OPTIMALITY CONDITIONS FOR SOME NONQUALIFIED PROBLEMS OF DISTRIBUTED CONTROL*

F. ABERGEL† AND R. TEMAM‡

Abstract. This article determines the necessary and sufficient optimality conditions for some nonqualified problems of optimal control, in the case of a distributed control for a system governed by a second-order elliptic partial differential equation. The authors study both bilateral and unilateral constraints on the state of the system.

Key words. distributed control, optimality conditions, nonqualified problems

AMS(MOS) subject classifications. 49B22, 49A22, 35K60

Introduction. One of the main difficulties in the study of optimal control problems is to give some necessary and sufficient conditions of optimality. For nonqualified problems, there is no standard way, even in the convex case, to give such conditions [L]. Nevertheless, the method developed by one of the authors for the study of variational problems in continuum mechanics [T] turns out to be very fruitful in the field of optimal control.

In this article we consider the following problems:

(**P**) Find (z, v) in $L^2(\Omega)\times L^2(\Omega)$ minimizing the cost function

$$J(z, v)=\left(\frac{1}{2\eta}\right)\int_\Omega v^2\,dx+\left(\frac{1}{2}\right)\int_\Omega |z-z_d|^2\,dx \tag{1.1.1}$$

with $(-\Delta z+z)=v$ in Ω, $z=0$ on $\partial\Omega$, $|z|\leqq\alpha$ almost everywhere in Ω.

The corresponding unilateral constraint problem reads:

(**R**) Find (z, v) in $L^2(\Omega)\times L^2(\Omega)$ minimizing the cost function

$$K(z, v)=\left(\frac{1}{2\eta}\right)\int_\Omega v^2\,dx+\left(\frac{1}{2}\right)\int_\Omega |z-z_d|^2\,dx \tag{2.1.1}$$

with $(-\Delta z+z)=v$ in Ω, $z=0$ on $\partial\Omega$, $z\leqq\alpha$ almost everywhere in Ω.

α and η are two strictly positive real numbers and z_d is given in $L^2(\Omega)$. In the case where Ω is a subset of the l-dimensional Euclidean space $\mathbb{R}^l$, $l=1, 2, 3$, Problems (**P**) and (**R**) correspond to the optimal heating of Ω: z is the temperature, v is the volumic heating (produced, for instance, by a laser beam), and z_d is the desired temperature. The constraint on z is a technological constraint, which can be easily interpreted as a no-burning condition.

In order to derive the system of optimality conditions for (**P**) and (**R**), we reformulate them as convex optimization problems in $H^2(\Omega)\cap H_0^1(\Omega)$, as follows. We let j, k be defined, respectively, as follows:

$$j(z)=\begin{cases}\left(\frac{1}{2}\right)\int_\Omega |z-z_d|^2\,dx+\left(\frac{1}{2\eta}\right)\int_\Omega |-\Delta z+z|^2\,dx & \text{if } z\in H^2(\Omega)\cap H_0^1(\Omega),\\ & |z|\leqq\alpha \text{ a.e. in } \Omega,\\ +\infty \quad \text{otherwise,}\end{cases}$$

‡ Laboratoire d'Analyse Numérique, Centre National de la Recherche Scientifique, Université Paris-Sud, 91405 Orsay Cedex, France.

$$k(z)=\begin{cases}\left(\frac{1}{2}\right)\int_\Omega |z-z_d|^2\,dx+\left(\frac{1}{2\eta}\right)\int_\Omega |-\Delta z+z|^2\,dx & \text{if } z\in H^2(\Omega)\cap H_0^1(\Omega),\\ & \text{if } z\leqq\alpha \text{ a.e. in } \Omega,\\ +\infty \quad \text{otherwise.}\end{cases}$$

Therefore, (**P**) and (**R**) respectively, are equivalent to

$$(P)\qquad \text{(i)}\qquad \operatorname*{Inf}_{z\in H^2(\Omega)\cap H_0^1(\Omega)}\{j(z)\}$$

and

$$(R)\qquad \text{(ii)}\qquad \operatorname*{Inf}_{z\in H^2(\Omega)\cap H_0^1(\Omega)}\{k(z)\}.$$

If we wish to use the duality methods of convex analysis to derive the optimality conditions for (i), (ii), then we are led to the following dual problems of maximization:

$$(P^*)\qquad \text{(i')}\qquad \operatorname*{Sup}_{z\in H^2(\Omega)\cap H_0^1(\Omega)}\left\{\left(\frac{-\eta}{2}\right)\int_\Omega z^2\,dx+\left(\frac{1}{2}\right)\int_\Omega z_d^2\,dx-\int_\Omega \psi_\alpha(-\Delta z+z+z_d)\,dx\right\}$$

where

$$\psi_\alpha(s)=\frac{s^2}{s}\quad \text{if } |s|\leqq\alpha$$
$$=\alpha\left(|s|-\frac{\alpha}{2}\right)\quad \text{elsewhere,}$$

and

$$(R^*)\qquad \text{(ii')}\qquad \operatorname*{Sup}_{z\in H^2(\Omega)\cap H_0^1(\Omega)}\left\{\left(-\frac{\eta}{2}\right)\int_\Omega z^2\,dx+\left(\frac{1}{2}\right)\int_\Omega z_d^2\,dx-\int_\Omega \theta_\alpha(-\Delta z+z+z_d)\,dx\right\}$$

where

$$\theta_\alpha(s)=\frac{s^2}{s}\quad \text{if } s\leqq\alpha$$
$$=\alpha\left(s-\frac{\alpha}{2}\right)\quad \text{elsewhere.}$$

The crux of the matter is that neither (P^*) nor (R^*) is coercive on the natural space $X=H^2(\Omega)\cap H_0^1(\Omega)$. Thus we must investigate the existence of solutions to (i') and (ii') in a larger space than X, in order to recover coercivity.

For (i'), the natural space is $\mathrm{BL}_0(\Omega)=\{u\in L^2(\Omega),\ (-\Delta u+u)$ is a bounded measure on Ω, $u=0$ on $\partial\Omega\}$ due to the linear behaviour of ψ_α at infinity. We prove that (P^*) has (generalized) solutions in $\mathrm{BL}_0(\Omega)$, and extend the classical optimality conditions to them.

As for (ii'), the problem is slightly more delicate, for (R^*) cannot be extended to the whole space $\mathrm{BL}_0(\Omega)$, due to the quadratic part in $\mathcal{C}_\alpha$. However, we prove that such an extension is possible if we restrict ourselves to the functions u in $\mathrm{BL}_0(\Omega)$ such that $(-\Delta u+u)$ is in a convex cone of the space of bounded measures on Ω. We then establish the system of optimality conditions.

We use the following classical notation: $W^{m,p}(\Omega)$ for the Sobolev space of order m on $L^p(\Omega)$, $W_0^{m,p}$ for the closure in $W^{m,p}(\Omega)$ of the Schwartz class $\mathcal{D}(\Omega)$, and $\mathcal{D}'(\Omega)$ for the dual space of the latter; we also classically write $H^m(\Omega)$ for $W^{m,2}(\Omega)$, and $M_1(\Omega)$ for the space of bounded measures on Ω (see [Ad], [LM], [B]).

1. A distributed control problem with bilateral constraints.

1.1. Variational formulation. Let Ω be an open bounded set of $\mathbb{R}^N$, whose boundary Γ is a compact C^∞, $(N-1)$-dimensional manifold, Ω being locally on one side of Γ. We want to study the following problem of optimal control.

(**P**) Find (z, v) in $L^2(\Omega)\times L^2(\Omega)$ minimizing the cost function

$$J(z, v)=\left(\frac{1}{2\eta}\right)\int_\Omega v^2\,dx+\left(\frac{1}{2}\right)\int_\Omega |z-z_d|^2\,dx \tag{1.1.1}$$

z being such that $(-\Delta z+z)=v$ in Ω, $z=0$ on Γ, $|z|\leqq\alpha$ a.e. on Ω.

z_d is given in $L^2(\Omega)$, and α, η are two strictly positive real numbers. The conditions on z imply that it belongs to $H^2(\Omega)\cap H_0^1(\Omega)$ [LM] and the variational formulation of (P) is then

$$(P)\qquad \operatorname*{Inf}_{z\in H^2(\Omega)\cap H_0^1(\Omega)}\{j(z)\}, \tag{1.1.2}$$

the functional j being defined by

$$j(z)=\begin{cases}\dfrac{1}{2}\displaystyle\int_\Omega |z-z_d|^2\,dx+\frac{1}{2}\eta\int_\Omega |-\Delta z+z|^2\,dx\\ \qquad\qquad \text{if } z\in X=H^2(\Omega)\cap H_0^1(\Omega),\quad |z|\leqq\alpha \text{ a.e. on } \Omega,\\ +\infty \quad \text{otherwise.}\end{cases} \tag{1.1.3}$$

We have Proposition 1.1.1 below (see [ET]).

PROPOSITION 1.1.1. *There exists a unique optimal state z for Problem (P), which is the only solution of (P).*

We are now going to give the expression of the dual problem (P^*) of (P), in order to study the system of optimality conditions for Problem (**P**).

1.2. Duality. We shall use the duality methods described in [ET].

Let Y be the space $(L^2(\Omega))^2$; we define the operator $\wedge$, from X into Y, by

$$\wedge z=(z, -\Delta z+z). \tag{1.2.1}$$

Problem (P) has the following form:

$$(P)\qquad \operatorname*{Inf}_{z\in X}\{F(z)+G(\wedge z)\} \tag{1.2.2}$$

where F, G are defined as follows: $F\equiv 0$; $G(p)=G_1(p_1)+G_2(p_2)$, with

$$G_1(p_1)=\begin{cases}\dfrac{1}{2}\displaystyle\int_\Omega |p_1-z_d|^2\,dx & \text{if } |p_1|\leqq\alpha \text{ a.e. on } \Omega,\\ +\infty \quad \text{otherwise,}\end{cases} \tag{1.2.3}$$

$$G_2(p_2)=\frac{1}{2\eta}\int_\Omega |p_2|^2\,dx. \tag{1.2.4}$$

The dual problem (P^*) of (P) is then

$$(P^*)\qquad \operatorname*{Sup}_{q\in Y}\{-F^*(\wedge^* q)-G^*(-1)\}, \tag{1.2.5}$$

F^* (respectively, G^*) being the convex conjugate function of F (respectively, G), and $\wedge^*$, the transposed operator of $\wedge$.

Remark 1.2.1. Y is identified with its conjugate Y^*, thanks to its Hilbertian structure.

Let us now compute the expression of F^* and G^*. For G^*, we easily find

$$G^*(p) = G_1^*(p_1) + G_2^*(p_2) \tag{1.2.6}$$

where

$$G_1^*(p_1) = -\frac{1}{2}\int_\Omega z_d^2\, dx + \int_\Omega \Psi_\alpha(p_1 + z_d)\, dx, \tag{1.2.7}$$

$$G_2^*(p_2) = \frac{\eta}{2}\int_\Omega |p_2|^2\, dx, \tag{1.2.8}$$

and the function Ψ_α is defined by

$$\Psi_\alpha(s) = \begin{cases} s^2/2 & \text{if } |s| \leqq \alpha, \\ \alpha(|s| - \alpha/2) & \text{if } |s| \geqq \alpha. \end{cases} \tag{1.2.9}$$

For F^*, we write

$$\begin{aligned} F^*(\wedge^* p) &= \operatorname*{Sup}_{z \in X} \langle p, \wedge z \rangle \\ &= \operatorname*{Sup}_{z \in X} \left(\int_\Omega [p_1 \cdot z + (-\Delta z + z) \cdot p_2]\, dx \right) \\ &\geqq \operatorname*{Sup}_{z \in \mathcal{D}(\Omega)} \left(\int_\Omega [p_1 \cdot z + (-\Delta z + z) \cdot p_2]\, dx \right) \\ &\geqq \begin{cases} 0 & \text{if } -\Delta p_2 + p_2 = -p_1 \text{ in } \Omega, \\ +\infty & \text{otherwise.} \end{cases} \end{aligned} \tag{1.2.10}$$

If p_2 is such that $(-\Delta p_2 + p_2)$ belongs to $L^2(\Omega)$, we can define its boundary values $(p, \partial p/\partial \nu)$ as distributions on Γ (see [LM]). Moreover, the following Green formula holds for z in $H^2(\Omega)$:

$$\int_\Omega (-\Delta z + z) \cdot p_2\, dx = \int_\Omega (-\Delta p_2 + p_2) \cdot z\, dx - \int_\Gamma \left(\left(\frac{\partial z}{\partial \nu} \right) p_2 - \left(\frac{\partial p_2}{\partial \nu} \right) \cdot z \right) d\Gamma \tag{1.2.11}$$

(the integral on Γ being, in fact, a duality product in the suitable distributions spaces on Γ).

From (1.2.11), we easily deduce the expression of F^*:

$$F^*(\wedge^* p) = \begin{cases} 0 & \text{if } -\Delta p_2 + p_2 = 0 \text{ in } \Omega, \quad p_2 = 0 \text{ on } \Gamma, \\ +\infty & \text{otherwise.} \end{cases} \tag{1.2.12}$$

After eliminating p_1, we find the following for (P^*):

$$(P^*) \qquad \operatorname*{Sup}_{p \in X} \left\{ \left(\frac{-\eta}{2} \right) \int_\Omega p^2\, dx + \left(\frac{1}{2} \right) \int_\Omega z_d^2\, dx - \int_\Omega \Psi_\alpha(-\Delta p + p + z_d)\, dx \right\}. \tag{1.2.13}$$

By lack of coercivity (see the definition of Ψ_α), we do not know whether Problem (P^*) has a solution in X. In the following sections, we shall show how it is possible to overcome this difficulty, by extending the class of admissible elements for Problem (P^*). We shall also give the necessary *and* sufficient conditions for an admissible state z, for problem P, to be the optimal state z.

For the moment, we give the following comparison result.

PROPOSITION 1.2.1. *The extrema of* (P) *and* (P^*) *are equal*:

$$-\infty < \operatorname{Sup}(P^*) = \operatorname{Inf}(P).$$

The proof is omitted. We show that Problem (P) is normal [ET].

1.3. The generalized problem. Definition (1.2.9) of Ψ_α shows that it is natural to look for solutions of (P^*) in the space $\mathrm{BL}_0(\Omega)$ defined by

$$\mathrm{BL}_0(\Omega) = \{u \in L^2(\Omega), (-\Delta u + u) \in M_1(\Omega), u = 0 \text{ on } \Gamma\} \tag{1.3.1}$$

where $M_1(\Omega)$ is the space of bounded measures on Ω (BL stands for "Bounded Laplacian"; the index 0 refers to the Dirichlet conditions on Γ). $\mathrm{BL}_0(\Omega)$ is a Banach space for the norm

$$\|u\|_{\mathrm{BL}_0(\Omega)} \equiv \|u\|_{L^2(\Omega)} + \|-\Delta u + u\|_{M_1(\Omega)}. \tag{1.3.2}$$

Moreover (see [M]), the space $\mathrm{BL}_0(\Omega)$ is continuously imbedded in the space

$$W_0^{1,s}(\Omega) \quad \text{for } 1 \leqq s < \frac{N}{N-1}.$$

In order to extend Problem (P^*) to $\mathrm{BL}_0(\Omega)$, we need to define $\Psi_\alpha(\mu)$, when μ is a bounded measure, and Ψ_α is defined by (1.2.9). We shall refer extensively to the results of [DT1], [DT2], [T], and recall what will be useful to us in Proposition 1.3.1.

PROPOSITION 1.3.1. *Let* Ψ *be a convex function of one real variable, let* Ψ^* *be its conjugate function, and let* Ψ_∞ *be its asymptotic function. We suppose that*

(i) *There exists* C, *such that for all* $s \in \mathbb{R}$, $|\Psi(s)| \leqq C(1+|s|)$;

(ii) Ψ^* *is bounded on its domain* K;

(iii) $\Psi \geqq 0, \Psi(0) = 0$.

Let μ *be a bounded measure having the decomposition* $\mu = h \cdot dx + \theta_s \cdot |\mu_s|$ *with respect to the Lebesgue measure* dx, μ_s *singular with respect to* dx [B]. *The measure* $\Psi(\mu)$ *is then defined as follows*:

$$\Psi(\mu) = (\Psi \circ h) \cdot dx + \Psi_\infty(\theta_s) \cdot |\mu_s|. \tag{1.3.3}$$

Furthermore, we have the duality formula

$$\forall \Phi \in \mathscr{C}_0(\Omega) \quad \langle \Psi(\mu), \Phi \rangle = \operatorname{Sup}\left\{ \int_\Omega \Phi \cdot g \, d\mu - \int_\Omega \Phi \cdot \Psi^*(g) \, dx \right\}, \tag{1.3.4}$$

the supremum being taken for $g \in \mathscr{C}_0(\Omega)$, $\Psi^*(g) \in L^1(\Omega)$; *and relation* (1.3.4) *is still valid for* $\Phi \in \mathscr{C}(\Omega)$, $\Phi \geqq 0$.

It is now obvious how to formulate the generalized problem (Q^*):

$$(Q^*) \qquad \operatorname*{Sup}_{u \in \mathrm{BL}_0(\Omega)} \left\{ \left(\frac{-\eta}{2}\right) \int_\Omega u^2 \, dx + \left(\frac{1}{2}\right) \int_\Omega z_d^2 \, dx - \int_\Omega \Psi_\alpha(-\Delta u + u + z_d) \right\}. \tag{1.3.5}$$

In the expression above, $\int_\Omega \Psi_\alpha(-\Delta u + u + z_d)$ represents the total mass of the bounded measure $\Psi_\alpha(-\Delta u + u + z_d)$. We obviously have the following inequality:

$$\operatorname{Sup}(P^*) \leqq \operatorname{Sup}(Q^*). \tag{1.3.6}$$

In § 4 we shall introduce a generalized duality, between (P) and (Q^*), that will enable us to prove that (1.3.6) is, in fact, an equality, and will also give the system of optimality conditions for Problem (P).

1.4. Generalized duality. Our purpose in this section is to give meaning to the expression "$(-\Delta u + u) \cdot z$" when z is in X, u is in $\mathrm{BL}_0(\Omega)$, and z is admissible for (P).

Actually, we are going to prove that $(-\Delta u+u)\cdot z$ can be defined as a bounded measure on Ω, and that there exists a generalized Green formula for z and u. More precisely, we have the following result.

PROPOSITION 1.4.1. *Let (z, u) belong to $X\times \mathrm{BL}_0(\Omega)$, z being admissible for Problem (P). We can define a distribution, denoted $(-\Delta u+u)\cdot z$, by the following formula:*

$$\forall \Phi\in \mathscr{D}(\Omega)\quad \langle(-\Delta u+u)\cdot z,\Phi\rangle=\int_\Omega [-\Delta(z\cdot\Phi)+z\cdot\Phi]\cdot u\,dx. \tag{1.4.1}$$

The distribution defined by (1.4.1) satisfies the following:

(i) *$(-\Delta u+u)\cdot z$ is a bounded measure on Ω.*

(ii) *We have the equality*

$$\int_\Omega (-\Delta u+u)\cdot z=\int_\Omega (-\Delta z+z)\cdot u\,dx. \tag{1.4.2}$$

Proof. We first remark that the right-hand side of (1.4.1) makes sense for u in $L^2(\Omega)$ and z in $X=H^2(\Omega)\cap H_0^1(\Omega)$. Let us now choose a sequence z_n of smooth functions approximating z in the following sense:

$$z_n \text{ tends to } z \quad \text{in } X, \tag{1.4.3}$$

$$\|z_n\|_{L^\infty(\Omega)}\leqq \|z\|_{L^\infty(\Omega)}. \tag{1.4.4}$$

Such a sequence is classically obtained, for instance, by solving the following problem associated to the heat equation:

$$\begin{aligned} &\partial v/\partial t-\Delta v=0 && \text{in } \Omega\times]0,\infty[,\\ &v=0 && \text{on } \Gamma\times]0,\infty[,\\ &v(x,0)=z(x) && \text{in } \Omega, \end{aligned} \tag{1.4.5}$$

and setting $z_n=v(\cdot, t_n)$, t_n being a sequence of strictly positive real numbers converging to zero. Frequently (1.4.4) is then a consequence of the maximum principle for second-order parabolic equations.

We now set $T_n=(-\Delta u+u)\cdot z_n$; T_n is a bounded measure satisfying

$$\|T_n\|_{M_1(\Omega)}\leqq \|z\|_{L^\infty(\Omega)}\cdot\|-\Delta u+u\|_{M_1(\Omega)}. \tag{1.4.6}$$

Moreover, T_n obviously converges to $(-\Delta u+u)\cdot z$ in $\mathscr{D}'(\Omega)$, and this proves assertion (i). We also remark that T_n converges to $(-\Delta u+u)\cdot z$ in the sense of the tight convergence of measures. That is true because the sequence (T_n) satisfies the Prokhorov condition [B]:

$$\forall\varepsilon>0\quad \exists K_\varepsilon\quad \forall n\quad \int_{\Omega\setminus K_\varepsilon}|T_n|<\varepsilon \tag{1.4.7}$$

where K_ε is a Borel subset of Ω. As a matter of fact, $(-\Delta u+u)$ is a bounded measure, and the functions z_n are uniformly bounded on Ω. Therefore, the sequence T_n is relatively compact for the topology of the tight convergence in $M_1(\Omega)$.

To prove (ii), let us now choose a function Φ in $\mathscr{C}^\infty(\bar\Omega)$; thanks to the results of [LM], we have the Green formula

$$\begin{aligned} \int_\Omega (-\Delta u+u)\cdot z_n\cdot\Phi=\int_\Omega [-\Delta(z_n\cdot\Phi)+z_n\cdot\Phi]\cdot u\,dx-\langle\partial u/\partial\nu, z_n\cdot\Phi\rangle_{\mathscr{D}(\Gamma)\times\mathscr{D}'(\Gamma)}\\ +\langle u,\partial(z_n\Phi)/\partial\nu\rangle_{\mathscr{D}(\Gamma)\times\mathscr{D}'(\Gamma)}. \end{aligned} \tag{1.4.8}$$

Taking into account the conditions ($u=0$ on Γ) and ($z_n=0$ on Γ), we obtain

$$(1.4.9)\qquad \forall n\in\mathbb{N},\quad \forall \Phi\in\mathscr{C}^\infty(\bar{\Omega})\quad \int_\Omega (-\Delta u+u)\cdot z_n\cdot\Phi=\int_\Omega [-\Delta(z_n\cdot\Phi)+z_n\cdot\Phi]\cdot u\,dx.$$

Assertion (ii) is then proved by letting n tend to ∞ in (1.4.9), with $\Phi\equiv 1$, and using the tight convergence of T_n to $(-\Delta u+u)\cdot z$. □

1.5. Existence of solution of (Q^*) in $BL_0(\Omega)$; system of optimality conditions for (P). In this section, we give our final results for the study of Problem (P), namely, the existence of an adjoint state in $BL_0(\Omega)$ for the optimal state z, and the system of optimality conditions related to that problem.

We start with a lemma.

LEMMA 1.5.1. *Let J^* be the functional defined on $BL_0(\Omega)$ by*

$$(1.5.1)\qquad J^*(u)=\frac{\eta}{2}\int_\Omega u^2\,dx-\frac{1}{2}\int_\Omega z_d^2\,dx+\int_\Omega \Psi_\alpha(-\Delta u+u+z_d).$$

Then we have the following:

(i) *J^* is lower semicontinuous on $BL_0(\Omega)$ for the weak topology τ_1 ($u_n\to u$ for τ_1 if $u_n\to u$ in $L^2(\Omega)$ weakly and $(-\Delta u_n+u_n)\to(-\Delta u+u)$ in $M_1(\Omega)$ vaguely).*

Moreover, any bounded set of $BL_0(\Omega)$ is relatively compact for the τ_1 topology.

(ii) *If (z,u) belongs to $X\times BL_0(\Omega)$, z being admissible for Problem (P), we have*

$$(1.5.2)\qquad (-J^*(u))\leqq j(z)-\left(\frac{\eta}{2}\right)\int_\Omega\left|\left(\frac{1}{\eta}\right)(-\Delta z+z)+u\right|^2 dx.$$

Proof. We first notice that (i) is a consequence of the definition of $BL_0(\Omega)$ and the properties of $\Psi(\mu)$[DT1].

For (ii), we use the sequence z_n above and the duality formula (1.3.4) to derive the following inequalities:

$$\begin{aligned}\int_\Omega \Psi_\alpha(-\Delta u+u+z_d)&\geqq\int_\Omega(-\Delta u+u+z_d)\cdot z_n-\int_\Omega\Psi_\alpha^*(z_n)\,dx\\&\geqq\left(\text{for }\Psi_\alpha^*(s)=\frac{1}{2}s^2,\ \forall s\in\mathbb{R},\ |s|\leqq\alpha\right)\\&\geqq\int_\Omega(-\Delta u+u+z_d)\cdot z_n-\frac{1}{2}\int_\Omega z_n^2\,dx\\&\geqq(\text{for } T_n \text{ converges tightly to } (-\Delta u+u)\cdot z)\\&\geqq\int_\Omega(-\Delta u+u+z_d)\cdot z-\frac{1}{2}\int_\Omega z^2\,dx.\end{aligned}$$

We now use the Green formula (1.4.2) to obtain

$$\begin{aligned}J^*(u)&\geqq\frac{\eta}{2}\int_\Omega u^2\,dx-\frac{1}{2}\int_\Omega z_d^2\,dx-\frac{1}{2}\int_\Omega z^2\,dx+\int_\Omega(-\Delta z+z)\cdot u\,dx+\int_\Omega z_d\cdot z\,dx\\&\geqq-j(z)+\frac{\eta}{2}\int_\Omega\left|\frac{1}{\eta}(-\Delta z+z)+u\right|^2 dx,\end{aligned}$$

and Lemma 1.5.1 is proved. □

Its fundamental importance is due to the fact that it makes possible the use of the standard method of calculus of variations to study Problem (Q^*) in $BL_0(\Omega)$. Our results are summed up in Theorem 1.5.2.

THEOREM 1.5.2.

(i) *We have the equality* $\operatorname{Inf}(P) = \operatorname{Sup}(Q^*)$.

(ii) *There exists, in* $BL_0(\Omega)$, *an adjoint state for the optimal state* z: *it is a solution of* (Q^*).

(iii) *The necessary and sufficient conditions for a couple* (z, u) *of admissible elements for* (P) *and* (Q^*) *to be an optimal couple are*:

$$\int_\Omega \Psi_\alpha(-\Delta u + u + z_d) = \int_\Omega (-\Delta u + u + z_d)\cdot z - \frac{1}{2}\int_\Omega z^2\,dx, \tag{1.5.3}$$

$$u = -\frac{1}{\eta}(-\Delta z + z) \quad \text{a.e. in } \Omega. \tag{1.5.4}$$

Proof. Theorem 1.5.2 follows directly from Lemma 1.5.1. □

2. A distributed control problem with a unilateral constraint. The purpose in § 2 is to extend our results to the unilateral case, where the constraint on the state z has the form ($z \leqq \alpha$ almost everywhere on Ω). The main differences with the bilateral problem **P** come from the fact that an admissible state z no longer belongs to $L^\infty(\Omega)$, and that the analogue of the function Ψ_α (1.2.9) does not satisfy condition (i) of Proposition 1.3.1, i.e., that it be at most linear at infinity. Nevertheless, we shall see that it is possible to overcome these new difficulties, with appropriate methods, and to prove a result as complete as Theorem 1.5.2.

2.1. Variational formulation. Primal and dual problems. The geometrical assumptions being as in § 1, we turn to the study of the following problem.

(**R**) Find (z, v) in $L^2(\Omega)\times L^2(\Omega)$ minimizing the cost function

$$K(z, v) = \frac{1}{2\eta}\int_\Omega v^2\,dx + \frac{1}{2}\int_\Omega |z - z_d|^2\,dx \tag{2.1.1}$$

z being such that $(-\Delta z + z) = v$ in Ω, $z = 0$ on Γ, $z \leqq \alpha$ almost everywhere on Ω.

z_d is given in $L^2(\Omega)$, and α, δ are two strictly positive real numbers. The variational formulation of (R) is

$$(R) \qquad \operatorname*{Inf}_{z\in X}\{k(z)\} \tag{2.1.2}$$

where the functional k is defined by

$$k(z) = \begin{cases} \left(\frac{1}{2}\right)\int_\Omega |z - z_d|^2\,dx + \frac{1}{2\eta}\int_\Omega |-\Delta z + z|^2\,dx \\ \qquad\qquad\qquad\qquad \text{if } z \in X, \quad z \leqq \alpha \quad \text{a.e. on } \Omega, \\ +\infty \quad \text{otherwise.} \end{cases} \tag{2.1.3}$$

As in the bilateral case, we easily see the following [ET].

PROPOSITION 2.1.1. *There exists a unique optimal state* z' *for* R; *it is the minimizer of* (R).

The dual problem (R^*) of (R) is obtained by the same methods as before, and its formulation is

$$(2.1.4) \qquad (R^*) \qquad \operatorname*{Sup}_{p\in X}\left\{\left(\frac{-\eta}{2}\right)\int_\Omega p^2\,dx+\frac{1}{2}\int_\Omega z_d^2\,dx-\int_\Omega \Theta_\alpha(-\Delta p+p+z_d)\,dx\right\}$$

where the function Θ_α is defined by

$$(2.1.5) \qquad \Theta_\alpha(s)=\begin{cases} s^2/2 & \text{if } s\leqq\alpha,\\ \alpha(s-\alpha/2) & \text{if } s\geqq\alpha.\end{cases}$$

We can show that the extrema of (R) and (R^*) are equal, but we do not know whether Problem (R^*) has a solution in X.

We want to extend Problem (R^*) to $\mathrm{BL}_0(\Omega)$, and the new difficulty is that we cannot define $\Theta_\alpha(\mu)$ for any bounded measure μ, due to the quadratic behaviour of Θ_α at infinity. We recall in the following proposition the results of [DT2] that are necessary to extend Problem (R^*) to $\mathrm{BL}_0(\Omega)$.

PROPOSITION 2.1.2. *Let Θ_α be defined as in* (2.1.5), *and μ be a bounded measure on Ω. We suppose that μ admits the Lebesgue decomposition $\mu=h\cdot dx+\theta_s\cdot|\mu_s|$, μ_s singular with respect to the Lebesgue measure and such that*

(i) *μ_s is positive (i.e., $\theta_s\equiv 1$ in Ω).*

(ii) *$h^-=-\mathrm{Inf}(h,0)$ is in $L^2(\Omega)$.*

Then the bounded measure $\Theta_\alpha(\mu)$ is defined by

$$(2.1.6) \qquad \Theta_\alpha(\mu)(\Theta_\alpha\circ h)\cdot dx+\Theta_{\alpha,\infty}(\theta_s)\cdot|\mu_s|$$

with $\Theta_{\alpha,\infty}(s)=0$ if $s<0$, and $+\infty$ if $s\geqq 0$, and we have the duality formula

$$(2.1.7) \qquad \forall\Phi\in\mathscr{C}_0(\Omega)\quad \langle\Theta_\alpha(\mu),\Phi\rangle=\operatorname{Sup}\left\{\int_\Omega \Phi\cdot g\cdot d\mu-\int_\Omega \Phi\cdot\Theta_\alpha^*(g)\cdot dx\right\},$$

the supremum being taken for $g\in\mathscr{C}_0(\Omega)$, $g\leqq\alpha$ in Ω. Moreover, relation (2.1.7) *is still valid for $\Phi\in\mathscr{C}(\Omega)$, $\Phi\geqq 0$ in Ω.*

(These results come from Theorem 2.1 of [DT2].)

Remark 2.1.1. In this particular case, the expression of $\Theta_\alpha(\mu)$ is

$$(2.1.8) \qquad \Theta_\alpha(\mu)=(\Theta_\alpha\circ h)\cdot dx+\alpha\cdot\mu_s.$$

We define the set $M^\alpha(\Omega)=\{\mu\in M_1(\Omega),\ \mu$ satisfies (i) and (ii)$\}$. One of its main properties [DT2, Lemma 3.2.1] is the following.

(A) If μ_n is a sequence in $M^\alpha(\Omega)$ such that $\Theta_\alpha(\mu_n)$ is bounded, and if μ_n converges vaguely to a measure μ, then μ belongs to $M^\alpha(\Omega)$. Furthermore, we have

$$\int_\Omega \Theta_\alpha(\mu)\leqq\varliminf_{n\to\infty}\int_\Omega \Theta_\alpha(\mu_n).$$

We can now give the expression of the generalized problem (S^*):

$$(2.1.9) \qquad (S^*) \qquad \operatorname{Sup}\left\{\left(\frac{-\eta}{2}\right)\int_\Omega u^2\,dx+\frac{1}{2}\int_\Omega z_d^2\,dx-\int_\Omega \Theta_\alpha(-\Delta u+u+z_d)\right\},$$

where the supremum is taken for $u\in\mathrm{BL}_0(\Omega)$, $(-\Delta u+u+z_d)\in M^\alpha(\Omega)$.

Obviously we have

$$(2.1.10) \qquad \mathrm{Inf}(R)\leqq\mathrm{Sup}(S^*).$$

Our purpose in the next section will be to define a generalized duality between (R) and (S^*), so as to give the system of optimality conditions for Problem (**R**).

2.2. Green's formula and duality. If z and u are admissible, respectively, for (R) and (S^*), we can see that it is no longer possible to define $(-\Delta u+u)\cdot z$ as a bounded measure by using the method of Proposition 1.4.1, for z is not bounded in Ω. However, we can prove a very similar result.

PROPOSITION 2.2.1. *Let (z, u) be a couple of admissible elements, respectively, for (R) and (S^*). The distribution $(-\Delta u+u)\cdot z$ is a bounded measure in Ω, and the Green formula* (1.4.2) *still holds.*

Proof. Let us admit for the moment the following result.

LEMMA 2.2.2. *Let (y, v) belong to $X\times \mathrm{BL}_0(\Omega)$, such that $(-\Delta v+v)$ is a positive measure; then the distribution $(-\Delta v+v)\cdot y$ defined in* (1.4.1) *is a bounded measure, and we have the equality*

$$\int_\Omega (-\Delta v+v)\cdot y=\int_\Omega (-\Delta y+y)\cdot v\,dx. \tag{2.2.1}$$

We can now prove Proposition 2.2.1. We write $u=u_1-u_2$, where u_1 and u_2 are obtained by solving the Dirichlet problems corresponding, respectively, to $(-\Delta u+u+z_d)^+$ and $((-\Delta u+u+z_d)^-+z_d)$. Then $(-\Delta u_1+u_1)\cdot z$ is defined as a measure by using Lemma 2.2.2, $(-\Delta u_2+u_2)\cdot z$ has a natural meaning (thanks to the assumptions on u), and the Green formula comes from (2.2.1) and the classical formula in X. That proves Proposition 2.2.1. □

Proof of Lemma 2.2.2. We start with the case where y has a constant sign, say $y\leqq 0$, and use a sequence y_n of smooth functions satisfying the following conditions:

(i) y_n converges to y in X;

(ii) For all $n\in\mathbb{N}$, $0\geqq y_n\geqq \operatorname{Inf} y$ in Ω.

Such a sequence is obtained in exactly the same way as the sequence z_n of Proposition 1.4.1. We set $T'_n=(-\Delta v+v)\cdot y_n$; T'_n is a bounded negative measure (for y_n is smooth in $\bar\Omega$), and we have the equality

$$\int_\Omega (-\Delta v+v)\cdot y_n=\int_\Omega (-\Delta y_n+y_n)\cdot v\,dx \tag{2.2.2}$$

(see the proof of Proposition 1.4.1). The right-hand side of (2.2.2) has a limit because of (i); moreover, due to the assumptions on the signs of $(-\Delta v+v)$ and y_n, the left-hand side of (2.2.1) is the opposite of the norm of $(-\Delta v+v)\cdot y_n$ in $M_1(\Omega)$. Hence, we can ensure that the sequence T'_n is bounded in $M_1(\Omega)$. Therefore, $(-\Delta v+v)\cdot y$ is a bounded measure on Ω, as the limit in $\mathscr{D}'(\Omega)$ of a bounded sequence in $M_1(\Omega)$.

Now one thing is left to prove, namely, the tight convergence of T'_n to $(-\Delta v+v)\cdot y$. As a matter of fact, that will be sufficient to prove (2.2.1). Let us consider the linear functional T''_n, defined on $\mathscr{C}(\bar\Omega)$ by

$$\langle T''_n,\Phi\rangle=\int_\Omega [-\Delta v+v]y_n\cdot\Phi. \tag{2.2.3}$$

For the same reasons as in Proposition 1.4.1, we have, for Φ in $\mathscr{C}^\infty(\bar\Omega)$:

$$\langle T''_n,\Phi\rangle=\int_\Omega [-\Delta(y_n\cdot\Phi)+y_n\cdot\Phi]\cdot v\,dx. \tag{2.2.4}$$

Hence, $(T''_n)_{n\in\mathbb{N}}$ is a sequence of negative linear functionals on $\mathscr{C}(\bar\Omega)$, which is bounded in $[\mathscr{C}(\bar\Omega)]'$ (use (2.2.4) with $\Phi\equiv 1$). Thus, there exists a subsequence, still denoted by T''_n, which is vaguely convergent to a functional T'' in $[\mathscr{C}(\bar\Omega)]'$. As $\bar\Omega$ is compact, the vague and tight convergences are equivalent, for positive measures on $\bar\Omega$. We now use this result from [B]:

Result. The canonical injection **i** from the positive cone of $M_1(\Omega)$ onto its image in $[\mathscr{C}(\bar{\Omega})]'$ is a homeomorphism when each space is endowed with the topology of tight convergence.

As we obviously have $\mathbf{i}(T'_n) = T''_n$, the tight convergence of T'_n to $[-\Delta v + v] \cdot y$ is proved.

We now return to the general case: when y is in X, we can always write it as the difference of two positive elements of X. For instance, we can solve the Dirichlet problems relative to the positive and negative parts of $(-\Delta y + y)$. Thanks to the maximum principle, the corresponding functions y_1 and y_2 are positive, and we obviously have $y = y_1 - y_2$; we then set $[-\Delta v + v] \cdot y = [-\Delta v + v] \cdot y_1 - [-\Delta v + v] \cdot y_2$ and, using the results above, define $[-\Delta v + v] \cdot y$ as a bounded measure. This definition of $[-\Delta v + v] \cdot y$ is independent of the decomposition of y as the difference of two positive functions in X; that is a consequence of (2.2.4), and of the density of $\mathscr{C}^\infty(\Omega)$ in $\mathscr{C}(\Omega)$. Hence Lemma 2.2.2 is proved. □

Remark 2.2.2. The application $y \to [-\Delta v + v] \cdot y$, for fixed v, is continuous from X endowed with its strong topology, into $M_1(\Omega)$ endowed with the topology of tight convergence. That is also a consequence of (2.2.4), and of the density of $\mathscr{C}^\infty(\Omega)$ in $\mathscr{C}(\Omega)$.

We now have all the technical elements required to solve Problem (R) completely. Before giving our final results, we state a lemma.

LEMMA 2.2.3. *Let K^* be the functional defined in* $\mathrm{BL}_0(\Omega)$ *by*

$$K^*(u) = \begin{cases} \left(\frac{\eta}{2}\right) \int_\Omega u^2 \, dx - \frac{1}{2} \int_\Omega z_d^2 \, dx + \int_\Omega \Theta_\alpha(-\Delta u + u + z_d) \\ \qquad \text{if } u \in \mathrm{BL}_0(\Omega),\ (-\Delta u + u + z_d) \in M^\alpha(\Omega), \\ +\infty \quad \text{otherwise.} \end{cases} \tag{2.2.5}$$

K^* enjoys the following properties:

(i) *If (z, u) is a couple of admissible elements respectively, for (R) and (S^*), we have*

$$(-K^*(u)) \leqq k(z) - \frac{\eta}{2} \int_\Omega \left| \frac{1}{\eta} (-\Delta z + z) + u \right|^2 dx. \tag{2.2.6}$$

(ii) *Any sequence u_n in* $\mathrm{BL}_0(\Omega)$ *such that $K^*(u_n)$ is bounded has a cluster point u for the τ_1 topology of* $\mathrm{BL}_0(\Omega)$, *and we have*

$$K^*(u) \leqq \varliminf_{n \to \infty} (K^*(u_n)). \tag{2.2.7}$$

Proof. The proof is omitted. It is definitely similar to that of Lemma 1.5.1 because of the duality formula (2.1.7) and Proposition 2.2.1.

We now conclude the study of the optimality system for Problem (R).

THEOREM 2.2.4. (i) *The extrema of (R) and (S^*) are equal.*

(ii) *There exists a solution of Problem (S^*) in* $\mathrm{BL}_0(\Omega)$.

(iii) *The necessary and sufficient conditions for a couple (z, u) of admissible elements to be an optimal couple are*

$$\int_\Omega \Theta_\alpha(-\Delta u + u + z_d) = \int_\Omega (-\Delta u + u + z_d) \cdot z - \frac{1}{2} \int_\Omega z_d^2 \, dx, \tag{2.2.8}$$

$$u = \left(\frac{1}{\eta}\right)(-\Delta z + z) \quad \text{a.e. in } \Omega. \tag{2.2.9}$$

Proof. The proof is the same as that of Theorem 1.5.2.

CONVERGENCE OF SQP-LIKE METHODS FOR CONSTRAINED OPTIMIZATION*

STEPHEN WRIGHT†

Abstract. The problem of constrained optimization

$$\min f(x) \quad \text{s.t. } x \in \Omega$$

is sometimes solved by an iterative method, in which Ω is replaced by some other set $\Omega(x_k)$ with simple geometry at each iteration x_k. Sequential quadratic programming methods for nonlinear programming are the most obvious examples of this. The convergence behavior of such methods is examined by comparing the sequence of iterates $\{x_k\}$ with a sequence $\{y_k\}$ of local minimizers for f in $\Omega(x_k)$. Issues of active constraint identification are also discussed in terms of the geometry of the sets $\Omega(x_k)$; conditions are given for x_{k+1} and y_k to lie on the same face of $\Omega(x_k)$.

Key words. constrained optimization, sequential quadratic programming, local convergence

AMS(MOS) subject classifications. 49D37, 90C30.

1. Introduction.

We consider the problem

$$\min f(x) \quad \text{s.t. } x \in \Omega \tag{1.1}$$

where $\Omega \subset \mathbb{R}^n$ and $f: \mathbb{R}^n \to \mathbb{R}$ is twice continuously differentiable. This problem has been analysed extensively by numerous authors (see, for example, the recent work of Dunn [5]-[7], Dunn and Sachs [8], Sachs [14], Calamai and Moré [3], and Burke and Moré [2]). Projected gradient, conditional gradient, and Newton-like methods have been proposed for its solution. In all these methods, it may be necessary at some stage to project a vector $x \in \mathbb{R}^n$ onto Ω, that is, to find

$$\arg\min \{\|x - z\| \mid z \in \Omega\}. \tag{1.2}$$

When Ω is geometrically simple (e.g., a disk, a cone, or a Cartesian product of these objects) or when Ω is defined by a set of linear equalities and inequalities, (1.2) may be computationally reasonable. However, when Ω is more complicated, it is impractical to repeatedly compute the projection (1.2). An example is when Ω is defined by a set of nonlinear equalities and inequalities, that is,

$$\Omega = \{z \mid c_j(z) \geqq 0, j = 1, \cdots, m_I, e_i(z) = 0, i = 1, \cdots, m_E\}. \tag{1.3}$$

A popular approach for such problems is known as sequential quadratic programming (SQP). At each iterate x_k, a "local linear approximation" $\Omega(x_k)$ to Ω is formed. A quadratic function is then minimized over this simpler set to obtain the next iterate x_{k+1}. This approach appears to have been originally suggested by Wilson [17].

The local convergence behavior of such methods is fairly well understood when "nondegeneracy" and "strict complementarity" conditions are satisfied at the solution x^*. Nondegeneracy conventionally refers to linear independence of the active constraint gradients at x^*, namely,

$$\{\nabla e_i(x^*), i = 1, \cdots, m_E, \nabla c_j(x^*), j \in \mathcal{A}^*\} \tag{1.4a}$$

where

$$\mathcal{A}^* = \{j \mid c_j(x^*) = 0\} \subset \{1, \cdots, m_I\}. \tag{1.4b}$$

* Received by the editors March 23, 1987; accepted for publication (in revised form) March 1, 1988.
† Department of Mathematics, North Carolina State University, Raleigh, North Carolina 27695-8205.

Strict complementarity means that the Lagrange multipliers satisfying the Kuhn-Tucker conditions, that is,

$$\nabla f(x^*) = \sum_{i=1}^{m_E} \lambda_i^E \nabla e_i(x^*) + \sum_{j \in \alpha^*} \lambda_j^I \nabla c_i(x^*), \tag{1.5}$$

are nonzero (in the case of the λ_i^E) and strictly positive (in the case of the λ_j^I). In this paper, we are concerned with local convergence when these assumptions are relaxed. In particular, when Ω is defined by (1.3), it is *not* assumed that the active constraint gradients are independent at x^*. A weaker nondegeneracy condition due to Dunn [7] is assumed instead. We examine the convergence of the sequence of iterates $\{x_k\}$ relative to a sequence $\{y_k\}$, where each y_k is a minimizer of $f(x)$ on the set $\Omega(x_k)$. (Of course, y_k is not computed.) Results concerning the convergence of $\{x_k\}$ to x^* are not obtained directly—these depend on the rate of convergence of $\{y_k\}$ to x^*, which may be linear when the constraint gradients are linearly dependent.

In § 2, we restate some definitions, due to Burke and Moré [2] and Clarke [4], which describe the geometry of sets in $\mathbb{R}^n$, the tangent and normal cones for such sets, and special subsets known as *faces*. The basic quadratic-programming subproblem is defined in § 3. Also, since the sequence of linear approximations $\{\Omega(x_k)\}$ does not generally converge to Ω, it may be that the SQP method will not converge to a solution of (1.1). Some sufficient conditions that ensure the limit point x^* *does* solve (1.1) are also discussed in § 3. In § 4, two theorems relating to the convergence are presented. Each uses a different approach, and makes different assumptions about the sequence of minimizers $\{y_k\}$ and the behavior of f in a feasible neighbourhood of the solution. Finally a discussion of possible choices of $\Omega(x_k)$ appears in § 5.

2. Definitions and notation. Here we restate some of the definitions of Clarke [4] and Burke and Moré [2], particularly those concerning faces of a convex set in $\mathbb{R}^n$.

For a general set $\Omega \subset \mathbb{R}^n$, the *tangent cone* $T(x; \Omega)$ at a point x is defined as "the set of vectors $u \in \mathbb{R}^n$ such that for every sequence w_i in Ω converging to x and every sequence t_i in $(0, \infty)$ converging to 0 there is a sequence u_i converging to u such that $w_i + t_i u_i \in \Omega$ for all i" (Clarke [4]). When Ω is *convex* this definition is equivalent to "the set of vectors $u \in \mathbb{R}^n$ such that there is a sequence w_i in Ω such that $(w_i - x)/\|w_i - x\|$ converges to $u/\|u\|$." The *normal cone* can be defined by polarity:

$$N(x; \Omega) = T^0(x; \Omega) = \{v \,|\, \langle u, v\rangle \leqq 0 \ \forall u \in T(x; \Omega)\}.$$

In the case of Ω convex,

$$N(x; \Omega) = \{v \,|\, \langle v, z - x\rangle \leqq 0 \ \forall z \in \Omega\}.$$

The projection operator P_Ω relative to Ω is

$$P_\Omega(x) = \arg\min \{\|z - x\| \,|\, z \in \Omega\}.$$

Clearly this is a contraction operator when Ω is convex, that is,

$$\|P_\Omega(x_1) - P_\Omega(x_2)\| \leqq \|x_1 - x_2\| \quad \forall x_1, x_2 \in \mathbb{R}^n$$

(see Calamai and Moré [3]).

The *affine hull* aff (S) of a set $S \subset \mathbb{R}^n$ is the smallest affine set that contains S, and we use ri (S) to denote the interior of S relative to aff (S). Using these definitions, we can state the first-order necessary conditions for a point $x^* \in \Omega$ to be optimal in problem (1.1).

DEFINITION 2.1. $x^* \in \Omega$ is said to be a *stationary point* for (1.1) if

$$-\nabla f(x^*) \in N(x^*; \Omega). \tag{2.1}$$

THEOREM 2.2 (Clarke [4]). *Condition* (2.1) *is a first-order necessary condition for* x^* *to be optimal for* (1.1).

Dunn's [7] nondegeneracy condition then follows.

DEFINITION 2.3. A stationary point x^* is said to be *nondegenerate* if

$$-\nabla f(x^*) \in \text{ri}\,(N(x^*; \Omega)).$$

Consider now a *convex* set $\Omega_* \subset \mathbb{R}^n$. There is a special class of subsets of Ω_* known as *faces*, that can be defined as follows (see Burke and Moré [2, Thm. 2.1], Rockafellar [12]).

DEFINITION 2.4. A convex subset Ω_F of Ω_* is a *face* of Ω_* if, for all convex $\Gamma \subset \Omega_*$ such that ri (Γ) meets Ω_F, we have $\Gamma \subset \Omega_F$.

A face $\Omega_E \subset \Omega_*$ is said to be *exposed* if

$$\Omega_E = \arg\max \{\phi(x) \,|\, x \in \Omega_*\}$$

where ϕ is some linear functional. It is proved in Burke and Moré [2] that the normal and tangent cones to Ω are the same for all $x \in \text{ri}\,(\Omega_F)$; hence we can use the notation $N(\Omega_F; \Omega_*)$ instead of $N(x; \Omega_*)$, where $x \in \text{ri}\,(\Omega_F)$.

A face Ω_F is referred to as a *quasi-polyhedral* face of Ω_* if

$$\text{aff}\,(\Omega_F) = x + \text{lin}\,(T(x)),$$

for any $x \in \Omega_F$, where the lineality lin $(T(x))$ is defined by

$$\text{lin}\,(T(x)) = T(x) \cap (-T(x)).$$

Some examples of such faces are given by Burke and Moré. In the special case of Ω_* polyhedral, all faces are quasi-polyhedral. The definition above is closely related to that of an *open facet*, as proposed by Dunn [7].

An important result regarding quasi-polyhedral faces is proved in [2].

THEOREM 2.5 [2, Thm. 2.8]. *Let* Ω_F *be a nonempty face of a convex set* Ω_*. *Then* Ω_F *is a nonempty quasi-polyhedral face if and only if* $\Omega_F + N(\Omega_F; \Omega_*)$ *has an interior. When this is true,*

$$\text{int}\,(\Omega_F + N(\Omega_F; \Omega_*)) = \text{ri}\,(\Omega_F) + \text{ri}\,(N(\Omega_F; \Omega_*)).$$

If Ω_F is a quasi-polyhedral face such that $x^* \in \text{ri}\,(\Omega_F)$, and if x^* is a nondegenerate stationary point, that is, $-\nabla f(x^*) \in \text{ri}\,(N(\Omega_F; \Omega_*))$, then it follows from Theorem 2.5 that

$$x^* - \nabla f(x^*) \in \text{int}\,(\Omega_F + N(\Omega_F; \Omega_*)).$$

This observation is used by Burke and Moré to obtain results concerning the identification of active constraints, and will be used here in subsequent sections.

Throughout this paper we use B to denote the closed unit ball in $\mathbb{R}^n$ and $\|\cdot\|$ to denote the Euclidean norm.

3. SQP methods—optimality conditions and active constraint identification. In this section we consider sequential quadratic programming methods for solving (1.1), in which the sequence $\{x_k\}$ is generated according to the following scheme:

$$\begin{aligned} &\text{At } x_k, \text{ solve} \\ &\min_{p_k} \langle p_k, \nabla f(x_k)\rangle + \tfrac{1}{2}\langle p_k, B_k p_k\rangle \\ &\text{s.t.} \quad x_k + p_k \in \Omega(x_k); \\ &\text{set} \quad x_{k+1} = x_k + p_k. \end{aligned} \tag{3.1}$$

Here $\{B_k\}$ is a bounded sequence of symmetric matrices and $\Omega(\cdot)$ can be regarded as

a multifunction that maps $\mathbb{R}^n$ to subsets of $\mathbb{R}^n$. Previous work by Dunn [5], [6], Burke and Moré [2], Sachs [14], and others has dealt with the case $\Omega(x_k) = \Omega$. That is, all iterates x_k are feasible with respect to the original feasible set Ω. If, as is usual in these papers, Ω is assumed to be convex, then $x_k + \lambda p_k \in \Omega$ for all $\lambda \in [0, 1]$, and so a line search can be used in such a way as to ensure global convergence of the method. This is not appropriate in (3.1), as it is possible that $x_k + \lambda p_k \notin \Omega(x_k)$ for all $\lambda \in [0, 1)$. Hence we are only concerned here with issues of local convergence, and we assume that the full step p_k is taken at each iteration.

In the remainder of the paper we use the following assumptions.

Assumption 3.1. (i) $\Omega(x)$ is closed and convex for all $x \in \mathbb{R}^n$.

(ii) If $\{x_k\}$ converges to x^*, then $\Omega(x_k)$ converges in the Kuratowski sense to some convex set $\Omega_* \subset \mathbb{R}^n$. That is,

(a) All sequences $\{y_k\}$ with $y_k \in \Omega(x_k)$ have all their accumulation points in Ω_*;

(b) For all $y \in \Omega_*$ there is a sequence $\{y_k\}$ with $y_k \in \Omega(x_k)$ such that $\lim y_k = y$.

Assumption 3.2. Algorithm (3.1) generates a sequence $\{x_k\}$ that converges to a point $x^* \in \Omega$ which is a nondegenerate stationary point of f in Ω_*. (Note that $x^* \in \Omega_*$ follows from (3.1) and Assumption 3.1.)

Notes. (i) Kuratowski convergence of sequences of sets is discussed in more detail in Salinetti and Wets [15] and Attouch [1]. For further information on convex multifunctions of the form $\Omega(x_k)$, see Robinson [11] and Rockafellar [13]. Assumption 3.1(ii) is weaker than any of the variants of Lipschitz continuity of multifunctions discussed in Rockafellar [13]. Note also that we do *not* assume above that $\Omega_* = \Omega(x^*)$.

(ii) Assumptions of the form 3.2 are usually made when the *local* convergence properties of a method are being studied. The purpose of a *global* convergence analysis is to show that convergence to a stationary point occurs from any given starting point. Since substantial modifications are usually required to ensure global convergence of SQP methods, we do not perform a global analysis here.

We do not assume that x^* is stationary with respect to Ω, and the following example shows that this does not generally follow from Assumption 3.2.

Example 3.3. Consider

$$\min x \quad \text{s.t. } c(x) = x^2 \geqq 0.$$

Applying the usual SQP algorithm starting at the point $x_0 = 1$, with $B_k \equiv 0$ and

$$\begin{aligned}\Omega(x_k) &= \{z \mid \nabla c(x_k)^T (z - x_k) + c(x_k) \geqq 0\} \\ &= \{z \mid 2x_k z - x_k^2 \geqq 0\},\end{aligned}$$

we obtain the sequence $x_k = 2^{-k}$ which converges to $x^* = 0$. For this problem $\Omega = \Omega(0) = \mathbb{R}$, but $\Omega_* = \mathbb{R}^+$. The point x^* is optimal in Ω_* but is not even a stationary point in Ω.

The following theorem gives a sufficient condition for x^* to be a stationary point of (1.1).

THEOREM 3.4. *Suppose x^* is a stationary point of f in Ω_*. If $T(x^*; \Omega) \subset T(x^*; \Omega_*)$ then x^* is also a stationary point of f in Ω.*

Proof. The proof follows from $N(x^*; \Omega_*) \subset N(x^*; \Omega)$. □

To find situations in which the condition of Theorem 3.4 holds, consider the nonlinear programming problem in its standard form:

$$\begin{aligned}&\min f(x) \\ &\text{s.t.} \quad c_j(x) \geqq 0, \qquad j = 1, \cdots, m_I, \\ &\qquad\quad e_i(x) = 0, \qquad i = 1, \cdots, m_E.\end{aligned} \tag{3.2}$$

Here the feasible set Ω is given by (1.3). The functions f, c_j, and e_i are assumed to be twice continuously differentiable. The multifunction $\Omega(x)$ is usually generated by linearization of the constraints about x:

$$\Omega(x) = \Lambda(x) \overset{\text{def}}{=} \left\{ z \,\middle|\, \begin{array}{ll} \langle z - x, \nabla c_j(x)\rangle + c_j(x) \geqq 0, & j = 1, \cdots, m_I \\ \langle z - x, \nabla e_i(x)\rangle + e_i(x) = 0, & i = 1, \cdots, m_E \end{array} \right\}. \tag{3.3}$$

An often-used sufficient condition for a stationary point x^* of f in Ω to be a Kuhn-Tucker point for problem (3.2) is that

$$T(x^*; \Omega) = T(x^*; \Lambda(x^*)) = \left\{ u \,\middle|\, \begin{array}{ll} \langle u, \nabla c_j(x^*)\rangle \geqq 0, & j \in \mathscr{A}^* \\ \langle u, \nabla e_i(x^*)\rangle = 0, & i = 1, \cdots, m_E \end{array} \right\} \tag{3.4}$$

where $\mathscr{A}^*$ is defined in (1.4b). This is referred to as the *Guignard constraint qualification* (see Gould and Tolle [10] and Fletcher [9]).

The conditions $T(x^*; \Omega) \subset T(x^*; \Omega_*)$ and (3.4) are not equivalent, nor does one imply the other. In Example 3.3, clearly $T(0; \Omega_*) = \mathbb{R}^+$ and $T(0; \Omega) = \mathbb{R}$, but $\Omega(0) = \Lambda(0) = \mathbb{R}$, and so (3.4) is satisfied. On the other hand, we have in the following example that $T(x^*; \Omega) \subset T(x^*; \Omega_*)$, but (3.4) is not satisfied.

Example 3.5. The problem

$$\min_{z \in \mathbb{R}^2} z_1 \quad \text{s.t. } z_2 \geqq 0, \quad z_2 \leqq z_1^3$$

has solution $x^* = 0$. From (3.3)

$$\Lambda(z) = \{y \,|\, y_2 \geqq 0,\ y_2 \leqq 3z_1^2 y_1 - 2z_1^3\}.$$

If the starting point $x_0 = (1, 0)^T$ is used, the method (3.1) with $B_k \equiv 0$ generates the sequence $x_k = ((\frac{2}{3})^k, 0)^T$. Clearly $\Omega_* = \{(y_1, 0)^T \,|\, y_1 \in \mathbb{R}^+\}$ and $T(0; \Omega_*) = \Omega_*$. However,

$$\Lambda(0) = \{(y_1, 0)^T \,|\, y_1 \in \mathbb{R}\},$$

and so condition (3.4) is not satisfied.

The following result gives sufficient conditions for both $T(x^*; \Omega_*) = T(x^*; \Omega)$ and (3.4), in some familiar cases.

THEOREM 3.6. *Consider problem* (3.2) *and assume that the* c_j, e_i *are all twice continuously differentiable. Suppose* $x^* \in \Omega$, *and let* $\{x_k\}$ *be any sequence converging to* x^*. *Assume also that* $\Omega(x) = \Lambda(x)$ (*from* (3.3)). *Then sufficient conditions for* $T(x^*; \Omega) = T(x^*; \Omega_*)$, *and condition* (3.4), *are the following*:

(a) $c_j(x)$, $j = 1, \cdots, m_I$ *and* $e_i(x)$, $i = 1, \cdots, m_E$ *are linear functions*;

(b) *The set* $\{\nabla e_i(x^*), i = 1, \cdots, m_E, \nabla c_j(x^*), j \in \mathscr{A}^*\}$ *is linearly independent.*

Proof. (a) The proof follows from the fact that $\Lambda(x) = \Omega = \Omega_*$ for all x, and since Ω is polyhedral, (3.4) holds for all feasible x^*.

(b) The inclusions $T(x^*; \Omega) \subset T(x^*; \Lambda(x^*))$ and $T(x^*; \Omega_*) \subset T(x^*; \Lambda(x^*))$ follow from the assumed continuity properties of the c_j and e_i, and Assumption 3.1. Linear independence is not needed here. The reverse inclusion $T(x^*; \Lambda(x^*)) \subset T(x^*; \Omega)$ is proved in Fletcher [9, Lemma 9.2.2] using the linear independence assumption.

We complete the proof by showing that $T(x^*; \Omega) \subset T(x^*; \Omega_*)$. Choose $u \in T(x^*; \Omega) \backslash \{0\}$ and assume without loss of generality (since $T(x^*; \Omega)$ is a cone) that $\|u\| = 1$. Then there are sequences $u_m \to u$ and $t_m \downarrow 0$ such that

$$\begin{aligned} c_j(x^* + t_m u_m) &\geqq 0, \qquad j = 1, \cdots, m_I, \\ e_i(x^* + t_m u_m) &= 0, \qquad i = 1, \cdots, m_E. \end{aligned}$$

Hence

$$
\begin{aligned}
&c_j(x_k)+\langle \nabla c_j(x_k),\, x^*+t_m u_m-x_k\rangle + d_j^{(1)} \geqq 0,\\
&e_i(x_k)+\langle \nabla e_i(x_k),\, x^*+t_m u_m-x_k\rangle + d_i^{(2)} = 0
\end{aligned} \tag{3.5}
$$

where $\|d_j^{(1)}\| = O(\|x^*+t_m u_m-x_k\|^2) = \|d_i^{(2)}\|$. Now it follows from the linear independence assumption and the fact that $x_k \to x^*$ that $\nabla c_j(x_k)$, $j \in \mathscr{A}^*$ and $\nabla e_i(x_k)$, $i = 1, \cdots, m_E$ are linearly independent for k sufficiently large. Hence for such k there is a vector g_{km} that satisfies

$$
\begin{aligned}
&\langle \nabla c_j(x_k), g_{km}\rangle = d_j^{(1)}, \qquad j \in \mathscr{A}^*,\\
&\langle \nabla e_i(x_k), g_{km}\rangle = d_i^{(2)}, \qquad i = 1, \cdots, m_E,\\
&g_{km} = O(\|x_k+t_m u_m-x^*\|^2).
\end{aligned}
$$

Hence from (3.5),

$$
\begin{aligned}
&c_j(x_k)+\langle \nabla c_j(x_k),\, x^*+t_m u_m+g_{km}-x_k\rangle \geqq 0, \quad j \in \mathscr{A}^*,\\
&e_i(x_k)+\langle \nabla e_i(x_k),\, x^*+t_m u_m+g_{km}-x_k\rangle = 0, \quad i = 1, \cdots, m_E.
\end{aligned} \tag{3.6}
$$

Note that the inactive inequalities in (3.5) will always be satisfied for all k, m sufficiently large. Now from (3.6) we have that

$$
x^*+t_m u_m+g_{km} \in \Lambda(x_k),
$$

so choosing a subsequence in k if necessary and taking the limit as $k \to \infty$ we obtain by Assumption 3.1 that

$$
x^*+t_m u_m+\bar{g}_m \in \Omega_* \tag{3.7}
$$

where $\bar{g}_m = \lim_k g_{km} = O(t_m^2)$. Defining

$$
\bar{u}_m = u_m + t_m^{-1}\bar{g}_m,
$$

we have from (3.7) that $x^*+t_m\bar{u}_m \in \Omega_*$, and that $\bar{u}_m \to u$, $t_m \downarrow 0$. Hence $u \in T(x^*; \Omega_*)$. □

The following result discusses a less familiar situation in which the condition of Theorem 3.4 holds. We make use of functions h_j that provide general measures of the curvature of the constraint functions near x^*. The result shows that when Ω is an intersection of convex sets, at least locally, then $T(x^*; \Omega) \subset T(x^*; \Omega_*)$.

THEOREM 3.7. *Suppose Ω is defined by* (1.3) *with only inequality constraints* ($m_E = 0$). *Let $x^* \in \Omega$ be such that each c_j is twice continuously differentiable at x^*. For each active constraint $j \in \mathscr{A}^*$ define the function*

$$
h_j(v) = c_j(x^*+v) - \langle \nabla c_j(x^*), v\rangle,
$$

and the set

$$
N_j = \{u \mid \|u\| = 1,\ u \in T(x^*; \Omega) \text{ and } \langle u, \nabla c_j(x^*)\rangle = 0\}.
$$

Assume that, for each $j \in \mathscr{A}^*$, either c_j is a linear function or there exist constants $\delta > 0$ and $T > 0$ such that if N_j is not empty,

$$
h_j(tv) < 0 \quad \text{for all } t \in (0, T], \quad v \in N_j + \delta B. \tag{3.8}
$$

Then if $\{x_k\}$ is any sequence converging to x^*, and $\Omega(x) = \Lambda(x)$, then $T(x^*; \Omega) \subset T(x^*; \Omega_*)$.

Proof. Take $u \in T(x^*; \Omega)\backslash\{0\}$ and assume without loss of generality that $\|u\| = 1$. Then there are sequences $u_m \to u$, $t_m \downarrow 0$ such that $x^* + t_m u_m \in \Omega$, that is,

$$c_j(x^* + t_m u_m) \geqq 0, \qquad j = 1, \cdots, m_I.$$

We aim to show that $x^* + t_m u_m \in \Lambda(x_k)$ for m sufficiently large, and for $k \geqq k_m$, where k_m is a positive integer to be defined. That is,

$$c_j(x_k) + \langle \nabla c_j(x_k), x^* + t_m u_m - x_k \rangle \geqq 0, \qquad j = 1, \cdots, m_I. \tag{3.9}$$

This will ensure that $x^* + t_m u_m \in \Omega_*$. Clearly (3.9) will be satisfied by the linear constraints, and will eventually be satisfied by the inactive constraints $j \notin \mathcal{A}^*$. For $j \in \mathcal{A}^*$ we have

$$\begin{aligned} & c_j(x^* + t_m u_m) \geqq 0, \\ \Leftrightarrow\ & \langle \nabla c_j(x^*), t_m u_m \rangle \geqq -h_j(t_m u_m), \\ \Leftrightarrow\ & c_j(x_k) + \langle \nabla c_j(x_k), t_m u_m \rangle \geqq -h_j(t_m u_m) + c_j(x_k) + \langle \nabla c_j(x_k) - \nabla c_j(x^*), t_m u_m \rangle. \end{aligned} \tag{3.10}$$

By taking the limit in k in (3.10) and noting that $h(t_m u_m) = O(t_m^2)$, we obtain

$$\langle \nabla c_j(x^*), u \rangle \geqq 0.$$

If this inequality is strict then $\langle \nabla c_j(x^*), u_m \rangle > 0$ for sufficiently large m, and then k_m can be chosen large enough to ensure (3.9). Otherwise $u \in N_j$, and so by the assumption of the theorem $h_j(t_m u_m) < 0$ for m sufficiently large. If we choose k_m large enough so that

$$\begin{aligned} & \left| c_j(x_k) + \langle \nabla c_j(x_k) - \nabla c_j(x^*), t_m u_m \rangle \right| \leqq -\tfrac{1}{2} h_j(t_m u_m), \\ & \left| \langle \nabla c_j(x_k), x^* - x_k \rangle \right| \leqq -\tfrac{1}{2} h_j(t_m u_m) \end{aligned}$$

for all $k \geqq k_m$, (3.9) follows from (3.10). □

Example 3.8. Let

$$\Omega = \{x \in \mathbb{R}^2 \,|\, c_1(x) = x_2 - x_1^K \geqq 0,\ c_2(x) = x_2 + x_1 \geqq 0,\ c_3(x) = x_2 \geqq 0\}$$

where K is some positive integer, at least 2, and let $x^* = (0, 0)^T$. Then

$$\Lambda(x) = \{y \in \mathbb{R}^2 \,|\, y_2 \geqq K x_1^{K-1} y_1 - (K-1) x_1^K,\ y_2 + y_1 \geqq 0,\ y_2 \geqq 0\}$$

and clearly, for any sequence converging to x^*,

$$\begin{aligned} & \Omega_* = \Lambda(x^*) = \{y \in \mathbb{R}^2 \,|\, y_2 + y_1 \geqq 0,\ y_2 \geqq 0\}, \\ & T(x^*; \Omega) = T(x^*; \Omega_*). \end{aligned}$$

By the definitions of Theorem 3.7,

$$N_1 = \{(1, 0)^T\} \quad \text{and} \quad h_1(tv) = -t^K v_1^K,$$

and condition (3.8) can be satisfied by choosing any δ with $0 < \delta < 1$, and any $T > 0$. Note that the conditions of Theorem 3.6 do not apply.

Note that a more intuitive, but more restrictive, condition than (3.8) would be that

$$\langle u, \nabla^2 c_j(x^*) u \rangle \leqq -\alpha_j < 0 \quad \text{for all } u \in N_j.$$

This condition implies (3.8) since

$$\begin{aligned} h(tv) &= \tfrac{1}{2} t^2 \langle v, \nabla^2 c_j(x^*) v \rangle + O(t^3) \\ &\leqq -\tfrac{1}{4} t^2 \alpha_j \leqq 0 \end{aligned}$$

for δ, T sufficiently small, and $t \in [0, T]$.

In the case in which Ω is defined by (1.3), the issue of active set identification consists of finding those indices $j = 1, \cdots, m_I$ for which $c_j(x^*) = 0$, before x^* itself has been identified exactly. This is usually done by checking the sign of the Lagrange multipliers at each iterate x_k, and by finding the linearized constraints from the previous iteration with respect to which x_k is active. Using the general formulation (3.1), we can instead state this issue in terms of finding the face of Ω_* on which x^* lies, and determining whether this face can be "predicted" by the face of $\Omega(x_k)$ on which x_{k+1} lies.

In the subsequent discussion, let Ω_F be the face of Ω_* for which $x^* \in \text{ri}\,(\Omega_F)$. The next results show how the faces of $\Omega(x_k)$ are related to Ω_F.

THEOREM 3.9. *Let $\{x_k\}$ be a sequence of points converging to x^*, with $x_{k+1} \in \Omega(x_k)$, and suppose that the sequence $\{\Omega(x_k)\}$ satisfies Assumptions 3.1. Let Ω_F be the face of Ω_* for which $x^* \in \text{ri}\,(\Omega_F)$. Suppose $\{y_k\}$ and $\{\nu_k\}$ are two sequences such that $y_k \in \Omega(x_k)$. $\nu_k \in N(y_k; \Omega(x_k))$, with $\nu_k \to \nu^* \in N(\Omega_F; \Omega_*)$. Then any accumulation point y^* of $\{y_k\}$ satisfies*

$$y^* \in \Omega_E \overset{\text{def}}{=} \arg\max \{\langle \nu^*, x\rangle \,|\, x \in \Omega_*\} \quad \textit{and} \quad \Omega_F \subset \Omega_E.$$

Proof. Clearly, by the assumptions on ν^* and x^*, the last part of the theorem is true.

By Assumptions 3.1, $y^* \in \Omega_*$. Assume without loss of generality that $y_k \to y^*$. If $y^* \notin \Omega_E$, then there is some point $z \in \Omega_*$ such that

$$\langle \nu^*, z - y^*\rangle > 0.$$

Defining the sequence $z_k = P_{\Omega(x_k)}(z)$, we have that $z_k \to z$, and hence that $\langle \nu^*, z_k - y^*\rangle > 0$ for k sufficiently large. In fact, by continuity, $\langle \nu_k, z_k - y_k\rangle > 0$ for k sufficiently large, which contradicts the assumption that $\nu_k \in N(y_k; \Omega(x_k))$. □

The inclusion $\Omega_F \subset \Omega_E$ can be strict unless Ω_F is quasi-polyhedral and $\nu^* \in \text{ri}\,(N(\Omega_F; \Omega_*))$, as the following result shows.

THEOREM 3.10. *Suppose there is a nonempty quasi-polyhedral face Ω_F of the convex set Ω_* and an element $\nu^* \in N(\Omega_F; \Omega_*)$. Define the face Ω_E as in Theorem 3.7. If $\nu^* \in \text{ri}\,(N(\Omega_F; \Omega_*))$, then $\Omega_E = \Omega_F$; otherwise it is possible that the inclusion $\Omega_F \subset \Omega_E$ is strict.*

Proof. Assume $\nu^* \in \text{ri}\,(N(\Omega_F; \Omega_*))$. We need only prove the inclusion $\Omega_E \subset \Omega_F$. Choosing points $x_0 \in \text{ri}\,(\Omega_F) \subset \Omega_E$ and $x_1 \in \Omega_E$, we have for all $\lambda \in [0, 1]$ that

$$x_\lambda = (1 - \lambda)x_0 + \lambda x_1 \in \Omega_E.$$

Also $\nu^* \in N(\Omega_E; \Omega_*)$, and so

$$P_{\Omega_*}(x_\lambda + \nu^*) = x_\lambda.$$

However, since $x_0 + \nu^* \in \text{int}\,(\Omega_F + N(\Omega_F; \Omega_*))$ (by Theorem 2.8 of Burke and Moré [2]) we have for some small positive λ that

$$x_\lambda + \nu^* \in \text{int}\,(\Omega_F + N(\Omega_F; \Omega_*)).$$

Hence

$$x_\lambda = P_{\Omega_*}(x_\lambda + \nu^*) \in \text{ri}\,(\Omega_F),$$

and so by Definition 2.4, $x_1 \in \Omega_F$, giving the first result.

For the second part, consider the example

$$\Omega_* = \{x \in \mathbb{R}^2 \,|\, x_2 \geqq |x_1|\}, \quad \Omega_F = (0, 0)^T, \quad \nu^* = (1, -1)^T.$$

Then

$$\Omega_E = \{x \in \mathbb{R}^2 \,|\, x_1 \geqq 0,\ x_1 = x_2\}.$$

□

COROLLARY 3.11. *Suppose the assumptions of Theorem* 3.10 *are satisfied, and that* $\{y_k\}$ *and* $\{v_k\}$ *are defined as in Theorem* 3.9 *with* $v^* \in \text{ri}\,(N(\Omega_F; \Omega_*))$. *Then all accumulation points of the sequence* $\{y_k\}$ *lie on* Ω_F. □

The assumption that Ω_F is quasi-polyhedral certainly holds when $\Omega(x_k) = \Lambda(x_k)$ (see (3.3)). Then each $\Omega(x_k)$ is a polyhedron, and hence Ω_* is also polyhedral. In this case *all* faces of Ω_* are quasi-polyhedral.

4. Convergence of SQP methods. Some results concerning the convergence of algorithm (3.1) are presented in this section. For the case of standard nonlinear programming (3.2), the convergence behavior is well known when the active constraint gradients are linearly independent at x^*. Here we establish results for the convergence of $\{x_k\}$ when this is not necessarily true.

It is assumed throughout that x^* is an *isolated local minimizer* of f in Ω_*, that is, there is $R > 0$ such that

$$f(x^*) < f(x) \quad \text{for all } x \in \Omega_* \cap (x^* + RB). \tag{4.1}$$

Convergence results are obtained by comparing the sequence $\{x_k\}$ with a sequence $\{y_k\}$ consisting of local minimizers of f in $\Omega(x_k)$. Lemma 4.1 shows that it is possible to choose the sequence $\{y_k\}$ such that $y_k \to x^*$.

The result makes use of the concept of epiconvergence of a sequence of functions, as discussed by Attouch [1, p. 26]. Briefly, we say that a sequence of functions $\{F_k\}$ is epiconvergent if for all $x \in \mathbb{R}^n$,

$$\sup_{V \in \mathcal{N}(x)} \liminf_k \inf_{u \in V} F_k(u) = \sup_{V \in \mathcal{N}(x)} \limsup_k \inf_{u \in V} F_k(u)$$

where $\mathcal{N}(x)$ is the set of all open neighbourhoods of x in $\mathbb{R}^n$. For $\varepsilon > 0$ we need to define the set

$$\varepsilon - \arg\min G = \{x \mid G(x) \leqq -1/\varepsilon \text{ or } G(x) \leqq \inf_{u \in \mathbb{R}^n} G(u) + \varepsilon\}.$$

The lim sup of a sequence of sets $\{S_k\}$ is defined similarly to Assumption 3.1(ii)(b), that is,

$$\bar{S} = \limsup_k S_k$$

if each $\bar{x} \in \bar{S}$ is an accumulation point of a sequence $\{x_k\}$ with $x_k \in S_k$. Finally, define the indicator function of a set S as

$$\Psi(x \mid S) = \begin{cases} 0, & x \in S, \\ +\infty, & x \notin S. \end{cases}$$

LEMMA 4.1. *Suppose Assumptions* 3.1 *and* 3.2 *are satisfied, and* x^* *is an isolated local minimizer of some twice continuously differentiable function* f *in* Ω_*. *Then there exists a sequence* y_k *such that* $y_k \in \Omega(x_k)$ *is a local minimizer of* f *in* $\Omega(x_k)$, *and* $y_k \to x^*$.

Proof. Let $R \geqq 0$ be chosen to satisfy (4.1). Define a sequence of functions

$$F_k(x) = f(x) + \Psi(x \mid \Omega_R(x_k)) \quad \text{where } \Omega_R(x_k) = \Omega(x_k) \cap (x^* + RB).$$

By Theorem 1.39 of Attouch [1], Kuratowski convergence of the sequence $\{\Omega_R(x_k)\}$ (which follows from our Assumptions 3.1) implies epiconvergence of the corresponding indicator functions. Hence the sequence $\{F_k\}$ is epiconvergent, with a limiting function

$$F_*(x) = f(x) + \Psi(x \mid \Omega_{R^*}) \quad \text{with } \Omega_{R^*} = \Omega_* \cap (x^* + RB).$$

Now Proposition 2.9 of Attouch [1] states that for any positive sequence $\varepsilon_k \downarrow 0$,

$$\limsup_k (\varepsilon_k - \arg\min F_k) \subset \arg\min F_*. \tag{4.2}$$

Since $\Omega_R(x_k)$ is closed, F_k takes on its minimum value at some point $y_k \in \Omega_R(x_R)$, and

$$y_k \in \varepsilon_k - \arg\min F_k.$$

Since $\arg\min F_* = \{x^*\}$, then by (4.2) all accumulation points of $\{y_k\}$ are x^*, and since by definition $y_k \in x^* + RB$ (a closed set) for all k, we have

$$\lim y_k = x^*,$$

as required. □

Each iteration of (3.1) entails the minimization of a quadratic approximation of $f(x)$ over a convex set $\Omega(x_k)$. Since the true minimizer of f on this set is y_k, it seems appropriate to establish a relationship between $\|x_k - y_k\|$ and $\|x_{k+1} - y_k\|$.

THEOREM 4.2. *Suppose $\Omega(x_k) \subset \mathbb{R}^n$ is a convex set and y_k is a local minimizer of a twice continuously differentiable function f in $\Omega(x_k)$. Let x_{k+1} be generated by the algorithm* (3.1). *Suppose Ω_{kF} is the face of $\Omega(x_k)$ for which $y_k \in \operatorname{ri}(\Omega_{kF})$, and that Ω_{kF} is quasi-polyhedral. Then there is a small positive number ε_k such that if*

$$\langle \mu, B_k \mu \rangle \geqq a_k \langle \mu, \mu \rangle \quad \text{for all } \mu \in \operatorname{lin}(T(\Omega_{kF}; \Omega(x_k))) \text{ and some } a_k > 0, \tag{4.3}$$

and $\|x_k - y_k\| \leqq \varepsilon_k$, then $x_{k+1} \in \operatorname{ri}(\Omega_{kF})$.

(*Note.* This result is similar to Theorem 4.1 of Burke and Moré [2]. However, we state a proof below that will be useful in subsequent discussions.)

Proof. We first seek a solution p_k of (3.1) such that $x_{k+1} = x_k + p_k \in \operatorname{aff}(\Omega_{kF})$. Then it is shown that $\|p_k\| = O(\|x_k - y_k\|) = O(\varepsilon_k)$, and hence that $\|x_{k+1} - y_k\| = O(\varepsilon_k)$. Since $y_k \in \operatorname{ri}(\Omega_{kF})$, it then follows that $x_{k+1} \in \operatorname{ri}(\Omega_{kF})$ for ε_k sufficiently small.

Since we are assuming $x_k + p_k \in \operatorname{aff}(\Omega_{kF})$, and since $y_k \in \Omega_{kF} \subset \operatorname{aff}(\Omega_{kF})$, we have

$$\begin{aligned} &\langle x_k + p_k - y_k, \nu \rangle = 0, \\ \Leftrightarrow &\langle p_k, \nu \rangle = \langle y_k - x_k, \nu \rangle \quad \text{for all } \nu \in N(\Omega_{kF}; \Omega(x_k)). \end{aligned} \tag{4.4}$$

Using the optimality conditions for (3.1), we have

$$-\nabla f(x_k) - B_k p_k \in N(\Omega_{kF}; \Omega(x_k)),$$

and hence

$$\langle \nabla f(x_k) + B_k p_k, z_1 - y_k \rangle = 0$$

for all $z_1 \in \operatorname{aff}(\Omega_{kF})$. A similar equation holds for $\nabla f(y_k)$, by the optimality of y_k in $\Omega(x_k)$:

$$\langle \nabla f(y_k), z_1 - y_k \rangle = 0 \quad \text{for all } z_1 \in \operatorname{aff}(\Omega_{kF}).$$

Since Ω_{kF} is quasi-polyhedral,

$$\operatorname{aff}(\Omega_{kF}) = y_k + \operatorname{lin}(T(\Omega_{kF}; \Omega(x_k))),$$

and so, from the two previous equations,

$$\langle B_k p_k, \mu \rangle = \langle \nabla f(y_k) - \nabla f(x_k), \mu \rangle \quad \text{for all } \mu \in \operatorname{lin}(T(\Omega_{kF}; \Omega(x_k))). \tag{4.5}$$

From Theorem 2.5, the vectors ν and μ in (4.4) and (4.5) span $\mathbb{R}^n$. In addition, (4.3) implies that p_k is uniquely determined by (4.4) and (4.5), and from the right-hand sides of these equations we have that

$$\|p_k\| = O(\|x_k - y_k\|).$$

Note that the second-order sufficient conditions for p_k to be a minimizer of (3.1) are satisfied because of (4.3). So we have found $x_{k+1} = x_k + p_k$ such that $x_{k+1} \in \operatorname{aff}(\Omega_{kF})$ and $\|x_{k+1} - y_k\| = O(\|x_k - y_k\|) = O(\varepsilon_k)$. Since $y_k \in \operatorname{ri}(\Omega_{kF})$ and $\operatorname{ri}(\Omega_{kF})$ is the interior of Ω_{kF} relative to $\operatorname{aff}(\Omega_{kF})$, it follows that $x_{k+1} \in \operatorname{ri}(\Omega_{kF})$ for ε_k sufficiently small. □

In the proof above it is not necessary for y_k to be a *nondegenerate* minimizer in $\Omega(x_k)$, nor is it assumed that $x_k \in \Omega(x_k)$.

THEOREM 4.3. *Let f be twice continuously differentiable, and suppose that the sequence $\{x_k\}$ generated by* (3.1) *with $B_k = \nabla^2 f(x_k)$ converges to x^*, an isolated local minimizer of f in Ω_*. Suppose Assumptions* 3.1 *and* 3.2 *are satisfied, and let $\{y_k\}$ be chosen as in Lemma* 4.1, *so that $y_k \to x^*$.*

For some k sufficiently large, assume that the face Ω_{kF} of $\Omega(x_k)$ for which $y_k \in \text{ri}\,(\Omega_{kF})$ is quasi-polyhedral, and that

$$\langle \mu, \nabla^2 f(x^*)\mu\rangle \geqq b_k\langle \mu, \mu\rangle \quad \text{for some } b_k > 0, \text{ and all } \mu \in \text{lin}\,(T(\Omega_{kF}; \Omega(x_k))). \tag{4.6}$$

Then there is $\varepsilon_k > 0$ such that if

$$\|x_k - y_k\| \leqq \varepsilon_k,$$

then

$$x_{k+1} \in \text{ri}\,(\Omega_{kF}) \quad \text{and} \quad \|x_{k+1} - y_k\| = O(\|x_k - y_k\|^2).$$

Proof. Set $a_k = \frac{1}{2}b_k$ and $B_k = \nabla^2 f(x_k)$. Then for k sufficiently large, (4.6) implies (4.3). Hence from Theorem 4.2 there is $\varepsilon_k > 0$ such that $x_k + p_k \in \Omega_{kF}$. Further, from (4.5) with $B_k = \nabla^2 f(x_k)$, we find that

$$\langle \nabla^2 f(x_k)(x_k + p_k - y_k), \mu\rangle = O(\|x_k - y_k\|^2) \quad \text{for all } \mu \in \text{lin}\,(T(\Omega_{kF}; \Omega(x_k))).$$

Combining this with (4.4), we obtain

$$\|x_k + p_k - y_k\| = O(\|x_k - y_k\|^2). \qquad \square$$

The result above follows from the analysis of Newton's method on a convex set (see, for example, Dunn [6], Dunn and Sachs [8], Sachs [14], and the references cited in these sources). It is shown in those papers that conditions other than (4.6) can be used to obtain convergence results. Below, the analysis of Sachs [14] is used to prove a variant of Theorem 4.3 in which the assumption of quasi-polyhedrality of Ω_{kF} is not required, and an alternative to (4.6) is used. We show subsequently that the alternative condition is neither weaker nor stronger than (4.6).

We start by defining a function that gives a measure of the increase of a quadratic approximation to f in a feasible neighbourhood of a given point ξ. Let V be a closed bounded set in $\mathbb{R}^n$ and suppose $\xi \in V$. Define

$$c(\sigma; \xi, V) = \inf_{\substack{\|x-\xi\| \geqq \sigma \\ x \in V}} \langle x - \xi, \nabla f(\xi)\rangle + \tfrac{1}{2}\langle x - \xi, \nabla^2 f(\xi)(x - \xi)\rangle.$$

In the following result we make use of the sets $\Omega_R(x_k)$ and Ω_{R^*}, as defined in the proof of Lemma 4.1, and show how the function $c(\sigma; x^*, \Omega_{R^*})$ is related to a perturbed version $c(\sigma; y_k, \Omega_R(x_k))$. Recall that R is chosen so that x^* is the unique global minimum of f in Ω_{R^*}.

LEMMA 4.4. *Let f be twice continuously differentiable. Suppose Assumptions* 3.1 *and* 3.2 *are satisfied, and that the sequence $\{y_k\}$ is chosen as in Lemma* 4.1. *Define*

$$\mu_1(k) = \max\{\|y_k - x^*\|, \|\nabla f(y_k) - \nabla f(x^*)\|, \|\nabla^2 f(y_k) - \nabla^2 f(x^*)\|\},$$

$$\mu_2(k) = \inf\{r \,|\, \Omega_R(x_k) \subset \Omega_{R^*} + rB\}.$$

Suppose that, for some $a > 0$ and $\alpha \in [2, 3)$,

$$c(\sigma; x^*, \Omega_{R^*}) \geqq a\sigma^\alpha \quad \text{for all } \sigma > 0.$$

Then for each $\bar{a} \in (0, a)$ *and* $\bar{\sigma} > 0$ *there is a* δ *that satisfies* $0 < \delta < \bar{\sigma}$ *such that if* $\mu_1(k) + \mu_2(k) \leqq \delta$ *then*

$$c(\sigma; y_k, \Omega_R(x_k)) \geqq \bar{a}\sigma^\alpha \quad \text{for all } \sigma > \bar{\sigma}.$$

Proof. The proof follows from Theorem 3.1 of [14] and Theorem 1 of [8]. □

LEMMA 4.5. *Suppose the assumptions of Lemma* 4.4 *hold. Then for each* $\bar{a} \in (0, a)$ *and each* $\bar{\sigma} > 0$ *there is an integer* $\bar{K}(\bar{a}, \bar{\sigma})$ *such that for all* $k \geqq \bar{K}(\bar{a}, \bar{\sigma})$,

$$c(\sigma; y_k, \Omega_R(x_k)) \geqq \bar{a}\sigma^\alpha \quad \text{for all } \sigma > \bar{\sigma}.$$

Proof. By Assumption 3.1, $\mu_2(k) \to 0$ as $k \to \infty$, and by the continuity properties of f and the fact that $y_k \to x^*$, also $\mu_1(k) \to 0$ as $k \to \infty$. The result follows from Lemma 4.4 by choosing $\bar{K}(\bar{a}, \bar{\sigma})$ so that $\mu_1(k) + \mu_2(k) \leqq \delta$ for all $k \geqq \bar{K}(\bar{a}, \bar{\sigma})$. □

These results show that, outside of a small ball around y_k, the increase rate of $c(\sigma; y_k, \Omega_R(x_k))$ matches that of $c(\sigma; x^*, \Omega_{R^*})$. Finally we use this fact to find a relationship between $\|x_k - y_k\|$ and $\|x_{k+1} - y_k\|$.

THEOREM 4.6. *Suppose the assumptions of Lemma* 4.4 *hold, and that the sequence* $\{x_k\}$ *is generated by* (3.1) *with* $B_k = \nabla^2 f(x_k)$. *Then for each* $\bar{\sigma} > 0$ *there is an integer* $K(\bar{\sigma})$ *such that for* $k \geqq K(\bar{\sigma})$,

$$\|x_{k+1} - y_k\| \leqq \gamma \|x_k - y_k\|^{2/(\alpha-1)},$$

provided

$$\bar{\sigma} \leqq \|x_k - y_k\| \leqq \varepsilon, \qquad \bar{\sigma} \leqq \|x_{k+1} - y_k\| \tag{4.7}$$

where ε *and* γ *are positive constants that do not depend on* $\bar{\sigma}$.

Proof. Choose $K(\bar{\sigma}) = \bar{K}(a/2, \bar{\sigma})$. Then by Lemma 4.5, $c(\sigma; y_k, \Omega_R(x_k)) \geqq (a/2)\sigma^\alpha$ for all $\sigma > \bar{\sigma}$. The result then follows directly from Theorem 2.3 of [14]. □

The assumption (4.7) may preclude the use of Theorem 4.6 when the convergence of y_k to x^* is slow. This is because, by the conditions of Lemma 4.4,

$$\|x^* - y_k\| \leqq \mu_1(k) \leqq \delta < \bar{\sigma},$$

and so (4.7) certainly cannot apply if

$$\|x_k - y_k\| \leqq \|x^* - y_k\|, \qquad \|x_{k+1} - y_k\| \leqq \|x^* - y_k\|. \tag{4.8}$$

Finally, we give examples to show that the assumptions of Theorems 4.3 and 4.6 are independent.

Example 4.7. (i) The problem

$$\min z_2^4 \quad \text{s.t. } z_2 \geqq z_1, \quad z_2 \geqq -z_1$$

has solution $x^* = (0, 0)^T$. Assume $\Omega(x) = \Lambda(x)$, and so $\Omega(x_k) \equiv \Omega = \{y \mid y_2 \geqq y_1, y_2 \geqq -y_1\}$, and $y_k \equiv 0$. Then $\operatorname{lin}(T(y_k; \Omega(x_k))) = \{(0, 0)^T\}$ for all k. Also $(0, 0)^T$ is a quasi-polyhedral face of $\Omega(x_k)$ and so the conditions of Theorem 4.3 are trivially satisfied. Clearly $\Omega_* = \Omega$ and so from the definition of c,

$$c(\sigma; 0, \Omega_*) = \inf_{\|x\| \geqq \sigma, x \in \Omega_*} \langle \nabla f(0), x \rangle + \tfrac{1}{2}\langle x, \nabla^2 f(0) x \rangle = 0;$$

therefore the conditions of Theorem 4.6 cannot be met.

(ii) Consider

$$\min (-\cos z_2) \quad \text{s.t. } z_2 \geqq |z_1|^{4/3}.$$

The solution is again $x^* = (0, 0)^T$. Define

$$\Omega(z) = \{y \mid y_2 \geqq -z_2^2 + |y_1|^{4/3}\}.$$

Denote the components of the current iterate x_k by $x_{k,1}$ and $x_{k,2}$. The subproblem in (3.1) at x_k with $B_k = \nabla^2 f(x_k)$ is

$$\min_{x_{k+1,2}} (\sin x_{k,2})(x_{k+1,2} - x_{k,2}) + \tfrac{1}{2}(\cos x_{k,2})(x_{k+1,2} - x_{k,2})^2$$

$$\text{s.t.} \quad x_{k+1,2} \geqq -x_{k,2}^2 + |x_{k+1,1}|^{4/3}.$$

So if we set $x_{0,1} = 0$, $x_{0,2}$ small, the sequence generated by (3.1) satisfies

$$x_{k+1,1} = 0, \qquad x_{k+1,2} \approx -\tfrac{1}{3}x_{k,2}^3.$$

Also $x^* = (0, 0)^T$ is always feasible, and so we can choose $y_k \equiv (0, 0)^T$. Then $\operatorname{lin}(T(y_k; \Omega(x_k))) = \mathbb{R}^n$, but clearly (4.6) is not satisfied. However, since $\Omega(x_k) \to \Omega(0) = \Omega$, Assumption 3.1 holds. Also c is defined by

$$c(\sigma; 0, \Omega) = \inf_{\substack{\|x\| \geqq \sigma \\ x \in \Omega}} \tfrac{1}{2} z_2^2.$$

The infimum is clearly attained when $z_2 = |z_1|^{4/3}$, and $z_1^2 + z_2^2 = \sigma^2$; hence

$$z_1^2 + |z_1|^{8/3} = \sigma^2 \Rightarrow |z_1| \approx \sigma \quad \text{for small } \sigma.$$

Hence

$$c(\sigma; 0, \Omega) \approx \tfrac{1}{2}\sigma^{8/3},$$

and so the condition on c can be satisfied for some choice of $a > 0$, $\alpha \in (2, 3)$, $R > 0$. Also note that for the sequence generated above, $\|x^* - y_k\| \equiv 0$, and so no problems of form (4.8) arise. Hence the conditions of Theorem 4.6 hold.

5. Discussion. The weakness of the assumptions on the sequence of sets $\Omega(x_k)$ (Assumptions 3.1) gives rise to consideration of some alternatives to the standard choice $\Lambda(x_k)$, which is often used in algorithms for problem (1.1)-(1.3). For instance, instead of forcing a linearized equality constraint to hold exactly, as in

$$\langle z - x_k, \nabla e_i(x_k) \rangle + e_i(x_k) = 0,$$

we could instead allow some "slack," as in

$$\langle z - x_k, \nabla e_i(x_k) \rangle + e_i(x_k) \geqq -\eta_{ik}, \qquad \langle z - x_k, \nabla e_i(x_k) \rangle + e_i(x_k) \leqq \eta_{ik}$$

where $\eta_{ik} \geqq 0$ and $\eta_{ik} \to 0$ as $k \to \infty$. If $\eta_{ik} = \tau_k |e_i(x_k)|$ with $\tau_k \in (0, 1)$, then (5.1) is enforcing a "linearized reduction" in e_i. Similarly, we may allow some "slack" in the linearized inequalities, as in

$$\langle z - x_k, \nabla c_j(x_k) \rangle + c_j(x_k) \geqq -\bar{\eta}_{jk}$$

where $\bar{\eta}_{jk} \geqq 0$ with $\bar{\eta}_{jk} \to 0$ as $k \to \infty$.

The use of an active set strategy, in which $\Omega(x_k)$ is defined as

$$\Omega(x_k) = \left\{ z \,\middle|\, \begin{array}{ll} \langle z - x_k, \nabla c_j(x_k) \rangle + c_j(x_k) = 0, & j \in \mathcal{A}_k \\ \langle z - x_k, \nabla e_i(x_k) \rangle + e_i(x_k) = 0, & i = 1, \cdots, m_E \end{array} \right.,$$

also satisfies Assumption 3.1, provided that the sequence of active sets $\mathcal{A}_k$ only changes finitely often. In a similar vein we could use the definition

$$\Omega(x_k) = \left\{ z \,\middle|\, \begin{array}{ll} \langle z - x_k, \nabla c_j(x_k) \rangle + c_j(x_k) \geqq 0, & j \in \bar{\mathcal{A}}_k \\ \langle z - x_k, \nabla e_i(x_k) \rangle + e_i(x_k) = 0, & i = 1, \cdots, m_E \end{array} \right.$$

where $\bar{\mathcal{A}}_k \subset \{1, \cdots, m_I\}$ excludes those constraints that obviously will not be active at x^* (thereby saving the cost of evaluating these constraints and their gradients).

The case in which $\nabla c_j(x_k)$ and $\nabla e_i(x_k)$ are *approximated* rather than calculated exactly is also covered, provided that the approximations are asymptotically exact as $k \to \infty$. For example, to avoid recalculation of ∇e_i and ∇c_j at every step, the same values might be used for more than one iteration. Finite-difference approximations might also be considered where appropriate.

A final possibility is the use of a trust region bound on the step size at each iteration, as in

$$\Omega(x_k) = \Lambda(x_k) \cap (x_k + R_k B)$$

where $R_k > 0$. It is clear that $\Omega(x_k)$ may be empty if R_k is too small and $x_k \notin \Omega(x_k)$. Hence in Vardi [16] this is combined with the use of slackness in the equality constraints of the form

$$\langle z - x_k, \nabla e_i(x_k) \rangle + \alpha e_i(x_k) = 0$$

where $\alpha \in (0, 1]$, to produce a globally convergent SQP method. This overall strategy is also covered by our earlier analysis.

Acknowledgment. I wish to acknowledge the detailed comments of a referee which greatly improved the paper.

THE REGULAR FREE-ENDPOINT LINEAR QUADRATIC PROBLEM WITH INDEFINITE COST*

HARRY L. TRENTELMAN†

Abstract. This paper studies an open problem in the context of linear quadratic optimal control, the free-endpoint regular linear quadratic problem with *indefinite* cost functional. It is shown that the optimal cost for this problem is given by a particular solution of the algebraic Riccati equation. This solution is characterized in terms of the geometry on the lattice of all real symmetric solutions of the algebraic Riccati equation as developed by Willems [*IEEE Trans. Automat. Control*, 16 (1971), pp. 621-634] and Coppel [*Bull. Austral. Math. Soc.*, 10 (1974), pp. 377-401]. A necessary and sufficient condition is established for the existence of optimal controls. This condition is stated in terms of a subspace inclusion involving the extremal solutions of the algebraic Riccati equation. The optimal controls are shown to be generated by a feedback control law. Finally, the results obtained are compared with "classical" results on the linear quadratic regulator problem.

Key words. linear quadratic optimal control, indefinite cost functional, free-endpoint problem

AMS(MOS) subject classifications. 93C05, 93C35, 93C60

1. Introduction. In this paper we are concerned with regular, infinite-horizon linear quadratic optimal control problems in which the cost functional is the integral of an *indefinite* quadratic form.

In most of the existing literature on the regular linear quadratic (LQ) problem, it is explicitly assumed that the quadratic form in the cost functional, apart from being positive definite in the control variable alone, is positive semidefinite in the control and state variables simultaneously. In fact, under this semidefiniteness assumption the LQ problem has become quite standard and is treated in many basic textbooks in the field of systems and control [1], [2], [9], [21]. Often a distinction is made between two versions of the problem, the *fixed-endpoint* version and the *free-endpoint* version. In the fixed-endpoint version it is necessary to minimize the cost functional under the constraint that the optimal state trajectory should converge to zero as time tends to infinity, while in the free-endpoint version it is only necessary to minimize the cost functional. For the case that the quadratic form in the cost functional is positive semidefinite both versions of the regular LQ problem are well-understood and completely satisfactory solutions of these problems are available.

Surprisingly, however, for the most general formulation of the regular LQ problem, that is, the case that the quadratic form in the cost functional is indefinite, a satisfactory treatment does not yet exist. In this case we can again distinguish between the fixed-endpoint version and the free-endpoint version. While for the fixed-endpoint version a complete solution has been described in [17] (see also [14]), the free-endpoint version has only been considered in [17] under a very restrictive assumption. Thus we see that, up to now, the free-endpoint regular LQ problem with indefinite cost functional has been an open problem. In the present paper we shall fill up this gap and present a fairly complete solution to this problem.

It is well known [12], [19] that for the free-endpoint regular LQ problem with positive semidefinite cost functional, the optimal cost is given by the smallest positive semidefinite real symmetric solution of the algebraic Riccati equation. We will see that this statement is no longer valid in general if the cost functional is the integral of an

* Received by the editors November 2, 1987; accepted for publication (in revised form) March 28, 1988.
† Department of Mathematics and Computer Science, Eindhoven University of Technology, 5600 MB Eindhoven, the Netherlands.

indefinite quadratic form. It will be shown, however, that in this case also the optimal cost is given by a solution of the algebraic Riccati equation. This particular solution will be characterized in terms of the geometry on the set of all real symmetric solutions of the algebraic Riccati equation as described in [17] and [4].

Another well-known fact is that, for the free-endpoint regular LQ problem with positive semidefinite cost functional, the *existence* of optimal controls is never an issue: under the assumption that the underlying system is controllable, for this problem unique optimal controls always exist for all initial conditions. This is in contrast with the fixed-endpoint LQ problem, where the existence of optimal controls for all initial conditions depends on the "gap" of the algebraic Riccati equation (i.e., the difference between the largest and smallest solutions of the Riccati equation). In this paper we will see that also, for the free-endpoint regular LQ problem with *indefinite* cost functional, optimal controls no longer need to exist for all initial conditions! Moreover, we will establish a necessary and sufficient condition in terms of the "gap" of the algebraic Riccati equation for the existence of optimal controls for all initial conditions. We will show that for the particular case that the cost functional is positive semidefinite this condition is always satisfied, thus explaining the fact that in this special case optimal controls always exist. Finally, we will show that also in the indefinite case the optimal controls for the free-endpoint regular LQ problem, if they exist, are given by a feedback control law.

The outline of this paper is as follows. In the remainder of this section we will introduce most of the notational conventions that will be used. In § 2 we give formulations of both the free-endpoint and fixed-endpoint regular LQ problems that we shall be dealing with. In § 3 we will briefly recall the most important facts that we need on the geometry of the set of all real symmetric solutions to the algebraic Riccati equation as developed in [17] and [4]. In § 4 we will state the solution to the fixed endpoint regular LQ problem with indefinite cost as established in [17]. Also, we will state its (incomplete) counterpart, the solution to the free-endpoint regular LQ problem with positive semidefinite cost functional. Then in § 5 we will state and prove our main theorem, a solution to the free-endpoint regular LQ problem. In order to establish a proof of this theorem we will state and prove a series of smaller lemmas. In § 6 we will show how the "classical" results on the free-endpoint regular LQ problem with positive semidefinite cost functional can be reobtained as a special case of our general solution. We will close this paper in § 7 with some concluding remarks.

We use the following notational conventions. For a given $n \times n$ matrix A its set of eigenvalues will be denoted by $\sigma(A)$. If V is a subspace of $\mathbb{R}^n$ and A is an $n \times n$ matrix then $A|V$ will denote the restriction of A to V. V will be called A-invariant if $AV \subset V$. In this case $\sigma(A|V)$ will denote the set of eigenvalues of $A|V$ and $\sigma(A|\mathbb{R}^n/V)$ will denote the set of eigenvalues of the mapping induced by A in the factor space $\mathbb{R}^n/V$ (see [21]). We will denote subsets of $\mathbb{C}$ by $\mathbb{C}^- := \{s \in \mathbb{C} | \operatorname{Re} s = 0\}$, $\mathbb{C}^0 := \{s \in \mathbb{C} | \operatorname{Re} s = 0\}$, and $\mathbb{C}^+ := \{s \in \mathbb{C} | \operatorname{Re} s > 0\}$. Given a real monic polynomial p there is a unique factorization $p = p_- \cdot p_0 \cdot p_+$ into real monic polynomials with p_-, p_0, and p_+ having all roots in $\mathbb{C}^-$, $\mathbb{C}^0$, and $\mathbb{C}^+$, respectively. If A is a real $n \times n$ matrix and if p denotes its characteristic polynomial then we define $X^-(A) := \ker p_-(A)$, $X^0(A) := \ker p_0(A)$, and $X^+(A) := \ker p_+(A)$. These subspaces are A-invariant and the restriction of A to $X^-(A)(X^0(A), X^+(A))$ has characteristic polynomial $p_-(p_0, p_+)$.

A subset $\mathbb{C}_g$ of $\mathbb{C}$ will be called symmetric if $a + bi \in \mathbb{C}_g \Leftrightarrow a - bi \in \mathbb{C}_g$. If $\mathbb{C}_g$ is given then we define $\mathbb{C}_b := \mathbb{C} \backslash \mathbb{C}_g$. If A is a real $n \times n$ matrix and if p is its characteristic polynomial then, again, p can be factored uniquely into $p = p_g \cdot p_b$, where p_g and p_b are real monic polynomials with all roots in $\mathbb{C}_g$ and $\mathbb{C}_b$, respectively. We denote

$X_g(A) := \ker p_g(A)$ and $X_b(A) := \ker p_b(A)$. Again these subspaces are A-invariant and the restriction of A to $X_g(A)(X_b(A))$ has characteristic polynomial $p_g(p_b)$. In fact, the subspace $X_g(A)(X_b(A))$ is equal to the linear span of all generalized eigenvectors of A corresponding to its eigenvalues in $\mathbb{C}_g(\mathbb{C}_b)$. Alternatively, $X_g(A)(X_b(A))$ is equal to the largest A-invariant subspace V of $\mathbb{R}^n$ such that $\sigma(A|V) \subset \mathbb{C}_g(\mathbb{C}_b)$.

If, in addition to A, a real $p \times n$ matrix C is given, then we denote

$$\langle \ker C|A\rangle := \bigcap_{i=1}^{n} \ker CA^{i-1},$$

the unobservable subspace of (C, A) [21, § 3.2]. Given a symmetric subset $\mathbb{C}_g$ of $\mathbb{C}$ we denote

$$X_{\text{det}} := \langle \ker C|A\rangle \cap X_b(A),$$

the undetectable subspace of (C, A) with respect to $\mathbb{C}_g$. The pair (C, A) is called detectable with respect to $\mathbb{C}_g$ if A is $(\mathbb{C}_{g-})$ stable on the unobservable subspace of (C, A), i.e., if

$$\langle \ker C|A\rangle \subset X_g(A)$$

(see [21, § 3.6]). It is easy to see that (C, A) is detectable if and only if $X_{\text{det}} = 0$. Also, (C, A) is detectable if and only if for all $\lambda \in \mathbb{C}_b$ we have $\ker (A - \lambda I) \cap \ker C = 0$ (see [15]).

In order to be rigorous on the interpretation of the cost functionals that will be considered in this paper, we will now explain what we mean by the statement that the limit of a function *exists in* $\mathbb{R}^e$. Let $\mathbb{R}^e := \mathbb{R} \cup \{-\infty, +\infty\}$. Given $f: \mathbb{R} \to \mathbb{R}$ we say that $\lim_{t\to\infty} f(t)$ exists if it is equal to a real number in the usual sense. We say that $\lim_{t\to\infty} f(t) = -\infty(+\infty)$ if for all $r \in \mathbb{R}$ there exists $T \in \mathbb{R}$ such that $t \geqq T$ implies $f(t) \leqq r(\geqq r)$. Then we say that $\lim_{t\to\infty} f(t)$ exists in $\mathbb{R}^e$ if it exists, is equal to $-\infty$, or is equal to $+\infty$.

If M is a real $n \times n$ matrix and V is a subspace of $\mathbb{R}^n$, then we define $M^{-1}V := \{x \in \mathbb{R}^n | Mx \in V\}$. If V is a subspace of $\mathbb{R}^n$ then $V^\perp$ denotes its orthogonal complement with respect to the standard Euclidean inner product.

Finally, we will denote by $L_{2,\text{loc}}(\mathbb{R}^+)$ the space of all measurable vector-valued functions on $\mathbb{R}^+$ that are square integrable over all finite intervals in $\mathbb{R}^+$. $L_2(\mathbb{R}^+)$ denotes the space of all measurable vector-valued functions on $\mathbb{R}^+$ that are square integrable over $\mathbb{R}^+$. Finally, $L_\infty(\mathbb{R}^+)$ denotes the space of all measurable vector-valued functions on $\mathbb{R}^+$ that are essentially bounded on $\mathbb{R}^+$. Here, $\mathbb{R}^+ := \{t \in \mathbb{R} | t \geqq 0\}$.

2. The regular LQ-problem. Consider the finite-dimensional linear time-invariant system

$$\dot{x} = Ax + Bu, \qquad x(0) = x_0. \tag{2.1}$$

Here, x and u are assumed to take their values in $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively. A and B are real $n \times n$ and $n \times m$ matrices, respectively. It will be a standing assumption that (A, B) is controllable. We shall consider optimization problems of the type

$$\inf \int_0^\infty \omega(x, u)\, dt, \tag{2.2}$$

where $\omega(x, u)$ is a real quadratic form on $\mathbb{R}^n \times \mathbb{R}^m$ defined by $\omega(x, u) := u^T R u + 2u^T S x + x^T Q x$. Here R, S, and Q are assumed to be real matrices such that $R = R^T$ and $Q = Q^T$. As in [17], no a priori definiteness conditions are imposed on

the form ω. For a given control function $u \in L_{2,\mathrm{loc}}(\mathbb{R}^+)$, let $x(x_0, u)$ denote the state trajectory of (2.1) and if $T \geqq 0$ let

$$J_T(x_0, u) := \int_0^T \omega(x(x_0, u)(t), u(t))\, dt.$$

We now explain how (2.2) should be interpreted. First, we specify two classes of control functions with respect to which the infimization in (2.2) should be performed. Define

$$U(x_0) := \{u \in L_{2,\mathrm{loc}}(\mathbb{R}^+) \mid \lim_{T\to\infty} J_T(x_0, u) \text{ exists in } \mathbb{R}^e\},$$

$$U_s(x_0) := \{u \in U(x_0) \mid \lim_{t\to\infty} x(x_0, u)(t) = 0\}.$$

Note that, due to the assumption that (A, B) is controllable, we have $U(x_0) \neq \varnothing$ and $U_s(x_0) \neq \varnothing$ for all $x_0 \in \mathbb{R}^n$. For $u \in U(x_0)$ we define

$$J(x_0, u) := \lim_{T\to\infty} J_T(x_0, u). \tag{2.3}$$

We note that $J(x_0, u) \in \mathbb{R}^e$. Now, define

$$V_f^+(x_0) := \inf\{J(x_0, u) \mid u \in U(x_0)\}, \tag{2.4a}$$

$$V^+(x_0) := \inf\{J(x_0, u) \mid u \in U_s(x_0)\}, \tag{2.4b}$$

the optimal cost for the free-endpoint problem and fixed-endpoint problem, respectively. By the fact that (A, B) is controllable we have that $V_f^+(x_0)$, $V^+(x_0) \in \mathbb{R} \cup \{-\infty\}$ for all $x_0 \in \mathbb{R}^n$. Following [17], we want to exclude the situation that for certain initial conditions x_0 the values (2.4a) or (2.4b) become equal to $-\infty$. It can be shown that a necessary condition for $V_f^+(x_0) > -\infty$ and $V^+(x_0) > -\infty$ for all x_0 to hold is that $R \geqq 0$ (see [17], [12]). In this paper a standing assumption will be that $R > 0$. Under this assumption the LQ problems defined by (2.4) are called *regular.*

The fixed-endpoint regular LQ problem, defined by (2.4b), was completely resolved in [17] (see also [14]). There, a satisfactory characterization was given for the optimal cost, necessary and sufficient conditions were given for the existence of optimal controls for all initial conditions, and these optimal controls were given in the form of a state-feedback control law. The problems of how to calculate the optimal cost for the free-endpoint regular LQ problem (2.4a), to state necessary and sufficient conditions for the existence of optimal controls, and to calculate these optimal controls have up to now been open. In this paper we will consider these problems.

3. Geometry of the algebraic Riccati equation. A central role in infinite horizon regular linear quadratic control problems is played by the algebraic Riccati equation (ARE)

$$A^TK + KA + Q - (KB + S^T)R^{-1}(B^TK + S) = 0. \tag{3.1}$$

Let Γ denote the set of all real symmetric solutions of the ARE. It was shown in [17] that if Γ is nonempty then it contains a unique element K^+ and a unique element K^- such that

$$\sigma(A - BR^{-1}(B^TK^+ + S)) \subset \mathbb{C}^- \cup \mathbb{C}^0,$$

$$\sigma(A - BR^{-1}(B^TK^- + S)) \subset \mathbb{C}^+ \cup \mathbb{C}^0.$$

Moreover, K^+ and K^- have the additional property that they are the *extremal solutions* of the ARE in the sense that if $K \in \Gamma$ then $K^- \leqq K \leqq K^+$.

Let $\Delta := K^+ - K^-$. Denote $A - BR^{-1}(B^TK^+ + S)$ and $A - BR^{-1}(B^TK^- + S)$ by A^+ and A^-, respectively. If $K \in \Gamma$ define $A_K := A - BR^{-1}(B^TK + S)$. Note that $X^+(A^+) = 0$ and $X^-(A^-) = 0$. Let Ω denote the set of all A^--invariant subspaces contained in $X^+(A^-)$. The following basic theorem is a generalization by Coppel [4] of a theorem that was originally proven by Willems in [17] (see also [16], [10]).

THEOREM 3.1. *Let (A, B) be controllable, and assume that Γ is nonempty. If V is an A^--invariant subspace of $X^+(A^-)$ (that is, if $V \in \Omega$) then $\mathbb{R}^n = V \oplus \Delta^{-1}V^\perp$. There exists a bijection $\gamma : \Omega \to \Gamma$ defined by*

$$\gamma(V) := K^-P_V + K^+(I - P_V),$$

where P_V is the projector onto V along $\Delta^{-1}V^\perp$. If $K = \gamma(V)$ then

$$X^+(A_K) = V,$$

$$X^0(A_K) = \ker \Delta,$$

$$X^-(A_K) = X^-(A^+) \cap \Delta^{-1}V^\perp.$$

Among other things, the result above states that there exists a one-to-one correspondence between the set of all real symmetric solutions of the ARE and the set of all A^--invariant subspaces of $X^+(A^-)$. Following [3], if $K = \gamma(V)$ then we will say that *the solution K is supported by the subspace V.* The next theorem from [4] states that this one-to-one correspondence in fact respects the partial orderings on the sets Γ and Ω.

THEOREM 3.2. *Let (A, B) be controllable and assume that Γ is nonempty. Let K_1 and K_2 be solutions to the* ARE *supported by V_1 and V_2, respectively. Then $K_1 \leqq K_2$ if and only if $V_2 \subset V_1$.*

From the above it follows, for example, that K^- is supported by $X^+(A^-)$ and that K^+ is supported by 0.

4. Classical results. In the present section we briefly summarize the solution of the fixed-endpoint regular LQ problem with indefinite cost functional as outlined in [17]. Subsequently, we will state the well-known result on the free-endpoint regular LQ problem with *positive semidefinite* cost functional. Finally, we will discuss some of the difficulties that can be expected in trying to generalize the latter result to the case that the semidefiniteness assumption is dropped.

Consider the infimization of (2.3) over the class of inputs $U_s(x_0)$. For a given x_0 an input u^* is called *optimal* if $u^* \in U_s(x_0)$ and $J(x_0, u^*) = V^+(x_0)$. The following was proven in [17].

THEOREM 4.1. *Let (A, B) be controllable and assume that $R > 0$. Then we have the following:*

(i) *$V^+(x_0)$ is finite for all $x_0 \in \mathbb{R}^n$ if and only if the* ARE *has a real symmetric solution (i.e., $\Gamma \neq \varnothing$).*

(ii) *If $\Gamma \neq \varnothing$ then for all $x_0 \in \mathbb{R}^n$, $V^+(x_0) = x_0^TK^+x_0$.*

(iii) *If $\Gamma \neq \varnothing$ then for all $x_0 \in \mathbb{R}^n$ there exists an optimal input u^* if and only if $\Delta > 0$.*

(iv) *If $\Gamma \neq \varnothing$ and $\Delta > 0$ then for each $x_0 \in \mathbb{R}^n$ there is exactly one optimal input u^* and, moreover, this input u^* is given by the feedback control law $u^* = -R^{-1}(B^TK^+ + S)x$.*

As already mentioned, an analogue of the latter theorem for the free-endpoint case, up to now, has only been available for the case that the quadratic form $\omega(x, u)$ is positive semidefinite, i.e., for the case that $\omega(x, u) \geqq 0$ for all $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$. In the sequel, let $\Gamma_+ := \{K \in \Gamma \mid K \geqq 0\}$. It is well known [8], [12] that if $\omega \geqq 0$ and if (A, B) is

controllable, then the ARE has a smallest positive semidefinite real symmetric solution. More precisely, there exists a (unique) $\tilde{K}$ such that

$$\tilde{K} \in \Gamma_+, \tag{4.1}$$

$$K \in \Gamma_+ \Rightarrow \tilde{K} \leqq K. \tag{4.2}$$

The solution $\tilde{K}$ characterized by (4.1) and (4.2) plays the central role in the solution of the free-endpoint regular LQ problem with positive semidefinite cost. In the following, for a given $x_0 \in \mathbb{R}^n$ an input u^* is called *optimal* if $u^* \in U(x_0)$ and $J(x_0, u^*) = V_f^+(x_0)$.

THEOREM 4.2. *Assume that (A, B) is controllable, that $R > 0$, and that $\omega(x, u) \geqq 0$ for all $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$. Then we have the following*:

(i) *For all $x_0 \in \mathbb{R}^n$, $V_f^+(x_0) = x_0^T \tilde{K} x_0$.*

(ii) *For each $x_0 \in \mathbb{R}^n$, there is exactly one optimal input u^*, and moreover, this input u^* is given by the feedback control law $u^* = -R^{-1}(B^T\tilde{K} + S)x$.*

Proof. This follows, for example, by combining [12, Thm. 8] and the results from [1, p. 36] (see also [19]). □

We note that in this theorem the *existence* of optimal controls is no issue. In contrast with the fixed-endpoint problem, the positive semidefiniteness assumption assures that in the free-endpoint problem for every initial condition there exists an optimal control.

In trying to generalize the latter theorem to the case that ω is an arbitrary indefinite quadratic form in (x, u) (with of course, as usual, $R > 0$), the following aspects should be considered. First, due to the indefiniteness of ω, the optimal cost $V_f^+(x_0)$ no longer needs to be finite. In this paper we want to restrict ourselves to the case that $V_f^+(x_0)$ is finite for all x_0. In order to establish a condition assuring this, we state the following well-known result. For $\nu \in \mathbb{R}^m$, denote $\|\nu\|_R^2 := \nu^T R \nu$.

LEMMA 4.3. *Let $K \in \Gamma$. Then for all $u \in L_{2,\mathrm{loc}}(\mathbb{R}^+)$ and for all $T \geqq 0$, we have*

$$J_T(x_0, u) = \int_0^T \|u(t) + R^{-1}(B^T K + S)x(t)\|_R^2 \, dt + x_0^T K x_0 - x^T(T) K x(T).$$

Here, we have denoted $x(t) := x(x_0, u)(t)$.

Proof. For a proof, refer to [2] or [17]. □

In the sequel, let $\Gamma_- := \{K \in \Gamma \mid K \leqq 0\}$. From the previous lemma the following is immediate.

LEMMA 4.4. *Let (A, B) be controllable and $R > 0$. If $\Gamma_- \neq \emptyset$ then $V_f^+(x_0)$ is finite for all $x_0 \in \mathbb{R}^n$.*

Proof. $\Gamma_- \neq \emptyset$ implies that $K^- \leqq 0$. Applying the previous lemma to K^- yields $J_T(x_0, u) \geqq x_0^T K^- x_0$ for all u and $T \geqq 0$. □

Remark 4.5. In [17] it is suggested that the converse of the above lemma also holds, i.e., that finiteness of $V_f^+(x_0)$ for all x_0 implies that $\Gamma_- \neq \emptyset$. We were able neither to establish a proof nor to construct a counterexample to this assertion. We were, however, able to relate the condition $\Gamma_- \neq \emptyset$ to an equivalent one in terms of the quantities $J_T(x_0, u)$ in a slightly different way. Indeed, if (A, B) is controllable and $R > 0$ then the following equivalence can be proven:

$$\Gamma_- \neq \emptyset \Leftrightarrow \inf\{\liminf_{T \to \infty} J_T(x_0, u) \mid u \in L_{2,\mathrm{loc}}(\mathbb{R}^+)\} \text{ is finite for all } x_0 \in \mathbb{R}^n. \tag{4.3}$$

Note that if we could prove the above equivalence with $L_{2,\mathrm{loc}}(\mathbb{R}^+)$ replaced by $U(x_0)$ we would be done. Indeed, for $u \in U(x_0)$ we have $\liminf_{T\to\infty} J_T(x_0, u) = \lim_{T\to\infty} J_T(x_0, u) = J(x_0, u)$, so the infimum in (4.3) would then be equal to $V_f^+(x_0)$. We close this remark by concluding that finding tractable necessary and sufficient

conditions for the finiteness of V_f^+ remains a difficult open problem (see also [18], [11], and [13]).

A final point we want to make here is that for the free-endpoint problem with indefinite cost, even if the optimal cost is finite for all initial conditions, it is not true in general that optimal controls *exist* for all initial conditions. We will illustrate this in the example below. It should therefore be clear that part of our problem is to formulate necessary and sufficient conditions for the existence of these optimal controls (as was also done in Theorem 4.1(iii)).

Example 4.6. Consider the controllable system $\dot{x} = -x + u$, $x(0) = x_0$ with indefinite cost functional

$$J(x_0, u) = \int_0^\infty -x(t)^2 + u(t)^2 \, dt,$$

that is, take $A = -1$, $B = 1$, $Q = -1$, $S = 0$, and $R = 1$. The corresponding ARE is given by $-2K - K^2 - 1 = 0$. Consequently, $K^- = K^+ = -1$. We claim that $V_f^+(x_0) = -x_0^2$. We will show this "from first principles." Let $u \in L_{2,\mathrm{loc}}(\mathbb{R}^+)$. For every $T \geqq 0$ we have

$$\begin{aligned}\int_0^T -x^2 + u^2 \, dt &= \int_0^T (x-u)^2 \, dt + 2\int_0^T x(-x+u) \, dt \\ &= \int_0^T (x-u)^2 \, dt + 2\int_0^T x\dot{x} \, dt = \int_0^T (x-u)^2 \, dt + x^2(T) - x_0^2.\end{aligned}$$

Consequently, $J(x_0, u) \geqq -x_0^2$ for all $u \in U(x_0)$. On the other hand, for $\varepsilon > 0$ define $u = (1-\varepsilon)x$. Then $\dot{x} = -\varepsilon x$ and

$$J(x_0, u) = [(1-\varepsilon)^2 - 1]x_0^2 \int_0^\infty e^{-2\varepsilon t} \, dt = -x_0^2 + \frac{\varepsilon}{2} x_0^2.$$

It follows that $V_f^+(x_0) = \inf\{J(x_0, u) | u \in U(x_0)\} = -x_0^2$. Thus, we see that the optimal cost is finite (as could also be deduced from the fact that $K^- = -1 \leqq 0$). We claim, however, that *no optimal control exists*! Indeed, assume u^* is optimal. Let x^* be the corresponding trajectory. We have

$$-x_0^2 = J(x_0, u^*) = -x_0^2 + \lim_{T\to\infty} \left(\int_0^T (x^* - u^*)^2 \, dt + x^*(T)^2 \right).$$

From this it follows that $\int_0^\infty (x^* - u^*)^2 \, dt = 0$ and that, consequently, $u^* = x^*$. However, using this feedback control law yields $J(x_0, u^*) = 0$. If $x_0 \neq 0$ this yields a contradiction.

5. The free-endpoint regular LQ-problem with indefinite cost. In this section we will resolve the free-endpoint version of the regular LQ problem with indefinite cost functional. In the sequel, an important role will be played by the subspace

$$N := \langle \ker K^- | A^- \rangle \cap X^+(A^-). \tag{5.1}$$

By definition of A^- it is immediately clear that, in fact,

$$N = \langle \ker K^- | A - BR^{-1}S \rangle \cap X^+(A - BR^{-1}S). \tag{5.2}$$

Obviously, N is equal to the undetectable subspace of (K^-, A^-) with respect to the stability set $\mathbb{C}_g = \mathbb{C}^- \cup \mathbb{C}^0$. We also note that N is an A^--invariant subspace of $X^+(A^-)$. By Theorem 3.1, N corresponds to a real symmetric solution $\gamma(N)$ of the ARE. Let P_N be the projector onto N along $\Delta^{-1}N^\perp$. Then this solution $\gamma(N)$ is given by

$$K_f^+ := \gamma(N) = K^- P_N + K^+(I - P_N). \tag{5.3}$$

It will turn out that K_f^+, the solution of the ARE supported by the subspace N, is the bottleneck in the problem we want to resolve. We will show that the optimal cost for the free-endpoint problem is obtained from K_f^+ and that the optimal controls, if they exist, are given by the feedback control law $u = -R^{-1}(B^T K_f^+ + S)x$. Before stating the exact result we first give an intuitive argument as to exactly why the subspace N given by (5.1) is the "right" supporting subspace. The argument is as follows. First recall that if $\omega \geqq 0$, then the optimal cost for the free-endpoint problem is obtained from the smallest positive semidefinite solution of the ARE (see Theorem 4.2). Now, it can be shown that, again if $\omega \geqq 0$, $K = \gamma(V)$ is positive semidefinite if and only if $V \subset \ker K^-$ (see Theorem 6.2). Consequently, if $\omega \geqq 0$ then the optimal cost is obtained from the smallest solution $K = \gamma(V)$ of the ARE such that $V \subset \ker K^-$. Now, our choice to consider exactly the subspace N given by (5.1) is based on the guess that the latter statement is also valid if ω is indefinite. Note that K_f^+ is indeed the smallest solution of ARE for which its supporting subspace is contained in $\ker K^-$: if $K = \gamma(V)$ is such that $V \subset \ker K^-$ then, since V is A^--invariant, we must have $V \subset \langle \ker K^- | A^- \rangle$ (the latter being the largest A^--invariant subspace in $\ker K^-$). Also, $V \subset X^+(A^-)$. Thus, $V \subset N$. Then it follows from Theorem 3.2 that $K_f^+ \leqq K$. The following theorem is the main result of this paper.

THEOREM 5.1. *Let (A, B) be controllable and assume that $R > 0$. Then we have the following:*

(i) *$V_f^+(x_0)$ is finite for all $x_0 \in \mathbb{R}^n$ if the* ARE *has a negative semidefinite real symmetric solution (i.e., $\Gamma_- \neq \varnothing$).*

(ii) *If $\Gamma_- \neq \varnothing$ then for all $x_0 \in \mathbb{R}^n$, $V_f^+(x_0) = x_0^T K_f^+ x_0$.*

(iii) *If $\Gamma_- \neq \varnothing$ then for all $x_0 \in \mathbb{R}^n$ there exists an optimal input u^* if and only if $\ker \Delta \subset \ker K^-$.*

(iv) *If $\Gamma_- \neq \varnothing$ and if $\ker \Delta \subset \ker K^-$, then for each $x_0 \in \mathbb{R}^n$ there is exactly one optimal input u^* and, moreover, this input is given by the feedback control law $u^* = -R^{-1}(B^T K_f^+ + S)x$.*

In the remainder of this section we will establish a proof of this theorem. In order to streamline this proof, we will state some of the most important ingredients as separate lemmas. In the first two lemmas, we will formulate some general structural properties of linear systems.

LEMMA 5.2. *Consider the system $\dot{x} = Ax + v$, $y = Cx$. Assume that (C, A) is observable. Let $v \in L_2(\mathbb{R}^+)$, $y \in L_\infty(\mathbb{R}^+)$. Then for every initial condition x_0 we have $x \in L_\infty(\mathbb{R}^+)$.*

Proof. Since (C, A) is observable there exists a matrix L such that $\sigma(A + LC) \subset \mathbb{C}^-$. Obviously, x satisfies the differential equation

$$\dot{x} = (A + LC)x - Ly + v, \qquad x(0) = x_0.$$

Using the variations of constants formula, together with some straightforward estimates, it is then easily verified that $x \in L_\infty(\mathbb{R}^+)$. □

Using the previous lemma we arrive at the following result that will be one of the main instruments in the proof of Theorem 5.1.

LEMMA 5.3. *Consider the system $\dot{x} = Ax + v$, $y = Cx$. Let $\mathbb{C}_g$ be a symmetric subset of $\mathbb{C}$. Assume that (C, A) is detectable with respect to $\mathbb{C}_g$. Let the state space $\mathbb{R}^n$ be decomposed into $\mathbb{R}^n = X_1 \oplus X_2$, where X_1 is A-invariant. In this decomposition, let $x = \binom{x_1}{x_2}$. Assume that $\sigma(A|X_1) \subset \mathbb{C}_g$ and $\sigma(A|\mathbb{R}^n/X_1) \subset \mathbb{C}_b$. Then for every initial condition x_0 we have: if $v \in L_2(\mathbb{R}^+)$ and $y \in L_\infty(\mathbb{R}^+)$ then $x_2 \in L_\infty(\mathbb{R}^+)$.*

Proof. We claim that, in fact, $X_1 = X_g(A)$. Indeed, the fact that $X_1 \subset X_g(A)$ is immediate. Denote $\sigma_0 := \sigma(A|X_g(A)/X_1)$. Then $\sigma_0 \subset \sigma(A|X_g(A)) \subset \mathbb{C}_g$. Also, $\sigma_0 \subset \sigma(A|\mathbb{R}^n/X_1) \subset \mathbb{C}_b$. This can only be the case if $\sigma_0 = \varnothing$ or, equivalently, if $X_1 = X_g(A)$.

By the fact that (C, A) is detectable with respect to $\mathbb{C}_g$ we may therefore conclude that $\langle \ker C|A\rangle \subset X_1$. Decompose $X_1 = X_{11} \oplus X_{12}$, with $X_{11} := \langle \ker C|A\rangle$ and X_{12} arbitrarily. Accordingly, let $x_1 = \binom{x_{11}}{x_{12}}$. We then have $\mathbb{R}^n = X_{11} \oplus X_{12} \oplus X_2$ with $x = (x_{11}^T, x_{12}^T, x_2^T)^T$. In this decomposition, let

$$A = \begin{pmatrix} A_{11} & A_{12} & A_{13} \\ 0 & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{pmatrix}, \quad C = (0, C_2, C_3), \quad \nu = \begin{pmatrix} \nu_{11} \\ \nu_{12} \\ \nu_2 \end{pmatrix}.$$

Obviously, the system

$$\left((C_2, C_3), \begin{pmatrix} A_{22} & A_{23} \\ 0 & A_{33} \end{pmatrix} \right)$$

is observable. Moreover,

$$\begin{pmatrix} \dot{x}_{12} \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} A_{22} & A_{23} \\ 0 & A_{33} \end{pmatrix} \begin{pmatrix} x_{12} \\ x_2 \end{pmatrix} + \begin{pmatrix} \nu_{12} \\ \nu_2 \end{pmatrix}, \qquad y = (C_2, C_3) \begin{pmatrix} \nu_{12} \\ \nu_2 \end{pmatrix}.$$

It thus follows from Lemma 5.2 that $\binom{x_{12}}{x_2} \in L_\infty(\mathbb{R}^+)$, which of course implies that $x_2 \in L_\infty(\mathbb{R}^+)$. □

Another important instrument in the proof that we will establish is the following result.

LEMMA 5.4. *Consider the system $\dot{x} = Ax + Bu$, $x(0) = x_0$. Assume that (A, B) is controllable and $\sigma(A) \subset \mathbb{C}^- \cup \mathbb{C}^0$. Then for all $\varepsilon > 0$ there exists a control $u \in L_2(\mathbb{R}^+)$ such that $\int_0^\infty \|u(t)\|^2 \, dt < \varepsilon$ and $x(x_0, u)(t) \to 0 (t \to \infty)$.*

Proof. For the given system consider the fixed-endpoint regular LQ problem

$$\inf \left\{ \int_0^\infty \|u(t)\|^2 \, dt | u \in L_2(\mathbb{R}^+) \text{ and } x(x_0, u)(t) \to 0, \, t \to \infty \right\}.$$

It is well known (see also Theorem 4.1) that the above infimum is equal to $x_0^T K^+ x_0$, where K^+ is the maximal solution to the ARE: $A^T K + KA = KBB^T K$. We claim that $K^+ = 0$. Assume $K^+ \neq 0$. Since $K = 0$ is a solution to the ARE, we must have $0 \leqq K^+$. So, $K^+ \geqq 0$ and $K^+ \neq 0$. Consequently, there exists an orthogonal matrix S such that

$$SK^+S^T = \begin{pmatrix} K_1 & 0 \\ 0 & 0 \end{pmatrix},$$

with $K_1 > 0$. Denote $\bar{K} := SK^+S^T$, $\bar{A} := SAS^T$, $\bar{B} := SB$. Then we have $\bar{A}^T\bar{K} + \bar{K}\bar{A} = \bar{K}\bar{B}\bar{B}^T\bar{K}$. Decompose

$$\bar{A} = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \quad \text{and} \quad \bar{B} = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}.$$

It is easily seen that $A_{11}^T K_1 + K_1 A_{11} = K_1 B_1 B_1^T K_1$. Also, $K_1 A_{12} = 0$. Since $K_1 > 0$, this implies $A_{12} = 0$. Define $P := K_1^{-1}$. Then $P > 0$ and satisfies the Lyapunov equation $PA_{11}^T + A_{11}P = B_1 B_1^T$. Since (A_{11}, B_1) is controllable, this implies $\sigma(A_{11}) \subset \mathbb{C}^+$ (see, e.g., [21, Lemma 12.2]. This, however, contradicts the fact that $\sigma(A_{11}) \subset \sigma(\bar{A}) = \sigma(A) \subset \mathbb{C}^- \cup \mathbb{C}^0$. We conclude that the above infimum is zero. □

We have now collected the most important ingredients we need in the proof of our main theorem. In order to give this proof, we shall make a suitable direct sum

decomposition of the state space. Let K_f^+ be the solution of the ARE (3.1) defined by (5.3). Denote $A_f^+ := A - BR^{-1}(B^TK_f^+ + S)$. By Theorem 3.1 we have

$$X^+(A_f^+) = N,$$

$$X^0(A_f^+) = \ker \Delta,$$

$$X^-(A_f^+) = X^-(A^+) \cap \Delta^{-1}N^\perp.$$

Define $X_1 := X^+(A_f^+)$, $X_2 := X^0(A_f^+)$, and $X_3 := X^-(A_f^+)$. Then $\mathbb{R}^n = X_1 \oplus X_2 \oplus X_3$. Since X_1 is A^--invariant and since X_2 is also A^--invariant ($\ker \Delta = X^0(A_K)$ for *all* $K \in \Gamma$) we have

$$A^- = \begin{pmatrix} A_{11} & 0 & A_{13} \\ 0 & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{pmatrix}, \tag{5.4}$$

for given matrices A_{ij}. We also have $K_f^+x = K^-x$ for all $x \in N$, and hence $A_f^+|X_1 = A^-|X_1$. Also, since $\ker \Delta \subset \Delta^{-1}N^\perp$ and therefore $\ker \Delta \subset \ker P_N$, for all $x \in \ker \Delta$ we have $K_f^+x = K^+x = K^-x$. Hence $A_f^+|X_2 = A^-|X_2$. Consequently,

$$A_f^+ = \begin{pmatrix} A_{11} & 0 & 0 \\ 0 & A_{22} & 0 \\ 0 & 0 & A'_{33} \end{pmatrix}, \tag{5.5}$$

for a given matrix A'_{33}. Note that $\sigma(A_{11}) \subset \mathbb{C}^+$, $\sigma(A_{22}) \subset \mathbb{C}^0$ and $\sigma(A'_{33}) \subset \mathbb{C}^-$. Since $X_1 \subset \ker K^-$ and K^- is symmetric,

$$K^- = \begin{pmatrix} 0 & 0 & 0 \\ 0 & K_{22}^- & K_{23}^- \\ 0 & K_{23}^{-T} & K_{33}^- \end{pmatrix}. \tag{5.6}$$

Furthermore, we claim that Δ has the form

$$\Delta = \begin{pmatrix} \Delta_{11} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \Delta_{33} \end{pmatrix}.$$

Indeed, by Theorem 3.1 we have $X_2 \oplus X_3 = \Delta^{-1}X_1^\perp$ and therefore we must have $\Delta_{13} = 0$. The other zero blocks are caused by the fact that $X_2 = \ker \Delta$ and by the symmetry of Δ. Combining the representations for K^- and Δ, we find

$$K^+ = \begin{pmatrix} K_{11}^+ & 0 & 0 \\ 0 & K_{22}^+ & K_{23}^+ \\ 0 & K_{23}^{+T} & K_{33}^+ \end{pmatrix}$$

for given matrices K_{ij}^+ (note that, in fact, $K_{23}^+ = K_{23}^-$ and $K_{22}^+ = K_{22}^-$). Combining all this, we find that

$$K_f^+ = \begin{pmatrix} 0 & 0 & 0 \\ 0 & K_{22}^- & K_{23}^- \\ 0 & K_{23}^{-T} & K_{33}^+ \end{pmatrix}. \tag{5.7}$$

We now proceed with the following lemma, which states that K_f^+ gives a lower bound for the optimal cost of the free-endpoint regular LQ problem.

LEMMA 5.5. *Assume that* (A, B) *is controllable,* $R>0$, *and* $\Gamma_{-}\neq\varnothing$. *For all* $x_0\in\mathbb{R}^n$ *and for all* $u\in U(x_0)$ *we have*

$$J(x_0,u)\geqq x_0^TK_f^+x_0+\int_0^\infty\|u(t)+R^{-1}(B^TK_f^++S)x(t)\|_R^2\,dt. \tag{5.8}$$

Here we have denoted $x(t):=x(x_0,u)(t)$.

Proof. Since $\Gamma_{-}\neq\varnothing$ we have $K^{-}\leqq 0$. Let $u\in U(x_0)$. It follows from Lemma 4.4 that $J(x_0,u)$ is either finite or equal to $+\infty$. Indeed, $J(x_0,u)=-\infty$ would imply $V_f^+(x_0)=-\infty$, which would contradict $\Gamma_{-}\neq\varnothing$. Of course, if $J(x_0,u)=+\infty$ then (5.8) holds trivially. Now assume that $J(x_0,u)$ is *finite*. By the fact that $K^{-}\leqq 0$ it follows from Lemma 4.3 that for all $T\geqq 0$

$$\int_0^T\|u(t)+R^{-1}(B^TK^{-}+S)x(t)\|_R^2\,dt\leqq J_T(x_0,u)-x_0^TK^{-}x_0.$$

Denote $v(t):=u(t)+R^{-1}(B^TK^{-}+S)x(t)$. It then follows that $\int_0^\infty\|v(t)\|_R^2\,dt<+\infty$, and hence that $v\in L_2(\mathbb{R}^+)$. Again using Lemma 4.3 and the fact that $-K^{-}\geqq 0$, we find that this implies $\lim_{T\to\infty}x^T(T)K^{-}x(T)$ exists (and is finite). Thus $K^{-}x$ must be bounded on $\mathbb{R}^+$. Denote $y(t):=K^{-}x(t)$. Since $\dot{x}=Ax+Bu$, we have that x, v, and y are related by the equations

$$\dot{x}=A^{-}x+Bv,\qquad y=K^{-}x.$$

Now let $\mathbb{R}^n$ be composed into $\mathbb{R}^n=X_1\oplus X_2\oplus X_3$ as introduced above. Write $K^{-}=(0,K_2^{-},K_3^{-})$, $B=(B_1^T,B_2^T,B_3^T)^T$, and $x=(x_1^T,x_2^T,x_3^T)^T$. Since $X_1=N$ is the undetectable subspace (with respect to $\mathbb{C}^{-}\cup\mathbb{C}^0$) of (K^{-},A^{-}), it is easily verified that the pair

$$\left((K_2^{-},K_3^{-}),\begin{pmatrix}A_{22}&A_{23}\\0&A_{33}\end{pmatrix}\right)$$

is detectable (with respect to $\mathbb{C}^{-}\cup\mathbb{C}^0$). Since $\sigma(A^{-})\subset\mathbb{C}^{+}\cup\mathbb{C}^0$ and since $X_2=X^0(A^{-})$, it can be verified that

$$\sigma\left(\begin{pmatrix}A_{11}&A_{13}\\0&A_{33}\end{pmatrix}\right)\subset\mathbb{C}^{+}.$$

Hence, $\sigma(A_{22})\subset\mathbb{C}^0$ and $\sigma(A_{33})\subset\mathbb{C}^{+}$. Also, we have

$$\begin{pmatrix}\dot{x}_2\\\dot{x}_3\end{pmatrix}=\begin{pmatrix}A_{22}&A_{23}\\0&A_{33}\end{pmatrix}\begin{pmatrix}x_2\\x_3\end{pmatrix}+\begin{pmatrix}B_2\\B_3\end{pmatrix}v,\qquad y=(K_2^{-},K_3^{-})\begin{pmatrix}x_2\\x_3\end{pmatrix}.$$

Since $v\in L_2(\mathbb{R}^+)$ and $y\in L_\infty(\mathbb{R}^+)$, by Lemma 5.3 (applied with $\mathbb{C}_g=\mathbb{C}^{-}\cup\mathbb{C}^0$) we have that $x_3\in L_\infty(\mathbb{R}^+)$.

Again by applying Lemma 4.3, this time with $K=K_f^+$, we find that for all $T\geqq 0$

$$J_T(x_0,u)=\int_0^T\|u(t)+R^{-1}(B^TK_f^++S)x(t)\|_R^2\,dt+x_0^TK_f^+x_0-x^T(T)K_f^+x(T). \tag{5.9}$$

Denote $w(t):=u(t)+R^{-1}(B^TK_f^++S)x(t)$. Combining (5.6), (5.7), and (5.9), we obtain that for all $T\geqq 0$

$$J_T(x_0,u)=\int_0^T\|w(t)\|_R^2\,dt+x_0^TK_f^+x_0-x_3^T(T)\Delta_{33}x_3(T)-x^T(T)K^{-}x(T). \tag{5.10}$$

Recall that $\lim_{T\to\infty}J_T(x_0,u)$ was assumed to be finite. Thus, $J_T(x_0,u)$ is a bounded function of T. Since also $x_3(T)$ and $x^T(T)K^{-}x(T)$ are bounded functions of T, (5.10) implies that $\int_0^\infty\|w(t)\|_R^2\,dt<\infty$. It follows that $w\in L_2(\mathbb{R}^+)$.

We again consider (5.10). Since now $J_T(x_0, u)$, $\int_0^T \|w(t)\|_R^2\, dt$ and $x^T(T)K^-x(T)$ *converge* for $T\to\infty$, it follows that $\lim_{T\to\infty} x_3^T(T)\Delta_{33}x_3(T)$ exists. Since $\Delta_{33}>0$ this implies that $\|x_3(T)\|$ converges as $T\to\infty$. Now, since $\dot{x}=Ax+Bu$, the variables x and w are related via $\dot{x}=A_f^+x+Bw$, and hence (see 5.5) $\dot{x}_3=A_{33}'x_3+B_3w$. Since $w\in L_2(\mathbb{R}^+)$ and $\sigma(A_{33}')\subset\mathbb{C}^-$ we have that $x_3\in L_2(\mathbb{R}^+)$. A fortiori, since $\|x_3(t)\|$ converges as $t\to\infty$, this yields $\lim_{t\to\infty} x_3(t)=0$. Using this, and the fact that $-K^-\geqq 0$, it then follows from (5.10) that (5.8) holds. □

Our next lemma states that, by choosing the control properly, the difference between K_f^+ and the value of the cost functional can be made arbitrarily small.

LEMMA 5.6. *Assume that* (A, B) *is controllable,* $R>0$, *and* $\Gamma\neq\varnothing$. *Then for all* $x_0\in\mathbb{R}^n$ *and for all* $\varepsilon>0$ *there exists an input* $u\in U(x_0)$ *such that* $J(x_0, u)\leqq x_0^TK_f^+x_0+\varepsilon$.

Proof. Again, let $\mathbb{R}^n$ be decomposed as above. It follows from (5.7) and (5.9) that for all $u\in L_{2,\mathrm{loc}}(\mathbb{R}^+)$ and for all $T\geqq 0$

$$(5.11)\quad J_T(x_0, u)=\int_0^T \|w(t)\|_R^2\, dt+x_0^TK_f^+x_0-(x_2^T(T), x_3^T(T))\begin{pmatrix} K_{22}^- & K_{23}^- \\ K_{23}^{-T} & K_{33}^+\end{pmatrix}\begin{pmatrix} x_2(T)\\ x_3(T)\end{pmatrix}.$$

Here, $w:=u+R^{-1}(B^TK_f^++S)x$. Since $\dot{x}=Ax+Bu$, the variables x and w are related by $\dot{x}=A_f^+x+Bw$, and hence (see (5.5))

$$\begin{pmatrix}\dot{x}_2\\ \dot{x}_3\end{pmatrix}=\begin{pmatrix} A_{22} & 0\\ 0 & A_{33}'\end{pmatrix}\begin{pmatrix} x_2\\ x_3\end{pmatrix}+\begin{pmatrix} B_2\\ B_3\end{pmatrix}w.$$

Note that $\sigma(A_{22})\subset\mathbb{C}^0$, $\sigma(A_{33}')\subset\mathbb{C}^-$ and that this system is controllable. Now let $\varepsilon>0$. It follows from Lemma 5.4 that there exists a control $w\in L_2(\mathbb{R}^+)$ such that $\int_0^\infty \|w(t)\|_R^2\, dt<\varepsilon$ and such that $x_2(T)\to 0$ and $x_3(T)\to 0$ as $T\to\infty$. Define $u:=-R^{-1}(B^TK_f^++S)x+w$. Then we have

$$J(x_0, u)=\lim_{T\to\infty} J_T(x_0, u)=\int_0^\infty \|w(t)\|_R^2\, dt+x_0^TK_f^+x_0\leqq\varepsilon+x_0^TK_f^+x_0.$$ □

We will now prove our main theorem.

Proof of Theorem 5.1. (i) This proof was already stated separately in Lemma 4.4.

(ii) Lemma 5.5 yields $J(x_0, u)\geqq x_0^TK_f^+x_0$ for all $u\in U(x_0)$. Together with Lemma 5.6 this implies $V_f^+(x_0)=x_0^TK_f^+x_0$ for all x_0.

(iii) Assume $\Gamma_-\neq\varnothing$. ($\Rightarrow$) Assume that for all x_0 there exists a control $u^*\in U(x_0)$ such that $J(x_0, u^*)=V_f^+(x_0)=x_0^TK_f^+x_0$. Let $x_0\in\mathbb{R}^n$ be arbitrary and let u^* be the corresponding optimal control. Denote $x^*:=x(x_0, u^*)$. By Lemma 5.5

$$x_0^TK_f^+x_0=J(x_0, u^*)\geqq x_0^TK_f^+x_0+\int_0^\infty \|u^*(t)+R^{-1}(B^TK_f^++S)x^*(t)\|_R^2\, dt.$$

It follows that u^* must be given by the feedback control law $u^*=-R^{-1}(B^TK_f^++S)x^*$. This implies that x^* satisfies the equation $\dot{x}^*=A_f^+x^*$. In terms of the decomposition introduced above, this of course yields $\dot{x}_2^*=A_{22}x_2^*$ and $\dot{x}_3^*=A_{33}'x_3^*$ (see 5.5). Since $\sigma(A_{33}')\subset\mathbb{C}^-$ we must have $x_3^*(t)\to 0 (t\to\infty)$. By (5.10)

$$J_T(x_0, u^*)=x_0^TK_f^+x_0-x_3^{*T}(T)\Delta_{33}x_3^*(T)-x^{*T}(T)K^-x^*(T).$$

By the fact that $J_T(x_0, u^*)\to x_0^TK_f^+x_0$ we obtain that $x^{*T}(T)K^-x^*(T)\to 0$ $(T\to\infty)$. Since K^- is semidefinite, a fortiori this implies $K^-x^*(T)\to 0$ $(T\to\infty)$. Using (5.6) this yields

$$K_{22}^-x_2^*(T)+K_{23}^-x_3^*(T)\to 0\qquad (T\to\infty).$$

Since $x_3^*(T) \to 0$ $(T \to \infty)$ the latter implies $K_{22}^- x_2^*(T) \to 0$ $(T \to \infty)$ or, equivalently, $K_{22}^- \exp(A_{22}T)x_2(0) \to 0$ $(T \to \infty)$. Now, $x_2(0)$ was completely arbitrary and therefore we find that

$$K_{22}^- e^{A_{22}T} \to 0 \qquad (T \to \infty).$$

Consequently, $K_{22}^-(Is - A_{22})^{-1}$ has all its poles in $\mathbb{C}^-$. On the other hand, however, since $\sigma(A_{22}) \subset \mathbb{C}^0$, it has all its poles in $\mathbb{C}^0$. Thus, $K_{22}^-(Is - A_{22})^{-1} = 0$, and hence $K_{22}^- = 0$. Since K^- is semidefinite this implies $K_{23}^- = 0$. It follows that $\ker \Delta = X_2 \subset \ker K^-$.

($\Leftarrow$) Conversely, assume $\ker \Delta \subset \ker K^-$. Then $K_{22}^- = 0$ and $K_{23}^- = 0$. Define $u = -R^{-1}(B^T K_f^+ + S)x$. We claim that this feedback law yields an optimal u. Indeed, by (5.11)

$$J_T(x_0, u) = x_0^T K_f^+ x_0 - x_3^T(T) K_{33}^+ x_3(T).$$

Moreover, $\dot{x}_3 = A_{33}' x_3$. Since $\sigma(A_{33}') \subset \mathbb{C}^-$ we have $x_3(T) \to 0$ $(T \to \infty)$. Thus $J(x_0, u) = x_0^T K_f^+ x_0 = V_f^+(x_0)$, so u is optimal.

(iv) The fact that $u^* = -R^{-1}(B^T K_f^+ + S)x^*$ is *unique* was already proven in (iii) ($\Rightarrow$). This concludes the proof of our theorem. □

Remark 5.7. At this point we would like to mention that, in addition to the option we have chosen in § 2, there is still another very natural and appealing way to formulate the regular LQ problem. Instead of restricting the class of controls to $U(x_0)$ in order to guarantee that the indefinite integrals in (2.2) are well-defined, it is also possible to choose $L_{2,\mathrm{loc}}(\mathbb{R}^+)$ for the class of admissible controls and to consider the following cost functional:

$$\tilde{J}(x_0, u) := \limsup_{T \to \infty} J_T(x_0, u).$$

Obviously, on the subclass $U(x_0) \subset L_{2,\mathrm{loc}}(\mathbb{R}^+)$ the functionals $\tilde{J}(x_0, \cdot)$ and $J(x_0, \cdot)$ coincide. Corresponding to this choice of cost functional, we can now consider the following version of the free-endpoint regular LQ problem:

$$\tilde{V}_f^+(x_0) := \inf\{\tilde{J}(x_0, u) | u \in L_{2,\mathrm{loc}}(\mathbb{R}^+)\}.$$

As it turns out, we can develop around this version of the problem a theory completely parallel to the one we developed in this section. In fact, Theorem 5.1 remains valid if in its statement we replace V_f^+ by $\tilde{V}_f^+$! In particular, both problems yield the same optimal controls u^*. Consequently, if u^* is optimal for the problem with functional $\tilde{J}(x_0, \cdot)$, then in fact $u^* \in U(x_0)$ and $\tilde{V}_f^+(x_0) = \tilde{J}(x_0, u^*) = \lim_{T \to \infty} J_T(x_0, u^*)$. Similar remarks hold for the fixed-endpoint problem.

6. Comparison and special cases. In this section we will discuss some questions that arise if we compare the optimal costs and optimal closed loop systems resulting from the free-endpoint and fixed-endpoint problem, respectively. In particular, we will establish conditions under which the respective optimal costs are the same. Also, conditions will be found under which the free-endpoint optimal closed loop system is asymptotically stable. Finally, we will show how our general results can be specialized to reobtain the most important results on the free-endpoint regular LQ problem with *positive semidefinite* cost functional. First, we have the following theorem.

THEOREM 6.1. *Assume that* (A, B) *is controllable,* $R > 0$, *and* $\Gamma \neq \emptyset$. *Then we have the following*:

(i) $K_f^+ = K^+$ *if and only if the pair* $(K^-, A - BR^{-1}S)$ *is detectable with respect to the stability set* $\mathbb{C}^- \cup \mathbb{C}^0$.

(ii) $\sigma(A_f^+) \subset \mathbb{C}^-$ *if and only if the pair* $(K^-, A - BR^-S)$ *is detectable with respect to* $\mathbb{C}^-$ *and* $\Delta > 0$.

Proof. (i) By (5.2), N is equal to the undetectable subspace of $(K^-, A - BR^{-1}S)$ with respect to $\mathbb{C}^- \cup \mathbb{C}^0$. Since K^+ is supported by the zero subspace, by Theorem 3.1 we have $K_f^+ = K^+$ if and only if $N = 0$.

(ii) ($\Leftarrow$) Detectability with respect to $\mathbb{C}^-$ implies detectability with respect to $\mathbb{C}^- \cup \mathbb{C}^0$. Hence $K_f^+ = K^+$ and $A_f^+ = A^+$. By [17, Thm. 5] $\Delta > 0$ if and only if $\sigma(A^+) \subset \mathbb{C}^-$.

($\Rightarrow$) Conversely, assume $\sigma(A_f^+) \subset \mathbb{C}^-$. By [17, Thm. 5] there is exactly one $K \in \Gamma$, namely $K = K^+$, such that $\sigma(A_K) \subset \mathbb{C}^- \cup \mathbb{C}^0$. Hence $K_f^+ = K^+$, $A_f^+ = A^+$. Consequently, $\Delta > 0$. Also, from (i) we obtain that the pair $(K^-, A - BR^{-1}S)$ is detectable with respect to $\mathbb{C}^- \cup \mathbb{C}^0$. Since $\Delta > 0$, $\sigma(A^-) \subset \mathbb{C}^+$. Hence $X^0(A^-) = 0$ so $(K^-, A - BR^{-1}S)$ is in fact detectable with respect to $\mathbb{C}^-$. □

We will now discuss how our results can be specialized to rederive some important "classical" results on the special case that the quadratic form ω is positive semidefinite. We have the following characterization of the positive semidefinite solutions of the ARE.

THEOREM 6.2. *Assume that* (A, B) *is controllable,* $R > 0$, $\Gamma_- \neq \emptyset$, *and* $\Gamma_+ \neq \emptyset$. *Let* $K \in \Gamma$ *be supported by* V. *Then* $K \in \Gamma_+$ *if and only if* $V \subset \ker K^-$.

Proof. By Theorem 3.1 we have $V \oplus \Delta^{-1}V^\perp = \mathbb{R}^n$.

($\Leftarrow$) Assume that $V \subset \ker K^-$. Then $\Delta^{-1}V^\perp = \{x \in \mathbb{R}^n \mid y^T K^+ x = 0, \text{ for all } y \in V\}$ and $K = K^+(I - P_V)$. Let $x \in \mathbb{R}^n$, $x = x_1 + x_2$ with $x_1 \in V$ and $x_2 \in \Delta^{-1}V^\perp$. It is easily seen that $x^T K x = x_2^T K^+ x_2$. Since $\Gamma_+ \neq \emptyset$ we have $K^+ \geqq 0$. It follows that $K \geqq 0$.

($\Leftarrow$) Conversely, if $K \geqq 0$ then for all $x \in V$ we have

$$0 \leqq x^T K x = x^T(K^- P_V + K^+(I - P_V))x = x^T K^- x.$$

Since $\Gamma_- \neq \emptyset$ we have $K^- \leqq 0$. It follows that $x^T K^- x = 0$, and hence that $x \in \ker K^-$. □

Our next result states that, under the assumption that $\Gamma_- \neq \emptyset$, if the ARE has positive semidefinite solutions at all, then it has a smallest positive semidefinite solution and this solution is equal to the one supported by N.

THEOREM 6.3. *Assume that* (A, B) *is controllable,* $R > 0$, *and* $\Gamma_- \neq \emptyset$. *Then the following hold: if* $\Gamma_+ \neq \emptyset$ *then* (i) $K_f^+ \in \Gamma_+$ *and* (ii) $K \in \Gamma_+$ *implies* $K_f^+ \leqq K$.

Proof. Since $N \subset \ker K^-$ it follows from Theorem 6.2 that $K_f^+ \in \Gamma_+$. Now assume $K \in \Gamma_+$ and K is supported by the A^--invariant subspace $V \subset X^+(A^-)$. Since $K \in \Gamma_+$ we have $V \subset \ker K^-$. Hence $V \subset \langle \ker K^- | A^- \rangle$ (the latter is the largest A^--invariant subspace in $\ker K^-$; see [21]). It follows that $V \subset N$. But then, by Theorem 3.2, $K_f^+ \leqq K$. □

From the above we deduce the following remarkable fact. Consider the free-endpoint regular LQ problem with *indefinite* cost functional. Let (A, B) be controllable. We already saw that the optimal cost is finite if we have $\Gamma_- \neq \emptyset$. Assume this to be the case. Then Theorem 6.3 states that *if the* ARE *has at least one positive semidefinite solution, then the optimal cost is given by the smallest of these solutions*! The case that the cost functional is positive semidefinite, i.e., $\omega(x, u) \geqq 0$, for all (x, u), is in fact a special case of this general principle. Indeed, if (A, B) is controllable and if $\omega \geqq 0$ then $\Gamma_+ \neq \emptyset$ (see [5]). Moreover, applying the latter to the controllable system $(-A, -B)$ and the same form $\omega \geqq 0$, we can also see that $\Gamma_- \neq \emptyset$. Thus we have reobtained Theorem 4.2(i).

Our next result shows that the fact that for the case $\omega \geqq 0$ optimal controls exist for all initial conditions is also a special case of a more general principle.

PROPOSITION 6.4. *Assume* (A, B) *is controllable,* $R > 0$, $\Gamma_- \neq \emptyset$, *and* $\Gamma_+ \neq \emptyset$. *Then* $\ker \Delta \subset \ker K^-$.

Proof. $\Gamma_- \neq \emptyset$ is equivalent to $K^- \leqq 0$ and $\Gamma_+ \neq \emptyset$ is equivalent to $K^+ \geqq 0$. Assume $x \in \ker \Delta$. Then $0 \leqq x^T K^+ x = x^T K^- x \leqq 0$. Thus $x^T K^- x = 0$, and hence $K^- x = 0$. □

By combining this with the above remarks and by applying Theorem 5.1(iii) and (iv) we reobtain Theorem 4.2(ii).

To conclude this section, we will briefly discuss what statements can be obtained from Theorem 6.1 for the case that our cost functional is positive semidefinite. In the rest of this section, assume that $\omega(x, u) \geqq 0$ for all (x, u). We claim that in this case

$$N = \langle \ker (Q - S^T R^{-1} S) | A - BR^{-1} S \rangle \cap X^+(A - BR^{-1} S). \tag{6.1}$$

First we claim that $\ker K^-$ is $(A - BR^{-1}S)$-invariant. Indeed, if $\omega \geqq 0$ then $Q - S^T R^{-1} S \geqq 0$. Also it is straightforward to verify that

$$(A - BR^{-1}S)^T K^- + K^-(A - BR^{-1}S) + Q - S^T R^{-1} S - K^- BR^{-1} B^T K = 0. \tag{6.2}$$

Let $x_0 \in \ker K^-$. Then from (6.2), $x_0^T (Q - S^T R^{-1} S) x_0 = 0$, and hence $(Q - S^T R^{-1} S) x_0 = 0$. Thus, again from (6.2), $K^-(A - BR^{-1}S)x_0 = 0$ so $(A - BR^{-1}S)x_0 \in \ker K^-$. It follows that $\langle \ker K^- | A - BR^{-1}S \rangle = \ker K^-$. Now, by using the interpretation of K^- as the optimal cost for a fixed-endpoint LQ problem in "reversed time" (see [21, Thm. 7]) it can be proved that

$$\begin{aligned} \ker K^- = \langle \ker (Q - S^T R^{-1} S) | A - BR^{-1} S \rangle \\ \cap (X^+(A - BR^{-1}S) \oplus X^0(A - BR^{-1}S)). \end{aligned} \tag{6.3}$$

Thus (6.1) follows immediately from (5.2). We have now shown that if $\omega \geqq 0$, then K_f^+ is in fact supported by the undetectable subspace of the pair $(Q - S^T R^{-1} S, A - BR^{-1} S)$ with respect to $\mathbb{C}^- \cup \mathbb{C}^0$. (See also [3, Thm. 1].) By applying Theorem 6.1(i) we may then conclude that $K_f^+ = K^+$ if and only if $(Q - S^T R^{-1} S, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^- \cup \mathbb{C}^0$ (see also [12, Cor., p. 356]).

Finally, we will re-establish the well-known fact that $\sigma(A_f^+) \subset \mathbb{C}^-$ if and only if $(Q - S^T R^{-1} S, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^-$ (see [6], [20], and [12]). Assume that $\omega \geqq 0$. We claim that if $(K^-, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^-$ then $\Delta > 0$. Indeed, if $(K^-, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^-$ then (K^-, A^-) is detectable with respect to $\mathbb{C}^-$. The latter is equivalent to

$$\langle \ker K^- | A^- \rangle \cap (X^+(A^-) \oplus X^0(A^-)) = 0. \tag{6.4}$$

By Theorem 3.1, $X^0(A^-) = \ker \Delta$. Also, since $\omega \geqq 0$, $\ker \Delta \subset \ker K^-$. Hence, by (6.4), $\ker \Delta + (\langle \ker K^- | A^- \rangle \cap X^+(A^-)) = 0$, whence $\ker \Delta = 0$. It follows that $\Delta > 0$. We may now conclude from Theorem 6.1(ii) that $\sigma(A_f^+) \subset \mathbb{C}^-$ if and only if the pair $(K^-, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^-$. From the fact that $\ker K^-$ is $(A - BR^{-1}S)$-invariant and from (6.3), the latter condition is, however, equivalent to the statement that the pair $(Q - S^T R^{-1} S, A - BR^{-1} S)$ is detectable with respect to $\mathbb{C}^-$.

7. Concluding remarks. In this paper we have studied just one of the many open basic questions that still exist in the context of linear quadratic optimal control. To name but a few of these open problems, we mention, for example, the question about the relationship between the *finite*-horizon free-endpoint problem and the infinite-horizon free-endpoint problem. It is well known that if the cost functional is positive semidefinite, then the finite-horizon optimal cost converges to the infinite-horizon optimal cost [1], [2], [9]. It would be interesting to investigate whether this is also true for the indefinite case. Another open problem is the *singular* LQ problem with indefinite cost functional, that is, the problem studied here without the assumption that R is positive definite. Recently [19] this problem was treated for the case that the

cost-functional is positive semidefinite. However, for both the free-endpoint case as well as the fixed-endpoint case, the indefinite version of this problem still remains to be solved.

Acknowledgments. I thank Dr. Jacob van der Woude and Professor Malo Hautus for some very useful discussions while the research leading to this paper was carried out.

SUBSPACE INVARIANCE OF BROYDEN'S θ-CLASS AND ITS APPLICATION TO NONLINEAR CONSTRAINED OPTIMIZATION*

RODRIGO FONTECILLA†

Abstract. Broyden's θ-class of updating formulae has the following property. If the current approximation matrix is symmetric and positive definite, then the updated matrix maintains those same properties under certain conditions. It is shown that if the current approximation matrix is symmetric and positive definite on a subspace of $\mathbf{R}^n$, then the updated matrix is symmetric and positive definite along the same subspace. An application of this result to the implementation of a quasi-Newton method for solving nonlinear constrained optimization problems is presented.

Key words. unconstrained minimization, constrained minimization, quasi-Newton methods, Broyden's θ-class

AMS(MOS) subject classifications. 65K05, 65K10

1. Introduction.

Consider the unconstrained minimization problem

$$\underset{x\in\mathbf{R}^n}{\text{minimize}}\, f(x), \tag{1.1}$$

with solution x_* for a twice continuously differentiable function $f:\mathbf{R}^n\to\mathbf{R}$ with gradient $\nabla f(x)$ and Hessian $\nabla^2 f(x)$. This problem is often solved by a class of quasi-Newton methods that generate points $\{x\}$ and $n\times n$ matrices $\{B\}$ such that

$$x_+ = x-\alpha d, \qquad d = B^{-1}\nabla f(x). \tag{1.2}$$

The stepsize $\alpha>0$ is chosen such that $f(x_+)<f(x)$. In order to ensure that $-d$ is a descent direction for f at x, we require that all B be symmetric and positive definite. In addition, we ask that the secant equation

$$B_+ s = y \tag{1.3}$$

be satisfied, where

$$s = x_+ - x \quad\text{and}\quad y = \nabla f(x_+)-\nabla f(x). \tag{1.4}$$

A general class of methods for computing a symmetric, positive definite B_+ satisfying (1.3) from a symmetric and positive definite B is Broyden's bounded θ-class of methods, which is given by an update formula depending on a constant θ which may even vary throughout the process. The matrices B approximating the Hessian $\nabla^2 f(x_*)$ are given by

$$B_+ = U(s,y,B,\theta) = B-\frac{Bss^TB}{s^TBs}+\frac{yy^T}{y^Ts}+\theta ww^T, \tag{1.5a}$$

with

$$w=\sqrt{s^TBs}\left[\frac{y}{y^Ts}-\frac{Bs}{s^TBs}\right]. \tag{1.5b}$$

Any $U(s,y,B,\theta)$ with $\theta\in[0,1]$ belongs to the "convex hull" of the differentiable function problem (DFP) and BFGS formulae, which are obtained as special cases, namely, $\theta=1$ for the DFP, and $\theta=0$ for the BFGS. Standard conditions are the

† Department of Computer Science and Institute for Advanced Computer Studies, University of Maryland, College Park, Maryland 20742.

following:

(A1) The functional $f \in C^2(D)$, with D an open convex subset of $\mathbf{R}^n$.

(A2) The point x_* is in D, and is a local minimizer of f with $\nabla f(x_*) = 0$ and $\nabla^2 f(x_*)$ positive definite.

(A3) The Hessian $\nabla^2 f(x)$ is Lipschitz continuous on D.

It has been shown [2], [3], [10] that under conditions (A1)-(A3), for any $x_0 \in D$ sufficiently close to x_*, and any positive definite matrix B_0 close to $\nabla^2 f(x_*)$, these methods generate a sequence of points $\{x_k\}$ and positive definite matrices $\{B_k\}$ with

$$\sup \|B_k\| < \infty, \qquad \sup \|B_k^{-1}\| < \infty, \tag{1.6}$$

$$\lim_{k \to \infty} \frac{\|x_{k+1} - x_*\|}{\|x_k - x_*\|} = 0 \quad \text{if } x_k \neq x_*. \tag{1.7}$$

This means that the sequence $\{x_k\}$ converges q-superlinearly to x_*. This convergence result rests heavily on the fact that if B is positive definite and $s^T y > 0$, then B_+ is also positive definite. However, this property does not necessarily hold if B is positive definite only on a subspace of $\mathbf{R}^n$. Such a situation arises in solving nonlinear constrained optimization problems; that is, the Hessian we approximate is symmetric and positive definite only on a subspace of $\mathbf{R}^n$. Since the Hessian is known to have such properties, we want to maintain the same properties for the approximating matrices B. We shall give conditions to guarantee that the matrices B are positive definite on a subspace of $\mathbf{R}^n$.

We present our work in the following fashion. In § 2, we present our main result. We prove that methods in Broyden's bounded θ-class satisfy the following property. If the current approximation matrix B is positive definite in the current subspace $S \in \mathbf{R}^n$, if the step s is in S, and if $y^T s > 0$, then the updated matrix B_+ is positive definite in S. In § 3, we show that the matrices B still satisfy a bounded deterioration relation. In § 4, we apply this result to solving nonlinear constrained optimization problems with some numerical experiments on a set of 10 test problems.

2. Hereditary positive definiteness. In this section we show that if the matrix B is positive definite on a subspace S of $\mathbf{R}^n$, and if $s \in S$ and $y^T s > 0$, then B_+ generated by (1.5) is positive definite in S, even when y, s are not necessarily given by (1.4).

In the following, we want the subspace $S(x)$ and the $n \times m$ full rank matrix $N(x)$ to be related by

$$S(x) = \{y \in \mathbf{R}^n \colon N(x)^T y = 0\}, \tag{2.1}$$

$$S(x)^{\perp} = \{N(x)z \colon z \in \mathbf{R}^m\}. \tag{2.2}$$

Thus, the orthogonal projection onto $S(x)$ is given by

$$P(x) = I - N(x)[N(x)^T N(x)]^{-1} N(x)^T. \tag{2.3}$$

In the following, to ease the notation, arguments for S, N, and P will be deleted, so $S(x)$, $N(x)$, and $P(x)$ become S, N, and P, respectively.

LEMMA 2.1. *Let A be an $n \times n$ symmetric matrix. Then A is positive definite on S if and only if $PAP + NN^T$ is positive definite on all of $\mathbf{R}^n$. Moreover, if A is positive definite on S, then the matrix $PA + NN^T$ is nonsingular.*

Proof. (i) Let A be a positive definite matrix on S, and let $x \in \mathbf{R}^n$, $x \neq 0$. Then $x = y + w$ for some $y \in S$ and $w = N$, $z \in S^{\perp}$. At least one of w and y must be nonzero. Since $Py = y$, $Pw = 0$, and $N^T y = 0$, we get

$$x^T(PAP + NN^T)x = y^T A y + \|N^T w\|_2^2 = y^T A y + \|N^T N z\|_2^2.$$

Thus, the right-hand side is strictly positive unless $y = 0$ and $z = 0$, but if $y = 0$ then $w \neq 0$, so $z \neq 0$. It follows that $PAP + NN^T$ is positive definite.

(ii) Now let $PAP + NN^T$ be positive definite and $x \in S$, $x \neq 0$; then

$$x^T A x = x^T(PAP + NN^T)x > 0,$$

so A is positive definite on S.

To prove the second part, suppose that $x \in \mathbf{R}^n$, $x \neq 0$, and

$$(PA + NN^T)x = 0.$$

Then $PAx = -NN^T x$, and since $PAx \in S$, this implies that $NN^T x = 0$ and $PAx = 0$. Hence, $N^T x = 0$, so $x \in S$ and $Px = x$. But $PAx = 0$, so $0 = x^T(PAx) = x^T A x$, which implies that A is not positive definite on S. □

LEMMA 2.2. *Let A be an $n \times n$ symmetric matrix and positive definite along S. Then, there exists a positive constant $\bar{c}$ such that the matrix $A + cNN^T$ is positive definite for all $c > \bar{c}$.*

Proof. The proof can be found in [1, Lemma 1.25]. □

The following result relies heavily on the hereditary positive definite property of the methods (1.5a) and (1.5b).

THEOREM 2.3. *Let the matrix $B \in \mathbf{R}^{n \times n}$ and vectors y, s be such that B is symmetric and positive definite on a subspace S of $\mathbf{R}^n$, $y^T s > 0$, and $s \in S$. Then, the matrix B_+ generated by the update formula* (1.5) *is well defined and is symmetric and positive definite on S.*

Proof. If we multiply both sides of (1.5) by P, and since $s \in S$, we get

$$PB_+P = U(s, Py, PBP, \theta), \tag{2.4}$$

$$PB_+P + NN^T = U(s, Py, PBP + NN^T, \theta). \tag{2.5}$$

Since $PBP + NN^T$ is positive definite and $s^T(Py) = s^T y > 0$, we have that $PB_+P + NN^T$ is positive definite, and from Lemma 2.1 we get that B_+ is positive definite on S. □

3. Preserving bounded deterioration. In this section we show that the matrices B generated by the update formula (1.5) preserve a bounded deterioration property even when they are not positive definite. This result is fundamental to proving any local convergence result related to the use of these matrices and the update formula (1.5) (see [2] and [3]).

It is necessary to exhibit a bounded deterioration property for the matrices B in order to show that these matrices, which are approximating a Hessian although they do not converge to it, tend not to go too far away from it. In other words, the approximation to the Hessian deteriorates, but in a bounded fashion.

For the remainder of this section let x_* be a point in $\mathbf{R}^n$ and let $H(x_*) = H_*$ be a symmetric matrix that is positive definite along $S(x_*) = S_*$. Let σ be defined by

$$\sigma = \max\{\|x + s - x_*\|, \|x - x_*\|\}.$$

Hereafter, we will assume that y and s are nonzero vectors. To be able to use Theorem 2.3 we need conditions that will ensure $y^T s > 0$. The following result shows when this is possible.

THEOREM 3.1. *Assume σ, the vectors y and s, and the matrices N and H_* satisfy*

$$\frac{\|y - H_* s\|}{\|s\|} = O(\sigma), \tag{3.1}$$

$$\|N_* N_*^T - NN^T\| = O(\sigma), \tag{3.2}$$

and $s \in S$. Then there exists a positive constant ε such that if $\sigma \leqq \varepsilon$, then $y^T s > 0$.

Proof. Since H_* is positive definite along S_* from Lemma 2.2 there exists a positive constant $\bar{c}$ such that the matrix $H_* + cN_* N_*^T$ is positive definite for all $c > \bar{c}$. Consider

$$M^{-2} = H_* + cN_* N_*^T \quad \text{for } c > \bar{c}.$$

If $s \in S$ then $N^T s = 0$, so

$$\begin{aligned} \|My - M^{-1}s\| &\leqq \|M\| \, \|y - M^{-2}s\| \\ &\leqq \|M\| [\|y - H_* s\| + c\|N_* N_*^T - NN^T\| \, \|s\|] \\ &\leqq O(\sigma)\|M^{-1}s\|. \end{aligned} \tag{3.3}$$

Consider

$$y^T s = (My)^T (M^{-1}s) = (My - M^{-1}s)^T (M^{-1}s) + (M^{-1}s)^T (M^{-1}s).$$

Taking norms and using the Cauchy-Schwartz inequality, we get

$$1 - \frac{\|My - M^{-1}s\|}{\|M^{-1}s\|} \leqq \frac{y^T s}{\|M^{-1}s\|^2} \leqq 1 + \frac{\|My - M^{-1}s\|}{\|M^{-1}s\|}.$$

Hence, by using (3.3) we can now choose ε sufficiently small and obtain our desired result. □

In general, it is not difficult to satisfy (3.1) or (3.2). It is usually true that $N(x)$ is twice continuously differentiable and therefore (3.2) holds.

The following is a technical lemma used later in the section.

LEMMA 3.2. *Let the matrices B' and B_+ be defined by*

$$B' = U(z, z, B, \theta) \quad \text{and} \quad B_+ = U(z, y, B, \theta),$$

and assume the vectors y and z satisfy $z^T B z \neq 0$ and

$$\frac{\|y - z\|}{\|z\|} = O(\sigma). \tag{3.4}$$

Then there exists $\varepsilon > 0$ such that if $\sigma \leqq \varepsilon$,

$$\|B_+ - B'\|_F \leqq [\|B\|_F + O(1)]O(\sigma). \tag{3.5}$$

Proof. Consider

$$y^T z = (y - z)^T z + z^T z.$$

Taking norms and using the Cauchy-Schwartz inequality, we obtain

$$1 - \frac{\|y - z\|}{\|z\|} \leqq \frac{y^T z}{\|z\|^2} \leqq 1 + \frac{\|y - z\|}{\|z\|}.$$

We now choose ε sufficiently small so that (3.4) implies

$$1 - O(\sigma) \leqq \frac{y^T z}{\|z\|^2} \leqq 1 + O(\sigma)$$

and $y^T z > 0$. We can restrict ε further so that $\frac{1}{2} \leqq 1 - O(\sigma)$ and therefore $y^T z \geqq \|z\|^2/2$. Now consider

$$B_+ - B' = E_1 + \theta(E_2 + E_2^T) + \theta z^T B z E_3,$$

where

$$E_1 = \frac{yy^T}{y^T z} - \frac{zz^T}{z^T z},$$

$$E_2 = \left[\frac{y}{y^T z} - \frac{z}{z^T z}\right](Bz)^T,$$

$$E_3 = \frac{yy^T}{(y^T z)^2} - \frac{zz^T}{(z^T z)^2}.$$

Rewrite E_1 as

$$E_1 = \frac{y(y-z)^T + (y-z)z^T}{y^T z} + zz^T\left[\frac{(z-y)^T z}{(y^T z)(z^T z)}\right].$$

Recall that $y^T z \geqq \|z\|^2/2$ and that (3.4) yields $\|y\| \leqq (1 + O(\sigma))\|z\|$. Taking norms, and using the triangle inequality and (3.4), we obtain

$$\|E_1\|_F \leqq 2\frac{\|y\|}{\|z\|}\frac{\|y-z\|}{\|z\|} + 4\frac{\|y-z\|}{\|z\|} = O(\sigma).$$

By a similar argument we obtain

$$\|E_2\|_F \leqq 4\frac{\|y-z\|}{\|z\|^2}\|Bz\| \leqq \|B\|O(\sigma),$$

$$|z^T B z|\,\|E_3\|_F \leqq \|z\|^2\|B\|\frac{\|E_1\|_F}{\|z\|^2} = \|B\|O(\sigma).$$

Therefore, we get

$$\|B_+ - B'\|_F \leqq O(\sigma) + 2\theta\|B\|O(\sigma) + \theta\|B\|O(\sigma)$$

which yields (3.5). □

The following result was given by Griewank and Toint [7] for the positive definite case. We now show that the matrices B still satisfy a bounded deterioration relation.

THEOREM 3.3. *Let the assumptions of Theorem* 3.1 *hold and the matrix B be symmetric and positive definite on S. Then there exist $\varepsilon > 0$ such that if $\sigma \leqq \varepsilon$, the matrix B_+ given by* (1.5) *satisfies*

$$\|B_+ - H_*\|_M \leqq [1 + O(\sigma)]\|B - H_*\|_M + O(\sigma), \tag{3.6}$$

with $\|Q\|_M = \|MQM\|_F$ and M as defined in the proof of Theorem 3.1.

Proof. First note that using Theorem 3.1 we can choose ε sufficiently small so that $y^T s > 0$. Thus, by Theorem 2.3 we obtain that B_+ is positive definite on S. Since H_* is positive definite on S_*, there exists a positive constant c_1 such that $H_* + c_1 N_* N_*^T$ is positive definite; since the matrices B_+ and B are positive definite on S, there exist positive constants c_2 and c_3 such that $B + c_2 NN^T$ and $B_+ + c_3 NN^T$ are positive definite. Now choose $c = \max\{c_1, c_2, c_3\}$, define M as in Theorem 3.1, i.e.,

$$M^{-2} = H_* + cN_* N_*^T = H_*^c,$$

and consider the positive definite matrices

$$B_c = B + cNN^T \quad \text{and} \quad B_+^c = B_+ + cNN^T. \tag{3.7}$$

Since $s \in S$, we have

$$\|y - M^{-2}s\| = \|y - H_* s - c(N_* N_*^T - NN^T)s\|.$$

The triangle inequality, (3.1), and (3.2) yield

$$\frac{\|y - z\|}{\|z\|} = O(\sigma), \tag{3.8}$$

with $z = M^{-2}s$. Let $\bar{B}$ be given by (1.5) with z instead of y:

$$\bar{B} = U(s, z, B, \theta),$$

and let $B_c' = \bar{B} + cNN^T = U(s, z, B_c, \theta)$.

For any nonsingular symmetric matrix M, (1.5) yields

$$MB_c'M = U(M^{-1}s, Mz, MB_cM, \theta) = U(M^{-1}s, M^{-1}s, MB_cM, \theta), \tag{3.9}$$

$$MB_+^cM = U(M^{-1}s, My, MB_cM, \theta). \tag{3.10}$$

Now use Lemma 3.2 with $M^{-1}s$, My, $MB_c'M$, and MB_cM in place of z, y, B', and B, respectively. Note that (3.4) holds because of (3.8) and $(M^{-1}s)^T(MB_cM)(M^{-1}s) \neq 0$ because $s \in S$. Thus, using Lemma 3.2 and further restricting ε if necessary, we obtain

$$\begin{aligned}\|MB_+^cM - MB_c'M\|_F &\leqq [\|MB_cM\|_F + O(1)]O(\sigma) \\ &\leqq [\|MB_cM - I\|_F + O(1)]O(\sigma).\end{aligned}$$

Therefore, we have

$$\|B_+^c - B_c'\|_M \leqq [\|B_c - H_*^c\|_M + O(1)]O(\sigma). \tag{3.11}$$

When we use the fact that $\|Q\|_F^2 = \operatorname{tr}(Q^TQ)$ and $z = M^{-2}s$ a tedious but elementary calculation using (3.9) yields

$$\begin{aligned}&\|B_c' - H_*^c\|_M^2 - \|B_c - H_*^c\|_M^2 \\ &\quad = \|MB_c'M - I\|_F^2 - \|MB_cM - I\|_F^2 \\ &\quad = -(1-\theta)\left\{\left(1 - \frac{s^TB_cM^2B_cs}{s^TB_cs}\right)^2 + 2\left[\frac{s^TB_cM^2B_cM^2B_cs}{s^TB_cs} - \left(\frac{s^TB_cM^2B_cs}{s^TB_cs}\right)^2\right]\right\} \\ &\qquad - \theta\left\{\left(1 - \frac{s^TB_cs}{s^Ts}\right)^2 + 2\theta\left[\frac{s^TB_cM^2B_cs}{s^Ts} - \left(\frac{s^TB_cs}{s^Ts}\right)^2\right]\right\} \\ &\qquad - \theta(1-\theta)\left\{\left(\frac{s^TB_cM^2B_cs}{s^TB_cs}\right)^2 - \left(\frac{s^TB_cs}{s^Ts}\right)^2\right\}.\end{aligned}$$

Now, using the Schwartz inequality, we can easily show that all three brackets are nonnegative and since $\theta \in [0, 1]$ we get

$$\|B_c' - H_*^c\|_M \leqq \|B_c - H_*^c\|_M. \tag{3.12}$$

Now (3.11), (3.12), and the triangle inequality give

$$\begin{aligned}\|B_+^c - H_*^c\|_M &\leqq \|B_+^c - B_c'\|_M + \|B_c' - H_*^c\|_M \\ &\leqq [\|B_c - H_*^c\|_M + O(1)]O(\sigma) + \|B_c - H_*^c\|_M \\ &\leqq [1 + O(\sigma)]\|B_c - H_*^c\|_M + O(\sigma).\end{aligned} \tag{3.13}$$

Finally, using (3.7), (3.2), and the triangle inequality, we obtain our desired result (3.6). □

4. An application to nonlinear constrained optimization. Consider the following nonlinear constrained optimization problem (NLCOP):

$$\begin{aligned} &\text{minimize} \quad f(x) \\ &\text{subject to} \quad g_i(x)=0, \quad i=1,\cdots,m, \end{aligned} \tag{4.1}$$

where f and g_i are functionals defined on an open convex subset D of $\mathbf{R}^n$, twice continuously differentiable with second derivatives that are Lipschitz continuous in a neighborhood of the solution x_*. The solution of (4.1) is based on the use of the Lagrangian function defined as

$$l(x,\lambda)=f(x)+g(x)^T\lambda, \tag{4.2}$$

with $g=(g_1,\cdots,g_m)^T$ and $\lambda\in\mathbf{R}^m$ being the Lagrange multipliers. The second-order sufficiency conditions state that if x_* is a regular point (i.e., $\nabla g(x_*)$ full rank), with $g(x_*)=0$ and Lagrange multipliers λ_* such that $\nabla_x l(x_*,\lambda_*)=0$ and for all $z\in\mathbf{R}^n$ with $\nabla g_*^T z=0$, $z^T\nabla_x^2 l(x_*,\lambda_*)z>0$, then x_* is a minimizer of (4.1).

Hence, our problem can be restated as follows. Find (x_*,λ_*) such that $\nabla l(x_*,\lambda_*)=0$ with the Hessian $\nabla_x^2 l(x_*,\lambda_*)$ being positive definite on a subspace of $\mathbf{R}^n$ given by

$$S(x_*)=S_*=\{z\in\mathbf{R}^n:\nabla g(x_*)^T z=0\}. \tag{4.3}$$

A method initially proposed by Tapia [11] and more recently studied by Fontecilla [5] is based on solution of the following nonlinear problem:

$$h(x)=P(x)\nabla f(x)+\nabla g(x)g(x)=0, \tag{4.4}$$

with $P(x)=I-\nabla g(x)[\nabla g(x)^T\nabla g(x)]^{-1}\nabla g(x)^T$. It is easily seen that $h(x_*)=0$ if and only if $\nabla l(x_*,\lambda_*)=0$ with $\lambda_*=-(\nabla g_*^T\nabla g_*)^{-1}\nabla g_*^T\nabla f_*$. The Jacobian of h at the solution x_* is $P_*\nabla_x^2 l(x_*,\lambda_*)+\nabla g_*\nabla g_*^T$, which by Lemma 2.1 is nonsingular. We define a Newton-like method for solving (4.4) as follows.

ALGORITHM 4.5.

Step 1. Given x_0

(4.5a) Step 2. Set $\lambda_{k+1}=-(\nabla g_k^T\nabla g_k)^{-1}\nabla g_k^T\nabla f_k$

(4.5b) Step 3. Solve $[P_k\nabla_x^2 l(x_k,\lambda_{k+1})+\nabla g_k\nabla g_k^T]s_k=-h_k$

(4.5c) Step 4. Set $x_{k+1}=x_k+s_k$

Step 5. Set $k=k+1$. Go to Step 2.

If second-order information is unavailable or too expensive to evaluate, the Hessian $H_*=\nabla_x^2 l(x_*,\lambda_*)$ can be approximated using matrices generated with the update formula (1.5). The algorithm follows.

ALGORITHM 4.6.

Step 1. Given x_0, B_0

(4.6a) Step 2. Set $\lambda_{k+1}=-(\nabla g_k^T\nabla g_k)^{-1}\nabla g_k^T\nabla f_k$

(4.6b) Step 3. Solve $(P_kB_k+\nabla g_k\nabla g_k^T)s_k=-(P_k\nabla f_k+\nabla g_k g_k)$

(4.6c) Step 4. Set $w_k=P_ks_k$

(4.6d) Step 5. Set $y_k=\nabla_x l(x_k+w_k,\lambda_{k+1})-\nabla_x l(x_k,\lambda_{k+1})$

(4.6e) Step 6. Set $B_{k+1}=U(w_k,y_k,B_k,\theta_k)$

(4.6f) Step 7. Set $x_{k+1}=x_k+s_k$

Step 8. Set $k=k+1$. Go to Step 2.

Note that if B_k is positive definite on S_k the linear system (4.6b) has a unique solution. Further, note that the step used to update the matrices B_k is $w_k \in S_k$ and that s_k is the step taken from x_k to get x_{k+1}. In [6] we showed that Algorithm 4.6 generates a sequence $\{x_k\}$ converging to x_* two-step q-superlinearly.

Algorithm 4.6 with the BFGS update in (4.6e) was run on a set of 10 test problems. The program was written using MATLAB, an interactive computer program for linear algebra computations developed by Cleve Moler. The double-precision version of MATLAB was run on a VAX 11/780 running UNIX™/4.2. The test problems were taken from Hock and Schittkowski [8] and Nocedal and Overton [9]. On all of them, the Hessian of the Lagrangian ($\nabla_x^2 l(x_*, \lambda_*)$) is not positive definite.

We were interested in studying the behavior of the eigenvalues of the matrices B_k and $P_k B_k P_k + \nabla g_k \nabla g_k^T$ at each iteration, and comparing them with the eigenvalues of the matrices $H_* = \nabla_x^2 l(x_*, \lambda_*)$ and $P_* H_* P_* + \nabla g_* \nabla g_*^T$, respectively. We ran the test problems with two different initial matrices B_0. We first tried a finite-difference (FD) approximation of $\nabla_x^2 l(x_0, \lambda_0)$ with a stepsize $h_j = \max(10^{-6}, 10^{-6}|x_0^{(j)}|)$ for the jth column and where $x_0^{(j)}$ is the jth component of x_0. We then checked that B_0 was positive definite along S_0 by verifying that the eigenvalues of $P_0 B_0 P_0 + \nabla g_0 \nabla g_0^T$ were all positive. The second choice for B_0 was the identity.

We stopped the algorithm when $\|h(x_k)\| = \|P_k \nabla f_k + \nabla g_k g_k\|$ and when $\|g_k\|$ became less than 10^{-6}. We also stopped if either the maximum number of iterations (50) was reached or the condition number of $P_k B_k + \nabla g_k \nabla g_k^T$ became greater than 10^8.

The results are summarized in Tables 1.1 and 1.2 for $B_0 = FD[\nabla_x^2 l(x_0, \lambda_0)]$ and in Tables 2.1 and 2.2 for $B_0 = I$. The first row of the tables gives the triplet (TP, n, m) where TP is the number of the test problem as given in Hock and Schittkowski [8]; if TP is P1 or P2 they correspond to those given by Nocedal and Overton [9]. The number of variables is n, and m is the number of constraints. The first column in Table 1.1 is read as follows:

eig (H_*)	the eigenvalues of H_*;
eig ($P_* H_*$)	the eigenvalues of $P_* H_* P_* + \nabla g_* \nabla g_*^T$;
eig (B_0)	the eigenvalues of B_0;
eig ($P_0 B_0$)	the eigenvalues of $P_0 B_0 P_0 + \nabla g_0 \nabla g_0^T$;
eig (B_k)	the eigenvalues of B_k at the last iteration;
eig ($P_k B_k$)	the eigenvalues of $P_k B_k P_k + \nabla g_k \nabla g_k^T$ at the last iteration.

The results in the tables are given as follows. We give a triplet (neg, zero, pos),

meaning the number of negative, zero, and positive eigenvalues of the corresponding matrix. For instance, if the eigenvalues of H_* are $(2, 1, 0, -1, -3, -4)$, then in the row corresponding to eig (H_*) we will have the triplet (3, 1, 2). An eigenvalue is set to zero if it is less than 10^{-16} in absolute value.

The last four rows in Table 1.1 are used to give more information about the performance of the algorithm:

id distance from x_0 to x_*;
fh the final value of $\|h(x_k)\|$;
fg the final value of $\|g(x_k)\|$;
iter the number of iterations.

The eigenvalues of the matrices $P_k B_k P_k + \nabla g_k \nabla g_k^T$ are given to check the positive definiteness of B_k along the subspace S_k. Let us now comment on the results. The finite difference approximation maintains the same structure on the eigenvalues. Nothing extra was needed for B_0 to be positive definite along S_0. The eigenvalues of B_k and $P_k B_k P_k + \nabla g_k \nabla g_k^T$ for all k, although not given here, were computed and no changes were reported. The eigenvalue structure remained the same during the process, as was expected due to the results of §§ 2 and 3.

Test problem 26 is interesting in itself. It is the only one for which the method failed to converge. The reason is that the Hessian H_* is not positive definite along S_* numerically; that is, one of the eigenvalues of the matrix $P_* H_* P_* + \nabla g_* \nabla g_*^T$ is 0.7×10^{-16}. The finite difference approximation $P_0 B_0 P_0 + \nabla g_0 \nabla g_0^T$ shows this eigenvalue to be 3.8×10^{-13}, and therefore the method diverges.

In test problem 47 (Table 1.1), B_0 is positive definite and so are the remainder of the B_k. However, we still have convergence even though the Hessian H_* that the B_k is approximating is only positive definite on S_*.

Tables 2.1 and 2.2 indicate that the method is quite robust with respect to the initial guess B_0. In fact, we even have convergence for test problem 26. We think this is partly because the matrices B_k remain positive definite throughout the process although H_* is positive definite only on S_*. This is predictable, since $y_k^T w_k > 0$ for all k and B_0 is positive definite.

Acknowledgments. The author thanks J. E. Dennis for the fruitful discussion that led to Theorem 2.3, and Jorge Moré for his helpful comments that led to Lemma 3.2 and made the paper more readable.

LOCAL TIME-OPTIMAL FEEDBACK CONTROL OF STRICTLY NORMAL TWO-INPUT LINEAR SYSTEMS*

L. DAVID MEEKER†

Abstract. This paper introduces a new technique for the analysis of time-optimal control of linear systems. A family of easily calculated invariants is developed and, for an important class of two-input systems, is shown to provide a complete description of the time-optimal flow near the origin. The two switching surfaces are described analytically and qualitatively in topological terms. The time-optimal feedback function is defined and analyzed with respect to its complexity and sensitivity to errors in state variable measurement. The results lead to the first explicit construction of a local regular synthesis for multi-input systems of arbitrary order.

Key words. time-optimal feedback, closed-loop, stability

AMS(MOS) subject classifications. primary 49E15, 49E25

1. Introduction. This paper is concerned with the description, synthesis, and classification of time-optimal control systems that can be modeled by equations of the following form:

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u}, \tag{1.1a}$$

$$\mathbf{x} \in \mathbb{R}^n, \qquad \mathbf{u} \in \mathscr{C}^r \equiv \{\mathbf{u} \in \mathbb{R}^r : |u_i| \leqq 1,\ i = 1, 2, \cdots, r\}, \tag{1.1b}$$

$$\mathbf{B} = [\mathbf{b}^1, \cdots, \mathbf{b}^r], \quad \mathbf{b}^i \in \mathbb{R}^n, \quad \operatorname{rank}(\mathbf{B}) = r. \tag{1.1c}$$

Time-optimal control has been the subject of considerable research effort during the past 25 years. As a result of these investigations the optimal control functions have been identified and shown to be conceptually simple—piecewise constant with each control component either $+1$ or -1—with switching surfaces $\mathbf{\Omega}_1, \cdots, \mathbf{\Omega}_r$ ($\mathbf{\Omega}_i$ is the set of points of $\mathbb{R}^n$ where the ith control component changes sign) shown to be homeomorphic to a relatively open convex subset of an $(n-1)$-dimensional hyperplane and to divide the **controllable set K** (the set of points of $\mathbb{R}^n$ controllable to $\mathbf{0}$) into two relatively open sets corresponding to the two values $u_i = 1$ and $u_i = -1$ (thus showing that $\mathbf{K} \backslash \mathbf{\Omega}_i$ is the union of two disjoint components) [25].

These results provide an essentially complete qualitative picture of the time-optimal flow (the time-optimal trajectories) in the case of scalar control (when $r = 1$). However, this is far from the case for multidimensional controls ($r > 1$). The presence of two, or more, control dimensions greatly complicates the problem. In this instance several interesting and important questions arise:

(1) How do the switching surfaces interact? What is $\mathbf{\Omega}_i \cap \mathbf{\Omega}_j$ topologically?
(2) Can $\mathbf{\Omega}_i = \mathbf{\Omega}_j$ if $i \neq j$?
(3) What is the topological structure of $\mathbf{\Omega} \equiv \bigcup \mathbf{\Omega}_i$?
(4) How complicated or how simple can the piecewise constant optimal feedback function be? That is, how many "pieces" can there be, or "what is the connectivity of $\mathbf{K} \backslash \mathbf{\Omega}$"?
(5) How sensitive is the time-optimal feedback function to measurement errors or time lags in the feedback loop? In particular, is the time-optimal feedback control system stable with respect to measurement as defined by Hermes [12]?
(6) How are the answers to these questions encoded in the two matrices **A** and **B**?

* Received by the editors September 19, 1979; accepted for publication (in revised form) April 5, 1988.
† Department of Mathematics, University of New Hampshire, Durham, New Hampshire 03824.

In general, the answers to these questions are unknown. With $r>1$ only the case $n=r=2$ is fully understood [3], [4]. Other investigations have been directed toward the local analogues of the questions. That is, procedures for the analysis of the time-optimal flow on $\mathbf{K}(T)$, the ***T*-controllable set** composed of those points of $\mathbb{R}^n$ controllable to $\mathbf{0}$ in time T, in terms of the corresponding relativized switching surfaces $\mathbf{\Omega}_i(T)\equiv\mathbf{\Omega}_i\cap\mathbf{K}(T)$, $i=1,\cdots,r$, and $\mathbf{\Omega}(T)\equiv\mathbf{\Omega}\cap\mathbf{K}(T)$, for sufficiently small T [9], [17]-[19], [21], [22], [26], [27], and [29]. The answers to the local versions of questions (1)-(6) for the minimally controllable systems (a generic class discussed in § 2 herein) appear in [20] and [21] for the case $n=3$, $r=2$, and all but question (5) are answered for the $n=4$, r = 2 case in [22]. The general n, r case is discussed in a preliminary fashion in [19]. In this paper the answers to the local versions of questions (1)-(4) and (6) are answered for the class of strictly normal systems (see [9], [29], and § 2 herein) for systems with arbitrary n and $r=2$. Sufficient conditions for measurement stability (*H*-stability) are also developed for this class of systems.

The analysis and description of the time-optimal flow for these systems is simplified by the introduction of two mathematical structures that as yet have not become familiar in control theory literature. The first of these, the *theory of cell complexes* or, more properly, the *theory of* CW-*complexes* (see [16]) is necessary to describe the collection of points in $\mathbf{K}(T)$ controlled to $\mathbf{0}$ by all control functions having the same specific sequence of control values. Below we show that $\mathbf{K}(T)$ can be decomposed into a collection of well-defined cell complexes each associated with known switching sequences. The description and analysis of the time-optimal flow on each component cell complex are facilitated by the concepts and results of the *theory of semidynamical systems* (see [1]) whose characterization of attracting and invariant sets is critical to the results that follow. The following discussion of the known results for the cases $n=2$ and 3, $r=2$ is intended to illustrate the value of these two mathematical systems for the study and description of time-optimal or, more generally, bang-bang control systems.

In the well-known case where $n=r=2$ the time-optimal flow on $\mathbf{K}(T)$ occurs, for sufficiently small T, in only the two distinct forms shown in Fig. 1. The relative structure of the switching curves $\mathbf{\Omega}_1(T)$ and $\mathbf{\Omega}_2(T)$ is very different in the two cases. For systems of the type shown in Fig. 1(a), such as

$$\mathbf{A}=\begin{bmatrix}0 & -1\\ 1 & 0\end{bmatrix},\qquad \mathbf{B}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},$$

the two curves intersect only at $\mathbf{0}$, while for systems of the type shown in Fig. 1(b), such as

$$\mathbf{A}=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},\qquad \mathbf{B}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},$$

the two curves coincide and $\mathbf{\Omega}_1(T)=\mathbf{\Omega}_2(T)=\mathbf{\Omega}(T)$. $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$ has four components for systems such as those of Fig. 1(a) but only two components for those of Fig. 1(b).

The time-optimal trajectories can be described on the component **ABOA** of Fig. 1(a) by "use control $\mathbf{u}^1$ until you reach curve **BO**, then switch to $\mathbf{u}^2$ and use it until arrival at $\mathbf{0}$" (assuming the proper "naming" of the control vectors). This sequence "$\mathbf{u}^1$ switch to $\mathbf{u}^2$" defines what we will call an optimal control (switching) policy $\mathbf{p}=\langle\mathbf{u}^1,\mathbf{u}^2\rangle$, or, when there is no chance of confusion, simply $\mathbf{p}=\langle 1,2\rangle$. The component **ABOA** is composed of those points of $\mathbf{K}(T)$ controlled to $\mathbf{0}$ by control functions following the policy $\langle 1,2\rangle$ and is, accordingly, denoted by $\mathbf{D}\langle 1,2\rangle$. If we define the other two vertices of the control domain $\mathscr{C}^2$ by $\mathbf{u}^3=-\mathbf{u}^1$ and $\mathbf{u}^4=-\mathbf{u}^2$, the other

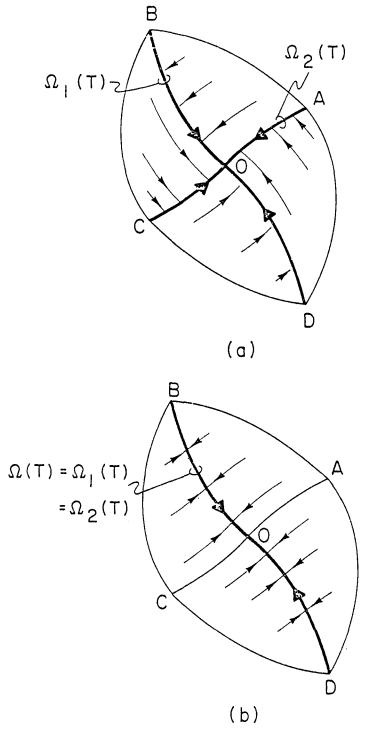

FIG. 1. *The two possible types of time-optimal flow near* $\mathbf{0}$ *for* $n = r = 2$.

components of $\mathbf{K}(T)$ in Fig. 1(a), **BCOB**, **CDOC**, and **DAOD**, are associated with the control policies $\langle 2, 3\rangle$, $\langle 3, 4\rangle$, and $\langle 4, 1\rangle$ and denoted by $\mathbf{D}\langle 2, 3\rangle$, $\mathbf{D}\langle 3, 4\rangle$, and $\mathbf{D}\langle 4, 1\rangle$, respectively. Similarly, $\mathbf{K}(T)$ of Fig. 1(b) can be described as the union of the four components $\mathbf{D}\langle 1, 2\rangle$, $\mathbf{D}\langle 3, 2\rangle$, $\mathbf{D}\langle 3, 4\rangle$, and $\mathbf{D}\langle 1, 4\rangle$.

Each set $\mathbf{D}\langle i, j\rangle$ is homeomorphic to the standard 2-cell $\boldsymbol{\sigma} = \{\mathbf{s} \in \mathbb{R}^2 : 0 \leqq s_1 \leqq s_2 \leqq T\}$ (this is discussed in detail in § 4). For example, $\mathbf{D}\langle 1, 2\rangle$ is the image of $\boldsymbol{\sigma}$ under the map

$$\mathbf{x}(s_1, s_2) = -\left[(\mathbf{u}^1 - \mathbf{u}^2) \int_0^{s_1} e^{-\mathbf{A}\tau} \mathbf{B}\, d\tau + \mathbf{u}^2 \int_0^{s_2} e^{-\mathbf{A}\tau} \mathbf{B}\, d\tau \right] \tag{1.2}$$

and is, therefore, a 2-cell (see [16]) composed of its interior open 2-cell and its three boundary 1-cells—the two constant control trajectories $\mathbf{D}\langle 1\rangle$ and $\mathbf{D}\langle 2\rangle$ (**AO** and **BO**) and the portion of the boundary T-isochrone (**AB**). Thus for each system type, as in Figs. 1(a) and 1(b), $\mathbf{K}(T)$ can be described as a cell complex consisting of the union (actually, in the language of CW-complexes, cellular adjunction) of four 2-cells each associated with a unique time-optimal switching policy (switching sequence). This is an example of the cellular decomposition proved for the general strictly normal system in § 6. However, we shall see that for general n, the maps corresponding to (1.2) of the standard n-cell into $\mathbf{K}(T)$ need not be injective except on the interior of the standard cell—certain boundary cells may coalesce or "lose dimension" under some maps. In such cases it is necessary to consider $\mathbf{K}(T)$ as a CW-complex rather than simply a cell complex.

The difference in the time-optimal flow pattern and the switching curve structure in Figs. 1(a) and 1(b) can be described by noting that the time-optimal trajectories

define a local semidynamical system on $\mathbf{K}(T)\backslash\{\mathbf{0}\}$ (a *semidynamical system* is a generalized dynamical system that permits intersecting trajectories; a *local* semidynamical system is a semidynamical system that has a finite escape time—provided, in this instance, by the optimal response time—for each point of the state space; see [1]).

The switching curve **BO** (or $\mathbf{D}\langle 2\rangle$) of **ABOA** (or $\mathbf{D}\langle 1, 2\rangle$) is the image of the 1-cell $\{(0, s_2): 0 < s_2 \leqq T\}$ of $\boldsymbol{\sigma}$ under (1.2) and is an **attracting set** of the flow while the curve **AO** (or $\mathbf{D}\langle 1\rangle$), the image of the 1-cell $\{(s_2, s_2): 0 < s_2 \leqq T\}$ under (1.2), is an **invariant set** of the flow. Note that $\mathbf{D}\langle 2\rangle$ is an attracting set of $\mathbf{D}\langle 1, 2\rangle$, but an invariant set of the adjoining cell $\mathbf{D}\langle 2, 3\rangle$. Indeed, the difference in the time-optimal flows of the two system types stems precisely from the fact that in systems such as those in Fig. 1(a), *attracting cells always adjoin invariant cells* and vice versa, while in systems such as those in Fig. 1(b), *attracting cells always adjoin attracting cells* and *invariant cells always adjoin invariant cells.* The structure theorem of § 9 extends these results to the general system (1.1) with $r = 2$.

As a consequence of the difference in their optimal flow patterns, the character of the time-optimal feedback function differs substantially between the two system types. In Fig. 1(b) the value it assumes on the switching curves **OB** and **OD** differ from the values assumed on either side of the curves. Obviously, implementation of such a closed-loop system would require infinitely precise measurement of the state variables, since the curves are sets of planar measure zero. On the other hand, the feedback function of systems of the type in Fig. 1(a) are much more tolerant of measurement errors, since small errors in state measurement yield either the correct control or a control value that drives the system across the switching curve and, thereby, increases the probability of determining the proper control. In § 7, where such matters are fully discussed, the feedback function of a system of the type in Fig. 1(a) is said to be **realizable**, while that of a system of the type in Fig. 1(b) is **nonrealizable** on the curve **BOD**.

As is to be expected, the closed-loop time-optimal systems of the two types differ in their response to measurement errors or time-lags in the control loop. As shown in Fig. 2(a) the realizable feedback control leads to a (small) "overshoot" in the trajectory, while in Fig. 2(b) the nonrealizable controller leads to "chatter" or a "sliding" motion back and forth across the time-optimal trajectory.

The system of Fig. 1(a) is actually "stable with respect to measurement" or H-stable in the sense of Hermes [12]. This concept will be discussed in § 11 herein.

Time-optimal control for the case $n = 3$, $r = 2$ is less well known. As shown in [20], strictly normal systems (to be defined below) occur in precisely three canonical and topologically distinct forms. Figure 3 provides sketches of typical switching surface structures (near the target point **0**) for each possible type.

In every case the switching surfaces $\boldsymbol{\Omega}_1(T)$ and $\boldsymbol{\Omega}_2(T)$ are composed of four two-dimensional cells. In Fig. 3(a) the surfaces have no 2-cell in common and intersect only in the 1-cells corresponding to constant control trajectories. This leads to the most complex structure with $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ consisting of six disjoint components (i.e., having connectivity equal to 6). It happens that for such systems the time-optimal feedback function is realizable on $\mathbf{K}(T)$ for sufficiently small T.

In Fig. 3(b), $\boldsymbol{\Omega}_1(T)$ and $\boldsymbol{\Omega}_2(T)$ contain two 2-cells in common. As a result $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ has connectivity equal to 4, and the feedback function is nonrealizable on the two common 2-cells where the closed-loop time-optimal system is "chatter-prone."

In the last case, Fig. 3(c), the two switching surfaces coincide and $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ has connectivity equal to 2. This situation is the three-dimensional analogue of the

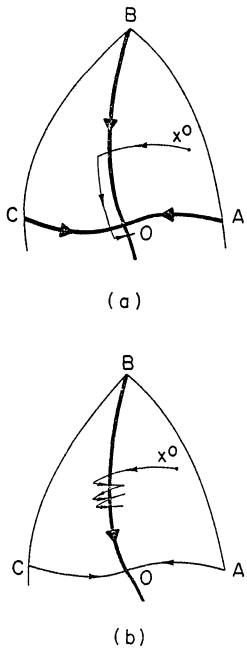

FIG. 2. *Typical responses of the systems of Fig.* 1 *to time lags or errors in state variable measurement in the time-optimal feedback loop.*

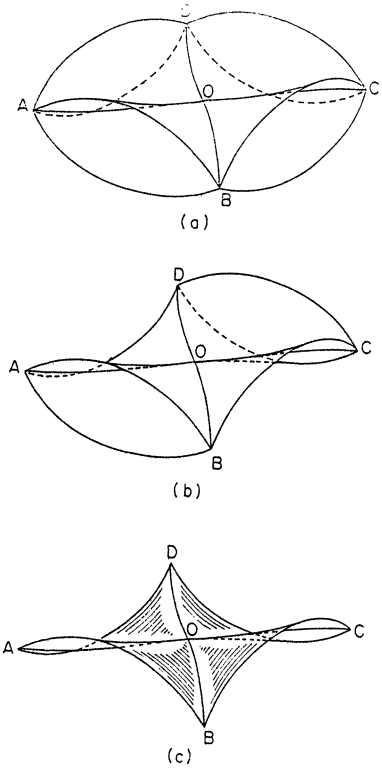

FIG. 3. *Qualitative description of switching surface structures for third-order two-input strictly normal systems.* (a) *The case* $\gamma(1) = \gamma(2) = 1$. (b) *The case* $\gamma(1) = -\gamma(2)$. (c) *The case* $\gamma(1) = \gamma(2) = -1$.

two-dimensional structure of Fig. 1(b) and the closed-loop feedback function is nonrealizable at each point of $\Omega(T)$.

In the sections to follow the analysis that has led to these results is extended to the class of strictly normal nth-order systems having two-dimensional controls. This analysis will show that the structure of the time-optimal flow near the origin is determined completely by geometric relationships among the $2n$ vectors $\mathbf{b}^1$, $\mathbf{Ab}^1$, $\cdots$, $\mathbf{A}^{n-1}\mathbf{b}^1$, $\mathbf{b}^2$, $\mathbf{Ab}^2$, $\cdots$, $\mathbf{A}^{n-1}\mathbf{b}^2$ as expressed by the values of the $n+1$ determinants:

$$\mathbf{d}(j) \equiv \det[\mathbf{b}^1, \mathbf{Ab}^1, \cdots, \mathbf{A}^{j-1}\mathbf{b}^1, \mathbf{b}^2, \mathbf{Ab}^2, \cdots, \mathbf{A}^{n-j-1}\mathbf{b}^2], \qquad j = 0, 1, \cdots, n \tag{1.3}$$

(which, for strictly normal systems, are all nonzero [9], [29]); their signs:

$$\delta(j) \equiv \operatorname{sgn}[\mathbf{d}(j)]; \tag{1.4}$$

and the **structure invariants**:

$$\gamma(j) = \gamma(j; \mathbf{A}, \mathbf{B}) \equiv \delta(j-1) \cdot \delta(j+1), \qquad j = 1, \cdots, n-1, \tag{1.5}$$

$$N(\mathbf{A}, \mathbf{B}) = \sum_{j=1}^{n-1} (1 - \gamma(j; \mathbf{A}, \mathbf{B}))/2, \tag{1.6}$$

$$M(\mathbf{A}, \mathbf{B}) \equiv \sum_{j=1}^{n-1} (1 - \gamma(j; \mathbf{A}, \mathbf{B}))\binom{n-2}{j-1}. \tag{1.7}$$

The vital role these invariants play in the theory is evident from the following theorem describing the local switching surface structure for two-input systems (the concepts of feedback function "realizability" and "Filippov type" are formally defined in § 7).

THEOREM 1.8. *Let system* (1.1) *be strictly normal, let* $r = 2$, *and let* T *be sufficiently small and positive. Then*

(a) $\mathbf{K}(T) \backslash \Omega(T)$ *has connectivity* $2(n - N(\mathbf{A}, \mathbf{B}))$;

(b) $\Omega_1(T) \cap \Omega_2(T)$ *is the union of* $M(\mathbf{A}, \mathbf{B})$ $(n-1)$*-dimensional cells*;

(c) $\Omega_1(T) = \Omega_2(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) = n-1$ (*that is,* $\gamma(1; \mathbf{A}, \mathbf{B}) = \cdots = \gamma(n-1; \mathbf{A}, \mathbf{B}) = -1$);

(d) *The time-optimal feedback function is realizable on* $\mathbf{K}(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) = 0$ (*that is,* $\gamma(1; \mathbf{A}, \mathbf{B}) = \cdots = \gamma(n-1; \mathbf{A}, \mathbf{B}) = 1$);

(e) *The feedback function is of Filippov type on the relative interior of some* $(n-1)$*-dimensional cell of* $\Omega(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) \leqq n-2$.

These results, which are consequences of the cellular decomposition theorem proved in § 6, imply that in the case $n = 2$, only the single invariant $\gamma(1) = \delta(0) \cdot \delta(2)$ is defined and the structures of Figs. 1(a) and 1(b) occur when $\gamma(1)$ equals 1 and -1, respectively. When $n = 3$, two invariants, $\gamma(1) = \delta(0) \cdot \delta(2)$ and $\gamma(2) = \delta(1) \cdot \delta(3)$, are defined. The switching surfaces have the structure of Fig. 3(a) when $\gamma(1) = \gamma(2) = 1$, the structure of Fig. 3(b) when $\gamma(1) = -\gamma(2)$, and the structure of Fig. 3(c) when $\gamma(1) = \gamma(2) = -1$.

While complex approximations and combinatorial analysis of §§ 3–6 underlie the proof of Theorem 1.8, the final result is a powerful and simple tool for the design and analysis of time-optimal control systems. As the following examples illustrate, the

theorem provides a series of easily calculated invariants which provide a complete qualitative description of the local switching surface structure and of the time-optimal feedback function.

Example A. The system

$$\mathbf{A}=\begin{bmatrix}0 & 0 & 1\\ 1 & 0 & -2\\ 0 & 1 & 0\end{bmatrix}, \qquad \mathbf{B}=\begin{bmatrix}1 & 0\\ 0 & 0\\ 0 & 1\end{bmatrix}$$

has $\mathbf{d}(0)=\mathbf{d}(1)=\mathbf{d}(3)=1$, $\mathbf{d}(2)=2$, and $\boldsymbol{\gamma}(1)=\boldsymbol{\gamma}(2)=1$, which implies the switching surface structure of Fig. 3(a) with $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ having maximal connectivity of 6 and $\boldsymbol{\Omega}_1(T)\cap\boldsymbol{\Omega}_2(T)$ consisting only of 1-cells. In addition, as will be shown in § 11, this system is locally measurement stable.

Example B. The system

$$\mathbf{A}=\begin{bmatrix}0 & 1 & 0\\ 1 & 0 & 1\\ 0 & 1 & 0\end{bmatrix}, \qquad \mathbf{B}=\begin{bmatrix}1 & 0\\ 0 & 0\\ 0 & 1\end{bmatrix}$$

has $\mathbf{d}(0)=\mathbf{d}(1)=1$, $\mathbf{d}(2)=\mathbf{d}(3)=-1$, and $\boldsymbol{\gamma}(1)=\boldsymbol{\gamma}(2)=-1$. This configuration implies the switching surface structure of Fig. 3(c) with $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ having minimal connectivity of 2 and $\boldsymbol{\Omega}_1(T)=\boldsymbol{\Omega}_2(T)$. In this situation the closed-loop system is "chatter-prone" (see Fig. 2(b)) at each point of $\boldsymbol{\Omega}(T)$.

Example C. The small angle roll-yaw motions of a satellite in circular orbit about a spherical earth in normalized time are of the form (1.1) with

$$\mathbf{A}=\begin{bmatrix}0 & 1 & 0 & 0\\ -\alpha_1 & 0 & 0 & 1-\alpha_1\\ 0 & 0 & 0 & 1\\ 0 & \alpha_2-1 & -4\alpha_2 & 0\end{bmatrix}, \qquad \mathbf{B}=\begin{bmatrix}0 & 0\\ 1 & 0\\ 0 & 0\\ 0 & 1\end{bmatrix},$$

with the two parameters α_1 and α_2 constrained by the conditions $0<\alpha_2<\alpha_1<1$ [22]. For this fourth-order system $\mathbf{d}(4)=4\alpha_2(1-\alpha_2)^2$, $\mathbf{d}(3)=1-\alpha_2$, $\mathbf{d}(2)=1$, $\mathbf{d}(1)=1-\alpha_1$, and $\mathbf{d}(0)=\alpha_1(1-\alpha_1)^2$ so, under the constraints above, $\boldsymbol{\gamma}(1)=\boldsymbol{\gamma}(2)=\boldsymbol{\gamma}(3)=1$. Thus, by Theorem 1.8, since $N(\mathbf{A},\mathbf{B})=M(\mathbf{A},\mathbf{B})=0$, $\mathbf{K}(T)\backslash\boldsymbol{\Omega}(T)$ has connectivity equal to 8, its (three-dimensional) switching surfaces intersect only in cells of dimensions 1 and 2, and its time-optimal feedback function is realizable on all of $\mathbf{K}(T)$ (i.e., Fig. 2(a)) and, therefore, tolerant of errors in the feedback loop.

2. Strictly normal and minimally controllable systems. The method of analysis described in this paper is applicable to a generic class of time-optimal control systems which have been termed "minimally controllable" [21].

DEFINITION 2.1. System (1.1) is said to be minimally controllable if there exists a neighborhood $\mathbf{U}$ of $\mathbf{0}\in\mathbb{R}^n$ such that for each $\mathbf{x}\in\mathbf{U}$ there exists an extremal control function $\mathbf{v}(\cdot,\mathbf{x})$ that controls $\mathbf{x}$ to the origin in minimum time and has no more than $n-1$ switches.

Remark 2.2. Since a system is controllable if $\mathbf{K}(T)$ contains a neighborhood of $\mathbf{0}$ [14], minimally controllable systems are controllable, but need not be normal (i.e., have unique time-optimal control functions [14]). For instance, the linearized rendezvous problem [18] presents an example of a minimally controllable but nonnormal system.

Remark 2.3. In the scalar control case ($r=1$) or the case $n=2$, a system is minimally controllable if and only if it is controllable. Sufficient conditions for minimal controllability have appeared in [17], [19], and [20].

Hájek [9] has called the general system (1.1) with r-dimensional controls **strictly normal** if, for any collection of integers, $j_1 \geqq 0, \cdots, j_r \geqq 0$ satisfying $j_1 + \cdots + j_r = n$, the n vectors $\mathbf{A}^m\mathbf{b}^i$, $0 \leqq m \leqq j_{i-1}$, $i = 1, 2, \cdots, r$, are linearly independent. For example, when $r=2$, the case of interest here, a system is strictly normal if and only if all the determinants $\mathbf{d}(0), \mathbf{d}(1), \cdots, \mathbf{d}(n)$ of (1.3) are nonzero.

Yeung [29] has shown that normal systems are strictly normal if and only if they are minimally controllable. He has also shown that for such systems and for small T, $\mathbf{K}(T)$ is the union of $2r^{n-1}$ sets, which Hájek [9] called "terminal manifolds," each of which has a nonempty interior and is associated with a distinct control-switching sequence. In the following sections these control sequences are identified for the case $r=2$ and the corresponding 2^n terminal manifolds shown to form natural groups whose interiors form the components of $\mathbf{K}(T)\backslash\mathfrak{Q}(T)$.

3. Identification of time-optimal control functions. In this section we identify, for strictly normal two-input systems, all time-optimal control functions having small response times. These controls are shown to be naturally grouped: first, by the number of first coordinate switches and, second, by the actual sequence of control values assumed by the functions.

Our primary tool in this investigation is, of course, the minimum principle of Pontryagin [14] which, in this instance, implies that a control function $\mathbf{v}$ is extremal for a point $\mathbf{x}$ (i.e., controls $\mathbf{x}$ to $\mathbf{0}$ in the shortest possible time) if and only if it satisfies

$$\boldsymbol{\lambda}' e^{-\mathbf{A}t}\mathbf{B}\mathbf{v}(t) = \min\{\boldsymbol{\lambda}' e^{-\mathbf{A}t}\mathbf{B}\mathbf{u}: \mathbf{u} \in \mathscr{C}^2\} \tag{3.1}$$

almost everywhere on $0 \leqq t \leqq T$, where T is the optimal response time for $\mathbf{x}$. The vector $\boldsymbol{\lambda} \in \mathbb{R}^n$ is an outernormal of a supporting hyperplane of $\mathbf{K}(T)$ at $\mathbf{x}$ [14]. Such a vector $\boldsymbol{\lambda}$ will be said to *generate control functions* $\mathbf{v}$ *and* $-\mathbf{v}$ *over the interval* [0, T] if $\boldsymbol{\lambda}$ and $\mathbf{v}$ satisfy (3.1). (It should be noted that, with this definition, $-\boldsymbol{\lambda}$ also generates $\mathbf{v}$ and $-\mathbf{v}$ over $[0, T]$.)

If $\boldsymbol{\lambda}$ *generates* $\mathbf{v} = (v_1, v_2)$ (we identify points in $\mathbb{R}^m$ with $m \times 1$ vectors) then (3.1) implies

$$v_i(t) = -\operatorname{sgn}[\boldsymbol{\lambda}' e^{-\mathbf{A}t}\mathbf{b}^i], \qquad i = 1, 2, \tag{3.2}$$

whenever $\boldsymbol{\lambda}' e^{-\mathbf{A}t}\mathbf{b}^i \neq 0$. Since the functions $t \mapsto \boldsymbol{\lambda}' e^{-\mathbf{A}t}\mathbf{b}^i$, $i=1, 2$, are analytic, they either vanish identically or have isolated zeros. In the latter instance such zeros, where v_1 or v_2 may change sign, correspond to possible *switching points* of $\mathbf{v}$. If neither of the two functions vanishes identically, $\mathbf{v}$ is uniquely defined by (3.2) and the additional requirement of continuity from the right. *The assumption of right continuity will be implicit below.*

Because of (3.1) each extremal control function is generated by some vector on the unit sphere in $\mathbb{R}^n$. Moroz [25] and others have studied the set of extremal functions using parametrizations of the sphere. Unfortunately, while these global parametrizations yield a description of the switching behavior of the control functions, they do so in an obscure and complicated fashion.

An alternate method of parametrization is developed here. While it is not global in scope—n parametric families are required to describe the extremal control functions on $[0, T]$ for small T—it has the virtue of being intimately related to the switching behavior of the control functions themselves. This description is based on the fact that the control function generated by the vector $\boldsymbol{\lambda}$ switches in component i ($i=1$ or 2) at

time s if and only if $\boldsymbol{\lambda}$ is orthogonal to the vector

$$\mathbf{E}^i(s) \equiv e^{-\mathbf{A}s}\mathbf{b}^i.$$

With this observation it is clear that $\mathbf{v}$ (in (3.1)) switches in components $\alpha, \beta, \gamma, \cdots$ (where $\alpha, \beta, \gamma, \cdots = 1$ or 2) at times $s_1, s_2, s_3, \cdots$ only if $\boldsymbol{\lambda}$ is orthogonal to $\mathbf{E}^\alpha(s_1), \mathbf{E}^\beta(s_2), \mathbf{E}^\gamma(s_3), \cdots$. The notation of exterior algebra [7] is useful in expressing such relationships. For example, if $\mathbf{x}^1, \cdots, \mathbf{x}^{n-1}$ are linearly independent vectors, the $(n-1)$-vector $\mathbf{x}^1 \wedge \cdots \wedge \mathbf{x}^{n-1}$ may be identified with the unique vector $\boldsymbol{\lambda} \in \mathbb{R}^n$ that satisfies

$$\boldsymbol{\lambda}'\mathbf{x} = \mathbf{x}^1 \wedge \cdots \wedge \mathbf{x}^{n-1} \wedge \mathbf{x} = \det[\mathbf{x}^1, \cdots, \mathbf{x}^{n-1}, \mathbf{x}],$$

for all $\mathbf{x}$ in $\mathbb{R}^n$. Clearly $\boldsymbol{\lambda}$ is orthogonal to $\mathbf{x}^1, \cdots, \mathbf{x}^{n-1}$ and $\boldsymbol{\lambda}'\mathbf{x} = 0$ only for those $\mathbf{x}$ in the span of $\mathbf{x}^1, \cdots, \mathbf{x}^{n-1}$.

The relationships among the outernormals of $\mathbf{K}(T)$ (the $\boldsymbol{\lambda}$'s), the switching times s_j, and the vectors $\mathbf{E}^i(s_j)$ permit (in the case of strict normality) the identification of all the time-optimal control functions over a sufficiently small interval $[0, T]$. For example, in the three-dimensional case, any $\boldsymbol{\lambda}$ generating a control function having a switch on the first coordinate when $t = s_1$, and a switch on the second coordinate when $t = s_2$, *must* be orthogonal to $\mathbf{E}^1(s_1)$ and $\mathbf{E}^2(s_2)$ and thus *must* be a multiple of $\boldsymbol{\lambda}^1(s_1, s_2) \equiv \mathbf{E}^1(s_1) \wedge \mathbf{E}^2(s_2)$.

The control function $\mathbf{v} = (v_1, v_2)$ generated by $\boldsymbol{\lambda}^1(s_1, s_2)$ is determined (via (3.2)) by the signs of

$$\begin{aligned}
-\boldsymbol{\lambda}^1(s_1, s_2)'\mathbf{E}^1(t) &= -(\mathbf{b}^1 - \mathbf{A}\mathbf{b}^1 s_1 + \cdots) \wedge (\mathbf{b}^2 - \mathbf{A}\mathbf{b}^2 s_2 + \cdots) \wedge (\mathbf{b}^1 - \mathbf{A}\mathbf{b}^1 t + \cdots) \\
&= (s_1 - t)[\mathbf{b}^1 \wedge \mathbf{A}\mathbf{b}^1 \wedge \mathbf{b}^2 + \cdots] = (s_1 - t)[\det[\mathbf{b}^1, \mathbf{A}\mathbf{b}^1, \mathbf{b}^2] + \cdots] \\
&= (s_1 - t)[\mathbf{d}(2) + \cdots]
\end{aligned}$$

and

$$\begin{aligned}
-\boldsymbol{\lambda}^1(s_1, s_2)'\mathbf{E}^2(t) &= -(\mathbf{b}^1 - \mathbf{A}\mathbf{b}^1 s_1 + \cdots) \wedge (\mathbf{b}^2 - \mathbf{A}\mathbf{b}^2 s_2 + \cdots) \wedge (\mathbf{b}^2 - \mathbf{A}\mathbf{b}^2 t + \cdots) \\
&= (s_2 - t)[-\mathbf{b}^1 \wedge \mathbf{b}^2 \wedge \mathbf{A}\mathbf{b}^2 + \cdots] = (s_2 - t)[-\mathbf{d}(1) + \cdots].
\end{aligned}$$

Therefore, the optimal control functions generated by $\boldsymbol{\lambda}^1(s_1, s_2)$ (which, we recall, are the only functions with a single switch on each coordinate) switch when $t = s_1$ and s_2 and, over a sufficiently small interval, $0 \leqq t \leqq T$, describe the control sequences (recall $\boldsymbol{\delta}(i) = \operatorname{sgn}[\mathbf{d}(i)]$)

$$(-\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)) \to (\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)) \to (\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)),$$

or

$$(\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)) \to (-\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)) \to (-\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)),$$

if $0 < s_1 < s_2 < T$, and the sequences

$$(-\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)) \to (-\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)) \to (\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)),$$

or

$$(\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1)) \to (\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)) \to (-\boldsymbol{\delta}(2), \boldsymbol{\delta}(1)),$$

if $0 < s_2 < s_1 < T$. Thus, of the eight possible control sequences having a switch in each coordinate, only these four are time-optimal. Note that the controls always begin with $\pm(-\boldsymbol{\delta}(2), \boldsymbol{\delta}(1))$ and end with $\pm(\boldsymbol{\delta}(2), -\boldsymbol{\delta}(1))$. Obviously control functions with other switching patterns (e.g., two switches on coordinate 1) can be identified in the same way. Their sequences of control values will be completely determined by

$\delta(1), \delta(2), \delta(0) = \operatorname{sgn}[\mathbf{b}^2 \wedge \mathbf{A}\mathbf{b}^2 \wedge \mathbf{A}^2\mathbf{b}^2]$ and $\delta(3) = \operatorname{sgn}[\mathbf{b}^1 \wedge \mathbf{A}\mathbf{b}^1 \wedge \mathbf{A}^2\mathbf{b}^1]$. This analysis underlies the results of [17], [20], and [21]. The same approach will now be used to identify optimal control switching sequences for the general nth-order two-input strictly normal system.

Any control function that switches in the first coordinate at times $s_1, \cdots, s_j$ and in the second coordinate at times $s_{j+1}, \cdots, s_{n-1}$ must be generated by a multiple of the vector

$$\boldsymbol{\lambda}(\mathbf{s}; j) \equiv \mathbf{E}^1(s_1) \wedge \cdots \wedge \mathbf{E}^1(s_j) \wedge \mathbf{E}^2(s_{j+1}) \wedge \cdots \wedge \mathbf{E}^2(s_{n-1}), \tag{3.3}$$

for $\mathbf{s} = (s_1, \cdots, s_n) \in \mathbb{R}^n$.

The sequence of control values assumed by a control function generated by $\boldsymbol{\lambda}(\mathbf{s}, j)$ is determined by the signs of $\boldsymbol{\lambda}(\mathbf{s}, j)'\mathbf{E}^i(t)$, $i = 1, 2$, for small values of t. From (3.3) it can be seen that these functions depend on k-vector factors of the form

$$\bigwedge_{j=1}^{k} \mathbf{E}^i(a_j) = \bigwedge_{j=1}^{k} \left(\sum_{m=0}^{\infty} (-1)^m \frac{\mathbf{A}^m \mathbf{b}^i a_j^m}{m!} \right). \tag{3.4}$$

This function is clearly analytic (even entire) in each a_j and vanishes when any two a's are equal. It therefore has the Vandermonde function

$$\operatorname{vdm}(a_1, \cdots, a_k; k) \equiv \prod_{j=1}^{k} \prod_{m=j+1}^{k} (a_m - a_j)$$

as a factor. The leading k-vector term in the expansion is easily seen to be $\mathbf{b}^i \wedge \mathbf{A}\mathbf{b}^i \wedge \mathbf{A}^2\mathbf{b}^i \wedge \cdots \wedge \mathbf{A}^{k-1}\mathbf{b}^i$.

With these two facts in mind it is easy to see that

$$\bigwedge_{j=1}^{k} \mathbf{E}^i(a_j) = \frac{(-1)^{k(k-1)/2}}{1! \cdot 2! \cdot \cdots \cdot (k-1)!} \operatorname{vdm}(a_1, \cdots, a_k)(\mathbf{b}^i \wedge \mathbf{A}\mathbf{b}^i \wedge \cdots \wedge \mathbf{A}^{k-1}\mathbf{b}^i + \cdots). \tag{3.5}$$

Now, in order to determine the sign sequences of $\boldsymbol{\lambda}(\mathbf{s}, j)'\mathbf{E}^1(t)$ and $\boldsymbol{\lambda}(\mathbf{s}, j)'\mathbf{E}^2(t)$, which determine the extremal controls generated by $\boldsymbol{\lambda}(\mathbf{s}, j)$, we assume that the switching times satisfy

$$0 < s_1 < \cdots < s_j < s_n < T \quad \text{and} \quad 0 < s_{j+1} < \cdots < s_{n-1} < s_n < T. \tag{3.6}$$

Then, using (3.5), we have

$$\begin{aligned} \boldsymbol{\lambda}(\mathbf{s}, j)'\mathbf{E}^1(t) &= (-1)^{n-1}\mathbf{E}^1(t) \wedge \bigwedge_{m=1}^{j} \mathbf{E}^1(s_m) \wedge \bigwedge_{m=j+1}^{n-1} \mathbf{E}^2(s_m) \\ &= (-1)^p \cdot \alpha \cdot \operatorname{vdm}(t, s_1, \cdots, s_j; j+1) \cdot \operatorname{vdm}(s_{j+1}, \cdots, s_{n-1}; n-j-1) \\ &\qquad \cdot [\mathbf{b}^1 \wedge \cdots \wedge \mathbf{A}^j\mathbf{b}^1 \wedge \mathbf{b}^2 \wedge \cdots \wedge \mathbf{A}^{n-j-2}\mathbf{b}^2 + \mathbf{O}(T)] \\ &= (-1)^p \cdot \alpha \cdot V(\mathbf{s}; j) \cdot \prod_{m=1}^{j} (s_m - t) \cdot [\mathbf{d}(j+1) + \mathbf{O}(T)] \end{aligned} \tag{3.7}$$

where

$$p = n - 1 + j(j+1)/2 + (n-j-1)(n-j-2)/2,$$

$$\alpha = 1/[1! \cdot 2! \cdot \cdots \cdot j! \cdot 1! \cdot 2! \cdot \cdots \cdot (n-j-2)!],$$

$$V(\mathbf{s}; j) = \operatorname{vdm}(s_1, \cdots, s_j; j) \cdot \operatorname{vdm}(s_{j+1}, \cdots, s_{n-1}; n-j-1).$$

Similarly, we find

$$\begin{aligned}\boldsymbol{\lambda}(\mathbf{s},j)'\mathbf{E}^2(t) &= (-1)^{n-j-1}\bigwedge_{m=1}^{j}\mathbf{E}^1(s_m)\wedge\mathbf{E}^2(t)\wedge\bigwedge_{m=j+1}^{n-1}\mathbf{E}^2(s_m)\\ &= (-1)^q\cdot\beta\cdot V(\mathbf{s},j)\cdot\prod_{m=j+1}^{n-1}(s_m-t)\cdot[\mathbf{d}(j)+\mathbf{O}(T)]\end{aligned}\tag{3.8}$$

where

$$q=n-j-1+j(j-1)/2+(n-j)(n-j-1)/2=-2j+p+n-j-1,$$
$$\beta=\alpha\cdot j!/(n-j-1)!.$$

From (3.7) and (3.8) we see, after canceling common sign factors, that if $\mathbf{d}(j)$ and $\mathbf{d}(j+1)$ are both nonzero and T is sufficiently small (so that $\operatorname{sgn}[\mathbf{d}(j)+\mathbf{O}(T)]=\boldsymbol{\delta}(j)$ and $\operatorname{sgn}[\mathbf{d}(j+1)+\mathbf{O}(T)]=\boldsymbol{\delta}(j+1)$), $\boldsymbol{\lambda}(\mathbf{s},j)$ generates a unique pair of control functions over the interval $0\leqq t\leqq s_n\leqq T$ which begin with the controls

$$\pm\mathbf{u}(1,j)\equiv\pm(\boldsymbol{\delta}(j+1),(-1)^{n-j-1}\boldsymbol{\delta}(j))\tag{3.9a}$$

and, after j changes of sign on the first coordinate (at $t=s_1,\cdots,s_j$) and $n-j-1$ changes on the second coordinate (at $t=s_{j+1},\cdots,s_{n-1}$), terminate with the controls

$$\pm\mathbf{u}(n,j)\equiv\pm((-1)^j\boldsymbol{\delta}(j+1),\boldsymbol{\delta}(j)).\tag{3.9b}$$

The requirement (3.6) is not, in fact, necessary. Indeed, (3.5), (3.7), and (3.8) show that

$$\boldsymbol{\lambda}^*(\mathbf{s},j)\equiv\boldsymbol{\lambda}(\mathbf{s},j)/[\operatorname{vdm}(s_1,\cdots,s_j;j)\cdot\operatorname{vdm}(s_{j+1},\cdots,s_{n-1};n-j-1)]\tag{3.10}$$

has removable singularities and is well defined at each point of the boundary of the n-dimensional cell complex

$$\boldsymbol{\Delta}(j,T)\equiv\{\mathbf{s}\in\mathbb{R}^n:0\leqq s_1\leqq\cdots\leqq s_j\leqq s_n\leqq T,0\leqq s_{j+1}\leqq\cdots\leqq s_n\leqq T\}\tag{3.11}$$

and generates the same control functions as $\boldsymbol{\lambda}(\mathbf{s},j)$ for points of its interior (that satisfy (3.6)).

These results are summarized in the following lemma.

LEMMA 3.12. *If*

(a) *The two determinants* $\mathbf{d}(j)$ *and* $\mathbf{d}(j+1)$ (*see* (1.3)) *are both nonzero and have signs* $\boldsymbol{\delta}(j)$ *and* $\boldsymbol{\delta}(j+1)$;

(b) T *is sufficiently small*;

(c) $\mathbf{s}\in\boldsymbol{\Delta}(j,T)=\{\mathbf{s}\in\mathbb{R}^n:0\leqq s_1\leqq\cdots\leqq s_j\leqq s_n\leqq T,0\leqq s_{j+1}\leqq\cdots\leqq s_n\leqq T\}$,

then the vector $\boldsymbol{\lambda}^*(\mathbf{s},j)$ (*see* (3.10)) *generates two time-optimal control functions,* $\mathbf{v}(\cdot;\mathbf{s},j)$ *and* $-\mathbf{v}(\cdot;\mathbf{s},j)$, *over the interval* $0\leqq t\leqq s_n$. *For those points* $\mathbf{s}$ *in the interior of* $\boldsymbol{\Delta}(j,T)$ *these functions satisfy the following*:

(1) $\mathbf{v}(t;\mathbf{s},j)=\mathbf{u}(1,j)\equiv(\boldsymbol{\delta}(j+1),(-1)^{n-j-1}\boldsymbol{\delta}(j))$, $0<t<\min(s_1,s_{j+1})$;

(2) $\mathbf{v}(\cdot;\mathbf{s},j)$ *changes sign in the first coordinate when* $t=s_1,s_2,\cdots,s_j$ *and in the second coordinate when* $t=s_{j+1},s_{j+2},\cdots,s_{n-1}$;

(3) $\mathbf{v}(t;\mathbf{s},j)=\mathbf{u}(n,j)\equiv((-1)^j\boldsymbol{\delta}(j+1),\boldsymbol{\delta}(j))$ *when* $\max(s_j,s_{n-1})<t<s_n$.

By Lemma 3.12, each point of the interior, $\boldsymbol{\Delta}(j,T)^0$, of $\boldsymbol{\Delta}(j,T)$ corresponds to a unique pair of time-optimal control functions satisfying the conclusions (1)-(3). If $\mathbf{s}\in\boldsymbol{\Delta}(j,T)^0$ has distinct coordinates, these control functions have $n-1$ switches and take on n values from among the extreme points of $\mathscr{C}^2$. In this case a typical control sequence for $\mathbf{v}(\cdot;\mathbf{s},j)$ is of the form $\mathbf{u}(1,j),\mathbf{u}^2,\cdots,\mathbf{u}^{n-1},\mathbf{u}(n,j)$ with the values of $\mathbf{u}^2,\cdots,\mathbf{u}^{n-1}$ determined by the relative order of $s_1,\cdots,s_j$ and $s_{j+1},\cdots,s_{n-1}$. For example, if $s_1<s_{j+1}$, $\mathbf{u}^2=(-\boldsymbol{\delta}(j+1),(-1)^{n-j-1}\boldsymbol{\delta}(j))$; while if $s_{j+1}<s_1$, $\mathbf{u}^2=(\boldsymbol{\delta}(j+1),(-1)^{n-j}\boldsymbol{\delta}(j))$. If some $s_\alpha=s_\beta$, $1\leqq\alpha\leqq j<\beta\leqq n-1$, then switches will occur

simultaneously on both coordinates, and one or more of the $\mathbf{u}^i$'s will be missing from the sequence of control values.

To be more precise, suppose that $\mathbf{s} \in \Delta(j, T)^0$ has distinct coordinates, and let $s_{\pi(1)}, s_{\pi(2)}, \cdots, s_{\pi(n-1)}$ be the first $n-1$ coordinates of $\mathbf{s}$ arranged in order of increasing magnitude. (Note that $s_{\pi(1)}$ must equal the smaller of s_1 and s_{j+1} while $s_{\pi(n-1)}$ must equal the larger of s_j and s_{n-1}.) The control function $\mathbf{v}(\cdot; \mathbf{s}, j)$ is then given by

$$
\begin{aligned}
\mathbf{v}(t; \mathbf{s}, j) &= \mathbf{u}(1, j), && 0 \leqq t < s_{\pi(1)}, \\
&= \mathbf{u}^2, && s_{\pi(1)} \leqq t < s_{\pi(2)}, \\
&\vdots && \vdots \\
&= \mathbf{u}^i, && s_{\pi(i-1)} \leqq t < s_{\pi(i)}, \\
&\vdots && \vdots \\
&= \mathbf{u}^n, && s_{\pi(n-1)} \leqq t \leqq s_n.
\end{aligned} \tag{3.13}
$$

The process of ordering the coordinates of those $\mathbf{s}$ in $\Delta(j, T)^0$ whose coordinates are distinct defines permutations of $\{1, 2, \cdots, n-1\}$ that are characterized by the fact that their inverses are order-preserving on the subsets $\{1, 2, \cdots, j\}$ and $\{j+1, \cdots, n-1\}$. There are precisely $\binom{n-1}{j} = (n-1)!/(j!(n-1-j)!)$ such ***j*-permissible permutations.** From (3.13), it is clear that if $\mathbf{s}^1$ and $\mathbf{s}^2$ are two different points of $\Delta(j, T)^0$ which define the same j-permissible permutation, π, then the relative order of all coordinates s_α and s_β, with $\alpha \leqq j < \beta$, are the same, and thus the corresponding control functions $\mathbf{v}(\cdot, \mathbf{s}^1, j)$ and $\mathbf{v}(\cdot, \mathbf{s}^2, j)$ assume the same sequence of control values but differ in at least one switching time. Let

$$
\Delta(j, T; \pi)^0 = \{\mathbf{s} \in \Delta(j, T)^0 \colon s_\alpha \neq s_\beta,\ 1 \leqq \alpha, \beta \leqq n-1, \text{ and } \pi \text{ orders } s_1, \cdots, s_{n-1}\} \tag{3.14}
$$

and let $\Delta(j, T; \pi)$ be its closure. The mapping

$$
\mathbf{s} \mapsto (s_{\pi(1)}, \cdots, s_{\pi(n-1)}, s_n)
$$

is a cellular homeomorphism [16] (under their natural topologies) of $\Delta(j, T; \pi)^0$ ($\Delta(j, T; \pi)$) and the open n-cell

$$
\sigma(n, T)^0 = \{\mathbf{y} \in \mathbb{R}^n \colon 0 < y_1 < \cdots < y_n < T\}
$$

(closed n-cell $\sigma(n, T)$).

In this way the interior of $\Delta(j, T)$ is seen to be the disjoint union of the $\binom{n-1}{j}$ open cells, $\{\Delta(j, T; \pi)^0 \colon \pi\ j\text{-permissible}\}$, and their common boundary $(n-1)$-cells defined by equalities of the form $s_\alpha = s_\beta$, where $1 \leqq \alpha \leqq j < \beta \leqq n-1$. The time-optimal controls, $\mathbf{v}(\cdot, \mathbf{s}, j)$, assume, for all $\mathbf{s} \in \Delta(j, T; \pi)^0$, the same sequence of n control values, $\mathbf{p}(\pi, j) \equiv \langle \mathbf{u}(1, j), \mathbf{u}^2, \cdots, \mathbf{u}^{n-1}, \mathbf{u}(n, j) \rangle$. Such sequences need to be formally identified if we are to understand the time-optimal flow.

DEFINITION 3.15. A sequence of control values, $\langle \mathbf{u}^1, \mathbf{u}^2, \cdots, \mathbf{u}^k \rangle$, which describes the sequential values assumed (each on a set of positive measure) by a time-optimal control function $\mathbf{v}$, and which satisfies the additional "policy condition" that $\mathbf{u}^i \neq \mathbf{u}^{i+1}$, $i = 1, \cdots, k-1$ (i.e., that it be such a sequence having minimal length), is called the (time-optimal) **switching policy of order k** or **k-policy** (or, simply, **switching policy**) of $\mathbf{v}$.

With this notation, for each $\mathbf{s}$ in $\Delta(j, T; \pi)^0$, $\mathbf{v}(\cdot; \mathbf{s}, j)$ has the optimal n-policy, $\mathbf{p}(j, \pi)$, and $-\mathbf{v}(\cdot; \mathbf{s}, j)$ the optimal n-policy $-\mathbf{p}(j, \pi) = \langle -\mathbf{u}(1, j), \cdots, -\mathbf{u}(n, j) \rangle$. When $\mathbf{s}$ lies in the boundary of $\Delta(j, T; \pi)$ (where one or more equalities of the form $s_{\pi(1)} = 0$, $s_{\pi(i)} = s_{\pi(i+1)}$, $s_{\pi(n-1)} = s_n$ hold), examination of (3.7) and (3.8) shows that the time-optimal control functions $\pm\mathbf{v}(\cdot; \mathbf{s}, j)$, generated by $\boldsymbol{\lambda}^*(\mathbf{s}, j)$ are also described by (3.13) and have switching policies that are **subpolicies** of $\pm\mathbf{p}(j, \pi)$ in the obvious sense.

Of particular importance are the subpolicies of order $n-1$ of the n-policies $\pm\mathbf{p}(j,\pi)$, of which there are always at least two (unless $n=1$). Namely, in the case of $\mathbf{p}(j,\pi)$, $\mathbf{p}(j,\pi;\mathrm{A})\equiv\langle\mathbf{u}^2,\cdots,\mathbf{u}(n,j)\rangle$ and $\mathbf{p}(j,\pi;\mathrm{I})\equiv\langle\mathbf{u}(1,j),\mathbf{u}^2,\cdots,\mathbf{u}^{n-1}\rangle$, where "A" and "I" indicate the attracting (A) and invariant (I) character of the associated cells in $\mathbf{K}(T)$ to be defined and discussed in §§ 5 and 6.

These two subpolicies may be the only ones of order $n-1$. For example, suppose $n=4$ and $j=0$. Then, for $\mathbf{s}$ in the interior of $\Delta(0,T)=\{\mathbf{s}\colon 0\leqq s_1\leqq s_2\leqq s_3\leqq s_4\leqq T\}$, $\boldsymbol{\lambda}(\mathbf{s},0)$ will generate controls that switch only in the second coordinate and $\mathbf{v}(\cdot\,;\mathbf{s},0)$ will have a switching policy of the form $\mathbf{p}=\langle\mathbf{u}^1,\mathbf{u}^2,\mathbf{u}^1,\mathbf{u}^2\rangle$ with $\mathbf{u}^1=\mathbf{u}(1,0)=(\boldsymbol{\delta}(1),-\boldsymbol{\delta}(0))$ and $\mathbf{u}^2=(\boldsymbol{\delta}(1),\boldsymbol{\delta}(0))$. Since the identity is the only zero permissible permutation, $\mathbf{p}$ and $-\mathbf{p}$ are the only time-optimal switching policies of order 4 when $j=0$.

The policy $\mathbf{p}$ has the two subpolicies of order 3: $\mathbf{p}(\mathrm{A})=\langle\mathbf{u}^2,\mathbf{u}^1,\mathbf{u}^2\rangle$, associated with the 3-cell of $\Delta(0,T)$ having $s_1=0$, and $\mathbf{p}(\mathrm{I})=\langle\mathbf{u}^1,\mathbf{u}^2,\mathbf{u}^1\rangle$, associated with the 3-cell defined by $s_3=s_4$. Since a subpolicy must satisfy the "policy condition" of (3.15), these are the only subpolicies of order 3. Points of other boundary cells of $\Delta(0,T)$ generate, through $\boldsymbol{\lambda}^*(\cdot\,,0)$, controls with policies of order 1 or 2. For example, the policy associated with the 3-cell of $\Delta(0,T)$ defined by $s_1=s_2$ and the 2-cell defined by $s_1=s_2=s_3$ is the order-2 policy, $\langle\mathbf{u}^1,\mathbf{u}^2\rangle$. Clearly, the controls generated by $\boldsymbol{\lambda}^*(\cdot\,,0)$ (or $\boldsymbol{\lambda}^*(\cdot\,,n-1)$) will exhibit similar behavior for any value of $n>2$.

The results derived above concerning the time-optimal control functions for strictly normal systems are summarized in the following proposition.

PROPOSITION 3.16. *Let $r=2$ and system (1.1) be strictly normal so that the determinants $\mathbf{d}(j)\neq 0$, $j=0,1,\cdots,n$. Then there exists a $T>0$ such that, for each $j=0,1,\cdots,n-1$, the vectors $\boldsymbol{\lambda}^*(\mathbf{s},j)$, $\mathbf{s}\in\Delta(j,T)$ (see (3.3) and (3.10)) generate time-optimal control functions, $\pm\mathbf{v}(\cdot\,;\mathbf{s},j)$, over the interval $[0,T]$ with the following properties:*

(1) *If $\mathbf{s}$ is in the interior of $\Delta(j,T)$, $\mathbf{v}(\cdot\,;\mathbf{s},j)$ is unique and if, in addition, $\mathbf{s}$ has distinct coordinates, then $\mathbf{v}(\cdot\,;\mathbf{s},j)$ defines one of the precisely*

$$\binom{n-1}{j}=\frac{(n-1)!}{j!(n-j-1)!}$$

distinct switching policies of order n, $\mathbf{p}(\pi;j)$, and

(a) *has initial control vector $\mathbf{u}(1,j)=(\boldsymbol{\delta}(j+1),(-1)^{n-j-1}\boldsymbol{\delta}(j))$;*

(b) *switches in the first coordinate when $t=s_1,\cdots,s_j$ and in the second coordinate when $t=s_{j+1},\cdots,s_{n-1}$;*

(c) *terminates with the control $\mathbf{u}(n,j)=((-1)^j\boldsymbol{\delta}(j+1),\boldsymbol{\delta}(j))$.*

(2) *The subset $\Delta(j,T;\pi)^0$ (see (3.14)) of $\Delta(j,T)$ consists of all points generating controls with policy $\mathbf{p}(j,\pi)$ and is, topologically, an open n-cell and its closure $\Delta(j,T;\pi)$ is a closed n-cell.*

(3) *If $\mathbf{p}(j,\pi)=\langle\mathbf{u}(1,j),\mathbf{u}^2,\cdots,\mathbf{u}^{n-1},\mathbf{u}(n,j)\rangle$ and $\mathbf{s}$ is in a boundary cell of $\Delta(j,T;\pi)$, then $\boldsymbol{\lambda}^*(\mathbf{s},j)$ generates control functions whose switching policies are subpolicies of $\mathbf{p}(j,\pi)$, in particular:*

(a) *If $\mathbf{s}$ is in the $(n-1)$-cell $\{\mathbf{s}\in\Delta(j,T;\pi)\colon s_{\pi(1)}=0\}$, then $\boldsymbol{\lambda}^*(\mathbf{s},j)$ generates a control function with switching policy $\mathbf{p}(j,\pi;\mathrm{A})=\langle\mathbf{u}^2,\cdots,\mathbf{u}(n,j)\rangle$ of order $n-1$;*

(b) *If $\mathbf{s}$ is in the $(n-1)$-cell $\{\mathbf{s}\in\Delta(j,T;\pi)\colon s_{\pi(n-1)}=s_n\}$, then $\boldsymbol{\lambda}^*(\mathbf{s},j)$ generates a control function with switching policy $\mathbf{p}(j,\pi;\mathrm{I})=\langle\mathbf{u}(1,j),\cdots,\mathbf{u}^{n-1}\rangle$ of order $n-1$.*

These results will now be used to determine the time-optimal switching policies for small response times of the three example systems introduced in § 1. To simplify

the description we use the notation $\mathbf{u}^1=(1,1)$, $\mathbf{u}^2=(-1,1)$, $\mathbf{u}^3=(-1,-1)$, and $\mathbf{u}^4=(1,-1)$ for the extreme points of $\mathscr{C}^2$. This permits, for example, the description of the policy $\langle \mathbf{u}^i, \mathbf{u}^j, \mathbf{u}^k\rangle$ by, simply, $\langle i,j,k\rangle$.

Example A (continued). For this system, $\delta(0)=\delta(1)=\delta(2)=\delta(3)=1$ and the optimal policies of order 3 are as follows:

$j=0$: $\mathbf{u}(1,0)=\mathbf{u}^1$ and the two optimal policies are $\mathbf{p}$-$\langle 1,4,1\rangle$ and $-\mathbf{p}=\langle 3,2,3\rangle$.

$j=1$: $\mathbf{u}(1,1)=\mathbf{u}^4$ and the optimal policies corresponding to the two permissible permutations are $\mathbf{p}_1=\langle 4,1,2\rangle$, $\mathbf{p}_2=\langle 4,3,2\rangle$ and $-\mathbf{p}_1=\langle 2,3,4\rangle$ and $-\mathbf{p}_2=\langle 2,1,4\rangle$.

$j=2$: $\mathbf{u}(1,2)=\mathbf{u}^1$ and the optimal policies are $\langle 1,2,1\rangle$ and $\langle 3,4,3\rangle$.

Example B (continued). For this system $\delta(0)=\delta(1)=1$ and $\delta(2)=\delta(3)=-1$. This situation leads to the following optimal policies of order 3:

$j=0$: $\mathbf{u}(1,0)=\mathbf{u}^1$ and the optimal policies are $\langle 1,4,1\rangle$ and $\langle 3,2,3\rangle$.

$j=1$: $\mathbf{u}(1,1)=\mathbf{u}^3$ leading to the optimal policies $\langle 3,4,1\rangle$ and $\langle 3,2,1\rangle$ and their negatives $\langle 1,2,3\rangle$ and $\langle 1,4,3\rangle$.

$j=2$: $\mathbf{u}(1,2)=\mathbf{u}^3$ with $\langle 3,4,3\rangle$ and $\langle 1,2,1\rangle$ as optimal policies.

Example C (continued). For the attitude control of the satellite we find $\delta(0)=\delta(1)=\delta(2)=\delta(3)=\delta(4)=1$ and the time-optimal switching policies of order four are as follows:

$j=0$: $\mathbf{u}(1,0)=\mathbf{u}^4$ and the optimal policies are $\langle 2,3,2,3\rangle$ and $\langle 4,1,4,1\rangle$.

$j=1$: $\mathbf{u}(1,1)=\mathbf{u}^1$ with the optimal policies corresponding to the three 1-permissible permutations being $\langle 1,2,3,2\rangle$, $\langle 1,4,3,2\rangle$, and $\langle 1,4,1,2\rangle$ and the negatives $\langle 3,4,1,4\rangle$, $\langle 3,2,1,4\rangle$, and $\langle 3,2,3,4\rangle$.

$j=2$: $\mathbf{u}(1,2)=\mathbf{u}^2$ with $\langle 2,1,2,3\rangle$, $\langle 2,1,4,3\rangle$, and $\langle 2,3,4,3\rangle$ and $\langle 4,3,4,1\rangle$, $\langle 4,3,2,1\rangle$, and $\langle 4,1,2,1\rangle$ as optimal policies.

$j=3$: $\mathbf{u}(2,1)=\mathbf{u}^1$ with the optimal policies $\langle 1,2,1,2\rangle$ and $\langle 3,4,3,4\rangle$.

Remark 3.17. Note that the notation employed to represent the switching policies is such that if two cells have common boundary cells, the associated switching policies have corresponding common subpolicies. For example (Example C, $j=1$), $\langle 1,2,3,2\rangle$ and $\langle 1,4,3,2\rangle$ associated with cells $\{s_1<s_2<s_3<s_4\}$ and $\{s_2<s_1<s_3<s_4\}$ (using an obvious notation), respectively, share the subpolicy $\langle 1,3,2\rangle$ which is the switching policy of control functions associated with the points of the 3-cell $\{s_1=s_2<s_3<s_4\}$. As a result, knowledge of the optimal control functions and their switching policies can be used to analyze the geometry of $\mathbf{K}(T)$ and its switching surfaces.

4. The time-optimal policy complex. In the previous section we identified, for each $j=0,\cdots,n$ and each $\mathbf{s}$ in $\Delta(j,T)$, a time-optimal control function, $\mathbf{v}(\cdot;\mathbf{s},j)$, defined over the interval $0\leqq t\leqq s_n\leqq T$. Because the system (1.1) is normal, $\mathbf{v}(\cdot;\mathbf{s},j)$ is the unique time-optimal control function for a point, $\mathbf{x}(\mathbf{s},j)$, in $\mathbf{K}(T)$. We can identify $\mathbf{x}(\mathbf{s},j)$ by constructing the solution φ to (1.1) with the unknown $\mathbf{x}(\mathbf{s},j)$ as initial data, noting that $\varphi(s_n)=\mathbf{0}$, and solving for $\mathbf{x}(\mathbf{s},j)$ to find

$$\mathbf{x}(\mathbf{s},j)=-\int_0^{s_n} e^{-\mathbf{A}t}\mathbf{B}\mathbf{v}(t;\mathbf{s},j)\,dt. \tag{4.1}$$

If the time-optimal switching policy of $\mathbf{v}(\cdot;\mathbf{s},j)$ is $\mathbf{p}(j,\pi)=\langle \mathbf{u}^1,\mathbf{u}^2,\cdots,\mathbf{u}^n\rangle$ (or a subpolicy of $\mathbf{p}(j,\pi)$), then

$$\begin{aligned}\mathbf{x}(\mathbf{s},j)&=-\int_0^{s_{\pi(1)}} e^{-\mathbf{A}t}\mathbf{B}\,dt\cdot\mathbf{u}^1-\int_{s_{\pi(1)}}^{s_{\pi(2)}} e^{-\mathbf{A}t}\mathbf{B}\,dt\cdot\mathbf{u}^2-\cdots-\int_{s_{\pi(n-1)}}^{s_n} e^{-\mathbf{A}t}\mathbf{B}\,dt\cdot\mathbf{u}^n\\&=-\sum_{k=1}^{n-1}\int_0^{s_{\pi(k)}} e^{-\mathbf{A}t}\mathbf{B}\,dt\cdot(\mathbf{u}^k-\mathbf{u}^{k+1})-\int_0^{s_n} e^{-\mathbf{A}t}\mathbf{B}\,dt\cdot\mathbf{u}^n.\end{aligned} \tag{4.2}$$

The relationship is simplified by defining

$$\mathbf{g}^i(\tau) \equiv -\int_0^\tau e^{-\mathbf{A}t}\mathbf{b}^i\,dt, \qquad i=1,2 \tag{4.3}$$

and noting that for $1 \leqq \pi(k) \leqq j$, the switch from $\mathbf{u}^k$ to $\mathbf{u}^{k+1}$ at time $t = s_{\pi(k)}$ involves the first coordinate and, from Lemma 3.12(1),

$$\mathbf{u}^k - \mathbf{u}^{k+1} = \begin{bmatrix} \pm 2\boldsymbol{\delta}(j+1) \\ 0 \end{bmatrix}$$

("+" if $\pi(k)=1$, "−" if $\pi(k)=2, \cdots$), while if $j+1 \leqq \pi(k) \leqq n-1$, the switch involves the second coordinate and

$$\mathbf{u}^k - \mathbf{u}^{k+1} = \begin{bmatrix} 0 \\ \pm(-1)^{n-j-1}2\boldsymbol{\delta}(j) \end{bmatrix}$$

("+" if $\pi(k)=j+1$, "−" if $\pi(k)=j+2, \cdots$). Then, in terms of

$$\mathbf{G}^1(\mathbf{s}; j) = \mathbf{g}^1(s_1) - \mathbf{g}^1(s_2) + \cdots + (-1)^{j-1}\mathbf{g}^1(s_j) + \frac{(-1)^j\mathbf{g}^1(s_n)}{2} \tag{4.4}$$

and

$$\mathbf{G}^2(\mathbf{s}; j) = \mathbf{g}^2(s_{j+1}) - \mathbf{g}^2(s_{j+2}) + \cdots + (-1)^{n-j-2}\mathbf{g}^2(s_{n-1}) + \frac{(-1)^{n-j-1}\mathbf{g}^2(s_n)}{2}$$

we have

$$\mathbf{x}(\mathbf{s}, j) = 2\boldsymbol{\delta}(j+1)\mathbf{G}^1(\mathbf{s}; j) + (-1)^{n-j-1}2\boldsymbol{\delta}(j)\mathbf{G}^2(\mathbf{s}; j), \tag{4.5}$$

which is independent of π, valid for all $\mathbf{s}$ in $\boldsymbol{\Delta}(j, T)$ and defines a C^∞ mapping $\mathbf{s} \mapsto \mathbf{x}(\mathbf{s}, j)$ of $\boldsymbol{\Delta}(j, T)$ onto a subset, $\mathbf{D}(j, T)$, of $\mathbf{K}(T)$. $\mathbf{D}(j, T)$, being the continuous image of a compact set, is compact and consists of all points $\mathbf{x}$ in $\mathbf{K}(T)$ which are time-optimally controlled to $\mathbf{0}$ by control functions $\mathbf{v}(\cdot; \mathbf{s}, j)$ with $\mathbf{s} \in \boldsymbol{\Delta}(j, T)$. Because of its cell structure, which is developed below, $\mathbf{D}(j, T)$ is called a **time-optimal policy complex.**

The map (4.5) is the composition $\mathbf{s} \mapsto \mathbf{v}(\cdot; \mathbf{s}, j) \mapsto \mathbf{x}(\mathbf{s}, j)$ and, while the latter is injective because of the normality of the system, the former is necessarily injective only on the interior of $\boldsymbol{\Delta}(j, T)$. In fact, it will not be injective on the boundary of $\boldsymbol{\Delta}(j, T)$ if either j or $n-j-1$ is greater than 1. Because of the central role these issues play in the sections to follow, it will be beneficial to explore an example in detail. Toward that end we turn to the case "$j=1$" for the fourth-order system, Example C, which provides a representative example.

For Example C and $j=1$, $\boldsymbol{\Delta}(1, T) = \{\mathbf{s} \in \mathbb{R}^4 : 0 \leqq s_1 \leqq s_4 \leqq T,\ 0 \leqq s_2 \leqq s_3 \leqq s_4 \leqq T\}$ and (recall that all $\boldsymbol{\delta}(i) = 1$ for all i)

$$\mathbf{x}(\mathbf{s}, 1) = 2[\mathbf{g}^1(s_1) - \mathbf{g}^1(s_4)/2] + 2[\mathbf{g}^2(s_2) - \mathbf{g}^2(s_3) + \mathbf{g}^2(s_4)/2] \tag{4.6}$$

maps $\boldsymbol{\Delta}(1, T) \mapsto \mathbf{D}(1, T) \subset \mathbf{K}(T) \subset \mathbb{R}^4$. The interior of $\boldsymbol{\Delta}(1, T)$ is composed of the three open 4-cells (using obvious notation) $\boldsymbol{\Delta}(1, T; \pi_0)^0 = \{0 < s_1 < s_2 < s_3 < s_4 < T\}$ (π_0 is the identity permutation), $\boldsymbol{\Delta}(1, T; \pi_1)^0 = \{0 < s_2 < s_1 < s_3 < s_4 < T\}$, and $\boldsymbol{\Delta}(1, t; \pi_2)^0 = \{0 < s_2 < s_3 < s_1 < s_4 < T\}$ and their shared open 3-cell boundaries $\{0 < s_1 = s_2 < s_3 < s_4 < T\}$ and $\{0 < s_2 < s_1 = s_3 < s_4 < T\}$.

Remark 4.7. In this context "open 3-cell (open 2-cell, etc.)" indicates a cellular homeomorphic image of the standard open 3-cell (open 2-cell, etc.) not necessarily, an open set in the topology of the space (see [16]).

Through the outer normal vectors $\boldsymbol{\lambda}(\cdot, 1)$ (see (3.3)), the points of these cells are associated with time-optimal control functions having the 4-policies (recall the notation from the previous section) $\langle 1, 2, 3, 2\rangle$, $\langle 1, 4, 3, 2\rangle$, and $\langle 1, 4, 1, 2\rangle$ and the 3-policies $\langle 1, 3, 2\rangle$ and $\langle 1, 4, 2\rangle$, respectively.

The boundary of $\boldsymbol{\Delta}(1, T)$ contains the set $\{\mathbf{s} \in \boldsymbol{\Delta}(1, T)\colon s_4 = T\}$, which $\mathbf{x}(\cdot, 1)$ maps into the T-isochrone, and the following cell complexes each composed of one or two open 3-cells:

Cell complex	Optimal policy
$\{0 = s_1, 0 < s_2 < s_3 < s_4 < T\}$	$\langle 2, 3, 2\rangle$
$\{s_1 = s_4 < T, 0 < s_2 < s_3 < s_4 < T\}$	$\langle 1, 4, 1\rangle$
$\{0 < s_1 < s_4 < T, 0 = s_2 < s_3 < s_4 < T\}$	$\langle 4, 3, 2\rangle$ and $\langle 4, 1, 2\rangle$
$\{0 < s_1 < s_4 < T, 0 < s_2 < s_3 = s_4 < T\}$	$\langle 1, 2, 3\rangle$ and $\langle 1, 4, 3\rangle$
$\{0 < s_1 < s_4 < T, 0 < s_2 = s_3 < s_4 < T\}$	$\langle 1, 2\rangle$

The last three complexes of this list each contain two open 3-cells (e.g., corresponding to $s_1 < s_3$ and $s_3 < s_1$ in the first instance) which, in the first two cases, determine two optimal 3-policies. In the last instance the points of the two open 3-cells determine a single 2-policy which is also the policy associated with the open 2-cell $\{0 < s_1 < s_2 = s_3 = s_4 < T\}$. Other boundary cells of $\boldsymbol{\Delta}(1, T)$ determine additional 2- and 1-policies. For example:

Cell complex	Optimal policy
$\{0 = s_1 < s_2 < s_3 = s_4 < T\}$	$\langle 2, 3\rangle$
$\{0 = s_1 = s_2 < s_3 < s_4 < T\}$	$\langle 3, 2\rangle$
$\{0 = s_2 < s_1 < s_3 = s_4 < T\}$	$\langle 4, 3\rangle$
$\{0 = s_2 < s_1 = s_3 = s_4 < T\}$	$\langle 4\rangle$

The connection between shared boundary cells of lower dimension and shared subpolicies (see Remark 3.17) is clearly evident from these examples. Furthermore, the "shared subpolicies" become, via (4.5), shared boundary cells of the policy complexes. This illustrates the geometric insight provided by the concept of "switching policy."

Now, as noted above, there is a one-to-one correspondence between control functions and points of $\mathbf{K}(T)$ because of the assumed normality of the system. However, as the examples above clearly demonstrate, the correspondence $\mathbf{s} \mapsto \mathbf{x}(\mathbf{s}, 1)$ is, in general, many to one when $\mathbf{s}$ lies on the boundary of $\boldsymbol{\Delta}(1, T)$. Before specifically addressing the many-to-one feature, let us consider the mapping in more detail. From (4.4) and (4.5), the Jacobian matrix of (4.6) (in column form) is

$$\frac{\partial \mathbf{x}(\mathbf{s}, 1)}{\partial \mathbf{s}} = [-2\mathbf{E}^1(s_1), -2\mathbf{E}^2(s_2), 2\mathbf{E}^2(s_3), \mathbf{E}^1(s_4) - \mathbf{E}^2(s_4)] \tag{4.8}$$

with the determinant

$$\begin{aligned} \det\left[\frac{\partial \mathbf{x}(\mathbf{s}, 1)}{\partial \mathbf{s}}\right] &= 8[\boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^1(s_4) - \boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^2(s_4)] \\ &= 8[|\boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^1(s_4)| + |\boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^2(s_4)|], \end{aligned} \tag{4.9}$$

given the signs assumed by the determinants $\boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^i(t)$ for $t > \max(s_1, s_3)$ (shown in (3.9b)). This result confirms the local injectivity of the mapping on the interior of $\boldsymbol{\Delta}(1, T)$ as long as both determinants, $\boldsymbol{\lambda}(\mathbf{s}, 1) \wedge \mathbf{E}^i(t)$, $i = 1, 2$, do not vanish identically. More important, it leads to a proof that on the relative interior of a boundary k-cell,

that is, an open k-cell (in this case $k = 1, 2$, or 3) corresponding to an optimal k-policy, the Jacobian matrix has rank k, and therefore, the image of this open k-cell in $\mathbf{D}(1, T)$ is also an open k-cell (note Remark (4.7)).

This example is typical of the general case. Calculations similar to those of (4.8) and (4.9) lead to the same conclusions concerning the Jacobian of (4.5) and show that this C^∞ mapping is injective on the interior of $\mathbf{\Delta}(j, T)$ and on any open k-cell associated with a time-optimal k-policy. However, the mapping is not injective on some cells defined by equalities of the form $s_i = s_m$, where $1 \leqq i,\ m \leqq j$, or $j+1 \leqq i,\ m \leqq n-1$. Examination of (4.5) shows that such a cell of dimension, say, m is associated with the same optimal k-policy, with $k < m$, as some open k-cell. Thus the two cells are, insofar as time-optimal controls are concerned, equivalent, since their points $\mathbf{s}$ map into the same open k-cell in $\mathbf{D}(j, T)$. The following proposition, proven in [23], uses the concepts and results of [16] to formalize these relationships.

PROPOSITION 4.10. *The equivalence relation on* $\mathbf{\Delta}(j, T)$ *defined by*

$$\mathbf{R}(j) \equiv \{(\mathbf{s}^1, \mathbf{s}^2)\colon \mathbf{s}^1, \mathbf{s}^2 \in \mathbf{\Delta}(j, T), \mathbf{v}(\cdot; \mathbf{s}^1, j) = \mathbf{v}(\cdot; \mathbf{s}^2, j)\}$$

is a cellular equivalence relation. Also,

(1) *With the usual topology on the cell complex* $\mathbf{\Delta}(j, t)$, *the quotient space* $\mathbf{\Delta}(j, T)/\mathbf{R}(j)$ *is a normal* CW-*complex*;

(2) *The map* $\mathbf{x}^*\colon \mathbf{\Delta}(j, T)/\mathbf{R}(j) \mapsto \mathbf{D}(j, T) \subset \mathbf{K}(T)$ *based on* (4.5) *is a cellular homeomorphism, and therefore, the* **time-optimal policy complex** $\mathbf{D}(j, T)$ *is also a normal* CW-*complex.*

This proposition provides a clear picture of the policy complex $\mathbf{D}(j, T)$. Its interior is, essentially, that of $\mathbf{\Delta}(j, T)$ while its boundary contains homeomorphic images of some of the $(n-1)$-dimensional boundary cells of $\mathbf{\Delta}(j, T)$. Other boundary cells of the latter cell complex are mapped by $\mathbf{x}(\cdot, j)$ into a single cell of lower dimension. This situation is especially clear in the third-order Examples A and B for $j = 0$ or 3. It is obvious that the face of the tetrahedron $\mathbf{\Delta}(0, T)$ defined by $s_1 = s_2$ is mapped by $\mathbf{x}(\mathbf{s}, 0) = \boldsymbol{\delta}(1)\mathbf{g}^1(s_3) + 2\boldsymbol{\delta}(0)[\mathbf{g}^2(s_1) - \mathbf{g}^2(s_2) + \mathbf{g}^2(s_3)/2]$ into a curve which is the homeomorphic image of the cell $\{\mathbf{s} \in \mathbf{\Delta}(0, T)\colon 0 = s_1 = s_2 \leqq s_3 \leqq T\}$.

This qualitative view is, however, not sufficient; we need considerably more detail in order to reconstruct the time-optimal flow on $\mathbf{K}(T)$. Much of the necessary information is provided by identification of the cells of $\mathbf{D}(j, T)$ having dimension n and $n-1$.

The only open n-cells of the complex $\mathbf{D}(j, T)$ are the images of the $\binom{n-1}{j}$ cells $\mathbf{\Delta}(j, T; \pi)^0$, defined by the j-permissible permutations π. Images of open $(n-1)$-cells of the form $\{\mathbf{s} \in \mathbf{\Delta}(j, T)^0\colon s_i = s_k, 1 \leqq i \leqq j < k \leqq n-1, s_\alpha \neq s_\beta, \alpha, \beta \neq i, j\}$ lie in the interior of $\mathbf{D}(j, T)$ and form the joint boundaries of the open n-cells. These cells play no particular role in the following. That is far from the case for the open $(n-1)$-cells forming the boundary of $\mathbf{D}(j, T)$ relative to $\mathbf{K}(T)$ (that is, ignoring the portion of the boundary contained in the T-isochrone). These cells occur in four groups and are the images under (4.5) of the cell complexes of $\mathbf{\Delta}(j, T)$ defined by $s_1 = 0$, by $s_j = s_n$, by $s_{j+1} = 0$, and by $s_{n-1} = s_n$. These complexes will be denoted by $\mathbf{D}(j|s_1 = 0)$, $\mathbf{D}(j|s_j = s_n)$, etc. The first two of these complexes correspond to those permutations in which the first, or last, switch occurs in the first coordinate; the latter two complexes corresponding to those permutations in which the first or last switch occurs in the second coordinate.

$\mathbf{D}(j|s_1 = 0)$ and $\mathbf{D}(j|s_j = s_n)$ each contain $\binom{n-2}{j-1}$ open $(n-1)$-cells corresponding to each j-permissible permutation with $\pi(1) = 1$ (so that $s_1 < s_{j+1}$) for the first complex and to the permutations with $\pi(n-1) = j$ (so that $s_{n-1} < s_j$) for the second. $\mathbf{D}(j|s_{j+1} = 0)$

and $\mathbf{D}(j|s_{n-1}=s_n)$ each contain $\binom{n-2}{j}$ open $(n-1)$-cells corresponding to those π satisfying $\pi(1)=j+1$ in the first instance, or $\pi(n-1)=n-1$ in the second.

These relationships can be made clearer by defining

$$\mathbf{D}(j, T; \pi)=\operatorname{clos}[\mathbf{x}(\mathbf{\Delta}(j, T; \pi), j)], \tag{4.11}$$

which is a closed n-cell and consists of all points of $\mathbf{K}(T)$ whose time-optimal control functions have switching policies that are subpolicies of $\mathbf{p}(j, \pi)$ (see 3.16). In particular, the open $(n-1)$-cell corresponding to the subpolicy defined as $\mathbf{p}(j, \pi, \mathrm{A})$ is a cell of the complex $\mathbf{D}(j|s_1=0)$ if $\pi(1)=1$, and of the complex $\mathbf{D}(j|s_{j+1}=0)$ if $\pi(1)=j+1$. Similarly, the open $(n-1)$-cell associated with the subpolicy $\mathbf{p}(j, \pi, \mathrm{I})$ is in $\mathbf{D}(j|s_j=s_n)$ or $\mathbf{D}(j|s_{n-1}=s_n)$ if $\pi(n-1)=j$ or $n-1$, respectively.

5. The time-optimal flow as a local semidynamical system. In this section we examine the time-optimal trajectories on the policy cell complexes $\pm\mathbf{D}(j, T)$, $j=0, \cdots, n$, of the previous sections from the perspective provided by the theory of semidynamical systems (see [1]). In the process we show that the policies $\mathbf{p}(j, \pi, \mathrm{A})$ and $\mathbf{p}(j, \pi, \mathrm{I})$ of order $n-1$ correspond, indeed, to attracting and invariant cells of the local semidynamical system defined by the time-optimal trajectories on $\mathbf{D}(j, T)\backslash\{\mathbf{0}\}$.

A point $\mathbf{x}(\mathbf{s}, j)$ in the interior of $\mathbf{D}(j, T)$ lies either in the interior of a unique closed n-cell $\mathbf{D}(j, T, \pi)$ or, if its optimal control function has a policy of order $<n$, in the boundary of two or more such n-cells. For the moment let us assume the former (i.e., that the coordinates of $\mathbf{s}$ are distinct) so that the time-optimal control for this point has the n-policy $\mathbf{p}(j, \pi)\equiv\langle\mathbf{u}^1, \mathbf{u}^2, \cdots, \mathbf{u}^{n-1}, \mathbf{u}^n\rangle$ with switches occurring in the sequence $t=s_{\pi(1)}, s_{\pi(2)}, \cdots, s_{\pi(n-1)}$. Define

$$\mathbf{y}(s_{\pi(1)}, s_{\pi(2)}, \cdots, s_{\pi(n-1)}, s_n)\equiv\mathbf{x}(s_1, s_2, \cdots, s_{n-1}, s_n, j). \tag{5.1}$$

Then, since $\mathbf{x}(\mathbf{s}, j)$ was found by "backing out from $\mathbf{0}$" in (4.1), the time-optimal trajectory from $\mathbf{x}(\mathbf{s}, j)$ to $\mathbf{0}$ is easily seen (using (4.2)) to be described by

$$\begin{aligned}
\varphi(t) &= \mathbf{y}(s_{\pi(1)}-t, s_{\pi(2)}-t, \cdots, s_{\pi(n-1)}-t, s_n-t), && 0\leqq t<s_{\pi(1)},\\
&= \mathbf{y}(0, s_{\pi(2)}-t, \cdots, s_{\pi(n-1)}-t, s_n-t), && s_{\pi(1)}\leqq t<s_{\pi(2)},\\
&= \mathbf{y}(0, 0, s_{\pi(3)}-t, \cdots, s_{\pi(n-1)}-t, s_n-t), && s_{\pi(2)}\leqq t<s_{\pi(3)},\\
&\ \ \vdots && \ \ \vdots\\
&= \mathbf{y}(0, 0, \cdots, 0, s_{\pi(k)}-t, \cdots, s_{\pi(n-1)}-t, s_n-t), && s_{\pi(k-1)}\leqq t<s_{\pi(k)},\\
&\ \ \vdots && \ \ \vdots\\
&= \mathbf{y}(0, 0, \cdots, 0, s_n-t), && s_{\pi(n-1)}\leqq t<s_n,\\
&= \mathbf{0}, && s_n\leqq t\leqq T.
\end{aligned} \tag{5.2}$$

This representation of the time-optimal trajectories can be extended to all of $\mathbf{D}(j, T)$ and is easily seen to define a semidynamical system [1] on this complex. It is clear that each point of the T-isochrone ($s_n=T$) is a "start-point" of the flow (i.e., is not "downstream" from another point of the complex). Furthermore, as the following proposition shows, the semidynamical system is strongly related to the cell structure of the policy complex.

PROPOSITION 5.3. *Let $\mathbf{x}^0=\mathbf{x}(\mathbf{s}, j)$ be a point of $\mathbf{D}(j, T)$ and suppose that the switching policy of the time-optimal control function for $\mathbf{x}^0$, $\mathbf{v}(\cdot; \mathbf{s}, j)$, is $\mathbf{p}(j, \pi)$ or a subpolicy of $\mathbf{p}(j, \pi)$. Let $\varphi(t)$, $0\leqq t<s_n$ describe the time-optimal trajectory from $\mathbf{x}^0$ to $\mathbf{0}$ (see (5.2)) and $\mathbf{D}(j, \pi, \alpha)$ be the image under $\mathbf{x}(\cdot, j)$ of the $(n-\alpha)$-dimensional cell of $\mathbf{\Delta}(j, T; \pi)$ defined by $s_{\pi(1)}=s_{\pi(2)}=\cdots=s_{\pi(\alpha)}=0$. Then*

(1) *$\mathbf{D}(j, \pi, \alpha)$ is a closed cell of $\mathbf{D}(j, T)$ of dimension $n-\alpha$;*

(2) *If* $s_{\pi(1)} > 0$, $\varphi(t)$ *lies in the interior of* $\mathbf{D}(j, T)$ *for* $0 \leqq t < s_{\pi(1)}$;

(3) *If* $s_{\pi(\alpha)} < s_{\pi(\alpha+1)}$, $\varphi(t)$ *lies in the relative interior of* $\mathbf{D}(j, \pi, \alpha)$ *for* $s_{\pi(\alpha)} < t < s_{\pi(\alpha+1)}$;

(4) *If* $\mathbf{s}$ *has distinct coordinates, then* $\varphi(t)$ *successively traverses the relative interior of each cell of the sequence* $\mathbf{D}(j, T), \mathbf{D}(j, \pi, 1), \mathbf{D}(j, \pi, 2), \cdots, \mathbf{D}(j, \pi, n-1)$ *as* t *traverses the interval* $[0, s_n]$.

Proof. The first result follows from continuity of the mapping $\mathbf{x}(\cdot, j)$ and calculations based on its Jacobian analogous to (4.8) and (4.9). The other assertions follow directly from (5.2). □

A subset M is an attracting set of a semidynamical system on a set X if the set of points of X that are attracted to M form a neighborhood of M (the notion of "attraction" is clear for the time-optimal flow considered here; see [1] for precise technical considerations). Thus, in considering the time-optimal flow on $\mathbf{D}(j, T)$, it is clear that any set containing $\mathbf{0}$ will be an attractor of the flow. This is, obviously, of little use in studying the time-optimal system. The notion of attraction, however, becomes much more discriminating when we consider the local semidynamical system defined on $\mathbf{D}(j, T)\backslash\{\mathbf{0}\}$ by the time-optimal flow. In this instance (5.2) and (5.3) show that the cells $\mathbf{D}(j, \pi, 1)$ and their subcells are attractors of the flow restricted to $\mathbf{D}(j, T; \pi)$. When all j-permissible permutations are considered, these cells form the **attracting cell complexes** denoted by $\pm\mathbf{D}(j|s_1 = 0)$ and $\pm\mathbf{D}(j|s_{j+1} = 0)$ in § 4.

A subset N is a positively invariant set of a semidynamical system on a set X if the trajectories starting in N remain in N. It is called negatively invariant if its complement is positively invariant, and invariant if it is both positively and negatively invariant. In applying these notions to the time-optimal flow on $\mathbf{D}(j, T)$, we note that the cellular nature of the flow makes each closed cell of the nested sequences $\mathbf{D}(j, \pi, 1)$, $\mathbf{D}(j, \pi, 2), \cdots, \mathbf{D}(j, \pi, n-1)$ positively invariant, but not invariant, cells. However, as (5.2) shows, the cells defined by $s_{\pi(n-1)} = s_n$ are both positively and negatively invariant. These $(n-1)$-dimensional cells form the **invariant cell complexes** previously denoted by $\pm\mathbf{D}(j|s_j = s_n)$ and $\pm\mathbf{D}(j|s_{n-1} = s_n)$. These results are summarized in Proposition 5.4.

PROPOSITION 5.4. *The local semidynamical system defined on* $\mathbf{D}(j, T)\backslash\{0\}$ *by the time-optimal flow characterizes the boundary cells of this policy complex as follows*:

(1) *The portion of the T-isochrone contained in the policy complex consists of "start points" of the time-optimal flow*;

(2) *The* $(n-1)$*-dimensional cell complexes* $\mathbf{D}(j|s_1 = 0)$ *and* $\mathbf{D}(j|s_{j+1} = 0)$ *are* **attracting sets** *of the time-optimal flow*;

(3) *The* $(n-1)$*-dimensional cell complexes* $\mathbf{D}(j|s_j = s_n)$ *and* $\mathbf{D}(j|s_{n-1} = s_n)$ *are* **invariant sets** *of the time-optimal flow.*

6. The assembly of K(*T*). In the previous section we identified the $n+1$ policy complexes $\mathbf{D}(j, T)$, $j = 0, 1, \cdots, n$ and the complexes composed of their $(n-1)$-dimensional boundary cells $\mathbf{D}(j|s_1 = 0), \cdots, \mathbf{D}(j|s_{n-1} = s_n)$, $j = 0, 1, \cdots, n$. Due to the symmetry of the system—$-\mathbf{v}(\cdot; \mathbf{s}, j)$ is a time-optimal control function if $\mathbf{v}(\cdot; \mathbf{s}, j)$ is a time-optimal control function—we also have their negatives $-\mathbf{D}(j, T)$, etc. In this section we show how this "n-dimensional jigsaw puzzle" assembles to form $\mathbf{K}(T)$. The basic step in the assembly process involves showing that each boundary $(n-1)$-cell of, for example, $\mathbf{D}(j, T)$ is also a boundary cell for precisely one of the four complexes $\pm\mathbf{D}(j-1, T)$ or $\pm\mathbf{D}(j+1, T)$. This we accomplish by direct calculation. The remainder of the construction relies on a technical lemma that shows the union of all the policy complexes to be $\mathbf{K}(T)$. In this process we are providing another proof of Yeung's result on the minimal controllability of strictly normal systems of the type (1.1) [29]

and providing a great deal more information on the time-optimal flow which will be of use in later sections.

LEMMA 6.1 (Structure lemma). *Let* $r=2$ *and system* (1.1) *be strictly normal and define*

$$\boldsymbol{\gamma}(k)=\boldsymbol{\delta}(k-1)\cdot\boldsymbol{\delta}(k+1),\qquad k=1,\cdots,n-1. \tag{6.2}$$

Then, for $1\leqq j\leqq n-1$:

(1) *If* $\boldsymbol{\gamma}(j)=1$

1) $\mathbf{D}(j|s_1=0)=-\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_{n-1}=s_n)$,

2) $\mathbf{D}(j|s_j=s_n)=\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_j=0)$;

(2) *If* $\boldsymbol{\gamma}(j)=-1$

1) $\mathbf{D}(j|s_1=0)=\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_j=0)$,

2) $\mathbf{D}(j|s_j=s_n)=-\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_{n-1}=s_n)$;

For $0\leqq j\leqq n-2$:

(3) *If* $\boldsymbol{\gamma}(j+1)=1$

1) $\mathbf{D}(j|s_{j+1}=0)=\boldsymbol{\delta}(j+1)\cdot\boldsymbol{\delta}(j)\cdot\mathbf{D}(j+1|s_{j+1}=s_n)$,

2) $\mathbf{D}(j|s_{n-1}=s_n)=-\boldsymbol{\delta}(j+1)\cdot\boldsymbol{\delta}(j)\cdot\mathbf{D}(j+1|s_1=0)$;

(4) *If* $\boldsymbol{\gamma}(j+1)=-1$

1) $\mathbf{D}(j|s_{j+1}=0)=\boldsymbol{\delta}(j+1)\cdot\boldsymbol{\delta}(j)\cdot\mathbf{D}(j+1|s_1=0)$,

2) $\mathbf{D}(j|s_{n-1}=s_n)=-\boldsymbol{\delta}(j+1)\cdot\boldsymbol{\delta}(j)\cdot\mathbf{D}(j+1|s_{j+1}=s_n)$.

Proof. As noted above, the proofs of these relationships are computational. Because, from (4.4), $\mathbf{G}^1(\mathbf{s};j)$ depends only on $s_1,\cdots,s_j,s_n$ and $\mathbf{G}^2(\mathbf{s};j)$ depends only on $s_{j+1},\cdots,s_{n-1},s_n$, we have the relationships

$$\mathbf{G}^1(0,s_2,\cdots,s_j,s_n;j)=-\mathbf{G}^1(s_2,\cdots,s_j,s_n;j-1),$$

$$\mathbf{G}^1(s_1,\cdots,s_{j-1},s_n,s_n;j)=\mathbf{G}^1(s_1,\cdots,s_{j-1},s_n;j-1)$$

and

$$\mathbf{G}^2(0,s_{j+2},\cdots,s_{n-1},s_n;j)=-\mathbf{G}^2(s_{j+2},\cdots,s_{n-1},s_n;j+1),$$

$$\mathbf{G}^2(s_{j+1},\cdots,s_{n-2},s_n,s_n;j)=\mathbf{G}^2(s_{j+1},\cdots,s_{n-2},s_n;j+1).$$

Now, using the first two of these equations and (4.5), we find that

$$\begin{aligned}\boldsymbol{\delta}(j-1)\cdot\mathbf{x}(\mathbf{s};j)|_{s_1=0}&=-2\boldsymbol{\gamma}(j)\mathbf{G}^1(s_2,\cdots,s_j,s_n;j-1)\\&\quad+(-1)^{n-j-1}2\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\mathbf{G}^2(s_{j+1},\cdots,s_n;j),\end{aligned} \tag{6.3a}$$

$$\begin{aligned}\boldsymbol{\delta}(j-1)\cdot\mathbf{x}(\mathbf{s};j)|_{s_j=s_n}&=2\boldsymbol{\gamma}(j)\mathbf{G}^1(s_1,\cdots,s_{j-1},s_n;j-1)\\&\quad+(-1)^{n-j-1}2\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\mathbf{G}^2(s_{j+1},\cdots,s_n;j),\end{aligned} \tag{6.3b}$$

$$\begin{aligned}\boldsymbol{\delta}(j)\cdot\mathbf{x}(\mathbf{s};j-1)|_{s_j=0}&=2\mathbf{G}^1(s_1,\cdots,s_{j-1},s_n;j-1)\\&\quad+(-1)^{n-j-1}2\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\mathbf{G}^2(s_{j+1},\cdots,s_n;j),\end{aligned} \tag{6.4a}$$

$$\begin{aligned}\boldsymbol{\delta}(j)\cdot\mathbf{x}(\mathbf{s};j-1)|_{s_{n-1}=s_n}&=2\mathbf{G}^1(s_1,\cdots,s_{j-1},s_n;j-1)\\&\quad+(-1)^{n-j}2\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\mathbf{G}^2(s_j,\cdots,s_{n-2},s_n;j).\end{aligned} \tag{6.4b}$$

Now, if $\boldsymbol{\gamma}(j)=1$, we see that the image of the $(n-1)$-cells making up the set $(\mathbf{s}\in\boldsymbol{\Delta}(j,T)\colon s_1=0\}$ under the map (6.3a) is exactly the same as the image of the $(n-1)$-cells of the set $\{\mathbf{s}\in\boldsymbol{\Delta}(j-1,T)\colon s_{n-1}=s_n\}$ under the negative of the map (6.4b).

Similarly, the image of $\{\mathbf{s}\in\boldsymbol{\Delta}(j, T)\colon s_j = s_n\}$ under the map of (6.3b) is equal to the image of $\{\mathbf{s}\in\Delta(j-1, T)\colon s_j = 0\}$ under the map of (6.4a). Thus, when $\boldsymbol{\gamma}(j)=1$, $\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j|s_1=0) = -\boldsymbol{\delta}(j)\cdot\mathbf{D}(j-1|s_{n-1}=s_n)$, and $\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j|s_j=s_n)=\boldsymbol{\delta}(j)\cdot\mathbf{D}(j-1|s_j=0\}$. This proves (1(1)) and (1(2)) of the lemma. The assertions (2(1)) and (2(2)) also follow from (6.3) and (6.4) under the assumption that $\boldsymbol{\gamma}(j)=-1$.

In the same fashion we can prove the remaining assertions of the lemma by considering the mappings $\boldsymbol{\delta}(j+1)\cdot\mathbf{x}(\cdot, j)$ and $\boldsymbol{\delta}(j)\cdot\mathbf{x}(\cdot, j+1)$ restricted to the appropriate cells of $\boldsymbol{\Delta}(j, T)$ and $\boldsymbol{\Delta}(j+1, T)$. □

Now let

$$\mathbf{K}_1 = \bigcup_{j=0}^{n-1}[\mathbf{D}(j, T)\cup(-\mathbf{D}(j, T))].$$

$\mathbf{K}_1$ is a closed cell complex contained in $\mathbf{K}(T)$ and, from (6.1), since $\mathbf{D}(0, T)$ shares an $(n-1)$-cell with $\mathbf{D}(1, T)$ and $-\mathbf{D}(1, T), \cdots, \mathbf{D}(n-1, T)$ shares an $(n-1)$-cell with $\mathbf{D}(n, T)$ and $-\mathbf{D}(n, T)$, it is clear that $\mathbf{K}_1$ is a connected complex which is symmetric with respect to $\mathbf{0}$. Furthermore, its interior $\mathbf{K}_1^0$ is also connected. To see this, let $\mathbf{x}^0$ be a point of the relative interior of one of the boundary $(n-1)$-cells of, say, $\mathbf{D}(j, T)$. Then the map (4.5) is locally a smooth homeomorphism and so, near $\mathbf{x}^0$, $\mathbf{D}(j, T)$ is a smooth n-dimensional manifold with boundary which contains a half-neighborhood of $\mathbf{x}^0$ intersecting the boundary $(n-1)$-cell in a relatively open set. The same result is true for the other complex, say, $\mathbf{D}(j-1, T)$, which shares the cell containing $\mathbf{x}^0$ with $\mathbf{D}(j, T)$. The union of the two half-neighborhoods forms a neighborhood of $\mathbf{x}^0$ contained in $\mathbf{D}(j, T)\cup\mathbf{D}(j-1, T)$ which, clearly, has a connected interior. This, given the relationships of Lemma 6.1, proves that $\mathbf{K}_1$ is a closed symmetric cell complex with nonempty connected interior.

THEOREM 6.5 (Cellular Decomposition Theorem). *Let $r=2$ and system (1.1) be strictly normal and let T be sufficiently small and positive. Then*

$$\mathbf{K}(T) = \bigcup_{j=0}^{n-1}[\mathbf{D}(j, T)\cup(-\mathbf{D}(j, T))].$$

Proof. $\mathbf{K}(T)$ is a connected convex set with nonempty interior, $\mathbf{K}(T)^0$. Thus $\mathbf{K}(T)^0\backslash\mathbf{K}_1$ is either empty or contains a point $\mathbf{x}^1$. In the first case the result is proved. In the second instance, let $\mathbf{x}^2$ be a point of the interior of $\mathbf{K}_1$. Since both $\mathbf{x}^1$ and $\mathbf{x}^2$ lie in the interior of the connected set $\mathbf{K}(T)^0$, there exists a curve lying in $\mathbf{K}(T)^0$ that connects them. The cells of $\mathbf{K}_1$ of dimension $n-2$ or less (the cells of the $(n-2)$-*skeleton* of $\mathbf{K}_1$; see [16]) are a relatively negligible part of the complex (and of $\mathbf{K}(T)$) and it is reasonable to suspect that the curve connecting these two points can be chosen to avoid all such cells. This is, in fact, possible by a general position argument [8], [28]. Thus, if $\mathbf{z}$ is the "last" point of the connecting curve lying in the closed set $\mathbf{K}_1$, it must lie in the relative interior of some cell of dimension $n-1$. This, however, is impossible, since we have just shown that the points of the relative interiors of all such $(n-1)$-cells are in the interior of $\mathbf{K}_1$. This contradiction proves the proposition. □

This result shows that the control functions $\pm\mathbf{v}(\cdot; j, \mathbf{s})$, $\mathbf{s}\in\boldsymbol{\Delta}(j, T)$, $j=0, \cdots, n-1$, we have identified are sufficient to control all points of $\mathbf{K}(T)$, for sufficiently small T, to $\mathbf{0}$ time-optimally. In the sections to follow we shall use this result to explore the time-optimal flow, the switching surface structure and the character of the time-optimal feedback function.

7. Time-optimal feedback control and regular synthesis. In the previous section we proved that $\mathbf{K}(T)$ is the union of the policy cell complexes $\pm\mathbf{D}(j, T)$, $j=0, \cdots, n-1$. By the normality of the system, time-optimal controls are unique. It is clear, therefore,

that the unique control function for a point lying in the intersection of two, or more, policy complexes has a policy that is a subpolicy of one or more of the n-policies associated with the original complexes. Thus, if we define the time-optimal feedback control function on each of the component n-complexes, $\pm\mathbf{D}(j, T)$, $j=0, \cdots, n-1$, it is uniquely defined on all of $\mathbf{K}(T)$.

Accordingly, let $\mathbf{x} \in \mathbf{K}(T)$ and suppose $\mathbf{x}=\mathbf{x}(s_1, \cdots, s_{n-1}, s_n, j) \in \mathbf{D}(j, T)$ and the unique control function for $\mathbf{x}$ has $\mathbf{p}(j, \pi)=\langle \mathbf{u}^1, \mathbf{u}^2, \cdots, \mathbf{u}^n \rangle$ (or a subpolicy of $\mathbf{p}(j, \pi)$) as its switching policy and switches consecutively at times $s_{\pi(1)}, \cdots, s_{\pi(n-1)}$ (or a subset of these times). Then define

$$
\begin{aligned}
\mathbf{F}[\mathbf{x}(s_1, \cdots, s_n, j)] &= \mathbf{u}^1 \quad \text{if } 0 < s_{\pi(1)}, \\
&= \mathbf{u}^2 \quad \text{if } 0 = s_{\pi(1)} < s_{\pi(2)}, \\
&= \mathbf{u}^3 \quad \text{if } 0 = s_{\pi(1)} = s_{\pi(2)} < s_{\pi(3)}, \\
&\vdots \\
&= \mathbf{u}^n \quad \text{if } 0 = s_{\pi(1)} = \cdots = s_{\pi(n-1)} < s_n \leqq T, \\
&= \mathbf{0} \quad \text{if } 0 = s_{\pi(1)} = \cdots = s_{\pi(n-1)} = s_n.
\end{aligned} \tag{7.1}
$$

PROPOSITION 7.2. *The time-optimal feedback function,* $\mathbf{F}$, *satisfies the following*:

(1) $\mathbf{F}$ *is piecewise constant and*:

(a) $\mathbf{F}(\mathbf{x})=\mathbf{u}(1, j)=(\boldsymbol{\delta}(j+1), (-1)^{n-1-j}\boldsymbol{\delta}(j))$ *if* $\mathbf{x}$ *lies in the interior of* $\mathbf{D}(j, T)$ *or in the relative interior of an* $(n-1)$*-cell belonging to either of the* $(n-1)$*-dimensional invariant cell complexes* $\mathbf{D}(j|s_j=s_n)$ *and* $\mathbf{D}(j|s_{n-1}=s_n)$.

