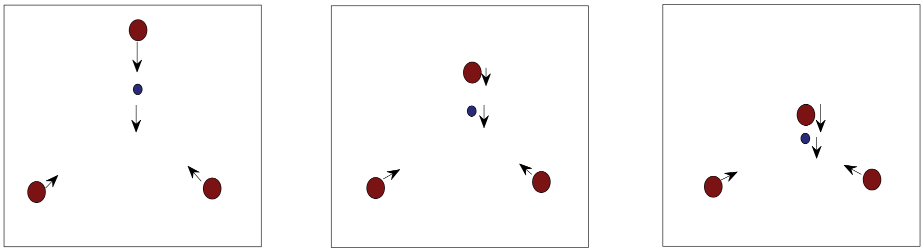

FIG. 5.1. *Example numerical solution of an approximate system with four initial droplets. The net repulsion experienced by the drop in the center is small, allowing one of the large droplets to catch up.*

where $\mathbf{I}$ is the identity matrix, it follows that

$$\int_{\partial D_j} (J \cdot \mathbf{n})\mathbf{n}\, ds \approx -2\pi R_j \sum_{k \neq j} B_k \frac{X_j - X_k}{|X_j - X_k|^2}. \tag{5.11}$$

It is instructive to examine a simple situation where only two droplets interact. By virtue of the quasi-steady diffusion (2.4) it follows that the flux J will on average be toward the smaller drop. In the context of the above approximation, that means that if $R_1 > R_2$, then $B_1 > 0 > B_2$. Using (2.6) and (5.11), it follows that the velocity of both droplets is in the direction of the *smaller* droplet.

By virtue of the mobility factor (2.7), a smaller droplet moves faster, and therefore it would simply "run away" from a single large droplet. On the other hand, if a smaller droplet is surrounded by several large droplets, the net repulsion can be small enough so that merging with a larger droplet is possible. Figure 5.1 shows a numerically computed example with three large droplets and a small droplet, which eventually touches one of the larger droplets. Simulations of the thin film equation indicate that this initiates a rapid coalescence of both drops [29].

5.2. Dynamic timescales. Consider now a reasonably large array of droplets which all have a similar size R and typical spacing L, so that the volume per unit area is

$$H_{average} = \frac{R^3}{L^2}, \tag{5.12}$$

which is constant as time progresses.

Timescale for ripening. The approximation (5.2) gives the scaling

$$B_j \sim R^{-1}/\ln L, \tag{5.13}$$

which with (5.8) further implies

$$\int_{\partial D_j} J \cdot \mathbf{n}\, ds \sim R^{-1}/\ln L. \tag{5.14}$$

For exponents $q < 2$, using (2.5), the timescale for ripening (i.e., mass exchange) can be computed as

$$\tau_{ripe} \sim \frac{R}{R_t} \sim R^4 \ln L \sim H_{average}^{4/3} L^{8/3} \ln L, \quad q < 2. \tag{5.15}$$

For exponents $q \geq 2$, the ripening dynamics occur on a timescale of the flux, i.e., ϵ^q rather than $\tau(\epsilon)$. This can be accommodated by including an extra factor in the timescale:

$$\tau_{ripe} \sim \frac{R}{R_t} \sim \frac{\tau(\epsilon)}{\epsilon^q} H_{average}^{4/3} L^{8/3} \ln L, \quad q \geq 2. \tag{5.16}$$

Timescale for migration. Using (5.11) and (5.13), one can obtain

$$\int_{\partial D_j} (J \cdot \mathbf{n})\mathbf{n}\, ds \sim L^{-1}/\ln L. \tag{5.17}$$

Using (2.6), the timescale for migration can be computed as

$$\tau_{mig} \sim \frac{L}{X_t} \sim \begin{cases} H_{average}^{2/3} L^{10/3} \ln L, & q < 2, \\ H_{average}^{\frac{4-q}{3}} L^{(14-2q)/3} \ln L, & q \in [2,3], \\ H_{average}^{1/3} L^{8/3} \ln L, & q > 3. \end{cases} \tag{5.18}$$

The limit of large droplet size in the unscaled equation. Here we show that our scaling results are, suitably interpreted, the same as those derived in the companion paper [9]. The starting point there was the unscaled thin film equation

$$h_t = \nabla \cdot (h^q \nabla p), \quad p = U'(h) - \Delta h, \quad q > 0. \tag{5.19}$$

In [9], the limit of large droplet volume was considered, in contrast to a small precursor film. In this case, let $V \gg 1$ be a typical droplet volume with characteristic interdroplet distance L'. This suggests that the natural small parameter is $\epsilon = V^{-1/3}$. Rescaling (5.19) using

$$x \to \epsilon^{-1} x, \quad t \to \tau(\epsilon)^{-1} \epsilon^{q-4}, \quad h \to h\epsilon^{-1} \tag{5.20}$$

gives exactly (1.1). The average droplet size after rescaling is $R = 1$, and the characteristic distance between droplets is

$$L = \epsilon L' = \frac{V^{1/6}}{\overline{H}^{1/2}}, \tag{5.21}$$

where $\overline{H} = V/(L')^2$. The mass density for the scaled equation is

$$H_{average} = \frac{1}{\epsilon^2 (L')^2} = \frac{\overline{H}}{V^{1/3}}. \tag{5.22}$$

Timescales with respect to the unscaled equation (5.19) can now be written in terms of V and $\overline{H}$. For the ripening times given by either (5.15) or (5.16) one obtains

$$\tau_{ripe}^{unscaled} = \tau(\epsilon)\epsilon^{4-q} \tau_{ripe} \sim V^{4/3} \ln V + \mathcal{O}(1), \quad V \to \infty. \tag{5.23}$$

For the migration timescale (5.18) one has

$$\tau_{mig}^{unscaled} = \tau(\epsilon)\epsilon^{4-q} \tau_{mig} = \mathcal{O}(1) + \frac{1}{\overline{H}} \begin{cases} V^{5/3} \ln V, & q \in (0,2), \\ V^{5/3}, & q = 2, \\ V^{\frac{7-q}{3}} \ln V, & q \in (2,3), \\ V^{4/3} \ln^2 V, & q = 3, \\ V^{4/3} \ln V, & q > 3. \end{cases} \quad V \to \infty, \tag{5.24}$$

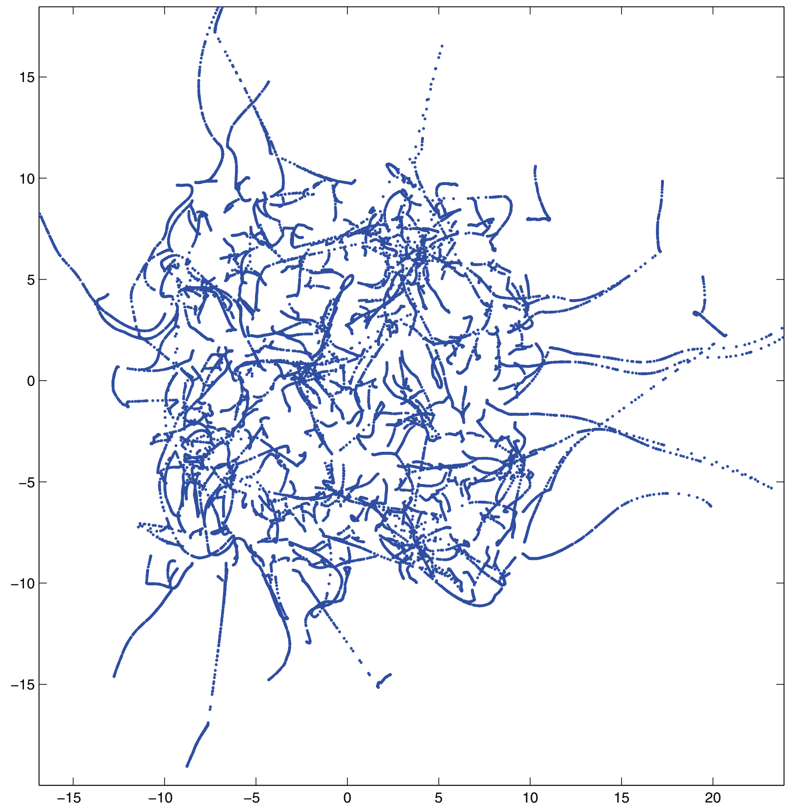

Fig. 6.1. *Trajectories for a simulation with* 500 *initial droplets* ($q = 3$)*. The direction of motion is mostly outward from the center. Note that small, uncoalesced droplets on the fringes are repelled.*

6. Large scale coarsening by coalescence. We conclude by using the approximations of the previous section to study the evolution of a large assembly of droplets. We focus on the most relevant mobility exponent $q = 3$, which corresponds to a fluid with Newtonian viscosity and a no-slip boundary condition. In doing this, the exchange of material between droplets is ignored, and only the leading order effect, migration, is considered. There are no boundaries in the calculation, so that (5.5) applies. An ad hoc criterion for coalescence is applied, which states that when the perimeters of two droplets overlap, their volume is combined and the center of mass is preserved.

Figure 6.1 is an illustration of the dynamics. The simulation was started with 500 droplets in random locations, each with a random but nearly uniform radius. Droplets in the middle of the assembly coalesce first, simply because they have a greater number of neighbors. As time progresses, it follows that smaller, more mobile droplets on the fringes will be driven away, since the motion is opposite the flux, which is toward larger droplets. The amount of time that droplets take to move (relative to the interdroplet distance) increases since the driving force given by flux decreases with increasing droplet size.

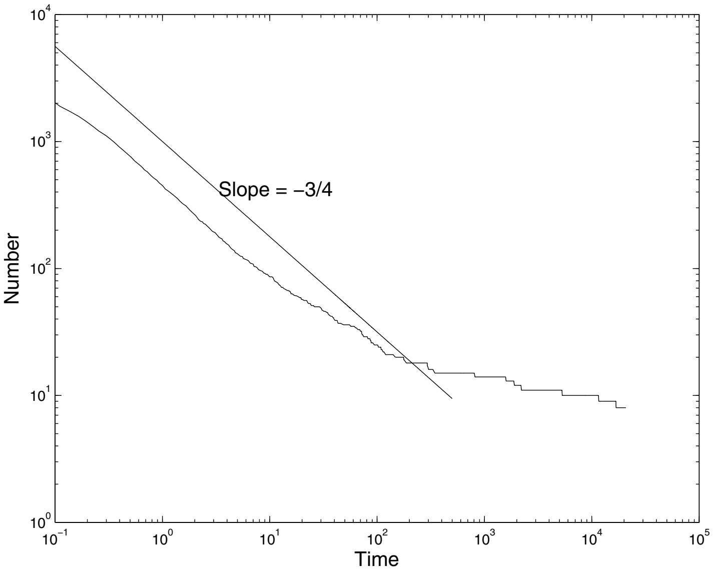

FIG. 6.2. *Dynamic scaling of coalescence-driven coarsening ($q = 3$), using* 5000 *initial droplets. A line with slope* $-3/4$ *is provided for comparison to the predictions of* [29].

Figure 6.2 shows the droplet number plotted as a function of time, for a simulation with 5000 droplets initially. Dynamic scaling of the coarsening process was predicted [29]; in particular, the relevant length scale (the typical interdroplet distance L) should increase as $t^{3/8}$. Since the number of droplets N scales according to

$$NL^2 \sim \text{area of domain},$$

N should scale in time like $t^{-3/4}$. This is more or less borne out by the results in Figure 6.2. At late times when the array has spread out to a somewhat larger area, there is a slowing of the coarsening process, also seen in the computational results.

7. Conclusions.

The main outcome of this paper is to establish a concrete link between a class of thin film equations and a free boundary problem for the motion of the contact line interface. In contrast to the classical situation of Ostwald ripening, we have shown that migration of droplets, and ultimately coalescence, is a likely mechanism for coarsening. Another feature which distinguishes this problem is its mixed dimensionality: droplets are three-dimensional, but the quasi-steady diffusion of material between them is effectively two-dimensional. This leads to dynamic scaling with exponents different than the familiar "1/3" power law.

There is some experimental support for the conclusions which we reach. Limary and Green [15, 16] examined the late stage structural evolution of droplets and measured their size and shape distributions. They found that droplet size (measured as a length scale) evolved as a power law with an exponent that varied from 1/10 to about 2/5. They conclude from their observations that "coarsening occurs via a self-similar, dynamic coalescence process, not Ostwald ripening" (referring to the exchange of material).

As mentioned in the introduction, [32] derives dynamic equations for droplet radius and position in the same thin film model as ours for mobility exponent $q = 3$. The procedure used there does not involve systematic asymptotic expansions and solvability conditions, but rather poses a traveling wave problem that loosely derives from the thin film equation. The authors connect the traveling wave speed to the influence felt by the disjoining pressure at the foot of the droplet. The resulting formulas are vaguely similar to ours but are not quantitatively the same. Most significantly, their assessment of the sign of migration seems to be opposite of ours and contradicts other analytical results [9, 11, 12] as well as direct numerical simulation of the partial differential equation [11, 29]. Indeed, in section IV.B of their paper, they claim that in a two-droplet system "both droplets migrate in the direction of the larger droplet" and show calculations where smaller droplets are attracted to larger droplets. According to (2.6), a larger droplet would move toward a smaller droplet since motion is *opposite* of the flux J. This certainly calls into question the reasoning that leads to their formulation.

There is reason to believe that our results (or at least our analytical procedures) are relevant for a variety of related thin film problems. The main ingredients which we required were the formation of near-equilibrium structures (droplets) and a separation of timescales between their formation and interaction. This separation of timescales is a simple consequence of the nearly degenerate kinetics common to many thin film models. A variety of other phenomena can create instability leading to structure formation and interaction. For example, the Rayleigh–Taylor or Rayleigh–Plateau instabilities lead to formation of migrating liquid ridges [10, 17]. Migration effects similar to ours have also been reported for droplets subject to Marangoni effects [4], chemically driven droplets [31], and two-layer fluids [18]. More broadly, one might expect that degenerate diffusion in other phase separation processes can lead to alternative mechanisms to coarsening.

NONLINEAR ELECTRON AND SPIN TRANSPORT IN SEMICONDUCTOR SUPERLATTICES*

L. L. BONILLA[†], L. BARLETTI[‡], AND M. ALVARO[†]

Abstract. Nonlinear charge transport in strongly coupled semiconductor superlattices is described by Wigner–Poisson kinetic equations involving one or two minibands. Electron-electron collisions are treated within the Hartree approximation, whereas other inelastic collisions are described by a modified BGK (Bhatnaghar–Gross–Krook) model. The hyperbolic limit is such that the collision frequencies are of the same order as the Bloch frequencies due to the electric field, and the corresponding terms in the kinetic equation are dominant. In this limit, spatially nonlocal drift-diffusion balance equations for the miniband populations and the electric field are derived by means of the Chapman–Enskog perturbation technique. For a lateral superlattice with spin-orbit interaction, electrons with spin up or down have different energies, and their corresponding drift-diffusion equations can be used to calculate spin-polarized currents and electron spin polarization. Numerical solutions show stable self-sustained oscillations of the current and the spin polarization through a voltage biased lateral superlattice thereby providing an example of superlattice spin oscillator.

1. Introduction.

Semiconductor superlattices are essential ingredients in fast nanoscale oscillators, quantum cascade lasers, and infrared detectors. Quantum cascade lasers are used to monitor environmental pollution in gas emissions, to analyze breath in hospitals, and in many other industrial applications [3]. A superlattice (SL) is a convenient approximation to a quasi-one-dimensional (quasi-1D) crystal that was originally proposed by Esaki and Tsu to observe Bloch oscillations, i.e., the periodic coherent motion of electrons in a miniband in the presence of an applied electric field. Figure 1.1(a) shows a simple realization of an N-period SL. Each period of length l consists of two layers of semiconductors with different energy gaps but with similar lattice constants. The SL lengths in the lateral directions, L_y and L_z, are much larger than l, typically tens of microns compared to about ten nanometers. The energy profile of the conduction band of this SL can be modeled as a succession of square quantum wells and barriers along the x direction (Kronig–Penney model) and, for an n-doped SL, we do not have to consider the valence band. A different quasi-1D crystal called a lateral superlattice (LSL) is shown in Figure 1.1(b). In this case, a periodic structure is formed on the top surface of a quantum well (QW), so that L_z is of the order of l and $L_y \gg l$. The wave functions of a single electron in the conduction band

of an SL can be expanded in terms of 1D Bloch wave functions times plane waves,

$$\frac{1}{\sqrt{S}}\, e^{ik_y y}\psi(z)\, e^{ikx}u_\nu(x,k), \tag{1.1}$$

$$\psi(z) = \begin{cases} e^{ik_z z} & \text{for an SL,} \\ \psi_n(z) & \text{for an LSL,} \end{cases} \tag{1.2}$$

where ν is the miniband index and n is the energy level of the quantum well in the case of an LSL. The function $u_\nu(x,k)$ is l-periodic in x and $2\pi/l$-periodic in k. S is the area of the lateral cross section, equal to L_yL_z for a rectangular cross section.

Many interesting nonlinear phenomena have been observed in voltage-biased SL comprising finitely many periods, including self-oscillations of the current through the SL due to motion of electric field pulses, multistability of stationary charge and field profiles, and so on [3]. It is important to distinguish between strongly and weakly coupled SLs depending on the coupling between their component QWs. Roughly speaking, if barriers are narrow, QWs are strongly coupled and we can use the electronic states (1.1) as a convenient basis in a quantum kinetic description. The resulting reduced balance equations for electron density and electric field are partial differential equations (which may be nonlocal, as we shall see in this paper). On the other hand, for SLs having wide barriers, their QWs are weakly coupled and the electronic states of a single well provide a good basis in a quantum kinetic description, replacing the Bloch functions $e^{ikx}u_\nu(x,k)$ in (1.1). In this case, the balance equations are spatially discrete, and phenomena such as multistability of stationary field profiles, formation and pinning of electric field domains, etc., are theoretically predicted and observed in experiments. See the review [3]. Another promising field of applications is spintronics. Electrons in SLs having at least one period doped with magnetic impurities and subject to a static magnetic field can be distinguished by their spin because the magnetic field splits each miniband in two, giving it different spin-dependent energy [19]. Recently an SL of this type has been proposed as a spin oscillator producing spin-polarized oscillatory currents and able to inject polarized electrons in a contact [6]. Alternatively, materials displaying strong spin-orbit effects can be used as spintronic devices without having to apply magnetic fields; cf. the case of the LSL considered in [14]. In this paper, we will show that an LSL can be used as a spin oscillator.

This paper presents systematic derivations of quantum balance equations for SLs with two populated minibands, and it shows that their numerical solutions may predict space- and time-dependent nonlinear phenomena occurring in these materials. Our methods can be used in 3D crystals, but their application to 1D structures such as SLs and LSLs leads to simpler equations that are less costly to solve. Although nonlinear charge transport in SLs has been widely studied in the last decade (see the reviews [3, 17, 21]), systematic derivations of tractable balance equations for miniband populations and electric field are scarce. One reason is that quantum kinetic equations are nonlocal in space and their collision terms may be nonlocal in space and time [10, 21]. Using them to analyze space- and time-dependent phenomena such as wave propagation or self-sustained oscillations is problematic. In fact, only extremely simple solutions of general quantum kinetic equations (such as thermal equilibrium, disturbances thereof due to weak external fields, and so on) are known; theoretical analysis of these equations is lacking and numerical solutions describing spatiotemporal phenomena are not available. One way to proceed is to adopt simple collision models similar to the Bhatnagar–Gross–Krook (BGK) collision model for classical kinetic theory [1]. We discuss in this paper how to implement a BGK collision model for a quantum kinetic equation that is simple to handle yet keeps an important quantum feature such as the broadening of energy levels [2]. Once we have a quantum kinetic equation for a sufficiently general SL having two minibands, we implement a Chapman–Enskog perturbation procedure to derive the sought balance equations and solve them numerically for realistic SL configurations.

Previous to this work, Lei and coworkers derived quantum hydrodynamic equations describing SL having only one miniband [16, 15]. They use a closure assumption to close a hierarchy of moment equations. For the case of quantum particles in an arbitrary external 3D potential, Degond and Ringhofer [8] have used a similar procedure to derive balance equations. They close the system of moment equations by means of a local equilibrium density obtained by maximizing entropy. The Chapman–Enskog method has been used to derive drift-diffusion equations for single-miniband SLs described by semiclassical [5] and quantum kinetic equations [2]. Earlier, Cercignani, Gamba, and Levermore used the Chapman–Enskog method to derive balance equations for a semiclassical BGK–Poisson kinetic description of a semiconductor with one parabolic band under strong external bias [7].

The rest of this paper is as follows. In section 2, we review the simpler case of nonlinear electron transport in a strongly coupled n-doped SL having only one populated miniband [2]. Starting with a kinetic equation for the Wigner function, we use the Chapman–Enskog perturbation method to derive balance equations for the electron density and the electric field. When these equations are solved numerically for a dc voltage–biased SL with finitely many QWs and realistic parameter values, stable self-sustained oscillations of the current through the SL are found among their solutions, in agreement with experimental observations [2]. Sections 3 to 5 contain the main results of the present work. In section 3, we describe an SL having two populated minibands by proposing a kinetic equation for the Wigner matrix. In section 4, we derive balance equations for the miniband electron populations and the electric field, using an appropriate Chapman–Enskog method and a tight-binding approximation to obtain explicit formulas. The case of an LSL having strong Rashba spin-orbit interaction [18] is important for spintronic applications and has been considered in section 5. We derive and solve numerically the resulting balance equations. Novel self-sustained oscillations of the spin current and polarization are obtained for appropriate values of the parameters. Finally section 6 contains our conclusions, and some technical matters are relegated to the appendix.

2. Single miniband superlattice. The Wigner–Poisson–Bhatnagar–Gross–Krook (WPBGK) system for 1D electron transport in the lowest miniband of a strongly coupled SL is

$$\begin{aligned}(2.1)\quad &\frac{\partial f}{\partial t}+\frac{i}{\hbar}\left[\mathcal{E}\left(k+\frac{1}{2i}\frac{\partial}{\partial x}\right)-\mathcal{E}\left(k-\frac{1}{2i}\frac{\partial}{\partial x}\right)\right]f\\ &+\frac{ie}{\hbar}\left[W\left(x+\frac{1}{2i}\frac{\partial}{\partial k},t\right)-W\left(x-\frac{1}{2i}\frac{\partial}{\partial k},t\right)\right]f\\ &=Q[f]\equiv-\nu_{en}\left(f-f^{FD}\right)-\nu_{\mathrm{imp}}\,\frac{f(x,k,t)-f(x,-k,t)}{2},\end{aligned}$$

$$(2.2)\quad \varepsilon\,\frac{\partial^2 W}{\partial x^2}=\frac{e}{l}\,(n-N_D),$$

$$(2.3)\quad n(x,t)=\frac{l}{2\pi}\int_{-\pi/l}^{\pi/l}f(x,k,t)dk=\frac{l}{2\pi}\int_{-\pi/l}^{\pi/l}f^{FD}(k;n(x,t))dk,$$

$$(2.4)\quad f^{FD}(k;n)=\frac{m^*k_BT}{\pi\hbar^2}\int_{-\infty}^{\infty}\ln\left[1+\exp\left(\frac{\mu-E}{k_BT}\right)\right]\frac{\sqrt{2}\,\Gamma^3/\pi}{[E-\mathcal{E}_1(k)]^4+\Gamma^4}\,dE.$$

Here f, n, N_D, $\mathcal{E}(k)$, d_B, d_W, $l=d_B+d_W$, W, ε, m^*, k_B, T, Γ, ν_{en}, ν_{imp}, and $-e<0$ are the one-particle Wigner function, the 2D electron density, the 2D doping density, the miniband dispersion relation, the barrier width, the well width, the SL period, the electric potential, the SL permittivity, the effective mass of the electron in the lateral directions, the Boltzmann constant, the lattice temperature, the energy broadening of the equilibrium distribution due to collisions [12, p. 28], the frequency of the inelastic collisions responsible for energy relaxation, the frequency of the elastic impurity collisions, and the electron charge, respectively.

The left-hand side of (2.1) can be straightforwardly derived from the Schrödinger–Poisson equation for the wave function in the miniband using the definition of the 1D Wigner function [2]:

$$(2.5)\qquad f(x,k,t)=\frac{2l}{S}\sum_{j=-\infty}^{\infty}\int_{\mathbb{R}^2}\langle\psi^\dagger(x+jl/2,y,z,t)\psi(x-jl/2,y,z,t)\rangle e^{ijkl}d\mathbf{x}_\perp$$

(the second quantized wave function $\psi(x,\mathbf{x}_\perp,t)=\sum_{q,\mathbf{q}_\perp}a(q,q_\perp,t)\phi_q(x)e^{i\mathbf{q}_\perp\cdot\mathbf{x}_\perp}$, $\mathbf{x}_\perp=(y,z)$, is a superposition of the Bloch states corresponding to the miniband and S is the SL cross section [2]). The right-hand side of (2.1) is the sum of $-\nu_e\left(f-f^{FD}\right)$, which represents energy relaxation towards a 1D effective Fermi–Dirac distribution $f^{FD}(k;n)$ (local equilibrium), and $-\nu_i[f(x,k,t)-f(x,-k,t)]/2$, which accounts for impurity elastic collisions [5]. For simplicity, the collision frequencies ν_e and ν_i are fixed constants. Exact and Fermi–Dirac distribution functions have the same electron density, thereby preserving charge continuity as in the classical BGK collision models [1]. The chemical potential μ is a function of n resulting from solving (2.3) with the integral of the collision-broadened 3D Fermi–Dirac distribution over the lateral components of the wave vector $(k,\mathbf{k}_\perp)=(k,k_y,k_z)$:

$$(2.6)\quad f^{FD}(k;n)=\int_{-\infty}^{\infty}\frac{D_\Gamma\left(E-\mathcal{E}_1(k)\right)}{1+\exp\left(\frac{E-\mu}{k_BT}\right)}\,dE,$$

$$(2.7)\quad D_\Gamma(E)=\frac{2}{(2\pi)^2}\int_{\mathbb{R}^2}\delta_\Gamma\left(\frac{\hbar^2\mathbf{k}_\perp^2}{2m^*}-E\right)d\mathbf{k}_\perp=\frac{m^*}{\pi\hbar^2}\int_0^\infty\delta_\Gamma(E_\perp-E)\,dE_\perp.$$

Using the residue theorem for a line-width,

$$\delta_\Gamma(E) = \frac{\sqrt{2}\,\Gamma^3/\pi}{\Gamma^4 + E^4}, \tag{2.8}$$

equation (2.7) yields

$$\begin{aligned} D_\Gamma(E) = \frac{m^*}{\pi\hbar^2}\Bigg\{ 1 + \frac{1}{4\pi}\,\ln\left[\frac{E^2 + \sqrt{2}\Gamma E + \Gamma^2}{E^2 - \sqrt{2}\Gamma E + \Gamma^2}\right] \\ - \frac{\theta(\sqrt{2}|E| - \Gamma)}{2\pi}\left[2\pi - \arctan\left(\frac{\Gamma}{\sqrt{2}|E| + \Gamma}\right) - \arctan\left(\frac{\Gamma}{\sqrt{2}|E| - \Gamma}\right)\right] \\ - \frac{\theta(\Gamma - \sqrt{2}|E|)}{2\pi}\left[\pi + \arctan\left(\frac{\Gamma}{\sqrt{2}E + \Gamma}\right) - \arctan\left(\frac{\Gamma}{\Gamma - \sqrt{2}E}\right)\right] \\ - \frac{\theta(\sqrt{2}E - \Gamma)}{2\pi}\left[\arctan\left(\frac{\Gamma}{\sqrt{2}E + \Gamma}\right) + \arctan\left(\frac{\Gamma}{\sqrt{2}E - \Gamma}\right)\right]\Bigg\}, \end{aligned} \tag{2.9}$$

which is equivalent to (2.4).[1] Here $\theta(E)$ is the Heaviside unit step function. As $\Gamma \to 0+$, the line-width (2.8) tends to the delta function $\delta(E)$, $D_\Gamma(E)$ tends to the 2D density of states, $D(E) = m^*\theta(E)/(\pi\hbar^2)$, and f^{FD} tends to the 3D Fermi–Dirac distribution function integrated over the lateral wave vector $\mathbf{k}_\perp$. In [2], a Lorentzian line-width was used instead of (2.8) and the integral over E in (2.6) extended from 0 to ∞. The integral with the Lorentzian function is not convergent in $E = -\infty$, which is why we prefer using convolution with the "super-Lorentzian" function (2.8) in this work. The integration in (2.7) cannot be carried out explicitly for other standard line-widths such as a Gaussian or a hyperbolic secant. This unnecessarily complicates the numerical integration of the balance equations we will obtain later. Note that, following Ignatov and Shashkin [11], we have not included the effects of the electric potential in our Fermi–Dirac distribution. These model equations can be improved by including scattering processes with change of lateral momentum and an electric field–dependent local equilibrium. However, the resulting model could only be treated numerically and the qualitative features of our derivation and of the nonlocal drift-diffusion equation would be lost in longer formulas.

A different way to introduce a quantum BGK collision model is to define a local equilibrium density matrix operator by minimizing quantum entropy (defined with the opposite sign of the convention that is usual in physics) under constraints giving the electron density and energy density in terms of the density matrix. The resulting expression involves an inverse Wigner transform, and another transform is needed to deduce the local equilibrium Wigner function f^{FD} entering the BGK formula [8]. This f^{FD} is nonlocal in space and can be found only by solving some partial differential equation [8]. As a model for quantum collisions [10, 21], the resulting quantum BGK model is not realistic, in the same way as the original BGK model is not a realistic model for classical collisions. Moreover, the implicit manner in which the model is defined defeats the main asset of the classical BGK collision model: its simplicity, which makes it possible to obtain results analytically. Thus we prefer to introduce a BGK model that can be handled more easily and still incorporates quantum effects. The most important quantum effect affecting the collision term is the broadening of energy levels due to scattering, $\Gamma \approx \hbar/\tau$ (where τ is the lifetime of the level) [12], and

[1] Integrate (2.6) by parts using (2.9).

this is taken phenomenologically into account by the convolution with the line-width function (2.8) in (2.6). In the semiclassical limit "$\hbar \to 0$," $\Gamma \to 0$ and we recover the semiclassical Fermi–Dirac distribution.

The WPBGK system (2.1) to (2.4) should be solved for a Wigner function which is $2\pi/l$-periodic in k and satisfies appropriate initial and boundary conditions. It is convenient to derive the charge continuity equation and a nonlocal Ampère's law for the current density. The Wigner function f is periodic in k; its Fourier expansion is

$$f(x,k,t) = \sum_{j=-\infty}^{\infty} f_j(x,t)\, e^{ijkl}. \tag{2.10}$$

Defining $F = \partial W/\partial x$ (*minus* the electric field) and the average

$$\langle F\rangle_j(x,t) = \frac{1}{jl}\int_{-jl/2}^{jl/2} F(x+s,t)\, ds, \tag{2.11}$$

it is possible to obtain the following equivalent form of the Wigner equation [2]:

$$\frac{\partial f}{\partial t} + \sum_{j=-\infty}^{\infty} \frac{ijl}{\hbar}\, e^{ijkl} \left(\mathcal{E}_j \frac{\partial}{\partial x}\langle f\rangle_j + e\,\langle F\rangle_j\, f_j \right) = Q[f]. \tag{2.12}$$

Here the nonzero Fourier coefficients of the dispersion relation are simply $\mathcal{E}_0 = \Delta/2$ and $\mathcal{E}_{\pm 1} = -\Delta/4$ for the tight-binding dispersion relation $\mathcal{E}(k) = \Delta\,(1 - \cos kl)/2$ (Δ is the miniband width), which yields a miniband group velocity $v(k) = \frac{\Delta l}{2\hbar}\sin kl$. Integrating this equation over k yields the charge continuity equation

$$\frac{\partial n}{\partial t} + \frac{\partial}{\partial x} \sum_{j=1}^{\infty} \frac{2jl}{\hbar}\, \langle \mathrm{Im}(\mathcal{E}_{-j} f_j)\rangle_j = 0. \tag{2.13}$$

Here we can eliminate the electron density by using the Poisson equation and then integrate over x, thereby obtaining the nonlocal Ampère's law for the total current density $J(t)$:

$$\varepsilon\,\frac{\partial F}{\partial t} + \frac{2e}{\hbar} \sum_{j=1}^{\infty} j\langle \mathrm{Im}(\mathcal{E}_{-j} f_j)\rangle_j = J(t). \tag{2.14}$$

To derive the quantum drift-diffusion equation, we shall assume that the electric field contribution in (2.12) is comparable to the collision terms and that they dominate the other terms (*the hyperbolic limit*) [5]. Let v_M and F_M be the electron velocity and field positive values at which the (zeroth order) drift velocity reaches its maximum. In this limit, the time t_0 it takes an electron with speed v_M to traverse a distance $x_0 = \varepsilon F_M l/(eN_D)$, over which the field variation is of order F_M, is much longer than the mean free time between collisions, $\nu_e^{-1} \sim \hbar/(eF_M l) = t_1$. We therefore define the *small parameter* $\lambda = t_1/t_0 = \hbar v_M N_D/(\varepsilon F_M^2 l^2)$ and formally multiply the first two terms on the left side of (2.1) or (2.12) by λ [5, 2]. The result is

$$\lambda\left(\frac{\partial f}{\partial t} + \sum_{j=-\infty}^{\infty} \frac{ijl}{\hbar}\, e^{ijkl}\mathcal{E}_j \frac{\partial}{\partial x}\langle f\rangle_j \right) = Q[f] - \sum_{j=-\infty}^{\infty} \frac{iejl}{\hbar}\, e^{ijkl}\langle F\rangle_j\, f_j. \tag{2.15}$$

The solution of (2.15) for $\lambda = 0$ is calculated in terms of its Fourier coefficients as

$$f^{(0)}(k;F) = \sum_{j=-\infty}^{\infty} \frac{(1 - ij\mathcal{F}_j/\tau_e)\, f_j^{FD}}{1 + j^2\mathcal{F}_j^2}\, e^{ijkl}, \tag{2.16}$$

where $\mathcal{F}_j = \langle F\rangle_j/F_M$, $F_M = \frac{\hbar}{el}\sqrt{\nu_e(\nu_e + \nu_i)}$ and $\tau_e = \sqrt{(\nu_e + \nu_i)/\nu_e}$.

The Chapman–Enskog ansatz for the Wigner function is [2]

$$f(x,k,t;\lambda) = f^{(0)}(k;F) + \sum_{m=1}^{\infty} f^{(m)}(k;F)\,\lambda^m, \tag{2.17}$$

$$\varepsilon \frac{\partial F}{\partial t} + \sum_{m=0}^{\infty} J^{(m)}(F)\,\lambda^m = J(t). \tag{2.18}$$

The coefficients $f^{(m)}(k;F)$ depend on the "slow variables" x and t only through their dependence on the electric field and the electron density. The electric field obeys a reduced evolution equation (2.18) in which the functionals $J^{(m)}(F)$ are chosen so that the $f^{(m)}(k;F)$ are bounded and $2\pi/l$-periodic in k. After we keep the desired number of terms and set $\lambda = 1$, (2.18) is the quantum drift-diffusion equation provided by our perturbation procedure.

Differentiating Ampère's law (2.18) with respect to x, we obtain the charge continuity equation. Moreover the compatibility condition

$$\int_{-\pi/l}^{\pi/l} f^{(m)}(k;n)\,dk = \frac{2\pi}{l}\, f_0^{(m)} = 0, \quad m \ge 1, \tag{2.19}$$

is obtained by inserting the expansion (2.17) into (2.3). Inserting (2.17) and (2.18) in (2.15), we find the hierarchy

$$\mathcal{L}f^{(1)} = -\left.\frac{\partial f^{(0)}}{\partial t}\right|_0 + \sum_{j=-\infty}^{\infty} \frac{ijl\mathcal{E}_j e^{ijkl}}{\hbar}\frac{\partial}{\partial x}\langle f^{(0)}\rangle_j, \tag{2.20}$$

$$\mathcal{L}f^{(2)} = -\left.\frac{\partial f^{(1)}}{\partial t}\right|_0 + \sum_{j=-\infty}^{\infty} \frac{ijl\mathcal{E}_j e^{ijkl}}{\hbar}\frac{\partial}{\partial x}\langle f^{(1)}\rangle_j \; - \left.\frac{\partial}{\partial t} f^{(0)}\right|_1, \tag{2.21}$$

and so on. Here

$$\mathcal{L}u(k) \equiv \frac{ie}{\hbar}\sum_{-\infty}^{\infty} jl\langle F\rangle_j u_j e^{ijkl} + \left(\nu_e + \frac{\nu_i}{2}\right) u(k) - \frac{\nu_i}{2}\, u(-k), \tag{2.22}$$

and the subscripts 0 and 1 on the right-hand side of these equations mean that $\varepsilon\,\partial F/\partial t$ is replaced by $J - J^{(0)}(F)$ and by $-J^{(1)}(F)$, respectively.

The condition (2.19) implies that

$$\int_{-\pi/l}^{\pi/l} \mathcal{L}f^{(m)} dk = 0 \tag{2.23}$$

for $m \ge 1$. Using this, the solvability conditions for the linear hierarchy of equations yield

$$J^{(m)} = \frac{2e}{\hbar}\sum_{j=1}^{\infty} j\langle \mathrm{Im}(\mathcal{E}_{-j} f_j^{(m)})\rangle_j, \tag{2.24}$$

which can also be obtained by insertion of (2.17) into (2.14).

Particularized to the case of the tight-binding dispersion relation and $\Gamma = 0$ in the Fermi–Dirac distribution (2.4), the leading order of the Ampère law (2.18) is

$$\varepsilon \frac{\partial F}{\partial t} + \frac{ev_M}{l} \langle n\mathcal{M}V(\mathcal{F})\rangle_1 = J(t), \tag{2.25}$$

$$V(\mathcal{F}) = \frac{2\mathcal{F}}{1+\mathcal{F}^2}, \quad v_M = \frac{\Delta l\, \mathcal{I}_1(M)}{4\hbar\tau_e \mathcal{I}_0(M)}, \quad \mathcal{M}\left(\frac{n}{N_D}\right) = \frac{\mathcal{I}_1(\tilde{\mu})\,\mathcal{I}_0(M)}{\mathcal{I}_1(M)\,\mathcal{I}_0(\tilde{\mu})}, \tag{2.26}$$

$$\mathcal{I}_m(s) = \int_{-\pi}^{\pi} \cos(mk)\, \ln\left(1 + e^{s-\delta+\delta\cos k}\right) dk, \tag{2.27}$$

provided $\mathcal{F} \equiv \mathcal{F}_1$, $\delta = \Delta/(2k_BT)$, and $\tilde{\mu} \equiv \mu/(k_BT)$. Here M (calculated graphically in Figure 1 of [5]) is the value of the dimensionless chemical potential $\tilde{\mu}$ at which (2.3) holds with $n = N_D$. The drift velocity $v_M V(\mathcal{F})$ has the Esaki–Tsu form with a peak velocity that becomes $v_M \approx \Delta l I_1(\delta)/[4\hbar\tau_e I_0(\delta)]$ in the Boltzmann limit [11] ($I_n(\delta)$ is the modified Bessel function of the nth order).

To find the first-order correction in (2.18), we first solve (2.20) and find $J^{(m)}$ for $m = 1$. The calculation yields the first correction to (2.25) (here $'$ means differentiation with respect to n) [2]:

$$\varepsilon \frac{\partial F}{\partial t} + \frac{ev_M}{l} \mathcal{N}\left(F, \frac{\partial F}{\partial x}\right) = \varepsilon \left\langle D\left(F, \frac{\partial F}{\partial x}, \frac{\partial^2 F}{\partial x^2}\right)\right\rangle_1 + \langle A\rangle_1\, J(t), \tag{2.28}$$

$$A = 1 + \frac{2ev_M}{\varepsilon F_M l(\nu_e+\nu_i)}\, \frac{1-(1+2\tau_e^2)\,\mathcal{F}^2}{(1+\mathcal{F}^2)^3}\, n\mathcal{M}, \tag{2.29}$$

$$\mathcal{N} = \langle nV\mathcal{M}\rangle_1 + \langle (A-1)\langle\langle nV\mathcal{M}\rangle_1\rangle_1\rangle_1 - \frac{\Delta l\tau_e}{F_M\hbar(\nu_e+\nu_i)} \left\langle \frac{B}{1+\mathcal{F}^2}\right\rangle_1, \tag{2.30}$$

$$D = \frac{\Delta^2 l^2}{8\hbar^2(\nu_e+\nu_i)(1+\mathcal{F}^2)} \left(\frac{\partial^2\langle F\rangle_1}{\partial x^2} - \frac{4\hbar v_M\tau_e C}{\Delta l}\right), \tag{2.31}$$

$$\begin{aligned} B = {} & \left\langle \frac{4\mathcal{F}_2 n\mathcal{M}_2}{(1+4\mathcal{F}_2^2)^2} \frac{\partial\langle F\rangle_2}{\partial x}\right\rangle_1 + \mathcal{F}\left\langle \frac{n\mathcal{M}_2(1-4\mathcal{F}_2^2)}{(1+4\mathcal{F}_2^2)^2}\frac{\partial\langle F\rangle_2}{\partial x}\right\rangle_1 \\ & - \frac{4\hbar v_M(1+\tau_e^2)\mathcal{F}(n\mathcal{M})'}{\Delta l\tau_e(1+\mathcal{F}^2)} \left\langle n\mathcal{M}\frac{1-\mathcal{F}^2}{(1+\mathcal{F}^2)^2}\,\frac{\partial\langle F\rangle_1}{\partial x}\right\rangle_1, \end{aligned} \tag{2.32}$$

$$\begin{aligned} C = {} & \left\langle \frac{(n\mathcal{M}_2)'}{1+4\mathcal{F}_2^2}\, \frac{\partial^2 F}{\partial x^2}\right\rangle_1 - 2\mathcal{F}\left\langle \frac{(n\mathcal{M}_2)'\mathcal{F}_2}{1+4\mathcal{F}_2^2}\, \frac{\partial^2 F}{\partial x^2}\right\rangle_1 \\ & + \frac{8\hbar v_M(1+\tau_e^2)(n\mathcal{M})'\,\mathcal{F}}{\Delta l\tau_e\,(1+\mathcal{F}^2)} \left\langle \frac{(n\mathcal{M})'\mathcal{F}}{1+\mathcal{F}^2}\, \frac{\partial^2 F}{\partial x^2}\right\rangle_1. \end{aligned} \tag{2.33}$$

Here $\mathcal{M}_2(n/N_D) \equiv \mathcal{I}_2(\tilde{\mu})\,\mathcal{I}_0(M)/[\mathcal{I}_1(M)\,\mathcal{I}_0(\tilde{\mu})]$. If the electric field and the electron density do not change appreciably over two SL periods, $\langle F\rangle_j \approx F$, the spatial averages can be ignored, and the *nonlocal* quantum drift-diffusion equation (2.28) becomes the *local* generalized drift-diffusion equation obtained from the semiclassical theory [5]. The boundary conditions for the quantum drift-diffusion equation (2.28) (which contains triple spatial averages) need to be specified on the intervals $[-2l, 0]$ and $[Nl, Nl + 2l]$, not just at the points $x = 0$ and $x = Nl$, as in the case of the parabolic generalized drift-diffusion equation. Similarly, the initial condition has to be defined on the extended interval $[-2l, Nl + 2l]$. For realistic values of the parameters representing a strongly coupled SL under dc voltage bias, the numerical solution of the quantum drift-diffusion equation yields a stable self-sustained oscillation of the current [2] in quantitative agreement with experiments [20]. Details of the numerical procedure can be found in [9].

3. Wigner description of a two-miniband superlattice. We shall consider a 2×2 Hamiltonian $\mathbf{H}(x, -i\partial/\partial x)$, in which [13]

$$\begin{aligned} \mathbf{H}(x,k) &= [h_0(k) - eW(x)]\boldsymbol{\sigma}_0 + \vec{h}(k)\cdot\vec{\boldsymbol{\sigma}}] \\ &\equiv \begin{pmatrix} (\alpha+\gamma)(1-\cos kl) - eW(x) + g & -i\beta\sin kl \\ i\beta\sin kl & (\alpha-\gamma)(1-\cos kl) - eW(x) - g \end{pmatrix}. \end{aligned} \tag{3.1}$$

Here

$$\begin{aligned} h_0(k) &= \alpha\,(1-\cos kl), & h_1(k) &= 0, \\ h_2(k) &= \beta\sin kl, & h_3(k) &= \gamma\,(1-\cos kl) + g, \end{aligned} \tag{3.2}$$

and

$$\boldsymbol{\sigma}_0 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \boldsymbol{\sigma}_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \boldsymbol{\sigma}_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \boldsymbol{\sigma}_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{3.3}$$

are the Pauli matrices.

The Hamiltonian (3.1) corresponds to the simplest 2×2 Kane model in which the quadratic and linear terms $(kl)^2/2$ and kl are replaced by $(1-\cos kl)$ and $\sin kl$, respectively. For an SL with two minibands, $2g$ is the miniband gap and $\alpha = (\Delta_1 + \Delta_2)/4$ and $\gamma = (\Delta_1 - \Delta_2)/4$, provided Δ_1 and Δ_2 are the miniband widths. In the case of an LSL, $g = \gamma = 0$, and $h_2\boldsymbol{\sigma}_2$ corresponds to the precession term in the Rashba spin-orbit interaction [14]. The other term, the intersubband coupling, depends on the momentum in the y direction, and we have not included it here. Small modifications of (3.1) represent a single miniband SL with dilute magnetic impurities in the presence of a magnetic field B: $g = \gamma = h_2 = 0$, and $h_1 = \beta(B)$ [19]. As in the case of a single miniband SL, $W(x)$ is the electric potential.

The energy minibands $\mathcal{E}^{\pm}(k)$ are the eigenvalues of the free Hamiltonian $\mathbf{H}_0(k) = h_0(k)\boldsymbol{\sigma}_0 + \vec{h}(k)\cdot\vec{\boldsymbol{\sigma}}$ and are given by

$$\mathcal{E}^{\pm}(k) = h_0(k) \pm |\vec{h}(k)|. \tag{3.4}$$

The corresponding spectral projections are

$$\mathbf{P}^{\pm}(k) = \frac{\boldsymbol{\sigma}_0 \pm \vec{\nu}(k)\cdot\vec{\boldsymbol{\sigma}}}{2}, \quad \text{where} \quad \vec{\nu}(k) = \vec{h}(k)/|\vec{h}(k)|, \tag{3.5}$$

so that we can write

$$\mathbf{H}_0(k) = \mathcal{E}^{+}(k)\mathbf{P}^{+}(k) + \mathcal{E}^{-}(k)\mathbf{P}^{-}(k). \tag{3.6}$$

We shall now write the WPBGK equations for the Wigner matrix written in terms of the Pauli matrices:

$$\mathbf{f}(x,k,t) = \sum_{i=0}^{3} f^i(x,k,t)\boldsymbol{\sigma}_i = f^0(x,k,t)\boldsymbol{\sigma}_0 + \vec{f}(x,k,t)\cdot\vec{\boldsymbol{\sigma}}. \tag{3.7}$$

The Wigner components are real and can be related to the coefficients of the Hermitian Wigner matrix by

$$\begin{aligned} f_{11} &= f^0 + f^3, & f_{12} &= f^1 - if^2, \\ f_{21} &= f^1 + if^2, & f_{22} &= f^0 - f^3. \end{aligned} \tag{3.8}$$

Hereinafter we shall use the equivalent notation

$$f = \begin{pmatrix} f^0 \\ \vec{f} \end{pmatrix} = \begin{pmatrix} f^0 \\ f^1 \\ f^2 \\ f^3 \end{pmatrix}. \tag{3.9}$$

The populations of the minibands with energies $\mathcal{E}^{\pm}$ are given by the moments

$$n^{\pm}(x,t) = \frac{l}{2\pi} \int_{-\pi/l}^{\pi/l} \left[f^0(x,k,t) \pm \vec{\nu}(k) \cdot \vec{f}(x,k,t) \right] dk, \tag{3.10}$$

and the total electron density is $n^+ + n^-$. After some algebra, we can obtain the following WPBGK equations for the Wigner components:

$$\frac{\partial f^0}{\partial t} + \frac{\alpha}{\hbar} \sin kl \, \Delta^- f^0 + \vec{b} \cdot \Delta^- \vec{f} - \Theta f^0 = Q^0[f], \tag{3.11}$$

$$\frac{\partial \vec{f}}{\partial t} + \frac{\alpha}{\hbar} \sin kl \, \Delta^- \vec{f} + \vec{b} \, \Delta^- f^0 + \vec{\omega} \times \vec{f} - \Theta \vec{f} = \vec{Q}[f], \tag{3.12}$$

$$\varepsilon \, \frac{\partial^2 W}{\partial x^2} = \frac{e}{l} \, (n^+ + n^- - N_D), \tag{3.13}$$

whose right-hand sides contain collision terms to be described later. Here

$$(\Delta^{\pm} u)(x,k) = u(x + l/2, k) \pm u(x - l/2, k), \tag{3.14}$$

$$\vec{\omega} = \vec{\omega}_0 + \vec{\omega}_1, \tag{3.15}$$

$$\vec{\omega}_0 = \frac{2g}{\hbar} \, (0, 0, 1), \tag{3.16}$$

$$\vec{\omega}_1 = \frac{1}{\hbar} \, (0, \beta \sin kl \, \Delta^+, 2\gamma - \gamma \cos kl \, \Delta^+), \tag{3.17}$$

$$\vec{b} = \frac{1}{\hbar} \, (0, \beta \cos kl, \gamma \sin kl), \tag{3.18}$$

$$\Theta f^i(x,k,t) = \sum_{j=-\infty}^{\infty} \frac{ejl}{i\hbar} \langle F(x,t) \rangle_j e^{ijkl} f^i_j(x,t). \tag{3.19}$$

Our collision model contains two terms: a BGK term which tries to send the miniband Wigner function to its local equilibrium and a scattering term from the miniband with higher energy to the lowest miniband:

$$Q^0[f] = -\frac{f^0 - \Omega^0}{\tau}, \tag{3.20}$$

$$\vec{Q}[f] = -\frac{\vec{f} - \vec{\Omega}}{\tau} - \frac{\vec{\nu} f^0 + \vec{f}}{\tau_{\mathrm{sc}}}, \tag{3.21}$$

$$\Omega^0 = \frac{\phi^+ + \phi^-}{2}, \quad \vec{\Omega} = \frac{\phi^+ - \phi^-}{2} \, \vec{\nu}, \tag{3.22}$$

$$\phi^{\pm}(k; n^{\pm}) = \frac{m^* k_B T}{\pi \hbar^2} \int_{-\infty}^{\infty} \frac{\sqrt{2}\, \Gamma^3/\pi}{\Gamma^4 + [E - \mathcal{E}^{\pm}(k)]^4} \, \ln\left(1 + e^{\frac{\mu^{\pm} - E}{k_B T}}\right) dE, \tag{3.23}$$

$$n^{\pm} = \frac{l}{2\pi} \int_{-\pi/l}^{\pi/l} \phi^{\pm}(k; n^{\pm}) \, dk. \tag{3.24}$$

The chemical potentials of the minibands, μ^+ and μ^-, are calculated in terms of n^+ and n^-, respectively, by inserting (3.23) in (3.24) and solving the resulting equations. Our collision model should enforce charge continuity. To check this, we first calculate the time derivative of $n^\pm$ using (3.10) to (3.12):

$$\begin{aligned}(3.25)\quad &\frac{\partial n^\pm}{\partial t} + \frac{\alpha l \Delta^-}{2\pi\hbar}\int_{-\pi/l}^{\pi/l} \sin kl\,(f^0 \pm \vec{\nu}\cdot\vec{f})\,dk + \frac{l\Delta^-}{2\pi}\int_{-\pi/l}^{\pi/l}(\vec{b}\cdot\vec{f} \pm \vec{\nu}\cdot\vec{b}f^0)\,dk\\ &\pm\frac{l\Delta^-}{2\pi}\int_{-\pi/l}^{\pi/l}\vec{\nu}\cdot\vec{\omega}\times\vec{f}\,dk \mp \frac{l\Delta^-}{2\pi}\int_{-\pi/l}^{\pi/l}\vec{\nu}\cdot\Theta\vec{f}\,dk\\ &= \frac{l\Delta^-}{2\pi}\int_{-\pi/l}^{\pi/l}(Q^0[f] \pm \vec{\nu}\cdot\vec{Q}[f])\,dk = \mp\frac{n^+}{\tau_{\rm sc}},\end{aligned}$$

where we have employed $\int \Theta f^0 dk = 0$. Then we obtain

$$(3.26)\qquad \frac{\partial}{\partial t}(n^+ + n^-) + \Delta^-\left[\frac{l}{\pi}\int_{-\pi/l}^{\pi/l}\left(\frac{\alpha}{\hbar}\sin kl\, f^0 + \vec{b}\cdot\vec{f}\right)dk\right] = 0.$$

Noting that $\Delta^- u(x) = l\,\partial\langle u(x)\rangle_1/\partial x$, we see that this equation corresponds to charge continuity. Differentiating in time the Poisson equation (3.13), using (3.26) in the result, and integrating with respect to x, we get the following nonlocal Ampère law for the balance of current:

$$(3.27)\qquad \varepsilon\frac{\partial F}{\partial t} + \left\langle \frac{el}{\pi}\int_{-\pi/l}^{\pi/l}\left(\frac{\alpha}{\hbar}\sin kl\, f^0 + \vec{b}\cdot\vec{f}\right)dk\right\rangle_1 = J(t).$$

Here the space-independent function $J(t)$ is the total current density. Since the Wigner components are real, we can rewrite (3.27) in the following equivalent form:

$$(3.28)\qquad \varepsilon\frac{\partial F}{\partial t} - \frac{2e}{\hbar}\left\langle \alpha\,\mathrm{Im} f_1^0 - \beta\,\mathrm{Re} f_1^2 + \gamma\,\mathrm{Im} f_1^3\right\rangle_1 = J(t).$$

4. Derivation of balance equations by the Chapman–Enskog method.

In this section, we shall derive the reduced balance equations for our two-miniband SL using the Chapman–Enskog method. First of all, we should decide the order of magnitude of the terms in the WPBGK equations (3.11) and (3.12) in the hyperbolic limit. Recall that in this limit, the collision frequency $1/\tau$ and the Bloch frequency $eF_M l/\hbar$ are of the same order, about 10 THz for the SL of section 2. Typically, $2g/\hbar$ is of the same order, so that the term containing $\vec{\omega}_0$ should also balance the BGK collision term. What about the other terms?

The scattering time $\tau_{\rm sc}$ is much longer than the collision time τ, and we shall consider $\tau/\tau_{\rm sc} = O(\lambda) \ll 1$. Moreover, the gap energy is typically much larger than the miniband widths or the spin-orbit coefficient, and a rich dominant balance is obtained by assuming that β/g and γ/g are of order λ. Then we can expand the unit vector $\vec{\nu}$ as follows:

$$\begin{aligned}(4.1)\qquad \vec{\nu} = (0,0,1) + \frac{\lambda\beta}{g}\sin kl\,(0,1,0) - \lambda^2\Bigg[&\frac{\beta\gamma}{g^2}\sin kl(1-\cos kl)\,(0,1,0)\\ &+\frac{\beta^2\sin^2 kl}{2g^2}\,(0,0,1)\Bigg] + O(\lambda^3).\end{aligned}$$

In this expansion, we have inserted the bookkeeping parameter λ, which is set equal to 1 at the end of our calculations (cf. section 2). From (3.11) and (3.12), we can write the scaled WPBGK equations as follows:

$$\mathbb{L}f - \Omega = -\lambda \left(\tau \frac{\partial f}{\partial t} + \Lambda f \right). \tag{4.2}$$

Here the operators $\mathbb{L}$ and Λ are defined by

$$\mathbb{L}f = f - \tau\,\Theta f + \delta_1 \begin{pmatrix} 0 \\ -f^2 \\ f^1 \\ 0 \end{pmatrix}, \tag{4.3}$$

$$\Lambda f = \delta_2 \begin{pmatrix} 0 \\ \vec{f} + \vec{\nu} f^0 \end{pmatrix} + \frac{\alpha\tau}{\hbar} \sin kl\, \Delta^- f + \Delta^- \begin{pmatrix} \tau \vec{b}\cdot\vec{f} \\ \tau\,\vec{b}\, f^0 \end{pmatrix} + \begin{pmatrix} 0 \\ \tau\,\vec{\omega}_1 \times \vec{f} \end{pmatrix}, \tag{4.4}$$

where

$$\delta_1 = \frac{2g\tau}{\hbar}, \quad \delta_2 = \frac{\tau}{\tau_{\mathrm{sc}}}. \tag{4.5}$$

The expansion of $\vec{\nu}$ in powers of λ gives rise to a similar expansion of Ω and Λ.

To derive the reduced balance equations, we use the following Chapman–Enskog ansatz:

$$f(x,k,t;\lambda) = f^{(0)}(k; n^+, n^-, F) + \sum_{m=1}^{\infty} f^{(m)}(k; n^+, n^-, F)\,\lambda^m, \tag{4.6}$$

$$\varepsilon \frac{\partial F}{\partial t} + \sum_{m=0}^{\infty} J_m(n^+, n^-, F)\,\lambda^m = J(t), \tag{4.7}$$

$$\frac{\partial n^{\pm}}{\partial t} = \sum_{m=0}^{\infty} A_m^{\pm}(n^+, n^-, F)\,\lambda^m. \tag{4.8}$$

The functions $A_m^{\pm}$ and J_m are related through the Poisson equation (3.13), so that

$$A_m^+ + A_m^- = -\frac{l}{e}\frac{\partial J_m}{\partial x}. \tag{4.9}$$

Inserting (4.6) to (4.8) into (4.2), we get

$$\mathbb{L}f^{(0)} = \Omega_0, \tag{4.10}$$

$$\mathbb{L}f^{(1)} = \Omega_1 - \tau \left.\frac{\partial f^{(0)}}{\partial t}\right|_0 - \Lambda_0 f^{(0)}, \tag{4.11}$$

$$\mathbb{L}f^{(2)} = \Omega_2 - \tau \left.\frac{\partial f^{(1)}}{\partial t}\right|_0 - \Lambda_0 f^{(1)} - \tau \left.\frac{\partial f^{(0)}}{\partial t}\right|_1 - \Lambda_1 f^{(0)}, \tag{4.12}$$

and so on. The subscripts 0 and 1 on the right-hand side of these equations mean that we replace $\varepsilon\,\partial F/\partial t|_m = J\delta_{0m} - J_m$, $\partial n^{\pm}/\partial t|_m = A_m^{\pm}$. Moreover, inserting (4.1) and (4.6) into (3.10) yields the following compatibility conditions:

$$f_0^{(1)\,0} = 0, \quad f_0^{(1)\,3} = \frac{\beta}{g}\,\mathrm{Im} f_1^{(0)\,2}, \tag{4.13}$$

$$\begin{aligned} &f_0^{(2)\,0} = 0, \\ &f_0^{(2)\,3} = \frac{\beta}{g}\,\mathrm{Im} f_1^{(1)\,2} + \frac{\beta^2}{4g^2}\,(f_0^{(0)\,3} - \mathrm{Re} f_2^{(0)\,3}) - \frac{\beta\gamma}{g^2}\,\mathrm{Im}\left(f_1^{(0)\,2} - \frac{f_2^{(0)\,2}}{2}\right), \end{aligned} \tag{4.14}$$

etc.

To solve (4.10) for $f^{(0)} \equiv \varphi$, we first note that

$$-\tau\,\Theta\varphi = \sum_{j=-\infty}^{\infty} i\vartheta_j \varphi_j e^{ijkl}, \tag{4.15}$$

$$\vartheta_j \equiv \frac{\tau e j l}{\hbar}\,\langle F\rangle_j. \tag{4.16}$$

Then (4.10), (3.22), and (4.1) yield

$$\varphi_j^0 = \frac{\phi_j^+ + \phi_j^-}{2}\,\frac{1 - i\vartheta_j}{1+\vartheta_j^2}, \quad \varphi_j^1 = \varphi_j^2 = 0, \quad \varphi_j^3 = \frac{\phi_j^+ - \phi_j^-}{2}\,\frac{1 - i\vartheta_j}{1+\vartheta_j^2}, \tag{4.17}$$

where we have used the fact that the Fourier coefficients

$$\phi_j^{\pm} = \frac{l}{\pi}\int_0^{\pi/l} \cos(jkl)\,\phi^{\pm}\,dk \tag{4.18}$$

are real because $\phi^{\pm}$ are even functions of k. Similarly, the solution of (4.11) is $f^{(1)} \equiv \psi$ with

$$\begin{aligned} \psi_j^m &= r_j^m\,\frac{1 - i\vartheta_j}{1+\vartheta_j^2} \quad (m = 0, 3), \\ \psi_j^1 &= \frac{(1+i\vartheta_j)\,r_j^1 + \delta_1\,r_j^2}{(1+i\vartheta_j)^2 + \delta_1^2}, \\ \psi_j^2 &= \frac{(1+i\vartheta_j)\,r_j^2 - \delta_1\,r_j^1}{(1+i\vartheta_j)^2 + \delta_1^2}. \end{aligned} \tag{4.19}$$

Here r is the right-hand side of (4.11). The balance equations can be found in two ways. We can calculate $A_m^{\pm}$ for $m = 0, 1$ by using the compatibility conditions (4.13) and (4.14) in (4.11) and (4.12), respectively. More simply, we can insert the solutions (4.17) and (4.19) in the balance equations (3.25) and in the Ampère law (3.27). The result is

$$\frac{\partial n^{\pm}}{\partial t} + \Delta^- D_{\pm}(n^+, n^-, F) = \pm R(n^+, n^-, F), \tag{4.20}$$

$$\begin{aligned} &\varepsilon\,\frac{\partial F}{\partial t} + \frac{e}{\hbar}\left\langle [\alpha\,(\phi_1^+ + \phi_1^-) + \gamma\,(\phi_1^+ - \phi_1^-)]\,\frac{\vartheta_1}{1+\vartheta_1^2}\right\rangle_1 \\ &\quad + \frac{2e}{\hbar}\,[\beta\mathrm{Re}\langle\psi_1^2\rangle_1 - \alpha\,\mathrm{Im}\langle\psi_1^0\rangle_1 - \gamma\,\mathrm{Im}\langle\psi_1^3\rangle_1] = J, \end{aligned} \tag{4.21}$$

$$D_{\pm} = \frac{\alpha \pm \gamma}{\hbar}\left[\frac{\phi_1^{\pm}\vartheta_1}{1+\vartheta_1^2} - \mathrm{Im}(\psi_1^0 \pm \psi_1^3)\right] + \frac{\beta}{\hbar}\,\mathrm{Re}\psi_1^2 \pm \frac{\beta^2\vartheta_2}{4g\hbar}\,\frac{\phi_2^+ + \phi_2^-}{1+\vartheta_2^2}, \tag{4.22}$$

$$R = -\frac{\delta_2 n^+}{\tau} - \frac{\beta^2\vartheta_2^2(\phi_2^+ - \phi_2^-)}{8g^2\tau(1+\vartheta_2^2)} + \frac{\beta}{g\tau}\,\vartheta_1\mathrm{Re}\psi_1^2 + \frac{\beta}{\hbar}\,(2 - \Delta^+)\mathrm{Im}\psi_1^1. \tag{4.23}$$

The appendix justifies this second and more direct method by showing that equivalent expressions are obtained from the compatibility conditions. Note that (4.21) can be obtained from (4.20) and the Poisson equation.

5. Spintronics: Quantum drift-diffusion equations for an LSL with Rashba spin-orbit interaction. In the simpler case of an LSL with the precession term of Rashba spin-orbit interaction (but no intersubband coupling), we can obtain explicit rate equations for $n^{\pm}$ by means of the Chapman–Enskog method. In the Hamiltonian (3.1), we have $\gamma = g = 0$, so that $h_3 = 0$ and $\vec{\nu} = (0, 1, 0)$. However, the Fermi–Dirac distribution is different from (2.6) for an LSL. We have to replace E_n instead of $\hbar^2 k_z^2/(2m^*)$, sum over n for all populated QW energy levels, and integrate over k_y only. Provided only E_1 is populated, we obtain the following expression instead of (3.23):

$$\phi^{\pm}(k; n^{\pm}) = \int_{-\infty}^{\infty} \frac{D_\Gamma\left(E - \mathcal{E}^{\pm}(k) - E_1\right)}{1 + \exp\left(\frac{E-\mu^{\pm}}{k_B T}\right)}\, dE, \tag{5.1}$$

where the broadened density of states is

$$D_\Gamma(E) = \frac{1}{2\pi L_z} \int_{-\infty}^{\infty} dk_y \delta_\Gamma \left(\frac{\hbar^2 k_y^2}{2m^*} - E\right) = \frac{\sqrt{2m^*}}{2\pi\hbar L_z} \int_0^{\infty} dE_y\, \frac{\delta_\Gamma(E_y - E)}{\sqrt{E_y}}. \tag{5.2}$$

Note that (5.2) becomes the 1D density of states $D(E) = \sqrt{2m^*}\theta(E)/(2\pi\hbar L_z\sqrt{E})$ as $\Gamma \to 0+$. We have not included a factor 2 in (5.2) because all the electrons in each of the minibands (with energies $\mathcal{E}^{\pm}(k)$) have the same spin. Inserting (2.8) in (5.2) and using the residue theorem to evaluate the integral, we obtain

$$\begin{aligned} D_\Gamma(E) = {} & \frac{\sqrt{m^*}}{4\pi\hbar L_z} \\ & \times \left[\frac{\sqrt{\sqrt{E^2 + \sqrt{2}\Gamma E + \Gamma^2} + E + \frac{\Gamma}{\sqrt{2}}} - \sqrt{\sqrt{E^2 + \sqrt{2}\Gamma E + \Gamma^2} - E - \frac{\Gamma}{\sqrt{2}}}}{\sqrt{E^2 + \sqrt{2}\Gamma E + \Gamma^2}} \right. \\ & \left. + \frac{\sqrt{\sqrt{E^2 - \sqrt{2}\Gamma E + \Gamma^2} + E - \frac{\Gamma}{\sqrt{2}}} + \sqrt{\sqrt{E^2 - \sqrt{2}\Gamma E + \Gamma^2} - E + \frac{\Gamma}{\sqrt{2}}}}{\sqrt{E^2 - \sqrt{2}\Gamma E + \Gamma^2}} \right]. \end{aligned} \tag{5.3}$$

As $E \to +\infty$, $D_\Gamma(E) \sim \sqrt{2m^*}/(2\pi\hbar L_z\sqrt{E})$, whereas $D_\Gamma(E) = O(|E|^{-5/2})$ as $E \to -\infty$. Then the convolution integral (5.1) is convergent.

In the present case, minibands correspond to electrons with spin up or down which have different energy. Scattering between minibands is the same as in (3.21), $-(\vec{\nu} f^0 + \vec{f})/\tau_{\text{sc}}$, which yields $\partial n^{\pm}/\partial t + \cdots = \mp n^{\pm}/\tau_{\text{sc}}$ in (3.25), only if the chemical potential of the miniband with lowest energy, μ^-, is less than the minimum energy of the other miniband, $\mathcal{E}^+_{\text{min}} = \min_k \mathcal{E}^+(k)$. Otherwise ($\mu^- > \mathcal{E}^+_{\text{min}}$), the scattering term should be $-2\vec{f}/\tau_{\text{sc}}$, which yields $\partial n^{\pm}/\partial t + \cdots = \mp(n^+ - n^-)/\tau_{\text{sc}}$ in (3.25), thereby trying to equalize n^+ and n^-; cf. [19].

Now we shall derive the balance equations in the hyperbolic limit using the Chapman–Enskog method as in section 4. In the scaled WPBGK equations (4.2), the operators $\mathbb{L}$ and Λ are

$$\mathbb{L}f = f - \tau\,\Theta f, \tag{5.4}$$

$$\Lambda f = \delta_2 \begin{pmatrix} 0 \\ 2\vec{f} + (\vec{\nu} f^0 - \vec{f})\,\theta(\mathcal{E}^+_{\min} - \mu^-) \end{pmatrix} + \frac{\alpha\tau}{\hbar}\sin kl\,\Delta^- f + \frac{\beta\tau}{\hbar}\cos kl\,\Delta^- \begin{pmatrix} f^2 \\ 0 \\ f^0 \\ 0 \end{pmatrix} + \frac{\beta\tau}{\hbar}\sin kl\,\Delta^+ \begin{pmatrix} 0 \\ f^3 \\ 0 \\ -f^1 \end{pmatrix}, \tag{5.5}$$

where δ_2 is given by (4.5), $\theta(x)$ is the Heaviside unit step function, and $\Omega^0 = (\phi^+ + \phi^-)/2$, $\vec{\Omega} = (0,1,0)\,(\phi^+ - \phi^-)/2$. The hierarchy of equations (4.10)–(4.12) is simply

$$\mathbb{L}f^{(0)} = \Omega, \tag{5.6}$$

$$\mathbb{L}f^{(1)} = -\,\tau\,\frac{\partial f^{(0)}}{\partial t}\bigg|_0 - \Lambda f^{(0)}, \tag{5.7}$$

$$\mathbb{L}f^{(2)} = -\,\tau\,\frac{\partial f^{(1)}}{\partial t}\bigg|_0 - \Lambda f^{(1)} - \tau\,\frac{\partial f^{(0)}}{\partial t}\bigg|_1, \tag{5.8}$$

and so on. The compatibility and solvability conditions are

$$f_0^{(m)\,0} = f_0^{(m)\,2} = 0 \quad \Longrightarrow (\mathbb{L}f^{(m)\,0})_0 = (\mathbb{L}f^{(m)\,2})_0 = 0, \quad m \geq 1. \tag{5.9}$$

The solution $f^{(0)} \equiv \varphi$ of (5.6) is

$$\varphi_j^0 = \frac{\phi_j^+ + \phi_j^-}{2}\,\frac{1 - i\vartheta_j}{1 + \vartheta_j^2}, \quad \varphi_j^1 = \varphi_j^3 = 0, \quad \varphi_j^2 = \frac{\phi_j^+ - \phi_j^-}{2}\,\frac{1 - i\vartheta_j}{1 + \vartheta_j^2}, \tag{5.10}$$

where we have used the fact that the Fourier coefficients $\phi_j^\pm$ are real because $\phi^\pm$ are even functions of k. Similarly, the solution of (5.7) is $f^{(1)} \equiv \psi$ with

$$\psi_j^m = r_j^m\,\frac{1 - i\vartheta_j}{1 + \vartheta_j^2} \quad (m = 0, 2), \quad \psi_j^1 = \psi_j^3 = 0. \tag{5.11}$$

Here r is the right-hand side of (5.7). The balance equations can be found in two ways. We can calculate $A_m^\pm$ for $m = 0, 1$ by using the solvability conditions (5.9) in (5.7) and (5.8), respectively. More simply, we can insert the solutions (5.10) and (5.11) in the balance equations (3.25) and in the Ampère law (3.27). In both cases, the result is

$$\frac{\partial n^\pm}{\partial t} + \Delta^- D_\pm(n^+, n^-, F) = \mp R(n^+, n^-, F), \tag{5.12}$$

$$\varepsilon\,\frac{\partial F}{\partial t} + e\,\langle D_+ + D_- \rangle_1 = J, \tag{5.13}$$

$$D_\pm = -\frac{\alpha}{\hbar}\,\Delta^- \mathrm{Im}(\varphi_1^0 \pm \varphi_1^2 + \psi_1^0 \pm \psi_1^2) \pm \frac{\beta}{\hbar}\,\Delta^- \mathrm{Re}(\varphi_1^0 \pm \varphi_1^2 + \psi_1^0 \pm \psi_1^2), \tag{5.14}$$

$$R = \frac{n^+ - n^-\,\theta(\mu^- - \mathcal{E}^+_{\min})}{\tau_{sc}}. \tag{5.15}$$

A straightforward calculation of (5.14) yields

$$
\begin{aligned}
D_{\pm} = {} & \frac{(\alpha\vartheta_1 \pm \beta)\phi_1^{\pm}}{\hbar\,(1+\vartheta_1^2)} \mp \frac{\tau\,(\phi_1^{+}-\phi_1^{-})\,[2\alpha\vartheta_1 \pm \beta(1-\vartheta_1^2)]}{2\hbar\tau_{\text{sc}}(1+\vartheta_1^2)^2} \\
& + \frac{[2\alpha\vartheta_1 \pm \beta(1-\vartheta_1^2)]\alpha\tau}{\hbar^2(1+\vartheta_1^2)^2}\,\frac{\partial\phi_1^{\pm}}{\partial n^{\pm}}\left[\Delta^{-}\left(\frac{\alpha\vartheta_1 \pm \beta}{\hbar\,(1+\vartheta_1^2)}\phi_1^{\pm}\right) \pm \frac{\hbar}{\alpha\tau_{sc}}(n^{+}-n^{-})\right] \\
& + \frac{\alpha\,(3\vartheta_1^2-1) \pm \beta\vartheta_1(3-\vartheta_1^2)}{\hbar(1+\vartheta_1^2)^3}\,\frac{l\tau^2\phi_1^{\pm}}{\hbar\varepsilon}\left(\frac{J}{e} - \left\langle\left\langle \frac{\alpha\,(\phi_1^{+}+\phi_1^{-})\vartheta_1}{\hbar(1+\vartheta_1^2)}\right\rangle_1\right\rangle_1\right. \\
& \left. - \left\langle\left\langle \frac{\beta\,(\phi_1^{+}-\phi_1^{-})}{\hbar(1+\vartheta_1^2)}\right\rangle_1\right\rangle_1\right) - \frac{(\alpha^2+\beta^2)\tau}{2\hbar^2(1+\vartheta_1^2)}\,\Delta^{-}n^{\pm} \\
& + \frac{\tau}{2\hbar^2(1+\vartheta_1^2)}\,\left[(\alpha^2-\beta^2 \mp 2\alpha\beta\vartheta_1)\,\Delta^{-}\left(\frac{\phi_2^{\pm}}{1+\vartheta_2^2}\right)\right. \\
& \left. + [(\beta^2-\alpha^2)\vartheta_1 \mp 2\alpha\beta]\,\Delta^{-}\left(\frac{\vartheta_2\phi_2^{\pm}}{1+\vartheta_2^2}\right)\right].
\end{aligned} \tag{5.16}
$$

We have numerically solved the system of equations (5.12)–(5.16), with the following boundary conditions in the interval $-2l \leq x \leq 0$:

$$\varepsilon\,\frac{\partial F}{\partial t} + \sigma\,F = J, \tag{5.17}$$

$$n^{+} = n^{-} = \frac{N_D}{2}, \tag{5.18}$$

whereas in the collector $Nl \leq x \leq Nl + 2l$,

$$\frac{\partial n^{\pm}}{\partial x} = \frac{\partial F}{\partial x} = 0 \tag{5.19}$$

hold. We have used the following values of the parameters: $\alpha = \Delta_1/2 = 8$ meV, $\beta = 2.63$ meV, $d_W = 3.1$ nm, $d_B = 1.96$ nm, $l = d_W + d_B = 5.06$ nm, $L_z = 3.1$ nm, $T = 5$ K, $\tau = 5.56 \times 10^{-14}$ s, $\tau_{\text{sc}} = 5.56 \times 10^{-13}$ s, $N_D = 4.048 \times 10^{10}$ cm^{-2}, $m^* = (0.067 d_W + 0.15 d_B) m_0/l$, $V = 3$ V, $N = 110$. We have used a large conductivity of the injecting contact $\sigma = 11.78\,\Omega^{-1}\text{m}^{-1}$. With these values, we select the following units to present our results graphically: $F_M = \hbar/(el\tau) = 23.417$ kV/cm, $x_0 = \varepsilon F_M l/(eN_D) = 19.4$ nm, $t_0 = \hbar/\alpha = 0.082$ ps, $J_0 = \alpha e N_D/(2\hbar) = 3.94 \times 10^4$ A/cm^2.

Figure 5.1(b)–(d) illustrates the resulting stable self-sustained current oscillations. They are due to the periodic formation of a pulse of the electric field at the cathode $x = 0$ and its motion through the LSL. Figure 5.1(b) depicts the pulse when it is far from the contacts, and the corresponding spin polarization is shown in Figure 5.1(d). It is interesting to consider the influence of the broadening Γ and the Fermi–Dirac statistics on the oscillations. At high temperatures, Boltzmann statistics and a semiclassical approximation should provide a good description. The semiclassical approximation is equivalent to dropping all spatial averages in our previous formulas. Since $x_0 \gg l$, the effect of dropping spatial averages should be rather small. Using Boltzmann statistics yields explicit formulas for $\mu^{\pm}$ in terms of $n^{\pm}$. In fact, we only have to replace $e^{(\mu^{\pm}-E)/(k_BT)}$ instead of the 3D Fermi distribution $[1 + e^{(E-\mu^{\pm})/(k_BT)}]^{-1}$ in (5.1). Using the relation (3.24) between $n^{\pm}$ and $\phi^{\pm}$, we obtain

$$\phi^{\pm} = n^{\pm}\,\frac{\pi\,\exp\left(\frac{\alpha\,\cos kl \mp \beta\,|\sin kl|}{k_BT}\right)}{\int_0^{\pi} dK\,\exp\left(\frac{\alpha\,\cos K \mp \beta\,\sin K}{k_BT}\right)}, \tag{5.20}$$

FIG. 5.1. and therefore,

$$\phi_j^{\pm} = n^{\pm} \frac{\int_0^{\pi} dK\, \cos(jK)\, \exp\left(\frac{\alpha \cos K \mp \beta \sin K}{k_B T}\right)}{\int_0^{\pi} dK\, \exp\left(\frac{\alpha \cos K \mp \beta \sin K}{k_B T}\right)} \tag{5.21}$$

for $j = 0, 1, \ldots$. Similar relations hold for the case of an SL with Boltzmann statistics in the tight-binding approximation.

The results are shown in Figure 5.1. Figure 5.1(a) depicts the relation between electron current and field for a spatially uniform stationary solution with $n^{\pm} = N_D/2$. We observe that all curves are similar. However, the curves for $\Gamma = 0$ and $\Gamma = 1$ meV are close, while the curve for $\Gamma = 5$ meV has dropped noticeably. The shapes of $J(t)$ for $\Gamma = 0$ and $\Gamma = 1$ meV in Figure 5.1(b) are close and quite different from that for $\Gamma = 5$ meV. If we look at the corresponding field profiles in Figure 5.1(c) and (d), for $\Gamma = 0$ and $\Gamma = 1$ meV the oscillations of the current are caused by the periodic nucleation of a pulse of the electric field at $x = 0$ and its motion towards the end of the LSL. The pulse far from the contacts shown in Figure 5.1(c) is larger in the case of $\Gamma = 0$ than for $\Gamma = 1$ meV. In the case of $\Gamma = 5$ meV (not shown), the pulse created at $x = 0$ becomes attenuated and disappears before arriving at $x = Nl$. This seems to indicate that the lowest voltage at which there exist stable self-sustained current oscillations is an increasing function of Γ: If we fix the voltage at 3 V and increase Γ, the critical voltage threshold to have stable oscillations approaches our fixed voltage of 3 V. Then the observed oscillations are smaller and the field profiles correspond to waves that vanish before reaching the end of the device, as it also occurs in models of the Gunn effect in bulk semiconductors [4].

6. Conclusions. We have presented a Wigner–Poisson–BGK system of equations with a collision broadened local Fermi–Dirac distribution for strongly coupled SLs having only one populated miniband. In the hyperbolic limit in which the collision and Bloch frequencies are of the same order and dominate all other frequencies, the Chapman–Enskog perturbation method yields a quantum drift-diffusion equation for the field. Numerical solutions of this equation exhibit self-sustained oscillations of the current due to recycling and motion of charge dipole domains [2].

For strongly coupled SLs having two populated minibands, we have introduced a periodic version of the Kane Hamiltonian and derived the corresponding Wigner–Poisson–BGK system of equations. The collision model comprises two terms, a BGK term trying to bring the Wigner matrix closer to a broadened Fermi–Dirac local equilibrium at each miniband, and a scattering term that brings down electrons from the upper to the lower miniband. By using the Chapman–Enskog method, we have derived quantum drift-diffusion equations for the miniband populations which contain generation-recombination terms. As it should be, the recombination terms vanish if there is no interminiband scattering and the off-diagonal terms in the Hamiltonian are zero. These terms may represent a Rashba spin-orbit interaction for an LSL. For an LSL under dc voltage bias in the growth direction, numerical solutions of the corresponding quantum drift-diffusion equations show self-sustained current oscillations due to periodic recycling and motion of electric field pulses. The periodic changes of the spin polarization and spin-polarized current indicate that this system acts as a spin oscillator.

Appendix. Balance equations from compatibility conditions We know that $\varphi^1 = \varphi^2 = 0$ from (4.11). Then the compatibility conditions (4.13) and (4.14) become

$$\psi_0^0 = 0, \quad \psi_0^3 = 0, \tag{A.1}$$

$$f_0^{(2)\,0} = 0, \quad f_0^{(2)\,3} = \frac{\beta}{g}\,\mathrm{Im}\psi_1^2 + \frac{\beta^2}{4g^2}\,(\varphi_0^3 - \mathrm{Re}\varphi_2^3). \tag{A.2}$$

Equations (A.1) imply that $(\mathbb{L}\psi)_0^m = 0$ for $m = 0, 3$ in (4.11). Since $\varphi_0^0 = (n^+ + n^-)/2$ and $\varphi_0^3 = (n^+ - n^-)/2$, these conditions yield

$$\begin{aligned}
&\frac{\tau}{2}\,\frac{\partial(n^+ + n^-)}{\partial t}\bigg|_0 - \frac{\alpha\tau}{\hbar}\,\Delta^-\mathrm{Im}\varphi_1^0 - \frac{\gamma\tau}{\hbar}\,\Delta^-\mathrm{Im}\varphi_1^3 = 0,\\
&\frac{\tau}{2}\,\frac{\partial(n^+ - n^-)}{\partial t}\bigg|_0 + \delta_2 n^+ - \frac{\alpha\tau}{\hbar}\,\Delta^-\mathrm{Im}\varphi_1^3 - \frac{\gamma\tau}{\hbar}\,\Delta^-\mathrm{Im}\varphi_1^0 = 0,
\end{aligned}$$

wherefrom we obtain

$$A_0^{\pm} = \mp\frac{n^+}{\tau_{\mathrm{sc}}} + \frac{\alpha \pm \gamma}{\hbar}\,\Delta^-\mathrm{Im}(\varphi_1^0 \pm \varphi_1^3). \tag{A.3}$$

Let us now calculate $A_1^\pm$. Equations (A.2) imply $(\mathbb{L}f^{(2)})_0^0 = 0$ and $(\mathbb{L}f^{(2)})_0^3 = f_0^{(2)\,3}$ given by (A.2) in (4.12). After a little algebra, we find

$$\begin{aligned} A_1^\pm = {}& \frac{\alpha \pm \gamma}{\hbar}\, \Delta^- \mathrm{Im}(\psi_1^0 \pm \psi_1^3) - \frac{\beta}{\hbar}\,(\Delta^- \mathrm{Re}\psi_1^2 \pm \Delta^+ \mathrm{Im}\psi_1^1) \\ & \mp \frac{\beta}{g\tau}\, \mathrm{Im}\psi_1^2 \pm \frac{\beta^2}{8g^2\tau}\,[2\mathrm{Re}\varphi_2^3 + \phi_2^+ - \phi_2^- - 2(n^+ - n^-)]. \end{aligned} \tag{A.4}$$

We will now transform (A.4) into an equivalent form by eliminating $\mathrm{Re}\varphi_2^3$ and $\mathrm{Im}\psi_1^2$ in favor of $\mathrm{Re}\varphi_2^3$ and $\mathrm{Im}\psi_1^2$, respectively. Equation (4.10) implies that $(1 + i\vartheta_2)\varphi_2^3 = (\phi_2^+ - \phi_2^-)/2$, and therefore

$$\mathrm{Re}\varphi_2^3 = \vartheta_2\, \mathrm{Im}\varphi_2^3 + \frac{\phi_2^+ - \phi_2^-}{2}. \tag{A.5}$$

Similarly, (4.11) implies that $(1 + i\vartheta_1)\,\psi_1^2 + \delta_1\,\psi_1^1 = r_1^2$, and therefore

$$\mathrm{Im}\psi_1^2 = -\vartheta_1\, \mathrm{Re}\psi_1^2 - \delta_1\, \mathrm{Im}\psi_1^1 + \mathrm{Im}r_1^2. \tag{A.6}$$

The right-hand side of (4.11) yields

$$r_1^2 = \frac{\beta}{2g}\left(\frac{1 - e^{-i2kl}}{2i}\,(\phi^+ - \phi^-)\right)_0 - \frac{\beta\tau}{\hbar}\,\Delta^-\left(\frac{1 + e^{-i2kl}}{2}\,\varphi^0\right)_0,$$

wherefrom

$$\mathrm{Im}r_1^2 = \frac{\beta}{4g}\,(\phi_2^+ - \phi_2^- - n^+ + n^-) - \frac{\beta\tau}{2\hbar}\,\Delta^- \mathrm{Im}\varphi_2^0. \tag{A.7}$$

Inserting (A.5), (A.6), and (A.7) into (A.4), we obtain the equivalent form

$$\begin{aligned} A_1^\pm = {}& \frac{\alpha \pm \gamma}{\hbar}\, \Delta^- \mathrm{Im}(\psi_1^0 \pm \psi_1^3) - \frac{\beta}{\hbar}\,(\Delta^- \mathrm{Re}\psi_1^2 \pm \Delta^+ \mathrm{Im}\psi_1^1) \\ & \pm \frac{2\beta}{\hbar}\, \mathrm{Im}\psi_1^1 \pm \frac{\beta}{g\tau}\, \vartheta_1 \mathrm{Re}\psi_1^2 \pm \frac{\beta^2}{4g^2\tau}\, \vartheta_2\, \mathrm{Im}\varphi_2^3 \pm \frac{\beta^2}{2\hbar g}\, \Delta^- \mathrm{Im}\varphi_2^0. \end{aligned} \tag{A.8}$$

Inserting (A.3) and this expression into (4.8) and using (4.17) yield (4.20), (4.22), and (4.23). Up to order λ^2, we have thus proven the following statement:

By using the compatibility conditions in the hierarchy of (4.11), (4.12), *we obtain the same balance equations for* $n^\pm$ *as by direct substitution of the solutions of the hierarchy into* (3.25) *(which arise from integration of the kinetic equation over* k*).*

THERMAL BLOW-UP IN A SUBDIFFUSIVE MEDIUM*

W. E. OLMSTEAD[†] AND CATHERINE A. ROBERTS[‡]

Abstract. The problem of thermal blow-up in a subdiffusive medium is examined within the framework of a fractional heat equation with a nonlinear source term. This model establishes that a thermal blow-up always occurs when a finite strip of subdiffusive material is exposed to the effects of a localized, high-energy source. This behavior is distinctly different from the classical diffusion case in which a blow-up can be avoided by locating the site of the energy source sufficiently close to one of the cold ends of the strip. The asymptotic growth of the solution near blow-up is determined for a nonlinear source whose output increases with temperature in either an algebraic or exponential manner. The blow-up growth rate is found to depend upon the anomalous diffusion parameter that defines the subdiffusive medium. This suggests that such media might be characterized by their response to a reaction-diffusion process.

Key words. subdiffusion, thermal blow-up, Volterra equation, asymptotic growth

1. Introduction.

The problem of a thermal blow-up in a subdiffusive medium is examined. The diffusion of heat is retarded in materials with subdiffusive properties, thereby allowing the presence of a high-energy source to be considerably more effective in producing extreme temperature growth. The results here will demonstrate that a thermal blow-up will always occur, regardless of the proximity of a cold boundary.

The underlying physics of subdiffusion is associated with a medium in which the mean square displacement of Brownian motion evolves on a slower-than-normal time scale. That is,

$$\left\langle X^2 \right\rangle \sim C\, t^{\alpha}, \quad 0 < \alpha < 1, \tag{1}$$

where α is the anomalous diffusion parameter. The limiting case of $\alpha = 1$ corresponds to classical (Gaussian) diffusion. From the viewpoint of a random walk, a subdiffusive process exhibits an infinitely long average time for the occurrence of a finite jump, thereby implying a diminished capacity for the flux of thermal energy.

Subdiffusion occurs in a variety of applications as discussed in the review papers [4], [5], [11]. For the problem presented here, it is convenient to think of the application to certain porous materials in which microscopic pores are filled with a substance that has a lower conductivity than that of the basic matrix material as described in [1], [3]. A continuum model of a subdiffusive material is consistent with the scenario in which the pore size is small in comparison to $\sqrt{\langle X^2 \rangle}$.

The modeling of subdiffusive phenomena that obeys (1) has motivated the implementation of fractional differential operators as discussed in [4]. For the initial-boundary value problem considered here, a fractional diffusion equation with a localized, high-energy source will be defined for a finite strip of subdiffusive material.

The ends of the strip are maintained at zero temperature so that some energy can be dissipated into the surroundings. In the context of a porous material, this model can be viewed as the thermal response associated with localized combustion of the porous material.

The investigation of a blow-up solution is carried out by converting the initial-boundary value problem to a nonlinear integral equation that governs the temperature at the site of the localized source. The resulting Volterra equation lends itself to the analytical techniques presented in [2], [6], [8], [9], and [10].

The results developed here for blow-up in a subdiffusive medium can be compared with those of [6] for the case of classical diffusion. In the classical diffusive problem, the results of [6] demonstrate that the occurrence of a blow-up with Dirichlet boundary conditions depends upon the proximity of the localized source to one of the ends of the strip. In particular, if the site of the source is located sufficiently close to either end, a blow-up will not occur. This implies that in the case of classical diffusion, the cold boundary can draw away enough heat from a nearby source to keep the temperature bounded throughout the strip.

In contrast to classical diffusion, the results here for the subdiffusive case will demonstrate that a blow-up will always occur, no matter how close the localized source is placed to a cold boundary. This behavior will be found to hold for all values of the anomalous diffusion parameter that correspond to the subdiffusive range. Further results developed here will show that the temporal growth of the temperature near blow-up can be characterized by the anomalous diffusion parameter.

2. Mathematical formulation. It is assumed that the temperature $T(x,t)$ in the strip of subdiffusive material satisfies the one-dimensional fractional diffusion equation given by

$$\frac{\partial T(x,t)}{\partial t} = \frac{\partial^2}{\partial x^2} D_t^{1-\alpha}[T(x,t)] + \delta(x-a)g[T(a,t)], \quad 0 < x < \ell, \quad t > 0, \tag{2}$$

$$T(0,t) = 0, \quad T(\ell,t) = 0, \quad t > 0, \tag{3}$$

$$T(x,0) = 0, \quad 0 \le x \le \ell. \tag{4}$$

The fractional derivative operator $D_t^{1-\alpha}$ is defined by

$$D_t^{1-\alpha}[T(x,t)] \equiv \frac{1}{\Gamma(\alpha)} \frac{\partial}{\partial t} \int_0^t \left(t-t'\right)^{\alpha-1} T\left(x,t'\right) \,\mathrm{d}t', \quad 0 < \alpha < 1, \tag{5}$$

where $\Gamma(\alpha)$ is the gamma function. This operator is introduced to model diffusive behavior that is consistent with (1). The particular form of (5) is known as the Riemann–Liouville fractional derivative. This form, as well as other alternative versions, is discussed in [7]. The limiting case of $\alpha = 1$ is associated with classical diffusion since D_t^0 is the identity operator.

The energy source term in (2) has been both localized and intensified by introducing the multiplicative delta function $\delta(x-a)$, $0 < a < \ell$. The nonlinearity $g(T)$ is assumed to have the properties

$$g(T) > 0, \quad g'(T) > 0, \quad g''(T) > 0, \quad T \ge 0, \tag{6}$$

which is typical for reaction-diffusion phenomena.

A physical interpretation of (2)–(6) is the temperature distribution in a strip of microscopically porous material that is capable of a chemical reaction only within a narrow zone centered at $x = a$. The source term in (2) includes a delta function to localize and intensify the reaction at $x = a$, while the nonlinearity $g(T)$ approximates an Arrhenius-type energy release.

3. Conversion to an integral equation. To investigate a possible blow-up solution of (2)–(6), it is advantageous to convert the initial-boundary value problem into an equivalent integral equation. This will be accomplished through the use of the Green's function $G_\alpha(x,t|\xi,0)$ that satisfies

$$\frac{\partial}{\partial t}G_\alpha(x,t|\xi,0) = \frac{\partial^2}{\partial x^2}D_t^{1-\alpha}\left[G_\alpha(x,t|\xi,0)\right] + \delta(x-\xi)\delta(t), \quad 0 < x < \ell, \quad t > 0^-, \tag{7}$$

$$G_\alpha(0,t|\xi,0) = 0, \quad G_\alpha(\ell,t|\xi,0) = 0, \quad t > 0, \tag{8}$$

$$G_\alpha(x,0^-|\xi,0) = 0, \quad 0 \le x \le \ell. \tag{9}$$

It follows from (2)–(4) and (7)–(9) that

$$T(x,t) = \int_0^t \int_0^\ell G_\alpha(x,t-s|\xi,0)\delta(\xi-a)g[T(a,s)]\,\mathrm{d}\xi\,\mathrm{d}s, \quad 0 \le x \le \ell, \quad t > 0. \tag{10}$$

Utilizing the sifting property of the delta function allows (10) to be reduced to

$$T(x,t) = \int_0^t G_\alpha(x,t-s|a,0)g[T(a,s)]\,\mathrm{d}s, \quad 0 \le x \le \ell, \quad t > 0. \tag{11}$$

It is clear from (11) that if $T(a,t)$ is known, then $T(x,t)$ is determined for $0 \le x \le \ell$, $t \ge 0$. Moreover, it is seen from (11) that any blow-up solution of (2)–(6) must be associated with a blow-up of $T(a,t)$.

In order to determine $T(a,t)$, set $x = a$ in (11), which produces the integral equation

$$u(t) = \int_0^t k(t-s)g[u(s)]\,\mathrm{d}s, \quad 0 \le t < \infty, \tag{12}$$

where

$$u(t) \equiv T(a,t) \tag{13}$$

and

$$k(t) \equiv G_\alpha(a,t|a,0). \tag{14}$$

Thus, the investigation of a possible blow-up solution of the initial-boundary value problem (2)–(6) has been reduced to the analysis of the integral equation (12).

To analyze (12), it is essential to know the properties of the kernel $k(t)$. Since those properties follow from $G_\alpha(x,t|\xi,0)$, it is necessary to solve (7)–(9). Results presented in [12] imply that the solution of (7)–(9) can be expressed in terms of the solution for the classical diffusion case in which $\alpha = 1$. That is,

$$G_\alpha(x,t|\xi,0) = \int_0^\infty f_\alpha(z)G_1(x,t^\alpha z|\xi,0)\,\mathrm{d}z. \tag{15}$$

To define $f_\alpha(z)$, it is necessary to introduce the definition of the Mellin transform

$$M\left[v(z);r\right] \equiv \int_0^\infty z^{r-1} v(z)\,\mathrm{d}z. \tag{16}$$

In [12], $f_\alpha(z)$ is introduced as an inverse Mellin transform as given by

$$f_\alpha(z) = M^{-1}\left[\frac{\Gamma(r)}{\Gamma(1-\alpha+\alpha r)}\right] = \sum_{j=0}^{\infty} \frac{(-1)^j z^j}{j!\,\Gamma(1-\alpha-\alpha j)}, \quad z \geq 0. \tag{17}$$

It follows from (17) that

$$f_\alpha(z) \geq 0, \quad z \geq 0, \tag{18}$$

and

$$f_\alpha(z) \to 0 \text{ exponentially as } z \to \infty. \tag{19}$$

For the classical diffusion case in which $\alpha = 1$, the solution of (7)–(9) can be expressed either as a Fourier sine series expansion,

$$G_1(x,t|\xi,0) = \frac{2H(t)}{\ell} \sum_{n=1}^{\infty} \sin\frac{n\pi\xi}{\ell}\,\sin\frac{n\pi x}{\ell}\,\exp\left(-\frac{n^2\pi^2}{\ell^2}t\right), \tag{20}$$

or as an image expansion,

$$G_1(x,t|\xi,0) = \frac{H(t)}{2(\pi t)^{\frac{1}{2}}} \sum_{n=-\infty}^{\infty} \left\{\exp\left[\frac{(x-\xi-2n\ell)^2}{-4t}\right] - \exp\left[\frac{(x+\xi-2n\ell)^2}{-4t}\right]\right\}, \tag{21}$$

where $H(t)$ is the Heaviside function.

Two versions of the solution to (7)–(9) can be derived from (15), (20), and (21). From (15) and (20) it follows that

$$G_\alpha(x,t|\xi,0) = \frac{2H(t)}{\ell} \sum_{n=1}^{\infty} \sin\frac{n\pi\xi}{\ell}\,\sin\frac{n\pi x}{\ell} \int_0^\infty f_\alpha(z)\exp\left(-\frac{n^2\pi^2}{\ell^2}t^\alpha z\right)\mathrm{d}z, \tag{22}$$

while from (15) and (21) it follows that

$$\begin{aligned} G_\alpha(x,t|\xi,0) = \frac{H(t)}{2\pi^{\frac{1}{2}}t^{\frac{\alpha}{2}}} \sum_{n=-\infty}^{\infty} \int_0^\infty & z^{-\frac{1}{2}} f_\alpha(z) \\ & \times \left\{\exp\left[\frac{(x-\xi-2n\ell)^2}{-4t^\alpha z}\right] - \exp\left[\frac{(x+\xi-2n\ell)^2}{-4t^\alpha z}\right]\right\}\mathrm{d}z. \end{aligned} \tag{23}$$

Two alternate expressions for the kernel $k(t)$, as defined by (14), follow from (22) and (23) either as

$$k(t) = \frac{2}{\ell}\sum_{n=1}^{\infty} \sin^2\frac{n\pi a}{\ell} \int_0^\infty f_\alpha(z)\exp\left(-\frac{n^2\pi^2}{\ell^2}t^\alpha z\right)\mathrm{d}z \tag{24}$$

or as

$$k(t) = \frac{1}{2\pi^{\frac{1}{2}}t^{\frac{\alpha}{2}}} \sum_{n=-\infty}^{\infty} \int_0^\infty z^{-\frac{1}{2}} f_\alpha(z)\left\{\exp\left[-\frac{n^2\ell^2}{t^\alpha z}\right] - \exp\left[-\frac{(a-n\ell)^2}{t^\alpha z}\right]\right\}\mathrm{d}z. \tag{25}$$

In (24)–(25), $H(t)$ has been dropped since it is superfluous to the interpretation of $k(t-s)$ in (12).

Various properties of $k(t)$ can be derived from (24)–(25). It is easily seen that $k(t)$ is a continuously differentiable function for $0<t<\infty$, and

$$k(t)>0, \quad k'(t)<0, \quad 0<t<\infty. \tag{26}$$

The asymptotic behavior of $k(t)$ as $t\to 0$ and as $t\to\infty$ is important in the analysis of (12). As $t\to 0$, the integrals in (25) are all negligible compared to the $n=0$ term. It then follows that

$$k(t)\sim \frac{1}{2\pi^{\frac{1}{2}}t^{\frac{\alpha}{2}}}\int_0^\infty z^{-\frac{1}{2}}f_\alpha(z)\,\mathrm{d}z=\frac{1}{2\,\Gamma\left(1-\frac{\alpha}{2}\right)t^{\frac{\alpha}{2}}} \text{ as } t\to 0. \tag{27}$$

As $t\to\infty$, it is useful to rescale the integration variable in (24) to obtain

$$k(t)=\frac{2}{\ell t^\alpha}\sum_{n=1}^{\infty}\sin^2\frac{n\pi a}{\ell}\int_0^\infty f_\alpha(z/t^\alpha)\exp\left(-\frac{n^2\pi^2}{\ell^2}z\right)\mathrm{d}z, \tag{28}$$

from which follows

$$k(t)\sim\left(\frac{2\ell}{\pi^2}\sum_{n=1}^{\infty}\frac{1}{n^2}\sin^2\frac{n\pi a}{\ell}\right)\frac{1}{\Gamma(1-\alpha)\,t^\alpha}=\frac{a(\ell-a)}{\ell\,\Gamma(1-\alpha)\,t^\alpha} \text{ as } t\to\infty. \tag{29}$$

4. Blow-up solution. A physical interpretation of a blow-up solution to (12), and hence to (2)–(6), is that the subdiffusive medium is unable to conduct enough heat away from the energy source to prevent a thermal runaway. A measure of the subdiffusive medium's ability to conduct heat is given by $I(t)$, which is defined by

$$I(t)\equiv\int_0^t k(s)\,\mathrm{d}s, \quad t\ge 0. \tag{30}$$

A measure of the strength of the energy source is given by κ, which is defined by

$$\kappa\equiv\int_0^\infty\frac{\mathrm{d}u}{g(u)}<\infty, \tag{31}$$

with the assumption that the integral is finite. Another measure of the strength of the energy source is given by Λ, where

$$\Lambda\equiv\sup_{0\le u<\infty}\left[\frac{u}{g(u)}\right]. \tag{32}$$

The properties of $g(u)$ in (6) ensure that

$$\Lambda\le\kappa<\infty. \tag{33}$$

The essential results on existence and blow-up of a solution to (12) are derived in [2], [6], [10]. The basic results on existence, uniqueness, and blow-up are given by the following lemmas.

Lemma 1. *Let $k(t)\ge 0$ be continuous for $0<t<\infty$ and integrable as $t\to 0$. Then (12) has a unique continuous solution for $0\le t<t^*$, where $t^*<\infty$ if t^* is such that*

$$I\left(t^*\right)=\Lambda, \tag{34}$$

while $t^* = \infty$ *if*

$$I(t) < \Lambda, \quad 0 \le t < \infty. \tag{35}$$

Lemma 2. *Let* $k(t) \ge 0$ *be continuous and nonincreasing for* $0 < t < \infty$ *and integrable as* $t \to 0$. *Then whenever there exists a* $t^{**} < \infty$ *such that*

$$I\left(t^{**}\right) = \kappa, \tag{36}$$

it follows that (12) *cannot have a continuous solution for* $t \ge t^{**}$.

The nonexistence of a global solution to (12) is associated with the blow-up behavior

$$u(t) \to \infty \text{ as } t \to \hat{t} < \infty. \tag{37}$$

An implication of Lemmas 1 and 2 is that when (12) has a blow-up solution, the blow-up time $\hat{t}$ can be bounded as

$$0 < t^* \le \hat{t} \le t^{**} < \infty, \tag{38}$$

where t^* and t^{**} are determined by (34) and (36), respectively.

In order to apply Lemmas 1 and 2, it is essential to know the properties of $I(t)$. From the properties of $k(t)$ expressed by (26), (27), and (29), it follows that $I(t)$ is continuous for $0 \le t < \infty$ and

$$I(t) > 0, \quad I'(t) > 0, \quad 0 < t < \infty, \quad I(0) = 0, \tag{39}$$

with the asymptotic behavior

$$I(t) \sim \frac{1}{2\left(1 - \frac{\alpha}{2}\right)\Gamma\left(1 - \frac{\alpha}{2}\right)} t^{1-\frac{\alpha}{2}} \text{ as } t \to 0, \tag{40}$$

and

$$I(t) \sim \frac{a(\ell - a)}{\ell\,\Gamma(2 - \alpha)} t^{1-\alpha} \text{ as } t \to \infty. \tag{41}$$

In view of the behavior of $I(t)$ provided by (39)–(40), it is clear that (34) will be satisfied by some t^*, $0 < t^* < \infty$. Moreover, the asymptotic growth of $I(t)$ provided by (41) ensures that (36) will be satisfied by some $t^{**} < \infty$. Thus we obtain the following theorem.

Theorem 3. *The integral equation* (12) *has a unique, continuous solution for* $0 \le t < t^* < \infty$. *That solution ultimately becomes unbounded as* $t \to \hat{t} < \infty$, *where* $\hat{t} > 0$ *satisfies* (38).

It is important to note that the result of Theorem 3 relies upon the restrictions that $0 < a < \ell$ and $0 < \alpha < 1$. Since (36) must be satisfied by some sufficiently large but finite value of t^{**} for the subdiffusion problem, a blow-up will ultimately occur no matter how close the energy source is located to one of the cold endpoints of the strip. This is contrary to the case of classical diffusion. For $\alpha = 1$, it was demonstrated in [6] that (35) could always be satisfied by making $a(\ell - a)$ sufficiently small, thereby ensuring a unique continuous solution of (12) for all $t \ge 0$. This result is also implied by (41) in the limit $\alpha \to 1$, since $I(t)$ remains bounded as $t \to \infty$.

5. Blow-up growth rate. The growth rate of $u(t)$ near blow-up can be determined from an asymptotic analysis of (12) as $t \to \hat{t}$. To carry out that analysis, it is appropriate to follow the approach developed in [9] for a class of nonlinear Volterra equations that includes (12). As shown in [9], the blow-up growth rate is determined by the asymptotic behavior of $k(t)$ as $t \to 0$ and the asymptotic behavior of $g(u)$ as $u \to \infty$.

The asymptotic behavior of $k(t)$ as $t \to 0$ is given by (27), which indicates its dependence on the anomalous diffusion parameter α. As for the asymptotic behavior of $g(u)$ near blow-up, the results here will be confined to the special cases in which $g(u)$ has either (i) algebraic growth or (ii) exponential growth as $u \to \infty$.

For the asymptotic analysis of (12), it is convenient to introduce the changes of variables

$$\eta = \left(\hat{t} - t\right)^{-1} - \eta_0, \quad \eta_0 = \hat{t}^{-1}, \quad w(\eta) = u(t). \tag{42}$$

This transformation converts (12) to the form

$$w(\eta) = \int_0^\eta k\left\{(\eta - \eta')\left[(\eta' + \eta_0)(\eta + \eta_0)\right]^{-1}\right\}(\eta' + \eta_0)^{-2} g[w(\eta')]\,\mathrm{d}\eta', \quad 0 \le \eta < \infty. \tag{43}$$

In terms of the new variables, the blow-up defined by (37) is expressed as

$$w(\eta) \to \infty \text{ as } \eta \to \infty. \tag{44}$$

Following the methods of [9], let $\eta' = \eta\tau$ so that (5) becomes

$$w(\eta) = \eta\, Q(\eta), \quad 0 \le \eta < \infty, \tag{45}$$

where

$$Q(\eta) = \int_0^1 k\left\{\eta(1-\tau)[(\eta\tau + \eta_0)(\eta + \eta_0)]^{-1}\right\}(\eta\tau + \eta_0)^{-2} g[w(\eta\tau)]\,\mathrm{d}\tau. \tag{46}$$

Thus, the blow-up growth rate of $w(\eta)$ can be determined from an asymptotic analysis of (45) as $\eta \to \infty$. It is shown in [9] that the leading order behavior of $Q(\eta)$ as $\eta \to \infty$ is determined by the leading order behavior of $k(t)$ as $t \to 0$. It then follows from (27) that

$$Q(\eta) \sim \frac{1}{2\,\Gamma\left(1 - \frac{\alpha}{2}\right)} \int_0^\infty (1-\tau)^{-\frac{\alpha}{2}} H(1-\tau)\Psi(\eta\tau)\,\mathrm{d}\tau \text{ as } \eta \to \infty, \tag{47}$$

where $H(\tau)$ is the Heaviside function and

$$\Psi(\eta\tau) = (\eta\tau + \eta_0)^{-2+\frac{\alpha}{2}} g[w(\eta\tau)]. \tag{48}$$

Following the method of [9], the integral in (47) is converted to an integral in the complex z-plane by the application of the Parseval formula for Mellin transforms. This gives

$$Q(\eta) \sim \frac{1}{4\pi i\,\Gamma\left(1 - \frac{\alpha}{2}\right)} \int_{c-i\infty}^{c+i\infty} M\left[(1-\tau)^{-\frac{\alpha}{2}} H(1-\tau); 1-r\right] M[\Psi(\eta\tau); r]\,\mathrm{d}r. \tag{49}$$

The Mellin transforms in (49) are consistent with the definition provided in (16). Further simplification of (49) is achieved by noting that

$$M\left[(1-\tau)^{-\frac{\alpha}{2}}H(1-\tau);1-r\right]=\frac{\Gamma\left(1-\frac{\alpha}{2}\right)\Gamma(1-r)}{\Gamma\left(2-\frac{\alpha}{2}-r\right)} \tag{50}$$

and

$$M[(\Psi(\eta\tau);r]=\eta^{-r}M[\Psi(\tau);r]. \tag{51}$$

This allows the integral equation (45) to be replaced by the asymptotic equation

$$w(\eta)\sim\frac{1}{4\pi i}\int_{c-i\infty}^{c+i\infty}\eta^{1-r}\frac{\Gamma(1-r)}{\Gamma\left(2-\frac{\alpha}{2}-r\right)}M[\Psi(\tau);r]\,\mathrm{d}r\text{ as }\eta\to\infty. \tag{52}$$

To proceed with the asymptotic analysis, it is necessary to introduce an assumption about the growth of $g(u)$. Consider the case in which $g(u)$ has algebraic growth:

$$g(u)\sim u^{m}(\eta),\ m>1\text{ as }\eta\to\infty. \tag{53}$$

To obtain an asymptotic solution of (52) for this case, it is assumed that

$$u(\eta)\sim A\eta^{p},\ p>0\text{ as }\eta\to\infty. \tag{54}$$

The constants A and p are to be determined by satisfying (52) to leading order.

From (48), (53), and (54), it follows that

$$\Psi(\eta)\sim A^{m}\eta^{-2+\frac{\alpha}{2}+mp}\text{ as }\eta\to\infty. \tag{55}$$

By imposing the restriction that $1>2-\frac{\alpha}{2}-mp$, it follows that $M[\Psi;r]$ has a simple pole at $r=2-\frac{\alpha}{2}-mp<1$ and

$$M[\Psi;r]\sim-\frac{A^{m}}{r-\left(2-\frac{\alpha}{2}-mp\right)}\text{ as }r\to2-\frac{\alpha}{2}-mp. \tag{56}$$

Now the leading asymptotic contribution from the integral in (52) comes from the pole implied by (56). As the vertical path of integration is displaced to the right, that pole is encountered before the pole at $r=1$ arising from $\Gamma(1-r)\sim-(r-1)^{-1}$ as $r\to1$. Thus (52) takes the form

$$A\,\eta^{p}\sim\frac{A^{m}\,\Gamma\left(mp+\frac{\alpha}{2}-1\right)}{2\,\Gamma(mp)}\,\eta^{mp+\frac{\alpha}{2}-1}\text{ as }\eta\to\infty. \tag{57}$$

From (57) it is concluded that

$$p=\frac{1-\frac{\alpha}{2}}{m-1},\quad A=\left\{\frac{2\,\Gamma\left[\frac{m\left(1-\frac{\alpha}{2}\right)}{m-1}\right]}{\Gamma\left[\frac{\left(1-\frac{\alpha}{2}\right)}{m-1}\right]}\right\}^{\frac{1}{m-1}}. \tag{58}$$

These results are seen to be consistent with the original constraint that $1>2-\frac{\alpha}{2}-mp=1-\left[\left(1-\frac{\alpha}{2}\right)/(m-1)\right]$. The complement of this constraint leads to a contradiction of any leading order asymptotic match in (52).

In view of (54) and (58), the asymptotic growth of the solution to (12) near blow-up is given by

$$u(t) \sim A(\hat{t}-t)^{-p} \text{ as } t \to \hat{t} \tag{59}$$

for the case in which $g(u)$ grows algebraically as specified by (53).

Next consider the case in which $g(u)$ has exponential growth,

$$g(u) \sim e^{u} \text{ as } \eta \to \infty. \tag{60}$$

To obtain an asymptotic solution of (52) for this case, it is assumed that

$$u(\eta) \sim \log\left(A\eta^{p}\right) \sim p\log\eta \text{ as } \eta \to \infty. \tag{61}$$

The constants A and p are to be determined by satisfying (52) to leading order.

From (48), (60), and (61), it follows that

$$\Psi(\eta) \sim A\eta^{-2+\frac{\alpha}{2}+p} \text{ as } \eta \to \infty. \tag{62}$$

It follows that $M[\Psi; r]$ has a simple pole at $r = 2 - \frac{\alpha}{2} - p$ and

$$M[\Psi; r] \sim -\frac{A}{r-\left(2-\frac{\alpha}{2}-p\right)} \text{ as } r \to 2-\frac{\alpha}{2}-p. \tag{63}$$

In order for the leading asymptotic contribution from the integral in (52) to yield a logarithmic term that will match (61), it is necessary that the simple pole for $M[\Psi; r]$ coalesce with that arising from $\Gamma(1-r) \sim -(r-1)^{-1}$ as $r \to 1$. This requires that

$$p = 1 - \frac{\alpha}{2}. \tag{64}$$

As the vertical path of integration is displaced to the right, the leading order contribution from the double pole reduces (52) to

$$\left(1-\frac{\alpha}{2}\right)\log\eta \sim \frac{A}{2\,\Gamma\left(1-\frac{\alpha}{2}\right)}\log\eta \text{ as } \eta \to \infty. \tag{65}$$

An asymptotic match in (65) is achieved by taking

$$A = 2\left(1-\frac{\alpha}{2}\right)\Gamma\left(1-\frac{\alpha}{2}\right) = 2\,\Gamma\left(2-\frac{\alpha}{2}\right), \tag{66}$$

although this constant plays no role in the leading order behavior. In view of (61) and (64), the leading order asymptotic growth of the solution to (12) near blow-up is given by

$$u(t) \sim \left(1-\frac{\alpha}{2}\right)\log\left(\frac{1}{\hat{t}-t}\right) \text{ as } t \to \hat{t} \tag{67}$$

for the case in which $g(u)$ grows exponentially as specified by (60).

6. Conclusions. For the case of a finite strip of subdiffusive material subjected to a localized high-energy source, as modeled by (2)–(6), a thermal blow-up always occurs. Unlike the case of classical (Gaussian) diffusion, the blow-up cannot be averted by locating the site of the source sufficiently close to a cold boundary. This result is consistent with the physics of subdiffusion in which the flux of energy is retarded.

The asymptotic growth of the temperature near blow-up was derived for nonlinear energy sources that increase with temperature in either an (i) algebraic or (ii) exponential manner. In each case, the explicit dependence of the growth rate on the anomalous diffusion parameter was found. This suggests the possibility of experimentally determining the anomalous diffusion parameter from data collected during an appropriate reaction-diffusion process.

STABILIZING ROLE OF A CURVATURE CORRECTION TO LINE TENSION*

RICCARDO ROSSO[†] AND MARCO VERANI[‡]

Abstract. We study the effects that a curvature correction to the line tension has on the equilibrium and stability of liquid droplets laid upon a rigid substrate. In the simple case of cylindric liquid bridges we prove that even a tiny curvature correction prevents the onset of wildly oscillating perturbations that would make the contact line unstable if a negative line tension were present alone. However, if the curvature correction is not large enough, unstable modes that are not related to the classical Rayleigh instability can persist.

Key words. line tension, wetting, curvature corrections

1. Introduction.

Since Gibbs' fundamental paper [1] on the equilibrium of heterogeneous substances, there has been an increasing interest in modeling both the statics and the dynamics of multiphase bodies. In particular, a faithful description of the interface separating two different phases has been sought along different lines originating from either the continuum point of view or the microscopic point of view that relies upon statistical mechanics. In his original approach, Gibbs modeled the thin interfacial *three*-dimensional region where the physical properties of two adjoining phases rapidly change as a *two*-dimensional surface, called the *dividing* surface, that separates two bulk regions where the phases are *homogeneous*. In general, extensive properties like energy or entropy differ in the real system and in the idealized one. Gibbs ascribed the excess energy or entropy to the dividing surface, adding surface energy and entropy to the bulk terms characterizing the homogeneous phases. The simplest surface energy introduced by Gibbs is proportional to the area of the dividing surface; the constant of proportionality—called the *surface tension*—being positive for stability reasons. Gibbs clearly stated that the surface energy he envisaged was appropriate only for *flat* or weakly curved interfaces, while in the general case other contributions depending on the interface curvature should enter the energy balance. It was Tolman [2] who first analyzed curvature corrections by expanding the surface tension pertaining to a spherical interface of radius R in powers of $1/R$. The length scale at which this correction is relevant is the *Tolman length* δ_T that has been found to be a molecular length both in numerical simulations [3] of Lennard–Jones fluids and in the analytic treatment of [4].

A general format to incorporate curvature corrections in the surface energy was sketched by Gibbs himself and later exploited, for instance, in [5], where the following

expression for the surface tension

$$\gamma = \gamma_0 + \kappa\left(c_0 H + \frac{1}{2}H^2\right) + \hat{\kappa}K \tag{1.1}$$

was proposed, in which γ_0 is the surface tension for a flat interface, c_0 is the *spontaneous curvature* of the interface, and H and K are the *total* and the *Gaussian* curvatures of the interface, respectively, while the constitutive parameters κ and $\hat{\kappa}$ are *bending rigidities.* We record here that the Tolman length can be expressed as [5]

$$\delta_T = \frac{\kappa c_0}{\gamma_0}\,. \tag{1.2}$$

Equation (1.1) is a truncated expansion that also covers the case of nonspherical interfaces. It can also be noticed that the correction (1.1) to the surface tension transforms the surface energy into the Canham–Helfrich Hamiltonian so successfully employed in modeling biological membranes. To obtain more tractable expressions for the curvature corrections, an alternative procedure was recently put forward in [6] by performing a curvature expansion of the lowest order equation in the Born–Green–Yvon hierarchy.

Up to this point we have considered interfaces separating two distinct phases. However, *contact lines* where *three* different phases coexist at equilibrium also occur. A line energy proportional to the length of the contact curve had been introduced by Gibbs himself in [1] to model the excess free energy residing there. The constant of proportionality is called the *line tension.* Since line tension effects on equilibrium are detectable for systems in the submicron regime, its role had been neglected until experimental techniques became available, which allow explorations of these small-sized droplets. As a consequence, the impact of line tension on the equilibrium [7, 8] and the stability [9, 10, 11, 12, 13, 14, 15, 16, 17] of sessile droplets was studied thoroughly during the past decade. In particular, a controversy arose on the admissibility of a negative line tension within a continuum model. At variance with surface tension, Gibbs did not put restrictions on the sign of line tension, but it was proved in [9] that negative values of line tension would make the free-energy functional unbounded from below, and so make any equilibrium configuration unstable. Precisely, if the contact line is corrugated enough, a droplet at equilibrium can follow a path along which its energy is reduced. It was pointed out [12, 17, 18], however, that the characteristic wavelength induced by destabilizing perturbations on the equilibrium droplet could be a molecular length, detectable at a length scale outside the realm of a continuum model. In [18, 19] a criterion of *marginal stability* was proposed to estimate, roughly speaking, the number of stable modes for a given equilibrium configuration and for a given negative line tension. In this way, we could ascertain that negative line tensions as those reported in [20] were compatible with a large set of stable modes, and that the onset of instability was related to perturbations with so short a wavelength that they presumably operate at a scale where also curvature corrections to the line tension should be accounted for [18]. Incorporating these corrections into a continuum model to study their impact on the stability of sessile droplets is the aim of this paper.

In fact Boruvka and Neumann introduced long ago [21] curvature corrections for both the surface and the line energy, by building a formal theory where the free energy contains contributions depending on both the normal and the geodesic curvatures as well as on the geodesic torsion of the contact line, conceived as a curve lying either on the substrate or on the free surface of the liquid droplet. Here we do not insist in making all these differential-geometric properties enter the free-energy functional, as this would lead to a large number of constitutive parameters which, in turn, would make predictions rather difficult, if at all possible. So, we simply imagine that the line tension depends on the curvature σ of the contact line. In this sense our approach departs from that of Boruvka and Neumann, who did not consider corrections depending only on the curvature σ of the contact line since σ has no relation with either the free surface of the droplet or the substrate. However, on computing the first and the second variation of the line free energy, we will see that it is natural to consider deformations of a sessile droplet that map contact lines into contact lines. In this way, the geometry of the substrate is naturally coupled with that of the contact line and both the first and the second variation of the line energy depend on the geometric properties of the contact line, conceived as a curve on the substrate.

It should also be recalled that recent studies [22] have focused on the dependence of line tension upon the radius of curvature of the dividing line. We also mention that a different kind of curvature correction to line tension was studied in [23], where the dependence of line tension on the substrate's curvature was examined within an effective interfacial Hamiltonian approach, in the limit of weakly curved cylindric substrates.

The reader might wonder why we do not treat line and surface tension on the same footing, by assuming a dependence of the latter on curvature too. While in the next section we will give a technical reason for neglecting such corrections, a simple argument can be given, by comparing the typical energy of the term $\kappa c_0 \int_{\mathcal{S}} H \mathrm{d}A$ associated with Tolman's correction with the energy $\beta \int_{\mathcal{C}} \sigma^2 \mathrm{d}\ell$ associated with the curvature correction of line tension. Taking a spherical capsule of radius R, and recalling (1.2), the contribution due to curvature correction of line tension prevails whenever

$$R \ll \sqrt{\frac{\beta}{\gamma_0 \delta_T}}\,.$$

Since δ_T is a molecular length, the set of values of the ratio β/γ_0 that make this inequality obeyed by micron-sized droplets is nonempty.

This paper is organized as follows. In section 2 we introduce the curvature correction to line tension and we discuss the length scales hidden in our model. In section 3 we compute the first variation of the curvature correction arriving at a modified Young equation obeyed along the contact line. Here we also write down the second variation of the curvature-dependent correction, deferring to an appendix the lengthly calculations needed to obtain it. As an application, in section 4 we address the stability of a liquid bridge lying on a flat substrate that was explored without curvature correction in [16] and [17]. We prove that the curvature correction cancels the systematic instability induced by negative line tension for modes with arbitrarily short wavelengths, regardless of the magnitude of the correction. However, different stability scenarios can be singled out, depending on the magnitude of both the bare line tension and its curvature correction. The paper is closed by a section where we summarize our results and we outline some possible applications.

2. Free energy. We consider a sessile droplet $\mathcal{B}$ consisting of incompressible fluid (see Figure 1). Its boundary $\partial\mathcal{B}$ is naturally split as $\partial\mathcal{B} = \mathcal{S}^* \cup \mathcal{S}_*$, where the *adhering* surface $\mathcal{S}_*$ is laid on a rigid substrate. The portion $\mathcal{S}^*$ of $\partial\mathcal{B}$ that is not in

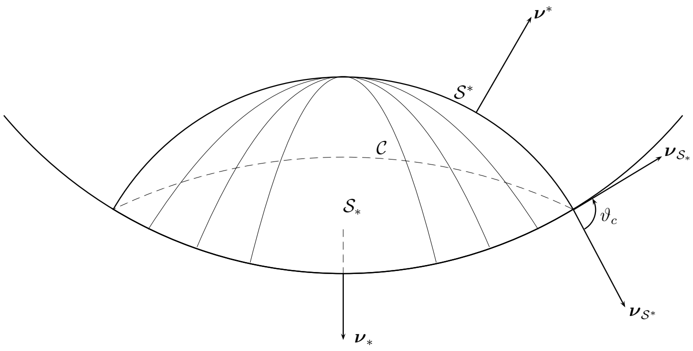

FIG. 1. *A sessile droplet laid on a rigid substrate. The boundary of the droplet is split into a free surface $\mathcal{S}^*$ and an adhering surface $\mathcal{S}_*$: on the former, the droplet is in contact with a vapor phase; on the latter it is in contact with the substrate. These surfaces meet along the contact line $\mathcal{C}$. The outer unit normal vectors $\boldsymbol{\nu}^*$ and $\boldsymbol{\nu}_*$ to $\mathcal{S}^*$ and $\mathcal{S}_*$ are also shown, together with the conormal unit vectors $\boldsymbol{\nu}_{\mathcal{S}^*}$ and $\boldsymbol{\nu}_{\mathcal{S}_*}$ to the contact line, conceived as a curve on $\mathcal{S}^*$ and $\mathcal{S}_*$, respectively. Finally, the contact angle ϑ_c, defined as the angle between $\boldsymbol{\nu}_{\mathcal{S}^*}$ and $\boldsymbol{\nu}_{\mathcal{S}_*}$, is also shown.*

contact with the substrate is referred to as the *free* surface. The curve $\mathcal{C} := \mathcal{S}^* \cap \mathcal{S}_*$ is the *contact* line, where three phases coexist at equilibrium. We shall assume, for simplicity, that $\mathcal{C}$ is connected. The equilibrium shapes of a droplet are the critical points of the free-energy functional

$$\mathcal{F}[\mathcal{B}] := \gamma_0 \int_{\mathcal{S}^*} \mathrm{d}a - w \int_{\mathcal{S}_*} \mathrm{d}a + \tau_0 \int_{\mathcal{C}} \mathrm{d}\ell + \beta \int_{\mathcal{C}} \sigma^2 \mathrm{d}\ell\,, \tag{2.1}$$

subject to the incompressibility constraint

$$\mathrm{vol}(\mathcal{B}) = \int_{\mathcal{B}} \mathrm{d}V = \text{constant.} \tag{2.2}$$

The functional (2.1) contains several contributions. First, $\gamma_0 \int_{\mathcal{S}^*} \mathrm{d}a$ accounts for the surface tension $\gamma_0 := \gamma_{lv} > 0$ associated with the interface between the liquid and the vapor phase. Here a is the area-measure on either $\mathcal{S}^*$ or $\mathcal{S}_*$. The term $-w \int_{\mathcal{S}_*} \mathrm{d}a$ is responsible for the excess energy at the solid-liquid interface. We introduced the *adhesion potential* $w > 0$ that is often expressed as $w = \gamma_{lv} - \gamma_{ls} + \gamma_{sv}$, that is, in terms of the surface tensions γ_{ls} and γ_{sv} associated with the liquid-solid and with the solid-vapor interfaces. We then consider two line energy contributions: the former, $\tau_0 \int_{\mathcal{C}} \mathrm{d}\ell$, models the *bare* line tension τ_0, a constant associated with an ideal straight contact line. The latter is $\beta \int_{\mathcal{C}} \sigma^2 \mathrm{d}\ell$, where σ is the curvature of the contact line $\mathcal{C}$, $\beta > 0$ is a constant parameter, and ℓ is the length-measure along $\mathcal{C}$. This term measures the curvature correction to the bare line tension and a squared dependence upon σ has been chosen to parallel the curvature correction to surface tension contained in (1.1): a linear term $\int_{\mathcal{C}} \sigma \mathrm{d}\ell$ is discarded as it would simply contribute a constant to $\mathcal{F}$, since $\mathcal{C}$ is a closed curve. If, for a moment, we consider the contact curve alone, leaving the droplet out of consideration, we are modelling $\mathcal{C}$ as an Euler's elastic curve. Pursuing this analogy, we could interpret β as a torsional rigidity of the contact line. In studying the relevance of curvature corrections on the stability of liquid droplets, Tolman length plays an ancillary role. In fact, we learned in previous work on this topic [16, 18] that the stability is determined by the natural boundary condition along the contact line that arises in the minimization of the second variation of the free-energy functional. Incorporating a curvature correction to the surface tension would add to this boundary condition terms depending on the curvature of the contact line that are qualitatively equivalent to those considered here. Moreover, this dependence would lead to a nonconstant mean curvature in the free surface profile that would render the normal mode analysis more intricate to follow. Hence, we think that the essential effects of curvature corrections are captured by just taking a curvature-dependent line tension. In the same vein, we did not consider bulk terms in (2.1) so that both gravity and a diluted interaction between the substrate and the droplet (see, e.g., [24]) are disregarded. It is true that, since bulk terms modify the equilibrium profile of the free surface, they could influence the stability analysis. However, the instability we are concerned with is driven by line tension and it seems plausible that bulk terms do not modify the qualitative features of the stability analysis.

We aim at exploring the stabilizing role of a curvature correction to the line tension and so we will assume hereafter $\tau_0 < 0$ since negative line tensions play a systematic, destabilizing effect. As we discussed in several geometries [16, 18, 19], conditionally stable equilibria in the presence of negative line tension are possible provided that $|\tau_0|$ is sufficiently small. In this case, it can be shown that the typical wavelength of destabilizing modes is a molecular length that lies outside the realm of application of the continuum picture adopted here. We expect that a curvature correction penalizing wild oscillations of the contact line could enhance the stability of an equilibrium configuration, even if line tension is negative.

We now digress slightly to introduce the characteristic lengths hidden in our model. A first length scale ℓ_τ can be defined as the typical linear dimension of a droplet for which the surface energy and the line energy associated with bare line tension τ_0 have the same order of magnitude:

$$\gamma_0 \int_{\mathcal{S}^*} \mathrm{d}a \approx |\tau_0| \int_{\mathcal{C}} \mathrm{d}\ell \,.$$

If $\mathcal{S}^*$ is a spherical capsule of radius ℓ_τ so that $\mathcal{C}$ is a circumference of radius $R \propto \ell_\tau$, we obtain $\ell_\tau \approx |\tau_0|/\gamma_0$. Estimates for ℓ_τ can be obtained from line tension measurements like those in [20], and range from 10^{-8} to 10^{-6} m. The ratio

$$\xi := \frac{\tau_0}{\gamma_0} \tag{2.3}$$

will be employed in the application shown in section 4. Finally, we can define a length ℓ_β as the typical size of a droplet for which

$$|\tau_0| \int_{\mathcal{C}} \mathrm{d}\ell \equiv \beta \int_{\mathcal{C}} \sigma^2 \mathrm{d}\ell$$

so that $\ell_\beta \approx \sqrt{\beta/|\tau_0|}$. We are unaware of any measure or estimate of ℓ_β. Although it might be reasonable to assume $\ell_\beta \ll \ell_\tau$, we will not make such a restriction in this paper. In any case, we do not need to apply our model up to the small lengths discussed here to appreciate the effects of line energies. As we will see in section 4, for instance, β could affect the stability of equilibrium configurations both quantitatively and qualitatively, even if it does not modify the equilibrium profile of $\mathcal{C}$ at all.

3. Equilibrium and stability. The first and the second variation of the free-energy functional $\mathcal{F}$ in (2.1) have been computed in [13] for $\beta = 0$. Here we simply arrive at the first variation $\delta\mathcal{F}^*$ of the reduced functional

$$\mathcal{F}^*[\mathcal{C}] := \int_{\mathcal{C}} \sigma^2 \mathrm{d}\ell. \tag{3.1}$$

The equilibrium equation obeyed by the droplet $\mathcal{B}$ is obtained by adding $\beta\delta\mathcal{F}^*$ to the Young equation (equation $(2.44)_2$ of [13]) specialized to the case where both the surface and the bare line tension are constant. It will be useful to write the functional $\mathcal{F}$ as

$$\mathcal{F} = \mathcal{F}_0 + \beta\mathcal{F}^*,$$

where $\mathcal{F}_0$ is the free-energy functional when $\beta = 0$.

Since $\mathcal{F}^*$ is concentrated along the contact line, it cannot affect the equilibrium shape of the free surface $\mathcal{S}^*$ which, in the absence of bulk contributions, is a surface with constant mean curvature.

To compute $\delta\mathcal{F}^*$ we perturb $\mathcal{C}$ by mapping points $p \in \mathcal{C}$ into points

$$p \mapsto p_\varepsilon := p + \varepsilon\boldsymbol{u} + \varepsilon^2\boldsymbol{v}, \tag{3.2}$$

where the regular fields $\boldsymbol{u}$ and $\boldsymbol{v}$ are defined on $\partial\mathcal{B}$. Since we do not repeat the computations for the complete functional $\mathcal{F}$, here we can deal with the restrictions of these fields along $\mathcal{C}$. In general, $\boldsymbol{u}$ and $\boldsymbol{v}$ are subject to the constraints [13]

$$\boldsymbol{u}\cdot\boldsymbol{\nu_*} = 0 \quad \text{and} \quad \boldsymbol{v}\cdot\boldsymbol{\nu_*} = -\frac{1}{2}\boldsymbol{u}\cdot(\nabla_{\mathrm{s}}\boldsymbol{\nu_*})\boldsymbol{u} \quad \text{on } \mathcal{S}_*, \tag{3.3}$$

where $\nabla_{\mathrm{s}}\boldsymbol{\nu_*} := (\nabla\boldsymbol{\nu_*})(\boldsymbol{I} - \boldsymbol{\nu_*}\otimes\boldsymbol{\nu_*})$ is the surface gradient of the outer unit normal $\boldsymbol{\nu_*}$ of $\mathcal{S}_*$. Equations (3.3) guarantee that the perturbed contact line glides on the substrate both at the first-order—$(3.3)_1$—and at the second-order—$(3.3)_2$—in the perturbation parameter ε. The field $\boldsymbol{v}$ does not enter into the equilibrium equations, but it plays a crucial role into the stability of the equilibrium configurations.

Let s be the arc-length of the contact line $\mathcal{C}$, and $\boldsymbol{t}_*$ its unit-tangent vector. We will frequently use the Darboux trihedron associated with $\mathcal{C}$: it is the set $\{\boldsymbol{t}_*, \boldsymbol{\nu}_*, \boldsymbol{\nu}_{\mathcal{S}_*}\}$ formed by three orthogonal unit vectors: $\boldsymbol{t}_*$, $\boldsymbol{\nu}_*$, and $\boldsymbol{\nu}_{\mathcal{S}_*} := \boldsymbol{t}_* \wedge \boldsymbol{\nu}_*$, the *conormal* unit vector of $\mathcal{C}$ on $\mathcal{S}_*$ (see Figure 1). When a point moves along $\mathcal{C}$, the associated Darboux trihedron obeys the following Darboux equations (see p. 241 of [26]):

$$\begin{cases} \dfrac{\mathrm{d}\boldsymbol{t}_*}{\mathrm{d}s} = \kappa_g^*\boldsymbol{\nu}_{\mathcal{S}_*} + \kappa_n^*\boldsymbol{\nu}_*, \\[2ex] \dfrac{\mathrm{d}\boldsymbol{\nu}_{\mathcal{S}_*}}{\mathrm{d}s} = -\kappa_g^*\boldsymbol{t}_* - \tau_g^*\boldsymbol{\nu}_*, \\[2ex] \dfrac{\mathrm{d}\boldsymbol{\nu}_*}{\mathrm{d}s} = -\kappa_n^*\boldsymbol{t}_* + \tau_g^*\boldsymbol{\nu}_{\mathcal{S}_*}, \end{cases} \tag{3.4}$$

where

$$\kappa_n^* := \frac{\mathrm{d}\boldsymbol{t}_*}{\mathrm{d}s}\cdot\boldsymbol{\nu}_*, \quad \kappa_g^* := \frac{\mathrm{d}\boldsymbol{t}_*}{\mathrm{d}s}\cdot\boldsymbol{\nu}_{\mathcal{S}_*}, \quad \text{and} \quad \tau_g^* := \frac{\mathrm{d}\boldsymbol{\nu}_*}{\mathrm{d}s}\cdot\boldsymbol{\nu}_{\mathcal{S}_*} \tag{3.5}$$

are, respectively, the *normal curvature*, the *geodesic curvature*, and the *geodesic torsion* of $\mathcal{C}$, viewed as a curve on the substrate $\mathcal{S}_*$. Hereafter, to avoid clutter, we keep the star * only when we are referring to the unit normal $\boldsymbol{\nu}_*$ of $\mathcal{S}_*$, and when confusion might occur. No ambiguity should arise, since we always imagine $\mathcal{C}$ as a curve on $\mathcal{S}_*$.

By (3.2), we obtain

$$\frac{\mathrm{d}p_\varepsilon}{\mathrm{d}s} = \boldsymbol{t} + \varepsilon \boldsymbol{u}' + \varepsilon^2 \boldsymbol{v}'$$

and so

$$\frac{\mathrm{d}s}{\mathrm{d}s_\varepsilon} = \left|\frac{\mathrm{d}p_\varepsilon}{\mathrm{d}s}\right|^{-1} = [1 + 2\varepsilon \boldsymbol{u}\cdot\boldsymbol{t} + \varepsilon^2(\boldsymbol{u}'\cdot\boldsymbol{u}' + 2\boldsymbol{v}'\cdot\boldsymbol{t})]^{-1/2},$$

where a prime denotes differentiation with respect to s. Since

$$\boldsymbol{t}_\varepsilon = \frac{\mathrm{d}p_\varepsilon}{\mathrm{d}s_\varepsilon} = \frac{\mathrm{d}p_\varepsilon}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}s_\varepsilon},$$

it follows that

$$\boldsymbol{t}_\varepsilon = \boldsymbol{t} + \varepsilon[\boldsymbol{u}' - (\boldsymbol{u}'\cdot\boldsymbol{t})\boldsymbol{t}] + \varepsilon^2\left[\boldsymbol{v}' - \frac{1}{2}(\boldsymbol{u}'\cdot\boldsymbol{u}')\boldsymbol{t} - (\boldsymbol{v}'\cdot\boldsymbol{t})\boldsymbol{t} + \frac{3}{2}(\boldsymbol{u}'\cdot\boldsymbol{t})^2\boldsymbol{t} - (\boldsymbol{u}'\cdot\boldsymbol{t})\boldsymbol{u}'\right] + O(\varepsilon^3).$$

We introduce the vector fields

$$\boldsymbol{a} := \boldsymbol{u}' - (\boldsymbol{u}'\cdot\boldsymbol{t})\boldsymbol{t} \quad \text{and} \quad \boldsymbol{c} := \boldsymbol{v}' - (\boldsymbol{v}'\cdot\boldsymbol{t})\boldsymbol{t} \tag{3.6}$$

that satisfy $\boldsymbol{a}\cdot\boldsymbol{t} = \boldsymbol{c}\cdot\boldsymbol{t} = 0$. By setting $a^2 := \boldsymbol{a}\cdot\boldsymbol{a}$, we have $\boldsymbol{u}'\cdot\boldsymbol{u}' = a^2 + (\boldsymbol{u}'\cdot\boldsymbol{t})^2$ and so we can recast $\boldsymbol{t}_\varepsilon$ as

$$\boldsymbol{t}_\varepsilon = \boldsymbol{t} + \varepsilon\boldsymbol{a} + \varepsilon^2\left[\boldsymbol{c} - \frac{a^2}{2}\boldsymbol{t} - (\boldsymbol{u}'\cdot\boldsymbol{t})\boldsymbol{a}\right] + O(\varepsilon^3). \tag{3.7}$$

For a regular curve, the first Frenet–Serret equation states that

$$\frac{\mathrm{d}\boldsymbol{t}}{\mathrm{d}s} = \sigma\boldsymbol{n}, \tag{3.8}$$

where $\boldsymbol{n}$ is the principal unit normal to the curve. Hence, on $\mathcal{C}_\varepsilon$ we have

$$\sigma_\varepsilon = \left[\frac{\mathrm{d}\boldsymbol{t}_\varepsilon}{\mathrm{d}s_\varepsilon}\cdot\frac{\mathrm{d}\boldsymbol{t}_\varepsilon}{\mathrm{d}s_\varepsilon}\right]^{1/2}$$

which, after rearrangements, yields

$$\sigma_\varepsilon^2\frac{\mathrm{d}s_\varepsilon}{\mathrm{d}s} = \frac{\mathrm{d}\boldsymbol{t}_\varepsilon}{\mathrm{d}s}\cdot\frac{\mathrm{d}\boldsymbol{t}_\varepsilon}{\mathrm{d}s}\frac{\mathrm{d}s}{\mathrm{d}s_\varepsilon}. \tag{3.9}$$

By use of (3.7) and (3.8) and after tedious but straightforward computations we obtain

$$\begin{aligned}\sigma_\varepsilon^2\frac{\mathrm{d}s_\varepsilon}{\mathrm{d}s} &= \sigma^2 + \varepsilon\Big[2\sigma\boldsymbol{a}'\cdot\boldsymbol{n} - \sigma^2(\boldsymbol{u}'\cdot\boldsymbol{t})] + \varepsilon^2[\boldsymbol{a}'\cdot\boldsymbol{a}' + 2\sigma\boldsymbol{n}\cdot\boldsymbol{c}' - \\ &-2\sigma(\boldsymbol{u}'\cdot\boldsymbol{t})'\boldsymbol{n}\cdot\boldsymbol{a} - 4\sigma(\boldsymbol{u}'\cdot\boldsymbol{t})\boldsymbol{n}\cdot\boldsymbol{a}' - \frac{3}{2}a^2\sigma^2 + \sigma^2(\boldsymbol{u}'\cdot\boldsymbol{t})^2 - \sigma^2\boldsymbol{v}'\cdot\boldsymbol{t}\Big].\end{aligned} \tag{3.10}$$

By definition, the first variation $\delta\mathcal{F}^*$ of $\mathcal{F}^*$ is given by

$$\delta\mathcal{F}^* := \left.\frac{\mathrm{d}\mathcal{F}^*[\mathcal{C}_\varepsilon]}{\mathrm{d}\varepsilon}\right|_{\varepsilon=0} = \int_{\mathcal{C}}[2\sigma\boldsymbol{a}'\cdot\boldsymbol{n} - \sigma^2(\boldsymbol{u}'\cdot\boldsymbol{t})]\mathrm{d}s = \int_{\mathcal{C}}[(\sigma^2\boldsymbol{t})'\cdot\boldsymbol{u} - 2(\sigma\boldsymbol{n})'\cdot\boldsymbol{a}]\mathrm{d}s, \tag{3.11}$$

where integration by parts has been used in the last passage. By recalling the definition of $\boldsymbol{a}$ in (3.6) and by performing several integrations by parts to get rid of the derivatives $\boldsymbol{u}'$, we obtain

$$\delta\mathcal{F}^* = \int_{\mathcal{C}}\{(\sigma^2\boldsymbol{t})' + 2(\sigma\boldsymbol{n})'' - 2[((\sigma\boldsymbol{n})'\cdot\boldsymbol{t})\boldsymbol{t}]'\}\cdot\boldsymbol{u}\mathrm{d}s.$$

Since the second Frenet–Serret equation reads

$$\frac{\mathrm{d}\boldsymbol{n}}{\mathrm{d}s} = -(\sigma\boldsymbol{t} + \widetilde{\tau}\boldsymbol{b}),$$

where $\widetilde{\tau}$ and $\boldsymbol{b} := \boldsymbol{t}\wedge\boldsymbol{n}$ are the torsion and the unit binormal vector of $\mathcal{C}$, we finally arrive at

$$\delta\mathcal{F}^* = \int_{\mathcal{C}}\boldsymbol{u}\cdot[3(\sigma^2\boldsymbol{t})' + 2(\sigma\boldsymbol{n})'']\mathrm{d}s.$$

The differential properties of $\mathcal{C}$ as a curve on $\mathcal{S}_*$ enter the scene when $(3.4)_1$ is compared with (3.8) so that $\delta\mathcal{F}^*$ reads as

$$\delta\mathcal{F}^* = \int_{\mathcal{C}}\boldsymbol{u}\cdot[6\sigma\sigma'\boldsymbol{t} + 3\sigma^3\boldsymbol{n} + 2(\kappa_g\boldsymbol{\nu}_{\mathcal{S}_*} + \kappa_n\boldsymbol{\nu}_{\boldsymbol{*}})'']\mathrm{d}s.$$

Since, by $(3.3)_1$,

$$\boldsymbol{u} = u_t\boldsymbol{t} + u_s\boldsymbol{\nu}_{\mathcal{S}_*} \tag{3.12}$$

along $\mathcal{C}$, by applying repeatedly the Darboux equations (3.4), by performing several integrations by parts, and by using the identity

$$\sigma^2 = \kappa_g^2 + \kappa_n^2, \tag{3.13}$$

we obtain

$$\begin{aligned}\delta\mathcal{F}^* = \int_{\mathcal{C}}\{[\kappa_g\sigma^2 + 2(\tau_g'\kappa_n + 2\tau_g\kappa_n' + \kappa_g'' - \kappa_g\tau_g^2)]u_s\\ + 2[\sigma\sigma' - \kappa_g\kappa_g' - \kappa_n\kappa_n']u_t\}\mathrm{d}s = \int_{\mathcal{C}}[\kappa_g\sigma^2 + 2(\tau_g'\kappa_n + 2\tau_g\kappa_n' + \kappa_g'' - \kappa_g\tau_g^2)]u_s\mathrm{d}s,\end{aligned}$$

where (3.13) was differentiated with respect to s to suppress the term multiplying u_t. The first variation $\delta\mathcal{F}^*$ is thus independent of the component u_t of $\boldsymbol{u}$ along the unit-tangent vector $\boldsymbol{t}$ of $\mathcal{C}$, as it should be, since u_t simply reparameterizes $\mathcal{C}$. One could assume a pragmatic attitude by setting $u_t \equiv 0$ from the very beginning. We prefer to keep this term since its disappearance from both the first and the second variation serves as a check of consistency for our computations.

If $\beta\delta\mathcal{F}^*$ is added to the first variation of $\mathcal{F}_0$ as given in (2.44) of [13], the following equilibrium equation should be obeyed along $\mathcal{C}$:

$$\gamma_0\cos\vartheta_c + \gamma_0 - w - \tau_0\kappa_g + \beta\kappa_g\sigma^2 + 2\beta(\tau_g'\kappa_n + 2\tau_g\kappa_n' + \kappa_g'' - \kappa_g\tau_g^2) = 0, \tag{3.14}$$

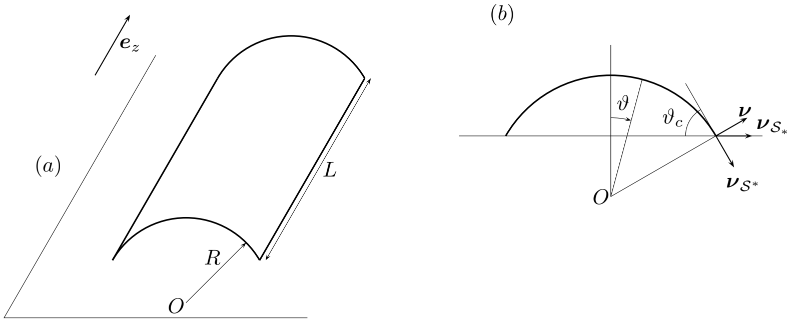

FIG. 2. (a) *Sketch of a liquid bridge, conceived as a straight circular cylinder of radius R, with symmetry axis along $\mathbf{e}_z$. The bridge is laid on a flat substrate. Here L denotes the typical length along which the cylinder is perturbed.* (b) *The cylindric polar coordinates z and ϑ used to parameterize the free surface of the bridge are shown together with the contact angle ϑ_c, which is constant along the contact line. The conormal unit vectors $\boldsymbol{\nu}_{\mathcal{S}^*}$ and $\boldsymbol{\nu}_{\mathcal{S}_*}$ of $\mathcal{C}$ as a curve on either the free or the adhering surface of the bridge have been drawn together with the unit normal vector $\boldsymbol{\nu}$ of the free surface along $\mathcal{C}$.*

where ϑ_c is the *contact angle*, that is, the angle between the conormal unit vectors $\boldsymbol{\nu}_{\mathcal{S}^*}$ and $\boldsymbol{\nu}_{\mathcal{S}_*}$ of $\mathcal{C}$ viewed as a curve on either $\mathcal{S}^*$ or $\mathcal{S}_*$, respectively (see Figure 1). At variance with (2.44) of [13], the subscript $_*$ has been dropped since no confusion can arise here. Although we will not study (3.14) in general, we note that setting $\beta \neq 0$ makes the curvature of the contact line appear at higher powers. This suggests that new branches of solutions might exist in this case.

The format just employed also gives the second variation of $\mathcal{F}^*$. Since computations are much more involved, however, we prefer to move the details into an appendix, while here we simply record the final result:

(3.15)
$$\begin{aligned}\delta^2\mathcal{F}^* \;&= \int_{\mathcal{C}}(u_s'')^2\mathrm{d}s + \int_{\mathcal{C}}(6\tau_g^2 - \kappa_g^2 - \tfrac{3}{2}\sigma^2)(u_s')^2\mathrm{d}s + \int_{\mathcal{C}}\Big\{\tau_g^4 + (\tau_g')^2 + \sigma^2(\kappa_g^2 - \tfrac{3}{2}\tau_g^2)\\ &\quad + (\kappa_n\tau_g)^2 + 2\kappa_n\kappa_g'\tau_g - 4\tau_g^2\kappa_g^2 + 4\kappa_g\tau_g\kappa_n' + [2\tau_g\kappa_g\kappa_n + 3\kappa_g\kappa_g']'\\ &\quad + (H-\kappa_n)(\frac{1}{2}\sigma^2\kappa_n + \kappa_n'' - 2\tau_g\kappa_g' - \kappa_g\tau_g' - \kappa_n\tau_g^2)\Big\}u_s^2\mathrm{d}s,\end{aligned}$$

where H is the total curvature of $\mathcal{S}_*$. By adding $\beta\delta^2\mathcal{F}^*$ to (3.16) of [13] we obtain the complete second variation of the functional $\mathcal{F}$. We remind the reader that u_{s*} in [13] coincides with u_s employed here.

4. Application. We apply the results of the previous sections to study the stability of a liquid bridge, conceived as a straight circular cylinder with radius R laid on a flat substrate (see Figure 2(a)). Since a cylinder is a surface with constant mean curvature, it represents an admissible equilibrium free surface. By (3.14), we see that a straight equilibrium contact line is unaffected by both the line tension and its curvature correction: the contact angle has a constant value ϑ_c along $\mathcal{C}$. We assume that the cylinder's axis lies along the $\boldsymbol{e}_z$ direction and we parameterize the free surface of the cylinder by using the angle $\vartheta \in [-\vartheta_c, \vartheta_c]$ and $z \in \mathbb{R}$ (see Figure 2(b)). Since

$\sigma = \kappa_n = \kappa_g = \tau_g = 0$, by (3.15) we have

$$\beta\delta^2\mathcal{F}^* = \beta\int_{\mathcal{C}}(u_s'')^2\mathrm{d}s,$$

which, when added to the second variation of $\mathcal{F}_0$ (see equation (3) of [16])

$$\delta^2\mathcal{F}_0[\boldsymbol{u}] = \gamma_0\int_{\mathcal{S}^*}\left\{|\nabla_{\mathrm{s}}u_\nu|^2 - \frac{1}{R^2}u_\nu^2\right\}\mathrm{d}a + \int_{\mathcal{C}}\left\{\tau_0(u_s')^2 - \frac{\gamma_0}{R}\cos\vartheta_c\sin\vartheta_c u_s^2\right\}\mathrm{d}s,$$

yields the second variation of the functional $\mathcal{F}$

(4.1)

$$\delta^2\mathcal{F}[\boldsymbol{u}] = \gamma_0\int_{\mathcal{S}^*}\left\{|\nabla_{\mathrm{s}}u_\nu|^2 - \frac{1}{R^2}u_\nu^2\right\}\mathrm{d}a + \int_{\mathcal{C}}\left\{\beta(u_s'')^2 + \tau_0(u_s')^2 - \frac{\gamma_0}{R}\cos\vartheta_c\sin\vartheta_c u_s^2\right\}\mathrm{d}s.$$

We warn the reader that in [16] the line tension was denoted by γ, and the surface tension by τ. In (4.1), $\nabla_{\mathrm{s}}u_\nu = (\boldsymbol{I} - \boldsymbol{\nu}\otimes\boldsymbol{\nu})\nabla u_\nu$ is the surface gradient of the scalar field u_ν, the component of $\boldsymbol{u}$ along the outer unit normal vector of the free surface $\mathcal{S}^*$. Along $\mathcal{C}$, u_ν is related to u_s, the projection of $\boldsymbol{u}$ along $\boldsymbol{\nu}_{\mathcal{S}_*}$, through the equation (see Figure 2(b))

$$u_\nu = \sin\vartheta_c u_s \tag{4.2}$$

to satisfy the gliding constraint $(3.3)_1$. Equation (4.2) can be obtained by expanding $\boldsymbol{u}$ along $\mathcal{C}$ as

$$\boldsymbol{u} = u_t\boldsymbol{t} + u_\nu\boldsymbol{\nu} + \overline{u}_s\boldsymbol{\nu}_{\mathcal{S}^*}, \tag{4.3}$$

which, together with (3.12), yields (4.2) after the scalar product with $\boldsymbol{\nu}$ has been formed and the equation $\boldsymbol{\nu}\cdot\boldsymbol{\nu}_{\mathcal{S}^*} = 0$ has been used too. With the aid of (4.2), $\delta^2\mathcal{F}$ becomes a quadratic functional of u_ν and so, either its minimum is zero, or it is unbounded from below. To deal with finite minima, we minimize $\delta^2\mathcal{F}$ on the set of functions obeying the constraint

$$\int_{\mathcal{S}^*}u_\nu^2\mathrm{d}a = 1. \tag{4.4}$$

If the minimum of $\delta^2\mathcal{F}$ on this set is positive, $\delta^2\mathcal{F}$ is positive definite, and so the equilibrium configuration is locally stable, whereas if the minimum of $\delta^2\mathcal{F}$ on the set (4.4) is negative, the equilibrium configuration is unstable [13]. Since we assume that the liquid bridge is made of incompressible fluid, u_ν should also obey the constraint (2.2). At first-order in ε (2.2) amounts to requiring [13]

$$\int_{\mathcal{S}^*}u_\nu\mathrm{d}a = 0\,. \tag{4.5}$$

The constraint (4.5), together with its second order implementation (equation $(2.29)_2$ of [13]) have been used in [13, 16] to obtain both the first and the second variation of $\mathcal{F}_0$. Until now we did not need them since we dealt only with $\mathcal{F}^*$ which is unaffected by this constraint, as it is concentrated on $\mathcal{C}$. However, to proceed we need to study $\delta^2\mathcal{F}$ and so we have to enforce incompressibility as well. Precisely, the first-order requirement (4.5) is needed since we have to compute only the first variation of $\delta^2\mathcal{F}$. Hence, we minimize the quadratic functional

$$\mathcal{G}[u_\nu] := \delta^2\mathcal{F}[u_\nu] - \frac{\mu}{2}\int_{\mathcal{S}}u_\nu^2\mathrm{d}a + \lambda\int_{\mathcal{S}^*}u_\nu\mathrm{d}a,$$

where $\mu/2$ and λ are Lagrange multipliers corresponding to the constraints (4.4) and (4.5). The scalar field u_ν is perturbed according to

$$u_\nu \mapsto u_{\nu\varepsilon} := u_\nu + \varepsilon\, h,$$

where h is a regular scalar field. Here we focus on the contribution arising from curvature correction. Much in the spirit of Rayleigh instability, we imagine that the cylinder has infinite length and we call L the length of $\mathcal{C}$ over which perturbations are effective. As a consequence, we require

$$u_\nu(\vartheta, 0) = u_\nu(\vartheta, L) = 0, \qquad \forall\vartheta \in [-\vartheta_c, \vartheta_c] \tag{4.6}$$

so that h also has to vanish at $z = 0, L$. By setting $\chi := 1/\sin\vartheta_c$, using (4.2), and integrating by parts twice, we obtain

$$\int_{\mathcal{C}} (u''_{s\varepsilon})^2 \mathrm{d}\ell = \int_0^L (u''_{s\varepsilon})^2 \mathrm{d}z = \chi^2 \int_0^L (u''_\nu)^2 \mathrm{d}z + 2\chi^2 \int_0^L h\, u_\nu^{(\mathrm{iv})} \mathrm{d}z + u''_\nu(L)\, h'(L) - u''_\nu(0)\, h'(0), \tag{4.7}$$

where a prime stands for differentiation along the arc-length z of $\mathcal{C}$, and use of (4.6) has been made. Since in this case $\mathcal{C}$ is an open curve we need to require

$$u''_\nu(\vartheta, 0) = u''_\nu(\vartheta, L) \qquad \forall\vartheta \in [-\vartheta_c, \vartheta_c]\,. \tag{4.8}$$

By adding (4.7) to the terms of the first variation of $\mathcal{G}$ that were computed in equations (7), (8) of [16], we conclude that finding the minimum of $\mathcal{G}$ on the set (4.4) amounts to finding the smallest eigenvalue μ of the following problem:

$$\triangle_{\mathrm{s}} u_\nu + \left(\mu + \frac{1}{R^2}\right) u_\nu + \lambda = 0 \quad \text{on } \mathcal{S}^*, \tag{4.9}$$

$$\sin^2\vartheta_c \nabla_{\mathrm{s}} u_\nu \cdot \boldsymbol{\nu}_{\mathcal{S}} + \frac{\beta}{\gamma_0} u_\nu^{(\mathrm{iv})} - \xi u''_\nu - \frac{1}{R}\sin\vartheta_c \cos\vartheta_c u_\nu = 0 \quad \text{along } \mathcal{C}, \tag{4.10}$$

where $\triangle_{\mathrm{s}}$ is the surface-Laplacian defined on $\mathcal{S}$ and ξ is defined according to (2.3). Hereafter we drop the subscript ν from u_ν. As proved in [13], the smallest value $\mu_{\min}$ of μ that solves the problem (4.9), (4.10) coincides with the minimum value of $\delta^2\mathcal{F}$ on the constraint (4.4) and so we conclude that an equilibrium configuration is locally stable or not according to whether $\mu_{\min}$ is positive or not.