(b) $\mathbf{F}(\mathbf{x})=(-\boldsymbol{\delta}(j+1), (-1)^{n-j-1}\boldsymbol{\delta}(j))$ *if* $\mathbf{x}$ *lies in the relative interior of an* $(n-1)$*-cell belonging to the* $(n-1)$*-dimensional attracting cell complex* $\mathbf{D}(j|s_1=0)$.

(c) $\mathbf{F}(\mathbf{x})=(\boldsymbol{\delta}(j+1), (-1)^{n-j}\boldsymbol{\delta}(j))$ *if* $\mathbf{x}$ *lies in the relative interior of an* $(n-1)$*-cell belonging to the* $(n-1)$*-dimensional attracting cell complex* $\mathbf{D}(j|s_{j+1}=0)$.

(2) *The time-optimal trajectories of* (1.1) *on* $\mathbf{K}(T)$ *are solutions of*

$$
\dot{\mathbf{x}}=\mathbf{A}\mathbf{x}+\mathbf{B}\mathbf{F}(\mathbf{x}), \qquad \mathbf{x}(0)=\mathbf{x}^0 \in \mathbf{K}(T). \tag{7.3}
$$

(3) *If* $\mathbf{x}$ *lies in the relative interior of the* $(n-\alpha)$*-cell* $\mathbf{D}(j, \pi, \alpha)$ (*defined in* (5.3)) *for* $\alpha=1, \cdots, n-1$, *the vector* $\mathbf{A}\mathbf{x}+\mathbf{B}\mathbf{F}(\mathbf{x})$ lies in the tangent space of $\mathbf{D}(j, \pi, \alpha)$ *at* $\mathbf{x}$ *and the vector field* $\mathbf{x} \mapsto \mathbf{A}\mathbf{x}+\mathbf{B}\mathbf{F}(\mathbf{x})$ *is transversal to the* $(n-\alpha-1)$*-cell,* $\mathbf{D}(j, \pi, \alpha+1)$.

Proof. The proof of these assertions follows directly from the definition of $\mathbf{F}$, (5.1)-(5.3), and the fact that the "jump" in the tangent vector to an optimal trajectory traversing $\mathbf{D}(j, \pi, \alpha)$ at a point of $\mathbf{D}(j, \pi, \alpha+1)$ is (from (5.2))

$$
\begin{aligned}
\dot{\varphi}(s_{\pi(\alpha+1)}+0)-\dot{\varphi}(s_{\pi(\alpha+1)}-0) &= \mathbf{B}(\mathbf{u}^{\alpha+1}-\mathbf{u}^{\alpha}) \\
&= \pm\mathbf{b}^1 \quad \text{or} \quad \pm\mathbf{b}^2,
\end{aligned}
$$

depending on the coordinate in which the $\alpha+1$ switch occurs. □

COROLLARY 7.4. *The collection of cells composed of the following*:

(1) *The interiors,* $\pm\mathbf{D}(j, T)^0$, $j=0, \cdots, n-1$, *of the policy complexes*;

(2) *The cells* $\mathbf{D}(j, \pi, \alpha)$, $\alpha=1, \cdots, n-1$, (*see* (5.3)) *for all* j*-permissible permutations* π *and for all* $j=0, \cdots, n-1$;

(3) *The cell* $\{\mathbf{0}\}$

with the time-optimal feedback function, $\mathbf{F}$, *of* (7.1) *form a* **regular synthesis** *on* $\mathbf{K}(T)$ *in which every cell is of type* I (*see* [5], [27]).

Proof. This result follows directly from (7.2) and (5.3). □

Since the cells of (7.4) are fully constructable using the maps of (4.5), this result provides the first explicit construction of a regular synthesis for systems of the generality considered here.

Equation (7.3) provides an example of a differential equation "with discontinuous right-hand side" as studied by Filippov [6], Hermes [12], and Hájek [10], [11]. For our purposes the most useful concept of "solution" for such systems is the one proposed by Filippov.

DEFINITION 7.5. Let $\mathbf{f}$ be suitably defined on a subset of $\mathbb{R}^n$ (see [6], [10], and [11]), then an absolutely continuous function φ is said to be a solution to

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}), \qquad \mathbf{x}(0) = \mathbf{x}^0$$

on the interval $0 \leqq t \leqq T$, in **the sense of Filippov** (an $\mathcal{F}$-solution) if $\varphi(0) = \mathbf{x}^0$ and $\dot{\varphi}(t) \in \mathcal{F}(\mathbf{f}, \mathbf{x}(t))$ almost everywhere on $[0, T]$, where $\mathcal{F}(\mathbf{f}, \mathbf{x})$ is the closed convex set

$$\mathcal{F}(\mathbf{f}, \mathbf{x}) \equiv \bigcap_{\delta>0} \bigcap_{\mu(E)=0} \overline{\text{co}}\,[\mathbf{f}(B(\delta, \mathbf{x}) \backslash E)], \tag{7.6}$$

where $B(\delta, \mathbf{x})$ is the intersection of a δ-ball about $\mathbf{x}$ with the domain of $\mathbf{f}$, μ is n-dimensional Lebesgue measure and $\overline{\text{co}}$ denotes the closed convex hull of its argument set.

Clearly, if $\mathbf{f}$ is continuous at $\mathbf{x}$, $\mathcal{F}(\mathbf{f}, \mathbf{x}) = \{\mathbf{f}(\mathbf{x})\}$. At the other extreme, values of $\mathbf{f}$ taken on near $\mathbf{x}$ only on sets of measure zero play no role in the determination of $\mathcal{F}(\mathbf{f}, \mathbf{x})$ or for $\mathcal{F}$-solutions through $\mathbf{x}$.

DEFINITION 7.7. A feedback function $\mathbf{F}: \mathbf{K} \mapsto \mathscr{C}^2$ is **of Filippov type at** $\mathbf{x} \in \mathbf{K}$ **if** $\mathbf{F}(\mathbf{x}) \in \mathcal{F}(\mathbf{F}, \mathbf{x})$. **F is realizable** on a subset S of $\mathbf{K}$ if it is of Filippov type at each point of S.

Remark 7.8. A practical feedback function should not require "infinitely precise" measurements for its implementation. The determination of function values taken only on sets of measure zero would require such extreme measurement precision. This observation motivates the definition of "realizable" feedback function.

The following proposition generalizes the results concerning the measurement requirements of the feedback function discussed earlier for the $n = 2$ and $n = 3$ cases pictured in Figs. 1-3.

PROPOSITION 7.9. *Let* $\mathbf{F}$ *be the time-optimal feedback function defined in* (7.1), $\mathbf{F}$ *is of Filippov type at each point* $\mathbf{x}$ *of* $\mathbf{K}(T)$ *that lies*

(1) *In the interior of a policy cell complex* $\pm\mathbf{D}(j, T)$;

(2) *In the relative interior of an* $(n-1)$*-cell of the invariant cell complex* $\mathbf{D}(j|s_j = s_n) \cup \mathbf{D}(j|s_{n-1} = s_n) \cup (-\mathbf{D}(j|s_j = s_n)) \cup (-\mathbf{D}(j|s_{n-1} = s_n))$;

(3) *In the relative interior of an* $(n-1)$*-cell of the attracting cell complex* $\pm\mathbf{D}(j|s_1 = 0)$ *if and only if* $\gamma(j) = 1$;

(4) *In the relative interior of an* $(n-1)$*-cell of the attracting cell complex* $\pm\mathbf{D}(j|s_{j+1} = 0)$ *if and only if* $\gamma(j+1) = 1$

for $j = 0, \cdots, n-1$.

Proof. If $\mathbf{x}^0$ lies in the interior or in the relative interior of an $(n-1)$-cell of an invariant cell complex of $\mathbf{D}(j, T)$, Proposition 7.2(1)(a) shows that $\mathbf{F}(\mathbf{x}^0) = \mathbf{u}(1, j)$. In either case, this value is assumed in a neighborhood or a half-neighborhood of $\mathbf{x}^0$ and therefore is assumed on a set of positive measure in every $B(\delta, \mathbf{x}^0)$. This proves assertions (1) and (2) of Proposition 7.9.

If $\mathbf{x}^0$ lies in the relative interior of an attracting $(n-1)$-cell of $\mathbf{D}(j|s_1 = 0)$, then, from the structure Lemma 6.1, it also lies in an invariant cell complex, $-\boldsymbol{\delta}(j) \cdot \boldsymbol{\delta}(j-1) \cdot \mathbf{D}(j-1|s_{n-1} = s_n)$, or an attracting cell complex, $\boldsymbol{\delta}(j) \cdot \boldsymbol{\delta}(j-1) \cdot \mathbf{D}(j-1|s_{j+1} = 0)$, of

$\pm\mathbf{D}(j-1, T)$, when $\boldsymbol{\gamma}(j)=+1$ or -1, respectively. In the first case, $\mathbf{F}$ is realizable at $\mathbf{x}^0$ by the previously proven assertion (2). In the second case, the value $\mathbf{F}(\mathbf{x}^0)$ differs from $\mathbf{u}(1, j)$ in the first coordinate and from $\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{u}(1, j-1)$, the value assumed by $\mathbf{F}$ in the interior of $\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1, T)$, in the second coordinate. This implies that this latter value is, in fact, $-\mathbf{u}(1, j)$. Consequently, in any sufficiently small ball, $B(\delta, \mathbf{x}^0)$, $\mathbf{F}$ takes on only three values: $\mathbf{u}(1, j)$ on points of the interior of $\mathbf{D}(j, T)$; $-\mathbf{u}(1, j)$ on points of the interior of $\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1, T)$; and $\mathbf{F}(\mathbf{x}^0)$ on points of the $(n-1)$-cell $\mathbf{D}(j|s_1=0)$. Since the set of points $\mathbf{x}$ where $\mathbf{F}(\mathbf{x})=\mathbf{F}(\mathbf{x}^0)$ is a set of measure zero and $\mathbf{F}(\mathbf{x}^0)$ is not a convex combination of $\pm\mathbf{u}(1, j)$, $\mathbf{F}$ is not realizable at $\mathbf{x}^0$. This proves (3), and (4) follows from similar arguments. □

8. The time-optimal switching surfaces. The time-optimal feedback function $\mathbf{F}$ is conceptually simple. Its two components F_1 and F_2 assume only the values ±1. As a result the controllable set $\mathbf{K}$ is decomposed, for each $i=1, 2$, into two sets $F_i^{-1}(\pm1)$. The ith switching surface, $\boldsymbol{\Omega}_i$, forms the boundary of these two sets. Moroz [25] has shown that $\boldsymbol{\Omega}_i$ has a one-to-one projection on the subspace orthogonal to $\mathbf{b}^i$.

While examples show that switching surfaces can, in general, be very complicated, the analysis presented above permits a complete description and study of the switching surfaces within the controllable set $\mathbf{K}(T)$, where the results developed in the previous sections apply. The switching surfaces are, in fact, precisely the attracting cell complexes described in (5.4).

PROPOSITION 8.1. *Let system* (1.1) *be strictly normal and* $r=2$. *Then*

$$\text{(a)}\qquad \boldsymbol{\Omega}_1(T)\equiv\boldsymbol{\Omega}_1\cap\mathbf{K}(T)=\bigcup_{j=1}^{n-1}[-\mathbf{D}(j|s_1=0)\cup\mathbf{D}(j|s_1=0)],$$

$$\text{(b)}\qquad \boldsymbol{\Omega}_2(T)\equiv\boldsymbol{\Omega}_2\cap\mathbf{K}(T)=\bigcup_{j=0}^{n-2}[-\mathbf{D}(j|s_{j+1}=0)\cup\mathbf{D}(j|s_{j+1}=0)].$$

Proof. The proof follows by construction and Proposition 7.2. □

PROPOSITION 8.2. *For each* $j=1, 2, \cdots, n-1$, *the* $(n-1)$*-dimensional cell complex* $\mathbf{D}(j|s_1=0)$ *lies in* $\boldsymbol{\Omega}_1(T)\cap\Omega_2(T)$ *if and only if* $\boldsymbol{\gamma}(j)=-1$; *and, for each* $j=0, 1, \cdots, n-2$, *the* $(n-1)$*-dimensional cell complex* $\mathbf{D}(j|s_{j+1}=0)$ *lies in* $\boldsymbol{\Omega}_1(T)\cap\boldsymbol{\Omega}_2(T)$ *if and only if* $\boldsymbol{\gamma}(j+1)=-1$.

Proof. This result follows directly from Lemma 6.1 (the structure lemma) and Proposition 8.1 (e.g., if $\boldsymbol{\gamma}(j)=-1$, $\mathbf{D}(j|s_1=0)$, which lies in $\boldsymbol{\Omega}_1$, is equal to $\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_j=0)$, which lies in $\boldsymbol{\Omega}_2$). □

This description of the switching surfaces coupled with the analytic mappings of (4.5) permit a complete analysis and construction of the switching surfaces for small response times. Such results formed the basis for construction of closed-loop time-optimal controllers for the third- and fourth-order systems reported in [17] and [18]. The switching policies describing the switching surfaces of our example systems are the following.

Example A.

$\boldsymbol{\Omega}_1$: $\langle1, 4\rangle$, $\langle2, 1\rangle$, $\langle3, 2\rangle$, and $\langle4, 3\rangle$,

$\boldsymbol{\Omega}$: $\langle4, 1\rangle$, $\langle1, 2\rangle$, $\langle2, 3\rangle$, and $\langle3, 4\rangle$.

Example B.

$\boldsymbol{\Omega}_1=\boldsymbol{\Omega}_2$: $\langle4, 1\rangle$, $\langle2, 3\rangle$, $\langle2, 1\rangle$, and $\langle4, 3\rangle$.

Example C.

$\mathbf{\Omega}_1$: $\langle 2,3,2\rangle, \langle 1,2,3\rangle, \langle 1,4,3\rangle, \langle 2,1,2\rangle, \langle 4,1,4\rangle, \langle 3,4,1\rangle, \langle 3,2,1\rangle$, and $\langle 4,3,4\rangle$,

$\mathbf{\Omega}_2$: $\langle 1,4,1\rangle, \langle 2,1,4\rangle, \langle 2,3,4\rangle, \langle 1,2,1\rangle, \langle 3,2,3\rangle, \langle 4,3,2\rangle, \langle 4,1,2\rangle$, and $\langle 3,4,3\rangle$.

9. Canonical structures: proof of Theorem 1.8. In this section we present the proof of Theorem 1.8, which, for convenience, we restate below. Recall that

$$\gamma(j) = \gamma(j; \mathbf{A}, \mathbf{B}) \equiv \delta(j-1) \cdot \delta(j+1), \qquad j = 1, \cdots, n-1,$$

$$N(\mathbf{A}, \mathbf{B}) = \sum_{j=1}^{n-1} (1 - \gamma(j; \mathbf{A}, \mathbf{B}))/2,$$

$$M(\mathbf{A}, \mathbf{B}) \equiv \sum_{j=1}^{n-1} (1 - \gamma(j; \mathbf{A}, \mathbf{B}))\binom{n-2}{j-1}.$$

THEOREM 1.8. *Let system* (1.1) *be strictly normal, let* $r = 2$, *and let* T *be sufficiently small and positive. Then the following apply*:

(a) $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$ *has connectivity* $2(n - N(\mathbf{A}, \mathbf{B}))$;

(b) $\mathbf{\Omega}_1(T) \cap \mathbf{\Omega}_2(T)$ *is the union of* $M(\mathbf{A}, \mathbf{B})$ $(n-1)$*-dimensional cells*;

(c) $\mathbf{\Omega}_1(T) = \mathbf{\Omega}_2(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) = n-1$, (*that is,* $\gamma(1; \mathbf{A}, \mathbf{B}) = \cdots = \gamma(n-1; \mathbf{A}, \mathbf{B}) = -1$);

(d) *The time-optimal feedback function is realizable on* $\mathbf{K}(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) = 0$ (*that is,* $\gamma(1; \mathbf{A}, \mathbf{B}) = \cdots = \gamma(n-1; \mathbf{A}, \mathbf{B}) = 1$); *and*

(e) *The feedback function is of Filippov type on the relative interior of some* $(n-1)$*-dimensional cell of* $\mathbf{\Omega}(T)$ *if and only if* $N(\mathbf{A}, \mathbf{B}) \leqq n-2$.

Proof. (a) We have seen that $\mathbf{K}(T)$ is the union of the cell complexes $\pm\mathbf{D}(j, T)$, for $j = 0, \cdots, n-1$. From Lemma 6.1 it is clear that $\mathbf{D}(j, T)$ adjoins $\pm\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$ and $\pm\delta(j) \cdot \delta(j+1) \cdot \mathbf{D}(j+1, T)$ (when $0 < j < n-1$, if $j = 0$ or $n-1$, only one such relationship exists). Its intersection with the former pair consists of the cell complexes $\mathbf{D}(j|s_1 = 0)$ and $\mathbf{D}(j|s_j = s_n)$. If $\gamma(j) = 1$, these complexes lie in $\mathbf{\Omega}_1$ and $\mathbf{\Omega}_2$, respectively (from (8.2)); each intersection is of the attracting/invariant type; and $\mathbf{D}(j, T)$ and $\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$ lie in distinct components of $\mathbf{K}(T)\backslash\Omega(t)$ as, of course, is also true of $-\mathbf{D}(j, T)$ and $-\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$. Similarly, if $\gamma(j+1) = 1$, the intersections of $\mathbf{D}(j, T)$ and $-\delta(j) \cdot \delta(j+1) \cdot \mathbf{D}(j+1, T)$ are of attracting/invariant type and the two n-complexes also lie in distinct components. Thus, if all $\gamma(k) = 1$ and therefore $N(\mathbf{A}, \mathbf{B}) = 0$, each of the $2n$ policy complexes lies in a distinct component of $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$. Consequently, $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$ has connectivity $2n$ when $N(\mathbf{A}, \mathbf{B}) = 0$.

On the other hand, if $\gamma(j) = -1$, the intersection of $\mathbf{D}(j, T)$ with $\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$ is of attracting/attracting type and its intersection with $-\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$ is of invariant/invariant type. The first implies that $\mathbf{D}(j, T)$ and $\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$ are separated by $(n-1)$-cells which lie in $\mathbf{\Omega}_1 \cap \mathbf{\Omega}_2$ and therefore lie in distinct components of $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$. The invariant/invariant intersection, however, obviously implies that the feedback function is continuous on the interior of $\mathbf{D}(j, T) \cup (-\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T))$ and that these two policy complexes lie in the same component. The same is true of $-\mathbf{D}(j, T)$ and $\delta(j) \cdot \delta(j-1) \cdot \mathbf{D}(j-1, T)$. Thus, for each $\gamma(j) = -1$, the connectivity of $\mathbf{K}(T)\backslash\mathbf{\Omega}(T)$ decreases by 2 and $N(\mathbf{A}, \mathbf{B})$ increases by 1. Clearly, this is the relationship presented in assertion (a).

(b) If all $\gamma(j) = 1$, all intersections of the policy complexes are of the attracting/invariant type, $\mathbf{\Omega}_1(T) \cap \mathbf{\Omega}_2(T)$ contains no cells of dimension $n-1$ and $M(\mathbf{A}, \mathbf{B}) = 0$. However, if $\gamma(j) = -1$, the attracting/attracting intersection of $\mathbf{D}(j, T)$ with

$\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1,T)$ in the $(n-1)$-dimensional cell complex $\mathbf{D}(j|s_1=0)=\boldsymbol{\delta}(j)\cdot\boldsymbol{\delta}(j-1)\cdot\mathbf{D}(j-1|s_j=0)$ implies that the

$$\binom{n-2}{j-1}$$

$(n-1)$-dimensional cells of $\mathbf{D}(j|s_1=0)$ lie in both switching surfaces. Then, by symmetry, the minimum number of $(n-1)$-cells in $\boldsymbol{\Omega}_1(T)\cap\boldsymbol{\Omega}_2(T)$ increases by

$$2\cdot\binom{n-2}{j-1}$$

if $\boldsymbol{\gamma}(j)=-1$. This proves (b).

(c) If all $\boldsymbol{\gamma}(j)=-1$, all policy complexes intersect in attracting/attracting combinations, each attracting cell lies in the intersection of the two switching surfaces and, since lower-dimensional cells all lie in each surface, $\boldsymbol{\Omega}_1(T)=\boldsymbol{\Omega}_2(T)$.

(d) If $N(\mathbf{A},\mathbf{B})$ is positive, there exists at least one $\boldsymbol{\gamma}(j)=-1$ and at least two $(n-1)$-cells in $\boldsymbol{\Omega}_1(T)\cap\boldsymbol{\Omega}_2(T)$. In this case the time-optimal feedback function $\mathbf{F}$ is not realizable on these cells by Proposition 7.9(4). However, if $N(\mathbf{A},\mathbf{B})=0$, all policy complex intersections are of the attracting/invariant type. As a result each time-optimal attracting subpolicy of one complex is simultaneously an invariant subpolicy of an adjacent policy complex. It is this property that permits us to show that $\mathbf{F}$ is of Filippov type at each point of $\mathbf{K}(T)$ and, therefore, realizable.

Now let $\mathbf{x}^0\in\mathbf{K}(T)$. If $\mathbf{x}^0$ lies in the interior of a policy complex or in the relative interior of an $(n-1)$-dimensional boundary complex, then $\mathbf{F}$ is of Filippov type at $\mathbf{x}^0$ by (7.9). Therefore, suppose $\mathbf{x}^0$ lies in some lower-dimensional boundary cell of $\mathbf{D}(j,\pi,T)$ and that the time-optimal control function for $\mathbf{x}^0$ has a switching policy that is a subpolicy of $\mathbf{p}(j,\pi)=\langle\mathbf{u}^1,\mathbf{u}^2,\cdots,\mathbf{u}^n\rangle$. Specifically, suppose $\mathbf{F}(\mathbf{x}^0)=\mathbf{u}^k$ and that the policy describing the control function for $\mathbf{x}^0$ is (a subpolicy of)$\langle\mathbf{u}^k,\mathbf{u}^{k+1},\cdots,\mathbf{u}^n\rangle$. Thus $\mathbf{x}^0$ lies in the $(n-k+1)$-dimensional cell $\mathbf{D}(j,\pi,k-1)$ (see (5.3)) corresponding to this control policy.

To show that $\mathbf{F}$ is of Filippov type at $\mathbf{x}^0$, it is sufficient to show that $\mathbf{F}$ takes on the value $\mathbf{u}^k$ on a set of positive measure inside any neighborhood of $\mathbf{x}^0$. To do this it is sufficient to show that $\mathbf{x}^0$ lies in a boundary cell of some policy complex, say $\mathbf{D}(j',T)$, with $\mathbf{F}(\mathbf{x})=\mathbf{u}(1,j')=\mathbf{u}^k$ on points, $\mathbf{x}$, in its interior.

The attracting subpolicy $\langle\mathbf{u}^2,\cdots,\mathbf{u}^n\rangle$ *of* $\mathbf{p}(j,\pi)$ is also an invariant policy of an n-policy $\langle\mathbf{u}^2,\cdots,\mathbf{u}^n,\mathbf{w}^1\rangle$ of an adjacent policy complex. In turn, the attracting subpolicy of this n-policy is an invariant subpolicy of another n-policy $\langle\mathbf{u}^3,\cdots,\mathbf{u}^n,\mathbf{w}^1,\mathbf{w}^2\rangle$. Clearly this process continues until we identify a time-optimal policy $\mathbf{p}(j',\pi')=\langle\mathbf{u}^k,\cdots,\mathbf{u}^n,\mathbf{w}^1,\cdots,\mathbf{w}^{k-1}\rangle$, where j' denotes the number of switches in the first control coordinate implied by the policy. Because the control policy of $\mathbf{x}^0$ is a subpolicy of $\mathbf{p}(j',\pi')$, $\mathbf{x}^0$ is a point of the boundary of $\mathbf{D}(j',T)$. It is clear that points of the boundary lie in the closure of the interior of $\mathbf{D}(j',T)$. Hence there exist interior points arbitrarily close to $\mathbf{x}^0$. Since each such interior point has a neighborhood in which $\mathbf{F}\equiv\mathbf{u}^k$, $\mathbf{F}$ is of Filippov type at $\mathbf{x}^0$ and (d) is proven.

(e) If $N(\mathbf{A},\mathbf{B})=n-1$ then $\boldsymbol{\Omega}_1(T)=\boldsymbol{\Omega}_2(T)$ and $\mathbf{F}$ is not realizable at any point of the relative interior of an $(n-1)$-dimensional cell of $\boldsymbol{\Omega}(T)$. On the other hand, if $N(\mathbf{A},\mathbf{B})\leqq n-2$, there exists at least one "attracting/invariant" intersection of $(n-1)$-cells. As has been previously shown, $\mathbf{F}$ is of Filippov type on the relative interior of each such cell. This completes the proof of Theorem 1.8. □

COROLLARY 9.1. *Under the hypotheses of Theorem* 1.8 *all time-optimal trajectories on* $\mathbf{K}(T)$ *are Filippov trajectories if and only if* $\boldsymbol{\gamma}(1;\mathbf{A},\mathbf{B})=\cdots=\boldsymbol{\gamma}(n-1;\mathbf{A},\mathbf{B})=1$.

Proof. A time-optimal trajectory through a point $\mathbf{x}^0$ is a Filippov trajectory if and only if $\mathbf{F}$ is of Filippov type at $\mathbf{x}^0$. □

Theorem 1.8 shows that the time-optimal flow and switching surface structure near $\mathbf{0}$ is completely determined, qualitatively, by the structure constants $\gamma(1), \cdots, \gamma(n-1)$. These integers, unlike the determinants $\mathbf{d}(0), \cdots, \mathbf{d}(n)$ are invariant under linear transformations and provide a canonical classification of strictly normal systems. Since the system is strictly normal it is possible to use the columns of any $\mathbf{d}(j)$ as a basis to transform the system into its equivalent Luenberger canonical form $\bar{\mathbf{A}}, \bar{\mathbf{B}}$ [15]. That is, if $0 < j < n$, and $\mathbf{T}$ denotes the matrix corresponding to the determinant $\mathbf{d}(j)$,

$$\bar{\mathbf{A}} = \mathbf{T}^{-1}\mathbf{A}\mathbf{T} = [\mathbf{e}^2, \cdots, \mathbf{e}^j, \mathbf{a}, \mathbf{e}^{j+2}, \cdots, \mathbf{e}^n, \mathbf{c}], \qquad \bar{\mathbf{B}} = \mathbf{T}^{-1}\mathbf{B} = [\mathbf{e}^1, \mathbf{e}^{j+1}]$$

where $\mathbf{e}^k$ denotes the kth column of the $n \times n$ identity matrix, $\mathbf{a} = \mathbf{T}^{-1}\mathbf{A}^j\mathbf{b}^1$ and $\mathbf{c} = \mathbf{T}^{-1}\mathbf{A}^{n-j}\mathbf{b}^2$.

With the system in canonical form, it can be shown that for the low-dimensional systems of primary interest, $n \leqq 6, \gamma(1), \cdots, \gamma(n-1)$ constitute a system of independent invariants and provide a complete canonical categorization of linear time-optimal control systems. This result, however, remains to be proven for general n.

10. L^*-systems. Olsder [26] introduced a class of systems he called L^*-systems. In the case of two-dimensional controls of interest here, system (1.1) is L^* if for $n = 2k$, $\mathbf{d}(k-1)$, $\mathbf{d}(k)$, and $\mathbf{d}(k+1)$ are nonzero, or if for $n = 2k+1$, $\mathbf{d}(k)$ and $\mathbf{d}(k+1)$ are nonzero.

For such systems Olsder shows that, for almost all $\mathbf{x}$ of the unit sphere in $\mathbb{R}^n$, there exists an $\varepsilon_{\mathbf{x}} > 0$ such that $\varepsilon_{\mathbf{x}}\mathbf{x}$ is time-optimally controlled to $\mathbf{0}$ by a unique control function having k switches in each coordinate when $n = 2k+1$ and k switches in one coordinate and $k-1$ switches in the other coordinate when $n = 2k$. Furthermore, the switching times and response times are analytic functions of a power of $\varepsilon_{\mathbf{x}}$.

In terms of the results developed in this paper, Olsder's work implies that in the $n = 2k+1$ case, for example, almost every ray from the origin intersects $-\mathbf{D}(k, T) \cup \mathbf{D}(k, T)$ in an interval containing $\mathbf{0}$ in its interior. Interpreted geometrically, this implies that the switching surfaces separating these complexes from the others meet tangentially at the origin. Furthermore, as $T \to 0$ the relative contribution of all other complexes $(\pm\mathbf{D}(j, T), j \neq k)$ to $\mathbf{K}(T)$ becomes negligible.

The two complexes $\pm\mathbf{D}(k, T)$ lie "above" and "below" both switching surfaces and contain the major portion of $\mathbf{K}(T)$. This is illustrated in Fig. 3 and evident in Examples A and B and the general analysis of [17], [20].

11. Stability with respect to measurement. Hermes [12] has introduced the concept of "stability with respect to measurement" to characterize those feedback systems

$$\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{F}(\mathbf{x}), \tag{11.1}$$

that are tolerant of measurement error. Hermes' original formulation has been shown by Hájek [10], [11] to be equivalent to "stability with respect to inner perturbations" (an *inner perturbation* of $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ is of the form $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x} + \mathbf{p}(\mathbf{x}))$ where $\mathbf{p}$ is essentially bounded). This formulation has proved to be more tractable than the original used by Hermes.

There are necessary conditions for measurement stability and sufficient conditions for measurement stability, but necessary *and* sufficient conditions only for the case of scalar controls, arbitrary n (see [11]), two-dimensional controls with $n = 2$ (see [3], [4]), and two-dimensional controls with $n = 3$ (see [21]). Furthermore, only [3] and

[4] deal with the global case; the other results consider only "local measurement stability" in a neighborhood of the origin.

PROPOSITION 11.2. *A necessary condition for a closed-loop time-optimal control system of the form* (11.1) *to be locally stable with respect to measurement is that* **F** *be realizable on some* $\mathbf{K}(T)$, $T>0$.

Proof. In his original paper [12] Hermes showed that if a system is measurement stable, every Carathéodory solution of (11.1) is also a Filippov solution ($\mathcal{F}$-solution). If **F** is not realizable, there exist Carathéodory solutions on every $\mathbf{K}(T)$ that are not $\mathcal{F}$-solutions. On the other hand, if **F** is realizable, every Carathéodory solution is an $\mathcal{F}$-solution. □

COROLLARY 11.3. *Let system* (1.1) *be strictly normal and* $r=2$; *then the condition*

$$\boldsymbol{\gamma}(1;\mathbf{A},\mathbf{B})=\cdots=\boldsymbol{\gamma}(n-1;\mathbf{A},\mathbf{B})=1$$

is necessary for the existence of a locally measurement stable time-optimal feedback function.

Proof. The proof follows directly from Theorem 1.8(d). □

PROPOSITION 11.4. *A closed-loop time-optimal control system of the form* (11.1) *with r-dimensional controls,* $1\leqq r\leqq n$, *and a realizable time-optimal feedback function on some* $\mathbf{K}(T)$, $T>0$, *is locally measurement stable if and only if Filippov solutions to* (11.1) *are unique for all* $\mathbf{x}^0\in\mathbf{K}(T)$.

Proof. If **F** is realizable on $\mathbf{K}(T)$, the classes of Filippov solutions, Krasovsky solutions, and Hermes solutions to (11.1) (see [10], [11]) coincide. The result then follows from [11, Lemma 9.1], which states that (11.1) is stable with respect to measurement if and only if Hermes solutions are unique. □

Unfortunately, existence of a realizable feedback function is not sufficient to imply uniqueness of Filippov solutions. The following result from [21] exhibits an additional requirement.

THEOREM 11.5. *A strictly normal system of the form* (1.1) *with* $n=3$ *and* $r=2$ *is locally stable with respect to measurement if and only if*

(a) $\boldsymbol{\gamma}(1;\mathbf{A},\mathbf{B})=\boldsymbol{\gamma}(2;\mathbf{A},\mathbf{B})=1$, *and*

(b) $\det[\mathbf{b}^1,\mathbf{b}^2,\boldsymbol{\delta}(2)\mathbf{E}^1(t)+\boldsymbol{\delta}(1)\mathbf{E}^2(t)]\not\equiv 0$.

Remark 11.6. In [21] the determinants $\mathbf{d}(j)$ are indexed by the number of $\mathbf{b}^2$-based columns rather than $\mathbf{b}^1$-based columns. As a consequence, the roles of $\boldsymbol{\delta}(1)$ and $\boldsymbol{\delta}(2)$ are reversed in the original paper.

The system of Example A is locally measurement stable.

In general, switching surfaces $\boldsymbol{\Omega}(T)$ will contain Boltyanskii "cells of the second kind" (see [2], [5]) for sufficiently large T. However, it is unlikely that such cells could introduce measurement instability. Indeed, with the proper cellular decomposition these cells should occur as attracting sets for some n-cell and "start-points" (see [1]) for another n-cell complex. If this turns out to be an accurate view of the switching surface structure, then Filippov solutions would be locally unique in a neighborhood of cells of the second kind. This analysis implies the following conjecture.

Conjecture 11.7. A time-optimal feedback system of the form (11.1) with r-dimensional controls, $1\leqq r\leqq n$, is stable with respect to measurement if and only if it is locally stable with respect to measurement.

12. Analysis of more general systems. The techniques employed here to analyze strictly normal two-input systems may be extended to general minimally controllable r-input systems. This work is in progress and will be reported later. In addition, the total information concerning the local regular synthesis gained from this analysis sheds

considerable light on the total switching surface structure for large T. It is expected that this information will permit a resolution of (11.7).

13. Summary. This paper has extended the analytical techniques of [20] to the general nth-order strictly normal two-input system. In this extension:

(1) A cellular decomposition of $\mathbf{K}(T)$, for sufficiently small T, has been described and shown to provide the first explicit construction of a local regular synthesis for multi-input systems of arbitrary order.

(2) A system of linear invariants has been identified and been shown to completely characterize the time-optimal flow and switching surface structure for small response times.

(3) New necessary, and necessary and sufficient, conditions for local measurement stability have been proven.

CONSISTENT APPROXIMATIONS OF LINEAR STOCHASTIC MODELS*

ANDREA GOMBANI†

Abstract. This paper considers the problem of approximating a stochastic process $\{y(t)\}$ with state space X. The desired process $\{y_1(t)\}$ has state space X_1, of dimension as small as possible, such that, in mean square norm,

$$\|y(t)-y_1(t)\| \leqq \varepsilon$$

for a given $\varepsilon \geqq 0$. The solution given here has the *inclusion property*, i.e., $X_1 \subset X$ and is *consistent*, that is, it reduces to the problem of finding a minimal realization of $y(t)$ when ε is set equal to zero.

Key words. stochastic realization, approximate model, splitting subspaces, ε-observability

AMS(MOS) subject classifications. 93E12, 93B20

1. Introduction.

In this paper we consider the problem of stochastic model reduction. This consists of finding, for a given process $\{y(t)\}$, a process $\{y_1(t)\}$ admitting a Markovian representation of lowest possible dimension that approximates $\{y(t)\}$ in some norm. This problem has received considerable attention in recent years [5], [7], [13], [14], especially in connection with the Hankel-norm approximation of a spectral factor of y. However, in this paper we investigate a different approach to the problem, one which exploits the geometric framework of stochastic realization theory [9], [10], [11]. The basic idea of this approach is to start with a state space X of y (not necessarily minimal) and build the reduced model *within* this space. This is done by cutting off the parts of X that are almost unobservable *or* almost unconstructible (in a sense to be described below).

There are several reasons for considering this approach. One is that the reduced model will have its state space included in the original one, which means that, in a suitable basis, the new model is a subsystem of the original in the sense explained below. A more important reason is that in this way our algorithm is *consistent*, that is, the procedure we propose solves as a special case the problem of finding a *minimal* realization of $\{y(t)\}$, given a nonminimal one.

The Hankel-norm approximation is generally not consistent; this implies that some care must be taken in the choice of the state space X we want to reduce. (In fact, it is shown in [16] that the best results are achieved with this method when the minimum-phase spectral factor is approximated.) So, for the problem of reducing *any given* state space X, the Hankel-norm is not very suitable.

On the other hand, our procedure might not perform any better than the Hankel-norm method in the finite-dimensional case (even if, in the given example, it yields a much better bound and there seems to be an advantage in infinite dimension).

Since we work with approximation of *stochastic* systems, we will use the mean square norm

$$\|x\| := (Ex^2)^{1/2}.$$

This research was conducted while the author was a student at the Royal Institute of Technology, Stockholm, Sweden, and was partially supported by the National Swedish Board of Technical Development under grant 83-3272, and by a fellowship from the Italian National Research Council.

† LADSEB-Consiglio Nazionale delle Ricerche, Corso Stati Uniti 4, 35020 Padova, Italy.

This is the natural norm for this setting, and is unitarily equivalent to the L^2 norm. As we recall, the Hankel-norm approximation in stochastic model reduction is generally used to achieve an upper bound on the L^2-norm [14], [16], and it is this context in which this paper refers to Hankel-norm approximation.

It could be argued that the problem, posed in a deterministic setting, could be better solved with H^∞-methods (with respect, for instance, to robustness) (see, e.g., [15]). However, these methods are not very suitable when a variable phase factor is built into the model. This situation is illustrated by the following example (due to J. C. Willems, and pointed to us by C. I. Byrnes).

Suppose we want to record a symphony. Then the different distances between the instruments and the recording apparatus will introduce a phase shift in the signal. This phase shift is not strongly continuous under the H^∞-norm. Therefore, any attempt to filter out noise, eliminate redundancy, etc., will encounter difficulty, since even slightly shifted versions of the same input will be very distant from each other in H^∞, and will have to be treated as different signals. The L^2 norm does not have this disadvantage.

2. Preliminaries. We review here some basic facts about stochastic realization (we refer the reader to [9]–[11] and references therein for the full story).

Let $y(t)$ be a real-valued discrete-time, stationary, centered, purely nondeterministic (p.n.d.), Gaussian process on the probability space $\{\Omega, \mathcal{F}, \mathbb{P}\}$. Consider the Hilbert space generated by the process

$$H = \overline{\text{span}}\,\{y(t);\ t \in \mathbb{Z}\}$$

where the closure is taken with respect to the inner product $\langle x, z\rangle = Exz$, E denoting expected value.

The space H comes naturally endowed with a bilateral shift U, defined by

$$Uy(t) := y(t+1)$$

and extended by linearity to the whole space.

The basic realization problem is the following: find *all* representations of the form

$$x(t+1) = Ax(t) + Bu(t), \qquad y(t) = Cx(t) + Du(t) \tag{2.1}$$

where $u(t)$ is a white noise process in H (i.e., for each t, $s \in \mathbb{Z}$, $Eu(t)u(s) = \delta_{t,s}$), and A, B, C, D are constant matrices. It is of particular interest to characterize all minimal representations of form (1) (minimal in the sense that the vector $x(t)$ has smallest possible dimension). This problem can be posed as a geometric problem in the Hilbert space H, namely, the problem of finding all subspaces X of H that are *Markovian* and *splitting* for y, in the following sense. A nonzero subspace X of H is said to be *Markovian* if it splits its own past and future, i.e., defining $X^+ = \overline{\text{span}}\,\{U^n X;\ n \geqq 0\}$ and $X^- = \overline{\text{span}}\,\{U^n X;\ n \leqq 0\}$; thus we have that

$$E^{X^-}X^+ = E^X X^+, \tag{2.2a}$$

$$E^{X^+}X^- = E^X X^- \tag{2.2b}$$

with E^A denoting the orthogonal projection on A.

The space X is *splitting* for y if it splits the past and future of y, i.e., if $H^+ = \overline{\text{span}}\,\{y(n);\ n \geqq 0\}$ and $H^- = \text{span}\,\{y(n);\ n < 0\}$ the following holds:

$$E^{H^- \vee X}H^+ = E^X H^+, \tag{2.3a}$$

or equivalently,

$$E^{H^+ \vee X}H^- = E^X H^-. \tag{2.3b}$$

For short, in the sequel we use the concept of *state space* to denote a Markovian splitting subspace (for y).

A state space X for y is *minimal* if any other state space $X_1 \subset X$ is necessarily equal to X. Minimality can be characterized geometrically, introducing the concepts of observability and constructibility. We say that a state space X is *observable* if

$$E^X H^+ = X \tag{2.4a}$$

and *constructible* if

$$E^X H^- = X. \tag{2.4b}$$

It is then consistent with these definitions to say that a subspace $X_1 \subset X$ is *unobservable* if $X_1 \subset (H^+)^\perp$, and that $X_2 \subset X$ is *unconstructible* if $X_2 \subset (H^-)^\perp$.

Markovianness can also be characterized in a more convenient way. We say that a subspace $Z \subset H$ is invariant for the shift U if $UZ \subset Z$ and invariant for the adjoint shift U^* if $U^*Z \subset Z$. We say that $Z_1, Z_2 \subset H$ *intersect perpendicularly* if one of the following equivalent conditions holds:

(2.5a) (i) $(Z_1)^\perp \subset Z_2$ ($\perp$ denoting orthogonal complement in H);

(2.5b) (ii) $E^{Z_1} Z_2 = E^{Z_2} Z_1$.

Then it can be shown [11] that any splitting subspace X can be represented as the intersection of a unique pair $(S, \bar{S})$ of perpendicularly intersecting subspaces of H, i.e.,

$$X = S \cap \bar{S}$$

such that

$$S \supset H^- \tag{2.6a}$$

and

$$\bar{S} \supset H^+. \tag{2.6b}$$

The space X is Markovian if and only if $U^*S \subset S$ (i.e., S is invariant for the backward shift and $U\bar{S} \subset \bar{S}$) and $U\bar{S} \subset \bar{S}$ (i.e., $\bar{S}$ is invariant for the forward shift). *Hence we have characterizations of all state spaces of y in H in terms of invariant perpendicularly intersecting subspaces satisfying* (2.6). This correspondence will be denoted by $X \cong (S, \bar{S})$. It can be shown [11] that the following decomposition holds:

$$H = \bar{S}^\perp \oplus X \oplus S^\perp. \tag{2.7}$$

In particular, $S = X \oplus \bar{S}^\perp$, and $\bar{S} = X \oplus S^\perp$. Now the question is how to get a *minimal* state space from a given $X \cong (S, \bar{S})$. The answer is provided by the following theorem and is the guideline of our model reduction scheme.

THEOREM 2.1 [11]. *Let $X \cong (S, \bar{S})$ be a Markovian splitting subspace. Let $\bar{S}_1 := H^+ \vee S^\perp$ and $S_1 := H^- \vee \bar{S}_1^\perp$. Then $X_1 \cong (S_1, \bar{S}_1)$ is a minimal Markovian splitting subspace such that $X_1 \subset X$.*

The importance of this theorem is that the construction of a minimal Markovian splitting subspace from a nonminimal one is a model reduction problem, in which the Markovian and splitting properties are both preserved.

To analyze this geometry in an efficient way, a functions model is needed. Therefore, as is customary, we shall work in the isomorphic setting of the Hardy spaces H^2 and $\bar{H}^2$.

We recall that $L^2(\mathbb{T})$ is the Hilbert space of square integrable complex-valued function on the unit circle.

Every $f \in L^2(\mathbb{T})$ has a representation (unique)

$$f(e^{i\omega}) = \sum_{n=-\infty}^{\infty} f_n e^{i\omega n}.$$

We write $H^2(\bar{H}^2)$ for the subspace of L^2 whose elements have positive (negative) vanishing Fourier coefficients. The symbol $H^\infty(\bar{H}^\infty)$ denotes the subspace of $H^2(\bar{H}^2)$ whose elements are essentially bounded functions. An *outer function* f in H^2 is an element with the property that $fH^2 := \overline{\text{span}}\{fg;\ g \in H^\infty\} = H^2$, and an *inner function* $h \in H^2$ is an element subject to $|h(e^{i\vartheta})| = 1$ almost everywhere.

The symmetric concepts in $\bar{H}^2$ will be called *conjugate outer* and *conjugate inner.* It can be shown that any function $g \in H^2(\bar{H}^2)$ can be factored as $g = fh$ with f (conjugate) outer and h (conjugate) inner.

Remark. The notation used here is not conventional (the standard mathematical notation being exactly the opposite). This choice has been adopted to be in agreement with most engineering literature.

One of the reasons Hardy spaces have become an indispensable tool in realization theory is illustrated by the next theorem. We recall that an $\mathbb{R}$-valued p.n.d., mean square continuous, stationary process $\{y(t)\}$ has the representation

$$\{y(t)\} = \int_{-\pi}^{\pi} e^{i\omega t}\, d\hat{y}(\omega),$$

$d\hat{y}(\omega)$ being an orthogonal random measure such that there exists a finite, positive, absolutely continuous measure $dF(e^{i\omega})$ with density $\phi(e^{i\omega})$, for which

$$E|d\hat{y}(\omega)|^2 = \phi(e^{i\omega})\, d\omega.$$

We also recall that the spectral measure of a white noise is an orthogonal random measure $d\hat{u}(\omega)$ subject to

$$E|d\hat{u}(\omega)|^2 = d\omega.$$

It can be shown that if $u(t)$ is a white noise in H (i.e., $Eu(t)u(s) = \delta_{ts}$), then the spectral measure defined by

$$u(t) = \int_{-\pi}^{\pi} e^{i\omega t}\, d\hat{u}(\omega) \tag{2.8}$$

induces an isometric isomorphism I_u from H onto L^2 defined via the trigonometric polynomials $p(z)$ as

$$I_u p(u)u(0) := p(e^{i\omega})$$

and extended to the whole of H by continuity. (See [12] for details.)

Let K be an inner function. By $H(K)$ we denote the subspace (invariant for the left shift)

$$H(K) = H^2 \ominus KH^2.$$

Analogously, by $\bar{H}^2(K^*)$ we denote the subspace $\bar{H}^2 \ominus K^*\bar{H}^2$.

THEOREM 2.2 [9]-[11]. *Let $X \cong (S, \bar{S})$ be Markovian splitting. Then there exists a unique pair of white noises $(u, \bar{u})$ such that*

$$I_u S = z^{-1}H^2, \tag{2.9a}$$

$$I_u \bar{S} = K\bar{H}^2, \tag{2.9b}$$

$$I_{\bar{u}} S = z^{-1}K^*H^2, \tag{2.9c}$$

$$I_{\bar{u}} \bar{S} = \bar{H}^2 \tag{2.9d}$$

where K is an inner function in H^2. The process $y(t)$ has the representation

$$y(t) = \int_{-\pi}^{\pi} e^{i\omega t} W(e^{i\omega})\, d\hat{u}(\omega) \tag{2.10a}$$

with $W \in H^2$, i.e., $I_u y(0) = W$. Analogously, $I_{\bar{u}} y(0) = \bar{W} \in \bar{H}^2$ and the following representation holds:

$$y(t) = \int_{-\pi}^{\pi} e^{i\omega t} \bar{W}(e^{i\omega})\, d\hat{\bar{u}}(\omega). \tag{2.10b}$$

Moreover,

$$K = W\bar{W}^{-1}.$$

The correspondence between state spaces X and pairs $(W, \bar{W})$ and $(u, \bar{u})$ is one to one. It will be denoted by $X \cong (W, \bar{W}) \cong (u, \bar{u})$. The functions $W(z)$ and $\bar{W}(z)$ are real for real z. The space X has the representations

$$X = \int \mathscr{X}\, d\hat{u} = \int \bar{\mathscr{X}}\, d\hat{\bar{u}} \tag{2.11}$$

where

$$\mathscr{X} = z^{-1}H(K) = z^{-1}(H^2 \ominus KH^2) \tag{2.12a}$$

and

$$\bar{\mathscr{X}} = \bar{H}^2(K^*) = \bar{H}^2 \ominus K^*\bar{H}^2. \tag{2.12b}$$

The functions W and $\bar{W}$ are called, respectively, *stable* and *strictly unstable spectral factors* of y associated to X. Consequently, in the spectral domain, we represent the pair $(S, \bar{S})$ by the pair $(W, \bar{W})$, or equivalently by $(u, \bar{u})$.

Let X be a Markovian splitting subspace for y. How are the pairs (X^-, X^+) and $(S, \bar{S})$ related? Clearly, $X^- \subset S$, and $X^+ \subset \bar{S}$, but it is not a priori clear if equality holds. The next theorem shows this.

THEOREM 2.3. *Let $X \cong (u, \bar{u}) \cong (S, \bar{S})$ be a state space for y. Then, $X^- = S$ and $X^+ = \bar{S}$.*

Proof. Since it can be shown [11] that $S = H^-(u)$, we need to show only that $u(-1) \in X^-$, because then the inclusion follows from the invariance of X^-. To this end, represent $y(t)$ as in [12]:

$$y(t) = \sum_{n=0}^{\infty} w_n u(-n+t) \tag{2.13}$$

where $\sum_{n=0}^{\infty} w_n z^{-n} = W(z)$, the forward spectral factor associated to X. Let $k > 0$ be the index of the first coefficient in (2.11) which is different from zero. Then

$$E^X y(k-1) = E^S \sum_{n=0}^{\infty} w_n(u)(-n+k-1)$$

$$= \sum_{n=k}^{\infty} w_n u(-n+k-1)$$

because $u(t) \perp S$ for $t \geqq 0$, and $u(t) \in S$ for $t < 0$. Similarly,

$$E^X y(k) = E^S \sum_{n=0}^{\infty} w_n u(-n+k)$$

$$= \sum_{n=k+1}^{\infty} w_n u(-n+k).$$

But $E^X y(k-1)$ and $U^* E^X y(k)$ both belong to X^-. Therefore

$$u(-1) = \frac{1}{w_k}[E^X y(k-1) - U^* E^X y(k)]$$

is also in X^-. The same is true for X^+ (use the representation induced by $\bar{u}$ for $y(t)$ instead of (2.13)).

Let $W \in L^\infty$. Then the Hankel operator with symbol W is

$$H_W := E^{H^{2\perp}} M_{W|H^2}.$$

The singular value $\sigma_k(A)$ of an operator A is defined as

$$\sigma_k(A) = \inf\{\|A - C\|;\ \text{rank } C \leqq u\}.$$

Denote by $\mathscr{R}_k$ the set of strictly proper stable rational functions of degree less than or equal to k. Then there exists the following result due to Adamjan, Arov, and Krein [1]:

$$\min_{f \in \mathscr{R}_k} \|H_W - H_f\| = \sigma_k(H_W).$$

Now let $g \in H^{2\perp}$. It is not difficult to see that

$$\|g\|_H := \|H_g\|$$

defines a norm on $H_2^\perp$ called the Hankel-norm. Then the result of [1] says that the Hankel-norm approximation error of a function W with a function $f \in \mathscr{R}_k$ is exactly $\sigma_k(H_W)$.

Finally, let y be given and let $X \cong (W, \bar{W})$ be splitting for y. By Hankel-norm approximation of y (given X) we mean the Hankel-norm approximation of W. □

3. The problem. This section is devoted to the problem formulation, a discussion of the consistency and inclusion properties, and the illustration of how methods already developed in the literature (such as Hankel-norm approximation) behave with respect to these properties.

We are considering, for the time being, the geometric structure of H, and therefore a coordinate-free approach is appropriate. Hence, given a process $z(t)$, and a Markovian splitting subspace Z for z, it is reasonable to use the word *model* to denote the pair (z, Z). We define the degree of the model to be the dimension of Z.

DEFINITION. We say that the model (y_1, X_1) is a submodel of the model (y, X) if $X \supset X_1$.

This definition is more restrictive than it might seem at first sight, and X_1 cannot be just any subspace of X. In fact, since (y_1, X_1) is a model, X_1 is Markovian, and if X is finite-dimensional, the number of its Markovian subspaces is also finite. Under the assumption $X^- = X_1^-$ this is equivalent to saying that there exists a basis $x(0)$ in X such that the Markov process

$$x(t+1) = Ax(t) + Bu(t)$$

(u is A white noise) can be split into

$$\begin{bmatrix} x_1(t+1) \\ x_2(t+1) \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} + Bu(t)$$

with x_1 basis for X_1 and $A_{12} = 0$ (which yields Markovianness of the process $x_1(t)$).

We consider two equivalent formulations of the model reduction problem. First define, for $\varepsilon \geqq 0$, the class $\mathscr{Z}_\varepsilon$ to be the class of models (z, Z) satisfying

$$\|z(t) - y(t)\| \leqq \varepsilon \tag{3.1}$$

and, for $k \in \mathbb{N}$, the class $\mathscr{Z}_k$ to be the set of models (z, Z) such that $\dim Z \leqq k$. Finally, the set of admissible models, which will depend on the approximation procedure, will be denoted by $\mathscr{Z}$.

PROBLEM 1. *Given a model* (y, X) *and* $\varepsilon \geqq 0$, *find in* $\mathscr{Z} \cap \mathscr{Z}_\varepsilon$, *a model* (y_1, X_1) *of minimal degree. If there exists more than one solution with the same degree, find one whose error*

$$\|y(t) - y_1(t)\| \tag{3.2}$$

is minimal.

PROBLEM 2. *Given a model* (y, X), *and* $k \geqq 0$, *find an* $\mathscr{Z} \cap \mathscr{Z}_k$, *a model* (y_2, X_2) *such that the quantity*

$$\|z(t) - y(t)\| \tag{3.3}$$

is minimized. If there exist more than one solution with the same error find one whose degree is minimal.

At first sight, it may seem reasonable to choose the class $\mathscr{Z}$ to be $\mathscr{Z}_\varepsilon$ (or $\mathscr{Z}_k$). This choice can certainly be made, but in this case we have to deal with a nonlinear minimization problem in L^2 over a set of rational functions (which is not even convex), and therefore this is quite a difficult problem to solve. We can then restrict the set of our candidates $\mathscr{Z}$ to some smaller and nicer class for which an explicit solution can be determined (as for the procedure proposed in this paper), or for which at least an approximate solution and an error bound can be computed (as for the Hankel-norm). In both cases we obtain an overall bound on the error of the actual solution. It is then clear that the performance of these algorithms will depend on the properties of the underlying set $\mathscr{Z}$.

DEFINITION. We say that an approximation algorithm is consistent if, whenever the smallest class $\mathscr{Z}_k$ containing the solution (y_1, X_1) also contains a minimal realization of y, then $y_1 = y$ almost everywhere, and (y, X_1) is also a minimal realization of y.

In other words, our algorithm should select a *minimal* exact model whenever there exists one of the same degree as in the solution.

In the Hankel-norm approximation scheme described in § 2, the set $\mathscr{Z}$ is, given (y, X) and k,

$$\mathscr{Z}_H := \{(z, Z) \in \mathscr{Z}_k ; Z^- = X^-\}.$$

The following example shows that this is not always a satisfactory choice.

Example 3.1. Let $X \cong (u, \bar{u})$ be any Markovian splitting subspace such that u is not equal to $\bar{u}$ and apply the Hankel-norm approximation to the model $(\bar{u}, X)$. Observe first that there exists a zero-dimensional exact realization of $\bar{u}$, namely $(\bar{u}, 0)$. Clearly we can obtain a zero-dimensional model using the Hankel norm, but this would not be exact. In fact, Hankel-norm approximation amounts to approximating the spectral factor of 1 (note that $\bar{u}$ is a white noise) corresponding to u, namely the structural function K/z (of degree, say, n) which is inner. The Hankel operator with symbol K/z has all its singular values equal to 1, and therefore the Hankel-norm approximant of K/z of degree $k < n$ will in fact be zero with error bound 1; then the corresponding model is $(0, 0)$, which clearly is not exact. Therefore we do not have consistency.

The example above shows that the choice of the original state space X is quite relevant to the quality of the Hankel-norm approximation. In fact, it is shown in [16] that the best behaviour is obtained by choosing the minimum-phase model. However, the given physical model may be far away from the minimum-phase one, and in this case a different approach is needed.

DEFINITION. We say that an algorithm has the inclusion property if for any solution (y_1, X_1) the relation $X_1 \subset X$ holds.

This property insures that in an appropriate basis the approximate model is a subsystem of the given one, as we will see below. In addition, as we shall show in § 5, *imposing* this property, namely choosing

$$\mathscr{Z}_I := \{(z, Z);\ Z \subset X\} \tag{3.4}$$

(where I stands for inclusion), will yield consistency. Therefore the Hankel-norm approximation cannot have the inclusion property, which is also seen from Example 9 in [7].

Desai and Pal [5] have suggested an approach to model reduction that has the inclusion and consistency properties and may, at first sight, seem very natural. However, as we shall see below, it yields a "model" that is not necessarily Markovian, and hence is not a model in our sense.

Let (y, X) be our given model. To simplify matters, we assume throughout the rest of this section that $X \subset H^-$ (the argument can be extended to any X with some slight modifications). Then X is splitting for y if

$$E^X \xi - E^{H^-} \xi = 0, \qquad \xi \in H^+, \tag{3.5}$$

i.e., the conditional angle between past and future given X is zero. It can be shown that $X_- = E^{H^+} H^-$ is the minimal subspace in H_- satisfying (3.5).

If a further reduction of X is needed, the splitting condition (3.5) must be waived. The natural way to do it is to impose that the angle between past and future, if not zero, is at least smaller than some given ε. That is, find $X_1 \subset H^-$ such that

$$\| E^{X_1} \xi - E^{H^-} \xi \| \leqq \varepsilon \| \xi \|, \qquad \xi \in H^+. \tag{3.6}$$

Mapping H^- onto $z^{-1}H^2$ and H^+ onto $\bar{H}^2$ via I_{u_-} and $I_{\bar{u}_+}$, respectively, the projection operator $E^{H^-} H^+$ has, as spectral representator, the Hankel operator H_T, where $T := z^{-1} W_- \bar{W}_+^{-1}$ is called phase function. Then the equivalent of (3.6) reads

$$\| E^{\mathscr{X}_1} M_T - E^{z^{-1}H^2} M_T \| \leqq \varepsilon, \tag{3.7}$$

$\mathscr{X}_1 \subset z^{-1}H^2$. It can be shown (see, e.g., [3], [5]) that if $\varepsilon = \sigma_k(H_T)$, and (ξ_i, η_i) is the Schmidt pair associated to $\sigma_i(H_T)$, then

$$\mathscr{X}_k := \operatorname{span}\{\xi_0, \cdots, \xi_{k-1}\}$$

satisfies condition (3.7). In fact, with a little computation, it can also be seen that

$$\langle \xi_k, \eta_k \rangle = \sigma_k(H_T)$$

and $\langle \xi_i, \eta_j \rangle = 0$ for $i \neq j$. In other words the value $\sigma_k(H_T)$ represents the cosine of the kth principal angle between H^+ and H^-, and is called the kth canonical correlation coefficient (see [2]). (The kth principal angle between two Hilbert spaces H, K is defined as

$$\arccos \inf \left\{ \sup_{\substack{\xi \in H_0, \eta \in K \\ \|\xi\| = \|\eta\| = 1}} < \xi, \eta;\ \operatorname{cod} H_0 = k,\ H_0 \subset H \right\}$$

and indicates roughly how near H and K are to being orthogonal, "given" $H \ominus H_0$.) Mapping $\mathscr{X}_1$ back to H^- via $I_{u_-}^{-1}$, we obtain an $X_1 \subset H^-$ satisfying (3.6). This representation is, in fact, the one obtained by Akaike using canonical correlation analysis [2]. It is rather straightforward to check that the canonical correlation coefficients are the

singular values of the Hankel operator H_T, and that the principal components of past and future are the inverse images under I_u of (ξ_k, η_k) (see [2]). The reason the procedure above looks interesting is that we can easily compute the approximate model from a realization of the original one, since it is always possible to find a basis in X such that the representation

$$x(t+1) = Ax(t) + Bu(t), \qquad y(t) = Cx(t) + Du(t)$$

of y induced by X has as its first k components exactly the images $I_{u-}^{-1}\eta_i$, for $i = 0, \cdots, k-1$, of the first k Schmidt pairs. In other words, we can write

$$\begin{bmatrix} x_1(t+1) \\ x_k(t+1) \\ x_{k+1}(t+1) \\ x_n(t+1) \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_k(t) \\ x_{k+1}(t) \\ x_n(t) \end{bmatrix} + \begin{bmatrix} b_1 \\ b_k \\ b_{k+1} \\ b_n \end{bmatrix} u(t),$$

$$y(t) = [c_1, \cdots, c_k \quad c_{k+1}, \cdots, c_n] \begin{bmatrix} x_1(t) \\ x_k(t) \\ x_{k+1}(t) \\ x_n(t) \end{bmatrix} \tag{3.8}$$

where $x_i(0) = I_{u-}^{-1}\eta_i$. Then an approximate model is naturally given by

$$\begin{bmatrix} x_1(t+1) \\ x_k(t+1) \end{bmatrix} = A_{11} \begin{bmatrix} x_1(t) \\ x_k(t) \end{bmatrix} + \begin{bmatrix} b_1 \\ b_k \end{bmatrix} u(t),$$

$$y(t) = [c_1, \cdots, c_k] \begin{bmatrix} x_1(t) \\ x_k(t) \end{bmatrix}. \tag{3.9}$$

This is the approach already suggested by Akaike in [2], and proposed by Desai and Pal [5]. The main drawback, however, is that (3.9) is indeed a submodel of (3.8) only if A_{12} is zero, and this generally cannot be achieved if we require the first k components to be the images of the η_i, $i = 0, \cdots, k-1$.

An equivalent statement is that X_1 is, in general, not Markovian. In fact, we are going to prove that X_1 cannot be Markovian if the singular values of H_T are distinct.

THEOREM 3.1. *Let* $(\xi_0, \eta_0), \cdots, (\xi_{n-1}, \eta_{n-1})$ *be the Schmidt pairs of* H_T *associated to* $\sigma_0 > \sigma_1 > \cdots > \sigma_{n-1}$. *Then* $X_k = T_u^{-1}$ span $\{\eta_0, \cdots, \eta_{k-1}\}$ *is not Markovian, for* $k < n-1$.

The proof is quite technical and is given in the Appendix.

The basic reason this algorithm does not yield a Markovian model is that what is reduced is simultaneously almost unobservable *and* almost unconstructible (this is the meaning of (3.6)). By contrast, the reduction algorithm of Theorem 2.1 cuts off the unobservable part of X. That is, letting $\bar{S}_1 := S^{\perp} \vee H^+$ and $\bar{S} \ominus \bar{S}_1 = X_u$ easily shows that $E^{H^+}X_u = 0$. But X_u is certainly not unconstructible, because $X_u \subset (H_1)^{\perp}$ implies $E^{X_u}H_- = X_u$, since $H^- \vee H^+ = H$. So in fact X_u is constructible.

We conclude that the philosophy of the solution to the model approximation problem is to take observability and constructibility into account separately, not at the same time. We will do this in the next two sections. It is easily seen that a procedure for solving Problem 1 can be easily transformed into a solution to Problem 2. Hence, in what follows, we will focus our attention on Problem 1.

4. The exact model. As we have said, we want a model reduction scheme that is consistent. To this end, we reformulate the exact reduction algorithm of Theorem 2.1

so that it can be easily generalized for approximation. This is the content of this section and is, in particular, the meaning of Theorem 4.2 and Algorithm 4, as Example 4.1 shows.

There are basically three variations of the algorithm of Theorem 2.1 when $X \cong (S, \bar{S})$ is given.

ALGORITHM 1. Set $\bar{S}_1 := S^\perp \vee H^+$, $S_1 := \bar{S}_1^\perp \vee H^+$.

We obtain the minimal state space contained in X that is closest to the future H^+ in the sense that X_1 is the maximal element in the complete sublattice of minimal splitting subspaces of X. In particular, if the backward predictor space $X_+ = E^{H^+}H^-$ is contained in X, then $X_1 = X_+$.

ALGORITHM 2. Set $S_1 := \bar{S}^\perp \vee H^+$, $S_1 := S^\perp \vee H^+$.

We get the subspace that is closest to the past in the above ordering. In particular, if $X \supset X_- = E^{H^-}H^+$, the predictor space, then $X_1 = X$.

ALGORITHM 3. Take S_1 to be any invariant subspace with the property

$$H^- \vee \bar{S}^\perp \subset S_1 \subset S_+ \cap S$$

and set $\bar{S}_1 := S_1^\perp \vee H^+$. Then clearly S_1 and $\bar{S}$ intersect perpendicularly and it can be shown that X_1 is minimal.

In the following we will focus our attention on the first two algorithms.

The frame space $X^\square$ is defined as

$$X^\square := X_- \vee X_+$$

where X_- and X_+ are the forward and backward predictor spaces. It can be shown that any minimal splitting subspace is contained in $X^\square$ [11]. Moreover, these subspaces have a complete lattice structure under the partial ordering described below. It can be shown [11] that if X is minimal splitting,

$$X = \int Q^* H(K)\, d\hat{u}_-$$

where Q is an inner function. The correspondence between X and Q is one to one.

Then given X_1 and X_2 minimal splitting and the corresponding inner function Q_1, Q_2, we say that $X_1 < X_2$ if $Q_1 | Q_2$.

THEOREM 4.1. *Suppose X Markovian splitting subspace for y and set $X_1 := X \cap X^\square$. Then the set of minimal subspaces of X_1 is a complete lattice with the ordering induced by $X^\square$ (i.e., it has a complete lattice structure). The maximal element is given by Algorithm* 1 *and the minimal element by Algorithm* 2.

For the proof we need the following lemma.

LEMMA 4.1. *Suppose $Z \subset X^\square$ is a Markovian splitting space with a complete lattice structure. Then $R \cap Z$ also has a complete lattice structure for any left invariant subspace R.*

Proof. Let $Z_- \cong (v_-, \bar{v}_-)$ be the minimal element in the lattice and Z_+ the maximal. Then [11]

$$Z_- = \int H(K)\, d\hat{v}_-, \qquad Z_+ = \int Q_+^* H(K)\, d\hat{v}_-$$

and any minimal subspace of Z has the form

$$X = \int Q^* H(K)\, d\hat{v}_-$$

for some $Q \mid Q_+^*$. Conversely, to any such Q there corresponds a minimal state space. The space R will have the representation

$$R = \int P^* H^2 \, d\hat{v}_-$$

for some P inner. Then set

$$Q_m := (Q_+, P).$$

Then

$$X_m := \int Q_m^* H(K) \, d\hat{v}_-$$

is the maximal element of our sublattice, since the inner divisors of an inner function form a complete sublattice. The minimal element is clearly Z_-, and the lemma is proven. □

Proof of Theorem 4.1. Since $X \cong (S, \bar{S})$ we can apply the lemma above to $X^\square \cap S$, and then (after time reversal) to $(X^\square \cap S) \cap \bar{S}$, and the first part of the theorem is thus proven.

To see that the minimal element is the one given by Algorithm 2, observe that $X_1 < X_2$ in the lattice if and only if $Q_1 \mid Q_2$, where

$$X_i = \int Q_i^* H(K) \, du_-,$$

and hence if $S_1 \subset S_2$, since

$$S_i = \int Q_i^* H^2 \, du_-.$$

Since $S_i \supset \bar{S}^\perp \vee H^-$, clearly the minimal element is the one for which $S = \bar{S}^\perp V H^-$. This is similar for the maximal element. □

We want to describe the reduction procedure of Theorem 2.1 in the spectral domain. Therefore we introduce a basis in the spectral image $\mathscr{X}$ of the given state space X, and hence also in X. Let I_u denote the isomorphism mapping X^- onto $z^{-1}H^2$. Then (cf. (2.13), (2.14))

$$X = \int z^{-1} H(K) \, d\hat{u}$$

where K is inner. Let $b_1, \cdots, b_n$ denote the poles of K. Then a basis for $\mathscr{X} = z^{-1}H(K)$ is

$$\begin{aligned} v_1(z) &= \frac{N_1}{z - b_1}, \\ v_2(z) &= \frac{N_2}{z - b_2} \frac{1 - z\bar{b}_1}{z - b_1}, \\ v_n(z) &= \frac{N_n}{z - b_n} \frac{1 - z\bar{b}_{n-1}}{z - b_{n-1}} \cdots \frac{1 - z\bar{b}_1}{z - b_1} \end{aligned} \tag{4.1}$$

where N_i is a normalizing factor given by $N_i = (1 - |b_i|^2)^{1/2}$. The basis $v_1, \cdots, v_n$ is orthonormal. For short we can write

$$v_i(z) = \frac{N_i}{z - b_i} \prod_{j=1}^{i-1} B_j(z), \qquad B_j(z) := \frac{1 - z\bar{b}_j}{z - b_j}.$$

The basis $v_1, \cdots, v_n$ also has the property that $\operatorname{span}\{v_1, \cdots, v_n\} = z^{-1}H(B_1, \cdots, B_i)$. This basis clearly depends on the ordering of the poles. If σ is a permutation of S_n, then $b_{\sigma_1}, \cdots, b_{\sigma_n}$ will generate another basis, i.e.,

$$v_i^\sigma(z) := \frac{N_{\sigma_i}}{z - b_{\sigma_i}} \prod_{j=1}^{i-1} B_{\sigma_j}(z).$$

The spectral factor W and the isomorphic image of $y(0)$ under I_u then have different representations as σ ranges over S_n:

$$W = \sum_{i=0}^{n} \alpha_i(\sigma) v_i^\sigma \tag{4.2}$$

where $v_0^\sigma = 1$. Let $\operatorname{Res}(v_i, b_j)$ denote the residue of the function $v_i(z)$ in b_j. Then the coefficients $\alpha_i(\sigma)$ are the solution to the following system:

(4.3)

$$\begin{bmatrix} 1 & 0 & 0 & \cdots & 0 \\ 0 & \operatorname{Res}(v_1^\sigma; b_{\sigma_1}) & \operatorname{Res}(v_1^\sigma; b_{\sigma_1}) & \cdots & \operatorname{Res}(v_n^\sigma; b_{\sigma_1}) \\ 0 & 0 & \operatorname{Res}(v_2^\sigma; b_{\sigma_2}) & \cdots & \operatorname{Res}(v_n^\sigma; b_{\sigma_2}) \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ 0 & 0 & 0 & \cdots & \operatorname{Res}(v_n^\sigma; b_{\sigma_n}) \end{bmatrix} \begin{bmatrix} \alpha_0(\sigma) \\ \alpha_1(\sigma) \\ \alpha_2(\sigma) \\ \vdots \\ \alpha_n(\sigma) \end{bmatrix} = \begin{bmatrix} W(\infty) \\ \operatorname{Res}(W; b_{\sigma_1}) \\ \operatorname{Res}(W; b_{\sigma_2}) \\ \vdots \\ \operatorname{Res}(W; b_{\sigma_n}) \end{bmatrix}$$

and can be computed recursively (cf. [3]).

Among all possible choices of basis, there are some that are particularly interesting.

LEMMA 4.2. *Let $X \cong (W, \bar{W}) \cong (u, \bar{u})$. Then X is observable if and only if there exists no permutation $\sigma \in S_n$ subject to $\alpha_n(0) = 0$ in the representation* (4.2) *of W.*

Proof (If). Suppose that, for some σ, $\operatorname{Res}(W; b_{\sigma_n}) = 0$. This means $\alpha_n(\sigma) = 0$, and hence the degree of W is at most $n-1$. It can be shown (cf. [11]) that, given $X \cong (W, \bar{W})$, there exist polynomials p and q such that $W(z) = p(z)|q(z)$ and $\bar{W}(z) = p(z)|\hat{q}(z)$, where $\hat{q}(z) = z^n q(z^{-n})$, $n = \deg q$. Moreover, $X \cong (W, \bar{W})$ is observable if p and q are coprime (see [11]). In our case, $\deg q = n$ and $\deg W \leqq n-1$ imply that p and q are not coprime, i.e., X is not observable. Reading the argument backward proves the (Only if).

In other words Lemma 4.2 characterizes the observable subspaces of X in the spectral domain. Clearly an analogous result holds for constructibility. To obtain it we simply need to consider the map $I_{\bar{u}}$ from X^+ onto $\bar{H}^2$. Then the conjugate basis of v_i^σ for $i = 1, \cdots, n+1$, is

$$\bar{v}_i^\sigma(z) := \frac{zN_{\sigma_i}}{1 - zb_{\sigma_i}} \prod_{j=i+1}^{n+1} B_{\sigma_j}^*(z), \qquad B_j(z) := \frac{1 - z\bar{b}_j}{z - b_j}. \tag{4.4}$$

(The $(n+1)$st component represents the constants. This is done to simplify notation later.) The *conjugate* spectral factor of y will therefore have the representation

$$\bar{W} = \sum_{i=1}^{n+1} \bar{\alpha}_i(\sigma) \bar{v}_i^\sigma. \tag{4.5}$$

Then the constructible version of Lemma 4.2 reads as follows.

LEMMA 4.3. *Let $X \cong (W, \bar{W}) \cong (u, \bar{u})$. Then X is constructible if and only if there exists no permutation $\sigma \in S_n$ subject to $\bar{\alpha}_1(\sigma) = 0$ in the representation* (4.5) *of $\bar{W}$.*

The reason Lemmas 4.2 and 4.3 are interesting is that they provide the key to the spectral version of Algorithm 2 (the reduction algorithm) as is shown in the next theorem.

First define, for a given Markovian subspace X splitting for y,

$$k_o := \min_{\sigma \in S_n} \{k;\ \alpha_j(\sigma) = 0, j > k\}, \tag{4.6}$$

$$k_c := \max_{\sigma \in S_n} \{k;\ \bar{\alpha}_j(\sigma) = 0, j < k\}. \tag{4.7}$$

Let σ_o and σ_c denote the minimizer and maximizer, respectively, in (4.6) and (4.7). The letters o and c here stand for observable and constructible, respectively.

LEMMA 4.4. *Let $X \cong (u, \bar{u})$. Then*

$$X_o := I_u^{-1} \operatorname{span} \{v_1^{\sigma_o}, \cdots, v_{k_o}^{\sigma_o}\} \tag{4.8}$$

and

$$X_c := I_{\bar{u}}^{-1} z^{-1} \operatorname{span} \{\bar{v}_{k_c}^{\sigma_c}, \cdots, \bar{v}_n^{\sigma_c}\} \tag{4.9}$$

are, respectively, observable and constructible Markovian splitting subspaces for y.

Before proving this lemma, we proceed to the main theorem of this section.

THEOREM 4.2. *Let $X \cong (S, \bar{S})$ be Markovian splitting for y, let X_o and X_c be defined as in Lemma* 4.4, *and set $\bar{S}_1 := S^{\perp} \vee H^{+}$. Then*

$$(S, \bar{S}_1) \cong X_o.$$

Analogously, let $S_1 := \bar{S}^{\perp} \vee H^{-}$. Then

$$(S_1, \bar{S}) \cong X_c.$$

The spectral version of Algorithm 1 is now clear.

ALGORITHM 4. Let $X \cong (u, \bar{u})$ be given.

(1) Set $X_o := I_u^{-1} \operatorname{span} \{v_1^{\sigma_o}, \cdots, v_{k_o}^{\sigma_o}\}$.

(2) Consider $X_o \cong (W, \bar{W}_o) \cong (u, \bar{u}_o)$, the basis $I_{\bar{u}}^{-1} z^{-1} \{\bar{v}_i^{\bar{\sigma}_o}\}$ in X_o, where $\bar{\sigma}_o \in S_{k_o}$, and the representation

$$\bar{W}_o = \sum_{i=1}^{k_o+1} \bar{\alpha}_1(\bar{\sigma}) \bar{v}_i^{\bar{\sigma}_o}.$$

(3) Set $k_{oc} := \max_{\sigma_o \in S_{k_o}} \{k\colon \bar{\alpha}_j(\bar{\sigma}_o) = 0, j < k\}$ and let σ_{oc} be the maximizer of this expression.

(4) Define $X_{oc} := I_{\bar{u}_o}^{-1} z^{-1} \operatorname{span} \{v_i^{\sigma_{oc}};\ i = k_{oc}, \cdots, k_o\}$.

Obviously, there is an analogous spectral domain version of Algorithm 2, yielding a minimal Markovian splitting subspace X_{co}.

COROLLARY 4.1. *Let $S_1, \bar{S}_1$, as in Algorithm* 1. *Then*

$$X_{oc} \cong (S_1, \bar{S}_1). \tag{4.10}$$

Analogously, if $S_2, \bar{S}_2$ are as in Algorithm 2, *then*

$$X_{co} \cong (S_2, \bar{S}_2).$$

With this corollary the spectral equivalents of Algorithms 1 and 2 are completely characterized. Before we look at the proofs, we consider an example, trivial by itself but useful for the understanding of the approximation procedure in the next chapter.

Example 4.1. Consider $X \cong (u, \bar{u})$:

$$X = I_u^{-1} \operatorname{span}\left\{\frac{1}{z+(1/2)}, \frac{1}{z+(4/5)}\right\} = I_{\bar{u}}^{-1} \operatorname{span}\left\{\frac{1}{1+(z/2)}, \frac{1}{1+z(4/5)}\right\}$$

and

$$y(0) = \int W(e^{i\omega})\, du(\omega)$$

with

$$W(z) = \frac{z+(1/3)}{1+(z/2)} \frac{1+z(4/5)}{z+(4/5)}.$$

Then $\bar{W}(z)$ can be written as

$$\bar{W}(z) = \frac{z+(1/3)}{1+(z/2)} \frac{1+z(4/5)}{1+z(4/5)}.$$

It is easily seen that, whereas no reduction is possible on W, for $\bar{W}$ there are two representations associated to two different bases:

$$\bar{W}(z) = \frac{1}{3} + \frac{1}{2} \frac{z}{1+z(4/5)} + \frac{5}{12} \frac{z}{1+(z/2)} \frac{z+(4/5)}{1+z(4/5)},$$

$$\bar{W}(z) = \frac{1}{3} + \frac{5}{6} \frac{z}{1+(z/2)} + 0 \frac{z}{1+z(4/5)} \frac{z}{1+(z/2)}.$$

The second representation shows that, according to Lemma 4.3, X is not constructible, because α_2 is zero, and hence it can be reduced in the second step of the algorithm. Then $X_0 = X$ and no reduction is made, whereas

$$X_{oc} = I_{\bar{u}}^{-1}\left\{\frac{1}{1+(z/2)}\right\}$$

is a one-dimensional minimal splitting subspace for y.

As we said, it is obvious that $\bar{W}$ can be represented by a rational function of first degree. It is important to construct the reduced state space in a way that is generalizable to approximation, as will be seen in the next chapter.

We turn now to the proofs. We consider only the observable case, the constructible one being symmetric.

LEMMA 4.5. *Let $X \cong (u, \bar{u})$ be a Markovian subspace. If for some constant d*

$$y(0) = E^X y(0) + du(0) \tag{4.11}$$

then X is splitting for y. Similarly, if $\mathscr{X}$ and W are the spectral representations of X and $y(0)$, X is splitting for y if for some constant d

$$W \in d + \chi.$$

Proof. Let $E^X y(t) = Cx(t)$, where C is a convenient matrix and $x(t) = U^t x(0)$, $x(0) \in X$. Since for $t \geqq 0$, $u(t) \perp X^-$, we have $E^{X^-} y(t) = E^{X^-} Cx(t)$ because X is Markovian. Similarly, for $t < 0$, since $u(t) \perp (X^-)^\perp = X^+ \ominus X$ from Theorem 2.3, we can write

$$E^{X^+} y(t) = E^{X^+} Cx(t) + E^{X^+} u(t) = E^X Cx(t) + E^X u(t) = E^X y(t).$$

In other words, $E^{H^- \vee X} H^+ = E^X H^+$ and $E^{H^+ \vee X} H^- = E^X H^-$, i.e., X is splitting. The second part follows by mapping (4.11) in the spectral domain.

Proof of Lemma 4.4. Let $X_o \cong (u_o, \bar{u}_o)$ and consider in H^2 the images $\mathscr{X}_o$ and W of X_o and $y(0)$ under the map I_u. Then Markovianness follows from the left invariance of $\mathscr{X}_o$. As for the splitting property, from (4.2) we see that $W \in d + \mathscr{X}$, and we can therefore apply Lemma 4.5. As for observability note first that, since X_o is splitting, the representation $X_o \cong (W_o, \bar{W}_o)$ holds for a convenient choice of spectral factors W_o, $\bar{W}_o$. We need to prove that $W_o = W$, or equivalently, that $S = X_o^-$. This equality becomes, in the spectral domain, under the map I_u,

$$\operatorname{span}\{z^n \mathscr{X}_o;\ n \leqq 0\} = z^{-1}H^2.$$

To prove this last equality we pick a cyclic element in $\mathscr{X}_o$. Consider the first element of the basis of $\mathscr{X}_o$, $v_1 = N_1(z - b_1)^{-1} = N_1 z^{-1}(1 - z^{-1}b_1)^{-1}$. The function $(1 - z^{-1}b_1)^{-1}$ is invertible in H^2, and hence outer, i.e., $v_1 H^2 = z^{-1}H^2$, as wanted. That is, $S = X_o^-$, and hence $W_o = W$. But then we can apply Lemma 4.2, and X_o is observable.

Proof of Theorem 4.2. Let $X_o \cong (S, \bar{S}_o)$, and $\bar{S}_1 := H^+ \vee S^\perp$. We need to show only that $\bar{S}_o = \bar{S}_1$. Since X_o is splitting, we have $H^+ \subset \bar{S}_o$, and since also $\bar{S}_o \supset S^\perp$, we obtain $\bar{S}_o \supset \bar{S}_1$. That is, $X_o \supset X_1 = (S, \bar{S}_1)$. Since both X_o and X_1 are observable subspaces, the following holds:

$$E^S H^+ = E^{X_1} H^+ = X_1 \subset X = E^X H^+ = E^S H^+, \tag{4.12}$$

i.e., $X_1 = X$. A similar argument holds for X_c.

5. Main results. We have seen that, if X is not minimal, there exists an algorithm to cut out the unobservable and unconstructible parts of X. Suppose now that we are in a situation where a minimal model is still too large for applications. Then some further reduction leading to an approximate model must be performed. This is the topic of this section.

The idea is to generalize the algorithm presented above by cutting off subspaces of X that are "almost" unobservable or "almost" unconstructible, in a specific sense to be described below.

To this end, let us examine Algorithm 1 more closely.

LEMMA 5.1. *Let* $X \cong (S, \bar{S})$ *and* $\bar{S}_o := S^\perp \vee H^+$. *Then* $X_o \cong (S, \bar{S}_o)$ *is characterized by the following properties*:

(5.1)
- (a) X_o *is Markovian*;
- (b) $X \ominus X_o$ *is unobservable*;
- (c) $X^- = X_o^-$;
- (d) X_o *is minimal with respect to the above properties* (*i.e., if* $X'_o \subset X_o$ *has properties* (a)-(c), *then* $X'_o = X_o$).

Proof. X_o is Markovian by construction, and since $X^- = S = X_1^-$, then (c) is also satisfied. Since $(X \ominus X_o) \perp (\bar{S}_o \cap S)$, but also $(X \ominus X_o) \subset S$, it follows that $(X \ominus X_o) \perp \bar{S}_o$. Since $\bar{S}_o \supset H^+$, a fortiori $(X \ominus X_o) \perp H^+$, i.e., $X \ominus X_o$ is unobservable, and this shows (b). Suppose now that $X'_o \subset X_o$ has the same properties. Then $(X \ominus X'_o) \cap X_o$ is also unobservable. But this implies $(X \ominus X'_o) \cap X_o = 0$, i.e., $X'_o = X_o$ and hence (d) holds.

Conversely, if a subspace $X_1 \subset X$ satisfies (a), (b), (c), (d), then it is splitting, because for each $\xi \in H^+$, the equality

$$E^X \xi = E^{X_1} \xi + E^{X \ominus X_1} \xi = E^{X_1} \xi$$

holds and, since X is splitting, we have

$$E^S \xi = E^X \xi = E^{X_1},$$

which is the splitting property for X_1. Observability follows from (d). In conclusion, X_1 is Markovian, observable, and splitting for y, and such that $X_1 = S$. But then, $X_1 = X_o$ (because $X_1^- = S$ and $X_1^+ \supset H^+ \vee S^\perp$). Using (4.12), we get $X_1 = X_o$.

For our approximation scheme, we need to replace the unobservability condition (b) by a weaker one (which will not imply, as condition (b) did, that X_o is splitting).

DEFINITION. Let $\varepsilon > 0$ be given. Then we say that a subspace Z of H is ε-unobservable if

$$\sup \|E^Z y(t)\| \leqq \varepsilon, \qquad t \geqq 0 \tag{5.2}$$

and ε-unconstructible if

$$\sup \|E^Z y(t)\| \leqq \varepsilon, \qquad t < 0. \tag{5.3}$$

The reason for this definition is explained by the following proposition.

PROPOSITION 5.1. *$Z \subset X$ is unobservable if it is ε-unobservable for all $\varepsilon > 0$.*

Proof. Z is unobservable if $Z \subset X \cap (H^+)^\perp$. But this implies that $E^Z x = 0$ for $x \in H^+$. In particular, $E^Z y(t) = 0$ for all t. Conversely, ε-unobservability of Z for all $\varepsilon > 0$ implies $E^Z y(t) = 0$ for $t > 0$, and since any $x \in H^+$ has a representation $x = \sum_{t \geqq 0} \alpha_t y(t)$, $E^Z y(t) = 0$ for $t \geqq 0$, we get $E^Z x = 0$. □

Condition (b) now becomes the following:

(b′) $X \ominus X_1$ is ε-unobservable.

THEOREM 5.1. *Suppose $X_1 \subset X$ satisfies condition* (a)-(c), *and $X \cong (u, \bar{u})$. Then there exists a process $\{y_1(t)\}$ such that*

$$\|y(t) - y_1(t)\| < \varepsilon \tag{5.4}$$

and X_1 is splitting for y_1. If condition (d) *is satisfied then X_1 is observable for y_1.*

Proof. Since X is splitting for y there exists a representation

$$y(0) = du(0) + E^X y(0)$$

where u is the forward process associated to X. Set

$$y_1(0) := du(0) + E^{X_1} y(0).$$

Then,

$$y_1(0) = du(0) + E^{X_1} y_1(0).$$

So, from Lemma 4.5, X_1 is splitting for y_1. Moreover, $X \ominus X_1$ is ε-unobservable, and hence

$$\begin{aligned} \|y(0) - y_1(0)\| &= \|E^X y(0) - E^{X_1} y(0)\| \\ &= \|E^{X \ominus X_1} y(0)\| < \varepsilon. \end{aligned}$$

Let us now assume that X_1 is not observable with respect to y_1. We shall show that condition (d) cannot then hold. If $X_1 \cong (S, \bar{S}_1)$ is not observable, then $X_2 \cong (S, S^\perp \vee H^+(y_1))$ is a proper subspace of X_1 satisfying properties (a), (b′), and (c); hence (d) cannot hold. □

Now we exhibit a constructive way to obtain a reduced space satisfying properties (a), (b′), (c), and (d). First the following lemma is needed.

LEMMA 5.2. *Let $X_1 \cong (S_1, \bar{S}_1) \subset X \cong (S, \bar{S})$. Then $\bar{S} \ominus \bar{S}_1$ is ε-unobservable if and only if*

$$\|E^{\bar{S} \ominus \bar{S}_1} y(0)\| < \varepsilon. \tag{5.5a}$$

Similarly, $S \ominus S_1$ is ε-unconstructible if and only if

$$\|E^{S \ominus S_1} y(0)\| < \varepsilon. \tag{5.5b}$$

Proof. Suppose (5.5a) holds, and let $y(0) = y_1(0) + y_2(0)$ with $y_1(0) \in \bar{S}_1$ and $y_2(0) \in \bar{S} \ominus \bar{S}_1$. Then $E^{\bar{S}\ominus\bar{S}_1} y_1(t) = 0$ and

$$\begin{aligned} \|E^{\bar{S}\ominus\bar{S}_1} y(t)\| &= \|E^{\bar{S}\ominus\bar{S}_1} y_2(t)\| \\ &= \|E^{\bar{S}\ominus\bar{S}_1} U' y_2(0)\| \leqq \|E^{\bar{S}\ominus\bar{S}_1} y_2(0)\| = \|y_2(0)\| \\ &= \|E^{\bar{S}\ominus\bar{S}_1} y(0)\| \end{aligned} \qquad t \geqq 0$$

because U is unitary and the projection is contractive. Hence $\bar{S} \ominus \bar{S}_1$ is ε-unobservable.

The other direction is obvious. A similar argument holds for constructibility.

THEOREM 5.2. *Let $X \cong (u, \bar{u})$ be given, and let $\mathscr{X} := I_u X$. Suppose there exists a $\sigma \in S_n$ such that $\sum_{i=k+1}^{n} \|\alpha_i(\sigma)\|^2 \leqq \varepsilon^2$. Then $X_\sigma = \operatorname{span}\{v_1^\sigma, \cdots, v_k^\sigma\}$ satisfies conditions* (a), (b′), *and* (c). *If $\sum_{i=k}^{n} |\alpha_i(\sigma)|^2 > \varepsilon^2$ for each $\sigma \in S_n$, then condition* (d) *is also satisfied.*

Proof. Clearly X_σ is Markovian. The space X^- is mapped under I_U onto $z^{-1}H^2$. Since $v_1^\sigma = z^{-1}(1 - zb_{\sigma^1})^{-1}$ spans $z^{-1}H^2$ (i.e., $\overline{\operatorname{span}}\{z^{-n}v_1;\ n \geqq 0\} = z^{-1}H^2$); also $X_\sigma^- = X^-$. To prove that condition (b′) holds, we apply Lemma 5.2 to X and X_σ. Concerning condition (d), if $X_{\sigma^1} \subset X_\sigma$, for some $\sigma^1 \in S_{k^1}$, with $k^1 < k$, and X_{σ^1} also satisfies conditions (a), (b′), and (c), then by definition $\sum_{i=k^1+1}^{n} |\alpha_i(\sigma^1)|^2 \leqq \varepsilon^2$. But this contradicts the hypothesis of the theorem.

The following algorithm concludes this story.

ALGORITHM 5a. Let the state space $X \cong (u, \bar{u})$ and $\varepsilon \geqq 0$ be given. We set

$$k_o := \min\left\{k;\ \sum_{i=k+1}^{n} |\alpha_i(\sigma)|^2 \leqq \varepsilon^2 \text{ for some } \sigma \in S_n\right\} \tag{5.6}$$

and let σ_o be a minimizer of (5.6). (This minimizer does not need to be unique. In this case we choose the one for which the above sum in parentheses is minimal.) We set

$$X_o := I_u^{-1} \operatorname{span}\{v_1^{\sigma_o}, \cdots, v_{k_o}^{\sigma_o}\},$$

$$y_o(0) := \int \sum_{i=0}^{k_o} \alpha_i(\sigma) v_i^\sigma \, d\hat{u}.$$

Then, by Theorem 5.1, X_o is Markovian, splitting, and observable for y_o. Moreover,

$$\|y(0) - y_o(0)\| \leqq \varepsilon.$$

To complete the analogy with Algorithm 1, we need to cut out an ε-unconstructible part from the resulting space. This can be easily done by reversing time and using the conjugate objects $\bar{u}$, $\bar{H}^2$, etc. instead of u, H^2. In the following example, we consider the same state space as in Example 4.1 but use a slightly different process.

Example 5.1. Let $X \cong (u, \bar{u})$ be given by

$$X = I_u^{-1} \operatorname{span}\left\{\frac{1}{z + (1/2)}, \frac{1}{z + (4/5)}\right\},$$

$$y(0) = \int_{-\pi}^{\pi} W(e^{i\omega}) \, du(\omega)$$

where

$$W(z) = \frac{z + (1/3)}{z + (1/2)} \frac{z + (11/9)}{z + (4/5)}.$$

The corresponding $\bar{W}$ is

$$\bar{W}(z)=\frac{z+(1/3)}{1+(z/2)}\,\frac{z+(11/9)}{1+(4z/5)}.$$

It is simple to see that X is now minimal. Therefore a one-dimensional model needs to be an approximation with some error $\varepsilon>0$. Let $\varepsilon=0.05$. Then it is easily seen that X has no ε-unobservable part, and hence $X_0=X$. On the other hand, $\bar{W}$ can be written as

$$\begin{aligned}\bar{W}(z)&=\alpha_0+\alpha_1\bar{v}_1+\alpha_2\bar{v}_2\\&=\frac{11}{27}+\frac{164}{81\sqrt{3}}\,\frac{z(\sqrt{3}/2)}{1+(z/2)}+\frac{11}{243}\,\frac{5/3}{1+(4z/5)}\,\frac{z+(1/2)}{1+(z/2)}\end{aligned}$$

with $\bar{v}_1\perp\bar{v}_2$ and $\|\bar{v}_1\|_{L^2}=\|\bar{v}_2\|_{L^2}=1$. Since

$$\frac{11}{243}=.045267489$$

we obtain that span $I_u^{-1}\bar{v}_2$ is ε-unconstructible and can be eliminated. Therefore

$$X_{oc}=\text{span } I_{\bar{u}}^{-1}\left\{\frac{1}{1+z/2}\right\},$$

$$y_{oc}(0)=\int_{-\pi}^{\pi}\left(\frac{11}{27}+\frac{164}{81\sqrt{3}}\,\frac{z\sqrt{3/2}}{1+z/2}\right)d\hat{\bar{u}}.$$

Now we compare our approximation with one obtained using Hankel-norm techniques. The Hankel-norm approximation applied to the spectral factor W yields the approximant

$$A(z)=-.388370\,\frac{z-.986176}{z+.857631}$$

with error bound

$$\sigma_1=.167481,$$

which is considerably larger than our bound. An objection might be that we did not apply Hankel-norm approximation to the most favourable case, since W is not minimum-phase (cf. [16]). The first answer to this objection is that we are interested in an approximation of the original model, which includes the state space, and not in that of the corresponding minimum-phase model.

Anyway, for sake of completeness, we approximate the outer factor of W:

$$W_1(z)=\frac{11}{9}\,\frac{z+1/3}{z+1/2}\,\frac{z+9/11}{z+4/5}.$$

The Hankel-norm approximation of W_1 yields an error of

$$\sigma_2=\frac{40}{27}\,\frac{7}{108}\cong.096022,$$

which is still more than twice our bound. Moreover, again we stress that this is *not* an approximant of the original spectral factor.

However, Hankel-norm approximation provides, in general, an upper bound on the L^2 norm of the error, which might a priori be smaller. This is not the case in the above setting, since in both cases the difference between the function and the Hankel-norm approximant is inner (cf. [7]), and therefore the errors in L^2-norm, Hankel-norm, and H^∞-norm do coincide. Therefore the errors σ_1 and σ_2 are also real L^2-errors.

There remain some questions to be answered relating to the minimality of the final space. A first question is what the basis of the backward representation will look like. The backward representation $I_{\hat{u}}$ maps $\bar{S}$ onto $\bar{H}^2$, and

$$y(0) = \int \bar{W}\, d\hat{u}.$$

Now we want to express W as the sum of a constant and something in $z\bar{\mathscr{X}} = I_{\hat{u}} UX$ (see 2.11). The canonical basis for $z\bar{\mathscr{X}}$ is thus given by

$$\bar{v}_i^\sigma := \frac{N_{\sigma_i}}{z^{-1} - b_{\sigma_i}} \prod_{j=i+1}^{n} \frac{z - b_{\sigma_j}}{1 - z b_{\sigma_j}}$$

and the conjugate spectral factor $\bar{W}$ will have the representation

$$\bar{W} = \sum_{i=1}^{n+1} \beta_i(\sigma) \bar{v}_i^\sigma \tag{5.7}$$

where $\bar{v}_{n+1}^\sigma = 1$. The forward and the backward basis are related via the following lemma.

LEMMA 5.3. *Let $\alpha_i(\sigma)$ and $\beta_i(\sigma)$ be the coefficients of W and $\bar{W}$ in* (4.2) *and* (5.7), *respectively, related to the same permutation of the poles σ. Then*

$$\beta_i(\sigma) = \alpha_i(\sigma) b_{\sigma_i} + N_{\sigma_i} \left(\sum_{k=0}^{i-1} \alpha_k(\sigma) N_{\sigma_k} p_{k,i}(\sigma) \right), \qquad i = 1, \cdots, n,$$

$$\beta_{n+1}(\sigma) = \sum_{k=0}^{n} \alpha_k(\sigma) N_{\sigma_k} p_{k,n}(\sigma)$$

where

$$p_{k,i}(\sigma) = \prod_{j=k+1}^{i-1} (-b_{\sigma_j}) \qquad (p_{k,i} = 1 \text{ for } 1 \leqq k+1)$$

and $N_{\sigma_0} = 1$.

Proof. We drop the dependence on σ in the proof, understanding that what holds for $1, \cdots, n$, is also true for $\sigma_1, \cdots, \sigma_n$. Let

$$C_i := \prod_{j=i+1}^{n} B_j^*.$$

Then, remembering that $\bar{W} = K^* W$ (and $K^* = C_0$), we obtain

$$\begin{aligned} v_i K^* &= \frac{N_i}{z - b_i} (B_{i-1} \cdots, B_1) K^* \\ &= \frac{N_i}{1 - z b_i} (B_{i+1}^* \cdots B_n^*) \\ &= \frac{z N_i b_i}{1 - z b_i} (B_{i+1}^* \cdots B_n^*) + N_i (B_{i+1}^* \cdots B_n^*) \\ &= b_i \bar{v}_i + N_i C_i. \end{aligned} \tag{5.8}$$

Next, $C_{i-1} = N_i\bar{v}_i - b_iC_i$. In fact,

$$C_{i-1} = \frac{z-b_i}{1-zb_i}\,C_i = \frac{1-z^{-1}b_i}{z^{-1}-b_i}\,C_i$$
$$= \left(\frac{1-\bar{b}_ib_i}{z^{-1}-b_i} - b_i\right)C_i = N_i\bar{v}_i - b_iC_i,$$

and therefore the following representation holds:

$$C_k = \sum_{i=k+1}^{n} N_i\bar{v}_i\left(\prod_{j=k+1}^{i-1}(-b_j)\right) + \prod_{j=k+1}^{n}(-b_j) \tag{5.9}$$
$$= \sum_{i=k+1}^{n} N_i\bar{v}_ip_{k,i} + p_{k,n+1}.$$

Hence, expressing $\bar{W}$ through (5.8) and (5.9) and setting $N_o = 1$, we get the following chain of equalities:

$$\bar{W} = WK^* = \sum_{k=0}^{n}\alpha_kv_kK^*$$
$$= \sum_{k=1}^{n}\alpha_kb_k\bar{v}_k + \sum_{k=0}^{n}\alpha_kN_kC_k$$
$$= \sum_{k=1}^{n}\alpha_kb_k\bar{v}_k + \sum_{k=0}^{n}\alpha_kN_k\left(\sum_{i=k+1}^{n}N_i\bar{v}_ip_{k,i} + p_{k,n+1}\right)$$
$$= \sum_{i=1}^{n}a_ib_i\bar{v}_i + \sum_{k=0}^{n-1}\alpha_kN_k\left(\sum_{i=k+1}^{n}N_i\bar{v}_ip_{k,i}\right) + \sum_{k=0}^{n}\alpha_kN_kp_{k,n+1}$$
$$= \sum_{i=1}^{n}\alpha_ib_i\bar{v}_i + \sum_{i=1}^{n}N_i\bar{v}_i\left(\sum_{k=0}^{i-1}\alpha_kN_kp_{k,i}\right) + \sum_{k=0}^{n}\alpha_kN_kp_{k,n+1}$$
$$= \sum_{i=1}^{n}\left(\alpha_ib_i + N_i\left(\sum_{k=0}^{i-1}\alpha_kN_kp_{k,i}\right)\right)\bar{v}_i + \sum_{k=0}^{n}\alpha_kN_kp_{k,n+1}$$
$$= \sum_{i=1}^{n}\beta_i\bar{v}_i + \beta_o,$$

which completes the proof. □

It is now clear how to truncate an ε-constructible part of a state space X.

ALGORITHM 5b. Let $\varepsilon \geqq 0$ be given. We set

$$k_c := \max\left\{k;\ \sum_{i=1}^{k-1}|\beta_i(\sigma)|^2 \leqq \varepsilon^2 \text{ for some } \sigma \in S_n\right\} \tag{5.10}$$

where the $\beta_i(\sigma)$ are as in (5.7), and set σ_c to be the maximizer of (5.10) (with the same precaution concerning nonuniqueness as in Algorithm 5a). Set

$$X_c := I_{\bar{u}}^{-1}\,\text{span}\,\{\bar{v}_{k_c}^{\sigma_c}, \cdots, \bar{v}_n^{\sigma_c}\},$$
$$y_c(0) := \int \sum_{i=k_c}^{n+1}\beta_i(\sigma)v_i^{\sigma}\,d\hat{\bar{u}}.$$

Then X_c is Markovian splitting and constructible for y_c. Moreover,

$$\|y(0) - y_c(0)\| \leqq \varepsilon.$$

To obtain an approximate model the general procedure is as follows.

ALGORITHM 5. Let $X \cong (u, \bar{u})$ and $\varepsilon \geqq 0$ be given. From X, using Algorithm 5a, derive the space $X_o \subset X$, and the process $\{y_o(t)\}$. Next, apply Algorithm 5b to X_o and $\{y_o(t)\}$, to get $X_{oc} \subset X_o$, and $\{y_{oc}(t)\}$. Then,

$$\|y(0) - y_{oc}(0)\| < 2\varepsilon.$$

An important question is whether the reduced model thus obtained is indeed minimal for the process $\{y_{oc}(0)\}$. We know that it is constructible (from the conjugate version of Theorem 5.2), but observability could have been destroyed a priori after the ε-unconstructible part was cut. The next theorem shows that this is not the case.

THEOREM 5.3. *Let y_{oc} and X_{oc} be, respectively, the process and the state space (splitting for y_{oc}) obtained through Algorithm 5. Then X_{oc} is minimal splitting for y_{oc}.*

Proof. All we need to show is the observability of X_{oc}, because constructibility follows from Theorem 5.2. Let W_{oc} be the spectral factor of the forward representation of y_{oc}, i.e.,

$$y(0) = \int W_{oc}\, d\hat{u}_{oc}$$

where $X_{oc} \cong (u_{oc}, \bar{u}_{oc})$. Let then $X_0 \cong (u_0, \bar{u}_0)$ be the observable space obtained with the first step of the procedure. Then, for any $\sigma \in S_{k_o}$, the coefficient $\alpha_{k_o}(\sigma)$ in the representation

$$W_o = \sum_{i=o}^{k_o} \alpha_i(\sigma) v_i^\sigma \tag{5.11}$$

is different from zero. We claim that

$$W_{oc} = \gamma + B_{\sigma_1} \cdots B_{\sigma_k} \left(\sum_{i=k_{oc}+1}^{k_o} \alpha_i(\sigma) v_i^\sigma \right) \tag{5.12}$$

where

$$\gamma = \sum_{i=0}^{k_{oc}} \left(\prod_{j=i+1}^{k_{oc}} (-b_{\sigma_j}) \right) \alpha_i N_i N_{k_{oc}}$$

and $N_o = 1$ for some $\sigma \in S_{k_{oc}}$. In fact, letting $K_o = W_o \bar{W}_o^{-1}$, we have

$$\begin{aligned} \bar{W}_o = W_o K_o^* &= \left(\sum_{i=0}^{k_o} \alpha_i(\sigma) v_i^\sigma \right) K_o^* \\ &= \left(\sum_{i=0}^{k_{oc}} \alpha_i(\sigma) v_i^\sigma \right) K_o^* + \left(\sum_{i=k_{oc}+1}^{k_o} \alpha_i(\sigma) v_i^\sigma \right) K_o^* \\ &= \sum_{i=1}^{k_{oc}} \beta_i(\sigma) \bar{v}_i^\sigma + \gamma C_{k_{oc}+1} + \left(\sum_{i=k_{oc}+1}^{k_o} \alpha_i(\sigma) v_i^\sigma \right) K_o^*. \end{aligned}$$

Since the second and the third added in the last term are orthogonal to span $\{\bar{v}_1^\sigma, \cdots, \bar{v}_i^\sigma\}$, when the ε-constructible part is truncated, we obtain exactly

$$\bar{W}_{oc} = \gamma_{k_{oc}+1} + \left(\sum_{i=k_{oc}+1}^{k_o} \alpha_i(\sigma) v_i^\sigma \right) K_0^*. \tag{5.13}$$

Multiplying (2.13) by $C_{k_{oc}+1}^*$ we get precisely (5.12). But the coefficients of the v_i are the same as the last $k_o - k_{oc}$ coefficients in (5.11), and observability then follows from that X_o.

Now we have the following important result about the consistency of Algorithm 5. In fact, we can easily show that the inclusion property, i.e., the very choice $\mathscr{Z} = \mathscr{Z}_I$ (cf. 3.4), implies consistency.

THEOREM 5.4. *Suppose an algorithm solves Problem* 1 *with* $\mathscr{Z} = \mathscr{Z}_I$. *Then this algorithm is consistent.*

Proof. Let $(\hat{y}, \hat{X})$ be a solution generated by our algorithm. Suppose there exists a minimal realization of y of dimension k equal to $\dim \hat{X}$. Since there exists in any state space X for y a minimal state space X_k contained in X, the minimal realization (y, X_k) of y belongs to $\mathscr{Z}_I$, and clearly with this choice the error (3.2) is minimized, since it is zero. So the error of $\hat{y}$ must also be zero, i.e., $\hat{y} = y$ almost surely, and hence $(y, \hat{X})$ is also a realization of y. Since its dimension equals that of X_k, it is minimal. Therefore the inclusion property implies consistency.

COROLLARY. *Algorithm* 5 *is consistent.*

We conclude with a remark on the infinite-dimensional case. One advantage of our procedure is that it extends very easily to the case when X has infinite dimension, and the structural function K is not rational. In fact, if K is a Blascke product, then the set (4.1) (which is now infinite-dimensional), forms a basis in $H(K)$, and hence W will have representation

$$W = \sum_{i=0}^{\infty} \alpha_i(\sigma) v_i^{\sigma}$$

with $\{\alpha_i(\sigma)\}_{i=0}^{\infty} \in l^2$. (This is because $\{v_i^{\sigma}\}$ is an orthonormal set.) That is, in the case when K is a Blascke product, the coefficients $\alpha_i(\sigma)$ will eventually become small. This does not happen with Hankel-norm approximation, where, to get a slower convergence of the singular values, the assumption $W \in H^{\infty} + C(\mathbb{T})$ is needed.

The general case, when K has a singular inner part, can be treated in a similar fashion. In fact, by Frostman's theorem [18], any inner function can be uniformly approximated by a Blascke product. Then, for any $\varepsilon > 0$, there exists a Blascke product B such that

$$\| W - E^{H(B)} W \| < \varepsilon,$$

and hence we can define the ε-unobservable part of X, etc. Again, this is not possible with Hankel-norm approximation.

Appendix: Proof of Theorem 3.1. A subspace X_1 of H^- is Markovian if and only if its image $\mathscr{X}_1$ under I_{u_-} has the form $\mathscr{X}_1 = Q(H^2 \ominus BH^2)$ with B_1, B_2 inner. Since $z\eta_0$ is outer, all we need to show is that $\mathscr{X}_1$ is not of the form $H^2 \ominus BH^2$, or equivalently (from Beurling's theorem), that $\mathscr{X}_1$, which is equal to $\operatorname{span}\{\eta_0, \cdots, \eta_{k-1}\}$, is not invariant for the left shift in $z^{-1}H^2$, which is to say that $\operatorname{span}\{z\eta_0, \cdots, z\eta_{k-1}\}$ is not left invariant in H^2. To this end, we consider the Hankel operator $\mathscr{H}_T$ from H^2 to $H^{2\perp}$:

$$\mathscr{H}_T := E^{H^{2\perp}} M_{T|H^2}.$$

We also define $T_- := E^{H^{2\perp}} T$. It is well known that $\mathscr{H}_T = \mathscr{H}_{T_-}$, and it is clear that

$$\mathscr{H} x_i = \sigma_i(\mathscr{H}_{T_-}) y_i \tag{A1}$$

where $x_i = z\eta_i$, $y_i = z\xi_i$, and $\sigma_i(\mathscr{H}_{T_-}) = \sigma_i(\mathscr{H}_T)$. Hence what we need to prove is that the space

$$\mathscr{H}_k := \operatorname{span}\{x_i;\ i = 0, \cdots, k-1\}$$

is not left invariant in H^2. To this end we need some technical lemmas.

LEMMA A1. *Let B be a Blaschke product, and let $H(B) := H^2 \ominus BH^2$. Then*

$$S(B) := E^{H(B)} M_{z^{-1}|H(B)} \tag{A2}$$

has no reducing subspace.

(A subspace X is reducing for an operator A if $AX \subset X$ and $AX^* \subset X^*$.)

Proof. The adjoint of $S(B)$ is easily seen to be $E^{H^2} M_{z|H(B)}$. Suppose Z_1 is reducing for $S(B)$. Then $A^* \mathscr{Z}_1 = E^{H^2} M_z \mathscr{Z}_1$ is contained in $\mathscr{Z}_1$. So $\mathscr{Z}_1$ is invariant for the left shift on H^2. For the same reason, $\mathscr{Z}_2 = X \ominus \mathscr{Z}_1$ is also invariant for the left shift U^*. But a subspace Z invariant for U^* has the form $Z = H^2 \ominus BH^2$ for some inner function Q (again from Beurling's theorem). Then

$$Z_1 = H^2 \ominus B_1 H^2 = H(B_1), \qquad Z_2 = H^2 \ominus B_2 H^2 = H(B_2)$$

with B_1, B_2 inner. We are going to show that $Z_1 \neq 0$ implies $Z_2 = 0$. Since Z_1 and Z_2 are orthogonal, Z_1 is contained in $Z_2^\perp = B_2 H^2$. Let $B_1 = q_1(z)/\tilde{q}_1(z)$. Then, $1/\tilde{q}_1(z) = B_2 f(z)$ for some $f \in H^2$; but $1/\tilde{q}_1(z)$ is outer, and hence $B_2 = 1$, i.e., $Z_2 = 0$.

From now on, B_{T_-} will denote the Blaschke product obtained with the poles of T_-.

LEMMA A2. *Let B_1 be an inner divisor of B_{T_-}. Then the operator*

$$\mathscr{H}_1 := \begin{cases} 0 & \text{on } H(B_1), \\ \mathscr{H} & \text{on } B_1 H^2 \end{cases} \tag{A3}$$

is Hankel if and only if the "prediction error" operator based on $H(B_1)$,

$$E_1 := (I - E^{H(B_1)}) M_{z^{-1}|H(B_1)},$$

has range contained in the kernel of H.

Proof. We recall that an operator H is Hankel if and only if $\mathscr{H} M_{z^{-1}} = E^{H^{2\perp}} M_z H$. In particular, since $H^2 = H^2(B_1) \oplus B_1 H^2$, $\mathscr{H}_1$ is Hankel if and only if

(i) $\mathscr{H}_1 M_{z^{-1}} f = E^{H^{2\perp}} M_{z^{-1}} f$ for $f \in B_1 H^2$;

(ii) $\mathscr{H}_1 M_{z^{-1}} f = 0$ for $f \in H^2 \ominus B_1 H^2$,

condition (i) is always satisfied. In fact, from the invariance of $B_1 H^2$ for $M_{z^{-1}}$, we have that $f \in B_1 H^2$ implies $M_{z^{-1}} f \in B_1 H^2$, and hence

$$\mathscr{H}_1 M_{z^{-1}} f = \mathscr{H} M_{z^{-1}} f = E^{H^{2\perp}} M_{z^{-1}} \mathscr{H} f = E^{H^{2\perp}} M_{z^{-1}} \mathscr{H}_1 f.$$

As for condition (ii), since $\mathscr{H}_1 = \mathscr{H} E^{B_1 H^2}$,

$$\mathscr{H}_1 M_{z^{-1}} f = \mathscr{H} E^{B_1 H^2} M_{z^{-1}} f = \mathscr{H}(I - E^{H(B_1)}) M_{z^{-1}} f.$$

Hence, condition (ii) is satisfied if and only if

$$\mathscr{H}(I - E^{H(B_1)}) M_{z^{-1}} = 0,$$

which is equivalent to $\mathscr{R}[(I - E^{H(B_1)}) M_{z-1}] \subset \ker \mathscr{H}$. □

LEMMA A3. *There is no left invariant subspace $H(B_1) \subset H(B)$ such that $\mathscr{H}_1$ is Hankel ($\mathscr{H}_1$ as in* (A3)).

Proof. In view of Lemma A2, if $\mathscr{H}_1$ is Hankel, then $(I - E^{H(B_1)}) M_{z^{-1}} H(B_1)$ is in the kernel BH^2 of $\mathscr{H}$. This means that $E^{H(B)}(I - E^{H(B_1)}) M_{z^{-1}} H(B_1) = 0$, which implies $S(B) H(B_1) \subset H(B_1)$. But this means that $H(B_1)$ is invariant for $S(B)$. Since it is already left invariant, it is reducing. But this contradicts Lemma A1.

We can now finish the proof of the theorem. Suppose that for some k, the space $\mathscr{X}_1 = \text{span}\{x_i;\ i = 0, \cdots, k-1\}$ is invariant for the adjoint shift. That is to say, $\mathscr{X}_1$ is equal to $(B_1 H^2)^\perp$ for some inner function $B_1 = q_1(z)/\tilde{q}_1(z)$ of degree k. The vector x_k admits in turn the representation $x_k = B_1(z)$, for some $f \in H^2$ of degree $n - k$ and outer

(cf. [1]). Express $T_-(z)$ as a sum of two rational functions, one in $(B_1H^2)^\perp$ and the other in B_1H^2:

$$T_-(z)=\frac{p_1(z)}{q_1(z)}+\frac{p_2(z)}{q_2(z)}=T_1(z)+T_2(z).$$

Since

$$T_1(z)x_k(z)=\frac{p_1(z)}{q_1(z)}f\in H^2$$

we get

$$E^{H^{2\perp}}T_1(z)=0. \tag{A4}$$

Now consider the Hankel operator

$$\mathscr{H}_2:=E^{H^{2\perp}}M_{T_2}.$$

In view of (A4), $\mathscr{H}w_2$ coincides with $\mathscr{H}$ on x_k, i.e.,

$$\mathscr{H}x_k=\mathscr{H}_2x_k.$$

That is to say, $\mathscr{H}$ and $\mathscr{H}_2$ coincide on the whole invariant subspace of H^2 generated by x_k, which is B_1H^2. This space contains x_i for $i\geqq k$ (because $x_i\perp\mathscr{X}_1$ for $i\geqq k$), i.e., $\mathscr{H}_2x_i=\sigma_i(\mathscr{H}_{T_-})y_i$, $i\geqq k$. Moreover, y_i is divisible by B_1^* (cf. [1]) for $i\geqq k$. Hence $\mathscr{H}_{T_1}^*y_i=0$ for $i\geqq k$, and

$$\mathscr{H}_{T_2}^*y_i=\mathscr{H}_{T_-}^*y_i=\sigma_i(\mathscr{H}_{T_-})x_i,\qquad i\geqq k,$$

which is to say that $\mathscr{X}_1\in\ker\mathscr{H}_2$ (Lemma A2), or equivalently,

$$\mathscr{H}_2:=\begin{cases}0 & \text{on } H(B_1),\\ \mathscr{H}_{T_-} & \text{on } B_1H^2.\end{cases}$$

But this, in view of Lemma A3, is a contradiction. □

Acknowledgments. We thank Professor Anders Lindquist for the patient and helpful advice he gave us during the long evenings of the Swedish winter, providing us with all possible kinds of suggestions that greatly contributed to the improvement of this paper. It is also a pleasure to thank Professors Chris Byrnes and Anthony Bloch for the encouragement and help they gave us during stimulating discussions at the Royal Institute of Technology in spring 1985; and the anonymous referee, whose kind and helpful comments largely contributed to the improvement of the paper.

DISTURBANCE DECOUPLING, (f, g)-INVARIANT AND CONTROLLABILITY SUBSPACES OF A CLASS OF HOMOGENEOUS POLYNOMIAL SYSTEMS*

WIJESURIYA P. DAYAWANSA† AND CLYDE F. MARTIN†

Abstract. This paper discusses control systems of the type

$$\dot{x} = f(x) + \sum_{i=1}^{m} b_i u_i + \sum_{j=1}^{k} d_j \omega_j, \qquad x \in \mathbb{R}^n$$

where $f(x)$ is a homogeneous polynomial vector field, b_i and d_i are constant vectors, and the output function is linear. It is shown that the well-known theory of disturbance decoupling of linear systems extends to this class in a very natural way. The resulting theory is far simpler than the general nonlinear theory. More important, all computations needed can be done using very simple algorithms, which require only a finite number of computations and use only methods from linear algebra.

Key words. polynomial systems, Lie algebras, decoupling, disturbance decoupling, (f, g)-invariance

AMS(MOS) subject classification. 93

1. Introduction.

We consider a system on $\mathbb{R}^n$ of the form

$$\dot{x} = f(x) + \sum_{i=1}^{m} b_i u_i + \sum_{j=1}^{k} d_j \omega_j, \tag{1}$$

$$y = Cx \tag{2}$$

where $f(x)$ is a vector field such that each entry is a homogeneous polynomial function of common degree p, b_i and d_j are constant vectors and C is an $n \times m$ matrix. The output is denoted by y, the inputs by u_i, and the disturbances by ω_j. Our primary purpose in this paper is to show that problems such as disturbance decoupling and controlling the state while keeping the output at zero can be easily solved in this class.

Nonlinear control systems of the type $\dot{x} = f(x) + g(x)u$ with f and g being polynomial vector fields previously have been the object of study by several authors (Brockett [3], Baillieul [1], [2], Jurdjevic and Kupka [10], and Bonnard and Tebbikh [5], [6]). Examples of type (1) include the very important problem of controlling the angular velocity of a rigid body. It is well known (see Baillieul [1] and Byrnes and Isidori [7], for example) that such a system can be described by

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{pmatrix} = \begin{pmatrix} a_1 x_2 x_3 \\ a_2 x_1 x_3 \\ a_3 x_1 x_2 \end{pmatrix} + Bu. \tag{3}$$

Therefore our theory developed here will solve the problem of disturbance decoupling of a rotating rigid body with linear output functions of angular velocities.

It was observed by Jurdjevic and Kupka [10] that, for systems of this type, the set of points that can be reached along trajectories with zero initial state is a subspace if the degree of f is odd. When the reachable subspace is $\mathbb{R}^n$, the state can be controlled from a given initial point to a desired final point in arbitrarily short time. This hints at the possibility of extending the geometric theory of linear control (see Wonham [15])

* Received by the editors September 21, 1987; accepted for publication (in revised form) April 11, 1988.

to this class without having to go through the complicated computations needed in the local nonlinear geometric theory. In this paper we show that, indeed, the theory of disturbance decoupling extends naturally. Moreover, we show that when the degree of f is odd there exists a largest controllability subspace in a given subspace of $\mathbb{R}^n$ (see § 5 for definition). It is perhaps surprising that all computations can be done using linear algebraic methods and we give algorithms for this.

Notation 1.1.

B The $n \times m$ matrix of which the columns are $b_1, \cdots, b_m$.
D The $n \times k$ matrix of which the columns are $d_1, \cdots, d_k$.
$\mathcal{B}, \mathcal{D}$ The column spans of B and D, respectively.
$\mathcal{F}$ The collection of vector fields $\{f, b_1, \cdots, b_m\}$.
$\mathcal{F}^+$ The collection of vector fields $\{f, b_1, \cdots, b_m, d_1, \cdots, d_k\}$.
Let $\mathcal{X}$ be a given subset of vector fields on $\mathbb{R}^n$ and $x \in \mathbb{R}^n$ be arbitrary.
Lie $(\mathcal{X})$ The Lie algebra of vector fields generated by $\mathcal{X}$.
Lie $(\mathcal{X})(x)$ The subspace of $\mathbb{R}^n$ obtained by evaluating Lie $(\mathcal{X})$ at x.
$\text{Lie}_0(\mathcal{X})$ The subset of constant vector fields in Lie $(\mathcal{X})$.
Let $\mathcal{Y}$ be a subset of $\mathcal{X}$.
$C^q(\mathcal{X}; \mathcal{Y})$ The set of q tuples $\{Y_1, \cdots, Y_q\} \subset \mathcal{X}$ such that at least one $Y_i \in \mathcal{Y}$; q is an arbitrary positive integer.
$\mathcal{I}(\mathcal{X}; \mathcal{Y})$ Lie ideal generated by $\mathcal{Y}$ in Lie $(\mathcal{X})$.
$\mathcal{I}(\mathcal{X}; \mathcal{Y})(x)$ Evaluation of $\mathcal{I}(\mathcal{X}, \mathcal{Y})$ at x.
$\mathcal{I}_0(\mathcal{X}; \mathcal{Y})$ The subset of constant vector fields in $\mathcal{I}(\mathcal{X}; \mathcal{Y})$.

We will identify $\text{Lie}_0(\mathcal{X})$ and $\mathcal{I}_0(\mathcal{X}; \mathcal{Y})$, etc. with subspaces of $\mathbb{R}^n$ in a natural way. Also, when $\mathcal{X}$ or $\mathcal{Y} = \{d_1, \cdots, d_k\}$ or $\{b_1, \cdots, b_m\}$, we will denote them simply by D or B. We will not distinguish between constant vectors and constant vector fields of $\mathbb{R}^n$ unless the distinction is required to clarify the context.

The Lie algebraic computations needed in this paper can be done most conveniently by using multilinear algebra. In this regard, note that if $h: \mathbb{R}^n \to \mathbb{R}^m$ is a homogeneous polynomial function of degree p, then it is well known that we can associate a unique symmetric p-linear map

$$H: \prod_{i=1}^{p} \mathbb{R}^n \to \mathbb{R}^{na}$$

having the following property:

$$h(x) = H(x, x, \cdots, x).$$

For example, if $h: \mathbb{R}^2 \to \mathbb{R}$ is

$$h(x_1, x_2) = x_1^2 + x_1 x_2$$

then $H: \prod_{i=1}^{2} \mathbb{R}^2 \to \mathbb{R}$ is given by

$$H((x_1^1, x_2^1), (x_1^2, x_2^2)) = x_1^1 x_1^2 + \tfrac{1}{2}(x_1^1 x_2^2 + x_1^2 x_2^1).$$

Recall that the kth derivative at zero of h of degree p is a symmetric k-linear map $(D^k h(0)): \prod_{i=1}^{k} \mathbb{R}^n \to \mathbb{R}^m$. The map H is defined in general by

$$H = \frac{1}{p!}(D^p h(0)).$$

Now by using the Taylor series of h we obtain

$$h(x) = \sum_{k=0}^{p} \frac{1}{k!}(D^k h)(0)(x, x, \cdots, x).$$

But $(D^k h)(0) = 0$ if $k < p$. Hence,

$$\begin{aligned} h(x) &= \frac{1}{p!}((D^p h)(0))(x, x, \cdots, x) \\ &= H(x, x, \cdots, x), \end{aligned} \tag{4}$$

as desired.

The symmetric p-linear map associated to f will be denoted by F. The main purpose of introducing F is the following identity. Let $\nu^1, \cdots, \nu^p$ be arbitrary elements of $\mathbb{R}^n$. Since there is no ambiguity, we will denote the associated constant vector fields by the same symbols. Now $\mathrm{ad}_{\nu^1} \cdots \mathrm{ad}_{\nu^p}(f)$ is a constant vector field on $\mathbb{R}^n$ and an easy calculation shows that

$$\begin{aligned} \mathrm{ad}_{\nu^1} \cdots \mathrm{ad}_{\nu^p}(f) &= (D^p f)(0)(\nu^1, \cdots, \nu^p) \\ &= (p!)F(\nu^1, \cdots, \nu^p). \end{aligned} \tag{5}$$

2. Accessibility and reachability subspaces. The key observation regarding the class of systems (1) was made in Baillieul [2], Bonnard [6], and Jurdjevic and Kupka [10].

THEOREM 2.1 [2], [6], and [10]. *Assume that no disturbances are present.*

(i) *The set of points reachable from the origin is contained in* $\mathrm{Lie}_0(\mathscr{F})$ *and has nonempty interior in* $\mathrm{Lie}_0(\mathscr{F})$.

(ii) *If the degree p of* $f(x)$ *is odd, then all points in* $\mathrm{Lie}_0(\mathscr{F})$ *are reachable from the origin in arbitrarily short time.*

Proof. For a complete proof we refer the reader to Jurdjevic and Kupka [10]. We will give a proof of (i) to motivate the computations of the rest of the paper.

Since $\mathrm{Lie}(\mathscr{F})$ is obviously polynomial, it is also analytic and hence integrable (Nagano [11], Sussmann [14]). Now by Sussmann and Jurdjevic's results [13] on controllability, it follows that the reachable set $\mathscr{R}$ from the origin is contained in the leaf L of $\mathrm{Lie}(\mathscr{F})$ through the origin and contains a nonempty open subset of L. We only need to show that $L = \mathrm{Lie}_0(\mathscr{F})$.

First, $\mathrm{Lie}_0(\mathscr{F})$ is obviously contained in L and $\mathscr{B} \subset \mathrm{Lie}_0(\mathscr{F})$. Consider the following algorithm:

$$A^0 = \mathscr{B},$$

$$A^{i+1} = \mathrm{span}\{F(\nu^1, \cdots, \nu^p) \mid \{\nu^1, \cdots, \nu^p\} \subseteq A^i\} + A^i.$$

Since $F(\nu^1, \cdots, \nu^p) = \mathrm{ad}_{\nu^1} \cdots \mathrm{ad}_{\nu^p} f$, it follows that each A^i is contained in $\mathrm{Lie}_0(\mathscr{F})$. Since the A^i form an increasing sequence of subspaces, they converge to some subspace A in a finite number of steps. Now $A \subset \mathrm{Lie}_0(\mathscr{F})$. We claim that $\mathrm{Lie}_0(\mathscr{F}) \subset A$ also. Remembering that $\mathscr{R}$ contains a nonempty open subset of $\mathrm{Lie}_0(\mathscr{F})$, it is enough to prove that the vector field f is tangential to A at all points of A (for then the controlled trajectories can never leave A showing that $\mathscr{R} \subset A$). But by the construction of A, it follows that if $x \in A$, then $f(x) = F(x, x, \cdots, x) \in A$. Now

$$\mathscr{R} \subset A = \mathrm{Lie}_0(\mathscr{F}) \subset L$$

and $\mathscr{R}$ contains a nonempty open subset of $\mathrm{Lie}_0(\mathscr{F})$ and hence $A = \mathscr{R} = L$. □

Definition 2.2. The algorithm,

$$
\begin{aligned}
&A^0 = \mathcal{B},\\
&A^{i+1} = \operatorname{span}\{F(\nu^1, \cdots, \nu^p) \,|\, \{\nu^1, \cdots, \nu^p\} \subseteq A^i\} + A^i
\end{aligned} \tag{6}
$$

will be referred to as the accessibility subspace algorithm.

Remark 2.3. Observe that (6) needs only finitely many computations. Let $\{e^1, \cdots, e^j\}$ be a basis of A^i. Then

$$A^{i+1} = A^i + \operatorname{span}\{F(e^{i(1)}, e^{i(2)}, \cdots, e^{i(p)}) \,|\, 1 \leqq i(1) \leqq \cdots \leqq i(p) \leqq j\}.$$

Two equivalent ways to compute A^{i+1} are:

$$A^{i+1} = A^i + \operatorname{span}\{f(x) \,|\, x \in A\},$$

$$A^{i+1} = A^i + \operatorname{span}\{f(\pm e^{i(1)} \pm e^{i(2)} \pm \cdots \pm e^{i(p)}) \,|\, 1 \leqq i(1) \leqq \cdots \leqq i(p) \leqq j\}.$$

These apparently different ways of looking at the accessibility subspace algorithm will be useful in the sequel.

Assumption 2.4. For the rest of the paper we will assume that $\operatorname{Lie}_0(\mathcal{F}) = \mathbb{R}^n$.

Actually we do not need this assumption for any of our theorems, yet this assumption simplifies the notation and ideas considerably. All of our results will be valid for all trajectories of (1) (allowing disturbances) starting at the origin, for example, and hence is particular when $\operatorname{Lie}_0(\mathcal{F}^+) = \mathbb{R}^n$.

3. Conditions for the disturbance to not affect the output. For the moment let us ignore feedback and find conditions for ω to not affect the output. The important subspace needed here is $\mathcal{I}_0(\operatorname{Lie}(\mathcal{F}^+); D)$ (see Notation 1.1 for the definition). For convenience $\mathcal{I}$ and $\mathcal{I}_0$ stands for $\mathcal{I}(\operatorname{Lie}(\mathcal{F}^+); D)$ and $\mathcal{I}_0(\operatorname{Lie}(\mathcal{F}^+); D)$, respectively. The following lemma characterizes $\mathcal{I}_0$. Its proof was adapted from the proof of Lemma 5 in [10].

LEMMA 3.1. *$\mathcal{I}_0$ is the smallest subspace V of $\mathbb{R}^n$ that satisfies the property*

$$D \subset V,$$

$$F(\nu_1, \nu_2, \cdots, \nu_p) \in V \quad \textit{for all } \nu_1 \in V, \textit{ all } \nu_2, \cdots, \nu_p \in \mathbb{R}^n.$$

Proof. Remembering that $\operatorname{Lie}_0(\mathcal{F}^+) = \mathbb{R}^n$ by Assumption 2.4, it follows easily that $V \subset \mathcal{I}_0$. We need to prove the reverse inclusion.

Each element of $\mathcal{I}$ is a linear combination of elements in D along with vector fields of the form $\operatorname{ad}_{Y_1} \cdots \operatorname{ad}_{Y_{q-1}}(Y_q)$ for some q and $\{Y_1, \cdots, Y_q\} \in C^q(\mathcal{F}^+, D)$. Since $D \subset V$ and $B \subset \operatorname{Lie}_0(\mathcal{F}^+)$, every element of $\mathcal{I}$ is a linear combination of an element belonging to V along with elements of the form $\operatorname{ad}_{Y_1} \cdots \operatorname{ad}_{Y_{q-1}}(Y_q)$, where $\{Y_1, \cdots, Y_q\} \in C^q(f \cup \mathbb{R}^n; V)$. Moreover, each such summand is a homogeneous vector field. By induction we will prove that all constant vector fields of the form $\operatorname{ad}_{Y_1} \cdots \operatorname{ad}_{Y_{q-1}}(Y_q)$, where

$$\{Y_1, \cdots, Y_q\} \in C^q(f \cup \mathbb{R}^q; V)$$

belong to V. Thereby we prove that $\mathcal{I}_0 \subset V$. We abbreviate $C^q(f \cup \mathbb{R}^q; V)$ to C^q.

Now let $X = \operatorname{ad}_{Y_1} \cdots \operatorname{ad}_{Y_{q-1}}(Y_q)$ be constant and $\{Y_1, \cdots, Y_q\} \in C^q$. Let r be the number of indices j such that $Y_j = f$. Define the notion of length of X, $l(X)$, as the smallest r among all such representations of $X \cdot (l(X) = 0$ if $X \in V)$. We will prove our assertion by using induction on length.

If $l(X) = 0$ or 1, by definition $X \in V$. The induction hypothesis is: $l(X) \leqq s$ implies that $l(X) = 0 \cdot (s \in \mathbf{N})$.

Assume that the hypothesis is true for some s. Let $X = \mathrm{ad}_{Y_1} \cdots \mathrm{ad}_{Y_q}(Y_{q+1})$ be such that the number of indices j with $Y_j = f$ is equal to $s+1$. There is a smallest integer t, $t \leqq q$ such that $Y_{t+1} = f$. Hence $X = \mathrm{ad}_{Y_1} \cdots \mathrm{ad}_{Y_t} \mathrm{ad}_f(\tilde{Y})$, where $\tilde{Y} = \mathrm{ad}_{Y_{t+2}} \cdots \mathrm{ad}_{Y_q}(Y_{q+1})$. Using the Jacobi identity, we can rewrite X as a sum of terms of the form $[\mathrm{ad}_{Y_{\gamma_1}} \cdots \mathrm{ad}_{Y_{\gamma_i}}(f), \mathrm{ad}_{Y_{\mu_1}} \cdots \mathrm{ad}_{Y_{\mu_{t-i}}}(\tilde{Y})]$, where $\gamma_1 < \cdots < \gamma_i \leqq t$ and $\mu_1 < \cdots < \mu_{t-i} \leqq t$. We have only to consider nonzero constant summands, which fall into four types:

Type 1. $i = p$, $\mathrm{ad}_{Y_{\mu_1}} \cdots \mathrm{ad}_{Y_{\mu_{t-i}}}(\tilde{Y})$ is linear and $\{Y_{\gamma_1}, \cdots, Y_{\gamma_i}\} \cap V \neq \varnothing$.

Type 2. $i = p$, $\mathrm{ad}_{Y_{\mu_1}} \cdots \mathrm{ad}_{Y_{\mu_{t-i}}}(\tilde{Y})$ is linear, $\{Y_{\gamma_1}, \cdots, Y_{\gamma_i}\} \cap V = \varnothing$.

Type 3. $i = p-1$, $\mathrm{ad}_{Y_{\mu_1}} \cdots \mathrm{ad}_{Y_{\mu_{t-i}}}(\tilde{Y})$ is constant, $\{Y_{\gamma_1}, \cdots, Y_{\gamma_i}\} \cap V = \varnothing$.

Type 4. $i = p-1$, $\mathrm{ad}_{Y_{\mu_1}} \cdots \mathrm{ad}_{Y_{\mu_{t-i}}}(\tilde{Y})$ is constant, $\{Y_{\gamma_1}, \cdots, Y_{\gamma_i}\} \cap V \neq \varnothing$.

It is easily seen that each of these types has length less than or equal to s, and hence by the induction hypothesis has zero length. □

THEOREM 3.2. *The following conditions are equivalent*:

(1) *For all bounded measurable disturbance inputs and all initial states, the disturbance does not affect the output.*

(2) $\mathscr{I}_0(\mathrm{Lie}(\mathscr{F}^+); D)$ *is contained in the kernel of* C.

Proof. We abbreviate $\mathscr{I}(\mathrm{Lie}(\mathscr{F}^+); D)$ to $\mathscr{I}_0$.

(2⇒1). Let W be a complimentary subspace to $\mathscr{I}_0$ in $\mathbb{R}^n$.

Let us write $x(t) = \xi(t) + \eta(t)$, where $\xi(t) \in W$, $\eta(t) \in \mathscr{I}_0$.

Now (1) implies that

$$\dot{x}(t) = f(\xi(t)) + \sum_{r=0}^{p-1} \frac{1}{r!(p-r)!} \underbrace{F(\xi(t), \cdots, \xi(t)}_{r}, \eta(t), \cdots, \eta(t))$$

$$+ \sum_{i=1}^{m} b_i u_i(t) + \sum_{j=1}^{k} d_j \omega_j(t).$$

But by our characterization of $\mathscr{I}_0$ in Lemma 3.1, it follows that

$$F(\xi(t), \cdots, \xi(t), \eta(t), \cdots, \eta(t)) \in \mathscr{I}_0.$$

Since $D \subset \mathscr{I}_0$ we can also write

$$\dot{\xi}(t) = \tilde{f}(\xi(t)) + \sum_{i=1}^{m} \tilde{b}_i u_i(t)$$

where $\tilde{f}$ and $\tilde{b}_i$ are the projections of f and b_i onto W along $\mathscr{I}_0$. In particular, the dynamics $\xi(t)$ are independent of the disturbances and, since $y(t) = Cx(t) = C\xi(t)$, the disturbance does not affect the output.

(1⇒2). Since $\mathscr{I}$ is spanned by

$$\{\mathrm{ad}_{Y_1} \cdots \mathrm{ad}_{Y_{q-1}}(Y_q) \mid \{Y_1, \cdots, Y_q\} \in C^q(\mathscr{F}^+; D); q \in \mathbf{N}\},$$

it follows that $\mathscr{I}_0$ is spanned by such vector fields that are constant. But it is well known that if the disturbance does not affect the output, then $\mathrm{ad}_{Y_1} \cdots \mathrm{ad}_{Y_{q-1}}(Y_q)(x) \in \mathrm{Ker}(C)$ for all x, for all $\{Y_1, \cdots, Y_1\} \in C^q(\mathscr{F}^+; D)$, and for all q. (See Theorem 3.2 of Isidori [9].) This can be proved rather directly using the Fliess series [8]. □

Remark 3.3. Even the (⇒) part above can be proved using the Fliess series.

In view of the Theorem 3.2 we give the following definition.

Definition 3.4. The subspace $\mathscr{I}_0(\mathrm{Lie}(\mathscr{F}^+); D)$ will be called the disturbance confining subspace.

The disturbance confining subspace can be computed using the following algorithm and its proof follows at once from Lemma 3.1.

ALGORITHM 3.5. DISTURBANCE CONFINING SUBSPACE ALGORITHM.

$$V^0 = \mathscr{D},$$

$$V^{i+1} = V^i + \operatorname{span}\{F(v_1, v_2, \cdots, v_p) \mid v_1 \in V^i,\ v_j \in \mathbb{R}^n \text{ for } j > 1\}.$$

Since the subspaces V^i are increasing, the algorithm converges in finitely many steps. As was stated in Remark 2.3, all computations are finite.

4. Disturbance decoupling and (f, B)-invariant subspaces. In this section we will study the problem of constructing feedback such that the output functions will not be affected by the disturbance inputs. The class of feedback functions considered is of the form

$$u_i(t) = \alpha_i(x(t)) + v_i(t) \tag{7}$$

where $\alpha_i(x)$ is a homogeneous polynomial of degree p. Our reasons for selecting this class of feedback laws are the following:

(1) This class of feedback laws preserves the structure of the system. The slightly more general class $u_i(t) = \alpha_i(x(t)) + \sum_{j=1}^m \beta_{ij} v_j(t)$ with constant β_{ij}'s does not give more freedom, since the disturbance confining subspace algorithm does not depend on β_{ij}'s.

(2) We will show later that if the disturbances can be decoupled from the output with feedback of the form (7) with *analytic functions* $\alpha_i(x)$, then there also exists a *homogeneous polynomial feedback* $\alpha_i(x)$, which solves the problem.

Remark 4.1. Presently we do not know whether reason (2) is valid for the class of feedback of the form $u_i(t) = \alpha_i(x(t)) + \sum_{j=1}^m \beta_{ij}(x(t)) v_j(t)$ with analytic functions α_i and β_{ij}.

Except in the proof of Theorem 4.9, $\alpha_i(x)$ will denote a homogeneous polynomial of degree p, and $\alpha(x)$ will denote an m-tuple of such functions.

Let $\mathscr{F}_\alpha = \{f + B\alpha, b_1, \cdots, b_m\}$ and $\mathscr{F}_\alpha^+ = \{f + B\alpha, b_1, \cdots, b_m, d_1, \cdots, d_k\}$. We will abbreviate $\mathscr{I}_0(\text{Lie}(\mathscr{F}_\alpha^+); D)$ to $\mathscr{I}_0^\alpha$.

Now if there exists feedback α in (7) that decouples the disturbances ω from the output, then from Theorem 3.2, $\mathscr{I}_0^\alpha \subset \operatorname{Ker}(C)$. By the characterization of $\mathscr{I}_0$ in Lemma 3.1 we have

$$\operatorname{ad}_{v_1} \cdots \operatorname{ad}_{v_p}(f + B\alpha) \subset \mathscr{I}_0^\alpha \quad \text{for } v_1 \in \mathscr{I}_0^\alpha \text{ and } v_2, \cdots, v_p \in \mathbb{R}^n.$$

Hence $\operatorname{ad}_{v_1} \cdots \operatorname{ad}_{v_p}(f) \subset \mathscr{I}_0^\alpha + \mathscr{B}$.

Definition 4.2. A subspace V of $\mathbb{R}^n$ satisfying

$$F(v_1, \cdots, v_p) \in V + \mathscr{B} \quad \text{for all } v_1 \in V \text{ and all } v_j \in \mathbb{R}^n \text{ for } j > 1 \tag{8}$$

will be called an (f, B)-invariant subspace.

Note that (8) is equivalent to $f(x+v) = f(x) \bmod (V + \mathscr{B})$ for all $x \in \mathbb{R}^n$, and all $v \in V$.

It is clear that the set of (f, B)-invariant subspaces is closed under the addition of subspaces and thus has a maximal element V^* in the kernel of C.

Definition 4.3. V^* will be called the maximal (f, B)-invariant subspace contained in the kernel of C.

THEOREM 4.4. *There exists feedback of form* (7) *which decouples the output from the disturbance input if and only if*

$$\mathscr{D} \subset V^*.$$

Proof. ($\Rightarrow$) $\mathscr{I}_0^\alpha$ is an (f, B)-invariant subspace contained in the kernel of C and containing $\mathscr{D}$. But the maximality of V^* implies that $\mathscr{D} \subset \mathscr{I}_0^\alpha \subset V^*$.

($\Leftarrow$) We are going to construct feedback α such that

$$(f+B\alpha)(x+v)=(f+B\alpha)(x) \bmod V^* \quad \text{for all } x\in\mathbb{R}^n \text{ and all } v\in V^*.$$

Pick a basis $\{e_1,\cdots,e_n\}$ of $\mathbb{R}^n$ such that $\{e_1,\cdots,e_q\}$ is a basis of V^*. Now $\{e_{i_1}\cdots e_{i_p}\}_{1\leqq i_1\leqq\cdots\leqq i_p\leqq n}$ forms a basis of the symmetric covariant p-tensors S_p on $\mathbb{R}^n$. Define a linear function $\hat{\alpha}: S_p\to\mathbb{R}^m$ such that

$$(F+B\hat{\alpha})(e_{i_1}\cdots e_{i_p})\in V^* \quad \text{whenever } i_1\leqq q. \tag{9}$$

Now $\hat{\alpha}$ defines a unique homogeneous polynomial function α of degree p and this α satisfies our requirement.

Now Algorithm 3.5 for constructing $\mathscr{I}_0^\alpha$ shows at once that $\mathscr{I}_0^\alpha\subset V^*\subset \operatorname{Ker} C$. □

Remark 4.5. Part ($\Rightarrow$) was proved by Bonnard [6] for quadratic systems.

Remark 4.6. Note that this is similar to the corresponding linear theorem. In that case $p=1$ and our V^* coincides with the maximal (A, B)-invariant subspace in the kernel of C. In fact we can even extend the corresponding linear algorithm (see Wonham [15]) to our situation.

ALGORITHM 4.7. COMPUTATION OF THE MAXIMAL (f, B)-INVARIANT SUBSPACE IN THE KERNEL OF C. Let $\{e_1,\cdots,e_n\}$ be an arbitrary basis of $\mathbb{R}^n$. Define the set of linear maps $A_{i_1,\cdots,i_{p-1}}:\mathbb{R}^n\to\mathbb{R}^n$; $1\leqq i_1\leqq\cdots\leqq i_{p-1}\leqq n$:

$$A_{i_1}\cdots i_{p-1}(x)=F(e_{i_1},\cdots,e_{i_{p-1}},x).$$

The collection of all such maps will be denoted by $\{A_i\}_{i\in I}$, where

$$I=\{(i_1,\cdots,i_{p-1})\,|\,1\leqq i_1\leqq\cdots\leqq i_{p-1}\leqq n\}.$$

Algorithm.

$$V^0=\operatorname{Ker}(C), \tag{10}$$

$$V^{i+1}=V^i\cap\Big(\bigcap_{i\in I}A_i^{-1}(V^i+B)\Big). \tag{11}$$

Clearly the sequence of subspaces is decreasing, and hence it converges to some subspace V^+. Moreover, $V^*\subset V^0$ by definition. Now suppose that $V^*\subset V^i$ for some i. Then it is clear from (11) that $V^*\subset V^{i+1}$. This proves by induction that $V^*\subset V^+$ and the maximality of V^*. The fact that V^+ satisfies (8) implies that $V^*=V^+$.

Remark 4.8. When $d_i\in V^*$, the disturbance decoupling feedback $\alpha(x)$ can be easily computed using (9).

We will show that the class of feedback functions we have been considering is fairly general.

THEOREM 4.9. *Suppose that there exists analytic feedback $u_i(t)=\alpha_i(x(t))+v_i(t)$ defined in a neighborhood of the origin that renders the closed-loop system disturbance decoupled. Then there exist feedback functions $\tilde{\alpha}_i(x)$ that are homogeneous of degree p that decouple the closed-loop system on $\mathbb{R}^n$.*

Proof. We will denote the m-tuple $\{\alpha_1,\cdots,\alpha_m\}$ by α and write $\alpha(x)=\sum_{j=0}^{\infty}\alpha^j(x)$ using the Taylor series. ($\alpha^j(x)$ is homogeneous of degree j.) Define $\tilde{\alpha}=\alpha^p$. Let f^α and $f^{\tilde{\alpha}}$ denote $f+B\alpha$ and $f+B\tilde{\alpha}$, respectively. Let $\mathscr{F}_\alpha^+=\{f^\alpha, B, D\}$ and $\mathscr{F}_{\tilde{\alpha}}^+=\{f^{\tilde{\alpha}}, B, D\}$. Similarly, we abbreviate $C^q(\mathscr{F}_\alpha^+; D)$ and $C^q(\mathscr{F}_{\tilde{\alpha}}^+; D)$ to C_α^q and $C_{\tilde{\alpha}}^q$, respectively. We also abbreviate $\mathscr{I}(\operatorname{Lie}(\mathscr{F}_\alpha^+); D)$, $\mathscr{I}(\operatorname{Lie}(\mathscr{F}_{\tilde{\alpha}}^+); D)$; $\mathscr{I}_0(\operatorname{Lie}(\mathscr{F}_\alpha^+); D)$ and $\mathscr{I}_0(\operatorname{Lie}(\mathscr{F}_{\tilde{\alpha}}^+); D)$ to $\mathscr{I}^\alpha$, $\mathscr{I}^{\tilde{\alpha}}$, $\mathscr{I}_0^\alpha$ and $\mathscr{I}_0^{\tilde{\alpha}}$, respectively.

Now $\mathscr{I}^\alpha$ is spanned by $\{\operatorname{ad}_{Y_1}\cdots\operatorname{ad}_{Y_{q-1}}(Y_q)\,|\,\{Y_1,\cdots,Y_q\}\in C_\alpha^q, q\geqq 1\}$. For each $\{Y_1,\cdots,Y_q\}\in C_\alpha^q$ we will denote by $\{\tilde{Y}_1,\cdots,\tilde{Y}_q\}$ the q-tuple in $C_{\tilde{\alpha}}^q$ obtained by

replacing feedback α by $\tilde{\alpha}$. Now suppose that $\{Y_1, \cdots, Y_q\} \in C_\alpha^q$ is such that $\operatorname{ad}_{\tilde{Y}_1} \cdots \operatorname{ad}_{\tilde{Y}_{q-1}}(\tilde{Y}_q) \in \mathcal{I}_0^{\tilde{\alpha}}$. Then $(\operatorname{ad}_{Y_1} \cdots \operatorname{ad}_{Y_{q-1}}(Y_l))(0) = \operatorname{ad}_{\tilde{Y}_1} \cdots \operatorname{ad}_{\tilde{Y}_{q-1}}(\tilde{Y}_q)$ and from this we conclude that $\mathcal{I}_0^{\tilde{\alpha}} \subset \mathcal{I}_0^{\alpha}$. But since $\mathcal{I}^{\alpha} \subset \operatorname{Ker} C$, it follows that $\mathcal{I}_0^{\tilde{\alpha}} \subset \operatorname{Ker} C$. We conclude by Theorem 3.2 that the feedback $u = \tilde{\alpha} + v$ decouples the disturbance and output. □

5. Reachability subspaces. Consider the following problem. We are given

$$\dot{x} = f(x) + Bu(t), \tag{12}$$

$$y = Cx \tag{13}$$

where f is a homogeneous polynomial of degree p, and B and C are $n \times m$ and $l \times n$ matrices. Can we partition the inputs, i.e., find an $m \times m$ nonsingular matrix $G = [G_{1n \times m_1} | G_{2n \times m_2}]$ and feedback

$$u = \alpha(x) + \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \begin{matrix} m_1 \times 1 \\ m_2 \times 1 \end{matrix}$$

where $\alpha(x)$ is a homogeneous polynomial of degree p such that when we write the closed-loop system as

$$\dot{x} = (f + \alpha)(x) + BG_1 v_1(t) + BG_2 v_2(t) \tag{14}$$

the inputs $v_1(t)$ do not affect the output y? In this section we give necessary and sufficient conditions for the existence of a solution to this problem, and show that when there is a solution, it can be found such that the set of points that can be reached by $v_1(t)$ is maximized. This problem is important in controlling a system while keeping the output at a constant value or when decoupling the effect of the inputs on the outputs.

Now let us consider the system (12), (13). Suppose that $v_2(t) = 0$ and $x(0) = 0$. Then it follows from Theorem 2.1 that the set of points that can be reached along measurable or piecewise constant control trajectories is contained in the subspace of constant vector fields in the Lie algebra generated by $\{f + B\alpha, BG_1\}$, where BG_1 denotes the vector fields given by the columns of BG_1. We will denote this subspace by

$$\langle f + B\alpha \,|\, \operatorname{Im}(BG_1) \rangle$$

and call it the *accessibility subspace* of $\{f + B\alpha, \operatorname{Im}(BG_1)\}$. Theorem 2.1 states that if p is odd, this space is the space of points that can be reached from the origin. In this case we can also call them controllability subspaces. Our theory here will be the counterpart of the theory of (A, B)-controllability subspaces of a linear system. Our proofs are generalizations of the corresponding proofs for (A, B)-controllability subspaces, as can be found in Wonham [15]. The subspace $\langle f + B\alpha \,|\, \operatorname{Im}(BG_1) \rangle$ can be computed using the accessibility subspace algorithm (6). We advise the reader to keep this algorithm in mind since it will be helpful in understanding the proofs of this section. As before we will assume that $\langle f \,|\, \operatorname{Im}(B) \rangle = \mathbb{R}^n$ for simplicity of exposition. We denote by $\mathcal{B}$, $\mathcal{B}_1$, $\mathcal{B}_2$, etc. the images of B, B_1, and B_2. When we refer to feedback α, we mean that α is a homogeneous polynomial function of degree p.

Notation 5.1. We define (f, B)-invariant subspaces as in § 4. The collection of all (f, B)-invariant subspaces contained in a given subspace $\mathcal{K}$ will be denoted by $S(f, B; \mathcal{K})$. As we saw in the proof of Theorem 4.4, for all $V \in S(f, B; \mathcal{K})$ there exists feedback α such that

$$\operatorname{ad}_{v_1} \cdots \operatorname{ad}_{v_{p-1}} \operatorname{ad}_x (f + B\alpha) \in V \quad \text{for all } v_1, \cdots, v_{p-1} \in \mathbb{R}^n \quad \text{for all } x \in V.$$

The set of all such feedback will be denoted by $\Lambda(V)$.

Definition 5.2. A subspace $\mathscr{R}$ of $\mathbb{R}^n$ is called an (f, B)-accessibility subspace if $\mathscr{R} = \langle f + B\alpha \,|\, \mathrm{Im}\,(BG_1)\rangle$ for some feedback α and G_1. The collection of all (f, B)-accessibility subspaces contained in a given subspace $\mathscr{K}$ will be denoted by $\mathscr{A}(f, B; \mathscr{K})$.

Let $\mathscr{K}$ be the kernel of C. If there is a solution to our problem, then according to Theorem 4.4, $\mathrm{Im}\,(BG_1)$ should be contained in V^*, the largest element of $S(f, B; \mathscr{K})$. Conversely, if there exist G_1 such that $\mathrm{Im}\,(BG_1) \subset V^*$, then we can find feedback $\alpha + G_1 v_1 + G_2 v_2$ such that the input v_1 does not affect the output. This completely solves the problem we posed earlier. However, we proceed further and ask whether G_1 can be found such that $\langle f + B\alpha \,|\, \mathrm{Im}\,(BG_1)\rangle$ is also maximal. In a sense, we are talking about maximizing our ability to control the state while keeping $y(t) \equiv 0$. We prove the existence of such a maximal (f, B)-accessibility subspace and give an algorithm to compute α, G_1, and G_2. We will proceed via a series of lemmas. We caution that if R is an (f, B)-accessibility subspace, then it may not be an (f, B)-invariant subspace. However, $\mathrm{ad}_{v_1} \cdots \mathrm{ad}_{v_p}(f) \in R + B$ for all $v_i \in R$. Hence it makes sense to define $\Lambda(R)$, the set of feedback functions α such that $(f + B\alpha)(V) \subset V$.

We reiterate that the basic ideas of the proofs are due to Wonham [15].

LEMMA 5.3. *Let G_1 be arbitrary and define $\mathscr{R} = \langle f \,|\, \mathrm{Im}\,(BG_1)\rangle$. Then $R = \langle f \,|\, \mathscr{B} \cap \mathscr{R}\rangle$. Conversely, if $R = \langle f \,|\, \mathscr{B} \cap \mathscr{R}\rangle$, then there exist G_1 such that $R = \langle f \,|\, \mathrm{Im}\,(BG_1)\rangle$.*

Proof. The second assertion is obvious. So we turn to the first one. Since $\mathrm{Im}\,(BG_1) \subset R$, the accessibility algorithm implies that $R \subset \langle f \,|\, \mathscr{B} \cap \mathscr{R}\rangle$. Conversely, $\mathscr{B} \cap \mathscr{R} \subset R$ and $f(R) \subset R$. Hence $\langle f \,|\, \mathscr{B} \cap \mathscr{R}\rangle \subset \mathscr{R}$. □

We obtain the following corollary.

COROLLARY 5.4. *$\mathscr{R} \in \mathscr{A}(f, B; \mathscr{K})$ if and only if there exist α such that*

$$R = \langle f + B\alpha \,|\, \mathscr{B} \cap R\rangle.$$

LEMMA 5.5. *If $\mathscr{R} \in \mathscr{A}(f, B; \mathscr{K})$, then $\mathscr{R} = \langle f + B\alpha \,|\, \mathscr{B} \cap \mathscr{R}\rangle$ for all $\alpha \in \Lambda(R)$.*

Proof. If $\mathscr{R} \in \mathscr{A}(f, B; \mathscr{K})$, then by definition there exist α_0 such that $R = \langle f + B\alpha_0 \,|\, \mathscr{B} \cap \mathscr{R}\rangle$. Let $\alpha_1 \in \Lambda(R)$ be arbitrary and let

$$\mathscr{R}_1 = \langle f + B\alpha_1 \,|\, \mathscr{B} \cap \mathscr{R}\rangle.$$

Since $(f + B\alpha_1)\mathscr{R} \subset \mathscr{R}$, it follows easily that $\mathscr{R}_1 \subset \mathscr{R}$. To prove the converse we use the accessibility subspace algorithm.

Let $V_0 = \mathscr{B} \cap \mathscr{R}$ and

$$V^{i+1} = \mathrm{span}\,\{(f + B\alpha_0)(v) \,|\, v \in V^i\} + V^i.$$

The induction hypothesis is

$$V^i \subset \mathscr{R} \quad \text{for } i \leqq k.$$

Clearly this is true for $k = 0$. Suppose that it is true for some k. Let $x \in V^k$. Then

$$(f + B\alpha_0)(x) = (f + B\alpha_1)(x) + B(\alpha_0(x) - \alpha_1(x)).$$

By the accessibility subspace algorithm, $(f + B\alpha_1)(x) \in \mathscr{R}_1$. Also, $B(\alpha_0(x) - \alpha_1(x)) \in B$ and

$$B(\alpha_0(x) - \alpha_1(x)) = (f + B\alpha_0)(x) - (f + B\alpha_1)(x) \in \mathscr{R}.$$

Hence $(f + B\alpha_0)(x) \in R_1 + (\mathscr{B} \cap \mathscr{R}) \subset R_1$, implying that $V^{k+1} \subset R_1$. By induction, $\mathscr{R} = \mathscr{R}_1$. □

LEMMA 5.6. *Let* $V \in S(f, B; \mathcal{K})$, $\mathcal{B}_0 \subset \mathcal{B} \cap \mathcal{V}$ *and* $\alpha_0 \in \Lambda(V)$ *and* $B(\alpha - \alpha_0)(V) \subset B_0$. *Then* $\mathcal{R} = \langle f + B\alpha \mid \mathcal{B}_0 \rangle$.

Proof. Let $\alpha \in \Lambda(V)$ and let $\mathcal{R}_1 = \langle f + B\alpha \mid \mathcal{B}_0 \rangle$. Define

$$V_0 = \mathcal{B}_0,$$

$$V^{i+1} = \text{span}\{(f + B\alpha_0)(v) \mid v \in V^i\} + V^i.$$

Then $V_0 = \mathcal{B}_0 \subset \mathcal{R}_1$. Suppose that $V^i \subset \mathcal{R}_1$ for $i \leqq k$ for some k. Let $x \in V^k$. Then, since obviously $\mathcal{R} \subset V$, it follows that

$$B(\alpha - \alpha_0)(x) \in V \cap \mathcal{B} = \mathcal{B}_0 \subset \mathcal{R}_1.$$

Hence

$$(f + B\alpha_0)(x) = (f + B\alpha_1)(x) + B(\alpha - \alpha_0)(x) \in \mathcal{R}_1.$$

By induction, $\langle f + B\alpha_0 \mid \mathcal{B}_0 \rangle \subset \mathcal{R}_1$. The inverse inclusion follows by the symmetry of the argument. □

LEMMA 5.7. *Let* $V \in S(f, B, \mathcal{K})$ *and let* $\mathcal{R} \subset V$ *and let* α_0 *be such that* $(f + B\alpha_0)(\mathcal{R}) \subset \mathcal{R}$. *Then there exist* $\alpha \in \Lambda(V) \cap \Lambda(R)$ *such that* $\alpha|_{\mathcal{R}} = \alpha_0|_{\mathcal{R}}$.

Proof. The proof follows by arguing as in the construction of α in the proof of Theorem 4.4. □

Now we are ready to state our maximality theorem.

THEOREM 5.8. *Let* $\mathcal{K}$ *be a given subspace and let* V^* *be the maximal* (f, B)*-invariant subspace contained in* $\mathcal{K}$. *Then there exists a maximal* (f, B)*-accessibility subspace* $\mathcal{R}^*$ *contained in* V^* *and* $\mathcal{R}^* = \langle f + B\alpha \mid V^* \cap \mathcal{B} \rangle$ *for arbitrary* $\alpha \in \Lambda(V^*)$.

Proof. Let $\alpha \in \Lambda(V^*)$ and let $\mathcal{R} = \langle f + B\alpha \mid \mathcal{B} \cap V^* \rangle$. Clearly $\mathcal{R} \subset V^*$. Let $\mathcal{R}_0 = \langle f + B\alpha_0 \mid \mathcal{B} \cap \mathcal{R}_0 \rangle$ be an arbitrary (f, B)-accessibility subspace in V^*. Pick $\alpha_1 \in \Lambda(R_0) \cap \Lambda(V^*)$ such that $\alpha_1 | R_0 = \alpha_0 R_0$. Now if $x \in V^*$, then

$$B(\alpha_1 - \alpha_0)(x) = (f + B\alpha_1)(x) - (f + B\alpha_0)(x) \in V^*.$$

Hence $B(\alpha - \alpha_0)(x) \in V^* \cap \mathcal{B}$ and now by Lemma 5.6,

$$\mathcal{R}_0 = \langle f + B\alpha_1 \mid \mathcal{B} \cap \mathcal{R}_0 \rangle \subset \langle f + B\alpha \mid \mathcal{B} \cap V^* \rangle = \mathcal{R}^*. \qquad \square$$

We also obtain the following important corollary.

COROLLARY 5.9. $\Lambda(V^*) \subset \Lambda(R^*)$.

Remark 5.10. Theorem 5.8 together with the accessibility subspace algorithm and the (f, B)-invariant subspace algorithm provides a means for computing the largest accessibility subspace.

6. Decoupling problem. We consider the system

$$\dot{x} = f(x) + Bu, \tag{15}$$

$$y_i = C_i x, \qquad i = 1, \cdots, r \tag{16}$$

where $f(x)$ (as before) is a homogeneous polynomial vector field of degree p; B is an $n \times m$ matrix; C_i is an $l_i \times n$ matrix. We propose a question. Can we find feedback

$$u = \alpha(x) + [G_1 | \cdots | G_r] \begin{bmatrix} v_1 \\ \vdots \\ v_r \end{bmatrix}$$

where $\alpha(x)$ is a homogeneous polynomial vector of degree p and $G_1, \cdots, G_r$ are constant matrices with the following properties:

(a) v_i does not affect y_j if $i \neq j$;

(b) The output y_i can be controlled to any desired value by v_i. We will assume that the subspaces $\{\text{Image}\,(C_i)\}_{i=1}^n$ are independent, for otherwise this problem does not make sense.

In view of Theorem 2.1, we will henceforth assume that p is odd. In view of the machinery we have at our disposal we can study this problem using (f, B)-accessibility subspaces just as in the linear case.

Notation 6.1. Let $\mathcal{K}$ be a subspace. Let $V^*(\mathcal{K})$ denote the largest (f, B)-invariant subspace in $\mathcal{K}$ and let $\mathcal{R}^*(\mathcal{K})$ denote the largest (f, B)-accessibility subspace contained in $V^*(\mathcal{K})$. If V is an (f, B)-invariant subspace, then $\Lambda(V)$ denotes the set of feedback functions α such that $(f+B\alpha)(x+v) = (f+B\alpha)(x) \bmod V$ for all $x \in \mathbb{R}^n$ and all $v \in V$.

THEOREM 6.2. *Suppose that there exists α such that*

(1) $\alpha \in \Lambda(V^*(\cap_{i\neq j} \ker(C_i)))$ *for* $j = 1, \cdots, r$,

(2) $\dim(C_j(\mathcal{R}^*(\cap_{i\neq j} \ker(C_i)))) = \text{rank}\, C_j$.

Then the decoupling problem has a solution.

Proof. Define matrices G_j such that

$$\text{Image}\,(BG_j) = \mathcal{R}^*\Big(\bigcap_{i\neq j} \ker(C_i)\Big) \cap \mathcal{B}, \qquad j = 1, \cdots, r.$$

Then by Theorem 5.8,

$$\mathcal{R}^*\Big(\bigcap_{i\neq J} \ker(C_i)\Big) = \langle f+B\alpha \,|\, \text{Image}\,(BG_j)\rangle, \qquad j = 1, \cdots, r.$$

Therefore by two, the input v_j completely controls the output y_j.

Moreover, our theory of disturbance decoupling (Theorem 4.4 and its proof) shows that y_j is not affected by v_i if $i \neq j$. □

In the previous theorem, having to verify the existence of α is cumbersome. If we want to decouple the state, a much nicer set of necessary and sufficient conditions can be stated. Let us denote by C the matrix $[C_1^T, \cdots, C_r^T]^T$.

THEOREM 6.3. *If* $\text{rank}\,(C) = n$, *then the decoupling problem is solvable if and only if*

$$\ker C_j + \mathcal{R}^*\Big(\bigcap_{i\neq j} \ker C_j\Big) = \mathbb{R}^n \quad \textit{for all } j.$$

Proof. The proof of necessity is trivial.

Sufficiency. Clearly our condition implies condition (2) of Theorem 6.2. Let $\mathcal{K}_j$ denote $\cap_{i\neq j} \ker C_i$. Then $\mathcal{K}_j \cap (\sum_{i\neq j} \mathcal{K}_i) = 0$, for all j. This follows at once since $\text{rank}\,(C) = n$. Therefore $V^*(\mathcal{K}_j) \cap (\sum_{k\neq j} (V^*(\mathcal{K}_j))) = 0$ for all j. Now the construction of α described in the proof of Theorem 4.4 easily shows that there exists some $\alpha \in \Lambda(V^*(\mathcal{K}))$, $j = 1, \cdots, r$. The sufficiency follows by Theorem 6.2. □

7. Concluding remarks. The primary purpose of this paper has been to show that the geometric theory of decoupling of linear control systems extends almost directly to the class of nonlinear systems given by (1) and (2). Along with Jurdjevic's and Kupka's theorem [10] on controllability quoted in Theorem 2.1, it almost seems to imply that the linear control theory we know of is actually an "odd degree polynomial" control theory. This merits investigation of the relationship between stabilizability and controllability. Unfortunately, controllability does not imply stabilizability even for this class.

Example 7.1. Consider the following system:

$$\dot{x}_1 = x_2^2 x_3,$$

$$\dot{x}_2 = x_3^3,$$

$$\dot{x}_3 = u.$$

This system is controllable. However, according to Brockett [4] and Byrnes and Isidori [7] a necessary condition for asymptotic stabilizability of this system is the existence of a function $\alpha(x_1, x_2, x_3)$ that renders the equation

$$\begin{bmatrix} x_2^2 x_3 \\ x_3^3 \\ \alpha(x_1, x_2, x_3) \end{bmatrix} = \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix}$$

solvable for x_1, x_2, x_3 whenever a_1, a_2, a_3 are arbitrarily specified small real numbers. However, it is seen that when $a_2 = 0$, then necessarily $a_1 = 0$ also for solvability, showing that the system is not asymptotically stabilizable.

We do not know of any reasonably simple extra conditions that would ensure stabilizability.

THE STRUCTURE OF SMALL-TIME REACHABLE SETS IN LOW DIMENSIONS*

ARTHUR J. KRENER† AND HEINZ SCHÄTTLER‡

Abstract. This paper outlines a general method to determine the geometric structure of small-time reachable sets for a single-input control system with a bounded linear control. The authors' analysis relies on free nilpotent systems as a guide, and hence their techniques only apply to nondegenerate situations. The paper illustrates the effectiveness of the method in low dimensions. Among other results is given a precise description of the small-time reachable set for a system $\dot{x} = f(x) + g(x)u$, $|u| \leqq 1$ in dimension four, under the generic assumption that the constant controls $u \equiv +1$ and $u \equiv -1$ are not singular. As a corollary, a local synthesis is obtained in dimension three for the time-optimal control problem under the analogous generic condition.

Key words. nonlinear systems, nilpotent approximation, reachable sets, bang-bang trajectories, singular arcs

1. Introduction.

In this paper we study the qualitative structure of small-time reachable sets in low dimensions for a single-input system with a bounded linear control. More precisely, we consider a system of the form

$$\Sigma: \dot{x} = f(x) + g(x)u, \quad |u| \leqq 1, \quad x \in \mathbb{R}^n \tag{1}$$

where f and g are smooth (C^∞) or analytic vector fields and admissible controls are measurable functions with values in $[-1, 1]$ almost everywhere. A trajectory of the system corresponding to a control $u(\cdot)$ is an absolutely continuous curve $x(\cdot)$ such that $\dot{x}(t) = f(x(t)) + g(x(t))u(t)$ almost everywhere. We say a point q is reachable from a point p within time T if and only if there exists a trajectory $x(\cdot)$ defined on an interval $[0, t]$, $t \leqq T$, such that $x(0) = p$ and $x(t) = q$. The set of all such points q is denoted by Reach $(p, \leqq T)$; Reach (p, T) denotes the set of points that are reachable exactly at time T. The reachable set from p, Reach (p), is the set of all points that are reachable from p within some time T.

Reachable sets play an important role in control theory. If a system can be stabilized to a given point by a feedback control law, then that point must be in the reachable set of every other point. In optimal control problems, if the cost is added as another coordinate, then the optimal trajectories must lie in the boundary of the set of reachable points. For this reason the Pontryagin Maximum Principle plays an important role in studying the boundaries of reachable sets.

The problem of describing a reachable set and the extremal trajectories that generate its boundary is closely related to the problem of regular synthesis in the sense of Boltyansky [1] and others [5], [18]. While the problem has been studied extensively for many years, only a few examples of regular syntheses have been described, for instance, [24]. Even in low dimensions, the reachable set of a general control system can be extremely complicated.

We shall attempt to avoid this difficulty by considering only "nondegenerate" systems. By a nondegenerate system we mean one where (i) f, g, and the low-order Lie brackets of f and g span as many dimensions as is possible given the dimensions of the state space; and where (ii) no nontrivial equality relations hold between those vector fields (for instance, if n is the space dimension, then any relation saying that n vector fields are dependent at a point is considered a nontrivial equality relation, whereas a relation that simply expresses the fact that a vector field can be written in terms of a basis is considered trivial).

This is in the spirit of Lobry [14], who described the small-time reachable set of (1) in dimension three under the assumption that f, g, and $[f, g]$ are linearly independent. The method described below is an attempt to extend Lobry's result to higher dimensions. As will be seen, it is successful in the four-dimensional case, but in higher-dimensional cases obstacles still have to be overcome. These obstacles, however, are not due to our general approach, but they lie in the fact that, at the moment, too little is known about the structure of extremal trajectories. We shall return to this question at the end of the paper. In the paper we shall give a precise description of the small-time reachable set in dimension four assuming that the constant controls $u=+1$ and $u=-1$ are not singular on the boundary of the reachable set. It can easily be seen (cf. § 4) that this is equivalent to an independence assumption on the vector fields f, g, $[f, g]$, and $[f+g, [f, g]]$, respectively, $[f-g, [f, g]]$. As a corollary we are able to improve on recent results of Bressan [4], Schättler [17], and Sussmann [21] on time-optimal control in dimension three.

Throughout this paper we will use nilpotent systems as a guide to the general situation. A system is nilpotent of order k if all brackets of orders greater than k vanish and if k is the smallest integer with this property. In a certain sense these systems play the same role as the polynomials do within the class of smooth functions. Nilpotent systems are the low-order part of the coordinate free Taylor series expansion of a general system.

To be more precise, we must define the Lie jet of system (1). At a point p the Lie jet consists of a list of the values at p of the Lie brackets of f and g written down in some prescribed order. Of course, because of the skew-symmetry and Jacobi relation

$$[f, g]+[g, f]=0, \qquad [f, [g, h]]+[g, [h, f]]+[h, [f, g]]=0,$$

we need only consider a list of distinct brackets. These brackets can be partially ordered by the total number of vector fields involved; for example, f is a bracket of order one and $[f, g]$ is of order two. The Lie jet of order k is a list of values at p of the distinct brackets of f and g of order less than or equal to k. The Lie jets of orders one through four are given below:

Order one: $\{f(p), g(p)\}$,
Order two: $\{f(p), g(p), [f, g](p)\}$,
Order three: $\{f(p), g(p), [f, g](p), [f, [f, g]](p), [g, [f, g]](p)\}$,
Order four: $\{f(p), g(p), [f, g](p), [f, [f, g]](p), [g, [f, g]](p),$
$[f, [f, [f, g]]](p), [f, [g, [f, p]]](p), [g, [g, [f, g]]](p)\}$.

If $N(k)$ is the number of distinct brackets of f and g of order k or less, then the kth-order Lie jet of (1) at p is a point in the vector bundle consisting of the Whitney sum of $N(k)$ copies of the tangent bundle.

A basic result of Krener [12], later proved in other contexts by Rothschild and Stein [15], Hermes [10], Crouch [8], Bressan [3], and Sussmann [20], [21] is that for analytic systems of the form (1), the kth-order Lie jet at p determines the trajectories emanating from p up to order $O(t^{k+1})$ and up to diffeomorphisms of the state space.

Sussmann [22], [23], Bressan [4], and Schättler [16], [17] have shown that the local structure of time-optimal controls in dimension two or three is determined in nondegenerate situations by the second, respectively, third-order Lie jet at a reference point. In degenerate situations higher-order jets need to be considered [16], [17], [23].

On the basis of these results we might conjecture that in nondegenerate situations the kth-order Lie jet at p determines the structure of the set of small-time reachable points where the Hörmander or controllability condition is satisfied, i.e., the rank of the kth-order Lie jet at p equals the dimension of the state space. And maybe the qualitative structure of the reachable set can be obtained by looking at a kth-order nilpotent approximation. Unfortunately, as we mention in the last section, these conjectures are not completely true, but they do motivate much of our work.

The paper is organized as follows. The next section reviews the Pontryagin Maximum Principle as applied to the system (1). This also gives us a chance to introduce some notation and terminology. In § 3, we will describe the main ideas and outline the general structure of our techniques by looking at the trivial two-dimensional case. We will also give a brief proof of Lobry's three-dimensional result. The main part of the paper is § 4, where we determine the geometric structure of the small-time reachable set for the nondegenerate four-dimensional system (assuming that both quadruples $(f, g, [f, g], [f+g, [f, g]])$ and $(f, g, [f, g], [f-g, [f, g]])$ consist of independent vectors at p). We also draw the obvious corollaries about time-optimal control in dimension three. Section 5 concludes with a brief discussion of the free nilpotent five-dimensional system and explains why the general nondegenerate five-dimensional case is different from this one.

2. The maximum principle. The Maximum Principle [13] gives necessary conditions for a point to lie on the boundary of the reachable set. Let $u(\cdot)$ be an admissible control defined on an interval $[0, T]$ and let $x(\cdot)$ be the corresponding trajectory starting at p. If $x(T) \in \partial$ Reach (p), then $x(t) \in \partial$ Reach (p) for all $t \in [0, T]$ and there exists an absolutely continuous curve $\lambda : [0, T] \to \mathbb{R}^n$, which does not vanish anywhere such that

$$\dot{\lambda}(t)^T = -\lambda(t)^T (Df(x(t)) + Dg(x(t)) \cdot u(t)), \tag{2}$$

$$\langle \lambda(t), g(x(t)) \rangle u(t) = \operatorname*{Min}_{|v| \leqq 1} \langle \lambda(t), g(x(t)) \rangle v, \tag{3}$$

$$H = \langle \lambda(t), f(x(t)) + g(x(t)) u(t) \rangle \equiv 0 \tag{4}$$

almost everywhere on $[0, T]$. (We write vectors as columns, $\langle \cdot, \cdot \rangle$ denotes the standard Euclidean inner product on $\mathbb{R}^n$, and Df and Dg denote the Jacobian matrices of f and g, respectively.) Any trajectory for which an adjoint variable $\lambda(\cdot)$ exists such that (2)-(4) are satisfied is called an extremal trajectory. The optimality condition (3) determines the control $u(t)$ whenever $\phi(t) := \langle \lambda(t), g(x(t)) \rangle \neq 0$; ϕ is called the switching function and $u \equiv -1$ $(u \equiv +1)$ on intervals where ϕ is positive (negative). Trajectories corresponding to these constant controls are called bang arcs and are denoted by X $(=f-g)$ and Y $(=f+g)$, respectively. A concatenation of bang arcs is a *bang-bang trajectory*. Observe that $\langle \lambda(t), f(x(t)) \rangle = 0$ at switching times t, i.e., where $\langle \lambda(t), g(x(t)) \rangle = 0$. At these times (3) gives no information about the optimal control. If, however, ϕ vanishes on an open interval I, then all the derivatives of ϕ also vanish on I and this may determine the control u. We have

$$\dot{\phi}(t) = \langle \lambda(t), [f, g](x(t)) \rangle,$$

$$\ddot{\phi}(t) = \langle \lambda(t), [f+gu, [f, g]](x(t)) \rangle,$$

and if $\langle \lambda(t), [g, [f, g]](x(t)) \rangle$ does not vanish on I, we can solve for u in $\ddot{\phi} = 0$ as follows:

$$u(t) = -\frac{\langle \lambda(t), [f, [f, g]](x(t)) \rangle}{\langle \lambda(t), [g, [f, g]](x(t)) \rangle}.$$

A control of this type is called singular and the corresponding trajectory is a *singular arc.*

This suggests that concatenations of bang and singular arcs are the natural candidates for trajectories in the boundary of the reachable set (but of course no such regularity statement can be drawn from the Maximum Principle alone). We denote concatenations of bang and singular arcs by the corresponding letter sequence; for instance, we simply write XSY for a concatenation of an X-arc, followed by a singular arc and a Y-trajectory, etc.

3. The main ideas of the technique: the nondegenerate two- and three-dimensional cases. In this section we analyze the (well-known) structure of small-time reachable sets in a nondegenerate situation in dimensions two and three. These cases are easy and give us an opportunity to outline the general ideas of our technique without getting preoccupied with technical details.

Suppose Σ is a system of the form (1) in dimension two and assume that f and g are independent at a reference point p (see Fig. 1). It is clear how the small-time reachable set from p will look. If we let Γ^+ (respectively, Γ^-) be the integral curves of the vector fields $f+g$ (respectively, $f-g$) for positive times, then for sufficiently small T, Reach $(p, \leqq T)$ is the union of Γ^+, Γ^-, and the open sector R between Γ^+ and Γ^- into which $f(p)$ points. It is easy to see that any point in R is reachable from p; for instance, if $q \in R$, just run a trajectory of Σ corresponding to the control $u \equiv +1$ backward in time until it hits Γ^-. The important point is that this is all of the small-time reachable set. This follows immediately from the Maximum Principle since only trajectories corresponding to the constant controls $u \equiv +1$ or $u \equiv -1$ can lie in the boundary of the reachable set. (There cannot be a junction, since then both $\langle \lambda(t), f(x(t)) \rangle$ and $\langle \lambda(t), g(x(t)) \rangle$ vanish, contradicting the nontriviality of λ.)

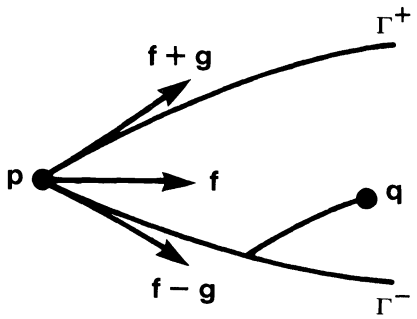

FIG. 1

Generalized to higher dimensions, the quintessence of this argument is to have two hypersurfaces Γ^* and Γ_* which are generated by extremal trajectories, have a common relative boundary and "enclose" a region R. Then, to prove that R is actually the reachable set Reach $(p, \leqq T)$, we must show (i) trajectories cannot leave R through Γ^* or Γ_*, and (ii) all points in the sector are reachable. The latter is immediate if we have a drift vector field f with $f(p) \neq 0$. This is exactly the same argument as in the

two-dimensional case. Take any point q inside R and run a trajectory of Σ corresponding to the control $u \equiv 0$ (or for that matter corresponding to any control) backward in time. Since $f(p) \neq 0$, this trajectory will hit Γ^* or Γ_*. So basically (i) must be checked; this is mostly a matter of computing tangent spaces, as will be shown below. This is the general strategy of our technique.

All technical issues left aside for a moment, the key question is how to come up with the surfaces Γ^* and Γ_*. We propose an inductive procedure. Let us explain it at the next step, which is the case of a three-dimensional system Σ, where we assume that f, g, and $[f, g]$ are independent at a reference point p. (This is the example considered by Lobry [14].)

Choose coordinates $x = (x_1, x_2, x_3)$ such that $\langle dx, (f(p), g(p), [f, g](p)\rangle = \mathrm{Id}$, the identity matrix. The projection of Σ into the (x_1, x_2)-plane is then the two-dimensional system considered above and we know the structure of its small-time reachable set. Our aim is to find two hypersurfaces Γ^* and Γ_* consisting of extremal trajectories that project onto the reachable set $\tilde{R}$ of the two-dimensional system in dimension three. If Γ^* and Γ_* have a common relative boundary that projects onto $\partial\tilde{R}$ and if Γ^* and Γ_* do not intersect in their relative interior, then it is clear that these surfaces "enclose" a region R. Then we must check whether trajectories can leave R. If this is impossible, R is the small-time reachable set.

The Maximum Principle gives preliminary information about Γ^* and Γ_* because it describes necessary conditions for trajectories to lie in the boundary of the reachable set. In this three-dimensional case it actually determines Γ^* and Γ_* precisely, but in higher dimensions this is no longer true. It is then that we will use nilpotent systems as our guide to find candidates for Γ^* and Γ_*. More on that appears in § 4.

Now that we have outlined the general approach, let us also illustrate the basic technical arguments by reproving Lobry's result. It follows from the Maximum Principle that all trajectories that lie on the boundary of the reachable set are bang-bang. For, if the switching function vanishes at some t, i.e., if $\langle \lambda(t), g(x(t))\rangle = 0$, then also $\langle \lambda(t), f(x(t))\rangle = 0$, and hence $\dot{\phi}_\Gamma(t) = \langle \lambda(t), [f, g](x(t))\rangle$ cannot vanish by the independence of f, g, and $[f, g]$ and the nontriviality of λ. For dimensionality reasons it is therefore reasonable to consider the following two surfaces as candidates for Γ^* and Γ_*:

$$\Gamma^* = \{p \exp(s_1(f-g)) \exp(s_2(f+g)) \colon s_i \geqq 0,\ s_1 + s_2 \text{ small}\},$$

$$\Gamma_* = \{p \exp(t_1(f+g)) \exp(t_2(f-g)) \colon t_i \geqq 0,\ t_1 + t_2 \text{ small}\}.$$

We write flows of vector fields as exponentials and we let the diffeomorphisms act on the right, i.e., $p \exp(tf)$ denotes the point obtained by following the integral curve of f that passes through p at time zero for t units of time.

It is clear that Γ^* and Γ_* are two-dimensional surfaces with boundary. In both cases the boundary consists of the two curves corresponding to the trajectories of $f+g$ and $f-g$ and the point p. Furthermore, by the Campbell–Hausdorff formula [11]

$$\begin{aligned} &p \exp(s_1(f-g)) \exp(s_2(f+g)) \\ &\quad = p \exp((s_1+s_2)f + (s_2-s_1)g + s_1 s_2[f, g] + s_1 s_2 \cdot O(T)), \end{aligned}$$

$$p \exp((t_1(f+g)) \exp(t_2(f-g)) = p \exp(t_1+t_2)f + (t_1-t_2)g - t_1 t_2[f, g] + t_1 t_2 \cdot O(T))$$

where $O(T)$ stands for terms that are linear in the total time T. This shows that Γ^* and Γ_* do not intersect in their relative interior. So Γ^* and Γ_* enclose a region R.

To prove that the enclosed sector R is the small-time reachable set we must show that there cannot be any other points in the reachable set. As in the two-dimensional case we have two options: either we show that we have exhausted all trajectories that

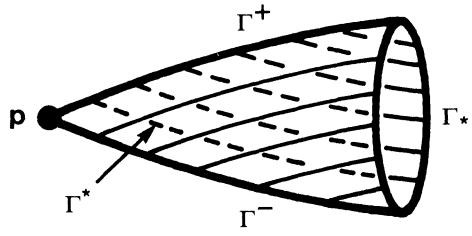

FIG. 2

possibly can lie on the boundary of the reachable set, or we show that trajectories starting at points on Γ^*, Γ_*, Γ^+, or Γ_- cannot leave $R \cup \Gamma^* \cup \Gamma_* \cup \Gamma^+ \cup \Gamma_-$. As it turns out, this is the same argument, only viewed differently.

Let us first show that we have exhausted all possible trajectories that can lie in the boundary of the small-time reachable set, i.e., that such a trajectory is bang-bang with at most one switching. Let γ be a bang-bang trajectory with two switches, say of the form XYX, with junctions p_0 and p_1 at times $t_0 < t_1$. If $\bar{\lambda} = \lambda(t_1)$, then we have $\langle \bar{\lambda}, g(p_1) \rangle = 0$ and $\langle \bar{\lambda}, f(p_1) \rangle = 0$. Also $\langle \lambda(t_0), g(p_0) \rangle = 0$ or, equivalently, if we move g ahead along the flow of the vector field Y we get $\langle \bar{\lambda}, \exp(-(t_1 - t_0) \operatorname{ad} Y) X(p_0) \rangle = 0$. But $\bar{\lambda} \neq 0$ and so these three vectors are dependent: p_0 and p_1 are *conjugate points* (Sussmann [22]). Therefore

$$X(p_1) \wedge Y(p_1) \wedge \exp(-\Delta t \operatorname{ad} Y) X(p_0) = 0$$

i.e., $X(p_1) \wedge Y(p_1) \wedge [X, Y](p_1) + O(\Delta t) = 0$, where $\Delta t = t_1 - t_0$. But such a relation cannot hold in small time by the independence of X, Y, and $[X, Y]$. Similarly it follows that YXY-concatenations cannot satisfy the Maximum Principle.

This computation can also be viewed in the following way. Define a map $F: (t_1, t_2, t_3) \mapsto p \exp(t_1 X) \exp(t_2 Y) \exp(t_3 X)$ for t_i small. Then this map has full rank if $t_i > 0$. For, if we compute the tangent space to the image, but pull back to $p \exp(t_1 X) \exp(t_2 Y)$, we get exactly the vectors $\exp(-t_2 \operatorname{ad} Y) X$, Y, and X. Therefore $F(t_1, t_2, t_3)$ is an interior point of the reachable set. Finally, if we pull back the tangent space one step further to $p \exp(t_1 X)$ we have the vectors X, Y, and $\exp(t_2 \operatorname{ad} Y) X = X - t_2[X, Y] + O(t_2^2)$. The minus sign at $[X, Y]$ implies that X-trajectories point inside R at points on Γ^*. Similarly, it follows that Y-trajectories steer the system into R from Γ^*. And this proves that trajectories of the system cannot leave R through Γ^*, Γ_*, Γ^+, or Γ_-. (Because of the Maximum Principle we can restrict ourselves to just looking at these regular controls instead of having to consider arbitrary measurable functions. For, if any trajectory would leave R, then there will also have to be additional trajectories lying on the boundary of the reachable set and these must be bang-bang.)

The structure of the small-time reachable set as a stratified set can easily be described using the following notation. For $n \in \mathbb{N}$ let

$$S_{n,-} := \{ p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) \cdots \exp(s_n B) : s_i > 0,\ B = X \text{ if } n \text{ is odd},\ B = Y \text{ if } n \text{ is even} \},$$

$$S_{n,+} := \{ p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) \cdots \exp(t_n B) : t_i > 0,\ B = X \text{ of } n \text{ is even } B = Y \text{ if } n \text{ is odd} \}.$$

In a nondegenerate situation each of the $S_{n,\pm}$ is a n-dimensional smooth manifold. (Certainly this will be true in all the cases we consider here.) In the three-dimensional case the boundary of the small-time reachable set consists of the two two-dimensional

strata $S_{2,\pm}$ which have in their boundary the two one-dimensional strata $S_{1,\pm}$ and the zero-dimensional stratum $S_0 = \{p\}$. S_0 also lies in the boundary of $S_{1,\pm}$. If we restrict the total time to be $\leqq T$ we must make the obvious adjustments. In particular, we must add the strata $\hat{S}_{n,\pm} := S_{n,\pm} \cap \text{Reach}(p, T)$ for $n = 1, 2$.

4. The nondegenerate four-dimensional systems. In this section we determine the geometric structure of the small-time reachable sets from a point p for a system Σ of the form (1) in dimension four, where we assume that the constant controls $u \equiv +1$ and $u \equiv -1$ are not singular. These conditions can easily be expressed in terms of independence assumptions on f, g, and lower-order brackets of f and g. For, a constant control $u \equiv u^0$ is singular on an interval I if and only if there exists an adjoint multiplier λ such that $\langle \lambda, f \rangle$, $\langle \lambda, g \rangle$, $\langle \lambda, [f, g] \rangle$, and $\langle \lambda [f + gu^0, [f, g]] \rangle$ vanish identically on I. By the nontriviality of λ this is impossible if f, g, $[f, g]$, and $[f + gu^0, [f, g]]$ are independent. Therefore in terms of the vector fields X and Y our conditions are equivalent to

(A) X, Y, $[X, Y]$ and $[X, [X, Y]]$ are independent near p;

(B) X, Y, $[X, Y]$ and $[Y, [X, Y]]$ are independent near p.

If we write $[X, [X, Y]]$ as a linear combination of X, Y, $[X, Y]$ and $[Y, [X, Y]]$ as

$$[X, [X, Y]] = \alpha X + \beta Y + \gamma [X, Y] + \delta [Y, [X, Y]],$$

then (A) is equivalent to $\delta \neq 0$.

The cases $\delta > 0$ and $\delta < 0$ are significantly different: if $\delta > 0$ only bang-bang trajectories can lie in the boundary of the reachable set, if $\delta < 0$ singular arcs are possible. Intuitively this is clear. If u is singular on an interval I, then (omitting the arguments t and $x(t)$)

$$\begin{aligned} \ddot{\phi} &= \langle \lambda, [f + gu, [f, g]] \rangle \\ &= \tfrac{1}{4} \langle \lambda, (1-u)[X, [X, Y]] + (1+u)[Y, [X, Y]] \rangle \\ &= \tfrac{1}{4} ((1-u)\delta + (1+u)) \cdot \langle \lambda, [Y [X, Y]] \rangle \neq 0 \end{aligned}$$

and so $u = (\delta + 1)/(\delta - 1)$. This is an admissible control only if $\delta \leqq 0$. Note that the singular vector field is given in feedback form as

$$S = f + \frac{\delta + 1}{\delta - 1} g = \frac{1}{1 - \delta} X + \frac{-\delta}{1 - \delta} Y, \quad \delta < 0.$$

4.1. The totally bang-bang case: $\delta > 0$. This is the generalization of Lobry's example to dimension four. We treat only the general case here, but we remark that the structure of the small-time reachable set is the same as for a nilpotent system where f, g, $[f, g]$, and $[f, [f, g]]$ form a basis and all other brackets vanish. In appropriate coordinates the latter system is linear.

The key observation again is that the Maximum Principle precisely determines the possible trajectories that can lie in the boundary of the small-time reachable set.

LEMMA 1. *If γ is a trajectory that lies in the boundary of the small-time reachable set, then γ is bang-bang with at most two switches.*

Proof. We first exclude bang-bang trajectories with more switches. Let γ be a $YXYX$-trajectory with switching points p_1, p_2, and p_3 and let s_1, s_2, s_3, s_4 be the length of the times along the respective X-arcs or Y-arcs. At every junction we have $\langle \lambda, X(p_i) \rangle = 0$ and $\langle \lambda, Y(p_i) \rangle = 0$. This gives rise to four conditions on λ.

If $\tilde{\lambda}$ is the value of the adjoint vector at the switching time at p_2, we have

$$\langle \tilde{\lambda}, X(p_2)\rangle = \langle \tilde{\lambda}, Y(p_2)\rangle = 0,$$

$$\langle \tilde{\lambda}, \exp(-s_2 \operatorname{ad} Y)X(p_1)\rangle = 0,$$

and

$$\langle \tilde{\lambda}, \exp(s_3 \operatorname{ad} X)\, Y(p_3)\rangle = 0.$$

Again, the nontriviality of $\tilde{\lambda}$ implies that these four vectors are dependent ("conjugate points"). So we get (dividing out s_2 and s_3)

$$0 = X \wedge Y \wedge \left(\frac{\exp(s_3 \operatorname{ad} X) - 1}{s_3}\right) Y \wedge \left(\frac{\exp(-s_2 \operatorname{ad} Y) - 1}{-s_2}\right) X$$

$$(5) \qquad = X \wedge Y \wedge [X, Y] + \frac{1}{2} s_3 [X, [X, Y]] + O(s_3^2) \wedge -[X, Y] + \frac{1}{2} s_2 [Y, [X, Y]] + O(T^2)$$

$$= \frac{1}{2}\sigma(s_2, s_3)(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])_{|p_2}$$

where T is the total time along γ and $O(T^2)$ stands for terms that are quadratic in T; σ is a smooth function of s_2 and s_3. If we express $[X, [X, Y]]$ in terms of X, Y, $[X, Y]$, and $[Y, [X, Y]]$, we see that

$$(6) \qquad \sigma(s_2, s_3) = s_2 + s_3\delta + O(T^2)$$

where δ is evaluated at p_2. In a sufficiently small neighborhood of p, δ is bounded away from zero and so the linear terms dominate quadratic remainders in small time. Hence $\sigma(s_2, s_3)$ is positive for s_i small; in particular, it cannot vanish, a contradiction.

Analogously, if $\tilde{\gamma}$ is a $XYXY$-concatenation with switching points q_1, q_2, and q_3 and if t_1, t_2, t_3, t_4 are the times along the respective trajectories, then we get

$$0 = X \wedge Y \wedge \left(\frac{\exp(-t_2 \operatorname{ad} X) - 1}{-t_2}\right) Y \wedge \left(\frac{\exp(t_3 \operatorname{ad} Y) - 1}{t_3}\right) X$$

$$(7) \qquad = \frac{1}{2}\tau(t_2, t_3)(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])_{|q_2}$$

where

$$(8) \qquad \tau(t_2, t_3) = -t_3 - t_2\delta + O(T^2)$$

is a smooth function of t_2 and t_3 near the origin. Again, since δ is bounded away from zero near p this function is negative for small times, a contradiction.

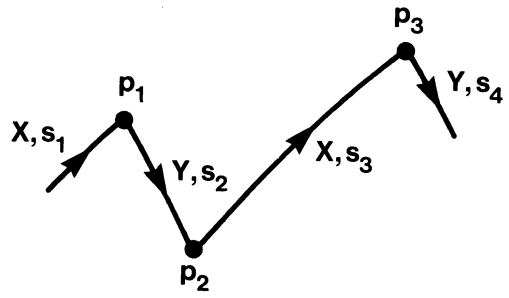

FIG. 3

It now follows that, in fact, any trajectory that lies in the boundary of the small-time reachable set is bang-bang. This is an easy but slightly technical argument. We will do it here rigorously since we will need the computations later on anyway. The point is that we do not have a priori knowledge about regularity properties of the controls, e.g., that they are piecewise constant. This is the case if and only if the zero set $Z(\phi)$ of the switching function ϕ is finite. If it were infinite, then the set N_ϕ of limit points of $Z(\phi)$ would be nonempty. In fact, it is a closed, nowhere dense, perfect set. (If $t_1 < t_2$ are points in $N(\phi)$ then, since ϕ cannot vanish identically, ϕ is different from zero somewhere in (t_1, t_2) and by continuity it is different from zero on a whole interval. It is perfect, i.e., every point $t \in N(\phi)$ is a limit point of points $t_n \in N(\phi)$, $t_n \neq t$, since $N(\phi)$ cannot have isolated points. We can see that this is so, since we know already that bang-bang trajectories with more than three switchings do not lie in the boundary of the small-time reachable set!) Suppose $t_1 < t_2$ are times in $N(\phi)$. There exists a $\tilde{t} \in (t_1, t_2)$ such that $\phi(\tilde{t}) \neq 0$. Let $\tilde{t}_1 := \sup([t_1, \tilde{t}] \cap N(\phi))$ and let $\tilde{t}_2 := \inf([\tilde{t}_1, t_2] \cap N(\phi))$. Then $\tilde{t}_1 < \tilde{t}_2$, $\tilde{t}_i \in N(\phi)$, and $Z(\phi) \cap [\tilde{t}_1, \tilde{t}_2]$ is finite. This implies that γ contains subarcs of the form $*B\cdot$ and $\cdot B*$, where B denotes a bang arc (X or Y), $\cdot$ stands for any switching, and $*$ stands for a junction in $N(\phi)$. Observe that $\dot{\phi}(t) = 0$ if $t \in N(\phi)$. We will now show that none of these concatenations can lie in the boundary of the reachable set and this will prove the lemma.

Without loss of generality we consider a concatenation of the form $*X\cdot$ with switching points p_0 and p_1 and let t be the time along X. Then, if $\tilde{\lambda}$ is the value of the adjoint vector at the switching time corresponding to p_0, we have

$$\langle \tilde{\lambda}, X(p_0) \rangle = \langle \tilde{\lambda}, Y(p_0) \rangle = \langle \tilde{\lambda}, [X, Y](p_0) \rangle = 0.$$

Also $\langle \tilde{\lambda}, \exp(-t \operatorname{ad} X) Y(p_1) \rangle = 0$ and so by nontriviality of $\tilde{\lambda}$ we again get

$$\begin{aligned} 0 &= X \wedge Y \wedge [X, Y] \wedge Y - t[X, Y] + \tfrac{1}{2}t^2[X, [X, Y]] + O(t^3) \\ &= \tfrac{1}{2}t^2(1 + O(t))(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])|_{p_0}. \end{aligned} \tag{9}$$

This cannot hold in small time. Analogously it follows that no $*B\cdot$ or $\cdot B*$ concatenation can lie in the boundary of the small-time reachable set if $\delta \neq 0$. This proves the lemma (and note that the argument is valid in general under assumptions (A) and (B)). □

It is now clear that the surfaces Γ^* and Γ_* must be as follows:

$$\Gamma^* = \{p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) : s_i \geqq 0, \text{small}\},$$

$$\Gamma_* = \{p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) : t_i \geqq 0, \text{small}\}.$$

Γ^* and Γ_* are three-dimensional surfaces with common boundary C that has precisely the structure of the boundary of the small-time reachable set in dimension three. It is the union of two two-dimensional surfaces made out of XY- and YX-trajectories respectively, glued together along the X- and Y-trajectories.

We will now show that Γ^* and Γ_* do not intersect away from C, in particular that they enclose an open region that will be the interior of the small-time reachable set.

DEFINITION. We say a point q is an entry point (respectively, an exit point) of a (closed) set S for a vector field Z if for some $\varepsilon > 0$, $S \cap \{q \exp(tZ) : -\varepsilon \leqq t \leqq 0\} = \{q\}$ (respectively, if $S \cap \{q \exp(tZ) : 0 \leqq t \leqq \varepsilon\} = \{q\}$).

LEMMA 2. *For sufficiently small T the points in Γ^* are entry points for the small-time reachable set from p for $[Y, [X, Y]]$. The points in Γ_* are exit points.*

Proof. If q is an exit (entry) point for $\operatorname{Reach}(p, \leqq T)$ that does not lie in $\operatorname{Reach}(p, T)$, i.e., exit or entry is not due to the time restriction, then the corresponding

trajectory is extremal and the adjoint multiplier satisfies the transversality condition $\langle \lambda, [Y,[X,Y]](q)\rangle \leqq 0$ ($\langle \lambda, [Y,[X,Y]](q)\rangle \geqq 0$). We claim that necessarily

$$q \in \Gamma_* \ (q \in \Gamma^*).$$

Recall that the second derivative of the switching function is given by

$$\begin{aligned} \ddot{\phi}(t) &= \langle \lambda(t), [f+gu,[f,g]](x(t))\rangle \\ &= \tfrac{1}{4}(1-u(t))\langle \lambda, [X,[X,Y]](x(t))\rangle \\ &\quad + \tfrac{1}{4}(1+u(t))\langle \lambda, [Y,[X,Y]](x(t))\rangle. \end{aligned} \tag{10}$$

Expressing $[X,[X,Y]]$ in terms of X, Y, $[X,Y]$, and $[Y,[X,Y]]$, we get a linear combination of terms $\langle \lambda, X\rangle$, $\langle \lambda, Y\rangle$, $\langle \lambda, [X,Y]\rangle$, and $\langle \lambda, [Y,[X,Y]]\rangle$, where the coefficient at $\langle \lambda, [Y,[X,Y]]\rangle$ is

$$\tfrac{1}{2}(1-u)\delta + \tfrac{1}{2}(1+u) \geqq \operatorname{Min}(1,\delta) > 0.$$

Suppose γ is a bang-bang trajectory with two junctions. Then the two junctions determine a multiplier λ up to a positive constant multiple. Normalize such that $\|\lambda(0)\|_2 = 1$. Because γ has two junctions $\langle \lambda, X\rangle$, $\langle \lambda, Y\rangle$, and $\langle \lambda, [X,Y]\rangle$ vanish somewhere on $[0,T]$, $T = t_1+t_2+t_3$. For sufficiently small T these functions will be bounded in absolute value on $[0,T]$ by any $\varepsilon > 0$. Because of (B) $|\langle \lambda(t), [Y,[X,Y]](x(t))\rangle|$ can be bounded away from zero on $[0,T]$. By choosing ε, i.e., T small enough, $\langle \lambda, [Y,[X,Y]]\rangle$ dominates all other terms in (10), that is, we have in small time: $\ddot{\phi}$ has constant sign equal to sign ($\langle \lambda, [Y,[X,Y]]\rangle$). But $\langle \lambda, [Y,[X,Y]]\rangle > 0$ allows only for XYX-trajectories and $\langle \lambda, [Y,[X,Y]]\rangle < 0$ permits only YXY-concatenations. This proves our claim.

We still need to show that points in Γ^* and Γ_* in fact have these optimization properties. Suppose γ is a XYX trajectory. Then the tangent space at the endpoint is spanned by X, $\exp(-t_3 \operatorname{ad} X)Y$ and $\exp(-t_3 \operatorname{ad} X)\exp(-t_2 \operatorname{ad} Y)X$. Note that $[Y,[X,Y]]$ always points to one side of the tangent space since

$$\begin{aligned} &X \wedge \exp(-t_3 \operatorname{ad} X)Y \wedge \exp(-t_3 \operatorname{ad} X)\exp(-t_2 \operatorname{ad} Y)X \wedge [Y,[X,Y]] \\ &= -t_2\left(X \wedge \exp(-t_3 \operatorname{ad} X)Y \wedge \exp(-t_3 \operatorname{ad} X)\left(\frac{\exp(-t_2 \operatorname{ad} Y)-1}{-t_2}\right)X \right. \\ &\qquad \left. \wedge [Y,[X,Y]]\right) \\ &= t_2(X \wedge Y - t_3[X,Y] + O(t_3^2) \wedge [X,Y] + O(T) \wedge [Y,[X,Y]]) \\ &= t_2(1+O(T))(X \wedge Y \wedge [X,Y] \wedge [Y,[X,Y]]). \end{aligned} \tag{11}$$

If we write the defining equations for Γ^* and Γ_* in terms of canonical coordinates of the second kind, that is, as products of the flows of the vector fields X, Y, $[X,Y]$, $[Y,[X,Y]]$ in the form

$$p \exp(x_1 X)\exp(x_2 Y)\exp(x_3[X,Y])\exp(x_4[Y,[X,Y]]), \tag{12}$$

then this implies that we can think of Γ^* as the graph of a function $x_4 = \psi(x_1, x_2, x_3)$. It also follows from (12) that the integral curve of $[Y,[X,Y]]$ through p and the compact set Reach (p, T) are disjoint for small positive T. Therefore, given T, there exists a $\tilde{T} \leqq T$ with the following property. Any integral curve of $[Y,[X,Y]]$ that passes through a point on $\Gamma^*(\tilde{T})$, the set of all trajectories in Γ^* of total time $\leqq \tilde{T}$, does not meet Reach (p, T). This implies that the points on $\Gamma^*(\tilde{T})$ are entry points for the small-time reachable set. For, if $q \in \Gamma^*(\tilde{T})$ is not an entry point, then by compactness

there exists an entry point of Reach $(p, \leqq T)$ of the form $q \exp r[Y, [X, Y]]$. Since this flow does not meet Reach (p, T) this point must lie on Γ^* and this contradicts the graph property. Analogously the result follows for Γ_*. □

An easy computation shows that, if Γ^* and Γ_* would intersect away from C, then it would have to happen transversally. This would contradict Lemma 2.

The geometric structure of the small-time reachable set is now clear. It is the exact analogue of Figs. 1 and 2 in four dimensions. Its boundary consists of the surfaces Γ_* and Γ^* that match up along C, the set of points reachable by a bang-bang trajectory with at most one switch. The open region enclosed by Γ^* and Γ_* is the interior of the reachable set. A stratification of its boundary is given by S_0 and $S_{n,\pm}$ for $n = 1, 2, 3$ (see § 3).

Remark. This qualitative structure of the small-time reachable set for a totally bang-bang system generalizes to arbitrary dimensions under the conditions of Krener's and Sussmann's nonlinear bang-bang theorem [19]. Suppose that the vector fields f and $\mathrm{ad}^i f(g)$, $i = 0, \cdots, n-1$ are independent at p and that for $i = 0, \cdots, n-1$ there exist smooth functions α_{ij} and β_i with $|\beta_i(p)| < 1$ such that

$$[g, \mathrm{ad}^i f(g)] = \sum_{j=0}^{i} \alpha_{ij} \mathrm{ad}^j f(g) + \beta_i \mathrm{ad}^{i+1} f(g).$$

Then it follows that for sufficiently small-time T all trajectories that lie in the boundary of the reachable set from p are bang-bang with at most n switchings. A stratification of the boundary is given by the strata $S_0 = \{p\}$ and $S_{k,\pm}$, $k = 1, \cdots, n$. In particular, points in $S_{n,+}$ are exit points of the reachable set for $(-1)^{n-1} \mathrm{ad}^{n-1} f(g)$, points in $S_{n,-}$ are entry points. Given the results on the structure of trajectories in the boundary, this is a straightforward generalization of the argument above. All the difficult work has been carried out by Sussmann in [19], specifically in the proof of Lemma 3 there.

4.2. The bang-bang singular case: $\delta < 0$. This case is a nontrivial extension of Lobry's result. Here not all the extremal trajectories actually lie in the boundary of the small-time reachable set. It is therefore not clear how we should choose Γ^* and Γ_*. We now use the structure of the small-time reachable set for the corresponding free nilpotent system as a guide. The only reasonable nilpotent approximation to choose is one where all brackets of orders greater than or equal to 4 vanish. Note that f, g, $[f, g]$, and $[g, [f, g]]$ are always independent in this case. Since we want to work with a system as simple as possible, we also assume $[f, [f, g]] \equiv 0$. This is an equality relation in the third-order Lie jet, but in a slightly more general setup (weighted Lie algebra) this would be a free nilpotent system. Therefore we refer to this system as the "free" nilpotent case. We will first analyze a model of this "free" nilpotent case, and then we will show that the general case has the same qualitative behavior.

4.2.1. The reachable set in the "free" nilpotent case. To simplify some computations we restrict ourselves to the following model $\tilde{\Sigma}$:

$$\dot{x}_0 = 1, \quad \dot{x}_1 = u, \quad \dot{x}_2 = x_1, \quad \dot{x}_3 = \tfrac{1}{2} x_1^2. \tag{13}$$

Note that $[g, f](x) = (\partial/\partial x_2) + x_1(\partial/\partial x_3)$, $[g, [g, f]] \equiv \partial/\partial x_3$ and all other brackets vanish identically. It is clear that the qualitative structure of the reachable set from the origin at any time is the same as for the small-time reachable set: one is a rescaling of the other. (If u is a control defined on $[0, T]$ and x is the corresponding trajectory, then the time 1 reachable set can be obtained from the time T reachable set by letting $\bar{u}(t) := u(t/T)$ and $\bar{x}_i(t) := T^i x_i(t/T)$ for $i = 1, 2, 3$.) To determine the reachable set it therefore suffices to look at time slices $T =$ constant, and without loss of generality we can assume $T = 1$.

If $\lambda = (\lambda_0, \lambda_1, \lambda_2, \lambda_3)^T$ is an adjoint vector for an extremal trajectory $x(\cdot)$, then λ_1 is the switching function and

$$\dot{\lambda}_1 = -\lambda_2 - \lambda_3 x_1, \quad \dot{\lambda}_2 = 0, \quad \dot{\lambda}_3 = 0,$$

and in particular $\ddot{\lambda}_1 = \lambda_3 u$, i.e., $u \equiv 0$ is the only singular control. Note that, if $\lambda_3 = 0$, then λ_1 is a linear function and the extremal trajectory is uniquely determined. By a theorem of Bressan [2] this implies that the reachable set is convex in direction of $(0, 0, 0, 1)^T$ or equivalently in the direction of $[g, [g, f]] = \frac{1}{2}[X, [X, Y]]$; that is, if (p_0, p_1, p_2, a) and (p_0, p_1, p_2, b) lie in the reachable set, then the whole segment $\{(p_0, p_1, p_2, c)\colon a \leqq c \leqq b\}$ lies in the reachable set. It is therefore clear what the surfaces Γ^* and Γ_* have to be: Γ^* consists of trajectories which are exit points for $[X, [X, Y]]$ and Γ_* of those which are entry points. Equivalently, we can speak of trajectories that maximize/minimize the coordinate x_3.

For extremal trajectories that give rise to entry/exit points for $[X, [X, Y]]$, an additional transversality condition was to hold. One of the directions $\pm[X, [X, Y]]$ can be separated from an approximating cone to the reachable set at this point. In our case these conditions simply say that $\lambda_3 \geqq 0$ for trajectories that minimize x_3 and $\lambda_3 \leqq 0$ for those that maximize x_3. In particular $\lambda_3 = 0$ for those that do both and these trajectories are bang-bang with at most one switching. So again the common boundary of Γ^* and Γ_* will be a set C that has the structure of the boundary of the small-time reachable set in dimension three.

We now determine Γ_*. We can assume $\lambda_3 > 0$ and without loss of generality normalize λ_3 to 1. Thus, $\ddot{\lambda}_1 = -u$ and so λ_1 is strictly convex and positive along X, strictly concave and negative along Y. Singular controls satisfy the generalized Legendre–Clebsch condition [13]: $\langle \lambda, [g, [f, g]] \rangle = -\lambda_3 < 0$. It follows that the only extremal trajectories are concatenations of a bang arc, followed by a singular arc and another bang arc. We now restrict to the time slice $T = 1$. Define

$$\Gamma_{-0-} := \{0 \exp(s_1 X) \exp(s_2 f) \exp(s_3 X)\colon s_i \geqq 0,\ s_1 + s_2 + s_3 = 1\},$$

$$\Gamma_{-0+} := \{0 \exp(s_1 X) \exp(s_2 f) \exp(s_3 Y)\colon s_i \geqq 0,\ s_1 + s_2 + s_3 = 1\},$$

$$\Gamma_{+0-} := \{0 \exp(t_1 Y) \exp(t_2 f) \exp(t_3 X)\colon t_i \geqq 0,\ t_1 + t_2 + t_3 = 1\},$$

$$\Gamma_{+0+} := \{0 \exp(t_1 Y) \exp(t_2 f) \exp(t_3 Y)\colon t_i \geqq 0,\ t_1 + t_2 + t_3 = 1\}.$$

We will show that these are two-dimensional surfaces with boundary which match up and together form Γ_* with

$$\partial\Gamma_* = \{0 \exp(s_1 X) \exp(s_2 Y)\colon s_i \geqq 0,\ s_1 + s_2 = 1\}$$
$$\cup \{0 \exp(t_1 Y) \exp(t_2 X)\colon t_i \geqq 0,\ t_1 + t_2 = 1\}.$$

LEMMA 3. *Each of the sets $\Gamma_{\pm 0\pm}$ is a two-dimensional surface with boundary. For any two of them the images of the open simplices are disjoint. Furthermore,*

$$\Gamma_{-0-} \cap \Gamma_{-0+} = \Gamma_{-0} = \{0 \exp(s_1 X) \exp(s_2 f)\colon s_i \geqq 0,\ s_1 + s_2 = 1\},$$

$$\Gamma_{-0-} \cap \Gamma_{+0-} = \Gamma_{0-} = \{0 \exp(s_1 f) \exp(s_2 X)\colon s_i \geqq 0,\ s_1 + s_2 = 1\},$$

$$\Gamma_{-0-} \cap \Gamma_{+0+} = \Gamma_0 = \{0 \exp(sf)\colon 0 \leqq s \leqq 1\} = \Gamma_{-0+} \cap \Gamma_{+0-},$$

$$\Gamma_{-0+} \cap \Gamma_{+0+} = \Gamma_{0+} = \{0 \exp(s_1 f) \exp(s_2 Y)\colon s_i \geqq 0,\ s_1 + s_2 = 1\},$$

$$\Gamma_{+0-} \cap \Gamma_{+0+} = \Gamma_{+0} = \{0 \exp(s_1 Y) \exp(s_2 f)\colon s_i \geqq 0,\ s_1 + s_2 = 1\}.$$

Graphically, these relations can be illustrated as shown in Fig. 4.

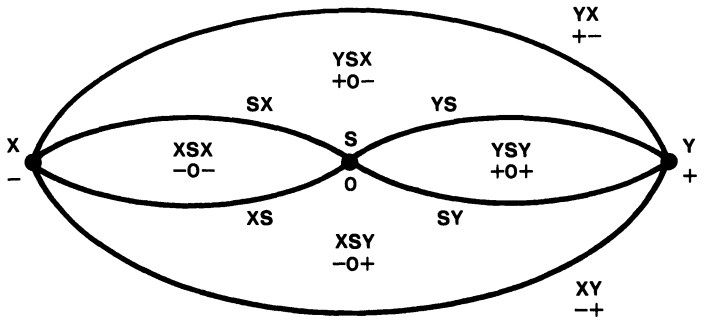

FIG. 4

The proof of the lemma consists of straightforward computations that we shall only illustrate in one case. It is easy to see that all the maps are regular with rank 2 in the interior, and it is clear how the maps behave on the boundary. So the $\Gamma_{\pm 0\pm}$ are two-dimensional surfaces with boundary. To prove that the images of the open simplex under different maps are disjoint, we choose a way that does not use the specific form of the equations, but works with a basis provided by the vector fields f, g, $[f, g]$, and $[g, [f, g]]$. This also gives an idea how the analogous argument in the general case runs. We rewrite the defining equations in terms of canonical coordinates of the second kind as products of the flows of the vector fields f, g, $[f, g]$, and $[g, [f, g]]$. Since in this case

$$\exp(f+g) = \exp([g,[f,g]]/3)\exp([f,g]/2)\exp(g)\exp(f), \tag{14}$$

we get, for instance, for Γ_{+0+}:

$$\begin{aligned}
&0\exp(t_1(f+g))\exp(t_2 f)\exp(t_3(f+g))\\
&\quad = 0\exp((\tfrac{1}{3}t_1^3[g,[f,g]])\exp(\tfrac{1}{2}t_1^2[f,g])\exp(t_1 g)\exp((t_1+t_2)f))\\
&\qquad \times\exp(\tfrac{1}{3}t_3^3[g,[f,g]])\exp(\tfrac{1}{2}t_3^2[f,g])\exp(t_3 g)\exp(t_3 f)\\
&\quad = 0\exp((\tfrac{1}{6}(t_1+t_3)^3 + t_2t_3(t_1+\tfrac{1}{2}t_3))[g,[f,g]])\exp((\tfrac{1}{2}(t_1+t_3)^2 + t_2t_3)[f,g])\\
&\qquad \times\exp((t_1+t_3)g)\exp(f).
\end{aligned}$$

Analogously we have for Γ_{-0+}:

$$\begin{aligned}
&0\exp(s_1(f-g))\exp(s_2 f)\exp(s_3(f+g))\\
&\quad = 0\exp((\tfrac{1}{3}s_1^3 - s_1^2s_3 + \tfrac{1}{3}s_3^3 + \tfrac{1}{2}s_2s_3^2 - s_1s_2s_3)[g,[f,g]])\\
&\qquad \times\exp((-\tfrac{1}{2}s_1^2 + \tfrac{1}{2}s_3^2 + (s_1+s_2)s_3)[f,g])\exp((s_3-s_1)g)\exp(f).
\end{aligned}$$

A simple computation shows that the equations we obtain by equating the coordinates have no positive solution. Similarly this is shown for all pairs of surfaces. The statements about the intersections are then clear. □

This shows that Γ_* is a two-dimensional stratified set with its one-dimensional relative boundary $\partial\Gamma_*$ made out of bang-bang trajectories with at most one switching. Figure 4 gives a precise description of the stratification. We now show that the points on Γ_* are, in fact, the points that have the smallest x_3 coordinate among all points of Reach $(0, 1)$ with a fixed (x_0, x_1, x_2).

Let us first compute the tangent spaces to the surfaces $\Gamma_{\pm 0\pm}$. Note that in each case the pullback of the tangent space to the endpoint of the singular arc simply consists of the space spanned by the vectors g and $[f, g]$ evaluated there (remember that we are working in the time slice $T=1$). This implies that $[X,[X, Y]]=2[g,[g,f]]$ always points to one side of the tangent space. In fact,

$$\exp(-t \operatorname{ad}(f \pm g))g \wedge \exp(-t \operatorname{ad}(f \pm g))[f, g] \wedge [g,[f, g]] \equiv 1(g \wedge [f, g] \wedge [g,[f, g]]).$$

In the limit this also holds for the one-dimensional strata. Therefore $[g,[g,f]]$ always points to one side of the stratified surface Γ_*. It is easy to see that, in fact, we can think of Γ_* as the graph of a piecewise defined function $x_3=\psi(x_1, x_2)$. (The projections of the images onto (x_1, x_2) intersect only along the projections of the intersections of the surfaces $\Gamma_{\pm 0\pm}$.) Since we have exhausted all possible extremal trajectories that can minimize the coordinate x_3 with Γ_*, it is now clear that given $(\bar{x}_1, \bar{x}_2, \bar{x}_3) \in \Gamma_*$ any other point $(x_1, x_2, x_3) \in \operatorname{Reach}(0, 1)$ with $x_1=\bar{x}_1$ and $x_2=\bar{x}_2$ must satisfy $x_3>\bar{x}_3$. This concludes the analysis of Γ_*.

Next we will determine Γ^*. Here we can assume $\lambda_3=-1$ and so $\ddot{\lambda}_1=u$, i.e., the switching function ϕ is convex when ϕ is negative and concave when ϕ is positive. This clearly suggests bang-bang extremals. However, now the situation is significantly different from all previous cases: it will turn out that the times along bang arcs are no longer free, which in turn will mean that we cannot a priori exclude bang-bang trajectories with a large number of switchings. In general, it is a very difficult problem to eliminate extremal trajectories with a large number of switchings (cf. [4] or [16]). It turns out that in our approach we do not even have to address this issue.

Let us start by showing that the times along bang arcs can no longer vary freely. Suppose we have a concatenation of a Y-trajectory followed by an X-arc with switchings at the beginning and the end $(\cdot XY\cdot)$. Call the switching points p_0, p_1, and p_2 and let s and t be the times along X and Y, respectively. Then p_0, p_1, and p_2 are conjugate points and therefore

$$\begin{aligned} 0 &= \exp(-s \operatorname{ad} X) Y \wedge X \wedge Y \wedge \exp(t \operatorname{ad} Y) X \\ &= \left(\frac{\exp(-s \operatorname{ad} X)-1}{-s}\right) Y \wedge X \wedge Y \wedge \left(\frac{\exp(t \operatorname{ad} Y)-1}{t}\right) X \\ &= X \wedge Y \wedge [X, Y]+s[g,[f, g]] \wedge [Y, X]-t[g,[f, g]] \\ &= (s-t)(X \wedge Y \wedge [X, Y] \wedge [g,[f, g]]). \end{aligned} \tag{15}$$

Hence $s=t$ and the same is true for a $\cdot YX\cdot$-concatenation. Therefore, so as not to violate the Maximum Principle, and since we do not expect any degeneracies in the structure of the reachable set, we restrict ourselves to the following two surfaces:

$$\tilde{\Gamma}^- = \{0 \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) \colon s_i \geqq 0,\ s_1+s_2+s_3=1,\ s_1 \leqq s_2,\ s_3 \leqq s_2\},$$

$$\tilde{\Gamma}^+ = \{0 \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) \colon t_i \geqq 0,\ t_1+t_2+t_3=1,\ t_1 \leqq t_2,\ t_3 \leqq t_2\}.$$

Our aim is to build Γ^* out of trajectories from $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$. However, as they are at the moment, we still have too many extremal trajectories. The surfaces $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ have a nontrivial intersection $\tilde{\gamma}$. To see this let us rewrite the defining maps in terms of canonical coordinates as follows:

$$\begin{aligned} 0 \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) = 0 \exp(s_1 s_2(s_2-s_1)[g,[f, g]]) \exp(s_1 s_2[X, Y]) \\ \times \exp(s_2 Y) \exp((s_1+s_3) X), \end{aligned}$$

$$0\exp(t_1Y)\exp(t_2X)\exp(t_3Y)=0\exp(t_2t_3(2t_1-t_2+t_3)[g,[f,g]])\exp(t_2t_3[X,Y])$$
$$\times\exp((t_1+t_3)Y)\exp(t_2X).$$

If we equate the coordinates, it follows easily that $s_1=t_3$, $s_2=t_2$, and $s_3=t_1$. It follows that $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$ also intersect along the one-dimensional curve

$$\tilde{\gamma}=\{0\exp(sX)\exp(Y/2)\exp((\tfrac{1}{2}-s)X)\colon 0\leqq s\leqq\tfrac{1}{2}\}.$$

We need to analyze the intersection more closely. Let

$$q=0\exp(s_1X)\exp(s_2Y)\exp(s_3X)\in\tilde{\gamma}.$$

Then the tangent space to $\tilde{\Gamma}^-$ at q is spanned by (recall that $s_3=1-s_1-s_2$)

$$\exp(-s_3\operatorname{ad}X)\exp(-s_2\operatorname{ad}Y)X-X=s_2([X,Y]+(2s_3-s_2)[g,[f,g]]),$$
$$\exp(-s_3\operatorname{ad}X)Y-X=2g-s_3[X,Y]-s_3^2[g,[f,g]].$$

The point q also lies on $\tilde{\Gamma}^+$ and a tangent vector to $\tilde{\Gamma}^+$ at q is

$$t=\exp(-t_3\operatorname{ad}Y)X-Y=-2g+t_3[X,Y]-t_3^2[g,[f,g]].$$

In the intersection $t_3=s_1=:s$, $s_2=\frac{1}{2}$ and $s_3=\frac{1}{2}-s$. Thus

$$T_q\tilde{\Gamma}^-\wedge t=A(2g\wedge[X,Y]\wedge[g,[f,g]])$$

where

$$A=\begin{vmatrix}1 & s-\frac{1}{2} & -(s-\frac{1}{2})^2\\ 0 & 1 & \frac{1}{2}-2s\\ -1 & s & -s^2\end{vmatrix}=2s(s-\tfrac{1}{2})\leqq 0.$$

Hence $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ intersect transversally except at the endpoints of $\tilde{\gamma}$ ($s=0$, $s=\frac{1}{2}$). Observe that the endpoints are characterized by the condition that the conjugate point relation $s=t$ ($=\frac{1}{2}$) holds. We need to know which surface has a larger x_3-coordinate. It follows from

$$T_q\tilde{\Gamma}^-\wedge[g,[g,f]]\equiv -2g\wedge[X,Y]\wedge[g,[f,g]]$$

that t and $[g,[g,f]]$ point to the same side of $\tilde{\Gamma}^-$ at q. Observe that $x_1=0$ for points on $\tilde{\gamma}$. Since the coefficient of t at g is negative, the points of $\tilde{\Gamma}^+$ for which $x_1<0$ have a larger x_3-coordinate than those points on $\tilde{\Gamma}^-$. Conversely for $x_1>0$ the x_3-coordinate of points on $\tilde{\Gamma}^-$ is larger. Therefore we define

$$\Gamma^-:=\{0\exp(s_1X)\exp(s_2Y)\exp(s_3X)\colon s_i\geqq 0,\ s_1+s_2+s_3=1,\ s_2\geqq\tfrac{1}{2}\},$$
$$\Gamma^+:=\{0\exp(t_1Y)\exp(t_2X)\exp(t_3Y)\colon t_i\geqq 0,\ t_1+t_2+t_3=1,\ t_2\geqq\tfrac{1}{2}\}.$$

Observe that Γ^- has the Y-trajectory in its boundary and that the X-trajectory lies in the boundary of Γ^+. Define $\Gamma^*:=\Gamma^-\cup\Gamma^+$. It follows from above that $[X,[X,Y]]=2[g,[g,f]]$ always points to one side of $\tilde{\Gamma}^-$, and similarly this holds for $\tilde{\Gamma}^+$. Since $x_1\geqq 0$ for points in Γ^-, $x_1\leqq 0$ for points in Γ^+ and $x_1=0$ exactly on the intersection, it follows that Γ^* is a piecewise defined function $x_3=\psi(x_1,x_2)$.

It is obvious that $\partial\Gamma^*$ consists of all trajectories that are bang-bang with at most one switching, i.e., $\partial\Gamma^*=\partial\Gamma_*$. Graphically, the structure is illustrated in Fig. 5.

By directional convexity it is clear that the whole set R between Γ_* and Γ^* lies in Reach $(0,1)$. We need to show that it lies nowhere else. The points of $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$ that we deleted lie in the interior of R. (We deleted those points on $\tilde{\Gamma}^+$, respectively, $\tilde{\Gamma}^-$ that lie below $\tilde{\Gamma}^-$, respectively, $\tilde{\Gamma}^+$ in the direction of $[X,[X,Y]]$.) But this implies that the endpoints of bang-bang trajectories with more than two switchings lie in the interior of the reachable set. Suppose we have an extremal $XYXY$-trajectory with

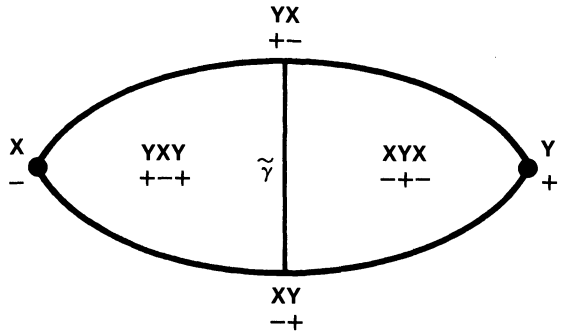

FIG. 5

times s_1, s_2, s_3, and s_4 along the trajectories. Then $s_2 = s_3$ by the conjugate point relation, and thus $s_2 < s_1 + s_3$. By the invariance of the structure of the reachable set it follows that $0 \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) \in \text{int Reach}(0, s_1 + s_2 + s_3)$. (This is a point of the type we deleted!) Hence the trajectories that define Γ^+ and Γ^- are the only extremal trajectories that can lie on the boundary of the reachable set. This proves $R = \text{Reach}(0, 1)$.

Summary. For every time t the time $-t-$ reachable set is a stratified set that is topologically a sphere. Its boundary consists of two hemispheres $\Gamma^*(t)$ and $\Gamma_*(t)$ whose common relative boundary $\partial\Gamma^*(t)$ consists of all points reachable in time t by a bang-bang trajectory with at most one switch. $\Gamma^*(t)$ consists of all bang-bang trajectories with at most two switchings for which the time along the intermediate arc is greater than or equal to the sum of the times of the adjacent arcs. $\Gamma_*(t)$ consists of all trajectories that are concatenations of a bang arc, followed by a singular arc and another bang arc, where the times along these trajectories are free subject to $0 \leqq \text{time} \leqq t$. The stratification of its boundary is given in Figs. 4 and 5.

4.2.2. The general case. We now show that the qualitative structure of the small-time reachable set does not change in the general case. Clearly, some of the arguments will have to be adjusted; for instance, the correct generalization of the arguments using directional convexity now use the integral curves of $[X, [X, Y]]$. However, finding a general version for the explicit computations in the analysis of the bang-bang extremal trajectories is crucial.

We first define Γ_*. Recall that the singular control is given in feedback form as $u = (\delta+1)/(\delta-1)$ and since $\delta < 0$ we have no problems with u hitting the control constraint $|u| = 1$ in small time. Let $\rho = 1/(1-\delta)$, $\rho \in (0, 1)$, and let $S := f + (\delta+1)/(\delta-1)g = \rho X + (1-\rho)Y$, be the singular vector field. Define

$$\Gamma_{-s-} := \{p \exp(s_1 X) \exp(s_2 S) \exp(s_3 X) : s_i \geqq 0, \text{small}\},$$

$$\Gamma_{-s+} := \{p \exp(s_1 X) \exp(s_2 S) \exp(s_3 Y) : s_i \geqq 0, \text{small}\},$$

$$\Gamma_{+s-} := \{p \exp(t_1 Y) \exp(t_2 S) \exp(t_3 X) : t_i \geqq 0, \text{small}\},$$

$$\Gamma_{+s+} := \{p \exp(t_1 Y) \exp(t_2 S) \exp(t_3 Y) : t_i \geqq 0, \text{small}\},$$

$$\Gamma_* := \Gamma_{-s-} \cup \Gamma_{-s+} \cup \Gamma_{+s-} \cup \Gamma_{+s+}.$$

If we replace f by S in Lemma 3, then the statement stays true verbatim for $\Gamma_{\pm s\pm}$ instead of $\Gamma_{\pm 0\pm}$. (The computations are a straightforward though somewhat messy extension of the computation in the "free" nilpotent case and we omit them.) So again Γ_* is a stratified two-dimensional surface; its one-dimensional relative boundary $\partial\Gamma_*$ is made out of the bang-bang trajectories with at most one switching.

LEMMA 4. *For sufficiently small T the points on Γ_* are entry points of* Reach $(p, \leqq T)$ *for* $[X,[X,Y]]$.

Proof. The strategy is the same as in the proof of Lemma 2. We first show that the extremals on Γ_* satisfy the necessary transversality condition for entry points (which are not due to the time constraint). Then we show that Γ_* actually is a graph with the coefficient of the flow of $[X,[X,Y]]$ as dependent variable. As in Lemma 2 this suffices to prove our result.

If γ is any trajectory containing a singular arc then, for sufficiently small time, $\langle\lambda,[X,[X,Y]]\rangle$ will dominate $\langle\lambda,X\rangle$, $\langle\lambda,Y\rangle$, and $\langle\lambda,[X,Y]\rangle$, in particular, it has constant sign. Along the singular arc $\langle\lambda,[X,[X,Y]]\rangle = 2\delta/(1-\delta)\,\langle\lambda,[g,[X,Y]]\rangle$ and the generalized Legendre-Clebsch condition implies that $\langle\lambda,[X,[X,Y]]\rangle$ is positive. This shows that points in Γ_* satisfy the necessary transversality condition. An argument analogous to the one made in the proof of Lemma 1 shows that, in fact, any extremal trajectory for which $\langle\lambda,[X,[X,Y]]\rangle$ is positive has to be of the form *BSB*, that is, we have exhausted all possible candidates. To prove that indeed each point on Γ_* has the entry property, we show again that we can think of Γ_* as the graph of a piecewise defined function $x_3 = \psi(x_0, x_1, x_2)$, where (x_0, x_1, x_2, x_3) are canonical coordinates of the second kind, and x_3 is the coefficient at the flow of $[X,[X,Y]]$. Let us consider, for instance, Γ_{+s-}. It is easier to compute the pullback of the tangent space to the endpoint of the singular arc. It is spanned by X, S, and $\exp(-t_2 \operatorname{ad} S)X$. Note that $S = \rho X + (1+\rho)Y$ and it follows by induction that $\operatorname{ad}^n S(X) = \alpha_n X + \beta_n Y + \gamma_n [X,Y]$ with smooth functions $\alpha_n, \beta_n, \gamma_n$:

$$\begin{aligned}[S, \operatorname{ad}^{n-1} S(X)] &= [\rho X + (1-\rho)Y,\ \alpha_{n-1}X + \beta_{n-1}Y + \gamma_{n-1}[X,Y]] \\ &= \gamma_{n-1}\underbrace{(\rho[X,[X,Y]] + (1-\rho)[Y,[X,Y]])}_{=\rho(\alpha X+\beta Y+\gamma[X,Y])} + f, g \text{ or } [f,g] \text{ terms}.\end{aligned}$$

Also $[S,X] = [\rho X + (1-\rho)Y, X] = 2L_x(\rho)g + (\rho-1)[X,Y]$. Therefore

$$X \wedge S \wedge \exp(-t_2 \operatorname{ad} S)X = (1-\rho)^2 t_2 (1 + O(t_2)) \cdot (f \wedge g \wedge [X,Y]).$$

Now if we take the wedge-product with $[X,[X,Y]]$ pulled back along X, t_3 this yields

$$\begin{aligned}&X \wedge S \wedge \exp(-t_2 \operatorname{ad} S)X \wedge \exp(t_3 \operatorname{ad} X)([X,[X,Y]]) \\ &\quad = (1-\rho)^2 t_2 (1 + O(T)) \cdot (f \wedge g \wedge [f,g] \wedge [X,[X,Y]])\end{aligned}$$

and there are no problems with dominance since t_2 factors. Hence $[X,[X,Y]]$ always points to one side of Γ_{+s-} in the interior. Analogously it follows for the other surfaces. By continuity this also follows for the one-dimensional strata. Straightforward but slightly more tedious computations show also that the projections of the relative interiors of the sets $\Gamma_{\pm s\pm}$ onto (x_0, x_1, x_2)-space are pairwise disjoint. Therefore Γ_* is a graph in canonical coordinates. This proves the lemma. □

The analysis of the bang-bang extremals is more difficult. We start by computing the conjugate point relations. Suppose γ is a $\cdot XYX\cdot$-concatenation starting at p with junctions at p, p_1, p_2, p_3 and times s_1, s_2, s_3 along the respective trajectories. Then we have (the vector fields are evaluated at p_1):

$$\begin{aligned}0 &= X \wedge Y \wedge \left(\frac{\exp(-s_1 \operatorname{ad} X) - 1}{-s_1}\right) Y \wedge \left(\frac{\exp(s_2 \operatorname{ad} Y) - 1}{s_2}\right) X \\ &= X \wedge Y \wedge [X,Y] - \frac{1}{2}s_1 [X,[X,Y]] + O(s_1^2) \wedge -[X,Y] - \frac{1}{2}s_2 [Y,[X,Y]] + O(s_2^2) \qquad (16) \\ &= \frac{1}{2}\sigma(s_1, s_2)(X \wedge Y \wedge [X,Y] \wedge [Y,[X,Y]])|_{p_1}\end{aligned}$$

where $\sigma(s_1, s_2) = -s_1\delta - s_2 + O(2)$.

The equation $\tilde{\sigma}(s_1, s_2) = 0$ has a unique solution $\overline{s_1}(s_2)$ and in general $XYYX$-trajectories only satisfy the necessary conditions of the Maximum Principle if $s_1 \leqq \overline{s_1}(s_2)$. Note that $\varrho(0, s_2) < 0$ and so this is equivalent to $\varrho(s_1, s_2) \leqq 0$. (Using an argument analogous to (9) it can be shown that extremal trajectories do indeed have switchings at $s_1 = \overline{s_1}$, but we will not need this.) Furthermore,

$$0 = X(p_2) \wedge Y(p_2) \wedge \left(\frac{\exp(-s_2 \operatorname{ad} Y) - 1}{-s_2}\right) X(p_1)$$
$$\wedge \left(\frac{\exp(s_3 \operatorname{ad} X) - 1}{s_3}\right) Y(p_3)$$
$$= X \wedge Y \wedge -[X, Y] + \frac{1}{2}s_2[Y, [X, Y]] + \cdots \wedge [X, Y] + \frac{1}{2}s_3[X, [X, Y]] + \cdots$$
$$= \frac{1}{2}\tilde{\sigma}(s_2, s_3)(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])|_{p_2}$$

where $\tilde{\sigma}(s_2, s_3) = -s_2 - s_3\delta + O(T^2)$.

Again the equation $\tilde{\sigma}(s_2, s_3) = 0$ can be solved by $\overline{s_3}(s_2)$, and YXY-concatenations only satisfy the Maximum Principle if $s_3 \leqq \overline{s_3}(s_2)$. Since $\tilde{\sigma}(s_2, 0) < 0$ this is equivalent to $\tilde{\sigma}(s_2, s_3) \leqq 0$.

Therefore we define

$$\tilde{\Gamma}^- = \{p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) : s_i \geqq 0, \text{ small}, s_2 \text{ is free},$$
$$\varrho(s_1, s_2) \leqq 0, \tilde{\sigma}(s_2, s_3) \leqq 0\}.$$

Analogously we must compute the conjugate point relations along a $\cdot YXY\cdot$-concatenation which yields

$$\tilde{\Gamma}^+ := \{p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) : t_1 \geqq 0, \text{ small } t_2 \text{ is free},$$
$$\tau(t_1, t_2) \geqq 0 \Leftrightarrow t_1 \leqq \bar{t}_1(t_2)\, \tilde{\tau}(t_2, t_3) \geqq 0 \Leftrightarrow t_3 \leqq \bar{t}_3(t_2)\}$$

where

$$\tau(t_1, t_2) = -t_1 - t_2\delta + O(T^2), \qquad \tilde{\tau}(t_2, t_3) = -t_2\delta - t_3 + O(T^2)$$

and $\bar{t}_1$ and $\bar{t}_3$ are the solutions of $\tau = 0$ and $\tilde{\tau} = 0$, respectively. $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$ are three-dimensional surfaces with relative boundary made up entirely of bang-bang trajectories with at most one switch.

LEMMA 5. *The surfaces $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ intersect along a two-dimensional surface $\hat{\Gamma}$.*

The intersection of $\hat{\Gamma}$ with the relative boundaries $\partial\tilde{\Gamma}^-$ and $\partial\tilde{\Gamma}^+$ are the following one-dimensional curves:

$$\tilde{\gamma} = \{p \exp(s_1 X) \exp(s_2 Y) : s_2 \geqq 0, \textit{small}, s_1 = \bar{s}_1(s_2)\},$$
$$\gamma = \{p \exp(t_1 Y) \exp(t_2 X) : t_2 \geqq 0, \textit{small}, t_1 = t_1^-(t_2)\}$$

(i.e., the trajectories corresponding to the conjugate points). Away from γ and $\tilde{\gamma}$ the surface entirely lies in the relative interior of $\tilde{\Gamma}^-$, respectively, $\tilde{\Gamma}^+$ and there the intersection is transversal.

Proof. We want to solve the equation

$$p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) = p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y). \tag{17}$$

Suppose a point q in the relative interior of $\tilde{\Gamma}^+$ or $\tilde{\Gamma}^-$ lies on $\hat{\Gamma}$. We claim that (16) can be solved in terms of t_1 and t_2 near q. This follows from the Implicit Function Theorem if the Jacobian with respect to (s_1, s_2, s_3, t_3) is nonsingular at q. If we compute these derivatives and pull the vectors back along X we get

$$\begin{aligned}
&\exp(-s_2 \operatorname{ad} Y)X \wedge Y \wedge X \wedge \exp(s_3 \operatorname{ad} X)Y \\
&\quad = s_2 s_3 \left(X \wedge Y \wedge \left(\frac{\exp(-s_2 \operatorname{ad} Y) - 1}{-s_2} \right) X \wedge \left(\frac{\exp(s_3 \operatorname{ad} X) - 1}{s_3} \right) Y \right) \\
&\quad = \frac{1}{2} s_2 s_3 \cdot \tilde{\sigma}(s_2, s_3)(X \wedge Y[X, Y] \wedge [Y, [X, Y]])|_{p_2 = p \exp(s_1 X) \exp(s_2 Y)}.
\end{aligned}$$

But in int $(\tilde{\Gamma}^-)$ s_2 and s_3 are positive and also $\tilde{\sigma}(s_2, s_3) < 0$ since the conjugate point relation does not hold. So we can solve in terms of t_1 and t_2. This computation shows also that $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$ intersect transversally in int $(\tilde{\Gamma}^+)$ or int $(\tilde{\Gamma}^-)$.

Next we show that points q of this type exist. For that we rewrite both sides of (17) in terms of canonical coordinates of the second kind. A short computation (cf., for instance, [16]) shows that

$$\begin{aligned}
p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) &= p \exp(\tfrac{1}{2} s_1 s_2 (s_1 \delta + s_2 + O(S^2))[Y, [X, Y]]) \\
&\quad \cdot \exp(s_1 s_2 (1 + O(S))[X, Y]) \\
&\quad \cdot \exp((s_2 + O(S^3))Y) \exp((s_1 + s_3 + O(S^3))X), \\
p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) &= p \exp(\tfrac{1}{2} t_2 t_3 (2t_1 + t_3 + t_2 \delta + O(T^2))[Y, [X, Y]]) \\
&\quad \cdot \exp(t_2 t_3 (1 + O(T))[X, Y]) \\
&\quad \cdot \exp((t_1 + t_3 + O(T^3))Y) \exp((t_2 + O(T^3))X)
\end{aligned}$$

where $O(S^k)$ or $O(T^k)$ stand for terms of order greater than or equal to k in the total time, $S = s_1 + s_2 + s_3$, $T = t_1 + t_2 + t_3$, and δ is evaluated at p. Equating coefficients we get

$$\begin{aligned}
&\text{(i)} && s_1 + s_3 + O(S^3) = t_2 + O(T^3), \\
&\text{(ii)} && s_2 + O(S^3) = t_1 + t_3 + O(T^3), \\
&\text{(iii)} && s_1 s_2 (1 + O(S)) = t_2 t_3 (1 + O(T)), \\
&\text{(iv)} && s_1 s_2 (s_1 \delta + s_2 + O(S^2)) = t_2 t_3 (2t_1 + t_3 + t_2 \delta + O(T^2)).
\end{aligned} \tag{18}$$

If we assume that all switching times are comparable, i.e., of order T, then (18(i), (ii)), and

$$\text{(iv')} \quad s_1 \delta + s_2 + O(S^2) = 2t_1 + t_3 + t_2 \delta + O(T^2)$$

can easily be solved for s in terms of t modulo higher-order terms:

$$\begin{aligned}
s_1 &= t_2 + \frac{1}{\delta} t_1 + O(T^2), \\
s_2 &= t_1 + t_3 + O(T^3), \\
s_3 &= -\frac{1}{\delta} t_1 + O(T^2).
\end{aligned} \tag{19}$$

With these times the conjugate point relations cannot hold since

$$\tilde{\sigma}(s_2, s_3) = -s_2 - s_3 \delta + O(T^2) = -t_3 + O(T^2) \tag{20}$$

is negative. So the corresponding point q lies in fact in the relative interior and therefore it is possible to solve for t_3 in terms of t_1 and t_2:

$$t_3 = -t_1 - \delta t_2 + O(T^2). \tag{21}$$

This gives a solution to (18). Note that

$$t_2 = \rho T + O(T^2) = \frac{T}{1-\delta} + O(T^2). \tag{22}$$

As long as (t_1, t_2, t_3) are bounded away from the boundary of the simplex $t_1 + t_2 + t_3 \leqq T$, the times are comparable, these computations are justified, and we get a two-dimensional intersection that we can parametrize by t_1 and t_2. The problem is whether it extends all the way to the boundary. But the equations (19) and (21) are well defined for $t_1 \to 0$ (in a time-slice $t_1 + t_2 + t_3 = T$ it follows that $t_3 \to -\delta t_2 + O(t_2^2)$, i.e., to a limit of order T. By (20) this implies that the two-dimensional surface defined by these functions of (t_1, t_2) stays away from the conjugate point condition $\tilde{\sigma}(s_2, s_3) = 0$. Hence the implicit function theorem is still applicable.) Therefore $\hat{\Gamma}$ extends all the way out to $t_1 = 0$, i.e., to the XY boundary surface.

A precise characterization of $\tilde{\Gamma}^+ \cap \tilde{\Gamma}^- \cap \{p \exp(s_1 X) \exp(s_2 Y)\colon s_i \geqq 0, \text{small}\}$ is possible. Clearly these are points such that $t_1 = 0$, $t_2 = s_1$, $t_3 = s_2$, and $0 = s_3$. Since $(s_1, s_2, 0) \in \operatorname{dom} \tilde{\Gamma}^-$ we have $\varrho(s_1, s_2) \leqq 0$, and since $(0, s_1, s_2) \in \operatorname{dom} \tilde{\Gamma}^+$ we have $\tilde{\tau}(s_1, s_2) \geqq 0$. But in this case $\varrho(s_1, s_2) = \tilde{\tau}(s_1, s_2)$ (cf. (16) and the analogous formula for $\tilde{\tau}$). Therefore $\varrho(s_1, s_2) = 0$, i.e., $s_1 = \overline{s_1}(s_2)$, the conjugate point relation.

This proves that $\tilde{\Gamma}^- \cap \tilde{\Gamma}^+$ extends all the way out to the XY-boundary surface and that the intersection with the XY-surface is the one-dimensional curve $\tilde{\gamma}$ consisting of the conjugate points.

Analogously we can show that (17) can also be solved in terms of s_1 and s_2 in int $(\tilde{\Gamma}^-)$. Using these formulas we can show that $\tilde{\Gamma}^- \cap \tilde{\Gamma}^+$ extends all the way up to the YX-boundary surface and that the intersection of $\tilde{\Gamma}^- \cap \tilde{\Gamma}^+$ with the YX-surface consists of the curve γ. □

Note that in a time-slice $t_1 + t_2 + t_3 = T$ the qualitative geometric structure of $\tilde{\Gamma}^- \cup \tilde{\Gamma}^+$ is exactly as in the free nilpotent case. Only the condition $t_2 = T/2$ is replaced by $t_2 \doteq (1/(1-\delta))T$ (modulo higher terms) which shifts $\hat{\Gamma}$ away from the center. This is illustrated in Fig. 6.

The surface $\hat{\Gamma}$ bisects $\tilde{\Gamma}^+$ and $\tilde{\Gamma}^-$ and only one of the two components has the Y-, respectively, X-trajectory in its boundary. We define Γ^- and Γ^+ to be these components

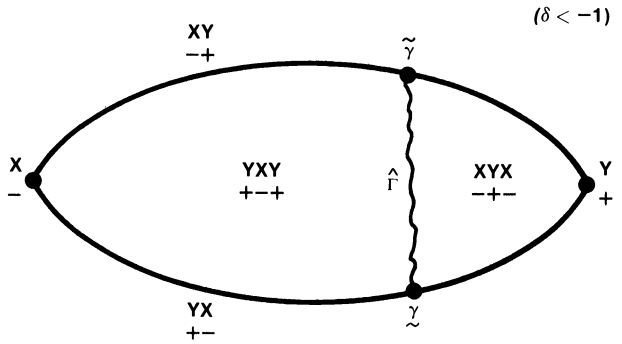

FIG. 6

and let $\Gamma^* = \Gamma^+ \cup \Gamma^-$. It is then clear that Γ^* is a three-dimensional stratified surface whose relative boundary consists of all bang-bang trajectories with at most one switching, i.e., $\partial\Gamma^* = \partial\Gamma_*$.

LEMMA 6. *The points in* Γ^* *are exit points of the small-time reachable set for* $[X, [X, Y]]$.

Proof. It is easy to see (cf. (10)) that, for sufficiently small time, all extremals on $\tilde{\Gamma}^-$ or $\tilde{\Gamma}^+$ satisfy the necessary transversality condition $\langle \lambda, [X, [X, Y]] \rangle \leqq 0$.

We show first that the points that we deleted from $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ are not exit points (see Fig. 7). Let

$$q = p \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) = p \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y)$$

be a point in the relative interior of $\hat{\Gamma}$. $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ intersect transversally. It follows as in the proof of Lemma 2 (cf. (11)) that the XYX- and YXY-surfaces are graphs $x_4 = \psi(x_1, x_2, x_3)$ in canonical coordinates of the second kind with x_4 the coefficient at the flow of $[X, [X, Y]]$. This inherits on $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$. To prove that the parts of $\tilde{\Gamma}^-$ (respectively, $\tilde{\Gamma}^+$) that we delete are not exit points, it suffices to show that these parts lie below $\tilde{\Gamma}^+$ (respectively, $\tilde{\Gamma}^-$) in direction of $[X, [X, Y]]$.

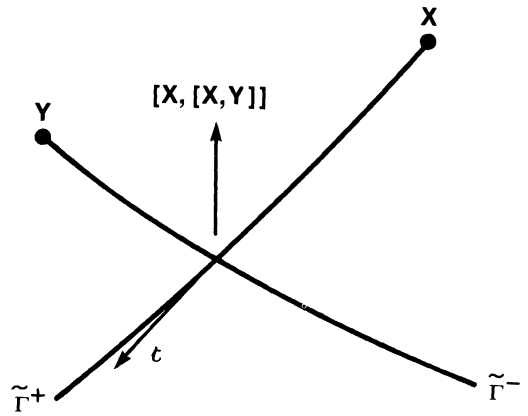

FIG. 7

The tangent space to $\tilde{\Gamma}^-$ at q is spanned by X, $\exp(-s_3 \operatorname{ad} X)Y$ and $\exp(-s_3 \operatorname{ad} X)(\exp((-s_2 \operatorname{ad} Y) - 1)/-s_2)X$. To show that the part of $\tilde{\Gamma}^+$ that we deleted lies below $\tilde{\Gamma}^-$ near q it suffices to show that $[X, [X, Y]]$ and a tangent vector t to $\tilde{\Gamma}^+$ that is oriented toward the sector of $\tilde{\Gamma}^+$ that we deleted point to opposite sides of $T_q\tilde{\Gamma}^-$. We get such a vector t if we lengthen the time along the last Y leg. (We delete the piece that contains in its boundary the trajectories corresponding to the conjugate point relation $t_3 = \bar{t}_3(t_2)$.)

Instead of computing at q we pull back all vectors along X, s_3 and get

$$\exp(+s_3 \operatorname{ad} X)(T_q\tilde{\Gamma}^-) \wedge \exp(+s_3 \operatorname{ad} X)[X, [X, Y]]$$

$$= \left(X \wedge Y \wedge \left(\frac{\exp(-s_2 \operatorname{ad} Y) - 1}{-s_2} \right) X \wedge \exp(s_3 \operatorname{ad} X)[X, [X, Y]] \right)$$

$$= -(\delta + O(T))(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])|_{p_2 = p \exp(s_1 X) \exp(s_2 Y)},$$

$$\exp(s_3 \operatorname{ad} X)(T_q\tilde{\Gamma}^-) \wedge \exp(s_3 \operatorname{ad} X)\, Y$$
$$= s_3\left(X \wedge Y \wedge \left(\frac{\exp(-s_2 \operatorname{ad} Y)-1}{-s_2}\right) X \wedge \left(\frac{\exp(s_3 \operatorname{ad} X)-1}{s_3}\right) Y\right)$$
$$= \frac{1}{2}\, s_3 \tilde{\sigma}(s_2, s_3)(X \wedge Y \wedge [X, Y] \wedge [Y, [X, Y]])|_{p_2}.$$

But q is a point in $\hat{\Gamma}$, and $\hat{\Gamma}$ lies entirely in the relative interior of $\tilde{\Gamma}^-$ except for the obvious boundary curves $\tilde{\gamma}$ and γ. In particular (cf. also the proof of Lemma 5) the conjugate point relation $s_3 = \bar{s}_3(s_2)$ does not hold, or equivalently, $\tilde{\sigma}(s_2, s_3) < 0$. So these wedge-products have opposite signs, which proves our claim. This also implies that the portion of $\tilde{\Gamma}^-$ that we delete lies below $\tilde{\Gamma}^+$, and since there is no other intersection this holds for all the points we deleted.

The stratified sets Γ^* and Γ_* enclose a region R that lies in the small-time reachable set. In particular, the portions of $\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ that we deleted therefore lie in the interior of the reachable set. Since these pieces contain the trajectories corresponding to the conjugate points $t_3 = \bar{t}_3(t_2)$ and $s_3 = \overline{s_3}(s_2)$, it follows that no bang-bang trajectory with more than two switchings lies in the boundary of the small-time reachable set. Hence the points in Γ^* are the only possible exit points of the small-time reachable set for $[X, [X, Y]]$. It follows from the construction of Γ^- and Γ^+ that Γ^* is also a graph. Again, the projections onto (x_1, x_2, x_3)-space are disjoint. Therefore it follows as in Lemma 2 that the points on Γ^* have the exit property for sufficiently small time. □

Finally, Γ^* and Γ_* do not intersect in their relative interiors. It is now clear how the *small-time reachable* set looks: It is the set of points enclosed by the two three-dimensional stratified surfaces Γ^* and Γ_*. Γ^* consists of bang-bang trajectories with at most two switchings such that modulo higher-order terms

$$t_1 + \delta t_2 + t_3 \leqq 0 \tag{23}$$

if t_1, t_2, and t_3 are the consecutive times along a YXY arc and

$$s_1\delta + s_2 + s_3\delta \geqq 0 \tag{24}$$

if s_1, s_2, s_3 are consecutive times along XYX. Γ_* consists of all concatenations of a bang arc, followed by a singular arc and another bang arc where the time along the trajectories is free. Γ^* and Γ_* have a common relative boundary C consisting of all trajectories that are bang-bang with at most one switching. For sufficiently small-time T a time-slice of the reachable set has exactly the same qualitative geometric structure as for the free nilpotent system (13). Furthermore, if $\delta(\cdot)$ is an integral curve of $[X, [X, Y]]$ such that $\delta(t_1)$ and $\delta(t_2)$, $t_1 < t_2$, lie in the small-time reachable set, then so does the whole curve $\delta(t)$, $t_1 \leqq t \leqq t_2$. The points on Γ_* are entry points for $[X, [X, Y]]$; the points on Γ^* are exit points.

Remark. We emphasize that the result is not what might be expected intuitively. From dimensionality we could conjecture the occurrence of bang-bang trajectories with two switchings, respectively, *BSB* trajectories in the boundary of the small-time reachable set. Also, this is essentially what was partially known from earlier results. However, we see no simple reasoning that could explain why, in fact, *some* of these *bang-bang trajectories with two switchings are not a part of the boundary.* This is only revealed by our analysis.

4.3. Time-optimal control in dimension three. Our results have immediate implications on time-optimal control in dimension three. Suppose the triples $(g, [f, g], [f+g, [f, g]])$ and $(g, [f, g], [f-g, [f, g]])$ consist of independent vectors at a point p in $\mathbb{R}^3$.

Equivalently, suppose that the constant controls $u \equiv +1$ and $u \equiv -1$ are not singular. If we augment the three-dimensional system Σ to a four-dimensional system $\hat{\Sigma}$ by introducing time as a coordinate, $\dot{x}_0 = 1$, $x_0(0) = 0$, i.e.,

$$\hat{f} = \begin{pmatrix} 1 \\ f \end{pmatrix}, \qquad \hat{g} = \begin{pmatrix} 0 \\ g \end{pmatrix},$$

then if a Σ-trajectory $x(\cdot) : [0, T] \to \mathbb{R}^3$ steering p to q is time-optimal, the augmented trajectory $\hat{x}$ lies in the boundary of the reachable set from p. The augmented system $\hat{\Sigma}$ satisfies our assumptions (A) and (B), and therefore time-optimal trajectories are bang-bang with at most two switchings or concatenations of a bang-arc, followed by a singular arc and one more bang arc. Under additional assumptions this result was obtained earlier by Bressan [4], who studied only trajectories emanating from an equilibrium point of f and by Sussmann [22] and Schättler [17] who both assumed in addition also that f, g and $[f, g]$ were independent. Our analysis shows that the vector field f is irrelevant and we do not have to make any assumptions about it. Our results are also more precise in the sense that we can exclude the optimality of those bang-bang trajectories with two switchings that violate (23) (respectively, (24)) in the bang-bang singular case. We summarize in the following corollary.

COROLLARY. *Suppose the vector fields* g, $[f, g]$ *and* $[f+g, [f, g]]$ *are independent near a reference point* $p \in \mathbb{R}^3$. *Write*

$$[f-g, [f, g]] = ag + b[f, g] + c[f+g, [f, g]]$$

and assume that c *does not vanish. Then we have in small time*:

(i) *If* $c > 0$, *then time-optimal trajectories are bang-bang with at most* 2 *switches.*

(ii) *If* $c < 0$, *then time-optimal trajectories are bang-bang with at most two switchings or are concatenations of a bang arc, a singular arc, and another bang arc. Time-optimal* XYX (*respectively*, YXY) *concatenations satisfy modulo higher-order terms*

$$c(s_1 + s_3) + s_2 \geqq 0 \qquad (\textit{resp.}, t_1 + t_3 + ct_2 \leqq 0)$$

where s_1, s_2, s_3 (*respectively*, t_1, t_2, t_3) *are the consecutive times along the bang arcs.*

5. A brief outlook to higher dimensions. We have outlined a general method to determine the structure of the small-time reachable sets and proved its effectiveness in nondegenerate cases in small dimensions. One of the difficulties that will become more and more prominent in higher dimensions is that the necessary conditions of the Maximum Principle will not restrict the class of extremal trajectories sufficiently enough to give the candidates for Γ^* and Γ_*.

Under assumptions (A) and (B) in dimension four, we could overcome this problem by taking a corresponding "free" nilpotent system of the same dimension as a guide. We do not expect this to happen in general. In fact, for the five-dimensional system Σ, where we assume that f, g, $[f, g]$, $[f, [f, g]]$, and $[g, [f, g]]$ are independent, the small-time reachable set has extremal trajectories in its boundary that do not appear in the analogous five-dimensional free nilpotent system. The reason for this lies in a qualitatively different behavior of the singular controls, specifically, in the fact that singular controls can now hit the control constraint $|u| = 1$ and may have to be terminated. Nevertheless, the free nilpotent system contains most of the information about the small-time reachable set, though it does not characterize it completely. To be more specific, we will briefly describe (without proofs) the structure of the reachable set for the free nilpotent system in dimension five and how the general case differs from it.

We take as our model:

$$\dot{x}_0 = 1, \quad \dot{x}_1 = u, \quad \dot{x}_2 = x_1, \quad \dot{x}_3 = x_2, \quad \dot{x}_4 = \tfrac{1}{2}x_1^2.$$

It is no problem whatsoever to carry out the analysis within our technique as in the construction in § 4.2.1. Now the reachable set is convex in direction of $(0, 0, 0, 0, 1)^T = [g, [g, f]]$ and Γ^*, respectively, Γ_* will consist of those trajectories that are exit, respectively, entry points.

It follows from the generalized Legendre-Clebsch condition that Γ_* contains concatenations with singular arcs, whereas Γ^* will consist of bang-bang trajectories only. Singular controls are constant, but now they can take on any value in $[-1, 1]$.

Let $\Gamma_* = \Gamma_{-u-} \cup \Gamma_{-u+} \cup \Gamma_{+u-} \cup \Gamma_{+u+}$, where

$$\Gamma_{-u-} := \{0 \exp(s_1 X) \exp(s_2(f+ug)) \exp(s_3 X) : s_i \geqq 0,\ s_1 + s_2 + s_3 = 1,\ u \in [-1, 1]\},$$

etc. (By the invariance property of the reachable set we can restrict to the time-slice $T = 1$.) The points on Γ_* are precisely the ones that minimize the coordinate x_4.

For a fixed value u_0 of the singular control, $-1 < u_0 < +1$, the qualitative structure of $\Gamma_{*,u_0} = \Gamma_*$ restricted to values $u = u_0$ is precisely as in 4.2.2, Fig. 4 (see Fig. 8).

For $u_0 = +1$, $\Gamma_{-u-} \upharpoonright u = 1$ reduces to Γ_{-+-} and all other strata become trivial whereas for $u_0 = -1$, $\Gamma_{+u+} \upharpoonright u = -1 = \Gamma_{+-+}$ and the remaining strata are trivial. For each of these two-dimensional surfaces (u_0 fixed) the relative boundary consists of all bang-bang trajectories with at most one switching. The surfaces Γ_{*,u_0} themselves interpolate between Γ_{+-+} for $u_0 = -1$ and Γ_{-+-} for $u_0 = 1$. Topologically Γ_* is a stratified sphere

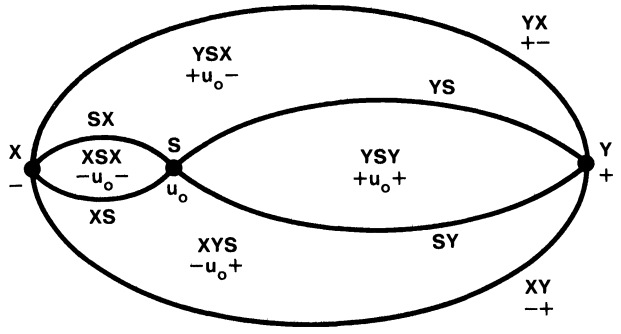

FIG. 8

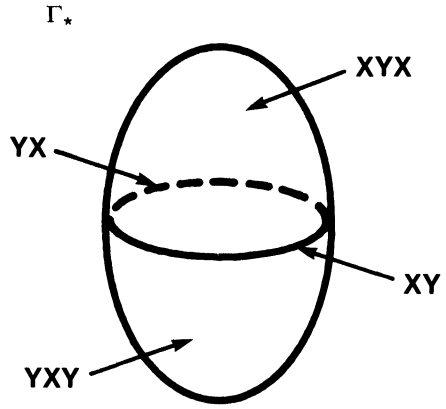

FIG. 9

with $\partial\Gamma_* = \Gamma_{-+-} \cup \Gamma_{+-+}$, i.e., all bang-bang trajectories with at most two switchings (see Fig. 9).

The surface Γ^* consists of bang-bang trajectories analogous to the bang-bang singular case in dimension four. Now

$$\tilde{\Gamma}^- = \{0 \exp(s_1 X) \exp(s_2 Y) \exp(s_3 X) \exp(s_4 Y) \colon s_i \geqq 0,\ s_1 + s_2 + s_3 + s_4 = 1,\ s_1 \leqq s_3,\ s_4 \leqq s_2\text{-conjugate point relations}\},$$

$$\tilde{\Gamma}^+ = \{0 \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) \exp(t_4 X) \colon t_i \geqq 0,\ t_1 + t_2 + t_3 + t_4 = 1,\ t_1 \leqq t_3,\ t_4 \leqq t_2\text{-conjugate point relations}\}.$$

$\tilde{\Gamma}^-$ and $\tilde{\Gamma}^+$ intersect in a two-dimensional surface $\hat{\Gamma}$, which consists of those trajectories for which

$$(s_1 + s_3)^2 - (s_1 + s_3) + 2 s_2 s_3 = 0,$$

respectively,

$$(t_1 + t_3)^2 - (t_1 + t_3) + 2 t_2 t_3 = 0.$$

The intersection is transversal except at those points that lie on the relative boundary of $\tilde{\Gamma}^-$ or $\tilde{\Gamma}^+$. These points are again characterized by the conjugate point relation

$$\hat{\Gamma} \cap \Gamma_{-+-} = \{0 \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) \exp(t_4 X) \colon t_1 = 0,\ t_4 = t_2\},$$

$$\hat{\Gamma} \cap \Gamma_{+-+} = \{0 \exp(t_1 Y) \exp(t_2 X) \exp(t_3 Y) \exp(t_4 X) \colon t_1 = t_3,\ t_4 = 0\}.$$

We define Γ^- (respectively, Γ^+) as the component of $\tilde{\Gamma}^-$ ($\tilde{\Gamma}^+$) containing the YX-curve $= \{0 \exp(s_2 Y) \exp(s_3 X) \colon s_i \geqq 0,\ s_2 + s_3 = 1\}$ (respectively, the XY-curve) in its boundary. Then $\Gamma^* := \Gamma^- \cup \Gamma^+$ consists precisely of those points that maximize x_4 on the reachable set. Note that topologically Γ^* also is a stratified sphere with $\partial\Gamma^* = \Gamma_{-+-} \cup \Gamma_{+-+}$, the set of all bang-bang trajectories with at most two switchings (see Fig. 10).

The key fact here is that it is still obvious that $\partial\Gamma^*$ and $\partial\Gamma_*$ match up. They are identical. It is therefore clear that Reach $(0, 1)$ is the set of all points that lie between Γ^* and Γ_*.

It is precisely this simple reasoning that breaks down in the general case. The cause for this lies in the structure of the singular controls. The analysis of the bang-bang trajectories carries over to the general case with only one minor change in the structure. Whereas in the free nilpotent system the two curves $\hat{\Gamma} \cap \Gamma_{+-+}$ and $\hat{\Gamma} \cap \Gamma_{-+-}$ both have points corresponding to the X- and Y-trajectories as endpoints, this need no longer be true: $\hat{\Gamma} \cap \Gamma_{+-+}$ is a curve starting at $0 \exp(1 \cdot Y)$ but which in general no longer ends in $0 \exp(1 \cdot X)$ but rather on a point in the XY-curve (respectively, YX-curve). This distortion is due to the presence of fourth-order brackets. One possible case is depicted in Fig. 11.

Still the relative boundary of Γ^* consists of all bang-bang trajectories with at most two switchings. The structure breaks down in the analysis of the singular surface Γ_* for u near ± 1. The reason is that in the presence of fourth-order brackets the singular controls are no longer constant, and thus the analogue of Γ_{*,u_0} for $u_0 = -1$ does not reduce to Γ_{+-+}, i.e., to bang-bang trajectories with two switchings. For instance, it may not be at all possible to start a singular control with $u_0 = -1$. This is the case if $\dot{u} < 0$ at $u_0 = -1$, which happens under generic assumptions on fourth-order brackets.

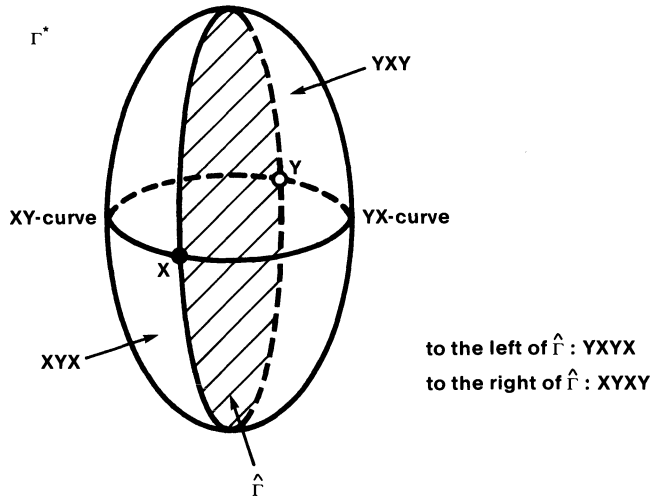

FIG. 10

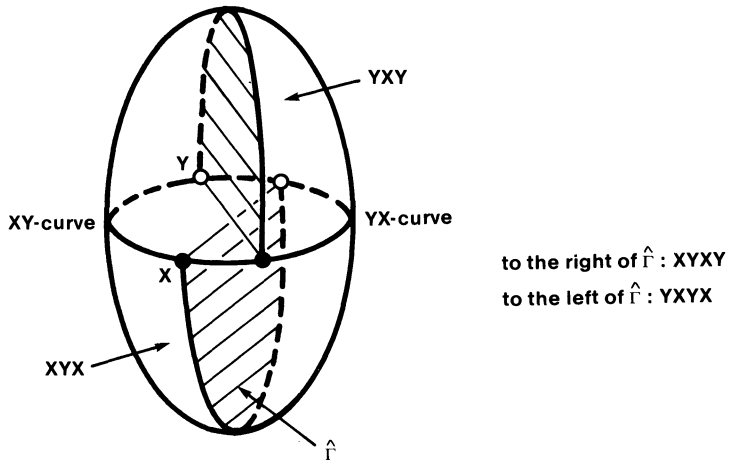

FIG. 11

For the same reason, singular controls with u_0 close to ± 1 may have to be terminated when they become one in absolute value. If the singular control becomes saturated (i.e., hits the constraint and cannot be continued) then this determines the subsequent structure of the trajectory and it is easy to see that concatenations such as *BSBB* or *BBSB*, which are not present in the free nilpotent system, come into play. Therefore Γ_* has trajectories in its relative boundary that contain singular arcs. The main challenge in applying our technique to higher dimensions seems to be finding a way to decide whether structurally different trajectories, such as a bang-bang trajectory, and a concatenation that contains a singular arc steer a system to the same point. Once $\partial\Gamma^*$ and $\partial\Gamma_*$ can be identified, it is clear that the set they enclose is the small-time reachable set.

Note, however, that this structural instability only happens near $\Gamma_{*,-1}$ and $\Gamma_{*,+1}$. The structure of most of the trajectories in the boundary is still the same as in the free nilpotent systems. And it is intuitively clear that the structure of the exceptional trajectories will come up in a higher-dimensional nilpotent system. Therefore, in our

view, the study of the structure of the reachable sets for nilpotent systems will be the key to the general problem.

6. Summary. We have described an approach to determining the qualitative structure of the small-time reachable set in a nondegenerate situation. It is a nontrivial extension of a construction done by Lobry in dimension three. In dimension four we succeed completely in determining the small-time reachable set. For higher dimensions obstacles still have to be overcome. However, they do not lie in the general structure of our approach, but in the fact that too little is known about the structure of extremal trajectories in higher dimensions. For instance, in the five-dimensional case, what is the precise structure of extremal trajectories that contain a saturated singular arc? For dimensions six and beyond, the crucial new ingredient appears to be the incorporation of chattering arcs, another structure of extremal trajectories about which little is still known.

SPECTRAL ASSIGNABILITY FOR DISTRIBUTED PARAMETER SYSTEMS WITH UNBOUNDED SCALAR CONTROL*

RICHARD REBARBER†

Abstract. This article studies a class of control systems in a Hilbert space H given by $\dot{x}(t) = Ax(t) + bu(t)$, where A generates a holomorphic semigroup on H, $u(t)$ is a scalar control, and the control input b is possibly unbounded. Many systems with boundary or point control can be represented in this form. The author considers the question of what eigenvalues $\{\alpha_k\}_{k\in I}$ the closed-loop system can have when $u(t)$ is a feedback control. Shun-Hua Sun's condition on $\{\alpha_k\}_{k\in I}$ [*SIAM J. Control Optim.*, 19 (1981), pp. 730-743] is generalized to the case where b is unbounded but satisfies an admissibility criterion; this condition is generalized further when unbounded feedback elements are allowed. These results are applied to a structurally damped elastic beam with a single point actuator. Similar techniques also prove a spectral assignability result for a damped elastic beam with a moment control force at one end, even though the associated input element is not admissible in the appropriate sense.

Key words. distributed parameter systems, spectral determination, feedback control, holomorphic semigroups, elastic beam

AMS(MOS) subject classifications. 93C20, 93B55, 93B60

1. Introduction.

In this paper we consider the eigenvalue specification problem for a class of distributed parameter systems with scalar control and unbounded input element. We consider the question of what closed-loop eigenvalues can be realized by a feedback control. Sun answers the question completely in [11] in the case where the input element and feedback element are bounded. We will generalize Sun's sufficient condition to the case where the input element is "admissible" in the sense given in [4], but is not necessarily bounded. We also consider a class of systems where the input element is not even admissible. We consider feedback elements that are not necessarily bounded, allowing us to further relax the conditions on the closed-loop eigenvalues. Furthermore, we give a formula for the closed-loop eigenvectors in terms of the open-loop eigenvectors, and a formula for the feedback element in terms of the dual basis to the open-loop eigenvectors. We will apply these results to two examples involving a structurally damped elastic beam.

The systems we consider are of the form

$$\dot{x}(t) = Ax(t) + bu(t), \qquad x(0) = x_0, \tag{1.1}$$

where $x(t) \in H$, which is a Hilbert space with norm $\|\cdot\|$, and $u(t)$ is a scalar control. We assume that A is a closed operator on H which has eigenvectors $\{\varphi_k\}_{k\in I}$ with associated eigenvalues $\{\lambda_k\}_{k\in I}$, and that $\{\varphi_k\}_{k\in I}$ is a Riesz basis for H, i.e., every $x \in H$ can be written as $\sum_{k\in I} x_k\varphi_k$, and there exists m, $M > 0$ such that

$$m\|x\|^2 \leqq \sum_{k\in I} |x_k|^2 \leqq M\|x\|^2.$$

Let the dual of H be represented by a Hilbert space H' (which can be chosen to be H, although this might not be convenient), and let $\langle\cdot,\cdot\rangle$ be the duality relation on $H' \otimes H$. Then the norm in H' is given by $\|y\|_* = \sup\{\langle y, x\rangle / \|x\|\}_{x\in H}$. For $h \in H'$ we

† University of Nebraska, Lincoln, Nebraska 68588.

denote the bounded linear functional $x \to \langle h, x\rangle$ by h^*, and any bounded linear functional on H has such a representation. Let $\{\psi_k\}_{k\in I}$ be the Riesz basis of H' which is biorthogonal to $\{\varphi_k\}_{k\in I}$; i.e., $\langle \psi_k, \varphi_j\rangle = \delta_{j,k}$.

The input element b is a one-dimensional "admissible input element" which can be represented by

$$b = \sum_{k\in I} b_k \varphi_k. \tag{1.2}$$

When b is in H, b_k is given by $\langle \psi_k, b\rangle$, and this will be generalized later. We will use a modification of the definition of admissible input given by Ho and Russell in [5], which we state in the next section. Many systems with boundary or point control can be put into the form (1.1) with an input element that is admissible but unbounded [4], [7], [10].

In this paper we are interested in the case where the eigenvalues lie between two curves of the form

$$\Gamma_a := \{a \pm ix\, e^{\pm i\sigma} | x \in (0, \infty)\}, \tag{1.3}$$

where $\sigma \in [0, \pi/2)$, and σ is fixed for the remainder of this paper. If $\sigma > 0$ A generates a holomorphic semigroup of operators $S(t)$ for t in

$$\tilde{\Omega} := \{z \in \mathbb{C} | |\arg(z)| < \sigma\}, \tag{1.4}$$

and $S(t)$ is strongly continuous on $\bar{\tilde{\Omega}}$. If $\sigma = 0$, A generates a group of operators for $t \in (-\infty, \infty)$. The semigroup (or group) generated by A is given by

$$S(t)\left(\sum_{k\in I} x_k \varphi_k\right) = \sum_{k\in I} x_k\, e^{\lambda_k t} \varphi_k. \tag{1.5}$$

In this paper we consider the following problem for the system (1.1).

Eigenvalue Specification Problem. Given a set of complex numbers $\{\alpha_k\}_{k\in I}$, can a linear functional h^*: $\mathcal{D}(h^*) \subset H \to \mathbb{R}$ be found so that the feedback control $u(t) = h^* x(t)$ leads to a closed-loop system which has eigenvalues at $\{\alpha_k\}_{k\in I}$? If possible, find h^* and the closed-loop eigenvectors $\{\chi_k\}_{k\in I}$.

In this paper we will consider a class of linear functionals h^* which are "admissible," as described in § 2.

For the problem with bounded input (i.e., $b \in H$) and bounded feedback control (i.e., $h \in H'$) the existence question is answered completely for some of the systems described above by Sun [11]. He proves the following necessary and sufficient condition that there exists a bounded functional h^*: $H \to \mathbb{R}$ such that $A + bh^*$ has eigenvalues at $\{\alpha\}_{k\in I}$:

$$\sum_{k\in I} |(\alpha_k - \lambda_k)/b_k|^2 < \infty, \tag{1.6}$$

when $b_j \neq 0$ for all $j \in I$. The restriction that b must be a bounded input rules out many interesting cases, including boundary control. Furthermore, this result is restricted to bounded feedback elements h^*, which is why we cannot move the closed-loop eigenvalues uniformly away from the original eigenvalues. In [11], no formulas are given for the eigenvectors of the closed-loop operator, although they can be found by solving an infinite-dimensional linear system of equations.

Sun's result, like most spectral determination results [2], [9], [12], and this paper, requires a spacing condition on $\{\lambda_k\}_{k\in I}$, so that the eigenvalues are not too close to each other asymptotically (see condition (6) in Definition 3 in the Appendix). In [4], Ho also considers systems with an admissible input element and describes a different

kind of generalization of Sun's condition, where the spacing conditions are relaxed and (1.6) is modified accordingly.

In [2], [7], [9], and [12], eigenvalue specification is studied using canonical forms for (1.1). In [7], [9], and [12], $\{\lambda_k\}_{k\in I}$ is the zero set of a *cardinal function*, which is an infinite-dimensional generalization of a characteristic polynomial of a finite-dimensional system. In [9] and [12] the cardinal functions are entire functions. In this paper we will be using the definition of a cardinal function given in [7], where the cardinal function is a meromorphic function, which is applicable to more cases than entire cardinal functions. This definition is given in the Appendix to this paper. We need to consider meromorphic cardinal functions for some systems because there is no entire function with zeros at $\{\lambda_k\}_{k\in I}$ which have appropriate growth conditions in the right half of the complex plane. Classes of cardinal functions are constructed in [8]. For the remainder of the paper, we will insist on the following assumption.

Assumption A. $\{\lambda_k\}_{k\in I}$ is the zero set of some cardinal function p.

In [7] we used canonical forms to consider the cases where $\{\alpha_k\}_{k\in I}$ is the zero set of a cardinal function with the same poles as p and either

(I) b is a bounded input, $b_k \neq 0$ for all $k \in I$, and (1.6) holds, or

(II) There exists $m, M > 0$ such that

$$m < b_k < M. \tag{1.7}$$

(Note that condition (II) includes no other restrictions on $\{\alpha_k\}_{k\in I}$.)

In both cases (I) and (II) we find a formula for an h^* such that $A+bh^*$ has eigenvalues at $\{\alpha_k\}_{k\in I}$, and give a formula for the closed-loop eigenvectors. In case (I), h^* is a bounded feedback element, and in case (II), h^* is an admissible feedback element, as defined in § 2. We also use the canonical form in [7] to prove a control spillover results for a finite-dimensional approximation to the infinite-dimensional feedback control in cases (I) and (II). In this paper we will generalize those formulas and study their applicability in detail. Those generalizations follow: let

$$J := \{j \in I \,|\, b_j \neq 0\}, \qquad K := \{k \in I \,|\, b_k = 0\}, \tag{1.8}$$

and assume that

$$\alpha_k = \lambda_k \quad \text{for } k \in K. \tag{1.9}$$

The closed-loop eigenvectors $\{\chi_k\}_{k\in I}$ associated with $\{\alpha_k\}_{k\in I}$ are

$$\begin{aligned} \chi_k &= (1/p'(\lambda_k)b_k) \sum_{j\in J} [p(\alpha_k)b_j/(\alpha_k - \lambda_j)]\varphi_j \quad \text{for } k \in J, \\ \chi_k &= \varphi_k \quad \text{for } k \in K. \end{aligned} \tag{1.10}$$

Under certain conditions, we will show that these form a Riesz basis for H. The basis for H' which is biorthogonal to $\{\chi_k\}_{k\in I}$ is defined as follows:

$$\begin{aligned} h_j &= b_j p'(\lambda_j) \sum_{k\in J} \{q(\lambda_k)/[q'(\alpha_j)(\lambda_k - \alpha_j)b_k p'(\lambda_k)]\}\psi_k \quad \text{for } j \in J, \\ h_j &= \psi_j \quad \text{for } j \in K, \end{aligned} \tag{1.11}$$

where q is a cardinal function with zeros at $\{\alpha_k\}_{k\in I}$ and the same poles as p. The feedback element will be given by

$$h^* = \sum_{j\in J} p(\alpha_j)h_j/b_j p'(\lambda_j). \tag{1.12}$$

In this paper we will work with these equations directly, without reference to canonical forms. We will show that these formulas solve the Eigenvalue Specification

Problem under conditions much less restrictive than conditions (I) and (II). In the next section we give the definitions of "admissible input element" and "admissible feedback element" which we will be using. In § 3 we will state and prove control results related to formulas (1.10)–(1.12) for systems with a general admissible input, and for systems with a class of input elements which are not even admissible. In § 4 we will describe in detail an example of a damped elastic beam with two kinds of controls. We apply our results to an example where the control is a single point actuator, and we study how the placement of the actuator affects the kind of eigenvalue specification results we obtain. In the other example, the control is a moment force at one end of the beam. In this case the input element is not even admissible, but we show that we can still use the above formulas to solve the Eigenvalue Specification Problem.

2. Definitions.

Admissible input element. We start by identifying the set of admissible controls $u(t)$: Since $S(t)$ generates a holomorphic semigroup, we will consider the system (1.1) along any ray

$$l_\theta = \{x e^{i\theta} \mid x \in [0, \infty)\} \tag{2.1}$$

for $\theta \in [-\sigma, \sigma]$. The set of admissible controls will be

$$\mathcal{U} := \bigcup_{-\sigma \leqq \theta \leqq \sigma} L^2_{\text{loc}}[l_\theta].$$

We will be using a modification of the definition of admissible input element given in Ho and Russell [5], which is the same modification used by Ho in [4]. To motivate this, we must first decide which space b should belong to.

When $z_0 \in \mathcal{D}(A)$, $S(t)z_0$ is an element of H for all $t \in \tilde{\tilde{\Omega}}$ and is the solution in H of

$$\dot{z}(t) = Az(t), \qquad z(0) = z_0. \tag{2.2}$$

If $z_0 \in H$, $z(t) = S(t)z_0$ is an element of H, and is the solution of (2.2) in a generalized sense, but (2.2) is no longer an equation in H. A can be extended to an operator on $\mathcal{H} := \mathcal{D}(A^*)'$ as follows:

$$\hat{A}\colon H \to \mathcal{H}\colon \quad \langle \hat{A}z, \eta \rangle := \langle z, A^*\eta \rangle \quad \forall \eta \in \mathcal{D}(A^*), \tag{2.3}$$

where A^* is the adjoint of A when the inner product $\langle \cdot, \cdot \rangle$ is used. In this context we think of $\mathcal{D}(A^*)$ as a Hilbert space with the graph norm, and $\mathcal{D}(A^*) \subset H'$. We think of $\mathcal{H}$ as a Hilbert space with the norm induced by the duality pairing $\langle \cdot, \cdot \rangle$. Therefore, (2.2) is an equation in $\mathcal{H}$. If we want (1.1) to be an equation in $\mathcal{H}$, we must at least require that b is an element of $\mathcal{H}$, i.e., b is a bounded linear functional on the Hilbert space $\mathcal{D}(A^*)$.

Not all $b \in \mathcal{H}$ will lead to a dynamical system in H. If $b \in H$, $t \in l_\theta$, and $u(t) \in L^2_{\text{loc}}[l_\theta]$, the solution of (1.1) with $x_0 = 0$ is

$$B(t)u = \int_{[0,t]} (S(t-s)b)u(s)\, ds,$$

where $[0, t]$ is the straight line segment from the origin to t. A generalization of this to the case where $b \in \mathcal{H}$ is

$$\langle B(t)u, y \rangle = \int_{[0,t]} \langle b, S(t-s)^* y \rangle u(s)\, ds \quad \text{for every } y \in \mathcal{D}(A^*). \tag{2.4}$$

DEFINITION 1. $b \in \mathcal{H}$ is an admissible input element on l_θ if $B(t)$ given by (2.4) is a strongly continuous family of bounded operators from $L^2_{\text{loc}}[l_\theta]$ into H. b is admissible on the wedge $\tilde{\tilde{\Omega}}$ (cf. (1.3)) if it is admissible on l_θ for all $\theta \in [-\sigma, \sigma]$.

If b is admissible on l_θ, $x(t)=S(t)x_0+B(t)u$ is a generalized solution of (1.1) in the sense that $x(t)\in H$, and $x(0)=x_0$, $\dot{x}(t)\in\mathscr{H}$, and $\dot{x}(t)=\hat{A}x(t)+bu(t)$ in $\mathscr{H}$ for all $t\in l_\theta$.

If $x_0=\sum_{k\in I}x_{0,k}\varphi_k$ and b is given by (1.2), the generalized solution of (1.1) is

$$x(t)=\sum_{k\in I}\left(x_{0,k}\,e^{\lambda_k t}+b_k\int_{[0,t]}e^{\lambda_k(t-s)}u(s)\,ds\right)\varphi_k. \tag{2.5}$$

In this case, b is admissible on l_θ if and only if $x(t)$ given by (2.5) is an element of H whenever $u\in L^2_{\mathrm{loc}}[l_\theta]$.

An easily checked sufficiency condition for admissibility is given in [5]. It involves checking whether a certain measure is a Carleson measure. For instance, using this method it is easy to see that, for the systems under consideration in this paper, an input element b with $\{b_k\}_{k\in I}\in l_\infty$ is admissible.

Admissible feedback elements. Let $h^*\colon H\to\mathbb{R}$ be a linear functional with domain $\mathscr{D}(h^*)$. For any $x\in\mathscr{D}(h^*)$, we can define $\hat{A}x+bh^*x$ (cf. (2.3)) as an element of $\mathscr{H}$. We will define the domain of $A+bh^*$ as

$$\mathscr{D}(A+bh^*):=\{x\in\mathscr{D}(h^*)\,|\,\hat{A}x+bh^*x\in H\}. \tag{2.6}$$

For $x\in\mathscr{D}(A+bh^*)$, we define

$$(A+bh^*)x=\hat{A}x+bh^*x. \tag{2.7}$$

DEFINITION 2. h^* is an admissible feedback element on l_θ if

(1) $\mathscr{D}(A+bh^*)$ is dense in H.

(2) There exists A_h, an extension of $A+bh^*$, such that A_h is the infinitesimal generator of a strongly continuous semigroup $S_h(t)$ for $t\in l_\theta$.

(3) For all $x\in H$ and $T\in l_\theta$,

$$\|h^*S_h(t)x\|_{L^2[0,T]}<\infty.$$

h^* is an admissible feedback element on $\tilde{\Omega}$ if h^* is admissible on l_θ for all $\theta\in[-\sigma,\sigma]$.

The third condition in this definition guarantees that the feedback control $u(t)=h^*x(t)$ is admissible. The other two conditions seem to be minimum requirements for the closed-loop operator $A+bh^*$ to be useful. Unbounded feedback elements are considered in [3], where conditions are given under which an unbounded feedback leads to a closed-loop operator with the properties given in Definition 2. In general it will be hard to verify the conditions in Definition 2. In this paper we will verify that h^* is an admissible feedback element by determining the basis properties of the closed-loop eigenvectors χ_k given in (1.12). For instance, it is easy to prove the following proposition, whose proof we omit.

PROPOSITION 1. *Suppose* $\{\chi_k\}_{k\in I}$ *forms a Riesz basis for* H:

$$(A+bh^*)\chi_k=\alpha_k\chi_k, \tag{2.8}$$

and

$$\left\{\sum_{k\in I}x_k\chi_k\,|\,\sum_{k\in I}|x_k\alpha_k|^2<\infty\right\}\subset\mathscr{D}(h^*). \tag{2.9}$$

Then

$$\mathscr{D}(A+bh^*)=\left\{\sum_{k\in I}x_k\chi_k\,|\,\sum_{k\in I}|x_k\alpha_k|^2<\infty\right\}, \tag{2.10}$$

and $A+bh^*$ is the infinitesimal generator of the semigroup

$$S(t)\left(\sum_{k\in I} x_k\chi_k\right) = \sum_{k\in I} x_k e^{\alpha_k t}\chi_k, \tag{2.11}$$

which is holomorphic on $\tilde{\Omega}$ and strongly continuous on $\bar{\tilde{\Omega}}$.

3. Control results. We will begin this section by stating the main results of this paper. We first need some notation. Suppose $\{\alpha_k\}_{k\in I}$ is the set we would like to realize as the closed-loop eigenvalues and $\{\alpha_k\}$ is the zero set of a cardinal function. Let m be such that

$$|\alpha_j-\alpha_k|\geqq m|j-k| \quad \text{and} \quad |\lambda_j-\lambda_k|\geqq m|j-k|, \tag{3.1}$$

where the existence of such an m is guaranteed by condition (6), the definition of a cardinal function, in Definition 3 in the Appendix. Fix m for the remainder of this section. Let

$$\begin{aligned} &j_k\in J_k := \{j\in I \,|\, |\alpha_j-\lambda_k| \text{ is minimized}\},\\ &\mathcal{J} := \{k\in I \,|\, |\alpha_{j_k}-\lambda_k|<m/2\}, \end{aligned} \tag{3.2}$$

$$\begin{aligned} &I_k = I \quad \text{for } k\notin\mathcal{J},\\ &I_k = I\backslash\{j_k\} \quad \text{for } k\in\mathcal{J}. \end{aligned} \tag{3.3}$$

THEOREM 2. *Suppose $\{\alpha_k\}_{k\in I}$ is the zero set of a cardinal function q which has the same poles as p, b is admissible on $\bar{\tilde{\Omega}}$, and*

$$\{(\alpha_k-\lambda_k)/b_k\}_{k\in I}\in l_\infty, \tag{3.4}$$

$$\left\{(\alpha_k-\lambda_k)\sum_{j\in\mathcal{J}}|1/(\alpha_k-\lambda_j)|^2\right\}_{k\in I}\in l_\infty. \tag{3.5}$$

Then h^* given by (1.12) *is an admissible feedback element on $\bar{\tilde{\Omega}}$ with domain*

$$\mathcal{D}(h^*) = \left\{\sum_{k\in I} x_k\chi_k \,\Big|\, \sum_{k\in I}|x_k|<\infty\right\}, \tag{3.6}$$

and $A+bh^*$ has eigenvalues at $\{\alpha_k\}_{k\in I}$ and eigenvectors $\{\chi_k\}_{k\in I}$ given by (1.10) *which form a Riesz basis for H.*

In some cases (3.5) is easy to verify—for instance, we will show that (3.5) is true if $\{\alpha_k-\lambda_k\}_{k\in I}\in l_\infty$.

The next theorem is a more direct generalization of Sun's result in [11].

THEOREM 3. *Suppose $\{\alpha_k\}_{k\in I}$ is the zero set of a cardinal function q which has the same poles as p, b is admissible on $\bar{\tilde{\Omega}}$, and*

$$\{(\alpha_j-\lambda_k)/b_k\}_{k\in I}\in l_2. \tag{3.7}$$

Then h^* is a bounded feedback element, and $A+bh^*$ has eigenvalues at $\{\alpha_k\}_{k\in I}$ and associated eigenvectors $\{\chi_k\}_{k\in I}$.

We can use similar methods to prove eigenvalue specification results for some systems which do not satisfy the hypotheses of Theorem 2 or Theorem 3.

THEOREM 4. *Let $b_k=\beta_k k$ and $\lambda_k=\eta_k k^2$, where*

$$M_1\geqq|\beta_k|\geqq m_1>0 \quad \text{and} \quad M_2\geqq|\eta_k|\geqq m_2>0 \tag{3.8}$$

for some m_1, M_1, m_2, and M_2. (In [8] *it is shown that there is a cardinal function p with zeros at $\{\lambda_k\}_{k\in I}$.) Suppose that $\{(\alpha_k-\lambda_k)/b_k\}_{k\in I}\in l_\infty$ and there exists a cardinal function q with the same poles as p. Then $\{\chi_k\}_{k\in I}$ given by* (1.10) *is a Riesz basis for H, h^* given by* (1.12) *with domain* (3.6) *is an admissible feedback element, and $A+bh^*$ has eigenvectors $\{\chi_k\}_{k\in I}$ and eigenvalues $\{\alpha_k\}_{k\in I}$.*

We will show that under the hypotheses of Theorem 4, the input element b is not admissible on $\bar{\Omega}$. It is usually difficult to analyze systems like this because the solution is not guaranteed to be in H when u is an admissible control.

The following results from [7] will be needed in this section, so they are stated as a lemma.

LEMMA 5. *Suppose p and q are both cardinal functions with the same poles, and let p have zeros at $\{\lambda_k\}_{k\in I}$ and q have zeros at $\{\alpha_k\}_{k\in I}$. Then*

$$\langle h_j, \chi_k\rangle_* = \delta_{j,k} \quad \text{for all } j, k \in J \quad (\text{cf. } (1.8)), \tag{3.9}$$

$$\varphi_k = (1/p'(\lambda_k)b_k)\sum_{j\in J}[q(\lambda_k)p'(\lambda_j)b_j/(\lambda_k-\alpha_j)q'(\alpha_j)]\chi_j, \tag{3.10}$$

$$\psi_k = \sum_{j\in J}[b_k p(\alpha_j)/(\alpha_j-\lambda_k)b_j]h_j, \tag{3.11}$$

$$\begin{aligned}&\{|p(\alpha_j)/(\lambda_k-\alpha_j)|\}_{j,k\in I}\in l_\infty,\\ &\{|q(\lambda_j)/(\alpha_k-\lambda_j)|\}_{j,k\in I}\in l_\infty,\end{aligned} \tag{3.12}$$

$$m \leqq p'(\lambda_k) \leqq M \quad \text{for some } m, M>0. \tag{3.13}$$

Formula (3.12) *and the second inequality in* (3.13) *are consequences of the definition of a cardinal function, and their proofs are given in the Appendix. The other results are proved in* [7].

Note that the index set in (3.10) and (3.11) is J, given by (1.8), and not I. Our first task is to show that it suffices to assume that $b_k \neq 0$ for all $k \in I$, i.e., that $J = I$.

LEMMA 6. *Suppose $\{\chi_k\}_{k\in J}$ given by* (1.10) *is a Riesz basis for*

$$H_J := \left\{\sum_{k\in J} x_k\varphi_k \,|\, \{x_k\}\in l_2\right\}.$$

Then $\{\chi_k\}_{k\in I}$ is a Riesz basis for H, and $\{\chi_k\}_{k\in I}$ is biorthogonal to $\{h_j\}_{j\in I}$ given by (1.11), *which is a Riesz basis for H'.*

Proof. Using (3.11), we can see that $\{h_j\}_{j\in J}$ is a basis for

$$H'_J := \left\{\sum_{k\in J} x_k\psi_k \,|\, \{x_k\}\in l_2\right\}.$$

It follows from (3.9) and the hypotheses that $\{h_j\}_{j\in J}$ is a Riesz basis for H'_J. $\{\chi_k\}_{k\in K}$ (cf. (1.8), (1.10)) is obviously a Riesz basis for

$$H_K := \left\{\sum_{k\in K} x_k\varphi_k \,|\, \{x_k\}\in l_2\right\}$$

and $\{h_j\}_{j\in K}$ (cf. (1.11)) is obviously a Riesz basis for

$$H'_K := \left\{\sum_{k\in K} x_k\varphi_k \,|\, \{x\}\in l_2\right\}.$$

If $x = \sum_{k\in I} x_k\varphi_k \in H$, x can be written as $x_1 + x_2$, where $x_1 \in H_J$ and $x_2 \in H_K$. The above statements then imply that

$$\|x\|^2 \leqq M\sum_{k\in I}|x_k|^2 \quad \text{for some } M>0. \tag{3.14}$$

Similarly, we can show that

$$\left\|\sum_{k\in I} y_k h_k\right\|^2 \leqq M\sum_{k\in I}|y_k|^2 \quad \text{for some } M>0. \tag{3.15}$$

We now prove that $\{\chi_k\}_{k\in I}$ is biorthogonal to $\{h_j\}_{j\in I}$: for j and k both in J, or j and k both in K, it is clear that $\langle h_k, \chi_j\rangle = \delta_{j,k}$. Suppose $j\in J$ and $k\in K$. Then $b_k = 0$, and $h_k = \psi_k$; therefore,

$$\langle h_k, \chi_j\rangle = (1/p'(\lambda_j)b_j) \sum_{j\in J} [p(\alpha_j)b_j/(\alpha_j - \lambda_i)]\langle \psi_k, \varphi_i\rangle = 0,$$

since k does not belong to J. Similarly, $\langle h_k, \chi_j\rangle = 0$ when $k\in J$ and $j\in K$; thus we have proved the biorthogonality.

Now note that

$$\sum_{k\in J} |x_k|^2 = \left\langle \sum_{k\in J} x_k h_k, \sum_{k\in I} x_k\chi_k \right\rangle \leqq \left\| \sum_{k\in J} x_k h_k \right\| \left\| \sum_{k\in I} x_k\chi_k \right\| \leqq M \left(\sum_{k\in I} |x_k|^2 \right)^{1/2} \left\| \sum_{k\in I} x_k\chi_k \right\|$$

for some M, using (3.15). Combining this with (3.14), we see that $\{\chi_k\}_{k\in I}$ is a Riesz basis for H, and so $\{h_j\}_{j\in I}$ is a Riesz basis for H'. □

LEMMA 7. *If* $\chi_k \in \mathcal{D}(h^*)$, *then* $(A + bh^*)\chi_k = \alpha_k\chi_k$.