To analyze (4.9), (4.10), we expand u as a sine series

$$u(\vartheta, z) = \sum_{n=1}^{\infty} a_n \sin\left(\frac{2n\pi}{L} z\right) u_n(\vartheta)\,, \tag{4.11}$$

where $u_n(\vartheta)$ are unknown functions of ϑ. In this class, we can satisfy the boundary conditions (4.6) and (4.8) as well as the incompressibility constraint (4.5), so that we can set $\lambda = 0$ in (4.9). The reader might wonder whether the second variation just obtained, as well as that computed in [13, 16] for sessile droplets with *closed* contact line are valid here, where the contact line is open. A glance at the derivations of the second variation in the appendix and in [13, 16] shows that terms at the end-points of the contact line are *always* coupled with the curvature—normal or geodesic—or with the geodesic torsion of $\mathcal{C}$ which vanish identically along a straight contact line and so never contribute.

We split our discussion into two parts, according to whether $u_n(\vartheta)$ is symmetric with respect to the plane $\vartheta = 0$, or if it is skew-symmetric. We call *peristaltic* modes those in the former class, for which

$$\left.\frac{\partial u_n}{\partial \vartheta}\right|_{\vartheta=0} = 0 \quad \forall z \in [0, L] \tag{4.12}$$

holds and we call *varicose* the modes in the latter class, which in turn obey

$$u_n(0) = 0 \quad \forall z \in [0, L]\,. \tag{4.13}$$

4.1. Peristaltic modes. When a mode

$$u(\vartheta, z) = \sin\left(\frac{2n\pi}{L}z\right) u_n(\vartheta) \tag{4.14}$$

in the expansion (4.11) is inserted into (4.9) with $\lambda = 0$ and the multiplier μ is scaled to R^2, $u_n(\vartheta)$ has to satisfy

$$\frac{1}{R^2}\ddot{u}_n - \left(\frac{2n\pi}{L}\right)^2 u_n + \left(\frac{\mu+1}{R^2}\right) u_n = 0,$$

where we exploited the expression

$$\triangle_{\mathrm{s}} f = \frac{1}{R^2}\frac{\partial^2 f}{\partial \vartheta^2} + \frac{\partial^2 f}{\partial z^2}$$

of the surface-Laplacian acting on a scalar function $f = f(\vartheta, z)$ defined on $\mathcal{S}^*$ and where a superimposed dot denotes differentiation with respect to ϑ. The dimensionless ratio

$$\varrho_n := \left(\frac{2\pi n R}{L}\right)^2 \tag{4.15}$$

is a relative measure of the typical size R of a cross-section of the liquid bridge compared to the wavelength $L/2\pi n$ induced on $\mathcal{C}$ by the perturbation (4.14). For given R and L, the larger the ϱ_n, the more corrugated the contact line. By (4.12) and setting

$$\sigma_n := \mu + 1 - \varrho_n, \tag{4.16}$$

the peristaltic modes are given by

$$u_n(\vartheta) = \begin{cases} A\cos(\sqrt{\sigma_n}\vartheta) & \text{if } \sigma_n > 0, \\ A & \text{if } \sigma_n = 0, \\ A\cosh(\sqrt{-\sigma_n}\vartheta) & \text{if } \sigma_n < 0, \end{cases} \tag{4.17}$$

where A is an inessential constant that can be adjusted by imposing the constraint (4.4). If the mode (4.14) is inserted into (4.10), and we use (4.17), we conclude that $u(\vartheta, z)$ is an acceptable eigenfunction if

(4.18)
$$\frac{\beta}{\gamma_0}\left(\frac{2n\pi}{L}\right)^4 u_n(\vartheta_c) + \frac{1}{R}\dot{u}_n(\vartheta_c) + \xi\left(\frac{2n\pi}{L}\right)^2 \varrho_n u_n(\vartheta_c) - \frac{1}{R}u_n(\vartheta_c)\sin\vartheta_c\cos\vartheta_c = 0$$

holds, where we noted that

$$\nabla_{\mathrm{s}} u \cdot \boldsymbol{\nu}_{\mathcal{S}} = \frac{\partial u}{\partial \vartheta} = \dot{u}(\vartheta)\,.$$

By recalling (2.3) we introduce the dimensionless parameters

$$\omega := \frac{\xi}{R} = \frac{\tau_0}{\gamma_0 R} \qquad \text{and} \qquad \eta := \frac{\beta}{\gamma_0 R^3}$$

that compare the length scales $|\tau_0|/\gamma_0$ and $\sqrt[3]{\beta/\gamma_0}$ hidden in the model with R, a characteristic length of the liquid bridge. By setting

$$x_n := \begin{cases} \sqrt{\sigma_n}\vartheta_c & \text{if } \sigma_n > 0, \\ \sqrt{-\sigma_n}\vartheta_c & \text{if } \sigma_n < 0, \end{cases} \tag{4.19}$$

we can recast (4.18) as

$$\eta\varrho_n^2 + \omega\varrho_n = \sin\vartheta_c \left[\cos\vartheta_c + \frac{\sin\vartheta_c}{\vartheta_c} x_n \tan x_n\right] \quad \text{if } \sigma_n > 0, \tag{4.20}$$

$$\eta\varrho_n^2 + \omega\varrho_n = \sin\vartheta_c \left[\cos\vartheta_c - \frac{\sin\vartheta_c}{\vartheta_c} x_n \tanh x_n\right] \quad \text{if } \sigma_n < 0, \tag{4.21}$$

and

$$\eta\varrho_n^2 + \omega\varrho_n = \sin\vartheta_c \cos\vartheta_c \quad \text{if } \sigma_n = 0\,. \tag{4.22}$$

Following [16], modes satisfying (4.20), (4.21), and (4.22) are called *circular*, *hyperbolic*, and *linear* modes, respectively. Compared to the analysis performed in [16], the left-hand side of (4.20)–(4.22) is a second- instead of a first-degree polynomial in ϱ_n: in this sense, the curvature correction acts as a singular perturbation term. As we remarked before, stable modes correspond to positive values of μ, whereas unstable modes correspond to $\mu < 0$. To ascertain the stability of a particular mode, it is then crucial to localize the *marginal modes*, corresponding to $\mu = 0$. By the definitions (4.16) and (4.19) we can write

$$\mu = \begin{cases} \varrho_n - 1 + \left(\frac{x_n}{\vartheta_c}\right)^2 & \text{if } \sigma_n > 0, \\ \varrho_n - 1 - \left(\frac{x_n}{\vartheta_c}\right)^2 & \text{if } \sigma_n < 0, \\ \varrho_n - 1 & \text{if } \sigma_n = 0\,. \end{cases} \tag{4.23}$$

From $(4.23)_1$ we conclude that points in the quadrant $\mathcal{Q} := \{(x_n, \varrho_n) \mid x_n \geq 0,\, \varrho_n \geq 0\}$ of the (x_n, ϱ_n)-plane that lie below the parabola

$$\varrho_n = 1 - \left(\frac{x_n}{\vartheta_c}\right)^2 \tag{4.24}$$

are unstable against circular modes, whereas points in $\mathcal{Q}$ above this parabola are stable against circular modes. Similarly, it follows from $(4.23)_2$ that points of $\mathcal{Q}$ below the parabola

$$\varrho_n = 1 + \left(\frac{x_n}{\vartheta_c}\right)^2 \tag{4.25}$$

are unstable against hyperbolic modes, whereas points above it are stable against hyperbolic modes. Finally, points in $\mathcal{Q}$ that lie below the straight line

$$\varrho_n = 1 \tag{4.26}$$

are unstable against linear modes, while points above this line are stable. We now replace ϱ_n in (4.20)–(4.22) with the appropriate expressions found in (4.24)–(4.26), and we divide (4.20)–(4.22) by ω and define the functions

$$g_c(x_n) := \phi\left\{\eta\left[1-\left(\frac{x_n}{\vartheta_c}\right)^2\right]^2 - \sin\vartheta_c[\cos\vartheta_c + \frac{\sin\vartheta_c}{\vartheta_c}x_n\tan x_n]\right\},$$

$$g_h(x_n) := \phi\left\{\eta\left[1+\left(\frac{x_n}{\vartheta_c}\right)^2\right]^2 - \sin\vartheta_c[\cos\vartheta_c - \frac{\sin\vartheta_c}{\vartheta_c}x_n\tanh x_n]\right\},$$

and

$$g_l(x_n) := \phi[\eta - \sin\vartheta_c\cos\vartheta_c],$$

where, for simplicity, we set $\phi := 1/|\omega|$. Increasing values of ϕ correspond to line tensions with decreasing magnitude. By (4.23), the marginal modes are the smaller pairs (x_n, ϱ_n) in $\mathcal{Q}$ that obey the equation

$$\begin{cases} 1-\left(\frac{x_n}{\vartheta_c}\right)^2 = g_c(x_n) & \text{if } \sigma_n > 0, \\ 1+\left(\frac{x_n}{\vartheta_c}\right)^2 = g_h(x_n) & \text{if } \sigma_n < 0, \\ 1 = g_l(x_n) & \text{if } \sigma_n = 0. \end{cases} \tag{4.27}$$

The pairs (ϕ, ϱ_n) that solve (4.27) and yield the most restrictive stability condition lie on the *marginal* curve which divides the (ϕ, ϱ_n)-plane into a stable and an unstable set. Figure 3 shows the marginal curves for $\vartheta_c = 65^\circ$ and for several values of η: no qualitative differences occur if other values of $\vartheta_c < \pi/2$ are chosen. To follow the discussion the reader is also urged to look at Figure 4, where the semilogarithmic plot of the marginal curves of Figure 3 is shown. The numerical solution of (4.27) (and of (4.28) below) has been performed in a Matlab environment by resorting to a simple bisection algorithm. An educated guess based on an a priori analytical study of the equation has been used to select the intervals in which the solutions are first sought. We stress that, by definition of ϕ and since we consider only negative line tensions, moving along the ϕ-axis from left to right amounts to spanning the interval $(-\infty, 0)$ for the line tension.

Hyperbolic modes are most effective and, depending on the value of η, we can single out three stability diagrams, according to the profile of the marginal curve. If $\eta = 0$ the marginal curve has a turning point and the stability diagram coincides with that obtained in [16]. A straight line $\phi = \phi_0 =$ const. either intersects the marginal curve twice or it does not intersect it at all, according to the value of ϕ_0. When two intersections $(\phi_0, \varrho_n^{(1)})$ and $(\phi_0, \varrho_n^{(2)})$ exist $(\varrho_n^{(1)} < \varrho_n^{(2)})$, Rayleigh instability makes liquid bridges unstable when $\varrho_n < \varrho_n^{(1)}$. When $\varrho_n \in (\varrho_n^{(1)}, \varrho_n^{(2)})$ liquid bridges are locally stable and they become unstable again when $\varrho_n > \varrho_n^{(2)}$. Since ϱ_n is proportional to n, modes with $n = 1$ are more likely to induce Rayleigh instability:

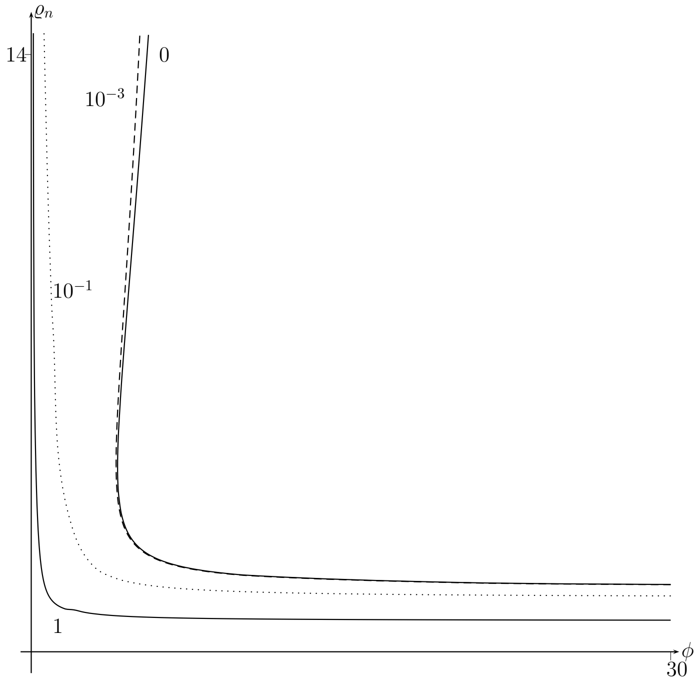

FIG. 3. *Stability diagram for peristaltic modes when* $\vartheta_c = 65°$*. Each curve is labelled by the corresponding value of* η*:* $\eta = 0$*,* $\eta = 10^{-3}$*,* $\eta = 10^{-1}$*, and* $\eta = 1$*). Only hyperbolic modes are effective. For a given value of* η*, the region bounded by the coordinate axes and the marginal curve is unstable, while the remaining portion of the* (ϕ, ϱ_n)*-plane is stable. On increasing* η*, Rayleigh instability persists while the instability induced by negative line tension for large values of* n *is reduced, since the marginal curve diverges only in the limit as* $\phi \to 0$*, that is, when the magnitude of line tension is exceedingly high (see also Figure* 4 *for further details).*

in fact, we leave the unstable set $\varrho_n < \varrho_n^{(1)}$ earlier and earlier on increasing n at fixed L and R. The effects of line tension are more related to the unstable set $\varrho_n > \varrho_n^{(2)}$. In this case, modes with large n are most likely to cause instability. However [16], n cannot be increased arbitrarily in a coherent theory since the typical length scale L/n associated with the corrugations induced on the contact line by the perturbation falls *below* the smallest scale that can be reached within a continuum approach. Hence, only a finite number of values of n can be considered and it is clear from Figure 3 that the smaller the line tension, the more values of n will fall within the region of local stability. When $\phi = \phi_0$ does not intersect the marginal curve, and so the line tension has a large magnitude, *no* stable modes survive, and no stable equilibrium liquid bridge exists.

If $\eta \in (0, \eta_c(\vartheta_c)]$ (curves labelled by $\eta = 10^{-3}$ in Figures 3 and 4) the marginal curve has two turning points. A line $\phi = \phi_0$ crosses the marginal curve three times if $\phi_0 \in [\phi_0^m, \phi_0^M]$ and only once elsewhere. In this latter case only Rayleigh instability occurs: it is slightly reduced by a curvature correction when $\phi_0 > \phi_0^M$ (i.e., when line tension is small), but it becomes more and more restrictive if $\phi_0 < \phi_0^m$ (i.e., when line tension is large), since the marginal curve diverges along the ϱ_n axis. When $\phi_0 \in [\phi_0^m, \phi_0^M]$ the points $(\phi_0, \varrho_n^{(1)})$, $(\phi_0, \varrho_n^{(2)})$, and $(\phi_0, \varrho_n^{(3)})$ $(\varrho_n^{(1)} < \varrho_n^{(2)} < \varrho_n^{(3)})$ on the marginal curve impose the following scenario: a liquid bridge is unstable when either $\varrho_n < \varrho_n^{(1)}$ (Rayleigh instability) or $\varrho \in (\varrho_n^{(2)}, \varrho_n^{(3)})$ and stable when either

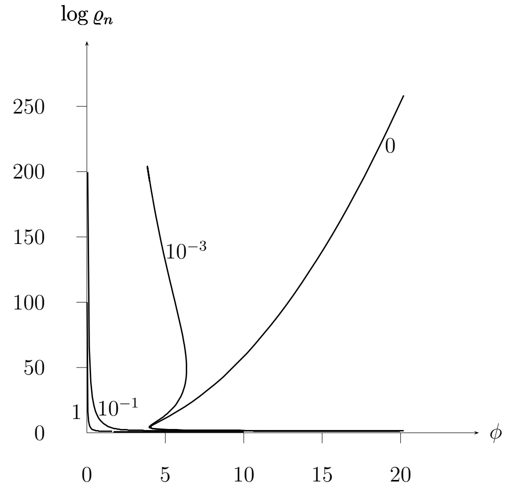

FIG. 4. *Semilogarithmic plot of the stability diagram for peristaltic modes shown in Figure* 3. *The four curves are labelled by the corresponding values of* η. *The region of Rayleigh instability can be perceived only for* $\eta = 10^{-1}$ *and* $\eta = 1$. *Three regimes exist, depending on the value of* η. *When* $\eta = 0$ *a line* $\phi = \phi_0$ *either crosses the marginal curve twice or it does not cross it at all. This mirrors the destabilizing role of negative line tension when there are no curvature corrections. The second regime covers the case* $\eta \in (0, \eta_c]$*: here,* $\eta = 10^{-3}$. *Then, when* ϕ *is either very small or large,* $\phi = \phi_0$ *crosses the marginal curve only once, and only Rayleigh instability occurs. There is an intermediate set of values of* ϕ_0 *for which three intersections exist between* $\phi = \phi_0$ *and the marginal curve. Finally, when* $\eta > \eta_c$*—here* $\eta = 10^{-1}$ *and* $\eta = 1$*—there is always one intersection between a line* $\phi = \phi_0$ *and the marginal curve: only Rayleigh instability occurs.*

$\varrho \in (\varrho_n^{(1)}, \varrho_n^{(2)})$ or $\varrho > \varrho_n^{(3)}$. In particular, the local stability when $\varrho > \varrho_n^{(3)}$ mirrors the stabilizing role of even a tiny curvature correction. The undulating behavior for $\varrho_n \in (\varrho_n^{(1)}, \varrho_n^{(3)})$ disappears when η attains a critical value $\eta_c(\vartheta_c)$ at which $\phi_0^m = \phi_0^M$. For larger values of η (curves labelled by $\eta = 10^{-1}$ and $\eta = 1$ in Figures 3 and 4) the marginal curve has a monotonic profile and it is crossed by a line $\phi = \phi_0$ at a unique point $(\phi_0, \varrho_n^{(1)})$: only liquid bridges such that $\varrho_n < \varrho_n^{(1)}$ are unstable: a Rayleigh instability occurs which becomes stronger and stronger when the magnitude of line tension increases (i.e., when $\phi \to 0^+$). Figure 5 shows the graph of $\eta_c(\vartheta_c)$ against the contact angle ϑ_c. We conclude that small and large values of ϑ_c require lower values of η to wash out the instability at large n typical of a negative line tension. To prove that the marginal curve cannot diverge in the limit $\phi \to \infty$ and when η assumes any *fixed*, nonvanishing value, we simply look at (4.27) *before* division by ω is performed. By applying the method of dominant balance [27], we conclude that $\varrho_n \to \infty$ and $\phi \to \infty$ would yield

$$\eta \varrho_n^2 = -\frac{\sin^2 \vartheta_c}{\vartheta_c} x_n \tanh x_n,$$

which is clearly inconsistent because of the different sign of the two sides. Similarly, we exclude that ϱ_n could diverge at a finite value of ϕ. Hence, given a fixed value of $\eta > 0$ ϱ_n could diverge only in the limit where $\phi \to 0$, that is, if the negative line tension has a large magnitude. This argument corroborates the outcomes of the numerical analysis of (4.27).

Figure 6 shows the stability diagram of a liquid bridge against peristaltic modes, when the contact angle is larger than $\pi/2$: precisely, here $\vartheta_c = 125°$. Both circular

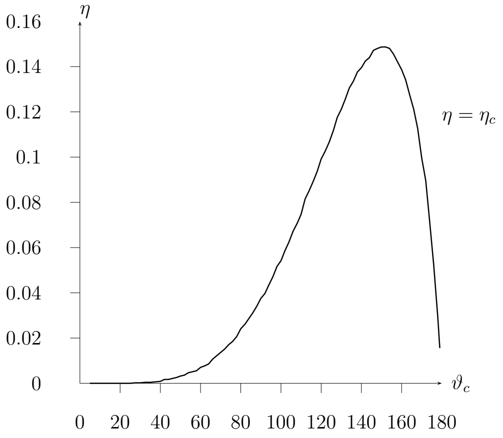

FIG. 5. *The critical value η_c of η is plotted against the contact angle ϑ_c for peristaltic modes. When η exceeds η_c, the marginal curve is a monotonic function of ϕ.*

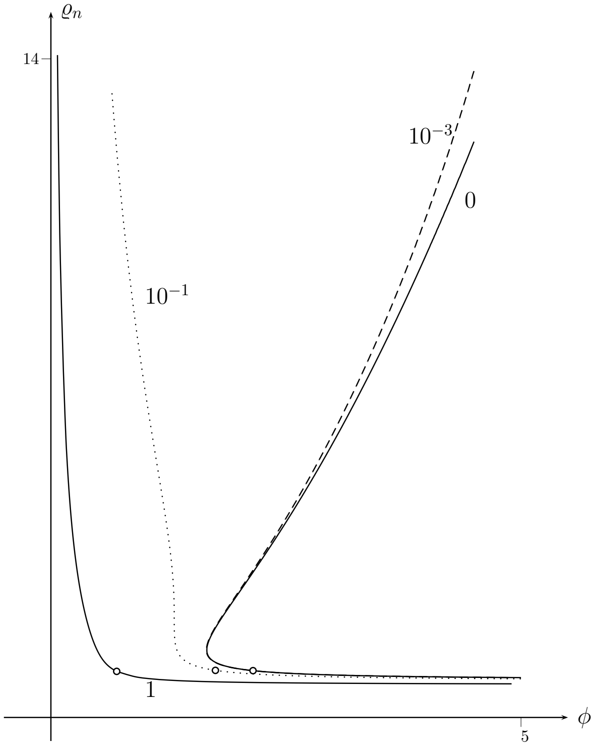

FIG. 6. *Stability diagram against peristaltic modes when $\vartheta_c = 125°$. The marginal curves plotted here are labelled with the corresponding values of η. Both circular and hyperbolic modes are effective in this case. The portion of a given marginal curve that lies above the circle consists of hyperbolic modes, while the portion below the circle consists of circular modes. Linear modes never affect the stability diagram. Apart from the presence of two families of modes, there is no qualitative difference with respect to the case $\vartheta_c < \pi/2$.*

and hyperbolic modes are effective in this case but, apart from this, there is no substantial difference from the case where $\vartheta_c < \pi/2$. Similarly, the semilogarithmic

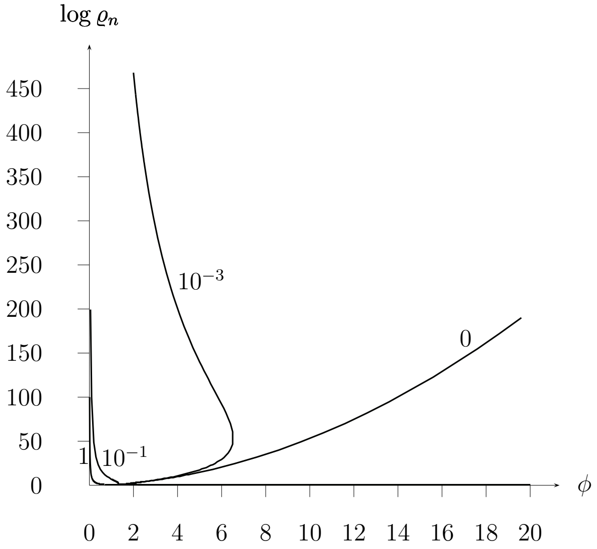

FIG. 7. *Semilogarithmic plot of the stability diagram for peristaltic modes shown in Figure* 6. *Each marginal curve is labelled by the corresponding value of* η.

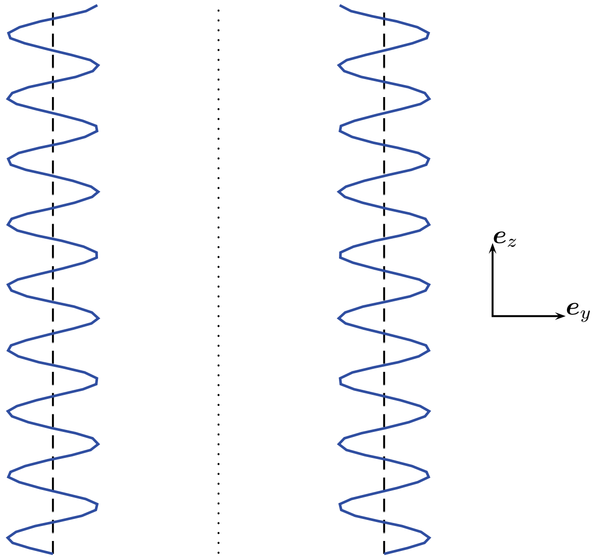

FIG. 8. *The unperturbed (dashed lines) and the perturbed (solid lines) contact lines of a marginally stable peristaltic mode are plotted here when* $\vartheta_c = 65°$, $R = 1$, *and* $L = 10$. *The two sinusoidal profiles are symmetric with respect to the axis of the bridge (dotted line).*

plot in Figure 7 does not have new features as compared with that in Figure 4.

Finally, Figures 8 and 9 show, respectively, the perturbed contact lines and the perturbed cross-section of a liquid bridge induced by a marginal mode. We chose an equilibrium liquid bridge with $\vartheta_c = 65°$, $R = 1$, and $L = 10$. The value of ϱ_n corresponding to the marginal mode is $\varrho_n = 30$ and the amplitude of the marginal mode has been magnified to appreciate its structure.

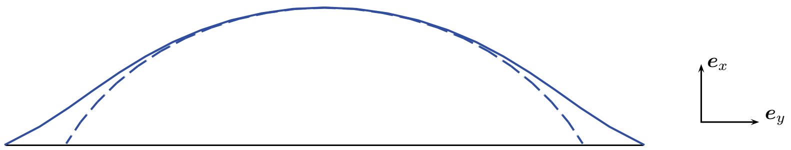

FIG. 9. *Cross-section in a plane $z = z_0$ of an unperturbed liquid bridge (dashed line) and of a marginally stable peristaltic mode (solid line). The geometric parameters are $\vartheta_c = 65°$, $R = 1$, and $L = 10$. For this value of z_0, the perturbed cross-section has larger area than the unperturbed one but, to obey the incompressibility constraint, the opposite is true for other values of z_0.*

To obtain the perturbed profile of the contact lines in Figure 8 we noted that the straight contact lines of the unperturbed bridge satisfy $y = \pm R\sin\vartheta_c$ and so, by (3.2), (4.2), and (4.14) we can write on them

$$p_\varepsilon - O = \pm\sin\vartheta_c \boldsymbol{e}_z \pm \varepsilon\frac{1}{\sin\vartheta_c}u_n(\pm\vartheta_c, z)\boldsymbol{e}_y\,.$$

Since $\nabla_s\boldsymbol{\nu}_* = \boldsymbol{0}$, by $(3.3)_2$ we have $\boldsymbol{v}\cdot\boldsymbol{\nu}_* = 0$ and so $\boldsymbol{v}$ in (3.2) is not needed here. To obtain the cross-section at $z = z_0$ of a perturbed profile we first note that the outer unit normal $\boldsymbol{\nu}$ to the unperturbed free surface is (see Figure 2(b))

$$\boldsymbol{\nu}(\vartheta) = \cos\vartheta\boldsymbol{e}_x + \sin\vartheta\boldsymbol{e}_y\,.$$

We then introduce a vector, still called $\boldsymbol{\nu}_{\mathcal{S}^*}$, which is tangent to the unperturbed cylinder and that coincides with the conormal unit vector $\boldsymbol{\nu}_{\mathcal{S}^*}$ at the contact line $y = R\sin\vartheta_c$, that is,

$$\boldsymbol{\nu}_{\mathcal{S}^*}(\vartheta) = \sin\vartheta\boldsymbol{e}_x - \cos\vartheta\boldsymbol{e}_y\,.$$

By combining (4.2) and (4.3) and recalling that $\boldsymbol{\nu}_{\mathcal{S}^*}\cdot\boldsymbol{\nu}_{\mathcal{S}_*} = \cos\vartheta_c$ along $\mathcal{C}$, we conclude that

$$\overline{u}_s(\vartheta_c, z) = u_s(\vartheta_c, z)\cos\vartheta_c = u_\nu(\vartheta_c, z)\cot\vartheta_c\,.$$

The value of $\overline{u}_s$ in the bulk is irrelevant since it simply amounts to a different parametrization of the cross-section. We are then free to select

$$\overline{u}_s(\vartheta, z) = \frac{\vartheta}{\vartheta_c}\overline{u}_s(\vartheta_c, z) \quad \vartheta\in[0,\vartheta_c]$$

that satisfies the only constraint it has to obey, namely to have a prescribed value along the contact line. Hence, the perturbed marginal profile is given by

$$p_\varepsilon - O = R\boldsymbol{\nu} + \varepsilon u(\vartheta, z_0)\boldsymbol{\nu} + \varepsilon\overline{u}_s(\vartheta, z)\boldsymbol{\nu}_{\mathcal{S}^*}(\vartheta) \quad \vartheta\in[0,\vartheta_c],$$

where $u(\vartheta, z)$ is given by (4.14). The profile of the perturbed cross-section for $\vartheta\in[-\vartheta_c, 0]$ is obtained by symmetry about the $\boldsymbol{e}_x$-axis.

4.2. Varicose modes. In this class, $u_n(0)\equiv 0$ and so, by retracing the same steps as before, we obtain

$$u_n = \begin{cases} A\sin(\sqrt{\sigma_n}\vartheta) & \text{if } \sigma_n > 0,\\ A\sinh(\sqrt{-\sigma_n}\vartheta) & \text{if } \sigma_n < 0,\end{cases}$$

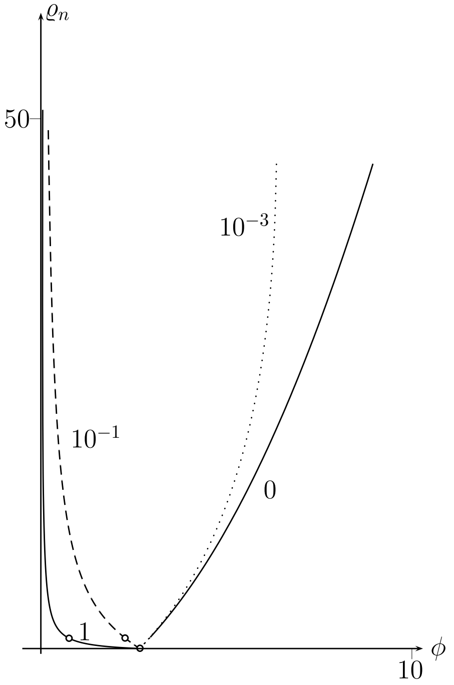

FIG. 10. *Stability diagrams for varicose—both circular and hyperbolic—modes. Here, $\vartheta_c = 65^\circ$ and the marginal curves are labelled by the corresponding values of η. The portion of a given marginal curve that lies above the circle consists of hyperbolic modes, while the portion below the circle consists of circular modes. The marginal curves coalesce along the ϕ axis, since $\varrho_n = 0$ always solves* (4.28)$_1$. *This solution does not cause instability since only positive values of ϱ_n are meaningful. For any given value of η the region bounded by the marginal curve and the ϱ_n-axis is unstable against varicose modes.*

for circular and hyperbolic modes, respectively, while linear modes are absent. From this point, the analysis of section 4.1 can be repeated *verbatim*. After introducing the functions

$$k_c(x_n) := \phi \left\{ \eta \left[1 - \left(\frac{x_n}{\vartheta_c} \right)^2 \right]^2 - \sin\vartheta_c [\cos\vartheta_c - \frac{\sin\vartheta_c}{\vartheta_c} x_n \cot x_n] \right\} ,$$

$$k_h(x_n) := \phi \left\{ \eta \left[1 + \left(\frac{x_n}{\vartheta_c} \right)^2 \right]^2 - \sin\vartheta_c [\cos\vartheta_c - \frac{\sin\vartheta_c}{\vartheta_c} x_n \coth x_n] \right\} ,$$

marginal modes are obtained by determining the smallest pairs in $\mathcal{Q}$ that obey

$$\left\{ \begin{array}{ll} 1 - \left(\frac{x_n}{\vartheta_c}\right)^2 = k_c(x_n) & \text{if } \sigma_n > 0 \\ 1 + \left(\frac{x_n}{\vartheta_c}\right)^2 = k_h(x_n) & \text{if } \sigma_n < 0 \, . \end{array} \right. \tag{4.28}$$

Figure 10 shows the stability diagram of a liquid bridge against varicose modes, when $\vartheta_c = 65^\circ$. The branch of the marginal curve corresponding to Rayleigh instability disappears. When $\phi \to \infty$, varicose modes are stable, as it should be, since they do

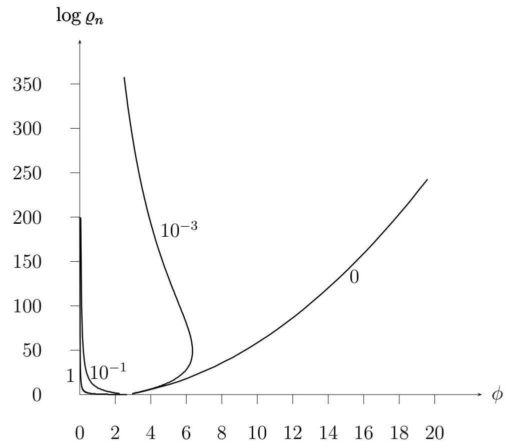

FIG. 11. *Semilogarithmic plot of the stability diagrams for varicose modes shown in Figure* 10.

not affect Rayleigh instability in the absence of line tension. Let us first consider the case $\eta = 0$. When the magnitude of negative line tension is progressively decreased, instability occurs for large values of ϱ_n. To grasp the behavior of the marginal curve in the limit where $\phi \to \infty$, we still employ the method of dominant balance. Since large values of ϱ_n also imply large values of x_n by (4.25), we can look for solutions to $(4.28)_2$ in the form $x_n = b\phi^\alpha$, where b and α are two positive numbers to be determined. When we replace this ansatz into $(4.28)_2$ and discard negligible terms, we arrive at

$$\frac{b}{\vartheta_c}\phi^\alpha \left[\frac{b}{\vartheta_c}\phi^\alpha - \phi \sin^2 \vartheta_c\right] = 0$$

whence $\alpha = 1$ and $b = \vartheta_c \sin^2 \vartheta_c$ follow. Figure 10 points out a difference between peristaltic and varicose modes since for these latter the marginal curves emanate from a precise point $\phi(\vartheta_c)$ of the ϕ axis: $\phi(65^\circ) = 2.66$. As for peristaltic modes, at any fixed, nonvanishing value for η, the marginal curve diverges along the ϱ_n axis (see the semilogarithmic plot shown in Figure 11), confirming the stabilizing role of curvature corrections. The same regimes discussed for peristaltic modes exist here, apart from the absence of Rayleigh instability when $\phi > \phi(\vartheta_c)$.

Figure 12 shows the stability diagram when $\vartheta_c = 125^\circ$. As already discussed for peristaltic modes, there are no essential differences with respect to the case $\vartheta_c \leq \pi/2$. Similar remarks hold for the semilogarithmic counterpart shown in Figure 13. Finally, Figure 14 shows the critical value of $\eta_c(\vartheta_c)$ at which the marginal curve follows a monotonic profile: it has the same qualitative behavior as that computed for peristaltic modes.

5. Conclusions. We determined the effects of a curvature correction to line tension on both the equilibrium and the stability of sessile droplets through a general variational analysis. While the effects on the equilibrium could even be absent, those on stability are relevant in any case. As a first consequence, we proved for liquid bridges that the curvature correction makes wildly oscillating perturbations unrewarding, and so the systematic instability against all modes with short wavelength induced by negative line tensions is removed, regardless of the magnitude of the correction. This magnitude, however, plays a crucial role in determining whether

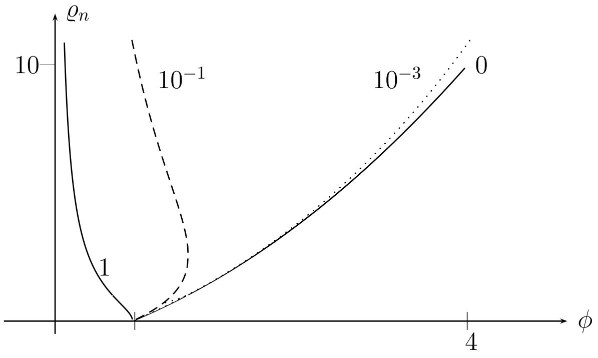

FIG. 12. *Stability diagram against varicose modes when $\vartheta_c = 125^\circ$. The marginal curves plotted here are labelled by the corresponding values of η. Both circular and hyperbolic modes are effective, but the transition between them is too close to the ϕ axis to be shown here. Linear modes never affect the stability diagram. Also in this case, the diagram is similar to that for the case $\vartheta_c < \pi/2$.*

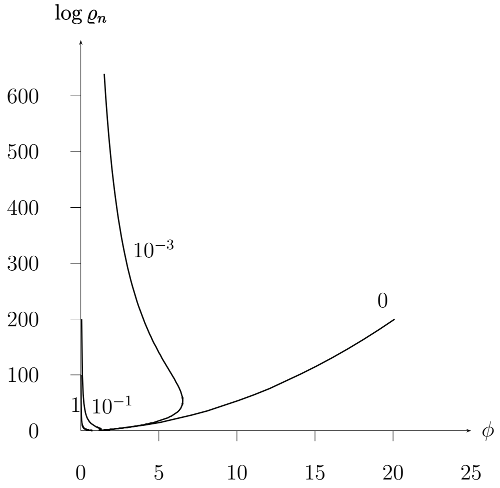

FIG. 13. *Semilogarithmic plot of the stability diagrams for varicose modes shown in Figure* 12. *The marginal curves are labelled by the corresponding values of η.*

only Rayleigh instability occurs or not. As a general result, Rayleigh instability is the only destabilizing mechanism whenever the curvature correction is large enough. The analysis employed here for liquid bridges could serve to explore the stabilizing effects of curvature corrections on droplets with a closed geometry like spherical caps. We expect that the stabilizing mechanism discussed here will work also in that context, although the computations will be more cumbersome.

Appendix. Second variation of $\mathcal{F}^*$. We show in detail how to arrive at the expression (3.15) for the second variation $\delta^2\mathcal{F}^*$ of $\mathcal{F}^*$, obtained by integrating along $\mathcal{C}$ the terms in (3.10) that are quadratic in ε. We start with

$$\mathcal{I}_1 := \int_{\mathcal{C}} [2\sigma \boldsymbol{c}' \cdot \boldsymbol{n} - \sigma' \boldsymbol{v} \cdot \boldsymbol{t}] \mathrm{d}s,$$

which contains contributions related to the field $\boldsymbol{v}$ defined in (3.2). The integral $\mathcal{I}_1$ has the same structure as the first variation of $\mathcal{F}^*$ given in (3.11), with $\boldsymbol{u}$ and $\boldsymbol{a}$ replaced

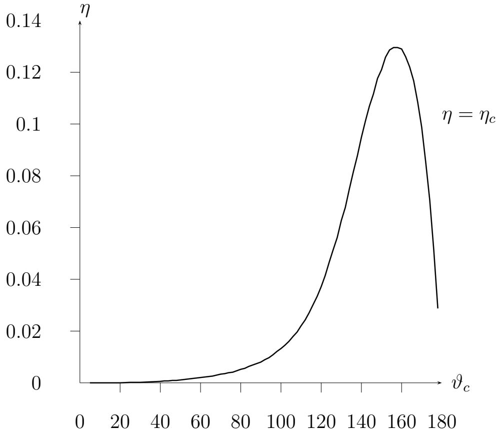

FIG. 14. *The critical value η_c of η is plotted against the contact angle ϑ_c for varicose modes. When η exceeds η_c, the marginal curve is a monotonic function of ϕ.*

by $\boldsymbol{v}$ and $\boldsymbol{c}$. The crucial difference in this formal change is that, at variance with $\boldsymbol{u}$, the field $\boldsymbol{v}$ has also a nontrivial component along the unit normal vector $\boldsymbol{\nu}_*$ of $\mathcal{S}_*$. By retracing the same steps as in section 3, we can check that the component $\boldsymbol{v}\cdot\boldsymbol{t}$ does not contribute and the component along $\boldsymbol{\nu}_{\mathcal{S}_*}$ vanishes by virtue of the equilibrium equation (3.14). Hence, we are left with the component $\boldsymbol{v}\cdot\boldsymbol{\nu}_*$ which, by use of $(3.3)_2$, can be recast as

$$\mathcal{I}_1 = -\int_{\mathcal{C}} \frac{1}{2}\boldsymbol{u}\cdot(\nabla_s\boldsymbol{\nu}_*)\boldsymbol{u}[\sigma^2\kappa_n + 2\kappa_n'' - 4\tau_g\kappa_g' - 2\kappa_g\tau_g' - 2\kappa_n\tau_g^2]\mathrm{d}s\,,$$

where perusal of Darboux equations (3.4) has been made. By recalling that [25]

$$\nabla_s\boldsymbol{\nu}_* = -\kappa_n\boldsymbol{t}\otimes\boldsymbol{t} - \kappa_{n\perp}\boldsymbol{\nu}_{\mathcal{S}}\otimes\boldsymbol{\nu}_{\mathcal{S}} + \tau_g(\boldsymbol{\nu}_{\mathcal{S}}\otimes\boldsymbol{t} + \boldsymbol{t}\otimes\boldsymbol{\nu}_{\mathcal{S}})\,, \tag{A.1}$$

where $\kappa_{n\perp} := H - \kappa_n$ is expressed in terms of the total curvature H of $\mathcal{S}_*$, we finally arrive at

$$\mathcal{I}_1 = \int_{\mathcal{C}} \frac{1}{2}[\kappa_n u_t^2 - 2\tau_g u_t u_s + (H-\kappa_n)u_s^2]\{\sigma^2\kappa_n + 2\kappa_n'' - 4\tau_g\kappa_g' - 2\kappa_g\tau_g' - 2\kappa_n\tau_g^2\}\mathrm{d}s. \tag{A.2}$$

It is also expedient to expand $\boldsymbol{u}'$ and $\boldsymbol{a}$ along the Darboux trihedron of $\mathcal{C}$, by resorting to (3.4), $(3.6)_1$, and (3.13):

$$\boldsymbol{u}' = (u_t' - \kappa_g u_s)\boldsymbol{t} + (u_s' + \kappa_g u_t)\boldsymbol{\nu}_{\mathcal{S}} + (\kappa_n u_t - \tau_g u_s)\boldsymbol{\nu} \tag{A.3}$$

and

$$\boldsymbol{a} = (u_s' + \kappa_g u_t)\boldsymbol{\nu}_{\mathcal{S}} + (\kappa_n u_t - \tau_g u_s)\boldsymbol{\nu}, \tag{A.4}$$

from which

$$a^2 = u_t^2\sigma^2 + u_s'^2 + \tau_g^2 u_s^2 + 2\kappa_g u_t u_s' - 2\tau_g\kappa_n u_t u_s$$

easily follows. By differentiating $\boldsymbol{a}$ with respect to s we also obtain, by (3.4),

$$\begin{aligned}\boldsymbol{a}' &= [\kappa_n\tau_g u_s - \kappa_g u_s' - \sigma^2 u_t]\boldsymbol{t} + [(u_s' + \kappa_g u_t)' + \tau_g(\kappa_n u_t - \tau_g u_s)]\boldsymbol{\nu}_{\mathcal{S}}\\ &\quad + [(\kappa_n u_t - \tau_g u_s)' - \tau_g(u_s' + \kappa_g u_t)]\boldsymbol{\nu},\end{aligned} \tag{A.5}$$

whence, after straightforward computations also involving differentiation of the identity (3.13), we arrive at

$$\text{(A.6)}\quad \begin{aligned}\mathcal{I}_2 &:= \int_{\mathcal{C}} \boldsymbol{a}' \cdot \boldsymbol{a}' \mathrm{d}s = \int_{\mathcal{C}} [\sigma^4 + (\kappa_g')^2 + (\kappa_n')^2 + \sigma^2\tau_g^2 + 2\tau_g(\kappa_n\kappa_g' - \kappa_g\kappa_n')]u_t^2 \\ &+ \int_{\mathcal{C}} (\sigma^2)' u_t u_t' + \int_{\mathcal{C}} \sigma^2 (u_t')^2 \mathrm{d}s + \int_{\mathcal{C}} 2[\kappa_g\sigma^2 - 2\tau_g(\kappa_n' - \tau_g\kappa_g)]u_t u_s' \\ &- \int_{\mathcal{C}} 2[\kappa_n\tau_g\sigma^2 + \tau_g^2(\kappa_g' + \kappa_n\tau_g) + \tau_g'(\kappa_n' - \tau_g\kappa_g)]u_t u_s - \int_{\mathcal{C}} 2[\tau_g(\kappa_n\kappa_g + 2\tau_g')]u_s u_s' \\ &+ \int_{\mathcal{C}} (\kappa_g^2 + 4\tau_g^2)(u_s')^2 + \int_{\mathcal{C}} [(\kappa_n\tau_g)^2 + \tau_g^4 + (\tau_g')^2]u_s^2 + \int_{\mathcal{C}} (u_s'')^2 + \int_{\mathcal{C}} 2\kappa_g u_t' u_s'' \\ &- \int_{\mathcal{C}} 2[\kappa_g\tau_g^2 + \tau_g'\kappa_n]u_s u_t' + \int_{\mathcal{C}} 2[\kappa_g' + \kappa_n\tau_g]u_t u_s'' - \int_{\mathcal{C}} 2\tau_g^2 u_s u_s'' - \int_{\mathcal{C}} 4\tau_g\kappa_n u_s' u_t' \,.\end{aligned}$$

To proceed, we consider the terms

$$\mathcal{I}_3 := \int_{\mathcal{C}} \sigma^2[(\boldsymbol{u}' \cdot \boldsymbol{t})^2 - \frac{3}{2}a^2]\mathrm{d}s,$$

which, by use of (A.3)–(A.4), can be recast as

$$\text{(A.7)}\quad \begin{aligned}\mathcal{I}_3 &= \int_{\mathcal{C}} \sigma^2 (u_t')^2 + \int_{\mathcal{C}} \sigma^2 \left(\kappa_g^2 - \frac{3}{2}\tau_g^2\right) u_s^2 - \int_{\mathcal{C}} 2\kappa_g\sigma^2 u_s u_t' - \int_{\mathcal{C}} \frac{3}{2}\sigma^4 u_t^2 - \int_{\mathcal{C}} \frac{3}{2}\sigma^2 (u_s')^2 - \\ &- \int_{\mathcal{C}} 3\sigma^2\kappa_g u_t u_s' + \int_{\mathcal{C}} 3\kappa_n\tau_g\sigma^2 u_t u_s \,.\end{aligned}$$

Finally, by integration by parts we change

$$\mathcal{I}_4 := -2\int_{\mathcal{C}} [(\boldsymbol{u}' \cdot \boldsymbol{t})'\sigma\boldsymbol{n} \cdot \boldsymbol{a} + 2(\boldsymbol{u}' \cdot \boldsymbol{t})\boldsymbol{a}' \cdot \sigma\boldsymbol{n}]\mathrm{d}s$$

into

$$\mathcal{I}_4 = 2\int_{\mathcal{C}} \boldsymbol{a} \cdot \sigma\boldsymbol{n}(\boldsymbol{u}' \cdot \boldsymbol{t})'\mathrm{d}s + 4\int_{\mathcal{C}} \boldsymbol{a} \cdot (\sigma\boldsymbol{n})'(\boldsymbol{u}' \cdot \boldsymbol{t})\mathrm{d}s,$$

which, also by use of $(3.4)_1$, (3.13), and (A.3), yields

$$\mathcal{I}_4 = \int_{\mathcal{C}} 2\sigma^2 u_t u_t'' + \int_{\mathcal{C}} 2\kappa_g u_s' u_t'' - \int_{\mathcal{C}} 2\kappa_n\tau_g u_s u_t'' + \int_{\mathcal{C}} 4[(\kappa_g' + \kappa_n\tau_g)]u_t' u_s'$$

$$\text{(A.8)}\quad \begin{aligned}&-2\int_{\mathcal{C}} \kappa_g^2 (u_s')^2 - \int_{\mathcal{C}} 2[\kappa_g[\kappa_n\tau_g + 3\kappa_g']]u_s u_s' + \int_{\mathcal{C}} 2[\kappa_g'\kappa_n\tau_g - 2\kappa_g(\kappa_g\tau_g^2 - \tau_g\kappa_n')]u_s^2 \\ &- \int_{\mathcal{C}} 2(\sigma^2\kappa_g)' u_s u_t + \int_{\mathcal{C}} 2(\sigma^2)' u_t u_t' + \int_{\mathcal{C}} 4(\kappa_g\tau_g - \kappa_n')\tau_g u_t' u_s - 2\int_{\mathcal{C}} \kappa_g\sigma^2 u_t u_s' \,.\end{aligned}$$

As already mentioned for $\delta\mathcal{F}^*$, the component u_t cannot appear in the final expression of $\delta^2\mathcal{F}^*$. To prove this, we collect terms in $\delta^2\mathcal{F}^*$ with the same dependence on u_t and its derivatives with respect to s, and integrate repeatedly by parts.

- Terms containing $u_t'^2$ and $u_t u_t''$ in $\mathcal{I}_3$ and $\mathcal{I}_4$ are

$$2\int_{\mathcal{C}} \sigma^2(u_t'^2 + u_t u_t'')\mathrm{d}s = -2\int_{\mathcal{C}}(\sigma^2)' u_t u_t' \mathrm{d}s, \tag{A.9}$$

which are combined with the term $3\int_{\mathcal{C}}\sigma^2 u_t u_t'\mathrm{d}s$ found in $\mathcal{I}_2$ and $\mathcal{I}_4$ to obtain, by (3.13),

$$\int_{\mathcal{C}}(\sigma^2)' u_t u_t'\mathrm{d}s = -\frac{1}{2}\int_{\mathcal{C}}(\sigma^2)'' u_t^2\mathrm{d}s = -\int_{\mathcal{C}}(\kappa_g'^2 + \kappa_n'^2 + \kappa_g\kappa_g'' + \kappa_n\kappa_n'')u_t^2\mathrm{d}s\,. \tag{A.10}$$

- Further terms containing u_t^2 in $\mathcal{I}_1$–$\mathcal{I}_3$ are collected together to yield, also by use of (3.13),

$$\int_{\mathcal{C}}\left[-\frac{\sigma^4}{2} + (\kappa_g')^2 + (\kappa_n')^2 + \tau_g^2\kappa_g^2 - 2\tau_g\kappa_g\kappa_n' + \frac{\sigma^2}{2}\kappa_n^2 + \kappa_n\kappa_n'' - \kappa_g\kappa_n\tau_g'\right]u_t^2\mathrm{d}s,$$

which, when added to (A.10), gives

$$\int_{\mathcal{C}}\left[-\frac{\sigma^4}{2} + \frac{\kappa_g}{2}(2\kappa_g\tau_g^2 - 4\tau_g\kappa_n' - 2\kappa_g'' - 2\kappa_n\tau_g') + \frac{\sigma^2}{2}\kappa_n^2\right]u_t^2\mathrm{d}s\,. \tag{A.11}$$

Now, terms in u_t should simplify separately for each integral in $\mathcal{F}$. Hence, we can use the reduced equilibrium equation

$$\kappa_g\sigma^2 + 2(\tau_g'\kappa_n + 2\tau_g\kappa_n' + \kappa_g'' - \kappa_g\tau_g^2) = 0, \tag{A.12}$$

obtained by setting $\delta\mathcal{F}^* = 0$ together with (3.13) to show that the integral (A.11) vanishes identically on any equilibrium configuration.

We now prove that mixed terms containing products of u_t and u_s or of their derivatives do not enter into $\delta^2\mathcal{F}^*$.

- The terms in $\mathcal{I}_2$ containing the product $u_t u_s''$ can be transformed via integration by parts as

$$2\int_{\mathcal{C}}(\kappa_g' + \kappa_n\tau_g)u_t u_s''\mathrm{d}s = -2\int_{\mathcal{C}}(\kappa_g' + \kappa_n\tau_g)u_t' u_s'\mathrm{d}s - 2\int_{\mathcal{C}} u_t u_s'(\kappa_g'' + \kappa_n'\tau_g + \kappa_n\tau_g')\mathrm{d}s,$$

to which we add the term in $\mathcal{I}_4$

$$2\int_{\mathcal{C}}\kappa_g u_t'' u_s'\mathrm{d}s = -2\int_{\mathcal{C}}(\kappa_g u_s'' u_t' + \kappa_g' u_s' u_t')\mathrm{d}s,$$

containing $u_t'' u_s'$ and then add the term in $\mathcal{I}_2$ that contains $u_s'' u_t'$: as a result, we are left with

$$-2\int_{\mathcal{C}}(2\kappa_g' + \kappa_n\tau_g)u_t' u_s'\mathrm{d}s - 2\int_{\mathcal{C}} u_t u_s'(\kappa_g'' + \kappa_n'\tau_g + \kappa_n\tau_g')\mathrm{d}s\,. \tag{A.13}$$

Since the remaining terms in $\mathcal{I}_2$ and $\mathcal{I}_4$ containing $u_t' u_s'$ reduce to

$$4\int_{\mathcal{C}}\kappa_g' u_t' u_s'\mathrm{d}s,$$

we finally arrive at

$$-2\int_{\mathcal{C}}\{[\kappa_g''+(\tau_g\kappa_n)']u_tu_s'+\kappa_n\tau_g u_t'u_s'\}\mathrm{d}s\,. \tag{A.14}$$

- The term

$$-2\int_{\mathcal{C}}\kappa_n\tau_g u_s u_t''\mathrm{d}s=2\int_{\mathcal{C}}[\kappa_n\tau_g u_t'u_s'+(\kappa_n\tau_g)'u_su_t']\mathrm{d}s$$

of $\mathcal{I}_4$ can be added to the integral (A.14) to arrive at

$$2\int_{\mathcal{C}}\{u_su_t'(\kappa_n\tau_g)'-[\kappa_g''+(\kappa_n\tau_g)']u_tu_s'\}\mathrm{d}s, \tag{A.15}$$

or, after integration by parts, at

$$-2\int_{\mathcal{C}}\{u_su_t(\kappa_n\tau_g)''+u_tu_s'[\kappa_g''+2(\kappa_n\tau_g)']\}\mathrm{d}s\,. \tag{A.16}$$

- We then consider the following terms in $\mathcal{I}_2$–$\mathcal{I}_4$ that contain $u_t'u_s$:

$$2\int_{\mathcal{C}}u_t'u_s[\kappa_g\tau_g^2-\tau_g'\kappa_n-\kappa_g\sigma^2-2\tau_g\kappa_n']\mathrm{d}s.$$

We integrate them by parts, obtaining

$$2\int_{\mathcal{C}}\{u_s'u_t[-\kappa_g\tau_g^2+\tau_g'\kappa_n+\kappa_g\sigma^2+2\tau_g\kappa_n']+u_tu_s[\tau_g'\kappa_n+\kappa_g\sigma^2+2\tau_g\kappa_n'-\kappa_g\tau_g^2]'\}\mathrm{d}s\,. \tag{A.17}$$

- Further integrals containing $u_s'u_t$ in $\mathcal{I}_2$–$\mathcal{I}_4$ are collected to give

$$-\int_{\mathcal{C}}[3\kappa_g\sigma^2+4\tau_g(\kappa_n'-\tau_g\kappa_g)]u_s'u_t\mathrm{d}s, \tag{A.18}$$

which, after algebraic manipulations and the use of (A.12), when added to (A.16) and (A.17) yield

$$2\int_{\mathcal{C}}u_su_t\{[\tau_g'\kappa_n+\kappa_g\sigma^2+2\tau_g\kappa_n'-\kappa_g\tau_g^2]'-(\kappa_n\tau_g)''\}\mathrm{d}s.$$

This simplifies to zero when it is added to the remaining terms in $\mathcal{I}_1$–$\mathcal{I}_4$ containing u_su_t, namely,

$$2\int_{\mathcal{C}}u_su_t[\tau_g^2\kappa_g'+2\tau_g\tau_g'\kappa_g-\tau_g'\kappa_n'-(\kappa_g\sigma^2)'-\kappa_n''\tau_g]\mathrm{d}s,$$

as can be easily checked.

Hence, we proved that only terms containing u_s'', u_s', and u_s appear in the second variation of $\mathcal{F}^*$. Precisely, we can recast $\delta^2\mathcal{F}^*$ into a diagonal form in which only $(u_s'')^2$, $(u_s')^2$, and $(u_s)^2$ appear.

- In $\mathcal{I}_2$ we consider the terms

$$\int_{\mathcal{C}}[(u_s'')^2-2\tau_g^2u_su_s'']\mathrm{d}s=\int_{\mathcal{C}}\{(u_s'')^2+2\tau_g^2(u_s')^2+4\tau_g\tau_g'u_su_s'\}\mathrm{d}s,$$

which, when added to the remaining terms in $\mathcal{I}_2$–$\mathcal{I}_4$ containing $(u_s')^2$, yield

$$\int_{\mathcal{C}}\left\{(u_s'')^2+\left(6\tau_g^2-\kappa_g^2-\frac{3}{2}\sigma^2\right)(u_s')^2+4\tau_g\tau_g' u_s u_s'\right\}\mathrm{d}s\,. \tag{A.19}$$

- We now add to (A.19) the terms in $\mathcal{I}_2$ and $\mathcal{I}_4$ with $u_s u_s'$ arriving at

$$\int_{\mathcal{C}}\left\{(u_s'')^2+\left(6\tau_g^2-\kappa_g^2-\frac{3}{2}\sigma^2\right)(u_s')^2-2[2\tau_g\kappa_g\kappa_n+3\kappa_g\kappa_g']u_s u_s'\right\}\mathrm{d}s\,. \tag{A.20}$$

Finally, if we add the remaining contributions in $\mathcal{I}_1$–$\mathcal{I}_4$ that contain u_s^2 and then integrate by parts the last term in (A.20), we obtain the expression (3.15) for $\delta^2\mathcal{F}^*$.

Acknowledgment. It is a pleasure to thank Prof. Epifanio G. Virga for his comments and suggestions.

STATISTICS OF POLARIZATION-MODE DISPERSION EMULATORS WITH UNEQUAL SECTIONS*

BRENTON R. STONE[†], GINO BIONDINI[‡], AND WILLIAM L. KATH[§]

Abstract. We study two models for the generation of polarization-mode dispersion (PMD) with unequal, fixed-length sections: an isotropic model, in which the orientations of all the sectional PMD vectors are taken to be randomly and uniformly varying across the Poincaré sphere, and a rotator model, in which all sections are taken to be linearly birefringent waveplates randomly rotatable with respect to one another. We describe the implementation of importance sampling for first- and second-order PMD in both models, including a targeting method for first-order PMD. We then use analytical and numerical methods to reconstruct the statistics of first- and second-order PMD for the two models. Our results show that the statistical properties of PMD depend significantly on the specific details of how PMD is generated.

Key words. optical fiber communications, Monte Carlo methods, importance sampling

1. Introduction.

Polarization-mode dispersion (PMD) is one of the major challenges facing the next generation of optical fiber communication systems [20]. Optical fiber is slightly birefringent due to slight deviations from circular symmetry, bending, stresses, etc. To first order in frequency, birefringence splits a pulse between the fast and the slow axes in an optical fiber; higher orders of birefringence induce depolarization and polarization-dependent chromatic dispersion. Also, the birefringence properties change randomly with distance, temperature, time, and wavelength, and these random variations are referred to as PMD. In system design, a certain power penalty is usually allotted to PMD, and one demands that the outage probability (the probability of the PMD-induced penalty exceeding this allowed value) be very small (typical requirements are a minute per year). Because of this stringent requirement, it has been difficult to use either Monte Carlo (MC) simulations or laboratory measurements to fully assess system outage probabilities, due to the extremely large number of PMD configurations that are necessary to obtain reliable estimates. Recently, it was shown that the technique of importance sampling (IS) [7, 8, 11] can often obviate this problem and allow efficient computation of PMD-induced transmission penalties and outage probabilities [6, 24, 25].

A measure of PMD is provided by the PMD vector [16]. The magnitude of the PMD vector, called differential group delay (DGD), quantifies the amount of local pulse splitting between fast and slow axes of birefringence. It has long been assumed that the probability density function (PDF) of the DGD follows a Maxwellian distribution [12], and that the process is ergodic, in the sense that time averages coincide

with frequency averages. Recent measurements of installed fiber links, however, have reported variations in the temporal statistics of DGD between different frequency channels in wavelength-division-multiplexed (WDM) systems [9, 19]. This more complicated behavior is consistent with a so-called hinge model of PMD [9], in which the system is composed of a concatenation of a small number of long, stable sections (long stretches of fiber which are buried underground) joined by short, unprotected sections, or "hinges" (bridges, amplifiers, service huts, etc.), which are more subject to environmental effects. While the hinges themselves bring little or no contribution to the total DGD of the system, their random fluctuations appear to be responsible for the temporal dynamics of PMD within each channel, whereas the longer sections appear to be essentially frozen in time. In the traditional model of PMD (which can be thought of as the limit in which the number of hinges is large and the stable sections are short), different wavelength bands behave independently but share the same statistical properties. In contrast, in the hinge model different wavelength bands are not statistically identical (because the individual PMD vector of each section is different for each wavelength). Thus, the ergodic hypothesis is not satisfied in the hinge model.

The properties of PMD in the hinge model have been well characterized [1, 2, 3, 10, 17, 21, 23, 26] under the assumption that the hinges randomize the orientation of the PMD vectors uniformly across the Poincaré sphere. In particular, analytical expressions for the PDF of the DGD are available [1, 17]. No analytical expressions exist, however, for the PDF of higher-order PMD, including second-order PMD. Moreover, some of the features of the hinge model also apply for different mechanisms of PMD generation that give rise to concatenations of fixed-length sections. No analytical expressions, however, are known for the statistics of PMD if one relaxes the assumption that the individual sections are uniformly distributed on the Poincaré sphere.

Here we address both of the above issues, and we discuss the PMD statistics produced by a finite concatenation of fixed-length sections for two specific PMD generation models. In the first model we take the orientation of the individual sections to be uniformly distributed on the Poincaré sphere. In the second model we take the individual sections to be linearly birefringent, with randomly oriented axes with respect to one another. We refer to the first and second models, respectively, as the "isotropic" and the "rotator" models of PMD. For both models, we study the case in which the individual section lengths are not all identical. Previously, we discussed the implementation of IS techniques for both models in the special case of equal-length sections [7, 8, 11]. Here we extend those results to the case of nonequal lengths, discussing the generation of large values of DGD, second-order PMD, as well as any combination of the two, plus a targeting method that allows one to concentrate samples where desired. Finally, we apply these methods to reconstruct PMD statistics of both models and show that significant differences exist among them.

2. Isotropic and rotator PMD models. The action of any lossless transmission element on an optical pulse can be described, up to a polarization-independent factor, by a unitary 2×2 frequency-dependent transmission matrix $U(z, \omega)$ called the Jones matrix, which describes the evolution of the transverse components of the optical field. Polarization effects can then be uniquely characterized by the real three-component PMD vector, $\vec{\tau}(\omega, z)$, defined by [16]

$$\vec{\tau}(\omega, z) \cdot \vec{\sigma} = 2i \frac{\partial U}{\partial \omega} U^{-1} , \tag{2.1}$$

where $\vec{\sigma}$ is a vector of Pauli matrices. Consider a concatenation a finite number of fixed-length fiber sections. The growth of PMD is governed, at each frequency, by the PMD concatenation equations. For first and second order, these are [16]

$$\vec{\tau}^{(n+1)} = \mathsf{R}_{n+1}\vec{\tau}^{(n)} + \Delta\vec{\tau}_{n+1}, \tag{2.2a}$$

$$\vec{\tau}_{\omega}^{(n+1)} = \mathsf{R}_{n+1}\vec{\tau}_{\omega}^{(n)} + \Delta\vec{\tau}_{n+1} \times \vec{\tau}^{(n+1)} + \Delta\vec{\tau}_{\omega,n+1}\,. \tag{2.2b}$$

Here $\vec{\tau}^{(n)}$ is the total PMD vector after the nth section, the fixed vector $\Delta\vec{\tau}_n$ is the PMD vector of the nth section, $\Delta\vec{\tau}_{\omega,n}$ is its frequency derivative, and the 3×3 matrix R_n is the Müller matrix of the nth section, which is related to the Jones matrix of that section by [16] $\mathsf{R}(\omega,z)\,\vec{\sigma} = U^{-1}\vec{\sigma}U$.

As is customary in both the traditional and the hinge model of PMD, we assume the sectional PMD vectors $\Delta\vec{\tau}_n$ to be constant in time and to have independent, identically distributed components that follow a normal distribution with mean zero and variance σ^2 with respect to wavelength. This of course implies that the sectional DGDs $\Delta\tau_n = |\Delta\vec{\tau}_n|$ are Maxwellian-distributed with respect to wavelength. Moreover, we assume that each section is linearly birefringent in frequency, namely, $\Delta\vec{\tau}_{\omega,n} = 0$. The matrix R_n then describes a rotation about an angle ϕ_n about the axis $\hat{r}_n = \Delta\vec{\tau}_n/|\Delta\vec{\tau}_n|$, namely,

$$\mathsf{R}_n = \exp\left[\phi_n\,\hat{r}_n \times \quad\right] = \cos\phi_n\,\mathsf{I}_3 + (1-\cos\phi_n)\,\hat{r}_n\hat{r}_n^T + \sin\phi_n\,\hat{r}_n \times \quad , \tag{2.3}$$

where I_3 is the 3×3 identity matrix and the superscript T denotes the matrix transpose. If hinges are present, a hinge rotation matrix H_n precedes R_{n+1} in (2.2).

In other words, mathematically there are two distinct random processes taking place. The first one governs the selection of the fiber sections, resulting in a set of wavelength-dependent sectional PMD vectors. These PMD vectors are stable over long periods of time (often months). The second random process is the one that governs the fast temporal variations due to environmental effects, and affecting the rotation angles in the matrices (2.3) as well as H_n. We model this situation by taking the section lengths to be fixed and by assuming that the only temporal variation in (2.2) arises from the rotation matrices R_{n+1} and, if present, from H_n. If the action of the hinges is sufficient to scatter the orientation of the PMD vectors uniformly across the Poincaré sphere, it is convenient to rewrite (2.2) as

$$\vec{\tau}^{(n+1)} = \mathsf{R}_{n+1}\mathsf{H}_n\big(\vec{\tau}^{(n)} + \Delta\vec{\tau}\,'_{n+1}\big), \tag{2.4a}$$

$$\vec{\tau}_{\omega}^{(n+1)} = \mathsf{R}_{n+1}\mathsf{H}_n\big(\vec{\tau}_{\omega}^{(n)} + \Delta\vec{\tau}\,'_{n+1} \times \vec{\tau}^{(n)}\big)\,, \tag{2.4b}$$

where $\Delta\vec{\tau}\,'_{n+1} = (\mathsf{R}_{n+1}\mathsf{H}_n)^{-1}\Delta\vec{\tau}_{n+1}$ is now uniformly distributed across the Poincaré sphere. We refer to this as the "isotropic" model of PMD. If one is interested only in first-order PMD, the problem is then equivalent to a 3-dimensional random walk. The DGD in the isotropic model and its impact on system behavior has been well characterized [1, 2, 3, 21, 26]. The isotropic hypothesis is a convenient assumption, since it makes an analytical treatment of the model possible. We emphasize, however, that it has not been experimentally validated, and that the question of whether or not it is accurate is an open issue.

When PMD is generated by birefringent waveplates, the individual PMD vectors lie on the equatorial plane of the Poincaré sphere. Since optical fiber is naturally linearly birefringent [14], the same statement holds for short fiber sections. Therefore, here we also consider the case in which the vectors $\Delta\vec{\tau}_{n+1}$ in (2.2) are uniformly distributed on the equatorial plane of the Poincaré sphere. We refer to this as the "rotator" model of PMD. Of course, because the fiber birefringence axes change with distance, the concatenated total PMD vector will wander off the equatorial plane. Since the fiber correlation length (which is the distance over which the birefringence properties become uncorrelated) is below a hundred meters [15], any fiber span longer than a few kilometers will have a PMD vector that does not lie in the equatorial plane. (At the same time, however, significant nonuniformities in the angular distribution of PMD persist up to medium-to-long distances [28].) Note also that the rotator model neglects the action of the hinge rotation matrix. Thus it is an oversimplification of the actual PMD generation mechanism in installed systems.

Even though both of the above-mentioned fixed-length models may not be a fully accurate representation of the actual mechanism of PMD generation, in the absence of more complete models or conclusive experimental data the comparison between them will serve to demonstrate that the statistical properties of PMD depend significantly on the physical details of how PMD is generated in the system. (These results generalize those previously obtained for the case of equal-length sections [7, 11].)

The case of unequal-length sections has recently received renewed interest (e.g., see [17, 18, 26]), but only within the framework of the isotropic assumption. The case of unequal lengths is worthy of study because, while no analytical expressions exist for the PDF of the DGD (for the rotator model) or second-order PMD (for either model), most installed systems are composed of sections with unequal lengths. We also emphasize that a key assumption in both of the models considered here is that the individual sections have *fixed length*, namely, that the sectional PMD vectors are essentially frozen. A different model, in which the individual PMD vectors are also varying and in which, in particular, they are Maxwellian-distributed, was studied in [5, 22]. Note, however, that allowing the section lengths to vary on the same temporal scales as the rotation matrices results in very different PMD properties from those of the models considered here, even in the isotropic case (e.g., the PDF of the total DGD is exactly Maxwellian-distributed for any number of sections).

3. Importance sampling for unequal sections.

Here we extend the IS methods that were derived in [7, 8, 11] for equal-length sections to the case of unequal section lengths, when the individual sections are either uniformly distributed on the Poincaré sphere or linearly birefringent. As mentioned previously, analytical expressions for the PDF of the DGD for the isotropic model are of course available both for equal and for unequal section lengths [1, 4, 17]. No similar expressions are known, however, when PMD is generated by birefringent waveplates. Moreover, no analytic expressions are known for the PDF of second-order PMD in either model. It was shown [24] that in systems which employ PMD compensation, knowledge of first-order PMD is not enough to accurately characterize PMD-induced transmission penalties. At the same time, it has also been shown that control of both first- and second-order PMD is enough in most cases of interest [24]. Finally, we should note that one of the advantages of IS is that, whether one is biasing for first- or second-order PMD, the method automatically generates PMD of all orders (due to the wavelength dependence of the sectional PMD vectors). This means that biasing for large DGDs can also be useful in the isotropic model (even though the PDF of the DGD is known), since the simultaneous presence of all orders of PMD can lead to a more accurate evaluation of PMD-induced distortions [24].

3.1. IS for the DGD. The first step when applying IS is to determine the most likely system configurations that lead to the event of interest. For first-order PMD, this proceeds exactly in the same way as in the case of equal-length sections [7]. Namely, one must choose the next PMD contribution $\Delta\vec{\tau}_{n+1}$ to be preferentially aligned with the previous PMD vector $\vec{\tau}^{(n)}$. For the isotropic model, this is done choosing the angle θ_n between $\Delta\vec{\tau}_{n+1}$ and $\vec{\tau}^{(n)}$ to be preferentially close to 0. For the rotator model, instead, since $\Delta\vec{\tau}_{n+1}$ must lie in the equatorial plane of the Poincaré sphere, the biasing is done by choosing the angle θ_n between $\Delta\vec{\tau}_{n+1}$ and the projection of $\vec{\tau}^{(n)}$ onto the equatorial plane to be preferentially close to 0.

To achieve this preferential alignment, for the isotropic model we take $\cos\theta = 2x^{1/\alpha} - 1$, while for the rotator model we take $\theta = \pi\ \mathrm{sgn}(2x-1)|2x-1|^\alpha$, in both cases with x uniform in $[0,1]$. These choices correspond respectively to the biasing distributions

$$p_{\alpha,\mathrm{iso}}(\theta) = (\alpha/2)\sin\theta\,[(1+\cos\theta)/2]^{\alpha-1}, \qquad p_{\alpha,\mathrm{wav}}(\theta) = (1/\alpha\pi)\,|\theta/\pi|^{1-\alpha}. \tag{3.1}$$

For both the isotropic and the rotator models the value $\alpha = 1$ reproduces the unbiased case, while larger values of α concentrate the samples θ near 0. In both models, the likelihood ratio is given by [8]

$$L(\theta_1,\dots,\theta_N) = \prod_{n=1}^{N} \frac{p_1(\theta_n)}{p_\alpha(\theta_n)}\,, \tag{3.2}$$

where N is the total number of sections. Of course, other choices of biasing distributions might work equally well, as long as the reference angles are correctly identified. Also, in both models the rotation angle ϕ_n is not important for IS purposes, and is taken to be varying and uniformly distributed in $[0,2\pi]$.

3.2. IS for first- and second-order PMD. Consider the orthogonal frame of reference defined by the unit vectors

$$\hat{u}_1^{(n)} = \vec{\tau}^{(n)}/|\vec{\tau}^{(n)}|\,, \qquad \hat{u}_2^{(n)} = \vec{\tau}_{\omega,\perp}^{(n)}/|\vec{\tau}_{\omega,\perp}^{(n)}|\,, \qquad \hat{u}_3^{(n)} = \hat{u}_1^{(n)} \times \hat{u}_2^{(n)}\,, \tag{3.3}$$

where $\vec{\tau}_{\omega,\|}$ and $\vec{\tau}_{\omega,\perp}$ are, respectively, the parallel and perpendicular components of $\vec{\tau}_\omega$ with respect to τ. As in [8], it is convenient to consider the continuum limit of (2.2). In the isotropic model, factoring out the inessential rotation $\mathsf{R}_{n+1}\mathsf{H}_n$ in (2.4), one then obtains

$$\frac{d\tau}{dz} = b_1\,, \qquad \frac{d\tau_{\omega,\|}}{dz} = b_2\,\frac{\tau_{\omega,\perp}}{\tau}\,, \qquad \frac{d\tau_{\omega,\perp}}{dz} = b_3\tau - b_2\,\frac{\tau_{\omega,\|}}{\tau}\,, \tag{3.4}$$

where $\vec{b}(z) = \lim_{\Delta z\to 0}\Delta\vec{\tau}_{n+1}/\Delta z$ quantifies the rate at which PMD is added, and (b_1,b_2,b_3) are the components of $\vec{b}$ with respect to the reference frame $\{\hat{u}_1,\hat{u}_2,\hat{u}_3\}$.

As shown in [8], (3.4) can be solved exactly for any $\vec{b}(z)$. One can then use calculus of variations to find the choice of $\vec{b}(z)$ which maximizes second-order PMD. In the case of equal-length sections, that is, $|\vec{b}(z)| = b = \text{const}$, it was shown in [11] that the solution of this maximization problem is

$$\vec{b}(z) = b\left(\hat{u}_1\,\cos[\Phi(z)] + \hat{u}_3\,\sin[\Phi(z)]\right), \tag{3.5}$$

where the biasing angle is $\Phi(z) = (z/z_{\max})\Phi_{\max}$ and where $\Phi_{\max} = \pi/2$. Other choices of $\Phi_{\max}$ maximize linear combinations of DGD and second-order PMD ($\Phi_{\max} = 0$ is simply first-order biasing).