Proof. First note that

$$\hat{A}\chi_k = \sum_{j\in I} \{p(\alpha_k)b_j\lambda_j/[p'(\lambda_k)b_k(\alpha_k - \lambda_j)]\}\varphi_j \quad \text{for } k\in J \tag{3.16}$$

and (since $\chi_k = \varphi_k$ and $\alpha_k = \lambda_k$ for $k\in K$)

$$\hat{A}\chi_k = \alpha_k\chi_k \quad \text{for } k\in K. \tag{3.17}$$

Also,

$$bh^*\chi_k = \sum_{j\in I} [p(\alpha_k)b_j/b_k p'(\lambda_k)]\varphi_j \quad \text{for } k\in J \tag{3.18}$$

and

$$h^*\chi_k = 0 \quad \text{for } k\in K. \tag{3.19}$$

Putting (3.16) and (3.18) together, we get $(A + bh^*)\chi_k = \hat{A}\chi_k + bh^*\chi_k = (1/p'(\lambda_k)b_k)$ $\sum_{j\in J} [\alpha_k p(\alpha_k)b_j/(\alpha_k - \lambda_j)]\varphi_j = \alpha_k\chi_k$, for $k\in J$. Putting (3.17) and (3.19) together, we also get $(A + bh^*)\chi_k = \alpha_k\chi_k$ for $k\in K$. □

The theorems in this section will be proved by showing that $\{\chi_k\}_{k\in I}$ is a Riesz basis for H and applying Proposition 1. Because of Lemma 6, to do this it suffices to assume that the index set K is empty, i.e., $b_k \neq 0$ for all $k\in I$.

We need to verify two inequalities in order to show that $\{\chi_k\}_{k\in I}$ is a Riesz basis. Suppose $\{x_k\}\in l_2$. Then

$$\sum_{k\in I} x_k\chi_k = \sum_{k\in I} x_k(1/p'(\lambda_k)b_k) \sum_{j\in I} [p(\alpha_k)b_j/(\alpha_k - \lambda_j)]\varphi_j = \sum_{j\in I} y_j\varphi_j, \tag{3.20}$$

where

$$y_j = \sum_{k\in I} x_k p(\alpha_k)b_j/[b_k p'(\lambda_k)(\alpha_k - \lambda_j)]. \tag{3.21}$$

Since $\{\varphi_k\}_{k\in I}$ is a Riesz basis of H, to show that

$$\left\| \sum_{k\in I} x_k\chi_k \right\|^2 \leqq M \sum_{k\in I} |x_k|^2 \tag{3.22}$$

is true for some M, we need to show that

$$\sum_{k\in I} |y_k|^2 \leqq M \sum_{k\in I} |x_k|^2 \tag{3.23}$$

is true for some M when y_k is given by (3.21). In this case $\{\chi_k\}_{k\in I}$ is said to be *uniformly* l_2*-convergent.*

If $\{\alpha_k\}_{k\in I}$ is the zero set of a cardinal function with the same poles as p, then (3.10) is true; therefore, we can write

$$\sum_{k\in I} x_k\varphi_k = \sum_{k\in I} x_k(1/p'(\lambda_k)b_k)\sum_{j\in I}[q(\lambda_k)p'(\lambda_j)b_j/(\lambda_k-\alpha_j)q'(\alpha_j)]\chi_j = \sum_{j\in I} y_j\chi_j \tag{3.24}$$

where

$$y_j = \sum_{k\in I} x_k q(\lambda_k)b_j p'(\lambda_j)/[b_k p'(\lambda_k)q'(\alpha_j)(\lambda_k-\alpha_j)]. \tag{3.25}$$

In this case $\{\chi_k\}_{k\in I}$ is a basis for H. Furthermore, the existence of a biorthogonal set (Lemma 5) implies that the χ_k are strongly independent. If $\{\chi_k\}_{k\in I}$ is uniformly l_2-convergent and also *uniformly l_2-independent*, i.e.,

$$m\sum_{k\in I}|x_k|^2 \leqq \left\|\sum_{k\in I} x_k\chi_k\right\|^2 \tag{3.26}$$

for some $m>0$, then $\{\chi_k\}_{k\in I}$ is a Riesz basis. This is true if (3.23) is true for some M when y_j is given by (3.25).

When $\sigma>0$ in (1.3) and A generates a holomorphic semigroup on $\tilde{\Omega}$ that is strongly continuous on $\bar{\tilde{\Omega}}$, the results in this section require that the input element should be admissible on $\bar{\tilde{\Omega}}$, not just on the positive real axis. When A generates a group, we require that the input element is admissible on the positive real axis. The following two lemmas are consequences of admissibility.

LEMMA 8. *Suppose b is admissible on $\bar{\tilde{\Omega}}$, $\{\alpha_k\}_{k\in I}$ satisfies* (3.1), *and we can find α and β such that $\{\alpha_k\}_{k\in I}$ and $\{\lambda_k\}_{k\in I}$ lie between Γ_α and Γ_β (cf.* (1.3)). (*Unlike the rest of the results in this paper, we do not require Assumption* A *for this lemma.*) *Then there exists M such that*

$$\sum_{k\in I}\left|\sum_{j\in I_k} b_k x_j/(\alpha_j-\lambda_k)\right|^2 \leqq M\sum_{j\in I_k}|x_j|^2 \tag{3.27}$$

(*cf.* (3.3)). *If there exists $c>0$ such that*

$$|\alpha_j-\lambda_k|>c \quad \textit{for all } j\in I \textit{ and } k\in I, \tag{3.28}$$

then

$$\sum_{k\in I}\left|\sum_{j\in I} b_k x_j/(\alpha_j-\lambda_k)\right|^2 \leqq M\sum_{j\in I}|x_j|^2. \tag{3.29}$$

Proof. Let m be as in (3.1), so that (cf. (3.2))

$$|\alpha_j-\lambda_k| \geqq |\alpha_{j_k}-\alpha_j|-|\alpha_{j_k}-\lambda_k| \geqq m|j-j_k|-|\alpha_j-\lambda_k|.$$

This implies that

$$|\alpha_j-\lambda_k| \geqq (m/2)|j-j_k|. \tag{3.30}$$

In particular, this implies $|\alpha_j-\lambda_k|\geqq m/2$ for $j\neq j_k$, so that $J_k=\{j_k\}$ if $|\alpha_{j_k}-\lambda_k|<m/2$. Hence (cf. (3.3))

$$|\alpha_j-\lambda_k| \geqq m/2 \quad \text{for } j\in I_k,\ k\in I. \tag{3.31}$$

For future reference, we also note that (3.30) implies that

$$\left\{\sum_{j\in I_k}|1/(\alpha_j-\lambda_k)|^2\right\}_{k\in I} \in l_\infty. \tag{3.32}$$

Let $u(s)=\sum_{j\in I} x_j e^{\alpha_j s}$. We will first assume that the following two conditions hold:

Condition 1. $\{\alpha_k\}_{k\in I}$ is to the left of Γ_0.

Condition 2. There exists $\rho, r\in\mathbb{R}$ such that $\rho<r$, $\{\alpha_k\}_{k\in I}$ is to the left of Γ_ρ (cf. (1.3)) and $\{\lambda_k\}_{k\in I}$ is to the right of Γ_r.

Then

$$\int_{l_\theta} |u(s)|^2\,|ds| \leqq M \sum_{j\in I} |x_j|^2 \tag{3.33}$$

for some M independent of $\theta\in[-\sigma,\sigma]$, by results in [6]. Using (2.5), we see that since b is admissible on $\tilde{\tilde{\Omega}}$,

$$\sum_{k\in I} \left| b_k \int_{[0,t]} e^{\lambda_k(t-s)} u(s)\,ds \right|^2 \leqq M \int_{[0,t]} |u(s)|^2 |ds| \tag{3.34}$$

for some M and all $t\in\tilde{\tilde{\Omega}}$. Let $J_1 := \{k\in I \mid \operatorname{Im}(\lambda_k)>0\}$ and $K_1 := \{k\in I \mid \operatorname{Im}(\lambda_k)\leqq 0\}$. For all $t\in l_{-\sigma}$, the left side of (3.34) is greater than or equal to

$$\sum_{k\in J_1} |e^{\lambda_k t}|^2 \left| b_k \int_{[0,t]} e^{-\lambda_k s} u(s)\,ds \right|^2 \geqq \tilde{m} \sum_{k\in J_1} \left| b_k \int_{[0,t]} e^{-\lambda_k s} u(s)\,ds \right|^2$$

for some $\tilde{m}>0$, since $\operatorname{Re}(\lambda_k t)$ is bounded below for $k\in J_1$ and $t\in l_{-\sigma}$. Let $t\to\infty$ on $l_{-\sigma}$, and the integral on the right side approaches the Laplace transform (as defined in [6]) of u evaluated at λ_k, or $\sum_{j\in I} x_j/(\alpha_j-\lambda_k)$.

Putting this together with (3.33) and (3.34), we see that

$$\sum_{k\in J_1} \left| \sum_{j\in I} b_k x_j/(\alpha_j-\lambda_k) \right|^2 \leqq M \sum_{j\in I} |x_j|^2$$

for some M. Now let $t\in l_\sigma$, and we do the same thing with the index set K_1 replacing J_1, yielding (3.29), as long as Conditions 1 and 2 are satisfied.

Let $a>0$ be large enough so that

$$\{\alpha_k - a\}_{k\in I} \text{ satisfies Conditions 1 and 2.} \tag{3.35}$$

We can verify that

$$\begin{aligned}
\sum_{k\in I} \left| \sum_{j\in I_k} b_k x_j/(\alpha_j-\lambda_k) \right|^2 &= \sum_{k\in I} \Bigg| \sum_{j\in I_k} b_k x_j/(\alpha_j - a - \lambda_k) \\
&\qquad - \sum_{j\in I_k} b_k x_j a/(\alpha_j - a - \lambda_k)(\alpha_j - \lambda_k) \Bigg|^2 \\
&\leqq \sum_{k\in I} \left| \sum_{j\in I_k} b_k x_j/(\alpha_j - a - \lambda_k) \right|^2 \\
&\qquad + \sum_{k\in I} \left| \sum_{j\in I_k} b_k x_j a/(\alpha_j - a - \lambda_k)(\alpha_j - \lambda_k) \right|^2 .
\end{aligned} \tag{3.36}$$

The first sum in the above line is bounded by $M\sum_{k\in I}|x_k|^2$ for some M, because (3.35) implies that (3.29) is true when $\{\alpha_k\}_{k\in I}$ is replaced by $\{\alpha_k - a\}_{k\in I}$. The second sum is less than or equal to

$$\begin{aligned}
&\sum_{k\in I} \sum_{j\in I_k} |b_k x_j a/(\alpha_j - a - \lambda_k)|^2 \left\{ \sum_{j\in I_k} |1/(\alpha_j - \lambda_k)|^2 \right\} \\
&\qquad \leqq \left\{ \sup_{k\in I} \sum_{j\in I_k} |1/(\alpha_j - \lambda_k)|^2 \right\} \sum_{j\in I} |x_j|^2 \left[\sum_{k\in I} |b_k a/(\alpha_j - a - \lambda_k)|^2 \right].
\end{aligned} \tag{3.37}$$

The first term on the right in (3.37) is bounded, from (3.32). Using (3.29) and (3.35), we see that

$$\sum_{k\in I} |b_k/(\alpha_j-\lambda_k-a)|^2 \leqq M \tag{3.38}$$

for some M. Hence (3.37) is bounded by $M\sum_{k\in I}|x_k|^2$ for some M. Combining this with (3.36) yields (3.27).

If (3.28) is true, we can go through the same proof by replacing the summation over $j\in I_k$ in (3.36) and (3.37) with the summation over $j\in I$. This leads to (3.29) and finishes the proof of the lemma. □

We can use Lemma 8 to study the basis properties of $\{\chi_k\}_{k\in I}$.

LEMMA 9. *Suppose b is admissible on $\tilde{\Omega}$, $\{\alpha_k\}_{k\in I}$ satisfies* (3.4), *and we can find α and β such that $\{\alpha_k\}_{k\in I}$ and $\{\lambda_k\}_{k\in I}$ lie between Γ_α and Γ_β. Then* (3.23) *is true with y_j given by* (3.21).

Proof. Using (3.21), we have that

$$\sum_{k\in I}|y_k|^2=\sum_{k\in I}\left|\sum_{j\in I}[x_jp(\alpha_j)b_k]/[b_jp'(\lambda_j)(\alpha_j-\lambda_k)]\right|^2. \tag{3.39}$$

The right side of (3.39) is less than or equal to

$$\sum_{k\notin\mathcal{J}}\left|\sum_{j\in I}[x_jp(\alpha_j)b_k]/[b_jp'(\lambda_j)(\alpha_j-\lambda_k)]\right|^2+\sum_{k\in\mathcal{J}}\left|\sum_{j\in I_k}[x_jp(\alpha_j)b_k]/[b_jp'(\lambda_j)(\alpha_j-\lambda_k)]\right|^2$$

$$+\sum_{k\in\mathcal{J}}|[x_{j_k}p(\alpha_{j_k})b_k]/[b_{j_k}p'(\lambda_{j_k})(\alpha_{j_k}-\lambda_k)]|^2 \tag{3.40}$$

(cf. (3.2), (3.3)). By (3.12), (3.13), and (3.4), $|p(\alpha_j)/b_jp'(\lambda_j)|$ is bounded. The first two sums are bounded by

$$M\sum_{k\notin\mathcal{J}}\left|\sum_{j\in I}x_jb_k/(\alpha_j-\lambda_k)\right|^2+M\sum_{k\in\mathcal{J}}\left|\sum_{j\in I_k}x_jb_k/(\alpha_j-\lambda_k)\right|^2\leqq\tilde{M}\sum_{j\in I}|x_j|^2$$

for some M and $\tilde{M}$, where we use the two results in Lemma 5.

Using (3.4) and (3.12), we see that there exists M such that the third sum in (3.40) is less than or equal to

$$M\sum_{k\in\mathcal{J}}|x_{j_k}b_k/b_{j_k}|^2. \tag{3.41}$$

To get an upper bound on this we need the following lemma.

LEMMA 10. $\{|b_k/b_{j_k}|\}_{k\in\mathcal{J}}$ *is bounded.*

Proof of Lemma 10. If $j_k=k$, then $|b_k/b_{j_k}|=1$. Now assume that $j_k\neq k$ and $k\in\mathcal{J}$. When we let a be as in (3.35), (3.38) is true and implies that

$$|b_k|\leqq M|\alpha_{j_k}-\lambda_k-a|,$$

which is bounded by $M(m/2+a)$ when $k\in\mathcal{J}$ (cf. (3.3)). Using (3.4), we have that

$$|1/b_{j_k}|\leqq\tilde{M}|1/(\alpha_{j_k}-\lambda_{j_k})$$

for some $\tilde{M}$. For $k\in\mathcal{J}$ and $j_k\neq k$, $|\alpha_{j_k}-\lambda_{j_k}|=|\alpha_{j_k}-\lambda_k+\lambda_k-\lambda_{j_k}|\geqq|\lambda_k-\lambda_{j_k}|-|\alpha_{j_k}-\lambda_k|\geqq m|k-j_k|-m/2\geqq m/2$ (cf. (3.1) and (3.31)). Therefore, $|b_k/b_{j_k}|\leqq M\tilde{M}(m/2+a)/(m/2)$ for $k\in\mathcal{J}$ and $j_k\neq k$, so Lemma 10 is true.

This means that (3.40), and hence (3.39), is bounded by $M\sum_{k\in I}|x_k|^2$ for some M, which completes the proof of Lemma 9. □

THEOREM 11. *Suppose* $\{\alpha_k\}_{k\in I}$ *is the zero set of a cardinal function* q *which has the same poles as* p. *Suppose* b *is admissible on* $\bar{\Omega}$, *and* (3.4) *and* (3.5) *hold. Then* $\{\chi_k\}_{k\in I}$ *is a Riesz basis for* H.

Remark. Note that (3.5) is true if $\{\alpha_k-\lambda_k\}_{k\in I}\in l_\infty$, because of (3.32).

Proof. In this proof let

$$j_k\in L_k:=\{j\in I\,|\,|\alpha_k-\lambda_j| \text{ is minimized}\} \tag{3.42}$$

so that $|\alpha_k-\lambda_j|\geqq|\lambda_{j_k}-\lambda_j|-|\lambda_{j_k}-\alpha_k|\geqq m|j-j_k|-|\alpha_k-\lambda_j|$, which implies that

$$|\alpha_k-\lambda_j|\geqq(m/2)|j-j_k|. \tag{3.43}$$

In particular, this implies that $|\alpha_k-\lambda_j|\geqq m/2$ for $j\neq j_k$, so $L_k=\{j_k\}$ if $|\lambda_{j_k}-\alpha_k|<m/2$. Let

$$\kappa:=\{k\in I\,|\,|\lambda_{j_k}-\alpha_k|<m/2\}, \tag{3.44}$$

$$\begin{aligned}&\mathcal{J}_k=I \quad \text{for } k\notin\kappa,\\ &\mathcal{J}_k=I\backslash\{j_k\} \quad \text{for } k\in\kappa;\end{aligned} \tag{3.45}$$

therefore,

$$|\alpha_k-\lambda_j|\geqq m/2 \quad \text{for } j\in\mathcal{J}_k, \quad k\in I. \tag{3.46}$$

Taking Lemma 9 into account, we see that $\{\chi_k\}_{k\in I}$ is a Riesz basis for H if (3.23) is true when y_j is given by (3.25). Therefore, we want a bound on

$$\sum_{k\in I}|y_k|^2=\sum_{k\in I}\left|\sum_{j\in I}x_jq(\lambda_j)b_kp'(\lambda_k)/[b_jp'(\lambda_j)q'(\alpha_k)(\lambda_j-\alpha_k)]\right|^2. \tag{3.47}$$

Taking (3.12) and (3.13) into account, we have that

$$\begin{aligned}&\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jq(\lambda_j)b_kp'(\lambda_k)/[b_jp'(\lambda_j)q'(\alpha_k)(\lambda_j-\alpha_k)]\right|^2\\ &\qquad\leqq M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_k/p'(\lambda_j)(\lambda_j-\alpha_k)\right|^2\end{aligned} \tag{3.48}$$

for some M. Letting a satisfy (3.35), we can write this as

$$\begin{aligned}&M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_k/p'(\lambda_j)(\alpha_j-\lambda_k-a)\right.\\ &\qquad\left.+\sum_{j\in\mathcal{J}_k}x_jb_k(\alpha_j-\lambda_j+\alpha_k-\lambda_k-a)/[p'(\lambda_j)(\alpha_j-\lambda_k-a)(\lambda_j-\alpha_k)]\right|^2\\ &\leqq M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_k/p'(\lambda_j)(\alpha_j-\lambda_k-a)\right|^2\\ &\quad+M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_k(\alpha_j-\lambda_j)/[p'(\lambda_j)(\alpha_j-\lambda_k-a)(\lambda_j-\alpha_k)]\right|^2\\ &\quad+M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_k(\alpha_k-\lambda_k)/[p'(\lambda_j)(\alpha_j-\lambda_k-a)(\lambda_j-\alpha_k)]\right|^2\\ &\quad+M\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k}x_jb_ka/[p'(\lambda_j)(\alpha_j-\lambda_k-a)(\lambda_j-\alpha_k)]\right|^2.\end{aligned}$$

We will refer to these last four sums as $S_1+S_2+S_3+S_4$. By Lemma 8, S_1 is bounded by $M\sum_{j\in I}|x_j|^2$ for some M. Taking (3.13) into account, we have that

$$S_2 \leqq M \sum_{k\in I}\sum_{j\in\mathscr{I}_k}|x_j b_k/(\alpha_j-\lambda_k-a)|^2\left\{\sum_{j\in\mathscr{I}_k}|(\alpha_j-\lambda_j)/(\lambda_j-\alpha_k)|^2\right\}. \tag{3.49}$$

When we use (3.4), the term in brackets is seen to be less than or equal to

$$\sum_{j\in\mathscr{I}_k}|b_j/(\lambda_j-\alpha_k)|^2=\sum_{j\in\mathscr{I}_k}|b_j/(\lambda_j-\alpha_k-\rho)|^2|(\lambda_j-\alpha_k-\rho)/(\lambda_j-\alpha_k)|^2. \tag{3.50}$$

Since the term $|(\lambda_j-\alpha_k-\rho)/(\lambda_j-\alpha_k)|$ is uniformly bounded for $j\in\mathscr{I}_k$ and $k\in I$, from (3.44), the right side of (3.50) is uniformly bounded, from (3.38).

Therefore the term in brackets in (3.49) is uniformly bounded for $j\in\mathscr{I}_k$ and $k\in I$, so

$$S_2 \leqq M_1\sum_{j\in I}|x_j|^2\left\{\sum_{k\in I}|b_k/(\alpha_j-\lambda_k-a)|^2\right\}\leqq M\sum_{j\in I}|x_j|^2$$

for some M and M_1, again because of (3.38).

To estimate S_3, use (3.38) and hypothesis (3.35) to see that

$$\begin{aligned}S_3 &\leqq M\sum_{k\in I}\sum_{j\in\mathscr{I}_k}|x_j b_k/(\alpha_j-\lambda_k-a)|^2\left\{\sum_{j\in\mathscr{I}_k}|(\alpha_k-\lambda_k)/(\lambda_j-\alpha_k)|^2\right\}\\ &\leqq M\sum_{j\in I}|x_j|^2\sum_{k\in I}|b_k/(\alpha_j-\lambda_k-a)|^2\leqq M_1\sum_{j\in I}|x_j|^2\end{aligned}$$

for some M and M_1. Similar estimates are easily seen to hold for S_4, so

$$\sum_{k\in I}\left|\sum_{j\in\mathscr{I}_k}x_j q(\lambda_j)b_k p'(\lambda_k)/[b_j p'(\lambda_j)q'(\alpha_k)(\lambda_j-\alpha_k)]\right|^2\leqq M\sum_{j\in I}|x_j|^2 \tag{3.51}$$

for some M. Comparing (3.51) with (3.47), we see that (3.23) is true if

$$\sum_{k\in\kappa}|x_{j_k}q(\lambda_{j_k})b_k p'(\lambda_k)/[b_{j_k}p'(\lambda_{j_k})q'(\alpha_k)(\lambda_{j_k}-\alpha_k)]|^2\leqq M\sum_{j\in I}|x_j|^2$$

(cf. (3.44)). Using (3.12), (3.13), and (3.17), we see that this is true if

$$\sum_{k\in\kappa}|x_{j_k}b_k/b_{j_k}|^2\leqq M\sum_{j\in I}|x_j|^2. \tag{3.52}$$

LEMMA 12. $\{b_k/b_{j_k}\}_{k\in\kappa}\in l_\infty$.

Proof. To prove Lemma 12, we first need to show that

$$\left\{\sum_{k\in I}|b_k/(\alpha_k-\lambda_j-a)|^2\right\}\in l_\infty.$$

This is done by an argument similar to that used to analyze (3.48). The proof then proceeds as does the proof of Lemma 10, so we will omit the details and consider Lemma 12 proved. The proof of Lemma 11 is then complete, because Lemma 12 implies (3.52). □

We now use this theorem to show that h^* is an admissible feedback element.

Proof of Theorem 2. We will prove this by referring to Proposition 1. $\{\chi_k\}_{k\in I}$ is a Riesz basis for H, by Theorem 11. Lemma 7 shows that (2.8) is true. Suppose x is in the set on the left side of (2.9), so x can be written as $\sum_{k\in I}(x_k/\alpha_k)\chi_k$, where $\{x_k\}_{k\in I}\in l_2$. Using condition (6) in Definition 3 in the Appendix, we see that $\{1/\alpha_k\}_{k\in I}\in l_2$. This implies that $\{x_k/\alpha_k\}_{k\in I}\in l_1$, so $x\in\mathscr{D}(h^*)$ and (2.9) is true. All of the hypotheses of Proposition 1 are satisfied, so h^* is admissible and $A+bh^*$ has eigenvalues at $\{\alpha_k\}_{k\in I}$ and eigenvectors $\{\chi_k\}_{k\in I}$. □

We can get similar results with different restrictions on $\{\alpha_k\}_{k\in I}$. We will go through a similar procedure to prove Theorem 3.

THEOREM 13. *Suppose $\{\alpha_k\}_{k\in I}$ is the zero set of a cardinal function q which has the same poles as p. Suppose b is admissible on $\tilde{\Omega}$, and (3.7) is true. Then $\{\chi_k\}_{k\in I}$ is a Riesz basis for H.*

Proof. As in the proof of Theorem 11, the above is true if (3.23) holds when y_j is given by (3.25). We see that the left side of (3.48) is less than or equal to

$$\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k} x_j q(\lambda_j)b_k p'(\lambda_k)/[b_j p'(\lambda_j)q'(\alpha_k)(\alpha_j-\lambda_k-a)]\right|^2$$
$$+\sum_{k\in I}\left|\sum_{j\in\mathcal{J}_k} M_{j,k}x_j q(\lambda_j)b_k p'(\lambda_k)/[b_j p'(\lambda_j)q'(\alpha_k)(\alpha_j-\lambda_k-a)]\right|^2,$$

where

$$M_{j,k}=[(\alpha_j-\lambda_j)+(\alpha_k-\lambda_k)-a]/(\alpha_k-\lambda_j),$$

which we write as S_1+S_2.

We use (3.12), (3.13), and (3.7) to show that $|q(\lambda_j)p'(\lambda_k)/b_j q'(\alpha_k)|$ is bounded, so Lemma 9 implies that $S_1\leqq M\sum_{j\in I}|x_j|^2$ for some M. To estimate S_2, we need the following result.

LEMMA 14. $\{M_{j,k}\}_{j\in\mathcal{J}_k,k\in I}\in l_\infty$.

Proof of Lemma 14. First note that we have

$$|(\alpha_j-\lambda_j)/(\alpha_k-\lambda_j)|\leqq M|b_j/(\alpha_k-\lambda_j)| \tag{3.53}$$

for some M, using (3.7). Using (3.38) and (3.46), we see that this is uniformly bounded for $j\in\mathcal{J}_k$ and $k\in I$. The term $|a/(\alpha_k-\lambda_j)|$ is also uniformly bounded for $j\in\mathcal{J}_k$ and $k\in I$, by (3.46). Hence, we are interested in showing that the term

$$N_{j,k}:=(\alpha_k-\lambda_k)/(\alpha_k-\lambda_j)$$

is uniformly bounded for $j\in\mathcal{J}_k$ and $k\in I$. Let

$$\eta_k:=(\lambda_k-\alpha_k)/b_k,\qquad \mu_{j,k}:=b_k/(\alpha_j-\lambda_k-a).$$

Formulae (3.7) and (3.38) imply that

$$\{\eta_k\}_{k\in I}\in l_2,\qquad |\mu_{j,k}|\leqq M \tag{3.54}$$

for some M independent of $j\in I$ and $k\in I$. It is easily checked that

$$N_{j,k}=\{[(\alpha_j-\lambda_j)/(\alpha_k-\lambda_j)]-1\}\eta_k\mu_{j,k}\{(\alpha_j-\lambda_k-a)/(\alpha_j-\alpha_k)\}.$$

We can use (3.38), (3.46), and (3.7) to show that $\{[(\alpha_j-\lambda_j)/(\alpha_k-\lambda_j)]-1\}$ is uniformly bounded for $j\in\mathcal{J}_k$ and $k\in I$. We can easily verify that

$$(\alpha_j-\lambda_k-a)/(\alpha_j-\alpha_k)=[\eta_k\mu_{j,k}+(\alpha_k-\lambda_j)/(\alpha_k-\lambda_j-a)]^{-1}.$$

The term $(\alpha_k-\lambda_j)/(\alpha_k-\lambda_j-a)$ is bounded below for $j\in\mathcal{J}_k$ and $k\in I$, and $\eta_k\mu_{j,k}$ goes to zero as k goes to ∞, uniformly in j. Therefore, there exists K such that $|\eta_k\mu_{j,k}+(\alpha_k-\lambda_j)/(\alpha_k-\lambda_j-a)|\geqq c>0$ for all $|k|\geqq K$ and $j\in I$. Hence, $N_{j,k}$ is uniformly bounded for $j\in\mathcal{J}_k$ and $|k|\geqq K$. Because $\{|\lambda_k-\alpha_k|\}_{|k|<K}$ is a bounded set, when it is combined with the definition in (3.44), we see that $N_{j,k}$ is uniformly bounded for $j\in\mathcal{J}_k$ and $|k|<K$. Thus the proof of Lemma 14 is complete. □

To continue analyzing S_2, we note that

$$S_2 \leqq \sum_{k\in I}\sum_{j\in\mathcal{I}_k} |M_{j,k}x_j b_k p'(\lambda_k)/[p'(\lambda_j)q'(\alpha_k)(\alpha_j-\lambda_k-a)]|^2 \sum_{j\in\mathcal{I}_k} |q(\lambda_j)/b_j|^2$$

$$\leqq M \sum_{k\in I}\sum_{j\in\mathcal{I}_k} |x_j b_k/(\alpha_j-\lambda_k-a)|^2 \left\{ \sum_{j\in\mathcal{I}_k} |q(\lambda_j)/b_j|^2 \right\},$$

for some M, where we used (3.13) and Lemma 14 for the last inequality. The term in brackets is bounded because of (3.2) and (3.57), so (3.38) then implies that this is bounded by $M\sum_{j\in I}|x_j|^2$ for some M. This verifies (3.23) when y_j is given by (3.25), and so the proof of Theorem 13 is complete. □

As in the proof of Theorem 2, the Riesz basis property of $\{\chi_k\}_{k\in I}$ is enough to show that h^* is an admissible feedback element. To show that h^* is bounded, we note that $\{h_j\}_{j\in I}$ is biorthogonal to $\{\chi_k\}_{k\in I}$ (cf. (3.9)), so $\{h_j\}_{j\in I}$ is a Riesz basis for H'. Since (3.12) and (3.7) imply that

$$\{p(\alpha_k)/b_k\}_{k\in I} \in l_2,$$

the boundedness of h^* follows from (3.13) and (1.12). This completes the proof of Theorem 3. □

Theorem 4 is less general than Theorems 2 or 3, so we can prove it in a more direct fashion. Before we prove Theorem 4, we will show that it is not a special case of either Theorem 2 or Theorem 3.

LEMMA 15. *Assume that the hypotheses of Theorem* 4 *hold. If* $\sigma>0$ *in* (1.3) b *is admissible on* $(0,\infty)$. *For any* $\sigma\in[0,\pi/2)$, b *is not admissible on* $\bar{\bar{\Omega}}$.

Proof. Referring to Definition 1, we have that the input element b is admissible on $(0,\infty)$ if (3.34) is true for each $t\in(0,\infty)$ for some $M=M(t)$. For each $t\in(0,\infty)$, let $\varphi(\lambda)=\int_0^t e^{-\lambda s}u(s)\,ds$, so the left side of (3.34) is

$$\sum_{k\in I} |b_k e^{\lambda_k t}|^2 |\varphi(\lambda_k)|^2. \tag{3.55}$$

It is well known (see, for instance, [6]) that $\sum_{k\in I}|\varphi(\lambda_k)|^2 \leqq M_1(t)\int_0^t |u(s)|^2\,ds$ for some $M_1(t)$. If $\sigma>0$, then $-\mathrm{Re}\,(\lambda_k)\geqq \tilde{m}k^2$ for some $\tilde{m}>0$ and large enough k, and $|b_k e^{\lambda_k t}|^2$ is bounded. Hence (3.55) is less than or equal to $M(t)\int_0^t |u(s)|^2\,ds$ for some $M(t)$, so (3.34) is verified. Therefore b is admissible on the positive real axis if $\sigma>0$.

To see that b is not admissible on $\bar{\bar{\Omega}}$, let $t=e^{-i\sigma}$. Plugging $u(s)=e^{\lambda_j s}$ into (3.34), we see that if b is admissible on $\bar{\bar{\Omega}}$, then

$$\sum_{k\in I} \left| b_k \int_{[0,t]} e^{\lambda_k(t-s)}\, e^{\lambda_j s}\,ds \right|^2 \leqq M \int_{[0,t]} e^{2\mathrm{Re}(\lambda_j s)}|ds|$$

for some M. Therefore, if b is admissible on $\bar{\bar{\Omega}}$,

$$\left| b_j \int_{[0,t]} e^{\lambda_j(t-s)}\, e^{\lambda_j s}\,ds \right|^2 \leqq M \int_{[0,t]} e^{2\mathrm{Re}(\lambda_j s)}|ds|.$$

When we compute the integrals above, this becomes

$$|b_j \exp(\lambda_j e^{-i\sigma})|^2 \leqq M\{\exp(2\,\mathrm{Re}\,(\lambda_j e^{i\sigma}))=1\}/2\,\mathrm{Re}\,(\lambda_j e^{-i\sigma}) \tag{3.56}$$

(if $\mathrm{Re}\,(\lambda_j e^{-i\sigma})$ is zero, then the term on the right is M). When $j>0$, $\mathrm{Re}\,(\lambda_j e^{-i\sigma})$ is bounded above and below, so that (3.56) is true only if $\{b_j\}_{j>0}$ is bounded, which we do not have in this case. Therefore b is not admissible on $\bar{\bar{\Omega}}$. □

Proof of Theorem 4. Once again, we start by showing that (3.23) is true for y_j given by (3.21). Since (3.12) is true, we see that $\{p(\alpha_k)\}_{k\in I}$ is a bounded sequence. Letting $z_{k,j} = x_k p(\alpha_k) b_j / b_k p'(\lambda_k)(\alpha_j - \lambda_k)$, we have that

$$\sum_{j\in I} |y_j|^2 \leqq 2\left\{ \sum_{j>0} \left| \sum_{k>0} z_{k,j} \right|^2 + \sum_{j>0} \left| \sum_{k<0} z_{k,j} \right|^2 + \sum_{j<0} \left| \sum_{k>0} z_{k,j} \right|^2 + \sum_{j<0} \left| \sum_{k<0} z_{k,j} \right|^2 \right\}. \tag{3.57}$$

We will estimate the first of these sums.

Let $z_k = \alpha_k - \lambda_k$. The hypotheses of Theorem 4 imply that there exist c_2, δ, and $c_1 > 0$ such that $|\lambda_k - \lambda_j| \geqq c_1 |k^2 - j^2|$ for $k > 0$, $j > 0$, and $|k-j| > \delta$, $|z_k| \leqq c_2 k$. Choose δ large enough so that $c = c_1\delta - c_2 > 0$. Then, for $k > 0$, $j > 0$, and $|k-j| > \delta$, $|\alpha_k - \lambda_j| = |\lambda_k - \lambda_j + z_k| \geqq c_1|k^2 - j^2| - c_2 k = c_1|k-j||k+j| - c_2 k \geqq (c_1\delta - c_2)k = ck \geqq M\|z_k\|$ (cf. (3.8)). This implies that for $k > 0$, $j > 0$, and $|k-j| > \delta$, we have that

$$|(\lambda_k - \lambda_j)/(\alpha_k - \lambda_j)| = |1 - z_k/(\alpha_k - \lambda_j)| \leqq M$$

for some M. This implies that

$$|1/(\alpha_k - \lambda_j)| \leqq M/(\lambda_\kappa - \lambda_j) \leqq (M/c_1)/(k^2 - j^2). \tag{3.58}$$

Let $\xi_k = x_k / p'(\lambda_k) a_k$, so that (using the hypotheses of Theorem 4)

$$\begin{aligned} \sum_{j>0} \left| \sum_{k>0} z_{k,j} \right|^2 &\leqq M \sum_{j>0} \left| \sum_{k>0} \xi_k p(\alpha_k) \beta_j j / \beta_k k(\alpha_j - \lambda_k) \right|^2 \\ &\leqq 2M \left\{ \sum_{j>0} \left| \sum_{\substack{k>0 \\ |k-j|>\delta}} \xi_k p(\alpha_k) \beta_j j / \beta_k k(\alpha_k - \lambda_j) \right|^2 \right. \\ &\qquad \left. + \sum_{j>0} \left| \sum_{\substack{k>0 \\ |k-j|\leqq\delta}} \xi_k p(\alpha_k) \beta_j j / \beta_k k(\alpha_k - \lambda_j) \right|^2 \right\} \end{aligned}$$

for some M, which we write as $S_1 + S_2$. Since $\{p(\alpha_k)\}_{k\in I}$ and $\{\beta_j/\beta_k\}_{j,k\in I}$ are bounded and (3.58) is true for $j > 0$, $k > 0$, and $|k-j| > \delta$, there exist M and M_1 such that

$$\begin{aligned} S_1 &\leqq M \sum_{j>0} \left| \sum_{\substack{k>0 \\ |k-j|>\delta}} |j/k(\alpha_k - \lambda_j)| \right|^2 \sum_{k>0} |\xi_k|^2 \\ &\leqq \left\{ M_1 \sum_{k>0} |\xi_k|^2 \right\} \sum_{k>0} (1/k^2) \left[\sum_{\substack{j>0 \\ |k-j|>\delta}} |j/(k+j)(k-j)|^2 \right]. \end{aligned}$$

Since the term in square brackets is easily seen to be bounded independently of $k > 0$, we have that $S_1 \leqq M \sum_{k>0} |\xi_k|^2$ for some M, which is seen to be less than $M \sum_{k>0} |x_k|^2$ for some M, from (3.12).

To show that S_2 is bounded, note that (3.12) implies that

$$S_2 \leqq M \sum_{j>0} \left| \sum_{\substack{k>0 \\ |k-j|\leqq\delta}} \xi_k j/k \right|^2 \leqq M_1 \sum_{j>0} \left\{ \sum_{\substack{k>0 \\ |k-j|\leqq\delta}} (j/k)^2 \right\} \sum_{\substack{k>0 \\ |k-j|\leqq\delta}} |\xi_k|^2$$

for some M and M_1. The term in brackets is easily seen to be bounded for any j, so that

$$S_2 \leqq M \sum_{k>0} |\xi_k|^2 \sum_{\substack{|k-j|\leqq\delta \\ k>0}} 1 \leqq M_1 \sum_{k>0} |x_k|^2$$

for some M and M_1. This shows that the first sum on the right side of (3.57) is bounded by $M \sum_{k>0} |x_k|^2$ for some M. We handle the other sums in (3.57) in a similar way, showing that (3.23) is true for $\{y_j\}_{j\in I}$ given by (3.21).

In order to show that $\{\chi_k\}_{k\in I}$ is a Riesz basis, it suffices to show that (3.23) is true for y_j given by (3.25). This is done by the methods used above. The rest of the theorem is a consequence of Lemma 7 and Proposition 1. □

4. Examples. Many vibrating systems can be written in the form (1.1) considered in this paper. Combining Theorems 2, 3, and 4 with the examples of cardinal functions given in [8], we can get specific eigenvalue specification results for these systems. We now give two examples involving an elastic beam with both ends hinged, and apply the results above to give eigenvalue specification results which, to the knowledge of the author, are new. In the first example the control is a point actuator, which yields an input element b that is admissible on $\tilde{\tilde{\Omega}}$, so we can apply Theorems 2 and 3. In this example the input is not bounded, and the input coefficients do not satisfy (1.7), which are the two typical restrictions on the input (cf. [7], [9], [12]). In the second example the control is a moment force on one end, which yields an input element that is not bounded or even admissible on $\tilde{\tilde{\Omega}}$. However, we can apply Theorem 4 to this example. To the author's knowledge, this is the first eigenvalue specification result for such a system.

Example 1. To describe a structurally damped beam with both ends hinged, we use the Euler-Bernoulli beam model, with the damping term arising from a lateral force on the beam negatively proportional to the rate of bending [10]. Let $w(x, t)$ be the lateral deflection of the beam, let w_t be the derivative of w with respect to time, and let w_x be the derivative with respect to the position $x\in[0, L]$. Assume that the flexural rigidity EI and the density ρ are constant. If there is no external force the beam is modeled by

$$w_{tt}(x, t)-2\gamma(EI/\rho)^{1/2}w_{txx}(x, t)+(EI/\rho)w_{xxxx}(x, t)=0, \qquad 0\leqq\gamma<1, \tag{4.1}$$

$$w(0, t)=0, \quad w(1, t)=0, \quad w_{xx}(0, t)=0, \quad w_{xx}(1, t)=0, \tag{4.2}$$

with initial conditions

$$w(x, 0)=w_0, \qquad w_t(x, 0)=w_1. \tag{4.3}$$

If we have a point actuator at $x_0\in[0, L]$, the zero on the right-hand side of (4.1) is replaced by $\delta(x-x_0)u(t)$, where u is a scalar control force and δ is the Dirac delta function. Without loss of generality, let $L=1$.

To put this in state space form, let $X=L^2[0, 1]$, and

$$B: X\to X: w\to(EI/\rho)w_{xxxx},$$

$$\mathcal{D}(B)=\{w\in H^4[0, 1]\,|\,w(0)=w(1)=w_{xx}(0)=w_{xx}(1)=0\}.$$

Then B has a set of eigenvectors $\{\Phi_k\}_{k\in Z^+}$ which form an orthonormal basis for X, and associated eigenvalues $\{\sigma_k\}_{k\in Z^+}$, where $\Phi_k(x)=2^{1/2}\sin(\pi kx)$ and $\sigma_k=(EI/\rho)(\pi k)^4$. With this choice of $\mathcal{D}(B)$, $B^{1/2}$ is given by the differential operator $B^{1/2}w=(EI/\rho)^{1/2}w_{xx}$ and

$$\mathcal{D}(B^{1/2})=\{w\in H^2[0, 1]\,|\,w(0)=w(1)=0\}.$$

Equations (4.1)-(4.3) then become (now we use a dot to denote differentiation with respect to time)

$$\ddot{w}+2\gamma B^{1/2}\dot{w}+Bw=\hat{b}u, \qquad 0<\gamma<1, \tag{4.4}$$

where $\hat{b}=\delta(x-x_0)$. If the control is distributed over the spatial extent of the beam, $\hat{b}$ is replaced by some element of X. Formula (4.4) with a homogeneous left side is a general model for structural damping, given by Chen and Russell in [1], when the

undamped, uncontrolled system is given by $\ddot{w} + Bw = 0$. Unfortunately, it is not always that easy to identify the square root of the operator B. For instance, in the cantilever case discussed in [10], $B^{1/2}$ is a pseudodifferential operator, so Russell introduces a damping term that has a more direct physical interpretation. However, numerical tests in [8] and [13] indicate that in the cantilever case, the damping term $-2\gamma(EI/\rho)^{1/2}w_{txx}(x, t)$ still leads to a system which has eigenvalues between two curves of the form Γ_a when γ is small.

Let

$$Y := \mathcal{D}(B^{1/2}), \qquad H := Y \oplus X,$$

and

$$A = \begin{bmatrix} 0 & I \\ -B & -2\gamma B^{1/2} \end{bmatrix}, \tag{4.5}$$

with domain $\mathcal{D}(A) = \mathcal{D}(B) \oplus Y \subset H$. Let

$$z(t) = [w(t), \dot{w}(t)]^T, \quad z_0 = [w_0, w_1]^T, \quad b = [0, \delta(\cdot - x_0)]^T.$$

Therefore (4.1) and (4.2) with the point actuator control at x_0 can be written in the form (1.1). To see that A generates a holomorphic semigroup on H it is sufficient to note that A has eigenvectors

$$\varphi_{\pm k} := \frac{1}{\sqrt{2}} \begin{bmatrix} \sigma_k^{-1/2}\Phi_k \\ e^{\pm i\eta}\Phi_k \end{bmatrix}, \quad e^{\pm i\eta} = (-\gamma \pm \sqrt{1-\gamma^2}), \quad k \in Z^+ \tag{4.6}$$

with associated eigenvalues

$$\lambda_{\pm k} = \sigma_k^{1/2} e^{\pm i\eta}, \tag{4.7}$$

that these eigenvectors are easily seen to form a Riesz basis for H, and that the eigenvalues lie on Γ_0 (cf. (1.3) with $\sigma = \eta - \pi/2$. Let I be the index set $Z^+ \cup Z^-$, so that A generates the semigroup given by (1.5). For our purposes, it is convenient to think of the dual space of H as being

$$H' := Y' \oplus X,$$

where

$$Y' := \mathcal{D}(B^{1/2})' = \left\{ \sum_{k \in I} x_k \Phi_k \Big| \sum_{k \in I} |x_k^2/\sigma_k| < \infty \right\} = \mathcal{D}(B^{-1/2}).$$

The inner product for $[z_1, z_2]^T \in H'$ and $[y_1, y_2]^T \in H$ is

$$\langle [z_1, z_2]^T, [y_1, y_2]^T \rangle := \int_0^1 \left(B^{-1/2} z_1(x) \overline{B^{1/2} y_1(x)} + z_2(x) \overline{y_2(x)} \right) dx. \tag{4.8}$$

The domain of A^*, the adjoint of A, is the subset of H' given by $\mathcal{D}(A^*) = X \oplus Y$. It is easy to see that

$$\psi_{\pm k} := (1/\sqrt{2} \sin(\eta)) \begin{bmatrix} -(\pm i\sigma_k^{1/2} e^{\pm i\eta})\Phi_k \\ \pm i\Phi_k \end{bmatrix}, \qquad k \in Z^+ \tag{4.9}$$

is an eigenvector of A^* with associated eigenvalue λ_k, that $\{\psi_k\}_{k \in I}$ is a Riesz basis for H', and that $\langle \varphi_j, \psi_k \rangle = \delta_{j,k}$, so that $\{\psi_k\}_{k \in I}$ is the dual basis to $\{\varphi_k\}_{k \in I}$.

The input coefficients can be easily computed in this case: they are

$$b_{\pm k} = \langle b, \psi_{\pm k} \rangle = \langle \delta(\cdot - x_0), \pm i\Phi_k \rangle = \pm i\Phi_k(x_0) = \pm i \sin(\pi k x_0)/\sin(\eta).$$

There are no nonzero values of x_0 for which $\{b_k\}_{k \in I}$ is in l_2. Since $\{b_k\}_{k \in I}$ is bounded,

it is easy to use methods in [5] to show that b is admissible on $\tilde{\tilde{\Omega}}$, so we can apply Theorems 2 and 3 to this system.

There is no value of x_0 for which b satisfies (1.7). If x_0 is rational, b_k is zero infinitely many times, and the $\{b_k\}_{k\in J}$ (cf. (1.8)) satisfies (1.7), so we can apply the methods in [7] to the system. (In fact, the results in [7] will be better in this case, since the only restriction on $\{\alpha_k\}_{k\in I}$ is that it is the zero set of a cardinal function with the same poles as p.) If x_0 is irrational, $b_k \neq 0$ for any $k \in I$, but (1.7) is not satisfied, and the author knows of no other eigenvalue specification results for this system. The following corollary of Theorems 2 and 3 gives us a class of eigenvalues that can be realized for the closed loop system.

COROLLARY 16. *Suppose* $\alpha_k = \lambda_k + \eta_k \sin(\pi k x_0)$, *where* $\{\eta_k\}_{k\in I} \in l_\infty$. *Then* $\{\chi_k\}_{k\in I}$ *given by* (1.10) *is a Riesz basis for* H, h^* *given by* (1.12) *with domain* (3.6) *is an admissible feedback element, and* $A+bh^*$ *has eigenvectors* $\{\chi_k\}_{k\in I}$ *and eigenvalues* $\{\alpha_k\}_{k\in I}$. *If* $\{\eta_k\}_{k\in I} \in l_2$, *then* h^* *is bounded, i.e.,* $h^* \in H$.

Proof. It is clear that (3.4) is satisfied. Since $\{\sin(\pi k x_0)\}_{k\in I}$ is bounded, $\{\alpha_k - \lambda_k\}_{k\in I}$ is bounded, so (3.5) is also satisfied (see the remark after the statement of Theorem 11). Let

$$p(\lambda) = \prod_{k\in I} (\lambda - \lambda_k)/(\lambda - \lambda_k - m), \quad q(\lambda) = \prod_{k\in I} (\lambda - \alpha_k)/(\lambda - \lambda_k - m), \tag{4.10}$$

where m is chosen so that there is a constant c such that $\{\alpha_k\}_{k\in I}$ lies to the right of Γ_c and $\{\lambda_k - m\}_{k\in I}$ lies to the left of Γ_c. It is shown in [8] that p and q are cardinal functions. Therefore we can apply Theorem 2 to this system if $\{\eta_k\}_{k\in I} \in l_\infty$. If $\{\eta_k\}_{k\in I} \in l_2$ we can apply Theorem 3. □

To illustrate this, let $x_0 = 1/\pi$, and the damping factor $\gamma = .2588$, and we will determine the feedback law that realizes the closed-loop eigenvalues $\alpha_{\pm k} = \lambda_{\pm k} - 5\sin(k)$. Let p and q be given by (4.10), with $m = 6$. We will approximate p and q by finite products to estimate $p(\alpha_j)$, $q(\lambda_k)$, $p'(\lambda_k)$, and $q'(\alpha_j)$ so that the last two approximations p_n and p_{n+1} satisfy $|(p_n/p_{n+1}) - 1| < .001$. Using formulae (1.11) and (1.12), we can find h^* in the form $\sum_{j>0} c_j\psi_j + \overline{c_j}\psi_{-j}$, where the first nine coefficients are

$$\{c_j\}_{j=1}^9 = \{.8804 + 5.1598i,\ 1.3474 + 4.4128i,\ 1.2395 + 4.3680i,\ .6952 + 4.6051i,$$
$$.0532 + 4.8249i,\ -.2895 + 4.9092i,\ -.2075 + 4.8877i,\ .0808 + 4.8120i,$$
$$.2614 + 4.7571i\}.$$

In this case h^* is not a bounded element, but we can truncate the series for h^* to get a bounded element. In [8] the effect of the truncated feedback element on the distributed parameter system is studied.

If h^* is written as $[h_1(s), h_2(s)]$, then the control is given by

$$u(t) = \langle h^*, z(t)\rangle = (\text{cf. } (4.8)) \int_0^1 [\tilde{h}_1(s)\overline{w_{xx}(x,t)} + h_2(x)\overline{w_t(x,t)}]\,dx, \tag{4.11}$$

where

$$\tilde{h}_1(x) = B^{-1/2}h_1(x) = \sum_{k>0} f_k\sqrt{2}\sin(\pi k x),$$
$$h_2(x) = \sum_{k>0} g_k\sqrt{2}\sin(\pi k x), \tag{4.12}$$

with the first nine coefficients given by

$$\{f_k\}_{k=1}^9 = \{-.7101, .2333, .0977, -.7619, -1.7531, -2.2697, -2.1456, -1.7091, -1.4329\},$$
$$\{g_k\}_{k=1}^9 = \{-7.5545, -6.4608, -6.3952, -6.7423, -7.0642, -7.1875, -7.1561,$$
$$-7.0452, -6.9649\}.$$

Example 2. We now consider a beam with both ends hinged and a moment force $u(t)$ at one end. This is modeled by (4.1), where we derive the correct boundary conditions for the damped beam by computing the time rate of change of the energy associated with (4.1). The energy for the Euler-Bernoulli beam is

$$(\mathscr{E}(w))(t) := \frac{1}{2}\int_0^1 (EI|w_{xx}(x,t)|^2 + \rho|w_t(x,t)|^2)\,dx. \tag{4.13}$$

Integration by parts twice yields

$$\frac{d(\mathscr{E}(w)(t))}{dt} + (EI\rho)^{1/2}\int_0^1 |w_{xt}(x,t)|^2\,dx$$
$$= \int_0^1 w_t(x,t)\{(EI)w_{xxxx}(x,t) + \rho w_{tt}(x,t) - 2\gamma(\rho EI)^{1/2}w_{txx}(x,t)\}\,dx$$
$$+ \{EIw_{xx}(x,t)\}w_{tx}(x,t) + \{2\gamma(\rho EI)^{1/2}w_x(x,t) - EIw_{xxx}(x,t)\}w_t(x,t)\Big|_0^1.$$

If w satisfies the differential equation (4.1) and the boundary conditions

$$w(0,t)=0, \quad w(1,t)=0, \quad w_{xx}(0,t)=0, \quad w_{xx}(1,t)=u(t), \tag{4.14}$$

then

$$\frac{d(\mathscr{E}(w)(t))}{dt} = EIu(t)w_{tx}(1,t) - (EI\rho)^{1/2}\int_0^1 |w_{tx}(x,t)|^2\,dx,$$

which is the correct form for the rate of change of the energy [10].

In this case (4.1) and (4.14) can also be written as (4.4), where the input element $\hat{b}$ will be determined from the boundary conditions (4.14). We will follow the procedure in [5]. We need two extensions of A. One extension is $\hat{A}$: $H \to \mathscr{H}$, given by (2.3). In the cases under consideration,

$$\hat{A}\left(\sum_{k\in I} x_k\varphi_k\right) = \sum_{k\in I} x_k\lambda_k\varphi_k$$

and

$$\mathscr{H} = \left\{\left(\sum_{k\in I} x_k\varphi_k\right)\,\middle|\, \sum_{k\in I}|x_k/\lambda_k|^2 < \infty\right\}.$$

To get the other extension, we first define an extension of B. Let

$$J: X \to X: w \to (EI/\rho)w_{xxxx},$$
$$\mathscr{D}(J) = \{w \in H^4[0,1] \mid w(0) = w(1) = w_{xx}(0) = 0\}.$$

If $\hat{w}(x) := (x^3 - x)/6$, then $\hat{w}$ is in $\mathscr{D}(J)$, and $\hat{w}_{xx}(1) = 1$. We can therefore write any element of $\mathscr{D}(J)$ as $\xi + u\hat{w}$, where $\xi \in \mathscr{D}(B)$ and u is a scalar. Let

$$L: H \to H: Lz = \begin{bmatrix} 0 & I \\ -J & -2\gamma B^{1/2} \end{bmatrix} z, \qquad \mathscr{D}(L) = \mathscr{D}(J) \oplus \mathscr{D}(B^{1/2}), \tag{4.15}$$

so that L is an extension of A. We can write $z \in \mathscr{D}(L)$ as $\xi + u[\hat{w}, 0]^T$, with u a scalar and $\xi \in \mathscr{D}(A)$. We would like the solution $z(t) = [w(t), \dot{w}(t)]^T$ to be in $\mathscr{D}(L)$. In fact, we can write the control system (4.1), (4.14) as

$$\dot{z}(t) = Lz(t), \quad z(t) = \xi(t) + u(t)\begin{bmatrix} \hat{w} \\ 0 \end{bmatrix}, \quad \xi(t) \in \mathscr{D}(A). \tag{4.16}$$

We will rewrite this in the form $\dot{z}(t) = \hat{A}z(t) + (L - \hat{A})z(t)$, where the term $(L - \hat{A})z(t)$ turns out to be of the form $bu(t)$.

Since $L\xi = \hat{A}\xi$, $Lz - \hat{A}z = uL[\hat{w}, 0]^T - u\hat{A}[\hat{w}, 0]^T = -u\hat{A}[\hat{w}, 0]^T$. To compute $\hat{A}[\hat{w}, 0]^T$, let $[\eta_1, \eta_2]^T \in \mathcal{D}(A^*) = X \oplus Y$ (note that this implies that $\eta_2(0) = \eta_2(1) = 0$); therefore,

$$\begin{aligned}\langle [\eta_1, \eta_2]^T, \hat{A}[\hat{w}, 0]^T \rangle &= \langle A^*[\eta_1, \eta_2]^T, [\hat{w}, 0]^T \rangle \\ &= \langle [-B\eta_2, \eta_1 - 2\gamma B^{1/2}\eta_2]^T, [\hat{w}, 0]^T \rangle \\ &= -\langle B^{-1/2}B\eta_2, B^{1/2}\hat{w} \rangle_{L^2[0,1]} \\ &= (-EI/\rho) \int_0^1 \overline{\hat{w}_{xx}(x)} \eta_{2xx}(x)\, dx \\ &= (\text{integrating by parts twice}) = (-EI/\rho)\eta_{2x}(1).\end{aligned}$$

Hence $-\hat{A}[\hat{w}, 0]^T = (EI/\rho)[0, \delta'(\cdot - 1)]^T := b$, and (4.15) becomes

$$\dot{z}(t) = \hat{A}z(t) + bu(t),$$

which is an equation in $\mathcal{H}$. The expansion coefficients of b are $b_{\pm k} = \langle b, \psi_{\pm k} \rangle = \pm i 2^{-1/2}(EI/\rho)\Phi_k'(1)/\sin(\eta) = \pm i(EI/\rho)\pi k(-1)^k/\sin(\eta)$ for $k \in Z^+$, since $\Phi_k(x) = 2^{1/2}\sin(\pi k x)$. Hence we can represent the input element in the form (1.2), and this system satisfies the hypotheses of Theorem 4. Therefore, we can realize any closed-loop eigenvalues such that there is a cardinal function q with the same poles as p, and $\{(\alpha_k - \lambda_k)/b_k\}_{k \in I} \in l_\infty$. For instance, if $\alpha_k = \lambda_k + \eta_k$, where $\eta_k \in l_\infty$, p and q given by (4.10) are shown to be cardinal functions in [8], so $A + bh^*$ has eigenvalues at $\{\alpha_k\}_{k \in I}$ if h^* is given by (4.12).

As an example we consider (4.1) and (4.14) with the damping factor $\gamma = .2588$. We can realize $\alpha_k = \lambda_k - 2$ by the control law (4.11), where $\tilde{h}_1$ and h_2 are given by (4.12), with the first nine coefficients given by

$$\{f_k\}_{k=1}^9 = \{.1790, -.0733, .0540, -.0434, .0279, -.0159, .0160, -.0152, .0141\},$$

$$\{g_k\}_{k=1}^9 = \{.9578, -.4535, .2995, -.2240, .1754, -.1419, .1228, -.1079, .0961\}.$$

Appendix: Definition of cardinal function and consequences.

DEFINITION 3. Let p be a meromorphic function with zero set $\{\lambda_k\}_{k \in I}$ and pole set $\{\mu_k\}_{k \in I}$. Assume that all λ_k's and μ_k's are distinct, and that $I = Z^+ \cup Z^-$. Then p is a cardinal function if:

(1) There exist real constants d, c, and m_1, with $d < c$, such that $|p(\lambda)| \leqq m_1$ for all $\lambda \in \{\lambda > \Gamma_c\} \cup \{\lambda < \Gamma_d\}$.

(2) There exist real constants a, b, and m_2 with $b < a$ such that $|p(\lambda)| \geqq m_2 > 0$ for all $\lambda \in \{\lambda > \Gamma_a\} \cup \{\lambda < \Gamma_b\}$.

(3) There exists $m_3 > 0$ such that $|p'(\lambda_k)|$, $|p'(\mu_k)/(p(\mu_k))^2| \geqq m_3$ for all $k \in I$.

(4) There exist paths $\{\Lambda_j\}_{j \in Z}$ between Γ_a and Γ_b such that
   (a) there exists m_4, independent of j, such that $|p(\lambda)| \geqq m_4 > 0$ for $\lambda \in \Lambda_j$;
   (b) $\{\text{length}(\Lambda_j)\}_{j \in Z}$ is bounded;
   (c) $(\inf_{\lambda \in \Lambda_j} \operatorname{Im}(\lambda)) \longrightarrow_{j \to \infty} \infty$ and $(\sup_{\lambda \in \Lambda_j} \operatorname{Im}(\lambda)) \longrightarrow_{j \to -\infty} -\infty$.

(5) There exist paths $\{\tilde{\Lambda}_j\}_{j \in Z}$ between Γ_c and Γ_d such that
   (a) there exists $m_5 > 0$, independent of j, such that $|p(\lambda)| \leqq m_5$ for $\lambda \in \tilde{\Lambda}_j$;
   (b) $\{\text{length}(\tilde{\Lambda}_j)\}_{j \in Z}$ is bounded;
   (c) $(\inf_{\lambda \in \tilde{\Lambda}_j} \operatorname{Im}(\lambda)) \longrightarrow_{j \to \infty} \infty$ and $(\sup_{\lambda \in \tilde{\Lambda}_j} \operatorname{Im}(\lambda)) \longrightarrow_{j \to -\infty} -\infty$.

(6) $\inf_{k>0}\{\operatorname{Im}(e^{-i\sigma}(\lambda_k - \lambda_{k-1})), \operatorname{Im}(e^{i\sigma}(\lambda_{-k} - \lambda_{-k+1}))\} > 0$, $\operatorname{Im}(\lambda_k) \geqq 0$ for $k > 0$, and $\operatorname{Im}(\lambda_k) \leqq 0$ for $k < 0$.

(7) $\inf_{k>0}\{\operatorname{Im}(e^{-i\sigma}(\mu_k-\mu_{k-1})), \operatorname{Im}(e^{i\sigma}(\mu_{-k}-\mu_{-k+1}))\}>0$, $\operatorname{Im}(\mu_k)\geqq 0$ for $k>0$, and $\operatorname{Im}(\mu_k)\leqq 0$ for $k<0$.

Remark 1. Two classes of cardinal functions are constructed in [8]. In one class, the zeros and poles are spaced asymptotically linearly, and in the other class they grow faster than linearly.

Remark 2. The definition of cardinal function given in [6], [7] requires that

$$|p'(\lambda_k)|\leqq M \quad \text{and} \quad |p'(\mu_k)/(p(\mu_k))^2|\leqq M$$

for some M independent of k. We also need this for results in § 3. To show that this is a consequence of that definition, let C_k be a small circle oriented counterclockwise with center λ_k and radius ε, where ε is chosen so that $p(\lambda)$ is bounded on all C_k. Then

$$|p'(\lambda_k)| = \left|\left(\frac{1}{2}\pi i\right)\int_{C_k}[p(\zeta)/(\zeta-\lambda_k)^2]\,d\zeta\right|,$$

which is easily seen to be bounded independent of k. We could do the same with p replaced by $1/p$ to show that $|p'(\mu_k)/(p(\mu_k))^2|$ is bounded independent of k.

To verify (3.12), let C be the curve $\Gamma_\alpha \cup \Gamma_\beta$, where $c<\alpha<b<a<\beta$, Γ_α is oriented from top to bottom, and Γ_β is oriented from bottom to top. When we use Cauchy's Theorem, we can easily show that

$$\begin{aligned}|p(\alpha_k)-p(\lambda_j)| &= (1/2\pi)\left|\int_C[p(\zeta)/(\alpha_k-\zeta)]\,d\zeta-\int_C[p(\zeta)/(\lambda_j-\zeta)]\,d\zeta\right| \\ &\leqq (1/2\pi)|\alpha_k-\lambda_j|\left\{\int_C|p(\zeta)/(\lambda_j-\zeta)(\alpha_k-\zeta)||d\zeta|\right\}.\end{aligned}$$

Since p is bounded on C, and λ_j and α_k lie between Γ_a and Γ_b, it is easy to see that the term in brackets is uniformly bounded. Since $p(\lambda_j)=0$, (3.12) follows.

CONTINGENT CONES TO REACHABLE SETS OF CONTROL SYSTEMS*

HALINA FRANKOWSKA†

Abstract. High-order necessary conditions for optimality for an optimal control problem are studied via properties of contingent cones to reachable sets along the optimal trajectory. It is shown that the adjoint vector of Pontryagin's maximum principle is normal to the set of variations of reachable sets. Results are applied to study optimal control problems for dynamical systems described by: (1) closed-loop control systems; (2) nonlinear implicit systems; (3) differential inclusions; (4) control systems with jumps.

Key words. high-order maximum principles, implicit control system, closed-loop control system, discontinuous trajectory, reachable set, contingent cone

AMS(MOS) subject classifications. 49B10, 49B34, 49B36, 49E15, 93C15

1. Introduction.

Consider the following optimal control problem in $\mathbb{R}^n$:

$$\text{minimize } g(x(T)) \tag{1.1}$$

over the solutions to the control system

$$x'(t) = f(x(t), u(t)) \quad \text{a.e. in } [0, T], \tag{1.2}$$

$$u(t) \in U \quad \text{is a measurable selection,} \tag{1.3}$$

$$x(0) \in C. \tag{1.4}$$

Let $R(t, C)$ denote its reachable set at time t from the set of initial conditions $C \subset \mathbb{R}^n$ and $T_{R(t,C)}(x_0)$ the contingent cone to $R(t, C)$ at $x_0 \in \mathbb{R}^n$.

If a trajectory z of the control system (1.2)–(1.4) solves the above problem, then the derivative $g'(z(T))$ is nonnegative in every tangent direction $w \in T_{R(T,C)}(z(T))$, i.e., $g'(z(T))$ belongs to the positive polar cone $T_{R(T,C)}(z(T))^+$ of $T_{R(T,C)}(z(T))$. This is the so-called Fermat rule. Thus we obtain the necessary conditions that allow us to test whether a given trajectory z is optimal whenever we can characterize this positive polar cone. In this paper we study some necessary conditions that can be derived from the above Fermat rule. In the case of nonlinear system, the best we can hope for is to characterize explicitly subsets Q of the tangent cone $T_{R(T,C)}(z(T))$, using variations of the solution $z(\cdot)$.

Then, by duality, $g'(z(T)) \in T_{R(T,C)}(z(T))^+ \subset Q^+$ and the inclusion $g'(z(T)) \in Q^+$ is a necessary condition of optimality. Q is the larger set and Q^+ is the smaller set, so that the necessary condition becomes stronger.

In particular, we prove that the reachable set at time T, $R^L(T)$, of the following linear control system:

$$\begin{cases} w'(t) = \dfrac{\partial f}{\partial x}(z(t), \bar{u}(t))w(t) + v(t) \quad \text{a.e.,} \\ v(t) \in T_{\text{co } f(z(t),U)}(z'(t)), \\ w(0) \in T_C(z(0)) \end{cases} \tag{1.5}$$

(where $\bar{u}$ is a control corresponding to z) is contained in $T_{R(T,C)}(z(T))$. Hence whenever z is optimal, $g'(z(T)) \in R^L(T)^+$.

† Centre de Recherche de Mathématique de la Décision, Université Paris-Dauphine, 75775 Paris, Cedex 16; International Institute for Applied System Analysis, Laxenburg, Austria.

Such inclusion implies easily the celebrated Pontryagin's maximum principle: the solution q of the adjoint system

$$-q'(t) = \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* q(t) \quad \text{a.e. in } [0, T], \tag{1.6}$$

$$q(T) = g'(z(T)) \tag{1.7}$$

satisfies the minimum principle

$$\langle q(t), z'(t)\rangle = \min_{u \in U} \langle q(t), f(z(t), u)\rangle \quad \text{a.e. in } [0, T] \tag{1.8}$$

and the transversality condition

$$q(0) \in T_C(z(0))^+. \tag{1.9}$$

The aim of this paper is to go beyond the maximum principle and to provide some additional properties of the adjoint vector $q(\cdot)$ that can help to eliminate more candidates for optimality than the maximum principle. Let us describe briefly the main ideas.

We introduce the "variations" $\{W(t, z): t \in [0, T]\}$ of $z(\cdot)$, defined by

$$W(t, z) := \{v : \exists h_i \to 0,\ h_i \geqq 0,\ \mu_i \to 0+ \text{such that } z(t+h_i) + \mu_i v \in R(t+h_i, C) + o(\mu_i)\}$$

(in particular, $T_{R(t,C)}(z(t)) \subset W(t, z)$).

For all $0 \leqq t \leqq t+h \leqq T$, define the reachable map $r(h, t): \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ of (1.5) by

$$r(h, t)\xi = \{w(t+h):\ w \in W^{1,1}(t, t+h) \text{ is a solution of (1.5)}, w(t) = \xi\}.$$

We shall prove that for all $t \in [0, T[$, $r(T-t, t)$ maps $W(t, z)$ into $T_{R(T,C)}(z(T))$ and, in particular,

$$r(T, 0) T_C(z(0)) \subset T_{R(T,C)}(z(T)).$$

Thus for all $t \in [0, T]$, $g'(z(T)) \in (r(T-t, t) W(t, z))^+$. If $r(T-t, t)$ is a linear operator, we deduce from the bipolar theorem that $g'(z(T)) \in r(T-t, t)^{*-1}(W(t, z)^+)$, where $r(T-t, t)^*$ is the transpose of $r(T-t, t)$. But the reachable map $r(T-t, t)$ is not single-valued: it is a positively homogeneous set-valued map (i.e., one whose graph is a cone) which can also be transposed. We shall then prove two things: first, that for any convex cone $Q \subset W(t, z)$,

$$(r(T-t, t)Q)^+ = r(T-t, t)^{*-1}(Q^+), \tag{1.10}$$

and second, that the transpose $r(T-t, t)^*$ can be computed in the following way:

$$r(T-t, t)^* \pi = q(t) \tag{1.11}$$

where q is a solution to the system (1.6), (1.8) satisfying $q(T) = \pi$. By piecing together all this information, we obtain the existence of a solution q of (1.6)-(1.9) satisfying

$$q(T) \in T_{R(T,C)}(z(T))^+, \tag{1.12}$$

$$q(t) \in W(t, z)^+ \quad \text{for all } t \in [0, T[. \tag{1.13}$$

It also implies the following invariance property of reachable sets:

(1.14) If $T_{R(T,C)}(z(T))^+ \neq \{0\}$, then for all $t \in [0, T]$, $T_{R(t,C)}(z(t))^+ \neq \{0\}$.

This result is of the same nature as a theorem of Ważewski stating that the boundary point of reachable set can be reached only by a boundary trajectory.

The inclusions (1.12)-(1.13) are additional information described via *reachable sets*. For nonlinear systems the reachable sets and, consequently, the set of variations $W(t, z)$ are not known a priori. But condition (1.13) still allows us to eliminate some candidates for optimality among those satisfying the maximum principle. Let us emphasize that it is enough to know *one* element $w \in W(t, z)$, such that the solution q of (1.6), (1.7) satisfies $\langle q(t), w\rangle < 0$, to deduce that z is not optimal.

Inclusion (1.13) can also be seen as a *higher-order* optimality condition, since it deals with variations of $z(\cdot)$ of all orders. High-order necessary conditions involving higher-order derivatives of g are (of course) of an entirely different nature.

The high-order necessary conditions in optimization have two features:

(1) Necessary conditions involving the high-order variations of constraints;

(2) Calculus of high-order variations.

Here we shall not divide any calculus of sets $W(t, z)$. In [19] the interested reader can find many examples of variations corresponding to piecewise C^∞-controls. They are constructed via Lie brackets of some vector fields. However, because of the Lavrentiev phenomenon, we should not expect such regularity of optimal trajectories. Still the results of [19] can be used at *regular* enough points of optimal control. The irregular points are much more difficult to address and require further investigations.

We shall study a more general dynamical system than the parametrized control system (1.2), (1.3), the so-called differential inclusion

$$x' \in F(x). \tag{1.15}$$

This is a generalized differential equation to which the control system (1.2), (1.3) can be reduced by setting $F(x) = f(x, U)$. When f is continuous, the Filippov Theorem (see [1, p. 91]) says that the solutions of (1.15) and (1.2), (1.3) do coincide.

In general the set-valued map F cannot be parametrized in a way that reduces the system (1.15) to (1.2), (1.3). The main reason for this is the restriction on admissible controls (1.3). Still this can be done when F has *convex* compact images and is continuous in the Hausdorff metric. But even in this case the parametrization would only be continuous, and therefore would not be very useful because of the lack of differentiability of f.

The differential inclusions, besides being a description of more general dynamical systems, provide a mathematical tool for studying nonsmooth control systems, closed-loop control systems:

$$x' = f(x, u), \qquad u \in U(x), \tag{1.16}$$

and implicit dynamical systems

$$f(x, x') = 0. \tag{1.17}$$

We refer to [1], [9], [22], [6], and references therein for the corresponding examples of systems whose models are described by (1.16), (1.17).

Setting $F(x) = \bigcup_{u \in U(x)} f(x, u)$ and $F(x) = \{v: f(x, v) = 0\}$ we reduce (1.16) and (1.17), respectively, to the differential inclusion (1.15).

Recall that the dynamical system (1.17) appears in the Lagrange problem (see [28]). Two ways to treat (1.17) are described in [28]. One is an unjustified multiplier rule. The second is (again) an unjustified assumption that (1.17) can be rewritten as a control system (1.2), (1.3). In this paper we treat (1.17) via differential inclusion techniques.

Properties of the dynamical system given by (1.15) depend on the graph of the set-valued map F.

Actually the generalized differential equation (1.15) inherits many features of ODEs (see [1]). The one we exploit the most here is the variational inclusion, which is as useful as variational equations arising in ODEs. It has been extended to variational inclusions in [13], [12], and independently in [23]. Many results concerning inclusions can be found in [1], [9]–[16], [18], [23] (see also the references therein).

The maximum principle for differential inclusions has been proved in [9], [10], [12], [18], [23]. It involves graphical derivatives of the set-valued map F ([12], [23]), generalized Jacobians of selections for F [18], or generalized gradients of Hamiltonians [9], [10]:

$$H(x, p) = \sup \{\langle p, e\rangle : e \in F(x)\}.$$

We prefer the "graphical" approach mainly for two reasons:

(1) In general, even for smooth control systems, H is merely Lipschitz. Hence we are led to differentiate H in one generalized way or another. There is not yet any convenient notion of higher-order generalized derivatives of H adequate for our purposes. Neither is it clear how we can solve the nonsmooth Hamiltonian inclusions. Rather, we deal with convex subcones of tangent cones to graph (F) and the associated convex processes. The convex process is a set-valued analogue of linear operators (see [25], [2]). In particular, the Kalman rank condition can be extended to convex processes [3].

(2) In the examples of applications we provide here, the Hamiltonian maximum principle is less powerful than that involving the adjoint system (see § 4, Remark 4.10 for a detailed discussion).

Tangent vectors to reachable sets are studied via local variations in § 2. In § 3 we investigate the adjoint of the reachable process, $r(T-t, t)^*$. The cone $T_{R(T,C)}(z(T))^+$ is studied in § 4. Section 5 is devoted to necessary conditions for problem (1.1) for the (usual) control system (1.2), (1.3), the closed-loop control system (1.16), and the implicit dynamical system (1.17). In § 6 we sketch how the same approach can be used to study control systems with jumps (deterministic impulse control systems). Examples are provided in § 7.

We do not present here a thorough study of high-order variation. Many results concerning smooth cases can be found in [19]. In the more general framework (1.15) we deal with the extended notion of Lie brackets for set-valued maps. A second-order result can be found in [14]. However, the higher-order variations require a further investigation.

2. Tangent vectors to reachable sets. One of the main tools we use here is the following result due to Filippov [11].

THEOREM (Filippov). *Let $y:[a, b]\to\mathbb{R}^n$ be an absolutely continuous function and $G:[a, b]\times\mathbb{R}^n\to\mathbb{R}^n$ be a set-valued map with closed images such that:*

(i) *For all $x\in\mathbb{R}^n$, the map $t\to G(t, x)$ is measurable;*

(ii) *For some $\varepsilon>0$, $k\in L^1(a, b)$ and all t, $G(t, \cdot)$ has nonempty images and is $k(t)$-Lipschitz on $y(t)+\varepsilon B$.*

Set $K=\exp(\int_a^b k(t)\,dt)$, $\rho:=\int_a^b \operatorname{dist}(y'(t), G(t, y(t)))\,dt$. If $\rho<\varepsilon/K$, then there exists an absolutely continuous function $x:[a, b]\to\mathbb{R}^n$ satisfying $x(a)=y(a)$,

$$x'(s)\in G(s, x(s)) \quad \text{a.e. in } [a, b],$$

$\|x-y\|_{C(a,b)}\leqq K\rho$ and for almost all $t\in[a, b]$

$$\|x'(t)-y'(t)\|\leqq k(t)\rho\exp\left(\int_a^t k(s)\,ds\right)+\operatorname{dist}(y'(t), G(t, y(t))).$$

Remark. The proof can also be found in [1] under an additional assumption that G is continuous in t. In [9, p. 115] the theorem above is stated in a weaker form, but the proof allows us to deduce the above stronger version. We provide a sketch of such a deduction. The function x is constructed as the limit of a Cauchy sequence $x_i \in C(a, b; \mathbb{R}^n)$ $i = 0, 1, \cdots$ of absolutely continuous functions satisfying $x_i(a) = y(a)$ and for almost all $t \in [a, b]$ and all $i \geqq 1$:

$$\|x_{i+1}'(t) - x_i'(t)\| \leqq k(t)\|x_i(t) - x_{i-1}(t)\| \leqq k(t)\rho \frac{(\int_a^t k(s)\, ds)^{i-2}}{(i-2)!},$$

$$\|x_1'(t) - y'(t)\| = \operatorname{dist}(y'(t), G(t, y(t))).$$

Hence for almost all $t \in [a, b]$ the sequence $\{x_i'(t)\}$ is also Cauchy. This and Lebesgue's dominated convergence theorem yield the existence of $x \in C(a, b)$ such that for all $t \in [a, b]$

$$x(t) = x(a) + \int_a^t \lim_{i \to \infty} x_i'(s)\, ds.$$

Hence x is absolutely continuous and we finally obtain that

$$x_i'(s) \to x'(s) \quad \text{a.e. in } [a, b].$$

Moreover, for almost all $t \in [a, b]$

$$\begin{aligned}\|x_{i+1}'(t) - y'(t)\| &\leqq \sum_{j=1}^{i} \|x_{j+1}'(t) - x_j'(t)\| + \|x_1'(t) - y'(t)\| \\ &\leqq k(t)\rho \sum_{j=0}^{i} \left(\int_a^t k(s)\, ds\right)^j \Big/ j! + \|x_1'(t) - y'(t)\| \\ &\leqq k(t)\rho \exp\left(\int_a^t k(s)\, ds\right) + \operatorname{dist}(y'(t), G(t, y(t))).\end{aligned}$$

Taking the limit we obtain that for almost all $t \in [a, b]$

$$\|x'(t) - y'(t)\| \leqq k(t)\rho \exp\left(\int_a^t k(s)\, ds\right) + \operatorname{dist}(y'(t), G(t, y(t))).$$

Consider a set-valued map F from $\mathbb{R}^n$ to $\mathbb{R}^n$ and a differential inclusion

$$x' \in F(x). \tag{2.1}$$

A function $x \in W^{1,1}(0, T)$, $T > 0$ (the Sobolev space) is called a trajectory of (2.1) if for almost all $t \in [0, T]$, $x'(t) \in F(x(t))$. We denote by S_t the set of all trajectories of (2.1) defined on the time interval $[0, t]$. The reachable set of the inclusion (2.1) from a point $\xi \in \mathbb{R}^n$ at time $t \geqq 0$ is given by

$$R(t, \xi) = \{x(t) : x \in S_t, x(0) = \xi\}.$$

We observe that the reachable sets enjoy the semigroup property:

$$\begin{aligned} &R(t + h, \xi) = R(t, R(h, \xi)) \quad \text{for all } t, h \geqq 0, \\ &R(0, \xi) = \xi. \end{aligned} \tag{2.2}$$

Let $z \in S_T$ be a given trajectory. In this section we study tangent vectors to the reachable set $R(T, C)$ at $z(T)$. We call a set $Q \subset \mathbb{R}^n$ a cone if for all $\lambda \geqq 0$, $\lambda Q \subset Q$. First recall the following definition.

DEFINITION 2.1. Let K be a subset of $\mathbb{R}^n$ and $x \in K$. The (Bouligand) contingent cone to K at x is given by

$$T_K(x) = \{v \in \mathbb{R}^n : \exists h_i \to 0+,\ v_i \to v \text{ such that } x + h_i v_i \in K\}.$$

The intermediate tangent cone to K at x is defined by

$$I_K(x) = \{v \in \mathbb{R}^n : \forall h_i \to 0+ \exists v_i \to v \text{ such that } x + h_i v_i \in K\}.$$

We refer to [2], [12] for properties of $T_K(x)$, $I_K(x)$. Throughout the entire paper we assume that the set-valued map F in the right-hand side of the differential inclusion (2.1) satisfies the following assumption:

$$(H_1) \quad \begin{cases} \text{Dom } F := \{x: F(x) \neq \emptyset\} \text{ is open,} \\ F \text{ has compact images and is Lipschitzian on Dom } F. \end{cases}$$

DEFINITION 2.2. Let $F: \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map that is locally Lipschitzian at x and $y \in F(x)$. The derivative of F at (x, y) is the set-valued map $dF(x, y): \mathbb{R}^n \rightrightarrows R^n$ given by the following: for all $u \in \mathbb{R}^n$,

$$v \in dF(x, y)u \Leftrightarrow \lim_{h \to 0+} \operatorname{dist}\left(v, \frac{F(x+hu)-y}{h}\right) = 0.$$

Observe that graph $(dF(x, y)) := \{(u, v): v \in dF(x, y)u\}$ is a closed cone equal to the intermediate tangent cone to graph (F) at (x, y). We refer to [12]-[14] for some properties and applications of the set-valued derivative.

We denote by co F the convexified set-valued map, i.e., for all $x \in \mathbb{R}^n$, co $F(x)$ is the convex hull of $F(x)$.

Consider the "linearized inclusion"

$$w'(s) \in d \text{ co } F(z(s), z'(s))w(s) \quad \text{a.e.} \tag{2.3}$$

For all h, $t \geqq 0$, $\xi \in \mathbb{R}^n$ define the reachable set $r(h, t)\xi$ of (2.3) by

$$r(h, t)\xi = \{w(t+h): w \in W^{1,1}(t, t+h) \text{ satisfies (2.3)}, w(t) = \xi\}.$$

DEFINITION 2.3. Let $t \in [0, T[$. Set

$$W(t, z) = \{v : \exists h_i \geqq 0,\ \mu_i \to 0+ \text{ such that } \lim_{i \to \infty} h_i = 0,\ z(t+h_i) + \mu_i v \in R(t+h_i, C) + o(\mu_i)B\},$$

$$\mathcal{W}(t, z) = \{v : \forall \mu_i \to 0+ \exists h_i \to 0,\ h_i \geqq 0 \text{ such that } z(t+h_i) + \mu_i v \in R(t+h_i, C) + o(\mu_i)B\}.$$

Observe that $W(t, z)$ and $\mathcal{W}(t, z)$ are closed cones. Moreover, for all $t \in [0, T[$

$$T_{R(t,C)}(z(t)) \subset W(t, z), \qquad I_{R(t,C)}(z(t)) \subset \mathcal{W}(t, z) \subset W(t, z) \tag{2.4}$$

and, in particular, $T_C(z(0)) \subset W(0, z)$.

Remark. When for some integer $k \geqq 1$, $\mu_i = h_i^k$, the vector v can be seen as the kth-order variation of $R(\cdot)$ at (t, z).

Actually, variations of $R(\cdot, C)$ at (t, z) are mapped by $r(T-t, t)$ into the tangent vectors to $R(T, C)$.

THEOREM 2.4. *Assume that* (H_1) *is verified and let* $t \in [0, T[$. *Then for all* $t < \tau < T$

$$r(\tau - t, t)W(t, z) \subset T_{R(\tau,C)}(z(\tau)),\ r(\tau - t, t)\mathcal{W}(t, z) \subset I_{R(\tau,C)}(z(\tau)),$$

$$r(T - t, t)T_{R(t,C)}(z(t)) \subset T_{R(T,C)}(z(T)).$$

To prove the theorem above, we need a consequence of the Filippov-Ważewski relaxation result (see [1, p. 124]):

Consider the convexified inclusion

$$\begin{cases} x'(s) \in \operatorname{co} F(x(s)) & \text{a.e.,} \\ x(0) \in C. \end{cases} \tag{2.5}$$

PROPOSITION 2.5. *Assume that* (H_1) *holds true. Then for all* $t \in [0, T]$ *the contingent (respectively, intermediate) cones to the reachable sets of* (2.1) *and* (2.5) *at time* t *taken at the point* $z(t)$ *do coincide.*

Proof of Theorem 2.4. By Proposition 2.5, we may asume that F has convex images. Fix a solution w of (2.3) and let $h_i \geqq 0$, $\mu_i \to 0+$, $v_i \to v = w(t)$ be such that $\lim_{i\to\infty} h_i = 0$, $z(t+h_i) + \mu_i v_i \in R(t+h_i, C)$. For all $s \in [t+h_i, \tau]$ set

$$y_i(s) = z(s) + \mu_i \left(v_i + \int_{t+h_i}^{s} w'(p)\, dp \right)$$

and let $L \geqq 1$ denote the Lipschitz constant of F. Then for almost all $s \in [t+h_i, \tau]$ and all large i

$$\begin{aligned} \operatorname{dist}(y_i'(s), F(y_i(s))) &\leqq \operatorname{dist}(z'(s) + \mu_i w'(s), F(z(s) + \mu_i w(s))) \\ &\quad + L\mu_i \left(\|v_i - v\| + \int_t^{t+h_i} \|w'(p)\|\, dp \right) \\ &\leqq L\mu_i \left(\|w'(s)\| + \|w(s)\| + \|v_i - v\| + \int_t^{t+h_i} \|w'(p)\|\, dp \right). \end{aligned} \tag{2.6}$$

Moreover,

$$\lim_{i\to\infty} \left(\|v_i - v\| + \int_t^{t+h_i} \|w'(p)\|\, dp \right) = 0$$

and, by definition of dF, for almost all $s \in [t, \tau]$

$$\lim_{i\to\infty} \operatorname{dist}(z'(s) + \mu_i w'(s), F(z(s) + \mu_i w(s)))/\mu_i = 0.$$

Thus, by the Lebesgue dominated convergence theorem and (2.6),

$$\lim_{i\to\infty} \int_{t+h_i}^{\tau} \operatorname{dist}(y_i'(s), F(y_i(s)))\, ds/\mu_i = 0.$$

By the Filippov Theorem there exist

$$r_i \in R(\tau - t - h_i, z(t+h_i) + \mu_i v_i) \subset R(\tau, C)$$

such that $\|r_i - y_i(\tau)\| = o(\mu_i)$.

Since

$$\lim_{i\to\infty} (y_i(\tau) - z(\tau))/\mu_i = \lim_{i\to\infty} \left(v_i + \int_{t+h_i}^{\tau} w'(p)\, dp \right) = w(\tau),$$

we end the proof. □

THEOREM 2.6. *Assume that* (H_1) *is verified and let* $0 \leqq t \leqq \tau \leqq T$. *Then the set*

$$\{(w(t), w(\tau)) : w(t) \in T_{R(t,C)}(z(t)),\ w \in W^{1,1}(t, \tau) \text{ is a trajectory of } (2.3)\}$$

is contained in

$$T_{\{(x,y):x\in R(t,C),y\in R(\tau-t,x)\}}(z(t), z(\tau)).$$

Proof. By the proof of Theorem 2.4 in the case when $h_i = 0$ for all $i \geqq 1$, we know that there exist $\mu_i \to 0+$, $v_i \to v$, $r_i \in R(\tau - t, z(t) + \mu_i v_i)$ such that $z(t) + \mu_i v_i \in R(t, C)$ and $\|r_i - z(\tau) - \mu_i(v_i + \int_t^\tau w'(p)\, dp)\| = o(\mu_i)$. Hence

$$\lim_{i\to\infty} (z(t) + \mu_i v_i - z(t), r_i - z(\tau))/\mu_i = \left(v, v + \int_t^\tau w'(p)\, dp\right) = (w(t), w(\tau)).$$

It is shown in [16] that under the hypothesis (H_1) the reachable map R has the following (first-order) expansion: for all ξ near $z(t)$ and all small $h > 0$

$$R(h, \xi) = \xi + h \text{ co } F(z(t)) + o(t, h) \tag{2.7}$$

where

$$\lim_{h\to 0+, \xi \to z(t)} \|o(t, h)\|/h = 0$$

and the equality in (2.7) must be understood in the following way:

$$R(h, \xi) \subset \xi + h \text{ co } F(z(t)) + o(t, h)B,$$

$$\xi + h \text{ co } F(z(t)) \subset R(h, \xi) + o(t, h)B.$$

On the other hand, the function $z(\cdot)$ being absolutely continuous, for almost all $t \in [0, T]$ and all $h > 0$ we can write $z(t + h) = z(t) + hz'(t) + o(h)$. Applying (2.7) with $\xi = z(t)$ and using Definition 2.3 we obtain

$$\text{co } F(z(t)) - z'(t) \subset \mathcal{W}(t, z) \quad \text{a.e. in } [0, T]. \tag{2.8}$$

We have even a stronger result that we shall use in Theorem 2.9.

THEOREM 2.7. *Assume that* (H_1) *holds true. Then* $\mathcal{W}(t, z) + T_{R(t,C)}(z(t)) \subset W(t, z)$, $\mathcal{W}(t, z) + I_{R(t,C)}(z(t)) = \mathcal{W}(t, z)$.

Proof. Fix $w \in \mathcal{W}(t, z)$, $v \in T_{R(t,C)}(z(t))$ and let $\mu_i \to 0+$, $v_i \to v$ be such that $z(t) + \mu_i v_i \in R(t, C)$. Fix $h_i \to 0+$, $w_i \to w$, $y_i \in S_{t+h_i}$ such that $z(t + h_i) + \mu_i w_i \in R(h_i, z(t))$, $y_i(t) = z(t)$, $y_i(t + h_i) = z(t + h_i) + \mu_i w_i$. Set $\bar{y}_i = y_i + \mu_i v_i$. Then dist $(\bar{y}_i'(s), F(\bar{y}_i(s))) \leqq$ dist $(y_i'(s), F(y_i(s))) + L\mu_i\|v_i\| = L\mu_i\|v_i\|$, where L denotes the Lipschitz constant of F. This and Filippov's Theorem imply the existence of $x_i \in S_{t+h_i}$ such that $x_i(t) = \bar{y}_i(t) = z(t) + \mu_i v_i \in R(t, C)$,

$$\begin{aligned} x_i(t + h_i) &= \bar{y}_i(t + h_i) + o(\mu_i) \\ &= z(t + h_i) + \mu_i(w_i + v_i) + o(\mu_i) \in R(h_i, x_i(t)) \subset R(h_i, R(t, C)). \end{aligned}$$

Hence, from (2.2),

$$z(t + h_i) + \mu_i(w_i + v_i) \in R(t + h_i, C) + o(\mu_i).$$

Definition 2.3 ends the proof of the first statement. The proof of the second one is analogous; therefore we omit it. □

In § 4 we study "normal" cones to reachable sets along the trajectory z via a duality technique applied to convex subcones of the set $W(t, z)$. Next we introduce an example of such a subcone.

DEFINITION 2.8. Let $t \in [0, T]$. A vector $v \in \mathbb{R}^n$ is called a smooth variation of order $k > 0$ at (t, z) if

$$\lim_{\substack{h \to 0+ \\ t' \to t+}} \operatorname{dist}\left(v, \frac{R(h, z(t')) - z(t'+h)}{h^k}\right) = 0.$$

The set of all variations of order k is denoted by $R^k(t, z)$. The closed cone spanned by all variations is called the expansion cone of the reachable map at (t, z) and is denoted by $R^\infty(t, z)$:

$$R^\infty(t, z) = \operatorname{cl} \bigcup_{\substack{\lambda \geqq 0 \\ k > 0}} \lambda R^k(t, z).$$

The expansion cone at a stationary trajectory is introduced in [14] for studying the problem of local controllability at a point of equilibrium. Clearly, whenever $v \in R^k(t, z)$, for all $\mu_i \to 0+$ there exist $h_i \to 0+$ such that $z(t+h_i) + \mu_i v \in R(h_i, z(t)) + o(\mu_i)$. Hence Theorem 2.7 yields $T_{R(t,C)}(z(t)) + R^k(t, z) \subset W(t, z)$. Moreover,

$$\begin{aligned} &I_{R(t,C)}(z(t)) + R^\infty(t, z) \subset \mathcal{W}(t, z), \\ &T_{R(t,C)}(z(t)) + R^\infty(t, z) \subset W(t, z). \end{aligned} \tag{2.9}$$

THEOREM 2.9. *Assume that* (H_1) *holds true. Then* $R^\infty(t, z)$ *is a closed convex subcone of the cone of variations* $\mathcal{W}(t, z)$ *satisfying* (2.9).

This result is an immediate consequence of the closedness of $\mathcal{W}(t, z)$ and Lemma 2.10.

LEMMA 2.10. *If* (H_1) *holds true then we have the following*:

(i) *For all* $K > k$, $0 \in R^k(t, z) \subset R^K(t, z)$;

(ii) *For all* $k > 0$, $(n+1)^{-k} \operatorname{co} R^k(t, z) \subset R^k(t, z)$.

Proof. Clearly, for all $k > 0$

$$0 \in R^k(t, z). \tag{2.10}$$

Fix $K > k > 0$ and observe that for all $v \in \mathbb{R}^n$, $t' \in [0, T[$, $h \in]0, 1[$ we have $h^{K/k} < h$ and

$$\begin{aligned} &\operatorname{dist}\left(v, \frac{R(h, z(t')) - z(t'+h)}{h^K}\right) \\ &\quad \leqq \operatorname{dist}\left(v, \frac{R(h^{K/k}, z(t'+h-h^{K/k})) - z(t'+h-h^{K/k}+h^{K/k})}{(h^{K/k})^k}\right). \end{aligned}$$

This and Definition 2.8 imply (i). To prove (ii) fix $k > 0$, $\lambda_i \geqq 0$, $v_i \in R^k(t, z)$, $i = 0, \cdots, m$ satisfying $\sum_{i=0}^m \lambda_i = 1$. We claim that

$$\sum_{i=0}^m \lambda_i^k v_i \in R^k(t, z). \tag{2.11}$$

Indeed, consider $t_j \to t+$, $h_j \to 0+$. Then

$$z(t_j + \lambda_0 h_j) + h_j^k \lambda_0^k v_0 \in R(\lambda_0 h_j, z(t_j)) + o(h_j^k) B$$

where $\lim_{j \to \infty} o(h_j^k)/h_j^k = 0$. We proceed by the induction. Assume that we have already proved that for some $0 \leqq s < n$ and all j

$$z\left(t_j + h_j \sum_{i=0}^s \lambda_i\right) + h_j^k \sum_{i=0}^s \lambda_i^k v_i \in R\left(h_j \sum_{i=0}^s \lambda_i, z(t_j)\right) + o(h_j^k) B \tag{2.12}$$

with $\lim_{j\to\infty} o(h_j^k)/h_j^k = 0$. By Definition 2.8 applied with $t' = t_j + h_j \sum_{i=0}^{s} \lambda_i$, $h = \lambda_{s+1} h_j$

$$z(t' + \lambda_{s+1} h_j) + h_j^k \lambda_{s+1}^k v_{s+1} \in R(h_j \lambda_{s+1}, z(t')) + o(h_j^k) B.$$

This and the Filippov Theorem yield

$$z(t' + \lambda_{s+1} h_j) + h_j^k \sum_{i=0}^{s+1} \lambda_i^k v_i \in R\left(h_j \lambda_{s+1}, z(t') + h_j^k \sum_{i=0}^{s} \lambda_i^k v_i\right) + o(h_j^k) B \subset \text{(by (2.12))},$$

$$R\left(h_j \lambda_{s+1}, R\left(h_j \sum_{i=0}^{s} \lambda_i, z(t_j)\right)\right) + o(h_j^k) B = R\left(h_j \sum_{i=0}^{s+1} \lambda_i, z(t_j)\right) + o(h_j^k) B.$$

Hence (2.12) is valid also with s replaced by $s+1$. Applying (2.12) with $s = m$, we obtain that

$$\lim_{j\to\infty} \operatorname{dist}\left(\sum_{i=0}^{m} \lambda_i^k v_i, \frac{R(h_j, z(t_j)) - z(t_j + h_j)}{h_j^k}\right) = 0,$$

and since $\{t_j\}$ and $\{h_j\}$ are arbitrary, Definition 2.8 implies (2.11). On the other hand, by the Carathéodory Theorem for all $v \in \operatorname{co} R^k(t, z)$ there exist $\mu_i \geqq 0$, $v_i \in R^k(t, z)$ such that $\sum_{i=0}^{n} \mu_i = 1$ and $\sum_{i=0}^{n} \mu_i v_i = v$. Observe that $\sum_{i=0}^{n} \sqrt[k]{\mu_i}/(n+1) \leqq 1$. Applying (2.11) with

$$\lambda_i = \sqrt[k]{\mu_i}/(n+1), \quad v_{n+1} = 0, \quad \lambda_{n+1} = 1 - \sum_{i=0}^{n} \sqrt[k]{\mu_i}/(n+1),$$

we obtain that $(n+1)^{-k} v = \sum_{i=0}^{n+1} \lambda_i^k v_i \in R^k(t, z)$. This proves (ii). □

3. The adjoint process $r(T-t, t)^*$. Recall that for a subset K of a Banach space E, its positive polar cone is given by

$$K^+ = \{p \in E^* : \forall u \in K, \langle p, u\rangle \geqq 0\}.$$

We also recall the following definition.

DEFINITION 3.1. A set-valued map $G : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is called a (closed) convex process if graph (G) is a closed convex cone.

We refer to Rockafellar [25], who introduced and studied this notion, and to Aubin and Ekeland [2] for further properties.

DEFINITION 3.2. Let $G : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a set-valued map. The adjoint map $G^* : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is given by $p \in G^*(q)$ if and only if for all $(x, y) \in \text{graph } (G)$, $\langle p, x\rangle \leqq \langle q, y\rangle$. In other words $p \in G^*(q) \Leftrightarrow (-p, q) \in \text{graph } (G)^+$.

Observe that the adjoint G^* is a closed convex process.

Let $\{A(s) : s \in [0, T]\}$ be a given family of closed convex processes from $\mathbb{R}^n$ to $\mathbb{R}^n$ satisfying the following:

(H_2) (i) For all $w \in \mathbb{R}^n$ the map $s \to A(s)w$ is measurable.
(ii) For all $s \in [0, T]$, the map $w \to A(s)w$ is $k(s)$-Lipschitzian, where $k \in L^\infty(0, T)$.

For all $0 \leqq t \leqq \tau \leqq T$, we investigate the adjoint $r(\tau - t, t)^*$ by studying the inclusions

$$w'(s) \in A(s)w(s) \quad \text{a.e.}, \tag{3.1}$$

$$-q'(s) \in A(s)^* q(s) \quad \text{a.e.} \tag{3.2}$$

in the case when

(H_3) $\qquad \text{graph } (A(s)) \subset \text{graph } (d \text{ co } F(z(s), z'(s)))$ a.e. in $[0, T]$.

For a subset $Q \subset \mathbb{R}^n$ we denote by $r_Q(\tau - t, t)$ the restriction of r to Q, i.e.,

$$r_Q(\tau - t, t)x = \begin{cases} r(\tau - t, t)x & \text{when } x \in Q, \\ \varnothing & \text{otherwise.} \end{cases}$$

The main result of this section is Theorem 3.3

THEOREM 3.3. *If a family* $\{A(s)\colon s \in [0, T]\}$ *of closed convex processes from* $\mathbb{R}^n$ *to* $\mathbb{R}^n$ *satisfies* (H_2) *and* (H_3), *then for all* $b \in \mathbb{R}^n$, *convex cone* $Q \subset \mathbb{R}^n$, *and* $0 \leqq t \leqq \tau \leqq T$:

(a) $r(\tau - t, t)^* b \subset \{q(t)\colon q \in W^{1,\infty}(t, \tau)$ *satisfies* (3.2), $q(\tau) = b\}$;

(b) $r_Q(\tau - t, t)^* b \subset \{q(t)\colon q \in W^{1,\infty}(t, \tau)$ *satisfies* (3.2), $q(\tau) = b\} - Q^+$;

(c) $(r(\tau - t, t)Q)^+ \subset \{q(\tau)\colon q \in W^{1,\infty}(t, \tau)$ *satisfies* (3.2), $q(t) \in Q^+\}$.

To prove the above theorem we associate with all $0 \leqq t \leqq \tau \leqq T$ the convex process $\hat{r}(\tau - t, t)\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ defined by the following: for all $\xi \in \mathbb{R}^n$,

$$\hat{r}(\tau - t, t)\xi = \{w(\tau)\colon w \text{ satisfies (3.1) on } [t, \tau],\ w(t) = \xi\}. \tag{3.3}$$

Then by the definition of the adjoint map, for all $b \in R^n$

$$r(\tau - t, t)^* b \subset \hat{r}(\tau - t, t)^* b, \tag{3.4}$$

$$r_Q(\tau - t, t)^* b \subset \hat{r}_Q(\tau - t, t)^* b, \tag{3.5}$$

$$(r(\tau - t, t)Q)^+ \subset (\hat{r}(\tau - t, t)Q)^+. \tag{3.6}$$

Theorem 3.3 follows from the inclusions above and the following two lemmas.

LEMMA 3.4. *If* (H_2) *holds true, then for any* $0 \leqq t \leqq \tau \leqq T$ *and* $b \in \mathbb{R}^n$

$$\hat{r}(\tau - t, t)^* b = \{q(t)\colon q \in W^{1,\infty}(t, \tau) \text{ satisfies (3.2)}, q(\tau) = b\}. \tag{3.7}$$

LEMMA 3.5. *If* (H_2) *holds true, then for any convex cone* $Q \subset \mathbb{R}^n$ *and* $b \in$ Dom $\hat{r}(\tau - t, t)^*$ *we have the following*:

$$\hat{r}_Q(\tau - t, t)^* b = \hat{r}(\tau - t, t)^* b - Q^+, \tag{3.8}$$

$$(\hat{r}(\tau - t, t)Q)^+ = \hat{r}(\tau - t, t)^{*-1}(Q^+).$$

Proof of Lemma 3.4. Fix $0 \leqq t \leqq \tau \leqq T$. Let us set:

$X = W^{1,2}(t, \tau)$, $Y = L^2(t, \tau) \times L^2(t, \tau)$;

$L = \{(x, y) \in Y\colon y(s) \in A(s)x(s)$ a.e. in $[t, \tau]\}$;

D, the differential operator on X, $Dx = x'$;

γ, the trace operator on X, $\gamma(x) = (x(t), x(\tau))$.

Observe that L is a closed convex cone and, by the measurable selection theorem (see [26]),

$$L^+ = \{(-p, q) \in Y^*\colon p(s) \in A(s)^* q(s) \text{ a.e. in } [t, \tau]\}. \tag{3.9}$$

We claim that

$$\operatorname{Im}(1 \times D) - L = Y. \tag{3.10}$$

To prove it we must verify that for all $(u, v) \in Y$ there exists $x \in X$ satisfying

$$x'(s) \in A(s)(x(s) - u(s)) + v(s) \quad \text{a.e. in } [t, \tau]. \tag{3.11}$$

Fix $(u, v) \in Y$ and observe that, by (H_2), the set-valued map $[t, \tau] \times \mathbb{R}^n \ni (s, x) \to A(s)(x - u(s)) + v(s)$ is measurable in s, and for almost all s it is Lipschitzian in x with the Lipschitz constant $k(s)$. Moreover, $\operatorname{dist}(0, A(s)(-u(s)) + v(s)) \leqq k(s)\ \|u(s)\| + \|v(s)\|$. By the Filippov Theorem there exist $M \geqq 0$ and $x \in W^{1,1}(t, \tau)$ satisfying (3.11) and such that

$$\|x'(s)\| \leqq Mk(s) + k(s)\|u(s)\| + \|v(s)\| \quad \text{a.e. in } [t, \tau].$$

Thus $\|x'\| \in L^2(t, \tau)$ and therefore $x \in X$. Hence we have proved (3.10). By Lemma 1.3 of [3] and (3.10) we obtain

$$((1 \times D)^{-1} L)^+ = (1 \times D)^*(L^+). \tag{3.12}$$

Clearly, $\gamma((1 \times D)^{-1} L) \subset \text{graph}\,(\hat{r}(\tau - t, t))$ and by (3.12), $\gamma^* \,\text{graph}\,(\hat{r}(\tau - t, t))^+ \subset ((1 \times D)^{-1} L)^+ = (1 \times D)^*(L^+)$. Hence for all $(a, b) \in \text{graph}\,(\hat{r}(\tau - t, t))^+$ there exists $(-p, q) \in L^+$ such that

$$\gamma^*(a, b) = (1 \times D)^*(-p, q). \tag{3.13}$$

This implies that for all $w \in W_0^{1,2}(t, \tau)$,

$$0 = \langle (1 \times D)^*(-p, q), w \rangle = \int_t^\tau (-pw + qw')(s)\, ds = \int_t^\tau w'(s) \left(q(s) + \int_t^s p(r)\, dr \right) ds.$$

Thus, $q \in W^{1,2}(t, \tau)$ and $q' = -p$. By (3.9), $-q'(s) \in A(s)^* q(s)$ almost everywhere in $[t, \tau]$. From Proposition 1.7b of [3] we deduce that $q \in W^{1,\infty}(t, \tau)$. Moreover by (3.13) for all $x \in X$, $\langle (a, b), (x(t), x(\tau)) \rangle = \langle (q', q), (x, x') \rangle = q(\tau)x(\tau) - q(t)x(t)$. Hence $(-a, b) = (q(t), q(\tau))$, and $q(t) \in \hat{r}(\tau - t, t)^* q(\tau)$. We have proved that for all $b \in \mathbb{R}^n$, $\hat{r}(\tau - t, t)^* b$ is contained in the right-hand side of (3.7). On the other hand, if q satisfies (3.2) then for all solutions w of (3.1)

$$q(\tau)w(\tau) - q(t)w(t) = \langle (q', q), (w, w') \rangle \geqq 0.$$

This yields that $q(t) \in r(\tau - t, t)^* q(\tau)$ and ends the proof. □

To prove Lemma 3.5 we apply some results from [2, pp. 142-143] concerning closed convex processes. Since in general $\hat{r}(\tau - t, t)$ is not closed we need the following lemma.

LEMMA 3.6. *If* (H_2) *holds true then* $\hat{r}(\tau - t, t)$ *is Lipschitzian on* $\mathbb{R}^n$ *and the set-valued map* cl $\hat{r}(\tau - t, t)$ *defined as follows: for all* $u \in \mathbb{R}^n$, cl $\hat{r}(\tau - t, t)u = \overline{\hat{r}(\tau - t, t)u}$ *is a Lipschitzian on* $\mathbb{R}^n$ *closed convex process. Moreover,* $(\text{cl}\,\hat{r}(\tau - t, t))^* = \hat{r}(\tau - t, t)^*$ *is an upper semicontinuous set-valued map with compact images mapping bounded sets to bounded sets and Dom* $\hat{r}(\tau - t, t)^* = \hat{r}(\tau - t, t)(0)^+$.

Proof of Lemma 3.6. Since $0 \in \hat{r}(\tau - t, t)0$, the set $\hat{r}(\tau - t, t)0$ is nonempty. Fix any $u \in \mathbb{R}^n$ such that $\hat{r}(\tau - t, t)u \neq \varnothing$ and let w be a solution of (3.1) on $[t, \tau]$ satisfying $w(t) = u$. Pick $v \in \mathbb{R}^n$ and set $y(\cdot) = w(\cdot) + v - u$. Then $\text{dist}\,(y'(s), A(s)y(s)) = \text{dist}\,(w'(s), A(s)(w(s) + v - u)) \leqq k(s)\|v - u\|$. This and the Filippov Theorem imply the existence of a solution $\bar{w}$ of (3.1) defined on $[t, \tau]$ and satisfying $\bar{w}(t) = y(t) = w(t) + v - u = v$,

$$\|\bar{w}(\tau) - y(\tau)\| \leqq M\|v - u\|$$

where M does not depend on v, u. Thus $\hat{r}(\tau - t, t)v \neq \varnothing$ and

$$\|\bar{w}(\tau) - w(\tau)\| \leqq \|\bar{w}(\tau) - y(\tau)\| + \|y(\tau) - w(\tau)\| \leqq M\|v - u\| + \|v - u\|,$$

i.e., $\hat{r}(\tau - t, t)$ is Lipschitzian on $\mathbb{R}^n$ with the constant $M + 1$. Pick any u, $u_1 \in \mathbb{R}^n$, $v \in \text{cl}\,\hat{r}(\tau - t, t)u$ and consider $v_i \to v$, $v_i \in \hat{r}(\tau - t, t)u$. By the Lipschitz continuity of $\hat{r}(\tau - t, t)$ for some $w_i \in \hat{r}(\tau - t, t)u_1$, $\|w_i - v_i\| \leqq (M + 1)\|u - u_1\|$. Taking a subsequence and keeping the same notation, we may assume that w_i converges to some $w \in \text{cl}\,\hat{r}(\tau - t, t)u_1$. Then $\|w - v\| \leqq (M + 1)\|u - u_1\|$ and this yields the Lipschitz continuity of cl $\hat{r}(\tau - t, t)$. Let $(u_i, v_i) \in \text{graph}\,(\hat{r}(\tau - t, t))$ be a sequence converging to some (u, v). Then $v_i \in \hat{r}(\tau - t, t)u_i$ and, by Lipschitz continuity, for some $w_i \in \hat{r}(\tau - t, t)u$ we have $\|w_i - v_i\| \leqq (M + 1)\|u - u_i\|$. Hence $w_i \to v$ and $v \in \text{cl}\,\hat{r}(\tau - t, t)u$. This implies that

$$\overline{\text{graph}\,(\hat{r}(\tau - t, t))} = \text{graph}\,(\text{cl}\,\hat{r}(\tau - t, t)) \tag{3.14}$$

and therefore graph $(\operatorname{cl} \hat{r}(\tau-t, t))$ is a closed convex cone. Hence $\operatorname{cl} \hat{r}(\tau-t, t)$ is a closed convex process and

$$\operatorname{graph}(\hat{r}(\tau-t, t))^{+}=\operatorname{graph}(\operatorname{cl} \hat{r}(\tau-t, t))^{+}.$$

From Definition 3.2 we deduce that $\hat{r}(\tau-t, t)^{*}=(\operatorname{cl} \hat{r}(\tau-t, t))^{*}$. The last statements follow from Proposition 1.7 of [3].

Proof of Lemma 3.5. We prove first that

$$\hat{r}_{Q}(\tau-t, t)^{*}=(\operatorname{cl} \hat{r}_{\bar{Q}}(\tau-t, t))^{*}. \tag{3.15}$$

Indeed, fix $u_i \in Q$, $v_i \in \hat{r}(\tau-t, t)u_i$ such that $\lim_{i\to\infty}(u_i, v_i)=(u, v)$. Then $u \in \bar{Q}$ and $(u, v) \in \overline{\operatorname{graph}(\hat{r}(\tau-t, t))}=\operatorname{graph}(\operatorname{cl} \hat{r}(\tau-t, t))$ (by (3.14)). Hence $v \in \operatorname{cl} \hat{r}_{\bar{Q}}(\tau-t, t)u$ and we proved that $\overline{\operatorname{graph}(\hat{r}_{Q}(\tau-t, t))}=\operatorname{graph}(\operatorname{cl} \hat{r}_{\bar{Q}}(\tau-t, t))$ this yields (3.15). We also know that $\operatorname{Dom}(\operatorname{cl} \hat{r}(\tau-t, t))=\mathbb{R}^{n}$. Hence using [2, pp. 142-143] we obtain (3.8).

To prove the second statement we observe that the Lipschitz continuity of $\operatorname{cl} \hat{r}(\tau-t, t)$ yields

$$\overline{\operatorname{cl} \hat{r}(\tau-t, t)\bar{Q}}=\overline{\operatorname{cl} \hat{r}(\tau-t, t)Q}.$$

hence $(\hat{r}(\tau-t, t)Q)^{+}=(\operatorname{cl} \hat{r}(\tau-t, t)Q)^{+}=(\operatorname{cl} \hat{r}(\tau-t, t)\bar{Q})^{+}=$(by [2, pp. 142-143]) $\operatorname{cl} \hat{r}(\tau-t, t)^{*-1}(Q^{+})=$(by Lemma 3.6) $\hat{r}(\tau-t, t)^{*-1}(Q^{+})$. The proof is complete.

4. The cone $T_{R(\tau,C)}(z(\tau))^{+}$. In this section we assume that (H_1) holds true and that there exists a family of closed convex processes $\{A(s)\}_{s\in[0,T]}$ satisfying (H_2) and (H_3).

Observe that the dual form of Theorem 2.4 is as follows: for all $0 \leqq t<\tau \leqq T$,

$$T_{R(\tau,C)}(z(\tau))^{+} \subset (r(\tau-t, t)W(t, z))^{+}. \tag{4.1}$$

Hence we can "estimate" $T_{R(\tau,C)}(z(\tau))^{+}$ using the set $(r(\tau-t, t)W(t, z))^{+}$. We study this last set via a duality technique.

Consider again the adjoint differential inclusion

$$-q'(s) \in A(s)^{*}q(s) \quad \text{a.e.} \tag{4.2}$$

THEOREM 4.1. *Assume that* (H_1)-(H_3) *hold true. Let* $Q(t) \subset W(t, z)$ *be a family of convex cones such that for all* $0 \leqq t \leqq t_1 \leqq T$, $\hat{r}(t_1-t, t)Q(t) \subset Q(t_1)$. *Then for all* $\tau \in [0, T]$

$$T_{R(\tau,C)}(z(\tau))^{+} \subset \{q(\tau): q \in W^{1,\infty}(0, \tau) \text{ satisfies (4.2)}, q(t) \in Q(t)^{+} \text{ on } [0, \tau[\}.$$

Consider next the differential inclusion

$$\begin{cases} -q'(s) \in A(s)^{*}q(s) & \text{a.e.,} \\ \langle q(s), z'(s)\rangle=\min\{\langle q(s), e\rangle: e \in F(z(s))\} & \text{a.e.} \end{cases} \tag{4.3}$$

THEOREM 4.2. *Assume that* (H_1)-(H_3) *hold true and let* $Q(t) \subset \mathcal{W}(t, z)$ *be any family of convex cones. Then for all* $\tau \in [0, T]$

$$T_{R(\tau,C)}(z(\tau))^{+} \subset \{q(\tau): q \in W^{1,\infty}(0, \tau) \text{ satisfies (4.3)}, q(t) \in Q(t)^{+} \text{ on } [0, \tau[\}.$$

In particular,

$$T_{R(\tau,C)}(z(\tau))^{+} \subset \{q(\tau): q \in W^{1,\infty}(0, \tau) \text{ satisfies (4.3)}, q(t) \in R^{\infty}(t, z)^{+}\}.$$

Observe that the statements of the above theorems depend on the choice of $\{A(s)\}$ and $\{Q(s)\}$. From (4.1) and Theorem 3.3(c) we obtain Lemma 4.3.

LEMMA 4.3. *If* (H_1)-(H_3) *hold true, then for any* $0 \leqq t < \tau \leqq T$ *and any convex cone* $Q \subset W(t, z)$

$$T_{R(\tau,C)}(z(\tau))^+ \subset \{q(\tau): q \in W^{1,\infty}(t, \tau) \text{ satisfies (4.2)}, q(t) \in Q^+\}.$$

Proof of Theorem 4.1. We apply the above lemma. Fix $\tau \in]0, T]$ and $b \in T_{R(\tau,C)} \times (z(\tau))^+$.

Step 1. Fix any $0 \leqq t_1 < \cdots < t_m < \tau$. We first prove the existence of $q \in W^{1,\infty}(0, \tau)$ satisfying (4.2) such that

$$q(\tau) = b, \tag{4.4}$$

$$q(t_i) \in Q(t_i)^+ \quad \forall i = 1, \cdots, m. \tag{4.5}$$

By the assumptions of the theorem, inclusion (4.5) implies that

$$q(t_i) \in (\hat{r}(t_i - t_{i-1}, t_{i-1})Q(t_{i-1}))^+. \tag{4.6}$$

We proceed by the induction. By Lemma 4.3 there exists $q \in W^{1,\infty}(t_m, \tau)$ satisfying (4.4), (4.5) with $i = m$. Assume that we already know that for some $2 \leqq j \leqq m$ there exists $q \in W^{1,\infty}(t_j, \tau)$ such that (4.2), (4.4), (4.5) hold true with $i \geqq j$. From (4.6) we deduce that $q(t_j) \in (\hat{r}(t_j - t_{j-1}, t_{j-1})Q(t_{j-1}))^+$. Applying Lemmas 3.4, 3.5 with $\tau = t_j$, $b = q(t_j)$, and $t = t_{j-1}$ we prove the existence of $\hat{q} \in W^{1,\infty}(t_{j-1}, t_j)$ satisfying (4.2) such that $\hat{q}(t_j) = q(t_j)$, $\hat{q}(t_{j-1}) \in Q(t_{j-1})^+$. Setting

$$q(s) = \begin{cases} q(s) & \text{when } s \in [t_j, \tau], \\ \hat{q}(s) & \text{when } s \in [t_{j-1}, t_j], \end{cases}$$

we end the proof of Step 1. □

Step 2. Let $t_i \in [0, \tau]$, $i = 1, 2, \cdots$ be a dense subset of $[0, \tau]$. Set

$$L = \{(x, y) \in L^2(0, \tau) \times L^2(0, \tau): x(s) \in A(s)^* y(s) \text{ a.e.}\}.$$

Since $A(s)^*$ are closed convex processes, by Mazur's Lemma, L is weakly closed in $L^2(0, \tau) \times L^2(0, \tau)$. By Step 1, for all $j \geqq 1$ there exists $q_j \in W^{1,\infty}(0, \tau)$, satisfying (4.2) and such that $q_j(\tau) = b$ and for all $1 \leqq i \leqq j$

$$q_j(t_i) \in Q(t_i)^+. \tag{4.7}$$

By Proposition 1.6(b) of [3], for all j and almost all $s \in [0, \tau]$, $\|q_j'(s)\| \leqq k(s)\|q_j(s)\|$. This and Gronwall's Lemma imply that $\{q_j\}$ is bounded in $W^{1,2}(0, \tau)$ and, by reflexivity, it has a weak cluster point q. Since L is weakly closed, q satisfies (4.2) and by (4.7), for all i, $q(t_i) \in Q(t_i)^+$. Fix $t \in [0, \tau]$, $w \in Q(t)$ and let $\{t_{i_k}\}$ be a subsequence converging to t from the right. Since $\{A(s)\}$ satisfies (H_2), by the Filippov Theorem there exist $w_k \in \hat{r}(t_{i_k} - t, t)w$ converging to w. Moreover, for all k, $\langle q(t_{i_k}), w_k \rangle \geqq 0$. Therefore, taking the limit, we get $q(t) \in Q(t)^+$ for all $t \in [0, \tau]$. This ends the proof. □

To prove Theorem 4.2 we need two lemmas.

The next lemma shows how a given family $\{A(s)\}$ can be "increased" to a larger family of closed convex processes still satisfying (H_2), (H_3).

LEMMA 4.4. *For all* $s \in [0, T]$ *such that* $z'(s) \in F(z(s))$ *and for all* $x \in \mathbb{R}^n$ *set*

$$G(s)x = \overline{A(s)x + T_{\text{co } F(z(s))}(z'(s))}$$

and set $G(s) = A(s)$ *for all other* s. *Then* $\{G(s)\}_{s \in [0,T]}$ *are closed convex processes satisfying* (H_2), (H_3) *and* $A(s) \subset G(s)$. *Moreover, for almost all* $s \in [0, T]$ *and all* $q \in \mathbb{R}^n$

$$G(s)^* q = \begin{cases} A(s)^* q & \text{when } q \in (F(z(s)) - z'(s))^+, \\ \varnothing & \text{otherwise.} \end{cases} \tag{4.8}$$

Proof. From the definition of $G(s)$, exactly as in the proof of Lemma 3.6, we deduce that $G(s)(\cdot)$ is $k(s)$-Lipschitz on $\mathbb{R}^n$. By Lemma 2.8 of [12] we know that

$\{G(s)\}$ satisfy (H_3). Since $G(s)(\cdot)$ is continuous and has closed images, graph $(G(s))$ is closed. It is also clear that graph $(G(s))$ is a cone. To prove its convexity it is enough to consider only those $s \in [0, T]$ that satisfy $z'(s) \in F(z(s))$. Fix such s and $u, v \in \mathbb{R}^n$. Since $A(s)$ is a convex process and $T_{\text{co } F(z(s))}(z'(s))$ is a convex cone, we obtain

$$A(s)u + T_{\text{co } F(z(s))}(z'(s)) + A(s)v + T_{\text{co } F(z(s))}(z'(s)) \subset A(s)(u+v) + T_{\text{co } F(z(s))}(z'(s)).$$

This yields that

$$G(s)u + G(s)v \subset \overline{A(s)(u+v) + T_{\text{co } F(z(s))}(z'(s))} = G(s)(u+v).$$

Hence $G(s)$ is a closed convex process. Moreover, by [25], for all $q \in \mathbb{R}^n$

$$G(s)^*q = \begin{cases} A(s)^*q & \text{when } q \in T_{\text{co } F(z(s))}(z'(s))^+, \\ \varnothing & \text{otherwise.} \end{cases} \tag{4.9}$$

Since co $F(z(s))$ is a convex set we also have

$$T_{\text{co } F(z(s))}(z'(s)) = \overline{\bigcup_{i=1,2,\cdots} i(\text{co } F(z(s)) - z'(s))}, \tag{4.10}$$

and therefore

$$T_{\text{co } F(z(s))}(z'(s))^+ = (\text{co } F(z(s)) - z'(s))^+.$$

Using (4.9), we deduce from the last equality that for almost all $s \in [0, T]$, (4.8) holds true. To end the proof it remains to show that for all $x \in \mathbb{R}^n$, the map $s \to G(s)x$ is measurable. Since the map $s \to F(z(s))$ is continuous it is also measurable. By Castaing's Representation Theorem [8] and the assumption (H_2)(i) there exist measurable selections

$$f_n(s) \in F(z(s)), \quad g_n(s) \in A(s)x, \quad n = 1, 2, \cdots,$$

such that for all s

$$\overline{\bigcup_{n \geq 1} f_n(s)} = F(z(s)), \qquad \overline{\bigcup_{n \geq 1} g_n(s)} = A(s)x.$$

Hence, using (4.10), we obtain

$$G(s)x = \overline{\bigcup_{n \geq 1} g_n(s) + \bigcup_{i \geq 1} i \bigcup_{n \geq 1} (f_n(s) - z'(s))} = \overline{\bigcup_{\substack{n \geq 1 \\ i,j \geq 1}} g_n(s) + i(f_j(s) - z'(s))}.$$

Since the functions $s \to g_n(s) + i(f_j(s) - z'(s))$ are measurable, the last equality and Castaing's Theorem imply that $s \to G(s)x$ is a measurable set-valued map. □

In Theorem 4.1 we deal with convex cones $Q(t) \subset W(t, z)$ that have the following invariance property:

$$\forall 0 \leqq t < t_1 \leqq T \quad \hat{r}(t_1 - t, t)Q(t) \subset Q(t_1). \tag{4.11}$$

The next result shows how such cones can be constructed.

LEMMA 4.5. *Let $\{A(s)\}_{s \in [0,T]}$ be any family of closed convex processes satisfying (H_2), (H_3) and $\hat{Q}(t) \subset \mathcal{W}(t, z)$ be convex cones. Then there exist convex cones $Q(t) \supset \hat{Q}(t)$ satisfying* (4.11).

Proof. For all $0 \leqq t_1 \leqq \cdots \leqq t_m \leqq T$, define recursively cones $P(t_1) = \hat{Q}(t_1) + \hat{r}(t_1, 0)\hat{Q}(0), \cdots, P(t_1, \cdots, t_{i+1}) = \hat{Q}(t_{i+1}) + \hat{r}(t_{i+1} - t_i, t_i)P(t_1, \cdots, t_i)$. Using an induction argument, we prove by Theorems 2.4 and 2.7 that for all $i \geqq 1$, $P(t_1, \cdots, t_i) \subset \mathcal{W}(t, z)$. Set

$$Q(t) = \bigcup_{\substack{0 \leqq t_1 \leqq \cdots \leqq t_m = t \\ m \geqq 1}} P(t_1, \cdots, t_m).$$

Clearly $Q(t)$ is a cone containing $\hat{Q}(t)$ and, by definition of $Q(t)$, for all $0 \leqq t \leqq t_1 \leqq T$, $\hat{r}(t_1 - t, t)Q(t) \subset Q(t_1)$. It remains to prove that $Q(t)$ is convex, i.e., we must check that for all $0 \leqq t_1 \leqq \cdots \leqq t_m = t$, $0 \leqq t'_1 \leqq \cdots \leqq t'_k = t$

$$P(t_1, \cdots, t_m) + P(t'_1, \cdots, t'_k) \subset Q(t). \tag{4.12}$$

We proceed by the induction with respect to $m + k$. Observe that for all $t \in [0, T]$, $P(t)$ is a convex cone. Fix $t \in [0, T]$. Assume that for some $j \geqq 2$ and all $m \geqq 1$, $k \geqq 1$, $0 \leqq t_1 \leqq \cdots \leqq t_m = t$, $0 \leqq t'_1 \leqq \cdots \leqq t'_k = t$ satisfying $m + k \leqq j$ the relation (4.12) holds true. Fix $0 \leqq t_1 \leqq \cdots \leqq t_{m+1} = t$, $0 \leqq t'_1 \leqq \cdots \leqq t'_k = t$ such that $m + k = j$, $t_{k-1} \leqq t_m$. Then $P(t_1, \cdots, t_m) + P(t'_1, \cdots, t'_{k-1}, t_m) \subset Q(t_m)$. Moreover, by definition of $P(\cdot)$, using that $\hat{r}$ is a convex process we obtain

$$\hat{r}(t_m - t'_{k-1}, t'_{k-1})P(t'_1, \cdots, t'_{k-1}) \subset P(t'_1, \cdots, t'_{k-1}, t_m).$$

This and the definition of $Q(t)$ imply:

$$\begin{aligned} P(t_1, \cdots, t_{m+1}) + P(t'_1, \cdots, t'_k) &= \hat{Q}(t) + \hat{r}(t - t_m, t_m)P(t_1, \cdots, t_m) \\ &\quad + \hat{Q}(t) + \hat{r}(t - t_m, t_m)\hat{r}(t_m - t'_{k-1}, t'_{k-1})P(t'_1, \cdots, t'_{k-1}) \\ &\subset \hat{Q}(t) + \hat{r}(t - t_m, t_m)(P(t_1, \cdots, t_m) + P(t_1, \cdots, t'_{k-1}, t_m)) \\ &\subset \hat{Q}(t) + \hat{r}(t - t_m, t_m)Q(t_m) \subset Q(t). \end{aligned}$$

Proof of Theorem 4.2. By Lemma 4.4 we replace the family $\{A(s)\}$ by the new family $\{G(s)\}$ satisfying (H_2), (H_3) and (4.8). From Lemma 4.5 it is not restrictive to assume that the family $\{Q(s)\}$ satisfies (4.11). Theorem 4.1 applied with $\{G(s)\}$ yields the result. □

COROLLARY 4.6. *Assume that* (H_1)-(H_3) *hold true and let* Q *be a convex subcone of* $T_C(z(0))$. *Then for all* $\tau \in [0, T]$

$$T_{R(\tau,C)}(z(\tau))^+ \subset \{q(\tau)\colon q \in W^{1,\infty}(0, \tau) \text{ satisfies (4.3)}, q(0) \in Q^+\}.$$

Proof. Setting $Q(t) = \hat{r}(t, 0)Q$ and applying Theorem 4.1 with closed convex processes $\{G(s)\}$ of Lemma 4.4, we deduce our statement from (4.8). □

THEOREM 4.7. *Assume that* (H_1)-(H_3) *hold true and that, for any* $t \in [0, T]$, q_1, $q_2 \in W^{1,\infty}(0, t)$ *satisfying* (4.3) *and equal at* t, *we have* $q_1/\|q_1\| = q_2/\|q_2\|$ *on* $[0, t]$. *Then for all* $\tau \in [0, T]$

$$T_{R(\tau,C)}(z(\tau))^+ \subset \{q(\tau)\colon q \in W^{1,\infty}(0, \tau) \text{ satisfies (4.3) and } q(t) \in W(t, z)^+ \text{ on } [0, \tau[\}.$$

In particular, the above happens when for almost all $s \in [0, T]$, *the adjoint* $A(s)^*$ *is single-valued and Lipschitzian on its domain of definition.*

Proof. Fix $\tau \in [0, T]$, $b \in T_{R(\tau,C)}(z(\tau))^+$, $t \in [0, \tau[$, $c \in W(t, z)$. By Theorem 4.1 applied with the family of closed convex processes $\{G(s)\}$ and the convex cones

$$Q(s) = \begin{cases} \varnothing & \text{for } s < t, \\ \mathbb{R}_+ c & \text{for } s = t, \\ \hat{r}(s - t, t)Q(t) & \text{for } s > t, \end{cases}$$

using (4.8), we prove the existence of $q \in W^{1,\infty}(0, \tau)$ satisfying (4.3) such that $q(\tau) = b$, $\langle q(t), c\rangle \geqq 0$. Since $c \in W(t, z)$ and $t \in [0, \tau[$ are arbitrary, by the assumptions of Theorem 4.1, $q(t) \in W(t, z)^+$ on $[0, \tau[$. □

COROLLARY 4.8. *Assume that* (H_1) *holds true and that there exist linear operators* $A(s) \in L(\mathbb{R}^n, \mathbb{R}^n)$ *satisfying* (H_2), (H_3). *Then for all* $\tau \in (0, T)$,

$$\begin{aligned} T_{R(\tau,C)}(z(\tau))^+ \subset \{q(\tau)\colon & -q'(s) = A(s)^* q(s), \\ & \langle q(s), z'(s)\rangle = \min_{e \in F(z(s))} \langle q(s), e\rangle, \ q(s) \in W(s, z)^+ \text{ in } [0, \tau[\}. \end{aligned}$$

Proof. The transposed linear operator $A(s)^*$ is equal to the adjoint process in the sense of Definition 3.1 (see Rockafellar [25]). Since for all $b \in T_{R(\tau,C)}(z(\tau))^+$, the solution of the linear equation $-q'(s) = A(s)^*q(s)$; $q(\tau) = b$ is unique, the proof follows from Theorem 4.7. □

THEOREM 4.9. *Let $R_C(T, \cdot)$ denote the restriction of the reachable map $R(T, \cdot)$ to the set C. Then for every convex cone $Q \subset T_C(z(0))$,*

$$T_{\text{graph } R_C(T,\cdot)}(z(0), z(T))^+ \subset \{(\pi - q(0), q(T)) : q \in W^{1,\infty}(0, T) \text{ satisfies (4.3) and } \pi \in Q^+\}.$$

Proof. By Theorem 2.6,

$$T_{\text{graph } R_C(T,\cdot)}(z(0), z(T))^+ \subset \{(w(0), r(T, 0)w(0)) : w(0) \in T_C(z(0))\}^+. \tag{4.13}$$

We replace closed convex processes $\{A(s)\}$ by $\{G(s)\}$ from Lemma 4.4 and keep the same notation $\hat{r}$ for the reachable map of the inclusion

$$w'(s) \in G(s)w(s) \quad \text{a.e.}$$

Then by (3.4), (4.13) we obtain

$$T_{\text{graph } R_C(T,\cdot)}(z(0), z(T))^+ \subset \{(a, \hat{r}(T, 0)a) : a \in Q\}^+,$$

and from Lemma 3.5 we deduce that for all $(p, q) \in T_{\text{graph } R_C(T,\cdot)}(z(0), z(T))^+$ we have $p + \hat{r}(T, 0)^*q \in Q^+$. Lemma 3.4 ends the proof. □

Remark 4.10 (*On the Hamiltonian inclusions*). For all $x, p \in \mathbb{R}^n$ the Hamiltonian of F is defined by

$$H(x, p) = \sup_{e \in F(x)} \langle p, e \rangle = \sup_{e \in \text{co } F(x)} \langle p, e \rangle.$$

If (H_1) holds true, then H is locally Lipschitz on Dom $F \times \mathbb{R}^n$ (see, for example, [9]). Let us assume that for all s, Dom $A(s)^*$ is a subspace of $\mathbb{R}^n$ and $A(s)^*$ is *linear on* Dom $A(s)^*$.

Consider an absolutely continuous solution q of (4.3) defined on the time interval $[0, T]$. Pick any $s \in]0, 1[$ such that $\langle q(s), z'(s) \rangle = \min_{e \in F(z(s))} \langle q(s), e \rangle$, $-q'(s) = A(s)^*q(s)$. Set $\bar{q} = -q$ and fix any u. Let $v \in A(s)u$ and $v_h \to v$ (when $h \to 0+$) be such that $z'(s) + hv_h \in \text{co } F(z(s) + hu)$. Then for all $w \in \mathbb{R}^n$ we have

$$\begin{aligned}
\limsup_{h \to 0+} & \frac{H(z(s) + hu, \bar{q}(s) + hw) - H(z(s), \bar{q}(s))}{h} \\
& \geqq \limsup_{h \to 0+} \frac{\langle \bar{q}(s) + hw, z'(s) + hv_h \rangle - \langle \bar{q}(s), z'(s) \rangle}{h} \\
& = \langle w, z'(s) \rangle + \langle \bar{q}(s), v \rangle \\
& \geqq \langle w, z'(s) \rangle + \langle q'(s), u \rangle = \langle (q'(s), z'(s)), (u, w) \rangle.
\end{aligned}$$

In particular this yields

$$(-\bar{q}'(s), z'(s)) \in \partial H(z(s), \bar{q}(s)) \tag{4.14}$$

where ∂H denotes the generalized gradient of H (see [9]). Hence in this particular case for every solution q of (4.3), $-q$ is a solution of the Hamiltonian inclusion (4.14). It may happen that for a family of closed convex processes satisfying (H_2), (H_3), the only solution of (4.3) is $q \equiv 0$, and at the same time the Hamiltonian inclusion (4.14) has solutions different from zero (see the example from [18]). Hence in this particular case it is more convenient to use the adjoint inclusion (4.3) than the Hamiltonian

inclusion (4.14) to estimate the cone $T_{R(T,C)}(z(T))^+$. In a more general case we do not know how to compare solutions of (4.3) and (4.14).

5. Application: high-order maximum principles.

5.1. Minimization with respect to the final state. Let U be a compact metric space and $f:\mathbb{R}^n \times U \to \mathbb{R}^n$ be a continuous function, $g:\mathbb{R}^n \to \mathbb{R}$, $C \subset \mathbb{R}^n$. Consider the following optimal control problem:

$$\text{minimize } g(x(1)) \tag{5.1}$$

over the solutions of the control system

$$\begin{cases} x'(t) = f(x(t), u(t)) & \text{a.e. in } [0,1], \\ x(0) \in C, \qquad u(t) \in U \text{ is measurable.} \end{cases} \tag{5.2}$$

Set $F(x) = f(x, U)$ for all $x \in \mathbb{R}^n$. By the Filippov Theorem [1, p. 91] solutions of the control system (5.2) and the differential inclusion

$$\begin{aligned} &x'(t) \in F(x(t)) \quad \text{a.e. on } [0,1], \\ &x(0) \in C \end{aligned} \tag{5.3}$$

do coincide.

THEOREM 5.1. *Assume that a trajectory control pair $(z, \bar{u})$ solves the above problem and for a constant L and all $u \in U$, $f(\cdot, u)$ is L-Lipschitzian on a neighborhood of $z([0,1])$. If g is differentiable at $z(1)$ and for almost all t, $f(\cdot, u(t))$ is differentiable at $z(t)$, then there exists $q \in W^{1,\infty}(0,1)$ such that*

$$\begin{aligned} &-q'(t) = q(t)\frac{\partial f}{\partial x}(z(t), \bar{u}(t)) \quad \text{a.e.}, \\ &\langle q(t), z'(t)\rangle = \min_{u \in U} \langle q(t), f(z(t), u)\rangle \quad \text{a.e.}, \end{aligned} \tag{5.4}$$

$$q(1) = g'(z(1)), \qquad q(0) \in T_C(z(0))^+, \tag{5.5}$$

$$q(t) \in W(t, z)^+ \quad \text{for all } t \in [0, 1[. \tag{5.6}$$

Proof. By the assumptions, the set-valued map F defined above satisfies (H_1). Moreover, for almost all $s \in [0,1]$, $(\partial/\partial x)f(z(s), \bar{u}(s)) \subset dF(z(s), z'(s)) \subset d \text{ co } F(z(s), z'(s))$. Set $A(s) = (\partial/\partial x)f(z(s), \bar{u}(s))$. Since $\|A(s)\| \leqq L$, then $A(s)$ is L-Lipschitz. Hence (H_2), (H_3) hold true. On the other hand, for every solution x of (5.3) we have $g(x(1)) - g(z(1)) \geqq 0$, which yields

$$\forall w \in T_{R(1,C)}(z(1)) \quad g'(z(1))w \geqq 0,$$

i.e.,

$$g'(z(1)) \in T_{R(1,C)}(z(1))^+.$$

Corollary 4.8 ends the proof. □

COROLLARY 5.2. *Under all assumptions of Theorem 5.1, assume that for some $t \in [0, 1[$, $W(t, z)^+ = \{0\}$. Then $z(1)$ is a critical point of g and if g is locally C^2 at $z(1)$ then $g''(z(1)) \geqq 0$ on $T_{R(1,C)}(z(1))$. In particular, this happens when $T_C(z(0))^+ = \{0\}$.*

Proof. Let q be as in Theorem 5.1 and let t be such that $W(t, z)^+ = \{0\}$. Then $q(t) = 0$ and, by the uniqueness of q, $q(1) = 0$. Hence, by (5.5), $g'(z(1)) = 0$. Assume next that g is locally C^2 and fix $w \in T_{R(1,C)}(z(1))$. Then for some $h_i \to 0+$, $w_i \to w$, $z(1) + h_i w_i \in R(1, C)$ and since z solves the problem (5.1), (5.2), $g(z(1) + h_i w_i) - g(z(1)) = \frac{1}{2}g''(z(1))w_i w_i h_i^2 + o(h_i^2) \geqq 0$. Taking the limit, we end the proof. □

5.2. Minimization with respect to both endpoints. Let f, U be as in § 5.1 and $\varphi : \mathbb{R}^{2n} \to \mathbb{R}$ be a given function. Consider the problem

$$\text{minimize } \varphi(x(0), x(1)) \tag{5.7}$$

over the solutions of the control system (5.2). If a trajectory-control pair $(z, \bar{u})$ solves the problem (5.7), (5.2) and φ is differentiable at $(z(0), z(1))$, then

$$\forall (w(0), w(1)) \in T_{\text{graph } R_C(1,\cdot)}(z(0), z(1)) \quad \varphi'(z(0), z(1))(w(0), w(1)) \geqq 0,$$

i.e., $\varphi'(z(0), z(1))$ is in the positive polar of the tangent cone. Let $W(t, z)$ denote the cone of variations of reachable sets $R(\cdot, z(0))$.

THEOREM 5.3. *Assume that a trajectory-control pair $(z, \bar{u})$ solves the above problem, f satisfies all the assumptions of Theorem* 5.1, *and φ is differentiable at $(z(0), z(1))$. Then there exists $q \in W^{1,\infty}(0, 1)$ satisfying* (5.4), (5.6) *and such that*

$$q(1) = \frac{\partial}{\partial x_2} \varphi(z(0), z(1)), \qquad q(0) \in T_C(z(0))^+ - \frac{\partial}{\partial x_1} \varphi(z(0), z(1)).$$

Proof. By the proof of Theorem 5.1 the family of maps $A(s) = (\partial/\partial x) f(z(s), \bar{u}(s))$, $s \in [0, 1]$ satisfies (H_2), (H_3). We already know that $\varphi'(z(0), z(1)) \in T_{\text{graph } R_C(1,\cdot)}(z(0), z(1))^+$. Fix $b \in T_C(z(0))$. Applying Theorem 4.9 with $Q = \mathbb{R}_+ b$ we deduce that the solution q of (5.4) satisfying $q(1) = (\partial/\partial x_2)\varphi(z(0), z(1))$ verifies

$$\frac{\partial}{\partial x_1} \varphi(z(0), z(1)) \in (\mathbb{R}_+ b)^+ - q(0).$$

Hence $\langle q(0) + (\partial/\partial x_1)\varphi(z(0), z(1)), b \rangle \geqq 0$. Since q does not depend on b, we obtain that $q(0) + (\partial/\partial x_1)\varphi(z(0), z(1)) \in T_C(z(0))^+$. It remains to show that q satisfies (5.6). Set $g(x) = \varphi(z(0), x)$. Then $g'(z(1)) = (\partial/\partial x_2)\varphi(z(0), z(1))$. Clearly, $(z, \bar{u})$ is an optimal solution of problem (5.1), (5.2) with $C = \{z(0)\}$. Applying Theorem 5.1 with $C = \{z(0)\}$ we end the proof. □

COROLLARY 5.4. *Under all assumptions of Theorem* 5.3 *assume that for some $t \in [0, 1[$, $W(t, z)^+ = \{0\}$. Then $(\partial/\partial x_1)\varphi(z(0), z(1)) \in T_C(z(0))^+$, $(\partial\varphi/\partial x_2)(z(0), z(1)) = 0$. Moreover, if $T_C(z(0))^+ = \{0\}$, then $(z(0), z(1))$ is a critical point of φ, and if φ is locally C^2 at $(z(0), z(1))$, then $\varphi''(z(0), z(1)) \geqq 0$ on $T_{\text{graph } R_C(1,\cdot)}(z(0), z(1))$.*

The proof follows by the same arguments as in Corollary 5.2.

5.3. Closed-loop control systems. Let $U : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ be a set-valued map with compact nonempty images, let C be a nonempty subset of $\mathbb{R}^n$, and let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be a locally Lipschitzian function, $g : \mathbb{R}^n \to \mathbb{R}$. Consider the following control problem:

$$\text{minimize } g(x(1)) \tag{5.8}$$

over trajectories of the control system

$$\begin{aligned} &x'(t) = f(x(t), u(t)) \quad \text{a.e. in } [0, 1], \\ &x(0) \in C, \qquad u(t) \in U(x(t)) \text{ is measurable.} \end{aligned} \tag{5.9}$$

Set $F(x) = \{f(x, u) : u \in U(x)\}$. It is clear that every trajectory of (5.9) is a trajectory of the differential inclusion

$$\begin{aligned} &x'(t) \in F(x(t)) \quad \text{a.e. in } [0, 1], \\ &x(0) \in C. \end{aligned} \tag{5.10}$$

LEMMA 5.5. *If U is upper semicontinuous, then the set of trajectories of the closed-loop control system* (5.9) *do coincide with the set of trajectories of the differential inclusion* (5.10).

Proof. We must show that, with every trajectory $x \in W^{1,1}(0,1)$ of the inclusion (5.10), we can associate a measurable function $u\colon [0,1] \to \mathbb{R}^m$ satisfying

$$x'(t) = f(x(t), u(t)), \quad u(t) \in U(x(t)) \quad \text{a.e. in } [0,1].$$

For all $t \in [0,1]$ set $\hat{U}(t) = \{u \in U(x(t))\colon x'(t) = f(x(t), u)\}$. Then for almost all $t \in [0,1]$, $\hat{U}(t)$ is a closed, nonempty set. We claim that $\hat{U}$ is a measurable set-valued map. Indeed fix a closed subset $\hat{C} \subset \mathbb{R}^m$ and observe that the set

$$D := \{(t, f(x(t), u))\colon t \in [0,1], u \in U(x(t)) \cap \hat{C}\}$$

is closed. Moreover,

$$\{t\colon \hat{U}(t) \cap \hat{C} \neq \varnothing\} = \{t\colon (t, x'(t)) \in D\}.$$

Thus $\{t\colon \hat{U}(t) \cap \hat{C} \neq \varnothing\}$ is a Lebesgue measurable set and, since $\hat{C}$ is an arbitrary closed subset of $\mathbb{R}^m$, we proved that $\hat{U}$ is measurable. From the measurable selection theorem (see, for example, [26]) follows the existence of a measurable selection $u(t) \in \hat{U}(x(t))$, $t \in [0,1]$. The very definition of the map $\hat{U}$ ends the proof. □

In the theorem below we assume that $f(x, U(x))$ is *regular* in the following sense: If for some x and $\bar{u} \in U(x)$, $q \neq q_1 \neq 0$ we have

$$\sup_{u \in U(x)} \langle q, f(x,u)\rangle = \langle q, f(x,\bar{u})\rangle, \qquad \sup_{u \in U(x)} \langle q_1, f(x,u)\rangle = \langle q_1, f(x,\bar{u})\rangle,$$

then for some $\lambda \geqq 0$ $q = \lambda q_1$. Geometrically this means that every boundary point of $\operatorname{co} f(x, U(x))$ has at most one normalized outer normal.

THEOREM 5.6. *Assume that a trajectory control pair $(z, \bar{u})$ solves the problem above, and that f is differentiable at $(z(t), \bar{u}(t))$, g is differentiable at $z(1)$, U is Lipschitzian on a neighborhood of $z([0,1])$, and $f(x, U(x))$ is regular. Further, assume that there exist closed convex processes $B(s) \subset dU(z(s), \bar{u}(s))$ satisfying (H_2). Then there exists a solution $q \in W^{1,\infty}(0,1)$ of the inclusion*

$$-q' \in \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* q + B(t)^* \frac{\partial f}{\partial u}(z(t), \bar{u}(t))^* q$$

satisfying (5.5), (5.6) *and the minimum principle*

$$\langle q(t), z'(t)\rangle = \min_{u \in U(z(t))} \langle q(t), f(z(t), u)\rangle \quad \text{a.e.}$$

Proof. From differentiability of f at $(z(t), \bar{u}(t))$ we deduce that for almost all t and for all $w \in \mathbb{R}^n$

$$\frac{\partial f}{\partial x}(z(t), \bar{u}(t))w + \frac{\partial f}{\partial u}(z(t), \bar{u}(t))\, dU(z(t), \bar{u}(t))w \subset dF(z(t), z'(t))w.$$

Hence the closed convex processes

$$A(t) := \frac{\partial f}{\partial x}(z(t), \bar{u}(t)) + \frac{\partial f}{\partial u}(z(t), \bar{u}(t))B(t)$$

satisfy (H_2), (H_3). Since z is the minimizing trajectory for all $w \in T_{R(1,C)}(z(1))$, $g'(z(1))w \geqq 0$. Thus, $g'(z(1)) \in T_{R(1,C)}(z(1))^+$. We apply Theorem 4.7. Let q_1, q_2 be two solutions of (4.3) such that $q_1(t) = q_2(t) \neq 0$. Then $q_i \neq 0$ on $[0,t]$ and

$$\langle q_1(s), z'(s)\rangle = \min_{e \in F(z(s))} \langle q_1(s), e\rangle \quad \text{a.e.},$$

$$\langle q_2(s), z'(s)\rangle = \min_{e \in F(z(s))} \langle q_2(s), e\rangle \quad \text{a.e.}$$

Since $f(x, U(x))$ is regular $q_1(s)/\|q_1(s)\| = q_2(s)/\|q_2(s)\|$ a.e. in $[0, 1]$ and, by continuity of $q(\cdot)$ we obtain $q_1/\|q_1\| = q_2/\|q_2\|$. Hence the result will follow from Theorem 4.7 if we show that

$$A(t)^* \subset \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* + B(t)^* \frac{\partial f}{\partial u}(z(t), \bar{u}(t))^*.$$

Fix $p \in A(t)^* q$. Then for all $w \in \mathbb{R}^n$, $v \in B(t)w$

$$\begin{aligned}\langle p, w\rangle &\leqq \langle q, \partial f/\partial x(z(t), \bar{u}(t))w + \partial f/\partial u\,(z(t), \bar{u}(t))v\rangle \\ &= \langle \partial f/\partial x(z(t), \bar{u}(t))^* q, w\rangle + \langle \partial f/\partial u(z(t), \bar{u}(t))^* q, v\rangle\end{aligned}$$

and therefore

$$\langle p - \partial f/\partial x(z(t), \bar{u}(t))^* q, w\rangle \leqq \langle \partial f/\partial u(z(t), \bar{u}(t))^* q, v\rangle.$$

By the definition of the adjoint process

$$p - \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* q \in B(t)^* \frac{\partial f}{\partial u}(z(t), \bar{u}(t))^* q,$$

and we finally obtain

$$p \in \frac{\partial f}{\partial x}(z(t), \bar{u}(t))^* q + B(t)^* \frac{\partial f}{\partial u}(z(t), \bar{u}(t))^* q.$$

The proof is complete. □

The next result is an extension of the main theorem from [22].

THEOREM 5.7. *Assume that a trajectory control pair $(z, \bar{u})$ solves the problem* (5.8), (5.9) *and that f is differentiable at $(z(t), \bar{u}(t))$, g is differentiable at $z(1)$, and U is Lipschitzian on a neighborhood of $z([0, 1])$. Further, assume that for almost all t there exists a selection $u_t(x) \in U(x)$ that is differentiable at $z(t)$ and satisfies $u_t(z(t)) = \bar{u}(t)$. Then there exists a solution $q \in W^{1,\infty}(0, 1)$ of the equation*

$$\begin{aligned} &-q' = q\left(\frac{\partial f}{\partial x}(z(t), \bar{u}(t)) + \frac{\partial f}{\partial u}(z(t), \bar{u}(t))\frac{\partial u_t}{\partial x}(z(t))\right), \\ &\langle q(t), z'(t)\rangle = \min_{u \in U(z(t))} \langle q(t), f(z(t), u)\rangle \text{ a.e.} \end{aligned} \tag{5.11}$$

satisfying (5.5) *and* (5.6).

The above theorem was proved by Leitmann in [22] without the inclusion (5.6).

Proof. The set-valued map $F(x) = f(x, U(x))$ satisfies the hypothesis (H_1) on a neighborhood of $z([0, 1])$. Moreover, the linear operators

$$A(t) = \frac{\partial f}{\partial x}(z(t), u(t)) + \frac{\partial f}{\partial u}(z(t), \bar{u}(t))\frac{\partial u_t}{\partial x}(z(t)), \qquad t \in [0, 1],$$

verify (H_2) and (H_3). Since z is the minimizing trajectory for all $w \in T_{R(1,C)}(z(1))$, $g'(z(1))w \geqq 0$. Thus $g'(z(1)) \in T_{R(1,C)}(z(1))^+$ and the result follows from Corollary 4.8 and the inclusion $W(0, z)^+ \subset T_C(z(0))^+$. □

5.4. An implicit dynamical system. Consider a continuously differentiable function $f: \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^m$ and a function $g: \mathbb{R}^n \to \mathbb{R}$, $C \subset \mathbb{R}^n$.

Here we study the problem

$$\text{minimize } g(x(1)) \tag{5.12}$$

over the absolutely continuous solutions of the implicit dynamical system

$$f(x(t), x'(t)) = 0 \quad \text{a.e. in } [0, 1] \tag{5.13}$$

satisfying the initial point constraint

$$x(0) \in C. \tag{5.14}$$

Such systems arise as models for nonlinear circuits. In general they cannot be reduced to the state variable form $z' = f(z, t)$ or to the control system (5.2) (see [6, p. 147, bibliographical comments].

Set $F(x) = \{v: f(x, v) = 0\}$ and consider the differential inclusion

$$x'(t) \in F(x(t)) \quad \text{a.e. in } [0, 1]. \tag{5.15}$$

Clearly solutions of (5.13) and (5.15) do coincide. Moreover, by continuity of f, graph (F) is a closed set. The following result is proved in [15]:

LEMMA 5.8. *Assume that for all $\bar{x} \in \mathbb{R}^n$ there exists $\varepsilon > 0$ such that*

$$\liminf_{\|v\| \to \infty} \inf_{\|x - \bar{x}\| \leqq \varepsilon} \|f(x, v)\| > 0. \tag{5.16}$$

Then F has compact images. If, moreover, for all $(x, v) \in \operatorname{graph}(F)$ the derivative $(\partial/\partial v) f(x, v)$ is surjective, then Dom F *is open and F is locally Lipschitzian on it, and*

$$\ker f'(x, v) = \operatorname{graph}(dF(x, v)).$$

In particular, this implies that $dF(x, v)$ is a closed convex process.

LEMMA 5.9. *Under all assumptions of Lemma 5.8 for every solution x of (5.13) there exist $L > 0$ such that for almost all $s \in [0, 1]$, $dF(x(s), x'(s))$ is L-Lipschitz on $\mathbb{R}^n$ and*

$$dF(x(s), x'(s))^* q = \begin{cases} -\dfrac{\partial f}{\partial x}(x(s), x'(s))^* \dfrac{\partial f}{\partial v}(x(s), x'(s))^{*-1} q & \text{if } q \in \ker \dfrac{\partial f}{\partial v}(x(s), x'(s))^{\perp} \\ \varnothing \quad \text{otherwise.} \end{cases}$$

Proof. Fix a solution x of (5.13). Since the derivative $\partial f/\partial v$ is surjective on graph (F), for all $(x, y) \in \operatorname{graph}(F)$ there exists $\rho > 0$ such that

$$\{v \in \mathbb{R}^m : \|v\| \leqq \rho\} \subset \frac{\partial f}{\partial v}(x, y)(\{u \in \mathbb{R}^n : \|u\| \leqq 1\}). \tag{5.17}$$

Since $f \in C^1$, the assumption (5.16) implies that there exists a compact set K such that for almost all $s \in [0, 1]$, $(x(s), x'(s)) \in K$. This, (5.17) and continuity of $\partial f/\partial v$ imply that for some $\rho > 0$ and almost all $s \in [0, 1]$

$$\{v \in \mathbb{R}^m : \|v\| \leqq \rho\} \subset \frac{\partial f}{\partial v}(x(s), x'(s))(\{u \in \mathbb{R}^n : \|u\| \leqq 1\}).$$

Using Theorem 10.1 of [15] again, we deduce that for some $L > 0$ and almost all $s \in [0, 1]$, $dF(x(s), x'(s))$ is L-Lipschitz on a neighborhood of zero. Since $dF(x(s), x'(s))$ is a convex process, we finally obtain that it is L-Lipschitz on $\mathbb{R}^n$. By the definition of the adjoint process $p \in dF(x(s), x'(s))^* q$ if and only if

$$(p, -q) \in (\ker f'(x(s), x'(s)))^{\perp} = \operatorname{Im} f'(x(s), x'(s))^*.$$

Hence for all $(p, q) \in \operatorname{graph}(dF(x(s), x'(s))^*)$ there exists $\alpha \in \mathbb{R}^m$ such that

$$p = \frac{\partial f}{\partial x}(x(s), x'(s))^* \alpha, \qquad -q = \frac{\partial f}{\partial v}(x(s), x'(s))^* \alpha.$$

Since $(\partial f/\partial v)(x(s), x'(s))$ is surjective, the adjoint linear operator $(\partial f/\partial v)(x(s), x'(s))^*$ is injective and hence invertible on

$$\operatorname{Im} \frac{\partial f}{\partial v}(x(s), x'(s))^* = \left(\ker \frac{\partial f}{\partial v}(x(s), x'(s))\right)^{\perp}.$$

Thus,

$$q \in \left(\ker \frac{\partial f}{\partial v}(x(s), x'(s))\right)^{\perp}, \qquad -p = \frac{\partial f}{\partial x}(x(s), x'(s))^* \frac{\partial f}{\partial v}(x(s), x'(s))^{*-1} q.$$

THEOREM 5.10. *Assume that z solves the problem* (5.12)-(5.14), *f satisfies all the assumptions of Lemma* 5.8, *and g is differentiable at $z(1)$. Then there exists $q \in w^{1,\infty}(0, 1)$ satisfying*

$$q'(s) = \frac{\partial f}{\partial x}(z(s), z'(s))^* \frac{\partial f}{\partial v}(z(s), z'(s))^{*-1} q(s) \quad \text{a.e.}, \tag{5.18}$$

$$q(1) = g'(z(1)), \qquad q(s) \in \left(\ker \frac{\partial f}{\partial v}(x(s), x'(s))\right)^{\perp}, \tag{5.19}$$

$$\min\{\langle q(s), e\rangle : f(z(s), e) = 0\} = \langle q(s), z'(s)\rangle \quad \text{a.e.}, \tag{5.20}$$

$$q(s) \in W(s, z)^+ \quad \text{for } s \in [0, 1[. \tag{5.21}$$

Proof. For all $w \in T_{R(1,C)}(z(1))$, $g'(z(1))w \geqq 0$. Hence $g'(z(1)) \in T_{R(1,C)}(z(1))^+$. Since the solution of (5.18) is uniquely defined, we may apply Theorem 4.7 with closed convex processes $\{dF(x(s), x'(s))\}_{s\in[0,1]}$. Lemma 5.9 ends the proof. □

6. An impulse closed-loop deterministic control problem. Let $U : \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ be a set-valued map with compact nonempty images, let C be a nonempty subset of $\mathbb{R}^n$, and let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be a locally Lipschitzian function, $g : \mathbb{R}^n \to \mathbb{R}$.

Further, let $V : \mathbb{R}^n \rightrightarrows \mathbb{R}^p$ be a set-valued map of shift parameters and $\varphi : \mathbb{R}^n \times \mathbb{R}^p \to \mathbb{R}^n$ be a given function.

Consider the closed-loop control system

$$\begin{aligned} &x'(t) = f(x(t), u(t)), \quad u(t) \in U(x(t)) \quad \text{a.e. in } [0, 1], \\ &\mathrm{x}(0) \in \mathrm{C}. \end{aligned} \tag{6.1}$$

A sequence $\{(t_i, v_i) : i = 1, \cdots, j\}$ is called an impulse strategy of a left-continuous trajectory $x : [0, 1] \to \mathbb{R}^n$, if $0 = t_1 \leqq \cdots \leqq t_j = 1$, and for all i

$$v_i \in V(x(t_i)), \tag{6.2}$$

$$x \in W^{1,1}(t_i, t_{i+1}), \tag{6.3}$$

$$x(t_i+) = x(t_i) + \varphi(x(t_i), v_i), \tag{6.4}$$

and x satisfies (6.1) with a measurable control u. Such trajectory x is called admissible.

This type of system is met in a number of optimal control problems in economics and management (see, for example, [7, pp. 281-285]). We refer to [5], [24], and the references therein for previous results on discontinuous optimal trajectories.

Consider a function $g : \mathbb{R}^n \to \mathbb{R}$. The problem we study here consists in characterization of a solution z to the problem

$$\min\{g(x(1)) : x \text{ is an admissible trajectory}\}. \tag{6.5}$$

The approach is essentially the same. So we shall only stress the main points. For all $x \in \mathbb{R}^n$ set $F(x) = f(x, U(x))$. We prove Lemma 6.1 exactly as we did Lemma 5.5.

LEMMA 6.1. *If U is upper semicontinuous, then the set of admissible trajectories coincide with the set of left-continuous functions $x:[0,1]\to\mathbb{R}^n$ satisfying for some $0=t_1\leqq\cdots\leqq t_j=1$ and some $v_i\in V(x(t_i))$ the following relations*:

$$\begin{aligned} &x\in W^{1,1}(t_i,t_{i+1}),\\ &x'(t)\in F(x(t)) \quad a.e.,\\ &x(0)\in C,\\ &x(t_i+)=x(t_i)+\varphi(x(t_i),v_i). \end{aligned} \tag{6.6}$$

THEOREM 6.2. *Assume that a trajectory-control pair $(z,\bar{u})$ solves the problem above and let $\{(t_i,v_i): i=1,\cdots,l\}$ be a corresponding strategy. Further, assume that U, $\bar{u}$, g, f satisfy all the assumptions of Theorem 5.7, that φ is differentiable at $(z(t_i),v_i)$, and for all i there exists a differentiable at $z(t_i)$ selection $\nu_i(x)\in V(x)$ such that $\nu_i(z(t_i))=v_i$. Then there exists a (left-continuous) function $q:[0,1]\to\mathbb{R}^n$ satisfying* (5.5), (5.11) *and such that for all i*

$$q\in W^{1,\infty}(t_i,t_{i+1}), \tag{6.7}$$

$$q(t_i)=q(t_i+)\left[\mathrm{id}+\frac{\partial\varphi}{\partial x}(z(t_i),v_i)+\frac{\partial\varphi}{\partial v}(z(t_i),v_i)\frac{\partial\nu_i}{\partial x}(z(t_i))\right], \tag{6.8}$$

$$q(t_i+)\in T_{\varphi(z(t_i),V(z(t_i)))}(\varphi(z(t_i),v_i))^+. \tag{6.9}$$

Furthermore, we have the following:

(a) *If the right derivative $z'(t_i+)$ does exist, then*

$$\min_{u\in U(z(t_i))}\langle q(t_i),f(z(t_i),u)\rangle\geqq\langle q(t_i+),z'(t_i+)\rangle;$$

(b) *If the left derivative $z'(t_i-)$ does exist, then*

$$\min_{u\in U(z(t_i+))}\langle q(t_i+),f(z(t_i+),u)\rangle\geqq\langle q(t_i),z'(t_i-)\rangle;$$

(c) *If z has the right and left derivatives at t_i, then*

$$\begin{aligned} \min_{u\in U(z(t_i+))}\langle q(t_i+),f(z(t_i+),u)&=\min_{u\in U(z(t_i))}\langle q(t_i),f(z(t_i),u)\rangle=\langle q(t_i),z'(t_i-)\rangle\\ &=\langle q(t_i+),z'(t_i+)\rangle. \end{aligned} \tag{6.10}$$

When U does not depend on x the assumption that $f(x,\cdot)$ is locally Lipschitzian can be omitted and we have Theorem 6.3.

THEOREM 6.3. *Let U be a compact metric space of controls, V be a set of shift parameters, $f:\mathbb{R}^n\times U\to\mathbb{R}^n$ be a continuous function, and $\varphi:\mathbb{R}^n\times V\to\mathbb{R}^n$. Assume that a trajectory-control pair (z,u) solves the problem*

$$\text{minimize } g(x(1)) \tag{6.11}$$

over the solution of the system

$$\begin{aligned} &x'(t)=f(x(t),u(t)),\quad u(t)\in U \quad a.e.\ in\ [0,1],\\ &x(0)\in C \quad and\ for\ some\ 0=t_1\leqq\cdots\leqq t_j=1,\\ &v_i\in V \quad and\ all\ i,\quad x\in W^{1,1}(t_i,t_{i+1}),\\ &x(t_i+)=x(t_i)+\varphi(x(t_i),v_i), \end{aligned} \tag{6.12}$$

and let $\{(t_i, v_i)\colon i=1, \cdots, l\}$ *be a strategy of* z. *If* f, g *satisfy all the assumptions of Theorem* 5.1 *and* $\varphi(\cdot, v_i)$ *is differentiable at* $z(t_i)$, *then there exists a left-continuous function* $q\colon[0,1]\to\mathbb{R}^n$ *satisfying* (5.4), (5.5), (6.7), (a)-(c) *of Theorem* 6.2 *and*

$$q(t_i) = q(t_i+)\left(\mathrm{id}+\frac{\partial\varphi}{\partial x}(z(t_i), v_i)\right), \tag{6.8'}$$

$$q(t_i+) \in T_{\varphi(z(t_i),V)}(\varphi(z(t_i), v_i))^+. \tag{6.9'}$$

As in § 2 we associate the reachable set $R(t, C)$ at time t with the differential inclusion (6.6).

To prove the Theorem 6.2 we need the following (simple) lemmas.

LEMMA 6.4. *For all* $i=1, \cdots, l-1$ *set*

$$C_i = R(t_i, C) \cup \{x+\varphi(x, v)\colon x\in R(t_i, C), v\in V(x)\}.$$

Then

$$T_{\varphi(z(t_i),V(z(t_i)))}(\varphi(z(t_i), v_i)) \subset T_{C_i}(z(t_i+)).$$

The proof follows from the inclusion $z(t_i)+\varphi(z(t_i), V(z(t_i)))\subset C_i$ and the definition of the contingent cone.

LEMMA 6.5. *For all* $i=1, \cdots, l-1$ *set*

$$A_i = \mathrm{id}+\frac{\partial\varphi}{\partial x}(z(t_i), v_i)+\frac{\partial\varphi}{\partial v}(z(t_i), v_i)\frac{\partial\nu_i}{\partial x}(z(t_i)).$$

Then

$$A_i(T_{R(t_i,C)}(z(t_i))) \subset T_{C_i}(z(t_i+)).$$

Proof. Fix $1\leqq i\leqq l-1$, $w\in T_{R(t_i,C)}(z(t_i))$ and let $h_j\to 0+$, $w_j\to w$ be such that $z(t_i)+h_jw_j\in R(t_i, C)$. Then

$$z(t_i)+h_jw_j+\varphi(z(t_i)+h_jw_j, \nu_i(z(t_i)+h_jw_j))$$

$$= z(t_i+)+h_jw_j+\frac{\partial\varphi}{\partial x}(z(t_i), v_i)h_jw_j+\frac{\partial\varphi}{\partial v}(z(t_i), v_j)\frac{\partial\nu_i}{\partial x}(z(t_i))h_jw_j+o(h_j)\in C_i.$$

The definition of the contingent cone ends the proof. □

LEMMA 6.6. *Assume that* z *has the right derivative* $z'(t_i+)$ *at* t_i *and let* $u\in U(z(t_i))$. *Then the solution* w *of the linear system*

$$w' = \left[\frac{\partial f}{\partial x}(z(t), \bar u(t))+\frac{\partial f}{\partial u}(z(t), \bar u(t))\frac{\partial u_t}{\partial x}(z(t))\right]w,$$

$$w(t_i) = A_if(z(t_i), u)-z'(t_i+)$$

satisfies

$$w(t_{i+1})\in T_{R(t_{i+1},C)}(z(t_{i+1})).$$

Proof. Fix $h_j\to 0+$ and let x be a solution of the inclusion

$$x'(t)\in F(x(t)) \quad \text{a.e. in } [t_i, t_{i+1}],$$

$$x(t_i) = z(t_i), \qquad x'(t_i) = f(z(t_i), u).$$

Then

$$x(t_i+h_j) = z(t_i)+h_jf(z(t_i), u)+o(h_j)\in R(t_i+h_j, C),$$

and therefore

$$x(t_i+h_j)+\varphi(x(t_i+h_j), \nu_i(x(t_i+h_j)))=z(t_i+)+h_jA_if(z(t_i), u)+o(h_j).$$

Thus

$$x(t_i+h_j)+\varphi(x(t_i+h_j), \nu_i(x(t_i+h_j)))=z(t_i+h_j)+h_j[A_if(z(t_i), u)-z'(t_i+)]+o(h_j)$$

and $A_if(z(t_i), u)-z'(t_i+)$ can be seen as a variation of $R(\cdot, C)$ at $(t_i, x(t_i+))$. The proof then follows by the same arguments as Theorem 2.4. □

LEMMA 6.7. *Assume that z has the left derivative $z'(t_i-)$ at t_i. Then for all $u\in U(z(t_i+))$*

$$f(z(t_i+), u)-A_iz'(t_i-)\in T_{C_i}(z(t_i+)).$$

Proof. Fix $h_j\to 0+$, $u\in U(z(t_i+))$ and set

$$x_j:=z(t_i-h_j)+\varphi(z(t_i-h_j), \nu(z(t_i-h_j))).$$

Since F is locally Lipschitzian there exists $M>0$ such that, for all j and $t\in[t_i-h_j, t_i]$, dist $(f(z(t_i+), u)$,

$$F(x_j+(t-t_i+h_j)f(z(t_i+), u))\leqq M(\|x_j-z(t_i+)\|+h_j\|f(z(t_i+), u)\|)=O(h_j).$$

This and Filippov's Theorem imply that

$$x_j+h_jf(z(t_i+), u)\in R(t_i, C)+o(h_j).$$

The definitions of x_j and of the contingent cone end the proof. □

LEMMA 6.8. *For all $p\in T_{R(t_{i+1}, C)}(z(t_{i+1}))^+$ there exists $q\in W^{1,\infty}(t_i, t_{i+1})$ satisfying* (5.11), *such that*

$$q(t_{i+1})=p, \qquad q(t_i+)\in T_{\varphi(z(t_i), V(z(t_i)))}(\varphi(z(t_i), v_i))^+, \tag{6.13}$$

$$q(t_i+)A_i\in T_{R(t_i, C)}(z(t_i))^+. \tag{6.14}$$

Moreover, q satisfies (a)-(c) *of Theorem* 6.2 *with $q(t_i)=q(t_i+)A_i$.*

Proof. Consider the differential inclusion

$$\begin{aligned} &x'(t)\in f(x(t), U(x(t))) \quad \text{a.e. in } [t_i, t_{i+1}],\\ &x(t_i)\in C_i \end{aligned} \tag{6.15}$$

and observe that its reachable set $\hat{R}(t_{i+1}, C_i)$ at time t_{i+1} is contained in $R(t_{i+1}, C)$. Thus $p\in T_{\hat{R}(t_{i+1}, C_i)}(z(t_{i+1}))^+$. By Corollary 4.8 applied on the time interval $[t_i, t_{i+1}]$ to (6.15) and linear operators

$$A(t)=\frac{\partial f}{\partial x}(z(t), \bar{u}(t))+\frac{\partial f}{\partial u}(z(t), \bar{u}(t))\frac{\partial u_t}{\partial x}(z(t)),$$

there exists $q\in W^{1,\infty}(t_i, t_{i+1})$ satisfying (5.11) such that $q(t_{i+1})=p$ and

$$q(t_i+)\in T_{C_i}(z(t_i+))^+. \tag{6.16}$$

Then (6.13) follows from (6.16) and Lemma 6.4 and (6.14) results from (6.16) and Lemma 6.5. Lemma 6.7 and (6.16) imply Theorem 6.2(b). Since q solves the linear equation (5.11), Lemma 6.6 implies that for all $u\in U(z(t_i))$

$$\langle q(t_i), A_if(z(t_i), u)-z'(t_i+)\rangle\geqq 0.$$

Hence we have Theorem 6.2(a). On the other hand, by [13]

$$z'(t_i-)\in\overline{\text{co}}\, F(z(t_i-)), \qquad z'(t_i+)\in\overline{\text{co}}\, F(z(t_i+)).$$

This and (a), (b) imply that

$$\langle q(t_i), z'(t_i-)\rangle \leqq \min_{u\in U(z(t_i+))} \langle q(t_i+), f(z(t_i+), u)\rangle$$

$$\leqq \langle q(t_i+), z'(t_i+)\rangle \leqq \min_{u\in U(z(t_i))} \langle q(t_i), f(z(t_i), u)\rangle \leqq \langle q(t_i), z'(t_i-)\rangle$$

and claim (c) follows. □

Proof of Theorem 6.2. Since z is an optimal trajectory, $g'(z(1))w \geqq 0$ for all $w \in T_{R(1,C)}(z(1))$. Thus, $g'(z(1)) \in T_{R(1,C)}(z(1))^+$ and we may apply Lemma 6.8 with $p = g'(z(1))$. Set

$$q(t_{l-1}) = q(t_{l-1}+)A_{l-1} \in T_{R(t_{l-1},C)}(z(t_{l-1}))^+.$$

Then Lemma 6.8 can be applied again with $p = q(t_{l-1})$. We complete the proof using an induction argument and Lemma 6.8. □

Observe that the Lipschitz continuity of $f(x, \cdot)$ is needed to prove the local Lipschitzianity of the map $x \to f(x, U(x))$. When the control map U does not depend on x, the set-valued map $x \to f(x, U)$ is locally Lipschitzian and therefore the same proof implies Theorem 6.3.

Remark. Theorems 6.2 and 6.3 can be stated together with a higher-order condition on the adjoint vector q. However, we do not do so here to simplify the presentation of the result.

7. Examples.

Example 1. *Smooth control system.* Consider the following optimal control problem in $\mathbb{R}^2$:

$$\text{minimize } y(1)$$

over the solutions of control system

$$\begin{aligned} &x' = 1 + u(x + y^2), \qquad u \in \{0, 1\}, \\ &y' = u(2y - x), \qquad x(0) = y(0) = 0. \end{aligned} \tag{7.1}$$

Set $\bar{u} \equiv 0$. Then $z(t) = (t, 0)$ is a solution of (7.1). Moreover, $q \equiv (0, 1)$ verifies the maximum principle (5.4). On the other hand, setting $u \equiv 1$, we obtain the following Taylor expansion of the corresponding solution (x, y) of (7.1):

$$x(t) = tx'(0) + \frac{t^2}{2}x''(0) + o(t^2) = t + \frac{t^2}{2} + o(t^2),$$

$$y(t) = ty'(0) + \frac{t^2}{2}y''(0) + o(t^2) = -\frac{t^2}{2} + o(t^2).$$

Hence $z(t) + t^2(\frac{1}{2}, -\frac{1}{2}) \in R(t, 0) + o(t^2)$, and therefore $(\frac{1}{2}, -\frac{1}{2}) \in W(0, z)$. But $\langle (0, 1), (\frac{1}{2}, -\frac{1}{2})\rangle < 0$. Comparing with (5.6), we deduce that the pair $(z, \bar{u})$ is not optimal.

Example 2. *Implicit dynamical system.* Consider the following problem in $\mathbb{R}^2$:

$$\text{minimize } 2 \sin y(1) - x(1)$$

over the solutions of the implicit system

$$\dot{x}^4 + \exp(\dot{y} - 2\dot{x}) - 16x^2 - \exp(4x^2 - y^2) = 0, \quad x(0) = 0, \quad y(0) = 0. \tag{7.2}$$

Then (7.2) satisfies all the assumptions of Lemma 5.8. Observe that $z = (x, y) \equiv 0$ is a solution of (7.2). Set $q \equiv (-1, 2)$ and

$$F(0) = \{(u, v): u^4 + \exp(u - 2v) - 1 = 0\}.$$

Then for all $(u, v) \in F(0)$, $u - 2v \leqq 0$. Hence $\min\{\langle q, e\rangle : e \in F(0)\} \geqq 0$. Therefore q verifies the maximum principle (5.18)-(5.20). On the other hand, the trajectory $t \to (-t^2, -2t^2)$ is a solution of (7.2). Hence $(-1, -2) \in W(0, z)$ and $\langle (-1, 2)(+1, -2)\rangle = -3 < 0$. Consequently (5.21) does not hold and therefore the zero trajectory is not optimal.

Example 3. *Differential inclusion.* Consider the problem

$$\text{minimize } g(x(1))$$

over the solutions of the differential inclusion

$$x' \in F(x), \qquad x(0) = x_0 \tag{7.3}$$

where $F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a set-valued map with convex images satisfying (H_1) and $g : \mathbb{R}^n \to \mathbb{R}$ is a differentiable function.

The high-order variations for this problem can be studied via an extension of Lie brackets to set-valued maps. Although, repeating arguments from [14], we can do it for general trajectory z of (7.3) at every point t where z is twice continuously differentiable, the calculations are quite lengthy. This is why in this example we only treat the case

$$0 \in F(x_0)$$

and the constant trajectory $z \equiv x_0$ using the ready results from [14].

From now on we assume that $0 \in F(x_0)$. To state a second-order condition for optimality we recall the following definition.

DEFINITION 7.1. Let $Q \subset F(x)$. We set

$$[F, F]_Q(x) = \{dF(x, a)b - dF(x, b)a : a, b \in Q\}.$$

The following theorem tests for optimality the constant trajectory $z \equiv x_0$.

THEOREM 7.2. *Let $A \subset dF(x_0, 0)$ be a Lipschitzian closed convex process, $Q \subset F(x_0)$ be a convex set such that*

(i) $0 \in \operatorname{r\,int} Q$;

(ii) *F is lower semicontinuously differentiable on $x_0 \times Q$ (see* [14]).

If $z \equiv x_0$ is optimal then there exists a solution q of the differential inclusion

$$-q' \in A^* q, \qquad q(1) = g'(x_0)$$

satisfying the minimum principle

$$\min_{e \in F(x_0)} \langle q(t), e\rangle = 0 \quad \text{for all } t \in [0, 1]$$

and the second-order condition

$$q(t) \in (dF(x_0, 0)Q)^+, \qquad q(t) \in ([F, F]_Q(x_0))^+$$

for all $t \in [0, 1[$.

Proof. Fix $t \in [0, 1[$. By [14, Thm. 5.2], $dF(x_0, 0)Q \subset R^\infty(t, x_0)$. From the proof of Theorem 6.1 in [14] we deduce that $[F, F]_Q(x_0) \subset R^\infty(t, x_0)$. Since $z \equiv x_0$ is optimal, $g'(x_0) \in T_{R(1, x_0)}(x_0)^+$. Theorem 4.2 ends the proof. □

Final remark. It is clear that the creation of a differential and "variational" calculus of set-valued maps (applied to reachable sets) is needed to make the field of applications broader. Special difficulties arise at all points where the trajectory tested for optimality is not continuously differentiable. Until now, this difficulty has not been overcome by any theorem in the literature concerning high-order necessary conditions. It is usually

assumed that the optimal trajectory is C^∞ (or piecewise C^∞) (see, for example, [20], [19], [4]). But, because of the Lavrentiev phenomenon, such an assumption is not reasonable. This is why we state necessary conditions here using "general" variations of reachable sets.

Acknowledgment. I thank Professor J. Zabczyk for bringing to my attention the applicability of the results to the considered impulse control problem.

NONLINEAR OBSERVER DESIGN BY OBSERVER ERROR LINEARIZATION*

XIAO-HUA XIA† AND WEI-BIN GAO†

Abstract. This paper studies the observer design problem by the observer error linearization approach for nonlinear systems with and without inputs. Necessary and sufficient conditions for the existence of the linearization transformation are derived. For nonlinear systems without inputs, the conditions are shown to be corrections to an existing result. A computation procedure and a different set of necessary and sufficient conditions based on the computation procedure are presented.

Key words. linearization, nonlinear observer, observer form, canonical forms, observability

AMS(MOS) subject classifications. 93B07, 93B10, 93B17, 93B50, 93C10, 93C35

1. Introduction.

Consider nonlinear systems of the following form:

$$\dot{x} = f(x, u), \quad x \in R^n, \quad u \in R^p, \tag{1.1a}$$

$$y = h(x), \quad y \in R^m \tag{1.1b}$$

where for each u, $f(\cdot, u) \in V(R^n)$, the set of smooth vector fields on R^n, $h(x) = (h_1(x), \cdots, h_m(x))^T$, $h_i(x) \in C^\infty(R^n)$, the set of smooth functions on R^n, $i = 1, \cdots, m$, and f is smooth with respect to u.

The observer error linearization problem is stated as follows.

Given a nonlinear system (1.1), and an initial state x^0, find (if possible) a neighborhood U of x^0, and a coordinates transformation

$$z = F(x) \quad (\text{or } x = W(z) = F^{-1}(z)) \tag{1.2}$$

defined on U, a pair of matrices (C, A) in dual Brunovsky canonical form with observability indices $k_1, \cdots, k_m$, i.e.,

$$A = \begin{array}{c} \begin{matrix} \sigma_1 & & \sigma_2 & & \cdots & & \sigma_m \end{matrix} \\ \left[\begin{array}{ccccccc} 0 & \cdots & 0 & & & & \\ 1 & & \vdots & 0 & \cdots & 0 & \\ & \ddots & \vdots & & & & \\ & 0 & 10 & & & & \\ & & 0 & \cdots & 0 & & \\ & & 1 & & & & \\ & 0 & & \ddots & \vdots & \cdots & 0 \\ & & & & 10 & & \\ \vdots & & \vdots & & & & \vdots \\ & & & & & 0 \cdots & 0 \\ & & & & & 1 & \\ 0 & & 0 & \cdots & & \ddots & \vdots \\ & & & & & & 10 \end{array}\right] \end{array} \begin{matrix} \\ \\ \sigma_1 \\ \\ \\ \\ \sigma_2, \\ \\ \\ \\ \sigma_m \end{matrix} \tag{1.3a}$$

$$C = \begin{array}{c} \begin{matrix} \sigma_1 & & \sigma_2 & & & & \sigma_m & \end{matrix} \\ \begin{bmatrix} 0 & \cdots & 010 & \cdots & 00 & \cdots & 0 & \cdots & 00 \\ 0 & \cdots & 000 & \cdots & 01 & \cdots & 0 & \cdots & 00 \\ & \vdots & & & & \vdots & & & \\ 0 & \cdots & 000 & \cdots & 00 & \cdots & 0 & \cdots & 01 \end{bmatrix} \end{array} \tag{1.3b}$$

where $\sigma_i = \sum_{j=1}^{i} k_j$, $i = 1, \cdots, m$, and a mapping $a : h(U) \times R^p \to R^n$ such that

$$h(W(z)) = Cz, \tag{1.4}$$

$$F_* f(W(z), u) = Az + a(Cz, u) \tag{1.5}$$

for all $z \in F(U)$, $u \in R^p$, where F_* is the Jacobian of F.

If this problem is solvable, then in the new coordinates, the system (1.1) is in the form

$$\dot{z} = Az + a(y, u) = g(z, u), \tag{1.6a}$$

$$y = Cz \tag{1.6b}$$

and then an observer for system (1.1) can be constructed easily so that the observer error satisfies a linear dynamical system (for details, see [6]).

A nonlinear system in form (1.6) is said to be in observer form. This approach for nonlinear observer design was first proposed by Krener and Isidori [1] and Bestle and Zeitz [2] independently as the loose-sense mathematical dual of that proposed by Jakubczyk and Repondek [3] and Hunt and Su [4] for the exact linearization problem of nonlinear systems. Necessary and sufficient conditions in terms of differential geometry are derived in [1] for nonlinear systems without inputs when $m = 1$.

Recently, Li and Tao [5] obtained a different set of conditions described as rank conditions of matrices for single-output nonlinear time-variable systems.

For the most general cases, Krener and Respondek [6] give a very good characterization of the approach.

In this paper, we shall consider the observer error linearization problem for nonlinear systems both with and without inputs. Some new results are presented. As a consequence, a correction to Theorem 5.1 in Krener and Respondek [6] is made. Moreover, our method for dealing with systems with inputs is different from that of [6]. We will give a computation procedure for the transformation. Based on this computation procedure, a different set of necessary and sufficient conditions is obtained.

The organization of the paper is as follows. Sections 2 and 3 deal with systems without inputs. Section 2 is devoted to necessary conditions and § 3 to sufficient conditions. Based on the discussion in the previous sections, we consider systems with inputs in § 4. Section 5 contains examples and § 6 conclusions.

2. Necessary conditions. In this section and in § 3, we consider systems without inputs. Let us first analyse the problem as follows.

If the state transformation exists, then from (1.5), we have in coordinates representation

$$f(x) = W_* g(z) = \frac{\partial W}{\partial z} g(z). \tag{2.1}$$

Partially differentiating both sides of (2.1) with respect to z_{ij} results in

$$\frac{\partial f(x)}{\partial z_{ij}} = \frac{\partial}{\partial z_{ij}}\left(\frac{\partial W}{\partial z}\right) g(z) + \frac{\partial W}{\partial z} \cdot \frac{\partial g(z)}{\partial z_{ij}}, \tag{2.2}$$

but

$$\frac{\partial f(x)}{\partial z_{ij}} = \frac{\partial f}{\partial x} \cdot \frac{\partial W}{\partial z_{ij}}, \tag{2.3}$$

$$\frac{\partial}{\partial z_{ij}}\left(\frac{\partial W}{\partial z}\right) g(z) = \frac{\partial}{\partial x}\left(\frac{\partial W}{\partial z_{ij}}\right)\frac{\partial W}{\partial z} g(z) = \frac{\partial}{\partial x}\left(\frac{\partial W}{\partial z_{ij}}\right) f(x), \tag{2.4}$$

$$\frac{\partial W}{\partial z} \cdot \frac{\partial g(z)}{\partial z_{ij}} = \begin{cases} \dfrac{\partial W}{\partial z_{ij+1}}, & i = 1, \cdots, m; \quad j = 1, \cdots, k_i - 1, \\ \dfrac{\partial W}{\partial z} \cdot \dfrac{\partial a}{\partial z_{ik_i}}, & i = 1, \cdots, m; \quad j = k_i. \end{cases} \tag{2.5}$$

By substituting (2.3)-(2.5) for (2.2), we obtain

$$\frac{\partial W}{\partial z_{ij+1}} = \frac{\partial f}{\partial x} \cdot \frac{\partial W}{\partial z_{ij}} - \frac{\partial}{\partial x}\left(\frac{\partial W}{\partial z_{ij}}\right) f, \quad i = 1, \cdots, m; \quad j = 1, \cdots, k_i - 1, \tag{2.6}$$

$$\frac{\partial W}{\partial z} \cdot \frac{\partial a}{\partial z_{ik_i}} = \frac{\partial f}{\partial x} \cdot \frac{\partial W}{\partial z_{ik_i}} - \frac{\partial}{\partial x}\left(\frac{\partial W}{\partial z_{ik_i}}\right) f, \qquad i = 1, \cdots, m; \tag{2.7}$$

in other words,

$$\frac{\partial W}{\partial z_{ij+1}} = \mathrm{ad}_{(-f)} \frac{\partial W}{\partial z_{ij}}, \quad i = 1, \cdots, m; \quad j = 1, \cdots, k_i - 1, \tag{2.8}$$

$$\frac{\partial W}{\partial z} \cdot \frac{\partial a}{\partial z_{ik_i}} = \mathrm{ad}_{(-f)} \frac{\partial W}{\partial z_{ik_i}}, \qquad i = 1, \cdots, m. \tag{2.9}$$

These can be rewritten as

$$\frac{\partial W}{\partial z_{ij+1}} = \mathrm{ad}^j_{(-f)} \frac{\partial W}{\partial z_{i1}}, \quad i = 1, \cdots, m; \quad j = 1, \cdots, k_i - 1, \tag{2.10}$$

$$\frac{\partial W}{\partial z} \cdot \frac{\partial a}{\partial z_{ik_i}} = \mathrm{ad}^{k_i}_{(-f)} \frac{\partial W}{\partial z_{i1}}, \qquad i = 1, \cdots, m. \tag{2.11}$$

On the other hand, from (1.4) we have

$$h_p(W(z)) = c_p z, \qquad p = 1, \cdots, m \tag{2.12}$$

where $c_p = (0 \cdots 010 \cdots 0)$ with the unit in the $(\sum_{i=1}^{p} k_i)$th position.

Partially differentiating both sides of (2.12) with respect to z_{ij}, we may have

$$\langle dh_p, \partial W / \partial z_{ij} \rangle = \delta_{i,p} \cdot \delta_{j,k_i}, \quad i = 1, \cdots, m; \quad p = 1, \cdots, m; \quad j = 1, \cdots, k_i \tag{2.13}$$

where δ is the Kronecker delta. By (2.8) and the Leibniz rule, we see that

$$\begin{aligned}\langle dh_p, \partial W/\partial z_{ij}\rangle &= \langle dh_p, \mathrm{ad}_{(-f)}\partial W/\partial z_{ij-1}\rangle \\ &= L_{(-f)}\langle dh_p, \partial W/\partial z_{ij-1}\rangle - \langle L_{(-f)}(dh_p), \partial W/\partial z_{ij-1}\rangle \\ &= \langle L_f(dh_p), \partial W/\partial z_{ij-1}\rangle, \quad i, p = 1, \cdots, m; \quad j = 2, \cdots, k_i,\end{aligned} \tag{2.14}$$

so formulae (2.13) imply, for $i = 1, \cdots, m$,

$$\langle L_f^{j-1}(dh_p), \partial W/\partial z_{i1}\rangle = \delta_{i,p} \cdot \delta_{j,k_i}, \quad p = 1, \cdots, m; \quad j = 1, \cdots, k_i. \tag{2.15}$$

Thus, the problem is reduced to the investigation of the solvability of (2.10), (2.11), and (2.15). We may formulate the analysis above as a theorem.

THEOREM 2.1. *The state transformation* (1.2) *transforms the system* (1.1a)-(1.1b) *into system* (1.6a)-(1.6b) *if and only if W and a satisfy* (2.10), (2.11), *and* (2.15).

Remark 2.2. Note that (2.15) are linear algebraic equations in $\partial W/\partial z_{i1}$. For each i, there are mk_i equations altogether. If $mk_i > n$, then these equations are overdetermined, and if $mk_i < n$, they are underdetermined. Therefore, $\partial W/\partial z_{i1}$ may not be uniquely obtained. When the observability indices are identical, i.e., $k_1 = k_2 = \cdots = k_m$, then $\partial W/\partial z_{i1}$ is uniquely determined.

Yet, the solvability of these linear algebraic equations is always guaranteed by a simple consequence of the necessary conditions developed below.

THEOREM 2.3. *The observer error linearization problem is solvable only if there exist m-tuple of integers* $(k_1, \cdots, k_m)$, $k_1 \geqq k_2 \geqq \cdots \geqq k_m > 0$, *and* $\sum_{i=1}^m k_i = n$, *such that we have the following*:

(i) *If we denote* (*with a possible reordering of the* h_i*'s*)

$$Q = \{L_f^{j-1}(dh_i): i = 1, \cdots, m; j = 1, \cdots, k_i\}, \tag{2.16}$$

then

$$\dim \operatorname{span} Q = n \tag{2.17}$$

in a neighborhood of x^0.

(ii) *If we denote*

$$Q_j = \{L_f^{k-1}(dh_i): i = 1, \cdots, m; k = 1, \cdots, k_j\} - \{L_f^{k_j-1}(dh_j)\} \tag{2.18}$$

for $j = 1, \cdots, m$, *then*

$$\dim \operatorname{span} Q_j = \dim \operatorname{span} Q \cap Q_j \tag{2.19}$$

for $j = 1, \cdots, m$.

Remark 2.4. Condition (i) means that the nonlinear system is observable in some sense.

Remark 2.5. Condition (ii) means that in representing those 1 forms in $Q_i - Q \cap Q_i$ as linear combinations of the 1 forms in Q, the coefficients attached to the 1 forms in $Q - Q \cap Q_i$ are zeros. This is a dual result of 1 in Hunt and Su [4].

Proof of Theorem 2.3. If $z = F(x)$ or $x = W(z)$ is the state transformation, then

$$\frac{\partial W}{\partial z} = \left(\frac{\partial W}{\partial z_{11}} \cdots \frac{\partial W}{\partial z_{1k_1}} \cdots \frac{\partial W}{\partial z_{m1}} \cdots \frac{\partial W}{\partial z_{mk_m}}\right)$$

is nonsingular. Denote the matrix $O(x)$ as

$$O(x)=\begin{bmatrix} dh_1 \\ L_f(dh_1) \\ \vdots \\ L_f^{k_1-1}(dh_1) \\ \vdots \\ dh_m \\ L_f(dh_m) \\ \vdots \\ L_f^{k_m-1}(dh_m) \end{bmatrix} \tag{2.20}$$

and consider the matrix product $O(x)\cdot \partial W/\partial z$.

From (2.10) and the Leibniz rule, it is easy to see that

$$O(x)\cdot\frac{\partial W}{\partial z}=\begin{bmatrix} 0 & 1 & & & & & & \\ & \ddots & x & 0 & \cdots & & 0 & \\ 1 & x & x & & & & & \\ & & & 0 & 1 & & & \\ & 0 & & \ddots & x & \cdots & 0 & \\ & & & 1 & x & x & & \\ & \vdots & & & \vdots & & & \\ & & & & & & 0 & 1 \\ & 0 & & 0 & & & \ddots & x \\ & & & & & & 1 & x & x \end{bmatrix}. \tag{2.21}$$

The matrix in the right-hand side of (2.21) is nonsingular. This implies (i).

Now we prove (ii). Obviously,

$$\text{span } Q_i \supseteq \text{span } Q \cap Q_i, \qquad i=1,\cdots,m, \tag{2.22}$$

so, if we can prove that $\dim \text{span } Q_i \leqq \dim \text{span } Q\cap Q_i$, we then have (ii).

On the one hand, because of (i), it is clear that

$$\dim \text{span } Q\cap Q_i = ik_i + k_{i+1}+\cdots+k_m-1 \tag{2.23}$$

for $i=1,\cdots,m$. On the other hand, by (2.13) and repeated use of the Leibniz rule, we may have

$$\langle L_f^{k-1}(dh_p)\partial W/\partial z_{js}\rangle = 0 \tag{2.24}$$

for $i=1,\cdots,m$; $k=1,\cdots,k_i-1$; $j=1,\cdots,i$; $s=1,\cdots,k_j-k_{i+1}$. That is, $\partial W/\partial z_{11},\cdots,\partial W/\partial z_{1k_1-k_i+1},\cdots,\partial W/\partial z_{i-11},\cdots,\partial W/\partial z_{i-1k_{i-1}-k_i+1}$, $\partial W/\partial z_{i1}$ annihilate the one forms in Q_i. Because of the independence of $\partial W/\partial z_{ij}$'s we deduce that

$$\begin{aligned} \dim \text{span } Q_i &\leqq n-(k_1-k_i)-\cdots-(k_{i-1}-k_i)-1 \\ &= ik_i+k_{i+1}+\cdots+k_m-1. \end{aligned} \tag{2.25}$$

So, from (2.23)

$$\dim \text{span } Q_i \leqq \dim \text{span } Q\cap Q_i.$$

This completes the proof. □

COROLLARY 2.6. *If conditions* (i) *and* (ii) *of Theorem* 2.3 *hold, then the linear algebraic equations* (2.15) *are solvable.*

Proof. By (ii) and Remark 2.5, we know that (2.15) are in fact equivalent to the following equations (write g for $\partial W/\partial z_{i1}$):

$$\begin{aligned}
&\langle dh_1, g\rangle = 0 \cdots \langle dh_i, g\rangle = 0, && \langle dh_{i+1}, g\rangle = 0 \cdots \langle dh_m, g\rangle = 0\\
&\langle L_f dh_1, g\rangle = 0 \cdots \langle L_f dh_i, g\rangle = 0, && \langle L_f dh_{i+1}, g\rangle = 0 \cdots \langle L_f dh_m, g\rangle = 0\\
&\quad\vdots \qquad\qquad \vdots && \quad\vdots \qquad\qquad \vdots\\
&\langle L_f^{k_i-1} dh_1, g\rangle = 0 \cdots \langle L_f^{k_i-1} dh_i, g\rangle = 1 && \langle L_f^{k_{i+1}} dh_{i+1}, g\rangle = 0 \cdots \langle L_f^{k_m-1} dh_m, g\rangle = 0.
\end{aligned} \tag{2.26}$$

Solutions always exist for these $ik_i + k_{i+1} + \cdots + k_m$ equations, since $\dim \operatorname{span}[Q_i \cup \{L_f^{k_i-1}(dh_i)\}] = ik_i + k_{i+1} + \cdots + k_m$. □

Now let $g^1, \cdots, g^m$ be solutions to (2.15), and define a matrix as follows:

$$\tilde{Q}(x) = (g^1 \operatorname{ad}_{(-f)} g^1 \cdots \operatorname{ad}_{(-f)}^{k_1-1} \cdots g^m \operatorname{ad}_{(-f)} g^m \cdots \operatorname{ad}_{(-f)}^{k_m-1} g^m). \tag{2.27}$$

As in the argument of Theorem 2.3, we have that $\tilde{Q}(x)$ is nonsingular if the system is observable (that is, if $O(x)$ is nonsingular). Thus from (2.11) we have

$$\frac{\partial a}{\partial z_{ik_i}} = \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_i} g^i. \tag{2.28}$$

Another necessary condition can be derived by (2.28).

THEOREM 2.7. *A necessary condition for the system* (1.1) *to admit an observer form* (1.6) *is that there exist solutions* $g^1, \cdots, g^m$ *of* (2.15) *such that*

$$\operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_1} g^1 \\ \vdots \\ \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_m} g^m \\ h(x) \end{bmatrix} = m. \tag{2.29}$$

Proof. If the state transformation $x = W(z)$ exists, then we have

$$y = (z_{1k_1} \cdots z_{mk_m})^T = h(x). \tag{2.30}$$

However, from the previous remark, (2.10), and (2.11), we have

$$\frac{\partial a}{\partial z_{ik_i}} = \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_i} g^i = b_i(y) = b_i(h(x)) \tag{2.31}$$

where

$$\begin{aligned}
b_i(y) &= (b_{00}^i(y) \cdots b_{mk_m-1}^i(y))^T \\
&= \frac{\partial a(y)}{\partial y_i} = \frac{\partial a(z_{1k_1}, \cdots, z_{mk_m})}{\partial z_{ik_i}}
\end{aligned} \tag{2.32}$$

is dependent only on y, so

$$\operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_1} g^1 \\ \vdots \\ \tilde{Q}^{-1}(x) \operatorname{ad}_{(-f)}^{k_m} g^m \\ h(x) \end{bmatrix} = \operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} b_1(h(x)) \\ \vdots \\ b_m(h(x)) \\ h(x) \end{bmatrix} = \operatorname{rank} \frac{\partial h}{\partial x} = m. \qquad \square$$

3. Sufficient conditions. We have already seen from the previous section that the observer error linearization problem is transformed to the study of the integrability of the partial differential equations (2.10) and (2.11) and the solvability of the linear algebraic equations (2.15). By considering (2.15) and (2.11), we have obtained the

necessary conditions. In this section we turn our attention to the integrability of the partial differential equations (2.10) and (2.11). As remarked by Krener and Respondek [6], the integrability of (2.10) implies the integrability of (2.11). We will show that the converse is also true. And the integrability of (2.10) and of (2.11) leads to sufficient conditions for the observer error linearization problem.

First, consider (2.10); we then have Theorem 3.1.

THEOREM 3.1. *The observer error linearization problem is solvable if and only if there exist m-tuple of integers* $(k_1, \cdots, k_m)$, $k_1 \geqq k_2 \geqq \cdots \geqq k_m > 0$, *and* $\sum_{i=1}^{m} k_i = n$, *such that we have the following*:

(i) *Conditions* (i) *and* (ii) *in Theorem* 2.3 *hold.*

(ii) *There exists a mapping* ϕ *of some open set* V *of* R^n *onto a neighborhood* U *of* x^0 *and vector fields* $g^1, \cdots, g^m$ *satisfying*

$$L_{g_i} L_f^{l-1}(h_j) = \delta_{i,j} \cdot \delta_{l,k_j}, \quad i = 1, \cdots, m, \quad l = 1, \cdots, k_i, \quad j = 1, \cdots, m \tag{3.1}$$

such that

$$\frac{\partial \phi}{\partial z} = (g^1 \operatorname{ad}_{(-f)} g^1 \cdots \operatorname{ad}_{(-f)}^{k_1 - 1} g^1 \cdots g^m \operatorname{ad}_{(-f)} g^m \cdots \operatorname{ad}_{(-f)}^{k_m - 1} g^m) \circ \phi(z) \tag{3.2}$$

for all $z \in V$.

Remark 3.2. The g^i's satisfying (3.1) can always be found if Theorem 3.1(i) holds. As a matter of fact, we need to solve only the set of equations

$$\langle L_f^{l-1}(dh_j), g^i \rangle = \delta_{i,j} \cdot \delta_{l,k_j}, \quad i, j = 1, \cdots, m; \quad l = 1, \cdots, k_i. \tag{3.3}$$

These are just the linear algebraic equations (2.15). Thus, Corollary 2.6 and (1) imply the solvability of (3.3). □

Remark 3.3. Equations (3.2) are, in fact, (2.10). So, the theorem implies that the integrability of (2.11) is guaranteed by the integrability of (2.10). Also, we can show the converse (see Xia and Gao [7]).

Proof of Theorem 3.1. The necessity follows easily from Remarks 3.2 and 3.3 and Theorem 2.3.

Sufficiency. Suppose (1), (2) hold. As in the proof of Theorem 2.3, we may immediately note that the matrix

$$\begin{bmatrix} dh_1 \\ L_f(dh_1) \\ \vdots \\ L_f^{k_{m^1}}(dh_1) \\ \vdots \\ dh_m \\ L_f(dh_m) \\ \vdots \\ L_f^{k_m - 1}(dh_m) \end{bmatrix} \cdot [g^1 \operatorname{ad}_{(-f)} g^1 \cdots \operatorname{ad}_{(-f)}^{k_1 - 1} g^1 \cdots g^m \operatorname{ad}_{(-f)} g^m \cdots \operatorname{ad}_{(-f)}^{k_m - 1} g^m]$$

has rank n in a neighborhood U of x^0. Therefore, the vector fields $\operatorname{ad}_{(-f)}^j g^i$, $i = 1, \cdots, m$; $j = 0, \cdots, k_i - 1$ are linearly independent in the neighborhood U of x^0.

Let $z^0 \in R^n$, such that $\phi(z^0) = x^0$. From the linear independence of the vector fields on the right-hand side of (3.2), we deduce that ϕ has rank n at z^0, i.e., that ϕ is a diffeomorphism of a neighborhood of z^0 onto a neighborhood of x^0.

Set $W=\phi$, or $F=\phi^{-1}$, and

$$F_* f\circ F^{-1}(z)=\hat{f}_{11}\frac{\partial}{\partial z_{11}}+\cdots+\hat{f}_{1k_1}\frac{\partial}{\partial z_{1k_1}}+\cdots+\hat{f}_{m1}\frac{\partial}{\partial z_{m1}}+\cdots+\hat{f}_{mk_m}\frac{\partial}{\partial z_{mk_m}}. \tag{3.4}$$

By (2), the mapping ϕ is such that

$$\phi_*\left(\frac{\partial}{\partial z_{ij+1}}\right)\circ\phi^{-1}(x)=\mathrm{ad}^j_{(-f)}g^i(x)$$

so that

$$F_*\,\mathrm{ad}^j_{(-f)}g^i\circ F^{-1}(z)=\frac{\partial}{\partial z_{ij+1}} \tag{3.5}$$

for $i=1,\cdots,m$; $j=0,\cdots,k_i-1$.

Using (3.4) and (3.5), we obtain, for $i=1,\cdots,m$; $j=0,\cdots,k_i-2$,

$$\begin{aligned}\frac{\partial}{\partial z_{ij+2}}&=F_*\,\mathrm{ad}^{j+1}_{(-f)}g^i\circ F^{-1}(z)=F_*[-f,\mathrm{ad}^j_{(-f)}g^i]\circ F^{-1}(z)\\&=[-F_*f\circ F^{-1}(z),F_*\,\mathrm{ad}^j_{(-f)}g^i\circ F^{-1}(z)]\\&=-\left[\hat{f}_{11}\frac{\partial}{\partial z_{11}}+\cdots+\hat{f}_{mk_m}\frac{\partial}{\partial z_{mk_m}},\frac{\partial}{\partial z_{ij+1}}\right]\\&=\frac{\partial\hat{f}_{11}}{\partial z_{ij+1}}\frac{\partial}{\partial z_{11}}+\cdots+\frac{\partial\hat{f}_{mk_m}}{\partial z_{ij+1}}\frac{\partial}{\partial z_{mk_m}}.\end{aligned}$$

Because of the linear independence of the $\partial/\partial z_{ij}$'s, this implies

$$\frac{\partial f_{lk}}{\partial z_{ij+1}}=\delta_{i,l}\cdot\delta_{k,j+2}. \tag{3.6}$$

We then deduce that $\hat{f}_{11},\cdots,\hat{f}_{m1}$ depend only on $z_{1k_1},\cdots,z_{mk_m}$, and that $\hat{f}_{ij}$ for $i=1,\cdots,m$; $j=2,\cdots,k_i$, is such that $\hat{f}_{ij}-z_{ij-1}$ depend only on $z_{1k_1},\cdots,z_{mk_m}$. In other words, we have

$$F_*f\circ F^{-1}(z)=Az+a(z_{1k_1},\cdots,z_{mk_m})$$

where a is a suitable mapping of z_{ik_i}, and this shows that condition (1.5) holds.

Moreover, since, by (3.1).

$$L_{\mathrm{ad}^{l-1}_{(-f)}g^i}h_j=\delta_{i,j}\cdot\delta_{l,k_i}$$

for $i,j=1,\cdots,m$; $l=1,\cdots,k_i$, we have that

$$\frac{\partial h_j\circ F^{-1}}{\partial z_{il}}=\delta_{i,j}\cdot\delta_{j,k_i}$$

for $i,j=1,\cdots,m$; $l=1,\cdots,k_i$. In other words,

$$\frac{\partial}{\partial z}(h\circ F^{-1}(z))=C.$$

This implies that condition (1.4) holds. □

The integrability of the partial differential equations (3.2) may be expressed in terms of a property of the vector fields on the right-hand side (see Spivak [8]).

THEOREM 3.4. *The observer error linearization problem is solvable if and only if* (i) *and* (ii) *in Theorem* 2.3 *hold and there exist vector fields* $g^1,\cdots,g^m$ *satisfying* (3.1)

such that

$$[\mathrm{ad}^{k}_{(-f)}g^{i}, \mathrm{ad}^{l}_{(-f)}g^{j}]=0 \tag{3.7}$$

for $i, j=1, \cdots, m$; $k=0, \cdots, k_i-1$; $l=0, \cdots, k_j-1$.

Now, several consequences of the results above are immediate.

COROLLARY 3.5. *A nonlinear system* (1.1a)-(1.1b) *admits an observer form* (1.6a)-(1.6b) *with the observability indices in the pair* (C, A) *all identical if and only if*:

(i) dim span $Q=n$;

(ii) $[\mathrm{ad}^{k}_{(-f)}g^{i}, \mathrm{ad}^{l}_{(-f)}g^{j}]=0$,

for $i, j=1, \cdots, m$; $k, l=0, \cdots, k_i-1$, *where* g^i *is the vector field determined by* (3.1).

Proof. If we notice that when $k_1=k_2=\cdots=k_m$, $Q \cap Q_i=Q_i$, then the proof is trivial. □

Also, if we prolong the linear algebraic equations such that g^i can be uniquely defined, a sufficient condition follows.

COROLLARY 3.6. *Let* g^j *be the vector field defined by the following n equations*:

$$L_{g^j}L_f^{l-1}h_i=\delta_{i,j}\cdot\delta_{l,k_i}, \quad i=1, \cdots, m; \quad l=1, \cdots, k_i \tag{3.8}$$

for $j=1, \cdots, m$, *then the observer error linearization problem is solvable if conditions* (3.7) *hold.*

Remark 3.7. Now we can see that the conditions in Theorem 5.1 of [6] are sufficient but not necessary, as a counterexample in the next section will show.

Remark 3.8. The partial differential equations satisfying condition (3.7) can be integrated by standard methods as outlined in [8]. The computation algorithm in Hunt and Su [4] can also be used to solve these equations.

The state transformation can also be obtained by considering the integrability of (3.11). This has been done in Xia and Gao [7] for nonlinear systems without inputs. In [7], a computation procedure is proposed, and based on the computation procedure, we obtained a different set of necessary and sufficient conditions. For comparison with the previous result and for the development of the next section, we briefly review some results in [7].

A COMPUTATION PROCEDURE.

(i) Compute $O(x)$ defined in (2.20).

(ii) Choose solutions $g^1, \cdots, g^m$ of (2.26) or (2.15), and compute $\tilde{Q}(x)$ defined in (2.27), and b_i's defined in (2.31).

(iii) If b_i's are functions of y (i.e., $z_{1k_1}, \cdots, z_{mk_m}$), solve the following equations:

$$\frac{\partial a}{\partial y_i}=b_i(y). \tag{3.9}$$

(iv) Compute the state transformation

$$z=F(x)=\begin{bmatrix} z_{11}(x) \\ \vdots \\ z_{1k_1}(x) \\ \vdots \\ z_{m1}(x) \\ \vdots \\ z_{mk_m}(x) \end{bmatrix} \tag{3.10}$$

as follows:

$$z_{ik_i}(x)=h_i(x) \quad \text{for } i=1, \cdots, m, \tag{3.11a}$$

$$z_{ij}(x) = L_f z_{ij+1}(x) - a_{ij}(h(x)) \tag{3.11b}$$

for $i = 1, \cdots, m$; $j = k_i - 1, k_i - 2, \cdots, 2, 1$.

(v) Redefine $a_{i0}(x_{1k_1}, \cdots, x_{mk_m}) = a_{i0}(y) = L_f z_{i1}(x)$, for $i = 1, \cdots, m$.

Before we introduce the results, some conventions are necessary.

For multivalued functions $g = (g_1, \cdots, g_m)$, $g_i = g_i(y_1, \cdots, y_m) \in R^n$, we denote the following $mn \times m$ matrix as $[\partial g / \partial y]$, i.e.,

$$\left[\frac{\partial g}{\partial y}\right] = \begin{bmatrix} \dfrac{\partial g_1}{\partial y_1} & \dfrac{\partial g_1}{\partial y_2} & \cdots & \dfrac{\partial g_1}{\partial y_m} \\ \vdots & \vdots & & \vdots \\ \dfrac{\partial g_m}{\partial y_1} & \dfrac{\partial g_m}{\partial y_2} & \cdots & \dfrac{\partial g_m}{\partial y_m} \\ 1 & 1 & \cdots & 1 \end{bmatrix} \begin{matrix} n \\ \vdots \\ n \end{matrix}. \tag{3.12}$$

An $mn \times m$ matrix A partitioned as follows will be denoted as $\bar{A}$,

$$\bar{A} = \begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1m} \\ A_{21} & A_{22} & \cdots & A_{2m} \\ \vdots & \vdots & & \vdots \\ A_{m1} & A_{m2} & \cdots & A_{mm} \\ 1 & 1 & & 1 \end{bmatrix} \begin{matrix} n \\ n \\ \vdots \\ n \\ mn \times m \end{matrix} = (a_{ij})_{mn \times m} = A. \tag{3.13}$$

An $mn \times m$ matrix A is called block symmetric if A_{ij}'s in the partitioned $\bar{A}$ in (3.13) satisfy

$$A_{ij} = A_{ji}, \qquad i, j = 1, \cdots, m$$

and the block symmetrical property of an $mn \times m$ matrix A is denoted as

$$\bar{A} = \bar{A}^T.$$

Now, we are ready to introduce our results.

THEOREM 3.9. *The system* (1.1) *admits an observer form* (1.6) *if and only if there exist m-tuple of integers* $(k_1, \cdots, k_m)$, $k_1 \geqq k_2 \geqq \cdots \geqq k_m > 0$, *and* $\sum_{i=1}^m k_i = n$, *such that*:

(1) *Conditions* (i) *and* (ii) *in Theorem* 2.3 *hold.*

(2) *There exist solutions* $g^1, \cdots, g^m$ *to* (2.26) *such that condition* (2.29) *in Theorem* 2.7 *holds.*

(3) *If we denote an* $mn \times m$ *matrix* $S(x)$ *as*

$$S(x) = \frac{\partial}{\partial x}\begin{bmatrix} \tilde{Q}^{-1}(x)\, \mathrm{ad}_{(-f)}^{k_1} g^1 \\ \vdots \\ \tilde{Q}^{-1}(x)\, \mathrm{ad}_{(-f)}^{k_m} g^m \end{bmatrix} \left(\frac{\partial h}{\partial x}\right)^T \left[\frac{\partial h}{\partial x}\left(\frac{\partial h}{\partial x}\right)^T\right]^{-1}, \tag{3.14}$$

then $S(x)$ *is block symmetric, i.e.,*

$$\overline{S(x)} = (\overline{S(x)})^T. \tag{3.15}$$

Remark 3.10. This theorem guarantees the computability of the procedure. We see that step (iii) is the most difficult part of the procedure. Under the conditions of this theorem, the partial differential equations (3.9) are usually referred to as exact equations. Solutions of exact equations are easier to obtain. So, from the computational point of view, the method here is more convenient than the method we used when solving the partial differential equations (3.2).

Remark 3.11. From this theorem, it is easily seen that the integrability of (2.11) implies the integrability of (2.10).

Remark 3.12. The proof of this theorem can be found in [7]. From the proof, we can see that there are some abundances in (3.9). In fact, equations concerning a_{i0}, $i=1,\cdots,m$, in (3.9) can be dropped. Thus, we need to check appropriate conditions of lower-dimensional matrices. For details see [7] and the next section.

4. Systems with inputs. In this section, we consider systems with inputs. From the previous discussions, it is easily known that (2.10), (2.11), and (2.16) hold in this case, except that L_f and $\mathrm{ad}_{(-f)}$ are replaced by $L_{f(\cdot,u)}$ and $\mathrm{ad}_{(-f(\cdot,u))}$, respectively. Throughout this section, for notational simplicity, we will assume that L_f and $\mathrm{ad}_{(-f)}$ stand for $L_{f(\cdot,u)}$ and $\mathrm{ad}_{(-f(\cdot,u))}$, respectively. Now the matrices O defined in (2.20) and $\tilde{Q}$ defined in (2.27), respectively, are u dependent. A u-dependent proposition is true if it is true for any u. Thus, the necessary conditions developed in § 2 are also valid here. We remark that the nonsingularity of the matrix $O(x,u)$ relates to a kind of observability property of the system (see [9]). To derive sufficient conditions, we note that the mapping a must satisfy some extra requirement because it is now u dependent. In this section, we will give a modification of the computation procedure introduced above.

First, we check each step in the computation procedure. Steps (i) and (ii) will present no problem. Step (iii) needs some modification. This is because there will be certain restrictions on the dependence of the mapping $a(y,u)$ on the inputs u to perform step (iv).

We explicitly do as follows. From step (iv), we have

$$\begin{aligned} z_{ik_i-j} &= L_f^j h_i(x) - L_f^{j-1} a_{ik_i-1} - \cdots - L_f a_{ik_i-j+1} - a_{ik_i-j} \\ &= L_f^j h_i(x) - L_f^{j-2} \frac{\partial a_{ik_i-1}}{\partial y} \frac{\partial h}{\partial x} \cdot f - \cdots \frac{\partial a_{ik_i-j+1}}{\partial y} \frac{\partial h}{\partial x} \cdot f - a_{ik_i-j} \end{aligned}$$

for $i=1,\cdots,m$; $j=0,1,\cdots,k_i-1$. Now, since

$$\frac{\partial a_{ij}}{\partial y} = \left(\frac{\partial a_{ij}}{\partial y_1} \cdots \frac{\partial a_{ij}}{\partial y_m}\right)^T = (b_{ij}^1 \cdots b_{ij}^m)^T$$

we have

$$\begin{aligned} z_{ik_i-j} &= L_f^j h_i(x) - \sum_{s=1}^{j-1} L_f^{j-s-1} \left((b_{ik_i-s}^1 \cdots b_{ik_i-s}^m)^T \frac{\partial h}{\partial x} f \right) - a_{ik_i-j} \\ &\triangleq \xi_{ik_i-j} - a_{ik_i-j}. \end{aligned}$$

If we denote

$$b_{p+i}(x,u) = \frac{\partial}{\partial u_i} (\xi_{10} \cdots \xi_{1k_1-1} \cdots \xi_{m0} \cdots \xi_{mk_m-1})^T \tag{4.1}$$

for $i=1,\cdots,m$, then we will have the extra equations the mapping a must satisfy

$$\frac{\partial a}{\partial u_i} = b_{p+i}(x,u) \tag{4.2}$$

for $i=1,\cdots,m$. Therefore, we have a modified computation procedure.

(i) Compute $O(x,u)$ defined in (2.20).

(ii) Choose solutions $g^1,\cdots,g^m$ of (2.26) or (2.15), and compute $\tilde{Q}(x,u)$ defined in (2.27) and b_i's defined in (2.31) and (4.1).

(iii) If b_i's are functions of y and u, then solve the following equations:

$$\frac{\partial a}{\partial y_i} = b_i(y, u), \qquad i = 1, \cdots, p, \tag{4.3a}$$

$$\frac{\partial a}{\partial u_j} = b_{p+j}(y, u), \qquad j = 1, \cdots, m. \tag{4.3b}$$

(iv) Compute the state transformation as follows:

$$z_{ik_i}(x) = h_i(x) \quad \text{for } i = 1, \cdots, m, \tag{4.4a}$$

$$z_{ij}(x) = L_f z_{ij+1}(x) - a_{ij}(h(x), u) \tag{4.4b}$$

for $i = 1, \cdots, m$; $j = k_i - 1, \cdots, 1$.

(v) Redefine $a_{i0}(y, u) = L_f z_{i1}(x) \triangleq \lambda_i(x, u)$, for $i = 1, \cdots, m$.

Now, we have to show that if a transformation exists (it is easily seen that all the above steps are computable), then the computation procedure shown above does give the transformation. Moreover, for the computation of step (iii), we must find conditions that ensure the integrability of (4.3), and we have to show that the z_{ij}'s computed in step (iv) are independent of the inputs u. This leads to the sufficient conditions below.

THEOREM 4.1. *The system* (1.1) *admits an observer form* (1.6) *if and only if there exist m-tuple of integers* $(k_1, \cdots, k_m)$, $k_1 \geqq k_2 \geqq \cdots \geqq k_m > 0$, and $\sum_{i=1}^{m} k_i = n$, *such that*:

(1) *Conditions* (i) *and* (ii) *in Theorem* 2.3 *hold.*

(2) *There exist solutions* $g^1, \cdots, g^m$ *to* (2.26) *such that*

$$\operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \lambda_1(x, u) \\ \vdots \\ \lambda_m(x, u) \\ b_1(x, u) \\ \vdots \\ b_{m+p}(x, u) \\ h(x) \end{bmatrix} = m \tag{4.5}$$

where the b_i*'s are from* (2.31) *and* (4.1), *and the* λ_i*'s are from step* (v).

(3) *If we denote an* $(m+p)n \times (m+p)$ *matrix* $S(x, u)$ *as*

$$S(x, u) = \left[\frac{\partial}{\partial x} \begin{bmatrix} b_1(x, u) \\ \vdots \\ b_{m+p}(x, u) \end{bmatrix} \left(\frac{\partial h}{\partial x} \right)^T \left[\frac{\partial h}{\partial x} \left(\frac{\partial h}{\partial x} \right)^T \right]^{-1} \middle| \frac{\partial}{\partial u} \begin{bmatrix} b_1(x, u) \\ \vdots \\ b_{m+p}(x, u) \end{bmatrix} \right], \tag{4.6}$$

then $S(x, u)$ *is block symmetric, i.e.,*

$$\overline{S(x, u)} = (\overline{S(x, u)})^T. \tag{4.7}$$

Proof. Necessity. We only prove (3); the other conditions are similarly proved, as are the necessary conditions proved in § 2.

If the state transformation exists, then from the above analysis, the following equations are satisfied by the differentiable function $a(x, u)$,

$$\frac{\partial a}{\partial y_i} = b_i(y, u) \quad \text{for } i = 1, \cdots, m, \tag{4.8a}$$

$$\frac{\partial a}{\partial u_j} = b_{m+j}(y, u) \quad \text{for } j = 1, \cdots, p \tag{4.8b}$$

where, by abuse of notation,

$$b_i(y, u) = b_i(h(x), u) = b_i(x, u)$$

and the last terms of the equality above are computed in step (ii) of the procedure. By condition (2), they are functions of y and u.

So, by Lemma 4.1 of Xia and Gao [7],

$$\overline{\left[\frac{\partial b}{\partial y}\ \frac{\partial b}{\partial u}\right]} = \left(\left[\overline{\frac{\partial b}{\partial y}\ \frac{\partial b}{\partial u}}\right]\right)^T. \tag{4.9}$$

But, again by abuse of notation,

$$\frac{\partial b_i}{\partial y}\frac{\partial h}{\partial x} = \frac{\partial b_i}{\partial x}.$$

Multiplying both sides by $(\partial h/\partial x)^T$, and noting that $\partial h/\partial x(\partial h/\partial x)^T$ is an $m \times m$ nonsingular matrix, we have

$$\frac{\partial b_i}{\partial y} = \frac{\partial b_i}{\partial x}\left(\frac{\partial h}{\partial x}\right)^T\left[\frac{\partial h}{\partial x}\left(\frac{\partial h}{\partial x}\right)^T\right]^{-1}. \tag{4.10}$$

From (4.10), we see immediately that

$$\left[\frac{\partial b}{\partial y}\ \frac{\partial b}{\partial u}\right] = S(x, u). \tag{4.11}$$

Hence, (4.9) gives (4.7). This completes the proof of necessity.

Sufficiency. By (2) we know that the b_i's are functionally dependent with $h(x)$. This implies that the b_i's are functions of $h(x)$, or y. And by (3), the same argument as in the proof of necessity will show that (4.9) holds. This in turn implies the integrability of (4.3). Moreover, a direct computation shows that the z_{ij}'s are independent of the inputs u.

Thus, we need only to show that the transformation $z = F(x)$ given by the above computation procedure does transform system (1.5) into (1.1).

As a matter of fact, we have

$$\dot{z} = F_* \dot{x} = \frac{\partial}{\partial x} F(x)\dot{x} \tag{4.12}$$

and from step (iv) and (v),

$$g(z, u) = L_f z(x) = \frac{\partial}{\partial x} F(x) f(x, u). \tag{4.13}$$

It can be shown that $(\partial/\partial x)F(x)$ is nonsingular, so (4.12) and (4.13) imply

$$\dot{x} = f(x, u)$$

and (4.4a) gives

$$y = Cz = h(x).$$

This completes the proof of the theorem. □

Also, we see that there are some abundances in (4.3). We can drop the equations concerning a_{i0}, $i = 1, \cdots, m$, in (4.3). Let $\hat{b}_i$ be the corresponding vector functions obtained by deleting the $(\sigma_i + 1)$th entries, $i = 0, 1, \cdots, m-1$, and σ_0 is assumed to be zero. Then, by considering the integrability of the corresponding equations in almost the same fashion, we have Theorem 4.2.

THEOREM 4.2. *The system* (1.1) *admits an observer form* (1.6) *if and only if there exist m-tuple of integers* $(k_1, \cdots, k_m)$, $k_1 \geqq k_2 \geqq \cdots \geqq k_m > 0$, *and* $\sum_{i=1}^{m} k_i = n$, *such that we have the following*:

(1)′ *Conditions* (i) *and* (ii) *in Theorem* 2.3 *hold.*

(2)′ *There exist solutions* $g^1, \cdots, g^m$ *to* (2.26) *such that*

$$\text{(4.5)}' \qquad \operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \lambda_1(x, u) \\ \vdots \\ \lambda_m(x, u) \\ \hat{b}_1(x, u) \\ \vdots \\ \hat{b}_{m+p}(x, u) \\ h(x) \end{bmatrix} = m.$$

(3)′ *If we denote an* $(m+p)(n-m) \times (m+p)$ *matrix* $S'(x, u)$ *as*

$$\text{(4.6)}' \qquad S'(x, u) = \left[\left[\frac{\partial}{\partial x} \begin{bmatrix} \hat{b}_1(x, u) \\ \vdots \\ \hat{b}_{m+p}(x, u) \end{bmatrix} \left(\frac{\partial h}{\partial x} \right)^T \left[\frac{\partial h}{\partial x} \left(\frac{\partial h}{\partial x} \right)^T \right]^{-1} \middle| \frac{\partial}{\partial u} \begin{bmatrix} \hat{b}_1(x, u) \\ \vdots \\ \hat{b}_{m+p}(x, u) \end{bmatrix} \right] \right],$$

then $S'(x, u)$ *is block symmetric, i.e.,*

$$\text{(4.7)}' \qquad \overline{S'(x, u)} = (\overline{S'(x, u)})^T.$$

5. Examples.

Example 1. Consider the system

$$\begin{aligned} \dot{x}_{11} &= x_{12}, & & \\ \dot{x}_{12} &= x_{12}x_{21}, & y_1 &= x_{11}, \\ \dot{x}_{21} &= x_{12}. & y_2 &= x_{21}, \end{aligned}$$

Since

$$dh_1 = (1\ 0\ 0), \quad L_f(dh_1) = (0\ 1\ 0), \quad dh_2 = (0\ 0\ 1),$$

$$L_f(dh_2) = (0\ \ x_{21}\ \ x_{12}) = 0 \cdot dh_1 + x_{21}(L_f(dh_1)) + x_{12}(dh_2),$$

the coefficient before $L_f(dh_1)$ is $x_{21} \neq 0$, and so, by Theorem 2.3, it is not transformable to an observer form.

Example 2. Consider the system

$$\text{(5.1)} \qquad \begin{aligned} \dot{x}_{11} &= x_{12}, & & \\ \dot{x}_{12} &= x_{12}x_{21}, & y_1 &= x_{11}, \\ \dot{x}_{21} &= x_{11}. & y_2 &= x_{21}, \end{aligned}$$

This system is in special observable form, thus from the discussion of Example 7.4 of [6], it is transformable to an observer form. (This can also be seen in our next example.)

But system (5.1) does not satisfy (5.4) in [6]. Since, g^1, g^2 defined by (3.8), i.e., (5.3) in [6], are $g^1 = (0\ 1\ 0)^T$, and $g^2 = (0\ 0\ 1)^T$, and since

$$\mathrm{ad}_{(-f)}g^1 = \frac{\partial f}{\partial x} g^1 \frac{\partial g^1}{\partial x} f = \frac{\partial f}{\partial x} g^1 = \begin{bmatrix} 1 \\ x_{21} \\ 0 \end{bmatrix},$$

$$[\mathrm{ad}_{(-f)}g^1, g^2] = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix} \neq 0.$$

That is, condition (5.4) in [6] fails.

Example 3. Consider system (5.1) again. Since

$$dh_1 = (1\ 0\ 0), \quad L_f(dh_1) = (0\ 1\ 0), \quad dh_2 = (0\ 0\ 1),$$
$$L_f(dh_2) = (1\ 0\ 0) = dh_1 + 0 \cdot L_f(dh_1) + 0 \cdot dh_2$$

with $k_1 = 2$, $k_2 = 1$, condition (i) of Theorem 3.1 is satisfied.

Moreover, consider (3.1). Obviously, $g^1 = (0\ 1\ 0)^T$. To determine g^2, we have only two equations:

$$\langle dh_1, g^2 \rangle = 0, \qquad \langle dh_2, g^2 \rangle = 1. \tag{5.2}$$

It can be easily seen that $g^2 = (0\ x_{11}\ 1)^T$ is a solution to these equations. And since

$$[g^1, g^2] = \frac{\partial g^2}{\partial x} g^1 - \frac{\partial g^1}{\partial x} g^2 = \frac{g^2}{x} g^1 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \cdot \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = 0,$$

$$\mathrm{ad}_{(-f)}g^1 = \frac{\partial f}{\partial x} g^1 - \frac{\partial g^1}{\partial x} f = \frac{\partial f}{\partial x} g^1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & x_{21} & x_{12} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ x_{21} \\ 0 \end{bmatrix},$$

and thus

$$[\mathrm{ad}_{(-f)}g^1, g^2] = \frac{\partial g^2}{\partial x} \mathrm{ad}_{(-f)}g^1 - \frac{\partial}{\partial x} (\mathrm{ad}_{(-f)}g^1) g^2$$
$$= \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ x_{21} \\ 0 \end{bmatrix} - \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ x_{11} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} - \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = 0;$$

similarly,

$$[\mathrm{ad}_{(-f)}g^1, g^1] = 0.$$

Therefore, (3.7) holds. This implies that the partial differential equations (3.2), which can now be explicitly written as

$$\frac{\partial \phi}{\partial z} = \begin{bmatrix} 0 & 1 & 0 \\ 1 & x_{21} & x_{11} \\ 0 & 0 & 0 \end{bmatrix} \circ \phi(z), \tag{5.3}$$

are integrable. In fact,

$$\phi = \begin{bmatrix} z_{12} \\ z_{11} + z_{12} z_{21} \\ z_{21} \end{bmatrix}$$

is a solution to (5.3). Hence, under the coordinates transformation

$$x_{11}=z_{12},\quad x_{12}=z_{11}+z_{12}z_{21},\quad x_{21}=z_{21}$$

or

$$z_{11}=x_{12}-x_{11}x_{21},\quad z_{12}=x_{11},\quad z_{21}=x_{21}$$

system (4.1) is transformable into an observer form

$$\begin{aligned}&\dot{z}_{11}=-z_{12}^2=-y_1^2,\\&\dot{z}_{12}=z_{11}+z_{12}z_{21}=z_{11}+y_1y_2,\\&\dot{z}_{21}=z_{12}=y_1,\end{aligned}\qquad\begin{aligned}&y_1=z_{12},\\&y_2=z_{21}.\end{aligned}$$

By employing the computation procedure, we can obtain the state transformation much more simply. For this example, choose g^1 and g^2 as before, and now

$$Q(x)=(g^1\ \mathrm{ad}_{(-f)}g^1g^2)=\begin{bmatrix}0&1&0\\1&x_{21}&x_{11}\\0&0&1\end{bmatrix},$$

$$\left(\frac{\partial a}{\partial y_1},\frac{\partial a}{\partial y_2}\right)=\tilde{Q}^{-1}(x)(\mathrm{ad}_{(-f)}^2g^1,\mathrm{ad}_{(-f)}g^2)$$

$$=\begin{bmatrix}-2x_{11}&0\\x_{21}&x_{11}\\1&0\end{bmatrix}=\begin{bmatrix}-2y_1&0\\y_2&y_1\\1&0\end{bmatrix}.$$

Integrating the above equations, which are much more simple than (5.3), we have

$$a(y)=\begin{bmatrix}-y_1^2\\y_1y_2\\y_1\end{bmatrix},$$

and step (iv) gives the state transformation just obtained.

Example 4. Consider the system

$$\begin{aligned}&\dot{x}_1=x_1x_3-x_1x_4^2-x_2x_3^2+x_2x_3x_4^2-x_2x_4^4+(x_2^2+x_4)u+(x_3-x_4^2)u^2,\\&\dot{x}_2=x_1-x_2x_3+x_2x_4^2+u^2,\\&\dot{x}_3=2x_3x_4-2x_4^3+x_2u-x_4u^2,\qquad\dot{x}_4=x_3-x_4^2+u^2\\&y_1=x_2,\qquad y_2=x_4.\end{aligned}$$

Since

$$0(x,u)=\begin{bmatrix}0&1&0&0\\1&-x_3+x_4^2&-x_2&2x_2x_4\\0&0&0&1\\0&0&1&-2x_4\end{bmatrix}$$

is nonsingular, the system is observable with observability indices $k_1=k_2=2$. Now

$g^1(x, u) = (1\ 0\ 0\ 0)^T$, $g^2(x, u) = (x_2\ 0\ 1\ 0)^T$, and

$$\tilde{Q}(x, u) = (g^1\ \mathrm{ad}_{(-f)}g^1 g^2\ \mathrm{ad}_{(-f)}g^2)$$

$$= \begin{bmatrix} 1 & x_3 - x_4^2 & x_2 & -x_2 x_4^2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 2x_4 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

$$\left(\frac{\partial a}{\partial y_1}, \frac{\partial a}{\partial y_2}\right) = \tilde{Q}^{-1}(x, u)(\mathrm{ad}^2_{(-f)}g^1, \mathrm{ad}^2_{(-f)}g^2) = (b_1(x, u), b_2(x, u))$$

$$= \begin{bmatrix} 0 & u \\ 0 & 0 \\ u & 0 \\ 0 & 0 \end{bmatrix}$$

and $b_3(x, u)$ computed by (4.1) is $b_3(x, u) = (x_4\ 2u\ x_2\ 2u)^T$. It is easily seen that b_1, b_2, b_3 are functions of y_1, y_2, and u. Now the matrix $S(x, u)$ is

$$S(x, u) = \left[\begin{array}{c|c|c} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ \hline 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ \hline 0 & 1 & 0 \\ 0 & 0 & 2 \\ 1 & 0 & 0 \\ 0 & 0 & 2 \end{array}\right].$$

Obviously, $S(x, u)$ is block symmetric. Finally, the computation procedure yields

$$a(y, u) = (y_2 u\ \ u^2\ \ y_1 u\ \ u^2)^T$$

and the state transformation

$$z(x) = F(x)$$

$$= \begin{bmatrix} x_1 - x_2 x_3 + x_2 x_4^2 \\ x_2 \\ x_3 - x_4^2 \\ x_4 \end{bmatrix}.$$

The observer form is

$$\dot{z}_1 = y_2 u, \qquad \dot{z}_2 = z_1 + u^2,$$

$$\dot{z}_3 = y_1 u, \qquad \dot{z}_4 = z_3 + u^2.$$

6. Conclusions. In this paper, we have identified a class of nonlinear systems whose observer design problem can be solved by the observer error linearization

approach. We have considered systems both with and without inputs. For systems without inputs, we have obtained a set of necessary and sufficient conditions in terms of the Lie algebra, which is a correction to a theorem in [6]. Moreover, we have proposed a computation procedure for the practical computation of the state transformation, and on the basis of this computation procedure we have derived a different set of necessary and sufficient conditions described in rank conditions of matrices. It is noted that our approach in dealing with systems with inputs is different from that of Krener and Respondek in [6]. Also, it may be of interest to consider output coordinates change that will certainly enlarge the class of nonlinear systems. For this point, we refer the reader to the paper mentioned above.

However, it should be noted that the conditions given here depend on the choice of solutions to the linear algebraic equations (2.26). How to choose these solutions remains open. But, as have been seen, the conditions are useful in understanding the observer error linearization problem and in giving various sufficient conditions.

REACHABILITY OF A CLASS OF INFINITE-DIMENSIONAL LINEAR SYSTEMS: AN EXTERNAL APPROACH WITH APPLICATIONS TO GENERAL NEUTRAL SYSTEMS*

YUTAKA YAMAMOTO†

Abstract. This paper studies the question of quasi- (approximate) reachability of the standard observable realizations of pseudorational impulse responses introduced by the author. The framework places the current theory of retarded and neutral delay-differential systems into a unified input/output framework. Several necessary and sufficient conditions for quasi-reachability are derived. In particular, new criteria for quasi-reachability and eigenfunction completeness are obtained for general delay-differential systems with no restriction on the type of delays. Furthermore, as a byproduct, the theory leads to necessary and sufficient conditions for approximate left coprimeness of matrices with distribution entries. Examples are discussed to illustrate the theory.

Key words. pseudo-rationality, infinite-dimensional systems, reachability, eigenfunction completeness, left coprimeness, distributions, delay-differential systems

AMS(MOS) subject classifications. 93B05, 93C20

1. Introduction.

Consider the following delay-differential system of neutral type:

$$\frac{d}{dt}x(t) = F_0x(t) + \sum_{i=1}^{N} F_ix(t-h_i) + \sum_{i=1}^{N} F_{-i}\dot{x}(t-h_i) + \int_{-h}^{0} E(\tau)x(t+\tau)\,d\tau + Gu(t), \tag{1.1}$$

where $0 < h_1 < h_2 < \cdots < h_N = h$. Approximate controllability of this system has been investigated by a number of authors ([6], [12], [13], [18]). One of them, Manitius [14], [15], gave a complete rank condition for the retarded case (i.e., $F_{-i} = 0$, $i = 1, \cdots, N$). O'Connor and Tarn [17] extended his results to the neutral case, but gave a complete algebraic condition only for the case $N = 1$ with no distributed delays. Salamon [20] extended these results to the case with delays in input, as well as giving the discussion of the general case using the notion of small solutions. However, a concrete algebraic criterion has not been obtained for the case when there is any distributed delay; obtaining such a criterion in the situation with general delays is left as an open problem. In view of the complexity of formulas there, it appears to be difficult to obtain a generalization in this setting.

These approaches all associate an a priori chosen function state space model (e.g., M_2- or W_2^1-) to (1.1) and then discuss approximate function space controllability (reachability) there. There are, however, cases in which a priori association of a state space is either inappropriate or inconvenient. For example, in the study of a servo problem, we often need to consider a reference signal generator, which is specified by the transfer function, and this transfer function does not easily fall into the existing category of function space models. The recently introduced control scheme called *repetitive control* [8], [9], [16], which uses a model $1/(\exp(Ls) - 1)$, is a typical example of such a case. Another example where a priori association of a state space causes difficulty is the case of (1.1), in which there is a pole-zero cancellation. In such a case,

† Department of Applied Systems Science, Faculty of Engineering, Kyoto University, Kyoto 606, Japan.

although we may expect to obtain an irredundant model after pole-zero reduction, the reduced state space will not be M_2 or W_2^1, because these spaces are not closed under such an operation.

In view of these, it is also desirable to develop an approach more directly associated with transfer functions, impulse responses, and realization theory, so that the analysis is not affected by the presumptive choice of a state space.

In finite-dimensional systems, it is well known that reachability (controllability) can be studied from both internal and external points of view. It is also known that the latter is advantageous in relating reachability to irredundancy of the external representation. For example, given a fractional representation $Q^{-1}(s)P(s)$ (Q, P = polynomial matrices) of a transfer function, we can always associate with it a standard observable realization Σ^Q (known as the *Fuhrmann* realization), and this realization is reachable if and only if the matrices Q and P are left coprime [5]. It is, therefore, natural to attempt to generalize this fact to infinite-dimensional systems. However, in spite of a number of investigations on fractional representations of irrational transfer matrices (e.g., [2], [3], [10], [25]), the reachability question above has not been studied in connection with the external behavior.

It is then natural to ask the following questions in this context:

(i) Given a transfer matrix of a delay-differential equation, what can be said about its realization? Is there an analogue of the Fuhrmann realization in this context?

(ii) If there is, what can be said about its reachability in terms of the transfer matrix (or its fractional representation)?

The first question has been studied in [28], and it has been shown that a precise analogue of the Fuhrmann observable realization exists. This has been done by introducing a class of fractional representation called *pseudo-rational.* At least all transfer matrices of delay-differential systems belong to this class. (In some other frameworks (e.g., [2], [3]) using the algebra $\mathcal{A}$ of stable impulse responses, this is not true.) Concerning (ii), it is also shown in [28] that the obtained observable realization Σ^Q (see § 2 for the definition) is approximately controllable (from here on we use the term *quasi-reachable* for consistency with [28]) if and only if the associated fractional representation of the transfer matrix is left coprime in some weaker sense. However, this condition gives only an abstract condition, and its consequence on a concrete reachability criterion has not been fully investigated there.

In this paper, we shall derive necessary and sufficient conditions for this reachability and coprimeness according to the above program. The results, when specialized to delay-differential systems, generalize the existing ones to those for systems with distributed/noncommensurable delays. To see the basic idea of the method, let us first write the transfer function of (1.1) in the folllowing form, by supplementing a fictitious output equation $y(t) := x(t-h)$:

$$\begin{aligned} &W(s) = \hat{Q}(s)^{-1}\hat{P}(s), \\ &\hat{Q} := [e^{-hs}(sI - F_0) - \sum e^{(-h+h_i)s}(F_i - sF_{-i}) - \hat{E}(s)], \\ &\hat{P} := G. \end{aligned} \tag{1.2}$$

Their inverse Laplace transforms induce the following representation for the impulse response matrix A:

$$\begin{aligned} &A = Q^{-1} * P, \\ &Q := \delta_{-h}(\delta' I - F_0) - \sum \delta_{-h+h_i}(F_i - \delta' F_{-i}) - E, \\ &P := G\delta, \end{aligned} \tag{1.3}$$

where $\delta :=$ Dirac distribution at 0, $\delta' :=$ its derivative, $\delta_{-a} :=$ Dirac distribution at $-a$. These entities are most naturally investigated in the convolution algebra $\mathscr{E}'(\mathbf{R}^-)$, which is the space of Schwartz distributions having compact support contained in $(-\infty, 0]$ (see the end of this section for the definition).

By using the convolution algebra structure of $\mathscr{E}'(\mathbf{R}^-)$, we will prove the following:

(i) The Fuhrmann-like observable realization Σ^Q is spectrally complete (i.e., the space spanned by eigenfunctions is dense in the state space) if and only if the matrix Q assumes full rank near the origin (see § 3 for a precise statement).

(ii) Σ^Q is quasi-reachable if and only if it is spectrally reachable (i.e., any eigenspace is reachable) and the matrix $[Q, P]$ assumes full rank near the origin.

In the above results, Q admits any type of delays (distributed/noncommensurable). Therefore, they generalize the existing criteria by Manitius [14], O'Connor and Tarn [17], and Salamon [20] to the general case *with no restrictions on the type of delays.*

The paper is organized as follows. In § 2 we review the basic realization framework given in [27]–[29], especially a type of fractional representation and its associated observable realization Σ^Q. Section 3 gives a general necessary and sufficient condition for eigenfunction completeness. In § 4, this result is applied to derive conditions for approximately controllability. Section 5 gives an application to delay-differential systems along with the discussion of an example. It is seen that the obtained criterion is simpler than the discussion involving small solutions.

Notation and conventions. In what follows, the following notation will be used. All vector spaces and function spaces are considered over a fixed field k, which is either $\mathbf{R}$ or $\mathbf{C}$. Functions and distributions are also k-valued. As usual, for a set V, V^n denotes the set of n-fold direct product of V. For a vector $x \in V^n$, x^T denotes its transpose. If V is a topological space, we endow V^n with the usual product topology. For a ring (or algebra) R, $R^{p\times m}$ denotes the set of $p \times m$ matrices with entries in R. When R is also a topological space, $R^{p\times m}$ is understood to be endowed with the product topology as above. To simplify notation we may sometimes drop these superscripts; for example, when it is clear that $x(t)$ is an n-vector, *we may write* $x(t) \in L^2[0, T]$, *instead of writing* $x(t) \in (L^2[0, T])^n$. We shall always consider the bilateral Laplace transform and regard the one-sided Laplace transform as a special case of it. The Laplace transform of a distribution α (if it exists) will be denoted by $\hat{\alpha}(s)$.

We assume standard knowledge on distribution theory, such as can be found in Schwartz's account [23]. Some familiarity with basic notions of the theory of locally convex topological vector spaces is also assumed [21], [23]. However, some of the following function spaces, although quite fundamental, may not be encountered in standard textbooks (see [26], [28] for details).

$L^2[a, b] :=$ the space of Lebesgue square-integrable functions on $[a, b]$.

$L^2_{\mathrm{loc}}[0, \infty) :=$ the space of functions square-integrable on every bounded interval.

$\Omega := \cup_{n=1}^{\infty} L^2[-n, 0]$ as a set. This space is endowed with the natural inductive limit topology [21], [26] induced by the sequence of spaces $\{L^2[-n, 0]\}_{n=1}^{\infty}$.

$\mathscr{D}(\mathbf{R}) :=$ the space of C^∞-functions defined on $\mathbf{R}$ with the usual topology (Schwartz [23]).

$\mathscr{D}'(\mathbf{R}) :=$ the space of distributions on $\mathbf{R}$. The support of a distribution α will be denoted by $\operatorname{supp} \alpha$. When $\alpha \in (\mathscr{D}'(\mathbf{R}))^n$, $\operatorname{supp} \alpha$ is understood to be the union of the supports of its entries.

$\mathscr{D}[0, \infty) :=$ the space of C^∞-functions *defined on* $[-\infty, \infty)$ *having compact support contained in* $[0, \infty)$.

$\mathscr{D}(-\infty, 0] :=$ the space of C^∞-functions *defined on* $(-\infty, \infty)$ *having compact support contained in* $(-\infty, 0]$.

$\mathscr{D}'[0, \infty) :=$ the dual space of $\mathscr{D}[0, \infty)$.

$\mathscr{D}'_+ :=$ the space of distributions on $\mathbf{R}$ *with support bounded on the left.* This is an algebra with respect to convolution with idenity δ (the Dirac delta distribution at the origin). The delta distribution at point a will be denoted by δ_a, and its derivative will be denoted by δ'_a. Convolution will be denoted by $*$, as usual.

$\mathscr{D}'_- :=$ the space of distributions on $\mathbf{R}$ with support bounded on the right. This is also a convolution algebra with identity δ.

$\mathscr{E}'(\mathbf{R}) :=$ the space of distributions on $\mathbf{R}$ with *compact* support.

$\mathscr{E}'(\mathbf{R}^-) :=$ the space of distributions on $\mathbf{R}$ having *compact support contained in* $(-\infty, 0]$.

Throughout the paper, duality will be denoted by $\langle \cdot, \cdot \rangle$, that is, the value of a distribution α evaluated at a test function φ will be denoted by $\langle \alpha, \varphi \rangle$ or by $\langle \varphi, \alpha \rangle$. Among the spaces above the following inclusions hold:

$$\mathscr{D}(-\infty, 0] \subset \Omega \subset \mathscr{E}'(\mathbf{R}^-) \subset \mathscr{E}'(\mathbf{R}) \subset \mathscr{D}'_+, \qquad \mathscr{E}'(\mathbf{R}^-) \subset \mathscr{E}'(\mathbf{R}) \subset \mathscr{D}'_-.$$

$\mathscr{D}(-\infty, 0]$ is dense in Ω, and Ω is dense in $\mathscr{E}'(\mathbf{R}^-)$. The space $\mathscr{D}'[0, \infty)$ is *not* a subspace of $\mathscr{D}'_+$, but there exists a *surjective* (continuous, of course) projection $\pi : \mathscr{D}'_+ \to \mathscr{D}'[0, \infty)$ which is induced from the obvious canonical inclusion $j : \mathscr{D}[0, \infty) \to \mathscr{D}_-$, that is,

$$\langle \pi\alpha, \varphi \rangle := \langle \alpha, j\varphi \rangle. \tag{1.7}$$

2. Preliminaries. Consider the usual linear (zero-initial state) input/output correspondence:

$$f(\omega)(t) = \int_0^t A(t-\tau)\omega(\tau)\, d\tau, \tag{2.1}$$

where ω is an input and A is an impulse response matrix that does not necessarily induce a finite-dimensional realization. For the purpose of realization theory, it is convenient to convert (2.1) to another form. In view of shift-invariance and causality of (2.1), it can be written as

$$f(\omega)(t) = \int_{-\infty}^0 A(t-\tau)\omega(\tau)\, d\tau \tag{2.2}$$

if the input ω is applied on $(-\infty, 0]$ and has compact support. Since the system must be causal, observation of all $f(\omega)(t)$ for all $t \geqq 0$ must be enough to determine the internal state space structure from (2.2) [27]. We thus take the *input function space* to be Ω^m ($m :=$ number of input channels), and the *output function space* Γ^p ($p :=$ number of output channels), so that inputs are applied before time zero and outputs are observed after zero. These spaces are naturally equipped with the left shift operators $\{\sigma_t\}$, $t \geqq 0$:

$$\begin{aligned} (\sigma_t\omega)(s) &:= \begin{cases} \omega(s-t) & \text{for } s < -t, \\ 0 & \text{for } 0 \leqq s \leqq 0, \end{cases} \quad \omega \in \Omega^m, \\ (\sigma_t\gamma)(s) &:= \gamma(s-t), \quad \gamma \in \Gamma^p. \end{aligned} \tag{2.3}$$

Thus we define a (constant, linear) *input/outmap* f to be a continuous linear map that commutes with these left shifts [27]. It is known [26], [27] that f can then be represented by (2.2), where A is a $p \times m$ matrix (Radon) measure on $[0, \infty)$.

Now note that (2.2) can be written as

$$f(\omega) = \pi(A * \omega), \qquad w \in \Omega^m, \tag{2.4}$$

where π is the truncation operator defined by (1.7). The matrix measure A here is called the *impulse response matrix* of the input/output map f. Let us introduce a fractional representation for such impulse response matrices.

DEFINITIONS 2.5. Let Q be a $p \times p$ matrix with entries in $\mathscr{E}'(\mathbf{R}^-)$. Q is said to be of *normal type* if the following conditions are satisfied:

(i) Q is invertible over $\mathscr{D}'_+$ with respect to convolution, i.e., det Q (computed in terms of convolution) is invertible with respect to convolution;

(ii) $\operatorname{ord}(\det Q)^{-1} = -\operatorname{ord}(\det Q)$,

where ord α denotes the *order* of a distribution α [23]. An impulse response matrix A is said to be *pseudo-rational* if it can be written in the form

$$A = \pi(Q^{-1} * P) \tag{2.6}$$

for some matrices Q and P over $\mathscr{E}'(\mathbf{R}^-)$, where the $p \times p$ matrix Q is of normal type.

Although not all impulse response matrices are pseudo-rational, at least all delay-differential impulse responses are known to be pseudo-rational [29], [30]. As can be seen from (1.2) or (1.3), there will be *no difficulty* in dealing with the distributed delay case.

We now define the standard observable realization Σ^Q associated with an impulse response matrix $A = Q^{-1} * P$. Let X^Q be a subspace of Γ^p defined by

$$X^Q := \{x(t) \in \Gamma^p;\ \pi(Q * x) = 0\}. \tag{2.7}$$

The condition $\pi(Q * x) = 0$ is clearly equivalent to $\operatorname{supp}(Q * x) \subset (-\infty, 0]$. By the separate continuity of convolution, X^Q is a closed subspace of Γ^p. The family $\{\sigma_t\}$ of left-shift operators constitutes a strongly continuous semigroup in Γ^p, and X^Q is easily seen to be a σ_t-invariant subspace of Γ^p. Let F denote the infinitesimal generator of this semigroup σ_t in X^Q; this is nothing but the differential operator d/dt. Define Σ^Q as follows:

(2.8) State space $= X^Q$;

State transition equation:

(2.9) $$\varphi(t, x, u) := \sigma_t x + \pi(A * \sigma_t^l u), \quad x \in X^Q, \quad (\sigma_t^l u)(s) := u(s+t),$$

where the right-hand side is the state at time t resulting from input u and initial state x;

Output equation:

(2.10) $$y = Hx := x(0).$$

This definition yields the mappings $g: \Omega^m \to X^Q$ and $h: X^Q \to \Gamma^p$ as follows:

$$g(\omega) := \varphi(T, 0, \sigma_T^r \omega), \tag{2.11}$$

$$h(x)(t) := H\sigma_t x, \qquad t \geqq 0. \tag{2.12}$$

Here T is any positive number such that $[-T, 0] \supset \operatorname{supp} \omega$ and $(\sigma_T^r \omega)(t) := \omega(t - T)$. It is easy to see that (2.11) is independent of the choice of T. We say that Σ^Q *realizes* an input/output map f (or its impulse response A) if $f = hg$; it is *quasi-reachable* (commonly referred to as approximately controllable) if the reachable set $g(\Omega^m)$ is dense in X^Q; *topologically observable* if h is a topological isomorphism; and *topologically observable in bounded time* if X^Q is topologically isomorphic to $h(X^Q)|_{[0,T]}$ for some $T > 0$.

Σ^Q is easily seen to give a realization of A. Furthermore, it is known that this realization possesses various desirable properties.

THEOREM 2.13 [27]–[29]. (i) Σ^Q *is always topologically observable in bounded time. This means that the initial state determination is well posed, and can be done based on the output data* $y(t)|_{[0,T]}$ *on a uniformly bounded time interval* $[0, T]$.

(ii) Σ^Q *is quasi-reachable if and only if the matrices* Q *and* P *are approximately left coprime, i.e.,*

$$Q * R_n + P * S_n \to \delta I_p \tag{2.14}$$

for some sequences R_n *and* S_n *of matrices with entries in* $\mathscr{E}'(\mathbf{R}^-)$.

We shall investigate the quasi-reachability of Σ^Q using (ii). To this end, we shall need some technical lemmas which we now summarize.

For a distribution $\psi \in \mathscr{D}'_-$, define $r(\psi)$ to be the *supremum* of the support of ψ, i.e.,

$$r(\psi) := \sup\{t \in \operatorname{supp} \varphi\}. \tag{2.15}$$

The following lemma is a consequence of the well-known theorem of Titchmarsh on convolution [4, p. 224].

LEMMA 2.16. *For* $\varphi, \psi \in \mathscr{D}'_-$,

$$r(\varphi * \psi) = r(\varphi) + r(\psi).$$

In § 3, we need to use a representation of the dual space of X^Q. To this end, we first introduce the following duality between Ω^p and Γ^p:

$$(\omega, \gamma) := \int_{-\infty}^{0} \omega^T(\tau)\gamma(-\tau)\, d\tau = \int_0^{\infty} \omega^T(-\tau)\gamma(\tau)\, d\tau = (\omega^T * \gamma)(0). \tag{2.17}$$

Then Ω and Γ turn out to be topologically dual to each other [29]. (Needless to say, $(\Omega^p)' \cong \Gamma^p$.) With respect to this duality, we have the following lemma.

LEMMA 2.18. *Let* X^Q *be as above, where* Q *is of normal type. Define the polar (orthogonal complement) of* X^Q *by*

$$(X^Q)^0 := \{\omega \in \Omega^p;\ (\omega, \gamma) = 0 \text{ for all } \gamma \in X^Q\}.$$

Then,

$$\begin{aligned}(X^Q)^0 &= \{\omega \in \Omega^p;\ \omega^T * Q^{-1} \in \mathscr{E}'(\mathbf{R}^-)\} \\ &= \overline{\{Q^T * \psi;\ \psi \in (\mathscr{D}(-\infty, 0])^p\}}.\end{aligned} \tag{2.19}$$

Proof. Suppose that ψ belongs to the right-hand side of (2.16) and γ belongs to X^Q. Observe that

$$(Q^T * \psi, \gamma) = (\psi^T * Q * \gamma)(0). \tag{2.20}$$

$Q * \gamma$ has compact support contained in $(-\infty, 0]$ because γ belongs to X^Q. Then the right-hand side of (2.20) is clearly zero, which implies that the left-hand side of (2.19) contains the right-hand side.

Conversely, suppose that $\omega \in \Omega^p$ belongs to $(X^Q)^0$. Suppose first that ω belongs to $\mathscr{D}(-\infty, 0]$. Take any $\varphi \in (\mathscr{D}(-\infty, 0])^p$. Then $\gamma := \pi(Q^{-1} * \varphi) \in X^Q$. Since it is easy to see that $\pi(\omega^T * \pi(Q^{-1} * \varphi)) = \pi(\omega^T * Q^{-1} * \varphi)$, we have

$$\begin{aligned}\pi(\omega^T * Q^{-1} * \varphi)(0) &= \pi(\omega^T * \pi(Q^{-1} * \varphi))(0) = (\omega^T * \pi(Q^{-1} * \varphi))(0) \\ &= (\omega, \pi(Q^{-1} * \varphi)) = 0\end{aligned}$$

because $\omega \in (X^Q)^0$. Since this is true for any $\delta_{-t} * \varphi$ $(t > 0)$, we have $\pi(\omega^T * Q^{-1} * \varphi) = 0$, and hence $\omega^T * Q^{-1} * \varphi \in (\mathscr{E}'(\mathbf{R}^-))^p$. Since this holds for any $\varphi \in (\mathscr{D}'(-\infty, 0])^p$, we

must have $\omega^T * Q^{-1} \in (\mathscr{E}'(\mathbf{R}^-))^p$. Thus $\omega = Q^T * \psi$ for some $\psi \in (\mathscr{E}'(\mathbf{R}^-))^p$. Since $\mathscr{D}(-\infty, 0]$ is dense in Ω, this implies that ω belongs to the second term of the right-hand side of (2.19). Then by continuity, we see that this is true for any $\omega \in X^Q$. □

We denote the right-hand side of (2.19) *by* ${}_QX$. Then we have the following lemma characterizing the dual space of X^Q.

LEMMA 2.21. *The dual space* $(X^Q)'$ *of* X^Q *is topologically isomorphic to* $\Omega^p/{}_QX$.

Proof. The proof is immediate from Lemma 2.18 and Schaefer [21, Chap. 4, § 4]. □

Before closing this section, we give a remark on another "realization" obtained from Σ^Q. Introduce the graph norm to the domain $D(F)$ of the infinitesimal generator F of the shift semigroup σ_t, i.e.,

$$\|x\|_F := \|x\| + \|Fx\|,$$

where $\|x\|$ is the norm in X^Q. Restricting σ_t to $D(F)$, we get another strongly continuous semigroup. Let us restrict the class of input and output functions to the spaces analogous to Ω^m and Γ^p that locally belong to the class of the first-order Sobolev space W_2^1. Then the state transition and the output equation given by (2.9) and (2.10) are well defined, and we obtain a well-defined system with state space $D(F)$ (although with different input/output spaces). Denote this system by Σ_F^Q. The following proposition, which claims the equivalence of quasi-reachability of Σ^Q and Σ_F^Q, will become necessary in § 5 for discussing the M_2-reachability and W_2^1-reachability for delay-differential systems.

PROPOSITION 2.22. Σ^Q *is quasi-reachable if and only if* Σ_F^Q *is also.*

Proof. See Appendix A for the proof.

3. Eigenfunction completeness. Let Σ^Q be the system defined in the previous section. We shall investigate the completeness of eigenfunctions of this system. As noted in § 2, the results below apply to neutral systems with *distributed delays* as well as those with *noncommensurable delays.* Let us first note that this system shares some nice spectral properties of delay-differential systems.

THEOREM 3.1. *Let* Σ^Q *be the system given by* (2.9), (2.10). *Let* $\sigma(F)$ *denote the spectrum of the infinitesimal generator* F *of the transition semigroup* σ_t. *Then the following statements hold*:

(i) $\sigma(F) = \{\lambda \in \mathbf{C};\ \det \hat{Q}(\lambda) = 0\}$;

(ii) *Every* $\lambda \in \sigma(F)$ *is an eigenvalue, and the generalized eigenspace* M_λ, *corresponding to* λ, *has finite dimension.*

(iii) $\dim M_\lambda = m\,(\det \hat{Q}(s), \lambda)$, *where the right-hand side denotes the multiplicity of* λ *as a zero of* $\det \hat{Q}(s)$.

(iv) *A vector* v *belongs to* M_λ *if and only if it is expressible in the form*

$$v = \sum_{j=0}^{m-1} \left(\frac{t^j e^{\lambda t}}{j!} \right) a_{j+1},$$

where

$$\begin{bmatrix} \hat{Q}(\lambda) & \cdots & & \hat{Q}^{(m-1)}(\lambda)/(m-1)! \\ & \ddots & & \vdots \\ 0 & & \hat{Q}(\lambda) & \hat{Q}^{(1)}(\lambda) \\ & & & \hat{Q}(\lambda) \end{bmatrix} \begin{bmatrix} a_1 \\ \vdots \\ a_{m-1} \end{bmatrix} = 0.$$

Here $\hat{Q}^{(i)}$ *is the ith derivative of* $\hat{Q}$, *and* m *is the multiplicity of* λ *as a zero of* $\det \hat{Q}(s)$.

For a proof, see [28]. The last statement is not given in [28], but it is obtained via minor modification of the proof given in Hale [7].

Let $M := \operatorname{span}\{M_\lambda; \lambda \in \sigma(F)\}$, i.e., the space spanned by all generalized eigenspaces. Let us prepare the following terminology.

DEFINITION 3.2. The system Σ^Q is said to be *spectrally complete* if the above-defined space M is dense in X^Q.

We raise the following question. *Under what condition is Σ^Q spectrally complete?* In other words, when is the set of all eigenfunctions complete in X^Q?

The same problem has been studied for retarded delay-differential systems by Manitius [13], [14] and by O'Connor and Tarn [17] for neutral systems. In the latter treatment, a concrete condition is given only for the case of one point delay. We shall generalize the results of [17] to Σ^Q. When specialized to delay-differential systems, this means that there is *no restriction* on the type of delays involved. As we shall see, the generalization here clearly exhibits the fact that spectral completeness depends only on *the local behavior of Q near the origin.*

The following lemma is an immediate consequence of Lemma 2.21, which asserts that the zero element of the dual space of X^Q is precisely ${}_QX$:

LEMMA 3.3. *M is dense in X^Q if and only if the following statement is true: If $\varphi \in \Omega^p$ satisfies $(\varphi, \varphi_k) = 0$ for all $\varphi_k \in M$, then φ belongs to ${}_QX$.*

The following proposition gives a characterization for the statement $(\varphi, \varphi_k) = 0$ for all $\varphi_k \in M$:

PROPOSITION 3.4. *An element $\varphi \in \Omega^p$ satisfies $(\varphi, \varphi_k) = 0$ for all φ_k in M if and only if $\hat{\varphi}(s)^T \hat{Q}(s)^{-1}$ is an entire function of s.*

Since we have Theorem 3.1, the proof is entirely similar to that for the corresponding result of O'Connor and Tarn [17], and hence is omitted.

The following stronger version of Lemma 3.3 is also an easy consequence of the separate continuity of the bilinear functional $\langle \cdot, \cdot \rangle$, the denseness of $\Omega \subset \mathscr{E}'(\mathbf{R}^-)$ and Proposition 3.4.

PROPOSITION 3.5. *Σ^Q is spectrally complete if and only if $\hat{\varphi}(s)^T \hat{Q}^{-1}(s) = \text{entire}$, $\varphi \in (\mathscr{E}'(\mathbf{R}^-))^p$, implies $\varphi^T * Q^{-1} \in (\mathscr{E}'(\mathbf{R}^-))^p$.*

Proof. Necessity. Take any $\varphi \in (\mathscr{E}'(\mathbf{R}^-))^p$ such that $\hat{\varphi}(s)^T \hat{Q}^{-1}(s)$ is entire. Take a sequence $\{\rho_n\} \in \mathscr{D}(-\infty, 0]$ such that

$$\operatorname{supp} \rho_n \subset [-1/n, 0]; \tag{3.6}$$

$$\int \rho_n(t)\, dt = 1. \tag{3.7}$$

Then it is well known (e.g., Schwartz [23]) that (i) $\rho_n * \varphi \to \varphi$, and (ii) $\rho_n * \varphi \in \Omega^p$. It follows that $\rho_n * \varphi$ satisfies the same hypothesis as φ, so that $\rho_n * \varphi$ must belong to $(X^Q)^0 = {}_QX$. Hence $\rho_n * \varphi^T * Q^{-1}$ all belong to $(\mathscr{E}'(\mathbf{R}^-))^p$ by Lemma 2.18. Since $\{\rho_n * \varphi^T * Q^{-1}\}$ is convergent, it follows that $\varphi^T * Q^{-1}$ belongs to $(\mathscr{E}'(\mathbf{R}^-))^p$.

Sufficiency. Conversely, suppose that $\varphi \in \Omega^p$ satisfies $\hat{\varphi}(s)^T \hat{Q}^{-1} = \text{entire}$. Then we have $\varphi^T * Q^{-1} = \omega^T \in (\mathscr{E}'(\mathbf{R}^-))^p$ by hypothesis. Since there exists a sequence $\{\omega_n\} \subset \Omega^p$ that converges to ω, we have $\varphi^T = \lim \omega_n^T * Q$, which implies $\varphi \in {}_QX$ by Lemma 2.18. Hence, by Lemma 3.3, Σ^Q is spectrally complete. □

The proof of the following key lemma will be given in Appendix B.

LEMMA 3.8. *Let $\varphi \in (\mathscr{E}'(\mathbf{R}^-))^p$ and suppose that $\hat{\varphi}(s)^T \hat{Q}^{-1}(s)$ is an entire function. Then $\varphi^T * Q^{-1}$ belongs to $(\mathscr{E}'(\mathbf{R}))^p$, i.e., each of its entries is a distribution with compact support (which is not necessarily contained in $(-\infty, 0]$).*

This lemma shows that if φ is orthogonal to M, then it is always expressible as $\varphi = Q^T * \psi$ for some ψ in $(\mathscr{E}'(\mathbf{R}))^p$. However, this ψ does not necessarily belong to $(\mathscr{E}'(\mathbf{R}^-))^p$, i.e., its support may not be contained in $(-\infty, 0]$. Therefore, the condition of Proposition 3.5 may not be satisfied. To obtain a condition for spectral completeness,

we need only to exclude the possibility of $\varphi \in (\mathscr{E}'(\mathbf{R}^-))^p$, but $\psi \notin (\mathscr{E}'(\mathbf{R}^-))^p$. This leads to the following theorem.

THEOREM 3.9. *The system Σ^Q is spectrally complete if and only if there exists no $\psi \in (\mathscr{E}'(\mathbf{R}))^p$ such that $r(\psi) > 0$ and $r(\psi^T * Q) \leqq 0$.*

Proof. In view of the definition of $r(\psi)$, $\psi \in (\mathscr{E}'(\mathbf{R}))^p$ belongs to $(\mathscr{E}'(\mathbf{R}^-))^p$ if and only if $r(\psi) \leqq 0$. Then the theorem is immediate from Proposition 3.5 and Lemma 3.8. □

To give a more concise expression to Theorem 3.9, let us prepare the following algebraic notions.

LEMMA 3.10. *Let $J := \{\varphi \in \mathscr{E}'(\mathbf{R}^-);\ r(\varphi) < 0\}$. Then J is a prime ideal of $\mathscr{E}'(\mathbf{R}^-)$.*

Proof. That J is closed under addition is obvious. Suppose $\varphi \in J$ and $a \in \mathscr{E}'(\mathbf{R}^-)$. Then we have

$$r(a * \varphi) = r(a) + r(\varphi) \leqq r(\varphi) < 0,$$

by Lemma 2.16. Hence $a * \varphi \in J$, so that J is an ideal.

Now suppose that $a * b \in J$, i.e., $r(a * b) < 0$. Since

$$r(a * b) = r(a) + r(b)$$

by Lemma 2.16, either $r(a) < 0$ or $r(b) < 0$. That is, $a \in J$ or $b \in J$. Thus J is a prime ideal. □

Lemma 3.10 enables us to form the quotient ring (algebra) $\mathscr{A} := \mathscr{E}'(\mathbf{R}^-)/J$, and this ring is an *integral domain* (i.e., it has no zero divisors) because J is a prime ideal. Therefore, we can further construct its quotient field $\mathscr{F}$ (the field of fractions formed by elements of $\mathscr{A}$). Let $\theta : \mathscr{E}'(\mathbf{R}^-) \to \mathscr{F}$ denote the composition of the canonical projection: $\mathscr{E}'(\mathbf{R}^-) \to \mathscr{A} = \mathscr{E}'(\mathbf{R}^-)/J$ with the inclusion: $\mathscr{A} \to \mathscr{F}$. In what follows, when we speak of the *rank of a matrix $W \in (\mathscr{E}'(\mathbf{R}^-))^{p \times m}$ over $\mathscr{F}$, we shall always mean the rank of the matrix $\theta(W)$ considered over $\mathscr{F}$.* Observe that *an element $w \in (\mathscr{E}'(\mathbf{R}^-))^p$ is nonzero when considered over $\mathscr{A}$* (or $\mathscr{F}$) *if and only if $r(w) = 0$.*

We are now ready to state and prove the main result of this section, which is a generalization of the existing results in [14], [17], [20]. Note that no restriction on the type of delays is imposed.

THEOREM 3.11. *The system Σ^Q is spectrally complete if and only if*

$$\operatorname{rank}_{\mathscr{F}} Q = p, \tag{3.12}$$

where $\mathscr{F}$ is the field introduced above.

Proof. Necessity. Suppose that $\det Q = 0$ over $\mathscr{F}$. Then there exist $\alpha_1, \cdots, \alpha_p \in \mathscr{F}$, not all zero, such that $\sum \alpha_i * q_i = 0$ where q_i is the ith row of Q. Since each α_i is an element of the quotient field of $\mathscr{E}'(\mathbf{R}^-)/J$, this means that there exist $a_1, \cdots, a_p \in \mathscr{E}'(\mathbf{R}^-)/J$, not all zero, such that $\sum a_i * q_i = 0$. In view of the definition of the ideal J, we see that there exist $b_1, \cdots, b_p \in \mathscr{E}'(\mathbf{R}^-)$ such that $r(\sum b_i * q_i) < 0$ and $r(b_i) = 0$ for some i. Let $r_0 := r(\sum b_i * q_i)$, and put

$$\psi := \delta_{-r_0} * [b_1, \cdots, b_p]^T.$$

Then $r(\psi) > 0$ but $r(\psi^T * Q) \leqq 0$, and hence by Theorem 3.9 this system is not spectrally complete.

Sufficiency. Conversely, suppose that rank $Q = p$ over $\mathscr{F}$ but there exists $\psi \in (\mathscr{E}'(\mathbf{R}))^p$ such that $r_0 := r(\psi) > 0$ but $r(\psi^T * Q) \leqq 0$. Put

$$\varphi := \delta_{-r_0} * \psi.$$

Then φ belongs to $(\mathscr{E}'(\mathbf{R}^-))^p$, $r(\varphi) = 0$, and $r(\varphi^T * Q) < 0$. But this clearly contradicts rank $Q = p$ over $\mathscr{F}$. □

The following corollaries are now easy to prove.

COROLLARY 3.13. *Suppose that Q can be written in the form*

$$Q = Q_0 + Q_1, \tag{3.14}$$

where Q_0 is atomic at the origin and supp Q_1 *is contained in $(-\infty, t_0]$ for some $t_0 < 0$. Then Σ^Q is spectrally complete if and only if*

$$\operatorname{rank} \hat{Q}_0(\lambda) = p \tag{3.15}$$

for some $\lambda \in \mathbf{C}$.

Proof. In view of the well-known result on distributions atomic at the origin, each entry of Q_0 is a polynomial in the derivative δ' of the Dirac distribution [23]. Hence its Laplace transform is a polynomial in s. By Theorem 3.11, Σ^Q is spectrally complete if and only if rank $Q_0 = p$ over $\mathcal{F}$. In view of the definition of the ideal J, this is true if and only if det Q_0 is a nontrivial polynomial of δ'. This is clearly equivalent to condition (3.15). □

COROLLARY 3.16. *Consider the scalar case, that is, assume that the number of output channels $p = 1$. The system Σ^Q is spectrally complete if and only if $r(Q) = 0$.*

Proof. The proof is immediate from Theorem 3.11. □

Remark 3.17. The relationship of the above theorems in terms of the existing results is now clear. For simplicity, consider the scalar case. If the system Σ^Q is not spectrally complete, then $r(Q) < 0$; that is, Q can be written as $Q = \delta_{-a} * Q_1$ for some $a > 0$ and $Q_1 \in \mathcal{E}'(\mathbf{R}^-)$ with $r(Q_1) = 0$. We then easily see that $X^Q = L^2[0, a] \oplus X^{Q_1}$. Here $L^2[0, a]$ is nothing but the totality of "small solutions" considered in the literature [13], [20] (see Fig. 1).

Remark 3.18. The theorems above include some of the classical results on eigenfunction completeness. For example, consider the simplest case $\hat{Q}(s) := e^s - 1 (Q = \delta'_{-1} - \delta)$. It is easy to see that X^Q is the space of locally L^2 functions on $[0, \infty)$ of period 1. The set of eigenfunctions is $\{\exp(2n\pi jt);\ n = 0, \pm 1, \pm 2, \cdots\}$, and since $r(Q) = 0$, this set of eigenfunctions is complete in X^Q, as expected.

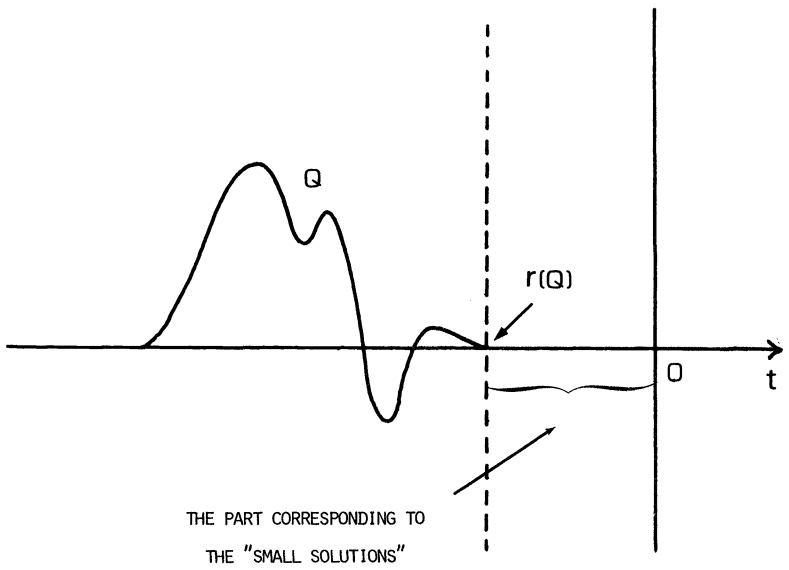

FIG. 1

4. Necessary and sufficient conditions for quasi-reachability. In this section, *we shall further assume that our impulse response matrix* $A = \pi(Q^{-1} * P)$ *is a regular distribution* (*i.e., locally integrable function*) *in a neighborhood of the origin.* Since all strictly causal impulse responses satisfy this requirement, this is not a very severe restriction. Then it follows that $\Psi := Q^{-1} * P - A$ must be a distribution belonging to $\mathscr{E}'(\mathbf{R}^-)$, and so is $Q * \Psi$. This implies that A can be rewritten as

$$A = Q^{-1} * P - \Psi = Q^{-1} * (P - Q * \Psi).$$

Obviously, the new pair $(Q, P - Q * \Psi)$ is also pseudo-rational, and by this modification, the truncation mapping π becomes unnecessary. In what follows, *we shall assume that* (Q, P) *satifies this condition*, i.e., $A = Q^{-1} * P$. (Note that the modification above does not change any of the conditions of the subsequent theorems.)

We are now ready to state and prove the following necessary and sufficient condition for quasi-reachability. As is the case with Theorem 3.11, there is no restriction on the type of delays involved.

THEOREM 4.1. *The system* Σ^Q *is quasi-reachable if and only if the following two conditions hold*:

(4.2) (i) $\operatorname{rank}[\hat{Q}(\lambda), \hat{P}(\lambda)] = p$ *for all* $\lambda \in \mathbf{C}$;

(4.3) (ii) $\operatorname{rank}_{\mathscr{F}}[Q, P] = p$.

Proof. Necessity. Condition (i) is clearly necessary, since it is a condition for spectral reachability (see [28]). Suppose that condition (ii) fails. Then there exist $a_1, \cdots, a_p \in \mathscr{F}$, not all zero, such that $a^T * [Q, P] = 0$ in $\mathscr{F}$ ($a = [a_1, \cdots, a_p]^T$). This readily implies that there exists $\psi \in (\mathscr{E}'(\mathbf{R}))^p$ such that $r(\psi) > 0$ but $r(\psi^T * Q) \leqq 0$, $r(\psi^T * P) \leqq 0$. If Σ^Q were quasi-reachable, there would exist sequences $\{R_n\}$ and $\{S_n\}$ of matrices over $\mathscr{E}'(\mathbf{R}^-)$ such that

$$Q * R_n + P * S_n \to \delta I_p, \tag{4.4}$$

i.e., Q and P are *approximately left coprime* by Theorem 2.13. Taking the convolution of (4.4) with ψ^T from the left, we see that the sequence $\psi^T * Q * R_n + \psi^T * P * S_n$ in $(\mathscr{E}'(\mathbf{R}^-))^p$ must converge to $\psi^T \notin (\mathscr{E}(\mathbf{R}^-))^p$ (because $r(\psi) > 0$). But this is clearly impossible.

Sufficiency. Conversely, suppose that the above two conditions hold. Since $\operatorname{rank}[Q, P] = p$ over $\mathscr{F}$, there exists a matrix K consisting only of zeros and ones such that $\operatorname{rank}[Q + PK] = p$ over $\mathscr{F}$. Furthermore,

$$\operatorname{rank}[\hat{Q}(\lambda) + \hat{P}(\lambda)K, \hat{P}(\lambda)] = \operatorname{rank}[\hat{Q}(\lambda), \hat{P}(\lambda)] = p \tag{4.5}$$

for all $\lambda \in \mathbf{C}$. According to Lemma 4.11 below, the pair $(Q + PK, P)$ is pseudo-rational. Thus we may consider the system Σ^{Q+PK} defined by the pair $(Q + PK, P)$; this system is quasi-reachable because it is spectrally reachable and, in addition to that, spectrally complete by Theorem 3.11. Therefore, by Theorem 2.13, there exist sequences $\{R_n\}$ and $\{S_n\}$ of matrices over $\mathscr{E}'(\mathbf{R}^-)$ such that

$$[Q + PK] * R_n + P * S_n \to \delta I_p. \tag{4.6}$$

Thus

$$Q * R_n + P * [KR_n + S_n] \to \delta I_p, \tag{4.7}$$

so that the pair (Q, P) is also approximately left coprime. Then again by Theorem 2.13, the system Σ^Q is quasi-reachable. □

In view of Theorem 2.13 we have simultaneously obtained the following theorem.

THEOREM 4.8. *The pair (Q, P) is approximately left coprime, i.e., there exist sequences of matrices R_n and S_n over $\mathscr{E}'(\mathbf{R}^-)$ of appropriate sizes such that*

$$Q * R_n + P * S_n \to \delta I \quad \text{in } (\mathscr{E}'(\mathbf{R}^-))^p$$

if and only if the above conditions (4.2) *and* (4.3) *hold.*

Proof. The proof is immediate from the fact that (Q, P) is approximately left coprime if and only if Σ^Q is quasi-reachable. □

The following corollaries are also direct consequences of Theorem 4.1.

COROLLARY 4.9. *Consider the scalar input/output system, i.e., the case $m = p = 1$. The system Σ^Q is quasi-reachable (and hence canonical) if and only if*

(i) $\operatorname{rank}[\hat{Q}(\lambda), \hat{P}(\lambda)] = 1$, *for all* $\lambda \in \mathbf{C}$;

(ii) $\max\{r(Q), r(P)\} = 0$.

Proof. The proof is immediate from Theorem 4.1. □

COROLLARY 4.10. *Consider a pair (Q, P) such that Q and P can be written in the form*

$$Q = Q_0 + Q_1, \qquad P = P_0 + P_1,$$

where Q_0 and P_0 are atomic at the origin, and supp Q_1, supp $P_1 \subset (-\infty, -t_0]$ *for some $t_0 > 0$. Then Σ^Q is quasi-reachable (and hence canonical) if and only if*

(i) $\operatorname{rank}[\hat{Q}(\lambda), \hat{P}(\lambda)] = p$ *for all* $\lambda \in \mathbf{C}$;

(ii) $\operatorname{rank}[\hat{Q}_0(\lambda), \hat{P}_0(\lambda)] = p$ *for some* $\lambda \in \mathbf{C}$.

Proof. Observe $Q \equiv Q_0$ and $P \equiv P_0$ modulo the ideal J. Then the result follows by the observation that $\operatorname{rank}[Q_0, P_0] = p$ over $\mathscr{F}$ if and only if the above condition (ii) holds as in the proof of Corollary 3.13. □

It remains only to prove that the pair $(Q + PK, P)$ considered above is pseudo-rational.

LEMMA 4.11. *Suppose that a pseudo-rational impulse response $A = Q^{-1} * P$ satisfies the hypothesis of the beginning of this section. Then the impulse response given by $[Q + PK]^{-1} * P$, where K is a constant matrix, is also pseudo-rational.*

Proof. We need to show the following:

(i) $Q + KP$ is invertible over $\mathscr{D}'_+$ with respect to convolution;

(ii) $\operatorname{ord}(\det(Q + KP)^{-1}) = -\operatorname{ord}(\det(Q + KP))$;

(iii) $[Q + PK]^{-1} * P$ is a valid impulse response.

Let us first show that $(\delta I + AK)^{-1}$ exists. Since we have assumed that A is a regular distribution (i.e., a locally integrable function) in a neighborhood of the origin, we may decompose A as $A = A_0 + A_1$, where A_0 is locally integrable and supp $A_1 \subset [t_0, \infty)$ for some $t_0 > 0$. It suffices to show that the Neumann series

$$\sum_{n=0}^{\infty} (-AK)^n \tag{4.12}$$

converges in $\mathscr{D}'_+$. In view of the topology of $\mathscr{D}'_+$ (Schwartz [23]), it is enough to see that the series (4.12) is convergent when applied to any C^∞-function φ with compact support. Note here that the support of A_1^n eventually becomes disjoint with that of φ. Then, expanding $(A_0 + A_1)^n$ by the binomial formula, and using the fact that the Neumann series (4.12) converges whenever A is a locally integrable function, we can easily show that (4.12) actually converges in $\mathscr{D}'_+$. Clearly, (4.12) gives $(\delta I + AK)^{-1}$ and

it is also a measure. Writing $[Q+PK]^{-1}$ as

$$[Q+PK]^{-1}=[\delta I+AK]^{-1}*Q^{-1}, \tag{4.13}$$

we see that $[Q+PK]^{-1}$ exists and is given indeed by (4.13).

Let us prove ord $(\det[Q+PK]^{-1})=-\text{ord}(\det[Q+PK])$. Since ord $(\alpha*\beta)\leqq$ ord $\alpha+$ord β is always valid, and since $\det[\delta I+AK]^{-1}$ is clearly a measure of order zero, we have

$$\text{ord}(\det[Q+PK]^{-1})\leqq\text{ord}(\det Q^{-1}), \tag{4.14}$$

by (4.13). Conversely, since $Q^{-1}=[\delta I+AK]*[Q+PK]^{-1}$ and since $\det[\delta I+AK]$ is also a measure of order zero, we have

$$\text{ord}(\det Q^{-1})\leqq\text{ord}(\det[Q+PK]^{-1}), \tag{4.15}$$

so that ord $(\det Q^{-1})=$ ord $(\det[Q+PK]^{-1})$. Now rewriting (4.13) as

$$Q+PK=Q*[\delta I+AK], \tag{4.16}$$

we also see that ord $(\det[Q+PK])=$ ord $(\det Q)$. Hence by the identity ord $(\det Q^{-1})=-$ord $(\det Q)$, we have ord $(\det[Q+PK]^{-1})=-$ord $(\det[Q+PK])$.

Finally, since $[\delta I+AK]^{-1}$ is a measure, $[Q+PK]^{-1}*P=[\delta I+AK]^{-1}*Q^{-1}*P=[\delta I+AK]^{-1}*A$ assumes the same regularity as A. Hence it is an impulse response matrix. □

5. Application to delay-differential systems. Consider the following neutral delay-differential system (with noncommensurable delays):

$$\frac{d}{dt}x(t)=F_0x(t)+\sum_{i=1}^{N}F_ix(t-h_i)+\sum_{i=1}^{N}F_{-i}\dot{x}(t-h_i)+Gu(t), \tag{5.1}$$

where $0<h_1<h_2<\cdots<h_N$. Let us temporarily take the output equation to be $y(t)=x(t-h_N)$. It is then appropriate to take Q and P as follows:

$$Q:=[\delta'_{-h_N}I-\delta_{-h_N}F_0-\textstyle\sum\delta_{-h_N+h_i}F_i-\sum\delta'_{-h_N+h_i}F_{-i}], \tag{5.2}$$

$$P:=G\delta. \tag{5.3}$$

Let $r_i:=h_i-h_{i-1}(h_0:=0)$, and $X:=\mathbf{R}^p\times\prod_{i=1}^{N}(L^2[0,r_i])^p$, where p is the dimension of x. Then, the realization Σ^Q corresponding to the factorization $Q^{-1}*P$ turns out to be of the following "M_2-type":

$$\begin{aligned}\frac{d}{dt}\begin{bmatrix}x\\z\end{bmatrix}&=\begin{bmatrix}F_0x+\sum_{i=1}^{N}[F_i+F_0F_{-i}]z_i(0)\\(\partial/\partial\theta)z(\theta)\end{bmatrix}+\begin{bmatrix}G\\0\end{bmatrix}u(t),\\&=F(x,z)^T+Gu(t),\end{aligned} \tag{5.4}$$

where $x\in\mathbf{R}^p$ and $z_i(\theta)\in(L^2[0,r_i])^p$. Here the domain $D(F)$ of the operator F is given by

$$\begin{aligned}D(F):=\{(x,z)\in X;\ z_i\in(W_2^1[0,r_i])^p,\ z_1(r_1)=x+\sum_i F_{-i}z_i(0),\\ z_k(r_k)=z_{k-1}(0),\ k=2,\cdots,N\}.\end{aligned} \tag{5.5}$$

(For details, see [30]; the difference between neutral and retarded is expressed in the definition of $D(F)$.)

THEOREM 5.6. *The neutral system* Σ^Q, *where* Q *and* P *are given by* (5.2) *and* (5.3), *is quasi-reachable if and only if*

(i) $\operatorname{rank}[\lambda e^{h_N\lambda} I - e^{h_N\lambda}F_0 - \sum e^{(h_N-h_i)\lambda}F_i - \sum \lambda e^{(h_N-h_i)\lambda}F_{-i},\ G] = p$ *for every* $\lambda \in \mathbf{C}$;

(ii) $\operatorname{rank}[F_N + \lambda F_{-N},\ G] = p$ *for some* $\lambda \in \mathbf{C}$.

Proof. The proof is immediate from Corollary 4.10. □

Theorem 5.6 extends the result of O'Connor and Tarn [17] to the noncommensurable delay case. It is also easy to consider the generalization to systems with distributed delays and to those with delays in input via Corollary 4.10, but the condition will look a little more involved for the distributed-delay case (in such a case, Theorem 4.1 is the final form). Note that there is no need to consider noncommensurable delays in any special way, since this is automatically taken care of by the framework itself.

Remark 5.7. According to Salamon [20, p. 39], the W_2^1-model of the neutral system (5.1) is nothing but the restriction of the M_2-realization (5.4) to the domain $D(F)$ of the infinitesimal generator F. In view of Proposition 2.22, this means that quasi-reachability is invariant for both systems. Thus the above condition also applies to the W_2^1-model.

The following example is taken from Salamon [20, Ex. 4.3.10].

Example 5.8. Consider the following neutral delay-differential system:

$$\dot{x}_1(t) = x_1(t) + \int_{-1}^{0} x_2(t+\tau)\,d\tau + \dot{x}_3(t-2),$$

$$\dot{x}_2(t) = x_2(t-1) + \int_{-1}^{0} x_3(t+\tau)\,d\tau,$$

$$\dot{x}_3(t) = \int_{-1}^{0} u(t+\tau)\,d\tau.$$

In conformity with the discussion there, take matrices $\hat{Q}$ and $\hat{P}$ as follows:

$$\hat{Q} := \begin{bmatrix} se^{2s} - e^{2s} & (e^{2s} - e^{s})/s & -s \\ 0 & se^{s} - 1 & (e^{s} - 1)/s \\ 0 & 0 & se^{s} \end{bmatrix}, \qquad \hat{P} := \begin{bmatrix} 0 \\ 0 \\ (e^{s} - 1)/s \end{bmatrix}. \tag{5.9}$$

It is easy to check that condition (i) of Theorem 4.1 is satisfied. Condition (ii) is also satisfied; i.e., the system is quasi-reachable. In fact, the matrices Q and P take the following form when considered over the ring $\mathscr{E}'(\mathbf{R}^{-1})/J$:

$$\tilde{Q} = \begin{bmatrix} 0 & 0 & -\delta' \\ 0 & -\delta & [1] \\ 0 & 0 & 0 \end{bmatrix}, \qquad \tilde{P} = \begin{bmatrix} 0 \\ 0 \\ [1] \end{bmatrix}, \tag{5.10}$$

where [1] denotes the equivalence class in $\mathscr{E}'(\mathbf{R}^{-1})/J$ of an element that is identically 1 for $-\varepsilon \leqq t \leqq 0$ and zero for $t \geqq 0$. Since this function has a jump of 1 at the origin, the determinant (with respect to convolution) formed by the second and third columns of $\tilde{Q}$ and $\tilde{P}$ is equal to $-\delta$, so that the pair $(\tilde{Q}, \tilde{P})$ assumes full rank over the quotient field $\mathscr{F}$. Hence by Theorem 4.1 the system Σ^Q is quasi-reachable.

Salamon [20] claims that this system is *not* quasi-reachable, contrary to the conclusion above. A detailed analysis shows that it is impossible to take a nontrivial small solution in his discussion [20, p. 155], and the system is in fact quasi-reachable. As can be seen from above, our test relying on (5.9) is much simpler than a discussion involving small solutions.

6. Concluding remarks. We have proved necessary and sufficient conditions for our standard observable realization Σ^Q to be quasi-reachable (and hence *canonical* in the sense of [27]). When we choose Q as a delay-differential operator, these results extend the known results on quasi-reachability of delay-differential systems. In particular, the results do not require *any restriction* on the type of delays (points or distributed). Aside from this, the approach here has the following advantages:

(1) It is suitable for the situation in which a priori association of a state space is not appropriate. A recently introduced control scheme called repetitive control is an example of this situation. The method here can be effectively used for proving the internal model principle for this nonclassical servo problem [8].

(2) The framework is closed under pole-zero cancellation. The existing state space approaches using M_2 or W_2^1, etc. do not possess this property.

(3) As a result of dealing with the input/output behavior, it clarifies the role of the distribution algebra $\mathscr{E}'(\mathbf{R}^-)$, which has not been considered in the literature. This is much more general than that considered by Manitius [14] (his algebra is not applicable to neutral systems).

(4) By virtue of the investigation of the convolution algebra structure, the obtained criterion (Theorem 4.1) is much simpler in the general case. The existing method requires an individual inspection of the nature of small solutions, which can often be quite complicated (see Example 5.8).

Appendix A.

Proof of Proposition 2.22. Sufficiency is obvious since $D(F)$ is always dense in X^Q (Yosida [31]).

Suppose that Σ^Q is quasi-reachable. Take any x in $D(F)$. Denote the reachable set of Σ_F^Q by X_R. We need to find a sequence in X_R converging to x with respect to the graph topology of $D(F)$. By hypothesis, the closure of X_R in X^Q is the whole space. Hence there exists a sequence $\{y_n\}$ in X_R such that $y_n \to Fx$ in X^Q. Let us again use g to denote the linear map sending inputs to states under the assumption of zero-initial state for Σ_F^Q. Let u_n be an input such that $y_n = g(u_n)$. Define

$$v_n(t) := \int_{-\infty}^{t} u_n(\tau)\, d\tau.$$

In view of the shift invariance of g and the fact that F is just the differential operator in X^Q, it is easy to verify that $g(v_n) \to x + x_0$ in X^Q, where x_0 is some constant function. Since x and $x + x_0$ belong to X^Q, x_0 does also. If x_0 were zero, there would be nothing left to prove, because we would have $Fg(v_n) = g((d/dt)v_n) = g(u_n) \to x$ and therefore find a desired sequence $\{g(v_n)\}$. Suppose $x_0 \neq 0$. This means that zero is an eigenvalue of F and x_0 is an eigenvector. By the assumption of quasi-reachability, every eigenvector must be reachable, and hence there exists v_0 such that $x_0 = g(v_0)$. Now let $w_n := v_n - v_0$. It readily follows that $g(w_n) \to x$, and $Fg(w_n) \to Fx$ in X^Q so that $g(w_n) \to x$ in $D(F)$. This completes the proof. □

Appendix B. We give a proof for Lemma 3.8. Let us first prove the following lemma.

LEMMA B1. *Let $\psi(s)$ and $q(s)$ be entire functions of exponential type, i.e., there exist C, $K > 0$ such that*

$$|\psi(s)| \leqq C e^{K|s|}, \qquad |q(s)| \leqq C e^{K|s|}.$$

Suppose that $\psi(s)q^{-1}(s)$ is an entire function. Then it is also an entire function of exponential type.

The result is nontrivial because, although $q(s)$ is of exponential type, there is no a priori guarantee that $q(s)^{-1}$ is of exponential type near a zero of $q(s)$. Indeed, the proof requires a deep result on the growth order of entire functions due to Lindelöf.

THEOREM B2 ([11], [1, Thm. 2.10.1]). *Let $f(s)$ be an entire function of order 1, i.e., for any $\varepsilon > 0$*

$$|f(s)| \leqq \exp(|s|^{1+\varepsilon})$$

for all sufficiently large $|s|$. Let $n(r)$ be the number of zeros of $f(s)$ in the circle $|s| \leqq r$, and let $\zeta_1, \cdots, \zeta_n, \cdots$ be the (nonzero) zeros of $f(s)$, counted according to multiplicities. Then $f(s)$ is of exponential type if and only if

(B3) (i) $n(r) \leqq O(r)$;
(ii) $S(r) := \sum_{|\zeta_n| \leqq r} 1/\zeta_n$

is bounded with respect to r.

Proof of Lemma B1. Let $f(s) := \psi(s) q(s)^{-1}$. Writing $\psi(s)$ and $q(s)$ in the form of the Hadamard factorization theorem [1, Thm. 2.7.1], we readily see that $f(s)$ is of order 1. Since all zeros of $q(s)$ must be cancelled by zeros of $\psi(s)$, it is clear that $n(r)$ of $f(s)$ is at most of $O(r)$. It remains to check the above condition (ii). Let $\{\xi_1, \cdots, \xi_n, \cdots\}$ and $\{\eta_1, \cdots, \eta_n, \cdots\}$ be the sets of (nonzero) zeros of $\psi(s)$ and $q(s)$, respectively. Let $S_1(r)$, $S_2(r)$ be the $S(r)$-functions for ψ and q, respectively. Again by the fact that all zeros of $q(s)$ are cancelled by those of $\psi(s)$, we have

$$\begin{aligned} |S(r)| &= \left| \sum_{|\xi_n| \leqq r} \frac{1}{\xi_n} - \sum_{|\eta_n| \leqq r} \frac{1}{\eta_n} \right| \\ &\leqq |S_1(r)| + |S_2(r)|, \end{aligned}$$

and the right-hand side is bounded by hypothesis on ψ, q. Hence $f(s)$ is also of exponential type. □

We are now ready to prove Lemma 3.8.

Proof of Lemma 3.8. Since $Q^{-1} = (\det Q)^{-1} * (\operatorname{adj} Q)$, we can apply the following argument to each entry of $\psi^T * Q^{-1}$, so we assume that ψ and Q are scalar distributions without loss of generality.

Case 1. Suppose that $f(s) = \psi(s) Q^{-1}(s)$ has only finitely many zeros. Then by the Hadamard factorization theorem [1, Thm. 2.7.1] we see that $f(s)$ must be of the form

$$f(s) = C \exp(as) \cdot \prod_{i=1}^{n} (s - \lambda_i), \tag{B4}$$

where C and a are suitable constants. Since $\psi * Q^{-1}$ is Laplace transformable, there exist b, $\beta \in \mathbf{R}$ such that its Laplace transform $e^{bs} f(s)$ is bounded by a polynomial in $|s|$ for $\operatorname{Re} s > \beta$ (Schwartz [22], [23]). In order that (B3) satisfy this requirement, the above constant a must be a real number. Then it is clear that its inverse Laplace transform is a distribution with compact support.

Case 2. Now consider the case in which $f(s)$ has infinitely many zeros. Since $\psi * Q^{-1}$ is Laplace transformable (i.e., $f(s)$ is inverse Laplace transformable), there exist b, $\beta \in \mathbf{R}$ such that $e^{bs} f(s)$ is bounded by a polynomial in $|s|$ for $\operatorname{Re} s > \beta$. We can take a vertical line $\operatorname{Re} s = \beta'$ such that there are infinitely many zeros of $f(s)$ except on this line. Collect suitably many of them, say $\lambda_1, \cdots, \lambda_n$, so that

$$\tilde{f}(s) := f(s)/(s - \lambda_1) \cdots (s - \lambda_n) \tag{B5}$$

remains an entire function and satisfies

$$|e^{bs} \tilde{f}(s)| \leqq C/|s|^2, \qquad \operatorname{Re} s = \beta'. \tag{B6}$$

By suitably shifting the coordinates, we may assume that this vertical line Re $s = \beta'$ is the imaginary axis. Denote this shifted function by $\bar{f}(s)$. It is easily seen that this shifted $\bar{f}(s)$ is square integrable on the imaginary axis and that it satisfies the estimate

$$|\bar{f}(s)| \leqq M \exp(K|s|) \tag{B7}$$

for some constants M and K. Then by a special version of the Paley-Wiener Theorem (Rudin [19, Thm. 19.3]), we see that $\bar{f}(s)$ is a Fourier transform of a function $F(t) \in L^2$ that has compact support in $[-K, K]$. This means that $\tilde{f}(s) = \bar{f}(s - \beta')$ is a Laplace transform of $F(t) \exp(\beta' t)$, which still has compact support. In view of (B4), $\psi * Q^{-1}$ can be obtained by applying the differential operator $(d/dt - \lambda_1) \cdots (d/dt - \lambda_n)$ to the inverse Laplace transform of $\tilde{f}(s)$, and hence $\psi * Q^{-1}$ has compact support. □

A ROBUST ADAPTIVE MINIMUM VARIANCE CONTROLLER*

L. PRALY†, S.-F. LIN‡, AND P. R. KUMAR‡

Abstract. This paper addresses the twin questions of *performance* and *robustness* of an adaptive controller for single-input, single-output, linear, stochastic systems. The authors present an adaptive controller that has the following properties:

(1) Attaining *optimal* regulation and tracking in the *ideal*, minimum phase, known upper bound on system order, known sign and lower bound for the leading coefficient (b_0), positive real condition on noise case, and *self-tuning in a Cesaro sense* to a minimum variance regulator in the case of pure regulation.