As we show next, the solution of the maximization problem in the case of unequal section lengths can be obtained from the case of equal section lengths by a simple change of variable. Given a function $b(z) = |\vec{b}(z)|$ that describes the magnitude of the local birefringence, define the rescaled distance

$$\zeta(z) = \int_0^z b(z')dz' \,. \tag{3.6}$$

Written in terms of ζ, equations (3.4) then are

$$\frac{d\tau}{d\zeta} = e_1 \,, \qquad \frac{d\tau_{\omega,||}}{d\zeta} = e_2 \,\frac{\tau_{\omega,\perp}}{\tau} \,, \qquad \frac{d\tau_{\omega,\perp}}{d\zeta} = e_3\tau - e_2 \,\frac{\tau_{\omega,||}}{\tau} \,, \tag{3.7}$$

where $\hat{e}(z) = \vec{b}(z)/|\vec{b}(z)|$ has unit magnitude. One can now use the results of the calculations for equal-length sections described above, obtaining

$$\hat{e}(\zeta) = \hat{u}_1 \, \cos[\Phi(\zeta)] + \hat{u}_3 \, \sin[\Phi(\zeta)] \,, \tag{3.8}$$

with $\Phi(\zeta) = (\zeta/\zeta_{\max})\,\Phi_{\max}$. In terms of the original variable z one then obtains (3.5), with b replaced by $b(z)$ and where now

$$\Phi(z) = \Phi_{\max} \int_0^z b(z')dz' \Big/ \int_0^{z_{\max}} b(z')dz' \,, \tag{3.9}$$

with the same meaning for $\Phi_{\max}$. (Of course, (3.9) reduces to the linearly varying profile (3.10) in the case of equal section lengths.) In the discrete version, with section lengths $\Delta\tau_n$, we then obtain Φ_n, which gives the proper biasing direction after n sections as a function of n:

$$\Phi_n = \Phi_{\max} \sum_{m=1}^{n} \Delta\tau_m/\tau_{\max}, \tag{3.10}$$

where

$$\tau_{\max} = \sum_{n=1}^{N} \Delta\tau_n \,. \tag{3.11}$$

As with the DGD, the biasing directions for the rotator model are just the projection of the vector $\vec{b}$ onto the equatorial plane. Moreover, once the deterministic biasing directions have been found, for both the isotropic and the rotator model, one selects the biasing distributions in order to concentrate the MC samples around the deterministic biasing directions exactly as when biasing for the DGD. When more than one choice of biasing is necessary, multiple IS can be used, and samples from different biasing distributions can be combined using the balance heuristic [8].

3.3. Targeted IS. It is sometimes useful to be able to choose where to concentrate the MC samples, especially when one is interested in only a small region of the PDF. We now obtain an estimate of the values of the biasing strength α that are needed to generate values of DGD concentrated near a given target.

A simple bound on α can be obtained by looking at the component of the next PMD vector, $\tau^{(n+1)}$, that is parallel to the previous PMD vector, $\tau^{(n)}$. From (2.4a) it is

$$\tau_{||}^{(n+1)} = \tau^{(n)} + \Delta\tau_{n+1} \cos\theta_{n+1}, \tag{3.12}$$

where θ_{n+1} is the angle between the differential contribution of the next section, $\Delta\tau_{n+1}$, and the previous PMD vector. Since it is obviously true that $|\vec{\tau}^{(n)}| \geq |\tau_{||}^{(n)}|$, from (3.12) we have

$$\tau_{||}^{(N)} \geq \sum_{n=1}^{N} \Delta\tau_n \cos\theta_n . \tag{3.13}$$

Then, since the section lengths are fixed, taking expectation values we have

$$\langle \tau^{(N)} \rangle \geq \sum_{n=1}^{N} \Delta\tau_n \langle \cos\theta_n \rangle = \langle \cos\theta \rangle \, \tau_{\max} \, , \tag{3.14}$$

where we used $\langle \tau^{(N)} \rangle \geq \langle \tau_{||}^{(N)} \rangle$, and where $\tau_{\max}$ is the maximum DGD, defined in (3.11). For the biased probability distribution for the isotropic model, (3.1), it is

$$\langle \cos\theta \rangle = (\alpha - 1)/(\alpha + 1). \tag{3.15}$$

Therefore in this case (3.14) yields

$$\langle \tau^{(N)} \rangle \geq [(\alpha - 1)/(\alpha + 1)] \, \tau_{\max} \, . \tag{3.16}$$

Note that as α increases, $\langle \tau^{(N)} \rangle$ approaches $\tau_{\max}$, as expected.

Equation (3.16) yields an upper bound on the value of the biasing parameter α that is necessary to obtain samples distributed near $\langle \tau^{(N)} \rangle = \tau_{\text{target}}$, namely, $\alpha_{\text{target}} \leq \alpha_o$, where

$$\alpha_o = (\tau_{\max} + \tau_{\text{target}})/(\tau_{\max} - \tau_{\text{target}}) \, . \tag{3.17}$$

Note, however, that the above result is only an upper bound, and the actual value of α_{target} that concentrates the samples around a desired target is often a great deal smaller than α_o, particularly if $\tau_{\max} - \tau_{\text{target}}$ is small. In those cases, the heuristic correction $\alpha = \alpha_o/\sqrt{1 + \alpha_o/4}$, where α_o is given by (3.17), provides a better estimate of α_{target} which is valid over the whole range of DGDs.

The bound on α_{target} is independent of the particular values of the section lengths, and therefore it holds equally well for equal as well as unequal lengths. Moreover, it also appears to hold for the rotator model. It should be noted that for PMD generation models in which the section lengths are also variable and are Maxwellian-distributed, one could also concentrate the samples around a target value of second-order PMD [5]. Note also that, using the so-called Brownian bridge method, one could hit exactly any value of DGD [27]. To the best of our knowledge, however, no targeting method was known for fixed-length sections.

4. Numerical simulations and PMD statistics.

We now proceed to compare statistical measures of PMD for the isotropic and the rotator models of PMD defined in section 2, using the methods discussed in section 3.

4.1. PDF of the DGD.

An exact formula for the PDF of the DGD in the isotropic model, hereafter $p_{\text{DGD}}(\tau)$, was obtained in [1]. That expression, however, involves a sum over 2^N terms, where as before N is the number of sections. Hence, the computational cost of evaluating it increases exponentially with N. As a result, the use of that formula is impractical except for very small values of N. Fortunately, an alternative exact expression exists for the PDF of the DGD, in terms of a Fourier sine series [4]:

$$p_{\mathrm{DGD}}(\tau) = \frac{2\pi\tau}{\tau_{\max}^2} \sum_{m=1}^{\infty} m \sin\left(\frac{m\pi\tau}{\tau_{\max}}\right) \prod_{n=1}^{N} \frac{\sin(m\pi\Delta\tau_n/\tau_{\max})}{m\pi\Delta\tau_n/\tau_{\max}} \,. \tag{4.1}$$

The evaluation of (4.1) is of course always affected by truncation error due to the finite number of Fourier modes. Nonetheless, (4.1) produced the same results as the formula in [1] up to roundoff error in all the cases we tested (which included situations where the DGD of one section is larger than the sum of all the others). In our tests the two methods had about the same execution time for $N = 6$ sections when 2^{10} Fourier modes were used in (4.1). The computational cost of evaluating (4.1), however, is essentially given by the number of Fourier modes used, and depends only very weakly on the number of sections [23]. For this reason we used (4.1) in our calculations. For the rotator model one must use importance-sampled MC (IS-MC) simulations as discussed in section 3.1, using a combination of biasing strengths, to cover the whole range of DGDs. The PDF of the DGD is then reconstructed from the IS-MC simulations using the likelihood ratios as described in [8].

Figure 4.1 shows the PDF of the DGD for the isotropic model (thick dashed line) and the rotator model (thick solid line) for two particular realizations of $N = 8$ section lengths, while Figure 4.2 shows the PDF of the DGD for a specific realization of $N = 20$ sections. The specific values of the sectional DGDs are given in Table 4.1; the corresponding values of $\tau_{\max}$ are, respectively, 10.99 ps, 16.19 ps, and 21.60 ps for cases A, B, and C. In each case, the sectional DGDs were all drawn from an identical Maxwellian distribution

$$p_{\mathrm{dgd}}(\tau) = \frac{\sqrt{2}\,\tau^2}{\sqrt{\pi}\,\sigma^3}\, e^{-\tau^2/2\sigma^2} \,, \tag{4.2}$$

where $\sigma^2 = (\pi/8)\langle\Delta\tau\rangle^2$. In particular, we set $\langle\Delta\tau\rangle = \langle\tau\rangle/\sqrt{N}$ with $\langle\tau\rangle = 5\,\mathrm{ps}$ in all cases, so as to obtain a nominal Maxwellian distribution with mean DGD of 5 ps for the whole line. Note, however, that due to the finite sample size (i.e., the finite value of N), the samples will generate a PDF of the DGD which is better approximated by an "effective" Maxwellian, obtained by (4.2) with $\sigma_{\mathrm{eff}}^2 = (\pi/8)\sum_{n=1}^{N}(\Delta\tau_n)^2$. These effective Maxwellian distributions are shown in Figure 4.1 as dot-dashed lines. Of course the difference between the nominal and effective Maxwellians will tend to zero on average as N goes to infinity.

For the rotator model we used the biasing strengths $\alpha = 1$ (unbiased), 4, 12, and 24 to perform IS-MC simulations in the cases with $N = 8$, and we used $\alpha = 1$, 2, 4, and 6 in the case $N = 20$ (since in this case smaller biasing strengths are sufficient to cover the desired range of values of the PDF). In all cases 400,000 samples per biasing strength were used. Note how, in all cases, the tails of the PDF for the isotropic model (that is, the values of the PDF for values of DGD near $\tau_{\max}$) are orders of magnitudes below those of the rotator model. This behavior occurred in all cases we studied, but it is not clear at present whether it is a general property, namely, whether it holds for any choice of section lengths and for any number of sections (as is indeed the case with equal lengths). As is to be expected, the PDF in the case of $N = 20$ sections agrees with a Maxwellian distribution over a larger range of DGDs.

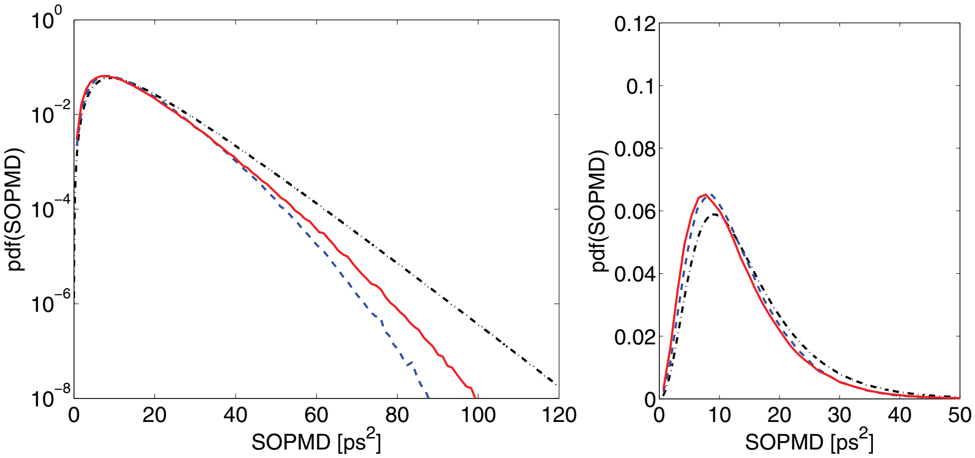

FIG. 4.4. *Same as Figure* 4.3, *but for* $N = 20$ *and with the same section DGDs as in Figure* 4.2.

4.2. PDF of second-order PMD. No analytical solutions exist for the PDF of second-order PMD generated by a concatenation of a finite number of fixed-length sections, even in the isotropic case and even in the case of equal-length sections. Therefore, one must resort to numerical simulations for both the isotropic and the rotator model. We used IS-MC simulations as discussed in section 3.2 with $\Phi_{\max} = \pi/2$, again with a combination of biasing strengths to cover the whole range of second-order PMD. More precisely, we used the same values of biasing strength as when biasing for large values of DGD.

Figure 4.3 shows the PDF of second-order PMD for the isotropic and the rotator model for the same section lengths as in Figure 4.1, while Figure 4.4 does the same for the same section lengths as in Figure 4.2. In all cases the solid line shows the nominal

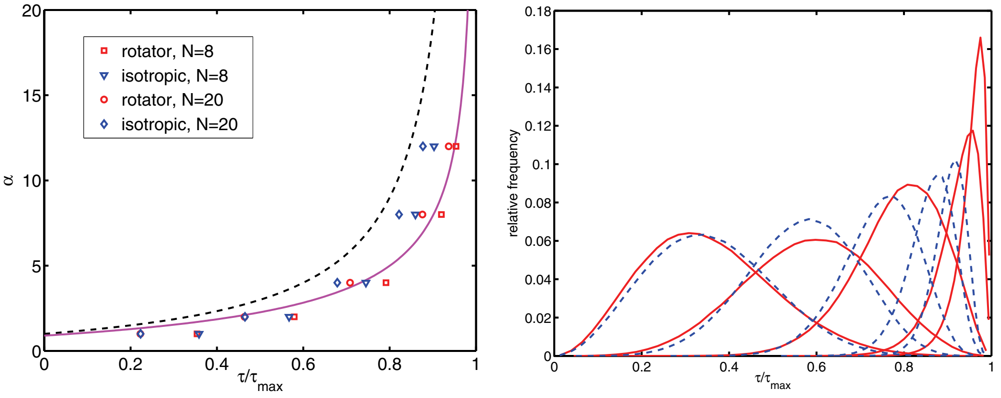

FIG. 4.5. *Left: The estimated value of the biasing strength needed to obtain a given fraction of the maximum DGD. Dashed line: uncorrected value; solid line: value with the heuristic correction. Also shown are the means of the biased MC samples obtained with the biasing strengths* $\alpha = 1, 2, 4, 8, 12$ *for both the isotropic and the rotator model with* $N = 8$ *and* $N = 20$*. Right: The relative frequency of the total DGD obtained with the biasing values for* $N = 8$ *in the isotropic model (dashed curves) and the rotator model (solid curves) in case* A.

"sech-tanh" distribution obtained in the limit of large number of sections [13], namely,

$$p_{\mathrm{sopmd}}(x) = \frac{8}{\pi\langle\tau\rangle^2}\, y(x)\,\mathrm{sech}[y(x)]\,\tanh[y(x)]\,, \tag{4.3}$$

where $y(x) = 4x/\langle\tau\rangle^2$. For both the isotropic and the rotator model, the simulations were done with the same biasing strengths as for the DGD, with 200,000 samples per biasing strength for both models. As with the DGD, the tails of the PDF of the rotator model are significantly larger than those of the isotropic model. (The maximum second-order PMD for an isotropic concatenation of sections was obtained in [18].) Here, however, the difference between the two models seems to be less pronounced than for the PDF of the DGD.

It should be clear from the figures that the overall PDFs of both DGD and second-order PMD can depend significantly on how much of the Poincaré sphere is being sampled by the hinge rotation matrix. It should also be clear that since the maximum DGD and maximum second-order PMD of any PMD emulator are determined by the particular values of the individual DGDs, the resulting PDFs can vary quite a bit for different choices of the section DGDs, even though the individual DGDs are all drawn from an identical Maxwellian distribution. In particular, these PDFs can occasionally differ significantly from the average Maxwellian and sech-tanh distributions, even at moderate values of DGD and second-order PMD, and even with a relatively large number of sections. This is indeed evident from Figures 4.1 and 4.3.

4.3. Targeting. Figure 4.5 shows (to the left) a comparison of the estimate (3.17) of the biasing strength α_o (dashed line) required to obtain a given target DGD versus the heuristic correction α (solid line). Both are plotted against the normalized total DGD (namely, the ratio $\tau/\tau_{\max}$). Also plotted is the mean of the biased MC samples obtained for both the isotropic and the rotator model with $\alpha = 1$ (unbiased), 2, 4, 8, and 12, computed for both $N = 8$ and $N = 20$ with the section lengths listed in Table 4.1. (The results from cases A and B are indistinguishable from each other.) As is evident from this comparison, a good agreement exists between the analytical approximation and the actual mean of the MC samples for both the isotropic and the rotator model for values of N up to 20, except for small values of α. (For $\alpha = 1$, (3.17) yields the unphysical value $\langle\tau\rangle = 0$.) Note, however, that the agreement becomes worse for larger values of N. This is to be expected, since $\langle\tau\rangle/\tau_{\max} \to 0$ in the limit $N \to \infty$, even when the mean DGD per section is scaled as $\langle\tau\rangle/\sqrt{N}$ so as to keep $\langle\tau\rangle$ fixed.

Also shown (to the right) are histograms showing the expected relative frequency of the values of total DGD (as estimated from biased MC simulations) for case A for both the isotropic (dashed lines) and the rotator (solid lines) models for the same values of α as above, illustrating how the IS-MC samples indeed cluster around the expected mean for both the isotropic and the rotator model.

5. Conclusions. We have discussed two models of PMD generation, both consisting of a concatenation of unequal-length sections: a conventional, isotropic model, based on the assumption that the action of the hinges connecting the individual fiber sections causes their relative orientations to vary uniformly across the Poincaré sphere; and a rotator model, based on linearly birefringent elements that rotate relative to one another. We have presented the implementation of IS for both the isotropic model and the rotator model with sections of arbitrary length, and we have used analytical and numerical methods to compute the statistics of first- and second-order PMD in both models. The results show that the PMD statistics depend significantly upon the details of how PMD is generated.

We should reiterate that even though only first- and second-order PMD are biased, a full range of higher-order PMD is also being generated. Moreover, it has been shown [24] that multiple IS with a proper choice of biasing strengths which cover the whole (DGD, second-order PMD) plane is sufficient to accurately capture the statistical distribution of PMD-induced transmission penalties even when multistage PMD compensators are used and even when first-order and second-order PMD are completely compensated.

Thus, the present methods can be employed to compute PMD-induced pulse distortions in systems with various configurations. The present work also provides a further demonstration that the PMD-induced penalties depend on the specific physical details of how PMD is generated in the system. More specifically, for the hinge model they depend on how much of the Poincaré sphere is sampled by the hinge rotation matrix. If the actual PMD generation mechanism in some realistic situation can be considered to be a hybrid between the isotropic and the rotator models, these two models could then provide useful upper and lower limits for the actual penalties in the system.

Acknowledgment. We thank H. Kogelnik and P. J. Winzer for many insightful discussions.

IMPEDANCE-ACOUSTIC TOMOGRAPHY*

BASTIAN GEBAUER† AND OTMAR SCHERZER‡

Abstract. In this work we present a new hybrid imaging technique that combines electrical impedance tomography (EIT) with acoustic tomography. The novel technique makes use of the fact that the absorbed electrical energy inside the body raises its temperature, thus leading to expansion effects. The expansion then induces an acoustic wave which can be recorded outside the body and consequently be used to calculate the absorbed energy inside the body, from which the electrical conductivity can be reconstructed. In other words, we try to combine the high contrast of EIT with the high resolution of ultrasound.

Key words. hybrid imagery, electrical impedance tomography (EIT), thermoacoustics

1. Introduction.

In electrical impedance tomography (EIT) an electrical voltage $f(x)$ is applied to the surface S of a body B, thus giving rise to an electrical potential $u(x)$ inside the body. One then measures the resulting surface current j and tries to reconstruct the conductivity inside the body from one or several voltage-current pair(s) $(f(x), j(x))$ on the boundary.

The problem is known to be severely ill-posed, and though a number of commercial EIT systems exists, a stable reconstruction algorithm still seems to be out of reach. As a starting point we refer the interested reader to the survey articles of Cheney, Isaacson, and Newell [7], Borcea [4, 5], Lionheart [19], and Bayford [3]. A recent study reporting on the high permittivity and conductivity contrast of different breast tissues over the frequency range 40Hz–100MHz can be found in Stoneman et al. [27]. It has to be noted, however, that the conductivity value alone does not seem to be a sufficient criterion to distinguish cancerous from healthy breast tissue; cf. also the studies of Lazebnik et al. [16, 17] for the microwave frequency range 0.5–20GHz.

A promising approach to overcoming the intrinsic ill-posedness of the problem is to combine EIT with another imaging system that provides additional information. The most prominent example is magnetic resonance electrical impedance tomography (MREIT), which combines EIT with measurements of the magnetic flux from which one obtains the current density *inside* the body; cf. the works of Kwon et al. [14], S. Kim et al. [12], Y. J. Kim et al. [11], and the recent work of Nachman, Tamasan, and Timonov [22]. Another approach is magnetoacoustic imaging, where an exterior magnetic field is used to generate displacements in the body via the Lorentz force. The resulting pressure wave is measured by ultrasound transducers and provides information about the interior current density; cf., e.g., Ma and He [20] and the preprint

[2] of Ammari et al. [1] for recent references. Independently of this work, Ammari et al. have recently proposed using ultrasound to produce localized elastic perturbations to locally change the conductivity inside a body. From the resulting change in the EIT measurements they obtain the energy density inside the body and use this additional information to reconstruct the conductivity.

In this work we propose a new method to obtain additional interior information for EIT by combining it with ultrasound tomography. Similarly to magnetoacoustic imaging, we obtain our additional information from creating a pressure wave inside the body. However, we do not rely on an externally applied magnetic field and the Lorentz force but on thermal expansion. The resulting additional interior information is the same that Ammari et al. obtain by elastic deformations, i.e., the interior energy density.

To be more specific, we will make use of the fact that the absorbed energy inside the body raises its temperature, thus leading to expansion effects. The expansion then induces an acoustic wave which can be recorded outside the body and consequently be used to calculate the absorbed energy inside the body. The advantage of using acoustical rather than electromagnetic measurements for the reconstruction is that we can then choose the excitation frequency small with respect to the speed of electromagnetic waves (so that the model of impedance tomography holds true) but large with respect to the speed of sound (so that the we obtain a high resolution in the reconstructions). In other words, we try to combine the high contrast of EIT with the high resolution of ultrasound. The ideas for this combination stem from thermoacoustic computerized tomography, where a body is illuminated and thus heated up with a short pulse of light and the resulting acoustic pressure wave is recorded. For an introduction to the field of thermoacoustic tomography, we refer the reader to the recent special section in the journal *Inverse Problems* [23]. A survey on experimental setups for thermoacoustic imaging can be found in Xu and Wang [28].

The outline of this work is as follows. We start by developing the model of impedance-acoustic tomography in section 2.1 and study the well-posedness of the resulting direct problem in section 2.2. In section 3 we study the associated inverse problems and derive first reconstruction algorithms. Finally, we show preliminary numerical examples for the simulation of impedance-acoustic tomography as well as for the reconstruction algorithms in section 4.

2. Impedance-Acoustic Computerized Tomography (ImpACT).

2.1. Derivation of the modeling equations.

2.1. Derivation of the modeling equations. If a stationary electrical voltage $f(x)$ is applied to the surface S of a body $B \subset \mathbb{R}^n$, $n = 2$ or $n = 3$, this gives rise to an electrical potential $u(x)$ inside the body. In the state of equilibrium the potential is given by the solution u of

$$\nabla \cdot (\sigma(x) \nabla u(x)) = 0 \qquad \text{in } B, \tag{2.1}$$

$$u(x)|_S = f(x) \qquad \text{on } S, \tag{2.2}$$

where $\sigma(x)$ is the specific conductivity of the body. One can then measure the resulting surface current

$$j(x) = \sigma(x) \partial_\nu u(x)|_S$$

($\nu = \nu(x)$ is the outer normal vector at a surface point $x \in S$) and try to reconstruct $\sigma(x)$ from one or several voltage-current pair(s) $(f(x), j(x))$.

An electrical potential almost instantly reaches its state of equilibrium, so that if we apply a time-dependent voltage $F(x,t) = f(x)\sqrt{g(t)}$ that varies slowly in time (compared to the speed of electromagnetic waves), the induced electric potential is given by its quasi-static limit $U(x,t) = u(x)\sqrt{g(t)}$, where $u(x)$ solves (2.1), (2.2). (We choose the notation $\sqrt{g(t)}$ in order to have g proportional to the amount of applied electrical power in (2.3) below.)

When electrical currents are flowing through a body, three effects can be observed: stimulation of nerves, electrolysis, and thermal heating; cf., e.g, [9]. We concentrate on the heating effect and suggest using high frequency currents, which have less stimulating effects on the nerves. Indeed, the effect of thermal heating with high frequency currents is exploited in *high frequency surgery*; cf., e.g., [9, 13].

We will make use of the usual convention that "∇" and "Δ" are taken only with respect to spatial variables and that first, respectively, second, partial time-derivatives are denoted by one, respectively, two, dots. *Joule's law* describes the relation between the rate of variation of energy Q, i.e., the absorbed electrical power density $\dot{Q}(x,t)$, and the electric potential by

$$\dot{Q}(x,t) = \sigma(x)|\nabla U(x,t)|^2 = \sigma(x)|\nabla u(x)|^2 g(t). \tag{2.3}$$

If the voltage is applied only for a short time, we can neglect thermal diffusion so that the change of temperature $T(x,t)$ is given by

$$\dot{T}(x,t) = \frac{1}{\rho(x,t)c(x)}\dot{Q}(x,t), \tag{2.4}$$

where $c(x)$ is the specific heat capacity (i.e., the amount of energy needed to heat up a unit mass of the material by one unit of temperature) and $\rho(x,t)$ is the mass density.

Before we continue with our modeling equation, let us give a rough quantitative estimate of practically realizable temperature changes. We use the standard SI-units cm, m for centimeters and meters, μs for microseconds, g for grams, Ω for ohm, A for ampere, MHz for megahertz, J for joule, and mK and K, for millikelvin and kelvin. For the specific heat capacity and density we take the values of breast fat from Robinson et al. [24, Table 5], $c = 2.43\text{J}/(\text{gK})$ and $\rho = 0.934\text{g}/\text{cm}^3$. The specific electrical conductivity of adipose tissue at a frequency of 1MHz is about $\sigma = 0.4/(\Omega\text{m})$; cf. [27, Fig. 5]. Thus, a specimen cube of 1cm side length has a mass of $M = 0.934\text{g}$, and its electrical resistance is $R = \sigma^{-1}\frac{\text{length}}{\text{area}} = 250\Omega$. Applying a pulse of $\Delta t = 1\mu\text{s}$ with $\sigma|\nabla u| = I = 3\text{A}$ will change the temperature of this cube by

$$\Delta T = \frac{1}{M}\frac{1}{c}RI^2\Delta t \approx 990\frac{\text{K}\,\Omega\,\text{A}^2\,\mu\text{s}}{\text{J}} = 0.99\,\text{mK}.$$

This temperature rise seems enough to produce ultrasound waves, which can be measured with ultrasound transducers while still being unharmful to biological tissue.

We now proceed as in the derivation of the equations of thermoacoustic tomography in the book of Scherzer et al. [26]; cf. also the publication of Haltmeier, Schuster, and Scherzer [10] or the recent review article of Xu and Wang [28]. The change in the material's temperature can be related to the change in its density ρ and to the change in its pressure p via the so-called (linearized) expansion equation

$$\beta(x)\dot{T}(x,t) = \frac{1}{v_s^2}\dot{p}(x,t) - \dot{\rho}(x,t), \tag{2.5}$$

where v_s is the speed of sound and $\beta(x)$ is the thermal expansion coefficient that specifies the increase of volume per increase of temperature. Under the assumption that the density ρ is only slightly varying from a constant value ρ_0 and only small velocities occur, the velocity v and the density ρ are coupled by the linearized continuity equation

$$\dot{\rho}(x,t) = -\rho_0 \nabla \cdot v(x,t). \tag{2.6}$$

Furthermore, assuming an inviscid, nonturbulent flow of material with just slightly varying pressure, the velocity v is related to the pressure p by the linearized Euler equation

$$\rho_0 \dot{v}(x,t) = -\nabla p(x,t). \tag{2.7}$$

Combining (2.3)–(2.7) and again applying our assumption that the density ρ is only slightly varying from ρ_0, we obtain

$$\frac{1}{v_s^2}\ddot{p}(x,t) - \Delta p(x,t) = \frac{\beta(x)}{\rho_0 c(x)}\sigma(x)|\nabla u(x)|^2 \dot{g}(t).$$

If the electric energy is applied only for a very short time (compared to the speed of sound), we can replace $g(t)$ by a δ-peak and obtain that p is the solution of

$$\begin{aligned} \frac{1}{v_s^2}\ddot{p}(x,t) - \Delta p(x,t) &= 0 && \text{in } \mathbb{R}^n, \\ p(x,0) &= \frac{\beta(x)}{\rho_0 c(x)}\sigma(x)|\nabla u(x)|^2 \chi_B(x) && \text{in } \mathbb{R}^n, \\ \dot{p}(x,0) &= 0 && \text{in } \mathbb{R}^n, \end{aligned}$$

where χ_B is the characteristic function of B. We furthermore assume that the specific heat capacity and the thermal expansion coefficient are approximately constant and known. By a standard change of units we can then eliminate v_s, β, ρ_0, and c from the equations and obtain, together with (2.1) and (2.2), the *equations of impedance-acoustic tomography*:

$$\nabla \cdot \sigma \nabla u(x) = 0 \quad \text{in } B, \tag{2.8}$$

$$u(x)|_S = f \quad \text{on } S, \tag{2.9}$$

$$\ddot{p}(x,t) - \Delta p(x,t) = 0 \quad \text{in } \mathbb{R}^n, \tag{2.10}$$

$$p(x,0) = \sigma(x)|\nabla u(x)|^2 \chi_B(x) \quad \text{in } \mathbb{R}^n, \tag{2.11}$$

$$\dot{p}(x,0) = 0 \quad \text{in } \mathbb{R}^n. \tag{2.12}$$

The *forward problem of impedance-acoustic tomography* can now be stated as follows: Given the conductivity σ and the applied voltage f on S, determine the resulting currents $\sigma\partial_\nu u|_S$ and the resulting pressure wave $p(x,t)$ that solves (2.8)–(2.12). The *inverse problem of impedance-acoustic tomography* consists of reconstructing the conductivity σ from knowledge of the applied voltage f and measurements of the resulting currents $\sigma\partial_\nu u|_S$ and the resulting pressure wave p on some part of $\mathbb{R}^3$. In this work we will restrict ourselves to the case where p is measured on the whole surface S for some time interval $[0,T]$, and we will furthermore assume that σ is known in a small neighborhood of this surface S.

Finishing this subsection, let us recapitulate the crucial assumptions regarding the time-scale in our model and give a rough estimate of feasible parameters. The applied voltage must vary slowly in time compared to the speed of electromagnetic waves, so that the (quasi-static) equations of impedance tomography are valid. The maximum frequency of Rensselaer's ACT 4 EIT system is 1MHz; cf. Saulnier et al. [25]. At the same time, the voltage must be applied only for such a small time that thermal diffusion can be neglected and that the applied energy takes the form of a delta-pulse in the time-scale of sound waves, i.e., also that stress propagation can be neglected during the application of the pulse. The latter two conditions are commonly referred to as *thermal and stress confinements* in thermoacoustic tomography; cf. Xu and Wang [28]. The stress confinement is the more stringent condition and, for a pulse of 1μs, limits the expected spatial resolution to 1.5mm; cf. [28].

2.2. Well-posedness of the direct problem. Throughout this work we will assume that $B \subset \mathbb{R}^n$, $n = 2$ or $n = 3$, is a smoothly bounded domain, $T > 0$, $f \in W^{7/4,4}(S)$, and $\sigma \in W_+^{1,\infty}(B)$, where the subscript $+$ denotes the subspace of functions with positive essential infima. Under this assumption we obtain the following lemma.

LEMMA 2.1. *For every $\sigma \in W_+^{1,\infty}(B)$, there exists a unique solution $u \in W^{2,4}(B)$ of* (2.8) *and* (2.9)*. Setting*

$$\mathcal{E}(\sigma) := \sigma|\nabla u|^2, \qquad \textit{where } u \textit{ solves } (2.8) \textit{ and } (2.9),$$

defines a mapping $\mathcal{E}: W_+^{1,\infty}(B) \to H^1(B)$.

Proof. Note that the space $W^{7/4,4}(S)$ is the space of traces of functions from $W^{2,4}(B)$. From standard regularity results for elliptic equations, we obtain that for every $\sigma \in W_+^{1,\infty}(B)$ there exists a unique solution $u \in W^{2,4}(B)$ of (2.8) and (2.9) (cf., e.g., Miranda [21, Thm. 38,VI]). Thus the result follows from the product rule for Sobolev functions. □

Some caution has to be taken in the treatment of the acoustic equations (2.10)–(2.12). Though we have just seen that our regularity assumptions guarantee that the initial condition is an H^1-function in B, its continuation by zero to $\mathbb{R}^n$ will in general have a jump across S. Roughly speaking, this jump persists in the pressure wave, so that our measurements $p|_S$ are in general not well defined (as a function). Of course, from a practical point of view, there cannot be ambiguity in the measurement data; thus this problem shows that the idealization of a pressure wave appearing instantly in a sharply bounded body is not consistent with the idealization of a measurement surface with zero thickness.

However, using our additional assumption that we know the conductivity σ on S, we can circumvent this problem without giving up one of these two idealizations. The quantity $\sigma(x)|\nabla u(x)|^2|_S$ can be calculated from $\sigma|_S$, the measured surface currents $\sigma(x)\partial_\nu u(x)|_S$, and the applied voltage $u(x)|_S = f(x)$. Using a function $\tilde{p}_0(x) \in H^1(B)$ with the same boundary values $\tilde{p}_0(x)|_S = \sigma(x)|\nabla u(x)|^2|_S$, we can define the solution $\tilde{p}$ of

$$\ddot{\tilde{p}}(x,t) - \Delta\tilde{p}(x,t) = 0 \qquad \text{in } \mathbb{R}^n, \tag{2.13}$$

$$\tilde{p}(x,0) = \tilde{p}_0(x)\chi_B(x) \qquad \text{in } \mathbb{R}^n, \tag{2.14}$$

$$\dot{\tilde{p}}(x,0) = 0 \qquad \text{in } \mathbb{R}^n. \tag{2.15}$$

The difference $q := p - \tilde{p}$ then solves the wave equation with an initial condition in $W^1(\mathbb{R}^n)$, and thus its trace on S is well defined. Before we state this in a rigorous form below, let us comment on the practical realization of this approach. One can easily compute a smooth approximation to $\tilde{p}$ and evaluate this on S. The difference of the measurement of p on S and this quantity can then be regarded as an approximation to the well-defined, idealized model measurements $q|_S$.

We now restate the above arguments in a rigorous form.

Lemma 2.2. *Denote by*

$$\gamma:\ H^1(B) \to H^{1/2}(S), \qquad v \mapsto v|_S,$$

the trace operator on S*, and let* $\gamma^-:\ H^{1/2}(S) \to H^1(B)$ *be a continuous right inverse of* γ*, i.e.,* $\gamma\gamma^- = Id$*.*

For every $\sigma \in W^{1,\infty}_+(B)$ *there exists a unique solution* $\tilde{p} \in C(0,T,L^2(\mathbb{R}^n))$ *of* (2.13)–(2.15) *with* $\tilde{p}_0 := \gamma^-\gamma\mathcal{E}(\sigma)$ *and a unique solution* $p \in C(0,T,L^2(\mathbb{R}^n))$ *of* (2.10) *and* (2.12) *with* $p(x,0) = \mathcal{E}(\sigma)\chi_B$*. Their difference* $q := p - \tilde{p}$ *is an element of* $C(0,T,W^1(\mathbb{R}^n))$ *and it is the unique solution of*

$$\ddot{q}(x,t) - \Delta q(x,t) = 0 \qquad \text{in } \mathbb{R}^n, \tag{2.16}$$

$$q(x,0) = q_0(x)\chi_B(x) \qquad \text{in } \mathbb{R}^n, \tag{2.17}$$

$$\dot{q}(x,0) = 0 \qquad \text{in } \mathbb{R}^n, \tag{2.18}$$

with $q_0 = (I - \gamma^-\gamma)\mathcal{E}(\sigma) \in H^1_0(B)$*. Also, the mapping*

$$\mathcal{F}:\ H^1_0(B) \to C(0,T,H^{1/2}(S)), \qquad q_0 \mapsto q|_S, \qquad \textit{where } q \textit{ solves } (2.16)\text{–}(2.18),$$

is continuous and linear.

Proof. This follows from classical results on the wave equation; cf., e.g., Lions and Magenes [18, Chp. 3, Thm. 9.3] for the unique existence of $\tilde{p}, p \in C(0,T,L^2(\mathbb{R}^n))$ and [18, Chp. 3, Thm. 8.2] for the unique existence of a solution $q \in C(0,T,W^1(\mathbb{R}^n))$ of (2.16)–(2.18). □

3. Inverse problems of ImpACT.

In the last section we saw that, using the known boundary values of the conductivity $\sigma|_S$, the measured surface currents $\sigma(x)\partial_\nu u(x)|_S$, and the applied voltage $f(x)$, we can calculate $\gamma\mathcal{E}(\sigma) = \sigma|\nabla u|^2|_S$ and thus the *modified pressure measurements* $q|_S$ from the real measurement data. The dependence of $q|_S$ from the unknown conductivity σ is given by

$$q|_S = \mathcal{F}(I - \gamma^-\gamma)\mathcal{E}(\sigma).$$

Hence, the inverse problems of determining the conductivity from the measurements leads to the problems of inverting the two linear operators $\mathcal{F}$, $(I - \gamma^-\gamma)$ and the nonlinear operator $\mathcal{E}$. Since $\gamma\mathcal{E}(\sigma)$ is known, the inversion of $(I - \gamma^-\gamma)$ consists simply of adding $\gamma^-\gamma\mathcal{E}(\sigma)$. It therefore remains to invert $\mathcal{F}$, i.e., to determine the initial value of a pressure wave from its trace on S, and to invert $\mathcal{E}$, i.e., to determine the conductivity of a body from its electrical energy density.

3.1. Determining the initial condition of the pressure wave.

Recall that $\mathcal{F}:\ H^1_0(B) \to C(0,T,H^{1/2}(S))$ maps the initial value $q_0 \in H^1_0$ to the boundary values $q|_S$, where $q \in C(0,T,H^1(\mathbb{R}^n))$ solves

$$\begin{aligned} \ddot{q}(x,t) - \Delta q(x,t) &= 0 && \text{in } \mathbb{R}^n,\\ q(x,0) &= q_0(x)\chi_B(x) && \text{in } \mathbb{R}^n,\\ \dot{q}(x,0) &= 0 && \text{in } \mathbb{R}^n. \end{aligned}$$

The inverse problem of determining q_0 from $q|_S$ has been studied to some extent in the context of thermoacoustical tomography. We will use a conceptionally simple time-reversal algorithm that is also mentioned in the work of Finch, Patch, and Rakesh [8, Thm. 5] and for which Burgholzer et al. show numerical results in the recent work [6]. Assume that $T > \operatorname{diam}(B)$; then in the case of three spatial dimensions, the pressure wave q will have completely left the body B, so that $q(x,T)|_B = 0$ and $\dot{q}(x,T)|_B = 0$. Thus the time-reversed pressure wave $r(x,t) := q(x,T-t)|_B$ solves the initial boundary value problem

$$\ddot{r}(x,t) - \Delta r(x,t) = 0 \quad \text{in } B, \tag{3.1}$$

$$r(x,t)|_S = g \quad \text{on } S, \tag{3.2}$$

$$r(x,0) = 0 \quad \text{in } B, \tag{3.3}$$

$$\dot{r}(x,0) = 0 \quad \text{in } B, \tag{3.4}$$

where the boundary data $g = q(x,T-t)|_S$ are just the time-reversed measurements.

Lemma 3.1. *For every $g \in C(0,T,H^{1/2}(S))$, there exists a unique solution $r \in C(0,T,L^2(B))$ to* (3.1)–(3.4).

Proof. Under the weaker assumption that $g \in L^2(0,T,L^2(S))$, this was shown by Lasiecka, Lions, and Triggiani in [15, Thm. 2.3]. □

Since $q(x,T-t)$ solves (3.1)–(3.4), the initial condition $q(x,0)|_B = r(x,T)$ can thus be reconstructed from $q(x,t)|_S$ by solving (3.1)–(3.4) with $g = q(x,T-t)|_S$. Physically this can be interpreted as a combination of a time-reversal of waves and the restriction to a bounded domain.

In the case of two spatial dimensions, the wave does not leave the body completely; thus the solution of (3.1)–(3.4) will not completely agree with $q(x,T-t)$. However, if T is chosen large enough, then only a small part of the wave will still be in B, so that one can expect that the above method will still yield a good approximation to $q(x,0)$.

3.2. Determining the conductivity from the electrical energy. We now turn to the determination of the conductivity from the electrical energy, i.e., to the inversion of the nonlinear mapping

$$\mathcal{E}: \ W_+^{1,\infty}(B) \to H^1(B), \qquad \sigma \mapsto \sigma(x)|\nabla u(x)|^2,$$

where u solves

$$\nabla \cdot \sigma \nabla u(x) = 0 \quad \text{in } B, \quad \text{and} \quad u|_S = f.$$

(Note we keep the applied voltage f fixed throughout this work.)

In [1], Ammari et al. reformulate this problem using the 0-Laplacian and propose an iterative reconstruction strategy that relies on the measurement of two different current patterns. We derive here a similar iterative scheme that is based on a formal Newton algorithm. Denote by u_σ the solution of

$$\nabla \cdot \sigma \nabla u = 0, \qquad u|_S = f.$$

It is well known (and easily shown) that (for $\operatorname{supp} \tau \subset B$) the directional derivative

$$v_\tau := \lim_{h \to 0} \frac{u_{\sigma + h\tau} - u_\sigma}{h}$$

is the solution of

$$\nabla \cdot \sigma \nabla v_\tau = -\nabla \cdot \tau \nabla u_\sigma, \qquad v|_S = 0. \tag{3.5}$$

It follows immediately that

$$\mathcal{E}'(\sigma)\tau = \tau |\nabla u_\sigma|^2 + 2\sigma \nabla u_\sigma \cdot \nabla v_\tau.$$

If $\hat{E} = \hat{\sigma}(x)|\nabla u_{\hat{\sigma}}(x)|^2$ is the reconstructed energy density and σ_n is an approximation to the true conductivity $\hat{\sigma}$, then a Newton-step would consist of solving

$$\mathcal{E}'(\sigma_n)\delta = \hat{E} - \sigma_n |\nabla u_{\sigma_n}(x)|^2$$

and the update $\sigma_{n+1} = \sigma_n + \delta$.

To get around the computationally expensive inversion of $\mathcal{E}'(\sigma)$, we can split it into two parts,

$$\mathcal{E}'(\sigma)\tau = (M_\sigma + P_\sigma)\tau,$$

with

$$M_\sigma \tau := \tau |\nabla u_\sigma|^2 \quad \text{and} \quad P_\sigma \tau := 2\sigma \nabla u_\sigma \cdot \nabla v_\tau.$$

Apart from the problem that $|\nabla u|$ might be zero, the inversion of the multiplication operator M is computationally easy. Instead of using the exact inverse $(M_\sigma + P_\sigma)^{-1}$, one can use the approximate inverse $(I - M_\sigma^{-1} P_\sigma) M_\sigma^{-1}$, which is justified when $M_\sigma^{-1} P_\sigma$ is small. Notably, this approximation results in the same algorithm that Ammari et al. propose in [1] and that is therein motivated by a 0-Laplacian formulation:

Given $\hat{E}$, f, and σ_n,

- calculate ∇u_{σ_n},
- set $\tau := \frac{\hat{E}}{|\nabla u_\sigma|^2} - \sigma_n$,
- calculate the solution v_τ of (3.5),
- update $\sigma_{n+1} := \frac{\hat{E} - 2\sigma \nabla u_\sigma \cdot \nabla v_\tau}{|\nabla u_\sigma|^2}$.

4. Numerical examples. We have tested our inversion algorithm on simulated two-dimensional data. The left side of Figure 4.1 shows the exact conductivity distribution σ that we chose as our test example. A background conductivity of 1 is distorted by two discs centered at $(-0.4, -0.15)$ and $(0.4, 0.15)$ in which the conductivity is given by

$$1 + A_j \exp(R_j^{-1} - (R_j^2 - \rho_j^2)^{-1/2}), \quad j = 1, 2,$$

where $R_1 = R_2 = 0.3$ are the radii of the two discs, ρ_j is the respective distance to the center of the jth disc, and $A_1 = 2$, $A_2 = 0.5$, so that the conductivity is smoothly raised to 3, respectively, lowered to 0.5, inside the discs.

Using the commercial finite element software Comsol, we calculated the corresponding electrical energy $\mathcal{E}(\sigma)$ and evaluated it using linear interpolation on the part of an equidistant 200×200 grid on $[-1, 1]^2$ that belongs to the unit circle. $\mathcal{E}(\sigma)$ is shown on the right side of Figure 4.1.

As the continuous right inverse γ^- of the trace operator we take the solution operator for the Dirichlet operator for the Laplace equation, which is implemented by expanding $\gamma\mathcal{E}(\sigma)$ into the L^2-orthonormal functions

$$\left\{ \frac{1}{\sqrt{2\pi}}, \frac{1}{\sqrt{\pi}} \sin(m\varphi), \frac{1}{\sqrt{\pi}} \cos(m\varphi) \;\middle|\; m = 1, \ldots, 100 \right\}$$

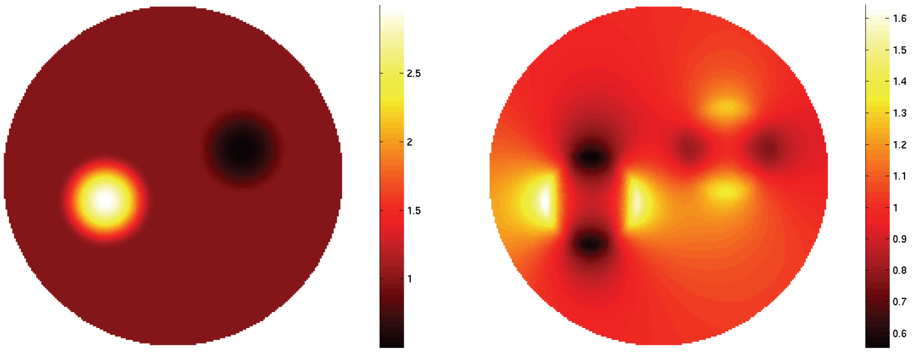

FIG. 4.1. *Exact conductivity and electrical energy distribution.*

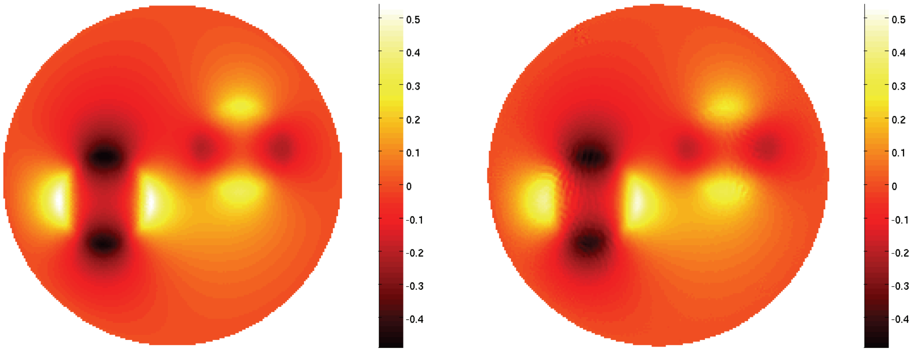

FIG. 4.2. *Exact and reconstructed (modified) energy distribution.*

and using the analytical solutions for the corresponding Dirichlet problems

$$\left\{ \frac{1}{\sqrt{2\pi}}, \frac{1}{\sqrt{\pi}} \sin(m\varphi) r^m, \frac{1}{\sqrt{\pi}} \cos(m\varphi) r^m \;\middle|\; m = 1, \dots, 100 \right\},$$

where (r, φ) denote the polar coordinates. Accordingly, the left side of Figure 4.2 shows the quantity $(I - \gamma^- \gamma)\mathcal{E}(\sigma)$.

The operator $\mathcal{F}$ is simulated by solving the wave equation with a standard central finite difference scheme on a sufficiently large domain. The values of q on the boundary S are then evaluated using linear interpolation on an equidistant grid on S. Thus, simulated (modified) measurements $q|_S$ are obtained.

We then tested our inversion algorithm on these simulated measurements. The Dirichlet problem for the wave equation was solved using the commercial finite element software Comsol. The reconstructed distribution $r(x, T)$, $T = 4$, is then evaluated using linear interpolation on the part of an equidistant 200×200 grid on $[-1, 1]^2$ that belongs to the unit circle. Figure 4.2 compares the exact (modified) energy distribution $q(x, 0) = (I - \gamma^- \gamma)\mathcal{E}(\sigma)$ (on the left side) with the reconstructed distribution $r(x, T)$, $T = 4$ (on the right side). Figure 4.3 shows profiles of the exact (solid black line) and of the reconstructed energy (dashed red line) on the x-axis (left plot) and on a line connecting the peaks of the true conductivity.

The known quantity $\gamma^- \gamma \mathcal{E}(\sigma)$ is then added to $r(x, T)$, and the Newton algorithm described in section 3.2 is used on this data. As an initial guess we used a constant

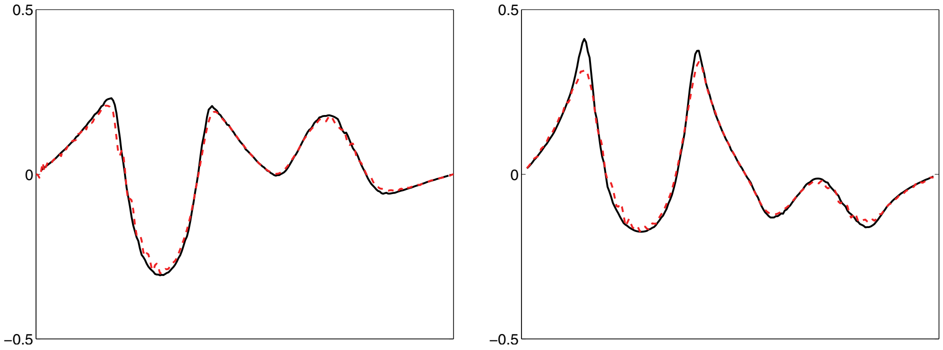

FIG. 4.3. *Profiles of exact and reconstructed (modified) energy.*

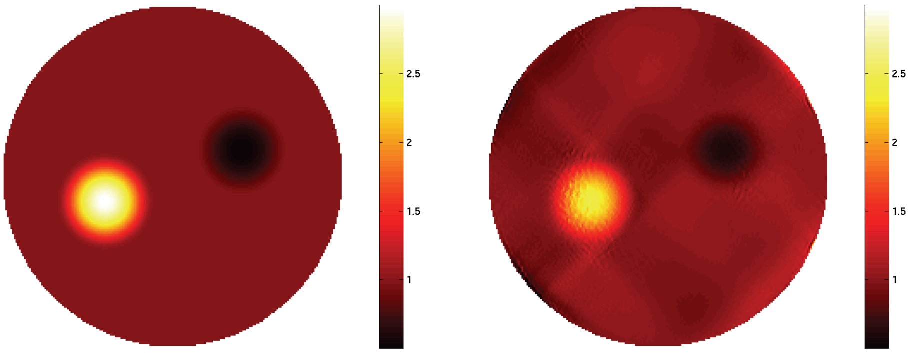

FIG. 4.4. *Exact and reconstructed conductivity distribution.*

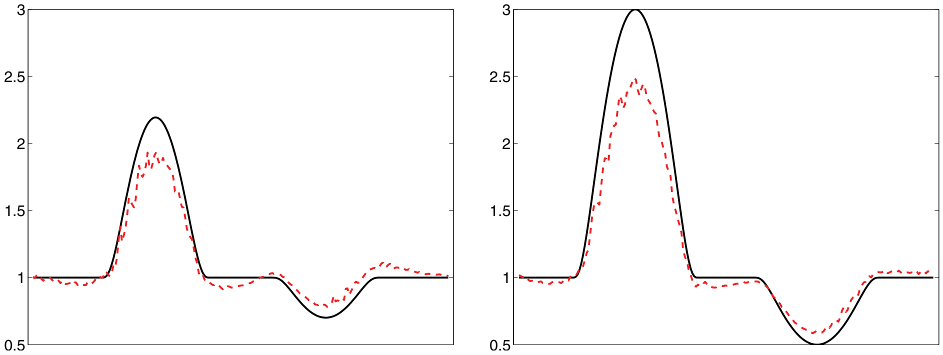

FIG. 4.5. *Profiles of exact and reconstructed conductivity.*

conductivity of 1. The equations appearing in the Newton algorithm were again solved using the commercial finite element software Comsol. Note that thus the same finite element grid is used for the simulation of $\mathcal{E}$ as well as for its inversion. However, the energy is not given, respectively, evaluated, on this grid but on the independent equidistant grid described above, which minimizes the risk of an inverse crime. For the convenience of the reader we show on the left side of Figure 4.4 again the true conductivity to compare it with the best reconstruction that was obtained in the 24th

Newton step (shown on the right side). We observed that the reconstructions do not improve afterward, which seems to be due to accumulated errors. Figure 4.5, which is organized in the same way as Figure 4.3, compares profiles of the true conductivity with the reconstruction.

Acknowledgments. We thank Prof. Dr. Günther Paltauf from the University of Graz for advising us on the practical feasibility of our method and for providing us with information about high frequency surgery. Otmar Scherzer also thanks Richard Kowar from the Infmath Imaging Group of the University of Innsbruck for support with physical quantities.

INCLUSION PAIRS SATISFYING ESHELBY'S UNIFORMITY PROPERTY[*]

HYEONBAE KANG[†], EUNJOO KIM[‡], AND GRAEME W. MILTON[§]

Abstract. Eshelby conjectured that if for a given uniform loading the field inside an inclusion is uniform, then the inclusion must be an ellipse or an ellipsoid. This conjecture has been proved to be true in two and three dimensions provided that the inclusion is simply connected. In this paper we provide an alternative proof of Cherepanov's result that an inclusion with two components can be constructed inside which the field is uniform for any given uniform loading for two-dimensional conductivity or for antiplane elasticity. For planar elasticity, we show that the field inside the inclusion pair is uniform for certain loadings and *not* for others. We also show that the polarization tensor associated with the inclusion pair lies on the lower Hashin–Shtrikman bound, and hence the conjecture of Pólya and Szegö is not true among nonsimply connected inclusions. As a consequence, we construct a simply connected inclusion, which is nothing close to an ellipse, but in which the field is almost uniform.

Key words. Eshelby's conjecture, Pólya–Szegö conjecture, uniformity property, inclusions with multiple components, polarization tensor, Weierstrass zeta function

1. Introduction.

Consider a conducting or elastic inclusion subject to a uniform applied field. For certain shapes of inclusions the field inside the inclusion is also uniform, and if this is the case, we say the inclusion has *Eshelby's uniformity property.* Eshelby showed in [9] that ellipses and ellipsoids have the uniformity property and conjectured in [10] that these are the only inclusions with the uniformity property. See also [15]. This conjecture of Eshelby has been proved to be true within the class of simply connected inclusions by Sendeckyj [28] for planar elasticity and by Ru and Schiavone [26] for antiplane elasticity or, equivalently, for two-dimensional conductivity. Recently, a completely different proof of the Eshelby conjecture in two dimensions based on the hodographic transformation was given by Kang and Milton [18]. In the same paper, Eshelby's conjecture in three dimensions was resolved as well. They showed that if a simply connected inclusion with Lipschitz boundary has the uniformity property, then the inclusion must take the shape of an ellipse or an ellipsoid. Independently, Liu (private communication) also established this. As a consequence of Eshelby's conjecture, the conjecture of Pólya and Szegö [25], which asserts that the domain whose polarization tensor has the minimal trace is a disk or a ball, is also proved [17].

Finding a structure inside which the field is uniform is important in the study of composite materials since such a property is required in order to reduce the internal stress of the structure [31]. In fact, it was proved by Grabovsky and Kohn [12] that

ellipses are the low volume fraction limit of the periodic Vigdergauz microstructure [29, 30], which contains a single inclusion per unit cell. The Vigdergauz microstructure is known to have minimal internal stress among periodic composites. There are also periodic geometries, based on the construction of Hashin [14], that contain a countable number of disks in the unit cell, having Eshelby's uniformity property as follows from section 4 of [6].

In this paper we continue our investigation on the shape of inclusions with the uniformity property. The primary concern of this paper is the construction of inclusions (structures) with two components having smooth boundaries which satisfy Eshelby's uniformity property. This was first solved by Cherepanov [8], and here we provide an alternative proof of Cherepanov's results and give explicit numerical computations of the inclusion shapes.

Another closely related question considered here is whether Eshelby's conjecture is true in a "practical" sense: If the field inside the inclusion is very close to being uniform in some sense, does it follow that the inclusion is very close to an ellipse? (By close to an ellipse we specifically mean that the symmetric difference of the inclusion and an ellipse has small measure.) It is a question of stability.

We construct, in a mathematically rigorous way, inclusions with two components inside which the field is uniform. Figure 2.1 in section 2 shows typical shapes of the inclusion pair. The field inside the inclusion is uniform for any uniform loading in the case of antiplane elasticity, as will be proved in section 3. In the case of linear elasticity, the field is uniform for certain loadings and *not* for other loadings. Using these inclusions, we also answer the question of stability. If we connect two components of the inclusion by a thin bridge, as in Figure 5.1, the field does not change much while the bridged inclusion is simply connected, but far from the shape of an ellipse. In order to construct the structures in this paper, we use the Weierstrass zeta function and the Schwarz–Christoffel formula to solve the free boundary problem. The method of construction in this paper is similar to that of Vigdergauz [29, 30] and Grabovsky and Kohn [12], where the Weierstrass $\mathcal{P}$-function is used to construct the Vigdergauz microstructure.

Eshelby's uniformity property is closely related to the conjecture of Pólya and Szegö on the polarization tensor. In [17] Kang and Milton showed that the polarization tensor satisfies the lower Hashin–Shtrikman bound; then the field inside the inclusion must be uniform, and thus the inclusion is an ellipse provided that it is simply connected. See section 4 for the Hashin–Shtrikman bounds on the polarization tensor. The Pólya–Szegö conjecture follows as an immediate consequence of it. It turns out that the polarization tensor associated with the structure constructed in this paper satisfies the lower Hashin–Shtrikman bound. Therefore, the Pólya–Szegö conjecture does not hold among nonsimply connected inclusions. In the same way as above we are also able to show that stability for the Pólya–Szegö conjecture fails to hold among simply connected inclusions: the bridged inclusion is nothing close to a disk, but the trace of its polarization tensor is very close to being minimal.

This paper is organized as follows: In section 2, we construct inclusions with two components using the Weierstrass zeta function and the Schwarz–Christoffel formula. In section 3, we show that these inclusions enjoy the uniformity property for antiplane elasticity. Section 4 shows that the polarization tensor of the inclusions satisfies the lower Hashin–Shtrikman bound, and hence the Pólya–Szegö conjecture fails to be true among nonsimply connected inclusions. In section 5, we discuss the instability of the uniformity property by connecting the inclusion pair by a thin bridge. In section 6, we analyze the planar elasticity case. We prove that the field inside the inclusion is uniform for certain types of loadings and then show, by numerical computations, that the field is not uniform for some other types of loadings.

2. Construction of the inclusions.

This paper is concerned with a structure consisting of two components, each with a smooth (specifically, Lipschitz) boundary, which satisfy Eshelby's uniformity property in antiplane elasticity or for two-dimensional conductivity. More precisely, we construct an inclusion with two components, B_1 and B_2, such that the solution u to the problem

$$\begin{cases} \nabla \cdot \big(1+(k-1)\chi(B_1\cup B_2)\big)\nabla u = 0 \quad \text{in } \mathbb{R}^2, \\ u(x,y) - a\cdot(x,y) = O(r^{-1}) \quad \text{as } r\to\infty \end{cases} \tag{2.1}$$

is such that ∇u is constant in $B_1\cup B_2$. Here $\chi(B_1\cup B_2)$ is the indicator function of $B_1\cup B_2$, a is a constant vector representing the direction of the uniform loading, and $r=\sqrt{x^2+y^2}$. The conductivity coefficient $1+(k-1)\chi(B_1\cup B_2)$ in (2.1) indicates that the conductivity of the inclusion $B_1\cup B_2$ is $k\neq 1$ while that of the background $\mathbb{R}^2\setminus\overline{B_1\cup B_2}$ is 1. It is worth mentioning that since ∇u is constant (and not 0) in $B_1\cup B_2$, ∂B_1 and ∂B_2 are analytic due to a regularity result of Alessandrini and Isakov [2, Corollary 2.2].

In order to construct such inclusions B_1 and B_2, we will construct a holomorphic function f in $\mathbb{C}\setminus\overline{B_1\cup B_2}$ satisfying

$$f(z) = \Re(cz) + q_j, \quad z\in\partial B_j, \tag{2.2}$$

for some complex constants c and q_j, $j=1,2$, and

$$f(z) = \alpha z + O(1) \quad \text{as } |z|\to\infty \tag{2.3}$$

for some complex number α. Here and afterward, we identify z with $x+iy$. Let us first briefly see why it is enough to construct such a function.

Suppose that there are such simply connected inclusions B_1 and B_2, and let u be the solution to (2.1). Let $u^e := u|_{\mathbb{R}^2\setminus\overline{B_1\cup B_2}}$ and $u^i := u|_{B_1\cup B_2}$. Then there exist holomorphic functions U^e in $\mathbb{C}\setminus\overline{B_1\cup B_2}$ and U^i in $B_1\cup B_2$ such that $\Re U^e = u^e$ and $\Re U^i = u^i$. To see the existence of U^e, it suffices to note that $\int_C \frac{\partial u^e}{\partial\nu}ds = 0$ for any closed piecewise C^1-curve C in $\mathbb{C}\setminus\overline{B_1\cup B_2}$, which can be easily verified using Green's theorem. By (2.1), the solution u satisfies the transmission conditions along the interface ∂B_1 and ∂B_2:

$$u|_+ = u|_- \quad \text{and} \quad \frac{\partial u}{\partial\nu}\Big|_+ = k\frac{\partial u}{\partial\nu}\Big|_- \quad \text{on } \partial B_j,\ j=1,2, \tag{2.4}$$

where the subscripts + and − denote the limits from outside and inside ∂B_j, respectively. It then follows from the Cauchy–Riemann equation that

$$\frac{k+1}{2}U^i - \frac{k-1}{2}\overline{U^i} = U^e + i\lambda_j \quad \text{on } \partial B_j,\ j=1,2, \tag{2.5}$$

for some real constant λ_j. See [16]. Since u^i is linear in each B_j, so is U^i, say,

$$U^i(z) = b_j z + d_j, \quad z\in B_j,\ j=1,2.$$

The constancy of ∇u in $B_1 \cup B_2$ implies $b_1 = b_2 (= b)$. Then (2.5) takes the form

$$\frac{k+1}{2}(bz + d_j) - \frac{k-1}{2}(\overline{bz} + \overline{d}_j) = U^e(z) + i\lambda_j \quad \text{on } \partial B_j, \ j = 1, 2. \tag{2.6}$$

If we put

$$f(z) = U^e(z) - kbz, \tag{2.7}$$

then f is holomorphic in $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ and satisfies (2.2) and (2.3). By reversing the previous arguments we see that if B_1 and B_2 admit a holomorphic function satisfying (2.2) and (2.3), then $B_1 \cup B_2$ has the uniformity property.

For the rest of this section we deal with the problem of constructing two inclusions B_1 and B_2 which admit a function f holomorphic in $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ satisfying (2.2) and (2.3). It turns out that this problem was solved by Cherepanov [8] in a more general setting. Cherepanov showed that there are inclusions with an arbitrary number of components which admit a holomorphic function (outside the inclusion) satisfying (2.2) and (2.3), and then constructed such inclusions with single and double components. The construction of this paper is different from that of [8], and it is more elementary using the explicit formula of the Weierstrass zeta function and the Schwarz–Christoffel formula.

Suppose that f is a holomorphic function in $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ satisfying (2.2) and (2.3). Since such an f maps $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ onto the complex plane with two slits, it is natural to construct an appropriate holomorphic function G on the complex plane with two slits and then define f as the hodographic transform (or the inverse) of G. The use of hodographic transforms is a well-known technique for solving free boundary problems.

Let $0 < a < b$ be two fixed real constants and consider the complex plane with two slits $[-b, -a]$ and $[a, b]$. We first construct a holomorphic function F so that its real parts are constant on each slit while its imaginary part vanishes on the other parts of the real axis. Once we construct such a function F, then the desired function G will be defined as $G(z) = F(z) + \alpha z$ for some real constant α, as we shall see later. For the construction of F, we make use of the Weierstrass zeta function and the Schwarz–Christoffel formula.

For given positive real numbers c and d, let $t_1 = 2c$ and $t_2 = i2d$. Then the Weierstrass zeta function $\zeta(w)$ is defined by

$$\zeta(w) := \frac{1}{w} + \sum_{t \neq 0} \left(\frac{1}{w-t} + \frac{1}{t} + \frac{w}{t^2} \right), \tag{2.8}$$

where the sum is over all $t = n_1 t_1 + n_2 t_2$ with integers n_1 and n_2 not both zero. The function ζ has the periodicity properties

$$\zeta(w + t_1) = \zeta(w) + \eta_1, \quad \zeta(w + t_2) = \zeta(w) + i\eta_2, \tag{2.9}$$

where η_1 and η_2 are constants satisfying

$$d\eta_1 - c\eta_2 = \pi. \tag{2.10}$$

See [1]. For each $t = n_1 t_1 + n_2 t_2$, its conjugate $\bar{t} = n_1 t_1 - n_2 t_2$ is on the same lattice of points as t lies on. Thus one can easily see that

$$\overline{\zeta(\bar{w})} = \zeta(w), \tag{2.11}$$

and hence $\zeta(w)$ is real when w is real. We also have

$$\overline{\zeta(-\bar{w})} = -\zeta(w), \tag{2.12}$$

from which it follows that $\zeta(w)$ is purely imaginary when w is purely imaginary. It then follows from (2.9) that η_1 and η_2 are real.

Note that by (2.11)

$$\overline{\zeta(\bar{w} - 2id)} = \overline{\zeta(\overline{w + t_2})} = \zeta(w) + i\eta_2, \tag{2.13}$$

and hence

$$\zeta(w) - \overline{\zeta(\bar{w} - 2id)} = -i\eta_2. \tag{2.14}$$

Thus we deduce that if $w = u - id$ with u real, then

$$\Im\zeta(u - id) = -\frac{\eta_2}{2}. \tag{2.15}$$

Similarly, using the first identity in (2.9) and (2.12), one can see that if $w = -c + iv$ with v real, then

$$\Re\zeta(-c + iv) = -\frac{\eta_1}{2}, \tag{2.16}$$

and if $w = c + iv$ with v real, then

$$\Re\zeta(c + iv) = \frac{\eta_1}{2}. \tag{2.17}$$

We will also need the following lemma.

Lemma 2.1. *When $d > c$ the following inequality holds:*

$$\Im\zeta(\pm c + iv) \geq \frac{\eta_2}{2d}v, \quad -d < v < 0. \tag{2.18}$$

Proof. Note first that $\Im\zeta(-c + iv) = \Im\zeta(c + iv)$ because of the first identity in (2.9). By scaling we may assume that $2c = 1$. Put $2d = \tau$ to shorten notation, and note that $\tau > 1$. Let

$$h(v) := \Im\zeta(c + iv) - \frac{\eta_2}{2d}v, \quad -\frac{\tau}{2} < v < 0.$$

Since $h(0) = h(-\frac{\tau}{2}) = 0$, it suffices to show that h is concave in $(-\frac{\tau}{2}, 0)$. Observe that

$$h''(v) = -2\Im \sum_{n_1,n_2} \frac{1}{(\frac{1}{2} + i(v - n_2\tau) - n_1)^3}.$$

From the well-known identity (see [1])

$$\sum_{m=-\infty}^{\infty} \frac{1}{(z - m)^2} = \frac{\pi^2}{\sin^2 \pi z},$$

we have

$$\sum_{m=-\infty}^{\infty} \frac{1}{(z - m)^3} = \frac{\pi^3 \cos \pi z}{\sin^3 \pi z}.$$

Therefore, we get

$$\begin{aligned}
h''(v) &= -2\pi^3 \Im \sum_{n_2=-\infty}^{\infty} \frac{\cos\pi\left(\frac{1}{2}+i(v-n_2\tau)\right)}{\sin^3\pi\left(\frac{1}{2}+i(v-n_2\tau)\right)} \\
&= 2\pi^3 \sum_{n=-\infty}^{\infty} \frac{\sinh\pi(v-n\tau)}{\cosh^3\pi(v-n\tau)} \\
&= 2\pi^3 \frac{\sinh\pi v}{\cosh^3\pi v} \\
&\quad + 2\pi^3 \sum_{n=1}^{\infty} \frac{\sinh\pi(v-n\tau)\cosh^3\pi(v+n\tau)+\sinh\pi(v+n\tau)\cosh^3\pi(v-n\tau)}{\cosh^3\pi(v-n\tau)\cosh^3\pi(v+n\tau)}.
\end{aligned}$$

Straightforward but tedious computation yields

$$\begin{aligned}
&\sinh\pi(v-n\tau)\cosh^3\pi(v+n\tau)+\sinh\pi(v+n\tau)\cosh^3\pi(v-n\tau) \\
&= \frac{1}{2}\sinh 2\pi v\left[2+\cosh 2\pi v\cosh 2\pi n\tau-\cosh^2 2\pi n\tau\right],
\end{aligned}$$

and hence

$$h''(v) = 8\pi^3\sinh\pi v\left[\frac{1}{4\cosh^3\pi v}+\sum_{n=1}^{\infty}\frac{2+\cosh 2\pi v\cosh 2\pi n\tau-\cosh^2 2\pi n\tau}{\left(\cosh 2\pi v+\cosh 2\pi n\tau\right)^3}\right].$$

Since $v<0$, it is now enough to show that the quantity inside the bracket, which we call $I(v)$, is positive. Indeed, we have

$$I(v) > \frac{1}{4\cosh^3\pi v}-\sum_{n=1}^{\infty}\frac{1}{\cosh 2\pi v+\cosh 2\pi n\tau}.$$

Since $-\frac{\tau}{2}<v<0$ and $\tau>1$, we now have

$$\begin{aligned}
I(v) &> \frac{1}{4\cosh^3\frac{\pi\tau}{2}}-2\sum_{n=1}^{\infty}e^{-2\pi n\tau} \\
&= \frac{1}{4\cosh^3\frac{\pi\tau}{2}}-\frac{2}{1-e^{-2\pi\tau}}e^{-2\pi\tau} \\
&= 2\left[\left(e^{-\frac{1}{6}\pi\tau}+e^{-\frac{7}{6}\pi\tau}\right)^{-3}-\frac{1}{1-e^{-2\pi\tau}}\right]e^{-2\pi\tau} \\
&> 2\left[\left(e^{-\frac{1}{6}\pi}+e^{-\frac{7}{6}\pi}\right)^{-3}-\frac{1}{1-e^{-2\pi}}\right]e^{-2\pi\tau}>0.
\end{aligned}$$

This completes the proof. We remark that the inequality is proved not only when $d>c$, but also when τ is such that the second to last line in the above chain of inequalities is positive. □

For a positive real number β, define h by

$$h(w) := \beta\left(\zeta(w-id)-\frac{\eta_2}{2d}w+i\frac{\eta_2}{2}\right). \tag{2.19}$$

Then h is a meromorphic function with poles at $2n_1c+2in_2d+id$ and satisfies

$$\begin{cases}
\Re h(-c+iv) = -\beta c_0, \\
\Re h(c+iv) = \beta c_0, \\
\Im h(u) = 0, \\
\Im h(u+id) = 0
\end{cases} \tag{2.20}$$

for u and v real, where

$$c_0 = \frac{\eta_1}{2} - \frac{c\eta_2}{2d} = \frac{\pi}{2d} \tag{2.21}$$

because of (2.10). Since $\beta > 0$, we also have from (2.18)

$$\Im h(\pm c + iy) > 0, \quad 0 < y < d, \quad \text{when } d > c. \tag{2.22}$$

Since $\zeta(w) = \frac{1}{w} + O(1)$ as $w \to 0$, we have

$$h(w) = \frac{\beta}{w - id} + O(1) \quad \text{as } w \to id. \tag{2.23}$$

Restricting our attention to the rectangle $R = \{z = x + iy \mid -c < x < c,\ 0 < y < d\}$, we now construct a conformal mapping from the upper half of the complex plane onto R. To this end, it is natural to use the Schwarz–Christoffel formula.

For $b > a > 0$, let

$$\begin{aligned} g(z) :&= (z^2 - a^2)^{-1/2}(z^2 - b^2)^{-1/2} \\ &= (z + b)^{-1/2}(z + a)^{-1/2}(z - a)^{-1/2}(z - b)^{-1/2}, \end{aligned}$$

and define for z in the upper half plane

$$w = \Phi(z) := -\int_0^z g(\xi) d\xi. \tag{2.24}$$

The mapping Φ maps the upper half plane onto the rectangle $R = \{z = x + iy \mid -c < x < c,\ 0 < y < d\}$, where

$$c = \int_0^a \frac{dx}{\sqrt{(a^2 - x^2)(b^2 - x^2)}} \quad \text{and} \quad d = \int_a^b \frac{dx}{\sqrt{(x^2 - a^2)(b^2 - x^2)}}\ . \tag{2.25}$$

Note that the intervals $[-b, -a]$ and $[a, b]$ on the real axis get mapped onto the vertical sides $\{-c + iy \mid 0 \le y \le d\}$ and $\{c + iy \mid 0 \le y \le d\}$ of R, $[-a, a]$ onto the bottom of R, and $(-\infty, -b) \cup (b, \infty)$ into the top of R. The point ∞ is mapped to $w = id$, and

$$\Phi(z) = id + O\left(\frac{1}{|z|}\right) \quad \text{as } |z| \to \infty. \tag{2.26}$$

To see this, we have

$$\begin{aligned} \Phi(z) &= -\int_0^z g(\xi) d\xi = -\int_0^\infty g(\xi) d\xi + \int_z^\infty g(\xi) d\xi \\ &= id + \int_z^\infty g(\xi) d\xi = id + \int_z^\infty O(|\xi|^{-2}) d\xi \\ &= id + O(|z|^{-1}) \end{aligned}$$

as $|z| \to \infty$.

We now define F in the upper half of $\mathbb{C}$ by

$$F(z) := (h \circ \Phi)(z), \tag{2.27}$$

where Φ is defined by (2.24). It then follows from (2.20) that

$$\begin{cases} \Re F(x+i0) = -\beta c_0, & x \in (-b,-a), \\ \Re F(x+i0) = \beta c_0, & x \in (a,b), \\ \Im F(x+i0) = 0, & x \in (-\infty,-b) \cup (b,\infty) \cup (-a,a), \end{cases} \tag{2.28}$$

and from (2.22) that

$$\Im F(x+i0) \geq 0, \quad x \in (-b,-a) \cup (a,b). \tag{2.29}$$

It also follows from (2.23) and (2.26) that

$$F(z) = \beta z + O(1) \quad \text{as } |z| \to \infty. \tag{2.30}$$

Because of (2.28), F has an obvious extension as a holomorphic function in $\mathbb{C} \setminus ([-b,-a] \cup [a,b])$ satisfying

$$\overline{F(\overline{z})} = F(z). \tag{2.31}$$

For a positive real number α, define G by

$$G(z) := F(z) + \alpha z, \tag{2.32}$$

and then define curves C_j^+, $j = 1,2$, by

$$C_1^+ := \left\{ \lim_{y \to 0+} G(x+iy) \mid -b \leq x \leq -a \right\}, \tag{2.33}$$

$$C_2^+ := \left\{ \lim_{y \to 0+} G(x+iy) \mid a \leq x \leq b \right\}. \tag{2.34}$$

Observe from (2.29) that, at least when $d > c$ and $\beta > 0$, the curves C_j^+ (except the endpoints) lie in the upper half plane and their endpoints lie on the real axis. In fact, the endpoints of C_1^+ are

$$G(-b) = -\beta \frac{\pi}{2d} - \alpha b \quad \text{and} \quad G(-a) = -\beta \frac{\pi}{2d} - \alpha a, \tag{2.35}$$

and those of C_2^+ are

$$G(a) = \beta \frac{\pi}{2d} + \alpha a \quad \text{and} \quad G(b) = \beta \frac{\pi}{2d} + \alpha b. \tag{2.36}$$

The positivity of α is necessary to ensure that $G(b) > G(a)$. We now define C_j^- to be the reflection of C_j^+ about the real axis, i.e.,

$$C_j^- := \{ \overline{z} \mid z \in C_j^+ \}, \quad j = 1,2. \tag{2.37}$$

Assuming $d > c$, we then define the domain B_j to be the domain whose boundary is $C_j^\pm$ for $j = 1,2$. These domains are determined by the choice of the four parameters a, b, α, and β. However if we replace a,b by $k_1 a, k_1 b$, then the corresponding inclusions are just rescaled by the factor k_1. The reason is as follows.

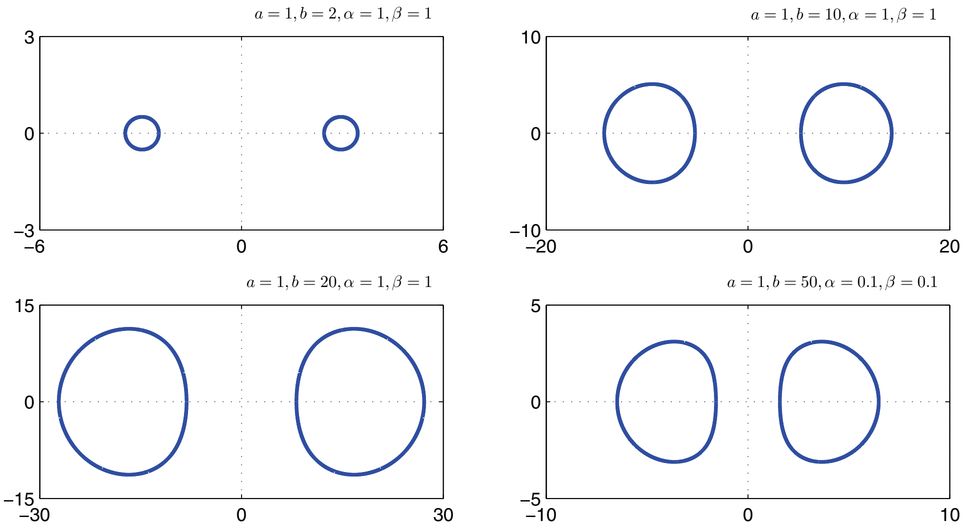

FIG. 2.1. *The typical shapes of inclusions. The scales for the figures are different. In the bottom right figure $\alpha = \beta = 0.1$, and the figure for $\alpha = \beta = 1$ is a similar one magnified ten times. In all figures, $c < d$.*

Let h_1, Φ_1, F_1, and G_1 be the functions defined by (2.19), (2.24), (2.27), (2.32), corresponding to $k_1 a, k_1 b$. Let h_0, etc., be those functions corresponding to a, b. Then we can see the following relations easily:

$$h_1(w) = k_1 h_0(k_1 w),$$
$$\Phi_1(z) = \frac{1}{k_1}\Phi_0\left(\frac{z}{k_1}\right).$$

Therefore, we have

$$G_1(z) = k_1 G_0\left(\frac{z}{k_1}\right).$$

This relation shows that the image of $[k_1 a, k_2 b]$ under G_1 is $k_1 C_2^+$, where C_2^+ is the image of $[a, b]$ under G_0 as given in (2.34).

If we replace α, β by $k_2\alpha, k_2\beta$, then the corresponding inclusions are just rescaled by k_2. This is more obvious. Thus without loss of generality one can choose $\alpha = \beta = 1$. If we just replace α by $k_3\alpha$, one can check that (2.28) implies that the boundary of each inclusion undergoes a linear stretching in the x-direction by a factor of k_3 (which is not in proportion to the change in the distance $2G(a)$ separating the inclusion pair). Thus, among all variations of the four parameters, changing only the ratio a/b leads to a nontrivial change in the inclusion shape. Figure 2.1 shows the shapes of B_1 and B_2, which are obtained numerically for various ratios a/b. Figure 2.2 shows a shape when $c > d$.

The following proposition shows that the inclusion constructed above enjoys the desired property.

PROPOSITION 2.2. *Let $B = B_1 \cup B_2$ be the inclusion constructed above. Then*

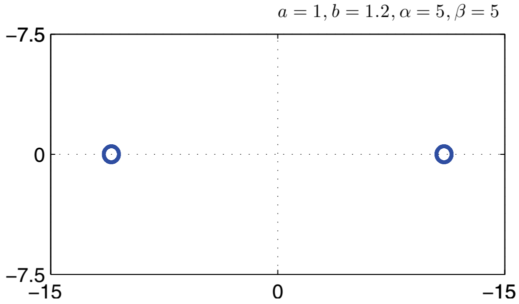

FIG. 2.2. *A shape when $c < d$. In this figure, $c = 1.7227$ and $d = 1.4310$.*

there is f holomorphic in $\mathbb{C} \setminus \overline{B}$ satisfying

$$f(z) = z + O(|z|^{-1}) \quad \textit{as } |z| \to \infty \tag{2.38}$$

and

$$f(z) = px + q_1 \quad \textit{for } z = x + iy \in \partial B_1, \tag{2.39}$$

$$f(z) = px + q_2 \quad \textit{for } z = x + iy \in \partial B_2, \tag{2.40}$$

for some real constant p and complex constants q_1 and q_2.

Proof. One can see from (2.33) and (2.34) that G is a homeomorphism from $[-b, -a] \cup [a, b]$ onto $C_1^+ \cup C_2^+$. One can also see that G is monotonically increasing on $(-\infty, -b]$, $[-a, a]$, and $[b, +\infty)$. Thus G is a homeomorphism from $\partial\Pi^+$ onto $\partial(\Pi^+ \setminus \overline{B_1 \cup B_2})$, where Π^+ is the complex upper half plane. Let φ and ψ be the conformal mappings from the unit disc Δ onto Π^+ and $\Pi^+ \setminus \overline{B_1 \cup B_2}$, respectively. Then $\psi^{-1} \circ G \circ \varphi : \Delta \to \Delta$ is holomorphic and a homeomorphism on $\partial\Delta$. Thus by Rado's theorem [27, p. 4], $\psi^{-1} \circ G \circ \varphi : \Delta \to \Delta$ is conformal, and hence univalent. Therefore, $G : \Pi^+ \to \Pi^+ \setminus \overline{B_1 \cup B_2}$ is univalent. Since $G(\bar{z}) = \overline{G(z)}$ and C_j^+ lies on the upper half plane, we conclude that G is univalent from $\mathbb{C} \setminus ([-b, -a] \cup [a, b])$ onto $\mathbb{C} \setminus \overline{B_1 \cup B_2}$. We emphasize that in order for G to be univalent, the upper part of ∂B_j, C_j^+ should lie on the upper half plane, as we proved before under the assumption that $d > c$. When $c < d$, the mapping G can sometimes be univalent and thus lead to other inclusion shapes, but we do not explore this possibility here.

Since G is univalent, G^{-1} is holomorphic in $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ and satisfies

$$G^{-1}(z) = \frac{1}{\alpha + \beta} z + O(1) \quad \text{as } |z| \to \infty, \tag{2.41}$$

and

$$G^{-1}(z) = \frac{1}{\alpha} x + \frac{\beta d}{2\pi\alpha} \quad \text{for } z = x + iy \in \partial B_1, \tag{2.42}$$

$$G^{-1}(z) = \frac{1}{\alpha} x - \frac{\beta d}{2\pi\alpha} \quad \text{for } z = x + iy \in \partial B_2. \tag{2.43}$$

Let

$$f(z) := (\alpha + \beta)[G^{-1}(z) - \gamma], \tag{2.44}$$

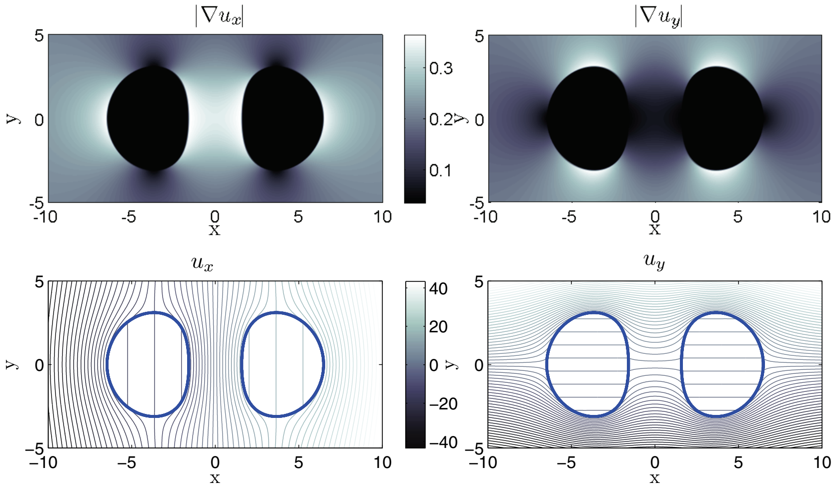

Fig. 3.1. *u_x and u_y are solutions corresponding to the $\mathbf{e}_1$ and $\mathbf{e}_2$ fields, respectively. The top figures are $|\nabla u_x|$ and $|\nabla u_y|$, and the bottom figures are equipotential lines of u_x and u_y.*

where γ is chosen so that f satisfies (2.38). By putting

$$p = \frac{\alpha+\beta}{\alpha}, \quad q_1 = (\alpha+\beta)\left[\frac{\beta d}{2\pi\alpha} - \gamma\right], \quad q_2 = (\alpha+\beta)\left[-\frac{\beta d}{2\pi\alpha} - \gamma\right], \tag{2.45}$$

we have (2.39) and (2.40). This completes the proof. □

We note that the most important property of f is that

$$\overline{-\frac{p}{2}z + f(z)} = \frac{p}{2}z + \overline{q_j} \quad \text{on } \partial B_j, \tag{2.46}$$

so that the function on the left-hand side of this equation, which is antiholomorphic outside the inclusion, can be extended inside B_j as a linear holomorphic function.

3. The uniformity property for antiplane elasticity.

We now show that the inclusions B_1 and B_2 have the uniformity property for antiplane elasticity (or for two-dimensional conductivity): For any uniform loading the field inside the inclusions is uniform. Before proving this, it may be helpful to the reader to refer to Figure 3.1, which clearly exhibits the uniformity property. This figure was obtained by solving (2.1) numerically using the boundary integral method.

We now prove the following theorem, which is a precise statement of the uniformity property for two-dimensional conductivity.

Theorem 3.1. *Let $B = B_1 \cup B_2$ be the inclusion constructed in section 2 with $\alpha > 0$ and $\beta > 0$. Let $k \neq 1$. For each nonzero constant vector a, let u be the solution to (2.1). Then ∇u is constant in B.*

Proof. Define U^e and U^i by

$$U^e(z) := \left(k + \frac{1-k}{p}\right)^{-1}\left(kz + \frac{1-k}{p}f(z)\right), \quad z \in \mathbb{C} \setminus \overline{B_1 \cup B_2}, \tag{3.1}$$

$$U^i(z) := \left(k + \frac{1-k}{p}\right)^{-1}(z + c_j), \quad z \in B_j, \ j = 1, 2, \tag{3.2}$$

where f is defined by (2.44). Choosing the complex constants c_j for $j = 1, 2$ properly, one can easily see that U^e and U^i satisfy (2.5) and $U^e(z) = z + O(|z|^{-1})$ as $|z| \to \infty$. Let $u := \Re U^e$ in $\mathbb{R}^2 \setminus \overline{B_1 \cup B_2}$ and $u := \Re U^i$ in $B_1 \cup B_2$. Then u satisfies (2.4), and hence u is the solution to (2.1) with $a = (1, 0)$. Note that we have

$$\nabla u = \frac{\alpha + \beta}{\alpha + k\beta} \mathbf{e}_1 \quad \text{in } B_j, \ j = 1, 2, \tag{3.3}$$

where $\mathbf{e}_1 = (1, 0)$. Thus for the uniform loading $\mathbf{e}_1 = (1, 0)$, the field inside B_1 and B_2 is given by (3.3).

One can show that the field inside the inclusion due to the loading $\mathbf{e}_2 = (0, 1)$ is also uniform using Keller's duality argument [19]. In fact, for a given $k \neq 1$, let $k_0 = 1/k$ and let u_0 be the solution to (2.1) with $a = \mathbf{e}_1$ and k replaced with k_0. Let v^e be the harmonic conjugate of u_0 in $\mathbb{C} \setminus \overline{B_1 \cup B_2}$ so that

$$v^e(x, y) - y = O(r^{-1}) \quad \text{as } r \to \infty. \tag{3.4}$$

The existence of such a harmonic conjugate is proved in [5]. Let v^i be the harmonic conjugate of u_0 in $B_1 \cup B_2$. Define w by

$$w(x, y) = \begin{cases} v^e(x, y), & (x, y) \in \mathbb{R}^2 \setminus \overline{B_1 \cup B_2}, \\ k_0 v^i(x, y) + C, & (x, y) \in B_1 \cup B_2, \end{cases} \tag{3.5}$$

where the constant C is chosen so that w is continuous across ∂B_j, $j = 1, 2$. Then using the Cauchy–Riemann equations one can show (see [5]) that w is the solution to (2.1) with $a = (0, 1)$. We also have from (3.3) and the Cauchy–Riemann equation that

$$\nabla w = \frac{\alpha + \beta}{k\alpha + \beta} \mathbf{e}_2 \quad \text{in } B_j, \ j = 1, 2. \tag{3.6}$$

This completes the proof. □

So far we have shown that the inclusions $B := B_1 \cup B_2$ have the uniformity property for the antiplane elasticity model: Given the applied field $\mathbf{e}_1$, the field inside B is uniform and given by $\frac{\alpha+\beta}{\alpha+k\beta}\mathbf{e}_1$, and for the applied field $\mathbf{e}_2$, the field inside B is uniform and given by $\frac{\alpha+\beta}{k\alpha+\beta}\mathbf{e}_2$.

4. Polarization tensors: Polyá–Szegö conjecture. In this section we compute the polarization tensor associated with $B = B_1 \cup B_2$ and show that the Polyá–Szegö conjecture fails to be true among inclusions with multiple components. To explain the polarization tensor associated with the inclusion B consisting of m components $B_1, \ldots, B_m$, we consider the following problem: For a vector $\xi \in \mathbb{R}^2$,

$$\begin{cases} \nabla \cdot \big(1 + (k-1)\chi(B)\big)\nabla u = 0 \quad \text{in } \mathbb{R}^2, \\ u(x, y) - \xi \cdot (x, y) = O(r^{-1}) \quad \text{as } r \to \infty. \end{cases} \tag{4.1}$$

The solution u to (4.1) admits the asymptotic expansion

$$u(x, y) = \xi \cdot (x, y) + \frac{1}{2\pi} \xi \cdot M \frac{(x, y)^T}{r^2} + O(r^{-2}) \quad \text{as } r \to \infty \tag{4.2}$$

for some 2×2 matrix M. This matrix $M = M(B)$ is the polarization tensor associated with B. It should be noted that the polarization tensor associated with the inclusion consisting of multiple components $B_1, \dots, B_m$ is not the sum or a combination of the polarization tensors of individual inclusions. It incorporates the interactions among components.

It is known that the eigenvalues of the polarization tensor must be confined within the so-called Hashin–Shtrikman bounds [21, 7] (see also [20, 23]):

$$\mathrm{Tr}(M) \leq (k-1)\left(1+\frac{1}{k}\right)|B| \tag{4.3}$$

and

$$\mathrm{Tr}(M^{-1}) \leq \frac{1+k}{(k-1)|B|}, \tag{4.4}$$

where Tr denotes the trace and $|B|$ is the area of B. If M has minimal trace, then M satisfies (4.4) and M is diagonal. These bounds are known to be optimal in the sense that all the points inside the bound, except the upper bound, are realized as the pair of eigenvalues of the polarization tensor associated with a certain shape—coated ellipses [7] and crosses [3]. The lower bound (4.4) is attained by ellipses. Thus a conjecture, which implies the Polyá–Szegö conjecture, is that if (4.4) holds for an inclusion, then that inclusion must be an ellipse.

Kang and Milton [18] proved this new conjecture affirmatively in two dimensions (and three dimensions) within the class of simply connected inclusions with Lipschitz boundaries. In fact, in [17], they showed that if the polarization tensor $M(B)$ satisfies the lower bound (4.4), then B must have the uniformity property and is therefore an ellipse by Eshelby's conjecture. The Pólya–Szegö conjecture, which asserts that the inclusion whose polarization tensor has the minimal trace is a disk, follows from this.

We now show that the polarization tensor associated with the inclusion constructed in section 2 satisfies (4.4), and hence the Pólya–Szegö conjecture is not true among nonsimply connected inclusions. To do that, let u^1 and u^2 be solutions to (2.1) with $a = \mathbf{e}_1$ and $a = \mathbf{e}_2$, respectively, and put $\mathbf{u} := (u^1, u^2)$. Then, the polarization tensor M is given by

$$M = (k-1)\int_B \nabla \mathbf{u}\, dxdy, \tag{4.5}$$

where $\nabla \mathbf{u}$ is the Jacobian matrix. See [4], for example, for the proof of (4.5). As an immediate consequence of (3.3) and (3.6) we obtain the following corollary.

Corollary 4.1. *The polarization tensor associated with the inclusion constructed in section* 2 *is given by*

$$M = (k-1)|B| \begin{pmatrix} \dfrac{\alpha+\beta}{\alpha+k\beta} & 0 \\ 0 & \dfrac{\alpha+\beta}{k\alpha+\beta} \end{pmatrix}. \tag{4.6}$$

Note that this tensor satisfies

$$\mathrm{Tr}(M^{-1}) = \frac{k+1}{(k-1)|B|}, \tag{4.7}$$

which is the lower Hashin–Shtrikman bound. It is quite interesting to observe that the polarization tensor (4.6) is the same as that for the ellipse $\frac{x^2}{\alpha^2} + \frac{y^2}{\beta^2} \leq 1$. In particular, the inclusion in Figure 2.1, which has $\alpha = \beta$, has the same polarization tensor as that of a circular disk.

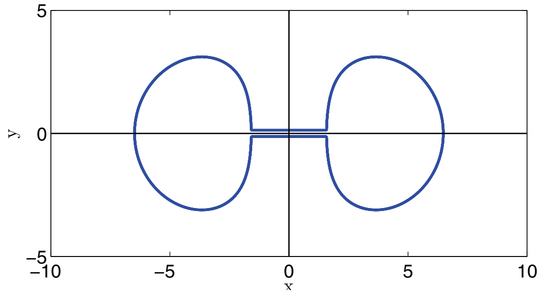

FIG. 5.1. *Bridged inclusion.*

5. Instability of the uniformity property. For a given $\epsilon > 0$, let δ be a positive number such that the rectangle $(-\delta, \delta) \times (\epsilon, \epsilon)$ is contained in the convex hull of B_1 and B_2. Let $B_\epsilon := B \cup ((-\delta, \delta) \times (\epsilon, \epsilon))$. B_ϵ is B_1 and B_2 connected by a thin bridge. Figure 5.1 shows the bridged inclusion.

Let γ and γ_ϵ be the conductivity distributions with inclusions B and B_ϵ, respectively, namely,

$$\gamma = 1 + (k-1)\chi(B), \quad \gamma_\epsilon = 1 + (k-1)\chi(B_\epsilon). \tag{5.1}$$

Let $h(x, y)$ be a harmonic function in $\mathbb{R}^2$, e.g., $h(x, y) = x$ or y. Let u be the solution to

$$\begin{cases} \nabla \cdot \gamma \nabla u = 0 \quad \text{in } \mathbb{R}^2, \\ u(x,y) - h(x,y) = O(r^{-1}) \quad \text{as } r \to \infty \end{cases} \tag{5.2}$$

and u_ϵ be the solution to (5.2) with γ replaced with γ_ϵ. Then a standard regularity theory of elliptic equations shows that

$$\|\nabla(u - u_\epsilon)\|_2 \to 0 \quad \text{as } \epsilon \to 0. \tag{5.3}$$

Here $\| \cdot \|_2$ is the norm of the square integral. In fact, if we put $w = u - u_\epsilon$, then w satisfies

$$\begin{cases} \nabla \cdot \gamma_\epsilon \nabla w = \nabla \cdot (\gamma_\epsilon - \gamma) \nabla u \quad \text{in } \mathbb{R}^2, \\ w(x,y) = O(r^{-1}) \quad \text{as } r \to \infty. \end{cases} \tag{5.4}$$

Thus it follows from a regularity theorem for the elliptic operator $\nabla \cdot \gamma_\epsilon \nabla$ (see [11]) that provided k is strictly positive

$$\|w\|_{H^1(\mathbb{R}^2)} \leq C \left(\int_{R_\epsilon} |\nabla u|^2 \right)^{1/2} \tag{5.5}$$

for some constant C independent of ϵ, where $R_\epsilon = B_\epsilon \setminus B$. In particular, we have (5.3).

If $h(x, y) = x$ or y, ∇u is constant in B_1 and B_2, as we have seen in section 3. Therefore, by (5.3), ∇u_ϵ is almost uniform (in the H^1 sense) if ϵ is small. It is obvious that B_ϵ is simply connected but nothing similar to an ellipse. Figure 5.2 shows the absolute value of the gradient of u_ϵ.

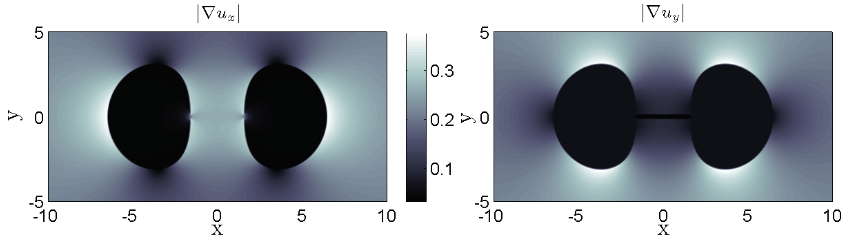

FIG. 5.2. *The graph of the absolute value of the gradient of the solutions corresponding to the bridged inclusion.*

We note that (5.5) implies that

$$\|M(B) - M(B_\epsilon)\| \leq C\epsilon, \tag{5.6}$$

where $M(B)$ is the polarization tensor of B and $M(B_\epsilon)$ is that of B_ϵ. In the case when $\alpha = \beta$, this equation shows that from a practical standpoint the Polyá–Szegö conjecture is false in two dimensions: a simply connected inclusion can have a polarizability tensor arbitrarily close to that of a circular disk yet not resemble a disk at all. We remark that in the extreme cases not treated here, when $k = 0$ or $k = \infty$, the insertion of even an infinitesimal bridge drastically changes the polarization tensor. So it is still an open question whether a void or perfectly conducting region is necessarily close in shape to an ellipse if it is simply connected and almost has the polarizability tensor of an ellipse.

6. Uniformity property: The elasticity case.

In this section we consider the uniformity property of the inclusion $B_1 \cup B_2$ for planar elasticity and show that for a certain loading the field inside $B_1 \cup B_2$ is uniform while for other loadings it is not uniform.

Let $C = (C_{ijkl})$ be the elasticity tensor of the inclusion-matrix composite, namely,

$$C_{ijkl} := \Big(\lambda\, \chi(\mathbb{R}^2 \setminus \overline{B}) + \widetilde{\lambda}\, \chi(B)\Big)\delta_{ij}\delta_{kl} + \Big(\mu\, \chi(\mathbb{R}^2 \setminus \overline{B}) + \widetilde{\mu}\, \chi(B)\Big)(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk}),$$

where $B = B_1 \cup B_2$. The elasticity tensor C indicates that the matrix (the background) has Lamé parameters (λ, μ), while the inclusion has parameters $(\widetilde{\lambda}, \widetilde{\mu})$. It is always assumed that

$$\mu > 0, \quad d\lambda + 2\mu > 0, \quad \widetilde{\mu} > 0, \quad \text{and} \quad d\widetilde{\lambda} + 2\widetilde{\mu} > 0$$

for ellipticity. For given constants a_{ij}, $i, j = 1, 2$, consider the following linear elastic problem:

$$\begin{cases} \nabla \cdot \big(C(\nabla \mathbf{u} + \nabla \mathbf{u}^T)\big) = 0 & \text{in } \mathbb{R}^2, \\ \mathbf{u}(x) - \displaystyle\sum_{i,j=1}^{2} a_{ij} x_i \mathbf{e}_j = O(|x|^{-1}) & \text{as } |x| \to \infty, \end{cases} \tag{6.1}$$

where $\mathbf{e}_j$, $j = 1, \ldots, d$, denotes the standard basis for $\mathbb{R}^2$. The uniform applied loading is determined by the matrix (a_{ij}).

Let us first seek a type of loading which yields a uniform field inside the inclusions. The existence of such a loading is expected due to the link between conductivity problems and elasticity problems in composites when the field in one phase is uniform [13]. We first invoke the following complex representation of the solution to (6.1) from [24, 4]: Let $\mathbf{u} = (u, v)$ be the solution of (6.1) and let $\mathbf{u}_e := \mathbf{u}|_{\mathbb{C}\setminus\overline{B}}$ and $\mathbf{u}_i := \mathbf{u}|_B$. Then there are unique functions φ_e and ψ_e holomorphic in $\mathbb{C} \setminus \overline{B}$ and φ_i and ψ_i holomorphic in B such that

$$2\mu(u_e + iv_e)(z) = \kappa\varphi_e(z) - z\overline{\varphi_e'(z)} - \overline{\psi_e(z)}, \quad z \in \mathbb{C} \setminus \overline{B}, \tag{6.2}$$

$$2\widetilde{\mu}(u_i + iv_i)(z) = \widetilde{\kappa}\varphi_i(z) - z\overline{\varphi_i'(z)} - \overline{\psi_i(z)}, \quad z \in B, \tag{6.3}$$

where

$$\kappa = \frac{\lambda + 3\mu}{\lambda + \mu}, \qquad \widetilde{\kappa} = \frac{\widetilde{\lambda} + 3\widetilde{\mu}}{\widetilde{\lambda} + \widetilde{\mu}}. \tag{6.4}$$

Moreover, the following hold on ∂B_j, $j = 1, 2$:

$$\frac{1}{2\mu}\left(\kappa\varphi_e(z) - z\overline{\varphi_e'(z)} - \overline{\psi_e(z)}\right) = \frac{1}{2\widetilde{\mu}}\left(\widetilde{\kappa}\varphi_i(z) - z\overline{\varphi_i'(z)} - \overline{\psi_i(z)}\right), \tag{6.5}$$

$$\varphi_e(z) + z\overline{\varphi_e'(z)} + \overline{\psi_e(z)} = \varphi_i(z) + z\overline{\varphi_i'(z)} + \overline{\psi_i(z)} + c, \tag{6.6}$$

where c is a constant. Equation (6.5) expresses continuity of displacement, and (6.6) expresses continuity of traction.

Let f be the function in (2.44) and let

$$\varphi_e(z) = A_e z, \quad \psi_e(z) = C_e\left[-\frac{p}{2}z + f(z)\right], \quad z \in \mathbb{C} \setminus \overline{B}, \tag{6.7}$$

where A_e and C_e are complex and real constants, respectively. As was observed in (2.46), $\overline{\psi}$ on ∂B_j has an extension to B_j as the linear holomorphic function $C_e(\frac{p}{2}z + \overline{q_j})$. Therefore, on ∂B_j, $j = 1, 2$, (6.5) and (6.6) now take the forms

$$\left(\widetilde{\kappa}\varphi_i(z) - z\overline{\varphi_i'(z)} - \overline{\psi_i(z)}\right) = \frac{\widetilde{\mu}}{\mu}\left(\kappa A_e - \overline{A_e} - \frac{C_e p}{2}\right)z + D_j, \tag{6.8}$$

$$\varphi_i(z) + z\overline{\varphi_i'(z)} + \overline{\psi_i(z)} = \left(A_e + \overline{A_e} + \frac{C_e p}{2}\right)z + E_j \tag{6.9}$$

for some constants D_j and E_j. Equations (6.8) and (6.9) force us to take $\varphi_i(z) = A_i z + \text{constant}$ and $\psi_i = \text{constant}$, and the complex number A_i should satisfy

$$\begin{cases} \widetilde{\kappa}A_i - \overline{A_i} = \dfrac{\widetilde{\mu}}{\mu}\left(\kappa A_e - \overline{A_e} - \dfrac{C_e p}{2}\right), \\[2ex] A_i + \overline{A_i} = A_e + \overline{A_e} + \dfrac{C_e p}{2}. \end{cases} \tag{6.10}$$

Let $A_e = a_1 + ia_2$. Equation (6.10) has a solution A_i if and only if

$$C_e = \frac{4}{p}\left[1 + \frac{2\widetilde{\mu}}{\mu(\widetilde{\kappa} - 1)}\right]^{-1}\left[\frac{\widetilde{\mu}(\kappa - 1)}{\mu(\widetilde{\kappa} - 1)} - 1\right]a_1, \tag{6.11}$$

and in this case

$$2\mu\begin{pmatrix} u_e \\ v_e \end{pmatrix} = \begin{pmatrix} (\kappa - 1)a_1 - C_e(1 - \frac{p}{2}) & -(\kappa + 1)a_2 \\ (\kappa + 1)a_2 & (\kappa - 1)a_1 + C_e(1 - \frac{p}{2}) \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + O(r^{-1}) \tag{6.12}$$

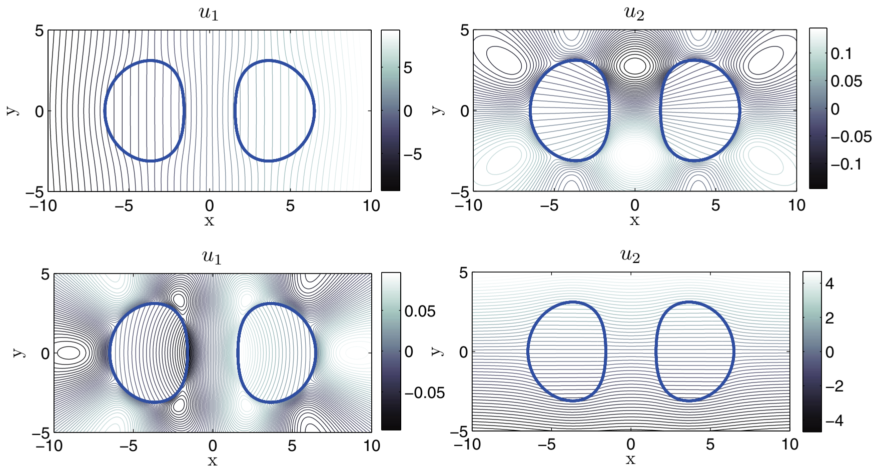

FIG. 6.1. *Equipotential lines of the solution* $\mathbf{u} = (u_1, u_2)$ *for the loading* $(x, 0)$ *(top) and* $(0, y)$ *(bottom).* ∇u_2 *is not uniform for the top, while* ∇u_1 *is not uniform for the bottom.*

as $r \to \infty$. Putting $t = \frac{(\kappa-1)a_1}{2\mu}$ and $s = \frac{(\kappa+1)a_2}{2\mu}$ and simplifying expressions using (2.45) and (6.4), we arrive at the following: If the loading (a_{ij}) is of the form

$$(a_{ij}) = \begin{pmatrix} (1-\theta)t & -s \\ s & (1+\theta)t \end{pmatrix}, \tag{6.13}$$

where t and s are real constants and

$$\theta = \frac{(\alpha - \beta)(\widetilde{\lambda} + \widetilde{\mu} - \lambda - \mu)}{(\alpha + \beta)(\mu + \widetilde{\lambda} + \widetilde{\mu})}, \tag{6.14}$$

then $\nabla \mathbf{u}$ is constant in B where $\mathbf{u}$ is the solution to (6.1). In particular, when $\alpha = \beta$, this corresponds to a hydrostatic loading. We mention that the inclusions constructed in this paper depend on the parameters α and β. In summary, we have proved the following theorem.

THEOREM 6.1. *If the* (a_{ij}) *are given by* (6.13) *for some real numbers* s *and* t *where* θ *is defined by* (6.14)*, then the solution* $\mathbf{u}$ *to* (6.1) *has the property that* $\nabla \mathbf{u}$ *is constant in* B*.*

We do not have a complete characterization of those loadings which yield a uniform strain field inside the inclusion, but numerical computations show that for certain loadings the field is not uniform. Figure 6.1 shows the equipotential lines for the solution $\mathbf{u} = (u_1, u_2)$ for the loadings $(x, 0)$ and $(0, y)$. It is worthwhile to compare the result of this paper with that for the simply connected inclusion in [28, 18]. For a simply connected inclusion, if the field inside the inclusion is uniform for a single loading, then the inclusion is of elliptical shape, and hence the field is uniform for any loading. Here we established that it is not the case for an inclusion with multiple components. It is an open question whether the uniformity of the interior field for all uniform applied loadings forces the inclusion (with possibly multiple components) to be an ellipse or not.

Conclusion. Providing an alternative proof to that of Cherepanov [8], we constructed a family of inclusions with two components which have the uniformity property for antiplane elasticity: for any loading the field inside the inclusions is uniform. In the case of planar elasticity the field is uniform for certain types of loadings but not uniform for other loadings. These results show that the conjectures of Eshelby and Pólya–Szegö are not true among nonsimply connected inclusions. By connecting two inclusions by a thin bridge we showed that these conjectures do not hold in a practical sense even for simply connected inclusions: even if the field inside an inclusion is very close to being uniform, the inclusion need not be close to an ellipse.

Acknowledgments. The authors are grateful to the referees for comments and in particular to one referee for drawing our attention to the work of Cherepanov. Also, after this work was submitted, the authors became aware of the beautiful paper of Liu [22], which treats multiple inclusions with the Eshelby property not only in two dimensions but also in three dimensions.

QUALITATIVE ANALYSIS OF A PREY-PREDATOR MODEL WITH STAGE STRUCTURE FOR THE PREDATOR[*]

YIHONG DU[†], PETER Y. H. PANG[‡], AND MINGXIN WANG[§]

Abstract. In this paper, we propose a diffusive prey-predator model with stage structure for the predator. We first analyze the stability of the nonnegative steady states for the reduced ODE system and then study the same question for the corresponding reaction-diffusion system with homogeneous Neumann boundary conditions. We find that a Hopf bifurcation occurs in the ODE system, but no Turing pattern happens in the reaction-diffusion system. However, when a natural cross diffusion term is included in the model, we can prove the emergence of stationary patterns (i.e., nonconstant positive stationary solutions) for this system; moreover, these stationary patterns do not exist in the considered parameter regime when there is no cross diffusion.

Key words. predator-prey model, stage structure, stability, cross diffusion, Turing pattern

1. Introduction and the mathematical model.

The life histories of plants, insects, and animals exhibit enormous diversity. Most species go through several stages during their lifetime, such as immature and mature stages; more specialized stages may exist for dispersal or dormancy. The vital rates (rates of survival, development, and reproduction) almost always depend on the development stage, among many other factors. Such stage structures have been largely ignored in early population modeling but have received much attention in recent years; see [2, 9, 11, 16, 22, 23, 31, 41, 42, 44, 45] and the references therein. Generally speaking, population growth models that include stage structure predict more complex population dynamics than those without taking this factor into account.

Hitherto, a common assumption in stage-structured prey-predator models is that the immature predator has no direct effect on the prey or the mature predator, and the immature prey is not subject to predation.

For example, in [22], the authors studied the following predator-prey models with

stage structure for the predator:

$$
(1.1)\quad \begin{cases} \dfrac{\mathrm{d}x}{\mathrm{d}t} = rx(t)\left(1 - \dfrac{x(t)}{K}\right) - \dfrac{bx(t)y(t)}{1 + k_1x(t) + k_2y(t)}, \\ \dfrac{\mathrm{d}y}{\mathrm{d}t} = \dfrac{nb\mathrm{e}^{-d_j\tau}x(t-\tau)y(t-\tau)}{1 + k_1x(t-\tau) + k_2y(t-\tau)} - dy(t), \\ \dfrac{\mathrm{d}y_j}{\mathrm{d}t} = \dfrac{nbx(t)y(t)}{1 + k_1x(t) + k_2y(t)} - \dfrac{nb\mathrm{e}^{-d_j\tau}x(t-\tau)y(t-\tau)}{1 + k_1x(t-\tau) + k_2y(t-\tau)} - d_jy_j(t), \end{cases}
$$

where x, y, and y_j are the densities of the prey, mature predator, and immature predator, respectively, d_j is the through-stage death rate of the immature predator, and the time delay τ is the duration that each immature predator needs to reach maturity. Thus $\mathrm{e}^{-d_j\tau}$ is the surviving rate of the immature predator (to mature predator). We note that the first two equations in this model are independent of the immature predator y_j, and they completely determine the dynamics of the system.

In this paper we propose a diffusive prey-predator model with stage structure for the predator which includes an explicit interaction between the immature predator and the prey as well as the mature predator. In particular, the interaction between the immature predator and the mature predator gives rise to a cross diffusion term (see (1.6) below). The resulting mathematical model is a strongly coupled system of three equations which is mathematically much more complex than those considered earlier. In particular, we will demonstrate several special features of the model which cannot be captured by the corresponding ODE model or by the corresponding reaction-diffusion model without cross diffusion.

To describe our model, we start with the classical Lotka–Volterra ODE model. Let x and y be the densities of the prey and the predator, respectively. We divide the predator y into two parts, the immature y_1 and mature y_2, with $y = y_1 + y_2$. Taking into account several biological considerations not adequately addressed before and with the view of simplicity, we make the following assumptions:

(i) The immature predators do not yield offspring.

(ii) The interaction terms are of Lotka–Volterra type, i.e., based on linear functional response.

(iii) The predation rate of the immature predator (which could be indirect, through increased consumption of prey by the mothers, for example) is positive but less than that of the mature predator. We denote them by εC and C, respectively, with $0 < \varepsilon < 1$.

(iv) The rate of conversion of prey to immature predator is proportional to the prey and is denoted by Kx. (In some literature, the constant K/C is called the rate of conversion of nutrients into the production of the immature predator.) The death rate of the immature predator is a constant denoted by M.

(v) In general, the rate of transition from immature predator to mature predator is a function of the prey. For simplicity, we assume that this rate is a constant denoted by D. The death rate of the mature predator is a constant denoted by P.

Under the above assumptions, the ODE prey-predator model with stage structure for the predator can be written as

$$\begin{cases} \dfrac{\mathrm{d}x}{\mathrm{d}t} = Ax - Bx^2 - \varepsilon Cxy_1 - Cxy_2, & t > 0, \\ \dfrac{\mathrm{d}y_1}{\mathrm{d}t} = Kxy_2 - Dy_1 - My_1, & t > 0, \\ \dfrac{\mathrm{d}y_2}{\mathrm{d}t} = Dy_1 - Py_2, & t > 0. \end{cases} \tag{1.2}$$

Using the scaling $u = Bx/(M + D)$, $v = Cy_1/(M + D)$, $w = Cy_2/(M + D)$, $\tau = (M + D)t$, and denoting τ by t again, the system (1.2) becomes

$$\begin{cases} \dfrac{\mathrm{d}u}{\mathrm{d}t} = au - u^2 - \varepsilon uv - uw, & t > 0, \\ \dfrac{\mathrm{d}v}{\mathrm{d}t} = kuw - v, & t > 0, \\ \dfrac{\mathrm{d}w}{\mathrm{d}t} = bv - mw, & t > 0, \end{cases} \tag{1.3}$$

where $a = A/(M + D)$, $b = D/(M + D) < 1$, $k = K/B$, and $m = P/(M + D)$.

Two obvious nonnegative steady states of the system (1.3) are $\mathbf{u}_0 = (0, 0, 0)$ and $\mathbf{u}_a = (a, 0, 0)$. Moreover, the problem (1.3) has a positive steady state if and only if $m < abk$, in which case the positive steady state is uniquely given by $\tilde{\mathbf{u}} = (\tilde{u}, \tilde{v}, \tilde{w})$, where

$$\tilde{u} = \frac{m}{bk}, \quad \tilde{v} = \frac{m(abk - m)}{bk(b + m\varepsilon)}, \quad \tilde{w} = \frac{abk - m}{k(b + m\varepsilon)}. \tag{1.4}$$

Now, the ODE model reflects only population changes due to predation in a situation where predator and prey densities are not spatially dependent. It does not take into account the fact that population is usually not homogeneously distributed, or the fact that the movements of the predator and prey are also caused by interactions within the same species or with other species. These considerations may be modeled by diffusion processes which can be quite intricate as different concentration levels of prey and predator cause different population movements. Such movements can be determined by the concentration of the same species (diffusion) and that of the other species (cross diffusion).

The role of diffusion in the modeling of many physical, chemical, and biological processes has been extensively studied. Starting with Turing's seminal 1952 paper [37], diffusion has been observed as causes of the spontaneous emergence of ordered structures, called patterns, in a variety of nonequilibrium situations. More recently, cross diffusion, in addition to diffusion, has also been used in some of these problems. There is a great variety of models that involve the applications of diffusion and cross diffusion; some examples are the Gierer–Meinhardt model [14, 18, 46], the Sel'kov model [20, 38], the chemotaxis diffusion model [21, 43], the competition model [24, 25, 26], the predator-prey model [7, 13, 19, 33, 34, 35, 40], and models of semiconductors, plasmas, chemical waves, combustion systems, embryogenesis, etc.; see, e.g., [3, 5, 10, 36] and references therein.

A stable stationary solution for an ODE system may lose its stability when regarded as a stationary solution of the corresponding reaction-diffusion system (i.e., with diffusion added to the system) over a bounded domain with Neumann boundary conditions and induce space dependent stationary solutions through local bifurcation. Turing [37] first observed this phenomenon and suggested that this may be used to model pattern formation. Such diffusion-driven instability, now known as Turing instability, has been verified empirically [4, 32]. Patterns arising from such a situation are called Turing patterns.

For our model, taking into account the inhomogeneous distribution of the prey and the predator in different spatial locations within a fixed bounded domain Ω at any given time, and the natural tendency of each species to diffuse to areas of smaller population concentration, we are naturally led to the following corresponding reaction-diffusion system:

$$(1.5)\qquad \begin{cases} u_t - d_1\Delta u = au - u^2 - \varepsilon uv - uw, & x\in\Omega,\ t>0,\\ v_t - d_2\Delta v = kuw - v, & x\in\Omega,\ t>0,\\ w_t - d_3\Delta w = bv - mw, & x\in\Omega,\ t>0,\\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x\in\partial\Omega,\ t>0,\\ w(x,0)\geq 0,\ v(x,0)\geq 0,\ w(x,0)\geq 0, & x\in\Omega, \end{cases}$$

where $\Omega\subset\mathbb{R}^N$ is a bounded domain with smooth boundary $\partial\Omega$ and ν is the outward unit normal vector of the boundary $\partial\Omega$. The homogeneous Neumann boundary condition indicates that this system is self-contained with zero population flux across the boundary. The constants d_1, d_2, and d_3, called diffusion coefficients, are positive. By standard theory of parabolic equations we can prove that (1.5) has a unique classical solution (u, v, w) defined for all $t > 0$ and that this solution is positive when the initial data $u(x, 0)$, $v(x, 0)$, $w(x, 0)$ are nonnegative and are positive somewhere in Ω. It is obvious that $(\tilde{u}, \tilde{v}, \tilde{w})$ given by (1.4) is the only positive constant steady state of (1.5) if $m < abk$.

From the analysis in section 3, we can see that Turing patterns do not occur for (1.5), because the constant nonnegative steady states $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ have the same stability properties whether viewed as stationary solutions of (1.3) or (1.5). This suggests (though does not prove) that the dynamics of (1.5) could be similar to that of (1.3).

However, in (1.5), only diffusion of each individual species is taken into account. The reality of the interaction between the mature members and their young is that the latter tend to stay close to the former. We model this by the cross diffusion term $\Delta[d_4v/(\sigma + w^2)]$ for the immature predator, where d_4, called the cross diffusion coefficient, and σ are positive constants. Combined with (self-)diffusion, the immature predator thus diffuses with flux

$$J = -\nabla\left(d_2v + \frac{d_4v}{\sigma + w^2}\right) = -\left(d_2 + \frac{d_4}{\sigma + w^2}\right)\nabla v + \frac{2d_4vw}{(\sigma + w^2)^2}\nabla w.$$

We observe that, as $2d_4vw(\sigma+w^2)^{-2} \geq 0$, the part $\{2d_4vw(\sigma+w^2)^{-2}\}\nabla w$ of the flux is directed toward increasing w, that is, increasing population density of the mature predator.

Mathematically, this choice of the cross diffusion is one of the simplest functions that is biologically sound. There is also a technical point for this choice. We can replace w^2 in the cross diffusion term by w^τ, and the results in this paper can be proved for all $\tau > 1$. However, if $\tau \leq 1$, then our Propositions 2 and 3 in section 4 and Theorems 5 and 6 in section 7 are no longer true. Please also see section 9 for further discussion on the choice of the cross diffusion term.

Thus, the cross diffusion system that we shall study is the following:

$$\begin{cases} u_t - d_1\Delta u = G_1(\mathbf{u}), & x \in \Omega,\ t > 0, \\ v_t - \Delta\Big(d_2 v + \dfrac{d_4 v}{\sigma + w^2}\Big) = G_2(\mathbf{u}), & x \in \Omega,\ t > 0, \\ w_t - d_3\Delta w = G_3(\mathbf{u}), & x \in \Omega,\ t > 0, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x \in \partial\Omega,\ t > 0, \\ w(x,0) \geq 0,\ v(x,0) \geq 0,\ w(x,0) \geq 0, & x \in \Omega, \end{cases} \tag{1.6}$$

where $\mathbf{u} = (u, v, w)^T$ and

$$\mathbf{G}(\mathbf{u}) = \begin{pmatrix} G_1(\mathbf{u}) \\ G_2(\mathbf{u}) \\ G_3(\mathbf{u}) \end{pmatrix} = \begin{pmatrix} u(a - u - \varepsilon v - w) \\ kuw - v \\ bv - mw \end{pmatrix}.$$

The general theory in [1] guarantees that (1.6) has a unique nonnegative local solution (u, v, w). In this paper, we will mainly consider the steady-state solutions of (1.6), as a complete analysis of the dynamics of the system seems out of reach at the moment.

In section 2, we will determine the stability of $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ as stationary solutions of (1.3) and show that a Hopf bifurcation occurs. In section 3, we prove that $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ have the same stability properties when regarded as stationary solutions of (1.5); therefore, no Turing pattern can be found for the reaction-diffusion system (1.5). In the remaining sections, we study the problem (1.6). First, in section 4, we analyze the linearized eigenvalue problem of (1.6) at $\tilde{\mathbf{u}}$ in order to calculate the fixed point index of $\tilde{\mathbf{u}}$, which is important for our later discussions on the existence of nonconstant positive steady states, i.e., stationary patterns, of (1.6). In section 5, we establish a priori upper and lower bounds for all possible positive steady states of (1.6). In section 6, we establish the nonexistence of nonconstant positive steady states of (1.6) when the cross diffusion coefficient $d_4 = 0$, that is, when no cross diffusion occurs in the model. In section 7, we study the existence of nonconstant positive steady states for suitable values of the parameters. This is done by using the Leray–Schauder degree theory and the results obtained in sections 4 and 5. In section 8, we briefly discuss the bifurcation of nonconstant positive steady states of (1.6). This is followed by concluding discussions in section 9.

It is perhaps worth emphasizing that our results in sections 6 and 7 show that in (1.6) stationary patterns can arise in suitable parameter ranges only if cross diffusion is included in the model (i.e., $d_4 > 0$). This is in sharp contrast to most existing studies for predator-prey models with cross diffusion, such as [6, 7, 8, 39], where stationary patterns already arise with the introduction of the diffusion term for each species.

The mathematical approach in this paper is similar in spirit to that of [35], where a two-predator one-prey system was studied, and it was shown that the system has a unique positive constant steady state, which is the global attractor for the corresponding ODE and reaction-diffusion systems, but becomes unstable in certain parameter ranges when a cross diffusion term is included, and nonconstant positive stationary solutions emerge. However, our problem (1.6) is much more complex. For example, its ODE version, namely, (1.3), already exhibits much richer dynamical behavior (e.g., a Hopf bifurcation occurs; see section 2 for details). As a result, our analysis here, especially in sections 5 and 6, is much more difficult and requires techniques beyond those of [35]. On the other hand, our results here reinforce the point demonstrated in [35]; namely, cross diffusion may have crucial impact on the dynamics of certain predator-prey models.

2. Stability of $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ and Hopf bifurcation for the ODE system (1.3).

We first consider the stability of $\mathbf{u}_a$.

THEOREM 1. *If $m > abk$, then $\mathbf{u}_a$ is the only nontrivial nonnegative stationary solution of* (1.3)*, and every nonnegative solution (u, v, w) of* (1.3) *with $u \not\equiv 0$ satisfies* $\lim_{t\to\infty}(u, v, w) = (a, 0, 0)$.

Proof. As $m > abk$, there exists a $\delta > 0$ such that $m > (a + \delta)bk$. It follows from the first equation of (1.3) that $\limsup_{t\to\infty} u(t) \le a$. Therefore, we can find $T > 0$ such that $u(t) \le a + \delta$ for all $t \ge T$.

Consider the nonnegative solution $(\hat{v}, \hat{w})$ of the following problem:

$$\begin{cases} \dfrac{\mathrm{d}\hat{v}}{\mathrm{d}t} = k(a+\delta)\hat{w} - \hat{v}, & t > T, \\ \dfrac{\mathrm{d}\hat{w}}{\mathrm{d}t} = b\hat{v} - m\hat{w}, & t > T, \\ \hat{v}(T) = v(T), \quad \hat{w}(T) = w(T). \end{cases}$$

Then $v(t) \le \hat{v}(t)$ and $w(t) \le \hat{w}(t)$ for all $t \ge T$. As $(a + \delta)bk < m$, it is obvious that $\lim_{t\to\infty}(\hat{v}(t), \hat{w}(t)) = (0, 0)$. Consequently, $\lim_{t\to\infty}(v(t), w(t)) = (0, 0)$.

Applying the first equation of (1.3) once again, we deduce that $\lim_{t\to\infty} u(t) = a$. □

Next we consider the case $m < abk$. In this case, (1.3) has two nontrivial nonnegative stationary solutions: $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$.

THEOREM 2. *Suppose $m < abk$. Then $\mathbf{u}_a$ is unstable. Moreover,*

(i) *if*

$$b \le \varepsilon\left(1 + \frac{m}{bk}\right), \tag{2.1}$$

then $\tilde{\mathbf{u}}$ is asymptotically stable;

(ii) *if* (2.1) *does not hold, then there exists a unique $a^* > m/(bk)$, determined by ε, b, k, and m, such that $\tilde{\mathbf{u}}$ is asymptotically stable for $a \in (m/(bk), a^*)$ and is unstable for $a > a^*$; moreover, a branch of periodic solutions bifurcates from $\tilde{\mathbf{u}}$ at $a = a^*$.*

Proof. Since $m < abk$, one easily checks that the linearization matrix of (1.3) at $\mathbf{u}_a$ has one positive and two negative eigenvalues; therefore, $\mathbf{u}_a$ is unstable.

We now consider the stability of $\tilde{\mathbf{u}}$. A straightforward calculation shows that the linearization matrix of the system (1.3) at $\tilde{\mathbf{u}}$ has the characteristic polynomial $g(\lambda) = \lambda^3 + A_1\lambda^2 + A_2\lambda + A_3$, where

$$\begin{cases} A_1 = 1 + m + \dfrac{m}{bk} > 0, \\ A_2 = \dfrac{m}{bk}\left(1 + m + \dfrac{\varepsilon(abk - m)}{b + m\varepsilon}\right) > 0, \\ A_3 = \dfrac{m(abk - m)}{bk} > 0. \end{cases} \tag{2.2}$$

Therefore,

$$\begin{aligned}A_1A_2 - A_3 &= \frac{m}{bk(b+m\varepsilon)}\Big\{(1+m)(b+m\varepsilon)\Big(1+m+\frac{m}{bk}\Big)\\ &\qquad - (abk-m)\Big[b-\varepsilon\Big(1+\frac{m}{bk}\Big)\Big]\Big\}\\ &\triangleq \frac{m}{bk(b+m\varepsilon)}f(\xi), \quad \text{where } \xi = abk-m.\end{aligned}$$

Clearly, if (2.1) holds, then $f(\xi) > 0$ for all $\xi \geq 0$; hence $A_1A_2 - A_3 > 0$. If (2.1) does not hold, then $f(0) > 0$ and $f(\xi) < 0$ for all large ξ. Thus the linear function $f(\xi)$ has a unique positive zero point ξ_0 where $f(\xi) > 0$ for $\xi \in [0, \xi_0)$ and $f(\xi) < 0$ for $\xi > \xi_0$. It follows that $A_1A_2 - A_3 > 0$ when $a \in (m/(bk), a^*)$ and $A_1A_2 - A_3 < 0$ if $a > a^*$, where $a^* = (m + \xi_0)/(bk)$.

We can now apply the Routh–Hurwitz criterion (see, e.g., [27, Appendix 2]) to conclude that $\tilde{\mathbf{u}}$ is linearly stable (and hence asymptotically stable) if (2.1) holds or $a \in (m/(bk), a^*)$; and is linearly unstable (and hence unstable) if (2.1) does not hold and $a > a^*$.

It remains to show that a Hopf bifurcation occurs at $a = a^*$ when (2.1) does not hold. Since A_1, A_2, A_3 are all positive, clearly the characteristic polynomial $g(\lambda)$ has no nonnegative root. Since $g(\lambda) \to -\infty$ as $\lambda \to -\infty$, it always has a negative root. We now have two possibilities:

(i) $g(\lambda)$ has three negative roots: λ_1, λ_2, λ_3;

(ii) $g(\lambda)$ has one negative root λ_1 and a pair of complex roots: $\lambda_2 = \alpha + \beta i$, $\lambda_3 = \alpha - \beta i$, $\beta \neq 0$.

When a is close to a^*, $\lambda_1\lambda_2\lambda_3 = -A_3 < -(1/2)m\xi_0/(bk) < 0$. Therefore, no eigenvalue is close to 0 (in the complex plane) when a is close to a^*, say, $|\lambda_i| \geq \sigma_0 > 0$, $i = 1, 2, 3$. We show next that this implies that case (i) cannot happen when a is close to a^*. Indeed, if (i) happens with a close to a^*, then $A_1A_2 - A_3 = -\big[\lambda_1^2(\lambda_2+\lambda_3) + \lambda_2^2(\lambda_1+\lambda_3) + \lambda_3^2(\lambda_1+\lambda_2) + 2\lambda_1\lambda_2\lambda_3\big] \geq 8\sigma_0^3$ for all a close to a^*, which is impossible since, by our choice of a^*, $A_1A_2 - A_3 = 0$ when $a = a^*$. Therefore, case (ii) must happen when a is close to a^*. It then follows that $A_1A_2 - A_3 = -2\alpha[(\alpha+\lambda_1)^2 + \beta^2]$. If we regard α, β, and λ_1 as functions of ξ, we can rewrite the above identity as

$$\frac{m}{bk(b+m\varepsilon)}f(\xi) = -2\alpha(\xi)\big[(\alpha(\xi)+\lambda_1(\xi))^2 + \beta^2(\xi)\big].$$

It follows that

$$\alpha(\xi_0) = 0, \quad \frac{m}{bk(b+m\varepsilon)}f'(\xi_0) = -2\alpha'(\xi_0)[\lambda_1^2(\xi_0) + \beta^2(\xi_0)].$$

Hence $\mathrm{d}\alpha/\mathrm{d}a\big|_{a=a^*} = \alpha'(\xi_0)bk \neq 0$, and the Hopf bifurcation theorem can be applied to conclude that (1.3) has a branch of periodic solutions bifurcating from $\tilde{\mathbf{u}}$ at $a = a^*$. □

Remark 1. Note that if $\varepsilon \geq 1$, then (2.1) always holds (since $d < 1$); hence $\tilde{\mathbf{u}}$ is stable and Hopf bifurcation never occurs. On the other hand, if $\varepsilon = 0$, then (2.1) never holds.

3. Stability of $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ for the PDE system without cross diffusion (1.5).

In this section, we show that $\mathbf{u}_a$ and $\tilde{\mathbf{u}}$ have the same stability properties as in section 2.

First, assume that $abk < m$, and let (u, v, w) be an arbitrary nonnegative solution of (1.5) with $u \not\equiv 0$. From the first equation in (1.5) we deduce that $\limsup_{t\to\infty} u(x, t) \le a$ uniformly in $x \in \bar{\Omega}$. Therefore, we can find $T > 0$ such that $u(x, t) \le a + \delta$ for all $t \ge T$, where $\delta > 0$ is small so that $(a + \delta)bk < m$.

Consider the nonnegative solution $(\hat{v}, \hat{w})$ of the problem

$$\begin{cases} \dfrac{\mathrm{d}\hat{v}}{\mathrm{d}t} = k(a+\delta)\hat{w} - \hat{v}, & t > T, \\ \dfrac{\mathrm{d}\hat{w}}{\mathrm{d}t} = b\hat{v} - m\hat{w}, & t > T, \\ \hat{v}(T) = \max\limits_{x\in\bar{\Omega}} v(x, T), & \hat{w}(T) = \max\limits_{x\in\bar{\Omega}} w(x, T). \end{cases}$$

Then, $v(x, t) \le \hat{v}(t)$ and $w(x, t) \le \hat{w}(t)$ for all $t \ge T$ and $x \in \bar{\Omega}$. As $(a+\delta)bk < m$, we have, as before, $\lim_{t\to\infty}(\hat{v}(t), \hat{w}(t)) = (0, 0)$, and thus $\lim_{t\to\infty}(v(x, t), w(x, t)) = (0, 0)$ uniformly in $x \in \bar{\Omega}$.

Applying the first equation of (1.5) once again, we deduce that $\lim_{t\to\infty} u(x, t) = a$. Therefore, $\mathbf{u}_a$ is globally attractive, as in section 2.

Next we assume that $m < abk$. By Theorem 2, we find that $\mathbf{u}_a$ is unstable. It remains to check the stability of $\tilde{\mathbf{u}}$.

Let $0 = \mu_1 < \mu_2 < \mu_3 < \cdots$ be the eigenvalues of the operator $-\Delta$ on Ω with the homogeneous Neumann boundary condition, and let $E(\mu_i)$ be the eigenspace corresponding to μ_i in $H^1(\Omega)$. Let $\mathbf{X} = [H^1(\Omega)]^3$, $\{\phi_{ij}\,;\, j = 1, \ldots, \dim E(\mu_i)\}$ be an orthonormal basis of $E(\mu_i)$, and let $\mathbf{X}_{ij} = \{\mathbf{c}\phi_{ij} : \mathbf{c} \in \mathbb{R}^3\}$. Then,

$$\mathbf{X} = \bigoplus_{i=1}^{\infty} \mathbf{X}_i \qquad \text{and} \qquad \mathbf{X}_i = \bigoplus_{j=1}^{\dim E(\mu_i)} \mathbf{X}_{ij}. \tag{3.1}$$

Theorem 3. *Suppose that $m < abk$. Then the constant positive steady state $\tilde{\mathbf{u}}$ of* (1.5) *is linearly stable, and hence asymptotically stable in the sense of* [17], *when* (2.1) *holds or $a \in (m/(bk), a^*)$; and is unstable when* (2.1) *does not hold and $a > a^*$.*

Proof. We note that when $\tilde{\mathbf{u}}$ is unstable for (1.3), it is also unstable for (1.5). Thus, we need only to prove the asymptotic stability of $\tilde{\mathbf{u}}$ when our stability assumptions hold.

Let $\mathcal{D}$ =diag(d_1, d_2, d_3) and $\mathcal{L} = \mathcal{D}\Delta + \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})$. The linearization of (1.5) at $\tilde{\mathbf{u}}$ is $\mathbf{u}_t = \mathcal{L}\mathbf{u}$. For each $i \ge 1$, $\mathbf{X}_i$ is invariant under the operator $\mathcal{L}$, and λ is an eigenvalue of $\mathcal{L}$ if and only if it is an eigenvalue of the matrix $-\mu_i\mathcal{D} + \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})$ for some $i \ge 1$, in which case there is an eigenvector in $\mathbf{X}_i$. The characteristic polynomial of $-\mu_i\mathcal{D} + \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})$ is given by $\psi_i(\lambda) = \lambda^3 + B_1\lambda^2 + B_2\lambda + B_3$, where

$$\begin{aligned} B_1 &= \mu_i(d_1 + d_2 + d_3) + 1 + m + \tilde{u} > 0, \\ B_2 &= \mu_i^2(d_1d_2 + d_1d_3 + d_2d_3) + \mu_i[(1+m)d_1 + (m+\tilde{u})d_2 + (1+\tilde{u})d_3] \\ &\qquad + (1 + m + \varepsilon k\tilde{w})\tilde{u} > 0, \\ B_3 &= \mu_i^3 d_1d_2d_3 + \mu_i^2(md_1d_2 + d_1d_3 + \tilde{u}d_2d_3) + \mu_i(md_2 + d_3 + \varepsilon k\tilde{w}d_3)\tilde{u} \\ &\qquad + (b + m\varepsilon)k\tilde{u}\tilde{w} > 0. \end{aligned}$$

A direct calculation yields $B_1B_2 - B_3 = c_3\mu_i^3 + c_2\mu_i^2 + c_1\mu_i + A_1A_2 - A_3$, where A_1, A_2, and A_3 are given by (2.2), and c_1, c_2, c_3 are positive. Hence $B_1B_2 - B_3 \ge A_1A_2 - A_3$. From the proof of Theorem 2 we see that $A_1A_2 - A_3 > 0$ under our conditions for stability. So, $B_1B_2 - B_3 > 0$. It thus follows from the Routh–Hurwitz criterion that, for each $i \geq 1$, the three roots $\lambda_{i,1}$, $\lambda_{i,2}$, $\lambda_{i,3}$ of $\psi_i(\lambda) = 0$ all have negative real parts.

In the following we shall prove that there exists a positive constant δ such that

$$\text{(3.2)} \qquad \mathrm{Re}\{\lambda_{i,1}\}, \quad \mathrm{Re}\{\lambda_{i,2}\}, \quad \mathrm{Re}\{\lambda_{i,3}\} \leq -\delta \qquad \forall\, i \geq 1.$$

Consequently, the spectrum of $\mathcal{L}$, which consists of eigenvalues, lies in $\{\mathrm{Re}\,\lambda \leq -\delta\}$, and the asymptotical stability of $\tilde{\mathbf{u}}$ follows [17, Theorem 5.1.1].

To see (3.2), let $\lambda = \mu_i\xi$. Then $\psi_i(\lambda) = \mu_i^3\xi^3 + B_1\mu_i^2\xi^2 + B_2\mu_i\xi + B_3 \overset{\Delta}{=} \tilde{\psi}_i(\xi)$. Since $\mu_i \to \infty$ as $i \to \infty$, it follows that $\lim_{i\to\infty}\{\tilde{\psi}_i(\xi)/\mu_i^3\} = \xi^3 + (d_1 + d_2 + d_3)\xi^2 + (d_1d_2 + d_1d_3 + d_2d_3)\xi + d_1d_2d_3 \overset{\Delta}{=} \bar{\psi}(\xi)$. Clearly $\bar{\psi}(\xi) = 0$ has three negative roots: $-d_1$, $-d_2$, $-d_3$. By continuity, we see that there exists i_0 such that the three roots $\xi_{i,1}$, $\xi_{i,2}$, $\xi_{i,3}$ of $\tilde{\psi}_i(\xi) = 0$ satisfy $\mathrm{Re}\{\xi_{i,1}\}$, $\mathrm{Re}\{\xi_{i,2}\}$, $\mathrm{Re}\{\xi_{i,3}\} \leq -\bar{\delta}/2$ for all $i \geq i_0$, where $\bar{\delta} = \min\{d_1, d_2, d_3\}$. In turn, $\mathrm{Re}\{\lambda_{i,1}\}$, $\mathrm{Re}\{\lambda_{i,2}\}$, $\mathrm{Re}\{\lambda_{i,3}\} \leq -\mu_i\bar{\delta}/2 \leq -\bar{\delta}/2$ for all $i \geq i_0$.

Let $-\tilde{\delta} = \max_{1\leq i\leq i_0}\{\mathrm{Re}\{\lambda_{i,1}\}, \mathrm{Re}\{\lambda_{i,2}\}, \mathrm{Re}\{\lambda_{i,3}\}\}$. Then $\tilde{\delta} > 0$, and (3.2) holds for $\delta = \min\{\tilde{\delta},\, \bar{\delta}/2\}$. □

4. Fixed point index of ũ for the stationary PDE system with cross diffusion. Let $\Phi(\mathbf{u}) = (d_1u,\, d_2v + d_4v/(\sigma + w^2),\, d_3w)^T$. Then the stationary problem of (1.6) can be written as

$$\text{(4.1)} \qquad -\Delta\Phi(\mathbf{u}) = \mathbf{G}(\mathbf{u}), \quad x \in \Omega; \qquad \frac{\partial \mathbf{u}}{\partial \nu} = 0, \quad x \in \partial\Omega.$$

In this section, we study the linearization of (4.1) at $\tilde{\mathbf{u}}$ and then proceed to calculate the fixed point index of $\tilde{\mathbf{u}}$ when it is an isolated solution.

Let $\mathbf{Y} = [C^1(\bar{\Omega})]^3$, and define $\mathbf{Y}^+ = \{\mathbf{u} \in \mathbf{Y} : u, v, w > 0 \text{ on } \bar{\Omega}\}$ and, for $C > 0$, $B(C) = \{\mathbf{u} \in \mathbf{Y} : C^{-1} < u, v, w < C \text{ on } \bar{\Omega}\}$.

Since the determinant of $\Phi_{\mathbf{u}}(\mathbf{u})$ is positive for all nonnegative $\mathbf{u}$, $\Phi_{\mathbf{u}}^{-1}(\mathbf{u})$ exists and $\det \Phi_{\mathbf{u}}^{-1}(\mathbf{u})$ is positive. Hence, $\mathbf{u}$ is a positive solution to (4.1) if and only if

$$\mathbf{F}(\mathbf{u}) \overset{\Delta}{=} \mathbf{u} - (\mathbf{I} - \Delta)^{-1}\{\Phi_{\mathbf{u}}^{-1}(\mathbf{u})[\mathbf{G}(\mathbf{u}) + \nabla\mathbf{u}\,\Phi_{\mathbf{uu}}(\mathbf{u})\nabla\mathbf{u}] + \mathbf{u}\} = 0 \ \text{ in } \ \mathbf{Y}^+,$$

where $(\mathbf{I} - \Delta)^{-1}$ is the inverse of $\mathbf{I} - \Delta$ under homogeneous Neumann boundary conditions. As $\mathbf{F}(\cdot)$ is a compact perturbation of the identity operator, for any $B = B(C)$, the Leray–Schauder degree $\deg(\mathbf{F}(\cdot),\, 0,\, B)$ is well defined if $\mathbf{F}(\mathbf{u}) \neq 0$ on ∂B.

Further, we note that $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}}) = \mathbf{I} - (\mathbf{I} - \Delta)^{-1}\{\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}}) + \mathbf{I}\}$ and recall that, if $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$ is invertible, the fixed point index of $\mathbf{F}$ at $\tilde{\mathbf{u}}$ is well defined and

$$\mathrm{index}(\mathbf{F}(\cdot),\, \tilde{\mathbf{u}}) = (-1)^{\gamma},$$

where γ is the sum of the algebraic multiplicities of all the negative eigenvalues of $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$ [29, Theorem 2.8.1].

Since the eigenvalues of $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$ and their algebraic multiplicities are the same regardless of whether it is considered an operator in $\mathbf{X}$ or in $\mathbf{Y}$, it is convenient to use the decomposition (3.1) in our discussion of the eigenvalues of $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$. A straightforward calculation shows that, for each integer $i \geq 1$ and each integer $1 \leq j \leq \dim E(\mu_i)$, $\mathbf{X}_{ij}$ is invariant under $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$. Moreover, λ is an eigenvalue of $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$ if and only if, for some $i \geq 1$, it is an eigenvalue of the matrix

$$\mathbf{B}_i := \mathbf{I} - \frac{1}{1 + \mu_i}[\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}}) + \mathbf{I}] = \frac{1}{1 + \mu_i}[\mu_i\mathbf{I} - \Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})].$$

Thus, $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$ is invertible if and only if the matrix $\mathbf{B}_i$ is nonsingular for all $i \geq 1$.

Let λ be an eigenvalue of $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$. We now calculate its algebraic multiplicity, which we denote by $\sigma(\lambda)$. By definition, $\sigma(\lambda) = \dim(E^{\lambda})$, where $E^{\lambda} := \bigcup_{n=1}^{\infty} \operatorname{Ker}\big[\lambda I - D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})\big]^n$.

For any $\phi \in \mathbf{X}$, we can uniquely express it in the form $\phi = \sum_{i=1}^{\infty}\sum_{j=1}^{\dim E(\mu_i)} C_{ij}\phi_{ij}$, where $C_{ij} \in \mathbb{R}^3$ and ϕ_{ij} is defined as before. Since $\mathbf{X}_{ij}$ is invariant under $D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$, it is also invariant under $\big[\lambda I - D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})\big]^n$ for any $n \geq 1$. Thus, $\phi \in \operatorname{Ker}\big[\lambda I - D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})\big]^n$ if and only if $\big[\lambda I - D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})\big]^n C_{ij}\phi_{ij} = 0$ for all $i \geq 1$ and $1 \leq j \leq \dim E(\mu_i)$. A direct calculation shows that $\big[\lambda I - D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})\big]^n C_{ij}\phi_{ij} = 0$ if and only if $\big[\lambda I - \mathbf{B}_i\big]^n C_{ij} = 0$. It follows that

$$\dim E^{\lambda} = \sum_{i=1}^{\infty}\left[\dim E(\mu_i) \times \dim\left(\bigcup_{n=1}^{\infty}\operatorname{Ker}(\lambda\mathbf{I} - \mathbf{B}_i)^n\right)\right].$$

Now, $\dim\big(\bigcup_{n=1}^{\infty}\operatorname{Ker}(\lambda I - \mathbf{B}_i)^n\big)$ is just the algebraic multiplicity of λ as an eigenvalue of the 3×3 matrix $\mathbf{B}_i$. Writing

$$H(\mu) = H(\tilde{\mathbf{u}};\, \mu) \overset{\Delta}{=} \det\big\{\mu\,\mathbf{I} - \Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})\big\} = \det\big\{(\mu - \mu_i)\mathbf{I} + (1+\mu_i)\mathbf{B}_i\big\}, \tag{4.2}$$

we easily see that $\lambda = (\mu_i - \mu)/(1+\mu_i)$ is an eigenvalue of $\mathbf{B}_i$ if and only if $H(\mu) = 0$. Moreover, if $H(\mu_i) \neq 0$, then the number of negative eigenvalues (counting algebraic multiplicity) of $\mathbf{B}_i$ is odd if and only if $H(\mu_i) < 0$. Therefore,

$$\sigma(\lambda) = \dim E^{\lambda} = \sum_{i\geq 1,\, H(\mu_i)<0} \dim E(\mu_i) \pmod 2.$$

As a consequence, we have the following proposition.

Proposition 1. *Suppose that, for all $i \geq 1$, $H(\mu_i) \neq 0$. Then*

$$\mathit{index}(\mathbf{F}(\cdot),\, \tilde{\mathbf{u}}) = (-1)^{\gamma}, \qquad \text{where} \qquad \gamma = \sum_{i\geq 1,\, H(\mu_i)<0} \dim E(\mu_i).$$

To facilitate our computation of index$(\mathbf{F}(\cdot),\, \tilde{\mathbf{u}})$, we need to determine the sign of $H(\mu_i)$. In particular, as the aim of this paper is to study the existence of stationary patterns of (1.6) with respect to the cross diffusion coefficient d_4 and diffusion coefficient d_1, we will concentrate on the dependence of $H(\mu_i)$ on d_4 and d_1. At this point, we note that $H(\mu) = \det\{\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\}\ \det\{\mu\,\Phi_{\mathbf{u}}(\tilde{\mathbf{u}}) - \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})\}$. Since we have already established that $\det\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})$ is positive, we will need only to consider $\det\{\mu\,\Phi_{\mathbf{u}}(\tilde{\mathbf{u}}) - \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})\}$.

As

$$\Phi_{\mathbf{u}}(\tilde{\mathbf{u}}) = \begin{pmatrix} d_1 & 0 & 0 \\ 0 & d_2 + \dfrac{d_4}{\sigma + \tilde{w}^2} & -\dfrac{2d_4\tilde{v}\tilde{w}}{(\sigma+\tilde{w}^2)^2} \\ 0 & 0 & d_3 \end{pmatrix},$$

we have

$$\begin{aligned} \det\{\mu\Phi_{\mathbf{u}}(\tilde{\mathbf{u}}) - \mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})\} &= C_3(\sigma, d_1, d_4)\mu^3 + C_2(\sigma, d_1, d_4)\mu^2 + C_1(\sigma, d_1, d_4)\mu \\ &\quad + k(b + m\varepsilon)\tilde{u}\tilde{w} \\ &\overset{\Delta}{=} \mathcal{C}(\sigma, d_1, d_4;\, \mu), \end{aligned} \tag{4.3}$$

where

$$\begin{aligned}
C_3(\sigma,d_1,d_4) &= d_1d_3\Big(d_2+\frac{d_4}{\sigma+\tilde{w}^2}\Big),\\
C_2(\sigma,d_1,d_4) &= (md_1+d_3\tilde{u})\Big(d_2+\frac{d_4}{\sigma+\tilde{w}^2}\Big)+d_1d_3-bd_1\frac{2d_4\tilde{v}\tilde{w}}{(\sigma+\tilde{w}^2)^2},\\
C_1(\sigma,d_1,d_4) &= m\tilde{u}\Big(d_2+\frac{d_4}{\sigma+\tilde{w}^2}\Big)+d_3\tilde{u}-b\tilde{u}\frac{2d_4\tilde{v}\tilde{w}}{(\sigma+\tilde{w}^2)^2}+\varepsilon kd_3\tilde{u}\tilde{w}.
\end{aligned}$$

First we consider the dependence of $\mathcal{C}$ on d_4. Let $\tilde{\mu}_1(d_4)$, $\tilde{\mu}_2(d_4)$, and $\tilde{\mu}_3(d_4)$ be the three roots of $\mathcal{C}(\sigma,d_1,d_4;\,\mu)=0$ with $\mathrm{Re}\{\tilde{\mu}_1(d_4)\}\le\mathrm{Re}\{\tilde{\mu}_2(d_4)\}\le\mathrm{Re}\{\tilde{\mu}_3(d_4)\}$. Then $\tilde{\mu}_1(d_4)\tilde{\mu}_2(d_4)\tilde{\mu}_3(d_4)<0$, at least one of $\tilde{\mu}_1(d_4)$, $\tilde{\mu}_2(d_4)$, $\tilde{\mu}_3(d_4)$ is real and negative, and the product of the other two is positive.

Consider the following limits:

$$\begin{aligned}
\lim_{d_4\to\infty}\frac{C_3(\sigma,d_1,d_4)}{d_4} &= \frac{d_1d_3}{\sigma+\tilde{w}^2}\ \triangleq\ a_3(\sigma,d_1),\\
\lim_{d_4\to\infty}\frac{C_2(\sigma,d_1,d_4)}{d_4} &= \frac{1}{\sigma+\tilde{w}^2}\Big(md_1+d_3\tilde{u}-2bd_1\frac{\tilde{v}\tilde{w}}{\sigma+\tilde{w}^2}\Big)\triangleq\ a_2(\sigma,d_1),\\
\lim_{d_4\to\infty}\frac{C_1(\sigma,d_1,d_4)}{d_4} &= \frac{\tilde{u}[m(\sigma+\tilde{w}^2)-2b\tilde{v}\tilde{w}]}{(\sigma+\tilde{w}^2)^2}=\frac{m\tilde{u}(\sigma-\tilde{w}^2)}{(\sigma+\tilde{w}^2)^2}\triangleq\ a_1(\sigma).
\end{aligned}$$

Therefore, $a_1(\sigma)<0$ when $\sigma<\tilde{w}^2$. In the following, we restrict our attention to $0<\sigma<\tilde{w}^2$. In this range, $a_1(\sigma)<0$, and $C_1(\sigma,d_1,d_4)<0$ for all sufficiently large d_4. Note that

$$\begin{aligned}
\lim_{d_4\to\infty}\frac{\mathcal{C}(\sigma,d_1,d_4;\,\mu)}{d_4} &= a_3(\sigma,d_1)\mu^3+a_2(\sigma,d_1)\mu^2+a_1(\sigma)\mu\\
&= \mu[a_3(\sigma,d_1)\mu^2+a_2(\sigma,d_1)\mu+a_1(\sigma)],
\end{aligned}$$

and $a_1(\sigma)<0<a_3(\sigma,d_1)$. A continuity argument shows that, when d_4 is large, $\tilde{\mu}_1(d_4)$ is real and negative. Furthermore, as $\tilde{\mu}_2(d_4)\tilde{\mu}_3(d_4)>0$, $\tilde{\mu}_2(d_4)$ and $\tilde{\mu}_3(d_4)$ are real and positive, and

$$(4.4)\qquad \begin{cases}
\displaystyle\lim_{d_4\to\infty}\tilde{\mu}_1(d_4)=\frac{-a_2(\sigma,d_1)-\sqrt{a_2^2(\sigma,d_1)-4a_1(\sigma)a_3(\sigma,d_1)}}{2a_3(\sigma,d_1)}<0,\\
\displaystyle\lim_{d_4\to\infty}\tilde{\mu}_2(d_4)=0,\\
\displaystyle\lim_{d_4\to\infty}\tilde{\mu}_3(d_4)=\frac{-a_2(\sigma,d_1)+\sqrt{a_2^2(\sigma,d_1)-4a_1(\sigma)a_3(\sigma,d_1)}}{2a_3(\sigma,d_1)}\triangleq\tilde{\mu}>0.
\end{cases}$$

Thus we have the following proposition.