(2) Providing *mean square stability* when the system is of minimum phase, with known upper bound on order *but not necessarily satisfying a positive real condition on the noise.*

(3) Providing *mean square stability* when the system is in a *graph topological neighborhood* (of computable size) of an ideal plant as in (1), and the statistical properties of the disturbance are violated.

(4) Continuing to *stabilize* the system when the *adaptation gain is prevented from vanishing.*

Key words. robustness, performance, adaptive control, optimal control, minimum variance control, graph topology, minimum variance regulator, self-tuning regulator

AMS(MOS) subject classification. 93C40

1. Introduction.

Over the past 15 years, stochastic adaptive control theory has seen much development. The notable pioneering contributions of Aström and Wittenmark [2] and Ljung [14], [15] analyzed, respectively, the *possible* equilibrium values of the parameters to which an adaptive control law could converge, and the *stability* properties of these equilibrium points. This set the stage for the subsequent rigorous development of the foundations of the asymptotic theory of the so-called self-tuning controllers.

In 1981, Goodwin, Ramadge, and Caines [6] were able to successfully use some extensions of the martingale convergence theorem to show the convergence of a certain stochastic Lyapunov function. They were thus able to establish that for a variety of stochastic gradient algorithms the time average of the squared tracking error is almost surely optimal, a property we shall refer to as *self-optimality.* These results were then extended by similar arguments to some other algorithms; for example, an adaptive controller based on a modified least-squares estimate was analyzed by Sin and Goodwin [24]. In 1985, Becker, Kumar, and Wei [3] addressed the issue of convergence of the parameter estimates, and, in so doing, they also established the convergence of the adaptive regulator. By exploiting some geometric properties of the parameter estimate sequence, and some subsequent probabilistic analysis, they were able to show that while the parameter estimates converge almost surely (a.s.), they do *not* converge to their true values. Instead, the parameter estimate vector converges to a *random scalar multiple* of the true parameter vector. However, since the particular control law used for the regulation problem employs only *ratios* of estimates of individual parameters,

The research of this author was supported in part by National Science Foundation grant ECS-84-14676, in part by the U.S. Army Research Office under contract DAAL03-88-K-0046, and in part by the Joint Services Electronics Program under contract N00014-84-C-0149.

the adaptive control law remains invariant under scaling of the parameter estimates. Hence convergence of the adaptive regulator to the true optimal regulator takes place almost surely. This result therefore proved the so-called *self-tuning* property of the adaptive regulator. Recently, this self-tuning property has been extended by Kumar and Praly [11] to the *tracking* problem, where the goal is not to regulate the system output to stay close to zero, but to *track* a given *reference trajectory* while *optimally rejecting* the noise entering into the system. The essential difference between the regulation and tracking problems is that in the former problem it is not necessary to estimate the coefficients of the colored noise polynomial (in the ARMAX representation of the system), while in the latter it is necessary to do so if we want to track arbitrary reference trajectories. Since an additional number of parameters have to be estimated in the tracking problem, it turns out that more "excitation" of the system is needed. This excitation is in turn guaranteed if the reference trajectory is sufficiently exciting of appropriately high order (see Kumar and Praly [11]). In many practically important situations, such as, for example, the *set-point problem*, however, the reference trajectory may only be a *constant* level, which is sufficiently exciting of *order one*, or some other trajectory that has a low order of excitation. In these situations, it turns out that not all the coefficients of the colored noise polynomial need be explicitly estimated, but rather knowledge of a smaller set of parameters derived from the coefficients is adequate. This allows the design of an adaptive tracker that uses a smaller dimension parameter estimator (which is still of larger dimension than is needed in the regulation problem). Such smaller dimensional adaptive trackers have also been proved to be *self-tuning* (see Kumar and Praly [11]).

The successful results quoted above essentially show that the adaptive regulators and trackers tune themselves to *optimal* regulators and trackers for the unknown system. Inevitably, such results are crucially dependent on making some "exact" assumptions about the unknown system being controlled. In particular, for such exact asymptotic optimality and strong convergence results to hold, it has been assumed that the stochastic system being controlled is linear, of minimum phase, of *known order*, and the disturbance entering into the system is a *stochastic process* satisfying some specified *statistical* properties.

Assumptions of the above type have been called "ideal" assumptions, and questions have been raised, especially in *deterministic* adaptive control (see Egardt [5], Rohrs, Valavani, Athans, and Stein [22], and Ioannou and Kokotovic [7]), about whether the adaptive controllers designed on the basis of these assumptions, and for which a successful "ideal" theory has been built, are *robust* with respect to these assumptions. Specifically, do "small' violations of these assumptions lead to drastically different behavior from that predicted by the ideal theory?

The *order* requirement arises since we must choose the dimension of the adaptive regulator before we can tune it. However, the true system need not necessarily be (and is frequently not) of the exact order that is assumed. It is well known that "small perturbations" of an nth-order linear system can lead to systems of arbitrarily high order.

Regarding the disturbance, the assumption made is that it is a *stochastic process* with a *rational spectral density*, and thus is representable as the output of a system driven by *white noise*. Moreover, the *order* of this "coloring" filter is assumed known. Finally, it is also assumed that the noise satisfies a certain "positive real" condition. This is essentially a requirement that the disturbance be close to a white noise and be not too colored. However, none of these assumptions need be strictly satisfied in practice. The positive realness condition also arises in recursive system identification using the pseudolinear regression method (see Solo [25], Ljung and Söderström [16],

and Kumar and Varaiya [12]). It is basically a *pseudogradient condition* (see Ljung and Söderström [16] and Kumar [10]) guaranteeing that the direction in which the parameter estimates are recursively adjusted (in the types of recursive identification algorithms being employed) is appropriate.

Regarding the minimum phase restriction, it is well known (see Aström [1], Peterka [17], Shaked and Kumar [23], and Kumar and Varaiya [12]) that when a *stationary* control law that minimizes the output variance is used to control the system, then the control actions used become unbounded if the system is of *nonminimum phase.* However, for *adaptive control* where a *nonstationary,* nonlinear control law is used, it is not necessary that the minimum phase assumption be satisfied in order for the control inputs to be bounded. Hence the minimum phase assumption is a restrictive condition; it is easily violated by a very fast unstable zero that corresponds to a very small numerator perturbation of the transfer function.

Much attention has therefore been given in recent years to the issue of *robust adaptive control,* especially in deterministic adaptive control, to determine under what conditions signals in the system remain bounded under violations of assumptions (for example, see [8], [9], [20]). In the adaptive control of *stochastic* systems, however, noise is an essential feature of the system, and it is of interest not only to guarantee boundedness of signals, but it is also important to reject the noise optimally, or at least much of it. Thus, *performance* of the adaptive control algorithm in rejecting the corrupting noise, and thus tracking the desired reference trajectory with *small* tracking error, is also an important goal in stochastic adaptive control.

In this paper, therefore, we address the twin questions of *performance as well as robustness* of adaptive control laws for linear stochastic systems. In particular, we address the issue of adaptive controllers that are *performance-optimal* when the ideal assumptions are satisfied, *and* that are *robust with respect to perturbations* of the system from the ideal assumptions.

We will consider two types of *perturbations* of the system from optimality. First we consider perturbations of the coefficients of the colored noise polynomial that can be large and that allow gross violation of the positive real assumption. This problem has been treated by Egardt [5] for bounded noise and extended in Praly [18] for mean-square bounded noise.

Second, we consider *system perturbations.* Vidyasagar [26] has identified the appropriate topology on the set of linear systems, called the *graph topology,* which is the *weakest topology* such that there is a stabilizing linear controller for a nominal ideal system that remains stabilizing, and such that the closed-loop transfer function is continuous (uniformly over all frequencies) when perturbations with respect to this topology are allowed. Thus, for any given weaker topology which thus allows *more* perturbations, there is not necessarily any single linear control law that continues to maintain stability. Since self-tuning or adaptive control is really an online or real-time search over the space of linear controllers, we cannot expect to do better than allow for perturbations with respect to this graph topology. Thus while (nonadaptive) linear controllers are designed for perturbations with respect to the graph topology from a *given nominal system,* adaptive control laws should be designed to maintain stability with respect to the graph topology from all possible nominal systems. This indeed is the goal of this paper. We will achieve it by extending the approach of Praly [19] to the vanishing gain case.

Last, asymptotic optimality and convergence results for adaptive controllers rely on adaptive parameter adjustment schemes that use an asymptotically vanishing step-size, i.e., the gain converges to zero. However, to maintain the ability to adapt, the

gain should be nonvanishing. Thus we also need to analyze the effect of nonvanishing gain on the ideal adaptive control algorithm.

In this paper we therefore exhibit an adaptive controller for linear stochastic systems that is *optimal for all ideal plants*, and remains stable with respect to violations of the positive real condition, and with respect to perturbations of the system, in the graph topology, from all ideal plants. Moreover, we show that stability is preserved when the gain is prevented from going to zero.

Specifically, we present an adaptive controller for which we prove the following performance and robustness properties:

(1) Attaining *optimal* regulation and tracking in the *ideal* case when the system is of minimum phase with a known upper bound on the system order, and when the coefficients of the colored noise polynomial satisfy a positive real condition (Theorem 5.1). In the case of the *regulation* problem, we also show that the adaptive controller *self-tunes in a Cesaro sense* to minimum variance regulator (Theorem 5.2).

(2) Providing *mean-square stability* when the system is of minimum phase with a known upper bound on the system order but *does not necessarily satisfy a positive real condition* (Theorem 4.6).

(3) Providing *mean-square stability* when the system is in a *graph topological neighborhood of computable size* of an ideal system as in (1) (Theorem 6.8).

(4) *Continuing to stabilize* the system when the *adaptive gain is prevented from vanishing to zero* (Theorem 7.7).

There are still many unresolved questions. Maybe the most important is to determine whether adaptive controllers without the modifications we have used are already robust, even though our modifications are well motivated. Moreover, we have not really been able to deal with the removal of the minimum phase assumption, even though, as we will show later, our adaptive controller is robust with respect to graph topological perturbations that do result in nonminimum phase systems.

2. The adaptive controller. In this section we present our adaptive controller. In the next five sections we analyze the effect of the adaptive controller when it is applied to a variety of systems satisfying varying assumptions. (Thus we are reversing the usual order of presentation, where the intended systems are first described before the adaptive controllers are defined!)

We will suppose that the system under control is a single-input, single-output system with input sequence $u(t)$ and output sequence $y(t)$. We will also suppose the following:

(A2.i) The reference trajectory $y^m(t)$ is bounded.

There are several fixed parameters that are chosen a priori. We choose the following:

(A2.ii) Three integers n_R, n_S, and n_C (which describe the dimensions of our adaptive controller, but not necessarily those of the system);

(A2.iii) Two positive numbers $0 < \lambda_0 < \lambda_1$ (which serve as bounds on certain eigenvalues);

(A2.iv) Three positive numbers $\rho > 0$, $\sigma_0 > 0$, and $K > 0$;

(A2.v) A parameter vector θ^c of dimension $(n_R + n_S + n_C + 2)$ whose first component is larger than or equal to σ_0;

(A2.vi) An integer $d \geqq 1$ (which models the delay but may not be equal to it).

We use the *regression vector* $\phi(t)$ defined as

$$\phi(t) := (u(t), \cdots, u(t-n_S), y(t), \cdots, y(t-n_R), y^m(t+d-1), \cdots, y^m(t+d-n_C))^T.$$

Given $\theta(n)$, $F(n)$, and $\rho(n) > 0$ for all $n \leqq t-1$, and having applied a new control input $u(t-1)$ and observed a new output $y(t)$, we *recursively* define the adaptive controller as follows:

$$\rho(t) := \rho(t-1) + \max(\rho, \|\phi(t-d)\|^2), \quad t \geqq 1 \quad \text{(we choose } \rho(t) = 0 \text{ for } t \leqq 0), \tag{2.1}$$

$$\bar{\phi}(t-d) := \frac{\phi(t-d)}{\rho^{1/2}(t)}, \tag{2.2}$$

$$g(t) := \frac{1}{1 + \bar{\phi}^T(t-d)F(t-d)\bar{\phi}(t-d)}, \tag{2.3}$$

$$e(t) := y(t) - \theta^T(t-d)\phi(t-d), \tag{2.4}$$

$$\bar{e}(t) := \frac{e(t)}{\rho^{1/2}(t)}, \tag{2.5}$$

$$F^1(t) := F(t-d) - g(t)F(t-d)\bar{\phi}(t-d)\bar{\phi}^T(t-d)F(t-d), \tag{2.6}$$

$$F(t) := \left(1 - \frac{\lambda_0}{\lambda_1}\right)F^1(t) + \lambda_0 I \quad \text{(we choose } \lambda_0 I \leqq F(0) \leqq \lambda_1 I), \tag{2.7}$$

$$\theta^1(t) := \theta(t-d) + g(t)F(t-d)\bar{\phi}(t-d)\bar{e}(t), \tag{2.8}$$

$$\theta^2(t) := \theta^1(t) + \max(0, \sigma_0 - s_0^1(t)) \frac{F_1(t)}{F_{11}(t)} \tag{2.9}$$

where

$$s_0^1(t) := \text{first element of the vector } \theta^2(t),$$

$$F_1(t) := \text{first column of the matrix } F(t),$$

$$F_{11}(t) := (1,1)\text{th element of } F(t),$$

$$\theta(t) := \theta^c + (\theta^2(t) - \theta^c) \min\left(1, \frac{K\lambda_1}{\lambda_0 \|\theta^2(t) - \theta^c\|}\right). \tag{2.10}$$

Finally, the control input is defined implicitly through

$$\theta^T(t)\phi(t) = y^m(t+d). \tag{2.11}$$

Explanation of adaptive control algorithm. There are essentially only three features of our adaptive control law that are different from the usual adaptive control laws.

Normalization. The sequence $\rho(t)$ is a *normalization* (or *scaling*) sequence. The vector $\bar{\phi}(t-d)$ obtained by normalizing (i.e., dividing) $\phi(t-d)$ by $\rho^{1/2}(t)$ is then the *normalized* regression vector, and similarly $\bar{e}(t)$ is the *normalized prediction error.* These normalized signals are then used to update the parameter estimates.

Condition number bounding. The matrix $F(t)$ is what is usually called the "covariance matrix." It is well known in recursive identification (see Lai and Wei [13] and Kumar and Varaiya [12]) that if the condition number of the so-called "covariance matrix" remains bounded as $t \to \infty$, then the parameter estimates converge to their true values. Equation (2.7) ensures that the eigenvalues of $F(t)$ remain within the interval $[\lambda_0, \lambda_1]$, thereby keeping the condition number uniformly bounded. (In fact, as the reader can verify, any $F(t) \geqq F^1(t)$ satisfying the property that its eigenvalues lie in the interval $[\lambda_0, \lambda_1]$ can be used.)

Parameter estimate projection. Finally there is a set of two modifications that ensure that the parameter estimates are kept bounded, while at the same time making sure that the first component of the vector $\theta(t)$ (which is an estimate of the so-called "high-frequency gain" of the system) is kept positive and bounded below. This is done in two stages. The first stage, (2.9), ensures that the first component is larger than σ_0. The second stage, (2.10), keeps the parameter estimates inside the sphere with center θ^c and radius $K\lambda_1/\lambda_0$ by projecting them radially onto the surface of the sphere whenever they wander outside.

Remarks on modifications. The reasonableness of the modifications of normalization and eigenvalue bounding can be seen from the following calculation. Normal *unmodified* adaptive control laws using least-squares parameter estimates would use the (d interlaced) recursions

$$\theta(t)=\theta(t-d)+\frac{R^{-1}(t-d)\phi(t-d)}{1+\phi^T(t-d)R^{-1}(t-d)\phi(t-d)}(y(t)-\theta^T(t-d)\phi(t-d)),$$

$$R(t)=R(t-d)+\phi(t-d)\phi^T(t-d).$$

These recursions are clearly equivalent to

$$\theta(t)=\theta(t-d)+\frac{\left(\frac{R(t-d)}{\rho(t)}\right)^{-1}\frac{\phi(t-d)}{\rho^{1/2}(t)}}{1+\frac{\phi^T(t-d)}{\rho^{1/2}(t)}\left(\frac{R(t-d)}{\rho(t)}\right)^{-1}\frac{\phi(t-d)}{\rho^{1/2}(t)}}\frac{(y(t)-\theta^T(t-d)\phi(t-d)}{\rho^{1/2}(t)},$$

i.e.,

$$\theta(t)=\theta(t-d)+\frac{\left(\frac{R(t-d)}{\rho(t)}\right)^{-1}\bar{\phi}(t-d)}{1+\bar{\phi}^T(t-d)\left(\frac{R(t-d)}{\rho(t)}\right)^{-1}\bar{\phi}(t-d)}\bar{e}(t).$$

Thus we see that modified adaptive control uses $F(t-d)$ instead of $(R(t-d)/\rho(t))^{-1}$. This is reasonable since $R(t-d)/\rho(t)\leqq I$, and $F(t-d)$ also has a lower-bounded minimum eigenvalue. Hence both $R^{-1}(t-d)/\rho(t)$ and $F(t-d)$ are of the *same order* and grow at the same rate. Last, the bounding of the *maximum eigenvalue* of $F(t-d)$ is a reasonable effort at keeping the condition number bounded.

An intuitive rationale for the introduction of normalization is the following. Let us consider the case where the system is not of the order assumed. Then, generally we can assume that the system can be represented in the following form (which also allows infinite-dimensional systems):

$$y(t)=ay(t-1)+bu(t-1)+\sum_{i=2}^{t}(\alpha_i y(t-i)+\beta_i u(t-i))$$

where the summation represents the portion of the system dynamics that has not been modeled. Then, under the assumption that $n_S=n_R=0$, we have $\phi(t-1)=(u(t-1),y(t-1))$, and so for any $\theta=(\theta_1,\theta_2)^T$,

$$y(t)-\phi^T(t-1)\theta=(a-\theta_2)y(t-1)+(b-\theta_1)u(t-1)+\sum_{i=2}^{t}(\alpha_i y(t-i)+\beta_i u(t-i)).$$

This *modeling error* may be unbounded irrespective of the choice of θ. However, the neglected component can be bounded by

$$\left|\sum_{i=2}^{t}(\alpha_i y(t-i)+\beta_i u(t-i))\right| \leqq \sqrt{2}\left(\sum_{i=2}^{t}\alpha_i^2+\beta_i^2\right)^{1/2}\left(\sum_{i=2}^{t} y^2(t-i)+u^2(t-i)\right)^{1/2}$$

by the Cauchy–Schwarz inequality. Noting that $\sum_{i=2}^{t}(y^2(t-i)+u^2(t-i)) \leqq \rho(t)$, where $\rho^{1/2}(t)$ is the *normalization factor*, we see that $|\bar{y}(t)-\bar{\phi}^T(t-1)\theta| \leqq M_0$, when $\{\alpha_i\}$ and $\{\beta_i\}$ are in l_2. Hence the error due to mismodeling is bounded when we use the normalized quantities instead of the original variables. This is the heuristic reason for our use of normalization.

The purposeful bounding of the parameter estimates (by keeping them in a certain sphere), which is our last modification, does not cause any problems, at least when the "true parameter vector" is known to satisfy a similar bound, thus allowing convergence of the parameter estimates to their "true values" if that is necessary. As we show later, there need not even be a "true parameter vector" for this modification to be reasonable. In fact, Egardt [5] has shown that some sort of parameter boundedness is necessary for good behavior. Similarly, keeping the first component of the parameter estimates bounded below is tolerable at least when the true parameter vector also has the same lower bound on its first component.

It should be noted that our bounding of the eigenvalues of $F(t)$ is somewhat similar to the case of the *stochastic gradient algorithm* (see Becker, Kumar, and Wei [3]). In fact, the stochastic gradient algorithm is a special case of our modified adaptive controller that is obtained when we choose $\lambda_0=\lambda_1$ in (2.7). In general, however, we expect that the initial transient performance of the adaptive controller will be closer to the least-squares algorithm, but that the asymptotic convergence rate will be governed by that of the gradient algorithm, although we have not been able to establish either of these results analytically.

The modifications present in our adaptive controller, which were first proposed in Praly [21], therefore, all stem from reasonable motivations. In what follows we actually show the power of these modifications in a variety of situations.

3. Some properties of the adaptive controller. Interestingly enough (and very useful to us), the adaptive controller that we defined earlier satisfies some useful conditions *irrespective* of the system to which it is applied.

Let us define Θ as the intersection of the closed sphere with center θ^c and radius K, with the closed half-space $s_0 \geqq \sigma_0$ (where s_0 = first component of vector $\theta \in \Theta$). Note that by construction (see (A2.v)) θ^c belongs to Θ. For any $\theta \in \Theta$, we define the *prediction error* by

$$w_\theta(t) := y(t)-\theta^T\phi(t-d) \tag{3.1}$$

and its *normalized* version by $\bar{w}_\theta(t) := w_\theta(t)/\rho^{1/2}(t)$.

We wish to emphasize that the results of this section are obtained without any assumptions on $\bar{w}_\theta(t)$. The following preliminary results are of much interest, and will be very useful to us. Since they are a direct consequence of our definitions, their proofs are omitted.

LEMMA 3.1.

(i) $1 \geqq g(t) \geqq 1/(1+\lambda_1)$;

(ii) *If* $\theta \in \Theta$, *then* $\|\theta(t)-\theta\| \leqq K_1$, *for some constant* K_1;

(iii) $\rho(T) \geqq \sum_{t=1}^{T}\|\phi(t-d)\|^2$.

Proof. The proof is trivial. □

It should be noted that $g(t)$ is the only eigenvalue of the matrix $[I - g(t)F(t-d)\bar{\phi}(t-d)\bar{\phi}^T(t-d)]$ that is not equal to 1. Since (2.8) can be rewritten as $\theta^1(t) = [I - g(t)F(t-d)\bar{\phi}(t-d)\bar{\phi}^T(t-d)]\theta(t-d) + g(t)F(t-d)\bar{\phi}(t-d)\bar{y}(t)$, it is then clear that $g(t)$ tells us how *contractive* the homogeneous part of this update equation is, and (i) provides a lower bound on the rate of convergence of the parameters. Statement (ii) above merely makes note of the fact that $\theta(t)$ is kept bounded.

LEMMA 3.2. *Define a Lyapunov function* $V_\theta(t) := (\theta(t)-\theta)^T F^{-1}(t)(\theta(t)-\theta)$, *for* $\theta \in \Theta$. *Then*

$$V_\theta(t) \leqq V_\theta(t-d) + \bar{w}_\theta^2(t) - g(t)\bar{e}^2(t).$$

Proof.

Step 1. $(F^1(t))^{-1} = F^{-1}(t-d) + \bar{\phi}(t-d)\bar{\phi}^T(t-d)$. After some algebra and (3.1), we have

$$(\theta^1(t)-\theta)^T(F^1(t))^{-1}(\theta^1(t)-\theta) = V_\theta(t-d) + \bar{w}_\theta^2(t) - g(t)\bar{e}^2(t). \tag{3.2}$$

Since $(F^1(t))^{-1} \geqq F^{-1}(t)$ and because of (3.2), we have

$$(\theta^1(t)-\theta)^T F^{-1}(t)(\theta^1(t)-\theta) \leqq V_\theta(t-d) + \bar{w}_\theta^2(t) - g(t)\bar{e}^2(t). \tag{3.3}$$

Step 2. Let $\Delta'(t) = (\theta^2(t)-\theta)^T F^{-1}(t)(\theta^2(t)-\theta) - (\theta^1(t)-\theta)^T F^{-1}(t)(\theta^1(t)-\theta)$. Then some algebra yields $\Delta'(t) = (\theta^2(t) + \theta^1(t) - 2\theta)^T F^{-1}(t)(\theta^2(t) - \theta^1(t))$.

Now we consider two cases.

Case 1. If $\sigma_0 \leqq s_0^1(t)$ then $\theta^1(t) = \theta^2(t)$ and so $\Delta'(t) = 0$.

Case 2. If $\sigma_0 > s_0^1(t)$ then

$$\Delta'(t) = (\theta^2(t) + \theta^1(t) - 2\theta)^T e_1 \frac{\sigma_0 - s_0^1(t)}{F_{11}(t)}$$

$$= \frac{\sigma_0 - s_0^1(t)}{F_{11}(t)}[s_0^1(t) + (\sigma_0 - s_0^1(t)) + s_0^1(t) - 2s_0] \leqq 0 \quad (\text{since } s_0^1(t) < \sigma_0 < s_0)$$

where $e_1 = (1, 0, \cdots, 0)^T$.

Hence, in any case we have

$$(\theta^2(t)-\theta)^T F^{-1}(t)(\theta^2(t)-\theta) \leqq V_\theta(t-d) + \bar{w}_\theta^2(t) - g(t)\bar{e}^2(t). \tag{3.4}$$

Step 3. For convenience, let M_1 and d_1 denote

$$M_1 := (\theta^2(t)-\theta)^T F^{-1}(t)(\theta^2(t)-\theta) \quad \text{and} \quad d_1 := K\frac{\lambda_1}{\lambda_0}\frac{1}{\|\theta^2(t)-\theta^c\|}.$$

Now consider two cases again.

Case 1. If $d_1 \geqq 1$, then $\theta(t) = \theta^2(t)$ and so $M_1 = V_\theta(t)$.

Case 2. If $d_1 < 1$, using (2.10) and the Cauchy-Schwarz inequality, then

$$M_1 - V_\theta(t) = (\theta^2(t) + \theta(t) - 2\theta)^T F^{-1}(t)(\theta^2(t) - \theta(t))$$

$$\geqq (1-d_1^2)\|\theta^2(t)-\theta^c\|^2\frac{1}{\lambda_1} - 2\frac{K}{\lambda_0}(1-d_1)\|\theta^2(t)-\theta^c\|$$

$$= \frac{\|\theta^2(t)-\theta^c\|^2}{\lambda_1}[1 - d_1^2 - 2(1-d_1)d_1] \geqq 0.$$

Hence, in any case, $M_1 \geqq V_\theta(t)$ and the result follows. □

The above recursive bound on the "Lyapunov function" will be useful subsequently.

LEMMA 3.3.

(i) $s_0(t) \geqq \sigma_0$;

(ii) $\|\theta(t)\| \leqq \|\theta^c\| + K(\lambda_1/\lambda_0) =: R$;

(iii) $e(t) = y(t) - y^m(t)$;

(iv) $\|\theta(t) - \theta(t-d)\| \leqq \sqrt{\lambda_1}(1+\sqrt{\lambda_1}/\sqrt{\lambda_0})|\bar{e}(t)|$;

(v) *For any* $\theta \in \Theta$, $e^2(t) \leqq \rho(t)(1+\lambda_1)(V_\theta(t-d) - V_\theta(t)) + (1+\lambda_1)w_\theta^2(t)$ *and* $0 \leqq V_\theta(t) \leqq V_4 := 1/\lambda_0(K + K(\lambda_1/\lambda_0))^2$.

Proof. Formulas (i)-(iii) follow almost by definition.

(iv) Because $\|g(t)F(t-d)\bar{\phi}(t-d)\| \leqq \sqrt{\lambda_1}/2$, it follows that

$$\|\theta^1(t) - \theta(t-d)\| \leqq \frac{\sqrt{\lambda_1}}{2}|\bar{e}(t)|. \tag{3.5}$$

From the algorithm, we can easily see that

$$(\theta^2(t) - \theta^1(t))^T F^{-1}(t)(\theta^2(t) - \theta^1(t)) \leqq \frac{(\sigma_0 - s_0^1(t))^2}{\lambda_0}, \tag{3.6}$$

$$\|\theta^2(t) - \theta^1(t)\|^2 \leqq \frac{\lambda_1}{\lambda_0}\|\theta(t-d) - \theta^1(t)\|^2, \tag{3.7}$$

$$\|\theta(t) - \theta^2(t)\| \leqq \|\theta^2(t) - \theta(t-d)\|. \tag{3.8}$$

Using (3.7) and (3.5), we have

$$\|\theta^2(t) - \theta^1(t)\|^2 \leqq \frac{\lambda_1^2}{4\lambda_0}|\bar{e}(t)|^2. \tag{3.9}$$

Combining (3.8), (3.9), and (3.5), we have

$$\|\theta(t) - \theta(t-d)\| \leqq \|\theta(t) - \theta^2(t)\| + \|\theta^2(t) - \theta(t-d)\| \leqq 2\|\theta^2(t) - \theta(t-d)\|$$

$$\leqq \sqrt{\lambda_1}\left(1 + \frac{\sqrt{\lambda_1}}{\sqrt{\lambda_0}}\right)|\bar{e}(t)|.$$

(v) From Lemmas 3.2 and 3.1(i),

$$\frac{\bar{e}^2(t)}{1+\lambda_1} \leqq g(t)\bar{e}^2(t) \leqq V_\theta(t-d) - V_\theta(t) + \bar{w}_\theta^2(t),$$

and the bound on $e^2(t)$ follows readily. On the other hand,

$$V_\theta(t) \leqq \frac{1}{\lambda_0}\|\theta(t) - \theta\|^2 \leqq \frac{1}{\lambda_0}\left(\|\theta^c - \theta\| + K\frac{\lambda_1}{\lambda_0}\right)^2$$

and the claimed bound follows, since $\|\theta^c - \theta\| \leqq K$ due to the requirement that $\Theta \in \Theta$. □

The first result above merely states that the subsequent projection onto the surface of the sphere continues to preserve the property (i). The fourth result above gives a bound on the *increments* of the parameter estimates in terms of the normalized errors, while the last result gives a *bound* on the normalized errors themselves.

This last result is fundamental. It shows that insofar as the norms of the sequences are concerned, the adaptation law may be regarded as a *static gain* operator with inputs $w_\theta(t)$, $\sqrt{\rho(t)}$ and output $e(t)$. The gain from $w_\theta^2(t)$ to $e^2(t)$ is simply $(1+\lambda_1)$, which increases as the *speed* of adaptation measured by the largest eigenvalue λ_1 is

concerned. It tells us that the error given by the parameter estimates will be smaller than $\sqrt{1+\lambda_1}$ times the error given by *any* vector $\theta \in \Theta$. The gain from $\rho(t)$ to $e^2(t)$ is $(1+\lambda_1)(V_\theta(t-d)-V_\theta(t))$. Suppose now that, due to the boundedness of $V_\theta(\cdot)$, the "mean" value of $V_\theta(t-d)-V_\theta(t)$ is close to zero. Then boundedness of $e^2(t)$ will follow from the small gain theorem [4] if the operator $e(t) \to \sqrt{\rho(t)}$ has bounded gain and the operator $e(t) \to w_\theta(t)$ is an operator whose gain multiplied by $\sqrt{1+\lambda_1}$ is smaller than 1. Moreover, since this result holds for *all* $\theta \in \Theta$, we have

$$\frac{1}{T}\sum_{i=t}^{t+T} e^2(i) \leqq \frac{1}{T}\sum_{i=t}^{t+T} \rho(i)(1-\lambda_1)(V_\theta(i-d)-V_\theta(i)) + (1+\lambda_1)\min_{\theta\in\Theta}\frac{1}{T}\sum_{i=t}^{t+T} w_\theta^2(i)$$

for all $t \geqq d$ and T. This tells us why optimality can reasonably be expected to hold.

4. Stability in ideal, not necessarily positive real case. In this section we analyze the performance of the adaptive controller when it is applied to minimum phase ARMAX systems of *known* order. We do *not* make the usual positive-real assumption on the coefficients of the colored noise polynomial; in fact, we do not even assume any *stochastic* properties of the disturbance except for mean-square boundedness. Nevertheless we show that the adaptive controller proposed in the previous section mean-square *stabilizes* the system. (In the next section we show that stability result can be strengthened to one of *optimality* when a positive real condition is satisfied.)

We consider therefore the following ideal system:

$$A(q^{-1})y(t) = q^{-d}B(q^{-1})u(t) + C(q^{-1})w(t), \qquad t \geqq 1 \tag{4.1}$$

where

$$A(q^{-1}) = 1 + \sum_{i=1}^{n_A} a_i q^{-i}, \quad B(q^{-1}) = \sum_{i=0}^{n_B} b_i q^{-i}, \quad b_0 \neq 0, \quad C(q^{-1}) = 1 + \sum_{i=1}^{n_C} c_i q^{-i}.$$

Note that we assume the following:

(A4.i) Positive numbers λ_0, λ_1, delay d and reference output $y^m(t)$ are the same as that used in the adaptive controller (see § 2).

We only assume that the noise or disturbance $\{w(t)\}$ is mean-square bounded, i.e.,

(A4.ii) $$\limsup_{T\to\infty}\frac{1}{T}\sum_{t=1}^{T} w^2(t) \leqq K < \infty \quad \text{a.s.}$$

Regarding the polynomials A, B, and C, we make the following assumptions.

(A4.iii) $B(z)$ has all zeros outside the closed unit disk.

Given $A(q^{-1})$, $B(q^{-1})$, and $C(q^{-1})$, there exist polynomials $S^*(q^{-1})$, $R^*(q^{-1})$, and $Q^*(q^{-1})$ so that

$$S^*(q^{-1})A(q^{-1}) + q^{-d}R^*(q^{-1})B(q^{-1}) = B(q^{-1}), \tag{4.2}$$

$$S^*(q^{-1}) = Q^*(q^{-1})B(q^{-1}). \tag{4.3}$$

We will assume that, with n_S and n_R corresponding to the choices in the adaptive controller, we have

(A4.iv) $S^*(q^{-1})$ is of degree n_S,

(A4.v) $R^*(q^{-1})$ is of degree n_R, i.e.,

$$S^*(q^{-1}) = \sum_{i=0}^{n_S} s_i^* q^{-i} \quad \text{and} \quad R^*(q^{-1}) = \sum_{i=0}^{n_R} r_i^* q^{-i}.$$

We define

$$\theta^* = (s_0^*, \cdots, s_{n_S}^*, r_0^*, \cdots, r_{n_R}^*, 0, \cdots, 0)^T, \tag{4.4}$$

and make the following assumptions:

(A4.vi) $(\theta^c-\theta^*)^T(\theta^c-\theta^*)\leqq K$;

(A4.vii) $s_0^*\geqq\sigma_0$, where s_0^* is the first component of θ^*.

With these assumptions in hand, we can proceed to our proof of stability. In what follows we denote the components of $\theta(t)$, the parameter estimate, by

$$\theta(t)=(s_0(t),\cdots,s_{n_S}(t),r_0(t),\cdots,r_{n_R}(t),-c_1(t),\cdots,-c_{n_C}(t))^T. \tag{4.5}$$

As we have observed at the end of § 3, we must first understand how the normalizing sequence $\rho(\cdot)$ is related to $e^2(t)$, the sum of the squares of $y(\cdot)$ and $u(\cdot)$.

LEMMA 4.1.

$$T\rho\leqq\rho(T)\leqq K_2\left(\sum_{t=1}^{T}y^{m^2}(t)+\sum_{t=1}^{T-1}(e^2(t)+w^2(t))\right)+T\rho \quad \textit{for some constant } K_2.$$

Proof. Let

$$\phi^r(t):=(u(t-1),\cdots,u(t-n_S),y(t),\cdots,y(t-n_R),y^m(t+d-1),\cdots,y^m\cdot(t+d-n_C))^T,$$

$$\theta^r(t):=(s_1(t),\cdots,s_{n_S}(t),r_0(t),\cdots,r_{n_R}(t),-c_1(t),\cdots,-c_{n_C}(t))^T.$$

Note that these "reduced" vectors are obtained by removing the first component from the vectors $\phi(t)$ and $\theta(t)$. From Lemma 3.3(iii) and assumption (A4.iii), we obtain that

$$\sum_{t=1}^{T}\|\phi^r(t-d)\|^2\leqq C_1\sum_{t=1}^{T-1}(y^{m^2}(t)+e^2(t)+w^2(t)), \tag{4.6}$$

for some constant C_1. From (2.1) we have

$$\rho(T)\leqq T\rho+\sum_{t=1}^{T}(u^2(t-d)+\|\phi^r(t-d)\|^2). \tag{4.7}$$

Using (2.11), (4.6), and Lemma 3.3(ii), we get

$$\begin{aligned}\sum_{t=1}^{T}u^2(t-d)&=\sum_{t=1}^{T-d}\left(\frac{y^m(t+d)-\theta^{rT}(t)\phi^r(t)}{s_0(t)}\right)^2\\ &\leqq\frac{2}{\sigma_0^2}\sum_{t=1}^{T}y^{m^2}(t)+\frac{2R^2}{\sigma_0^2}\sum_{t=d+1}^{T}\|\phi^r(t-d)\|^2 \qquad (4.8)\\ &\leqq C_2\sum_{t=1}^{T}(y^{m^2}(t)+e^2(t)+w^2(t)) \quad \text{for some constant } C_2.\end{aligned}$$

When we combine (4.6)-(4.8) the result follows. □

The following is a technical result that we use below.

LEMMA 4.2. *Let $v(t)\geqq 0$ be a sequence of positive real numbers for all $t\geqq 1$. If $1/T\sum_{t=1}^{T}v(t)\leqq V$, for all $T\geqq 1$, then*

(i) $$\sum_{t=q+1}^{q+k}\frac{v(t)}{t}\leqq V\left(1+\log\frac{q+k}{q}\right) \quad \textit{where } q\geqq 1;$$

(ii) $$\sum_{t=q+1}^{q+k}\frac{v(t)}{t^\alpha}\leqq\frac{V}{1-\alpha}(q+k)^{1-\alpha} \quad \textit{where } q\geqq 1,\quad 0\leqq\alpha<1.$$

Proof. Let $X(T)=(1/T)\sum_{t=1}^{T} v(t)$; then $v(t)=tX(t)-(t-1)X(t-1)$.

(i)
$$\sum_{t=q+1}^{q+k}\frac{v(t)}{t}=\sum_{t=q+1}^{q+k}X(t)-X(t-1)+\frac{1}{t}X(t-1)$$
$$=X(q+k)-X(q)+\sum_{t=q+1}^{q+k}\frac{X(t-1)}{t}$$
$$\leqq V\left(1+\sum_{t=q+1}^{q+k}\frac{1}{t}\right)\leqq V\left(1+\log\frac{q+k}{q}\right);$$

(ii)
$$\sum_{t=q+1}^{q+k}\frac{v(t)}{t^{\alpha}}=\sum_{t=q+1}^{q+k}\frac{t}{t^{\alpha}}X(t)-\frac{(t-1)}{t^{\alpha}}X(t-1)$$
$$\leqq (q+k)^{1-\alpha}X(q+k)+\sum_{t=q+1}^{q+k}(t-1)\left(\frac{1}{(t-1)^{\alpha}}-\frac{1}{t^{\alpha}}\right)X(t-1).$$

If $0\leqq\alpha<1$, then $t^{\alpha}-(t-1)^{\alpha}\leqq\alpha(t-1)^{\alpha-1}$. Therefore we have

$$\sum_{t=q+1}^{q+k}(t-1)\left(\frac{1}{(t-1)^{\alpha}}-\frac{1}{t^{\alpha}}\right)\leqq\alpha\sum_{t=q+1}^{q+k}t^{-\alpha}\leqq\frac{\alpha}{1-\alpha}(q+k)^{1-\alpha}.$$

Hence the result follows. □

LEMMA 4.3. *For any α, $0\leqq\alpha<1$, and with $V_\theta(\cdot)$ the sequence shown to be bounded in Lemma 3.3, there exists a constant C such that*

$$\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-d)-V_\theta(t))\leqq C(q+k)^{\alpha},\qquad q\geqq d\geqq 1.$$

Proof. The proof is by induction. Consider the case where $d=1$. Then,

$$\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-1)-V_\theta(t))\quad(\text{where } 0\leqq V_\theta(t)\leqq V_4 \text{ from Lemma 3.3})$$
$$\leqq q^{\alpha}V_4+\alpha V_4\sum_{t=q+1}^{q+k}(t-1)^{\alpha-1}\leqq 2V_4(q+k)^{\alpha}.$$

The induction is now on d. Suppose that for $i=1,\cdots,d-1$ there exist C_i such that

$$\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-i)-V_\theta(t))\leqq C_i(q+k)^{\alpha},\qquad q\geqq d.$$

Then, let us consider

$$\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-d)-V_\theta(t))$$
$$=\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-d)-V_\theta(t-d+1))+\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-d+1)-V_\theta(t))$$
$$\leqq\sum_{t=q+1}^{q+k}t^{\alpha}(V_\theta(t-d)-V_\theta(t-d+1))+C_{d-1}(q+k)^{\alpha}$$
$$\leqq 2(q+k)^{\alpha}(d-1)V_4+(2V_4+C_{d-1})(q+k)^{\alpha}=:C_d(q+k)^{\alpha}$$

and the induction is complete. □

We now reinterpret Lemma 3.3(v) to show that $\bar{e}(t)$ is small in the mean-square sense. This will then show that the operator $e(t)\to\sqrt{\rho(t)}$ can be considered small in the mean static gain operator, at least as far as norms are considered. Unfortunately, this property holds true only for time intervals where $\rho(t)$ is much larger than t.

LEMMA 4.4. *There exist almost surely finite random variables* $\tilde{L}$ *and* $\tilde{w}$ *such that for some given* $\varepsilon > 0$, $q+1 \leqq t \leqq q+k$, $q \geqq 1$, *if* $t/\rho(t) \leqq \varepsilon$ *then* $\sum_{t=q+1}^{q+k} \bar{e}^2(t) \leqq \tilde{L} + \varepsilon\tilde{w}(1+\lambda_1)\log(q+k)/q$.

Proof. From Lemma 3.3(v) and Lemma 3.2, we have

$$\sum_{t=q+1}^{q+k} \bar{e}^2(t) \leqq C_0 + (1+\lambda_1) \min_{\theta\in\Theta} \left(\sum_{t=q+1}^{q+k} \bar{w}_\theta^2(t) \right) \tag{4.9}$$

for some constant C_0. By the definition of θ^*, we have

$$w_{\theta^*}(t) = Q^*(q^{-1})C(q^{-1})w(t). \tag{4.10}$$

Because $w(t)$ is almost surely mean-square bounded, i.e., $\limsup_T (1/T)\sum_{t=1}^{T} w^2(t) < \infty$ a.s., $Q^*(q^{-1})$ and $C(q^{-1})$ are polynomials, from (4.10) we see that there exists an almost surely finite random variable $\tilde{w}$ such that

$$\sup \frac{1}{T} \sum_{t=1}^{T} w_{\theta^*}^2(t) \leqq \tilde{w} \quad \text{a.s.} \tag{4.11}$$

If $t/\rho(t) \leqq \varepsilon$, then $\bar{w}_{\theta^*}^2(t) \leqq \varepsilon(w_{\theta^*}^2(t)/t)$ for $t \in [q+1, q+k]$, $q \geqq 1$. Combining this inequality, Lemma 4.2(i), and (4.11), we have

$$\sum_{t=q+1}^{q+k} \bar{e}^2(t) \leqq C_0 + (1+\lambda_1)\varepsilon\tilde{w}\left(1+\log\frac{q+k}{q}\right) = \tilde{L} + \varepsilon\tilde{w}(1+\lambda_1)\log\frac{q+k}{q}. \qquad \square$$

With Lemmas 4.1 and 4.4 now established, we are in a position to "close the loop." To do so we need an appropriate version of the small gain theorem given in the next result.

LEMMA 4.5 (Bellman-Gronwall Lemma). *If* $\rho(T) \leqq \tilde{M}_4 T + M_2\rho(T_0) + \gamma\sum_{t=T_0+1}^{T-1} \bar{e}^2(t)\rho(t)$, *then*

$$\rho(T) \leqq \tilde{M}_4 T + M_2\rho(T_0) \prod_{t=T_0+1}^{T-1} (1+\gamma\bar{e}^2(t)) + \gamma\tilde{M}_4 \sum_{t=T_0+1}^{T-1} t\bar{e}^2(t) \prod_{i=t+1}^{T-1} (1+\gamma\bar{e}^2(i))$$

for some positive constant M_2 *and some positive random variable* $\tilde{M}_4$.

Proof. The proof uses mathematical induction and we provide a sketch. For $T = T_0+1$ statement is obviously true. Suppose that the statement is true for $T_0+1 \leqq T \leqq T_1$, then $\rho(T_1+1) \leqq \tilde{M}_4(T_1+1) + M_2\rho(T_0)X_1 + \gamma\tilde{M}_4 X_2$, where

$$X_1 := 1 + \gamma \sum_{t=T_0+1}^{T_1} \bar{e}^2(t) \prod_{j=T_0+1}^{t-1} (1+\gamma\bar{e}^2(j)) = \prod_{j=T_0+1}^{T_1} (1+\gamma\bar{e}^2(j))$$

and

$$\begin{aligned} X_2 &:= \sum_{t=T_0+1}^{T_1} t\bar{e}^2(t) + \gamma \sum_{t=T_0+1}^{T_1} \bar{e}^2(t) \sum_{j=T_0+1}^{t-1} j\bar{e}^2(j) \prod_{i=j+1}^{t-1} (1+\gamma\bar{e}^2(i)) \\ &= \sum_{t=T_0+1}^{T_1} t\bar{e}^2(t) \prod_{i=t+1}^{T_1} (1+\gamma\bar{e}^2(i)). \end{aligned}$$

$\square$

We now show that the adaptive controller mean square stabilizes the system under the assumptions stated at the beginning of this section. Note that we are *not* assuming a positive real condition on the noise.

THEOREM 4.6. *For system* (4.1), *subject to the assumptions* (A4.i)-(A4.vii), *our algorithm ensures that*:

(i) $\limsup_{T\to\infty} \frac{1}{T}\sum_{t=1}^{T} y^2(t) < \infty$ *a.s.*,

(ii) $\limsup_{T\to\infty} \frac{1}{T}\sum_{t=1}^{T} u^2(t) < \infty$ *a.s.*

Proof. For $\tilde{w}$ (given by (4.11)), K_2 (given by Lemma 4.1), and λ_1, there exist random variables $\tilde{\varepsilon}$ and $\tilde{\alpha}$ such that

$$\tilde{\alpha} = 1 - K_2\tilde{\varepsilon}\tilde{w}(1+\lambda_1) \quad \text{and} \quad 0 < \tilde{\alpha} < 1 \quad \text{a.s.} \tag{4.12}$$

Suppose now that there exists a time interval $(T_0, T_1]$ such that

$$\frac{T}{\rho(T)} \leqq \tilde{\varepsilon} \quad \text{for all } T \in (T_0, T_1] \quad \text{and} \quad T_0/\rho(T_0) > \tilde{\varepsilon}$$

where T_1 may be infinite. (Note that if such an interval does not exist, then we are done.)

Because $y^m(t)$ is uniformly bounded and $w(t)$ is almost surely mean-square bounded, by means of Lemma 4.1, there exists $\tilde{M}_1$ such that $\rho(T) \leqq \tilde{M}_1 T + K_2 \sum_{t=1}^{T-1} e^2(t)$ almost surely.

Since $e(t) = (\theta^* - \theta(t-d))^T \phi(t-d) + w_{\theta^*}(t)$, from Lemma 3.1 and (4.11) there exist M_2 and $\tilde{M}_3$ such that $\sum_{t=1}^{T_0} e^2(t) \leqq M_2\rho(T_0) + \tilde{M}_3 T_0$.

Using this inequality and the Bellman-Gronwall Lemma, we have

$$\rho(T) \leqq \tilde{M}_4 T + M_5\rho(T_0) \prod_{t=T_0+1}^{T-1} (1 + K_2\bar{e}^2(t)) + K_2\tilde{M}_4 \sum_{t=T_0+1}^{T-1} t\bar{e}^2(t) \prod_{i=t+1}^{T-1} (1 + K_2\bar{e}^2(i)).$$

From Lemma 4.4 and (4.12), we have $\prod_{t=q+1}^{q+k} (1 + K_2\bar{e}^2(t)) \leqq e^{K_2\tilde{L}((q+k)/q)^{1-\tilde{\alpha}}}$. Therefore there exists an almost surely finite random variable $\tilde{M}_6$ such that

$$\rho(T) \leqq \tilde{M}_6\left[T + \rho(T_0)\left(\frac{T-1}{T_0}\right)^{1-\tilde{\alpha}} + (T-1)^{1-\tilde{\alpha}} \sum_{t=T_0+1}^{T-1} t^{\tilde{\alpha}}\bar{e}^2(t) \right]. \tag{4.13}$$

Choosing $\theta = \theta^*$ in Lemma 3.2, we have $(1/(1+\lambda_1))\bar{e}^2(t) \leqq (V_{\theta^*}(t-d) - V_{\theta^*}(t)) + \bar{w}^2_{\theta^*}(t)$. Hence we get

$$\sum_{t=T_0+1}^{T-1} t^{\tilde{\alpha}}\bar{e}^2(t) \leqq (1+\lambda_1) \sum_{t=T_0+1}^{T-1} t^{\tilde{\alpha}}(V_{\theta^*}(t-d) - V_{\theta^*}(t) + \bar{w}^2_{\theta^*}(t)).$$

From Lemmas 4.3 and 4.2(ii), we have

$$\sum_{t=T_0+1}^{T-1} t^{\tilde{\alpha}}\bar{e}^2(t) \leqq C_1(T-1)^{\tilde{\alpha}} + (1+\lambda_1)\tilde{\varepsilon} \sum_{t=T_0+1}^{T-1} \frac{w^2_{\theta^*}(t)}{t^{1-\tilde{\alpha}}} \leqq \tilde{M}_7(T-1)^{\tilde{\alpha}},$$

for some $\tilde{M}_7$. We can rewrite (4.13) as $\rho(T)/T \leqq \tilde{M}_6(1 + 1/\tilde{\varepsilon} + \tilde{M}_7)$. Hence there exists a random variable $\tilde{\varepsilon}_1$ such that

$$\frac{T}{\rho(T)} \geqq \tilde{\varepsilon}_1 > 0. \tag{4.14}$$

From Lemma 3.1(iii), we know that $1/\tilde{\varepsilon} > (1/T)\sum_{t=1}^{T-d} y^2(t)$. This implies that $\limsup_{T\to\infty} 1/T\sum_{t=1}^{T} y^2(t) < \infty$ a.s. Similarly, $\limsup_{T\to\infty} (1/T)\sum_{t=1}^{T} u^2(t) < \infty$ a.s. □

5. Optimality in the ideal, positive real case. Now we turn attention to the so-called *ideal case*, where the noise *satisfies a positive real condition*, and show that the preceding

stability results can be improved to prove that the sample mean-square variance of the output error is actually *optimal.* Also, in the case of *regulation,* we prove that the adaptive controller *self-tunes in a Cesaro sense* to a minimum variance regulator.

Given the system in the previous section, let us suppose that the polynomials

$$S(q^{-1}) := \sum_{i=0}^{n_S} s_i q^{-i} \quad \text{and} \quad R(q^{-1}) := \sum_{i=0}^{n_R} r_i q^{-i}$$

satisfy the equations

$$S(q^{-1})A(q^{-1}) + q^{-d}R(q^{-1})B(q^{-1}) = C(q^{-1})B(q^{-1}), \tag{5.1}$$

$$S(q^{-1}) = Q(q^{-1})B(q^{-1}). \tag{5.2}$$

Then we can define $\theta^0(t) := (s_0, \cdots, s_{n_S}, r_0, \cdots, r_{n_R}, -c_1, \cdots, -c_{n_C})^T$.

Regarding the noise $\{w(t)\}$ we assume the following:

(A5.i) It is a martingale difference sequence on a probability space (Ω, F, P).

Specifically, denoting by F_t the sub-σ-algebra generated by the observation up to and including time t. We assume that:

(A5.ii) $E\{w(t)|F_{t-1}\} = 0$ a.s.;

(A5.iii) $E\{w^2(t)|F_{t-1}\} = \sigma^2$ a.s.;

(A5.iv) $\sup_t E\{|w(t)|^{2+\delta}|F_{t-1}\} < \infty$ a.s. for some $\delta > 0$.

Next, let $v(t) := Q(q^{-1})w(t)$; then

$$E\{v^2(t+d)|F_t\} = \sigma^2 \sum_{i=0}^{d-1} q_i^2 =: v^2 \quad \text{a.s.} \quad \text{where } Q(q^{-1}) := \sum_{i=0}^{d-1} q_i q^{-i}. \tag{5.3}$$

Clearly the minimum tracking variance is v^2 (see Kumar and Varaiya [12]). We now show that our adaptive controller achieves this optimal tracking performance.

THEOREM 5.1. *Suppose that the system* (4.1) *satisfies assumptions* (A4.i), (A4.iii)-(A4.vii), *and* (A5.i)-(A5.iv). *Furthermore, assume the positive realness condition* $\sup_\omega |C(e^{i\omega}) - 1| < 1/\sqrt{1+\lambda_1}$ *and also that* $\theta^0 \in \Theta$. *Then* $\lim_{T\to\infty} 1/T \sum_{t=d}^{T+d} (y(t) - y^m(t))^2 = v^2$ *almost surely.*

Proof. From (5.1) and (4.1), it is easy to see that $(e(t) - v(t))$ is F_{t-d}-measurable. Now let

$$z(t-d) := e(t) - v(t), \tag{5.4}$$

$$b(t) := (\theta^0 - \theta(t))^T \phi(t), \tag{5.5}$$

$$h(t) := b(t) - z(t); \tag{5.6}$$

then it is easy to see that $C(q^{-1})z(t) = b(t)$. Hence $h(t) = (C(q^{-1}) - 1)z(t)$.

Because $C(e^{i\omega})$ is strictly inside the circle with center 1, and radius $1/\sqrt{1+\lambda_1}$, there exists a positive ε such that $\sum_{j=1}^{t} (z^2(j)/(1+\lambda_1) - h^2(j)) \geqq \varepsilon \sum_{j=1}^{t} z^2(j)$ for all t.

Let us define a function

$$S(t) := \sum_{j=d+1}^{t} \left(\frac{z^2(j-d)}{1+\lambda_1} - h^2(j-d) - \varepsilon z^2(j-d) \right), \qquad t \geqq d+1 \tag{5.7}$$

with $S(d) := 0$. Obviously, $S(t) \geqq 0$ for $t \geqq d$ and

$$S(t) - S(t-1) = \frac{z^2(t-d)}{1+\lambda_1} - h^2(t-d) - \varepsilon z^2(t-d) \quad \text{for } t \geqq d+1.$$

Since $w_{\theta^0}(t) = e(t) - b(t-d)$, from Lemma 3.2 and (5.4) we get

$$\begin{aligned} V_{\theta^0}(t) &\leqq V_{\theta^0}(t-d) + (\bar{e}(t) - \bar{b}(t-d))^2 - g(t)\bar{e}^2(t) \\ &= V_{\theta^0}(t-d) + (\bar{z}(t-d) + \bar{v}(t))^2 - 2(\bar{z}(t-d) + \bar{v}(t))\bar{b}(t-d) + \bar{b}^2(t-d) \\ &\quad - g(t)(\bar{z}(t-d) + \bar{v}(t))^2 \end{aligned}$$

where $\bar{b}(t-d) := b(t-d)/\rho^{1/2}(t)$, $\bar{v}(t) := v(t)/\rho^{1/2}(t)$, and $\bar{z}(t-d) := z(t-d)/\rho^{1/2}(t)$.

Taking the conditional expectation and using Lemma 3.1(i),

$$\begin{aligned} E\{V_{\theta^0}(t) \mid F_{t-d}\} &\leqq V_{\theta^0}(t-d) + (1-g(t))\frac{v^2}{\rho(t)} + (\bar{z}(t-d) - \bar{b}(t-d))^2 - \frac{1}{1+\lambda_1}\bar{z}^2(t-d) \\ &\leqq V_{\theta^0}(t-d) + (1-g(t))\frac{v^2}{\rho(t)} + \frac{S(t-1) - S(t)}{\rho(t)} - \varepsilon\bar{z}^2(t-d). \end{aligned}$$

However,

$$\frac{S(t-1)}{\rho(t)} \leqq \frac{S(t-1)}{\rho(t-1)}, \qquad \frac{S(d)}{\rho(d)} \leqq \frac{M_1}{d\rho},$$

and so,

$$\sum_{t=d+1}^{T} E\{V_{\theta^0}(t) \mid F_{t-d}\} \leqq \sum_{t=d+1}^{T} V_{\theta^0}(t-d) + v^2 \sum_{t=d+1}^{T} \frac{1-g(t)}{\rho(t)} + \frac{M_1}{d\rho} - \varepsilon \sum_{t=d+1}^{T} \bar{z}^2(t-d).$$

Because

$$\begin{aligned} \frac{1-g(t)}{\rho(t)} &= \frac{\bar{\phi}^T(t-d)F(t-d)\bar{\phi}(t-d)}{\rho(t)(1+\bar{\phi}^T(t-d)F(t-d)\bar{\phi}(t-d))} \\ &\leqq \frac{\lambda_1\phi^T(t-d)\phi(t-d)}{\rho(t)(\rho(t)+\lambda_1\phi^T(t-d)\phi(t-d))} \\ &\leqq \lambda_1\frac{\rho(t)-\rho(t-1)}{\rho^2(t)} \leqq \lambda_1\left(\frac{1}{\rho(t-1)} - \frac{1}{\rho(t)}\right). \end{aligned}$$

This implies that $\sum_{t=d+1}^{T}(1-g(t))/\rho(t) \leqq \lambda_1/d\rho$.

Taking unconditional expectation, and noting that $V_{\theta^0}(t)$ is bounded (surely), there exists M_2 such that $\varepsilon E\{\sum_{t=d+1}^{T}\bar{z}^2(t-d)\} \leqq M_2$. Hence

$$\sum_{t=d+1}^{\infty} \frac{(e(t)-v(t))^2}{\rho(t)} < \infty \quad \text{a.s.} \tag{5.8}$$

From Kronecker's lemma and (4.14), we get

$$\lim_{T\to\infty} \frac{1}{T}\sum_{t=1}^{T}(e(t)-v(t))^2 = 0 \quad \text{a.s.} \tag{5.9}$$

Hence $E\{(y(t)-y^m(t))^2 \mid F_{t-d}\} = E\{(e(t)-v(t)+v(t))^2 \mid F_{t-d}\} = (e(t)-v(t))^2 + v^2$.

Now, continuing as in Lemma 7 of Becker, Kumar, and Wei [3], we get the desired result. □

It should be noted that as $(1+\lambda_1)$ increases, the *speed* of adaptation is increased. However, the condition $\sup_\omega |C(e^{i\omega}) - 1| < 1/\sqrt{1+\lambda_1}$ then becomes more stringent, requiring that the noise be even closer to pure white noise. Hence we see that λ_1 allows a tradeoff between the rate of parameter convergence and the tolerance of the algorithm to colored noise.

In fact, we can even prove that the adaptive regulator self-tunes in a Cesaro sense to the set of optimum minimum variance regulators. To exhibit this result, we concentrate temporarily on the regulation problem. In this case,

$$y^m(t)=0 \quad \text{for every } t,$$

$$\theta^T(t)=(\theta_1(t),\cdots,\theta_{n_S+1}(t),\theta_{n_S+2}(t),\cdots,\theta_{n_S+n_R+2}(t)),$$

$$\phi^T(t)=(u(t),\cdots,u(t-n_S),y(t),\cdots,y(t-n_R))$$

and (2.11) can be rewritten as

$$\theta^T(t)\phi(t)=0. \tag{5.10}$$

Let us define $R'(q^{-1},\theta(t)):=\sum_{i=0}^{n_R}\theta_{n_S+2+i}(t)q^{-i}$ and $S'(q^{-1},\theta(t)):=\sum_{i=0}^{n_S}\theta_{i+1}(t)q^{-i}$. Then from (5.10), we have $u(t)=-(R'(q^{-1},\theta(t))/S'(q^{-1},\theta(t)))y(t)$.

Note that $D:=\{\theta\,|\,R'(q^{-1},\theta)S(q^{-1})=S'(q^{-1},\theta)R(q^{-1})\}$ is the set of parameters that yield a minimum variance regulator. We now have the following result on self-tuning in a Cesaro sense.

THEOREM 5.2. *For every open set* $O\supset D$, $\lim_{T\to\infty}1/T\sum_{t=1}^{T}1(\theta(t)\in O)=1$ *almost surely, where* $1(\cdot)$ *is the indicator function.*

Proof. Because $z(t)=y(t+d)-Q(q^{-1})w(t+d)=E\{y(t+d)\,|\,F_t\}$, from (5.9) we know that (14.i) in Becker, Kumar, and Wei [3] is true. From Lemma 3.3(iv), we have

$$\|\theta(t)-\theta(t-d)\|^2\leqq 2\lambda_i\left(1+\frac{\sqrt{\lambda_1}}{\sqrt{\lambda_0}}\right)^2\left[\frac{(e(t)-v(t))^2}{\rho(t)}+\frac{v^2(t)}{\rho(t)}\right].$$

It is easy to see that $\{X(t):=\sum_{i=1}^{t}(v^2(i)-v)/i;\,F_t\}$ is a martingale. Due to (A5.iv) $X(t)$ converges and so on $(v^2(t)-v)/t\to 0$ almost surely and this implies $v^2(t)/t\to 0$ almost surely. Because $1/\rho$ is the upper bound of $t/\rho(t)$ for every $t>0$, so $v^2(t)/\rho(t)=(v^2(t)/t)t/\rho(t)\to 0$ almost surely. Combining with (5.8), we get $\|\theta(t)-\theta(t-d)\|^2\to 0$ almost surely. Therefore (14.ii) in [3] is true.

From Lemma 3.3(ii), (5.10), Theorem 4.6(ii), and Lemma 3.3(i), we can see that (14.iii)-(14.vi) in [3] are true. Hence our result follows from Theorem 19(ii) in [3]. □

6. Robustness of optimal adaptive controller. Having proved in the previous section that our adaptive controller yields *optimal performance* for ideal systems, we now turn in this section to proving that the preceding adaptive controller is *robust.* This means that if mean-square stability holds for an ideal system Π_0 (and it does, as we have shown), it will continue to hold for all systems in an *open neighborhood* of Π_0. For this to make sense, we need to define a topology on the set of linear systems. We will consider the *graph topology* (see Vidyasagar [26]) and show that the adaptive controller applied to systems in a graph topological neighborhood retains mean-square stability. Furthermore, we will also give lower bounds on the size of these graph topological neighborhoods.

Let Γ be the set of proper rational functions $F(q)$ whose poles are all in the open unit disk. Γ is equipped with the norm $\gamma(\cdot)$, defined as $\gamma(F):=\sup_{|q|=1}|F(q)|$, for all $F\in\Gamma$. For a sequence $x(t)$, we define its l_2-norm as $\|x\|_T^2:=\sum_{t=1}^{T}x^2(t)$.

We will prove that our adaptive controller stabilizes nonideal systems Π if they satisfy the following assumptions:

(A6.i) Let the system Π be described by the equation

$$A(q)y(t)=B(q)u(t-1)+C(q)w(t), \qquad t\geqq 1 \tag{6.1}$$

where A, B, $C \in \Gamma$, A, B are coprime, B/A is a proper rational function, $A(\infty) = 1 = C(\infty)$, and the noise is a stochastic process that satisfies merely $\sup_T (1/T \sum_{t=1}^{T} w^2(t))^{1/2} \leqq V$, where V is a *deterministic* finite number. (This clearly holds if, for example, the noise is bounded.) We also assume that $|y^m(t)| \leqq M$ for all $t > 0$ and $y^m(t) = u(t) = y(t) = w(t) = 0$ for all $t \leqq 0$.

Because $B(q)$ is an analytic function outside the unit disk, we can write a Laurent series $B(q) = \sum_{i=0}^{\infty} h_i q^{-i}$ and, for $d \geqq 2$, set $P(q^{-1})$ equal to $\sum_{i=0}^{d-2} h_i q^{-i}$; otherwise it equals zero, and $D(q) := \sum_{i=0}^{\infty} h_{i+d-1} q^{-i}$.

It is easy to see that

$$B(q) = P(q^{-1}) + q^{1-d} D(q). \tag{6.2}$$

Note that for the ideal system Π_0 (as in § 5), $P_0(q^{-1}) = 0$ and $D_0(q) = B_0(q^{-1}) \in \Gamma$. Because Π_0 is minimum phase, $D_0(q)$ is strictly stably invertible. Motivated by this, we assume the following:

(A6.ii) $D(q)$ is an invertible element of Γ (i.e., $D(q)$ and $D^{-1}(q)$ belong to Γ, or we can say $D(q)$ is a *unit* of Γ).

For a system Π, we define

$$T(q) = (A(q), \cdots, q^{-n_S} A(q), q^{-1} B(q), \cdots, q^{-(n_R+1)} B(q), 0, \cdots, 0)^T.$$

With $D(q)$ a unit of Γ, for every θ we can define a new element of Γ by

$$H_\theta(q) := 1 - D^{-1}(q) T^T(q) \theta. \tag{6.3}$$

Clearly $\gamma(H_\theta)$ is a continuous function of θ. Hence we can choose $\tilde{\theta} \in \Theta$ so that $\gamma(H_{\tilde{\theta}}) \leqq \gamma(H_\theta)$ for all $\theta \in \Theta$. Next we assume the following:

(A6.iii) $\gamma(H_{\tilde{\theta}}) < \gamma_h$, where $\gamma_h = 1/\gamma_4 = 1/\sqrt{1+\lambda_1}$;

(A6.iv) $\gamma(P) < (\gamma_h - \gamma(H_{\tilde{\theta}})/(\gamma(D^{-1})(k_1 \gamma(D^{-1}) \gamma(A) + k_2 + k_3(\gamma_h - \gamma(H_{\tilde{\theta}}))) \gamma_3^{d-1}))$, where k_1, k_2, and k_3 are strictly positive constants given in the Table 1 in the Appendix (as is γ_3 also).

We illustrate these assumptions by the following two examples.

Example 1. Consider the adaptive controller with $n_S = 0$, $n_R = 0$, $n_C = 0$, i.e., $\phi(t) = (u(t), y(t))$. We now examine the above assumptions by allowing only one parameter to vary. Consider $\theta = (1, r)$, which denotes that the adaptive controller is associated with the idealized plant

$$(1 + rq^{-1}) y(t) = u(t-1) + w(t).$$

However, suppose that the true plant is given by

$$A(q) = 1 + a_1 q^{-1} + a_2 q^{-2}, \quad B(q) = 1, \quad C(q) = 1.$$

Then straightforward computations give

$$T(q) = (1 + a_1 q^{-1} + a_2 q^{-2}, q^{-1})^T, \qquad D(q) = 1,$$
$$H_\theta(q) = -q^{-1}(a_1 + r + a_2 q^{-1})$$

and it follows that

$$\gamma(H_\theta) = \sup_{0 \leqq \alpha \leqq 2\pi} \sqrt{(a_1+r)^2 + 2a_2(a_1+r)\cos\alpha + a_2^2} = |a_1 + r| + |a_2|.$$

Therefore we get $\tilde{\theta} = (1, -a_1)^T$, $H_{\tilde{\theta}} = -a_2 q^{-2}$, and $\gamma(H_{\tilde{\theta}}) = |a_2|$.

Hence, for this problem, with the expression of γ_h, assumption (A6.iii) is just equivalent to $|a_2| < 1/\sqrt{1+\lambda_1}$.

Note that all the other assumptions are satisfied. Thus by this inequality we see that λ_1 also allows a tradeoff between the rate of parameter convergence and the size of the allowed value of a_2 (see also the last comment of § 5).

Example 2. To illustrate that our assumptions do not require the system to be of minimum phase, we now consider $n_S = 1$, $n_R = 0$, $n_C = 0$, $d = 2$, i.e., $\phi(t) = (u(t), u(t-1), y(t))$. We now study the assumptions by the variation of two parameters, so suppose that $\theta = (1, s, r)^T$; this clearly corresponds to an adaptive controller for an idealized plant:

$$(1+aq^{-1})y(t) = q^{-1}u(t-1) + w(t).$$

However, suppose that the true plant is $(1+aq^{-1})y(t) = (b+q^{-1})u(t-1) + w(t)$. Then we have

$$T(q) = (1+aq^{-1}, q^{-1}(1+aq^{-1}), (b+q^{-1})q^{-1}), \qquad D(q) = 1,$$

$$P(q^{-1}) = b, \qquad H_\theta(q) = -q^{-1}(a+s+rb+(as+r)q^{-1}).$$

Therefore we get

$$\gamma(H_\theta) = |a+s+rb| + |as+r|, \quad \gamma(H_{\tilde\theta}) = 0, \quad \tilde\theta = \left(1, -\frac{a}{1-ab}, \frac{a^2}{1-ab}\right).$$

Hence all the assumptions are satisfied if (A6.iv) holds, i.e.,

$$|b| < \frac{\gamma_h}{k_1(1+|a|)+k_2+k_3\gamma_h\gamma_3},$$

which reduces to

$$|b|\left\{\sqrt{2(1+\lambda_1)}R(1+|a|)+R\sqrt{1+\lambda_1}+2\sqrt{2}\left\{\left(1+\frac{2R^2}{\sigma_0^2}\right)\left[\frac{\sup|w(t)|}{\sqrt{\rho}}+2(|a|+|b|)+2\right]^2 + 3+\frac{\sup y^{m^2}}{\rho}\left[1+\frac{2}{\sigma_0^2}(1+R^2)\right]+\frac{2R^2}{\sigma_0^2}\right\}^{1/2}\right\} < 1.$$

Note that the actual plant has a zero at $-1/b$. Thus we see that if the plant is nonminimum phase, then we can model the unstable zeros by delays, provided these zeros are *large* enough. We notice that by reducing the size of the parameter domain (i.e., by decreasing R and increasing σ_0), we allow smaller unstable zeros. This is a manifestation of the well-known fact that high gains may cause problems in the presence of unmodeled dynamics.

We see also that the threshold for the unmodeled unstable zero depends on the l_∞-norm of the forcing signals w and y^m of the closed-loop system. This is a manifestation of its nonlinear nature. However, since these norms are divided by $\sqrt{\rho}$, we can overcome this difficulty by choosing the threshold ρ in (2.1) proportional to the square of these norms.

We consider a graph topology constructed from the set Γ. All the properties of [26] can be rederived here. Specifically, this topology is the weakest one such that feedback stability is robust and closed-loop transfer functions are continuous (with respect to the "sup" norm). Since this topology on the collection of systems Π follows from the topology on Γ^3, our robustness result follows from the following theorem.

THEOREM 6.1. *The set of* (A, B, C) *satisfying assuptions* (A6.ii)-(A6.iv) *is open.*

Proof. The set

$$\left\{(\bar{A}, \bar{B}, \bar{C}, F, H, G) \,|\, \bar{A}, \bar{B}, \bar{C}, F, H, G \in \Gamma,\ F \in U,\ \gamma(H) < \gamma_h,\right.$$

$$\left.\gamma(G) < \frac{\gamma_h - \gamma(H)}{\gamma(F)(k_1\gamma(F)\gamma(\bar{A}) + k_2 + k_3(\gamma_h - \gamma(H)))\gamma_3^{d-1}(\bar{A}, \bar{B}, \bar{C})}\right\}$$

is an open set of Γ^6 where U denotes the set of units of Γ. This holds since U is an open subset of Γ, and the mapping $F^{-1} \to F$ is continuous on U (see [26]).

Let us prove that the mapping $(A, B, C) \to P$ is continuous. Using the Cauchy-Schwarz inequality, and Parseval's theorem (see [4]) we have $\gamma(P) \leqq \sum_{i=0}^{d-2} |h_i| \leqq \sqrt{d-1}\gamma(B)$. Since the mapping $(A, B, C) \to P$ is linear, and as we have just shown, also bounded, this proves that it is continuous. This implies that the mapping $(A, B, C) \to D$ is continuous, and $(A, B, C) \to H_\theta$ is continuous, for any fixed θ. Hence, for any fixed θ, the mapping $(A, B, C) \to (D, H_\theta, P)$ is continuous.

Therefore the set

$$\psi_\theta := \left\{(A, B, C) \,|\, D \in U,\ \gamma(H_\theta) < \gamma_h,\right.$$

$$\left.\gamma(P) < \frac{\gamma_h - \gamma(H_\theta)}{\gamma(D^{-1})(k_1\gamma(D^{-1})\gamma(A) + k_2 + k_3(\gamma_h - \gamma(H_\theta)))\gamma_3^{d-1}(A, B, C)}\right\}$$

is open, and therefore $\bigcup_{\theta \in \Theta} \psi_\theta$ is also open. The result follows. □

Before showing the proof of Theorem 6.8, the main robustness theorem, we need some results. As Lemma 3.3 shows, it is sufficient to prove that the operator $e(t) \to \sqrt{\rho(t)}$ has a finite gain and the operator $e(t) \to w_{\tilde{\theta}}(t)$ has a gain bounded by $1/\sqrt{1+\lambda_1}$. In what follows, we use a number of positive constants α_i, β_i, γ, δ_i, V_i, and k_i, given in Table 1 in the Appendix, that depend on $\gamma(A)$, $\gamma(B)$, $\gamma(C)$, M, V, K, R, n_C, n_S, n_R, μ, d, ρ, λ_0, λ_1, and σ_0.

LEMMA 6.2.

(i) $\rho(t) \geqq \rho(t-1)$;

(ii) $\|\phi\|_T^2 \leqq \rho(T+d) \leqq \|\phi\|_T^2 + T\rho + V_1$;

(iii) $\frac{1}{2}(\|u\|_t + \|y\|_t) \leqq \|\phi\|_t \leqq \gamma_1\|u\|_t + \gamma_2\|y\|_t + \sqrt{t}\alpha_1$;

(iv) $\|w\|_T \leqq \sqrt{T}V \leqq (V/\sqrt{\rho})\rho^{1/2}(T)$.

Proof. Formulae (i) and (iv) are immediate.

(ii) Since $\rho(t+d) - \rho(t+d-1) \leqq \rho + \|\phi(t)\|^2$, we have $\sum_{t=1}^{T}(\rho(t+d) - \rho(t+d-1)) \leqq T\rho + \|\phi\|_T^2$. Choosing $V_1 := \rho(d)$, we find that $\rho(T+d) \leqq T\rho + \|\phi\|_T^2 + V_1$.

(iii) The left-hand inequality is obvious; for the right-hand side,

$$\|\phi\|_t^2 \leqq (1+n_S)\|u\|_t^2 + (1+n_R)\|y\|_t^2 + n_C t M^2.$$

Now choosing $\gamma_1 := \sqrt{1+n_S}$, $\gamma_2 := \sqrt{1+n_R}$, and $\alpha_1 := M\sqrt{n_C}$, we get the result. □

LEMMA 6.3. $\rho(t+1) \leqq \gamma_3^2\rho(t)$.

Proof.

$$|y(t+1)| \leqq w(t+1)| + \gamma(B)\|u\|_t + \gamma(A-1)\|y\|_t + \gamma(C-1)\|w\|_t. \tag{6.4}$$

Define $\phi'(t) := (u(t-1), \cdots, u(t-n_S), y(t), \cdots, y(t-n_R), y^m(t+d-1), \cdots, y^m(t+d-n_C))^T$ and $\theta'(t) := (s_1(t), \cdots, s_{n_S}(t), r_0(t), \cdots, r_{n_R}(t), -c_1(t), \cdots, -c_{n_C}(t))^T$. Then the control law becomes

$$u(t) = \frac{y^m(t+d) - \theta^{rT}(t)\phi^r(t)}{s_0(t)}. \tag{6.5}$$

By Lemma 6.2(ii) we have

$$\|\phi^r(t)\|^2 \leqq \rho(t+d-1)+y^2(t)+M^2. \tag{6.6}$$

Putting (6.5) and (6.6) together, we have

$$u^2(t) \leqq \frac{2}{\sigma_0^2}(M^2+R^2(\rho(t+d-1)+y^2(t)+M^2)). \tag{6.7}$$

Next, with Lemma 6.2(ii), we have

$$\|\phi(t-d+1)\|^2 \leqq \rho(t)+u^2(t-d+1)+y^2(t-d+1)+M^2. \tag{6.8}$$

From (6.4) and Lemma 6.2, we have

$$\begin{aligned} y^2(t-d+1) &\leqq [|w(t-d+1)|+(\gamma(B)+\gamma(A-1))(\|u\|_{t-d}+\|y\|_{t-d}) \\ &\qquad +\gamma(C-1)\|w\|_{t-d}]^2 \qquad (6.9) \\ &\leqq \left(\frac{V}{\sqrt{\rho}}+2(\gamma(B)+\gamma(A-1))+\frac{\gamma(C-1)}{\sqrt{\rho}}V\right)^2\rho(t). \end{aligned}$$

Combining (6.7)-(6.9), we have

$$\begin{aligned} \rho(t+1) &\leqq \rho(t)+\rho+\|\phi(t-d+1)\|^2 \\ &\leqq \left(2+\frac{2}{\sigma_0^2}R^2\right)\rho(t)+\left(1+\frac{2}{\sigma_0^2}R^2\right)y^2(t-d+1)+M^2+\rho+\frac{2}{\sigma_0^2}M^2(1+R^2) \\ &\leqq \left(1+\frac{2}{\sigma_0^2}R^2\right)\left[\frac{V}{\sqrt{\rho}}+2(\gamma(B)+\gamma(A-1))+\gamma\frac{(C-1)}{\sqrt{\rho}}V\right]^2\rho(t) \\ &\quad +\left[2+\frac{2}{\sigma_0^2}R^2+\frac{M^2}{\rho}+1+\frac{2}{\rho\sigma_0^2}M^2(1+R^2)\right]\rho(t) \\ &=: \gamma_3^2\rho(t). \end{aligned}$$

□

LEMMA 6.4.

$$\|u\|_{t-d} \leqq \gamma(D^{-1})[\gamma(A)\|y\|_t+\gamma(C)\|w\|_t+\gamma(P)\|u\|_{t-1}].$$

Proof. Using (6.2), we have $D(q)u(t-d)=A(q)y(t)-C(q)w(t)-P(q^{-1})u(t-1)$, that is, $u(t-d)=D^{-1}(q)\{A(q)y(t)-C(q)w(t)-P(q^{-1})u(t-1)\}$. The result follows. □

The next lemma is immediate.

LEMMA 6.5.

(i) $\|y\|_t \leqq \|y^m\|_t+\|e\|_t$;

(ii) $\|\phi(t)\| \leqq \alpha_1$ *for* $t \leqq 0$, *where* $\alpha_1 = M\sqrt{n_C}$.

We therefore see from Lemmas 6.2, 6.4, and 6.5 that the operator $e(t) \to \sqrt{\rho(t)}$ has a bounded l_2-gain, neglecting $\gamma(P)$.

LEMMA 6.6.

$$\|w_{\tilde{\theta}}\|_t \leqq \gamma(H_{\tilde{\theta}})\|y\|_t+\gamma(D^{-1})\gamma(P)\beta_1(\|\phi\|_{t-1}+\alpha_1)+\gamma(D^{-1})\alpha_3\|w\|_t+\gamma(D^{-1})\alpha_2 M\sqrt{t}.$$

Proof.

$$\tilde{\theta}^T T(q)y(t) = \tilde{\theta}^T[B(q)(\phi(t-1)-W(q^{-1})y^m(t+d-1))+C(q)U(q^{-1})w(t)]^T,$$

where

$$\begin{aligned} U(q^{-1}) &:= (1, \cdots, q^{-n_S}, 0, \cdots, 0, 0, \cdots, 0)^T, \\ W(q^{-1}) &:= (0, \cdots, 0, 0, \cdots, 0, q^{-1}, \cdots, q^{-n_C})^T. \end{aligned}$$

From (3.1), (6.6), and the equality above, we have

$$D(q)w_{\tilde\theta}(t)=[D(q)-T^T(q)\tilde\theta]y(t)+P(q^{-1})\tilde\theta^T\phi(t-1)$$
$$-\tilde\theta^TB(q)W(q^{-1})y^m(t+d-1)+\tilde\theta^TC(q)U(q^{-1})w(t).$$

Using (6.3), we get

$$w_{\tilde\theta}(t)=H_{\tilde\theta}(q)y(t)+D^{-1}(q)P(q^{-1})\tilde\theta^T\phi(t-1)+D^{-1}(q)\tilde\theta^TC(q)U(q^{-1})w(t)$$
$$-D^{-1}(q)\tilde\theta^TB(q)W(q^{-1})y^m(t+d-1).$$

Hence

$$\|w_{\tilde\theta}\|_t\leqq\gamma(H_{\tilde\theta})\|y\|_t+\gamma(D^{-1})\gamma(P)R(\|\phi\|_{t-1}+\alpha_1)$$
$$+\gamma(D^{-1})R\gamma(B)\sqrt{n_C}M\sqrt{t}+\gamma(D^{-1})R\gamma(C)\sqrt{1+n_S}\|w\|_t.$$

If we choose $\alpha_2:=R\gamma(B)\sqrt{n_C}$, $\beta_1:=R$, and $\alpha_3:=R\gamma(C)\sqrt{1+n_S}$, the result follows. □

If we neglect the last three terms, this lemma and Lemma 6.5 tell us that the gain of operator $e(t)\to w_{\tilde\theta}(t)$ is $\gamma(H_{\tilde\theta})$.

LEMMA 6.7.

$$\|y^m\|_t\leqq M\sqrt{t}\leqq\alpha_4\rho^{1/2}(t)\quad\textit{where }\alpha_4:=M/\sqrt{\rho}.$$

Proof. From the fact that $|y^m(t)|\leqq M$ and $T\rho\leqq\rho(T)$, the result follows. □

Our result on the robustness of the adaptive controller with respect to the graph topology is given by the following theorem.

THEOREM 6.8. *Under assumptions* (A6.i)-(A6.iv), *the adaptive controller in feedback with the system* Π, *yields mean-square bounded inputs and outputs.*

Proof. As observed at the end of § 3, and due to the lemmas above, we can use a small gain argument.

Because $\rho(T)/T\geqq 1/T\sum_{t=1}^{T-d}y^2(t)$, if we can prove that there exists N so that

$$N>\frac{\rho(T)}{T},\tag{6.10}$$

then $\limsup_{T\to\infty}1/T\sum_{t=1}^{T}y^2(t)<\infty$. Similarly, we will have $\limsup_{T\to\infty}\cdot 1/T\sum_{t=1}^{T}u^1(t)<\infty$.

We now prove (6.10).

From Lemma 3.3(v), we get $\|e\|_T^2\leqq(1+\lambda_1)\sum_{t=1}^{T}(V_{\tilde\theta}(t-d)-V_{\tilde\theta}(t))\rho(t)+(1+\lambda_1)\|w_{\tilde\theta}\|_T^2$. Let

$$\Delta^2(T):=\max\left(0,\sum_{t=1}^{T}(V_{\tilde\theta}(t-d)-V_{\tilde\theta}(t))\frac{\rho(t)}{\rho(T)}\right)\quad\text{and}\quad\gamma_4:=(1+\lambda_1)^{1/2};\tag{6.11}$$

then

$$\|e\|_T\leqq\gamma_4\Delta(T)\rho^{1/2}(T)+\gamma_4\|w_{\tilde\theta}\|_T.\tag{6.12}$$

From Lemma 6.6 and Lemma 6.2(ii), (iii), we have

$$\|w_{\tilde\theta}\|_t\leqq\gamma(H_{\tilde\theta})\|y\|_t+\gamma(D^{-1})\gamma(P)\beta_1(\rho^{1/2}(t-1+d)+\alpha_1)$$
$$+\gamma(D^{-1})\alpha_3V\sqrt{t}+\gamma(D^{-1})\alpha_2M\sqrt{t}.\tag{6.13}$$

Substituting (6.13) into (6.12), with Lemmas 6.5 and 6.7 we obtain

$$\|e\|_T\leqq[\gamma_4\Delta(T)+\gamma_4\gamma(D^{-1})\gamma(P)\beta_1\gamma_3^{d-1}]\rho^{1/2}(T)+\gamma_4\gamma(D^{-1})\gamma(P)\beta_1\alpha_1$$
$$+\gamma_4\gamma(H_{\tilde\theta})\|e\|_T+[\gamma_4\gamma(H_{\tilde\theta})M+\gamma_4\gamma(D^{-1})(\alpha_3V+\alpha_2M)]\sqrt{T}.$$

Choose $\beta_2 := \beta_1\gamma_4$, $V_2 := \gamma_4 M$, $\delta_1 := \gamma_4\alpha_3$, $\beta_3 := \gamma_4\beta_1\alpha_1$, $\alpha_5 := \gamma_4\alpha_2 M$; then

(6.14)
$$(1-\gamma_4\gamma(H_{\tilde{\theta}}))\frac{\|e\|_T}{\sqrt{T}} \leqq (\gamma_4\Delta(T)+\beta_2\gamma(D^{-1})\gamma(P)\gamma_3^{d-1})\frac{\rho^{1/2}(T)}{\sqrt{T}} + V_2\gamma(H_{\tilde{\theta}})+\delta_1\gamma(D^{-1})V + \alpha_5\gamma(D^{-1})+\frac{\gamma(D^{-1})\gamma(P)\beta_3}{\sqrt{T}}.$$

From Lemmas 6.4 and 6.2 we have

$$\|u\|_{T-d} \leqq \gamma(D^{-1})[\gamma(A)\|y\|_T+\gamma(C)V\sqrt{T}+2\gamma(P)\rho^{1/2}(T+d-1)].$$

Using this inequality and Lemma 6.2, we have

$$\rho^{1/2}(T) \leqq \gamma_1\gamma(D^{-1})\gamma(A)\|y\|_T+\gamma_1\gamma(D^{-1})\gamma(C)\sqrt{T}V + 2\gamma_1\gamma(D^{-1})\gamma(P)\rho^{1/2}(T)\gamma_3^{d-1}+\gamma_2\|y\|_T+(\alpha_1+\sqrt{\rho})\sqrt{T-d}+\sqrt{V_1}.$$

Choose $\beta_4 = 2\gamma_1$, $\delta_2 = \gamma_1\gamma(C)$, $V_3 = \sqrt{\rho}$, and $\gamma_5 = \gamma_1\gamma(A)$; then

(6.15)
$$(1-\gamma(D^{-1})\gamma(P)\gamma_3^{d-1}\beta_4)\frac{\rho^{1/2}(T)}{\sqrt{T}} \leqq (\gamma(D^{-1})\gamma_5+\gamma_2)\frac{\|e\|_T}{\sqrt{T}}+(\gamma(D^{-1})\delta_2 V+\alpha_1+V_3+\gamma(D^{-1})\gamma_6+\gamma_7)+\frac{\sqrt{V_1}}{\sqrt{T}}$$

where we let $\gamma_6 := \gamma_5 M$, $\gamma_7 := \gamma_2 M$.

From assumption (A6.iii), there exists $\varepsilon > 0$, so that $1-\gamma(H_{\tilde{\theta}})\gamma_4 = \varepsilon$. Substituting (6.14) into (6.15), we get

(6.16)
$$\left(1-\gamma(D^{-1})\gamma(P)\beta_4\gamma_3^{d-1}-\frac{(\gamma(D^{-1})\gamma_5+\gamma_2)}{\varepsilon}(\gamma_4\Delta(T)+\beta_2\gamma_3^{d-1}\gamma(D^{-1})\gamma(P))\right)\frac{\rho^{1/2}(T)}{\sqrt{T}} \leqq M_1\frac{1}{\sqrt{T}}+M_0$$

where

$$M_0 := \gamma(D^{-1})\delta_2 V+\alpha_1+V_3+\gamma(D^{-1})\gamma_6+\gamma_7 + \frac{(\gamma(D^{-1})\gamma_5+\gamma_2)}{\varepsilon}[V_2\gamma(H_{\tilde{\theta}})+\alpha_5\gamma(D^{-1})+\gamma(D^{-1})\delta_1 V],$$

$$M_1 := \sqrt{V_1}+\frac{(\gamma(D^{-1})\gamma_5+\gamma_2)}{\varepsilon}\gamma(D^{-1})\gamma(P)\beta_3.$$

From assumption (A6.iv), we know that $\gamma(P)\gamma(D^{-1})(\beta_4+\beta_2((\gamma(D^{-1})\gamma_5+\gamma_2)/\varepsilon))\gamma_3^{d-1} < 1$. For convenience, define $\eta := 1-\gamma(D^{-1})\gamma(P)(\beta_4+\beta_2((\gamma(D^{-1})\gamma_5+\gamma_2)/\varepsilon))\gamma_3^{d-1} > 0$. Choose some fixed δ such that

(6.17)
$$0 < \delta < \frac{\eta\varepsilon}{\gamma_4(\gamma_2+\gamma_5\gamma(D^{-1}))}.$$

Case 1. For each time T such that $\Delta(T) \leqq \delta$, (6.16) can be rewritten as

$$\left(\eta-\frac{\gamma_4(\gamma_2+\gamma_5\gamma(D^{-1}))}{\varepsilon}\Delta(T)\right)\frac{\rho^{1/2}(T)}{\sqrt{T}} \leqq M_0+\frac{M_1}{\sqrt{T}}.$$

Let

$$M_2 := \eta-\frac{\gamma_4(\gamma_2+\gamma_5\gamma(D^{-1}))}{\varepsilon}\delta > 0 \quad \text{(from (6.17))};$$

then

$$\frac{\rho^{1/2}(T)}{\sqrt{T}} \leqq \frac{1}{M_2}\left(M_1 \frac{1}{\sqrt{T}} + M_0\right).$$

Hence $\rho(T)/T$ is bounded almost surely.

Case 2. Consider some time interval, say (T_0, T_1), such that

$$\begin{aligned} &\frac{\rho^{1/2}(T_0)}{\sqrt{T_0}} \leqq \left(\frac{M_1}{\sqrt{T_0}} + M_0\right)\frac{1}{M_2}, \\ &\frac{\rho^{1/2}(T)}{\sqrt{T}} > \left(\frac{M_1}{\sqrt{T}} + M_0\right)\frac{1}{M_2} \\ &\qquad\qquad \text{for every } T \in (T_0, T_1) \text{ (where } T_1 - T_0 \text{ may be infinite)}, \\ &\frac{\rho^{1/2}(T_1)}{\sqrt{T_1}} \leqq \left(\frac{M_1}{\sqrt{T_1}} + M_0\right)\frac{1}{M_2}. \end{aligned} \tag{6.18}$$

On such intervals, we necessarily have $\Delta(T) > \delta$ for every $T \in (T_0, T_1)$. From (6.11), $\Delta(T) > \delta$ yields

$$\sum_{t=1}^{T} (V_{\tilde{\theta}}(t-d) - V_{\tilde{\theta}}(t)) \frac{\rho(t)}{\rho(T)} > \delta^2. \tag{6.19}$$

Define $W_{\tilde{\theta}}(T) = \sum_{t=T-d+1}^{T} V_{\tilde{\theta}}(t)$, $T \geqq 0$. Note that $W_{\tilde{\theta}}(T) - W_{\tilde{\theta}}(T-1) = V_{\tilde{\theta}}(T) - V_{\tilde{\theta}}(T-d)$ for $T \geqq 1$. Because $0 \leqq V_{\tilde{\theta}}(t) \leqq V_4$, We have

$$0 \leqq W_{\tilde{\theta}}(T) \leqq dV_4. \tag{6.20}$$

From (6.19), we know that

$$\sum_{t=1}^{T} (W_{\tilde{\theta}}(t-1) - W_{\tilde{\theta}}(t)) \frac{\rho(t)}{\rho(T)} > \delta^2. \tag{6.21}$$

We define

$$W_{\tilde{\theta}}^{av}(T) = \left(\sum_{t=1}^{T} W_{\tilde{\theta}T} \frac{\rho(t+1) - \rho(t)}{\rho(T+1)}\right) + \frac{W_{\tilde{\theta}}(0)\rho(1)}{\rho(T+1)}.$$

Note the following:

(i) From (6.20), $0 \leqq W_{\tilde{\theta}}^{av}(T) \leqq dV_4$;

(ii) From (6.21), $\sum_{t=1}^{T} (W_{\tilde{\theta}}(t-1) - W_{\tilde{\theta}}(t))(\rho(t)/\rho(T)) > \delta^2$;

(iii) $$W_{\tilde{\theta}}^{av}(T) = W_{\tilde{\theta}}^{av}(T-1)\frac{\rho(T)}{\rho(T+1)} + \left(1 - \frac{\rho(T)}{\rho(T+1)}\right) W_{\tilde{\theta}}(T);$$

(iv) From (ii) and (iii),

$$W_{\tilde{\theta}}^{av}(T-1) - W_{\tilde{\theta}}^{av}(T) > \delta^2 \frac{\rho(T+1) - \rho(T)}{\rho(T+1)} \geqq \left(\frac{\delta}{\gamma_3}\right)^2 \frac{\rho(T+1) - \rho(T)}{\rho(T)}, \qquad T \in (T_0, T_1).$$

hence for any $T \in (T_0, T_1)$, we have $\sum_{t=T_0+1}^{T} (\rho(t+1) - \rho(t))/\rho(t) \leqq (\gamma_3/\delta)^2 V_4 d$. Since $\rho(t)$ is increasing,

$$\log \frac{\rho(T)}{\rho(T_0+1)} \leqq \left(\frac{\gamma_3}{\delta}\right)^2 V_4 d \quad \text{or} \quad \frac{\rho^{1/2}(T)}{\rho^{1/2}(T_0+1)} \leqq \exp\left(\frac{1}{2}\left(\frac{\gamma_3}{\delta}\right)^2 V_4 d\right).$$

From Lemma 6.3 and (6.18), we get

$$\frac{\rho^{1/2}(T)}{\sqrt{T}} \leqq \frac{\gamma_3}{M_2}\left(M_1 \frac{1}{\sqrt{T_0}} + M_0\right) \exp\left(\frac{1}{2}\left(\frac{\gamma_3}{\delta}\right)^2 V_4 d\right).$$

Cases 1 and 2 tell us $\rho^{1/2}(T)/\sqrt{T}$ is bounded. □

7. Stability with nonvanishing adaptive gains. In the previous sections the gain of the parameter estimates, or equivalently the stepsize of the adaptation algorithm, has been allowed to converge asymptotically to zero. Indeed this is necessary if we asymptotically want to achieve optimal tracking. However, this vanishing gain also causes the adaptive controller to have asymptotically *diminishing* ability to adjust to *system changes.* Hence, in practice, adaptation gains are frequently prevented from going to zero. Therefore in this section we address the nonvanishing gain case of our adaptive controller.

We choose μ such that $0 < \mu < 1$. Let Γ' be the set of proper rational functions $F(q)$ whose poles are all in the open disk of radius μ. Γ' is equipped with the norm

$$\gamma(F) = \sup_{|q|=\mu} |F(q)|, \qquad F \in \Gamma'.$$

For a sequence $x(t)$, we define its $l_2(\mu)$-norm as $\|x\|_T^2 := \sum_{t=1}^{T} \mu^{-2t} x^2(t)$. Note that if $F(q) \in \Gamma'$ and $z(t) = F(q)x(t)$, then $\|z\|_T \leqq \gamma(F)\|x\|_T$.

Let us consider system Π, which can be described as follows:

(A7.i) We suppose that the true system satisfies

$$A(q)y(t) = B(q)u(t-1) + C(q)w(t), \qquad t \geqq 1 \tag{7.1}$$

where A, B, $C \in \Gamma'$, A, B are coprime, B/A is a proper rational function, and $A(\infty) = 1 = C(\infty)$. Regarding the noise $w(t)$ we will merely assume that it is bounded, $|w(t+1)| \leqq V$, where V is a *deterministic* finite positive number.

As before we will also assume that $|y^m(t)| \leqq M$ for all $t > 0$ and

$$y^m(t) = u(t) = y(t) = w(t) = 0 \quad \text{for all } t \leqq 0.$$

Because $B(q)$ is an analytic function outside the disk of radius μ, we can write a Laurent series $B(q) = \sum_{i=0}^{\infty} h_i q^{-i}$ and state that if $d \geqq 2$, then $P(d^{-1}) = \sum_{i=0}^{d-2} h_i q^{-i}$; otherwise it equals zero and $D(q) = \sum_{i=0}^{\infty} h_{i+d-1} q^{-i}$. It is easy to see that $B(q) = P(q^{-1}) + q^{1-d} D(q)$. Then we assume the following:

(A7.ii) $D(q)$ is an invertible element of Γ'.

As before, we define

$$T(q) := (A(q), \cdots, q^{-n_S} A(q), q^{-1} B(q), \cdots, q^{-(n_R+1)} B(q), 0, \cdots, 0)^T.$$

For any θ, we define $H_\theta(q) := 1 - D^{-1}(q) T^T(q)\theta$ and choose $\tilde{\theta} \in \Theta$ so that $\gamma(H_{\tilde{\theta}}) \leqq \gamma(H_\theta)$, for all $\theta \in \Theta$. We also make the following two assumptions:

(A7.iii) $\gamma(H_{\tilde{\theta}}) < \gamma_h$ where $\gamma_h := 1/\gamma_4$;

(A7.iv) $\gamma(P) < (\gamma_h - \gamma(H_{\tilde{\theta}}))/(\gamma(D^{-1})(k_4 \gamma(D^{-1})\gamma(A) + k_5 + k_6(\gamma_h - \gamma(H_{\tilde{\theta}})))\gamma_{10}^{d-1})$ where k_4, k_5, and k_6 are strictly positive constants given in Table 1 in the Appendix (as is γ_{10} also).

Because the mapping $F(q) \to F(\mu q)$ is an isomorphism on the field of rational functions, all the properties of [26] can be used here. In particular we obtain a topology that is the weakest one, such that feedback μ-exponential stability is robust.

THEOREM 7.1. *The set of* (A, B, C) *satisfying assumptions* (A7.ii)-(A7.iv) *is open.*

Proof. The proof is the same as in Theorem 6.1 except that we need to prove that the mapping $(A, B, C) \to P$ is continuous. Note first that $\gamma(P) \leqq \sum_{i=0}^{d-2} |h_i| \mu^{-i}$ and $\sum_{i=0}^{d-2} |h_i| \mu^{-i} \leqq \sqrt{d-1} (\sum_{i=0}^{\infty} h_i^2 \mu^{-2i})^{1/2}$. Now, using Parseval's theorem, we have $\sum_{i=0}^{\infty} h_i^2 \mu^{-2i} \leqq \sup_{|q| \geqq \mu} |B(q)|^2$. Hence $\gamma(P) \leqq \sqrt{d-1}\gamma(B)$ proves that the mapping $(A, B, C) \to P$ is continuous. □

Now we define a *new* normalization sequence:

$$\rho(t) = \mu^2 \rho(t-1) + \max(\rho, \|\phi(t-d)\|^2), \qquad t \geqq 1 \tag{7.2}$$

where $\rho(t) = 0$ if $t \leqq 0$ and $0 < \rho < \infty$.

It is important to note that in going from (2.1), where we had simply $\mu^2 = 1$, to (7.2), we have made our assumptions more restrictive. This can be seen by comparing Theorems 6.1 and 7.1, In the latter we need μ-exponential stability, whereas in the former mere exponential stability is sufficient. In particular, this means that in the latter case we cannot neglect a pole-zero pair that nearly cancels and that corresponds to an eigenvalue larger than μ in modulus. We can also note that for the first example of § 6, we now obtain the restriction $|a_2| < \mu/\sqrt{1+\lambda_1}$.

The following lemmas are essentially similar to those in § 6, and so we abbreviate the proofs.

LEMMA 7.2.

(i) $\mu^{-T}|w(T)| \leqq \|w\|_T \leqq \delta_3 \mu^{-T} V$;

(ii) $\mu^{-2t}\rho(t) \geqq \mu^{-2(t-1)}\rho(t-1)$;

(iii) $\frac{1}{2}(\|u\|_T + \|y\|_T) \leqq \|\phi\|_T \leqq \gamma_9 \|u\|_T + \gamma_{11}\|y\|_T + \alpha_6 \mu^{-T}$;

(iv) $\|\phi\|_T \leqq \gamma_8 \mu^{-(T+d)} \rho^{1/2}(T+d) \leqq \|\phi\|_T + V_6 \mu^{-T} + V_5$.

Proof. (i) The proof follows from the definition of the norm $\|w\|_T$ as $\|w\|_T = \sum_{t=1}^{T} \mu^{-2t} w^2(t)$ and from (A7.i), which assumes $|w(t+1)| \leqq V$.

Inequality (ii) follows from (7.2).

(iii) $\|\phi\|_T^2 \leqq (1+n_S)\mu^{-2n_S}\|u\|_T^2 + (1+n_R)\mu^{-2n_R}\|y\|_T^2 + n_C M^2(\mu^{-2T}/(1-\mu^2))$. Now choose $\gamma_9 = \sqrt{1+n_S}\,\mu^{-n_S}$, $\gamma_{11} = \sqrt{1+n_R}\,\mu^{-n_R}$, and $\alpha_6 = M(\sqrt{n_C}/\sqrt{1-\mu^2})$ and the result follows.

(iv) $\mu^{-2(T+d)}\rho(T+d) \geqq \sum_{t=1}^{T+d} \mu^{-2t}\|\phi(t-d)\|^2 \geqq \mu^{-2d}\|\phi\|_T^2$.

When we choose $\gamma_8 = \mu^d$, the left inequality in (iv) follows. On the other hand, when we use

$$\sum_{t=1}^{T+d} \mu^{-2t}(\|\phi(t-d)\|^2 + \rho) \geqq \mu^{-2(T+d)}\rho(T+d) - \rho(0),$$

$$\mu^{-2d}\left(\frac{1-\mu^{2d}}{1-\mu^2}\alpha_1^2 + \|\phi\|_T^2\right) \geqq \sum_{t=1}^{T+d} \mu^{-2t}\|\phi(t-d)\|^2 \quad (\text{where } \alpha_1 := M\sqrt{n_C}),$$

$$\sum_{t=1}^{T+d} \mu^{-2t}\rho = \frac{\mu^{-2}(1-\mu^{-2(T+d)})}{1-\mu^2} p,$$

the right-hand side inequality in (iv) holds if we choose

$$V_5 = \alpha_1 \frac{\sqrt{1-\mu^{2d}}}{\sqrt{1-\mu^2}} \quad \text{and} \quad V_6 = \frac{\sqrt{\rho}}{\sqrt{1-\mu^2}}.$$

□

LEMMA 7.3. $\rho(t-1) \leqq \gamma_{10}^2 \rho(t)$.

Proof. If we use $|y(t+1)| \leqq |w(t+1)| + \mu t\gamma(B)\|u\|_t + \mu^{t+1}\gamma(A-1)\|y\|_t + \mu^{t+1}\gamma(C-1)\|w\|_t$ instead of (6.4), and

$$y^2(t-d+1) \leqq [|w(t-d+1)| + (\gamma(B)+\mu\gamma(A-1))\mu^{t-d} \cdot (\|u\|_{t-d} + \|y\|_{t-d}) + \mu^{t-d+1}\gamma(C-1)\|w\|_{t-d}]^2$$

$$\leqq \left[2(\gamma(B)+\mu\gamma(A-1))\mu^{-d}\gamma_8 + (1+\gamma(C-1)\mu)\delta_3 \frac{V}{\sqrt{\rho}}\right]^2 \rho(t)$$

instead of (6.9), then we get the desired result. □

LEMMA 7.4.

$$\|u\|_{T-d} \leqq \mu^d \gamma(D^{-1})(\gamma(A)\|y\|_T + \gamma(C)\|w\|_T + \mu^{-1}\gamma(P)\|u\|_{T-1}).$$

Proof. Because $D(q)u(t-d) = A(q)y(t) - C(q)w(t) - P(q^{-1})u(t-1)$, we have $\|u\|_{T-d} \leqq \mu^d\gamma(D^{-1})(\|Ay\|_T + \|Cw\|_T + \mu^{-1}\|Pu\|_{T-1})$. □

The next result is immediate.

LEMMA 7.5.

(i) $\|y\|_T \leqq \|y^m\|_T + \|e\|_T$;

(ii) $\|y^m\|_T \leqq M(\mu^{-2T}(1-\mu^{2T})/(1-\mu^2))^{1/2} \leqq \alpha_8\mu^{-T}$.

LEMMA 7.6.

$$\|w_{\tilde{\theta}}\|_T \leqq \gamma(H_{\tilde{\theta}})\|y\|_T + \gamma(D^{-1})\gamma(P)\beta_6(\|\phi\|_{T-1} + \alpha_1) + \gamma(D^{-1})\alpha_9\mu^{-T} + \gamma(D^{-1})\alpha_{10}\|w\|_T.$$

Proof. The proof is similar to that of Lemma 6.6. □

THEOREM 7.7. *Under assumptions* (A7.i)-(A7.iv), *the adaptive controller in feedback with the system* Π, *yields bounded inputs and outputs almost surely.*

Proof. From Lemma 7.2(iv) and (iii), we have $\frac{1}{2}\mu^{-T}y(T) \leqq \mu^{-T}\rho^{1/2}(T+d)$. If we can now prove that there exists $N < \infty$ almost surely so that

$$\rho^{1/2}(T) < N \quad \text{for } T > 0, \tag{7.3}$$

then clearly $y(T) \leqq 2\rho^{1/2}(T+d) < 2N$, so we will have shown that $y(T)$ is bounded almost surely. A similar situation holds regarding $u(T)$ also.

So we only need to prove (7.3). From Lemma 3.3(v), we have

$$\|e\|_T^2 \leqq (1+\lambda_1)\mu^{-2T}\rho(T)\Delta^2(T) + (1+\lambda_1)\|w_{\tilde{\theta}}\|_T^2$$

where

$$\Delta^2(T) := \max\left(0, \sum_{t=1}^{T} (V_{\tilde{\theta}}(t-d) - V_{\tilde{\theta}}(t))\mu^{2(T-t)}\frac{\rho(t)}{\rho(T)}\right). \tag{7.4}$$

Thus

$$\|e\|_T \leqq \gamma_4\mu^{-T}\rho^{1/2}(T)\Delta(T) + \gamma_4\|w_{\tilde{\theta}}\|_T \quad \text{where } \gamma_4 = \sqrt{1+\lambda_1}. \tag{7.5}$$

From Lemmas 7.6 and 7.2, we have

$$\|w_{\tilde{\theta}}\|_T \leqq \gamma(H_{\tilde{\theta}})\|y\|_T + \gamma(D^{-1})\gamma(P)\beta_7\mu^{-T}\rho^{1/2}(T)\gamma_{10}^{d+1} + \gamma(D^{-1})\gamma(P)\delta_4 + \gamma(D^{-1})(\alpha_9 + \alpha_{10}\delta_3 V)\mu^{-T} \tag{7.6}$$

where $\beta_7 := \beta_6\gamma_8\mu^{1-d}$ and $\delta_4 := \beta_6\alpha_1$. Substituting (7.6) into (7.5), we obtain

$$\begin{aligned}\|e\|_T \leqq{}& \gamma_4\mu^{-T}\rho^{1/2}(T)\Delta(T) + \gamma_4\gamma(H_{\tilde\theta})\|y\|_T + \gamma(D^{-1})\gamma(P)\beta_8\mu^{-T}\rho^{1/2}(T)\gamma_{10}^{d-1} \\ &+ \gamma(D^{-1})\gamma(P)\delta_5 + \gamma(D^{-1})(\alpha_{11}+\alpha_{12}V)\mu^{-T}\end{aligned} \tag{7.7}$$

where $\beta_8 := \gamma_4\beta_7$, $\delta_5 := \gamma_4\delta_4$, $\alpha_{11} := \alpha_9\gamma_4$, and $\alpha_{12} := \alpha_{10}\delta_3\gamma_4$.

From Lemma 7.5, we have $\|y\|_T \leqq \|y^m\|_T + \|e\|_T \leqq \alpha_8\mu^{-T} + \|e\|_T$. Using this, we rewrite (7.7) as

$$\begin{aligned}(1-\gamma_4\gamma(H_{\tilde\theta}))\|e\|_T \leqq{}& [\gamma_4\Delta(T) + \gamma(D^{-1})\gamma(P)\beta_8\gamma_{10}^{d-1}]\mu^{-T}\rho^{1/2}(T) + \gamma(D^{-1})\gamma(P)\delta_5 \\ &+ [\gamma_4\gamma(H_{\tilde\theta})\alpha_8 + \gamma(D^{-1})(\alpha_{11}+\alpha_{12}V)]\mu^{-T}.\end{aligned} \tag{7.8}$$

From Lemmas 7.4, 7.2, and 7.3, we have

$$\|u\|_{T-d} \leqq \gamma(D^{-1})[\gamma_{15}\|y\|_T + \gamma(P)\delta_7\mu^{-T}\rho^{1/2}(T)\gamma_{10}^{d-1} + \delta_8\mu^{-T}V]$$

where $\gamma_{15} := \mu^d\gamma(A)$, $\delta_7 := 2\gamma_8\mu$, and $\delta_8 := \gamma(C)\mu^d\delta_3$.

From Lemma 7.2(iv), (iii), and this last inequality, we have

$$\begin{aligned}\mu^{-T}\rho^{1/2}(T) &\leqq \frac{\gamma_9}{\gamma_8}\|u\|_{T-d} + \frac{\gamma_{11}}{\gamma_8}\|y\|_{T-d} + \frac{\alpha_6}{\gamma_8}\mu^{-(T-d)} + \frac{V_5}{\gamma_8} + \frac{V_6}{\gamma_8}\mu^{-(T-d)} \\ &\leqq \left(\frac{\gamma_9}{\gamma_8}\gamma(D^{-1})\gamma_{15} + \frac{\gamma_{11}}{\gamma_8}\right)\|y\|_T + \frac{\gamma_9}{\gamma_8}\gamma(D^{-1})\gamma(P)\delta_7\mu^{-T}\rho^{1/2}(T)\gamma_{10}^{d-1} \\ &\quad + \frac{\gamma_9}{\gamma_8}\gamma(D^{-1})\delta_8\mu^{-T}V + \frac{1}{\gamma_8}\alpha_6\mu^d\mu^{-T} + \frac{V_5}{\gamma_8} + \frac{V_6}{\gamma_8}\mu^{-T}\mu^d.\end{aligned}$$

If we choose

$$\begin{aligned}&\delta_9 := \frac{\gamma_9}{\gamma_8}\delta_7, \quad \gamma_{14} := \frac{\gamma_9}{\gamma_8}\gamma_{15}, \quad \gamma_{13} := \frac{\gamma_{11}}{\gamma_8}, \quad \delta_6 := \frac{\gamma_9}{\gamma_8}\delta_8, \\ &\alpha_7 := \frac{1}{\gamma_8}\alpha_6\mu^d, \quad V_7 := \frac{V_5}{\gamma_8}, \quad V_8 := \frac{V_6}{\gamma_8}\mu^d,\end{aligned}$$

then the inequality above becomes

$$\begin{aligned}&(1-\gamma(D^{-1})\delta_9\gamma(P)\gamma_{10}^{d-1})\mu^{-T}\rho^{1/2}(T) \\ &\quad \leqq [\gamma(D^{-1})\gamma_{14}\alpha_8 + \gamma_{13}\alpha_8 + \gamma(D^{-1})\delta_6 V + \alpha_7 + V_8]\mu^{-T} \\ &\quad\quad + [\gamma(D^{-1})\gamma_{14} + \gamma_{13}]\|e\|_T + V_7.\end{aligned} \tag{7.9}$$

From assumption (A7.iii) there exists $\varepsilon > 0$ such that $1-\gamma(H_{\tilde\theta})\gamma_4 = \varepsilon$. Substituting (7.8) into (7.9), we have

$$\begin{aligned}&\left[1-\gamma(D^{-1})\delta_9\gamma(P)\gamma_{10}^{d-1} - \frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}\right. \\ &\qquad \left.\cdot\,(\gamma_4\Delta(T) + \gamma(D^{-1})\gamma(P)\beta_8\gamma_{10}^{d-1})\right]\rho^{1/2}(T) \leqq M_0 + \mu^T M_1\end{aligned} \tag{7.10}$$

where

$$\begin{aligned}M_0 :={}& \frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}[\gamma_4\gamma(H_{\tilde\theta})\alpha_8 + \gamma(D^{-1})(\alpha_{11}+\alpha_{12}V)] + \gamma(D^{-1})\gamma_{14}\alpha_8 + \gamma_{13}\alpha_8 \\ &+ \gamma(D^{-1})\delta_6 V + \alpha_7 + V_8, \\ M_1 :={}& \frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}\gamma(D^{-1})\gamma(P)\delta_5 + V_7.\end{aligned}$$

Now, assumption (A7.iv) implies

$$\gamma(P)\gamma(D^{-1})\left(\delta_9+\beta_8\frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}\right)\gamma_{10}^{d-1}<1.$$

Hence, there exists $\eta>0$ so that

$$\eta:=1-\gamma(D^{-1})\gamma(P)\left(\delta_9+\frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}\beta_8\right)\gamma_{10}^{d-1}.$$

Now we choose and fix a $\delta>0$ that satisfies $0<\delta<(\eta\varepsilon/(\gamma_4[\gamma(D^{-1})\gamma_{14}+\gamma_{13}]))$ and examine two cases.

Case 1. If for each time T, $\Delta(T)\leqq\delta$, then from (7.10),

$$\left(\eta-\frac{\gamma(D^{-1})\gamma_{14}+\gamma_{13}}{\varepsilon}\gamma_4\Delta T\right)\rho^{1/2}(T)\leqq M_0+\mu M_1.$$

Hence

$$\rho^{1/2}(T)\leqq\frac{\varepsilon(M_0+\mu M_1)}{\eta\varepsilon-[\gamma(D^{-1})\gamma_{14}+\gamma_{13}]\delta\gamma_4}=:N_1$$

and so $\rho(T)$ is bounded.

Case 2. Suppose, however, that there is a certain time interval (T_0, T_1) such that

$$\rho^{1/2}(T_0)\leqq N_1,$$

$$\rho^{1/2}(T)>N_1 \quad \text{for } T\in(T_0, T_1) \quad \text{(where } T_1-T_0 \text{ may be infinite)}, \tag{7.11}$$

$$\rho^{1/2}(T_1)\leqq N_1.$$

On such an interval, we must have $\Delta(T)>\delta$ for $T\in(T_0, T_1)$. From (7.4) we get

$$\sum_{t=1}^{T}(V_{\tilde{\theta}}(t-d)-V_{\tilde{\theta}}(t))\mu^{2(T-d)}\frac{\rho(t)}{\rho(T)}<\delta^2.$$

Let us define $W_{\tilde{\theta}}(T):=\sum_{t=T-d+1}^{T}V_{\tilde{\theta}}(t)$, for $T\geqq 0$, then

$$\sum_{t=1}^{T}(V_{\tilde{\theta}}(t-d)-V_{\tilde{\theta}}(t))\frac{\mu^{-2t}\rho(t)}{\mu^{-2T}\rho(T)}=\sum_{t=1}^{T}(W_{\tilde{\theta}}(t-1)-W_{\tilde{\theta}}(t))\frac{\mu^{-2t}\rho(t)}{\mu^{-2T}\rho(T)}>\delta^2.$$

Note that $0\leqq W_{\tilde{\theta}}(T)\leqq dV_4$, for $T\geqq 0$.

If we now define

$$W_{\tilde{\theta}}^{av}(T):=\sum_{t=1}^{T}W_{\tilde{\theta}}(t)\frac{\mu^{-2(t+1)}\rho(t+1)-\mu^{-2t}\rho(t)}{\mu^{-2(T+1)}\rho(T+1)}+\frac{W_{\tilde{\theta}}(0)\mu^{-2}\rho(1)}{\mu^{-2(T+1)}\rho(T+1)},$$

then

$$\sum_{t=1}^{T}(W_{\tilde{\theta}}(t-1)-W_{\tilde{\theta}}(t))\frac{\mu^{-2t}\rho(t)}{\mu^{-2T}\rho(T)}=W_{\tilde{\theta}}^{av}(T-1)-W_{\tilde{\theta}}(T)>\delta^2. \tag{7.12}$$

Note that because $W_{\hat{\theta}}(T) \leqq dV_4$, it follows that $W_{\hat{\theta}}^{av}(T) \leqq dV_4$. It is easy to see that

$$W_{\hat{\theta}}^{av}(T) = \frac{\mu^{-2T}\rho(T)}{\mu^{-2(T+1)}\rho(T+1)} W_{\hat{\theta}}^{av}(T-1) + \left(1 - \frac{\mu^{-2T}\rho(T)}{\mu^{-2(T+1)}\rho(T+1)}\right) W_{\hat{\theta}}(T).$$

Using (7.12) we have

$$\begin{aligned} & W_{\hat{\theta}}^{av}(T-1) - W_{\hat{\theta}}^{av}(T) \\ & > \left(1 - \frac{\mu^{-2T}\rho(T)}{\mu^{-2(T+1)}\rho(T+1)}\right)(\delta^2 + W_{\hat{\theta}}(T)) - \left(1 - \frac{\mu^{-2T}\rho(T)}{\mu^{-2(T+1)}\rho(T+1)}\right) W_{\hat{\theta}}(T) \\ & \geqq \left(\frac{\delta\mu}{\gamma_{10}}\right)^2 \left(\frac{\mu^{-2(T+1)}\rho(T+1) - \mu^{-2T}\rho(T)}{\mu^{-2T}\rho(T)}\right). \end{aligned}$$

Hence,

$$\begin{aligned} \sum_{t=T_0+1}^{T} \frac{\mu^{-2(t+1)}\rho(t+1) - \mu^{-2t}\rho(t)}{\mu^{-2t}\rho(t)} & \leqq \sum_{t=T_0+1}^{T} \left(\frac{\gamma_{10}}{\delta\mu}\right)^2 [W_{\hat{\theta}}^{av}(t-1) - W_{\hat{\theta}}^{av}(t)] \\ & \leqq \left(\frac{\gamma_{10}}{\delta\mu}\right)^2 dV_4 \quad \text{for } T \in (T_0, T_1). \end{aligned}$$

Because $\mu^{-2t}\rho(t)$ is increasing with respect to time t, from the last inequality we get

$$\frac{\mu^{-2T}\rho(T)}{\mu^{-2(T_0+1)}\rho(T_0+1)} < \exp\left(\left(\frac{\gamma_{10}}{\delta\mu}\right)^2 dV_4\right).$$

and so again $\rho(T)$ is bounded.

When we combine Cases 1 and 2, the theorem is proved. □

8. Conclusions. Here we have analyzed the twin issues of obtaining both *good performance* and *robustness* out of an adaptive controller for linear stochastic systems.

For minimum phase plants of known order, with a known compact set containing a stabilizing regulator, and for which we know the sign and a lower bound for the leading coefficient of the control polynomial, we have shown that our adaptive controller yields *mean-square bounded* inputs and outputs. If the noise additionally satisfies a positive real condition, then we have shown that the adaptive controller is asymptotically *optimal* in the sense of *minimizing* output error variance. We have also presented a *graph topological neighborhood* of an ideal plant, such that the system is mean-square stabilized even when that system is not ideal and when the statistical properties of the noise are violated. This holds true whether the adpative controller is used in a vanishing or a nonvanishing gain mode.

Several open problems remain. It is still not known whether the standard self-tuning regulator using a *least-squares* parameter estimate is mean-square stable, let alone optimal. Moreover, it is not known whether the unmodified adaptive controller possesses good robustness properties. The first question deals essentially with the loss of identifiability, and the consequent unboundedness of the condition number of the so-called "covariance matrix," when the parameter estimates converge. Unfortunately the second issue cannot really be resolved until the first issue is better understood.

Appendix.

PROPERTIES OF THE RELAXED TRAJECTORIES OF EVOLUTION EQUATIONS AND OPTIMAL CONTROL*

NIKOLAOS S. PAPAGEORGIOU†

Abstract. This paper considers a class of nonconvex control problems in a Banach space, governed by a semilinear evolution equation and establishes the existence of admissible pairs. Then the introduction of measure-valued controls convexifies the system, and under general assumptions it is shown that the set of trajectories of the original system is dense (in an appropriate topology) in the set of relaxed trajectories. Some useful topological properties of the set of relaxed trajectories are also determined. Furthermore, some optimization problems are solved and in many cases the values of the original and relaxed problems are shown to be equal. Finally, another relaxation result is proved for a different class of systems, described by a general nonlinear evolution equation.

Key words. evolution inclusion, measurable multifunction selection, evolution operator, weak compactness

AMS(MOS) subject classification. 49A20

1. Introduction.

It is well known to researchers working in optimal control theory that to guarantee existence of optimal "state-control" pairs we need, among other things, a convexity hypothesis on a certain orientor field. The well-known property (Q) of Cesari is an example of such a hypothesis. It was first introduced by Cesari [12a] to prove the lower semicontinuity of the cost functional and since then it has become a popular tool among people working on variational and optimal control problems. This is very nicely exemplified in Berkovitz [7] and Cesari [13].

When this convexity hypothesis is no longer satisfied, to have optimal solutions we need to pass to a larger system, in which the orientor field (also known as the velocity field or tangent bundle) has been convexified. Such a convexification, on a control theoretic level, corresponds to the introduction of measure-valued controls. Those controls are called "relaxed controls" (see Warga [37], [38]) or "chattering controls" (see Gamkrelidze [22]) or "sliding regimes" (see Filippov [21]) or "generalized curves" (see Young [39]). Here we adopt the name "relaxed control," which is more widely used among mathematicians working in control theory. Having introduced this augmented system, it is natural to ask what the relation is between the set of relaxed trajectories and the set of original trajectories. More precisely, given the fact that under mild assumptions the relaxed problem has a solution, we would like to know whether every relaxed optimal trajectory can be approximated arbitrarily close by trajectories of the original system.

For finite-dimensional control systems this problem has already been studied in the literature. For details we refer to the books of Gamkrelidze [22], Hermes and LaSalle [24], and Warga [38]. For infinite-dimensional systems, where most of the results concern linear systems, the most general of such results appears to be that of Ahmed [2]. However, the main theorem of that paper (Theorem 5.2) has a serious gap in its proof and, in our opinion, is incorrect. Namely, Ahmed [2, p. 262] claims that $y^n \to y$ strongly in the Lebesgue-Bochner space $L^p(E)$ (we use the notation of [2]). However, such a conclusion is not justified from the properties of the sequence $\{y^n\}_{n\geq 1}$ and additional, considerably stronger conditions are eventually needed to get this

strong convergence in $L^p(E)$ (for details, see the results of Brooks and Dinculeanu [8], Castaing [10], and Gutman [23]). After all, it is well known (among people working on differential inclusions; see Aubin and Cellina [4]) that to have a relaxation result (even for finite-dimensional differential inclusions), we must have a Hausdorff-Lipschitz orientor field (unless we are dealing with a semilinear inclusion, in which case the solution admits an integral representation in terms of the evolution operator). Given that a control system, under very general measurability hypotheses, can be written as an equivalent evolution inclusion (deparametrization), to have a relaxation result for the control system, we need the resulting velocity field (i.e., the union of all vector fields over all admissible controls), to be Hausdorff-Lipschitz in the state variable. However, in Ahmed's work [2], which deals with general nonlinear systems, this is not the case. In this paper, by using some recent results on measurable multifunctions obtained in [27], we are able to overcome the difficulties that have appeared in Ahmed's work. In fact, a crucial point in our approach is the relative compactness of the set of original trajectories, which is achieved through appropriate hypotheses on the evolution equation describing the dynamics of the system. Nevertheless, the work of Ahmed [2] is still valuable because it suggests way to address the relaxation problem for infinite-dimensional systems. In this paper, we adopt some of those ideas and techniques which, combined with other tools from different areas, give us two relaxation theorems: one for semilinear and the other for nonlinear infinite-dimensional control systems. We also go beyond Ahmed [2] and study the properties of the set-relaxed trajectories and their dependence on the relaxed controls that generate them. We also prove that, even in the absence of a relaxation result, we can show under mild assumptions on the cost functional that the value of the original optimal control problem equals the value of the one that is relaxed. We conclude with some examples from distributed parameter systems.

2. Preliminaries. Let (Ω, Σ) be a measurable space and X a separable Banach space. Throughout this paper we will be using the following notation:

$$P_{f(c)}(X) = \{A \subseteq X: \text{nonempty, closed, (convex)}\},$$

$$P_{(w)k(c)}(X) = \{A \subseteq X: \text{nonempty, } (w\text{-})\text{compact, (convex)}\}.$$

A multifunction $F: \Omega \to P_f(X)$ is said to be measurable, if for all $z \in X$, $\omega \to d(z, F(\omega)) = \inf\{\|z - x\|: x \in F(\omega)\}$ is measurable. When there is a σ-finite measure $\mu(\cdot)$, with respect to which Σ is complete, the above definition of measurability is equivalent to saying that $\operatorname{Gr} F = \{(\omega, x) \in \Omega \times X: x \in F(\omega)\} \in \Sigma \times B(X)$, where $B(X)$ is the Borel σ-field of X (graph measurability of $F(\cdot)$). We use $S_F^p (1 \leqq p \leqq \infty)$ to denote the set of selectors of $F(\cdot)$ that belong in the Lebesgue-Bochner space $L^p(X)$, i.e., $S_F^p = \{f \in L^p(X): f(\omega) \in F(\omega) \mu\text{-a.e.}\}$. This set may be empty. When $F(\cdot)$ is L^p-integrably bounded (i.e., $F(\cdot)$ is measurable and $\omega \to |F(\omega)\| = \sup\{\|z\|: z \in F(\omega)\} \in L^p\Omega)$), then $S_F^p \neq \varnothing$. Using S_F^1, we can define a set-valued integral for $F(\cdot)$ by setting $\int_\Omega F = \{\int_\Omega f: f \in S_F^1\}$. We also use S_F to denote the set of measurable selectors of $F(\cdot)$.

Let Y, Z be Hausdorff topological spaces and let $G: Y \to 2^Z \setminus \{\varnothing\}$ be a multifunction. We say that $G(\cdot)$ is upper semicontinuous (u.s.c.) (respectively, lower semicontinuous (l.s.c.)), if for all $V \subseteq Z$ open, $G^+(V) = \{y \in Y: G(y) \subseteq V\}$ is open (respectively, $G^-(V) = \{y \in Y: G(y) \cap V \neq \varnothing\}$ is open). Observe that when $G(\cdot)$ is single-valued, then the notions above coincide with the continuity of $G(\cdot)$. If X is a metric space on $P_f(X)$ we can define a metric, known as the Hausdorff metric, by setting: $h(A, B) = \max(\sup[d(a, B), a \in A], \sup[d(b, A), b \in B])$. If X is complete, then so is $(P_f(X), h)$.

Let Z be a separable, complete metric space (i.e., a Polish space) and $B(Z)$ its Borel σ-field. By $M_+^1(Z)$ we will denote the space of probability measures on Z. A

transition probability is a function $\lambda : \Omega \times B(Z) \to [0, 1]$ such that for every $A \in B(Z)$, $\lambda(\cdot, A)$ is Σ-measurable and for every $\omega \in \Omega$, $\lambda(\omega, \cdot) \in M_+^1(Z)$. We use $R(\Omega, Z)$, to denote the set of all transition probabilities from (Ω, Σ, μ) into $(Z, B(Z))$. Following Balder [5] (see also Warga [38]), we can define a topology on $R(\Omega, Z)$ as follows. Let $f : \Omega \times Z \to R$ be a Carathéodory function (i.e., $\omega \to f(\omega, x)$ is measurable, $x \to f(\omega, x)$ is continuous, and $|f(\omega, x)| \leqq \alpha(\omega)$ μ-almost everywhere, with $\alpha(\cdot) \in L^1$) and let $I_f : R(\Omega, Z) \to R$ be defined by $I_f(\lambda) = \int_\Omega \int_Z f(\omega, z)\lambda(\omega)(dz)\, d\mu(\omega)$. The weakest topology on $R(\Omega, Z)$ that makes the above functionals continuous (for any Carathéodory integrand $f(\cdot, \cdot)$) is called the weak topology on $R(\Omega, Z)$. Observe that when Ω is a singleton, then $R(\Omega, Z) = M_+^1(Z)$, and the weak topology just defined is nothing else but the well-known narrow topology on $M_+^1(Z)$ (see Dellacherie and Meyer [17]).

In the rest of this section, for the convenience of the reader, we state without proof (although detailed references are given) some theorems that we will need in the sequel.

We start with the Arzelà-Ascoli Theorem for vector-valued functions. A proof of this result can be found in Carroll [9, Thm. 8.18, p. 34] (see also Lakshmikantham and Leela [28, Thms. 1.15, 1.1.6, p. 5]).

THEOREM 2.1 (Arzelà-Ascoli). *Let Y and Z be Hausdorff topological spaces with Y locally compact. Then $K \subseteq C(Y, Z)$ is relatively compact for the topology of uniform convergence on compacta if and only if K is equicontinuous and for all $y \in Y$, $K(y) = \{f(y) : f \in K\}$ is relatively compact in Z.*

We will use this theorem twice, in the proofs of Theorems 3.1 and 6.1. In the first case $Y = T = [0, b] \subseteq R_+$ and $Z = H$, a separable Hilbert space with the strong (norm) topology. The equicontinuity follows from the fact that the continuous functions in question have an integral representation in terms of an evolution operator $S(t, s)$ that is compact for $t - s > 0$ and hence has nice continuity properties. The pointwise relatively compact range requirement follows from the compactness of $S(t, s)$ for $t - s > 0$ and the Rådström embedding theorem (see below), which tells us that a certain set-valued integral, containing the functions at t translated by $S(t, 0)x_0$, is compact. In the second case (proof of Theorem 6.1), again $Y = T = [0, b]$, while $Z = X_w$ is a separable, reflexive Banach space with weak topology. Here the equicontinuity is a consequence of some a priori estimates that can be deduced from the hypotheses on the data of the problem. On the other hand, the functions are bounded uniformly in t by a constant $\bar{M}$ (see the proof of Theorem 6.1), and in a separable, reflexive Banach space, the closed balls with the weak topology are compact and metrizable. The metrizability then justifies the sequential compactness that we have.

Now let us state the Rådström embedding theorem, which as we say above, will be used in connection with the Arzelà-Ascoli Theorem. The interested reader can find more details in Hiai and Umegaki [25, § 3].

THEOREM 2.2 (Rådström). *Let X be a separable Banach space. The metric space $(P_{kc}(X), h)$ can be embedded as a convex cone in a separable Banach space $\hat{X}$ such that*: (i) *the embedding is isometric*; (ii) *addition in $\hat{X}$ induces addition in $P_{kc}(X)$*; (iii) *multiplication by nonnegative real numbers in $\hat{X}$ induces the corresponding operation in $P_{kc}(X)$.*

This theorem allows us to view integrably bounded multifunctions with values in $P_{kc}(X)$ as $\hat{X}$-valued functions belonging in the Lebesgue-Bochner space $L^1(\hat{X})$. Therefore the set-valued integral of such a multifunction will produce a set in $P_{kc}(X)$.

In some cases we will need to guarantee that the set of admissible controls is nonempty, or to express a selector of the field of velocities as a vector field corresponding

to an admissible control function. This can be done with an application of the so-called "Aumann Selection Theorem." The version presented here is due to Saint-Beuve [33, Thm. 3]. Recall that a Souslin space is a Hausdorff topological space V such that there exists a Polish space W and a continuous map from W onto V (recall that a Polish space is a complete, separable, metrizable space). Clearly every Polish space (for example, a separable Banach space) is Souslin. However, in general, a Souslin space need not be metrizable. Consider, for example, a separable Banach space with the weak topology. This is Souslin but not metrizable.

THEOREM 2.3 (Aumann). *Let (Ω, Σ, μ) be a σ-finite measure space, V a Souslin space, and $F: \Omega \to 2^V \setminus \{\emptyset\}$ a graph-measurable multifunction. Then there exist Σ-measurable functions $f_n: \Omega \to V$ such that $F(\omega) \subseteq \overline{\{f_n(\omega)\}}_{n \geq 1}$ μ-almost everywhere.*

If Σ is μ-complete in the theorem above, then the conclusion will hold for all $\omega \in \Omega$. Finally, if there is no measure μ on (Ω, Σ), then the selectors $f_n(\cdot)$ will be $\hat{\Sigma}$-measurable, where $\hat{\Sigma}$ is the universal σ-field corresponding to Σ.

Another result of measure-theoretic nature that we will need is a "projection theorem," known in the literature as the "Arsenin-Novikov Theorem." The version we present here is due to Dellacherie [16] and Saint-Beuve [34, Thm. 1].

THEOREM 2.4 (Arsenin-Novikov). *Let X, Y be Polish spaces with $B(X)$ and $B(Y)$ the corresponding Borel σ-fields. Let $K \in B(X) \times B(Y)$ be such that for all $x \in X$, $K(x)$ is σ-compact in Y. Then* $\operatorname{proj}_X K \in B(X)$.

Note that instead of $(X, B(X))$, we could have considered any standard measurable space.

In our work (see the proof of Theorem 6.3), $Y = W$, a weakly compact, convex set of a separable Banach space. Recall (see Dunford and Schwartz [19, Thm. 3, p. 434]), that W with the weak topology (denoted by W_w) is metrizable, and hence a Polish space. On the other hand, in that proof we will have $K \in B(X) \times B(W)$. Since $B(W_w) \subseteq B(W)$, to apply the Arsenin-Novikov Theorem, we need to know if equality can hold. This is guaranteed by the following result of Edgar [20, Cor. 2.4]. Recall that a norm $\|\cdot\|$ on a Banach space X is called a "Kadec norm" if and only if the weak and norm topologies of X coincide on $S_X = \{x \in X: \|x\| = 1\}$. We say that X admits a Kadec norm if and only if there is an equivalent norm that is a Kadec norm.

THEOREM 2.5 (Edgar). *Let X be a Banach space that admits a Kadec norm. Let X_w denote the Banach space X with the weak topology. Then $B(X) = B(X_w)$.*

Every weakly compactly-generated Banach space (in particular, every separable Banach space) admits a Kadec norm.

Finally we make a straightforward but nevertheless useful observation. Suppose $T = [0, b] \subseteq R_+$ and Z is a compact Polish space. Then the Carathéodory integrands on $T \times Z$ can be identified with the Lebesgue-Bochner space $L^1(C(Z))$. To see this, associate to each Carathéodory integrand $\phi(\cdot, \cdot)$ the map $t \to \phi(t, \cdot) \in C(Z)$. Now, from the Riesz Representation Theorem we know that $[C(Z)]^* = M(Z)$ is the space of all bounded Borel measures on $B(Z)$. So $M(Z)$ is a separable, dual Banach space and hence has the Radon-Nikodym property. This observation combined with Theorem 1 of Diestel and Uhl [18, p. 98], tells us that $[L^1(C(Z))]^* = L^\infty(M(Z))$. So the weak topology on $R(T, Z)$ coincides with the relative $w^*(L^\infty(M(Z)), L^1(C(Z)))$-topology (see Warga [38]). This fact will be useful in the study of the relaxed control system, where the control functions are transition probabilities.

3. Existence and relaxation results. Let $T = [0, b]$ be closed and bounded. Let H be a separable Hilbert space and X a separable, reflexive Banach space with the following properties: X is dense in H, and the inclusion of X in H is continuous. We

identify H with its dual (pivot space) and denote by X^* the topological dual of X. So $X \hookrightarrow H \hookrightarrow X^*$. By $\|\cdot\|$ (respectively, $|\cdot|$, $\|\cdot\|_*$) we will denote the norm of X (respectively of H, X^*). We also use $(\cdot,\cdot)$ to denote the inner product in H and by $\langle\cdot,\cdot\rangle$ the duality brackets for the dual pair (X, X^*). The two are compatible, i.e., if $x \in X \subseteq H$ and $h \in H \subseteq X^*$, we have $\langle x, h\rangle = (x, h)$. Also as our control space we take Z, a Polish space. We consider the following distributed parameter control system:

$$(*) \qquad \begin{aligned} &\dot{x}(t) + A(t)x(t) = f(t, x(t), u(t)), \\ &x(0) = x_0, \qquad u \in S_U^1. \end{aligned}$$

We will make the following hypotheses concerning the system above:

(H(A)) For $t \in T$, $A(t): X \to X^*$ is such that:
(1) $A(t)(\cdot)$ is linear, monotone;
(2) For every $x \in X$, $t', t \in T$ $\|A(t')x - A(t)x\|_* \leqq k|t' - t|\,\|x\|$, $k > 0$;
(3) $\|A(t)x\|_* \leqq c + c_1\|x\|$ almost everywhere $c_1 > 0$, $c \geqq 0$;
(4) $\langle A(t)x, x\rangle \geqq c_2\|x\|^2$, $c_2 > 0$.

(H(f)) $f: T \times H \times Z \to H$ is a function such that:
(1) $(t, z) \to f(t, x, z)$ is measurable;
(2) $x \to f(t, x, z)$ is continuous;
(3) $|f(t, x, z)| \leqq \alpha(t) + b(t)|x|$ almost everywhere with $\alpha(\cdot)$, $b(\cdot) \in L^2_+$.

(H(U)) $U: T \to 2^Z_{\setminus}\{\varnothing\}$ is graph measurable.

Let $g \in L^2(X^*)$ and consider the following evolution equation:

$$(*)' \qquad \begin{aligned} &\dot{x}(t) + A(t)x(t) = g(t), \\ &\dot{x}(0) = x_0 \in X. \end{aligned}$$

Because of hypothesis (H(A)), from Proposition 5.5.1 of Tanabe [35], we know that $(*)'$ has a unique strong solution belonging in

$$W(T) = \{x(\cdot) \in L^2(X) : \dot{x}(\cdot) \in L^2(X^*)\} \subseteq C(T, H).$$

Furthermore, there exists a strongly continuous evolution operator $S(t, s) \in L(H)$, with respect to which the unique strong solution of $(*)'$ has the following integral representation:

$$x(t) = S(t, 0)x_0 + \int_0^t S(t, s)g(s)\,ds.$$

We make the following hypothesis concerning $S(t, s)$:

(H_c) For all $t > s$, $S(t, s)$ is compact.

Note that because of (H(U)), by Aumann's Selection Theorem (see Theorem 2.3 above), we have that $S_U \neq \varnothing$.

First we will establish the nonemptiness of the set of admissible "state-control" pairs for system $(*)$.

THEOREM 3.1. *If* (H(A)), (H(f)), (H(U)), *and* (H_c) *hold and* $u \in S_U$, *then there exists* $x(u)$, *admissible trajectory of* $(*)$ *corresponding to* $u(\cdot)$.

Proof. First we obtain an a priori bound for the solutions of (∗). Let $x(\cdot)$ be such a strong solution. Since $\|S(t,s)\| \leqq M$ for all $0 \leqq s \leqq t \leqq b$ we have that

$$|x(t)| \leqq M|x_0| + \int_0^t M|f(s, x(s), u(s))|\, ds$$

$$\leqq M|x_0| + \int_0^t M(\alpha(s) + b(s)|x(s)|)\, ds$$

$$\Rightarrow |x(t)| \leqq M(|x_0| + \|\alpha\|_1) + M\int_0^t b(s)|x(s)|\, ds.$$

Applying Gronwall's inequality, for all $t \in T$ we obtain

$$|x(t)| = M(|x_0| + \|\alpha\|_1) \exp M\|b\|_1 = M_2.$$

Now let $\hat{f}: T \times H \times Z \to H$ be defined by

$$\hat{f}(t,x,z) = \begin{cases} f(t,x,z), & |x| \leqq M_2, \\ f(t, (M_2 x/|x|), z), & |x| > M_2. \end{cases}$$

Thus $\hat{f}(t,x,z) = f(t, p_{M_2}(x), z)$, where $p_{M_2}(\cdot)$ is the M_2-radial retraction in H. Recalling that $p_{M_2}(\cdot)$ is Lipschitz continuous, we deduce that $\hat{f}(t,x,z)$ has the same measurability and continuity properties as $f(\cdot,\cdot,\cdot)$, i.e., $(t,z) \to \hat{f}(t,x,z)$ is measurable and $x \to \hat{f}(t,x,z)$ is continuous. Furthermore, $|\hat{f}(t,x,z)| \leqq \varphi(t) = \alpha(t) + b(t)M_2$ almost everywhere, $\varphi(\cdot) \in L^2$.

Let $B(\varphi) = \{g \in L^2(H): |g(t)| \leqq \varphi(t) \text{ a.e.}\} \subseteq L^2(H)$.

Pick $g \in B(\varphi)$ and consider the following evolution equation:

$$(*)(g) \qquad \begin{aligned} &\dot{x}(t) + A(t)x(t) = g(t), \\ &x(0) = x_0. \end{aligned}$$

From Theorem 4.2 of Barbu [6, p. 167], we know that $(*)(g)$ has a unique strong solution in $W(T)$. Let $r: B(\varphi) \to C(T,H)$ be the map that assigns to each $g \in B(\varphi)$ the corresponding unique strong solution of $(*)(g)$. We claim that $r(\cdot)$ is continuous. So let $g_n \xrightarrow{S} g$ in $B(\varphi)$. Then we have

$$r(g_n)(t) = x_n(t) = S(t,0)x_0 + \int_0^t S(t,s)g_n(s)\, ds,$$

$$r(g)(t) = x(t) = S(t,0)x_0 + \int_0^t S(t,s)g(s)\, ds$$

$$\Rightarrow |x_n(t) - x(t)| \leqq M\|g_n - g\|_1 \leqq M\sqrt{b}\|g_n - g\|_2 \to 0$$

$$\Rightarrow x_n \to x \quad \text{in } C(T,H)$$

$$\Rightarrow r(\cdot) \text{ is indeed continuous as claimed.}$$

Now let W be the subset of $C(T,H)$ defined by

$$W = \{r(g) \in C(T,H): g \in B(\varphi)\}.$$

The new claim is that W is compact in $C(T,H)$.

To this end let $x \in W$ and let $t', t \in T$, $t < t'$. We have

$$|x(t') - x(t)| \leqq |S(t',0)x_0 - S(t,0)x_0| + \int_t^{t'} \|S(t',s)\|\,|g(s)|\, ds$$

$$+ \int_0^t \|S(t',s) - S(t,s)\|\,|g(s)|\, ds.$$

Because of the strong continuity of the evolution operator $S(t, s)$, given $\varepsilon > 0$ there exists $\delta_1 > 0$ such that if $|t' - t| < \delta_1$, then

$$|S(t', 0)x_0 - S(t, 0)x_0| < \frac{\varepsilon}{3}.$$

Also

$$\int_t^{t'} \|S(t', s)\| |g(s)| \, ds \leqq M \int_t^{t'} |g(s)| \, ds,$$

and since the Lebesgue integral is absolutely continuous, there exists $\delta_2 > 0$ such that if $|t' - t| < \delta_2$, then

$$M \int_t^{t'} |g(s)| \, ds < \frac{\varepsilon}{3}.$$

Finally, because of hypothesis (H_c), from Proposition 2.1 of [30], we know that $t \to S(t, s)$ is continuous in the operator norm topology, uniformly for all $s \in (0, t)$ such that $t - s$ is bounded away from zero. So let $\delta_3 > 0$ such that

$$\int_{t-\delta_3}^{t'} \|S(t', s) - S(t, s)\| |g(s)| \, ds \leqq 2M \int_{t-\delta_3}^{t} |g(s)| \, ds < \frac{\varepsilon}{6}.$$

Also we can find $\delta_4 > 0$ such that for $|t' - t| < \delta_4$ we have

$$\int_0^{t-\delta_3} \|S(t', s) - S(t, s)\| |g(s)| \, ds < \frac{\varepsilon}{6}.$$

So, finally, for $\delta = \min(\delta_1, \delta_2, \delta_3, \delta_4)$ and for $|t' - t| < \delta$, $x(\cdot) \in W$, we have $|x(t') - x(t)| < \varepsilon \Rightarrow W$ is equicontinuous. Also note that $s \to S(t, s)B(\varphi)(s)$ is a measurable, and, due to hypothesis $(H_{c'})$, a $P_{kc}(H)$-valued multifunction. Thus, using Rädström's Embedding Theorem (see Theorem 2.2 in this paper), we have that for all $x \in W$ and all $t \in T$, $x(t) \in S(t, 0)x_0 + \int_0^t S(t, s)B(\varphi)(s) \, ds \in P_{kc}(H)$. Finally it remains to show that W is closed in $C(T, H)$. Let $x_n \to x$ in $C(T, H)$ $x_n \in W$. Then we have

$$x_n(t) = S(t, 0)x_0 + \int_0^t S(t, s)g_n(s) \, ds, \qquad g_n \in B(\varphi).$$

Note that since $L^2(H)$ is Hilbert, $B(\varphi)$ is sequentially w-compact. So by passing to a subsequence if necessary, we may assume that $g_n \xrightarrow{w} g \in B(\varphi)$ in $L^2(H)$ (Alaoglu's Theorem). Then we have

$$\int_0^t S(t, s)g_n(s) \, ds \xrightarrow{w} \int_0^t S(t, s)g(s) \, ds$$

$$\Rightarrow x(t) = S(t, 0)x_0 + \int_0^t S(t, s)g(s) \, ds$$

$$\Rightarrow x = r(g) \in W$$

$$\Rightarrow W \text{ is closed.}$$

Therefore, invoking the Arzelà-Ascoli Theorem, we get that W is compact in $C(T, H)$. Let $F: W \to L^2(H)$ be defined by

$$F(y)(\cdot) = \hat{f}(\cdot, y(\cdot), u(\cdot)).$$

Exploiting the continuity of $y \to \hat{f}(t, y, z)$, through the dominated convergence theorem we get that $F(\cdot)$ is continuous. Furthermore, note that for every $y \in W$, $F(y) \in B(\varphi)$. Then let $k: W \to W$ be defined by $k = r \circ F$. Clearly $k(\cdot)$ is continuous. Applying Schauder's Fixed-Point Theorem to get $x \in W$ such that $k(x) = x \Rightarrow x(\cdot)$, we solve $(*)(g)$ with $g(t) = \hat{f}(t, x(t), u(t))$. As in the beginning of the proof, through Gronwall's inequality, we get that $|x(t)| \leqq M_2 \Rightarrow \hat{f}(t, x(t), u(t)) = f(t, x(t), u(t)) \Rightarrow x(\cdot)$ is the desired admissible trajectory of $(*)$. □

As we mentioned in the Introduction, to solve optimization problems involving $(*)$ and obtain optimal admissible pairs, we need some kind of convexity hypothesis on the orientor field $f(t, x, U(t))$. Here we drop this convexity hypothesis and instead pass on to a larger system with measure controls, known as "relaxed controls." This then raises the fundamental question of how much we enlarged the set of trajectories of the original system. The next theorem answers this question by stating that this process does not essentially alter the original solution set.

First let us introduce this new, larger system, known as the "relaxed system":

$$(*) \qquad \begin{aligned} &\dot{x}(t) + A(t)x(t) = \int_Z f(t, x(t), z)\lambda(t)(dz), \\ &x(0) = x_0, \qquad \lambda \in S_\Sigma. \end{aligned}$$

Here $\Sigma(t) = \{\lambda \in M_+^1(Z): \lambda(U(t)) = 1\}$ and S_Σ is the set of transition probabilities that are selectors of $\Sigma(\cdot)$. We will denote the set of trajectories of $(*)_r$ by P_r and those of $(*)$ by P. Note that since $\delta(U(t)) \subseteq \Sigma(t)$, we have $P \subseteq P_r$ and if the hypotheses of Theorem 3.1 are satisfied, $P \neq \varnothing \Rightarrow P_r \neq \varnothing$. More specifically, given any relaxed control $\lambda \in S_\Sigma$, if we set $\bar{f}(t, x(t), \lambda(t)) = \int_Z f(t, x(t), z)\lambda(t)(dz)$, then working as in the proof of Theorem 3.1, we can show that there exists a relaxed admissible trajectory $x(\lambda)(\cdot)$, corresponding to λ.

To get a useful relation between P and P_r, we need the following stronger hypotheses.

$(\mathrm{H(f)}_1)$ $f: T \times H \times Z \to H$ is a function such that:

(1) $t \to f(t, x, z)$ is measurable;

(2) $x \to -f(t, x, z)$ is continuous, monotone;

(3) $(x, z) \to f(t, x, z)$ is continuous from $H \times Z$ into H_w;

(4) $|f(t, x, z)| \leqq \alpha(t) + b(t)|x|$ almost everywhere, with $\alpha(\cdot)$, $b(\cdot) \in L_+^2$.

$(\mathrm{H(U)}_1)$ $U: T \to P_f(Z)$ is a measurable multifunction.

THEOREM 3.2. *If hypotheses* (H(A)), $(\mathrm{H(f)}_1)$, $(\mathrm{H(U)}_1)$, *and* $(\mathrm{H_c})$ *hold and Z is a compact Polish space then $\varnothing \neq \bar{P} = P_r$ and the set is convex (the closure is taken in $C(T, H)$).*

Proof. From Theorem 3.1 we know that $P \neq \varnothing$ and clearly $P \subseteq P_r$. Take $y \in P_r$ and for $s \in T$ set

$$K(s) = \{f(s, y(s), u): u \in U(s)\},$$

$$K_r(s) = \left\{\bar{f}(s, y(s), \lambda) = \int_Z f(s, y(s), z)\lambda(dz): \lambda \in \Sigma(s)\right\}.$$

Our claim is that $K_r(s) = \overline{\mathrm{conv}}\, K(s)$. Because Z is compact, it is easy to check that $K_r(s) \in P_{fc}(H)$. Thus, since $\delta(U(s)) \subseteq \Sigma(s)$, we get that $\overline{\mathrm{conv}}\, K(s) \subseteq K_r(s)$. On the other hand, let $v \in K_r(s)$. Then

$$v = \int_Z f(t, y(s), z)\lambda(dz)$$

for some $\lambda \in \Sigma(s)$. From Theorem 12.11 of Choquet [14] (see also Corollary 3 of Balder [5]), we know that there exist $\delta(u_n(s))$ and $\lambda_n \in [0, 1]$ such that $\sum_{k=1} \lambda_k \delta(u_k(s)) = \mu_n \to \lambda$ in the narrow topology. So we have that

$$\int_Z f(s, y(s), z)\mu_n(s)(dz) = \sum_{k=1}^{n} \lambda_k f(s, y(s), u_k(s)) \xrightarrow{w} \int_Z f(s, y(s), z(dz))$$
$$= \bar{f}(s, y(s), \lambda)$$
$$\Rightarrow \overline{\text{conv}}\, K(s) \supseteq K_r(s)$$
$$\Rightarrow \overline{\text{conv}}\, K(s) = K_r(s).$$

Also note that if $\{u_n(\cdot)\}_{n \geq 1}$ is a Castaing representation of the measurable multifunction $U(\cdot)$ (see Wagner [36]), then because of $\text{H(f)}_1(1)$ we have that

$$K(s) = \text{cl}\{f(s, y(s), u_n(s)) : n \geq 1\}.$$

Because of (H(f)_1) (1) and (2), for every $n \geq 1$, $s \to f(s, y(s), u_n(s))$ is measurable $\Rightarrow$ $s \to K(s)$ is a measurable $P_{wk}(H)$-valued multifunction (recall that Z is compact and $f(t, y(t), \cdot)$ is continuous from Z into H_w). Invoking the Krein-Smulian Theorem (see Diestel and Uhl [18, Thm. 11, p. 51]), we deduce that $s \to \overline{\text{conv}}\, K(s)$ is a $P_{wkc}(H)$-valued, measurable multifunction. Now from Corollary II of [27] we know that $\overline{S^1_K}^w = S^1_{K_r}$.

From Proposition 3.1 of [31] we know that $S^1_{K_r}$ is w-compact in $L^1(H)$, and since the space is separable, we deduce that the weak topology on $S^1_{K_r}$ is metrizable. Note that $g(\cdot) = \bar{f}(\cdot, y(\cdot), \lambda(\cdot)) \in S^1_{K_r}$. So according to the above, we can find $g_n \in S^1_K$ such that $g_n \xrightarrow{w} g$, $g_n \in S^1_K$. A simple application of the Aumann Selection Theorem gives us $u_n \in S^1_U$ such that $g_n(s) = f(s, y(s), u_n(s))$ almost everywhere. Let $x_n(\cdot)$ be the original trajectories corresponding to the control functions $u_n(\cdot)$. From the proof of Theorem 3.1, we know that $\{x_n(\cdot)\}_{n \geq 1}$ is relatively compact in $C(T, H)$, and so, by passing to a subsequence if necessary, we may assume that $x_n \to x$ in $C(T, H)$.

Now, note that

$$\frac{d}{dt}|y(s) - x_n(s)|^2 = 2\langle \dot{y}(s) - \dot{x}_n(s), y(s) - x_n(s)\rangle$$
$$= 2\langle -A(s)y(s) + \bar{f}(s, y(s), \lambda(s)) + A(s)x_n(s)$$
$$- f(s, x_n(s), u_n(s)), y(s) - x_n(s)\rangle.$$

Exploiting the monotonicity of $A(s)(\cdot)$, we get

$$\frac{d}{dt}|y(s) - x_n(s)|^2 \leq 2\langle \bar{f}(s, y(s), \lambda(s)) - f(s, x_n(s), u_n(s)), y(s) - x_n(s)\rangle.$$

Integrating both sides we get

$$|y(t) - x_n(t)|^2 \leq 2\int_0^t \langle \bar{f}(s, y(s), \lambda(s)) - f(s, y(s), u_n(s)), y(s) - x_n(s)\rangle\, ds$$
$$+ 2\int_0^t \langle f(s, y(s), u_n(s)) - f(s, x_n(s), u_n(s)), y(s) - x_n(s)\rangle\, ds.$$

Exploiting the dissipativity property of $f(t, \cdot, z)$, we get that the second integral is less or equal to zero. So

$$|y(t) - x_n(t)|^2 \leq 2((g - g_n, y - x_n))$$

where $((\cdot,\cdot))$ denotes the duality brackets for the pair $(L^1(H), L^\infty(H))$. Recall that $g_n \xrightarrow{w} g$ in $L^1(H)$, while $y - x_n \xrightarrow{s} y - x$ in $L^\infty(H)$. Therefore

$$\begin{aligned}
&((g - g_n, y - x_n)) \to 0\\
&\Rightarrow |y(t) - x_n(t)|^2 \to |y(t) - x(t)|^2 = 0 \quad \text{for all } t \in T,\\
&\Rightarrow y = x, \quad \text{i.e.,} \quad y \in \bar{P} \quad \text{(the closure in } C(T, H)).
\end{aligned}$$

Finally we will show that P_r is closed in $C(T, H)$. So let $y_n \to y$ in $C(T, H)$, $y_n \in P_r$. By definition we have

$$y_n(t) = S(t, 0)x_0 + \int_0^t S(t, s)\bar{f}(s, y_n(s), \lambda_n(s))\, ds, \qquad y_n \in S_\Sigma.$$

From Theorem V-1 of Castaing and Valadier [11] we know that S_Σ is w^*-compact in $L^\infty(M(Z))$. Since this topology on S_Σ is metrizable (see Dunford and Schwartz [19, Thm. 1, p. 426]), by passing to a subsequence if necessary, we may assume that $\lambda_n \xrightarrow{w} \lambda$ in $L^\infty(M(Z))$. Then using Theorem 3.1 of Jawhar [26], we get that

$$\begin{aligned}
&y_n(t) \xrightarrow{w} y(t) = S(t, 0)x_0 + \int_0^t S(t, s)\bar{f}(s, y(s), \lambda(s))\, ds, \qquad \lambda \in S_\Sigma\\
&\Rightarrow y \in P_r\\
&\Rightarrow P_r \quad \text{is closed in } C(T, H)\\
&\Rightarrow \bar{P} = P_r \quad \text{in } C(T, H)
\end{aligned}$$

and it is clear that P_r is convex. □

Remarks. Scrutinizing the proof above, we can see that instead of the dissipativity hypothesis on $x \to f(t, x, z)$, we could have assumed that $x \to f(t, x, z)$ is Lipschitz continuous. Also it is clear now that the attainable set of $(*)$ is dense in that of $(*)_r$.

4. Relaxed trajectories. We start with a result describing the dependence of the relaxed trajectories on the relaxed controls that generate them.

Such a continuity result gives us valuable information about the topological structure of the set of relaxed trajectories and is an indispensable tool in establishing the existence of optimal "state-control" pairs in various optimal control problems (see § 5).

From § 3 we know that, given $\lambda \in S_\Sigma$, there exists a unique relaxed trajectory $x(\lambda)$ corresponding to it (uniqueness follows from the dissipativity hypothesis on $f(t, \cdot, u)$; see hypothesis $(\mathrm{H(f)_1})(2)$). In the next theorem we examine the continuity properties of the map $\lambda \to x(\lambda)$ from $S_\Sigma \subseteq R(T, Z)$ into $C(T, H)$.

THEOREM 4.1. *If hypotheses* (H(A)), $(\mathrm{H(f)_1})$, $(\mathrm{H(U)_1})$, *and* $(\mathrm{H_c})$ *hold and Z is compact, then $\lambda \to x(\lambda)$ is continuous from $S_\Sigma \subseteq R(T, Z)$ into $C(T, H)$.*

Proof. By identifying the Carathéodory integrands with the separable Banach space $L^1(C(Z))$, we see that the $R(T, Z)$-topology on S_Σ coincides with the relative $w^*(L^\infty(M(Z)), L^1(C(Z)))$ topology (recall that $(L^1(C(Z))^* = L^\infty(M(Z)))$ and the latter is metrizable). So we will work with sequences. Let $\lambda_n \to \lambda$ in $R(T, Z) \Rightarrow \lambda_n \xrightarrow{w^*} \lambda$. By definition we have

$$x_n(t) = S(t, 0)x_0 + \int_0^t \int_Z S(t, s)f(x, x_n(s), z)\lambda_n(s)(dz)\, ds.$$

Let $h \in H$. We have

$$(h, x_n(t)) = (h, S(t, 0)x_0) + \int_0^t (g(h)(s, x_n(s), \cdot), \lambda_n(s))_0\, ds$$

where $g(h)(s, x_n(s), \cdot) = (h, S(t, s)f(s, x_n(s), \cdot)) \in C(Z)$ and $(\cdot, \cdot)_0$ denotes the duality brackets for the pair $(C(Z), M(Z))$. We may assume that $x_n(\cdot) \to x(\cdot)$ in $C(T, H)$.

Note that $\sup\{|(h, S(t, s)(f(s, x_n(s), z) - f(s, x(s), z)))| : z \in Z\} = |(h, S(t, s)(f(s, x_n(s), z_n) - f(s, x(s), z_n)))|$, for some $z_n \in Z$ depending on (h, t, s). Since Z is compact, by passing to a subsequence if necessary we may assume that $z_n \to z$. Then from hypothesis $(\mathrm{H(f)}_2)(3)$ we have that

$$|(h, S(t, s)(f(s, x_n(s), z_n) - f(s, x(s), z)))| \to 0$$

$$\Rightarrow g(h)(s, x_n(s), \cdot) \to g(h)(s, x(s), \cdot) \quad \text{in } C(Z)$$

$$\Rightarrow g(h)(\cdot, x_n(\cdot), \cdot) \to g(h)(\cdot, x(\cdot), \cdot) \quad \text{in } L^1(C(Z))$$

because of the dominated convergence theorem. Since $\lambda_n \xrightarrow{w^*} \lambda$ in $L^\infty(M(Z)) = [L^1(C(Z))]^*$, we get

$$\int_0^t (g(h)(s, x_n(s), \cdot), \lambda_n(s))_0 \, ds \to \int_0^t (g(h)(s, x(s), \cdot), \lambda(s))_0 \, ds.$$

Thus in the limit we have

$$(h, x(t)) = (h, S(t, 0)x_0) + \left(h, \int_0^t \int_Z S(t, s)f(s, x(s), z)\lambda(s)(dz)\, ds\right)$$

$$\Rightarrow x(t) = S(t, 0)x_0 + \int_0^t S(t, s) \int_Z f(s, x(s), z)\lambda(s)(dz)\, ds$$

$$\Rightarrow x = x(\lambda)$$

$$\Rightarrow \lambda \to x(\lambda) \text{ is continuous on } S_\Sigma \subseteq R(T, Z) \text{ as claimed.} \qquad \square$$

An immediate, interesting consequence of Theorem 4.1 is the following theorem.

THEOREM 4.2. *If the hypotheses of Theorem* 4.1 *hold, then P_r is compact in $C(T, H)$.*

Proof. Recall that S_Σ is w^*-compact in $L^\infty(M(Z))$ and is weakly compact in $R(T, Z)$, and the map $\lambda \to x(\lambda)$ is continuous (Theorem 4.1). Therefore $x(S_\Sigma) = P_r$ is compact in $C(T, H)$.

Remark. We could have deduced Theorem 4.2 from the proofs of Theorems 3.1 and 3.2, where we say that P_r is closed in $C(T, H)$ and lives inside a compact subset of $C(T, H)$.

5. Optimal control problems. As we have already mentioned, the introduction of the larger relaxed system, guarantees the existence of an optimal solution. This is illustrated by the following general result.

Consider the relaxed control system $(*)_r$, with the following cost functional:

$$J_r(x, \lambda) = \int_0^b \int_Z L(t, x(t), z)\lambda(t)(dz)\, dt.$$

We will make the following hypotheses concerning the integrand $L(\cdot, \cdot, \cdot)$:

(H(L)) $L: T \times X \times Z \to \bar{R} = R \cup \{+\infty\}$:

(1) $(t, x, z) \to L(t, x, z)$ is measurable,

(2) $(x, z) \to L(t, x, z)$ is l.s.c.,

(3) $\psi(t) \leqq L(t, x, z)$ almost everywhere, with $\psi(\cdot) \in L^1$.

Let $m_r = \inf\{J_r(x, u) : (x, u) \in A_r(x_0)\}$, where $A_r(x_0)$ is the set of relaxed admissible pairs.

THEOREM 5.1. *If hypotheses* (H(A)), (H(f)$_1$), (H(U)$_1$), (H$_c$), *and* (H(L)) *hold and* Z *is compact, then there exists* $(x, \lambda) \in A_r(x_0)$ *such that* $m_r = J_r(x, \lambda)$.

Proof. Let $\{(x_n, \lambda_n)\}_{n \geq 1}$ be a minimizing sequence in $A_r(x_0)$. Recall that S_Σ is w^*-compact in $L^\infty(M(Z))$ and because of the metrizability of this relative w^*-topology ($(L^1(C(Z))$ being separable), by passing to a subsequence if necessary, we may assume that $\lambda_n \overset{w^*}{\to} \lambda$. Identifying as before $L^1(C(Z))$ with the space of Carathéodory integrands, we see that $\lambda_n \to \lambda$ in $R(T, Z)$ with the weak topology. Applying Theorem 4.1 we get that $x(\lambda_n) = x_n \to x(\lambda) = x$ in $C(T, H)$. Recalling that every lower semicontinuous measurable integrand is the limit of an increasing sequence of Carathéodory integrands, from the definition of the weak topology on $R(T, Z)$ (see also Balder [5] and Jawhar [26]), we have that

$$\underline{\lim}\, J_r(x_n, \lambda_n) \geq \int_0^b \int_Z L(t, x(t), z)\lambda(t)(dz)\, dt$$

$$\Rightarrow m_r \geq J(x, \lambda).$$

But $(x, \lambda) \in A_r(x_0)$. Therefore, $m_r = J(x, \lambda)$ as claimed by the theorem. □

Remark. If $J(x, u) = \int_0^b L(t, x(t), u(t))\, dt$ is the cost functional for the original system and $m = \inf\{J(x, u) : (x, u) \in A(x_0)\}$, the value of the corresponding optimization problem, then if the cost functional is upper semicontinuous on $C(T, H) \times R(T, Z)$, the space $R(T, Z)$ endowed the weak topology, then, because of the density result proved in Theorem 3.2, we have that $m = m_r$.

Here is a more general situation, for which this equality of the values of the two problems is still true.

We will need the following stronger hypotheses on $L(\cdot, \cdot, \cdot)$.

(H(L)$_1$) $L : T \times X \times Z \to R$ is an integrand such that:
(1) $t \to L(t, x, z)$ is measurable;
(2) $(x, z) \to L(t, x, z)$ is continuous;
(3) $|L(t, x, z)| \leq \psi_1(t) + \psi_2(t) r(x)$ almost everywhere, with $\psi_1(\cdot), \psi_2(\cdot) \in L^1$ and $r : X \to R$ bounded.

THEOREM 5.2. *If hypotheses* (H(A)), (H(f)$_1$), (H(U)$_1$), (H$_c$), *and* (H(L)$_1$) *hold and* Z *is compact, then there exists* $(x, \lambda) \in A_r(x_0)$ *such that* $J_r(x, \lambda) = m_r$ *and* $m = m_r$.

Proof. From Theorem 5.1 we know that there exists $(x, \lambda) \in A_r(x_0)$ such that

$$m_r = J_r(x, \lambda).$$

Note that we always have $m_r \leq m$. On the other hand, using Corollary 3 of Balder [5], we can find $u_n \in S_U$ such that $\delta(u_n) \to \lambda$ in $R(T, Z)$ with the weak topology. Then from hypothesis (H(L)$_1$) we have that

$$\int_0^b L(t, x(t), u_n(t))\, dt \to \int_0^b \int_Z L(t, x(t), z)\lambda(t)(dz)\, dt = m_r$$

$$\Rightarrow m \leq m_r$$

$$\Rightarrow m = m_r.$$ □

We conclude this section with a time optimal control problem. So let $V : T \to P_f(H)$ be a moving target set that is u.s.c. from T into H_w. Our goal is to reach $V(\cdot)$ in minimum time. We will make the following controllability type hypothesis: $\{t \in T : V(t) \cap P_r(t) \neq \emptyset\} \neq \emptyset$.

THEOREM 5.3. *If the hypotheses of Theorem* 4.2 *hold, then there exists a time-optimal relaxed control.*

Proof. Let $\tau = \inf\{t \in T : V(t) \cap P_r(t) \neq \varnothing\}$. Let $t_n \downarrow \tau$. Then there exist $x_n \in P_r$ such that $x_n(t_n) \in V(t_n) \cap P_r(t_n)$. Using Theorem 4.2 and passing to a subsequence, we may assume that $x_n \to x \in P_r \Rightarrow x_n(t_n) \to x(\tau) \in P_r(\tau)$. Also $x(\tau) \in w - \overline{\lim}\, V(t_n) \subseteq V(\tau) \Rightarrow x(\tau) \in V(\tau) \cap P_r(\tau)$. Let $\lambda \in S_\Sigma$ be the relaxed control that generates x. This is the desired relaxed time-optimal control. □

6. Nonlinear evolution equations. We can also have a relaxation result for evolution equations that is more general than the results for semilinear equations considered in the previous sections.

Let (X, H, X^*) be a Gelfand triple of spaces as before and let Z be a separable Banach space (control space). Consider the following nonlinear, infinite-dimensional control system:

$$(**) \qquad \begin{aligned} &\dot{x}(t) + A(t, x(t), u(t)) = 0, \\ &x(0) = x_0, \qquad u \in S^1_U. \end{aligned}$$

By P we will denote the set of admissible trajectories of (**).

We will need the following hypotheses.

$(\mathrm{H(A)}_1)$ $A : T \times X \times Z \to X^*$ is an operator such that:

(1) $t \to A(t, x, z)$ is measurable;

(2) $(x, z) \to A(t, x, z)$ is sequentially weakly continuous;

(3) $x \to A(t, x, z)$ is monotone;

(4) $\|A(t, x, z)\|_* \leqq \alpha(t) + c_1\|x\|^{p-1}$ almost everywhere, with $\alpha \in L^q$,

$$c_1 > 0, \quad 1 < p < \infty, \quad 1/p + 1/q = 1;$$

(5) $\langle A(t)x, x\rangle \geqq c_2\|x\|^p$ almost everywhere, with $c_2 > 0$.

$(\mathrm{H(U)}_2)$ $U : T \to P_{wkc}(X)$ is integrably bounded.

The first theorem describes the topological properties of P. Its proof is based on a pair of simple lemmata that produce some a priori bounds implied by hypotheses $(\mathrm{H(A)}_1)$.

LEMMA 6.1. *If hypotheses* $(\mathrm{H(A)}_1)$ *and* $(\mathrm{H(U)}_2)$ *hold and* $x_0 \in X$, *then* P *is relatively weakly compact in* $L^p(X)$.

Proof. From Barbu [6], we know that $P \neq \varnothing$. Let $x(\cdot) \in P$. We have

$$\langle \dot{x}(t), x(t)\rangle = \langle -A(t, x(t), u(t)), x(t)\rangle \quad \text{a.e.}, \qquad u \in S^1_U$$

$$\Rightarrow \frac{d}{dt}|x(t)|^2 + 2\langle A(t, x(t), u(t)), x(t)\rangle = 0 \quad \text{a.e.}$$

Because of hypotheses $(\mathrm{H(A)}_1)(1)$ and (2), $t \to \langle A(t, x(t), u(t)), x(t)\rangle$ is measurable. So integrating and using hypothesis $(\mathrm{H(A)}_1)(5)$ we get

$$|x(b)|^2 - |x_0|^2 + c_2\|x\|_p^p \leqq 0$$

$$\Rightarrow P \text{ is bounded in } L^p(X).$$

But $L^p(X)$ is reflexive, since X is. So from Alaoglu's theorem we get the conclusion of the lemma. □

As before, we can have a compactness result for the set of admissible velocities of (**). Let us denote this set by the suggestive notation $\dot{P}$.

LEMMA 6.2. *If hypotheses* $(H(A)_1)$ *and* $(H(U)_2)$ *hold and* $x_0 \in X$, *then* $\dot{P}$ *is relatively weakly compact in* $L^q(X^*)$.

Proof. Recall that $P \subseteq W(T) \Rightarrow \dot{P} \subseteq L^q(X^*)$. Let $v \in L^p(X)$. Then for $x \in P$ we have

$$\int_0^b \langle \dot{x}(t), v(t) \rangle \, dt = \int_0^b -\langle A(t, x,(t), u(t)), v(t) \rangle \, dt$$

$$\leqq \int_0^b \|A(t, x(t), u(t))\|_* \|v(t)\| \, dt.$$

Applying Hölder's inequality and using hypothesis (H(A))(4), we get

$$\int_0^b \|A(t, x(t), u(t))\|_* \|v(t)\| \, dt \leqq \left[\int_0^b \|A(t, x(t), u(t))\|_*^q \, dt \right]^{1/q} \cdot \|v\|_p$$

$$\leqq \left[\int_0^b (\alpha(t) + c_1 \|x(t)\|^{p-1})^{p/(p-1)} \right]^{1/q} \cdot \|v\|_p$$

$$\leqq \left(\|\alpha\|_q^q + c_1 \|x\|_p^p \right)^{1/q} \cdot \|v\|_p.$$

But from Lemma 3.1 we know that $\sup \{\|x\|_p : x \in P\} \leqq M < \infty$. Hence we get

$$((\dot{x}, v)) \leqq [\|\alpha\|_q^q + c_1 M^p]^{1/q} \|v\|_p$$

where $((\cdot, \cdot))$ denotes the duality brackets between $L^p(X)$ and $L^q(X^*)$. Therefore, we finally have that

$$\sup \{((\dot{x}, v)) : \|v\|_p \leqq 1\} = \|\dot{x}\|_q \leqq [\|\alpha\|^q + c_1 M^p]^{1/q} = M_0 < \infty$$

$$\Rightarrow \dot{P} \text{ is bounded in } L^q(X^*)$$

$$\Rightarrow \dot{P} \text{ is relatively weakly compact in } L^q(X^*). \qquad \square$$

Now we are ready for the theorem on the topological properties of P. A result of Ahmed and Teo [3] is similar but concerns a smaller class of nonlinear systems with more restrictive hypotheses.

THEOREM 6.1. *If hypotheses* $(H(A)_1)$ *and* $(H(U)_2)$ *hold and* $x_0 \in X$ *then* P *is relatively sequentially compact in* $C(T, X_w)$.

Proof. Let $R = \{y \in L^q(X^*) : \int_A y(s) \, ds \in X \text{ for all } A \subseteq T, \text{ Lebesgue measurable}\}$. Clearly R is a linear subspace of $L^q(X^*)$. Let $\{y_n\}_{n \geqq 1} \subseteq R$, $y_n \xrightarrow{s} y$ in $L^q(X^*)$.

Then for every $x \in X$ we have

$$\int_0^b \langle \chi_A(s)x, y_n(s) \rangle \, ds \to \int_0^b \langle \chi_A(s)x, y(s) \rangle \, ds,$$

$$\left\langle x, \int_A y_n(s) \, ds \right\rangle \to \left\langle x, \int_A y(s) \, ds \right\rangle.$$

Since $X \hookrightarrow H \hookrightarrow X^*$ with all injections continuous and dense, we deduce that $\int_A y_n(s) \, ds \xrightarrow{w} \int_A y(s) \, ds$ in X. But X, being reflexive, is w-complete. So for all $A \subseteq T$ Lebesgue measurable, we have $\int_A y(s) \, ds \in X \Rightarrow y \in R \Rightarrow R$ is a reflexive, separable Banach space in $L^q(X^*)$.

Next, for $A \subseteq T$ Lebesgue measurable, consider the linear operator $K(A) : R \to X$ defined by

$$K(A)(y) = \int_0^b \chi_A(t) y(t) \, dt.$$

For every $x^* \in X^*$, we see that $y \to \langle x^*, K(A)(y)\rangle$ is a continuous linear functional on R. Thus we can find $g(x^*)(\cdot) \in L^p(X)$ such that

$$\langle x^*, K(A)(y)\rangle \int_A \langle g(x^*)(s), y(s)\rangle \, ds \leqq \left[\int_A \|g(x^*)(s)\|^p \, ds\right]^{1/p} \|y\|_p.$$

Also, since $x \in P$, is X^*-absolutely continuous and so from Diestel and Uhl [18, p. 217], we have that

$$x(t+h) - x(t) = \int_t^{t+h} \dot{x}(s) \, ds$$

and because $x_0 \in X$, we get $x \in R$. Then if we set $A = [t, t+h]$ we have

$$\begin{aligned}\langle x^*, x(t+h) - x(t)\rangle &= \langle x^*, K(A)(\dot{x})\rangle \\ &\leqq \left[\int_t^{t+h} \|g(x^*)(s)\|^p \, ds\right]^{1/p} \|\dot{x}\|_q\end{aligned}$$

and since, by Lemma 6.2, $\dot{P}$ is $L^q(X^*)$-bounded, we deduce that P is w-equicontinuous.

Furthermore, for every $t \in T$ and every $x \in P$, we have

$$|\langle x^*, x(t)\rangle| \leqq \|x_0\| \|x^*\| + \left[\int_0^b \|g(x^*)(s)\|^p \, ds\right]^{1/p} |\dot{P}| \leqq \bar{M}.$$

From the uniform boundedness principle, we get that for all $t \in T$ and all $x \in P$, $x(t) \in B(0, \bar{M}) = \{z \in X : \|z\| \leqq M\}$, which is w-compact. So invoking the Arzelà-Ascoli Theorem (see Theorem 2.1 in this paper and Theorem 1.1.6 of [28]), we have that P is relatively sequentially compact in $C(T, X_w)$. □

To system (**) we associate the following relaxed system:

$$(**) \qquad \begin{aligned} &\dot{x}(t) + \int_Z A(t, x(t), z)\lambda(t)(dz) = 0, \\ &x(0) = x_0, \qquad \lambda \in S_\Sigma \end{aligned}$$

where as before, $\Sigma(t) = \{\lambda \in M_+^1(Z) : \lambda(U(t)) = 1\}$ and S_Σ are the transition probabilities that are selectors of $\Sigma(\cdot)$.

We will need the following stronger version of hypothesis $(\mathrm{H(U)}_2)$.

$(\mathrm{H(U)}_3)$ $U : T \to P_{fc}(Z)$ is measurable and $U(t) \subseteq W$ almost everywhere with $W \in P_{wkc}(Z)$.

Recall (see Dunford and Schwartz [9, Thm. 3, p. 434]) that the weak topology on W is metrizable. So W with the weak topology is a compact Polish space.

By P_r we will denote the set of trajectories of $(**)_r$. Clearly $P \subseteq P_r$. As we did for P, we can have that P_r is relatively sequentially compact in $C(T, X_w)$. In fact we can say more.

THEOREM 6.2. *If hypotheses* $(\mathrm{H(A)}_1)$ *and* $(\mathrm{H(U)}_3)$ *hold and* $x_0 \in X$, *then* P_r *is sequentially compact in* $C(T, X_w)$.

Proof. It suffices to show that P_r is sequentially closed in $C(T, X_w)$. Let $x_n \to x$ in $C(T, X_w)$ with $x_n \in P_r$. We have

$$\dot{x}_n(t) + \int_Z A(t, x_n(t), z)\lambda_n(t)(dz) = 0, \qquad \lambda_n \in S_\Sigma.$$

Since W with the weak topology is a compact Polish space, Theorem V-2 of Castaing and Valadier [11] tells us that S_Σ is w^*-compact in $L^\infty(M(Z))$ (recall that $L^\infty(M(Z)) = (L^1(C(Z)))^*$). So by passing to a subsequence we may assume that $\lambda_n \xrightarrow{w} \lambda$. Then we have

$$x_n(t) - x_0 + \int_0^t \int_W A(s, x_n(s), z)\lambda_n(s)(dz)\, ds$$

$$\xrightarrow{w} x(t) - x_0 + \int_0^t \int_W A(s, x(s), z)\lambda(s)(dz)\, ds$$

$$\Rightarrow x \in P_r$$

$$\Rightarrow P_r \text{ is sequentially compact in } C(T, X_w). \qquad \square$$

Next we prove a relaxation result, involving the sets P and P_r. For this we will need the following stronger version of hypothesis $(\mathrm{H(A)}_1)$.

$(\mathrm{H(A)}_2)$ $A(t, x, z) = A(t, x) - f(t, x, z)$ where $A: T \times X \to X^*$ satisfies $(\mathrm{H(A)}_1)$ (without z) and $f: T \times H \times Z \to H$ satisfies $(\mathrm{H(f)}_1)(1)$, (3), (4) and

(6) $|f(t, x', z) - f(t, x, z)| \leqq k(t)|x' - x|$ almost everywhere, with $k(\cdot) \in L^1_+$.

Also recall that if $f \in L^1(H)$, the weak norm of $f(\cdot)$ is defined by $\|f\|_w = \sup\{\|\int_t^{t'} f(s)\, ds\| : t', t \in T\}$.

THEOREM 6.3. *If hypotheses* $(\mathrm{H(A)}_2)$ *and* $(\mathrm{H(U)}_3)$ *hold,* $x_0 \in X$, *the embedding* $X \hookrightarrow H$ *is compact and* Z *is as before a separable Banach space, then* $\varnothing \neq \bar{P} = P_r$ *and the set is convex* (*the closure is taken in* $C(T, X_w)$).

Proof. Let $x \in P_r(x_0)$ and let $\varepsilon > 0$. Set $F(t, x) = f(t, x, U(t))$ and $F_r(t, x) = \int_w f(t, x, z)\Sigma(t)(dz)$.

Since $\overline{S_{\delta(U(\cdot))}}^{w^*} = S_\Sigma$ in $L^\infty(M(Z))$, working as in the proof of Theorem 3.2, we can show that $F_r(t, x) = \overline{\mathrm{conv}}\, F(t, x)$. Also by definition we have

$$\begin{aligned} \mathrm{Gr}\, F &= \{(t, x, y) \in T \times H \times H : y \in F(t, x)\} \\ &= \{(t, x, y) \in T \times H \times H : y = f(t, x, u),\ u \in U(t)\}. \end{aligned}$$

Set

$$k(t, x, y, u) = y - f(t, x, u) \text{ and } l(t, x, y, u) = d(u, U(t)).$$

Then

$$\begin{aligned} \mathrm{Gr}\, F &= \{(t, x, y) \in T \times H \times H : k(t, x, y, u) = 0,\ l(t, x, y, u) = 0\} \\ &= \mathrm{proj}_{T \times H \times H}\, [(t, x, y, u) : k(t, x, y, u) = 0,\ l(t, x, y, u) = 0]. \end{aligned}$$

Note that both k and l are $B(T) \times B(H) \times B(H) \times B(W)$ measurable. From Theorem 2.5 of this paper (Edgar's Theorem), we know that $B(Z) = B(Z_w)$, where Z_w is the Banach space Z with the weak topology. Hence $B(Z) \cap W = B(Z_w) \cap W$, which implies that $B(W) = B(W_w)$ (again W_w is the set W with the relative weak topology). But recall that W_w is a compact Polish space. So applying Theorem 2.4 (the Arsenin-Novikov Theorem), we get

$$\mathrm{proj}_{T \times H \times H}\, [(t, x, y, u) : k(t, x, y, u) = 0,\ l(t, x, y, u) = 0] \in B(T) \times B(H) \times B(H)$$

$$\Rightarrow \mathrm{Gr}\, F \in B(T) \times B(H) \times B(H).$$

So $F(\cdot,\cdot)$ is graph measurable. This allows us to apply Theorem 2 of Chuong [15] and get that $S^1_{F(\cdot,x(\cdot))}$ is dense in $S^1_{\text{conv } F(\cdot,x(\cdot))} = S^1_{F_r(\cdot,x(\cdot))}$ for the weak norm $\|\cdot\|_w$ introduced earlier. Hence, for every $n \geqq 1$, we can find $f_n \in S^1_{F(\cdot,x(\cdot))}$ such that $\|\dot{g} - f_n\|_w \to 0$, where $g(t) = \dot{x}(t) + A(t, x(t))$. Now consider the multifunction $L_n : T \to 2^Z$ $n \geqq 1$ defined by

$$L_n(t) = \{u \in U(t) : f_n(t) = f(t, x(t), u)\}.$$

From the definition of $F(\cdot,\cdot)$ it is clear that for all $t \in T$, $L_n(t) \neq \varnothing$. Let $\{x_m\}_{m \geqq 1}$ be dense in X and consider the following functions:

$$h^n_m(t, u) = (x_m, f_n(t) - f(t, x(t), u)).$$

Because of hypotheses $(\mathrm{H(f)}_1)$ (1) and (3) we see that for every $m \geqq 1$, $t \to h^n_m(t, u)$ is measurable and $u \to h^n_m(t, u)$ is continuous. Hence we deduce that $(t, u) \to h^n_m(t, u)$ is jointly measurable and so we have that

$$\{(t, u) \in T \times Z : h^n_m(t, u) = 0\} \in B(T) \times B(Z) \quad \text{for every } m \geqq 1.$$

Now observe that

$$\text{Gr } L_n = \left[\bigcap_{m \geqq 1} \{(t, u) \in T \times Z : h^n_m(t, u) = 0\} \right] \cap \text{Gr } U.$$

Recalling that $\text{Gr } U \in B(T) \times B(Z)$ (hypothesis $(\mathrm{H(U)}_3)$), we conclude that for every $n \geqq 1$, we have

$$\text{Gr } L_n \in B(T) \times B(Z).$$

So we can apply Theorem 2.3 (Aumann's Selection Theorem) to find $u_n : T \to Z$ measurable, $n \geqq 1$, such that $u_n(t) \in L_n(t)$ almost everywhere. So we have that $f_n(t) = f(t, x(t), u_n(t))$ almost everywhere with $u_n \in S^1_U$.

Let $y_n(\cdot)$ be the unique strong solution of the original control system $(**)$ corresponding to the admissible control $u_n(\cdot)$. From Theorem 6.1 we know that P is relatively sequentially compact in $C(T, X_w)$. So by passing to a subsequence, if necessary, we may assume that $y_n \to y \in \bar{P}$ in $C(T, X_w)$. Then for any $x \in X$ we have

$$\begin{aligned}
\frac{d}{dt}|x(t) - y_n(t)|^2 &= 2\langle \dot{x}(t) - \dot{y}_n(t), x(t) - y_n(t) \rangle \\
&\leqq 2\langle -A(t, x(t)) + g(t) + A(t, y_n(t)) - f(t, y_n(t), u_n(t), x(t) - y_n(t) \rangle \\
&\Rightarrow |x(t) - y_n(t)|^2 \\
&\leqq \int_0^t (g(s) - g_n(s), x(s) - y_n(s))\, ds \int_0^t k(s)|x(s) - y_n(s)|^2\, ds.
\end{aligned}$$

We know that $y_n \to y$ in $C(T, X_w)$. So $y_n(t) \xrightarrow{w} y(t)$ in X, and since by hypothesis X imbeds compactly into H, we get that $y_n(t) \xrightarrow{s} y(t)$ in H. Also, by construction, $\|g - f_n\|_w \to 0$. Therefore $f_n \xrightarrow{w} g$ in $L^2(H)$ and in the limit as $n \to \infty$ we obtain

$$|x(t) - y(t)|^2 \leqq \int_0^t k(s)|x(s) - y(s)|^2\, ds.$$

Invoking Gronwall's inequality, we get that $x = y$. So we have that x belongs in the closure of P in $C(T, X_w)$. Since $x \in P_r$ is arbitrary we have that $P_r \subseteq \bar{P}$. On the other hand, $P \subseteq P_r$, and by Theorem 6.2, P_r is sequentially compact in $C(T, X_w)$. Therefore we conclude that $\bar{P} = P_r$ as claimed in our theorem. □

Remark. From the proof above it is clear that the Lipschitz condition in the state variable of the vector field $A(t, x, u)$ is essential in obtaining the density result. There is also the counterexample due to Plis (see Aubin and Cellina [4]), showing that even for differential inclusions in R^2, to have a relaxation result we need a Lipschitz hypothesis.

The relaxation result tells us that "essentially" we can have the same attainable set by economizing on the set of controls.

7. Examples. In this section we present two examples from control systems governed by partial differential equations that illustrate the applicability of our results.

Example 1. Let W be an open domain in R^n with smooth boundary $W = G$ and let $T = [0, b]$. On $T \times W$ we consider the following distributed parameter control system:

$$(***)_1 \qquad \frac{\partial x(t,y)}{\partial y} - \sum_{k=1}^{n} \frac{\partial}{\partial y_k}\left(p(t,y) \frac{\partial x(t,y)}{\partial y_k} \right) = f(t, x(t,y), u(t,y)),$$

$x(t, y) = 0$ on $T \times \Gamma$, $x(0, y) = x_0(y)$ on $\{0\} \times W$, $|u(t, y)| \leqq c(t)$ almost everywhere.

Here $p: T \times \bar{W} \to R_+$ is k-Lipschitz in the t-variable, C^1- in the y-variable and $t \to \|p(t, \cdot)\|_\infty \in L^\infty_+$. Also $c: T \to R_+$ is measurable.

Let $X = H^1_0(W)$, $H = L^2(W)$, $X^* = H^{-1}(W) = (H^1_0(W))^*$.

For $t \in T$, let $A(t): X \to X^*$ be the linear operator defined through the Dirichlet form

$$\alpha(t, x, v) = \sum_{k=1}^{n} \int_W p(t, y) \frac{\partial x}{\partial y_k} \frac{\partial v}{\partial y_k} dy$$

y setting $\langle A(t)x, v \rangle = \alpha(t, x, v)$ for all $x, v \in X$.

Because of our hypothesis on $p(\cdot, \cdot)$, we have that $t \to A(t)x$ is k-Lipschitz for $x \in X$. Also for $x, v \in X$, we have

$$\begin{aligned} \langle A(t)x - A(t)v, x - v \rangle &= \alpha(t, x, x - v) - \alpha(t, v, x - v) \\ &= \int_W \sum_{k=1}^{n} p(t, y)\left(\frac{\partial x}{\partial y_k} - \frac{\partial v}{\partial y_k} \right)\left(\frac{\partial x}{\partial y_k} - \frac{\partial v}{\partial y_k} \right) dy \geqq 0. \end{aligned}$$

Furthermore, for $x \in X$ we have

$$\begin{aligned} \|A(t)x\|_* &= \sup \{\langle A(t)x, v \rangle : \|v\| \leqq 1\} \\ &= \sup \{\alpha(t, x, v) : \|v\| \leqq 1\} \\ &= \sup \left\{ \int_W \sum_{k=1}^{n} p(t, y) \frac{\partial x}{\partial y_k} \frac{\partial v}{\partial y_k} dy : \|v\| \leqq 1 \right\}. \end{aligned}$$

Invoking the Cauchy and Poincaré inequalities, we finally have that

$$\|A(t)x\|_* \leqq \|p(t)\|_\infty \|x\|.$$

Finally if $x \in X$, through Poincare's inequality we deduce that

$$\langle A(t)x, x\rangle = \int_W \sum_{k=1}^{n} p(t, y)\left|\frac{\partial x}{\partial y_k}\right|^2 dy \geqq \lambda \|x\|^2.$$

From all of the above, we see that hypothesis $(\mathrm{H(A)}_1)$ is satisfied.

Next assume that $f: T \times \bar{W} \times R \times R^m \to R$ is a function such that it is measurable in $(t, y, u) \in T \times \bar{W} \times R^m$ and continuous in $x \in R$ (so jointly measurable in all variables). Also assume that

$$|f(t, y, x, u)| \leqq \alpha(t, y) + b(y)|x| \quad \text{a.e.}$$

where $\alpha(\cdot, \cdot) \in L^2(T \times W)$ and $b \in L^\infty(W)$. Let $F: T \times L^2(W) \times L^2_m(W) \to L^2(W)$, be defined by

$$F(t, x, u)(y) = f(t, y, x(y), u(y)), \qquad y \in W.$$

From Krasnoselski's Theorem we know that $x \to F(t, x, u)$ is continuous, while $(t, u) \to F(t, x, u)$ is measurable. Furthermore we have

$$|F(t, x, u)| \leqq \alpha(t, \cdot)\|_{L^2(W)} + \|b\|_{L^2(W)}\|x\|_{L^2(W)}.$$

So $F(\cdot, \cdot, \cdot)$ defined as above satisfies hypothesis (H(f)).

Next let $U: T \to P_f(H)$ be defined by

$$U(t) = \{u \in L^2(W): |u(z)| \leqq c(t) \text{ a.e.}\}.$$

Clearly, since $c(\cdot)$ is measurable, $U(\cdot)$ is also measurable. Thus hypothesis (H(U)) is satisfied.

Finally, note that the family of linear operators $\{A(t): t \in T\}$ generates an evolution operator $S(t, s)$ that is compact for $t - s > 0$ (see Martin [29] or Pavel [32]). Therefore hypothesis $(\mathrm{H_c})$ is satisfied. Then Theorem 3.1 gives us the existence of admissible pairs.

If $f(t, y, x, u) = f_0(t, y, x) \cdot u$, where $f_0: T \times \bar{W} \times R \to R^m$ is measurable in (t, y), continuous, dissipative in x, and $|f_0(t, y, x)u| \leqq \alpha(t, y) + b(y)|x|$ almost everywhere as above, then the Nemitsky operator $F(t, x, u)(\cdot) = f_0(t, \cdot, x(\cdot)) \cdot u(\cdot)$ satisfies hypothesis $(\mathrm{H(f)}_1)$. Also if $c(t) = c$ for all $t \in T$, then for all $t \in T$ $U(t) \subseteq \overline{B(0, c\lambda(W))}$ is equal to a ball of radius $c\lambda(W)$ in $L^2(W)$, which is compact-metrizable in the weak topology. Hence if $Z = \overline{B(0, M)}$, then all hypotheses of Theorem 3.2 are satisfied and we have that the set of trajectories of the original system (***) are dense in $C(T, H)$ in those of the convexified (relaxed) system (the one with orientor field $F_r(t, x) = \overline{\text{conv}}\, F(t, x)$). Also, Theorems 4.1 and 4.2 are satisfied and we have information about the properties of the set of relaxed trajectories. Furthermore, the results on the optimal control problems are also valid.

Example 2. In this example, we consider the following nonlinear distributed parameter system (we use the multi-index notation):

$$\begin{aligned}
&\frac{\partial x(t, y)}{\partial y} + \sum_{|\alpha| \leqq m-1} (-1)^{|\alpha|} D^\alpha A_\alpha(t, y, x, \cdot\, Dx, \cdots, Dx^{m-1}) = B(t)u(t, y),\\
&\qquad D^\beta x = 0 \quad \text{on } T \times \Gamma, \qquad |\beta| \leqq m-1,\\
(***)_2 \qquad &\qquad x(0, y) = x_0(y),\\
&\qquad u(t, \cdot) \in V \quad \text{a.e.} \quad \text{with } V \subseteq L^2(W), \text{ } w\text{-compact.}
\end{aligned}$$

As in the previous example, W is a bounded domain in R^n with regular boundary $\partial W = \Gamma$.

For the functions A_α we assume the following:

(1) $(t, y) \to A_\alpha(t, y, r_0, \cdots, r_{m-1})$ is measurable;

(2) $(r_0, \cdots, r_{m-1}) \to A_\alpha(t, y, r_0, \cdots, r_{m-1})$ is continuous;

(3) $|A_\alpha(t, y, r)| \leqq g(t, y) + c \sum_{k=0}^{m-1} |r_k|$ almost everywhere $g \in L^2(T \times W)$; $r = (r_1, \cdots, r_{m-1})$.

(4) $\sum_{|\alpha| \leqq m-1} (A_\alpha(t, y, r) - A_\alpha(t, y, v), r_\alpha - v_\alpha) \geqq 0$.

To the differential operator in divergence form

$$A(t)x = \sum_{|\alpha| \leqq m} (-1)^{|\alpha|} D^\alpha A_\alpha(t, y, x, Dx, \cdots, D^{m-1}x)$$

we associate the following Dirichlet form:

$$p(t, x, v) = \sum_{|\alpha| \leqq m-1} \int_W (A_\alpha(t, y, x, Dx, \cdots, D^{m-1}x), Dv^\alpha)\, dy.$$

For $p: T \times W^{m,2}(W) \times W^{m,2}(W) \to R$ we assume that $p(t, x, x) \geqq c' \|x\|^p_{m,p}$ for all $x \in W^{m,2}(W)$. Let $A(t): W_0^{m,2}(W) \to W^{-m,2}(W) = (W_0^{m,2}(W))^*$ be defined by $p(t, x, v) = \langle A(t)x, v \rangle$ for all $x, v \in W_0^{m,2}(W)$. It is easy to see that because of (4), $A(t)(\cdot)$ is monotone.

We will show that $A(t)(\cdot)$ is sequentially weakly continuous. Let $x_n \xrightarrow{w} x$ in $W_0^{m,2}(W)$. Since $W_0^{m,2}(W) \hookrightarrow W_0^{m-1,2}(W)$ compactly (see Adams [1]), we have that $x_n \xrightarrow{s} x$ in $W_0^{m-1,2}(W)$. So if $\hat{A}_\alpha$ is the Nemitsky operator corresponding to A_α, from Krasnoselski's theorem we have that $\hat{A}_\alpha(t)(x_n) \to \hat{A}_\alpha(t)(x)$ in $L^2(W)$ and by passing to a subsequence if necessary, we may assume that $\hat{A}_\alpha(t)(x_n)(y) \to \hat{A}_\alpha(t)(x)(y)$ almost everywhere $\Rightarrow A_\alpha(t, y, x_n, Dx_n, \cdots, D^{m-1}x_n) \to A_\alpha(t, y, x, Dx, \cdots, D^{m-1}x)$ almost everywhere. Using (1) and (3) and the dominated convergence theorem, for every $z \in W_0^{m,2}(W)$ we get

$$\lim \langle A(t)x_n, z \rangle = \langle A(t)x, z \rangle$$

$$\Rightarrow A(t)x_n \xrightarrow{w} A(t)x \quad \text{in } W^{-m,2}(W),$$

and so we have shown the weak continuity of $A(t)(\cdot)$ on $W_0^{m,2}(W)$.

Also, through Pettis' Measurability Theorem (see Diestel and Uhl [18]), it is easy to check that $t \to A(t)x$ is measurable.

Furthermore,

$$\|A(t)x\|_{-m,2} \leqq \hat{g}(t) + c\|x\|_{m,2} \quad \text{a.e.}$$

with $\hat{g}(\cdot) \in L^2$ and from (5) we have that

$$\langle A(t)x, x \rangle \geqq c' \|x\|^2_{m,2}$$

for all $x \in W_0^{m,2}(W)$.

Let $f: T \times L^2(W) \to L^2(W)$ be defined by $f(t, u)(\cdot) = B(t)u(\cdot)$ and $Z = S^1_V$, which is w-compact in $L^2(T, L^2(W))$, and hence a compact Polish space for the weak topology.

Let $x_0(\cdot) \in W_0^{m,2}(W)$. Take $X = W_0^{m,2}(W)$, $H = L^2(W)$ and $X^* = W^{-m,2}(W)$. Then $(***)_2$ can be written as the following evolution equation:

$$(***)_2' \qquad \begin{aligned} &\dot{x}(t) + A(t, x(t)) = f(t, u(t)), \\ &x(0) = x_0, \qquad u \in Z. \end{aligned}$$

Then trajectories of this system are dense in the trajectories of the convexified system. Furthermore, those relaxed trajectories form a sequentially compact subset of $C(T, X_w)$.

Acknowledgment. The author expresses his gratitude to Professor L. Berkovitz and the referee for the constructive criticisms and suggestions that improved the material of this paper considerably.

EXISTENCE OF OPTIMAL STRATEGIES IN ZERO-SUM NONSTATIONARY STOCHASTIC GAMES WITH LACK OF INFORMATION ON BOTH SIDES*

ANDRZEJ S. NOWAK†

Abstract. This paper studies a zero-sum discrete-time stochastic game model with Borel state and action spaces. The law of motion of the system in the model is assumed to be nonstationary. Following M. Schäl, at each stage of the game every player is assumed to know the sequence of states occurring up to this stage, but has no explicit information about his opponent's previous decisions. Under certain semicontinuity and compactness conditions, the existence of a value is proved for such a game and the existence of optimal (ε-optimal) universally measurable strategies for the minimizer (maximizer). This essentially improves a result of Schäl on this subject.

Key words. zero-sum nonstationary stochastic games, imperfect information, minimax theorem, universally measurable strategies

AMS(MOS) subject classifications. primary 90D15; secondary 60K99, 93C55

1. Introduction and a minimax theorem. In this paper we study a two-person zero-sum nonstationary stochastic game introduced by Schäl [18]. It is assumed that at every stage of the game neither player has any explicit information about his opponent's earlier choices. We assume, however, that every player knows the sequence of states of the system occurring up to this stage and remembers all his previous choices. Our aim is to prove that in Schäl's game every player has an optimal (or ε-optimal, $\varepsilon > 0$) strategy independent of any probability distribution of the initial state. This is an essential improvement of Schäl's theorem from [18]. For a more extensive discussion of our results, see Remarks 1-4.

Let X be a Borel space, i.e., a nonempty Borel subset of a complete separable metric space. We assume that X is endowed with the relative topology and the Borel σ-algebra $\mathcal{B}(X)$. By $\mathcal{U}(X)$ we denote the σ-algebra of all universally measurable subsets of X (see [1, Chap. 7, Appendix B]). Clearly, $\mathcal{B}(X) \subset \mathcal{U}(X)$. Let $P(X)$ be the space of all probability measures on $\mathcal{B}(X)$. We shall assume that for every Borel space X, $P(X)$ is given the weak topology (see [1, Chap. 7]).

Let X and Y be Borel spaces. By a universally measurable transition probability from X to Y we mean a universally measurable mapping from X to $P(Y)$. It is known that every universally measurable transition probability $f: X \to P(Y)$ may be identified with a function $f(\cdot|\cdot)$, so that, for each $x \in X$, $f(\cdot|x) \in P(Y)$, and for each $B \in \mathcal{B}(Y)$, $f(B|\cdot)$ is a universally measurable mapping from X to $[0,1]$ (see [1, Lemma 7.28]).

Let $X_1, X_2, \cdots$ be a sequence of nonempty sets. The Cartesian products of $X_1, \cdots, X_n$ and $X_1, X_2, \cdots$, are denoted by $X_1 \cdots X_n$ and $X_1 X_2 \cdots$, respectively. Let $X_1, X_2, \cdots$ be Borel spaces. Throughout this paper we assume that the product spaces $X_1 \cdots X_n$ and $X_1 X_2 \cdots$ are given their product topologies and product σ-algebras. It is well known that the product σ-algebra $\mathcal{B}(X_1) \cdots \mathcal{B}(X_n)$ in $X_1 \cdots X_n$ is equal to $\mathcal{B}(X_1 \cdots X_n)$. A similar result is also valid for the product space $X_1 X_2 \cdots$, [1, Prop. 7.13].

A *zero-sum nonstationary stochastic game with lack of information on both sides* is defined by a sequence of objects $\{S_n, A_n, B_n, t_{n+1}, u_n;\ n \in N\}$, where:

(i) S_n is the *state space* at time $n \in N$ and is assumed to be a Borel space.

(ii) A_n and B_n are the *action spaces* at time $n \in N$ of players I and II, respectively. It is assumed that A_n is a Borel space and B_n is a nonempty compact metric space.

Let $H_1 = S_1$, $H_n = S_1 A_1 B_1 \cdots S_{n-1} A_{n-1} B_{n-1} S_n$, $H_\infty = S_1 A_1 B_1 S_2 A_2 B_2 \cdots$. Then H_n is the set of histories of the game for horizon $n \in N$, while H_∞ is the set of all infinite histories of the game.

(iii) $\{t_{n+1}\}$ is the *law of motion* of the system; t_{n+1} is a Borel measurable transition probability from $H_n A_n B_n$ to S_{n+1}, $n \in N$. We assume that t_{n+1} is dominated by a probability measure $q_{n+1} \in P(S_{n+1})$. The density c_{n+1} of t_{n+1} with respect to q_{n+1} is assumed to be a Borel measurable function on H_{n+1} such that, for each $a_1, \cdots, a_n$ and $s_1, \cdots, s_n$, s_{n+1}, $c_{n+1}(s_1, a_1, \cdot, \cdots, s_n, a_n, \cdot, s_{n+1})$ is lower semicontinuous on $B_1 \cdots B_n$.

(iv) u_n is the *payoff function* of player I at stage $n \in N$ ($-u_n$ is the payoff function for player II). It is assumed that u_n is a nonnegative Borel measurable function on $H_n A_n B_n$ such that, for each $s_1, \cdots, s_n$ and $a_1, \cdots, a_n$, $u_n(s_1, a_1, \cdot, \cdots, s_n, a_n, \cdot)$ is lower semicontinuous on $B_1 \cdots B_n$. Of course, every u_n may be recognized as a function on H_∞. Doing so, we assume that the sequence $\{u_n\}$ is nondecreasing and $u = \lim_n u_n$ is the *infinite horizon payoff function* for player I.

The game is played as follows. The players observe an initial state $s_1 \in S_1$ and independently choose actions $a_1 \in A_1$ and $b_1 \in B_1$, respectively. Then the system moves to a new state $s_2 \in S_2$ according to the probability distribution $t_2(\cdot \mid s_1, a_1, b_1)$ on which, knowing $s_2 \in S_2$, the players choose independently $a_2 \in A_2$ and $b_2 \in B_2$, respectively. The system moves to a new state $s_3 \in S_3$ according to the probability distribution $t_3(\cdot \mid s_1, a_1, b_1, s_2, a_2, b_2)$ and so on. The result of such an infinite sequence of moves is a point $h \in H_\infty$ and player II pays player I the amount $u(h)$. Note that at each stage n of the game every player knows the sequence of states $s_1, \cdots, s_n$ and his own previous choices.

We put $H_1^1 = H_1^2 = S_1$, $H_n^1 = S_1 A_1 \cdots S_{n-1} A_{n-1} S_n$, $H_n^2 = S_1 B_1 \cdots S_{n-1} B_{n-1} S_n$, for $n \geqq 2$. Let $F_n(G_n)$ be the set of all universally measurable transition probabilities from $H_n^1(H_n^2)$ to $A_n(B_n)$. A universally measurable *strategy* for player I(II) is a sequence $f = \{f_n\}$ ($g = \{g_n\}$), where $f_n \in F_n(g_n \in G_n)$ for each $n \in N$. Denote by $F(G)$ the set of all strategies for player I(II).

Let $E_{f_n}, E_{g_n}, E_{t_{n+1}}$ denote the conditional expectation operator with respect to $f_n \in F_n$, $g_n \in G_n$, t_{n+1}, respectively. By the Ionescu-Tulcea Theorem [10, Prop. V.1.1] and [1, Lemma 7.28], each pair of strategies $f = \{f_n\}$, $g = \{g_n\}$, together with the law of motion $\{t_{n+1}\}$, uniquely defines a universally measurable transition probability $P_{fg}(\cdot \mid \cdot)$ from S_1 to $A_1 B_1 S_2 A_2 B_2 S_3 \cdots$ such that, for every Borel measurable function w: $H_n A_n B_n \to R$ ($n \in N$) bounded below, we have

$$E(w, f, g)(s_1) := \int w(h) P_{fg}(dh \mid s_1) = (E_{f_1} E_{g_1} E_{t_2} \cdots E_{f_{n-1}} E_{g_{n-1}} E_{t_n} E_{f_n} E_{g_n} w)(s_1),$$

where $s_1 \in S_1$. (Here w is also regarded as a function on H_∞.) Thus, each pair f, g of strategies defines an *expected payoff* to player I at an initial state $s_1 \in S_1$ to be

$$E(u, f, g)(s_1) = \int u(h) P_{fg}(dh \mid s_1).$$

Under our assumption (iv), from the monotone convergence theorem and Fubini's theorem we infer that, for each $s_1 \in S_1$, $f = \{f_n\} \in F$, $g = \{g_n\} \in G$,

$$
\begin{aligned}
E(u,f,g)(s_1) &= \lim_n E(u_n,f,g)(s_1) \\
&= \lim_n (E_{f_1}E_{g_1}E_{t_2}\cdots E_{f_{n-1}}E_{g_{n-1}}E_{t_n}E_{f_n}E_{g_n}u_n)(s_1) \\
&= \lim_n (E_{g_1}E_{f_1}E_{t_2}\cdots E_{g_{n-1}}E_{f_{n-1}}E_{t_n}E_{g_n}E_{f_n}u_n)(s_1).
\end{aligned} \tag{1}
$$

From now on we assume that

(v) $\quad E(u,f,g)(s_1) < \infty$ for all $s_1 \in S_1, f \in F, g \in G$.

Define, for each initial state $s_1 \in S_1$,

$$
v_*(s_1) = \sup_{f\in F}\inf_{g\in G} E(u,f,g)(s_1) \quad \text{and} \quad v^*(s_1) = \inf_{g\in G}\sup_{f\in F} E(u,f,g)(s_1).
$$

Then $v_*(v^*)$ is called the *lower-* (*upper-*) *value function* of the game. If $v_* = v^*$, then this common function is called the *value function* of the game and is denoted by v.

Suppose the value function v exists. A strategy $f^* \in F$ is called *ε-optimal* for player I for given $\varepsilon > 0$ if

$$
\inf_{g\in G} E(u,f^*,g)(s_1) + \varepsilon > v(s_1) \quad \text{provided that } v(s_1) < \infty,
$$

$$
\inf_{g\in G} E(u,f^*,g)(s_1) > \frac{1}{\varepsilon} \quad \text{if } v(s_1) = \infty.
$$

A strategy $g^* \in G$ is called *optimal* for player II if

$$
\sup_{f\in F} E(u,f,g^*)(s_1) \leqq v(s_1) \quad \text{for all } s_1 \in S_1.
$$

Here is the main result of this paper.

MINIMAX THEOREM. *Assume* (i)-(v). *Then the stochastic game has a value function, which is universally measurable. Player* II *has an optimal universally measurable strategy while, for any* $\varepsilon > 0$, *player* I *has an* ε*-optimal universally measurable strategy.*

Remarks. (1) The same information structure is considered in Schäl's stochastic game model [18]. It should be noted, however, that, for any pair of strategies $f \in F$ and $g \in G$, the payoff for player I in Schäl's game is the expectation of $E(u,f,g)(\cdot)$ with respect to a probability measure $p \in P(S_1)$, called the probability distribution of the initial state. Thus, the optimal (ε-optimal) strategies in Schäl's approach depend on p. Such strategies are often called in the literature $\bar{p}$-optimal (or ε-$\bar{p}$-optimal) (see [6], [16], [18]). The optimality criterion considered in this paper is essentially stronger than that of Schäl [18]. For example, every optimal strategy for player II is $\bar{p}$-optimal for each probability distribution p of the initial state.

(2) From [18], it follows that our game has a value for each initial state, but to prove the remaining details of the Minimax Theorem we have to do some extra work. We consider an auxiliary game in which the strategy sets are the spaces $\Pi(A)$ and $\Pi(B)$ of probability measures induced by strategies of players I and II, respectively (see § 2). Our approach is then based on the equivalence of the weak topology and the ws^∞-topology of Schäl [16] in $\Pi(B)$ proved by Nowak in [15] (see Lemma 6) and the minimax selection theorem of [12]. We note that the issues described above do not arise, if we restrict attention only to $\bar{p}$-optimal strategies as in [18].

(3) Our convergence assumption (iv) includes the discounted and positive stochastic games (see, for example, [9], [11] and the references therein). It is worth noting

that optimal strategies for player I need not exist even if he has finite action spaces (see, for example, [3], [9]). Therefore, we make no compactness assumptions regarding the action spaces of player I.

(4) Imposing certain semicontinuity and compactness conditions on player I, as well as a stronger convergence assumption on the n-stage payoff functions u_n, we can restrict ourselves to Borel measurable strategies (see [12, Remark 3]).

(5) Universally measurable strategies have been broadly used in control and gambling theory (see, for example, [1], [2], [7]). They have been applied to zero-sum stochastic games by Nowak in [11], [12], and [14].

(6) Nonstationary stochastic games with standard information structures where, at each stage of the play, every player has full information about the states of the system and decisions made by the players in the past, have already been studied in [13], [14], and some of the references therein. It should be noted that the approaches taken in [13] and [14] cannot be applied to the present model. We hope that the methods used in this paper can also be applied to some more general models of games of incomplete information.

2. Proof of the main result. Let $\bar{F}_n(\bar{G}_n)$ be the set of all transition probabilities from $F_n(G_n)$ that are independent of the initial state $s_1 \in S_1$. We put $\bar{F} = \bar{F}_1\bar{F}_2 \cdots$ and $\bar{G}_1\bar{G}_2 \cdots$, and further, we put $A = A_1S_2A_2S_3 \cdots$ and $B = B_1S_2B_2S_3 \cdots$. To each $f = \{f_n\} \in \bar{F}$ is associated a probability measure $P_f = f_1q_2f_2q_3 \cdots$ on $\mathcal{B}(A)$, given by the product measure theorem of Ionescu Tulcea (see [1, Prop. 7.45] or [10, Prop. V.1.1]). (Recall our assumption (iii).) Similarly, to each $g \in \bar{G}$ is associated a probability measure P_g on $\mathcal{B}(B)$.

We put $\Pi(A) = \{P_f \in P(A): f \in \bar{F}\}$ and $\Pi(B) = \{P_g \in P(B): g \in \bar{G}\}$.

From the proof of Proposition 7.45 in [1], we infer the following lemma.

LEMMA 1. *For each $f \in \bar{F}$ and $g \in \bar{G}$, there are Borel measurable transition probabilities $f_n \in \bar{F}_n$ and $g_n \in \bar{G}_n$, $n \in N$ so that $P_f = P_{\bar{f}}$ and $P_g = P_{\bar{g}}$, where $\bar{f} = \{\bar{f}_n\}$ and $\bar{g} = \{\bar{g}_n\}$.*

In the remainder of this paper, we assume that $P(A)$, $P(B)$ are given the weak topologies and $\Pi(A)$, $\Pi(B)$ are endowed with the relative topologies and Borel σ-algebras.

LEMMA 2. (a) $\Pi(A)$ *is a convex Borel subset of a Borel space $P(A)$.*

(b) $\Pi(B)$ *is a compact convex subset of a Borel space $P(B)$.*

Proof. By Lemma 1, we can restrict ourselves to Borel measurable transition probabilities in the definitions of $\Pi(A)$ and $\Pi(B)$. The spaces $P(A)$ and $P(B)$ are Borel by [1, Prop. 7.13 and Cor. 7.25.1]. Now (a) follows from [17, Thm. 7.11] and [19, Lemma 7.2] while (b) is a corollary to [16, Thm. 5.6] and [17, Thm. 7.11]. □

Results closely related to Lemma 3 below have appeared in dynamic programming and gambling literature (see [19, p. 885], [8, § 4], [7, Lemma 3.3(b), Remark 3.1]).

LEMMA 3. (a) *Let $f = \{f_n\}$ be any strategy of player* I. *Then $s_1 \to (f_1q_2f_2q_3 \cdots)(\cdot|s_1)$ is a universally measurable mapping from S_1 to $\Pi(A)$.*

(b) *Let $\varphi: S_1 \to \Pi(A)$ be a universally measurable mapping. Then there exist universally measurable transition probabilities $f_n \in F_n$, $n \in N$, so that $\varphi(s_1)(\cdot) = (f_1q_2f_2q_3 \cdots)(\cdot|s_1)$, for every $s_1 \in S_1$.*

Proof. Part (a) follows from [10, Prop. V.1.1] and [1, Lemma 7.28]. The proof of (b) is similar to that of Lemma 3.3(b) in [7]. The transition probabilities in (b) are constructed inductively by means of [1, Prop. 7.27] and a characterization of the space of probability measures induced by strategies (alias policies) given by Strauch [19, Lemma 7.2] and Hinderer [6, Lemma 13.1]. □

Remark 7. Replacing $\Pi(A)$ by $\Pi(B)$ in Lemma 3, we get a similar result concerning strategies of player II.

Let us put $A^n = A_1 \cdots A_n$, $B^n = B_1 \cdots B_n$ and $S^n = S_2 \cdots S_n$, $n \geq 2$. The elements of A^n, B^n, and S^n will be denoted by a^n, b^n, and s^n, respectively.

For each $f = \{f_n\} \in \bar{F}$ and $n \geq 2$, there exists a universally measurable transition probability $f^n = f_1 \cdots f_n$ from S^n to A^n such that, for every bounded below Borel measurable function w: $S^n A^n \to R$, we have

$$(E_{f^n} w)(s^n) := \int w(s^n, a^n) f^n(da^n \mid s^n) = (E_{f_1} \cdots E_{f_n} w)(s^n), \qquad s^n \in S^n,$$

(see [1, pp. 175-177] or [10, Prop. V.1.1]). Here $E_{f^n} w$ is the conditional expectation of w with respect to f^n. Similarly, to each $g = \{g_n\} \in \bar{G}$, we associate universally measurable transition probabilities $g^n (n \geq 2)$ from S^n to B^n. We write E_{g^n} for the conditional expectation with respect to g^n.

Let q^n be the product of probability measures $q_2, \cdots, q_n$. The expectation with respect to q^n is denoted by E_{q^n}.

LEMMA 4. *Assume $P_f = P_{\bar{f}}$ for some $f = \{f_n\}$ and $\bar{f} = \{\bar{f}_n\}$ belonging to $\bar{F}$. Then, for each $n \geq 2$, we have $f^n(\cdot \mid s^n) = \bar{f}^n(\cdot \mid s^n)$ almost everywhere q^n.*

Proof. Let $n \geq 2$ be fixed. From [1, Props. 7.19, 7.20], it follows that there exists a sequence $\{w_m\}$ of bounded continuous functions on A^n that separate elements of $P(A^n)$. Of course, for each $m \in N$ and every Borel subset C of S^n, we have

$$\int w_m \chi_C \, dP_f = \int w_m \chi_C \, dP_{\bar{f}},$$

where χ_C means the characteristic function of C. By Fubini's theorem, it follows that $E_{q^n} E_{f^n} w_m \chi_C = E_{q^n} E_{\bar{f}^n} w_m \chi_C$, for each $C \in \mathcal{B}(S^n)$, $m \in N$. Thus, for every $m \in N$, there is $C_m \in \mathcal{B}(S^n)$ with $q^n(C_m) = 0$ and $E_{f^n} w_m = E_{\bar{f}^n} w_m$ on $S^n - C_m$. Define $C = \bigcup_{m \in N} C_m$. Then $q^n(C) = 0$ and $E_{f^n} w_m = E_{\bar{f}^n} w_m$ on $S^n - C$, for each $m \in N$. Since $\{w_m\}$ separates elements of $P(A^n)$, the result follows. □

Remark 8. It is obvious that if $P_g = P_{\bar{g}}$ for some $g, \bar{g} \in \bar{G}$, then a similar result is in force for the transition probabilities g^n and $\bar{g}^n (n \geq 2)$ determined by g and $\bar{g}$, respectively.

Let u_n: $H_n A_n B_n \to R$ be an n-stage payoff function of player I. From our assumption (iii) and (1), it follows that, for each $s_1 \in S_1$, $f = \{f_n\} \in \bar{F}$, and $g = \{g_n\} \in \bar{G}$, we have (cf. [17, § 7])

$$E(u_n, f, g)(s_1) = (E_{q^n} E_{f^n} E_{g^n} u_n c_2 \cdots c_n)(s_1) = (E_{q^n} E_{g^n} E_{f^n} u_n c_2 \cdots c_n)(s_1). \tag{2}$$

Moreover, we have

$$E(u_n, f, g)(s_1) = (E_\varphi E_{g^n} u_n c_2 \cdots c_n)(s_1) = (E_\gamma E_{f^n} u_n c_2 \cdots c_n)(s_1), \tag{3}$$

where $E_\varphi (E_\gamma)$ is the expectation with respect to $\varphi = P_f$ ($\gamma = P_g$), $s_1 \in S_1$.

Define $F_\varphi = \{f \in \bar{F}: \varphi = P_f\}$, $G_\gamma = \{g \in \bar{G}: \gamma = P_g\}$, where $\varphi \in \Pi(A)$, $\gamma \in \Pi(B)$. From Lemma 4, Remark 8, and (2) it follows that if $\varphi \in \Pi(A)$ and $\gamma \in \Pi(B)$, then $E(u_n, f, g)(s_1)$ has the same value for every $f \in F_\varphi$ and $g \in G_\gamma$. Therefore, for each $\varphi \in \Pi(A)$ and $\gamma \in \Pi(B)$ and $s_1 \in S_1$, we may define

$$U_n(\varphi, \gamma)(s_1) := E(u_n, f, g)(s_1),$$

where $f(g)$ is an arbitrary element of $F_\varphi (G_\gamma)$. Further, for every $\varphi \in \Pi(A)$, $\gamma \in \Pi(B)$, and $s_1 \in S_1$, we put

$$U(\varphi, \gamma)(s_1) = \lim_n U_n(\varphi, \gamma)(s_1).$$

By the monotone convergence theorem

$$U(\varphi, \gamma)(s_1) = E(u, f, g)(s_1), \tag{4}$$

for every $s_1 \in S_1$, $\varphi \in \Pi(A)$, $\gamma \in \Pi(B)$, and $f \in F_\varphi$, $g \in G_\gamma$.

The following lemma is obvious.

LEMMA 5. *For each initial state $s_1 \in S_1$, we have*

$$v_*(s_1) = \sup_{f \in \bar{F}} \inf_{g \in \bar{G}} E(u, f, g)(s_1) = \sup_{\varphi \in \Pi(A)} \inf_{\gamma \in \Pi(B)} U(\varphi, \gamma)(s_1),$$

$$v^*(s_1) = \inf_{g \in \bar{G}} \sup_{f \in \bar{F}} E(u, f, g)(s_1) = \inf_{\gamma \in \Pi(B)} \sup_{\varphi \in \Pi(A)} U(\varphi, \gamma)(s_1).$$

Recall that $\Pi(A)$ ($\Pi(B)$) is given the relative weak topology from $P(A)(P(B))$ and the Borel σ-algebra.

LEMMA 6. *The function $U : \Pi(A)\Pi(B)S_1 \to R$ defined by* (4) *is Borel measurable. Moreover, for each $s_1 \in S_1$, $\varphi \in \Pi(A)$, the function $U(\varphi, \cdot)(s_1)$ is lower semicontinuous on $\Pi(B)$.*

Proof. Let $n \geqq 2$ be fixed. The function $u_n c_2 \cdots c_n$ is Borel measurable and lower semicontinuous in the actions of player II. Under our compactness assumption (ii), there exists a nondecreasing sequence of bounded Borel measurable functions $w_k : H_n A_n B_n \to R$, $k \in N$, such that $w_k \uparrow u_n c_2 \cdots c_n$ as $k \to \infty$, and, for each $k \in N$, w_k is continuous in the actions of player II [17, Eq. (4.1)].

Define

$$W_k(\varphi, \gamma)(s_1) := (E_\gamma E_{f^n} w_k)(s_1), \qquad k \in N,$$

where $s_1 \in S_1$, $\varphi \in \Pi(A)$, $\gamma \in \Pi(B)$, and f is an arbitrary element of F_φ. Clearly, W_k is a well-defined function on $\Pi(A)\Pi(B)S_1$. Note that, for each $\varphi \in \Pi(A)$, $f \in F_\varphi$, $E_{f^n} w_k$ is a bounded Borel measurable function on $S_1 S^n B^n$. Moreover, $E_{f^n} w_k$ depends continuously with respect to $b^n \in B^n$. By Lemma 1 and [15, Thm. 1, Remark 2], the function $\gamma \to (E_\gamma E_{f^n} w_k)(s_1)$ is continuous on $\Pi(B)$ for each $\varphi \in \Pi(A)$, $f \in F_\varphi$, $s_1 \in S_1$. (This is a consequence of the equivalence of the weak topology on $\Pi(B)$ and the ws^∞-topology of Schäl [16] proved in [15].)

Let $\gamma \in \Pi(B)$ be fixed. Then $W_k(\varphi, \gamma)(s_1) = (E_\varphi E_{g^n} w_k)(s_1)$, $s_1 \in S_1$, $\varphi \in \Pi(A)$, and g is an arbitrary element of G_γ. Applying standard arguments and Proposition 7.25 of [1], we infer that $(\varphi, s_1) \to (E_\varphi E_{g^n} w_k)(s_1)$ is a Borel measurable function on $\Pi(A)S_1$, for each $g \in G_\gamma$. Thus, we have shown that $W_k(\varphi, \cdot)(s_1)$ is continuous on $\Pi(B)$, for every $s_1 \in S_1$, $\varphi \in \Pi(A)$, $k \in N$, and $W_k(\cdot, \gamma)(\cdot)$ is Borel measurable on $\Pi(A)S_1$, for each $\gamma \in \Pi(B)$, $k \in N$. This implies that W_k is Borel measurable [5, Thm. 6.1]. By the monotone convergence theorem, $W_k \uparrow U_n$ on $\Pi(A)\Pi(B)S_1$ as $k \to \infty$, and $U_n \uparrow U$ as $n \to \infty$. This completes the proof of the required properties of the function U. □

LEMMA 7. *For each $s_1 \in S_1$, $\varphi \in \Pi(A)$, and $\gamma \in \Pi(B)$ the functions $U(\cdot, \gamma)(s_1)$ and $U(\varphi, \cdot)(s_1)$ are affine on $\Pi(A)$ and $\Pi(B)$, respectively.*

Proof. The proof follows from (3) and Lemma 2. □

Proof of Minimax Theorem. By Fan's Minimax Theorem [4, Thm. 2] and Lemmas 2, 6, and 7, the zero-sum game with payoff function $U(\cdot, \cdot)(s_1)$ has a value, for each $s_1 \in S_1$, which (by Lemma 5) is equal to $v(s_1)$, the value of our stochastic game at an initial state s_1. Using Lemmas 2, 6, and the minimax selection theorem given as Theorem 2.2 of [12], we infer that the value function is universally measurable. Moreover, from

[12, Thm. 2.2], it follows that there exists a universally measurable mapping $\gamma^*: S_1 \to \Pi(B)$ such that

$$\sup_{\varphi \in \Pi(A)} U(\varphi, \gamma^*(s_1))(s_1) = v(s_1) \quad \text{for all } s_1 \in S_1,$$

and, for each $\varepsilon > 0$, there exists a universally measurable mapping $\varphi^*: S_1 \to \Pi(A)$ such that

$$\inf_{\gamma \in \Pi(B)} U(\varphi^*(s_1), \gamma)(s_1) + \varepsilon > v(s_1) \quad \text{provided that } v(s_1) < \infty,$$

$$\inf_{\gamma \in \Pi(B)} U(\varphi^*(s_1), \gamma)(s_1) > \frac{1}{\varepsilon} \quad \text{when } v(s_1) = \infty.$$

Appealing now to Lemma 3, Remark 7, (3), and (4) we note that $\gamma^*(\varphi^*)$ determines an optimal (ε-optimal) strategy for player II (player I). □

THE EXISTENCE OF A MINIMUM PAIR OF STATE AND POLICY FOR MARKOV DECISION PROCESSES UNDER THE HYPOTHESIS OF DOEBLIN*

M. KURANO†

Abstract. This paper studies the average-cost Markov decision process with compact state and action spaces and bounded lower semicontinuous cost functions. Following the idea of Borkar's excellent papers [*SIAM J. Control Optim.*, 21 (1983), pp. 652-666; 22 (1984), pp. 965-978], the general case where irreducibility is not assumed is considered under the hypothesis of Doeblin and the existence of a minimum pair of state and policy, which attains the infimum of the average expected cost over all initial states and policies, is established. Further, it is proved that under additional weak conditions there exists an optimal stationary policy in the usual sense.

Key words. Markov decision process, average cost criterion, Doeblin condition

AMS(MOS) subject classifications. primary 90C40; secondary 90C39

1. Introduction and notation. The study of the average-cost Markov decision process with general state and action spaces has been done by Ross [14], Tijms [15], Kurano [10], and others. But as far as the author is aware, they have treated the case in which there is a single ergodic class and approximate recurrency under all policies.

In this paper, we treat with the general case, in which several ergodic classes and transient sets are permitted for the Markov process induced by any randomized stationary policy, under the compactness of state and action spaces. And introducing the hypothesis of Doeblin [7], we show the existence of a minimum pair of state and policy, which attains the infimum of the average expected cost over all initial states and policies. Further, under additional weak conditions it is proved that there exists an optimal stationary policy in the usual sense. Here we do not use the traditional approach taken by Ross [14], Tijms [15], and others which treats the problem as a limiting case of the discounted cost problem. To prove the existence of a minimum pair of state and policy we apply the direct method by the empirical distribution, which Borkar [4], [5] uses to establish the existence of optimal stationary policies for countable-state Markov decision processes in cases where a single communicating class exists under any stationary policy.

For examples of treatment of the general (multichain) case with the finite or denumerable state space, see Deppe [6], Howard [9], Schweitzer [16], and Zijm [17].

In the remainder of this section, we shall establish the notation that will be used throughout the paper and define the problem to be examined. Also, a minimum pair of state and policy is defined. In §§ 2 and 3, we give the existence and characterization of minimum pairs under the hypothesis of Doeblin. In § 2 it is proved that there exists a subset C of the state space such that there is a minimum pair only for all initial states belonging to C, implying the existence of an optimal stationary policy for these initial states. The extension of these results to all of the state space is done under additional assumptions in § 3. Finally, in § 4, the more general case is discussed under some continuity conditions.

A Borel set is a Borel subset of a complete separable metric space. For a Borel set X, $\mathcal{B}_X$ denotes the Borel subsets of X. A Markov decision process is a controlled

dynamic system defined by four objects: S, $\{A(x), x \in S\}$, c, and Q, where S is any Borel set representing the state space of some system and for each $x \in S$, the admissible action space $A(x)$ is a nonempty subset of some Borel set A such that $\{(x, a): x \in S, a \in A(x)\}$ is an element of $\mathcal{B}_S \times \mathcal{B}_A$, the immediate cost function c is a real-valued Borel measurable function on $S \times A$, and $Q(\cdot | x, a)$ is the law of motion, which is taken to be stochastic kernel on $\mathcal{B}_S \times S \times A$; i.e., for each $(x, a) \in S \times A$, $Q(\cdot | x, a)$ is a probability measure on $\mathcal{B}_S$; and, for each $D \in \mathcal{B}_S$, $Q(D|\cdot)$ is a Borel measurable function on $S \times A$.

Throughout this paper, the following assumptions will remain operative:

(i) S and $R := \{(x, a) | x \in S, a \in A(x)\}$ are compact;

(ii) c is a nonnegative real-valued bounded lower semicontinuous function;

(iii) whenever $x_n \to x$, $a_n \to a$, $Q(\cdot | x_n, a_n)$ converges weakly to $Q(\cdot | x, a)$.

The sample space is the product space $\Omega = (S \times A)^\infty$ such that the projections X_t, Δ_t on the tth factors S, A describe the state and the action of the tth time of the process ($t \geqq 0$).

A policy is a sequence $\pi = (\pi_0, \pi_1, \cdots)$ such that, for each $t \geqq 0$, π_t is a stochastic kernel on $\mathcal{B}_A \times S \times (A \times S)^t$ with $\pi_t(A(x_t) | x_0, a_0, \cdots, a_{t-1}, x_t) = 1$ for all $(x_0, a_0, \cdots, a_{t-1}, x_t) \in S \times (A \times S)^t$.

Let Π denote the class of policies.

We denote by $T(A|S)$ the set of all stochastic kernels Φ, on $\mathcal{B}_A \times S$ with $\Phi(A(x)|x) = 1$ for all $x \in S$.

A policy $\pi = (\pi_0, \pi_1, \cdots)$ is a randomized stationary policy if there exists a $\Phi \in T(A|S)$ such that $\pi_t(\cdot | x_0, a_0, \cdots, x_t) = \Phi(\cdot | x_t)$ for all $(x_0, a_0, \cdots, x_t) \in S \times (A \times S)^t$ and $t \geqq 0$. Denote the corresponding policy by $\Phi^{(\infty)}$.

For any $D \in \mathcal{B}_S$, we denote by $B(D \to A)$ the set of all Borel measurable functions $u: D \to A$ with $u(x) \in A(x)$ for all $x \in D$.

A randomized stationary policy $\Phi^{(\infty)}$ is called stationary if there exists an $f \in B(S \to A)$ such that $\Phi(\{f(x)\}|x) = 1$ for all $x \in S$. Such a policy will be written by $f^{(\infty)}$.

We denote by Π' and Π'', respectively, the sets of all randomized stationary and stationary policies. For any Borel set X, we denote by $P(X)$ the set of all probability measures on X.

Let $H_t = (X_0, \Delta_0, \cdots, \Delta_{t-1}, X_t)$. It is assumed that, for each $\pi = (\pi_0, \pi_1, \cdots) \in \Pi$, $\text{Prob}(\Delta_t \in D_1 | H_t) = \pi_t(D_1 | H_t)$ and $\text{Prob}(X_{t+1} \in D_2 | H_{t-1}, \Delta_{t-1}, X_t = x, \Delta_t = a) = Q(D_2 | x, a)$ for every $D_1 \in \mathcal{B}_A$ and $D_2 \in \mathcal{B}_S$.

Then, for each $\pi \in \Pi$ and initial state distribution $\nu \in P(S)$, we can define the probability measure P_π^ν on Ω in an obvious way.

We shall consider the following average cost criterion.

For any policy π and initial state distribution $\nu \in P(S)$, let

$$\psi(\nu, \pi) = \limsup_{T \to \infty} E_\pi^\nu \left[\sum_{t=0}^{T-1} c(X_t, \Delta_t) \right] \Big/ T,$$

where E_π^ν is the expectation with respect to P_π^ν.

Let $\psi(\nu) = \inf_{\pi \in \Pi} \psi(\nu, \pi)$ and $\psi^* = \inf_{\nu \in P(S)} \psi(\nu)$. Then we say that $(\nu, \pi) \in P(S) \times \Pi$ is a minimum pair if $\psi(\nu, \pi) = \psi^*$ and $\pi^* \in \Pi$ is optimal if $\psi(x, \pi^*) \leqq \psi(x, \pi)$ for all $x \in S$ and $\pi \in \Pi$, where the initial distribution degenerate at the point x is denoted by x.

2. The existence of minimum pairs in $S \times \Pi''$. In this section we use the hypothesis of Doeblin [7], and give the characterization of minimum pairs.

For any $\Phi \in T(A|S)$, the t-step transition probabilities are defined by

$$Q^{(1)}(\cdot|x, \Phi) = \int Q(\cdot|x, a)\Phi(da|x),$$

$$Q^{(t+1)}(\cdot|x, \Phi) = \int Q^{(t)}(\cdot|x_1, \Phi)Q^{(1)}(dx_1|x, \Phi) \qquad (t \geqq 1).$$

Unless stated otherwise, the following hypothesis holds throughout this paper.

Hypothesis (Doeblin [7]). There is a finite measure γ of sets $D \in \mathcal{B}_S$ with $\gamma(S) > 0$, an integer l and a positive ε, such that

$$Q^{(l)}(D|x, \Phi) \leqq 1 - \varepsilon \quad \text{if } \gamma(D) \leqq \varepsilon, \quad \text{for all } \Phi \in T(A|S) \text{ and } x \in S.$$

For any Borel set X, we denote by $C(X)$ and $C_s(X)$, respectively, the sets of all bounded continuous and lower semicontinuous functions on X. Let $\{s_i\}$ be dense in S and define $f_{ij} \in C(S)$ for $i, j = 1, 2, \cdots$ by

$$f_{ij}(s) = 2(1 - jd(s, s_i)) \vee 0,$$

where d is the metric defined in S and $x \vee y = \max\{x, y\}$. Let $M = \{f_{ij}: i, j = 1, 2, \cdots\}$. Then M is separating, i.e., whenever $P_1, P_2 \in P(S)$ and $\int f_{ij}\, dP_1 = \int f_{ij}\, dP_2$ for $i, j = 1, 2, \cdots$, we have $P_1 = P_2$ (for example, see [8]).

Let us prove the following result using the idea given by Borkar [4], [5].

LEMMA 2.1. *For any* $(\nu, \pi) \in P(S) \times \Pi$, *there exists a* $\mu \in P(R)$ *such that*

$$\int c(x, a)\mu(d(x, a)) \leqq \psi(\nu, \pi), \tag{2.1}$$

$$\int g(x)\mu(d(x, a)) = \int \mu(d(x, a)) \int g(x')Q(dx' \mid x, a) \quad \text{for all } g \in M. \tag{2.2}$$

Proof. For any given $(\nu, \pi) \in P(S) \times \Pi$, we consider $\{X_t, \Delta_t; t = 0, 1, \cdots\}$ governed by P_π^ν. For simplicity put $P = P_\pi^\nu$ and $E = E_\pi^\nu$. Then by the stability theorem of Loève [11], we have, P-almost surely,

$$\lim_{T\to\infty} \left(\sum_{t=0}^{T-1} \{g(X_t) - E[g(X_t)|\mathcal{B}_{t-1}]\} \right) \Big/ T = 0 \quad \text{for all } g \in M, \tag{2.3}$$

where $\mathcal{B}_t = \sigma(X_0, \Delta_0, \cdots, X_t, \Delta_t)$ is the sub-σ-field generated by H_t and Δ_t. Let $\tilde{\psi}_T = \sum_{t=0}^{T-1} c(X_t, \Delta_t)/T$ $(T \geqq 1)$. Then, since $E[\liminf_{T\to\infty} \tilde{\psi}_T] \leqq \psi(\nu, \pi)$, we have

$$P(\liminf_{T\to\infty} \tilde{\psi}_T \leqq \psi(\nu, \pi)) > 0,$$

so that there exists a sample path $\omega \in \Omega$ such that (2.3) and $\liminf_{T\to\infty} \tilde{\psi}_T \leqq \psi(\nu, \pi)$ hold.

Now, let us construct the probability measure for which (2.1) and (2.2) hold by using the fixed sample path $\omega \in \Omega$, which is suppressed for notational convenience. For this $\omega \in \Omega$, there exists a subsequence $\{T_j\}$ for which (2.3) and the following (2.4) hold:

$$\lim_{j\to\infty} \tilde{\psi}_{T_j} \leqq \psi(\nu, \pi). \tag{2.4}$$

For any $D \in \mathcal{B}_R$, define the empirical probability measure μ_T by

$$\mu_T(D) = \sum_{t=0}^{T-1} I_D(X_t, \Delta_t)/T \qquad (T \geqq 0),$$

where, for any set G, I_G is the indicator function of G and $I_G(y)$ is equal to 1 if $y \in G$ and equal to 0 otherwise.

Since R is compact, $P(R)$ is also compact in the topology of weak convergence [3], so that there exists a probability measure $\mu \in P(R)$ such that μ_{T_j} converges weakly to μ along a subsequence (also called $\{T_j\}$ by abuse of notation). We shall show that this μ has the desired property.

By the definition of μ_T, (2.3) and (2.4) are rewritten, respectively, by

$$\lim_{j\to\infty}\left[\int g(x)\mu_{T_j}(d(x,a)) - \int \mu_{T_j-1}(d(x,a)) \int g(x')Q(dx'|x,a)\right] = 0 \tag{2.5}$$

for all $g \in M$

and

$$\lim_{j\to\infty} \int c(x,a)\mu_{T_j}(d(x,a)) \leqq \psi(\nu,\pi). \tag{2.6}$$

By the weak continuity of Q, for each $g \in M$, $\int g(x')Q(dx'|x,a)$ is continuous in $(x,a) \in S \times A$, so that, as $j \to \infty$ in (2.5), we get (2.2). Also, since $c \in C_s(S \times A)$, there exists a nondecreasing sequence $\{\phi_k'\} \subset C(S \times A)$ for which $\phi_k \to c$ as $k \to \infty$.

By (2.6), we have for each $k \geqq 1$,

$$\lim_{j\to\infty} \int \phi_k(x,a)\mu_{T_j}(d(x,a)) = \int \phi_k(x,a)\mu(d(x,a)) \leqq \psi(\nu,\pi).$$

As $k \to \infty$ in the above, using the monotone convergence theorem we get (2.1). □

THEOREM 2.1. *For any* $(\nu,\pi) \in P(S) \times \Pi$, *there exists a* $(\nu_0, \Phi^{(\infty)}) \in P(S) \times \Pi'$ *such that*

$$\psi(\nu_0, \Phi^{(\infty)}) \leqq \psi(\nu,\pi). \tag{2.7}$$

Proof. For $(\nu,\pi) \in P(S) \times \Pi$, let $\mu \in P(R)$ be such that (2.1) and (2.2) hold. Then, we can decompose the probability measure μ into $\nu_0 \in P(S)$ and $\Phi \in T(A|S)$ such that

$$\mu(D_1 \times D_2) = \int_{D_1} \Phi(D_2|x)\nu_0(dx) \text{ for any } D_1 \in \mathcal{B}_S \text{ and } D_2 \in \mathcal{B}_A$$

(for example, see [1]).

Let $Q(\cdot|x,\Phi) = \int Q(\cdot|x,a)\Phi(da|x)$. Then since M is separating, by (2.2) we have

$$\nu_0(\cdot) = \int Q(\cdot|x,\Phi)\nu_0(dx),$$

which means that ν_0 is a stationary absolute probability measure for the Markov process induced by $\{Q(\cdot|x,\Phi)\}$. Hence, we have $\psi(\nu_0,\Phi^{(\infty)}) = \int c(x,a)\mu(d(x,a))$, so by (2.1) we get (2.7). □

Here we can give the main result, which states that there exists a minimum pair in $S \times \Pi''$.

THEOREM 2.2. *There exists* $C \in \mathcal{B}_S$ *with* $\gamma(C) > \varepsilon$ *and* $\bar{f}^{(\infty)} \in \Pi''$ *such that* $(x, \bar{f}^{(\infty)}) \in S \times \Pi''$ *is a minimum pair and* $Q(C|x,\bar{f}(x)) = 1$ *for all* $x \in C$.

Proof. Let $\{\varepsilon_n\}$ be such that $\varepsilon_n > 0$ and $\varepsilon_n \to 0$ as $n \to \infty$. From the definition of ψ^*, there exists a sequence $\{(\nu^n,\pi^n)\} \subset P(S) \times \Pi$ for which it holds that

$$\psi(\nu^n,\pi^n) \leqq \psi^* + \varepsilon_n \quad \text{for all } n \geqq 1. \tag{2.8}$$

From Lemma 2.1, for each (ν^n, π^n) there exists a $\mu^n \in P(R)$ satisfying (2.1) and (2.2) with respect to μ^n.

Also, from (2.1) and (2.8) we have

$$\int c(x, a)\mu^n(d(x, a)) \leqq \psi^* + \varepsilon_n \quad \text{for all } n \geqq 1. \tag{2.9}$$

From the compactness of $P(R)$, without loss of generality there exists a $\mu \in P(R)$ such that μ^n converges weakly to $\mu \in P(R)$ and μ satisfies (2.2). Also, for a nondecreasing sequence $\{\phi_k\} \subset C(S \times A)$ with $\phi_k \to c$ as $k \to \infty$, we have, from (2.9),

$$\int \phi_k(x, a)\mu^n(d(x, a)) \leqq \psi^* + \varepsilon_n.$$

As $n \to \infty$ and $k \to \infty$ in the above, using the monotone convergence theorem we get

$$\int c(x, a)\mu(d(x, a)) \leqq \psi^*. \tag{2.10}$$

Since μ satisfies (2.2), if we decompose μ into $\nu \in P(S)$ and $\Phi \in T(A|S)$, ν is a stationary absolute probability measure for $\{Q(\cdot|x, \Phi)\}$. Thus, by (2.10) we get $\psi(\nu, \Phi^{(\infty)}) \leqq \psi^*$, which implies from the definition that

$$\psi(\nu, \Phi^{(\infty)}) = \psi^*. \tag{2.11}$$

Now we consider the Markov process induced by $\{Q(\cdot|x, \Phi)\}$. Then by the theory of Markov processes, under the hypothesis of Doeblin [7], we can define a decomposition of the state space S into a transient set and a finite number of ergodic sets $C_1, C_2, \cdots, C_k$ with $\gamma(C_j) > \varepsilon$ for all $1 \leqq j \leqq k$.

Here we define a $\gamma_j \in P(C_j)(1 \leqq j \leqq k)$ by

$$\gamma_j(\cdot) = \lim_{T \to \infty} P^{(T)}(\cdot|x, \Phi) \quad \text{for each } x \in C_j,$$

where $P^{(T)}(\cdot|x, \Phi) = \sum_{t=0}^{T-1} Q^{(t)}(\cdot|x, \Phi)/T$ and $Q^{(0)}(\cdot|x, \Phi) = I_{\{x\}}(\cdot)$. Also we have $\nu(\cdot) = \int P^{(T)}(\cdot|x, \Phi)\nu(dx)$ for all $T \geqq 1$.

Hence, as $T \to \infty$ in the above, using the dominated convergence theorem we get

$$\nu(\cdot) = \sum_{j=1}^{k} \gamma_j(\cdot)\nu(C_j). \tag{2.12}$$

Let $c(x, \Phi) = \int c(x, a)\Phi(da|x)$. Then, by definition of $\psi(x, \Phi^{(\infty)})$, we have that, for any $x \in C_j$,

$$\begin{aligned} \psi(x, \Phi^{(\infty)}) &= \limsup_{T \to \infty} \int c(x', \Phi) P^{(T)}(dx'|x, \Phi) \\ &= \int_{C_j} c(x', \Phi)\gamma_j(dx'). \end{aligned} \tag{2.13}$$

On the other hand,

$$\begin{aligned} \psi(\nu, \Phi^{(\infty)}) &= \int c(x, \Phi)\nu(dx) \\ &= \sum_{j=1}^{k} \nu(C_j) \int_{C_j} c(x, \Phi)\gamma_j(dx) \quad \text{from (2.12)} \\ &= \sum_{j=1}^{k} \nu(C_j)\psi(x_j, \Phi^{(\infty)}) \quad \text{for any } x_j \in C_j \qquad (1 \leqq j \leqq k) \quad \text{from (2.13)}, \end{aligned}$$

so that since $\psi(x, \Phi^{(\infty)}) \geqq \psi^*$ for all $x \in S$, it holds from (2.11) that for C_j with $\nu(C_j) > 0$,

$$\psi(x, \Phi^{(\infty)}) = \psi^* \quad \text{for all } x \in C_j. \tag{2.14}$$

Now we prove that $\Phi^{(\infty)}$ above can be replaced by a stationary policy. First we show that for each C_j with $\nu(C_j) > 0$, there exists an $f_j \in B(C_j \to A)$ and a Borel measurable function v_j such that

$$Q(C_j \mid x, f_j(x)) = 1, \tag{2.15}$$

$$v_j(x) + \psi^* \geqq c(x, f_j(x)) + \int_{C_j} v_j(x') Q(dx' \mid x, f_j(x)) \quad \text{for all } x \in C_j. \tag{2.16}$$

The inequality above will be used to show that $f_j^{(\infty)}$ is optimal for all initial states belonging to C_j.

Using the theory of Markov process again, we find that, if ${}_1C_j, {}_2C_j, \cdots, {}_dC_j$ are the cyclically moving classes in C_j and $x \in {}_1C_j$, the following holds:

$$\lim_{t \to \infty} Q^{(td+m-1)}(\cdot \mid x, \Phi) = {}_m\gamma_j(\cdot) \quad \text{and} \quad \gamma_j(\cdot) = \sum_{m=1}^{d} {}_m\gamma_j(\cdot)/d. \tag{2.17}$$

For $T \geqq 1$ and $x \in C_j$, let

$$v_j^T(x) = \sum_{t=0}^{[T/d]d-1} E_{\Phi^{(\infty)}}^{x} (c(X_t, \Delta_t) - \psi^*),$$

where for a real number z, $[z]$ is the largest integer equal to or less than z. Then, from (2.13) and (2.14) we can rewrite, for any $x \in {}_1C_j$,

$$\begin{aligned} v_j^T(x) &= \sum_{t=0}^{[T/d]d-1} \int c(x', \Phi)\{Q^{(t)}(dx' \mid x, \Phi) - \gamma_j(dx')\} \\ &= \sum_{t=0}^{[T/d]-1} \left(\sum_{m=1}^{d} \int c(x', \Phi)\{Q^{(td+m-1)}(dx' \mid x, \Phi) - {}_m\gamma_j(dx')\} \right). \end{aligned}$$

So, since the convergence in (2.17) is uniform and exponentially fast and c is bounded, $\lim_{T \to \infty} v_j^T(x)$ exists and is finite. Let $v_j(x) = \lim_{T \to \infty} v_j^T(x)$ for each $x \in C_j$.

Then by the definition of v_j it holds that

$$v_j(x) + \psi^* = \int \Phi(da \mid x) \left\{ c(x, a) + \int v_j(x') Q(dx' \mid x, a) \right\}. \tag{2.18}$$

Since C_j is an invariant set, $\int Q(C_j \mid x, a)\Phi(da \mid x) = 1$ for all $x \in C_j$, so that for each $x \in C_j$

$$Q(C_j \mid x, a) = 1, \qquad \Phi(\cdot \mid x) \text{ a.s.} \tag{2.19}$$

Here, let

$$\bar{R} = \left\{ (x, a) \,\middle|\, Q(C_j \mid x, a) = 1, x \in C_j, a \in A(x), v_j(x) + \psi^* \geqq c(x, a) + \int v_j(x') Q(dx' \mid x, a) \right\}.$$

Then, by (2.18) and (2.19), $\Phi(\bar{R}_x \mid x) > 0$ for all $x \in C_j$, where

$$\bar{R}_x = \{a \in A(x) \mid (x, a) \in \bar{R}\}.$$

Thus, from the selection theorem of [2], there exists an $f_j \in B(C_j \to A)$ such that $f_j(x) \in \bar{R}_x$ for all $x \in C_j$.

Clearly (2.15) and (2.16) hold for this f_j.

Let $C = \bigcup C_j$, where the union is over all $j \in \{i \mid \nu(C_i) > 0\}$. For any $f \in B(S \to A)$, if we define $\bar{f} \in B(S \to A)$ by

$$\bar{f}(x) = \begin{cases} f_j(x) & \text{if } x \in C_j \text{ and } \nu(C_j) > 0, \\ f(x) & \text{otherwise,} \end{cases}$$

it holds from (2.15) and (2.16) that

$$Q(C \mid x, \bar{f}(x)) = 1 \quad \text{for all } x \in C, \tag{2.20}$$

$$v(x) + \psi^* \geqq c(x, \bar{f}(x)) + \int v(x') Q(dx' \mid x, \bar{f}(x)) \quad \text{for all } x \in C, \tag{2.21}$$

where $v(x) = v_j(x)$ if $x \in C_j$ with $\nu(C_j) > 0$.

Let us show that $\psi(x, \bar{f}^{(\infty)}) \leqq \psi^*$ for all $x \in C$ by the same way as the proof of Theorem 7.6 in [13].

For $x \in C$, from (2.21) it holds that, for each $t \geqq 0$,

$$E^x_{\bar{f}^{(\infty)}}[c(X_t, \Delta_t)] \leqq \psi^* + E^x_{\bar{f}^{(\infty)}}[v(X_t) - v(X_{t+1})].$$

Therefore,

$$\begin{aligned} \psi(x, \bar{f}^{(\infty)}) &= \limsup_{T \to \infty} \sum_{t=0}^{T-1} E^x_{\bar{f}^{(\infty)}}[c[X_t, \Delta_t)]/T \\ &\leqq \psi^* + \limsup_{T \to \infty} (v(x) - E^x_{\bar{f}^{(\infty)}}[v(X_t)]/T) \\ &= \psi^*. \end{aligned}$$

□

Theorem 2.2 does not establish the existence of a minimum pair for all initial states—only for those in a Borel subset C of S. At the same time, it shows the existence of an optimal stationary policy for these restricted initial states. In the next section, the extension of these results to all of S is done assuming additional conditions.

3. Optimal stationary policies. In this section we discuss the existence of optimal stationary policies under the following two conditions.

Condition A (Reachability). For any $x \in S$ and $D \in \mathcal{B}_S$ with $\gamma(D) > \varepsilon$, there exists a $\pi \in \Pi$ such that

$$P^x_\pi\left(\bigcup_{t=0}^{\infty} \{X_t \in D\}\right) = 1,$$

where ε and γ are as in the hypothesis of Doeblin.

Condition B. One of the following two conditions is satisfied:

(B1) For γ as in the hypothesis of Doeblin, $\gamma(\partial D) = 0$ if $\gamma(D) > 0$, where ∂D is the boundary of D.

(B2) For each $D \in \mathcal{B}_S$ with $\gamma(D) > \varepsilon$, $Q(D \mid x, a)$ is continuous in $(x, a) \in S \times A$.

Now we can state the following theorem.

THEOREM 3.1. *Under Conditions* A *and* B, *there exists an optimal stationary policy.*

To prove Theorem 3.1 we need several lemmas.

Let C and $\bar{f} \in B(S \to A)$ be given in Theorem 2.2 and $F = S - C$.

Let $\tilde{t} = \inf\{t \geqq 0 \mid X_t \in C\}$, where $\inf \phi = \infty$.

For any $x \in F$, let π be such that $P^x_\pi(\bigcup_{t=0}^{\infty} \{X_t \in C\}) = 1$, whose existence is guaranteed by Condition A.

For this π, we define $\pi^* = (\pi_0^*, \pi_1^*, \cdots)$ by, for each $D \in \mathcal{B}_A$,

$$\pi_t^*(D \mid H_t) = \begin{cases} I_D(\bar{f}(X_t)) & \text{if } t \geqq \tilde{t}, \\ \pi(D \mid H_t) & \text{if } t < \tilde{t}. \end{cases}$$

We note that $P_{\pi^*}^x(\bigcup_{t=0}^{\infty} \{X_t \in C\}) = 1$.

LEMMA 3.1. $\psi(x, \pi^*) = \psi^*$.

Proof. For simplicity set $E = E_{\pi^*}^x$. Since $\psi(x, \bar{f}^{(\infty)}) = \psi^*$ for all $x \in C$, it follows from the definition of π^* that for any $k \geqq 0$ with $P_{\pi^*}^x(\tilde{t} = k) > 0$,

$$\begin{aligned} &\limsup_{T\to\infty} E\left[\sum_{t=k}^{T-1} c(X_t, \Delta_t) \,\middle|\, \tilde{t} = k\right] \Big/ T \\ &= \lim_{T\to\infty} E\left[\sum_{t=k}^{T-1} c(X_t, \Delta_t) \,\middle|\, \tilde{t} = k, X_k \in C\right] \Big/ (T-k) \qquad (3.1) \\ &= \psi^*. \end{aligned}$$

Also,

$$\begin{aligned} \psi(x, \pi^*) \leqq &\sum_{k=0}^{\infty} E\left[\limsup_{T\to\infty} E\left[\sum_{t=0}^{(T-1)\wedge k} c(X_t, \Delta_t) \,\middle|\, \tilde{t} = k\right] \Big/ T\right] \\ &+ \sum_{k=0}^{\infty} E\left[\limsup_{T\to\infty} E\left[\sum_{t=(T-1)\wedge k+1}^{T-1} c(X_t, \Delta_t) \,\middle|\, \tilde{t} = k\right] \Big/ T\right], \end{aligned}$$

where $a \wedge b = \min\{a, b\}$.

Since c is bounded, the first term of the right-hand side of the above inequality is zero, so that by (3.1) we get

$$\psi(x, \pi^*) \leqq \psi^* P_{\pi^*}^x\left(\bigcup_{t=0}^{\infty} \{X_t \in C\}\right) = \psi^*. \qquad \square$$

For $u \in C_s(F)$, we define Ku, for each $x \in F$, by

$$Ku(x) = \inf_{a \in A(x)} \left\{\psi^* Q(C^* \mid x, a) + \int_F u(x') Q(dx' \mid x, a)\right\}, \qquad (3.2)$$

where $C^* = \mathring{C}$ under (B1) and $C^* = C$ under (B2), and $\mathring{C}$ is the set of interior points of C.

LEMMA 3.2. *$u \in C_s(F)$ implies $Ku \in C_s(F)$.*

Proof. Let $u \in C_s(F)$. Under (B1), $\gamma(\mathring{C}) \geqq \varepsilon$, and from the weak continuity of Q, $\liminf_{x' \to x, a' \to a} Q(\mathring{C} \mid x', a') \geqq Q(\mathring{C} \mid x, a)$, which means that $Q(\mathring{C} \mid x, a) \in C_s(F \times A)$.

Also, $\int_F u(x') Q(dx' \mid x, a) \in C_s(F \times A)$, so that $Ku \in C_s(F)$ (cf. [1], [12]).

Under (B2), similarly $Ku \in C_s(F)$. $\square$

LEMMA 3.3. *Let v be a bounded Borel measurable function on F such that*

$$v = Kv. \qquad (3.3)$$

Then, $v(x) \leqq \psi^*$ for all $x \in F$.

Proof. For $x \in F$ and $\pi^* \in \Pi$ as in Lemma 3.1, let

$$B_T(x, \pi^*) = \psi^* P_{\pi^*}^x(X_t \in C^* \text{ for some } t \leqq T).$$

For simplicity set $P = P^x_{\pi^*}$ and $E = E^x_{\pi^*}$. We have

$$B_T(x, \pi^*) = E\left[\sum_{t=0}^{T-1} \psi^* Q(C^* | X_t, \Delta_t) I_{\{X_0 \in F, \cdots, X_t \in F\}}\right]$$

$$\geqq E\left[\sum_{t=0}^{T-1} (v(X_t) - E[v(X_{t+1}) I_{\{X_{t+1} \in F\}} | X_t, \Delta_t]) \cdot I_{\{X_0 \in F, \cdots, X_t \in F\}}\right] \quad \text{from (3.3)}$$

$$\geqq v(x) - H \cdot P(X_t \in F \text{ for all } 0 \leqq t \leqq T) \quad \text{for some } H > 0.$$

Thus, as $T \to \infty$ in the formula above, we get

$$\lim_{T\to\infty} B_T(x, \pi^*) = \psi^* P\left(\bigcup_{t=0}^{\infty} \{X_t \in C\}\right) = \psi^* \geqq v(x). \qquad \square$$

Proof of Theorem 3.1. For any $\alpha > \psi^*$, let $v_0 \equiv \alpha$ and $v_{n+1} = Kv_n (n \geqq 0)$. Then we observe from Lemma 3.2 that $v_n \in C_s(F)$ and $v_n \geqq v_{n+1} \geqq \psi^*$ for all $n \geqq 0$. Let $v = \lim_{n\to\infty} v_n$. Then $Kv \leqq Kv_n = v_{n+1} (n \geqq 1)$, which implies $Kv \leqq v$. On the other hand, for any $\eta > 0$,

$$\eta + Kv > \psi^* Q(C | x, a) + \int v(x') Q(x' | x, a) \quad \text{for some } a \in A(x). \tag{3.4}$$

By the monotone convergence theorem,

$$\lim_{n\to\infty} \int v_n(x') Q(dx' | x, a) = \int v(x') Q(dx' | x, a).$$

Hence, from (3.4) we have

$$\eta + Kv > \psi^* Q(C | x, a) + \int v_n(x') Q(dx' | x, a)$$

$$\geqq v_{n+1}(x) \quad \text{for all } n \geqq N \text{ and some } N.$$

As $n \to \infty$ in the above, $\eta + Kv(x) \geqq v(x)$, which gets $Kv(x) \geqq v(x)$ when $\eta \to 0$.

From the discussion above, we have $v = Kv$.

By Lemma 3.2, we get $v \leqq \psi^*$. Hence, if we let $\tilde{k} = \min\{k | v_k(x) < \alpha\}$ and $F_k = \{x \in F | \tilde{k}(x) = k\}$ for each $k \geqq 1$, it holds that

$$F = \bigcup_{k=1}^{\infty} F_k. \tag{3.5}$$

By the selection theorem (cf. [1], [12]), for each $k \geqq 1$ there exists an $f_k \in B(F_k \to A)$ with

$$v_k(x) = \psi^* Q(C | x, f_k(x)) + \int v_{k-1}(x') Q(dx' | x, f_k(x)) \quad \text{for all } x \in F_k. \tag{3.6}$$

Now, considering (3.5), we define $\bar{\bar{f}} \in B(S \to A)$ by

$$\bar{\bar{f}}(x) = \begin{cases} \bar{f}(x) & \text{if } x \in C, \\ f_k(x) & \text{if } x \in F_k \quad \text{for some } k \geqq 1. \end{cases}$$

Here, we consider the stationary Markov process induced by $\{Q(\cdot | x, \bar{\bar{f}}(x))\}$. For each $k \geqq 1$, it holds from the definition of F_k that $Q(F_{k-1} | x, \bar{\bar{f}}(x)) > 0$ for all $x \in F_k$, so that by (3.5) F is a transient set, which implies $P^x_{\bar{\bar{f}}^{(\infty)}}(\bigcup_{t=0}^{\infty} \{X_t \in C\}) = 1$ for all $x \in F$, where $F_0 = C$.

Using Lemma 3.1, we get $\psi(x, \bar{\bar{f}}^{(\infty)}) = \psi^*$ for all $x \in S$. $\square$

Remark. We introduce the following condition to consider the unichain case.

Condition C. For any $f \in B(S \to A)$, the Markov process induced by $\{Q(\cdot | x, f(x))\}$ has only one ergodic set.

Examination of the discussion in §§ 2 and 3 shows that there exists an optimal stationary policy under Conditions B and C. These are extensions of the results obtained in [14], [15] by approximating the average cost problem by the discounted cost problems.

4. Further results. In this section we derive the general results under the following continuity condition.

Condition D. The following hold:

(D1) For any $G \in \mathcal{B}_S$, $Q(G|\cdot) \in C(R)$.

(D2) For any sequence $\{x_n\}$ and x in S with $x_n \to x$ as $n \to \infty$ and any $a \in A(x)$, there exists a sequence $\{a_n\}$ with $a_n \in A(x_n)$ and $a_n \to a$ as $n \to \infty$.

THEOREM 4.1. *Suppose that Condition* D *holds; then there exists a decomposition of* S:

$$S = F \cup S_1 \cup \cdots \cup S_r, \quad F \in \mathcal{B}_S, \quad S_i \in \mathcal{B}_S, \tag{4.1}$$
$$S_i \cap S_j = \phi \quad (i \neq j), \quad F \cap S_j = \phi,$$

and a stationary policy $f^{(\infty)}$ *and constants* $\alpha_1, \alpha_2, \cdots, \alpha_r$ *with the following properties*:

(i) $\psi(x, f^{(\infty)}) = \psi(x)$ *for all* $x \in S^*$ *and* $\psi(x) = \alpha_i$ *for each* $x \in S_i$ $(1 \leqq i \leqq r)$, *where* $S^* = \bigcup_{i=1}^{r} S_i$.

(ii) *Each* $S_i (1 \leqq i \leqq r)$ *is invariant for the Markov process induced by* $f^{(\infty)}$.

(iii) $\psi(x, f^{(\infty)}) \leqq \psi(x, \pi)$ *for all* $x \in F$ *and any* $\pi \in \Pi$ *with*

$$P_\pi^x(X_t \in S^* \text{ for some } t \geqq 0) = 1. \tag{4.2}$$

Proof. By Theorem 2.2, there exists a constant α_1, a set $S_1 \in \mathcal{B}_S$ with $\gamma(S_1) > \varepsilon$, and a stationary policy $\bar{f}_1^{(\infty)}$ for which $\psi(x, \bar{f}_1^{(\infty)}) = \psi(x) = \alpha_1$ and $Q(S_1|x, \bar{f}_1(x)) = 1$ for all $x \in S_1$, where γ and ε are as in the hypothesis of Doeblin. We note that S_1 corresponds to C in Theorem 2.2. Put $D_0 = S_1$ and $D = S - D_0$. If we set, for each $j \geqq 1$, $D_j = \{x \in D - \bigcup_{i=1}^{j-1} D_i \mid Q(D_{j-1}|x, a) > 0 \text{ for some } a \in A(x)\}$, D_j is open. In fact, let $\{x_n\}$ be any sequence such that $x_n \notin D_j$ and $x_n \to x$ as $n \to \infty$. Then for any $a \in A(x)$, by (D2) there exists a sequence $\{a_n\}$ with $a_n \in A(x_n)$ and $a_n \to a$ as $n \to \infty$. From (D1), we have $Q(D_{j-1}|x, a) = \lim_{n\to\infty} Q(D_{j-1}|x_n, a_n) = 0$.

In the case where $D = \bigcup_{j=1}^{\infty} D_j$, from the selection theorem (for example, [1]), there exists an $\hat{f} \in B(D \to A)$ such that for each $j \geqq 1$

$$Q(D_{j-1}|x, \hat{f}(x)) = \max_{a \in A(x)} Q(D_{j-1}|x, a) \quad \text{for all } x \in D_j.$$

Here we define f by

$$f(x) = \begin{cases} \bar{f}_1(x) & \text{if } x \in S_1, \\ \hat{f}(x) & \text{if } x \in D. \end{cases}$$

Clearly, $P_{f^{(\infty)}}^x(X_t \in S_1 \text{ for some } t \geqq 0) = 1$ for all $x \in D$, so that by Lemma 3.1, $\psi(x, f^{(\infty)}) = \alpha_1$. Thus, putting $F = D$, the proof is complete.

In the case where $D \neq \bigcup_{j=1}^{\infty} D_j$, let $G = D - \bigcup_{j=1}^{\infty} D_j$. Then, using (D2) we can prove that $Q(\bar{G}|x, a) = 1$ for all $x \in \bar{G}$ and $a \in A(x)$, where $\bar{G}$ is the closure of G. We note from the hypothesis of Doeblin that $\gamma(\bar{G}) > \varepsilon$.

Here, we apply Theorem 2.2 to the sub-Markov decision process with the restricted state space $\bar{G}$. Then there exists a constant α_2, a set $S_2 \in \mathcal{B}_{\bar{G}}$ with $\gamma(S_2) > \varepsilon$ and a stationary policy $\bar{f}_2^{(\infty)}$ for which $\psi(x, \bar{f}_2^{(\infty)}) = \psi(x) = \alpha_2$ and $Q(S_2|x, \bar{f}_2(x)) = 1$ for all $x \in S_2$.

For any given $g \in B(S \to A)$, we define $\bar{f} \in B(S \to A)$ by

$$\bar{f}(x) = \begin{cases} \bar{f}_i(x) & \text{if } x \in S_i, \quad i = 1, 2, \\ g(x) & \text{otherwise.} \end{cases}$$

Then we observe that $\psi(x, \bar{f}^{(\infty)}) = \alpha_i$ if $x \in S_i$, $i = 1, 2$. Now, putting $D_0 = S_1 \cup S_2$ and $D = S - D_0$, we repeat the discussion above. Since $\gamma(S) < \infty$, by repeating this method successively we come to the conclusion that there exists a decomposition (4.1) and $\hat{f} \in B(S \to A)$ satisfying (i) and (ii). If we let $G_0 = S^*$ and for each $j \geqq 1$,

$$G_j = \left\{ x \in F - \bigcup_{i=1}^{j-1} G_i \mid Q(G_{j-1} \mid x, a) > 0 \text{ for some } a \in A(x) \right\},$$

we have

$$F = \bigcup_{j=1}^{\infty} G_j, \tag{4.3}$$

where $F = S - S^*$.

For $u \in C(\bar{F})$, we define Uu by, for each $x \in \bar{F}$,

$$Uu(x) = \inf_{a \in A(x)} U(x, a, u), \tag{4.4}$$

where

$$U(x, a, u) = \sum_{i=1}^{r} \alpha_i Q(S_i \mid x, a) + \int_F u(x') Q(dx' \mid x, a) \quad \text{for } x \in \bar{F} \text{ and } a \in A(x). \tag{4.5}$$

Let $v_0 \equiv \max\{\alpha_i; i = 1, \cdots, r\}$ and $v_{n+1} = Uv_n (n \geqq 0)$. Then, clearly $v_n \geqq v_{n+1} (n \geqq 1)$ and $v_n \in C(\bar{F})$. If we put $v = \lim_{n \to \infty} v_n$, $v \in C(\bar{F})$ from Dini's Theorem.

Also, similarly as the proof of Theorem 3.1, we get

$$v(x) = Uv(x) \quad \text{for all } x \in F. \tag{4.6}$$

Now we define, for each $x \in F$ and $\pi \in \Pi$,

$$B(x, \pi) = \lim_{T \to \infty} B_T(x, \pi),$$

where

$$B_T(x, \pi) = \sum_{i=1}^{r} \alpha_i P_\pi^x \quad (X_t \in S_i \text{ for some } 0 \leqq t \leqq T).$$

Let π be any policy satisfying (4.2). Then it is easily proved that

$$\psi(x, \pi) = B(x, \pi) \geqq v(x) \quad \text{for all } x \in F. \tag{4.7}$$

Here, again by the selection theorem, there exists an $f^* \in B(F \to A)$ such that $v(x) = U(x, f^*(x), v)$ for all $x \in F$. Using this f^*, we define $f \in B(S \to A)$ by

$$f(x) = \begin{cases} \hat{f}(x) & \text{if } x \in S^*, \\ f^*(x) & \text{if } x \in F. \end{cases}$$

From (4.3) we observe that $f^{(\infty)}$ satisfies (4.2). Therefore,

$$v(x) = \lim_{T \to \infty} U^T v(x) \geqq \lim_{T \to \infty} B_T(x, f^{(\infty)}) = B(x, f^{(\infty)}) = \psi(x, f^{(\infty)}),$$

which implies (iii) from (4.7). □

REGULAR SYNTHESIS FOR THE LINEAR TIME-OPTIMAL CONTROL PROBLEM WITH CONVEX CONTROL CONSTRAINTS*

MARGARÉTA HALICKÁ†

Abstract. The problem of existence of a regular synthesis for the linear time-optimal control problem with convex control constraints is studied. A regular synthesis on the whole reachable set cannot be established for this problem by direct use of Brunovsky's general existence theorem. This is in accord with the example of a nonsubanalytic reachable set due to Lojasiewicz and Sussmann [S. Lojasiewicz, Jr. and H. J. Sussmann, "Some examples of reachable sets and optimal cost functions that fail to be subanalytic," *SIAM J. Control Optim.*, 23 (1985), pp. 584-598]. A closed subset H of the reachable set K that has Lebesgue measure zero is constructed and the existence of a regular synthesis on $K - H$ is proved.

Key words. control theory, linear time-optimal problem, regular synthesis, reachable set, subanalytic set

AMS(MOS) subject classifications. 49C20, 34H05

1. Introduction. The class of linear time-optimal control problems is one of the simplest and most developed classes of optimal control problems. Linear time-optimal control problems having polyhedral control restraint sets and satisfying a normality condition are the first larger class of problems for which the existence of a regular synthesis has been proved [2]. This result was obtained by using the method of subanalytic sets, which has found wide application to other problems in control theory as well.

Using the abstract theorem on the existence of regular synthesis [3] (ERS theorem) the existence of a regular synthesis for the linear-quadratic problem (LQ problem) has been proved in [4]. The control set is a polyhedron and a normality condition is assumed. A certain generalization of the LQ problem is given in [6], which contains a proof of the existence of the regular synthesis for a linear-convex problem (LC problem), the system is linear, the Lagrangian is convex and strictly convex in the control variable, and the convex compact control set is given by analytic inequalities.

All the classes of problems [2], [4], [6] mentioned have one common property derived from the application of the method of subanalytic sets: they admit a subanalytic regular synthesis, e.g., all the cells of the regular synthesis are subanalytic sets. From this property it follows that the whole reachable set is subanalytic.

The results achieved in control theory using the method of subanalytic sets seem to indicate that subanalyticity is a property of other, larger classes of control problems. Hence the paper by Lojasiewicz and Sussmann [8] was a surprise. It presents some examples of rather simple problems that do not possess the property of subanalyticity. This is first of all an example of a linear control system with a convex control set. In this example the reachable set is not subanalytic, and therefore the optimal control problem for this system does not admit a subanalytic regular synthesis on the whole reachable set. So, in this case, the applicability of the method of subanalytic sets in control theory reaches its limits.

Here we deal with the same class of linear time-optimal control problems with a convex, compact control set given by analytic inequalities. For this class of problems we investigate the existence of a subanalytic regular synthesis. From [8], however, it

* Received by the editors September 8, 1986; accepted for publication (in revised form) May 13, 1988. This paper is part of the author's doctoral thesis written at Comenius University.

† Institute of Applied Mathematics and Computing, Comenius University, Mlynská dolina, Bratislava, Czechoslovakia.

is evident that a subanalytic regular synthesis does not exist on the whole reachable set. Therefore, using the ERS theorem, we construct a closed subset H of the reachable set K, and we prove the existence of a regular synthesis on $K-H$, the cells being subanalytic subsets of $K-H$ (§§ 1-6). In §§ 7 and 8 we prove that the Lebesgue measure of H is zero, i.e., $K-H$ almost exhausts K.

2. The linear time-optimal control problem. We consider the time-optimal control problem given by the linear system

$$\dot{x} = Ax + Bu \tag{1}$$

where A, B are $n \times n$ and $n \times m$ matrices, respectively, $n \geqq m$, rank $B > 1$, and the $n \times nm$ matrix $(B, AB, A^2B, \cdots, A^{n-1}B)$ has rank n.

Here the class of admissible controllers consists of measurable functions defined on intervals $[0, T]$, $T > 0$, with values in the set $U \subset R^m$. The initial point is $x_0 \in R^n$ and the target point is $\hat{x} = 0 \in R^n$.

The control restraint set U is a compact, convex set, $0 \in \operatorname{int} U$ and it is assumed to be of the form

$$U = \{u \in R^m / g^i(u) \leqq 0,\ i \in S,\ c^{j*}u \leqq d^j,\ j \in P\}$$

(* stands for transposition), $S = \{1, \cdots, s\}$, $P = \{1, \cdots, p\}$, where

(a) $g^i : R^m \to R$, $i \in S$, are analytic functions, $c^j \in R^m$, $d^j \in R^1$;

(b) $M_i(u) = (\partial^2 g^i(u)/\partial u^2) > 0$ for $u \in U$, $i \in S$;

(c) If for $\hat{u} \in U$ we have $g^i(\hat{u}) = 0$ for $i \in P_1 \subseteq P$ and $c^{j*}\hat{u} = d^j$ for $j \in S_1 \subseteq S$, then the vectors $(\partial g^i(u)/\partial u)^*$, c^j, $i \in P_1, j \in S_1$, are linearly independent;

(d) Among the inequalities defining U there are no redundant ones, i.e., for every $i \in S$ there exists a $u \in R^m$ such that $g^i(u) > 0$, $g^k(u) \leqq 0$, $c^{j*}u \leqq d^j$ for $k \in S - \{i\}, j \in P$, and for every $j \in P$ there exists a $u \in R^m$ such that $c^{j*}u > d^j$, $c^{k*}u \leqq d^k$, $g^i(u) \leqq 0$ for $k \in P - \{j\}$, $i \in S$.

Before presenting the last assumption about the set U we introduce some notation. We define

$$U_{IJ} = \{u \in R^m / g^i(u) = 0,\ i \in I,\ g^i(u) < 0,\ i \notin I,\ c^{j*}u = d^j,\ j \in J,\ c^{j*}u < d^j,\ j \notin J\}$$

for every index set $I \times J$, where $I \subseteq S$, $J \subseteq P$, and $|I| + |J| \leqq m$, $|I|$ being the cardinality of I.

The sets U_{IJ} can be empty for some I, J. For $I = \varnothing$, $J = \varnothing$, U_{IJ} is the interior of U. We shall call the index set $I \times J$ admissible if $|I| + |J| \leqq m$ and U_{IJ} is not empty and denoted by IJ. Instead of U_{IJ} we shall sometimes write U_I, U_J, or U_0, respectively, when $J = \varnothing$, $I = \varnothing$, or $IJ = \varnothing$.

Now we return to the formulation of the assumption for U.

(e) For every U_J, J admissible, there are $z^1, z^2 \in \bar{U}_J$ such that the vectors $B(z^1 - z^2), AB(z^1 - z^2), \cdots, A^{n-1}B(z^1 - z^2)$ are linearly independent.

For given $x_0 \in R^n$ we will denote by $\mathrm{LT}(x_0)$ the time-optimal control problem just formulated.

Let us note that for our purpose it is sufficient if the assumptions (a), (b) are valid on some neighbourhood of U.

Assumption (e) will also be called the normality condition. From this condition it follows that the LT problem is normal in the sense of [9].

A controller $u(t)$ and its response $x(t)$, $t \in [0, T]$, will be called extremal for the LT problem (with respect to a nonzero solution $\psi(t)$ of the adjoint equation $\dot{\psi} = -A^*\psi$)

if the triple x, u, ψ satisfies the maximum condition

$$\psi(t)^* Bu(t) = \max_{u \in U} \psi(t)^* Bu$$

almost everywhere on $[0, T]$.

We recall some well-known properties of the linear time-optimal control problem that are valid under our assumptions (cf. [7], [9]).

(LT1) If $0 \leqq T_1 < T_2$, then $K(T_1) \subseteq \operatorname{int} K(T_2)$ ($K(T)$ is the set of all initial points x from which (1) can be steered to the origin using an admissible controller defined on the interval $[0, T]$).

(LT2) The reachable set K (i.e., the set of all points x from which (1) can be steered to the origin using an admissible controller defined on some finite interval) is an open subset of R^n.

(LT3) For given $x \in K$ there exists a unique extremal controller $u_x(t)$ defined on $[0, T_x]$. This extremal controller is optimal.

(LT4) The function $T(x)$ associating with every x the minimal time T_x in which (1) can be steered from x to zero is continuous on K.

Our aim is to investigate the existence of a subanalytic regular synthesis for the problem LT(x), $x \in K$. As in the LQ problem and the LC problem we use the ERS theorem.

3. The solution of the maximum condition. To verify the hypothesis of the ERS theorem we must express the solution of the maximum condition as a function of ψ. Since U is compact, for each $\psi \in R^n - \{0\}$ there exists a $w_\psi \in U$ such that the linear function $H_\psi(u) = \psi^* Bu$ has its maximum in w_ψ, i.e.,

$$\psi^* B w_\psi = \max_{u \in U} \psi^* Bu. \tag{2}$$

Contrary to the LC problem, the solution w_ψ of condition (2) is not uniquely determined by the value ψ in general. For example, if $\psi \in \operatorname{Ker} B^*$ or $B^*\psi$ is from the convex cone generated by the vectors $c^j, j \in J$, we can choose for w_ψ, $u \in U$, or $u \in U_J$, respectively.

We denote by $\bar{w}(\psi)$ the set of all solutions w_ψ of the condition (2) for given ψ.

In the sequel we decompose the space of the adjoint variables into two sets W_A and W_B. The solution of (2) will be uniquely determined by ψ on W_A, which enables us to use the procedure from [6] on W_A. First, we introduce some notation and prove some lemmas.

If a property V_i (V_j, respectively) holds for every $i \in I$ ($j \in J$), then we shall write $V_I(V_J)$ instead of $V_i, i \in I$ ($V_j, j \in J$).

In the same way as in the LC problem [6] we can prove the following lemma about an analytic stratification of U.

LEMMA 1. *The family of the sets U_{IJ}, IJ admissible, is an analytic stratification of U.*

COROLLARY 1. *Let IJ be an admissible set. Then* $\dim U_{IJ} = m - (|I| + |J|)$ *and U_{IJ} has at most a finite number of components.*

The proof follows from the linear independence of the vectors $(\partial g^i(u)/\partial u)^*$, c^j, $i \in I, j \in J$. The finiteness of the numbers of components follows from the semianalyticity of U_{IJ}.

Further, we define

$$W_{IJ} = \{\psi \in R^n - \{0\} / \bar{w}(\psi) \cap U_{IJ} \neq \varnothing\} \tag{3}$$

for every IJ admissible. It is easy to see that for $IJ = \emptyset$ the set $U_{IJ} = \operatorname{int} U$ and $W_{IJ} = \operatorname{Ker} B^* - \{0\}$. Instead of W_{IJ} we shall sometimes write W_I, W_J, or W_0, respectively, when $J = \emptyset$, $I = \emptyset$, or $IJ = \emptyset$. However, any statement about IJ, I, or J admissible will be understood to hold for the case $IJ = \emptyset$, $I = \emptyset$, or $J = \emptyset$ as well.

Because of the positive homogeneity of H in ψ the sets W_{IJ}, IJ admissible, completed by the point zero, are cones. These sets cover $R^n - \{0\}$. In contrast to the LC problem the sets W_{IJ}, IJ admissible, do not partition the space $R^n - \{0\}$.

Example. Let the restraint set U be given by the inequalities

$$u_1 \leqq \tfrac{1}{2}, \qquad u_1^2 + u_2^2 + u_3^2 \leqq 1,$$

and let $n = m = 3$ and B be an identity matrix. We denote

$$U_{12} = \{u \in R^3 / u_1 = \tfrac{1}{2},\ u_1^2 + u_2^2 + u_3^2 = 1\},$$

$$U_1 = \{u \in R^3 / u_1 < \tfrac{1}{2},\ u_1^2 + u_2^2 + u_3^2 = 1\},$$

$$U_2 = \{u \in R^3 / u_1 = \tfrac{1}{2},\ u_1^2 + u_2^2 + u_3^2 < 1\}.$$

The sets U_{12}, U_1, U_2 form an analytic stratification of U defined in the general case above. The corresponding set W_{12} is the closed circular cone with the vertex in the origin of the space of adjoint variables and with the axis ψ_1. The set W_2 is the positive half-axis ψ_1, W_1 is the open circular cone $R^3 - W_{12} - \{0\}$.

As with the LC problem, we can prove a lemma about subanalyticity of W_{IJ} and the necessary and sufficient condition for $\psi \in W_{IJ}$ in our LT problem. The proofs of these lemmas are the same as the corresponding ones for the LC problem.

LEMMA 2. *For every IJ admissible the set W_{IJ} is a subanalytic subset of R^n.*

LEMMA 3. *Let $\psi \in R^n - \{0\}$, IJ admissible. Then $\psi \in W_{IJ}$ if and only if there exist a $u \in U_{IJ}$ and $a^i \geqq 0$, $i \in I$, $b^j \geqq 0$, $j \in J$, such that*

$$-B^*\psi + \sum_{i \in I} a^i \left(\frac{\partial g^i(u)}{\partial u} \right)^* + \sum_{j \in J} b^j c^j = 0. \tag{4}$$

u is a solution of (2) for given ψ.

Remark 1. Let $u \in U_{IJ}$, IJ admissible. By the symbol C_u we denote the convex cone generated by the vectors $(\partial g^i(u)/\partial u)^*$, c^j, $i \in I, j \in J$. Then Lemma 3 can be written in the form

$$B^* W_{IJ} = \bigcup_{u \in U_{IJ}} C_u. \tag{5}$$

COROLLARY 2. *For every J admissible the set W_J is a closed subset of $R^n - \{0\}$.*

Proof. Evidently $B^* W_J = C_u$, where u is an arbitrary chosen element from U_J. The set C_u is closed for every $u \in U_J$ and therefore its B^*-preimage is closed. □

COROLLARY 3. (a) $\dim B^* W_J = |J|$ *for every J admissible.*

(b) *If $|J| = m - k$, then* $\dim W_J \leqq n - k$.

(c) $\dim W_0 < n - 1$.

Proof. Assertion (a) is a corollary of the linear independence of the vectors c^j, $j \in J$, J admissible.

Condition (b) follows from the fact that a linear mapping does not increase the dimension of an analytic manifold.

If $J = \emptyset$, then $|J| = m - m$, and because of $m > 1$ we have $\dim W_0 = \dim W_J \leqq n - m < n - 1$. □

COROLLARY 4. *For every IJ, J' admissible, such that $J' \subseteq J$ the inclusion $W_{J'} \subseteq W_{IJ}$ holds.*

Proof. Let $\psi \in W_{J'}$; then according to Lemma 3 there exist $b^j \geqq 0$, $j \in J'$ such that

$$-B^*\psi + \sum_{j \in J} b^j c^j = 0.$$

We take $a^i = 0$, $i \in I$, $b^j = 0$, $j \in J - J'$, and an arbitrary $u \in U_{IJ}$. Then, for $\psi, a^i, i \in I, b^j, j \in J, u$, condition (4) holds and therefore $\psi \in W_{IJ}$. This completes the proof. □

For every IJ admissible we define the set V_{IJ} by

$$V_{IJ} = \begin{cases} W_{IJ} - W_J & \text{if } |I| \neq 0, \\ W_{IJ} - \bigcup_{J' \subset J} W_{J'} & \text{if } |I| = 0. \end{cases} \tag{6}$$

As in the case of W's instead of V_{IJ} we shall sometimes write V_I, V_J, or V_0, respectively, when $J = \emptyset$, $I = \emptyset$, or $IJ = \emptyset$.

LEMMA 4. *For every $\psi \in V_{IJ}$, IJ admissible, IJ such that either $|I| \neq 0$ or $|J| = m$, there is a unique solution w_ψ of the maximum condition* (2).

Proof. Let $\psi \in V_{IJ}$, IJ admissible, $|I| \neq 0$. Then there exists a $w_\psi \in U_{IJ}$ such that

$$\psi^* B w_\psi = \max_{u \in U} \psi^* B u. \tag{7}$$

Let $\hat{w}_\psi \in U_{I'J'}$, $\hat{w}_\psi \neq w_\psi$, be such that

$$\psi^* B \hat{w}_\psi = \max_{u \in U} \psi^* B u. \tag{8}$$

Then it follows immediately from (7), (8) and from the convexity of U that for every $\lambda \in [0, 1]$

$$\psi^* B(\lambda w_\psi + (1-\lambda)\hat{w}_\psi) = \max_{u \in U} \psi^* B u. \tag{9}$$

Hence $\tilde{w}_\psi(\lambda) = \lambda w_\psi + (1-\lambda)\hat{w}_\psi$ is a solution of the maximum condition for every $\lambda \in [0, 1]$, i.e., $\tilde{w}_\psi(\lambda)$ is a maximum of a linear function on a compact set. Since $\psi \in V_{IJ}$, $\psi \notin W_0$ and therefore $w_\psi(\lambda)$ is from the boundary of U for every $\lambda \in [0, 1]$. From the definition of U (the strict convexity and the linearity of the inequalities defining U) it can be seen that if the segment $\tilde{w}_\psi(\lambda)$, $\lambda \in [0, 1]$, is from the boundary of U, then there is a J'' admissible such that $\tilde{w}_\psi(\lambda) \in U_{J''}$ for every $\lambda \in (0, 1)$ and $J'' \subseteq J'$, $J'' \subseteq J$. Consequently, $\psi \in W_{J''} \subseteq W_J$, which contradicts the definition of V_{IJ}.

Let $\psi \in V_J$, $|J| = m$; then there exists a unique $w_\psi \in U_J$ since U_J is a vertex of U. Now, because of the same argument as in the case of $|I| \neq 0$ we obtain the uniqueness of $w_\psi \in U$. □

COROLLARY 5. *The sets V_{IJ}, IJ admissible, form a partition of $R^n - \{0\}$.*

Proof. Due to the definition of the sets V_{IJ} they cover $R^n - \{0\}$. First, we prove that if IJ is admissible such that either $|I| \neq 0$ or $|J| = m$, then $V_{IJ} \cap V_{I'J'} = \emptyset$ for every $I'J'$ admissible, $IJ \neq I'J'$.

Let $\psi \in V_{IJ} \cap V_{I'J'}$. Then there are $w_\psi^1, w_\psi^2 \in \bar{w}(\psi)$ such that $w_\psi^1 \in U_{IJ}$, $w_\psi^2 \in U_{I'J'}$. According to Lemma 1 we have $U_{IJ} \cap U_{I'J'} = \emptyset$ and therefore $w_\psi^1 \neq w_\psi^2$, which contradicts Lemma 4.

Now we prove that if J is admissible, $J < m$, then $V_J \cap V_{J'} = \emptyset$ for every J' admissible, $J' \neq J$, $|J'| < m$. Let $\psi \in V_J \cap V_{J'}$. Then there exist $w_\psi^1 \in U_J$, $w_\psi^2 \in U_{J'}$ and $w_\psi^1 \neq w_\psi^2$. Due to the definitions of U and w_ψ there is J'' admissible, $J'' \subseteq J'$, $J'' \subseteq J$ such that $\psi \in W_{J''}$. This contradicts the definition of V_J.

We denote

$$W_A = \bigcup V_{IJ}, \tag{10}$$

where the union is taken over all IJ admissible such that either $|I| \neq 0$ or $|J| = m$. Further, we denote

$$W_Y = (R^n - \{0\}) - W_A. \tag{11}$$

Since the sets V_{IJ}, IJ admissible, form a partition of $R^n - \{0\}$ the following relation holds:

$$W_Y = \bigcup_{|J|<m} V_J = \bigcup_{|J|<m} W_J. \tag{12}$$ □

COROLLARY 6. *The set W_A is an open subset of $R^n - \{0\}$.*

This follows immediately from (10)-(12) and Corollary 2.

Now it is easy to see the geometric meaning of the definitions of W_A and W_Y: W_A is the complement of W_Y in $R^n - \{0\}$; W_Y is the union of the polyhedral cones W_J of dimensions smaller than n; W_J is the B^*-pre-image of the convex cone generated by the vectors $c^j, j \in J$.

From Lemma 4 and the definition of W_A the uniqueness of solutions of the maximum condition for $\psi \in W_A$ follows. This enables the definition of a function $w(\psi)$ on the set W_A by the formula $w(\psi) \in \bar{w}(\psi)$.

LEMMA 5. *The function $w(\psi)$ is continuous on its domain of definition.*

The proof follows much the same lines as that of the similar lemma in [6] and therefore is omitted.

Remark 2. The uniqueness of the solution of the maximum condition (2), Lemma 3, and the linear independence of the vectors $(\partial g^I(u)/\partial u)^*$, c^J result in the uniqueness of the numbers a^I, b^J from Lemma 3. For this reason we can define the functions $a^I(\psi)$, $b^J(\psi)$ on V_{IJ} for every IJ admissible.

4. Properties of the function $w(\psi)$. In the previous lemmas we have shown that the function $w(\psi)$ possesses properties on the set W_A similar to the analogous function $w(x, \psi)$ mentioned in the LC problem. The fact that it is continuous and satisfies the maximum condition has enabled us to prove in the LC problem that the functions $w_I(x, \psi)$ can be extended as analytic functions to neighbourhoods of the closures of the sets W_I. In this section we prove a similar property for the function $w(\psi)$ on V_{IJ}. The closures and neighbourhoods of the sets V_{IJ}, IJ admissible, where either $|I| \neq 0$ or $|J| = m$, will be considered as subsets of W_A. We denote by cl_A the relative closure in W_A.

The proofs of the next three lemmas follow the same pattern as the proofs of the similar lemmas in [6]. Therefore we do not present their proofs.

LEMMA 6. *Let IJ be admissible such that $|I| \neq 0$. Then* int $V_{IJ} \neq \emptyset$.

LEMMA 7. *Let IJ be admissible such that $I \neq \emptyset$. Then*

$$\mathrm{cl}_A V_{IJ} \subseteq \bigcup_{I'J' \supseteq IJ} V_{I'J'} \tag{13}$$

where the union is taken over all $I'J'$ admissible such that $I'J' \supseteq IJ$.

LEMMA 8. *Let IJ be admissible, $|I| \neq 0$, let $\psi \in \mathrm{cl}_A V_{IJ}$. Then there is an admissible set $I'J'$, $I'J' \supseteq IJ$ such that $\psi \in V_{I'J'}$ and the functions $a^{I'}$, $b^{J'}$ defined for $I'J'$ satisfy*

$$a^i(\psi) = 0 \quad \text{for } i \in I' - I,$$

$$b^j(\psi) = 0 \quad \text{for } j \in J' - J.$$

Remark 3. Because of Lemma 8 we extend the functions a^I, b^J defined on V_{IJ} to $\mathrm{cl}_A V_{IJ}$ by the formulas

$$a^i(\psi) = a'^i(\psi), \qquad i \in I,$$
$$b^j(\psi) = b'^j(\psi), \qquad j \in J$$

for $\psi \in \mathrm{cl}_A V_{IJ} - V_{IJ}$. Here a'^i, b'^j are, respectively, the ith component of the function a'^I from Lemma 8 and the jth component of b'^J from Lemma 8.

LEMMA 9. *Let IJ be admissible,* $|I| \neq 0$. *Suppose for* $\hat{\psi} \in R^n$, $\hat{u} \in U$, $\hat{a}^I \geqq 0$, $\hat{b}^J \geqq 0$ *the conditions*

$$-B^*\hat{\psi} + \sum_{i \in I} \hat{a}^i \left(\frac{\partial g^i(\hat{u})}{\partial u}\right)^* + \sum_{j \in J} \hat{b}^j c^j = 0, \tag{14}$$

$$g^I(\hat{u}) = 0, \tag{15}$$

$$c^{J*}\hat{u} = d^J \tag{16}$$

hold, where $\hat{a}^i > 0$ *for at least one* $i \in I$. *Then there exist a neighbourhood* O *of* $\hat{\psi}$ *and analytic functions* $\alpha^I(\psi), \beta^J(\psi), u(\psi)$ *defined on* O *such that* $\alpha^I(\hat{\psi}) = \hat{a}^I$, $\beta^J(\hat{\psi}) = \hat{b}^J$, $u(\hat{\psi}) = \hat{u}$ *and the equations*

$$-B^*\psi + \sum_{i \in I} \alpha^i(\psi) \left(\frac{\partial g^i(u(\psi))}{\partial u}\right)^* + \sum_{j \in J} \beta^j(\psi) c^j = 0,$$
$$g^I(u(\psi)) = 0, \qquad c^{J*}u(\psi) = d^J$$

hold for every $\psi \in O$ *and* $\alpha^i(\psi) > 0$.

Proof. Let us define the function

$$F : R^n \times R^{|I|} \times R^{|J|} \times R^m \to R^m \times R^{|I|} \times R^{|J|}$$

by the formula

$$F(\psi, a^I, b^J, u) = \begin{pmatrix} -B^*\psi + \sum_{i \in I} a^i \left(\frac{\partial g^i(u)}{\partial u}\right)^* + \sum_{j \in J} b^j c^j \\ g^I(u) \\ c^{J*}u - d^J \end{pmatrix}$$

Then $F(\hat{\psi}, \hat{a}^I, \hat{b}^J, \hat{u}) = 0$. We denote

$$M_I(\hat{u}) = \sum_{i \in I} \hat{a}^i M_i(\hat{u}), \qquad G_{IJ}(\hat{u}) = \left(\left(\frac{\partial g^I(\hat{u})}{\partial u}\right)^*, c^J\right),$$

where $M_i(u)$ has been defined in § 2. The matrices $M_I(\hat{u})$ and $G_{IJ}(\hat{u})$ are of the types $n \times m$ and $m \times (|I| + |J|)$, respectively. The matrix $M_I(\hat{u})$ is positive definite and according to [5]

$$\det \frac{\partial F(\hat{\psi}, \hat{a}^I, \hat{b}^J, \hat{u})}{\partial(a^I, b^J, u)} = \det \begin{pmatrix} M_I(\hat{u}) & G_{IJ}(\hat{u}) \\ G_{IJ}(\hat{u})^* & 0 \end{pmatrix}$$
$$= \det M_I(\hat{u}) \cdot \det \left(G_{IJ}(\hat{u})^* M_I(\hat{u})^{-1} G_{IJ}(\hat{u})\right) \neq 0.$$

The statement of our theorem follows immediately from the implicit function theorem. □

Remark 4. From the previous lemma we obtain

$$\frac{\partial(u, a^I, b^J)}{\partial \psi}(\hat{\psi}) = \begin{pmatrix} M_I(\hat{u}) & G_{IJ}(\hat{u}) \\ G_{IJ}(\hat{u})^* & 0 \end{pmatrix}^{-1} \begin{pmatrix} B^* \\ 0 \end{pmatrix}. \tag{17}$$

Then, using Frobenius' formula [5] we obtain

$$\frac{\partial u}{\partial \psi} = (M_I^{-1} - M_I^{-1} G_{IJ} (G_{IJ}^* M_I^{-1} G_{IJ})^{-1} G_{IJ}^* M_I^{-1}) B^*, \tag{18}$$

$$\frac{\partial (a^I, b^J)}{\partial \psi} = (G_{IJ}^* M_I^{-1} G_{IJ})^{-1} G_{IJ}^* M_I^{-1} B^*. \tag{19}$$

THEOREM 1. *For given V_{IJ}, IJ admissible, where either $|I| \neq 0$ or $|J| = m$, there exists a neighbourhood B_{IJ} of $\mathrm{cl}_A V_{IJ}$ in W_A and an analytic function $w_{IJ}(\psi)$ defined on B_{IJ} such that $w_{IJ}(\psi) = w(\psi)$ for every $\psi \in \mathrm{cl}_A V_{IJ}$.*

Proof. The statement of this theorem for IJ admissible, $|I| \neq 0$, can be proved from Lemmas 6–9 by a procedure similar to the one by which Theorem 3 of [6] is proved from Lemmas 5–8 in the LC problem.

If $|J| = m$, then the function $w(\psi)$ is constant on V_J and therefore the assertion of this theorem is trivial. □

Now, the example from § 3 will show that for V_{IJ}, $|J| < m-1$, the function $w_{IJ}(\psi)$ defined on V_{IJ} cannot always be continuously extended to the neighbourhood of the closure of V_{IJ} in $R^n - \{0\}$.

Example. Let U_1, U_2, U_{12}, W_1, W_2, W_{12}, B, m, n be as in the example of § 3. Then, by (2), $w_\psi = u = (u_1, u_2, u_3)$ can be expressed as a function of $\psi = (\psi_1, \psi_2, \psi_3)$ on $V_{12} = W_{12} - W_2$, i.e.,

$$u_1 = \tfrac{1}{2}, \qquad u_1^2 + u_2^2 + u_3^2 = 1,$$

$$\psi_1 = 2au_1 + b, \quad \psi_2 = 2au_2, \quad \psi_3 = 2au_3.$$

Solving this system, we obtain

$$u_1 = \tfrac{1}{2},$$

$$u_2 = \psi_2 \sqrt{3} / (2\sqrt{\psi_2^2 + \psi_3^2}),$$

$$u_3 = \psi_3 \sqrt{3} / (2\sqrt{\psi_2^2 + \psi_3^2}).$$

It is easy to see that, for example,

$$\lim_{\substack{\psi_2 \to 0 \\ \psi_3 \to 0}} u_2(\psi)$$

does not exist and therefore the function $w_{12}(\psi) = (u_1(\psi), u_2(\psi), u_3(\psi))$ cannot be continuously extended to W_{12}.