PROPOSITION 2. *Assume that* $0<\sigma<\tilde{w}^2$. *Then there exists a positive number* d_4^* *such that, when* $d_4\ge d_4^*$, *the three roots* $\tilde{\mu}_1(d_4)$, $\tilde{\mu}_2(d_4)$, $\tilde{\mu}_3(d_4)$ *of* $\mathcal{C}(\sigma,d_1,d_4;\,\mu)=0$ *are all real and satisfy* (4.4). *Moreover, for all* $d_4\ge d_4^*$,

$$(4.5)\qquad \begin{cases}
-\infty<\tilde{\mu}_1(d_4)<0<\tilde{\mu}_2(d_4)<\tilde{\mu}_3(d_4),\\
\mathcal{C}(\sigma,d_1,d_4;\,\mu)<0\quad\textit{when}\quad \mu\in(-\infty,\,\tilde{\mu}_1(d_4))\cup(\tilde{\mu}_2(d_4),\,\tilde{\mu}_3(d_4)),\\
\mathcal{C}(\sigma,d_1,d_4;\,\mu)>0\quad\textit{when}\quad \mu\in(\tilde{\mu}_1(d_4),\,\tilde{\mu}_2(d_4))\cup(\tilde{\mu}_3(d_4),\,\infty).
\end{cases}$$

Next we consider the dependence of $\mathcal{C}$ on d_1. In this case, we consider the limits

$$\begin{aligned}
\lim_{d_1\to\infty} \frac{C_3(\sigma,d_1,d_4)}{d_1} &= d_3\Big(d_2+\frac{d_4}{\sigma+\tilde{w}^2}\Big) \triangleq b_3(\sigma,d_4),\\
\lim_{d_1\to\infty} \frac{C_2(\sigma,d_1,d_4)}{d_1} &= md_2+d_3+\frac{md_4}{(\sigma+\tilde{w}^2)^2}(\sigma-\tilde{w}^2) \triangleq b_2(\sigma,d_4),\\
\lim_{d_1\to\infty} \frac{C_1(\sigma,d_1,d_4)}{d_1} &= 0,\\
\lim_{d_1\to\infty} \frac{\mathcal{C}(\sigma,d_1,d_4;\,\mu)}{d_1} &= \mu^2[b_3(\sigma,d_4)\mu+b_2(\sigma,d_4)].
\end{aligned}$$

When the parameters satisfy $b_2(\sigma,d_4)<0$, i.e.,

$$md_2+d_3+\frac{m\sigma d_4}{(\sigma+\tilde{w}^2)^2} < \frac{m\tilde{w}^2 d_4}{(\sigma+\tilde{w}^2)^2}, \tag{4.6}$$

one can establish the following similarly to Proposition 2.

Proposition 3. *Assume that* (4.6) *holds. Then there exists a positive constant d_1^* such that, when $d_1\ge d_1^*$, the three roots $\bar\mu_1(d_1)$, $\bar\mu_2(d_1)$, $\bar\mu_3(d_1)$ of $\mathcal{C}(\sigma,d_1,d_4;\,\mu)=0$ are all real and satisfy* $\lim_{d_1\to\infty}\bar\mu_1(d_1)=\lim_{d_1\to\infty}\bar\mu_2(d_1)=0$ *and*

$$\lim_{d_1\to\infty}\bar\mu_3(d_1)=\frac{-b_2(\sigma,d_4)}{b_3(\sigma,d_4)} \triangleq \bar\mu>0. \tag{4.7}$$

Moreover, when $d_1\ge d_1^*$, we have

$$\begin{cases} -\infty<\bar\mu_1(d_1)<0<\bar\mu_2(d_1)<\bar\mu_3(d_1),\\ \mathcal{C}(\sigma,d_1,d_4;\,\mu)<0 \quad when \quad \mu\in(-\infty,\,\bar\mu_1(d_1))\cup(\bar\mu_2(d_1),\,\bar\mu_3(d_1)),\\ \mathcal{C}(\sigma,d_1,d_4;\,\mu)>0 \quad when \quad \mu\in(\bar\mu_1(d_1),\,\bar\mu_2(d_1))\cup(\bar\mu_3(d_1),\,\infty). \end{cases} \tag{4.8}$$

Remark 2. Assume that $\sigma<\tilde{w}^2$. If (i) d_4 is large, or (ii) d_4 is positive and d_2,d_3 are sufficiently small, then the inequality (4.6) holds.

5. A priori estimates. The main purpose of this section is to give a priori positive upper and lower bounds for the positive solutions to (4.1). For this, we shall make use of the following two results.

Proposition 4 (Harnack inequality [21]). *Let $z\in C^2(\Omega)\cap C^1(\bar\Omega)$ be a positive solution to $\Delta z(x)+c(x)z(x)=0$, where $c\in C(\bar\Omega)$, satisfying the homogeneous Neumann boundary condition. Then there exists a positive constant C which depends only on B where $\|c\|_\infty\le B$ such that* $\max_{\bar\Omega} z\le C\min_{\bar\Omega} z$.

Proposition 5 (maximum principle [25]). *Suppose that $g\in C(\bar\Omega)$ and $b_j\in C(\bar\Omega)$, $j=1,2,\dots,N$.*

(i) *If $z\in C^2(\Omega)\cap C^1(\bar\Omega)$ satisfies*

$$\Delta z(x)+\sum_{j=1}^N b_j(x)z_{x_j}+g(x)\ge 0 \quad in \quad \Omega, \qquad \frac{\partial z}{\partial\nu}\Big|_{\partial\Omega}\le 0,$$

and $z(x_0)=\max_{\bar\Omega} z$, then $g(x_0)\ge 0$.

(ii) *If $z \in C^2(\Omega) \cap C^1(\bar{\Omega})$ satisfies*

$$\Delta z(x) + \sum_{j=1}^{N} b_j(x) z_{x_j} + g(x) \le 0 \quad in \ \ \Omega, \qquad \frac{\partial z}{\partial \nu}\Big|_{\partial\Omega} \ge 0,$$

and $z(x_0) = \min_{\bar{\Omega}} z$, then $g(x_0) \le 0$.

For clarity, we write the problem (4.1) explicitly:

$$(5.1) \qquad \begin{cases} -d_1 \Delta u = au - u^2 - \varepsilon uv - uw, & x \in \Omega, \\ -\Delta \left(d_2 v + \dfrac{d_4 v}{\sigma + w^2} \right) = kuw - v, & x \in \Omega, \\ -d_3 \Delta w = bv - mw, & x \in \Omega, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases}$$

In the rest of this section, we fix the parameters a, b, k, m, ε, and σ and estimate the upper and lower positive bounds of positive solutions to (5.1) with respect to the diffusion and cross diffusion coefficients d_i. The generic constants C, C_i to be used below will depend on the parameters a, b, k, m, ε, and σ. As they are fixed, this dependence will not be stated explicitly.

Proposition 6. *Let d and d^* be two fixed positive constants. Then there is a positive constant $C(d, d^*)$ such that, for any $d_1, d_2, d_3 \ge d$, and $0 \le d_4 \le d^*$, every possible positive solution (u, v, w) of* (5.1) *satisfies*

$$(5.2) \qquad \|u, v, w\|_{C^{2+\alpha}(\bar{\Omega})} \le C(d, d^*).$$

Proof. We first prove the estimate

$$(5.3) \qquad \max_{\bar{\Omega}} u, \ \max_{\bar{\Omega}} v, \ \max_{\bar{\Omega}} w \le C(d, d^*).$$

Applying the maximum principle to the equation of u, it is directly deduced that $\max_{\bar{\Omega}} u \le a$. If the estimate (5.3) is not true, then there exist $(d_{1n}, d_{2n}, d_{3n}, d_{4n})$ satisfying d_{1n}, d_{2n}, $d_{3n} \ge d$, and $0 \le d_{4n} \le d^*$, and a corresponding positive solution (u_n, v_n, w_n) of (5.1) with $(d_1, d_2, d_3, d_4) = (d_{1n}, d_{2n}, d_{3n}, d_{4n})$, such that

$$(5.4) \qquad \max_{\bar{\Omega}} v_n + \max_{\bar{\Omega}} w_n \to \infty \quad \text{as } n \to \infty.$$

Applying the maximum principle to the equation of w_n, we have

$$(5.5) \qquad \max_{\bar{\Omega}} w_n \le (b/m) \max_{\bar{\Omega}} v_n.$$

Let $\varphi_n = d_{2n} v_n + \frac{d_{4n} v_n}{\sigma + w_n^2}$ and $x_0 \in \bar{\Omega}$ be such that $\varphi_n(x_0) = \max_{\bar{\Omega}} \varphi_n$. Applying the maximum principle to the equation of v_n, we have $v_n(x_0) \le k u_n(x_0) w_n(x_0) \le ka \max_{\bar{\Omega}} w_n$. Hence,

$$\begin{aligned} d_{2n} \max_{\bar{\Omega}} v_n \le \max_{\bar{\Omega}} \varphi_n = \varphi_n(x_0) &= d_{2n} v_n(x_0) + \frac{d_{4n} v_n(x_0)}{\sigma + w_n^2(x_0)} \\ &\le v_n(x_0) \left(d_{2n} + \frac{d^*}{\sigma} \right) \le ka \max_{\bar{\Omega}} w_n \left(d_{2n} + \frac{d^*}{\sigma} \right), \end{aligned}$$

which implies that

$$\max_{\bar\Omega} v_n \le ka\left(1+\frac{d^*}{\sigma d}\right)\max_{\bar\Omega} w_n. \tag{5.6}$$

It follows from (5.4)–(5.6) that $\lim_{n\to\infty}\max_{\bar\Omega} v_n = \lim_{n\to\infty}\max_{\bar\Omega} w_n = \infty$. Set $\hat v_n = \frac{v_n}{\|v_n\|_\infty}$ and $\hat w_n = \frac{w_n}{\|w_n\|_\infty}$. Then $(u_n, \hat v_n, \hat w_n)$ satisfies

$$\begin{cases} -d_{1n}\Delta u_n = u_n\big[a-u_n-\varepsilon\|v_n\|_\infty \hat v_n - \|w_n\|_\infty \hat w_n\big], & x\in\Omega,\\ -\Delta\left(\hat v_n + \dfrac{d_{4n}\hat v_n}{d_{2n}(\sigma+\|w_n\|_\infty^2\hat w_n^2)}\right) = \dfrac{1}{d_{2n}}\left(ku_n\dfrac{\|w_n\|_\infty}{\|v_n\|_\infty}\hat w_n - \hat v_n\right), & x\in\Omega,\\ -\Delta \hat w_n = \dfrac{1}{d_{3n}}\left(b\dfrac{\|v_n\|_\infty}{\|w_n\|_\infty}\hat v_n - m\hat w_n\right), & x\in\Omega,\\ \|\hat v_n\|_\infty = \|\hat w_n\|_\infty = 1, \quad \dfrac{\partial u_n}{\partial\nu} = \dfrac{\partial \hat v_n}{\partial\nu} = \dfrac{\partial \hat w_n}{\partial\nu} = 0, & x\in\partial\Omega. \end{cases} \tag{5.7}$$

In view of (5.5) and (5.6) we have $A\|v_n\|_\infty \le \|w_n\|_\infty \le B\|v_n\|_\infty$ for some positive constants A and B. Since $0\le u_n\le a$ and $0\le \hat v_n, \hat w_n \le 1$, subject to a subsequence we may assume that $\|v_n\|_\infty/\|w_n\|_\infty \to \theta$ for some positive constant θ, and

$$\begin{gathered} d_{in}\to d_i \quad \text{with } d_1,d_2,d_3\ge d, \text{ and } 0\le d_4\le d^*,\\ u_n\to u \ \text{ strongly in } \ L^p(\Omega), \quad \hat v_n\to\hat v \ \text{ weakly in } \ L^p(\Omega),\\ \hat\varphi_n\to\hat\varphi,\quad \hat w_n\to\hat w \quad \text{weakly in } \ W^{2,p}(\Omega), \quad \text{and } \ \|\hat w\|_\infty = 1, \end{gathered}$$

where $p>N$ and $\hat\varphi_n = \hat v_n + \frac{d_{4n}\hat v_n}{d_{2n}(\sigma+\|w_n\|_\infty^2\hat w_n^2)}$. Hence $\hat\varphi$, $\hat w\in C^{1+\alpha}(\bar\Omega)$ for some $\alpha>0$, and $\hat\varphi_n\to\hat\varphi$, $\hat w_n\to\hat w$ in $C^{1+\alpha}(\bar\Omega)$.

If $d_3=\infty$, then $\hat w$ satisfies

$$-\Delta\hat w = 0 \quad \text{in } \ \Omega, \qquad \frac{\partial\hat w}{\partial\nu} = 0 \quad \text{on } \ \partial\Omega, \qquad \|\hat w\|_\infty = 1,$$

which implies that $\hat w = 1$. If $d_3<\infty$, then $\hat w$ satisfies $\|\hat w\|_\infty = 1$ and

$$-d_3\Delta\hat w = b\theta\hat v - m\hat w \quad \text{in } \ \Omega, \qquad \frac{\partial\hat w}{\partial\nu} = 0 \quad \text{on } \ \partial\Omega. \tag{5.8}$$

By the strong maximum principle and the Hopf boundary lemma for the $W^{2,N}(\Omega)$ solution (see [15, Theorem 9.6] and [12, Theorem 2.11]), we see that $\hat w>0$ on $\bar\Omega$.

The above analysis shows that, for both cases $d_3=\infty$ and $d_3<\infty$, we have $\hat w>0$ on $\bar\Omega$. Hence, there is a positive constant δ such that $\hat w\ge\delta$ on $\bar\Omega$. Consequently, $\hat w_n\ge\delta/2$ on $\bar\Omega$ for all large n. Since $\|w_n\|_\infty\to\infty$ as $n\to\infty$, from the equation of u_n in (5.7) we have that, for large n,

$$\begin{cases} -d_{1n}\Delta u_n = u_n\big[a-u_n-\varepsilon\|v_n\|_\infty\hat v_n - \|w_n\|_\infty\hat w_n\big]\\ \qquad\qquad\quad \le u_n\big[a-(\delta/2)\|w_n\|_\infty\big] < 0, \qquad x\in\Omega,\\ \dfrac{\partial u_n}{\partial\nu} = 0, \qquad x\in\partial\Omega. \end{cases}$$

This is impossible since $\int_\Omega \Delta u_n dx = 0$.

Now, we prove the estimate (5.2). Due to (5.3), by the regularity for elliptic equations we have that u, w, and $v\left[d_2 + d_4/(\sigma + w^2)\right]$ belong to $C^{1+\alpha}(\bar{\Omega})$, and the $C^{1+\alpha}(\bar{\Omega})$ norms of them depend only on the parameters d, d^* and the parameters $a, b, k, m, \varepsilon, \sigma$. It follows that $v \in C^{1+\alpha}(\bar{\Omega})$ and $\|v\|_{C^{1+\alpha}(\bar{\Omega})}$ depends only on the parameters d, d^* and $a, b, k, m, \varepsilon, \sigma$. Using the regularity of elliptic equations again, the estimate (5.2) follows. □

In the following we estimate the positive lower bound of positive solutions. We first state a lemma whose proof we shall omit.

Lemma 1. *Let $d_{in} \in (0, \infty)$, $i = 1, 2, 3, 4$, and (u_n, v_n, w_n) be the corresponding positive solution of* (5.1) *with $d_i = d_{in}$. Assume that $d_{in} \to d_i \in [0, \infty]$ and $(u_n, v_n, w_n) \to (u^*, v^*, w^*)$ uniformly on $\bar{\Omega}$. If u^*, v^*, and w^* are constants, then (u^*, v^*, w^*) must satisfy $a - u^* - \varepsilon v^* - w^* = 0$, $ku^*w^* - v^* = 0$, and $bv^* - mw^* = 0$. In particular, if u^*, v^*, and w^* are positive constants, then $(u^*, v^*, w^*) = (\tilde{u}, \tilde{v}, \tilde{w})$, the unique positive constant solution of* (5.1).

Proposition 7. *Let d and d^* be two fixed positive constants. Then there is a positive constant $C(d, d^*)$ such that, for any $d_1, d_2, d_3 \geq d$, and $0 \leq d_4 \leq d^*$, every possible positive solution (u, v, w) of* (5.1) *satisfies*

$$\min_{\bar{\Omega}} u,\ \min_{\bar{\Omega}} v,\ \min_{\bar{\Omega}} w \geq \frac{1}{C(d, d^*)}.$$

Proof. If the conclusion does not hold, then there exist a sequence $\{(d_{1n}, d_{2n}, d_{3n}, d_{4n})\}$ which satisfies $d_{1n}, d_{2n}, d_{3n} \geq d$, and $0 \leq d_{4n} \leq d^*$ and a sequence of corresponding positive solutions (u_n, v_n, w_n) of (5.1) with $d_i = d_{in}$, such that $\min\{\min_{\bar{\Omega}} u_n, \min_{\bar{\Omega}} v_n, \min_{\bar{\Omega}} w_n\} \to 0$. As $d_{1n}, d_{2n}, d_{3n} \geq d$, subject to a subsequence, we may assume that $d_{in} \to d_i \in [d, \infty]$ for $i = 1, 2, 3$, and $d_{4n} \to d_4 \in [0, d^*]$. By (5.2), we may also assume that $(u_n, v_n, w_n) \to (u, v, w)$ in $[C^{2+\alpha}(\bar{\Omega})]^3$ for some nonnegative functions u, v, w. It is easy to see that (u, v, w) also satisfies the estimate (5.2), and $\min_{\bar{\Omega}} u = 0$ or $\min_{\bar{\Omega}} v = 0$ or $\min_{\bar{\Omega}} w = 0$. Moreover, we observe that, if $d_1, d_2, d_3 < \infty$, then (u, v, w) satisfies (5.1). If $d_1 = \infty$, as (u_n, v_n, w_n) satisfies (5.3), then u satisfies $-\Delta u = 0$ in Ω and $\partial u/\partial \nu = 0$ on $\bar{\Omega}$, and hence u is constant. Analogous conclusions hold for d_2 and d_3.

Next we derive a contradiction for every possible case.

Step 1. We consider the case $d_1, d_2, d_3 < \infty$. First, in view of (5.3), the Harnack inequality shows $\min_{\bar{\Omega}} u = 0$ implies that $u = 0$ on $\bar{\Omega}$. In that case, by the strong maximum principle and the Hopf boundary lemma, it follows that $v = w = 0$ on $\bar{\Omega}$. But this is a contradiction to Lemma 1. Thus, $\min_{\bar{\Omega}} u > 0$.

Next, we show that $\min_{\bar{\Omega}} v = \min_{\bar{\Omega}} w = 0$. By our assumption, at least one of these is 0. If $\min_{\bar{\Omega}} w = 0$, we denote $w(x_0) = \min_{\bar{\Omega}} w$. By the maximum principle we have $bv(x_0) \leq mw(x_0) = 0$, and so $\min_{\bar{\Omega}} v = 0$. Conversely, if $v(x_1) = \min_{\bar{\Omega}} v = 0$, then $v(x_1)[d_2 + d_4/(\sigma + w^2(x_1))] = 0 = \min_{\bar{\Omega}} v[d_2 + d_4/(\sigma + w^2)]$. Applying the maximum principle to the second equation of (5.1), we have $ku(x_1)w(x_1) \leq v(x_1) = 0$. As $u(x_1) > 0$, we conclude that $w(x_1) = 0$, and so $\min_{\bar{\Omega}} w = 0$. In conclusion, we always have $\min_{\bar{\Omega}} v = \min_{\bar{\Omega}} w = 0$; that is, $\lim_{n\to\infty} \min_{\bar{\Omega}} v_n = \lim_{n\to\infty} \min_{\bar{\Omega}} w_n = 0$.

Define

$$\hat{v}_n = \frac{v_n}{\|v_n\|_\infty + \|w_n\|_\infty}, \quad \hat{w}_n = \frac{w_n}{\|v_n\|_\infty + \|w_n\|_\infty}. \tag{5.9}$$

Then $(u_n, \hat{v}_n, \hat{w}_n, w_n)$ satisfies

$$\begin{cases} -d_{1n}\Delta u_n = u_n(a - u_n - \varepsilon v_n - w_n), & x \in \Omega, \\ -\Delta\left(d_{2n}\hat{v}_n + \dfrac{d_{4n}\hat{v}_n}{\sigma + w_n^2}\right) = ku_n\hat{w}_n - \hat{v}_n, & x \in \Omega, \\ -d_{3n}\Delta\hat{w}_n = b\hat{v}_n - m\hat{w}_n, & x \in \Omega, \\ \dfrac{\partial u_n}{\partial\nu} = \dfrac{\partial\hat{v}_n}{\partial\nu} = \dfrac{\partial\hat{w}_n}{\partial\nu} = 0, & x \in \partial\Omega. \end{cases}$$

Similarly to the above, we can prove that there exist a subsequence of $\{(\hat{v}_n, \hat{w}_n)\}$, denoted by itself, and nonnegative functions $\hat{v}$ and $\hat{w}$, such that $(\hat{v}_n, \hat{w}_n) \to (\hat{v}, \hat{w})$ in $[C^{2+\alpha}(\bar{\Omega})]^2$ and $\|\hat{v}\|_\infty + \|\hat{w}\|_\infty = 1$. Moreover, if $\|v_n\|_\infty + \|w_n\|_\infty \geq \delta$ for some constant $\delta > 0$, then $(u, \hat{v}, \hat{w}, w)$ satisfies $\min_{\bar{\Omega}} \hat{v} = \min_{\bar{\Omega}} \hat{w} = 0$ and

$$\begin{cases} -d_1\Delta u = u(a - u - \varepsilon v - w), & x \in \Omega, \\ -\Delta\left(d_2\hat{v} + \dfrac{d_4\hat{v}}{\sigma + w^2}\right) = ku\hat{w} - \hat{v}, & x \in \Omega, \\ -d_3\Delta\hat{w} = b\hat{v} - m\hat{w}, & x \in \Omega, \\ \dfrac{\partial u}{\partial\nu} = \dfrac{\partial\hat{v}}{\partial\nu} = \dfrac{\partial\hat{w}}{\partial\nu} = 0, & x \in \partial\Omega. \end{cases} \tag{5.10}$$

If $\lim_{n\to\infty}\big(\|v_n\|_\infty + \|w_n\|_\infty\big) = 0$, then $v = w = 0$ and $(u, \hat{v}, \hat{w})$ satisfies

$$\begin{cases} -d_1\Delta u = u(a - u), & x \in \Omega, \\ -(d_2 + d_4/\sigma)\Delta\hat{v} = ku\hat{w} - \hat{v}, & x \in \Omega, \\ -d_3\Delta\hat{w} = b\hat{v} - m\hat{w}, & x \in \Omega, \\ \dfrac{\partial u}{\partial\nu} = \dfrac{\partial\hat{v}}{\partial\nu} = \dfrac{\partial\hat{w}}{\partial\nu} = 0, & x \in \partial\Omega. \end{cases} \tag{5.11}$$

In the case where (5.10) holds, writing the equation of $\hat{w}$ as

$$-d_3\Delta\hat{w} + m\hat{w} = b\hat{v} \geq 0 \ \text{ in } \ \Omega, \qquad \partial\hat{w}/\partial\nu = 0 \ \text{ on } \ \partial\Omega,$$

using $\min_{\bar{\Omega}} \hat{w} = 0$, and applying the strong maximum principle and the Hopf boundary lemma, we derive that $\hat{w} = 0$, and in turn $\hat{v} = 0$. This is a contradiction to $\|\hat{v}\|_\infty + \|\hat{w}\|_\infty = 1$.

When (5.11) holds, as $u > 0$, from the equation of u we conclude that $u = a$. Thus we have

$$\begin{cases} -(d_2 + d_4/\sigma)\Delta\hat{v} = ka\hat{w} - \hat{v}, & x \in \Omega, \\ -d_3\Delta\hat{w} = b\hat{v} - m\hat{w}, & x \in \Omega, \\ \dfrac{\partial\hat{v}}{\partial\nu} = \dfrac{\partial\hat{w}}{\partial\nu} = 0, & x \in \partial\Omega. \end{cases} \tag{5.12}$$

Since the parameters a, b, k, m are positive, and $\hat{v}$ and $\hat{w}$ are nonnegative and satisfy $\|\hat{v}\|_\infty + \|\hat{w}\|_\infty = 1$, by the strong maximum principle and the Hopf boundary lemma, we find that $\hat{v}$ and $\hat{w}$ are positive functions. Let $x_i, y_i \in \bar{\Omega}$ be such that $\hat{v}(x_1) = \min_{\bar{\Omega}} \hat{v}$,

$\hat{v}(y_1) = \max_{\bar{\Omega}} \hat{v}$, $\hat{w}(x_2) = \min_{\bar{\Omega}} \hat{w}$, and $\hat{w}(y_2) = \max_{\bar{\Omega}} \hat{w}$. Applying the maximum principle to (5.13), we have $\hat{v}(x_1) \geq ka\hat{w}(x_1) \geq ka\hat{w}(x_2)$, $\hat{v}(y_1) \leq ka\hat{w}(y_1) \leq ka\hat{w}(y_2)$, $m\hat{w}(x_2) \geq b\hat{v}(x_2) \geq b\hat{v}(x_1)$, $m\hat{w}(y_2) \leq b\hat{v}(y_2) \leq b\hat{v}(y_1)$. Since $\hat{v}(x_1) > 0$, it follows that $m = abk$, which is a contradiction to the condition $m < abk$.

Step 2. We now consider the remaining cases.

Since (u_n, v_n, w_n) satisfies $\int_\Omega v_n \mathrm{d}x = k \int_\Omega u_n w_n \mathrm{d}x$ and $m \int_\Omega w_n \mathrm{d}x = b \int_\Omega v_n \mathrm{d}x$, we have that

$$\int_\Omega v \mathrm{d}x = k \int_\Omega uw \mathrm{d}x, \quad m \int_\Omega w \mathrm{d}x = b \int_\Omega v \mathrm{d}x. \tag{5.13}$$

(i) If $d_1 = \infty$, then $u = u^* =$ constant. If $u^* = 0$, from (5.13), we have in turn that $v = w = 0$. This contradicts Lemma 1. So, $u^* > 0$.

(ia) If $d_2, d_3 < \infty$, then since either $\min_{\bar{\Omega}} v = 0$ or $\min_{\bar{\Omega}} w = 0$, similar to the arguments of Step 1, we have that $\min_{\bar{\Omega}} v = \min_{\bar{\Omega}} w = 0$. Note that the functions $\hat{v}_n, \hat{w}_n$ defined by (5.9) satisfy

$$\begin{cases} -\Delta\left(d_{2n}\hat{v}_n + \dfrac{d_{4n}\hat{v}_n}{\sigma + w_n^2}\right) = ku_n\hat{w}_n - \hat{v}_n, & x \in \Omega, \\ -d_{3n}\Delta\hat{w}_n = b\hat{v}_n - m\hat{w}_n, & x \in \Omega, \\ \dfrac{\partial \hat{v}_n}{\partial \nu} = \dfrac{\partial \hat{w}_n}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{5.14}$$

Similar to the above, we may assume that $(\hat{v}_n, \hat{w}_n) \to (\hat{v}, \hat{w})$ in $[C^{2+\alpha}(\bar{\Omega})]^2$ for some nonnegative functions $\hat{v}$ and $\hat{w}$, and $(\hat{v}, \hat{w})$ satisfies $\|\hat{v}\|_\infty + \|\hat{w}\|_\infty = 1$.

If $\|v_n\|_\infty + \|w_n\|_\infty \geq \delta$ for some constant $\delta > 0$, then $(\hat{v}, \hat{w})$ satisfies $\min_{\bar{\Omega}} \hat{v} = \min_{\bar{\Omega}} \hat{w} = 0$ and

$$\begin{cases} -\Delta\left(d_2\hat{v} + \dfrac{d_4\hat{v}}{\sigma + w^2}\right) = ku^*\hat{w} - \hat{v}, & x \in \Omega, \\ -d_3\Delta\hat{w} = b\hat{v} - m\hat{w}, & x \in \Omega, \\ \dfrac{\partial \hat{v}}{\partial \nu} = \dfrac{\partial \hat{w}}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases}$$

Similar to the discussion of the problem (5.10) we can get a contradiction. If $\lim_{n\to\infty} \big(\|v_n\|_\infty + \|w_n\|_\infty\big) = 0$, then $v = w = 0$ and $(\hat{v}, \hat{w})$ satisfies

$$\begin{cases} -(d_2 + d_4/\sigma)\Delta\hat{v} = ku^*\hat{w} - \hat{v}, & x \in \Omega, \\ -d_3\Delta\hat{w} = b\hat{v} - m\hat{w}, & x \in \Omega, \\ \dfrac{\partial \hat{v}}{\partial \nu} = \dfrac{\partial \hat{w}}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{5.15}$$

As $(u, v, w) = (u^*, 0, 0)$, by Lemma 1, we have $u^* = a$. Thus, (5.15) is exactly (5.12). Similar to the arguments of the last part of Step 1, we arrive at $m = abk$—a contradiction.

Similarly, we can derive contradictions for all the other cases. □

6. Nonexistence of nonconstant positive solutions of (5.1) without cross diffusion. In this section we shall prove that, when $d_4 = 0$, the problem (5.1) has no nonconstant positive solution if d_1 is large. When $d_4 = 0$, (5.1) becomes

$$\begin{cases} -d_1\Delta u = au - u^2 - \varepsilon uv - uw, & x \in \Omega, \\ -d_2\Delta v = kuw - v, & x \in \Omega, \\ -d_3\Delta w = bv - mw, & x \in \Omega, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x \in \partial\Omega. \end{cases} \tag{6.1}$$

The main result of this section is the following theorem.

THEOREM 4. *Let the parameters $d_2, d_3, a, b, k, m,$ and ε be fixed positive constants, and $m < abk$. Then there exists a positive constant $\hat{d}_1$ such that, when $d_1 \geq \hat{d}_1$,* (6.1) *has no nonconstant positive solutions.*

To prove this theorem, we will make use of the following lemma, which can be proved using results and methods of section 5. We shall omit the details.

LEMMA 2. *Let (u, v, u) be the positive solution of* (6.1). *Then we have*

$$\lim_{d_1 \to \infty} (u, v, w) = (\tilde{u}, \tilde{v}, \tilde{w}) \quad \textit{in } [C^2(\bar{\Omega})]^3, \tag{6.2}$$

where $(\tilde{u}, \tilde{v}, \tilde{w})$ is the positive constant solution of (6.1) *given by* (1.4).

Proof of Theorem 4. Define $W_\nu^{2,2}(\Omega) = \{u \in W^{2,2}(\Omega) : \frac{\partial u}{\partial \nu}|_{\partial\Omega} = 0\}$ and $W_{\nu,0}^{2,2}(\Omega) = W_\nu^{2,2}(\Omega) \cap L_0^2(\Omega)$, where $L_0^2(\Omega) = \{u \in L^2(\Omega) : \int_\Omega u \mathrm{d}x = 0\}$. Denote $\rho = d_1^{-1}$ and decompose $u = h + z$ with $h \in \mathbb{R}^1$ and $z \in W_{\nu,0}^{2,2}$. Let

$$F(\rho, h, z, v, w) = \begin{pmatrix} \displaystyle\int_\Omega (h+z)(a - h - z - \varepsilon v - w)\mathrm{d}x \\ \Delta z + \rho(h+z)(a - h - z - \varepsilon v - w) \\ d_2\Delta v - v + k(h+z)w \\ d_3\Delta w - mw + bv \end{pmatrix}.$$

Then $F : \mathbb{R}^2 \times W_{\nu,0}^{2,2}(\Omega) \times [W_\nu^{2,2}(\Omega)]^2 \to \mathbb{R}^1 \times L_0^2(\Omega) \times [L^2(\Omega)]^2$, and, for any $\rho > 0$, (u, v, w) solves (6.1) if and only if $F(\rho, h, z, v, w) = 0$. It is obvious that, for any ρ, we have $F(\rho, \tilde{u}, 0, \tilde{v}, \tilde{w}) = 0$.

Let Ψ be the Fréchet derivative of F at $(0, \tilde{u}, 0, \tilde{v}, \tilde{w})$ with respect to (h, z, v, w). A direct computation yields

$$\Psi(h, z, v, w) = \begin{pmatrix} \displaystyle -\tilde{u}\int_\Omega (h + z + \varepsilon v + w)\mathrm{d}x \\ \Delta z \\ d_2\Delta v - v + k\tilde{w}(h+z) + k\tilde{u}w \\ d_3\Delta w - mw + bv \end{pmatrix}.$$

We prove that Ψ is injective and surjective: It suffices to show that for any given $(h_1, z_1, v_1, w_1) \in \mathbb{R}^1 \times L_0^2(\Omega) \times [L^2(\Omega)]^2$, the equation $\Psi(h, z, v, w) = (h_1, z_1, v_1, w_1)$ has a unique solution $(h, z, v, w) \in \mathbb{R}^1 \times W_{\nu,0}^{2,2}(\Omega) \times [W_\nu^{2,2}(\Omega)]^2$, or equivalently, the following system has a unique solution:

$$\int_\Omega (h+z+\varepsilon v+w)\mathrm{d}x = -\frac{h_1}{\tilde{u}}, \tag{6.3}$$

$$\Delta z = z_1 \text{ in } \Omega, \quad \frac{\partial z}{\partial \nu}\Big|_{\partial\Omega} = 0, \quad \int_\Omega z\mathrm{d}x = 0, \tag{6.4}$$

$$\begin{cases} d_2\Delta v - v + k\tilde{w}(h+z) + (m/b)w = v_1, & x\in\Omega, \\ d_3\Delta w - mw + bv = w_1, & x\in\Omega, \\ \dfrac{\partial v}{\partial\nu} = \dfrac{\partial w}{\partial\nu} = 0, & x\in\partial\Omega. \end{cases} \tag{6.5}$$

Since $z_1 \in L_0^2(\Omega)$, (6.4) has a unique solution z. From (6.5) we have that

$$\begin{cases} \Delta(bd_2v + d_3w) + bk\tilde{w}(h+z) = bv_1 + w_1, & x\in\Omega, \\ \dfrac{\partial(bd_2v+d_3w)}{\partial\nu} = 0, & x\in\partial\Omega. \end{cases} \tag{6.6}$$

Since $\int_\Omega z\mathrm{d}x = 0$, (6.6) has a solution if and only if h satisfies

$$bk\tilde{w}h|\Omega| = \int_\Omega (bv_1 + w_1)\mathrm{d}x. \tag{6.7}$$

With such an h, which is obviously uniquely determined, (6.6) has a solution of the form $bd_2v + d_3w = g(x) + \lambda$, where λ is a constant (which will be uniquely determined later) and $g(x)$ is uniquely determined and satisfies $\int_\Omega g(x)\mathrm{d}x = 0$. The equation of w in (6.5) now becomes

$$d_3\Delta w - \left(m + \frac{d_3}{d_2}\right)w + \frac{g+\lambda}{d_2} = w_1 \text{ in } \Omega, \qquad \frac{\partial w}{\partial\nu} = 0 \text{ on } \partial\Omega.$$

For a given constant λ, this problem has a unique solution $w = w_\lambda(x)$ that satisfies

$$\int_\Omega w_1 dx + \left(m + \frac{d_3}{d_2}\right)\int_\Omega w\mathrm{d}x = \frac{1}{d_2}\int_\Omega g(x)\mathrm{d}x + \frac{\lambda}{d_2}|\Omega| = \frac{\lambda}{d_2}|\Omega|. \tag{6.8}$$

As a result, we have

$$\begin{aligned} \int_\Omega (\varepsilon v + w)\mathrm{d}x &= \int_\Omega \left(\varepsilon\frac{g(x)+\lambda-d_3w}{bd_2} + w\right)\mathrm{d}x \\ &= \frac{\lambda\varepsilon}{bd_2}|\Omega| + \left(1 - \frac{\varepsilon d_3}{bd_2}\right)\int_\Omega w\mathrm{d}x \\ &= \lambda\frac{(b+m\varepsilon)|\Omega|}{b(md_2+d_3)} - \frac{d_2}{md_2+d_3}\left(1-\frac{\varepsilon d_3}{bd_2}\right)\int_\Omega w_1 dx. \end{aligned}$$

Substituting this identity into (6.3) and making use of (6.7), we find that λ is uniquely determined by

$$-\frac{h_1}{\tilde{u}} - \frac{1}{bk\tilde{w}}\int_\Omega (bv_1+w_1)\mathrm{d}x = \lambda\frac{(b+m\varepsilon)|\Omega|}{b(md_2+d_3)} - \frac{d_2}{md_2+d_3}\left(1-\frac{\varepsilon d_3}{bd_2}\right)\int_\Omega w_1 dx,$$

and thus w and hence v are uniquely determined. In conclusion, for any given $(h_1, z_1, v_1, w_1) \in \mathbb{R}^1 \times L_0^2(\Omega) \times [L^2(\Omega)]^2$, the equation $\Psi(h,z,v,w) = (h_1,z_1,v_1,w_1)$

has a unique solution. This proves that Ψ is a one-to-one and surjective map between two Banach spaces. Therefore, Ψ^{-1} exists and is a bounded linear operator.

To complete the proof of Theorem 4, we note that, by the implicit function theorem, there is a constant $\delta > 0$ such that, for all $0 < \rho < \delta$, in a small neighborhood of $(\tilde{u}, 0, \tilde{v}, \tilde{w})$, the equation $F(\rho, h, z, v, w) = 0$ has a unique solution, which must be $(\tilde{u}, 0, \tilde{v}, \tilde{w})$. Correspondingly, when d_1 is large, in a small neighborhood of $(\tilde{u}, \tilde{v}, \tilde{w})$, the problem (6.1) has only the constant solution $(\tilde{u}, \tilde{v}, \tilde{w})$. This fact, combined with Lemma 2, concludes the proof. $\square$

7. Existence of stationary patterns for the PDE system with cross diffusion (1.6). In this section we shall discuss the existence of nonconstant positive solutions to (5.1). These solutions are not close to a constant solution and are obtained for large cross diffusion coefficient d_4, or for large diffusion coefficient d_1 (and $d_4 > 0$), with the other parameters $d_2, d_3, a, b, k, m, \varepsilon$, and σ suitably fixed. Those stationary patterns which are close to a positive constant solution are discussed in the next section, through bifurcation analysis. Our results here are as follows.

THEOREM 5. *Let the parameters $d_1, d_2, d_3, a, b, k, m, \varepsilon$, and σ be fixed such that $m < abk$ and $\sigma < \tilde{w}^2$. Let $\tilde{\mu}$ be given by the limit* (4.4). *If $\tilde{\mu} \in (\mu_n, \mu_{n+1})$ for some $n \geq 2$ and the sum $\sum_{i=2}^{n} \dim E(\mu_i)$ is odd, then there exists a positive constant d_4^* such that, for $d_4 \geq d_4^*$,* (5.1) *has at least one nonconstant positive solution.*

THEOREM 6. *Let the parameters $d_2, d_3, d_4, a, b, k, m, \varepsilon$, and σ be fixed so that $m < abk$ and* (4.6) *holds. Let $\bar{\mu}$ be given by the limit* (4.7). *If $\bar{\mu} \in (\mu_n, \mu_{n+1})$ for some $n \geq 2$ and the sum $\sum_{i=2}^{n} \dim E(\mu_i)$ is odd, then there exists a positive constant d_1^* such that, for $d_1 \geq d_1^*$,* (5.1) *has at least one nonconstant positive solution.*

Remark 3. The allowable values of $\tilde{\mu}$ and $\bar{\mu}$ in Theorems 5 and 6 may cover a wide range as the parameters vary. For example, $\tilde{\mu}$ is large when d_1 and d_3 are small while all the other parameters in Theorem 5 are fixed; $\bar{\mu}$ is large when d_3 is small and d_4 is large while all the other parameters in Theorem 6 are fixed and the required conditions are satisfied. Another way to see that the conditions $\tilde{\mu} \in (\mu_n, \mu_{n+1})$ and $\bar{\mu} \in (\mu_n, \mu_{n+1})$ are easily satisfied is to fix all the parameters but vary the underlying domain Ω. For example, if we replace Ω by $s\Omega = \{sx : x \in \Omega\}$, then μ_i is changed to $s^{-2}\mu_i$, and therefore the above conditions for $\tilde{\mu}$ and $\bar{\mu}$ are satisfied, respectively, for all s in a certain bounded interval.

Remark 4. Theorems 4 and 6 imply that when d_1 is large, stationary patterns arise only when cross diffusion is present, that is, $d_4 > 0$.

As the proofs of Theorems 5 and 6 are similar, we will prove only Theorem 6.

Proof of Theorem 6. By Proposition 3 and our assumption on $\bar{\mu}$, there exists a positive constant d_1^* such that, when $d_1 \geq d_1^*$, (4.8) holds and

$$\bar{\mu}_1(d_1) < 0 = \mu_1 < \bar{\mu}_2(d_1) < \mu_2, \quad \bar{\mu}_3(d_1) \in (\mu_n, \mu_{n+1}). \tag{7.1}$$

We shall prove that for any $d_1 \geq d_1^*$, (5.1) has at least one nonconstant positive solution. The proof, which is by contradiction, is based on the homotopy invariance of the topological degree.

Suppose on the contrary that the assertion is not true for some $d_1 = \bar{d}_1 \geq d_1^*$. In what follows we fix $d_1 = \bar{d}_1$.

For $t \in [0, 1]$, define $\Phi(t; \mathbf{u}) = \big([td_1 + (1-t)\hat{d}_1]u,\ d_2 v + t d_4 v/(\sigma + w^2),\ d_3 w\big)^T$, and consider the problem

$$\begin{cases} -\Delta\Phi(t; \mathbf{u}) = \mathbf{G}(\mathbf{u}), & x \in \Omega, \\ \dfrac{\partial \mathbf{u}}{\partial \nu} = 0, & x \in \partial\Omega, \end{cases} \tag{7.2}$$

where the positive constant $\hat{d}_1$ is determined by Theorem 4. Then $\mathbf{u}$ is a positive nonconstant solution of (5.1) if and only if it is such a solution of (7.2) for $t = 1$. It is obvious that $\tilde{\mathbf{u}}$ is the unique constant positive solution of (7.2) for any $0 \le t \le 1$. As we observed in section 4, for any $0 \le t \le 1$, $\mathbf{u}$ is a positive solution of (7.2) if and only if

$$\mathbf{F}(t;\,\mathbf{u}) \overset{\Delta}{=} \mathbf{u} - (\mathbf{I} - \Delta)^{-1}\Big\{\Phi_{\mathbf{u}}^{-1}(t;\,\mathbf{u})[\mathbf{G}(\mathbf{u}) + \nabla \mathbf{u}\,\Phi_{\mathbf{uu}}(t;\,\mathbf{u})\nabla \mathbf{u}] + \mathbf{u}\Big\} = 0 \quad \text{in} \quad \mathbf{Y}^+.$$

It is obvious that $\mathbf{F}(1;\,\mathbf{u}) = \mathbf{F}(\mathbf{u})$. Theorem 4 shows that $\tilde{\mathbf{u}}$ is the only solution of $\mathbf{F}(0;\,\mathbf{u}) = 0$ in $\mathbf{Y}^+$. By a direct computation, $D_{\mathbf{u}}\mathbf{F}(t;\,\tilde{\mathbf{u}}) = \mathbf{I} - (\mathbf{I} - \Delta)^{-1}\{\Phi_{\mathbf{u}}^{-1}(t;\,\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}}) + \mathbf{I}\}$. In particular, $D_{\mathbf{u}}\mathbf{F}(0;\,\tilde{\mathbf{u}}) = \mathbf{I} - (\mathbf{I} - \Delta)^{-1}\{\mathcal{D}^{-1}\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}}) + \mathbf{I}\}$ and $D_{\mathbf{u}}\mathbf{F}(1;\,\tilde{\mathbf{u}}) = \mathbf{I} - (\mathbf{I} - \Delta)^{-1}\{\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}}) + \mathbf{I}\} = D_{\mathbf{u}}\mathbf{F}(\tilde{\mathbf{u}})$, where $\mathcal{D} = \operatorname{diag}(\hat{d}_1, d_2, d_3)$. From (4.2) and (4.3) we see that

$$H(\mu) = \det\{\Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\}\mathcal{C}(\sigma, d_1, d_4; \mu). \tag{7.3}$$

In view of (4.8) and (7.1), it follows from (7.3) that

$$\begin{cases} H(\mu_1) = H(0) > 0, \\ H(\mu_i) < 0, \quad 2 \le i \le n, \\ H(\mu_i) > 0, \quad i \ge n+1. \end{cases}$$

Therefore, zero is not an eigenvalue of the matrix $\mu_i\mathbf{I} - \Phi_{\mathbf{u}}^{-1}(\tilde{\mathbf{u}})\mathbf{G}_{\mathbf{u}}(\tilde{\mathbf{u}})$ for all $i \ge 1$. Applying Proposition 1, we have that

$$\gamma = \sum_{i \ge 1, H(\mu_i) < 0} \dim E(\mu_i) = \sum_{i=2}^{n} \dim E(\mu_i), \quad \text{which is odd,}$$

and

$$\operatorname{index}(\mathbf{F}(1;\,\cdot),\,\tilde{\mathbf{u}}) = (-1)^\gamma = -1. \tag{7.4}$$

By Theorem 3 and its proof (where $B_3 > 0$), we can easily show that

$$\operatorname{index}(\mathbf{F}(0;\,\cdot),\,\tilde{\mathbf{u}}) = (-1)^0 = 1. \tag{7.5}$$

Now, by Propositions 6 and 7, there exists a positive constant C such that, for all $0 \le t \le 1$, the positive solutions of (7.2) satisfy $1/C < u,\, v,\, w < C$. Therefore, $\mathbf{F}(t;\,\mathbf{u}) \ne 0$ on $\partial B(C)$ for all $0 \le t \le 1$. By the homotopy invariance of the topological degree,

$$\deg(\mathbf{F}(1;\,\cdot),\,0,\,B(C)) = \deg(\mathbf{F}(0;\,\cdot),\,0,\,B(C)). \tag{7.6}$$

On the other hand, by our supposition, both equations $\mathbf{F}(1;\,\mathbf{u}) = 0$ and $\mathbf{F}(0;\,\mathbf{u}) = 0$ have only the positive solution $\tilde{\mathbf{u}}$ in $B(C)$, and hence, by (7.4) and (7.5), $\deg(\mathbf{F}(0;\,\cdot),\,0,\,B(C)) = \operatorname{index}(\mathbf{F}(0;\,\cdot),\,\tilde{\mathbf{u}}) = 1$ and $\deg(\mathbf{F}(1;\,\cdot),\,0,\,B(C)) = \operatorname{index}(\mathbf{F}(1;\,\cdot),\,\tilde{\mathbf{u}}) = -1$. This contradicts (7.6), and the proof is complete. □

8. Bifurcation. In this section, we discuss the bifurcation of nonconstant positive solutions of (5.1) with respect to the cross diffusion coefficient d_4 and the diffusion coefficient d_1.

In the consideration of bifurcation with respect to d_4, we recall that, for a constant solution $\mathbf{u}^*$, $(\tilde{d}_4;\, \mathbf{u}^*) \in (0,\, \infty) \times \mathbf{X}$ is a *bifurcation point* of (5.1) if, for any $\delta \in (0,\, \tilde{d}_4)$, there exists $d_4 \in [\tilde{d}_4 - \delta,\, \tilde{d}_4 + \delta]$ such that (5.1) has a nonconstant positive solution close to $\mathbf{u}^*$. Otherwise, we say that $(\tilde{d}_4;\, \mathbf{u}^*)$ is a *regular point*. Bifurcation and regular points with respect to d_1 are defined analogously.

We shall consider the bifurcation of (5.1) at the equilibrium points $(\tilde{d}_4;\, \tilde{\mathbf{u}})$, $\tilde{d}_4 > 0$, and $(\tilde{d}_1;\, \tilde{\mathbf{u}})$, $\tilde{d}_1 > 0$, respectively, while all other parameters are fixed. Let $\mathcal{S}_p = \{\mu_1,\, \mu_2,\, \mu_3,\, \ldots\}$ and $\Sigma = \{\mu > 0 \mid H(\mu) = 0\}$, where $H(\mu)$ is as defined in (4.2). To emphasize the dependence of $H(\mu)$ and Σ on d_4 or d_1, we write $H(d_4;\, \mu)$ or $H(d_1;\, \mu)$, and $\Sigma_{d_4}(d_4)$ or $\Sigma_{d_1}(d_1)$, respectively. We note that for each $d_4 > 0$ and $d_1 > 0$, Σ may have 0 or 2 elements.

The results of this section are contained in the following two theorems. Their proofs are based on the topological degree arguments used earlier in this paper. We shall omit them but refer the reader to similar treatments in [34].

THEOREM 7 (bifurcation with respect to d_4).

(1) *If* $\mathcal{S}_p \cap \Sigma_{d_4}(\tilde{d}_4) = \emptyset$, *then* $(\tilde{d}_4;\, \tilde{\mathbf{u}})$ *is a regular point of* (5.1).

(2) *Suppose* $\mathcal{S}_p \cap \Sigma_{d_4}(\tilde{d}_4) \neq \emptyset$ *and the positive roots of* $H(\tilde{d}_4;\, \mu) = 0$ *are all simple. If the number of elements in* $\mathcal{S}_p \cap \Sigma_{d_4}(\tilde{d}_4)$ *is odd, then* $(\tilde{d}_4;\, \tilde{\mathbf{u}})$ *is a bifurcation point of* (5.1). *In this case, there exists an interval* $(\alpha, \beta) \subset \mathbb{R}^+$, *where*

(i) $\tilde{d}_4 = \alpha < \beta < \infty$ *and* $\mathcal{S}_p \cap \Sigma_{d_4}(\beta) \neq \emptyset$, *or*

(ii) $0 < \alpha < \beta = \tilde{d}_4$ *and* $\mathcal{S}_p \cap \Sigma_{d_4}(\alpha) \neq \emptyset$, *or*

(iii) $(\alpha, \beta) = (\tilde{d}_4, \infty)$,

such that for every $d_4 \in (\alpha, \beta)$, (5.1) *admits a nonconstant positive solution.*

THEOREM 8 (bifurcation with respect to d_1).

(1) *If* $\mathcal{S}_p \cap \Sigma_{d_1}(\tilde{d}_1) = \emptyset$, *then* $(\tilde{d}_1;\, \tilde{\mathbf{u}})$ *is a regular point of* (5.1).

(2) *Suppose* $\mathcal{S}_p \cap \Sigma_{d_1}(\tilde{d}_1) \neq \emptyset$ *and the positive roots of* $H(\tilde{d}_1;\, \mu) = 0$ *are all simple. If the number of elements in* $\mathcal{S}_p \cap \Sigma_{d_1}(\tilde{d}_1)$ *is odd, then* $(\tilde{d}_1;\, \tilde{\mathbf{u}})$ *is a bifurcation point of* (5.1). *In this case, there exists an interval* $(c,\, d) \subset \mathbb{R}^+$, *where*

(i) $\tilde{d}_1 = c < d < \infty$ *and* $\mathcal{S}_p \cap \Sigma_{d_1}(d) \neq \emptyset$, *or*

(ii) $0 < c < d = \tilde{d}_1$ *and* $\mathcal{S}_p \cap \Sigma_{d_1}(c) \neq \emptyset$, *or*

(iii) $(c,\, d) = (\tilde{d}_1,\, \infty)$, *or*

(iv) $(c,\, d) = (0,\, \tilde{d}_1)$,

such that for every $d_1 \in (c,\, d)$, (5.1) *admits a nonconstant positive solution.*

9. Discussion. In this paper, we have introduced a more realistic mathematical model for a diffusive (spatially dependent) prey-predator system where the predator has a stage structure comprising immature and mature members. In this model, we have explicitly incorporated the interaction between the immature predator and the prey (through increased intake by the mature predators), and the interaction between the immature and the mature predator. In the latter interaction, we model the tendency of the immature predator to stay close to the mature predator by a cross diffusion. As a result, our model is a strongly coupled reaction-diffusion system, which is mathematically more complex than systems used to model stage-structured prey-predator behavior hitherto.

What is noteworthy about this model is that, as the cross diffusion term arises naturally as a reflection of the most salient feature of the immature-mature interaction (namely, that the immature tends to stay close to the mature within a species), it is precisely this cross diffusion that gives rise to stationary patterns for the model. Indeed, we have shown that stationary patterns do not arise for the ODE (spatially independent) model, nor the PDE model without cross diffusion.

We further remark that, besides capturing a salient biological behavior, this particular cross diffusion term is also significant from the mathematical point of view. Indeed, we are able to show that, of all the possible cross diffusions in (a simplified version of) this model (arising from various types of interactions between the different species and subspecies), only this cross diffusion term causes Turing instability. We therefore have the fortuitous situation where *the biological and mathematical interests converge on this cross diffusion term.*

To be more precise, the following represents the most general form of cross diffusions in the prey-predator model (1.5):

(9.1)
$$\begin{cases} u_t - \operatorname{div}\{K_{11}(\mathbf{u})\nabla u + K_{12}(\mathbf{u})\nabla v + K_{13}(\mathbf{u})\nabla w\} = G_1(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ v_t - \operatorname{div}\{K_{22}(\mathbf{u})\nabla v + K_{21}(\mathbf{u})\nabla u + K_{23}(\mathbf{u})\nabla w\} = G_2(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ w_t - \operatorname{div}\{K_{33}(\mathbf{u})\nabla w + K_{31}(\mathbf{u})\nabla u + K_{32}(\mathbf{u})\nabla v\} = G_3(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x \in \partial\Omega, \quad t > 0, \\ w(x,0) \geq 0, \ v(x,0) \geq 0, \ w(x,0) \geq 0, & x \in \Omega, \end{cases}$$

where $\mathbf{u}$ and $\mathbf{G}$ are as in (1.6), and biological considerations require that $K_{ij}(\mathbf{u})$ satisfy [28], [30, Ch.10]

$$\begin{cases} K_{11}(\mathbf{u}),\, K_{22}(\mathbf{u}),\, K_{33}(\mathbf{u}) > 0, \ \ K_{12}(\mathbf{u}),\, K_{13}(\mathbf{u}) \geq 0, \\ K_{21}(\mathbf{u}), \ \ K_{23}(\mathbf{u}), \ \ K_{31}(\mathbf{u}), \ \ K_{32}(\mathbf{u}) \leq 0. \end{cases} \tag{9.2}$$

A simpler version of (9.1) is the following:

$$\begin{cases} u_t - \Delta(d_1 u + u d_{12}(v) + u d_{13}(w)) = G_1(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ v_t - \Delta(d_2 v + v d_{21}(u) + v d_{23}(w)) = G_2(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ w_t - \Delta(d_3 w + w d_{31}(u) + w d_{32}(v)) = G_3(\mathbf{u}), & x \in \Omega, \quad t > 0, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v}{\partial \nu} = \dfrac{\partial w}{\partial \nu} = 0, & x \in \partial\Omega, \quad t > 0, \\ w(x,0) \geq 0, \ v(x,0) \geq 0, \ w(x,0) \geq 0, & x \in \Omega, \end{cases}$$

where d_{ij} are nonnegative C^1 functions satisfying, according to (9.2), $d'_{12}(v)$, $d'_{13}(w) \geq 0$, $d'_{21}(u)$, $d'_{23}(w)$, $d'_{31}(u)$, $d'_{32}(v) \leq 0$.

Our analysis along the lines of this paper for each d_{ij} revealed that $d_{23}(w)$ has the most significant effect on the stability of $\tilde{\mathbf{u}}$. Indeed, except for $d_{23}(w)$, each of the other d_{ij} alone does not seem to cause instability of $\tilde{\mathbf{u}}$.

Finally, we also remark that, while our choice of the cross diffusion term is mainly mathematically motivated, as one of the simplest functions with the required property $d'_{23}(w) \leq 0$ and also giving rise to Turing instability and stationary patterns, it also reflects, as demonstrated earlier, the natural biological behavior of the immature and mature predators. As mentioned in section 1, a slightly more general form of cross diffusion can be adopted for essentially the same mathematical treatment.

Acknowledgments. The authors are grateful to the editor and the referees for helpful comments that greatly improved this paper.

COEXISTENCE OF LIMIT CYCLES AND HOMOCLINIC LOOPS IN A SIRS MODEL WITH A NONLINEAR INCIDENCE RATE[*]

YILEI TANG[†], DEQING HUANG[‡], SHIGUI RUAN[§], AND WEINIAN ZHANG[‡]

Abstract. Recently, Ruan and Wang [*J. Differential Equations*, 188 (2003), pp. 135–163] studied the global dynamics of a SIRS epidemic model with vital dynamics and a nonlinear saturated incidence rate. Under certain conditions they showed that the model undergoes a Bogdanov–Takens bifurcation; i.e., it exhibits saddle-node, Hopf, and homoclinic bifurcations. They also considered the existence of none, one, or two limit cycles. In this paper, we investigate the coexistence of a limit cycle and a homoclinic loop in this model. One of the difficulties is to determine the multiplicity of the weak focus. We first prove that the maximal multiplicity of the weak focus is 2. Then feasible conditions are given for the uniqueness of limit cycles. The coexistence of a limit cycle and a homoclinic loop is obtained by reducing the model to a universal unfolding for a cusp of codimension 3 and studying degenerate Hopf bifurcations and degenerate Bogdanov–Takens bifurcations of limit cycles and homoclinic loops of order 2.

Key words. degenerate Bogdanov–Takens bifurcation, degenerate Hopf bifurcation, limit cycle, homoclinic loop, revised sign list

1. Introduction.

Periodic oscillations are common phenomena observed in the incidence of many infectious diseases such as chickenpox, influenza, measles, mumps, rubella, etc. (see Hethcote [10, 11], Hethcote and Levin [12], Hethcote, Stech, and van den Driessche [13]). It is very important to understand such epidemic patterns in order to introduce public health interventions and control the spread of diseases. Recent studies have demonstrated that the incidence rate plays a crucial role in producing periodic oscillations in epidemic models (Alexander and Moghadas [1, 2], Derrick and van den Driessche [6], Hethcote and van den Driessche [14], Liu et al. [17, 18], Lizana and Rivero [19], Moghadas [21], Moghadas and Alexander [22], Ruan and Wang [25], Wang [26]).

In most epidemic models (see Anderson and May [3]), the *incidence rate* (the number of new cases per unit time) takes the mass-action form with bilinear interactions, namely, $\kappa S(t)I(t)$, where $S(t)$ and $I(t)$ are the numbers of susceptible and infectious individuals at time t, respectively, and the constant κ is the probability of transmission per contact. Epidemic models with such bilinear incidence rates usually have at most one endemic equilibrium and do not exhibit periodicity; the disease will be eradicated if the basic reproduction number is less than one and will persist otherwise (Anderson and May [3], Hethcote [11]). There are many reasons for using nonlinear incidence rates, and various forms of nonlinear incidence rates have

been proposed recently. For example, in order to incorporate the effect of behavioral changes, Liu, Levin, and Iwasa [18] used a nonlinear incidence rate of the form

$$g(I)S = \frac{\kappa I^{\ell} S}{1 + \alpha I^{h}}, \tag{1.1}$$

where κI^{ℓ} measures the infection force of the disease, $1/(1+\alpha I^h)$ describes the inhibition effect from the behavioral change of the susceptible individuals when the number of infectious individuals increases, ℓ, h, and κ are all positive constants, and α is a nonnegative constant. See also Alexander and Moghadas [1, 2], Derrick and van den Driessche [6], Hethcote and van den Driessche [14], Moghadas [21], etc. Notice that the bilinear interaction is a special case of (1.1) with $\alpha = 0$ and $\ell = 1$.

The nonlinear function $g(I)$ given by (1.1) includes three types. (a) Unbounded incidence function: $\ell > h$. The case when $\ell = h + 1$ was considered by Hethcote and van den Driessche [14]. The function is unbounded as the bilinear incidence rate (see Figure 1(a)). (b) Saturated incidence function: $\ell = h$. The case when $\ell = h = 1$, i.e., $g(I) = \kappa I/(1+\alpha I)$, was proposed by Capasso and Serio [5] to describe a "crowding effect" or "protection measures" in modeling the cholera epidemics in Bari in 1973. A similar type of sigmoidal function was also used to represent dose-response relationships observed in parasite infection experiments (Regoes, Ebert, and Bonhoeffer [23]). The function tends to a saturation level as the number of infectious individuals I becomes large (see Figure 1(b)). (c) Nonmonotone incidence function: $\ell < h$. Such functions can be used to interpret the "psychological effects" (Capasso and Serio [5]): for a very large number of infectious individuals the infection force may decrease as the number of infectious individuals increases (see Figure 1(c)), because in the presence of a large number of infectious individuals the population may tend to reduce the number of contacts per unit time, as seen with the spread of SARS (see Wang [26], Xiao and Ruan [28]).

From the graphs in Figure 1, one would expect that the dynamics of epidemic models with unbounded incidence rates are similar to those with bilinear incidence rates. In fact, Hethcote and van den Driessche [14] found that in a SEIRS model with $\ell = h + 1$, the classical threshold results hold; namely, the disease dies out below the threshold, and the disease level approaches the endemic equilibrium above the threshold. For a SIRS model with the nonmonotone incidence function $g(I) = kI/(1 + \alpha I^2)$, Xiao and Ruan [28] demonstrated that either the number of infectious individuals tends to zero as time evolves or the disease persists. We conjecture that the dynamics of SIRS models with nonmonotone incidence rates are similar to those observed by Xiao and Ruan [28].

On the other hand, the dynamics of epidemic models with saturated incidence rates (when $\ell = h$) have been shown to be very rich and complex. For a SEIRS model with $\ell = h$, Hethcote and van den Driessche [14] observed that the threshold concept becomes more complicated since the asymptotic behavior can depend on both the threshold and the initial values. The model can have none, one, or two endemic equilibria, and the disease can die out above the threshold for some initial values. Periodic solutions appear through Hopf bifurcation. The results are analogous to those obtained by Liu, Hethcote, and Levin [17] for SIRS models with $\ell = h$. The case $\ell = h = 1$ has been discussed briefly by Capasso and Serio [5] and recently in some detail by Gomes et al. [8], who obtained the existence of backward bifurcations, oscillations, and Bogdanov–Takens points in SIR and SIS models. These indicate that the case when $\ell = h \geq 2$ can be very complicated and deserves further investigation.

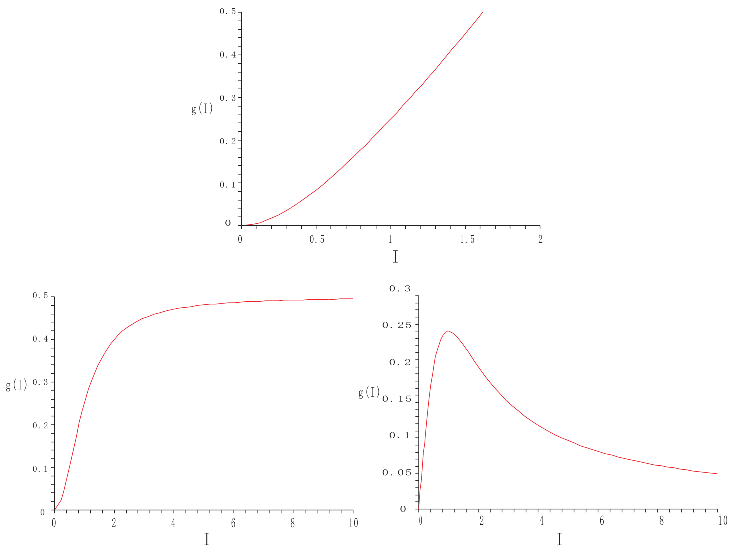

FIG. 1. *Graphs of the incidence function* $g(I) = \frac{\kappa I^\ell}{1+\alpha I^h}$. (a) *Top: Unbounded incidence when* $\ell > h$ *(*$\ell = 2, h = 1$*).* (b) *Bottom-left: Saturated incidence when* $\ell = h$ *(*$\ell = h = 2$*).* (c) *Bottom-right: Nonmonotone incidence when* $\ell < h$ *(*$\ell = 1, h = 2$*). Here,* $k = 0.5, \alpha = 1$.

In order to better understand the generic bifurcations in SIRS models with saturated incidence rates and also motivated by the work of Liu et al. [17, 18] and Hethcote and van den Driessche [14], Ruan and Wang [25] studied the global dynamics of a SIRS model with the nonlinear incidence function $g(I) = \kappa I^2/(1 + \alpha I^2)$, i.e., $\ell = h = 2$:

$$
(1.2) \qquad \begin{cases} \dfrac{dS}{dt} &= b - \delta S - \dfrac{\kappa I^2 S}{1 + \alpha I^2} + \nu R, \\ \dfrac{dI}{dt} &= \dfrac{\kappa I^2 S}{1 + \alpha I^2} - (\delta + \gamma) I, \\ \dfrac{dR}{dt} &= \gamma I - (\delta + \nu) R, \end{cases}
$$

where $b > 0$ is the recruitment rate of the population, $\delta > 0$ is the death rate of the population, $\gamma > 0$ is the recovery rate of infectious individuals, and $\nu > 0$ is the rate of removed individuals who lose immunity and return to the susceptible class. Summing up the three equations in (1.2), we obtain an equation $dN/dt = b - \delta N$ with $N(t) = S(t) + I(t) + R(t)$. Obviously, all solutions of this equation tend to its equilibrium $N(t) \equiv N_0 = b/\delta$ as $t \to +\infty$. Thus, all important dynamical behaviors of system (1.2) occur on the plane $S + I + R = N_0$, and the restricted system on the plane becomes

$$
(1.3) \qquad \begin{cases} \dfrac{dI}{dt} = \dfrac{\kappa I^2}{1 + \alpha I^2}(N_0 - I - R) - (\delta + \gamma) I, \\ \dfrac{dR}{dt} = \gamma I - (\delta + \nu) R. \end{cases}
$$

Under certain conditions Ruan and Wang [25] showed that the simplified model (1.3) undergoes a Bogdanov–Takens bifurcation; i.e., it exhibits saddle-node, Hopf, and homoclinic bifurcations. They also established the existence of none, one, or two limit cycles by applying the Bendixson–Dulac criterion [32], the Poincaré–Bendixson theorem [9], and a classic method for uniqueness of limit cycles in the Liénard equation [32], respectively. The coexistence (Theorem 2.9 in [25]) of two limit cycles is obtained by assuming that the successor function [32] (denoted by d in [25]) can switch its signs.

In Ruan and Wang [25] the uniqueness of limit cycles was obtained under the assumption that a polynomial $h(x)$ of degree 6 is nonpositive for all x in a definite interval, which is actually not easy to check. Moreover, only the first order Liapunov value of the weak focus (I_2, R_2) in Theorem 2.6 of [25] was calculated. To have a better understanding of the dynamics of the system, we need to calculate higher order Liapunov values of the weak focus, which is difficult in general. In fact, the weak focus (I_2, R_2) in Theorem 2.6 of [25] (E_+ in this paper) may have multiplicity 2, two limit cycles may arise from a degenerate Hopf bifurcation, and a limit cycle and a homoclinic loop may coexist via the degenerate Bogdanov–Takens bifurcation.

The study of model (1.3) is interesting and significant since it exhibits different and complicated dynamics such as periodic solutions, homoclinic orbits, multiple endemic equilibria, etc. The global dynamics is still not well understood. In this paper we further study the dynamical behavior of system (1.3). By rescaling the variables

$$x = \left(\sqrt{\frac{\kappa}{\delta+\nu}}\right) I, \quad y = \left(\sqrt{\frac{\kappa}{\delta+\nu}}\right) R, \quad d\tau = (\delta+\nu)dt/(1+pI^2)$$

and parameters

$$p = \frac{\alpha(\delta+\nu)}{\kappa}, \quad A = N_0\sqrt{\frac{\kappa}{\delta+\nu}}, \quad m = \frac{\delta+\gamma}{\delta+\nu}, \quad q = \frac{\gamma}{\delta+\nu},$$

system (1.3) is transformed into an equivalent system

$$(1.4) \qquad \begin{cases} \dfrac{dI}{dt} &= -I[(mp+1)I^2 + (R-A)I + m] &=: \mathcal{I}(I,R), \\ \dfrac{dR}{dt} &= (1+pI^2)(qI-R) &=: \mathcal{R}(I,R), \end{cases}$$

where we still use I, R, t to present x, y, τ for simplicity and $I, R \geq 0$, $A, m, p, q > 0$. We first calculate the second order Liapunov value at the weak focus and prove that the maximal multiplicity of the weak focus is 2 by technically dealing with some complicated multivariable polynomials, which implies that at most two limit cycles can arise near the weak focus. Then, by reducing the determination of the sign for polynomials of higher degrees to revised sign lists [31], we give some clean conditions on the parameters for the uniqueness of limit cycles. Finally, we reduce system (1.4) to a form of universal unfolding for a cusp of codimension 3 so as to give the bifurcation surfaces and display all limit cycles and homoclinic loops of order up to 2, from which the coexistence of limit cycles and homoclinic loops is established.

The paper is organized as follows. Some preliminary results on the existence and properties of equilibria are reviewed in section 2. Section 3 is devoted to the study of degenerate Hopf bifurcation. The uniqueness of limit cycles is considered in section 4. In section 5, we study the degenerate Bogdanov–Takens bifurcation of the model. A brief discussion on the models, motivations, methods, and results is given in section 6.

2. Preliminaries.

We first recall some known results on the existence of equilibria. As shown in Ruan and Wang [25], system (1.4) has at most three equilibria $O = (0,0)$, $E_- = (I_-, R_-)$, and $E_+ = (I_+, R_+)$ in the first quadrant, where

$$I_\pm = \frac{A \pm (A^2 - 4m(mp+q+1))^{1/2}}{2(mp+q+1)}, \quad R_\pm = qI_\pm.$$

It is easy to see that O is the disease-free equilibrium of system (1.4) and is a stable node. Moreover, there are no positive equilibria if $A^2 < 4m(mp+q+1)$ and two positive ones E_- and E_+ if $A^2 > 4m(mp+q+1)$. They coincide at $E_0 = (I_0, R_0) = (A/2(mp+q+1), qA/2(mp+q+1))$ if $A^2 = 4m(mp+q+1)$. It is indicated in [25] that E_- is a saddle and E_+ is a node, a focus, or a center. Moreover, the following results are given in Theorem 2.1 in [25].

Lemma 2.1. *The equilibrium E_+ is stable if one of the following inequalities holds:*

$$A^2 > A_c^2, \;\; m \le 1, \;\; q < \frac{2mp+1}{m-1},$$

where

$$A_c^2 =: \frac{(mq+2m-1-q+2m^2p)^2}{(m-1)(mp+p+1)}.$$

E_+ is unstable if

$$A^2 < A_c^2, \;\; m > 1, \;\; \text{and} \;\; q > \frac{2mp+1}{m-1}.$$

When the parameters lie in the region

$$\Omega = \{(A,m,p,q) |\, m > 1,\, q > (2mp+1)/(m-1),\, A^2 = A_c^2\}, \tag{2.1}$$

the linearization of system (1.4) at E_+ has a pair of purely imaginary eigenvalues. Let

$$\mu = (1+2m-q(m-1)) + (4+2m+4q-6mq+6m^2+2m^2q)p + 4m(m^2+2)p^2. \tag{2.2}$$

The following results on Hopf bifurcation are given in Theorem 2.6 in [25].

Lemma 2.2. *Suppose that conditions in Ω hold. If $\mu < 0$, then there is a stable periodic orbit in* (1.4) *as A^2 decreases from A_c^2. If $\mu > 0$, there is an unstable periodic orbit in* (1.4) *as A^2 increases from A_c^2. If $\mu = 0$, a Hopf bifurcation with codimension* 2 *may occur.*

Obviously, in [25] a question remains open: Is E_+ possibly a center when $\mu = 0$? A negative answer will be given in section 3. Regarding μ as a quadratic polynomial of p, we can easily see that the case $\mu = 0$ happens if and only if the discriminant of (2.2) is ≥ 0.

As shown previously, when $A = A_0 =: 2\sqrt{m(mp+q+1)}$, the equilibrium E_0 appears in the interior of the first quadrant and is degenerate because the Jacobian matrix of the linearized system of (1.4) at E_0 has determinant 0.

Lemma 2.3. *When $A = A_0$, E_0 is either a saddle-node if $p \ne ((m-1)q-1)/(2m)$ or a cusp otherwise.*

Proof. For $p = ((m-1)q-1)/(2m)$ it was proved in [25] that system (1.4) has a cusp at E_0. Consider the case that $p \ne ((m-1)q-1)/(2m)$. With the change of variables $(I,R) \mapsto (x,y)$ defined by

$$x = -\frac{(1+q+2mp)(I-I_0)}{1+q+mp} + \frac{m(R-R_0)}{1+q+mp}, \quad y = -\frac{mq(I-I_0)}{1+q+mp} + \frac{m(R-R_0)}{1+q+mp},$$

system (1.4) is rewritten as

$$
\text{(2.3)}\quad \left\{\begin{array}{rcl}
\dot{x} &=& \frac{-d_0\sqrt{1+mp+q}\sqrt{m}}{(b_0q-d_0)^2}x^2 + \frac{2(pqb_0^2+b_0d_0+b_0d_0mp-b_0pd_0+d_0^2)\sqrt{m}}{b_0\sqrt{1+mp+q}(b_0q-d_0)^2}xy \\
&& -\frac{(2pqb_0^2-b_0d_0q+b_0d_0-2b_0pd_0+b_0d_0mp+2d_0^2)\sqrt{m}}{b_0\sqrt{1+mp+q}(b_0q-d_0)^2}y^2 + O(|(x,y)|^3) \quad =: X_1(x,y), \\
\dot{y} &=& (d_0-b_0q)y - \frac{b_0q\sqrt{1+mp+q}\sqrt{m}}{(b_0q-d_0)^2}x^2 + \frac{2(b_0q+qmpb_0+qpb_0+qd_0-pd_0)\sqrt{m}}{\sqrt{1+mp+q}(b_0q-d_0)^2}xy \\
&& -\frac{(-b_0q^2+b_0q+qmpb_0+2qpb_0+2qd_0-2pd_0)\sqrt{m}}{\sqrt{1+mp+q}(b_0q-d_0)^2}y^2 + O(|(x,y)|^3) \qquad =: Y_1(x,y),
\end{array}\right.
$$

where $b_0 = -m/(1+q+mp)$, $d_0 = -(1+q+2mp)/(1+q+mp)$, and E_0 is translated to the origin. By the implicit function theorem, there is a unique function $y = \varsigma(x)$ such that $\varsigma(0) = 0$ and $Y_1(x, \varsigma(x)) = 0$. Actually, we can solve from $Y_1(x,y) = 0$ that

$$
\varsigma(x) = -\frac{qb_0\sqrt{1+q+mp}\sqrt{m}}{(b_0q-d_0)^3}x^2 + O(|x|^3).
$$

Substituting $y = \varsigma(x)$ into the first equation of (2.3), we get

$$
\text{(2.4)}\qquad \dot{x} = X_1(x, \varsigma(x)) = -\frac{d_0\sqrt{1+q+mp}\sqrt{m}}{(b_0q-d_0)^2}x^2 + O(|x|^3).
$$

Theorem 7.1 in Chapter 2 of [32] implies that the origin is a saddle-node of system (2.3). Thus, E_0 is a saddle-node of system (1.4). □

3. Degenerate Hopf bifurcation. This section is a complement to the Hopf bifurcation analysis in Ruan and Wang [25]. In Lemma 2.2 the sign of μ is the same as the sign of the first Liapunov value of (1.4) if E_+ is a weak focus, but [25] does not determine the sign of the higher order Liapunov values and whether E_+ is a center. In this section, we overcome some technical difficulties in the computation of the higher order Liapunov values and prove that E_+ is a weak focus of multiplicity at most 2.