The example shows that the LT problem does not in general satisfy Assumption 2 of the ERS theorem and therefore the existence of a regular synthesis cannot be proved directly using this theorem on the whole reachable set K. In § 6 we shall define a subset H of K such that the existence of a regular synthesis can be proved on $K - H$.

First, we shall extend the set W_A to a set $\tilde{W}_A$ which will include the sets V_J, $|J| = m-1$ and we shall prove an analogue to Theorem 1 on $\tilde{W}_A$. We denote

$$\tilde{W}_A = W_A \cup \bigcup_{|J| = m-1} V_J, \tag{20}$$

$$W_Z = \bigcup_{|J| < m-1} V_J = \bigcup_{|J| < m-1} W_J. \tag{21}$$

Because of Corollary 5,

$$\tilde{W}_A = R^n - \{0\} - W_Z \tag{22}$$

and from Corollary 3 it follows that

$$\dim W_Z < n-1. \tag{23}$$

LEMMA 10. *The sets* $\mathrm{cl}_{\tilde{A}} V_{IJ}$, *IJ admissible such that either* $|I| \neq 0$ *or* $|J| = m$, *cover* $\tilde{W}_A$.

Proof. Because of Corollary 5 the sets V_{IJ}, *IJ* admissible and such that either $|I| \neq 0$ or $|J| = m$, form a partition of W_A. Let J be admissible, $|J| = m-1$. Then U_J is an open segment of a line; because of the boundedness of U and Lemma 1 there exists $I'J'$ admissible such that $J \subseteq I'J'$ and $|I'| + |J'| = m$. It follows from Corollary 4 and the definition of the sets V_{IJ} that $V_J \subseteq \mathrm{cl}_A V_{I'J'}$, which completes the proof. □

COROLLARY 7. *For every component X of* V_{IJ}, *IJ admissible, where either* $|I| \neq 0$ or $|J| = m$, *there exist a neighbourhood* O_{IJ} *of* $\mathrm{cl}_{\tilde{A}} X$ *in* $\tilde{W}_A$ *and an analytic function* w_{IJ} *defined on* O_{IJ} *such that* $w_{IJ}(\psi) = w(\psi)$, $\psi \in X$.

Proof. Let *IJ* be such that $|I| + |J| = m$. Then $\dim U_{IJ} = 0$ and $w(\psi)$ is constant on each component of V_{IJ}. Therefore, $w_{IJ}(\psi) = w(\psi)/V_{IJ}$ can be extended as constant to a neighbourhood of the relative closure of V_{IJ} in $\tilde{W}_A$.

Let V_{IJ} be such that $|I| \neq 0$ and $|J| < m-1$. Due to the definitions of W_A and $\tilde{W}_A$, $\mathrm{cl}_A V_{IJ} = \mathrm{cl}_{\tilde{A}} V_{IJ}$ and the statement is a direct corollary of Theorem 1. □

5. Finiteness of the number of switchings. In this section we demonstrate a connection between $w(\psi)$ and extremal controllers and we prove that these controllers have a locally finite number of switchings.

The function $w(\psi)$ has not been defined on W_Y (for W_Y see (12)). Because of the normality condition and analyticity of $e^{-A^*t}\psi$, for every $\psi \in R^n - \{0\}$ and for a finite interval $\mathcal{T}$ there is at most a finite number of points $t_i \in \mathcal{T}$ such that $e^{-A^*t_i}\psi \in W_Y$. This enables us to define the function $v(\psi, t): R^n \times R \to R^m$ be the formula

$$v(\psi, t) = w(e^{-A^*t}\psi).$$

Moreover, if we take into account the continuity of $w(\psi)$ on the complement W_A of W_Y (Lemma 5), we obtain the following two properties of $v(\psi, t)$.

LEMMA 11. *The function* $v(\psi, t)$ *is a measurable function of t for every given* ψ.

LEMMA 12. *For every* $\psi_0 \in R^n - \{0\}$ *there exists a set* $H \subset R$ *of measure zero such that for each* $t \in R - H$, $v(\cdot, t)$ *is continuous at* ψ_0.

We define the function $F: (R^n - \{0\}) \times [0, \infty) \to R$ by the formula

$$F(\psi, T) = -\int_0^T e^{-At} B v(\psi, t)\, dt. \tag{24}$$

THEOREM 2. *The function* $F(\psi, T)$ *is continuous. The range of F is the reachable set K.*

Proof. The continuity of F is a consequence of Lemmas 11 and 12 and the boundedness of $v(\psi, t)$. Since F is continuous in T uniformly with respect to ψ, the function $F(\psi, T)$ is continuous.

The inclusion range $F \subseteq K$ being trivial, we prove $K \supseteq$ range F. Let $x \in K$. Due to (LT3) there exists an extremal controller $u_x(t)$ steering x to the origin in time T. Let $\psi(t)$ be a corresponding adjoint solution. Since $v(\psi(0), t)$ is uniquely defined as a solution of the maximum condition for every $t \in [0, T]$ outside a finite set, $v(\psi(0), t) = u_x(t)$ holds almost everywhere on $[0, T]$. As $u_x(t)$ steers x to the origin on $[0, T]$, we

have

$$x = -\int_0^T e^{-At} B u_x(t)\, dt = -\int_0^T e^{-At} B v(\psi(0), t)\, dt.$$

Now it is easy to see that $(\psi(0), T) \in F^{-1}(x)$ and that the range of F contains K. □

From the theorem just proved and from the uniqueness of the extremal controllers (LT3), we obtain the following corollary.

COROLLARY 8. *If $(\psi, T) \in F^{-1}(x)$, then $v(\psi, \cdot)$ as a function of $t \in [0, T]$ for fixed ψ is the unique extremal controller steering x to the origin.*

THEOREM 3. *For every compact subset M of the reachable set K there exists a $\nu(M) > 0$ such that an extremal controller of the* LT(x) *problem has at most ν switching points for every $x \in M$.*

Proof. Due to Corollary 8 it suffices to prove that if $x \in M$, $(\psi, T) \in F^{-1}(x)$, then the function $v(\psi, \cdot)$, $t \in [0, T]$, has at most $\nu(M)$ switching points, where $\nu(M)$ is independent of x. That means we need to verify only that for fixed ψ the curve $e^{-A^* t}\psi$ crosses at most $\nu(M)$ times from one set V_{IJ} to another.

Let M be a compact subset of K. Its pre-image under the continuous map F is a closed subset of the space $(R^n - \{0\}) \times R$ of the variables (ψ, T). Due to (LT4) the set $F^{-1}(M)$ is bounded by a constant T_1. We denote

$$M_1 = \{\psi \in R^n / (\psi, T) \in F^{-1}(M) \text{ for some } T, |\psi| = 1\},$$

$$M_2 = \{e^{-A^* t}\psi \in R^n / \psi \in M_1, 0 \leqq t \leqq T_1\}.$$

The sets M_1 and M_2 are compact.

Consider the partition $\mathcal{P}$ of the space $R^n - \{0\}$ of ψ into the sets V_{IJ}, IJ admissible. The vector field $-A^*\psi$ and the partition $\mathcal{P}$ satisfy the assumption of Theorem II in [11]. By this theorem there exists $\nu(M_2) > 0$ such that every trajectory $e^{-A^* t}\psi$, $\psi \in M_1$, $t \in [0, T_1]$ crosses from one member of the partition $\mathcal{P}$ to another at most $\nu(M)$ times. This completes the proof. □

6. Domain of the existence of a regular synthesis. In § 4 we showed that in general the LT problem does not satisfy Assumption 2 of the ERS theorem on the whole space $R^n - \{0\}$ of the adjoint variables. We found, however, that on the open set $\tilde{W}_A \subset R^n - \{0\}$ the assumption is satisfied. In this section we construct an open subset of the reachable set K, such that the extremal responses going from the points of this set to the origin stay in it, and such that the corresponding solutions $\psi(t)$ of the adjoint equation are from $\tilde{W}_A$. We shall prove the existence of a regular synthesis on this subset.

We have

$$C = \{\psi \in R^n / |\psi| = 1 \text{ and there exists a } t \in R \text{ such that } e^{-A^* t}\psi \in W_Z\}. \tag{25}$$

Remark 5. From the maximum condition (2) it is easy to see that if w is a solution of (2) for given ψ, then w is a solution of (2) for every $c\psi$, $c > 0$. Therefore $w(\psi) = w(c\psi)$, $c > 0$. Since the solutions $\psi(t) = e^{-A^* t}\psi$ are homogeneous in ψ, then also $v(c\psi, t) = w(e^{-A^* t} c\psi) = w(c\, e^{-A^* t}\psi) = w(e^{-A^* t}\psi) = v(\psi, t)$. Therefore $F(c\psi, T) = F(\psi, T)$ as well, where F is the function defined by (24).

Since the set W_Z completed by the origin is a cone, we have the following:

(a) $F(cC \times [0, T)) = F(C \times [0, T))$, where $cC = \{c\psi / \psi \in C\}$, $c > 0$;

(b) If $x \in K - F(C \times [0, \infty))$ such that $F(\psi, T) = x$, then there does not exist a $t \in [0, \infty)$ such that $e^{-A^* t}\psi \in W_Z$.

We denote

$$H = F(C \times [0, \infty)). \tag{26}$$

LEMMA 13. *The set H is a closed subset of the reachable set K for the* LT *problem.*

Proof. Let $\{x_n\} \to x$, $x_n \in H$, $x \in K$. Let $\{\psi_n, T_n\}$ be a sequence of points from $C \times [0, \infty)$ such that $F(\psi_n, T_n) = x_n$. From Corollary 8 and (LT3) it follows that $T_n = T(x_n)$, i.e., T_n is a minimal time for LT(x_n). Because of (LT4) there exists $T_0 = T(x)$ such that $\{T_n\} \to T_0$. Since C is compact there exists a subsequence $\{\psi_{n_k}\}$ of $\{\psi_n\}$ convergent in C. Let $\{\psi_{n_k}\} \to \psi_0$, $\psi_0 \in C$. Due to the continuity of F it follows that $x = \lim_{n\to\infty} x_n = \lim_{k\to\infty} F(\psi_{n_k}, T_{n_k}) = F(\psi_0, T_0)$. Therefore $x \in H$. □

As a direct consequence of Lemma 13 and (LT2) we obtain Corollary 9.

COROLLARY 9. *The set $K - H$ is an open subset of R^n.*

Since $K - H$ is an open subset of R^n and the extremal trajectories of the points from $K - H$ stay in $K - H$, we can consider on it the existence of a regular synthesis in the sense of the definition of [3].

In this section we shall prove the existence of a regular synthesis for the LT(x), $x \in K - H$. We use the property that Assumption 2 of the ERS theorem can be replaced by an assumption that the functions $w_{IJ}(\psi)$ can be extended as analytic functions along the solutions of the adjoint system in our case (here the target point is from the interior of K).

THEOREM 4. *The* LT *problem admits a regular synthesis in the sense of* [3] *on $K - H$.*

Proof. The theorem will be proved using the ERS theorem.

Assumption 1 of the ERS theorem is satisfied trivially.

For the sets N_i and the functions w_i of Assumption 2 we take the sets $N_{IJ} = (K - H) \times \bar{V}_{IJ}$, IJ admissible such that either $|I| \neq 0$ or $|J| = m$, and the functions $w'_{IJ}(x, \psi) = w_{IJ}(\psi)$ (for w_{IJ} see Corollary 7). The sets N_{IJ} and the functions w'_{IJ} satisfy all the required assumptions except the one stating that they can be extended as analytic functions to a neighbourhood of N_{IJ} in $R^n \times (R^n - \{0\})$. This hypothesis from [3] is, however, unnecessary. The proof of the ERS theorem [3] uses only the fact that w_i can be extended as an analytic function to a neighbourhood of N_i along the flow of the differential equation [3, Eq. (12)]. This means in our case that the function $w_{IJ}(\psi)$, defined and analytic on V_{IJ}, can be extended as an analytic function to the set $C_{IJ} = \{\psi \in R^n - \{0\} / \exists \psi_0 \in \bar{V}_{IJ}, t > 0$, such that $\psi = e^{-A^* t}\psi_0\}$. This holds by Corollary 7.

The first part of Assumption 3 of the ERS theorem is satisfied due to (LT3). The second can be proved in the same way as the similar assertion in [6].

Assumptions 4–6 of the ERS theorem follow from the argument of Theorem 3 and (LT4). Assumption 7 can be proved in the same way as in [6].

In the following two sections we shall prove that the set H is "small." For the criterion of "smallness" we shall take its Lebesgue measure to be zero. The proof consists of two steps. The first step proves that the function $w(\psi)$ can be extended as a locally Lipschitz continuous function in a weakened sense to a part of W_Z. The second step uses a countable covering of $C \times [0, \infty)$ such that the function $F(\psi, T)$ is locally Lipschitz continuous on every element of this covering.

7. Lipschitz continuity of $w(\psi)$. In this section we study the Lipschitz continuity properties of $w(\psi)$ on the set C. Some properties of $w(\psi)$ on $C - W_Z$ follow from the previous sections: $w(\psi)$ is continuous on $C - W_Z$ (Lemma 5) and $w(\psi)$ is analytic on every $V_{IJ} \cap C$ and can be analytically extended to some neighbourhood of the closure of $V_{IJ} \cap C$ in $C - W_Z$ (Theorem 1). The following lemma is a direct consequence of [11, Lemma 1] and the mentioned properties of $w(\psi)$ on $C - W_Z$.

LEMMA 14. *The function $w(\psi)$ is locally Lipschitz continuous on $C - W_Z$, i.e., for every compact subset K of $R^n - W_Z$ there is an $L > 0$ such that $|w(\psi_1) - w(\psi_2)| \leqq L|\psi_1 - \psi_2|$ for every $\psi_1, \psi_2 \in K \cap C$.*

In a series of lemmas we shall find an upper bound for $\partial w(\psi)/\partial\psi$ given by (17) and (18).

Let A be the $p \times r$ matrix with elements a_{ij}. We denote by $|A|$ and $\|A\|$, respectively, the Euclidean and operator norms of A, i.e., $|A| = \sqrt{\sum_{i,j} (a_{ij})^2}$ and $\|A\| = \sup_{x \neq 0} (|Ax|/|x|)$. Further, we recall that $M_I(u, a^I) = \sum_{i \in I} a^i M_i(u)$ is an $m \times m$ positive definite matrix for each $a^I \geqq 0$, $a^I \neq 0$, $u \in U$, and $G_{IJ}(u) = ((\partial g^I(u)/\partial u), c^J)$ is an $m \times (|I| + |J|)$ matrix of rank $|I| + |J|$ for every $u \in \bar{U}_{IJ}$.

In what follows we shall denote by P_J the $|J| \times m$ matrix of the orthogonal projection of R^m into the linear hull of $c^j, j \in J$, and by S_J the $(m - |J|) \times m$ matrix of the orthogonal projection of R^m into the orthogonal complement of the linear hull of $c^j, j \in J$. We denote

$$R_J = \begin{pmatrix} P_J \\ S_J \end{pmatrix},$$

i.e., R_J is a regular $m \times m$ matrix.

LEMMA 15. *Let IJ be admissible, $|I| \neq 0$. Let $a^I(\psi)$ be the function defined on $\mathrm{cl}_A V_{IJ}$ in Remark 3. Then there exist positive numbers k_1, k_2 such that the relation*

$$k_1 |S_J B^* \psi| \leqq \sum_{i \in I} a^i(\psi) \leqq k_2 |S_J B^* \psi| \tag{27}$$

holds for each $\psi \in \mathrm{cl}_A V_{IJ}$.

Proof. By Lemmas 3 and 8, for each $\psi \in \mathrm{cl}_A V_{IJ}$ there exist a $u \in \bar{U}_{IJ}$ and an $a^I(\psi), b^J(\psi) \geqq 0$ such that

$$B^* \psi = \sum_{i \in I} a^i \frac{\partial g^i(u)}{\partial u} + \sum_{j \in J} b^j c^j. \tag{28}$$

Since $|I| \neq 0$, $\psi \notin W_0$, and $\psi \notin W_J$, and therefore at least one $a^i > 0$. Because of the linear independence of $(\partial g^I(u)/\partial u), c^J$ for each $u \in \bar{U}_{IJ}$, the rank of the $m \times (|I| + |J|)$ matrix $(\partial g^I(u)/\partial u, c^J)$ is $|I| + |J|$. Due to the regularity of R_J the rank of the matrix

$$\begin{pmatrix} P_J \\ S_J \end{pmatrix} \left(\frac{\partial g^I(u)}{\partial u}, c^J \right) = \begin{pmatrix} P_J \dfrac{\partial g^I(u)}{\partial u} & P_J c^J \\ S_J \dfrac{\partial g^I(u)}{\partial u} & 0 \end{pmatrix}$$

is $|I| + |J|$ and so the rank of the $(m - |J|) \times |I|$ matrix $S_J(\partial g^I(u)/\partial u)$ is $|I|$ for every $u \in \bar{U}_{IJ}$. Let us multiply (28) by the matrix R_J from the left. Then (28) is equivalent to

$$P_J B^* \psi = \sum_{i \in I} a^i P_J \frac{\partial g^i(u)}{\partial u} + \sum_{j \in J} b^j P_J c^j, \tag{29}$$

$$S_J B^* \psi = \sum_{i \in I} a^i S_J \frac{\partial g^i(u)}{\partial u}. \tag{30}$$

Consider the function

$$h(a^I, u) = \sum_{i \in I} a^i S_J \frac{\partial g^i(u)}{\partial u} \tag{31}$$

defined for every $a^I \in R^{|I|}$, $u \in \bar{U}_{IJ}$. Since for $u \in \bar{U}_I$ the rank of $S_J(\partial g^I(u)/\partial u)$ is $|I|$, $h(a^I, u) = 0$ if and only if $a^I = 0$. We divide both sides of (30) by $\sum_{l \in I} a^l$. Then

$$\frac{|S_J B^* \psi|}{\sum_{l \in I} a^l} = \sum_{i \in I} a'^i S_J \frac{\partial g^i(u)}{\partial u} \tag{32}$$

where

$$a'^i = a^i \Big/ \sum_{l \in I} a^l. \tag{33}$$

From (33) it follows that $\sum_{i \in I} a'^i = 1$. The right-hand side of (32) is the value of h in $u \in \bar{U}_{IJ}$ and a'^I such that $\sum_{i \in I} a'^i = 1$. Since h is continuous and the set of all a'^i such that $\sum_{i \in I} a'^i = 1$ and the set $\bar{U}_{IJ}$ are compact, the function h attains its maximum and minimum values on this set. Hence, there exist positive numbers h_1, h_2 such that

$$h_2 \leqq \left| \sum_{i \in I} a'^i S_J \frac{\partial g^i(u)}{\partial u} \right| \leqq h_1 \tag{34}$$

for each $u \in \bar{U}_{IJ}$ and all numbers a'^i such that $\sum_{i \in I} a'^i = 1$. Relation (27) follows from (32)–(34); there, $k_1 = 1/h_1$ and $k_2 = 1/h_2$. □

LEMMA 16. *For each IJ admissible,* $|I| \neq 0$, *there exist constants* $k_1 > 0$, $k_2 > 0$ *such that*

$$|M_I^{-1}(u, a^I)| \leqq k_1 \Big/ \left(\sum_{i \in I} a^i \right), \tag{35}$$

$$|(G_{IJ}^*(u) M_I^{-1}(u, a^I) G_{IJ}(u))^{-1}| \leqq k_2 \sum_{i \in I} a^i \tag{36}$$

for each $u \in \bar{U}_{IJ}$ *and* $a^I \geqq 0$, $a^I \neq 0$.

Proof. Let $\lambda_0(u, a^I)$ and $\lambda_1(u, a^I)$ be, respectively, the smallest and largest eigenvalues of the matrix $M_I(u, a^I)$. Then

$$\lambda_0(u, a^I) \leqq \|M_I(u, a^I)\| = \lambda_1(u, a^I), \tag{37}$$

$$\frac{1}{\lambda_1(u, a^I)} \leqq \|M_I^{-1}(u, a^I)\| = \frac{1}{\lambda_0(u, a^I)}, \tag{38}$$

$$\frac{1}{\lambda_1(u, a^I)} = \min_{x \neq 0} \frac{x^* M_I^{-1}(u, a^I) x}{|x|^2}. \tag{39}$$

We denote by $m_0^i(u)$ and $m_1^i(u)$, respectively, the smallest and the largest eigenvalues of $M_i(u)$ for each $i \in I$. Since $m_0^i(u)$ and $m_1^i(u)$ are continuous functions of u defined on $\bar{U}_{IJ}$ with positive values, there exist

$$m_0^i = \min_{u \in \bar{U}_{IJ}} m_0^i(u) \quad \text{and} \quad m_1^i = \max_{u \in \bar{U}_{IJ}} m_1^i(u).$$

Let us denote $m_0 = \min_{i \in I} m_0^i$ and $m_1 = \max_{i \in I} m_1^i$. Then

$$x^* M_I(u, a^I) x = \sum_{i \in I} x^* a^i M_i(u) x \leqq m_1 |x|^2 \sum_{i \in I} a^i,$$

$$x^* M_I(u, a^I) x \geqq m_0 |x|^2 \sum_{i \in I} a^i$$

from which it follows that

$$\lambda_1(u, a^I) \leqq m_1 \sum_{i \in I} a^i, \tag{40}$$

$$\lambda_0(u, a^I) \geqq m_0 \sum_{i \in I} a^i. \tag{41}$$

From (38), (40), and (41) we obtain

$$\frac{1}{m_1 \sum_{i\in I} a^i} \leqq \|M_I^{-1}(u, a^I)\| \leqq \frac{1}{m_0 \sum_{i\in I} a^i}. \tag{42}$$

Therefore it follows from (40) and (39) that

$$x^* G_{IJ}^*(u) M_I^{-1}(u, a^I) G_{IJ}(u) x \geqq \frac{|G_{IJ}(u)x|^2}{m_1 \sum_{i\in I} a^i}. \tag{43}$$

Since the rank of the matrix $G_{IJ}(u)$ is $|I|+|J|$, there exists an $m_2>0$ such that $|G_{IJ}(u)x| \geqq m_2|x|$ for each $u \in \bar{U}_{IJ}$. Also

$$|x|\,|G_{IJ}^*(u)M_I^{-1}(u, a^I)G_{IJ}(u)x| \geqq x^* G_{IJ}^*(u)M_I^{-1}(u, a^I)G_{IJ}(u)x \geqq \frac{m_2^2|x|^2}{m_1 \sum_{i\in I} a^i} \tag{44}$$

from which we obtain

$$|G_{IJ}^*(u)M_I^{-1}(u, a^I)G_{IJ}(u)x| \geqq \frac{m_2^2|x|}{m_1 \sum_{i\in I} a^i}. \tag{45}$$

We take $x=(G_{IJ}^* M_I^{-1} G_{IJ})^{-1} y$ and substitute into (45). This yields

$$|y| \geqq \frac{m_2^2 |(G_{IJ}^*(u)M_I^{-1}(u, a^I)G_{IJ}(u))^{-1} y|}{m_1 \sum_{i\in I} a^i}$$

for every y, i.e.,

$$\begin{aligned} &\sup_{y\neq 0} \frac{|(G_{IJ}^*(u)M_I^{-1}(u, a)G_{IJ}(u))^{-1}y|}{|y|} \\ &\quad = \|(G_{IJ}^*(u)M_I^{-1}(u, a^I)G_{IJ}(u))^{-1}\| \leqq \frac{m_1 \sum_{i\in I} a^i}{m_2^2} \end{aligned} \tag{46}$$

for every $u \in \bar{U}_{IJ}$.

Due to the equivalence of the Euclidean and operator norms, the assertion of the lemma follows directly from (42) and (46). □

LEMMA 17. *For every IJ admissible, $|I| \neq 0$, there exist positive constants k_3, k_4, k_5 such that for every $u \in \bar{U}_{IJ}$, $a^I \geqq 0$, $a^I \neq 0$*

$$|D^{-1}| \leqq k_1 \Big/ \sum_{i\in I} a^i + k_2 + k_3 \sum_{i\in I} a^I \tag{47}$$

where

$$D = \begin{pmatrix} S_J M_I & S_J(\partial g^I/\partial u)^* \\ G_{IJ}^* & 0 \end{pmatrix} \tag{48}$$

is an $(m+|I|)\times(m+|I|)$ matrix.

Proof. Let m_3 be a positive number such that

$$|G_{IJ}(u)| \geqq m_3 \tag{49}$$

for every $u \in \bar{U}_{IJ}$. We denote $h=(G_{IJ}M_I^{-1}G_{IJ})^{-1}$. Using the formula for the inverse of

a block matrix [5] and (49), (35), and (36) we obtain

$$\left|\begin{pmatrix} M_I & G_{IJ} \\ G_{IJ}^* & 0 \end{pmatrix}^{-1}\right| = \left|\begin{pmatrix} M_I^{-1}+M_I^{-1}G_{IJ}HG_{IJ}^*M_I^{-1} & -M_I^{-1}G_{IJ}H \\ HG_{IJ}^*M_I^{-1} & H \end{pmatrix}\right|$$

$$\leqq k_1 \Big/ \sum_{i\in I} a^i + k_1^2 m_3^2 k_2 \Big/ \sum_{i\in I} a^i + 2k_2 m_3 k_1 + k_2 \sum_{i\in I} a^i \tag{50}$$

$$= k_1' \Big/ \sum_{i\in I} a^i + k_2' + k_2 \sum_{i\in I} a^i.$$

We denote by N an $(m+|I|+|J|)\times(m+|I|+|J|)$ matrix that arises with the addition to D of some rows and columns by the formula

$$N = \begin{pmatrix} P_J M_I & 0 & P_J c^J \\ S_J M_I & S(\partial g^I/\partial u) & 0 \\ G_{IJ}^* & 0 & 0 \end{pmatrix}.$$

It is easy to see that

$$N = \begin{pmatrix} R_J & 0 \\ 0 & E \end{pmatrix}\begin{pmatrix} M_I & G_{IJ} \\ G_{IJ}^* & 0 \end{pmatrix} \tag{51}$$

where E is a $(|I|+|J|)\times(|I|+|J|)$ identity matrix. We denote

$$k_3' = \left|\begin{pmatrix} R_I & 0 \\ 0 & E \end{pmatrix}^{-1}\right| > 0. \tag{52}$$

Then, using (51) and (50), we obtain

$$|D^{-1}| \leqq |N^{-1}| \leqq k_3'\left(k_1' \Big/ \sum_{i\in I} a^i + k_2' + k_2 \sum_{i\in I} a^i\right).$$

Hence Lemma 17 is proved. □

LEMMA 18. *Let IJ be admissible such that $|I| \neq 0$. Let Z be a linear operator $Z: R^z \to R^n$. Then there are positive constants h_1, h_2, and h_3 such that*

$$\left|\frac{\partial w(Z\zeta)}{\partial \zeta}\right| \leqq \left(\frac{h_1}{|S_J B^* Z\zeta|} + h_2 + h_3|S_J B^* Z\zeta|\right)|S_J B^* Z| \tag{53}$$

for every $\zeta \in R^z$ such that $Z\zeta \in V_{IJ}$.

Proof. In Lemma 9 we have obtained $w(\psi)$ as a solution of the system (14)-(16). This system is equivalent to the system (29), (30), (15), (16) in which (29) is independent of the other equations. That is why by solving (30), (15), (16), we obtain the same solutions $w(\psi)$ as when we solve (14)-(16). Applying the formula for a derivative of a function given implicitly to $w(\psi)$ given by (30), (15), and (16), and using Lemmas 15 and 17, we obtain

$$\left|\frac{\partial w_{IJ}(Z\zeta)}{\partial \zeta}\right| \leqq |D^{-1}||S_J B^* Z| \leqq \left(k_1 \Big/ \sum_{i\in I} a^i + k_2 + k_3 \sum_{i\in I} a^i\right)|S_J B^* Z|$$

$$\leqq \left(\frac{k_1}{k_1'|S_J B^* Z\zeta|} + k_2 + k_3 k_1'|S_J B^* Z\zeta|\right)|S_J B^* Z|.$$

This proves the lemma. □

For every $i=1,\cdots,n-1$, J admissible, $|J|<m-1$, ($|J|=0$ as well) we define

$$V_{Ji}=\{\psi\in V_J / S_JB^*\psi=0,\cdots,S_JB^*A^{*i-1}\psi=0, S_JB^*A^{*i}\psi\neq 0\} \tag{54}$$

(for V_J see (6)).

LEMMA 19. *The family $\mathcal{P}$ of sets V_{Ji}, $i=1,\cdots,n-1$, $|J|<m-1$, J admissible, is a* CASA (*connected analytic submanifold which is a subanalytic set*) *stratification of W_Z, where by the* CASA *stratification we understand a stratification whose members are* CASA *sets.*

Proof. From the definition of V_{Ji} it is easy to see that every V_{Ji} is a CASA set. Now we prove that V_{Ji} form a partition of W_Z.

The sets V_J, $|J|<m-1$, form a partition of W_Z. Obviously $V_{Ji}\subseteq V_J$ and all the sets V_{Ji} are pairwise disjoint. It suffices to prove that V_{Ji}, $i=1,\cdots,n-1$ cover V_J.

Let there exist a $\psi\in V_J$ such that $S_JB^*A^{*i}\psi=0$ for every $i=1,\cdots,n-1$. Then from the normality condition it follows that there exists a $k>0$ such that $S_JB^*A^{*k}\psi\neq 0$ and $S_JB^*A^{*j}\psi=0$ for $j<k$. According to the Cayley-Hamilton theorem there exist constants $\alpha_1,\cdots,\alpha_n$ such that

$$\begin{aligned} S_JB^*A^{*k}\psi &= -S_JB^*(\alpha_1A^{*k-1}+\cdots+\alpha_nA^{*k-n})\psi \\ &= -\alpha_1S_JB^*A^{*k-1}\psi-\cdots-\alpha_nS_JB^*A^{*k-n}\psi=0, \end{aligned}$$

which contradicts our assumption. The sets V_{Ji} cover V_J. The stratification property follows directly from the definition of V_{Ji}. The lemma is proved. □

We denote by L_{Ji} the linear space given by the equations $S_JB^*A^{*j}\psi=0, j=1,\cdots,i-1$. Obviously V_{Ji} is an open subset of L_{Ji}. Let $\dim L_{Ji}$ be r_{Ji}, let Y_{Ji} be an $n\times r_{Ji}$ matrix of rank r_{Ji} such that the linear operator $Y_{Ji}: R^r\to L_{Ji}$ is a bijection.

LEMMA 20. *For every $\psi=Y_{Ji}\zeta\in V_{Ji}$ we have*

$$\lim_{t\to 0}\frac{|S_JB^*\mathcal{F}_tY_{Ji}|}{|S_JB^*\mathcal{F}_tY_{Ji}\zeta|}=\frac{|S_JB^*A^{*i}Y_{Ji}|}{|S_JB^*A^{*i}Y_{Ji}\zeta|} \tag{55}$$

where $\mathcal{F}_t=e^{-A^*t}$ is the flow of the adjoint equation.

Proof. It suffices to prove that

$$\lim_{t\to 0}\frac{|S_JB^*\mathcal{F}_tY_{Ji}|^2}{|S_JB^*\mathcal{F}_tY_{Ji}\zeta|^2}=\frac{|S_JB^*A^{*i}Y_{Ji}|^2}{|S_JB^*A^{*i}Y_{Ji}\zeta|^2}. \tag{56}$$

But (56) follows if we use L'Hôpital's rule $2i$ times and from the definition of V_{Ji}.

DEFINITION. Let K be a compact subset of an analytic submanifold M of R^n. Let $\mathcal{F}_t$ be a flow of an analytic vector field on R^n such that $\mathcal{F}_{[-T,0)}(K)\cap M=\emptyset$. Let g be a function defined on $\mathcal{F}_{[-T,0)}(K)\to R^m$ and let g be locally Lipschitz continuous on $\mathcal{F}_{[-T,0)}(K)$. We shall say that g can be extended as a Lipschitz continuous function on $\mathcal{F}_{[-T,0]}(K)$ along the flow $\mathcal{F}$ from the left, if for every $\tau\in(0,T)$ there exist an $L>0$ such that if $s\in[\tau,T]$ and $x_1,x_2\in K$; then

$$|g(\mathcal{F}_{t-s}(x_1))-g(\mathcal{F}_{t-s}(x_2))|\leqq L|\mathcal{F}_{-s}(x_1)-\mathcal{F}_{-s}(x_2)| \tag{57}$$

then every $t\in[0,s)$.

Remark 6. Analogously we can define the Lipschitz continuous extendability of a function g defined on $\mathcal{F}_{(0,T]}(K)$ to $\mathcal{F}_{[0,T]}(K)$ along the flow $\mathcal{F}$ from the right.

THEOREM 5. *Let IJ be admissible, $|I|\neq 0$, $i\in\{1,\cdots,n-1\}$. Let R be an analytic submanifold of V_{Ji} with the following property: for any compact subset K of R there exists a $T>0$ such that $\mathcal{F}_{[-T,0)}(K)\subset V_{IJ}$, $\mathcal{F}_t=e^{-A^*t}$. Then for every $\psi_0\in K$ there exists a compact neighbourhood O of ψ_0 in R such that the function $w_0(\psi)=w_{IJ}(\psi)/\mathcal{F}_{[-T,0)}(O)$ can be extended as a Lipschitz continuous function on $\mathcal{F}_{[-T,0]}(O)$ along the flow $\mathcal{F}_t$ from the left.*

Proof. Let $L = L_{Ji}$, $r = r_{Ji}$, $Y = Y_{Ji}$ be, respectively, the linear space, its dimension, and the matrix of the linear operator, corresponding to V_{Ji}. Let $\psi_0 \in R$ and let O_{ψ_0} be a compact neighbourhood of ψ_0 in R. For O_{ψ_0} there exists a compact neighbourhood $\tilde{O}_{\psi_0}$ of ψ_0 in L such that $\tilde{O}_{\psi_0} \cap R = O_{\psi_0}$. Because of the assumption of our theorem there is a $T > 0$ such that $\mathscr{F}_{[-T,0)}(O_{\psi_0}) \subset V_{IJ}$. The neighbourhoods O_{ψ_0} and $\tilde{O}_{\psi_0}$ could be chosen such that $\mathscr{F}_{[-T,0)}(\tilde{O}_{\psi_0}) \subset B_{IJ}$ where B_{IJ} is the neighbourhood of V_{IJ} in W_A (from Theorem 1) on which the analytic function $w_{IJ}(\psi)$ is defined.

Let $\zeta_0 \in R^r$ such that $\psi_0 = Y\zeta_0$. Let $O_{\psi_0} = YO_{\zeta_0}$ and $\tilde{O}_{\psi_0} = Y\tilde{O}_{\zeta_0}$. Let $\tau \in (0, T)$. We prove the existence of $L_1 > 0$ such that

$$\left|\frac{\partial w_{IJ}(\mathscr{F}_{t-s} Y\zeta)}{\partial \zeta}\right| \leqq L_1 \tag{58}$$

for all $t \in [0, s)$, $s \in [\tau, T)$, and $\zeta \in O_{\zeta_0}$.

According to Lemma 18 there exist positive constants h_1, h_2, h_3 such that

$$\left|\frac{\partial w_{IJ}(\mathscr{F}_{t-s} Y\zeta)}{\partial \zeta}\right| \leqq \left(\frac{h_1}{|S_J B^* \mathscr{F}_{t-s} Y\zeta|} + h_2 + h_3 |S_J B^* \mathscr{F}_{t-s} Y\zeta|\right) |S_J B^* \mathscr{F}_{t-s} Y|$$

for all $t \in [0, s)$, $s \in [\tau, T)$, and $\zeta \in O_{\psi_0}$.

From the definition of V_{Ji} it is easy to see that

$$\lim_{t \to s} |S_J B^* \mathscr{F}_{t-s} Y| = 0 \quad \text{and} \quad \lim_{t \to s} |S_J B^* \mathscr{F}_{t-s} Y\zeta| = 0.$$

By Lemma 20 we have

$$\lim_{t \to s} \frac{|S_J B^* \mathscr{F}_{t-s} Y|}{|S_J B^* \mathscr{F}_{t-s} Y\zeta|} = \frac{|S_J B^* A^{*i} Y|}{|S_J B^* A^{*i} Y\zeta|}.$$

Since $|S_J B^* A^{*i} Y\zeta|$ is bounded below (ζ lies in a compact set) the existence of an L_1 with property (58) is proved. Therefore the neighbourhoods O_{ψ_0} and O_{ζ_0} can be chosen such that

$$|w_{IJ}(\mathscr{F}_{t-s}(Y\zeta_1)) - w_{IJ}(\mathscr{F}_{t-s}(Y\zeta_2))| \leqq L_1 |\zeta_1 - \zeta_2| \tag{59}$$

for every $s \in [\tau, T)$, $t \in [0, s)$, and $\zeta_1, \zeta_2 \in O_{\zeta_0}$.

Further, the operator $\mathscr{F}_{-s} Y$ is linear and bounded below on the compact set O_{ζ_0}. Therefore there exists an $L_2 > 0$ such that for $s \in [\tau, T]$,

$$|\mathscr{F}_{-s}(Y\zeta_1) - \mathscr{F}_{-s}(Y\zeta_2)| \geqq L_2 |\zeta_1 - \zeta_2|. \tag{60}$$

Then from (59) and (60) we obtain

$$|w_{IJ}(\mathscr{F}_{t-s}(\psi_1) - w_{IJ}(\mathscr{F}_{t-s}(\psi_2))| \leqq L |\mathscr{F}_{-s}(\psi_1) - \mathscr{F}_{-s}(\psi_2)|,$$

where $L = L_1 / L_2$, for all $t \in [0, s)$, $s \in [\tau, T)$, and $\psi_1, \psi_2 \in O_{\psi_0}$. The theorem is proved. □

Remark 7. Analogously we can formulate and prove the modification of this theorem for the Lipschitz continuous extendability of the function $w_{IJ}(\psi)$ defined on $\mathscr{F}_{(0,T]}(O)$ to $\mathscr{F}_{[0,T]}(O)$ in the flow from the right.

8. The locally Lipschitz continuity of $F(\psi, T)$. Now, in addition to the analytic vector flow $\mathscr{F}_t = e^{-A^* t}$ of the adjoint equation on $R^n - \{0\}$, we shall consider the flow ϕ_t on $S^{n-1} = \{\psi \in R^n / |\psi| = 1\}$, which is a radial projection of $\mathscr{F}_t$. Let us denote by $\chi : R^n - \{0\} \to S^{n-1}$ the projection $\chi(\psi) = \psi |\psi|^{-1}$. Then $\phi_t(\chi(\psi)) = \chi(\mathscr{F}_t(\psi))$ for all t. For every $A \subseteq R^n - \{0\}$ such that $A \cup \{0\}$ is a cone, we shall denote by A^χ its radial

projection on S^{n-1}, that is, $A^X = \{\psi \in A/|\psi| = 1\}$. The set C defined by (25) can be written as

$$C = \{\psi \in S^{n-1}/\exists t \in R,\ \phi_t(\psi) \in W_Z^X\},$$

$$W_Z^X = \bigcup_{|J|<m-1} V_J^X.$$

By Lemma 2 every V_J^X is a subanalytic subset of S^{n-1}, and according to Corollary 3 we have dim $V_J^X < n-2$. Hence W_Z^X is a subanalytic set of dimension smaller than $n-2$. According to Lemma 19 the family $\mathcal{P}^X = \{V_{Ji}^X/J$ admissible, $i = 1, \cdots, n-1\}$ is a CASA stratification of W_Z^X with a finite number of members. Obviously the dimension of every member of $\mathcal{P}^X$ is smaller than $n-2$. For any $P \in \mathcal{P}^X$ and l natural, we define

$$C_{P,l} = \{\psi \in S^{n-1}/\exists t \in [-l, l] \text{ such that } \phi_t(\psi) \in P\}. \tag{61}$$

Evidently every $C_{P,l}$ is a subanalytic set the dimension of which is smaller than $n-1$ and

$$C = \bigcup_{P \in \mathcal{P}} \bigcup_{l=1}^{\infty} C_{P,l}.$$

Hence

$$H = F(C \times [0, \infty)) = \bigcup_{i=1}^{\infty} \bigcup_{P \in \mathcal{P}^X} \bigcup_{l=1}^{\infty} F(C_{P,l} \times [0, i]). \tag{62}$$

The dimension of the sets $C_{P,l} \times [0, i]$ is smaller than n. To prove $\mu(H) = 0$ it suffices to show (1) that for every $P \in \mathcal{P}^X$, l, i natural, there exists a locally finite partition of $C_{P,k} \times [0, k] \supset C_{P,l} \times [0, i]$, where $k = \max\{i, l\}$, whose components are analytic manifolds and (2) that the function $F(\psi, T)$ is locally Lipschitz continuous on every member of this partition.

THEOREM 6. *Let $P_0 \in \mathcal{P}^X$, l natural. Then there exists a* CASA *stratification $\mathcal{Y}$ of $C_{P_0,l}$ such that $F(\psi, T)$ is locally Lipschitz continuous on every $S \times [0, l]$, $S \in \varphi$.*

Proof. Let $\psi \in C_{P_0,l}$. Due to the normality condition the trajectory $\phi_t(\psi)$, $t \in [0, l]$ meets the set W_Z in at most a finite number of points. We define a function h from $C_{P_0,l}$ to the set of all natural numbers N that associates to each $\psi \in C_{P_0,l}$ the number of common points of the sets $\phi_{[0,l]}(\psi)$ and W_Z^X. From the definition of h it is easy to see that h is a subanalytic and locally bounded function (for the definitions see [10]). Then by [10] there exists a CASA stratification $\mathcal{Y}_1$ of $C_{P_0,l}$ compatible with $\mathcal{P}$ such that h is analytic and therefore constant on every member of $\mathcal{Y}_1$.

We choose an $S \in \mathcal{Y}_1$. Let $k \in N$ be the value of h that is constant on S. For given S, k consider finite sequences $i_1, \cdots, i_k$, where $i_j = (IJ_{i_j}^-, P_{i_j}, IJ_{i_j}^+)$, $j = 1, \cdots, k$, $IJ_{i_j}^+$, $IJ_{i_j}^-$ are admissible index sets such that if $IJ_{i_j}^- = J_{i_j}^-$, then $|J_{i_j}^-| = m$ and if $IJ_{i_j}^+ = J_{i_j}^+$, then $|J_{i_j}^+| = m$, $P_{i_j} \in \mathcal{P}$. We call such i_j admissible triples. For every sequence $i_1, \cdots, i_k$ of admissible triples we define the subset $S_{i_1 \cdots i_k}$ of S by

$$\psi \in S_{i_1 \cdots i_k} \Leftrightarrow (\psi \in S)$$

$$\wedge(\exists t_1)[(0 \leqq t_1 < l) \wedge (\phi_{t_1}(\psi) \in P_{i_1})$$

$$\wedge(\exists t_1^-)[(-\tfrac{1}{2} \leqq t_1^- < t_1) \wedge (\forall t)((t_1^- \leqq t < t_1) \Rightarrow (\phi_t(\psi) \in V_{IJ_{i_1}^-}))]$$

$$\wedge(\exists t_1^+)[(t_1 < t_1^+ \leqq l) \wedge (\forall t)((t_1 < t \leqq t_1^+) \Rightarrow (\phi_t(\psi) \in V_{IJ_{i_1}^+}))]]$$

$$\bigwedge(\exists t_k)[(t_{k-1}^+ < t_k \leqq l) \wedge (\phi_{t_k}(\psi) \in P_{i_k})$$
$$\bigwedge(\exists t_k^-)[(t_{k-1}^+ \leqq t_k^- < t_k) \wedge (\forall t)((t_k^- \leqq t < t_k) \Rightarrow (\phi_t(\psi) \in V_{IJ_i^-}))]$$
$$\bigwedge(\exists t_k^+)[(t_k \leqq t_k^+ \leqq l + \tfrac{1}{2}) \wedge (\forall t)((t_k < t \leqq t_k^+) \Rightarrow (\phi_t(\psi) \in V_{IJ_i^+}))]].$$

Roughly speaking, all the trajectories $\phi_t(\psi)$, $\psi \in S_{i_1 \cdots i_k}$, $t \in [0, l]$ meet the same subsets P_{i_j} of W_Z^X in the same order; they enter P_{i_j} from the same $V_{IJ_i^-}$ and go out of P_{i_j} to the same $V_{IJ_i^+}$.

The sets $S_{i_1 \cdots i_k}$ are subanalytic subsets of S. Further, for $(i_1, \cdots, i_k)$ running over all the ordered k-tuples of all admissible triples they constitute a finite partition of S. For every set $S_{i_1 \cdots i_k}$ we define a function $\sigma_{i_1 \cdots i_k} : S_{i_1 \cdots i_k} \to R^{3k}$ by the formula

$$\sigma_{i_1 \cdots i_k} = (t_1^-(\psi), t_1(\psi), t_1^+(\psi), \cdots, t_k^-(\psi), t_k(\psi), t_k^+(\psi))$$

where $t_j(\psi)$ are the points from the definition of $S_{i_1 \cdots i_k}$ such that $\phi_{t_j(\psi)}(\psi) \in P_{i_j}$ and

$$t_j^-(\psi) = \inf\{t / t_{j-1}^+(\psi) \leqq t \leqq t_j(\psi),\ \phi_t(\psi) \in V_{IJ_i^-}\},$$
$$t_j^+(\psi) = \sup\{t / t_j(\psi) \leqq t \leqq t_{j+1}^+(\psi),\ \phi_t(\psi) \in V_{IJ_i^+}\}$$

for all $j = 1, \cdots, k$, where $t_0^+(\psi) = -\frac{1}{2}$ and $t_{k+1}^-(\psi) = l + \frac{1}{2}$.

The function $\sigma_{i_1 \cdots i_k}$ is clearly subanalytic and bounded on $S_{i_1 \cdots i_k}$. Then, due to [10], there exists a CASA stratification of $S_{i_1 \cdots i_k}$ such that $\sigma_{i_1 \cdots i_k}$ is analytic on every member of this stratification. Since the function σ can be extended as a subanalytic and bounded function on the whole S^{n-1}, the stratifications of the sets $S_{i_1 \cdots i_k}$ are locally finite in S^{n-1} and therefore their union is locally finite in S^{n-1} as well. That is why there exists a CASA stratification $\mathscr{Y}$ of $C_{P_0, l}$ compatible with the partition $\mathscr{Y}_1$ and with $\mathscr{P}$ as well.

Let $S_0 \in \mathscr{Y}$. Then the following properties hold.

(a) There is a number $K(S_0) \in N$, a sequence of sets $P_1, \cdots, P_k \in \mathscr{P}$ and analytic functions $t_1(\psi), \cdots, t_k(\psi)$, $0 \leqq t_1(\psi) < \cdots < t_k(\psi) \leqq l$ such that $\mathscr{F}_{t_i(\psi)}(\psi) \in P_i$ and for any $t \neq t_i(\psi)$, $i = 1, \cdots, k$ we have $\mathscr{F}_t(\psi) \cap W_Z = \varnothing$.

(b) For any P_i, $i = 1, \cdots, k$, there are IJ_i^-, IJ_i^+ admissible such that if $IJ_i^+ = J_i^+$, then $|J_i^+| = m$ and there exist analytic functions $t_i^-(\psi)$, $t_i^+(\psi)$ such that $t_i^-(\psi) < t_i(\psi) < t_i^+(\psi)$ and $\mathscr{F}_t(\psi) \in V_{IJ^-}$ for every $t \in (t_i^-(\psi), t_i(\psi))$, and $\mathscr{F}_t(\psi) \in V_{IJ_i^+}$ for every $t \in (t_i(\psi), t_i^+(\psi))$ and $\psi \in S_0$, $i = 1, \cdots, k$.

From (a) and (b) it follows that

(c) The sets $R_i = \{\mathscr{F}_{t_i(\psi)}(\psi) / \psi \in S_0\}$, $i = 1, \cdots, k$ are analytic manifolds such that for any compact subset K of R_i there exist $T_i^- > 0$, $T_i^+ > 0$ such that

$$\mathscr{F}_{[-T_i^-, 0)}(K) \subset V_{IJ_i^-}, \qquad \mathscr{F}_{(0, T_i^+]}(K) \subset V_{IJ_i^+}.$$

We shall prove locally Lipschitz continuity of $F(\psi, T)$ on $S_0 \times [0, 1]$. Since the function $F(\psi, T)$ is continuous and Lipschitz continuous in T, it suffices to prove that for any $\psi_0 \in S_0$ there exists a neighbourhood O_{ψ_0} of ψ_0 such that $F(\psi, T)$ is Lipschitz continuous in $\psi \in O_{\psi_0}$ for any given T, $T \leqq l$.

Let $\psi_0 \in S_0$. Let O_{ψ_0} be a compact neighbourhood of ψ_0 in S_0. We denote $O_{\psi_0}^i = \mathscr{F}_{t_i(\psi)} O_{\psi_0}$, $i = 1, \cdots, k$. Obviously $O_{\psi_0}^i$ are compact neighbourhoods of R_i, $i = 1, \cdots, k$. Due to property (c) for any $O_{\psi_0}^i$ there exist $T_i^+ > 0$, $T_i^- > 0$ such that

$$\mathscr{F}_{[-T_i^-, 0)} O_{\psi_0}^i \subset V_{IJ_i^-} \quad \text{and} \quad \mathscr{F}_{(0, T_i^+]} O_{\psi_0}^i \subset V_{IJ_i^+}.$$

The neighbourhood O_{ψ_0} could be chosen suitably small such that there are τ_i^-, τ_i^+,

$$\tau_i^- < \min_{\psi \in O_{\psi_0}} t_i(\psi) \quad \text{and} \quad \mathscr{F}_{\tau_i^-}(O_{\psi_0}) \subset \mathscr{F}_{[-T_i^-, 0]}(O_{\psi_0}^i),$$
$$\max_{\psi \in O_{\psi_0}} t_i(\psi) < \tau_i^+ \quad \text{and} \quad \mathscr{F}_{\tau_i^-}(O_{\psi_0}) \subset \mathscr{F}_{(0, T_i^+]}(O_{\psi_0}^i)$$

for $i = 1, \cdots, k$.

Then by Theorem 5 there are $L_i^- > 0, L_i^+ > 0$ such that for any $s \in [\min_{\psi \in O_{\psi_0}} t_i(\psi) - \tau_i^-, T_i^-]$ or $s \in [\max_{\psi \in O_{\psi_0}} \tau_i^+ - t_i(\psi), T_i^+]$ and for each $\psi_1, \psi_2 \in O_{\psi_0}^i$ we have

$$|w(\mathscr{F}_{t-s}(\psi_1)) - w(\mathscr{F}_{t-s}(\psi_2))| \leqq L_i^- |\mathscr{F}_{-s}(\psi_1) - \mathscr{F}_{-s}(\psi_2)|, \tag{63}$$

or

$$|w(\mathscr{F}_{s-t}(\psi_1)) - w(\mathscr{F}_{s-t}(\psi_2))| \leqq L_i^+ |\mathscr{F}_s(\psi_1) - \mathscr{F}_s(\psi_2)| \tag{64}$$

for $t \in [0, s)$.

Let $\psi_1, \psi_2 \in O_{\psi_0}$ and let $T \leqq l$. We denote $t_0(\psi_1) = t_0(\psi_0) = 0$, $t_{k+1}(\psi_1) = t_{k+1}(\psi_1) = T$. Then

$$\begin{aligned} &|F(\psi_1, T) - F(\psi_2, T)| \\ &\leqq \sum_{j=1}^{k} \left| \int_{t_j(\psi_1)}^{t_{j+1}(\psi_1)} e^{-At} B v(\psi_1, t)\, dt - \int_{t_j(\psi_2)}^{t_{j+1}(\psi_2)} e^{-At} B v(\psi_2, t)\, dt \right|. \end{aligned} \tag{65}$$

The theorem will be proved if we find $L_j > 0$ for every $j = 0, \cdots, k$, such that

$$\left| \int_{t_j(\psi_1)}^{t_{j+1}(\psi_1)} e^{-At} B v(\psi_1, t)\, dt - \int_{t_j(\psi_2)}^{t_{j+1}(\psi_2)} e^{-At} B v(\psi_2, t)\, dt \right| \leqq L_j |\psi_1 - \psi_2|. \tag{66}$$

For simplicity, we prove the existence of the constant L_0 and the validity of (66) for $j = 0$. The relation (66) for other j's can be proved analogously.

Since the function $t_1(\psi)$ is analytic on O_{ψ_0}, there is a $k_1 > 0$ such that

$$|t_1(\psi_1) - t_1(\psi_2)| \leqq k_1 |\psi_1 - \psi_2|. \tag{67}$$

Obviously, there is a $k_2 > 0$ such that

$$|e^{-At} B| \leqq k_2 \tag{68}$$

for every $t \in [-l, l]$ and there is a k_3 such that

$$|v(\psi, t)| \leqq k_3 \tag{69}$$

for every ψ, t. Also, there is a k_4 such that

$$|\mathscr{F}_t| \leqq k_4 \tag{70}$$

for every $t \in [-l, l]$.

We assume that $0 < t_1(\psi_1) < t_1(\psi_2)$. Since $\mathscr{F}_{[0, \tau_1^-)}(O_{\psi_0}) \subset (R^n - \{0\}) - W_Z$, according to Lemma 14 there is a constant $k_5 > 0$ such that

$$|v(\psi_1, t) - v(\psi_2, t)| \leqq k_5 |\mathscr{F}_t(\psi_1) - \mathscr{F}_t(\psi_2)| \tag{71}$$

for each $t \in [0, \tau_i^-]$. Using (63), (67)-(71), and fundamental properties of integrals, we

can derive the following estimates:

$$\begin{aligned}
&\left|\int_0^{t_1(\psi_1)} e^{-At}Bv(\psi_1,t)\,dt-\int_0^{t_1(\psi_2)} e^{-At}Bv(\psi_2,t)\,dt\right| \\
&\quad\leqq\left|\int_0^{\tau_1^-}|e^{-At}B|\,|v(\psi_1,t)-v(\psi_2,t)|\,dt\right| \\
&\qquad+\left|\int_{\tau_1^-}^{t_1(\psi_1)} e^{-At}Bv(\psi_1,t)\,dt-\int_{\tau_1^-}^{t_1(\psi_2)} e^{-At}Bv(\psi_2,t)\,dt\right| \\
&\quad\leqq lk_2k_5k_4|\psi_1-\psi_2|+\left|\int_{\tau_1^-t_1(\psi_1)}^{0} e^{-A(q+t_1(\psi_1))}Bv(\psi_1,q+t_1(\psi_1))\,dq\right. \\
&\qquad\left.-\int_{\tau_1^-t_1(\psi_2)}^{0} e^{-A(q+t_1(\psi_2))}Bv(\psi_2,q+t_1(\psi_2))\,dq\right| \\
&\quad\leqq lk_2k_5k_4|\psi_1-\psi_2|+\left|\int_{\tau_1^-t_1(\psi_1)}^{0}|e^{-A(q+t_1(\psi_1))}B|\,|w(\mathscr{F}_{q+t_1(\psi_1)}\psi_1)-w(\mathscr{F}_{q+t_1(\psi_2)}\psi_2)|\,dq\right| \\
&\qquad+\left|\int_{\tau_1^-t_1(\psi_1)}^{0}|e^{-A(q+t_1(\psi_1))}-e^{-A(q+t_1(\psi_2))}|\,|v(\psi_2,q+t_1(\psi_2))|\,dq\right| \\
&\qquad+\left|\int_{\tau_1^-t_1(\psi_2)}^{\tau_1^-t_1(\psi_1)}|e^{-A(q+t_1(\psi_2))}B|\,|v(\psi_2,q+t_1(\psi_2))|\,dq\right| \\
&\quad\leqq lk_2k_4k_5|\psi_1-\psi_2|+lk_2L_1^-|\mathscr{F}_{-(t_1(\psi_1)-\tau_1^-)}\mathscr{F}_{t_1(\psi_1)}\psi_1-\mathscr{F}_{-(t_1(\psi_1)-\tau_1^-)}\mathscr{F}_{t_1(\psi_2)}\psi_2| \\
&\qquad+lk_3k_4|e^{-At_1(\psi_1)}-e^{-At_1(\psi_2)}|+k_1|\psi_1-\psi_2|k_2k_3.
\end{aligned}$$

Due to the analyticity of the e^{-At}, for $t\in[-l,l]$ there is a constant $k_6\geqq 0$ such that

$$|e^{-At_1(\psi_1)}-e^{-At_1(\psi_2)}|\leqq k_6|t_1(\psi_1)-t_1(\psi_2)|\leqq k_6k_1|\psi_1-\psi_2|.$$

Because of $\psi_1,\psi_2\in O_{\psi_0}$, where O_{ψ_0} is compact, there is a $k_7>0$ such that $|\psi|\leqq k_7$ for each $\psi\in O_{\psi_0}$. Then

$$\begin{aligned}
&|\mathscr{F}_{-(t_1(\psi_1)-\tau_1^-)}\mathscr{F}_{t_1(\psi_1)}\psi_1-\mathscr{F}_{-(t_1(\psi_1)-\tau_1^-)}\mathscr{F}_{t_1(\psi_2)}\psi_2| \\
&\quad\leqq k_4|\mathscr{F}_{t_1(\psi_1)}\psi_1-\mathscr{F}_{t_1(\psi_2)}\psi_2| \\
&\quad\leqq k_4(|\mathscr{F}_{t_1(\psi_1)}\psi_1-\mathscr{F}_{t_1(\psi_1)}\psi_2|+|\mathscr{F}_{t_1(\psi_1)}\psi_2-\mathscr{F}_{t_1(\psi_2)}\psi_2|) \\
&\quad\leqq k_4(k_4|\psi_1-\psi_2|+k_1k_6|\psi_1-\psi_2|).
\end{aligned}$$

This completes the proof.

COROLLARY 10. $\mu(H)=0$.

The proof follows directly from Theorem 6, (62), and the well-known fact that the image of the locally Lipschitz continuous function from an analytic submanifold of R^n of a dimension smaller than n to R^n is of the Lebesgue measure zero.

EXACT CONTROLLABILITY OF THE EULER-BERNOULLI EQUATION WITH CONTROLS IN THE DIRICHLET AND NEUMANN BOUNDARY CONDITIONS: A NONCONSERVATIVE CASE*[1]

I. LASIECKA† AND R. TRIGGIANI†

Abstract. This paper considers the Euler-Bernoulli problem (1.1a-d) with boundary controls g_1, g_2 in the Dirichlet and Neumann boundary conditions, respectively. Several exact controllability results are shown, including the following. Problem (1.1a-d) is exactly controllable in an arbitrarily short time $T>0$ in the space (of maximal regularity) $H^{-1}(\Omega)\times V'$, V as in (1.4), (i) with boundary controls $g_1\in L^2(\Sigma)$, $g_2\equiv 0$ under some geometrical conditions on Ω; (ii) with boundary controls $g_1\in L^2(\Sigma)$ and $g_2\in L^2(0, T; H^{-1}(\Gamma))$ without geometrical conditions on Ω. A direct approach is given, based on an operator model for problem (1.1a-d) and on multiplier techniques. An additional difficulty of the particular boundary conditions is due to the fact that, in the natural norms for the solution arising in the application of multiplier techniques, the corresponding homogeneous problem is *not* conservative. This difficulty is overcome by passing to an equivalent norm for the solution, with respect to which the homogeneous problem becomes conservative.

Key words. exact controllability, Euler-Bernoulli equation, boundary control

AMS(MOS) subject classifications. 35, 93

1. Introduction, statement of main results, and literature. Throughout this paper Ω is an open, bounded domain in R^n, $n\geqq 2$, with sufficiently smooth boundary $\partial\Omega=\Gamma$. In Ω, we consider the following nonhomogeneous problem for the Euler-Bernoulli equation in the solution $w(t, x)$:

$$w_{tt}+\Delta^2 w=0 \qquad \text{in } (0, T]\times\Omega\equiv Q, \tag{1.1a}$$

$$w(0,\circ)=w^0, \quad w_t(0,\circ)=w^1 \qquad \text{in } \Omega, \tag{1.1b}$$

$$w|_\Sigma\equiv g_1 \qquad \text{in } (0, T]\times\Gamma\equiv\Sigma, \tag{1.1c}$$

$$\left.\frac{\partial w}{\partial\nu}\right|_\Sigma\equiv g_2 \qquad \text{in } (0, T]\times\Gamma\equiv\Sigma, \tag{1.1d}$$

with control functions g_1, g_2 to be suitably selected below. Here, ν is the unit outward normal vector to Γ. In this paper we study the problem of *exact controllability* for the dynamics of (1.1a-d). As a matter of fact, the case $g_1\equiv 0$ and $g_2\in L^2(\Sigma)$ has already been studied by Lions in [L3, § 3], where he obtains exact controllability results in the space $L^2(\Omega)\times H^{-2}(\Omega)$ for T greater than some suitable $T_0>0$. Lions' results were then refined by Komornik [K1], who improved the estimate of T_0, and then by Zuazua [Z1], who showed that T can be taken arbitrarily small (as expected) by using an idea, first introduced in [BLR1], to prove a needed uniqueness result.

In the same Von Neumann Lecture [L3, Remark 3.5], Lions raises the question as to whether problem (1.1a-d) with boundary controls

$$g_1\in L^2(\Sigma), \qquad g_2\equiv 0 \tag{1.2}$$

(i.e., with purely Dirichlet control) is exactly controllable and, if so, in what space. In particular, Lions raises the question of characterizing his space F for problem (1.1a-d) subject to (1.2).

[1] An announcement of the present paper with a brief sketch of the proofs is given in [LT6].

The main aim of the present paper is to provide affirmative answers to the above (and related) questions. To give a proper foundation for our subsequent analysis on exact controllability, we begin by stating regularity results for problem (1.1a-d) in the cases of interest. To this end, we introduce the following spaces:

$$X \equiv H^{-1}(\Omega) \times V', \tag{1.3}$$

$$V \equiv \left\{ f \in H^3(\Omega) : f|_\Gamma = \left. \frac{\partial f}{\partial \nu} \right|_\Gamma = 0 \right\}. \tag{1.4}$$

The space X in (1.3) can be likewise identified as

$$X \equiv [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]' \tag{1.5}$$

(with equivalent norms), where A is the positive self-adjoint operator defined by $Af = \Delta^2 f$, $\mathscr{D}(A) = H^4(\Omega) \cap H_0^2(\Omega)$ (see (2.2) below). In (1.5), the symbol $'$ denotes duality of $\mathscr{D}(A^{1/4})$ and $\mathscr{D}(A^{3/4})$, respectively, with respect to the $L_2(\Omega)$-topology. The norms are given by

$$\|x\|_{\mathscr{D}(A^\alpha)} \equiv \|A^\alpha x\|_{L^2(\Omega)}, \qquad \|x\|_{[\mathscr{D}(A^\beta)]'} = \|A^{-\beta} x\|_{L^2(\Omega)}, \tag{1.6}$$

where $\alpha, \beta \geqq 0$.

THEOREM 1.0 (Regularity). *Consider problem* (1.1a-d) *subject to*

$$\{w^0, w^1\} \in X, \quad g_1 \in L^2(\Sigma), \quad g_2 \in L^2(0, T; H^{-1}(\Gamma)).$$

Then the map

$$\{w^0, w^1, g_1, g_2\} \to \{w(t), w_t(t)\} \in C([0, T]; X)$$

is continuous for any $0 < T < \infty$, *where the space* X *is defined by* (1.3)-(1.5).

The proof of Theorem 1.0 follows by applying a transposition argument to recent results of Lions [L2] combined with cosine-sine operator theory on the initial data. Details are omitted. See also Remark 4.1 and (5.16) below.

Remark 1.1. For the purposes of the subsequent Theorem 1.2, we note that with, say, $w^0 = w^1 = g_2 \equiv 0$, the corresponding map

$$g_1 \to \{w(t), w_t(t)\}$$

is *not* continuous $H_0^1(0, T; L^2(\Gamma)) \to C([0, T]; Y)$, where (with equivalent norms):

$$Y \equiv H_0^1(\Omega) \times H^{-1}(\Omega) \equiv \mathscr{D}(A^{1/4}) \times [\mathscr{D}(A^{1/4})]'. \tag{1.7}$$

Instead, $g_1 \to \{w(T), w_t(T)\}$ is continuous into Y, by virtue of the smoothing due to the condition $g_1(T) = 0$. See more specifically Remark 3.1.

With the regularity theorem at hand, we can now state our main exact controllability results. They will be listed in the order in which they are proved, even though a given result may be extended by a subsequent one (e.g., Theorem 1.1 is improved in Theorem 1.4, etc.).

THEOREM 1.1. *Assume that there exists a point* $x_0 \in R^n$ *such that*

$$(x - x_0) \cdot \nu \geqq \text{const} = \gamma > 0 \quad \text{on } \Gamma. \tag{1.8}^2$$

---

[2] It is observed in [L7] that our proof here can be generalized to include the case $\gamma = 0$. This is done by using the estimate $\int_\Sigma |\nabla_\sigma(\Delta\phi)|^2 \, d\Sigma \leqq c_T \|\{\phi^0, \phi^1\}\|_Z^2$, $Z = \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})$ from [L2], in the analysis of the left-hand side of identity (2.24), carried out in step (vii) of the proof of Lemma 2.2, or in the proof of Theorem 4.5. The authors now have a different proof of the above estimate on $\nabla_\sigma(\Delta\phi)$.

Then there exists $T_0 > 0$ (*which can be explicitly estimated from the proof of Lemma* 2.2) *such that if* $T > T_0$, *then, given any pair of initial data* $\{w^0, w^1\} \in X$ (*see* (1.3)-(1.5)), *there exists a boundary control* $g_1 \in L^2(0, T; L^2(\Gamma))$ *such that the corresponding solution of problem* (1.1a-d), (1.2) *satisfies*

$$w(T, \cdot) = w_t(T, \cdot) = 0, \qquad \begin{vmatrix} w \\ w_t \end{vmatrix} \in C([0, T]; X).$$

Remark 1.2. Actually, the proof of Theorem 1.1 extends with no extra effort to domains Ω for which there exists a vector field $h(x) = [h_1(x), \cdots, h_n(x)]$ defined by

$$h_i(x) = \sum_{j=1}^{n} a_{ij}(x_j - x_{0,j}) \quad \text{for some } x_0 = [x_{0,1}, \cdots, x_{0,n}] \in R^n, \tag{1.9}$$

where the coefficients $\{a_{ij}\}$ satisfy (1.12) below, such that

$$h(x) \cdot \nu(x) \geqq \text{const} = \gamma > 0 \quad \text{on } \Gamma \tag{1.10}$$

as in (1.8).

Set

$$H(x) \equiv \begin{vmatrix} \partial h_1/\partial x_1 & \cdots & \partial h_1/\partial x_n \\ \vdots & & \vdots \\ \partial h_n/\partial x_1 & & \partial h_n/\partial x_n \end{vmatrix} = \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} \equiv H \tag{1.11}$$

and require that the symmetric matrix

$$H + H^* = \begin{vmatrix} 2a_{11} & \cdots & a_{1n} + a_{n1} \\ \vdots & & \vdots \\ a_{n1} + a_{1n} & \cdots & 2a_{nn} \end{vmatrix} \tag{1.12}$$

be strictly positive definite:

$$H + H^* \geqq \rho I \quad \text{for some } \rho > 0, \tag{1.13}$$

so that

$$\int_\Omega H(x)v(x) \cdot v(x)\, d\Omega \geqq \rho \int_\Omega |v(x)|^2_{R^n}\, d\Omega \quad \text{for all } v(x) \in [L^2(\Omega)]^n. \tag{1.14}$$

Moreover, the definition (1.9) of h implies (in the notation of § 6 below (see (6.4)))

$$4G_h \equiv \max_{\bar{\Omega}} |\nabla(\text{div } h)| = 0. \tag{1.15}$$

Subject to the standing assumption (1.10), the proof of Theorem 1.1 in § 2 applies equally well for linear vector fields $h(x)$, as in (1.9), which satisfy the positivity condition (1.13) (as well as (1.15)). See also the proof in § 6 for the more general situation of Theorem 1.5, or of Theorem 6.2; these results allow domains Ω for which there is a general vector field $h(x) \in C^2(\bar{\Omega})$ satisfying (1.10), (1.14) and another condition to take care of $G_h \neq 0$.

The next result considers a smoother control g_1 and consequently a smoother target space in part (i). In part (ii), it interpolates between Theorem 1.1 and Theorem 1.2(i).

THEOREM 1.2. (i) *Under condition* (1.8) *of Theorem* 1.1, *there exists* $T_0 > 0$ (*which can be explicitly estimated from the proof*) *such that if* $T > T_0$, *then given any pair of initial data* $\{w^0, w^1\} \in Y$ (*see* (1.7)), *there exists a boundary control* $g_1 \in H_0^1(0, T; L^2(\Gamma))$ *such that the corresponding solution to problem* (1.1a-d) *with such* g_1 *and* $g_2 \equiv 0$ *satisfies* $w(T, \cdot) = w_t(T, \cdot) = 0$.

(ii) *Moreover, for T sufficiently large, exact controllability of problem* (1.1a-d) *in the sense described by the preceding statement is equivalent to exact controllability of problem* (1.1a-d) *in the sense described by Theorem* 1.1, *and the simultaneous characterization of these two notions is given by* (2.11) *below. As a result, under assumption* (1.8), *an interpolation result between Theorem* 1.1 *and Theorem* 1.2 *is available and is described in detail in Corollary* 3.3(ii) *below.*

The next result manages to *dispense altogether with the geometrical condition* (1.8) imposed on the (smooth) domain Ω, at the price of inserting an additional control function g_2 in the Neumann boundary condition (1.1d).

Also, exact controllability is achieved in an arbitrarily short time.

THEOREM 1.3. *For any* $T > 0$, *given any pair of initial data* $\{w^0, w^1\} \in X$ (*see* (1.3)-(1.5)) *there exist boundary controls*

$$g_1 \in L^2(0, T; L^2(\Gamma)) \quad \text{and} \quad g_2 \in L^2(0, T; H^{-1}(\Gamma))$$

such that the corresponding solution of problem (1.1a-d) *satisfies*

$$w(T, \cdot) = w_t(T, \cdot) = 0, \qquad \begin{vmatrix} w \\ w_t \end{vmatrix} \in C([0, T]; X).$$

A direct extension of Theorem 1.3 to the case where the second control g_2 (with the same regularity) acts only on a suitable portion of the boundary is provided in Theorem 4.5, which likewise does not require geometrical conditions on Ω.

The proof of Theorem 1.3, suitably modified and complemented, will allow us to obtain the following improved version of Theorem 1.1.

THEOREM 1.4. *For the case* $g_1 \in L^2(\Sigma)$ *and* $g_2 \equiv 0$, *Theorem* 1.1 *admits a stronger conclusion in the sense that the time T of exact controllability stated there* (*universal, i.e., independent of the initial conditions*) *may be taken arbitrarily small.*

Remark 1.3. Consider the following homogeneous problem:

$$\phi_{tt} + \Delta^2 \phi \equiv 0 \qquad \text{in } Q, \tag{1.16a}$$

$$\phi|_{t=0} = \phi^0, \quad \phi_t|_{t=0} = \phi^1 \qquad \text{in } \Omega, \tag{1.16b}$$

$$\phi|_\Sigma \equiv 0 \qquad \text{in } \Sigma, \tag{1.16c}$$

$$\left.\frac{\partial \phi}{\partial \nu}\right|_\Sigma \equiv 0 \qquad \text{in } \Sigma. \tag{1.16d}$$

The proof of Theorem 1.1 shows that exact controllability of (1.1a-d)-(1.2) on the space X is *equivalent* to the following inequality: There exists C'_T such that

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial \nu}\right)^2 d\Sigma \geq C'_T \|\{\phi^0, \phi^1\}\|^2_{\mathcal{D}(A^{3/4}) \times \mathcal{D}(A^{1/4})}; \tag{1.17}$$

see the (backward in time) problem (2.9a-d) in Lemma 2.1. Lemma 2.2 shows then that this inequality holds true under (1.8) for $T > T_0$, where $C'_T = c(T - T_0)$ (or, more generally, for domains Ω that admit a linear field $h(x)$ as in (1.9) that satisfies (1.10) as well as (1.13). Moreover, Lemma 5.5 shows that T_0 can be taken arbitrarily small.

On the other hand, the opposite inequality:

$$\int_0^T \int_\Gamma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \leqq C_T \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{1.18}$$

is always true for all $0 < T < \infty$, as it follows by transposition from Lions' results [L2]. Hence for $T > T_0$, where T_0 can be taken arbitrarily small, and for Ω subject to condition (1.8) (or as in Remark 1.2), we can define a norm

$$\|\{\phi^0, \phi^1\}\|^2_F \equiv \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \tag{1.19}$$

on the space F which is, therefore, $F \equiv \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4}) \equiv V \times H_0^1(\Omega)$. Such a norm (1.12) is equivalent to the norm

$$\|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \equiv \|A^{3/4}\phi^0\|^2_{L_2(\Omega)} + \|A^{1/4}\phi^1\|^2_{L_2(\Omega)}. \tag{1.20}$$

This answers a question raised by Lions [L3, Remark 3.5].

Remark 1.4. Inequality (1.17) (to be proved in Lemma 2.2 for T_0 finite and in Lemma 5.5 for T_0 arbitrarily small for domains Ω for which there exists a vector field $h(x)$, as in (1.9), that satisfies (1.13), in particular a radial vector field) establishes a fortiori an apparently new uniqueness theorem under condition (1.10) (respectively, (1.8)): If ϕ solves (1.16a) and moreover the three boundary conditions

$$\phi|_\Sigma \equiv 0, \quad \left.\frac{\partial\phi}{\partial\nu}\right|_\Sigma \equiv 0, \quad \left.\frac{\partial(\Delta\phi)}{\partial\nu}\right|_\Sigma \equiv 0, \quad T > 0 \text{ arbitrary},$$

then $\phi \equiv 0$ in Q.

By contrast, a standard uniqueness theorem (Holmgren-John) (see [H2, Thm. 5.33, p. 129]), to be crucially invoked in the proof of Theorem 1.3; see (4.39) in the proof of Lemma 4.4, is instead: If ϕ solves (1.16a) and moreover the four boundary conditions

$$\phi|_\Sigma \equiv 0, \quad \left.\frac{\partial\phi}{\partial\nu}\right|_\Sigma \equiv 0, \quad \Delta\phi|_\Sigma \equiv 0, \quad \left.\frac{\partial(\Delta\phi)}{\partial\nu}\right|_\Sigma \equiv 0$$

for $T > 0$ arbitrary, then $\phi \equiv 0$ in Q.

The result in Theorem 1.1 admits the following generalization, whose proof will be given in § 6. It requires, in addition to the reasoning in the proof of Theorem 1.1, a nontrivial extra argument, which is presented first (in a slightly different context) in the proof of § 4 to establish that with two control functions g_1 and g_2, the time T for exact controllability can be taken arbitrarily small.

THEOREM 1.5. *The conclusion of Theorem* 1.1 *on exact controllability on* $X = [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$ *(see* (1.5)*) over any* $[0, T]$, $T > T_u$ *defined by* (1.24) *below holds true more generally for (smooth) domains* Ω *possessing the following geometrical properties: there exists a (general) vector field* $h(x) \in C^2(\bar{\Omega})$ *such that*

(1.21) (i_1) $h(x) \cdot \nu(x) \geqq \text{const} = \gamma > 0$ *on* Γ;
(i_2) *If we set*

$$H(x) \equiv \begin{vmatrix} \partial h_1/\partial x_1 & \cdots & \partial h_1/\partial x_n \\ \vdots & & \vdots \\ \partial h_n/\partial x_1 & \cdots & \partial h_n/\partial x_n \end{vmatrix}, \tag{1.22}$$

then

(1.23)

$$\int_\Omega H(x)v(x)\cdot v(x)\,d\Omega \geqq \rho \int_\Omega |v(x)|^2_{R^n}\,d\Omega \quad \textit{for some } \rho>0 \textit{ and all } v(x)\in[L^2(\Omega)]^n.$$

(*A sufficient checkable condition for* (1.23) *to hold true is that the symmetric matrix* $H(x)+H^*(x)$ *be uniformly strictly positive definite on* $\bar{\Omega}$.)

(ii) *Moreover,* Ω *satisfies the following uniqueness property*:

(1.24)

$$\phi_{tt}+\Delta^2\phi\equiv 0 \quad \textit{in } Q, \quad \phi|_\Sigma\equiv 0, \quad \left.\frac{\partial\phi}{\partial\nu}\right|_\Sigma\equiv 0, \quad \left.\frac{\partial(\Delta\phi)}{\partial\nu}\right|_\Sigma\equiv 0 \quad \textit{for } 0<t\leqq T_u$$

$$\textit{implies } \phi\equiv 0 \quad \textit{in } Q.$$

(*As shown in Remark* 1.4, *such a uniqueness property is satisfied for any* $T_u>0$ *by domains* Ω *for which there is a radial vector field* $x-x_0$ *satisfying* (1.8), *or more generally, for which there is a linear vector field as in* (1.9) *satisfying* (1.13) (*i.e.*, (1.23)) *as well as* (1.10) = (1.21).)

Remark 1.5 (on the smoothness of Γ). The proofs given below require the existence of a dense set of initial data for which the solutions of the corresponding homogeneous problem (1.16a-d) possess the regularity required to carry out the actual computations in the multiplier methods of Lemma 2.2, Proposition 4.2, etc.

The proofs of the preceding results will be given in the next sections according to the following strategy. In §§ 2 and 3 we provide the proofs of Theorems 1.1 and 1.2 in the case where $g_2=0$ and for T sufficiently large, respectively, in the special but important case in which the assumed vector field $h(x)$ is radial, or as in Remark 1.2. These sections form the core of proofs in the general case. The additional arguments required to prove, say, Theorem 1.1 for a general vector field as in Theorem 1.5 are presented in § 6. When we pass from a radial to a general vector field, the main nontrivial extra difficulty consists in the need to "absorb" lower-order interior terms on Q by appropriate boundary terms on Σ. This is accomplished in § 6 by reasoning in the same conceptual way (but with different details) as in the preceding §§ 4 and 5 in proving Theorems 1.3 and 1.4 for T arbitrarily small. (Reasoning of the same conceptual type, again with different technical details depending on the circumstances, is also used for wave equations [L3], [LT3], and [T2], and crucially exploited in [L8] and [L9].)

The exact controllability theorems (Theorems 1.1, 1.3, and 1.4) in the space of regularity X (see (1.3)-(1.5)) have an important implication in the quadratic cost problem over an infinite interval (regulator problem) corresponding to the dynamics (1.1a-d): Minimize

(1.25)

$$J(g_1,g_2,w) \equiv \int_0^\infty \left\{ \|w(t)\|^2_{[\mathscr{D}(A^{1/4})]'} + \|w_t(t)\|^2_{[\mathscr{D}(A^{3/4})]'} + \|g_1(t)\|^2_{L^2(\Gamma)} + \|g_2(t)\|^2_{H^{-1}(\Gamma)} \right\} dt$$

over all $\{g_1,g_2\}\in L^2(0,\infty;L^2(\Gamma))\times L^2(0,\infty;H^{-1}(\Gamma))\equiv U$. Indeed, Theorems 1.1 and 1.3 guarantee a fortiori that the corresponding finite-cost condition be fulfilled: For each $\{w^0,w^1\}\in X$ there is some $\{\bar{g}_1,\bar{g}_2\}\in U$ such that for the corresponding solution $\{\bar{w}(t),\bar{w}_t(t)\}$ we have $J(\bar{g}_1,\bar{g}_2,\bar{w})<\infty$, and indeed g_2 may be taken to be zero.

On the other hand, problem (1.1a-d) fits the abstract model considered in [FLT1], which offers a rather comprehensive study of the regulator problem and corresponding

algebraic Riccati equation (see Appendix 2 of [FLT1]). Thus we have the following theorem.

THEOREM 1.6. *The regulator theory of* [FLT1] *with cost function* (1.25) *applies to problem* (1.1a-d), (1.2) *under assumption* (1.8) *of Theorem* 1.1. *It provides, among other things, a boundary feedback* $g_1^0(t) = -B^*P[w^0(t), w_t^0(t)]$ *(in the notation of* [FLT1]*, we have* $u^0(t) = \{g_1^0(t), 0\}$*, where* $[g_1^0(t), \{w^0(t), w_t^0(t)\}]$ *is the unique optimal pair in problem* (1.25) *and P is a Riccati operator). Such feedback inserted in* (1.1c) *produces exponential decay in the uniform norm X of the corresponding feedback system. More specifically we have from* [FLT1] *(see* (2.1a-c) *and* (2.4) *below*):

$$\begin{aligned} g_1^0(t) &= -G_1^* A^{-1/2}[P\{w(t), w_t(t)\}]_2 \\ &= -G_1^* A A^{-3/2}[P\{w(t), w_t(t)\}]_2 \\ &= \frac{\partial \Delta}{\partial \nu} A^{-3/2}[P\{w(t), w_t(t)\}]_2, \end{aligned}$$

where $[y]_2$ *means the second component* y_2 *of the vector* $y = [y_1, y_2]$*. Alternatively, the regulator theory of* [FLT1] *applies with both* g_1 *and* g_2*, but with no geometrical conditions (Theorem* 1.3).

Notation. Unless otherwise specified, the norms $\| \ \|_\Omega$, $\| \ \|_\Gamma, \cdots$ and the inner products $(,)_\Omega$, $(,)_\Gamma, \cdots$ are all L^2 over the specified domain Ω, Γ, Q, Σ, etc.

Orientation. Our strategy in this paper consists, in short, of two main points (as in [T2], [LT3], and [LT8]):

(i) An operator approach to identifying an *equivalent* condition for exact controllability, in terms of the corresponding homogeneous partial differential problem with solution ϕ (such a condition is a bound from below of suitable traces of ϕ on Σ in terms of the interior norm of the initial data on Ω).

(ii) A multiplier technique for proving the condition in (i). Here we use the multipliers $h \cdot \nabla(\Delta\phi)$ and $\Delta\phi$ div h, where $h(x)$ is a smooth vector field on $\bar{\Omega}$. Instead, in [L3, § 3] for $g_1 = 0$ and $g_2 \in L^2(\Sigma)$, the multipliers $h \cdot \nabla\phi$ and ϕ, h a radial field, are employed (these are the same multipliers that were successful in the treatment of regularity and exact controllability questions for wave equations [L1]-[L6], [LLT1], [H1], [LT3], and [T2]). An additional difficulty of the particular boundary conditions in this paper is due to the fact that the natural norms arising in the application of the multiplier technique are

$$\left\{\int_\Omega |\nabla(\Delta\phi)|^2 \, d\Omega\right\}^{1/2} \quad \text{and} \quad \left\{\int_\Omega |\nabla\phi_t|^2 \, d\Omega\right\}^{1/2}$$

and in these norms the homogeneous problem in ϕ is *nonconservative.* (This is a novel feature over past literature on these problems.) This difficulty is overcome by realizing that the above norms are *equivalent* to the norms

$$\|A^{3/4}\phi\|_{L^2(\Omega)} \quad \text{and} \quad \|A^{1/4}\phi_t\|_{L^2(\Omega)}$$

with respect to which the homogeneous problem in ϕ becomes conservative. Once exact controllability is established, the simple argument of Appendix D provides the minimal norm steering control. The corresponding uniform stabilization problem is studied in [BT1].

2. Proof of Theorem 1.1. The radial vector field case.

Step 0. In line with the authors' approach to time-invariant problems with second-order differential operators in the space variables [LT1]-[LT5] and [T1]-[T3] we introduce an explicit input $g_1 \to$ solution $[w, w_t]$ map. To this end, we first define an

operator G_1 (Green map) by

$$G_1 g = y \Leftrightarrow \begin{cases} \Delta^2 y = 0 & \text{in } \Omega, \quad (2.1a) \\ y|_\Gamma = g, & (2.1b) \\ \partial y/\partial \nu|_\Gamma = 0, & (2.1c) \end{cases}$$

which is continuous $L^2(\Gamma) \to L^2(\Omega)$ (in fact, $L^2(\Gamma) \to H^{1/2}(\Omega)$ [LM1, Vol. I, pp. 188-189]). Next, we define the operator A: $L^2(\Omega) \supset \mathscr{D}(A) \to L^2(\Omega)$ by ([F1, p. 101])

$$\begin{aligned} &Af = \Delta^2 f, \\ &\mathscr{D}(A) = \left\{ f \in L^2(\Omega) : \Delta^2 f \in L^2(\Omega), f|_\Gamma = \left.\frac{\partial f}{\partial \nu}\right|_\Gamma = 0 \right\} = H^4(\Omega) \cap H_0^2(\Omega). \end{aligned} \quad (2.2)$$

The operator A is positive self-adjoint: $(Af, f)_\Omega = \|\Delta f\|_\Omega^2$ for $f \in \mathscr{D}(A)$, by Green's second theorem. Thus, $-A$ generates a strongly continuous (s.c.) cosine operator $C(t)$ on $L^2(\Omega)$, $t \in R$, with $S(t)z = \int_0^t C(\tau)z\, d\tau$, $z \in L^2(\Omega)$. Then, as in the authors' references above, the solution to problem (1.1a-d) with $w^0 = w^1 = 0$ at time T can be written in operator form as

$$\begin{vmatrix} w(T, t=0; w^0=0, w^1=0) \\ w_t(T, t=0; w^0=0, w^1=0) \end{vmatrix} = \mathscr{L}_{1T} g_1 = \begin{vmatrix} A \int_0^T S(T-t) G_1 g_1(t)\, dt \\ A \int_0^T C(T-t) G_1 g_1(t)\, dt \end{vmatrix}. \quad (2.3)$$

The following lemma in the style of [T1]-[T3] and [LT2] will be needed.

LEMMA 2.0. *Let G_1^* denote the continuous operator $L^2(\Omega) \to L^2(\Gamma)$, which is the adjoint of G_1: $(G_1 g, v)_\Omega = (g, G_1^* v)_\Gamma$, $g \in L^2(\Gamma)$, $v \in L^2(\Omega)$. Then*

$$G_1^* Af = \left.\frac{\partial(\Delta f)}{\partial \nu}\right|_\Gamma, \qquad f \in \mathscr{D}(A). \quad (2.4)$$

Proof. For $f \in \mathscr{D}(A)$ and $g \in L^2(\Omega)$ we compute by Green's second theorem applied twice:

$$\begin{aligned} (G_1^* Af, g)_\Gamma &= (Af, G_1 g)_\Omega = (\Delta(\Delta f), G_1 g)_\Omega \\ &= (\Delta f, \Delta(G_1 g))_\Omega + \left(\frac{\partial(\Delta f)}{\partial \nu}, G_1 g\right)_\Gamma - \left(\Delta f, \frac{\partial(G_1 g)}{\partial \nu}\right)_\Gamma \quad \text{(by (2.1c))} \\ &= (f, \Delta^2(G_1 g))_\Omega + \left(\frac{\partial f}{\partial \nu}, \Delta(G_1 g)\right)_\Gamma - \left(f, \frac{\partial(\Delta G_1 g)}{\partial \nu}\right)_\Gamma \\ &\qquad + \left(\frac{\partial(\Delta f)}{\partial \nu}, g\right)_\Gamma \quad \text{(by 2.1a) and (2.2))} \\ &= \left(\frac{\partial(\Delta f)}{\partial \nu}, g\right)_\Gamma. \end{aligned}$$

□

Step 1. The (regularity) Theorem 1.0 gives us that $\mathscr{L}_{1T}$ is continuous $L^2(\Sigma) \to X \equiv [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$. By time reversibility of problem (1.1a-d), exact controllability of problem (1.1a)-(1.1d) on the space X over $[0, T]$ is equivalent to

$$\mathscr{L}_{1T} : L^2(\Sigma) \xrightarrow{\text{ONTO}} X \equiv [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]' \quad (2.5)$$

which in turn is equivalent [TL1, p. 235] to the condition that the Hilbert space adjoint $\mathscr{L}_{1T}^*$ has continuous inverse: $X \to L^2(\Sigma)$ ("continuous observability" in the terminology of [DR1]); i.e., there exists $C_T > 0$ such that

$$\left\| \mathscr{L}_{1T}^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right\|_{L^2(\Sigma)} \geqq C_T \|\{z_1, z_2\}\|_{[\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'} \tag{2.6}$$

for all $z = \{z_1, z_2\} \in X$, where for $g \in L^2(\Sigma)$

$$(\mathscr{L}_{1T} g, z)_X = (g, \mathscr{L}_{1T}^* z)_{L^2(\Sigma)}. \tag{2.7}$$

Step 2. An equivalent partial differential equation characterization of inequality (2.6) is given by the following lemma.

LEMMA 2.1. (i) *For* $z = \{z_1, z_2\} \in X \equiv [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$, *we have*

$$\left(\mathscr{L}_{1T}^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right)(t) = \frac{\partial}{\partial \nu} (\Delta \phi(t)) \quad \text{on } \Sigma, \tag{2.8}$$

where $\phi(t) \equiv \phi(t; \phi^0, \phi^1)$ *is the solution of the following backward problem*:

$$\phi_{tt} + \Delta^2 \phi \equiv 0 \qquad \text{in } Q, \tag{2.9a}$$

$$\phi|_{t=T} = \phi^0, \quad \phi_t|_{t=T} = \phi^1 \quad \text{in } \Omega, \tag{2.9b}$$

$$\phi|_\Sigma \equiv 0 \qquad \text{in } \Sigma, \tag{2.9c}$$

$$\left. \frac{\partial \phi}{\partial \nu} \right|_\Sigma \equiv 0 \qquad \text{in } \Sigma, \tag{2.9d}$$

with

$$\phi^0 = A^{-3/2} z_2, \quad \phi^1 = -A^{-1/2} z_1 \quad \text{in } \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4}). \tag{2.10}$$

(ii) *For any* $0 < T < \infty$, (2.5) *is equivalent to the following*:
There exists $C_T' > 0$ *such that*

$$\int_\Sigma \left(\frac{\partial(\Delta \phi)}{\partial \nu} \right)^2 d\Sigma \geqq C_T' \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})} \tag{2.11}$$

for all $\{\phi^0, \phi^1\} \in \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})$.

Proof. (i) As in [LT2]-[LT3] and [T1]-[T3] we compute from (2.3), (2.5), and (1.6)

$$\begin{aligned}
\left(\mathscr{L}_{1T} g_1, \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right)_X &= \left(\begin{vmatrix} A \int_0^T S(T-t) G_1 g_1(t)\, dt \\ A \int_0^T C(T-t) G_1 g_1(t)\, dt \end{vmatrix}, \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right)_{[\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'} \\
&= \left(A \int_0^T S(T-t) G_1 g_1(t)\, dt, A^{-1/2} z_1 \right)_\Omega \\
&\qquad + \left(\int_0^T C(T-t) G_1 g_1(t)\, dt, A^{-1/2} z_2 \right)_\Omega \\
&= (g_1, G_1^* A[S(T-t) A^{-1/2} z_1 + C(T-t) A^{-3/2} z_2])_\Sigma \\
&= (g_1, G_1^* A[C(t-T) A^{-3/2} z_2 + S(t-T)(-A^{-1/2} z_1)])_\Sigma,
\end{aligned} \tag{2.12}$$

where in the last step we have used $C(\cdot)$ even while $S(\cdot)$ is odd. Thus from (2.7) and (2.12) we deduce

$$\left(\mathscr{L}_{1T}^{*}\begin{vmatrix} z_1 \\ z_2 \end{vmatrix}\right)(t) = G_1^{*}A[C(t-T)A^{-3/2}z_2 + S(t-T)(-A^{-1/2}z_1)] \quad \text{on } \Sigma. \tag{2.13}$$

But the solution of problem (2.9a-d), (2.10) is precisely

$$\phi(t) = C(t-T)\phi^0 + S(t-T)\phi^1 \tag{2.14}$$

and by (2.4)

$$\frac{\partial(\Delta\phi(t))}{\partial\nu} = G_1^{*}A[C(t-T)\phi^0 + S(t-T)\phi^1] \quad \text{on } \Sigma. \tag{2.15}$$

Comparing (2.13) with (2.15) (with initial data as in (2.10)) yields the desired conclusion (2.8). Then part (i) immediately implies part (ii) via (2.8) used in (2.6), with initial data

$$\begin{aligned} z_1 = -A^{1/2}\phi^1 \in [\mathscr{D}(A^{1/4})]' \quad &\text{so that } A^{-1/4}z_1 = -A^{1/4}\phi^1 \in L^2(\Omega) \\ &\text{and} \quad \phi^1 \in \mathscr{D}(A^{1/4}), \end{aligned} \tag{2.16}$$

$$\begin{aligned} z_2 = A^{3/2}\phi^0 \in [\mathscr{D}(A^{3/4})]' \quad &\text{so that } A^{-3/4}z_2 = A^{3/4}\phi^0 \in L^2(\Omega) \\ &\text{and} \quad \phi^0 \in \mathscr{D}(A^{3/4}). \end{aligned} \tag{2.17}$$

Hence,

$$\begin{aligned} &\|\{z_1 = -A^{1/2}\phi^1,\ z_2 = A^{3/2}\phi^0\}\|_{[\mathscr{D}(A^{1/4})]'\times[\mathscr{D}(A^{3/4})]'} \\ &\quad \text{is equivalent to } \|\{\phi^0, \phi^1\}\|_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}. \end{aligned} \tag{2.18}$$

The proof of Lemma 2.1 is complete. □

Step 3. It remains to show if or when (2.11) holds true. The following lemma is the key technical issue of the exact controllability problem for (1.1a-d).

LEMMA 2.2. *Under the same assumptions as in Theorem* 1.1, *there is* $T_0 > 0$ *as in Theorem* 1.1 *such that if* $T > T_0$, *then* (2.11) *holds true with* $C'_T = c(T - T_0)$:

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \geqq c(T-T_0)\|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{2.19}$$

where, by time reversal in (2.9a-d), *we may take* ϕ *to be the solution of the homogeneous problem*

$$\phi_{tt} + \Delta^2\phi \equiv 0 \qquad \text{in } Q, \tag{2.20a}$$

$$\phi(0,\cdot) = \phi^0 \in \mathscr{D}(A^{3/4}), \qquad \phi_t(0,\cdot) = \phi^1 \in \mathscr{D}(A^{1/4}) \quad \text{in } \Omega, \tag{2.20b}$$

$$\phi|_\Sigma \equiv 0 \qquad \text{in } \Sigma, \tag{2.20c}$$

$$\left.\frac{\partial\phi}{\partial\nu}\right|_\Sigma \equiv 0 \qquad \text{in } \Sigma. \tag{2.20d}$$

Remark 2.1. As pointed out in Remark 1.3, (1.18), the inequality opposite to (2.19), i.e.,

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \leqq CT\|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{2.21}$$

always holds true (with Γ sufficiently smooth as in Remark 1.4) for all $0 < T < \infty$, as

a consequence of Lions' results [L2] followed by a transposition argument.

Proof of Lemma 2.2.

Step (i). Let $h(x)=x-x_0$, the radial vector field assumed in the statement of Theorem 1.1. With reference to Remark 1.4 we multiply (2.20a) by the multiplier $h\cdot\nabla(\Delta\phi)$ and integrate over $\int_0^T\int_\Omega dQ$. We obtain (see Appendix A)

$$\begin{aligned}&\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\,h\cdot\nabla(\Delta\phi)\,d\Sigma-\frac{1}{2}\int_\Sigma|\nabla(\Delta\phi)|^2h\cdot\nu\,d\Sigma\\&=\int_Q|\nabla\phi_t|^2+|\nabla(\Delta\phi)|^2\,dQ+\frac{n}{2}\int_Q\{|\nabla\phi_t|^2-|\nabla(\Delta\phi)|^2\}\,dQ\\&\quad-[(\phi_t,h\cdot\nabla(\Delta\phi))_\Omega]_0^T\end{aligned}\tag{2.22}$$

after using the boundary conditions (2.20c-d).

Step (ii). We estimate the second integral on the right of (2.22). We multiply (2.20a) by $\Delta\phi$ and obtain (Appendix B)

$$\int_Q\{|\nabla\phi_t|^2-|\nabla(\Delta\phi)|^2\}\,dQ=\left[\int_\Omega\nabla\phi\cdot\nabla\phi_t\,d\Omega\right]_0^T-\int_\Sigma\frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi\,d\Sigma\tag{2.23}$$

after using the boundary conditions (2.20c-d).

Step (iii). Thus, inserting (2.23) into (2.22) results in

$$\begin{aligned}&\int_\Sigma\frac{\partial(\Delta\phi)}{\partial\nu}\,h\cdot\nabla(\Delta\phi)\,d\Sigma+\frac{n}{2}\int_\Sigma\frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi\,d\Sigma-\frac{1}{2}\int_\Sigma|\nabla(\Delta\phi)|^2h\cdot\nu\,d\Sigma\\&=\int_0^T\left\{\int_\Omega|\nabla\phi_t|^2+|\nabla(\Delta\phi)|^2\,d\Omega\right\}dt+\beta_{0,T},\end{aligned}\tag{2.24}$$

where $\beta_{0,T}$ (boundary terms at $t=T$ and $t=0$) is

$$\beta_{0,T}=\frac{n}{2}\left[\int_\Omega\nabla\phi\cdot\nabla\phi_t\,d\Omega\right]_0^T-[(\phi_t,h\cdot\nabla(\Delta\phi))_\Omega]_0^T.\tag{2.25}$$

Step (iv). We now use the standard fact that with A the positive self-adjoint operator defined by (2.2), the operator

$$\mathscr{A}=\begin{vmatrix}0 & I\\ -A & 0\end{vmatrix},\qquad \mathscr{D}(\mathscr{A})=\mathscr{D}(A)\times\mathscr{D}(A^{1/2}),\tag{2.26}$$

which describes the dynamics of (2.20),

$$\frac{d}{dt}\begin{vmatrix}\phi\\ \phi_t\end{vmatrix}=\mathscr{A}\begin{vmatrix}\phi\\ \phi_t\end{vmatrix},\tag{2.27}$$

is the generator of an s.c. *unitary* group on the space $\mathscr{D}(A^{1/2})\times L^2(\Omega)$. Accordingly, A with domain $\mathscr{D}(A^{5/4})\times\mathscr{D}(A^{3/4})$ generates likewise an s.c. *unitary* group on the space

$$Z=\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})\tag{2.28}$$

so that from (2.27),

$$\begin{aligned}\left\|\begin{vmatrix}\phi(t)\\ \phi_t(t)\end{vmatrix}\right\|_Z^2&\equiv\|\phi(t)\|^2_{\mathscr{D}(A^{3/4})}+\|\phi_t(t)\|^2_{\mathscr{D}(A^{1/4})}\\&\equiv\|A^{3/4}\phi(t)\|_\Omega^2+\|A^{1/4}\phi_t(t)\|_\Omega^2\quad\text{(from (1.6))}\\&=\left\|e^{\mathscr{A}t}\begin{vmatrix}\phi^0\\ \phi^1\end{vmatrix}\right\|_Z^2\equiv\left\|\begin{vmatrix}\phi^0\\ \phi^1\end{vmatrix}\right\|_Z^2\\&=\|A^{3/4}\phi^0\|_\Omega^2+\|A^{1/4}\phi^1\|_\Omega^2,\qquad t\in R,\end{aligned}\tag{2.29}$$

the norm-preserving identity to be crucially exploited below. Identity (2.29) is also obtained by multiplying problem (2.20a-d), rewritten abstractly as $\phi_{tt}+A\phi=0$, by $A^{1/2}\phi_t$ and integrating over $L^2(Q)$.

Step (v). Crucial to the utilization of (2.29) in analyzing (2.24) is the following lemma.

LEMMA 2.3. (i) *With reference to the positive self-adjoint operator A in* (2.2), *we have*

$$\mathscr{D}(A^{3/4})=\left\{f\in H^3(\Omega): f|_\Gamma=\left.\frac{\partial f}{\partial \nu}\right|_\Gamma=0\right\}, \tag{2.30}$$

$$\mathscr{D}(A^{1/4})=\{f\in H^1(\Omega): f|_\Gamma=0\}=H_0^1(\Omega) \tag{2.31}$$

the identifications being set theoretically and topologically, with equivalent norms. In particular, we have the following:

(ii) *For* $f\in\mathscr{D}(A^{3/4})$, *the norms*

$$\|f\|_{\mathscr{D}(A^{3/4})}=\|A^{3/4}f\|_\Omega \quad \textit{and} \quad \left\{\int_\Omega |\nabla(\Delta f)|^2\,d\Omega\right\}^{1/2} \tag{2.32}$$

are equivalent.

(iii) *Similarly, for* $f\in\mathscr{D}(A^{1/4})$, *the norms*

$$\|f\|_{\mathscr{D}(A^{1/4})}=\|A^{1/4}f\|_\Omega \quad \textit{and} \quad \left\{\int_\Omega |\nabla f|^2\,d\Omega\right\}^{1/2} \tag{2.33}$$

are equivalent.

(iv) *Parts* (ii) *and* (iii) *apply in particular to the solution* ϕ *of problem* (2.20a-d) *or* (2.27), *for which we have that the norm*

$$\begin{aligned}\left\|\begin{matrix}\phi(t)\\ \phi_t(t)\end{matrix}\right\|_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} &\equiv\{\|A^{3/4}\phi(t)\|_\Omega^2+\|A^{1/4}\phi_t(t)\|_\Omega^2\}^{1/2}\\ &\equiv\{\|A^{3/4}\phi^0\|_\Omega^2+\|A^{1/4}\phi^1\|_\Omega^2\}^{1/2},\end{aligned} \tag{2.34}$$

which is time-invariant by (2.29), *and the norm*

$$\left\{\int_\Omega |\nabla(\Delta\phi)|^2\,d\Omega+\int_\Omega |\nabla\phi_t|^2\,d\Omega\right\}^{1/2}=\{\|\nabla(\Delta\phi)\|_\Omega^2+\|\nabla\phi_t\|_\Omega^2\}^{1/2} \tag{2.35}$$

are equivalent.

Proof of Lemma 2.3. See Appendix C for the proof. □

Remark 2.2. Multiplying problem (2.20a-d) by $\Delta\phi_t$ and applying Green's theorems yields, as usual,

$$\frac{1}{2}\frac{\partial}{\partial t}\left\{\int_\Omega |\nabla\phi_t|^2+|\nabla(\Delta\phi)|^2\,d\Omega\right\}=\int_\Gamma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi_t\,d\Gamma. \tag{2.36}$$

Thus, we cannot claim by (2.36) that the norm occurring naturally in the multiplier method leading to identity (2.24) is time-invariant, as the boundary term at the right of (2.36) not only cannot be claimed to vanish, but moreover presents a delicate issue as to its well-posedness. (In fact, from the initial data in (2.20b) we deduce only that

$$\phi(t)=C(t)\phi^0+S(t)\phi^1\in C([0,T];\mathscr{D}(A^{3/4})),$$

$$\phi_t(t)=C(t)\phi^1-AS(t)\phi^0\in C([0,T];\mathscr{D}(A^{1/4})),$$

so that the expression in the brackets { } in (2.36) is continuous in time.) On the other hand, the equivalent norm (2.34) is time-invariant. Thus, in analyzing the terms in identity (2.24) we shall always refer to the time-invariant norm (2.34).

Step (vi). We now analyze the term $\beta_{0,T}$ in (2.25) by referring to the norm (2.28) of Z for $\{\phi, \phi_t\}$, as mentioned in Remark 2.2. For the first term in (2.25) we have by the Schwarz inequality

$$\left|\left[\int_\Omega \nabla\phi\cdot\nabla\phi_t\,d\Omega\right]_0^T\right| \leqq |||\nabla\phi(T)|||_\Omega |||\nabla\phi_t(T)|||_\Omega + |||\nabla\phi^0|||_\Omega |||\nabla\phi^1|||_\Omega$$

$$\leqq \tfrac{1}{2}\{|||\nabla\phi(T)|||_\Omega^2 + |||\nabla\phi_t(T)|||_\Omega^2 + |||\nabla\phi^0|||_\Omega^2 + |||\nabla\phi^1|||_\Omega^2\}$$

(using the norm-equivalence (2.33))

$$\leqq \frac{C}{2}\{\|A^{1/4}\phi(T)\|_\Omega^2 + \|A^{1/4}\phi_t(T)\|_\Omega^2 + \|A^{1/4}\phi^0\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2\}$$

$$\leqq \frac{C}{2}\{\|A^{3/4}\phi(T)\|_\Omega^2 + \|A^{1/4}\phi_t(T)\|_\Omega^2 + \|A^{3/4}\phi^0\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2\}.$$

Thus

$$\left|\left[\int_\Omega \nabla\phi\cdot\nabla\phi_t\,d\Omega\right]_0^T\right| \leqq C\{\|A^{3/4}\phi^0\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2\} \quad \forall T\in R, \tag{2.37}$$

where in the last step we have used the time invariance (2.29). Similarly for the second term in (2.25) we obtain by using the Poincaré inequality:

$$\int_\Omega \psi^2\,d\Omega \leqq C_p^2\int_\Omega |\nabla\psi|^2\,d\Omega, \quad \psi\in H_0^1(\Omega), \quad C_p = \text{Poincaré constant}$$

on $\phi^1\in H_0^1(\Omega)$ and on ϕ_t (legitimate by $\phi_{t|\Sigma}=0$, in view of (2.20c)) and $2M_h = \max_{\bar\Omega}|h|$:

$$|[\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T| \leqq 2M_h\{\|\phi_t(T)\|_\Omega |||\nabla(\Delta\phi(T))|||_\Omega + \|\phi^1\|_\Omega |||\nabla(\Delta\phi^0)|||_\Omega\}$$

$$\leqq 2M_hC_p\{|||\nabla\phi_t(T)|||_\Omega |||\nabla(\Delta\phi(T))|||_\Omega + |||\nabla\phi^1|||\nabla(\Delta\phi^0)|||_\Omega\}$$

$$\leqq M_hC_p\{|||\nabla\phi_t(T)|||_\Omega^2 + |||\nabla(\Delta\phi(T))|||_\Omega^2 + |||\nabla\phi^1|||_\Omega^2 + |||\nabla(\Delta\phi^0)|||_\Omega^2\}$$

(using the norm-equivalence (2.32) and (2.33))

$$\leqq M_hCC_p\{\|A^{1/4}\phi_t(T)\|_\Omega^2 + \|A^{3/4}\phi(T)\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2 + \|A^{3/4}\phi^0\|_\Omega^2\}.$$

Thus by the time invariance (2.29) we obtain

$$|[(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T| \leqq 2M_hCC_p\{\|A^{1/4}\phi^1\|_\Omega^2 + \|A^{3/4}\phi^0\|_\Omega^2\} \quad \forall T\in R, \tag{2.38}$$

where C_p is the Poincaré constant. Thus from (2.25), (2.37), and (2.38), we conclude that for all $0<T<\infty$,

$$|\beta_{0,T}| \leqq \text{const}_{h,n}\{\|A^{3/4}\phi^0\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2\} = \text{const}_{h,n}\|\{\phi^0,\phi^1\}\|_Z^2, \tag{2.39}$$

with Z as in (2.28).

Remark 2.3. The present method of estimating $\beta_{0,T}$ leads to (2.39) with a *finite* constant in front of $\|\{\phi^0,\phi^1\}\|_Z^2$. This fact is responsible for obtaining, in Theorem 1.1, exact controllability only for T greater than a finite time $T_0>0$ (see (2.50)–(2.52) below).

In Lemma 4.3 of § 4, we shall instead estimate $\beta_{0,T}$ in a different way and obtain in (4.21) an *arbitrarily small constant* in front of $\|\{\phi^0, \phi^1\}\|_Z^2$, at the price, however, of introducing two new terms in the interior Q. Via an argument that ultimately rests on a uniqueness theorem, these two additional terms over Q will then be "absorbed" for an arbitrary $T>0$ into the desired boundary terms over Σ that occur when a second control g_2 is also active in (1.1d). This way, exact controllability on an arbitrarily short time is achieved in Theorem 1.3 and in Proposition 5.1, both cases having g_2 active in (1.1d). However, this latter result can be improved by using it, in a kind of bootstrap argument, in combination with Lemma 2.2 for T large, and with a regularity result. This will be done in § 5.2, which is based on a recent idea of [BLR1]. Here we finally obtain T arbitrarily small, also with $g_1 \in L^2(\Sigma)$ and $g_2 \equiv 0$, as in Theorem 1.4.

Step (vii). Returning to the left-hand side (LHS) of identity (2.24), we compute with $2C_h = \max_\Gamma |h|$ and for any $\varepsilon > 0$:

First term.

$$\left| \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h \cdot \nabla(\Delta\phi)\, d\Sigma \right| \leqq C_h \int_\Sigma \left\{ \frac{1}{\varepsilon} \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 + \varepsilon |\nabla(\Delta\phi)|^2 \right\} d\Sigma; \tag{2.40}$$

Second term.

$$\begin{aligned} \left| \frac{n}{2} \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} \Delta\phi\, d\Sigma \right| &\leqq \frac{n}{4} \int_\Sigma \left\{ \frac{1}{\varepsilon} \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 + \varepsilon |\Delta\phi|^2 \right\} d\Sigma \\ &= \frac{n}{4\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 d\Sigma + \frac{n\varepsilon}{4} \|\Delta\phi\|^2_{L^2(0,T;L^2(\Gamma))} \\ &\leqq \frac{n}{4\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 d\Sigma + n\varepsilon C \|\phi\|^2_{L^2(0,T;\mathscr{D}(A^{3/4}))}, \end{aligned} \tag{2.41}$$

where in the last step we have used trace theory followed by Lemma 2.3, (2.30) for ϕ (which satisfies (2.20c–d)).

$$\|\Delta\phi\|_\Gamma \leqq c \|\Delta\phi\|_{H^1(\Omega)} \leqq C \|\phi\|_{H^3(\Omega)} \leqq C \|\phi\|_{\mathscr{D}(A^{3/4})}; \tag{2.42}$$

Third term. Using assumption (1.8) on the radial vector field $h(x)$ we have

$$-\frac{1}{2} \int_\Sigma |\nabla(\Delta\phi)|^2 h \cdot \nu\, d\Sigma \leqq -\frac{\gamma}{2} \int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma. \tag{2.43}$$

Summing up (2.40), (2.41), and (2.43) we obtain

$$\begin{aligned} &\left(\frac{C_h}{\varepsilon} + \frac{n}{4\varepsilon} \right) \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 d\Sigma + \left(C_h\varepsilon - \frac{\gamma}{2} \right) \int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma \\ &\quad + n\varepsilon c \|\phi\|^2_{L^2(0,T;\mathscr{D}(A^{3/4}))} \geqq \text{LHS of (2.24)}. \end{aligned} \tag{2.44}$$

Now, choosing $\varepsilon > 0$ sufficiently small to make $(C_h\varepsilon - \gamma/2) < 0$, we drop the second integral in (2.44) and finally obtain

$$C_{1,nh\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu} \right)^2 d\Sigma + n\varepsilon c \int_0^T \|A^{3/4}\phi\|^2_\Omega\, dt \geqq \text{LHS of (2.24)}. \tag{2.45}$$

Step (viii). We now work on the right-hand side (RHS) of identity (2.24), where we use the equivalence of Lemma 2.3(iii) (and time-invariance (2.29)), along with the bound (2.39). We obtain

$$\begin{aligned} \text{RHS of (2.24)} &\geqq C_2 \int_0^T \|A^{3/4}\phi\|^2_\Omega + \|A^{1/4}\phi_t\|^2\, dt - C_{h,n} \|\{\phi^0, \phi^1\}\|^2_Z \\ &= C_2 T \|\{\phi^0, \phi^1\}\|^2_Z - C_{h,n} \|\{\phi^0, \phi^1\}\|^2_Z. \end{aligned} \tag{2.46}$$

Step (ix). Combining (2.45) and (2.46), we obtain, using again the time-invariance (2.29) and $Z = \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})$ as in (2.28),

$$C_{1,nh\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + n\varepsilon c \int_0^T \|A^{3/4}\phi\|_\Omega^2 + \|A^{1/4}\phi_t\|_\Omega^2 \, dt$$

$$\equiv C_{1,nh\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + Tn\varepsilon c \|\{\phi^0, \phi^1\}\|_Z^2 \geqq \text{LHS of (2.24)} \tag{2.47}$$

$$= \text{RHS of (2.24)} \geqq C_2 T \|\{\phi^0, \phi^1\}\|_Z^2 - C_{hn} \|\{\phi^0, \phi^1\}\|_Z^2.$$

From here we obtain

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \geqq T\frac{(C_2 - n\varepsilon c)}{C_{1,nh\varepsilon}} \|\{\phi^0, \phi^1\}\|_Z^2 - \frac{C_{hn}}{C_{1nh\varepsilon}} \|\{\phi^0, \phi^1\}\|_Z^2 \tag{2.48}$$

and selecting $\varepsilon > 0$ suitably small so that

$$C'_{\varepsilon nh} = \frac{C_2 - n\varepsilon c}{C_{1,h\varepsilon n}} > 0, \tag{2.49}$$

we finally arrive at

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \geqq C'_{\varepsilon,nh}(T - T_0) \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})} \tag{2.50}$$

with

$$T_0 = \frac{C_{hn}}{C_{1nh\varepsilon}} \frac{1}{C'_{\varepsilon nh}} = \frac{C_{hn}}{C_2 + n\varepsilon c} > 0, \tag{2.51}$$

which is precisely (2.19). Lemma 2.2 is proved. □

Lemmas 2.1 and 2.2 along with (2.5) and (2.6) prove Theorem 1.1. □

Remark 2.4. For future use (in the proof of Theorem 1.4 in § 5), we note that the argument above yields the following inequality, which is more precise than (2.48):

$$C_{1,nh\varepsilon} \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \geqq (C_2 - n\varepsilon c) T \|\{\phi^0, \phi^1\}\|_Z^2 - |\beta_{0,T}|,$$
$$Z = \mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4}). \tag{2.52}$$

3. Proof of Theorem 1.2. We parallel and complement the proof of Theorem 1.1.

Step 1. As mentioned in Remark 1.1, the operator $\mathscr{L}_{1T}$ in (2.3) is continuous, $H_0^1(0, T; L^2(\Gamma)) \to H_0^1(\Omega) \times H^{-1}(\Omega)$ (see Remark 3.1), and the exact controllability requirement is

$$\mathscr{L}_{1T} : H_0^1(0, T; L^2(\Gamma)) \xrightarrow{\text{ONTO}} H_0^1(\Omega) \times H^{-1}(\Omega) \equiv \mathscr{D}(A^{1/4}) \times [\mathscr{D}(A^{1/4})]'. \tag{3.1}$$

But the $H_0^1(0, T)$-norm is equivalent to the gradient-norm. Then the condition—equivalent to (3.1)—that the corresponding Hilbert space adjoint $\mathscr{L}_{1T}^*$ of $\mathscr{L}_{1T}$ have continuous inverse can now be expressed: There exists $C_T > 0$ such that

$$\left\| \frac{d}{dt} \left(\mathscr{L}_{1T}^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right) \right\|_{L^2(\Sigma)} \geqq C_T \|\{z_1, z_2\}\|_{\mathscr{D}(A^{1/4}) \times [\mathscr{D}(A^{1/4})]'}, \tag{3.2}$$

where now for $g_1 \in H_0^1(0, T; L^2(\Gamma))$ and $z = [z_1, z_2] \in \mathcal{D}(A^{1/4}) \times [\mathcal{D}(A^{1/4})]'$ we have

$$(\mathcal{L}_{1T} g_1, z)_{\mathcal{D}(A^{1/4}) \times [\mathcal{D}(A^{1/4})]'} = (g_1, \mathcal{L}_{1T}^* z)_{H_0^1(0,T;L^2(\Gamma))} = \left(\frac{d}{dt} g_1, \quad \frac{d}{dt} \mathcal{L}_{1T}^* z \right)_{L^2(\Sigma)}$$

$$= \left(g_1, -\frac{d^2}{dt^2} \mathcal{L}_{1T}^* z \right)_{L^2(\Sigma)} \tag{3.3}$$

since g_1 vanishes at $t = 0$ and $t = T$.

Step 2. An equivalent partial differential equation characterization of (3.2) is given by the following lemma.

LEMMA 3.1. *With reference to* $\mathcal{L}_{1T}^*$ *in* (3.3) *we have for* $z = [z_1, z_2] \in \mathcal{D}(A^{1/4}) \times [\mathcal{D}(A^{1/4})]'$:

(i)

$$(\mathcal{L}_{1T}^* z)(t) = G_1^*[C(t-T)A^{-1/2} z_2 + S(t-T)(-A^{1/2} z_1)] + K_1 t + K_2 \in H_0^1(0, T; L^2(\Gamma)), \tag{3.4}$$

$$K_1 = K_{1T} = \frac{G_1^*}{T} \{[C(T) - I]A^{-1/2} z_2 + S(T)A^{1/2} z_1\}, \tag{3.5a}$$

$$K_2 = K_{2T} = -G_1^*[C(T)A^{-1/2} z_2 + S(T)A^{1/2} z_1], \tag{3.5b}$$

$$\frac{d}{dt}(\mathcal{L}_{1T}^* z)(t) = -\frac{\partial(\Delta\phi(t))}{\partial\nu} + K_{1T}, \tag{3.6}$$

where $\phi(t) = \phi(t, \phi^0, \phi^1)$ *is the solution of the following homogeneous problem, backward in time*

$$\phi_{tt} + \Delta^2 \phi = 0, \tag{3.7a}$$

$$\phi|_{t=T} = \phi^0, \quad \phi_t|_{t=T} = \phi^1, \tag{3.7b}$$

$$\phi|_\Sigma \equiv 0, \tag{3.7c}$$

$$\left.\frac{\partial\phi}{\partial\nu}\right|_\Sigma \equiv 0, \tag{3.7d}$$

with

$$\phi^0 = A^{-1/2} z_1, \qquad \phi^1 = A^{-1/2} z_2 \tag{3.8}$$

explicitly given by

$$\phi(t) = C(t-T)\phi^0 + S(t-T)\phi^1. \tag{3.9}$$

(ii) *For any* $T > 0$, (3.2) (*which characterizes exact controllability of problem* (1.1a–d) *with* $g_1 \in H_0^1(0, T; L^2(\Gamma))$ *and* $g_2 \equiv 0$ *on the space* $\mathcal{D}(A^{1/4}) \times [\mathcal{D}(A^{1/4})]'$ *over the interval* $[0, T]$) *is equivalent to saying: There exists* $C_T' > 0$ *such that*

$$\int_\Sigma \left[-\frac{\partial(\Delta\phi)}{\partial\nu} + K_{1T} \right]^2 d\Sigma \geqq C_T' \|\{\phi^0, \phi^1\}\|^2_{\mathcal{D}(A^{3/4}) \times \mathcal{D}(A^{1/4})}, \tag{3.10}$$

$$K_{1T} = \frac{G_1^*}{T} \{[C(T) - I]\phi^1 + AS(T)\phi^0\} = \frac{1}{T} \frac{\partial}{\partial\nu} \Delta\{[C(T) - I]A^{-1}\phi^1 + S(T)\phi^0\}. \tag{3.11}$$

Proof of Lemma 3.1. (i) With $g \in H_0^1(0, T; L^2(\Gamma))$ we compute from (2.3) and (1.6) by proceeding as in the proof of Lemma 2.1:

$$(\mathscr{L}_{1T} g_1, z)_{\mathscr{D}(A^{1/4})\times[\mathscr{D}(A^{1/4})]'} = \left(\int_0^T S(T-t)G_1 g_1(t)\, dt, A^{3/2} z_1\right)_{L^2(\Omega)}$$

$$+\left(\int_0^T C(T-t)G_1 g_1(t)\, dt, A^{1/2} z_2\right)_{L^2(\Omega)} \tag{3.12}$$

$$= \int_0^T (g_1(t), G_1^*[S(T-t)A^{3/2} z_1 + C(T-t)A^{1/2} z_2])_{L^2(\Gamma)}\, dt.$$

By comparing (3.3) with (3.12), we conclude that

$$\frac{-d^2}{dt^2}(\mathscr{L}_{1T}^* z)(t) = G_1^*[C(t-T)A^{1/2} z_2 + S(t-T)(-A^{3/2} z_1)], \tag{3.13}$$

since $C(\cdot)$ is even and $S(\cdot)$ is odd. Integrating in t, we find

$$\frac{d}{dt}(\mathscr{L}_{1T}^* z)(t) = -G_1^*[S(t-T)A^{1/2} z_2 - A^{-1}C(t-T)(-A^{3/2} z_1)] + K_1, \tag{3.14}$$

$$(\mathscr{L}_{1T}^* z)(t) = G_1^*[A^{-1}S(t-T)(-A^{3/2} z_1) + A^{-1}C(t-T)A^{1/2} z_2] + K_1 t + K_2. \tag{3.15}$$

By imposing that $(\mathscr{L}_{1T}^* z)(t)$ vanishes at $t=0$ and $t=T$, so that $\mathscr{L}_{1T}^* z \in H_0^1(0, T; L^2(\Gamma))$, we readily identify the operators K_1 and K_2 as in (3.5a-b) and then (3.15) becomes (3.4). For the purposes of (3.2), we now rewrite (3.14) as

$$\frac{d}{dt}(\mathscr{L}_{1T}^* z)(t) = -G_1^* A[C(t-T)A^{-1/2} z_1 + S(t-T)A^{-1/2} z_2] + K_{1T}$$

$$= -\frac{\partial(\Delta\phi(t))}{\partial\nu} + K_{1T}, \tag{3.16}$$

where in the last step we have used (2.4) and (3.9), (3.8), and part (i) is proved.

(ii) We first note that by (3.8)

$$\|\{z_1 = A^{1/2}\phi^0, z_2 = A^{1/2}\phi^1\}\|^2_{\mathscr{D}(A^{1/4})\times[\mathscr{D}(A^{1/4})]'}$$

$$= \|\{A^{3/4}\phi^0, A^{1/4}\phi^1\}\|^2_{L^2(\Omega)\times L^2(\Omega)} \tag{3.17}$$

$$= \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}.$$

Moreover, by virtue of (3.8) and (2.4), then (3.5a) becomes (3.11). Then (3.2) becomes (3.10) as desired, by use of (3.6), (3.11), and (3.17). The proof of Lemma 3.1 is complete. □

Step 3. The next lemma provides a sufficient condition for the exact controllability of problem (1.1a-d) considered in the present section for T arbitrary.

LEMMA 3.2. *A sufficient condition for* (3.10) *to hold is that there exists a constant* $C_T' > 0$ *such that*

$$\int_\Sigma \left(\frac{\partial(\Delta\phi(t))}{\partial\nu}\right)^2 d\Sigma \geqq C_T' \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} + 2T\|K_{1T}\|^2_{L^2(\Gamma)}, \tag{3.18}$$

where the term K_{1T} *is given by* (3.11) *and satisfies*

$$2\int_\Sigma |K_{1T}|^2\, d\Sigma = 2T\|K_{1T}\|^2_{L^2(\Gamma)} \leqq f(T)\|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}, \tag{3.19}$$

$$f(T)=4\frac{\|G_1^*\|^2}{T}\max\{\|[C(T)-I]A^{-1/4}\|^2,\|A^{1/4}S(T)\|^2\} \tag{3.20a}$$

$$\leqq\frac{C_f}{T},\qquad T>0. \tag{3.20b}$$

Proof. From $(a+b)^2=a^2+b^2+2ab\geqq a^2+b^2-\varepsilon a^2-1/\varepsilon b^2$ we obtain $(a+b)^2\geqq\frac{1}{2}a^2-b^2$ by selecting $\varepsilon=\frac{1}{2}$. Thus,

$$\begin{aligned}\int_\Sigma\left[-\frac{\partial(\Delta\phi)}{\partial\nu}+K_{1T}\right]^2 d\Sigma&\geqq\frac{1}{2}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma-\int_\Sigma|K_{1T}|^2\,d\Sigma\\&=\frac{1}{2}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma-T\|K_{1T}\|^2_{L^2(\Gamma)}.\end{aligned} \tag{3.21}$$

Thus, recalling (3.17), we see from (3.21) that (3.18) implies (3.10) as desired. To show (3.19) we rewrite K_{1T} in (3.11) accordingly as

$$K_{1T}=\frac{G_1^*}{T}[(C(T)-I)A^{-1/4}A^{1/4}\phi^1+A^{1/4}S(T)A^{3/4}\phi^0]. \tag{3.22}$$

□

Step 4. We now show that, under assumption (1.8), the analysis of § 2 guarantees that the sufficient condition (3.18) is fulfilled for T sufficiently large. Indeed, Lemma 2.2 yields (2.19), which we rewrite here for convenience

$$\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma\geqq c(T-T_0)\|\{\phi^0,\phi^1\}\|_Z^2,\qquad Z\equiv\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4}), \tag{3.23}$$

with c, T_0 identified in (2.50), (2.51). Recalling (3.20a-b), we write for any $\delta>0$:

$$c(T-T_0)\geqq\frac{c}{1+\delta}(T-T_0)+\frac{C_f}{T}\geqq\frac{c}{1+\delta}(T-T_0)+f(T) \tag{3.24}$$

for T sufficiently large, in fact, $T>T_\delta$

$$T_\delta=\frac{T_0+\sqrt{T_0^2+4C_f(1+\delta)/c\delta}}{2}\downarrow\frac{T_0+\sqrt{T_0^2+4C_f/c}}{2}$$

as $\delta\uparrow\infty$. Thus, recalling (3.19),

$$\begin{aligned}c(T-T_0)\|\{\phi^0,\phi^1\}\|_Z^2&\geqq\left[\frac{c}{1+\delta}(T-T_0)+f(T)\right]\|\{\phi^0,\phi^1\}\|_Z^2\\&\geqq\frac{c}{1+\delta}(T-T_0)\|\{\phi^0,\phi^1\}\|_Z^2+2T\|K_{1T}\|^2_{L^2(\Gamma)}.\end{aligned} \tag{3.25}$$

Thus, (3.23) and (3.25) imply (3.18) as desired, for $T>T_\delta$. The proof of (i) of Theorem 1.2 is complete. □

We show part (ii) of Theorem 1.2 in the next corollary.

COROLLARY 3.3. (i) *For T sufficiently large,* (3.10) (*which characterizes exact controllability of problem* (1.1a-d) *with* $g_1\in H_0^1(0,T;L^2(\Gamma))$ *and* $g_2\equiv 0$ *on the space* $\mathscr{D}(A^{1/4})\times[\mathscr{D}(A^{1/4})]'$ *over* $[0,T]$) *and* (2.11) (*which characterizes exact controllability of problem* (1.1a-d) *with* $g_1\in L^2(\Sigma)$ *and* $g_2\equiv 0$ *on the space* $[\mathscr{D}(A^{1/4})]'\times[\mathscr{D}(A^{3/4})]'$ *over* $[0,T]$) *are equivalent conditions.*

(ii) *By interpolation* [LM1, pp. 64-66], *problem* (1.1a-d) *with controls*

$$g_1\in H_0^{1-\theta}(0,T;L^2(\Gamma)),\quad g_2\equiv 0,\quad 0\leqq\theta\leqq 1,\quad \theta\neq\tfrac{1}{2}, \tag{3.26}$$

$$g_1\in H_{00}^{1/2}(0,T;L^2(\Gamma)),\quad g_2\equiv 0,\quad \theta=\tfrac{1}{2} \tag{3.27}$$

is exactly controllable for T sufficiently large on the space

$$\mathscr{D}(A^{1/4-\theta/2})\times\mathscr{D}(A^{-1/4-\theta/2}), \tag{3.28}$$

where we are using the convention that

$$\mathscr{D}(A^{-\beta}), \qquad \beta\geqq 0 \text{ means } [\mathscr{D}(A^{\beta})]'. \tag{3.29}$$

Proof. (i) Step 4 above shows that (2.11) implies (3.18) for T sufficiently large, and hence (3.10) by Lemma 3.2. The converse follows from

$$2\int_\Sigma\left(\frac{\partial\Delta\phi}{\partial\nu}\right)^2 d\Sigma+2\int_\Sigma|K_{1T}|^2\,d\Sigma\geqq\int_\Sigma\left[-\frac{\partial\Delta\phi}{\partial\nu}+K_{1T}\right]^2 d\Sigma$$

by use of (3.19), (3.20a-b) with T sufficiently large.

(ii) We apply the interpolation Theorem [LM1, Thm. 5.1, p. 27] to the operator $\mathscr{L}_{1T}^{*-1}$ which, by part (i), is bounded between the space in (3.28) and the space in (3.26) at the endpoint values $\theta=0$ and $\theta=1$. Hence $\mathscr{L}_{1T}^{*-1}$ is continuous

$$[\mathscr{D}(A^{1/4})\times\mathscr{D}(A^{-1/4}),\ \mathscr{D}(A^{-1/4})\times\mathscr{D}(A^{-3/4})]_\theta\to[H_0^1(0,T;L^2(\Gamma)),L^2(\Sigma)]_\theta, \tag{3.30}$$

which means that $\mathscr{L}_{1T}$ is onto in the opposite direction. Then [LM1, pp. 64-66] gives (3.26)-(3.27). □

Remark 3.1. With reference to Remark 1.1, we show next that the space of exact controllability $H_0^1(\Omega)\times H^{-1}(\Omega)$ with controls $g_1\in H_0^1(0,T;L^2(\Gamma))$ and $g_2\equiv 0$ as in Theorem 1.2 does *not* coincide with the space of regularity of the solutions of the corresponding problem (1.1a-d). More precisely, we have that the map

$$g_1\to\begin{cases}w(t)-G_1g_1(t),\\ w_t(t)\end{cases} \tag{3.31}$$

for problem (1.1a-d) with $g_2\equiv 0$, $w^0=w^1=0$, is continuous $H_0^1(0,T;L^2(\Gamma))\to C([0,T];H_0^1(\Omega)\times H^{-1}(\Omega))$, while $G_1g_1(t)\in H_0^1(0,T;H^{1/2}(\Omega))$ by elliptic theory and $G_1g_1(T)=0$ so that $\{w(T),w_t(T)\}\in H_0^1(\Omega)\times H^{-1}(\Omega)$.

In fact, if we return to (2.3) we have, after an integration by parts in t, using standard properties of cosine/sine operators:

$$w(t)=[C(t-\tau)G_1g(\tau)]_0^t-\int_0^t C(t-\tau)G_1\dot g_1(\tau)\,d\tau,$$

$$w_t(t)=A\left\{[S(t-\tau)G_1g_1(t)]_0^t-\int_0^t S(t-\tau)G_1\dot g_1(\tau)\,d\tau\right\},\quad\text{i.e.,}$$

$$w(t)-G_1g(t)=-\int_0^t C(t-z)G_1\dot g_1(\tau)\,d\tau, \tag{3.32}$$

$$w_t(t)=A\int_0^t S(t-z)G_1\dot g_1(\tau)\,d\tau. \tag{3.33}$$

Since $\dot g_1\in L^2(\Sigma)$, the (optimal) regularity theory of Theorem 1.0 together with (2.3) gives that (see (1.7))

$$w_t(t)=A\int_0^t S(t-\tau)G_1\dot g_1(\tau)\,d\tau\in C([0,T];[\mathscr{D}(A^{1/4})]'=H^{-1}(\Omega)), \tag{3.34}$$

$$A\int_0^t C(t-\tau)G_1\dot g_1(\tau)\,d\tau\in C([0,T];[\mathscr{D}(A^{3/4})]'), \tag{3.35}$$

and hence (see (1.7))

$$w(t)-G_1g_1(t)=-A^{-1}A\int_0^t C(t-\tau)G_1\dot{g}_1(\tau)\,d\tau\in C([0,T];\mathcal{D}(A^{1/4})=H_0^1(\Omega)) \tag{3.36}$$

as desired.

4. Proof of Theorem 1.3. We parallel and complement the proof of Theorem 1.1.

Step 0. We introduce a second Green map G_2 defined by

$$G_2g=y\leftrightarrow\begin{cases}\Delta^2y=0 & \text{in }\Omega, \quad (4.1a)\\ y|_\Gamma=0, & (4.1b)\\ \partial y/\partial\nu|_\Gamma=g, & (4.1c)\end{cases}$$

which is continuous $L^2(\Gamma)\to L^2(\Omega)$ (indeed, $L^2(\Gamma)\to H^{3/2}(\Omega)$ [LM1, Vol. I, pp. 188-189]). Then we define the operator $\mathcal{L}_{2T}$ by

$$\mathcal{L}_{2T}g_2=\begin{vmatrix} A\displaystyle\int_0^T S(T-t)G_2g_2(t)\,dt,\\ A\displaystyle\int_0^T C(T-t)G_2g_2(t)\,dt\end{vmatrix} \tag{4.2}$$

(in the notation of (2.3)). The solution to problem (1.1a-d) with

$$g_1\in L^2(\Sigma),\qquad g_2\in L^2(0,T;H^{-1}(\Gamma)) \tag{4.3}$$

is likewise given by

$$\begin{vmatrix} w(T;\,t=0;\,w^0=0,\,w^1=0)\\ w_t(T,\,t=0;\,w^0=0,\,w^1=0)\end{vmatrix}=\mathcal{L}_{1T}g_1+\mathcal{L}_{2T}g_2. \tag{4.4}$$

The following lemma can be proved as the corresponding Lemma 2.0 by Green's second theorem, (4.1a-c), and (2.2). Therefore details are omitted.

LEMMA 4.0. *Let G_2^* be the continuous operator $L^2(\Omega)\to L^2(\Gamma)$, which is the adjoint of G_2: $(G_2g,v)_\Omega=(g,G_2^*v)_\Gamma$, $g\in L^2(\Gamma)$, $v\in L^2(Q)$. Then*

$$G_2^*Af=-\Delta f|_\Gamma,\qquad f\in\mathcal{D}(A). \tag{4.5}$$

Step 1. The (regularity) Theorem 1.0 gives a fortiori that the operator

$$\mathcal{L}_T=[\mathcal{L}_{1T},\mathcal{L}_{2T}] \tag{4.6}$$

is continuous $L^2(\Sigma)\times L^2(0,T;H^{-1}(\Gamma))\to X\equiv[\mathcal{D}(A^{1/4})]'\times[\mathcal{D}(A^{3/4})]'$, and thus exact controllability of problem (1.1a-d), (4.3) on the space X over $[0,T]$ is equivalent to the following. There is $C_T>0$ such that

$$\begin{aligned}\left\|\mathcal{L}_T^*\begin{vmatrix}z_1\\ z_2\end{vmatrix}\right\|^2_{L^2(\Sigma)\times L^2(0,T;H^{-1}(\Gamma))}&=\left\|\mathcal{L}_{1T}^*\begin{vmatrix}z_1\\ z_2\end{vmatrix}\right\|^2_{L^2(\Sigma)}+\left\|\mathcal{L}_{2T}^*\begin{vmatrix}z_1\\ z_2\end{vmatrix}\right\|^2_{L^2(0,T;H^{-1}(\Gamma))}\\ &\geqq C_T\|\{z_1,z_2\}\|^2_{[\mathcal{D}(A^{1/4})]'\times[\mathcal{D}(A^{3/4})]'}\end{aligned} \tag{4.7}$$

as it follows by using (4.6). In (4.7), $*$ denotes Hilbert space adjoint. Since $\mathcal{L}_{1T}^*$ is identified by (2.8), (2.9a-d), we proceed to characterize $\mathcal{L}_{2T}^*$. The counterpart of Lemma 2.1 is Lemma 4.1.

LEMMA 4.1. (i) *For $z=\{z_1,z_2\}\in X\equiv[\mathcal{D}(A^{1/4})]'\times[\mathcal{D}(A^{3/4})]'$, we have*

$$\left(\mathcal{L}_{2T}^*\begin{vmatrix}z_1\\ z_2\end{vmatrix}\right)(t)=-\Lambda^2\Delta\phi(t,\phi^0,\phi^1)|_\Sigma\quad \text{on }\Sigma, \tag{4.8}$$

where $\phi(t, \phi^0, \phi^1)$ *solves problem* (2.9a–d), (2.10) *and where*

(4.9) Λ *is isomorphism* $H^s(\Gamma) \to H^{s-1}(\Gamma)$ *and self-adjoint on* $L^2(\Gamma)$

(*first-order tangential operator on* Γ *with smooth coefficients*). *Hence, if* ∇_σ *denotes the tangential gradient, we have*

$$\text{(4.10a)} \qquad \left\| \mathscr{L}_{2T}^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right\|^2_{L^2(0,T;H^{-1}(\Gamma))} = \|\Lambda \Delta \phi(\cdot, \phi^0, \phi^1)\|^2_{L^2(\Sigma)}$$

$$\text{(4.10b)} \qquad = \|\|\nabla_\sigma(\Delta\phi)\|\|^2_{L^2(\Sigma)} + \|\Delta\phi\|^2_{L^2(\Sigma)}.$$

(ii) *For any* $0 < T < \infty$, (4.7) *is equivalent to saying*: *There is* $C'_T > 0$ *such that*

$$\text{(4.11)} \qquad \begin{aligned} &\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_\Sigma |\nabla_\sigma(\Delta\phi)|^2 \, d\Sigma + \int_\Sigma |\Delta\phi|^2 \, d\Sigma \\ &\quad = \int_\Sigma |\nabla(\Delta\phi)|^2 \, d\Sigma + \int_\Sigma |\Delta\phi|^2 \, d\Sigma \geqq C'_T \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4}) \times \mathscr{D}(A^{1/4})}. \end{aligned}$$

Proof. (i) By definition of $\mathscr{L}_{2T}^*$ and Λ we have

$$\text{(4.12)} \qquad \begin{aligned} (\mathscr{L}_{2T} g_2, z)_X &= (g_2, \mathscr{L}_{2T}^* z)_{L^2(0,T;H^{-1}(\Gamma))} \\ &= (\Lambda^{-1} g_2, \Lambda^{-1} \mathscr{L}_{2T}^* z)_{L^2(\Sigma)} \\ &= (g_2, \Lambda^{-2} \mathscr{L}_{2T}^* z)_{L^2(\Sigma)}. \end{aligned}$$

On the other hand, starting from (4.2) we compute as usual:

$$\text{(4.13)} \qquad \left(\mathscr{L}_{2T} g_2, \begin{vmatrix} z_1 \\ z_2 \end{vmatrix}\right)_X = \int_0^T (g_2(t), G_2^*[C(T-t)A^{-1/2} z_2 + S(T-t)A^{1/2} z_1])_\Gamma \, dt,$$

and hence, using (4.12) and (4.13), since $C(\cdot)$ is even and $S(\cdot)$ is odd we obtain

$$\text{(4.14)} \qquad \Lambda^{-2} \mathscr{L}_{2T}^* z = G_2^* A[C(t-T)A^{-3/2} z_2 - S(t-T)A^{-1/2} z_1] = G_2^* A \phi(t, \phi^0, \phi^1)$$

with $\phi(t, \phi^0, \phi^1)$ solution of (2.9a–d), (2.10). Thus, (4.14) leads to (4.8), as desired, by virtue of (4.5). Moreover, since by (4.9) we have

$$\text{(4.15)} \qquad \|f\|_{H^{-1}(\Gamma)} = \|\Lambda^{-1} f\|_{L^2(\Gamma)},$$

then (4.15) applied to (4.8) yields (4.10a). To obtain (4.10b) we first note that by (4.9) we have

$$\text{(4.16)} \qquad \|\Lambda\psi\|^2_{L^2(\Gamma)} = \|\psi\|^2_{H^1(\Gamma)} = \|\|\nabla_\sigma \psi\|\|^2_{L^2(\Gamma)} + \|\psi\|^2_{L^2(\Gamma)},$$

where ∇_σ denotes the tangential gradient. More specifically, at each point of Γ, with ν the unit outward normal and $\tau_1, \cdots, \tau_{n-1}$ on orthogonal systems of unit vectors on the tangent plane, we may write:

$$\text{(4.17a)} \qquad \nabla\psi = (\nabla\psi \cdot \nu)\nu + \sum_{i=1}^{n-1} (\nabla\psi \cdot \tau_i)\tau_i = \frac{\partial\psi}{\partial\nu}\nu + \nabla_\sigma \psi, \qquad \nabla_\sigma \psi = \sum_{i=1}^{n-1} \frac{\partial\psi}{\partial\tau_i} \tau_i,$$

$$\text{(4.17b)} \qquad \|\|\nabla\psi\|\|^2_{L^2(\Gamma)} = \left\|\frac{\partial\psi}{\partial\nu}\right\|^2_{L^2(\Gamma)} + \|\|\nabla_\sigma\psi\|\|^2_{L^2(\Gamma)}.$$

Then using (4.16) with $\psi = \Delta\phi$ in (4.10a) yields (4.10b).

(ii) We use (4.7) along with (2.8) and (4.10b), and (4.17b) with $\psi = \Delta\phi$; finally we use (2.18). This way (4.11) is obtained. □

Step 2. The key of the controllability problem in Theorem 1.3 is the following proposition.

PROPOSITION 4.2. *Inequality* (4.11) *holds true for any* $T>0$ *where, by time reversal in* (2.9a-d), (2.10), *we may take* ϕ *to be the solution of the homogeneous problem* (2.20a)-(2.20d).

Remark 4.1. The inequality opposite to (4.11), i.e.,

$$\int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma + \int_\Sigma |\Delta\phi|^2\, d\Sigma \leqq CT\|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{4.18}$$

is true for all $0<T<\infty$ (transposition on [L2]).

Proof of Proposition 4.2. We return to the fundamental identity (2.24) with $h(x)=x-x_0$, for some $x_0\in R^n$.

Step (i). Setting, as in (2.40), $2C_h=\max_\Gamma |h|$, we have for the LHS of (2.24):

$$\begin{aligned}\text{LHS of (2.24)} &\leqq C_h\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 + |\nabla(\Delta\phi)|^2\, d\Sigma \\ &\quad + \frac{n}{4}\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 + |\Delta\phi|^2\, d\Sigma + C_h\int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma \\ &\leqq \left(3C_h+\frac{n}{4}\right)\int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma + \frac{n}{4}\int_\Sigma |\Delta\phi|^2\, d\Sigma \quad \text{(by (4.17b))} \\ &= c_{n,h}\int_\Sigma |\nabla(\Delta\phi)|^2 + |\Delta\phi|^2\, d\Sigma.\end{aligned} \tag{4.19}$$

Step (ii). As to the RHS of (2.24), we invoke the norm-equivalence (2.32)-(2.33) and write

$$\begin{aligned}\text{RHS of (2.24)} &\geqq c\int_0^T \|A^{1/4}\phi_t\|^2_\Omega + \|A^{3/4}\phi\|^2_\Omega\, dt + \beta_{0,T} \\ &= cT\|\{\phi^0, \phi^1\}\|^2_Z + \beta_{0,T},\end{aligned} \tag{4.20}$$

where in the last step we have used the norm-preserving identity (2.29), and where $Z=\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})$ as in (2.28). Now, however, we estimate β_{0T} in a manner different from Step (vi) in the proof of Theorem 1.1 (see (2.39)).

LEMMA 4.3. *With reference to* (2.25) *we have for any* $\varepsilon>0$,

$$|\beta_{0,T}| \leqq \frac{C_{1h,n}}{\varepsilon}[\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))}] + 2CC_{2n}\varepsilon\|\{\phi^0, \phi^1\}\|^2_Z, \tag{4.21}$$

with Z *as in* (2.28), *where* C *is the constant of norm equivalence in* (2.32)-(2.33) *and*

$$C_{1h,n}=\max\left\{\frac{n}{2}, 2M_h\right\}, \quad C_{2n}=\max\left\{\frac{n}{2}, 1\right\}, \quad 2M_h=\max_{\bar\Omega}|h|.$$

Proof of Lemma 4.3. We estimate each term of (2.25) separately. By the Schwarz inequality and (2.32), (2.33), we obtain

$$\begin{aligned}\left|\left[\int_\Omega \nabla\phi\cdot\nabla\phi_t\, d\Omega\right]_0^T\right| &\leqq \|\|\nabla\phi(T)\|\|_\Omega\|\|\nabla\phi_t(T)\|\|_\Omega + \|\|\nabla\phi^0\|\|_\Omega\|\|\nabla\phi^1\|\|_\Omega \\ &\leqq \frac{1}{2}\left\{\frac{1}{\varepsilon}[\|\|\nabla\phi(T)\|\|^2_\Omega + \|\|\nabla\phi^0\|\|^2_\Omega] + \varepsilon[\|\|\nabla\phi_t(T)\|\|^2_\Omega + \|\|\nabla\phi^1\|\|^2_\Omega]\right\} \\ &\leqq \frac{1}{\varepsilon}\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))} + \frac{\varepsilon}{2}\{\|\|\nabla\phi_t(T)\|\|^2_\Omega + \|\|\nabla\phi^1\|\|^2_\Omega\}.\end{aligned} \tag{4.22}$$

Similarly with $2M_h \equiv \max_{\bar{\Omega}} |h|$:

$$[(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T \leqq 2M_h\{\|\phi_t(T)\|_\Omega |||\nabla(\Delta\phi(T))|||_\Omega + \|\phi^1\|_\Omega |||\nabla(\Delta\phi^0)|||_\Omega\}$$

$$\leqq M_h\left\{\frac{1}{\varepsilon}[\|\phi_t(T)\|_\Omega^2 + \|\phi^1\|_\Omega^2] + \varepsilon[|||\nabla(\Delta\phi(T))|||_\Omega^2 + |||\nabla(\Delta\phi^0)|||_\Omega^2]\right\} \tag{4.23}$$

$$\leqq \frac{2M_h}{\varepsilon}\|\phi_t\|^2_{C([0,T];L^2(\Omega))} + M_h\varepsilon[|||\nabla(\Delta\phi(T))|||_\Omega^2 + |||\nabla(\Delta\phi^0)|||_\Omega^2].$$

Hence, using (2.25), (4.22), and (4.23), we obtain

$$|\beta_{0,T}| \leqq \frac{C_{1h,n}}{\varepsilon}[|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))}]$$

$$+ C_{2n}\varepsilon[|||\nabla\phi_t(T)|||_\Omega^2 + |||\nabla(\Delta\phi(T))|||_\Omega^2 + |||\nabla\phi^1|||_\Omega^2 + |||\nabla(\Delta\phi^0)|||_\Omega^2]$$

(using the norm equivalence (2.32), (2.33))

$$\leqq (C_{1h,n}/\varepsilon)[|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))}]$$

$$+ CC_{2n}\varepsilon[\|A^{1/4}\phi_t(T)\|_\Omega^2 + \|A^{3/4}\phi(T)\|_\Omega^2 + \|A^{1/4}\phi^1\|_\Omega^2 + \|A^{3/4}\phi^0\|_\Omega^2] \tag{4.24}$$

from which the desired conclusion (4.21) follows by using the norm identity (2.29). □

Step (iii). Combining (4.20) with (4.21), we obtain

$$\text{RHS of (2.24)} \geqq (cT - 2CC_{2n}\varepsilon)\|\{\phi^0, \phi^1\}\|_Z^2$$

$$- \frac{C_{1h,n}}{\varepsilon}[|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} - \|\phi_t\|^2_{C([0,T];L^2(\Omega))}. \tag{4.25}$$

Moreover, combining (4.25) with (4.19) we arrive at

$$\frac{C_{1h,n}}{\varepsilon}[|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))}] + C_{n,h}\int_\Sigma \nabla|(\Delta\phi)|^2 + |\Delta\phi|^2\, d\Sigma$$

$$\geqq c\left(T - \frac{2CC_{2n}\varepsilon}{c}\right)\|\{\phi^0, \phi^1\}\|_Z^2. \tag{4.26}$$

To complete the proof of Proposition 4.2, we need the following lemma based on compactness arguments, of the type already used in Littman [L9], who invokes Hormander [H2], in Lions [L3], who uses a remark of P. L. Lions, and in [LT3] in the context of the wave equations. This lemma consists in "absorbing" the lower-order interior terms on the left of (4.26) by the boundary terms on the left of (4.26).

LEMMA 4.4. *Inequality* (4.26) *implies that for any* $T > 0$ *there exists* $C_T > 0$ *such that*

$$|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))} \leqq C_T\int_\Sigma |\nabla(\Delta\phi)|^2 + |\Delta\phi|^2\, d\Sigma \tag{4.27}$$

(*and indeed, we could replace* $\int_\Sigma |\nabla(\Delta\phi)|^2\, d\Sigma$ *with* $\int_\Sigma |\partial\Delta\phi/\partial\nu|^2\, d\Sigma$ *on the right of* (4.27); *see also Lemma* 5.4 *below*).

Proof of Lemma 4.4. The proof is by contradiction. Let there exist a sequence $\{\phi_n(t)\}$ of solutions to problem (2.20a–d) over $[0, T]$:

$$\phi_n'' + \Delta^2\phi_n = 0 \qquad \text{in } Q, \tag{4.28a}$$

$$\phi_n(0,\cdot) = \phi_n^0 \in \mathcal{D}(A^{3/4}), \quad \phi_n'(0,\cdot) = \phi_n^1 \in \mathcal{D}(A^{1/4}) \qquad \text{in } \Omega, \tag{4.28b}$$

$$\phi_n|_\Sigma \equiv 0 \qquad \text{in } \Sigma, \tag{4.28c}$$

$$\left.\frac{\partial\phi_n}{\partial\nu}\right|_\Sigma \equiv 0 \qquad \text{in } \Sigma \tag{4.28d}$$

$(d/dt = ')$, given explicitly by

$$\phi_n(t) = C(t)\phi_n^0 + S(t)\phi_n^1 \in C([0, T]; \mathcal{D}(A^{3/4})), \tag{4.29a}$$

$$\phi_n'(t) = -AS(t)\phi_n^0 + C(t)\phi_n^1 \in C([0, T]; \mathcal{D}(A^{1/4})) \tag{4.29b}$$

such that

$$|||\nabla \phi_n|||_{C([0,T];L^2(\Omega))} \equiv 1, \tag{4.30a}$$

$$\|\phi_n'\|_{C([0,T];L^2(\Omega))} \equiv 1, \tag{4.30b}$$

$$\int_\Sigma |\nabla(\Delta\phi_n)|^2 + |\Delta\phi_n|^2 \, d\Sigma \to 0 \quad \text{as } n \to \infty. \tag{4.30c}$$

By the preceding steps (i)-(iii), each solution $\phi_n(t)$ satisfies (4.26), and thus we have

$$\|\{\phi_n^0, \phi_n^1\}\|_{\mathcal{D}(A^{3/4})\times\mathcal{D}(A^{1/4})} \leqq \text{const} \quad \text{uniformly in } n. \tag{4.31}$$

Hence there is a subsequence, still subindexed by n, such that

$$\phi_n^0 \to \text{some function } \phi^0 \text{ in } \mathcal{D}(A^{3/4}) \quad \text{weakly}, \tag{4.32a}$$

$$\phi_n^1 \to \text{some function } \phi^1 \text{ in } \mathcal{D}(A^{1/4}) \quad \text{weakly}. \tag{4.32b}$$

We then consider the solution to problem (2.20a-d) with initial data found in (4.32a, b):

$$\tilde{\phi}(t) = C(t)\phi^0 + S(t)\phi^1 \in C([0, T]; \mathcal{D}(A^{3/4}) = V), \tag{4.33a}$$

$$\tilde{\phi}'(t) = -AS(t)\phi^0 + C(t)\phi^1 \in C([0, T]; \mathcal{D}(A^{1/4}) = H_0^1(\Omega)). \tag{4.33b}$$

Then (see details, e.g., in [LT3, § 2] in a similar situation corresponding to the wave equation), it follows that

$$\phi_n(t) \to \tilde{\phi}(t) \text{ in } L^\infty(0, T; \mathcal{D}(A^{3/4})) \quad \text{weak star}, \tag{4.34a}$$

$$\phi_n'(t) \to \tilde{\phi}'(t) \text{ in } L^\infty(0, T; \mathcal{D}(A^{1/4})) \quad \text{weak star}. \tag{4.34b}$$

Then (4.34a, b) implies that $\phi_n(t)$ and $\phi_n'(t)$ are uniformly bounded in $L^\infty(0, T; \mathcal{D}(A^{3/4}))$ and $L^\infty(0, T; \mathcal{D}(A^{1/4}))$, respectively. This fact, along with the compactness of $\mathcal{D}(A^{3/4}) \to \mathcal{D}(A^{1/4}) = H_0^1(\Omega)$ (see (2.31)) and of $\mathcal{D}(A^{1/4}) \to L^2(\Omega)$, implies that there is a subsequence, still subindexed by n, such that

$$\phi_n(t) \to \tilde{\phi}(t) \quad \text{strongly in } L^\infty(0, T; H_0^1(\Omega)), \tag{4.35a}$$

$$\phi_n'(t) \to \tilde{\phi}'(t) \quad \text{strongly in } L^\infty(0, T; L^2(\Omega)). \tag{4.35b}$$

A fortiori for (3.30a, b) and (3.35a, b), we obtain

$$\begin{aligned} 1 \equiv |||\nabla \phi_n|||_{C([0,T];L^2(\Omega))} &\to |||\nabla \tilde{\phi}|||_{C([0,T];L^2(\Omega))} = 1, \\ 1 \equiv \|\phi_n'\|_{C([0,T];L^2(\Omega))} &\to \|\tilde{\phi}'\|_{C([0,T];L^2(\Omega))} = 1. \end{aligned} \tag{4.36}$$

Moreover, a fortiori from (4.30c)

$$\left.\frac{\partial(\Delta\tilde{\phi})}{\partial\nu}\right|_\Sigma = 0 \quad \text{and} \quad \Delta\tilde{\phi}|_\Sigma = 0. \tag{4.37}$$

Thus $\tilde{\phi}(t)$ satisfies

$$\tilde{\phi}'' + \Delta^2\tilde{\phi} = 0, \tag{4.38a}$$

$$\tilde{\phi}|_\Sigma \equiv 0, \quad \left.\frac{\partial\tilde{\phi}}{\partial\nu}\right|_\Sigma \equiv 0 \qquad \text{from (4.33a)}, \tag{4.38b}$$

$$\left.\frac{\partial(\Delta\tilde{\phi})}{\partial\nu}\right|_\Sigma \equiv 0, \quad \Delta\tilde{\phi}|_\Sigma \equiv 0 \quad \text{from (4.37)} \tag{4.38c}$$

on $[0, T]$. Then, with $T>0$ arbitrarily small, Holmgren's classical uniqueness theorem of Remark 1.4 implies

$$\tilde{\phi} \equiv 0 \quad \text{in } Q \tag{4.39}$$

and this contradicts (4.36). The proof of Lemma 4.4 is complete. □

Step (iv). We use Lemma 4.4 in (4.26) and obtain for an arbitrary $T>0$ and with ε chosen sufficiently small:

$$C_{\varepsilon,n,T,h} \int_{\Sigma} |\nabla(\Delta\phi)|^2 + |\Delta\phi|^2 \, d\Sigma \geqq c\left[T - \frac{2CC_{2n}\varepsilon}{c}\right] \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{4.40}$$

and (4.40) proves (4.11) for $T>0$ arbitrarily small. The proof of Proposition 4.2 is now complete. □

Then Lemma 4.1, Proposition 4.2, and (4.7) prove Theorem 1.3. □

We conclude this section by providing, with minor extra effort, an extension of Theorem 1.3 to the case when g_2 acts only on a suitable portion of Γ, still with no geometrical conditions on Ω. To this end, given an arbitrary positive number $\gamma>0$ and an arbitrary fixed point $x^0 \in R^n$, we can always decompose Γ into two complementary parts:

$$\Gamma = \Gamma_+(x^0, \gamma) \cup \Gamma_-(x^0, \gamma), \tag{4.41}$$

$$\Gamma_+(x^0, \gamma) = \{x \in \Gamma : (x - x^0) \cdot \nu(x) \geqq \gamma > 0\}, \tag{4.42}$$

$$\Gamma_-(x^0, \gamma) = \{x \in \Gamma : (x - x^0) \cdot \nu(x) < \gamma\}. \tag{4.43}$$

Henceforth we shall drop the explicit dependence on γ and write more simply $\Gamma_+(x^0)$ and $\Gamma_-(x^0)$. In the next corollary we take g_2 to be active only on $\Gamma_-(x^0)$, assumed nonempty.

THEOREM 4.5. *The exact controllability result of Theorem* 1.3 *remains true for an arbitrary* $T>0$, *and still with no geometrical conditions on* Ω, *with respect to the boundary conditions* $w|_{\Sigma} = g_1 \in L^2(\Sigma)$ *as in Theorem* 1.3 *and*

$$\left.\frac{\partial w}{\partial \nu}\right|_{\Sigma} = \begin{cases} 0 \quad \text{on } (0, T)\times\Gamma_+(x^0) = \Sigma_+(x^0), \\ g_2 \in L^2(0, T; [H^1(\Gamma_-(x^0))]') \end{cases} \tag{4.44}$$

instead of $g_2 \in L^2(0, T: H^{-1}(\Gamma))$ *as in Theorem* 1.3, *with* $\Gamma_-(x^0)$ *nonempty.*

Proof. The proof is a minor variation of the proof of Theorem 1.3. Instead of the operator G_2 in (4.1a-c) we now define the operator $\tilde{G}_2$ by $\tilde{G}_2 g = y$, where y solves problem (4.1a, b) and

$$\left.\frac{\partial y}{\partial \nu}\right|_{\Gamma_+(x^0)} = 0, \qquad \left.\frac{\partial y}{\partial \nu}\right|_{\Gamma_-(x^0)} = g \tag{4.45}$$

instead of (4.1c). Accordingly, (4.5) of Lemma 4.0 now becomes

$$\tilde{G}_2^* A f = -\Delta f|_{\Gamma_-(x^0)}, \qquad f \in \mathscr{D}(A). \tag{4.46}$$

Hence, the counterpart of Lemma 4.1 is as follows. We obtain (4.8), this time restricted only on $\Sigma_-(x^0)$, however, and hence

$$\|\mathscr{L}_{2T}^* z\|^2_{L^2(0,T;[H^1(\Gamma_-(x^0))]')} = \|\|\nabla_\sigma(\Delta\phi)\|\|^2_{L^2(\Sigma_-(x^0))} + \|\Delta\phi\|^2_{L^2(\Sigma_-(x^0))} \tag{4.47}$$

[3] See footnote 2 on (1.8) (p. 331).

instead of (4.10b). Thus, for any $T>0$, the new condition, a counterpart of (4.11), characterizes exact controllability in the present case with control g_2 as in (4.44):

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_{\Sigma_-(x^0)} (|\nabla_\sigma(\Delta\phi)|^2 + |\Delta\phi|^2)\, d\Sigma_-(x^0) \geqq C_T' \|\{\phi^0, \phi^1\}\|_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}, \tag{4.48}$$

where ϕ solves problem (2.9a–d), (2.10) as before. To prove (4.48), we need only to refine slightly the proof of Theorem 1.3 at the level of analyzing the LHS of identity (2.24). We decompose $\nabla(\Delta\phi)$ into its normal and tangential component as in (4.17a, b) with $\psi = \Delta\phi$, so that we obtain

$$\begin{aligned}\text{LHS of (2.24)} = {} & \frac{1}{2}\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 h\cdot\nu\, d\Sigma + \frac{n}{2}\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi\, d\Sigma \\ & + \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla_\sigma(\Delta\phi)\, d\Sigma - \frac{1}{2}\int_\Sigma |\nabla_\sigma(\Delta\phi)|^2 h\cdot\nu\, d\Sigma,\end{aligned} \tag{4.49}$$

where $h(x) = (x - x^0)$.

Next, setting $2M_h^+ = \max|h|$ over $\Gamma_+(x^0)$ and recalling (4.42), we obtain

$$\begin{aligned}&\int_{\Sigma_+(x^0)} \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla_\sigma(\Delta\phi)\, d\Sigma_+(x^0) - \frac{1}{2}\int_{\Sigma_+(x^0)} |\nabla_\sigma(\Delta\phi)|^2 h\cdot\nu\, d\Sigma_+(x^0) \\ &\leqq \frac{(M_h^+)^2}{\varepsilon}\int_{\Sigma_+(x_0)} \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma_+(x^0) + \left(\varepsilon - \frac{\gamma}{2}\right)\int_{\Sigma_+(x^0)} |\nabla_\sigma(\Delta\phi)|^2\, d\Sigma_+(x^0) \\ &\leqq \frac{(M_h^+)^2}{\varepsilon}\int_{\Sigma_+(x^0)} \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma_+(x^0)\end{aligned} \tag{4.50}$$

after selecting $0<\varepsilon<\gamma/2$. Then, by (4.49) and (4.50), if we recall (2.41) we obtain

$$\begin{aligned}&C_{hn\varepsilon}\left\{\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_{\Sigma_-(x^0)} (|\nabla_\sigma(\Delta\phi)|^2 + |\Delta\phi|^2)\, d\Sigma_-(x^0)\right\} \\ &\quad + n\varepsilon_1 c_1 \int_0^T \|A^{3/4}\phi\|_\Omega^2\, dt \geqq \text{LHS of (2.24)},\end{aligned} \tag{4.51}$$

which is the counterpart of (2.45), or of (4.19). Combining (4.51) with (4.25) for the right-hand side of (2.24), yields for any $T>0$ and for any $\varepsilon_1>0$, $\varepsilon>0$

$$\begin{aligned}&C_{1h\varepsilon n}\{|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|_{C([0,T];L^2(\Omega))}\} \\ &\quad + C_{2hn}\left\{\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_{\Sigma_-(x^0)} (|\nabla_\sigma(\Delta\phi)|^2 + |\Delta\phi|^2)\, d\Sigma_-(x^0)\right\} \\ &\geqq [(c - n\varepsilon_1 c_1)T - 2cc_{2n}\varepsilon]\|\{\phi^0, \phi^1\}\|_Z^2,\end{aligned} \tag{4.52}$$

counterpart of (4.26). Next, the counterpart of Lemma 4.4 is that inequality (4.52) implies that for all $T>0$ there exists C_T such that

$$\begin{aligned}&|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))} \\ &\quad \leqq C_T\left\{\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_{\Sigma_-(x^0)} |\Delta\phi|^2\, d\Sigma_-(x^0)\right\}\end{aligned} \tag{4.53}$$

instead of (4.27). Indeed, the contradiction argument of Lemma 4.4 still works, since the corresponding uniqueness property—that $\tilde{\phi}$ in (4.33a, b) satisfies (4.38a, b) as well as

$$\frac{\partial(\Delta\tilde{\phi})}{\partial\nu}\bigg|_{\Sigma} \equiv 0, \qquad \Delta\tilde{\phi}|_{\Sigma_-(x^0)} \equiv 0 \tag{4.54}$$

on $[0, T]$, T arbitrary >0 (instead of (4.38c))—still implies that $\phi \equiv 0$ in Q, by the Holmgren Uniqueness Theorem as in [H2, Thm. 5.33, p. 129] (four homogeneous boundary conditions on a nonempty portion of the boundary are enough). Hence (4.52) and (4.54) imply

$$\begin{aligned} C'_{nh\varepsilon}\left\{\int_{\Sigma}\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \int_{\Sigma_-(x^0)} (|\nabla_\sigma(\Delta\phi)|^2 + |\Delta\phi|^2)\, d\Sigma_-(x^0)\right\} \\ \geqq [(C - n\varepsilon c_1)T - 2CC_{2n}\varepsilon]\|\{\phi^0, \phi^1\}\|_Z^2 \end{aligned} \tag{4.55}$$

for any $T>0$, and any $\varepsilon_1>0$, $\varepsilon>0$ (counterpart of (4.40)). Thus (4.48) is proved. The proof of Theorem 4.5 is complete. □

5. Theorem 1.4. Improvement of Theorem 1.1 to T arbitrarily small. The proof is divided into two steps, which will be treated separately in the following two subsections.

5.1. A preliminary result: exact controllability on the space $X \equiv [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$ with $g_1 \in L^2(\Sigma)$, $g_2 \in H^k(\Sigma)$, k an arbitrary nonnegative integer in arbitrarily short time and with geometrical conditions. A first preliminary result is the following proposition.

PROPOSITION 5.1. *Assume condition* (1.8) *on the domain* Ω. *Then for all* $T>0$, *given* $\{w^0, w^1\} \in X$ *there exist control functions* $g_1 \in L^2(\Sigma)$, $g_2 \in H^k(\Sigma)$, k *a preassigned fixed nonnegative integer, such that the corresponding solution of problem* (1.1) *satisfies*

$$w(T) = w_t(T) = 0, \qquad \{w(t), w_t(t)\} \in C([0, T]; X)$$

Proof of Proposition 5.1.

Step 1. We now return to the operator $\mathscr{L}_T$ defined by (4.6), (4.4), (2.3), and (4.2), and require that

$$\mathscr{L}_T : L^2(\Sigma) \times H^k(\Sigma) \quad \text{onto } X. \tag{5.0}$$

Equivalently, there exists C_T such that

$$\begin{aligned} \left\| \mathscr{L}_T^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right\|^2_{L^2(\Sigma)\times H^k(\Sigma)} &= \left\| \mathscr{L}_{1T}^* \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right\|^2_{L^2(\Sigma)} + \left\| \mathscr{L}_{2T}^{\#} \begin{vmatrix} z_1 \\ z_2 \end{vmatrix} \right\|^2_{H^k(\Sigma)} \\ &\geqq C_T \|\{z_1, z_2\}\|^2_{[\mathscr{D}(A^{1/4})]'\times[\mathscr{D}(A^{3/4})]'}, \end{aligned} \tag{5.1}$$

a counterpart of (4.7), where $\mathscr{L}_{1T}^*$ is identified by (2.8), (2.9a–d) and where $\mathscr{L}_{2T}^{\#}$ is defined by

$$\begin{aligned} (\mathscr{L}_{2T} g_2, z)_X &= (g_2, \mathscr{L}_{2T}^{\#} z)_{H^k(\Sigma)} = (\Lambda_k g_2, \Lambda_k \mathscr{L}_{2T}^{\#} z)_{L^2(\Sigma)} \\ &= (g_2, \Lambda_k^2 \mathscr{L}_{2T}^{\#} z)_{L^2(\Sigma)}, \end{aligned} \tag{5.2}$$

with

$$\Lambda_k : \text{isomorphism } H^k(\Sigma) \quad \text{onto } L^2(\Sigma) \text{ and self-adjoint on } L^2(\Sigma). \tag{5.3}$$

The counterpart of Lemma 4.1 is Lemma 5.2.

LEMMA 5.2. (i) *For* $z=[z_1, z_2]\in X\equiv[\mathscr{D}(A^{1/4})]'\times[\mathscr{D}(A^{3/4})]'$ *we have with reference to* (5.3)

$$(\mathscr{L}^{\#}_{2T}z)(t)=-\Lambda_k^{-2}\Delta\phi(t,\phi^0,\phi^1), \tag{5.4}$$

where $\phi(t,\phi^0,\phi^1)$ *solves problem* (2.9)-(2.10). *Moreover,*

$$\|\mathscr{L}^{\#}_{2T}z\|_{H^k(\Sigma)}=\|\Delta\phi(t,\phi^0,\phi^1)\|_{H^{-k}(\Sigma)}. \tag{5.5}$$

(ii) *For any* $0<T<\infty$, *inequality* (5.1), *which is equivalent to exact controllability in the present case, is in turn equivalent to saying: There is* $C'_T>0$ *such that*

$$\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\|\Delta\phi\|^2_{H^{-k}(\Sigma)}\geqq C'_T\|\{\phi^0,\phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}. \tag{5.6}$$

Proof. (i) Comparison between (5.2) and (4.13) now yields, by (4.5),

$$\Lambda_k^2\mathscr{L}^{\#}_{2T}z=G_2^*A[C(t-T)A^{-3/2}z_2-S(t-T)A^{-1/2}z_1]=-\Delta\phi(t,\phi^0,\phi^1), \tag{5.7}$$

a counterpart of (4.14). Thus, by (5.3) and (5.7),

$$\begin{aligned}\|\mathscr{L}^{\#}_{2T}z\|_{H^k(\Sigma)}&=\|\Lambda_k\mathscr{L}^{\#}_{2T}z\|_{L^2(\Sigma)}=\|\Lambda_k^{-1}\Delta\phi(t,\phi^0,\phi^1)\|_{L^2(\Sigma)}\\&=\|\Delta\phi(t,\phi^0,\phi^1)\|_{H^{-k}(\Sigma)}\end{aligned}$$

as desired.

(ii) Inequality (5.6) follows from (5.1) via (2.8), (2.9a-d), and (5.5). □

Step 2. The key of the present controllability problem is the following proposition, which is the counterpart of Proposition 4.2.

PROPOSITION 5.3. *Under assumption* (1.8), *inequality* (5.6) *holds true for any* $T>0$ *where, by time reversal in* (2.9a-d), (2.10), *we may take* ϕ *to be the solution of the homogeneous problem* (2.20a-d).

Proof of Proposition 5.3. We return to the fundamental identity (2.24) with $h(x)=x-x_0$, for some $x_0\in R^n$. As to the LHS of (2.24), we invoke Step (vii) in § 2, thus obtaining (2.45) under assumption (1.8). Hence the top of (2.47) holds true; we rewrite it here for convenience:

$$C_{1,nh\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+Tn\varepsilon C\|\{\phi^0,\phi^1\}\|^2_Z\geqq\text{LHS of (2.24)}. \tag{5.8}$$

As to the RHS of identity (2.24), we invoke instead Lemma 4.3, and hence (4.25), which we again rewrite here for convenience:

$$\begin{aligned}\text{RHS of (2.24)}\geqq{}&(cT-2CC_{2n}\varepsilon)\|\{\phi^0,\phi^1\}\|^2_Z\\&-\frac{-C_{1h,n}}{\varepsilon}[\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))}-\|\phi_t\|^2_{C([0,T];L^2(\Omega))}].\end{aligned} \tag{5.9}$$

Thus, combining (5.8) with (5.9), we obtain

$$\begin{aligned}&C_{1,nh\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\frac{C_{1hn}}{\varepsilon}[\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))}+\|\phi_t\|^2_{C([0,T];L^2(\Omega))}]\\&\quad\geqq[(c-n\varepsilon C)T-2CC_{2n}\varepsilon]\|\{\phi^0,\phi^1\}\|^2_Z.\end{aligned} \tag{5.10}$$

Then to complete the proof and obtain (5.6) we need the following lemma, which is a counterpart of Lemma 4.4.

LEMMA 5.4. *Inequality* (5.10) *implies that for any* $T>0$ *there exists* $C_T>0$ *such that*

$$\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))}+\|\phi_t\|^2_{C([0,T];L^2(\Omega))}\leqq C_T\left\{\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\|\Delta\phi\|^2_{H^{-k}(\Sigma)}\right\}. \tag{5.11}$$

Proof of Lemma 5.4. The proof is similar to that of Lemma 4.4 to which it reduces for $k=0$. By contradiction, let there exist a sequence $\{\phi_n(t)\}$ of solutions to problem (2.20a-d) = (4.28) over $[0, T]$, given by (4.29) such that

$$|||\nabla \phi_n|||_{C([0,T];L^2(\Omega))} \equiv 1, \tag{5.12a}$$

$$\|\phi_n'\|_{C([0,T];L^2(\Omega))} \equiv 1, \tag{5.12b}$$

$$\int_\Sigma \left(\frac{\partial(\Delta\phi_n)}{\partial\nu}\right)^2 d\Sigma + \|\Delta\phi_n\|^2_{H^{-k}(\Sigma)} \to 0, \qquad n\to\infty. \tag{5.12c}$$

Then, since each $\phi_n(t)$ satisfies inequality (5.10), we obtain (4.31); hence (4.34a, b), (4.35a, b), and (4.36). Moreover, with $\tilde{\phi}$ given by (4.33a, b) we again obtain (4.37) (this time by (5.12c)), and thus (4.38). Hence (4.39) follows and contradicts (4.36). Inequality (5.11) is thus proved. □

5.2. Completion of the proof of Theorem 1.4. We return to inequality (5.10), which is valid for all $T>0$. From here we see that, to obtain (2.11) for any $T>0$ (and hence the desired exact controllability claimed by Theorem 1.4), we need the following improvement of Lemma 5.4.

LEMMA 5.5. (i) *Inequality* (5.10) *implies that for any* $T>0$ *there is* $C_T>0$ *such that*

$$|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))} \leqq C_T \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma. \tag{5.13}$$

(ii) *Thus, under assumption* (1.8) *on* Ω, *for any* $T>0$ *there exists* $C_T>0$ *such that the following inequality holds true for the solution of problem* (2.9a, b), (2.10):

$$\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma \geqq C_T \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})} \tag{5.14}$$

(*improvement from T sufficiently large to T arbitrarily small over* (2.19) *of Lemma* 2.2).

Proof. From the argument of Lemma 5.4, it is clear that (5.13) is indeed achieved, provided the following uniqueness property holds true:

$$\begin{aligned} &\phi_{tt} + \Delta^2\phi \equiv 0, \qquad \phi|_\Sigma \equiv \partial\phi/\partial\nu|_\Sigma \equiv \partial(\Delta\phi)/\partial\nu|_\Sigma \equiv 0 \quad \text{on } [0, T], \\ &\qquad\qquad T>0 \text{ arbitrarily fixed implies } \phi\equiv 0 \quad \text{in } Q, \end{aligned} \tag{5.15}$$

which is needed to obtain the required contradiction. To establish (5.15), we use a recent argument of [Z1], adapted to the present situation, which rests on an idea from [BLR1]. The proof of (5.15) will hinge on the following three results, which have been already obtained.

Result 1. The same uniqueness property holds true as in (5.15), except that T is now greater than some finite $T_0>0$.

As we have seen, this result follows a fortiori from Lemma 2.2, (2.19), under the geometrical condition (1.8) for Ω, with T_0 as in (2.51).

Result 2. Inequality (5.6) is valid for any $T>0$ under assumption (1.8), as guaranteed by Proposition 5.3. (Note that (5.6) was obtained via Lemma 5.4, which we now seek to improve to the form expressed by (5.13).)

Result 3. For any $T>0$, we have

$$\left\|\frac{\partial(\Delta\phi)}{\partial\nu}\right\|^2_{L^2(\Sigma)} \leqq C_T \|\{\phi^0, \phi^1\}\|^2_{\mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4})}. \tag{5.16}$$

Inequality (5.16) follows by transposition on recent results in [L2].

With these three results at hand, and following an idea in [BLR1], we are now in a position to prove (5.15), and hence (5.13). We introduce the space

$$\mathscr{F} \equiv L^\infty(0, T; \mathscr{D}(A^{3/4})) \cap W^{1,\infty}(0, T; \mathscr{D}(A^{1/4})), \tag{5.17}$$

which contains the solutions $\{\phi(t)\}$ of the homogeneous problem (2.9) with data $\{\phi^0, \phi^1\} \in \mathcal{D}(A^{3/4}) \times \mathcal{D}(A^{1/4})$. Also, let

(5.18) $\mathcal{Y} \equiv$ space of all solutions in $\mathcal{F}$ of problem (2.9) that, moreover, satisfy the additional boundary condition $\partial(\Delta\phi)/\partial\nu|_\Sigma \equiv 0$.

The key point is to show that $\mathcal{Y}$ is finite-dimensional. (This is the idea discussed in [BLR1].) To this end, with $\mathcal{Y}$ closed in $\mathcal{F}$ by virtue of (5.16) (Result 3), we seek to establish that

$$B_{\mathcal{F}} \cap \mathcal{Y} \quad \text{is compact,} \tag{5.19}$$

where $B_{\mathcal{F}}$ is the closed unit ball in $\mathcal{F}$ centered at the origin.

Let $\phi \in B_{\mathcal{F}} \cap \mathcal{Y}$. Then we plainly have that ϕ_t satisfies

$$(\phi_t)_{tt} + \Delta^2(\phi_t) \equiv 0 \qquad \text{in } Q, \tag{5.20a}$$

$$\phi_t|_\Sigma \equiv \frac{\partial \phi_t}{\partial \nu}\bigg|_\Sigma \equiv \frac{\partial(\Delta\phi_t)}{\partial \nu} \equiv 0 \quad \text{in } \Sigma. \tag{5.20b}$$

In addition, interior regularity and trace theory imply that $\Delta\phi|_\Sigma \in H^{1/2}(\Sigma)$ and a fortiori

$$\Delta\phi_t \in H^{-1}(0, T; L^2(\Gamma)). \tag{5.21}$$

Next, we use Result 2, i.e., (5.6) of Proposition 5.3 as applied to ϕ_t (which is also a solution of problem (2.9a, b)). We obtain for T arbitrarily short as in (5.15):

$$\begin{aligned} \|\{(\phi_t)^0, (\phi_t)^1\}\|^2_{\mathcal{D}(A^{3/4})\times\mathcal{D}(A^{1/4})} &\leqq C'_T\left\{\int_\Sigma \left(\frac{\partial \Delta\phi_t}{\partial \nu}\right)^2 d\Sigma + \|\Delta\phi_t\|^2_{H^{-k}(\Sigma)}\right\} \\ &\leqq C'_T\|\Delta\phi_t\|_{H^{-1}(0,T;L^2(\Gamma))} \\ &\leqq C_T\|\{\phi^0, \phi^1\}\|_{\mathcal{D}(A^{3/4})\times\mathcal{D}(A^{1/4})}, \end{aligned} \tag{5.22}$$

where in the last step we have used the last boundary condition in (5.20b) as well as (5.21). Thus $\{(\phi_t)^0, (\phi_t)^1\} \in \mathcal{D}(A^{3/4}) \times \mathcal{D}(A^{1/4})$. From (5.22) we deduce (recalling (1.7)) that

$$\phi_t(t) = C(t)(\phi_t)^0 + S(t)(\phi_t)^1 \in C([0, T]; \mathcal{D}(A^{3/4}) \equiv V), \tag{5.23a}$$

$$\phi_{tt}(t) = -AS(t)(\phi_t)^0 + C(t)(\phi_t)^1 \in C([0, T]; \mathcal{D}(A^{1/4}) \equiv H_0^1(\Omega)), \tag{5.23b}$$

i.e.,

$$\phi_t \in \mathcal{F}. \tag{5.24}$$

From the equation satisfied by ϕ, we deduce via (5.23b)

$$\phi_{tt} = -\Delta^2\phi \in C([0, T]; \mathcal{D}(A^{1/4}) \equiv H_0^1(\Omega)). \tag{5.25}$$

Hence,

$$\phi \in C([0, T]; H^5(\Omega)). \tag{5.26}$$

Then (5.26) and (5.23a) prove the following: If $\phi \in B_{\mathcal{F}} \cap \mathcal{Y}$, then

$$\{\phi(t), \phi_t(t)\} \in C([0, T]; H^5(\Omega)) \times C([0, T]; V) \subset C([0, T]; V) \times C([0, T]; H_0^1(\Omega)),$$

where the containment has compact injection. Thus, $\mathcal{Y}$ is finite-dimensional. Then, as in [BLR1], the elements of $\mathcal{Y}$ are solutions of an equivalent finite-dimensional ordinary differential equation with constant coefficients. Since such solutions vanish for $T > T_0 > 0$ by Result 1, they also vanish for $T > 0$ arbitrarily small. Thus property (5.15) follows. □

6. Extension of the proof of § 2 to general vector fields. In this section, we provide the additional arguments—over those of § 2—required to prove Theorem 1.5 in the generality that involves a vector field satisfying conditions (1.21), (1.23) only, not just a radial vector field as in Theorem 1.1 (or a linear vector field as in Remark 1.2).

6.1. Extension of Lemma 2.2. The key point that remains to be established in Proposition 6.1.

PROPOSITION 6.1. *The conclusions of Lemma* 2.2 *with* $T > T_u$ *defined by* (1.24) *hold true for a domain* Ω *satisfying the vector field conditions* (1.21), (1.23) *as well as the uniqueness condition* (1.24).

Proof. Step (i). We return to (A8) and (A10) in Appendix A, where by imposing the boundary conditions (2.20c, d) we obtain the identity:

$$\begin{aligned}
&\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla(\Delta\phi)\,d\Sigma - \frac{1}{2}\int_\Sigma |\nabla(\Delta\phi)|^2 h\cdot\nu\,d\Sigma \\
&\quad = \int_Q H\nabla(\Delta\phi)\cdot\nabla(\Delta\phi)\,dQ + \int_Q H\nabla\phi_t\cdot\nabla\phi_t\,dQ \\
&\quad\quad + \frac{1}{2}\int_Q \{|\nabla\phi_t|^2 - |\nabla(\Delta\phi)|^2\}\,\mathrm{div}\,h\,dQ \\
&\quad\quad + \int_Q \phi_t\nabla(\mathrm{div}\,h)\cdot\nabla\phi_t\,dQ - [(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T,
\end{aligned} \tag{6.1}$$

counterpart of identity (2.22).

Step (ii). We use identity (B4) in Appendix B. Inserting (B4) in (6.1) yields the identity

$$\begin{aligned}
&\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla(\Delta\phi)\,d\Sigma + \frac{1}{2}\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi\,\mathrm{div}\,h\,d\Sigma - \frac{1}{2}\int_\Sigma |\nabla(\Delta\phi)|^2 h\cdot\nu\,d\Sigma \\
&\quad = \int_Q H\nabla(\Delta\phi)\cdot\nabla(\Delta\phi)\,dQ + \int_Q H\nabla\phi_t\cdot\nabla\phi_t\,dQ \\
&\quad\quad + \frac{1}{2}\int_Q \Delta\phi\,\nabla(\mathrm{div}\,h)\cdot\nabla(\Delta\phi)\,dQ + \frac{1}{2}\int_Q \phi_t\nabla(\mathrm{div}\,h)\cdot\nabla\phi_t\,dQ + \beta_{0,T,h},
\end{aligned} \tag{6.2}$$

where

$$\beta_{0,T,h} = \frac{1}{2}\left[\int_\Omega \nabla\phi\cdot\nabla(\phi_t\,\mathrm{div}\,h)\,d\Omega\right]_0^T - [(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T, \tag{6.3}$$

counterpart of (2.24)-(2.25). Equation (6.2) shows the presence of two new terms over (2.24). We shall now deal with them.

Step (iii). Let

$$4G_h \equiv \max_{\bar\Omega} |\nabla(\mathrm{div}\,h)|. \tag{6.4}$$

Then, for any $\varepsilon > 0$,

$$\begin{aligned}
\frac{1}{2}\int_Q \Delta\phi\,\nabla(\mathrm{div}\,h)\cdot\nabla(\Delta\phi)\,dQ &\geqq -2G_h\int_Q |\Delta\phi||\nabla(\Delta\phi)|\,dQ \\
&\geqq -\varepsilon G_h\int_Q |\nabla(\Delta\phi)|^2\,dQ - \frac{G_h}{\varepsilon}\int_Q |\Delta\phi|^2\,dQ.
\end{aligned} \tag{6.5}$$

Similarly,

$$\begin{aligned}\frac{1}{2}\int_Q \phi_t \nabla(\operatorname{div} h)\cdot\nabla\phi_t\,dQ &\geqq -2G_h\int_Q |\phi_t||\nabla\phi_t|\,dQ \\ &\geqq -\varepsilon G_h\int_Q |\nabla\phi_t|^2\,dQ - \frac{G_h}{\varepsilon}\int_Q \phi_t^2\,dQ.\end{aligned} \tag{6.6}$$

Therefore, if we return to (6.2), use (6.5)-(6.6), and recall assumption (1.23), we see that the RHS of (6.2) satisfies

$$\begin{aligned}\text{RHS of (6.2)} &\geqq (\rho-\varepsilon G_h)\int_Q |\nabla(\Delta\phi)|^2+|\nabla\phi_t|^2\,dQ \\ &\quad -\frac{G_h}{\varepsilon}\int_Q |\Delta\phi|^2+\phi_t^2\,dQ+\beta_{0,T,h} \\ &\geqq (\rho-\varepsilon G_h)C_1\int_0^T \|A^{3/4}\phi\|_\Omega^2+\|A^{1/4}\phi_t\|^2\,dt \\ &\quad -\frac{G_h}{\varepsilon}\int_Q |\Delta\phi|^2+\phi_t^2\,dQ+\beta_{0,T,h},\end{aligned} \tag{6.7}$$

where we have used the norm-equivalence (2.32)-(2.33) of Lemma 2.3(ii), (iii) with constant C_1 of equivalence.

Next, the very same proof as in Lemma 4.3, applied to (6.3) rather than to (2.25), produces for any $\varepsilon'>0$

$$|\beta_{0,T,h}| \leqq \frac{C_{1h}}{\varepsilon'}[|||\nabla\phi|||^2_{C([0,T];L^2(\Omega))}+\|\phi_t\|^2_{C([0,T];L^2(\Omega))}+\varepsilon' C_{2h}\|\{\phi^0,\phi^1\}\|_Z^2, \tag{6.8}$$

$$Z \equiv \mathscr{D}(A^{3/4})\times\mathscr{D}(A^{1/4}) \quad \text{as in (2.28)} \tag{6.9}$$

(counterpart of (4.21)). Combining now (6.8) with (6.7) and using the time invariance (2.29), we finally obtain via (6.9):

$$\begin{aligned}\text{RHS of (6.2)} &\geqq [(\rho-\varepsilon G_h)C_1 T-\varepsilon' C_{2h}]\|\{\phi^0,\phi^1\}\|_Z^2-\frac{G_h}{\varepsilon}\int_Q |\Delta\phi|^2+\phi_t^2\,dQ \\ &\quad -\frac{C_{1h}}{\varepsilon'}[|||\nabla\phi|||^2_{C([0,T];\,L^2(\Omega))}+\|\phi_t\|^2_{C([0,T];\,L^2(\Omega))}],\end{aligned} \tag{6.10}$$

counterpart of (2.46) or (4.25). Equation (6.10) shows the presence of new terms due to $G_h\neq 0$ over (2.46) or (4.25). How to deal with them represents the main additional difficulty over the proof of § 2.

Step (iv). For the LHS of (6.2) we recall (2.40)

$$\left|\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\,h\cdot\nabla(\Delta\phi)\,d\Sigma\right| \leqq \frac{C_h}{\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\varepsilon C_h\int_\Sigma |\nabla(\Delta\phi)|^2\,d\Sigma \tag{6.11}$$

and likewise

$$\begin{aligned}\left|\frac{1}{2}\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi\,\operatorname{div} h\,d\Sigma\right| &\leqq 2D_{h,b}\int_\Sigma\left|\frac{\partial(\Delta\phi)}{\partial\nu}\right||\Delta\phi|\,d\Sigma \\ &\leqq \frac{D_{h,b}}{\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\varepsilon D_{h,b}\int_\Sigma |\Delta\phi|^2\,d\Sigma\end{aligned} \tag{6.12}$$

with $D_{h,b} = \max_\Gamma |\operatorname{div} h|$, $b =$ boundary. Using (6.11)-(6.12) on the LHS of (6.2), we obtain

$$\left(\frac{C_h + D_{h,b}}{\varepsilon}\right) \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \varepsilon D_{h,b} \int_\Sigma |\Delta\phi|^2 \, d\Sigma \geqq \text{LHS of (6.2)}, \tag{6.13}$$

by selecting $\varepsilon > 0$ small enough that

$$\varepsilon C_h \int_\Sigma |\nabla(\Delta\phi)|^2 \, d\Sigma - \frac{1}{2} \int_\Sigma |\nabla(\Delta\phi)|^2 h \cdot \nu \, d\Sigma \leqq \left(\varepsilon C_h - \frac{\gamma}{2}\right) \int_\Sigma |\nabla(\Delta\phi)|^2 \, d\Sigma \leqq 0 \tag{6.14}$$

in view of assumption (1.21).

We now combine (6.13) with (6.10) and obtain

$$\begin{aligned} &\left(\frac{C_h + D_{h,b}}{\varepsilon}\right) \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \varepsilon D_{h,b} \int_\Sigma |\Delta\phi|^2 \, d\Sigma + \frac{G_h}{\varepsilon} \int_Q |\Delta\phi|^2 + \phi_t^2 \, dQ \\ &\qquad + \frac{C_{1h}}{\varepsilon'} [\|\|\nabla\phi\|\|^2_{C([0,T];\, L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];\, L^2(\Omega))}] \qquad (6.15) \\ &\geqq [(\rho C_1 - \varepsilon G_h C_1) T - \varepsilon' C_{2h}] \|\{\phi^0, \phi^1\}\|^2_Z, \end{aligned}$$

counterpart of (2.48).

Step (v). Since $\phi(t) \in \mathcal{D}(A^{3/4}) \subset \mathcal{D}(A^{1/4})$ (see Remark 2.2) and $\phi(t)$ satisfies the boundary conditions (2.20c, d), Green's second theorem yields

$$\|A^{1/2}\phi\|^2_\Omega = (A\phi, \phi)_\Omega = (\Delta(\Delta\phi), \phi)_\Omega = (\Delta\phi, \Delta\phi)_\Omega = \int_\Omega |\Delta\phi|^2 \, d\Omega. \tag{6.16}$$

Thus, recalling the norm-equivalence (2.33), and using (6.16), we obtain

$$\int_\Omega |\nabla\phi|^2 \, d\Omega \leqq c\|A^{-1/4}\phi\|^2_\Omega \leqq c\|A^{-1/4}\|^2 \|A^{1/2}\phi\|^2_\Omega = C \int_\Omega |\Delta\phi|^2 \, d\Omega = C\|\Delta\phi\|^2_\Omega \tag{6.17}$$

so that

$$\|\|\nabla\phi\|\|^2_{C([0,T];L^2(\Omega))} \leqq C\|\Delta\phi\|^2_{C([0,T];L^2(\Omega))}. \tag{6.18}$$

Moreover,

$$\int_Q |\Delta\phi|^2 + \phi_t^2 \, dQ \leqq T\{\|\Delta\phi\|^2_{C([0,T];L^2(\Omega))} + \|\phi_t\|^2_{C([0,T];L^2(\Omega))}\}. \tag{6.19}$$

Using (6.18)-(6.19) in (6.15) yields

$$\begin{aligned} &\left(\frac{C_h + D_{h,b}}{\varepsilon}\right) \int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma + \varepsilon D_{h,b} \int_\Sigma |\Delta\phi|^2 \, d\Sigma \\ &\qquad + \left(\frac{G_h T}{\varepsilon} + \frac{CC_{1h}}{\varepsilon'}\right) \|\Delta\phi\|^2_{C([0,T];L^2(\Omega))} + \left(\frac{G_h T}{\varepsilon} + \frac{C_{1h}}{\varepsilon'}\right) \|\phi_t\|^2_{C([0,T];L^2(\Omega))} \qquad (6.20) \\ &\geqq [(\rho C_1 - \varepsilon G_h C_1) T - \varepsilon' C_{2h}] \|\{\phi^0, \phi^1\}\|^2_Z. \end{aligned}$$

Thus we are in a situation similar (but not identical) to the one we encountered in (4.26) in the proof of Proposition 4.2. We then need a lemma, the counterpart of Lemma 4.4, that will allow us to "absorb" the interior terms on Q on the left of (6.20)

by the boundary terms on Σ on the left of (6.20). This is indeed provided by the following step.

Step (vi). We proceed to Lemma 6.2.

LEMMA 6.2. *Inequality* (6.20) *for problem* (2.20a-d) *implies that, for any* $T>0$, *there exists a constant* $C_T>0$ *such that*

$$\|\Delta\phi\|^2_{C([0,T];L^2(\Omega))}+\|\phi_t\|^2_{C([0,T];L^2(\Omega))}\leqq C_T\left\{\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\int_\Sigma|\Delta\phi|^2\,d\Sigma\right\}. \tag{6.21}$$

Proof of Lemma 6.2. The proof is similar to that of Lemma 4.4. Thus only the relevant differences from the latter proof will be noted here. Suppose that there exists a sequence $\{\phi_n(t)\}$ of solution to problem (2.20) over $[0, T]$, as in (4.28a-d), (4.29a, b) such that

$$\|\Delta\phi_n\|_{C([0,T];L^2(\Omega))}\equiv 1, \tag{6.22a}$$

$$\|\phi_n'\|_{C([0,T];L^2(\Omega))}\equiv 1, \tag{6.22b}$$

$$\int_\Sigma\left(\frac{\partial(\Delta\phi_n)}{\partial\nu}\right)^2+|\Delta\phi_n|^2\,d\Sigma\to 0 \quad \text{as } n\to\infty. \tag{6.22c}$$

Then the same argument as in Lemma 4.4 from (4.31)-(4.34a, b) applies, and we have

$$\begin{aligned}&\phi_n(t)\to\tilde\phi(t) \quad \text{in } L^\infty(0,T;\mathscr{D}(A^{3/4})) \quad \text{weak star},\\ &\phi_n'(t)\to\tilde\phi'(t) \quad \text{in } L^\infty(0,T;\mathscr{D}(A^{1/4})) \quad \text{weak star},\end{aligned} \tag{6.23}$$

and thus $\phi_n(t)$ and $\phi_n'(t)$ are uniformly bounded in $L^\infty(0, T; \mathscr{D}(A^{3/4}))$ and $L^\infty(0, T; \mathscr{D}(A^{1/4}))$. We now use the compactness of the injections $\mathscr{D}(A^{3/4})\to\mathscr{D}(A^{1/2})$ and $\mathscr{D}(A^{1/4})\to L^2(\Omega)$ and recall (6.16) (while in the proof of Lemma 4.4 we used the compactness of the injection $\mathscr{D}(A^{3/4})\to\mathscr{D}(A^{1/4})=H_0^1(\Omega)$). As a consequence there is a subsequence, still subindexed by n, such that

$$\begin{aligned}&\phi_n(t)\to\tilde\phi(t) \quad \text{strongly in } L^\infty(0,T;\mathscr{D}(A^{1/2})),\\ &\phi_n'(t)\to\tilde\phi'(t) \quad \text{strongly in } L^\infty(0,T;L^2(\Omega))\end{aligned} \tag{6.24}$$

(counterpart of (4.35)). A fortiori, from (6.22), (6.24), and (6.16), we obtain for the sequence $\{\phi_n\}$ of solutions of (2.20a-d):

$$1\equiv\|\Delta\phi_n\|_{C([0,T];L^2(\Omega))}\to\|\Delta\tilde\phi\|_{C([0,T];L^2(\Omega))}=1, \tag{6.25}$$

$$1\equiv\|\phi_n'\|_{C([0,T];L^2(\Omega))}\to\|\tilde\phi'\|_{C([0,T];L^2(\Omega))}=1, \tag{6.26}$$

as well as (from (6.22c))

$$\left.\frac{\partial(\Delta\tilde\phi)}{\partial\nu}\right|_\Sigma\equiv 0 \quad \text{and} \quad \Delta\tilde\phi|_\Sigma\equiv 0. \tag{6.27}$$

Thus, $\tilde\phi(t)$ satisfies

$$\begin{aligned}&\tilde\phi_{tt}+\Delta^2\tilde\phi=0\\ &\tilde\phi|_\Sigma\equiv 0, \quad \left.\frac{\partial\tilde\phi}{\partial\nu}\right|_\Sigma\equiv 0 \qquad \text{from (4.33a) written for } \phi_n,\\ &\left.\frac{\partial(\Delta\tilde\phi)}{\partial\nu}\right|_\Sigma\equiv 0, \quad \Delta\tilde\phi|_\Sigma\equiv 0 \quad \text{from (6.27)}\end{aligned} \tag{6.28}$$

on $[0, T]$. Then, for any $T>0$ arbitrarily small, Holmgren's classical uniqueness theorem of Remark 1.4 implies

$$\tilde\phi\equiv 0 \quad \text{in } Q \tag{6.29}$$

and this contradicts (6.25)-(6.26). The proof of Lemma 6.2 is complete. □

As an immediate corollary of Lemma 6.2 and (6.20) we obtain Corollary 6.3.

COROLLARY 6.3. *For any $T>0$, we have*

$$C_{h,T,\varepsilon,\varepsilon'}\left\{\int_\Sigma \left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2+|\Delta\phi|^2\,d\Sigma\right\}\geqq[(\rho C_1-\varepsilon G_h C_1)T-\varepsilon' C_{2h}]\|\{\phi^0,\phi^1\}\|_Z^2. \tag{6.30}$$

Step (vii). We next "absorb" $\int_\Sigma(\Delta\phi)^2\,d\Sigma$ by $\int_\Sigma(\partial(\Delta\phi)/\partial\nu)^2\,d\Sigma$ by using assumption (1.24).

LEMMA 6.4. *Under the uniqueness property* (1.24), *inequality* (6.30) *implies that for any $T>T_u$, T_u as in* (1.24), *there is a constant $C_T>0$ such that*

$$\int_\Sigma|\Delta\phi|^2\,d\Sigma\leqq C_T\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma. \tag{6.31}$$

Proof. Suppose by contradiction that there is a sequence $\{\phi_n(t)\}$ of solutions to problem (2.20a–d), as in (4.28a–d), (4.29a, b), such that

$$\int_\Sigma|\Delta\phi_n|^2\,d\Sigma\equiv 1, \tag{6.32a}$$

$$\int_\Sigma\left(\frac{\partial(\Delta\phi_n)}{\partial\nu}\right)^2 d\Sigma\to 0. \tag{6.32b}$$

Then, by the preceding analysis, each solution $\phi_n(t)$ satisfies (6.30) and thus the uniform bound as in (4.31) holds true. The same argument as in (4.31)–(4.34) applies, so that from (4.34a) coupled with $\mathcal{D}(A^{3/4})=V$, V as in (1.4), we deduce that

$$\{A^{1/2}\phi_n\}\text{ is uniformly bounded in }L^\infty(0,T;\mathcal{D}(A^{1/4})). \tag{6.33}$$

Hence, by (2.32) and (2.33), we also have that

$$\{\Delta\phi_n\}\text{ is uniformly bounded in }L^\infty(0,T;\mathcal{D}(A^{1/4})). \tag{6.34}$$

By (2.32) and (4.29) we actually have $|\nabla(\Delta\phi_n)|\in C([0,T];L^2(\Omega))$ and $\Delta\phi_n\in C([0,T];L^2(\Omega))$. Thus, $\Delta\phi_n\in C([0,T];H^1(\Omega))$. By standard trace theory we deduce

$$\{\Delta\phi_n|_\Gamma\}\text{ uniformly bounded in }C([0,T];H^{1/2}(\Gamma)), \tag{6.35}$$

and thus

$$\{\Delta\phi_n|_\Gamma\}\text{ lies in a compact set of }C([0,T];L^2(\Gamma)). \tag{6.36}$$

Hence, recalling (4.34a, b) we obtain

$$\Delta\phi_n|_\Sigma\to\Delta\tilde{\phi}|_\Sigma\quad\text{in }L^2(0,T;L^2(\Gamma))\quad\text{strongly}. \tag{6.37}$$

Invoking (6.32a), we then conclude that

$$\int_\Sigma|\Delta\tilde{\phi}|^2\,d\Sigma=1. \tag{6.38}$$

On the other hand, (6.32b) implies

$$\left.\frac{\partial(\Delta\tilde{\phi})}{\partial\nu}\right|_{\Sigma} \equiv 0. \tag{6.39}$$

Thus $\tilde{\phi}$ satisfies

$$\begin{aligned} &\tilde{\phi}_{tt} + \Delta^2\tilde{\phi} \equiv 0 \\ &\tilde{\phi}|_{\Sigma} \equiv 0 \qquad \text{from (4.33)}, \\ &\left.\frac{\partial\tilde{\phi}}{\partial\nu}\right|_{\Sigma} \equiv 0, \\ &\left.\frac{\partial(\Delta\tilde{\phi})}{\partial\nu}\right|_{\Sigma} \equiv 0 \qquad \text{from (6.33)} \end{aligned} \tag{6.40}$$

for $0 \leqq t \leqq T_u < T$. The uniqueness property (1.24), which we have assumed, then implies that $\tilde{\phi} \equiv 0$ in Q, a contradiction to (6.38). The proof of Proposition 6.1 is complete. □

Remark 6.1. A (much simpler) modification of the arguments above leads to the sought-after exact controllability on X of problem (1.1a-d), (1.2) under different assumptions, whereby the undesirable assumption (1.24) on uniqueness is eliminated and replaced with another assumption on the vector field h, stating qualitatively that the constant G_h in (6.4) is small with respect to the constant ρ in (1.23).

To state this new result, we first introduce some constants:

$$\begin{aligned} &4G_h \equiv \max_{\bar{\Omega}} |\nabla(\operatorname{div} h)| \quad \text{from (6.4)} \\ &\cdot \int_{\Omega} \psi^2\, d\psi \leqq C_p \int_{\Omega} |\nabla\psi|^2\, d\Omega, \quad \psi \in H_0^1(\Omega), \quad C_p = \text{Poincaré constant} \end{aligned} \tag{6.41}$$

and according to the norm-equivalences (2.32), (2.33),

$$c\|A^{3/4}f\|_{\Omega}^2 \leqq \int_{\Omega} |\nabla(\Delta f)|^2\, d\Omega \leqq C\|A^{3/4}f\|_{\Omega}^2, \tag{6.42}$$

$$k\|A^{1/4}f\|_{\Omega}^2 \leqq \int_{\Omega} |\nabla f|^2\, d\Omega \leqq K\|A^{1/4}f\|_{\Omega}^2; \tag{6.43}$$

finally

$$C_m = \max\{\|A^{-1/4}\|, KC_p\}. \tag{6.44}$$

We can now state the following variation of Theorem 1.5, which extends Theorem 1.1 to the case where $G_h \neq 0$ (see [T1] for a similar result for the wave equation with Dirichlet boundary control).

THEOREM 6.2. *The conclusion of Theorem* 1.1 *holds true for problem* (1.1a-d)-(1.2), *with T sufficiently large as in* (6.51) *below, provided* Ω *satisfies the following geometrical conditions. There exists a vector field* $h(x) = [h_1(x), \cdots, h_n(x)] \in C^2(\bar{\Omega})$ *such that*

(i) $h \cdot \nu \geqq$ *constant* $\gamma > 0$ *on* Γ (*assumption* (1.21));

(ii) $\int_{\Omega} H(x)v(x) \cdot v(x)\, d\Omega \geqq \rho \int_{\Omega} |v(x)|_{R^n}^2\, d\Omega$, *for some* $\rho > 0$ *and all* $v \in [L^2(\Omega)]^n$ (*assumption* (1.23));

(iii) *With reference* (6.41)-(6.44),

$$\rho(c+k) - 2G_hC_m > 0. \tag{6.45}$$

Proof. Only the modifications on the proof of Theorem 1.5 will be indicated. We return to identity (6.2) and estimate as follows:

$$\begin{aligned}\frac{1}{2}\int_Q \Delta\phi\nabla(\operatorname{div} h)\cdot\nabla(\Delta\phi)\,dQ &\geqq -2G_h\int_Q |\Delta\phi||\nabla(\Delta\phi)|\,dQ\\ &\geqq -2G_h\|\Delta\phi\|_Q\|\|\nabla(\Delta\phi)\|\|_Q \quad \text{(by Schwarz's inequality)}\\ &\geqq -2G_hC\|A^{1/2}\phi\|_Q\|A^{3/4}\phi\|_Q \quad \text{(by (6.16) and (6.42))}\\ &\geqq -2G_hC\|A^{-1/4}\|\,\|A^{3/4}\phi\|_Q^2\end{aligned} \tag{6.46}$$

in place of (6.5). Similarly,

$$\begin{aligned}\frac{1}{2}\int_Q \phi_t\nabla(\operatorname{div} h)\cdot\nabla\phi_t\,dQ &\geqq -2G_h\int_Q |\phi_t||\nabla\phi_t|\,dQ \geqq -2G_h\|\phi_t\|_Q\|\|\nabla\phi_t\|\|_Q\\ &\geqq -2G_hC_p\|\|\nabla\phi_t\|\|_Q^2\\ &\geqq -2G_hC_pK\|A^{1/4}\phi_t\|_Q^2 \quad \text{(by (6.41) since } \phi_t\equiv \text{on } \Sigma)\end{aligned} \tag{6.47}$$

in place of (6.6). Thus, using (6.46), (6.47) in the RHS of identity (6.2) and recalling assumption (ii), we obtain

$$\begin{aligned}\text{RHS of (6.2)} &\geqq \rho\int_Q |\nabla(\Delta\phi)|^2+|\nabla\phi_t|^2\,dQ - 2G_hC\|A^{-1/4}\|\,\|A^{3/4}\phi\|_Q^2\\ &\quad -2G_hC_pK\|A^{1/4}\phi_t\|_Q^2+\beta_{0,T,h}\\ &\geqq [\rho(c+k)-2G_hC_m]\{\|A^{3/4}\phi\|_Q^2\\ &\quad +\|A^{1/4}\phi_t\|_Q^2\}+\beta_{0,T,h} \quad \text{(by (6.44))}.\end{aligned} \tag{6.48}$$

Thus, invoking the time invariance identity (2.29) and (2.39) as well, we obtain

$$\begin{aligned}\text{RHS of (6.2)} &\geqq [\rho(c+k)-2G_hC_m]T\{\|A^{3/4}\phi^0\|_\Omega^2+\|A^{1/4}\phi^1\|_\Omega^2\}\\ &\quad -\text{const}_{h,n}\{\|A^{3/4}\phi^0\|_\Omega^2+\|A^{1/4}\phi^1\|_\Omega^2\}.\end{aligned} \tag{6.49}$$

Moreover, for the LHS of (6.2) we have, as before,

$$C_{1nh\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma+\varepsilon c_h\int_0^T\|A^{3/4}\phi\|_\Omega^2\,dt \geqq \text{LHS of (6.2)} \tag{6.50}$$

(see (2.45), or else (6.13) combined with (2.42)).

Thus (6.50) and (6.49) combined yield (by proceeding as in obtaining (2.47) in particular, by using the time invariance (2.29))

$$C_{1nh\varepsilon}\int_\Sigma\left(\frac{\partial(\Delta\phi)}{\partial\nu}\right)^2 d\Sigma\geqq\{[\rho(c+k)-2G_hC_m-\varepsilon c_h]T-\text{const}_{h,n}\}\|\{\phi^0,\phi^1\}\|_Z^2$$

and the conclusion follows via Lemma 2.1(ii), (2.11) with

$$T>\frac{\text{const}_{h,n}}{\rho(c+k)-2G_hC_m}. \tag{6.51}$$

Appendix A. Proof of a general identity and of (2.22). For future reference to exact controllability problems for (1.1a) with boundary conditions of a type possibly different from (1.1c, d), we shall first derive a general identity for ϕ only solution of (2.20a) with no use of boundary conditions (2.20c, d), in terms of an arbitrary smooth vector field $h(x)\in C^2(\bar{\Omega})$ (see (A8) below). Only subsequently, we shall specialize such an

identity (A8) to ϕ that satisfies also the boundary conditions (2.20c-d), and to $h(x)$ that is a radial vector field $h(x) = x - x_0$, thus obtaining (2.22).

Identity for ϕ that satisfies (2.20a) for general vector field $h(x)$. Let $h(x) \in C^2(\bar{\Omega})$. With reference to Remark 1.4, we multiply (2.20a) by $h \cdot \nabla(\Delta\phi)$ and integrate over Q. We shall use the identity

$$\int_\Omega h \cdot \nabla f \, d\Omega = \int_\Gamma f h \cdot \nu \, d\Gamma - \int_\Omega f \operatorname{div} h \, d\Omega \tag{A1}$$

obtained from $\operatorname{div}(fh) = h \cdot \nabla f + f \operatorname{div} h$, f scalar function, and the divergence theorem. In addition, we shall use the identity

$$\begin{aligned} \int_Q \Delta\psi (h \cdot \nabla\psi) \, dQ = \int_\Sigma \frac{\partial\psi}{\partial\nu} (h \cdot \nabla\psi) \, d\Sigma - \frac{1}{2} \int_\Sigma |\nabla\psi|^2 h \cdot \nu \, d\Sigma \\ - \int_Q H\nabla\psi \cdot \nabla\psi \, dQ + \frac{1}{2} \int_Q |\nabla\psi|^2 \operatorname{div} h \, dQ, \end{aligned} \tag{A2}$$

already proved in, say, [T2, (A3) of Appendix A] (with similar multiplier $h \cdot \nabla\psi$), where $H = H(x)$ is the transpose of the Jacobian matrix of $h(x)$:

$$H(x) = \begin{vmatrix} \dfrac{\partial h_1}{\partial x_1} & \cdots & \dfrac{\partial h_1}{\partial x_n} \\ \vdots & \cdots & \vdots \\ \dfrac{\partial h_n}{\partial x_1} & \cdots & \dfrac{\partial h_n}{\partial x_n} \end{vmatrix}. \tag{A3}$$

Term $\phi_{tt} h \cdot \nabla(\Delta\phi)$. Integrating at first by parts in t:

$$\int_\Omega \int_0^T \phi_{tt} h \cdot \nabla(\Delta\phi) \, dt \, d\Omega = \left[\int_\Omega \phi_t h \cdot \nabla(\Delta\phi) \, d\Omega \right]_0^T - \int_Q \phi_t h \cdot \nabla(\Delta\phi_t) \, dQ$$

(using (A1) with h replaced by $\phi_t h$, with $f = \Delta\phi_t$, and with $\operatorname{div}(\phi_t h) = \nabla\phi_t \cdot h + \phi_t \operatorname{div} h$)

$$\begin{aligned} = \left[\int_\Omega \phi_t h \cdot \nabla(\Delta\phi) \, d\Omega \right]_0^T - \int_\Sigma \phi_t \Delta\phi_t h \cdot \nu \, d\Sigma \\ + \int_Q \Delta\phi_t h \cdot \nabla\phi_t \, dQ + \int_Q \Delta\phi_t \phi_t \operatorname{div} h \, dQ. \end{aligned} \tag{A4}$$

If we use identity (A2) with $\psi = \phi_t$ for the third integral on the right of (A4),

$$\begin{aligned} \int_\Omega \int_0^T \phi_{tt} h \cdot \nabla(\Delta\phi) \, dt \, d\Omega = \left[\int_\Omega \phi_t h \cdot \nabla(\Delta\phi) \, d\Omega \right]_0^T - \int_\Sigma \phi_t \Delta\phi_t h \cdot \nu \, d\Sigma \\ - \frac{1}{2} \int_\Sigma |\nabla\phi_t|^2 h \cdot \nu \, d\Sigma + \int_\Sigma \frac{\partial\phi_t}{\partial\nu} h \cdot \nabla\phi_t \, d\Sigma \\ - \int_Q H\nabla\phi_t \cdot \nabla\phi_t \, dQ + \frac{1}{2} \int_Q |\nabla\phi_t|^2 \operatorname{div} h \, dQ \\ + \int_Q \Delta\phi_t \phi_t \operatorname{div} h \, dQ. \end{aligned} \tag{A5}$$

Using Green's first theorem on the last integral at the right of (A5) along with the identity

$$\nabla\phi_t \cdot \nabla(\phi_t \operatorname{div} h) = \phi_t \nabla(\operatorname{div} h) \cdot \nabla\phi_t + |\nabla\phi_t|^2 \operatorname{div} h,$$

we finally obtain from (A5)

$$\begin{aligned}\int_Q \phi_{tt} h\cdot\nabla(\Delta\phi)\,dQ &= [(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T - \int_\Sigma \phi_t\Delta\phi_t h\cdot\nu\,d\Sigma\\ &\quad -\frac{1}{2}\int_\Sigma |\nabla\phi_t|^2 h\cdot\nu\,d\Sigma + \int_\Sigma \frac{\partial\phi_t}{\partial\nu} h\cdot\nabla\phi_t\,d\Sigma\\ &\quad +\int_\Sigma \frac{\partial\phi_t}{\partial\nu}\phi_t \operatorname{div} h\,d\Sigma - \int_Q H\nabla\phi_t\cdot\nabla\phi_t\,dQ\\ &\quad -\frac{1}{2}\int_Q |\nabla\phi_t|^2 \operatorname{div} h\,dQ - \int_Q \phi_t\nabla(\operatorname{div} h)\cdot\nabla\phi_t\,dQ.\end{aligned} \tag{A6}$$

Term $\Delta^2\phi h\cdot\nabla(\Delta\phi)$. Using identity (A2), this time with $\psi=\Delta\phi$, we obtain

$$\begin{aligned}\int_Q \Delta(\Delta\phi)h\cdot\nabla(\Delta\phi)\,dQ &= \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla(\Delta\phi)\,d\Sigma - \frac{1}{2}\int_\Sigma |\nabla(\Delta\phi)|^2 h\cdot\nu\,d\Sigma\\ &\quad -\int_Q H\nabla(\Delta\phi)\cdot\nabla(\Delta\phi)\,dQ + \frac{1}{2}\int_Q |\nabla(\Delta\phi)|^2 \operatorname{div} h\,dQ.\end{aligned} \tag{A7}$$

Summing up (A6) and (A7), we finally obtain

$$\begin{aligned}&\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla(\Delta\phi)\,d\Sigma + \int_\Sigma \frac{\partial\phi_t}{\partial\nu} h\cdot\nabla\phi_t\,d\Sigma + \int_\Sigma \frac{\partial\phi_t}{\partial\nu}\phi_t \operatorname{div} h\,d\Sigma\\ &\quad -\frac{1}{2}\int_\Sigma |\nabla\phi_t|^2 h\cdot\nu\,d\Sigma - \frac{1}{2}\int_\Sigma |\nabla(\Delta\phi)|^2 h\cdot\nu\,d\Sigma - \int_\Sigma \phi_t\Delta\phi_t h\cdot\nu\,d\Sigma\\ &= \int_Q H\nabla(\Delta\phi)\cdot\nabla(\Delta\phi)\,dQ + \int_Q H\nabla\phi_t\cdot\nabla\phi_t\,dQ + \frac{1}{2}\int_Q \{|\nabla\phi_t|^2 - |\nabla(\Delta\phi)|^2\}\operatorname{div} h\,dQ\\ &\quad + \int_Q \phi_t\nabla(\operatorname{div} h)\cdot\nabla\phi_t\,dQ - [(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T,\end{aligned} \tag{A8}$$

which is the sought-after identity for ϕ satisfying (2.20a).

Specialization of left-hand side of (A8) to ϕ satisfying also the boundary conditions (2.20c, d). Recalling (2.20c, d) we have:

(A9a) $\phi_t|_\Sigma \equiv 0$, $\nabla\phi \perp \Gamma$ and $|\nabla\phi| = |\partial\phi/\partial\nu| \equiv 0$ on Σ by (2.20d),

(A9b) $\partial\phi_t/\partial\nu|_\Sigma \equiv 0$, $\nabla\phi_t \perp \Gamma$ and $|\nabla\phi_t| = |\partial\phi_t/\partial\nu| \equiv 0$ in Σ.

Thus, using (2.20c, d) and (A9a, b) in the LHS of (A8) we find that this simplifies to

$$\text{(A10)}\qquad \text{LHS of (A8)} = \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu} h\cdot\nabla(\Delta\phi)\,d\Sigma - \frac{1}{2}\int_\Sigma |\nabla(\Delta\phi)|^2 h\cdot\nu\,d\Sigma.$$

Specialization of the right-hand side of (A8) to radial vector fields $h(x)=x-x_0$. In this case, recalling (A3) we obtain

$$\text{(A11)}\qquad H(x)\equiv \text{identity matrix}, \qquad \operatorname{div} h \equiv n = \dim\Omega,$$

which used in the RHS of (A8) yield

$$\begin{aligned}\text{RHS of (A8)} &= \int_Q \{|\nabla\phi_t|^2 + |\nabla(\Delta\phi)|^2\}\,dQ\\ &\quad + \frac{n}{2}\int_Q \{|\nabla\phi_t|^2 - |\nabla(\Delta\phi)|^2\}\,dQ - [(\phi_t, h\cdot\nabla(\Delta\phi))_\Omega]_0^T.\end{aligned} \tag{A12}$$

Combining (A10) and (A12) proves (2.22), as desired.

Appendix B. Proof of identity (2.23). Again, we shall first obtain an identity, (B3) below, for ϕ that solves only (2.20a) and for an arbitrary smooth vector field $h \in C^2(\bar{\Omega})$. Next we shall specialize this identity (B3) to the case where ϕ satisfies, in addition, the boundary conditions (2.20c)-(2.20d) and, moreover, the vector field is radial.

We multiply (2.20a) by $\Delta\phi$ div h and integrate over Q by parts in t and by Green's first theorem:

(B1)

$$\begin{aligned}
&\int_\Omega \int_0^T \phi_{tt}\,\Delta\phi \operatorname{div} h\, dt\, d\Omega \\
&\quad = \left[\int_\Omega \Delta\phi\, \phi_t \operatorname{div} h\, d\Omega\right]_0^T - \int_0^T \int_\Omega \Delta\phi_t\, \phi_t \operatorname{div} h\, d\Omega\, dt \\
&\quad = \left[\int_\Gamma \frac{\partial\phi}{\partial\nu}\phi_t \operatorname{div} h\, d\Gamma - \int_\Omega \nabla\phi\cdot\nabla(\phi_t \operatorname{div} h)\, d\Omega\right]_0^T \\
&\qquad - \int_\Sigma \frac{\partial\phi_t}{\partial\nu}\phi_t \operatorname{div} h\, d\Sigma + \int_Q |\nabla\phi_t|^2 \operatorname{div} h\, dQ + \int_Q \phi_t \nabla(\operatorname{div} h)\cdot\nabla\phi_t\, dQ.
\end{aligned}$$

Also,

(B2)

$$\begin{aligned}
&\int_0^T \int_\Omega \Delta(\Delta\phi)\Delta\phi \operatorname{div} h\, d\Omega\, dt \\
&\quad = \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi \operatorname{div} h\, d\Sigma - \int_Q |\nabla(\Delta\phi)|^2 \operatorname{div} h\, dQ \\
&\qquad - \int_Q \Delta\phi \nabla(\operatorname{div} h)\cdot\nabla(\Delta\phi)\, dQ.
\end{aligned}$$

Summing up (B1) and (B2), we find the identity

(B3)

$$\begin{aligned}
&\int_Q \{|\nabla\phi_t|^2 - |\nabla(\Delta\phi)|^2\} \operatorname{div} h\, dQ \\
&\quad = \int_\Sigma \frac{\partial\phi_t}{\partial\nu}\phi_t \operatorname{div} h\, d\Sigma - \int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi \operatorname{div} h\, d\Sigma \\
&\qquad + \int_\Omega \Delta\phi \nabla(\operatorname{div} h)\cdot\nabla(\Delta\phi)\, dQ - \int_Q \phi_t \nabla(\operatorname{div} h)\cdot\nabla\phi_t\, dQ \\
&\qquad + \left[\int_\Omega \Delta\phi\cdot\nabla(\phi_t \operatorname{div} h)\, d\Omega - \int_\Gamma \frac{\partial\phi}{\partial\nu}\phi_t \operatorname{div} h\, d\Gamma\right]_0^T
\end{aligned}$$

for ϕ satisfying (2.20a).

Now if ϕ satisfies, in addition, the boundary conditions (2.20c, d), we have (for future use in § 5) the identity

(B4)

$$\begin{aligned}
&\int_Q \{|\nabla\phi_t|^2 - |\nabla(\Delta\phi)|^2\} \operatorname{div} h\, dQ \\
&\quad = -\int_\Sigma \frac{\partial(\Delta\phi)}{\partial\nu}\Delta\phi \operatorname{div} h\, d\Sigma + \int_Q \Delta\phi \nabla(\operatorname{div} h)\cdot\nabla(\Delta\phi)\, dQ \\
&\qquad - \int_Q \phi_t \nabla(\operatorname{div} h)\cdot\nabla\phi_t\, dQ + \left[\int_\Omega \nabla\phi\cdot\nabla(\phi_t \operatorname{div} h)\, d\Omega\right]_0^T.
\end{aligned}$$

Finally, if $h(x)$ is a radial vector field, then (B4) specializes to (2.23).

Appendix C. Proof of Lemma 2.3. We begin by recalling definition (2.2), the definition of the positive self-adjoint operator A. It suffices to show parts (i) and (ii), since part (iii) is a specialization of (ii) for ϕ solution of problem (2.20a-d).

Part (i). This follows from known interpolation results of Grisvard [G1] (see also Lions and Magenes [LM1]). If $0<\theta<1$, with $4\theta+\frac{1}{2}$ a nonpositive integer, then

$$\text{(C1)} \qquad \mathscr{D}(A^{\theta})=[\mathscr{D}(A), L^2(\Omega)]_{1-\theta}=\{f\in H^{4\theta}(\Omega): B_j f=0, \text{ if } m_j<4\theta-\tfrac{1}{2}\}$$

where the B_j are the boundary operators defining A and m_j their order. In our case we have $B_1=|_\Gamma$ and $B_2=\partial/\partial\nu|_\Gamma$ of orders zero and one, respectively. Then (C1) specializes at once to (2.30) and (2.31) for $\theta=\frac{3}{4}$ and $\theta=\frac{1}{4}$, respectively.

Part (ii). By (2.31), the $\mathscr{D}(A^{1/4})$-norm, defined by (1.6), is equivalent to the $H_0^1(\Omega)$-norm, which in turn is equivalent to the gradient norm by Poincaré inequality. This proves (2.33).

As for (2.32), we first note that $\int_\Omega |\nabla(\Delta f)|^2\, d\Omega=0$, i.e.,

$$\text{(C2)} \qquad \Delta f\equiv \text{const in } \Omega \quad \text{with } f|_\Gamma=\left.\frac{\partial f}{\partial \nu}\right|_\Gamma=0$$

readily implies $f\equiv 0$ in Ω. In fact, the boundary conditions give $|\nabla f|=|\partial f/\partial\nu|=0$ on Γ; hence $f=f_{x_j}\equiv 0$ on Γ. These, coupled with $\partial(\Delta f)/\partial x_j=\partial(\text{const})/\partial x_j$, i.e., $\Delta f_{x_j}=0$ in Ω, yield $f_{x_j}\equiv 0$ in Ω; hence $f=$ const in Ω and finally $f\equiv 0$ in Ω, as desired. Similarly, if $|\nabla(\Delta f)|\in L^2(\Omega)$, with $f=\partial f/\partial\nu=0$ on Γ, i.e., $f=f_{x_j}=0$ on Γ, then $f\in H^3(\Omega)$. In fact, $\partial(\Delta f)/\partial x_j=\Delta f_{x_j}\equiv v_j\in L^2(\Omega)$ and $f_{x_j}=0$ on Γ yield $f_{x_j}\in H^2(\Omega)$ by elliptic theory. This along with $f|_\Gamma=0$ yields $f\in L^2(\Omega)$ by Poincaré inequality; thus $f\in H^3(\Omega)$, as desired. □

Appendix D. The minimal norm steering control. Once exact controllability is established, the following elementary argument provides the minimal norm steering control u^0. We shall first carry out the reasoning for an abstract equation, and then specialize its conclusions as they apply to, say, problem (1.1a-d) with $\Gamma_0=\varnothing$, on the state space $H^1(\Omega)\times L^2(\Omega)$ with control space $L^2(\Sigma)$.

Abstract treatment. Consider the abstract equation

$$\text{(D1)} \qquad \dot{y}=\mathscr{A}y+\mathscr{B}u, \qquad y(0)=y_0,$$

$\mathscr{A}$ being the generator of an s.c. semigroup of operators on the Hilbert space Y and $\mathscr{B}: U\supset D(\mathscr{B})\to Y$ being a linear, generally unbounded operator from another Hilbert space U to Y, with $\mathscr{A}^{-1}\mathscr{B}$ continuous from U to Y (without loss of generality we may assume that $\mathscr{A}$ is boundedly invertible). The solution to (D1) with $y_0=0$ is

$$\text{(D2)} \qquad \mathscr{L}_T u=\mathscr{A}\int_0^T e^{\mathscr{A}(T-t)}\mathscr{A}^{-1}\mathscr{B}u(t)\, dt.$$

Let z be a target state in Y and consider the following minimization problem: Minimize

$$J(u)=\tfrac{1}{2}\|u\|^2_{L_2(0,T;U)}$$

over all $u\in L_2(0, T; U)$ such that $\mathscr{L}_T u=z$, under the (exact controllability) assumption that there exists at least one such u. If we indicate by $((\ ,\ ))$ the duality pairing between Y' and Y, the Lagrangian can be written as

$$L(u,p)=\tfrac{1}{2}(u,u)_{L_2(0,T;U)}-((p,\mathscr{L}_T u-z)), \qquad p\in Y'.$$

Taking $L_u=0$ yields

$$\text{(D3)} \qquad u^0=\mathscr{L}_T^{\#}p^0; \quad \text{thus } z=\mathscr{L}_T u^0=\mathscr{L}_T\mathscr{L}_T^{\#}p^0,$$

where $\mathscr{L}_T^\#$ is the conjugate operator from Y' to $L^2(0, T; U)$ defined by $((v, \mathscr{L}_T u)) = (\mathscr{L}_T^\# v, u)_{L^2(0,T;U)}$, $v \in Y'$. From (D2) it readily follows that

$$\mathscr{L}_T^\# p^0 = \mathscr{B}^* e^{\mathscr{A}^*(T-t)} J^{-1} p^0, \tag{D4}$$

where J is the norm-preserving isomorphism Y onto Y' given by Riesz's theorem. Note that

$$\mathscr{L}_T^* = \mathscr{L}_T^\# J \tag{D5}$$

is the Hilbert space adjoint $Y \to L^2(0, T; U)$ of $\mathscr{L}_T$ which we have used in the paper. Moreover, from (D3), (D5) we obtain

$$\begin{aligned} ((p^0, z)) &= ((p^0, \mathscr{L}_T \mathscr{L}_T^\# p^0)) = \|\mathscr{L}_T^\# p^0\|^2_{L^2(0,T;U)} = \|\mathscr{L}_T^* J^{-1} p^0\|^2_{L^2(0,T;U)} \\ &\geqq C_T \|J^{-1} p^0\|^2_Y = C_T \|p^0\|^2_{Y'}, \end{aligned} \tag{D6}$$

where we have used the lower-bound inequality for $\mathscr{L}_T^*$ which states that $\mathscr{L}_T$ is $L^2(0, T; U)$ onto Y, i.e., the exact controllability assumption on (D1). Thus, the operator $\mathscr{L}_T \mathscr{L}_T^\#$ defines an isomorphism Y' onto Y by the Lax-Milgram Theorem applied to (D6), and from (D3) we have

$$p^0 = [p_1^0, p_2^0] = (\mathscr{L}_T \mathscr{L}_T^\#)^{-1} z \in Y'. \tag{D7}$$

Hence, by (D3), (D4), and (D7) we find that the optimal minimal norm steering control is given by

$$u^0 = \mathscr{L}_T^\# (\mathscr{L}_T \mathscr{L}_T^\#)^{-1} z = \mathscr{B}^* e^{\mathscr{A}^*(T-t)} J^{-1} (\mathscr{L}_T \mathscr{L}_T^\#)^{-1} z \tag{D8}$$

in terms of the target z and the dynamics $\mathscr{A}$, $\mathscr{B}$, $\mathscr{L}_T$.

Specialization to problem (1.1a–d) with $U = U_1 \times U_2$, $U_1 = L^2(\Gamma)$, $U_2 = \{0\}$, $Y = [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$ so that $Y' = \mathscr{D}(A^{1/4}) \times \mathscr{D}(A^{3/4})$. Here the norm preserving isomorphism J from Y onto Y' is defined by $J = A^{-1/2} \times A^{-3/2}$ so that if $p^0 = [p_1^0, p_2^0] \in Y'$ then $J^{-1} p^0 = [A^{1/2} p_1^0, A^{3/2} p_2^0] \in Y$. Using the operator model for problem (1.1a–d) (see e.g., [FLT1, App. C, case 2]) we obtain that

$$u^0 = \mathscr{L}_T^\# p^0 = \mathscr{B}^* e^{\mathscr{A}^*(T-t)} J^{-1} p^0 = \frac{\partial \Delta \phi(t)}{\partial \nu}\bigg|_\Gamma \tag{D9}$$

where ϕ solves problem (2.9a–d) with

$$\begin{aligned} \phi^0 &= A^{-3/2} [J^{-1} p^0]_2 = p_2^0 \in \mathscr{D}(A^{3/4}), \\ \phi^1 &= -A^{-1/2} [J^{-1} p^0]_1 = -p_1^0 \in \mathscr{D}(A^{1/4}). \end{aligned} \tag{D10}$$

The case $U_1 = \{0\}$, $U_2 = L^2(\Gamma)$ with $Y = L^2(\Omega) \times H^{-2}(\Omega)$ can also be treated (see [FLT1, App. C, Case 1]) and leads to

$$u^0 = \mathscr{B}^* e^{\mathscr{A}^*(T-t)} J^{-1} p^0 = \Delta \phi(t)|_\Gamma \tag{D11]}$$

where ϕ solves problem (2.9a–d) with $\phi^0 = -p_2^0 \in H_0^2(\Omega)$ and $\phi^0 = p_1^0 \in L^2(\Omega)$. The minimal norm steering control (D11) is the one used in [L3] (through a different approach) in the case $g_1 = 0$, $g_2 \in L^2(\Sigma)$ for problem (1.1a–d), while the case $g_1 \in L^2(\Sigma)$, $g_2 = 0$ which was proposed for investigation in [L3] leads in fact to the minimal norm steering control (D9).

A more extended discussion of the conceptual content of this Appendix is given in [LT3, App. B].

EXACT BOUNDARY CONTROLLABILITY OF MAXWELL'S EQUATIONS IN A GENERAL REGION*

JOHN E. LAGNESE†

Abstract. By the Hilbert uniqueness method, it is proved that the evolution of solutions of Maxwell's equations in a general region can be exactly controlled by means of currents flowing tangentially in the boundary of the region.

Key words. Maxwell's equations, exact controllability, boundary controllability

AMS(MOS) subject classifications. 93C20, 35L50

1. Introduction and problem formulation. Let Ω be a bounded, open, connected region in $\mathbb{R}^3$ with a smooth boundary Γ. We suppose that Ω is occupied by an electromagnetic medium of constant electric permittivity ε and constant magnetic permeability μ. We further assume that the electrical charge density ρ and the current density J in Ω are zero. Let $E(x, t)$ and $H(x, t)$ denote the electric field and magnetic field, respectively, at a point $x \in \Omega$ at time $t \geqq 0$. These satisfy Maxwell's equations

$$\varepsilon \frac{\partial E}{\partial t} - \operatorname{curl} H = 0, \quad \mu \frac{\partial H}{\partial t} + \operatorname{curl} E = 0, \quad \operatorname{div} E = \operatorname{div} H = 0 \quad \text{in } \Omega, \quad t > 0. \tag{1.1}$$

It is assumed that the time evolution of the electric and magnetic fields is driven by an externally applied density of current flowing tangentially in Γ. We then have the boundary condition

$$\nu \times H = -J \quad \text{on } \Gamma, \qquad t > 0, \tag{1.2}$$

where ν is the unit normal vector to Γ pointing into the exterior of Ω. Let E^0, H^0 denote the distribution of E and H, respectively, at time $t = 0$:

$$E(0) = E^0, \qquad H(0) = H^0 \quad \text{in } \Omega. \tag{1.3}$$

In this paper we consider the following problem.

EXACT CONTROLLABILITY PROBLEM. Given the initial distribution $\{H^0, E^0\}$, a time $T > 0$, and a desired terminal state $\{H^T, E^T\}$ with $\{H^0, E^0\}, \{H^T, E^T\}$ in appropriate function spaces, find (if possible) a surface density of current J in a suitable function space such that the solution of (1.1)–(1.3) satisfies

$$E(T) = E^T, \qquad H(T) = H^T \quad \text{in } \Omega.$$

Remark 1.1. Because solutions of (1.1) propagate with finite velocity, the exact controllability problem can have a solution only if T is sufficiently large. The determination of T is part of the problem.

The exact controllability problem for Maxwell's equations with boundary control has been studied previously by Russell [6] for a right circular cylindrical region Ω, and by Kime [2] for a spherical region Ω. In the cylindrical region situation, it is assumed that the fields E and H (and control J) do not depend on the axial coordinate. The control problem can then be transformed into a problem of *simultaneous* exact controllability of a pair of ordinary wave equations in a circular region (i.e., the exact

* Received by the editors January 25, 1988; accepted for publication May 31, 1988. This research was supported by Air Force Office of Scientific Research grant AFOSR-86-0162.

† Department of Mathematics, Georgetown University, Washington, D.C. 20057.

controllability of two wave equations by means of a single control). The latter control problem is then solved by the moment problem method. A moment problem approach is also used in [2] to find a solution to the exact controllability problem in a spherical region. In both [2] and [6], $\mathscr{L}^2$ boundary controls J are employed. It should be noted that the control functions J considered in [6] are further constrained by a *preassigned direction* in the tangent space to Γ, a very important requirement for applications. The control functions are not so constrained in [2] nor will they be in this paper. (In fact, for a general region, it is a challenge to even formulate such a constraint in a reasonable way.)

The moment problem approach employed in [2] and [6] is not feasible for dealing with the exact controllability problem in a general region. Rather, we shall attack the problem by means of the *Hilbert uniqueness method* (HUM) introduced by Lions [4], [5]. In this method we consider, in addition to the system (1.1), (1.2), the homogeneous adjoint system

$$\varepsilon\frac{\partial\varphi}{\partial t}-\operatorname{curl}\psi=0,\quad \mu\frac{\partial\psi}{\partial t}+\operatorname{curl}\varphi=0,\quad \operatorname{div}\varphi=\operatorname{div}\psi=0\quad\text{in }\Omega,\quad t>0, \tag{1.4}$$

$$\nu\times\varphi=0\quad\text{on }\Gamma,\qquad t>0. \tag{1.5}$$

Solvability of the exact controllability problem is shown to be equivalent to uniqueness of solutions of (1.4), (1.5) when certain additional *boundary data* are prescribed. We then construct Hilbert spaces associated with these uniqueness results (this can be done in infinitely many ways) and prove exact controllability in the duals of these spaces. In this way we obtain a variety of exact controllability results, depending on the particular Hilbert spaces constructed. In all cases, the method is *constructive*: the control J is defined in terms of the solution to (1.4), (1.5) with initial data

$$\varphi(0)=\varphi^0,\qquad \psi(0)=\psi^0\quad\text{in }\Omega, \tag{1.6}$$

where φ, ψ^0 are uniquely determined from the data of the original control problem.

The remainder of this paper is organized as follows. Section 2 defines the appropriate function spaces and discusses the well-posedness of problem (1.4)–(1.6). Energy estimates for solutions of (1.4), (1.5) are derived in § 3 (Lemmas 3.1–3.4); these are the basis for the application of HUM to our control problem. Three different exact controllability results are presented in Theorems 4.1–4.3 of § 4. They are distinguished by what we assume regarding regularity of the data—the geometry of Γ and the regularity that the control J possesses. In particular, it is proved that the system (1.1)–(1.3) is exactly controllable in the space $J(\Omega)\times\hat{J}(\Omega)$ (see (2.1), (2.2) below) using $\mathscr{L}^2(\Gamma\times(0,T))$ controls, provided Γ is star-shaped with respect to some point $x_0\in\Omega$ and T is $O(\sqrt{\varepsilon\mu})$ (this is made precise in (3.15) below).

2. Function spaces and well-posedness of (1.4)–(1.6). The spaces $L^2(\Omega)$, $L^2(\Gamma)$, $H^k(\Omega)$, $H^k(\Gamma)$ will denote the standard real L^2 and Sobolev spaces over Ω or Γ as notation implies. We shall use script notation to denote the corresponding spaces of $\mathbb{R}^3$-valued functions:

$$\mathscr{L}^2(\Omega)=(L^2(\Omega))^3,\qquad \mathscr{L}^2(\Gamma)=(L^2(\Gamma))^3,$$

$$\mathscr{H}^k(\Omega)=(H^k(\Omega))^3,\qquad \mathscr{H}^k(\Gamma)=(H^k(\Gamma))^3,$$

with the product topology in each case. The inner product and norm, respectively, in $\mathscr{L}^2(\Omega)$ are denoted by $(\cdot,\cdot)$ and $\|\cdot\|$.

We also introduce the following spaces (the notation is adopted from Ladyzhenskaya and Solonikov [3]):

$$J(\Omega) = \text{closure in } \mathscr{L}^2(\Omega) \text{ of } \{\chi | \chi \in C^\infty(\bar{\Omega}), \operatorname{div} \chi = 0\}, \tag{2.1}$$

$$\hat{J}(\Omega) = \text{closure in } \mathscr{L}^2(\Omega) \text{ of } \{\chi | \chi \in C_0^\infty(\Omega), \operatorname{div} \chi = 0\}, \tag{2.2}$$

where C^∞ denotes the class of infinitely differentiable $\mathbb{R}^3$-valued functions. For $k \geqq 1$, we set

$$J^k(\Omega) = J(\Omega) \cap \mathscr{H}^k(\Omega),$$

$$J_\nu^k(\Omega) = \{\chi | \chi \in J^k(\Omega), \nu \cdot \chi = 0 \text{ on } \Gamma\},$$

$$J_\tau^k(\Omega) = \{\chi | \chi \in J^k(\Omega), \nu \times \chi = 0 \text{ on } \Gamma\}$$

with the topology in each case that induced by $\mathscr{H}^k(\Omega)$. We further introduce

$$J_\nu^*(\Omega) = \{\chi | \chi \in J_\nu^2(\Omega), \nu \times \operatorname{curl} \chi = 0 \text{ on } \Gamma\},$$

$$J_\tau^*(\Omega) = \{\chi | \chi \in J_\tau^2(\Omega), \nu \cdot \operatorname{curl} \chi = 0 \text{ on } \Gamma\}$$

with topology in each space inherited from $\mathscr{H}^2(\Omega)$. The spaces above are known to have the following properties (see [3, § 7]):

$$J_\tau^*(\Omega) \subset J_\tau^1(\Omega) \subset J(\Omega), \qquad J_\nu^*(\Omega) \subset J_\nu^1(\Omega) \subset \hat{J}(\Omega) \tag{2.3}$$

with each space dense and continuously embedded in the one that follows it. In addition,

(2.4) If $k \geqq 1$, then the map $\varphi \to \operatorname{curl} \varphi$ is a continuous linear bijection of $J_\tau^k(\Omega)$ (respectively, $J_\nu^k(\Omega)$) onto $J_\nu^{k-1}(\Omega)$ (respectively, $J_\tau^{k-1}(\Omega)$), where $J_\tau^0(\Omega) \doteq J(\Omega)$ and $J_\nu^0(\Omega) \doteq \hat{J}(\Omega)$.

It follows from (2.3), (2.4) that $J_\tau^1(\Omega)$ and $J_\nu^1(\Omega)$ may be renormed using

$$\|\varphi\|_{J_\tau^1(\Omega)} = \|\operatorname{curl} \varphi\|, \qquad \|\psi\|_{J_\nu^1(\Omega)} = \|\operatorname{curl} \psi\|, \tag{2.5}$$

and that the norms (2.5) are *equivalent* to the $\mathscr{H}^1$ norms on these spaces.

Remark 2.1. If $\varphi \in J_\tau^1(\Omega)$ and $\psi \in J_\nu^1(\Omega)$, we have

$$(\operatorname{curl} \varphi, \psi) = (\varphi, \operatorname{curl} \psi);$$

hence

$$|(\operatorname{curl} \varphi, \psi)| \leqq \|\varphi\| \, \|\psi\|_{J_\nu^1(\Omega)}.$$

Therefore the mapping $\varphi \to \operatorname{curl} \varphi \colon J_\tau^1(\Omega) \to \hat{J}(\Omega)$ may be extended to a continuous linear mapping from $J(\Omega)$ into $(J_\nu^1(\Omega))'$, where $(J_\nu^1(\Omega))'$ denotes the dual of $J_\nu^1(\Omega)$ with respect to $\hat{J}(\Omega)$. Similarly, the mapping $\varphi \to \operatorname{curl} \varphi \colon J_\nu^1(\Omega) \to J(\Omega)$ has an extension to a continuous linear mapping from $\hat{J}(\Omega)$ into $(J_\tau^1(\Omega))'$, the dual of $J_\tau^1(\Omega)$ with respect to $J(\Omega)$. From (2.4) we may see that each of these extensions is a homeomorphism.

We now consider the well-posedness of the problem (1.4)–(1.6). Proceeding formally for the moment, let $\{\varphi, \psi\}$ be a solution. Since $\operatorname{div} \varphi = 0$, there is an $\mathbb{R}^3$-valued function W, determined up to a gradient ∇f, such that $\varepsilon\varphi = \operatorname{curl} W$. From the equation

$$0 = -\operatorname{curl} \psi + \varepsilon\varphi' = -\operatorname{curl} \psi + \operatorname{curl} W',$$

there is a real function g such that

$$\psi = W' + \nabla g.$$

It is classical that the function f may be chosen so that $g = 0$ and that, with this choice of f, W satisfies (see, e.g., Friedrichs [1])

$$\varepsilon\mu W'' + \operatorname{curl}(\operatorname{curl} W) = 0, \quad \operatorname{div} W = 0 \quad \text{in } \Omega, \quad t > 0, \tag{2.6}$$

$$\nu \times \operatorname{curl} W = 0 \quad \text{on } \Gamma, \qquad t > 0, \tag{2.7}$$

$$W(0) = W^0, \qquad W'(0) = \psi^0 \tag{2.8}$$

where $\varepsilon \operatorname{curl} \varphi^0 = W^0$.

Conversely, if W is a solution to (2.6)-(2.8), then setting $\varepsilon\varphi = \operatorname{curl} W$, $\psi = W'$, we see that $\{\varphi, \psi\}$ is a solution to (1.4), (1.5) with initial data $\varphi^0 = (1/\varepsilon) \operatorname{curl} W^0$, $\psi^0 = W^1$.

Now let us make the correspondence between (1.4)-(1.6) and (2.6)-(2.8) precise. First, we take the following variational problem as the *definition* of the problem (2.6)-(2.8):

$$\varepsilon\mu(W'', \hat{W}) + (\operatorname{curl} W, \operatorname{curl} \hat{W}) = 0 \quad \forall \hat{W} \in J^1_\nu(\Omega), \qquad t > 0, \tag{2.9}$$

$$W(0) = W^0 \in J^1_\nu(\Omega), \qquad W'(0) = W^1 \in \hat{J}(\Omega). \tag{2.10}$$

This as justified by the fact that (2.6)-(2.8) and (2.9), (2.10) are equivalent for smooth $J^1_\nu(\Omega)$-valued functions W. Next, we note that the form $a(W, \hat{W}) = (\operatorname{curl} W, \operatorname{curl} \hat{W})$ is strictly coercive on $J^1_\nu(\Omega)$. Since $J^1_\nu(\Omega)$ is dense in $\hat{J}(\Omega)$ with continuous injection, it follows from standard variational theory that there is one and only one function W satisfying

$$W \in C([0, \infty); J^1_\nu(\Omega)), \quad W' \in C([0, \infty); \hat{J}(\Omega)), \quad W'' \in C([0, \infty); (J^1_\nu(\Omega))')$$

and (2.9), (2.10). In (2.9), $(W'', \hat{W})$ is interpreted in the $(J^1_\nu(\Omega))' - J^1_\nu(\Omega)$ duality.

Remark 2.2. In view of Remark 2.1, (2.9) is equivalent to

$$\varepsilon\mu W'' + \operatorname{curl}(\operatorname{curl} W) = 0 \quad \text{in } (J^1_\nu(\Omega))'. \tag{2.11}$$

2.1. Weak solutions of (1.4)–(1.6). Suppose that $\{W^0, W^1\}$ satisfies (2.10) and let W be the solution to (2.9), (2.10). Define

$$\varepsilon\varphi = \operatorname{curl} W, \qquad \psi = W'. \tag{2.12}$$

Then

$$\begin{aligned} &\varphi \in C([0, \infty); J(\Omega)), \qquad \varphi' \in C([0, \infty); (J^1_\tau(\Omega))'), \\ &\psi \in C([0, \infty); \hat{J}(\Omega)), \qquad \psi' \in C([0, \infty); (J^1_\nu(\Omega))'), \\ &\varphi(0) = \varphi^0 \doteq (1/\varepsilon) \operatorname{curl} W^0 \in J(\Omega), \qquad \psi(0) = \psi^0 \doteq W^1 \in \hat{J}(\Omega), \end{aligned} \tag{2.13}$$

$$\mu\psi' + \operatorname{curl} \varphi = 0 \quad \text{in } (J^1_\nu(\Omega))'. \tag{2.14}$$

From (2.12) it is clear that

$$\varepsilon\varphi' - \operatorname{curl} \psi = 0 \quad \text{in } (J^1_\tau(\Omega))'. \tag{2.15}$$

Conversely, suppose that $\{\varphi, \psi\}$ satisfies (2.13)-(2.15) and

$$\varphi(0) = \varphi^0 \in J(\Omega), \qquad \psi(0) = \psi^0 \in \hat{J}(\Omega). \tag{2.16}$$

From (2.4) there is a unique function $W \in C([0, \infty); J^1_\nu(\Omega))$ such that $\operatorname{curl} W = \varepsilon\varphi$. Since, from (2.14), $\operatorname{curl} \psi = \varepsilon\varphi' = \operatorname{curl} W'$ in $(J^1_\tau(\Omega))'$, it follows from Remark 2.1 that $\psi = W'$. Therefore W satisfies (2.11), and

$$W(0) = W^0, \qquad W'(0) = \psi^0,$$

where $W^0 \in J^1_\nu(\Omega)$ is defined by $\operatorname{curl} W^0 = \varepsilon\varphi^0$.

We have therefore proved Theorem 2.1.

THEOREM 2.1. *Assume that* $\{\varphi^0, \psi^0\} \in J(\Omega) \times \hat{J}(\Omega)$. *There is one and only one pair* $\{\varphi, \psi\}$ *that satisfies* (2.13)-(2.16).

Remark 2.3 (*Conservation of energy for weak solutions*). From (2.9) it follows that

$$\varepsilon\mu \|W'(t)\|^2 + \|\text{curl } W(t)\|^2 = \varepsilon\mu \|W^1\|^2 + \|\text{curl } W^0\|^2. \tag{2.17}$$

In terms of φ, ψ, this conservation law is

$$\mu \|\psi(t)\|^2 + \varepsilon \|\varphi(t)\|^2 = \mu \|\psi^0\|^2 + \varepsilon \|\varphi^0\|^2. \tag{2.18}$$

2.2. Strong solutions of (1.4)–(1.6). Let us set $U = W'$ and formally differentiate (2.11) in t. Then U satisfies

$$\varepsilon\mu U'' + \text{curl}\,(\text{curl } U) = 0 \quad \text{in } (J^1_\nu(\Omega))', \tag{2.19}$$

$$U(0) = W^1, \qquad U'(0) = -(1/\varepsilon\mu)\,\text{curl}\,(\text{curl } W^0). \tag{2.20}$$

The system (2.19), (2.20) has a unique solution if

$$W^1 \in J^1_\nu(\Omega), \qquad \text{curl}\,(\text{curl } W^0) \in \hat{J}(\Omega),$$

that is, if curl $W^0 \in J^1_\tau(\Omega)$. It is standard theory that this solution is exactly W'; hence we have

$$W' \in C([0,\infty); J^1_\nu(\Omega)), \quad W'' \in C([0,\infty); \hat{J}(\Omega)), \quad \text{curl } W \in C([0,\infty); J^1_\tau(\Omega)). \tag{2.21}$$

It follows from (2.21) and the discussion leading to Theorem 2.1 that we have the following theorem.

THEOREM 2.2. *Assume that* $\{\varphi^0, \psi^0\} \in J^1_\tau(\Omega) \times J^1_\nu(\Omega)$. *There is one and only one pair* $\{\varphi, \psi\}$ *satisfying*

$$\{\varphi, \psi\} \in C([0,\infty); J^1_\tau(\Omega) \times J^1_\nu(\Omega)), \qquad \{\varphi', \psi'\} \in C([0,\infty); J(\Omega) \times \hat{J}(\Omega))$$

and (1.4)-(1.6).

Remark 2.4 (*Conservation of energy for strong solutions*). From (2.17), applied to $U = W'$, we have the conservation law

$$\varepsilon \|\text{curl } \varphi(t)\|^2 + \mu \|\text{curl } \psi(t)\|^2 = \varepsilon \|\text{curl } \varphi^0\|^2 + \mu \|\text{curl } \psi^0\|^2. \tag{2.22}$$

Let us take Theorem 2.2 a step further by differentiating (2.19) in t. Setting $V = U'$, we obtain

$$\varepsilon\mu V'' + \text{curl}\,(\text{curl } V) = 0 \quad \text{in } (J^1_\nu(\Omega))',$$

$$V(0) = -(1/\varepsilon\mu)\,\text{curl}\,(\text{curl } W^0), \qquad V'(0) = -(1/\varepsilon\mu)\,\text{curl}\,(\text{curl } W^1).$$

This problem is uniquely solvable, and the solution is exactly W'', provided

$$\text{curl}\,(\text{curl } W^0) \in J^1_\nu(\Omega), \qquad -(1/\varepsilon\mu)\,\text{curl}\,(\text{curl } W^1) \in \hat{J}(\Omega). \tag{2.23}$$

In terms of $\{\varphi^0, \psi^0\}$, (2.23) is curl $\varphi^0 \in J^1_\nu(\Omega)$, curl $\psi^0 \in J^1_\tau(\Omega)$, that is,

$$\varphi^0 \in J^*_\tau(\Omega), \qquad \psi^0 \in J^*_\nu(\Omega). \tag{2.24}$$

With (2.24), the solution of Theorem 2.2 satisfies

$$\varphi \in C([0,\infty); J^*_\tau(\Omega)), \quad \varphi' \in C([0,\infty); J^1_\tau(\Omega)), \quad \varphi'' \in C([0,\infty); J(\Omega)), \tag{2.25}$$

$$\psi \in C([0,\infty); J^*_\nu(\Omega)), \quad \psi' \in C([0,\infty); J^1_\nu(\Omega)), \quad \psi'' \in C([0,\infty); \hat{J}(\Omega)). \tag{2.26}$$

THEOREM 2.3. *Assume that* $\{\varphi^0, \psi^0\} \in J^*_\tau(\Omega) \times \hat{J}^*_\nu(\Omega)$. *Then the unique solution* $\{\varphi, \psi\}$ *of* (1.4)-(1.6) *satisfies* (2.25)-(2.26).

3. Energy estimates for solutions of the homogeneous problem. In this section we will derive energy estimates for solutions of (1.4), (1.5), that will be the basis for the application of HUM to the exact controllability problem.

We will assume that $\varepsilon = 1$ in (1.4), which amounts to the change $t \to t/\varepsilon$ in the time scale. (The reverse transformation will be done at the end.) Thus we consider the system

$$\frac{\partial \varphi}{\partial t} - \operatorname{curl} \psi = 0, \tag{3.1a}$$

$$\gamma \frac{\partial \psi}{\partial t} + \operatorname{curl} \varphi = 0, \qquad \operatorname{div} \varphi = \operatorname{div} \psi = 0 \quad \text{in } Q = \Omega \times (0, T), \tag{3.1b}$$

$$\nu \times \varphi = 0 \quad \text{on } \Sigma = \Gamma \times (0, T), \tag{3.2}$$

where $T > 0$ and $\gamma = \mu/\varepsilon$. The initial values are assumed to satisfy

$$\varphi(0) = \varphi^0 \in J_\tau^*(\Omega), \qquad \psi(0) = \psi^0 \in J_\nu^0(\Omega). \tag{3.3}$$

The solution to (3.1)–(3.3) then satisfies

$$\varphi \in C([0, T]; J_\tau^*(\Omega)), \quad \varphi' \in C([0, T]; J_\tau^1(\Omega)), \quad \varphi'' \in C([0, T]; J(\Omega)),$$
$$\psi \in C([0, T]; J_\nu^*(\Omega)), \quad \psi' \in C([0, T]; J_\nu^1(\Omega)), \quad \psi'' \in C([0, T]; \hat{J}(\Omega)).$$

We introduce the vector field m in $\mathbb{R}^3$ defined by

$$m(x; x_0) = x - x_0,$$

where x_0 is fixed. Let us form the inner product of (3.1a) and curl $(m \cdot \nabla)\psi$ and integrate the result over $\Omega \times (0, T)$. Thus,

$$\int_0^T (\varphi' - \operatorname{curl} \psi, \operatorname{curl} (m \cdot \nabla)\psi)\, dt = 0. \tag{3.4}$$

We have

$$\begin{aligned} \int_0^T (\varphi', \operatorname{curl} (m \cdot \nabla)\psi)\, dt &= \int_0^T (\operatorname{curl} \varphi', (m \cdot \nabla)\psi)\, dt + \int_\Sigma \nu \cdot (((m \cdot \nabla)\psi) \times \varphi')\, d\Gamma\, dt \\ &= -\gamma \int_0^T (\psi'', (m \cdot \nabla)\psi)\, dt \\ &= -\gamma (\psi', (m \cdot \nabla)\psi)\Big|_0^T + \gamma \int_0^T (\psi', (m \cdot \nabla)\psi')\, dt, \end{aligned} \tag{3.5}$$

since $\nu \times \varphi' = 0$ on Σ. We set

$$X_1 = -\gamma (\psi', (m \cdot \nabla)\psi)\Big|_0^T = (\operatorname{curl} \varphi, (m \cdot \nabla)\psi)\Big|_0^T.$$

Then (3.5) may be written:

$$\begin{aligned} \int_0^T (\varphi', \operatorname{curl} (m \cdot \nabla)\psi)\, dt &= X_1 + \frac{\gamma}{2} \int_Q \operatorname{div} (m|\psi'|^2)\, dx\, dt - \frac{3\gamma}{2} \int_Q |\psi'|^2\, dx\, dt \\ &= X_1 + \frac{\gamma}{2} \int_\Sigma m \cdot \nu |\psi'|^2\, d\Gamma\, dt - \frac{3\gamma}{2} \int_Q |\psi'|^2\, dx\, dt. \end{aligned} \tag{3.6}$$

Next, we note that

$$\operatorname{curl} (m \cdot \nabla)\psi = 2 \operatorname{curl} \psi + (m \cdot \nabla) \operatorname{curl} \psi - \operatorname{curl} ((\psi \cdot \nabla)m).$$

But $(\psi \cdot \nabla)m = \psi$, so that

$$\begin{aligned}(\operatorname{curl}\psi)\cdot(\operatorname{curl}(m\cdot\nabla)\psi) &= |\operatorname{curl}\psi|^2 + (\operatorname{curl}\psi)\cdot((m\cdot\nabla)\operatorname{curl}\psi)\\ &= |\operatorname{curl}\psi|^2 + \tfrac{1}{2}\operatorname{div}(m|\operatorname{curl}\psi|^2) - \tfrac{3}{2}|\operatorname{curl}\psi|^2\\ &= -\tfrac{1}{2}|\operatorname{curl}\psi|^2 + \tfrac{1}{2}\operatorname{div}(m|\operatorname{curl}\psi|^2).\end{aligned}$$

Therefore

(3.7)

$$\int_0^T (\operatorname{curl}\psi, \operatorname{curl}(m\cdot\nabla)\psi)\,dt = -\frac{1}{2}\int_Q |\operatorname{curl}\psi|^2\,dx\,dt + \frac{1}{2}\int_\Sigma m\cdot\nu|\operatorname{curl}\psi|^2\,d\Gamma\,dt.$$

Substituting (3.6), (3.7) into (3.4), we obtain

(3.8)

$$X_1 - \frac{3\gamma}{2}\int_Q |\psi'|^2\,dx\,dt + \frac{1}{2}\int_Q |\operatorname{curl}\psi|^2\,dx\,dt + \frac{1}{2}\int_\Sigma m\cdot\nu(\gamma|\psi'|^2 - |\operatorname{curl}\psi|^2)\,d\Gamma\,dt = 0.$$

Next, we form the inner product of (3.1b) with ψ' and integrate over $\Omega\times(0, T)$. We obtain

$$\begin{aligned}0 &= \gamma\int_Q |\psi'|^2\,dx\,dt + \int_0^T (\operatorname{curl}\varphi, \psi')\,dt\\ &= \gamma\int_Q |\psi'|^2\,dx\,dt + \int_0^T (\varphi, \operatorname{curl}\psi')\,dt + \int_\Sigma \nu\cdot(\varphi\times\psi')\,d\Gamma\,dt\\ &= \gamma\int_Q |\psi'|^2\,dx\,dt + \int_0^T (\varphi, \varphi'')\,dx\,dt + \int_\Sigma \psi'\cdot(\nu\times\varphi)\,d\Gamma\,dt\\ &= \gamma\int_Q |\psi'|^2\,dx\,dt + (\varphi, \varphi')|_0^T - \int_Q |\varphi'|^2\,dx\,dt.\end{aligned}$$

Therefore

$$\gamma\int_Q |\psi'|^2\,dx\,dt = \int_Q |\operatorname{curl}\psi|^2\,dx\,dt - X_2, \tag{3.9}$$

where

$$X_2 = (\varphi, \varphi')|_0^T = (\varphi, \operatorname{curl}\psi)|_0^T.$$

Substitution of (3.9) into (3.8) yields

$$\int_Q (\gamma|\psi'|^2 + |\operatorname{curl}\psi|^2)\,dx\,dt = 2(X_1 + X_2) + \int_\Sigma m\cdot\nu(\gamma|\psi'|^2 - |\operatorname{curl}\psi|^2)\,d\Gamma\,dt,$$

which may be written

$$\begin{aligned}&\int_Q (\varepsilon|\operatorname{curl}\varphi|^2 + \mu|\operatorname{curl}\psi|^2)\,dx\,dt\\ &\qquad = 2\mu(X_1 + X_2) + \mu\int_\Sigma m\cdot\nu(\gamma|\psi'|^2 - |\operatorname{curl}\psi|^2)\,d\Gamma\,dt.\end{aligned} \tag{3.10}$$

If we replace T by T/ε and rewrite (3.10) in the original time scale, we obtain

$$\int_Q (\varepsilon|\text{curl } \varphi|^2+\mu|\text{curl } \psi|^2)\, dx\, dt$$

$$(3.11)\qquad = 2\varepsilon\mu(X_1+X_2)+\mu\int_\Sigma m\cdot\nu(\mu\varepsilon|\psi'|^2-|\text{curl } \psi|^2)\, d\Gamma\, dt.$$

But since

$$\frac{d}{dt}\int_\Omega (\varepsilon|\text{curl } \varphi|^2+\mu|\text{curl } \psi|^2)\, dx = 0,$$

(3.11) becomes

$$T(\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2)$$

$$(3.12)\qquad = 2\varepsilon\mu(X_1+X_2)+\mu\int_\Sigma m\cdot\nu(\varepsilon\mu|\psi'|^2-|\text{curl } \psi|^2)\, d\Gamma\, dt.$$

3.1. A priori estimates. Let c_1, c_2 be the smallest constants such that

$$\|\chi\|_{\mathscr{H}^1(\Omega)} \leqq c_1\|\text{curl } \chi\| \quad \forall \chi \in J^1_\nu(\Omega),$$
$$\|\chi\|_{\mathscr{L}^2(\Omega)} \leqq c_2\|\text{curl } \chi\| \quad \forall \chi \in J^1_\tau(\Omega).$$

Then

$$|X_2| \leqq c_2(\|\text{curl } \varphi(T)\|\,\|\text{curl } \psi(T)\|+\|\text{curl } \varphi^0\|\,\|\text{curl } \psi^0\|)$$
$$\leqq (c_2/\sqrt{\varepsilon\mu})(\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2).$$

Define

$$(3.13)\qquad R(x_0) = \sup_{x\in\Omega}|m(x; x_0)|.$$

We have

$$|X_1| \leqq c_1R(x_0)(\|\text{curl } \varphi(T)\|\,\|\text{curl } \psi(T)\|+\|\text{curl } \varphi^0\|\,\|\text{curl } \psi^0\|)$$
$$\leqq (c_1/\sqrt{\varepsilon\mu})R(x_0)(\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2).$$

Therefore

$$(3.14)\qquad 2\varepsilon\mu|X_1+X_2| \leqq 2\sqrt{\varepsilon\mu}\,\max[c_1R(x_0), c_2](\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2).$$

Let us define

$$(3.15)\qquad T_0 = 2\sqrt{\varepsilon\mu}\,\max[c_1R(x_0), c_2].$$

From (3.12)-(3.15) we have

$$(3.16)\qquad (T-T_0)(\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2) \leqq \mu\int_\Sigma m\cdot\nu(\varepsilon\mu|\psi'|^2-|\text{curl } \psi|^2)\, d\Gamma\, dt.$$

We now introduce a *geometric assumption*: Γ is star-shaped with respect to some point $x_0\in\Omega$, i.e.,

$$(3.17)\qquad m\cdot\nu \geqq 0 \quad \text{on } \Gamma.$$

With (3.17), (3.16) simplifies to

$$(3.18)\qquad (T-T_0)(\varepsilon\|\text{curl } \varphi^0\|^2+\mu\|\text{curl } \psi^0\|^2) \leqq \varepsilon\mu^2\int_\Sigma m\cdot\nu|\psi'|^2\, d\Gamma\, dt.$$

Formula (3.18) has been obtained under assumption (3.3) on the data φ^0, ψ^0. Assume that $T > T_0$, and introduce the *norm*

$$(3.19)\qquad \|\{\varphi^0, \psi^0\}\|_{F_1} = \left[\int_\Sigma |\psi'|^2\, d\Gamma\, dt\right]^{1/2}.$$

Let F_1 be the completion of $J_\tau^*(\Omega)\times J_\nu^*(\Omega)$ with respect to the norm (3.19). It follows from standard trace theory that the imbedding $J_\tau^*(\Omega)\times J_\nu^*(\Omega)\to F_1$ is continuous. From (3.18) we have

$$F_1\subset J_\tau^1(\Omega)\times J_\nu^1(\Omega) \tag{3.20}$$

algebraically and topologically.

LEMMA 3.1. *Assume that* Γ *satisfies* (3.17) *and that* $T>T_0$, *where* T_0 *is defined in* (3.15). *Then for all* $\{\varphi^0,\psi^0\}\in F_1$,

$$(T-T_0)(\varepsilon\|\operatorname{curl}\varphi^0\|^2+\mu\|\operatorname{curl}\psi^0\|^2)\leqq\varepsilon\mu^2R(x_0)\int_\Sigma|\psi'|^2\,d\Gamma\,dt. \tag{3.21}$$

Remark 3.1. Another characterization of F_1 is

$$F_1=\{\{\varphi^0,\psi^0\}|\varphi^0\in J_\tau^1(\Omega),\ \psi^0\in J_\nu^1(\Omega),\ \psi|_\Sigma\in H^1(0,T;\mathscr{L}^2(\Gamma))\}.$$

If the star-shaped condition (3.17) is not satisfied, we obtain from (3.16) the estimate

$$(T-T_0)(\varepsilon\|\operatorname{curl}\varphi^0\|^2+\mu\|\operatorname{curl}\psi^0\|^2)\leqq\varepsilon\mu R(x_0)\int_\Sigma(\mu|\psi'|^2+\varepsilon|\varphi'|^2)\,d\Gamma\,dt. \tag{3.22}$$

Assume that $T>T_0$ and introduce the space F_2, the completion of $J_\tau^*(\Omega)\times J_\nu^*(\Omega)$ with respect to the norm

$$\|\{\varphi^0,\psi^0\}\|_{F_2}=\left[\int_\Sigma(|\psi'|^2+|\varphi'|^2)\,d\Gamma\,dt\right]^{1/2}.$$

We then have from (3.22)

$$F_2\subset J_\tau^1(\Omega)\times J_\nu^1(\Omega)$$

algebraically and topologically.

LEMMA 3.2. *Assume that* $T>T_0$, *defined in* (3.15). *Then for all* $\{\varphi^0,\psi^0\}\in F_2$,

$$(T-T_0)(\varepsilon\|\operatorname{curl}\varphi^0\|^2+\mu\|\operatorname{curl}\psi^0\|^2)\leqq\varepsilon\mu\max(\mu,\varepsilon)R(x_0)\int_\Sigma(|\psi'|^2+|\varphi'|^2)\,d\Gamma\,dt. \tag{3.23}$$

We shall now use (3.18), (3.22) to obtain additional energy estimates. Let us assume that the initial values satisfy

$$\varphi^0\in J_\tau^1(\Omega),\qquad \psi^0\in J_\nu^1(\Omega).$$

From (1.4) we have

$$\varepsilon\varphi(t)-\varepsilon\varphi^0-\operatorname{curl}\int_0^t\psi(s)\,ds=0,\qquad \mu\psi(t)-\mu\psi^0+\operatorname{curl}\int_0^t\varphi(s)\,ds=0\quad\text{in } Q. \tag{3.24}$$

We introduce the functions

$$\vartheta(t)=\int_0^t\psi(s)\,ds+\vartheta^0,\qquad \chi(t)=\int_0^t\varphi(s)\,ds+\chi^0, \tag{3.25}$$

where ϑ^0, χ^0 are chosen so that

$$\chi^0\in J_\tau^*(\Omega),\qquad \vartheta^0\in J_\nu^*(\Omega), \tag{3.26}$$

$$\operatorname{curl}\vartheta^0=\varepsilon\varphi^0,\qquad \operatorname{curl}\chi^0=-\mu\psi^0. \tag{3.27}$$

Let us assume for the moment that ϑ^0, χ^0 can be so determined. From (3.24)-(3.27) we have

$$\varepsilon\chi'-\operatorname{curl}\vartheta=0,\quad \mu\vartheta'+\operatorname{curl}\chi=0,\quad \operatorname{div}\chi=\operatorname{div}\vartheta=0\quad\text{in } Q, \tag{3.28}$$

$$\nu \times \chi = 0 \quad \text{on } \Sigma, \tag{3.29}$$

$$\chi(0) = \chi^0 \in J^*_\tau(\Omega), \qquad \vartheta(0) = \vartheta^0 \in J^*_\nu(\Omega). \tag{3.30}$$

We may therefore apply (3.18) (or (3.22)) to the solution of (3.28)–(3.30) and thereby obtain the following energy estimates:

$$(T - T_0)(\varepsilon \|\varphi^0\|^2 + \mu \|\psi^0\|^2) \leqq \mu \int_\Sigma m \cdot \nu |\psi|^2 \, d\Gamma \, dt \tag{3.31}$$

provided (3.17) holds; otherwise

$$(T - T_0)(\varepsilon \|\varphi^0\|^2 + \mu \|\psi^0\|^2) \leqq R(x_0) \int_\Sigma (\mu |\psi|^2 + \varepsilon |\varphi|^2) \, d\Gamma \, dt. \tag{3.32}$$

Assume that $T > T_0$, and introduce the norm

$$\|\{\varphi^0, \psi^0\}\|_{G_1} = \left[\int_\Sigma |\psi|^2 \, d\Gamma \, dt \right]^{1/2}$$

provided (3.17) is satisfied, and the norm

$$\|\{\varphi^0, \psi^0\}\|_{G_2} = \left[\int_\Sigma (|\psi|^2 + |\varphi|^2) \, d\Gamma \, dt \right]^{1/2}$$

in the general case. Define

$$G_1 = \text{completion of } J^1_\tau(\Omega) \times J^1_\nu(\Omega) \text{ with respect to } \| \cdot \|_{G_1},$$

$$G_2 = \text{completion of } J^1_\tau(\Omega) \times J^1_\nu(\Omega) \text{ with respect to } \| \cdot \|_{G_2}.$$

From (3.31), (3.32) we have

$$G_1 \subset J(\Omega) \times \hat{J}(\Omega) \tag{3.33}$$

algebraically and topologically whenever (3.17) is satisfied, and

$$G_2 \subset J(\Omega) \times \hat{J}(\Omega) \tag{3.34}$$

algebraically and topologically in the general case.

We have therefore proved (modulo (3.26), (3.27)) the following.

LEMMA 3.3. *Assume that* Γ *satisfies* (3.17) *and that* $T > T_0$, *where* T_0 *is defined in* (3.15). *Then for all* $\{\varphi^0, \psi^0\} \in G_1$,

$$(T - T_0)(\varepsilon \|\varphi^0\|^2 + \mu \|\psi^0\|^2) \leqq \mu R(x_0) \int_\Sigma |\psi|^2 \, d\Gamma \, dt.$$

LEMMA 3.4. *Assume that* $T > T_0$, *as defined in* (3.15). *Then for all* $\{\varphi^0, \psi^0\} \in G_2$,

$$(T - T_0)(\varepsilon \|\varphi^0\|^2 + \mu \|\psi^0\|^2) \leqq R(x_0) \max(\varepsilon, \mu) \int_\Sigma (|\psi|^2 + |\varphi|^2) \, d\Gamma \, dt.$$

Remark 3.2. From the estimates above we obtain the following *uniqueness results* for Maxwell's equations:

(i) Let φ, ψ be a solution to the Maxwell system (1.4), and assume that $T > T_0$, defined in (3.15). Then

$$\psi = \varphi = 0 \quad \text{on } \Sigma \Rightarrow \{\varphi, \psi\} = 0 \quad \text{in } \Omega \times (0, T).$$

(ii) If $T > T_0$ and (3.17) holds, then

$$\psi = \nu \times \varphi = 0 \quad \text{on } \Sigma \Rightarrow \{\varphi, \psi\} = 0 \quad \text{in } \Omega \times (0, T).$$

Proof of (3.26), (3.27). Since the map $\varphi \to \operatorname{curl} \varphi$ is a homeomorphism from $J^2_\nu(\Omega)$ (respectively, $J^2_\tau(\Omega)$) onto $J^1_\tau(\Omega)$ (respectively, $J^1_\nu(\Omega)$), there are functions $\tilde{\varphi}^0 \in J^2_\nu(\Omega)$,

$\tilde{\varphi}^0 \in J_\tau^2(\Omega)$ such that

$$\varphi^0 = \operatorname{curl} \tilde{\varphi}^0, \qquad \psi^0 = \operatorname{curl} \tilde{\psi}^0.$$

We define

$$\vartheta^0 = \varepsilon\tilde{\varphi}^0 + \varepsilon\nabla f, \qquad \chi^0 = -\mu\tilde{\psi}^0 + \mu\nabla g,$$

where f, g are chosen according to

$$\nabla^2 f = -\operatorname{div} \tilde{\varphi}^0 \quad \text{in } \Omega, \qquad \frac{\partial f}{\partial \nu} = -\nu \cdot \tilde{\varphi}^0 \quad \text{on } \Gamma,$$

$$\nabla^2 g = \operatorname{div} \tilde{\psi}^0 \quad \text{in } \Omega, \qquad g = 0 \quad \text{on } \Gamma.$$

Then (3.27) is satisfied and

$$\nu \cdot \vartheta^0 = 0, \qquad \nu \times \chi^0 = \nu \times \nabla g = 0 \quad \text{on } \Gamma,$$

the latter equality being a consequence of the fact that $\nu \times \nabla$ is a vector of *tangential* first-order differential operators in Γ. Thus χ^0, ϑ^0 satisfy (3.26).

4. Exact controllability. In this section we will use the energy estimates of § 3 in conjunction with HUM to prove exact controllability to rest of solutions of (1.1)-(1.3). Several different results will be presented, depending on the geometry of Γ and the regularity of the initial data. We note that proving controllability to rest at time T is equivalent to proving controllability to an arbitrary state (in a suitable function space) at time T since, for the *homogeneous* problem, the map $\{E^0, H^0\} \to \{E(T), H(T)\}$ is an isomorphism in the appropriate spaces.

4.1. Exact controllability in $J(\Omega) \times \hat{J}(\Omega)$ with $\mathscr{L}^2(\Sigma)$ boundary controls, under a geometric assumption on Γ. In this section we suppose that Γ satisfies (3.17). Assume that $T > T_0$. Let $\{\varphi^0, \psi^0\} \in G_1$, and let $\{\varphi, \psi\}$ be the solution to (1.4)-(1.6). Then $\psi|_\Sigma \in \mathscr{L}^2(\Sigma)$. Consider the following problem (where $\hat{\varepsilon} = 1/\varepsilon$, $\hat{\mu} = 1/\mu$):

$$\frac{\partial E}{\partial t} - \hat{\varepsilon} \operatorname{curl} H = 0, \quad \frac{\partial H}{\partial t} + \hat{\mu} \operatorname{curl} E = 0, \quad \operatorname{div} E = \operatorname{div} H = 0 \quad \text{in } Q, \tag{4.1}$$

$$E(T) = H(T) = 0 \quad \text{in } \Omega, \tag{4.2}$$

$$\nu \times H = \psi|_\Sigma \quad \text{on } \Sigma. \tag{4.3}$$

We will see below that (4.1)-(4.3) has a unique solution (in a weak sense). Let us form the expression

$$0 = \int_Q \left[\left(\frac{\partial E}{\partial t} - \hat{\varepsilon} \operatorname{curl} H \right) \cdot \psi - \left(\frac{\partial H}{\partial t} + \hat{\mu} \operatorname{curl} E \right) \cdot \varphi \right] dx\, dt. \tag{4.4}$$

Proceeding formally (everything will be justified in Remark 4.2 below), after an integration by parts we obtain from (4.4)

$$\begin{aligned} &-(E(0), \psi^0) + (H(0), \varphi^0) - \int_Q \left(E \cdot \frac{\partial \psi}{\partial t} - H \cdot \frac{\partial \varphi}{\partial t} \right) dx\, dt \\ &- \int_Q (\hat{\varepsilon}\psi \cdot \operatorname{curl} H + \hat{\mu}\varphi \cdot \operatorname{curl} E)\, dx\, dt = 0. \end{aligned} \tag{4.5}$$

The second integral in (4.5) may be written as

$$\int_Q (\hat{\varepsilon}H \cdot \operatorname{curl} \psi + \hat{\mu}E \cdot \operatorname{curl} \varphi)\, dx\, dt - \int_\Sigma [\nu \cdot (H \times \psi) + \nu \cdot (E \times \varphi)]\, d\Gamma\, dt$$

$$= \int_Q (\hat{\varepsilon}H \cdot \operatorname{curl} \psi + \hat{\mu}E \cdot \operatorname{curl} \varphi)\, dx\, dt - \int_\Sigma |\psi|^2\, d\Gamma\, dt.$$

Therefore (4.5) reduces to

$$(E(0), \psi^0) - (H(0), \varphi^0) = \int_\Sigma |\psi|^2\, d\Gamma\, dt,$$

which may be written as

$$\langle \{-H(0), E(0)\}, \{\varphi^0, \psi^0\} \rangle = \int_\Sigma |\psi|^2\, d\Gamma\, dt. \tag{4.6}$$

Let us define a linear mapping Λ by

$$\Lambda\{\varphi^0, \psi^0\} = \{-H(0), E(0)\}. \tag{4.7}$$

In terms of Λ, (4.6) becomes

$$\langle \Lambda\{\varphi^0, \psi^0\}, \{\varphi^0, \psi^0\} \rangle = \|\{\varphi^0, \psi^0\}\|^2_{G_1}, \tag{4.8}$$

and therefore Λ *is an isomorphism from* G_1 *onto* G_1' (G_1' = dual of G_1 with respect to $J(\Omega) \times \hat{J}(\Omega)$). Consequently, if $\{-H^0, E^0\} \in G_1'$ and if we choose $\{\varphi^0, \psi^0\} = \Lambda^{-1}\{-H^0, E^0\}$, then the unique solution of (4.1), (4.3) with initial data

$$E(0) = E^0, \qquad H(0) = H^0 \quad \text{in } \Omega$$

will (by construction) satisfy (4.2). Since $G_1' \supset J(\Omega) \times \hat{J}(\Omega)$, we have Theorem 4.1.

THEOREM 4.1. *Assume that* Γ *satisfies* (3.17), *that* $\{-H^0, E^0\} \in J(\Omega) \times \hat{J}(\Omega)$, *and that* $T > T_0$ *as defined in* (3.15). *Then the control* $J = -\psi|_\Sigma \in \mathscr{L}^2(\Sigma)$ *drives the system* (1.1)-(1.3) *to rest at time* T.

Remark 4.1. For initial data $\{-H^0, E^0\} \in J(\Omega) \times \hat{J}(\Omega)$, the control $J = -\psi|_\Sigma$ *minimizes* the norm $\int_\Sigma |J|^2\, d\Gamma\, dt$ among all controls $J \in \mathscr{L}^2(\Sigma)$ which drive the system (1.1)-(1.3) to rest at time T.

Remark 4.2. We still need to make precise the sense in which (4.1)-(4.3) (and (1.1)-(1.3)) are to be understood. This is done using the transposition method. In fact, let us consider the forward problem (1.1)-(1.3) with $J \in \mathscr{L}^2(\Sigma)$ and initial data satisfying $\{H^0, -E^0\} \in \mathscr{H}'$, where $\mathscr{H} = J_\tau^1(\Omega) \times J_\nu^1(\Omega)$ and $\mathscr{H}'$ is the dual of $\mathscr{H}$ with respect to $J(\Omega) \times \hat{J}(\Omega)$. Let $\{\varphi^0, \psi^0\} \in \mathscr{H}$ and $\{\varphi, \psi\}$ be the solution to (1.4)-(1.6). Consider the expression

$$0 = \int_0^t \int_\Omega \left[\left(\frac{\partial E}{\partial t} - \hat{\varepsilon} \operatorname{curl} H \right) \cdot \psi - \left(\frac{\partial H}{\partial t} + \hat{\mu} \operatorname{curl} E \right) \cdot \varphi \right] dx\, ds.$$

If we apply integration by parts in t and Green's formula in x we are led to

$$(H(t), \varphi(t)) - (E(t), \psi(t)) = (H^0, \psi^0) - (E^0, \psi^0) - \int_0^t \int_\Gamma J \cdot \psi\, d\Gamma\, ds. \tag{4.9}$$

We rewrite (4.9) as

$$\langle \{H(t), -E(t)\}, \{\varphi(t), \psi(t)\} \rangle = \langle \{H^0, -E^0\}, \{\varphi^0, \psi^0\} \rangle - \int_0^t \int_\Gamma J \cdot \psi\, d\Gamma\, ds. \tag{4.10}$$

Equation (4.10) is the *definition* of the solution of (1.1)-(1.3). In fact, we have

$$\begin{aligned}\left|\langle\{H^0,-E^0\},\{\varphi^0,\psi^0\}\rangle-\int_0^t\int_\Gamma J\cdot\psi\,d\Gamma\,ds\right| &\leqq \|\{H^0,-E^0\}\|_{\mathscr{K}'}\|\{\varphi^0,\psi^0\}\|_{\mathscr{K}}+\|J\|_{\mathscr{L}^2(\Sigma)}\|\psi\|_{\mathscr{L}^2(\Sigma)}\\ &\leqq \|\{H^0,-E^0\}\|_{\mathscr{K}'}\|\{\psi^0,\psi^0\}\|_{\mathscr{K}}+c_1\|J\|_{\mathscr{L}^2(\Sigma)}\|\operatorname{curl}\psi\|_{\mathscr{L}^2(\Sigma)}\\ &\leqq [\|\{H^0,-E^0\}\|_{\mathscr{K}'}+c_1\|J\|_{\mathscr{L}^2(\Sigma)}]\|\{\varphi^0,\tilde{\psi^0}\}\|_{\mathscr{K}}.\end{aligned}\tag{4.11}$$

Since the map $\{\varphi^0,\psi^0\}\to\{\varphi(t),\psi(t)\}\colon\mathscr{K}\to\mathscr{K}$ is an *isomorphism*, it follows from (4.11) that there is a unique pair $\{H,-E\}\in L^\infty(0,T;\mathscr{K}')$ that satisfies (4.10). (In fact, $\{H,-E\}\in C([0,T];\mathscr{K}')$.) This pair is, by definition, the solution to (1.1)-(1.3). (The fact that $T>T_0$ plays no role in the existence theory so far.)

Now suppose that $T>T_0$ and that $\{H^0,-E^0\}\in G_1'$ (recall that $G_1'\subset\mathscr{K}'$). From (4.10) with $t=T$ we obtain

$$|\langle\{H(T),E(T)\},\{\varphi(T),-\psi(T)\}\rangle|\leqq[\|\{H^0,-E^0\}\|_{G_1'}+\|J\|_{\mathscr{L}^2(\Sigma)}]\|\{\varphi^0,\psi^0\}\|_{G_1}.$$

From the definition of G_1 it can be seen that $\{\varphi^0,\psi^0\}\in G_1$ if, and only if, $\{\varphi(T),-\psi(T)\}\in G_1$; further, the map $\{\varphi^0,\psi^0\}\to\{\varphi(T),-\psi(T)\}\colon G_1\to G_1$ is an isometry. Thus, $\{H^0,-E^0\}\in G_1'$ implies that $\{H(T),E(T)\}\in G_1'$.

For the problem (4.1)-(4.3), it follows from the preceding discussion that there exists a unique solution $\{H,-E\}\in C([0,T];\mathscr{K}')$, and $\{H(0),\pm E(0)\}\in G_1'$. In particular, (4.6) holds *by definition* of the solution.

4.2. Exact controllability in $(J_\tau^1(\Omega))'\times(J_\nu^1(\Omega))'$ with $(H^1(0,T;\mathscr{L}^2(\Gamma)))'$ boundary controls, under a geometric assumption on Γ. We may extend the space of initial data that can be exactly controlled to rest beyond the space G_1', but at the expense of working with controls weaker than the $\mathscr{L}^2(\Sigma)$ controls of Theorem 4.1.

Let $\{\varphi^0,\psi^0\}\in J_\tau^*(\Omega)\times J_\nu^*(\Omega)$, assume that $T>T_0$ and consider the problem consisting of the Maxwell system (4.1), the terminal data (4.2) and the boundary condition

$$\nu\times H=-\psi''|_\Sigma\quad\text{on }\Sigma.\tag{4.12}$$

Formally applying Green's formula as in § 4.1, we obtain (analogous to (4.6))

$$\langle\{-H(0),E(0)\},\{\varphi^0,\psi^0\}\rangle=-\int_\Sigma\psi\cdot\psi''\,d\Gamma\,dt.\tag{4.13}$$

In (4.12), (4.13) we *define* $\psi''|_\Sigma\in(H^1(0,T;\mathscr{L}^2(\Gamma)))'$ by the duality

$$\langle\psi'',\chi\rangle=-\int_\Sigma\psi'\cdot\chi'\,d\Gamma\,dt\quad\forall\chi\in H^1(0,T;\mathscr{L}^2(\Gamma)).\tag{4.14}$$

Equation (4.14) has a meaning whenever $\{\varphi^0,\psi^0\}\in F_1$. Note that $\psi''|_\Sigma$ is *not* the distributional derivative $d/dt(\psi')\in H^{-1}(0,T;\mathscr{L}^2(\Gamma))$.

With the mapping Λ defined in (4.7) we obtain from (4.13), (4.14)

$$\langle\Lambda\{\varphi^0,\psi^0\},\{\varphi^0,\psi^0\}\rangle=\int_\Sigma|\psi'|^2\,d\Gamma\,dt=\|\{\varphi^0,\psi^0\}\|_{F_1}^2.\tag{4.15}$$

Consequently, Λ is an isomorphism from F_1 into F_1'. Since $F_1'\supset(J_\tau^1(\Omega))'\times(J_\nu^1(\Omega))'$ we have Theorem 4.2.

THEOREM 4.2. *Assume that* Γ *satisfies* (3.17), *that* $\{-H^0, E^0\} \in (J_\tau^1(\Omega))' \times (J_\nu^1(\Omega))'$, *and that* $T > T_0$ *as defined in* (3.15). *Then the control* $J = -\psi'|_\Sigma \in (H^1(0, T; \mathscr{L}^2(\Gamma)))'$ *drives the system* (1.1)-(1.3) *to rest at time* T.

Remark 4.3. For initial data $\{H^0, -E^0\}$ and boundary data J satisfying

$$\{H^0, -E^0\} \in (J_\tau^*(\Omega))' \times (J_\nu^*(\Omega))' \doteq \mathscr{Y}', \qquad J \in (H^1(0, T; \mathscr{L}^2(\Gamma)))',$$

the problem (1.1)-(1.3) may once again be solved by transposition, using (4.10) as the definition of the solution. We get $\{H, -E\} \in C([0, T]; \mathscr{Y}')$ with

$$\|\{H, -E\}\|_{L^\infty(0, T; \mathscr{Y}')} \leqq \|\{H^0, -E^0\}\|_{\mathscr{Y}'} + c_1 \|J\|_{(H^1(0, T; \mathscr{L}^2(\Gamma)))'}.$$

If, in particular, $\{H^0, -E^0\} \in F_1'$, then $\{H(T), E(T)\} \in F_1'$.

4.3. Exact controllability without geometric restrictions on Γ. If the geometric restriction (3.17) on Γ is lifted, we must work with the spaces F_2 and G_2 rather than F_1 and G_1 when applying HUM. As usual, the object is to choose the boundary control so that Λ is an isomorphism of F_2 (respectively, G_2) onto F_2' (respectively, G_2'). We then obtain exact controllability in the space F_2' (respectively, G_2'). It is shown below that exact controllability in the space F_2' can be established in this manner. However, we are unable to prove exact controllability in the space G_2'.

One possible explanation for the lack of (provable) exact controllability in G_2' is the following. The topology of G_2 is weaker than that of F_2, and therefore the opposite is true of their duals. Consequently, exact controllability in G_2' means controllability of states that are smoother than those in F_2', by means of controls more regular than those used to control states in F_2'. Because no restrictions of a geometric nature are assumed regarding Γ, it is not implausible that there are smooth initial states that *cannot* be steered to rest using such regular controls, i.e., exact controllability in G_2' may not be possible without geometric restrictions on Γ.

To establish exact controllability in F_2', we consider as usual for $T > T_0$ the Maxwell system (4.1) with terminal data (4.2) and boundary data

$$\nu \times H = -J \quad \text{on } \Sigma. \tag{4.16}$$

We consider also the homogeneous problem (1.4)-(1.6) with initial data $\{\varphi^0, \psi^0\} \in J_\tau^*(\Omega) \times J_\nu^*(\Omega)$. The solution of (4.1), (4.2), and (4.16) is defined by transposition. In particular, the pair $\{-H(0), E(0)\}$ satisfies (by definition!)

$$\langle \{-H(0), E(0)\}, \{\varphi^0, \psi^0\} \rangle = -\int_\Sigma \psi \cdot J \, d\Gamma dt. \tag{4.17}$$

The object is to choose the control J such that

$$-\int_\Sigma \psi \cdot J \, d\Gamma \, dt = \|\{\varphi^0, \psi^0\}\|_{F_2}^2 = \int_\Sigma (|\psi'|^2 + |\operatorname{curl} \psi|^2) \, d\Gamma \, dt. \tag{4.18}$$

With (4.17), (4.18), we have that Λ is an isomorphism of F_2 onto F_2', which proves exact controllability in that space.

Now (4.18) will be satisfied if

$$J = -\psi'|_\Sigma + \chi,$$

where χ satisfies

$$-\int_\Sigma \chi \cdot \psi \, d\Gamma \, dt = \int_\Sigma |\operatorname{curl} \psi|^2 \, d\Gamma \, dt.$$

To determine χ, we first note that for sufficiently smooth functions $\hat{\psi}: \Omega \to \mathbb{R}^3$ we have

$$\frac{\partial \hat{\psi}_i}{\partial x_k} = \nu_k \frac{\partial \hat{\psi}_i}{\partial \nu} + \sigma_k \hat{\psi}_i \quad \text{on } \Gamma,$$

where σ_k is a tangential operator in Γ of order 1. Therefore

$$\operatorname{curl} \hat{\psi} = \nu \times \frac{\partial \hat{\psi}}{\partial \nu} + \sigma \times \hat{\psi} \quad \text{on } \Gamma.$$

The operator $\psi \to \sigma \times \psi$ is a formally self-adjoint operator on Γ: for all sufficiently smooth functions $\hat{\varphi}$, $\hat{\psi}$ defined on Γ,

$$\int_\Gamma \hat{\varphi} \cdot (\sigma \times \hat{\psi})\, d\Gamma = \int_\Gamma (\sigma \times \hat{\varphi}) \cdot \hat{\psi}\, d\Gamma. \tag{4.19}$$

Since $\{\varphi^0, \psi^0\} \in J_\tau^*(\Omega) \times J_\nu^*(\Omega)$, $(\operatorname{curl} \psi)|_\Gamma$ and $\varphi'|_\Gamma$ are defined in the sense of traces and therefore $\operatorname{curl} \psi = \varepsilon \varphi'$ on Σ. As a result,

$$|\operatorname{curl} \psi|^2 = \varepsilon \varphi' \cdot \operatorname{curl} \psi = \varepsilon \varphi' \cdot \left(\nu \times \frac{\partial \psi}{\partial \nu} \right) + \varepsilon \varphi' \cdot (\sigma \times \psi) = \varepsilon \varphi' \cdot (\sigma \times \psi) \quad \text{on } \Sigma,$$

since $\nu \times \varphi = 0$ on Σ. Consequently,

$$\int_\Sigma |\operatorname{curl} \psi|^2\, d\Gamma\, dt = \varepsilon \int_\Sigma \varphi' \cdot (\sigma \times \psi)\, d\Gamma\, dt = \varepsilon \int_\Sigma \psi \cdot (\sigma \times \varphi')\, d\Gamma\, dt.$$

Therefore, if we choose the control J according to

$$J = \psi''|_\Sigma - \varepsilon \sigma \times \varphi',$$

then (4.18) will hold.

Remark 4.4. It follows from (4.19) that $\sigma \times \varphi' \in L^2(0, T; \mathscr{H}^{-1}(\Gamma))$.

THEOREM 4.3. *Assume that* $\{-H^0, E^0\} \in (J_\tau^1(\Omega))' \times (J_\nu^1(\Omega))'$ *and that* $T > T_0$ *as defined in* (3.15). *Then the control*

$$J = \psi''|_\Sigma - \varepsilon \sigma \times \varphi' \in (H^1(0, T; \mathscr{L}^2(\Gamma)))' \oplus L^2(0, T; \mathscr{H}^{-1}(\Gamma)) \tag{4.20}$$

drives the system (1.1)-(1.3) *to rest at time T.*

ROBUST STABILITY AND PERFORMANCE VIA FIXED-ORDER DYNAMIC COMPENSATION*

DENNIS S. BERNSTEIN†

Abstract. Two robust control-design problems are considered. The Robust Stabilization Problem involves deterministically modeled, bounded but unknown, time-varying parameter variations, while the Robust Performance Problem includes, in addition, a quadratic performance criterion averaged over stochastic disturbances and maximized over the admissible parameter variations. For both problems the design goal is a fixed-order (i.e., reduced- or full-order) dynamic (strictly proper) feedback compensator. A sufficient condition for solving the Robust Stabilization Problem is given by means of a quadratic Lyapunov function parameterized by the compensator gains. For the Robust Performance Problem the Lyapunov function provides an upper bound for the closed-loop performance. This leads to consideration of the Auxiliary Minimization Problem: Minimize the performance bound over the class of fixed-order controllers subject to the Lyapunov-function constraint. Necessary conditions for optimality in the auxiliary problem thus serve as sufficient conditions for robust stability and performance in the original problem. Two particular bounds are considered for constructing the quadratic Lyapunov function. The first corresponds to a right shift/multiplicative white noise model, while the second was suggested by recent work of Petersen and Hollot. The main result is an extended version of the optimal projection equations for fixed-order dynamic compensation whose solutions are guaranteed to provide both robust stability and robust performance.

Key words. robust control, stability, performance, dynamic compensation, Lyapunov bounds

AMS(MOS) subject classification. 93

1. Introduction.

Although considerable effort has been devoted to frequency-domain robust-control design methods [1]-[10], there remain open questions concerning stability with respect to real-valued, structured plant parameter variations [11]-[13]. Specifically, it is shown in [11]-[13] that classical gain and phase margin specifications can be satisfied, while sensitivity to structured plant parameter variations can be arbitrarily large. From a time-domain point of view, the parametric robustness problem has been widely studied using Lyapunov's second method as the principal technique [14]-[28].

In this paper we develop an approach to control design that provides sufficient conditions for robust stability and performance over a prescribed range of time-varying structured plant parameter variations by means of a feedback law in the form of a fixed-order (i.e., reduced- or full-order) dynamic (strictly proper) compensator. The approach is based upon the merging of two techniques, namely, the guaranteed cost control approach to robust performance [14], [17] and the optimal projection approach to quadratically optimal fixed-order dynamic compensation [29], [30]. One of our goals is to obtain robust output-feedback compensators rather than full-state-feedback controllers. Also, since we wish to account for real-time computational burden in implementating the controller, we impose a constraint on the dimension (i.e., order) of the dynamic compensator. This approach thus generalizes standard LQG theory, which yields full-order output-feedback controllers for systems without parameter uncertainty. We note that our approach is constructive in the sense that, upon satisfaction of the sufficient conditions, the feedback gains required for implementing the robust feedback controller are explicitly synthesized. Existential issues are also addressed

herein, although to a lesser extent. For further background see [29], [30]. For extensions to nonstrictly proper controllers see [31], and for extensions to H_∞ control see [32].

To explain the rationale behind the development we briefly describe the main elements of the approach. The following discussion is intended to be descriptive; precise conditions appear in the main body of the paper.

1.1. Robust Stability Problem. For a nominal linear time-invariant (A, B, C) system we consider deterministically modeled bounded but otherwise unknown Lebesgue measurable time-varying parameter variations of the form

$$A+\sum_{i=1}^{p}\hat{\sigma}_i(t)A_i, \quad B+\sum_{i=1}^{p}\hat{\sigma}_i(t)B_i, \quad C+\sum_{i=1}^{p}\hat{\sigma}_i(t)C_i. \tag{1.1}$$

The nominal matrices A, B, C and the perturbation matrices A_i, B_i, C_i denoting the structure of the parametric uncertainty are assumed known, while the time-varying uncertain parameters $\hat{\sigma}_i(t)$ are assumed only to satisfy the bounds

$$|\hat{\sigma}_i(t)| \leqq \delta_i, \quad i=1,\cdots,p, \quad t\in[0,\infty). \tag{1.2}$$

The form of (1.1) permits an arbitrary number of uncertain parameters with arbitrary linear structure. Although we do not require matching conditions as in [21], the linear structure of (1.1) is more restrictive than the functional form $A(q(t))$ used in [21]. It is this structure that we exploit to obtain sufficiency conditions. Note also that the representation (1.1) is independent of state space basis, since replacing A by SAS^{-1} corresponds to replacing A_i by SA_iS^{-1}. As will be seen, our robustness bounds and optimality conditions are also basis independent. Also, scaling techniques [6], [7] will not play a role here. Finally, we note that because of the time-varying nature of the uncertain perturbations (1.1) it is virtually impossible to determine the *actual* stability region of a given design by means of empirical methods.

1.2. Quadratic Lyapunov function. As a sufficient condition for characterizing solutions of the Robust Stability Problem we consider a closed-loop quadratic Lyapunov function $V(\tilde{x})=\tilde{x}^T\mathcal{P}\tilde{x}$, where the matrix $\mathcal{P}$ satisfies

$$0=\tilde{A}^T\mathcal{P}+\mathcal{P}\tilde{A}+\Omega(\mathcal{P}, B_c, C_c) \tag{1.3}$$

and the function Ω is a bound satisfying

$$\sum_{i=1}^{p}\sigma_i(\tilde{A}_i^T\mathcal{P}+\mathcal{P}\tilde{A}_i)<\Omega(\mathcal{P}, B_c, C_c) \tag{1.4}$$

over the parameter range

$$|\sigma_i| \leqq \delta_i, \qquad i=1,\cdots,p. \tag{1.5}$$

Note that the constant σ_i in (1.4) and (1.5) plays the role of $\hat{\sigma}_i(t)$, i.e., t is "frozen" in (1.4) and (1.5). In (1.3) and (1.4), $\tilde{A}$ and $\tilde{A}_i$ denote the closed-loop dynamics and closed-loop parameter-uncertainty matrices given by

$$\tilde{A}=\begin{bmatrix} A & BC_c \\ B_cC & A_c \end{bmatrix}, \qquad \tilde{A}_i=\begin{bmatrix} A_i & B_iC_c \\ B_cC_i & 0 \end{bmatrix}. \tag{1.6}$$

Since $\tilde{A}_i$ is independent of A_c, Ω depends only on B_c and C_c. As discussed later in this section, (1.4) is automatically satisfied by construction of the function Ω. Furthermore, the existence of a solution $\mathcal{P}$ to (1.3) need not be verified directly, but rather is a result of numerically solving the optimality conditions discussed below.

1.3. Robust Performance Problem. In addition to the *deterministic* parameter uncertainty model (1.1), (1.2), the Robust Performance Problem includes *stochastic* plant disturbances and measurement noise with performance measured by means of the quadratic functional

$$\tilde{J}(t) = x^T(t)R_1x(t) + 2x^T(t)R_{12}u(t) + u^T(t)R_2u(t). \tag{1.7}$$

To obtain a steady-state design problem we (1) average $\tilde{J}(t)$ over the disturbance and measurement noise statistics; (2) pass to the steady-state limit; and (3) maximize over the class of parameter uncertainties. Hence the performance of a given controller (A_c, B_c, C_c) is given by

$$J(A_c, B_c, C_c) = \sup_{\tilde{\sigma}(\cdot)} \limsup_{t\to\infty} \mathbb{E}[\tilde{J}(t)]. \tag{1.8}$$

The use of "lim sup" is a technicality that accounts for cases in which the steady-state limit may not exist. Note that although (1.8) is an averaging criterion over the disturbances as in LQG theory, it is also a worst-case measure over the uncertain parameters. Thus (1.8) is a *hybrid* criterion in the sense that is *stochastic* in the disturbance space (i.e., external uncertainties) and *deterministic* in the parameter space (i.e., internal uncertainties). By "internal uncertainties" we have in mind quantities such as mass, damping, or stiffness; by "external uncertainties" we are referring to phenomena such as turbulent flow for which only power spectrum statistics may be available. No claim is made, however, with regard to the universal validity of such a mathematical uncertainty model. In particular applications, uncertainty models that are either wholly deterministic or wholly stochastic may be more appropriate. In general, our setting appears to be consistent with the available literature (see [1]-[28]).

1.4. Performance bound. To obtain a tractable design problem, we use the matrix $\mathcal{P}$ to bound the performance of each controller solving the Robust Stability Problem. Specifically, by assuming in addition to (1.4) that

$$\sum_{i=1}^{p} \sigma_i(\tilde{A}_i^T\mathcal{P} + \mathcal{P}\tilde{A}_i) + \tilde{R} \leqq \Omega(\mathcal{P}, B_c, C_c), \tag{1.9}$$

it follows that

$$J(A_c, B_c, C_c) \leqq \operatorname{tr} \mathcal{P}\tilde{V}. \tag{1.10}$$

In (1.9) and (1.10) $\tilde{R}$ and $\tilde{V}$ denote closed-loop weighting and disturbance intensity matrices. The idea of bounding the performance by means of a Lyapunov function is the basis for guaranteed cost control [14], [17].[1]

1.5. Construction of the Lyapunov function. So far the Lyapunov function has only been abstractly characterized by means of (1.3) and (1.4). To obtain a useful design theory Ω is now given a concrete form. Specifically, to satisfy (1.9) it is assumed that

$$\Omega(\mathcal{P}, B_c, C_c) = \sum_{i=1}^{p} \Lambda_i(\mathcal{P}, B_c, C_c) + \tilde{R}, \tag{1.11}$$

where, for each i, the Λ_i are chosen such that

$$\sigma_i(\tilde{A}_i^T\mathcal{P} + \mathcal{P}\tilde{A}_i) \leqq \Lambda_i(\mathcal{P}, B_c, C_c), \qquad |\sigma_i| \leqq \delta_i. \tag{1.12}$$

[1] It is also interesting to note that in Hamilton-Jacobi-Bellman sufficiency theory the performance functional is expressed in terms of a value function that also serves as a Lyapunov function for the closed-loop system. These connections will be explored in a future paper.

Note that (1.12) implies that (1.4) holds with Ω given by (1.11). Since $\tilde{A}_i$ depends on B_c and C_c, the bound Λ_i will be constructed to be *gain-invariant*, that is, so that (1.12) holds for *all* B_c and C_c. Thus no difficulty will arise from the fact that the controller gains are yet to be determined by optimality considerations.

It should be noted that the bounding in (1.12) is defined in the sense of the cone of nonnegative definite matrices. Since this is only a partial ordering and not a total ordering, a least upper bound (i.e., a "sharpest" bound) does not exist in general and the conservatism of the inequality in (1.12) cannot be quantified by a scalar measure. Hence, Λ_i satisfying (1.12) is not necessarily unique and two particular choices of Λ_i are developed in this paper. Since we shall utilize first-order necessary conditions for optimality, we confine our consideration to bounds that are differentiable. The first choice of Λ_i satisfying (1.12) is given by the linear (in $\mathscr{P}$) function

$$\Lambda_i(\mathscr{P}, B_c, C_c) = \delta_i(\alpha_i \mathscr{P} + \alpha_i^{-1} \tilde{A}_i^T \mathscr{P} \tilde{A}_i), \tag{1.13}$$

where α_i is an arbitrary positive number. As shown in [33], the bound (1.13) can be viewed as arising from a stochastic optimal control problem with exponentially weighted cost and state-, control- and measurement-dependent white noise. The stochastic multiplicative white noise model serves only as an *interpretation*, however, and need not be viewed as having physical significance. A similar bound is used in [28].

The second choice for Λ_i satisfying (1.12) is given by the quadratic (in $\mathscr{P}$) function

$$\Lambda_i(\mathscr{P}, B_c, C_c) = \delta_i(\tilde{E}_i^T \tilde{E}_i + \mathscr{P} \tilde{D}_i \tilde{D}_i^T \mathscr{P}), \tag{1.14}$$

where $\tilde{D}_i$, $\tilde{E}_i$ denote an arbitrary factorization of $\tilde{A}_i$ of the form

$$\tilde{A}_i = \tilde{D}_i \tilde{E}_i. \tag{1.15}$$

The bound (1.14) was used in [26] for full-state feedback with rank 1 uncertainties. Note that using congruence transformations shows that both bounds (1.13) and (1.14) are basis independent; that is, replacing $\tilde{A}_i$ by $\tilde{S}\tilde{A}_i\tilde{S}^{-1}$ leads to replacing $\mathscr{P}$ by $\tilde{S}^{-T}\mathscr{P}\tilde{S}^{-1}$.

1.6. Auxiliary Minimization Problem. The next step in our development for robust performance is the following. Inasmuch as the performance of a robustly stabilizing controller is bounded via (1.10) over the given range of parameter variations, it is desirable to minimize the upper bound

$$\mathscr{J}(\mathscr{P}, A_c, B_c, C_c) \triangleq \operatorname{tr} \mathscr{P} \tilde{V} \tag{1.16}$$

subject to the constraint (1.3). This is referred to as the Auxiliary Minimization Problem. For a given choice (1.13) or (1.14) of Λ_i for each i, a solution of the Auxiliary Minimization Problem provides a controller whose steady-state performance is guaranteed to remain below the bound (1.16) over the range of parameter variations, hence guaranteeing robust performance. Since the Auxiliary Minimization Problem is a smooth mathematical programming problem, a minimum always exists on compact sets. To actually characterize extremals of the Auxiliary Minimization Problem we proceed by deriving first-order necessary conditions. Because these necessary conditions are derived for the Auxiliary Minimization Problem, they effectively serve as sufficient conditions for robustness in the original problem.

It should be noted that the guaranteed cost control approach developed in [14] does not permit this line of development since Λ_i is given by

$$\Lambda_i(\mathscr{P}, B_c, C_c) = \delta_i |\tilde{A}_i^T \mathscr{P} + \mathscr{P} \tilde{A}_i|, \tag{1.17}$$

where $|\cdot|$ denotes the matrix obtained by replacing each eigenvalue by its absolute value. Since this bound is not differentiable with respect to the controller gains, first-order necessary conditions cannot be used.

1.7. The optimality conditions: full-order case. For the full-order case, i.e., when the order of the controller is equal to the order of the plant, the first-order necessary conditions can be derived in a form that is a direct generalization of the pair of separated Riccati equations of LQG theory. Specifically, the necessary conditions comprise a coupled system of four algebraic matrix equations including a pair of modified Riccati equations and a pair of Lyapunov equations. For plant models involving multiplicative white noise these equations have been studied in [34]–[36]. This form of the equations thus essentially corresponds to choosing bound (1.13).

1.8. The optimality conditions: reduced-order case. For design flexibility we also consider controllers of arbitrary reduced dimension. For the linear-quadratic problem without parameter uncertainty, the formulation of the necessary conditions given in [29] provides a generalization of LQG theory. Specifically, the optimal gains are characterized by a system of algebraic matrix equations consisting of a pair of modified Riccati equations and a pair of modified Lyapunov equations coupled by an oblique projection. When the order of the controller is equal to the order of the plant, the projection becomes the identity and the standard LQG result is recovered.

The outcome of the development above is a set of algebraic matrix equations that correspond to the necessary conditions for the Auxiliary Minimization Problem and hence to sufficient conditions for robust stability and performance. These necessary conditions characterize full- or reduced-order controllers with either choice of bounds (1.13) and (1.14) for each uncertain parameter. For control-system design, these equations can be used as follows. If a solution to the necessary conditions is obtained computationally and if certain definiteness conditions hold, *then* the explicitly synthesized controller (1) solves the Robust Stability Problem and (2) is guaranteed to provide robust performance bounded by $\operatorname{tr} \mathcal{P}\tilde{V}$ over the stipulated uncertainty range.

The applicability of these results is, of course, limited to plants that are nominally stabilizable via controllers of the given order. Indeed, in this case it has been shown [37] via topological degree theory that the optimality conditions for the case $\delta_i = 0$, $i = 1, \cdots, p$, possess at least one stabilizing solution. For the parameter uncertainty problem, i.e., $\delta_i > 0$, it follows from continuity properties that a solution also exists for sufficiently small δ_i. The *actual* range of uncertainty that can be stabilized and the tightness of the performance bound depend on the *conservatism* of our bounds. As will be seen from a numerical example, our bounds are not generally sharp. This is not unexpected, however, due to both the sense of the partial ordering employed in (1.12) and the fact that our choice of gain-invariant bounds permits a one-step, *noniterative* synthesis (rather than analysis) procedure. It should be noted that necessary and sufficient conditions for robust analysis of a block-structured class of uncertainties are obtainable using the μ-function [6]. This block structure, however, does not appear to include either the linear uncertainty model (1.1) or the matched uncertainty model of [21] as special cases.

In the present paper we present results of an illustrative numerical study for a well-known example used in [2] to demonstrate the lack of gain margin for LQG controllers. This type of uncertainty is a special case of (1.1) obtained by taking $p = m$ and defining B_i to be the matrix whose ith column is the same as the ith column of B, and zero otherwise. To obtain full-order, robustified controllers exhibiting performance/robustness tradeoffs, we use bound (1.13) for several values of δ_i. To obtain

these numerical results we used a straightforward iterative algorithm that requires only an LQG-type software package. The homotopy algorithm of [37] with appropriate extensions can also be used. Further descriptions of related algorithms and numerical results can be found in [38]-[40].

The development herein is self-contained, with the exception that the detailed derivation of the optimality conditions has been omitted. In specialized cases the derivation has been given previously. For the case of bound (1.13) only, a derivation using Kronecker products appears in [36]. Also, a derivation without parameter uncertainties has been given in [29] using Lagrange multipliers. Overall, the derivation involves considerable matrix manipulation. Since the detailed derivation does not appear to warrant the required space, we give an outline of the proof to assist the sufficiently motivated reader in reconstructing the details.

2. Notation and definitions. (Note that all matrices have real entries.)

$\mathbb{R}$, $\mathbb{R}^{r\times s}$, $\mathbb{R}^r$, $\mathbb{E}$	real numbers, $r\times s$ real matrices, $\mathbb{R}^{r\times 1}$, expectation
$\|\cdot\|$	Euclidean vector norm
I_r, $0_{r\times s}$, 0_r	$r\times r$ identity matrix, $r\times s$ zero matrix, $0_{r\times r}$
$(\,)^T$, $(\,)^{-1}$, $(\,)^{-T}$	transpose, inverse, inverse transpose
tr	trace
$\oplus$, $\otimes$	Kronecker sum, Kronecker product [41]
$\mathbb{S}^r$	$r\times r$ symmetric matrices
$\mathbb{N}^r$	$r\times r$ symmetric nonnegative-definite matrices
$\mathbb{P}^r$	$r\times r$ symmetric positive-definite matrices
$Z_1 \geqq Z_2$	$Z_1 - Z_2 \in \mathbb{N}^r$, $Z_1, Z_2 \in \mathbb{S}^r$
$Z_1 > Z_2$	$Z_1 - Z_2 \in \mathbb{P}^r$, $Z_1, Z_2 \in \mathbb{S}^r$
asymptotically stable matrix	matrix with eigenvalues in open left half-plane
n, m, l, p, n_c, n_i, m_i	positive integers, $i\in\{1,\cdots,p\}$
$\tilde{n}$, $\tilde{n}_i$	$n+n_c$, n_i+m_i, $i\in\{1,\cdots,p\}$
x, u, y, x_c	n, m, l, n_c-dimensional vectors
A, A_i; B, B_i; C, C_i	$n\times n$ matrices, $n\times m$ matrices, $l\times n$ matrices, $i\in\{1,\cdots,p\}$
A_c, B_c, C_c	$n_c\times n_c$, $n_c\times l$, $m\times n_c$ matrices
$\tilde{A}$, $\tilde{A}_i$	$\begin{bmatrix} A & BC_c \\ B_cC & A_c \end{bmatrix}$, $\begin{bmatrix} A_i & B_iC_c \\ B_cC_i & 0 \end{bmatrix}$, $i\in\{1,\cdots,p\}$
δ_i	positive number, $i\in\{1,\cdots,p\}$
Δ	$[-\delta_1,\delta_1]\times\cdots\times[-\delta_p,\delta_p]$
σ_i	real number, $i\in\{1,\cdots,p\}$
σ	$(\sigma_1,\cdots,\sigma_p)$
$\hat{\sigma}_i(\cdot)$	Lebesgue measurable function on $[0,\infty)$, $i\in\{1,\cdots,p\}$
$\hat{\sigma}(\cdot)$	$(\hat{\sigma}_1(\cdot),\cdots,\hat{\sigma}_p(\cdot))$
$L_\infty([0,\infty),\Delta)$	Lebesgue measurable functions on $[0,\infty)$ with values in Δ
α_i	positive number, $i\in\{1,\cdots,p\}$
D_i, E_i, H_i, K_i	$n\times n_i$, $n_i\times n$, $n\times m_i$, $m_i\times m$ matrices, $i\in\{1,\cdots,p\}$
$\tilde{D}_i$, $\tilde{E}_i$	$\tilde{n}\times\tilde{n}_i$, $\tilde{n}_i\times\tilde{n}$ matrices, $i\in\{1,\cdots,p\}$
$\sum'$, $\sum''$	see § 6
R_1	state weighting matrix in $\mathbb{N}^n$

R_2	control weighting matrix in $\mathbb{P}^m$
R_{12}	$n \times m$ cross weighting matrix such that $R_1 - R_{12}R_2^{-1}R_{12}^T \geqq 0$
$\tilde{R}$	$\begin{bmatrix} R_1 & R_{12}C_c \\ C_c^T R_{12}^T & C_c^T R_2 C_c \end{bmatrix}$
$w_1(\cdot)$	n-dimensional white noise
$w_2(\cdot)$	l-dimensional white noise
V_1	intensity of $w_1(\cdot)$ in $\mathbb{N}^n$
V_2	intensity of $w_2(\cdot)$ in $\mathbb{P}^l$
V_{12}	$n \times l$ cross-intensity of $w_1(\cdot)$, $w_2(\cdot)$
$\tilde{V}$	$\begin{bmatrix} V_1 & V_{12}B_c^T \\ B_c V_{12}^T & B_c V_2 B_c^T \end{bmatrix}$

3. Robust Stability and Robust Performance Problems. In this section we state the Robust Stability Problem and Robust Performance Problem along with related notation for later use.

3.1. Robust Stability Problem. For fixed $n_c \leqq n$, determine $(A_c, B_c, C_c) \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$ such that the closed-loop system consisting of the nth-order controlled plant

$$\dot{x}(t) = \left(A + \sum_{i=1}^{p} \hat{\sigma}_i(t) A_i\right) x(t) + \left(B + \sum_{i=1}^{p} \hat{\sigma}_i(t) B_i\right) u(t) \quad \text{a.a. } t \in [0, \infty), \tag{3.1}$$

measurements

$$y(t) = \left(C + \sum_{i=1}^{p} \hat{\sigma}_i(t) C_i\right) x(t), \tag{3.2}$$

and n_cth-order dynamic compensator

$$\dot{x}_c(t) = A_c x_c(t) + B_c y(t), \tag{3.3}$$

$$u(t) = C_c x_c(t) \tag{3.4}$$

are asymptotically stable[2] for all $\hat{\sigma}(\cdot) \in L_\infty([0, \infty), \Delta)$.

3.2. Robust Performance Problem. For fixed $n_c \leqq n$, determine $(A_c, B_c, C_c) \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$ such that, for the closed-loop system consisting of the nth-order controlled and disturbed plant

$$\dot{x}(t) = \left(A + \sum_{i=1}^{p} \hat{\sigma}_i(t) A_i\right) x(t) + \left(B + \sum_{i=1}^{p} \hat{\sigma}_i(t) B_i\right) u(t) + w_1(t) \quad \text{a.a. } t \in [0, \infty), \tag{3.5}$$

noisy measurements

$$y(t) = \left(C + \sum_{i=1}^{p} \hat{\sigma}_i(t) C_i\right) x(t) + w_2(t), \tag{3.6}$$

and n_cth-order dynamic compensator (3.3), (3.4), the performance criterion

$$J(A_c, B_c, C_c) \triangleq \sup_{\hat{\sigma}(\cdot) \in L_\infty([0,\infty),\Delta)} \limsup_{t \to \infty} \mathbb{E}[x^T(t) R_1 x(t) + 2x^T(t) R_{12} u(t) + u^T(t) R_2 u(t)] \tag{3.7}$$

is minimized.

[2] Asymptotic stability for a nonautonomous system is defined in the standard way (see, e.g., [42]).

For each controller (A_c, B_c, C_c) and parameter variation $\hat{\sigma}(\cdot) \in L_\infty([0, \infty), \Delta)$ the undisturbed closed-loop system (3.1)-(3.4) is given by

$$\dot{\tilde{x}}(t) = \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right) \tilde{x}(t) \quad \text{a.a. } t \in [0, \infty), \tag{3.8}$$

while the disturbed closed-loop system (3.3)-(3.6) is

$$\dot{\tilde{x}}(t) = \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right) \tilde{x}(t) + \tilde{w}(t) \quad \text{a.a. } t \in [0, \infty). \tag{3.9}$$

Also (see, e.g., [43, p. 194]), let $\tilde{\Phi} : [0, \infty) \to \mathbb{R}^{\tilde{n} \times \tilde{n}}$ be the unique absolutely continuous solution to

$$\dot{\tilde{\Phi}}(t) = \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right) \tilde{\Phi}(t) \quad \text{a.a. } t \in [0, \infty), \tag{3.10}$$

$$\tilde{\Phi}(0) = I_{\tilde{n}}, \tag{3.11}$$

and recall that $\tilde{\Phi}^{-1}(\cdot)$ satisfies

$$\frac{d}{dt} \tilde{\Phi}^{-1}(t) = -\tilde{\Phi}^{-1}(t) \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right) \quad \text{a.a. } t \in [0, \infty). \tag{3.12}$$

4. Sufficient conditions for robust stability and performance. For robust stability we characterize quadratic Lyapunov functions for the closed-loop system.

THEOREM 4.1. *Let* $\Omega : \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c} \to \mathbb{S}^{\tilde{n}}$ *satisfy*

$$\begin{aligned} &\sum_{i=1}^{p} \sigma_i (\tilde{A}_i^T \mathcal{P} + \mathcal{P} \tilde{A}_i) < \Omega(\mathcal{P}, B_c, C_c), \qquad \sigma \in \Delta, \\ &(\mathcal{P}, B_c, C_c) \in \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}. \end{aligned} \tag{4.1}$$

If, for some $(A_c, B_c, C_c) \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$, *there exists* $\mathcal{P} \in \mathbb{P}^{\tilde{n}}$ *satisfying*

$$0 = \tilde{A}^T \mathcal{P} + \mathcal{P} \tilde{A} + \Omega(\mathcal{P}, B_c, C_c), \tag{4.2}$$

then (A_c, B_c, C_c) *solves the Robust Stability Problem.*

Proof. Define the Lyapunov function

$$V(\tilde{x}) \triangleq \tilde{x}^T \mathcal{P} \tilde{x}, \qquad \tilde{x} \in \mathbb{R}^{\tilde{n}}.$$

For almost all $t \in [0, \infty)$ and $\tilde{x}(t)$ satisfying (3.8), it follows from (4.2) that

$$\begin{aligned} \dot{V}(\tilde{x}(t)) &= \dot{\tilde{x}}^T(t) \mathcal{P} \tilde{x}(t) + \tilde{x}^T(t) \mathcal{P} \dot{\tilde{x}}(t) \\ &= \tilde{x}^T(t) \left[\left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right)^T \mathcal{P} + \mathcal{P} \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t) \tilde{A}_i \right) \right] \tilde{x}(t) \\ &= \tilde{x}^T(t) \left[\sum_{i=1}^{p} \hat{\sigma}_i(t) (\tilde{A}_i^T \mathcal{P} + \mathcal{P} \tilde{A}_i) - \Omega(\mathcal{P}, B_c, C_c) \right] \tilde{x}(t). \end{aligned}$$

Since $\hat{\sigma}(t) \in \Delta$, almost all $t \in [0, \infty)$, it follows from (4.1) that there exists $\gamma > 0$ such that $\dot{V}(\tilde{x}(t)) \leqq -\gamma \|\tilde{x}(t)\|^2$, almost all $t \in [0, \infty)$. □

Remark 4.1. If (A_c, B_c, C_c) solves the Robust Stability Problem, then

$$\lim_{t \to \infty} \tilde{\Phi}(t) = 0, \qquad \hat{\sigma}(\cdot) \in L_\infty([0, \infty), \Delta). \tag{4.3}$$

Remark 4.2. As will be seen, the bound (4.1) will be guaranteed for all $\mathcal{P}$, B_c, C_c by suitable construction of the function Ω. In addition, the existence of a solution $\mathcal{P}$ to (4.2) need not be verified in practice. Rather, (4.2) is a result of numerically solving the necessary conditions for the Auxiliary Minimization Problem given in Theorem 6.1.

For the Robust Performance Problem the cost can be expressed in terms of the closed-loop second-moment matrix.

PROPOSITION 4.1. *For* $(A_c, B_c, C_c) \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$ *and* $\hat{\sigma}(\cdot) \in L_\infty([0, \infty), \Delta)$ *the second-moment matrix*

$$\tilde{Q}(t) \triangleq \mathbb{E}[\tilde{x}(t)\tilde{x}^T(t)], \qquad t \in [0, \infty), \tag{4.4}$$

satisfies

$$\dot{\tilde{Q}}(t) = \left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t)\tilde{A}_i\right)\tilde{Q}(t) + \tilde{Q}(t)\left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t)\tilde{A}_i\right)^T + \tilde{V} \quad \text{a.a. } t \in [0, \infty), \tag{4.5}$$

or, equivalently,

$$\tilde{Q}(t) = \tilde{\Phi}(t)\tilde{Q}(0)\tilde{\Phi}^T(t) + \int_0^t \tilde{\Phi}(t)\tilde{\Phi}^{-1}(s)\tilde{V}\tilde{\Phi}^{-T}(s)\tilde{\Phi}^T(t)\, ds, \qquad t \in [0, \infty). \tag{4.6}$$

Furthermore,

$$J(A_c, B_c, C_c) = \sup_{\hat{\sigma}(\cdot) \in L_\infty([0,\infty),\Delta)} \limsup_{t \to \infty} \operatorname{tr} \tilde{Q}(t)\tilde{R}, \tag{4.7}$$

or, equivalently,

$$\begin{aligned} J(A_c, B_c, C_c) \triangleq \sup_{\hat{\sigma}(\cdot) \in L_\infty([0,\infty),\Delta)} \limsup_{t \to \infty} \operatorname{tr} \Bigg[& \tilde{\Phi}(t)\tilde{Q}(0)\tilde{\Phi}^T(t)\tilde{R} \\ & + \int_0^t \tilde{\Phi}(t)\tilde{\Phi}^{-1}(s)\tilde{V}\tilde{\Phi}^{-T}(s)\tilde{\Phi}^T(t)\, ds\, \tilde{R} \Bigg]. \end{aligned} \tag{4.8}$$

Proof. The second-moment equation (4.5) is a direct consequence of the Itô differential rule (see [44, p. 142]), while (4.6) follows by direct verification. Finally, (4.7) is immediate. □

We now obtain an upper bound for J in terms of the matrix $\mathscr{P}$. The following lemma is required.

LEMMA 4.1. *Let* $\Omega : \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c} \to \mathbb{S}^{\tilde{n}}$ *and* $(A_c, B_c, C_c) \in \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$ *be given. Then* $\mathscr{P} \in \mathbb{P}^{\tilde{n}}$ *satisfies* (4.2) *if and only if* $\mathscr{P}$ *satisfies*

$$\begin{aligned} \mathscr{P} = \tilde{\Phi}^T(t)\mathscr{P}\tilde{\Phi}(t) + \int_0^t \tilde{\Phi}^T(t)\tilde{\Phi}^{-T}(s) \\ \cdot \left[\Omega(\mathscr{P}, B_c, C_c) - \sum_{i=1}^{p} \hat{\sigma}_i(t)(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i)\right]\tilde{\Phi}^{-1}(s)\tilde{\Phi}(t)\, ds, \\ \hat{\sigma}(\cdot) \in L_\infty([0, \infty), \Delta), \qquad t \in [0, \infty). \end{aligned} \tag{4.9}$$

Proof. Suppose $\mathscr{P}$ satisfies (4.2). Then for $t \in [0, \infty)$,

$$\begin{aligned} 0 &= \tilde{\Phi}^{-T}(t)\left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t)\tilde{A}_i\right)^T \mathscr{P}\tilde{\Phi}^{-1}(t) + \tilde{\Phi}^{-T}(t)\mathscr{P}\left(\tilde{A} + \sum_{i=1}^{p} \hat{\sigma}_i(t)\tilde{A}_i\right)\tilde{\Phi}^{-1}(t) \\ &\quad + \tilde{\Phi}^{-T}(t)\left[\Omega(\mathscr{P}, B_c, C_c) - \sum_{i=1}^{p} \hat{\sigma}_i(t)(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i)\right]\tilde{\Phi}^{-1}(t) \\ &= -\frac{d}{dt}\left[\tilde{\Phi}^{-T}(t)\mathscr{P}\tilde{\Phi}^{-1}(t)\right] + \tilde{\Phi}^{-T}(t)\left[\Omega(\mathscr{P}, B_c, C_c) - \sum_{i=1}^{p} \hat{\sigma}_i(t)(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i)\right]\tilde{\Phi}^{-1}(t), \end{aligned}$$

which yields

$$\begin{aligned} 0 = -\tilde{\Phi}^{-T}(t)\mathscr{P}\tilde{\Phi}^{-1}(t) + \mathscr{P} \\ + \int_0^t \tilde{\Phi}^{-T}(s)\left[\Omega(\mathscr{P}, B_c, C_c) - \sum_{i=1}^{p} \hat{\sigma}_i(s)(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i)\right]\tilde{\Phi}^{-1}(s)\, ds. \end{aligned}$$

Thus (4.9) is satisfied. Conversely, suppose $\mathscr{P}$ satisfies (4.9). Differentiating with respect to t using Leibniz's rule yields

$$
\begin{aligned}
0 &= \Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)^T\tilde{\Phi}^T(t)\mathscr{P}\tilde{\Phi}(t)+\tilde{\Phi}^T(t)\mathscr{P}\tilde{\Phi}(t)\Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)\\
&\quad+\Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)^T\int_0^t\tilde{\Phi}^T(t)\tilde{\Phi}^{-T}(s)\\
&\quad\cdot\Big[\Omega(\mathscr{P},B_c,C_c)-\sum_{i=1}^{p}\hat{\sigma}_i(s)(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)\Big]\tilde{\Phi}^{-1}(s)\tilde{\Phi}(t)\,ds\\
&\quad+\int_0^t\tilde{\Phi}^T(t)\tilde{\Phi}^{-T}(s)\Big[\Omega(\mathscr{P},B_c,C_c)-\sum_{i=1}^{p}\hat{\sigma}_i(s)(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)\Big]\\
&\quad\cdot\tilde{\Phi}^{-1}(s)\tilde{\Phi}(t)\,ds\Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)\\
&\quad+\Omega(\mathscr{P},B_c,C_c)-\sum_{i=1}^{p}\hat{\sigma}_i(t)(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)\\
&=\Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)^T\mathscr{P}+\mathscr{P}\Big(\tilde{A}+\sum_{i=1}^{p}\hat{\sigma}_i(t)\tilde{A}_i\Big)+\Omega(\mathscr{P},B_c,C_c)-\sum_{i=1}^{p}\hat{\sigma}_i(t)(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)\\
&=\tilde{A}^T\mathscr{P}+\mathscr{P}\tilde{A}+\Omega(\mathscr{P},B_c,C_c).
\end{aligned}
$$

Hence (4.2) is satisfied. □

Remark 4.3. Note the identity

$$
\begin{aligned}
&\operatorname{tr}\int_0^t\tilde{\Phi}(t)\tilde{\Phi}^{-1}(s)\tilde{V}\tilde{\Phi}^{-T}(s)\tilde{\Phi}^T(t)\,ds\,\tilde{R}=\operatorname{tr}\int_0^t\tilde{\Phi}^T(t)\tilde{\Phi}^{-T}(s)\tilde{R}\tilde{\Phi}^{-1}(s)\tilde{\Phi}(t)\,ds\,\tilde{V},\\
&(A_c,B_c,C_c)\in\mathbb{R}^{n_c\times n_c}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c},\quad\hat{\sigma}(\cdot)\in L_\infty([0,\infty),\Delta),\quad t\in[0,\infty).
\end{aligned}
\tag{4.10}
$$

We are now in a position to bound the cost J by means of the matrix $\mathscr{P}$.

THEOREM 4.2. *Let* $\Omega:\mathbb{P}^{\tilde{n}}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c}\to\mathbb{S}^{\tilde{n}}$ *satisfy* (4.1) *and*

$$
\begin{aligned}
&\sum_{i=1}^{p}\sigma_i(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)+\tilde{R}\leqq\Omega(\mathscr{P},B_c,C_c),\qquad\sigma\in\Delta,\\
&(\mathscr{P},B_c,C_c)\in\mathbb{P}^{\tilde{n}}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c}.
\end{aligned}
\tag{4.11}
$$

If, for some $(A_c,B_c,C_c)\in\mathbb{R}^{n_c\times n_c}\times\mathbb{R}^{n_c\times l}\times\mathbb{R}^{m\times n_c}$, *there exists* $\mathscr{P}\in\mathbb{P}^{\tilde{n}}$ *satisfying* (4.2), *then*

$$
J(A_c,B_c,C_c)\leqq\operatorname{tr}\mathscr{P}\tilde{V}.
\tag{4.12}
$$

Proof. From (4.8)–(4.10) and (4.3) it follows that

$$
\begin{aligned}
&J(A_c,B_c,C_c)\\
&=\sup_{\hat{\sigma}(\cdot)\in L_\infty([0,\infty),\Delta)}\limsup_{t\to\infty}\operatorname{tr}\Big\{\tilde{\Phi}(t)\tilde{Q}(0)\tilde{\Phi}^T(t)\tilde{R}+\mathscr{P}\tilde{V}-\tilde{\Phi}^T(t)\mathscr{P}\tilde{\Phi}(t)\tilde{V}\\
&\quad-\int_0^t\tilde{\Phi}^T(t)\tilde{\Phi}^{-T}(s)\Big[\Omega(\mathscr{P},B_c,C_c)-\tilde{R}-\sum_{i=1}^{p}\hat{\sigma}_i(s)(\tilde{A}_i^T\mathscr{P}+\mathscr{P}\tilde{A}_i)\Big]\tilde{\Phi}^{-1}(s)\tilde{\Phi}(t)\,ds\,\tilde{V}\Big\}\\
&\leqq\sup_{\hat{\sigma}(\cdot)\in L_\infty([0,\infty),\Delta)}\limsup_{t\to\infty}\operatorname{tr}[\tilde{\Phi}(t)\tilde{Q}(0)\tilde{\Phi}^T(t)\tilde{R}+\mathscr{P}\tilde{V}]\\
&=\operatorname{tr}\mathscr{P}\tilde{V}.
\end{aligned}
$$

□

Remark 4.4. Note that since $\tilde{R} \geqq 0$, (4.11) implies

$$\sum_{i=1}^{p} \sigma_i(\tilde{A}_i^T \mathscr{P} + \mathscr{P}\tilde{A}_i) \leqq \Omega(\mathscr{P}, B_c, C_c), \qquad \sigma \in \Delta, \tag{4.13}$$

which is a weak form of (4.1). If $\tilde{R} > 0$ then (4.11) implies (4.1). This implication is not surprising since (4.11) implies robust performance while (4.1) implies robust stability.

5. Choice of bounds. To satisfy (4.11), $\Omega(\cdot, \cdot, \cdot)$ is chosen to be of the form

$$\Omega(\mathscr{P}, B_c, C_c) = \sum_{i=1}^{p} \Lambda_i(\mathscr{P}, B_c, C_c) + \tilde{R}, \tag{5.1}$$

where, for each $i = 1, \cdots, p$, $\Lambda_i : \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c} \to \mathbb{S}^{\tilde{n}}$ satisfies

$$\begin{aligned} &\sigma_i(\tilde{A}_i^T \mathscr{P} + \mathscr{P}\tilde{A}_i) \leqq \Lambda_i(\mathscr{P}, B_c, C_c), \qquad \sigma_i \in [-\delta_i, \delta_i], \\ &(\mathscr{P}, B_c, C_c) \in \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}. \end{aligned} \tag{5.2}$$

Two distinct choices for the bound Λ_i are considered. As we pointed out in § 1, the first choice corresponds to a right shift/multiplicative white noise model [33], while the second bound generalizes results found in [26].

PROPOSITION 5.1. *For all $\alpha_i > 0$ the function*

$$\Lambda_i(\mathscr{P}, B_c, C_c) = \delta_i(\alpha_i \mathscr{P} + \alpha_i^{-1} \tilde{A}_i^T \mathscr{P} \tilde{A}_i) \tag{5.3}$$

satisfies (5.2).

Proof. Note that

$$\begin{aligned} 0 &\leqq [\sigma_i(\alpha_i/\delta_i)^{1/2} I_{\tilde{n}} - (\delta_i/\alpha_i)^{1/2} \tilde{A}_i]^T \mathscr{P} [\sigma_i(\alpha_i/\delta_i)^{1/2} I_{\tilde{n}} - (\delta_i/\alpha_i)^{1/2} \tilde{A}_i] \\ &= \sigma_i^2(\alpha_i/\delta_i)\mathscr{P} + (\delta_i/\alpha_i)\tilde{A}_i^T \mathscr{P} \tilde{A}_i - \sigma_i(\tilde{A}_i^T \mathscr{P} + \mathscr{P}\tilde{A}_i), \end{aligned}$$

which, since $\sigma_i^2 \leqq \delta_i^2$, implies (5.2). □

PROPOSITION 5.2. *For all $\tilde{D}_i \in \mathbb{R}^{\tilde{n} \times \tilde{n}_i}$ and $\tilde{E}_i \in \mathbb{R}^{\tilde{n}_i \times \tilde{n}}$ satisfying*

$$\tilde{A}_i = \tilde{D}_i \tilde{E}_i, \tag{5.4}$$

the function

$$\Lambda_i(\mathscr{P}, B_c, C_c) = \delta_i(\tilde{E}_i^T \tilde{E}_i + \mathscr{P}\tilde{D}_i \tilde{D}_i^T \mathscr{P}) \tag{5.5}$$

satisfies (5.2).

Proof. Note that

$$\begin{aligned} 0 &\leqq [\delta_i^{1/2} \tilde{E}_i - \sigma_i \delta_i^{-1/2} \tilde{D}_i^T \mathscr{P}]^T [\delta_i^{1/2} \tilde{E}_i - \sigma_i \delta_i^{-1/2} \tilde{D}_i^T \mathscr{P}] \\ &= \delta_i \tilde{E}_i^T \tilde{E}_i + (\sigma_i^2/\delta_i)\mathscr{P}\tilde{D}_i \tilde{D}_i^T \mathscr{P} - \sigma_i(\tilde{A}_i^T \mathscr{P} + \mathscr{P}\tilde{A}_i), \end{aligned}$$

which implies (5.2). □

6. The auxiliary minimization problem and necessary conditions for optimality. To optimize robust performance while retaining robust stability, we consider the following problem for which the cost functional is given by the bound (4.12).

6.1. Auxiliary Minimization Problem. For $i = 1, \cdots, p$, let Λ_i be given by either (5.3) or (5.5). Determine $(\mathscr{P}, A_c, B_c, C_c) \in \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times n_c} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$, which minimizes

$$\mathscr{J}(\mathscr{P}, A_c, B_c, C_c) \triangleq \operatorname{tr} \mathscr{P}\tilde{V} \tag{6.1}$$

subject to

$$0 = \tilde{A}^T\mathscr{P} + \mathscr{P}\tilde{A} + \sum_{i=1}^{p} \Lambda_i(\mathscr{P}, B_c, C_c) + \tilde{R}, \tag{6.2}$$

$$\sum_{i=1}^{p} \sigma_i(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i) < \sum_{i=1}^{p} \Lambda_i(\mathscr{P}, B_c, C_c) + \tilde{R}, \qquad \sigma \in \Delta. \tag{6.3}$$

Remark 6.1. Note that (6.3) enforces both (4.1) and (4.11) to guarantee robust stability and performance.

To derive first-order necessary conditions for the Auxiliary Minimization Problem, note that the constraint (6.3) defines an open set.

PROPOSITION 6.1. *The set of* $(\mathscr{P}, B_c, C_c) \in \mathbb{P}^{\tilde{n}} \times \mathbb{R}^{n_c \times l} \times \mathbb{R}^{m \times n_c}$ *satisfying* (6.3) *is open.*

Proof. Since $\Lambda_i(\cdot, \cdot, \cdot)$ is continuous it can be shown that the function

$$f(\mathscr{P}, B_c, C_c) \triangleq \min_{\sigma \in \Delta} \lambda_{\min} \left\{ \sum_{i=1}^{p} \Lambda_i(\mathscr{P}, B_c, C_c) + \tilde{R} - \sum_{i=1}^{p} \sigma_i(\tilde{A}_i^T\mathscr{P} + \mathscr{P}\tilde{A}_i) \right\}$$

is also continuous. Since (6.3) is equivalent to $0 < f(\mathscr{P}, B_c, C_c)$, the result is immediate. □

To obtain explicit feedback gain expressions we shall require two additional technical assumptions. If bound (5.3) is chosen for a given $i \in \{1, \cdots, p\}$ we require

$$B_i \neq 0 \Rightarrow C_i = 0, \tag{6.4}$$

i.e., B_i and C_i are not simultaneously nonzero. Of course, both B_i and C_i may be zero. Assumption (6.4) implies that parameter uncertainties in B and C must be modeled as uncorrelated. Correlation between uncertainties in A and B or A and C is, of course, permitted. Furthermore, if bound (5.5) is chosen for a given $i \in \{1, \cdots, p\}$ we require

$$C_i = 0. \tag{6.5}$$

We stress that (6.4) and (6.6) can be removed, but at the expense of explicit gain expressions.

When we use bound (5.3) the positive constant α_i will be considered fixed but arbitrary. Furthermore, for bound (5.5), let $D_i \in \mathbb{R}^{n \times n_i}$, $E_i \in \mathbb{R}^{n_i \times n}$, $H_i \in \mathbb{R}^{n \times m_i}$, and $K_i \in \mathbb{R}^{m_i \times m}$ satisfy

$$A_i = D_iE_i, \qquad B_i = H_iK_i, \tag{6.6}$$

and define $\tilde{D}_i$, $\tilde{E}_i$ satisfying (5.4) by

$$\tilde{D}_i \triangleq \begin{bmatrix} D_i & H_i \\ 0_{n_c \times n_i} & 0_{n_c \times m_i} \end{bmatrix}, \qquad \tilde{E}_i \triangleq \begin{bmatrix} E_i & 0_{n_i \times n_c} \\ 0_{m_i \times n} & K_iC_c \end{bmatrix}. \tag{6.7}$$

In addition to the open set defined by (6.3), the derivation of the necessary conditions requires that $(\mathscr{P}, A_c, B_c, C_c)$ be further restricted so that

$$\left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i\alpha_i I_{\tilde{n}} + \sum{}'' \delta_i\tilde{D}_i\tilde{D}_i^T\mathscr{P}\right) \oplus \left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i\alpha_i I_{\tilde{n}} + \sum{}'' \delta_i\tilde{D}_i\tilde{D}_i^T\mathscr{P}\right) + \sum{}' (\delta_i\alpha_i^{-1})\tilde{A}_i \otimes \tilde{A}_i \quad \text{is asymptotically stable,} \tag{6.8}$$

$$(A_c, B_c, C_c) \text{ is controllable and observable.} \tag{6.9}$$

In (6.8) the notation $\sum'$ and $\sum''$ denotes summation over indices for which bounds (5.3) and (5.5), respectively, have been chosen. Note that (6.8) and (6.9) play no role in the Auxiliary Minimization Problem and thus need not be verified for robust stability or robust performance.

For arbitrary $Q, P, \hat{Q}, \hat{P} \in \mathbb{R}^{n\times n}$ define the following notation:

$$R_{2a} \triangleq R_2 + \sum{}' (\delta_i \alpha_i^{-1}) B_i^T (P+\hat{P}) B_i + \sum{}'' \delta_i K_i^T K_i,$$

$$V_{2a} \triangleq V_2 + \sum{}' (\delta_i \alpha_i^{-1}) C_i (Q+\hat{Q}) C_i^T,$$

$$P_a \triangleq B^T P + R_{12}^T + \sum{}' (\delta_i \alpha_i^{-1}) B_i^T (P+\hat{P}) A_i,$$

$$Q_a \triangleq QC^T + V_{12} + \sum{}' (\delta_i \alpha_i^{-1}) A_i (Q+\hat{Q}) C_i^T,$$

$$D \triangleq \sum{}'' \delta_i (D_i D_i^T + H_i H_i^T), \qquad E \triangleq \sum{}'' \delta_i E_i^T E_i,$$

$$\hat{A} \triangleq A + \frac{1}{2} \sum{}' \delta_i \alpha_i I_n, \quad \hat{A}_P \triangleq \hat{A} - B R_{2a}^{-1} P_a, \quad \hat{A}_Q \triangleq \hat{A} - Q_a V_{2a}^{-1} C.$$

The following lemma will be needed.

LEMMA 6.1. *If* $\hat{Q}, \hat{P} \in \mathbb{N}^n$ *and* rank $\hat{Q}\hat{P} = n_c$, *then there exist* $G, \Gamma \in \mathbb{R}^{n_c \times n}$ *and invertible* $M \in \mathbb{R}^{n_c \times n_c}$ *such that*

$$\hat{Q}\hat{P} = G^T M \Gamma, \tag{6.10}$$

$$\Gamma G^T = I_{n_c}. \tag{6.11}$$

Furthermore, G, M, and Γ *are unique except for a change of basis in* $\mathbb{R}^{n_c}$.

Proof. The result is an immediate consequence of [45, Thm. 6.2.5, p. 123]. □

Note that because of (6.11), the $n \times n$ matrix $\tau \triangleq G^T \Gamma$ is idempotent, i.e., $\tau^2 = \tau$. Since τ is not necessarily symmetric, it is an oblique projection. Also, define $\tau_\perp \triangleq I_n - \tau$.

THEOREM 6.1. *Suppose* $(\mathscr{P}, A_c, B_c, C_c)$ *solves the Auxiliary Minimization Problem subject to* (6.8) *and* (6.9). *Then there exist* $P, Q, \hat{P}, \hat{Q} \in \mathbb{N}^n$ *such that* $\mathscr{P}, A_c, B_c, C_c$ *are given by*

$$\mathscr{P} = \begin{bmatrix} P+\hat{P} & -\hat{P}G^T \\ -G\hat{P} & G\hat{P}G^T \end{bmatrix}, \tag{6.12}$$

$$A_c = \Gamma (A - Q_a V_{2a}^{-1} C - B R_{2a}^{-1} P_a + DP) G^T, \tag{6.13}$$

$$B_c = \Gamma Q_a V_{2a}^{-1}, \tag{6.14}$$

$$C_c = -R_{2a}^{-1} P_a G^T, \tag{6.15}$$

and such that $P, Q, \hat{P}, \hat{Q}$ *satisfy*

$$\begin{aligned} 0 = {} & \hat{A}^T P + P\hat{A} + R_1 + \sum{}' (\delta_i \alpha_i^{-1}) [A_i^T P A_i + (A_i - Q_a V_{2a}^{-1} C_i)^T \hat{P} (A_i - Q_a V_{2a}^{-1} C_i)] \\ & + E + PDP - P_a^T R_{2a}^{-1} P_a + \tau_\perp^T P_a^T R_{2a}^{-1} P_a \tau_\perp, \end{aligned} \tag{6.16}$$

$$\begin{aligned} 0 = {} & [\hat{A} + D(P+\hat{P})] Q + Q[\hat{A} + D(P+\hat{P})]^T + V_1 \\ & + \sum{}' (\delta_i \alpha_i^{-1}) [A_i Q A_i^T + (A_i - B_i R_{2a}^{-1} P_a) \hat{Q} (A_i - B_i R_{2a}^{-1} P_a)^T] \\ & - Q_a V_{2a}^{-1} Q_a^T + \tau_\perp Q_a V_{2a}^{-1} Q_a^T \tau_\perp^T, \end{aligned} \tag{6.17}$$

$$0 = (\hat{A}_Q + DP)^T \hat{P} + \hat{P}(\hat{A}_Q + DP) + \hat{P} D \hat{P} + P_a^T R_{2a}^{-1} P_a - \tau_\perp^T P_a^T R_{2a}^{-1} P_a \tau_\perp, \tag{6.18}$$

$$0 = (\hat{A}_P + DP)\hat{Q} + \hat{Q}(\hat{A}_P + DP)^T + Q_a V_{2a}^{-1} Q_a^T - \tau_\perp Q_a V_{2a}^{-1} Q_a^T \tau_\perp^T, \tag{6.19}$$

$$\text{rank } \hat{Q} = \text{rank } \hat{P} = \text{rank } \hat{Q}\hat{P} = n_c. \tag{6.20}$$

Conversely, if there exist $P, Q, \hat{P}, \hat{Q} \in \mathbb{N}^n$ *satisfying* (6.16)-(6.20), *then* $\mathscr{P}$ *given by* (6.12) *satisfies* (6.2) *or, equivalently,* (4.2) *with* (A_c, B_c, C_c) *given by* (6.13)-(6.15).

Outline of proof. As discussed in § 1, we limit the presentation of the proof to the salient details. First note that with the choice of bounds Λ_i, (6.2) becomes

$$\begin{aligned} 0 = &\left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i \alpha_i I_{\tilde{n}}\right)^T \mathscr{P} + \mathscr{P}\left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i \alpha_i I_{\tilde{n}}\right) + \tilde{R} \\ &+ \sum{}' (\delta_i \alpha_i^{-1}) \tilde{A}_i^T \mathscr{P} \tilde{A}_i + \sum{}'' \delta_i (\tilde{E}_i^T \tilde{E}_i + \mathscr{P} \tilde{D}_i \tilde{D}_i^T \mathscr{P}). \end{aligned} \tag{6.21}$$

By introducing multipliers $\lambda \in \mathbb{R}$, $\lambda \geqq 0$, and $\mathscr{Q} \in \mathbb{R}^{\tilde{n} \times \tilde{n}}$, a Lagrangian can be defined as

$$\mathscr{L}(\mathscr{P}, A_c, B_c, C_c) \triangleq \operatorname{tr}[\lambda \mathscr{P} \tilde{V} + \mathscr{Q}(\text{RHS of (6.21)})]. \tag{6.22}$$

Setting $\partial \mathscr{L}/\partial \mathscr{P} = 0$ and using (6.8) implies that $\lambda = 1$ without loss of generality, $\mathscr{Q} \geqq 0$, and $\mathscr{Q}$ satisfies

$$\begin{aligned} 0 = &\left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i \alpha_i I_{\tilde{n}} + \sum{}'' \tilde{D}_i \tilde{D}_i^T \mathscr{P}\right) \mathscr{Q} + \mathscr{Q}\left(\tilde{A} + \frac{1}{2}\sum{}' \delta_i \alpha_i I_{\tilde{n}} + \sum{}'' \tilde{D}_i \tilde{D}_i^T \mathscr{P}\right)^T \\ &+ \sum{}' (\delta_i \alpha_i^{-1}) \tilde{A}_i \mathscr{Q} \tilde{A}_i^T + \tilde{V}. \end{aligned} \tag{6.23}$$

The remainder of the derivation is exactly parallel to the techniques utilized in [29] and [36]. Briefly, the principal steps are as follows:

Step 1. Compute $\partial \mathscr{L}/\partial A_c$, $\partial \mathscr{L}/\partial B_c$, and $\partial \mathscr{L}/\partial C_c$.
Step 2. Use (6.9) to show that the lower right $n_c \times n_c$ blocks of $\mathscr{Q}$ and $\mathscr{P}$ are positive definite.
Step 3. Use $\partial \mathscr{L}/\partial A_c = 0$ to define a projection τ and new variables $P, Q, \hat{P}, \hat{Q}, G, \Gamma$.
Step 4. Partition (6.21) and (6.23) into six equations (1)-(6) corresponding to the $n \times n$, $n \times n_c$ and $n_c \times n_c$ blocks of $\mathscr{P}$ and $\mathscr{Q}$, respectively.
Step 5. Use (2) and (3) to solve for A_c; show that (5) and (6) also yield A_c; note that with A_c now given, (3) and (6) are superfluous and can be eliminated.
Step 6. Manipulate (1), (2), (4), and (5) to yield (6.16)-(6.19).
Step 7. Show that Steps 4-6 are reversible so that (6.16)-(6.20) are equivalent to (6.2) or, equivalently, (4.2).

By enforcing the strict inequalities $\mathscr{P} > 0$ and (6.3), solutions of (6.16)-(6.20) guarantee robust stability with a robust performance bound. The following result follows from Theorem 4.1, Theorem 4.2, and the converse of Theorem 6.1.

THEOREM 6.2. *Suppose there exist* $P, Q, \hat{P}, \hat{Q} \in \mathbb{N}^n$ *satisfying* (6.16)-(6.20), *and suppose that* (6.3) *and* $\mathscr{P} > 0$ *are satisfied with* $(\mathscr{P}, A_c, B_c, C_c)$ *given by* (6.12)-(6.15). *Then the compensator* A_c, B_c, C_c *given by* (6.13)-(6.15) *solves the Robust Stability Problem and the closed-loop performance* (3.7) *satisfies the bound*

$$J(A_c, B_c, C_c) \leqq \operatorname{tr} \mathscr{P} \tilde{V}. \tag{6.24}$$

The following existence result concerns the solvability of (6.16)-(6.20). Let n_u denote the dimension of the unstable subspace of the plant dynamics matrix A.

THEOREM 6.3. *Assuming* $n_c \geqq n_u$, $R_1 > 0$, $V_1 > 0$, *suppose the nominal plant, i.e.,* (3.1), (3.2) *with* $\delta_i = 0$, $i = 1, \cdots, p$, *is stabilizable and detectable and, in addition, is stabilizable by means of an* n_c*th-order strictly proper dynamic compensator* (3.3), (3.4). *Then there exist* $\bar{\delta}_1, \cdots, \bar{\delta}_p > 0$ *such that if* $\delta_i \in [0, \bar{\delta}_i)$, $i = 1, \cdots, p$, *then* (6.16)-(6.20) *have a solution* $P, Q, \hat{P}, \hat{Q} \in \mathbb{N}^n$ *for which* (A_c, B_c, C_c) *given by* (6.13)-(6.15) *solve the robust stability problem with robust performance bound* (6.24).

Proof. From Theorem 3.1 of [37] it follows that there exists a solution to (6.16)-(6.20) that stabilizes the nominal plant. By continuity there exists a neighborhood over which robust stability with performance bound (6.24) holds. □

Theorem 6.3 is an existence result that guarantees solvability of the sufficiency conditions over a range of parameter uncertainties. The actual range of uncertainty that can be bounded and the conservatism of the performance bound are problem dependent. To this end we now consider a numerical example.

7. Illustrative numerical example. To demonstrate the theory above we present an illustrative numerical example. The example chosen was originally used in [2] to illustrate the lack of a guaranteed gain margin for LQG controllers. This example was also considered in [35] for a preliminary robustness study and reconsidered in [46] using μ-analysis. Define the following:

$$n = n_u = 2, \qquad m = l = p = 1,$$

$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad C = [1 \quad 0],$$

$$A_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad C_1 = [0 \quad 0],$$

$$R_1 = V_1 = \begin{bmatrix} 60 & 60 \\ 60 & 60 \end{bmatrix}, \quad R_{12} = V_{12} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad R_2 = V_2 = 1.$$

Note that the system is open-loop unstable and becomes uncontrollable at $\sigma_1 = -1$. As can be seen using root locus, a strictly proper stabilizing controller must be of at least second order. Hence we consider (6.16)-(6.20) with $n_c = n$ and $\tau_\perp = 0$. Furthermore, we use bound (5.3) and thus set $D = E = 0$. Using algorithms described in

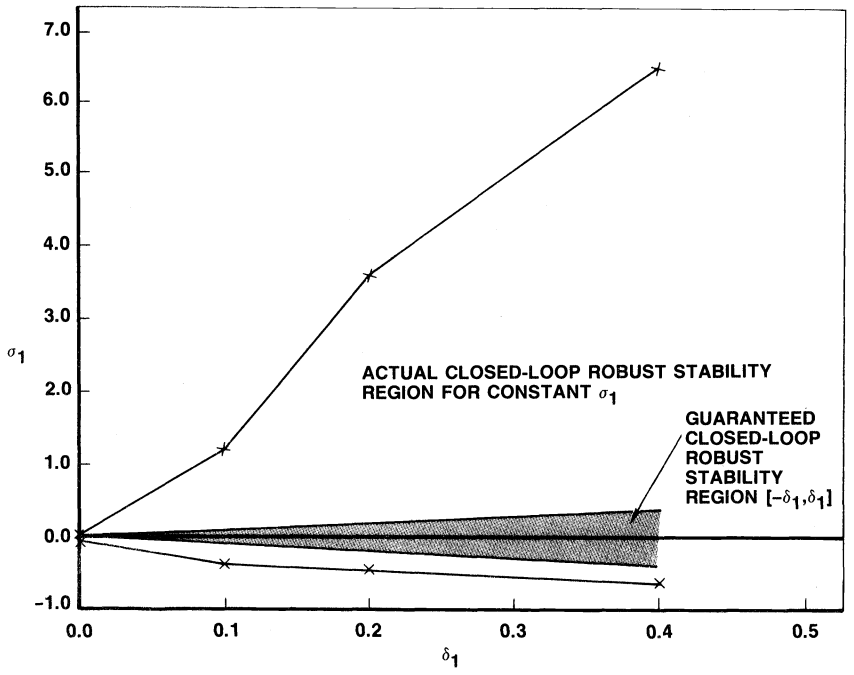

FIG. 1

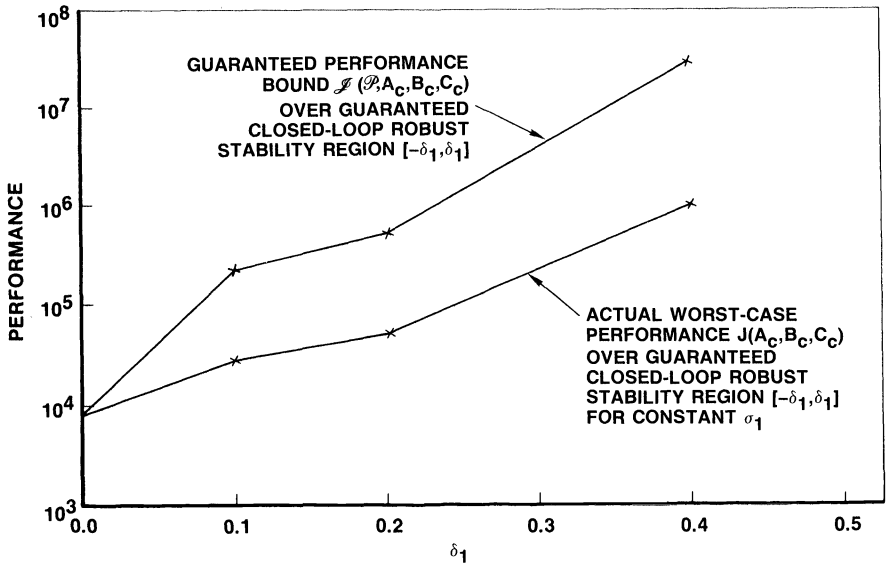

FIG. 2

TABLE 1

(δ_1, α_1)	A_c	B_c	C_c
(.1, 1)	$\begin{bmatrix} -14.917 & 1.0 \\ -85.177 & 3.9657 \end{bmatrix}$	$\begin{bmatrix} 15.917 \\ 79.959 \end{bmatrix}$	$[-5.2182 \quad -4.9657]$
(.2, 2)	$\begin{bmatrix} -17.963 & 1.0 \\ -133.65 & -4.4614 \end{bmatrix}$	$\begin{bmatrix} 18.963 \\ 127.05 \end{bmatrix}$	$[-6.6011 \quad -5.4614]$
(.4, 4)	$\begin{bmatrix} -47.813 & 1.0 \\ -1087.3 & -6.5463 \end{bmatrix}$	$\begin{bmatrix} 48.813 \\ 1073.5 \end{bmatrix}$	$[-13.766 \quad -7.5463]$

[38]-[40], controllers were obtained by solving (6.16)-(6.20) for $(\delta_1, \alpha_1) = (.1, 1), (.2, 2)$, and $(.4, 4)$. As stated previously, these numerical solutions also verify (4.2) with $\mathscr{P}$ given by (6.12). Figure 1 compares the guaranteed robust stability region to the "actual" robust stability region. This robust stability region was evaluated assuming constant $\hat{\sigma}_1(\cdot)$, although the theory actually guarantees robustness with respect to time-varying uncertainties. Thus, the gap between these regions may not be a reliable measure of the conservatism of the results. Note, however, that the design approach appears to provide more stability than is guaranteed a priori. This feature may be attributable to the desire for a symmetric stability interval so close to an unstabilizable plant perturbation, i.e., $\sigma_1 = -1$. Nevertheless, the stability design objectives have been met in accordance with Theorem 6.2. Interestingly, the form of the actual stability region mimics the classical 6-dB-downward/infinite-dB-upward gain margin of full-state-feedback LQR controllers [1]. Thus, this approach appears to provide an alternative to gain-margin recovery techniques [9], which address this specialized form of plant uncertainty. Finally, Fig. 2 compares guaranteed closed-loop performance to "actual" closed-loop performance over the guaranteed closed-loop robust stability region. Again the "actual" region was determined for constant $\hat{\sigma}_1(\cdot)$. Controller gains are given in

Table 1. Finally, we note that higher-order robust controllers were obtained for this example in [46] using the μ-function approach.

Acknowledgments. I thank Jill M. Straehla for preparing the manuscript versions of this paper, Scott W. Greeley for carrying out the numerical computations, Dr. Wassim M. Haddad for several helpful suggestions, and the reviewers for numerous helpful comments.

ON THE STABILITY PROPERTIES OF SPLINE APPROXIMATIONS FOR RETARDED SYSTEMS*

F. KAPPEL† AND D. SALAMON‡

Abstract. This paper studies the qualitative properties of the spline approximation scheme for retarded functional differential equations introduced by Kappel and Salamon [*SIAM J. Control Optim.*, 25 (1987), pp. 1082-1117]. It is shown that the approximating systems are stable for large N if the underlying retarded functional differential equation is stable. In this case the approximating equations are in some sense uniformly (with respect to the approximation index) stable in the vector component of the state but not so in the complete state.

Key words. retarded functional differential equations, approximation, splines, controllability

AMS(MOS) subject classifications. 34K35, 41A15, 93D15

1. Introduction. In [10] and [11] we have introduced a new spline approximation scheme for retarded functional differential equations. The aim of this paper is to study the qualitative properties of this approximation scheme with particular emphasis on the stability problem.

The fundamental convergence properties of this approximation scheme have been established in [11]. The central result is a convergence proof for both the original semigroup $S(t)$ and its adjoint $S^*(t)$ in the strong operator topology. Here lies the main advantage over the spline approximation scheme, developed earlier in [2], for which the adjoint semigroup is only approximated in the weak operator topology. In addition, we have observed a quite significant improvement in the convergence behaviour of our numerical computations, some of which are reported in [11].

The main result of this paper is that the approximating systems (Σ^N) are stable (stabilizable, detectable) for sufficiently large N provided the original system (Σ) is stable (stabilizable and detectable.) The proof consists of three parts. The first part is a convenient characterization of the stability, stabilizability, and detectability of the approximating systems in terms of a certain characteristic matrix $\Delta^N(\lambda)$. The second part is a convergence proof for these matrices $\Delta^N(\lambda)$. The third part establishes a priori bounds for the unstable eigenvalues of the approximating systems.

We also discuss the role of the structural operator F in the spline approximation scheme. Moreover, we prove that the approximating systems cannot be stable in a uniform sense with respect to N and illustrate this result with computations of the spectrum. In this respect the spline approximation differs from the averaging approximation scheme in [1] for which the uniform exponential stability property has been established in [19]. But if we take the output of the system to be the vector component of the state, then the approximating systems are in a sense uniformly output stable with respect to N if the hereditary system is stable. For simplicity of presentation we restrict ourselves to the single delay case. All results are true for equations with multiple commensurate delays and without distributed delay. Some results are also true for the general case. For details see [10].

2. Linear retarded control systems.

2.1. Functional differential equations. We consider the linear retarded functional differential equation (RFDE)

$$\dot{x}(t) = A_0 x(t) + A_1 x(t-h) + B_0 u(t), \qquad y(t) = C_0 x(t), \tag{2.1}$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^l$, $y(t) \in \mathbb{R}^m$, A_0, $A_1 \in \mathbb{R}^{n\times n}$, $B_0 \in \mathbb{R}^{n\times l}$, $C_0 \in \mathbb{R}^{m\times n}$, and $h > 0$. It is obvious that (2.1) admits a unique solution $x(\cdot) \in L^2(-h, T; \mathbb{R}^n) \cap W^{1,2}(0, T; \mathbb{R}^n)$ for every input $u(\cdot) \in L^2(0, T; \mathbb{R}^l)$ and every initial condition of the form

$$x(0) = \phi^0, \quad x(\tau) = \phi^1(\tau), \quad -h \leqq \tau < 0, \tag{2.2}$$

where $\phi = (\phi^0, \phi^1) \in M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$ (see, for instance, [6], [9]). By $X(t) \in \mathbb{R}^{n\times n}$, $t \geqq -h$, we denote the fundamental matrix solution of (2.1), which corresponds to the initial condition $X(0) = I$, $X(\tau) = 0$, $-h \leqq \tau < 0$, and the input $u(t) \equiv 0$. Its Laplace transform is given by $\Delta(\lambda)^{-1}$, where $\Delta(\lambda) = \lambda I - A_0 - A_1 e^{-\lambda h}$, $\lambda \in \mathbb{C}$, is the characteristic matrix of (2.1).

2.2. State space theory. We consider two state concepts for (2.1). In the classical sense the state at time $t \geqq 0$ is defined to be the pair $z(t) = (x(t), x_t) \in M^2$, where $x_t(\tau) = x(t+\tau)$ for $-h \leqq \tau \leqq 0$. This state defines a weak solution of the abstract Cauchy problem

$$\dot{z}(t) = Az(t) + Bu(t), \quad z(0) = \phi, \quad y(t) = Cz(t), \tag{Σ}$$

where $B \in \mathscr{L}(\mathbb{R}^l, M^2)$ and $C \in \mathscr{L}(M^2, \mathbb{R}^m)$ are defined by $Bu = (B_0 u, 0)$ and $C\phi = C_0 \phi^0$ for $u \in \mathbb{R}^l$ and $\phi \in M^2$. The unbounded operator A: dom $A \to M^2$ is given by

$$A\phi = (A_0 \phi^1(0) + A_1 \phi^1(-h), \dot{\phi}^1), \qquad \text{dom } A = \{\phi \in M^2 \mid \phi^1 \in W^{1,2}, \phi^0 = \phi^1(0)\}$$

and generates a strongly continuous semigroup $S(t)$ of bounded linear operators on M^2. Therefore $z(t) \in M^2$ is given by the variation-of-constants formula

$$z(t) = S(t)\phi + \int_0^t S(t-s)Bu(s)\, ds. \tag{2.3}$$

Now let $S_T(t)$ denote the semigroup corresponding to the RFDE $\dot{x}(t) = A_0^T x(t) + A_1^T x(t-h)$ so that its generator A_T is defined as A with A_0, A_1 replaced by A_0^T, A_1^T. Then there is an alternative (dual) state concept for the RFDE (2.1) that relates the semigroups $S(t)$ and $S_T^*(t)$. It can be defined in terms of the structural operator $F \in \mathscr{L}(M^2)$ (for a normed linear space X we denote by $\mathscr{L}(X)$ the space of all bounded linear operators $X \to X$) given by

$$[F\phi]^0 = \phi^0, \quad [F\phi]^1(\sigma) = A_1 \phi(-h-\sigma), \quad -h \leqq \sigma \leqq 0 \tag{2.4}$$

for $\phi \in M^2$ (we define $\phi^1(\tau) = 0$ for $\tau \notin [-h, 0]$). It is a remarkable fact that for every weak solution $z(t) \in M^2$ of the Cauchy problem (Σ) the function $w(t) = Fz(t) \in M^2$ defines a weak solution of the abstract Cauchy problem

$$\dot{w}(t) = A_T^* w(t) + Bu(t), \quad w(0) = f \in M^2, \quad y(t) = Cw(t), \tag{Σ_T^*}$$

with $f = F\phi$.

Equivalently, the structural operator F satisfies the following equations:

$$FS(t) = S_T^*(t)F, \quad FB = B, \quad CF = C \tag{2.5}$$

for $t \geqq 0$. In particular, for every solution $x(t) \in \mathbb{R}^n$, $t \geqq -h$, of (2.1) the function $w(t) = F(x(t), x_t) \in M^2$ is given by

$$w(t) = S_T^*(t)F\phi + \int_0^t S_T^*(t-s)Bu(s)\, ds. \tag{2.6}$$

For more detailed discussion of these two state concepts and their relation see [6], [13], [16], and [18].

2.3. Stability, stabilizability, and controllability. System (2.1) is said to be *stable* if every solution $x(t)$ of the free system ($u(t) \equiv 0$) tends to zero as t goes to infinity. Equivalently, $\det \Delta(\lambda) = 0$ implies that $\operatorname{Re} \lambda < 0$ for $\lambda \in \mathbb{C}$ (see, for instance, [9]). Note that $\sigma(A) = \sigma(A_T^*) = \{\lambda \in \mathbb{C} \mid \det \Delta(\lambda) = 0\}$. Moreover, system (2.1) is said to be *stabilizable* if

$$\operatorname{rank} [\Delta(\lambda), B_0] = n \quad \text{for } \operatorname{Re} \lambda \geqq 0 \tag{2.7}$$

and *detectable* if

$$\operatorname{rank} \begin{bmatrix} \Delta(\lambda) \\ C_0 \end{bmatrix} = n \quad \text{for } \operatorname{Re} \lambda \geqq 0. \tag{2.8}$$

An abstract Cauchy problem is said to be *observable* if a nonzero initial state produces a nonzero output. Hence the Cauchy problem (Σ) is observable if and only if

$$y(t) = 0 \quad \text{for } t \geqq 0 \quad \text{implies } x(t) = 0 \quad \text{for all } t \geqq -h$$

for every solution of (2.1) and the Cauchy problem (Σ_T^*) is observable if and only if

$$y(t) = 0 \quad \text{for } t \geqq -h \quad \text{implies } x(t) = 0 \quad \text{for all } t \geqq -h$$

(see [17]). These two properties have been characterized as follows [13], [14], [17].

THEOREM 2.1. *System* (Σ) *is observable if and only if*

$$\operatorname{rank} \begin{bmatrix} \Delta(\lambda) \\ C_0 \end{bmatrix} = \operatorname{rank} A_1 = n \quad \textit{for all } \lambda \in \mathbb{C};$$

(Σ_T^*) *is observable if and only if*

$$\operatorname{rank} \begin{bmatrix} \Delta(\lambda) \\ C_0 \end{bmatrix} = \operatorname{rank} \begin{bmatrix} A_1 \\ C_0 \end{bmatrix} = n \quad \textit{for all } \lambda \in \mathbb{C}.$$

If (2.7) and (2.8) are satisfied, then there exist unique nonnegative, selfadjoint operators Π, $P \in L(M^2)$ satisfying range $\Pi \subset \operatorname{dom} A^*$, range $P \subset \operatorname{dom} A_T$, and the algebraic Riccati operator equations

$$A^*\Pi\phi = \Pi A\phi - \Pi BB^*\Pi\phi + C^*C\phi = 0, \tag{2.9}$$

$$A_T Pf + PA_T^* f - PBB^* Pf + C^*Cf = 0 \tag{2.10}$$

for $\phi \in \operatorname{dom} A$ and $f \in \operatorname{dom} A_T^*$ (see [4], [20]). It follows from (2.5) that the solution operators Π of (2.9) and P of (2.10) satisfy the identity

$$\Pi = F^*PF. \tag{2.11}$$

This was first observed in [5] for the Riccati differential equation. Finally, we point out that Π is injective if and only if (Σ) is observable, and that P is injective if and only if (Σ_T^*) is observable.

For a detailed discussion of the Riccati equation and its connection to optimal control theory see [4], [7], and [20].

3. Spline approximation.

3.1. Notation and terminology. Consider the finite-dimensional linear subspace

$$X^N = \left\{ \phi \in M^2 \;\middle|\; \phi^1 = \sum_{j=0}^{N} e_j^N z_j,\ z_j \in \mathbb{R}^n \right\},$$

where the scalar functions $e_j^N(\cdot) \in L^2(-h, 0)$ are defined by

$$e_0^N(\tau) = \begin{cases} \dfrac{N}{h}(\tau - t_1^N), & t_1^N \leqq \tau < t_0^N, \\ 0 \quad \text{elsewhere,} \end{cases}$$

$$e_j^N(\tau) = \begin{cases} \dfrac{N}{h}(\tau - t_{j+1}^N), & t_{j+1}^N \leqq \tau \leqq t_j^N, \\ -\dfrac{N}{h}(\tau - t_{j-1}^N), & t_j^N \leqq \tau \leqq t_{j-1}^N, \\ 0 \quad \text{elsewhere,} \end{cases}$$

$$e_N^N(\tau) = \begin{cases} -\dfrac{N}{h}(\tau - t_{N-1}^N), & t_N^N \leqq \tau \leqq t_{N-1}^N, \\ 0 \quad \text{elsewhere,} \end{cases}$$

for $j = 1, \cdots, N-1$ and meshpoints $t_j^N = -jh/N$ for $j = 0, \cdots, N$. Note that the function component of every $\phi \in X^N$ is a piecewise linear spline function on the interval $[-h, 0)$. The subspace $X^N \subset M^2$ can be identified with the Euclidean space $\mathbb{R}^{k(N)}$, $k(N) = n + (N+1)n$, via the embedding $\iota^N : \mathbb{R}^{k(N)} \to M^2$ defined by

$$\iota^N z = \left(z_0, \sum_{j=0}^{N} e_j^N z_j \right) \tag{3.1}$$

for $z = \operatorname{col}(z_0, z_1) \in \mathbb{R}^{k(N)}$, where $z_0 \in \mathbb{R}^n$ and $z_1 = \operatorname{col}(z_{10}, \cdots, z_{1N})$, $z_{ij} \in \mathbb{R}^n$, $j = 0, \cdots, N$. On $\mathbb{R}^{k(N)}$ we will always consider the induced inner product

$$\langle w, z \rangle_N = w^T Q^N z = \langle \iota^N w, \iota^N z \rangle_{M^2}, \tag{3.2}$$

where

$$Q^N = \begin{pmatrix} 1 & 0 \\ 0 & (h/N) q^N \end{pmatrix} \otimes I,$$

$$q^N = \begin{pmatrix} \frac{1}{3} & \frac{1}{6} & 0 & \cdots & 0 \\ \frac{1}{6} & \frac{2}{3} & & & 0 \\ 0 & & \ddots & & \vdots \\ & & & \frac{2}{3} & \frac{1}{6} \\ 0 & & \cdots & \frac{1}{6} & \frac{1}{3} \end{pmatrix} \in \mathbb{R}^{(N+1)\times(N+1)}.$$

Here I denotes the $n \times n$ identity matrix. The corresponding vector and matrix norms will be denoted by $\| \cdot \|_N$. The adjoint operator $\pi^N = (\iota^N)^* : M^2 \to \mathbb{R}^{k(N)}$ is then given by

$$\pi^N \phi = (Q^N)^{-1} z, \qquad z_0 = \phi^0,$$

$$z_{1j} = \int_{-h}^{0} e_j^N(\tau) \phi^1(\tau)\, d\tau, \qquad j = 0, \cdots, N,$$

and satisfies the identities

$$\pi^N \iota^N = id, \qquad \iota^N \pi^N = p^N, \tag{3.3}$$

where $p^N: M^2 \to X^N$ denotes the orthogonal projection. Let the matrices $H^N \in \mathbb{R}^{k(N)\times k(N)}$, $B^N \in \mathbb{R}^{k(N)\times l}$, and $C^N \in \mathbb{R}^{m\times k(N)}$ be defined by

$$H^N = \left(\begin{array}{c|ccc} A_0 & 0 & \cdots & A_1 \\ \hline I & & & \\ 0 & & h^N \otimes I & \\ \vdots & & & \\ 0 & & & \end{array}\right), \qquad B^N = \begin{pmatrix} B_0 \\ 0 \\ \vdots \\ 0 \end{pmatrix},$$

$$C^N = (C_0 \quad 0 \quad \cdots \quad 0),$$

$$h^N = \begin{pmatrix} -\frac{1}{2} & -\frac{1}{2} & 0 & \cdots & 0 \\ \frac{1}{2} & 0 & \ddots & & \vdots \\ & \ddots & \ddots & \ddots & 0 \\ 0 & & \ddots & 0 & -\frac{1}{2} \\ & & & \frac{1}{2} & -\frac{1}{2} \end{pmatrix} \in \mathbb{R}^{(N+1)\times(N+1)}.$$

Finally, we define

$$A^N = (Q^N)^{-1}H^N, \qquad A_T^N = (Q^N)^{-1}H_T^N,$$
$$(A_T^N)^* = (Q^N)^{-1}(H_T^N)^T, \qquad (A^N)^* = (Q^N)^{-1}(H^N)^T,$$

where the matrix $H_T^N \in \mathbb{R}^{(k(N)\times k(N))}$ is obtained from H^N by transposing the matrices A_0, A_1.

Now we consider two control systems on the state space $\mathbb{R}^{k(N)}$:

$$(\Sigma^N) \qquad \dot{z}^N(t) = A^N z^N(t) + B^N u(t), \quad z^N(0) = \pi^N \phi, \quad y^N(t) = C^N z^N(t),$$

$$(\Sigma_T^N{}^*) \qquad \dot{w}^N(t) = (A_T^N)^* w^N(t) + B^N u(t), \quad w^N(0) = \pi^N f, \quad y^N(t) = C^N w^N(t).$$

In [11] we establish the following convergence theorem.

THEOREM 3.1. (i) *For every $\phi \in M^2$ we have $\phi = \lim_{N\to\infty} p^N \phi$.*

(ii) *$B = \iota^N B^N$, $C = C^N \pi^N$ for every $N \in \mathbb{N}$.*

(iii) *There exist constants $M \geqq 1$, $\omega \geqq 0$ such that*

$$\|e^{A^N t}\|_N \leqq M e^{\omega t}, \qquad \|e^{(A_T^N)^* t}\|_N \leqq M e^{\omega t}$$

for every $t \geqq 0$ and every $N \in \mathbb{N}$.

(iv) *For all $\phi, f \in M^2$,*

$$S(t)\phi = \lim_{N\to\infty} \iota^N e^{A^N t} \pi^N \phi, \qquad S_T^*(t) f = \lim_{N\to\infty} \iota^N e^{(A_T^N)^* t} \pi^N f$$

and the limits are uniform on every compact time interval $[0, T]$.

In particular, this implies that for every $\phi \in M^2$ and every input $u(\cdot) \in L^2(0, T; \mathbb{R}^l)$ we have $z(t) = \lim_{N\to\infty} \iota^N z^N(t)$ for $0 \leqq t \leqq T$ (uniformly), where $z(t)$ is the unique weak solution of (Σ) and $z^N(t)$ satisfies (Σ^N). In the same manner the solutions $w^N(t)$ of $(\Sigma_T^N{}^*)$ approximate the solution $w(t)$ of (Σ_T^*).

In the remainder of this section we will study the structural properties of the approximating systems (Σ^N) and $(\Sigma_T^N{}^*)$.

3.2. The structural operator. In § 2 we have seen that the structural operator $F: M^2 \to M^2$ plays an important role for the state-space description of retarded systems. In this section we introduce an analogous operator for the description of the approximating systems (Σ^N) and (Σ_T^N). The first step in this direction is Lemma 3.2.

Suppose $u(\cdot)$ is an arbitrary control in $V_{(0,T)}[h]$ and its projection on the closed subspace $\bar{\mathcal{U}}$ is denoted by $u_p(\cdot)$. For each ψ in X one has

$$\begin{aligned}(u_p(\cdot), (\mathcal{S}_T B)^*(\cdot)\psi)_{L^2(0,T;U)} &= (u(\cdot), (\mathcal{S}_T B)^*(\cdot)\psi)_{L^2(0,T;U)} \\ &= (h, \psi)_X = (G\varphi, \psi)_X \\ &= ((\mathcal{S}_T B)^*(\cdot)\varphi, (\mathcal{S}_T B)^*(\cdot)\psi)_{L^2(0,T;U)},\end{aligned}$$

or

$$(u_p(\cdot) - (\mathcal{S}_T B)^*(\cdot)\varphi, (\mathcal{S}_T B)^*(\cdot)\psi)_{L^2(0,T;U)} = 0.$$

Since $\mathcal{U}$ is dense in $\bar{\mathcal{U}}$ and $[u_p(\cdot) - (\mathcal{S}_T B)^*(\cdot)\varphi] \in \mathcal{U}$, we have

$$u_p(\cdot) = (\mathcal{S}_T B)^*(\cdot)\varphi \quad \text{for each } u(\cdot) \in V_{(0,T)}[h].$$

Therefore

$$\|(\mathcal{S}_T B)^*(\cdot)\varphi\|_{L^2(0,T;U)} = \|u_p(\cdot)\|_{L^2(0,T;U)} \leqq \|u(\cdot)\|_{L^2(0,T;U)} \quad \text{for each } u(\cdot) \in V_{(0,T)}[h].$$

By uniqueness of the minimum norm optimal control of the linear system (1.5), (3.15) holds and $u^*(\cdot) \in \mathcal{U}$.

Since $u_\varepsilon = u^* - \varepsilon(\varepsilon + \hat{G})^{-1}u^*$ (see (3.10)), (3.14) is equivalent to

$$\lim_{\varepsilon \to 0} \varepsilon(\varepsilon + \hat{G})^{-1}u^* = 0 \quad \text{in } L_2(0, T; U). \tag{3.16}$$

If we consider another family with parameter $\varepsilon > 0$ of associated quadratic optimal control problems,

$$J_\varepsilon(v; \varphi) = \|(\mathcal{S}_T B)v - \varphi\|^2 + \varepsilon\|v(\cdot)\|^2_{L^2(0,T;U)},$$

then $J_\varepsilon(v; \varphi)$ takes its minimum at $v = v_\varepsilon$ defined by

$$v_\varepsilon = (\varepsilon + \hat{G})^{-1}(\mathcal{S}_T B)^*\varphi = (\varepsilon + \hat{G})^{-1}u^*.$$

If we can show

$$\lim \varepsilon\|v_\varepsilon(\cdot)\|^2_{L^2(0,T;U)} = 0, \tag{3.17}$$

then

$$\begin{aligned}\lim_{\varepsilon \to 0} \varepsilon\|v_\varepsilon(\cdot)\|_{L^2(0,T;U)} &\leqq \lim_{\varepsilon \to 0} \max\{\varepsilon; \varepsilon\|v_\varepsilon(\cdot)\|_{L^2(0,T;U)}\} \\ &\leqq \lim_{\varepsilon \to 0} \max\{\varepsilon; \varepsilon\|v_\varepsilon(\cdot)\|^2_{L^2(0,T;U)}\} = 0.\end{aligned}$$

The last equation just is (3.16). The rest is to show (3.17) holds for $\varphi \in X$. (Notice, if $\varphi \in \bar{K}_{(0,T)}$ then (3.17) holds. Here we may show (3.17) holds for any given $\varphi \in X$.)

Suppose φ is arbitrarily given in X and

$$\varphi = \bar{\varphi} + \varphi^\perp,$$

where $\bar{\varphi} \in \bar{K}_{(0,T)}$ and $\varphi^\perp \in K^\perp_{(0,T)}$—the orthogonal complement of $K_{(0,T)}$. Since $X = \bar{K}_{(0,T)} \oplus K^\perp_{(0,T)}$, one has

$$\|\varphi\|^2 = \|\bar{\varphi}\|^2 + \|\varphi^\perp\|^2 \quad \text{for any } \varphi \in X.$$

Denote

$$\bar{v}_\varepsilon = (\varepsilon + \hat{G})^{-1}(\mathcal{S}_T B)^*\bar{\varphi} \quad \text{and} \quad v^\perp_\varepsilon = (\varepsilon + \hat{G})^{-1}(\mathcal{S}_T B)^*\varphi^\perp.$$

Then

$$v_\varepsilon = \bar{v}_\varepsilon + v^\perp_\varepsilon.$$

3.3. Criteria for stability, stabilizability, and controllability. We shall need the following facts on the real $(N+1)\times(N+1)$-matrix $a^N=(q^N)^{-1}h^N$.

LEMMA 3.5. (a) *Let* $\|\cdot\|_N$ *be the operator norm corresponding to the vector norm* $|x|_N^2=\bar{x}^Tq^Nx$ *on* $\mathbb{C}^{N+1}$. *Then* $\|e^{a^Nt}\|_N\leqq 1$ *for* $N=1,2,\cdots$ *and* $t\geqq 0$.

(b) *Let* $\mu\in\sigma(a^N)$ *and* $x=\operatorname{col}(x_0,\cdots,x_N)\in\mathbb{C}^{N+1}$, $x\neq 0$, *such that either* $(\mu q^N-h^N)x=0$ *or* $(\mu q^N-(h^N)^T)x=0$. *Then* $x_0\neq 0$ *and* $x_N\neq 0$.

(c) *Let* $\mu\in\sigma(a^N)$ *and* $x=\operatorname{col}(1,0,\cdots,0)$ *or* $x=\operatorname{col}(0,\cdots,0,1)$. *Then* $x\notin\operatorname{range}(\mu q^N-h^N)$ *and* $x\notin\operatorname{range}(\mu q^N-(h^N)^T)$.

(d) $\operatorname{Re}\mu<0$ *for every* $\mu\in\sigma(a^N)$.

Proof. (a) For every $x\in\mathbb{C}^{N+1}$ the following equation holds:

$$\begin{aligned}\operatorname{Re}(\bar{x}^Th^Nx)&=(\operatorname{Re}x)^Th^N(\operatorname{Re}x)+(\operatorname{Im}x)^Th^N(\operatorname{Im}x)\\&=-\tfrac{1}{2}|x_0|^2-\tfrac{1}{2}|x_N|^2.\end{aligned}\tag{3.7}$$

Hence a^N is a dissipative operator on $\mathbb{C}^{N+1}$ with respect to the inner product

$$\langle y,x\rangle_N=\bar{y}^Tq^Nx,\qquad x,y\in\mathbb{C}^{N+1}.$$

Therefore $\exp(a^Nt)$, $t\geqq 0$, is a contraction semigroup on $\mathbb{C}^{N+1}$ supplied with the norm $|\cdot|_N$ (see, for instance, [15]).

(b) This follows from

$$\mu q^N-h^N=\begin{pmatrix}\frac{\mu}{3}+\frac{1}{2} & \frac{\mu}{6}+\frac{1}{2} & 0 & \cdots & 0\\ \frac{\mu}{6}-\frac{1}{2} & \frac{2\mu}{3} & & & \\ & & & & 0\\ & & & & \\ 0 & & & & \frac{\mu}{6}+\frac{1}{2}\\ & & & & \frac{2\mu}{3}\\ 0 & \cdots & 0 & \frac{\mu}{6}-\frac{1}{2} & \frac{\mu}{3}+\frac{1}{2}\end{pmatrix}$$

and the fact that $\mu=\pm 3$ is not an eigenvalue of a^N.

(c) $x\in\operatorname{range}(\mu q^N-h^N)$ would imply $x\perp\ker(\mu q^N-(h^N)^T)$, which is impossible by (b).

(d) Assume that $\mu\in\sigma(a^N)$ and $\operatorname{Re}\mu\geqq 0$. Then there exists an $x\in\mathbb{C}^{N+1}$, $x\neq 0$, such that $(\mu q^N-h^N)x=0$. By (3.7) this implies

$$\begin{aligned}0\leqq(\operatorname{Re}\mu)\bar{x}^Tq^Nx&=\operatorname{Re}(\bar{x}^Th^Nx)\\&=-\tfrac{1}{2}|x_0|^2-\tfrac{1}{2}|x_N|^2.\end{aligned}$$

Hence $x_0=x_N=0$, and therefore $x=0$ by (b) in contradiction to $x\neq 0$. □

For every $\mu\in\mathbb{C}$ not in the spectrum of a^N (in particular, for every μ in the closed right half-plane) we introduce the vector

$$\alpha^N(\mu)=\operatorname{col}(\alpha_0^N(\mu),\cdots,\alpha_N^N(\mu))\tag{3.8}$$

as the unique solution of

$$(\mu q^N-h^N)\alpha^N(\mu)=\operatorname{col}(1,0,\cdots,0).\tag{3.9}$$

The complex $n\times n$-matrix

$$\Delta^N(\lambda)=\lambda I-A_0-A_1\alpha_N^N\left(\frac{\lambda h}{N}\right)\tag{3.10}$$

plays a role for the approximating systems (Σ^N) and (Σ_T^{N*}) analogous to that of the characteristic matrix $\Delta(\lambda)$ for the original systems (Σ) and (Σ_T^*). In particular, it determines their input-output behaviour (see Proposition 3.7 below).

Next we characterize the resolvent operator $(\lambda Q^N - H^N)^{-1}$ in terms of the matrices $\Delta^N(\lambda)$, F^N and $E^N(\lambda) \in \mathbb{C}^{k(N)\times n}$, $T^N(\lambda) \in \mathbb{C}^{k(N)\times k(N)}$. The latter are defined as follows:

$$E^N(\lambda) = \operatorname{col}\left(1, \alpha_0^N\left(\frac{\lambda h}{N}\right), \cdots, \alpha_N^N\left(\frac{\lambda h}{N}\right)\right) \otimes I, \tag{3.11}$$

$$T^N(\lambda) = \begin{pmatrix} 0 & 0 \\ 0 & ((\lambda h/N)q^N - h^N)^{-1} \end{pmatrix} \otimes I. \tag{3.12}$$

PROPOSITION 3.6. *Let $\lambda \in \mathbb{C}$ with $\lambda h/N \notin \sigma(a^N)$ and $x, z \in \mathbb{C}^{k(N)}$, where x is written as $x = (x_0, x_1)$ with $x_0 \in \mathbb{R}^n$, then*

(a) $(\lambda Q^N - H^N)x = z$ *if and only if*

$$x = E^N(\lambda)x_0 + T^N(\lambda)z, \tag{3.13.1}$$

$$\Delta^N(\lambda)x_0 = E^N(\lambda)^T F^N z. \tag{3.13.2}$$

(b) $(\lambda Q^N - (H_T^N)^T)x = z$ *if and only if*

$$x = F^N E^N(\lambda)x_0 + T^N(\lambda)^T z, \tag{3.14.1}$$

$$\Delta^N(\lambda)x_0 = E^N(\lambda)^T z. \tag{3.14.2}$$

Proof. We put $z = (z_0, z_1)$, $x_1 = (x_{10}, \cdots, x_{1N})$, $z_1 = (z_{10}, \cdots, z_{1N})$. It is easy to see that $(\lambda Q^N - H^N)x = z$ if and only if

$$(\lambda I - A_0)x_0 - A_1 x_{1N} = z_0, \tag{3.15.1}$$

$$\left(\left(\frac{\lambda h}{N} q^N - h^N\right) \otimes I\right) x_1 = z_1 + \operatorname{col}(x_0, 0, \cdots, 0). \tag{3.15.2}$$

Observing that (see (3.9))

$$\left(\frac{\lambda h}{N} q^N - h^N\right)^{-1} = \begin{pmatrix} \alpha_0^N\left(\frac{\lambda h}{N}\right) & * \text{---} * \\ \vdots & | \quad\quad | \\ \alpha_N^N\left(\frac{\lambda h}{N}\right) & \cdots \quad \alpha_0^N\left(\frac{\lambda h}{N}\right) \end{pmatrix},$$

we get from (3.15.2):

$$x_1 = \left(\left(\frac{\lambda h}{N} q^N - h^N\right) \otimes I\right)^{-1} z_1 + E^N(\lambda)x_0,$$

which proves (3.13.1) and

$$x_{1N} = \alpha_N^N\left(\frac{\lambda h}{N}\right)x_0 + \sum_{k=0}^{N} \alpha_{N-k}^N\left(\frac{\lambda h}{N}\right) z_{1k}.$$

The last expression together with (3.15.1) establishes (3.13.2).

For (b) we observe that $(\lambda Q^N - (H_T^N)^T)x = z$ is equivalent to

$$\lambda x_0 - A_0 x_0 - x_{10} = z_0, \tag{3.16.1}$$

$$\left(\left(\frac{\lambda h}{N} q^N - (h^N)^T\right) \otimes I\right) x_1 = z_1 + \operatorname{col}(0, \cdots, 0, A_1 x_0). \tag{3.16.2}$$

Observing

$$\left(\frac{\lambda h}{N} q^N - (h_T^N)^T\right)^{-1} = \begin{pmatrix} \alpha_0^N\left(\frac{\lambda h}{N}\right) & \cdots & \alpha_N^N\left(\frac{\lambda h}{N}\right) \\ * & & \vdots \\ \vdots & & \\ * & & \alpha_0^N\left(\frac{\lambda h}{N}\right) \end{pmatrix},$$

we get from (3.16.2):

$$x = F^N E^N(\lambda) x_0 + T^N(\lambda) z,$$

which proves (3.14.1), and

$$x_{10} = \sum_{k=0}^{N} \alpha_k^N\left(\frac{\lambda h}{N}\right) z_{1k} + A_1 \alpha_N^N\left(\frac{\lambda h}{N}\right) x_0,$$

which together with (3.16.1) gives (3.14.2). □

In particular, the previous proposition shows that

$$(\lambda Q^N - H^N)^{-1} = E^N(\lambda)\Delta^N(\lambda)^{-1} E^N(\lambda)^T F^N + T^N(\lambda),$$
$$(\lambda Q^N - (H_T^N)^T)^{-1} = F^N E^N(\lambda)\Delta^N(\lambda)^{-1} E^N(\lambda)^T + T^N(\lambda)^T,$$

and hence

$$(\lambda I - A^N)^{-1} = E^N(\lambda)\Delta^N(\lambda)^{-1} E^N(\lambda)^T Q^N F^N + T^N(\lambda) Q^N, \tag{3.17}$$

$$(\lambda I - (A_T^N)^*)^{-1} = F^N E^N(\lambda)\Delta^N(\lambda)^{-1} E^N(\lambda)^T Q^N + T^N(\lambda)^T Q^N \tag{3.18}$$

provided $\lambda \notin \sigma(a^N)$ and $\det \Delta^N(\lambda) \neq 0$.

PROPOSITION 3.7. (a) *The left upper $n \times n$ block $X^N(t)$ in the matrix $e^{A^N t}$ coincides with that of the matrix $e^{(A_T^N)^* t}$. Its Laplace transform is given by $\Delta^N(\lambda)^{-1}$ (see* (3.10) *for the definition of $\Delta^N(\lambda)$).*

(b) *Let $w^N(t) = \operatorname{col}(w_0^N(t), \cdots)$ and $z^N(t) = \operatorname{col}(z_0^N(t), \cdots)$ be the unique solutions of (Σ^N) and $(\Sigma_T^N{}^*)$, respectively, with initial state zero. Then*

$$w_0^N(t) = z_0^N(t) = \int_0^t X^N(t-s) B_0 u(s)\, ds, \qquad t \geqq 0.$$

(c) *The transfer matrices of (Σ^N) and $(\Sigma_T^N{}^*)$ coincide and are given by*

$$G^N(\lambda) = C_0 \Delta^N(\lambda)^{-1} B_0.$$

Proof. Statement (a) is an immediate consequence of (3.17), (3.18), and the special form of the matrices $E^N(\lambda)$, $T^N(\lambda)$, f^N, Q^N. Statements (b) and (c) follow directly from (a). □

The following characterization of stabilizability and detectability for the approximating systems (Σ^N) and $(\Sigma_T^N{}^*)$ is precisely the analogue to (2.7) and (2.8).

THEOREM 3.8. (a) *For $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ the following properties are equivalent:*

(i) $\lambda \in \sigma(A^N)$;

(ii) $\lambda \in \sigma((A_T^N)^*)$;

(iii) $\det \Delta^N(\lambda) = 0$.

In particular, the matrix A^N (or equivalently $(A_T^N)^*$) is stable if and only if $\det \Delta^N(\lambda) \neq 0$ for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$.

(b) *The system (Σ^N) (or equivalently $(\Sigma_T^N{}^*)$) is stabilizable if and only if*

$$\operatorname{rank}[\Delta^N(\lambda), B_0] = n$$

for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$.

(c) *The system* (Σ^N) *(or equivalently* (Σ_T^N*)*) is detectable if and only if*

$$\operatorname{rank}\begin{pmatrix}\Delta^N(\lambda)\\ C_0\end{pmatrix}=n$$

for every $\lambda\in\mathbb{C}$ *with* $\operatorname{Re}\lambda\geqq 0$.

Proof. It is well known from finite-dimensional linear system theory that (Σ^N) is detectable if and only if $\ker(\lambda I-A^N)\cap\ker C^N=\{0\}$, or equivalently,

$$\ker(\lambda Q^N-H^N)\cap\ker C^N=\{0\}$$

for every $\lambda\in\mathbb{C}$ with $\operatorname{Re}\lambda\geqq 0$. But $\lambda(h/N)\notin\sigma(a^N)$ for $\operatorname{Re}\lambda\geqq 0$ (Lemma 3.5(d)). Therefore, according to Proposition 3.6(a), $x=\operatorname{col}(x_0,x_1)\in\ker(\lambda Q-H^N)$ is equivalent to $\Delta^N(\lambda)x_0=0$ and $x=E^N(\lambda)x_0$. This implies that detectability of (Σ^N) is equivalent to

$$\ker\Delta^N(\lambda)\cap\ker C^N=\{0\}$$

for every $\lambda\in\mathbb{C}$ with $\operatorname{Re}\lambda\geqq 0$. When we use Proposition 3.6(b), it follows analogously that this condition is also equivalent to detectability of (Σ_T^N*).

Statement (b) follows from (c) by duality and statement (a) follows from (b) with $B_0=0$. □

THEOREM 3.9. (a) *Let* $\lambda\in\mathbb{C}$ *be such that* $\lambda(h/N)\notin\sigma(a^N)$. *Then* $\lambda\in\sigma(A^N)$ *if and only if* $\det\Delta^N(\lambda)=0$. *If* $\lambda(h/N)\in\sigma(a^N)$, *then* $\lambda\in\sigma(A^N)$ *if and only if* $\det A_1=0$. *Moreover,* $\sigma((A_T^N)*)=\sigma(A^N)$.

(b) *System* (Σ^N) *is controllable if and only if*

$$\operatorname{rank}[\Delta^N(\lambda),B_0]=n\quad\text{for all }\lambda\in\mathbb{C}\backslash\sigma\left(\frac{N}{h}a^N\right),$$

$$\operatorname{rank}[A_1,b_0]=n.$$

(c) *System* (Σ^N) *is observable if and only if*

$$\operatorname{rank}\begin{pmatrix}\Delta^N(\lambda)\\ C_0\end{pmatrix}=n\quad\text{for all }\lambda\in\mathbb{C}\backslash\sigma\left(\frac{N}{h}a^N\right),$$

$$\operatorname{rank}A_1=n.$$

(d) *System* (Σ_T^N*) *is controllable if and only if*

$$\operatorname{rank}[\Delta^N(\lambda),B_0]=n\quad\text{for all }\lambda\in\mathbb{C}\backslash\sigma\left(\frac{N}{h}a^N\right),$$

$$\operatorname{rank}A_1=n.$$

(e) *System* (Σ_T^N*) *is observable if and only if*

$$\operatorname{rank}\begin{pmatrix}\Delta^N(\lambda)\\ C_0\end{pmatrix}=n\quad\text{for all }\lambda\in\mathbb{C}\backslash\sigma\left(\frac{N}{h}a^N\right),$$

$$\operatorname{rank}\begin{pmatrix}A_1\\ C_0\end{pmatrix}=n.$$

Proof. We first prove (c), i.e., we must show that $\ker(\lambda I-A^N)\cap\ker C^N=\{0\}$ for all $\lambda\in\mathbb{C}$. For $\lambda\notin\sigma((N/h)a^N)$, or equivalently, for $\lambda h/N\notin\sigma(a^N)$ we see as in the proof of Theorem 3.8(c) that this is equivalent to $\operatorname{rank}\binom{\Delta^N(\lambda)}{C_0}=n$.

Now let $\lambda \in \sigma((N/h)a^N)$. We assume $\operatorname{rank} A_1 = n$ and take $x = \operatorname{col}(x_0, x_{10}, \cdots, x_{1N}) \in \ker(\lambda I - A^N) \cap \ker C^N$. Then (3.15.2) implies $(((\lambda h/N)q^N - h^N) \otimes I)x_1 = \operatorname{col}(x_0, 0, \cdots, 0)$ and therefore $x_0 = 0$ by Lemma 3.5(c). This and (3.15.1) imply $A_1 x_{1N} = 0$, i.e., $x_{1N} = 0$. Then we get from Lemma 3.5(b) $x_1 = 0$, and thus $x = 0$.

Conversely assume that $\ker(\lambda I - A^N) \cap \ker C^N = \{0\}$ and take $\xi \in \ker A_1$. According to Lemma 3.5(b) there exists a vector $x_1 = \operatorname{col}(x_{10}, \cdots, x_{1N}) \in \mathbb{C}^{(N+1)n}$ such that $[(\lambda(h/N)q^N - h^N) \otimes I]x_1 = 0$ and $x_{1N} = \xi$. For $x = \operatorname{col}(0, x_1)$ equations (3.15) (with $z_0 = 0$) imply $(\lambda Q^N - H^N)x = 0$. Obviously we have $C^N x = 0$. By assumption this implies $x = 0$, and thus $\xi = 0$. We conclude $\operatorname{rank} A_1 = n$. This finishes the proof of statement (c).

It still holds that $\lambda \in \sigma((N/h)a^N)$. Assume that $\ker A_1 \cap \ker c_0 = \{0\}$ and let $x \in \mathbb{C}^{k(N)}$ satisfy $(\lambda Q - (H_T^N)^T)x = 0$, $C^N x = 0$. Then (3.16.2) and Lemma 3.5(c) imply $A_1 x_0 = 0$. This together with $C_0 x_0 = 0$ shows $x_0 = 0$. Hence it follows by (3.16.1) that $x_{10} = 0$. Finally we get from Lemma 3.5(b) that $x_1 = 0$, and thus $x = 0$, i.e., $\ker(\lambda I - (A^N)^*) \cap \ker C^N = \{0\}$.

Conversely, suppose that $\ker(\lambda I - (A_T^N)^*) \cap \ker C^N = \{0\}$ and let $x_0 \in \ker A_1 \cap \ker C_0$. By Lemma 3.5(b) there exists a vector $\alpha = \operatorname{col}(\alpha_0, \cdots, \alpha_N) \in \mathbb{C}^{N+1}$ such that

$$\left(\lambda \frac{h}{N} q^N - (h^N)^T\right)\alpha = 0 \quad \text{and} \quad \alpha_0 = 1.$$

We define $x_1 = \operatorname{col}(x_{10}, \cdots, x_{1N}) \in \mathbb{C}^{n(N+1)}$ by

$$x_{1k} = \alpha_k(\lambda I - A_0)x_0$$

for $k = 0, \cdots, N$. Then it follows from (3.16) that $x = \operatorname{col}(x_0, x_1) \in \ker(\lambda Q^N - (H_T^N)^T) \cap \ker C^N$. By assumption this implies $x = 0$, and hence $x_0 = 0$, i.e., $\ker A_1 \cap \ker C_0 = \{0\}$. Thus statement (e) is proved.

Statements (b) and (d) follow from (e) and (c) by duality. The proof of statement (a) is the same as for (c) with $C^N = 0$, respectively $C_0 = 0$. □

4. Stability. It is our goal to prove that stability (respectively, stabilizability, or detectability) of the original system (Σ) implies the corresponding property for the approximating system (Σ^N) and (Σ_T^{N*}) provided N is sufficiently large. The first step in this direction was the characterization of these properties in Theorem 3.8 using the matrices $\Delta^N(\lambda)$. The second step will be a convergence result for the characteristic matrices $\Delta^N(\lambda)$. As a third step we need a priori bounds for the unstable eigenvalues of the matrices A^N.

4.1. Convergence of $\Delta^N(\lambda)$. First we derive explicit formulas for the $\alpha_k^N(\mu)$ (as defined in (3.8) and (3.9)) and use those to prove convergence of $\Delta^N(\lambda)$ to $\Delta(\lambda)$. Let the rational functions $d_k^N(\mu)$, $k = 0, \cdots, N$, and the polynomials $p_k(\mu)$, $q_k(\mu)$, $k = -1, \cdots, N$, respectively, $k = 1, \cdots, N$, be defined recursively by

$$\begin{aligned} &d_0^N(\mu) = 2\mu + 3, \\ &d_k^N(\mu) = 4\mu + \frac{9 - \mu^2}{d_{k-1}^N(\mu)}, \qquad k = 1, \cdots, N-1, \\ &d_N^N(\mu) = 2\mu + 3 + \frac{9 - \mu^2}{d_{N-1}^N(\mu)}, \end{aligned} \tag{4.1}$$

$$\begin{aligned} &p_{-1}(\mu) = 1, \qquad p_0(\mu) = 2\mu + 3, \\ &p_k(\mu) = 4\mu p_{k-1}(\mu) + (9 - \mu^2)p_{k-2}(\mu), \\ &q_k(\mu) = (2\mu + 3)p_{k-1}(\mu) + (9 - \mu^2)p_{k-2}(\mu). \end{aligned} \tag{4.2}$$

The function $w = w(\mu)$ is defined by

$$w(\mu) = (9+3\mu^2)^{1/2}, \qquad \mu \in \mathbb{C}, \tag{4.3}$$

taking the branch that is positive for $\mu = i\theta$, $\theta \in \mathbb{R}$, $|\theta| < \sqrt{3}$. Furthermore, we set

$$\gamma_0(\mu) = 2\mu + w(\mu), \quad \gamma_1(\mu) = 2\mu - w(\mu), \quad \mu \in \mathbb{C}. \tag{4.4}$$

Since $w(\mu)$ is real for $\mu = i\theta$, $|\theta| \leqq \sqrt{3}$, we obtain

$$|\gamma_0(i\theta)| = |\gamma_1(i\theta)| = |3 - i\theta|, \quad |\theta| \leqq \sqrt{3}, \quad \theta \in \mathbb{R}. \tag{4.5}$$

Therefore the function $\delta = \delta(\theta)$ is well defined by

$$e^{i\delta(\theta)} = \frac{\gamma_1(i\theta)}{\gamma_0(i\theta)} = \frac{7\theta^2 - 9 + 4i\theta w(i\theta)}{9+\theta^2}, \quad |\theta| \leqq \sqrt{3}, \quad \theta \in \mathbb{R},$$
$$0 \leqq \delta(\theta) \leqq 2\pi. \tag{4.6}$$

LEMMA 4.1. (a) *For $k = 0, \cdots, N$ and $\mu \notin \sigma(a^N)$,*

$$\alpha_k^N(\mu) = \frac{6(3-\mu)^k}{d_{N-k}^N(\mu) \cdot \cdots \cdot d_N^N(\mu)} = \frac{6(3-\mu)^k p_{N-k-1}(\mu)}{q_N(\mu)}. \tag{4.7}$$

(b) $\det(\mu q^N - h^N) = (1/6^{N+1}) q_N(\mu)$ *and*

$$2 \cdot 6^{N+1} w \det(\mu q^N - h^N) = (3+w)^2(\gamma_0)^N - (3-w)^2(\gamma_1)^N$$

for all $\mu \in \mathbb{C}$.

(c) *For $\mu \notin \sigma(a^N)$ and $\mu \neq \pm i\sqrt{3}$,*

$$\alpha_k^N(\mu) = 6(3-\mu)^k \frac{(3+w)(\gamma_0)^{N-k} - (3-w)(\gamma_1)^{N-k}}{(3+w)^2(\gamma_0)^N - (3-w)^2(\gamma_1)^N}, \tag{4.8}$$

$k = 0, \cdots, N$. Moreover,

$$|\alpha_{N-k}^N(i\theta)|^2 = 36 \frac{9(1-\cos k\delta(\theta)) + w^2(i\theta)(1+\cos k\delta(\theta))}{(9+w^2(i\theta))^2(1-\cos N\delta(\theta)) + 36w^2(i\theta)(1+\cos N\delta(\theta))} \tag{4.9}$$

for $k = 0, \cdots, N$, $|\theta| < \sqrt{3}$, $\theta \in \mathbb{R}$.

Proof. Suppose that the functions $d_k = d_k^N(\mu)$, $k = 0, \cdots, N$, are given by (4.1) and define

$$b_k = \frac{-3-\mu}{d_{k-1}}, \quad c_k = \frac{3-\mu}{d_{k-1}}, \quad k = 1, \cdots, N.$$

Then it is easy to see that

$$6(\mu q^N - h^N) = \begin{pmatrix} 1 & -b_N & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & -b_1 \\ 0 & \cdots & \cdots & 0 & 1 \end{pmatrix} \begin{pmatrix} d_N & 0 & \cdots & 0 \\ 0 & \ddots & & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & d_0 \end{pmatrix}$$
$$\times \begin{pmatrix} 1 & 0 & \cdots & 0 \\ -c_N & \ddots & \ddots & 0 \\ 0 & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 \end{pmatrix}.$$

It is not difficult to calculate the inverse matrices. Since $\alpha^N(\mu)$ is the first column of $(\mu q^N - h^N)^{-1}$ (see (3.9)) we conclude that

$$\alpha_k^N(\mu) = \frac{6c_{N-k+1} \cdot \cdots \cdot c_N}{d_N} = \frac{6(3-\mu)^k}{d_{N-k} \cdot \cdots \cdot d_N},$$

$k = 0, \cdots, N$.

If the polynomials $p_k(\mu)$ and $q_k(\mu)$ are given by (4.2) and the rational functions $d_k^N(k)$ by (4.1), then we see by induction that

$$d_k^N(\mu) = p_k(\mu)/p_{k-1}(\mu), \qquad k = 0, \cdots, N-1,$$
$$d_N^N(\mu) = q_N(\mu)/p_{N-1}(\mu).$$

This implies

$$p_k(\mu) = d_0^N(\mu) \cdot \cdots \cdot d_k^N(\mu), \qquad k = 0, \cdots, N-1,$$
$$q_N(\mu) = d_0^N(\mu) \cdot \cdots \cdot d_N^N(\mu) = \det[6(\mu q^N - h^N)].$$

This finishes the proof of (a) and also establishes the first part of (b).

To prove (c) we choose $\mu \in \mathbb{C}$, $\mu \neq \pm i\sqrt{3}$. Then $\gamma_0 \neq \gamma_1$ and

$$\gamma_i^2 - 4\mu\gamma_i - (9-\mu^2) = 0, \qquad i = 0, 1.$$

Hence γ_0 and γ_1 are the characteristic roots of the difference equation in (4.2). This implies that

$$p_k(\mu) = \frac{3+w}{2w}(\gamma_0)^{k+1} - \frac{3-w}{2w}(\gamma_1)^{k+1}, \tag{4.10}$$

$k = -1, 0, \cdots, N-1$. Using $\gamma_0\gamma_1 = \mu^2 - 9$, we get from (4.2) and (4.10) that

$$\begin{aligned} q_N(\mu) &= (2\mu+3)p_{N-1}(\mu) + (9-\mu^2)p_{N-2}(\mu) \\ &= \frac{3+w}{2w}[(2\mu+3)(\gamma_0)^N + (9-\mu^2)(\gamma_0)^{N-1}] \\ &\quad - \frac{3+w}{2w}[(2\mu+3)(\gamma_1)^N + (9-\mu^2)(\gamma_1)^{N-1}] \\ &= \frac{(3+w)^2}{2w}(\gamma_0)^N - \frac{(3-w)^2}{2w}(\gamma_1)^N. \end{aligned} \tag{4.11}$$

The second part of (b) and (4.8) are immediate consequences of (4.10), (4.11).

To prove (4.9) we use (4.8) and observe $\gamma_1(i\theta) = e^{i\delta(\theta)}\gamma_0(i\theta)$ and (4.5). □

The explicit formulas in the previous lemma allow us to prove that the matrices $\Delta^N(\lambda)$ actually converge to the characteristic matrix $\Delta(\lambda)$ of the delay system.

THEOREM 4.2. $\Delta(\lambda) = \lim_{N\to\infty} \Delta^N(\lambda)$, $\lambda \in \mathbb{C}$, *the limit being uniform on bounded subsets of* $\mathbb{C}$.

Proof. Fix $\delta \in (0, \sqrt{3})$. Then $w(\mu)$ as defined in (4.3) is continuous and $|w(\mu)+3| \geqq 3$ on $|\mu| \leqq \delta$. From $w(\mu) - 3 = 3\mu^2/(w(\mu)+3)$ we see that

$$|w(\mu) - 3| \leqq |\mu|^2 \quad \text{if } |\mu| \leqq \delta. \tag{4.12}$$

In the next step we prove that $\alpha_N^N(\mu/N)$ converges for arbitrary $c > 0$ uniformly to $e^{-\mu}$ on $|\mu| \leqq c$ as $N \to \infty$. To this end we use formula (4.8) for $k = N$ and obtain, with $w = w(\mu/N)$, $N \geqq c\delta^{-1}$,

$$\alpha_N^N\left(\frac{\mu}{N}\right)^{-1} = \frac{(3+w)^2}{12w}\left(w + 2\frac{\mu}{N}\Big/3 - \frac{\mu}{N}\right)^N - \frac{(3-w)^2}{12w}\left(-w - 2\frac{\mu}{N}\Big/3 - \frac{\mu}{N}\right)^N. \tag{4.13}$$

From (4.12) and $\lim_{N\to\infty} w(\mu/N) = 3$ uniformly on $|\mu| \leqq c$ we see that

$$\lim_{N\to\infty} \frac{(3+w(\mu/N))^2}{12w(\mu/N)} = 1 \quad \text{and} \quad \lim_{N\to\infty} \frac{(3-w(\mu/N))^2}{12w(\mu/N)} = 0$$

uniformly on $|\mu| \leqq c$. Moreover, we also obtain from (4.12):

$$\frac{w+2\mu/N}{3-\mu/N} = 1+\frac{\mu}{N}+\frac{w-3+(\mu/N)^2}{3-\mu/N} = 1+\frac{\mu}{N}+O\left(\frac{1}{N^2}\right),$$

$$\frac{w-2\mu/N}{3-\mu/N} = 1-\frac{\mu}{3N}+\frac{w-3-\frac{1}{3}(\mu/N)^2}{3-\mu/N} = 1-\frac{\mu}{3N}+O\left(\frac{1}{N^2}\right)$$

as $N \to \infty$ uniformly on $|\mu| \leqq c$. These relations together with (4.13) show

$$\lim_{N\to\infty} \alpha_N^N\left(\frac{\mu}{N}\right)^{-1} = e^{\mu}$$

uniformly on $|\mu| \leqq c$. Finally, the theorem follows from (3.10). □

4.2. Uniform bounds. We first establish bounds for the $\alpha_N^N(\mu)$ in $\operatorname{Re}\mu \geqq 0$.

LEMMA 4.3. *The estimate* $|\alpha_N^N(\mu)| \leqq 2$ *is valid for all* $\mu \in \mathbb{C}$ *with* $\operatorname{Re}\mu \geqq 0$ *and all* $N = 1, 2, \cdots$.

Proof. Since, according to Lemmas 3.5(d) and 4.1(b), the polynomial $q_N(\mu)$ is stable, $\alpha_N^N(\mu)$ is a proper rational function without poles in $\operatorname{Re}\mu \geqq 0$ (cf. (4.7)). It follows from the maximum principle for analytic functions that $|\alpha_N^N(\mu)|$ achieves its maximum value in $\operatorname{Re}\mu \geqq 0$ on the imaginary axis. Therefore we only have to prove $|\alpha_N^N(i\omega)| \leqq 2$ for all $\omega \in \mathbb{R}$ and all N.

First we consider $\mu \in i\mathbb{R}$ with $|\mu| \geqq \sqrt{3}$. In this case we have

$$|d_k^N(\mu)| \geqq |3-\mu|, \qquad k = 0, \cdots, N-1, \tag{4.14.1}$$

$$|d_N^N(\mu)| \geqq 3 \tag{4.14.2}$$

for all N. The first estimate is obviously satisfied for $k=0$. Using $2|\mu| \geqq (9+|\mu|^2)^{1/2} = |3-\mu|$, we obtain from (4.1), assuming that the estimate is already established for k:

$$\begin{aligned} |\operatorname{Im} d_{k+1}^N(\mu)| &= \left| 4 \operatorname{Im}\mu - \frac{9+|\mu|^2}{|d_k^N(\mu)|^2} \operatorname{Im} d_k^N(\mu) \right| \\ &\geqq 4|\mu| - \frac{9+|\mu|^2}{|d_k^N(\mu)|^2} \geqq 4|\mu| - (9+|\mu|^2)^{1/2} \\ &\geqq (9+|\mu|^2)^{1/2}, \qquad k = 0, \cdots, N-2. \end{aligned}$$

This proves (4.14.1). To prove (4.14.2) we note that $\operatorname{Re} d_k^N(\mu)$ is always positive (and decreasing with respect to k) because

$$\operatorname{Re} d_{k+1}^N(\mu) = \frac{9+|\mu|^2}{|d_k^N(\mu)|^2} \operatorname{Re} d_k^N(\mu), \qquad k = 0, \cdots, N-2.$$

Therefore the last equation in (4.1) implies

$$\operatorname{Re} d_N^N(\mu) = 3 + \frac{9+|\mu|^2}{|d_{N-1}^N(\mu)|^2} \operatorname{Re} d_{N-1}^N(\mu) \geqq 3,$$

which proves (4.14.2). Now it follows from (4.14) and (4.7) that

$$|\alpha_N^N(\mu)| = 2\frac{|3-\mu|}{|d_0^N(\mu)|} \cdot \cdots \cdot \frac{|3-\mu|}{|d_{N-1}^N(\mu)|} \cdot \frac{3}{|d_N^N(\mu)|} \leqq 2.$$

It remains to consider $\mu = i\theta$ with $|\theta| < \sqrt{3}$, $\theta \in \mathbb{R}$.

Then we obtain from (4.9), with $k = N$,

$$|\alpha_N^N(\mu)|^2 = 36w^2 \Big/ \left((9+w^2)^2 \frac{1-\cos N\delta}{2} + 36w^2 \frac{1+\cos N\delta}{2} \right) \leqq 1,$$

because $6w \leqq 9 + w^2$. □

From Lemma 4.3 we obtain the following a priori bounds for the unstable eigenvalues of the matrices A^N and $(A_T^N)^*$.

PROPOSITION 4.4. *Let* $\omega = \|A_0\| + 2\|A_1\|$. *For every* $N \in \mathbb{N}$ *and every* $\lambda \in \mathbb{C}$ *with* $\operatorname{Re} \lambda \geqq 0$ *and* $\det \Delta^N(\lambda) = 0$ *we have* $|\lambda| \leqq \omega$.

Proof. It follows from Lemma 4.3 that

$$\left\| A_0 + A_1 \alpha_N^N\left(\frac{\lambda h}{N}\right) \right\| \leqq \|A_0\| + 2\|A_1\| = \omega$$

for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ and every $N \in \mathbb{N}$. Therefore we obtain from (3.10) that $\|\lambda I - \Delta^N(\lambda)\| \leqq \omega$ for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ and every $N \in \mathbb{N}$. Hence $\det \Delta^N(\lambda) \neq 0$ for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ and $|\lambda| > \omega$. This proves the statement of the proposition. □

Now we are in a position to prove the desired result on stabilizability and detectability for the approximating systems (Σ^N).

4.3. Stability, stabilizability, and detectability.

THEOREM 4.5. *The following statements are true*:

(a) *If system* (Σ) *is stable, then there exists an* N_0 *such that system* (Σ^N) *is stable for every* $N \geqq N_0$.

(b) *If system* (Σ) *is stabilizable* (*respectively, detectable*) *then there exists an* N_0 *such that system* (Σ^N) *is stabilizable* (*respectively, detectable*) *for every* $N \geqq N_0$.

Proof. Suppose (Σ) is stable. Then $\det \Delta(\lambda) \neq 0$ for every $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$. Hence the uniform convergence result for $\Delta^N(\lambda)$ on bounded domains (Theorem 4.2) shows that $\det \Delta^N(\lambda) \neq 0$ for $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ and $|\lambda| \leqq \omega$ provided N is sufficiently large. If $\omega > 0$ is large enough then we obtain from Proposition 4.4 that $\det \Delta^N(\lambda) \neq 0$ for all $\lambda \in \mathbb{C}$ with $\operatorname{Re} \lambda \geqq 0$ provided N is sufficiently large. Now the stability of (Σ^N) follows from Theorem 3.8(a). This proves (a). Statement (b) can be established analogously. □

Now we might ask whether the stability of system (Σ) implies stability of the approximating systems (Σ^N) uniformly with respect to N, i.e., the existence of constants $M \geqq 1$, $\varepsilon > 0$ such that

$$\|e^{A^N t}\|_N \leqq M e^{-\varepsilon t}, \qquad t \geqq 0$$

for N sufficiently large. A result of this type would be needed to apply a result of Gibson [8] concerning the approximation of the solution to the algebraic Riccati equation. Moreover, the uniform stability has been stated as a conjecture in [3] for the spline approximation scheme developed in [2]. Our result below shows that such a conjecture is definitely wrong for the approximation scheme developed in this paper. This also indicates that it is wrong for the spline approximation scheme in [2].

PROPOSITION 4.6. *Suppose that there exist constants* $M \geqq 1$ *and* $\varepsilon_N > 0$ *such that*

$$\|\exp(Na^N t)\|_N \leqq M e^{-\varepsilon_N t}, \qquad t \geqq 0,$$

for all N. Then $\varepsilon_N = o(1/N^{1/2})$. *Here* $\|\cdot\|_N$ *denotes the operator norm corresponding to the vector norm* $|x|_N^2 = (1/N) x^T q^N x$ *on* $\mathbb{R}^{N+1}$.

Proof. First note that

$$\tfrac{1}{6}x^T x \leqq x^T q^N x \leqq x^T x, \qquad x \in \mathbb{R}^{N+1},$$

and therefore

$$x^T x \leqq x^T (q^N)^{-1} x \leqq 6 x^T x, \qquad x \in \mathbb{R}^{N+1}.$$

This implies, for $x_0 = \operatorname{col}(1, 0, \cdots, 0)$ and $\mu \in i\mathbb{R}$ (cf. (3.9)),

$$\begin{aligned}
\sum_{k=0}^{N} |\alpha_k^N(\mu)|^2 &\leqq 6N |\alpha^N(\mu)|_N^2 = 6N |(\mu q^N - h^N)^{-1} x_0|_N^2 \\
&= 6N \left| \int_0^\infty e^{-\mu t} \exp(N a^N t/N)(q^N)^{-1} x_0 \, dt \right|_N^2 \\
&= 6NM^2 |(q^N)^{-1} x_0|^2 \left(\int_0^\infty e^{-\varepsilon_N(t/N)} \, dt \right)^2 \\
&= \frac{6N^3 M^2}{\varepsilon_N^2} |(q^N)^{-1} x_0|_N^2 = \frac{6N^2 M^2}{\varepsilon_N^2} x_0^T (q^N)^{-1} x_0 \\
&\leqq \frac{36 N^2 M^2}{\varepsilon_N^2}.
\end{aligned}$$

Therefore

$$\varepsilon_N \leqq 6NM \left(\sum_{k=0}^{N} |\alpha_k^N(\mu)|^2 \right)^{-1/2} \tag{4.15}$$

for all $\mu \in i\mathbb{R}$.

Now let $\mu = i\theta$ satisfy $|\theta| < \sqrt{3}$, $\theta \in \mathbb{R}$. Since $\delta(i\theta) \to 0$ as $|\theta| \to \sqrt{3}$, we can choose a sequence $\theta_N \in \mathbb{R}$, $|\theta_N| < \sqrt{3}$, such that $|\theta_N| \to \sqrt{3}$ and $\delta_N = \delta(i\theta_N) = 2\pi/N$. We put $w_N = w(i\theta_N)$ and get, using (4.9) and $\sum_{k=0}^{N} \cos(2k\pi/N) = 1$,

$$\begin{aligned}
\sum_{k=0}^{N} \left| \alpha_{N-k}^N(i\theta_N) \right|^2 &= \frac{9}{w_N^2} \sum_{k=0}^{N} \left(1 - \cos \frac{2k\pi}{N} \right) + \frac{1}{2} \sum_{k=0}^{N} \left(1 + \cos \frac{2k\pi}{N} \right) \\
&\geqq \frac{9}{2w_N^2} N.
\end{aligned} \tag{4.16}$$

From (4.6) we get

$$\sin \delta(\theta) = \frac{4\theta w(i\theta)}{9 + \theta^2},$$

which shows that for positive constants c_1, c_2,

$$\frac{c_1}{N} \leqq w_N \leqq \frac{c_2}{N} \quad \text{for all } N.$$

This and (4.16) imply

$$\sum_{k=0}^{N} |\alpha_k^N(\mu_N)|^2 \geqq \text{const. } N^3.$$

This last estimate and (4.15) show that

$$\varepsilon_N \leqq \text{const.} \frac{1}{N^{1/2}}.$$

FIG. 2

The result above shows that exponential stability uniform with respect to N is, in general, impossible for our scheme. Numerical studies show that there is a sequence λ_N, $N=1,2,\cdots$, of eigenvalues $\lambda_N \in \sigma((N/h)a^N)$ such that $\operatorname{Re}\lambda_N \to 0$ and $\operatorname{Im}\lambda_N \to \infty$. In fact, the numerical results indicate $\operatorname{Re}\lambda_N = O(1/N^2)$. In the general case where $\sigma((N/h)a^N)$ is not part of $\sigma(A^N)$, numerical studies still show the existence of a sequence λ_N, $N=1,2,\cdots$, such that $\lambda_N \in \sigma(A^N)$ with $\operatorname{Re}\lambda_N < 0$, $\operatorname{Re}\lambda_N \to 0$ and $\operatorname{Im}\lambda_N \to \infty$. Figure 1 illustrates the location of the spectrum for the approximating systems in case of the scalar equation $\dot{x}(t) = x(t) + x(t-1)$. For comparison Fig. 2 illustrates the spectrum of Na^N.

5. Uniform output stability. Despite the negative result of Proposition 4.6 and the fact that some eigenvalues of the approximating systems approach the imaginary axis, we are still able to prove a uniform L^2-estimate for the $\mathbb{R}^n$-components

$$z_0^N(t;\phi) \in \mathbb{R}^n, \qquad w_0^N(t;f) \in \mathbb{R}^n$$

of the unique solutions of (Σ^N) and (Σ_T^{N*}) (with $u \equiv 0$). We call this property the uniform output stability of the systems (Σ^N) and (Σ_T^{N*}).

THEOREM 5.1. *Suppose system* (Σ) *is stable. Then the approximating systems* (Σ^N) *and* (Σ_T^{N*}) *are uniformly output stable for* N *sufficiently large, i.e., there exists an* $N_0 \in \mathbb{N}$ *and a constant* $c > 0$ *such that for* $N \geqq N_0$

$$\int_0^\infty |z_0^N(t;\phi)|_{\mathbb{R}^n}^2 \, dt \leqq c\|\phi\|_{M^2}^2 \quad \text{for all } \phi \in M^2, \tag{5.1}$$

$$\int_0^\infty |w_0^N(t;f)|_{\mathbb{R}^n}^2 \, dt \leqq c\|f\|_{M^2}^2 \quad \text{for all } f \in M^2. \tag{5.2}$$

Proof. Choose $N_0 \in \mathbb{N}$ such that $\det \Delta^N(\lambda) \neq 0$ for all $\lambda \in \mathbb{C}$ with $\operatorname{Re}\lambda \geqq 0$ and all $N \geqq \mathbb{N}_0$ (Theorem 4.5). Then it follows from (3.17), (3.18), and Lemma 3.2 that the Fourier transforms of $z_0^N(t;\phi)$ and $w_0^N(t;f)$ (determined to be identically zero for $t<0$) are given by

$$\hat{z}_0^N(i\omega;\phi) = \Delta^N(i\omega)^{-1} E^N(i\omega)^T Q^N \pi^N F\phi, \qquad \omega \in \mathbb{R},$$

$$\hat{w}_0^N(i\omega;\phi) = \Delta^N(i\omega)^{-1} E^N(i\omega)^T Q^N \pi^N f, \qquad \omega \in \mathbb{R},$$

for $N \geqq N_0$. Using Plancherel's theorem, we see that to prove (5.1) and (5.2) it is enough to show

$$\int_{-\infty}^\infty |\Delta^N(i\omega)^{-1} E^N(i\omega)^T Q^N z|_{\mathbb{R}^n}^2 \, dt \leqq 2\pi c z^T Q^N z$$

for all $z \in \mathbb{R}^{k(N)}$ and all $N \geqq N_0$. The definition of $E^N(\lambda)$ in (3.11), together with Lemma 4.3, show that it suffices to prove a uniform estimate of the form

$$\frac{1}{N}\int_{-\infty}^\infty \|\Delta^N(i\omega)^{-1}\|^2 \sum_{k=0}^N \left|\alpha_k^N\left(\frac{i\omega h}{N}\right)\right|^2 d\omega \leqq c \tag{5.3}$$

for all $N \geqq N_0$ (with a possibly different constant c). Of course, it is only necessary to consider $\omega \geqq 0$.

Using (3.10) and Lemma 4.3 we immediately get the estimate

$$\|\Delta^N(i\omega)^{-1}\| \leqq \frac{1}{|\omega| - c_0} \quad \text{for } |\omega| > c_0, \quad N = 1, 2, \cdots,$$

where $c_0 = \|A_0\| + 2\|A_1\|$. By Theorem 4.2 and the stability assumption on (Σ) we obtain

$$\|\Delta^N(i\omega)^{-1}\|^2 \leqq \frac{c_1}{1+\omega^2} \quad \text{for all } \omega \in \mathbb{R} \tag{5.4}$$

and N sufficiently large, where c_1 is not dependent on N.

Defining

$$f^N(\theta) = \frac{1}{N} \sum_{k=0}^{N} |\alpha_k^N(i\theta)|^2,$$

we find that for all $N = 1, 2, \cdots$

$$f^N(\theta) \leqq \frac{N+1}{N} 4 \leqq 8 \quad \text{for } \theta \geqq \sqrt{3} \tag{5.5}$$

and for any $\alpha \in (0, 1)$

$$f^N(\theta) \leqq \frac{N+1}{N} \frac{2}{1-\alpha^2} \leqq \frac{4}{1-\alpha^2} \quad \text{for } 0 \leqq \theta \leqq \alpha\sqrt{3}. \tag{5.6}$$

The estimate (5.5) is a straightforward consequence of (4.7) and estimates (4.14). To obtain (5.6) we can use the representation (4.9) and the estimates $w^2(i\theta) = 9 - 3\theta^2 \geqq 9(1-\alpha^2)$, $w^2(i\theta) \leqq 9$, and $9 + w^2(i\theta) \geqq 6w(i\theta)$ for $0 \leqq \theta \leqq \alpha\sqrt{3}$.

It remains to investigate the behaviour of $f^N(\theta)$ at intervals of the form $(\alpha\sqrt{3}, \sqrt{3})$, $0 < \alpha < 1$. There we cannot expect to have a bound for $f^N(\theta)$ uniformly with respect to N. Formula (4.9) shows that we should expect difficulties for those θ near $\sqrt{3}$ such that $N\delta(\theta)$ is close to an integer multiple of 2π. This reflects the fact that the eigenvalues of a^N are closest to the imaginary axis near $\pm iN\sqrt{3}$ (see Fig. 2), i.e., for $\theta = \omega h / N$ close to $\pm\sqrt{3}$. In Fig. 3 we show the plot for $f^N(\omega h/N)$, $N = 10, 20, 30, 40$, $h = 1$, which illustrates the difficulties.

We first determine those parts of $(\alpha\sqrt{3}, \sqrt{3})$, where we still can find a uniform bound for $f^N(\theta)$. Since α is not yet fixed we consider $\theta \in [0, \alpha\sqrt{3}]$.

CLAIM 1. *If $\theta \in [0, \sqrt{3}]$ is such that $0 \leqq \delta(\theta) \leqq \pi/3N$, then*

$$f^N(\theta) \leqq 8 \quad \textit{for all } N. \tag{5.7}$$

Proof. From $\frac{1}{2} \leqq \cos N\delta(\theta) \leqq \cos k\delta(\theta)$, $k = 0, \cdots, N$, and (4.9) we get

$$|\alpha_{N-k}^N(i\theta)|^2 \leqq 4 \frac{9(1-\cos N\delta(\theta)) + w^2(i\theta)(1+\cos k\delta(\theta))}{9(1-\cos N\delta(\theta)) + 4w^2(i\theta)(1+\cos N\delta(\theta))}$$

$$\leqq 4 \frac{9(1-\cos N\delta(\theta)) + 2w^2(i\theta)}{9(1-\cos N\delta(\theta)) + 6w^2(i\theta)} \leqq 4,$$

for $k = 0, \cdots, N$, which implies the result. □

CLAIM 2. *If $\theta \in [0, \sqrt{3}]$ is such that $|\delta(\theta) - 2\pi(\nu/N)| \geqq \pi/3N$ for $\nu = 0, \cdots, [N/2]$, then*

$$f^N(\theta) \leqq 64 \quad \textit{for all } N. \tag{5.8}$$

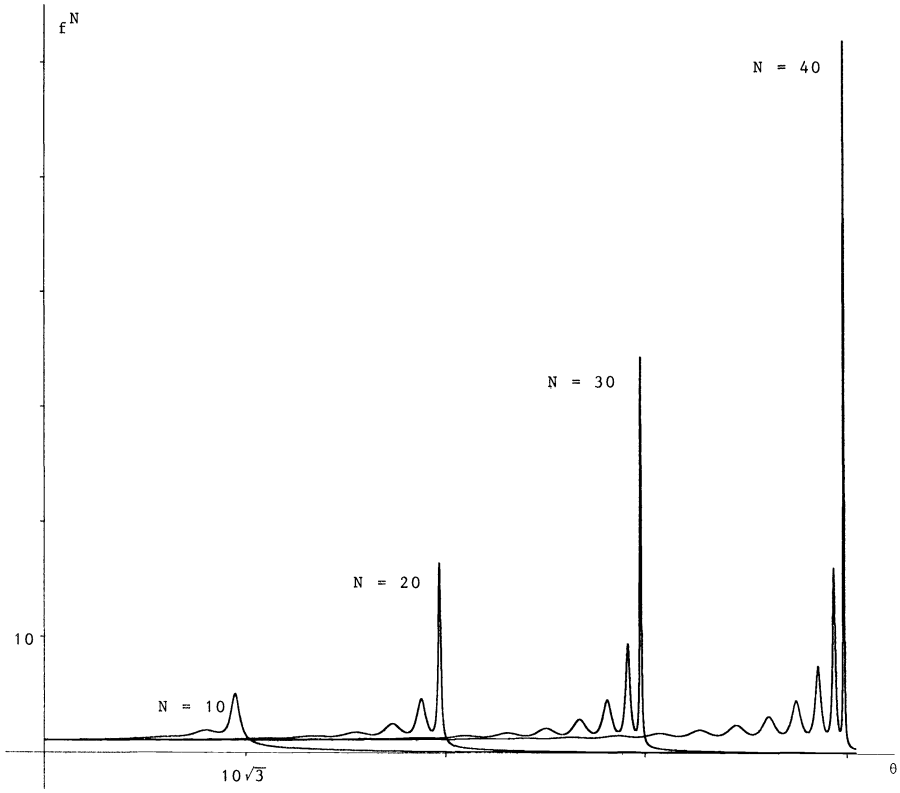

FIG. 3

Proof. From $\cos N\delta(\theta) \leqq \cos(\pi/3) = \frac{1}{2}$, $w^2(i\theta) \leqq 9$ and (4.9) we obtain

$$|\alpha_{N-k}^N(i\theta)|^2 \leqq 36 \frac{2 \cdot 9 + 2 \cdot 9}{9^2(1 - \cos N\delta(\theta))} \leqq 36, \qquad k = 0, \cdots, N. \qquad \square$$

For ν, $N \in \mathbb{N}$ and $\alpha \in (0, 1)$ we define the intervals

$$I_\nu^N = \left\{ \theta \in [\alpha\sqrt{3}, \sqrt{3}] \,\middle|\, |N\delta(\theta) - 2\pi\nu| < \frac{\pi}{3} \right\}.$$

We have $I_\nu^N \neq \varnothing$ if and only if $\nu = 0, \cdots, \nu_1$, where $\nu_1 < N$ is determined by the conditions $2\pi\nu_1 - \pi/3 < N\delta(\alpha\sqrt{3})$ and $2\pi(\nu_1 + 1) - \pi/3 \geqq N\delta(\alpha\sqrt{3})$. Inequalities (5.5)-(5.8) imply that for any $\alpha \in (0, 1)$ there exists a constant $c = c(\alpha)$ independent of N such that

$$f^N(\theta) \leqq c(\alpha), \qquad \theta \in M := [0, \infty) \Big\backslash \bigcup_{\nu=1}^{\nu_1} I_\nu^N \tag{5.9}$$

for all $N \in \mathbb{N}$. Let $\tilde{M} = \{\omega \geqq 0 \,|\, \omega h/N \in M\}$. Then by (5.4) and (5.9)

$$\int_{\tilde{M}} \|\Delta^N(i\omega)^{-1}\|^2 f^N\left(\frac{\omega h}{N}\right) d\omega \leqq c(\alpha) c_1 \frac{\pi}{2}. \tag{5.10}$$

Let $\tilde{I}_\nu^N = \{\omega \geqq 0 \,|\, (\omega h/N) \in I_\nu^N\}$, ν, $N \in \mathbb{N}$. Then by (5.4) (note, that $\omega > \alpha_0\sqrt{3}(N/h)$ for $\omega \in \tilde{I}_\nu^N$)

$$J = \sum_{\nu=1}^{\nu_1} \int_{\tilde{I}_\nu^N} \|\Delta^N(i\omega)^{-1}\|^2 f^N\left(\frac{\omega h}{N}\right) d\omega$$

$$\leqq \frac{c_1}{1+3\alpha_0^2 N^2/h^2} \sum_{\nu=1}^{\nu_1} \frac{N}{h} \int_{I_\nu^N} f^N(\theta)\, d\theta \tag{5.11}$$

for N sufficiently large. It remains to prove an estimate of the form

$$\sum_{\nu=1}^{\nu_1} \frac{N}{h} \int_{I_\nu^N} f^N(\theta)\, d\theta \leqq c$$

for all $N = 1, 2, \cdots$, where c is independent of N.

Now we fix $\alpha = \alpha_0$ by imposing the condition

$$\delta(\alpha_0\sqrt{3}) = \frac{\pi}{2}. \tag{5.12}$$

Then there exists a constant c_2 such that

$$\frac{1}{c_2}\delta(\theta) \leqq w(i\theta) \leqq c_2\delta(\theta), \qquad \theta \in [\alpha_0\sqrt{3}, \sqrt{3}]. \tag{5.13}$$

Proof of (5.13). From (4.6) we see that $\sin \delta(\theta) = 4\theta w(i\theta)/(9+\theta^2)$. Therefore

$$\frac{4\alpha_0\sqrt{3}}{12} w(i\theta) \leqq \sin \delta(\theta) \leqq \frac{4\sqrt{3}}{9} w(i\theta), \qquad \theta \in [\alpha_0\sqrt{3}, \sqrt{3}]. \tag{5.14}$$

The monotonicity of $\delta(\theta)$ and (5.11) imply $0 \leqq \delta(\theta) \leqq \pi/2$. Then $(2/\pi)\delta(\theta) \leqq \sin \delta(\theta) \leqq \delta(\theta)$, which together with (5.14) implies the result. □

CLAIM 3. *There exists a constant c_3 independent of N and ν such that*

$$|I_\nu^N| \leqq c_3 \frac{\nu}{N^2} \tag{5.15}$$

for $N = 1, 2, \cdots$ and $\nu = 1, \cdots, \nu_1$. Here $|I_\nu^N|$ denotes the length of the interval I_ν^N.

Proof. From (5.13) we get

$$-\frac{1}{w(i\theta)} \leqq -\frac{1}{c_2\delta(\theta)}, \qquad \theta \in [\alpha_0\sqrt{3}, \sqrt{3}]. \tag{5.16}$$

The definition (4.6) of $\delta(\theta)$ together with (4.3) implies

$$\delta'(\theta) = -\frac{36}{(9+\theta^2)w(i\theta)}.$$

Using (5.16), for $\theta \in I_\nu^N$ we obtain

$$\delta'(\theta) \leqq -\frac{36}{9+\theta^2} \cdot \frac{1}{c_2\delta(\theta)} \leqq -\frac{3}{c_2\delta(\theta)} \leqq -\frac{1}{c_2\pi} \frac{N}{\nu}.$$

Therefore

$$\frac{2\pi}{3N} = -\int_{I_\nu^N} \delta'(\theta)\, d\theta \geqq \frac{1}{c_2\pi} \frac{N}{\nu} |I_\nu^N|$$

for $N = 1, 2, \cdots$ and $\nu = 1, \cdots, \nu_1$, which proves the result. □

CLAIM 4. *There exists a constant c_4 independent of N and ν such that*

$$f^N(\theta) \leqq c_4 \left(\frac{N}{\nu}\right)^2 \tag{5.17}$$

for $\theta \in I_\nu^N$, $N = 1, 2, \cdots$ and $\nu = 1, \cdots, \nu_1$.

Proof. Let $\theta \in I_\nu^N$. Then $\delta(\theta) > (2\pi\nu - \pi/3)/N$ and by (5.13) we obtain

$$w(i\theta) > \frac{1}{c_2} \cdot \frac{1}{N}\left(2\pi\nu - \frac{\pi}{3}\right) \geqq \frac{5\pi}{3c_2} \cdot \frac{\nu}{N}.$$

This together with (4.9), $w^2(i\theta) \leqq 9$, and $\cos N\delta(\theta) > \frac{1}{2}$ for $\theta \in I_\nu^N$ implies

$$|\alpha_{N-k}^N(i\theta)|^2 \leqq \frac{18}{(1+\cos N\delta(\theta))w^2(i\theta)} \leqq \frac{108c_2^2}{25\pi^2} \cdot \frac{N^2}{\nu^2}.$$

Then the result follows immediately. □

Using (5.11), (5.15), and (5.17) we get the following estimate for J:

$$\begin{aligned} J &\leqq \frac{c_1c_3c_4}{1+3\alpha_0^2N^2/h^2} \frac{N}{h} \sum_{\nu=1}^{\nu_1} \left(\frac{N}{\nu}\right)^2 \frac{\nu}{N^2} \\ &\leqq \frac{c_1c_3c_4}{h} \frac{N}{1+3\alpha_0^2N^2/h^2} \sum_{\nu=1}^{N} \frac{1}{\nu} \leqq \frac{c_1c_2c_3}{h} \frac{N(1+\ln N)}{1+3\alpha_0^2N^2/h^2} \end{aligned}$$

for N sufficiently large. This together with (5.10) establishes (5.3). Thus the proof of Theorem 5.1 is finished.

Remarks. (1) Uniform output stability in general does not imply a uniform (with respect to N) exponential decay for the $\mathbb{R}^n$-components of solutions of the approximating equations. If we are willing to accept the existence of eigenvalues λ_N for the approximating equations with $\operatorname{Re}\lambda_N \to 0$ as $N \to \infty$ also in case $\det A_1 \neq 0$ (as is demonstrated numerically in Fig. 1 but not proved in this paper), it is sufficient to show that in case $\det A_1 \neq 0$ any eigenvector for the approximating system has a nonzero $\mathbb{C}^n$-component. To prove this, assume $y^N = \operatorname{col}(y_0^N, y_1^N)$ with $y_0^N \in \mathbb{C}^n$, $y_1^N \in \mathbb{C}^{(N+1)n}$ is an eigenvector of A^N corresponding to the eigenvalue λ_N. Assume $y_0^N = 0$. Then $A^N y^N = \lambda_N y^N$ is equivalent to

$$(0 \text{ ——— } 0\ A_1)y_1^N = 0 \quad \text{and} \quad \frac{N}{h}(a^N \otimes I)y_1^N = \lambda_N y_1^N. \tag{5.18}$$

The second equation implies $y_1^N = x \otimes v$, where $a^N x = (\lambda h/N)x$, $x = (x_0, \cdots, x_N) \in \mathbb{C}^{N+1}\backslash\{0\}$ and $v \in \mathbb{C}^n\backslash\{0\}$. By Lemma 3.5(b) we have $x_N \neq 0$. The first equation in (5.18) implies $A_1(x_N v) = x_N A_1 v = 0$, a contradiction to $\det A_1 \neq 0$.

(2) It is interesting to state a consequence of uniform output stability for the eigenvectors of the approximating equations. Assume (Σ) is stable so that (5.1) is true, and let $y^N = (y_0^N, y_1^N)$, $y_0^N \in \mathbb{C}^n$, $y_1^N \in \mathbb{C}^{(N+1)n}$ be an eigenvector of A^N corresponding to an eigenvalue λ_N. Then $z_0^N(t; \iota^N y^N) = y_0^N e^{\lambda_N t}$, $t \geqq 0$, and therefore

$$\int_0^\infty |z_0^N(t; \iota^N y^N)|_{\mathbb{C}^n}^2 \, dt = \frac{1}{2|\operatorname{Re}\lambda_N|} |y_0^N|_{\mathbb{C}^n}^2.$$

For $N \geqq N_0$, (5.1) implies

$$|y_0^N|_{\mathbb{C}^n}^2 \leqq \frac{2c|\operatorname{Re}\lambda_N|}{1-2c|\operatorname{Re}\lambda_N|} |(\iota^N y^N)^1|_{L^2}^2$$

provided $|\operatorname{Re}\lambda_N| < 1/2c$. Therefore if $|\operatorname{Re}\lambda_N| \to 0$ as $N \to \infty$ then also $y_0^N \to 0$ in $\mathbb{C}^n$.

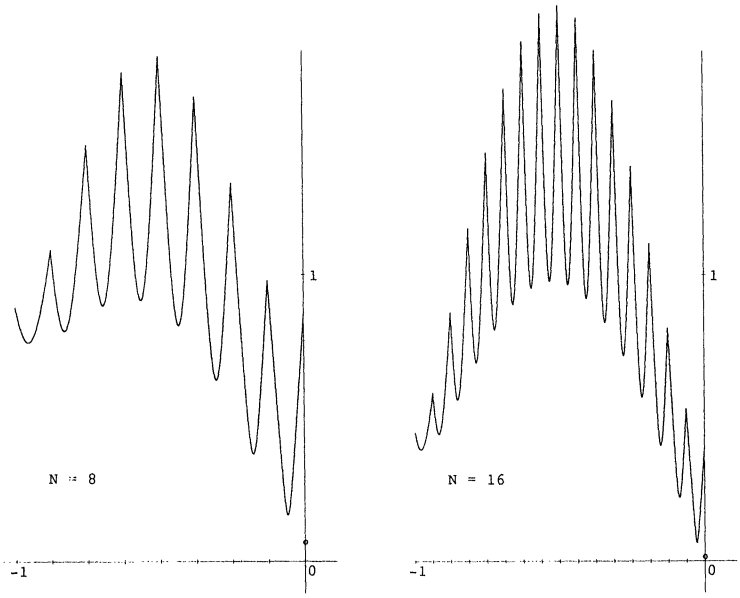

FIG. 4

Figure 4 shows, for $N=8$, 16, $|(\iota^N y^N)^1(\theta)|$, $-1 \leqq \theta \leqq 0$, and $|(\iota^N y^N)^0|$ for the normalized eigenvector y^N (i.e., $\|\iota^N y\|_{M^2}=1$) of A^N corresponding to the eigenvalue λ_N with the smallest real part (and at the same time largest imaginary part) in case of the scalar equation $\dot{x}(t)=-2x(t)+x(t-1)$. The eigenvalues λ_N and $|(\iota^N y^N)^0|$, $N=4$, 8, 16, are given by

$$\lambda_4=-2.9294+5.1788i, \quad \lambda_8=-0.7218+12.7848i, \quad \lambda_{16}=-0.1874+27.0462i,$$
$$|(\iota^4 y^4)^0|=0.3536, \quad |(\iota^8 y^8)^0|=0.0690, \quad |(\iota^{16} y^{16})^0|=0.0167.$$

(3) Uniform output stability is sufficient to prove convergence of the approximating Riccati operators in the case of the infinite time horizon problem observed numerically in [11]. This will be shown in a forthcoming paper [12].

Acknowledgment. We thank W. Prager for the computations concerning Figs. 1-4.

MINIMIZING ESCAPE PROBABILITIES: A LARGE DEVIATIONS APPROACH*

PAUL DUPUIS† AND HAROLD KUSHNER‡

Abstract. This paper considers the problem of controlling a possibly degenerate diffusion process so as to minimize the probability of escape over a given time interval. It is assumed that the control acts on the process through the drift coefficient, and that the noise coefficient is small. Developing a large deviations type of theory for the controlled diffusion produces several results. The limit of the normalized log of the minimum exit probability is identified as the value I of an associated (deterministic) differential game. Furthermore, we identify a deterministic (and ε-independent) mapping g from the sample values $\varepsilon w(s)$, $0 \leqq s \leqq t$, into the control space such that if we define the control used at time t by $u(t) = g(\varepsilon w(s), 0 \leqq s \leqq t)$, then the resulting control process is progressively measurable and δ-optimal (in the sense that the limit of the normalized log of the exit probability is within δ of I).

1. Introduction.

Consider the white-noise-driven control system living in $\mathbb{R}^d$:

$$dx^{u,\varepsilon} = b(x^{u,\varepsilon}, u)\,dt + \varepsilon\sigma(x^{u,\varepsilon})\,dw, \tag{1.1}$$

where u takes values in a compact set $K \subset \mathbb{R}^n$. There are many problems where we want to keep $x^{u,\varepsilon}(\cdot)$ in a set G until some particular job is finished. For example, in the problem of pointing a telescope on a satellite, the domain G and the duration are determined by the object to be photographed and the time required. See Meerkov and Runolfsson [6] for additional examples.

The associated control problem can be formulated in several different ways, depending on the time interval of interest. We consider two criteria. Define $\tau^{u,\varepsilon} = \inf\{t: x^{u,\varepsilon}(t) \in \partial G\}$. One criterion is to minimize

$$P_x\{\tau^{u,\varepsilon} \leqq T\}, \qquad x \in G^0 = \text{interior of } G \tag{1.2a}$$

for given T. The other criterion of interest here is the maximization of

$$E_x\tau^{u,\varepsilon}, \qquad x \in G^0. \tag{1.2b}$$

P_x and E_x denote the probability and expectation (respectively) given $x^{u,\varepsilon}(0) = x$.

In general, it is very difficult to solve for the optimal control. However, in many problems the parameter ε is small. The theory of large deviations provides an alternative that can give a nearly optimal control for small ε, and a great deal more information and insight into the control process, likely escape routes, error bounds, etc. Take u to be a feedback function $u(x, t)$ that is smooth in x, uniformly in $t \leqq T$. Let r be the

dimension of $w(\cdot)$. For $v(\cdot)$ that is measurable, lives in $\mathbb{R}^r$, and is such that $\int_0^1 |v|\, dt < \infty$, define the system

$$\dot{\phi} = b(\phi, u(\phi, t)) + \sigma(\phi)v, \qquad \phi(0) = x,$$

and define

$$S(x, u, T) = \inf\left\{\frac{1}{2}\int_0^T |v(t)|^2\, dt\colon \phi(t) \in \partial G \text{ for some } t \leqq T\right\}.$$

The theory of large deviations tells us (under some other regularity conditions) that

$$S(x, u, T) = -\lim_{\varepsilon} \varepsilon^2 \log P_x\{\tau^{u,\varepsilon} \leqq T\}.$$

Because of this result, we are tempted to try to maximize (or nearly maximize) $S(x, u, T)$, and to use the corresponding (if any) maximizing (or "smooth" nearly maximizing) control. This approach encounters serious unresolved technical difficulties. In particular, it is not at all clear that the supremum over smooth feedback controls will be as large as that obtained over alternative classes of controls, such as those used below. Note that since we wish to supremize (over u) an infimum over v, the basic problem can be formulated as a differential game.

We mention here that calculating the limit of the normalized log of the minimum exit probability is by itself not useful in establishing the optimal performance for all small ε of any given control scheme. It may happen that a control that is found to be good for a small but fixed $\varepsilon > 0$ actually behaves poorly in the limit $\varepsilon \to 0$. Obtaining a "good" control that depends on ε only through the actual driving noise process will be an important part of the development below.

Known results in this area are few in number. Fleming and Souganidis [3] consider the large deviations problem associated with the minimization of (1.2a) over the class of feedback controls taking values in K. By use of PDE-viscosity solution techniques they calculate the asymptotics of the infimum of the exit probabilities. Their approach is restricted to the case where the diffusion is uniformly nondegenerate: $\sigma(x)\sigma'(x) \geqq cI$, with $c > 0$. Furthermore, they identify the limit as the value of a certain associated (deterministic) differential game. They do not deal with the uniformity issue raised previously, nor with the problem of construction of δ-optimal policies and their uniformity properties. Wentzell and Freidlin [5] consider the optimization problem associated with (1.2b) for a wide class of processes that includes (1.1) in the uniformly nondegenerate case. However, to obtain a solution with the desired properties, they restrict the class of available controls in a way that is probably not natural for these types of problems. For example, they consider feedback controls that are continuous, except possibly at one point. Simple examples in dimension greater than one show that the "best" control may have discontinuities along manifolds of dimension one less.

The objective of this paper is to extend the conclusions of [3]. By use of probabilistic arguments (as opposed to PDE), we recover the results presented there. The probabilistic arguments allow us to extend these results to the important *degenerate case*, which is in fact more natural in applications. We also address the uniformity issue raised above. The results in this direction are not completely satisfactory in that the exhibited control is not of the simple feedback form, but depends on the "full information" of the past. However, they do suggest that feedback controls are available that do not depend on ε explicitly, and are nearly optimal for small ε.

Our basic assumptions and definitions are as follows.

Assumption A1.

(1) $b(\cdot,\cdot)$ and $\sigma(\cdot)$ are Lipschitz with constant $\bar{K}$ and bounded with constant B on an open set containing $\bar{G}$, the closure of G.

(2) The control space K is compact and independent of time.

(3) G is an open set in $\mathbb{R}^d$.

(4) Either (i) $\sigma(\cdot)$ is a square matrix and uniformly nondegenerate, or (ii) we can partition b and σ in the form

$$b(x,u)=\begin{bmatrix} b_1(x,u) \\ b_2(x) \end{bmatrix}, \qquad \sigma(x)=\begin{bmatrix} \sigma_1(x) \\ 0 \end{bmatrix},$$

where $\sigma_1(\cdot)$ is a square matrix and uniformly nondegenerate.

Throughout the paper we shall assume that we are given a probability space $(\Omega, \mathcal{F}, \mathcal{F}(t), P)$ and a Wiener process $w(\cdot)$ on $[0,1]$ with respect to $\mathcal{F}(t)$. We then take as our class of admissible controls the set of K-valued progressively measurable processes. We denote the set of all such processes by F. For convenience we recall the definition of a progressively measurable process (with respect to $\mathcal{F}(t)$).

DEFINITION. A stochastic process $\xi(t)$ on the sample space Ω and time interval $[0,1]$ is $\mathcal{F}(t)$-progressively measurable if the mapping $[0,t]\times\Omega \ni (s,\omega)\to\xi(s)(\omega)$ is $B(t)\times\mathcal{F}(t)$ measurable for every $0\leqq t\leqq 1$, where $B(t)$ is the Borel σ-algebra of $[0,t]$.

Remark. The symbol u will be used to represent two different types of control processes, depending on the context. At times it will be a deterministic process used in the differential game, and at times it will denote a stochastic process used to control the diffusion. Likewise v will be used to represent both stochastic and deterministic processes, depending on the context. In all cases the intended use should be clear.

The organization of the remainder of the paper is as follows. In § 2 we give a precise definition of the associated differential game in terms of an adaptation of the Elliott-Kalton [4] formulation, and discuss how the existence of value for this differential game relates to our problem. The only difference between our definition and the usual Elliott-Kalton definition is the added requirement that the maps α and β defined below must be measurable. The additional requirement of measurability is due to the fact that several uses are made of stochastic processes defined by composing α (or β) with a given progressively measurable process. Measurability of α (or β) ensures that the resulting process is adapted. The addition of this condition does not change the resulting "value" of the game. Section 3 contains the statement and proof of the main theorem. The proofs of several technical lemmas make up a concluding Appendix. For notational simplicity, we shall consider the problem on the interval $[0,1]$. The results carry over to an arbitrary interval in the obvious way.

Notation. We use $C_x[0,1]$ to denote the set of continuous functions taking values in $\mathbb{R}^k$ (with k depending on the context) and starting at x, and take $d(\cdot,\cdot)$ as the sup norm metric in this space.

2. The associated differential game. Define

$$M=\{u:[0,1]\to K: u \text{ is measurable}\},$$

$$N=\left\{v:[0,1]\to\mathbb{R}^r: \int_0^1 |v|\,dt<\infty\right\}.$$

We identify any two functions that agree almost everywhere and consider M and N as metric spaces with the L^1 metric. A mapping $\alpha: N\to M$ is called a *strategy for the maximizing player* if α is measurable (with respect to the Borel σ-algebras induced

by the inherited metric), and if whenever $0 \leqq s \leqq 1$ and

$$v(t) = \hat{v}(t) \quad \text{for a.e. } 0 \leqq t \leqq s,$$

then

$$\alpha[v](t) = \alpha[\hat{v}](t) \quad \text{for a.e. } 0 \leqq t \leqq s.$$

A *strategy for the minimizing player* is defined in an analogous way, and such a strategy will be denoted by the symbol β. The set of all minimizing (respectively, maximizing) strategies will be denoted by Δ (respectively, Γ).

Next define $\chi(x)$ to be zero if $x \in \partial G$ and $+\infty$ if $x \in G^0$. The definition of the differential game (DG) is then given in terms of the following dynamical equation and cost.

Dynamics.

$$\dot{\phi} = b(\phi, u) + \sigma(\phi)v, \qquad \phi(0) = x. \tag{2.1}$$

Let $\tau_x = \inf\{t: \phi(t) \in \partial G\} \wedge 1$.

Cost. For $\phi(\cdot)$ defined through (2.1), set

$$C(u, v) = \frac{1}{2}\int_0^{\tau_x} |v(t)|^2 \, dt + \chi(\phi(\tau_x)).$$

We then define the *lower value* of the DG by

$$I^-(x) = \inf_{\beta \in \Delta} \sup_{u \in M} C(u, \beta[u]).$$

The *upper value* is defined by

$$I^+(x) = \sup_{\alpha \in \Gamma} \inf_{v \in N} C(\alpha[v], v).$$

Remarks. The terms "upper" and "lower" refer to which player has the "information advantage." In a heuristic sense, for the game corresponding to the lower value we allow the minimizing player (v here) to know the next move of the maximizing player (u) before choosing his own move. Although this distinction is somewhat obscured in the abstract Elliott-Kalton formulation, it is intuitively obvious in the Fleming and Friedman formulations [1], which are equivalent to the Elliott-Kalton formulation under some hypotheses. The reader is referred to [1] for further discussion. The DG we consider differs from that of [3], but it seems to be more natural for this type of problem. The remarks that follow illustrate this point.

The Elliott-Kalton definitions of upper and lower values in terms of strategies have interesting interpretations in terms of the large deviations properties of the controlled diffusion. First note that the v-control in the DG plays the role of the small noise $\varepsilon \dot{w}$ in the diffusion. Let small $\delta > 0$ be given. Consider the upper value $I^+(x)$, and let α be a "nearly" optimizing strategy for the maximizing player. Let $v \in N$ be given. Then the "nearly" supremizing α gives us a strategy that accomplishes one of two things. Either $\chi(\phi(\tau_x)) = \infty$ (ϕ never escapes from G) or

$$\frac{1}{2}\int_0^{\tau_x} |v(t)|^2 \, dt \geqq I^+(x) - \delta$$

(ϕ escapes from G, but at a "cost" of not less than $I^+(x) - \delta$). Large deviations theory for the process $\varepsilon \dot{w}$ then suggests that, when ε is small, the probability of $\varepsilon \dot{w}$ "tracking" one of the v functions corresponding to escape from G (in the sense that $x^{u,\varepsilon}$ is near to the corresponding ϕ associated with $\alpha[v], v$) is no greater than $\exp -(I^+(x) - 2\delta)/\varepsilon^2$.

This suggests that we can obtain a progressively measurable control u_0 from the "nearly" supremizing α so that when ε is small,

$$P_x\{\tau^{u_0,\varepsilon} \leqq 1\} \leqq \exp -(I^+(x)-2\delta)/\varepsilon^2.$$

On the other hand, consider the lower value $I^-(x)$, and let β be "nearly" infimizing. Then, no matter what progressively measurable control strategy $u(t)$ is used, β describes a path for the noise to follow whose "action" or "cost" is no greater than $I^-(x)+\delta$, and that leads to escape. The large deviations properties of $\varepsilon\dot{w}$ now suggest that no matter what control is used, the probability of escape should (roughly) be bounded below by $\exp -(I^-(x)-2\delta)/\varepsilon^2$.

Thus we have (roughly)

$$\exp -(I^-(x)-2\delta)/\varepsilon^2 \leqq P_x\{\tau^{u_0,\varepsilon} \leqq 1\} \leqq \exp -(I^+(x)-2\delta)/\varepsilon^2,$$

with the conclusion that $I^-(x) \geqq I^+(x)$. From the definition of the game it is possible to show $I^-(x) \leqq I^+(x)$, which implies that the game has a value.

3. The main theorem. Before stating the main theorem, we introduce a "continuity" assumption on the domain G. Define G^δ for small δ as follows: if $\delta \geqq 0$, then

$$G^\delta = \{x \in \mathbb{R}^d : \inf\{|x-y|: y \in G\} \leqq \delta\};$$

if $\delta < 0$, then

$$G^\delta = \{x \in \mathbb{R}^d : \inf\{|x-y|: y \notin G\} \geqq -\delta\}.$$

Next define $I^+(x, \delta)$, $I^-(x, \delta)$ as the upper and lower values of the DG defined in § 2, but with G^δ replacing G there. Since $I^+(x, \delta)$ (respectively, $I^-(x, \delta)$) is monotone nondecreasing in δ, the set of discontinuities of $I^+(x, \cdot)$ (respectively, $I^-(x, \cdot)$) is countable. (Note that x is fixed here.)

Assumption A2. $I^+(x, \delta)$ and $I^-(x, \delta)$ are continuous at $\delta = 0$.

Remarks. It is simple to prove in the uniformly nondegenerate case that $I^+(x, \cdot)$ and $I^-(x, \cdot)$ are in fact continuous functions. This follows from the fact that $b(\cdot, \cdot)$ is bounded on $G \times K$, while v is allowed to "push" the state in any direction. In the degenerate case it can happen that $I^+(x, \cdot)$ (or $I^-(x, \cdot)$) is in fact discontinuous at $\delta = 0$, but even then Assumption A2 is not very restrictive, since it is satisfied for an arbitrarily small perturbation of G. A consequence of the theorem stated below is that at points at which both $I^+(x, \cdot)$ and $I^-(x, \cdot)$ are continuous, we have $I^+(x, \delta) = I^-(x, \delta)$. Monotonicity then implies that $I^+(x, \cdot)$ and $I^-(x, \cdot)$ have the same set of discontinuity points. It should also be noted that in order to obtain the result analogous to the main theorem in the simpler case of uncontrolled diffusion processes:

$$\lim_\varepsilon \varepsilon^2 \log P_x\{\tau^\varepsilon \leqq 1\} = -I(x),$$

the assumption obtained from Assumption A2 when the set K contains only one element is also required.

THEOREM. *Assume* A1 *and* A2, *and let* $I^+(x)$ *and* $I^-(x)$ *be the upper and lower values of the* DG *described in* § 2. *For any* $u \in F$, *let* $x^{u,\varepsilon}(\cdot)$ *be the solution of*

$$dx^{u,\varepsilon} = b(x^{u,\varepsilon}, u)\,dt + \varepsilon\sigma(x^{u,\varepsilon})\,dw, \qquad x^{u,\varepsilon}(0) = x, \tag{3.1}$$

and define

$$\tau^{u,\varepsilon} = \inf\{t: x^{u,\varepsilon}(t) \in \partial G\}. \tag{3.2}$$

Then

$$\underline{\lim_\varepsilon}\, \varepsilon^2 \log \inf_{u \in F} P_x\{\tau^{u,\varepsilon} \leqq 1\} \geqq -I^-(x), \tag{3.3 (1)}$$

(2) *Given $c>0$ there exists a measurable function $g: C_0[0,1] \to M$ with the following properties*:

(i) *If $0 \leqq s \leqq 1$ and $f(t) = \hat{f}(t)$ for $0 \leqq t \leqq s$, then $g[f](t) = g[\hat{f}](t)$ for $0 \leqq t \leqq s$, almost everywhere*;

(ii) *If we define $u = g[\varepsilon w]$, then $u \in F$ and*

$$\overline{\lim_{\varepsilon}}\, \varepsilon^2 \log P_x\{\tau^{u,\varepsilon} \leqq 1\} \leqq -I^+(x) + c, \tag{3.4}$$

$$I^+(x) = I^-(x). \tag{3}$$

Remarks. Part (2) of the theorem gives the existence of a c-optimal (in the asymptotic sense) control u that depends on $x^{u,\varepsilon}(s)$, $0 \leqq s \leqq t$, at time t. Part (1) yields an important uniformity property. For any given $c>0$ and any (possibly ε-dependent) progressively measurable control u_ε, there is $\varepsilon_0 > 0$ such that for $0 < \varepsilon \leqq \varepsilon_0$,

$$P_x\{\tau^{u_\varepsilon,\varepsilon} \leqq 1\} \geqq P_x\{\tau^{u,\varepsilon} \leqq 1\} \exp - c/\varepsilon^2.$$

Proof of (1). For $c>0$ there exists $\delta > 0$ such that $I^-(x,\delta) \leqq I^-(x) + c$. Consider now the DG with domain G^δ and let $C^\delta(u,v)$ denote the cost associated with the domain G^δ. Then there exists a minimizing strategy $\beta \in \Delta$ such that

$$\sup_{u \in M} C^\delta(u, \beta[u]) \leqq I^-(x) + 2c. \tag{3.5}$$

If we redefine $\beta[u](t)$ to be zero when $t \geqq \tau_x$ (given by (2.1)), then β is still a strategy and obviously still satisfies (3.5).

Without loss of generality we may assume the following property of the chosen strategy $\beta: (d/dt)\beta[u](t)$ exists for all $u \in M$ (almost surely in t) and furthermore there is $C_1 < \infty$ such that

$$\left|\frac{d}{dt}\beta[u](t)\right| \vee |\beta[u](t)| \leqq C_1$$

(almost surely in t) for all $u \in M$. This fact follows from Assumption A2 and Lemma A1 of the Appendix.

Take any control process $u \in F$, and define the processes

$$v(t) = \beta[u](t),$$

$$\dot{\phi}^\varepsilon = b(x^{u,\varepsilon}, u) + \sigma(\phi^\varepsilon)v, \qquad \phi^\varepsilon(0) = x.$$

We then have

$$|\dot{v}(t)| \vee |v(t)| \leqq C_1 \quad \text{(a.s. in } t\text{)}$$

for every ω. It follows from the definition of a strategy that $v(t)$ is $\mathcal{F}(t)$ measurable. Since the β under consideration has the property that $\beta[u](\cdot)$ is continuous for every $u \in M$, $v(\cdot)$ and $\phi^\varepsilon(\cdot)$ are $\mathcal{F}(t)$-progressively measurable processes [7, Thm. 1.5.1].

Now define $y^\varepsilon = x^{u,\varepsilon} - \phi^\varepsilon$. Then y^ε satisfies the stochastic equation

$$dy^\varepsilon = \sigma(x^{u,\varepsilon})\varepsilon\, dw - \sigma(\phi^\varepsilon)v\, dt, \qquad y^\varepsilon(0) = 0. \tag{3.6a}$$

Let P_1 denote the measure induced on $C_0[0,1]$ by the solution to (3.6a). By Girsanov's theorem there is a Brownian motion $\bar{w}(\cdot)$ (with respect to the same filtration $\mathcal{F}(\cdot)$ as $w(\cdot)$) such that

$$dy^\varepsilon = \sigma(x^{u,\varepsilon})\varepsilon\, d\bar{w}, \qquad y^\varepsilon(0) = 0, \tag{3.6b}$$

and such that if P_0 is the measure induced on $C_0[0,1]$ by (3.6b), then

$$\frac{dP_1}{dP_0} = \exp\left[\frac{1}{\varepsilon^2}\int_0^1 \langle \sigma(\phi^\varepsilon)v, \sigma(x^{u,\varepsilon})\varepsilon\, d\bar{w}\rangle - \frac{1}{2\varepsilon^2}\int_0^1 |\sigma^{-1}(x^{u,\varepsilon})\sigma(\phi^\varepsilon)v|^2\, dt\right].$$

(In the degenerate case replace σ by σ_1 in the above.)

Define $\Omega^\varepsilon_{\delta_2} = \{\omega: \sup_{0\le t\le 1}|y^\varepsilon(t)| \le \delta_2\}$. We will use the equality

$$P_1(\Omega^\varepsilon_{\delta_2}) = \int_{\Omega^\varepsilon_{\delta_2}} \frac{dP_1}{dP_0}\, dP_0.$$

First note that for any $\delta_2 > 0$, $P_0(\Omega^\varepsilon_{\delta_2}) \to 1$, as $\varepsilon \to 0$. Using the nondegeneracy and the Lipschitz continuity of $\sigma(\cdot)$ (or of $\sigma_1(\cdot)$ in the degenerate case), for given $\delta' > 0$ there is $\delta'' > 0$ such that $|x-y| \le \delta''$ implies $|\sigma^{-1}(x)\sigma(y) - I| \le \delta'$. This, together with (3.5), yields

$$\frac{1}{2}\int_0^1 |\sigma^{-1}(x^{u,\varepsilon})\sigma(\phi^\varepsilon)v|^2\, dt \le I^-(x) + 3c \tag{3.7}$$

on $\Omega^\varepsilon_{\delta_2}$, if δ_2 is small enough.

Finally, we consider the term

$$\left|\int_0^1 \langle \sigma(\phi^\varepsilon)v, dy^\varepsilon\rangle\right|.$$

Since $(d/dt)\sigma(\phi^\varepsilon(t))v(t)$ is bounded, an integration by parts yields the bound $\delta_2 C_2$ for some fixed finite constant C_2, on the set $\Omega^\varepsilon_{\delta_2}$.

Assembling these estimates, we have (for small enough δ_2)

$$P_1(\Omega^\varepsilon_{\delta_2}) \ge \exp -(I^-(x) + 5c)/\varepsilon^2 \tag{3.8}$$

when ε is small. We now pick δ_2 small enough so that the event $\sup_{0\le t\le 1}|y^\varepsilon(t)| \le \delta_2$ implies $x^{u,\varepsilon}(t)$ exits G before $t=1$. The Lipschitz condition on $b(\cdot,\cdot)$ implies that on $\Omega^\varepsilon_{\delta_2}$,

$$\dot{\phi}^\varepsilon = b(\phi^\varepsilon, u) + \gamma + \sigma(\phi^\varepsilon)v, \qquad \phi^\varepsilon(0) = x,$$

where $\sup_{0\le t\le 1}|\gamma(t)| \le \bar{K}\delta_2$. We compare ϕ^ε to the solution of

$$\dot{\psi} = b(\psi, u) + \sigma(\psi)v, \qquad \psi(0) = x.$$

By Gronwall's lemma, and the various Lipschitz and boundedness conditions, we can pick $\delta_2 \le \delta/2$ so that $d(\phi^\varepsilon, \psi) \le \delta/2$ on $\Omega^\varepsilon_{\delta_2}$. By the definition of β, $\psi(\cdot)$ must exit G^δ before time $t=1$. Hence on $\Omega^\varepsilon_{\delta_2}$ it must happen that $x^{u,\varepsilon}(\cdot)$ exits G before $t=1$. This, combined with (3.8), finishes the proof. □

Proof of (2). Now consider the upper value of the differential game:

$$I^+(x) = \sup_{\alpha\in\Gamma}\inf_{v\in N} C(\alpha[v], v).$$

Fix $c > 0$, and pick $\delta > 0$ so that $I^+(x, -\delta) \ge I^+(x) - c$. Let α be a "nearly" maximizing strategy for the differential game with domain $G^{-\delta}$, in the sense that

$$\inf_{v\in N} C^{-\delta}(\alpha[v], v) \ge I^+(x, -\delta) - c. \tag{3.9}$$

We next describe how we use α to control the diffusion process. Let the Wiener process $w(\cdot)$ be given, and define (for $\Delta > 0$)

$$v^{\Delta}(t) = \begin{cases} 0 & \text{for } t \in [0, \Delta), \\ [w(n\Delta) - w(n\Delta - \Delta)]/\Delta & \text{for } t \in [n\Delta, n\Delta + \Delta), \quad n \geqq 1. \end{cases} \tag{3.10}$$

We then define our control process by

$$u(t) = \alpha[\varepsilon v^{\Delta}](t). \tag{3.11}$$

From Assumption A2 and Lemma A2 of the Appendix it follows that we may assume without loss of generality that the strategy α has been chosen so that $\alpha[v](\cdot)$ is a piecewise constant function for every $v \in N$. As was the case previously, the definition of a strategy implies $u(t)$ is $\mathscr{F}(t)$ measurable. Hence $u(t)$ is an $\mathscr{F}(t)$-progressively measurable process [7, Thm. 1.5.1].

The controlled diffusion is therefore

$$dx^{u,\varepsilon} = b(x^{u,\varepsilon}, u)\, dt + \varepsilon\sigma(x^{u,\varepsilon})\, dw, \qquad x^{u,\varepsilon}(0) = x. \tag{3.12}$$

To prove the desired result it is convenient to compare $x^{u,\varepsilon}(\cdot)$ with the solution to

$$\dot{x}^{\varepsilon,\Delta} = b(x^{\varepsilon,\Delta}, u) + \varepsilon\sigma(x^{\varepsilon,\Delta})v^{\Delta}, \qquad x^{\varepsilon,\Delta}(0) = x.$$

Assume that for any given $\rho > 0$ and $M < \infty$ we can show the existence of $\varepsilon_0 > 0$ and $\Delta_0 > 0$ so that for $\Delta \leqq \Delta_0$, $\varepsilon \leqq \varepsilon_0$

$$P_x\{d(x^{u,\varepsilon}, x^{\varepsilon,\Delta}) \geqq \rho\} \leqq \exp - M/\varepsilon^2. \tag{3.13}$$

Then by taking $M = I^{+}(x) + 1$ and $\rho = \delta$, it is obvious that the upper bound is proved if we can show

$$\overline{\lim}\ \varepsilon^2 \log P_x\{x^{\varepsilon,\Delta}(t) \in \partial G^{-\delta} \text{ for some } t < 1\} \leqq -I^{+}(x, -\delta) + 2c. \tag{3.14}$$

However, this follows from our choice of α. Since (3.9) holds, there are only two possibilities for each $v \in N$. Either

$$\frac{1}{2}\int_0^1 |v(t)|^2\, dt \geqq I^{+}(x, -\delta) - c, \tag{3.15}$$

or the solution of (2.1) *does not* escape $G^{-\delta}$ by time $t = 1$. Hence $x^{\varepsilon,\Delta}(\cdot)$ escapes only on the set of paths for which

$$\frac{\varepsilon\Delta}{2} \sum_{0}^{1/\Delta - 1} v^{\Delta}(i\Delta)^2 = \varepsilon \sum_{1}^{1/\Delta - 1} [w(i\Delta) - w(i\Delta - \Delta)]^2/2\Delta \geqq I^{+}(x, -\delta) - c. \tag{3.16}$$

Standard estimates from the theory of large deviations [2] imply that there exist $\Delta_0 > 0$, $\varepsilon_0 > 0$ such that for $\Delta \leqq \Delta_0$, $\varepsilon \leqq \varepsilon_0$ the probability of the event given in (3.16) is less than $\exp - (I^{+}(x, -\delta) + 2c)/\varepsilon^2$. We are therefore finished, except for the proof of (3.13). The details of this estimate are given in Lemma A3 of the Appendix.

Proof of (3). It follows from (1) and (2) that $I^{-}(x) \geqq I^{+}(x)$. We give the easy proof of $I^{-}(x) \leqq I^{+}(x)$ in Lemma A4 of the Appendix, which completes the proof. □

Appendix. In this Appendix we prove several technical lemmas that are needed to prove the main theorem of § 3. Before presenting the lemmas we introduce some new notation. For $-1 \leqq s \leqq 1$, we define $\Delta(s)$ as the set of all measurable mappings β from $M \to N$ such that

$$u(r) = \hat{u}(r) \quad \text{for a.e. } 0 \leqq r \leqq t$$

implies

$$\beta[u](r) = \beta[\hat{u}](r) \quad \text{for a.e. } 0 \leqq r \leqq \min(t+s, 1).$$

Hence β has a "reaction time" of s, which means it anticipates if $s<0$. The set $\Gamma(s)$ of mappings from $N \to M$ is defined in the obvious analogous way.

LEMMA A1. *Let $I<\infty$, $\delta>0$, and $\beta \in \Delta$ be given such that*

$$\sup_{u \in M} C(u, \beta[u]) \leqq I. \tag{A.1}$$

Then there exists $\beta' \in \Delta$ and $C_1<\infty$ such that for all $u \in M$,

$$\left|\frac{d}{dt}\beta'[u](t)\right| \vee |\beta'[u](t)| \leqq C_1 \quad (a.s.), \tag{A.2}$$

$$C^{-\delta}(u, \beta'[u]) \leqq I. \tag{A.3}$$

(As before, $C^{-\delta}$ is the cost associated with the domain $G^{-\delta}$.) Furthermore, there exists $s<0$ such that given $\beta \in \Delta(s)$ satisfying (A.1) *there exists $\beta'' \in \Delta$ such that* (A.3) *holds for all $u \in M$ (with β'' replacing β' there.)*

Proof. The cost associated with β is simply $\frac{1}{2}\int_0^1 (\beta[u](t))^2\, dt \leqq I$, since exit before time $t=1$ *must* occur. Define

$$S(u, C_1) = \{t: |\beta[u](t)| \geqq C_1\},$$

$$\beta_1[u](t) = \begin{cases} 0, & t \in S(u, C_1), \\ \beta[u](t), & t \notin S(u, C_1). \end{cases}$$

Then β_1 is obviously a strategy, and

$$\frac{1}{2}\int_0^1 (\beta_1[u](t))^2\, dt \leqq \frac{1}{2}\int_0^1 (\beta[u](t))^2\, dt.$$

To show $C^{-\delta}(u, \beta_1[u]) \leqq C(u, \beta[u])$, it is sufficient to prove that if ϕ and ψ are defined by

$$\begin{aligned} \dot{\phi} &= b(\phi, u) + \sigma(\phi)\beta[u] \\ &= b(\phi, u) + \sigma(\phi)\beta_1[u] + \sigma(\phi)\beta[u] I_{S(u, C_1)}(t), \\ \dot{\psi} &= b(\psi, 0) + \sigma(\psi)\beta_1[u], \qquad \phi(0) = \psi(0) = x, \end{aligned}$$

then $d(\phi, \psi) \leqq \delta$. First note that

$$\left|\int_0^t \sigma(\phi(s))\beta[u](s) I_{S(u, C_1)}(s)\, ds\right| \leqq 2BI/C_1$$

for $0 \leqq t \leqq 1$. Hence,

$$|\phi(t) - \psi(t)| \leqq \int_0^t \bar{K}|\phi(s) - \psi(s)|\, ds + \int_0^t \bar{K}|\phi(s) - \psi(s)||\beta_1[u](s)|\, ds + 2BI/C_1.$$

Using the inequality $ab \leqq (a^2+b^2)/2$ in the second integral, and the Gronwall inequality, we obtain

$$d(\phi, \psi) \leqq 2BI[1 + \bar{K}(2+I)\, e^{\bar{K}(2+I)}]/C_1.$$

By choosing C_1 large, we have

$$C^{-\delta}(u, \beta'[u]) \leqq C(u, \beta[u])$$

for all $u \in M$.

Next we obtain β' by smoothing β_1. For $\Delta > 0$, define

$$\beta'[u](t) = \frac{1}{\Delta}\int_{t-\Delta}^{t} \beta_1[u](s)\, ds$$

(we define $\beta_1[u](s) = 0$ for $s < 0$). Obviously β' satisfies (A.2). We also have

$$\frac{1}{2}\int_0^1 (\beta'[u](t))^2\, dt \leqq \frac{1}{2}\int_0^1 (\beta_1[u](t))^2\, dt.$$

Formula (A.3) now follows if we can show that small $\Delta > 0$ implies that the solutions of

$$\dot{\phi} = b(\phi, u) + \sigma(\phi)\beta'[u], \qquad \phi(0) = x,$$
$$\dot{\psi} = b(\psi, u) + \sigma(\psi)\beta_1[u], \qquad \psi(0) = x$$

satisfy $d(\phi, \psi) \leqq \delta$. This follows from another application of Gronwall's lemma and an integration by parts.

Finally we consider the last statement of the lemma.

Let $s < 0$ be given. By the same argument as above we may assume the existence of $\beta' \in \Delta(s)$ satisfying (A.2) and (A.3). Define

$$\beta''[u](t) = \begin{cases} 0, & 0 \leqq t \leqq -s, \\ \beta'[u](t+s), & -s < t \leqq 1, \end{cases}$$
$$\dot{\phi} = b(\phi, u) + \sigma(\phi)\beta''[u], \qquad \phi(0) = x,$$
$$\dot{\psi} = b(\psi, u) + \sigma(\psi)\beta'[u], \qquad \psi(0) = x.$$

Then $\beta'' \in \Delta$. Arguments such as those used above, combined with the boundedness of β', β'' imply that when $s < 0$ is sufficiently large $d(\phi, \psi) \leqq \delta$. Hence we have $\beta'' \in \Delta$ such that

$$C^{-2\delta}(u, \beta''[u]) \leqq C(u, \beta[u]),$$

and the lemma is proved. □

LEMMA A2. *Let I, $\delta > 0$, and $\alpha \in \Gamma$ be given such that*

$$\inf_{v \in N} C(\alpha[v], v) \geqq I. \tag{A.4}$$

Then there exists $\alpha' \in \Gamma$ such that for all $v \in N$

$$\alpha'[v](\cdot) \text{ is a piecewise constant function,} \tag{A.5}$$

$$C^{\delta}(\alpha'[v], v) \geqq I. \tag{A.6}$$

Furthermore, there is an $s < 0$ such that given $\alpha \in \Gamma(s)$ satisfying (A.4) *there exists $\alpha'' \in \Gamma$ such that* (A.6) *holds for all $v \in N$ (where α'' replaces α' there).*

Proof. N may be written as the disjoint union $N = N_1 \cup N_2 \cup N_3$ with

$$N_1 = \{v \in N: \chi(\phi(\tau_x)) = 0\},$$
$$N_2 = \left\{ v \in N: \chi(\phi(\tau_x)) = \infty \text{ and } \frac{1}{2}\int_0^1 v^2\, dt \geqq I \right\},$$
$$N_3 = \left\{ v \in N: \chi(\phi(\tau_x)) = \infty \text{ and } \frac{1}{2}\int_0^1 v^2\, dt < I \right\}$$

(here $\dot{\phi} = b(\phi, \alpha[v]) + \sigma(\phi)v$, $\phi(0) = x$, and $\tau_x = \inf\{t: \phi(t) \in \partial G\} \wedge 1$). It is clear that we may define α' in any way we like on N_1 and N_2, as long as it is a strategy. For $\varepsilon > 0$ let $\{u_i, i = 1, \cdots, J\}$ be an ε-net of the control space K, and let $\{K_i, i = 1, \cdots, J\}$ be a Borel measurable partition of K such that the Hausdorff distance between $\{u_i\}$ and K_i is less than ε for $i = 1, \cdots, J$. For $\gamma > 0$, and $0 \leqq l \leqq 1/\gamma$, define

$$\tau(i, l, v) = \int_{l\gamma}^{l\gamma+\gamma} I_{\{\alpha[v](t) \in K_i\}}\, dt.$$

Then for all $v \in N$, l,

$$\sum_1^J \tau(i, l, v) = \gamma.$$

We define $\alpha'[v]$ by $\alpha'[v](t) = u_1$, for $0 \leqq t \leqq \gamma$, and

$$\alpha'[v](t) = u_i \quad \text{for } t \in \left(l\gamma + \sum_1^{i-1} \tau(j, l-1, v),\ l\gamma + \sum_1^{i} \tau(j, l-1, v) \right),$$

$l = 1, \cdots, 1/\gamma$.

Owing to the definition of α', we have

$$\sup_{0 \leqq t \leqq 1} \left| \int_0^t [b(\phi(r), \alpha[v](r)) - b(\phi(r), \alpha'[v](r))]\, dr \right| \leqq \varepsilon \bar{K} + \gamma B$$

for every $v \in N$ and measurable function $\phi(\cdot)$ taking values in G^δ. Define

$$\dot{\phi} = b(\phi, \alpha[v]) + \sigma(\phi)v, \qquad \phi(0) = x,$$

$$\dot{\psi} = b(\psi, \alpha'[v]) + \sigma(\psi)v, \qquad \psi(0) = x.$$

In order to prove (A.6) it is sufficient to prove $d(\phi, \psi) \leqq \delta$ when ε and γ are sufficiently small, and when $v \in N_3$. Using the estimate

$$\begin{aligned} |\phi(t) - \psi(t)| &\leqq \left| \int_0^t [b(\phi, \alpha[v]) - b(\phi, \alpha'[v])]\, ds \right| \\ &\quad + \left| \int_0^t [b(\phi, \alpha'[v]) - b(\psi, \alpha'[v]) + \sigma(\phi)v - \sigma(\psi)v]\, ds \right| \\ &\leqq \varepsilon \bar{K} + \gamma B + 3\bar{K} \int_0^t |\phi - \psi|\, ds/2 + \bar{K} \int_0^t |\phi - \psi| v^2\, ds/2, \end{aligned}$$

and Gronwall's lemma, we obtain

$$d(\phi, \psi) \leqq (\varepsilon \bar{K} + \gamma B)[1 + \bar{K}(2 + I) \exp \bar{K}(2 + I)]. \tag{A.7}$$

Hence we obtain (A.6) for small ε, γ.

If we are given $\alpha \in \Gamma(s)$, and define

$$\alpha''[v](t) = \begin{cases} u_1 & \text{for } 0 \leqq t \leqq -s, \\ \alpha[v](t+s) & \text{for } -s < t \leqq 1, \end{cases}$$

then $\alpha'' \in \Gamma$, and by the same argument as above we can obtain (A.6) when $s < 0$ is sufficiently large. The only difference is that in (A.7) we replace $\varepsilon \bar{K} + \gamma B$ by $-sB$. □

LEMMA A3. *Given $\rho > 0$ and $M < \infty$, there exist $\Delta_0 > 0$ and $\varepsilon_0 > 0$ such that* (3.13) *holds for $\varepsilon \leqq \varepsilon_0$, $\Delta \leqq \Delta_0$.*

Proof. We begin by defining a stopping time (all stopping times are with respect to $w(\cdot)$) for $\rho_1 > 0$:

$$\tau_1 = \inf\{t : |x^{\varepsilon,\Delta}(t) - x^{\varepsilon,\Delta}([t/\Delta]\Delta)| \geqq \rho_1\} \wedge 1.$$

A simple calculation shows there exist $\varepsilon_{0,1} > 0$ and $\Delta_{0,1} > 0$ (depending on ρ_1) such that $\varepsilon \leqq \varepsilon_{0,1}$ and $\Delta \leqq \Delta_{0,1}$ imply

$$P_x\{\tau_1 < 1\} \leqq \exp(-(M+2)/\varepsilon^2). \tag{A.8}$$

Next we rewrite the equation for $x^{\varepsilon,\Delta}$ as

$$dx^{\varepsilon,\Delta} = b(x^{\varepsilon,\Delta}, u)\, dt + \varepsilon\sigma(x^{\varepsilon,\Delta})\, dw + d\gamma^{\varepsilon,\Delta}, \qquad x^{\varepsilon,\Delta}(0) = x, \tag{A.9}$$

where

$$\begin{aligned} &d\gamma^{\varepsilon,\Delta} = \varepsilon\sigma(x^{\varepsilon,\Delta})[v^\Delta\, dt - dw], \\ &\int_{i\Delta}^{i\Delta+\Delta} \varepsilon\sigma(x^{\varepsilon,\Delta}(i\Delta))v^\Delta(t)\, dt = \int_{i\Delta-\Delta}^{i\Delta} \varepsilon\sigma(x^{\varepsilon,\Delta}(i\Delta))\, dw(t). \end{aligned} \tag{A.10}$$

We therefore have decomposition

$$\gamma^{\varepsilon,\Delta}(t) = I_1(t) + I_2(t) + I_3(t) + I_4(t),$$

where (for $k = [t/\Delta] - 1$)

$$\begin{aligned} I_1(t) &= -\sum_1^k \int_{i\Delta-\Delta}^{i\Delta} \varepsilon[\sigma(x^{\varepsilon,\Delta}(s)) - \sigma(x^{\varepsilon,\Delta}(i\Delta))]\, dw(s), \\ I_2(t) &= \sum_1^k \int_{i\Delta}^{i\Delta+\Delta} \varepsilon[\sigma(x^{\varepsilon,\Delta}(s)) - \sigma(x^{\varepsilon,\Delta}(i\Delta))]v^\Delta(s)\, ds, \\ I_3(t) &= \int_{k\Delta+\Delta}^{t} \varepsilon\sigma(x^{\varepsilon,\Delta}(s))v^\Delta(s)\, ds, \qquad I_4(t) = \int_{k\Delta}^{t} \varepsilon\sigma(x^{\varepsilon,\Delta}(s))\, dw(s). \end{aligned}$$

For $\rho_2 > 0$, define the stopping times

$$\tau_{2,i} = \inf\{t : |I_i(t)| \geqq \rho_2/4\} \wedge 1.$$

The same estimates as those used to show (A.8) give the existence of $0 < \varepsilon_{0,2} \leqq \varepsilon_{0,1}$, and $0 < \Delta_{0,2} \leqq \Delta_{0,1}$ such that for $\varepsilon \leqq \varepsilon_{0,2}$ and $\Delta \leqq \Delta_{0,2}$,

$$P_x\{\tau_{2,i} < 1\} \leqq \exp -(M+1)/\varepsilon^2$$

for $i = 3, 4$.

Next consider $\tau_{2,1}$. Using

$$P_x\{\tau_{2,1} < 1\} \leqq P_x\{\tau_{2,1} < 1,\ \tau_1 = 1\} + P_x\{\tau_1 < 1\},$$

(A.8), and a standard estimate on stochastic integrals [8, Lemma 4.7], by picking ρ_1 small we obtain $0 < \varepsilon'_{0,2} \leqq \varepsilon_{0,2}$ and $0 < \Delta'_{0,2} \leqq \Delta_{0,2}$ such that $\varepsilon \leqq \varepsilon'_{0,2}$ and $\Delta \leqq \Delta'_{0,2}$ imply

$$P_x\{\tau_{2,1} < 1\} \leqq \exp -(M+1)/\varepsilon^2.$$

Finally we consider $\tau_{2,2}$. Using the Lipschitz property of $\sigma(\cdot)$, we have the following bound on a typical summand in $I_2(t)$:

$$\begin{aligned} &\int_{i\Delta}^{i\Delta+\Delta} \varepsilon[\sigma(x^{\varepsilon,\Delta}(s)) - \sigma(x^{\varepsilon,\Delta}(i\Delta))]v^\Delta(s)\, ds \\ &\quad \leqq \int_{i\Delta}^{i\Delta+\Delta} \varepsilon\bar{K} \left| \int_{i\Delta}^{t} (b(x^{\varepsilon,\Delta}(s)) + \varepsilon\sigma(x^{\varepsilon,\Delta}(s))v^\Delta(s))\, ds \right| |v^\Delta(t)|\, dt \\ &\quad \leqq \varepsilon\bar{K}B\Delta^2|v^\Delta(i\Delta)|/2 + \varepsilon^2\bar{K}B\Delta^2|v^\Delta(i\Delta)|^2/2. \end{aligned}$$

We therefore have

$$P_x\{\tau_{2,2}<1\} \leqq P\left\{\varepsilon\Delta^2\bar{K}B\sum_1^{1/\Delta}|\theta_i| \geqq \frac{\rho_2}{4}\right\} + P\left\{\varepsilon^2\Delta^2\bar{K}B\sum_1^{1/\Delta}|\theta_i|^2 \geqq \frac{\rho_2}{4}\right\}, \tag{A.11}$$

where $\{\theta_i\}$ is a sequence of independent and identically distributed $N(0, 1/\Delta)$ random variables. For the sake of notational simplicity, we estimate these terms in the case where $\{\theta_i\}$ is a scalar-valued sequence.

Using $E \exp c\theta_i^2 = (1-2c/\Delta)$ (for $2c/\Delta<1$), we obtain (for any $\xi>0$ such that $2\varepsilon^2\Delta\bar{K}B\xi<1$)

$$P\left\{\varepsilon^2\Delta^2\bar{K}B\sum_1^{1/\Delta}|\theta_i|^2 \geqq \frac{\rho_2}{4}\right\} \leqq \left(\exp -\frac{\xi\rho_2}{4}\right)(1-2\varepsilon^2\Delta\bar{K}B\xi)^{1/\Delta}$$

$$= \exp\left[-\frac{\xi\rho_2}{4} + \frac{1}{\Delta}\log(1-2\varepsilon^2\Delta\bar{K}B\xi)\right].$$

Now take $\xi = (M+2)4/\rho_2\varepsilon^2$, and use the fact that the log term $\to -8(M+2)\bar{K}B/\rho_2$ as $\Delta\to 0$ to get the estimate of the type (A.8) for the second term of (A.11).

For the first term of (A.11), we will use the fact that $E \exp c|\theta_i| \leqq 2E \exp c\theta_i = 2\exp c^2/2\Delta$. For $\xi>0$ we have

$$P\left\{\varepsilon\Delta^2\bar{K}B\sum_1^{1/\Delta}|\theta_i| \geqq \frac{\rho_2}{4}\right\} \leqq \exp -\frac{\xi\rho_2}{4}\cdot\exp\xi^2\varepsilon^2\Delta^2\bar{K}^2B^2/2\cdot\exp\frac{1}{\Delta}\log 2.$$

Minimizing with respect to $\xi>0$, we obtain the bound

$$\exp[-\rho_2^2/32\varepsilon^2\Delta^2\bar{K}^2B^2 + (\log 2)/\Delta],$$

which again gives the desired bound of type (A.8) for small Δ, ε.

Hence there are $0<\varepsilon''_{0,2} \leqq \varepsilon'_{0,2}$ and $0<\Delta''_{0,2} \leqq \Delta'_{0,2}$ such that for $\varepsilon \leqq \varepsilon''_{0,2}$ and $\Delta \leqq \Delta''_{0,2}$,

$$P_x\{\tau_{2,2}<1\} \leqq \exp -(M+1)/\varepsilon^2.$$

Now set $\tau_2 = \bigwedge_1^4 \tau_{2,i}$. On the set where $\tau_2 = 1$, $\sup_{0\leqq t\leqq 1}|\gamma^{\varepsilon,\Delta}(t)| \leqq \rho_2$. We have shown that for ε sufficiently small, $P_x\{\tau_2<1\} \leqq \exp -(M+1)/\varepsilon^2$. These facts, together with a standard estimate in large deviations theory [2, Proof of Lemma 6.2], yield the lemma. □

LEMMA A4. *Assume* A1 *and* A2. *Then* $I^-(x) \leqq I^+(x)$.

Proof. Let $c>0$ be given. By A2 there is $\delta>0$ such that $I^-(x) \leqq I^-(x,-\delta)+c$, $I^+(x) \geqq I^+(x,\delta)-c$. Next choose $s<0$ such that the second statements of Lemmas A1 and A2 hold, with $I^-(x)+1$ (respectively, $I^+(x)-1$) replacing I in Lemma A1 (respectively, A2). Suppose $\beta\in\Delta(s)$ is a c-optimal solution to the problem

$$\inf_{\beta\in\Delta(s)}\sup_{u\in M} C(u,\beta[u]). \tag{A.12}$$

Let $\bar{I}^-(s)$ denote the value of the expression given in (A.12). Then by Lemma A1 we may find $\beta''\in\Delta$ such that

$$\sup_{u\in M} C^{-\delta}(u,\beta''[u]) \leqq \bar{I}^-(s).$$

Hence we may conclude $I^-(x,-\delta) \leqq \bar{I}^-(s)$. In an analogous manner we may prove $I^+(x,\delta) \geqq \bar{I}^+(s)$, where

$$\bar{I}^+(s) = \sup_{\alpha\in\Gamma(s)}\inf_{v\in N} C(\alpha[v],v).$$

It follows that $I^-(x) - I^+(x) \leqq \bar{I}^-(s) - \bar{I}^+(s) + 2c$. Since $c > 0$ is arbitrary, we are finished if we can show there is $s_0 < 0$ such that $\bar{I}^-(s) \leqq \bar{I}^+(s)$ for all $s_0 < s < 0$. However, as is proved in [4, p. 17], when $-2^{-N} < s$, $\bar{I}^-(s)$ is a lower bound for the value v_N^- defined in the sense of Friedman having stepsize 2^{-N} and allowing the minimizing player to move first (for the full definition of values in the sense of Friedman, see [4, § 3]). An analogous statement holds for the corresponding upper values; $v_N^+ \leqq \bar{I}^+(s)$. Since (as is easily proved) $v_N^- \leqq v_N^+$ for every N [4, p. 11], we are finished. □

OPTIMAL CONTROL OF SEMILINEAR MULTISTATE SYSTEMS WITH STATE CONSTRAINTS*

JOSEPH FREDERIC BONNANS† AND EDUARDO CASAS‡

Abstract. This paper deals with state-constrained optimal control problems governed by a semilinear multistate equation. The authors prove the existence of solutions and derive optimality conditions.

Key words. optimal control, subdifferential calculus, optimality conditions, elliptic operators, semilinear equations, multistate systems

AMS(MOS) subject classifications. 49B22, 49A22

1. Introduction. This paper is concerned with state-constrained optimal control problems governed by a semilinear elliptic operator. As we make no monotonicity assumption, the state equation may be unsolvable or may have several solutions. These kinds of ill-posed systems may arise in connection with bifurcation theory; some models arising in enzymatic reactions, plasma physics, and chemistry have this property (see some examples in Crandall and Rabinowitz [11] and Lions [15]). However, this paper studies only a model problem. Our aim is to obtain existence results and to derive the optimality system.

There exists a vast literature on the control of well-posed state-constrained systems. The subdifferential calculus of convex analysis is a useful tool for dealing with linear state equations (see Mackenroth [16], [17], Bonnans and Casas [7], and Casas [8], [9]). In the nonlinear case, Bonnans and Casas [4]-[6] derived the optimality system using the results of Clarke [10].

The control of nonmonotone elliptic systems, but without state constraints, has been studied by Lions [15] (see also Komornik [14]). The optimality system is derived there by penalizing the state equation and passing to the limit in the optimality conditions of the penalized problem.

The novelty of this paper lies in the simultaneous presence of state constraints and of an ill-posed system. Our method consists of approximating the problem by removing the nonlinearity from the state equation and penalizing a part of the state constraints. We formulate the problem and obtain an existence result in § 2, derive the optimality system in § 3, and study several examples in § 4.

2. Formulation of the control problem. Let Ω be an open bounded subset of $\mathbb{R}^n$ ($n \leqq 3$) with C^2 boundary Γ. Let us consider the following system:

$$\begin{aligned} &Ay + \phi(y) = u \quad \text{in } \Omega, \\ &y = 0 \quad \text{on } \Gamma, \end{aligned} \tag{2.1}$$

where

$$Ay = -\sum_{i,j=1}^{n} \partial_{x_j}(a_{ij}(x)\partial_{x_i} y) + a_0(x)y,$$

$$
\begin{aligned}
&a_0 \in L^\infty(\Omega), \qquad a_0(x) \geqq 0 \quad \text{a.e. } x \in \Omega,\\
&a_{ij} \quad \text{is Lipschitz on } \bar{\Omega}\ (1 \leqq i, j \leqq n),\\
&\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq \alpha_0 \|\xi\|^2, \qquad \alpha_0 > 0 \quad \forall \xi \in R^n, \quad \forall x \in \Omega,
\end{aligned} \tag{2.2}
$$

$$
\phi : R \to R \quad \text{is } C^1. \tag{2.3}
$$

Let K be a nonempty, convex, closed subset of $L^2(\Omega)$, σ be greater than or equal to 2, N be nonnegative, and y_d in $L^\sigma(\Omega)$ be given, and let $J : L^\sigma(\Omega) \times L^2(\Omega) \to \mathbb{R}$ be the functional

$$
J(y, u) = \frac{1}{\sigma} \int_\Omega |y(x) - y_d(x)|^\sigma \, dx + \frac{N}{2} \int_\Omega u^2(x) \, dx. \tag{2.4}
$$

Let Z be a separable Banach space, B be a closed convex subset of Z with nonempty interior, and a be given in $\mathbb{R}^m$ ($m \geqq 0$; we identify $\mathbb{R}^0$ and $\{0\}$). Define $Y = H^2(\Omega) \cap H_0^1(\Omega)$, where $H^s(\Omega)$ and $H_0^s(\Omega)$ are the usual Sobolev spaces (see Adams [1], Nečas [18]). Let $C_0(\Omega)$ be the space of real continuous functions on $\bar{\Omega}$ vanishing on Γ, endowed with the supremum norm $\| \ \|_\infty$. It is known that Y is compactly embedded in $C_0(\Omega)$ for $n \leqq 3$. The dual of $C_0(\Omega)$ is the space $M(\Omega)$ of real and regular Borel measures on Ω, endowed with the norm

$$
\|\mu\|_{M(\Omega)} = |\mu|(\Omega),
$$

where $|\mu|$ is the total variation measure of μ (Rudin [19]). Finally, let $T : C_0(\Omega) \to \mathbb{R}^m$ and $L : C_0(\Omega) \to Z$ be linear continuous mappings. In order to derive the optimality conditions, we will suppose that

$$
T(Y) = \mathbb{R}^m \quad \text{and} \quad \overline{L(Y)} = Z. \tag{2.5}
$$

We consider the following control problem:

$$
\begin{aligned}
&\text{minimize} \quad J(y, u)\\
&\text{subject to} \quad (2.1), \quad u \in K, \quad y \in Y, \quad Ty = a, \quad Ly \in B.
\end{aligned} \tag{P}
$$

Remark 1. The assumptions on Ω and A imply (Nečas [18]) that for each f in $L^2(\Omega)$ there exists a unique solution $y \in Y$ of the Dirichlet problem

$$
Ay = f \quad \text{in } \Omega, \qquad y = 0 \quad \text{on } \Gamma,
$$

and moreover, there exists C_1 independent of f such that

$$
\|y\|_{H^2(\Omega)} \leqq C_1 \|f\|_{L^2(\Omega)}. \tag{2.6}
$$

In fact all our results still hold if we assume that Ω is bounded, Y is compactly embedded in $C_0(\Omega)$, and (2.6) holds. This is the case, for instance, if A is symmetric and satisfies (2.2) and Ω is bounded and convex (Grisvard [13]).

Remark 2. The existence of several states associated to the same control has been obtained, e.g., with cubic nonlinearities [11]. The inclusion of Y in $C_0(\Omega)$ for $n \leqq 3$ (Adams [1]) implies that $A + \phi$ maps Y into $L^2(\Omega)$; hence all elements of Y are associated to a control. For parabolic systems the situation is essentially different (Bonnans [3]).

Let us now give some examples of control problem that fall into the previous formulation.

$$\text{(P1)} \qquad \begin{aligned} &\text{minimize} \quad J(y,u) \\ &\text{subject to} \quad (2.1), \quad u \in K, \quad y \in Y, \quad y(x_i) = a_i, \quad 1 \leqq i \leqq m. \end{aligned}$$

Here $\{x_i\}$ are given in Ω and we may take $B = Z = C_0(\Omega)$, L is the identity in $C_0(\Omega)$, and $Ty = \{y(x_i)\}$.

$$\text{(P2)} \qquad \begin{aligned} &\text{minimize} \quad J(y,u) \\ &\text{subject to} \quad (2.1), \quad u \in K, \quad y \in Y, \quad \int_\Omega |y(x)|\,dx \leqq \delta \quad \text{with } \delta > 0. \end{aligned}$$

Here $m = 0$, $T = 0$, $Z = L^1(\Omega)$, B is the closed ball with center zero and radius δ, and L is the canonical injection from $C_0(\Omega)$ into $L^1(\Omega)$.

$$\text{(P3)} \qquad \begin{aligned} &\text{minimize} \quad J(y,u) \\ &\text{subject to} \quad (2.1), \quad u \in K, \quad y \in Y, \quad \int_\Omega y(x)\,dx = a, \\ &|y(x)| \leqq \delta \quad \forall x \in \Omega, \quad \text{with } \delta > 0. \end{aligned}$$

Here $m = 1$ and $Ty = \int_\Omega y(x)\,dx$, $Z = C_0(\Omega)$, B is the closed ball with radius δ and center zero, and L is the identity. These three examples obviously satisfy (2.5).

We now give a result concerning the existence of a solution to problem (P). For this we need a relation between σ and the nonmonotone part of ϕ.

THEOREM 1. *Suppose* (2.2) *and* (2.3) *hold, and suppose the following*:

(i) *There exists* (y, u) *satisfying the constraints of* (P) (*i.e.*, (P) *is feasible*).

(ii) *Either* $N > 0$ *or* K *is bounded in* $L^2(\Omega)$.

(iii) *We may write* $\phi(t) = \phi_1(t) + \phi_2(t)$, *with* ϕ_i *continuous,* $i = 1, 2$, $\phi_1(t)$ *nondecreasing, and such that for some* $C > 0$

$$|\phi_2(t)| \leqq C(1 + |t|^{\sigma/2}).$$

Then problem (P) *has* (*at least*) *one solution.*

Proof. As (P) is feasible, there exists a minimizing sequence $\{(y_n, u_n)\}$ in $Y \times K$. Because of (ii), $\{u_n\}$ is bounded in $L^2(\Omega)$. We are going to prove that $\{Ay_n\}$ is bounded in $L^2(\Omega)$, and for this we may assume that ϕ_1 is differentiable. Otherwise, we would approximate ϕ_1 by a standard convolution technique and then pass to the limit. We also may assume without loss of generality that $\phi_1(0) = 0$.

The form of J implies that $\{y_n\}$ is bounded in $L^\sigma(\Omega)$; hence with (iii), $\phi_2(y_n)$ is bounded in $L^2(\Omega)$, as is $f_n = -\phi_2(y_n) + u_n = Ay_n + \phi_1(y_n)$. As $\phi_1(y_n)$ is in $C_0(\Omega)$, Ay_n belongs to $L^2(\Omega)$. Computing the scalar product of f_n with Ay_n in $L^2(\Omega)$, and integrating the nonlinear term by parts, we obtain

$$\|Ay_n\|^2_{L^2(\Omega)} + \int_\Omega \phi_1'(y_n) \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial y_n}{\partial x_i} \frac{\partial y_n}{\partial x_j}\,dx$$

$$+ \int_\Omega a_0(x) \phi_1(y_n(x)) y_n(x)\,dx \leqq \|f_n\|_{L^2(\Omega)} \|Ay_n\|_{L^2(\Omega)}.$$

The second and third term of the left-hand side are nonnegative because of (2.2), the monotonicity of ϕ_1, and the equality $\Phi_1(0) = 0$. Hence $\|Ay_n\|$ is bounded in $L^2(\Omega)$;

with (2.6), this implies that $\{y_n\}$ is bounded in Y. As Y is compactly embedded in $C_0(\Omega)$ for $n \leqq 3$, selecting a subsequence if necessary, we may assume that

$$y_n \to \bar{y} \quad \text{weakly in } Y, \quad \text{strongly in } C_0(\Omega),$$
$$Ay_n \to A\bar{y} \quad \text{weakly in } L^2(\Omega),$$
$$u_n \to \bar{u} \quad \text{weakly in } L^2(\Omega).$$

This implies $T\bar{y} = a$, $L\bar{y} \in B$, and $\phi(y_n) \to \phi(\bar{y})$ in $C_0(\Omega)$; hence Ay_n weakly converges in $L^2(\Omega)$ toward $\bar{u} - \phi(\bar{y})$; hence $(\bar{y}, \bar{u})$ satisfies (2.1). As K is closed and convex, hence weakly closed, $\bar{u}$ is in K. Finally, the convexity and continuity of J implies its weak lower semicontinuity; the result follows. □

3. The optimality system. For any set C, denote its indicatrix by I_C, defined by

$$I_C(x) = \begin{cases} 0 & \text{if } x \in C, \\ +\infty & \text{otherwise.} \end{cases}$$

We denote the subdifferential of a convex function f by ∂f (see Barbu and Precupanu [2], Ekeland and Temam [12]). The spaces $W_0^{1,s}(\Omega)$ and $W^{1,s}(\Omega)$ are the usual Sobolev spaces (Adams [1]). We denote by T^* the adjoint operator of T and by $R(T^*)$ its range. The aim of this section is to prove the following result.

THEOREM 2. *Let $(\bar{y}, \bar{u})$ be a solution of* (P). *We assume that* (2.2)-(2.5) *hold and that*

$$\partial(I_B \circ L)(\bar{y}) \cap R(T^*) = \{0\}. \tag{3.1}$$

Then there exists $\bar{p}$ in $W_0^{1,s}(\Omega)$ for all $s < n/(n-1)$, $\bar{\lambda}$ in $\mathbb{R}^m$, $\bar{\mu}$ in Z', and $\bar{\alpha} \geqq 0$ such that

$$\bar{\alpha} + \|\bar{p}\|_{W_0^{1,s}(\Omega)} > 0, \tag{3.2}$$

$$A^*\bar{p} + \phi'(\bar{y})\bar{p} = \bar{\alpha}|\bar{y} - y_d|^{\sigma-2}(\bar{y} - y_d) + T^*\bar{\lambda} + L^*\bar{\mu}, \tag{3.3}$$

$$\langle \bar{\mu}, z - L\bar{y} \rangle \leqq 0 \quad \forall z \in B, \tag{3.4}$$

$$\int_\Omega (\bar{p} + \bar{\alpha} N\bar{u})(v - \bar{u})\, dx \geqq 0 \quad \forall v \in K. \tag{3.5}$$

Remark 3. Since B has a nonempty interior, we deduce from (2.5) that $R(L) \cap \mathring{B} \neq \varnothing$. This implies (see Barbu and Precupanu [2], Ekeland and Teman [12]) that $\partial(I_B \circ L) \cdot (\bar{y}) = L^* \partial I_B(L\bar{y})$.

Remark 4. We will verify that hypothesis (3.1) holds in our three examples. However, if (3.1) does not hold, then by Remark 3 there exists $(\bar{\lambda}, \bar{\mu})$ in $\mathbb{R}^m \times \partial I_B(L\bar{y})$ such that $\|\bar{\lambda}\| + \|\bar{\mu}\| > 0$ and $T^*\bar{\lambda} + L^*\bar{\mu} = 0$. In other words, if all hypotheses of Theorem 2 are satisfied except perhaps (3.1), there exist $\bar{p}$, $\bar{\lambda}$, $\bar{\mu}$, $\bar{\alpha}$ as in Theorem 1, not all null, satisfying (3.3)-(3.5).

In order to prove Theorem 2, we need to establish some preliminary results.

LEMMA 1. *Let W be a Banach space and D be a convex subset of W (not necessarily closed) with nonempty interior. Let $\{(w_n, \eta_n)\}$ be a sequence in $W \times W'$ such that $w_n \in D$, $w_n \to w$ and $\eta_n \in \partial I_D(w_n)$. If $\liminf \|\eta_n\| > 0$, then zero is not a weak-star limit point of $\{\eta_n\}$.*

Proof. Assume that the conclusion does not hold. Let w_0 be given in $\mathring{D}$. There exists $r > 0$ such that $\|w\| \leqq r$ implies that $w_0 + w$ is in D; hence

$$\langle \eta_n, w_0 + w - w_n \rangle \leqq 0,$$

and this implies

$$r\|\eta_n\| = \sup_{\|w\| \leqq r} \langle \eta_n, w \rangle \leqq \langle \eta_n, w_n - w_0 \rangle.$$

The strong convergence of w_n allows us to pass to the limit and we get

$$r \liminf \|\eta_n\| \leqq 0,$$

which gives a contradiction. □

LEMMA 2. *Let W be a Banach space, and f (respectively, g) be a Gâteaux-differentiable (respectively, convex) mapping from W into $\mathbb{R}$ (respectively, $]-\infty, +\infty]$). Let $\bar{x}$ be a solution of the following problem*:

$$\min f(x)+g(x), \qquad x \in W.$$

Then

$$\langle \nabla f(\bar{x}), x-\bar{x}\rangle + g(x) - g(\bar{x}) \geqq 0 \quad \forall x \in W,$$

or, equivalently,

$$\nabla f(\bar{x}) + \partial g(\bar{x}) \ni 0.$$

Proof. A straightforward application of the definition of the subdifferential [12] allows us to verify the equivalence of the two statements of the conclusion. Now consider $x^t = \bar{x} + t(x-\bar{x})$ for t in $]0, 1[$. We have, using the convexity of g: $f(x^t) + g(x^t) \leqq f(x^t) + (1-t)g(\bar{x}) + tg(x)$; hence, as $\bar{x}$ is a solution of the problem above,

$$0 \leqq f(x^t) + g(x^t) - (f(\bar{x}) + g(\bar{x})) \leqq f(x^t) - f(\bar{x}) + t(g(x) - g(\bar{x})).$$

Dividing by t and passing to the limit, we obtain the result. □

We now consider the following approximate problem. Let the state equation be

$$\begin{aligned} Ay &= u + w \quad \text{in } \Omega, \\ y &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{3.6}$$

The control is now (u, w) in $L^2(\Omega) \times L^2(\Omega)$. We define

$$J_\varepsilon(y, u, w) = J(y, u) + \frac{1}{2\varepsilon} \int_\Omega (w + \phi(y))^2 \, dx + \frac{1}{2\varepsilon} \|Ty - a\|^2 + \frac{1}{2} \int_\Omega (u - \bar{u})^2 \, dx + \frac{1}{2} \int_\Omega (w + \phi(\bar{y}))^2 \, dx.$$

The approximate problem is

$$(\mathrm{P}_\varepsilon) \qquad \begin{aligned} &\text{minimize} \quad J_\varepsilon(y, u, w) \\ &\text{subject to} \quad (3.6), \quad u \in K, \quad w \in L^2(\Omega), \quad y \in Y, \quad Ly \in B. \end{aligned}$$

THEOREM 3. *Let $(\bar{y}, \bar{u})$ be a solution of* (P). *We assume that* (2.2)-(2.5) *hold. Then we have the following*:

(i) *Problem* (P_ε) *has at least one solution.*

(ii) *To each solution $(y_\varepsilon, u_\varepsilon, w_\varepsilon)$ of (P_ε) is associated p_ε in $W_0^{1,s}(\Omega)$ for all $s < n/(n-1)$, $\mu_\varepsilon \in Z'$, and λ_ε in $\mathbb{R}^m$ such that*

$$A^* p_\varepsilon = |y_\varepsilon - y_d|^{\sigma-2}(y_\varepsilon - y_d) + T^* \lambda_\varepsilon + L^* \mu_\varepsilon + \frac{1}{\varepsilon} \phi'(y_\varepsilon)(w_\varepsilon + \phi(y_\varepsilon)),$$

$$p_\varepsilon = 0 \quad \text{on } \Gamma,$$

$$\langle \mu_\varepsilon, z - Ly_\varepsilon \rangle \leqq 0 \quad \forall z \in B,$$

$$\int_\Omega (p_\varepsilon + Nu_\varepsilon + u_\varepsilon - \bar{u})(v - u_\varepsilon) \, dx \geqq 0 \quad \forall v \in K,$$

$$p_\varepsilon + \frac{1}{\varepsilon}[w_\varepsilon + \phi(y_\varepsilon)] + w_\varepsilon + \phi(\bar{y}) = 0.$$

Proof. (i) The triple $(\bar{y}, \bar{u}, -\phi(\bar{y}))$ is feasible for (P_ε). Any minimizing sequence is bounded in $L^\sigma(\Omega) \times L^2(\Omega) \times L^2(\Omega)$, and hence by (3.6) in $Y \times L^2(\Omega) \times L^2(\Omega)$. Taking a subsequence if necessary and using the compactness of Y in $C_0(\Omega)$ $(n \leqq 3)$ to pass to the limit in the nonlinear terms, we get the result as in the proof of Theorem 1.

(ii) Denote by $y_{u,w}$ the solution of (3.6) and by $\theta(u, w)$ the mapping $(u, w) \to J_\varepsilon(y_{u,w}, u, w)$. It is easy to verify that θ is C^1 and that

$$\theta'_u(u, w) = q + Nu + u - \bar{u},$$

$$\theta'_w(u, w) = q + \frac{1}{\varepsilon}(w + \phi(y_{u,w})) + w + \phi(\bar{y}),$$

where q is the solution of (A^* being the formal transpose of A):

$$A^*q = |y_{u,w} - y_d|^{\sigma-2}(y_{u,w} - y_d) + \frac{1}{\varepsilon}\phi'(y_{u,w})(w + \phi(y_{u,w})) + \frac{1}{\varepsilon}T^*(Ty_{u,w} - a) \quad \text{in } \Omega,$$

$$q = 0 \quad \text{on } \Gamma.$$

Let $(y_\varepsilon, u_\varepsilon, w_\varepsilon)$ be a solution of (P_ε) and q_ε the associated adjoint-state. Let us define

$$\hat{L}: L^2(\Omega) \times L^2(\Omega) \to Z,$$

$$(u, w) \to Ly_{u,w},$$

$$\hat{K} = K \times L^2(\Omega),$$

$$g(u, w) = I_B(\hat{L}(u,w)) + I_{\hat{K}}(u, w).$$

Problem (P_ε) is equivalent to

$$\min \theta(u, w) + g(u, w), (u, w) \in L^2(\Omega) \times L^2(\Omega).$$

Now applying Lemma 2, we get

$$\nabla\theta(u_\varepsilon, w_\varepsilon) + \partial g(u_\varepsilon, w_\varepsilon) \ni 0.$$

The mapping $w \to y_{u,w}$(with u fixed) is an isomorphism from $L^2(\Omega)$ onto Y. Hence by (2.1) there exists (u, w) in $\hat{K}$ with $\hat{L}(u, w)$ in $\mathring{B}$. This allows us [12] to apply the rules of subdifferential calculus to the mapping g and we get the equality

$$\partial g(u_\varepsilon, w_\varepsilon) = \hat{L}^* \partial I_B(Ly_\varepsilon) + \partial I_{\hat{K}}(u_\varepsilon, w_\varepsilon).$$

Hence there exists μ_ε in $\partial I_B(Ly_\varepsilon)$ such that

$$\nabla\theta(u_\varepsilon, w_\varepsilon) - \hat{L}^*\mu_\varepsilon + \partial I_{\hat{K}}(u_\varepsilon, w_\varepsilon) \ni 0,$$

or equivalently,

$$(\theta'_u(u_\varepsilon, w_\varepsilon), u - u_\varepsilon) + (\theta'_w(u_\varepsilon, w_\varepsilon), w - w_\varepsilon) + \langle \mu_\varepsilon, Ly_{u,w} - Ly_\varepsilon \rangle \geqq 0 \quad \forall (u, w) \in K \times L^2(\Omega).$$

Let r_ε be the solution of

$$A^*r_\varepsilon = L^*\mu_\varepsilon \quad \text{in } \Omega,$$

$$r_\varepsilon = 0 \quad \text{on } \Gamma.$$

We get

$$(\theta'_u(u_\varepsilon, w_\varepsilon) + r_\varepsilon, u - u_\varepsilon) \geqq 0 \quad \forall u \in K,$$

$$\theta'_w(u_\varepsilon, w_\varepsilon) + r_\varepsilon = 0.$$

We obtain the result with $p_\varepsilon = q_\varepsilon + r_\varepsilon$ and $\lambda_\varepsilon = (1/\varepsilon)(Ty_\varepsilon - a)$. As $A^* p_\varepsilon$ is in $M(\Omega)$, p_ε is in $W_0^{1,s}(\Omega)$ for all $s < n/(n-1)$ (see [9], [21]). □

LEMMA 3. *Let* $\{(y_\varepsilon, u_\varepsilon, w_\varepsilon)\}$ *be a sequence of solutions of* (P_ε). *Then*

$$0 = \lim_{\varepsilon \downarrow 0} \|y_\varepsilon - \bar{y}\|_Y = \lim_{\varepsilon \downarrow 0} \|u_\varepsilon - \bar{u}\|_{L^2(\Omega)} = \lim_{\varepsilon \downarrow 0} \|w_\varepsilon + \phi(\bar{y})\|_{L^2(\Omega)}.$$

Proof. From the inequality $J_\varepsilon(y_\varepsilon, u_\varepsilon, w_\varepsilon) \leqq J_\varepsilon(\bar{y}, \bar{u}, -\phi(\bar{y})) = J(\bar{y}, \bar{u})$ and the form of J, we deduce that $\{(y_\varepsilon, u_\varepsilon, w_\varepsilon)$ is bounded in $L^\sigma(\Omega) \times L^2(\Omega) \times L^2(\Omega)$; hence $\{y_\varepsilon\}$ is bounded in Y by (3.6) and (2.6). This implies that for $\varepsilon \in D$, D being a subset of $]0, \infty[$ having zero as limit point, we have for some (y, u, w) in $Y \times L^2(\Omega) \times L^2(\Omega)$ when $\varepsilon \to 0$:

$$y_\varepsilon \to y \quad \text{in } Y \text{ weak}, \quad C_0(\Omega) \text{ strong},$$

$$u_\varepsilon \to u \quad \text{in } L^2(\Omega) \text{ weak},$$

$$w_\varepsilon \to w \quad \text{in } L^2(\Omega) \text{ weak},$$

with (y, u, w) satisfying (3.6). As K and B are closed and convex in $L^2(\Omega)$ and Z we have $u \in K$ and $Ly \in B$. The form of J_ε implies that $\|w_\varepsilon + \phi(y_\varepsilon)\|_{L^2(\Omega)} \to 0$ and $\|Ty_\varepsilon - a\| \to 0$; hence $w + \phi(y) = 0$. With (3.6) this implies that (y, u) satisfies (2.1). As J is lower semicontinuous, we have that

$$\begin{aligned} J(\bar{y}, \bar{u}) &\geqq \limsup J_\varepsilon(y_\varepsilon, u_\varepsilon, w_\varepsilon) \\ &\geqq \limsup \{J(y_\varepsilon, u_\varepsilon) + \tfrac{1}{2}\|u_\varepsilon - \bar{u}\|^2_{L^2(\Omega)} + \tfrac{1}{2}\|w_\varepsilon + \phi(\bar{y})\|^2_{L^2(\Omega)}\} \\ &\geqq J(y, u) + \tfrac{1}{2}\|u - \bar{u}\|^2_{L^2(\Omega)} + \tfrac{1}{2}\|w + \phi(\bar{y})\|^2_{L^2(\Omega)}. \end{aligned}$$

As (y, u) is feasible for (P), this implies that $u = \bar{u}$ and $w + \phi(\bar{y}) = 0$; hence $\phi(y) = \phi(\bar{y})$. With (2.1) this implies that $y = \bar{y}$. But the inequality above also implies $\|u_\varepsilon - \bar{u}\|_{L^2(\Omega)} \to 0$ and $\|w_\varepsilon + \phi(\bar{y})\|_{L^2(\Omega)} \to 0$; when we use (2.6), the result follows. □

We now are in position to prove Theorem 2, by passing to the limit in the optimality system of (P_ε).

Proof of Theorem 2. Let $(y_\varepsilon, u_\varepsilon, w_\varepsilon)$ denote a solution of (P_ε) and $(p_\varepsilon, \mu_\varepsilon, \lambda_\varepsilon)$ be given by Theorem 3. If $\{(p_\varepsilon, \mu_\varepsilon, \lambda_\varepsilon)\}$ is bounded we obtain the result with $\bar{\alpha} = 1$ by passing to the limit in the optimality system of (P_ε) with the help of Lemma 3. Now suppose that $\alpha_\varepsilon = 1/(\|p_\varepsilon\|_{L^2(\Omega)} + \|\mu_\varepsilon\|_{Z'} + \|\lambda_\varepsilon\|)$ converges toward zero. Multiplying by α_ε the optimality system given by Theorem 3 and defining

$$\bar{p}_\varepsilon = \alpha_\varepsilon p_\varepsilon, \quad \bar{\mu}_\varepsilon = \alpha_\varepsilon \mu_\varepsilon, \quad \bar{\lambda}_\varepsilon = \alpha_\varepsilon \lambda_\varepsilon,$$

we obtain, eliminating $(1/\varepsilon)(w_\varepsilon + \phi(y_\varepsilon))$ from the last equality of Theorem 3,

$$\begin{aligned} &A^* \bar{p}_\varepsilon + \phi'(y_\varepsilon)\bar{p}_\varepsilon = \alpha_\varepsilon |y_\varepsilon - y_d|^{\sigma-2}(y_\varepsilon - y_d) + T^* \bar{\lambda}_\varepsilon + L^* \bar{\mu}_\varepsilon \\ &\qquad\qquad - \alpha_\varepsilon \phi'(y_\varepsilon)(w_\varepsilon + \phi(\bar{y})) \quad \text{in } \Omega, \\ &\bar{p}_\varepsilon = 0 \quad \text{on } \Gamma, \\ &\langle \bar{\mu}_\varepsilon, z - Ly_\varepsilon \rangle \leqq 0 \quad \forall z \in B, \\ &\int_\Omega [\bar{p}_\varepsilon + \alpha_\varepsilon (Nu_\varepsilon + u_\varepsilon - \bar{u})](v - u_\varepsilon) \geqq 0 \quad \forall v \in K. \end{aligned} \tag{3.7}$$

As $\|\bar{p}_\varepsilon\|_{L^2(\Omega)} + \|\bar{\mu}_\varepsilon\|_{Z'} + \|\bar{\lambda}_\varepsilon\|$ is bounded, we may pass to the limit in the systems above by using Lemma 3; then we obtain (3.3)-(3.5), with $\bar{\alpha} = 0$ here. It remains to prove that $\bar{p} \neq 0$. If $\bar{p} = 0$, then $T^* \bar{\lambda} + L^* \bar{\mu} = 0$ by (3.3). However, (3.1) and the injectivity of T^* and L^* (by (2.5)) then imply that $\bar{\mu} = 0$ and $\bar{\lambda} = 0$. Since $\{\bar{\lambda}_\varepsilon\}$ is in $\mathbb{R}^m$ and

because of Lemma 1, we infer that $\liminf \|\bar{\mu}_\varepsilon\|_{Z'} = 0$ and $\|\bar{\lambda}_\varepsilon\| \to 0$; hence $\|\bar{p}_\varepsilon\|_{L^2(\Omega)} \to 1$. From (3.7) and Lemma 3 we deduce that $A^*\bar{p}_\varepsilon$ is bounded in $M(\Omega)$; hence $\{\bar{p}_\varepsilon\}$ is bounded in $W_0^{1,s}(\Omega)$ for all $s < n/(n-1)$. The compact injection from $W_0^{1,s}(\Omega)$ into $L^2(\Omega)$ (for $n \leqq 3$ and s close to $n/(n-1)$) implies that $\|\bar{p}_\varepsilon\|_{L^2(\Omega)} \to \|\bar{p}\|_{L^2(\Omega)} = 0$, which gives a contradiction. □

4. Applications. In this section we consider the three examples stated in § 2, and we derive the optimality system for each of them.

Example 1.

THEOREM 4. *Let $(\bar{y}, \bar{u}) \in Y \times K$ be a solution of* (P1). *Then there exist a real number $\bar{\alpha} \geqq 0$ and elements $\bar{\lambda} \in R^m$ and $\bar{p} \in W_0^{1,s}(\Omega)$ for all $s < n/(n-1)$ satisfying*

$$\bar{\alpha} + \|\bar{p}\|_{W_0^{1,s}(\Omega)} > 0, \tag{4.1}$$

$$\begin{aligned} &A\bar{y} + \phi(\bar{y}) = \bar{u} \quad \text{in } \Omega, \\ &\bar{y} = 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.2}$$

$$\begin{aligned} &A^*\bar{p} + \phi'(\bar{y})\bar{p} = \bar{\alpha}|\bar{y} - y_d|^{\sigma-2}(\bar{y} - y_d) + \sum_{i=1}^{m} \bar{\lambda}_i \delta_{[x_i]} \quad \text{in } \Omega, \\ &\bar{p} = 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.3}$$

$$\int_\Omega (\bar{p} + \bar{\alpha} N\bar{u})(v - \bar{u})\, dx \geqq 0 \quad \forall v \in K. \tag{4.4}$$

Proof. Hypothesis (3.1) is trivially satisfied as $B = C_0(\Omega)$. Hence we may apply Theorem 2, which gives the result. □

In some cases it is possible to prove that the previous theorem is true with $\bar{\alpha} = 1$. We are going to study two situations where this is so.

THEOREM 5. *Let $a_{ij} \in C^2(\bar{\Omega})$, $1 \leqq i \leqq j \leqq n$. Then the results of Theorem* 2 *are obtained with $\bar{\alpha} = 1$ if Ω is connected and one of the two following hypotheses holds:*

(i) *There exists an open subset Ω_0 of Ω such that $K = K + \widetilde{L^2(\Omega_0)}$ ($\widetilde{L^2(\Omega_0)}$ is the extension by zero from $L^2(\Omega_0)$ to $L^2(\Omega)$).*

(ii) *$K = \{v \in L^2(\Omega)\colon v(x) \geqq 0$ a.e. $x \in \Omega\}$, and $u = 0$ is not optimal for* (P1).

Proof. (i) If $\bar{\alpha} = 0$, it follows from (4.3) that

$$\begin{aligned} &A^*\bar{p} + \phi'(\bar{y})\bar{p} = \sum_{i=1}^{m} \bar{\lambda}_i \delta_{[x_i]} \quad \text{in } \Omega, \\ &\bar{p} = 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.5}$$

Now from (4.4) and the property of K, we get that $\bar{p} = 0$ in Ω_0. Taking $\Omega_1 = \Omega \backslash \{x_i\}_{i=1}^m$, we have

$$\begin{aligned} &A^*\bar{p} + \phi'(\bar{y})\bar{p} = 0 \quad \text{in } \Omega_1, \\ &\bar{p} = 0 \quad \text{in } \Omega_0 \backslash \{x_i\}_{i=1}^m. \end{aligned} \tag{4.6}$$

Then we can use the Prolongation Unicity Theorem (Saut and Scheurer [20]) and we deduce that $\bar{p} = 0$ in Ω_1, hence in Ω, which contradicts (4.1).

(ii) If $\bar{\alpha} = 0$, we deduce from (4.4) that $\bar{p} \geqq 0$ in Ω. If $\bar{p}$ is null on an open subset Ω_0 of Ω, we can do as in (i) and obtain a contradiction. Otherwise, for each open subset Ω_0 with $\bar{\Omega}_0$ included in Ω_1 we have

$$\max_{x \in \Omega_0} \bar{p}(x) > 0. \tag{4.7}$$

We remark that $\bar{p}$ satisfies

$$A^*\bar{p} + \max(0, \phi'(\bar{y}))\bar{p} \geqq 0 \quad \text{in } \Omega_1,$$
$$\bar{p} = 0 \quad \text{on } \Gamma.$$

Applying the Harnack inequality to $A^* + \max(0, \phi'(\bar{y}))$ (Stampacchia [21]) as in [5], we deduce that $\bar{p}(x) > 0$ everywhere in Ω_1, which with (4.4) implies that $\bar{u} = 0$ almost everywhere. □

Example 2.

THEOREM 6. *If* $(\bar{y}, \bar{u}) \in Y \times K$ *is solution of* (P2), *then there exists a real number* $\bar{\alpha} \geqq 0$ *and elements* $\bar{\mu} \in L^\infty(\Omega)$ *and* $\bar{p} \in W_0^{1,s}(\Omega)$ *such that for all* $s < n/(n-1)$:

$$\bar{\alpha} + \|\bar{p}\|_{W_0^{1,s}(\Omega)} > 0, \tag{4.8}$$

$$\begin{aligned} A\bar{y} + \phi(\bar{y}) &= \bar{u} \quad \textit{in } \Omega, \\ \bar{y} &= 0 \quad \textit{on } \Gamma, \end{aligned} \tag{4.9}$$

$$\begin{aligned} A^*\bar{p} + \phi'(\bar{y})(\bar{p}) &= \bar{\alpha}|\bar{y} - y_d|^{\sigma-2}(\bar{y} - y_d) + \bar{\mu} \quad \textit{in } \Omega, \\ \bar{p} &= 0 \quad \textit{on } \Gamma, \end{aligned} \tag{4.10}$$

$$\int_\Omega \bar{\mu}(z - \bar{y})\, dx \leqq 0 \quad \forall z \in B, \tag{4.11}$$

$$\int_\Omega (\bar{p} + \bar{\alpha} N\bar{u})(v - \bar{u})\, dx \geqq 0 \quad \forall v \in K. \tag{4.12}$$

Proof. Here again, (3.1) is satisfied because $T = 0$. Hence we may apply Theorem 2 and remark that $Z' = L^\infty(\Omega)$ and L^* is the canonical injection into $M(\Omega)$. Moreover, the regularity of $\bar{p}$ follows from (2.6), (4.10), and the fact that $\bar{\alpha}|\bar{y} - y_d|^{\sigma-2}(\bar{y} - y_d) + \bar{\mu} - \phi'(\bar{y})\bar{p}$ belongs to $L^1(\Omega)$. □

Example 3.

THEOREM 7. *If* $(\bar{y}, \bar{u}) \in Y \times K$ *is solution of* (P3), *then there exist a real number* $\bar{\alpha} \geqq 0$ *and elements* $\bar{p} \in W_0^{1,s}(\Omega)$ *for all* $s < n/(n-1)$, $\bar{\lambda} \in \mathbb{R}$, *and* $\bar{\mu} \in M(\Omega)$ *such that*

$$\bar{\alpha} + \|\bar{p}\| W_0^{1,s}(\Omega) > 0, \tag{4.13}$$

$$\begin{aligned} A\bar{y} + \phi(\bar{y}) &= \bar{u} \quad \textit{in } \Omega, \\ \bar{y} &= 0 \quad \textit{on } \Gamma, \end{aligned} \tag{4.14}$$

$$\begin{aligned} A^*\bar{p} + \phi'(\bar{y})\bar{p} &= \bar{\alpha}|\bar{y} - y_d|^{\sigma-2}(\bar{y} - y_d) + \bar{\lambda} + \bar{\mu} \quad \textit{in } \Omega, \\ \bar{p} &= 0 \quad \textit{on } \Gamma, \end{aligned} \tag{4.15}$$

$$\int_\Omega (z - \bar{y})\, d\bar{\mu} \leqq 0 \quad \forall z \in B, \tag{4.16}$$

$$\int (\bar{p} + \bar{\alpha} N\bar{u})(v - \bar{u})\, dx \geqq 0 \quad \forall v \in K. \tag{4.17}$$

Proof. We have to verify that (3.1) is satisfied. Remember that in this case L is the identity in $C_0(\Omega)$ and $T \in C_0(\Omega)'$. Take $\mu \in \partial I_B(\bar{y})$ and $\lambda \in R$ such that

$$\langle \mu, z \rangle = \langle T^*\lambda, z \rangle = \lambda \int_\Omega z\, dx \quad \forall z \in C_0(\Omega);$$

this implies that $\mu = \lambda m$, where m is the Lebesgue measure. If $\lambda \neq 0$, this implies that $\bar{y}(x) = \pm\delta$ almost everywhere, which contradicts the boundary condition. □

ASPECTS OF POSITIVITY IN CONTROL THEORY*

TILMAN SCHANBACHER†

Abstract. This paper studies finite- and infinite-dimensional linear control systems of the form $df/dt = Af + Bu$, where A is the infinitesimal generator of a C_0-semigroup that preserves a cone C, and where Bu takes values in C. Since the reachable states are all in C, the system is not controllable in the usual sense. Of concern is "positive controllability," which means that the entire cone C can be (approximately) reached. It turns out that positive controllability is rather difficult to achieve but that for stable systems an important subclass of states can be reached. Different examples are provided.

Key words. controllability, positive controllability, positive systems, positive controls, stationary pairs

AMS(MOS) subject classifications. primary 93B05; secondary 93C05

1. Introduction. In this paper we are concerned with a linear distributed parameter control system of the form

$$\frac{d}{dt} f(t) = Af(t) + Bu(t), \qquad f(0) = f_0.$$

General questions such as controllability and stabilizability of this system have been intensively investigated in recent years by means of functional analysis, especially by the theory of strongly continuous semigroups (see, e.g., Balakrishnan [1], Curtain and Pritchard [4], [5]). Saperstone and Yorke [10], Brammer [3], Son [16], Korobov and Son [7], and Schanbacher [12] consider controllability with the additional requirement that the controls are restricted to a certain subset of the original space, thereby making particular use of the theorems of Krein and Rutman [8] on positive operators.

Until now, scarce attention has been paid to the important case where the control of a system is realizable in only one direction. In the papers on controllability with restrictions on the controls mentioned above, this problem has been taken into account, whereas the aim has still been to (approximately) reach the entire linear state space or at least a neighborhood of the initial state. However, this is possible only if the system is oscillating in some sense; in particular, it is impossible for the large class of systems described by positive semigroups. Our concern is to ask which positive states can be reached for positivity-preserving systems if the controls are taken to be positive. In analogy to the usual definition of controllability we call the system positive controllable if all positive states can be reached.

In § 2 we present the definitions and notation needed later, mainly for readers who are not familiar with the abstract theory of Banach lattices and positive operators.

Section 3 is a heuristic introduction to the problems examined in this paper. We study two examples illustrating the questions to be considered in §§ 4 and 5.

In § 4 we discuss the concept of positive controllability for positive systems, both on finite-dimensional and infinite-dimensional spaces. We obtain a neat characterization of positive controllability for finite-dimensional spaces, and show that positive controllability on infinite-dimensional spaces is rather difficult to achieve, contrary to the usual notion of controllability.

* Received by the editors October 13, 1986; accepted for publication (in revised form) May 12, 1988. This paper is part of the author's Ph.D. dissertation of the same title.

† Mathematisches Institut der Universität Tübingen, Morgenstelle 10, 7400 Tübingen, Federal Republic of Germany.

In § 5 we consider a subclass of positive states that can be reached more easily than arbitrary positive states. Existence of such states is mainly connected with asymptotic stability of the system.

We conclude §§ 4 and 5 with practical examples.

2. Preliminaries. In this section we introduce some basic notation and definitions from functional analysis following Schaefer [11] and Nagel [9].

2.1. Sets and spaces. Throughout this paper we use E and U to denote Banach spaces over the same real or complex field, endowed with a norm $\| \ \|$.

By $L(E)$, $L(U, E)$ we denote the space of linear continuous (or bounded) operators from E into E, respectively, from U into E, endowed with the canonical operator norm.

By $L^p([0, t]; U)$ $(1 \leqq p \leqq \infty)$ we denote the space of all p-integrable functions on $[0, t]$ with values in U, and by $L^p_{\mathrm{loc}}(\mathbb{R}_+; U) := \{f : \mathbb{R}_+ \to U : f_{|[0,t]} \in L^p([0, t]; U)$ for all $t > 0\}$ the space of all locally p-integrable functions on $\mathbb{R}_+$ with values in U.

Let Ω be a subset of E or U. We use the following notation:

cl Ω	the closure of Ω,
co Ω	the smallest convex set containing Ω,
cone Ω	the smallest cone containing Ω and 0,
cocone Ω	the smallest convex cone containing Ω and 0.

Following [11] we define a (real) Banach lattice E as a Banach space over $\mathbb{R}$ endowed with an order written as $\leqq$ such that $(E, \leqq)$ is a lattice and the ordering is compatible with the Banach space structure of E. We will elaborate on this.

The axioms of compatibility between the linear structure of E and the order are as follows:

$$f \leqq g \text{ implies } f + h \leqq g + h \quad \text{for all } f, g, h \text{ in } E,$$
$$f \geqq 0 \text{ implies } \lambda f \geqq 0 \quad \text{for all } f \text{ in } E \text{ and } \lambda \geqq 0.$$

Any real vector space with an ordering satisfying these two axioms is called an *ordered vector space*. The axioms imply that the set $E_+ := \{f \in E : f \geqq 0\}$ is a convex set and a cone with vertex zero, the *positive cone* of E. It follows that $f \leqq g$ if and only if $g - f \in E_+$. The elements $f \in E_+$ are called *positive*, and we write $f > 0$ if f is positive and different from zero.

An ordered vector space E is called a *vector lattice* if any two elements f, g in E have a supremum and an infimum denoted by $\sup(f, g)$, respectively, $\inf(f, g)$. For an element f of a vector lattice we write

$$|f| = \sup(f, -f) \text{ and call it the } \textit{absolute value} \text{ of } f.$$

We call two elements f, g of a vector lattice *orthogonal*, if $\inf(|f|, |g|) = 0$.

The axiom of compatibility between norm and order required for a Banach lattice is shown below:

$$|f| \leqq |g| \quad \text{implies } \|f\| \leqq \|g\|. \tag{2.1}$$

A norm on a vector lattice satisfying this axiom is called a *lattice norm*. Finally, a (real) *Banach lattice* is a Banach space E over $\mathbb{R}$ endowed with an ordering $\leqq$ such that $(E, \leqq)$ is a vector lattice and the norm on E is a lattice norm.

In particular, in Banach lattices the following formulas are valid:

$$|f + g| \leqq |f| + |g| \quad \text{and} \quad \| |f| \| = \|f\|.$$

A linear subspace I of E is called an *ideal* if $f \in I$, $|g| \leqq |f|$ implies $g \in I$.

Two ideals I, J of a vector lattice E are called *orthogonal* if any two elements $f \in I$, $g \in J$ are orthogonal. It is immediate that two ideals are orthogonal if and only if they have trivial intersection $\{0\}$. An ideal I is called *proper* if I is different from E and from $\{0\}$.

Typical ideals are all sets of the form

$$J_{f'} := \{f \in E : \langle f', |f| \rangle = 0\} \quad \text{for some } 0 \leqq f' \in E'.$$

A linear form $f' \in E'$ is called

Positive $(f' \geqq 0)$ if $\langle f', f \rangle \geqq 0$ for all $f \geqq 0$;

Strictly positive $(f' \gg 0)$ if $\langle f', f \rangle > 0$ for all $f > 0$.

A *complex Banach lattice* E is the complexification of a real Banach lattice $E_{\mathbb{R}}$ in the sense that

$$E = E_{\mathbb{R}} \oplus iE_{\mathbb{R}},$$

i.e., $E = E_{\mathbb{R}} \times iE_{\mathbb{R}}$ with scalar multiplication $(\alpha + i\beta)(f, g) = (\alpha f - \beta g, \beta f + \alpha g)$. $E_{\mathbb{R}}$ is called the *real part* of E. The absolute value of an element $h = f + ig \in E$ is defined by

$$|h| = \sup \{\cos \theta \cdot f + \sin \theta \cdot g : 0 \leqq \theta \leqq 2\pi\} \in E_{\mathbb{R}},$$

and the norm still satisfies (2.1).

Since the absolute value exists for all $f \in E$ the definition of an ideal can be extended unchanged to the complex situation. An element $f \in E$ is called positive if $f = |f|$, which means that f is a positive element of $E_{\mathbb{R}}$.

In the following, a Banach lattice denotes either a real or a complex Banach lattice.

Relevant examples of Banach lattices are given by the following spaces: $\mathbb{R}^n$, $n \in \mathbb{N}$ with the coordinatewise ordering; the function spaces $C_0(Y)$ (Y locally compact) and $L^p(\Omega)$ (Ω a measure space, $1 \leqq p \leqq \infty$) with the ordering $f \leqq g$ for $f, g \in C_0(Y)$, respectively, $L^p(\Omega)$, if $f(x) \leqq g(x)$ for all $x \in Y$, respectively, for almost all $x \in \Omega$.

2.2. Operators and semigroups. Let E and U be Banach spaces, $T \in L(E)$ and $S \in L(U, E)$. We denote the kernel of S by $\ker S$, the spectrum of T by $\sigma(T)$, the point spectrum by $p\sigma(T)$, and the resolvent set by $\rho(T)$. For all $\lambda \in \rho(T)$ we define the resolvent $R(\lambda, T) := (\lambda \operatorname{Id} - T)^{-1}$, where Id denotes the identity on E. S is called *positive* $(S \geqq 0)$ if E and U are Banach lattices and if $Su \geqq 0$ for $0 \leqq u \in U$.

Now we consider a *strongly continuous semigroup* $\mathcal{T} = (T(t))_{t \geqq 0}$ of linear continuous operators on a Banach space E, i.e.,

$$T(t+s) = T(t) \cdot T(s) \quad \text{for } t, s \geqq 0,$$

$$T(0) = \operatorname{Id},$$

$$\lim_{t \to 0} T(t)f = f \quad \text{for all } f \in E.$$

In the following we simply call $\mathcal{T}$ a *semigroup* on E.

Let $(A, D(A))$ be its *generator*, i.e.,

$$D(A) := \left\{ f \in E : \lim_{t \to 0} \frac{T(t)f - f}{t} \text{ exists} \right\},$$

$$Af := \lim_{t \to 0} \frac{T(t)f - f}{t}.$$

Then $(A, D(A))$ is a closed operator on E that determines $\mathcal{T}$ uniquely. In general, A is unbounded. We call $\omega(A) := \omega(\mathcal{T}) := \inf\{w \in \mathbb{R}$: There exists M_w such that $\|T(t)\| \leqq M_w e^{wt}$ for all $t \geqq 0\}$ the *growth bound* of A (or of $\mathcal{T}$). Then $-\infty \leqq \omega(A) < +\infty$ by [9, A-I, § 1.2].

If $A \in L(E)$ then $T(t) = \exp(tA) := \sum_{n=0}^{\infty} ((tA)^n/n!)$ by [9, A-I, 2.1].

The semigroup $\mathcal{T}$ is called *bounded* if there exists $M > 0$ such that $\|T(t)\| \leqq M$ for every $t \geqq 0$ (this implies $\omega(A) \leqq 0$).

A special class of bounded semigroups are the following: $\mathcal{T}$ is called *weakly stable* if $\langle f', T(t)f\rangle \to 0$ as $t \to \infty$ for every $f \in E$ and $f' \in E'$; *strongly stable* if $\|T(t)f\| \to 0$ as $t \to \infty$ for every $f \in E$; and *uniformly exponentially stable* if $\omega(A) < 0$. On finite-dimensional spaces these three notions of stability coincide (and we simply call the semigroup *stable*), whereas in the case of infinite-dimensional spaces these notions are strictly different ([9, A-IV, § 1]). Obviously uniform exponential stability implies strong stability, and strong stability implies weak stability. Finally we call the semigroup $\mathcal{T}$ *positive* ($\mathcal{T} \geqq 0$) if E is a Banach lattice and if $T(t)$ is a positive operator for every $t \geqq 0$.

3. Examples and questions. As a heuristic motivation for this paper we present two practical examples of linear control systems providing both the finite- and the infinite-dimensional case. In both cases we will notice that the solution of the system remains in the positive cone of a Banach lattice and we can pose two questions that will be discussed in the §§ 4 and 5, respectively. We will return to these two examples in each of these sections.

3.1. Electrically heated oven. We consider a simple model of an electrically heated oven (see [2, Ex. 1.2]) consisting of a jacket, an inner part, and a coil that directly heats the jacket and indirectly heats the interior part by means of radiation of the jacket. Let τ_0 denote the outside temperature, $\tau_1(t)$ the temperature of the jacket at time t, and $\tau_2(t)$ the temperature of the interior part at time t.

If we set

$$f(t) = \begin{pmatrix} \tau_1(t) - \tau_0 \\ \tau_2(t) - \tau_0 \end{pmatrix},$$

then the system is described by

$$\frac{d}{dt} f(t) = \begin{pmatrix} -\alpha & \beta \\ \gamma & -\delta \end{pmatrix} f(t) + \begin{pmatrix} 1 \\ 0 \end{pmatrix} u(t), \qquad f(0) = f_0, \tag{3.1}$$

where $u(t)$ measures the heat input at time t and is always nonnegative (since it is proportional to the square of the voltage in the coil), $\alpha, \beta, \gamma, \delta$ are nonnegative constants, and f_0 is assumed to be nonnegative ($f_0 \in \mathbb{R}^2_+$). This means that the differences $\tau_1(t) - \tau_0$ and $\tau_2(t) - \tau_0$ at time $t = 0$ are nonnegative. Then it seems plausible that $f(t)$ is nonnegative for all times. Indeed, if we denote by A the matrix $\left(\begin{smallmatrix} -\alpha & \beta \\ \gamma & -\delta \end{smallmatrix}\right)$ and by B the matrix $\left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$ then by [5, 2.23] for every $u \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ a mild solution of (3.1) is given by

$$f(t) = T(t)f_0 + \int_0^t T(t-s)Bu(s)\, ds, \tag{3.2}$$

where $\mathcal{T} = (T(t))_{t \geqq 0}$ is the strongly continuous semigroup generated by A and is positive by [9, B-II, Ex. 1.4.b]. From (3.2) we see that $f(t) \in \mathbb{R}^2_+$ for all $t \geqq 0$.

The *first question* is now whether each $f_1 \in \mathbb{R}^2_+$ can be approximately reached from the origin ($f_0 = 0$) by means of a suitable nonnegative control u.

It seems possible that by means of a high input we can reach, at least for a short period of time, an arbitrarily high jacket temperature while simultaneously the interior temperature is low. However, the opposite situation, given by a low jacket and arbitrarily high interior temperature, seems to be impossible. Therefore we expect a negative answer to this question.

For our second question we consider a special class of states f_1, namely those belonging to a positive stationary pair (f_1, u_1). This means that f_1 is a constant positive solution of (3.1) for constant nonnegative input u_1 and initial state $f_0 = f_1$, i.e., $Af_1 + Bu_1 = 0$, $0 \neq f_1 \in \mathbb{R}_+^2$, $u_1 \in \mathbb{R}_+$. If we can reach these states f_1, then we can keep them constant by further input u_1. If the system is stable and if we can reach them only approximately, then it should also be possible to keep them approximately constant by further input u_1.

Therefore our *second question* follows: Can we (approximately) reach each state f_1 belonging to a positive stationary pair starting from any $f_0 \in \mathbb{R}_+^2$? The question makes sense only if there exists a positive stationary pair, and moreover if stability of the system is desirable as just mentioned.

In the concrete example and if $\gamma + \delta \neq 0$ we can show by a simple calculation the following two equivalences:

A positive stationary pair exists if and only if A has only eigenvalues with nonpositive real part.

A positive stationary pair (f_1, u_1) with $u_1 \neq 0$ exists if and only if A has only eigenvalues with negative real part (i.e., A is stable).

In practice (see [2, Ex. 1.2]) A is stable and the parameters α, β, γ, δ are (strictly) positive.

3.2. Heat equation on a finite rod with noninsulated ends. We consider the heat equation on a rod of length 1 with noninsulated ends given by

$$\frac{\partial}{\partial t}\chi(t, x) = \frac{\partial^2}{\partial x^2}\chi(t, x), \quad 0 \leqq x \leqq 1, \quad t \geqq 0,$$

$$\chi(t, 0) = \chi(t, 1) = 0,$$

$$\chi(0, x) = \chi_0(x),$$

where χ_0 is a given nonnegative function on $[0, 1]$.

Again we wish to control the system by a nonnegative one-dimensional input, i.e., by a function $\psi(x) \cdot u(t)$, where $\psi(x) \geqq 0$ for $0 \leqq x \leqq 1$, $u(t) \geqq 0$ for $t \geqq 0$. As in the first example, we can interpret this control as an electrical heating input that for all time is proportional to a given heat distribution ψ. Then we obtain

$$\begin{aligned} &\frac{\partial}{\partial t}\chi(t, x) = \frac{\partial^2}{\partial x^2}\chi(t, x) + \psi(x) \cdot u(t), \quad 0 \leqq x \leqq 1, \quad t \geqq 0, \\ &\chi(t, 0) = \chi(t, 1) = 0, \\ &\chi(0, x) = \chi_0(x), \end{aligned} \tag{3.3}$$

and again it seems plausible that χ remains nonnegative for all times.

We state this problem as an abstract control problem on the space $E := L^2[0, 1]$. Assume $\psi \in E$ and let $U = \mathbb{R}$, $B \in L(U, E)$, $B\alpha := \alpha \cdot \psi$, $f_0 := \chi_0$ and let $A = d^2/dx^2$ be the operator on E with domain $D(A) = \{f \in E : f'' \in E, f(0) = f(1) = 0\}$. It is known [5, Eq. 3.9], [9, C-II, Ex. 1.5.b] that $(A, D(A))$ generates a positive semigroup

$\mathcal{T} = (T(t))_{t \geqq 0}$ on E given by

$$T(t)f = \sum_{n=1}^{\infty} e^{-n^2\pi^2 t}\langle f, e_n\rangle e_n,$$

where $f \in E$, $e_n(x) = \sqrt{2} \cdot \sin(n\pi x)$ for $0 \leqq x \leqq 1$, $\langle f, e_n\rangle := \int_0^1 f(x)e_n(x)\,dx$. Then (3.3) can be written as (set $f(t) := \chi(t, \cdot) \in E$):

$$\frac{d}{dt} f(t) = Af(t) + Bu(t),$$

$$f(t) \in D(A),$$

$$f(0) = f_0$$

and for $u \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ a mild solution is again given by (3.2).

We observe that the semigroup $\mathcal{T}$ is uniformly exponentially stable:

$$\|T(t)f\| \leqq \left(\sum_{n=1}^{\infty} e^{-2n^2\pi^2 t}\langle f, e_n\rangle^2\right)^{1/2}$$

$$\leqq e^{-\pi^2 t}\left(\sum_{n=1}^{\infty} \langle f, e_n\rangle^2\right)^{1/2} = e^{-\pi^2 t}\|f\|$$

and we claim that a positive stationary pair exists.

Proof. Let

$$f(x) := -\int_0^x \int_0^y \psi(z)\,dz\,dy + x\int_0^1 \int_0^y \psi(z)\,dz\,dy,$$

where ψ is chosen as above; then for $f \in D(A)$ we obtain $Af(x) = -\psi(x)$. Assume that f is not contained in the positive cone of E. Since $f(0) = f(1) = 0$ implies that f has a negative minimum in some $x_0 \in (0, 1)$ we obtain

$$0 = f'(x_0) = -\int_0^{x_0} \psi(z)\,dz + \int_0^1 \int_0^y \psi(z)\,dz\,dy,$$

and since $\psi \geqq 0$

$$f'(x) = -\int_0^x \psi(z)\,dz + \int_0^1 \int_0^y \psi(z)\,dz\,dy \geqq f'(x_0) = 0 \quad \text{for } 0 \leqq x \leqq x_0,$$

$$f(x_0) = f(0) + \int_0^{x_0} f'(x)\,dx = 0 + \int_0^{x_0} f'(x)\,dx \geqq 0,$$

which is a contradiction. Hence $f \geqq 0$, $Af + B1 = 0$, which means that $(f, 1)$ is a positive stationary pair, □

Therefore it might be interesting to consider the same two questions as in the first example.

4. Positive controllability. The notion of controllability usually is defined in the sense that we want to reach a dense subset of the entire state space or at least of a neighborhood of zero. However, in many instances for systems with restrictions on the controls, it is a priori known that all reachable states are contained in a closed cone C of the state space (as in the examples of the previous section). In this case controllability in the former sense is impossible but it is interesting to know conditions under which the reachable states are dense in C (which was precisely our first question in § 3). In the present section we characterize systems for which the reachable states are contained in the positive cone of a Banach lattice, and then try to find conditions

for a particular class under which a dense subset of the positive cone can be reached. This is defined as positive controllability; we will see that this implies the usual controllability. We will be able to give feasible criteria for positive controllability for finite-dimensional state spaces and strong necessary conditions for infinite-dimensional state spaces and finite-dimensional input spaces. We conclude this section with some applications.

Let E and U be Banach spaces, let $(A, D(A))$ be the generator of a strongly continuous semigroup $\mathcal{T} = (T(t))_{t \geq 0}$ on E, and $B \in L(U, E)$. We consider the following linear control system:

$$\frac{d}{dt} f(t) = Af(t) + Bu(t), \qquad f(0) = f_0, \tag{4.1}$$

where $f(t) \in E$, $f_0 \in E$, $u(t) \in U$.

By [5, 2.23] for every $u \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ a mild solution of (4.1) is given by

$$f(t) = T(t)f_0 + \int_0^t T(t-s)Bu(s)\, ds. \tag{4.2}$$

We recall the following definition.

DEFINITION 4.1. Let $1 \leqq p \leqq \infty$ and consider (4.1). We call E the *state space* and U the *input space*. Define for $t > 0$ the set of *reachable* states from the origin ($f_0 = 0$) in time t as

$$R_t := \left\{ \int_0^{t'} T(t'-s)Bu(s)\, ds \colon u \in L^p([0, t']; U), 0 \leqq t' \leqq t \right\},$$

and define the set of reachable states from the origin in arbitrary time as $R = \bigcup_{t>0} R_t$. The pair (A, B) is called

Exactly controllable in time t if $R_t = E$;

Exactly controllable if $R = E$;

Approximately controllable in time t if R_t is dense in E;

Approximately controllable if R is dense in E.

The following proposition for finite-dimensional state spaces is known as the "rank condition."

PROPOSITION 4.2 [4, 11.4]. *If* $\dim E = n < \infty$, $\dim U = m < \infty$, *then all controllability notions in* (4.1) *are equivalent to the fact that the* $n \times nm$*-matrix* $(B, AB, A^2B, \cdots, A^{n-1}B)$ *has rank* n.

Now we assume that E is a Banach lattice, that u in (4.1) takes values in a subset Ω of U and that f_0 is an element of the positive cone E_+ of E. First we want to know conditions under which the solution $f(t)$ of (4.1) remains in E_+ for all such u and f_0. We state the following proposition.

PROPOSITION 4.3. *Let E be a Banach lattice, let U be a Banach space, let $(A, D(A))$ be the generator of a strongly continuous semigroup $\mathcal{T} = (T(t))_{t \geq 0}$ on E, $B \in L(U, E)$, and $0 \in \Omega \subseteq U$. The following assertions are equivalent*:

(i) *The mild solutions of* (4.1) *remain in E_+ for every $f_0 \in E_+$ and every $u \in L^1_{\mathrm{loc}}(\mathbb{R}_+, U)$ with $u(t) \in \Omega$ for $t \geqq 0$.*

(ii) *$\mathcal{T}$ is a positive semigroup and $B\Omega \subseteq E_+$.*

Proof. The implication (ii) $\rightarrow$ (i) follows immediately from the variation of constants formula (4.2).

(i) $\rightarrow$ (ii): Since $0 \in \Omega$ we can take $u(\cdot)$ identical zero, then $f(t) = T(t)f_0 \in E_+$ for all $f_0 \in E_+$, i.e., $\mathcal{T}$ is positive. On the other hand, taking $f_0 = 0$, $u(s) = u/t$ for some $u \in \Omega$ and all $0 \leqq s \leqq t$, we obtain by (4.2) $f(t) = 1/t \int_0^t T(s)Bu\, ds$, which tends to Bu as $t \rightarrow 0$. The closedness of E_+ implies $Bu \in E_+$. □

After this characterization we restrict our considerations to the case where U is also a Banach lattice, Ω the positive cone U_+, and therefore B is a positive operator by the preceding proposition. Then we define positive controllability as follows.

DEFINITION 4.4. Let E and U be Banach lattices, let $(A, D(A))$ be the generator of a positive semigroup $\mathcal{T} = (T(t))_{t \geqq 0}$ on E, and take $B \in L(U, E)$ positive. For $t > 0$ and $1 \leqq p \leqq \infty$ the set of *reachable* states from the origin in time t by means of nonnegative controls u is defined as

$$R_t^+ := = \left\{ \int_0^{t'} T(t'-s)Bu(s)\, ds \colon u \in L^p([0, t']; U),\ u(s) \in U_+,\ 0 \leqq s \leqq t' \leqq t \right\},$$

and the set of reachable states from the origin in arbitrary time by means of nonnegative controls u as $R^+ := U_{t>0} R_t^+$. The pair (A, B) is called:

Exactly positive controllable in time t if $R_t^+ = E_+$;

Exactly positive controllable if $R^+ = E_+$;

Approximately positive controllable in time t if $\operatorname{cl}(R_t^+) = E_+$;

Approximately positive controllable if $\operatorname{cl}(R^+) = E_+$.

Of course, each notion implies the corresponding controllability notion in Definition 4.1 since $R_t = R_t^+ - R_t^+$. The notion of approximate positive controllability (in time t) is independent of p and we can even restrict the controls to C^∞-functions.

We give some simple examples.

Example 4.5. (a) Let $E = U$ be a Banach lattice, $A = 0$, $B = \mathrm{Id}$. Then obviously (A, B) is exactly positive controllable in any time $t > 0$.

(b) Let $E = U = L^p(\mathbb{R}_+)$, $1 \leqq p < \infty$, and $\mathcal{T}$ the translation semigroup on E given by $(T(t)f)(x) = f(x+t)$ for all x, $t \geqq 0$. Let $(A, D(A))$ be its generator and $B = \mathrm{Id}$. Then (A, B) is exactly positive controllable in any time $t > 0$.

Proof. A strongly continuous semigroup $\mathcal{S} = (S(t))_{t \geqq 0}$ on E is given by

$$S(t)f(x) = \begin{cases} f(x-t) & \text{for } x \geqq t, \\ 0 & \text{for } x < t, \end{cases}$$

and $T(t)S(t) = \mathrm{Id}$ for all $t \geqq 0$. For $f \in E_+$ we set $u(s) := (1/t)S(t-s)f$ and obtain $f = \int_0^t (1/t) f\, ds = \int_0^t T(t-s)u(s)\, ds \in R_t^+$.

Example 4.6. Let $E = \mathbb{R}^2$, $U = \mathbb{R}$, $A = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 \\ 1 \end{smallmatrix}\right)$. (A, B) is exactly controllable in any time $t > 0$ by Proposition 4.2. However, (A, B) is not approximately positive controllable. Since

$$\exp(tA) = \begin{pmatrix} e^t & 0 \\ 0 & e^{2t} \end{pmatrix}$$

we see that $R^+ \subseteq \left\{ \left(\begin{smallmatrix} a \\ b \end{smallmatrix}\right) \in \mathbb{R}_+^2 \colon a \leqq b \right\}$.

We state the following proposition, which gives a useful representation of the sets $\operatorname{cl}(R_t^+)$ and $\operatorname{cl}(R^+)$. For a subset M of a Banach space E let $\operatorname{co} M$, $\operatorname{cocone} M$ be defined as in § 2.

PROPOSITION 4.7. *Let the assumptions be as in Definition* 4.4.

(a) $\operatorname{cl}(R_t^+) = \operatorname{cl}(\operatorname{co}\{T(s)Bu \colon 0 \leqq s \leqq t,\ u \in U_+\})$,
$\operatorname{cl}(R^+) = \operatorname{cl}(\operatorname{co}\{T(s)Bu \colon 0 \leqq s,\ u \in U_+\})$.

(b) *Let $U = \mathbb{R}^m$ and let $e(1), \cdots, e(m)$ be the canonical unit vectors of $\mathbb{R}^m$. Then*
$\operatorname{cl}(R_t^+) = \operatorname{cl}(\operatorname{cocone}\{T(s)Be(i) \colon 0 \leqq s \leqq t,\ 1 \leqq i \leqq m\})$,
$\operatorname{cl}(R^+) = \operatorname{cl}(\operatorname{cocone}\{T(s)Be(i) \colon 0 \leqq s,\ 1 \leqq i \leqq m\})$.

Proof. (a) By definition of the integral we see that the sets on the left-hand side are contained in the sets on the right. On the other hand, R_t^+, R^+ are convex since U_+

is convex; it remains to show that $T(s)Bu \in \operatorname{cl}(R_t^+)$ for all $0 \leqq s \leqq t$, $t > 0$, $u \in U_+$. For this let $u \in U_+$ and

$$u_n(s) = \begin{cases} nu & \text{for } 0 \leqq s \leqq 1/n, \\ 0 & \text{for } 1/n \leqq s \leqq t. \end{cases}$$

Then $u_n(\cdot) \in L^\infty([0, t]; U)$ and

$$\left\| \int_0^t T(t-s)Bu_n(s)\, ds - T(t)Bu \right\| \leqq n \cdot \int_0^{1/n} \| T(t-s)Bu - T(t)Bu \|\, ds \to 0 \text{ as } n \to \infty.$$

(b) Since $B\mathbb{R}_+^m = \operatorname{cocone}\{Be(1), \cdots, Be(m)\}$ we see that (a) implies (b). □

We apply Proposition 4.7 to the following example.

Example 4.8. Let $E = U = l^p$, $1 \leqq p < \infty$, and let the operators A, B be given by

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 1 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ \vdots & & & \vdots & & & \vdots \end{bmatrix}, \qquad B = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 1 & 0 & 0 & 0 & \cdots \\ \vdots & & & \vdots & & & \vdots \end{bmatrix}.$$

Obviously $A \in L(E)$, $B \in L(U, E)$ and A generates the positive semigroup $\mathcal{T} = (T(t))_{t \geqq 0}$ given by

$$T(t) = \begin{bmatrix} 1 & t & 0 & 0 & 0 & 0 & \cdots \\ 0 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 1 & t & 0 & 0 & \cdots \\ 0 & 0 & 0 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 1 & t & \cdots \\ 0 & 0 & 0 & 0 & 0 & 1 & \cdots \\ \vdots & & & \vdots & & & \vdots \end{bmatrix}.$$

Let $e(1)$, $e(2), \cdots$ denote the canonical unit vectors of E and U. Then for $i \in \mathbb{N}$, $T(0)Be(i) = e(2i)$ and $\lim_{t \to \infty} (T(t)Be(i)/\| T(t)Be(i) \|) = e(2i-1)$. Hence $\operatorname{cl}(R^+) = E_+$ by Proposition 4.7(a), i.e., (A, B) is approximately positive controllable. However, for all $t > 0$ the ratio of the $2i$th coordinate of $\int_0^t T(t-s)Bu(s)\, ds$ to the $(2i-1)$th coordinate is greater than $1/t$; hence $e(2i-1)$ cannot be contained in $\operatorname{cl}(R_t^+)$ or R^+, i.e., (A, B) is neither approximately positive controllable in any finite time $t > 0$ nor exactly positive controllable. □

4.1. The finite-dimensional case. The following theorem gives a characterization for approximate positive controllability on finite-dimensional state spaces.

THEOREM 4.9. *Let the assumptions be as in Definition* 4.4, $E = \mathbb{R}^n$, $U = \mathbb{R}^m$, *and* $e[1], \cdots, e[n]$, $e(1), \cdots, e(m)$ *the canonical unit vectors of* E, *respectively,* U.

(a) (A, B) *is approximately positive controllable in time* $t > 0$ *if and only if*

(4.3) *For all* $1 \leqq i \leqq n$ *there exists* $1 \leqq j \leqq m$ *and* $\mu > 0$ *such that* $e[i] = \mu Be(j)$.

(b) (A, B) *is approximately positive controllable if and only if*

(4.4) *For all* $1 \leqq i \leqq n$ *there exist* $1 \leqq j \leqq m$ *and* $\mu > 0$ *such that* $e[i] = \mu Be(j)$ *or* $e[i] = \lim_{t \to \infty} (T(t)Be(j)/\| T(t)Be(j) \|)$.

Proof. We first remark that by [13] $\lim_{t\to\infty}(T(t)f/\|T(t)f\|)$ exists for every $0<f\in\mathbb{R}^n$.

The sufficiency of (a) and (b) then is obvious by Proposition 4.7(b).

To show necessity we may assume, as in the proof of Lemma A2 in the Appendix, that $Be(j)\neq 0$ for all $1\leqq j\leqq m$.

(a) If (A, B) is approximately positive controllable in some time $t>0$, then by Lemma A2(a)

$$\{T(s)Be(j)\colon 0\leqq s\leqq t,\ 1\leqq j\leqq m\}\cap J_{f'}\neq\varnothing \quad \text{for all } J_{f'}\neq\{0\}. \tag{4.5}$$

Since $A+\|A\|\,\mathrm{Id}\geqq 0$ [9, C-II, Thm. 1.11], we obtain for every $s>0$ and $1\leqq j\leqq m$

$$\begin{aligned} e^{s\|A\|}\cdot T(s)Be(j) &= Be(j)+\sum_{n=1}^{\infty}\frac{1}{n!}(s(A+\|A\|\,\mathrm{Id}))^n Be(j)\\ &\geqq Be(j). \end{aligned} \tag{4.6}$$

Now (4.5) and (4.6) yield $\{Be(j)\colon 1\leqq j\leqq m\}\cap J_{f'}\neq\varnothing$ for all $J_{f'}\neq\{0\}$. This implies the assertion (4.3).

(b) If (A, B) is approximately controllable, then by Lemma A2(b)

$$\left[\{T(s)Be(j)\colon 0\leqq s,\ 1\leqq j\leqq m\}\cup\left\{\lim_{t\to\infty}\frac{T(t)Be(j)}{\|T(t)Be(j)\|}\colon 1\leqq j\leqq m\right\}\right]\cap J_{f'}\neq\varnothing$$

for all $J_{f'}\neq\{0\}$. Again by (4.6) we obtain

$$\left[\{Be(j)\colon 1\leqq j\leqq m\}\cup\left\{\lim_{t\to\infty}\frac{T(t)Be(j)}{\|T(t)Be(j)\|}\colon 1\leqq j\leqq m\right\}\right]\cap J_{f'}\neq\varnothing$$

for $J_{f'}\neq\{0\}$ and this implies the assertion (4.4). □

COROLLARY 4.10. *Let the assumptions be as in the preceding theorem.*

(a) *(A, B) is approximately positive controllable in time $t>0$ if and only if $BU_+=E_+$. In particular, approximate positive controllability in time $t>0$ implies $m\geqq n$.*

(b) *If (A, B) is approximately positive controllable then $2m\geqq n$, and for every $1\leqq i\leqq n$ the following holds: $e[i]$ is an eigenvector of A or $e[i]=\mu Be(j)$ for some $1\leqq j\leqq m$, $\mu>0$.*

(c) *If (A, B) is exactly positive controllable then (A, B) is approximately positive controllable in every time $t>0$.*

Proof. (a) If $Bu=e[i]$ for $u>0$ then $\mu Be(j)=e[i]$ for some $\mu>0$, $1\leqq j\leqq m$ since B is positive. The assertion follows from Theorem 4.9(a).

(b) By [13] $\lim_{t\to\infty}(T(t)f/\|T(t)f\|)$ is for every $0<f\in\mathbb{R}^n$ an eigenvector of A; therefore the assertion follows from Theorem 4.9(b).

(c) We show that (4.3) holds. Since (A, B) is exactly positive controllable there exists for all $J_{f'}\neq\{0\}$ and $0<f\in J_{f'}$ a time $t>0$ such that $f\in R_t^+$; by Lemma A2(a), we obtain that $\{T(s)Be(j)\colon 0\leqq s\leqq t,\ 1\leqq j\leqq m\}\cap J_{f'}\neq\varnothing$. As in the proof of Theorem 4.9(a) this yields (4.3). □

We point out that Theorem 4.9 and Corollary 4.10 show that the different positive controllability notions do not coincide on finite-dimensional state spaces, contrary to the usual controllability notions (Proposition 4.2).

As an example for these results we mention again Example 4.6. By Theorem 4.9(b) it is immediate that (A, B) in (4.6) is not approximately positive controllable. More examples will be discussed below.

4.2. The infinite-dimensional case. The results of Corollary 4.10 for finite-dimensional state spaces may lead to the conjecture that positive controllability is

impossible if the state space is infinite-dimensional and the input space is finite-dimensional. In fact, we will show that approximate positive controllability in finite time $t>0$ is never possible for a large class of systems on nearly all state spaces of practical interest. Moreover, on the same state spaces, approximate positive controllability is impossible for systems for which (as in the finite-dimensional case) $\lim_{t\to\infty}(T(t)Bf/\|T(t)Bf\|)$ exists for all $f>0$. However, as pointed out in [13], the limit may not exist, in which case there exists an example where the system is approximately positive controllable.

Finally we should mention that by [5, 3.2] and by the remark in Definition 4.4 (that positive controllability implies the usual controllability) exact positive controllability is never possible in the case where the state space is infinite-dimensional and the input space finite-dimensional.

We state the following theorem.

THEOREM 4.11. *Let E be an infinite-dimensional Banach lattice with a strictly positive linear form $f'\in E'$. Let $(A, D(A))$ be the generator of a positive semigroup $\mathcal{T}=(T(t))_{t\geq 0}$ on E and take $B\in L(\mathbb{R}^m, E)$ positive, $m\in\mathbb{N}$. Denote by $e(1),\cdots,e(m)$ the canonical unit vectors of $\mathbb{R}^m$ and assume $Be(j)\neq 0$ for $1\leq j\leq m$.*

(a) *(A, B) is not approximately positive controllable in time $t>0$ if $T(s)Be(j)\neq 0$ for every $0\leq s\leq t$ and $1\leq j\leq m$.*

(b) *(A, B) is not approximately positive controllable if $T(s)Be(j)\neq 0$ for every $0\leq s$ and $1\leq j\leq m$ and if $\lim_{t\to\infty}(T(t)Be(j)/\|T(t)Be(j)\|)$ exists for every $1\leq j\leq m$.*

We will prove the theorem after Remark 4.12.

Remark 4.12. The assumption that there exists a strictly positive linear form is fulfilled for all state spaces of practical interest, e.g., $C_0(X)$, X a locally compact subset of $\mathbb{R}^n$, $L^p(\Omega, \lambda)$, Ω a measurable subset of $\mathbb{R}^n$, λ the Lebesgue measure.

The assumption $Be(j)\neq 0$ in the theorem is made only for convenience. If $Be(j)=0$ for some j we modify the conditions stated in the theorem:

(a) $0\notin\{T(s)Be(j): 0\leq s\leq t, 1\leq j\leq m, Be(j)\neq 0\}$,

(b) $0\notin\{T(s)Be(j): 0\leq s, 1\leq j\leq m, Be(j)\neq 0\}$ and $\lim_{t\to\infty}(T(t)Be(j)/\|T(t)Be(j)\|)$ exists for all $1\leq j\leq m$ for which $Be(j)\neq 0$.

For the proof of this fact we restrict B to the sublattice of $\mathbb{R}^m$ generated by those $e(j)$ for which $Be(j)\neq 0$, and then apply Theorem 4.11.

The condition in Theorem 4.11(a), as well as the first condition in Theorem 4.11(b), is obviously fulfilled by every positive semigroup that can be extended to a (not necessarily positive) strongly continuous *group* and also by every *analytic* positive semigroup. Let $\mathcal{T}=(T(t))_{t\geq 0}$ be an analytic positive semigroup and $T(t)f=0$ for some $t>0$, $f\in E$; then $T(s)f=0$ for $s\geq t$, and hence $\langle f', T(s)f\rangle=0$ for every $s\geq t$ and $f'\in E'$. Since $\mathcal{T}$ is analytic this implies that $\langle f', T(s)f\rangle=0$ for all $s>0$ and $f'\in E'$; hence $\langle f', f\rangle=0$ and $f=0$.

Proof of Theorem 4.11. (a) As mentioned in the proof of Lemma A2(a), the set $C:=\{T(s)Be(j): 0\leq s\leq t, 1\leq j\leq m\}$ is compact and does not contain zero by assumption. On the other hand, by Lemma A4 there exist infinitely many pairwise orthogonal ideals $J_{f'}\neq\{0\}$, $0<f'\in E'$, and by Lemma A.3, C can only intersect finitely many of them. By Lemma A2(a) this implies that $\mathrm{cl}(R_t^+)$ has nontrivial intersection with only finitely many of these ideals; hence $\mathrm{cl}(R_t^+)\neq E_+$, i.e., (A, B) is not approximately positive controllable in time t.

(b) Again, as mentioned in the proof of Lemma A2(b), the assumption implies that

$$\left\{\frac{T(s)Be(j)}{\|T(s)Be(j)\|}: 0\leq s, 1\leq j\leq m\right\}\cup\left\{\lim_{t\to\infty}\frac{T(t)Be(j)}{\|T(t)Be(j)\|}: 1\leq j\leq m\right\}$$

is compact and does not contain zero. Lemmas A4, A3, and A2(b) yield as in (a) that $\mathrm{cl}(R^+) \neq E_+$, i.e., (A, B) is not approximately positive controllable. □

We do not know whether we can drop the condition in Theorem 4.11(a) as well as the condition that there exists a strictly positive linear form. In other words, we do not know of any example where E is infinite-dimensional, $U = \mathbb{R}^m$, and where (A, B) is positive controllable in some finite time $t > 0$. But the following example shows that (A, B) may be approximately positive controllable if the limit in the assumption of Theorem 4.11(b) does not exist. The basic idea of the example is due to Zabczyk [17].

Example 4.13. Let $E = L^p(\mathbb{R}_+)$, $1 \leqq p < \infty$, $U = \mathbb{R}$, $\mathcal{T} = (T(t))_{t \geqq 0}$ being the (positive) translation semigroup on E given by

$$(T(t)f)(x) = f(x+t) \quad \text{for } x, t \geqq 0$$

with generator $(A, D(A))$, and let $B \in L(\mathbb{R}, E)$ be a positive operator given by

$$Bu = u \cdot b \quad \text{for some } b \in E_+.$$

We claim that (A, B) is approximately positive controllable for a suitable $b \in E_+$, which we will construct as follows.

First we know that there exists a countable subset S of normalized positive functions with compact support such that $\mathrm{cl}(\mathrm{cocone}\, S) = E_+$: Take, for example, all characteristic functions on intervals $[q, q+r]$, $q, r \in Q_+ \setminus \{0\}$ divided by their L^p-norm. In S there exists a sequence $f_1, f_2, \cdots$ in which each element of S occurs infinitely often.

By assumption the support $\mathrm{spt}(f_i)$ is contained in $[0, t_i]$ for some $t_i > 0$. Define

$$s(1) := 0, \quad s(n+1) := \sum_{i=1}^{n} t_i \quad \text{for } n \geqq 1$$

and let

$$f_i^{(s)} \text{ denote the function } t \to \begin{cases} f_i(t-s) & \text{for } t \geqq s, \\ 0 & \text{for } t < s. \end{cases}$$

Since $\mathrm{spt}(f_i^{(s(i))}) \cap \mathrm{spt}(f_j^{(s(j))}) \subseteq [s(i), s(i+1)] \cap [s(j), s(j+1)]$ has measure zero for $i \neq j$, we can define

$$b := \sum_{i=1}^{\infty} 2^{-i^2} \cdot f_i^{(s(i))}$$

and obtain $\|b\| \leqq (\sum_{i=1}^{\infty} 2^{-pi^2})^{1/p} \leqq 1$; hence $b \in E_+$.

Because of Proposition 4.7(a) (A, B) is approximately positive controllable for this b if $S \subseteq \mathrm{cl}\{T(s)bu\colon 0 \leqq s,\ u \geqq 0\}$. For this we now show that for each $f \in S$ and $n \in \mathbb{N}$ there exists $s, u > 0$ such that

$$\|T(s)bu - f\| < 2^{-n}. \tag{4.7}$$

Since f occurs infinitely often in the sequence (f_i), we can find $k > n$ such that $f = f_k$. Let $s = s(k)$, $u = 2^{k^2}$. Then by definition of $\mathcal{T}$ we obtain

$$T(s)f^{(s(i))} = T(s(i) + t_i + \cdots + t_{k-1})f^{(s(i))} = 0 \quad \text{for } i < k,$$

$$T(s)f^{(s(k))} = f,$$

$$T(s)f^{(s(i))} = T(s(k))f^{(s(k)+s(i)-s(k))} = f^{(s(i)-s(k))} \quad \text{for } i > k.$$

Hence

$$T(s)bu - f = \sum_{i=k+1}^{\infty} 2^{k^2-i^2} \cdot f^{(s(i)-s(k))}.$$

Since

$$\operatorname{spt}(f_i^{(s(i)-s(k))}) \cap \operatorname{spt}(f_j^{(s(j)-s(k))}) \subseteq [s(i)-s(k), s(i+1)-s(k)] \cap [s(j)-s(k), s(j+1)-s(k)]$$

has measure zero for $i \neq j$, we obtain

$$\|T(s)bu-f\| \leqq \left(\sum_{i=k+1}^{\infty} 2^{p(k^2-i^2)}\right)^{1/p} = \left(\sum_{i=k+1}^{\infty} 2^{p(k+i)(k-i)}\right)^{1/p} = \left(\sum_{i=1}^{\infty} 2^{-p(2k+i)i}\right)^{1/p}$$
$$\leqq \left(\sum_{i=1}^{\infty} 2^{-p2k} \cdot 2^{-pi^2}\right)^{1/p} \leqq 2^{-2k}\left(\sum_{i=1}^{\infty} 2^{-pi^2}\right)^{1/p} \leqq 2^{-2k} < 2^{-n}.$$

Thus (4.7) is proved. □

4.3. Applications. We apply the main Theorems 4.9 and 4.11 to some concrete examples.

Example 4.14. The electrically heated oven of § 3 is neither approximately positive controllable in any time $t>0$ nor exactly positive controllable because of Corollary 4.10(a), (c). It is approximately positive controllable by Theorem 4.9(b) if and only if

$$\binom{0}{1} = \lim_{t\to\infty}\left(T(t)\binom{1}{0} \Big/ \left\|T(t)\binom{1}{0}\right\|\right). \tag{4.8}$$

By [13] a necessary condition for (4.8) is that $\binom{0}{1}$ is an eigenvector to A, i.e., $\beta = 0$. We verify that

$$T(t) = \begin{pmatrix} e^{-\alpha t} & 0 \\ \gamma t\, e^{-\alpha t} & e^{-\delta t} \end{pmatrix} \quad \text{if } \alpha = \delta,$$

$$T(t) = \begin{pmatrix} e^{-\alpha t} & 0 \\ \gamma(e^{-\alpha t} - e^{-\delta t}) \cdot (\delta - \alpha)^{-1} & e^{-\delta t} \end{pmatrix} \quad \text{if } \alpha \neq \delta.$$

Hence (4.8) holds if and only if

$$\gamma \neq 0, \quad \beta = 0, \quad \delta \leqq \alpha.$$

In the physical situation we have $\alpha, \beta, \gamma, \delta > 0$ and therefore the oven is not approximately positive controllable. But by Proposition 4.2, (A, B) is (exactly) controllable if and only if the matrix $\binom{1\ -\alpha}{0\ \ \gamma}$ is nonsingular, i.e., $\gamma \neq 0$.

Example 4.15. In [6] the following system is discussed as an approximation for a distributed network:

$$\frac{d}{dt}f(t) = A_0 f(t) + \mathrm{Id}\,[\psi(f_1(t)), \cdots, \psi(f_n(t))], \tag{4.9}$$

where

$$A_0 = \begin{bmatrix} -2 & 1 & 0 & 0 & \cdots & 0 \\ 1 & -2 & 1 & 0 & \cdots & 0 \\ 0 & 1 & -2 & 1 & \cdots & 0 \\ 0 & 0 & 1 & -2 & \cdots & 0 \\ & & & \cdots & & \\ 0 & 0 & & \cdots & -2 & 1 \\ 0 & 0 & & \cdots & 1 & -2 \end{bmatrix},$$

$f(t)=(f_1(t),\cdots,f_n(t))\in\mathbb{R}^n=:E$, and ψ is a real function on $\mathbb{R}$. If ψ is linear, then (4.9) reads as follows:

$$\frac{d}{dt}f(t)=A_0f(t)+\mu\ \mathrm{Id}\,f(t) \tag{4.10}$$

for some $\mu\in\mathbb{R}$.

Define $A:=A_0+\mu$ Id. Then by [9, B-II, Ex. 1.4.b], A generates a positive semigroup and we can consider the linear control system (4.1) for some positive $B\in L(\mathbb{R}^m,\mathbb{R}^n)$, $m\in\mathbb{N}$. Since none of the canonical unit vectors $e[i]$ of $\mathbb{R}^n$ is an eigenvector of A, we infer from [13] that the second condition in Theorem 4.9(b) can never be fulfilled. Hence (A, B) is approximately positive controllable if and only if it is approximately positive controllable for any time $t>0$, i.e., if and only if $BU_+=E_+$ (by Corollary 4.10(a)). However, from Proposition 4.2 it is immediate that (A, B) is (exactly) controllable if BU contains, e.g., $e[1]$ or $e[n]$, in particular, B may even have rank 1.

Example 4.16. We consider the heat equation on a finite rod with Dirichlet boundary conditions as in § 3. As shown in [14], $\lim_{t\to\infty}(T(t)f/\|T(t)f\|)$ exists for every $f>0$; in particular, $T(t)f\neq 0$ for all $t\geqq 0$, $f>0$. Since there exists a strictly positive linear form on $L^2[0, 1]$, by Theorem 4.11 we obtain that the control system is not approximately positive controllable.

In the same way we can show, using the results of [13] and [14], that the system is also not approximately positive controllable if we replace the Dirichlet by Neumann boundary conditions.

Example 4.17. Consider the Laplacian on $\mathbb{R}^n$. This means we consider the control problem (4.1) for $E=C_0(\mathbb{R}^n)$ or $E=L^p(\mathbb{R}^n)$, $1\leqq p<\infty$, $U=\mathbb{R}^m$, $0<B\in L(U, E)$, $D(A)=\{f\in E:\Delta f\in E\}$, $Af=\Delta f$. By [9, C-II, Ex. 1.5.c and d and Remark] $(A, D(A))$ generates a positive contraction semigroup $\mathcal{T}=(T(t))_{t\geqq 0}$ on E given by

$$T(t)f(x)=(4\pi t)^{-n/2}\int_{\mathbb{R}^n}\exp(-|x-y|^2/4t)\circ f(y)\,dy,$$

where $|x-y|$ denotes the Euclidean norm of $x-y$ in $\mathbb{R}^n$.

This shows that $T(t)f(x)>0$ for all $x\in\mathbb{R}^n$ whenever $f>0$ and the assumptions of Theorem 4.11(a) are fulfilled. Hence (A, B) is not approximately positive controllable in any time $t>0$. On the other hand, (A, B) may be approximately controllable in every time $t>0$ even for $U=\mathbb{R}^2$ (see [5, 3.17]).

5. Positive stationary pairs. In § 4 we have obtained somewhat negative answers to the first question posed in § 3. However, it is often not so important to reach the entire positive cone of the state space. It suffices to design a nonnegative control by which particular positive states can be approximated and held constant for all times. This was just the problem formulated in the second question of § 3 for positive states belonging to positive stationary pairs. Moreover, we have observed in § 3 a relationship between existence of a positive stationary pair and stability of the system. In this section we will discuss these problems systematically.

Let E and U be Banach lattices, let $\mathcal{T}=(T(t))_{t\geqq 0}$ be a positive semigroup on E with generator $(A, D(A))$, and take $B\in L(U, E)$ positive. As in the previous section we consider the control problem (4.1), where $u\in L^1_{\mathrm{loc}}(\mathbb{R}_+, U)$ takes values in U_+ and $f_0\in E_+$.

We call a pair $(f_1, u_1)\in(E_+\setminus\{0\})\times U_+$ *positive stationary* if $Af_1+Bu_1=0$. In this case $f(\cdot)\equiv f_1$ is a nonzero constant solution of (4.1) for $u(\cdot)\equiv u_1$, $f_0=f_1$. We are interested in whether each $f_1\in E_+$ belonging to a positive stationary pair can be

(approximately) reached and held constant by a nonnegative control $u(\cdot)$. Moreover, we study the connection between existence of positive stationary pairs and stability of the semigroup $\mathcal{T}$ as defined in § 2.

Our main results will be formulated in Theorem 5.1 and 5.6, and applications will be given at the end of the section.

We state the following theorem.

THEOREM 5.1. *Let E and U be Banach lattices, let $\mathcal{T}=(T(t))_{t\geq 0}$ be a uniformly exponentially stable positive semigroup on E with generator $(A, D(A))$, and take $B\in L(U, E)$ positive. Then we have the following*:

(a) *To each $u_1\in U_+\backslash\ker B$ there exists exactly one $f_1\in E_+$ such that (f_1, u_1) is a positive stationary pair.*

(b) *If (f_1, u_1) is a positive stationary pair, $f_0\in E_+$ and $u(\cdot)\equiv u_1$, then the solution of (4.1) tends to f_1 as $t\to\infty$.*

Proof. (a) If $\mathcal{T}$ is uniformly exponentially stable, then $0\in\rho(A)$ and $-A^{-1}$ is positive by [9, C-III, Thm. 1.1]. For all $u_1\in U_+\backslash\ker B$ we therefore obtain that $(-A^{-1}Bu_1, u_1)$ is a positive stationary pair. On the other hand, $0\in\rho(A)$ implies that for each $u_1\in U_+$, there exists at most one f_1 such that (f_1, u_1) is a positive stationary pair.

(b) For a positive stationary pair (f_1, u_1) and $u(\cdot)\equiv u_1$, we obtain for the mild solution of (4.1) that $f(t)=T(t)f_0-\int_0^t T(t-s)Af_1\,ds$. This is equal to $T(t)(f_0-f_1)+f_1$, and therefore tends to f_1 as $t\to\infty$ since $\mathcal{T}$ is stable. □

From the proof above we obtain the following corollary.

COROLLARY 5.2. *Let E and U be Banach lattices, let $\mathcal{T}=(T(t))_{t\geq 0}$ be a weakly stable positive semigroup on E with generator $(A, D(A))$, and take $B\in L(U, E)$ positive. Then we have the following*:

(a) *For each $u_1\in U_+\backslash\ker B$ there exists at most one $f_1\in E_+$ such that (f_1, u_1) is a positive stationary pair; such $f_1\in E_+$ exists if $0\in\rho(A)$.*

(b) *If (f_1, u_1) is a positive stationary pair $f_0\in E_+$ and $u(\cdot)\equiv u_1$, then the solution of (4.1) tends to f_1 in the weak topology of E as $t\to\infty$; the convergence holds in the norm-topology if $\mathcal{T}$ is strongly stable.*

Proof. (a) The uniqueness of f_1 follows from the fact that A is injective if $\mathcal{T}$ is weakly stable. Moreover, weak stability implies that the growth bound $\omega(A)$ of A is not positive and therefore, by [9, C-III, Thm. 1.1], the resolvent $R(\lambda, A)$ of A in λ is a positive operator for all $\lambda>0$. Thus if $0\in\rho(A)$ we have $-A^{-1}=\lim_{\lambda\to 0}R(\lambda, A)\geqq 0$, and as in the proof of Theorem 5.1(a) we obtain the existence of a positive stationary pair.

(b) This follows immediately from the proof of Theorem 5.1(b). □

For another immediate consequence of Theorem 5.1 we recall the definition of R^+ from Definition 4.4.

COROLLARY 5.3. *Let E and U be Banach lattices, let $\mathcal{T}=(T(t))_{t\geq 0}$ be a positive semigroup on E with generator $(A, D(A))$, and take $B\in L(U, E)$ positive. Then $\{R(\lambda, A)Bu\colon u\in U_+, \lambda>\omega(A)\}\subseteq \mathrm{cl}\,(R^+)$.*

Proof. Obviously R^+ does not change if we multiply $T(t)$ by $e^{-\lambda t}$ for $\lambda>\omega(A)$. Then $(e^{-\lambda t}T(t))_{t\geq 0}$ is an exponentially stable semigroup with generator $A_\lambda:=A-\lambda$, and $-(A_\lambda)^{-1}=R(\lambda, A)$. The assertion then follows from the proof of Theorem 5.1. □

The following example shows that there may not exist a positive stationary pair if the semigroup $\mathcal{T}$ is strongly stable only.

Example 5.4. We consider the Laplacian on $E=C_0(\mathbb{R})$ or $L^p(\mathbb{R})$, $1\leqq p<\infty$ as in Example 4.17 with $B\in L(\mathbb{R}^m, E)$ positive. The semigroup $\mathcal{T}$ generated by $(A, D(A))$ is strongly stable [9, A-IV, Ex. 1.2]. We claim that there does not exist a positive

stationary pair. Suppose that $Af+Bu=0$ for some $0\leqq f\in D(A)$, $u\geqq 0$. We show $f=0$.

The equation $Af+Bu=0$ implies that the second derivative f'' of f takes only nonpositive values. Now for some constants $c_1, c_2\in\mathbb{R}$ the function f is given by

$$f(x)=c_2+c_1x+\int_0^x\int_0^y f''(z)\,dz\,dy, \qquad x\in\mathbb{R}. \tag{5.1}$$

Let g be the function that maps y on $\int_0^y f''(z)\,dz$. Then $g(0)=0$ and g is antitone. Since $g(y)\leqq 0$ for $y\geqq 0$ and since $f\geqq 0$, we obtain by (5.1) (if we choose x to be large) that $c_1\geqq 0$. On the other hand, $g(y)\geqq 0$ for $y\leqq 0$ implies that $\int_0^x\int_0^y f''(z)\,dz\,dy=-\int_x^0 g(y)\,dy\leqq 0$ for $x\leqq 0$. Equation (5.1) and $f\geqq 0$ imply $c_1\leqq 0$; hence $c_1=0$.

Since g is antitone, $\alpha:=\lim_{y\to-\infty} g(y)$ and $\beta:=\lim_{y\to+\infty} g(y)$ exist in the extended real field and $\alpha\geqq 0$, $\beta\leqq 0$. Assume $\alpha>0$; then $\int_0^x\int_0^y f''(z)\,dz\,dy=-\int_x^0 g(y)\,dy\to-\infty$ as $x\to-\infty$, which contradicts the facts that $f\geqq 0$ and $c_1=0$. In the same way the case $\beta<0$ is impossible. Thus $\alpha=\beta=0$, i.e., $g=0$; hence $f(x)=c_2$ for all x. Since $f\in C_0(\mathbb{R})$ or $f\in L^p(\mathbb{R})$, this is only possible if $f=0$. □

Thus we have shown that strong stability is not sufficient to ensure the existence of a positive stationary pair. On the other hand, the following example shows that not even boundedness of the semigroup is necessary for the existence of such a pair.

Example 5.5. Let $E=\mathbb{R}^2$, $U=\mathbb{R}$, $A=\left(\begin{smallmatrix}-1 & 0\\ 0 & 1\end{smallmatrix}\right)$, $B=\left(\begin{smallmatrix}1\\ 0\end{smallmatrix}\right)$. Then $\left(\left(\begin{smallmatrix}1\\ 0\end{smallmatrix}\right), 1\right)$ is a positive stationary pair, but $(e^{tA})_{t\geqq 0}$ is an unbounded semigroup since $1\in p\sigma(A)$.

The following theorem states the conditions under which the existence of a positive stationary pair implies boundedness or even stability of the semigroup $\mathcal{T}$.

THEOREM 5.6. *Let E and U be Banach lattices, and let $\mathcal{T}=(T(t))_{t\geqq 0}$ be a positive semigroup on E with generator $(A, D(A))$. Take $B\in L(U, E)$ positive and let (f_1, u_1) be a positive stationary pair.*

(a) *$\mathcal{T}$ is bounded if $f_1\in \operatorname{int} E_+$.*

(b) *$\mathcal{T}$ is stable if E is finite-dimensional, $f_1\in \operatorname{int} E_+$, and $Bu_1\in \operatorname{int} E_+$.*

Proof. (a) If f_1 is an interior point of E_+, then to each $f\in E_+$ there exists $\lambda_f>0$ such that $f\leqq \lambda_f\cdot f_1$. Since $f_1-T(t)f_1=-\int_0^t T(s)Af_1\,ds=\int_0^t T(s)Bu_1\,ds\geqq 0$ we obtain $0\leqq T(t)f\leqq \lambda_f T(t)f_1\leqq \lambda_f f_1$ and $\|T(t)f\|\leqq \lambda_f\|f_1\|$ for all $t\geqq 0$. By the uniform boundedness principle T is bounded.