As in section 2, we consider those parameters in the region Ω, defined in (2.1), where the Jacobian matrix at E_+ has a pair of purely imaginary eigenvalues and the parameters A, m, p, and q satisfy $A^2 = A_c^2 > 4m(mp+q+1)$. In this case, the first coordinate of E_+ takes the form $I_+ = (2m^2p - q + mq - 1 + 2m)/(A(mp+p+1))$. A simple transformation $(I, R) \mapsto (x, y)$, which translates E_+ to the origin and diagonalizes the linear part, reduces system (1.4) to

$$
\text{(3.1)}\qquad \left\{\begin{array}{rcl}
\frac{dx}{dt} &=& -wy + ma_1x^2 + 2a_1wxy - ma_1^2x^3 - a_1^2wx^2y, \\
\frac{dy}{dt} &=& wx - a_1b_2x^2 - 2a_1xy + a_1^2b_1x^3 + a_1^2x^2y,
\end{array}\right.
$$

where

$$
\begin{aligned}
w &= \sqrt{k_1}, \quad k_1 = -\frac{(2mp+1)(2mp-mq+1+q)}{(mp+p+1)^2}, \quad a_1 = \frac{mp+p+1}{\sqrt{(m-1)(mp+p+1)}}, \\
b_1 &= \frac{2m^3p^2+pqm^2+3m^2p+2mp^2-2pqm+m+p+qp}{(mp+p+1)^2w}, \\
b_2 &= \frac{2m^3p^2-2m^2p^2+3m^2p+2qm^2p+4mp^2-4pqm-mp+m+2qp+2p}{(mp+p+1)^2w}.
\end{aligned}
$$

Obviously, $k_1 > 0$ because $m > 1$ and $q > (2mp+1)/(m-1)$. Using the polar coordinates $x_1 = r\cos\theta$, $y_1 = r\sin\theta$, we obtain from (3.1) that

$$\begin{aligned}\frac{dr}{d\theta} &= \tfrac{G_2(\theta)}{w}r^2 + (\tfrac{G_3(\theta)}{w} - \tfrac{G_2(\theta)H_1(\theta)}{w^2})r^3 + (-\tfrac{G_3(\theta)H_1(\theta)}{w^2} - \tfrac{G_2(\theta)H_2(\theta)}{w^2} + \tfrac{G_2(\theta)H_1^2(\theta)}{w^3})r^4 \\ &\quad +(-\tfrac{G_3(\theta)H_2(\theta)}{w^2} + \tfrac{2G_2(\theta)H_1(\theta)H_2(\theta)}{w^3} + \tfrac{G_3(\theta)H_1^2(\theta)}{w^3} - \tfrac{G_2(\theta)H_1^3(\theta)}{w^4})r^5 + \text{h.o.t.},\end{aligned} \tag{3.2}$$

where

$$\begin{aligned}G_2(\theta) &= a_1(m+2)\sin^3\theta + a_1(2w-b_2)\sin^2\theta\cos\theta - 2a_1\sin\theta,\\ G_3(\theta) &= -a_1^2(m+1)\sin^4\theta + a_1^2(b_1-w)\sin^3\theta\cos\theta + a_1^2\sin^2\theta,\\ H_1(\theta) &= a_1(2w-b_2)\sin^3\theta - a_1(m+2)\sin^2\theta\cos\theta - 2a_1w\sin\theta,\\ H_2(\theta) &= a_1^2(b_1-w)\sin^4\theta + a_1^2(m+1)\sin^3\theta\cos\theta + a_1^2w\sin^2\theta,\end{aligned}$$

and

$$G_4(\theta) = G_5(\theta) = H_3(\theta) = H_4(\theta) = H_5(\theta) = 0.$$

Consider solutions of (3) in the formal series $r(\theta, r_0) = \sum_{j=1}^{+\infty} r_j(\theta)r_0^j$ together with the initial condition $r(0, r_0) = r_0$, where $|r_0|$ is sufficiently small. Obviously, $r_1(0) = 1$, $r_2(0) = r_3(0) = \cdots = 0$. Substituting the series into (3) and comparing the coefficients, we obtain a system of differential equations for $r_j(\theta), j = 1, 2, \ldots$, i.e.,

$$\frac{dr_1}{d\theta} = 0, \quad \frac{dr_2}{d\theta} = r_1^2\frac{G_2(\theta)}{w}, \quad \frac{dr_3}{d\theta} = r_1^3\left(\frac{G_3(\theta)}{w} - \frac{G_2(\theta)H_1(\theta)}{w^2}\right) + 2r_1r_2\frac{G_2(\theta)}{w}, \ldots. \tag{3.3}$$

Solving them together with the initial conditions, we get

$$\begin{aligned}r_1(\theta) \equiv 1, \quad r_2(\theta) &= \int_0^\theta \frac{G_2(\xi)}{w}d\xi,\\ r_3(\theta) &= \int_0^\theta \left\{\frac{G_3(\xi)}{w} - \frac{G_2(\xi)H_1(\xi)}{w^2} + \frac{2G_2(\xi)r_2(\xi)}{w}\right\}d\xi, \ldots.\end{aligned}$$

Using Maple V.7 software, we compute the Liapunov value as follows:

$$L_3(m, w, a_1, b_1, b_2) = \frac{1}{2\pi}r_3(2\pi) = \frac{a_1^2(m-1)(2b_2-w)}{8w^2}. \tag{3.4}$$

For parameters in Ω, the sign of L_3 is determined by $2b_2 - w$ and therefore is the same as the sign of μ, which demonstrates the corresponding results in Lemma 2.2.

If $w = 2b_2$ (i.e., $\mu = 0$), then $L_3(m, w, a_1, b_1, b_2) = 0$. In this case the Liapunov value of order 5 can be calculated as follows:

$$L_5(m, w, a_1, b_1, b_2) = \frac{1}{2\pi}r_5(2\pi) = \frac{a_1^4(m-1)\kappa(m, w, a_1, b_1, b_2)}{768w^4} > 0, \tag{3.5}$$

where, using (3.1) and the fact that $\mu = 0$, we have

$$\begin{aligned}\kappa(m, w, a_1, b_1, b_2) &= 121w^3 - 332w^2b_2 + 143w^2b_1 - 75wm^2 - 218wm - 190wb_2b_1\\ &\quad -8w + 155wb_2^2 + 150b_2m^2 + 436mb_2 + 16b_2 + 50b_2^3\\ &= \frac{(2p+1)(mp+p+1)^3(-4mp+8p+2)^{1/2}}{64(m-1)(2mp+1)^2(m^2p+mp+m)^{1/2}} > 0.\end{aligned}$$

By the theory of Hopf bifurcation [20, 32], we obtain the following results.

THEOREM 3.1. *Suppose that $A^2 > 4m(mp + q + 1)$ and conditions in Ω hold.*

(i) *If $\mu \neq 0$, then the equilibrium E_+ of system* (1.4) *is a weak focus of multiplicity* 1 *and at most one limit cycle arises from the Hopf bifurcation. Moreover, E_+ is stable and the limit cycle is also stable when $\mu < 0$, or E_+ is unstable and the limit cycle is also unstable when $\mu > 0$.*

(ii) *If $\mu = 0$, then the equilibrium E_+ is a weak focus of multiplicity* 2 *and at most two limit cycles arise from the Hopf bifurcation. Moreover, E_+ is unstable and the outer cycle is also unstable, but the inner cycle (if it appears) is stable.*

To carry out numerical simulations on two limit cycles, we choose parameters $m = 3$, $p = 0.1$, $q = 15$, and $A = 21.99$. We can verify that the conditions of result (ii) in Theorem 3.1 are satisfied. In this case the two limit cycles can be simulated by using MATLAB 6.5 software. In Figure 2, the trajectory started at the point $P_1 = (1, 5)$ spirals inward as the time $t \to -\infty$ and the trajectory started at $P_2 = (1.2, 12)$ spirals inward as $t \to \infty$. Hence, an unstable outer limit cycle exists and lies in the annular region bounded by these two trajectories. Similarly, the orbit started at $P_3 = (1.5, 15)$ spirals inward as $t \to \infty$ and the orbit started at $P_4 = (1.3, 17)$ spirals outward as $t \to \infty$. Therefore, there is a stable inner limit cycle lying in the annular region bounded by these two orbits. The equilibrium $E_+ = (1.195073225, 17.92609838)$ is unstable.

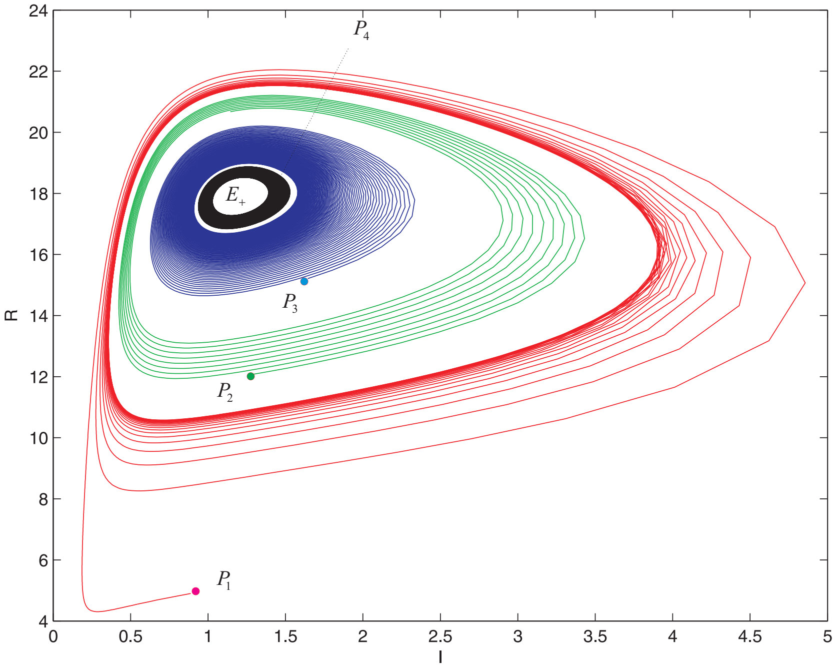

FIG. 2. *Two limit cycles bifurcate from the weak focus of multiplicity* 2.

4. Uniqueness of limit cycles. In this section we consider the uniqueness of limit cycles of system (1.4) and provide a relatively simpler proof compared to that of [25]. As shown in Theorem 2.2 of [25] and section 2, it suffices to discuss the case when $m > 1$ and $A^2 > 4m(mp + q + 1)$, in which system (1.4) possibly has closed orbits and E_+ lies in the first quadrant.

Our strategy is to reduce system (1.4) to the form of the Liénard system

$$\dot{x} = y - F(x), \qquad \dot{y} = -g(x) \tag{4.1}$$

and apply the known Theorem 1.1 in Kooij and Zegeling [15] and Theorem 2.1 in Xiao and Zhang [29]. Rearranging terms in the order of powers of R, we rewrite system (1.4) as

$$\dot{I} = g_0(I) - g_1(I)R, \qquad \dot{R} = qI - R, \tag{4.2}$$

where $g_0(I) = (A - I)I^2/(1 + pI^2) - mI$ and $g_1(I) = I^2/(1 + pI^2)$. We need only to consider $I > 0$ because $I = 0$ is an orbit. Thus $g_1(I) > 0$, and system (4.2) has the same phase portrait as the system

$$\dot{I} = R - \frac{g_0(I)}{g_1(I)}, \qquad \dot{R} = \frac{R}{g_1(I)} - \frac{qI}{g_1(I)}. \tag{4.3}$$

With the transformation

$$I = x, \qquad y = R - \int_{I_+}^{x} \frac{1}{g_1(x)} dx, \tag{4.4}$$

system (4.3) is reduced to the Liénard system (4.1) with

$$F(x) = \frac{g_0(x)}{g_1(x)} - \int_{I_+}^{x} \frac{1}{g_1(x)} dx, \qquad g(x) = \frac{qx}{g_1(x)} - \frac{g_0(x)}{g_1^2(x)}. \tag{4.5}$$

LEMMA 4.1. *Suppose that $m > 1$ and $A^2 > 4m(mp + q + 1)$. Then system* (4.2) *has at most one closed orbit in the interior of the first quadrant if either the function $F'(x)/g(x)$, where F' denotes the derivative of F, is neither decreasing nor a constant or $F'(I_+)\frac{d}{dx}(F'(x)/g(x)) < 0$ for $x \neq I_+$. Moreover, the closed orbit is hyperbolic if it exists.*

Proof. Note that limit cycles of system (4.2) (if any exist) lie in the stripe region between the vertical lines $\ell_0 : I = I_-$ and $\ell_1 : I = I_D$, where

$$I_D = \frac{A + (A^2 - 4m(mp + 1))^{1/2}}{2(mp + 1)}.$$

In fact, a vertical isocline of (4.2) intersects the I-axis at $D = (I_D, 0)$, i.e., $(mp + 1)I_D^2 - AI_D + m = 0$. Restricted to ℓ_1 in the interior of the first quadrant, the derivative $\dot{I}$ satisfies

$$\dot{I}|_{\ell_1} = I_D\{[-m + AI_D - (mp + 1)I_D^2] - RI_D\} = -RI_D^2 < 0.$$

This implies that limit cycles of system (4.2) (if any exist) lie on the left of ℓ_1 because $I_+ < I_D$ (i.e., the equilibrium E_+ lies on the left of ℓ_1). On the other hand, limit cycles lie on the right of ℓ_0; otherwise, a limit cycle intersects ℓ_0 because $I_+ > I_-$ (i.e., E_+ lies on the right of ℓ_0), implying that $\dot{I} = 0$ at a point on ℓ_0. This is a contradiction because on ℓ_0 the derivative

$$\dot{I} = I_-\{[-m + (A - R_-)I_- - (mp + 1)I_-^2] + R_-I_- - RI_-\} = (R_- - R)I_-^2 \neq 0$$

except at the saddle E_-. Let $S(I_-, I_D)$ denote the stripe region. Since transformations between (4.2) and (4.1) do not change x, it suffices to discuss (4.1) in $S(I_-, I_D)$, i.e., $I_- < x < I_D$.

Transformation (4.4) is one-to-one for $I > 0$ and $R > 0$, so it is equivalent to discuss the uniqueness of closed orbits for system (4.1) where $x > 0$. Corresponding to E_+, system (4.1) has an equilibrium (x_+, y_+) with the same coordinates, i.e., $x_+ = I_+$ and $y_+ = R_+$. From (4.5) we have $F'(x) = -\{(mp + p + 1)x^2 + 1 - m\}/x^2$ and $g(x) = \rho(x)(1 + px^2)/x^3$, where $\rho(x) = (mp + q + 1)x^2 - Ax + m$ has exactly two zeros at I_- and I_+. It follows that

$$g(x_+) = -\frac{g_0(I_+) - g_1(I_+)R_+}{g_1^2(I_+)} = 0, \quad (x - x_+)g(x) = \left(\frac{1 + px^2}{x^3}\right)(x - x_+)\rho(x) > 0$$

in $S(I_-, I_D)$, verifying partly either the condition in [29, Theorem 2.1] (as $F'(x)/g(x)$ is neither decreasing nor a constant) or the condition in [15, Theorem 1.1] (as $F'(I_+) \cdot (d/dx)\{F'(x)/g(x)\} < 0$ for $x \neq I_+$). The other conditions can be checked explicitly by the assumptions in our lemma. Thus the lemma is proved. □

In order to obtain conditions in terms of the original parameters for the uniqueness of limit cycles and complete the results of the uniqueness in [25], we use the notation

$$c_0 = m(m-1), \quad c_2 = 5m^2p + mp + 4m + mq - q - 1, \quad c_3 = 2A(1 + 2mp),$$
$$c_4 = (5m^2p^2 - mp^2) + (4mpq - 2pq) + (6mp - 2p) + q + 1, \quad c_6 = p(1+p+mp)(1+q+mp).$$

These constants are obviously all positive. Using the conditions in Lemma 4.1, we obtain the following theorem.

THEOREM 4.2. *Suppose that $m > 1$ and $A^2 > 4m(mp + q + 1)$. If either* (i) $c_3^2 - 4c_2c_4 > 0$ *and $\sigma_- < I_-$, $\sigma_+ > I_D$, where $\sigma_\pm = (c_3 \pm \sqrt{c_3^2 - 4c_2c_4}/(2c_4)$, or* (ii) $c_3^2 - 4c_2c_4 < 0$, *$F'(I_+) > 0$, and both c_6 and $m(m-1)$ are small enough, then system* (4.2) *has at most one limit cycle in the interior of the first quadrant. Moreover, under assumption* (i) *(resp.,* (ii)*) the limit cycle is unstable (resp., stable) if it exists.*

Proof. Calculate $(d/dx)\{F'(x)/g(x)\} = h(x)/x^6g^2(x)$ in $S(I_-, I_D)$, where

$$h(x) = c_0 - c_2x^2 + c_3x^3 - c_4x^4 + c_6x^6.$$

By Lemma 4.1, we need to determine the sign of $h(x)$. Our strategy is to discuss the quadratic function $\eta(x) = -c_2 + c_3x - c_4x^2$, for which we have $h(x) = m(m-1) + c_6x^6 + \eta(x)x^2$.

In case (i), the function η has exactly two real roots $\sigma_\pm$ and $[I_-, I_D] \subset (\sigma_-, \sigma_+)$. Since η has the leading coefficient $c_4 > 0$, we see that $\eta(x) > 0$ for $x \in (\sigma_-, \sigma_+)$, i.e., $\eta(x) > 0$ in $S(I_-, I_D)$. Since $m > 1$, as required in (2.1), we have $h(x) > 0$ or equivalently $(d/dx)\{F'(x)/g(x)\} > 0$ in $S(I_-, I_D)$. Then Lemma 4.1 implies the result in case (i).

In case (ii), $c_3^2 - 4c_2c_4 < 0$, so $\eta(x) \neq 0$. On the compact interval $[I_-, I_D]$ the function $|\eta|$ is bounded by a positive number. Therefore, $\mathrm{sgn} h(x) = \mathrm{sgn} \eta(x)$ for $x \in (I_-, I_D)$ as c_6 and $m(m-1)$ are both sufficiently small. Since η has the leading coefficient $c_4 > 0$, we ensure that $\eta(x) < 0$ as $x \in (I_-, I_D)$, implying that $h(x) < 0$ in $S(I_-, I_D)$. Thus, $F'(I_+)(d/dx)\{F'(x)/g(x)\} < 0$; i.e., the second condition in Lemma 4.1 holds in $S(I_-, I_D)$. From the notion introduced at the beginning of the proof of Lemma 4.1, it suffices to verify the condition in $S(I_-, I_D)$. Therefore, the conclusion in case (ii) is obtained. □

Consider $p = q = \epsilon^k$, $m = 1/\epsilon$, and $(2A(2mp+1))^2 = a_1c_2c_4$, for example, where $\epsilon > 0$ is sufficiently small, $k \geq 3$, and $4 < a_1 < 9/2$. These parameters satisfy assumption (i) in Theorem 4.2. Another choice of parameters in which $p = \epsilon^{2k}$, $m = 1+\epsilon$, and $q = 1/\epsilon^k$, where $\epsilon > 0$ is sufficiently small and $k \geq 3$, verifies assumption (ii) in Theorem 4.2.

For c_6 and $m(m-1)$ to be sufficiently small in case (ii) of Theorem 4.2, we have to restrict p and m near 0 and 1, respectively. Efforts are also made to extend the restriction by some known results on the zeros of high degree polynomials (Yang [31]). As shown in the above proof for Theorem 4.2 (ii), we can generally suppose that $m > 1$, $A^2 > 4m(mp+q+1)$ and that $h(I_-) < 0$, $h(I_D) < 0$ and claim that h has no real zeros in the interval (I_-, I_D). By Lemma 3.1 in [31], the number of real zeros of h in (I_-, I_D) is equal to the number of negative zeros of the function

$$\Psi(x) = (1-x)^6 h\left(\frac{I_D - I_- x}{1-x}\right) = \alpha_0 x^6 + \alpha_1 x^5 + \alpha_2 x^4 + \alpha_3 x^3 + \alpha_4 x^2 + \alpha_5 x + \alpha_6,$$

where

$$\begin{aligned}
\alpha_0 &= h(I_-) = c_0 - c_2 I_-^2 + c_3 I_-^3 - c_4 I_-^4 + c_6 I_-^6,\\
\alpha_1 &= -3c_3 I_D I_-^2 + 4c_4 I_D I_-^3 - 6c_6 I_D I_-^5 + 2c_2 I_D I_- + 2c_4 I_-^4 - 6c_0 + 4c_2 I_-^2 - 3c_3 I_-^3,\\
\alpha_2 &= 9c_3 I_D I_-^2 + 3c_3 I_D^2 I_- - 8c_4 I_D I_-^3 - 6c_4 I_D^2 I_-^2 + 15c_6 I_D^2 I_-^4 - 8c_2 I_D I_- - c_4 I_-^4\\
&\quad +15c_0 - c_2 I_D^2 - 6c_2 I_-^2 + 3c_3 I_-^3,\\
\alpha_3 &= -9c_3 I_D I_-^2 - 9c_3 I_D^2 I_- + 4c_4 I_D I_-^3 + 12c_4 I_D^2 I_-^2 + 4c_4 I_D^3 I_-\\
&\quad -20c_6 I_D^3 I_-^3 + 12c_2 I_D I_- - 20c_0 + 4c_2 I_D^2 + 4c_2 I_-^2 - c_3 I_-^3 - c_3 I_D^3,\\
\alpha_4 &= 3c_3 I_D I_-^2 + 9c_3 I_D^2 I_- - 6c_4 I_D^2 I_-^2 - 8c_4 I_D^3 I_- + 15c_6 I_D^4 I_-^2 - 8c_2 I_D I_- + 15c_0\\
&\quad -c_4 I_D^4 - 6c_2 I_D^2 - c_2 I_-^2 + 3c_3 I_D^3,\\
\alpha_5 &= -3c_3 I_D^3 - 3c_3 I_D^2 I_- - 6c_6 I_D^5 I_- + 4c_2 I_D^2 + 2c_2 I_D I_- + 2c_4 I_D^4 + 4c_4 I_D^3 I_- - 6c_0,\\
\alpha_6 &= h(I_D) = c_0 - c_2 I_D^2 + c_3 I_D^3 - c_4 I_D^4 + c_6 I_D^6.
\end{aligned}$$

Let Discr(Ψ) be the *discrimination matrix* of the polynomial Ψ, constructed in the appendix as in [31, Definition 2.1] and its following paragraph, and calculate its principal minors $\varpi_1, \varpi_2, \ldots, \varpi_{13}$ as in the appendix. Consider the sequence $SE = \{\varpi_1\varpi_2, \varpi_2\varpi_3, \ldots, \varpi_{12}\varpi_{13}\}$ and its sign list $\mathcal{S}(SE) = \{\mathrm{sgn}(\varpi_1\varpi_2), \ldots, \mathrm{sgn}(\varpi_{12}\varpi_{13})\}$, where $\mathrm{sgn}(x)$ denotes the sign of x. Now revise the signs according to the following rule (Definition 2.3 in [31]): (S1) If $\{\varrho_i, \varrho_{i+1}, \ldots, \varrho_{i+j}\}$ is a section of $\mathcal{S}(SE)$ such that $\varrho_i \neq 0, \varrho_{i+1} = \cdots = \varrho_{i+j-1} = 0, \varrho_{i+j} \neq 0$, then replace the section with the finite sequence $\{-\varrho_i, -\varrho_i, \varrho_i, \varrho_i, -\varrho_i, -\varrho_i, \varrho_i, \varrho_i, \ldots\}$ by truncating for the same number of terms; (S2) otherwise, do not change. Let $\mathcal{S}'(SE)$ denote the *revised sign list.* By Theorem 3.3 in [31], the number of distinct negative zeros of Ψ is equal to $\xi_1 - \xi$, where ξ is the number of sign changes in $\mathcal{S}'(SE)$ and $2\xi_1$ is the number of nonzero members in $\mathcal{S}'(SE)$. Thus we conclude that Ψ *has no negative zeros, i.e.,* $h(x) < 0$ *in* (I_-, I_D) *if* $\xi = \xi_1$.

The above conclusion shows that the condition on parameters for $h(x) < 0$ can be determined by the list $\mathcal{S}'(SE)$. It is easy to calculate that $\varpi_1\varpi_2 = 6\alpha_0^3 < 0$, i.e., $\mathrm{sgn}(\varpi_1\varpi_2) = -1$. So in total we have 3^{11}(=177147) cases to discuss because each of the remaining 11 elements in $\mathcal{S}'(SE)$ has three options: $-1, 0, 1$. We illustrate a general method for conditions on parameters with a further discussion on $\varpi_{12}\varpi_{13}$. In the case that $\varpi_{12}\varpi_{13} \neq 0$, $\mathcal{S}'(SE)$ contains 12 nonzero members, implying that $\xi_1 = 6$. So we need only to construct a revised sign list with $\xi = 6$. We easily find such a list $\{-1,1,-1,1,-1,1,-1,-1,-1,-1,-1,-1\}$, which gives a condition on parameters:

$$\begin{aligned}(\mathrm{C}_1):&\varpi_2\varpi_3\geq 0, \varpi_3\varpi_4<0, \varpi_4\varpi_5>0, \varpi_5\varpi_6<0, \varpi_6\varpi_7>0, \varpi_7\varpi_8<0,\\ &\varpi_8\varpi_9<0, \varpi_9\varpi_{10}<0, \varpi_{10}\varpi_{11}<0, \varpi_{11}\varpi_{12}<0, \varpi_{12}\varpi_{13}<0.\end{aligned}$$

In the case that $\varpi_{12}\varpi_{13}=0$, the number of nonzero members in $\mathcal{S}'(SE)$ is <12, i.e., $\xi_1\leq 5$. Note that the list $\{-1,1,-1,1,-1,1,1,1,1,1,0,0\}$ has $\xi=5$. Being a revised sign list, it gives a condition of parameters:

$$\begin{aligned}(\mathrm{C}_2):&\varpi_2\varpi_3\geq 0, \varpi_3\varpi_4<0, \varpi_4\varpi_5>0, \varpi_5\varpi_6<0, \varpi_6\varpi_7>0, \varpi_7\varpi_8>0,\\ &\varpi_8\varpi_9>0, \varpi_9\varpi_{10}>0, \varpi_{10}\varpi_{11}>0, \varpi_{11}\varpi_{12}=\varpi_{12}\varpi_{13}=0.\end{aligned}$$

Finally, Lemma 4.1 and the conclusion given in the last paragraph enable us to summarize that if $m>1$, $A^2>4m(mp+q+1)$, $h(I_-)<0$, $h(I_D)<0$, $F'(I_+)>0$, and if either (C_1) or (C_2) holds, then system (4.2) has at most one limit cycle in the interior of the first quadrant. Moreover, the limit cycle is stable if it exists. More conditions other than (C_1) and (C_2) can similarly be obtained for the uniqueness of limit cycles.

5. Degenerate Bogdanov–Takens bifurcation. By Lemma 2.3, when $A=A_0=:2\sqrt{m(mp+q+1)}$ and $p=p_0=:((m-1)q-1)/(2m)$, the equilibrium $E_0=:(A_0/(2(mp_0+q+1)), qA_0/(2(mp_0+q+1)))$ is a cusp, where the Bogdanov–Takens bifurcation may occur by a perturbation. By the standard theory of the Bogdanov–Takens bifurcation (of codimension 2), Ruan and Wang [25] assert only that the system has at most *one* limit cycle and the obtained homoclinic loop is of order 1 (see the definition in [16]).

In the following, we display the possible bifurcations of multiple limit cycles and homoclinic loops of order higher than 1. Note that as $A=A_0$ and $p=p_0$, we have $(m-1)q=2mp_0+1>0$, implying $m>1$. So we fix $m_0>1$ near 1 arbitrarily and consider three bifurcation parameters A,p,m near A_0,p_0,m_0, respectively. Let

$$A=A_0+\epsilon_1,\quad p=p_0+\epsilon_2,\quad m=m_0+\epsilon_3, \tag{5.1}$$

where $\epsilon_3>0$. Then, we discuss bifurcations of the equivalent system (1.4) for the parameters $\epsilon=(\epsilon_1,\epsilon_2,\epsilon_3)$ near $(0,0,0)$.

Lemma 5.1. *For A,p,m close to A_0,p_0,m_0, respectively,* (1.4) *is equivalent to the system*

$$\frac{dx}{dt}=y,\quad \frac{dy}{dt}=\mu_1+x^2+(\mu_2+\mu_3x+x^3+O(|x|^4))y+G(x,\mu)y^2, \tag{5.2}$$

where μ_i's are functions of $\epsilon_1,\epsilon_2,\epsilon_3$ such that $\frac{\partial(\mu_1,\mu_2,\mu_3)}{\partial(\epsilon_1,\epsilon_2,\epsilon_3)}|_{\epsilon=0}\neq 0$ and $G(x,\mu)$ is a C^∞ function.

Proof. With the substitution (5.1), equation (1.4) can be written as

$$\begin{cases}\dot{I}=\mathcal{I}(I+\frac{A_0}{2((m_0+\epsilon_3)(p_0+\epsilon_2)+q+1)}, R+\frac{qA_0}{2((m_0+\epsilon_3)(p_0+\epsilon_2)+q+1)}),\\ \dot{R}=\mathcal{R}(I+\frac{A_0}{2((m_0+\epsilon_3)(p_0+\epsilon_2)+q+1)}, R+\frac{qA_0}{2((m_0+\epsilon_3)(p_0+\epsilon_2)+q+1)}),\end{cases} \tag{5.3}$$

where $\mathcal{I}$ and $\mathcal{R}$ are defined in (1.4). When $\epsilon=0$, system (5.3) has a cusp at the origin $O_2=(0,0)$, as shown in [25]; i.e., the equilibrium E_0 is translated to O_2. Expanding (5.3) at O_2, rescaling time by $t=\tau(q+1+qm_0)/(2qm_0)$, and then applying a linear transformation T_1: $(I,R)\mapsto(\tilde{I},\tilde{R})$, defined by $\tilde{I}=I$ and $\tilde{R}=I-R/q$ to reduce the matrix of the linear part for $\epsilon=0$ to the Jordan canonical form, we can reduce (5.3) further to the form

$$\begin{bmatrix}\dot{\tilde{I}}\\ \dot{\tilde{R}}\end{bmatrix}=\begin{bmatrix}\vartheta_1(\epsilon)\\ \vartheta_2(\epsilon)\end{bmatrix}+\begin{bmatrix}\iota_{11}(\epsilon) & \iota_{12}(\epsilon)\\ \iota_{21}(\epsilon) & \iota_{22}(\epsilon)\end{bmatrix}\begin{bmatrix}\tilde{I}\\ \tilde{R}\end{bmatrix}+\begin{bmatrix}\omega_1(\tilde{I},\tilde{R},\epsilon)\\ \omega_2(\tilde{I},\tilde{R},\epsilon)\end{bmatrix}, \tag{5.4}$$

where all ϑ_j,ι_{ij}, and ω_j $(i,j=1,2)$ are calculated as in the appendix, which satisfies that $\vartheta_1(0)=\vartheta_2(0)=0$, $\iota_{12}(0)=1$, and $\iota_{11}(0)=\iota_{21}(0)=\iota_{22}(0)=0$. Another transformation T_2: $(\tilde{I},\tilde{R})\mapsto(X,Y)$, defined by

$$\tilde{I}=X+\frac{\sqrt{2m_0(q+1+qm_0)}}{2m_0}X^2,\quad \tilde{R}=Y+\frac{\sqrt{2m_0(q+1+qm_0)}(q+1+qm_0)}{4qm_0}X^2, \tag{5.5}$$

reduces system (5.4) to

$$\dot{X}=E_{11}(X,\epsilon)+E_{12}(X,\epsilon)Y,\quad \dot{Y}=E_{21}(X,\epsilon)+E_{22}(X,\epsilon)Y, \tag{5.6}$$

where

$$\begin{aligned}E_{1j}(X,\epsilon)&= a_{j0}(\epsilon)+a_{j1}(\epsilon)X+a_{j2}(\epsilon)X^2+a_{j3}(\epsilon)X^3+O(|X^4|),\quad j=1,2,\\ E_{2j}(X,\epsilon)&= b_{j0}(\epsilon)+b_{j1}(\epsilon)X+b_{j2}(\epsilon)X^2+b_{j3}(\epsilon)X^3+O(|X^4|),\quad j=1,2,\end{aligned}$$

and all $a_{ij}(\epsilon)$'s and $b_{ij}(\epsilon)$'s are given in the appendix. Applying the change of variables $\tilde{X}=X$, $\tilde{Y}=E_{11}(X,\epsilon)+E_{12}(X,\epsilon)Y$ in (5.6), we obtain a system in which the first equation is same as the first equation of (5.2), that is,

$$\dot{\tilde{X}}=\tilde{Y},\quad \dot{\tilde{Y}}=F_1(\tilde{X},\epsilon)+F_2(\tilde{X},\epsilon)\tilde{Y}+F_3(\tilde{X},\epsilon)\tilde{Y}^2, \tag{5.7}$$

where $F_i(\tilde{X},\epsilon)=\sum_{j=0}^{3}c_{ij}(\epsilon)\tilde{X}^j+O(|\tilde{X}|^4)$, $i=1,2$, and both $c_{ij}(\epsilon)$'s and $F_3(\tilde{X},\epsilon)$ are given in the appendix. Note that $c_{12}(0)=-\sqrt{2m_0(q+1+qm_0)}(q+1+qm_0)/4qm_0$ <0, which implies that $c_{12}(\epsilon)<0$ for small ϵ, and it is reasonable to apply the rescaling $\tilde{X}\mapsto-\tilde{X}$, $\tilde{Y}\mapsto-\sqrt{-c_{12}(\epsilon)}\,\tilde{Y}$, $\tau\mapsto\tau/\sqrt{-c_{12}(\epsilon)}$ to system (5.7) and obtain

$$\dot{\tilde{X}}=\tilde{Y},\quad \dot{\tilde{Y}}=\tilde{F_1}(\tilde{X},\epsilon)+\tilde{F_2}(\tilde{X},\epsilon)\tilde{Y}+\tilde{F_3}(\tilde{X},\epsilon)\tilde{Y}^2, \tag{5.8}$$

where $\tilde{F_1}(\tilde{X},\epsilon)=c_{10}(\epsilon)/c_{12}(\epsilon)-(c_{11}(\epsilon)/c_{12}(\epsilon))\tilde{X}+\tilde{X}^2+O(|\tilde{X}|^3)$, $\tilde{F_2}(\tilde{X},\epsilon)=\{c_{20}(\epsilon)-c_{21}(\epsilon)\tilde{X}+c_{22}(\epsilon)\tilde{X}^2-c_{23}(\epsilon)\tilde{X}^3\}/\sqrt{-c_{12}(\epsilon)}+O(|\tilde{X}|^4)$, and $\tilde{F_3}(\tilde{X},\epsilon)=-F_3(-\tilde{X},\epsilon)$. Thus, the coefficient of $\tilde{X}^2$ in $\tilde{F_1}$ in the second equation of (5.8) reduces to 1, the same as the corresponding one in (5.2).

In order to reduce system (5.8) to the induced form (5.2), we need to remove the term of $\tilde{X}$ in the second equation of (5.8). We achieve this by the affine transformation $u=\tilde{X}-c_{11}(\epsilon)/2c_{12}(\epsilon)$, $v=\tilde{Y}$ in $\tilde{X}$, and change system (5.8) into

$$\dot{u}=v,\quad \dot{v}=G_1(u,\epsilon)+G_2(u,\epsilon)v+G_3(u,\epsilon)v^2, \tag{5.9}$$

where $G_1(u,\epsilon)=d_{10}(\epsilon)+u^2+O(|u|^3,\epsilon^2)$, $G_2(u,\epsilon)=d_{20}(\epsilon)+d_{21}(\epsilon)u+d_{22}(\epsilon)u^2+d_{23}(\epsilon)u^3+O(|u|^4)$, $G_3(u,\epsilon)=-F_3(-u-c_{11}/(2c_{12}),\epsilon)$, and the coefficients $d_{ij}(\epsilon)$ are displayed in the appendix. Because

$$d_{23}(0) = \frac{2^{-\frac{3}{4}}\{m_0(q+1+qm_0)\}^{1/4}(q+1+qm_0)^{1/2}(3m_0-1)(q+1+qm_0)}{m_0^2(qm_0)^{1/2}} > 0,$$

for small $\epsilon \neq 0$ system (5.9) can be rescaled by $\tilde{u} = d_{23}^{2/5}(\epsilon)u,\ \tilde{v} = d_{23}^{3/5}(\epsilon)v,\ \tilde{\tau} = d_{23}^{-1/5}(\epsilon)\tau$ into the form

$$\dot{\tilde{u}} = \tilde{v}, \qquad \dot{\tilde{v}} = \tilde{G}_1(\tilde{u},\epsilon) + \tilde{G}_2(\tilde{u},\epsilon)\tilde{v} + \tilde{G}_3(\tilde{u},\epsilon)\tilde{v}^2, \tag{5.10}$$

where $\tilde{G}_1(\tilde{u},\epsilon) = d_{23}^{4/5}d_{10}(\epsilon) + \tilde{u}^2 + O(|\tilde{u}|^3)$, $\tilde{G}_2(\tilde{u},\epsilon) = d_{23}^{1/5}d_{20}(\epsilon) + d_{23}^{-1/5}d_{21}(\epsilon)\tilde{u} + d_{23}^{-3/5}d_{22}(\epsilon)\tilde{u}^2 + \tilde{u}^3 + O(|\tilde{u}|^4)$, and $\tilde{G}_3(\tilde{u},\epsilon) = -d_{23}^{-2/5}F_3(-d_{23}^{-2/5}\tilde{u} - c_{11}/(2c_{12}),\epsilon)$, so that the coefficient of the term $\tilde{u}^3\tilde{v}$ in the second equation of (5.10) becomes 1, the same as in the corresponding term in system (5.2). The invertibility of all undergone transformations for small $\epsilon \neq 0$ implies that system (5.10) is topologically conjugate to system (5.2) locally. Hence (5.3) is an induced family of vector fields from system (5.2), the universal unfolding of the degenerate cusp as shown in the Main Theorem in [7]. Comparing the 4-jet of (5.10) with (5.2), we obtain the relation between the induced system and the universal unfolding, i.e.,

$$\mu_1(\epsilon) = d_{23}^{4/5}d_{10}(\epsilon), \quad \mu_2(\epsilon) = d_{23}^{1/5}d_{20}(\epsilon), \quad \mu_3(\epsilon) = d_{23}^{-1/5}d_{21}(\epsilon). \tag{5.11}$$

In particular, $\mu_1(0) = \mu_2(0) = \mu_3(0) = 0$. Computing the Jacobian determinant of relation (5.11) at $(0,0,0)$ with Maple V.7 software, we get

$$\left.\frac{\partial(\mu_1,\mu_2,\mu_3)}{\partial(\epsilon_1,\epsilon_2,\epsilon_3)}\right|_{\epsilon=0} = \frac{1+q+4m_0+3qm_0+5qm_0^2-m_0^2-m_0^3q)(q+1+qm_0)^2}{2},$$

which is > 0 for m_0 near 1. This implies that the induced family (5.3) parameterized by ϵ, and therefore (1.4), is locally equivalent to the unfolding (5.2). The proof is completed. □

Concerning the universal unfolding (5.2), Theorem 4 in [7] gives bifurcation surfaces

$$\begin{array}{lcl}
\mathcal{SN} & = & \{(\mu_1,\mu_2,\mu_3) \in V \,|\, \mu_1 = 0\}, \\
\mathcal{H} & = & \{(\mu_1,\mu_2,\mu_3) \in V \,|\, \mu_2 = \mu_3(-\mu_1)^{\frac{1}{2}} + (-\mu_1)^{\frac{3}{2}} + O((-\mu_1)^{\frac{7}{4}}),\ \mu_1 < 0\}, \\
\mathcal{HL} & =: & \{(\mu_1,\mu_2,\mu_3) \in V \,|\, \mu_2 = \frac{5}{7}\mu_3(-\mu_1)^{\frac{1}{2}} + \frac{103}{77}(-\mu_1)^{\frac{3}{2}} + O((-\mu_1)^{\frac{7}{4}}),\ \mu_1 < 0\}, \\
\mathcal{L} & =: & \{(\mu_1,\mu_2,\mu_3) \in V \,|\, \Xi(\mu_1,\mu_2,\mu_3) = 0,\ \mu_1 < 0\},
\end{array}$$

where V is a neighborhood of $(0,0,0)$ and the surface $\Xi(\mu_1,\mu_2,\mu_3) = 0$ is defined by

$$\mu_2 = (-\mu_1)^{\frac{3}{2}}\left(-\frac{6P(b)}{11P'(b)} + \frac{6b}{11}) + o((-\mu_1)^{\frac{3}{2}}\right), \quad \mu_3 = -\mu_1\left(-\frac{6}{11P'(b)} - \frac{15}{11}\right) + o(-\mu_1)$$

for $\mu_1 < 0$ with the parameter b. Here $P(b)$ is a solution of the Riccati equation $(9b^2-4)P' = 7P^2 + 3bP - 5$, as shown in [7]. Applying the inverse of (5.11) together with (5.1), from $\mathcal{SN}, \mathcal{H}, \mathcal{HL}$, and $\mathcal{L}$ we can give for system (1.4) the corresponding bifurcation surfaces $\mathcal{SN}', \mathcal{H}', \mathcal{HL}'$, and $\mathcal{L}'$, respectively. Thus, Theorem 4 in [7] implies the following.

THEOREM 5.2. *In the (A,p,m)-space there are four surfaces $\mathcal{SN}', \mathcal{H}', \mathcal{HL}'$, $\mathcal{L}'$ near (A_0,p_0,m_0), defined as above, such that system* (1.4) *produces a saddle-node bifurcation near E_0 as (A,p,m) crosses $\mathcal{SN}'$, a Hopf bifurcation near E_0 as (A,p,m)*

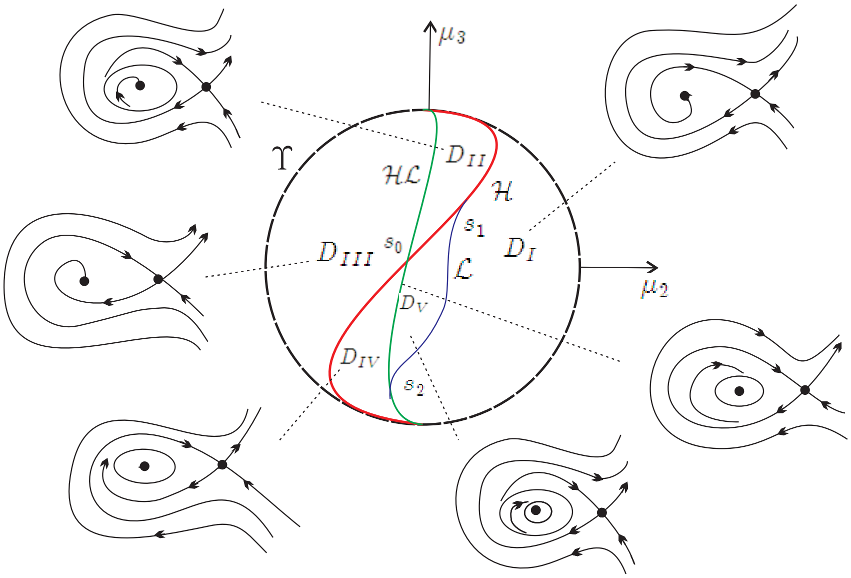

FIG. 3. *Projections of $\mathcal{SN}, \mathcal{H}$, $\mathcal{HL}$, and $\mathcal{L}$ on the (μ_2, μ_3)-plane.*

crosses $\mathcal{H}'$, a homoclinic bifurcation near E_0 as (A, p, m) crosses $\mathcal{HL}'$, and a coalescence of two limit cycles near E_0 as (A, p, m) crosses $\mathcal{L}'$.

The expressions of these bifurcation surfaces given in Theorem 5.2 can be computed by using (5.11) and (5.1). For example, consider $A_0 = 63.73, p_0 = 4.45, m_0 = 1.01$, and $q = 1000$. The surface $\mathcal{HL}'$ is presented as

$$\begin{aligned}&\frac{5}{7}(0.003018260808\epsilon_2 + 1.509170071\epsilon_3)\Theta(\epsilon_1, \epsilon_2, \epsilon_3)\\&+\frac{103}{77}(\Theta(\epsilon_1, \epsilon_2, \epsilon_3))^3 + o(|(\epsilon_1, \epsilon_2, \epsilon_3)|^{3/2}) = 0,\end{aligned}$$

where $\Theta(\epsilon_1, \epsilon_2, \epsilon_3) = \sqrt{0.09569545272\epsilon_1 - 0.003062992329\epsilon_2 - 3.033146367\epsilon_3}$. Parameter values are given by the expression where the homoclinic bifurcation occurs. Expressions of other bifurcation surfaces $\mathcal{SN}', \mathcal{H}'$, and $\mathcal{L}'$ can be given similarly. For a better understanding of the bifurcation diagram, let us observe bifurcation surfaces $\mathcal{SN}, \mathcal{H}, \mathcal{HL}$, and $\mathcal{L}$ in Figure 3. Since each of them is a cone with vertex at the origin (up to a homeomorphism in the parameter space), as in [7], it suffices to observe the bifurcation diagram in a small half ball $S_{\mu_0} = \{(\mu_1, \mu_2, \mu_3) | \, \mu_1^2 + \mu_2^2 + \mu_3^2 < \mu_0, \ \mu_1 < 0\}$ for sufficiently small $\mu_0 > 0$ and project the diagram to the plane $\mathcal{SN}$ (i.e., $\mu_1 = 0$). As indicated in [7], projected on the disk $\Upsilon = S_{\mu_0} \cap \mathcal{SN}$, the curve $\mathcal{H}$ intersects the curve $\mathcal{HL}$ at a point s_0 and $\mathcal{L}$ is tangent to curves $\mathcal{H}$ and $\mathcal{HL}$ at two points s_1 and s_2, respectively. Thus the half ball S_{μ_0} is divided into five open regions D_j $(j = I, II, \dots, V)$, as shown in Figure 3. Let D_j' $(j = I, II, \dots, V)$ be the corresponding regions in the (A, p, m)-space and s_0', s_1', s_2' be the corresponding intersection points, which can be calculated with (5.11). When (A, p, m) lies in these regions, by Theorem 3.1, system (1.4) has two equilibria E_+ and E_- in the interior of the first quadrant and E_- is

TABLE 1
Qualitative properties for various parameters.

(A, p, m)	E_+	Limit cycles	Homoclinic orbits
D'_I	unstable focus or node	no	no
$\mathcal{H}'\backslash\{\widehat{s'_0s'_1}\}$	weak focus(order 1)	no	no
s'_1	weak focus(order 2)	no	no
$\widehat{s'_0s'_1}$	stable weak focus(order 1)	1(order 1)	0
D'_{II}	stable focus or node	1(order 1)	no
$\mathcal{HL}'\backslash\{\widehat{s'_0s'_2}\}$	focus or node	no	1(order 1)
s'_0	stable weak focus(order 1)	no	1(order 1)
D'_{III}	stable focus or node	no	no
D'_{IV}	unstable focus or node	1(order 1)	no
s'_2	unstable focus or node	no	1(order 2)
$\widehat{s'_0s'_2}$	unstable focus or node	1(order 1)	1(order 1)
D'_V	unstable focus or node	2(order 1)	no
$\mathcal{L}'$	unstable focus or node	1(order 2)	0

always a saddle but E_+ is either a focus or a node. Furthermore, by Lemma 4.1 and Theorem 5.2 together with the theorems in [7] and [25], we can list more detailed dynamical behaviors in Table 1, where $\widehat{s'_0s'_1}$ and $\widehat{s'_0s'_2}$ denote the parts of bifurcation surfaces determined by the arcs on $\mathcal{H}$ and $\mathcal{HL}$, respectively, as shown in Figure 3. More concretely, neither a limit cycle nor a homoclinic loop appears in D'_I; a limit cycle arises as parameters go through $\mathcal{H}'$ from D'_I to D'_{II}; the limit cycle expands, deforms into a homoclinic loop and finally breaks as parameters go through $\mathcal{HL}'$ from D'_{II} to D'_{III}; a limit cycle arises again as parameters go through $\mathcal{H}'$ from D'_{III} to D'_{IV}. By continuity, if parameters go through the part of $\mathcal{HL}'$ below s'_2 and return to D'_I from D'_{IV}, the limit cycle disappears; if parameters go from D'_{IV} and hit the arc $\widehat{s'_0s'_2}$, the limit cycle coexists with a homoclinic loop. Furthermore, if parameters enter the region D'_V, the limit cycle persists and another limit cycle arises as the homoclinic loop breaks, i.e., two cycles coexist.

6. Discussion.

The existence of limit cycles in epidemic models can be used to explain oscillatory phenomena observed in the dynamics of some infectious diseases. One of the mechanisms by which epidemic models exhibit periodic oscillations is bifurcation, which occurs when the parameters vary. Early work on studying the dynamics of epidemic models focused on Hopf bifurcation, homoclinic bifurcation, or saddle-node bifurcation separately by using only one bifurcation parameter (Derrick and van den Driessche [6], Hethcote and van den Driessche [14], Liu et al. [17, 18]). Recent studies indicate that some epidemic models undergo codimension 2 bifurcations near degenerate equilibria; i.e., a Bogdanov–Takens bifurcation, which includes a Hopf bifurcation, a homocline bifurcation and a saddle-node bifurcation, can occur when two parameters vary near their critical values (Lizana and Rivero [19], Ruan and Wang [25], Alexander and Moghadas [1, 2], Moghadas [21], Wang [26]). It is interesting to notice that not only epidemic models with nonlinear incidence rates but also simple epidemic models with bilinear mass-action incidence rates can have complex dynamics such as the occurrence of Bogdanov–Takens bifurcations. For instance, Wang and Ruan [27] considered an epidemic model with a bilinear mass-action incidence rate and a constant removal rate of infectious individuals and showed that the model undergoes a sequence of bifurcations, including saddle-node bifurcation, subcritical Hopf bifurcation, and homoclinic bifurcation.

In those epidemic models exhibiting Bogdanov–Takens bifurcations, periodic solutions can arise through a Hopf bifurcation for some parameter values and disappear through a homoclinic bifurcation for some other parameter values, but neither the existence of multiple limit cycles nor the coexistence of a limit cycle and a homoclinic loop is revealed. However, recent work (Alexander and Moghadas [1, 2], Liu, Hethcote, and Levin [17], Moghadas and Alexander [22], Ruan and Wang [25], Wang [26]) indicates that some epidemic models can have two limit cycles. One may expect that the appearance of two limit cycles is due to the fact that degenerate Hopf and degenerate Bogdanov–Takens bifurcations [4] may occur in such epidemic models as well. However, to the best of our knowledge, so far there is no such study on the degenerate Hopf bifurcation and degenerate Bogdanov–Takens bifurcation on epidemic models. One of the difficulties is the lack of general criteria in calculating the multiplicity of a weak focus (see Xiao and Zhu [30] for such a criterion for a predator-prey model; see also Ruan and Xiao [24]).

In this paper, we continued studying the dynamics of a simplified epidemic model (1.3) with a nonlinear incidence rate that was originally considered by Ruan and Wang [25] (see also Liu et al. [17, 18] and Hethcote and van den Driessche [14]). Under certain conditions Ruan and Wang [25] showed that the simplified model (1.3) undergoes a Bogdanov–Takens bifurcation; i.e., it exhibits saddle-node, Hopf, and homoclinic bifurcations. They also established the existence of none, one, or two limit cycles. In this paper, we first calculated the second order Liapunov value of the weak focus and proved that the maximal multiplicity of the weak focus is 2 by technically dealing with some complicated multivariable polynomials, which implies that at most two limit cycles can arise near the weak focus. Then, by reducing the determination of the sign for polynomials of higher degrees to revised sign lists, we re-established the uniqueness of the limit cycle. Finally, we reduced system (1.4) to a form of universal unfolding for a cusp of codimension 3 and showed the coexistence of limit cycles and homoclinic loops via a degenerate Bogdanov–Takens bifurcation.

The coexistence of limit cycles and homoclinic loops demonstrates that epidemic models with saturated incidence rates exhibit very different and complex dynamics. Furthermore, the results indicate that the dynamical behavior of the model is very sensitive to the initial densities of the susceptible and infectious individuals. When the initial values lie inside the homoclinic loop, the numbers of susceptible and infectious individuals fluctuate periodically about the endemic levels. Such periodic patterns will be helpful in designing control and intervention policies for the disease. When the initial values lie outside the homoclinic loop, the disease will die out even if there are two endemic equilibria (see Figure 3). This means that the disease can be controlled and eradicated even above the threshold.

To the best of our knowledge, this is the first time that a limit cycle and a homoclinic loop have been shown to coexist in a realistic epidemic model. Though we focused on a simple case of SIRS models with a specific saturated incidence rate, we believe that such rich and complex dynamics can occur in other epidemic models with general saturated incidence rates as well as other types of nonlinear incidence rates (Hethcote and van den Driessche [14], Liu et al. [17, 18]).

Appendix.

(A1) As claimed in section 4, for each $j = 1, \dots, 13$, the polynomial ϖ_j in variables

$\alpha_1, \ldots, \alpha_6$, being the jth principal minor of the matrix

$$\mathrm{Discr}(\Psi) = \begin{bmatrix} \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 6\alpha_0 & 5\alpha_1 & 4\alpha_2 & 3\alpha_3 & 2\alpha_4 & \alpha_5 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \alpha_0 & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 \end{bmatrix},$$

can be calculated directly with Maple software. For example, $\varpi_1 = \alpha_0, \varpi_2 = 6\alpha_0^2, \varpi_3 = \alpha_0^2\alpha_1, \varpi_4 = -\alpha_0^2(-5\alpha_1^2 + 12\alpha_2\alpha_0)$, $\varpi_5 = \alpha_0^2(\alpha_1^2\alpha_2 - 4\alpha_0\alpha_2^2 + 3\alpha_0\alpha_3\alpha_1)$, $\varpi_6 = 2\alpha_0^2(24\alpha_0^2\alpha_4\alpha_2 - 27\alpha_0^2\alpha_3^2 - 8\alpha_0\alpha_2^3 + 24\alpha_0\alpha_3\alpha_1\alpha_2 - 10\alpha_0\alpha_4\alpha_1^2 + 2\alpha_2^2\alpha_1^2 - 5\alpha_3\alpha_1^3)$. The expressions for others will be much longer.

(A2) The polynomials $\vartheta_j, \iota_{ij}, \omega_j$ claimed in (5.4), a_{ij} and b_{ij} in (5.6), c_{ij} and F_3 in (5.7), and d_{ij} in (5.9) can be calculated directly with Maple software. Except for

$$c_{10} = a_{20}b_{10} - a_{10}b_{20},\ c_{11} = a_{20}b_{11} - a_{10}b_{21} + a_{21}b_{10} - a_{11}b_{20},\ c_{12} = -\sqrt{2m_0(q+1+qm_0)}(q+1+qm_0)/(4qm_0) + O(|\epsilon|),$$
$$c_{13} = -b_{22}a_{11} + b_{13}a_{20} - b_{23}a_{10} + b_{10}a_{23} - b_{21}a_{12} + b_{12}a_{21} - b_{20}a_{13} + b_{11}a_{22},$$
$$c_{20} = (a_{11}a_{20} + b_{20}a_{20} - a_{10}a_{21})/a_{20}, \quad c_{21} = -(2a_{10}a_{22}a_{20} - bb21a_{20}^2 - 2a_{12}a_{20}^2 + a_{21}a_{11}a_{20} - a_{10}a_{21}^2)/a_{20}^2,$$
$$c_{22} = -(-3a_{13}a_{20}^3 + 2a_{22}a_{20}^2a_{11} + a_{21}a_{12}a_{20}^2 + 3a_{10}a_{23}a_{20}^2 - b_{22}a_{20}^3 - 3a_{22}a_{20}a_{10}a_{21} - a_{21}^2a_{11}a_{20} + a_{10}a_{21}^3)/a_{20}^3,$$
$$c_{23} = -\{\sqrt{2}(3m_0 - 1)(q + 1 + qm_0)^3\}/\{4m_0^2q\sqrt{m_0(q + 1 + qm_0)}\} + O(|\epsilon|),$$
$$d_{10} = (4c_{10}c_{12} - c_{11}^2)/(4c_{12}^2) + O(|\epsilon|^2), \quad d_{20} = -(-8c_{20}c_{12}^3 + 4c_{21}c_{11}c_{12}^2 + c_{23}c_{11}^3 - 2c_{22}c_{11}^2c_{12})/(8c_{12}^3\sqrt{-c_{12}}) + O(|\epsilon|^2),$$
$$d_{21} = -(-4c_{22}c_{11}c_{12} + 4c_{21}c_{12}^2 + 3c_{23}c_{11}^2)/(4c_{12}^2\sqrt{-c_{12}}) + O(|\epsilon|^2), \quad d_{22} = (2c_{22}c_{12} - 3c_{23}c_{11})/(2c_{12}\sqrt{-c_{12}}) + O(|\epsilon|^2),$$
$$d_{23} = (\frac{1}{2})^{3/4}(\sqrt{m_0(q + 1 + qm_0)}(q + 1 + qm_0)/(qm_0))^{1/2}(3m_0 - 1)(q + 1 + qm_0)/m_0^2 + O(|\epsilon|),$$
$$F_3(\tilde{X}) = a_{21}/a_{20} + \{(-a_{21}^2 + 2a_{22}a_{20})/a_{20}^2\}\tilde{X} - \{(3a_{21}a_{22}a_{20} - 3a_{23}a_{20}^2 - a_{21}^3)/a_{20}^3\}\tilde{X}^2 - \{(4a_{21}a_{23}a_{20}^2 + 2a_{22}^2a_{20}^2 - 4a_{22}a_{20}a_{21}^2 + a_{21}^4)/a_{20}^4\}\tilde{X}^3 + O(|\tilde{X}^4|).$$

The other polynomials have long expressions. Their presentations and the Maple scripts are available upon request.

PHASE FIELD MODELS FOR BIOFILMS. I. THEORY AND ONE-DIMENSIONAL SIMULATIONS*

TIANYU ZHANG†, N. G. COGAN†, and QI WANG†

Abstract. We derive a set of phase field models for biofilms using the one-fluid two-component formulation in which the combination of extracellular polymeric substances (EPS, or polymer networks) and the bacteria is effectively modeled as one fluid component, while the collective ensemble of nutrient substrates and the solvent are modeled as the other. The biofilm is assumed to be an incompressible continuum, in which the motion of the polymer network and the solvent relative to the average velocity is accounted for by binary mixing kinetics. Various constitutive stress models are proposed for the effective polymer network component according to the property of the polymer network. Steady states are identified, their stability is analyzed (where two long wave growth modes are identified), and numerical solutions of different variations of the model in one space dimension are discussed and compared.

1. Introduction.

Biofilms are ubiquitous in natural and industrial settings. They exist on wet surfaces and consist of myriad microbes, their byproducts, and trapped particles. A biofilm community can be formed by a single bacterial species, but in nature biofilms almost always consist of rich mixtures of many species of bacteria, as well as fungi, algae, yeasts, protozoa, other microorganisms, debris, and corrosion products. Biofilms are held together primarily by polysaccharides and other long chain molecules, collectively termed "extracellular polymeric substances" or EPS. The bacteria cells produce the EPS and are held together by EPS strands, allowing them to develop complex, three-dimensional, resilient, attached communities [7, 9, 11, 12, 17, 18, 19, 24].

The Center for Disease Control and National Institutes of Health recently estimated that 65% to 85% of all chronic infections can be attributed to bacterial biofilms [10]. In human diseases, biofilm infections are some of the most difficult to treat. Even with rigorous antibiotic regimens, some biofilms, such as those within the thick airway mucus of cystic fibrosis (CF) patients, persist throughout the course of the disease process [16]. Bacterial biofilms can also be utilized in bioterrorism in which persistent "bioterrorist agent biofilms" formed by *Francisella tularensis* can grow on surfaces where environmental amoebas can phagocytose them, allowing for growth of fibrosis [16].

Biofilms cost the U.S. literally billions of dollars every year in energy losses, equipment damage, product contamination, and medical infections. Understanding the dynamics of the growth, transport, and destruction of biofilms is important for improving water treatment and medical treatment of diseases, protecting equipment

or devices from corrosion, and even preventing bioterrorism. The improved understanding of biofilms will have a significant impact on environmental sciences, medicine, civil engineering, naval sciences, military applications, and homeland security.

There have been increasing efforts to model biofilm structures and dynamics over the last two decades [25, 26, 27, 28], in which methods based on cellular automata, particle-based methods, continuum models, and multispecies modeling are attempted [1, 13, 20, 21, 30]. Recently Cogan and Keener developed a two-fluid model for biofilms, treating bacteria as a part of the polymer network [7]. The nutrient substrate is also treated passively as a part of the solvent. This work extended the polymeric mixture models of Tanaka [29] and Milner [23] and the work of Wolgemuth et al. [31] for biological material mixtures. Similar multifluid modeling extension has also been done by Klapper and colleagues [1, 20].

We briefly recall the multifluid theory of Cogan and Keener for biofilms next. Let ϕ_n be the volume fraction of the polymer network, ϕ_s that of the solvent, $\mathbf{v}_n$ the velocity of the polymer network, $\mathbf{v}_s$ the velocity of the solvent, c the concentration of the nutrient substrate, p the pressure, and τ_n and τ_s the network and solvent stress tensor, respectively. In the Cogan–Keener model, the substrate is passively treated as a part of the solvent. This two-fluid model consists of the linear momentum balance equation for each fluid, where inertia for all species are ignored, and the transport equation for the nutrient concentration as well as the volume fraction of the polymer network [7].

The momentum balance equation for each species is respectively given by

$$\begin{gathered}\nabla\cdot(\phi_n\tau_n) - h_f\phi_n\phi_s(\mathbf{v}_n-\mathbf{v}_s) - \nabla\Psi - \phi_n\nabla p = 0,\\ \nabla\cdot(\phi_s\tau_s) + h_f\phi_n\phi_s(\mathbf{v}_n-\mathbf{v}_s) - \phi_s\nabla p = 0,\end{gathered}\tag{1.1}$$

where h_f is the coefficient of friction and Ψ is the osmotic pressure due to the existence of the polymer network; the transport equation of the polymer volume fraction and the conservation of the volume fraction for the solvent are respectively given by

$$\begin{gathered}\frac{\partial\phi_n}{\partial t} + \nabla\cdot(\phi_n\mathbf{v}_n) = g_n,\\ \frac{\partial\phi_s}{\partial t} + \nabla\cdot(\phi_s\mathbf{v}_s) = 0,\end{gathered}\tag{1.2}$$

and the equation for the nutrient substrate consumption is given by

$$\frac{\partial}{\partial t}(\phi_s c) + \nabla\cdot(c\mathbf{v}_s\phi_s - D_s\phi_s\nabla c) = -g_c,\tag{1.3}$$

where g_n is the production rate for the polymer network, g_c is the consumption rate of the nutrient substrate in the solvent, and D_s is the diffusion constant of the nutrient substrate.

Both the polymer network and the solvent are assumed viscous in the Cogan–Keener model. The extra stress tensor, the osmotic pressure, and the production as well as consumption rates are given by the following constitutive laws:

$$\begin{aligned}&\tau_n = 2\eta_n\mathbf{D}_n,\\ &\tau_s = 2\eta_s\mathbf{D}_s,\\ &g_c = \phi_n A c,\\ &g_n = \epsilon\mu\phi_n\frac{c}{K_c+c},\\ &\Psi = \frac{kT}{v_1}\left[\ln(1-\phi_n) + \left(1-\frac{1}{N}\right)\phi_n + \chi\phi_n^2\right],\end{aligned}\tag{1.4}$$

where $\eta_{n,s}$ are the viscosity of the network and the solvent, respectively, $\mathbf{D}_{n,s} = \frac{1}{2}[\nabla \mathbf{v}_{n,s} + \nabla \mathbf{v}_{n,s}^T]$ is the rate of strain tensor for the network and the solvent, respectively, A is the consumption rate of the substrate, μ is the maximum production rate, K_c is the half-saturation constant, ϵ is a scaling parameter, N is the polymerization index, v_1 is the volume of the solvent molecule, k is the Boltzmann constant, T is the temperature, and χ is the Flory–Huggins mixing parameter [14, 15]. We note that the equation for the concentration of bacteria is a decoupled equation in the Cogan–Keener model and is therefore not listed above.

Given that

$$\phi_n + \phi_s = 1, \tag{1.5}$$

the following constraints arise:

$$\begin{aligned} \nabla \cdot (\phi_n \mathbf{v}_n + \phi_s \mathbf{v}_s) = g_n, \\ \nabla \cdot (\phi_n \tau_n + \phi_s \tau_s) = \nabla(\Psi + p). \end{aligned} \tag{1.6}$$

We note that $\mathbf{v} = \phi_n \mathbf{v}_n + \phi_s \mathbf{v}_s$ is the volume averaged velocity. Clearly, it is not divergence-free when $g_n \neq 0$, indicating that the material is in fact “compressible.” The second constraint gives the force balance equation for the volume averaged stress.

We note that the constraint above leads the bulk volume of the two-fluid material system to increase when $g_n \neq 0$. Practically, the individual velocity of each species is hardly measurable; moreover, it is impossible to impose the boundary conditions for velocities at inflow and outflow boundaries for each species. Therefore two-fluid theories are not easy to adopt in fluid dynamics and rheological studies. The practical use of the two-fluid models includes ignoring the solvent velocity [7], ignoring the stress deformation [20], or simply imposing periodic boundary conditions. This clearly limits the applicability of the multifluid biofilm theories.

In this paper, we embark on a different approach, assuming the biofilm-solvent mixture is incompressible, whose bulk motion is measured by a divergence-free averaged velocity field, adopting the one-fluid multicomponent formulation for mixture theories [2]. We retain the effective treatment of the polymer network/bacteria and substrate/solvent combinations. The excessive velocity in addition to the average one is accounted for by polymer-solvent mixing dynamics. Through an essentially mean field approach, we can couple the polymer network deformation and biofilm/solvent interfacial dynamics into the fluid mixture motion, which to the best of our knowledge has not been done to biofilm models systematically so far. The effective polymer comprising the EPS and bacteria is modeled as a viscoelastic “solution” in which the bacterium is the solution since it is viscous while the EPS is modeled as a linear polymer strand of a network [3].

The rest of this paper is organized as follows. First we develop a set of phase field models for biofilms by accounting for the transport of polymer networks, nutrient substrates, and the response of the polymer network in flow in several plausible ways within the theoretical framework of one-fluid multicomponent systems. We then analyze the stability of some steady states to investigate possibly unstable modes. Finally, we numerically study the biofilm growth and expansion in one space dimension and compare the results with respect to various formulations of the mixture theory.

2. Mathematical models. We study the biofilm in solvent as a fluid mixture of two components: the effective polymer network encompassing the bacteria trapped inside and the effective solvent which includes the nutrient substrates and pure solvent.

We adopt the one-fluid two-component formalism for fluid mixtures to develop a single-fluid, multicomponent model using the volume averaged velocity and the volume fractions of the two distinctive components. The polymer network volume fraction ϕ_n plays the role of a phase field variable in the theory. When $\phi_n = 0$, the fluid consists of entirely the solvent; otherwise, it is a true binary mixture when $0 < \phi_n < 1$. (The case of $\phi_n = 1$ is excluded in biofilms since they are never dry.) Therefore, the resulting theory is an effective phase field model. The two distinctive phases are modeled by $\phi_n = 0$ and $\phi_n > 0$, respectively. The inhomogeneity of the biofilm is accounted for by the variation of ϕ_n.

2.1. Phase field formulation. When the fluid mixture is incompressible, the average velocity is divergence-free. The bulk fluid is convected by the average velocity. In addition to the bulk convection, the polymer network is also transported by an additional flux due to mixing of two different components. Specifically, the local instantaneous flux consists of two parts: the flux convected by the average velocity $\mathbf{v}$ and the excessive flux due to polymer-solvent binary mixing. The latter contribution to the flux of the polymer volume fraction is assumed proportional to the mixing force given by the gradient of the free energy variation

$$\mathbf{f}_n = -\lambda_{ch} \nabla \frac{\delta f}{\delta \phi_n}, \tag{2.1}$$

where λ_{ch} is the proportionality parameter that has the same unit as the mobility. This is consistent with the Ginzburg–Landau dynamics in condensed matter physics [6]. The mixing free energy density f as a function of ϕ_n is given by the extended Flory–Huggins free energy density [14, 15]

$$f = kT \left[\frac{\gamma_1}{2} \|\nabla \phi_n\|^2 + \gamma_2 \left(\frac{\phi_n}{N} \ln \phi_n + (1-\phi_n)\ln(1-\phi_n) + \chi \phi_n (1-\phi_n) \right) \right], \tag{2.2}$$

where γ_1 and γ_2 measure the strength of the distortional and bulk mixing free energy, respectively, χ is the Flory–Huggins mixing parameter, N is the generalized polymerization index, $1/\gamma_2$ is proportional to the specific volume of the solvent molecule, and $\| \cdot \|$ denotes the l_2 norm of a vector in $\mathbf{R}^3$. The distortional free energy is included in the extended Flory–Huggins mixing free energy to account for the surface tension effect at the solvent-biofilm interface defined by $\{\mathbf{x} | \phi_n(\mathbf{x}, t) = \epsilon \text{ as } \epsilon \to 0^+\}$ and penalizing spatial inhomogeneity in the mixture. The variation of f with respect to ϕ_n (known as the chemical potential) is given by

$$\frac{\delta f}{\delta \phi_n} = -kT \left[\gamma_1 \Delta \phi_n + \gamma_2 \left[-\frac{1}{N} - \frac{\ln \phi_n}{N} + \ln(1-\phi_n) + 1 - \chi + 2\chi\phi_n \right] \right]. \tag{2.3}$$

Representing the growth rate of the polymer network produced by bacteria as the reaction rate for the polymer volume fraction, we propose the transport equation for the volume fraction of the polymer network as follows:

$$\frac{\partial \phi_n}{\partial t} + \nabla \cdot (\phi_n \mathbf{v}) = \nabla \cdot \left(\lambda_{ch} \nabla \frac{\delta f}{\delta \phi_n} \right) + g_n. \tag{2.4}$$

This is the Cahn–Hilliard equation [4, 5] with a reaction term (polymer production). From the given excessive flux, we can identify the instantaneous excessive velocity as

$$\mathbf{v}_n^e = -\lambda_{ch} \frac{1}{\phi_n} \nabla \frac{\delta f}{\delta \phi_n} \tag{2.5}$$

when $\phi_n \neq 0$. It is zero when $\phi_n = 0$.

Another form of the transport equation for ϕ_n can be obtained by arguing that the excessive flux is due to an excessive velocity which is proportional to the mixing force and takes the form $\mathbf{v}_n^e = -\lambda \nabla \frac{\delta f}{\delta \phi_n}$, in which the excessive flux is given by $-\lambda \phi_n \nabla \frac{\delta f}{\delta \phi_n}$. Here λ is the mobility parameter. This can also be obtained from the Ginzburg–Landau dynamics by assuming that λ_{ch} is proportional to the polymer volume fraction: $\lambda_{ch} = \lambda \phi_n$. The transport equation for ϕ_n is given by

$$\frac{\partial \phi_n}{\partial t} + \nabla \cdot (\phi_n \mathbf{v}) = \nabla \cdot \left[\lambda \phi_n \nabla \frac{\delta f}{\delta \phi_n} \right] + g_n. \tag{2.6}$$

This is called the modified or singular Cahn–Hilliard equation. When the fluid is entirely occupied by polymer networks, one of the extreme cases, we argue that mixing will cease. Therefore, it is plausible to assume that the mobility matrix is proportional to the solvent volume fraction as well:

$$\lambda = \lambda_0 (1 - \phi_n). \tag{2.7}$$

However, this perhaps would never happen in biofilm materials since biofilms always contain solvent in their sponge-like structures. Both the Cahn–Hilliard and the modified Cahn–Hilliard models will be tested in the following. The numerical simulation presented in later sections shows that the modified Cahn–Hilliard equation is more appropriate for the transport of ϕ_n, especially with the polymer production included in the transport.

The remaining governing equations for the mixture consist of the continuity equation, the momentum transport or balance equation, and the transport equation for the nutrient:

$$\begin{aligned} &\nabla \cdot \mathbf{v} = 0, \\ &\rho \frac{d\mathbf{v}}{dt} = \nabla \cdot (\tau_{extra}) - [\nabla p + \gamma_1 kT \nabla \cdot (\nabla \phi_n \nabla \phi_n)], \\ &\frac{\partial}{\partial t}(\phi_s c) + \nabla \cdot (c \mathbf{v} \phi_s - D_s \phi_s \nabla c) = -g_c, \end{aligned} \tag{2.8}$$

where ρ_s and ρ_n are the density of the solvent and polymer, respectively, $\rho = \phi_s \rho_s + \phi_n \rho_n$ is the averaged density, and τ_{extra} is the total extra bulk stress for the mixture. Here g_n, g_c are the reaction rates defined in (1.4). We note that when the densities of the polymer network and solvent are equal, the density of the mixture is a constant and the volume fraction averaged velocity is the mass averaged velocity.

In the above momentum balance equation, the presence of the extra term $\gamma_1 kT \nabla \cdot (\nabla \phi_n \nabla \phi_n)$ is due to the spatial inhomogeneity resulting from a virtual work principle [22]. The nutrient transport is assumed to be convected by the average velocity. The incompressibility condition $\nabla \cdot \mathbf{v} = 0$ and the constraint $\phi_n + \phi_s = 1$ require that the transport equation for ϕ_s have a decay term $-g_n$, leading to

$$\frac{\partial \phi_s}{\partial t} + \nabla \cdot (\phi_s \mathbf{v}) = -\nabla \cdot \left(\lambda_{ch} \nabla \frac{\delta f}{\delta \phi_n} \right) - g_n \tag{2.9}$$

in the Cahn–Hilliard model or

$$\frac{\partial \phi_s}{\partial t} + \nabla \cdot (\phi_s \mathbf{v}) = -\nabla \cdot \lambda \left(\phi_n \nabla \frac{\delta f}{\delta \phi_n} \right) - g_n \tag{2.10}$$

in the modified Cahn–Hilliard model. In the Cahn–Hilliard model, the excessive solvent velocity can be identified as

$$\mathbf{v}_s^e = \lambda_{ch}\frac{1}{\phi_s}\nabla\frac{\delta f}{\delta\phi_n}, \tag{2.11}$$

whereas the velocity is given by

$$\mathbf{v}_s^e = \lambda\frac{\phi_n}{\phi_s}\nabla\frac{\delta f}{\delta\phi_n} \tag{2.12}$$

in the modified Cahn–Hilliard model. The actual solvent velocity can be calculated by

$$\mathbf{v}_s = \mathbf{v} + \mathbf{v}_s^e. \tag{2.13}$$

Analogously, the polymer network velocity is given by

$$\mathbf{v}_n = \mathbf{v} + \mathbf{v}_n^e. \tag{2.14}$$

With this definition, we easily see that the average velocity is indeed the volume averaged velocity

$$\mathbf{v} = \phi_n\mathbf{v}_n + \phi_s\mathbf{v}_s. \tag{2.15}$$

In the above formulation of the theory, the nutrient substrate is assumed to be transported along with the average velocity. If we assume that the nutrient is transported with the solvent velocity instead, the nutrient transport equation is given by

$$\frac{\partial}{\partial t}(\phi_s c) + \nabla\cdot(c\mathbf{v}_s\phi_s - D_s\phi_s\nabla c) = -g_c. \tag{2.16}$$

2.2. Constitutive equations for effective polymer. The extra stress for the polymer network–solvent mixture will supply the crucial link to complete the governing system of equations for the biofilm model. The simplest choice is treating the polymer-solvent mixture as an extended Newtonian fluid like in (2.17). When both the solvent and the polymer are modeled as viscous fluids, the constitutive equations for the extra stresses are given by

$$\tau_n = 2\eta_n\mathbf{D}, \qquad \tau_s = 2\eta_s\mathbf{D}, \tag{2.17}$$

where $\mathbf{D} = \frac{1}{2}[\nabla\mathbf{v} + \nabla\mathbf{v}^T]$ is the rate of strain tensor and η_n, η_s are the polymer and solvent viscosities, respectively. Alternatively, we assume the extra stress to be proportional to the rate of strain tensor given by the velocity field of each component:

$$\tau_n = 2\eta_n\mathbf{D}_n, \qquad \tau_s = 2\eta_s\mathbf{D}_s, \tag{2.18}$$

where $\mathbf{D}_n = \frac{1}{2}(\nabla\mathbf{v}_n + \nabla\mathbf{v}_n^T)$, $\mathbf{D}_s = \frac{1}{2}(\nabla\mathbf{v}_s + \nabla\mathbf{v}_s^T)$. To account for the shear thinning effect, the polymer viscosity could depend on the rate of strain tensor like the power-law type [3].

However, because biofilms are hydrogels, they exhibit elastic and/or viscoelastic behavior depending on the time-scale of interest. To account for these contributions of the network, more sophisticated constitutive equations should be employed. We propose both an elastic and a viscoelastic model next. Given the composition of the effective polymer network, the stress associated to it should contain a viscous part accounting for the stress due to the viscous bacterial component denoted by τ_{ns}. It has two variations

$$\tau_{ns} = 2\eta_n \mathbf{D} \quad \text{or} \quad \tau_{ns} = 2\eta_n \mathbf{D}_n, \tag{2.19}$$

where η_n is the bacterial contribution to the polymeric viscosity in the effective polymer.

Rubber-elastic model. We model the EPS network as a gel. According to rubber-elastic theory, the elastic constitutive equation is given by

$$\tau_n = \nu kT \mathbf{F} \cdot \mathbf{F}^T = \nu kT \mathbf{B}, \tag{2.20}$$

where $\mathbf{F}$ is the deformation gradient tensor, $\mathbf{B} = \mathbf{F} \cdot \mathbf{F}^T$ is the Finger tensor, and v is the polymer number density. The time evolution of the deformation gradient tensor in the absence of solvent is given by

$$\frac{d\mathbf{F}}{dt} = \nabla \mathbf{v}_n \cdot \mathbf{F}, \tag{2.21}$$

where $\mathbf{v}_n$ is the polymer network velocity. The time evolution of the elastic stress tensor (as well as Finger tensor $\mathbf{B}$) follows the equation

$$\frac{\partial \tau_n}{\partial t} + \mathbf{v}_n \cdot \nabla(\tau_n) - [\nabla \mathbf{v}_n \cdot \tau_n + \tau_n \cdot \nabla \mathbf{v}_n^T] = 0. \tag{2.22}$$

An alternative choice for the rate-of-strain tensor is the rate of strain associated with the average velocity. Then, the constitutive equation for the elastic stress tensor is given by

$$\frac{d\tau_n}{dt} - [\nabla \mathbf{v} \cdot \tau_n + \tau_n \cdot \nabla \mathbf{v}^T] = 0, \tag{2.23}$$

where $\frac{d}{dt}(\bullet) = \frac{\partial}{\partial t}(\bullet) + \mathbf{v} \cdot \nabla(\bullet)$ is the material derivative and the polymer network is assumed to deform with the average velocity gradient.