(b) Since $\|T(t)f\|\leqq \lambda_f\|T(t)f_1\|$ for every $f\in E_+$, it suffices to show that $T(t)f_1\to 0$ as $t\to\infty$. Now $T(t)f_1=f_1-\int_0^t T(s)Bu_1\,ds$; hence

$$T(r+t)f_1=T(r)f_1-\int_r^{t+r} T(s)Bu_1\,ds\leqq T(r)f_1 \quad \text{for } r\geqq 0.$$

Thus $(T(t)f_1)_{t\geqq 0}$ is decreasing and therefore converges to some $g\in E_+$ as $t\to\infty$ since E is finite-dimensional [11, II, Thm. 5.11]. Then g is a fixed vector of every $T(t)$ and $0\leqq g\leqq T(t)f_1$ for all $t\geqq 0$. Moreover $Bu_1\in \operatorname{int} E_+$ implies $1/t\int_0^t T(s)Bu_1\,ds\in \operatorname{int} E_+$ for small $t>0$. Since

$$\frac{1}{t}(f_1-g)\geqq\frac{1}{t}(f_1-T(t)f_1)=\frac{1}{t}\int_0^t T(s)Bu_1\,ds,$$

we obtain $1/t(f_1-g)\in \operatorname{int} E_+$. Thus, $f_1-g\in \operatorname{int} E_+$; hence there exists $\mu>0$ such that $f_1\leqq \mu(f_1-g)$, and therefore

$$0\leqq T(t)f_1\leqq \mu T(t)(f_1-g)=\mu(T(t)f_1-g)\to 0 \quad \text{as } t\to\infty.$$

This implies $T(t)f_1\to 0$ as $t\to\infty$. □

We remark that Theorem 5.6 can be applied only to spaces E that are isomorphic to $C(X)$, X compact, since for all other spaces $\operatorname{int} E_+=\varnothing$ [11, II, § 7].

As we have seen in Example 5.5, $\mathcal{T}$ may not be bounded if (f_1, u_1) is a positive stationary pair with $f_1 \notin \operatorname{int} E_+$. Moreover, $\mathcal{T}$ may not be strongly stable if $f_1 \in \operatorname{int} E_+$ and $Bu_1 \notin \operatorname{int} E_+$, as the following example shows.

Example 5.7. Let $E = \mathbb{R}^2$, $U = \mathbb{R}$, $A = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$; then $\left(\left(\begin{smallmatrix} 1 \\ 1 \end{smallmatrix}\right), 1\right)$ is a positive stationary pair but $(\exp(tA))_{t \geqq 0}$ is not stable since $0 \in p\sigma(A)$.

We apply our results to the examples of § 3.

Example 5.8. We consider the electrically heated oven from § 3. As mentioned there, A is stable if and only if there exists a positive stationary pair (f_1, u_1) with $u_1 > 0$.

Since $\alpha, \beta, \gamma, \delta \geqq 0$ it is immediate that A is stable if and only if $\det A > 0$. Then all positive stationary pairs are scalar multiples of $\left((\det A)^{-1}\left(\begin{smallmatrix} \delta \\ \gamma \end{smallmatrix}\right), 1\right)$.

Moreover, in § 3 we have seen that for $\gamma + \delta \neq 0$ a positive stationary pair $(x_1, 0)$ exists if and only if A is not stable but has eigenvalues with nonpositive real parts, i.e., $\det A = 0$. Then all positive stationary pairs are scalar multiples of $\left(\left(\begin{smallmatrix} \delta \\ \gamma \end{smallmatrix}\right), 0\right)$.

In the physical situation we have $\det A > 0$ (cf. 4.14) and Theorem 5.1 is applicable.

Example 5.9. We consider the heat equation of § 3. As shown there the semigroup is uniformly exponentially stable and a positive stationary pair exists (cf. Theorem 5.1(a)). All f_1 belonging to a positive stationary pair (f_1, u_1) can be approximately reached by the control $u(\cdot) \equiv u_1$ according to Theorem 5.1(b).

Appendix A. The following four lemmas on order ideals are needed in § 4. We recall the definition of the ideals $J_{f'}$ from § 2.

LEMMA A1. *Let C be a compact subset of the positive cone E_+ of a Banach lattice E, and let $0 < f' \in E'$ be a positive linear form. If there exists $0 < f \in \operatorname{cl}(\operatorname{cocone} C) \cap J_{f'}$, then $C \cap J_{f'} \neq \emptyset$.*

Proof. The assertion is trivial if $0 \in C$. Therefore let $0 \notin C$ and

$$f = \lim_{m \to \infty} \sum_{i=1}^{n(m)} \alpha_{i,m} \cdot f_{i,m} \quad \text{for some } \alpha_{i,m} > 0, \quad f_{i,m} \in C, \quad n(m) \in \mathbb{N}.$$

We set

$$\beta_{i,m} := \alpha_{i,m} \|f_{i,m}\| > 0, \qquad g_{i,m} := f_{i,m} \cdot \|f_{i,m}\|^{-1}$$

and obtain

$$0 = \langle f', f \rangle = \lim_{m \to \infty} \sum_{i=1}^{n(m)} \alpha_{i,m} \langle f', f_{i,m} \rangle$$

$$= \lim_{m \to \infty} \sum_{i=1}^{n(m)} \beta_{i,m} \langle f', g_{i,m} \rangle.$$

Moreover,

$$\sum_{i=1}^{n(m)} \beta_{i,m} = \sum_{i=1}^{n(m)} \beta_{i,m} \|g_{i,m}\| \geqq \left\| \sum_{i=1}^{n(m)} \beta_{i,m} \cdot g_{i,m} \right\| \to \|f\| \quad \text{as } t \to \infty.$$

Thus we can assume that

$$\sum_{i=1}^{n(m)} \beta_{i,m} \langle f', g_{i,m} \rangle < \frac{\|f\|}{2m} \quad \text{and} \quad \sum_{i=1}^{n(m)} \beta_{i,m} \geqq \frac{\|f\|}{2} \quad \text{for every } m \in \mathbb{N}.$$

Hence for every m there exists $i(m)$ such that $\langle f', g_{i(m),m} \rangle < 1/m$. Since C is compact we can find a subsequence of $(f_{i(m),m})_m$ that converges to some $f_0 \in C$. Hence a

subsequence $(h_m)_m$ of $(g_{i(m),m})_m$ converges to $g := f_0 \cdot \|f_0\|^{-1}$, and $\langle f', g\rangle = \lim_{m\to\infty}\langle f', h_m\rangle = 0$. Thus we obtain $\langle f', f_0\rangle = 0$, $f_0 \in J_{f'}$. □

LEMMA A2. *Let the assumptions be as in Definition* 4.4, *let* $U = \mathbb{R}^m$, $e(1), \cdots, e(m)$ *be the canonical unit vectors of* $\mathbb{R}^m$, *and* $0 < f' \in E'$. *Then the following assertions are valid.*

(a) *If* $0 < f \in \mathrm{cl}\,(R_t^+) \cap J_{f'}$ *then*

$$\{T(s)Be(i)\colon 0 \leqq s \leqq t,\ 1 \leqq i \leqq m,\ Be(i) \neq 0\} \cap J_{f'} \neq \varnothing.$$

(b) *Assume that* $0 \notin \{T(s)Be(i)\colon 0 \leqq s,\ 1 \leqq i \leqq m,\ Be(i) \neq 0\}$ *and that* $\lim_{t\to\infty}(T(t)Be(i)/\|T(t)Be(i)\|)$ *exists for every* $1 \leqq i \leqq m$ *for which* $Be(i) \neq 0$. *If* $0 < f \in \mathrm{cl}\,(R^+) \cap J_{f'}$ *then*

$$\left[\{T(s)Be(i)\colon 0 \leqq s,\ 1 \leqq i \leqq m,\ Be(i) \neq 0\} \cup \left\{\lim_{t\to\infty}\frac{T(t)Be(i)}{\|T(t)Be(i)\|}\colon 1 \leqq i \leqq m,\ Be(i) \neq 0\right\}\right] \cap J_{f'} \neq \varnothing.$$

Proof. We can assume that $Be(i) \neq 0$ for all $1 \leqq i \leqq m$; otherwise we restrict B to the sublattice of $\mathbb{R}^m$ spanned by those vectors $e(i)$ for which $Be(i) \neq 0$. This will not affect the set R_t^+ and the assumptions of the lemma remain valid.

(a) $\{T(s)Be(i)\colon 0 \leqq s \leqq t\}$ is compact for $1 \leqq i \leqq m$ since $\mathcal{T}$ is strongly continuous. Set $C := \{T(s)Be(i)\colon 0 \leqq s \leqq t,\ 1 \leqq i \leqq m\}$ and apply Proposition 4.7(b) and Lemma A1 to obtain the assertion.

(b) By Proposition 4.7(b) we know that the set

$$\mathrm{cocone}\left[\left\{\frac{T(s)Be(i)}{\|T(s)Be(i)\|}\colon 0 \leqq s,\ 1 \leqq i \leqq m\right\} \cup \left\{\lim_{t\to\infty}\frac{T(t)Be(i)}{\|T(t)Be(i)\|}\colon 1 \leqq i \leqq m\right\}\right]$$

is dense in R^+. Now continuity of $t \to (T(t)Be(i)/\|T(t)Be(i)\|)$ and the existence of $\lim_{t\to\infty}(T(t)Be(i)/\|T(t)Be(i)\|)$ imply compactness of the set

$$\left\{\frac{T(s)Be(i)}{\|T(s)Be(i)\|}\colon 0 \leqq s,\ 1 \leqq i \leqq m\right\} \cup \left\{\lim_{t\to\infty}\frac{T(t)Be(i)}{\|T(t)Be(i)\|}\colon 1 \leqq i \leqq m\right\}.$$

By Lemma A1 we know that this set has nonvoid intersection with $J_{f'}$. The assertion follows immediately since $T(t)Be(i)/\|T(t)Be(i)\| \in J_{f'}$ if and only if $T(t)Be(i) \in J_{f'}$. □

LEMMA A3. *Let* E *be a Banach lattice, let* C *be a compact subset of* E_+, $0 \notin C$, *and let* $(I_i)_{i\in J}$ *be a class of proper ideals of* E *that are pairwise orthogonal. Then* $C \cap I_i = \varnothing$ *for almost all* $i \in J$ (*i.e., for all except finitely many*).

Proof. Assume that C has nontrivial intersection with infinitely many ideals I_i. Since $0 \notin C$ there exists a sequence of pairwise orthogonal elements f_n with $\inf_{n\in\mathbb{N}}(\|f_n\|) > \alpha > 0$. But this implies by [11, II, Prop. 1.4] that $\|f_n - f_m\| > \alpha$ for all $n \neq m$ in contradiction to the compactness of C. □

LEMMA A4. *Let* E *be an infinite-dimensional Banach lattice. Then the following assertions are equivalent*:

(i) *There exists an infinite number of pairwise orthogonal ideals of the form* $J_{f'} := \{f \in E\colon \langle f', |f|\rangle = 0\}$, $J_{f'} \neq \{0\}$, $0 < f' \in E'$.

(ii) *There exist two orthogonal ideals of the form* $J_{f'}$, $J_{f'} \neq \{0\}$, $0 < f' \in E'$.

(iii) *There exists a strictly positive linear form* f' *on* E.

The proof of the lemma is due to Räbiger [18] and can be found in [15]. □

Acknowledgments. I thank Professors R. Nagel and J. Zabczyk for their stimulation and guidance in the preparation of this paper.

NEW RESULTS IN THE REDUCTION OF LINEAR TIME-VARYING DYNAMICAL SYSTEMS*

J. ZHU†‡ AND C. D. JOHNSON†

Abstract. This paper considers finite-dimensional, linear time-varying dynamical systems (LDS) of the form $\dot{\mathbf{x}} = \mathbf{A}(t)\mathbf{x}$, $\mathbf{x}(t_0) = \mathbf{x}_0$. Such systems are said to be *semiproper* (self-commuting) if for all t, τ, $\mathbf{A}(t)\mathbf{A}(\tau) = \mathbf{A}(\tau)\mathbf{A}(t)$. Using some recent results for obtaining explicit solutions for semiproper systems (see [26]-[29], [34], [35]), the family of Lyapunov reducible systems is expanded to include those systems that can be reduced to semiproper ones via what will be called D-similarity transformations. Within this new framework is defined the notion of primary D-similarity transformations, and every LDS that is "well defined" in a certain sense is proved reducible by a finite sequence of primary D-similarity transformations. The paper also presents an explicit technique for constructing such transformations for LDS with virtually triangular $\mathbf{A}(t)$ (i.e., $\mathbf{A}(t) = \mathbf{L}\mathbf{T}(t)\mathbf{L}^{-1}$ for some nonsingular constant matrix $\mathbf{L}$ and triangular matrix $\mathbf{T}(t)$). There are difficulties in obtaining, explicitly, primary D-similarity transformations for the reduction of general LDS. However, this paper shows that, instead of studying such general cases, it suffices to investigate only the reduction of LDS with *normal* $\mathbf{A}(t)$. To achieve these results, $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}\} = \mathbf{A}\mathbf{x} - \dot{\mathbf{x}}$ is treated as an operator on a vector space over a differential field, and thereby some familiar results in the theory of matrices are generalized over a number field. In particular, the authors introduce the notions of partial spaces, partially linear operators, linear differential equation (LDE) operators $\mathscr{P}_{\mathbf{A}}$, and D-similarity transformations, all of which are believed to be new.

1. Introduction and overview of the main results.

This paper concerns the class of finite-dimensional, homogeneous linear differential equations, with variable coefficient matrix, having the form

$$\dot{\mathbf{x}} = \mathbf{A}(t)\mathbf{x}, \qquad \mathbf{x}(t_0) = \mathbf{x}_0. \tag{1.1}$$

This type of differential equation is the mathematical model for finite-dimensional linear time-varying dynamical systems when the entries $a_{ij}(t)$ in $\mathbf{A}(t)$ are real functions of a real variable t in time. We shall denote a fundamental solution matrix of (1.1) by $\mathbf{X}_{\mathbf{A}}(t)$, and denote the state-transition matrix of (1.1) by $\boldsymbol{\phi}_{\mathbf{A}}(t, t_0)$, which is given by

$$\boldsymbol{\phi}_{\mathbf{A}}(t, t_0) = \mathbf{X}_{\mathbf{A}}(t)\mathbf{X}_{\mathbf{A}}^{-1}(t_0). \tag{1.2}$$

Because of well-known difficulties in obtaining analytical solutions and stability information for systems (1.1), it is desirable to transform (1.1), by some invertible transformation, to a simpler form that can be solved analytically or studied qualitatively by existing techniques. At the end of the last century, Lyapunov introduced the important notion of a reducible system [14] which can be stated as follows.

* Received by the editors August 31, 1987; accepted for publication (in revised form) May 19, 1988. DEFINITION 1.1 (Lyapunov). A linear system (1.1) is said to be reducible, in the sense of Lyapunov, if there exist real numbers M, N, and a nonsingular matrix $\mathbf{L}(t)=[l_{ij}(t)]$ satisfying:

(i) $|l_{ij}(t)| \leqq M < \infty$ and $|dl_{ij}(t)/dt| \leqq M < \infty$ for all i, j and for all $t > t_0$,

(ii) $|\det \mathbf{L}(t)| > N > 0$, for all $t > t_0$

such that the matrix

$$\mathbf{B} = \mathbf{L}^{-1}(t)\mathbf{A}(t)\mathbf{L}(t) - \mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t) \tag{1.3}$$

is constant.

The transformation (1.3) with $\mathbf{L}(t)$ satisfying (i) and (ii) is known as a Lyapunov transformation. It is well known that all periodic systems (1.1) are reducible in the sense of Lyapunov and, moreover, that the stability of such systems can be studied qualitatively via Floquet theory [5]. However, general criteria for the reducibility of nonperiodic systems (1.1) are not known. Moreover, even if a system (1.1) is known to be reducible, it is not clear how to find a Lyapunov transformation to accomplish that reduction.

In this paper, we introduce a new and somewhat broader point of view for investigating reducibility and generating reduction transformations for systems (1.1). It is recalled that a matrix function $\mathbf{A}(t)$ is said to be semiproper (self-commutative) on an interval $I \subseteq \mathbb{R}$ if $\mathbf{A}(t)\mathbf{A}(\tau) = \mathbf{A}(\tau)\mathbf{A}(t)$, for all $t, \tau \in I$. A linear system (1.1) is said to be semiproper if $\mathbf{A}(t)$ is semiproper. Note that, in particular, all time-varying systems (1.1) with *diagonal* or *Jordan* coefficient matrices, and all systems (1.1) with *constant* coefficient matrices, are semiproper. Recently, we have developed some new results for deriving finite-form analytical solutions $\boldsymbol{\phi}_{\mathbf{A}}(t, t_0)$ and stability criteria [26], [27], [34], [35] for the class of semiproper systems (1.1). Therefore it is natural to extend the family of Lyapunov reducible systems to include those systems that can be reduced to semiproper ones via Lyapunov transformations. In this regard, it should be noted that the classical boundedness requirements (i) and (ii) for Lyapunov transformations were traditionally imposed to preserve stability properties of the original system. However, those classical requirements are often overly restrictive and may rule out many candidate equivalence transformations that would enable derivation of explicit solutions and/or stability information for (1.1). Therefore it is desirable to relax requirements (i) and (ii) in Definition 1.1, to the extent possible.

Motivated by the foregoing argument, we introduce the following (new) definition of a "semiproper reducible" system.

DEFINITION 1.2. A linear system (1.1) is said to be *semiproper reducible* if there exists a matrix $\mathbf{L}(t)$ satisfying

$$\det \mathbf{L}(t) \equiv \text{constant} \neq 0 \tag{1.4}$$

such that the matrix

$$\mathbf{B}(t) = \mathbf{L}^{-1}(t)\mathbf{A}(t)\mathbf{L}(t) - \mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t) \tag{1.5}$$

is semiproper.

Remarks. (1) In this paper it will be shown in Theorem 5.2 that every Lyapunov reducible system (1.1) is semiproper reducible.

(2) Note that (1.4) assures the existence of $\mathbf{L}^{-1}(t)$ as well as the *same* divergence rates for $\mathbf{L}(t)$ and $\mathbf{L}^{-1}(t)$. The intrinsic significance of imposing condition (1.4) will be further explored in the sequel, and in separate papers [30], [31].

Hereafter, we refer to the transformation defined by (1.4) and (1.5) as a D-similarity transformation. A linear system (1.1) will be called *well defined* if $\mathbf{A}(t)$ is locally Lebesgue integrable.

In this paper, we employ Definition 1.2 to prove the following important theorem regarding semiproper reducibility.

THEOREM 1.1. *For every well-defined linear system* (1.1) *there exists a diagonal matrix* $\mathbf{D}(t)$, *and a matrix* $\mathbf{L}(t)$ *having nonzero constant determinant, such that*

$$\mathbf{D}(t)=\mathbf{L}^{-1}(t)\mathbf{A}(t)\mathbf{L}(t)-\mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t). \tag{1.6}$$

To find explicitly the D-similarity transformation matrix $\mathbf{L}(t)$ in (1.6), we will introduce in § 4 the notions of left and right D-elementary operations and D-elementary matrices as a natural generalization of the elementary operations and elementary matrices in the theory of matrices over a number field. By this means we will prove the following important theorem characterizing D-similarity transformations.

THEOREM 1.2. *Every matrix* $\mathbf{L}(t)$ *having nonzero constant determinant can be written as a product of a finite number of D-elementary matrices.*

Theorem 1.2 suggests that every D-elementary matrix constitutes a D-similarity transformation. Such a D-similarity transformation will be called *primary.* Using this terminology and the results of Theorems 1.1 and 1.2, we will establish the following fundamental result for semiproper reducible systems.

THEOREM 1.3. *Every well-defined linear system* (1.1) *is reducible to a* (*diagonal*) *semiproper system by a finite sequence of primary D-similarity transformations.*

Although Theorem 1.3 is an exciting theoretical result, its practical application is hampered because procedures for finding the primary D-similarity transformations involve, in general, solving systems of Riccati-type nonlinear differential equations that are usually as difficult to solve as the original ones. However, it is not necessary to study such general cases because we shall prove, as another of the main results in this paper, that every well-defined linear system (1.1) can be "decomposed" into two subsystems of form (1.1) with *normal* coefficient matrices. Moreover, the solution of the original system can be expressed in terms of the solutions of those two normal subsystems. It suffices, therefore, to investigate only semiproper reductions for normal systems.

Despite the difficulties mentioned above, for those systems (1.1) with virtually triangular $\mathbf{A}(t)$ (i.e., $\mathbf{A}(t)=\mathbf{L}\mathbf{T}(t)\mathbf{L}^{-1}$ for some nonsingular constant matrix $\mathbf{L}$ and triangular matrix $\mathbf{T}(t)$), the primary D-similarity transformations can always be found explicitly. The procedures for doing so, along with some illustrative examples, are developed in this paper.

To achieve our results with mathematical rigor, we shall first take the matrix functions $\mathbf{A}(t)$ as operators on a vector space over a differential field, and generalize some of the familiar results in the theory of matrices over a number field (note that a number field can be viewed as a special case of differential fields with the usual derivative operation). Those results are then relaxed so they can be applied to well-defined matrices $\mathbf{A}(t)$. As a byproduct of this approach, we obtain some additional results, which are interesting and important in their own right.

2. Vector spaces over a differential field. In this section, we establish the mathematical foundation for our main results. It is assumed that the reader is familiar with the algebraic notions such as fields, vector spaces over a number field, linear operators on a vector space, etc. Using those concepts, we adopt the notion of a *differential field* [11] defined as follows.

DEFINITION 2.1 [11]. A field $\mathbb{F}$ with addition and multiplication $\{+,\cdot\}$ is called an *ordinary differential field* if $\mathbb{F}$ adopts a derivation operator $\boldsymbol{\delta}$, and $\mathbb{F}$ is closed under

the derivative operation defined by

(a) $\boldsymbol{\delta}\{x+y\}=\boldsymbol{\delta}\{x\}+\boldsymbol{\delta}\{y\}$,

(b) $\boldsymbol{\delta}\{x\cdot y\}=\boldsymbol{\delta}\{x\}\cdot y+x\cdot\boldsymbol{\delta}\{y\}$

for all $x, y\in\mathbb{F}$. An element $C\in\mathbb{F}$ is said to be *constant* if $\boldsymbol{\delta}\{C\}=0$. All constants in $\mathbb{F}$ form a field called the *constant subfield* $\mathbb{F}_c$ of $\mathbb{F}$.

Without causing confusion, in the sequel we will simply call $\mathbb{F}$ a differential field, or D-field. Note that, with the ordinary derivative operation, the number fields $\mathbb{R}, \mathbb{C}$ are (trivial) D-fields. Nontrivial examples of D-field are the field of rational functions and the field of meromorphic functions in a complex domain.

Because of the lack of a multiplicative inverse for the zero element in the constant subfield $\mathbb{F}_c$, a D-field $\mathbb{F}$ cannot contain functions vanishing on a subinterval of positive measure. Hampered by this constraint, many functions having important applications, such as piecewise constant functions ($\mathbb{C}^\infty$ functions), cannot be studied using the powerful notion of the D-field. For this reason we now introduce the notion of an *augmented differential field* defined as follows.

DEFINITION 2.2. The union of a field $\mathbb{F}$ with a multiplicative inverse of its zero element, denoted by 0^{-1}, is called an *augmented field.* The union of a differential field $\mathbb{F}$ with a multiplicative inverse 0^{-1} for its zero element is called an *augmented differential field.* The zero element 0 and the element 0^{-1} are then called the singular elements in that augmented (differential) field.

Remarks. (1) By convention, multiplicity and powers of the zero element 0 in a number field is insignificant. But this is not the case in an augmented (differential) field when 0^{-1} comes into play. For instance, $(0+0)0^{-1}=1$, whereas $0\cdot 0^{-1}+0\cdot 0^{-1}=2$. To avoid indefinite computation results, the following rules should be observed when the operands include the singular numbers 0 and 0^{-1}:

(i) Keep track of multiplicity and powers of the singular numbers 0 and 0^{-1} at each intermediate stage, e.g., $0+0=2\cdot 0$, $0\cdot 0=0^2$, $0^{-1}+0^{-1}=2\cdot 0^{-1}$, $0^{-1}\cdot 0^{-1}=0^{-2}$.

(ii) Combine 0 and 0^{-1} at each intermediate stage according to the rules: $0+0^{-1}=0^{-1}$, $0\cdot 0^{-1}=1$, until only one type of singular number, 0 or 0^{-1}, is left.

(iii) At the last stage, combine the singular number, 0 or 0^{-1}, that remains from the preceeding computations with a regular number C by the rules:

$$0+C=C,\quad 0\cdot C=0,\quad 0^C=0,\quad C^0=1,$$

or

$$0^{-1}+C=0^{-1},\quad 0^{-1}\cdot C=0^{-1},\quad 0^{-C}=0^{-1},\quad C^{0^{-1}}=0^{-1},$$

or interpret the final result according to specific application purposes.

(2) Let $\mathbb{F}$ be an augmented differential field of functions $f: I\to\mathbb{F}_c$ and let $f, g\in\mathbb{F}$ such that $g(t)=1/f(t)$, $t\in\boldsymbol{I}$. If $t_0\in I$ is a continuity and an isolated zero of f, then $g(t_0)=0^{-1}$. But as $t\to t_0$, $g(t_0)\to\pm\infty\neq 0^{-1}$, i.e., $g(t_0)$ is discontinuous at t_0, and consequently nondifferentiable there. Now let $J\subseteq I$ be an open subinterval of positive measure. If $f(t)\equiv 0$, $t\in J$, then $g(t)\equiv 0^{-1}$ and $g'(t)\equiv 0$, $t\in J$. In particular, for every $t_0\in J$, $g(t)\to 0^{-1}$ as $t\to t_0$, i.e., $g(t)$ is continuous on J. A fundamental solution to the equation $\dot{x}=g(t)x$, $t\in J$, is then symbolically denoted by $x=\exp(0^{-1}t)$.

(3) In what follows we shall denote by $\mathbb{R}^0(\mathbb{C}^0)$ the augmented field $\mathbb{R}\cup\{0^{-1}\}\cdot(\mathbb{C}\cup\{0^{-1}\})$.

In order to apply the notions of D-field and augmented D-field to the analysis of time-varying linear systems (1.1), it is highly desirable that if the elements $a_{ij}(t)$ of the coefficient matrix $\mathbf{A}(t)$ are in an (augmented) D-field $\mathbb{F}$, then the elements $x_{ij}(t)$ of any fundamental solution matrix $\mathbf{X}_A(t)$ for (1.1) are also in that (augmented) field

$\mathbb{F}$. This motivates the following definition which parallels the conventional notion of algebraic closedness in the theory of number fields.

DEFINITION 2.3. An (augmented) D-field $\mathbb{F}$ is said to be *differentially closed* if for any finite number of elements $a_i \in \mathbb{F}$, $i = 1, 2, \cdots, n$, the nth-order linear differential equation

$$\frac{d^n}{dt^n} y + \alpha_n(t) \frac{d^{n-1}}{dt^{n-1}} y + \cdots + \alpha_2(t) \frac{d}{dt} y + \alpha_1(t) y = 0$$

has a fundamental set of n solutions $y_i \in \mathbb{F}$.

We now define a differentially closed augmented D-field that will be used in the sequel.

DEFINITION 2.4. Let $\mathbf{C}^{\infty}_{\text{a.e.}}(I, \mathbb{F}_c)$ be the set of almost everywhere (a.e.) $\mathbf{C}^{\infty}$ functions $f: I \to \mathbb{F}_c$, $I \subseteq \mathbb{R}$, and $\mathbb{F}_c = \mathbb{R}^0$ (or $\mathbb{F}_c = \mathbb{C}^0$). Then an augmented differential field $\mathbb{F}$ with the constant subfield $\mathbb{F}_c = \mathbb{R}^0$ ($\mathbb{F}_c = \mathbb{C}^0$) is defined by the set $\mathbf{C}^{\infty}_{\text{a.e.}}(I, \mathbb{F}_c)$, together with the operations $\{+, \cdot, d/dt\}$.

Remark. The differential closedness of the augmented D-field $\mathbb{F}$ defined above can be verified by the well-known reduction of order technique for linear differential equations and by mathematical induction.

Next we construct a vector space over an (augmented) D-field.

DEFINITION 2.5. Let $\mathbb{V}(\mathbb{F})$ be an n-dimensional vector space over a field $\mathbb{F}$. Let $\boldsymbol{\beta} = \{\mathbf{b}^1, \mathbf{b}^2, \cdots, \mathbf{b}^n\}$, $\mathbf{b}^k \in \mathbb{V}$, be a basis for $\mathbb{V}$ and $\mathbf{x}_\beta = [x_1, x_2, \cdots, x_n]$, $x_k \in \mathbb{F}$, be the coordinate vector relative to $\boldsymbol{\beta}$ for each $\mathbf{x} \in \mathbb{V}$. Then $\mathbb{V}$ is called a *differential vector space*, or simply a *D-space*, if $\mathbb{F}$ adopts a derivation operator $\boldsymbol{\delta}$ so that it becomes a differential field. The derivative operation induced on $\mathbb{V}$ is given by:

(a) $\boldsymbol{\delta}\{\mathbf{x}\} = [\boldsymbol{\delta}\{x_1\}, \boldsymbol{\delta}\{x_2\}, \cdots, \boldsymbol{\delta}\{x_n\}]$,

(b) $\boldsymbol{\delta}\{\mathbf{x}+\mathbf{y}\} = \boldsymbol{\delta}\{\mathbf{x}\} + \boldsymbol{\delta}\{\mathbf{y}\}$,

(c) $\boldsymbol{\delta}\{a\mathbf{x}\} = \boldsymbol{\delta}\{a\}\mathbf{x} + a\boldsymbol{\delta}\{\mathbf{x}\}$

for all $\mathbf{x}, \mathbf{y} \in \mathbb{V}$ and for all $a \in \mathbb{F}$. A subset $\mathbb{W}$ of $\mathbb{V}$ is called a *D-subspace* if $\mathbb{W}$ is itself a D-space over $\mathbb{F}$.

An interesting and important structure in a D-space is provided by the following definition.

DEFINITION 2.6. Let $\mathbb{V}(\mathbb{F})$ be an n-dimensional D-space over $\mathbb{F}$ with a basis $\boldsymbol{\beta} = \{\mathbf{b}^k\}$. The set of all constant linear combinations of the basis vectors $\mathbf{b}^k \in \boldsymbol{\beta}$ forms an n-dimensional vector space over the constant subfield $\mathbb{F}_c$, called a *partial space* of $\mathbb{V}$ *relative to* β and denoted by $\mathbb{V}_\beta(\mathbb{F}_c)$. In particular, if all the coordinate vectors for $\mathbf{b}^k \in \boldsymbol{\beta}$ are constants, $\mathbb{V}_\beta(\mathbb{F}_c)$ is called the *constant partial space* of $\mathbb{V}$ and is denoted by $\mathbb{V}_c$.

The adoption of the derivative operation on a D-space $\mathbb{V}$ introduces an important family of nonlinear operators on $\mathbb{V}$, defined as follows.

DEFINITION 2.7. Let $\mathscr{P}: \mathbb{V} \to \mathbb{V}$ be an operator on a D-space $\mathbb{V}$. Then $\mathscr{P}$ is said to be partially linear if

(a) $\mathscr{P}\{\mathbf{x}+\mathbf{y}\} = \mathscr{P}\{\mathbf{x}\} + \mathscr{P}\{\mathbf{y}\}$,

(b) $\mathscr{P}\{C\mathbf{x}\} = C\mathscr{P}\{\mathbf{x}\}$

for all $C \in \mathbb{F}_c$ and for all $\mathbf{x}, \mathbf{y} \in \mathbb{V}$.

It is readily verified that if $\mathscr{P}_1$ and $\mathscr{P}_2$ are partially linear on V, then $\mathscr{P}_1 + \mathscr{P}_2$ and $\mathscr{P}_1\mathscr{P}_2$ are also partially linear. In essence, a partially linear operator on $\mathbb{V}$ is a nonlinear operator that is linear on every partial space $\mathbb{V}_\beta(\mathbb{F}_c)$ in $\mathbb{V}$. In particular, every linear operator on $\mathbb{V}$ is partially linear. Note that the derivation operator $\boldsymbol{\delta}$ on $\mathbb{V}$ is partially linear. In the next section we investigate linear differential equations (1.1) viewed as partially linear operators on some D-space.

Before concluding this section, we recall the following important result on matrix decomposition, which will be needed in the subsequent sections of this paper. In the sequel, a matrix $\mathbf{A}=[a_{ij}]$, $a_{ij}\in\mathbb{F}$, $i,j=1,2,\cdots,n$, will be denoted by $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$.

DEFINTION 2.8 [15]. Let $A\in\mathbb{M}_n(\mathbb{F})$, where $\mathbb{F}$ is an (augmented) differential field with $\mathbb{F}_c=\mathbb{C}$. ($\mathbb{F}_c=\mathbb{C}^0$). The *Cartesian decomposition* of $\mathbf{A}$ is defined by $\mathbf{A}=\operatorname{Re}\{\mathbf{A}\}+i\operatorname{Im}\{\mathbf{A}\}$, where $\operatorname{Re}\{\mathbf{A}\}$ and $\operatorname{Im}\{\mathbf{A}\}$ are Hermitian, and are given by $\operatorname{Re}\{\mathbf{A}\}=(\mathbf{A}+\mathbf{A}^*)/2$, and $\operatorname{Im}\{\mathbf{A}\}=(\mathbf{A}-\mathbf{A}^*)/2i$.

3. The LDE operator on $\mathbb{V}(\mathbb{F})$. In the sequel we will be concerned with the n-dimensional vector space $\mathbb{V}(\mathbb{F})=\mathbb{F}^n$, where $\mathbb{F}$ is the differential field $\mathbb{F}=\mathbf{C}^{\infty}_{\text{a.e.}}(I,\mathbb{F}_c)$, $I=[t_0,\infty)$, and $\mathbb{F}_c=\mathbb{C}^0$. The derivative operation $d\mathbf{x}/dt$ on $\mathbb{V}$ will be denoted by $\dot{\mathbf{x}}$ (or $(\mathbf{x})'$). With this notation we define the LDE (Linear Differential Equation) operator on $\mathbb{V}$ as follows.

DEFINITION 3.1. Let $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$. The LDE *operator* $\mathscr{P}_{\mathbf{A}}:\mathbb{V}\to\mathbb{V}$ is defined by $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}(t)\}=\mathbf{A}(t)\mathbf{x}(t)-\dot{\mathbf{x}}(t)$, $t\in I$. The matrix $\mathbf{A}$ will be called the *characteristic matrix* for the LDE operator $\mathscr{P}_{\mathbf{A}}$.

Now we can establish the following properties of an LDE operator.

THEOREM 3.1. *Let* $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$. *Then*:

(a) *The* LDE *operator* $\mathscr{P}_{\mathbf{A}}$ *is partially linear*;

(b) *The mapping* $\mathscr{P}_{\mathbf{A}}:\mathbb{V}\to\mathbb{V}$ *is onto*;

(c) *The kernel* $\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ *of* $\mathscr{P}_{\mathbf{A}}$ *is an n-dimensional partial space* $\mathbb{V}_{\beta}(\mathbb{F}_c)$ *of* $\mathbb{V}$, *where* $\boldsymbol{\beta}\subseteq\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ *is a basis for* $\mathbb{V}$.

Proof. (a) This part of the proof can be verified by Definition 2.7.

(b) If suffices to show that $\mathbb{V}\subseteq\mathscr{P}_{\mathbf{A}}\{\mathbb{V}\}$. Let $\mathbf{y}\in\mathbb{V}$. We need to show that there exists an $\mathbf{x}\in\mathbb{V}$ such that $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}\}=\mathbf{A}\mathbf{x}-\dot{\mathbf{x}}=\mathbf{y}$. Recognizing $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}\}=\mathbf{y}$ as the nonhomogeneous linear differential equation $\dot{\mathbf{x}}(t)=\mathbf{A}(t)\mathbf{x}(t)-\mathbf{y}(t)$, and invoking the existence theory for linear differential equations, we have the existence of such a solution $\mathbf{x}\in\mathbb{V}$.

(c) Since $\mathbf{x}\in\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ implies that $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}\}=\mathbf{0}$, $\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ contains nothing but solutions to the homogeneous linear differential equation

$$\dot{\mathbf{x}}(t)=\mathbf{A}(t)\mathbf{x}(t). \tag{3.1}$$

From the theory of linear differential equations, $\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ is the n-dimensional solution space of equation (3.1) over $\mathbb{F}_c$. Since $\mathbf{K}(\mathscr{P}_{\mathbf{A}})\subseteq\mathbb{V}$, it is a partial space of $\mathbb{V}$ with a basis consisting of n linearly independent (over $\mathbb{F}_c$) solutions to (3.1). Now, let $\mathbf{X}_{\mathbf{A}}$ be the matrix consisting of the n basis vectors in β; then $\det\mathbf{X}_{\mathbf{A}}(t)\neq 0$, $t\in I$. Therefore, β is also a basis of $\mathbb{V}$. □

Remarks. (1) Let $\boldsymbol{\beta}=\{\mathbf{x}^1,\mathbf{x}^2,\cdots,\mathbf{x}^n\}$ be a basis for the partial space $\mathbf{K}(\mathscr{P}_{\mathbf{A}})$. Then the matrix $\mathbf{X}_{\mathbf{A}}=[\mathbf{x}^1\mathbf{x}^2\cdots\mathbf{x}^n]$ satisfies $\mathscr{P}_{\mathbf{A}}\{\mathbf{X}_{\mathbf{A}}\}=\mathbf{0}$, and is known as a fundamental solution matrix for a linear differential equation (3.1) represented by $\mathscr{P}_{\mathbf{A}}$. In the sequel, $\mathbf{X}_{\mathbf{A}}$ will be called a *fundamental matrix* associated with $\mathbf{A}$, and for $\mathscr{P}_{\mathbf{A}}$.

(2) The partial space $\mathbb{V}_{\beta}(\mathbb{F}_c)=\mathbf{K}(\mathscr{P}_{\mathbf{A}})$ and the constant partial space $\mathbb{V}_c$ are of the same dimension n and over the same field $\mathbb{F}_c$; therefore they are isomorphic. For any $\mathbf{x}_0\in\mathbb{V}_c$, $\mathscr{P}_{\mathbf{A}}\{\mathbf{X}_{\mathbf{A}}\mathbf{x}_0\}=\mathbf{0}$, i.e., $\mathbf{X}_{\mathbf{A}}\mathbf{x}_0=\mathbf{x}\in\mathbb{V}_{\beta}$. Since $\det\mathbf{X}_{\mathbf{A}}(t)\neq 0$, $t\in I$, $\mathbf{X}_{\mathbf{A}}^{-1}$ exists. Thus $\mathbf{X}_{\mathbf{A}}$ is an isomorphism that maps $\mathbb{V}_c$ onto $\mathbb{V}_{\beta}$. In particular, for any $t_0\in I$, the state-transition matrix $\boldsymbol{\phi}_{\mathbf{A}}(t,t_0)$ given by (1.2) (also known as the normalized fundamental matrix) is the isomorphism that maps any given initial vector $\mathbf{x}(t_0)=\mathbf{x}_0\in\mathbb{V}_c$ to the state evolution vector (the unique solution to (1.1)) $\mathbf{x}(t)\in\mathbb{V}_{\beta}(\mathbb{F})$.

(3) Note that not all partial spaces of $\mathbb{V}$ constitute a kernel for LDE operators. In particular, linear independence over $\mathbb{F}_c$ does not imply linear independence over $\mathbb{F}$.

The following theorem restates some well-known properties of a fundamental matrix $\mathbf{X}_{\mathbf{A}}$ for an LDE operator $\mathscr{P}_{\mathbf{A}}$.

THEOREM 3.2 [7], [22]. *Let $\mathscr{P}_{\mathbf{A}}$ be an* LDE *operator on $\mathbb{V}$ with characteristic matrix $\mathbf{A}\in\mathbb{M}_{\eta}(\mathbb{F})$. Let $\mathbf{X}_{\mathbf{A}}$ be a fundamental matrix for $\mathscr{P}_{\mathbf{A}}$. Then*:

(a) $\det \mathbf{X}_{\mathbf{A}} = \exp\int \operatorname{tr} \mathbf{A}(\tau)\, d\tau$;

(b) *If* $\mathbf{A}=\mathbf{B}+\mathbf{C}$, *then* $\mathbf{X}_{\mathbf{A}}=\mathbf{X}_{\mathbf{B}}\mathbf{X}_{\mathbf{Q}}$, *where* $\mathbf{Q}=\mathbf{X}_{\mathbf{B}}^{-1}\mathbf{C}\mathbf{X}_{\mathbf{B}}$;

(c) *If* $\mathbf{A}$ *is semiproper on* I, *then* $\mathbf{X}_{\mathbf{A}}=\exp\int \mathbf{A}(\tau)\, d\tau$.

The following result will be used in the next section.

THEOREM 3.3. *Let $\mathbf{A}, \mathbf{X}_{\mathbf{A}}\in\mathbb{M}_{\eta}(\mathbb{F})$ such that $\mathscr{P}_{\mathbf{A}}\{\mathbf{X}_{\mathbf{A}}\}=\mathbf{0}$. If $\mathbf{X}_{\mathbf{A}}$ is unitary, then $\mathbf{A}$ is skew-Hermitian. If $\mathbf{A}$ is skew-Hermitian, then there exists a unitary $\mathbf{X}_{\mathbf{A}}$.*

Proof. Suppose that $\mathbf{X}_{\mathbf{A}}$ is unitary. Then $\mathscr{P}_{\mathbf{A}}\{\mathbf{X}_{\mathbf{A}}\}=\mathbf{0}$ implies that $\mathbf{A}=(\mathbf{X}_{\mathbf{A}})'\mathbf{X}_{\mathbf{A}}^{*}$, so that $\mathbf{A}^{*}=\mathbf{X}_{\mathbf{A}}[(\mathbf{X}_{\mathbf{A}})']^{*}=\mathbf{X}_{\mathbf{A}}(\mathbf{X}_{\mathbf{A}}^{*})'$. Since $\mathbf{A}+\mathbf{A}^{*}=(\mathbf{X}_{\mathbf{A}}\mathbf{X}_{\mathbf{A}}^{*})'=\mathbf{0}$, $\mathbf{A}=-\mathbf{A}^{*}$.

Conversely, suppose that $\mathbf{A}$ is skew-Hermitian. Let $\mathbf{Y}_{\mathbf{A}}$ be an arbitrary fundamental matrix for $\mathscr{P}_{\mathbf{A}}$. Then $(\mathbf{Y}_{\mathbf{A}})'=\mathbf{A}\mathbf{Y}_{\mathbf{A}}$, and

$$(\mathbf{Y}_{\mathbf{A}}^{*})'=[(\mathbf{Y}_{\mathbf{A}})']^{*}=\mathbf{Y}_{\mathbf{A}}^{*}\mathbf{A}^{*}=-\mathbf{Y}_{\mathbf{A}}^{*}\mathbf{A}=-\mathbf{Y}_{\mathbf{A}}^{*}(\mathbf{Y}_{\mathbf{A}})'\mathbf{Y}_{\mathbf{A}}^{-1}.$$

Thus, $(\mathbf{Y}_{\mathbf{A}}^{*})'\mathbf{Y}_{\mathbf{A}}+\mathbf{Y}_{\mathbf{A}}^{*}(\mathbf{Y}_{\mathbf{A}})'=(\mathbf{Y}_{\mathbf{A}}^{*}\mathbf{Y}_{\mathbf{A}})'=0$. This implies that $\mathbf{Y}_{\mathbf{A}}^{*}\mathbf{Y}_{\mathbf{A}}=\mathbf{C}$, which is a nonsingular constant Hermitian matrix, and thus $\mathbf{C}$ can be written as $\mathbf{C}=\mathbf{B}^{*}\mathbf{B}$, for some nonsingular constant matrix $\mathbf{B}$. Now let $\mathbf{X}_{\mathbf{A}}=\mathbf{Y}_{\mathbf{A}}\mathbf{B}^{-1}$; hence $\mathbf{X}_{\mathbf{A}}^{*}\mathbf{X}_{\mathbf{A}}=(\mathbf{B}^{-1})^{*}\mathbf{Y}_{\mathbf{A}}^{*}\mathbf{Y}_{\mathbf{A}}\mathbf{B}^{-1}=\mathbf{I}$. □

Next, we introduce the notions of D-eigenvectors and D-eigenvalues for an LDE operator $\mathscr{P}_{\mathbf{A}}$, and its characteristic matrix $\mathbf{A}$, where the prefix "D" is used to avoid confusion with the ordinary eigenvectors and eigenvalues for the matrix $\mathbf{A}$. Although these "D-eigen" concepts are not explicitly used in the subsequent developments in this paper, they will be useful tools for extending the results of this paper and for addressing other related issues in linear time-varying system theory [30]–[33].

DEFINITION 3.2. A nonzero vector $\mathbf{x}\in\mathbb{V}$ is called a *D-eigenvector* of an LDE operator $\mathscr{P}_{\mathbf{A}}$, and of its characteristic matrix $\mathbf{A}$, if there exists a $\gamma\in\mathbb{F}$ such that $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}(t)\}=\mathbf{A}(t)\mathbf{x}(t)-\dot{\mathbf{x}}(t)=\gamma(t)\mathbf{x}(t)$. The scalar γ is then called the *D-eigenvalue* associated with $\mathbf{x}$.

Remarks. (1) In Definition 3.2, we have used the morpheme "eigen" primarily because of the special form $\mathscr{P}_{\mathbf{A}}\mathbf{x}=\gamma\mathbf{x}$ and operator theoretic convention. However, the entities $\mathbf{x}\in\mathbb{V}$ and $\gamma\in\mathbb{F}$ satisfying $\mathscr{P}_{\mathbf{A}}\mathbf{x}=\gamma\mathbf{x}$ for a given matrix $\mathbf{A}(t)$ are not what we would call *natural* extensions of the tradiditional "eigenconcepts" used for constant matrices, even though when $\mathbf{A}(t)\equiv\mathbf{A}$ is constant, the conventional constant eigenvalues and eigenvectors are, by Definition 3.2, D-eigenvalues and D-eigenvectors of $\mathbf{A}$. In fact, by the well-known Existence Theorem for solutions of linear systems (1.1), *any* scalar function $\gamma\in\mathbb{F}$ is a D-eigenvalue of *any* LDE operator with $\mathbf{A}\in\mathbb{M}_{n}(\mathbb{F})$ (but not every vector $\mathbf{x}\in\mathbb{V}$ is a D-eigenvector for a given LDE operator $\mathscr{P}_{\mathbf{A}}$). Therefore, the "D-eigenconcepts" as they appear in Definition 3.2 may have only limited usefulness in applications such as solving for analytical solutions of linear time-varying systems (1.1), and/or analyzing stability of linear time-varying systems (1.1). However, we have recently used the D-eigenconcepts in Definition 3.2 to develop two new notions called *ED*-eigenvectors and *ED*-eigenvalues ("*ED*-" stands for "Essential *D*-") which have been quite useful in certain theoretical and practical applications [30]–[33].

(2) In a recent paper [24] (see also [23]), Wu introduces the notions of X-eigenvectors and X-eigenvalues for arbitrary linear time-varying systems (1.1) ("X-" stands for "Extended-") and has treated those notions as extensions of the conventional eigenconcepts for linear time-invariant systems (1.1). Although the D-eigenconcepts we have introduced are derived from a totally different line of reasoning, those concepts do coincide with Wu's X-eigenconcepts when the coefficient matrix $\mathbf{A}$ in (1.1) is restricted to the D-field $\mathbb{F}$. By a similar argument used in Remark 1 above, *any* (locally

integrable) scalar function $\lambda(t)$ is an X-eigenvalue for *any* (locally integrable) matrix $\mathbf{A}(t)$. Therefore the very essence of being "eigen" is lost in such attempts to extend the traditional eigenconcepts for linear time-invariant systems (1.1). Our new results on ED-eigenvalues and ED-eigenvectors [30], [33] are believed to constitute a more precise and more meaningful basis, compared to the X-eigenconcepts, for extending traditional time-invariant eigenconcepts to time-varying linear dynamical systems (1.1).

(3) In an operator theoretic sense we can speak of the eigenvalues $\lambda(t)$ and eigenvectors $\mathbf{y}(t)$ of a matrix $\mathbf{A}(t)$. To find $\lambda(t)$ and $\mathbf{y}(t)$ we need to solve the secular equation $[\mathbf{A}(t)-\lambda(t)\mathbf{I}]\mathbf{y}(t)=0$. However, to find the D-eigenvalues $\gamma(t)$ and D-eigenvectors $\mathbf{x}(t)$ of $\mathbf{A}(t)$, we may have to solve the linear differential equation

$$[\mathbf{A}(t)-\gamma(t)\mathbf{I}]\mathbf{x}(t)=\dot{\mathbf{x}}(t),$$

which in general is not an easy matter. It should be pointed out here that the "recursive" procedure for finding X-eigenvectors and X-eigenvalues presented by Wu in [24] is, in fact, a trial-and-error procedure.

(4) In the special case $\mathbf{A}(t)=\mathbf{A}\in\mathbb{M}_n(\mathbb{F}_c)$ and $\mathbf{x}\in\mathbb{V}(\mathbb{F})$, where $\mathbb{F}=\mathbf{C}^{\infty}_{\text{a.e.}}(I,\mathbb{F}_c)$, $\mathbb{F}_c=\mathbb{R}$, the LDE operator represents a linear differential equation with a real, constant coefficient matrix $\mathbf{A}$. In this case, it is often necessary to extend the underlying field $\mathbb{F}_c$ to $\mathbb{C}$ in order to have a full set of eigenvalues and eigenvectors. However, there always exists a full set of constant D-eigenvalues $\Gamma=\{\gamma_k\}$ in $\mathbb{F}_c=\mathbb{R}$ and a full set of D-eigenvectors in $\mathbb{V}(\mathbb{F})$. Moreover, to every eigenvalue λ of $\mathbf{A}$ there corresponds a D-eigenvalue $\gamma\in\Gamma$ such that $\gamma=\operatorname{Re}\{\lambda\}$; the corresponding D-eigenvector is also real-valued, but no longer constant. Therefore, the well-known stability criterion that a linear time-invariant system is asymptotically stable if and only if all eigenvalues λ of $\mathbf{A}$ have a negative real part can be modified to read: if and only if all the D-eigenvalues $\gamma\in\Gamma$ are negative.

(5) In the special case $\mathbf{A}(t)=\mathbf{A}\in\mathbb{M}_n(\mathbb{F}_c)$ and $\mathbf{x}(t)=\mathbf{x}\in\mathbb{V}_c$, the LDE operator becomes $\mathscr{P}_{\mathbf{A}}\{\mathbf{x}\}=\mathbf{A}\mathbf{x}$, and the D-eigenvectors $\mathbf{x}$ and D-eigenvalues γ of $\mathscr{P}_{\mathbf{A}}$ and $\mathbf{A}$ are given by $\mathbf{A}\mathbf{x}=\gamma\mathbf{x}$. In other words, the (partially linear) LDE operator then coincides with the (linear) left-multiplication operator $\mathscr{L}_{\mathbf{A}}\{\mathbf{x}\}=\mathbf{A}\mathbf{x}$ on $\mathbb{V}_c$, and the notions of D-eigenvalues and D-eigenvectors then coincide with the conventional notions of eigenvalues and eigenvectors on $\mathbb{V}_c$.

4. *D*-similarity transformations. In this section we study LDE operators under a "change of coordinate" transformation on $\mathbb{V}$. Let $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ be two distinct ordered bases for $\mathbb{V}$. Let $\mathbf{x}_\beta$ and $\mathbf{x}_\gamma$ be the coordinate vectors for a vector $\mathbf{x}\in\mathbb{V}$ relative to the bases $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$, respectively. Then we can always find an invertible matrix $\mathbf{L}\in\mathbb{M}_n(\mathbb{F})$ such that $\mathbf{x}_\beta=\mathbf{L}\mathbf{x}_\gamma$, for all $\mathbf{x}\in\mathbb{V}$. The matrix $\mathbf{L}$ is known as a "change of coordinate" (CC) transformation matrix. Since $\mathbf{L}$ is invertible, the change of coordinate transformation is an equivalence relation. A linear operator $\mathscr{L}$ on $\mathbb{V}$ under CC transformations takes different forms, which are said to be similar.

Now let $\mathscr{P}_{\mathbf{A}}$ be an LDE operator on $\mathbb{V}$ with characteristic matrix $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$ relative to an ordered basis $\boldsymbol{\beta}$. Let $\boldsymbol{\gamma}$ be another ordered basis and $\mathbf{L}\in\mathbb{M}_n(\mathbb{F})$ be the CC transformation matrix. Then

$$\mathscr{P}_{\mathbf{A}}\{\mathbf{x}_\beta\}=\mathbf{P}_{\mathbf{A}}\{\mathbf{L}\mathbf{x}_\gamma\}=(\mathbf{A}\mathbf{L}-\dot{\mathbf{L}})\mathbf{x}_\gamma-\mathbf{L}\dot{\mathbf{x}}_\gamma=\mathbf{y}_\beta.$$

This latter result, when expressed with respect to the basis $\boldsymbol{\gamma}$, becomes

$$\mathbf{y}_\gamma=\mathbf{L}^{-1}\mathbf{y}_\beta=(\mathbf{L}^{-1}\mathbf{A}\mathbf{L}-\mathbf{L}^{-1}\dot{\mathbf{L}})\mathbf{x}_\gamma-\dot{\mathbf{x}}_\gamma=\mathbf{B}\mathbf{x}_\gamma-\dot{\mathbf{x}}_\gamma=\mathscr{P}_{\mathbf{B}}\{\mathbf{x}_\gamma\},$$

where the matrix $\mathbf{B}\in\mathbb{M}_n(\mathbb{F})$ is given by

$$\mathbf{B}=\mathbf{L}^{-1}\mathbf{A}\mathbf{L}-\mathbf{L}^{-1}\dot{\mathbf{L}}=\mathscr{T}\{\mathbf{A}\} \tag{4.1}$$

and is the characteristic matrix for the same LDE operator relative to the basis $\boldsymbol{\gamma}$. Notice that $d(\mathbf{L}\mathbf{L}^{-1})/dt = \dot{\mathbf{I}} = \mathbf{0}$. It is straightforward to verify the following result.

THEOREM 4.1. *The transformation* $\mathscr{T}: \mathbb{M}_n(\mathbb{F}) \to \mathbb{M}_n(\mathbb{F})$ *defined by* (4.1) *is an equivalence relation.*

Now we can define D-similarity transformations of LDE operators, and of their characteristic matrices, as follows.

DEFINITION 4.1. (a) The transformation $\mathscr{T}: \mathbb{M}_n(\mathbb{F}) \to \mathbb{M}_n(\mathbb{F})$ defined by (4.1) is called a *D-similarity transformation* of a matrix $\mathbf{A} \in \mathbb{M}_n(t)$ if and only if

$$\det \mathbf{L}(t) \equiv C \neq 0$$

for some constant $C \in \mathbb{F}_c$ and for all $t \in I$. The matrices $\mathbf{A}$ and $\mathbf{B}$ in (4.1) are then said to be D-similar via $\mathbf{L}$.

(b) Two LDE operators $\mathscr{P}_{\mathbf{A}}$ and $\mathscr{P}_{\mathbf{B}}$ are said to be D-similar via $\mathbf{L}$ if and only if their associated characteristic matrices $\mathbf{A}$ and $\mathbf{B}$ are D-similar via $\mathbf{L}$.

Remarks. (1) The restriction that $\det \mathbf{L}$ be a nonzero constant provides many desirable properties which will be used in subsequent developments in this paper.

(2) D-similarity transformations coincide with conventional similarity transformations on the constant partial space $\mathbb{V}_c$.

The next result relates D-similarity transformations on a matrix $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$ with the usual similarity transformations on $\mathbf{A}$ over $\mathbb{F}$. This relation may be useful in the construction of D-similarity transformations for particular applications.

THEOREM 4.2. *Let* $\mathbf{A}, \mathbf{B}, \mathbf{L} \in \mathbb{M}_n(\mathbb{F})$ *such that* $\det \mathbf{L} \equiv C \neq 0$. *If* $\mathbf{B} = \mathbf{L}^{-1}\mathbf{A}\mathbf{L} - \mathbf{L}^{-1}\dot{\mathbf{L}}$, *then there exists a matrix* $\mathbf{C} \in \mathbb{M}_n(\mathbb{F})$ *such that* $\mathbf{B} = \mathbf{L}^{-1}(\mathbf{A} - \mathbf{C})\mathbf{L}$.

Proof. Suppose that $\mathbf{B} = \mathbf{L}^{-1}\mathbf{A}\mathbf{L} - \mathbf{L}^{-1}\dot{\mathbf{L}}$. Let $\mathbf{C} = \dot{\mathbf{L}}\mathbf{L}^{-1}$. Then $\mathbf{C} \in \mathbb{M}_n(\mathbb{F})$ and $\mathbf{B} = \mathbf{L}^{-1}(\mathbf{A} - \mathbf{C})\mathbf{L}$. □

Note that the matrix $\mathbf{C}$ defines an LDE operator $\mathscr{P}_c$ such that $\mathbf{P}_c\{\mathbf{L}\} = \mathbf{C}\mathbf{L} - \dot{\mathbf{L}} = \mathbf{0}$, or $\mathbf{L} = \mathbf{X}_c$. In essence, Theorem 4.2 states that if $\mathbf{B}$ is D-similar to $\mathbf{A}$ via $\mathbf{L}$, then $\mathbf{B}$ is also similar (in the usual sense) to a portion of $\mathbf{A}$ via $\mathbf{L}$. In particular, if $\mathbf{B}$ is *unitarily D-similar* to $\mathbf{A}$, i.e., the transformation matrix $\mathbf{L}$ is unitary (thus $|\det \mathbf{L}| = 1$), we have the following interesting corollary.

COROLLARY 4.1. *Let* $\mathbf{A}, \mathbf{B}, \mathbf{U} \in \mathbb{M}_n(\mathbb{F})$, *where* $\mathbf{U}$ *is a unitary matrix. If* $\mathbf{B}$ *is unitarily D-similar to* $\mathbf{A}$ *via* $\mathbf{U}$, *then* $\operatorname{Re}\{\mathbf{B}\}$ *is unitarily similar (in the usual sense) to* $\operatorname{Re}\{\mathbf{A}\}$ *via the same* $\mathbf{U}$ *matrix.*

Proof. Suppose that $\mathbf{B} = \mathbf{U}^*\mathbf{A}\mathbf{U} - \mathbf{U}^*\dot{\mathbf{U}}$. By Theorem 4.2, there exists a matrix $\mathbf{C}$ such that $\dot{\mathbf{U}} = \mathbf{C}\mathbf{U}$ and $\mathbf{B} = \mathbf{U}^*(\mathbf{A} - \mathbf{C})\mathbf{U}$. Note that by Theorem 3.3, $\mathbf{C}$ is skew-Hermitian; thus,

$$\begin{aligned}
\operatorname{Re}\{\mathbf{B}\} &= (\mathbf{B} + \mathbf{B}^*)/2 \\
&= \{\mathbf{U}^*(\mathbf{A} - \mathbf{C})\mathbf{U} + [\mathbf{U}^*(\mathbf{A} - \mathbf{C})\mathbf{U}]^*\}/2 \\
&= [\mathbf{U}^*(\mathbf{A} + \mathbf{A}^*)\mathbf{U}]/2 \\
&= \mathbf{U}^* \operatorname{Re}\{\mathbf{A}\}\mathbf{U}.
\end{aligned}$$

□

In light of Theorem 3.2, we can now give another interesting characterization of a D-similarity transformation matrix.

THEOREM 4.3. *Let* $\mathbf{L} \in \mathbb{M}_n(\mathbb{F})$. *Then* $\mathbf{L}$ *is a D-similarity transformation matrix, i.e.,* $\det \mathbf{L} = C \neq 0$, *for some* $C \in \mathbb{F}_c$, *if and only if there exists a* $\mathbf{B} \in \mathbb{M}_n(\mathbb{F})$ *with* $\operatorname{tr} \mathbf{B}(t) = 0$ *such that* $\mathbf{L}(t) = \mathbf{X}_{\mathbf{B}}(t)$, *i.e.,* $\mathscr{P}_{\mathbf{B}}\{\mathbf{L}\} = \mathbf{B}\mathbf{L} - \dot{\mathbf{L}} = \mathbf{0}$.

Proof. Suppose that $\mathbf{L} \in \mathbb{M}_n(\mathbb{F})$ satisfying $\det \mathbf{L} = C \neq 0$, $C \in \mathbf{F}_c$. Let $\mathbf{B} = \dot{\mathbf{L}}\mathbf{L}^{-1}$. Then $\mathbf{B} \in \mathbb{M}_n(\mathbb{F})$ and $\mathbf{L} = \mathbf{X}_\mathbf{B}$. By Theorem 3.2,

$$\det \mathbf{L}(t) = \det \mathbf{X}_\mathbf{B}(t) = \exp \int \operatorname{tr} \mathbf{B}(t)\, dt = C \neq 0,$$

which implies that $\operatorname{tr} \mathbf{B} = 0$.

Conversely, suppose that there exists a matrix $\mathbf{B} \in \mathbb{M}_n(\mathbb{F})$ with $\operatorname{tr} \mathbf{B} = 0$, such that $\mathbf{L} = \mathbf{X}_\mathbf{B}$. Then by Theorem 3.2,

$$\det \mathbf{L}(t) = \det \mathbf{X}_\mathbf{B}(t) = \exp \int \operatorname{tr} \mathbf{B}(t)\, dt = e^s \neq 0,$$

for some constant $S \in \mathbb{F}_c$. □

At this point, it is useful to recall the following well-known result on the extent of a D-similarity transformation.

THEOREM 4.4. *Let* $\mathbf{A}, \mathbf{B}, \mathbf{L} \in \mathbb{M}_n(\mathbb{F})$. *Then* $\mathbf{B}$ *is D-similar to* $\mathbf{A}$ *via* $\mathbf{L}$, *i.e.*, $\mathbf{B} = \mathbf{L}^{-1}\mathbf{A}\mathbf{L} - \mathbf{L}^{-1}\dot{\mathbf{L}}$, *if and only if* $\mathbf{X}_\mathbf{A} = \mathbf{L}\mathbf{X}_\mathbf{B}$.

Now we define what are called *primary* D-similarity transformations. Such transformations have many important applications. For instance, they may be used to construct some desired D-similarity transformations, or, as in the main results of this paper, can be used to reduce a linear differential equation (1.1) to some simpler form. We start with the definition of the D-elementary row (column) operations on a matrix $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$.

DEFINITION 4.2. Let $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$. Any one of the following three operations on the rows (columns) of $\mathbf{A}$ is called a *D-elementary row (column) operation*:

(a) Interchanging any two rows (columns) of $\mathbf{A}$;

(b) Multiplying any row (column) of $\mathbf{A}$ by a nonzero constant $C \in \mathbb{F}_c$;

(c) Adding to any row (column) of $\mathbf{A}$ another row (column) of $\mathbf{A}$ multiplied by a scalar $a \in \mathbb{F}$.

Remark. Note that part (b) of Definition 4.2 is different from the usual definition of elementary matrix operations over a field $\mathbb{F}$. However those two definitions coincide over the constant subfield $\mathbb{F}_c$.

DEFINITION 4.3. A matrix obtained from the identity matrix $\mathbf{I}$ by application of any one of the D-elementary row (column) operations in Definition 4.2 is called a *left (right) D-elementary matrix* of type (a), (b), or (c), and will be denoted by $\mathbf{F}^a$, $\mathbf{F}^b$, or $\mathbf{F}^c$ ($\mathbf{E}^a$, $\mathbf{E}^b$, or $\mathbf{E}^c$), accordingly. The superscript ^{a}, ^{b}, or ^{c} will be replaced by ^{x} if the type of a D-elementary matrix is indeterminate.

Remarks. (1) The determinant of any D-elementary matrix is a nonzero constant. In particular, $\det \mathbf{F}^a = -1$ ($\det \mathbf{E}^a = -1$); $\det \mathbf{F}^b = C$ ($\det \mathbf{E}^b = C$), where $C \in \mathbf{F}_c$ is the nonzero constant involved in the D-elementary operation; $\det \mathbf{F}^c = 1$ ($\det \mathbf{E}^c = 1$).

(2) By Remark 1 the D-elementary matrices are always nonsingular. The inverse of $\mathbf{E}^x(\mathbf{F}^x)$ is a D-elementary matrix of the same type, and will be denoted by $\mathbf{E}^{-x}(\mathbf{F}^{-x})$.

With this notation we can now define the *primary* D-similarity transformations as follows.

DEFINITION 4.4. Let $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$. A *right (left) primary D-similarity transformation* is a D-similarity transformation with the change of coordinate matrix $\mathbf{L}$ in (4.1) given by $\mathbf{L} = \mathbf{E}^x$ ($\mathbf{L} = \mathbf{F}^{-x}$).

The first two central results of this paper (Theorems 4.5 and 4.6) can now be stated as follows.

THEOREM 4.5. *Let* $\mathbf{L}\in\mathbb{M}_n(\mathbb{F})$. *Then* $\mathbf{L}$ *is a D-similarity transformation matrix, i.e.,* $\det \mathbf{L}(t)\equiv C\neq 0$ *for some* $C\in\mathbb{F}_c$, *if and only if* $\mathbf{L}$ *can be written as a finite product of left and right D-elementary matrices.*

In order to prove this theorem, we first need to establish two important lemmas. For this purpose, denote by $\Delta_k(t)$ the kth leading principle minor of $\mathbf{L}(t)$, i.e.,

$$\Delta_k(t)=\det\begin{bmatrix} l_{11} & \cdots & l_{1k}\\ \vdots & & \vdots\\ l_{k1} & \cdots & l_{kk}\end{bmatrix}.$$

The notation $\mathbf{A}\sim\mathbf{B}$ will be used to indicate that the matrix $\mathbf{B}$ is obtained from $\mathbf{A}$ by a finite sequence of D-elementary operations.

LEMMA 4.1. *Let* $\mathbf{L}\in\mathbb{M}_n(\mathbb{F})$. *If* $\Delta_k(t)\neq 0$, $t\in I$, $k\leqq n$, *then by means of a finite number of D-elementary row operations* $\mathbf{L}(t)$ *can be reduced to a diagonal matrix* $\mathbf{D}$ *of the form*

$$\mathbf{D}(t)=\operatorname{diag}\left[\frac{\Delta_1}{\Delta_0},\frac{\Delta_2(t)}{\Delta_1(t)},\cdots,\frac{\Delta_n(t)}{\Delta_{n-1}(t)}\right],$$

where $\Delta_0=1$. *Moreover,* $\det\mathbf{D}(t)=\det\mathbf{L}(t)$.

Lemma 4.1 can be proved by induction on n and therefore the proof is omitted.

LEMMA 4.2. *Let* $\mathbf{D}\in\mathbb{M}_n(\mathbb{F})$ *be a diagonal matrix with nonzero constant determinant. Then* $\mathbf{D}$ *can be written as a product of a finite number of D-elementary matrices.*

Proof. First it will be shown, by induction on n, that $\mathbf{D}\sim\mathbf{D}_0$, where $\mathbf{D}_0=\operatorname{diag}[1,\cdots,1,\det\mathbf{D}]$. Clearly, this is true for $n=1$. Now for arbitrary n, apply the following D-elementary operations:

(a) Add the first row to the second row.

(b) Add to the first row the second row multiplied by $(1-d_{11})/d_{11}$.

(c) Add to the second row the first row multiplied by $-d_{11}$.

(d) Add to the first row the second row multiplied by $(d_{11}-1)/d_{11}^2$.

These steps lead to the final result:

$$\mathbf{D}\sim\operatorname{diag}[1,d_{11}d_{22},d_{33},\cdots,d_{\eta\eta'}]\sim\mathbf{D}_0,$$

where the last step follows from the induction hypothesis. Since $\det\mathbf{D}$ is a nonzero constant, the proof is completed with a D-elementary row operation of type (b) applied to the last row of $\mathbf{D}_0$. □

Proof of Theorem 4.5. The sufficiency is an immediate consequence of Remark 1 following Definition 4.3. To prove the necessity, suppose that $\det\mathbf{L}(t)\equiv C\neq 0$. By means of m, $m\leqq 2(n-1)$, D-elementary row and column operations we can obtain an $\mathbf{L}_1$ whose leading principal minors $\Delta_k(t)\neq 0$, $t\in I$, $k\leqq n$. Moreover, $\det\mathbf{L}_1(t)=(-1)^m C$. The proof is then completed by applying Lemma 4.1 and 4.2 to $\mathbf{L}_1$. □

Remarks. As can be seen from the proofs of Theorem 4.5 and Lemmas 4.1 and 4.2 (and from proofs of other theorems in the sequel of this paper), the D-elementary matrices of type (c) play an important role in D-similarity transformations. Thus it is appropriate to observe here some properties of a D-elementary matrix of type (c). Let $\mathbf{E}_{rs}^c$, $r\neq s$, denote a right D-elementary matrix that performs the addition of the rth column, multiplied by some nonzero scalar function $q\in\mathbb{F}$, to the sth column. Then $\mathbf{E}_{rs}^c=\mathbf{I}+\mathbf{Q}_{rs}$, where $\mathbf{I}$ is the identity matrix, and $\mathbf{Q}_{rs}=[q_{ij}]$ such that $q_{rs}=q$, and $q_{ij}=0$ otherwise. Clearly, $\dot{\mathbf{E}}_{rs}^c=\dot{\mathbf{Q}}_{rs}$. Now let $\mathbf{Z}_{rs}=[z_{ij}]$ such that $z_{ij}=0$ if $i\neq r$ or $j\neq s$. Then it can be shown that $\mathbf{Q}_{rs}\mathbf{Z}_{rs}=\mathbf{0}$ if $r\neq s$. In particular, for $r\neq s$, $\mathbf{E}_{rs}^{-c}=\mathbf{I}-\mathbf{Q}_{rs}$, and $\mathbf{E}_{rs}^{-c}\dot{\mathbf{E}}_{rs}^c=\dot{\mathbf{Q}}_{rs}$. Similarly, a left D-elementary matrix, denoted by $\mathbf{F}_{rs}^c=\mathbf{I}+\mathbf{Q}_{rs}$, adds the sth row, multiplied by the nonzero entry q_{rs} in $\mathbf{Q}_{rs}$, to the rth row. Now let $\mathbf{B}$, $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$

such that $\mathbf{B}=\mathbf{L}^{-1}\mathbf{A}\mathbf{L}-\mathbf{L}^{-1}\dot{\mathbf{L}}$, where $\mathbf{L}=\mathbf{E}_{rs}^{c}=\mathbf{I}+\mathbf{Q}_{rs}$. Then $\mathbf{B}$ can be written as $\mathbf{B}=\mathbf{E}_{rs}^{-c}\mathbf{A}\mathbf{E}_{rs}^{c}-\dot{\mathbf{Q}}_{rs}=[b_{ij}]$, where

$$
\begin{aligned}
&b_{ij}=a_{ij} && \text{if } i\neq r,\quad j\neq s,\\
&b_{rj}=a_{rj}-q_{rs}a_{sj} && \text{if } j\neq s,\\
&b_{is}=a_{is}+q_{rs}a_{ir} && \text{if } i\neq r,\\
&b_{rs}=a_{rs}+(a_{rr}-a_{ss})q_{rs}-a_{sr}q_{rs}^{2}-\dot{q}_{rs}.
\end{aligned}
\tag{4.2}
$$

The observations and notation above will be used in the proofs of Theorem 4.6 and Lemma 4.3 given below.

THEOREM 4.6. *Every matrix* $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$ *can be reduced to a diagonal matrix* $\mathbf{D}\in\mathbb{M}_n(\mathbb{F})$ *by a finite sequence of primary D-similarity transformations.*

In order to prove this theorem, the following two important lemmas are needed. The first one presented below is also a main result of this paper.

LEMMA 4.3. *Every upper-triangular matrix* $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$ *can be reduced to a diagonal matrix* $\mathbf{D}\in\mathbb{M}_n(\mathbb{F})$ *by a finite number of primary D-similarity transformations.*

Proof. Let $\mathbf{A}=[a_{ij}]\in\mathbb{M}_n(\mathbb{F})$ be an upper-triangular matrix. The proof is by induction on n. For $n=2$, let

$$
\mathbf{L}=\mathbf{E}_{12}^{c}=\mathbf{I}+\mathbf{Q}_{12}=\begin{bmatrix}1 & q_{12}\\ 0 & 1\end{bmatrix}
$$

for some $q_{12}\in F$. Now set

$$
\begin{aligned}
\mathbf{D}&=\mathbf{L}^{-1}\mathbf{A}\mathbf{L}-\mathbf{L}^{-1}\dot{\mathbf{L}}\\
&=\begin{bmatrix}a_{11} & a_{12}+(a_{11}-a_{22})q_{12}-\dot{q}_{12}\\ 0 & a_{22}\end{bmatrix}=\begin{bmatrix}a_{11} & 0\\ 0 & a_{22}\end{bmatrix}.
\end{aligned}
$$

It can be seen that q_{12} satisfies

$$
\dot{q}_{12}(t)=[a_{11}(t)-a_{22}(t)]q_{12}(t)+a_{12}(t).
$$

From classical linear differential equation theory, such a $q_{12}\in\mathbb{F}$ can be expressed as

$$
q_{12}(t)=\phi_{12}(t)\int\phi_{12}^{-1}(t)a_{12}(t)\,dt,
$$

where

$$
\phi_{12}(t)=\exp\int[a_{11}(t)-a_{22}(t)]\,dt.
$$

Now for arbitrary n, assume that Lemma 4.3 is true for $n-1$. Partition $\mathbf{A}$ into block matrices:

$$
\mathbf{A}=\left[\begin{array}{c|c}\mathbf{A}_{11} & \mathbf{A}_{12}\\ \hline \mathbf{A}_{21} & \mathbf{A}_{22}\end{array}\right]
$$

such that $\mathbf{A}_{11}=[a_{11}]$. Let $\mathbf{D}_{22}=\operatorname{diag}[a_{22},a_{33},\cdots,a_{nn}]$, and let $\mathbf{L}_1=\operatorname{diag}[\mathbf{L}_{11},\mathbf{L}_{22}]$ such

that $\mathbf{L}_{11}=[1]$ and $\mathbf{L}_{22}^{-1}\mathbf{A}_{22}\mathbf{L}_{22}-\mathbf{L}_{22}^{-1}\dot{\mathbf{L}}_{22}=\mathbf{D}_{22}$. Then we have

$$\mathbf{B}=\mathbf{L}_1^{-1}\mathbf{A}\mathbf{L}_1-\mathbf{L}_1^{-1}\dot{\mathbf{L}}_1$$

$$=\left[\begin{array}{c|c} a_{11} & \mathbf{A}_{12}\mathbf{L}_{22} \\ \hline \mathbf{0} & \mathbf{D}_{22} \end{array}\right]=\left[\begin{array}{c|ccc} a_{11} & b_{12} & \cdots & b_{1n} \\ \hline 0 & a_{22} & 0 \cdots & 0 \\ \vdots & 0 & \ddots \quad \ddots & \vdots \\ \vdots & \vdots & \ddots \quad \ddots & 0 \\ 0 & 0 & \cdots \quad 0 & a_{nn} \end{array}\right].$$

Now let $\mathbf{L}_2=\mathbf{E}_{12}^c\mathbf{E}_{13}^c\cdots\mathbf{E}_{1n}^c$, where $\mathbf{E}_{1k}^c=\mathbf{I}+\mathbf{Q}_{1k}$. Set

$$\mathbf{D}=\mathbf{L}_2^{-1}\mathbf{A}\mathbf{L}_2-\mathbf{L}_2^{-1}\dot{\mathbf{L}}_2$$

$$=\left[\begin{array}{c|ccc} a_{11} & d_{12} & \cdots & d_{1n} \\ \hline 0 & a_{22} & 0 \cdots & 0 \\ \vdots & 0 & \ddots \quad \ddots & \vdots \\ \vdots & \vdots & \ddots \quad \ddots & 0 \\ 0 & 0 & \cdots \quad 0 & a_{nn} \end{array}\right]=\left[\begin{array}{c|ccc} a_{11} & 0 & \cdots & 0 \\ \hline 0 & a_{22} & 0 \cdots & 0 \\ \vdots & 0 & \ddots \quad \ddots & \vdots \\ \vdots & \vdots & \ddots \quad \ddots & 0 \\ 0 & 0 & \cdots \quad 0 & a_{nn} \end{array}\right],$$

where

$$d_{1k}=(a_{11}-a_{kk})q_{1k}+b_{1k}-\dot{q}_{1k}=0, \tag{4.3}$$

$k=2,3,\cdots,n$. Thus a $q_{1k}\in\mathbb{F}$ can be found as

$$q_{1k}(t)=\phi_{1k}(t)\int\phi_{1k}^{-1}(t)b_{1k}(t)\,dt, \tag{4.4}$$

where

$$\phi_{1k}(t)=\exp\int[a_{11}(t)-a_{kk}(t)]\,dt. \tag{4.5}$$

Now let $\mathbf{L}=\mathbf{L}_1\mathbf{L}_2$; the lemma then follows from Theorem 4.1. □

Lemma 4.3 has an immediate corollary, which greatly increases its applicability.

COROLLARY 4.2. *Every virtually triangular matrix* $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$ *can be reduced to a diagonal matrix* $\mathbf{D}\in\mathbb{M}_n(\mathbb{F})$ *by a finite number of primary D-similarity transformations.*

The next lemma is due to Perron [18] (see also [13] and [19]).

LEMMA 4.4. *Let* $\mathbf{A}\in\mathbb{M}_n(\mathbb{F})$. *If* $\mathbf{X}_\mathbf{A}$ *is a fundamental matrix for* $\mathscr{P}_\mathbf{A}$, *then there exist a unitary matrix* $\mathbf{U}\in\mathbb{M}_n(\mathbb{F})$ *and a nonsingular upper-triangular matrix* $\mathbf{T}\in\mathbb{M}_n(\mathbb{F})$ *such that* $\mathbf{X}_\mathbf{A}=\mathbf{U}\mathbf{T}$.

Proof of Theorem 4.6. Let $\mathbf{A}, \mathbf{X}_\mathbf{A}, \mathbf{U}$, and $\mathbf{T}$ be matrices as given in Lemma 4.4. Let $\mathbf{B}=\mathbf{T}^{-1}\dot{\mathbf{T}}$. Then $\mathbf{B}$ is upper triangular and $\mathbf{X}_\mathbf{B}=\mathbf{T}$. By Theorem 4.4, $\mathbf{B}=\mathbf{U}^{-1}\mathbf{A}\mathbf{U}-\mathbf{U}^{-1}\dot{\mathbf{U}}$. Now by Lemma 4.3, there exists a D-similarity transformation matrix $\mathbf{L}_1\in\mathbb{M}_n(\mathbb{F})$ such that $\mathbf{L}_1^{-1}\mathbf{B}\mathbf{L}_1-\mathbf{L}_1^{-1}\dot{\mathbf{L}}_1=\mathbf{D}_1$, where $\mathbf{D}_1$ is a diagonal matrix. Since $|\det\mathbf{U}|=1$, we can, taking the principal branch, define $\xi(t)=\det\mathbf{U}(t)^{-1/n}$. Now let $\mathbf{L}=\xi\mathbf{U}\mathbf{L}_1$. Then $\det\mathbf{L}=\det\mathbf{L}_1$, and $\mathbf{L}^{-1}\mathbf{A}\mathbf{L}-\mathbf{L}^{-1}\dot{\mathbf{L}}=\mathbf{D}_1-\xi^{-1}\dot{\xi}\mathbf{I}=\mathbf{D}$ is a diagonal matrix. The theorem hence follows from Theorems 4.5 and 4.1. □

Remarks. Theorem 4.6 is an exciting theoretical result and has immediate applications in the semiproper reducible systems (1.1) defined by Definition 1.2. However, there are limitations to the practical application of this technique because procedures for finding the primary D-similarity transformations for the reduction of linear systems

(1.1) with coefficient matrices $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$ involve, in general, solving systems of Riccati-type nonlinear differential equations that are usually as difficult to solve as the original ones. These limitations are significantly reduced by the following important result.

THEOREM 4.7. *For every matrix* $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$, *there exist a unitary matrix* $\mathbf{U} \in \mathbb{M}_n(\mathbb{F})$, *and a Hermitian matrix* $\mathbf{H} \in \mathbb{M}_n(\mathbb{F})$, *such that* $\mathbf{H} = \mathbf{U}^*\mathbf{A}\mathbf{U} - \mathbf{U}^*\dot{\mathbf{U}} = \mathbf{U}^* \operatorname{Re}\{\mathbf{A}\}\mathbf{U}$.

Proof. Let $\mathbf{A} \in \mathbb{M}_n(\mathbb{F})$. For convenience, let $\mathbf{A}_R = \operatorname{Re}\{\mathbf{A}\}$, and $\mathbf{A}_I = i \operatorname{Im}\{\mathbf{A}\}$. Since $\mathbf{A}_I$ is skew-Hermitian, by Theorem 3.3, there exists a unitary matrix $\mathbf{U}$ such that $\dot{\mathbf{U}} = \mathbf{A}_I\mathbf{U}$. Thus, $\mathbf{H} = \mathbf{U}^*\mathbf{A}\mathbf{U} - \mathbf{U}^*\dot{\mathbf{U}} = \mathbf{U}^*(\mathbf{A} - \mathbf{A}_I)\mathbf{U} = \mathbf{U}^*\mathbf{A}_R\mathbf{U}$. Note that $\mathbf{A}_R$ is Hermitian, and it is readily verified that $\mathbf{H}$ is also Hermitian. □

Remark. The importance of Theorem 4.7 lies in the fact that instead of investigating D-similarity transformations for a *general* matrix $\mathbf{A}$, we need to study such transformations only for the two *normal* matrices $\mathbf{A}_I$ and $\mathbf{H} = \mathbf{U}^*\mathbf{A}_R\mathbf{U}$, where $\mathbf{U}$ satisfies $\dot{\mathbf{U}} = \mathbf{A}_I\mathbf{U}$. That is, a procedure for finding D-similarity transformations for normal matrices is, in general, all that is needed. This result, when applied to the reduction of linear systems (1.1), enables us to "decompose" a general system (1.1) with coefficient matrix $\mathbf{A}(t)$ into two normal systems, i.e., a skew-Hermitian system defined by $\mathbf{A}_I(t)$, and a Hermitian system defined by $\mathbf{H}(t)$. The solution of the original system can then be expressed, by Theorem 3.2, as $\mathbf{X}_\mathbf{A} = \mathbf{U}\mathbf{X}_\mathbf{H}$. Therefore it suffices to investigate only the reduction problem for normal systems.

5. Reducible systems and reducibility. Some examples. In this section, the results obtained in the preceding section are applied to semiproper reducible linear dynamical systems (1.1) defined by Definition 1.2. Note that although the matrices $\mathbf{A}(t)$ considered in the previous section are assumed to be of class $\mathbf{C}^\infty$ almost everywhere on an interval I, that requirement is not essential when we are interested in solving a particular case of (1.1). Namely, from the proof of Theorem 4.6 it can be seen that, in a specific problem, $\mathbf{A}(t)$ is only required to be locally Lebesgue integrable. Moreover, if $\mathbf{A}(t)$ is upper-triangular, it is only necessary that the D-similarity transformation matrix $\mathbf{L}(t)$ be over a ring of finitely differentiable functions. In this sense, therefore, we can relax our results obtained over a differential field to what we called "well-defined" matrices in Definition 1.2 and Theorems 1.1 and 1.3. With this remark, Theorems 1.1–1.3 follow immediately from Theorems 4.5 and 4.6. We are now in a position to establish the following fundamental result of this paper which characterizes the solutions of semiproper reducible systems (1.1).

THEOREM 5.1. *A system* (1.1) *is semiproper reducible if and only if for any* $t_0 \in I$ *and* $\mathbf{x}(t_0) \in \mathbb{V}_c$, *the solution to* (1.1) *can be written as*

$$\mathbf{x}(t) = \mathbf{L}(t) \exp\left[\int_{t_0}^{t} \mathbf{B}(\tau)\, d\tau\right] \mathbf{L}^{-1}(t_0)\mathbf{x}(t_0) \tag{5.1}$$

for some sufficiently differentiable matrix function $\mathbf{L}(t)$ *with nonzero constant determinant and for some locally integrable matrix* $\mathbf{B}(t)$.

Proof. Suppose that there exist a locally integrable $\mathbf{B}(t)$ and a sufficiently differentiable $\mathbf{L}(t)$ with nonzero constant determinant such that (5.1) is satisfied. Let $\mathbf{y}(t) = \mathbf{L}^{-1}(t)\mathbf{x}(t)$; then

$$\mathbf{x}(t) = \mathbf{L}(t)\mathbf{y}(t). \tag{5.2}$$

Substituting (5.2) into (1.1) and (5.1) yields

$$\begin{aligned} \dot{\mathbf{y}}(t) &= [\mathbf{L}^{-1}(t)\mathbf{A}(t)\mathbf{L}(t) - \mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t)]\mathbf{y}(t) \\ &= \mathbf{B}_0(t)\mathbf{y}(t), \end{aligned} \tag{5.3}$$

$$\mathbf{y}(t_0) = \mathbf{L}^{-1}(t_0)\mathbf{x}(t_0), \qquad t_0 \in I, \tag{5.4}$$

$$
\begin{aligned}
y(t) &= \left[\exp \int_{t_0}^{t} \mathbf{B}(\tau)\, d\tau\right] \mathbf{y}(t_0) \\
&= \left[\sum_{k=0}^{\infty} \frac{1}{k!}\left[\int_{t_0}^{t} \mathbf{B}(\tau)\, d\tau\right]^k\right] \mathbf{y}(t_0).
\end{aligned} \tag{5.5}
$$

Note that the power series in (5.5) is uniformly convergent. Thus, differentiating (5.5) and comparing with (5.3) term by term yields

$$
\begin{aligned}
&\mathbf{B}_0(t) = \mathbf{B}(t), \\
&\mathbf{B}(t) \int_{t_0}^{t} \mathbf{B}(\tau)\, d\tau = \int_{t_0}^{t} \mathbf{B}(\tau)\, d\tau\, \mathbf{B}(t),
\end{aligned}
$$

for any $t_0 \in I$. Therefore, by a result of Martin [16, Thm. 1] we conclude that $\mathbf{B}(t)$ is semiproper, and consequently the given system (1.1) is semiproper reducible.

The converse is a straightforward consequence of Theorems 4.4 and 3.2. □

The remark following Definition 1.2 regarding the relationship between Lyapunov reducibility and the semiproper reducibility can now be formally stated and proven as follows.

THEOREM 5.2. *Every Lyapunov reducible system* (1.1) *is semiproper reducible.*

Proof. Suppose that system (1.1) is Lyapunov reducible and $\mathbf{L}(t)$ and $\mathbf{B}$ are as given in Definition 1.1. Since $0 < N < |\det \mathbf{L}(t)|$, we can by taking the principal branch, define $\xi(t) = (\det \mathbf{L}(t))^{1/n}$. Now let $\mathbf{L}_0(t) = \xi^{-1}(t)\mathbf{L}(t)$, then $\det \mathbf{L}_0(t) = 1$. Thus $\mathbf{L}_0(t)$ is a D-similarity transformation matrix. Moreover, let $\beta(t) = \dot{\xi}(t)/\xi(t)$; then

$$
\begin{aligned}
\mathbf{B}(t) &= \mathbf{L}_0^{-1}(t)\mathbf{A}(t)\mathbf{L}_0(t) - \mathbf{L}_0^{-1}(t)\dot{\mathbf{L}}_0(t) \\
&= \mathbf{L}^{-1}(t)\mathbf{A}(t)\mathbf{L}(t) - \mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t) + \beta(t)\mathbf{I} \\
&= \mathbf{B} + \beta(t)\mathbf{I},
\end{aligned}
$$

which is readily verified to be semiproper. □

Some illustrative examples. In the remainder of this section we work some specific examples to illustrate the application and limitations of our results.

Example 5.1. Consider the system (1.1) with an upper-triangular $\mathbf{A}(t)$ given by

$$
\mathbf{A}(t) = \begin{bmatrix}
2t & -(2t+\cos t)\, e^{-\sin t - \cos t} & (\cos t + \sin t)\, e^{-\cos t - e^{-t}} \\
0 & -\sin t & (\cos t + \sin t)\, e^{\sin t - e^{-t}} \\
0 & 0 & -e^{-t}
\end{bmatrix}.
$$

According to the inductive proof of Lemma 4.2, let

$$
\mathbf{L}_1 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & l_{23} \\ 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{L}_1^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & -l_{23} \\ 0 & 0 & 1 \end{bmatrix}, \quad \dot{\mathbf{L}}_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & \dot{l}_{23} \\ 0 & 0 & 0 \end{bmatrix},
$$

where $l_{23}(t)$ can be bound by formulas (4.4) and (4.5) as

$$
l_{23}(t) = \phi_{23}(t) \int \phi_{23}^{-1}(t) a_{23}(t)\, dt = e^{\sin t - e^{-t}},
$$

where

$$
\phi_{23}(t) = \exp\left\{\int [a_{22}(t) - a_{33}(t)]\, dt\right\} = e^{\cos t - e^{-t}};
$$

then

$$\mathbf{B} = \mathbf{L}_1^{-1}\mathbf{A}\mathbf{L}_1 - \mathbf{L}_1^{-1}\dot{\mathbf{L}}_1 = \left[\begin{array}{c|cc} a_{11} & a_{12} & a_{13}+l_{23}a_{12} \\ \hline 0 & a_{22} & 0 \\ 0 & 0 & a_{33} \end{array}\right].$$

Now let

$$\mathbf{L}_2 = \begin{bmatrix} 1 & l_{12} & l_{13} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{L}_2^{-1} = \begin{bmatrix} 1 & -l_{12} & -l_{13} \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \dot{\mathbf{L}}_2 = \begin{bmatrix} 0 & \dot{l}_{12} & \dot{l}_{13} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

where l_{12} and l_{13} are found to be

$$l_{12}(t) = \phi_{12}(t) \int \phi_{12}^{-1}(t) b_{12}(t)\, dt = e^{-\sin t - \cos t},$$

$$l_{13}(t) = \phi_{13}(t) \int \phi_{13}^{-1}(t) b_{13}(t)\, dt = e^{-\cos t - e^{-t}},$$

where

$$\phi_{12}(t) = \exp\left\{\int [a_{11}(t) - a_{22}(t)]\, dt\right\} = e^{t^2 - \cos t},$$

$$\phi_{13}(t) = \exp\left\{\int [a_{11}(t) - a_{33}(t)]\, dt\right\} = e^{t^2 - e^{-t}}.$$

Then

$$\begin{aligned} \mathbf{D}(t) &= \mathbf{L}_2^{-1}(t)\mathbf{B}(t)\mathbf{L}_2(t) - \mathbf{L}_2^{-1}(t)\dot{\mathbf{L}}_2(t) \\ &= \operatorname{diag}[a_{11}(t), a_{22}(t), a_{33}(t)] \\ &= \operatorname{diag}[2t, -\sin(t), -e^{-t}]. \end{aligned}$$

Now let $\mathbf{L} = \mathbf{L}_1\mathbf{L}_2$; then

$$\mathbf{L} = \begin{bmatrix} 1 & l_{12} & l_{13} \\ 0 & 1 & l_{23} \\ 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{L}^{-1} = \begin{bmatrix} 1 & -l_{12} & l_{12}l_{23} - l_{13} \\ 0 & 1 & -l_{13} \\ 0 & 0 & 1 \end{bmatrix}, \quad \dot{\mathbf{L}} = \begin{bmatrix} 0 & \dot{l}_{12} & \dot{l}_{13} \\ 0 & 0 & \dot{l}_{23} \\ 0 & 0 & 0 \end{bmatrix}.$$

We see that $\mathbf{L}^{-1}\mathbf{A}\mathbf{L} - \mathbf{L}^{-1}\dot{\mathbf{L}} = \mathbf{D}$. Denote by $\mathbf{X}_\mathbf{D}$ a fundamental matrix associated with D; then

$$\begin{aligned} \mathbf{X}_\mathbf{D}(t) &= \operatorname{diag}\left[\exp\int d_{11}(t)\, dt, \exp\int d_{22}(t)\, dt, \exp\int d_{33}(t)\, dt\right] \\ &= \operatorname{diag}[e^{t^2}, e^{\cos t}, e^{e^{-t}}]. \end{aligned}$$

By Theorem 4.4, a fundamental matrix $\mathbf{X}_\mathbf{A}$ for (1.1) with the given $\mathbf{A}(t)$ is found to be

$$\begin{aligned} \mathbf{X}_\mathbf{A}(t) &= \mathbf{L}(t)\mathbf{X}_\mathbf{D}(t) \\ &= \begin{bmatrix} e^{t^2} & e^{-\sin t} & e^{-\cos t} \\ 0 & e^{\cos t} & e^{\sin t} \\ 0 & 0 & e^{e^{-t}} \end{bmatrix}. \end{aligned}$$

As a special case of Lemma 4.2, every linear system (1.1) with a Jordan coefficient matrix $\mathbf{A}(t)=\mathbf{J}(t)$ can be reduced to a diagonal system by primary D-similarity transformations. The next example demonstrates this idea with a Jordan block of order 3.

Example 5.2. Consider the Jordan block of order 3:

$$\mathbf{J}(t)=\begin{bmatrix}\lambda(t) & 1 & 0\\ 0 & \lambda(t) & 1\\ 0 & 0 & \lambda(t)\end{bmatrix}.$$

By the technique illustrated in Example 5.1, we can find a D-similarity transformation $\mathbf{L}$ such that

$$\mathbf{L}(t)=\begin{bmatrix}1 & t & t^2/2\\ 0 & 1 & t\\ 0 & 0 & 1\end{bmatrix},\quad \mathbf{L}^{-1}(t)=\begin{bmatrix}1 & -t & t^2/2\\ 0 & 1 & -t\\ 0 & 0 & 1\end{bmatrix},\quad \dot{\mathbf{L}}_2(t)=\begin{bmatrix}0 & 1 & t\\ 0 & 0 & 1\\ 0 & 0 & 0\end{bmatrix}.$$

Then

$$\begin{aligned}\mathbf{D}(t)&=\mathbf{L}^{-1}(t)\mathbf{B}(t)\mathbf{L}(t)-\mathbf{L}^{-1}(t)\dot{\mathbf{L}}(t)\\ &=\operatorname{diag}[\lambda(t),\lambda(t),\lambda(t)].\end{aligned}$$

The following example demonstrates a limitation of the primary D-similarity transformation technique for the reduction of linear systems (1.1).

Example 5.3. Consider a general second-order linear system (1.1) with $\mathbf{A}=[a_{ij}]\in \mathbb{M}_n(\mathbb{F})$. Suppose we attempt to reduce $\mathbf{A}(t)$ to an upper-triangular matrix by letting

$$\mathbf{L}_1=\begin{bmatrix}1 & 0\\ l_{21} & 1\end{bmatrix}.$$

By formula (4.2), in the matrix $\mathbf{B}=\mathbf{L}_1^{-1}\mathbf{A}\mathbf{L}_1-\mathbf{L}_1^{-1}\dot{\mathbf{L}}_1=[b_{ij}]$ we should set

$$b_{21}=a_{21}+(a_{22}-a_{11})l_{21}-a_{12}l_{21}^2-\dot{l}_{21}=0.$$

However, this latter condition yields the following nonlinear Riccati equation with time-varying coefficients $a_{ij}(t)$:

$$\dot{l}_{21}=a_{21}+(a_{22}-a_{11})l_{21}-a_{12}l_{21}^2,$$

which may be as difficult to solve as the original equation.

6. Summary and conclusions. A century ago Lyapunov introduced the notion of reducing a linear differential equation (1.1) with a "time-varying" coefficient matrix $\mathbf{A}(t)$ to one with a constant coefficient matrix. Since that time a great deal of research effort has been devoted to the qualitative analysis of reducible systems and procedures for construction of the reduction transformations. As a consequence, it appears that today there is not much room for further developments within the original confines of Lyapunov's reduction technique.

Inspired by recent results [26]–[29], [34], [35] for obtaining explicit solutions for time-varying semiproper systems (1.1), the present paper has formally extended the family of Lyapunov reducible systems to include those systems that can be reduced to semiproper ones via D-similarity transformations. We call such systems "semiproper reducible." Within this new framework for reducibility studies, we have defined primary D-similarity transformations, and have proven that every "well-defined" linear system (1.1) is semiproper reducible by a finite sequence of primary D-similarity transformations. We have also presented an explicit technique for constructing such transformations for systems (1.1) with virtually triangular coefficient matrices.

From the results in [26]–[29], and in the present paper, the family of time-varying linear systems which is now analytically solvable consists of all systems (1.1) with virtually triangular coefficient matrices $\mathbf{A}(t) = \mathbf{L}\mathbf{T}(t)\mathbf{L}^{-1}$. This family includes the special cases of (i) *time-invariant*, (ii) *time-varying proper*, and (iii) *time-varying semiproper* systems (1.1) and can be summarized as follows:

$$\left\{\begin{array}{c}\text{Constant}\\ \text{coefficient}\\ \mathbf{A}(t)=\mathbf{A}\end{array}\right\} \subset \left\{\begin{array}{c}\text{Proper}\\ \mathbf{A}(t)=f(t,\mathbf{A})\end{array}\right\} \subset \left\{\begin{array}{c}\text{Semiproper}\\ \mathbf{A}(t)\mathbf{A}(\tau)=\mathbf{A}(\tau)\mathbf{A}(t)\end{array}\right\} \subset \left\{\begin{array}{c}\text{Virtually triangular}\\ \text{coefficient}\\ \mathbf{A}(t)=\mathbf{L}\mathbf{T}(t)\mathbf{L}^{-1}\end{array}\right\}.$$

The last inclusion follows from a result due to Martin [16], which states that every semiproper (functionally commutative) matrix is virtually triangular. Now, by virtue of Theorem 4.7, the reduction of a general linear system (1.1) can be achieved by the reduction of two normal subsystems. Therefore, *the only family of linear systems* (1.1) *that needs further investigations, in terms of solvability, is that of the normal systems* (1.1).

As a byproduct of achieving our main results (Theorems 1.1–1.3, 4.5–4.7, 5.1, 5.2, and Lemma 4.3 and its corollary), we have also obtained some important and interesting new results in the theory of matrices over a differential field, among which are the notions of partial spaces and partially linear operators; the introduction of LDE operators and associated D-eigenvalues, D-eigenvectors, and D-similarity transformations; and Theorems 3.1, 3.3, 4.2, and 4.3, Lemmas 4.1 and 4.2, and Corollary 4.1.

Example 5.3 in § 5 of this paper has been presented to illustrate a limitation of the proposed technique for constructing D-similarity transformations for reduction of general linear systems (1.1). However, other approaches to such problems are currently being investigated, and these alternative approaches may circumvent those limitations. Further characterizations of D-similarity transformations and qualitative properties of the solutions of semiproper reducible systems are other topics currently being investigated. Results from these investigations will appear in forthcoming papers.

GENERALIZED REACHABILITY SUBSPACES FOR SINGULAR SYSTEMS*

K. ÖZCALDIRAN† AND F. L. LEWIS‡

Abstract. One of the most important concepts of the geometric theory for proper linear systems is that of the controllability subspaces of (A, B). In an attempt to extend this concept to singular systems, it became clear that the nonequivalence of reachability and controllability for singular systems makes it necessary to define both controllability and reachability subspaces of (E, A, B) as different, though naturally related, entities.

A subspace $\mathbf{R}$ (respectively, $\mathbf{C}$) is defined to be a *generalized reachability subspace* (respectively, *generalized controllability subspace*) if there exist linear maps F and G, such that $\mathbf{R}$ (respectively, $\mathbf{C}$) is the reachable (respectively, controllable) subspace of a regular singular system $E\dot{x} = (A + BF)x + BGv$. It is proved that (1) $\mathbf{R}$ is a generalized reachability subspace if and only if it is a (generalized) $(A, E, \mathbf{B})$-invariant almost reachability subspace; (2) every subspace $\mathbf{K}$ contains a unique supremal generalized reachability subspace $\mathbf{R}^*(\mathbf{K})$; and (3) a subspace $\mathbf{C} \subset \mathbf{Im}\, \mathbf{E}$ is a generalized controllability subspace if and only if $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{K})$. In the case where $\mathbf{R}$ is a generalized reachability subspace, the F and G matrices that make $\mathbf{R}$ the reachable subspace of the closed-loop system are constructed explicitly. Spectral assignability properties of generalized reachability and controllability subspaces are also treated. For completeness, all results are finally extended to the nonregular case (i.e., $\det(sE - A) = 0$).

Key words. singular systems, descriptor systems, geometrical system theory, reachability subspaces, controllability subspaces

1. Introduction.

In recent years, the study of generalized or singular systems of the form $E\dot{x} = Ax + Bu$, with E generally singular, has become of interest (see references). Indeed, the study of singular pencils of matrices of the form $sE - A$ has been of mathematical interest since the writings of Weierstrass in 1867 [25] and Kronecker in 1890 [6]. (See [5] and [26] for a summary of their work.)

There are many reasons for the current revival of singular systems. They arise more naturally than state-space systems in the study of naturally occurring systems, such as in power, economics [10], [11], neural networks [16], and circuit theory [14]; in the last instance, they may additionally be used to model hysteresis [15]. They also provide a convenient form for the dynamical equations of large-scale interconnected systems [21]. Even the usual state and costate equations for optimal control are singular if the control weighting matrix is singular [1]. For a survey of linear singular systems, see [9].

Although, under certain conditions, some semistate variables may be eliminated to reduce the system to the usual state-space formulation, there are several good reasons for not doing so. Among these is the loss of sparsity, both in the system matrices and of the physical meaning of the variables. Some cases where the state equations do not exist may also be useful from a physical point of view.

Moreover, the state-space formulation has some notorious deficiencies. For example, these systems are closed under neither system inversion, where derivatives of the output are generally required, nor derivative feedback, which classical control theory has shown to be useful in many cases.

It is, therefore, desirable to extend the state-space techniques of design, which have been so successful in the control of dynamical systems, to the singular case.

Unfortunately, in so doing we find a major problem. Even if a singular system is well defined (i.e., $\det(sE - A \not\equiv 0)$ so that there exist unique solutions $x(t)$ for all $x(0)$ and suitable $u(t)$), it may be ill defined after the application of feedback of the proportional $(sE-(A+BF))$ or derivative $(s(E-BK)-A)$ sort. Therefore, the extension of state-space results is notoriously difficult.

In [23], a group-theoretic approach was used to extend the state-space geometric theory to singular systems, providing solutions to many design problems for these systems. However, because the feedback used was of a constrained form (e.g., "constant-ratio proportional-plus-derivative" (CRPD)), all of the limitations of state-space systems, such as the two mentioned above, were also extended to singular systems.

Our goal in writing this paper was to provide a rigorous foundation for a geometric theory for singular systems under proportional feedback (since such a feedback is generally easier to implement than proportional-plus-derivative feedback). This case is more difficult to deal with than the CRPD case. To achieve our goal, we rigorously define some basic geometric entities for these systems, exploring their properties, and examining some important distinctions that do not occur in the state-space case.

For simplicity in the following, we assume a regular (i.e., well-defined) system. Then, for completeness, at the end of the paper we extend all results to the nonregular case.

Let $\mathbf{X}$ and $\mathbf{U}$ be finite-dimensional vector spaces and let $A:\mathbf{X}\to\mathbf{X}$ and $B:\mathbf{U}\to\mathbf{X}$ be linear maps. A subspace $\mathbf{R}\subset\mathbf{X}$ is said to be a *reachability subspace* of the pair (A, B) if there exist two linear maps $F:\mathbf{X}\to\mathbf{U}$ and $G:\mathbf{U}\to\mathbf{U}$ such that $\mathbf{R}$ is the reachable subspace of the linear, time-invariant system defined by $(A+BF, BG)$ [28].

The notion of reachability subspaces of (A, B) has been demonstrated to be a very applicable as well as versatile tool in analysis and synthesis for linear systems, and consequently, it remains one of the major achievements of linear system theory. For a thorough discussion of the reachability subspaces and of the practical problems to which the concept has been successfully applied, the reader is referred to the classical text by Wonham [28].

One of the major results of the geometric system theory answers the question: Exactly when is a given subspace $\mathbf{R}\subset\mathbf{X}$ a reachability subspace of (A, B)?

THEOREM 1.1 [28]. *Let* $\mathbf{B}$ *denote the image of* B. $\mathbf{R}\subset\mathbf{X}$ *is a reachability subspace of* (A, B) *if and only if*:

(1) $A\mathbf{R}\subset\mathbf{R}+\mathbf{B}$;

(2) $\mathbf{R}=\lim_k \mathbf{S}_k$, *where* $\mathbf{S}_k$ *is defined by* $\mathbf{S}_{k+1}=\mathbf{R}\cap\{A\mathbf{S}_k+\mathbf{B}\}$; $\mathbf{S}_0=0$.

It is the aim of this paper to show that the pioneering work of Wonham and Morse on reachability subspaces can be extended to encompass the linear, time-invariant singular system

$$E\dot{x}(t)=Ax(t)+Bu(t) \tag{1.1}$$

where $x(t)\in\mathbf{X}$, $u(t)\in\mathbf{U}$, and E, A, and B are linear maps with $\det(E)$ possibly equal to zero. For a discussion of the diversified disciplines where singular systems do arise naturally, see [1], [9]. If the constant-ratio proportional-plus-derivative feedback $u=F(x\cos\theta-\dot{x}\sin\theta)$ (with θ a parameter) is allowed, the extension of geometric notions to singular systems is straightforward [23]. However, our aim is to use only proportional feedback (i.e., $K=0$). In this case, as we shall see, the situation is far more challenging.

Now, let α be the index of nilpotency of E and let $C^{\alpha-1}$ and $C_p^{\alpha-1}$ denote the spaces of $(\alpha-1)$ times continuously differentiable and $(\alpha-1)$ times piecewise continuously differentiable mappings of $\mathbf{R}$ into $\mathbf{U}$, with $\mathbf{R}$ the real numbers. We consider both spaces as embedded subspaces of D', the space of distributions on $\mathbf{R}$ (with range space in $\mathbf{X}$). We also let D'_p denote the space of piecewise continuous distributions (again, with range space in $\mathbf{X}$).

Equation (1.1), or simply the pair (E, A), is said to be *regular* [5] if $\det(\lambda E - A) \not\equiv 0$. It will be our standing assumption throughout the paper that (1.1) is a regular system. Given any initial condition $x(0) = x_0$ and any $u \in C_p^{\alpha-1}$, there exists a unique distributional solution $x \in D'_p$ of (1.1) if and only if (1.1) is regular. Then, $x \in D'_p$ is the solution of (1.1) in the following sense. If x_+ and u_+ denote the (unique) restrictions of x and u to $[0, \infty)$ and if $x[\tau]$ denotes the impulsive part of x at τ (as defined in [3]), then $E\dot{x}_+ = Ax_+ + Bu_+ + \delta E x_0$, $x(0) = x_0$, and $E\dot{x}[\tau] = Ax[\tau] - \delta E \Delta_\tau x$, where δ is the Dirac delta and $\Delta_\tau x$ is the jump in x at τ. For imporous definitions of these entities and for details, see [3] and also [2], [24].

Here we would like to point out that this formulation renders both of the feedback laws $u = Fx + v$ and $u = K\dot{x} + Fx + v$, $v \in C_p^{\alpha-1}$ as admissible inputs.

Noting that it is really Ex_0 rather than x_0 that determines x_+, we say that a point $y \in X$ is *reachable* from $Ex_0 \in EX$ if there exists $u \in C^{\alpha-1}$ and $T > 0$ such that the solution $x(t)$ does not contain an impulsive part on $[0, T)$, is continuously differentiable on $(0, T)$, and satisfies $x(T) = y$. It is shown in [17] that there exists a subspace, called the *reachable subspace* of (1.1) and denoted by $\langle E, A|\mathbf{B}\rangle$, such that $y \in \mathbf{X}$ can be reached from the origin if and only if $y \in \langle E, A|\mathbf{B}\rangle$. Similarly, the origin can be reached from an Ex_0 if and only if $Ex_0 \in E\langle E, A|\mathbf{B}\rangle$ [17]. Consequently, $E\langle E, A|\mathbf{B}\rangle$ is called the *controllable subspace* of (1.1). Equation (1.1) is called *reachable* if $\langle E, A|\mathbf{B}\rangle = \mathbf{X}$ and controllable if $E\langle E, A|\mathbf{B}\rangle = E\mathbf{X}$ (or, equivalently, if $\langle E, A|\mathbf{B}\rangle + \mathbf{Ker}\ \mathbf{E} = \mathbf{X}$). Reachability (respectively, controllability) is equivalent to the absence of both finite and infinite zeros of the pencil $[\lambda E - AB]$ in the sense of Rosenbrock (respectively, Verghese) [3], [8].

The question that will be posed and investigated in the sections to follow is: Given a subspace $R \subset \mathbf{X}$, how and when can two linear maps $F: \mathbf{X} \to \mathbf{U}$ and $G: \mathbf{U} \to \mathbf{U}$ be found so that (1) $(E, A + BF)$ is regular; and (2) $\mathbf{R}$ is the reachable subspace of $(E, A + BF, BG)$? Note that a careless choice of F may yield a closed-loop system that is not regular. As the definitions of reachability and controllability depend on regularity, we need to guarantee the regularity of the closed-loop system to be able to talk about its reachable subspace. If there exists F and G to yield $\mathbf{R} = \langle E, A + BF|\mathbf{BG}\rangle$ with $(E, A + BF)$ regular, then $\mathbf{R}$ will be denoted a *reachability subspace of* (E, A, B) or a *generalized reachability subspace.*

Naturally, we will also define a subspace $C \subset E\mathbf{X}$ to be a *controllability subspace of* (E, A, B) or a *generalized controllability subspace* if $\mathbf{C} = E\mathbf{R}$ for some generalized reachability subspace $\mathbf{R}$. It should be clear that once a characterization of generalized reachability subspaces is available, a similar characterization for generalized controllability subspaces follows immediately. Therefore, we will mainly be interested in a geometric characterization of generalized reachability subspaces.

Notation. In this paper, vector spaces and their subspaces are written in boldface capital letters. Vectors are denoted by lowercase and linear maps are denoted by uppercase letters. If $E: \mathbf{X} \to \mathbf{Y}$ is a linear map, then the image of E is written as $\mathbf{E}$. If $\mathbf{S} \subset \mathbf{Y}$, then $E^{-1}\mathbf{S}$ is the inverse image of E (i.e., $\{x \in X : Ex \in S\}$), and $\mathbf{Ker}\ \mathbf{E} = E^{-1}\mathbf{0}$. The restriction of E to a subspace $\mathbf{R}$ is written as $E|\mathbf{R}$, and $E|\mathbf{R}$ with restricted codomain $\mathbf{S}$ is denoted by $\mathbf{S}|E|\mathbf{R}$. If $\mathbf{R} \subset \mathbf{X}$, then $\mathbf{R}_\mathbf{E} := \mathbf{R} \cap \mathbf{Ker}\ \mathbf{E}$. If $\mathbf{S}$ is a vector space, then $d\mathbf{S}$

denotes its dimension. The symbol + stands for direct sum of subspaces (or of linear maps). If q is a positive integer, then $\underline{q}$ denotes the set $\{1, 2, \cdots, q\}$. If $\{S_K\}$ is a sequence of subspaces and if $\mathbf{S}$ is a subspace, then $\{\mathbf{S_K}\}\uparrow\mathbf{S}$ (respectively, $\{\mathbf{S_K}\}\downarrow\mathbf{S}$) means that $\{\mathbf{S_K}\}$ is nondecreasing (respectively, nonincreasing) and converges to $\mathbf{S}$. Where the operations of subspace intersection ($\cap$) and summation ($+$) occur without parentheses in a single expression (e.g., $\mathbf{RS}+\mathbf{T}$), we use the convention that the intersection is performed first. Finally, the reader should note that the shorthand notation A_F will sometimes be used for $A+BF$.

2. Background and problem formulation. Let $\mathbf{K}$ and $\mathbf{Q}$ be fixed but otherwise arbitrary subspaces of $\mathbf{X}$. A subspace $\mathbf{R} \subset \mathbf{K}$ is said to be an $(A, E, \mathbf{Q})$-*invariant subspace of* $\mathbf{K}$ if $\mathbf{AR} \subset E\mathbf{R}+\mathbf{Q}$. If $\mathbf{R}$ satisfies $\mathbf{R} = \mathbf{K} \cap E^{-1}(A\mathbf{R}+\mathbf{Q})$, then $\mathbf{R}$ is called a *restricted* $(E, A, \mathbf{Q})$-*invariant* (or, in short, an $(E, A, \mathbf{Q})_r$-inv.) *subspace of* $\mathbf{K}$. The class of all $(A, E, \mathbf{Q})$-inv. subspaces of $\mathbf{K}$ contains a unique supremal element $\mathbf{V}^*(A, E, \mathbf{Q}; \mathbf{K})$ [19]. The class of all $(E, A, \mathbf{Q})_r$-inv. subspaces of $\mathbf{K}$ contains a unique least member $\mathbf{S}_*(E, A, \mathbf{Q}; \mathbf{K})$ [19]. If $\mathbf{V_k}$ and $\mathbf{S_k}$ are defined by

$$\mathbf{V}_{k+1} = \mathbf{K} \cap A^{-1}(E\mathbf{V}_k + \mathbf{Q}), \qquad \mathbf{V}_0 = \mathbf{K}, \tag{2.1}$$

$$\mathbf{S}_{k+1} = \boldsymbol{K} \cap E^{-1}(A\mathbf{S}_k + \mathbf{Q}), \qquad \mathbf{S}_0 = \mathbf{K}\ \mathbf{Ker}\ \mathbf{E}, \tag{2.2}$$

then $\{\mathbf{V}_k\}\downarrow\mathbf{V}^*(A, E, \mathbf{Q}; \mathbf{K})$ and $\{\mathbf{S_k}\}\uparrow S_*(E, A, \mathbf{Q}; \mathbf{K})$ [19].

In the sequel, (2.1) and (2.2) will be performed with different maps and $\mathbf{Q}$'s. To economize in space, the following abbreviations will be used:

$$\mathbf{V}_0^* := \mathbf{V}^*(A, E, \mathbf{0}; \mathbf{X}), \qquad \mathbf{S}_*^0 := \mathbf{S}_*(E, A, \mathbf{0}; \mathbf{X}),$$

$$\mathbf{V}_{F,0}^* := \mathbf{V}^*(A+BF, E, \mathbf{0}; \mathbf{X}), \qquad \mathbf{S}_*^{F,0} := \mathbf{S}_*(E, A+BF, \mathbf{0}; \mathbf{X}),$$

$$\mathbf{V}^* := \mathbf{V}^*(A, E, \mathbf{B}; \mathbf{X}), \qquad \mathbf{S}_* := \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{X}),$$

$$\mathbf{V}_{F,G}^* := \mathbf{V}^*(A+BF, E, \mathbf{BG}; \mathbf{X}), \qquad \mathbf{S}_*^{F,G} := \mathbf{S}_*(E, A+BF, \mathbf{BG}; \mathbf{X}).$$

$\mathbf{V}_0^*$ and $\mathbf{S}_*^0$ were first studied in [27]. If $\sigma(E, A)$ denotes $\{\lambda \in C;\ \det(\lambda E - A) = 0\}$, then $\mathbf{V}_0^*$ is the direct sum of the eigenspaces corresponding to $\lambda \in \sigma(E, A)$ [17] and is called the *initial manifold* of (E, A) [27]; $\mathbf{S}_*^0$ on the other hand, is called the *final manifold* of (E, A) [27], and is the eigenspace corresponding to the unbounded eigenvalue of E and A [17]. The import of the analysis in [27] is the following theorem that presents what seems to be the only geometric test for the regularity of (E, A).

THEOREM 2.1 [27].

(1) (E, A) *is regular if and only if* $\mathbf{Ker}\ \mathbf{E} \cap \mathbf{V}_0^* = \mathbf{0}$;

(2) *If* (E, A) *is regular, then* $\mathbf{V}_0^* \oplus \mathbf{S}_*^0 = \mathbf{X}$;

(3) $\sigma(E, A) = \sigma(E|\mathbf{V}_0^*, A|\mathbf{V}_0^*)$ *and* $\mathrm{d}\mathbf{V}_0^* = \deg|\lambda E - A|$.

$\mathbf{V}^*$ and $\mathbf{S}_*$ have been defined in [19], where they have been shown to be instrumental in a coordinate-free characterization of the reachable subspace $\langle E, A|\mathbf{B}\rangle$ of (E, A, B). Generalizing Schumacher's algebraic characterization of almost invariance [22], Malabre has shown in [12] that if $Q = B$, then (2.2) generates the *supremal (generalized) almost reachability subspace contained in* $\mathbf{K}$. Thus, a subspace $\mathbf{R}$ that satisfies $\mathbf{R} = \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{R})$ will be said to be a (*generalized*) *almost reachability subspace.* The reader should also note the initial condition of the recursion (2.2), which was taken to be $\mathbf{0}$ in [19], has been modified in light of the analysis given in [12].

This change, however, does not affect the limit of the recursion. The main result of [19] is the following.

THEOREM 2.2 [19].

(1) $\langle E, A|\mathbf{B}\rangle = \mathbf{V}^* \cap \mathbf{S}_*$;

(2) $\langle E, A|\mathbf{B}\rangle = \mathbf{V}^*(A, E, \mathbf{B}; \mathbf{S}_*)$.

The following result was stated as a conjecture in [19].

THEOREM 2.3. $\langle E, A|\mathbf{B}\rangle = \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{V}^*)$.

Proof. See the Appendix for the proof.

An immediate consequence of Theorem 2.3 that will prove to be crucial in our discussion is given by the following corollary.

COROLLARY 2.1. $\langle E, A|\mathbf{B}\rangle = \mathbf{S}_*(E, A, \mathbf{B}; \langle E, A|\mathbf{B}\rangle)$. *That is, if* $\mathbf{S}_k$ *is defined by*

$$\mathbf{S}_{k+1} = \langle E, A|\mathbf{B}\rangle \cap E^{-1}\{A\mathbf{S}_k + \mathbf{B}\}, \qquad \mathbf{S}_0 = \langle E, A|\mathbf{B}\rangle \cap \mathbf{Ker}\ \mathbf{E}, \tag{2.3}$$

then $\{\mathbf{S}_k\} \uparrow \langle E, A|\mathbf{B}\rangle$.

Proof. Let $\mathbf{S}_k$ be defined by (2.3) and define $\tilde{S}_k$ by

$$\tilde{\mathbf{S}}_{k+1} = \mathbf{V}^* \cap E^{-1}\{A\tilde{S}_k + \mathbf{B}\}, \qquad \tilde{\mathbf{S}}_0 = \mathbf{V}^* \cap \mathbf{Ker}\ \mathbf{E},$$

then, by Theorem 2.3, $\{\tilde{\mathbf{S}}_k\} \uparrow \langle E, A|\mathbf{B}\rangle$. Hence, $\tilde{\mathbf{S}}_k \subset \langle E, A|\mathbf{B}\rangle$ for all k, and therefore

$$\tilde{\mathbf{S}}_{k+1} = \langle E, A|\mathbf{B}\rangle \cap \mathbf{V}^* \cap E^{-1}\{A\tilde{S}_k + \mathbf{B}\}. \tag{2.4}$$

Using Theorem 2.2(1) in (2.4), we have

$$\tilde{\mathbf{S}}_{k+1} = \langle E, A|\mathbf{B}\rangle E^{-1}\{A\tilde{\mathbf{S}}_k + \mathbf{B}\}.$$

Then, $\mathbf{S}_k = \tilde{\mathbf{S}}_k$ for all k. Consequently, $\lim_k \mathbf{S}_k = \lim_k \tilde{\mathbf{S}}_k$. That is, $\{\mathbf{S}_k\} \uparrow \langle E, A|\mathbf{B}\rangle$. □

In view of Theorems 2.1 and 2.2(1), the question of whether or not a given subspace $R \subset \mathbf{X}$ is a generalized reachability subspace can now be formulated as follows.

Problem formulation. Given $\mathbf{R} \subset \mathbf{X}$, find, if and when possible, two linear maps $F: \mathbf{X} \to \mathbf{U}$ and $G: U \to U$ so that if $\mathbf{V}^*_{F,0}$, $\mathbf{V}^*_{F,G}$, and $\mathbf{S}^{F,G}_*$ denote $\lim_k \mathbf{V}^k_{F,0}$, $\lim_k \mathbf{V}^k_{F,G}$, and $\lim_k \mathbf{S}^{F,G}_k$, respectively, where

$$\mathbf{V}^{k+1}_{F,0} = (A + BF)^{-1}E\mathbf{V}^k_{F,0}, \qquad \mathbf{V}^0_{F,0} = \mathbf{X}, \tag{2.5}$$

$$\mathbf{V}^{k+1}_{F,G} = (A + BF)^{-1}\{E\mathbf{V}^k_{F,G} + \mathbf{BG}\}, \qquad \mathbf{V}^0_{F,G} = \mathbf{X}, \tag{2.6}$$

$$\mathbf{S}^{F,G}_{k+1} = E^{-1}\{(A + BF)\mathbf{S}^{F,G}_k + \mathbf{BG}\}, \qquad \mathbf{S}^{F,G}_0 = \mathbf{Ker}\ \mathbf{E}, \tag{2.7}$$

then we have the following:

(1) $\mathbf{Ker}\ \mathbf{E} \cap \mathbf{V}^*_{F,0} = \mathbf{0}$;

(2) $\mathbf{R} = \mathbf{V}^*_{\mathbf{F},\mathbf{G}} \cap \mathbf{S}^{F,G}_*$.

The solution of this problem will involve a generalization of the notion of the *friends* of an (A, B)-invariant subspace [28] that will be discussed in § 3.

It is clear from the problem formulation that what is at hand is a set of two intertwined problems formulated by (1) and (2) above. The problem of choosing F to render $(E, A + BF)$ regular will be tackled in § 3. The latter problem, as given by (2), will be solved in § 4.

Before closing this section, we present three properties that will find very frequent applications in the sequel. Let $\mathbf{R}$, $\mathbf{S}$, and $\mathbf{Q}$ be subspaces of $\mathbf{X}$.

PROPERTY 2.1. *If* $\mathbf{R} \subset \mathbf{S}$, *then* $\mathbf{S} \cap (\mathbf{R} + \mathbf{Q}) = \mathbf{R} + \mathbf{S} \cap \mathbf{Q}$. *This is* (3.1.b) of [28, p. 4].

PROPERTY 2.2. $E^{-1}(\mathbf{R} + \mathbf{S}) = E^{-1}\mathbf{R} + E^{-1}\mathbf{S}$ *if and only if* $\mathbf{E} \cap (\mathbf{R} + \mathbf{S}) = \mathbf{E} \cap \mathbf{R} + \mathbf{R} \cap \mathbf{S}$. (See [28, p. 8].)

PROPERTY 2.3. $\mathbf{R} \cap E^{-1}(A\mathbf{S} \cap E\mathbf{R} + \mathbf{Q}) = \mathbf{R} \cap E^{-1}A\mathbf{S} + \mathbf{R} \cap E^{-1}\mathbf{Q}$.

Proof. By Property 2.2,

$$\begin{aligned}\mathbf{R}\cap E^{-1}(A\mathbf{S}\cap E\mathbf{R}+\mathbf{Q}) &= \mathbf{R}\cap\{E^{-1}(A\mathbf{S}\cap E\mathbf{R})+E^{-1}\mathbf{Q}\}\\ &= \mathbf{R}\cap\{E^{-1}A\mathbf{S}\cap E^{-1}E\mathbf{R}+E^{-1}\mathbf{Q}\}\\ &= \mathbf{R}\cap\{E^{-1}A\mathbf{S}\cap(\boldsymbol{R}+\mathbf{Ker\ E})+E^{-1}\mathbf{Q}\}.\end{aligned}$$

$\mathbf{Ker\ E}\subset E^{-1}A\mathbf{S}$ and therefore, by Property 2.1,

$$\begin{aligned}\mathbf{R}\cap E^{-1}(A\mathbf{S}\cap E\mathbf{R}+\mathbf{Q}) &= \mathbf{R}\cap\{E^{-1}A\mathbf{S}\cap\mathbf{R}+\mathbf{Ker\ E}+E^{-1}\mathbf{Q}\}\\ &= \mathbf{R}\cap\{E^{-1}A\mathbf{S}\cap\mathbf{R}+E^{-1}\mathbf{Q}\}.\end{aligned}$$

Applying Property 2.1 one more time,

$$= \mathbf{R}\cap E^{-1}A\mathbf{S}+\mathbf{R}\cap E^{-1}\mathbf{Q}. \qquad \square$$

3. Friends and regular friends of an (A, E, B)-invariant subspace. We start our discussion by recalling that a linear map is said to be a "friend" of an $(A, \mathbf{B})$-inv. subspace $\mathbf{V}$ if $(A+BF)\mathbf{V}\subset\mathbf{V}$ [28]. A naive generalization of the notion of "friends" of an $(A, \mathbf{B})$-inv. subspace [28] motivates the definition of a linear map $F:\mathbf{X}\to\mathbf{U}$ as a friend of a given subspace $R\subset\mathbf{X}$ if $(A+BF)\mathbf{R}\subset E\mathbf{R}$. Let $\mathbf{F}(\mathbf{R})$ denote the class of all friends of $\mathbf{R}$. It follows easily that $\mathbf{F}(\mathbf{R})\neq\phi$ if and only if $\mathbf{R}$ is $(A, E, \mathbf{B})$-inv.

The necessity of choosing F to make $(E, A+BF)$ regular, and the following proposition, which states that some friends of $\mathbf{R}$ may be "bad friends," severely limit the applicability of the notion of "friends" to singular systems.

PROPOSITION 3.1. *Let* $\mathbf{R}$ *be* $(A, E, \mathbf{B})$*-invariant. If* $\mathbf{R}\cap\mathbf{Ker\ E}\neq\mathbf{0}$ *and if* $F\in\mathbf{F}(\mathbf{R})$, *then* $(E, A+BF)$ *is not regular.*

Proof. Define $\mathbf{R}_E := \mathbf{R}\cap\mathbf{Ker\ E}$ and assume $\mathbf{R}_E\neq\mathbf{0}$. If $F\in\mathbf{F}(\mathbf{R})$, then $(A+BF)\mathbf{R}$ $E\mathbf{R}$; that is, $\mathbf{R}$ is $(A+BF, E, \mathbf{0})$-inv. As $\mathbf{V}^*_{F,0}$ is the supremal $(A+BF, E, \mathbf{0})$-inv. subspace of $\mathbf{X}$, R $\mathbf{V}^*_{F,0}$. Therefore, $\mathbf{Ker\ E}\cap\mathbf{V}^*_{F,0}\supset\mathbf{R}_E\neq\mathbf{0}$ and, by Theorem 2.1(1), $(E, A+BF)$ is not regular. $\square$

We remark that in general we cannot expect that $\mathbf{R}\cap\mathbf{Ker\ E}=\mathbf{0}$. To remedy the situation, the following definition is introduced. It will become clear in the sequel that the central role played by friends of an $(A, \mathbf{B})$-inv. subspace in the analysis of reachability subspaces of (A, B) will, in the context of singular systems, be played by *regular friends* of an $(A, E, \mathbf{B})$-inv. subspace, as next defined.

DEFINITION 3.1. A linear map $F:\mathbf{X}\to\mathbf{U}$ is called a *regular friend* of a subspace $\mathbf{R}\subset\mathbf{X}$ if (1) $(E, A+BF)$ is regular; and (2) F is a friend of $\mathbf{R}_1$ for some $\mathbf{R}_1$ satisfying $\mathbf{R}=\mathbf{R}_1\oplus\mathbf{R}_E$.

The class of all regular friends of $\mathbf{R}$ will be denoted by $\mathbf{RF}(\mathbf{R})$. Clearly, if $\mathbf{R}_E=\mathbf{0}$, then $\mathbf{RF}(\mathbf{R})=\mathbf{F}(\mathbf{R})$. If $\mathbf{R}_E\neq\mathbf{0}$, then Proposition 3.1 yields $\mathbf{RF}(\mathbf{R})\cap\mathbf{F}(\mathbf{R})=\varnothing$. However, it is not because $\mathbf{RF}(\mathbf{R})=\varnothing$ when $\mathbf{R}_E\neq 0$ that the intersection is empty. Indeed, by explicitly constructing a regular friend, the following theorem establishes that $\mathbf{RF}(\mathbf{R})\neq\varnothing$ whenever R is (A, E, B)-inv.

THEOREM 3.1. *If* R *is* $(A, E, \mathbf{B})$*-invariant, then* $\mathbf{RF}(\mathbf{R})\neq\varnothing$.

Proof. Recall that $\mathbf{V}^*$ is the supremal $(A, E, \mathbf{B})$-inv. subspace of $\mathbf{X}$. Then $\mathbf{R}\subset\mathbf{V}^*$. Write $\mathbf{R}=\mathbf{R}_1\oplus\mathbf{R}_E$ for some $\mathbf{R}_1$. As $\mathbf{R}_1\cap\mathbf{Ker\ E}=\mathbf{0}$, there exists a $\mathbf{V}$ satisfying (1) $\mathbf{R}_1\subset\mathbf{V}$; and (2) $\mathbf{V}^*=\mathbf{V}\oplus\mathbf{V}^*\cap\mathbf{Ker\ E}$. Let $\mathbf{V}^*_E := \mathbf{V}^*\cap\mathbf{Ker\ E}$. Note that $E\mathbf{R}=E\mathbf{R}_1$ and $E\mathbf{V}^*=E\mathbf{V}$. Then $A\mathbf{R}_1\subset E\mathbf{R}_1+\mathbf{B}$ and $A\mathbf{V}\subset E\mathbf{V}+\mathbf{B}$. Choose $K_1:\mathbf{X}\to\mathbf{U}$ to satisfy $(A+BK_1)\mathbf{V}\subset\mathbf{EV}$. Then $(A+BK_1)\mathbf{R}_1\subset A\mathbf{R}_1+\mathbf{B}\subset E\mathbf{R}_1+\mathbf{B}$ and let a $K_2:\mathbf{R}_1\to\mathbf{U}$ be chosen to yield $(A+BK_1+BK_2)\mathbf{R}_1\subset E\mathbf{R}_1$. Let $K_2\equiv 0$ on a complement of R_1 in X. Then it immediately follows that $K_1+K_2\in\mathbf{F}(\mathbf{R}_1)\cap\mathbf{F}(\mathbf{V})$. Let $F_0 := K_1+K_2$.

It follows from [19] that $\mathbf{V}^*$ satisfies $d(E\mathbf{V}^*+\mathbf{B}) = d\mathbf{V}^*$. Write $E\mathbf{V}^*+\mathbf{B} = E\mathbf{V}^* \oplus \tilde{\mathbf{B}}$ for some $\tilde{\mathbf{B}} \subset \mathbf{B}$. Then $d\tilde{\mathbf{B}} = d(E\mathbf{V}^*+\mathbf{B}) - dE\mathbf{V}^* = d\mathbf{V}^* - dE\mathbf{V}^* = d\mathbf{V}_E^*$. Define $q := d\mathbf{V}_E^*$. Let $\{v_i: i \in \mathbf{q}\}$ and $\{B\omega_i: i \in \mathbf{q};\ \omega_i \in \mathbf{U}\}$ be bases for $\mathbf{V}_E^*$ and $\tilde{\mathbf{B}}$, respectively.

Note that $(A+BF_0)\ \mathbf{V}_E^* \subset A\mathbf{V}_E^* + \mathbf{B} \subset A\mathbf{V}^* + \mathbf{B} \subset E\mathbf{V}^* + \mathbf{B} = E\mathbf{V} + \mathbf{B}$. Then there exists $\bar{v}_i \in \mathbf{V}$ and $u_i \in \mathbf{U}$ such that

$$(A+BF_0)v_i = E\bar{v}_i + Bu_i, \qquad i \in \mathbf{q}.$$

Define $F_1: \mathbf{V}_E^* \to \mathbf{U}$ by

$$F_1 v_i = -u_i + \omega_i, \qquad i \in \mathbf{q}.$$

Note that $(A+BF_0+BF_1)\mathbf{V}_E^* \subset E\mathbf{V}^* + \tilde{\mathbf{B}}$, but $(A+BF_0+BF_1)\mathbf{V}_E^* \cap E\mathbf{V}^* = \mathbf{0}$. Extend F_1 to $\mathbf{X}$ by defining $F_1 \equiv 0$ on a complement of $\mathbf{V}_E^*$ in $\mathbf{X}$. Finally, let $F \equiv F_0 + F_1$. Then $(A+BF)\mathbf{R}_1 = (A+BF_0)\mathbf{R}_1 \subset E\mathbf{R}_1$ because $F_0 \in \mathbf{F}(\mathbf{R}_1)$. Therefore $F \in \mathbf{F}(\mathbf{R}_1)$, too. Also note that $(A+BF)\mathbf{V} = (A+BF_0)\mathbf{V} \subset E\mathbf{V}$, and consequently, $F \in \mathbf{F}(\mathbf{V})$. It remains to show that $(E, A+BF)$ is regular.

Recall that $\mathbf{V}_{F,0}^*$ denotes the supremal $(A+BF, E, \mathbf{0})$-inv. subspace of $\mathbf{X}$. As $\mathbf{V}_{F,0}^*$ satisfies $(A+BF)\mathbf{V}_{F,0}^* \subset E\mathbf{V}_{F,0}^*$, there follows $A\mathbf{V}_{F,0}^* \subset E\mathbf{V}_{F,0}^* + \mathbf{B}$, i.e., $\mathbf{V}_{F,0}^* \subset \mathbf{V}^*$. Then $(A+BF)\mathbf{V}_{F,0}^* \subset E\mathbf{V}_{F,0}^* E\mathbf{V}^*$. This and $(A+BF)\mathbf{V}_E^* \cap E\mathbf{V}^* = 0$ imply $\mathbf{V}_{F,0}^* \cap \mathbf{V}_E^* = 0$. Then, as $\mathbf{V}_{F,0}^* \subset \mathbf{V}^*$, $\mathbf{V}_{F,0}^* \cap \mathbf{Ker}\ \mathbf{E} = \mathbf{V}_{F,0}^* \cap \mathbf{V}^* \cap \mathbf{Ker}\ \mathbf{E} = \mathbf{V}_{F,0}^* \cap \mathbf{V}_E^* = 0$. Therefore, by Theorem 2.1(1), $(E, A+BF)$ is regular. Thus, $F \in \mathbf{RF}(\mathbf{R})$. □

Remarks. (1) The reader should note that the last paragraph of the proof above shows that if F satisfies $A_F V_E^* \cap E\mathbf{V}^* = \mathbf{0}$ and $dA_F\mathbf{V}_E^* = d\mathbf{V}_E^*$, then (E, A_F) is regular.

(2) It is by construction that F is a regular friend of $\mathbf{V}^*$ also. Thus, if R is $(A, E, \mathbf{B})$-inv., then $\mathbf{RF}(\mathbf{V}^*) \cap \mathbf{RF}(\mathbf{R}) \neq 0$.

COROLLARY 3.1. *Define* $\mathbf{V}^*(\mathbf{R}) := \mathbf{V}^*(A, E, B; \mathbf{R})$. *Then* $\mathbf{RF}(\mathbf{R}) \neq 0$ *if and only if* $\mathbf{R} = \mathbf{V}^*(\mathbf{R}) + \mathbf{R} \cap \mathbf{Ker}\ \mathbf{E}$.

Proof. If $F \in \mathbf{RF}(\mathbf{R})$, then $A_F\mathbf{R}_1 \subset E\mathbf{R}_1$ for some $\mathbf{R}_1$ satisfying $\mathbf{R} = \mathbf{R}_1 \oplus \mathbf{R} \cap \mathbf{Ker}\ \mathbf{E}$. As $A_F\mathbf{R}_1 \subset E\mathbf{R}_1$ implies $A\mathbf{R}_1 \subset E\mathbf{R}_1 + \mathbf{B}$, we have $\mathbf{R}_1 \subset \mathbf{V}^*(\mathbf{R})$. Consequently, $R = \mathbf{V}^*(\mathbf{R}) + \mathbf{R} \cap \mathbf{Ker}\ \mathbf{E}$. To prove the converse, simply note that, by Theorem 3.1, $\mathbf{RF}(\mathbf{V}^*(\mathbf{R})) \neq 0$ and by definition, any regular friend of $\mathbf{V}^*(\mathbf{R})$ is also a regular friend of $\mathbf{R}$. □

Some of the properties of regular friends of $\mathbf{R}$ are presented below.

PROPOSITION 3.2. *If* $F \in R\mathbf{F}(\mathbf{R})$ *and if* $A_F := A+BF$, *then the following are true*:

(1) $\mathbf{R}_1 \subset \mathbf{V}_{F,0}^*$ *for some* $\mathbf{R}_1$ *satisfying* $\mathbf{R} = \mathbf{R}_1 \oplus \mathbf{R}_E$;

(2) $d(A_F\mathbf{R}_E) = d\mathbf{R}_E$;

(3) $A_F\mathbf{R}_E \cap E\mathbf{R} = \mathbf{0}$;

(4) $A_F\mathbf{R} + E\mathbf{R} = A_F\mathbf{R}_E + E\mathbf{R} \subset \mathbf{R} + \mathbf{B}$;

(5) $d(A_F\mathbf{R} + E\mathbf{R}) = d\mathbf{R}$;

(6) $A_F\mathbf{R} + E\mathbf{R} + \hat{\mathbf{B}}$ *for some* $\hat{\mathbf{B}} \subset B$ *with* $d\hat{\mathbf{B}} = d\mathbf{R}_E$;

(7) $\sigma(E|\mathbf{R}, A_F|\mathbf{R}) = \sigma(E|\mathbf{V}^*(\mathbf{R}), A_F|\mathbf{V}^*(\mathbf{R})) = \sigma(E|\mathbf{R}_1, A_F|\mathbf{R}_1)$;

(8) *If* $\mathbf{K} \in \mathbf{RF}(\mathbf{R})$ *also, then* $B(K-F)\mathbf{R} \subset B \cap (E\mathbf{R} + A_F\mathbf{R})$.

Proof. (1) The proof of (1) is immediate from Definition 3.1 and the fact that $\mathbf{V}_{F,0}^*$ is the supremal $(A_F, E, \mathbf{0})$-inv. subspace of $\mathbf{X}$.

(2) Note that $\mathbf{V}_{F,0}^*$ satisfies $\mathbf{V}_{F,0}^* = A_F^{-1}E\mathbf{V}_{F,0}^*$. Then $\mathbf{Ker}\ \mathbf{A_F} \subset \mathbf{V}_{F,0}^*$. If $F \in \mathbf{RF}(\mathbf{R})$, then $\mathbf{Ker}\ \mathbf{E} \cap \mathbf{Ker}\ \mathbf{A_F} \subset \mathbf{Ker}\ \mathbf{E} \cap \mathbf{V}_{F,0}^* = \mathbf{0}$ (by Theorem 2.1(1)). Therefore, $d(A_F\mathbf{R}_E) = d\mathbf{R}_E$.

(3) Recall that $\mathbf{S}_*^{F,0}$, the least $(E, A_F, \mathbf{0})_r$-inv. subspace of $\mathbf{X}$, satisfies $\mathbf{S}_*^{F,0} = E^{-1}A_F\mathbf{S}_*^{F,0}$. Now, let $\mathbf{R}_1$ be as in (1) and let $x \in A_F\mathbf{R}_E \cap E\mathbf{R}$. Then $x = A_F r_E = Er_1$ for some $r_E \in \mathbf{R}_E$ and $r_1 \in \mathbf{R}_1$. Then $r_1 \in E^{-1}A_F R_E \subset E^{-1}A_F\mathbf{Ker}\ \mathbf{E} \subset E^{-1}A_F\mathbf{S}_*^{F,0} = \mathbf{S}_*^{F,0}$, and therefore $r_1 \in \mathbf{R}_1 \cap \mathbf{S}_*^{F,0}$. Since (E, A_F) is regular, Theorem 2.1(2) implies $r_1 = 0$, which in turn implies $x = 0$.

(4) Note that if $\mathbf{R}_1$ is as in (1), then $A_F\mathbf{R}_1 \subset E\mathbf{R}_1$ and $A_F\mathbf{R} + E\mathbf{R} = A_F\mathbf{R}_E + E\mathbf{R}_1$. Also, $A_F\mathbf{R} + E\mathbf{R} \subset E\mathbf{R} + \mathbf{B} + E\mathbf{R} = E\mathbf{R} + \mathbf{B}$.

(5) $d(A_F\mathbf{R} + E\mathbf{R}) = d(A_F\mathbf{R}_E + E\mathbf{R}) = d(A_F\mathbf{R}_E) + dE\mathbf{R} - d(A_F\mathbf{R}_E \cap E\mathbf{R})$. Note that $E\mathbf{R} = E\mathbf{R}_1$. As $\mathbf{R}_1 \subset \mathbf{V}^*_{F,0}$ and as $\mathbf{Ker}\,\mathbf{E} \cap \mathbf{V}^*_{F,0} = \mathbf{0}$, $d(E\mathbf{R}) = d\mathbf{R}_1$. Then the result follows from (2) and (3).

(6) Write $(A_F\mathbf{R} + E\mathbf{R}) \cap B = E\mathbf{R} \cap \mathbf{B} \oplus \hat{\mathbf{B}}$ for some $\hat{\mathbf{B}} \subset \mathbf{B}$. Note that (4) implies

$$A_F R + E\mathbf{R} = (A_F R + E\mathbf{R}) \cap (E\mathbf{R} + \mathbf{B}).$$

Using Property 2.1, we have

$$\begin{aligned} A_F\mathbf{R} + E\mathbf{R} &= E\mathbf{R} + (A_F\mathbf{R} + E\mathbf{R}) \cap B \\ &= E\mathbf{R} + E\mathbf{R} \cap \mathbf{B} \oplus \hat{\mathbf{B}} \\ &= E\mathbf{R} \oplus \hat{\mathbf{B}}. \end{aligned}$$

Then, (5) implies $d\mathbf{R} = d(E\mathbf{R} + \hat{\mathbf{B}})$. As $\hat{\mathbf{B}}\ E\mathbf{R} = \mathbf{0}$, $d\hat{\mathbf{B}} = d\mathbf{R} - dE\mathbf{R} = d\mathbf{R}_E$.

(7) The first equality follows immediately from Theorem 2.1(3) and the fact that the initial manifold of $(E|\mathbf{R}, A_F|\mathbf{R})$ is contained in $\mathbf{V}^*(\mathbf{R})$. To prove the second equality, write $\mathbf{R} = \mathbf{R}_1 \oplus \mathbf{R}_E$ and let v_i be the eigenvector corresponding to $\lambda_i \in \sigma(E|\mathbf{R}, A_F|\mathbf{R})$. Writing $v_i = r_i + r^i_E$, where $r_i \in \mathbf{R}_1$ and $r^i_E \in \mathbf{R}_E$, we have $\lambda_i E r_i = A_F r_i + A_F r^i_E$. As $A_F r_i \in A_F\mathbf{R}_1 \subset E\mathbf{R}_1$, we have, by (3) above, $r^i_E = 0$. Thus, $v_i \in \mathbf{R}_1$ and, therefore, $\sigma(E|R, A_F|R) = \sigma(E|\mathbf{R}_1, A_F|\mathbf{R}_1)$.

(8) Let $\mathbf{K} \in \mathbf{RF}(\mathbf{R})$. Then by (5),

$$\begin{aligned} d\mathbf{R} &= d[E\mathbf{R} + (A + BK)\mathbf{R}] \\ &= d[E\mathbf{R} + (A + BF)\mathbf{R} + B(K - F)\mathbf{R}]. \end{aligned}$$

Since $F \in \mathbf{RF}(\mathbf{R})$, $d\mathbf{R} = d[E\mathbf{R} + (A + BF)\mathbf{R}]$. Thus, $B(K - F)\mathbf{R} \subset \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})$. □

4. Generalized reachability subspaces. Recall that a subspace $R \subset \mathbf{X}$ was defined in § 1 to be a generalized reachability subspace if there existed linear maps $F: \mathbf{X} \to \mathbf{U}$ and $G: U \to U$ such that (1) $(E, A + BF)$ was regular; and (2) $\mathbf{R}$ was the reachable subspace of $(E, A + BF, BG)$.

An immediate consequence of the definition and Corollary 2.1 is the following theorem.

THEOREM 4.1. *If R is a generalized reachability subspace, then $\mathbf{R}$ is $(A, E, \mathbf{B})$-invariant and $\mathbf{R} = \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{R})$.*

Proof. If there exist F and G such that $\mathbf{R}$ is the reachable space of $(E, A + BF, BG)$, then, by Theorem 2.2(2), $\mathbf{R}$ satisfies $\mathbf{R} = \mathbf{S}^{F,G}_* \cap (A + BF)^{-1}\{E\mathbf{R} + \mathbf{BG}\}$. Then $(A + BF)\mathbf{R} \subset E\mathbf{R} + \mathbf{BG}$ implying $AR \subset E\mathbf{R} + \mathbf{B}$.

Corollary 2.1 shows that $R = \mathbf{S}_*(E, A + BF, \mathbf{BG}; \mathbf{R})$. Note that $\mathbf{R} = \mathbf{S}_*(E, A + BF, \mathbf{BG}; \mathbf{R}) \subset \mathbf{S}_*(E, A + BF, \mathbf{B}; \mathbf{R})$ because $\mathbf{BG} \subset \mathbf{B}$. On the other hand, it is by definition that $\mathbf{S}_*(E, A + BF, \mathbf{B}; \mathbf{R}) \subset \mathbf{R}$. Therefore, $\mathbf{R} = \mathbf{S}_*(E, A + BF, \mathbf{BG}; \mathbf{R}) \subset \mathbf{S}_*(E, A + BF, \mathbf{B}; \mathbf{R}) \subset \mathbf{R}$. Then $\mathbf{R} = \mathbf{S}_*(E, A + BF, \mathbf{B}; \mathbf{R})$. As $(A + BF)\mathbf{S}_k + \mathbf{B}$ for any $\mathbf{S}_k \subset \boldsymbol{X}$, it trivially follows that $S_*(E, A, \mathbf{B}; \mathbf{R}) = \mathbf{S}_*(E, A + BF, \mathbf{B}; \mathbf{R}) = \mathbf{R}$. Hence the theorem is proved. □

The reader should remember that $\mathbf{R} = \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{R})$ means $\mathbf{R} = \lim_k \mathbf{S}_k$, where $\mathbf{S}_k$ is defined by

$$\mathbf{S}_{k+1} = \mathbf{R} \cap E^{-1}\{A\mathbf{S}_k + \mathbf{B}\}, \qquad \mathbf{S}_0 = \mathbf{R} \cap \mathbf{Ker}\,\mathbf{E}. \tag{4.1}$$

It is not only because the algorithm (4.1) reduces to the well-known almost-reachability subspace algorithm of Willems [29] in case $E = I$, but also because of the reasoning given in [12] that we call (4.1) the generalized almost reachability subspace algorithm (GARSA). A subspace $\mathbf{R}$ will be said to satisfy GARSA if $\lim_k \mathbf{S}_k = \mathbf{R}$; that is to say,

$\mathbf{R}$ is the *supremal generalized almost reachability subspace contained* in $\mathbf{R}$. By proving that the converse of Theorem 4.1 is also true, Theorem 4.2 below will show that $\mathbf{R}$ is a generalized reachability subspace if and only if $\mathbf{R}$ is an $(A, E, \mathbf{B})$-inv. generalized almost-reachability subspace. However, before proceeding to Theorem 4.2, we need to prove two propositions.

PROPOSITION 4.1. *Let an* $(A, E, \mathbf{B})$*-invariant subspace* $\mathbf{R}$ *satisfy* GARSA. *Given an* $F \in \mathbf{RF}(\mathbf{R})$, *choose* $G: \mathbf{U} \to \mathbf{U}$ *so that* $\mathbf{BG} = \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})$. *Then* $\mathbf{R} = \mathbf{S}_*(E, A+BF, \mathbf{BG}; \mathbf{R})$.

Proof. Let $F \in \mathbf{RF}(\mathbf{R})$. Then $F \in \mathbf{F}(\mathbf{R}_1)$ for some $\mathbf{R}_1$ satisfying $\mathbf{R} = \mathbf{R}_1 \oplus \mathbf{R}_E$. (Recall that $\mathbf{R}_E = \mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}$.) Note that $\mathbf{S}_*(E, A, \mathbf{B}; \mathbf{R}) = \mathbf{S}_*(E, A+BF, \mathbf{B}; \mathbf{R}) = \mathbf{R}$. Let $\mathbf{B}^{(1)} = \mathbf{B}$, $\mathbf{B}^{(2)} = (E\mathbf{R} + A_F\mathbf{R}) \cap B$, and define $\mathbf{S}_k^{(i)}$ for $i = 1, 2$ by

$$\mathbf{S}_{k+1}^{(i)} = \mathbf{R} \cap E^{-1}\{A_F\mathbf{S}_k^{(i)} + \mathbf{B}^{(i)}\}, \qquad \mathbf{S}_0^{(i)} = \mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}$$

where, as before, A_F denotes $(A+BF)$. Clearly, if $\mathbf{S}_*^{(1)}(\mathbf{R}) := \lim_k \mathbf{S}_k^{(1)}$ and $\mathbf{S}_*^{(2)}(\mathbf{R}) := \lim_k \mathbf{S}_k^{(2)}$, then $\mathbf{S}_*^{(2)}(\mathbf{R}) \subset \mathbf{S}_*^{(1)}(\mathbf{R})$ because $\mathbf{B}^{(2)} \subset \mathbf{B}^{(1)}$. On the other hand, $\mathbf{S}_0^{(1)} \subset \mathbf{S}_*^{(2)}(\mathbf{R})$ and if $\mathbf{S}_k^{(1)} \subset \mathbf{S}_*^{(2)}(\mathbf{R})$, then $\mathbf{S}_{k+1}^{(1)} \subset \mathbf{R} \cap E^{-1}\{A_F\mathbf{S}_*^{(2)}(\mathbf{R}) + \mathbf{B}\}$. Let $x \in \mathbf{S}_{k+1}^{(1)}$. Then, $x \in \mathbf{R}$ and $Ex = A_F s + Bu$ for some $u \in \mathbf{U}$ and $s \in \mathbf{S}_*^{(2)}(\mathbf{R})$. Then, $Bu = Ex - A_F s \in E\mathbf{R} + A_F\mathbf{S}_*^{(2)}(\mathbf{R}) \subset E\mathbf{R} + A_F\mathbf{R}$ and, therefore, we have $x \in \mathbf{R} \cap E^{-1}\{A_F\mathbf{S}_*^{(2)}(\mathbf{R}) + \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})\}$. Since $x \in \mathbf{S}_{k+1}^{(1)}$ is arbitrary, we conclude that $\mathbf{S}_{k+1}^{(1)} \subset \mathbf{R} \cap E^{-1}\{A_F\mathbf{S}_*^{(2)}(\mathbf{R}) + \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})\} = \mathbf{S}_*^{(2)}(\mathbf{R})$. This proves that $\mathbf{S}_k^{(1)} \subset \mathbf{S}_*^{(2)}(\mathbf{R})$ for all k. Thus $\mathbf{S}_*^{(1)}(\mathbf{R}) \subset \mathbf{S}_*^{(2)}$. This and $\mathbf{S}_*^{(2)}(\mathbf{R}) \subset \mathbf{S}_*^{(1)}(\mathbf{R})$ together imply $\mathbf{S}_*^{(1)}(\mathbf{R}) = \mathbf{S}_*^{(2)}(\mathbf{R})$. Then, defining G by $\mathbf{BG} = (E\mathbf{R} + A_F\mathbf{R}) \cap B$ completes the proof. □

PROPOSITION 4.2. *Let an* $(A, E, \mathbf{B})$*-invariant subspace* $\mathbf{R}$ *satisfy* GARSA. *Let* $F \in \mathbf{RF}(\mathbf{R})$. *Write* $R = \mathbf{R}_1 \oplus \mathbf{R}_E$, *where* $F \in \mathbf{F}(\mathbf{R}_1)$ *and* $\mathbf{R}_E = \mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}$. *If* G *is chosen to satisfy* $\mathbf{BG} = (E\mathbf{R} + A_F\mathbf{R}) \cap \mathbf{B}$, *then*:

(1) $\mathbf{S}_*^{F,G} = \mathbf{S}_*^{F,0} + \mathbf{R}_1$;

(2) $\mathbf{V}_{F,G}^* = \mathbf{V}_{F,0}^* + \mathbf{R}_E$.

Remark. Recall that if $\mathbf{V}_{F,G}^k$, $\mathbf{V}_{F,0}^0$, $\mathbf{S}_k^{F,G}$, and $\mathbf{S}_k^{F,0}$ are defined by

$$\mathbf{V}_{F,G}^{k+1} = A_F^{-1}\{E\mathbf{V}_{F,G}^k + \mathbf{BG}\}, \qquad \mathbf{V}_{F,G}^0 = \mathbf{X}, \tag{4.2}$$

$$\mathbf{V}_{F,0}^{k+1} = A_F^{-1}\{E\mathbf{V}_{F,0}^k\}, \qquad \mathbf{V}_{F,0}^0 = \mathbf{X}, \tag{4.3}$$

$$\mathbf{S}_{k+1}^{F,G} = E^{-1}\{A_F\mathbf{S}_k^{F,G} + \mathbf{BG}\}, \qquad \mathbf{S}_0^{F,G} = \mathbf{Ker}\, \mathbf{E}, \tag{4.4}$$

$$\mathbf{S}_{k+1}^{F,0} = E^{-1}A_F\mathbf{S}_k^{F,0}, \qquad \mathbf{S}_0^{F,0} = \mathbf{Ker}\, \mathbf{E}, \tag{4.5}$$

then $\{\mathbf{V}_{F,G}^k\} \downarrow \mathbf{V}_{F,G}^*$, $\{\mathbf{V}_{F,0}^k\} \downarrow \mathbf{V}_{F,0}^*$, $\{\mathbf{S}_k^{F,G}\} \uparrow \mathbf{S}_*^{F,G}$, and $\{\mathbf{S}_k^{F,0}\} \uparrow \mathbf{S}_*^{F,0}$. It should be clear that $\mathbf{V}_{F,0}^* \subset \mathbf{V}_{F,G}^*$ and $\mathbf{S}_*^{F,0} \subset \mathbf{S}_*^{F,G}$.

Proof. (1) Note that $\mathbf{S}_*(E, A_F, \mathbf{BG}; \mathbf{R}) \subset \mathbf{S}_*(E, A_F, \mathbf{BG}; \mathbf{X}) = \mathbf{S}_*^{F,G}$. Since R satisfies GARSA, $\mathbf{R} = \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{R})$, and by Proposition 4.1, $\mathbf{R} = \mathbf{S}_*(E, A_F, \mathbf{BG}; \mathbf{R})$. Therefore

$$\mathbf{R} = \mathbf{S}_*(E, A_F, \mathbf{BG}; \mathbf{R}) \subset \mathbf{S}_*(E, A_F, \mathbf{BG}; \mathbf{X}) = \mathbf{S}_*^{F,G}.$$

This and $\mathbf{S}_*^{F,0} \subset \mathbf{S}_*^{F,G}$ imply $\mathbf{S}_*^{F,0} + \mathbf{R} \subset \mathbf{S}_*^{F,G}$. To prove $\mathbf{S}_*^{F,G} \subset \mathbf{S}_*^{F,0} + \mathbf{R}$ define $\mathbf{S}_k$ by

$$\begin{aligned} \mathbf{S}_{k+1} &= E^{-1}\{A_F\mathbf{S}_k + \mathbf{BG}\} \\ &= E^{-1}\{A_F\mathbf{S}_k + \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})\}, \\ \mathbf{S}_0 &= \mathbf{Ker}\, \mathbf{E}, \end{aligned}$$

and note that $\mathbf{S}_0 \subset \mathbf{S}_*^{F,0} + \mathbf{R}$. If $\mathbf{S}_k \subset \mathbf{S}_*^{F,0} + \mathbf{R}$ is assumed, then

$$\begin{aligned} \mathbf{S}_{k+1} &\subset E^{-1}\{A_F\mathbf{S}_*^{F,0} + A_F\mathbf{R} + \mathbf{B} \cap (E\mathbf{R} + A_F\mathbf{R})\} \\ &\subset E^{-1}\{A_F\mathbf{S}_*^{F,0} + A_F\mathbf{R} + E\mathbf{R}\} \\ &= E^{-1}\{A_F\mathbf{S}_*^{F,0} + A_F\mathbf{R}_E + E\mathbf{R}\} \quad \text{(by Proposition 3.2(4))} \\ &= E^{-1}\{A_F\mathbf{S}_*^{F,0} + E\mathbf{R}\}. \end{aligned}$$

The last equality follows from the fact that $R_E = \mathbf{R} \cap \mathbf{Ker}\, \mathbf{E} \subset E^{-1}A_F\mathbf{S}_*^{F,0} = \mathbf{S}_*^{F,0}$. Then, by Property 2.3, we have

$$\begin{aligned}\mathbf{S}_{k+1} &= E^{-1}A_F\mathbf{S}_*^{F,0} + \mathbf{R} + \mathbf{Ker}\, \mathbf{E} \\ &= E^{-1}A_F\mathbf{S}_*^{F,0} + \mathbf{R} \\ &= \mathbf{S}_*^{F,0} + \mathbf{R}.\end{aligned}$$

Thus $\mathbf{S}_*^{F,G} = \lim_k \mathbf{S}_k \subset \mathbf{S}_*^{F,0} + \mathbf{R}$. Together with $\mathbf{S}_*^{F,0} + \mathbf{R} \subset \mathbf{S}_*^{F,G}$, this implies $\mathbf{S}_*^{F,G} = \mathbf{S}_*^{F,0} + \mathbf{R}$. Then $\mathbf{S}_*^{F,G} = \mathbf{S}_*^{F,0} + \mathbf{R}_1 + \mathbf{R}_E = \mathbf{S}_*^{F,0} + \mathbf{R}_1$.

(2) Let $\mathbf{V}_{F,G}^k$ be defined by (4.2). As $\mathbf{V}_{F,0}^* \subset \mathbf{V}_{F,G}^*$ and $\{\mathbf{V}_{F,G}^k\}$ is nonincreasing, there follows $\mathbf{V}_{F,0}^* \subset \mathbf{V}_{F,G}^* \subset \mathbf{V}_{F,G}^k$ for all k. Let $\mathbf{R}_1$ be as before. As $A_F\mathbf{R}_1 \subset E\mathbf{R}_1$, $\mathbf{R}_1 \subset \mathbf{V}_{F,0}^*$ because $\mathbf{V}_{F,0}^*$ is the supremal $(A_F, E, \mathbf{0})$-inv. subspace of $\mathbf{X}$. Then $E\mathbf{R} = E\mathbf{R}_1 \subset E\mathbf{V}_{F,0}^* \subset E\mathbf{V}_{F,G}^* \subset E\mathbf{V}_{F,G}^k$ for all k. Thus (4.2) can be rewritten as

$$\mathbf{V}_{F,G}^{k+1} = A_F^{-1}\{E\mathbf{V}_{F,G}^k + E\mathbf{R} + (A_F\mathbf{R} + E\mathbf{R}) \cap B\}$$

and the proofs of Proposition 3.2(4) and (6) imply

$$\begin{aligned}\mathbf{V}_{F,G}^{k+1} &= A_F^{-1}\{E\mathbf{V}_{F,G}^k + E\mathbf{R} + A_F\mathbf{R}_E\} \\ &= A_F^{-1}\{E\mathbf{V}_{F,G}^k + A_F\mathbf{R}_E\}.\end{aligned}$$

Property 2.3, applied to the equations above, yields

$$\begin{aligned}\mathbf{V}_{F,G}^{k+1} &= A_F^{-1}E\mathbf{V}_{F,G}^k + \mathbf{R}_E + \mathbf{Ker}\, \mathbf{A_F} \\ &= A_F^{-1}E\mathbf{V}_{F,G}^k + \mathbf{R}_E;\end{aligned} \tag{4.6}$$

$\mathbf{R}_E \subset \mathbf{V}_{F,G}^k$ for all k yields $\mathbf{R}_E \subset \mathbf{V}_{F,G}^*$. This and $\mathbf{V}_{F,0}^* \subset \mathbf{V}_{F,G}^*$ together show that $\mathbf{V}_{F,0}^* + \mathbf{R}_E \subset \mathbf{V}_{F,G}^*$. If $\mathbf{V}_{F,0}^k$ is defined by (4.3), then $\mathbf{V}_{F,G}^0 \subset \mathbf{V}_{F,0}^0 + \mathbf{R}_E$. Assume $\mathbf{V}_{F,G}^k \subset \mathbf{V}_{F,0}^k + \mathbf{R}_E$. Then by (4.6),

$$\begin{aligned}\mathbf{V}_{F,G}^{k+1} &\subset A_F^{-1}E(\mathbf{V}_{F,0}^k + \mathbf{R}_E) + \mathbf{R}_E \\ &= A_F^{-1}E\mathbf{V}_{F,0}^k + \mathbf{R}_E \\ &= \mathbf{V}_{F,0}^{k+1} + \mathbf{R}_E.\end{aligned}$$

As $\mathbf{V}_{F,G}^k \subset \mathbf{V}_{F,0}^k + \mathbf{R}_E$ for all k, there follows $\mathbf{V}_{F,G}^* \mathbf{V}_{F,0}^* + \mathbf{R}_E$. This, together with $\mathbf{V}_{F,G}^* \supset \mathbf{V}_{F,0}^* + \mathbf{R}_E$, proves (2). □

The main result of this paper can now be proved.

THEOREM 4.2. *A subspace* $\mathbf{R} \subset \mathbf{X}$ *is a generalized reachability subspace if and only if*:

(1) $A\mathbf{R} \subset E\mathbf{R} + \mathbf{B}$;

(2) $\mathbf{R} = \lim_k \mathbf{S}_k$, *where*

$$\mathbf{S}_{k+1} = \mathbf{R} \cap E^{-1}\{A\mathbf{S}_k + \mathbf{B}\}, \qquad \mathbf{S}_0 = \mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}.$$

Proof. Necessity was proved in Theorem 4.1. To prove sufficiency, let $F \in \mathbf{RF}(\mathbf{R})$ and define G by $BG = (A_F\mathbf{R} + E\mathbf{R}) \cap B$. By Theorem 2.2(1) $\langle E, A + BF | \mathbf{BG} \rangle$, the reachable subspace of $(E, A + BF, BF)$, is given by $\mathbf{S}_*^{F,G} \cap \mathbf{V}_{F,G}^*$. Proposition 4.2 implies

$$\langle E, A + BF | \mathbf{BG} \rangle = (\mathbf{S}_*^{F,0} + \mathbf{R}_1) \cap (\mathbf{V}_{F,0}^* + \mathbf{R}_E) \tag{4.7}$$

where $R_1 + \mathbf{R}_E = \mathbf{R}$ and $(A + BF)\mathbf{R}_1 \subset E\mathbf{R}_1$, i.e., $\mathbf{R}_1 \subset \mathbf{V}_{F,0}^*$. Then $\mathbf{R}_1 \subset \mathbf{V}_{F,0}^* + \mathbf{R}_E$ and Property 2.1, applied to (4.7), yields

$$\langle E, A + BF | \mathbf{BG} \rangle = \mathbf{S}_*^{F,0} \cap (\mathbf{V}_{F,0}^* + \mathbf{R}_E) + \mathbf{R}_1.$$

As $\mathbf{R}_E$ $\mathbf{Ker}\, \mathbf{E}$ $\mathbf{S}_*^{F,0}$ (see (4.5)), it follows by Property 2.1 that

$$\langle E, A + BF | \mathbf{BG} \rangle = \mathbf{R}_E + \mathbf{S}_*^{F,0} \cap \mathbf{V}_{F,0}^* + \mathbf{R}_1.$$

Because $F \in \mathbf{RF}(\mathbf{R})$, $(E, A + BF)$ is regular. Then, by Theorem 2.1(2), $\mathbf{S}_*^{F,0} \cap \mathbf{V}_{F,0}^* = \mathbf{0}$ and the result follows. □

Now let $\mathbf{K} \subset \mathbf{X}$ be a subspace and let $\mathbf{R}(E, A, \mathbf{B}; \mathbf{K})$ denote the class of all generalized reachability subspaces contained in $\mathbf{K}$. As $\mathbf{0}$ is a reachability subspace, $\mathbf{R}(E, A, \mathbf{B}; \mathbf{K})$ is nonempty, and the proof of Lemma 5.5 in [28] with only very minor modifications shows that $\mathbf{R}(E, A, \mathbf{B}; \mathbf{K})$ is closed under the operation of subspace addition. Therefore, $\mathbf{K}$ contains a unique supremal generalized reachability subspace that will be denoted by $\mathbf{R}^*(\mathbf{K})$.

Recall that $\mathbf{V}^*(A, E, \mathbf{B}; \mathbf{K})$ denotes supremal $(A, E, \mathbf{B})$-inv. subspace contained in $\mathbf{K}$ and can be computed by the recursion

$$\mathbf{V}_{k+1} = \mathbf{K} \cap A^{-1}\{E\mathbf{V}_k + \mathbf{B}\}, \qquad \mathbf{V}_0 = \mathbf{K}.$$

Let $\mathbf{V}^*(\mathbf{K}) := \mathbf{V}^*(A, E, \mathbf{B}; \mathbf{K})$. Then the proof of the following theorem mimics the proof of Theorem 5.6 in [28] and will be left to the reader.

THEOREM 4.3. $\mathbf{R}^*(\mathbf{K})$ *is given by* $\lim_k \mathbf{R}_k$, *where*

$$\mathbf{R}_{k+1} = \mathbf{V}^*(\mathbf{K}) \cap E^{-1}\{A\mathbf{R}_k + \mathbf{B}\} \qquad \mathbf{R}_0 = \mathbf{V}^*(\mathbf{K}) \cap \mathbf{Ker}\ \mathbf{E}.$$

Recall that in § 1, a subspace $\mathbf{C}$ was defined to be a generalized controllability subspace if $\mathbf{C} = E\mathbf{R}$ for some generalized reachability subspace $\mathbf{R}$. More precisely we have Theorem 4.4.

THEOREM 4.4. $\mathbf{C}$ *is a generalized controllability subspace if and only if* $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{C})$.

Proof. If $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{C})$, then $\mathbf{C}$ is clearly a generalized controllability subspace. If $\mathbf{C} = E\mathbf{R}$ for some generalized reachability subspace $\mathbf{R} \subset E^{-1}\mathbf{C}$, then

$$\mathbf{C} = E\mathbf{R} \subset E\mathbf{R}^*(E^{-1}\mathbf{C}) \subset EE^{-1}\mathbf{C} \subset \mathbf{C}$$

and consequently, $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{C})$. □

The class of all generalized controllability subspaces contained in a given subspace $\mathbf{K}$ contains $\mathbf{0}$ and is closed under the operation of subspace addition. Thus, it contains a unique supremal element $\mathbf{C}^*(\mathbf{K})$. Theorem 4.5 follows immediately from Theorem 4.4.

THEOREM 4.5. $\mathbf{C}^*(\mathbf{K}) = E\mathbf{R}^*(E^{-1}\mathbf{K})$.

5. On spectral assignability. The equivalence of reachability and controllability for (1.1) to $E = I$ is well known. Therefore in this case it is unnecessary to distinguish between reachability and controllability subspaces. Indeed, the accepted practice is to talk about the property of controllability and controllability subspaces of (A, B) [28]. However, this simplification in the terminology of proper state-space systems has the adverse effect of concealing the relations between different characterizations of controllability subspaces and the different properties that produce such characterizations. Indeed, the dynamic characterization [28] of a controllability subspace $\mathbf{R}$ of (I, A, B) as having the property that any $x \in \mathbf{R}$ can be reached from the origin in finite time along a smooth trajectory, generated by a smooth input and not leaving $\mathbf{R}$, clearly and explicitly reflects the property of reachability. In light of our discussion in the previous sections, it should be clear that a similar dynamic characterization applies to reachability subspaces, though not necessarily to controllability subspaces, of (E, A, B).

On the other hand, a very important result [28] states that $\mathbf{R}$ with $d\mathbf{R} = q$ is a controllability subspace of (I, A, B) if and only if, for every symmetric set Λ of q complex numbers, there exists a friend F of $\mathbf{R}$ such that the spectrum $\alpha((A + RF)|R)$ of $(A + BF)|\mathbf{R}$, the restriction of $(A + BF)$ to $\mathbf{R}$, is precisely Λ. In this section, we show that this characterization depends on the property of controllability (as opposed to reachability) by showing that an extension of the characterization applies to controllability subspaces but not, in general, to reachability subspaces of (E, A, B). Indeed, the following theorem, which has already appeared in the literature [4], [7], [13] explicitly

or implicitly, justifies this comment immediately. However, our proof, which is geometric in nature, is new.

THEOREM 5.1. *Given any symmetric set* Λ *of* $r := \text{rank } E$ *complex numbers, there exists a linear map* $F: X \to U$ *so that* $\Lambda = \sigma(E, A_F)$ *if and only if* (E, A, B) *is controllable.*

Remarks. (1) Note that $\Lambda = \sigma(E, A_F)$ implies that $\sigma(E, A_F) \neq C$, that is, (E, A_F) is regular.

(2) Note that reachability of (E, A, B) - the condition $\langle E, A|\mathbf{B}\rangle = \mathbf{X}$ - implies controllability, that is, the condition $E\langle E, A|\mathbf{B}\rangle = E\mathbf{X}$, but not vice versa. Thus, reachability of (E, A, B) is sufficient but not necessary for the arbitrary assignment of $\sigma(E, A_F)$.

Proof. Let Λ have r distinct elements and assume that $\Lambda \cap \sigma(E, A) = \varnothing$. Let F assign Λ as $\sigma(E, A_F)$. For $\lambda_i \in \Lambda$, let v_i be the corresponding eigenvector. Then $v_i \in \langle E, A|B\rangle$ and $\{Ev_i: i \in \underline{r}\}$ is a linearly independent set [18]. Then $E\langle E, A|\mathbf{B}\rangle = E\mathbf{X}$ and (E, A, B) is controllable.

Let (E, A, B) be controllable. Then $\langle E, A|\mathbf{B}\rangle + \mathbf{Ker}\ \mathbf{E} = \mathbf{X}$ and thus, $V^* + \mathbf{Ker}\ \mathbf{E} = \mathbf{X}$. Let F_0 be a regular friend of $\mathbf{V}^*$. Then F_0 assigns some $\mathbf{V}$ satisfying $\mathbf{V} \oplus \mathbf{V}^* \cap \mathbf{Ker}\ \mathbf{E} = \mathbf{V}^*$ as the initial manifold of a regular system (E, A_{F_0}, B). Then, by Theorem 2.1, $\mathbf{V} \oplus \mathbf{Ker}\ \mathbf{E} = \mathbf{X}$ and $E\mathbf{V} \oplus A_{F_0}\mathbf{Ker}\ \mathbf{E} = \mathbf{X}$. Let V and N be basis matrices for $\mathbf{V}$ and $\mathbf{Ker}\ \mathbf{E}$. Let $P = [VN]$ and $Q = [EVA_FN]$. Then $(Q^{-1}EP, Q^{-1}A_FP, Q^{-1}B)$ becomes

$$\begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} A_1 & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u \tag{5.1}$$

where $x_1 \in \mathbf{R}^r$ and $x_2 \in \mathbf{R}^{n-r}$.

As controllability is preserved by regular friends and by coordinate transformations, (5.1) is controllable, implying that (A_1, B_1) is a controllable pair [2], [3]. Then, there exists an $F_1: \mathbf{R}^r \to \mathbf{U}$ such that $\Lambda = \sigma(A_1 + B_1F_1)$. Let $F_2: \mathbf{X} \to \mathbf{U}$ be the extension of F_1, which is zero on $\mathbf{R}^{n-r}$. Then

$$\det \begin{bmatrix} \lambda I - A_1 - B_1F_1 & 0 \\ -B_2F_1 & I \end{bmatrix} = \det (\lambda I - A_1 - B_1F_1).$$

Thus, $F = F_0 + F_2P^{-1}$ is the map that yields $\Lambda = \sigma(E, A_F)$. □

In light of Theorem 5.1, the following result is not unexpected.

THEOREM 5.2. *Let* $\mathbf{C} \subset E\mathbf{X}$ *be a subspace with* $d\mathbf{C} = q \geqq 1$. $\mathbf{C}$ *is a generalized controllability subspace if and only if, given any symmetric set* Λ *of* q *complex numbers, there exists a linear map* $F: \mathbf{X} \to \mathbf{U}$ *so that*:

(1) F *is a regular friend of* $E^{-1}\mathbf{C}$;

(2) $\Lambda = \sigma(E|E^{-1}\mathbf{C}, A_F|E^{-1}\mathbf{C})$.

Proof. Let $\mathbf{C}$ be a generalized controllability subspace, i.e., $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{C})$. Let $F_0 \in \mathbf{RF}(\mathbf{R}^*(E^{-1}\mathbf{C})) \cap \mathbf{RF}(\mathbf{V}^*)$ be as constructed in Theorem 3.1. Since $E^{-1}\mathbf{C} = \mathbf{R}^*(E^{-1}\mathbf{C}) + \mathbf{Ker}\ \mathbf{E}$, F_0 is also a regular friend of $E^{-1}\mathbf{C}$. Define $\bar{\mathbf{C}} = EE^{-1}\mathbf{C} + A_{F_0}E^{-1}\mathbf{C}$ and let $E_0 := \bar{C}|E|E^{-1}\mathbf{C}$, $A_0 := \bar{\mathbf{C}}|A_{F_0}|E^{-1}\mathbf{C}$ and choose G so that $B_0 = BG$ satisfies $\mathbf{B}_0 = \mathbf{B} \cap \bar{\mathbf{C}}$. Now

$$\begin{aligned} \mathbf{R}^*(E^{-1}\mathbf{C}) &= \mathbf{R}^*(E, A, B; E^{-1}\mathbf{C}) \\ &= \mathbf{R}^*(E, A_{F_0}, \mathbf{B}; E^{-1}\mathbf{C}) \\ &= \mathbf{R}^*(E, A_{F_0}, \mathbf{B}_0; E^{-1}\mathbf{C}) \quad \text{(Proposition 4.1)} \\ &= \mathbf{R}^*(E_0, A_0, \mathbf{B}_0; E^{-1}\mathbf{C}). \end{aligned}$$

Since $E_0\mathbf{R}^*(E_0, A_0, \mathbf{B}_0; E^{-1}\mathbf{C}) = E_0\mathbf{R}^*(E^{-1}\mathbf{C}) = E_0E^{-1}\mathbf{C} = \mathbf{E}_0$, then (E_0, A_0, B_0) is controllable. Then, by Theorem 5.1, given any symmetric set Λ of rank $E_0 = dE_0E^{-1}\mathbf{C} = q$ complex numbers, there exists an $F_1: E^{-1}\mathbf{C} \to \mathbf{U}$ such that $\Lambda = \sigma(E_0, A_0 + B_0F_1)$.

It remains to extend F_1 to $\mathbf{X}$ without destroying the regularity of the closed-loop system. To that end, let $\mathbf{R}$ denote the initial manifold of $(E_0, A_0+B_0F_1)$. By Theorem 2.1(3), $d\mathbf{R} = \deg|\Lambda E_0 - (A_0+B_0F_1)| = q$. This and regularity of $(E_0, A_0+B_0F_1)$ imply that $\mathbf{R}\oplus\mathbf{Ker\ E} = \mathbf{R}\oplus\mathbf{Ker\ E} = E^{-1}\mathbf{C}$. Let $F_2 = F_1$ on $\mathbf{R}$ and let $F_2 = 0$ on a subspace which complements $\mathbf{R}$ to $\mathbf{X}$. Finally, let $F = F_0 + GF_2$. Since $F|\mathbf{V}_E^* = F_0|\mathbf{V}_E^*$ and since, by construction, F_0 satisfies $A_{F_0}\mathbf{V}_E^*\ E\mathbf{V}^* = \mathbf{0}$ and $dA_{F_0}\mathbf{V}_E^* = d\mathbf{V}_E^*$, (E, A_F) is regular (see the remark following Theorem 3.1). Also note that $(A+BF)\mathbf{R} = (A+B(F_0+GF_1))\mathbf{R} = [(A+BF_0)+B_0F_1]\mathbf{R} = (A_0+B_0F_1)\mathbf{R} \subset E_0\mathbf{R} = E\mathbf{R}$. Thus, F is a regular friend of $E^{-1}\mathbf{C}$. Also, $\Lambda = \sigma(E_0, A_0+B_0F_1) = \sigma(E|E^{-1}C, A_F|E^{-1}C)$.

To prove the converse statement, note that the existence of an F in $\mathbf{RF}(E^{-1}\mathbf{C})$ implies, through Corollary 3.1, that $E^{-1}\mathbf{C} = \mathbf{V}^*(E^{-1}\mathbf{C}) + \mathbf{Ker\ E}$. Fix $F_0 \in RF(\mathbf{V}^*|E^{-1}\mathbf{C}) \cap \mathbf{RF}(\mathbf{V}^*)$ (use Theorem 3.1 to construct F_0). If F is another regular friend of $E^{-1}\mathbf{C}$, then, by Proposition 3.2, $B(F-F_0)E^{-1}\mathbf{C} \subset \mathbf{B}\cap(EE^{-1}\mathbf{C} + A_{F_0}E^{-1}\mathbf{C}) = \mathbf{B}\cap(C + A_{F_0}E^{-1}\mathbf{C}) = \mathbf{B}_0$. Defining F_1: $E^{-1}\mathbf{C} \to \mathbf{U}$ by $B_0F_1 = B(F-F_0)E^{-1}\mathbf{C}$, we conclude that given any symmetric set Λ of q complex numbers, there exists an F_1 such that $\sigma(E_0, A_0+B_0F_1) = \Lambda$. Then, by Theorem 5.1, (E_0, A_0, B_0) is controllable. That is to say, $E_0\mathbf{R}^*(E_0, A_0, \mathbf{B}_0; E^{-1}\mathbf{C}) = \mathbf{E}_0 = E_0E^{-1}\mathbf{C} = \mathbf{C}$. Then the result follows by noting that $\mathbf{R}^*(E_0, A_0, \mathbf{B}_0; E^{-1}\mathbf{C}) = \mathbf{R}^*(E, A, \mathbf{B}; E^{-1}\mathbf{C})$. Thus, $\mathbf{C} = E\mathbf{R}^*(E^{-1}\mathbf{C})$ and $\mathbf{C}$ is a generalized controllability subspace. □

COROLLARY 5.1. *Let* $\mathbf{R}$ *be a generalized reachability subspace with* $dE\mathbf{R} = q \geqq 1$. *Given any symmetric set* Λ *of* q *complex numbers, there exists a regular friend* F *of* R *that renders* $\Lambda = \sigma(E|\mathbf{R}, A_F|\mathbf{R})$.

Proof. Note that $\mathbf{ER}$ is a controllability subspace, and $\mathbf{RF}(\mathbf{R}) \cap \mathbf{RF}(\mathbf{E}^{-1}\mathbf{ER}) \neq 0$. Then choose $F_0 \in \mathbf{RF}(\mathbf{R}) \cap \mathbf{RF}(\mathbf{E}^{-1}\mathbf{ER}) \cap \mathbf{RF}(\mathbf{V}^*)$. Then the proof of Theorem 5.2 also proves the corollary because $\sigma(E|R, A_F|\mathbf{R}) = \sigma(E|\mathbf{E}^{-1}\mathbf{ER}, A_F|\mathbf{E}^{-1}\mathbf{ER}) = \sigma(E|\mathbf{R}+\mathbf{Ker\ E}, A_F|\mathbf{R}+\mathbf{Ker\ E})$. □

As the nonequivalence of reachability and controllability for singular systems is due to the singularity of E, it may be conjectured that if $\mathbf{R}\cap\mathbf{Ker\ E} = 0$, then the converse of Corollary 5.1 is also true. This indeed is the case.

LEMMA 5.1. *Let* $\mathbf{R}$ *with* $d\mathbf{R} = q \geqq 1$ *satisfy* $\mathbf{R}\ \mathbf{Ker\ E} = \mathbf{0}$. *Suppose that, given any symmetric set* Λ *of* q *complex numbers, there exists a regular friend* F *of* $\mathbf{R}$ *that yields* $\Lambda = \sigma(E|\mathbf{R}, A_F|\mathbf{R})$. *Then* $\mathbf{R}$ *is a generalized reachability subspace.*

Proof. If $\mathbf{R}$ has a regular friend, then by Corollary 3.1, $\mathbf{R} = \mathbf{V}^*(\mathbf{R}) + \mathbf{R}\cap\mathbf{Ker\ E}$. As $\mathbf{R}\cap\mathbf{Ker\ E} = \mathbf{0}$, we have $\mathbf{R} = \mathbf{V}^*(\mathbf{R})$, that is, $\mathbf{R}$ is $(A, E, \mathbf{B})$-inv. To show that $R^*(E, A, \mathbf{B}; \mathbf{R}) = \mathbf{R}$, fix $F_0 \in RF(\mathbf{R}) \cap \mathbf{RF}(\mathbf{V}^*)$ and let $E_0 = E\mathbf{R} + A_{F_0}\mathbf{R}|E|\mathbf{R}$; $A_0 = E\mathbf{R} + A_{F_0}\mathbf{R}|A|\mathbf{R}$ and $\mathbf{B}_0 = \mathbf{B}\cap(E\mathbf{R} + A_F\mathbf{R})$. Then the premise of the lemma is equivalent to asserting the existence of an F_1: $R \to U$ that yields $\sigma(E_0, A_0+B_0F_1) = \Lambda$ for any given symmetric set Λ of q complex numbers (see the proof of Theorem 5.2). As rank $E_0 = dE\mathbf{R} = d\mathbf{R} = q$, we conclude by Theorem 5.1 that (E_0, A_0, B_0) is controllable, that is, $\langle E_0, A_0|\mathbf{B}_0\rangle + \mathbf{Ker\ E}_0 = \mathbf{R}$. As $\mathbf{Ker\ E}_0 = \mathbf{Ker\ E}\cap\mathbf{R} = \mathbf{0}$, we have $\langle E_0, A_0|\mathbf{B}_0\rangle = \mathbf{R}$. Then $\mathbf{S}_*(E_0, A_0, \mathbf{B}_0; \mathbf{R}) = \mathbf{R}$ and as $\mathbf{S}_*(E_0, A_0, \mathbf{B}_0; \mathbf{R}) = S_*(E, A, \mathbf{B}; \mathbf{R})$, $\mathbf{R}$ is a generalized almost-reachability subspace also. Thus R is a generalized reachability subspace. □

We shall end our discussion by investigating the effects of using proportional-plus-derivative feedback (rather than only proportional feedback) on the spectral assignability properties of generalized reachability subspaces. We first note Lemma 5.2.

LEMMA 5.2. $\mathbf{R}$ *is a generalized reachability subspace if and only if there exist* F, K, *and* G *such that* $\mathbf{R} = \langle E_k, A_F|\mathbf{BG}\rangle$.

Proof. (If.) Take $K = 0$ and F, G as in § 4. (Only if.) $\mathbf{R}$ is $(A_F, E_k, \mathbf{BG})$-inv. and, therefore, it is $(A, E, \mathbf{B})$-inv. Also, $\mathbf{S}_*(E_k, A_F, \mathbf{BG}; \mathbf{R}) = \mathbf{R}$ clearly implies $\mathbf{S}_*(E, A, \mathbf{R}; \mathbf{R}) = \mathbf{R}$. □

LEMMA 5.3. *There exists a linear map* $K: \mathbf{X} \to \mathbf{U}$ *such that if* R *is* $(A, E, \mathbf{B})$*-invariant, then* $\mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}_k = \mathbf{0}$.

Proof. Note that $d(E\mathbf{V}^* + \mathbf{B}) = d\mathbf{V}^*$[3], [20]. Write $E\mathbf{V}^* + \mathbf{B} = E\mathbf{V}^* \oplus \mathbf{B}_1$. Then $d(\mathbf{V}^* \cap \mathbf{Ker}\, \mathbf{E}) = d\mathbf{B}_1$. Let $p = d\mathbf{B}_1$ and choose $\{v_i: i \in \mathbf{p}\}$ and $\{Bw_i: i \in \mathbf{p}\}$ as bases for $\mathbf{V}^* \cap \mathbf{Ker}\, \mathbf{E}$ and B_1, respectively. Define $K_0 v_i = -w_i$, $i \in \mathbf{p}$ and let K be any extension of K_0 to $\mathbf{X}$. Then $E_k\mathbf{V}^* = E\mathbf{V}^* + \mathbf{B}$ and thus, $dE_k\mathbf{V}^* = d\mathbf{V}^*$. If $\mathbf{R}$ is $(A, E, \mathbf{B})$-inv., then $\mathbf{R} \subset \mathbf{V}^*$, and therefore $\mathbf{R} \cap \mathbf{Ker}\, \mathbf{E}_k = \mathbf{0}$. □

Lemma 5.3 will be instrumental in showing the following fact.

THEOREM 5.3. *A subspace* $\boldsymbol{R}$ *with* $d\mathbf{R} = q \geqq 1$ *is a generalized reachability subspace if and only if, given any symmetric set* Λ *of* q *complex numbers, there exist linear maps* F *and* K *such that we have the following*:

(1) (E_k, A_F) *is regular*;

(2) $A_F\mathbf{R} \subset E_k\mathbf{R}$;

(3) $\sigma(E_k|\mathbf{R}, A_F|\mathbf{R}) = \Lambda$.

Proof. Let $\mathbf{R}$ be a generalized reachability subspace. Choose K as in Lemma 5.3. Then $\mathbf{R}$ is a reachability subspace of (E_k, A, B) satisfying $\mathbf{R}\ \mathbf{Ker}\, \mathbf{E}_k = \mathbf{0}$. The result now follows from Corollary 5.1.

Now, suppose that there exist F and K to satisfy (1)-(3). As $q = \text{card}\ \sigma(E_k|\mathbf{R}, A_F|\mathbf{R}) \leqq \text{rank}\,(E_k|\mathbf{R}) \leqq q$, we have $\text{rank}\,(E_k|\mathbf{R}) = q$, that is, $\text{Ker}\,(E_k/\mathbf{R}) = 0$. Thus, $\mathbf{Ker}\, \mathbf{E}_k \cap \boldsymbol{R} = 0$. Then, by Lemma 5.1, $\mathbf{R}$ is a reachability subspace of (E_k, A, B). But then $\mathbf{R}$ is clearly a reachability subspace of (E, A, B) also. □

Indeed, it is also possible to prove a much stronger version of Theorem 5.3. However, as the proof that we have is too long to be reproduced here, we would rather state it as a conjecture.

CONJECTURE. *A subspace* $\mathbf{R}$ *with* $d\mathbf{R} = \geqq 1$ *is a generalized reachability subspace if and only if, given any integer* r, $0 \leqq r \leqq q$, *and any symmetric set* Λ *of* r *complex numbers, there exist linear maps* F *and* K *such that*:

(1) (E_k, A_F) *is regular*;

(2) $A_F\mathbf{R} \subset E_k\mathbf{R}$;

(3) $\sigma(E_k|\mathbf{R}, A_F|\mathbf{R}) = \Lambda$.

The conjecture above states that some or all of the eigenvalues of the closed-loop system restricted to R can be shifted to infinity if so desired.

6. Extension to nonregular systems. We emphasize that, although regularity of the open-loop system (1.1) has been a standing assumption throughout the paper, this choice has not been motivated by the dependence of the results on the regularity condition. Rather, we have been trying to simplify the exposition that has already been complicated enough by the condition of the closed-loop regularity. Now, assume that (1.1) is not regular, but is regularizable as defined in [20]. That is to say, suppose that $(E, A + BF_0, B)$ is a regular system for some linear map F_0. Suppose $\mathbf{R}$ is an $(A, E, \mathbf{B})$-inv. subspace that also satisfies GARSA given by (4.1). Then, $(A + BF_0)\mathbf{R} \subset E\mathbf{R} + \mathbf{B}$ and $\mathbf{R}$ also satisfies (4.1) when the recursion is performed with $(A + BF_0)$ rather than A. Thus, $\mathbf{R}$ is a reachability subspace of $(E, A + BF_0, B)$, and there exist linear maps F_1 and G so that $\mathbf{R}$ becomes the reachable subspace $\langle E, A + BF_0 + BF_1 | BG\rangle$ of a regular closed-loop system $(E, A + BF_0 + BF_1, BG)$. Letting $F = F_0 + F_1$, we realize that even when (1.1) is not regular, if $\mathbf{R}$ is an $(A, E, \mathbf{B})$-inv. subspace satisfying GARSA, then there exist linear maps F and G so that $R = \langle E, A + BF | \mathbf{BG}\rangle$.

7. Conclusions. It has been shown that the concept of reachability subspaces can be generalized to encompass singular systems also. This was accomplished by demonstrating that if (and only if) a given subspace $\mathbf{R}$ is an $(A, E, \mathbf{B})$-inv. (generalized)

almost-reachability subspace, then there exist two linear maps F and G such that $\mathbf{R}$ is the reachable subspace of a regular closed-loop system $(E, A+BF, BG)$. Instrumental in handling the complexities caused by the condition of closed-loop regularity was the notion of "regular friends" of an $(A, E, \mathbf{B})$-inv. subspace. We emphasize that our approach uses only proportional feedback, as opposed to the constant-ratio proportional-plus-derivative feedback used in [23].

A subspace $\mathbf{C} \subset E\mathbf{X}$ was defined to be a generalized controllability subspace if $\mathbf{C} = E\mathbf{R}$ for some generalized reachability subspace (in which case C becomes the controllable subspace of a regular system $(E, A+AB, BG)$ for some F and G). Spectral assignability properties of generalized controllability subspaces (as well as those of generalized reachability subspaces) were also discussed.

To simplify the presentation, we assumed a regular (i.e., $\det(sE-A) \not\equiv 0$) system. However, all the results were finally extended to the nonregular case.

Appendix.

Proof of Theorem 2.3. Let $K : \mathbf{X} \to \mathbf{U}$ be as constructed in the proof of Lemma 5.3. Then K satisfies $\mathbf{Ker}\, \mathbf{E}_k \cap \mathbf{V}^* = \mathbf{0}$ and $E\mathbf{V}^* + \mathbf{B} = E_k\mathbf{V}^*$. Now, it is easy to mimic the proof of Theorem 5.6 in [27] to show that $\mathbf{S}_*(\mathbf{V}^*) := \mathbf{S}_*(E, A, \mathbf{B}; \mathbf{V}^*)$ is $(A, E, \mathbf{B})$-inv. Then an $F: \mathbf{X} \to \mathbf{U}$ satisfying $A_F\mathbf{S}_*(\mathbf{V}^*) \subset E_k\mathbf{S}_*(\mathbf{V}^*)$ can be found. Note that $A_F\mathbf{V}^* \subset A\mathbf{V}^* + \mathbf{B} \subset E\mathbf{V}^* + \mathbf{B} = E_k\mathbf{V}^*$. This $\mathbf{V}^*$ is $(A_F, E_k, \mathbf{0})$-inv. and is, therefore, included in the initial manifold of (E_k, A_F). On the other hand, as $(A_F, E_k, \mathbf{0})$ invariance clearly implies $(A, E, \mathbf{B})$ invariance, the initial manifold of (E_k, A_F) is also included in $\mathbf{V}^*$. That is to say, $\mathbf{V}^*$ is the initial manifold of (E_k, A_F). Note that Theorem 2.1 and the fact that $\mathbf{Ker}\, \mathbf{E}_k \cap \mathbf{V}^* = \mathbf{0}$ imply that (E_k, A_F) is regular. Let $\mathbf{S}_k^0$ denote the final manifold $S_*(E_k, A_F, \mathbf{0}; \mathbf{X})$ of (E_k, A_F).

If S_k is defined by $\mathbf{S}_{k+1} = E^{-1}(A\mathbf{S}_k + \mathbf{B})$; $\mathbf{S}_0 = \mathbf{0}$, then $\mathbf{S}_0\, \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0$. If $\mathbf{S}_k\mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0$ is assumed, then it follows that

$$
\begin{aligned}
\mathbf{S}_{k+1} &\subset E^{-1}\{A\mathbf{S}_*(\mathbf{V}^*) + A\mathbf{S}_*^0 + \mathbf{B}\} \\
&\subset E_k^{-1}\{A_F\mathbf{S}_*(\mathbf{V}^*) + A_F\mathbf{S}_*^0 + \mathbf{B}\} \\
&\subset E_k^{-1}\{E_k\mathbf{S}_*(\mathbf{V}^*) + E_k\mathbf{S}_*^0 + \mathbf{B}\} \\
&\subset E_k^{-1}\{E_k\mathbf{S}_*(\mathbf{V}^*) + E_k\mathbf{S}_*^0 + \mathbf{B} \cap \mathbf{E}_k\mathbf{V}^*\} \quad \text{(because } B \subset E_k\mathbf{V}^*\text{)} \\
&\subset \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0 + \mathbf{V}^* \cap E_k^{-1}\mathbf{B} + \mathbf{Ker}\, \mathbf{E}_k \quad \text{(by Properties 2.1 and 2.2)} \\
&\subset \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_k^0 \quad \text{(because } \mathbf{Ker}\, \mathbf{E}_k \subset \mathbf{S}_*^0 \text{ and } \mathbf{V}^* \cap E_k^{-1}\mathbf{B} \subset \mathbf{S}_*(\mathbf{V}^*)\text{)}.
\end{aligned}
$$

Thus, $\mathbf{S}_k \subset \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0$ for all k, and therefore, $\lim_k \mathbf{S}_k := \mathbf{S}_* \subset \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0$. Then

$$
\begin{aligned}
\mathbf{S}_* \cap \mathbf{V}^* &\subset (\mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0) \cap \mathbf{V}^* \\
&\subset \mathbf{S}_*(\mathbf{V}^*) + \mathbf{S}_*^0 \cap \mathbf{V}^* \quad \text{(by Property 2.1)}.
\end{aligned}
$$

As (E_k, A_F) is regular and $\mathbf{V}^*$ and $\mathbf{S}_*^0$ are the initial and final manifolds of (E_k, A_F), respectively, $\mathbf{S}_*^0 \cap \mathbf{V}^* = \mathbf{0}$ by Theorem 2.1. Consequently, $\mathbf{S}_* \cap \mathbf{V}^* \subset \mathbf{S}_*(\mathbf{V}^*)$. It is also trivially true that $\mathbf{S}_*(\mathbf{V}^*) \subset \mathbf{S}_* \cap \mathbf{V}^*$. Then $\mathbf{S}_*(\mathbf{V}^*) = \mathbf{S}_* \cap \mathbf{V}^*$, and the proof is complete. □

H_∞ INTERPOLATION IN SYSTEMS WITH COMMENSURATE INPUT LAGS*

GILEAD TADMOR†

Abstract. H_∞ optimal control and system design problems are known to mathematically reduce to the framework of operator interpolation. Here a solution scheme in the context of systems with multiple input lags is provided. The main result, a linear algebraic characterization of eigenvalue/eigenfunction pairs, can be utilized also in finite-dimensional approximations of the associated Hankel Operator. A particular feature of the analysis is the heavy reliance on time-domain techniques and utilization of explicit time-domain properties of the transfer function.

Key words. H_∞ interpolation, input delays, time domain analysis, eigenvalues, eigenfunctions

AMS(MOS) subject classifications. 47A20, 30D55, 49A34

1. Introduction. Our note is part of a recent effort to develop a theory of H_∞ optimization for distributed parameter systems. Strong motivations come from control and system engineering. H_∞ theory addresses a wide spectrum of worst-case analysis design and control issues, including robust control, weighted sensitivity minimization, model matching, tracking error attenuation, gain-phase margins, and the like (see [12], [13], [17], [22], [23] for overviews and references). Problems involving distributed parameter systems that are currently of great interest, such as the robust design of large space structures, or the control of flexible robot arms, naturally fall in its domain. The general difficulty is, of course, in handling the inherent infinite dimensionality of distributed parameter systems.

The central component in an H_∞ optimization procedure is the (approximate or exact) solution of an operator interpolation problem. (An account of the relation of operator interpolation to H_∞ optimization can be found in the manuscript [12]. The technical details of the problem are given in § 2.) In the context of distributed parameter systems, the operator to be interpolated, say T, becomes infinite-dimensional, which renders the problem quite difficult. First attempts to solve it were restricted, therefore, to case studies [3]–[6] of SISO (scalar) systems with single pure delay; these are perhaps the simplest distributed parameter systems. Nonetheless, the analysis revealed considerable complexity already in this case.

Delay systems are of interest for their own virtue. But they also serve as relatively simple realizations of input-output maps, in some systems that are actually governed by partial differential equations (PDEs), and distributed control mechanisms. (Examples are linear elements subject to tension, compression and torsion, with boundary control and observations. These systems are internally modeled by the wave equation; yet, their input-output transfer function is that of a delay system.) To my knowledge, the present investigation is the first beyond the initial studies mentioned above to provide a solution scheme in the context of an infinite-dimensional system. It treats the entire class of systems with multiple (commensurate) input lags, which seems a natural follow-up. Our technique readily generalizes to also cover certain systems with distributed input delays [21]. Hopefully, it will provide insight into H_∞ optimization problems in other interesting classes.

† Program in Mathematical Sciences, The University of Texas at Dallas, Richardson, Texas 75083-0688.

A special feature of the developments in this paper is that they are based on a predominately time-domain analysis. We derive and work with time-domain formulae for the operator T and for its adjoint T^*. We do so utilizing the time-domain meaning of the system's transfer function and some elementary semigroup theory. In particular, we do not use an inner-outer factorization of the transfer function, as is the common practice.

Our main result, Observation 4.1, is a workable (linear algebraic) characterization of eigenvalue/eigenfunction pairs for T^*T. These pairs are known to play a key role in suboptimal solutions, via finite-dimensional approximations of T (see, e.g., [18]), and in optimal solutions, as we describe in § 2, below.

Indeed, studies that became available following the preparation of the first version of this paper [7]–[11], [24] concentrate also on spectral analysis of the operator T, with some beautiful results. In particular, [11] provides an algebraic characterization of eigenvalue/eigenfunction pairs in a very general setting. In point of fact, we were motivated by the discussion in [24] to improve certain developments from the original version of this paper. We shall make note of these improvements during the discussion.

The paper is organized as follows: the problem statement and some preliminary results are given in § 2. Time domain formulae for T and for T^* are derived in § 3. In § 4 we characterize eigenvalue/eigenfunction pairs for T^*T, and conclude, in § 5, with an illustrating example.

2. Preiiminaries. H_2 and H_∞ are the usual Hardy spaces of analytic functions on the open right half complex plane, with L_2 and L_∞ boundary values (respectively) on the imaginary axis (the frequency domain). Since the Laplace transform defines an isometry between $L_2[0,\infty)$ and H_2, we shall not distinguish between a function in $L_2[0,\infty)$ and its transform in H_2 by some particular notation (e.g., by "$\wedge$" or "$\vee$"). Thus if $f\in H_2$ then $f(t)$ will be the time-domain function, $f(s)$ will be its Laplace transform, defined over the right half-plane, and $f(j\omega)$ will be the boundary function of the latter, over the frequency domain. A good source on Hardy spaces, inner and outer functions, etc., is [14].

A star will denote the adjoint of an operator (e.g., T^*, in particular, if A is a matrix then A^* is the transposed complex conjugate of A), and the conjugate $f^*(s)=\overline{f(-\bar{s})}$ of an analytic function.

The following is a general setup of the operator interpolation problem. Given are a rational function $w(s)\in H_\infty$, and an inner function $m(s)$. Let K be the orthogonal complement of $m(s)H_2$ in H_2 ($K=H_2\ominus mH_2$), let π be the orthogonal projection of H_2 onto K, and let $T: K\to K$ be the bounded linear operator formed by compression of multiplication by $w(s)$ to the space K. Namely, $Tf=\pi(wf)$ for $f\in K$. A function $w_0\in H_\infty$ *interpolates* T if it satisfies (i) $Tf=\pi(w_0f)$ and (ii) $\|w_0\|_\infty=\|T\|$ (equals the induced operator norm of T). We look for an interpolating function.

Notice that, by definition of T, the function $w(s)$ satisfies (i), but that in general it can only be expected that $\|w\|_\infty\geqq\|T\|$. Condition (ii) is therefore an optimality requirement on the family of functions $w_0\in H_\infty$ that define T via (i).

Details on the way to reduce an H_∞ system optimization problem to the framework of an interpolation problem can be found in [12]. Let us just mention here that $m(s)$ is the inner part of the transfer function $G(s)$ of a system at hand, and that $w(s)$ reflects a design objective; e.g., a weight function in the context of weighted sensitivity minimization. Consequently, optimal compensators are computed in terms of interpolating functions.

Let us also mention that substituting $G(s)$ for $m(s)$ in the definition of the subspace K will have no effect on that definition. The reason is that for an outer function $\psi(s) \in H_2$, the linear manifold $\psi(s)H_2$ is dense in H_2.

Here we are interested in systems with multiple input delays. We assume, therefore, that $G(s) = P(e^{-s})$, where $P(z) = \sum_{i=0}^{n} a_i z^i$ is a polynomial. For technical simplicity we also assume the following: $w(s)$ has only first-order poles; using the notation $w(s) = \eta + \sum_{i=1}^{m} \alpha_i/(s+\beta_i)$; $w(s) = 0$ implies Re $s < 0$ (i.e., $w(s)$ is of minimum phase); and $P(z) = 0$ implies $|z| < 1$.

Sarason [20] has established the existence of an interpolating function. The following observation of Sarason is generally used as a starting point for computing it.

LEMMA 2.1 [20, Prop. 5.1]. *Suppose the operator T has a maximal function $f \in K$. Then the unique interpolating function is $w_0(s) = Tf(s)/f(s)$. The function $w_0(s)$ is all-pass: $|w_0(jw)| = \|T\|$ almost everywhere.*

It follows from Weyl's lemma [16, pp. 32, 295] that $\|T^*T\|$ is equal to the spectral radius $\rho(T^*T)$. (We shall justify the use of Weyl's lemma in the proof of Observation 2.2 in § 4.) We are therefore led to compute $\rho(T^*T)$ and check whether it is an eigenvalue of T^*T. For if it is, then the associated eigenfunction is the desired maximal function for T. Via Lemma 2.1, that function provides the solution to the interpolation problem.

In § 4 we find a parameterized family of $2m \times 2m$ matrices $\Omega(\lambda^2)$, $\lambda^2 \geqq 0$, such that λ^2 is an eigenvalue if and only if $\det \Omega(\lambda^2) = 0$. Associated eigenfunctions are then easily recovered from zero vectors of $\Omega(\lambda^2)$. This characterization is to be used in searching for maximal eigenvalue/eigenfunction pairs. The following observation restricts the domain of the numerical search. (The proof is deferred to § 4.)

OBSERVATION 2.2. (1) *If for some $\omega_0 > 0$ there holds $|w(j\omega)| > |\eta|$ almost everywhere for $|\omega| > \omega_0$, then a maximal eigenvalue exists.*

(2) *If a maximal eigenvalue exists, it is situated in the interval $[|\eta|^2, \|w\|_\infty^2]$.*

(3) *If $|w(j\omega)| \leqq \eta$ for all ω, then unless $w(s) \equiv \eta$ (then $T = \eta I$), a maximal eigenvalue does not exist. Yet, then $w(s)$ itself is an interpolating function.*

3. The time-domain setup. Our first task is to provide a tangible description of the subspace $K = H_2 \ominus P(e^{-s})H_2$, and a workable formula for the projection π. We do so in the time domain, identifying H_2 with $L_2[0, \infty)$.

OBSERVATION 3.1. *The subspace K consists of all the solutions to the difference equation*

$$\sum_{i=0}^{\infty} \bar{a}_i f(t+i) = 0 \quad \text{for } t \in [0, \infty), \tag{3.1}$$

that satisfy $f|_{[0,n]} \in L_2[0, n]$.

Proof. Let $\mathbf{P}: H_2 \to H_2$ be the multiplication operator associated with the function $P(e^{-s})$. By Fredholm's alternative, $K = \ker \mathbf{P}^* \subset L_2[0, \infty)$. Provided that $f \in L_2[0, \infty)$, equation (3.1) explicitly rewrites the equality $\mathbf{P}^* f = 0$. Hence, we have the necessity of the conditions on f.

To establish sufficiency it has to be shown that a solution of (3.1), with an initial trajectory in $L_2[0, n]$, must belong to $L_2[0, \infty)$. Indeed, let $S(t)$ be the c_0-semigroup on $L_2[0, n]$, which shifts along solutions. That is, if f is a solution with $f|_{[0,n]} = \xi \in L_2[0, n]$, then $[S(t)\xi](\tau) = f(t+\tau)$ for $\tau \in [0, n]$. The characteristic equation of the infinitesimal generator of $S(\cdot)$ is $G^*(s) = P(e^{\bar{s}}) = 0$. Our assumption ($P(z) = 0 \Rightarrow |z| < 1$, in § 2) is that solutions of this equation all lie strictly within the open left half-plane.

Thus it follows, from the standard theory of delay and difference equations (see, e.g., [15]), that $\|S(t)\| \leqq Me^{-\varepsilon t}$ for some positive constants M and ε. Hence the claim is true.

For future use we add the following notation: $E = S(n)$ and $Q = \sum_{i=0}^{\infty} E^{*i}E^i$ are operators on $L_2[0, n]$. (The stability of $S(\cdot)$ assures that Q is well defined.) Given a function f on $[0, \infty)$, and $t \geqq 0$, the symbol f^t stands for the function on $[0, n]$, defined by $\tau \to f(t+\tau)$.

COROLLARY 3.2. *The orthogonal projection $\pi : L_2[0, \infty) \to K$ is given by the formula*

$$[\pi f]^{ln} = E^l Q^{-1} \sum_{i=0}^{\infty} E^{*i} f^{in}, \qquad l = 0, 1, 2, \cdots. \tag{3.2}$$

Proof. Taking the right-hand side of (3.2) as a definition of π, we shall now show that it is the orthogonal projection onto K. That is, that (i) Im $\pi \subset K$, (ii) $\pi|_K = I|_K$, and (iii) $\pi^* = \pi$.

(i) As in the previous proof, $\|E^{*i}\| \leqq Me^{-\varepsilon in}$. Hence, the series on the right-hand side of (3.2) converges for $f \in L_2[0, \infty)$, and $[\pi f]^0 \in L_2[0, n]$. The definition of E implies that πf satisfies (3.1), and by Observation 3.1 it is a function in K.

(ii) If $f \in K$ then $f^{in} = E^i f^0$, whereby

$$\begin{aligned}[\pi f]^{ln} &= E^l Q^{-1} \sum_{i=0}^{\infty} E^{*i} E^i f^0 \\ &= E^l Q^{-1} Q f^0 = E^l f^0 = f^{ln}.\end{aligned}$$

So $\pi|_K = I|_K$.

(iii)

$$\begin{aligned}\langle \pi f, g\rangle_{L_2[0,\infty)} &= \sum_{l=0}^{\infty} \langle \pi f^{ln}, g^{ln}\rangle_{L_2[0,n]} \\ &\sum_{l=0}^{\infty} \left\langle E^l Q^{-1} \sum_{i=0}^{\infty} E^{*i} f^{in}, g^{ln} \right\rangle_{L_2[0,n]} \\ &= \sum_{i=0}^{\infty} \left\langle f^{in}, E^{in} Q^{-1} \sum_{l=0}^{\infty} E^{*ln} g^{ln} \right\rangle_{L_2[0,n]} \\ &= \langle f, \pi g\rangle_{L_2[0,\infty]}.\end{aligned}$$

COROLLARY 3.3. *Let X be the space $L_2[0, n]$ when endowed with the inner product $\langle \cdot, \cdot \rangle_X = \langle \cdot, Q\cdot \rangle_{L_2[0,n]}$. Then K and X are isometric, and the isometry is defined by the mapping $\iota : X \to K$, where*

$$[\iota\xi]^{ln} := E^l \xi \quad \text{for } l = 0, 1, 2, \cdots.$$

Proof. Following from Observation 3.1, we have that the mapping ι defines an isomorphism between X and K, and $\iota^{-1} f = f^0$ for $f \in K$. The observation that ι is isometric follows from

$$\begin{aligned}\|\iota\xi\|_K^2 &= \langle \iota\xi, \iota\xi\rangle_{L_2[0,\infty)} \\ &= \sum_{i=0}^{\infty} \langle [\iota\xi]^{in}, [\iota\xi]^{in}\rangle_{L_2[0,n]} \\ &= \sum_{i=0}^{\infty} \langle E^i\xi, E^i\xi\rangle_{L_2[0,n]} \\ &= \langle \xi, Q\xi\rangle_{L_2[0,n]} = \|\xi\|_X^2.\end{aligned}$$

So far we have essentially used only the fact that the difference equation $\mathbf{P}^* f = 0$ gives rise to an exponentially stable semigroup. Taking into account the commensurate structure of the delay operator $P(e^{-s})$, we discover that the operators E, E^*, and Q (indeed, the key elements in our formulae) have very simple, finite-dimensional structures, as follows: Set

$$\tilde{E} = -\begin{bmatrix} \bar{a}_n & 0 & \cdots & & 0 \\ \bar{a}_{n-1} & \bar{a}_n & 0 & \cdots & 0 \\ \vdots & & & & \\ \bar{a}_1 & \cdots & & \bar{a}_{n-1} & \bar{a}_n \end{bmatrix}^{-1} \begin{bmatrix} \bar{a}_0 & \bar{a}_1 & \cdots & & \bar{a}_{n-1} \\ 0 & \bar{a}_0 & \bar{a}_1 & \cdots & \bar{a}_{n-2} \\ \vdots & & & & \\ 0 & \cdots & & 0 & \bar{a}_0 \end{bmatrix},$$

and, given a (scalar) function $\xi \in X$, define an n-vector function $\tilde{\xi}$, on $[0, 1)$, by

$$\tilde{\xi}(\tau) = \begin{bmatrix} \xi(\tau) \\ \xi(\tau+1) \\ \vdots \\ \xi(\tau+n-1) \end{bmatrix} \quad \text{for } \tau \in [0, 1).$$

OBSERVATION 3.4. *$\zeta = E\xi \Leftrightarrow \tilde{\zeta} = \tilde{E}\tilde{\xi}$ and $\zeta = E^*\xi \Leftrightarrow \tilde{\zeta} = \tilde{E}^*\tilde{\xi}$.*

Proof. The observation follows directly from (3.1).

Consequently, $\tilde{Q} = \sum_{i=0}^{\infty} \tilde{E}^{*i}\tilde{E}^i$ is a matrix representation of the operator Q. It can be computed in a finite process, as a solution of the Lyapunov equation $\tilde{Q} - \tilde{E}^*\tilde{Q}\tilde{E} = \tilde{I}$ (see [1] for detail). Henceforth we shall use these matrix representations, and in particular, the associated matrix version $\tilde{\pi}$ of the projection onto K.

We turn to the operators T and T^*. In view of Corollary 3.3, we shall interpret them as defined over the space X. The appropriate definition of T is thereby $T\xi = [\pi(w * \iota\xi)]^0$, where $*$ stands for the convolution in $L_2[0, \infty)$ and $w(t)$ is given by

$$w(t) = \eta\delta(t) + \sum_{i=1}^{m} \alpha_i e^{-\beta_i t}, \qquad t \geqq 0$$

(with $\operatorname{Re} \beta i > 0$, since $w(s) \in H_\infty$).

Since for $\xi \in X$ we have $\delta * \eta\xi = \eta\xi$ and $[\pi \circ \iota\eta\xi]^0 = \eta\xi$, it remains to compute concrete formulae for terms of the form $[\pi(e^{-\beta \cdot} * \iota\xi)]^0$, where $\operatorname{Re} \beta > 0$. Invoking Observation 3.4, a straightforward computation yields

$$\widetilde{[e^{-\beta \cdot} * \iota\xi]^{in}}(\tau) = \tilde{E}^i \int_0^\tau e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\, d\theta$$

$$+ \left(\tilde{F}_0\tilde{E}^i + \tilde{F}_1 \sum_{k=0}^{i-1} e^{(k-i)n\beta}\tilde{E}^k \right) \int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\, d\theta, \qquad \tau \in [0, 1) \tag{3.3}$$

where $\sum_{k=0}^{i-1} := 0$ for $i = 0$, and the matrices $\tilde{F}_0 = \tilde{F}_0(\beta) = [(f_0)_{pq}]$ and $\tilde{F}_1 = \tilde{F}_1(\beta) = [(f_1)_{pq}]$ are as follows:

$$(f_0)_{pq} = \begin{cases} e^{(q-p)\beta} & \text{for } n \geqq p > q \geqq 1, \\ 0 & \text{for } 1 \leqq p \leqq q \leqq n, \end{cases}$$

and

$$(f_1)_{pq} = e^{(q-p)\beta} \quad \text{for } p, q = 1, 2, \cdots, n.$$

For simplicity we assume that $e^{-n\beta}$ is not an eigenvalue of $\tilde{E}$ and rewrite (3.3) as

$$
\begin{aligned}
(3.3^0)\qquad \cdots &= \tilde{E}^i \int_0^\tau e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta \\
&\quad + ((\tilde{F}_0 - \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1})\tilde{E}^i + \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1}\,e^{-in\beta}) \int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta.
\end{aligned}
$$

Now

$$
\begin{aligned}
[\pi(\widetilde{e^{-\beta\cdot}} * \iota\xi)]^0(\tau) &= \tilde{Q}^{-1}\sum_{i=0}^{\infty} \tilde{E}^{*i}[\widetilde{e^{-\beta\cdot}} * \iota\xi]^{in}(\tau) \\
&= \tilde{Q}^{-1}\sum_{i=0}^{\infty} \tilde{E}^{*i}\tilde{E}^i \int_0^\tau e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta \\
&\quad + \tilde{Q}^{-1}\sum_{i=0}^{\infty} \tilde{E}^{*i}((\tilde{F}_0 - \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1})\tilde{E}^i \\
&\quad + \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1}\,e^{-in\beta}) \\
&\quad \cdot \int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta \\
&= \tilde{Q}^{-1}\tilde{Q}\int_0^\tau e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta \\
&\quad + \tilde{Q}^{-1}\left(\left(\sum_{i=0}^{\infty} \tilde{E}^{*i}(\tilde{F}_0 - \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1})\tilde{E}^i\right)\right. \\
&\quad \left. + (\tilde{I}-\tilde{E}^*\,e^{-n\beta})^{-1}\tilde{F}_1(I-\tilde{E}\,e^{n\beta})^{-1}\right) \cdot \int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta \\
&= \int_0^\tau e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta + \tilde{G}\int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta
\end{aligned}
\tag{3.4}
$$

where

$$
\tilde{G} = \tilde{G}(\beta) = \tilde{Q}^{-1}(\tilde{Y} + (\tilde{I}-\tilde{E}^*\,e^{-n\beta})^{-1}\tilde{F}_1(I-\tilde{E}\,e^{n\beta})^{-1})
$$

and

$$
\tilde{Y} = \sum_{i=0}^{\infty} \tilde{E}^{*i}(\tilde{F}_0 - \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1})\tilde{E}^i.
$$

Note that by assumption ($\operatorname{Re}\beta > 0$) the matrix $\tilde{I}-\tilde{E}^*\,e^{-n\beta}$ is indeed invertible, and that $\tilde{Y}$ can be computed by solving the Lyapunov equation $\tilde{Y}-\tilde{E}^*\tilde{Y}\tilde{E} = \tilde{F}_0 - \tilde{F}_1(\tilde{I}-\tilde{E}\,e^{n\beta})^{-1}$. Substituting β_i for β and $\tilde{G}_i = \tilde{G}(\beta_i)$ for G, we thus have observation 3.5.

OBSERVATION 3.5. *Interpreted as defined on X, the operators T and T^* are given by the formulae*

$$
\begin{aligned}
[\widetilde{T\xi}](\tau) &= \eta\tilde{\xi}(\tau) + \sum_{i=1}^{m} \alpha_i \int_0^\tau e^{\beta_i(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta + \sum_{i=1}^{m} \alpha_i G_i \int_0^1 e^{\beta_i(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta, \\
[\widetilde{T^*\zeta}](\tau) &= \bar{\eta}\tilde{\zeta}(\tau) + \sum_{i=1}^{m} \bar{\alpha}_i \int_\tau^1 e^{\bar{\beta}_i(\tau-\theta)}\tilde{\zeta}(\theta)\,d\theta + \sum_{i=1}^{m} \bar{\alpha}_i\tilde{Q}^{-1}\tilde{G}_i^*\tilde{Q}\int_0^1 e^{\bar{\beta}_i(\tau-\theta)}\tilde{\zeta}(\theta)\,d\theta \\
&= \bar{\eta}\tilde{\zeta}(\tau) - \sum_{i=1}^{n} \bar{\alpha}_i \int_0^\tau e^{\bar{\beta}_i(\tau-\theta)}\tilde{\zeta}(\theta)\,d\theta + \sum_{i=1}^{n} \bar{\alpha}_i[\tilde{I}+\tilde{Q}^{-1}\tilde{G}_i^*\tilde{Q}]\int_0^1 e^{\bar{\beta}_i(\tau-\theta)}\tilde{\zeta}(\theta)\,d\theta
\end{aligned}
$$

for $\tau\in[0,1]$, and where $\tilde{G}_i^*$ is the usual matrix adjoint.

The proof is obvious once we notice that the adjoint of the operator $G: X \to X$ has the matrix representation $\tilde{Q}^{-1}\tilde{G}^*\tilde{Q}$.

In what follows, it will be useful to work also with scalar formulae for T and T^*, utilizing this next observation on the exact structure of the matrices $\tilde{G}_i$ and $\tilde{I} + \tilde{Q}^{-1}\tilde{G}_i^*\tilde{Q}$.

OBSERVATION 3.6. *Let $\tilde{G}$ be as in formula* (3.4). *Then three exist n-vectors $\tilde{a}$, $\tilde{b}$, $\tilde{c}$, and $\tilde{d}$ such that*

$$\tilde{G}(\beta) - \tilde{F}_0(\beta) = ab^* \quad \text{and} \quad \tilde{I} + \tilde{Q}^{-1}\tilde{G}^*(\beta)\tilde{Q} + \tilde{F}_0(-\bar{\beta}) = \tilde{c}\tilde{d}^*.$$

Proof. For the moment we return to a frequency domain discussion, motivated by [24, § 1.2]. Let π_+ and π_- be the orthogonal projections from $L_2(j\mathfrak{R})$ onto H_2 and $H_2^\perp$, respectively, and recall that $m(s)$ is the inner part of $G(s) = P(e^{-s})$. It is very easy to see that the frequency domain formula for the projection $\pi: H_2 \to K$ is $\pi f(s) = m(s)\pi_-(m^*(s)f(s))$. Thus

$$\begin{aligned} \pi\left(\frac{1}{s+\beta}f(s)\right) &= m(s)\pi_-\left(m^*(s)\frac{1}{s+\beta}f(s)\right) \\ &= \frac{1}{s+\beta}f(s) - m(s)\pi_+\left(\frac{1}{s+\beta}m^*(s)f(s)\right) \end{aligned} \tag{3.5}$$

for $f \in K$.

Consider the second term on the right-hand side of (3.5). For $f \in K$, the function $m^*(s)f(s)$ belongs to $H_2^\perp$. It follows from the standard theory of Hankel operators (see, e.g., [12, Chap. 6]) that the operator that takes $h(s) \in H_2^\perp$ to $\pi_+(1/(s+\beta)h(s)) \in H_2$ is of rank one. We rewrite the conclusion in a vector form, and in the time domain

$$\pi(\widetilde{e^{-\beta\cdot}} * f) - \widetilde{e^{-\beta\cdot}} * f = \text{a first-order operator applied to } f \quad \text{for } f \in K. \tag{3.6}$$

Now we are almost done! Invoking formulae (3.3^0) (with $i = 0$) and (3.4), the left-hand side of (3.6) is equal to

$$\cdots = (\tilde{G} - \tilde{F}_0)\int_0^1 e^{\beta(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta.$$

So $\tilde{G} - \tilde{F}_0$ must be a matrix of rank one, namely, of the form $\tilde{a}\tilde{b}^*$.

The conclusion regarding the matrix $\tilde{I} + \tilde{Q}^{-1}\tilde{G}^*\tilde{Q}$ follows from a completely similar line of arguments, applied to the operator T^*.

COROLLARY 3.7. *Let $\tilde{a}_i$, $\tilde{b}_i$, $\tilde{c}_i$, and $\tilde{d}_i$ correspond to the matrix $\tilde{G}_i$, $i = 1, \cdots, m$, as in the previous observation. Then*

$$\begin{aligned} T\xi(\tau) &= \eta\xi(\tau) + \sum_{i=1}^m \alpha_i \int_0^\tau e^{\beta_i(\theta-\tau)}\xi(\theta)\,d\theta \\ &\quad + \sum_{i=1}^m \alpha_i e^{-\beta_i\tau}\sum_{k=0}^{n-1} e^{\beta_i k}a_{ik}\chi_{[k,k+1)}(\tau)\int_0^1 e^{\beta_i\theta}\langle\tilde{b}, \tilde{\xi}(\theta)\rangle\,d\theta, \\ T^*\zeta(\tau) &= \bar{\eta}(\tau) - \sum_{i-1}^m \bar{\alpha}_i \int_0^\tau e^{\bar{\beta}_i(\tau-\theta)}\zeta(\theta)\,d\theta \\ &\quad + \sum_{i=1}^m \bar{\alpha}_i e^{\bar{\beta}_i\tau}\sum_{k=0}^{n-1} e^{-\bar{\beta}_i k}c_{ik}\chi_{[k,k+1)}(\tau)\int_0^1 e^{-\bar{\beta}_i\theta}\langle\tilde{d}, \tilde{\zeta}(\theta)\rangle\,d\theta \end{aligned}$$

for $\tau \in [0, n]$, and where $\chi_{[\varepsilon,\delta]}(\cdot)$ is the usual characteristic function of the interval $[\varepsilon, \delta]$. The scalars a_{ik} and c_{ik} are the $k+1$ components of the n-vectors $\tilde{a}$ and $\tilde{c}$, respectively.

Remark. Information on the order of zero of $P(z)$ at $z=0$ can help in simplifying some of the constructions above and facilitate the numerical computations suggested in the following section. The particular case $P(z)=z^n$ is the simplest: it stands for a single, pure input lag, which is the case studied in [2]–[6]. In those papers it is observed that then K is isometric to $L_2[0, n]$, and that T is the restriction of the Volterra operator of convolution with $w(t)$, to the interval $[0, n]$. Indeed, it turns out that if $a_0=a_1=\cdots=a_{n-1}=0$, and $a_n\neq 0$ (which is our case), then the matrix $\tilde{E}$ vanishes, $\tilde{Q}$ is simply the identity, and $\tilde{G}=\tilde{F}_0$, for all i.

In a more general case $P(z)$ will have a zero of order $1\leqq k\leqq n$ at the origin, i.e., $a_0=a_1=\cdots+a_{k-1}=0$, $a_k\neq 0$. This information can be utilized as follows. Denote $b_i=a_{i+k}$ for $i=0, 1, \cdots, n-k$, and define a new version of E, for the polynomial $\sum_{i=0}^{n-k} b_i z^i$. Now E is an operator on $L_2[0, n-k]$. It easily turns out that the following counterpart of Corollary 3.2 holds.

COROLLARY 3.2^0. *The orthogonal projection $\pi: H^2\to K$, is given by the following*:

(i) $[\pi f](\tau)=f(\tau)$ *for* $\tau\in[0, k)$;

(ii) $[\pi f]^k(\tau)=Q^{-1}\sum_{i=1}^{\infty}[E^{*i}f^{k+i(n-k)}](\tau)$ *for* $\tau\in[0, n-k)$;

(iii) $[\pi f]^{k+i(n-k)}(\tau)=[E^i[\pi f]^k](\tau)$ *for* $\tau\in[0, n-k)$, $\quad i=0, 1, 2, \cdots$.

Of course, Corollaries 3.2 and 3.2^0 are equivalent, but the latter offers a simpler computational tool: the matrices $\tilde{E}$ and $\tilde{Q}$ corresponding to the revised definition of E are of smaller size, $(n-k)\times(n-k)$ instead of $n\times n$, as before. The computation of the coefficients $\tilde{G}_i$ (which will remain $n\times n$) will then require solutions of Lyapunov equations of lower dimensionality, and thus simplify the numerical computations needed for the solution of the maximal eigenvalue/eigenfunction problem, as explained in the following section. For notational simplicity, we shall nonetheless continue the discussion in the general framework of Corollary 3.2 and Observation 3.5.

4. Characterization of eigenvalues and eigenfunctions of T^*T. In what follows we rule out the trivial case $w(s)\equiv\eta$ (for then $T=\eta I$). Our solution strategy is to identify a $2mn$-dimensional subspace $U=U(\lambda^2)\subset X$, associated with each positive number λ^2, such that if λ^2 is an eigenvalue of T^*T, then all its eigenfunctions must belong to U. Then we shall narrow the domain of possible eigenfunctions of λ^2 to a smaller subspace $U_0\subset U$, with dim $U_0=2m$. Finally we shall define an operator $\Omega(\lambda^2)$ on U_0, with the property that $0\neq\xi\in U_0$ is an eigenfunction if and only if $\Omega(\lambda^2)\xi=0$. The operator $\Omega(\lambda^2)$ will have an easy-to-construct matrix representation, so the characterization reduces to simple linear algebra. The original statement of the following useful observation was made by Flamm and Mitter [3], [5], for the particular case $P(z)=z$.

OBSERVATION 4.1. *Suppose that λ^2 is an eigenvalue of T^*T, and that $\xi\in X$ is an associated eigenfunction. Let $U=U(\lambda^2)\subset X$ be the subspace spanned by the functions $\kappa(\tau)$, such that $\tilde{\kappa}(\tau)=\tau^q e^{\mu\tau}\tilde{u}$, where $\tilde{u}$ is a constant n-vector, and where $s=\mu(\neq\infty)$ is a zero of order $\geqq q+1$ of the equation*

$$w^*(s)w(s)=\lambda^2. \tag{4.1}$$

Then $\xi\in U$.

(*Note that* dim $U=2nm$, *unless for the case* $\lambda^2=|\eta|^2$, *where* dim $U=2n(m-1)$.)

Proof. Suppose $\phi=T\xi$ and $\zeta=T^*\phi$, for some ξ, ϕ, and $\zeta\in X$. Denote

$$\tilde{x}_i(\tau)=\alpha_i\left(\int_0^{\tau} e^{\beta_i(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta+\tilde{G}_i\int_0^1 e^{\beta_i(\theta-\tau)}\tilde{\xi}(\theta)\,d\theta\right),$$

$$\tilde{x}_{i+m}(\tau)=\bar{\alpha}_i\left(\int_{\tau}^1 e^{\beta_i(\tau-\theta)}\tilde{\phi}(\theta)\,d\theta+\tilde{Q}^{-1}\tilde{G}_i^*\tilde{Q}\int_0^1 e^{\bar{\beta}_i(\tau-\theta)}\tilde{\phi}(\theta)\,d\theta\right)$$

for $i = 1, 2, \cdots, m$ and $\tau \in [0, 1]$. Then the following equations hold:

$$
\begin{aligned}
&\dot{\tilde{x}}_i = -\beta_i \tilde{x}_i + \alpha_i \tilde{\xi}, \qquad i = 1, \cdots, m, \\
&\tilde{\phi} = \eta \tilde{\xi} + \sum_{i=1}^{m} \tilde{x}_i, \\
&\dot{\tilde{x}}_{i+m} = \bar{\beta}_i \tilde{x}_{i+m} - \bar{\alpha}_i \tilde{\phi}, \qquad i = 1, \cdots, m, \\
&\tilde{\zeta} = \bar{\eta} \tilde{\phi} + \sum_{i=1}^{m} \tilde{x}_{i+m}.
\end{aligned} \tag{4.2}
$$

Equation (4.2) can be written in a standard system form as

$$
\dot{z} = Az + B\tilde{\xi}, \qquad \tilde{\zeta} = Cz + |\eta|^2 \tilde{\xi} \tag{4.2^0}
$$

where z is a $2nm$ vector. We leave out the obvious detail of the matrices A, B, and C, and mention just the following two facts.

The first is captured in the formula

$$
C(s - A)^{-1} B = (W^*(s) W(s) - |\eta|^2) \tilde{I}, \tag{4.3}
$$

where $\tilde{I}$ is the $n \times n$ identity matrix.

The second fact is that for each $k = 0, 1, 2, \cdots$, the matrix $CA^k B$ is a scalar multiple, say, by some $\varepsilon(k)$, of the matrix $\tilde{I}$. In particular, either $CA^k B$ vanishes, or it is an invertible matrix.

Suppose now that λ^2 is an eigenvalue of T^*T associated with the eigenfunction $\xi \in X$. Then $\lambda^2 \tilde{\xi}$ substitutes for $\tilde{\zeta}$ in (4.2^0), and we have the following proposition.

PROPOSITION. *There exists a matrix L such that $\tilde{\xi} = Lz$.*

Proof. The case $\lambda^2 \neq |\eta|^2$ is easier: from the second equation in (4.2^0) we obtain $L = C/(\lambda^2 - |\eta|^2)$.

Suppose that $\lambda^2 = |\eta|^2$. By assumption ($w(s) \not\equiv \eta$, $w(s) = 0 \Rightarrow \operatorname{Re} s < 0$, and $w(s)^{-1} = 0 \Rightarrow \operatorname{Re} s < 0$), there holds $w^*(s) w(s) \not\equiv |\eta|^2$. It thus follows from (4.3) that an integer $k \geqq 0$ exists, such that $CA^j B = 0$ for $0 \leqq j < k$ and $CA^k B \neq 0$. (By Cayley-Hamilton, $k \leqq n - 1$.) As we have noted above, $CA^k B = \varepsilon(k) \tilde{I}$ for some nonzero scalar $\varepsilon(k)$. In particular, $CA^k B$ is an invertible matrix.

Now, $Cz \equiv 0$ since $\lambda^2 = |\eta|^2$ and $\tilde{\zeta} = \lambda^2 \tilde{\xi}$. Thus,

$$
0 \equiv C\dot{z} = CAz + CB\tilde{\xi}.
$$

If $k > 0$ it follows that $CAz \equiv 0$, which in turn implies

$$
0 \equiv CA\dot{z} = CA^2 z + CAB\tilde{\xi}.
$$

Continuing this way inductively, we deduce that $CA^j z \equiv 0$ for $j = 0, 1, \cdots, k$, and consequently that

$$
0 \equiv CA^{k+1} z + CA^k B\tilde{\xi}.
$$

Thus, $L = -(CA^k B)^{-1} CA^{k+1}$ is the desired matrix.

Having established the claim, it follows that $z(\tau)$ satisfies a linear, autonomous, time-invariant ordinary differential equation (ODE) for $\tau \in [0, 1]$. It can therefore be extended analytically to a solution over the positive ray $\tau \geqq 0$. The Laplace transform, $z(s)$, of the extended solution, is a strictly proper rational function. Consequently, $\tilde{\xi}(\tau)$ is analytically extendable for all $\tau \geqq 0$, and the Laplace transform of the extended

function, $\tilde{\xi}(s)$, is a well-defined, strictly proper rational function. Following Laplace transformation, (4.2^0) becomes

$$(\lambda^2-|\eta|^2)\tilde{\xi}(s)=C(s-A)^{-1}(z_0+B\tilde{\xi}(s))$$
$$=C(s-A)^{-1}z_0+(w^*(s)w(s)-|\eta|^2)\tilde{\xi}(s) \quad \text{by (4.3)}\cdots$$

and we finally get

$$\tilde{\xi}(s)=-(w^*(s)w(s)-\lambda^2)^{-1}C(s-A)^{-1}z_0, \tag{4.4}$$

where z_0 is the initial value of the (time domain) function $z(\tau)$.

By definition of A, the poles of $C(s-A)^{-1}z_0$ are poles of $w^*(s)w(s)$. Hence, poles of $\tilde{\xi}(s)$ are finite ($\neq\infty$) zeros of $w^*(s)w(s)-\lambda^2$; that is, they are solutions of (4.1). Hence ξ belongs to U as claimed.

Our next effort is to restrict the initial $2mn$ vector z_0 (from (4.4)) to a subspace of dimension $2m$.

We easily observe that the matrices A, B, and C of (4.2^0) are all built of $n\times n$ blocks which are each a constant multiple of the $n\times n$ identity. Let A_0, B_0, and C_0 be the matrices obtained by collapsing each of these blocks to a scalar entry. Let κ be the $2m\times 2m$ main-diagonal matrix-valued measure on $[0, n]$ where the first m main-diagonal entries are $\alpha_i e^{-\beta_i\tau}d[\sum_{k=0}^{n-1} e^{\beta_i k}a_{ik}\chi_{[k,k+1)}(\tau)]$, $i=1,\cdots,m$ followed by the m entries $\bar{\alpha}_i e^{\beta_i\tau}d[\sum_{k=0}^{n-1} e^{-\bar{\beta}_i k}c_{ik}\chi_{[k,k+1)}(\tau)]$, $i=1,\cdots,m$. Let y be the $2m$-vector whose first m components are $\int_0^1 e^{\beta_i\theta}\langle\tilde{b}_i, \tilde{\xi}(\theta)\rangle\, d\theta$, $i=1,\cdots,m$ followed by $\int_0^1 e^{-\bar{\beta}_i\theta}\langle\tilde{d}_i, \tilde{\phi}(\theta)\rangle\, d\theta$, $i=1,\cdots,m$. Finally, let $x(\tau)$ be the $2m$-vector valued function, whose ith entry, $x_i(\tau)$, is the scalar version of the function $\tilde{x}_i(\cdot)$ from (4.2).

Then, in the same way that (4.2^0) follows from Observation 3.5, Corollary 3.7 implies the dynamics

$$\begin{aligned} dx(\tau)&=[A_0x(\tau)+B_0\xi(\tau)]\,d\tau+d\kappa(\tau)y,\\ \zeta(\tau)&=C_0x(\tau)+|\eta|^2\xi(\tau)\end{aligned} \tag{4.5}$$

for $\tau\in[0, n]$, and with $x(0-)=0$. By arguments similar to those in the proof of Observation 4.1 we deduce that if $\xi(\tau)$ is an eigenfunction for λ^2, then there exists a $1\times 2m$ matrix L_0 with $\xi(\tau)=L_0x(\tau)$.

The first equation in (4.5) thus becomes

$$dx(\tau)=(A_0+B_0L_0)x(\tau)\,d\tau+d\kappa(\tau)y, \tag{4.6}$$

or, in an integrated form (since $x(0-)=0$)

$$x(\tau)=[e^{(A_0+B_0L_0)\cdot}*d\kappa](\tau)y. \tag{4.6^0}$$

Now define functions $x(\tau)$ via (4.6^0) where y is allowed to be any $2m$-vector. The linear mapping from the vector y to the $2mn$ vector $z=(z_{(i-1)n+k}=x_i(k-1+)\colon i=1,\cdots,2m \text{ and } k=1,\cdots,n)$ is therefore a $2mn=2m$ matrix which we denote by M. This matrix depends on λ^2 since L_0 does, and it can be obtained via numerical integration (that is, by computing n different $2m\times 2m$ matrix exponentials).

COROLLARY 4.2. *Fix λ^2 and let $U_0\subset U$ be the space spanned by functions $\xi(\tau)\in L_2[0, n)$, such that $\tilde{\xi}(\tau)$ is the restriction to the interval $\tau\in[0, 1]$ of the inverse Laplace transform of*

$$\tilde{\xi}(s)=(w^*(s)w(s)-\lambda^2)^{-1}C(s-A)^{-1}My$$

for some $2m$-vector y. If λ^2 is an eigenvalue of T^*T, then associated eigenfunctions must belong to U_0.

Proof. From the above, the initial vector $z_0 = z(0)$ in (4.2^0) and (4.4) must be of the form $z_0 = My$ for some $2m$-vector y.

Now, given λ^2, we restrict our attention to the subspace $U_0(\lambda^2)$. For notational convenience we also introduce the subspaces V, W, U_1, V_1, and $W_2 \subset X$ as follows:

$$V = \text{span}\{v(\tau)\colon \tilde{v}(\cdot) = e^{-\beta_i \cdot}\tilde{v} \quad \text{for } i = 1, \cdots, n \text{ and constant } n-\text{vectors } \tilde{v}\},$$

$$W = \text{span}\{w(\tau)\colon \tilde{w}(\cdot) = e^{\bar{\beta}_i \cdot}\tilde{w} \quad \text{for } i = 1, \cdots, n \text{ and constant } m-\text{vectors } \tilde{w}\},$$

$$U_1 = T(U_0) \cap U, \quad V_1 = T(U_0) \cap V, \quad W_2 = T^*(U_1) \cap W.$$

(The latter three spaces depend on λ^2.)

Following from Observation 3.4 the operator T maps U into $U+V$, and T^* maps $U+V$ into $U+V+W$. From the assumptions on $w(s)$ it is born that $U \cap V = \{0\}$, $U \cap W = \{0\}$, and indeed, $V \cap W = \{0\}$. Thus, the appropriate restrictions of T and T^* have the block structures

$$T|_U = \begin{bmatrix} T_1 \\ T_2 \end{bmatrix} \quad \text{and} \quad T^*|_{U+V} = \begin{bmatrix} T_{11}^* & 0 \\ 0 & T_{22}^* \\ T_{31}^* & T_{32}^* \end{bmatrix}$$

where T_1 and $T_{11}^*\colon U \to U$, T_2 and $T_{22}^*\colon V \to V$, $T_{31}^*\colon U \to W$ and $T_{32}^*\colon V \to W$. We denote

$$\Omega(\lambda^2) = \begin{bmatrix} T_2 \\ T_{31}^* T_1 \end{bmatrix}\Bigg|_{U_0}.$$

The following is our main result.

THEOREM 4.3. *The number λ^2 is an eigenvalue of T^*T and is associated with the eigenfunction $\xi(\tau) \in X$ if and only if $\xi(\tau) \in U_0$ and $\Omega(\lambda^2)\xi = 0$.*

Before bringing the proof, let us note that $\Omega(\lambda^2)$ maps U_0 into $V_1 + W_2$. Computed in terms of the formulae in Observation 3.5, a matrix representation of $\Omega(\lambda^2)$ is (at most) $2m \times 2m$, and the theorem becomes a linear algebraic rank condition.

Proof. By Corollary 4.2, λ^2 is an eigenvalue of T^*T associated with the eigenfunction ξ, if and only if $\xi \in U_0$ and the following equations hold:

$$T_{11}^* T_1 \xi = \lambda^2 \xi \tag{4.7}$$

and

$$\begin{bmatrix} 0 & T_{22}^* \\ T_{31}^* & T_{32}^* \end{bmatrix}\begin{bmatrix} T_1 \\ T_2 \end{bmatrix}\xi = 0. \tag{4.8}$$

Notice that (4.8) can be rewritten also as

$$\begin{bmatrix} T_{22}^* & 0 \\ T_{32}^* & I \end{bmatrix}\Omega(\lambda^2)\xi = 0 \tag{4.8^0}$$

so that the theorem will follow from these next two propositions.

PROPOSITION 4.4. $T_{11}^* T_1 = \lambda^2 I_U$.

PROPOSITION 4.5. *T_{22}^* is invertible.*

Proof of Proposition 4.4. It will be easier to establish this claim in the frequency domain, referring to the Laplace transforms of analytic extensions of functions from U. This space is spanned by functions of the form $\tilde{u}/(s-\mu)^q$ where μ is a zero of

order $\geqq q$ of (4.1) and $\tilde{u}$ is a constant n-vector. Now, as in the proof of Observation 4.1, we take the Laplace transform of (4.2^0), and invoke (4.3), to obtain

$$\begin{aligned} T^*T(\tilde{u}/(s-\mu)^q) &= C(S-A)^{-1}(z_0+B\tilde{u}/(s-\mu)^q)+|\eta|^2\tilde{u}/(s-\mu)^q \\ &= C(s-A)^{-1}z_0+w^*(s)w(s)\tilde{u}/(s-\mu)^q \end{aligned} \tag{4.9}$$

where z_0 is a $2mn$ vector. By the assumption on μ and by straightforward factorization of rational functions, the right-hand side of (4.9) is further equal to

$$\cdots = \lambda^2\tilde{u}/(s-\mu)^q + \text{terms with poles at } \{-\beta_i, \bar{\beta}_i, i=1,\cdots,m\},$$

which completes the proof of Proposition 4.4.

Proof of Proposition 4.5. Following from the formula for T^* in Observation 3.5, it turns out that (given a constant vector $\tilde{\xi}$)

$$\tilde{T}^*(\tilde{v}\,e^{-\beta_i\cdot})(t) = w^*(-\beta_i)\tilde{v}\,e^{-\beta_i t} + \text{terms in } e^{\bar{\beta}_i t}, \qquad j=1,\cdots,m.$$

So T_{22}^* has the block diagonal representation $\operatorname{diag}[w^*(-\beta_i)\tilde{I}, i=1,\cdots,n]$. Since $\operatorname{Re}\beta_i>0$ and $w(s)$ is of minimum phase, that matrix is invertible.

Remark. Based on the theorem, the computations needed for the characterization of eigenvalues and eigenfunctions include: (i) linear algebraic computations (including a set of Lyapunov matrix equations that are solved once, at a preparatory stage): (ii) solution of (4.1) (for various λ^2), which is a polynomial equation; (iii) numerical integration, in order to compute the matrices $M(\lambda^2)$. We can avoid the need for numerical integrations, at a cost. The theorem remains true (with the same proof), if we extend the definition of $\Omega(\lambda^2)$ to the whole of U, thus relying on Observation 4.1 instead of on Corollary 4.2. The cost is, of course, that now the matrix representation of $\Omega(\lambda^2)$ will be of a larger size, $2nm\times 2nm$ ($2nm\times 2n(m-1)$, if $\lambda^2=|\eta|^2$) instead of $2m\times 2m$.

Indeed, the latter has been the scheme suggested in an earlier version of this article. The current form of the theorem is based on Observation 3.6, and is motivated by the observation that the rank of the operator $(I-\pi)(e^{-\beta\cdot}*\cdot)|_K$ is at most one.

We conclude this section, as promised, with the following proof.

Proof of Observation 2.2. To be able to apply Weyl's lemma, which we need in the proof, it should be first checked that $T^*T-|\eta|^2$ is a compact operator. And indeed it is: By the formulae given in Observation 3.5, both $T-\eta$ and $T^*-\bar{\eta}$ are of the form of Volterra plus finite-dimensional operators on $L_2([0,1],\mathbf{C}^n)$, and the latter space is homeomorphic to X. Hence $T-\eta$ and $T^*-\bar{\eta}$ are compact, and so is $T^*T-|\eta|^2=(T^*-\bar{\eta})(T-\eta)+\bar{\eta}(T-\eta)+\eta(T^*-\bar{\eta})$. (A more general, yet abstract, argument was suggested by the referee. The compactness of $T^*T-|\eta|^2$ follows from the continuity of $G^*(s)w(s)$ on the extended imaginary axis, via a Hartman–Theorem-type result of Muhly [19].)

Having made this observation, we deduce that the norm $\|T^*T\|$ equals the spectral radius $\rho(T^*T)$ and that $|\eta|^2$ is the only limit point of eigenvalues of T^*T. We shall now prove Observation 2.2, point by point.

(ii) Suppose λ^2 were the maximal eigenvalue of T^*T. By Weyl's Lemma $\rho(T^*T)=\|T^*T\|=\|T\|^2$ and $|\eta|^2\leqq\lambda^2$. Obviously, $\|T\|\leqq\|w\|_\infty$. Hence $\lambda^2\in[|\eta|^2,\|w\|_\infty^2]$.

(iii) Suppose $\|w\|_\infty=|\eta|$. We then have the "sandwich" argument $|\eta|^2\leqq\rho(T^*T)=\|T^*T\|=\|T\|^2\leqq\|w\|_\infty^2=|\eta|^2$, which implies that $\|T\|=\|w\|_\infty$. Hence $w(s)$ interpolates T.

Yet if $w(s)\not\equiv\eta$ then $|\eta|^2$ cannot be an eigenvalue of T^*T. Suppose it were; then Sarason's Lemma 2.1 tells us that $w(s)$ should be all-pass, that is, a constant multiple of a Blascke product. In particular then, $w(s)$ cannot be of minimum phase, as assumed.

(i) Since $|\eta|^2$ is the only limit point of eigenvalues of T^*T, it suffices to verify the existence of one eigenvalue $\lambda^2 > |\eta|^2$ to deduce the existence of a maximal eigenvalue. The equality $\rho(T^*T) = \|T^*T\|$ further reduces the proof to a search for a function $f \in K$ such that $\|Tf\|_2^2 > |\eta|^2 \|f\|_2^2$. We now establish the existence of such a function.

We shall use the following fact which is stated in the frequency domain. (Namely, if $f(s)$ is a member of K, we restrict our attention to its values over the imaginary axis, $s = j\omega$.)

PROPOSITION. *The restrictions of functions from K to any compact interval $[-j\omega_1, j\omega_1]$ form a dense subspace of $L_2[-j\omega_1, j\omega_1]$.*

Proof. Following from Corollary 3.3, a frequency domain description of K is given by

$$K = \left\{ f(j\omega) = \zeta(j\omega) \int_0^1 e^{-j\omega\tau} \tilde{\xi}(\tau)\, d\tau \colon \tilde{\xi} \in L_2[0, 1] \right\}$$

where

$$\zeta(j\omega) = [1, e^{-j\omega}, \cdots, e^{-(n-1)j\omega}](\tilde{I} - \tilde{E}\, e^{-j\omega n})^{-1}.$$

Suppose that $g(j\omega) \in L_2[-j\omega_1, j\omega_1]$ were orthogonal to all members of K, over the said interval. Then

$$\begin{aligned} 0 &= \int_{-j\omega_1}^{j\omega_1} \left\langle g(j\omega), \zeta(j\omega) \int_0^1 e^{-j\omega\tau} \tilde{\xi}(\tau)\, d\tau \right\rangle d\omega \\ &= \int_0^1 \left\langle \int_{-j\omega_1}^{j\omega_1} e^{j\omega\tau} \zeta^*(j\omega) g(j\omega)\, d\omega, \tilde{\xi}(\tau) \right\rangle d\tau \end{aligned}$$

for all $\tilde{\xi}(\tau) \in L_2[0, 1]$. Hence

$$\int_{-j\omega_1}^{j\omega_1} e^{j\omega\tau} \zeta^*(j\omega) g(j\omega)\, d\omega = 0 \quad \text{for } \tau \in [0, 1],$$

and by Plancherals equality and the analyticity of the Fourier transform, it follows that $\zeta^*(j\omega) g(j\omega) \equiv 0$. Consequently, $g = 0$, as claimed.

Denote by $R : K \to K^\perp$ the mapping $f \to (I - \pi)(w * f)$. Following from the proof of Observation 3.6, rank $R \leqq m$.

Recall that by our assumption in part (i) of Observation 2.2, there exists some $\omega_0 > 0$ such that $|\omega| > |\omega_1|$ implies $|w(j\omega)| > |\eta|$. Thus there exist $\varepsilon > 0$ and $\omega_2 > \omega_1 > \omega_0$, such that for $|\omega| \in [\omega_1, \omega_2]$ there holds $|w(j\omega)| > |\eta| + \varepsilon$. Given ω_1 and ω_2, let $Y \subset L_2[-j\omega_2, j\omega_2]$ be the space formed by the L_2 closure of restrictions of functions from $\ker(R)$ to the interval $[-j\omega_2, j\omega_2]$. Let $Z \subset Y$ be the subspace of functions from Y that vanish along $[-j\omega_1, j\omega_1]$. Following from the proposition above, codim $Y < \infty$ and dim $Z = \infty$.

Now choose $\delta > 0$ such that $(|\eta| + \varepsilon)^2(1 - \delta) > (|\eta| + \varepsilon/2)^2$. Every nonzero function $g \in Z$ can be approximated (in $L_2[-j\omega_2, j\omega_2]$) by the restriction to $[-j\omega_2, j\omega_2]$ of some function $f \in \ker(R)$, which satisfies

$$\int_{|\omega| \in [\omega_1, \omega_2]} |f(j\omega)|^2\, d\omega > (1 - \delta) \int_{-\omega_2}^{\omega_2} |f(j\omega)|^2\, d\omega.$$

In particular, we conclude that there exists at least one function $f \in \ker(R)$ that satisfies this inequality.

Since $f \in \ker(R)$, there holds $Tf(s) = w(s)f(s)$, whence,

$$\begin{aligned}
\|Tf\|_2^2 &= \int_{-\infty}^{\infty} |w(j\omega)f(j\omega)|^2 \, d\omega \\
&\geqq \left(\int_{|\omega|>\omega_2} + \int_{|\omega|\in[\omega_1,\omega_2]} \right) |w(j\omega)f(j\omega)|^2 \, d\omega \\
&\geqq |\eta|^2 \int_{|\omega|>\omega_2} |f(j\omega)|^2 \, d\omega + (|\eta|+\varepsilon)^2 \int_{|\omega|\in[\omega_1,\omega_2]} |f(j\omega)|^2 \, d\omega \\
&\geqq \left(|\eta|^2 \int_{|\omega|>\omega_2} + (|\eta|+\varepsilon)^2(1-\delta) \int_{|\omega|\leqq\omega_2} \right) |f(j\omega)|^2 \, d\omega \\
&\geqq \left(|\eta|^2 \int_{|\omega|>\omega_2} + \left(|\eta|+\frac{\varepsilon}{2}\right)^2 \int_{|\omega|\leqq\omega^2} \right) |f(j\omega)|^2 \, d\omega \\
&> |\eta|^2 \|f\|_2^2.
\end{aligned}$$

As indicated above, the existence of f completes the proof of part (i), and hence of the observation.

5. A simple example. Set $P(z) = 1 - e^{\alpha} z$ and $w(s) = 1/(\beta + s)$ where α and β are real, positive numbers and $\alpha \neq \beta$. Then $n = 1$, and the matrices $\tilde{E}$ and $\tilde{Q}$ are scalars. We get $\tilde{E} = e^{-\alpha}$ and $\tilde{Q} = 1/(1 - e^{-2\alpha})$. Computation of the coefficient $\tilde{G} = \tilde{G}_1$ yields $\tilde{G} = e^{-(\alpha+\beta)}/(1 - e^{-(\alpha+\beta)})$.

In our example, (4.1) takes the form

$$\frac{1}{\beta + s} \cdot \frac{1}{\beta - s} = \lambda^2,$$

and solutions satisfy $s = \pm\varepsilon$, for $\varepsilon = (\sqrt{\beta^2\lambda^2 - 1})/\lambda$. So (given λ), the space $U = U_0$ is spanned by $\xi_1(\tau) = e^{\varepsilon\tau}$ and $\xi_2(\tau) = e^{-\varepsilon\tau}$. Computations of the matrices T_1, T_2, and T_{31}^* yield

$$T_1 = \begin{bmatrix} \dfrac{1}{\beta+\varepsilon} & 0 \\ 0 & \dfrac{1}{\beta-\varepsilon} \end{bmatrix},$$

$$T_2 = \frac{1}{1 - e^{-(\alpha+\beta)}} \left[\frac{e^{\varepsilon-\alpha} - 1}{\beta+\varepsilon}, \frac{e^{-\varepsilon-\alpha} - 1}{\beta-\varepsilon} \right],$$

$$T_{31}^* = \frac{e^{-(\alpha+\beta)}}{1 - e^{-(\alpha+\beta)}} \left[\frac{e^{\varepsilon+\alpha} - 1}{\beta-\varepsilon}, \frac{e^{-\varepsilon+\alpha} - 1}{\beta+\varepsilon} \right].$$

So $\Omega(\lambda^2)$ is given by

$$\Omega(\lambda^2) = \frac{1}{1 - e^{-(\alpha+\beta)}} \begin{bmatrix} \dfrac{e^{\varepsilon-\alpha} - 1}{\beta+\varepsilon} & \dfrac{e^{-\varepsilon-\alpha} - 1}{\beta-\varepsilon} \\ \dfrac{(e^{\varepsilon+\alpha} - 1)\, e^{-(\alpha+\beta)}}{(\beta-\varepsilon)(\beta+\varepsilon)} & \dfrac{(e^{-\varepsilon+\alpha} - 1)\, e^{-(\alpha+\beta)}}{(\beta+\varepsilon)(\beta-\varepsilon)} \end{bmatrix}$$

$$= \frac{1}{1 - e^{-(\alpha+\beta)}} \begin{bmatrix} 1 & 0 \\ 0 & e^{-(\alpha+\beta)} \end{bmatrix} \cdot \begin{bmatrix} e^{\varepsilon-\alpha} - 1 & e^{-\varepsilon-\alpha} - 1 \\ e^{\varepsilon+\alpha} - 1 & e^{-e+\alpha} - 1 \\ \hline \beta-\varepsilon & \beta+\varepsilon \end{bmatrix} \cdot \begin{bmatrix} \dfrac{1}{\beta+\varepsilon} & 0 \\ 0 & \dfrac{1}{\beta-\varepsilon} \end{bmatrix}.$$

The rank condition (since $\Omega(\lambda^2)$ is 2×2) is that λ^2 is an eigenvalue when

$$(\beta-\varepsilon)(e^{\varepsilon-\alpha}-1)(e^{-\varepsilon+\alpha}-1)-(\beta+\varepsilon)(e^{-\varepsilon-\alpha}-1)(e^{\varepsilon+\alpha}-1)=0. \tag{5.1}$$

In this example we have $\|w(s)\|_\infty = 1/\beta$ and $\eta = 0$. By Observation 2.2 a maximal eigenvalue exists, and it belongs to the interval $(0, 1/\beta^2]$. When λ^2 descends from $1/\beta^2$ to zero, the corresponding ε ranges from zero to $+j\infty$ along the imaginary axis. Thus, our scheme prompts a search for the minimal imaginary solution $\varepsilon = j\omega$ to (5.1). Given such a solution, and the corresponding eigenvalue λ^2, it is easy to find a zero vector $x=[x_1, x_2]'$ for $\Omega(\lambda^2)$. Given such x, a maximal function for T in the space X would be

$$\xi(\tau) = x_1 e^{\varepsilon\tau} + x_2 e^{-\varepsilon\tau}.$$

To use Sarason's Lemma, we also need $T\xi(\tau)$, which is

$$T\xi(\tau) = \frac{x_1}{\beta+\varepsilon} e^{\varepsilon\tau} + \frac{x_2}{\beta-\varepsilon} e^{-\varepsilon\tau} + \frac{1}{1-e^{-(\alpha+\beta)}}\left[\frac{x_1(e^{\varepsilon-\alpha}-1)}{\beta+\varepsilon} + \frac{x_2(e^{-\varepsilon-\alpha}-1)}{\beta-\varepsilon}\right] e^{-\beta\tau}.$$

Using Corollary 3.2 (as in the proof of Observation 2.2, above), we obtain the Laplace transforms of the corresponding members of K:

$$[\xi](s) = \frac{1}{1-e^{-(\alpha+s)}}\left[\frac{x_1(e^{\varepsilon-s}-1)}{\varepsilon-s} + \frac{x_2(e^{-\varepsilon-s}-1)}{-\varepsilon-s}\right],$$

$$[T\xi](s) = \frac{1}{1-e^{-(\alpha+s)}}\left[\frac{x_1(e^{\varepsilon-s}-1)}{(\beta+\varepsilon)(\varepsilon-s)} + \frac{x_2(e^{-\varepsilon-s}-1)}{(\beta-\varepsilon)(-\varepsilon-s)} + \frac{e^{-(\alpha+\beta)}(e^{-\beta-s}-1)}{(1-e^{-(\alpha+\beta)})(-\beta-s)}\left[\frac{x_1(e^{\varepsilon-\alpha}-1)}{\beta+\varepsilon} + \frac{x_2(e^{-\varepsilon-\alpha}-1)}{\beta-\varepsilon}\right]\right].$$

The interpolating function would then be $[T\xi](s)/[\xi](s)$.

ADMISSIBILITY OF UNBOUNDED CONTROL OPERATORS*

GEORGE WEISS†

Abstract. For linear systems described by $\dot{x}(t) = Ax(t) + Bu(t)$, where A generates a semigroup on the state space X and B is an unbounded operator, some necessary as well as some sufficient conditions are given for B to be admissible, i.e., for any t, the state $x(t)$ should be in X and should depend continuously on the input $u \in L^p$. This approach begins with an axiomatic description of such a system in terms of a functional equation. The results are applied to the wave equation on a bounded interval.

Key words. infinite-dimensional linear systems, unbounded control operators, admissibility, multipliers

AMS(MOS) subject classifications. 93C25, 93C20

1. Introduction. In this paper we deal with infinite-dimensional linear time-invariant systems. If we denote by $x(t)$ the state at time t of such a system, then the evolution of $x(t)$ is, in a certain sense, described by the differential equation

$$\dot{x}(t) = Ax(t) + Bu(t). \tag{1.1}$$

Here $x(t) \in X$, the Banach space X being the state space, $u(t) \in U$, the Banach space U being the input space, and A is the generator of a strongly continuous semigroup $\mathbb{T}$ on X. The input function $u(\cdot)$ is assumed to be locally L^p for some $p \in [1, \infty]$.

Our interest will focus on the linear operator B, the *control operator* of the system. B is called *bounded* if it is a bounded operator from U to X, and *unbounded* if it is a bounded operator from U to some larger Banach space V,

$$X \subset V,$$

but not from U to X. (This terminology may seem strange but it is now generally agreed upon.)

Unbounded control operators appear naturally, for example, when we model boundary or point control for systems described by linear PDE's. There is extensive literature dealing with systems having unbounded control operators, for example, Curtain and Pritchard [4, Chap. 8], Curtain and Salamon [5], Desch, Lasiecka, and Schappacher [7], Ho and Russell [12], Lasiecka [14], Lasiecka and Triggiani [15]-[17], Pritchard and Wirth [23], Russell [25], Salamon [26]-[29], and Washburn [30].

Here we address the following problems: which operators B should be accepted as "legitimate," and how to recognize them. We want to make those points somewhat more precise.

Assume that X is dense in V and the semigroup $\mathbb{T}$ has a continuous extension to V (denoted by the same symbol). This assumption might seem artificial at this stage but we shall see later that it is a consequence of natural assumptions about the system we want to model by (1.1). By a solution $x(\cdot)$ of (1.1), for initial conditions given at, say, $t = 0$, we mean the function defined for $t \geqq 0$ by the variation of parameters formula

$$x(t) = \mathbb{T}_t x(0) + \int_0^t \mathbb{T}_{t-\sigma} Bu(\sigma)\, d\sigma. \tag{1.2}$$

* Received by the editors May 6, 1987; accepted for publication (in revised form) May 31, 1988.
† Department of Theoretical Mathematics, Weizmann Institute, Rehovot 76100, Israel.

For the formula above to define an X-valued function, the integral in (1.2) must be in the state space X, despite the fact that what we integrate is in V. If that is indeed the case, for any $t \geqq 0$ and any p-integrable U-valued function $u(\cdot)$ on $[0, t]$, then we say that for the given semigroup $\mathbb{T}$, the control operator B is *admissible*.

Admissible control operators that yield (through (1.2)) the same solution $x(\cdot)$, for any given $x(0)$ and $u(\cdot)$, will be identified.

We shall show that, given the state space X and the semigroup $\mathbb{T}$ on X, there is a Banach space X_{-1}, the *same for all* admissible control operators B (for various U and p) such that X is dense in X_{-1}, $\mathbb{T}$ has a continuous extension to X_{-1}, and B is a bounded operator from U to X_{-1} (see § 3).

However, even for fixed U and p, there is generally no Banach space V with the property that B is admissible if and only if it belongs to $\mathscr{L}(U, V)$ (the space of bounded operators from U to V) (see § 5).

Example 1.1. Consider the wave equation on $[0, \pi]$, without input for the time being:

$$\frac{\partial^2}{\partial t^2}\psi(\zeta, t) = \frac{\partial^2}{\partial \zeta^2}\psi(\zeta, t), \qquad \psi(0, t) = \psi(\pi, t) = 0,$$

$$\psi(\zeta, 0) = \psi_0(\zeta), \qquad \frac{\partial}{\partial t}\psi(\zeta, 0) = \psi_1(\zeta).$$

The weak solution ψ, as a function of ζ, is supposed to be absolutely continuous and to have its ζ-derivative in $L^r[0, \pi]$, for a given $r \in [1, \infty)$. For that, the initial data ψ_0 and ψ_1 have to be given accordingly.

To translate these equations into the semigroup language, let us denote

$$W_0^{1,r}[0, \pi] = \left\{ x \in \mathrm{AC}\,[0, \pi] \,\middle|\, \frac{d}{d\zeta} x \in L^r[0, \pi], x(0) = x(\pi) = 0 \right\},$$

$$W^{2,r}[0, \pi] = \left\{ x \in \mathrm{AC}\,[0, \pi] \,\middle|\, \frac{d}{d\zeta} x \in \mathrm{AC}\,[0, \pi], \frac{d^2}{d\zeta^2} x \in L^r[0, \pi] \right\};$$

AC means "absolutely continuous." We consider these spaces equipped with their usual L^r-type norms. Introducing the state variable and state space

$$x(t) = \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} = \begin{pmatrix} \psi(\cdot, t) \\ \dot{\psi}(\cdot, t) \end{pmatrix}, \qquad X = \begin{matrix} W_0^{1,r} \\ \times \\ L^r \end{matrix},$$

we have

$$\dot{x}(t) = Ax(t),$$

where

$$A = \begin{pmatrix} 0 & I \\ d^2/d\zeta^2 & 0 \end{pmatrix}, \qquad D(A) = \begin{matrix} W^{2,r} \cap W_0^{1,r} \\ \times \\ W_0^{1,r} \end{matrix},$$

and A generates a contraction group $\mathbb{T}$ on X.

We take the simplest input space, $U = \mathbb{R}$, and $p \in [1, \infty]$. A bounded control operator B may be identified with an element $b \in X$, having components b_1 and b_2.

The corresponding partial differential equation is

$$\frac{\partial^2}{\partial t^2}\psi(\zeta, t)=\frac{\partial^2}{\partial \zeta^2}\psi(\zeta, \tau)+b_1(\zeta)\frac{\partial}{\partial t}u(t)+b_2(\zeta)u(t).$$

Concerning unbounded control operators for the above semigroup, we shall prove the following. The admissible control operators B are the image through a certain isomorphism of those periodic distributions on $[0, 2\pi]$ whose Fourier coefficients are in the space of multipliers (L^p, L^r). Like the bounded control operators, the unbounded ones have two components b_1 and b_2 that are both distributions on $[0, \pi]$, so the PDE above is satisfied in a certain distributional sense.

We outline the contents of the following sections. In §§ 2 and 3 we derive a general necessary condition for B to be admissible (in fact, we do more than that). Our approach is the following. Suppose B is admissible and define for $t \geqq 0$ and $u \in L^p([0, \infty), U)$

$$\Phi_t u=\int_0^t \mathbb{T}_{t-\sigma}Bu(\sigma)\,d\sigma. \tag{1.3}$$

Then $\Phi=(\Phi_t)_{t\geqq 0}$ is a family of bounded linear operators from $L^p([0, \infty), U)$ to X. (Clearly Φ_t depends only on the restriction of u to $[0, t]$ but we want to avoid the unnecessary complications that would arise if the domain of Φ_t depended on t.)

The semigroup $\mathbb{T}$ and the family Φ satisfy a natural functional equation (see (2.1)) called the *composition property* (Kalman, Falb, and Arbib [13, p. 6]). We define an *abstract linear control system* as a pair $(\mathbb{T}, \Phi)$, where $\mathbb{T}$ is a strongly continuous semigroup and Φ is a family of operators such that the composition property holds. Clearly (1.1), if B is admissible, defines an abstract linear control system via (1.3). The latter is a simple and natural concept in whose definition no mention of unbounded operators is needed. In § 2 we derive some properties of such systems which will be needed later.

In § 3 we prove a representation theorem stating that for $p<\infty$ any abstract linear control system is described by (1.1), with B admissible, and moreover $B \in \mathscr{L}(U, X_{-1})$, where X_{-1} is a certain extension of X depending only on $\mathbb{T}$. The necessary condition $B \in \mathscr{L}(U, X_{-1})$ may be regarded as an upper limit for "how unbounded" an admissible B may be.

In § 4 we introduce the Banach space of admissible control operators B for given U, X, $\mathbb{T}$, and p, denoted $\mathscr{B}_p$, determine $\mathscr{B}_1$ for reflexive X, and give necessary and sufficient conditions for $B \in \mathscr{B}_p$ in the case of invertible semigroups.

In § 5 we first deal with the periodic left shift semigroup on $L^r[0, 2\pi]$, describing $\mathscr{B}_p$ in terms of multipliers. Then we turn to the controlled wave equation of Example 1.1 which is closely related to the controlled periodic left shift.

Some of the abstract machinery developed in §§ 2–4 of this paper has already been used (see Weiss [31]). For admissible unbounded observation operators, see Weiss [32].

2. Abstract linear control systems. We begin by giving the formal definition of an abstract linear control system, as announced in § 1. For that we need the notion of *concatenation* on $\Omega=L^p([0, \infty), U)$, where U is a Banach space.

Let $u, v \in \Omega$ and let $\tau \geqq 0$. Then the *τ-concatenation of u and v*, $u \underset{\tau}{\diamond} v \in \Omega$, is given by

$$\left(u \underset{\tau}{\diamond} v\right)(t)=\begin{cases} u(t) & \text{for } t \in [0, \tau), \\ v(t-\tau) & \text{for } t \geqq \tau. \end{cases}$$

Recall that we work with Ω because we want to define our system as receiving U-valued locally p-integrable input functions, and any segment of such an input function can be thought of as the restriction to a bounded interval of an element of Ω.

DEFINITION 2.1. Let U and X be Banach spaces, $p \in [1, \infty]$ and $\Omega = L^p([0, \infty), U)$. An *abstract linear control system* on X and Ω is a pair

$$\Sigma = (\mathbb{T}, \Phi),$$

where $\mathbb{T} = (\mathbb{T}_t)_{t \geqq 0}$ is a strongly continuous semigroup on X and $\Phi = (\Phi_t)_{t \geqq 0}$ is a family of bounded operators from Ω to X such that

$$\Phi_{\tau+t}\left(u \underset{\tau}{\diamond} v\right) = \mathbb{T}_t \Phi_\tau u + \Phi_t v \tag{2.1}$$

for any $u, v \in \Omega$ and any $\tau, t \geqq 0$.

The functional equation (2.1) is called the *composition property*. The operators Φ_t are called *input maps*.

Remark 2.2. Taking $\tau = t = 0$ in (2.1) we get $\Phi_0 = 0$, whence, taking now only $t = 0$ in (2.1), we get that Φ is *causal*, i.e., for any $\tau \geqq 0$

$$\Phi_\tau = \Phi_\tau P_\tau, \tag{2.2}$$

where P_τ is the projection of Ω onto $L^p([0, \tau], U)$ defined by

$$P_\tau u = u \underset{\tau}{\diamond} 0.$$

In practice, an abstract linear control system can be given in the form (1.1) and (1.2) (the "semigroup formulation") as in Curtain and Pritchard [4], or as a boundary control system (i.e., described by a nonhomogeneous boundary value problem), as in Lions and Magenes [20], Russell [25], or as a neutral functional differential equation, as in Salamon [26]. The system can also be modeled using a strongly continuous cosine operator, as in Lasiecka and Triggiani [15]. The problem of translation of the boundary value formulation into the semigroup formulation is discussed in Curtain [3], Curtain and Salamon [5], Desch, Lasiecka, and Schappacher [7], Fattorini [11], and Washburn [30]. For an abstract and very general treatment of when and how this translation is possible, see Salamon [27] or [28].

PROPOSITION 2.3. *Let X and Ω be as in Definition* 2.1 *with $p < \infty$ and let $\Sigma = (\mathbb{T}, \Phi)$ be an abstract linear control system on X and Ω. Then the function*

$$\varphi(t, u) = \Phi_t u$$

is continuous on the product $[0, \infty) \times \Omega$, in particular $\Phi = (\Phi_t)_{t \geqq 0}$ is a strongly continuous family of operators.

Proof. Taking in (2.1) $u = 0$ and taking the supremum for $\|v\| = 1$ we get, denoting $T = \tau + t$,

$$\|\Phi_t\| \leqq \|\Phi_T\| \quad \text{for} \quad t \leqq T, \tag{2.3}$$

i.e., $\|\Phi_t\|$ is nondecreasing.

Let us first prove the continuity of $\varphi(t, u)$ with respect to the time t, so for the time being let $u \in \Omega$ be fixed and let

$$f(t) = \Phi_t u.$$

Inequality (2.3) together with causality (2.2) implies that for $t \in [0, 1]$

$$\|f(t)\| \leqq \|\Phi_1\| \cdot \|P_t u\|.$$

Obviously $\|P_t u\| \to 0$ for $t \to 0$ (because of $p < \infty$), so

$$\lim_{t \to 0} f(t) = 0.$$

The right continuity of f in any $\tau > 0$ now follows easily from the composition property (2.1). To prove the left continuity of f in $\tau > 0$ we take a sequence (ε_n) with $\varepsilon_n \in [0, \tau]$ and $\varepsilon_n \to 0$ and define $u_n(t) = u(\varepsilon_n + t)$, so $u_n \in \Omega$ and $u_n \to u$ (because of $p < \infty$). We have

$$u = u \underset{\varepsilon_n}{\diamond} u_n,$$

so according to (2.1)

$$\Phi_{\varepsilon_n + (\tau - \varepsilon_n)} u = \mathbb{T}_{\tau - \varepsilon_n} \Phi_{\varepsilon_n} u + \Phi_{\tau - \varepsilon_n} u_n.$$

From here

$$\Phi_\tau u - \Phi_{\tau - \varepsilon_n} u = \mathbb{T}_{\tau - \varepsilon_n} \Phi_{\varepsilon_n} u + \Phi_{\tau - \varepsilon_n}(u_n - u),$$

which yields

$$\|\Phi_\tau u - \Phi_{\tau - \varepsilon_n} u\| \leqq M \cdot \|f(\varepsilon_n)\| + \|\Phi_\tau\| \cdot \|u_n - u\|,$$

where M is a bound for $\|\mathbb{T}_t\|$ on $[0, \tau]$. Thus the left continuity of f in any $\tau > 0$ is also proved.

The joint continuity of φ follows easily now from the decomposition

$$\Phi_t v - \Phi_\tau u = \Phi_t(v - u) + (\Phi_t - \Phi_\tau) u$$

where $(t, v) \to (\tau, u)$. □

PROBLEM 2.4. In the above proof we have twice used the fact that $p < \infty$. I do not know if the proposition holds for $p = \infty$.

We give an estimate for the growth rate of $\|\Phi_t\|$.

PROPOSITION 2.5. *Let X and Ω be as in Definition* 2.1 *and let $(\mathbb{T}, \Phi)$ be an abstract linear control system on X and Ω.*

If $M \geqq 1$ and $\omega > 0$ are such that

$$\|\mathbb{T}_t\| \leqq M e^{\omega t} \quad \forall t \geqq 0,$$

then there is some $L \geqq 0$ such that

$$\|\Phi_t\| \leqq L e^{\omega t} \quad \forall t \geqq 0.$$

Proof. From (2.1) we get through induction

$$\Phi_n\left(\cdots\left(u_1 \underset{1}{\diamond} u_2\right) \underset{2}{\diamond} \cdots \underset{n-1}{\diamond} u_n\right) = \mathbb{T}_{n-1}\Phi_1 u_1 + \mathbb{T}_{n-2}\Phi_1 u_2 + \cdots + \Phi_1 u_n, \tag{2.4}$$

whence for $t \in (n-1, n]$ (using (2.3))

$$\|\Phi_t\| \leqq \|\Phi_n\| \leqq (\|\mathbb{T}_{n-1}\| + \|T_{n-2}\| + \cdots + \|I\|) \cdot \|\Phi_1\|$$

$$\leqq M \frac{e^{\omega n} - 1}{e^\omega - 1} \|\Phi_1\|,$$

so we can take

$$L = M \frac{e^\omega}{e^\omega - 1} \|\Phi_1\|.$$

□

Remark 2.6. For $\omega = 0$, Φ does not have to be uniformly bounded but we can easily obtain from (2.4), using the Cauchy-Hölder inequality, that

$$\|\Phi_t\| \leqq L \cdot (1+t)^{1-1/p} \quad \forall t \geqq 0,$$

for some $L \geqq 0$. For $\omega < 0$, Φ is uniformly bounded.

Remark 2.7. Let $\tilde{\Omega} = L^p_{\text{loc}}([0, \infty), U)$. Concatenation and the projections P_τ have obvious extensions to $\tilde{\Omega}$. $\tilde{\Omega}$ is a Fréchet space with the family of seminorms $p_n(u) = \|P_n u\|$, $n \in \mathbb{N}$. Any family of input maps Φ defined on Ω can be extended to $\tilde{\Omega}$ by continuity, which is the same as using formula (2.2) as a definition.

3. The representation theorem.

DEFINITION 3.1. Let X be a Banach space and $\mathbb{T}$ a strongly continuous semigroup on X with generator $A: D(A) \to X$. Let $\beta \in \rho(A)$, the resolvent set of A (if X is real, take $\beta \in \mathbb{R}$). We define the space X_1 to be $D(A)$ with the norm

$$\|x\|_1 = \|(\beta I - A)x\|,$$

and the space X_{-1} to be the completion of X with respect to the norm

$$\|x\|_{-1} = \|(\beta I - A)^{-1} x\|.$$

Remark 3.2. It is easy to verify that for any different $\beta_1 \in \rho(A)$ instead of β we get equivalent norms $\|\cdot\|_1$ and $\|\cdot\|_{-1}$ (so X_{-1} does not depend on β). In particular, $\|\cdot\|_1$ is equivalent to the graph norm on $D(A)$, so X_1 is complete.

The spaces X_1, X_{-1} appear, for example, in Nagel [21, p. 19] and Da Prato [6]. If X is *reflexive* then X_{-1} can be defined equivalently as the dual of $(X^*)_1$, where $(X^*)_1 = D(A^*)$ with the graph norm. In this setting, X_1 and X_{-1} are investigated in Salamon [26] and also appear in Salamon [27]-[29], Lasiecka and Triggiani [17].

PROPOSITION 3.3. *With the notation of Definition* 3.1, *let* $\mu \in \rho(A)$ (*if* X *is real, take* $\mu \in \mathbb{R}$). *Then the operator*

$$R_\mu = (\mu I - A)^{-1}$$

has a (*unique*) *continuous extension to an operator in* $\mathcal{L}(X_{-1})$, *which we denote by the same symbol.* R_μ *is an isomorphism from* X_{-1} *to* X *and from* X *to* X_1.

If $L \in \mathcal{L}(X)$ *commutes with* A, *i.e., if*

$$LAx = ALx \quad \forall x \in D(A),$$

then the restriction of L *to* X_1 *belongs to* $\mathcal{L}(X_1)$ *and is the image of* L *via any of the isomorphisms* R_μ. *Further,* L *has a* (*unique*) *continuous extension to an operator in* $\mathcal{L}(X_{-1})$, *which is the image of* L *via any of the isomorphisms* R_μ^{-1}.

Proof. The fact that R_μ is an isomorphism from X_{-1} to X and from X to X_1 follows from Remark 3.2. The properties of L follow from the identities

$$Lx = R_\mu L R_\mu^{-1} x \quad \forall x \in D(A),$$

$$Lx = R_\mu^{-1} L R_\mu x \quad \forall x \in X. \qquad \square$$

Remark 3.4. Taking $L = \mathbb{T}_t$, $t \geqq 0$, we get from Proposition 3.3 that $\mathbb{T}$ has a restriction to a semigroup on X_1 whose generator is the restriction of A to $D(A^2)$ and $\mathbb{T}$ has an extension to a semigroup on X_{-1} whose generator is an extension of A, with domain X. Thus

$$A \in \mathcal{L}(X_1, X) \quad \text{and} \quad A \in \mathcal{L}(X, X_{-1}).$$

DEFINITION 3.5. Let X be a Banach space, let $\mathbb{T}$ be a semigroup on X with generator A, and let

$$f \in L^1_{\text{loc}}([0, \infty), X_{-1}).$$

Then we say that the function

$$x(\cdot) \in L^1_{\text{loc}}([0, \infty), X)$$

is a *strong solution* of the differential equation

$$\dot{x}(t) = Ax(t) + f(t) \tag{3.1}$$

if for any $t \geqq 0$

$$x(t) - x(0) = \int_0^t [Ax(s) + f(s)]\, ds.$$

If additionally, $x(\cdot)$ is continuous in X, i.e., if

$$x(\cdot) \in C([0, \infty), X),$$

then we say that $x(\cdot)$ is a *continuous state strong solution* of the differential equation above.

Our definition of strong solution follows that of Pazy [22, p. 109], if we replace X_{-1} by X and X by X_1. (His Definition 2.8 is slightly flawed; we must add an absolute continuity condition.) What we call a continuous state strong solution is called simply a solution by Salamon [26] (his Definition 3.3).

Remark 3.6. It is obvious that, as an X_{-1}-valued function, any strong solution of (3.1) is absolutely continuous and almost everywhere differentiable. However, since as an X-valued function it is only defined almost everywhere, it might happen that on a null set $x(t) \notin X$. For example, suppose X is a Hilbert space, $\mathbb{T}$ is analytic, and $f \in L^2_{\text{loc}}([0, \infty), X_{-1})$. Then for any initial condition $x(0) = x_0$, (3.1) has a strong solution $x(\cdot) \in L^2_{\text{loc}}([0, \infty), X)$ (see Lions and Magenes [20, Vol. II, p. 22] or Lasiecka [14, p. 325]). However, this strong solution might blow up in finite time with respect to the norm of X (see, for example, Lions [19, p. 202]).

Remark 3.7. In Definition 3.5, the condition

$$x(\cdot) \in L^1_{\text{loc}}([0, \infty), X)$$

is equivalent to

$$Ax(\cdot) \in L^1_{\text{loc}}([0, \infty), X_{-1})$$

and to

$$\dot{x}(\cdot) \in L^1_{\text{loc}}([0, \infty), X_{-1}).$$

If $0 \in \rho(A)$, then this is obvious, A being an isomorphism from X to X_{-1}. If A is not invertible, then to prove the equivalence we must take some $\lambda \in \rho(A)$, replace $x(t)$ by $y(t) = e^{-\lambda t} x(t)$, and do some simple computations.

Remark 3.8. In the conditions of Definition 3.5, if (3.1) has some strong solution, then for any $x_0 \in X$ it has a unique strong solution with $x(0) = x_0$ and that is given by the variation of parameters formula (see (1.2) with $f = Bu$).

To prove this statement it is most convenient to introduce the space X_{-2}, which is obtained from X_{-1} in the same way as X_{-1} is obtained from X. When we take X_{-1} as our new state space and X_{-2} as our new extended space, it is clear that *any strong solution in X is a continuous state strong solution in X_{-1}*. For continuous state strong

solutions, we can easily prove the statement by slightly adjusting a proof in Pazy [22, p. 105].

Now we can state the representation theorem.

THEOREM 3.9. *Let U and X be Banach spaces, let $p \in [1, \infty)$, and let $\Omega = L^p([0, \infty), U)$. Let $(\mathbb{T}, \Phi)$ be an abstract linear control system on X and Ω. Then there is a unique operator $B \in \mathcal{L}(U, X_{-1})$ such that for any $u \in \Omega$ and any $t \geqq 0$*

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma)\, d\sigma. \tag{3.2}$$

Moreover, for any $x_0 \in X$ and $u \in \Omega$ the function of $t \geqq 0$

$$x(t) = \mathbb{T}_t x_0 + \Phi_t u \tag{3.3}$$

is the (unique) continuous state strong solution of the differential equation

$$\dot{x}(t) = Ax(t) + Bu(t) \tag{3.4}$$

with

$$x(0) = x_0.$$

Proof. For any $v \in U$ let us denote by ω_v the constant function on $[0, \infty)$ equal to v everywhere. Then ω_v belongs to the space $\tilde{\Omega}$ (see Remark 2.7) and so

$$\phi_v(t) = \Phi_t \omega_v$$

is a well-defined function from $[0, \infty)$ to X. Proposition 2.3 and causality (2.2) imply that $\phi_v(\cdot)$ is continuous. Using again causality (2.2) and the fact that $\|P_t \omega_v\| = t^{1/p}\|v\|$, we get from Proposition 2.5 that for suitable $\omega > 0$,

$$\|\phi_v(t)\| \leqq L\, e^{\omega t} t^{1/p} \|v\|.$$

It follows that for $s \in \mathbb{C}$ with $\operatorname{Re} s$ sufficiently big, the Laplace transform $\hat{\phi}_v(s)$ of ϕ_v is well defined.

The composition property (2.1), in the particular case of the input ω_v, means that for any $t, \tau \geqq 0$

$$\phi_v(t+\tau) = \mathbb{T}_t \phi_v(\tau) + \phi_v(t).$$

Applying the Laplace transformation with respect to t, we get

$$e^{s\tau}\hat{\phi}_v(s) - e^{s\tau}\int_0^\tau e^{-st}\phi_v(t)\, dt = (sI - A)^{-1}\phi_v(\tau) + \hat{\phi}_v(s),$$

or, rearranging and assuming $\tau > 0$, we have

$$\frac{e^{s\tau} - 1}{\tau}\hat{\phi}_v(s) = \frac{e^{s\tau}}{\tau}\int_0^\tau e^{-st}\phi_v(t)\, dt + (sI - A)^{-1}\frac{\phi_v(\tau)}{\tau}.$$

Taking the limit for $\tau \to 0$ (with respect to the norm of X) and using the continuity of ϕ_v and the fact that $\phi_v(0) = 0$ (Remark 2.2), we get

$$s\hat{\phi}_v(s) = \lim_{\tau \to 0} (sI - A)^{-1}\frac{\phi_v(\tau)}{\tau}, \tag{3.5}$$

in particular the limit on the right-hand side exists. Since $(sI - A)^{-1}$ is an isomorphism from X_{-1} to X (Proposition 3.3), it follows that with respect to the norm of X_{-1} the limit

$$Bv = \lim_{\tau \to 0} \frac{\phi_v(\tau)}{\tau} \tag{3.6}$$

exists and defines a linear operator from U to X_{-1}. We can rewrite (3.5) in the form

$$\hat{\phi}_v(s) = \frac{1}{s}(sI - A)^{-1}Bv, \tag{3.7}$$

which shows ($(sI-A)^{-1}$ being an isomorphism) that

$$B \in \mathscr{L}(U, X_{-1}).$$

The Laplace transformation being one-to-one on the space of continuous, exponentially bounded functions, (3.7) implies that

$$\phi_v(t) = \int_0^t \mathbb{T}_\sigma Bv \, d\sigma. \tag{3.8}$$

Next we show that if $u \in \Omega$ is a step function, then (3.2) holds. We proceed by induction after the number n of bounded intervals on which u is constant (which are of course followed by an unbounded interval on which $u(t) = 0$). For $n = 1$ we already know that the statement is true (see (3.8)). Suppose we know it is true for some $n \in \mathbb{N}$ and let $u \in \Omega$ be constant on $n+1$ bounded intervals, the last of these being $[\tau, T)$. Let $u_\tau(t) = u(\tau + t)$, so $u = u \underset{\tau}{\diamond} u_\tau$. We have for $t \geqq \tau$ (see (2.1))

$$\begin{aligned}
\Phi_t u &= \mathbb{T}_{t-\tau}\Phi_\tau u + \Phi_{t-\tau}u_\tau \\
&= \int_0^\tau \mathbb{T}_{t-\sigma}Bu(\sigma)\, d\sigma + \int_0^{t-\tau} \mathbb{T}_{t-\tau-\sigma}Bu(\tau+\sigma)\, d\sigma \\
&= \int_0^t \mathbb{T}_{t-\sigma}Bu(\sigma)\, d\sigma.
\end{aligned}$$

Thus we have proved (3.2) for any step function. The step functions being dense in Ω (recall that we have assumed $p < \infty$), it follows that (3.2) is true for any $u \in \Omega$.

The uniqueness of the operator B for which (3.2) holds is obvious.

Let us prove that $x(\cdot)$ given by (3.3) is the continuous state strong solution of (3.4) with $x(0) = x_0$. Using

$$\mathbb{T}_t x_0 - x_0 = \int_0^t A\mathbb{T}_s x_0 \, ds$$

the integral equation that $x(\cdot)$ must verify (see Definition 3.5) reduces to

$$\Phi_t u = \int_0^t A\Phi_s u \, ds + \int_0^t Bu(s)\, ds,$$

which is verified by an easy computation using the representation (3.2).

The fact that $x(\cdot) \in C([0, \infty), X)$ follows from Proposition 2.3. For uniqueness see Remark 3.8. □

PROBLEM 3.10. How much of Theorem 3.9 remains valid for $p = \infty$?

Remark 3.11. Salamon [28] has proved a representation theorem that partly overlaps our Theorem 3.9. It concerns systems that have input, state, and output (as opposed to our theorem, which considers only input and state). The part of Salamon's representation theorem that concerns the relationship between input and state is somewhat less general than our Theorem 3.9 in that X and U are assumed to be Hilbert spaces and $p = 2$. Further, the continuity of the state $x(t)$ as a function of the time t is assumed from the outset. Salamon's technique of proof is different from ours.

We mention another representation theorem which appears in Desch, Lasiecka, and Schappacher [7, p. 194]. There, it is proved that the solution of a well-posed initial boundary value problem is given by a formula equivalent to (1.2) of our paper.

Remark 3.12. It follows from Proposition 2.5 that for any $u \in \Omega$, $\Phi_t u$ has a Laplace transform $\hat{\Phi}_s u$. Using the representation (3.2) for $p < \infty$ we get that

$$\hat{\Phi}_s u = (sI - A)^{-1} B\hat{u}(s).$$

Remark 3.13. In the Introduction we have given a definition of admissible control operators. According to that definition, we can say that Theorem 3.9 yields a *necessary condition for admissibility* of B, namely $B \in \mathscr{L}(U, X_{-1})$. However, in the definition of admissibility, which we give at the beginning of § 4, we cut things short by demanding from the beginning $B \in \mathscr{L}(U, X_{-1})$, which makes the formulation easier.

Remark 3.14. If we assume from the outset that the system is modeled by (1.2), where $X \subset V$ with continuous and dense embedding, $B \in \mathscr{L}(U, V)$, $\mathbb{T}$ has a continuous extension to V and A has a continuous extension to an operator in $\mathscr{L}(X, V)$, then the necessary condition $B \in \mathscr{L}(U, X_{-1})$ can be obtained directly from the identity

$$B\mathrm{v} = \int_0^1 \mathbb{T}_t B\mathrm{v}\, dt - A \int_0^1 \mathbb{T}_{1-t} B\mathrm{v} t\, dt,$$

valid for any $\mathrm{v} \in U$ (proof by continuity, approximating $B\mathrm{v}$ by elements of $D(A)$). No reference to Theorem 3.9 is needed.

4. Spaces of admissible control operators. It is natural to ask whether the converse of Theorem 3.9 is true. More precisely, the problem is as follows. Let U and X be Banach spaces, $p \in [1, \infty)$ and $\Omega = L^p([0, \infty), U)$. Any abstract linear control system $(\mathbb{T}, \Phi)$ is, according to Theorem 3.9, completely determined by the pair (A, B), where A generates $\mathbb{T}$ and $B \in \mathscr{L}(U, X_{-1})$. However, as we shall see, not any such pair generates an abstract linear control system. This fact motivates the following definition.

DEFINITION 4.1. Let U and X be Banach spaces, let $p \in [1, \infty]$, and let $\Omega = L^p([0, \infty), U)$. Let $\mathbb{T}$ be a strongly continuous semigroup on X and let $B \in \mathscr{L}(U, X_{-1})$. For any $t \geqq 0$ we define the operator $\Phi_t : \Omega \to X_{-1}$ by

$$\Phi_t u = \int_0^t \mathbb{T}_{t-\sigma} B u(\sigma)\, d\sigma. \tag{4.1}$$

Then we say that B is *p-admissible* for $\mathbb{T}$ if for any $t \geqq 0$, $\Phi_t \in \mathscr{L}(\Omega, X)$.

It is easy to see that B is p-admissible if and only if the corresponding families of operators $(\mathbb{T}, \Phi)$ are an abstract linear control system on X and Ω (see Definition 2.1). For $p < \infty$ this is further equivalent with the fact that for any $u \in \Omega$ the differential equation (1.1) has a continuous state strong solution (see Definition 3.5). If the exponent p is clear from the context, we simply say that B is admissible.

Hypotheses equivalent to p-admissibility have appeared several times in the literature. For example, in Salamon [26] this condition is called hypothesis H2; in Salamon [29], S2; in Curtain and Salamon [5], H1; in Pritchard and Townley [24], A6. In Dolecki and Russell [9] and Ho and Russell [12] the condition appears in a dual form, essentially expressing that Φ_t^* is bounded. The following simple proposition permits us to relax the condition posed on B in Definition 4.1.

PROPOSITION 4.2. *Let U, X, p, Ω, and $\mathbb{T}$ be as in Definition* 4.1, *let $B \in \mathscr{L}(U, X_{-1})$, and let Φ_t be given by* (4.1). *If for some fixed $T > 0$ and any $u \in \Omega$*

$$\Phi_T u \in X,$$

then B is admissible.

Proof. With the notation of Proposition 3.3, let $B_0 = R_\mu B$. Then $B_0 \in \mathscr{L}(U, X)$ and we have

$$\Phi_T u = (\mu I - A) \int_0^T \mathbb{T}_{T-\sigma} B_0 u(\sigma)\, d\sigma,$$

which shows that Φ_T is closed. By the closed graph theorem Φ_T is bounded.

By (2.3) (see the proof of Proposition 2.3), Φ_t is bounded for all $t \leqq T$. The identity (2.4) (see the proof of Proposition 2.5), with rescaling, implies that if Φ_t is bounded for some t, it is bounded for all multiples of t. Therefore Φ_t is bounded for all $t \geqq 0$. □

For invertible semigroups, Proposition 4.2 admits the following strengthening, which is useful in applications.

PROPOSITION 4.3. *Let U, X, p, Ω, and $\mathbb{T}$ be as in Definition* 4.1, *let $B \in \mathscr{L}(U, X_{-1})$, and let Φ_t be given by* (4.1). *If $\mathbb{T}$ is invertible and if for some fixed $T > 0$ and any $u \in \Omega$*

$$\{t \geqq T \,|\, \Phi_t u \in X\} \neq \varnothing,$$

then B is admissible.

Proof. If B is not admissible, by Proposition 4.2, for any $T > 0$, we can find a $v \in \Omega$ such that $\Phi_T v \notin X$. Let $u \in \Omega$ be equal to v on $[0, T]$, and zero for $t > T$; then $\Phi_t u \notin X$ for any $t \geqq T$. □

Later we will prove a nontrivial strengthening of this proposition for the case $p < \infty$ (see Theorem 4.12). For semigroups that are not invertible, Proposition 4.3 is generally false (see Remark 3.6).

Remark 4.4. It happens that for certain A and B we can prove that for any $u \in \Omega$ (1.1) has a strong solution $x(\cdot)$ (see Definition 3.5), so $x(\cdot) \in L^1_{\text{loc}}([0, \infty), X)$, in particular $x(t)$ is almost everywhere in X. If $\mathbb{T}$ is invertible then Proposition 4.3 implies that B is admissible. In particular, if $p < \infty$ then, by Proposition 2.3, $x(\cdot)$ is continuous.

In other words, for $\mathbb{T}$ invertible, $p < \infty$, and $x(\cdot)$ given by (1.2), we have

$$x(\cdot) \in L^1_{\text{loc}}([0, \infty), X) \;\Rightarrow\; x(\cdot) \in C([0, \infty), X).$$

There are some other techniques to lift regularity from L^1_{loc} to C (see Lasiecka and Triggiani [16] and Lasiecka, Lions, and Triggiani [18]).

DEFINITION 4.5. Let U, X, p, and $\mathbb{T}$ be as in Definition 4.1. The space $\mathscr{B}_p(U, X, \mathbb{T})$ is the vector space of all p-admissible control operators B for the given U, X, and $\mathbb{T}$, with the norm

$$|||B|||_p = \sup_{\|u(\cdot)\|_{L^p([0,T],U)} \leqq 1} \left\| \int_0^T \mathbb{T}_{T-\sigma} B u(\sigma)\, d\sigma \right\|, \tag{4.2}$$

where $T > 0$ is fixed (see Remark 4.6 below).

We use the notation $|||\cdot|||$ (with three bars) to avoid confusion with the norm of B as an element of $\mathscr{L}(U, X_{-1})$. When U is just $\mathscr{K}$, the field of the scalars ($\mathbb{R}$ or $\mathbb{C}$), we denote

$$\ell_p(X, \mathbb{T}) = \mathscr{B}_p(\mathscr{K}, X, \mathbb{T}).$$

We usually write $\mathscr{B}_p$ and ℓ_p, without the arguments, when there is no danger of confusion. An operator from the scalars $\mathscr{K}$ to a space will always be identified with

an element of that space; in particular, elements of ℓ_p will be identified with elements of X_{-1}.

Remark 4.6. It is easy to verify, using (2.3) and (2.4), that for any different $T_1 > 0$ instead of T in (4.2) we get an equivalent norm and, using the representation theorem (Theorem 3.9), that $\mathcal{B}_p$ is complete for $p < \infty$ (for $p = \infty$, I do not know).

Remark 4.7. The following inclusions are immediate:

$$\mathcal{L}(U, X) \subset \mathcal{B}_p \subset \mathcal{L}(U, X_{-1}), \qquad X \subset \ell_p \subset X_{-1},$$

$$\mathcal{B}_{p_1} \subset \mathcal{B}_{p_2} \quad \text{for} \quad p_1 \leqq p_2, \tag{4.3}$$

all with continuous embedding. Further, it is clear that a *necessary condition* for $B \in \mathcal{B}_p$ is that the range of B satisfies

$$\operatorname{Ran} B \subset \ell_p \tag{4.4}$$

(this condition is not sufficient; see § 5).

It now seems plausible that $\mathcal{B}_p$ can be obtained as the completion of $\mathcal{L}(U, X)$ with respect to $|||\cdot|||_p$. But we shall see in § 5 that this is not the case.

There is one case when the determination of $\mathcal{B}_p$ is very easy, namely when $p = 1$ and X is reflexive.

THEOREM 4.8. *Let U, X, and $\mathbb{T}$ be as in Definition* 4.1 *and suppose X is reflexive. Then*

$$\mathcal{B}_1 = \mathcal{L}(U, X).$$

Proof. It will be enough to show that

$$\ell_1 = X. \tag{4.5}$$

Indeed, if (4.5) holds, then by (4.4) we have for any $B \in \mathcal{B}_1$ that $\operatorname{Ran} B \subset X$, and by the closed graph theorem, $B \in \mathcal{L}(U, X)$.