Johnson–Segalman model. Considering the creation and annihilation rate for the network strands or segments in the network, we adopt the temporary network model for the viscoelastic EPS [3]. When the two rates are balanced, the constitutive equation for the elastic stress tensor is given by the following Johnson–Segalman model:

$$\frac{\partial \tau_n}{\partial t} + \nu_n \nabla \cdot (\mathbf{v}_n \tau_n) - \mathbf{W}_n \cdot \tau_n + \tau_n \cdot \mathbf{W}_n - a[\mathbf{D}_n \cdot \tau_n + \tau_n \cdot \mathbf{D}_n] + \frac{\tau_n}{\lambda_1} = \frac{2\eta_p}{\lambda_1} \mathbf{D}_n, \tag{2.24}$$

where a is a rate parameter between -1 and 1, λ_1 is the EPS relaxation time, and η_p is the EPS polymer network viscosity in the effective polymer [3]. $a = 1$ yields the Oldroyd-B model with the upper convected derivative, and $a = -1$ corresponds to the lower convected derivative. The rubber-elastic model can be viewed as a limiting case of the current model as $\lambda_1 \to \infty$ and $a = 1$; the viscous limit is recovered if $\lambda_1 \to 0$; whereas the highly elastic model is the limit of $\lambda_1 \to \infty$, $\frac{\eta_p}{\lambda_1} \to G$, where G is the elastic modulus.

An alternative formulation is to replace the network velocity $\mathbf{v}_n$ by the average velocity $\mathbf{v}$ analogous to the rubber-elastic case. The constitutive equation for the extra stress is then given by

$$\frac{d\tau_n}{dt} - \mathbf{W}\cdot\tau_n + \tau_n\cdot\mathbf{W} - a[\mathbf{D}\cdot\tau_n + \tau_n\cdot\mathbf{D}] + \frac{\tau_n}{\lambda_1} = \frac{2\eta_p}{\lambda_1}\mathbf{D}. \tag{2.25}$$

In summary, the phase field theories for biofilms consist of four sets of equations of multiple variations. In the following, the suffix A indicates that the average velocity is used, while N denotes that the network and the solvent velocity, respectively, are used.

Momentum and continuity equation.

$$\begin{aligned} &\nabla\cdot\mathbf{v} = 0,\\ &\rho\frac{d\mathbf{v}}{dt} = \nabla\cdot(\tau_{extra}) - [\nabla p + \gamma_1 kT\nabla\cdot(\nabla\phi_n\nabla\phi_n)],\\ &\tau_{extra} = \phi_n(a\tau_n + \tau_{ns}) + \phi_s\tau_s. \end{aligned} \tag{2.26}$$

Transport equation for nutrients.

$$\begin{aligned} &\frac{\partial}{\partial t}(\phi_s c) + \nabla\cdot(c\mathbf{v}\phi_s - D_s\phi_s\nabla c) = -g_c, \qquad \text{(CA-model)}\\ &\frac{\partial}{\partial t}(\phi_s c) + \nabla\cdot(c\mathbf{v}_s\phi_s - D_s\phi_s\nabla c) = -g_c. \qquad \text{(CN-model)} \end{aligned} \tag{2.27}$$

Transport equation for the polymer network volume fraction.

$$\begin{aligned} &\frac{\partial\phi_n}{\partial t} + \nabla\cdot(\phi_n\mathbf{v}) = \nabla\cdot\left[\lambda_{ch}\nabla\frac{\delta f}{\delta\phi_n}\right] + g_n, \qquad \text{(CH-model)}\\ &\frac{\partial\phi_n}{\partial t} + \nabla\cdot(\phi_n\mathbf{v}) = \nabla\cdot\left[\lambda\phi_n\nabla\frac{\delta f}{\delta\phi_n}\right] + g_n. \qquad \text{(MCH-model)} \end{aligned} \tag{2.28}$$

Constitutive equations.

$$\begin{gathered} \tau_n = 2\eta_n\mathbf{D},\ \tau_{ns} = 0,\ \tau_s = 2\eta_s\mathbf{D},\ a = 1, \qquad \text{(VA-model)}\\ \tau_n = 2\eta_n\mathbf{D}_n,\ \tau_{ns} = 0,\ \tau_s = 2\eta_s\mathbf{D}_s,\ a = 1, \qquad \text{(VN-model)}\\ \frac{d\tau_n}{dt} - \mathbf{W}\cdot\tau_n + \tau_n\cdot\mathbf{W} - a[\mathbf{D}\cdot\tau_n + \tau_n\cdot\mathbf{D}] + \frac{\tau_n}{\lambda_1} = \frac{2\eta_p}{\lambda_1}\mathbf{D},\\ \tau_{ns} = 2\eta_n\mathbf{D},\ \tau_s = 2\eta_s\mathbf{D}, \qquad \text{(JSA-model)}\\ \frac{\partial\tau_n}{\partial t} + \nabla\cdot(\mathbf{v}_n\tau_n) - \mathbf{W}_n\cdot\tau_n + \tau_n\cdot\mathbf{W}_n - a[\mathbf{D}_n\cdot\tau_n + \tau_n\cdot\mathbf{D}_n] + \frac{\tau_n}{\lambda_1} = \frac{2\eta_p}{\lambda_1}\mathbf{D}_n,\\ \tau_{ns} = 2\eta_n\mathbf{D}_n,\ \tau_s = 2\eta_s\mathbf{D}_s. \qquad \text{(JSN-model)} \end{gathered} \tag{2.29}$$

The production rate for polymer network and the consumption rate for the nutrient follow those of the Cogan–Keener model defined in section 1. In the MCH model, the mobility parameter λ can also be assigned to $\lambda_0\phi_s$ in case the solvent volume fraction is low and varies drastically in space.

3. Nondimensionalization. We use a characteristic time-scale t_0 and length-scale h, whose values will be specified in specific applications, to nondimensionalize the variables

$$\tilde{t} = \frac{t}{t_0},\quad \tilde{\mathbf{x}} = \frac{\mathbf{x}}{h},\quad \tilde{\mathbf{v}} = \frac{\mathbf{v}t_0}{h},\quad \tilde{p} = \frac{pt_0^2}{\rho_0 h^2},\quad \tilde{\tau}_n = \frac{\tau_n t_0^2}{\rho_0 h^2},\quad \tilde{c} = \frac{c}{c_0}, \tag{3.1}$$

where c_0 is a characteristic substrate concentration. The following dimensionless quantities arise:

(3.2)
$$\Lambda = \frac{\lambda \rho_0}{t_0},\ \Gamma_1 = \frac{\gamma_1 k T t_0^2}{\rho_0 h^4},\ \Gamma_2 = \frac{\gamma_2 k T t_0^2}{\rho_0 h^2},\ Re_s = \frac{\rho_0 h^2}{\eta_s t_0},\ Re_n = \frac{\rho_0 h^2}{\eta_n t_0},\ Re_p = \frac{\rho_0 h^2}{\eta_p t_0},$$
$$\tilde{D}_s = \frac{D_s t_0}{h^2},\ \Lambda_1 = \frac{\lambda_1}{t_0},\ \tilde{\rho} = \phi_s \frac{\rho_s}{\rho_0} + \phi_n \frac{\rho_n}{\rho_0},\ \tilde{A} = A t_0,\ \tilde{\mu} = \mu t_0,\ \tilde{K}_c = \frac{K_c}{c_0},$$

where ρ_0 is an averaged density; $Re_{s,n,p}$ are the Reynolds numbers for the solvent, bacteria in the effective EPS polymer network, and EPS polymer network; Λ_1 is the Deborah number for the polymer network; Λ, $\Gamma_{1,2}$, $\tilde{D}_s$, $\tilde{A}$, $\tilde{\mu}$, $\tilde{K}_c$ are the dimensionless parameters of their dimensional counterparts. For simplicity, we drop the $\tilde{\bullet}$ on the dimensionless variables, and the parameters. The system of governing equations in these dimensionless variables are given, for example in the CH+CA+JSA model, by

$$\begin{aligned}
&\nabla \cdot \mathbf{v} = 0, \\
&\rho \frac{d\mathbf{v}}{dt} = \nabla \cdot (\phi_n (a\tau_n + \tau_{ns}) + \phi_s \tau_s) - [\nabla p + \Gamma_1 \nabla \cdot (\nabla \phi_n \nabla \phi_n)], \\
&\frac{\partial}{\partial t}(\phi_s c) + \nabla \cdot (c\mathbf{v}\phi_s - D_s \phi_s \nabla c) = -g_c, \quad \text{(CA)} \\
&\frac{\partial \phi_n}{\partial t} + \nabla \cdot (\phi_n \mathbf{v}) = \nabla \cdot \left[\Lambda \nabla \frac{\delta f}{\delta \phi_n}\right] + gn, \quad \text{(CH)} \\
&\frac{d\tau_n}{dt} - \mathbf{W} \cdot \tau_n + \tau_n \cdot \mathbf{W} - a[\mathbf{D} \cdot \tau_n + \tau_n \cdot \mathbf{D}] + \frac{\tau_n}{\Lambda_1} = \frac{2}{\Lambda_1 Re_p} \mathbf{D}, \\
&\tau_{ns} = \frac{2}{Re_n} \mathbf{D}, \quad \tau_s = \frac{2}{Re_s} \mathbf{D}, \quad g_c = A\phi_n c, \quad gn = \epsilon \mu \phi_n \frac{c}{K_c + c}.
\end{aligned} \tag{3.3}$$

The dimensionless mixing free energy density is now given by

$$f = \frac{\Gamma_1}{2} \|\nabla \phi_n\|^2 + \Gamma_2 \left[\frac{\phi_n}{N} \ln \phi_n + (1 - \phi_n) \ln(1 - \phi_n) + \chi \phi_n (1 - \phi_n)\right]. \tag{3.4}$$

The other dimensionless equations can be obtained analogously. To save space, we will not enumerate them here.

4. Steady states in one dimension and their linear stability. In this section we examine the solution of the governing system of equations that depends on one spatial variable $y \in I = [0, 1]$, where the characteristic length-scale h is chosen as the width of the stripe which the fluid mixture occupies. The boundary conditions for the governing system of equations are

$$\mathbf{v}|_{\partial I} = \mathbf{v}^0, \quad \left[\phi_n \mathbf{n} \cdot \nabla \frac{\delta f}{\delta \phi_n}\right]_{\partial I} = 0, \quad [\mathbf{n} \cdot \nabla \phi_n]_{\partial I} = 0, \quad [\phi_s \mathbf{n} \cdot \nabla c]_{\partial I} = 0, \tag{4.1}$$

where $\mathbf{n}$ is the unit external normal at the boundary of the domain I and ∂I denotes the boundary of the domain. These boundary conditions consist of the no-slip boundary condition on the solid boundary for the average velocity, the no-penetration boundary condition for the excessive polymer network velocity, and a no-flux boundary condition for the polymer network volume fraction and for the nutrient concentration, respectively.

4.1. Viscous limit. We first discuss the solution given by the viscous model (CH+VA). Let $\eta_m = \frac{1-\phi_n}{Re_s} + \frac{\phi_n}{Re_n}$, where $1/\eta_m$ is the effective Reynolds number and

$$\hat{f}(\phi_n) = \frac{\phi_n}{N} \ln \phi_n + (1-\phi_n)\ln(1-\phi_n) + \chi\phi_n(1-\phi_n). \tag{4.2}$$

$\hat{f}$ is the bulk Flory–Huggins mixing free energy density. Considering the boundary condition at the wall, we set $v_y^0 = 0$.

The constant steady state solution for all models is given by

$$\begin{array}{llll} \mathbf{v} = \mathbf{0}, & p = p_0, & \phi_n = \phi_0, & c = 0, \text{ or} \\ \mathbf{v} = \mathbf{0}, & p = p_0, & \phi_n = 0, & c = c_0, \end{array} \tag{4.3}$$

where p_0 is an arbitrary constant, c_0 is an arbitrary positive constant, and $0 \leq \phi_0 < 1$ is a constant. In addition to the constant solutions, there can exist a nonconstant steady state at $c = 0$ for ϕ_n governed by

$$\Gamma_1 \phi_n'' - \Gamma_2 \frac{\partial \hat{f}}{\partial \phi_n} = \Gamma_1 C_0. \tag{4.4}$$

A closed form of the solution is not available for this equation. However, (4.4) can be integrated to yield

$$\phi_n' = \pm\sqrt{2C_0\phi_n + \frac{2\Gamma_2}{\Gamma_1}\hat{f}(\phi_n) + 2C_1}, \tag{4.5}$$

where C_0 and C_1 are integrating constants. A qualitative phase space analysis on an analogous system is given in [20]. Here we focus on the nonconstant steady state satisfying the Neumann boundary condition.

Using the boundary condition $\phi_n'(1) = \phi_n'(0) = 0$, we can determine C_0 and C_1:

$$\begin{aligned} 2C_0\phi_n(1) + \frac{2\Gamma_2}{\Gamma_1}\hat{f}(\phi_n(1)) + 2C_1 = 0, \\ 2C_0\phi_n(0) + \frac{2\Gamma_2}{\Gamma_1}\hat{f}(\phi_n(0)) + 2C_1 = 0. \end{aligned} \tag{4.6}$$

If $\phi_n(0) \neq \phi_n(1)$,

$$C_0 = \frac{\Gamma_2}{\Gamma_1}\,\frac{\hat{f}(\phi_n(0)) - \hat{f}(\phi_n(1))}{\phi_n(1) - \phi_n(0)}, \qquad C_1 = -\frac{\Gamma_2}{\Gamma_1}\,\frac{\phi_n(1)\hat{f}(\phi_n(0)) - \phi_n(0)\hat{f}(\phi_n(1))}{\phi_n(1) - \phi_n(0)}. \tag{4.7}$$

If we denote

$$g(\phi) = -\frac{\Gamma_1}{\Gamma_2}[C_0\phi_n + C_1], \tag{4.8}$$

$g(\phi)$ is the secant-line interpolating the points $(\phi_n(0), \hat{f}(\phi_n(0)))$ and $(\phi_n(1), \hat{f}(\phi_n(1)))$. In order to have a smooth real solution, $\hat{f} - g > 0$; i.e., $\hat{f}$ is concave down between $\phi_n(0)$ and $\phi_n(1)$. The concavity region of $\hat{f}$ is depicted in Figure 1 in phase space (ϕ, χ) at $N = 1000$. In the concave down region, a smooth solution can exist depending on the magnitude of $\frac{2\Gamma_2}{\Gamma_1}$.

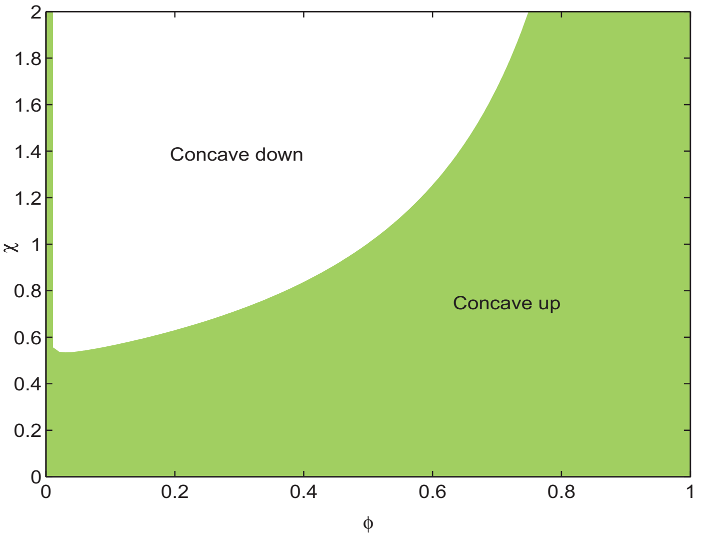

FIG. 1. *The regions of concavity in phase space* (ϕ, χ) *at* $N = 1000$*.*

From (4.5), we can see that the steady state solution is either monotonically increasing or decreasing if it exists. Integrating (4.5), we arrive at

$$\pm \int_{\phi_n(0)}^{\phi_n(y)} \frac{d\phi}{\sqrt{\hat{f}(\phi) - g(\phi)}} = y\sqrt{\frac{2\Gamma_2}{\Gamma_1}}, \tag{4.9}$$

where the solution of the boundary value problem is constrained by

$$\pm \int_{\phi_n(0)}^{\phi_n(1)} \frac{d\phi}{\sqrt{\hat{f}(\phi) - g(\phi)}} = \sqrt{\frac{2\Gamma_2}{\Gamma_1}}. \tag{4.10}$$

Notice that $\frac{2\Gamma_2}{\Gamma_1} = \frac{2h^2\gamma_2}{\gamma_1}$. Unless this dimensionless quantity is small, there could not be a solution to the integral equation. When the right-hand side is small, the chance to have a smooth solution increases considerably.

If $\phi_n(0) = \phi_n(1)$, we can determine C_0 only in terms of C_1:

$$C_1 = -C_0\phi_n(1) - \frac{\Gamma_2}{\Gamma_1}\hat{f}(\phi_n(1)). \tag{4.11}$$

The governing equation is given by

$$\phi_n' = \pm\sqrt{\frac{2\Gamma_2}{\Gamma_1}\left[\hat{f}(\phi_n) - \left(-\frac{C_0\Gamma_1}{\Gamma_2}(\phi_n - \phi_n(0)) + \hat{f}(\phi_n(0))\right)\right]}. \tag{4.12}$$

The constant solution $\phi_n = \phi_n(0)$ is a solution. When $\hat{f}$ is concave down, there could be a nonconstant steady state given below, provided that $\frac{2h^2\gamma_2}{\gamma_1}$ is small:

$$\begin{aligned}(4.13)\quad &\int_{\phi_n(0)}^{\phi_n(y)} \frac{d\phi}{\sqrt{\left[\hat{f}(\phi_n) - \left(-\frac{C_0\Gamma_1}{\Gamma_2}(\phi_n - \phi_n(0)) + \hat{f}(\phi_n(0))\right)\right]}} = y\sqrt{\frac{2\Gamma_2}{\Gamma_1}}, \quad 0 \le y \le \frac{1}{2},\\ &\int_{\phi_n(1/2)}^{\phi_n(y)} \frac{d\phi}{\sqrt{\left[\hat{f}(\phi_n) - \left(-\frac{C_0\Gamma_1}{\Gamma_2}(\phi_n - \phi_n(0)) + \hat{f}(\phi_n(0))\right)\right]}} = -y\sqrt{\frac{2\Gamma_2}{\Gamma_1}}, \quad \frac{1}{2} < y \le 1,\end{aligned}$$

or

$$\begin{aligned}(4.14)\quad &\int_{\phi_n(0)}^{\phi_n(y)} \frac{d\phi}{\sqrt{\left[\hat{f}(\phi_n) - \left(-\frac{C_0\Gamma_1}{\Gamma_2}(\phi_n - \phi_n(0)) + \hat{f}(\phi_n(0))\right)\right]}} = -y\sqrt{\frac{2\Gamma_2}{\Gamma_1}}, \quad 0 \le y \le \frac{1}{2},\\ &\int_{\phi_n(1/2)}^{\phi_n(y)} \frac{d\phi}{\sqrt{\left[\hat{f}(\phi_n) - \left(-\frac{C_0\Gamma_1}{\Gamma_2}(\phi_n - \phi_n(0)) + \hat{f}(\phi_n(0))\right)\right]}} = y\sqrt{\frac{2\Gamma_2}{\Gamma_1}}, \quad \frac{1}{2} < y \le 1.\end{aligned}$$

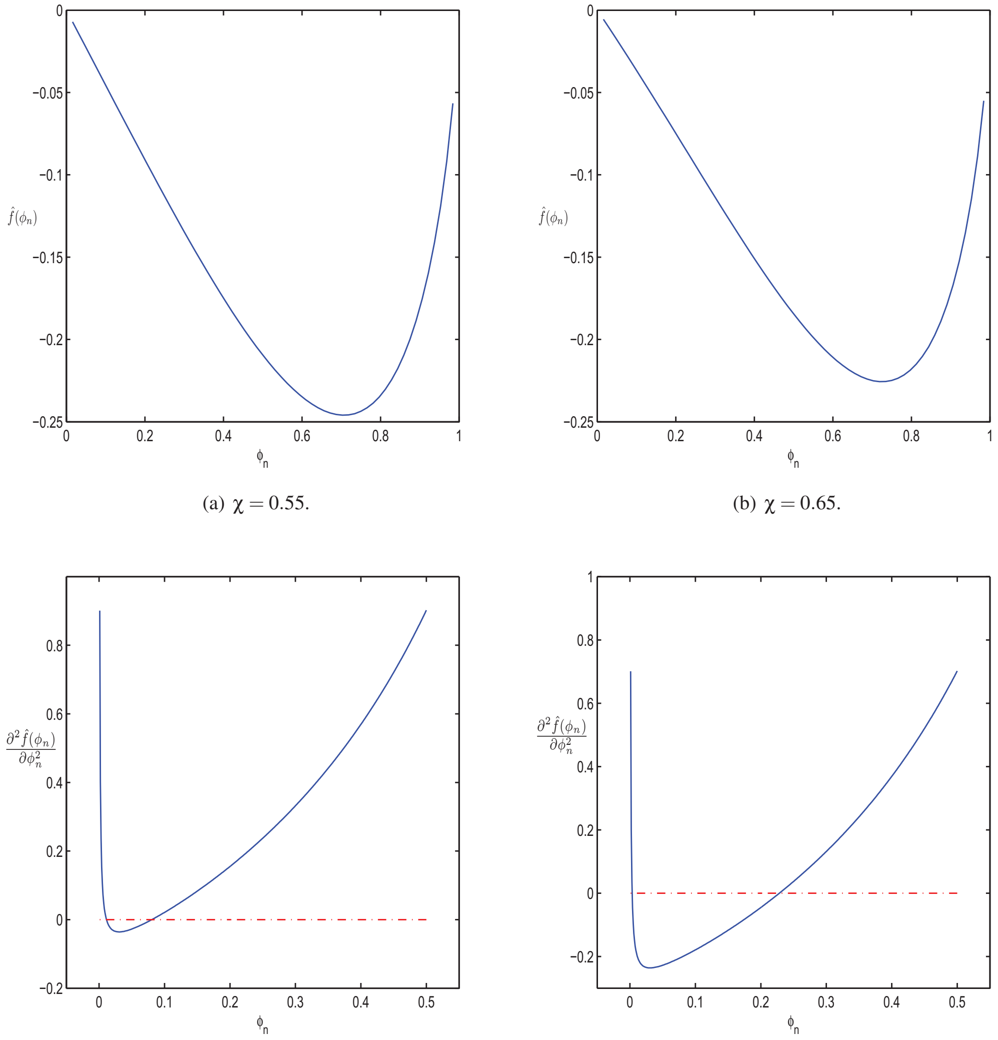
This solution is spatially periodic with period 1.

Next, we examine the linearized stability of the constant states. Let $\rho^0 = \rho(\phi_0)$ be the averaged density at the steady state. The eigenfunction for the velocity components is $\sin(\beta y)$ and for c and ϕ_n is $\cos(\beta y)$, respectively, where $\beta = m\pi$, $m = 1, \ldots, \infty$. The growth rates of the linearized system are given by

$$\begin{aligned}\alpha_{1,2} &= -\frac{1}{\rho^0}\left(\frac{1-\phi_0}{Re_s} + \frac{\phi_0}{Re_n}\right)\beta^2,\\ \alpha_3 &= \Lambda\left(-\Gamma_2\frac{\partial^2 \hat{f}}{\partial \phi^2}(\phi_0)\beta^2 - \Gamma_1\beta^4\right),\\ \alpha_4 &= -D_s\beta^2 - A\phi_0,\end{aligned} \tag{4.15}$$

where $\alpha_{1,2}$ are the growth rates obtained from the linearized momentum equations, α_3 is the growth rate corresponding to the linearized transport equation for ϕ_n, and α_4 is the growth rate for the nutrient concentration. If $\frac{\partial^2 \hat{f}}{\partial \phi^2}(\phi_0) \ge 0$, i.e., the bulk mixing energy density curve is concave up, all the growth rates are nonpositive; in fact, they are decay rates. Otherwise, in the portion where the mixing energy density is concave down, α_3 is positive for small values of β and negative for large values of β, i.e., the steady state suffers the long wave instability. We note that $\frac{\partial^2 \hat{f}}{\partial \phi_n^2} = \frac{1}{N\phi_n} + \frac{1}{1-\phi_n} - 2\chi$, and thus $\frac{\partial^2 \hat{f}}{\partial \phi_n^2} = 0$ has two solutions $\phi_n^{\pm}$. If $\phi_n^{\pm}$ are real, $\frac{\partial^2 \hat{f}}{\partial \phi_n^2} < 0$ and $\hat{f}$ is concave down for $\phi_n^- < \phi_n < \phi_n^+$. The instability occurs in the concave down region. Figure 2 depicts $\hat{f}$ and $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}$ at $N = 10^3$ and two different values of χ. In (c) and (d), the intersections of the dashed line with the curve give values of $\phi_n^{\pm}$. It can be seen for larger values of χ that the range of ϕ_n where $\frac{\partial^2 \hat{f}}{\partial \phi^2 n} < 0$ becomes wider.

For the second family of constant steady states (4.3.2) the eigenfunctions for the velocity, the nutrient substrate concentration, and the polymer network volume fraction are identical to the previous case given by either $\sin(\beta y)$ or $\cos(\beta y)$. The growth rates of the linearized system are given by



(a) $\chi = 0.55$.

(b) $\chi = 0.65$.

(c) $\chi = 0.55$.

(d) $\chi = 0.65$.

FIG. 2. *The normalized bulk mixing energy density* $\hat{f}(\phi_n)$ *and its second derivatives* $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}$ *at* $\chi = 0.55, 0.65$. *At* $\chi = 0.55$, *the concave down region does not include* $\phi_n = 0.19$, *whereas it does at* $\chi = 0.65$.

(4.16)
$$\alpha_{1,2} = -\frac{1}{\rho^0 Re_s}\beta^2, \quad \alpha_3 = \Lambda\left(-\Gamma_2 \frac{\partial^2 \hat{f}}{\partial \phi^2}(0)\beta^2 - \Gamma_1 \beta^4\right) + \frac{\epsilon \mu c_0}{K + c_0}, \quad \alpha_4 = -D_s \beta^2.$$

We note that $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}(0)$ is not defined in the original definition of the Flory–Huggins mixing free energy density. However, if we modify the $\phi_n \ln \phi_n$ term in the mixing energy density f by $(\phi_n + \delta\phi)\ln(\phi_n + \delta\phi)$, where $0 < \delta\phi \ll 1$, then we have

$$\frac{\partial^2 \hat{f}}{\partial \phi_n^2} = \frac{1}{N(\phi_n + \delta\phi)} + \frac{1}{1 - \phi_n} - 2\chi,$$

and $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}(0) = \frac{1}{N\delta\phi} + 1 - 2\chi$. Here, $\Delta\phi$ is a small positive number. If $\delta\phi \leq \frac{1}{N}$ and $0 \leq \chi \leq 1$, then $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}(0) \geq 0$ and the only positive growth rate comes from the polymer network production term at small β. For practical purposes, we use $\delta\phi = 10^{-6}$ throughout this paper.

We remark that the linearized stability analysis applies to the equations in an infinite domain and higher space dimensions as well. In this case, $\beta = \mathbf{k} \cdot \mathbf{l}$, where $\mathbf{k}$ is the wave number, $\mathbf{l}$ is a fixed direction in the multidimensional space, and the eigenfunctions are the Fourier (normal) modes. The analysis also applies to the three-dimensional cubic domain with homogeneous or periodic boundary conditions.

Figure 3 depicts the growth rates for the two families of constant steady states with dimensionless parameters $\Lambda = 10^{-9}$, $\Gamma_1 = 41.8337$, $\Gamma_2 = 418337$, $N = 10^3$, $\epsilon = 1$ and two selected values of χ at $\phi_n = 0.19$. For the first family of constant steady states, when $\chi = 0.55$, Figure 2(c) shows $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}(0.19) > 0$, and thus the growth rate $\alpha_3 < 0$ for all $\beta > 0$; when $\chi = 0.65$, Figure 2(d) shows $\frac{\partial^2 \hat{f}}{\partial \phi_n^2}(0.19) < 0$, and thus $\alpha_3 > 0$ for β between 0 and approximately 24. For the second family of constant steady states, a long wave instability persists to the infinitely long wave limit at any χ. Numerical results confirming the long wave instability in nonlinear regimes are presented in section 6.

For the MCH model, the growth rate α_3 is simply modified by a factor of ϕ_0 for the first family of constant steady states

$$\alpha_3 = \phi_0 \Lambda \left(-\Gamma_2 \frac{\partial^2 \hat{f}}{\partial \phi^2}(\phi_0)\beta^2 - \Gamma_1 \beta^4 \right), \tag{4.17}$$

whereas it is given by

$$\alpha_3 = \frac{\epsilon \mu c_0}{K_c + c_0} \tag{4.18}$$

for the second family of constant steady states, which equals the infinitely long wave limit of the growth rate α_3 in (4.16).

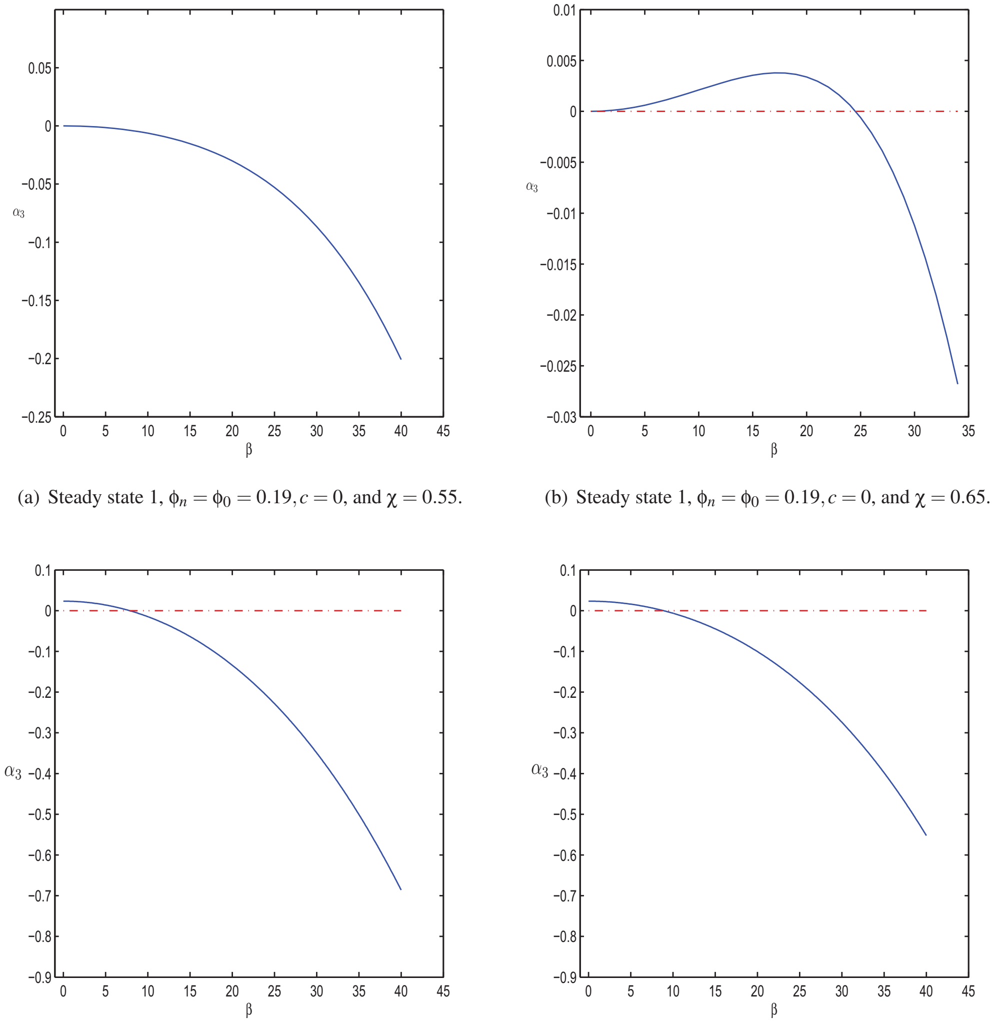
We next examine the steady states and their stability in the viscoelastic models.

4.2. Viscoelastic model. The viscoelastic model adds a set of constitutive equations for the elastic stress to the governing system of equations and couples the elastic stress to the momentum transport equation. For brevity, we use τ in place of τ_n from here on for the polymer elastic stress tensor.

Notice that the steady state of the elastic stress tensor is zero; the constitutive equation for the polymer network stress is independent of the volume fraction ϕ_n and concentration c; given the zero boundary conditions on $\mathbf{v}$, it is not necessary to impose any boundary conditions on the polymer elastic stress components. We obtain that four modes in the linearized constitutive equation are independent, and their growth rates are given by

$$\alpha_{5,7,8,10} = -\frac{1}{\Lambda_1}, \tag{4.19}$$

where the indices track the four decoupled modes of the elastic stress tensor. The other two modes $\alpha_{6,9}$ are coupled to the momentum equation. For the first family of steady states $\phi = \phi_0$, $c = 0$, the coupled growth rates are calculated as



(a) Steady state 1, $\phi_n = \phi_0 = 0.19, c = 0$, and $\chi = 0.55$.

(b) Steady state 1, $\phi_n = \phi_0 = 0.19, c = 0$, and $\chi = 0.65$.

(c) Steady state 2, $\phi_n = 0, c = c_0$, and $\chi = 0.55$.

(d) Steady state 2, $\phi_n = 0, c = c_0$, and $\chi = 0.65$.

FIG. 3. *Growth rate of the linearized CH model. The values of the dimensionless parameters are* $\Lambda = 10^{-9}$, $\Gamma_1 = 41.8337$, $\Gamma_2 = 418337$, $N = 10^3$, $\delta\phi = 10^{-3}$, $\epsilon = 1$, $c_0 = 0.1$, $\mu = 0.14$, $K_c = 0.5$. *For the first family of steady states, the long wave growth is due to the polymer-solvent mixing kinetics shown in* (b). *Panel* (a) *depicts a negative growth rate. In contrast, for the second family of steady states, the long wave growth rate depends only on the polymer production shown in* (c) *and* (d).

(4.20)

$$\alpha_{1,2,6,9} = \frac{1}{2\rho_0}\left[-\left(\frac{\rho_0}{\Lambda_1} + \left(\frac{1-\phi_0}{Re_s} + \frac{\phi_0}{Re_n}\right)\beta^2\right) \pm\sqrt{\left(\frac{\rho_0}{\Lambda_1} + \frac{1-\phi_0}{Re_s}\beta^2\right)^2 - 4\rho_0\left(\left(\frac{1-\phi_0}{\Lambda_1 Re_s} + \frac{\phi_0}{\Lambda_1 Re_n}\right) + \frac{2a\phi_0}{\Lambda_1 Re_p}\beta^2\right)}\,\right].$$

The rates all have negative real parts. The corresponding eigenfunction for the velocity components is $\sin\beta y$, and that for the stress components is $\cos\beta y$. The growth rates

$\alpha_{3,4}$ and eigenfunctions for ϕ_n and c are identical to those in the viscous limit.

For the second family of steady states $\phi = 0$, $c = c_0$. The linearized momentum and constitutive equations decouple. So, the growth rates in the viscous limit $\alpha_{1,2}$ remain in addition to the decay rates from the constitutive equations,

$$\alpha_{5,6,7,8,9,10} = -\frac{1}{\Lambda_1}. \tag{4.21}$$

In the gel model ($\Lambda_1 \to \infty$), the growth rates for the first family of steady states are given by

$$\begin{aligned} \alpha_{1,2} &= -\left(\frac{1-\phi_0}{Re_s} + \frac{\phi_0}{Re_n}\right)\beta^2, \\ \alpha_{5,6,7,8,9,10} &= 0. \end{aligned} \tag{4.22}$$

The results for the JSN model are qualitatively the same and are omitted here. The analysis shows that the viscoelasticity at the linear regime does not have any negative effects on the stability. We next study the nonlinear dynamics of the biofilm flows in one space dimension. But first we present the numerical method that we use to compute the nonlinear transient solutions.

5. Numerical scheme for the one-dimensional biofilm models. In this section we investigate the growth of the biofilm in one dimension: $y \in I = [0, 1]$ governed by the momentum, Cahn–Hilliard or modified Cahn–Hilliard equations, the nutrient transport equation, and the stress constitutive equation JSA or JSN with the continuous supply of nutrient substrates through the top boundary. We adopt the boundary conditions given in (4.1) except that the nutrient boundary conditions are replaced by

$$[D\phi_s \nabla_y c] \cdot \mathbf{n}|_{y=0} = 0, \qquad c|_{y=1} = c^\star, \tag{5.1}$$

where $\mathbf{n}$ is the unit outward normal of domain I. The boundary condition of c at $y = 1$ is the Dirichlet one, $c|_{y=1}\ c^\star$, indicating that the substrate is fed at the top boundary to maintain a constant level of $c = c^\star$. The boundary condition for the velocity is chosen to be $\mathbf{v}_0|_{y=0} = (0, 0, 0)^T$, $\mathbf{v}_0|_{y=1} = (10^{-3}, 0, 0)^T$. We note that the vanishing boundary condition for v_y along with the continuity condition warrants a vanishing velocity component in the y direction. Thus the transport of the polymer network is entirely due to the excessive flux.

The numerical scheme used to study the dynamics of biofilm growth is a finite difference scheme. We use uniform spatial and time step sizes, denoted by Δy and Δt, respectively. For given solutions at time step $n-1$ and n the polymer volume fraction at time step $n+1$, ϕ_n^{n+1} governed by the Cahn–Hilliard equation is calculated by

$$\begin{aligned} &\frac{\phi_n^{n+1} - \phi_n^n}{\Delta t} + \theta\Lambda\nabla_y^2[\Gamma_1\nabla_y^2\phi_n^{n+1} + 2\Gamma_2\chi\phi_n^{n+1}] \\ &\quad = g_n(\bar{\phi}_n^{n+\theta}, \bar{c}^{n+\theta}) - (1-\theta)\Lambda\nabla_y^2[\Gamma_1\nabla_y^2\phi_n^n + 2\Gamma_2\chi\phi_n^n] \\ &\qquad - \Lambda\nabla_y^2\Gamma_2\left(-\frac{1}{N}\ln\bar{\phi}_n^{n+\theta} + \ln(1-\bar{\phi}_n^{n+\theta})\right). \end{aligned} \tag{5.2}$$

After this, the volume fraction of the solvent at time step $n+1$ is obtained by $\phi_s^{n+1} = 1 - \phi_n^{n+1}$, and the nutrient substrate concentration at time step $n+1$, c^{n+1} is calculated by

$$
\begin{aligned}
(5.3)\qquad &\frac{\phi_s^{n+1}c^{n+1}-\phi_s^n c^n}{\Delta t}-\theta\nabla_y\cdot(D_s\phi_s^{n+1}\nabla_y c^{n+1}-\mathbf{v}^{n+1}\phi_s^{n+1}c^{n+1})\\
&\quad=-g_c(\bar{\phi}_n^{n+\theta},\bar{c}^{n+\theta})+(1-\theta)\nabla_y\cdot(D_s\phi_s^n\nabla_y c^n-\mathbf{v}^n\phi_s^n c^n).
\end{aligned}
$$

The θ-method is used in time discretization of both equations, where $0\le\theta\le 1$, and the spatial discretization is done using central differences to ensure the second order accuracy in space and volume preservation for ϕ_n when there is no polymer production. Here, $\bar{\phi}_n^{n+\theta}=(1+\theta)\phi_n^n-\theta\phi_n^{n+1}$, $\bar{c}^{n+\theta}=(1+\theta)c^n-\theta c^{n+1}$ are the extrapolated values of ϕ_n and c at time step $n+\theta$, and the nonlinear functions g_n, g_c and the terms involving log-functions are evaluated at these extrapolated values. In our simulation throughout the paper, we use $\theta=1/2$, and thus the overall scheme is second order in time and space. The MCH equation is discretized similarly by

$$
\begin{aligned}
&\frac{\phi_n^{n+1}-\phi_n^n}{\Delta t}+\theta\Lambda\nabla\cdot[\bar{\phi}_n^{n+\theta}\nabla_y(\Gamma_1\nabla_y^2\phi_n^{n+1}+2\Gamma_2\chi\phi_n^{n+1})]\\
(5.4)\qquad &\quad=g_n(\bar{\phi}_n^{n+\theta},\bar{c}^{n+\theta})-(1-\theta)\Lambda\nabla\cdot[\phi_n^n\nabla_y(\Gamma_1\nabla_y^2\phi_n^n+2\Gamma_2\chi\phi_n^n)]\\
&\qquad-\Lambda\Gamma_2\nabla\cdot\left[\phi_n^n\nabla_y\left(-\frac{1}{N}\ln\bar{\phi}_n^{n+\theta}+\ln(1-\bar{\phi}_n^{n+\theta})\right)\right].
\end{aligned}
$$

Assuming that interval $I=[0,1]$ is divided into M uniform subintervals of size $\Delta y=1/M$ by $M+1$ nodes $y_0,y_1,\dots,y_M$, we denote the value of the numerical solution of (5.2) and (5.3) at $(n\Delta t, j\Delta y)$ by $\phi_{n,j}^n$, c_j^n, $j=0,\dots,M$. Since $\mathbf{v}\cdot\mathbf{n}|_{\partial I}=\mathbf{v}_0\cdot\mathbf{n}=0$, the discrete form of the boundary conditions (5.1) is given by

$$
\begin{aligned}
(5.5)\qquad &\phi_{n,1}^n=\phi_{n,-1}^n,\quad \phi_{n,2}^n=\phi_{n,-2}^n,\quad \phi_{n,M+1}^n=\phi_{n,M-1}^n,\quad \phi_{n,M+2}^n=\phi_{n,M-2}^n,\\
&c_1^n=c_{-1}^n,\quad c_M^n=c^\star.
\end{aligned}
$$

For the purpose of completeness, we also compute the nonzero velocity components v_x, v_z and the stress components $\tau_{xx},\tau_{xy},\dots,\tau_{zz}$, even though they are driven by ϕ_n and c. The time discretization of the equation for v_x is given by

$$
\begin{aligned}
&\rho^{n+1}\frac{v_x^{n+1}-v_x^n}{\Delta t}-\theta\frac{\partial}{\partial y}\left(\left(\frac{\phi_s^{n+1}}{Re_s}+\frac{\phi_n^{n+1}}{Re_p}\right)\frac{\partial v_x^{n+1}}{\partial y}\right)\\
(5.6)\qquad &\quad=(1-\theta)\frac{\partial}{\partial y}\left(\left(\frac{\phi_s^n}{Re_s}+\frac{\phi_n^n}{Re_p}\right)\frac{\partial v_x^n}{\partial y}\right)+\frac{\partial(a\phi_n^n\tau_{xy}^n)}{\partial y}.
\end{aligned}
$$

The spatial discretization is again central difference. The discrete equation for v_z is done similarly. Dirichlet boundary conditions are imposed for v_x and v_z; i.e., $v_{x,0}^n$, $v_{x,M}^n$, $v_{z,0}^n$, $v_{z,M}^n$ are given.

We note that all six components of the stress tensor satisfy a generic equation of the form

$$
(5.7)\qquad \frac{\partial\tau}{\partial t}+v_y\frac{\partial\tau}{\partial y}=F(\tau,\nabla\mathbf{v}).
$$

Here $F(\tau,\mathbf{v})$ has different forms for different components of the stress tensor, and it does not contain terms involving partial derivatives of τ. We also note that $\mathbf{v}$ can be either the polymer network velocity (JSN) (the sum of the average velocity and the excessive velocity) or the average velocity (JSA), depending on the model we choose. In the following, we adopt the constitutive model using the polymer network velocity. Since $v_y = 0$ at $y = 0, 1$, there are no boundary conditions for the elastic stress tensor τ; thus, τ actually satisfies an ODE: $\frac{\partial \tau}{\partial t} = F(\tau, \nabla \mathbf{v})$ at $y = 0, 1$. Then at the discrete level, we solve τ_0, τ_M by the following Runge–Kutta method:

$$\tau^{n+1} = \tau^n + \frac{\Delta t}{6}(K_1 + 2K_2 + K_3 + K_4), \tag{5.8}$$

where

$$K_1 = F(\tau^n, \nabla \mathbf{v}^n), \qquad K_2 = F\left(\tau^n + \frac{\Delta t}{2}K_1, \nabla\left(\frac{\mathbf{v}^n + \mathbf{v}^{n+1}}{2}\right)\right),$$

$$K_3 = F\left(\tau^n + \frac{\Delta t}{2}K_2, \nabla\left(\frac{\mathbf{v}^n + \mathbf{v}^{n+1}}{2}\right)\right), \qquad K_4 = F(\tau^n + \Delta t K_3, \nabla \mathbf{v}^{n+1}).$$

Away from the boundaries, we solve τ_j^n, $1 \leq j \leq M - 1$, by the following upwind scheme:

$$\begin{aligned} \frac{\tau_j^{n+1} - \tau_j^n}{\Delta t} = -\frac{1}{2\Delta y}\Big\{&[1 - \operatorname{sign}(v_{y,j+1/2}^n)]v_{y,j+1/2}^n(\tau_{j+1}^n - \tau_j^n) \\ &+ [1 + \operatorname{sign}(v_{y,j-1/2}^n)]v_{y,j-1/2}^n(\tau_j^n - \tau_{j-1}^n)\Big\} + F(\tau_j^n, \nabla \mathbf{v}^{\mathbf{n}}). \end{aligned} \tag{5.9}$$

6. Numerical results and dynamics of one-dimensional biofilms. We study the expansion and growth of one-dimensional biofilms that are homogeneous in the (x, z) plane and confined to the range $0 \leq y \leq 1$ using the numerical scheme developed in the previous section. Table 1 lists the values of the dimensional parameters used in our simulations [7]. In the phase field model, the mobility of the polymer network is assumed a material parameter, whose value can only be calibrated through material characterization in vitro or in vivo. In this numerical study, however, we

TABLE 1
Parameter values used in the simulation.

Symbol	Parameter	Value	Unit
T	Temperature	303	Kelvin
γ_1	Distortional energy	1×10^7	m kg s^{-2}
γ_2	Mixing free energy	1×10^{17}	m^{-1} kg s^{-2}
χ	Flory–Huggins parameter	0.55 or 0.65	dimensionless
N	Generalized polymerization parameter	1×10^3	dimensionless
μ	Max. production rate	1.4×10^{-4}	$\mathrm{kgm}^{-3}\mathrm{s}^{-1}$
K_c	Half saturation constant	5×10^{-4}	kgm^{-3}
A	Max. consumption rate	1	$\mathrm{kgm}^{-3}\mathrm{s}^{-1}$
D_s	Substrate diffusion coefficient	2.3×10^{-9}	$\mathrm{m}^2\mathrm{s}^{-1}$
η_n	Viscosity due to bacteria	4.3×10^2	$\mathrm{kgm}^{-1}\mathrm{s}^{-1}$
η_p	EPS polymer network viscosity	4.3	$\mathrm{kgm}^{-1}\mathrm{s}^{-1}$
η_s	Dynamic viscosity of solvent	1.002×10^{-3}	$\mathrm{kgm}^{-1}\mathrm{s}^{-1}$
ρ_n	Network density	1×10^3	kgm^{-3}
ρ_s	Solvent density	1×10^3	kgm^{-3}

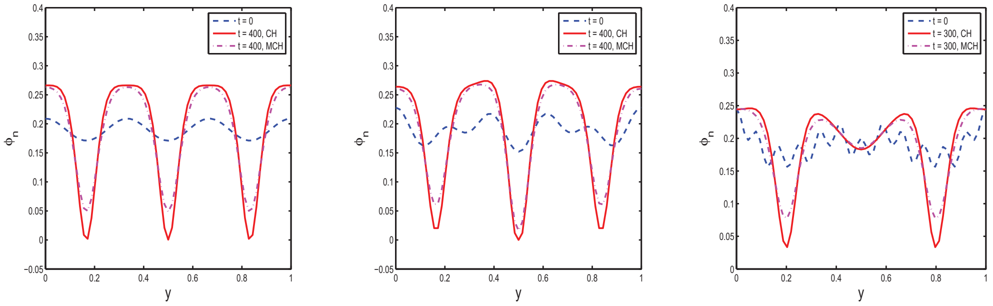
treat it as an operating parameter. Our first attempt is to characterize the effect of mobility on the dynamics of biofilms for both the CH and MCH models without the polymer production, i.e., $\epsilon = 0$, in which the volume fraction dynamics decouple from that of the nutrient substrate concentration. We then examine the variation of the mobility in the CH and MCH models when the polymer network production is present to select the appropriate model for our study of biofilm expansion and growth.

6.1. Biofilm dynamics with negligible EPS production. We begin with an initial profile of the polymer volume fraction distribution as a step function with a nonzero value at the bottom side of the domain and zero at the other side, e.g., $\phi_n(0, y) = 0.19$ for $0 \leq y \leq 0.2$, $\phi_n(0, y) = 0$ for $0.2 < y \leq 1$. This mimics the existence of a flat layer of biofilms in a gap of thickness 1 initially. Figure 4 depicts the evolution of the polymer volume fraction in the one-dimensional biofilm according to the CH model (5.2) for different values of mobility λ, in which the horizontal axis is y and the vertical axis is ϕ_n. In each plot, the step curve is the initial profile of ϕ_n at $t = 0$, and the solid smooth curve is ϕ_n at $t = 400$. Here, we choose the characteristic time-scale $t_0 = 1000$ seconds, so the dimensionless time $t = 400$ corresponds to about 4.6 days. λ as the mobility parameter controls the magnitude of the excessive flux for the polymer network due to polymer solvent mixing. We observe that when λ is small ($\lambda = 10^{-11} \sim 10^{-10}$), the effect of the excessive flux is small and the ϕ_n profile is only smoothed around the initial sharp interface (discontinuity) with a slightly accumulative expansion and growth, since the excessive polymer flux is not fast enough to transport the biomass out of the active mixing region. However, as λ increases to ($10^{-9} \sim 10^{-8}$), the biomass of the polymer network is transported rapidly to the nearby polymer-scarce region leading to sizable expansion of biofilms in the domain. We note that the no-flux boundary condition for ϕ_n at $y = 0$ and $y = 1$ leads to the total amount of conservation in ϕ_n, i.e., $\int_0^1 \phi_n(t, y)dy =$ const. Accompanying the sizable expansion of the biofilm, the volume fraction of the polymer network reduces in the nonzero ϕ_n (or biofilm) region at larger mobility due to this conservation property.

As a comparison, Figure 4 also plots the time evolution of the polymer volume fraction in one-dimensional biofilms according to the MCH model (5.4) for a comparable set of mobility values of λ rescaled by $\lambda \to \lambda/0.19$ to match the amount of polymeric fluxes in both models initially. The solutions of the MCH model are depicted in dot-dashed curves in the figure; they are qualitatively the same as those predicted using the CH model. However, there exists a subtle difference in the solution profile in ϕ_n in that the transport effect of the modified Cahn–Hilliard equation (5.4) outside the polymer-rich region is much weaker than that of the Cahn–Hilliard dynamics (5.2). This is due to the fact that the excessive polymeric flux in the MCH model is given by $-\lambda\phi_n\nabla\frac{\delta f}{\delta\phi_n}$ and vanishes when $\phi_n = 0$. On the other hand, the excessive flux in the CH model is given by $-\lambda\nabla\frac{\delta f}{\delta\phi_n}$ and may not be zero even if $\phi_n = 0$ due to the dissipative property of the CH equation and the numerical error. For example, in the case of $\lambda = 10^{-10}/0.19$, at $t = 400$, the value of ϕ_n at $y = 1$ is equal to 0 for the MCH model, and it is about 6×10^{-5} for the CH model at $\lambda = 10^{-10}$. This shows that the modified Cahn–Hilliard dynamics gives a much sharper excessive flux estimation in the solvent region than the Cahn–Hilliard dynamics does, and it also maintains a sharper interface between the biofilm and the solvent. This subtlety will be amplified in the following numerical studies when the polymer network production is accounted for.

Next we study the dynamics of the biofilm expansion without polymer network production ($\epsilon = 0$) in the neighborhood of constant steady states, considering an initial polymer volume fraction profile that is the perturbation from a constant steady state, e.g., $\phi_n(0, y) = 0.19 + 0.019\cos(2\pi k y)$, where k is the wave number. This transient simulation aims to investigate the nonlinear evolution of the constant steady states perturbed by either linearly stable or unstable modes. We choose two wave numbers: one falls into the linearly stable range ($k = 5$) and the other into the unstable range ($k = 3$) at $\chi = 0.65$. Our simulations demonstrate that the transient solutions corresponding to the linearly stable modes all converge to the homogenized steady state $\phi_0 = 0.19$, while the initial polymer volume fraction with the perturbation corresponding to the unstable mode evolves into a spatially inhomogeneous profile. Figure 5(a) depicts the polymer volume fraction profile corresponding to an unstable mode ($k = 3$) at $t = 400$. Since the difference in the stability between the CH and MCH models is seen only in the magnitude of the linearized growth rate, the results obtained from both models are qualitatively the same. The variation of volume fraction in the MCH model is smaller than that in the CH model though. Coarsening is observed in the transient simulation.

To further illustrate the nonlinear dynamics of the biofilm in the range of unstable wave numbers for $\chi = 0.65$, we investigate the evolution of the biofilm with initial polymer volume fraction of a perturbation of two different wave numbers: $\phi_0(y) = 0.19 + 0.019[\cos(2\pi \cdot 3 \cdot y) + \cos(2\pi \cdot 5 \cdot y)]$, where the perturbation of the constant steady state $\phi_0 = 0.19$ contains a growth mode $k = 3$ and a decay mode $k = 5$. Figure 5(b) depicts the numerical result at $t = 400$ for both the CH and MCH models, where the shorter wave mode ($k = 5$) decays and the longer one ($k = 3$) survives and grows, confirming the linear stability analysis. The nonlinear profile calculated from the MCH model is comparable to that from the CH model at the rescaled mobility parameter shown in Figure 5(b). Figure 5(c) portrays the evolution of the polymer volume fraction with initial condition given by a superposition of four different modes:



(a) one mode.

(b) two modes.

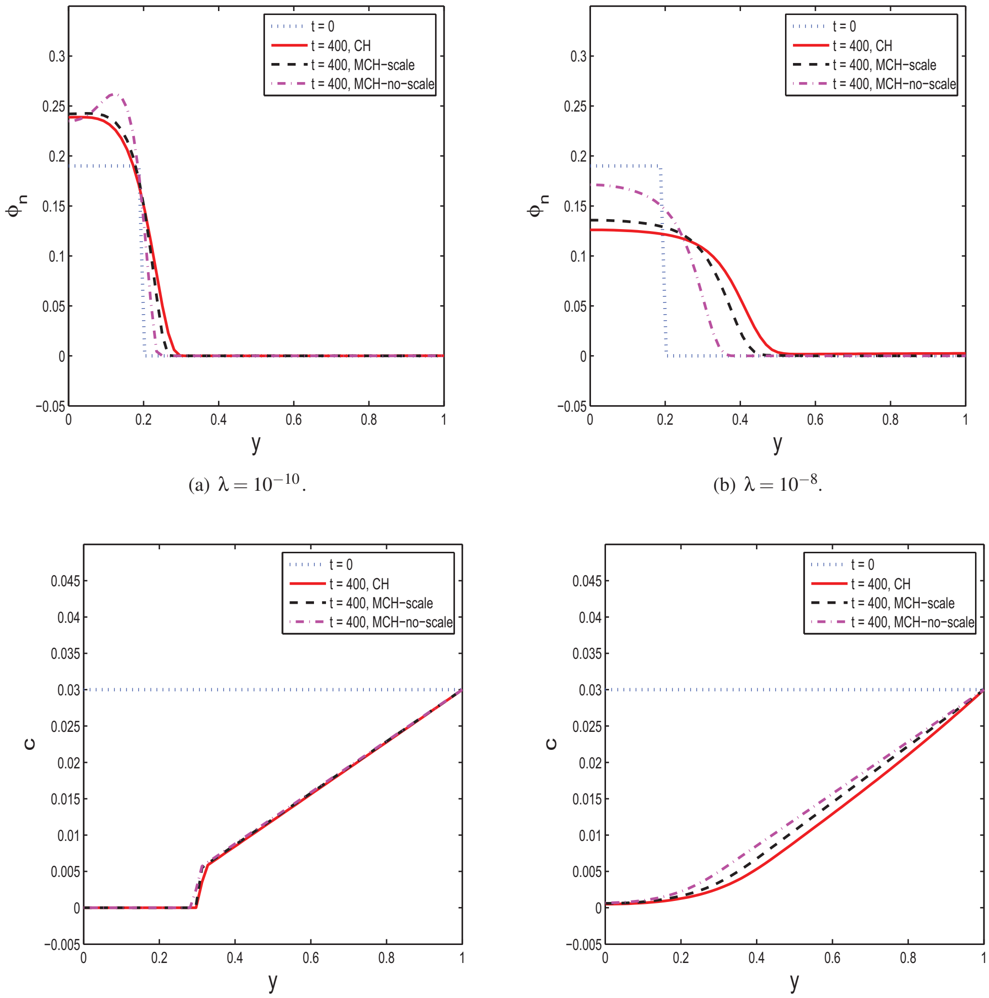
(c) four modes.

FIG. 5. *Evolution of the polymer volume fraction ϕ_n in one-dimensional biofilms by the CH and MCH models without polymer production at $\chi = 0.65$. The parameter $\lambda = 10^{-9}$.* (a) *The initial profile is given by $\phi_0(y) = 0.19 + 0.019\cos(2\pi k y)$, where $k = 3$. The polymer volume fraction tends to evolve (or coarsen) into islands with length-scale proportional to $1/k$.* (b) *The initial profile is given by $\phi_0(y) = 0.19 + 0.019[\cos(2\pi \cdot 3 \cdot y) + \cos(2\pi \cdot 5 \cdot y)]$.* (c) *The initial profile is given by $\phi_0(y) = 0.19 + 0.019[\xi_1 \cos(2\pi \cdot 2 \cdot y) + \xi_2 \cos(2\pi \cdot 3 \cdot y) + \xi_3 \cos(2\pi \cdot 5 \cdot y) + \xi_4 \cos(2\pi \cdot 12 \cdot y)]$, where ξ_i, $i = 1, \dots, 4$, are four randomly chosen constants.*

$\phi_0(y) = 0.19 + 0.019[\xi_1 \cos(2\pi \cdot 2 \cdot y) + \xi_2 \cos(2\pi \cdot 3 \cdot y) + \xi_3 \cos(2\pi \cdot 5 \cdot y) + \xi_4 \cos(2\pi \cdot 12 \cdot y)]$, where ξ_i, $1 \leq i \leq 4$, are random numbers chosen between 0 and 1. Here the perturbation contains two growth modes $k = 2, 3$ and two decay ones $k = 5, 12$. We observe that for both the CH and MCH models, the shorter waves ($k = 5, 12$) decay and the longer ones ($k = 2, 3$) grow. The profile of ϕ_n at $t = 300$ is a combination of the two "nonlinear modes" corresponding to $k = 2$ and $k = 3$, and the mode with $k = 3$ seems to be dominant, especially near the boundary. Note that $\beta = 2\pi k$, $k = 2$ and 3, correspond to $\beta = 12.57$ and 18.85, respectively. Figure 3(b) in section 4 indicates that the growth rate for $k = 3$ is bigger than that for $k = 2$, and thus our numerical results simply illustrate that the linear instability amplifies in the nonlinear regime.

6.2. Biofilm dynamics with EPS production in weak shear. Next, we turn to the growth case ($\epsilon = 1$) and study the expansion and growth of the biofilm with an initial profile of a step function in weak shear. The dimensionless shear speed at $y = 1$ is fixed at $v_x = 0.001$. The initial condition of the nutrient concentration is set at $c = c^\star = 0.03$ for $0 \leq y \leq 1$. Figure 6 depicts the results for the CH and MCH models. The step profile is ϕ_n at $t = 0$, and the smooth ones are ϕ_n at $t = 400$ obtained from both models. For the CH model, we observe that for small λ ($\lambda = 10^{-11} \sim 10^{-10}$), since the excessive flux is small, the polymer network mostly grows at the position where it is initially positive, and only a very small amount is transported to the right. It is also seen that the polymer network grows more rapidly around the interface between the biomass (mixture of polymer and solvent) and the pure solvent. This is because the nutrient to the left of the interface tends to be consumed in a short period of the film growth so as to cause the polymer network growth to cease after that, but the polymer around the interface can always access the nutrient due to the nutrient diffusion at the interface. Thus, the growth near the interface can be sustained. As λ increases (in $10^{-9} \sim 10^{-8}$), the polymer network expands into the solvent region, leading to a lower polymer volume fraction in the biofilm.

As a comparison, we repeat the same calculations using the MCH model at the



(a) $\lambda = 10^{-10}$.

(b) $\lambda = 10^{-8}$.

(c) $\lambda = 10^{-10}$.

(d) $\lambda = 10^{-8}$.

Fig. 6. *Growth of the polymer volume fraction in one-dimensional biofilms and the nutrient concentration profile. The parameter values are $\epsilon = 1$, $\mu = 0.14$, $K_c = 0.5$. The biofilm-solvent interface predicted by the MCH model always falls to the left of that predicted by the CH model. In addition, the MCH model gives a more realistic estimation of the volume fraction away from the biofilm in the solvent region and allows a slightly richer supply of nutrient into the interfacial region.*

same mobility parameters and the rescaled ones, respectively. Figure 6 shows the growth of the polymer volume fraction in one-dimensional biofilms according to the MCH model for the same set of values of λ as well as the rescaled one $\lambda \to \lambda/0.19$, respectively. They are qualitatively the same as the results obtained from the CH model, but the transport effect in the MCH model yields weaker polymeric fluxes. For example, the expansion of the biomass predicted by the MCH model with the rescaled mobility is slower than that done by the CH model. In the two MCH models discussed here, the one with the original (nonscaled) mobility parameters clearly delivers weaker polymeric flux, so that the profile of the polymer volume fraction in the majority biofilm-rich region is always higher than those predicted by others. Figure 6 depicts the nutrient concentration calculated from the two models with the same set of mobility parameters as well. The slightly higher nutrient concentration in the case of the MCH solution without rescaling the mobility parameter correlates well with the volume fraction profile at $t = 400$, justifying the fact that the growth is fueled by the supply of the nutrient.

In the one-dimensional situation, the average velocity, the pressure, and the elastic stress tensor components are driven dynamical variables in that their governing equations decouple from the transport equation for ϕ_n and c. We next examine the driven quantities in the one-dimensional models. First, we note that $v_y = 0$ is dictated by the continuity equation. Hence, the polymer network velocity is actually given by (v_x, v_y^e). Figure 7 plots the average velocity component v_x and the excessive velocity component v_y^e. The initial profile of v_x is zero in the biofilm region and nonlinear meeting the prescribed terminal shear speed at $y = 1$. The magnitude of v_x is small in the biofilm region, and all models give comparable predictions. In the solvent region, the CH model gives the largest v_x, while the MCH model of either rescaled or nonscaled mobility parameters is comparable at small mobility and distinct at a larger mobility value. The magnitude of v_x is much smaller in the biofilm region, indicating a lack of spatial motion in the biofilm despite the weak shear. The excessive velocity v_y^e is zero in the solvent region and nonzero in biofilms at $t = 400$. The behavior of v_y^e in the range of small mobility parameters is qualitatively the same. However, the velocity predicted using the MCH model differs from that of the CH model as the mobility increases. In the latter case, the velocities in y predicted by the MCH are all positive, indicating a slight transient growth in the volume fraction at $t = 400$. The negative velocity in the CH model prediction indicates a transient decay of the polymer volume fraction. In all cases, the difference as well as the magnitudes are rather small (on the order of $O(10^{-4})$).

Figure 7 also depicts the normal stress component $\phi_n \tau_{yy}$, where the JSN model with $a = 0.92$ is used. The normal stress components predicted by the three models are similar qualitatively at small mobility parameter $\lambda = 10^{-10}$, where the stress component exhibits a peak in the middle of the biofilm region and a negative value at the biofilm-solvent interface. The same qualitative behavior can be described for the pressure. At higher mobility values, the stress component and the pressure calculated from the CH model yield the largest stress fluctuation in a neighborhood of the interface. The stress obtained from the MCH model with rescaled and nonscaled mobility parameters shows larger numerical values in the biofilm region and smaller fluctuations across the interface. The CH model predicts a stress and pressure undershoot followed by an overshoot in the biofilm region near the interface. Since the transport equation for the polymer volume fraction impacts the polymer network velocity, which in turn drives the polymer elastic stress as well as the pressure, the drastically different behavior is another manifestation of the velocity difference in v_y^e near the interface.

We have contrasted the prediction of the CH model with that of the MCH model. One question remains: which one is better suited for modeling biofilms numerically? In the CH model, the polymeric flux is completely controlled by the variation of the free energy density, while it depends on both the polymer volume fraction and the free energy density variation in the MCH model. Figure 8 depicts the computed profile of the polymer volume fraction in one-dimensional biofilms with a higher nutrient concentration $c^\star = 0.2$ at $y = 1$ and two different mobility parameters. The higher concentration tends to speed up the polymer network expansion and growth across the entire domain. For the CH model, when t is small, we observe that the polymer

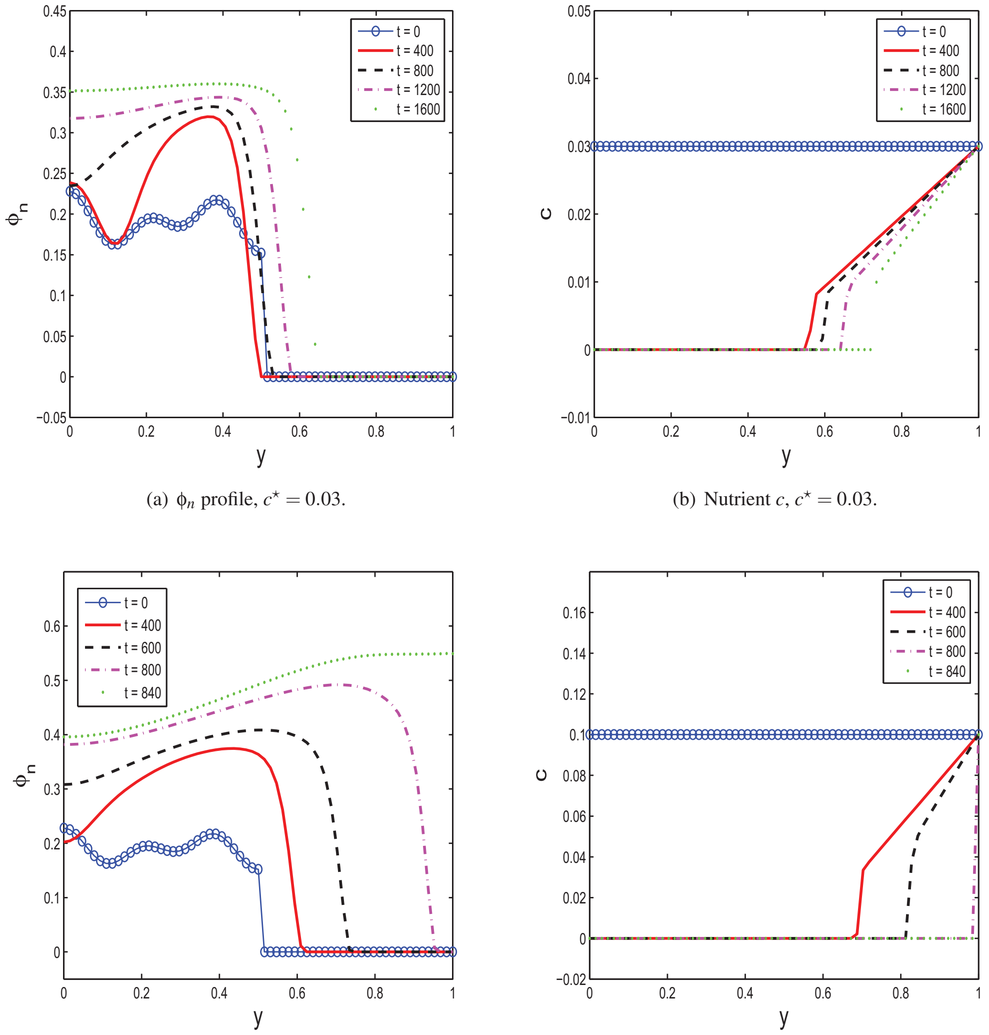
(b) $\lambda = 10^{-10}$.

FIG. 8. *Growth of the polymer volume fraction in one-dimensional biofilms with a higher nutrient concentration $c^\star = 0.2$. For the CH model, the numerically generated artificial growth at the top boundary disqualifies the model when polymer production is present. The MCH model renders a physically correct prediction in the nutrient-rich solvent, making it our choice of models for studying fluid mixtures.*

network grows due to the production term and expands to the solvent region due to the excessive polymeric flux. As t increases, ϕ_n becomes nonzero at $y = 1$ due to the numerical dissipation and the truncation errors. When ϕ_n becomes nonzero at $y = 1$, an exponential growth ensues due to growth rate g_n in the governing equation for ϕ_n and soon reaches 1, causing our computations to break down. The value of ϕ_n at $y = 1$ reaches 1 faster for $\lambda = 10^{-9}$ (shortly after $t = 260$) than for $\lambda = 10^{-10}$ (shortly after $t = 320$). This numerical evidence demonstrates the limitation of the CH model in modeling the polymer production numerically. The MCH model, on the other hand, does not suffer the unphysically numerical growth of ϕ_n at $y = 1$, since the polymeric flux near $y = 1$ vanishes due to $\phi_n = 0$ in the pure solvent region. Numerically, the zero polymeric flux condition in the solvent region is much easier to maintain in the MCH model before the growth reaches the boundary than in the CH model. We also notice that ϕ_n grows faster near the original interface in the MCH model than in the CH model. This is because once ϕ_n starts to grow at $y = 1$ in the CH model, the nutrient is consumed there quickly, which in turn reduces the amount of the nutrient being diffused to the original interface and thus reduces the polymer production rate. Physically, the MCH model is based on a better assumption on the polymeric flux. The above numerical result hence supports that the MCH model is more appropriate for modeling the transport of the polymer network for its accurate modeling of the transport of the polymeric flux than the CH model.

Finally, we investigate the expansion and growth of an inhomogeneous biofilm initially located at one side of the domain, shown in Figure 9, using the MCH model. When the initial profile contains unstable long wave modes, the dominating growth occurs in the biofilm region with significant coarsening and little expansion into the solvent region initially. In this calculation, we solve the governing system of equations at $\chi = 0.65$ using the MCH model for an extended period of time. Figure 9 depicts the expansion and growth of biofilms from perturbed initial data calculated by the MCH (with the rescaled mobility) model at two different values of nutrient-supply



(a) ϕ_n profile, $c^\star = 0.03$.

(b) Nutrient c, $c^\star = 0.03$.

(c) ϕ_n profile, $c^\star = 0.1$.

(d) Nutrient c, $c^\star = 0.1$.

Fig. 9. *The polymer volume fraction ϕ_n and nutrient concentration c computed by the MCH model with a perturbed initial data with growth for two different $c^\star$, simulated for a sufficiently long time. The parameter values are $\chi = 0.65$, $c^\star = 0.03, 0.1$, $\lambda = 10^{-9}$, $\phi_0(y) = 0.19 + 0.019[\cos(2\pi \cdot 3 \cdot y) + \cos(2\pi \cdot 5 \cdot y)]$ for $y \leq 0.5$, $\phi_0(y) = 0$ for $y > 0.5$. After an initial pulling back, the biofilm expands into the solvent region as long as there is a continuous supply of nutrient.*

boundary value $c^\star$ and for sufficiently long time. Figures 9(a) and (b) show the profile of ϕ_n and c for $c^\star = 0.03$ at five different times. Since $\chi = 0.65$, we know that there are some long wave unstable modes from the linear stability analysis to fuel the expansion and growth of the biofilm. For relatively short time ($t \leq 400$), we observe that the long wave to the left of the interface grows, and the polymer volume fraction profile undergoes a sharp transition near the interface, pulling the polymer network to the biofilm-rich region relative to the initial profile. An intuitive explanation for this is that due to the weaker dissipation in the model, the rapid growth of the polymer network and coarsening in the biofilm draw the polymers near the interface into the polymer-rich region, a consequence of the long wave instability.

The pulling back phenomenon is clearly tied to the coarsening, because the nutrient concentration at $t = 400$ is nearly zero in the biofilm region shown in the figure. As time goes by, we observe that the profile of the polymer volume fraction in the biofilm tends to level off, or coarsening ceases, so that the growth of the polymer network becomes more uniform away from the biofilm-solvent interface and the interface starts to expand into the solvent. From the bulk free energy density $\hat{f}(\phi_n)$, we can see that the bulk contribution to the polymer network flux decreases as the volume fraction ϕ_n continuously grows. At a lower polymer volume fraction, the expansion of the biofilm is facilitated by the bulk free energy along with the conformational free energy tied to the curvature of the interface profile of ϕ_n. As the polymer volume fraction exceeds a critical value though (zero of $\frac{\partial^2 \hat{f}}{\partial \phi_n^2} = 0$), the driving force behind the expansion is due purely to the curvature effect.

We also examine the nutrient distribution during the above-mentioned process. We notice that the nutrient tends to be depleted within the biofilm as the polymer network tends to reach a uniform distribution; however, the nutrient supply is sufficient at the biofilm-solvent interface which fuels the expansion and growth of the polymer network continuously outwards. This explains the dynamics of the polymer network expansion in biofilms for long times. Figures 9(c) and (d) depict the results for a higher nutrient concentration at $c^\star = 0.1$. They are qualitatively the same as the case of $c^\star = 0.03$, except that the dynamics take place at a much faster pace here.

7. Conclusions. In this paper, we present a phase field theory modeling biofilm and solvent mixtures as incompressible complex fluids. In this one-fluid two-component theory, the extracellular polymeric substance (EPS) along with the bacteria is treated as one effective viscous or viscoelastic component, and the nutrient and the solvent are treated as the other effective viscous component. The growth of the effective polymer network component is modeled by a saturated growth, while the nutrient consumption is approximated by a linear decay. Three constitutive models for the mixture are proposed: extended Newtonian, rubber elastic gel, and viscoelastic model. That the mixture in the bulk is incompressible leads to a divergence-free averaged velocity field. The interpenetrating between the two effective components is measured by the excessive velocities accounted for by the Flory–Huggins polymer mixing dynamics. Surface tension between the pure solvent section of the solvent fluid and the biofilm is naturally built in through a nonlocal entropic mixing free energy density. The Cahn–Hilliard dynamics coupled with the Flory–Huggins mixing is investigated with respect to various mobility parameters. Modified Cahn–Hilliard dynamical transport is shown to be more appropriate for the biofilm expansion and growth, which can effectively eliminate the unwanted and unphysical growth in the solvent region due to the numerical error and dissipation.

There are a limited number of results that can be used to validate the model presently. One of the results used in a few reports [8, 13, 25] is that the flat biofilm-fluid interfaces are unstable for a finite interval of perturbation modes, with a single maximally unstable mode. Both the linear analysis and the nonlinear simulations of the present model confirm these predictions.

The advantage of modeling biofilms using a multicomponent material includes robust treatment of the physics and interacting dynamics among the components. Meanwhile, deriving a model consisting of a single fluid eliminates several potential difficulties associated with the coupled biofilm-bulk fluid flow like velocity, boundary conditions, etc. In particular, the interface conditions are dramatically simplified, since the interface is not separated from the rest of the system. In addition, influent and effluent boundary conditions are natural in the single fluid case. The present treatment also provides a framework in which various constitutive relations for each constituent can be investigated in conjunction with the motion of the bulk fluid. Both of these are important in order to address dispersal, detachment, and sloughing events which have substantial impact in industrial and medical settings of the biofilm.

RECURSIVE DISPERSION RELATIONS IN ONE-DIMENSIONAL PERIODIC ELASTIC MEDIA[*]

ANI P. VELO[†], GEORGE A. GAZONAS[‡], ERWIN BRUDER[†§], AND NANCY RODRIGUEZ[†]

Abstract. A frequency bandgap is a range of wave frequencies that are prohibited from passing through a medium. The dispersion relation, which links the frequency to the wave number, enables us to illustrate the bandgaps. In [E. H. Lee, "A survey of variational methods for elastic wave propagation analysis in composites with periodic structures," in Dynamics of Composite Materials, E. H. Lee, ed., ASME, New York, 1972, pp. 122–138] and [E. H. Lee and W. H. Yang, *SIAM J. Appl. Math.*, 25 (1973), pp. 492–499] the dispersion relation was studied theoretically for the one-dimensional periodic structure made of two materials arranged symmetrically with respect to the center of the cell. Their dispersion relation formulas can be similarly extended to a multilayered symmetric cell configuration, but not to a general (nonsymmetric) cell configuration. The general model was considered in [M. Shen and W. Cao, *J. Phys. D*, 33 (2000), pp. 1150–1154], where each unit cell of the periodic layered structure contains several sublayers of arbitrary lengths and materials. Using the transfer matrix method, the dispersion relation was successfully derived, involving very lengthy explicit formulas. In this paper, we generalize the work of Lee and Yang and develop recursive dispersion relation formulas for a general cell configuration. The recursive formulas are easy to implement and, through several numerical experiments, successfully corroborate the results of Shen and Cao.

Key words. dispersion relation, recursive formulas, wave propagation, Floquet theory, periodic layered media

1. Introduction.

The existence of bandgaps in one-dimensional periodic elastic media appears to have been first established by Lord Rayleigh [17], and a good review of the early work on wave propagation in periodic elastic media can be found in Brillouin's classic text [2]; a more recent comprehensive review that outlines the development of the "band theory" for electrons, photons, and phonons can be found in Kushwaha [10]. A variety of technological applications has been suggested for phononic bandgap materials which include transducers, acoustic filters, or barriers for noise reduction, and even as a means for mitigating the effects of seismic surface waves. The study of phonons and phononic bandgaps associated with elastic wave propagation in periodic elastic media have also been used to study quantum field effects such as tunneling phenomena [24].