So let $b \in \ell_1$ and let the operator $\phi : L^1[0, 1] \to X_{-1}$ be given by

$$\phi v = \int_0^1 \mathbb{T}_\sigma b v(\sigma)\, d\sigma. \tag{4.6}$$

Because ϕ is obtained from Φ_1 by a change of variable in the integration, we have that, in fact, $\phi \in \mathcal{L}(L^1, X)$. X, being reflexive, has the Radon-Nikodym property (see Diestel and Uhl [8, pp. 76, 82]), so ϕ is representable (see [8, p. 63], i.e., there is some $g \in L^\infty([0, 1], X)$ such that for any $v \in L^1$

$$\phi v = \int_0^1 g(\sigma) v(\sigma)\, d\sigma.$$

When we compare the above equality with (4.6) it follows that $g(\sigma) = \mathbb{T}_\sigma b$ (a.e.), i.e., $\mathbb{T}_\sigma b \in L^\infty([0, 1], X)$ (but we do not know yet if $\mathbb{T}_\sigma b \in X$ for all σ, in particular, for $\sigma = 0$). From the identity

$$\frac{\mathbb{T}_t - I}{t} b = A \frac{1}{t} \int_0^t \mathbb{T}_\sigma b\, d\sigma$$

we get that for all $t \in (0, 1]$

$$\left\| \frac{\mathbb{T}_t - I}{t} b \right\|_{-1} \leqq \|A\| \cdot \|g\|$$

(by $\|A\|$ we mean the $\mathscr{L}(X, X_{-1})$ norm). By a theorem in Butzer and Berens [2, p. 88], b is in the domain of the generator of the semigroup $\mathbb{T}$ acting on X_{-1}, i.e., $b \in X$ (see Remark 3.4). □

Remark 4.9. In the above proof, once we have established that $\mathbb{T}_\sigma b$ is essentially bounded in X we could have alternatively used a lemma in Lions and Magenes [20, Vol. I, p. 275] to get the final result.

The above theorem is not true for general X, as we shall see in § 5.

Next we show that if a control operator is not admissible, then the state trajectory can be driven out of the state space using a smooth input on an arbitrarily short time-interval.

PROPOSITION 4.10. *Let U, X, p, and $\mathbb{T}$ be as in Definition* 4.1, *with $p<\infty$. Let $B \in \mathscr{L}(U, X_{-1})$ not be p-admissible. Then for any $T>0$ there is a function $u \in L^p[0, T]$ such that u is of class C^∞ on $[0, T)$ and*

$$\int_0^T \mathbb{T}_{T-\sigma} B u(\sigma)\, d\sigma \notin X. \tag{4.7}$$

Proof. Let $T>0$. Consider the Fréchet space

$$F = L^p[0, T] \cap C^\infty[0, T),$$

with the topology given by the increasing family of norms

$$q_n(u) = \|u\|_{L^p} + \sum_{k=0}^{n} \sup_{t \in [0,(1-(1/n))T]} \|u^{(k)}(t)\|,$$

where $n \in \mathbb{N}$. Let Φ_T denote the operator from $L^p[0, T]$ to X_{-1} defined by the left-hand side of (4.7). We have to show that $\Phi_T F$ is not contained in X. Suppose the contrary, then by the closed graph theorem $\Phi_T \in \mathscr{L}(F, X)$, i.e., there is some $n \in \mathbb{N}$ and some $K \geqq 0$ such that

$$\|\Phi_T u\| \leqq K \cdot q_n(u) \quad \forall u \in F.$$

In particular, for functions $u \in F$ the support of which is contained in $((1-(1/n))T, T)$, we have $q_n(u) = \|u\|_{L^p}$, so for such u

$$\left\| \int_{(1-(1/n))T}^{T} \mathbb{T}_{T-\sigma} B u(\sigma)\, d\sigma \right\| \leqq K \cdot \|u\|_{L^p}.$$

Making the change of variable $\sigma = (1-(1/n))T + s$, we get that for any $v \in C_0^\infty(0, T/n)$

$$\left\| \int_0^{T/n} \mathbb{T}_{(T/n)-s} B v(s)\, ds \right\| \leqq K \cdot \|v\|_{L^p}.$$

By the density of C_0^∞ in L^p (it is here that we need that $p<\infty$) we get that $B \in \mathscr{B}_p$, a contradiction. □

Now we give a necessary and sufficient condition for admissibility in the case when the semigroup is invertible. For that, we need the following remark concerning groups.

Remark 4.11. If the semigroup $\mathbb{T}$ acting on X is invertible, then for any (input) Banach space U and any $p \in [1, \infty]$, the admissible control operators for $\mathbb{T}$ and $\mathbb{T}^{-1}$ are the same, i.e.,

$$\mathscr{B}_p(U, X, \mathbb{T}) = \mathscr{B}_p(U, X, \mathbb{T}^{-1}).$$

The proof is very simple, by a change of variable.

THEOREM 4.12. *Let U, X, p, Ω, and $\mathbb{T}$ be as in Definition* 4.1, *with $p<\infty$, let $B\in\mathscr{L}(U, X_{-1})$ and let Φ_t be given by* (4.1). *If $\mathbb{T}$ is invertible and if for any $u\in\Omega$*

$$\{t>0 \mid \Phi_t u\in X\}\neq\varnothing, \tag{4.8}$$

then B is admissible.

Proof. Suppose B is not admissible. Then it is not admissible for $\mathbb{T}^{-1}$ either (see Remark 4.11), so by Proposition 4.10 there is some $v\in L^p[0,1]\cap C^\infty[0,1)$ for which $z\notin X$, where

$$z=\int_0^1 \mathbb{T}_{1-\sigma}^{-1}Bv(\sigma)\,d\sigma.$$

Let

$$u(s)=\begin{cases} v(1-s) & \text{for } s\in[0,1],\\ 0 & \text{for } s>1.\end{cases}$$

Then $\Phi_1 u=\mathbb{T}_1 z$, so $\Phi_1 u\notin X$. For any $t>0$ we have

$$\Phi_t u=\int_1^t \mathbb{T}_{t-\sigma}Bu(\sigma)\,d\sigma+\mathbb{T}_{t-1}\Phi_1 u.$$

The first term on the right-hand side is in X (by the smoothness of u), but the second is not. It follows that $\Phi_t u\notin X$, so condition (4.8) is not satisfied. □

I do not know if Theorem 4.12 remains true for $p=\infty$.

Remark 4.13. In the conditions of Theorem 4.12, if B is not admissible, then for any $T>0$ there is an L^p-function with support in $[0,T]$, of class C^∞ on $(0,\infty)$, such that $\Phi_t u\notin X$ for any $t>0$. To see that, we must multiply the function u constructed in the last proof by an appropriate cutoff function.

5. The wave equation on [0, π]. To deal with the controlled wave equation of Example 1.1, it will be helpful to analyse the periodic left-shift semigroup on $[0,2\pi]$ first. We introduce some notation.

We shall denote by $\mathbf{C}^\infty$ the Fréchet space of infinitely differentiable functions on the circle group $\mathbb{R}/2\pi\mathbb{Z}$ (periodic test functions). Following Edwards [10, Vol. II, p. 52], we shall denote by $\mathbf{D}$ the space of periodic distributions on $[0,2\pi]$, the dual of $\mathbf{C}^\infty$. For $s\in\mathbb{Z}$ and $r\in[1,\infty)$, $W_P^{s,r}$ will denote the periodic Sobolev space of order s and type r on $[0,2\pi]$, which we define as the space of those $\psi\in\mathbf{D}$ for which the Fourier transform $(\hat{\psi}_k)$ (which is a sequence over $\mathbb{Z}$) satisfies

$$(1+ik)^s\hat{\psi}_k=\hat{\varphi}_k,$$

where $i=\sqrt{-1}$ and $\varphi\in L^r[0,2\pi]$. For such ψ we set

$$\|\psi\|_{s,r}=\|\varphi\|_{L^r}.$$

For $r=2$ that becomes the more familiar

$$\|\psi\|_{s,2}=\sqrt{2\pi}\cdot\|(1+k^2)^{s/2}\hat{\psi}_k\|_{l^2}.$$

It is easy to prove, using propositions in Edwards [10, Vol. I, pp. 56, 114], that $W_P^{s,r}$ is decreasing with increasing s. It follows that for $s>0$, $W_P^{s,r}$ contains exactly those $\psi\in\mathbf{D}$ for which $\psi,\psi',\cdots,\psi^{(s)}$ are all in $L^r[0,2\pi]$.

Since the trigonometric polynomials are dense in $L^r[0,2\pi]$, it follows that they are dense in all the spaces $W_P^{s,r}$. In particular, for $s<0$, $W_P^{s,r}$ can be thought of as the completion of $W_P^{0,r}=L^r[0,2\pi]$ with respect to the norm $\|\cdot\|_{s,r}$.

For any combination of indices $1 \leqq p, r \leqq \infty$, (L^p, L^r) will denote the corresponding space of *Fourier multipliers*. The elements of (L^p, L^r) are functions $\beta : \mathbb{Z} \to \mathbb{C}$, for which the map $\psi \to \varphi$, $\hat{\varphi}_k = \beta_k \cdot \hat{\psi}_k$, is a bounded linear operator from $L^p[0, 2\pi]$ to $L^r[0, 2\pi]$. The norm of β is the norm of this operator. For more on multipliers see, for example, Edwards [10, Vol. II, Chap. 16].

Example 5.1. Let $1 \leqq r < \infty$. Let $\mathbf{S}$ be the semigroup of periodic left shifts on $Z = L^r[0, 2\pi]$, i.e.,

$$(\mathbf{S}_t z)(\zeta) = z(\zeta + t - k \cdot 2\pi) \quad \text{for} \quad k \cdot 2\pi \leqq \zeta + t < (k+1) \cdot 2\pi.$$

$\mathcal{A}$, the generator of $\mathbf{S}$, is given by

$$D(\mathcal{A}) = W_P^{1,r}, \qquad (\mathcal{A}z)(\zeta) = z'(\zeta).$$

The eigenvalues of $\mathcal{A}$ are ik, $k \in \mathbb{Z}$, and the corresponding eigenfunctions are $e^{ik\zeta}$, so $\mathbf{S}$ can be expressed in terms of Fourier series by

$$\widehat{(\mathbf{S}_t z)}_k = e^{ikt} \hat{z}_k.$$

It is easy to check that for this semigroup $Z_{-1} = W_P^{-1,r}$.

We want to determine the space $\mathcal{B}_p(Z, \mathbf{S})$ of admissible control operators for scalar L^p-inputs.

PROPOSITION 5.2. *For the semigroup above and for any index p with $1 \leqq p \leqq \infty$, we have*

$$\mathcal{B}_p(Z, \mathbf{S}) = \{b \in \mathbf{D} \mid \hat{b} \in (L^p, L^r)\},$$
$$|||b|||_p = 2\pi \cdot \|\hat{b}\|_{(L^p, L^r)}.$$

Proof. First we prove that

$$\{b \in \mathbf{D} \mid \hat{b} \in (L^p, L^r)\} \subset Z_{-1}.$$

Let b be in the set on the left-hand side above. Then obviously $\hat{b} \in l^\infty$. It follows that for any $\nu \in (1, 2]$, $(1+ik)^{-1}\hat{b}_k \in l^\nu$. By the Hausdorff-Young Theorem (Edwards [10, Vol. II, p. 153]) we get that $(1+ik)^{-1}\hat{b}_k = \hat{\varphi}_k$, where $\varphi \in L^\mu[0, 2\pi]$ for any $\mu \in [2, \infty)$, and hence for any $\mu \in [1, \infty)$. In particular, $\varphi \in L^r[0, 2\pi] = Z$, so $b \in W_P^{-1,r} = Z_{-1}$.

Next we take $b \in Z_{-1}$. It is easy to check that for any $u \in L^p[0, 2\pi]$,

$$z = \int_0^{2\pi} \mathbf{S}_{2\pi-\sigma} b u(\sigma)\, d\sigma \quad \text{iff} \quad \hat{z}_k = 2\pi \hat{b}_k \cdot \hat{u}_k. \tag{5.1}$$

Using Proposition 4.2 with $T = 2\pi$, we bet that $b \in \mathcal{B}_p(Z, \mathbf{S})$ if and only if $\hat{b} \in (L^p, L^r)$. Moreover, choosing $T = 2\pi$ in the definition of $|||\cdot|||_p$,

$$|||b|||_p = \sup_{\|u\|_{L^p}=1} \|z\|_{L^p} = 2\pi \|\hat{b}\|_{(L^p, L^r)}. \qquad \square$$

Generally, it is not easy to describe the spaces (L^p, L^r), but there are cases when it is. One such case is $r \leqq 2 \leqq p$. Then $(L^p, L^r) = l^\infty$ (see Edwards [10, Vol. II, p. 301]). Periodic distributions b for which $\hat{b} \in l^\infty$ are called pseudomeasures and following Edwards [10, Vol. II, p. 108], we shall denote their space by P. The norm on P is $\|b\|_P = \|\hat{b}\|_{l^\infty}$. So we have for $r \leqq 2 \leqq p$,

$$\mathcal{B}_p(Z, \mathbf{S}) = P,$$

with equivalent norms.

The completion of Z with respect to $|||\cdot|||_p$, still considering $r \leqq 2 \leqq p$, is the space of periodic distributions b for which $\hat{b} \in c_0$, where c_0 is the space of sequences convergent to zero for $|k| \to \infty$. But this is only a closed subspace of P. Therefore we have the following.

NEGATIVE RESULT 5.3. The state space Z may be a nondense subspace of $\ell_p(Z, \mathbf{S})$. In other words, in the space $\ell_p(Z, \mathbf{S})$, admissible unbounded control operators cannot always be approximated by bounded ones.

NEGATIVE RESULT 5.4. If Z is not reflexive, $\ell_1(Z, \mathbf{S})$ may contain unbounded elements (i.e., which are not in Z) (cf. Theorem 4.8).

That can be seen taking $p = r = 1$ in Proposition 5.2. Indeed, (L^1, L^1) consists of the Fourier transforms of elements of M, the space of regular bounded Borel measures ("Radon measures") on $[0, 2\pi)$ (see Edwards [10, Vol. II, pp. 53, 289]). Hence $\ell_1(Z, \mathbf{S}) = M$, which contains $L^1[0, 2\pi]$ strictly.

We give a negative result concerning reachability.

NEGATIVE RESULT 5.5. It is possible to have elements $z \in Z$ that are *completely unreachable*. By that we mean

$$z \neq \int_0^t \mathbf{S}_{t-\sigma} b u(\sigma)\, d\sigma$$

for any $t > 0$, any $b \in \ell_p(Z, \mathbf{S})$ and any $u \in L^p[0, t]$.

Indeed, consider the case $r \leqq 2 \leqq p$ in Example 5.1. Then, as we have seen, $\ell_p(Z, \mathbf{S}) = P$, which is independent of r and p. Therefore the reachable states are contained in the smallest of the state spaces for the various $r \leqq 2$, namely in $L^2[0, 2\pi]$. If $r < 2$, the state space $Z = L^r[0, 2\pi]$ is larger than that and therefore contains completely unreachable elements.

We mention that for $r = 2$, all elements of Z are reachable, for any $p \in [2, \infty)$. Indeed, for any given $z \in L^2[0, 2\pi]$ and $p \in [2, \infty)$, we can choose $b \in P$ with $\hat{b}_k = \pm 1$ and $u \in L^p[0, 2\pi]$ such that $\hat{z}_k = 2\pi \hat{b}_k \cdot \hat{u}_k$. That follows from a theorem in Edwards [10, Vol. II, p. 220], about changing signs of Fourier coefficients. According to (5.1), z is reachable.

The equality

$$\mathscr{B}_p(U, Z, \mathbf{S}) = \mathscr{L}(U, \ell_p(Z, \mathbf{S})) \tag{5.2}$$

is true for finite-dimensional U, and simple reasoning shows that if the equality $\mathscr{B}_p(U, Z, \mathbf{S}) = \mathscr{L}(U, V)$ holds for some $p \in [1, \infty]$ and some Banach spaces U and V, then $V = \ell_p(Z, \mathbf{S})$. However, we have the following negative result, already mentioned in the Introduction.

NEGATIVE RESULT 5.6. The representation (5.2) does not hold in general.

Indeed, take $r = p = 2$, $U = \ell_2(Z, \mathbf{S}) = \{b \in \mathbf{D} \mid \hat{b} \in l^\infty\}$, and $B = I$ (the identity on U). Let $u_0 \in U \backslash Z$ with $\hat{u}_0 \in c_0$. Then $u(t) = \mathbf{S}_t u_0$ is a continuous U-valued function and

$$\int_0^{2\pi} \mathbf{S}_{2\pi-\sigma} B u(\sigma)\, d\sigma = 2\pi \cdot u_0,$$

so B is not admissible.

Now we turn to the controlled one-dimensional wave equation. The notation X, A, $\mathbb{T}$, r, p, $W_0^{1,r}$, $W^{2,r}$ will have the same meaning as in Example 1.1. In addition, the notation of Example 5.1 still holds. We want to determine the space $\ell_p(X, \mathbb{T})$ of admissible one-dimensional control operators.

Using an isomorphism, we shall reduce this problem to that discussed in Example 5.1, with the minor difference that the coefficient with index $k = 0$ in all Fourier transforms must be set to zero. Let

$$\mathbf{D}^0 = \{\psi \in \mathbf{D} \mid \hat{\psi}_0 = 0\}.$$

The spaces

$$Z^0 = Z \cap \mathbf{D}^0, \qquad Z^0_{-1} = Z_{-1} \cap \mathbf{D}^0$$

are closed subspaces of Z and Z_{-1}, respectively. Let the isomorphism $H: Z^0 \to X$ be given by

$$(Hz)(\zeta) = \begin{pmatrix} \int_0^\zeta [z(\xi) + z(2\pi - \xi)]\, d\xi \\ z(\zeta) - z(2\pi - \zeta) \end{pmatrix} \quad \forall \zeta \in [0, \pi].$$

The operator H^{-1} is given by

$$(H^{-1}x)(\zeta) = \begin{cases} \frac{1}{2}[x_1'(\zeta) + x_2(\zeta)] & \text{for} \quad \zeta \in [0, \pi], \\ \frac{1}{2}[x_1'(2\pi - \zeta) - x_2(2\pi - \zeta)] & \text{for} \quad \zeta \in (\pi, 2\pi]. \end{cases}$$

The image of $\mathbb{T}$ through H^{-1} is the semigroup $\mathbf{S}^0$ on Z^0 generated by

$$\mathscr{A}^0 = H^{-1}AH = d/d\zeta,$$
$$D(\mathscr{A}^0) = H^{-1}D(A) = D(\mathscr{A}) \cap \mathbf{D}^0.$$

Hence $\mathbf{S}^0$ is the restriction of $\mathbf{S}$ to Z^0, i.e., the periodic left-shift semigroup on Z^0. Intuitively, the restriction of z to $[0, \pi]$ represents the left-bound component of x_2 and the restriction of z to $[\pi, 2\pi]$ represents the right-bound component of x_2, with opposite sign and reversed. The eigenvectors of A are

$$H e^{ik\zeta} = 2i \begin{pmatrix} \frac{1}{ik} \sin k\zeta \\ \sin k\zeta \end{pmatrix} \qquad \text{for} \quad k \in \mathbb{Z} \backslash \{0\}.$$

Since $(sI - \mathscr{A}^0)^{-1} = H^{-1}(sI - A)^{-1}H$, the operator H can be extended (uniquely) to an isomorphism from Z^0_{-1} to X_{-1}, still denoted H.

We get the general characterization

$$\ell_p(X, \mathbb{T}) = H\ell_p(Z^0, \mathbf{S}^0) = H\{\beta \in \mathbf{D}^0 \,|\, \hat{\beta} \in (L^p, L^r)\}. \tag{5.3}$$

For example, for $r \leqq 2 \leqq p$,

$$\ell_p(X, \mathbb{T}) = H\{\beta \in \mathbf{D}^0 \,|\, \hat{\beta} \in l^\infty\}.$$

We give a more concrete description of the operator H appearing in (5.3), defined only as a (hard to visualize) continuous extension. For this we need some notation.

For periodic test functions $\varphi \in \mathbf{C}^\infty$ we shall denote $\check{\varphi}(\zeta) = \varphi(2\pi - \zeta)$. For $\psi \in \mathbf{D}$, $\check{\psi}$ denotes the distribution defined by $\langle \varphi, \check{\psi} \rangle = \langle \check{\varphi}, \psi \rangle$. A distribution $\psi \in \mathbf{D}$ is called *antisymmetric* if $\check{\psi} = -\psi$. The antisymmetric elements of $\mathbf{D}$ form a closed subspace of $\mathbf{D}$, which we denote $\mathbf{D}^A$.

We introduce the test function space

$$\mathscr{D} = \left\{ \varphi \in C^\infty[0, \pi] \,\middle|\, \frac{d^k}{d\zeta^k} \varphi(0) = \frac{d^k}{d\zeta^k} \varphi(\pi) = 0, \quad \text{for } k = 0, 2, 4, \cdots \right\},$$

with the topology of uniform convergence of all derivatives. Any $\varphi \in \mathscr{D}$ has a (unique) *antisymmetric extension to* $[0, 2\pi]$, denoted Aext φ, which is an element of $\mathbf{C}^\infty$. The operator Aext is an isomorphism from $\mathscr{D}$ onto the antisymmetric part of $\mathbf{C}^\infty$.

Any $\psi \in \mathbf{D}^A$ has a natural *restriction to* $[0, \pi]$, denoted Rest ψ, which is an element of $\mathscr{D}'$, the dual of $\mathscr{D}$. Rest ψ is defined by

$$\langle \varphi, \text{Rest } \psi \rangle = \tfrac{1}{2} \langle \text{Aext } \varphi, \psi \rangle.$$

If the distribution ψ is represented by an integrable function, then Rest ψ, as defined above, coincides with the usual restriction. The operator Rest is an isomorphism from $\mathbf{D}^A$ onto $\mathscr{D}'$.

On $\mathbf{D}^0$, as opposed to $\mathbf{D}$, we can integrate distributions freely. That means that for any $\psi \in \mathbf{D}^0$ there is a unique $\psi_1 \in \mathbf{D}^0$ such that $\psi_1' = \psi$. We shall write $\psi_1 = \int \psi$.

We define the isomorphism $H_1 : \mathbf{D}^0 \to \mathbf{D}^A \times \mathbf{D}^A$ by

$$H_1\psi = \begin{pmatrix} \int \psi + \int \check{\psi} \\ \psi - \check{\psi} \end{pmatrix}.$$

It is easy to check that for any $z \in Z^0$

$$Hz = \text{Rest } H_1 z.$$

Since Rest H_1 is an isomorphism from $\mathbf{D}^0$ onto $\mathscr{D}' \times \mathscr{D}'$, the formula above must also hold for elements z in the extended space Z^0_{-1}.

We give now a more concrete description of X_{-1}.

On $\mathscr{D}$, the operator $d/d\zeta$ makes no sense, but $d^2/d\zeta^2$ is well defined and even invertible. By duality, this operator can be defined on $\mathscr{D}'$:

$$\left\langle \varphi, \frac{d^2}{d\zeta^2}\psi \right\rangle = \left\langle \frac{d^2}{d\zeta^2}\varphi, \psi \right\rangle.$$

If ψ happens to be twice differentiable and $\psi(0) = \psi(\pi) = 0$, then the definition above coincides with that of the usual second derivative.

If we denote by $W^{-1,r}[0, \pi]$ the image of $W_0^{1,r}[0, \pi]$ through $d^2/d\zeta^2$, then

$$X_{-1} = \bigtimes_{W^{-1,r}}^{L^r}.$$

Acknowledgments. I am grateful to Professor Zvi Artstein for his generous help and advice during the preparation of this paper. Professors Ruth Curtain, Irena Lasiecka, Anthony Pritchard, and Dietmar Salamon, through their letters, encouraged me and drew my attention to a number of papers of which I was not aware. The referees corrected some errors, and one pointed out reference [28] and suggested Remark 3.14.

APPROXIMATIONS AND OPTIMAL CONTROL FOR THE PATHWISE AVERAGE COST PER UNIT TIME AND DISCOUNTED PROBLEMS FOR WIDEBAND NOISE-DRIVEN SYSTEMS*

HAROLD J. KUSHNER†

Abstract. The average cost per unit time problem for wide bandwidth noise-driven control systems is considered, where the average cost is in the pathwise sense; no expectations are used. Let t = time of control and BW = bandwidth. For the class of processes considered here, various unformity properties are proven for the convergence of the pathwise average costs as $t \to \infty$, BW $\to \infty$. Let $u^\delta(\cdot)$ be a smooth δ-optimal control for the limit controlled diffusion (the limit as BW $\to \infty$) for the (mean) average cost per unit time problem. It is shown that for large enough t and BW, $u^\delta(\cdot)$ is 2δ-optimal (with a probability arbitrarily close to one) for the pathwise wide bandwidth problem. This uniformity is important in applications, for often there is only one long sequence to control, and the expectation is inappropriate. Also, otherwise, as BW $\to \infty$, it might take longer and longer to approximate the limit pathwise average cost well. Applications to related "pathwise average" problems are given: the convergence of the average pathwise errors for an "approximate" nonlinear filter with wide bandwidth observation and system driving noise, and the convergence and accuracy of Monte Carlo calculations of Lyapunov exponents for wide bandwidth noise-driven systems (as BW $\to \infty$) via average cost/unit time methods. It is also shown for the discounted cost problem that the optimum pathwise costs converge to the minimum average cost per unit time as both the discount factor goes to zero and BW $\to \infty$.

Key words. pathwise average cost per unit time, ergodic control, approximations of ergodic control, wide band noise driven systems, approximate nonlinear filtering, Lyapunov exponents, discounted cost

1. Introduction.

Average cost per unit time (over an infinite time horizon) optimal control problems for diffusion and other Markov models have been dealt with in various ways, as in, e.g., [1]-[3]. We treat such a problem for "wideband, noise-driven," and related systems, which are "close" to a diffusion, and when the average is in the pathwise but not necessarily in the mean value sense. The general method works for many other classes of processes that are suitably approximated by an appropriate controlled Markov process. As is pointed out below and in §§ 4 and 5, the results have applications to many other problems where pathwise averages are important, and the noises are "wide band." For example, in § 5 we treat the problem where both BW $\to \infty$ and the discount factor goes to zero.

Let the diffusion model be given in the relaxed control form:

$$dx = \left[\int \bar{b}(x, \alpha) m_t(d\alpha)\right] dt + \sigma(x)\, dw, \qquad x \in R^r, \quad \text{Euclidean } r\text{-space} \tag{1.1}$$

where $\bar{b}(\cdot, \cdot)$ and $\sigma(\cdot)$ are continuous (other conditions will be listed below) and $m_t(\cdot)$ is an admissible relaxed control [1], [3], [4], over a compact control value space U. The relaxed control might be of the feedback form. The $w(\cdot)$ is a standard vector-valued Wiener process, and the dimensions of the vectors b, w, and σ are compatible.

DEFINITION. Relaxed Control. Let U be a compact set in some Euclidean space. Let the $w(\cdot)$ in (1.1) be a Wiener process with respect to a filtration $\{\mathcal{F}_t\}$. A measure valued (a measure on the Borel sets of $U\times[0,\infty)$) random variable $m(\cdot)$ is an admissible relaxed control if $\iint_0^t f(s,\alpha)m(ds\,d\alpha)$ is progressively measurable for each bounded and continuous $f(\cdot)$ and $m([0,t]\times U)=t$, for all $t\geqq 0$. If $m(\cdot)$ is admissible, then there is a derivative $m_t(\cdot)$ (defined for almost all t) that is nonanticipative and

$$\int_0^t\int f(s,\alpha)m(ds\,d\alpha)=\int_0^t ds\int f(s,\alpha)m_s(d\alpha)$$

for all t with probability one (w.p.1). Sometimes we use the "feedback" relaxed control (which we write as $m_x(\cdot)$), which is a measure on the Borel sets of U for each x, and $m_x(B)$ is Borel-measurable for each Borel B. The $m_t(\cdot)$ and $m_x(\cdot)$ will also be referred to as relaxed controls.

In [1], relaxed controls have been used to get nearly optimal controls for several "wideband" noise-driven systems, and in [3], they have been used cleverly to get an "occupation measure" for the state-control pair, which ultimately allowed the authors to demonstrate the existence of an optimal stationary control. These advantages also occur for the particular problems described below. In [1] and [2], the cost of concern is ([2] does not use relaxed controls)

$$\bar{\gamma}(m)=\overline{\lim_T}\frac{1}{T}\int_0^T\int Ek(x(t),\alpha)m_t(d\alpha)\,dt \tag{1.2}$$

for a bounded continuous $k(\cdot)$.

In practice, of course, we do not have a process that is a diffusion, and it is of considerable interest to consider systems of the following form:

$$\dot{x}^\varepsilon=\int b(x^\varepsilon,\alpha)m_t(d\alpha)+F_\varepsilon(x^\varepsilon,\xi^\varepsilon), \tag{1.3}$$

where $\xi^\varepsilon(\cdot)$ is a wide bandwidth noise process and we wish to minimize the following:

$$\bar{\gamma}^\varepsilon(m)=\overline{\lim}\frac{1}{T}\int_0^T\int Ek(x^\varepsilon(t),\alpha)m_t(d\alpha)\,dt. \tag{1.4}$$

For convenience in the development (to simplify the details), we use a process defined by the scaling $\xi^\varepsilon(t)=\xi(t/\varepsilon^2)$, where the "primitive" process $\xi(\cdot)$ satisfies certain mixing conditions (one of the four sets (A2.3), (A2.4), (A2.5) or (A2.10) or (A3.2), (A3.3), (A3.4) or (A3.5) below). This scaling is, in fact, a common way of constructing a wide bandwidth process, and is also used in [13] and [14]. But it should be clear from the development that the method is much more generally applicable. Reference [1] has dealt with a system of type (1.3) (with weak limit of type (1.1)) and cost of the form (1.2). It has been shown, under the conditions there, that for any $\delta>0$, a smooth δ-optimal control u^δ for (1.1), (1.2) was also "nearly" optimal for (1.3) and (1.4), for small ε in the sense that $\underline{\lim}_\varepsilon \bar{\gamma}^\varepsilon(m^\varepsilon)\geqq\lim_\varepsilon\bar{\gamma}^\varepsilon(u^\delta)-\delta$ for any sequence m^ε. Such results are helpful in justifying the use of the ideal limit process (1.1) for use in control theory.

In [3], Borkar and Ghosh have shown the existence of an optimal feedback control for the diffusion model (under this control the diffusion could be taken to be stationary) and cost function (1.2), but *with the E deleted*—a pathwise result. This paper is devoted to a related problem for the model (1.3). Define

$$\gamma_T(m)=\frac{1}{T}\int_0^T\int k(x(s),\alpha)m_s(d\alpha)\,ds,\qquad \gamma(m)=\overline{\lim_T}\,\gamma_T(m), \tag{1.5}$$

$$\gamma_T^\varepsilon(m) = \frac{1}{T}\int_0^T \int k(x^\varepsilon(s), \alpha) m_s(d\alpha)\, ds. \tag{1.6}$$

If $m(\cdot)$ is equivalent to a classical control function $u(\cdot)$, we write u in lieu of m in $\gamma_T(m)$, etc. The "pathwise" convergence result in [3] is of particular importance in applications, since we often have a single long realization, and then the expectation is not appropriate in the cost function. The results in [3] (under their conditions) give the existence of a feedback relaxed control $\bar{m}(\cdot)$ such that

$$\gamma_T(\bar{m}) \to \gamma = \inf_m \cdot \overline{\lim_T}\, \gamma_T(m) \quad \text{w.p.1.} \tag{1.7}$$

In our problem here, owing to the wideband noise and the appearance of the two parameters ε and T, convergence results of the "almost sure" type are often rather meaningless from a practical point of view as well as being nearly impossible to obtain. They might have little meaning for the following reason. Typically, in an application we have a particular process with a given wide bandwidth driving force. We are interested in knowing how well good controls for the "limit" problem do on the actual "physical" problem as well as various qualitative properties of the "physical" process. The wide bandwidth driving term is *imbedded into a sequence* for the purpose of getting such an approximation result, and "almost sure"-type results might have little practical importance.

Let $u^\delta(\cdot)$ denote a "nice" δ-optimal classical control ("nice" is defined in the next section) for model (1.1) and cost function (1.4). Then we wish to show:

$$\gamma_T^\varepsilon(u^\delta) \xrightarrow{P} \bar{\gamma}(u^\delta) \quad \text{as } \varepsilon \to 0, \quad T \to \infty, \tag{1.8a}$$

$$\underline{\lim_{\varepsilon, T}}\, P\{\gamma_T^\varepsilon(m^\varepsilon) \geqq \bar{\gamma}(u^\delta) - \delta\} = 1 \tag{1.8b}$$

for any sequence of admissible relaxed controls $m^\varepsilon(\cdot)$. Since the time derivative of $\gamma_T^\varepsilon(m)$ is $O(1/T)$ uniformly in ε, m, ω, the convergence is somewhat stronger than indicated by (1.8). Equation (1.8b) implies a type of uniformity of convergence, since the way that $\varepsilon \to 0$ and $T \to \infty$ is not important. Were this "uniformity" not the case, it would be possible that as $\varepsilon \to 0$, a larger and larger T is needed to closely approximate the limit value. In that case, the white noise limit (1.1) would not be useful for predictive or control purposes when the true model is (1.3).

In § 2, we list several assumptions and prove (1.8). To simplify the development, the technique of perturbed test functions from [5] is used. To facilitate the calculations, some of the conditions will be adapted from those used in that reference—but many useful generalizations should be clear. In § 3, we redevelop the result of § 2, using a "first-order perturbed test function" method, with less smoothness required on the functions and less mixing required on the noise but more details required in the proof. Some extensions are discussed in § 4. The ideas of "pathwise uniform" convergence of a sample average cost per unit time have many other applications; for example in the Monte Carlo evaluation of Lyapunov exponents with wide bandwidth noise coefficients for linear systems [6]. The formula for the Lyapunov exponent is of the form of an average cost per unit time. For this problem, it is shown in § 4 that the Monte Carlo-evaluated pathwise average cost per unit time converges (as $\varepsilon \to 0$, $T \to \infty$) to the same limit that we would obtain were the actual limit diffusion used for the evaluation. The limit depends only on the correlation function of the noise $\xi^\varepsilon(\cdot)$. Such a result is essential for the Monte Carlo method to be useful and for the Lyapunov exponents of the limit system to be meaningful indicators of the behavior of the actual (wide bandwidth, noise-driven) physical system.

An extension to a problem of average pathwise error per unit time for an "approximate" nonlinear filter for a system with wide bandwidth driving and observation noise is also discussed in § 4.

In § 5, we treat extensions to the discounted cost case. Define the pathwise discounted cost

$$V_\beta^\varepsilon(m) = \beta \int_0^\infty e^{-\beta s} \int k(x^\varepsilon(s), \alpha) m_s(d\alpha)\, ds,$$

and let $m^\varepsilon(\cdot)$ be a sequence of "δ_1-optimal" controls. We show that, for $u^\delta(\cdot)$ defined as above (1.8):

$$V_\beta^\varepsilon(u^\delta) \xrightarrow{P} \bar{\gamma}(u^\delta) \quad \text{as } \beta \to 0, \quad \varepsilon \to 0, \tag{1.9a}$$

$$\varliminf_{\varepsilon,\beta} P\{V_\beta^\varepsilon(m^\varepsilon) \geqq \bar{\gamma}(u^\delta) - \delta\} = 1. \tag{1.9b}$$

The uniformity result is important, since we would not want the speed with which $\beta \to 0$ to depend on the bandwidth—to get the proper approximation. The sense in which $m^\varepsilon(\cdot)$ is δ_1-optimal is purposely left vague—since (1.9) holds for any $\{m^\varepsilon(\cdot)\}$, under the conditions below. Thus for small ε, β, $u^\delta(\cdot)$ is always nearly optimal. There also are extensions to impulsive and singular control problems.

2. A basic convergence theorem. For convenience in this section, we use the assumptions of [5, Chap. 4.6], with appropriate modification for the relaxed controls (definitions given below). The system (1.3) will take the following form:

$$\dot{x}^\varepsilon = \int \bar{G}(x^\varepsilon, \alpha) m_t(d\alpha) + G_0(x^\varepsilon, \xi^\varepsilon(t)) + F(x^\varepsilon, \xi^\varepsilon(t))/\varepsilon. \tag{2.1}$$

DEFINITION. An *admissible relaxed control* $m(\cdot)$ *for* (2.1) is also a measure-valued random variable (as above) but $\int_0^t f(s, \alpha) m(ds\, d\alpha)$ is progressively measurable with respect to $\{\mathcal{F}_t^\varepsilon\}$, where $\mathcal{F}_t^\varepsilon$ is the minimal σ-algebra measuring $\{\xi^\varepsilon(s), x^\varepsilon(s), s \leqq t\}$. Also, we impose $m([0, t] \times U) = t$ for all $t \geqq 0$. As in the definition given in § 1, there is also a derivative $m_t(\cdot)$, where the $m_t(B)$ are $\mathcal{F}_t^\varepsilon$-measurable for Borel B. We sometimes use the symbol $m^\varepsilon(\cdot)$ or $m_t^\varepsilon(\cdot)$ for the relaxed controls, when (2.1) is used.

The scaling in (2.1) is a common way of getting a wide bandwidth, noise-driven system [5], [13], [14]. Other forms for $\xi^\varepsilon(\cdot)$ can be used. Many examples of alternatives are in [5], where the use of perturbed test functions for weak convergence is illustrated. In particular, Example 2.2 of [5, chap. 4] describes a noise process composed of suitably scaled sums of "physical impulses"—a commonly occurring model in applications. For G_0 and F linear in ξ, noises of the "Wong-Zakai" type can also be used—although these do not represent physical models. In this paper, we use either bounded noise or Gaussian noise. For the first case (A2.1)-(A2.6) are used. The second case is covered by (A2.10). Let E_t^ε denote the expectation, conditioned on $\xi^\varepsilon(s) = \xi(s/\varepsilon^2)$, $s \leqq t$, and E_t the expectation conditioned on $\xi(s)$, $s \leqq t$.

(A2.1) $\bar{G}(\cdot, \cdot)$, $F(\cdot, \cdot)$, $G_0(\cdot, \cdot)$, $F_x(\cdot, \cdot)$ are continuous and are bounded by $O(1 + |x|)$. $G_{0,x}(\cdot, \xi)$ is continuous in x for each ξ and is bounded. $\xi(\cdot)$ is bounded, right-continuous, and $EG_0(x, \xi(t)) \to 0$, $EF(x, \xi(t)) \to 0$ as $t \to \infty$, for each x.

(A2.2) $F_{xx}(\cdot, \xi)$ is continuous for each ξ, and is bounded.

(A2.3) Let $V(x, \xi)$ denote either $\varepsilon G_0(x, \xi)$, $G_{0,x}(x, \xi)$, $F(x, \xi)$, or $F_x(x, \xi)$. Then for compact Q,

$$\varepsilon \sup_{x \in Q} \left| \int_{t/\varepsilon^2}^{\infty} E_t^{\varepsilon} V(x, \xi(s))\, ds \right| \xrightarrow{\varepsilon} 0$$

in the mean square sense, uniformly in t.

Let F_i denote the ith component of F.

(A2.4) There are continuous $\bar{F}_i(\cdot)$, $\tilde{a}(\cdot) = \{\tilde{a}_{ij}(\cdot)\}$ such that

$$\int_t^{\infty} EF'_{i,x}(x, \xi(s))F(x, \xi(t))\, ds \to \bar{F}_i(x),$$

$$\int_t^{\infty} \mathrm{E}F_i(x, \xi(s))F_j(x,(t))\, ds \to \frac{\tilde{a}_{ij}(x)}{2},$$

as $t \to \infty$, and the convergence is uniform in any bounded x-set.

Since $\tilde{a}_{ij}(\cdot)$ is not necessarily equal to $\tilde{a}_{ji}(\cdot)$ for $i \neq j$, and we need a symmetric covariance matrix below, we define $a(x) = \frac{1}{2}[\tilde{a}(x) + \tilde{a}'(x)]$.

(A2.5) For each compact set Q, and all i, j,

(a) $$\sup_{x \in Q} \varepsilon \left| \int_{t/\varepsilon}^{\infty} d\tau \int_{\tau}^{\infty} ds [E_{t/\varepsilon^2} F'_{i,x}(x, \xi(s))F(x, \xi(\tau)) - EF'_{i,x}(x, \xi(s))F(x, \xi(\tau))] \right| \to 0;$$

(b) $$\sup_{x \in Q} \varepsilon \left| \int_{t/\varepsilon^2}^{\infty} d\tau \int_{\tau}^{\infty} ds [E_{t/\varepsilon^2} F_i(x, \xi(s))F_j(x, \xi(\tau)) - EF_i(x, \xi(s))F_j(x, \xi(\tau))] \right| \to 0,$$

in the mean square sense as $\varepsilon \to 0$, uniformly in t. The last sentence also holds when the bracketed terms are replaced by their x-gradients.

Remark. If $\xi(\cdot)$ is stationary, then we need not let $t \to \infty$ in (A2.4), but can set $t = 0$. As (A2.4) is written, it allows asymptotic stationarity, i.e., it allows the effects of the initial condition to "disappear." A similar interpretation can be given for (A2.3), since the "stationary" values are $EV(x, \xi(t)) = 0$. Essentially, (A2.5b) is a condition on the rate of convergence of the conditional expectation $\int_{\tau}^{\infty} ds\, E_t F_i(x, \xi(s))F_j(x, \xi(\tau))$ to $\tilde{a}_{ij}(x)$ as $\tau - t \to \infty$, and similarly for (A2.5a). They can be shown [5, p. 82] to be satisfied if $\xi(\cdot)$ satisfied a uniform mixing condition with mixing rate $\phi(\cdot)$, where $\int_0^{\infty} \phi^{1/2}(s)\, ds < \infty$ (e.g., a finite state ergodic Markov chain) or a stable ARMA model with bounded and independently and identically distributed inputs. Very similar conditions were used in [13], [14], but where the $\xi(\cdot)$ were restricted to a class of Markov processes. The conditions in § 3 are closer to "ergodic" conditions, and are often easier to verify.

Define $\bar{b}(x, \alpha) = \bar{G}(x, \alpha) + \bar{F}(x)$ and the operators A^m (when m is a feedback relaxed control m_x), and A^{α} and A^u as follows:

$$A^{\alpha} f(x) = F'_x(x)\bar{b}(x, \alpha) + \frac{1}{2} \sum_{i,j} a_{ij}(x) f_{x_i x_j}(x),$$

$$A^m f(x) = \int A^{\alpha} f(x) m_x(d\alpha),$$

and for A^u, we replace the α in the definition of A^α by the classical control function $u(\cdot)$. For a fixed control value α, A^α will be the operator of the process that is the weak limit of $\{x^\varepsilon(\cdot)\}$.

(A2.6) The martingale problem for operator A^m has a unique solution for each relaxed admissible feedback control $m_x(\cdot)$, and each initial condition. The process is a Feller process. The solution of (2.1) is unique in the weak sense for each $\varepsilon > 0$. Also $a(x) = \sigma(x)\sigma'(x)$ for some continuous finite-dimensional matrix $\sigma(\cdot)$.

Remark. The uniqueness and existence is guaranteed if the operator A^m is that for the system

$$dx = \tilde{b}(x)\,dt + \begin{pmatrix} \int \hat{b}(x,\alpha) m_x(d\alpha)\,dt \\ 0 \end{pmatrix} + \begin{pmatrix} \sigma(x)\,dw \\ 0 \end{pmatrix}, \tag{2.2}$$

where

$$a(x) = \begin{bmatrix} \sigma_1(x)\sigma_1'(x) & 0 \\ 0 & 0 \end{bmatrix},$$

and where $\sigma_1\sigma_1' \geqq \delta I$ for all x and some $\delta > 0$, $\tilde{b}(\cdot)$ and $\sigma_1(\cdot)$ are Lipschitz-continuous and $\hat{b}(\cdot,\cdot)$ is merely bounded and Borel-measurable and the dimensions of (the vector) $\hat{b}$ and (square matrix) $\sigma_1\sigma_1'$ are equal.

Let $\mathcal{M}$ denote the space of *probability measures* on the Borel sets of $R^r \times U$, with the "weak compact" topology where $P_n \to P$ if and only if $\int f(x,\alpha) P_n(dx\,d\alpha) \to \int f(x,\alpha) P(dx\,d\alpha)$ for each continuous function $f(\cdot)$ with compact support. For an admissible relaxed control for (2.1) and (1.1), respectively, define the (occupation) measure-valued random variables $P_T^{m,\varepsilon}(\cdot)$ and $P_T^m(\cdot)$ by, respectively,

$$P_T^{m,\varepsilon}(B \times C) = \frac{1}{T}\int_0^T I_{\{x^\varepsilon(t) \in B\}} m_t(C)\,dt,$$

$$P_T^m(B \times C) = \frac{1}{T}\int_0^T I_{\{x(t) \in B\}} m_t(C)\,dt.$$

We sometimes write $m^\varepsilon(\cdot)$, if the model is (2.1). If the relaxed control for (1.1) is of the feedback form (m_x or $u(x)$), then we use the modification

$$P_T^m(B) = \frac{1}{T}\int_0^T I_{\{x(t) \in B\}}\,dt$$

(or with u replacing m), and similarly define $P_T^{m,\varepsilon}(B)$, $P_T^{u,\varepsilon}(B)$ for feedback $m(\cdot)$ and $u(\cdot)$.

Let $\{m^\varepsilon(\cdot)\}$ be a given sequence of admissible relaxed controls and let $u^\delta(\cdot)$ be defined by (A2.8) below. The value of δ is fixed in (A2.7).

(A2.7) The sets of random variables

$$\{x^\varepsilon(t), \text{ small } \varepsilon > 0,\ t \in \text{dense set in } [0,\infty),\ m^\varepsilon \text{ used}\},$$

$$\{x^\varepsilon(t), \text{ small } \varepsilon > 0,\ t \in \text{dense set in } [0,\infty),\ u^\delta \text{ used}\}$$

are tight.

Actually (A2.7) is used only because it implies that (A2.7a) holds—so we can use (A2.7a) in lieu of (A2.7).

(A2.7a) The sets of measure-valued random variables

$$\{P_T^{m^\varepsilon,\varepsilon}(\cdot), \text{ small } \varepsilon>0,\ T<\infty\},$$

$$\{P_T^{u^\delta,\varepsilon}(\cdot), \text{ small } \varepsilon>0,\ T<\infty\}$$

are tight.

In turn, (A2.7a) is implied by (A2.7b).

(A2.7b) There is a function $q(\cdot)$ such that $0\leqq q(x)\to\infty$ as $|x|\to\infty$ and

$$\overline{\lim_{\varepsilon,T}} E^{m^\varepsilon,\varepsilon}\frac{1}{T}\int_0^T q(x^\varepsilon(s))\,ds<\infty,$$

and similarly for u^δ replacing m^ε.

A criterion of a Lyapunov function type for (A2.7b) is given at the end of the section.

In many applications, a stabilizing control is used—in the sense that the system is stable for any set of bounded disturbances. Then an additional bounded control term $\bar{G}(x,u)$ is added, and we choose the new control to minimize an average cost. Of course, if the state space is compact, as for the "Lyapunov exponent" problem in § 4, then (A2.7) always holds. In lieu of a "universal stability condition," a condition on the minimum (over the control values) magnitude of the cost $k(\cdot)$ as $|x|\to\infty$ was used in [3] (for the model (1.1)) to get that an optimal control for that model is "stabilizing." Perhaps a similar idea can be used here. But this point will not be pursued.

(A2.8) For $\delta>0$, there is a continuous δ-optimal control for (1.1) and (1.2), for which the martingale problem has a unique solution for each initial condition. The solution is a Feller process and there is a unique invariant measure $\mu(u^\delta,\cdot)$. (u^δ is δ-optimal in the sense that $\bar{\gamma}(u^\delta)\leqq\bar{\gamma}(m_x)+\delta$ for any feedback relaxed control m_x for which there is a stationary solution to the associated martingale problem and the initial condition is the invariant distribution.)

(A2.9) $k(\cdot)$ is bounded and continuous.

Remark. The existence of such *smooth δ-optimal controls* (for any $\delta>0$) is dealt with in [7]. They will exist under an appropriate stability condition on the uncontrolled (1.1), and either nondegeneracy of (1.1) or for a system of the form (2.2) [7]. It turns out that $\gamma(u^\delta)=\bar{\gamma}(u^\delta)$ w.p.1 (this follows from the method of proof of Theorem 1 below, or from the method in [3], under the conditions there).

(A2.10) (Gaussian case.) $\xi(\cdot)$ is a stable Gauss-Markov process with a stationary transition function and let $F(x,\xi)=F(x)\xi$, $G_0(x,\xi)=G_0(x)\xi$, where $\bar{G}$, G_0, and F satisfy the smoothness in (A2.1)-(A2.2). Define $\bar{F}(\cdot)$ and $a(\cdot)$ as in (A2.4). (Note that all other parts of (A2.3)-(A2.5) hold.)

THEOREM 1. *Assume either* (A2.1)-(A2.9) *or* (A2.6)-(A2.10) (*with either* (A2.7) *or* (A2.7a) *or* (A2.7b) *used*). *Let* (2.1) *have a unique solution for each admissible relaxed control and each ε. Then* (1.8a) *and* (1.8b) *hold.*

Proof. We do the "Gaussian" case only. The other case is treated in essentially the same way. Let $\mathscr{D}$ be a (countable) measure determing set of bounded real-valued continuous functions on R^r having continuous second partial derivatives and compact support. Let $m_t^\varepsilon(\cdot)$ be the relaxed control in (A2.7). For a test function $f(\cdot)\in\mathscr{D}$, define the test function perturbations (the change of scale $\tau/\varepsilon^2\to\tau$ yielding the right sides

of the equations below will be used frequently and often without specific mention):

$$f_0^\varepsilon(x,t)=\int_t^\infty E_t^\varepsilon f_x'(x)G_0(x,\xi^\varepsilon(\tau))\,d\tau$$
$$=\varepsilon^2\int_{t/\varepsilon^2}^\infty E_t^\varepsilon f_x'(x)G_0(x,\xi(\tau))\,d\tau=O(\varepsilon^2)|\xi^\varepsilon(t)|,$$
$$f_1^\varepsilon(x,t)=\int_t^\infty E_t^\varepsilon f_x'(x)F(x,\xi^\varepsilon(\tau))\,d\tau/\varepsilon$$
$$=\varepsilon\int_{t/\varepsilon^2}^\infty E_t^\varepsilon f_x'(x)F(x,\xi(\tau))\,d\tau=O(\varepsilon)|\xi^\varepsilon(t)|,$$
$$f_2^\varepsilon(x,t)=\frac{1}{\varepsilon^2}\int_t^\infty d\tau\int_\tau^\infty ds\,\{E_t^\varepsilon[f_x'(x)F(x,\xi^\varepsilon(s))]_x'F(x,\xi^\varepsilon(\tau))$$
$$-E[f_x'(x)F(x,\xi^\varepsilon(s))]_x'F(x,\xi^\varepsilon(\tau))\}$$
$$=\varepsilon^2\int_{t/\varepsilon^2}^\infty d\tau\int_\tau^\infty ds\{E_t^\varepsilon[f_x'(x)F(x,\xi(s))]_x'F(x,\xi(\tau))$$
$$-E[f_x'(x)F(x,\xi(s))]_x'F(x,\xi(\tau))\}$$
$$=O(\varepsilon^2)[|\xi^\varepsilon(t)|^2+1].$$

To evaluate the integrals write $F(x,\xi)=F(x)\xi$, and use the conditional expectations or expectations associated with the Gauss-Markov process.

Define the perturbed test function

$$f^\varepsilon(t)=f(x^\varepsilon(t))+\sum_{i=0}^2 f_i^\varepsilon(x^\varepsilon(t),t).$$

The operator $\hat{A}^{m^\varepsilon,\varepsilon}$ and its domain $\mathcal{D}(\hat{A}^{m^\varepsilon,\varepsilon})$ are defined in the Appendix. By a direct calculation, using the correlation and conditional expectation properties of the Gauss-Markov process $\xi(\cdot)$, we get that $f(x^\varepsilon(\cdot))$ and the $f_i^\varepsilon(x^\varepsilon(\cdot),\cdot)$ are all in $\mathcal{D}(\hat{A}^{m,\varepsilon})$, and[1]

$$\hat{A}^{m^\varepsilon,\varepsilon}f(x^\varepsilon(t))=f_x'(x^\varepsilon(t))\dot{x}^\varepsilon(t)$$
$$=f_x'(x^\varepsilon(t))\left[\int\bar{G}(x^\varepsilon(t),\alpha)m_t^\varepsilon(d\alpha)\right.$$
$$\left.+G_0(x^\varepsilon(t),\xi^\varepsilon(t))+F(x^\varepsilon(t),\xi^\varepsilon(t))/\varepsilon\right].$$

(The "small" perturbations f_i^ε are added to the test function to facilitate the averaging of the "noise" in the above expression. Related calculations are used in [13] and [14].) continuing, we have

$$\hat{A}^{m^\varepsilon,\varepsilon}f_0^\varepsilon(x^\varepsilon(t),t)=-f_x'(x^\varepsilon(t))G_0(x^\varepsilon(t),\xi^\varepsilon(t))$$
$$+\int_t^\infty[E_t^\varepsilon f_x'(x^\varepsilon(t))G_0(x^\varepsilon(t),\xi^\varepsilon(s))]_x'\dot{x}^\varepsilon(t)\,ds/\varepsilon,$$
$$\hat{A}^{m^\varepsilon,\varepsilon}f_1^\varepsilon(x^\varepsilon(t),t)=-f_x'(x^\varepsilon(t))F(x^\varepsilon(t),\xi^\varepsilon(t))/\varepsilon$$
$$+\int_t^\infty ds[E_t^\varepsilon f_x'(x^\varepsilon(t))F(x^\varepsilon(t),\xi^\varepsilon(s))]_x'\dot{x}^\varepsilon(t)/\varepsilon,$$

[1] Acting on functions $f(x^\varepsilon(t))$, the operator $\hat{A}^{m^\varepsilon,\varepsilon}$ is just a differentiation operator. It is also a differentiation operator when acting on functions such as $f_1^\varepsilon(x^\varepsilon(t),t)$ or $f_2^\varepsilon(x^\varepsilon(t),t)$. The calculation is actually a differentiation with respect to the t appearing in $x^\varepsilon(t)$ and also in the lower limit of integration. The t in E_t^ε plays no role in the calculation, owing to the way that E_t^ε appears in the definition of $\hat{A}^{m^\varepsilon,\varepsilon}$.

$$\hat{A}^{m^\varepsilon,\varepsilon}f_2^\varepsilon(x^\varepsilon(t),t)=-\frac{1}{\varepsilon^2}\int_t^\infty ds\{E_t^\varepsilon[f_x'(x^\varepsilon(t))F(x^\varepsilon(t),\xi^\varepsilon(s))]_x'F(x^\varepsilon(t),\xi^\varepsilon(t))$$
$$-E[f_x'(x)F(x,\xi^\varepsilon(s))]_x'F(x,\xi^\varepsilon(t))|_{x=x^\varepsilon(t)}\}$$
$$+[f_2^\varepsilon(x,t)]_x'\dot{x}^\varepsilon(t)|_{x=x^\varepsilon(t)}.$$

The dominant component of the right-hand term of the last expression is $O(\varepsilon)[1+|\xi^\varepsilon(t)|^3]$. This can be seen by using the double scale change in $f_2^\varepsilon(x,t)$ (namely, $s/\varepsilon^2\to s$, $\tau/\varepsilon^2\to\tau$) and the properties of the Gauss-Markov process $\xi(\cdot)$.

We have

$$|f(x^\varepsilon(t))-f^\varepsilon(t)|=O(\varepsilon)[|\xi^\varepsilon(t)|^2+1]. \tag{2.3a}$$

By adding $\sum_{i=0}^2\hat{A}^{m^\varepsilon,\varepsilon}f_i^\varepsilon(t)$ to $\hat{A}^{m^\varepsilon,\varepsilon}f(x^\varepsilon(t))$, subtracting from $A^{m^\varepsilon}f(x^\varepsilon(t))=\int A^\alpha f(x^\varepsilon(t))m_t^\varepsilon(d\alpha)$ and canceling terms where possible, we get

$$|\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(t)-A^{m^\varepsilon}f(x^\varepsilon(t))|=O(\varepsilon)[|\xi^\varepsilon(t)|^3+1]. \tag{2.3b}$$

(The perturbations were constructed just to get the cancellations of the bad terms or the replacement by their averages.) All the $O(\varepsilon)$ are uniform in t, ε, and ω. By (6.4) of the Appendix (with our f^ε replacing the q there), the function

$$M_f^\varepsilon(t)=f^\varepsilon(t)-f^\varepsilon(0)-\int_0^t\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(s)\,ds \tag{2.4}$$

is a zero mean martingale. We next show that $M_f^\varepsilon(t)/t\xrightarrow{P}0$ as $t\to\infty$ and $\varepsilon\to0$ in any way at all.

Write (where $[t]$ denotes the greatest integer part of t)

$$\frac{M_f^\varepsilon(t)}{t}=\frac{1}{t}[(M_f^\varepsilon(t)-M_f^\varepsilon([t]))+M_f^\varepsilon(0)]+\frac{1}{t}\sum_{n=0}^{[t]-1}[M_f^\varepsilon(n+1)-M_f^\varepsilon(n)]. \tag{2.5}$$

Using the fact that $f(\cdot)$ is bounded and (2.3), (2.5), and the martingale property of $M_f^\varepsilon(\cdot)$, we get that $E[M_f^\varepsilon(t)/t]^2=O(1)/t$. The fact that $M_f^\varepsilon(t)/t$, $f^\varepsilon(t)/t$, and $f^\varepsilon(0)/t$ all go to zero in probability as $t\to\infty$ (uniformly in ε) together with (2.4) and the second line of (2.3) implies that as $t\to\infty$ and $\varepsilon\to0$,

$$\int_0^t A^{m^\varepsilon}f(x^\varepsilon(s))\,ds/t\xrightarrow{P}0. \tag{2.6a}$$

By the definition of $P_T^{m^\varepsilon,\varepsilon}(\cdot)$, (2.6a) can be written as

$$\int A^\alpha f(x)P_T^{m^\varepsilon,\varepsilon}(dx\,d\alpha)\xrightarrow{P}0\quad\text{as } T\to\infty\text{ and }\varepsilon\to0. \tag{2.6b}$$

Now, let the control be the classical control function $u^\delta(\cdot)$, and choose a weakly convergent subsequence of the set of random variables $\{P_T^{u^\delta,\varepsilon}(\cdot),\varepsilon,T\}$ (and also such that $1/t\int_0^t A^{u^\delta}f(x^\varepsilon(s))\,ds\to0$ w.p.1 for all $f(\cdot)\in\mathcal{D}$), indexed by ε_n, T_n, and with (random) limit denoted by $\tilde{\mu}(\cdot)$. We let the limits $\tilde{\mu}(\cdot)$ be defined on some probability space $(\bar{\Omega},\bar{P},\bar{\mathcal{F}})$ with generic variable $\bar{\omega}$. Now, (2.6b) implies that

$$\int A^{u^\delta}f(x)\tilde{\mu}(dx)=0\quad\text{for }\bar{P}\text{-almost all }\bar{\omega}. \tag{2.7}$$

Since our class of $f(\cdot)$ is measure-determining, (2.7) implies that almost all realizations of $\tilde{\mu}(\cdot)$ are invariant measures for (1.1) (under u^δ). (This is proved by a slight extension of Proposition 9.2 of [8].) By uniqueness of the invariant measure,

we can take $\mu(u^\delta, \cdot) = \tilde{\mu}(\cdot)$ for all $\bar{\omega}$, and the limit $\tilde{\mu}(\cdot)$ does not depend on the chosen subsequence ε_n, T_n. Furthermore, by the definition of $P_T^{u^\delta,\varepsilon}(\cdot)$,

$$\int_0^t k(x^\varepsilon(s), u^\delta(x^\varepsilon(s)))\, ds/t = \int_0^t k(x, u^\delta(x)) P_t^{u^\delta,\varepsilon}(dx)$$

$$\xrightarrow{P} \int k(x, u^\delta(x))\mu(u^\delta, dx) = \bar{\gamma}(u^\delta).$$

Next, choose a weakly convergent subsequence of $\{P_T^{m^\varepsilon,\varepsilon}(\cdot), \varepsilon, T\}$ (and also such that (2.6a) $\to 0$ w.p.1 for all $f(\cdot) \in \mathscr{D}$) indexed by ε_n, T_n, and with limit denoted by $\tilde{P}(\cdot)$ (again, defined on some probability space $(\bar{\Omega}, \bar{P}, \bar{\mathscr{F}})$). For each $\bar{\omega}$, we can factor $\tilde{P}(\cdot)$ as $\tilde{P}(dx\, d\alpha) = m_x(d\alpha)\mu(dx)$. We can suppose that the $m_x(B)$ are x-measurable for each Borel B and $\bar{\omega}$.

By (2.6), for all $f(\cdot) \in \mathscr{D}$,

$$\iint A^\alpha f(x) m_x(d\alpha)\mu(dx) = 0 \quad \text{for } \bar{P}\text{-almost all } \bar{\omega}. \tag{2.8}$$

This implies that (for $\bar{\omega}$ almost all $\bar{\omega}$), $\mu(\cdot)$ is an invariant measure for the process (1.1) with relaxed feedback control $m_x(\cdot)$. As above we also have

$$\iint k(x, \alpha) m_x(d\alpha)\mu(dx) = \lim_{\varepsilon_n, T_n} \gamma_{T_n}^{\varepsilon_n}(m^\varepsilon) = \bar{\gamma}(m_x). \tag{2.9}$$

But, by the δ-optimality of $u^\delta(\cdot)$, for almost all $\bar{\omega}$ we have $\bar{\gamma}(m_x) \geqq \bar{\gamma}(u^\delta) - \delta$. Since this is true for all the limits of the tight set $\{P_T^{m^\varepsilon,\varepsilon}(\cdot); \varepsilon, T\}$, (1.8b) follows. □

A Lyapunov function criterion for (A2.7b). For illustrative purposes, we do a simple case where the stabilizing dynamics "$\bar{G}$" are dominant. In [5, Chap. 6.6], a related calculation is given for a case where the F-terms must be taken into account. Our case concerns the situation where a globally stabilizing control for the limit system is given a priori, and the control to be chosen is bounded. The main problem arises from the $F(x, \xi)/\varepsilon$ term. We will use the following assumptions.

(A2.11) There is a twice continuously differentiable function $0 \leqq V(x)$ and a $0 \leqq g(\cdot)$ and $K < \infty$ such that $g(x) \to \infty$ as $|x| \to \infty$ and $V_x'(x)\bar{G}(x, \alpha) \leqq -g(x) + K$, all x, α. Also $V_x(x)/g(x) \to 0$ as $|x| \to \infty$.

(A2.12) $G_0(\cdot, \cdot)$, $F(\cdot, \cdot)$ are bounded and continuous, $F(\cdot, \xi)$ has a bounded and continuous (uniformly in ξ) derivative, and (2.1) has a unique solution for each admissible relaxed control. $\xi(\cdot)$ is right-continuous and bounded $\bar{G}(\cdot, \cdot)$ is continuous and is bounded by $O(1 + |x|)$.

Define the perturbation to $V(\cdot)$:

$$V_1^\varepsilon(x, t) = \frac{1}{\varepsilon} \int_t^\infty E_t^\varepsilon V_x'(x) F(x, \xi^\varepsilon(s))\, ds = \varepsilon \int_{t/\varepsilon^2}^\infty E_{t/\varepsilon^2} V_x'(x) F(x, \xi(s))\, ds.$$

(A2.13) The limits below are uniform in t, ω (w.p.1),

$$\lim_{|x| \to \infty} |V_1^\varepsilon(x, t)/V(x)| = 0, \qquad \overline{\lim_{|x| \to \infty}} |(V_1^\varepsilon(x, t))_x / g(x)| = O(\varepsilon),$$

$$\overline{\lim_{|x| \to \infty}} |(V_1^\varepsilon(x, t))_x' \bar{G}(x, \alpha)/g(x)| = O(\varepsilon).$$

THEOREM 2. *Assumption* (A2.7b) *holds under* (A2.11)-(A2.13), *for each initial condition* $x^\varepsilon(0) = x$.

Proof. Fix $\{m^\varepsilon\}$ and define the perturbed Lyapunov function $V^\varepsilon(x^\varepsilon(t), t) = V(x^\varepsilon(t)) + V_1^\varepsilon(x^\varepsilon(t), t)$. Similarly to what has been done in Theorem 1, $V^\varepsilon(x^\varepsilon(t), t) \in \mathscr{D}(\hat{A}^{m^\varepsilon,\varepsilon})$ and

$$\begin{aligned}\hat{A}^{m^\varepsilon,\varepsilon}V^\varepsilon(x^\varepsilon(t), t) &= V_x'(x^\varepsilon(t))\int \bar{G}(x^\varepsilon(t), \alpha)m_t^\varepsilon(d\alpha)\\ &\quad + V_x'(x^\varepsilon(t))G_0(x^\varepsilon(t), \xi^\varepsilon(t))\\ &\quad + \frac{1}{\varepsilon}\int_t^\infty ds\, E_t^\varepsilon[V_x'(x^\varepsilon(t))F(x^\varepsilon(t), \xi^\varepsilon(s))]_x'\\ &\quad \cdot\left[G_0(x^\varepsilon(t), \xi^\varepsilon(t)) + \int \bar{G}(x^\varepsilon(t), \alpha)m_t^\varepsilon(d\alpha) + F(x^\varepsilon(t), \xi^\varepsilon(t))/\varepsilon\right].\end{aligned} \tag{2.10}$$

By (A2.13) and a change of scale $s/\varepsilon^2 \to s$ we have that the right-hand term of (2.10) is bounded in absolute value by $O(\varepsilon)g(x) + o(g(x))$, where $o(g)/g \to 0$ as $g \to \infty$. Thus there is $K_1 < \infty$ such that for small ε

$$\hat{A}^{m^\varepsilon,\varepsilon}V^\varepsilon(x^\varepsilon(t), t) \leqq -\tfrac{1}{2}g(x^\varepsilon(t)) + K_1.$$

Hence

$$\begin{aligned}&[E^{m,\varepsilon}V(x^\varepsilon(t)) + E^{m,\varepsilon}V_1^\varepsilon(x^\varepsilon(t), t) - V(x) - V_1^\varepsilon(x, 0)]/t\\ &\leqq -\frac{1}{2t}E^{m^\varepsilon,\varepsilon}\int_0^t g(x^\varepsilon(s))\, ds + K_1.\end{aligned} \tag{2.11}$$

By the first line of (A2.13) and the fact that $V(x) \geqq 0$, by taking $t \to \infty$ we get

$$\overline{\lim_{\varepsilon,t}}\frac{1}{t}E^{m^\varepsilon,\varepsilon}\int_0^t g(x^\varepsilon(s))\, ds \leqq 2K_1,$$

which is (A2.7b). □

3. Alternative conditions. In this section we redo Theorem 1 under somewhat different conditions. The perturbed test function is only "first-order" here and (2.3) will not hold. But similar results are obtained via a direct averaging method of the type introduced in [5, chap. 5]. We will use either bounded "mixing" or Gaussian noise, as in § 2, and subsets of the following conditions. Let E_t denote the expectation given $\xi(s)$, $s \leqq t$.

(A3.1) $\xi(\cdot)$ is bounded, and right-continuous $G_0(\cdot,\cdot)$, $\bar{G}(\cdot,\cdot)$, $F(\cdot,\cdot)$, and $F_x(\cdot,\cdot)$ are continuous and bounded by $O(1+|x|)$.

(A3.2) $\int_t^\infty E_sF(x, \xi(s))\, ds$, $\int_t^\infty E_t[f_x'(x)F(x, \xi(s))]_x'F(x, \xi(t))\, ds$, are bounded and x-continuous uniformly on each compact x-set and uniformly in t, ω.

(A3.3) $1/T\int_t^{t+T} E_tG_0(x, \xi(s))\, ds \xrightarrow{P} 0$, for each x as t and $T \to \infty$.

(A3.4) There are continuous $\bar{F}(\cdot)$, $a(\cdot)$ such that with A_0 (acting on twice continuously differentiable real-valued functions $f(\cdot)$ with compact support) given by

$$A_0f(x) = f_x'(x)\bar{F}(x) + \frac{1}{2}\sum_{i,j} a_{ij}(x)f_{x_ix_j}(x), \qquad a_{ij}(x) = a_{ji}(x),$$

we have

$$\frac{1}{T}\int_t^{t+T} ds \int_s^\infty du\, E_t[f_x'(x)F(x, \xi(u))]_x'F(x, \xi(s)) \xrightarrow{P} A_0f(x),$$

for each x as t and $T \to \infty$.

(A3.5) $\xi(\cdot)$ is a stable Gauss-Markov process, with a stationary transition function, and $F(x,\xi)=F(x)\xi$, $G_0(x,\xi)=G_0(x)\xi$, and $F(\cdot)$, $\bar{G}(\cdot,\cdot)$ and $G_0(\cdot)$ have the smoothness of (A3.1). (We continue to define $\bar{F}(\cdot)$, $a(\cdot)$, and A_0 as in (A3.4), when (A3.5) is used.)

As in § 1, set $A^\alpha f(x)=f_x'(x)\bar{G}(x,\alpha)+A_0 f(x)$, and $\bar{b}(x,\alpha)=\bar{G}(x,\alpha)+\bar{F}(x)$.

THEOREM 3. *Assume* (A2.6)-(A2.9) *with either* (A2.7) *or* (A2.7a) *or* (A2.7b) *used, and either* (A3.1)-(A3.4) *or else* (A3.5). *Let* (2.1) *have a unique solution for each admissible relaxed control and each* $\varepsilon>0$. Then (1.8a) *and* (1.8b) *hold.*

Proof. Let $f(\cdot)$ be as in Theorem 1. We use the "direct averaging first-order perturbed test function method" of [5, Chap. 5], [9], [1], but the development here is self-contained. Define $f_1^\varepsilon(x,t)$ as in Theorem 1 and set $f^\varepsilon(t)=f(x^\varepsilon(t))+f_1^\varepsilon(x^\varepsilon(t),t)$. Then (write x for $x^\varepsilon(t)$ for convenience here) $f^\varepsilon(\cdot)\in\mathcal{D}(\hat{A}^{m^\varepsilon,\varepsilon})$ and

$$\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(t)=f_x'(x)\left[\int\bar{G}(x,\alpha)m_t^\varepsilon(d\alpha)+G_0(x,\xi^\varepsilon(t))\right]$$
$$+\frac{1}{\varepsilon^2}\int_t^\infty ds[E_t^\varepsilon f_x'(x)F(x,\xi^\varepsilon(s))]_x'F(x,\xi^\varepsilon(t))$$
$$+\text{terms of order } O(\varepsilon)[|\xi^\varepsilon(t)|^2+1].$$

(See the expressions given above (2.3).) When we use the scale change $s/\varepsilon^2\to s$, the second term can be seen to be bounded in mean square for the bounded noise case and $O(1)[|\xi^\varepsilon(t)|^2+1]$ in the Gaussian case.

Define the martingale

$$M_f^\varepsilon(t)=f^\varepsilon(t)-f^\varepsilon(0)-\int_0^t\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(s)\,ds.$$

If

$$M_f^\varepsilon(t)/t\xrightarrow{P}0\quad\text{as }\varepsilon\to0,\quad t\to\infty, \tag{3.1}$$

then as in Theorem 1, we have

$$\int_0^t\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(s)\,ds/t\xrightarrow{P}0\quad\text{as }\varepsilon\to0,\quad t\to\infty.$$

If we also have that

$$\frac{1}{t}\int_0^t[\hat{A}^{m^\varepsilon,\varepsilon}f^\varepsilon(s)-A^{m^\varepsilon}f(x^\varepsilon(s))]\,ds\xrightarrow{P}0\quad\text{as }\varepsilon\to0,\quad t\to\infty, \tag{3.2}$$

(and also for u^δ used in lieu of $m^\varepsilon(\cdot)$), then the proof can be completed as in Theorem 1. Thus, we need only show (3.1) and (3.2).

To get (3.1), we use the representation (2.5). The martingale difference $M_f^\varepsilon(n+1)-M_f^\varepsilon(n)$ equals

$$f^\varepsilon(n+1)-f^\varepsilon(n)-\int_n^{n+1}ds\left[f_x'(x^\varepsilon(s))\int\bar{G}(x^\varepsilon(s),\alpha)m_s^\varepsilon(d\alpha)+G_0(x^\varepsilon(s),\xi^\varepsilon(s))\right]$$
$$+\int_n^{n+1}ds\,O(1)[|\xi^\varepsilon(s)|^2+1]. \tag{3.3}$$

Since the mean square value of (3.3) is bounded uniformly in n, ω, ε, we get that $E[M_f^\varepsilon(t)]^2/t=O(1/t)$ and (3.1) holds, exactly as for Theorem 1.

We now prove (3.2). To *simplify the proof, we drop the terms* $\int \bar{G}(x,\alpha)m_t^\varepsilon(d\alpha)$ *and* $G_0(x,\xi)$. The first dropped term causes no problems (as in Theorem 1) and the second is dealt with by an averaging method similar to that employed below. Now, we have

$$\begin{aligned}
&\frac{1}{t}\int_0^t \hat{A}^{m^\varepsilon,\varepsilon} f^\varepsilon(s)\,ds \\
&= \frac{1}{t}\int_0^t ds \int_s^\infty du\, E_s^\varepsilon [f_x'(x^\varepsilon(s))F(x^\varepsilon(s),\xi^\varepsilon(u))]_x' F(x,\xi^\varepsilon(s))/\varepsilon^2 \\
&\qquad + \text{negligible terms} \\
&= \frac{\varepsilon^2}{t}\int_0^{t/\varepsilon^2} ds \int_s^\infty du\, E_s [f_x'(x^\varepsilon(\varepsilon^2 s)F(x^\varepsilon(\varepsilon^2 s),\xi(u))]_x' F(x^\varepsilon(\varepsilon^2 s),\xi(s)) \\
&\qquad + \text{negligible terms}
\end{aligned} \tag{3.4}$$

where the negligible terms go to zero in the mean square sense as $\varepsilon \to 0$. Henceforth, for simplicity, we consider the *scalar* case and work with only the term $f_{xx}(x)F(x,\xi(u))F(x,\xi(s))$ in (3.4). Write $t = N\Delta$ for integer N and $\Delta > 0$. Define

$$Q^\varepsilon(x,s) = \int_s^\infty du\, E_s f_{xx}(x)F(x,\xi(u))F(x,\xi(s)).$$

Then the desired term in (3.4) can be written as follows:

$$\begin{aligned}
&\frac{1}{N}\sum_1^N \frac{\varepsilon^2}{\Delta}\int_{i\Delta/\varepsilon^2}^{(i\Delta+\Delta)/\varepsilon^2} ds[E_{i\Delta}^\varepsilon Q^\varepsilon(x^\varepsilon(\varepsilon^2 s),s) - Q^\varepsilon(x^\varepsilon(\varepsilon^2 s),s)] \\
&\qquad + \frac{1}{N}\sum_1^N \frac{\varepsilon^2}{\Delta}\int_{i\Delta/\varepsilon^2}^{(i\Delta+\Delta)/\varepsilon^2} E_{i\Delta}^\varepsilon Q^\varepsilon(x^\varepsilon(\varepsilon^2 s),s)\,ds.
\end{aligned} \tag{3.5}$$

Since $E|E_{i\Delta}^\varepsilon Q^\varepsilon(x^\varepsilon(\varepsilon^2 s),s) - Q^\varepsilon(x^\varepsilon(\varepsilon^2 s),s)|^2$ is bounded uniformly in s, ε, and Δ, the first set of *summands* in (3.5) are martingale differences with uniformly (in ε, N, t) bounded mean square values. Thus the first sum is $O(1/N)$ and goes to zero in probability as $N \to \infty$, uniformly in ε, t. Let $f(x) = 0$ for $|x| \geqq K$. By [5, Thm. 4, Chap. 3], and the uniform integrability of $\{\hat{A}^{m^\varepsilon,\varepsilon} f^\varepsilon(t), \varepsilon > 0, t < \infty\}$, the sequence

$$\{[x^\varepsilon(i\Delta+\cdot) - x^\varepsilon(i\Delta)]I_{\{|x^\varepsilon(i\Delta)|\leqq 2K\}},\ i, \Delta > 0,\ \varepsilon > 0\}$$

is tight in $D[0,\infty)$ (Skorokhod topology) and has continuous limits w.p.1. Because of this, we can replace the $x^\varepsilon(\varepsilon^2 s)$ in the ith summand of the second term in (3.5) by $x^\varepsilon(i\Delta)$ for all i, and only alter the sum by an amount that goes to zero in probability (uniformly in ε and N) as $\Delta \to 0$.

Doing this replacement and using either the Gaussian property (A3.5) or else (A3.4) for the bounded noise case, and the continuity of $F(\cdot,\xi)$ (uniform in ξ in the bounded noise case) and the continuity and compact support of $f_{xx}(\cdot)$ yields that the second sum in (3.5) and

$$\frac{1}{N}\sum_1^N \frac{\varepsilon^2}{\Delta}\int_{i\Delta/\varepsilon^2}^{(i\Delta+\Delta)/\varepsilon^2} ds\, f_{xx}(x^\varepsilon(i\Delta))a(x^\varepsilon(i\Delta))/2 \tag{3.6}$$

have the same limit in probability as $N \to \infty$, $\Delta \to 0$, $\varepsilon \to 0$, $N\Delta \to \infty$. We next use the rightness of

$$\{[x^\varepsilon(i\Delta+\cdot) - x^\varepsilon(i\Delta)]I_{\{|x^\varepsilon(i\Delta)|\leqq 2K\}},\ i, \Delta > 0,\ \varepsilon > 0\}$$

again to replace the $x^\varepsilon(i\Delta)$ in (3.6) by $x^\varepsilon(\varepsilon^2 s)$, and get the same result, namely that the limit in probability is the same as $N\to\infty$, $\Delta\to 0$, $\varepsilon\to 0$, $N\Delta\to\infty$. Finally, repeating the approximation procedure used from (3.5) on for the various neglected terms yields (3.2). □

4. Extensions.

Discrete time problem. There are direct extensions to the discrete parameter model

$$X^\varepsilon_{n+1} = X^\varepsilon_n + \varepsilon \int \bar{G}(X^\varepsilon_n, \alpha) m_n(d\alpha) + \varepsilon G_0(X^\varepsilon_n, \xi^\varepsilon_n) + \sqrt{\varepsilon} F(X^\varepsilon_n, \xi^\varepsilon_n). \tag{4.1}$$

In both (4.1) and (2.1), we can allow some "state dependence" of the noise (cf. the "Markov"-dependent type used in [5, Chaps. 4.4 or 5.5]).

Approximate nonlinear filtering. In the following two applications, there is no control. In § 7 of [10], an "approximate" nonlinear filtering problem was dealt with, where the system driving and observation noises were wideband. It was shown (under a condition concerning the uniqueness of a certain invariant measure) that the average error (using the notation of that paper)

$$\lim_\varepsilon \frac{1}{T}\int_0^T E[\phi(x^\varepsilon(t)) - (P^\varepsilon(t), \phi)]^2\, dt \tag{4.2}$$

converged to what we would get if the true optimal filter were used on the "limit" process. Here $x^\varepsilon(\cdot)$ is the state of the "signal system" (say, of the form (2.1)), $\phi(\cdot)$ is bounded and continuous, and $P^\varepsilon(\cdot)$ is the measure-valued output (not necessarily the conditional distribution) of the "approximate" filters used in [12]. Via the technique of this paper, similar results can be obtained if the E in (4.2) were dropped. This is useful, since we would normally filter only one path—over a long time—and the use of the expectation might give an inappropriate measure of the filter performance.

Lyapunov exponents for wide bandwidth noise-driven systems. The theory of Lyapunov exponents is well developed for systems of the form

$$dx = Ax\, dt + \sum_{i=1}^k B_i x \circ dw_i, \tag{4.3}$$

where the $\circ$ denotes that the stochastic integral is in the "Stratonovich" sense and where the $w_i(\cdot)$ are real-valued and mutually independent standard Wiener processes [11]. The "Stratonovich" sense integral is used to be consistent with the usage in [11] and because it simplifies the identification of the limit process and its "projection" below in this case. Of practical interest are the convergence properties of numerical methods of evaluating these exponents, as well as the study of the asymptotic behavior of wideband noise-driven systems (4.4) via

$$\dot{x}^\varepsilon = Ax^\varepsilon + \sum_{i=1}^k B_i x \xi^\varepsilon_i, \tag{4.4}$$

the method of Lyapunov exponents. In (4.4), the $\xi^\varepsilon_i(\cdot)$ are orthogonal and scalar-valued processes. Of particular interest is whether the exponents for (4.4) converge to those for the limit system (which will be of the general form of (4.3)) as $\varepsilon\to 0$.

Under the conditions of Theorem 3 on $\xi^\varepsilon_i(\cdot) = \xi(\cdot/\varepsilon^2)$, the above orthogonality condition, and the normalization

$$\frac{1}{T}\int_t^{t+T} ds \int_s^\infty E_t \xi_i(s)\xi_i(u)\, du \to \frac{1}{2}$$

in probability as t and T go to ∞, the $x(\cdot)$ of (4.3) is the weak limit of (4.4), if the initial conditions converge. We can assume this normalization to hold in general, since otherwise we absorb the "constants" into the B_i in the obvious way.

Define $y = x/|x|$. Then

$$\dot{y} = \dot{x}/|x| - x[x'\dot{x}]/|x|^{3/2}$$

and

$$\dot{y}^\varepsilon = Ay^\varepsilon + \sum_{i=1}^{k} B_i y^\varepsilon \xi_i^\varepsilon - y^\varepsilon [y^{\varepsilon\prime} A y^\varepsilon] - y^\varepsilon \left[y^{\varepsilon\prime} \sum_{i=1}^{k} \xi_i^\varepsilon B_i y^\varepsilon \right]. \tag{4.5}$$

Assume the noise conditions of Theorem 3. Then, it is not hard to show that $P\{x^\varepsilon(s) \neq 0, \text{ any } s \leqq T\} = 1$ for all ε, T.

Of interest is the calculation of quantities such as $\lim_t E \int_0^t q(y^\varepsilon(s))\, ds/t$ for bounded and continuous $q(\cdot)$. In the Monte Carlo evaluation of the limit, we often use

$$\frac{1}{t} \int_0^t q(y^\varepsilon(s))\, ds \tag{4.6}$$

for large t and some small ε; it is of interest to know whether or not the convergence is to the correct limit and whether it is uniform in ε and t in the sense of (1.8a). (An alternative is of course to fix $T < \infty$ and approximate $E \int_0^T q(y^\varepsilon(s))\, ds/T$ for small ε by taking many independent runs and averaging. But, the "uniformity" questions still arise.)

Define $y(t) = x(t)/|x(t)|$ and

$$q(y) = y'Ay + \frac{1}{2} \sum_{i=1}^{k} [y'(B_i + B_1')B_i y - (y'B_i y)^2],$$

and assume that $y(\cdot)$ has a unique invariant measure on the sphere (this is true under a Lie algebraic condition on the set $(A, B_i, i \leqq k)$ [11]). Then [11] the (maximal) Lyapunov exponent is the limit (which is a constant w.p.1)

$$\lim_t \int_0^t q(y(s))\, ds/t. \tag{4.7}$$

We are interested in whether or not (4.6) converges to (4.7) as $\varepsilon \to 0$ and $t \to \infty$.

By Theorem 3 $(x^\varepsilon(\cdot), y^\varepsilon(\cdot)) \Rightarrow (x(\cdot), y(\cdot))$ (Skorokhod topology), and the weak limit process $y(\cdot)$ is characterized completely by the correlation functions of the $\xi_i(\cdot)$. Let $\mu(\cdot)$ denote the assumed unique invariant measure for $y(\cdot)$. Then

$$\frac{1}{t} \int_0^t q(y^\varepsilon(s))\, ds \xrightarrow{P} \int q(y)\mu(dy) \quad \text{as } \varepsilon \to 0, \quad t \to \infty, \tag{4.8}$$

and the limit value is just the (maximum) Lyapunov exponent for $x(\cdot)$. The general method is applicable to a wide variety of noise processes and can readily be extended to yield convergence of various numerical approximations to the (maximal) Lyapunov exponent for (4.3), via use of either a discrete time approximation to (4.3) or the various interpolations that can be used to approximate the stochastic integrals.

5. Convergence of pathwise discounted costs to the ergodic cost. In this section, we treat the discounted cost result (1.9). Again, the exact sense in which the $m^\varepsilon(\cdot)$ are δ_1-optimal is left a little vague. Since $u^\delta(\cdot)$ is asymptotically δ-optimal, no matter

what the $m^\varepsilon(\cdot)$ are, the pathwise costs are (for small β, ε) no better (modulo 2δ) than the costs for the $u^\delta(\cdot)$, with an arbitrary large probability.

THEOREM 4. *Under the conditions of either Theorem* 1 *or* 2, *the limits* (1.9) *hold.*

Remarks on the Proof. The proof is essentially the same as those of Theorems 1 or 3, and we only remark on the differences. We use the discounted occupation measures

$$
\begin{aligned}
P_\beta^{m,\varepsilon}(B\times C) &= \beta \int_0^\infty e^{-\beta t} I_{\{x^\varepsilon(t)\in B\}} m_t(C)\, dt,\\
P_\beta^{m}(B\times C) &= \beta \int_0^\infty e^{-\beta t} I_{\{x(t)\in B\}} m_t(C)\, dt
\end{aligned}
\tag{5.1}
$$

and analogously for the feedback control cases.

Then the cost can be written as

$$
V_\beta^\varepsilon(m^\varepsilon) = \int\int k(x,\alpha) P_\beta^{m^\varepsilon,\varepsilon}(dx\, d\alpha).
$$

By the tightness condition (A2.7), or (A2.7a), or (A2.7b), the $\{P_\beta^{m^\varepsilon,\varepsilon}(\cdot)\}$ and $\{P^{u^\delta,\varepsilon}(\cdot)\}$ are tight. Define

$$
f_\beta^\varepsilon(t) = \beta\, e^{-\beta t} f^\varepsilon(t). \tag{5.2}
$$

This will be used in lieu of the $f^\varepsilon(\cdot)$ defined in either Theorems 1 or 3. We have

$$
\hat{A}^{m^\varepsilon,\varepsilon} f_\beta^\varepsilon(t) = -\beta^2 e^{-\beta t} f^\varepsilon(t) + \beta\, e^{-\beta t} \hat{A}^{m^\varepsilon,\varepsilon} f^\varepsilon(t). \tag{5.3}
$$

Define the martingale

$$
\begin{aligned}
&f_\beta^\varepsilon(t) - f_\beta^\varepsilon(0) - \int_0^t \hat{A}^{m^\varepsilon,\varepsilon} f_\beta^\varepsilon(s)\, ds\\
&\quad = \beta\, e^{-\beta t} f^\varepsilon(t) - \beta f^\varepsilon(0) - \int_0^t [-\beta^2 e^{-\beta s} f^\varepsilon(s) + \beta\, e^{-\beta s} \hat{A}^{m^\varepsilon,\varepsilon} f^\varepsilon(s)]\, ds.
\end{aligned}
$$

As in Theorems 1 or 3

$$
0 = \lim_{\substack{(\beta,\varepsilon)\to 0\\ t\to\infty}} \beta \int_0^t e^{-\beta s} A^{m^\varepsilon,\varepsilon} f(x^\varepsilon(s))\, ds. \tag{5.4}
$$

Thus,

$$
0 = \lim_{(\beta,\varepsilon)\to 0} \int\int A^\alpha f(x) P_\beta^{m^\varepsilon,\varepsilon}(dx\, d\alpha). \tag{5.5}
$$

Again we choose weakly convergent subsequences of the $\{P_\beta^{m^\varepsilon,\varepsilon}(\cdot)\}$ or $\{P_\beta^{u^\delta,\varepsilon}(\cdot)\}$ and continue as in the proofs of either Theorems 1 or 3 to get Theorem 4.

6. Appendix.

DEFINITION. Let $q(\cdot)$ be progressively measurable with respect to $\{\mathcal{F}_t^\varepsilon\}$, the minimal σ-algebra measuring $\{\xi^\varepsilon(s), x^\varepsilon(s), s \leqq t\}$. Suppose that there is a progressively measurable (with respect to $\{\mathcal{F}_t^\varepsilon\}$) $g(\cdot)$ such that

$$
\sup_{t\leqq T} E|g(t)| < \infty, \quad E|g(t+s) - g(t)| \to 0 \quad \text{as } s\downarrow 0 \quad \text{almost all } t, \tag{6.1}
$$

$$
\sup_{\substack{t\leqq T\\ \delta>0}} E\left|\frac{E_t^\varepsilon q(t+\delta) - q(t)}{\delta} - g(t)\right| < \infty \tag{6.2}
$$

$$
\lim_{\delta\downarrow 0} E\left|\frac{E_t^\varepsilon q(t+\delta) - q(t)}{\delta} - g(t)\right| \to 0 \quad \text{almost all } t. \tag{6.3}
$$

Then we say that $q(\cdot) \in \mathcal{D}(\hat{A}^{m,\varepsilon})$, the domain of the operator $\hat{A}^{m,\varepsilon}$ and that $\hat{A}^{m,\varepsilon} q = g$. If $q(\cdot) \in \mathcal{D}(\hat{A}^{m,\varepsilon})$, then [3, Chap. 3], [12],

$$q(t) - \int_0^t \hat{A}^{m,\varepsilon} q(s)\, ds \tag{6.4}$$

is an $\mathcal{F}_t^\varepsilon$-martingale. This martingale property will be heavily used in the proofs. We define $\hat{A}^{\alpha,\varepsilon}$ to be $\hat{A}^{m,\varepsilon}$ with m_t concentrated at α, and $\hat{A}^{u,\varepsilon}$ is defined in the obvious way

The form given for $\hat{A}^{m,\varepsilon}$ in Theorem 1 satisfies (6.1)–(6.3) if $\int \bar{G}(x, \alpha) m_t(d\alpha)$ is right-continuous w.p.1. Since we are only concerned in this paper with the use of $\hat{A}^{m,\varepsilon} q$ in an integral—to get the martingale property (6.4)—the forms for $\hat{A}^{m,\varepsilon}$ given in the text are valid even without the right continuity, as shown below.

If $\int \bar{G}(x, \alpha) m_t(d\alpha)$ is not right-continuous, we can get the correct $\hat{A}^{m,\varepsilon} q$ that makes (6.4) an $\mathcal{F}_t^\varepsilon$-martingale by an approximation procedure. Simply let $m^\varepsilon(\cdot)$ be replaced by a piecewise constant right-continuous admissible control $m^{\varepsilon,\Delta}$, and replace $x^\varepsilon(\cdot)$ by the associated process $x^{\varepsilon,\Delta}(\cdot)$. Calculate $\hat{A}^{m^{\varepsilon,\Delta},\varepsilon} q(x^{\varepsilon,\Delta}(t), t)$ for the functions $q(\cdot, \cdot)$ used in the text, then take limits in $q(x^{\varepsilon,\Delta}(t), t) - \int_0^t \hat{A}^{m^{\varepsilon,\Delta},\varepsilon} q(x^\varepsilon(s), s)\, ds$. This will yield the forms used in the text, which are, in fact, just what we get by assuming the right continuity of $\int \bar{G}(x, \alpha) m_t(d\alpha)$.

DISTRIBUTED COMPUTATION OF NASH EQUILIBRIA IN LINEAR-QUADRATIC STOCHASTIC DIFFERENTIAL GAMES*

TAMER BAŞAR† AND SHU LI‡

Abstract. In this paper, a class of n-person stochastic linear-quadratic differential games under multiple probabilistic modeling is studied, with each player acquiring a noisy measurement of the initial state. Conditions for the existence and uniqueness of the Nash equilibrium is obtained, and a method is provided for an iterative distributed computation of the solution. The distributed algorithm involves learning in the policy space, and it does not require that each player knows the others' perceptions of the probabilistic model underlying the decision process. For the finite horizon problem, such an iteration converges whenever the length of the time horizon is sufficiently small, and the limit in this case is an affine policy for all players if the underlying distributions are jointly Gaussian. When the horizon is infinite and a discount factor is used in the cost functionals, the iteration converges under conditions depending on the magnitude of the discount factor, the limiting policies again being affine in the case of Gaussian distributions.

Key words. stochastic differential games, stable Nash equilibria, multiple probabilistic models, repeated incomplete games, distributed algorithms

AMS(MOS) subject classifications. 93E05, 90D25

1. Introduction.

The majority of the results in dynamic and differential game theory pertain to the so-called "complete games" where the players have a complete knowledge of the rules of the game and the cost functionals of other players, while "incomplete games" (cf. [1]-[3]) have attracted relatively little attention. One recent study on the latter class of problems is [4], which has developed a framework that allows different decision makers (synonymously, players) to adopt different (not necessarily consistent) probabilistic models. In this framework, [4] obtains conditions for existence, uniqueness, and stability of Nash and Stackelberg equilibria in quadratic static games and shows that under jointly Gaussian distributions, the Nash equilibrium is affine in the observations while the Stackelberg equilibrium policies are intrinsically nonlinear. Furthermore, it has been shown in [4] that multimodeling is well posed under the Nash solution concept (in the sense that the solution is "structurally continuous" in the limit as we go from multiple probabilistic models to a single model for all decision-makers), whereas it is structurally nonrobust under the Stackelberg solution concept.

In this paper, we extend the multiple probabilistic model of [4] to n-person stochastic differential games. The mathematical framework allows each player not to have access to the probability measure and parameters of the cost functionals adopted by other players, and the presence of a communication link between the players permits transmission of policy information, thereby enhancing learning in the policy space. We show that distributed computation and iteration in policy space leads to a unique Nash equilibrium when the finite time horizon is sufficiently short, and that this solution

is affine for all players when the underlying distributions are jointly Gaussian. When the horizon is infinite and a discount factor is allowed, we show that the conditions depend on the magnitude of this discount factor.

In § 2 of the paper, we formulate the problem in precise mathematical terms in a Hilbert space setting, using a multiple probabilistic description; we also develop necessary and sufficient conditions for existence of an equilibrium solution. These conditions are further refined in § 3 in the proof of uniqueness and stability of the Nash solution and convergence of a related distributed algorithm. Section 3 also includes results on the special case when prior distributions are jointly Gaussian. Section 4 extends these results to the infinite horizon case, and the paper ends with the concluding remarks of § 5 and an Appendix.

2. Problem formulation and characterization of Nash equilibria. Let $(\Omega, \mathbf{F})$ be a measurable space, and let $\mathbb{P}$ denote the class of probability measures defined on it. Let $X = \mathbb{R}^m$ be the state space, let $Y_i = \mathbb{R}^{m_i}$ be the observation space for decision maker (DMi), $i \in \mathbb{N} := \{1, 2, \cdots, n\}$, and let $Z := X \times Y_1 \times \cdots \times Y_n$. Introduce $\mathbf{B}_z$ = Borel field of subsets of Z, $\mathbf{B}^k$ = Borel field of subsets of $\mathbb{R}^k$, $k = m, m_1, \cdots, m_n$, and random vectors $x_0 : (\Omega, \mathbf{F}) \to (X, \mathbf{B}^m)$, $y_i : (\Omega, \mathbf{F}) \to (Y_i, \mathbf{B}^{m_i})$, with corresponding Borel probability measures $\mathbf{P}_{x_0}$ and $\mathbf{P}_{y_i}$ induced by each $\mathbf{P} \in \mathbb{P}$.

Now, we consider a system modeled by an m-dimensional sample-path-continuous random process, satisfying the Itô stochastic differential equation

$$dx_t = \left(A(t)x_t + \sum_{i=1}^{n} B_i(t)u_{it} \right) dt + C(t)\, dw_t, \qquad t \geqq 0 \tag{1}$$

under the n probability measures $\mathbf{P}^1, \cdots, \mathbf{P}^n \in \mathbb{P}$, perceived by DM1, $\cdots$, DMn. Here x_0 is a random vector under the n probability measures $\mathbf{P}^1, \cdots, \mathbf{P}^n$, $x_0(\omega) \in X$; $\{w_t\}$ is an m-dimensional Brownian motion under $\mathbf{P}^1, \cdots, \mathbf{P}^n$; $A(t), B_1(t), \cdots, B_n(t), C(t)$ are appropriate dimensional matrices, continuous in $[0, t_f]$; $\{u_{it}\}$ is a p_i-dimensional random process denoting DMi's action, $i \in \mathbb{N}$; and $y_i(\omega) \in Y_i$ is the static measurement of DMi, $i \in \mathbb{N}$, related to the initial state x_0, with all these random quantities being well defined under the probability measures $\mathbf{P}^1, \cdots, \mathbf{P}^n$. Furthermore, $y_1, \cdots, y_n$ and x_0 are independent of $\{w_t\}$ under the n measures. Note that this is an open-loop information pattern, and one possible relationship between the y_is and the x_0 would be given by the linear measurement model:

$$y_i = H_i x_0 + v_i,$$

where H_i is an $m_i \times m$ dimensional matrix for each $i \in \mathbb{N}$, and $\{v_i, i \in \mathbb{N}\}$ is a sequence of independent random vectors, defined under each of the measures $\mathbf{P}^1, \cdots, \mathbf{P}^n$. We will have occasion to use this specific model later in § 3.

A permissible decision rule for DMi is a Borel-measurable mapping $\gamma_i : [0, t_f] \times R^{m_i} \to R^{p_i}$ such that

$$E^i \left\{ \int_0^{t_f} \| \gamma_i(t, y_i) \|^2 \, dt \right\} < \infty$$

where the norm $\|\cdot\|$ is taken as the Euclidean norm on R^{p_i}, for $i \in \mathbb{N}$, and E^i refers to unconditional expectation under the probability measure $\mathbf{P}^i$. Let Γ_i denote the set of all such permissible decision rules (strategies) for DMi, $i \in \mathbb{N}$.

Define the quadratic cost functional for DMi as follows:

$$J_i(\gamma) = E^i \left\{ \frac{1}{2} x_{t_f}^T Q_{if} x_{t_f} + \int_0^{t_f} \left(\frac{1}{2} x_t^T Q_i(t) x_t + \frac{1}{2} \sum_{j \in N} u_{jt}^T R_{ij}(t) u_{jt} \right) dt \,\middle|\, u_{lt} = \gamma_l(t, y_l), l \in \mathbb{N} \right\},$$

$$i \in \mathbb{N},$$

where $Q_{if} \geqq 0$, $Q_i(t) \geqq 0$ for all t, $R_{ii}(t) > 0$ for all t, for $i \in \mathbb{N}$, "T" denotes the transpose and $\gamma := (\gamma_1, \cdots, \gamma_n)$. Note that the above specifications make J_i strictly convex in γ_i for each $i \in \mathbb{N}$. Furthermore, for each J_i to be well defined and finite for all $(\gamma_1, \cdots, \gamma_n) \in \Gamma_1 \times, \cdots, \times \Gamma_n$, and under the given n probability measures, we have to make the following two basic assumptions, as in [4].

Assumption 2.1. For each fixed $i \in \mathbb{N}$, $\mathbf{P}^j_{y_i}, j \neq i, j \in \mathbb{N}$, *are absolutely continuous with respect to* $\mathbf{P}^i_{y_i}$.

Assumption 2.2. The Radon-Nikodym derivatives [5] satisfy, for some non-negative scalars h^i_{ji}

$$g^i_{ji}(\xi) = \mathbf{P}^j_{y_i}(d\xi)/\mathbf{P}^i_{y_i}(d\xi) \leqq h^i_{ji} < \infty$$

uniformly in ξ almost everywhere $\mathbf{P}^i_{y_i}$, for $j \neq i$, $i, j \in \mathbb{N}$.

To establish existence and uniqueness results, we also introduce the Hilbert spaces $\mathbf{X}_1, \cdots, \mathbf{X}_n$ and $\mathbf{\Gamma}_1, \cdots, \mathbf{\Gamma}_n$ as follows. First, we let $\mathbf{X}_i$ denote the completion of the space of continuous functions from $[0, t_f] \times \Omega$ into X, under the inner product

$$\langle x^1, x^2 \rangle_{\mathbf{x}_i} = E^i \left\{ \int_0^{t_f} x_t^{1^T} x_t^2 \, dt + x_{t_f}^{1^T} x_{t_f}^2 \right\}, \qquad i \in \mathbb{N}.$$

$\mathbf{\Gamma}_i$, on the other hand, is the policy space for DMi, defined as earlier but now also endowed with the inner product

$$\langle \gamma, \beta \rangle_{\mathbf{\Gamma}i} = E^i \left\{ \int_0^{t_f} \gamma^T(t, y_i) \beta(t, y_i) \, dt \right\}, \qquad i \in \mathbb{N}.$$

Finally we let $\mathbf{\Gamma} := \mathbf{\Gamma}_1 \times, \cdots, \times \mathbf{\Gamma}_n$ and $\gamma_{-i} := (\gamma_1, \cdots, \gamma_{i-1}, \gamma_{i+1}, \cdots, \gamma_n)$. We are now in a position to introduce in precise terms (in Definition 2.1 below) the equilibrium solution adopted in this paper, and also (in Definition 2.2) a refined version to be studied in § 3.

DEFINITION 2.1. An n-tuplet of policies $(\gamma_1^N, \cdots, \gamma_n^N) := \gamma^N \in \mathbf{\Gamma}$ is in Nash equilibrium if

$$J_i(\gamma^N) \leqq J_i(\gamma_i, \gamma^N_{-i}) \quad \forall \gamma_i \in \mathbf{\Gamma}_i, \quad i \in \mathbb{N}.$$

DEFINITION 2.2. A Nash equilibrium solution $\gamma^N \in \mathbf{\Gamma}$ is *stable* (with respect to a parallel update of the players' strategies) if for all $\gamma^{(0)} \in \Gamma$,

$$\gamma_i^N = \lim_{k \to \infty} \gamma_i^{(k)}, \qquad i \in \mathbb{N},$$

where

$$\gamma_i^{(k+1)} = \arg\min_{\gamma_i \in \Gamma_i} J_i(\gamma_i, \gamma_{-i}^{(k)}), \qquad i \in \mathbb{N}, \quad k = 0, 1, 2, \cdots.$$

Remark 2.1. It is important to note that the above is one possible definition of a stable Nash equilibrium, which is the one we are going to adopt in this paper. Here, the players update on their strategies in parallel, with each player using the most recently computed (and announced) strategies of the other players as fixed and given. There could be other definitions of stability, where the players update their strategies following a particular sequential order (see, for example, [6]). However, the different sequences generated by these different schemes will all have the same limit (provided that they converge), even though each may require a different condition of convergence, some being more restrictive than others. The parallel scheme adopted in this paper

seems to be well suited for an analysis in the framework of repeated games, and also it enables us to obtain rather strong results on the existence of a unique Nash equilibrium. It is needless to say that, since the definition of a stable Nash equilibrium requires convergence for all starting strategies $\gamma_i^{(0)}$, $i \in \Gamma$, a stable Nash equilibrium is necessarily *unique*.

Remark 2.2. The formulation above models a decision scenario where the players have different (and necessarily inconsistent) perceptions of the statistics of the underlying stochastic phenomena, and stay with this perception until the end of the decision process. However, to completely characterize (and compute) the Nash equilibrium solution, all this statistical information and the cost structure of each player have to be common information to all. In view of this, what the algorithm presented in Definition 2.2 accomplishes is to free the players from the task of acquiring all this information, at the expense of repeating the game a number of times and by transmitting (only) policy information from one stage to another. At each stage, DMi uses the same measurement y_i he acquired at stage zero, and in this sense there is no learning with respect to the random variables involved, nor is there any learning with respect to the measurements made by the other players (i.e., there is no learning in action space); however, if this had been the case, then the convergent solution of the sequence of repeated games would have no relationship with the solution of the original stochastic differential game. In our formulation, learning takes place only in the policy space, ensuring the players to arrive at the (Nash) equilibrium (in the limit), with this end result depending explicitly on the different probabilistic perceptions and the cost functions of *all* players (even though this information is never shared by them).

We will now first focus on the derivation of necessary and sufficient conditions for Nash equilibria, without giving consideration to stability. This is done below in Theorem 2.1. Subsequently, in § 3, we turn to the stability analysis of the solution, using the iterative scheme of Definition 2.2.

THEOREM 2.1. *For the continuous-time decision problem formulated above, there exists a Nash equilibrium solution if and only if there exist* $2n$ *processes* $\hat{x}_{it}$, λ_{it}, $i \in \mathbb{N}$, *satisfying the following set of coupled differential equations with mixed boundary conditions*:

$$\begin{pmatrix} \dot{\hat{x}}_{it} \\ \dot{\lambda}_{it} \end{pmatrix} = \begin{pmatrix} A & -B_i R_{ii}^{-1} B_i^T \\ -Q_i & -A^T \end{pmatrix} \begin{pmatrix} \hat{x}_{it} \\ \lambda_{it} \end{pmatrix} + \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} \begin{pmatrix} B_j \\ 0 \end{pmatrix} \hat{u}_{jit}, \tag{2}$$

$$\hat{x}_{i0} = E^i(x_0 | y_i), \qquad \lambda_{it_f} = Q_{if} \hat{x}_{it_f},$$

where

$$\hat{u}_{jit} := E^i\{\gamma_j^N(t, y_j) | y_i\}, \qquad j \neq i, \quad i, j \in \mathbb{N}.$$

If (2) *admits a solution subject to the given boundary conditions, then the set of policies*

$$\gamma_i^N(t, y_i) = -R_{ii}^{-1} B_i^T \lambda_{it}(y_i) \quad a.e.\ \mathbf{P}^i, \quad i \in \mathbb{N} \tag{3}$$

constitutes a Nash equilibrium solution.

Proof. We prove the theorem by using a variational approach. For fixed i, and fixed $\gamma, \beta \in \mathbf{\Gamma}$, perturb $\gamma_i \to \gamma_i + \varepsilon\beta_i$ where ε is a nonzero scalar; then, correspondingly, $x_t \to x_t + \varepsilon\eta_{it}$, $\eta_i \in \mathbf{X}_i$. Using this in (1), we obtain

$$\dot{\eta}_{it} = A\eta_{it} + B_i\beta_i(t, y_i), \quad \eta_{i0} = 0, \quad i \in \mathbb{N}. \tag{4}$$

Now,

$$\begin{aligned}\Delta J_i &= J_i(\gamma_i + \varepsilon\beta_i, \gamma_{-i}) - J_i(\gamma_i, \gamma_{-i}) \\ &= E^i\left\{ x_{t_f}^T Q_{if}\eta_{it_f} + \int_0^{t_f} (x_t^T Q_i\eta_{it} + u_{it}^T R_{ii}\beta_i(t, y_i))\, dt \right\}\varepsilon \\ &\quad + \frac{1}{2} E^i\left\{ \eta_{it_f}^T Q_{if}\eta_{it_f} + \int_0^{t_f} (\eta_{it}^T Q_i\eta_{it} + \beta_i^T(t, y_i) R_{ii}\beta_i(t, y_i))\, dt \right\}\varepsilon^2.\end{aligned}$$

Since $Q_{if} \geqq 0$, $Q_i(\cdot) \geqq 0$, $R_{ii}(\cdot) > 0$, the second term above is positive for all $\beta_i \in \mathbf{\Gamma}_i$, $\beta_i \neq 0$, and hence a necessary and sufficient condition for (γ_i, γ_{-i}) to constitute a Nash equilibrium solution is that

$$(5)\quad \forall \beta_i \in \mathbf{\Gamma}_i, \quad \delta J_i = E^i\left\{ E^i(x_{t_f}^T | y_i) Q_{if}\eta_{it_f} + \int_0^{t_f} [E^i(x_t^T | y_i) Q_i\eta_{it} + u_{it}^T R_{ii}\beta_i(t, y_i)]\, dt \right\} = 0, \quad i \in \mathbb{N}.$$

Now, by (4),

$$(6)\qquad \eta_{it} = \int_0^t \Phi(t, \tau) B_i\beta_i(\tau, y_i)\, d\tau =: T_{Ai}\beta_i, \qquad i \in \mathbb{N},$$

where $T_{Ai} : \mathbf{\Gamma}_i \to \tilde{\mathbf{X}}_i \subset \mathbf{X}_i$; $\tilde{\mathbf{X}}_i = \{x \in \mathbf{X}_i, x \text{ is a } y_i\text{-measurable (under } \mathbf{P}^i\text{) stochastic process}\}$, and $\dot{\Phi}(t, s) = A(t)\Phi(t, s)$, $\Phi(s, s) = I$, i.e., Φ is the state transition matrix associated with A. It is not hard to see that the adjoint of T_{Ai} is

$$(7)\qquad (T_{Ai}^* x)_t = B_i^T(t) \int_t^{t_f} \Phi^T(\tau, t) x_\tau\, d\tau + B_i^T(t)\Phi^T(t_f, t) x_{t_f}.$$

First substituting (6) into (5), and then using (7) in the resulting expression under the inner product defined earlier on $\mathbf{X}_i$, we obtain for all $\beta_i \in \mathbf{\Gamma}_i$ (cf. [7]):

$$E^i\left\{ \left\langle B_i^T(t) \int_t^{t_f} \Phi^T(\tau, t) Q_i(\tau) E^i(x_\tau | y_i)\, d\tau + B_i^T(t)\Phi^T(t_f, t) Q_{if} E^i(x_{t_f} | y_i) + R_{ii}u_{it}, \beta_i \right\rangle_{\mathbf{\Gamma}_i} \right\} = 0$$

which holds if and only if

$$u_{it} = -R_{ii}^{-1} B_i^T \lambda_{it}, \quad \text{a.e. } \mathbf{P}^i$$

where

$$\lambda_{it} := \int_t^{t_f} \Phi^T(\tau, t) Q_i(\tau) E^i(x_\tau | y_i)\, d\tau + \Phi^T(t_f, t) Q_{if} E(x_{t_f} | y_i).$$

The latter can equivalently be written as

$$\dot{\lambda}_{it} = -Q_i\hat{x}_{it} - A^T\lambda_{it}, \qquad \lambda_{it_f} = Q_{if}\hat{x}_{it_f},$$

where $\hat{x}_{it}$ is the conditional mean of x_t under the measure $\mathbf{P}_i$, given y_i and the set of fixed policies $\gamma \in \mathbf{\Gamma}$:

$$\hat{x}_{it} := E^i(x_t | y_i).$$

For each $i \in \mathbb{N}$ it satisfies the differential equation:

$$\dot{\hat{x}}_{it} = A\hat{x}_{it} - B_i R_{ii}^{-1} B_i^T \lambda_{it} + \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} B_j \hat{u}_{jit}, \qquad \hat{x}_{i0} = E^i[x_0 | y_i],$$

with

$$\hat{u}_{jit} := E^i\{\gamma_j(t, y_j)\,|\,y_i\}, \qquad j \neq i, \quad i, j \in \mathbb{N}.$$

This completes the proof of the theorem. □

We observe that the condition given in the theorem is reminiscent of the one available for deterministic linear-quadratic differential games (cf. [6]), but here we have n different state equations, because of different perceptions of the players, and likewise n different co-state equations (see Remark 3.4 in the next section for further elaboration on this point).

3. A distributed algorithm and existence of a stable equilibrium. We now study further the condition of Theorem 2.1 and in particular the stability of the equilibrium solution, as in Definition 2.2. Recall that the iterative (distributed) computation of the Nash solution involves the sequences $\{\gamma_i^{(k)};\ k = 0, 1, \cdots\}$, $i \in \mathbb{N}$, generated by

$$\gamma_i^{(k+1)} = \arg\min_{\gamma_i \in \Gamma_i} J_i(\gamma_i, \gamma_{-1}^{(k)}), \qquad k = 0, 1, \cdots, \quad i \in \mathbb{N} \tag{8}$$

for fixed (but arbitrarily chosen) $\gamma^{(0)} \in \mathbf{\Gamma}$. Now, utilizing the main idea of the proof of Theorem 2.1, we can rewrite algorithm (8) equivalently as follows:

$$\gamma_i^{(k+1)}(t, y_i) = -R_{ii}^{-1} B_i^T \lambda_{it}^{(k)}(y_i), \qquad i \in \mathbb{N}, \tag{9}$$

$$\begin{pmatrix} \dot{\hat{x}}_{it}^{(k)} \\ \dot{\lambda}_{it}^{(k)} \end{pmatrix} = \begin{pmatrix} A & -B_i R_{ii}^{-1} B_i^T \\ -Q_i & -A^T \end{pmatrix} \begin{pmatrix} \hat{x}_{it}^{(k)} \\ \lambda_{it}^{(k)} \end{pmatrix} + \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} \begin{pmatrix} B_j \\ 0 \end{pmatrix} \hat{u}_{jit}^{(k)},$$

$$\begin{pmatrix} \hat{x}_{i0}^{(k)} \\ \lambda_{it_f}^{(k)} \end{pmatrix} = \begin{pmatrix} E^i(x_0\,|\,y_i) \\ Q_{if} \hat{x}_{it_f}^{(k)} \end{pmatrix}, \qquad i \in \mathbb{N} \tag{10}$$

where $\hat{u}_{jit}^{(k)} = E^i\{\gamma_j^{(k)}(t, y_j)\,|\,y_i\}$. Hence, to implement the learning scheme, at each stage $k+1$, DMi chooses $\gamma_i^{(k+1)}$ as the optimal response to $\gamma_j^{(k)}$, $j \in \mathbb{N}$, $j \neq i$, by (9) and (10). Our goal is to obtain conditions under which the sequences $\{\gamma_i^{(k)}\}$, $i \in \mathbb{N}$ converge, with the limit necessarily being the n-tuplet $(\gamma_i^N,\ i \in \mathbb{N})$, which constitutes the unique Nash solution to the original game. Note that if such conditions can be found, then the players can achieve the *stable* Nash solution through the given learning process (cf. Remark 2.2), even though DMi does not know $\mathbf{R}_{jj}$, Q_j, and $\mathbf{P}^j$, $j \neq i$, $i, j \in \mathbb{N}$.

First, by the transition matrix method, we can solve (2) and obtain the solution to be the following lemma.

LEMMA 3.1. *The solution to* (2) *is given by*

$$\begin{aligned} \hat{x}_{it} &= X_i(t) X_i^{-1}(0) \hat{x}_{i0} + \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} \int_0^t F_i(t, \tau) B_j(\tau) \hat{u}_{ji\tau}\, d\tau, \\ \lambda_{it} &= \Lambda_i(t) X_i^{-1}(0) \hat{x}_{i0} + \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} \int_t^{t_f} G_i(t, \tau) B_j(\tau) \hat{u}_{ji\tau}\, d\tau \end{aligned} \tag{11}$$

where

$$\begin{bmatrix} X_i(t) \\ \Lambda_i(t) \end{bmatrix} = \begin{bmatrix} \hat{x}_{it}^{(1)} \cdots \hat{x}_{it}^{(m)} \\ \lambda_{it}^{(1)} \cdots \lambda_{it}^{(m)} \end{bmatrix};$$

and for each s, $(\hat{x}_{it}^{(s)}, \lambda_{it}^{(s)})$ *is a solution of* (2) *with zero input* (*i.e.*, $\hat{u}_{jit} \equiv 0$), *and with the initial condition*

$$\hat{x}_{i0}^{(s)} = [0, \cdots, 0, 1, 0, \cdots]^T$$

where the s*th component is one*; *and* $\lambda_{if}^{(s)} = Q_{if} x_{if}^{(s)}$.

Furthermore, $F_i(t,\tau)$, $G_i(t,\tau)$ satisfy the following equations:

(i)
$$\frac{dF_i(t,\tau)}{dt} = A(t)F_i(t,\tau) - B_i(t)R_{ii}^{-1}(t)B_i^T(t)G_i(t,\tau), \qquad F_i(t,t) = I,$$
$$\frac{dG_i(t,\tau)}{dt} = -Q_i(t)F_i(t,\tau) - A^T(t)G_i(t,\tau), \qquad G_i(t,t) = 0;$$

(ii)
$$\begin{cases} F_i(t,\tau) = 0 & \text{for } t < \tau \leqq t_f, \\ G_i(t,\tau) = 0 & \text{for } 0 \leqq \tau \leqq t. \end{cases}$$

Note that in (11), $\hat{x}_{it}$ *denotes the conditional mean of the state vector* x_t, *as perceived by* DM*i*.

Proof. See the Appendix for the proof of Lemma 3.1. □

Next, we substitute (11) into (9) to obtain, for each $i \in \mathbb{N}$,

$$\gamma_i^{(k+1)}(t, y_i) = \xi_i(t, y_i) + (\Psi_i \gamma^{(k)})_t \tag{12}$$

where

$$\xi_i(t, y_i) = -R_{ii}^{-1}(t)B_i^T(t)\Lambda_i(t)X_i^{-1}(0)\hat{x}_{i0}, \qquad \hat{x}_{i0} = E^i(x_0 | y_i), \tag{13a}$$

and $\Psi_i : \mathbf{\Gamma} \to \mathbf{\Gamma}_i$ is the linear operator

$$(\Psi_i \gamma)_t = \int_t^{t_f} K_i(t,\tau)\hat{u}^i(\tau)\, d\tau \tag{13b}$$

with

$$K_i(t,\tau) := -R_{ii}^{-1}(t)B_i^T(t)G_i(t,\tau), \tag{14a}$$

$$\hat{u}^i(\tau) := \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} B_j(\tau)E^i[\gamma_j(\tau, y_j) | y_i]. \tag{14b}$$

Let $\Psi : \Gamma \to \Gamma$ be defined by

$$\Psi = [\Psi_1^T, \cdots, \Psi_n^T]^T.$$

Then, the convergence of the distributed algorithm (8) (or, equivalently, of the sequence generated by (12)) is equivalent to existence of a limit, in the Hilbert space $\mathbf{\Gamma}$, to the sequence $\{\gamma^{(k)}\}$ generated by

$$\gamma^{(k+1)} = \Psi\gamma^{(k)}, \qquad k = 0, 1, \cdots, \tag{15}$$

for arbitrary $\gamma^{(0)} \in \mathbf{\Gamma}$. Such a limit is guaranteed to exist if, for some $\alpha \in [0, 1)$,

$$\|\Psi_\gamma\|_{\mathbf{\Gamma}}^2 = \sum_{i \in \mathbb{N}} \|\Psi_i\gamma\|_{\mathbf{\Gamma}_i}^2 \leqq \alpha^2 \|\gamma\|_{\mathbf{\Gamma}}^2 \equiv \alpha^2 \sum_{i \in \mathbb{N}} \|\gamma_i\|_{\mathbf{\Gamma}_i}^2, \tag{16}$$

this result being a direct consequence of the contraction mapping theorem in complete metric spaces (cf. [7]). Our main result below makes this condition precise.

THEOREM 3.1. *Let functions* $a_i(s)$ *and* $\lambda^i{}_B(s)$, $i \in \mathbb{N}$, *be defined on* $[0, t_f]$ *as follows*:

$$a_i^2(t) := \int_t^{t_f} \operatorname{tr}[K_i(t,s)K_i^T(t,s)]\, ds, \qquad t \in [0, t_f], \tag{17a}$$

$$\lambda^i{}_B(s) := \lambda_{\max}[b^{iT}(s)b^i(s)] \tag{17b}$$

where

$$b^i(s) := [B_1(s), \cdots, B_{i-1}(s), 0, B_{i+1}(s), \cdots, B_n(s)], \tag{17c}$$

$\lambda_{\max}[\cdot]$ *denotes the largest eigenvalue of the matrix* $[\cdot]$, *and* $K_i(t, s)$ *is as defined by* (14a). *Let there exist a scalar* α, *such that*

$$\alpha^2 := \max_{\substack{i,s \\ i\in N \\ s\in[0,t_f]}} \sum_{\substack{j\in\mathbb{N} \\ j\neq i}} h_{ji}^i \lambda_B^i(s) \int_0^s a_j^2(t)\, dt < 1, \tag{18}$$

where h_{ji}^i *are as introduced in Assumption* 2.2.

Then,

(i) *There exists a unique Nash equilibrium solution*;

(ii) *The solution is stable, i.e., the distributed algorithm* (8) (*equivalently* (12)) *converges to the Nash equilibrium regardless of the choice of initial strategies.*

Proof. Since Ψ_i in (12) is a linear operator, it will be sufficient to show that under the hypotheses of the theorem, Ψ is a contraction mapping [7]. Toward this end, first consider the quantity

$$(*) \qquad \|\Psi_i\gamma\|_{\Gamma_i}^2 = \int_0^{t_f} dt\, E^i\left\{\left\|\int_t^{t_f} K_i(t,\tau)\hat{u}^i(\tau)\, d\tau\right\|^2\right\}$$

where as before, $\|\cdot\|$ (without a subscript) denotes the Euclidean norm. To show that this quantity is bounded above by

$$(**) \qquad \int_0^{t_f} dt\, a_i^2(t) \int_t^{t_f} E^i\{\|\hat{u}^i(\tau)\|^2\}\, d\tau.$$

we introduce the partitioned representation

$$K_i(t, s) = [k_{i1}^T(t, s), \cdots, k_{ip_i}^T(t, s)]^T$$

and note that the integrand of (*) can be written as follows:

$$E^i\left(\sum_{j=1}^{p_i}\left[\int_t^{t_f} d\tau\, k_{ij}(t,\tau)\hat{u}^i(\tau)\right]^2\right\} \leqq E^i\left\{\sum_{j=1}^{p_i}\left(\int_t^{t_f} d\tau\|k_{ij}(t,\tau)\|^2\right)\int_t^{t_f} d\tau\|\hat{u}^i(\tau)\|^2\right\}$$

$$= \int_t^{t_f}\sum_{j=1}^{p_i}\|k_{ij}(t,s)\|^2\, ds \cdot \int_t^{t_f} E^i\{\|\hat{u}^i(\tau)\|^2\}\, d\tau,$$

which is equivalent to the integrand of (**) since the first (product) term above is $a_i^2(t)$ by (17a). We should note that in arriving at the inequality above we have used the Cauchy–Schwarz inequality (cf. [7]) (twice) in two different inner product spaces. Next, let us concentrate on the inner integrand of (**):

$$E^i\{\|\hat{u}^i(s)\|^2\} = E^i\left\{\left\|\sum_{\substack{j\in\mathbb{N} \\ j\neq i}} B_j(s)E^i[\gamma_j(s, y_j)\,|\,y_i]\right\|^2\right\}$$

(majorizing by the largest eigenvalue of the weighting matrix)

$$\leqq \lambda_B^i(s)E^i\left\{\sum_{\substack{j\in\mathbb{N} \\ j\neq i}}\|E^i[\gamma_j(s, y_j)\,|\,y_i]\|^2\right\}$$

(nonexpansive property of conditional expectation (cf. [5])

$$\leqq \lambda_B^i(s)E^i\left\{\sum_{\substack{j\in\mathbb{N} \\ j\neq i}}\|\gamma_j(s, y_j)\|^2\right\}$$

(change of measure)

$$= \lambda^i_B(s) \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} E^j\{g^j_{ij}(y_j)\|\gamma_j(s,y_j)\|^2\} \leqq \lambda^i_B \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^j_{ij} E^j\{\|\gamma_j(s,y_j)\|^2\}.$$

Using this bound in (**) we can thus bound (*) by

$$\|\Psi_i\gamma\|^2_{\Gamma_i} \leqq \int_0^{t_f} dt\, a_i^2(t) \int_t^{t_f} ds\, \lambda^i_B(s) \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^i_{ij} E^j\{\|\gamma_j(s,y_j)\|^2\}$$

$$= \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^j_{ij} \int_0^{t_f} ds\, \lambda^i_B(s) E^j\{\|\gamma_j(s,y_j)\|^2\} \int_0^s a_i^2(t)\, dt.$$

Now, finally,

$$\|\Psi\gamma\|^2_{\Gamma} = \sum_{i=1}^n \|\Psi_i\gamma\|^2_{\Gamma_i} \leqq \sum_{i=1}^n \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^j_{ij} \int_0^{t_f} ds\, \lambda^i_B(s) E^j\{\|\gamma_j(s,y_j)\|^2\} \int_0^s a_i^2(t)\, dt$$

$$= \int_0^{t_f} \sum_{i=1}^n E^i\{\|\gamma_i(s,y_i)\|^2\}\, ds \cdot \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^i_{ji} \lambda^j_B(s) \int_0^s a_j^2(t)\, dt$$

$$\leqq \int_0^{t_f} \sum_{i=1}^n E^i\{\|\gamma_i(s,y_i)\|^2\}\, ds \cdot \alpha^2 = \alpha^2 \|\gamma\|^2_{\Gamma}$$

where, in arriving at the next to the last line, we have interchanged the order of the two summations, and in the last we have used (18). This, then, shows that Ψ is a contraction mapping, thus completing the proof of the theorem (using the Banach contraction mapping theorem (cf. [7]). □

Remark 3.1. A courser bound for (18) is

$$\alpha^2 \leqq t_f \max_{i,s} \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h^i_{ji} \lambda^j_B(s) \bar{a}_j^2$$

where $\bar{a}_j^2 := \max_s a_j^2(s)$. This shows that there always exists a t_f, sufficiently small, such that the learning process converges.

Remark 3.2. In general, it is difficult to solve the two-point boundary value problem (2) explicitly (other than to obtain the implicit representation provided in Lemma 3.1) because we cannot "close the loop" by substituting $\gamma_i(t, y_i) = -R_{ii}^{-1} B_i^T \lambda_{it}(y_i)$ into the differential equations. The presence of the conditional expectation term $E^i\{\lambda_{jt}|y_i\}$ (which is the stochastic product term of $\hat{u}_{jit}\}$ contributes to this difficulty. When the distributions are jointly Gaussian, however, certain simplifications are possible, and there emerges the possibility of obtaining the solution analytically, as we discuss next.

Now, let us consider the special class of problems in which the joint distributions of $x_0, y_1, \cdots, y_n$ are zero-mean Gaussian under all n measures. In this case there exist matrices Σ_{0i}, Σ_{ij}, of appropriate dimensions, such that[1]

$$\hat{x}_{i0} = E^i[x_0|y_i] = \Sigma_{0i} y_i, \qquad E^i[\hat{x}_{j0}|y_i] = \Sigma_{ji}\hat{x}_{i0}, \qquad i \neq j, \quad i,j \in \mathbb{N}.$$

[1] This would be true if, for example, $y_i = H_i x_0 + v_i$, $i \in N$, as given in § 2, where $x_0, v_1, \cdots, v_n$ are independent Gaussian random vectors under the measures $\mathbf{P}^1, \cdots, \mathbf{P}^n$.

We introduce matrix functions $M_i(m \times m)$ and $N_i(m \times m)$ on $[0, t_f]$, $i \in N$, satisfying the differential equations

$$(19a) \qquad [\dot{M}_i + M_i A + A^T M_i + Q_i - M_i B_i R_{ii}^{-1} B_i^T M_i] N_i - \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} M_i B_j R_{jj}^{-1} B_j^T M_j N_j \Sigma_{ji} = 0,$$

$$M_i(t_f) = Q_{i_f},$$

$$(19b) \qquad \dot{N}_i = A N_i - B_i R_{ii}^{-1} B_i^T M_i N_i - \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} B_j R_{jj}^{-1} B_j^T M_j N_j \Sigma_{ji}, \qquad N_i(0) = I.$$

Then the following result follows as a corollary to Theorem 3.1.

COROLLARY 3.1. *When the underlying distributions are zero-mean Gaussian under the n measures we have the following*:

(i) *There exists a unique stable Nash equilibrium solution, linear in the measurements, provided that* $\alpha^2 < 1$;

(ii) *The unique linear solution is given by*

$$(20) \qquad \gamma_i^N(t, y_i) = -R_{ii}^{-1}(t) B_i^T(t) M_i(t) \hat{x}_{it} \quad a.e.\ \mathbf{P}^i, \quad i \in \mathbb{N},$$

where

$$(21) \qquad \hat{x}_{it} = N_i(t) \Sigma_{0i} y_i, \qquad i \in \mathbb{N},$$

provided that (19) *admits a solution.*

Proof. Linearity of the solution alluded to in Theorem 3.1 follows readily from recursions (9)-(10) by taking $\gamma_i^{(0)}(y_i)$ to be any linear function of y_i, $i \in \mathbb{N}$, and seeing that, since the underlying distributions are jointly Gaussian under all n measures, $\hat{x}_{it}^{(k)}$ and $\lambda_{it}^{(k)}$ are linear in y_i for all $i \in \mathbb{N}$, $k = 0, 1, \cdots$. For a proof of part (ii) of the corollary, it is sufficient to note that if (19) admits a solution, then $\hat{x}_{it} = N_i(t) \Sigma_{0i} y_i$ and $\lambda_{it} = M_i(t) \hat{x}_{it}$, $i \in \mathbb{N}$, solve (2). □

Remark 3.3. Even though (19) is a complicated set of differential equations, it does offer the advantage of computing the unique Nash policies off-line, as opposed to the general result of Lemma 3.1 which requires on-line computation (for the non-Gaussian case).

Remark 3.4. For the special case when the players make identical measurements, $y_1 = \cdots = y_n \equiv y$, we have $\Sigma_{ji} = I$ (but still Σ_{0i} is dependent of the index i, since the subjective probabilities are different), under which (19a) and (19b) simplify, with $N_i(t) = N(t)$, to

$$(19a') \qquad \dot{M}_i + M_i A + A^T M_i + Q_i - M_i B_i R_{ii}^{-1} B_i^T M_i - M_i \sum_{\substack{j \in \mathbb{N} \\ j \neq i}} B_j R_{jj}^{-1} B_j^T M_j = 0,$$

$$M_i(t_f) = Q_{if},$$

$$(19b') \qquad \dot{N} = \left(A - \sum_{j \in \mathbb{N}} B_j R_{jj}^{-1} B_j^T M_j \right) N, \qquad N(0) = I,$$

where in arriving at (19a') from (19a) we have made use of the fact that the unique solution of (19b') for each fixed $\{M_j\}$ is a full-rank matrix function (in fact a state transition matrix). The above are precisely the matrix differential equations arising in the open-loop Nash solution of deterministic differential games (see, e.g., [6, Thm. A-2]); (19a') is the open-loop (coupled) matrix Riccati differential equation, and (19b') is the linear differential equation satisfied by the state transition matrix N.

4. Infinite horizon games. In this section we obtain counterparts of the results in § 3 for similarly structured infinite horizon stochastic differential games with discounted costs. We can cite at least two main reasons for studying such a problem. First, for differential games with long (but not infinite) horizon (be they repeated or not), the results presented here could provide a good approximation for the true Nash solution. Second, for genuine infinite-horizon stochastic differential games with different subjective probabilities for the players, the distributed learning algorithm presented here could provide an effective means of computing the Nash strategies.

With this prelude, we now go into a precise formulation of the problem. The system is still characterized by the stochastic differential equation (1), with the apparent modification that every quantity is defined on the interval $[0, \infty)$. The cost functions are

$$J_i(\gamma) = E^i\left\{\int_0^\infty e^{-\beta_i t}\left(\frac{1}{2}x_t^T Q_i(t)x_t + \frac{1}{2}\sum_{j\in\mathbb{N}} u_{jt}^T R_{ij}(t)u_{jt}\right)dt \,\middle|\, u_{lt} = \gamma_l(t, y_l),\ l\in\mathbb{N}\right\},$$

$$i\in\mathbb{N},$$

where $\beta_i > 0$, $i\in\mathbb{N}$ are the discount factors. A permissible policy for *DMi* is a Borel-measurable mapping $\gamma_i : [0, \infty)\times\mathbb{R}^{m_i}\to\mathbb{R}^{P_i}$ such that

$$E^i\left\{\int_0^\infty e^{-\beta_i t}\|\gamma_i(t, y_i)\|^2\,dt\right\} < \infty.$$

The policy space $\mathbf{\Gamma}_i$ for *DMi* is now the Hilbert space of all permissible policies, under the inner product

$$\langle\gamma, \beta\rangle_{\mathbf{\Gamma}_i} := E^i\left\{\int_0^\infty e^{-\beta_i t}\gamma^T(t, y_i)\beta(t, y_i)\,dt\right\}, \qquad i\in\mathbb{N}.$$

Similarly, we define the Hilbert spaces $\mathbf{X}_i$, $i\in\mathbb{N}$, as the completion of the space of continuous functions from $[0, \infty)\times\Omega$ into $\mathbf{X}$, under the inner products

$$\langle x^1, x^2\rangle_{x_i} := E^i\left\{\int_0^\infty e^{-\beta_i t}[x_t^{1T}x_t^2]\,dt\right\}.$$

Clearly, in order that the state trajectory $\{x_t\}$ be in $\mathbf{X}_i$, we need the following assumption:

Assumption 4.1. The system parameters $A, B_1, \cdots, B_n, C$, and the discount factors β_i are such that for all $\gamma_i\in\mathbf{\Gamma}_i$, the resulting trajectory $\{x_t\}$ (that is, the solution of (1)) satisfies the boundedness condition

$$E^i\left\{\int_0^\infty e^{-\beta_i t}x_t^T x_t\,dt\right\} < \infty \quad \text{for } i\in\mathbb{N}.$$

Now we state the following two results, which are the counterparts of Theorem 2.1 and Lemma 3.1, respectively.

THEOREM 4.1. *Suppose that Assumption* 4.1 *is satisfied, and that*

$$\lim_{t\to+\infty}\int_t^\infty e^{-\beta_i(\tau-t)}\Phi^T(\tau, t)Q_i(\tau)E^i(x_{i\tau}\,|\,y_i)\,dt = 0, \qquad i\in\mathbb{N}, \tag{2.3}$$

where $\Phi(\tau, t)$ is the state transition matrix function associated with A.

Then, the infinite-horizon stochastic differential game admits a Nash equilibrium solution if, and only if, there exist $2n$ processes $\hat{x}_{it}$, λ_{it}, $i\in\mathbb{N}$, satisfying the following set

of coupled differential equations with mixed boundary conditions:

$$\begin{bmatrix}\dot{\hat{x}}_{it}\\ \dot{\lambda}_{it}\end{bmatrix}=\begin{bmatrix}A & -B_iR_{ii}^{-1}B_i^T\\ -Q_i & \beta_iI-A^T\end{bmatrix}\begin{bmatrix}\hat{x}_{it}\\ \lambda_{it}\end{bmatrix}+\sum_{\substack{j\in\mathbb{N}\\ j\neq i}}\begin{bmatrix}B_j\\ 0\end{bmatrix}\hat{u}_{jit},$$

$$\hat{x}_{i0}=E^i(x_0|y_i),\quad \lim_{t\to\infty}\lambda_{it}=0,\quad i\in\mathbb{N}, \tag{24}$$

where

$$\hat{u}_{jit}:=E^i\{\gamma_j^N(t,y_j)|y_i\},\qquad j\neq i,\quad i,j\in\mathbb{N}.$$

If (24) *admits a solution subject to the given boundary conditions, then the set of policies*

$$\gamma_i^N(t,y_i)=R_{ii}^{-1}(t)B_i^T(t)\lambda_{it}(y_i)\quad a.e.\ \mathbf{P}^i,\quad i\in\mathbb{N},$$

constitutes a Nash equilibrium solution.

LEMMA 4.1. *The solution to* (24) *is given by*

$$\hat{x}_{it}=\hat{x}_{it}^{(h)}+\sum_{\substack{j\in\mathbb{N}\\ j\neq i}}\int_0^t\bar{F}_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau, \tag{25a}$$

$$\lambda_{it}=\lambda_{it}^{(h)}+\sum_{\substack{j\in\mathbb{N}\\ j\neq i}}^{\infty}\int_t^{\infty}\bar{G}_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau \tag{25b}$$

where $(\hat{x}_{it}^{(h)},\lambda_{it}^{(h)})$ *is a solution to the homogeneous part (assuming* $\hat{u}_{jit}\equiv 0$*), and* $\bar{F}_i(t,\tau)$, $\bar{G}_i(t,\tau)$ *satisfy the following*:

(i)
$$\frac{d\bar{F}_i(t,\tau)}{dt}=A(t)\bar{F}_i(t,\tau)-B_i(t)R_{ii}^{-1}(t)B_i(t)\bar{G}_i(t,\tau),\qquad \bar{F}_i(t,t)=I,$$
$$\frac{d\bar{G}_i(t,\tau)}{dt}=-Q_i(t)\bar{F}_i(t,\tau)+(\beta_iI-A^T(t))\bar{G}_i(t,\tau),\qquad \bar{G}_i(t,t)=0;$$

(ii)
$$\bar{F}_i(t,\tau)=0\quad \textit{for } t<\tau<\infty,$$
$$\bar{G}_i(t,\tau)=0\quad \textit{for } 0<\tau\leqq t.$$

Now, the distributed algorithm replacing (12) in this case is

$$\gamma_i^{(k+1)}(t,y_i)=\bar{\xi}_i(t,y_i)+(\bar{\Psi}_i\gamma^{(k)})_t\qquad i\in\mathbb{N}, \tag{26}$$

where all terms are as defined before (without overbar), with the obvious change that $t_f\to\infty$. We therefore seek conditions for existence of a limit to the sequence $\{\gamma^{(k)}\}$ generated by the counterpart of (15):

$$\gamma^{(k+1)}=\bar{\Psi}\gamma^{(k)},\qquad k=0,1,\cdots$$

for arbitrary $\gamma^{(0)}\in\mathbf{\Gamma}$. Toward establishing the validity of (16) for some $\alpha^2<1$, we first proceed as in the proof of Theorem 3.1 and obtain the following sequence of equalities and inequalities:

$$\begin{aligned}\|\bar{\Psi}_i\gamma\|_{\mathbf{\Gamma}_i}^2&=\int_0^{\infty}e^{-\beta_it}E^i\left\{\left\|\int_t^{\infty}\bar{K}_i(t,\tau)\hat{u}^i(\tau)\,d\tau\right\|^2\right\}\\
&=\int_0^{\infty}e^{-\beta_it}E^i\left\{\sum_{j=1}^{p_2}\left[\int_t^{\infty}d\tau\,\bar{k}_{ij}(t,\tau)\hat{u}^i(\tau)\right]^2\right\}\\
&\leqq\int_0^{\infty}e^{-\beta_it}E^i\left\{\sum_{j=1}^{p_2}\int_t^{\infty}d\tau\,e^{\beta_i\tau}\|\bar{k}_{ij}(t,\tau)\|^2\cdot\int_t^{\infty}e^{-\beta_is}\|\hat{u}^i(s)\|^2\,ds\right\}\qquad(*)\\
&=\int_0^{\infty}ds\,e^{-\beta_is}E^i\{\|\hat{u}^i(s)\|^2\}\int_0^s e^{-\beta_it}\,dt\int_t^{\infty}e^{\beta_i\tau}\,\mathrm{tr}\,[\bar{K}_i(t,\tau)\bar{K}_i^T(t,\tau)]\,d\tau\\
&=\int_0^{\infty}ds\,e^{-\beta_is}E^i\{\|\hat{u}^i(s)\|^2\}\int_0^s e^{-\beta_it}\bar{a}_i^2(t)\,dt\end{aligned}$$

where we have introduced the term

$$\bar{a}_i^2(t) := \int_t^\infty \operatorname{tr}\,[\bar{K}_i(t,\tau)\bar{K}_i^T(t,\tau)]\, e^{\beta_i \tau}\, d\tau, \qquad t \in [0,\infty). \tag{27}$$

Now, using in (*) the bound on $E^i\{\|\hat{u}^i(s)\|^2\}$ obtained in the proof of Theorem 3.1, we arrive at the result

$$\begin{aligned}\|\bar{\Psi}_i\gamma\|_{\Gamma_i}^2 &\leqq \int_0^\infty ds \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ij}^j \lambda_B^i(s)\, e^{-\beta_i s} E^j\{\|\gamma_j(s,y_j)\|^2\} \int_0^s \bar{a}_i^2(t)\, dt\, e^{-\beta_i t} \\ &= \int_0^\infty ds\, e^{-\beta_i s}\lambda_B^i(s) \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ij}^j\, e^{+\beta_j s}\, e^{-\beta_i s} E^i\{\|\gamma_j(s,y_j)\|^2\} \int_0^s e^{-\beta_i t}\bar{a}_i^2(t)\, dt.\end{aligned}$$

Hence,

$$\begin{aligned}\|\bar{\Psi}\gamma\|_{\Gamma}^2 &= \sum_{i=1}^n \|\bar{\Psi}_i\gamma\|_{\Gamma_i}^2 \\ &\leqq \int_0^\infty \sum_{i\in\mathbb{N}} e^{-\beta_i s} E^i\{\|\gamma_i(s,y_i)\|^2\}\, ds \cdot \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ji}^i \lambda_B^j(s)\, e^{-(\beta_j-\beta_i)s} \int_0^s e^{-\beta_j t}\bar{a}_j^2(t)\, dt \\ &\leqq \bar{\alpha}^2 \|\gamma\|_{\Gamma}\end{aligned}$$

where

$$\bar{\alpha}^2 := \max_{\substack{i,s\\ i\in\mathbb{N}\\ s\in[0,\infty)}} \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ji}^i \lambda_B^j(s)\, e^{-(\beta_j-\beta_i)s} \int_0^s e^{-\beta_j t}\bar{a}_j^2(t)\, dt. \tag{28}$$

Then, the following result readily follows from the classical contraction mapping theorem (cf. [7]).

THEOREM 4.2. *Let $\lambda_B^i(s)$ and $b^i(s)$ be as defined by* (17a)-(17c), *h_{ji}^i be as introduced in Assumption* 2.2, *and $\bar{a}_i^2(\cdot)$ and $\bar{\sigma}^2$ be as defined by* (27)-(28). *Furthermore, let*

$$\bar{\alpha}^2 < 1. \tag{29}$$

Then, for the infinite-horizon stochastic differential game, we have the following:

(i) *There exists a unique Nash equilibrium solution*;

(ii) *The solution is stable under the distributed algorithm* (26).

Remark 4.1. The main condition of the theorem above, i.e., (29), may be overly restrictive, especially if the discount factors in different cost functions are different (i.e., $\beta_i \neq \beta_j$, $i \neq j$). However, if $\beta_i = \beta_j \equiv \beta$, *then* $\bar{\alpha}^2$ can be written as follows:

$$\bar{\alpha}^2 = \max_{\substack{i,s\\ i\in\mathbb{N}\\ s\in[0,\infty)}} \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ji}^i \lambda_B^j(s) \int_0^s e^{-\beta t}\bar{a}_j^2(t)\, dt$$

and if, furthermore,

$$\bar{A}_i^2 := \max_t \bar{a}_i^2(t) < \infty, \qquad i \in \mathbb{N},$$

then condition (29) can be replaced by the courser bound:

$$\frac{1}{\beta}\max_{i,s}\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} h_{ji}^{i}\lambda^{j}{}_{B}(s)\bar{A}_j[1-e^{-\beta s}]<1,$$

which makes the dependence on β more explicit.

To parallel the development in § 3, let us now consider the special class of infinite horizon problems wherein the joint distributions of $x_0, y_1, \cdots, y_n$ are zero-mean Gaussian under all n measures. Let Σ_{0i}, Σ_{ij} be defined as in § 3, and introduce matrix functions $\bar{M}_i$ and $\bar{N}_i$ on $[0,\infty)$, $i\in\mathbb{N}$, satisfying

$$\left(\dot{\bar{M}}_i+\bar{M}_i\left(A-\frac{\beta_i}{2}I\right)+\left(A-\frac{\beta_i}{2}I\right)^{T}\bar{M}_i+Q_i-\bar{M}_iB_iR_{ii}^{-1}B_i^{T}\bar{M}_i\right]\bar{N}_i$$

$$-\sum_{\substack{j\in\mathbb{N}\\ j\neq i}}\bar{M}_iB_jR_{jj}^{-1}B_j^{T}\bar{M}_j\bar{N}_j\Sigma_{ji}=0, \tag{30a}$$

$$\lim_{t_f\to\infty}\bar{M}_i(t_f)=0,$$

$$\dot{\bar{N}}_i=A\bar{N}_i-B_iR_{ii}^{-1}B_i^{T}\bar{M}_i\bar{N}_i-\sum_{\substack{j\in\mathbb{N}\\ j\neq i}}B_jR_{jj}^{-1}B_j^{T}\bar{M}_j\bar{N}_j\Sigma_{ji},\qquad \bar{N}_i(0)=I. \tag{30b}$$

The same reasoning as in the proof of Corollary 3.1, now leads to the following result.

COROLLARY 4.1. *For the infinite horizon differential game problem, let the underlying distributions be zero-mean Gaussian under the n measures. Then, under the conditions of Theorem* 4.1, *we have the following*:

(i) *There exists a unique stable Nash equilibrium solution, under the distributed algorithm* (26), *linear in the measurements*;

(ii) *The unique linear solution is given by*

$$\gamma_i^{N}(t,y_i)=-R_{ii}^{-1}(t)B_i^{T}(t)\bar{M}_i(t)\hat{x}_{it}\quad a.e.\ \mathbf{P}^{i},\quad i\in\mathbb{N},$$

where

$$\hat{x}_{it}=\bar{N}_{it}\Sigma_{0i}y_i,\qquad i\in\mathbb{N},$$

provided that (30) *admits a solution.*

5. Conclusions. In this paper, we have presented results for a class of n-person stochastic linear-quadratic differential games under multiple probabilistic modeling, and with each player acquiring noisy measurement(s) of the initial state. We have seen that if the time interval on which the game is defined is sufficiently short, then the stochastic differential game admits a unique stable Nash equilibrium solution, and this solution can be obtained as the limit of a distributed learning algorithm that involves iteration in the policy space. For the special case when the underlying distributions are Gaussian, this limiting solution is affine in the measurements. If the time horizon is infinite and possibly different discount factors are included in the cost functionals, the same qualitative results hold, this time the conditions of existence and convergence depending also on the magnitude(s) of the discount factor(s).

The distributed algorithm adopted in this paper (see (12) or (26)) allows each player to update on his policy by taking the most recently computed policies of the other players as given. This "parallel scheme" is not the only possible updating scheme if $n\geqq 3$; the players may, for example, update on their policies sequentially either in a fixed order or in an order which changes from stage to stage in a predetermined

manner, or there may be a combination of sequential and parallel schemes, also allowing a delay in the transmission of policy information from one player to others (see [9] and [10] for elucidation of this point in the context of static games). Since the conditions for convergence under these different schemes are, in general, different even in static games [10], [12], it is quite natural to expect them to be different also for the class of stochastic differential games considered in this paper. In principle, the approach developed in this paper could be applied to these other "nonparallel" schemes; however, since the expressions involved are in general quite complicated even for $n=3$, not leading to clean results (see, e.g., [12] for the strictly sequential scheme for the static case and $n=3$), we have not discussed such schemes in this paper.

Another possible major extension would be the study of more general distributed algorithms incorporating memory, such as the relaxation algorithms introduced in [13] for static games. As evidenced from the analysis of [13], incorporation of past values of self-policies in the update mechanism by each player could result in considerable improvements in the conditions of convergence and the speed of convergence towards the unique Nash equilibrium. Developing precise conditions for such relaxation-type algorithms, and obtaining the "best" mix between the other players' past policies and self-policies in the update mechanism would be a promising avenue of research for the future. Yet another challenging extension would be to games with dynamic information patterns, where the players receive on-line (imperfect) information on the current value of the state; but such problems are much more difficult to analyze, even in the case when players have an identical perception of the underlying statistics, partly due to "informational nonuniqueness" (cf. [14]) and partly because a separation of estimation and control is not possible in stochastic games. For the special case of zero-sum games, however, such an extension would be manageable (at least in principle), by taking the results of [15] as the starting point; this is a topic that is currently under investigation.

Appendix.

Proof of Lemma 3.1. First, we note that the zero input solution to (2) is

$$\hat{x}_{it}^{(h)} = X_i(t)\hat{x}_{if} = X_i(t)X_i^{-1}(0)\hat{x}_{i0},$$

$$\lambda_{it}^{(h)} = \Lambda_i(t)\hat{x}_{if} = \Lambda_i(t)X_i^{-1}(0)\hat{x}_{i0}.$$

Now if we can find a particular solution $(\hat{x}_{it}^{(p)}, \lambda_{it}^{(p)})$ to (2), then

$$\hat{x}_{it} = \hat{x}_{it}^{(h)} + \hat{x}_{it}^{(p)}, \qquad \lambda_{it} = \lambda_{it}^{(h)} + \lambda_{it}^{(p)}.$$

To guarantee that $\hat{x}_{it}$ and λ_{it} satisfy the boundary conditions $\hat{x}_{it|_{t=0}} = \hat{x}_{i0}$ and $\lambda_{it|t=t_f} = Q_{if}\hat{x}_{if}$, respectively, let us choose

$$\hat{x}_{it}^{(p)} = \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_0^t F_i(t,\tau)B_j\hat{u}_{j\tau}\,d\tau,$$

$$\lambda_{it}^{(p)} = \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_t^{t_f} G_i(t,\tau)B_j(\tau)\hat{u}_{j\tau}\,d\tau.$$

substituting back into (7), we obtain n sets of equations:

$$
\begin{aligned}
&F_i(t,t)\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} B_j(t)\hat{u}_{jit} + \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_0^t \frac{dF_i(t,\tau)}{dt} B_j(\tau)\hat{u}_{ji\tau}\,d\tau \\
&\quad = A(t)\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_0^t F_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau - B_iR_{ii}^{-1}B_i^T \\
&\qquad \times \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_t^{t_f} G_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau + \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} B_j(t)\hat{u}_{jit}, \\
&\qquad -G_i(t,t)\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} B_j(t)\hat{u}_{jit} + \sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_t^{t_f} \frac{dG_i(t,\tau)}{dt} B_j(\tau)\hat{u}_{ji\tau}\,d\tau \\
&\quad = -Q_i\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_0^t F_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau - A^T(t)\sum_{\substack{j\in\mathbb{N}\\ j\neq i}} \int_t^{t_f} G_i(t,\tau)B_j(\tau)\hat{u}_{ji\tau}\,d\tau.
\end{aligned}
$$

We now observe that the above equations are satisfied if $G_i(t,\tau)$, $F_i(t,\tau)$ satisfy (i) and (ii) of Lemma 3.1, thereby completing the proof. □

SOME ESTIMATES FOR FINITE DIFFERENCE APPROXIMATIONS*

JOSE-LUIS MENALDI†

Abstract. Some estimates for the approximation of optimal stochastic control problems by discrete time problems are obtained. In particular an estimate for the solutions of the continuous time versus the discrete time Hamilton-Jacobi-Bellman equations is given. The technique used is more analytic than probabilistic.

Key words. diffusion process, Markov chain, dynamic programming, finite difference, Hamilton-Jacobi-Bellman equations

AMS(MOS) subject classifications. 65K10, 65G99, 49D25, 93E25, 93E20

Introduction. We are interested in the approximation of optimal control problems for diffusion processes by means of finite difference methods. It is well known (e.g., Kushner [16], [17]) that a basic probabilistic counterpart is the approximation of a diffusion process by a Markov chain. A typical problem in stochastic control theory is the following.

In a complete filtered probability space $(\Omega, P, \mathcal{F}, \mathcal{F}(t), t \geqq 0)$ suppose we have two progressively measurable processes $(y(t), \lambda(t), t \geqq 0)$ satisfying the following stochastic differential equation in the Itô sense:

$$\begin{aligned} &dy(t) = g(y(t), \lambda(t))\, dt + \sigma(y(t), \lambda(t))\, dw(t), \qquad t \geqq 0, \\ &y(0) = x, \end{aligned} \tag{0.1}$$

for given x, g, σ, and some n-dimensional Wiener process $(w(t), t \geqq 0)$. The processes $(y(t), t \geqq 0)$ and $(\lambda(t), t \geqq 0)$ represent the state in $\mathcal{R}^d$ and the control in Λ (a compact metric space) of the dynamic system, respectively.

The cost functional is given by

$$J(x, \lambda) = E\left\{\int_0^{\tau} f(y(t), \lambda(t))\, e^{-\alpha t}\, dt\right\}, \tag{0.2}$$

where f is a given function, $\alpha > 0$, and τ is the first exit time of a domain D in $\mathcal{R}^d$ for the process $(y(t), t \geqq 0)$.

The associated Hamilton-Jacobi-Bellman (HJB) equation (e.g., Bensoussan and Lions [2], Fleming and Rishel [9], Krylov [14]) to be satisfied by the optimal cost

$$u(x) = \inf\{J(x, \lambda): \text{any control } \lambda(\cdot)\} \tag{0.3}$$

is indeed

$$\begin{aligned} &\alpha u = \inf\{L(\lambda)u + f(\cdot, \lambda): \lambda \in \Lambda\} \quad \text{in } D, \\ &u = 0 \quad \text{on } \in \partial D, \end{aligned} \tag{0.4}$$

with the differential operator

$$L(\lambda) = \frac{1}{2} \sum_{i,j=1}^{d} \left(\sum_{k=1}^{n} \sigma_{ik}(\cdot, \lambda)\sigma_{jk}(\cdot, \lambda) \right) \partial_{ij} + \sum_{i=1}^{d} g_i(\cdot, \lambda)\, \partial_i, \tag{0.5}$$

where $\partial_{ij}, \partial_i$ denote the partial derivatives and $g = (g_i, i = 1, \cdots, d)$, $\sigma = (\sigma_{ik}, i = 1, \cdots, d, k = 1, \cdots, n)$.

† Department of Mathematics, Wayne State University, Detroit, Michigan 48202.

Let $\mathcal{R}_h^d$ denote a h-finite difference grid in $\mathcal{R}^d$. Consider the finite difference operator

$$L_h(\lambda)\varphi(x) = h^{-1} \sum_{k=1}^{n} \{\beta_k^+(x, \lambda, h)[\varphi(x + \gamma_k^+(x, \lambda, h)) - \varphi(x)] + \beta_k^-(x, \lambda, h)[\varphi(x + \gamma_k^-(x, \lambda, h)) - \varphi(x)]\}, \tag{0.6}$$

where the coefficients satisfy

$$\beta_k^{\pm}(x, \lambda, h) \geqq 0 \quad \forall x, \lambda, h,$$
$$x + \gamma_k^{\pm}(x, \lambda, h) \in \mathcal{R}_h^d \quad \forall x \in \mathcal{R}_h^d, \quad \lambda \in \Lambda. \tag{0.7}$$

The finite difference approximation of the HJB equation (0.4) using the operator (0.6) is

$$\alpha u_h = \inf\{L_h(\lambda)u_h + f(\cdot, \lambda) : \lambda \in \Lambda\} \quad \text{in } D_h,$$
$$u_h = 0 \quad \text{in } \mathcal{R}_h^d \setminus D_h, \tag{0.8}$$

where D_h is the set of points in $\mathcal{R}_h^d$ belonging to D.

Our purpose is to estimate the difference

$$\sup\{|u(x) - u_h(x)| : x \in D_h\} \tag{0.9}$$

in terms of the parameter h. We expect to dominate (0.9) by

$$\sup\{\inf\{|l(x, \lambda) - l(x', \lambda)| : x' \in \mathcal{R}_h^d\} : x \in \mathcal{R}^d, \lambda \in \Lambda\}, \quad \text{for } l = f, g_i, \sigma_{ik},\ i = 1, \cdots, d,\ k = 1, \cdots, n. \tag{0.10}$$

For instance, if f, g, σ are Lipschitz-continuous in x, then

$$|u(x) - u_h(x)| \leqq Ch^{1/2} \quad \forall x \in D_h, \quad h \in (0, 1], \tag{0.11}$$

for some constant C independent of x and h.

Let us mention that finite difference operators of the form (0.6) satisfy automatically the so-called discrete maximum principle. Problem (0.8) is indeed the discrete HJB equation associated with some suitable optimal control problem of a Markov chain. We remark that several computational methods are available for the discrete HJB equation (0.8) (e.g., Kushner and Kleinman [18], Puterman [29], Puterman and Brumelle [30], Quadrat [31], and Theosys [33]).

Actually, the objective of the paper is to show how the underlying technique can be used with a typical problem (0.1)–(0.5). The probabilistic interpretation of the finite difference operator (0.6) is part of the key idea. From a purely stochastic control viewpoint, an estimate on an approximation to the optimal cost is certainly of great value. However, we may question how optimal the discrete optimal feedback is when it is applied to the actual continuous time problem. Toward an answer to the preceding questions, we can argue in the following way. First of all, what really matters for the optimizers is to know how far they are from the minimum cost in the real model. The stochastic equation (0.1) is only an approximation of the real evolution, as well as being the Markov chain associated with the operator (0.6). Our claim is that by preserving the structure of the problem, i.e., to have a probabilistic interpretation of the approximating HJB equation (0.8), and by getting some estimates of the convergence of the corresponding optimal costs, we cannot be far away from the real model.

Even if the Markov chain associated with the operator (0.6) always has finite state, we may want to discretize the set Λ, just to improve the implementation of the

infimum in equation (0.8). In this case, we can replace Λ in (0.7) and (0.8) by a discretization $\Lambda(h)$, and similar results hold true (cf. [24]).

Deterministic versions along with the same kind of ideas can be found in Capuzzo-Dolcetta [4], Capuzzo-Dolcetta and Ishii [5], Crandall and Lions [6], Falcone [8], Gonzalez and Rofman [12], Menaldi and Rofman [27], and Souganidis [36].

The cases where the discount factor α is actually a function, the coefficients g, σ are time-dependent, the horizon is finite, the HJB equation is indeed a set of inequalities, and the domain D is unbounded can also be studied.

In § 1 we consider the one-dimensional case. Even if this case is very restrictive, we obtain enough information from it to deal with the multidimensional case. Moreover, this section can stand by itself, but we believe it is a natural step in the technique to be developed. General problems are treated in § 2.

1. One-dimensional case. It is clear that for one-dimensional problems we dispose of many classic tricks, probably more efficient in practice than the one we will describe. However, we claim that by studying this simple case we may obtain some nonstandard ways of looking at a multidimensional finite difference scheme.

Let g, σ be real continuous functions on $\mathcal{R} \times \Lambda$ such that

$$\begin{aligned} &|g(x,\lambda)|+|\sigma(x,\lambda)| \leqq C \quad \forall x \in \mathcal{R}, \quad \lambda \in \Lambda, \\ &|g(x,\lambda)-g(x',\lambda)|+|\sigma(x,\lambda)-\sigma(x',\lambda)| \leqq K|x-x'| \quad \forall x, x' \in \mathcal{R}, \quad \lambda \in \Lambda, \end{aligned} \tag{1.1}$$

for some constants $C = C(g, \sigma)$ and $K = K(g, \sigma)$. The set Λ is a compact metric space, generally a compact subset of $\mathcal{R}^m$.

On a complete Wiener space $(\Omega, P, \mathcal{F}, \mathcal{F}(t), w(t), t \geqq 0)$, i.e., $(\Omega, P, \mathcal{F})$ is a complete probability space, $(\mathcal{F}(t), t \geqq 0)$ is a right-continuous family of complete sub-σ-algebras of $\mathcal{F}$, $(w(t), t \geqq 0)$ is a one-dimensional standard Wiener process adapted to $(\mathcal{F}(t), t \geqq 0)$; we consider the controlled diffusion process

$$dy(t) = g(y(t), \lambda(t))\, dt + \sigma(y(t), \lambda(t))\, dw(t), \qquad t > 0, \tag{1.2}$$

where the control $(\lambda(t), t \geqq 0)$ is a progressively measurable process taking values in Λ. Its associated infinitesimal generator $L(\lambda)$ is the second-order differential operator

$$L(\lambda)\varphi = \tfrac{1}{2}\sigma^2(\cdot, \lambda)\varphi'' + g(\cdot, \lambda)\varphi', \qquad \sigma(\cdot, \cdot) \geqq 0, \tag{1.3}$$

where φ' and φ'' are the first and second derivatives of φ.

For the moment, let us forget about the h-finite grid $\mathcal{R}_h$, i.e., the last condition of (0.7) is disregarded. Consider the finite difference operator

$$\begin{aligned} &L_h(\lambda)\varphi = \frac{1}{h}\left[\frac{1}{2}\varphi(\cdot + gh + \sigma\gamma\sqrt{h}) + \frac{1}{2}\varphi(\cdot + gh - \sigma\gamma\sqrt{h}) - \varphi\right], \\ &g = g(x,\lambda), \quad \sigma = \sigma(x,\lambda), \quad \gamma = \gamma(x,\lambda,h); \end{aligned} \tag{1.4}$$

the function $\gamma \geqq 0$ is to be chosen later (cf. (1.8)).

In § 1.1 we will construct a controlled Markov chain associated with the finite difference operator, from which a piecewise constant (on stochastic time intervals) process $(y_h(t); t \geqq 0)$ is defined in such a way that

$$E \sup\{|y(t) - y_h(t)|^p e^{-\alpha t} : t \geqq 0\} \leqq Ch^{p/2} \quad \forall h \in (0, 1], \tag{1.5}$$

for some constants C, $\alpha > 0$ depending only on g, σ, and $p > 0$ uniformly with respect to a class of controls to be specified.

Next, we use this estimate to obtain (0.11) for a linear equation, i.e., without control λ.

In § 1.3 we realize the above technique gives only a one-sided estimate of the type (0.11) for nonlinear problems. The difficulty is the lack of information on the optimal control $\lambda(\cdot)$. At this point, we need to use analytic techniques to obtain (0.11).

1.1. A Markov chain. Define

$$\begin{aligned}
&\tau(x,\lambda,h,w)=\inf\{t\geqq 0:\ g(x,\lambda)(t-h)+\sigma(x,\lambda)w(t)\\
&\qquad\qquad\qquad\qquad\text{equals either } \delta(x,\lambda,h) \text{ or } -\delta(x,\lambda,h)\},\\
&\delta(x,\lambda,h)=\sigma(x,\lambda)\gamma(x,\lambda,h)\sqrt{h}, \qquad w(0)=0,\\
&\xi(x,\lambda,h,w)=g(x,\lambda)\tau(x,\lambda,h,w)+\sigma(x,\lambda)w(\tau(x,\lambda,h,w)).
\end{aligned} \tag{1.6}$$

Note that $w(\cdot)$ is a standard Wiener process and $\tau=h$ and $\xi=gh$ whenever σ vanishes.

Let $\lambda(\cdot)$ be a feedback control, i.e., a Borel-measurable function from $\mathcal{R}$ into Λ. We construct by induction the sequences of random variables $(X_n, \theta_n, n=0,1,\cdots)$ as follows. For a given initial data x,

$$\begin{aligned}
&X_0=x, \quad \theta_0=0, \quad w_0(t)=w(t),\\
&X_{n+1}=X_n+\xi(X_n,\lambda(X_n),h,w_n),\\
&\theta_{n+1}=\theta_n+\tau(X_n,\lambda(X_n),h,w_n),\\
&w_{n+1}(t)=w(t+\theta_n)-w(\theta_n), \qquad n=0,1,\cdots.
\end{aligned} \tag{1.7}$$

If instead of a feedback control $\lambda(\cdot)$ we have a nonanticipating control $(\lambda_n, n=0,1,\cdots)$, where λ_n is a random variable valued in Λ and adapted to $(X_0,\cdots,X_{n-1})$, then the procedure (1.7) still works.

Let us define the function $\gamma(x,\lambda,h)$ by

$$\begin{aligned}
&\gamma=0 \quad \text{if } 0\leqq\sigma<|g|\sqrt{h},\\
&\gamma=1 \quad \text{if } g=0,\\
&\gamma=\gamma_0(g\sigma^{-1}\sqrt{h}) \quad \text{if } 0<|g|\sqrt{h}\leqq\sigma,
\end{aligned} \tag{1.8}$$

where

$$\gamma_0(r)=(2r)^{-1}\ln[e^{2r^2}+\operatorname{sign}(r)(e^{4r^2}-1)^{1/2}], \tag{1.9}$$

for $r\neq 0$, $-1\leqq r\leqq 1$. Note that $\gamma_0(r)>0$; moreover,

$$0<\gamma_0(r)-1\leqq|r| \quad \forall r\in[-1,0)\cup(0,1]. \tag{1.10}$$

This implies the inequality

$$|\sigma(x,\lambda)\gamma(x,\lambda,h)-\sigma(x,\lambda)|\leqq 2|g(x,\lambda)|\sqrt{h}, \tag{1.11}$$

for every x, λ, h.

THEOREM 1.1. *If we choose $\gamma(x,\lambda,h)$ by* (1.8), *then for any feedback $\lambda(\cdot)$ the procedure* (1.7) *defines a Markov chain $(X_n, n=0,1,\cdots)$ with transition probability determined by*

$$\begin{aligned}
&E(\varphi(X_{n+1})\,|\,X_n=x)=\Pi_h(\lambda(x))\varphi(x),\\
&\Pi(\lambda)\varphi(x)=\tfrac{1}{2}\varphi(x+g(x,\lambda)h+\sigma(x,\lambda)\gamma(x,\lambda,h)\sqrt{h})\\
&\qquad\qquad+\tfrac{1}{2}\varphi(x+g(x,\lambda)h-\sigma(x,\lambda)\gamma(x,\lambda,h)\sqrt{h}),
\end{aligned} \tag{1.12}$$

and a sequence $(\theta_n, n=0,1,\cdots)$ of stopping times relative to $(\mathcal{F}(t), t\geqq 0)$, with independent increments $\tau_n=\theta_n-\theta_{n-1}$,

$$E\tau_n=h \quad \forall n=1,2,\cdots. \tag{1.13}$$

Proof. Without loss of generality, we may assume g and σ constants. Consider the two functions $u(x)$ and $v(x)$ defined by the equations

$$\tfrac{1}{2}\sigma^2 u'' + gu' = -1 \quad \text{in } (\delta, \delta), \quad u(-\delta) = u(\delta) = 0,$$

$$\tfrac{1}{2}\sigma^2 v'' + gv' = 0 \quad \text{in } (-\delta, \delta), \quad v(-\delta) = 0, \quad v(\delta) = 1,$$

where $\delta = \sigma\gamma\sqrt{h}$. If $-\delta \leqq -gh \leqq \delta$, then

$$E\tau(h, \cdot) = u(-gh), \qquad P(\xi(h, \cdot) = gh + \delta) = v(-gh), \tag{1.14}$$

with the notation (1.6). Since we can compute explicitly,

$$u(x) = -\frac{x}{g} + \frac{\delta}{g}\left(\frac{e^{\alpha\delta} + e^{-\alpha\delta} - 2e^{\alpha x}}{e^{\alpha\delta} - e^{-\alpha\delta}}\right), \quad \alpha = 2g\sigma^{-2}, \quad v(x) = \frac{e^{\alpha\delta} - e^{-\alpha x}}{e^{\alpha\delta} - e^{-\alpha\delta}},$$

yielding

$$u(-gh) = h + \frac{\gamma h}{r}\left(\frac{e^{2r\gamma} + e^{-2r\gamma} - 2e^{2r^2}}{e^{2r\gamma} - e^{-2r\gamma}}\right), \quad v(-gh) = \frac{e^{2r\gamma} - e^{2r^2}}{e^{2r\gamma} - e^{-2r\gamma}}, \quad r = g\sigma^{-1}\sqrt{h}.$$

Suppose we have chosen γ such that $u(-gh) = h$, i.e.,

$$e^{2r\gamma} + e^{-2r\gamma} - 2e^{2r^2} = 0, \qquad \gamma > 1. \tag{1.15}$$

Since

$$1 - v(-gh) = \frac{e^{2r^2} - e^{2r\gamma}}{e^{2r\gamma} - e^{-2r\gamma}},$$

the relation (1.15) implies $v(-gh) = \frac{1}{2}$, i.e.,

$$E\tau(h, \cdot) = h, \qquad P(\xi(h, \cdot) = gh \pm \sigma\gamma\sqrt{h}) = \tfrac{1}{2}, \tag{1.16}$$

whenever $0 < |g|\sqrt{h} \leqq \sigma\gamma$. Note that (1.16) still holds if we take $\gamma = 1$ for $g = 0$ and that (1.15) gives $\gamma = \gamma_0(r)$ as in (1.9), for $0 < |g|\sqrt{h} \leqq \sigma$, because $\gamma > 1$.

If $0 \leqq \sigma < |g|\sqrt{h}$, then the equalities (1.14) hold true for functions u and v satisfying

$$\tfrac{1}{2}\sigma^2 u'' + gu' = -1 \quad \text{in } (-\infty, -\delta), \quad u(-\delta) = 0, \quad u \text{ with polynomial growth},$$

$$\tfrac{1}{2}\sigma^2 v'' + gv' = 0 \quad \text{in } (-\infty, -\delta), \quad v(-\delta) = 1, \quad v \text{ with polynomial growth},$$

for $g > 0$ and replacing the interval $(-\infty, -\delta)$ by $(\delta, +\infty)$ if $g < 0$. It is clear that $v = 1$ and

$$u(x) = -\frac{x}{g} + \frac{\delta}{|g|}.$$

So

$$u(-gh) = h + |g|^{-1}\sigma\gamma\sqrt{h},$$

and $\gamma = 0$ is the right choice.

All of the above proves (1.12) and (1.13) after using standard facts on Brownian motions. □

Remark 1.1. If $g = 0$ and $\sigma = 1$ then the construction (1.7) coincides with the classic Skorokhod's representation (cf. [35]).

For a given feedback $\lambda(\cdot)$ let us denote by $(y_x^h(t, \lambda(\cdot)), t \geqq 0)$ and $(\lambda^h(t), t \geqq 0)$ the processes

$$
\begin{aligned}
&y_x^h(t, \lambda(\cdot)) = X_n \quad \text{if } \theta_n \leqq t < \theta_{n+1}, \quad n = 0, 1, \cdots, \\
&\lambda^h(t) = \lambda(X_n) \quad \text{if } \theta_n \leqq t < \theta_{n+1}, \quad n = 0, 1, \cdots,
\end{aligned} \tag{1.17}
$$

where $(X_n, \theta_n, n = 0, 1, \cdots)$ are defined by (1.7) with the choice (1.8) of function γ.

Note that these processes are adapted to $(\mathcal{F}(t), t \geqq 0)$ and piecewise constants on stochastic intervals. This approach is different from the one used by Pardoux and Talay [28]. Our partition is on the range, i.e., X_n takes values in a variable grid of $\mathcal{R}$, and the time partition is chosen accordingly; our time intervals are random.

Now consider the controlled diffusion process $(y(t) = y_x(t, \lambda^h), t \geqq 0)$ given by the stochastic equation (1.2) with initial data $y(0) = x$ and control process $\lambda(t) = \lambda^h(t)$.

THEOREM 1.2. *Let the assumption* (1.1) *and the choice* (1.8) *hold. Then for any positive number p there exist two positive constants C, α depending only on p and the constants* $C(g, \sigma)$, $K(g, \sigma)$ *of* (1.1) *such that*

$$
E \sup \{|y_x(t, \lambda^h) - y_x^h(t, \lambda(\cdot))|^p e^{-\alpha t} : t \geqq 0\} \leqq C h^{p/2}, \tag{1.18}
$$

uniformly for any feedback $\lambda(\cdot)$ *and x in* $\mathcal{R}$.

Proof. Based on the procedure (1.6), (1.7) we have

$$
X_{n+1} = X_n + g(X_n, \lambda(X_n))(\theta_{n+1} - \theta_n) + \sigma(X_n, \lambda)(w(\theta_{n+1}) - w(\theta_n)), \qquad n = 0, 1, \cdots,
$$

which gives

$$
X_n = x + \int_0^{\theta_n} g(y^h(t), \lambda^h(t))\, dt + \int_0^{\theta_n} \sigma(y^h(t), \lambda^h(t))\, dw(t),
$$

where $y^h(t) = y_x^h(t, \lambda(\cdot))$ and $\lambda^h(t)$ are the processes defined by (1.17). If we set

$$
q^h(t) = x + \int_0^t g(y^h(s), \lambda^h(s))\, ds + \int_0^t \sigma(y^h(s))\, dw(s), \qquad t \geqq 0,
$$

then

$$
q^h(t) - y^h(t) = g(X_n, \lambda(X_n))(t - \theta_n) + \sigma(X_n, \lambda(X_n))(w(t) - w(\theta_n)) \quad \text{if } \theta_n \leqq t < \theta_{n+1}.
$$

Again, in view of the definition (1.6) we deduce

$$
|q^h(t) - y^h(t)| \leqq C(g, \sigma)\sqrt{h} \quad \forall t \geqq 0, \quad 0 < h \leqq 1, \tag{1.19}
$$

where $C(g, \sigma)$ is the constant of the assumption (1.1).

Now, consider the process $z(t) = y(t) - q^h(t)$, with $y(t) = y_x(t, \lambda^h)$,

$$
\begin{aligned}
dz(t) = {} & [g(y(t), \lambda^h(t)) - g(y^h(t), \lambda^x(t))]\, dt \\
& + [\sigma(y(t), \lambda^h(t)) - \sigma(y^h(t), \lambda^h(t))]\, dw(t), \qquad t \geqq 0, \quad z(0) = 0,
\end{aligned}
$$

and apply Itô's formula to the function

$$
\varphi(z, t) = (\beta^2 + z^2)^{p/2} e^{-\alpha t}, \qquad \alpha, \beta, p > 0,
$$

to get

$$
\begin{aligned}
d\varphi(z(t), t) = {} & \{pz(t)[g(y(t), \lambda^h(t)) - g(y^h(t), \lambda^h(t))](\beta^2 + z^2(t)) \\
& + \tfrac{1}{2}(p\beta^2 + p(p-1)z^2(t))[\sigma(y(t), \lambda^h(t)) - \sigma(y^h(t), \lambda^h(t))]^2 \\
& - \alpha(\beta^2 + z^2(t))^2\}(\beta^2 + z^2(t))^{p/2-2} e^{-\alpha t}\, dt \\
& + pz(t)[\sigma(y(t), \lambda^h(t)) - \sigma(y^h(t), \lambda^h(t))](\beta^2 + z^2(t))^{p/2-1} e^{-\alpha t}\, dw(t).
\end{aligned}
$$

If we take $\alpha > \alpha_p$,

$$\alpha_p = p \sup \{[g(x,\lambda)-g(x',\lambda)](x-x')^{-1} + (p \vee 1)[\sigma(x,\lambda)-\sigma(x',\lambda)]^2(x-x')^{-2}: x \neq x' \text{ in } \mathcal{R},\ \lambda \text{ in } \Lambda\}, \tag{1.20}$$

where $\vee$ denotes the maximum, and

$$\beta = \sup \{|q^h(t)-y^h(t)|: t \geqq 0,\ \omega \text{ in } \Omega\};$$

then we obtain

$$d\varphi(z(t),t) \leqq (\alpha_p - \alpha)\varphi(z(t),t)\,dt + dM_t, \qquad t \geqq 0,$$
$$|y(t)-y^h(t)|^p e^{-\alpha t} \leqq \varphi(z(t),t), \qquad t \geqq 0,$$

with M_t being the martingale term. In virtue of (1.19) we deduce

$$E\left\{|y(t)-y^h(t)|^p e^{-\alpha t} + (\alpha-\alpha_p)\int_0^t |y(s)-y^h(s)|^p e^{-\alpha s}\,ds\right\} \leqq [C(g,\sigma)\sqrt{h}]^p \quad \forall t \geqq 0, \quad 0 < h \leqq 1. \tag{1.21}$$

Next, by means of the stochastic inequality

$$E \sup\left\{\left|\int_0^t \varphi(s)\,dw(s)\right|: t \geqq 0\right\} \leqq 3E\left\{\left(\int_0^\infty \varphi^2(t)\,dt\right)^{1/2}\right\},$$

we bound the martingale term

$$E \sup\left\{\left|\int_0^t dM_s\right|: t \geqq 0\right\} \leqq 3pK(g,\sigma)\left(E\left\{\int_0^\infty \varphi^2(z(t),t)\,dt\right\}\right)^{1/2},$$
$$\{\varphi^2(z(t),t)\} \leqq [C(g,\sigma)\sqrt{h}]^{2p} e^{-(2\alpha-\alpha_{2p})t}, \quad t \geqq 0.$$

Hence we obtain (1.18) for $2\alpha > \alpha_{2p}$ as in (1.20) and

$$C = C(g,\sigma)[1+3pK(g,\sigma)(2\alpha-\alpha_{2p})^{-1}],$$

where $C(g,\sigma)$ and $K(g,\sigma)$ are the constants of (1.1). □

Remark 1.2. Notice that the constant α_p defined by (1.20) is bounded by $p(p \vee 1)K(g,\sigma)$, the constant of (1.1). It is clear then that α_p vanishes as p goes to zero.

Remark 1.3. Similarly, we can show for any $t \geqq 0$ the estimate

$$E\{|y_x^h(t,\lambda(\cdot)) - y_{x'}^h(t,\lambda(\cdot))|^p e^{-\alpha_p t}\} \leqq (C^2(g,\sigma)h + |x-x'|^2)^{p/2}, \tag{1.22}$$

where $C(g,\sigma)$, α_p are the constants of (1.1), (1.20) and x, x' belong to $\mathcal{R}$, h in $(0,1]$, and the feedback $\lambda(\cdot)$ is arbitrary.

1.2. The linear equation. In this section we consider the case without controls, i.e., the set Λ reduces to one element, and we drop it.

Recall the stochastic differential equation

$$dy(t) = g(y(t))+\sigma(y(t))\,dw(t), \qquad t \geqq 0, \quad y(0) = x, \tag{1.23}$$

where g, σ are bounded and Lipschitz-continuous. For a bounded and uniformly continuous function f we set

$$u(x,t) = E\left\{\int_0^t f(y_x(s))\,ds\right\}, \quad \forall x \in \mathcal{R}, \quad t \geqq 0. \tag{1.24}$$

This function is the unique solution of the following partial differential equation that is bounded and uniformly continuous:

$$\partial_t u(x,t) = Lu(x,t) + f(x) \quad \forall x \in \mathcal{R}, \quad t > 0, \quad u(x,0) = 0 \quad \forall x \in \mathcal{R} \tag{1.25}$$

where ∂_t denotes the partial derivative in t and L is the differential operator

$$L\varphi(x,t) = \tfrac{1}{2}\sigma^2(x)\partial_x^2\varphi(x,t) + g(x)\partial_x\varphi(x,t). \tag{1.26}$$

The partial differential equation (PDE) (1.25) is understood in the Schwartz' distributions sense. On the other hand, we set

$$u_h(x, nh) = h \sum_{i=0}^{n} E\{f(X_i)\}, \qquad n = 0, 1, \cdots,$$

where $(X_n, \theta_n, n = 0, 1, \cdots)$ is the sequence of Theorem 1.1. It is clear that

$$u_h(x, nh) = E\left\{\int_0^{\theta_n} f(y_x^h(t))\, dt\right\}, \qquad n = 0, 1, \cdots, \tag{1.27}$$

with the notation of Theorem 1.2. For convenience we set

$$u_h(x,t) = u_h(x, nh) \quad \text{if } nh \leqq t < (n+1)h.$$

By means of Markov's property, we can deduce

$$\begin{aligned} &\nabla_h u_h(x,t) = L_h u_h(x,t) + f(x) \quad \forall x \in \mathcal{R}, \quad t > 0, \\ &u_h(x,0) = 0 \quad \forall x \in \mathcal{R}, \end{aligned} \tag{1.28}$$

where L_h is now the finite difference operator

$$\begin{aligned} L_h\varphi(x) = \frac{1}{2h}[&\varphi(x + g(x)h + \sigma(x)\gamma(x,h)\sqrt{h}) \\ &+ \varphi(x + g(x)h - \sigma(x)\gamma(x,h)\sqrt{h}) - 2\varphi(x)] \quad \forall h \text{ in } (0,1], \end{aligned} \tag{1.29}$$

and

$$\nabla_h\varphi(t) = \frac{1}{h}[\varphi(t+h) - \varphi(t)] \quad \forall h \text{ in } (0,1]. \tag{1.30}$$

Note that x belongs to $\mathcal{R}$, so our Markov chain has states in $\mathcal{R}$. Actually, we discretize first the time variable and then the state variable.

Denote by $\rho(r)$ the modulus of continuity of f, i.e.,

$$\rho(r) = \sup\{|f(x) - f(x')| : x, x' \in \mathcal{R}, |x - x'| \leqq r\}. \tag{1.31}$$

THEOREM 1.3. *Under the assumptions of Theorem* 1.2, *for any* p, $T > 0$ *there exists a constant* C *depending only on* p, T, *the Lipschitz constants of* g, σ, *and the bound of* f, *such that*

$$|u(x,t) - u_h(x,t)| \leqq C[\sqrt{h} + \rho(r) + (r^{-1}\sqrt{h})^p] \quad \forall r > 0, \tag{1.32}$$

valid for any x *in* $\mathcal{R}$, t *in* $[0, T]$, h *in* $(0, 1]$.

Proof. In view of the representations (1.24) and (1.27) we have

$$|u(x,t) - u_h(x,t)| \leqq E\left\{\int_0^t |f(y(s)) - f(y^h(s))|\, ds\right\} + C(f)E\{|\theta_n - t|\} = I + II,$$

where

$$|f(x)-f(x')|\leqq C(f) \quad \forall x, x'\in \mathcal{R}.$$

Thus,

$$I\leqq \alpha^{-1}(e^{\alpha t}-1)C(f)r^{-p}E\left\{\int_0^t |y(s)-y^h(s)|^p\, e^{-\alpha s}\, ds\right\}$$
$$+ t\rho(r)\leqq \alpha^{-1}(e^{\alpha T}-1)C(f)C_1(r^{-1}\sqrt{h})^p + T\rho(r),$$

with α, $C=C_1$ being the constants of (1.18) in Theorem 1.2. Also,

$$E\{|\theta_n - t|\}\leqq h + E\{|\theta_n - nh|\}\leqq h + (E\{|(\tau_1-h)+\cdots+(\tau_n-h)|^2\})^{1/2}$$
$$= h + (nE\{(\tau_1-h)^2\})^{1/2}\leqq h + C_2\sqrt{th},$$

where $\tau_i=\theta_i-\theta_{i-1}$, and C_2 is a constant such that

$$E\{(\tau_1-h)^2\}\leqq (C_2h)^2 \quad \forall h\in(0,1]. \tag{1.33}$$

It is clear that the above proves (1.32) provided we have established (1.33).

To show (1.33), we see that if $-\delta\leqq -gh\leqq\delta$, $\delta=\sigma\gamma\sqrt{h}$ then the characteristic function of τ_1,

$$u(x,s)=E\{e^{s\tau_1}\}, \qquad s>0 \text{ fixed},$$

is the solution of the differential equation

$$\tfrac{1}{2}\sigma^2u''+gu'-su=0 \quad \text{in } (-\delta,\delta), \quad u(-\delta,s)=u(-\delta,s)=1,$$

and

$$E\{(\tau_1)^2\}=\frac{\partial^2 u}{\partial s}(-gh,0).$$

Hence, after some calculations we obtain (1.33). □

Remark 1.4. Analogously to the above theorem, and by means of Remark 1.3, we can prove that

$$|u_h(x,t)-u_h(x',t)|\leqq C\{\sqrt{h}+\rho(r)+r^{-p}[h+|x-x'|^2]^{p/2}\} \quad \forall r>0 \tag{1.34}$$

for any h in $(0,1]$, x in $\mathcal{R}$, t in $[0,T]$ and some constant C depending only on the bound of f, the Lipschitz constants of g, σ and the constants T, $p>0$. Actually, we can do better, i.e., in the estimates (1.22) and (1.34) we may have the right-hand side with $h=0$, but this requires the use of another explicit Markov chain, the one used in § 1.3.

1.3. Fully nonlinear equation. Let us return to the control problem (0.1)-(0.5) for one dimension, i.e., D is the whole real line $\mathcal{R}$, Λ is some compact subset of $\mathcal{R}$, $n=d=1$ in (0.5). Recall that for any adapted control process $(\lambda(t), t\geqq 0)$ we obtain the state process $(y(t)=y_x(t,\lambda), t\geqq 0)$ as the solution of the stochastic differential equation (1.2) with initial condition $y(0)=x$. Next, the cost functional is defined by

$$J(x,\lambda)=E\left\{\int_0^\infty f(y(t),\lambda(t))\, e^{-\alpha t}\, dt\right\}, \tag{1.35}$$

and the optimal cost is

$$u(x)=\inf\{J(x,\lambda): \lambda \text{ any control process}\}. \tag{1.36}$$

The associated HJB equation is

$$\alpha u = \inf\{L(\lambda)u + f(\cdot, \lambda): \lambda \in \Lambda\} \quad \text{in } \mathcal{R}, \tag{1.37}$$

which is indeed an ordinary differential equation in the real line, since $L(\lambda)$ is given by (1.3). If the data are smooth and the operator is uniformly elliptic, then the HJB equation (1.37) has one and only one solution with Lipschitz second derivative (cf. Krylov [13]). In general we use either the viscosity solution (cf. Lions [20]) or the maximum subsolution in the Schwartz' distribution sense (cf. Lions and Menaldi [21]).

The approximate control is then

$$\begin{aligned} &J_h(x, \lambda(\cdot)) = E\left\{\int_0^\infty f(y^h(t), \lambda(y^h(t)))\chi_h^\alpha(t)\, dt\right\}, \\ &\chi_h^\alpha(t) = (1+\alpha h)^{-n} \quad \text{if } \theta_n \leqq t < \theta_{n+1}, \quad n = 0, 1, \cdots, \end{aligned} \tag{1.38}$$

where $(y^h(t) = y_x^h(t, \lambda(\cdot)), t \geqq 0)$ and $(\theta_n, n = 0, 1, \cdots)$ are defined by (1.17) and (1.7). Note that

$$J_h(x, \lambda(\cdot)) = E\left\{h \sum_{n=0}^{\infty} f(X_n, \lambda(X_n))(1+\alpha+\alpha h)^{-n}\right\}. \tag{1.39}$$

The optimal cost is

$$u_h(x) = \inf\{J_h(x, \lambda(\cdot)): \lambda(\cdot) \text{ feedback control}\}, \tag{1.40}$$

$$\alpha u_h = \inf\{L_h(\lambda)u_h + f(\cdot, \lambda): \lambda \in \Lambda\} \quad \text{in } \mathcal{R}. \tag{1.41}$$

It is clear that an estimate of the type (1.18) will provide only a one-side bound for the rate of convergence of u_h toward u. Then we will modify the continuous time control problem as follows.

To simplify the exposition we assume g, σ Lipschitz-continuous in the control variable, i.e.,

$$|g(x, \lambda) - g(x, \lambda')| + |\sigma(x, \lambda) - \sigma(x, \lambda')| \leqq K|\lambda - \lambda'| \quad \forall x \in \mathcal{R}, \lambda, \quad \lambda' \in \Lambda, \tag{1.42}$$

for some constant $K = K(g, \sigma)$, and we call $\lambda(\cdot)$ an M-feedback control if $\lambda(\cdot)$ is Lipschitz-continuous, i.e.,

$$|\lambda(x) - \lambda(x')| \leqq M|x - x'| \quad \forall x, x' \in \mathcal{R}. \tag{1.43}$$

Consider the M-optimal cost

$$u(x, M) = \inf\{J_h(x, \lambda(\cdot)): \lambda(\cdot) M\text{-feedback control}\}, \tag{1.44}$$

for any $M > 0$, M destined to become infinite.

It is clear that $u(x, M) \geqq u(x)$ and, under reasonable assumptions we will have

$$u(x, M) \to u(x) \quad \forall x \in \mathcal{R} \quad \text{as } M \to \infty.$$

Moreover, sometimes the M-optimal cost is meaningful by itself.

THEOREM 1.4. *Let the assumptions of Theorem* 1.2 *and* (1.42) *hold. Then for any* M, $p > 0$ *there exist two constants* $C(M)$, $C > 0$ *depending only on* p, α, *the bound of* f, *and the constants of hypothesis* (1.1); $C(M)$ *depends also on* M *and the* $K(g, \sigma)$ *of* (1.42), *such that*

$$\begin{aligned} &u(x) - u_h(x) \leqq C[\sqrt{h} + \rho(r) + (r^{-1}\sqrt{h})^p] \quad \forall r > 0, \\ &u_h(x) - u(x, M) \leqq C(M)[\sqrt{h} + \rho(r) + (r^{-1}\sqrt{h})^p] \quad \forall r > 0, \end{aligned} \tag{1.45}$$

for any x *in* $\mathcal{R}$, h *in* $(0, 1]$ *and* $\rho(r)$ *given by* (1.31), *uniformly for* λ *in* Λ.

Proof. Starting from

$$u(x)-u_h(x)\leqq \sup\{J(x,\lambda_h)-J_h(x,\lambda(\cdot))\colon \lambda(\cdot)\},$$

$$e^{-\alpha t}\leqq \chi_h^{\alpha}(t)\leqq e^{-\alpha(t-h)}\quad \forall t\geqq 0$$

and in view of the estimate (1.18), we deduce the first part of (1.45) as in Theorem 1.3.

For the second part of (1.45) we use

$$u_h(x)-u(x,M)\leqq \sup\{J_h(x,\lambda(\cdot))-J(x,\lambda(\cdot))\colon \lambda(\cdot)\text{ any } M\text{-feedback control}\}$$

and we prove

$$E\sup\{|y_x(t,\lambda(\cdot))-y_x^h(t,\lambda(\cdot))|^p e^{-\alpha t}\colon t\geqq 0\}\leqq C(M)h^{p/2}, \tag{1.46}$$

as in Theorem 1.2, but now, $C(M)$ depends also on the Lipschitz constant M of the feedback control $\lambda(\cdot)$, as well as on the constant $K(g,\sigma)$ of (1.42). Thus, we complete the proof of the estimate (1.45). □

Until now, we have used only estimates on the stochastic state equation to obtain some bounds for the rate of convergence of the discrete HJB toward the continuous-time HJB.

Now we will look at the approximation problem in a more analytic way.

Suppose $\varphi(x)$ is a smooth function; then we can write

$$L_h(\lambda)\varphi=\frac{1}{2}\sigma^2\int_{-1}^{1}\varphi''(\cdot+gh+t\sigma\sqrt{h})(1-|t|)\,dt+g\int_0^1\varphi'(\cdot+tgh)\,dt \tag{1.47}$$

where the primes denote derivatives and we must take $\gamma=1$ in (1.4), i.e., for $g=g(x,\lambda)$, $\sigma=\sigma(x,\lambda)$,

$$L_h(\lambda)\varphi=\frac{1}{h}\left[\frac{1}{2}\varphi(\cdot+gh+\sigma\sqrt{h})+\frac{1}{2}\varphi\,\middle|\,(\cdot+gh-\sigma\sqrt{h})-\varphi(x)\right]. \tag{1.48}$$

First,

$$|L(\lambda)\varphi(x)-L_h\lambda\varphi(x)|\leqq C_\varphi h^{p/2}\quad \forall x\in\mathcal{R},\quad h\in(0,1], \tag{1.49}$$

and λ in Λ, and some constant C_φ depending on the bounds of g,σ,φ'', and the p-Hölder constant of φ'', i.e., the constant $K=K(\varphi'')$ satisfying

$$|\varphi''(x)-\varphi''(x')|\leqq K|x-x'|^p\quad \forall x,x'\in\mathcal{R}, \tag{1.50}$$

for some exponent $0<p\leqq 1$.

Let us define $[\varphi]_p$ as the infimum of the set of all constant C satisfying

$$\begin{aligned}&\inf\{L(\lambda)\varphi(y)\colon |y-x|\leqq C\sqrt{h}\}-Ch^{p/2}\leqq L_h(\lambda)\varphi(x)\\&\qquad\leqq \sup\{L(\lambda)\varphi(y)\colon |y-x|\leqq C\sqrt{h}\}+Ch^{p/2}\quad \forall h\in(0,1],\end{aligned} \tag{1.51}$$

for any x in Λ. It is clear that $|\varphi|_p$ can be bounded by the constant C_φ of (1.49). However, here we can do better:

(i) $[\varphi]_1$ is dominated by the bounds of the second derivative φ'' and the constants $C(g,\sigma)$, $K(g,\sigma)$ of hypothesis (1.1).

(ii) If $\sigma=\sigma(\lambda)$, i.e., constant in x, then $[\varphi]_p$ is dominated by the p-Hölder constant and the bound of the first derivative φ', and $C(g,\sigma)$, $K(g,\sigma)$.

(iii) If $g=0$ and $\sigma=\sigma(\lambda)$, then $[\varphi]_1$ is dominated by the bound of σ and does not depend on φ.

Suppose that f is bounded continuous and for some constant C, $K>0$, $0<p\leqq 1$,

$$\begin{aligned} &|f(x,\lambda)|\leqq C \quad \forall x\in\mathcal{R}, \quad \lambda\in\Lambda,\\ &|f(x,\lambda)-f(x',\lambda)|\leqq K|x-x'|^p \quad \forall x,x'\in\mathcal{R}, \quad \lambda\in\Lambda, \end{aligned} \tag{1.52}$$

and

$$\alpha>\alpha_p, \text{ the constant given by (1.20).} \tag{1.53}$$

THEOREM 1.5. *Under the assumptions* (1.1), (1.52), *and* (1.53) *there exists a constant* C *depending only on the constants* $C(g,\sigma)$, $K(g,\sigma)$, $C(f)$, $K(f)$ *of* (1.1), (1.52), *the constant* α *of* (1.53), *and the value* $[u]_p$ *with* u *being the maximum solution of the* HJB *equations* (1.37), *such that*

$$|u(x)-u_h(x)|\leqq Ch^{p/2} \quad \forall x\in\mathcal{R}, \quad h\in(0,1], \tag{1.54}$$

where $u_h(x)$ *is solution of the discrete* HJB *equation* (1.41) *with the finite difference operator* (1.48).

Proof. We remark that the fact that $[u]_p$ is finite is implicit. To check that the discrete HJB equation (1.41) has a solution, we rewrite it as follows:

$$\begin{aligned} &u_h=\inf\{\Pi_h^\alpha(\lambda)u_h+hf(\cdot,\lambda):\lambda\in\Lambda\} \quad \text{in } \mathcal{R},\\ &\Pi_h^\alpha(\lambda)\varphi=(1+\alpha h)^{-1}[hL_h(\lambda)\varphi-\varphi], \end{aligned} \tag{1.55}$$

and we note that the operator involved is a contraction map in the space of bounded continuous functions on $\mathcal{R}$.

First we will show that for some constants C, $K>0$ depending only on the constants in the assumptions (1.1), (1.52), and (1.53) such that

$$\begin{aligned} &|u_h(x)|+|u(x)|\leqq C \quad \forall x\in\mathcal{R},\\ &|u_h(x)-u_h(x')|+|u(x)-u(x')|\leqq K|x-x'|^p \quad \forall x,x'\in\mathcal{R}, \end{aligned} \tag{1.56}$$

for any h in $(0,1]$, $0<p\leqq 1$, the same p as in (1.52). It is relatively easy to obtain (1.50) for u from the stochastic representation (1.36); however, we prefer to use analytic arguments to present the technique used.

Consider the function

$$m(x,q,\varepsilon)=(\varepsilon^2+x^2)^{q/2} \quad \forall x\in\mathcal{R}, \tag{1.57}$$

for $q,\varepsilon>0$ fixed, and the solution $u(x)$ of the HJB equation (1.37). To prove the second part of (1.56) we look at the point (x_0,y_0) of $\mathcal{R}\times\mathcal{R}$ where the function

$$w(x,y)=u(x)-u(y)-Km(x-y,p,\varepsilon)m(x+y,q,1)$$

attains its maximum value, for a fixed K to be selected later. We want to show that $w(x_0,y_0)\leqq 0$ for an appropriate choice of K.

The extended operator

$$\begin{aligned} \tilde{L}(\lambda)\varphi(x,y)=&\tfrac{1}{2}\sigma^2(x,\lambda)\varphi''_{xx}+\sigma(x,\lambda)\sigma(y,\lambda)\varphi''_{xy}\\ &+\tfrac{1}{2}\sigma^2(y,\lambda)\varphi''_{yy}+g(x,\lambda)\varphi'_x+g(y,\lambda)\varphi'_y, \end{aligned} \tag{1.58}$$

is elliptic and satisfies

$$\tilde{L}(\lambda)[u(x)-u(y)]=L(\lambda)u(x)-L(\lambda)u(y).$$

After some calculations, we have

$$\begin{aligned}\tilde{L}(\lambda)[m(x-y,p,\varepsilon)m(x+y,q,1)]=&\frac{p}{2}[\sigma(x,\lambda)-\sigma(y,\lambda)]^2\\&\cdot m(x-y,p-2,\varepsilon)m(x+y,q,1)\\&\cdot[(p-1)(x-y)^2m(x-y,-2,\varepsilon)+1]\\&+\frac{q}{2}[\sigma(x,\lambda)+\sigma(y,\lambda)]^2m(x-y,p,\varepsilon)\\&\cdot m(x+y,1,q-2)\\&\cdot[(q-1)(x+y)^2m(x+y,-2,1)]\\&+pq[\sigma(x,\lambda)+\sigma(y,\lambda)][\sigma(x,\lambda)-\sigma(y,\lambda)]\\&\cdot(x-y)(x+y)m(x-y,p-2,\varepsilon)\\&\cdot m(x+y,q-2,1)+p[g(x,\lambda)-g(y,\lambda)]\\&\cdot(x-y)m(x-y,p-2,\varepsilon)m(x+y,q,1)\\&+q[g(x,\lambda)+g(y,\lambda)]\\&\cdot(x+y)m(x-y,p,\varepsilon)m(x+y,q-2,1),\end{aligned}$$

which shows that

$$\tilde{L}(\lambda)[m(x-y,p,\varepsilon)m(x+y,q,1)]\leqq(\alpha_p-qC)m(x-y,p,\varepsilon)m(x+y,q,1), \tag{1.59}$$

where α_p is the constant defined by (1.20) and C is a constant independent of λ, x, y, ε, p, and $0<q<1$. We choose $q>0$ such that $\alpha-\alpha_p+qC\geqq\alpha_0>0$.

Now, by means of the maximum principle, we have $L(\lambda)w(x_0,y_0)\leqq 0$, i.e.,

$$L(\lambda)u(x_0)-L(\lambda)u(y_0)\leqq(\alpha-\alpha_0)Km(x_0-y_0,p,\varepsilon)m(x_0+y_0,1,q), \tag{1.60}$$

assuming that u is smooth and after using (1.59). But, from HJB equation (1.37) we deduce

$$\alpha[u(x_0)-u(y_0)]\leqq[K(f)+(\alpha-\alpha_0)K]m(x_0-y_0,p,\varepsilon)m(x_0+y_0,1,q),$$

where $K(f)$ is the p-Hölder Lipschitz of f in (1.52). Hence, if we choose $K=\alpha_0^{-1}K(f)$, then we conclude that $w(x_0,y_0)\leqq 0$. Therefore, we should have

$$u(x)-u(y)\leqq Km(x-y,p,\varepsilon)m(x+y,q,1).$$

Because the constant K does not depend on ε, q, we send ε, q to zero to obtain the second part of (1.56) for u, assuming that u is smooth.

Similarly, we show the Hölder-continuous estimate for u_h. In that case we use the extended operator

$$\begin{aligned}&\tilde{L}_h(\lambda)\varphi(x,y)=\frac{1}{h}\left[\frac{1}{2}\varphi(z^+(x,\lambda),z^+(y,\lambda)+\frac{1}{2}\varphi(z^-(x,\lambda),z^-(y,\lambda))-\varphi(x,y)\right],\\&z^{\pm}(\cdot,\lambda)=\cdot+g(\cdot,\lambda)h\pm\sigma(\cdot,\lambda)\sqrt{h}.\end{aligned} \tag{1.61}$$

Note that if u is not smooth then we have to approximate u by a smooth function u_e, either by regularization, i.e., $\sigma+\varepsilon$ replaces σ, or by the so-called infimum convolution. The proof of the first part of (1.56) uses a technique analogous to the above.

Let us prove the estimate (1.54). Consider the function

$$w(x,y)=u_h(x)-u(y)-C_1m(x-y,p,\varepsilon)m(x+y,q,1)-C_2h^{p/2}$$

for some constants C_1, C_2, q, $\varepsilon > 0$ to be selected later, and let (x_0, y_0) be a point where $w(x, y)$ attains its maximum value. A calculation similar to the one to obtain (1.59) shows that

$$\tilde{L}_h(\lambda)[m(x-y, p, \varepsilon)m(x+y, q, 1)] \leqq (\alpha_p - rq)m(x-y, p, \varepsilon)m(x+y, q, 1), \tag{1.62}$$

for any x, y in $\mathcal{R}$, λ in Λ, h, q in $(0, 1]$, some constant $r > 0$ and the same α_p of (1.20). We take $q > 0$ such that $\alpha_p - rq \leqq \alpha - \alpha_0$, $\alpha_0 > 0$.

Because $\tilde{L}_h(\lambda)w(x_0, y_0) \leqq 0$ we deduce

$$L_h(\lambda)u_h(x_0) - L_h(\lambda)u(y_0) \leqq (\alpha - \alpha_0)C_1 m(x_0 - y_0, p, \varepsilon)m(x_0 + y_0, q, 1),$$

and in view of (1.51),

$$L_h(\lambda)u(y_0) \leqq L(\lambda)u(y_1) + [u]_p h^{p/2}, \qquad |y_0 - y_1| \leqq [u]_p \sqrt{h}. \tag{1.63}$$

From the HJB equations satisfied by u_h and u we obtain

$$\alpha[u_h(x_0) - u(y_1)] \leqq \sup\{|f(x_0, \lambda) - f(y_1, \lambda)| : \lambda \in \Lambda\} + (\alpha - \alpha_0)Cm(x_0 - y_0, p, \varepsilon)m(x_0 + y_0, q, 1) + [u]_p h^{p/2},$$

and by means of (1.52), (1.56), (1.63) we get

$$|f(x_0, \lambda) - f(y_1, \lambda)| + |u(y_0) - u(y_1)| \leqq [K(f) + K(u)]m(x_0 - y_0, p, \varepsilon),$$

provided $\varepsilon = [u]_p \sqrt{h}$.

Collecting all, we have

$$\alpha[u_h(x_0) - u(y_0)] \leqq [K(f) + K(u) + (\alpha - \alpha_0)C_1]m(x_0 - y_0, p, \varepsilon) \cdot m(x_0 + y_0, q, 1) + [u]_p h^{p/2}.$$

Hence, if we choose

$$C_1 = \alpha_0^{-1}[K(f) + K(u)], \quad C_2 = [u]_p, \quad \varepsilon = [u]_p \sqrt{h},$$

then $w(x_0, y_0) \leqq 0$, i.e.,

$$u_h(x) - u(y) \leqq C_1 m(x - y, p, \varepsilon)m(x + y, q, 1) + C_2 h^{p/2}, \tag{1.64}$$

for any x, y in $\mathcal{R}$, h, q in $(0, 1]$. Letting q vanish and taking $x = y$, we establish one side of (1.54).

Reversing the role of u_h and u we complete the proof. □

Remark 1.5. Note that in the proof of Theorem 1.5 we assume implicitly that the function u is smooth. However, once the estimates have been established, we can remove that assumption on u, only $[u]_p$ needs to be finite.

1.4. Extension and comments. The fact that the functions g, σ are bounded is not really important, we need only to assume linear growth, i.e.,

$$|g(x)| + |\sigma(x)| \leqq C(1 + |x|) \quad \forall x \in \mathcal{R}, \tag{1.65}$$

for some constant $C = C(g, \sigma)$. In this case the estimate (1.18) of Theorem 1.2 becomes

$$E \sup\{|y_x(t, \lambda^h) - y_x^h(t, \lambda(\cdot))|^p e^{-\alpha t} : t \geqq 0\} \leqq C(1 + |x|^2)^{p/2} h^{p/2} \quad \forall x \in \mathcal{R}, \tag{1.66}$$

for some constants C, $\alpha > 0$.

To adapt Theorem 1.1 to the time-dependent case, we modify the construction (1.6), (1.7), for instance,

$$\tau(x, t, \lambda, h, w) = \inf\{s \geqq 0 : g(x, s + t, \lambda)(s - h) + \sigma(x, s + t, \lambda)w(s) \text{ equals } \pm\delta(x, t, \lambda, h)\}. \tag{1.67}$$

A generalization to dimension $d \geqq 2$ is possible but more delicate. Let us describe the procedure. We write σ as the matrix formed by the column vectors $\sigma_1, \sigma_2, \cdots, \sigma_n$; the drift vector g is expressed as $g = g^1 e_1 + \cdots + g^n e_n$, where g^i are scalars and e_i are vectors in the direction σ_i, i.e., $\sigma_i = \sigma^i e_i$, σ^i is scalar. We want to define τ_i as the first time for which

$$g^i e_i(\tau_i - h) + \sigma^i e_i w_i(\tau_i) = \pm \sigma^i \gamma^i \sqrt{h}\, e_i.$$

This is the same as cancelling the vector e_i and defining τ_i as in (1.6) with g, σ, γ, w, replaced by $g^i, \sigma^i, \gamma^i, w_i$. Then we are interested in the stopping time $\tau = \min\{\tau_i: i = 1, \cdots, n\}$, which is the first exit time of the box in $\mathcal{R}^n$ bounded by the hyperplane $z_i = \pm \sigma^i \gamma^i \sqrt{h}$, $z = (z_1, \cdots, z_n)$ in $\mathcal{R}^n$, for a Wiener process in $\mathcal{R}^n$ with drift $(g^1, \cdots, g^n)$ and diffusion term the diagonal matrix $(\sigma^1, \cdots, \sigma^n)$, starting at the point $(-g^1\sqrt{h}, \cdots, -g^n\sqrt{h})$. Details of this construction will be presented in a future work.

In Theorems 1.3, 1.4, and 1.5 we can allow the functions g, σ to satisfy (1.65) and the function f to have polynomial growth, i.e.,

$$\begin{aligned} &|f(x, \lambda)| \leqq C(1 + x^2)^{q/2} \quad \forall x \in \mathcal{R}, \\ &|f(x, \lambda) - f(y, \lambda)| \leqq K|x - y|^p (1 + x^2 + y^2)^{r/2} \quad \forall x, y \in \mathcal{R}, \end{aligned} \tag{1.68}$$

for $q > 0$; $0 < q \leqq 1$, $r = \max\{q - p, 0\}$. The estimate (1.54) is modified accordingly. For the estimates (1.32) and (1.45) we use

$$\rho(r) = \inf\{|f(x, \lambda) - f(y, \lambda)|(1 + x^2 + y^2)^{q/2}: x, y \text{ in } \mathcal{R}, \lambda \text{ in } \Lambda\}. \tag{1.69}$$

A discretization in Λ can also be incorporated. In that case, a term of the form

$$r(h) = \sup\{\inf\{|l(x, \lambda) - l(x, \lambda')|: \lambda' \in \Lambda(h)\}: x \in \mathcal{R}^d, \lambda \in \Lambda, l = f, g, \sigma\} \tag{1.70}$$

will appear in the estimates (1.32), (1.45), and (1.54) of Theorems 1.3, 1.4, and 1.5. Here $\Lambda(h)$ is a discretization of Λ.

The constant $\alpha > 0$ can be replaced by a function $\alpha(x, \lambda)$.

The fact that we made only the discretization in the time variable is just the first step. To discretize the space variable, we can add the second part of condition (0.7), as in the next section. An alternative is to use finite elements to solve the discrete HJB of the type (1.41). This issue is reserved for a future work.

2. General problems. In this section we will consider the typical control problem (0.1)-(0.5) in a bounded open subset D of $\mathcal{R}^d$.

Let g and σ be bounded continuous functions from $\mathcal{R}^d \times \Lambda$ into $\mathcal{R}^d$ and $\mathcal{R}^d \times \mathcal{R}^n$, respectively, such that $g = (g_i, i = 1, \cdots, d)$, $\sigma = (\sigma_{ik}, i = 1, \cdots, d, k = 1, \cdots, n)$,

$$\begin{aligned} &|g(x, \lambda)|\sigma(x, \lambda)| \leqq C \quad \forall x \in \mathcal{R}^d \quad \forall \lambda \in \Lambda, \\ &|g(x, \lambda) - g(x', \lambda)| + |\sigma(x, \lambda) - \sigma(x', \lambda)| \leqq K|x - x'| \quad \forall x, x' \in \mathcal{R}^d, \quad \lambda \in \Lambda, \end{aligned} \tag{2.1}$$

for some constants $C = C(g, \sigma)$, $K = K(g, \sigma)$, some locally compact metric space Λ and where $|\cdot|$ denotes the Euclidean norm in the corresponding space.

On a complete Wiener space $(\Omega, P, \mathcal{F}, \mathcal{F}(t), w(t), t \geqq 0)$ in $\mathcal{R}^n$ we consider the state equation

$$dy(t) = g(y(t), \lambda(t))\, dt + \sigma(y(t), \lambda(t))\, dw(t), \quad t > 0, \quad y(0) = x, \tag{2.2}$$

where the control $(\lambda(t), t \geqq 0)$ is a progressively measurable process taking values in Λ. Denote by τ the first exit time of $\bar{D}$, closure of D, for the process $(y(t), t \geqq 0)$, i.e.,

$$\tau = \inf\{t \geqq 0: y(t) \notin \bar{D}\}. \tag{2.3}$$

For a given real bounded-continuous function f on $\mathcal{R}^d \times \Lambda$ such that

$$
\begin{aligned}
&|f(x,\lambda)| \leqq C \quad \forall x \in \mathcal{R}^d, \quad \lambda \in \Lambda, \\
&|f(x,\lambda) - f(x',\lambda)| \leqq K|x-x'|^p \quad \forall x, x' \in \mathcal{R}^d, \quad \lambda \in \Lambda,
\end{aligned} \tag{2.4}
$$

for some constants C, $K > 0$, $0 < p \leqq 1$, we define

$$
J(x,\lambda) = E\left\{ \int_0^\tau f(y(t), \lambda(t))\, e^{-\alpha t}\, dt \right\}, \qquad \alpha > 0, \tag{2.5}
$$

and the optimal cost function

$$
u(x) = \inf\{J(x,\lambda): \text{ any control process } \lambda\}. \tag{2.6}
$$

The HJB equation is

$$
\alpha u = \inf\{L(\lambda)u + f(\cdot,\lambda): \lambda \in \Lambda\} \quad \text{in } D, \quad u = 0 \quad \text{on } \partial D, \tag{2.7}
$$

where the differential operator

$$
L(\lambda) = \frac{1}{2} \sum_{i,j=1}^{d} \left(\sum_{k=1}^{n} \sigma_{ik}(\cdot,\lambda)\sigma_{jk}(\cdot,\lambda) \right) \partial_{ij} + \sum_{i=1}^{d} g_i(\cdot,\lambda)\partial_i, \tag{2.8}
$$

and the bounded domain D has a uniform exterior sphere, i.e.,

$$
\begin{aligned}
&\text{there exists } r > 0 \text{ such that for any } x \text{ in } \partial D \text{ there is } y \text{ in } \mathcal{R}^d \setminus D \text{ such that} \\
&\{z: |y-z| \leqq r\} \cap \bar{D} = \{x\},
\end{aligned} \tag{2.9}
$$

and $L(\lambda)$ is not degenerate on the boundary, i.e.,

$$
\sum_{k=1}^{n} \sum_{i=1}^{d} |\sigma_{ik}(x,\lambda)\eta_i(x)| \geqq \nu_0 > 0 \quad \forall x \in \partial D, \quad \lambda \in \Lambda, \tag{2.10}
$$

with $\eta = (\eta_1, \cdots, \eta_d)$ being a normal direction to ∂D.

In § 2.1 we will give some properties of the finite difference operator (0.6). Next, we study the discrete HJB equations and its associated Markov chain. We present the main estimate in § 2.3 and then we give some comments and extensions.

2.1. The finite difference operator. Recall the operator (0.6),

$$
\begin{aligned}
L_h(\lambda)\varphi(x) = h^{-1} \sum_{k=1}^{n} \{ &\beta_k^+(x,\lambda,h)[\varphi(x+\gamma_k^+(x,\lambda,h)) - \varphi(x)] \\
&+ \beta_k^-(x,\lambda,h)[\varphi(x+\gamma_k^-(x,\lambda,h)) - \varphi(x)]\},
\end{aligned} \tag{2.11}
$$

where $\beta_k^\pm$, $\gamma_k^\pm$ are bounded Borel-measurable functions in x, λ for h fixed,

$$
\beta_k^\pm(x,\lambda,h) \geqq 0, \quad x + \gamma_k^\pm(x,\lambda,h) \in \mathcal{R}_h^d \quad \forall x \in \mathcal{R}_h^d, \quad \lambda \in \Lambda. \tag{2.12}
$$

The h-finite difference grid $\mathcal{R}_h^d$ is given, $0 < h \leqq 1$.

We denote

$$
L_h(k,\lambda)\varphi(x) = h^{-1}\{\beta_k^+[\varphi(x+\gamma_k^+) - \varphi(x)] + \beta_k^-[\varphi(x+\gamma_k^-) - \varphi(x)]\}, \tag{2.13}
$$

and

$$
\gamma_k^0 = (\beta_k^+ + \beta_k^-)^{-1}(\beta_k^+\gamma_k^+ + \beta_k^-\gamma_k^-), \tag{2.14}
$$

where the variables x, λ, h have been omitted.

We can rewrite

$$L_h(k,\lambda)\varphi(x) = h^{-1}\{\beta_k^+[\varphi(x+\gamma_k^+)-\varphi(x+\gamma_k^0)] + \beta_k^-[\varphi(x+\gamma_k^-)-\varphi(x+\gamma_k^0)]+(\beta_k^+ + \beta_k^-)[\varphi(x+\gamma_k^0)-\varphi(x)]\},$$

and when φ is smooth,

$$\varphi(x+\gamma_k^\pm)-\varphi(x+\gamma_k^0) = \sum_{i=1}^d (\gamma_{ik}^\pm - \gamma_{ik}^0)\int_0^1 \partial_i\varphi(x+\gamma_k^0+t(\gamma_k^\pm-\gamma_k^0))\,dt,$$

$$\varphi(x+\gamma_k^0)-\varphi(x) = \sum_{i=1}^d \gamma_{ik}^0 \int_0^1 \partial_i\varphi(x+t\gamma_k^0)\,dt,$$

with $\gamma_{ik}^\pm$, γ_{ik}^0 being the components of $\gamma_k^\pm$, γ_k^0. Using the fact that

$$\gamma_k^\pm - \gamma_k^0 = \pm\beta_k^\pm(\beta_k^+ + \beta_k^-)^{-1}(\gamma_k^+ - \gamma_k^-),$$

we have

$$\beta_k^+[\varphi(x+\gamma_k^+)-\varphi(x+\gamma_k^0)]+\beta_k^-[\varphi(x+\gamma_k^-)-\varphi(x+\gamma_k^0)]$$
$$= \beta_k^+\beta_k^-(\beta_k^+ + \beta_k^-)^{-2}\sum_{i,j=1}^d (\gamma_{ik}^+ - \gamma_{ik}^-)(\gamma_{jk}^+ - \gamma_{jk}^-)$$
$$\cdot \int_0^1 dt \int_{t\beta_k^+}^{t\beta_k^-} \partial_{ij}\varphi(x+\delta_k(s))\,ds,$$

where

$$\delta_k(s) = (\beta_k^+ + \beta_k^-)^{-1}[(\beta_k^+ - s)\gamma_k^+ + (\beta_k^- - s)]\gamma_k^-.$$

If

$$\chi_k(s) = \begin{cases} 2(\beta_k^+ + \beta_k^-)^{-1}[1 - s(\beta_k^-)^{-1}] & \text{if } s \geqq 0, \\ 2(\beta_k^+ + \beta_k^-)^{-1}[1 + s(\beta_k^+)^{-1}] & \text{if } s \leqq 0, \end{cases}$$

then

$$hL_h(k,\lambda)\varphi(x) = \frac{1}{2}\beta_k^+\beta_k^-(\beta_k^+ + \beta_k^-)^{-1}\sum_{i,j=1}^d (\gamma_{ik}^+ - \gamma_{ik}^-)(\gamma_{jk}^+ - \gamma_{jk}^-)$$
$$\cdot \int_{-\beta_k^+}^{\beta_k^-} \partial_{ij}\varphi(x+\delta_k(s))\chi_k(s)\,ds$$
$$+ \sum_{i=1}^d (\beta_k^+\gamma_{ik}^+ + \beta_k^-\gamma_{ik}^-)\int_0^1 \partial_i\varphi(x+t\gamma_k^0)\,dt. \tag{2.15}$$

Note that

$$\int_{-\beta_k^+}^{\beta_k^-} \chi_k(s)\,ds = 1$$

and that $\delta_k(s)$, γ_k^0 are convex combinations of γ_k^+ and γ_k^-.

Therefore, let us assume that for some constant $C > 0$ and any $i, j = 1, \cdots, d$, we have

$$\left|\sum_{k=1}^n [\sigma_{ik}\sigma_{jk}h - (\beta_k^+ + \beta_k^-)^{-1}\beta_k^+\beta_k^-(\gamma_{ik}^+ - \gamma_{ik}^-)(\gamma_{jk}^+ - \gamma_{jk}^-)]\right| \leqq C^2h^{3/2},$$

$$\left|g_ih - \sum_{k=1}^n (\beta_k^+\gamma_{ik}^+ + \beta_k^-\gamma_{ik}^-)\right| \leqq Ch^{3/2}, \tag{2.16}$$

$$|\gamma_{ik}^+| + |\gamma_{ik}^-| \leqq Ch^{1/2}$$

uniformly for the variables x in $\mathcal{R}_h^d$, λ in Λ, h in $(0, 1]$. Then we have the following estimate:

$$|L_h(\lambda)\varphi(x) - L(\lambda)\varphi(x)| \leqq C_\varphi h^{p/2} \quad \forall x, \lambda, h, \tag{2.17}$$

where C_φ is a constant depending only on the bounds of functions $g, \sigma, \partial_{ij}, \varphi$ and the Hölder-continuous constants of the second derivatives $\partial_{ij}\varphi$ with exponent $0 < p \leqq 1$, i.e., the constant $K(\partial_{ij}\varphi)$ of (2.4) for $\partial_{ij}\varphi$ in lieu of f.

Typical examples where the assumption (2.16) holds are the following cases: any $\gamma_{ik}^{\pm}$, $\beta_k^{\pm}$, g_{ik}, σ_{ik} satisfying

$$\begin{aligned}
&\gamma_{ik}^{\pm} = g_{ik}(x, \lambda, h)\beta_k^{-2}(x, \lambda, h)h \pm \sigma_{ik}(x, \lambda, h)\beta_k^{-1}(x, \lambda, h)\sqrt{h},\\
&\beta_k^{\pm} = \frac{1}{2}\beta_k(x, \lambda, h), \quad \beta_k(x, \lambda, h) > 0, \quad k = 1, \cdots, n,\\
&\left| g_i(x, \lambda) - \sum_{k=1}^{n} g_{ik}(x, h, \lambda) \right| \leqq Ch^{1/2},\\
&|\sigma_{ik}(x, \lambda)\sigma_{jk}(x, \lambda) - \sigma_{ik}(x, \lambda, h)\sigma_{jk}(x, \lambda, h)| \leqq Ch^{1/2},
\end{aligned} \tag{2.18}$$

uniformly in x, λ, h and for some constant $C > 0$. A more classic possibility is to choose $n = d$,

$$\gamma_{ik}^{\pm}(x, \lambda, h) = \begin{cases} \pm\sqrt{h} & \text{if } i = k,\\ 0 & \text{otherwise,} \end{cases} \tag{2.19}$$

and accordingly the coefficients $\beta_k^{\pm}(x, \lambda, h)$ to insure (2.16). Also, we may take $n = d + 1$,

$$\begin{aligned}
&\gamma_{ik}^{\pm} = \pm\sigma_{ik}(x, \lambda, h)\beta_k^{-1}(x, \lambda, h)\sqrt{h} \quad \text{if } k = 1, \cdots, n-1,\\
&\beta_k^{\pm} = \tfrac{1}{2}\beta_k(x, \lambda, h) > 0 \quad \text{if } k = 1, \cdots, n-1,\\
&\gamma_{in}^{\pm} = g_i(x, \lambda, h)\beta_n^{-2}(x, \lambda, h)h, \qquad \beta_n > 0,\\
&\beta_n^{\pm} = \beta_n(x, \lambda, h), \qquad \beta_n^{-} = 0, \quad \sigma_{in}(x, \lambda) = 0 \quad \forall\\
&|g_i(x, \lambda) - g_i(x, \lambda, h)| \leqq Ch^{1/2} \quad \forall i,\\
&|\sigma_{ik}(x, \lambda)\sigma_{jk}(x, \lambda) - \sigma_{ik}(x, \lambda, h)\sigma_{jk}(x, \lambda, h)| \leqq Ch^{1/2} \quad \forall i, jk, \quad k \neq n,
\end{aligned} \tag{2.20}$$

uniformly in x, λ, h for some constant $C > 0$.

When the differential operator (2.8) is degenerate with constant order of degeneration, i.e.,

$$L(\lambda) = \frac{1}{2}\sum_{i,j=1}^{m}\left(\sum_{k=1}^{n}\sigma_{ik}(\cdot, \lambda)\sigma_{jk}(\cdot, \lambda)\right)\partial_{ij} + \sum_{i=1}^{d} g_i(\cdot, \lambda)\partial_i, \tag{2.21}$$

where $0 \leqq m \leqq d$, $n \geqq 0$ and clearly $d - m$ is the order of degeneration, it is convenient to choose (2.18) or (2.20) instead of (2.19). In this case the constant C_φ of (2.17) will depend only on the constants $K(\partial_{ij}, \varphi)$ and bounds of $g, \sigma, \partial_{ij}\varphi$, for $i, j = 1, \cdots, m$.

Denote by $\mathcal{R}_h^d$ an h-finite difference grid in $\mathcal{R}^d$, i.e.,

$$\begin{aligned}
&\mathcal{R}_h^d = \{x = (x_1, \cdots, x_d) : \forall i = 1, \cdots, d, \exists k = 0, \pm 1, \cdots, \text{such that } x_i = hr_i(k)\},\\
&1 \leqq r_i(k) - r_i(k-1) < 2 \quad \forall k = 0, \pm 1, \cdots.
\end{aligned} \tag{2.22}$$

For the open bounded subset D of $\mathcal{R}^d$ we denote

$$D_h = \{x \in D \cap \mathcal{R}_h^d : x + \gamma_k^{\pm}(x, \lambda, h) \in \bar{D}, \forall \lambda, k\}, \tag{2.23}$$

and its boundary

$$\begin{aligned}&\Gamma_h = \cup\{\Gamma_k^+(\lambda)\cup\Gamma_k^-(\lambda)\colon \lambda, k\},\\ &\Gamma_k^\pm(\lambda) = \{x\in D\cap R_h^d\colon x+\gamma_k^\pm(x,\lambda,h)\in \bar{D}\cap \mathscr{R}_h^d \text{ and } x+\gamma_k^\mp(x,\lambda,h)\notin \bar{D}\cap\mathscr{R}_h^d\},\end{aligned} \tag{2.24}$$

for a fixed h in $(0, 1]$.

Under the assumptions (2.11), (2.12) we can easily prove the discrete maximum principle for the finite difference operator $L_h(\lambda)$. It is as follows. If a function $u_h(x)$ defined on $\bar{D}_h = D_h\cup\Gamma_h$ attains its maximum value at some point x_0, then

$$\begin{aligned}&\text{(i)}\quad \text{If } x_0\in D_h, \text{ then } L_h(\lambda)u_h(x_0)\leqq 0 \quad \forall\lambda\in\Lambda;\\ &\text{(ii)}\quad \text{If } x_0\in\Gamma_k^\pm(\lambda), \text{ then } \nabla_k^\pm(\lambda)u_h(x_0)\leqq 0,\end{aligned} \tag{2.25}$$

where $\nabla_k^\pm(\lambda)$ is the operator given by

$$\nabla_k^\pm(\lambda)\varphi(x) = h^{-1}\beta_k^\pm(x,\lambda,h)[\varphi(x+\gamma_k^\pm(x,\lambda,h))-\varphi(x)], \tag{2.26}$$

for any φ.

2.2. Study of the discrete equation. Here, we are interested in the discrete HJB equation (0.8), i.e., in finding a function $u_h(x)$, x in $\bar{D}_h$ such that

$$\alpha u_h = \inf\{L_h(\lambda)u_h + f(\cdot,\lambda)\colon \lambda\in\Lambda\} \quad \text{in } D_h, \quad u_h = 0 \quad \text{on } \Gamma_h, \tag{2.27}$$

where D_h, Γ_h, $\bar{D}_h$ are defined by (2.23), (2.24), and the finite difference operator $L_h(\lambda)$ is given by (2.11), (2.12).

First, we will associate an optimal control problem of a Markov chain to the HJB equation (2.27).

Let

$$G(\xi) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\xi}\exp\left(-\frac{t^2}{2}\right)dt, \qquad -\infty\leqq\xi\leqq+\infty, \tag{2.28}$$

and

$$\begin{aligned}&G(\tilde{\beta}_1^+) = \beta^{-1}\beta_1^+, \qquad G(\tilde{\beta}_1^-) = \beta^{-1}(\beta_1^+ + \beta_1^-),\\ &G(\tilde{\beta}_k^+) = \beta^{-1}(\beta_1^+ + \beta_1^- + \cdots + \beta_k^+), \qquad k = 2,\cdots,n,\\ &G(\tilde{\beta}_k^-) = \beta^{-1}(\beta_1^+ + \beta_1^- + \cdots + \beta_k^+ + \beta_k^-), \qquad k = 2,\cdots,n-1,\\ &\beta = \beta_1^+ + \beta_1^- + \cdots + \beta_n^+ + \beta_n^-, \quad \beta_0^- = -\infty, \quad \tilde{\beta}_n^- = +\infty\end{aligned} \tag{2.29}$$

where the variables x, λ, h have been omitted. For a random variable η with Gaussian density (2.28), we define the random fields $\xi_k^\pm(w) = \xi_k^\pm(x,\lambda,h;\eta)$ by

$$\xi_k^\pm(w) = \begin{cases}1 & \text{if } w\in A_k^\pm,\\ 0 & \text{otherwise}\end{cases} \tag{2.30}$$

where

$$\begin{aligned}&A_k^+ = \{w\colon \tilde{\beta}_{k-1}^- < \eta(w) < \tilde{\beta}_k^+\}, \qquad \tilde{\beta}_0^- = -\infty,\\ &A_k^- = \{w\colon \tilde{\beta}_k^+ < \eta(w) < \tilde{\beta}_k^-\}, \qquad k = 1, 2, \cdots, n.\end{aligned} \tag{2.31}$$

Suppose we are given a sequence $(\eta_i: i=1,2,\cdots)$ of independent random variables with the same Gaussian density (2.28) in a complete probability space $(\Omega, P, \mathcal{F})$. Then we consider the following controlled Markov chain:

$$
\begin{aligned}
X^{i+1} = X^i + \sum_{k=1}^{n} [&\gamma_k^+(X^i, \lambda(X^i), h)\xi_k^+(X^i, \lambda(X^i), h; \eta_{i+1}) \\
&+ \gamma_k^-(X^i, \lambda(X^i), h)\xi_k^-(X^i, \lambda(X^i), h; \eta_{i+1})], \qquad i=0,1,\cdots, \\
&X^0 \text{ given in } \mathcal{R}_h^d,
\end{aligned} \tag{2.32}
$$

where $\lambda = \lambda(\cdot)$ is a feedback control, i.e., a Borel-measurable function from $\mathcal{R}^d$ into Λ; actually it suffices that λ be defined only on $\mathcal{R}_h^d$.

A simple calculation shows that the transition probability operators of the Markov chain (2.32) is given by

$$
\begin{aligned}
&E\{\varphi(X^{i+1}) \mid X^i = x\} = \pi_h(\lambda(x))\varphi(x), \\
&\pi_h(\lambda)\varphi(x) = \beta^{-1}(x, \lambda, h) \sum_{k=1}^{n} [\beta_k^+(x, \lambda, h)\varphi(x + \gamma_k^+(x, \lambda, h)) \\
&\qquad + \beta_k^-(x, \lambda, h)\varphi(x + \gamma_k^-(x, \lambda, h))] \quad \forall \varphi, \\
&\beta(x, \lambda, h) = \sum_{k=1}^{n} [\beta_k^+(x, \lambda, h) + \beta_k^-(x, \lambda, h)] \quad \text{for any } x, \lambda, h.
\end{aligned} \tag{2.33}
$$

Standard arguments of the discrete optimal control theory (e.g., Bertsekas and Shreve [3], Gihkman and Skorokhod [10], Ross [32]) show that the optimal cost function

$$
\begin{aligned}
&u_h(x) = \inf\{J_h(x, \lambda): \lambda(\cdot) \text{ any feedback control}\}, \\
&J_h(x, \lambda) = E\left\{\sum_{i=0}^{\nu-1} hf(X^i, \lambda(X^i))[q_h(X^i, \lambda(X^i))]^i \mid X^0 = x\right\}, \\
&q_h(x, \lambda) = [h\alpha + \beta(x, \lambda, h)]^{-1}\beta(x, \lambda, h), \\
&\nu = \inf\{i=0,1,\cdots: X^i \in \Gamma_h\}
\end{aligned} \tag{2.34}
$$

satisfies the discrete HJB equation (2.27). Note that

$$
\begin{aligned}
&E\{X^{i+1} \mid X^i = x\} = x + \sum_{k=1}^{n} \gamma_k^0, \\
&\text{Var}\{X^{i+1} \mid X^i = x\} = \sum_{k,i,j} [(\gamma_k^+ - \gamma_i^0)(\gamma_k^+ - \gamma_i^0)^* + (\gamma_k^- - \gamma_i^0)(\gamma_k^- - \gamma_i^0)^*], \\
&\gamma_k^0 = \beta^{-1}(\beta_k^+\gamma_k^+ + \beta_k^-\gamma_k^-),
\end{aligned} \tag{2.35}
$$

which are related to the condition (2.16).

We remark that the random fields (2.30) possess the following property:

$$
\begin{aligned}
P\{w \in \Omega: \xi_k^{\pm}(x, \lambda, h; \eta(w)) \neq \xi_k^{\pm}(x', \lambda', h; \eta(w))\} &\leqq 2\beta^{-1}(x, \lambda, h) \\
&\cdot \sum_{k=1}^{n} [|\beta_k^+(x, \lambda, h) - \beta_k^+(x', \lambda', h)| + |\beta_k^-(x, \lambda, h) - \beta_k^-(x', \lambda', h)|],
\end{aligned} \tag{2.36}
$$

for any x, λ, h. All the above properties are useful for directly studying the dependence on the data of the optimal cost (2.34) (cf. [24]).

On the other hand, we can use the technique of barrier functions used in continuous time control problems (e.g., Lions [20], Lions and Menaldi [21]) to construct subsolutions of the discrete HJB equation; this method uses the assumptions (2.9) and (2.10). So, we suppose that:

(2.37) There exist functions $\bar{u}_h(x)$ defined on $\mathcal{R}^d$ that are bounded and Hölder-continuous uniformly in h with exponent $0<p\leqq 1$ such that for some constants $\beta_p \geqq 0$, $K>0$ we have $L_h(\lambda)\bar{u}_h \leqq -1+\beta_p \bar{u}_h$, in D_h, $\forall \lambda \in \Lambda$, $\bar{u}_h(x)=0$, $\forall x \in \Gamma_h$, $h\in(0,1]$, $|\bar{u}_h(x)-\bar{u}_h(x')| \leqq K|x-x'|^p$, $\forall x, x' \in \mathcal{R}^d$.

THEOREM 2.1. *Let us assume* (2.11), (2.12), (2.37). *Then for any bounded Borel-measurable function* $f(x,\lambda)$ *and any constant* $\alpha>0$ *there exist a unique solution of the discrete* HJB *equation* (2.27). *Moreover, for two data* $f, \tilde{f}$ we have

$$\|u_h-\tilde{u}_h\| \leqq \alpha^{-1}\|f-\tilde{f}\| \quad \forall h\in(0,1], \tag{2.38}$$

where $\tilde{u}_h$ *denotes the solution corresponding to* $\tilde{f}$ *and* $\|\cdot\|$ *is the supremum norm. Furthermore, if* $\alpha \geqq \beta_p$ *in* (2.37) *then*

$$|u_h(x)| \leqq \|f\|\bar{u}_h(x) \quad \forall x \in \bar{D}_h, \quad h\in(0,1]. \tag{2.39}$$

Proof. It is possible to use the Markov chain (2.32) to establish the results as in [24], but we prefer to illustrate its analytic counterpart.

First of all, we rewrite the discrete HJB equation (2.27) as

$$u_h = \inf\{g_h(\cdot,\lambda)\pi_h(\lambda)u_h + f_h(\cdot,\lambda) : \lambda\in\Lambda\} \quad \text{in } D_h, \quad u_h=0 \quad \text{on } \Gamma_h, \tag{2.40}$$

where

$$f_h(x,\lambda) = h[h\alpha+\beta(x,\lambda,h)]^{-1}f(x,\lambda), \tag{2.41}$$

and $\pi_h(\lambda)$, $\beta(x,\lambda,h)$, $q_h(x,\lambda)$ are defined by (2.33), (2.34). If we denote by $T_h(u_h)$ the right-hand side of (2.40), then T_h is a contraction mapping on the space of bounded Borel-measurable functions from $\bar{D}_h$ onto $\mathcal{R}$ (actually just functions, since $\bar{D}_h$ is a finite set) with the norm

$$\|v\| = \sup\{|v(x)| : x\in\bar{D}_h\}. \tag{2.42}$$

Hence there exists a unique solution to (2.40).

Since we can express for any u_h^0 given the following:

$$u_h = \lim_{i\to\infty} u_h^i, \quad u_h^{i+1} = T_h(u_h^i), \quad i=0,1,\cdots,$$

we easily deduce (2.38), where $\|\cdot\|$ denotes the supremum norm in the corresponding space, i.e., for $\|f\|$ we take the supremum over $\bar{D}_h\times\Lambda$ or $\mathcal{R}_h^d\times\Lambda$.

To check (2.39), we use the discrete maximum principle on the function $w = \pm u_h - \|f\|\bar{u}_h$. □

Consider the extended finite difference operator $\tilde{L}_h(\lambda)$ given by

$$\begin{aligned}
&\tilde{L}_h(\lambda)(x,y) = h^{-1}\sum_{k=1}^{n}[\tilde{L}_h^+(k,\lambda)\varphi(x,y)+\tilde{L}_h^-(k,\lambda)\varphi(x,y)],\\
&h\tilde{L}_h^{\pm}(k,\cdot)\varphi(x,y) = p_k^{\pm}(x,y,h)[\varphi(x+\gamma_k^{\pm}(x,h), y+\gamma_k^{\pm}(y,h))-\varphi(x,y)]\\
&\qquad\qquad + q_k^{\pm}(x,y,h)[\varphi(x+\gamma_k^{\pm}(x,h), y)-\varphi(x,y)]\\
&\qquad\qquad + q_k^{\pm}(y,x,h)[\varphi(x,y+\gamma_k^{\pm}(y,h))-\varphi(x,y)],
\end{aligned} \tag{2.43}$$

where

$$
\begin{aligned}
&p_k^{\pm}(x, y, \lambda, h) = \beta_k^{\pm}(y, \lambda, h), \quad \wedge = \text{minimum}, \\
&q_k^{\pm}(x, y, \lambda, h) = \beta_k^{\pm}(x, \lambda, h) - \beta_k^{\pm}(x, \lambda, h) \wedge \beta_k^{\pm}(y, \lambda, h).
\end{aligned} \tag{2.44}
$$

Note that our choice implies that

$$
\tilde{L}_h(\lambda)[\varphi(x) + \psi(y)] = L_h(\lambda)\varphi(x) + L_h(\lambda)\psi(y), \tag{2.45}
$$

for any functions $\varphi(x)$, $\psi(y)$, and $L_h(\lambda)$ as in (2.11), (2.12). It is clear that

$$
\alpha_p(h) = \sup\{m(x-y, -p, h)\tilde{L}_h(\lambda)m(x-y, h): x, y \in \mathscr{R}_h^d, \lambda \in \Lambda\}, \tag{2.46}
$$

is finite, for h in $(0, 1]$, $0 < p \leqq 1$, and

$$
m(x, p, \varepsilon) = (\varepsilon + |x|^2)^{p/2}, \qquad x \in \mathscr{R}^d, \quad \varepsilon > 0. \tag{2.47}
$$

Suppose that (2.1), (2.16), and

$$
\begin{aligned}
&|\beta_k^{\pm}(x, \lambda, h) - \beta_k^{\pm}(y, \lambda, h)| \leqq K|x-y|, \\
&|\gamma_k^{\pm}(x, \lambda, h) - \gamma_k^{\pm}(y, \lambda, h)| \leqq Kh^{1/2}|x-y|, \\
&|q_k^{+}(x, y, h)\gamma_k^{+}(x, \lambda, h) + q_k^{-}(x, y, \lambda, h)\gamma_k^{-}(x, \lambda, h)| \leqq Kh|x-y|,
\end{aligned} \tag{2.48}
$$

for some constant $K > 0$, uniformly for the variables x, y in $\mathscr{R}_h^d$, λ in Λ, h in $(0, 1]$, $k = 1, 2, \cdots, n$, hold true. Then, for some constant C depending on the various constants of the hypotheses (2.1), (2.16), and (2.48), we have

$$
\alpha_p(h) \leqq \alpha_p + Ch^{p/2}, \qquad p > 0, \tag{2.49}
$$

where

$$
\begin{aligned}
\alpha_p = k \sup \Bigg\{ & |x-y|^{-2} \sum_{i=1}^{d} [g_i(x, \lambda) - g_i(y, \lambda)](x_i - y_i) \\
& + (p \vee 1)|x-y|^4 \sum_{k=1}^{n} \sum_{i,j=1}^{d} (x_i - y_i)(x_j - y_j)[\sigma_{ik}(x, \lambda) - \sigma_{jk}(y, \lambda)] \\
& \cdot [\sigma_{jk}(x, \lambda) - \sigma_{jk}(y, \lambda)] + |x-y|^{-2} \sum_{k=1}^{n} \sum_{i=1}^{d} [\sigma_{ik}(x, \lambda) - \sigma_{ik}(x, \lambda)]^2 : \\
& x \neq y' \text{ in } \mathscr{R}^d, \lambda \text{ in } \Lambda \Bigg\}.
\end{aligned} \tag{2.50}
$$

Note that $\alpha_p(h)$ and α_p vanish as p goes to zero. The condition (2.48) is almost equivalent to the Lipschitz condition of (2.1), i.e., that (2.16) and (2.48) imply (2.1) and (2.48) is expected to hold if we wish to insure (2.1).

THEOREM 2.2. *Under the assumptions* (2.4), (2.11), (2.12), (2.37), *and*

$$
\alpha > \max\{\alpha_p(h), \beta_p\} \quad \forall h \in (0, 1], \tag{2.51}
$$

the unique solution u_h *to the discrete* HJB *equation* (2.27) *satisfies*

$$
|u_h(x) - u_h(y)| \leqq K|x-y|^p \quad \forall x, y \in \bar{D}_h, \quad h \in (0, 1], \tag{2.52}
$$

for some constant K depending only on the various constants appearing in the hypotheses (2.4), (2.37), *and* (2.51).

Proof. Consider the function

$$
w(x, y) = u_h(x) - u_h(y) - Km(x-y, h, p),
$$

where $m(\cdot,\cdot,\cdot)$ is given by (2.47) and $K>0$ is a constant to be selected later. We want to show that $w(x,y)\leqq 0$ at any point x, y of $\bar{D}_h$, which implies (2.52), since $|x-y|\geqq h$, if $x\neq y$. Let (x_0, y_0) be a point in $\bar{D}_h\times\bar{D}_h$ where the function $w(x,y)$ attains its maximum value; such a point exists always. If either $x_0\in\Gamma_h$ or $y_0\in\Gamma_h$ then $w(x_0,y_0)\leqq 0$ provided $K\geqq\|f\|K(\bar{u}_h)$, the constant of (2.37). Herein we have used the estimate (2.39). Let us look at the case when x_0, y_0 belong to D_h.

By means of the discrete maximum principle for the extended operator $\tilde{L}_h(\lambda)$ we have $\tilde{L}_h(\lambda)w(x_0,y_0)\leqq 0$, which implies

$$L_h(\lambda)u_h(x_0)-L_h(\lambda)u_h(y_0)\leqq K\tilde{L}_h(\lambda)m(x_0-y_0,h,p)$$

after using (2.45). If we choose $0<\alpha_0\leqq\alpha-\alpha_p(h)$, for any h in $(0,1]$, then in view of (2.46) we get

$$\tilde{L}_h(\lambda)m(x_0-y_0,p,h)\leqq(\alpha-\alpha_0)m(x_0-y_0,p,h)$$

for any l in Λ. Since u_h satisfies the discrete HJB equation (2.27) at x_0 and y_0, we deduce

$$\begin{aligned}\alpha[u_h(x_0)-u_h(y_0)]&\leqq\sup\{|f(x_0,\lambda)-f(y_0,\lambda)|:\lambda\in\Lambda\}\\&\quad+K\sup\{\tilde{L}_h(\lambda)m(x_0-y_0,p,h):\lambda\in\Lambda\}\\&\leqq[K(f)+(\alpha-\alpha_0)K]m(x_0-y_0,p,h)\end{aligned}$$

where $K(f)$ is the constant of hypothesis (2.4). Hence if we take $K=\alpha_0^{-1}K(f)$, then $w(x_0,y_0)\leqq 0$, i.e.,

$$u_h(x)-u_h(y)\leqq Km(x-y,p,h)\quad\forall x,y\in\bar{D}_h,\quad h\in(0,1].$$

Thus, the estimate (2.52) follows. □

Remark 2.1. Note that in the assumption (2.51) we suppose implicitly that (2.16) and (2.48) hold true.

2.3. Main estimate. Let us look at the continuous time HJB equation (2.7), i.e.,

$$\alpha u=\inf\{L(\lambda)u+f(\cdot,\lambda):\lambda\in\Lambda\}\quad\text{in } D,\quad u=0\quad\text{on }\partial D, \tag{2.53}$$

where the differential operator is

$$L(\lambda)=\sum_{i,j=1}^{d}a_{ij}(\cdot,\lambda)\partial_{ij}+\sum_{i=1}^{d}a_i(\cdot,\lambda)\partial_i, \tag{2.54}$$

and we have identified the coefficients

$$\begin{aligned}&\sum_{k=1}^{n}\sigma_{ik}(x,\lambda)\sigma_{jk}(x,\lambda)=2a_{ij}(x,\lambda)\quad\forall x\in\bar{D},\quad\lambda\in\Lambda,\\&g_i(x,\lambda)=a_i(x,\lambda)\quad\forall x\in\bar{D},\quad\lambda\in\Lambda.\end{aligned} \tag{2.55}$$

Suppose that

$$\begin{aligned}&D\text{ is a bounded domain in }\mathcal{R}^d\text{ with smooth boundary }\partial D,\text{ say }C^{2,p}\text{ for}\\&\text{some }0<p\leqq 1,\end{aligned} \tag{2.56}$$

and

$$\begin{aligned}&\alpha\geqq 0,\text{ and for some }\nu_0>0\text{ we have }\nu_0|x|^2\leqq\textstyle\sum_{i,j=1}^{d}a_{ij}(x,\lambda)\xi_i\xi_j\leqq\nu_0^{-1}|\xi|^2,\\&\forall x\in\bar{D},\ \lambda\in\bar{D},\ \lambda\in\Lambda,\ \xi\in\mathcal{R}^d.\end{aligned} \tag{2.57}$$

It has been proven independently by Evans [7] and Krylov [14] (cf. Gilbarg and Trudinger [11]) that under the assumptions (2.56), (2.57), and

$$a_{ij},\ a_i,\ f\text{ are smooth, say }C^3\text{ in }x\text{ uniformly in }\lambda, \tag{2.58}$$

the HJB equation (2.53) has a unique classic solution, which is continuous on the closure $\bar{D}$ and its first- and second-order derivatives are Hölder-continuous for some exponent $0<p_0<1$ on the open domain D.

This result has been improved by Krylov [15] to show that under the same assumptions, the first- and second-order derivatives of the solution u are indeed Hölder-continuous on the closure $\bar{D}$.

Then an almost optimal result due to Safonov [34] provides an equivalent of Schauder estimates for HJB equations. Precisely, under the assumptions (2.56), (2.57), and

$$\|\varphi\|_{(p)} \leqq K \quad \forall \varphi = a_{ij}(\cdot, \lambda), a_i(\cdot, \lambda) \quad \forall \lambda \in \Lambda, \tag{2.59}$$

where $\|\cdot\|_{(p)}$ denotes the Hölder norm in $C^p(\bar{D})$, $0<p\leqq 1$, there exists a constant $p_0(\nu_0, d)$ in $(0, 1]$ such that the estimate

$$\|u\|_{(2+p)} \leqq C \sup\{\|f(\cdot, \lambda)\|_{(p)}: \lambda \in \Lambda\}, \tag{2.60}$$

holds for some constant C depending only in K, ν_0, p and the domain D, provided $0<p<p_0(\nu_0, d)$. Note that $\|\cdot\|_{(2+p)}$ denotes the Hölder norm in the space $C^{2,p}(\bar{D})$.

Another case in the quasilinear equation is

$$a_{ij}(x, \lambda) = a_{ij}(x) \quad \forall x \in \bar{D} \quad \forall \lambda \in \Lambda. \tag{2.61}$$

Thus we do not control the diffusion term. Under the conditions (2.56), (2.57), (2.59), and (2.61) the estimate (2.60) holds for every $0<p<1$ (cf. Ladyzhenskaya and Uraltseva [19]).

It is known (cf. Lions [20], Lions and Menaldi [21], Krylov [13]) that under the assumptions (2.1), (2.4), (2.9), and (2.10) the HJB equation (2.53) has a unique solution in some weak sense, e.g., either as the maximum subsolution with $L(\lambda)$ acting in the Schwarz distributions sense or as the unique viscosity solution. Moreover, if we denote by u_ε the solution of the HJB equation (2.53) with $L(\lambda)$ replaced by $L(\lambda)+\varepsilon\Delta$, Δ the Laplacian operator, then we can assert that

$$u_\varepsilon \in C^2(\bar{D}), \quad u_\varepsilon \to u \quad \text{in } C(\bar{D}), \tag{2.62}$$

where $C(\bar{D})$ is the space of continuous functions on $\bar{D}$.

For a smooth function φ, say $C^{2,p}(\bar{D})$, $0<p\leqq 1$, let us define $[\varphi]_p$ as the infimum of the set of all constant C satisfying

$$\begin{aligned} &\inf\{L(\lambda)\varphi(y): |y-x| \leqq C\sqrt{h}\} - Ch^{p/2} \leqq L_h(\lambda)\varphi(x) \\ &\qquad \leqq \sup\{L(\lambda)\varphi(y): |y-x| \leqq C\sqrt{h}\} + Ch^{p/2} \quad \forall h \in (0, 1], \end{aligned} \tag{2.63}$$

for any x in D_h, λ in Λ.

It is clear that $[\varphi]_p$ can be bounded by the constant C_φ of the estimate (2.17). However, occasionally we can do better:

(i) $[\varphi]_1$ is dominated by the bounds of the second-order derivatives of φ and the constants $C(g, \sigma)$, $K(g, \sigma)$, C of hypotheses (2.1), (2.16), provided $n=1$. This means that only one-dimensional Brownian motion is allowed, e.g., the system associated with an equation of order d perturbed by a white noise.

(ii) If $\sigma = \sigma(\lambda)$ and $n=1$, i.e., constant in x and only one Brownian motion, and

$$\sigma_{i1}\sigma_{j1}h = (\beta_1^+ + \beta_1^-)^{-1}\beta_1^+\beta_1^-(\gamma_{i1}^+ - \gamma_{i1}^-)(\gamma_{j1}^+ - \gamma_{j1}^-) \quad \forall i, j, \lambda,$$

then $[\varphi]_p$ is dominated by the p-Hölder norm of the first-order derivatives of φ and the constants $C(g, \sigma)$, $K(g, \sigma)$,

(iii) If $g=0$ and (ii) holds, then $[\varphi]_1$ is dominated by the bound of σ and does not depend on φ.

THEOREM 2.3. *Let the assumptions* (2.1), (2.4), (2.9)-(2.12), (2.16), (2.37), (2.48), *and*

$$\alpha > \max\{\alpha_p, \beta_p\}, \qquad 0 < p \leqq 1 \tag{2.64}$$

hold true. Then there exists a constant $C>0$ *depending only on the various constants of the hypotheses* (2.4), (2.37), (2.48), (2.64), *and* $[u]_p$ *as in* (2.63), *such that*

$$|u_h(x)-u(x)| \leqq Ch^{p/2} \quad \forall x \in \bar{D}_h, \quad h \in (0,1], \tag{2.65}$$

where u_h *is the solution of the discrete* HJB *equation* (2.27) *and* u *is the viscosity solution of the* HJB *equation* (2.53).

Proof. We remark that we are using (2.62) to suppose $[u]_p$ finite and defined as the limit of $[u_\varepsilon]_p$.

First, we will give a proof where the constant C of (2.65) depends on the C_φ, $\varphi = u$ of the convergence property (2.17), i.e., the p-Hölder norm of the second-order derivatives of u. This argument uses implicitly the discrete maximum principle in a way similar to Lions and Mercier [22].

Indeed, let us define the nonlinear resolvent operators

$$R(\varphi) = v \text{ iff } v=0 \text{ on } \partial D \text{ and } \alpha v = \varphi + \inf\{L(\lambda)v + f(\cdot,\lambda): \lambda \in \Lambda\} \text{ in } D, \tag{2.66}$$

and

$$\begin{aligned} &R_h(\varphi_h) = v_h \text{ iff } v_h = 0 \text{ on } \Gamma_h \text{ and} \\ &\alpha v_h = \varphi_h + \inf\{L_h(\lambda)v_h + f(\cdot,\lambda): \lambda \in \Lambda\} \text{ in } D_h. \end{aligned} \tag{2.67}$$

It is clear that if u_h and u denote the solutions to the HJB equations (2.27) and (2.53), then

$$u_h - u = R_h(0) - R(0) = R_h[R^{-1}(R(0))] - R_h[R_h^{-1}(R(0))],$$

where R^{-1} and R_h^{-1} are the inverse operators. By means of Theorem 2.1, the inequality (2.38) gives

$$\|R_h(\varphi) - R_h(\psi)\| \leqq \alpha^{-1}\|\varphi - \psi\| \quad \forall h \in (0,1],$$

for any functions φ, ψ and with $\|\cdot\|$ denoting the supremum norm on $\bar{D}_h$. Hence

$$\|u_h - u\| \leqq \alpha^{-1}\|R^{-1}(u) - R_h^{-1}(u)\|.$$

Since we can bound

$$\begin{aligned} |R^{-1}(u) - R_h^{-1}(u)| &= |\inf\{L(\lambda)u + f(\cdot,\lambda): \lambda \in \Lambda\} - \inf\{L_h(\lambda)u + f(\cdot,\lambda): \lambda \in \Lambda\}| \\ &\leqq \sup\{|L(\lambda)u - L_h(\lambda)u|: \lambda \in \Lambda\} \leqq C_u h^{p/2}, \end{aligned}$$

where C_u is the constant in (2.17), we deduce the estimate (2.65) with $C = \alpha^{-1}C_u$.

Next, to fully prove (2.65) we will show first that

$$|u(x)| \leqq C[\operatorname{dist}(x, \partial D)]^p \quad \forall x \in \bar{D}, \tag{2.68}$$

$$|u(x) - u(y)| \leqq K|x-y|^p \quad \forall x, y \in \bar{D}, \tag{2.69}$$

for some constants C, K depending only on the various constants of (2.4), (2.9), (2.10), and (2.64). To that effect, we construct a p-Hölder-continuous subsolution $\bar{u}$, i.e., a function $\bar{u}$ satisfying in a weak sense,

$$\begin{aligned} &L(\lambda)\bar{u} \leqq -1 + \beta_p \bar{u} \quad \text{in } D, \quad \bar{u} = 0 \quad \text{on } \partial D, \\ &|\bar{u}(x) - \bar{u}(y)| \leqq K|x-y|^p \quad \forall x, y \in \bar{D}, \end{aligned} \tag{2.70}$$

for some constants $K = K(\bar{u})$, $\beta_p \geqq 0$, as in (2.37). The maximum principle applied to the function

$$w(x) = \pm u(x) - \|f\| \bar{u}(x)$$

yields $w(x) \leqq 0$, i.e., (2.68).

To obtain (2.69) we proceed as in Theorem 2.2. We consider the extended differential operator

$$\begin{aligned} \tilde{L}(\lambda) = \frac{1}{2} \sum_{i,j=1}^{d} \sum_{k=1}^{n} [& \sigma_{ik}(x,\lambda)\sigma_{jk}(x,\lambda)\partial_{ij}^{x} + \sigma_{ik}(x,\lambda)\sigma_{jk}(y,\lambda)\partial_{ij}^{xy} \\ & + \sigma_{ik}(y,\lambda)\sigma_{jk}(x,\lambda)\partial_{ij}^{yx} + \sigma_{ik}(y,\lambda)\sigma_{jk}(y,\lambda)\partial_{ij}^{y} \\ & + \sum_{i=1}^{d} [g_i(x,\lambda)\partial_i^x + g_i(y,\lambda)\partial_i^y]], \end{aligned} \tag{2.71}$$

where ∂_{ij}^{x} and ∂_{ij}^{xy} denote the derivatives with respect to x_i, x_j and x_i, y_j, respectively. A simple calculation shows that

$$\tilde{L}(\lambda) m(x-y, p, \varepsilon) \leqq \alpha_p m(x-y, p, \varepsilon) \quad \forall x, y \in \mathcal{R}^d, \quad \lambda \in \Lambda, \tag{2.72}$$

any $\varepsilon > 0$ and with α_p being the constant (2.50). The function $m(\cdot, \cdot, \cdot)$ is given by (2.47).

Now, define the function

$$w(x, y) = u(x) - u(y) - Km(x-y, p, \varepsilon),$$

for some constant $K > 0$ to be selected. Let (x_0, y_0) be a point in $\bar{D} \times \bar{D}$ where $w(x, y)$ attains its maximum values. We want to prove that $w(x_0, y_0) \leqq 0$, which implies (2.69) as ε vanishes. In fact, if either $x_0 \in \partial D$ or $y_0 \in \partial D$, then $w(x_0, y_0) \leqq 0$ provided $K \geqq C(u)$, the constant in (2.68). So, if x_0, y_0 belong to D, then the maximum principle yields $\tilde{L}(\lambda) w(x_0, y_0) \leqq 0$, i.e.,

$$L(\lambda)u(x_0) - L(\lambda)u(y_0) \leqq K\tilde{L}(\lambda) m(x_0 - y_0, p, \varepsilon).$$

In view of the HJB equation (2.53) and the inequality (2.72) we get

$$\begin{aligned} \alpha[u(x_0) - u(y_0)] &\leqq \sup\{|f(x_0, \lambda) - f(y_0, \lambda)| : \lambda \in \Lambda\} \\ &\quad + K \sup\{\tilde{L}(\lambda) m(x_0 - y_0, p, \varepsilon) : \lambda \in \Lambda\} \\ &\leqq [K(f) + \alpha_p K] m(x_0 - y_0, p, \varepsilon), \end{aligned}$$

where $K(f)$ is the constant of hypotheses (2.4). Hence, take $K = (\alpha - \alpha_p)^{-1} K(f)$ to obtain $w(x_0, y_0) \leqq 0$.

Let us prove the estimate (2.65). To that effect, we consider the function

$$w(x, y) = u_h(x) - u(y) - C_1 m(x-y, p, h) - C_2 h^{p/2},$$

for any x, y in $\bar{D}_h$, and some constants $C_1, C_2 > 0$ to be selected. We want to show that at the point (x_0, y_0) in $\bar{D}_h \times \bar{D}_h$ where $w(x, y)$ attains its maximum value, we have $w(x_0, y_0) \leqq 0$, from which (2.65) follows immediately. Indeed if either $x_0 \in \Gamma_h$ or $y_0 \in \Gamma_h$ then $w(x_0, y_0) \leqq 0$, provided $C_1 = \max\{K(u_h), K(u)\}$, the p-Hölder constants given by (2.52) and (2.69). Actually, the constants in (2.39) and (2.68) suffice, i.e., p-Hölder constants near the boundary. When $x_0, y_0 \in D_h$, we can use the discrete maximum principle for the extended operator $\tilde{L}_h(\lambda)$, defined by (2.43), to get $\tilde{L}_h(\lambda) w(x_0, y_0) \leqq 0$, i.e.,

$$L_h(\lambda)u_h(x_0) - L_h(\lambda)u(y_0) \leqq C_1 \tilde{L}_h(\lambda) m(x_0 - y_0, p, h).$$

In view of the discrete HJB equation (2.27) we get

$$L_h(\lambda)u_h(x_0) - L_h(\lambda)u(y_0) \geqq \alpha u_h(x_0) - [L(\lambda)u(y) + f(y, \lambda)] + [L(\lambda)u(y) - L_h(\lambda)u(y_0)] + [f(y, \lambda) - f(x_0, \lambda)].$$

Thus, by taking the supremum over λ in Λ and y such that

$$|y - y_0| \leqq [u]_p \sqrt{h},$$

we deduce

$$\alpha[u_h(x_0) - u(y_0)] - [u]_p h^{p/2} - [\alpha K(u) + K(f)](1 + [u]_p^p) m(x_0 - y_0, p, h) \leqq \alpha_p(h) C_1 m(x_0 - y_0, p, h),$$

after using the definition (2.46) and (2.63), and the p-Hölder constants $K(f)$, $K(u)$ of (2.4), (2.69). Since we need only to show (2.65) for $h > 0$ sufficiently small, the hypothesis (2.64) and the inequality (2.49) permit us to choose

$$C_1 \geqq [\alpha - \alpha_p(h)]^{-1}(1 + [u]_p^p)[\alpha K(u) + K(f)],$$

$$C_2 = \alpha^{-1}[u]_p,$$

in order to have $w(x_0, y_0) \leqq 0$, i.e.,

$$u_h(x) - u(y) \leqq C m(x - y, p, h) \quad \forall x, y \in \mathcal{R}_h^d, \quad h \in (0, 1],$$

where $C = a + C_2$; this implies one side of (2.65).

By symmetry we obtain (2.65) after using the estimate (2.52) of Theorem 2.2. □

2.4. Final comments. Sometimes we need to discretize the set Λ, where the control takes values. In this case, a new term of the form

$$\sup\{\inf\{|l(x, \lambda) - l(x, \lambda')|: \lambda' \in \Lambda(h)\}: x \in \mathcal{R}^d, \lambda \in \Lambda\}, \tag{2.73}$$

for $l = f$, g_i, σ_{ik}, $i = 1, \cdots, d$, $k = 1, \cdots, n$, will appear in the right-hand side of the estimate (2.65). Here $\Lambda(h)$ is a discretization of Λ. Also, the constant α could be a function $\alpha(x, \lambda)$, for which the preceding results extend. If the domain D is unbounded and the data f has polynomial growth, then the solutions $u(x)$, $u_h(x)$ will have also polynomial growth, and some weight function is needed to obtain an estimate similar to (2.65) (cf. [24]).

We may be interested in the performance of the optimal control of the discrete problem, when suitably extended and applied to the initial problem. That issue is not considered here. However, the optimizer will face the problem of actually computing $u_h(x)$. In general, only an approximation $\tilde{u}_h(x)$ is computed and from that, a control policy $\tilde{\lambda}_h(\cdot)$ is derived. This $\tilde{\lambda}_h(\cdot)$ allows us to simulate a trajectory $\tilde{y}_h(\cdot)$. To this policy $(\tilde{\lambda}_h(\cdot), \tilde{y}_h(\cdot))$ a new cost $\hat{u}_h(x)$ is associated. Then, starting from (2.65) we need really to estimate $|\tilde{u}_h(x) - \hat{u}_h(x)|$. Again, this issue is not addressed here.

As mentioned in the theorems, the assumption on uniform ellipticity (2.57) is not required, at least explicitly. For instance, the case of a one-dimensional Brownian motion can be considered. This includes the control of a one-dimensional ordinary equation of order n, perturbed by a white noise.

We have assumed (2.10) for simplicity and to have the Dirichlet condition on the whole boundary ∂D. However, we need only to correctly identify the part Γ of the boundary where the diffusion process exists, and then we can use the technique described in this paper. This requires supposing that the operator $L(\lambda)$ is degenerate with constant order of degeneration, i.e., (2.21).

From the practical point of view, the estimate $h^{1/2}$ is not relevant, since better results are usually expected. However, this gives a precise relation between the grid for the space variable and the control variable, when $\Lambda(h)$ is used. The constant $\alpha_p(h)$ defined by (2.46) plays an important role in the stability of the numerical schemes. This is not obtained in classical schemes.

Perhaps the most interesting part is the fact that the finite difference operator (0.6) does not require any condition of "stability." It is stable in nature, and most estimates valid for the differential operator (0.5) have an equivalent in the discrete case.

In Bancora-Imbert, Chow, and Menaldi [1], the numerical solution of an optimal correction problem for a damped random linear oscillator is studied. The HJB equation takes the form of a variational inequality, namely,

$$\begin{aligned} &\partial_t u + Lu \geqq 0 \quad \text{in } \mathcal{R}_2 \times [0, T), \qquad -c \leqq \partial_2 u \leqq c \quad \text{in } \mathcal{R}_2 \times [0, T), \\ &(\partial_t u + Lu)(\partial_2 u + c)(\partial_2 u - c) = 0 \quad \text{in } \mathcal{R}_2 \times [0, T), \\ &u(\cdot, T) = f \quad \text{in } \mathcal{R}_2, \end{aligned} \tag{2.74}$$

where the differential operator is given by

$$Lu(x_1, x_2, t) = \tfrac{1}{2} r^2 \partial_2^2 u(x_1, x_2, t) - (px_2 + q^2 x_1)\partial_2 u(x_1, x_2, t) + x_2 u(x_1, x_2, t),$$

and r, p, q, c are constants; $r, q, c > 0$; and f is a given function. A precise algorithm is described and used there. The solution of the discrete problem is found as the common limit of two sequences, one decreasing and the other increasing. This allows us to bound the error and to give an almost optimal policy. We refer also to Sun and Menaldi [37], [25]. Note that in the case of (2.74), the solution u is Lipschitz-continuous together with its second derivative in the x_2 variable.

In a subsequent paper, the (quasi-) variational inequalities will be studied. It is well known that for those problems the solution is not smooth, i.e., the second derivative must have a jump. For that reason, only the second approach of Theorem 2.3, i.e., using $[u]_p$, seems to be appropriate. Perhaps a combination with finite elements of the type used by Menaldi and Rofman [26], [23] could be of some help.

Acknowledgments. The author thanks Professor P. L. Chow for the useful discussions on this work and the reviewers for the opportunity to improve the first version of the paper.

ASYMPTOTIC PROPERTIES OF OPTIMAL SOLUTIONS IN PLANAR DISCOUNTED CONTROL PROBLEMS*

FRITZ COLONIUS†‡ AND MALTE SIEVEKING†

Abstract. The classical Poincaré-Bendixson Theorem on limit sets of solutions of planar differential equations is generalized to solutions of planar optimal control problems maximizing a discounted present value that does not depend explicitly on the control function.

Key words. infinite horizon optimal control, Poincaré-Bendixson Theorem, optimal resource management

AMS(MOS) subject classifications. 49D50, 49A99, 34C25, 92A15

1. Introduction. The main result of this paper is a generalization of the classical Poincaré-Bendixson Theorem for the following class of optimal control problems (P) (with $n=2$):

$$\text{(1.1)} \qquad \text{Maximize} \quad \int_0^\infty e^{-\delta t} R(x(t))\, dt,$$

subject to

$$\text{(1.2)} \qquad \dot{x}_j(t) = x_j(t)\left[f_0^j(x(t)) + \sum_{i=1}^m u_i(t) f_i^j(x(t)) \right] \quad \text{a.a. } t \in \mathbb{R}_+, \quad j = 1, \cdots, n,$$

$$\text{(1.3)} \qquad u(t) = (u_i(t)) \in \Omega \subset \mathbb{R}^m \quad \text{a.a. } t \in \mathbb{R}_+,$$

$$\text{(1.4)} \qquad x(0) = x \in \mathbb{R}_+^n;$$

here $\delta > 0$ and $R : \mathbb{R}_+^n \to \mathbb{R}$, $f_i = (f_i^j) : \mathbb{R}_+^n \to \mathbb{R}$ are locally Lipschitz continuous, the set Ω of control values is compact and convex, and the control functions are chosen in

$$\text{(1.5)} \qquad U_{\text{ad}} = U_{\text{ad}}(\mathbb{R}_+) := \{u : \mathbb{R}_+ \to \Omega, \text{ measurable}\}.$$

Thus we consider discounted optimal control problems where the integral of the performance index does not depend explicitly on the control, and the system equation has the "ecological form" (1.2) with control appearing linearly. Our original motivation for considering asymptotic properties of optimal solutions comes from bioeconomics. Here the study of such problems is often decomposed into two parts.

First an optimal equilibrium point e is searched for and then a determination optimal approach path from the initial point x_0 to e is tried (compare, e.g., Clark [5, p. 317]). This approach is justified in the case of a single-state variable ($n=1$), since here, in general, bounded solution $x(\cdot)$ of (P) converge monotonically to an optimal equilibrium as t tends to $+\infty$ (see Theorem 2.7 below). For two state variables ($n=2$) the classical Poincaré-Bendixson Theorem describes the asymptotic behavior of the special class of (uncontrolled) differentiable dynamical systems; here the limit set $\omega(x)$ of a trajectory either is a periodic trajectory or consists of trajectories connecting

equilibria. The Poincaré-Bendixson theorem generalizes within the framework of local (nondifferentiable) dynamical systems (see Hajek [10]). However, optimal solutions of (P) are not, in general, unique (cf. the examples given in § 6 below). Hence they need not form a local dynamical system. Nevertheless, the present paper shows that the Poincaré-Bendixson Theorem can be generalized to optimal control problems of the type above. The problem of nonuniqueness must be met at the following crucial steps in the reconstruction of the classical argument for proving the Poincaré-Bendixson Theorem.

(1) We want to form Jordan arcs from parts of solutions; however, solutions may be self-intersecting. This problem is solved via the optimality principle: if an optimal solution x returns at time $t_2 > t_1$ into the same state as at time t_1, then it is also optimal to run through the same piece of trajectory $x|[t_1, t_2]$ again and again. The solution obtained this way is optimal and periodic after time t_1. This is our justification for studying only the limit sets of nonself-intersecting solutions.

(2) To construct "flow boxes" at nonequilibria we cannot rely on a local parallelization theorem such as in dynamical systems. To prove existence of transversal sections and appropriately defined "flow boxes" we use that the integrand in (1.1) does not depend explicitly on the control u. Sometimes more general problems can be reduced to this form (cf. Remarks 2.12, 4.8). The possibility of defining optimality by means of such a functional has been exploited by Clark in a number of resource management problems.

The literature on the asymptotic behavior of optimal solutions for (P) concentrates mainly on establishing sufficient conditions for convergence to equilibrium. We only mention Arrow [2], Rockafellar [15], [16], Feinstein and Luenberger [8], and Feinstein and Oren [9]. The convexity assumptions made here are quite restrictive and are usually not satisfied in resource management. Haurie [12], [13] relaxes the convexity condition, such that they are, e.g., applicable to Volterra-Lotka equations. However, he must assume existence of optimal equilibria (with additional properties).

Oscillatory behavior of optimal solutions is often attributed to nonlinear cost effects and to age structure (Clark [5, pp. 166, 293], Deklerk and Gatto [7]). In § 5 we present an example that possesses neither of these attributes.

For a problem arising in economics, Benhabib and Nishimura [4] analyze the optimality system resulting from the Pontryagin maximum principle. Taking the discount rate δ as a bifurcation parameter, they show that Hopf bifurcations occur. The corresponding periodic solutions are optimal due to convexity assumptions.

The paper is organized as follows. Section 2 contains the basic assumptions and what is needed later about convergent subsequences of solutions and their limit sets. Furthermore the key lemma about transversal segments is proved as well as the existence of "flow boxes." Section 3 is a study of optimal equilibria. As a consequence of Pontryagin's maximum principle it is shown that in "general" there are only finitely many optimal equilibria, and a sufficient condition for attractivity of optimal equilibria is established. The main result is Theorem 3.5, which settles a case in the Poincaré-Bendixson Theorem. Section 4 contains the proof of the Poincaré-Bendixson Theorem for nonself-intersecting solutions. Section 5 discusses resource management problems. A predator-prey system where the predator is subject to harvesting is analyzed. As a consequence of the Poincaré-Bendixson Theorem, there are optimal solutions having as limit set an optimal periodic solution. Section 6 discusses nonuniqueness arising when an optimal periodic trajectory does not contain an optimal equilibrium in its interior as well as nonuniqueness in an example of a symmetric system of two harvested competing species. Here nonuniqueness stems from the bifurcation of behavior in the nonharvested system.

2. Limit sets and flow boxes. We will denote solutions of (1.2), (1.4) by $\varphi(t, x, u)$, $t \geqq 0$, and always assume global existence of $\varphi(\cdot, x, u)$ on $\mathbb{R}_+$ (uniqueness follows from local Lipschitz continuity). Let $\varphi(x, u) := \{\varphi(t, x, u): t \in \mathbb{R}_+\}$ and denote the value of (1.1) corresponding to (x, u) by $V(x, u)$. If not specified otherwise, convergence in U_{ad} means weak convergence in the L_2-sense on compact intervals. We will also use

$$U_{\text{ad}}(\mathbb{R}) := \{u : \mathbb{R} \to \Omega, \text{measurable}\}.$$

Throughout this paper, we assume that the following hypothesis is satisfied:

(2.1) For every compact subset $K \subset \mathbb{R}^n_+$, the set $\{\varphi(t, x, u): t \in \mathbb{R}_+, x \in K, u \in U_{\text{ad}}\}$ is bounded.

DEFINITION 2.1. A pair $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ is called optimal if for all $v \in U_{\text{ad}}$ we have

$$V(x, u) \geqq V(x, v).$$

A pair $(e, u^e) \in \mathbb{R}^n_+ \times \Omega$ is called an optimal equilibrium, if $e = \varphi(t, e, u^e)$ for all $t \in \mathbb{R}_+$ and the pair (e, u^e) is optimal (here u^e is identified with the constant control in U_{ad} with value u^e). For an optimal pair (x, u), we let $V(x) := V(x, u)$.

Remark 2.2. The notion of optimality above keeps the initial point $x(0) = x$ fixed and considers only the effect of different control actions v.

Remark 2.3. Frequently it will—instead of (2.1)—be sufficient that for a fixed (optimal) pair (x, u), we have that $\varphi(x, u) \subset \mathbb{R}^n_+$ is bounded.

Remark 2.4. Let $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ be given and suppose that for some $t > 0$, we have $\varphi_j(t, x, u) = 0$ for all $j \in J \subset \{1, 2, \cdots, n\}$. Define

$$\psi_i(s, x, u) = \begin{cases} 0, & i \in J, \\ \varphi_i(s, x, u), & i \notin J, \end{cases}$$

for s in a neighborhood of t. Then ψ also solves (1.2) and $\psi(t, x, u) = \varphi(t, x, u)$. Hence by the uniqueness of solutions of ordinary differential equations $\varphi = \psi$ in a neighborhood of t. Hence either $\varphi_j(s, x, u) = 0$ for all $s \geqq 0$ or $\varphi_j(s, x, u) > 0$ for all $s \geqq 0$. Therefore none of the species can become extinct in finite time and for any $J \subset \{1, \cdots, n\}$ $\{y \mid y_j = 0, j \in J\} \cap \mathbb{R}^n_+ = \mathbb{R}^{(J)}_+$ is invariant and the restriction of the system to $\mathbb{R}^{(J)}_+$ is a system of the same form.

LEMMA 2.5. *Suppose* $x^k \to x^0$ *in* $\mathbb{R}^n_+$ *and* $u^k \to u^0$ *in* U_{ad}. *Then* $\varphi(\cdot, x^k, u^k) \to \varphi(\cdot, x^0, u^0)$ *uniformly on bounded intervals and* $V(x^k, u^k) \to V(x^0, u^0)$.

Proof. The first assertion follows in a standard way from Gronwall's inequality. For the second one, take $\varepsilon > 0$. Then for T and k large enough and $x^k(t) := \varphi(t, x^k, u^k)$, $t \in \mathbb{R}_+$, $k = 0, 1, 2, \cdots$,

$$\begin{aligned} \left| V(x^0, u^0) - \int_0^\infty e^{-\delta t} R(x^k(t))\, dt \right| &\leqq \left| V(x^0, u^0) - \int_0^T e^{-\delta t} R(x^0(t))\, dt \right| \\ &\quad + \left| \int_0^T e^{-\delta t} [R(x^0(t)) - R(x^k(t))]\, dt \right| \\ &\quad + \left| \int_T^\infty e^{-\delta t} R(x^k(t))\, dt \right| \\ &\leqq 3\varepsilon, \end{aligned}$$

using the first assertion and (2.1).

COROLLARY 2.6. *Let* $(x^k, u^k) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ $(k \in \mathbb{N})$ *be optimal and* $(x^k)_k$ *bounded. Then there are a subsequence* (x^{k_i}, u^{k_i}) $(i \in \mathbb{N})$ *and an optimal* (x, u) *such that* $\lim_i \varphi(\cdot, x^{k_i}, u^{k_i}) = \varphi(\cdot, x, u)$ *locally uniformly and* $\lim_i u^{k_i} = u$ *in* U_{ad}.

Proof. Existence of a subsequence (x^{k_i}, u^{k_i}) converging to (x, u) follows from boundedness. Now let $v \in U_{\text{ad}}$. Then, by optimality of (x^{k_i}, u^{k_i}),

$$V(x, u) = \lim V(x^{k_i}, u^{k_i}) \geqq \lim V(x^{k_i}, v) = V(x, v).$$

This proves optimality of (x, u).

Let $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ be optimal and define $x(\cdot) := \varphi(\cdot, x, u)$.

THEOREM 2.7. (1) *Suppose that $n = 1$ and $x(t)$ is neither increasing nor decreasing; then $\alpha < \beta$ exist such that each $e \in (\alpha, \beta)$ is an optimal equilibrium.*

(2) *If $e = \lim_{t\to\infty} x(t)$ then e is an optimal equilibrium.*

Proof. (1) If $x(t)$ is neither increasing nor decreasing, there exist $r < s < t$ such that $x(r) = x(t)$, $x(s) \neq x(r)$. We may choose s such that either $x(s) = \min x([r, t])$ or $x(s) = \max x([r, t])$, say $x = \max x([r, t])$. Choose any $b \in (\alpha, \beta) = (x(r), x(s))$. There is a first instant $r_\varepsilon > r$ such that $x(r_\varepsilon) = b$, a first instant $s_\varepsilon > r_\varepsilon$ such that $x(s_\varepsilon) = b + \varepsilon$, and a first instant $t_\varepsilon > s_\varepsilon$ such that $x(t_\varepsilon) = b$. Let s'_ε be the last instant $< t_\varepsilon$ such that $x(s'_\varepsilon) = b + \varepsilon$. Then define

$$u_\varepsilon(\sigma) = u(r_\varepsilon + \sigma) \qquad \text{for } 0 \leqq \sigma \leqq s_\varepsilon - r_\varepsilon,$$

$$u_\varepsilon(s_\varepsilon - r_\varepsilon + \sigma) = u(s'_\varepsilon + \sigma) \quad \text{for } 0 \leqq \sigma \leqq t_\varepsilon - s_\varepsilon.$$

This way $u_\varepsilon(\sigma)$ is defined for $0 \leqq \sigma \leqq s_\varepsilon - r_\varepsilon + t_\varepsilon - s'_\varepsilon = \pi_\varepsilon$. Now extend u_ε to obtain a periodic function on $\mathbb{R}_+$ with period π_ε. Define x_ε in the same way as u_ε using $x(t)$ instead of $u(t)$. Then x_ε satisfies $\dot{x}_\varepsilon(t) = f(x_\varepsilon(t), u_\varepsilon(t))$ almost everywhere on $\mathbb{R}_+$ and $(x_\varepsilon, u_\varepsilon)$ is a solution of (1.1)-(1.4) with $x_\varepsilon(0) = b$. Note that for all $t \geqq 0$ we have $|x_\varepsilon(t) - b| \leqq \varepsilon$. Let $\varepsilon_n > 0$ tend to zero. Then Corollary 2.6 implies that b is an optimal equilibrium.

(2) Suppose $e = \lim_{t\to\infty} x(t)$. For $n \in \mathbb{N}$ put $x_n(t) = x(t+n)$, $u_n(t) = u(t+n)$. Then (x_n, u_n) solves (1.1)-(1.4) with $x_n(0) = x(n)$. Hence e is an optimal equilibrium by Corollary 2.6.

Next we introduce the central notions of this paper.

DEFINITION 2.8. For $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}$ define the omega limit set $\omega(x, u)$ by

$$\omega(x, u) := \{y \in \mathbb{R}^n : \text{there exist } t_k \in \mathbb{R}_+ \text{ such that } t_k \to \infty \text{ and } \varphi(t_k, x, u) \to y\} = \bigcap_{n\in\mathbb{N}} \operatorname{cl}\{\varphi(t, x, u) : t \geqq n\}. \tag{2.2}$$

For $I = \mathbb{R}_+$ or $I = \mathbb{R}$, we call $(x, u) \in \mathbb{R}^n_+ \times U_{\text{ad}}(I)$ an optimal I-solution if the corresponding solution $\varphi(\cdot, x, u)$ of (1.2) exists on I and for all $t \in I$

$$V(\varphi(t, x, u), u(t + \cdot)) = V(\varphi(t, x, u)).$$

Frequently, we call optimal $\mathbb{R}_+$-solutions simply optimal. If (x, u) is an optimal $\mathbb{R}$-solution, define the alpha limit set $\alpha(x, u)$ by

$$\alpha(x, u) := \bigcap_{n\in\mathbb{N}} \operatorname{cl}\{\varphi(t, x, u) : t \leqq -n\}. \tag{2.3}$$

Finally define for optimal (x, u)

$$\hat{\omega}(x, u) := \{(y, v) : (y, v) \text{ is an optimal } \mathbb{R}\text{-solution and there are } t_k \in \mathbb{R}_+ \text{ such that } t_k \to \infty \text{ and } \varphi(t_k + \cdot, x, u) \to \varphi(\cdot, y, v) \text{ locally uniformly on } \mathbb{R} \text{ and } u(t_k + \cdot) \to v \text{ in } U_{\text{ad}}\}. \tag{2.4}$$

DEFINITION 2.9. A subset L of $\mathbb{R}^n_+$ is called (*positively*) *invariant* if for all $y \in L$ there is an optimal ($\mathbb{R}_+$-) $\mathbb{R}$-solution (y, v) with $\varphi(\mathbb{R}, y, v) \subset L$ (respectively, $\varphi(\mathbb{R}_+, y, v) \subset L$).

PROPOSITION 2.10. *Let (x, u) be optimal. Then $\omega(x, u)$ is nonvoid, compact, and connected. For every $y \in \omega(x, u)$ there is $v \in U_{ad}$ such that $(y, v) \in \hat{\omega}(x, u)$ and $\varphi(\mathbb{R}, y, v) \subset \omega(x, u)$. In particular, $\omega(x, u)$ is invariant.*

Proof. Using (2.1), we see that $\omega(x, u)$ is nonvoid, connected, and compact. Let $y \in \omega(x, u)$. Then there are $t_k \to \infty$ with $\varphi(t_k, x, u) \to y$. By Corollary 2.6, we can, without loss of generality, assume that $s \to u(t_k + s)$, $s \in \mathbb{R}_+$, converges in U_{ad} to some $u_0 \in U_{ad}$ and $s \to \varphi(t_k + s, x, u)$, $s \in \mathbb{R}_+$, converges uniformly on bounded intervals to $\varphi(\cdot, y, u_0)$. Taking again, if necessary, subsequences, $s \to u(t_k - 1 + s)$, $s \in \mathbb{R}_+$, converges weakly on bounded intervals to $u_{-1} : [-1, \infty) \to \Omega$ and $s \to \varphi(t_k - 1 + s, x, u)$ converges uniformly on bounded intervals to $\varphi(\cdot, y, u_{-1}) : [-1, \infty) \to \mathbb{R}^n$ with $u_0 = u_{-1}$ and $\varphi(\cdot, y, u_0) = \varphi(\cdot, y, u_{-1})$ on $[0, \infty)$. By successively taking subsequences of (t_k) we obtain sequences $u_{-n} : [-n, \infty) \to \Omega$, $\varphi(\cdot, y, u_{-n}) : [-n, \infty) \to \mathbb{R}^n$ with $u_{-n} = u_{-n+1}$ on $[-n+1, \infty)$ and

$$\frac{d}{dt}\varphi(t, y, u_{-n}) = f(\varphi(t, y, u_{-n}), u_{-n}(t)),$$

$$V(\varphi(-n, y, u_{-n}), u_{-n}(-n + \cdot)) = V(\varphi(-n, y, u_{-n})).$$

Defining

$$v(t) = u_{-n}(t) \quad \text{on } [-n, \infty),$$

we obtain an optimal $\mathbb{R}$-solution (y, v).

The following lemma is our key for the construction of local transversal sections.

LEMMA 2.11. *Let L be a compact positively invariant set and $R(e) = \sup\{R(x) \mid x \in L\}$ for some $e \in L$. Then one of the following conditions is satisfied:*

(i) *e is an optimal equilibrium;*

(ii) *L contains a point x^0 with $0 \notin f(x^0, \Omega)$.*

Proof. If (ii) is violated there is $v^e \in \Omega$ such that $f(e, v^e) = 0$. By invariance of L we find $v \in U_{ad}$ such that (e, v) is optimal with $\varphi(\mathbb{R}_+, e, v) \subset L$. Hence

$$V(e) = \int_0^\infty e^{-\delta t} R(\varphi(t, e, v))\, dt \leqq \int_0^\infty e^{-\delta t} R(e)\, dt$$

$$= \int_0^\infty e^{-\delta t} R(\varphi(t, e, v^e))\, dt = V(e, v^e).$$

Thus (e, v^e) is an optimal equilibrium, i.e., (i) holds.

Remark 2.12. In § 5, we will consider a two-dimensional problem from resource management ($n = 2$), where the integrand of the performance criterion depends also on u. However, the problem can be transformed into one in which in the *interior* of $\mathbb{R}^2_+$ we obtain a criterion of the form (1.1) ($R(x)$ becomes unbounded for $x \to \partial\mathbb{R}^2_+$). In fact, Lemma 2.11 remains true here, since it holds in the following general situation.

Suppose (1.1) is replaced by

$$\int_0^\infty e^{-\delta t}\left[g_0(x(t)) + \sum_{i=1}^m u_i(t) g_i(x(t))\right] dt, \tag{2.5}$$

with $g_i : \mathbb{R}^2_+ \to \mathbb{R}$, $i = 0, 1, \cdots, m$, locally Lipschitz continuous, and the following condition holds:

(2.6) There is a continuous function $R : \operatorname{int} \mathbb{R}^2_+ \to \mathbb{R}$ such that

(α) $\int_0^\infty e^{-\delta t} R(\varphi(t, a, u))\, dt$ converges for every $a \in \operatorname{int} \mathbb{R}^2_+$, $u \in U_{ad}$

to a real number $V_R(a, u)$.

(β) A pair $(a, u) \in \operatorname{int} \mathbb{R}^2_+ \times U_{\text{ad}}$ is optimal if and only if $V_R(a, u) \geqq V_R(a, v)$ for all $v \in U_{\text{ad}}$.

First observe that Corollary 2.6, Proposition 2.10, and Theorem 2.7 remain true for the criterion (2.5). If $L \subset \operatorname{int} \mathbb{R}^2_+$ this follows from Lemma 2.11. Otherwise, $L \cap \partial \mathbb{R}^2_+ \neq \emptyset$; suppose, for example, $L_1 = L \cap \pi_1^{-1}(0) \neq \emptyset$ where $\pi(x_1, x_2) = x_1$. By Remark 2.4, the restriction of the system to $\pi_1^{-1}(0)$ is well defined and L_1 is compact and invariant for this system. Since the restricted system again is of the form (2.5), (1.2)-(1.4), Theorem 2.7 yields the assertion.

We first consider case (ii) of Lemma 2.11, and show that it translates into a geometric condition.

DEFINITION 2.13. Let $x^0 \in \mathbb{R}^n$, $l: \mathbb{R}^n \to \mathbb{R}$ linear and $\alpha > 0$. If

$$lf(y, u) > \alpha$$

for all y in a neighborhood W of x^0 and all $u \in \Omega$, then

$$S := W \cap l^{-1}(x^0)$$

is called a local transversal section through x^0.

PROPOSITION 2.14. *Suppose that $0 \notin f(x^0, \Omega)$. Then x^0 possesses a local transversal section. Hence a compact positively invariant set L either contains an optimal equilibrium or a point possessing a local transversal segment.*

Proof. In view of Lemma 2.11, we only have to show the first assertion. If $0 \notin f(x^0, \Omega)$, then by the Hahn-Banach Theorem this assertion follows, since $f(x^0, \Omega)$ is compact and convex.

Obviously, trajectories "can cross a local transversal section only from one side." The next result presents an important consequence from the existence of a local transversal section.

We need the following definition.

DEFINITION 2.15. Let S be a local transversal section through x^0, and let $V_1 \subset V_0$ be neighborhoods of x^0. Then the triple (V_0, V_1, S) is called a flow box around x^0, if it has the following property:

If $\varphi(\cdot, x^0, u)$ satisfies

$$\varphi(t_0, x^0, u) \notin V_0, \quad \varphi(t_1, x^0, u) \in V_1, \quad \varphi(t_2, x^0, u) \notin V_0$$

for some $0 \leqq t_0 < t_1 < t_2$, then there exists $t \in (t_0, t_2)$ such that $\varphi(t, x^0, u) \in S$ and $\varphi(s, x^0, u) \in V_0$ for all s between t and t_1.

THEOREM 2.16. *Let S be a local transversal section through x^0. Then there are neighborhoods V_0 and V_1 of x^0 such that (V_0, V_1, S) is a flow box around x^0.*

Proof. There exist a linear map $l: \mathbb{R}^n \to \mathbb{R}$, a constant $\alpha > 0$, and a neighborhood W of x^0 such that $S \supset W \cap l^{-1}(x^0)$ and

$$l(f(y, v)) > \alpha \quad \text{for all } y \in W, \quad v \in \Omega.$$

Choose a ball $V_0 = B(r_0, x^0)$ around x^0 with radius $r_0 > 0$ such that $V_0 \subset W$ and put $c := \sup \{|f(y, u)| \mid y \in V_0, v \in \Omega\}$. Then choose $r_1 \in (0, r_0)$ so small that

$$lz - \alpha/2c(r_0 - r_1) \leqq ly \leqq lz + \alpha/2c(r_0 - r_1) \tag{2.7}$$

for all z, $y \in V_1 = B(r_1, x^0)$. We have for $t > t' \geqq 0$:

$$\varphi(t, x, u) = \varphi(t', x, u) + \int_{t'}^{t} f(\varphi(s, x, u), u(s))\, ds$$

and hence

$$l(\varphi(t, x, u)) = l(\varphi(t', x, u)) + \int_{t'}^{t} lf(\varphi(s, x, u), u(s))\, ds$$
$$\geqq l(\varphi(t', x, u)) + \alpha(t - t')$$

provided that $\varphi(s, x, u) \in W$, $t' \leqq s \leqq t$. Without loss of generality, we may assume

$$\varphi(s, x, u) \in V_0 \quad \text{for all } t_0 \leqq s \leqq t_2$$

replacing, if necessary, t_0 by the last time before t_1 at which $\varphi(t, x, u)$ is in the complement of V_0 and t_2 by the first time after t_1 at which $\varphi(t, x, u)$ leaves V_0. We have

$$r_0 - r_1 \leqq |\varphi(t_1, x, u) - \varphi(t_0, x, u)| \leqq c(t_1 - t_0),$$
$$r_0 - r_1 \leqq |\varphi(t_2, x, u) - \varphi(t_1, x, u)| \leqq c(t_2 - t_1).$$

If $l\varphi(t_0, x, u) \leqq lx^0 \leqq l\varphi(t_2, x, u)$, or $l\varphi(t_2, x, u) \leqq lx^0 \leqq l\varphi(t_0, x, u)$, the assertion follows by continuity of $t \to lf(t, x, u)$. Hence we only have to consider the following two cases.

Case 1. $\dot{l}x^0 < \min\{l\varphi(t_0, x, u), l\varphi(t_2, x, u)\}$. Here $l\varphi(t_1, x, u) \geqq l\varphi(t_0, x, u) + \alpha(t_1 - t_0) > lx^0 + \alpha/c(r_0 - r_1)$, contradicting (2.7) for $y = \varphi(t_1, x, u)$.

Case 2. $lx^0 > \max\{l\varphi(t_0, x, u), l\varphi(t_2, x, u)\}$. Here $l\varphi(t_2, x, u) \geqq l\varphi(t_1, x, u) + a(t_2 - t_1) > l\varphi(t_1, x, u) + \alpha/c(r_0 - r_1)$, again contradicting (2.7).

3. Optimal equilibria. In this section we first characterize optimal equilibria by necessary optimality conditions. It turns out that "in general" only finitely many optimal equilibria exist. Strong additional assumptions ensure that optimal equilibria in a limit set are already reached in finite time. Furthermore, limit sets $\omega(x, u)$ reduce to a single optimal equilibrium provided that $\omega(x, u)$ consists of equilibria only and contains at most finitely many optimal equilibria.

First we discuss the following problem:

$$\text{Maximize (2.5)} \quad \text{subject to (1.2)-(1.4)}$$

where Ω is a rectangle in $\mathbb{R}^2$ (in fact, the "ecological form" of (1.2) is not needed in this section, if not stated otherwise).

Abbreviate

$$g(x, u) = g_0(x) + \sum_{i=1}^{m} u_i g_i(x), \qquad f(x, u) = f_0(x) + \sum_{i=1}^{m} u_i g_i(x).$$

For any equilibrium $e = (x_1, x_2)$, there are the two equations (for x_1, x_2, u_1, u_2) defining an equilibrium, namely

$$o = f(x, u). \tag{3.1}$$

To derive a second set of equations we shall use Pontryagin's maximum principle (cf. Halkin [11]). Write

$$H = \lambda_0 e^{-\delta t} g + \lambda \cdot f,$$
$$\dot{\lambda}(t) = -\lambda_0 e^{-\delta t} g_x - f_x^t \lambda \quad \text{(adjoint equation)}.$$

Here

$$f = \begin{pmatrix} f^1 \\ f^2 \end{pmatrix} \quad \text{and} \quad f_x^t = \begin{pmatrix} f^1_{x_1} & f^2_{x_1} \\ f^1_{x_2} & f^2_{x_2} \end{pmatrix}, \quad \lambda = \begin{pmatrix} \lambda_1 \\ \lambda_2 \end{pmatrix}.$$

Thus,

$$H = \lambda_0 e^{-\delta t} g_0 + \lambda_1 f_0^1 + \lambda_2 f_0^2 + u_1(\lambda_0 e^{-\delta t} g_1 + \lambda_1 f_1^1 + \lambda_2 f_1^2) + u_2(\lambda_0 e^{-\delta t} g_2 + \lambda_1 f_2^1 + \lambda_2 f_2^2).$$

Put $\mu = e^{\delta t}\lambda$. Then $\dot{\mu} = \delta\mu + e^{\delta t}\dot{\lambda}$. Hence the adjoint equation reads

$$\dot{\mu} = -\lambda_0 g_x + (\delta I - f_x^t)\mu,$$

and

$$H = h(t, x, \lambda) + u_1(\lambda_0 g_1 + \mu_1 f_1^1 + \mu_2 f_1^2) + u_2(\lambda_0 g_2 + \mu_1 f_2^1 + \mu_2 f_2^2).$$

Pontryagin's maximum principle implies that $(\lambda_0, \lambda(t) \neq 0$ for all $t \geqq 0$ and H attains its maximum over Ω in (u_1, u_2). We may assume that $\lambda_0 = 0$ or $\lambda_0 = 1$.

Now we discuss the possible numbers of optimal equilibria. There are three cases:

Case 1. $u = (u_1, u_2)$ is one of the corners of Ω.

Case 2. u lies in the relative interior of one of the edges of Ω.

Case 3. $u \in \operatorname{int} \Omega$.

Case 1. Recall that there are only four corners of Ω.

Case 2. One equation for u is given by the condition that u lies on one of the edges of Ω. Furthermore the derivative of H in direction, say $v = (v_1, v_2)$ (parallel to the edge of Ω containing u), vanishes, i.e.,

$$(\lambda_0 g_1 + \mu_1 f_1^1 + u_2 f_1^2)v_1 + (\lambda_0 g_2 + \mu_1 f_2^1 + \mu_2 f_2^2)v_2 = 0 \quad \text{for all } t.$$

Thus with $\varphi := (v_1 f_1^1 + v_2 f_2^1,\ v_1 f_1^2 + v_2 f_2^2)$

$$\varphi\mu = -\lambda_0(g_1 v_1 + g_2 v_2) \quad \text{for all } t. \tag{3.2}$$

Insertion into the adjoint equation yields

$$0 = \varphi\dot{\mu} = \varphi(-\lambda_0 g_x + (\delta I - f_x^t)\mu) \quad \text{or} \quad \varphi(\delta I - f_x^t)\mu = \lambda_0 \gamma_x \quad \text{for all } t. \tag{3.3}$$

If φ and $\varphi(\delta I - f_x^t)$ are linearly dependent we obtain with (3.1), the assumption that u lies on an edge of Ω and

$$\det(\varphi', (\delta I - f_x^t)\varphi') = 0, \tag{3.4}$$

four equations for the unknowns x_1, x_2, u_1, u_2. If φ and $\varphi(\delta I + f_x^t)$ are linearly independent, (3.2) and (3.3) imply that μ is constant and that $\lambda_0 = 1$. We assume $\det(\delta I - f_x^t) \neq 0$. Then by the adjoint equation and (3.2)

$$\varphi(\delta I - f_x^t)^{-1} g_x = -g_1 v_1 + -g_2 v_2, \tag{3.5}$$

and again we obtain four equations for x_1, x_2, u_1, u_2.

Case 3. Put

$$F = \begin{pmatrix} f_1^1 & f_1^2 \\ f_2^1 & f_2^2 \end{pmatrix}.$$

Then

$$-\lambda_0 \begin{pmatrix} g_1 \\ g_2 \end{pmatrix} = F\mu.$$

Suppose $\det F \neq 0$. Then

$$\mu = -\lambda_0 F^{-1} \begin{pmatrix} g_1 \\ g_2 \end{pmatrix}$$

and it follows that $\lambda_0 = 1$, and $\mu = 0$. The adjoint equation yields

$$0 = g_x + (\delta I - f_x^t)\mu \quad \text{and} \quad g_x = (\delta I - f_x^t) F^{-1} \begin{pmatrix} g_1 \\ g_2 \end{pmatrix}. \tag{3.6}$$

Hence together with (3.1) we obtain four equations for (x_1, x_2, u_1, u_2).

Now suppose $\det F = 0$. By introducing new control variables we can eliminate one control variable in the system equation and proceed with the discussion as in Case 1 or Case 2 above.

We formulate the conclusion of this discussion in the following remark.
